The 2016 update of the WHO brain tumor classification

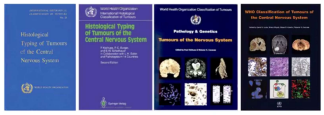
Dr. Adelheid Wöhrer

Institute of Neurology

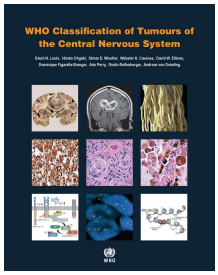
Outline

- The Making of the 2016 Update of the WHO brain tumor classification
- Update on most important changes
  - Diffuse glioma
  - Embryonal tumors
  - Other newly introduced entities and variants
- Implications on neuropathological practice & molecular marker testing

The WHO brain tumor classification



1st edition 1979 | 2nd edition 1993 | 3rd edition 2000 | 4th edition 2007

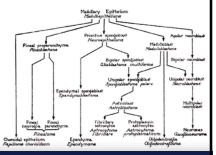


2016 update of the 4th edition

Prior to 2016

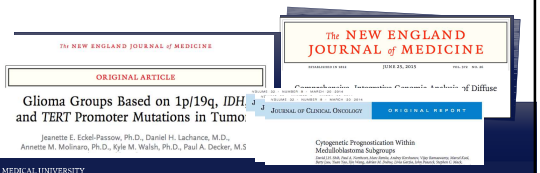
- Brain tumor classification based on histogenesis
  - Microscopic similarities of tumors with different cells of origin
- Based on hematoxylin and eosin-stained sections + immunohistochemical expression of lineage-associated proteins (+ ultrastructure)

Harvey Cushing



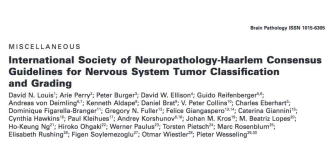
In the meantime

- Large-scale studies revealed the genetic basis of tumorigenesis of adult and pediatric brain tumors
- Molecular markers provide prognostic and/or predictive information *within* diagnostic categories
- Canonical genetic alterations may be used to define specific entities



2014 Haarlem Meeting, the Netherlands

- Under the auspices of the International Society of Neuropathology
- Aim: Providing guidelines for how to incorporate molecular findings into brain tumor diagnostics
- Set the stage for a major revision of the 2007 CNS WHO classification



Proposed format & overarching goal

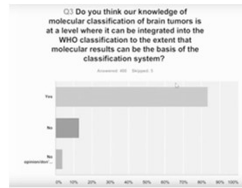
- Layer 1: Morphological classification
- Layer 2: WHO grade (reflects natural tumor history)
- Layer 3: Molecular information

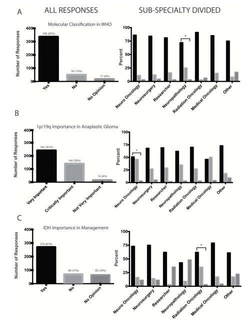
Integrated diagnosis

CAVE Diagnostic delay

- Adds a level of objectivity to the diagnostic process
- Stratifies tumors into biologically homogenous groups
- Enhances diagnostic accuracy & prognostic rating

Community Surveys (SNO & ISN)





Surveys provided overwhelmingly positive feedback

Classification based on histology & genetics

- International collaboration of 117 contributors from 20 countries
- Three-day consensus conference by a working group of 35 neuropathologists, clinical advisors and scientists from 10 countries

Austrian contributors:
Johannes A. Hainfellner
Matthias Preusser

How many brain tumor entities are differentiated according to the WHO 2016 classification?

- A1. 1-30
- A2. 40-70
- A3. 80-110
- A4. 120+

A4 is correct

WHO classification of tumours of the central nervous system

Diffuse astrocytic and oligodendroglial tumours	
Diffuse astrocytoma, IDH-mutant	9400/3
Gemistocytic astrocytoma, IDH-mutant	9411/3
Diffuse astrocytoma, IDH-wildtype	*9400/3*
Diffuse astrocytoma, NOS	9400/3
Anaplastic astrocytoma, IDH-mutant	9401/3
Anaplastic astrocytoma, IDH-wildtype	*9401/3*
Anaplastic astrocytoma, NOS	9401/3
Glioblastoma, IDH-wildtype	9440/3
Giant cell glioblastoma	9441/3
Gliosarcoma	9442/3
Epithelioid glioblastoma	*9440/3*
Glioblastoma, IDH-mutant	9445/3*
Glioblastoma, NOS	9440/3
Diffuse midline glioma, H3 K27M–mutant	9385/3*
Oligodendroglioma, IDH-mutant and 1p/19q-codeleted	9450/3
Oligodendroglioma, NOS	9450/3
Anaplastic oligodendroglioma, IDH-mutant and 1p/19q-codeleted	9451/3
Anaplastic oligodendroglioma, NOS	*9451/3*
Oligoastrocytoma, NOS	*9382/3*
Anaplastic oligoastrocytoma, NOS	*9382/3*
Other astrocytic tumours	
Pilocytic astrocytoma	9421/1
Pilomyxoid astrocytoma	9425/3
Subependymal giant cell astrocytoma	9384/1
Pleomorphic xanthoastrocytoma	9424/3
Anaplastic pleomorphic xanthoastrocytoma	9424/3
Ependymal tumours	
Subependymoma	9383/1
Myxopapillary ependymoma	9394/1
Ependymoma	9391/3
Papillary ependymoma	9393/3
Clear cell ependymoma	9391/3
Tanycytic ependymoma	9391/3
Ependymoma, *RELA* fusion–positive	9396/3*
Anaplastic ependymoma	9392/3
Other gliomas	
Chordoid glioma of the third ventricle	9444/1
Angiocentric glioma	9431/1
Astroblastoma	9430/3
Choroid plexus tumours	
Choroid plexus papilloma	9390/0
Atypical choroid plexus papilloma	9390/1
Choroid plexus carcinoma	9390/3
Neuronal and mixed neuronal-glial tumours	
Dysembryoplastic neuroepithelial tumour	9413/0
Gangliocytoma	9492/0
Ganglioglioma	9505/1
Anaplastic ganglioglioma	9505/3
Dysplastic cerebellar gangliocytoma (Lhermitte–Duclos disease)	9493/0
Desmoplastic infantile astrocytoma and ganglioglioma	9412/1
Papillary glioneuronal tumour	9509/1
Rosette-forming glioneuronal tumour	9509/1
Diffuse leptomeningeal glioneuronal tumour	
Central neurocytoma	9506/1
Extraventricular neurocytoma	9506/1
Cerebellar liponeurocytoma	9506/1
Paraganglioma	8693/1
Tumours of the pineal region	
Pineocytoma	9361/1
Pineal parenchymal tumour of intermediate differentiation	9362/3
Pineoblastoma	9362/3
Papillary tumour of the pineal region	9395/3
Embryonal tumours	
Medulloblastomas, genetically defined	
Medulloblastoma, WNT-activated	9475/3*
Medulloblastoma, SHH-activated and *TP53*-mutant	9476/3*
Medulloblastoma, SHH-activated and *TP53*-wildtype	9471/3
Medulloblastoma, non-WNT/non-SHH	9477/3*
Medulloblastoma, group 3	
Medulloblastoma, group 4	
Medulloblastomas, histologically defined	
Medulloblastoma, classic	9470/3
Medulloblastoma, desmoplastic/nodular	9471/3
Medulloblastoma with extensive nodularity	9471/3
Medulloblastoma, large cell / anaplastic	9474/3
Medulloblastoma, NOS	9470/3
Embryonal tumour with multilayered rosettes, C19MC-altered	9478/3*
Embryonal tumour with multilayered rosettes, NOS	*9478/3*
Medulloepithelioma	9501/3
CNS neuroblastoma	9500/3
CNS ganglioneuroblastoma	9490/3
CNS embryonal tumour, NOS	9473/3
Atypical teratoid/rhabdoid tumour	9508/3
CNS embryonal tumour with rhabdoid features	*9508/3*
Tumours of the cranial and paraspinal nerves	
Schwannoma	9560/0
Cellular schwannoma	9560/0
Plexiform schwannoma	9560/0
Melanotic schwannoma	9560/1
Neurofibroma	9540/0
Atypical neurofibroma	9540/0
Plexiform neurofibroma	9550/0
Perineurioma	9571/0
Hybrid nerve sheath tumours	
Malignant peripheral nerve sheath tumour	9540/3
Epithelioid MPNST	9540/3
MPNST with perineurial differentiation	9540/3
Meningiomas	
Meningioma	9530/0
Meningothelial meningioma	9531/0
Fibrous meningioma	9532/0
Transitional meningioma	9537/0
Psammomatous meningioma	9533/0
Angiomatous meningioma	9534/0
Microcystic meningioma	9530/0
Secretory meningioma	9530/0
Lymphoplasmacyte-rich meningioma	9530/0
Metaplastic meningioma	9530/0
Chordoid meningioma	9538/1
Clear cell meningioma	9538/1
Atypical meningioma	9539/1
Papillary meningioma	9538/3
Rhabdoid meningioma	9538/3
Anaplastic (malignant) meningioma	9530/3
Mesenchymal, non-meningothelial tumours	
Solitary fibrous tumour / haemangiopericytoma**	
Grade 1	8815/0
Grade 2	8815/1
Grade 3	8815/3
Haemangioblastoma	9161/1
Haemangioma	9120/0
Epithelioid haemangioendothelioma	9133/3
Angiosarcoma	9120/3
Kaposi sarcoma	9140/3
Ewing sarcoma / PNET	9364/3
Lipoma	8850/0
Angiolipoma	8861/0
Hibernoma	8880/0
Liposarcoma	8850/3
Desmoid-type fibromatosis	8821/1
Myofibroblastoma	8825/0
Inflammatory myofibroblastic tumour	8825/1
Benign fibrous histiocytoma	8830/0
Fibrosarcoma	8810/3
Undifferentiated pleomorphic sarcoma / malignant fibrous histiocytoma	8802/3
Leiomyoma	8890/0
Leiomyosarcoma	8890/3
Rhabdomyoma	8900/0
Rhabdomyosarcoma	8900/3
Chondroma	9220/0
Chondrosarcoma	9220/3
Osteoma	9180/0
Osteochondroma	9210/0
Osteosarcoma	9180/3
Melanocytic tumours	
Meningeal melanocytosis	8728/0
Meningeal melanocytoma	8728/1
Meningeal melanoma	8720/3
Meningeal melanomatosis	8728/3
Lymphomas	
Diffuse large B-cell lymphoma of the CNS	9680/3
Immunodeficiency-associated CNS lymphomas	
AIDS-related diffuse large B-cell lymphoma	
EBV-positive diffuse large B-cell lymphoma, NOS	
Lymphomatoid granulomatosis	9766/1
Intravascular large B-cell lymphoma	9712/3
Low-grade B-cell lymphomas of the CNS	
T-cell and NK/T-cell lymphomas of the CNS	
Anaplastic large cell lymphoma, ALK-positive	9714/3
Anaplastic large cell lymphoma, ALK-negative	9702/3
MALT lymphoma of the dura	9699/3
Histiocytic tumours	
Langerhans cell histiocytosis	9751/3
Erdheim–Chester disease	9750/1
Rosai–Dorfman disease	
Juvenile xanthogranuloma	
Histiocytic sarcoma	9755/3
Germ cell tumours	
Germinoma	9064/3
Embryonal carcinoma	9070/3
Yolk sac tumour	9071/3
Choriocarcinoma	9100/3
Teratoma	9080/1
Mature teratoma	9080/0
Immature teratoma	9080/3
Teratoma with malignant transformation	9084/3
Mixed germ cell tumour	9085/3
Tumours of the sellar region	
Craniopharyngioma	9350/1
Adamantinomatous craniopharyngioma	9351/1
Papillary craniopharyngioma	9352/1
Granular cell tumour of the sellar region	9582/0
Pituicytoma	9432/1
Spindle cell oncocytoma	8290/0
Metastatic tumours	

The morphology codes are from the International Classification of Diseases for Oncology (ICD-O) [742A]. Behaviour is coded /0 for benign tumours; /1 for unspecified, borderline, or uncertain behaviour; /2 for carcinoma in situ and grade III intraepithelial neoplasia; and /3 for malignant tumours. The classification is modified from the previous WHO classification, taking into account changes in our understanding of these lesions. *These new codes were approved by the IARC/WHO Committee for ICD-O. *Italics*: Provisional tumour entities. **Grading according to the 2013 *WHO Classification of Tumours of Soft Tissue and Bone*.

2016

Diffuse astrocytic and oligodendroglial tumours	
Diffuse astrocytoma, IDH-mutant	9400/3
Gemistocytic astrocytoma, IDH-mutant	9411/3
Diffuse astrocytoma, IDH-wildtype	*9400/3*
Diffuse astrocytoma, NOS	9400/3
Anaplastic astrocytoma, IDH-mutant	9401/3
Anaplastic astrocytoma, IDH-wildtype	*9401/3*
Anaplastic astrocytoma, NOS	9401/3
Glioblastoma, IDH-wildtype	9440/3
Giant cell glioblastoma	9441/3
Gliosarcoma	9442/3
Epithelioid glioblastoma	*9440/3*
Glioblastoma, IDH-mutant	9445/3*
Glioblastoma, NOS	9440/3
Diffuse midline glioma, H3 K27M–mutant	9385/3*
Oligodendroglioma, IDH-mutant and 1p/19q-codeleted	9450/3
Oligodendroglioma, NOS	9450/3
Anaplastic oligodendroglioma, IDH-mutant and 1p/19q-codeleted	9451/3
Anaplastic oligodendroglioma, NOS	*9451/3*
Oligoastrocytoma, NOS	*9382/3*
Anaplastic oligoastrocytoma, NOS	*9382/3*
Other astrocytic tumours	
Pilocytic astrocytoma	9421/1
Pilomyxoid astrocytoma	9425/3
Subependymal giant cell astrocytoma	9384/1
Pleomorphic xanthoastrocytoma	9424/3
Anaplastic pleomorphic xanthoastrocytoma	9424/3

2007

Diffuse astrocytomas more similar to oligodendrogliomas than pilocytic astrocytomas -> family trees redrawn

Protoplasmic astrocytoma 9410/3

Gliomatosis cerebri deleted (invasive growth of diffuse astrocytoma, oligodendroglioma or glioblastoma)

Anaplastic oligodendroglioma 9451/3

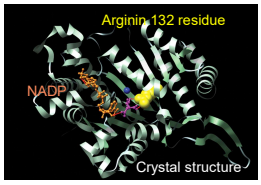
WHO grading II-III retained

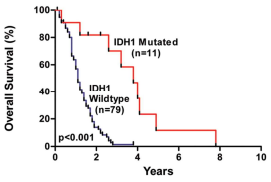
Anaplastic oligoastrocytoma 9382/3

Diffuse astrocytoma categories:
IDH-mutant
IDH-wildtype
NOS

Molecular markers now mandatory
IDH, 1p19q, H3K27

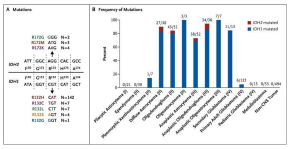
IDH 1/2 mutations

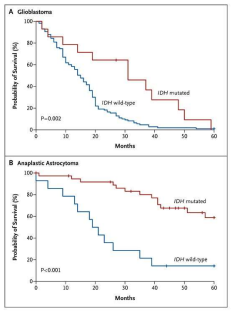




- Recurrent mutations in *IDH1* on chromosome 2q33 found in glioblastoma
- *IDH1* encodes isocitrate dehydrogenase 1 that catalyzes the oxidative carboxylation of isocitrate to alpha-ketoglutarate resulting in the production of NADPH
- Novel marker for *secondary glioblastoma*

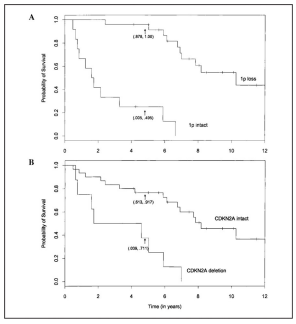
IDH mutations

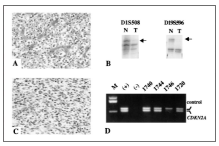


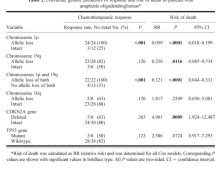


- IDH mutations implicated in the pathogenesis of malignant gliomas
- Common in lower grade gliomas
- IDH mutant tumors are genetically & clinically distinct

1p 19q deletion







What is the major reason for the observed discrepancy in chemotherapy sensitivity between oligodendroglioma and astrocytoma?

A1. Astrocytic cells show a higher number of multidrug resistant-associated ABC transporters

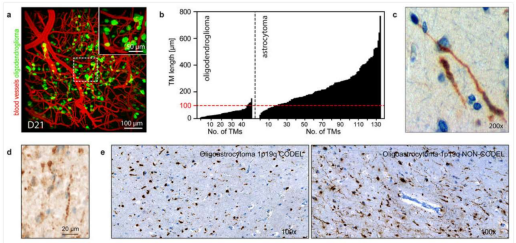
A2. Chromosome 1 encodes the temozolomide-resistance gene *zinc finger protein C2H2*

A3. Astrocytic cells communicate more efficiently in cellular networks

A4. Oligodendroglial cells show impaired mitochondrial metabolism

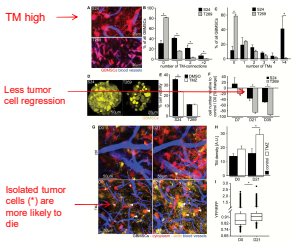
A3 is correct

Brain tumor cells interconnect to a functional and resistant networt



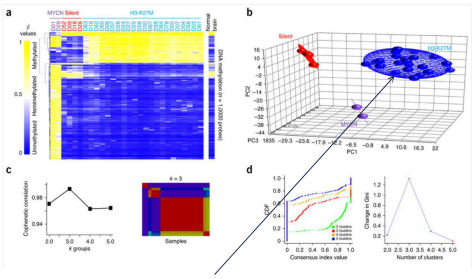
Oligodendrogliomas lack long 'tumor microtubes' that enable multicellular communication in astrocytomas

Tumor microtubes convey resistance to surgical lesions and chemotherapy in gliomas



Highly interconnected astrocytic tumor cells are more resistant to TMZ treatment

H3 K27M mutation



- Defines a subgroup of diffuse intrinsic pontine gliomas
- Mutation in histone protein -> epigenetic implications

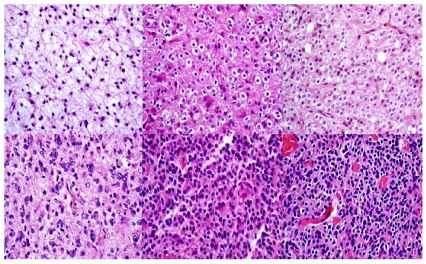
Buczkowicz P et al, Nature Genetics 2014

2016

Diffuse astrocytic and oligodendroglial tumours	
Diffuse astrocytoma, IDH-mutant	9400/3
Gemistocytic astrocytoma, IDH-mutant	9411/3
Diffuse astrocytoma, IDH-wildtype	9400/3
Diffuse astrocytoma, NOS	9400/3
Anaplastic astrocytoma, IDH-mutant	9401/3
Anaplastic astrocytoma, IDH-wildtype	9401/3
Anaplastic astrocytoma, NOS	9401/3
Glioblastoma, IDH-wildtype	9440/3
Giant cell glioblastoma	9441/3
Gliosarcoma	9442/3
Epithelioid glioblastoma	9440/3
Glioblastoma, IDH-mutant	9445/3*
Glioblastoma, NOS	9440/3
Diffuse midline glioma, H3 K27M-mutant	9385/3*
Oligodendroglioma, IDH-mutant and 1p/19q-codeleted	9450/3
Oligodendroglioma, NOS	9450/3
Anaplastic oligodendroglioma, IDH-mutant and 1p/19q-codeleted	9451/3
Anaplastic oligodendroglioma, NOS	9451/3
Oligoastrocytoma, NOS	9382/3
Anaplastic oligoastrocytoma, NOS	9382/3
Other astrocytic tumours	
Pilocytic astrocytoma	9421/1
Pilomyxoid astrocytoma	9425/3
Subependymal giant cell astrocytoma	9384/1
Pleomorphic xanthoastrocytoma	9424/3
Anaplastic pleomorphic xanthoastrocytoma	9424/3

What happened to Oligoastrocytoma?

Oligoastrocytoma



Astrocytoma — *Difficult to define* — Oligodendroglioma

High interobserver discordance

Oligoastrocytoma

J Neuropathol Exp Neurol. 2007 Jun;66(6):545-51.

Panel review of anaplastic oligodendroglioma from European Organization For Research and Treatment of Cancer Trial 26951: assessment of consensus in diagnosis, influence of 1p/19q loss, and correlations with outcome.

Kros JM[1], Gorlia T, Kouwenhoven MC, Zheng PP, Collins VP, Figarella-Branger D, Giangaspero F, Giannini C, Mokhtari K, Mørk SJ, Paetau A, Reifenberger G, van den Bent MJ.

J Clin Oncol. 2015 Jun 10;33(17):1943-50. doi: 10.1200/JCO.2014.59.0168. Epub 2015 Apr 27.

Evidence-Based Diagnostic Algorithm for Glioma: Analysis of the Results of Pathology Panel Review and Molecular Parameters of EORTC 26951 and 26882 Trials.

Kros JM[1], Huizer K[2], Hernández-Laín A[2], Marucci G[2], Michotte A[2], Pollo B[2], Rushing EJ[2], Ribalta T[2], French P[2], Jaminé D[2], Bekka N[2], Lacombe D[2], van den Bent MJ[2], Gorlia T[2].

Acta Neuropathol. 2014 Oct;128(4):551-9. doi: 10.1007/s00401-014-1326-7. Epub 2014 Aug 21.

Farewell to oligoastrocytoma: in situ molecular genetics favor classification as either oligodendroglioma or astrocytoma.

Sahm F[1], Reuss D, Koelsche C, Capper D, Schittenhelm J, Heim S, Jones DT, Pfister SM, Herold-Mende C, Wick W, Mueller W, Hartmann C, Paulus W, von Deimling A.

Acta Neuropathol. 2015 Jan;129(1):147-9. doi: 10.1007/s00401-014-1353-4. Epub 2014 Oct 11.

Oligoastrocytomas: throwing the baby out with the bathwater?

Wilcox P[1], Li CC, Lee M, Shivalingam B, Brennan J, Suter CM, Kaufman K, Lum T, Buckland ME.

Oligoastrocytoma

- Using phenotype & genotype (i.e., *IDH* mutation and 1p19q codeletion) allows to allocate them to either astrocytic or oligodendroglial subtypes
- Discordant results of phenotype & genotype -> genotype trumps histological phenotype!

Molecular information	Histologic classification: Diffuse astrocytoma	Oligodendroglioma	"Oligoastrocytoma" or ambiguous histology
IDH-mut, 1p/19q-nondel, ATRX loss	*Diffuse astrocytoma, ATRX loss of expression*	*Diffuse glioma* (oligodendroglioma phenotype), 1p/19q non-deleted, ATRX loss of expression*	*Diffuse astrocytoma, ATRX loss of expression*
IDH-mut, 1p/19q-codel, ATRX intact	*Diffuse glioma (astrocytoma phenotype), 1p/19q-codeleted*	*Oligodendroglioma, 1p/19q-codeleted*	*Oligodendroglioma, 1p/19q-codeleted*
IDH wild type	*Diffuse astrocytoma, IDH wild type**	*Diffuse glioma* (oligodendroglioma phenotype), IDH wild type**	*Diffuse astrocytoma, IDH wild type**
Testing not performed	*Diffuse astrocytoma, NOS*	*Oligodendroglioma, NOS*	*"Diffuse glioma, NOS"*

- Introduction of „not otherwise specified, NOS"

Is genotype alone sufficient for diagnosis?

- At this point in time: **No**
- WHO grading is still based on histologic criteria
- Challenges with respect to testing and reporting
  - Availability & choice of genotyping or surrogate genotyping assays

Cancer Cell
Previews

Fall of the Optical Wall: Freedom from the Tyranny of the Microscope Improves Glioma Risk Stratification

Vijay Ramaswamy[1] and Michael D. Taylor[2,3]

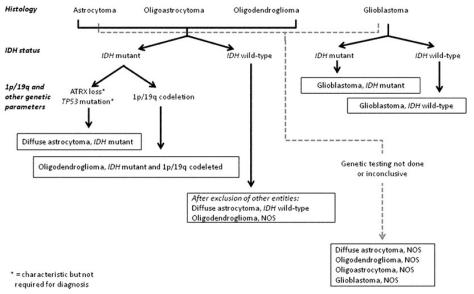
Diffuse gliomas



What is the correct 'integrated diagnosis' in the following case?

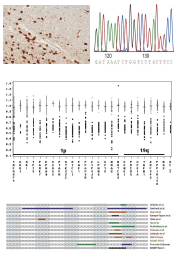
Histology: Oligoastrocytoma
WHO grade: II
Molecular markers: IDH2 mutant, 1p19q codeleted, TERT mutation, ATRX retained

- A1. Oligodendroglioma, WHO grade II, IDH2 mutant and 1p19q codeleted
- A2. Oligoastrocytoma, WHO grade II, IDH2 mutant and 1p19q codeleted
- A3. Astrocytoma, WHO grade II, IDH2 mutant and 1p19q codeleted
- A4. Oligodendroglioma, WHO grade II, NOS

A1 is correct

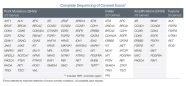
Commonly used molecular techniques

- *IDH* genes:
  - Step 1: mutation-specific IDH1 R132H antibody
  - Step 2: targeted IDH1/2 gene sequencing
    - **Screening of all lower grade gliomas (II-III)**
    - **Screening of GBM, IV only in patients aged <55 years**
- 1p 19q chromosomal arms:
  - Multiplex ligation probe amplification
  - Fluorescence in situ hybridization
- *MGMT* promoter methylation:
  - Pyrosequencing
  - Methylation-specific PCR

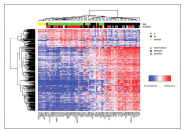


Advanced molecular techniques

- Gene-panel sequencing
- Exome/RNA sequencing



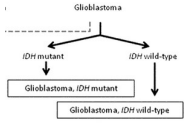
- DNA methylation array
  - G-CIMP/IDH, copy numbers, MGMT



- CAVE:
  - Quality control / data standardization
  - DNA quality of FFPE tissues

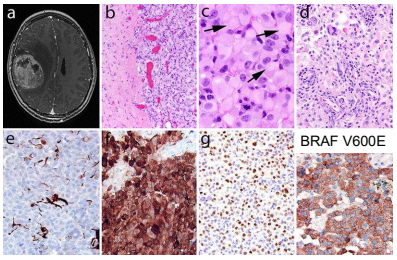
Glioblastoma

- Glioblastoma, IDH-wildtype (about 90% of cases)
- Glioblastoma, IDH-mutant (about 10% of cases) corresponds closely to secondary glioblastoma
- Glioblastoma, NOS in cases without full IDH assessment
  - Sequencing required for all patients > 55 years of age



Glioblastoma

- New variant: Epitheloid glioblastoma
- Stratifies into established diagnostic subsets upon molecular diagnosis

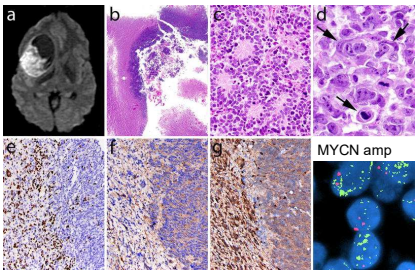


Louis et al, Acta Neuropath 2016

Variant = Subtype of an entity of clinical utility

Glioblastoma

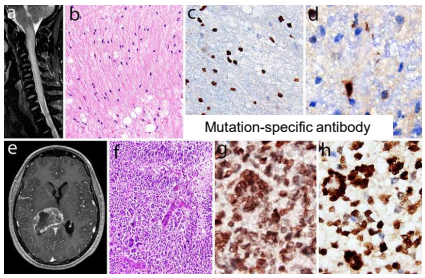
- New pattern: Glioblastoma with primitive neuronal component



Louis et al, Acta Neuropath 2016

Diffuse midline glioma

- K27M mutations in histone H3 gene *H3F3A* defines a group



Louis et al, Acta Neuropath 2016

Embryonal tumors

Embryonal tumours	
Medulloblastomas, genetically defined	
Medulloblastoma, WNT-activated	9475/3*
Medulloblastoma, SHH-activated and *TP53*-mutant	9476/3*
Medulloblastoma, SHH-activated and *TP53*-wildtype	9471/3
Medulloblastoma, non-WNT/non-SHH	9477/3*
Medulloblastoma, group 3	
Medulloblastoma, group 4	
Medulloblastomas, histologically defined	
Medulloblastoma, classic	9470/3
Medulloblastoma, desmoplastic/nodular	9471/3
Medulloblastoma with extensive nodularity	9471/3
Medulloblastoma, large cell / anaplastic	9474/3
Medulloblastoma, NOS	9470/3
Embryonal tumour with multilayered rosettes, C19MC-altered	9478/3*
Embryonal tumour with multilayered rosettes, NOS	9478/3
Medulloepithelioma	9501/3
CNS neuroblastoma	9500/3
CNS ganglioneuroblastoma	9490/3
CNS embryonal tumour, NOS	9473/3
Atypical teratoid/rhabdoid tumour	9508/3
CNS embryonal tumour with rhabdoid features	9508/3

Greatest conceptual challenge

Dismissal of "PNET, primitive neuroectodermal tumor"
-> "Embryonal tumor"

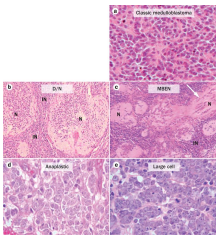
How many medulloblastoma groups are (currently) defined based on genetics?

- A1. 3
- A2. 4
- A3. 5
- A4. 9

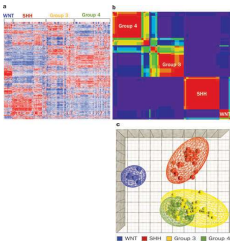
A2 is correct

Medulloblastoma

Long established histological groups

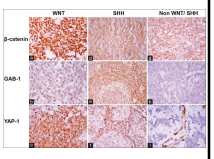


Four genetically defined groups



Medulloblastoma

Genetic profile	Histology	Prognosis
Medulloblastoma, WNT-activated	Classic	Low-risk tumour; classic morphology found in almost all WNT-activated tumours
	Large cell / anaplastic (very rare)	Tumour of uncertain clinicopathological significance
Medulloblastoma, SHH-activated, *TP53*-mutant	Classic	Uncommon high-risk tumour
	Large cell / anaplastic	High-risk tumour; prevalent in children aged 7–17 years
	Desmoplastic / nodular (very rare)	Tumour of uncertain clinicopathological significance
Medulloblastoma, SHH-activated, *TP53*-wildtype	Classic	Standard-risk tumour
	Large cell / anaplastic	Tumour of uncertain clinicopathological significance
	Desmoplastic / nodular	Low-risk tumour in infants; prevalent in infants and adults
	Extensive nodularity	Low-risk tumour of infancy
Medulloblastoma, non-WNT/non-SHH, group 3	Classic	Standard-risk tumour
	Large cell / anaplastic	High-risk tumour
Medulloblastoma, non-WNT/non-SHH, group 4	Classic	Standard-risk tumour; classic morphology found in almost all group 4 tumours
	Large cell / anaplastic (rare)	Tumour of uncertain clinicopathological significance



Surrogate IHC markers for pathway activation

+ TP53 sequencing
+ MYC amplification by FISH

Genetics & histology & clinical factors stratify patients into risk groups

New risk stratification since 2016

TABLE. Comparison between Risk Classification based on Clinical Criteria and New Patient Risk Groups based on the 2016 Expert Consensus Statement[19]

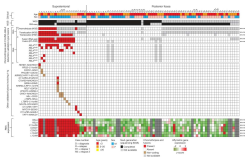
Current risk classification	Proposed new risk classification
Based on clinical criteria (children > 3 yr)	Integrating clinical and molecular criteria
Average risk	Low risk (>90% survival)
≤1.5 cm^2 of residual disease	Localized WNT MB (<16 yr)
No metastatic disease	Localized group 4 MB with chromosome 11 loss or whole chromosome 17 gain
High risk	Standard risk (75%–90% survival)
>1.5 cm^2 of residual disease	Localized p53 WT-SHH MB
Metastatic disease	Localized, non-*MYC* amplified group 3 MB
(Anaplasia)	Localized group 4 MB
	Localized group 4 MB without chromosome 11 loss or 17 gain
	High risk (50%–75% survival)
	Metastatic noninfant p53 WT-SHH or localized *MYCN*-amplified SHH MB
	Metastatic group 4 MB
	Very high risk (<50% survival)
	p53-mutated SHH MB
	Metastatic group 3 MB

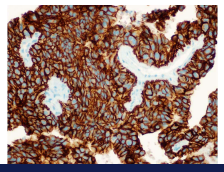
Other embryonal tumors

- Dismissal of PNET, primitive neuroectodermal tumor
- Instead:
  - ***C19MC*-amplified Embryonal tumor with multilayered rosettes**
    - ETANTR + ependymoblastoma + medulloepithelioma
    - Immunohistochemical marker LIN28
  - **Atypical teratoid/rhabdoid tumor (AT/RT)**
    - defined by *INI1* or very rarely *BRG1*
    - Immunohistochemical marker SMARCB1/INI1
  - Wastebasket category for all others: CNS embryonal tumor, NOS

Other tumors: Ependymoma

- WHO grading of unclear clinical significance
- One narrowly defined subgroup: Ependymoma, RelA gene fusion
  - Drives NFkappaB signaling (outside of the mutation box!)
  - Majority of supratentorial tumors in children, poor prognosis!
  - L1CAM expression as immunohistochemical surrogate

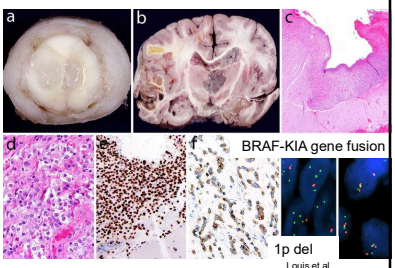




Neuronal and mixed neuronal-glial tumors

Diffuse leptomeningeal glioneuronal tumor

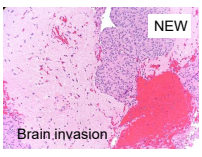
- Mostly in children and adolescents
- Histologically reminiscent of oligodendroglioma

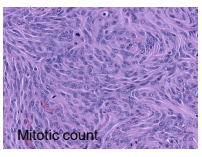


Louis et al, Acta Neuropath 2016

Meningioma

- Classification and grading not revised
- Except: *brain invasion* as a criterion for atypical meningioma, WHO grade II
  - Mitotic count (5 mitoses per 10 high-power fields) or
  - Brain invasion is sufficient





Solitary fibrous tumor - hemangiopericytoma

- Soft tissue pathologists moved away from the designation hemangiopericytoma
- Considered within the spectrum of solitary fibrous tumors
- Both share genetic constellations, most notably *STAT6* gene fusion -> one common entity
- Grade I-III
  - Grade I: highly collagenous, low cellularity
  - Grade II: more cellular, less collagenous „staghorn" vessels
  - Grade III: + 5 mitoses per 10 high-power fields

Summary

- Substantial step forward & paradigm change
- Introduction of molecular parameters
  - Challenge molecular marker testing!
- Associated changes of diagnostic format
  - Integrated diagnoses (CAVE time delay to molecular results)
- Greatest impact on diffuse gliomas & embryonal tumors
- More objective and precisely defined entities for enhanced patient management

Reactions

"H K, how can we cope with the new molecular requirements in the WHO ?" – Chitra Sarkar, India

"WHO 2016 has let the scientific world down" – Richard Gilbertson, ISPNO June 2016

"We are ten years ahead of WHO" – Martin van den Bent, EANO Oct 2016

Outlook next WHO classification

- Diffuse gliomas
  - WHO grading system will be revised
- Pediatric low-grade gliomas
  - Integrated diagnoses will be introduced, e.g., for *BRAF* gene fusion in pilocytic astrocytomas
- Ependymoma
  - WHO grading will be revised
- Meningioma
  - WHO grading will be revised
  - DNA methylation profiling might be introduced (?)

Asking neuropathologists in 2016 *post* WHO

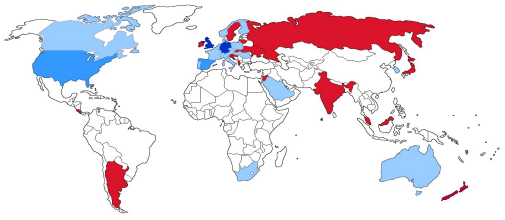
11th European Congress of Neuropathology, Bordeaux, France

Aim: Assessing practice patterns regarding adult diffuse glioma during times of transition

- Which molecular markers have already been incorporated in routine practice
- Which molecular techniques are in daily use or will be implemented in the near future
- Set a baseline for future assessments

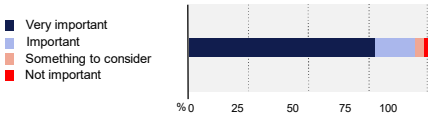
Methods: Structured survey distributed onsite and among Euro-CNS members

130 Respondents from 40 countries



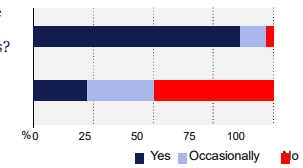
- 93.8 % indicate to work as (neuro-)pathologist
- 75 % report to work within Europe
- Single respondents from 17 different countries (in red)

1. How would you rate the relevance of molecular marker testing in diagnostic neuropathology?

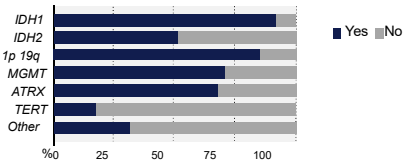


2. Do you currently use molecular information for diagnostic purposes?

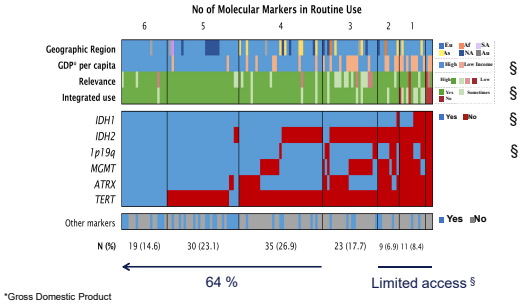
3. Do you use „oligoastrocytoma" as histological diagnosis?



4. Which molecular markers do you routinely test for neuropathological work-up of diffuse gliomas?

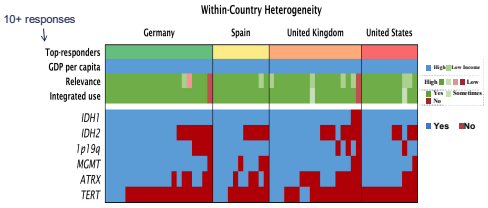


4. Which molecular markers do you routinely test for neuropathological work-up of diffuse gliomas?



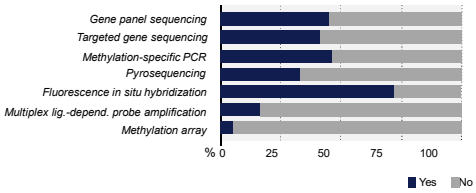
*Gross Domestic Product

4. Which molecular markers do you routinely test for neuropathological work-up of diffuse gliomas?

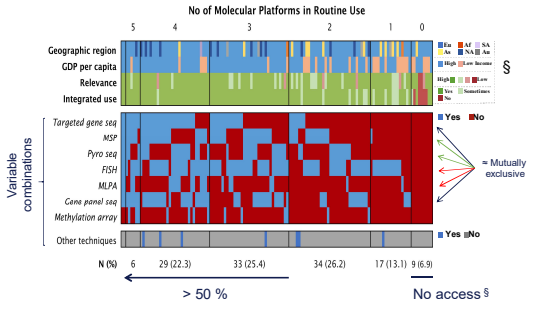


High within-country heterogeneity

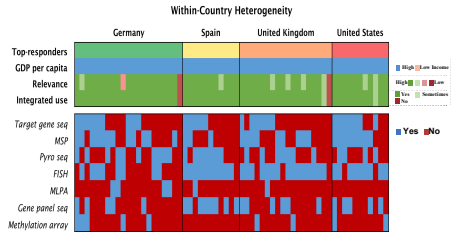
5. Which molecular techniques and platforms do you currently use?



5. Which molecular techniques and platforms do you currently use?

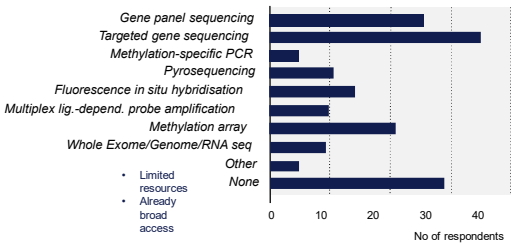


5. Which molecular techniques and platforms do you currently use?



High within-country heterogeneity (might indicate centralization of diagnostic services)

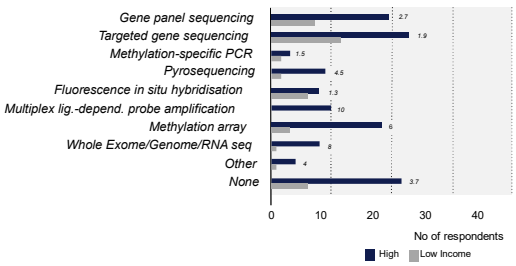
6. Which additional platforms are you going to implement within the next 1-2 years?



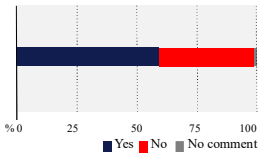
- Limited resources
- Already broad access

60 % of neuropathologists aim at implementing one additional technique

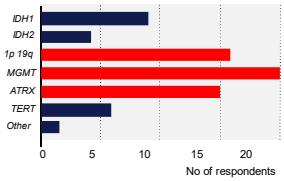
6. Which additional platforms are you going to implement within the next 1-2 years?



7. Are you concerned about the analytical test performance of any of those markers?

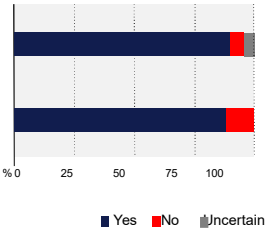


8. If yes, which marker would you rate most problematic?



9. Is there a need for guidelines on marker testing?

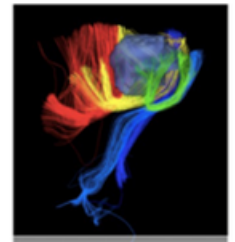
10. Would you be willing to participate in a ring trial?



Summary

- *Post 2016 WHO* survey focused on neuropathologists
- Neuropathologists uniformly rate **molecular marker testing as highly relevant** and **already incorporate molecular information** in their diagnostic assessments
- **Differences in access to crucial biomarkers and molecular techniques** across geographic regions AND within individual countries
- Concerns regarding the validity of test assays (with MGMT, 1p 19q, and ATRX being perceived most problematic) underline the **need for consensus guidelines** on molecular marker testing (cIMPACT now, Euro-CNS)

Thank you.



Modern Imaging of Brain Tumours

Mr Ranjeev Bhangoo
Consultant Neurosurgeon / Clinical Director Neuroscience
Mr Christian Brogna

King's College Hospital
King's College London
London, United Kingdom

- CT and routine MRI protocol
- Anatomic Imaging
- Metabolic Imaging
- Physiological Imaging
- Functional Imaging
- Pros and Cons Imaging followup

CT

- **CT:** acute symptomatology, first line assessment
  - to exclude: - intracranial hemorrhage
    - brain herniation
    - acute hydrocephalus

⇨ Urgent Neurosurgical Treatment

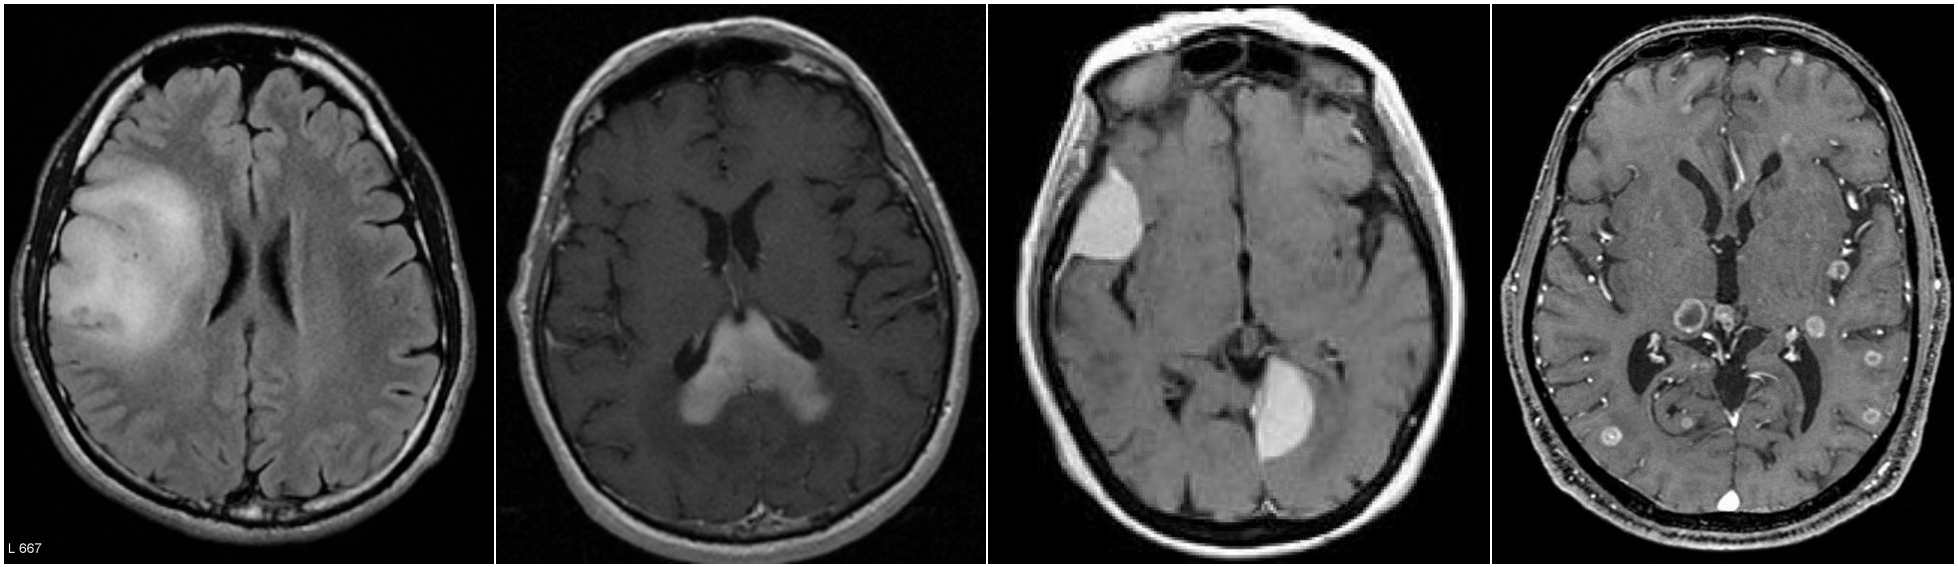
CONVENTIONAL STRUCTURAL MRI BRAIN TUMOURS

- **MRI**: routine protocol

  - 3D T1-weighted sequence before IV contrast medium
  - Axial T2 weighted
  - Axial T2 weighted FLAIR sequence (for lesions within the cortex or paraventricular - useful in low grade gliomas)
  - Axial Diffusion Weighted Imaging (DWI)
  - Axial T2*-weighted sequence (sensitive to blood and calcifications)
  - Susceptibility-weighted imaging (SWI)
  - 3D Contrast enhanced T1 weighted sequences

CONVENTIONAL STRUCTURAL MRI

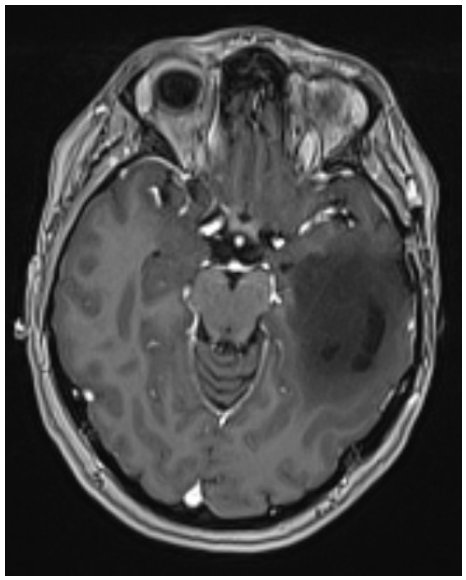
- Anatomical Location (Intra or extra-axial)
- Extent of tissue involvement
- Mass effect upon brain, ventricular system and vasculature
- Suggest a short list of differential diagnosis (particularly in t he clinical context)

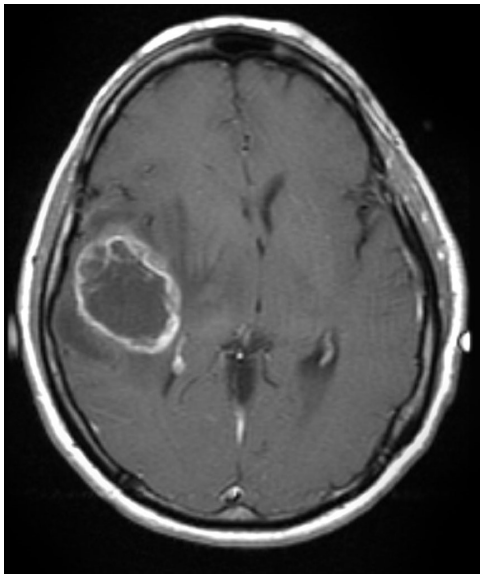


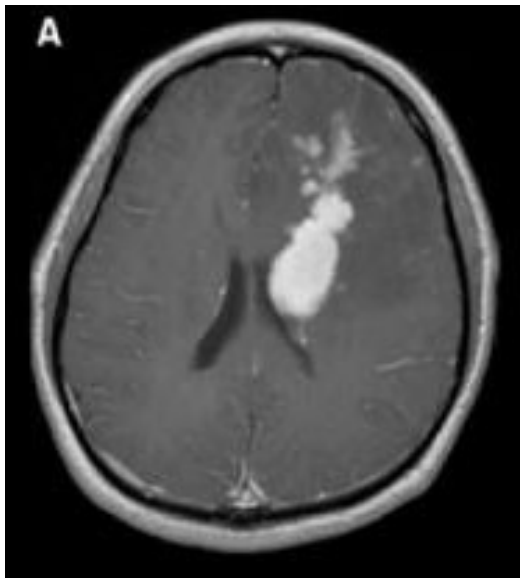
Oligodendroglioma | Lymphoma | Meningiomas | Multiple Mets

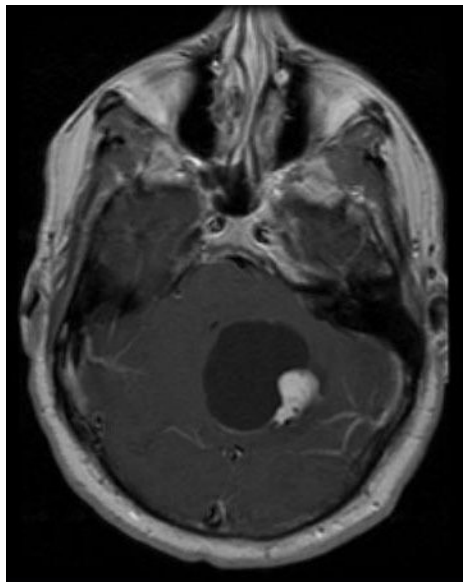
CONVENTIONAL STRUCTURAL MRI

- Pattern of enhancement









Pitfall:
Non enhancing
astrocytoma grade III
IDH1 negative,1p
19q non codeleted

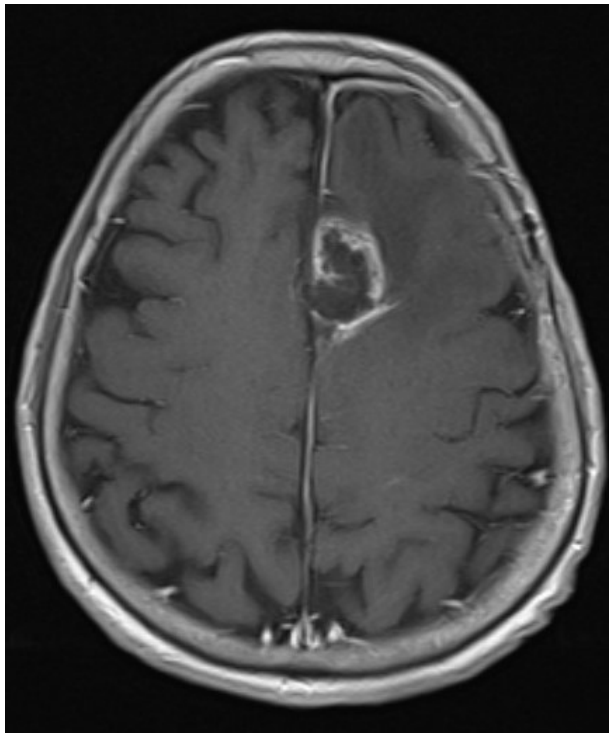
GBM

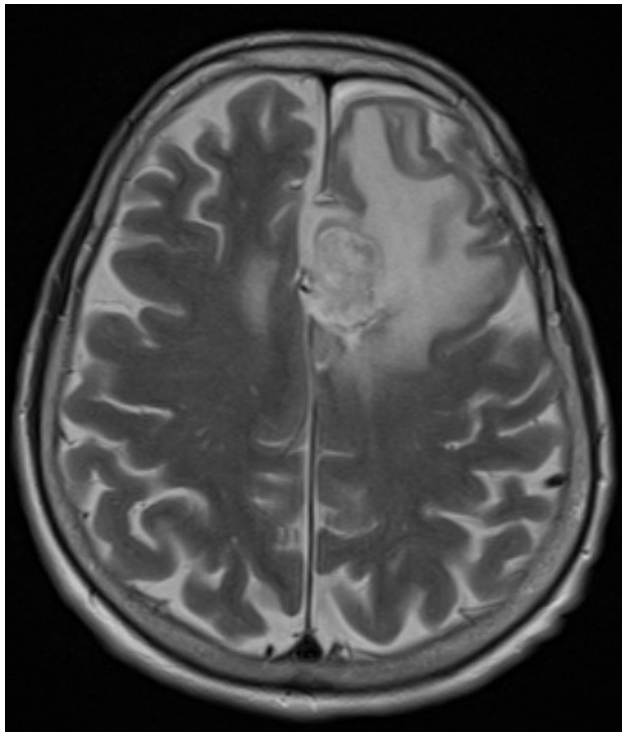
LYMPHOMA

HEMANGIOBLASTOMA

CONVENTIONAL STRUCTURAL MRI

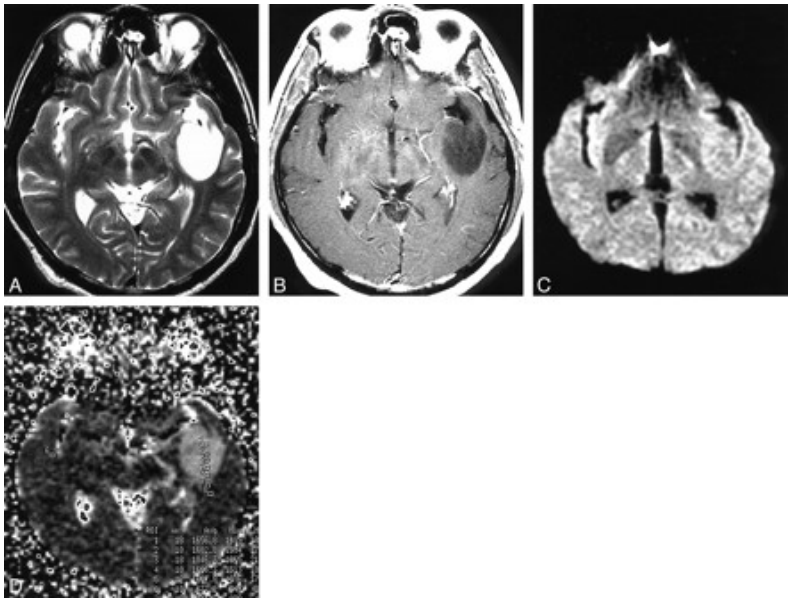
Pitfall: VASOGENIC EDEMA vs INFILTRATING TUMOUR





PHYSIOLOGICAL IMAGING
DWI MRI

- Probes Brownian motion of water molecules
- Assess tumor cellularity, peritumoral edema, regions of tumor hypoxia, integrity of white matter
- Corresponding ADC values reflect the magnitude of diffusivity



Diffusion weighted image

	DWI	ADC	Examples
Diffusion restriction	○	●	*cytotoxic edema (acute ischemia), abscess/inflammation, acute demyelination*
Increased diffusion	●	○	*cerebrospinal fluid (CSF)*
T2 shine-through	○	○	*vasogenic edema, gallbladder, endometrium*

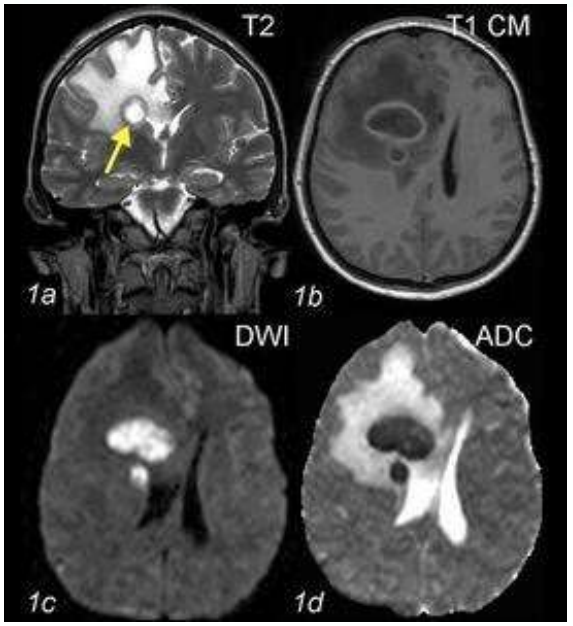
PHYSIOLOGICAL IMAGING
DWI MRI

- Differential diagnosis of abscess, epidermoid cyst, traumatic shearing injury, toxic and infectious encephalitis, immediate post brain injury

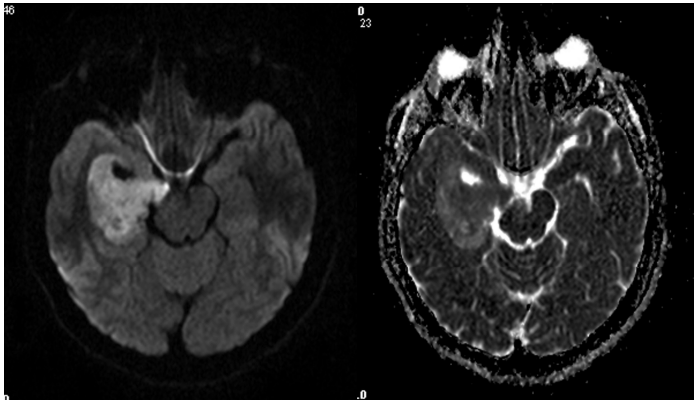
- Accurate interpretation of new abnormal contrast enhancement developing soon after tumor resection

- Postoperative ischemia

PITFALL: Para or ferromagnetic materials such as blood products or calcium within the brain can simulate pathology on DWI as well as perfusion MRI



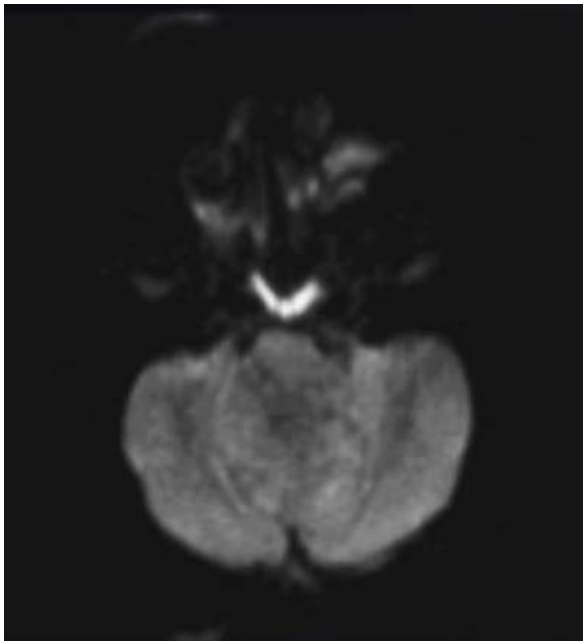
Brain abscess



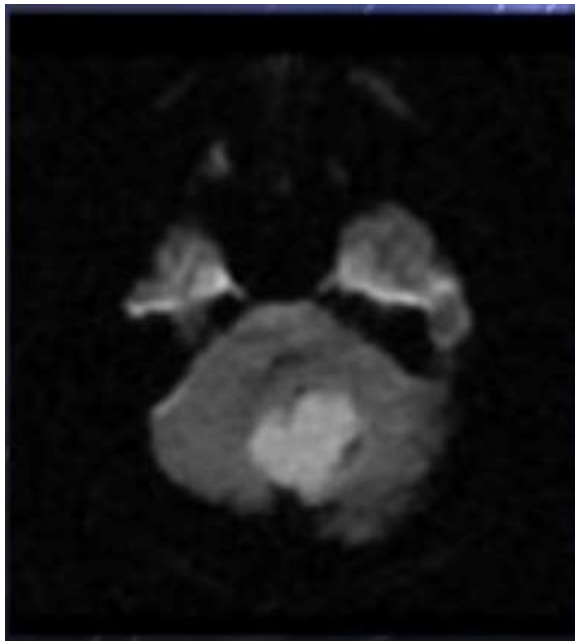
Epidermoid

PHYSIOLOGICAL IMAGING
DWI MRI

High ADC values
Ependymoma

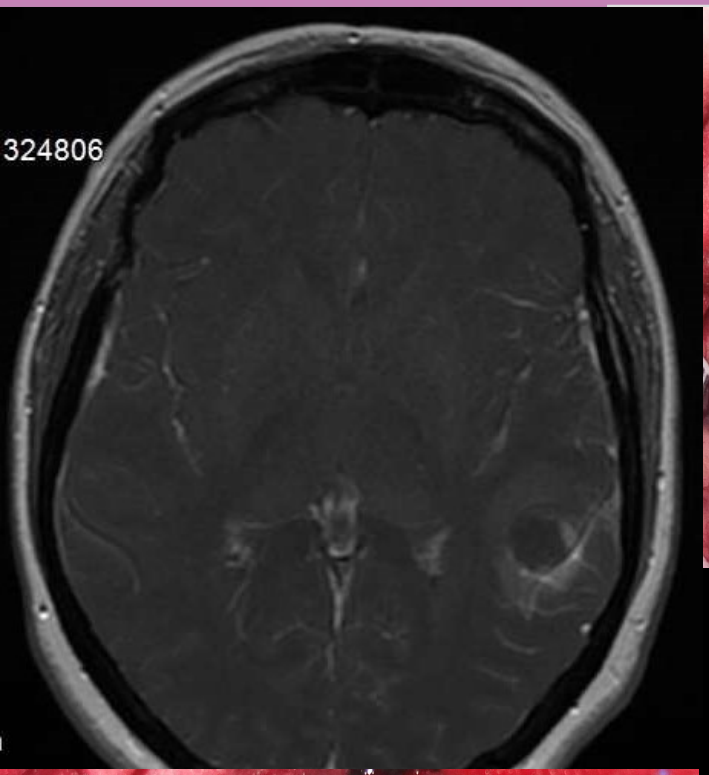


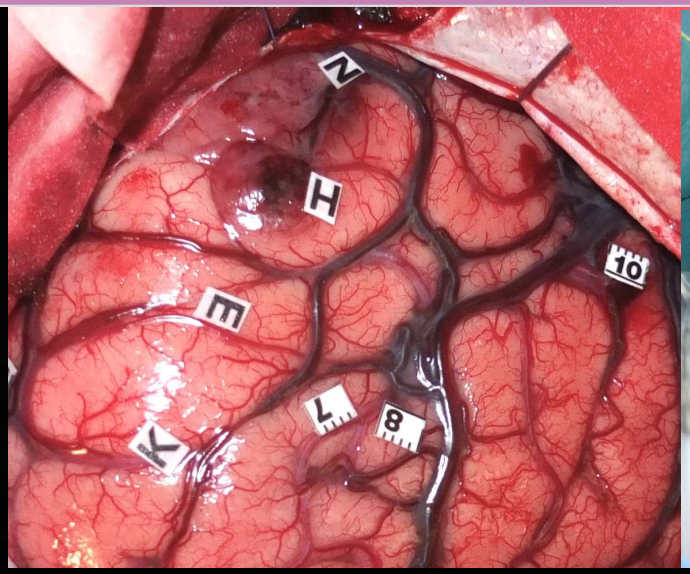
Low ADC values
Medulloblastoma

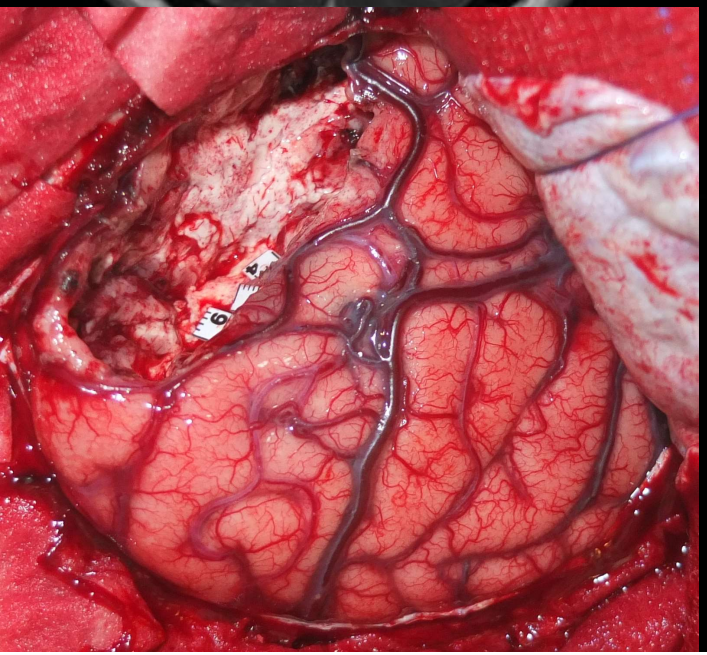


PHYSIOLOGICAL IMAGING

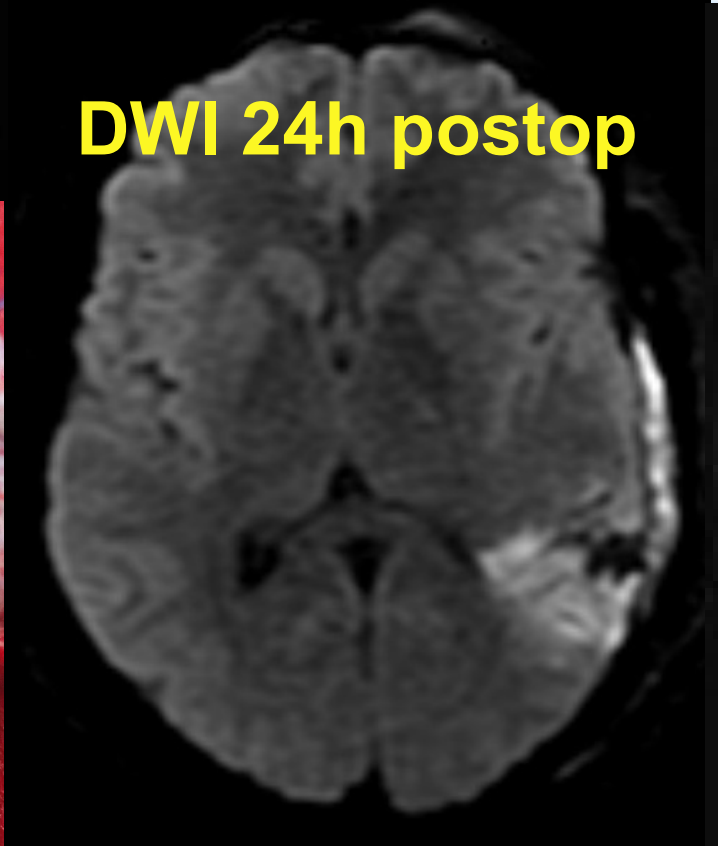
DWI- MRI



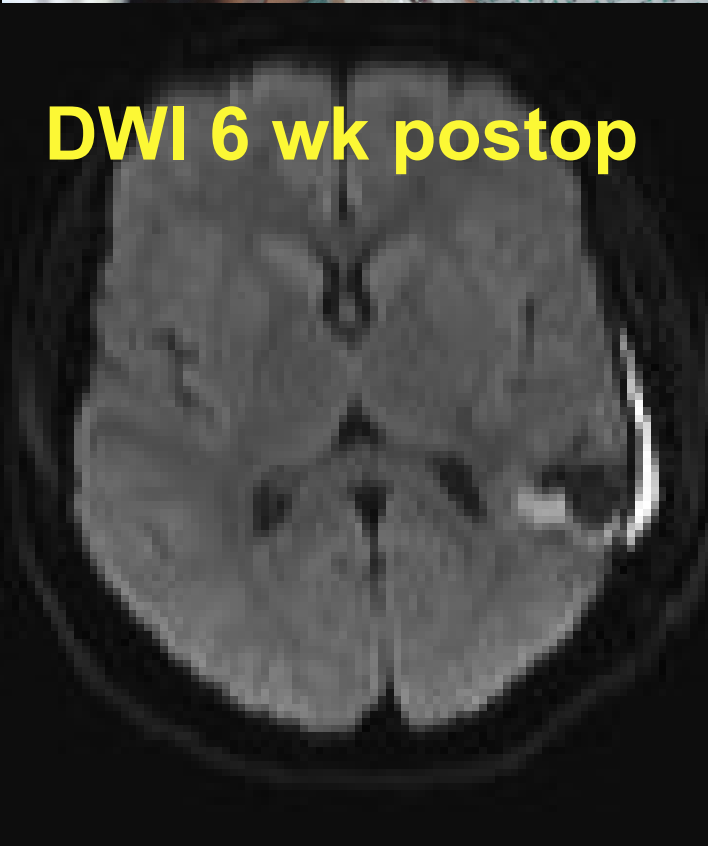




DWI 24h postop



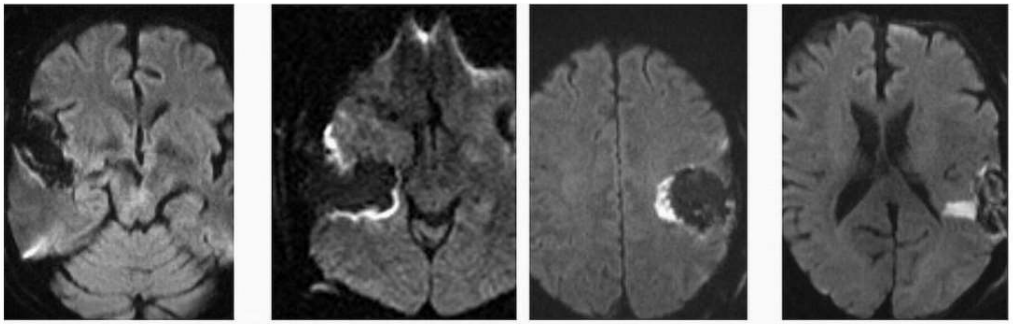
DWI 6 wk postop



PHYSIOLOGICAL IMAGING
DWI- MRI

Surgically Acquired Deficits and Diffusion Weighted MRI Changes after Glioma Resection - A Matched Case-Control Study with Blinded Neuroradiological Assessment

Asgeir S. Jakola[1,2,3*], Erik M. Berntsen[4,5], Pål Christensen[4], Sasha Gulati[1], Geirmund Unsgård[1,3,6], Kjell A. Kvistad[4,5], Ole Solheim[1,2,3]



No significant ischemic lesion

Ischemic lesion around the tumor cavity

Sector shaped ischemic lesion

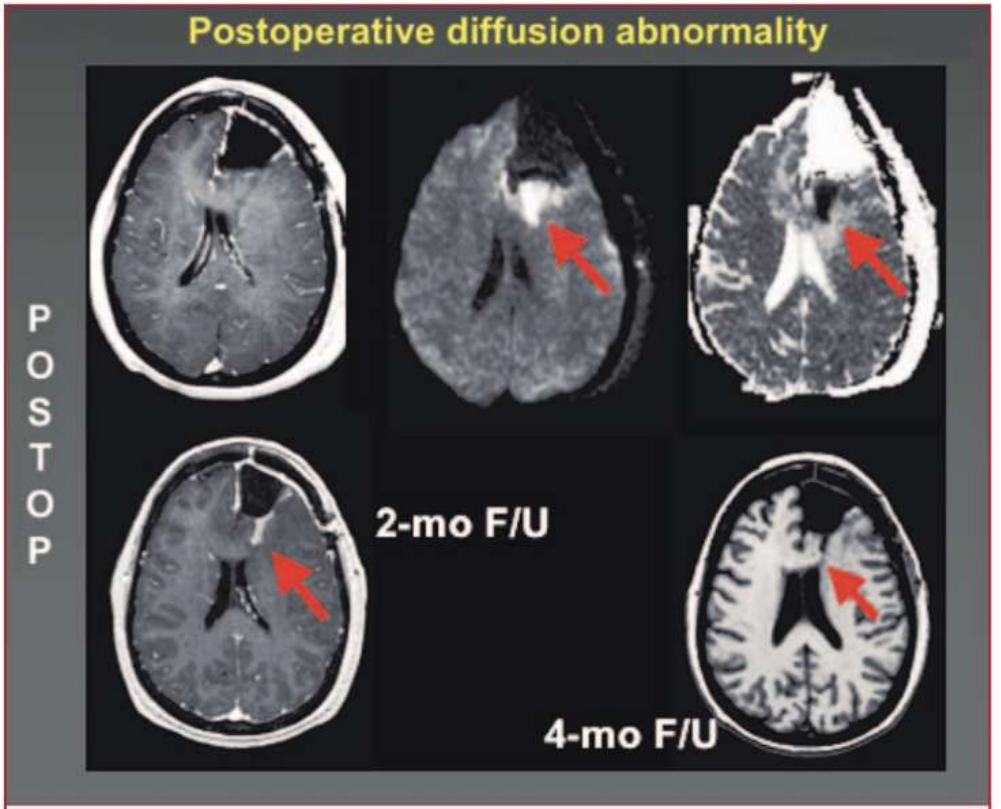


FIGURE 7. *DWI obtained 2 and 4 months postoperatively to identify areas of ischemia (bright signal DWI, dark signal void apparent diffusion coefficient) that enhances briefly postoperatively.*

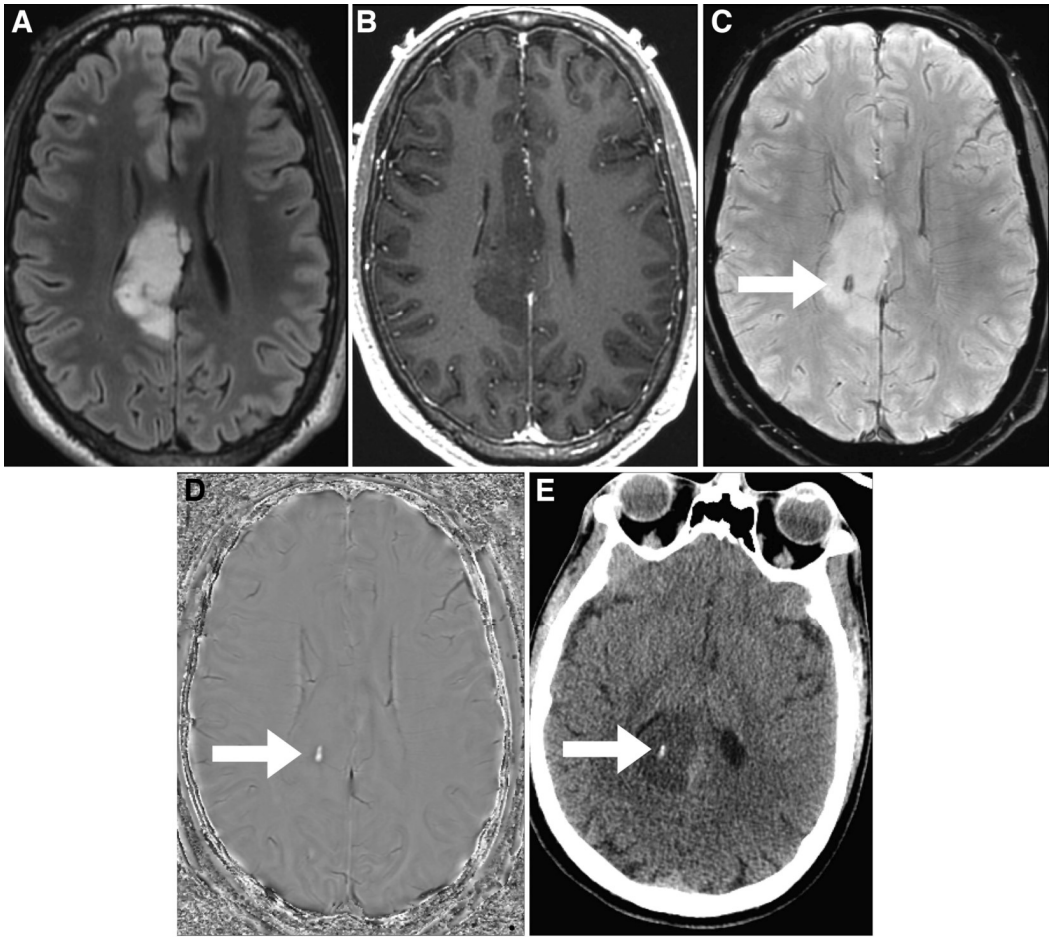
M. Berger et al. Neurosurgery 2000

PHYSIOLOGICAL IMAGING
SWI-MRI

Sensitive to blood products, microvessels and calcium



Oligodendroglioma

PHYSIOLOGICAL IMAGING
PERFUSION MRI

- Provides hemodynamic informations and estimates the cerebral blood volume that reflect the underlying microvasculature, marker of angiogenesis
- Exploit signal changes that accompany the passage of a paramagnetic contrast agent thorugh the cerebrovascular system
- Useful if patients receive antiangiogenetic cancer therapies to monitor its efficacy
- Maps of cerebral blood volume can serve as an additional targets for brain tumour biopsies
- May help in differentiating radiation necrosis and recurrent tumour
- May help differentiating tumor infiltrated edema (high grade gliomas) and vasogenic edema (in case of metastases)

PITFALL:
NO CORRELATION
WITH TUMOR GRADING

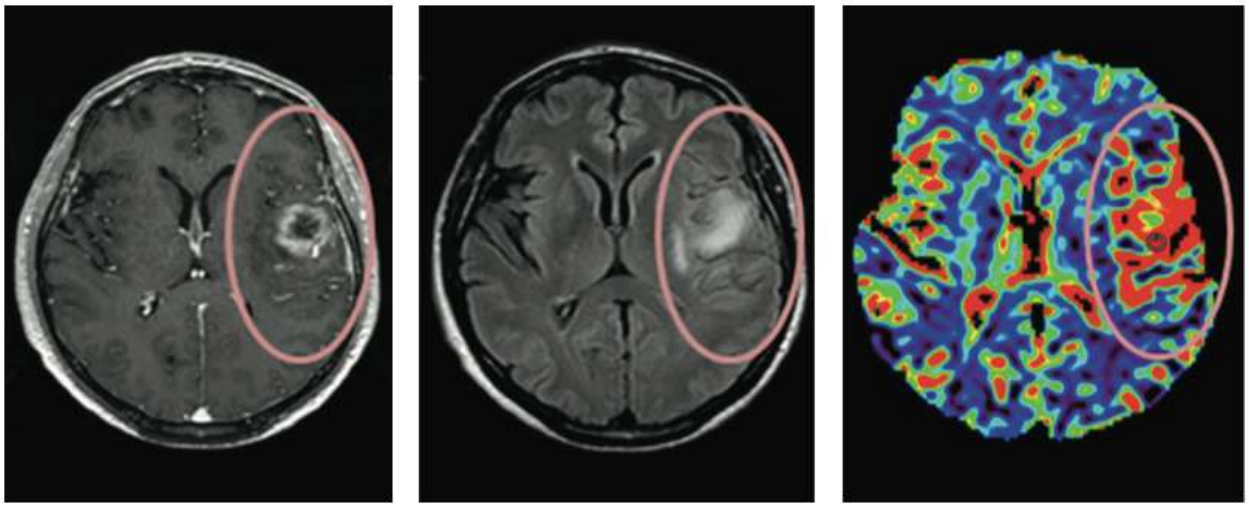


FIGURE 2: Axial coregistered contrast-enhanced axial T1-weighted image (a), FLAIR image (b), and CBV map (c) from a patient affected by glioma grade IV. In the CBV map (c) warmer colors indicate higher CBV values suggesting higher perfusion and neovascularization. Comparison of CBV map (c) and contrast-enhanced axial T1-weighted image highlights a mismatch area (surrounded by the circle) corresponding to the extension of the high perfusion area outside the contrast-enhancement: this indicates a more extensive neovascularization than that shown by conventional MRI (a, b).

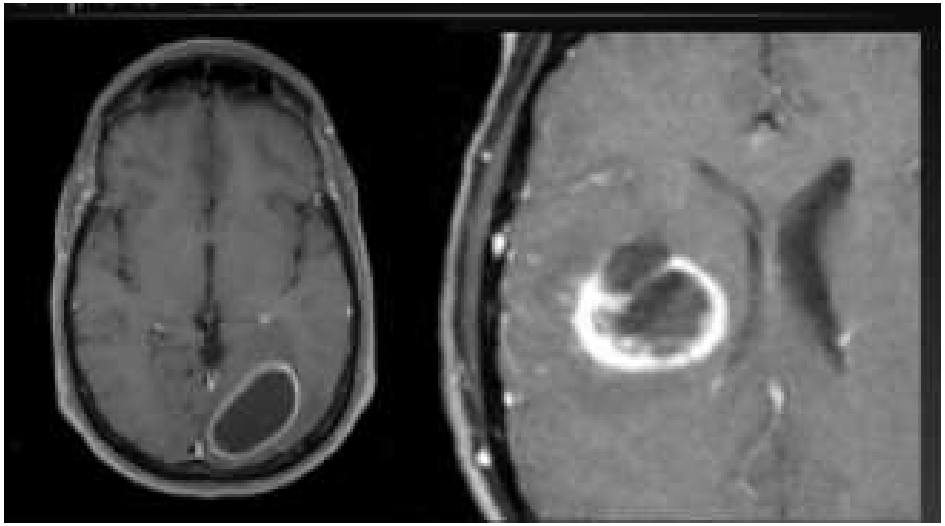
Di Stefano et al. 2014

TUMOR MIMICS

Ring- enhancing lesions

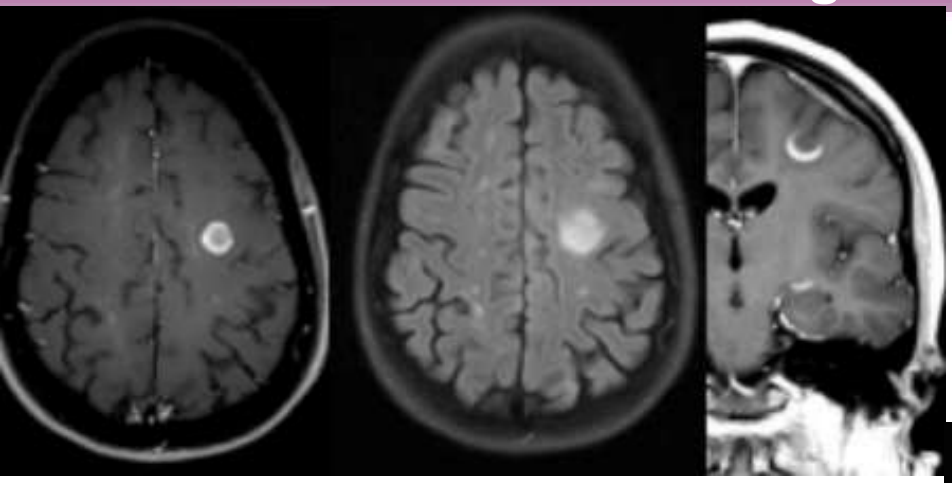


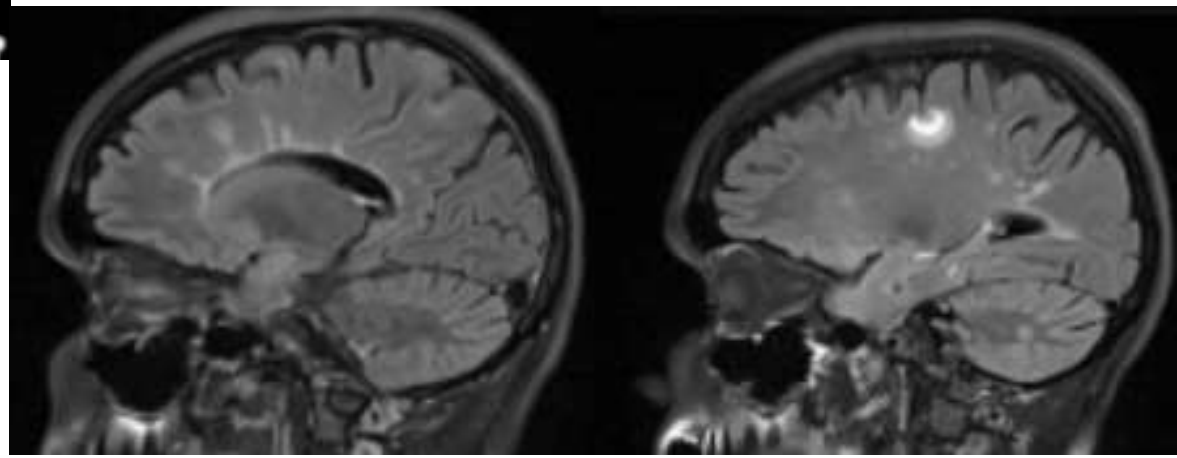
Met GBM

- **Demyelination**
  - Incomplete peripheral enhancement
- **GBM**
  - More irregular enhancement
- **Infection**
  - Toxoplasmosis, neurocysticercosis, TB, Abscess, Nocardia
- **Lymphoma**
  - Ring-enhancement if immunocompromised
- **Metastases**

TUMOR MIMICS

Ring- enhanicing lesions

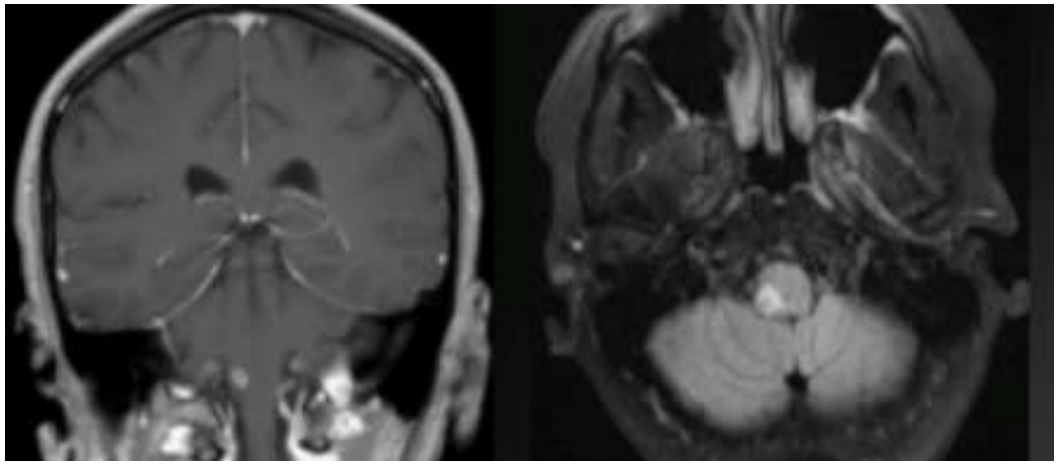


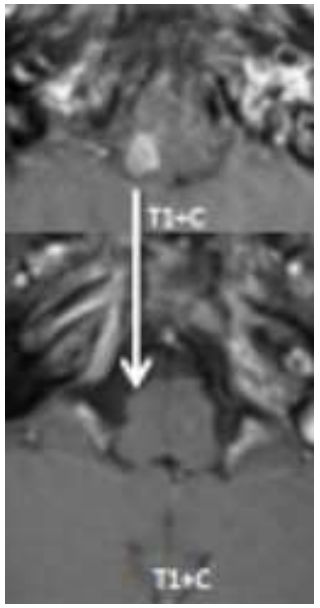


- 24 yy, Multiple sclerosis
- Ring-enhancement that opens toward the cortex

TUMOR MIMICS

Ring- enhanicing lesions

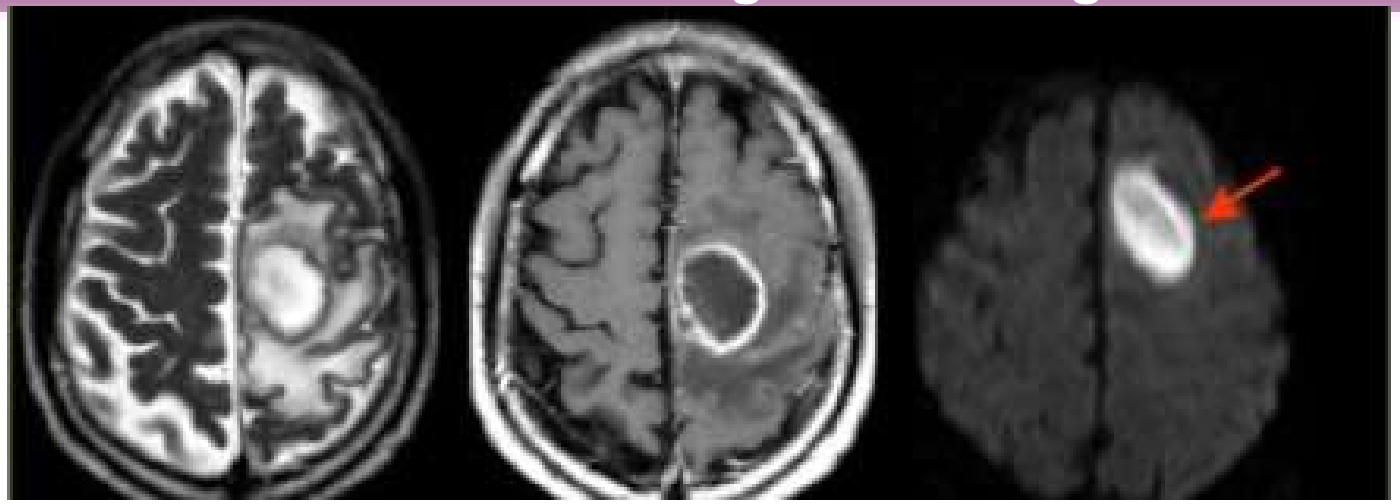




- ADEM
- 4 months later lesion resolved

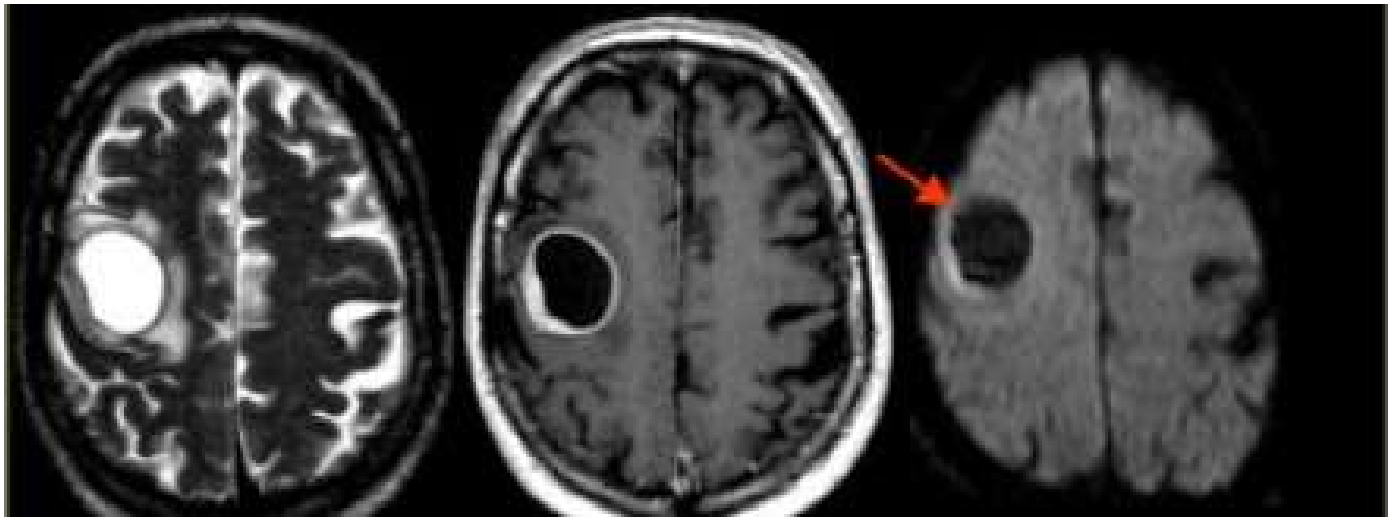
TUMOR MIMICS

Ring- enhanicing lesions



Abscess

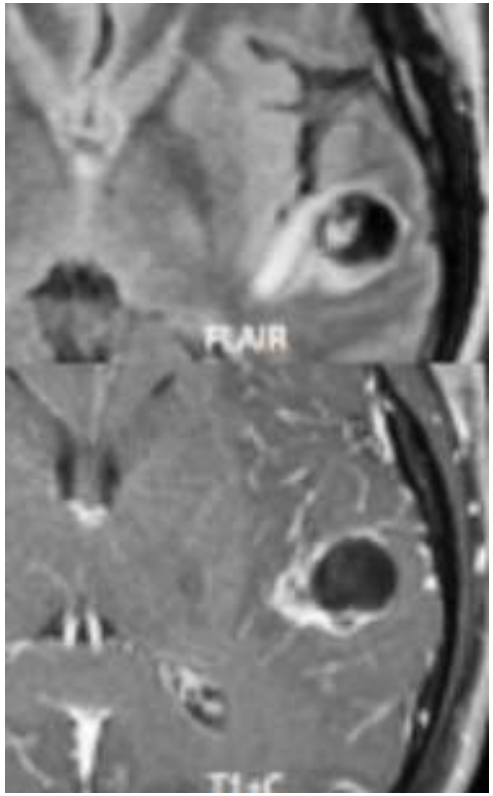
Vs



Lung Met

TUMOR MIMICS

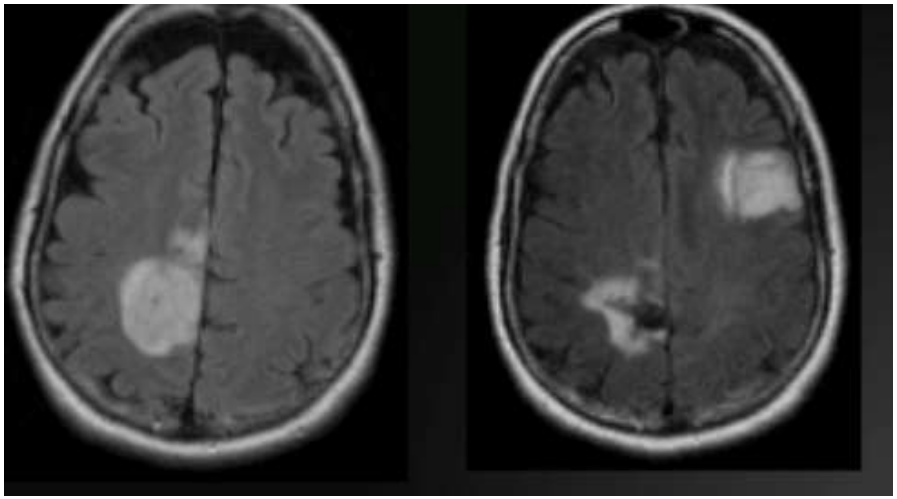
Ring- enhanicing lesions



- Neurocysticercosis as opposed to low grade solid neoplasm

TUMOR MIMICS

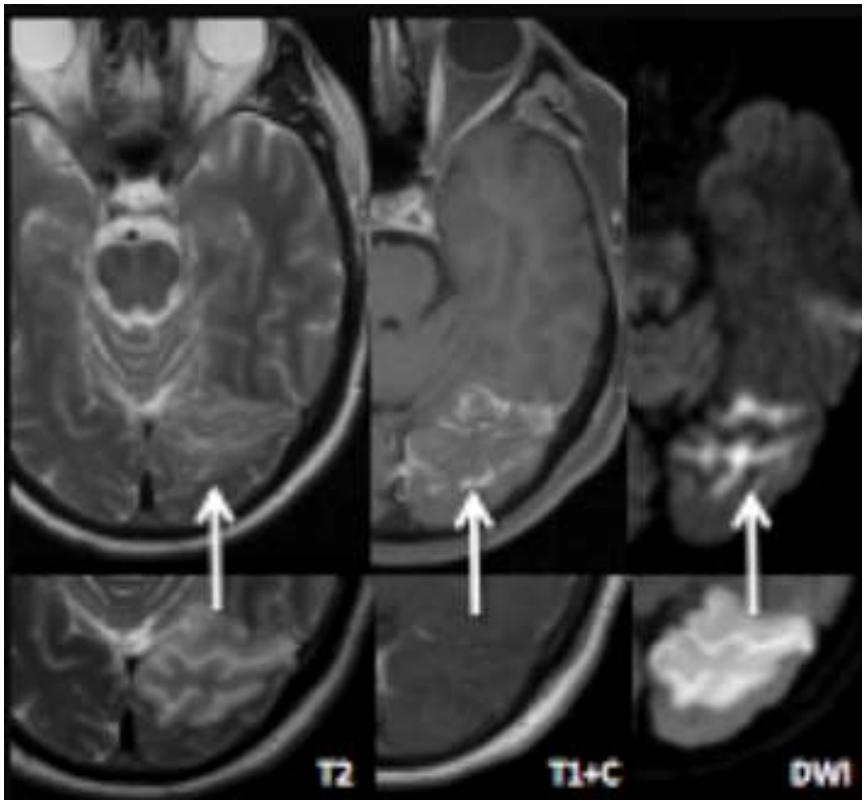
Ring- enhanicing lesions



3 months later

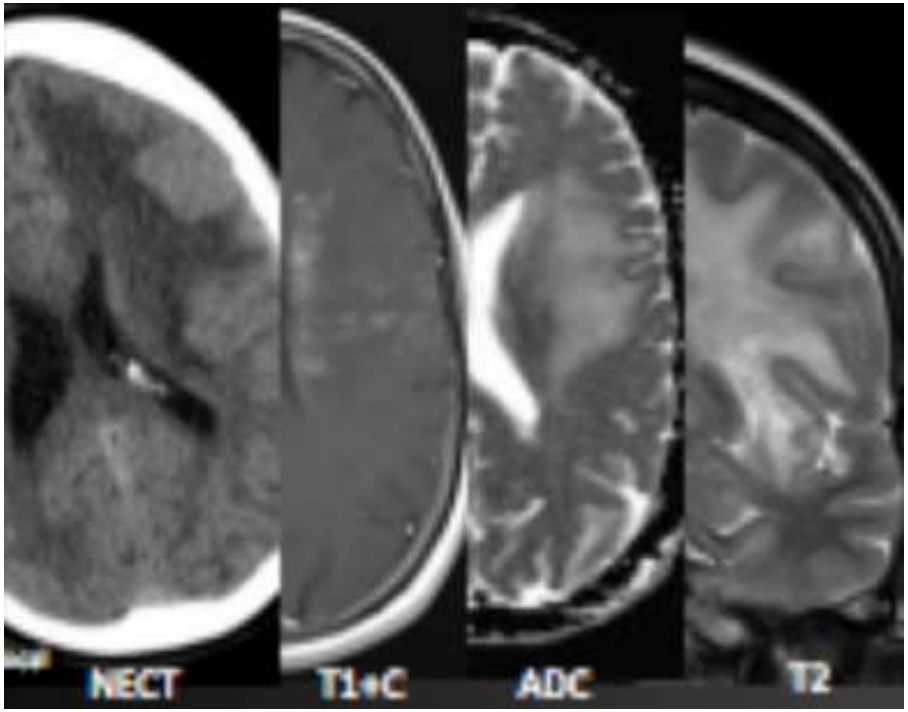
- Tumefactive demyelination as opposed to glioma

TUMOR MIMICS



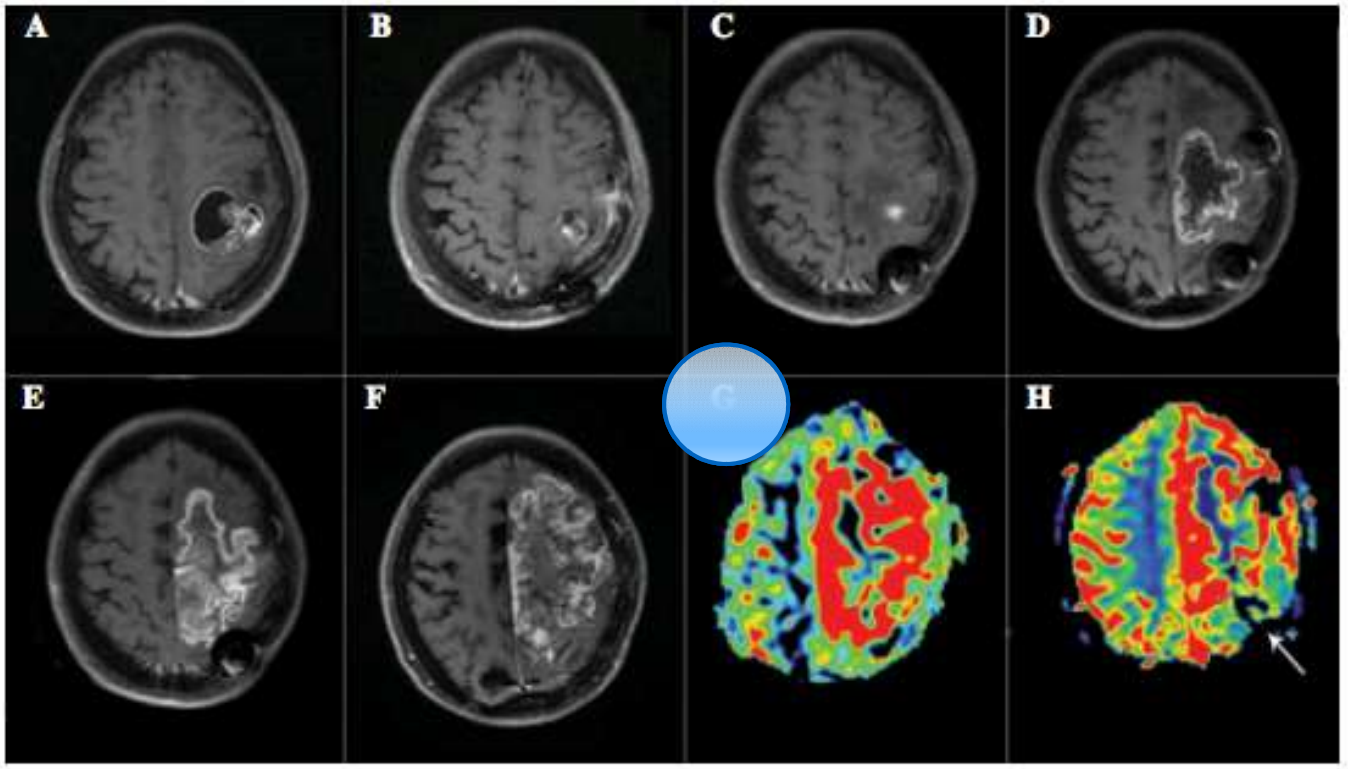
- Subacute stroke: in doubts re-image 2 weeks later

TUMOR MIMICS



- Vasculitis with microthrombosis as opposed to tumour

TUMOR MIMICS

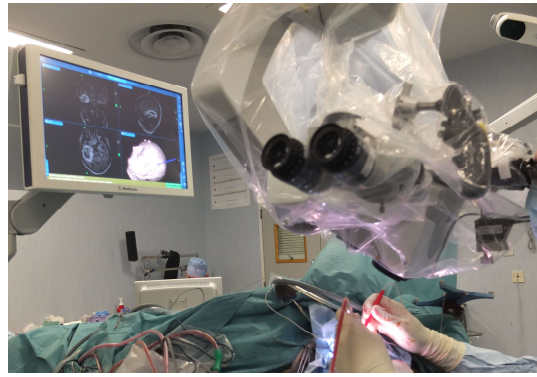


- Radiation Necrosis vs Recurrent High Grade:
- (G) Arterial Spin Labeling Perfusion Imaging

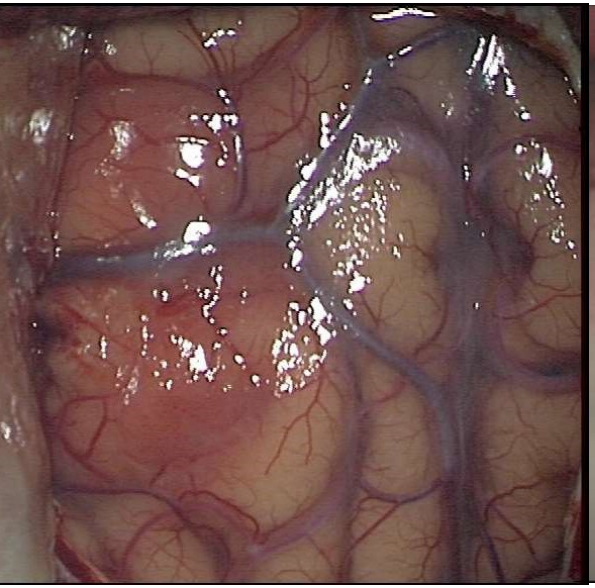
ASL-MRI: measure tumour perfusion. No Gd administered, No Gd extravasation

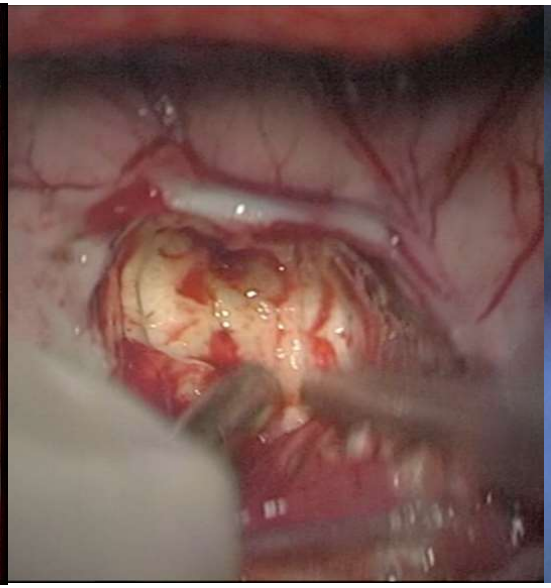
ANATOMIC IMAGING
EARLY POSTOP MRI

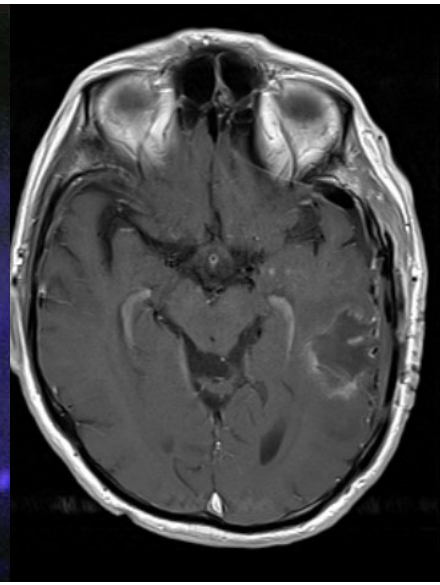
Enhancing granulation tissue begins to develop 3 days after surgery, persist for weeks to month, and mimics tumour



Post op imaging should be performed within 48h of surgery, the sooner the better





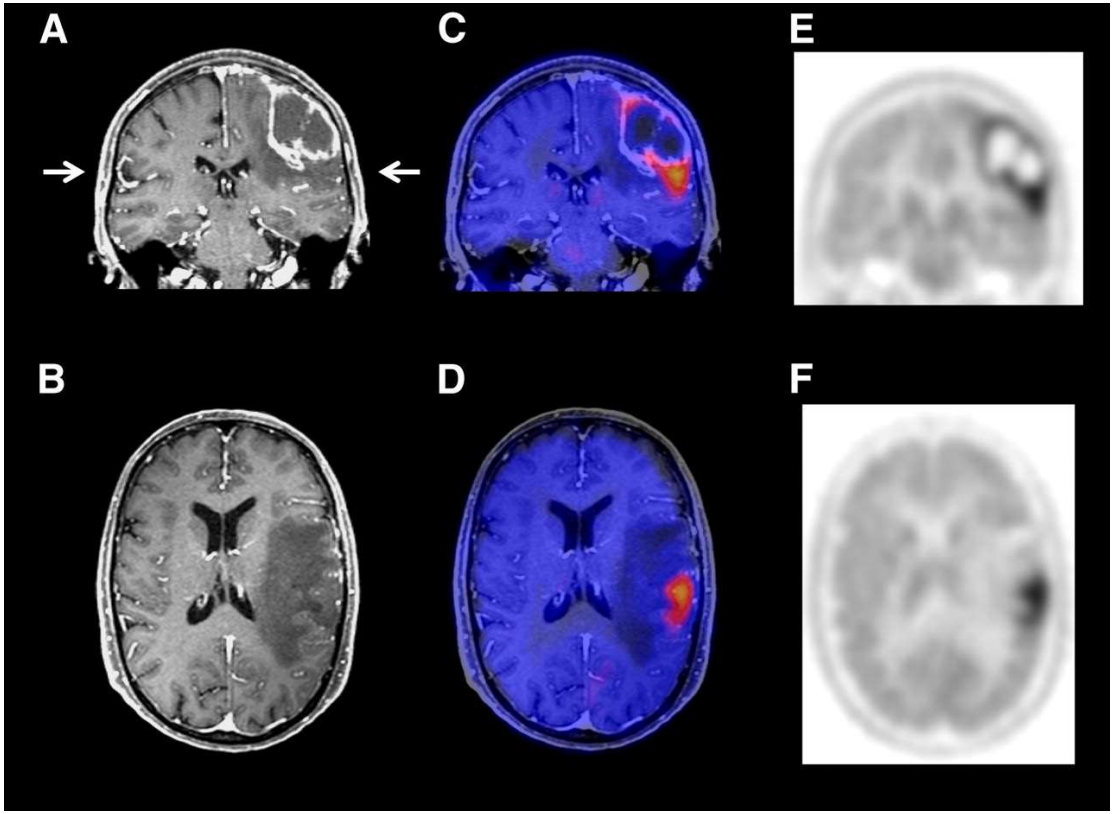


Pitfall: when comparing studies, the size and shape of a tumor can appear substantially different due to differences in the angle of imaging, slice thickness and gaps between slices

METABOLIC IMAGING

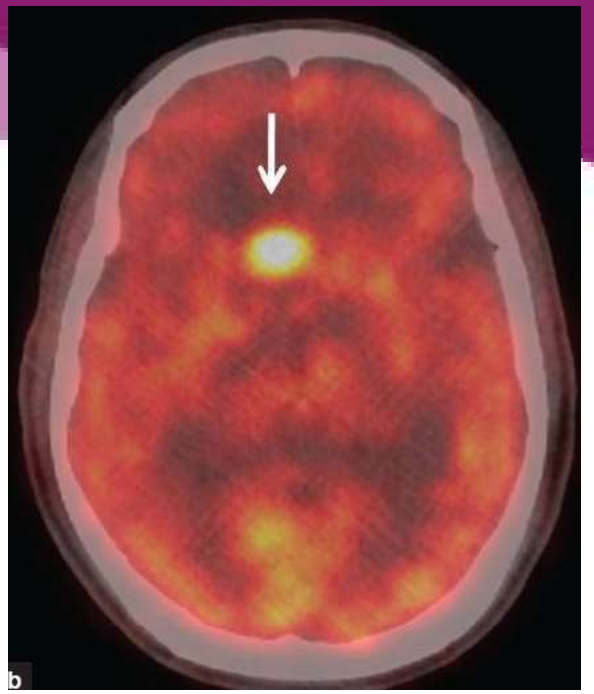
PET provides <u>metabolic in vivo measurement</u> of local tracer activity at a very high sensitivity

(Best if coupled with MRI scan)



- **[(18)F]-FDG-PET**
- **[11C]Methionine (MET)**
- **[(18)F]-FLT-PET fluorothymidine**

[(18)F]-FDG-PET



Pitfalls of [(18)F]-FDG-PET

- **LGG uptake is similar to normal white matter**
- **HGG uptake is similar to normal gray matter**

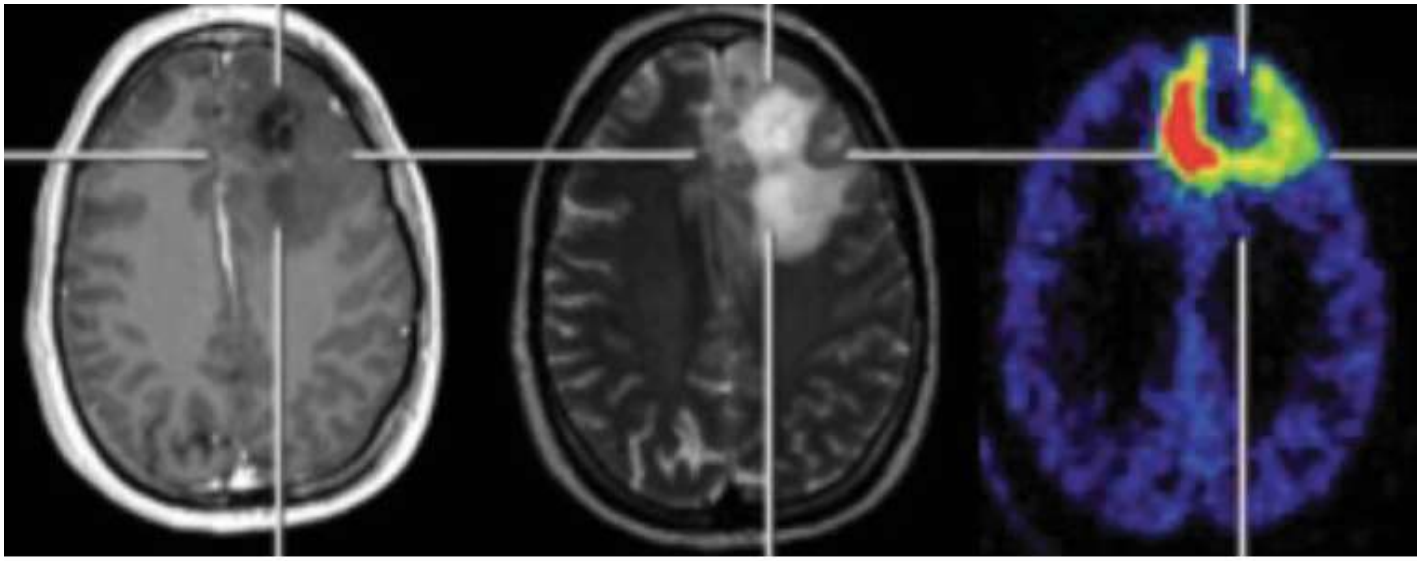
- **Cannot differentiate tumour vs inflammation vs acute stroke**
- **Radiation necrosis may be indistinguishable from recurrent tumour**

(Due to accumulation of [(18)F]-FDG in macrophages that may infiltrate the sites having received radiation therapy)

High pretreatment glucose metabolic rate is higher in responders to TMZ than non responders in patients with high grade glioma *(Brock CS. Br J Cancer 2000)*

METABOLIC IMAGING
PET [11C]Methionine (MET)

- **Marker for <u>ACTIVE TUMOR PROLIFERATION AND ANGIOGENESIS</u> (Correlates with Ki-67 expression, proliferating cell nuclear antigen expression and micro vessel density)**
- **<u>TRUE TUMOR EXTENSION?</u>** *[11C] MET uptake ratios compared with the background is favourable.*



GBM MARGINS IN PET-MET WELL BEYOND THE ENHANCING COMPONENT

King's KING'S College LONDON ESTRO School

METABOLIC IMAGING
PET [11C]Methionine (MET)

- The highest uptake is observed in anaplastic oligodendrogliomas WHO grade III
- LGG are better detected by aminoacid tracers due to increased uptake in the absence of blood-brain barrier damage
- LGG: useful for differentiation from nonntumorous lesions, detection of recurrences, indication of progressing disease

- Can differentiate better between Recurrent tumour and Radiation Necrosis with high sensitivity and specificity (~75%): necrosis and glioses after therapy show a reduction of ammoniated uptake in contrast to recurrent and residual tumour growth.
- Deactivation of aminoacid transport is a early sign of response to chemotherapy (Galldicks N et al Mol Imaging 2010). PET responders with a decrease of tumour brain/ration of >10% had a significant longer TTP and OS than patient with increase tracer uptake after RT and CHT in GBM.

PITFALLS OF PET-MET

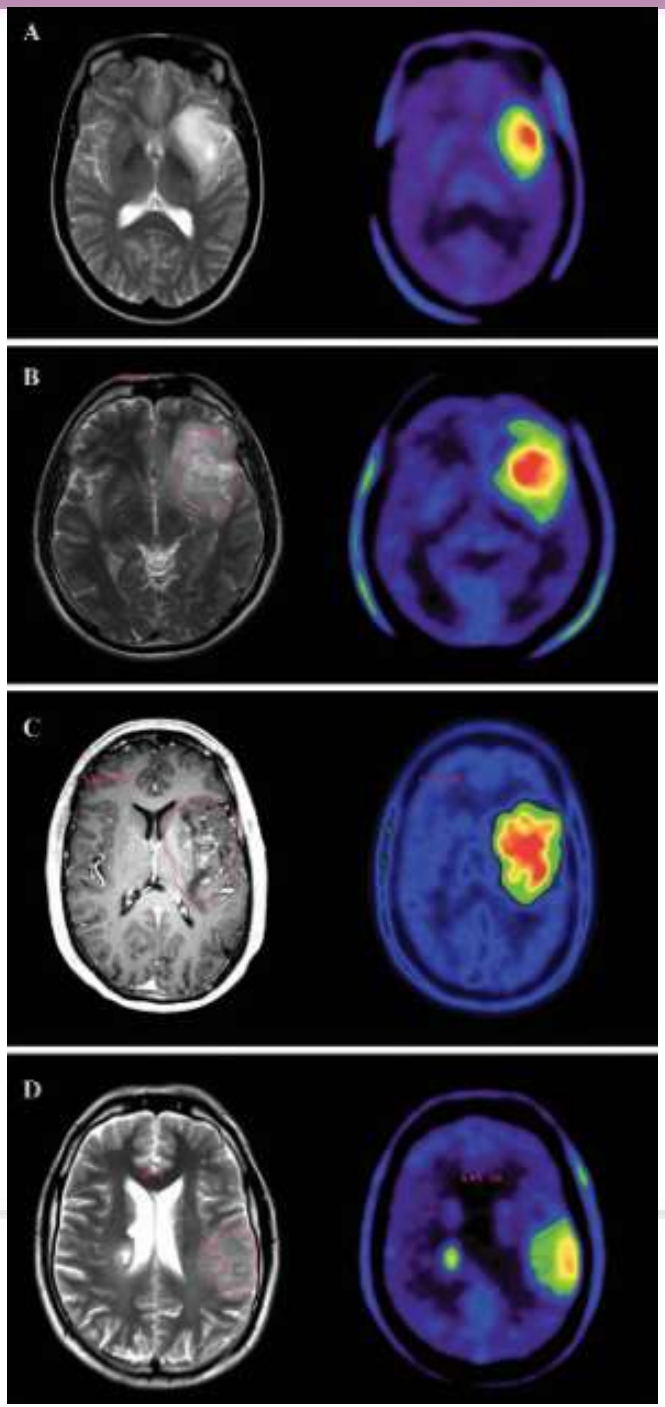
- some low grade astrocytomas demonstrates only low tracer uptake
- acute inflammation or ischemic stroke might manifest with increased aminoacid uptake
- NOT POSSIBLE TO PREDICT HISTOLOGICAL GRADE which is paramount in treatment decision making

IMAGING TUMOR PROLIFERATION

[(18)F]-FLT-PET *fluorothymidine*

- Uptake of FLT correlates with Thymidine kinase-1 activity expressed during DNA synthesis
- High correlation with Ki-67 expression (Yamamoto J Nucl Med 2012)
- Might be superior to MET for tumour grading
- The kinetics of FLT uptake are closely related to prognosis, early efficacy of treatment and to outcome (Wardak Clin Cancer Research 2011)

- **PITFALLS**:
  - less sensitivity than MET for low grade gliomas
  - **CANNOT PREDICT GRADE**



Astrocytoma Grade II

Oligodendroglioma Grade II

Anaplastic Oligodendroglioma Grade III

GBM Grade IV

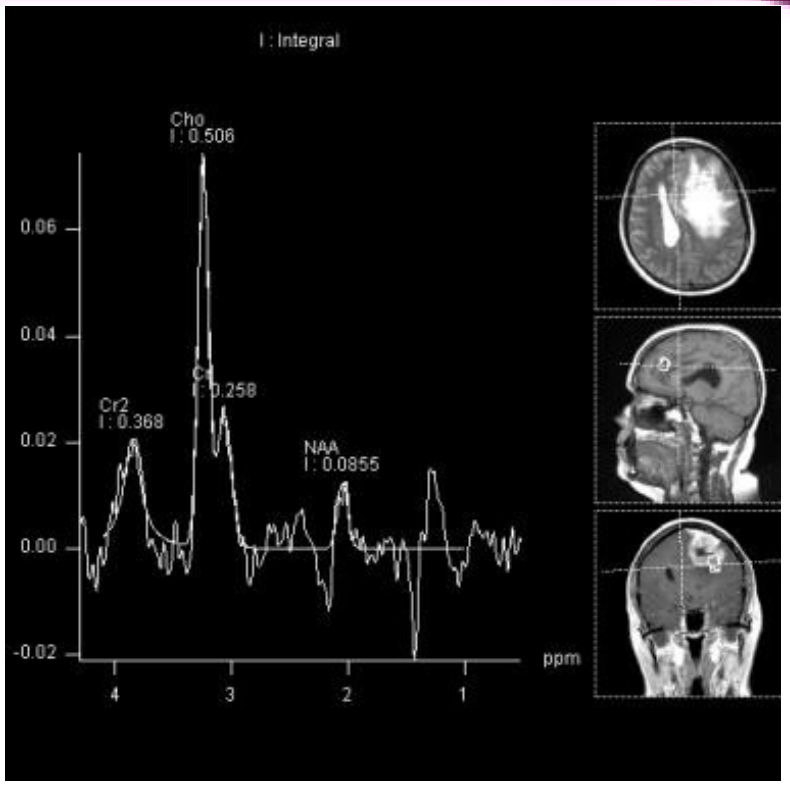
King's College London

ESTRO School

PHYSIOLOGICAL IMAGING
MRI SPECTROSCOPY

Provides insight into the biochemical profile

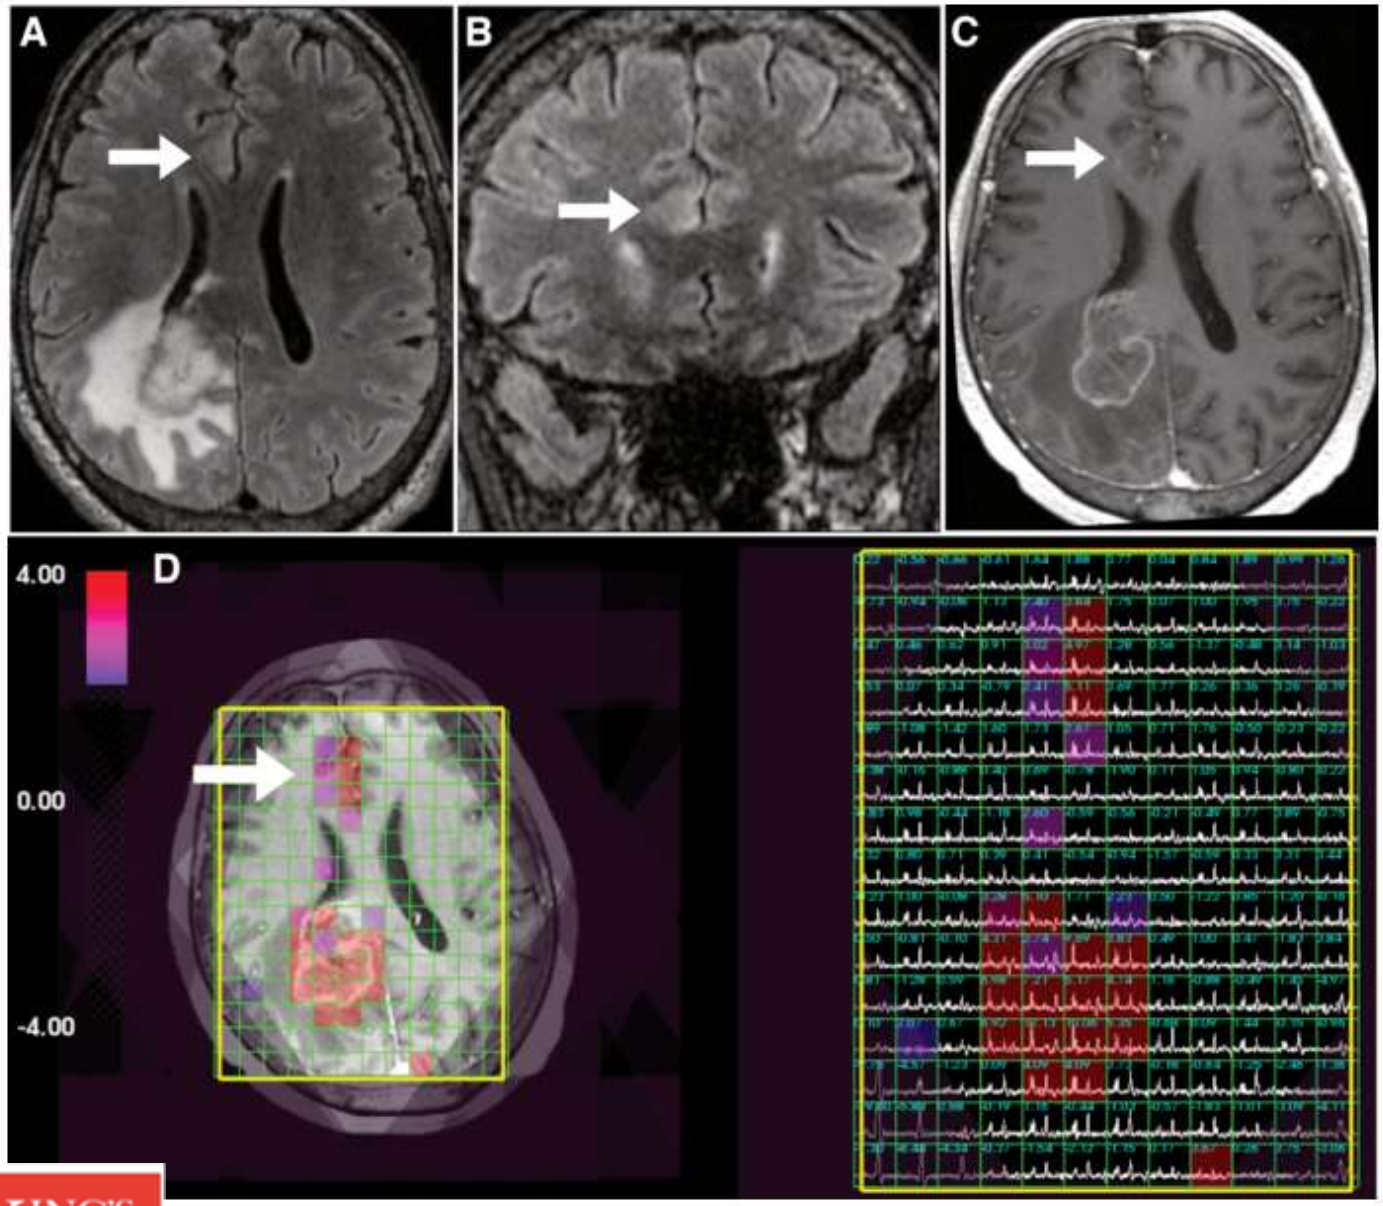
- **NAA**: marker of neural integrity
- **Choline**: membrane turnover
- Creatine: energetic
- **Myoinositol**: astrocytic marker
- **Lipid**: tissue destruction/necrosis marker
- Lactate: hypoxia marker
- Glutamine and Glutamate: excitatory markers



High choline correlates with high tumor proliferative index
Lower grades are associated with elevated MI/Cr ratio

Pitfalls: - min 1 cm3 voxel size
- not suitable for posterior fossa lesions and lesions near bone
- common aspecific spectral findings

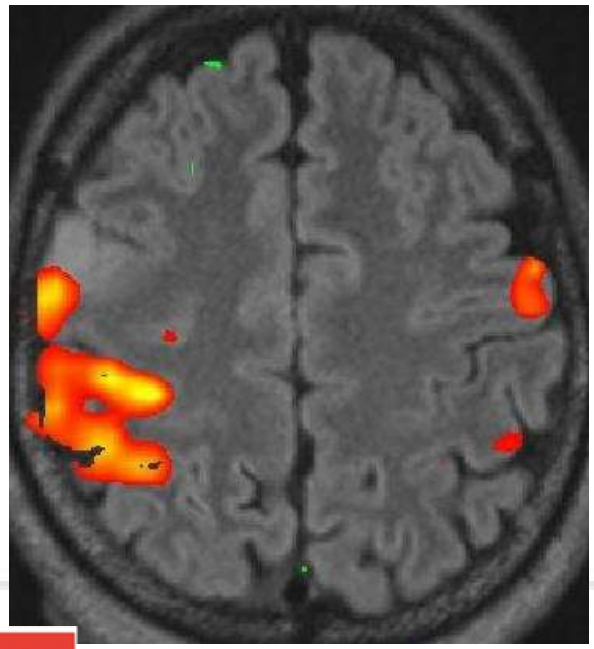
PHYSIOLOGICAL IMAGING
MRI SPECTROSCOPY



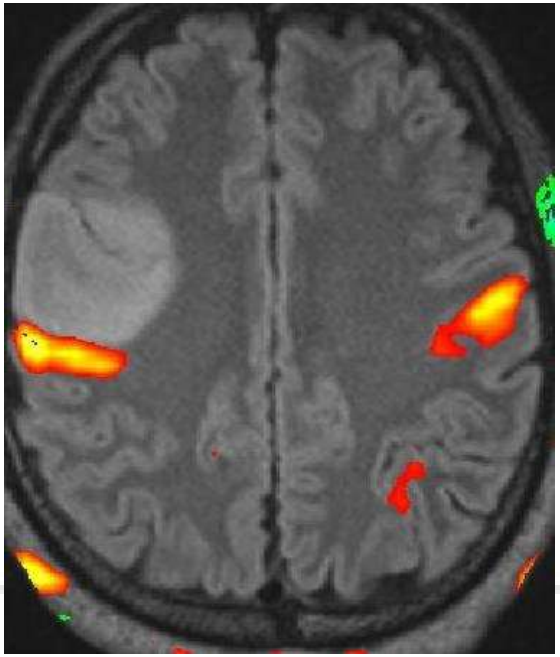
Villanueva-Meyer et al. Neurosurgery 2017

PHYSIOLOGICAL IMAGING
FUNCTIONAL IMAGING - fMRI

- **Pitfalls:**
  - Does not monitor the neural response but a "surrogate" hemodynamic response
  - Cannot distinguish essential hubs -> need for intraoperative monitoring
  - Low localisation accuracy
  - **Neurovascular uncoupling** (tumor infiltration zone, neovascularity) with reduced fMRI signal in perilesional cortex
  - More accurate for motor mapping than for speech
  - Not giving any functional information about subcortical white matter pathways



Finger Tapping



Semantic speech

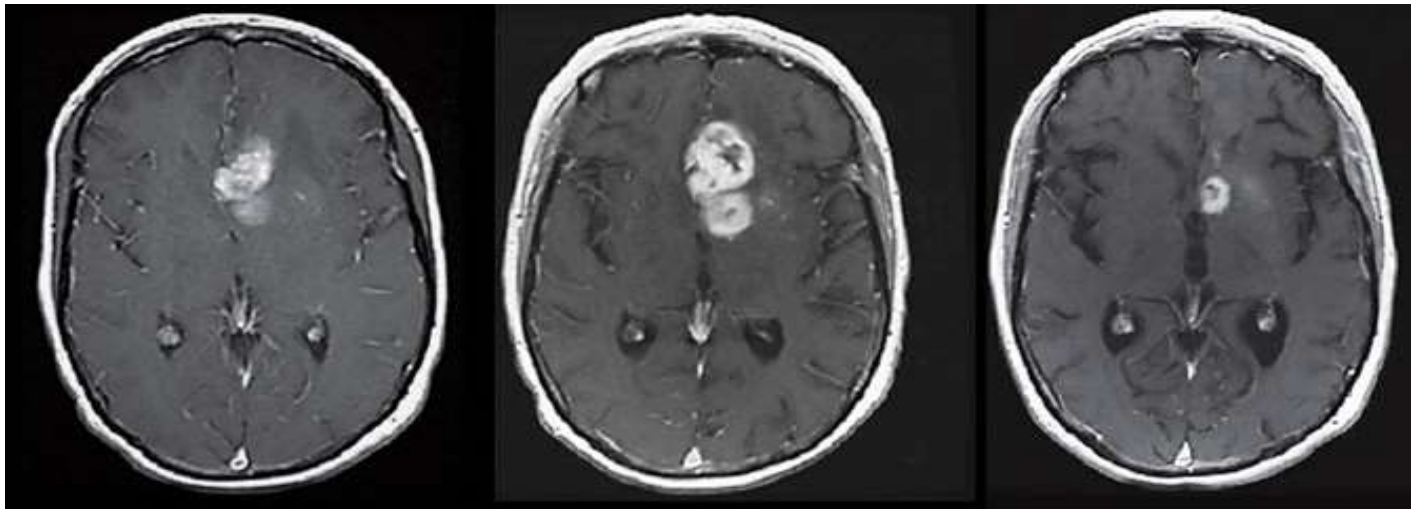
PROGRESSION

- Multifocality
- Signal abnormality extending across corpus callosum
- Subependymal involvement
- Low ADC values

PSEUDO-PROGRESSION

PSEUDO-PROGRESSION is a self-limited type of treatment-related tissue injury that is common in the first 3-6 months after TMZ and radiation therapy, and mimics tumor progression, but then stabilises and decreases *(Brandsma D et al. Lancet oncol 2008) – up to 30% of high grade gliomas, also seen in low grade gliomas-*

-more frequent in MGMT Met tumours



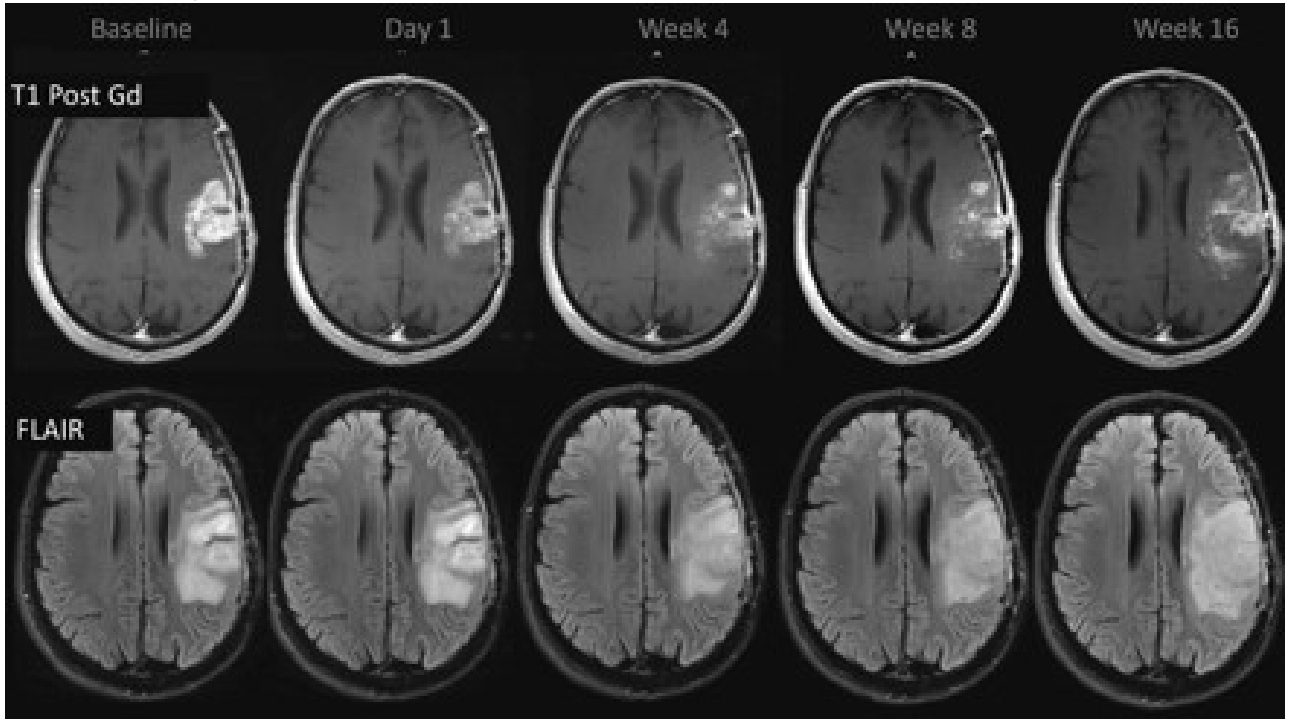
Before RT+TMZ | Before adjuvant TMZ | After 2 cycles adj TMZ

Differ from classic radiation necrosis, which can also mimics tumor progression, but is typically more severe and delayed in onset.

RANO criteria: within the first 12 weeks following completion of radiotherapy, progression can only be determined if new enhancement is seen outside of the radiation field or if there is histopathological confirmation

PSEUDO-RESPONSE

PSEUDO-RESPONSE: Angiogenetic inhibitors can cause a decrease in contrast enhancement due to reduction in blood-brain barrier permeability rather then true reduction in volume (*Clarke JL et al. Curr Neurol Neurosci Rep 2009).*



A 47-year-old man with GBM. A reduction of the enhancing portion of the lesion is observed 1 day after initiation of cediranib treatment. Four weeks later, besides a continuing reduction in the enhancing portion, an expansion is observed in the FLAIR images. Expansions in both the enhancing area and abnormal hyperintense areas consistent with tumor progression were observed subsequently (L.C. Hygino da Cruz Jr et al. AJNR 2011)

Pseudo-response might be an indicator of subsequent favourable response

RANO Criteria for pseudoresponse: greater than 50% reduction in contrast enhancement without a significant decrease in nonenhancing tumour.
Decreased enhancement should persist more than 4 weeks to be considered true response.

SMART SYNDROME

- Remote history of intracranial irradiation
- Headaches and neurological deficits
- Cortical contrast-enhancement
- SWI – Microhemorrhages (delayed radiation toxicity on cerebral microvasculature)

CONCLUSION:

On the WAIS-IV M[redacted]s shows a large difference between her verbal and nonverbal skills, in favour of nonverbal skills. Her score on the Verbal Comprehension subscale fell into the average range and her score on the Perceptual Reasoning subscale fell at the upper end of the high average range. Although it is possible that this reflects a longstanding pattern of strengths and weaknesses, given that her verbal score is consistent with her estimated 'average' optimal level of ability based on her reading score, a difference of the size found is unusual. Her scores on the Working memory and Processing Speed subscales also fell into the average range. Verbal recall memory scores are mixed, with below average story recall but average list learning. Verbal and visual recognition memory is satisfactory. Language, perceptual functions and performance on selected executive tests are satisfactory.

5-ALA fluorescence in intraparenchymal endodermal cysts.

Lavrador JP[1], Brogna C[2,3], Vergani F[2], Greenway F[2], Aizpurua M[4], Bhangoo R[2].

⊕ **Author information**

Abstract

In recent years, new indications have been suggested for 5-ALA, particularly for cystic lesions. We report the use of 5-ALA fluorescence in an intraparenchymal supratentorial endodermal cyst of a 52-year-old female presenting with headache, progressive right side hemiparesis and anomic aphasia. She underwent an image-guided 5-ALA-assisted left minicraniotomy for fenestration of the cystic lesion into the ventricular system. The capsule of the cyst was noted to fluoresce with 5-ALA. She recovered from the previous deficits and the cyst decreased in size. To the best of our knowledge, this is the first time 5-ALA fluorescence is reported in a case of endodermal cyst.

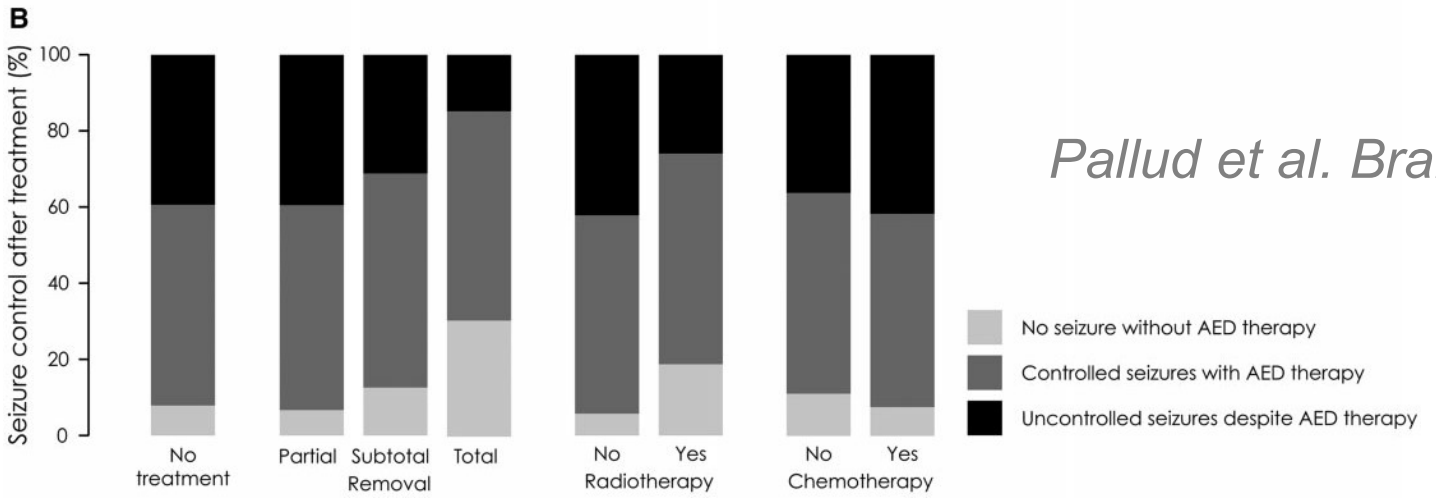
BRAIN
A JOURNAL OF NEUROLOGY

Epileptic seizures in diffuse low-grade gliomas in adults



Pallud et al. Brain, 2014

Patient age ($P \leq 0.001$), subtotal ($P = 0.007$) and total ($P \leq 0.001$) resections were independent predictors of total epileptic seizure control after oncological treatment. Patients diagnosed with epileptic seizures andthose with complete and early surgical resections have better oncological outcomes.

Early and maximal surgical resection is thus required for diffuse low-grade gliomas, both for oncological and epileptological purposes.

Brain metastases

AUTHORS' CONCLUSIONS

Implications for practice

It is difficult to advise either patients or colleagues on the basis of evidence from such small studies. It is important to note that these results were obtained in a highly selected group of patients - under close follow-up and receiving further active therapy in many cases - who are not necessarily representative of the majority of those with single brain metastasis. In this group, the surgical approach did not improve OS. Surgery may reduce the number of deaths due to neurological cause, while one trial has suggested an increase in the duration of a patients FIS. Adverse events were similar in each group whilst QoL was not directly examined. Those most likely to benefit from surgery are of young age, have good neurological function, and controlled primary disease (Noordijk 1994). Careful attention to prognostic factors will see only those who have the most to gain from surgery, while those who are less well will avoid unnecessary risks and morbidity. It must not be forgotten that the overall outlook for patients at two years is dismally poor with either intervention and death is commonly due to systemic disease. Currently, the management for the majority of those with single brain metastasis will be WBRT alone, due to active systemic disease and other co-morbidity. Decisions of the most appropriate treatment for an individual patient should be made at an MDT meeting in line with NICE guidance (NICE 2006).

THE COCHRANE COLLABORATION®

Difficult to draw conclusions from small trials

OS no different in pooled analysis – possible improvement in FIS and reduction of neurological deaths

Pts likely to benefit: young age, good neurological function and controlled primary disease

Decision should be made in MDT

⊕ Author information

Abstract

PURPOSE: To evaluate the frequency and amount of displacements after repositioning a patient on the physical simulator following virtual simulation.

MATERIAL AND METHODS: After laser marking at the CT scanner and virtual simulation, patients were repositioned on the simulator. The isocenter obtained from the calculated table movements was checked by fluoroscopically measuring the distances to standardized anatomic landmarks and comparing them to the treatment plan.

RESULTS: In 86% of patients, displacements were < or = 0.5 cm. There was no significant difference between the supine and prone position, diagnosis categories or CT reconstruction indices. The use of immobilization devices and cranial versus body stem localization did make a significant difference. Rates of exact repositioning were high in brain and head and neck patients and comparatively low in abdominal tumors and breast cancer.

CONCLUSIONS: Immobilization devices play an important role for the precision of radiotherapy. Whenever precise positioning is possible (e. g. with a head mask), virtual simulation alone might be sufficient. Patients with abdominal and breast tumors, were repositioning precision is often suboptimal, might profit from an additional physical simulation.

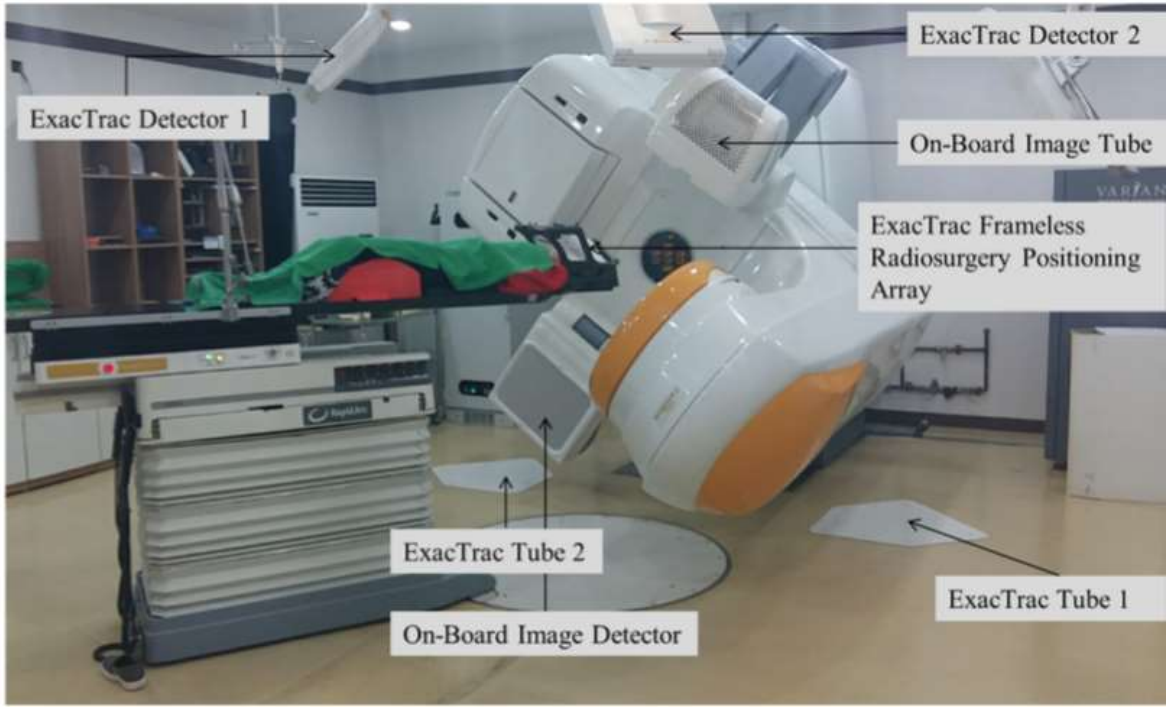
RESEARCH ARTICLE

Evaluations of the setup discrepancy between BrainLAB 6D ExacTrac and cone-beam computed tomography used with the imaging guidance system Novalis-Tx for intracranial stereotactic radiosurgery

Se An Oh[1], Jae Won Park[1,2], Ji Woon Yea[1,2], Sung Kyu Kim[1,2]*

1 Department of Radiation Oncology, Yeungnam University Medical Center, Daegu, Korea, **2** Department of Radiation Oncology, Yeungnam University College of Medicine, Daegu, Korea



- Comparison between ExacTrac, 3D CBCT and 6D CBCT
- Minor, but not negiglible variations

ESTRO School

Conclusions

- First requirement is the proper setting to discuss and help the patient well understand and helping him and his caregivers to take part to the decisions
- Proper explanation and preparation of the simulation/positioning will avoid, anxiety, errors and improve patient's wellbeing
- Buy the better technology you can, based on scientific evidence (tools, not toys)

Radiotherapy- treatment techniques wide field irradiation CS and WBRT

Karin Dieckmann

Rolf Kortmann

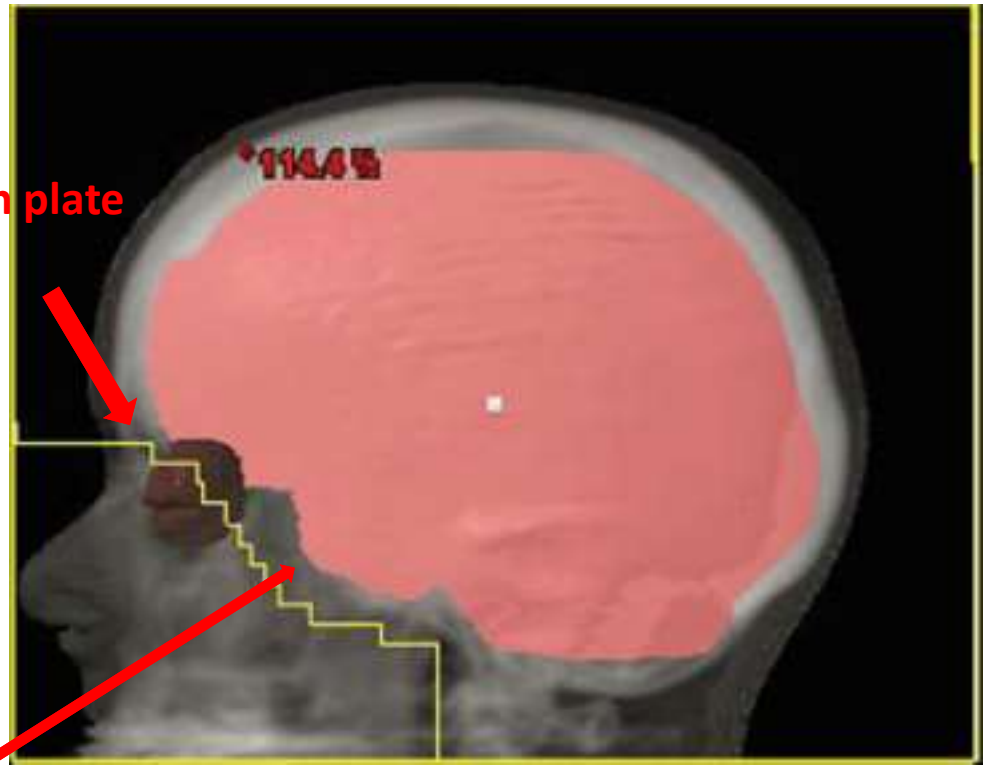
Department of Radiotherapy

Medical University of Vienne

Techniques

- Conventional technologies
  (according to simulation based technique)
- IMRT
- V-MAT technologies
- Tomotherapy
- Protontherapy (different technologies)

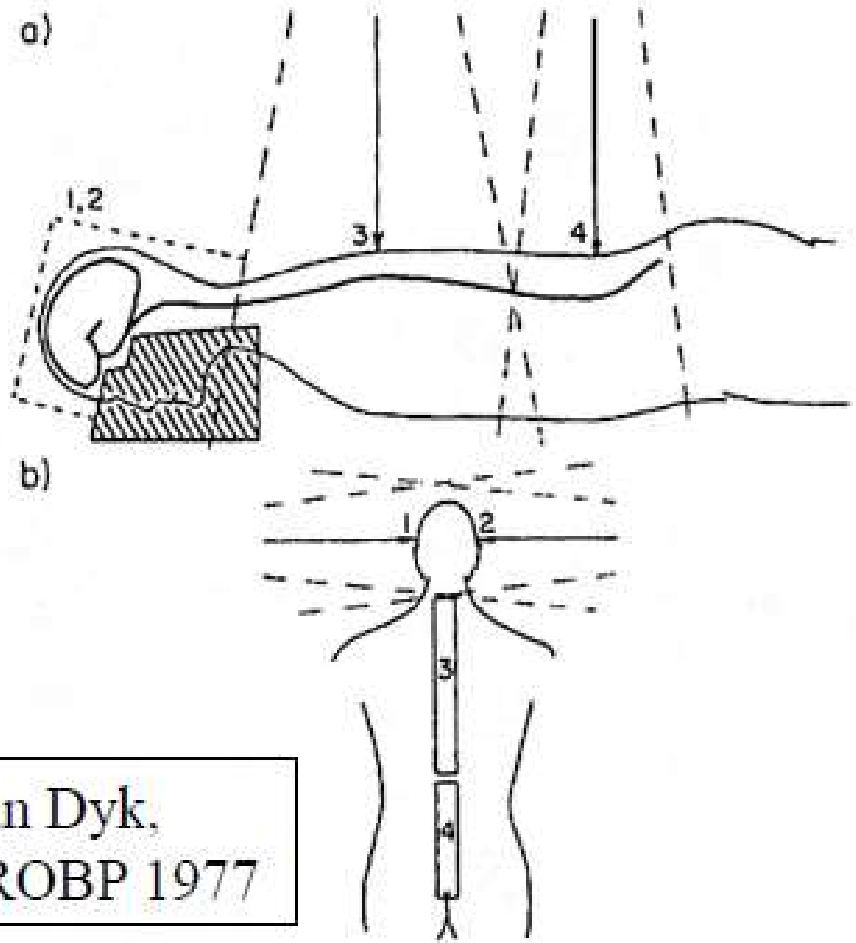
Whole Brain Radiotherapy



- Anterior cranial fossa
- Middle cranial fossa
- Posterior fossa

A margin of 1-2cm margin to the base of the brain includes the foramina which the cranial nerves exit.

Standard CSRT Technique



Van Dyk, IJROBP 1977

- Patient prone in a head rest with neck extended
- Junction of non-coplanar fields over the cervical spine
- Extended SSD or second posterior field to cover whole length of spine/second junction over the spinal cord

van Dyk et al 1977 (IJROBP 2: 993-1005)

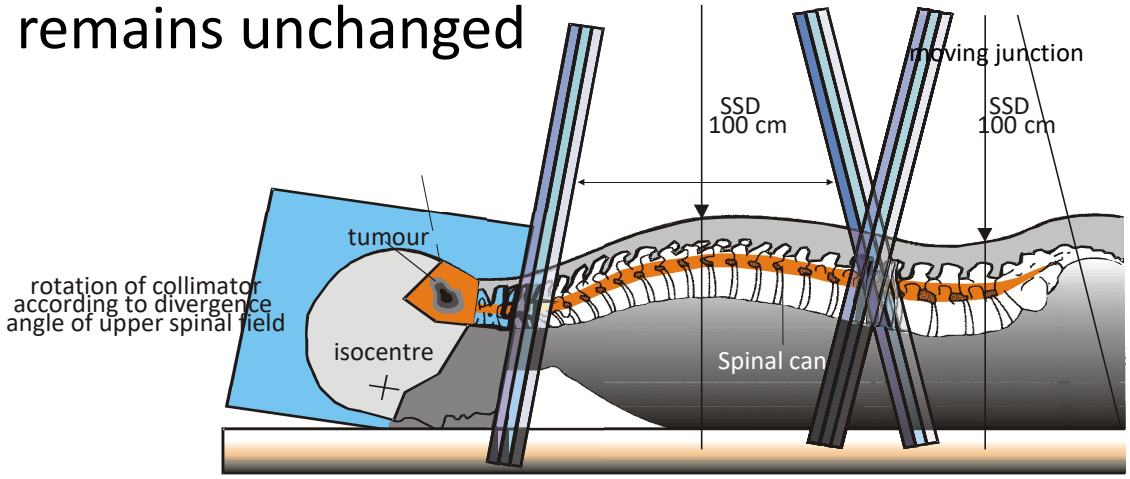
Technical Procedure

Junction lines are moved 0.5-1.0 cm every 8-12 Gy

to avoid overdosing or underdosing segments of the cord

Procedure:

1. shortening the inferior margin of the lateral cranial fields
2. Symmetrically lengthening the superior and inferior margins of the posterior spine field
3. Shortening the cranail margin of the caudal spinal field
4. The caudal spinal field remains unchanged



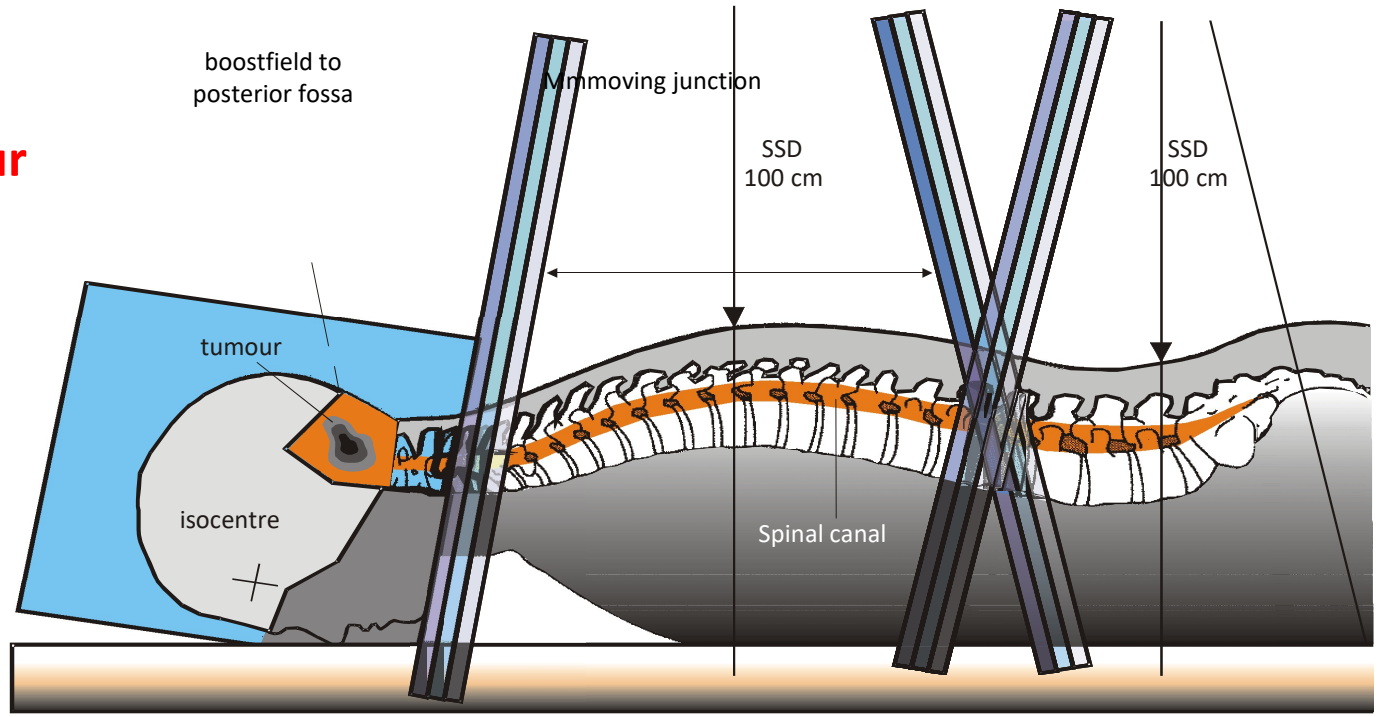
SSD : source to skin distance

Areas at Risk

1. Leptomeningeal space
(subclinical disease / „low risk“)

2. Posterior fossa
(subclinical disease
„high risk“ ?)

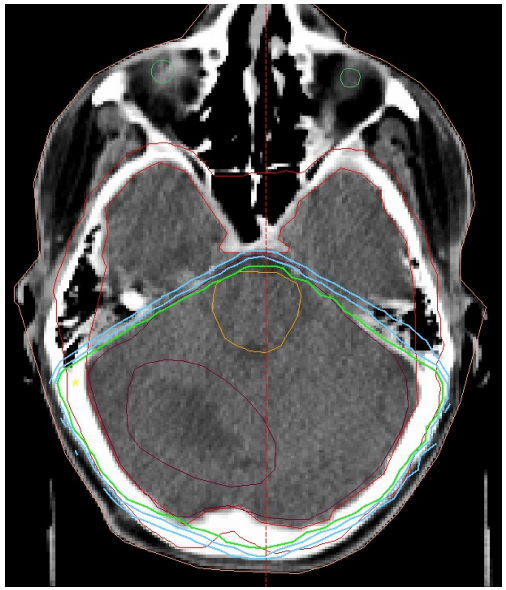
3. Tumour site
(residual tumour
R1-2)



rotation of collimator
according to divergence
angle of upper spinal field

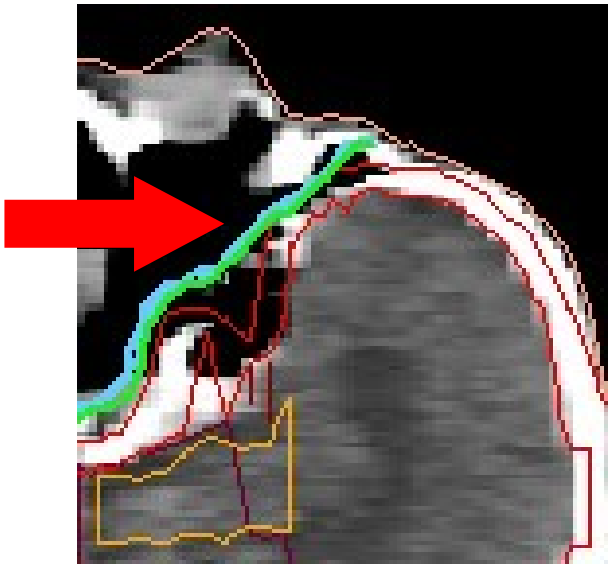
SSD : source to skin distance

Medulloblastoma

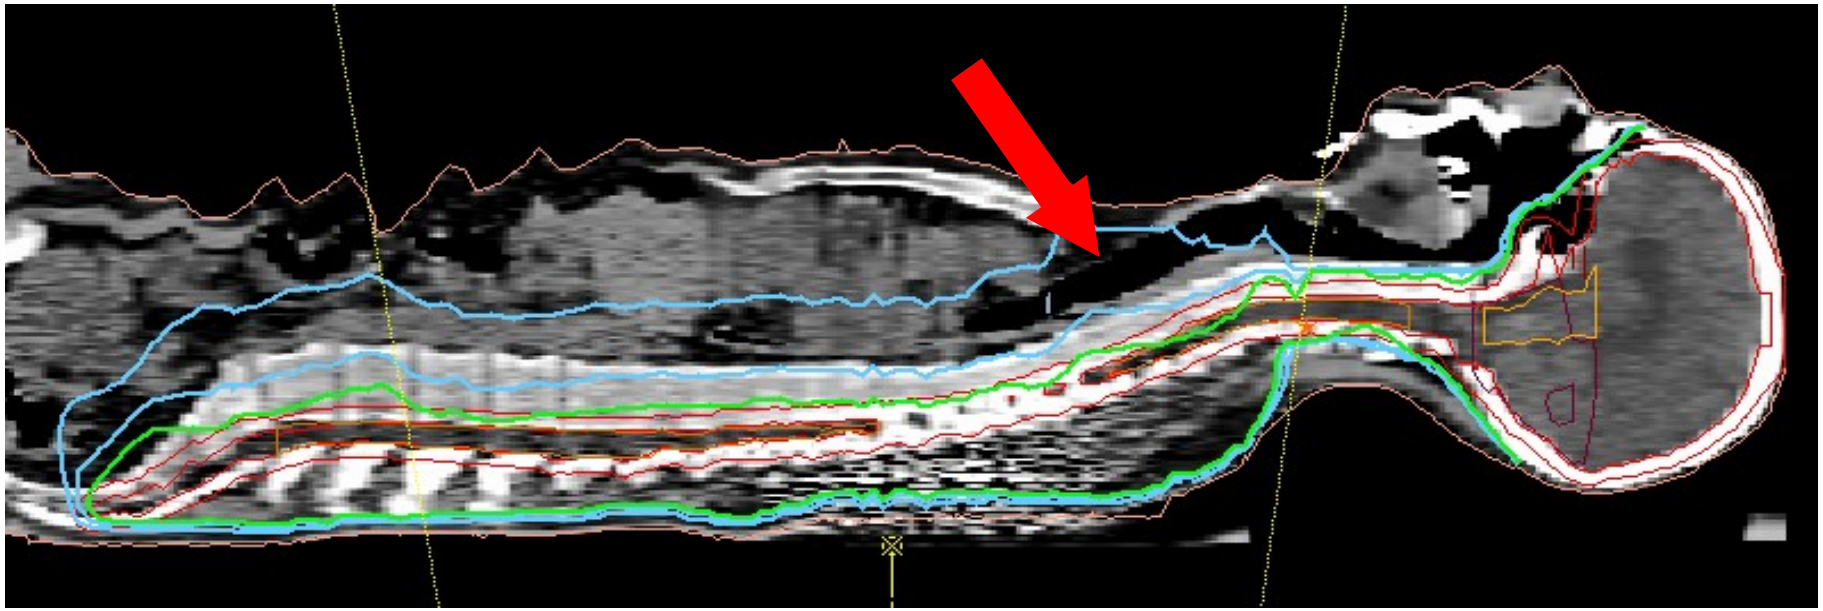


1. Coverage of target volume

2. Homogeneous dose distribution



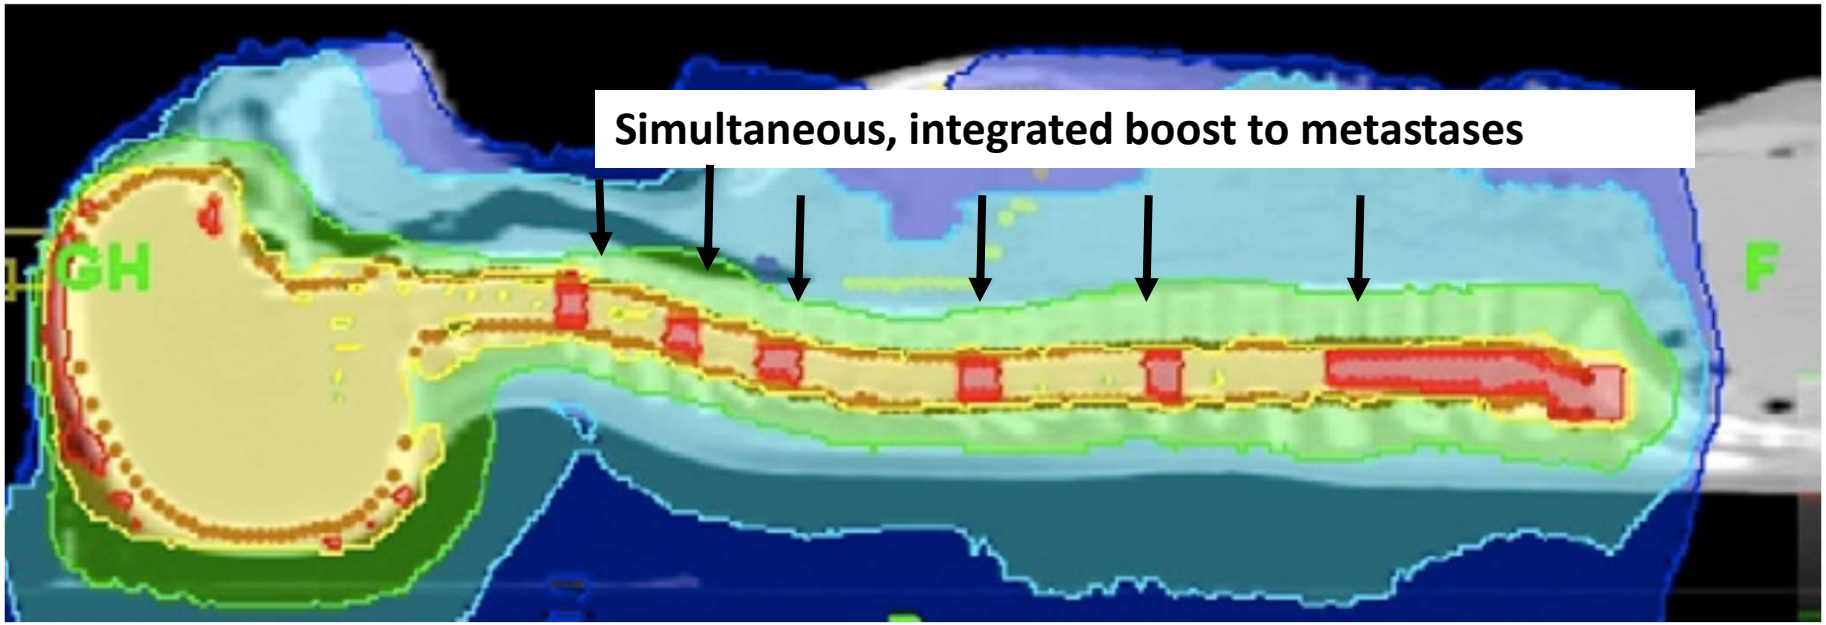
CT planning CSA



Craniospinal Irradiation Tomotherapy (IMRT)

Advantage: homogeneous dose distribution
(no field junctions)
integrated boosts possible

Disadvantage: higher dose exposure to non-target tissue

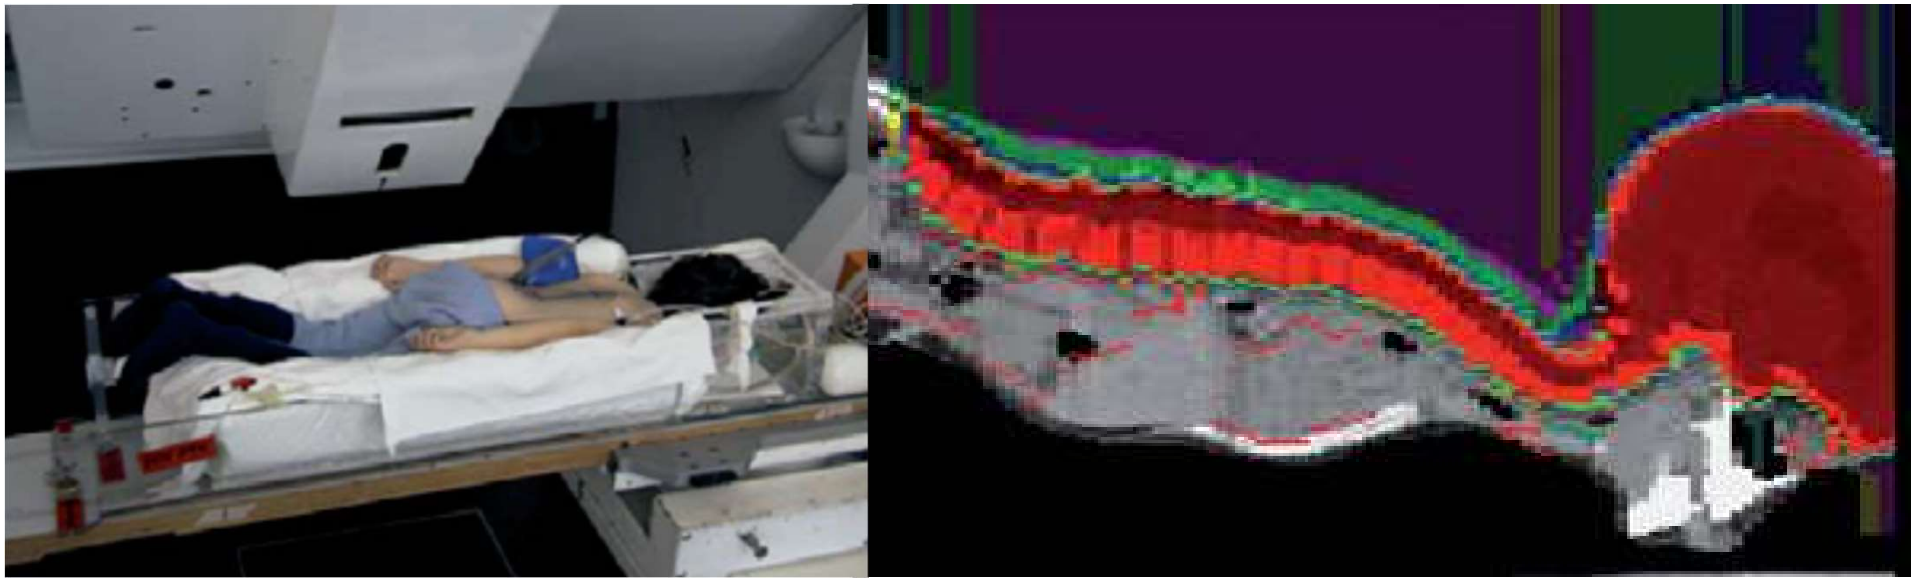


Parker et al., 2010

Craniospinal irradiation
Protons spot scanning technique

Advantage: homogeneous dose distribution (no field junctions)
lower dose to non-target tissue (reduced risk for 2nd malignancies)

Disadvantage: high costs



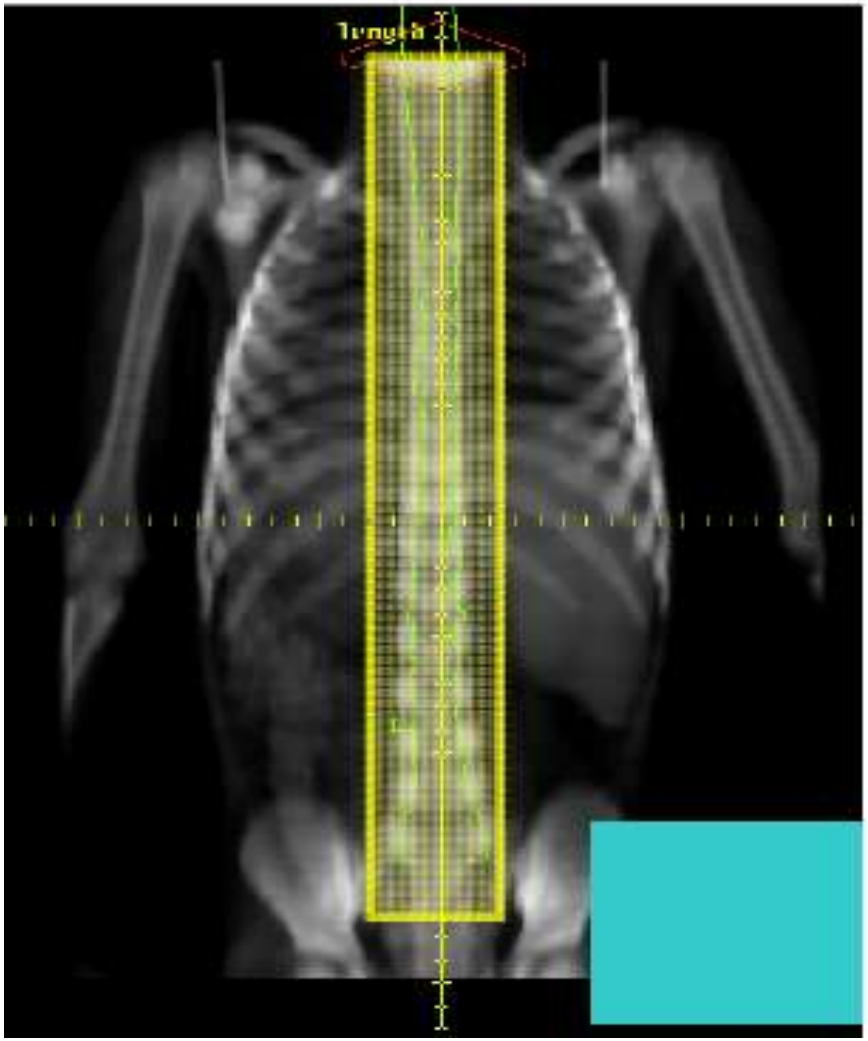
Timmermann et al., 2007

Target Volumes

Do we known how to define the targets ?

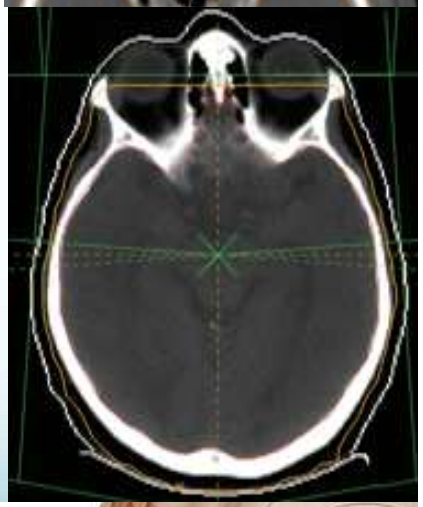
- Optic nerve
- Craniospinal Axis
- Posterior Fossa
- Tumour Bed

Target Volume for CSRT Spine



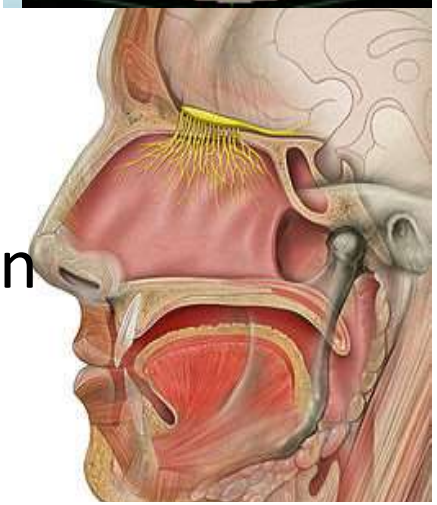
- ACNS0331:
  - "…laterally on both sides to cover the recesses of the entire vertebral bodies, with at least 1cm margin on either side"
  - Lower limit "…2 cm below the termination of the subdural space"…"at least to the inferior border of the 2nd sacral segment (S2/3 interspace)"

Target Volume (CTV) / Cranial Fields



- Meninges surrounding whole brain and ventricular system

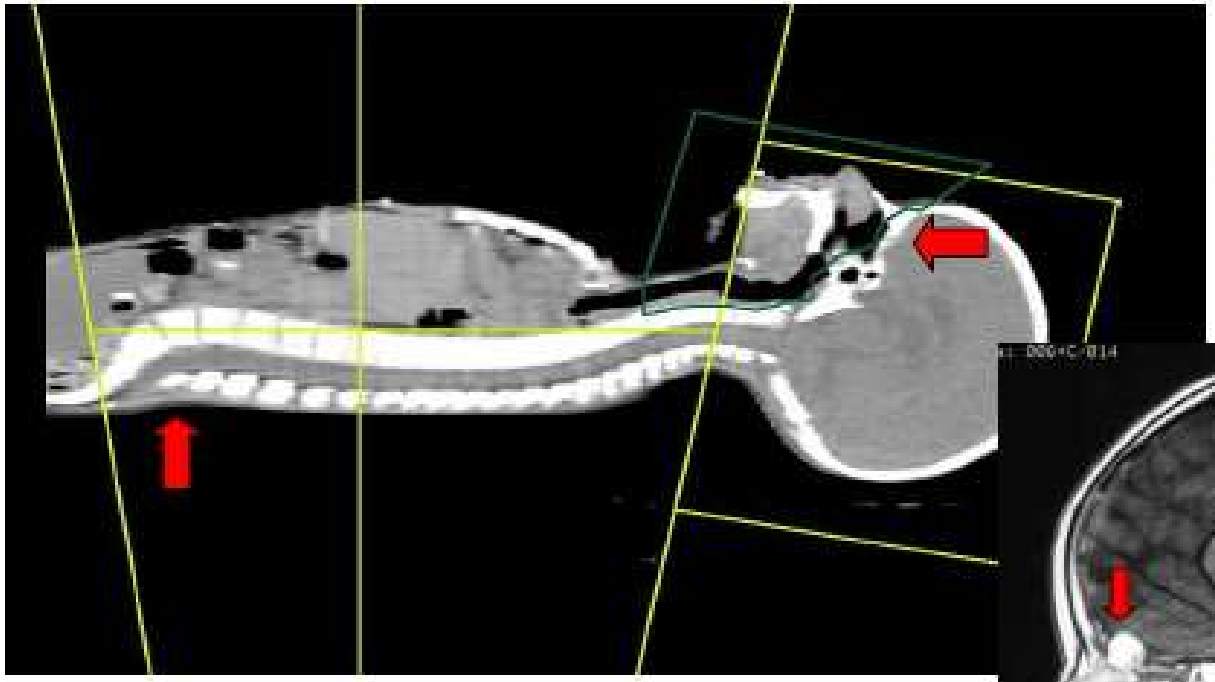
- Particular attention to cribriform fossa, temporal fossa, base of skull, Caudal extend of the tecal sac



- Irradiate the full width of vertebrae for children

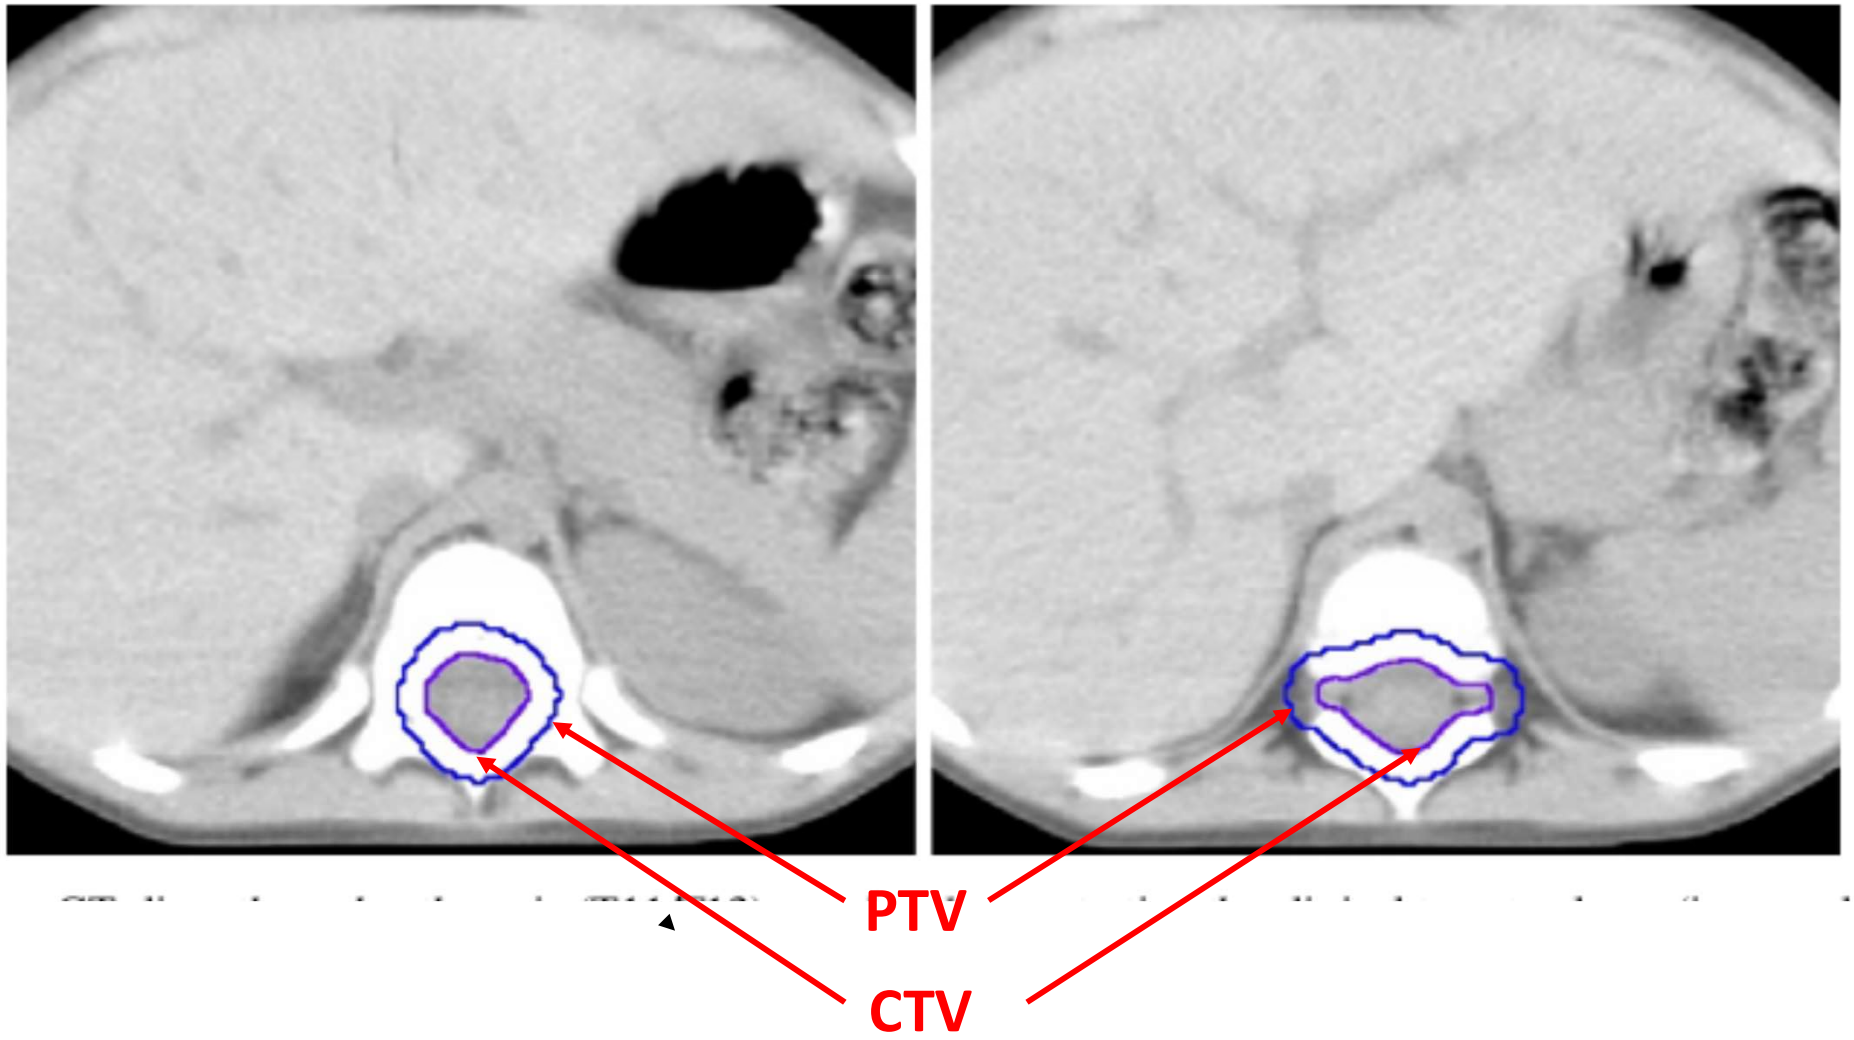
Target Volume for CSRT

- Problem areas:
  - frontal region/ cribriform plate
  - caudal extent of thecal sac

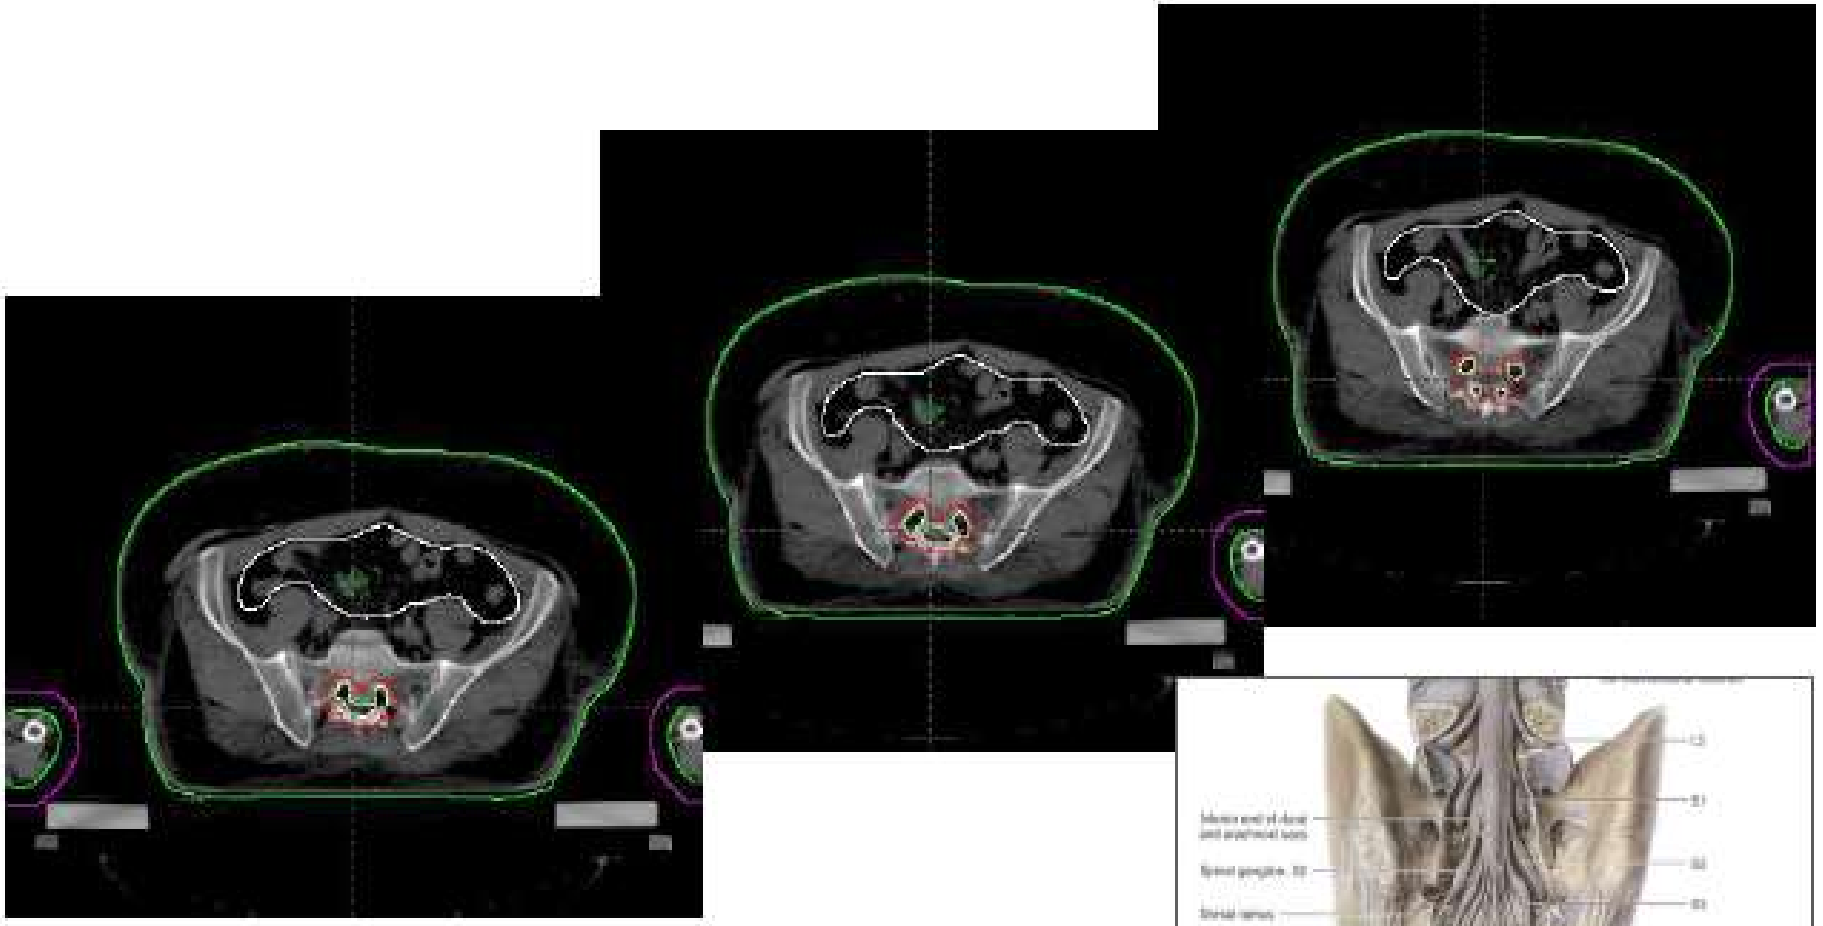


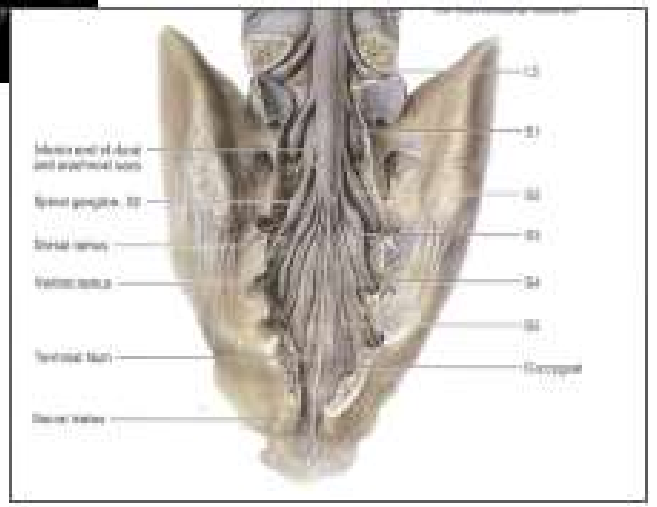
Spinal CTV and PTV

Extensions of nerve roots as far as intervertebral foramina



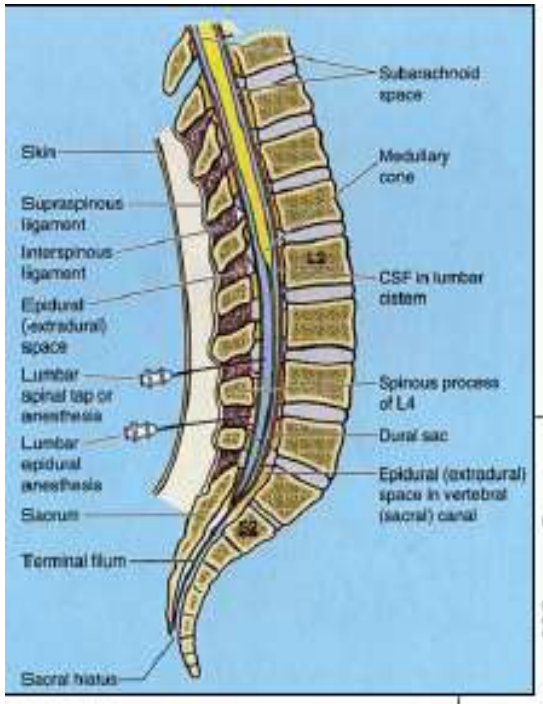
Target Volume for CSRT Sacral Roots

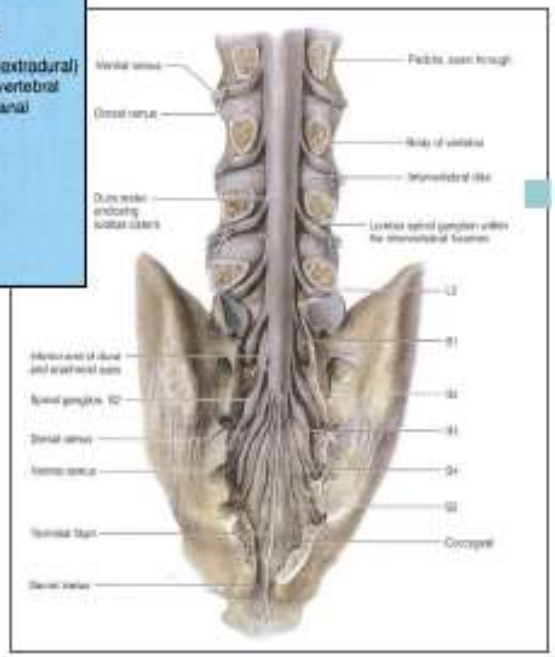




Meninges extending to the lower border of the thecal sac as determined by MR scanning

CSRT – Thecal Sac





- Dural sac "generally" ends at S1/2
- But:
  - ~50% by bottom S1
  - >90% by bottom S2
  - <10% above L5/S1

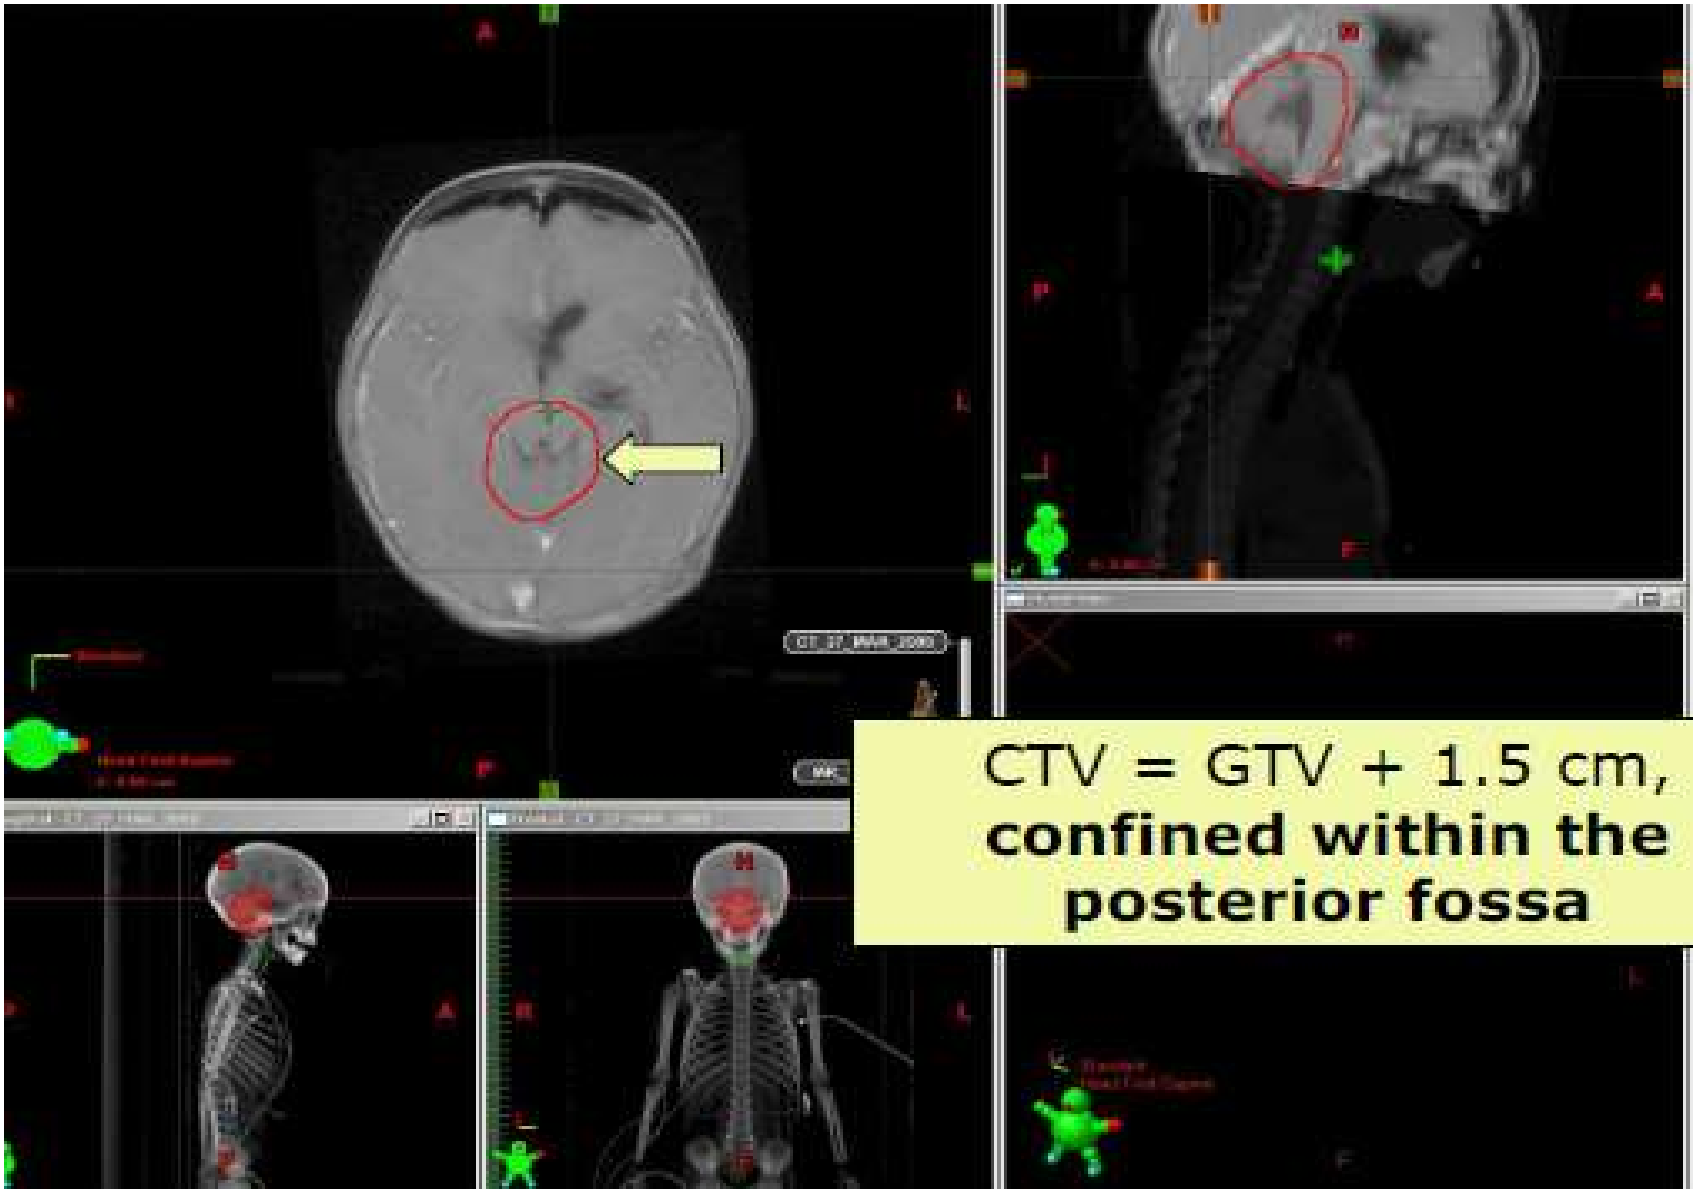
MRI is **essential** for accurate determination of the caudal extent of the thecal sac

Target Volume for Tumour Bed RT

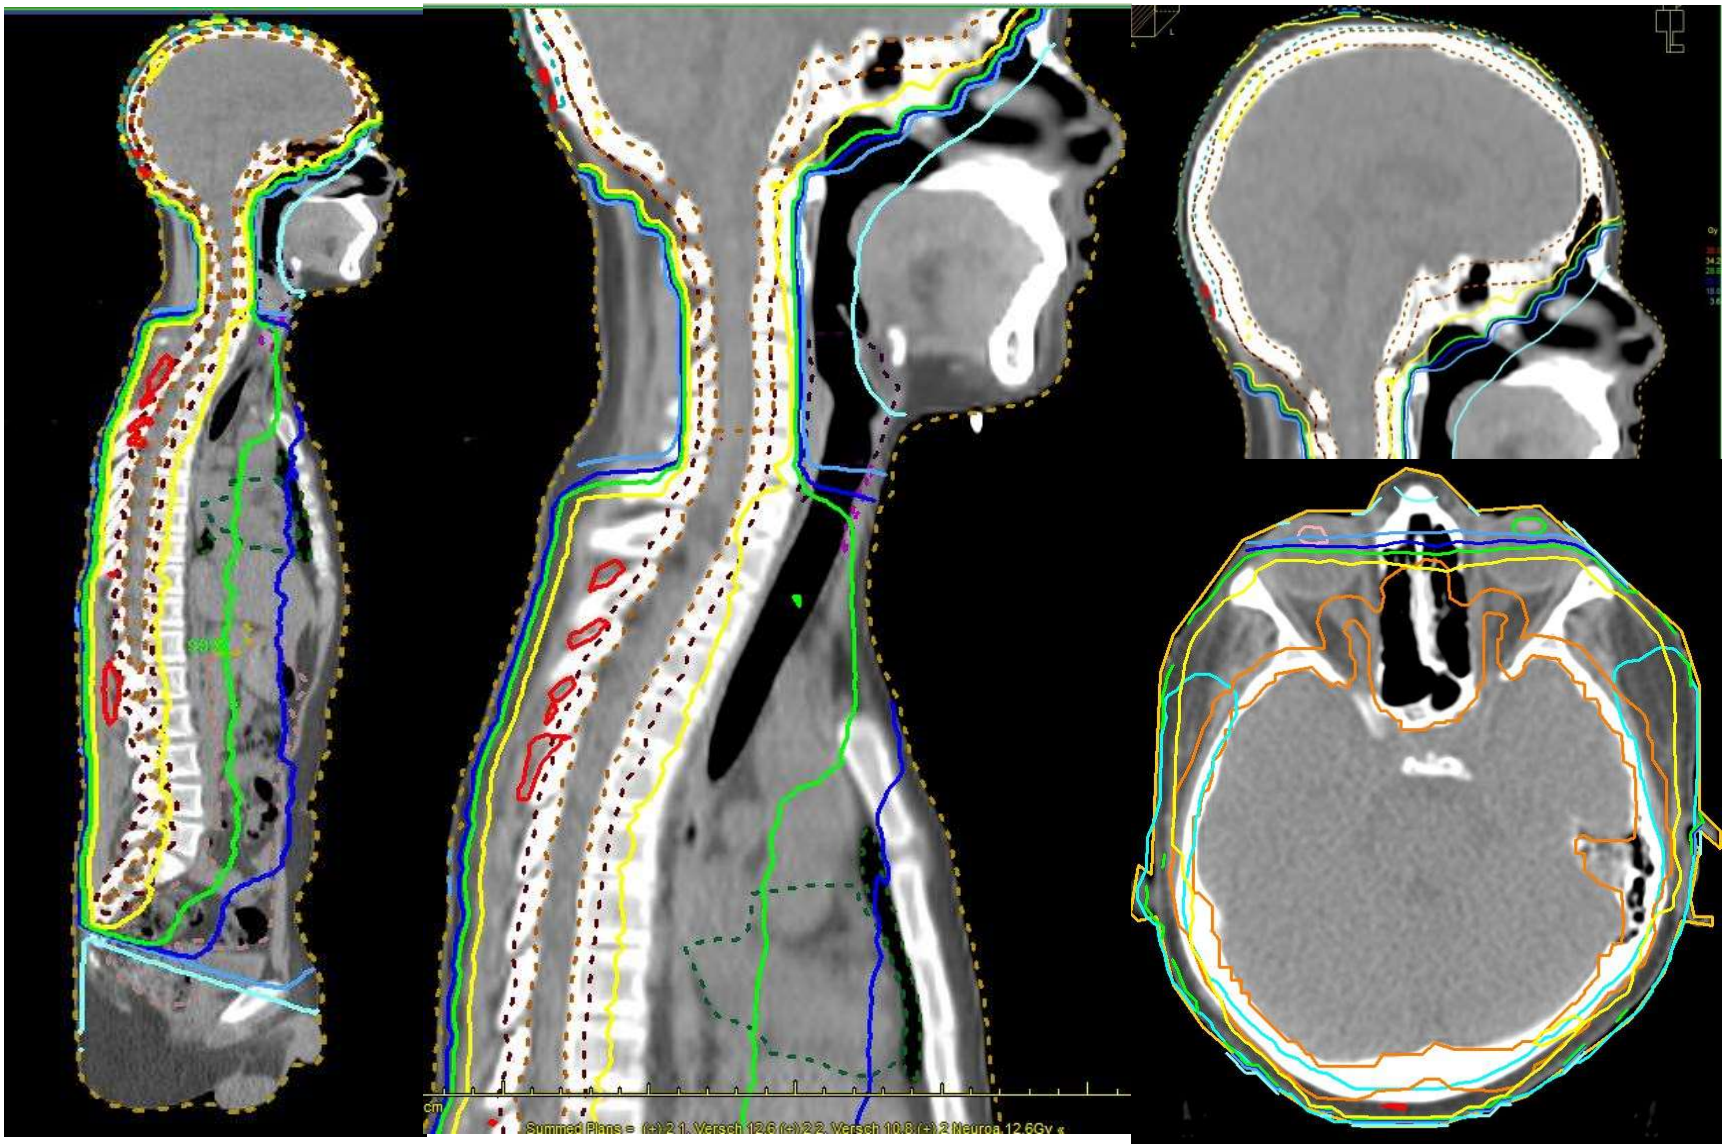
GTV:

- Any residual tumour on imaging
- Post-surgical cavity including tumour/brain interface prior to resection
- Allow for post-surgical changes to anatomy **CTV** margin
- **PTV** according to institutional policy

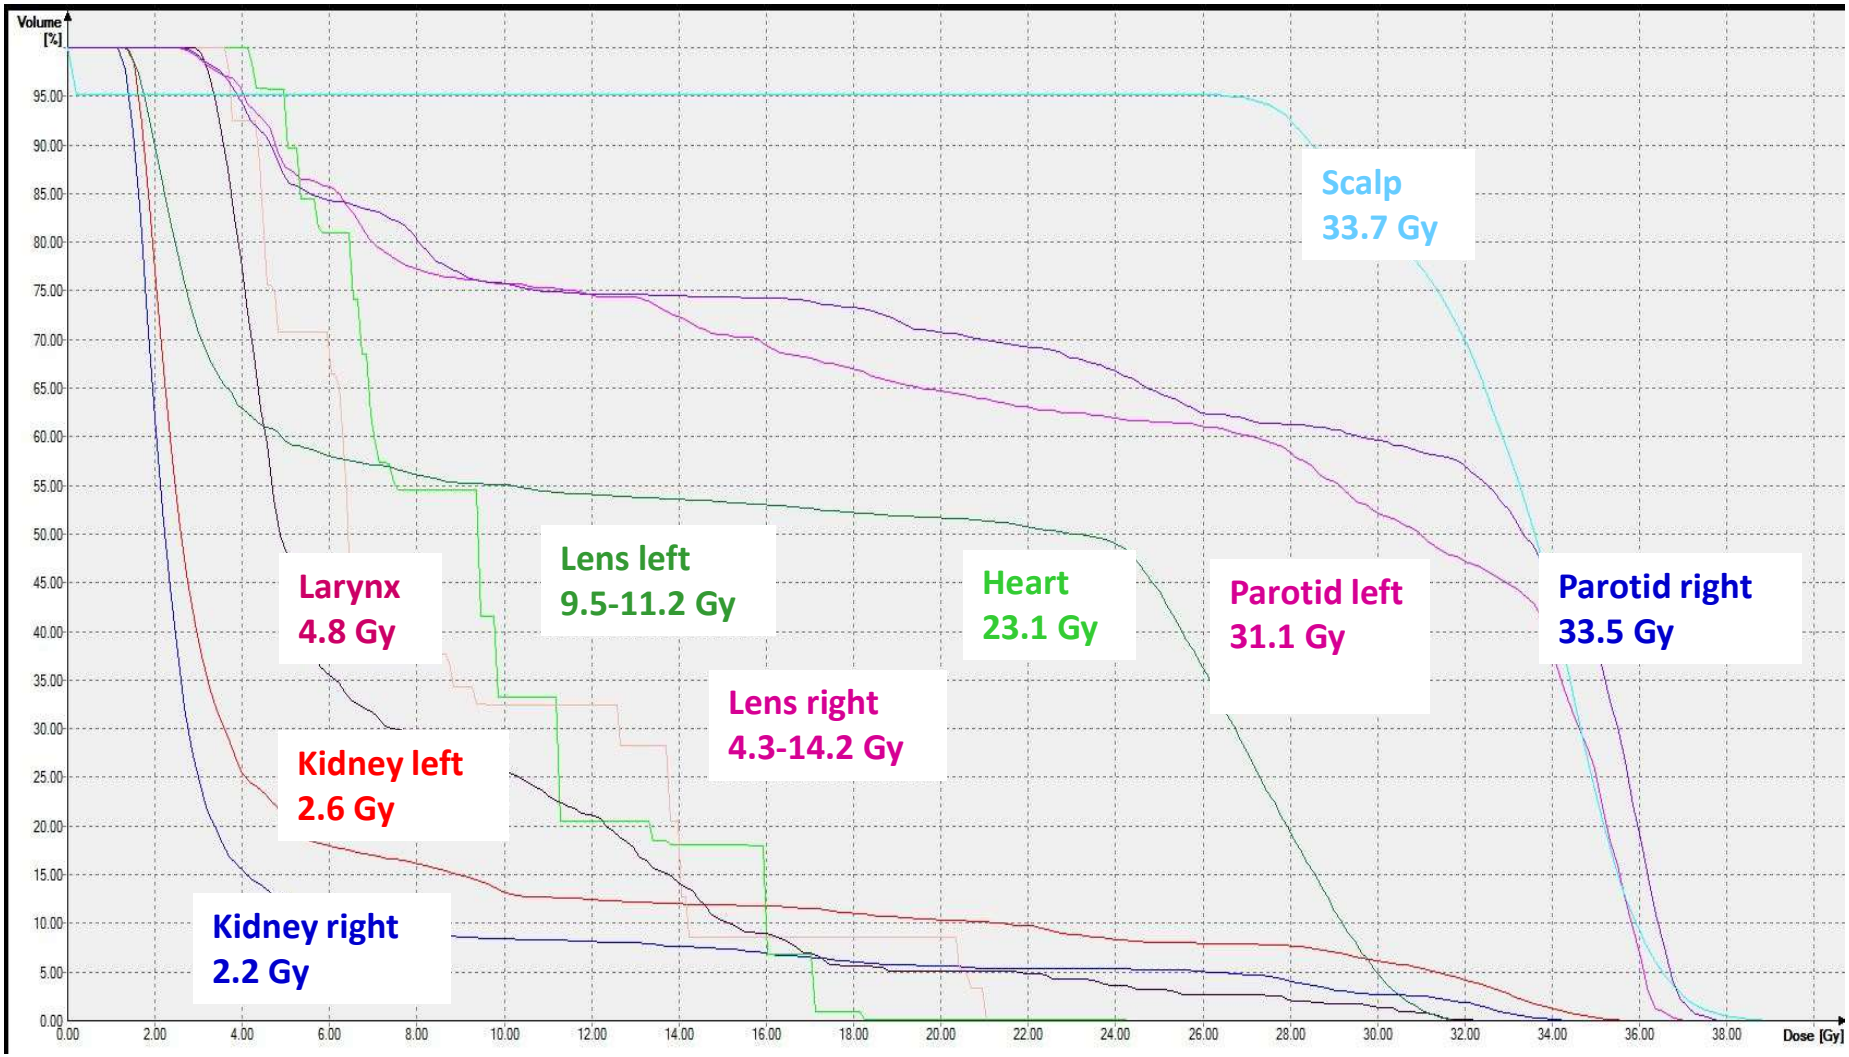
Medulloblastoma -Tumour Bed Boost



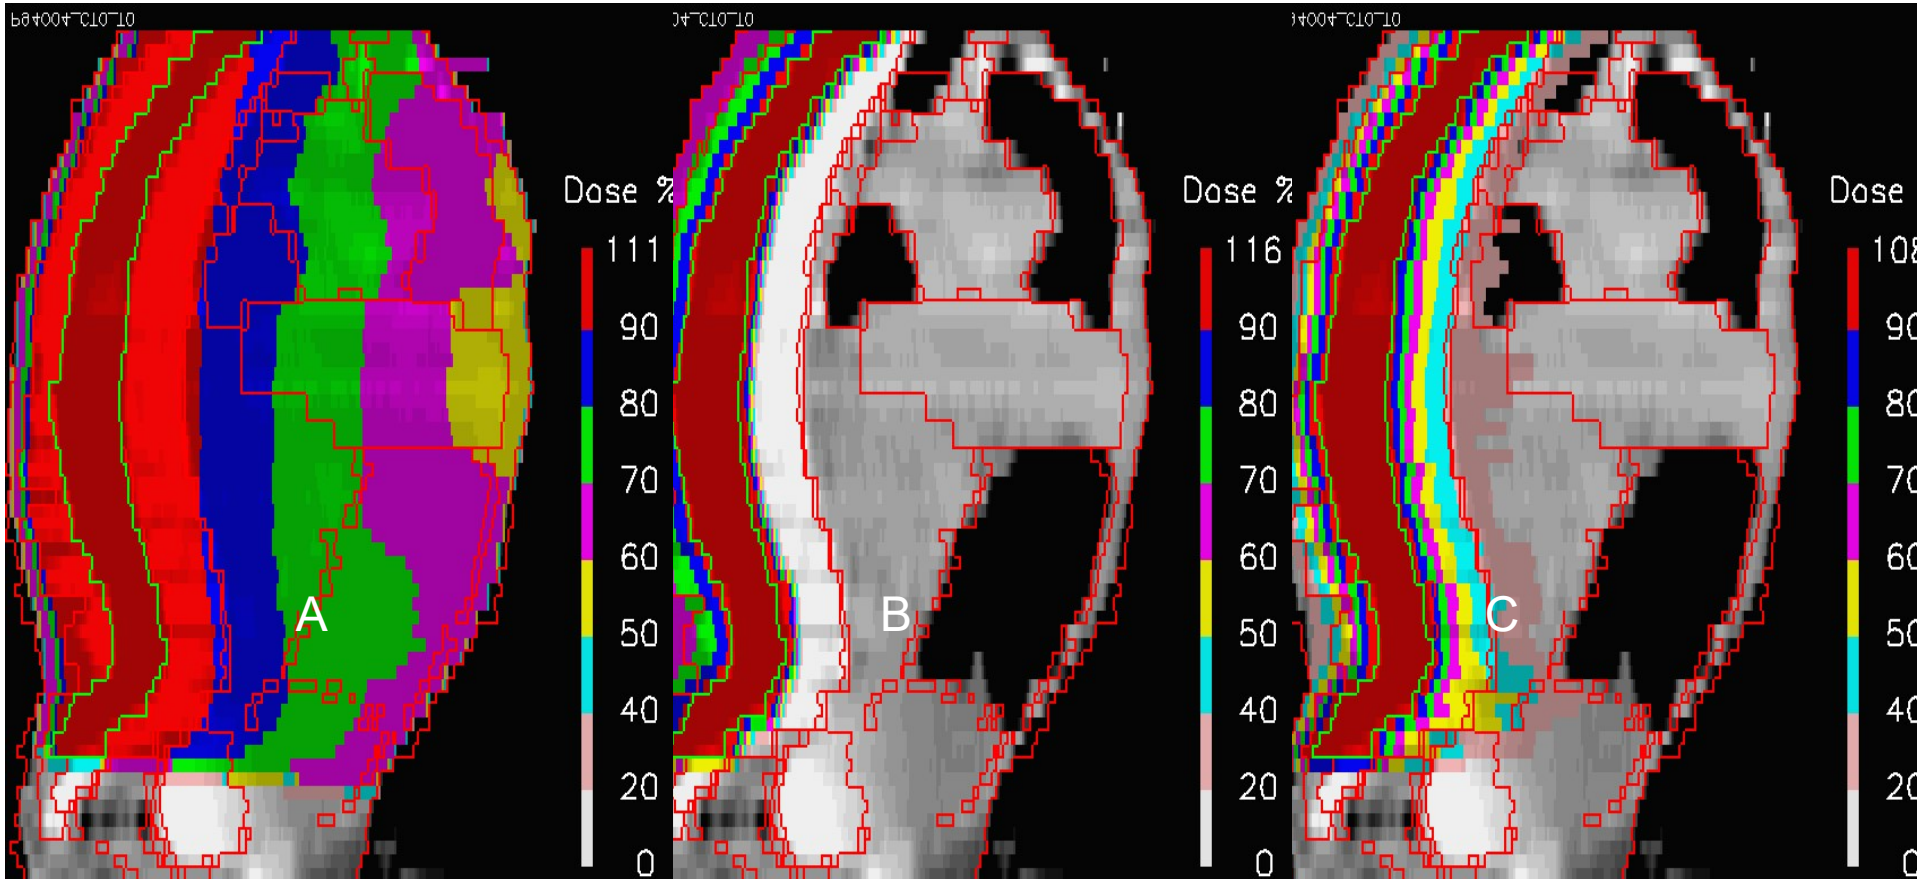
Treatment Plan / Isodose Distribution



Treatment Plan / DVH / Median Dose

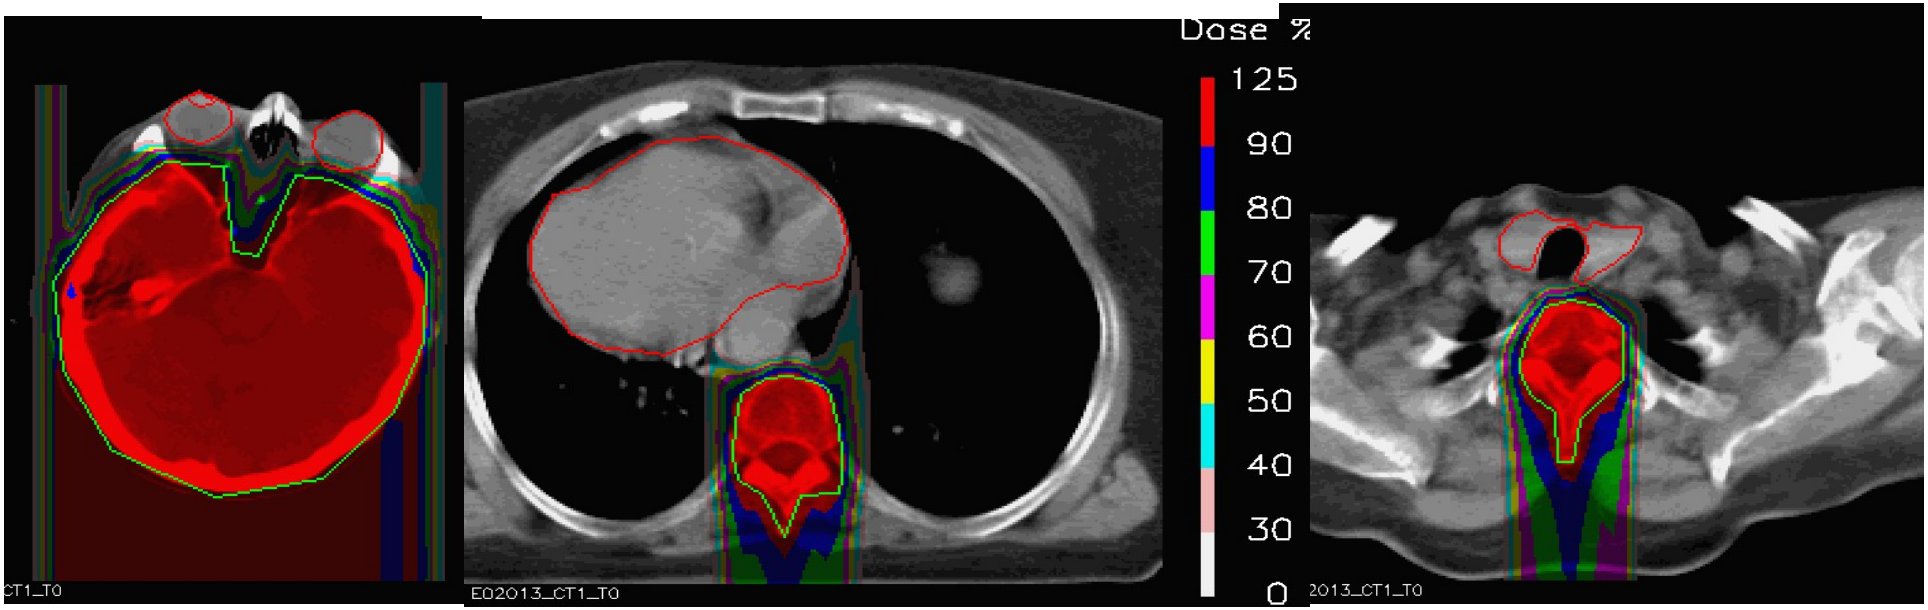


Comparative dose distributions in a sagittal plane through the center of the spinal axis



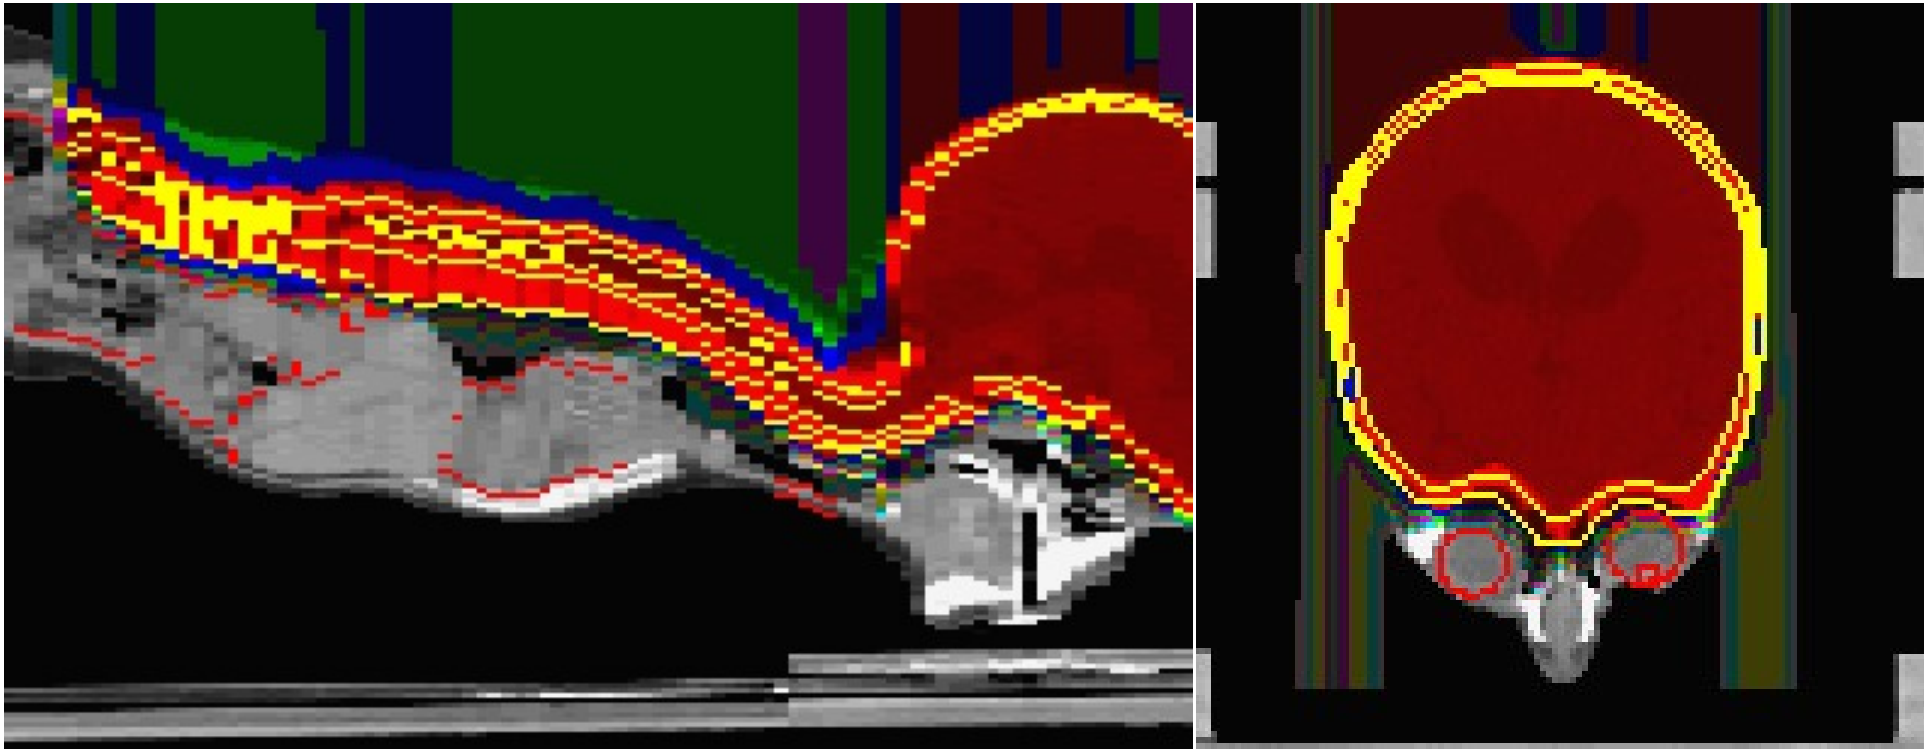
conventional photons **spot scanned protons** **IM photons**

CSI with Protons



Optimisation of the ventral dose distribution

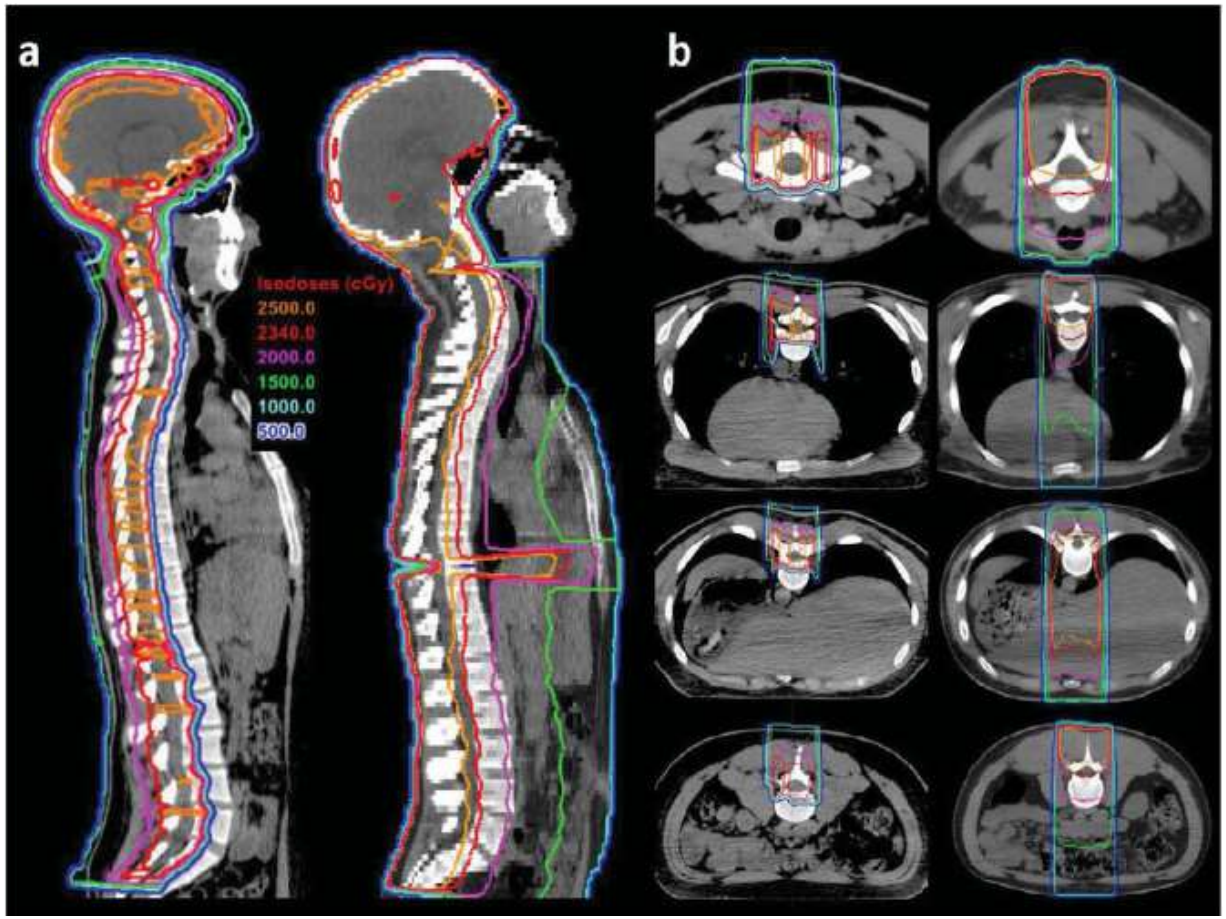
CSI with Protons in a 5 years old boy



Whole vertebras are included into the PTV

Proton Beam Craniospinal Irradiation Reduces Acute Toxicity for Adults with Medulloblastoma

Aaron P. Brown



Proton CSI Photon CSI

CSI protons: n=21

CSI photons: n=19

Dose 30.6 Gy/50.4Gy

Dose reduction

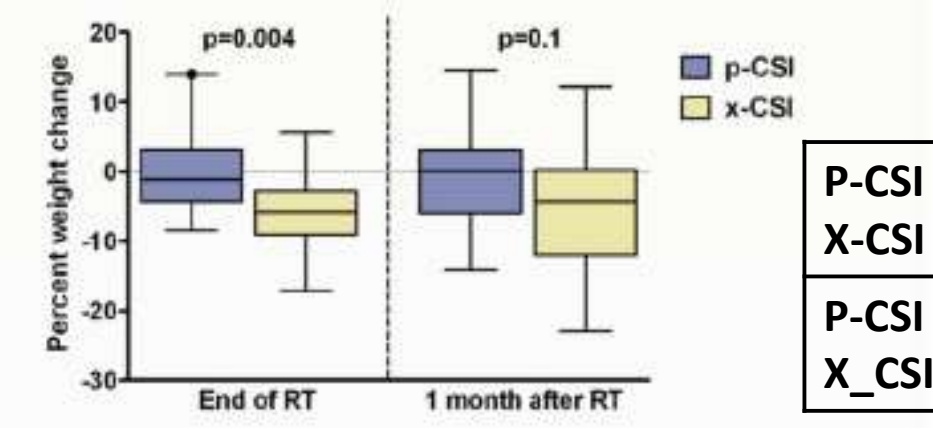
- Thyroid gland
- Esophagus
- Heart
- Lungs
- Liver
- Stomach
- Bowel
- Ant. vertebral body

Int J Radiat Oncol Biol Phys. 2013 June 1; 86(2): 277–284.

Proton Beam Craniospinal Irradiation Reduces Acute Toxicity for Adults with Medulloblastoma

Aaron P. Brown

Weight loss



P-CSI X-CSI	-1.2% (range +14 to -8.4%) -5.8% (range +5.8to -17.1%)	p=0.004
P-CSI X_CSI	+0.1% (range +14.6 to -14.2%) -4.4% (range 12.2 to-23%)	P=0.1

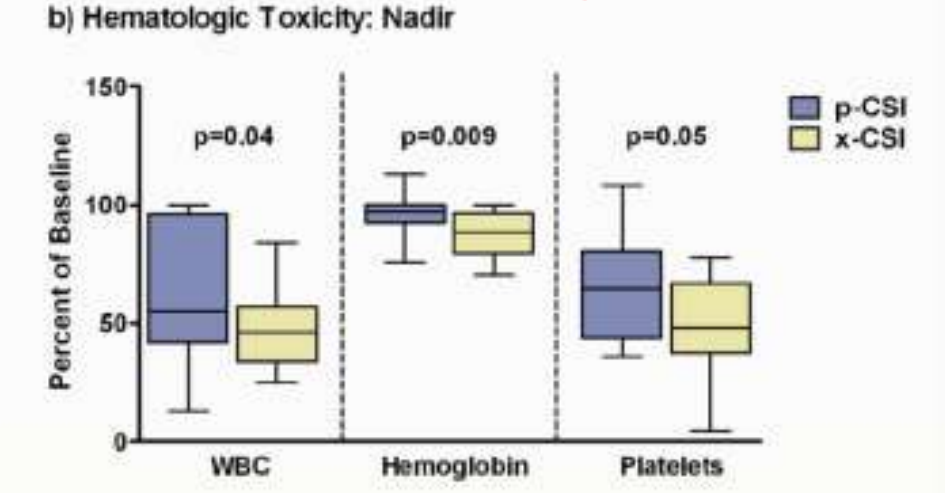
- GI toxicities (nausea, vomiting, dysphagia, anorexia and weight loss) are relatively common and can affect outcomes and quality of life.
- P-CSI had significant less weight loss and better recovery.

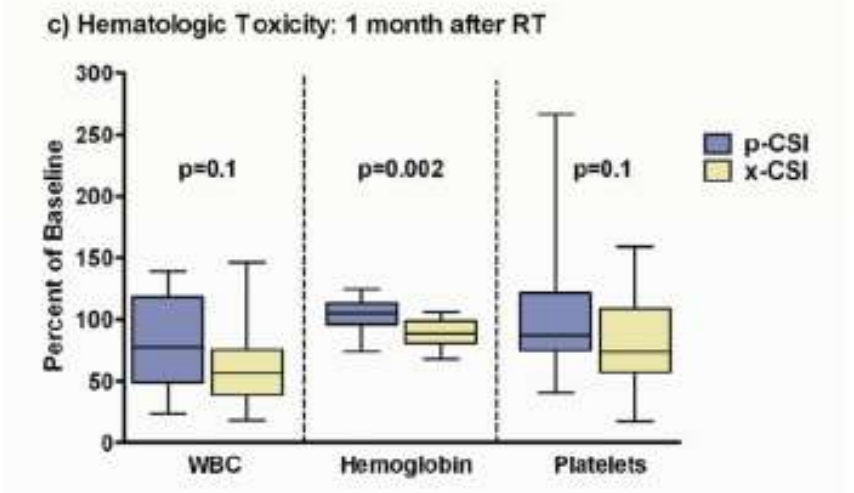
Int J Radiat Oncol Biol Phys. 2013 June 1; 86(2): 277–284.

Proton Beam Craniospinal Irradiation Reduces Acute Toxicity for Adults with Medulloblastoma

Aaron P. Brown

Median percentage of baseline WBCs, hemoglobine, platelets



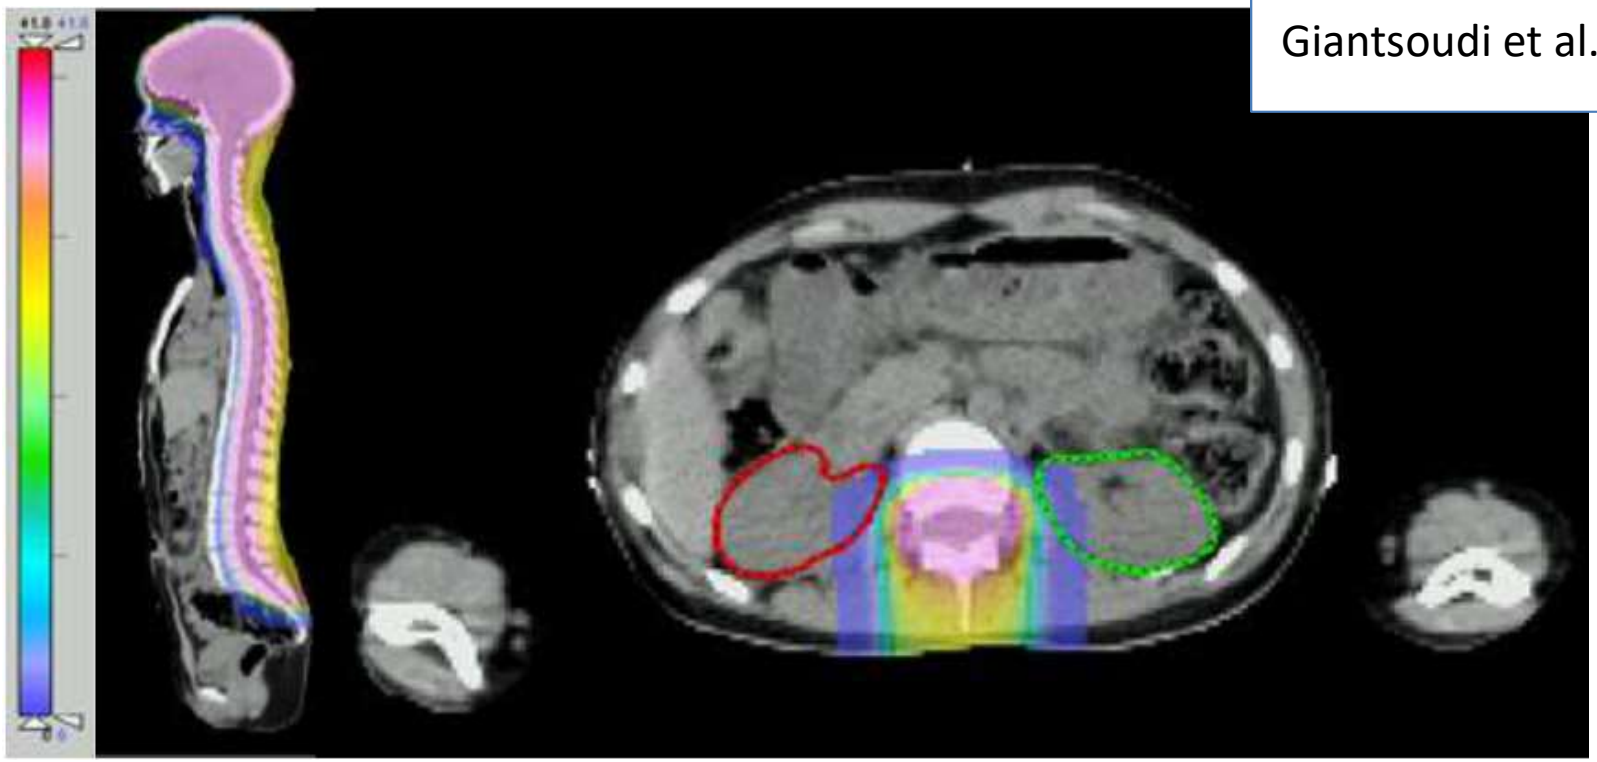


WBC	P-CSI x-CSI	55% (13-100%) 46% (25-84%)	P=0.04
Hemo-globin	P-CSI x-CSI	97% (76-113%) 88% (74-100%)	P=0.009
Platelets	P-CSI x-CSI	65% (36-108%) 48% (5-78%)	P=0.05

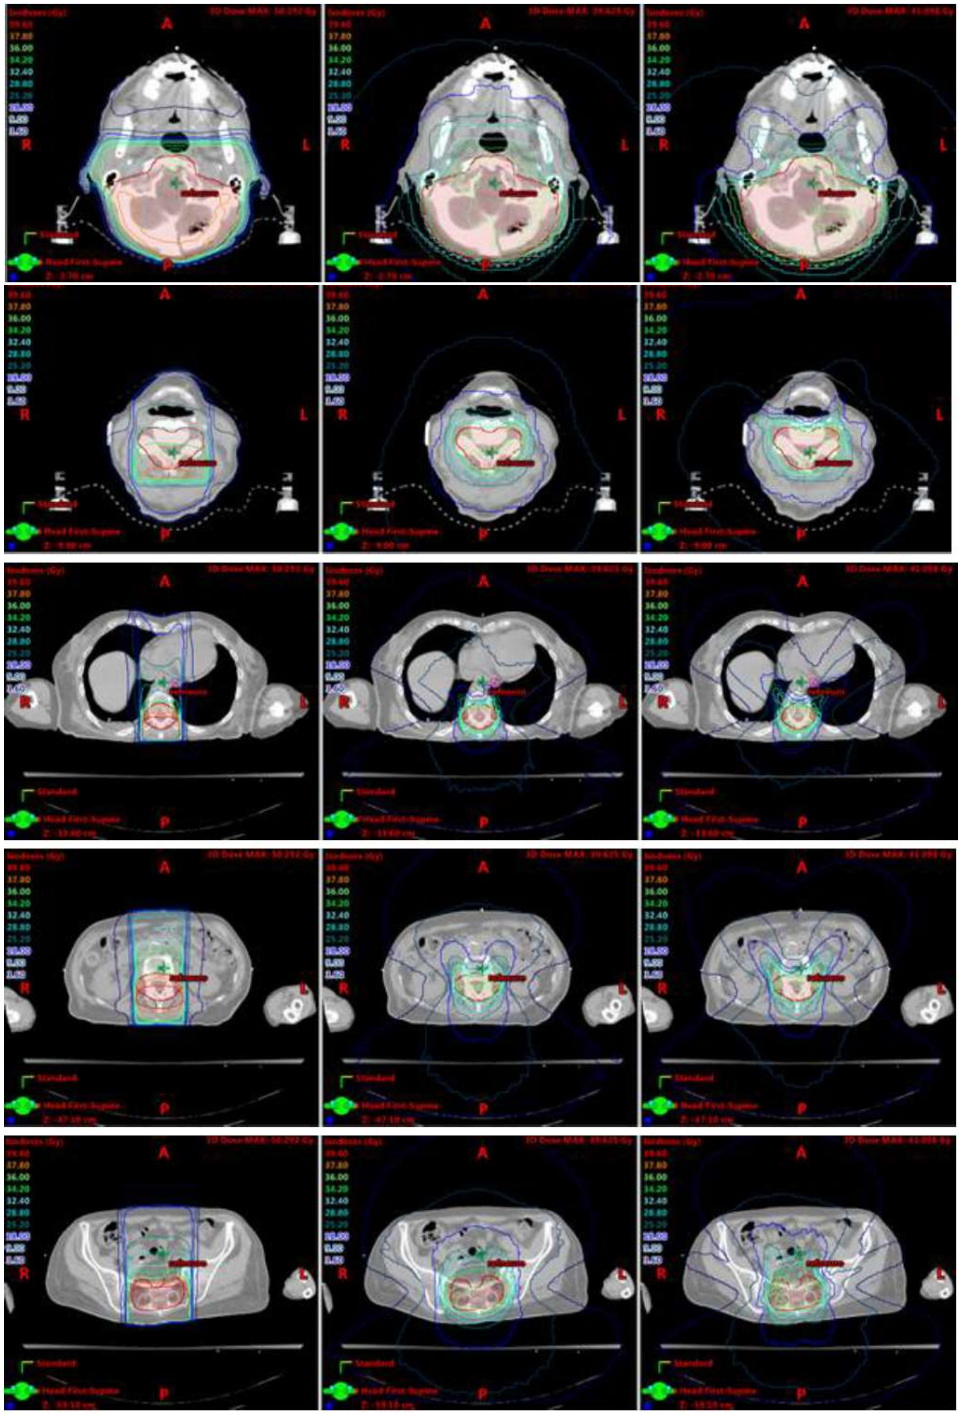
WBC	P-CSI x-CSI	78% (24-139%) 56% (18-146%)	P=0.1
Hemo-globin	P-CSI x-CSI	105% (74-124%) 88% (68-106%)	P=0.002
Platelets	P-CSI x-CSI	87% (41-266%) 73% (17-158%)	P=0.1

- P-CSI experienced significantly smaller reductions in blood counts than x-CSI
- Better recovery one month after RT in P-CSI than after x-CSI patients

Giantsoudi et al. 2017



Prescribed dose 23.4 RBE		Photons	Protons
V 10	cranial	100%	59.5%-76%
	thoracic		29.9% - 34.6%
	lumbal		20.6% - 25.1%
V20	cranial	99%	17.8% - 20 %
	thoracic		7.2% - 7.6%
	lumbal		4% -4.6%



Michal Devecka

Plan comparison:

- 3D-CRT
- Original HT
- Optimized HT

- Increasing mean vertebral dose is significantly associated with Nadir in WBC (thrombocytes,hemoglobin) after one month.
- More suff. Techniques can reduceBone marrow side effects.

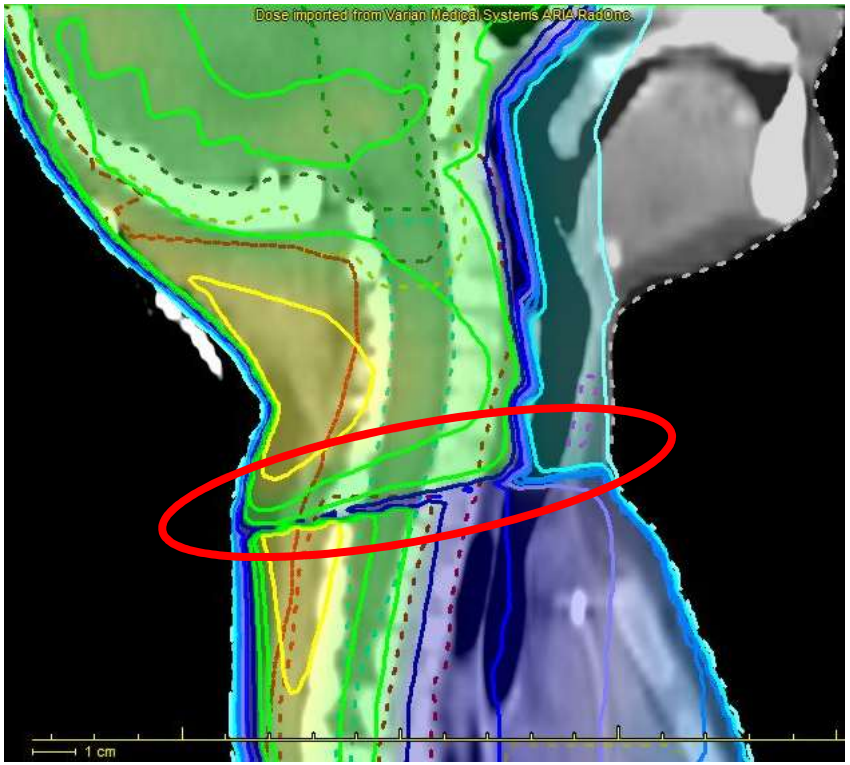
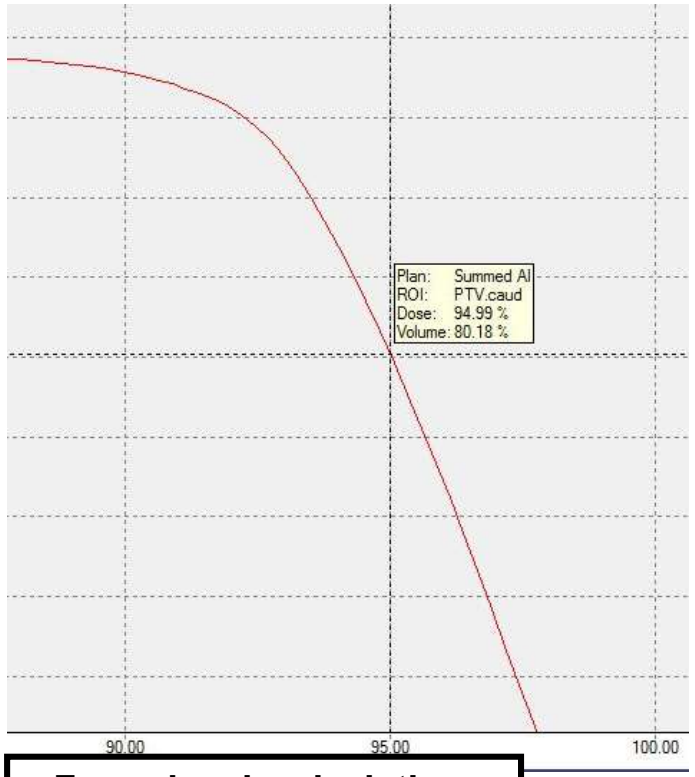
Field junction, underdosage



DVH



Formal major deviation, Underdoses at other site (soft tissue and junction) clin. not relevant

Conclusion

- There will be an advantage in switching from conventional photon therapy to complex techniques and proton therapy.

- Target delineation and definition becomes more and more Important in treatment planning.

  - Cave: Lamina cribrosa
    optic nerve
    Inner ear
    Skull base

- Stable and reproducible positioning of the patient on daily imaging control is necessary adapting targets to anatomical structures.

- Late effects of radiotherapy
- Theory turns to experiences
- Guidelines on constraints (Emami, QUANTEC and the others)
- Consequences on practice: Planning, DVH evaluation, Image guidance

ESTRO School

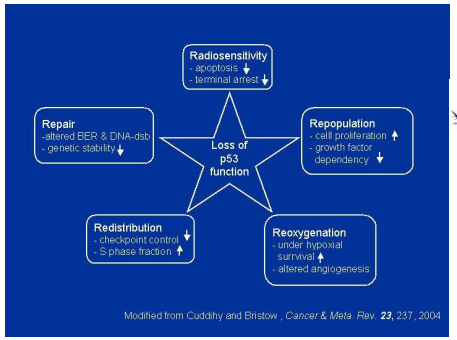
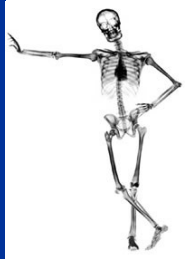
Radiobiology of RT/SRS/FSRT

- The goal of any medical intervention is to reach the highest role of *clinical success* in terms of desired effect with the minimum rate of side effects *treatment related*
- Historically radiation was delivered considering a variable safety margin to include *microscopic tumor infiltration* in normal tissue
- The relationship between time of radiation, dose and number of fractions, to influence the biological effect is based on 4Rs of ionizing radiation





A. Santacroce, et al., biomed research International, 2013

ESTRO School

Different tissues different responses to radiation

(1) late responding target embedded within late responding tissue: AVM,

(2) late responding target surrounded by late responding tissue: meningioma/schwannoma,

(3) early responding target embedded within late responding tissue: low grade glioma,

(4) early responding target surrounded by late responding tissue: glioblastomas/metastases.

Santacroce, et al., biomed research International, 2013
Larsson, et. al., IJROBP, 1993

ESTRO School

Radiobiology in the CNS: the vascular effect (SRS)

- Mainly for the case of benign lesions (AVM and meningioma, namely) large parte of the effect is determined by the combination of:
  - **Citotoxic effect** of the high dose of radiation with direct double strand DNA damage
  - **Vascular injury** with doubled number of apoptotic cells in the first 48 hours
  - Such a vascular effect is seen on tumor and AVM, but **not in normal vessels** (different vascular/endothelial radiosensitivity)
  - The probability of vascular damage is directly proportional to the fraction dose (particularly when higher than 10 Gy!!!)
  - High dose induces reduction of vascular mass and increase of vascular permeability

Park and Griffin, Rad Res., 2012

Radiotherapy – Radiation Tolerance of the Brain

Risk of Neurocognitive impairment after RT

- The risk in patients treated for glioma is mainly related to large volume (no WB better) (1)
- The risk of dementia in long survivors after WBRT in patients treated for brain metastases is strongly related to fractionation (<3Gy better)
- Rate of Neurocog sequelae is lower than 3% for partial brain irradiation, while respecting dose constraints
- Experiences on normal NSCs department avoidance also with larger treatment volumes are promising (3)

Quantec for the brain

What are the recommended dose constraints for the following organs and clinical scenarios? *(Continued)*	
ORGAN	***CONSTRAINTS***
CNS (single fraction)	
Brain	**V12 Gy <5-10 cc** (QUANTEC)
Chiasm/optic nerves	**max 10 Gy** (QUANTEC)
Brainstem	**max 12.5 Gy** (QUANTEC)
Sacral plexus	**V18 <0.035 cc, V14.4 <5 cc** (RTOG 0631)
Cauda equina	**V16 <0.035 cc, V14 <5 cc** (RTOG 0631)

ESTRO School

Quantec for the brain

What are the recommended dose constraints for the following organs and clinical scenarios?	
ORGAN	***CONSTRAINTS***
CNS (1.8-2.0 Gy/fx)	
Spinal cord	**max 50 Gy** (full cord cross-section); tolerance increases by 25% 6 mos after 1st course (for re-irradiation) (QUANTEC)
Brain	**max 72 Gy** (partial brain); avoid >2 Gy/fx or hyperfractionation (QUANTEC)
Chiasm/optic nerves	**max 55 Gy** (QUANTEC)
Brainstem	**Entire brainstem <54 Gy, V59 Gy <1-10 cc** (QUANTEC)
Eyes (globe)	**Mean <35 Gy** (RTOG 0225), **max 54 Gy** (RTOG 0615)
Lens	**max 7 Gy** (RTOG 0539)
Retina	**max 50 Gy** (RTOG 0539)
Lacrimal Gland	**max 40 Gy** (Parsons)
Inner ear/cochlea	**mean ≤45 Gy** (consider constraining to ≤35 Gy with concurrent cisplatin) (QUANTEC)
Pituitary gland	**max 45 Gy** (for panhypopituitarism, lower for GH deficiency) (Emami)
Cauda equina	**Max 60 Gy** (Emami)
CNS (single fraction)	
Spinal cord	**max 13 Gy** (if 3 fxs, max 20 Gy) (QUANTEC)

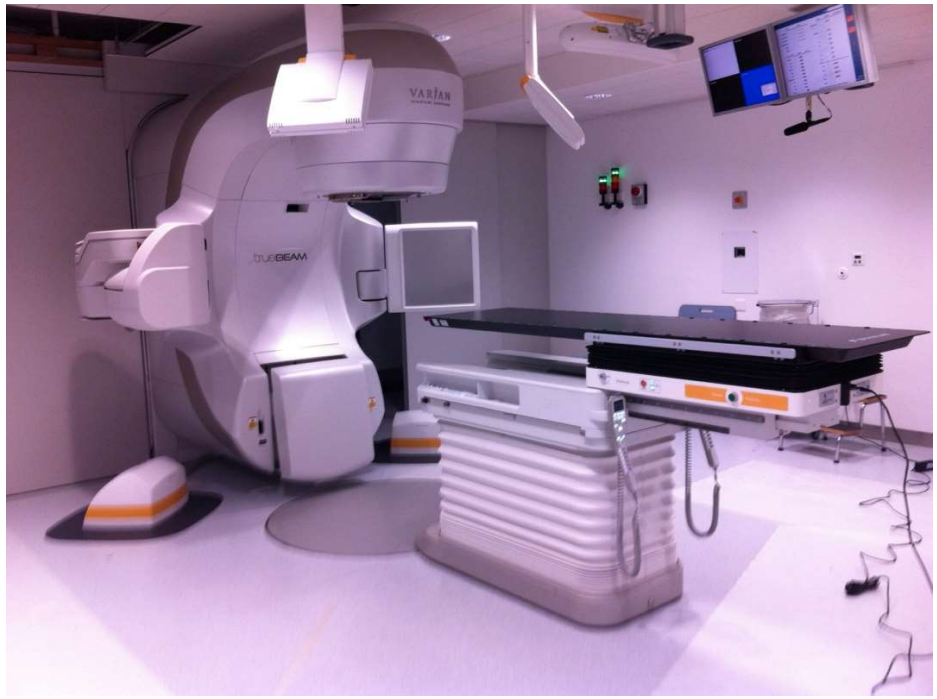
Radiotherapy – Radiation Tolerance of the Brain

- Radiobiology of Nervous tissue
- Acute effects of radiotherapy
- Late effects of radiotherapy
- Theory turns to experiences
- Guidelines on constraints (QUANTEC)
- Consequences on practice: Planning, DVH evaluation, Image guidance

ESTRO School

Technology Improvement

- Improved accuracy
- Improved imaging (MRI, PET, CT fusion)
  - planning/contouring
  - verification (ExacTrac®, CBCT, e.g.)
- Improved dose delivery
  - Higher dose rate, shorter treatment time



ESTRO School

Neural Stem Cells and RT toxicity

- NSCs exhibit exquisite in situ radiosensitivity
- Radiation can directly depopulate NSC niches, causing immediate loss of NSC-mediated repair and plasticity
- Indirect effects of radiation are inflammatory in nature, dose dependent, and capable of stunting neurogenesis even at low doses
- The scope of NSC dysfunction is age dependent, with greater effects noted in immature brains

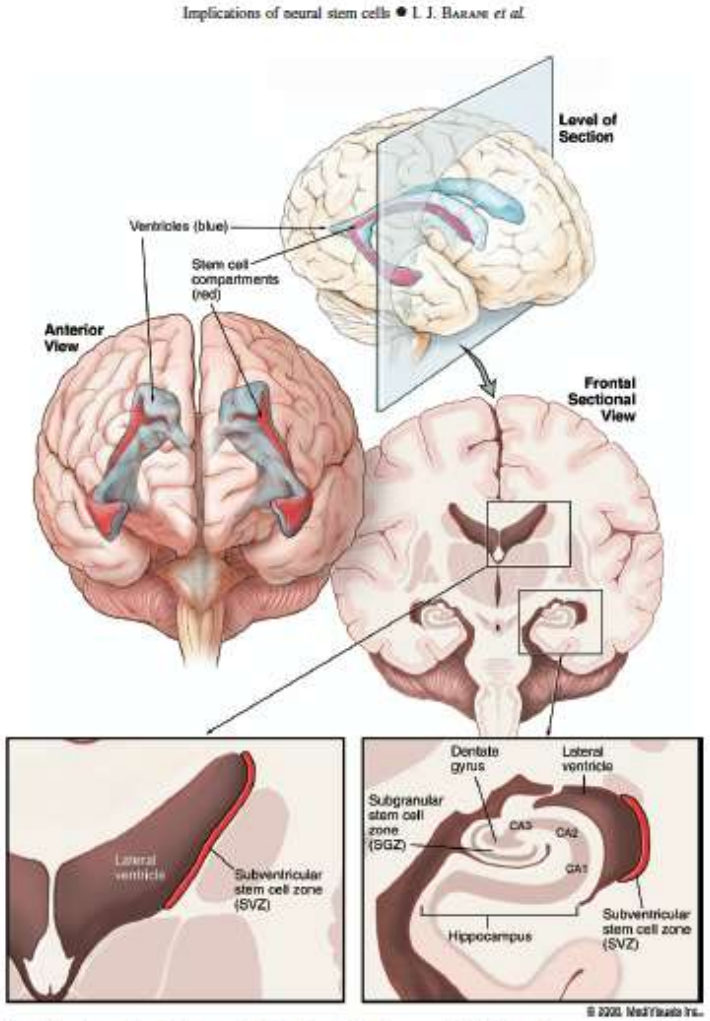


Fig. 1. Germinal regions of adult human brain. Subventricular zone (SVZ) is the largest germinal region in adult mammalian brain. The subgranular zone (SGZ) is located within dentate gyrus of hippocampus. CA1, CA2, and CA3 represent Cornu Ammonis fields of hippocampus proper and, along with dentate gyrus, constitute the hippocampal formation, primary memory center in brain.

REIRRADIATION TOLERANCE OF THE HUMAN BRAIN

RAMONA MAYER, M.D., M.SC.,* AND PETER SMINIA, PH.D.[y]

* Department of Therapeutic Radiology and Oncology, Medical University of Graz, Graz, Austria; and [y]Department of Radiation Oncology, Division Radiobiology, VU University Medical Center, Amsterdam, The Netherlands

- Radiation-induced normal brain tissue necrosis was found to occur at $NTD_{cumulative}$ >100 Gy
- The applied reirradiation dose and $NTD_{cumulative}$ were found to increase with a change in irradiation technique from conventional to conformal techniques such as FSRT to SRS, without increasing the probability of normal brain necrosis.
- The analysis shows the applied total cumulative dose to be the most important factor with regard to the development of radionecrosis
- Reirradiation is a feasible option as palliative therapy for recurrent high grade glioma

R Mayer, et al., IJROBP, 2008

?

ESTRO School

Conclusions

- ✓ Improvement of radiotherapy safety, with promising efficacy in patients with brain metastases
- ✓ Well defined dose constraints (QUANTEC, ESTRO, RTOG)
- ✓ New knowledge concerning the role of Neural Stem Cells permitted to identify brain regions involved in plasticity and repair processes (Hippocampus e.g.)
- ✓ Randomized controlled trials have demonstrated significant activity of Memantine and Donepezil for neurocognitive impairment prevention, in patients treated with cranial radiotherapy for primary and metastatic brain tumors
- ✓ Even with new treatments (BEV e.g.) radiation necrosis remains a challenge; better treatment for that is prevention

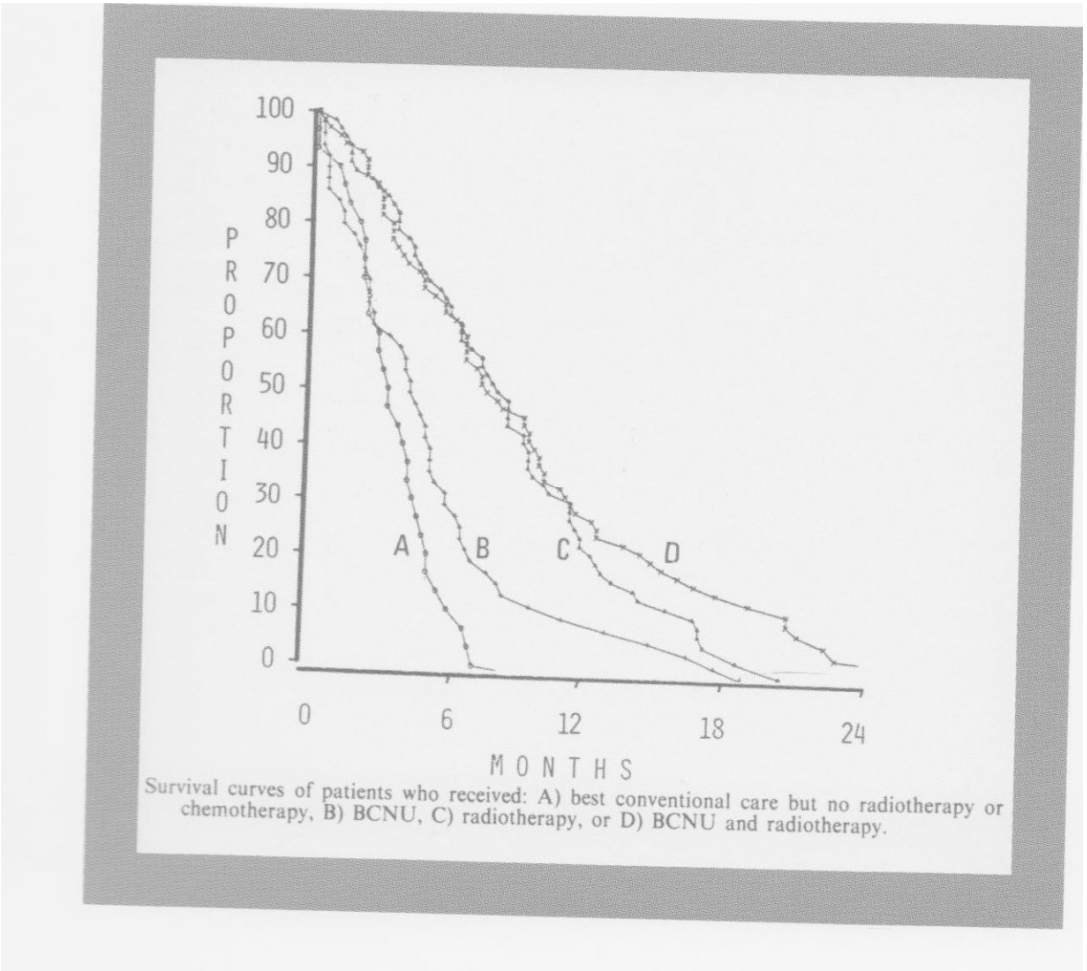
Systemic therapy for glioma: the early days



Survival curves of patients who received: A) best conventional care but no radiotherapy or chemotherapy, B) BCNU, C) radiotherapy, or D) BCNU and radiotherapy.

J Neurosurg 49:333–343, 1978

Evaluation of BCNU and/or radiotherapy in the treatment of anaplastic gliomas

A cooperative clinical trial

MICHAEL D. WALKER, M.D., EBEN ALEXANDER, JR., M.D., WILLIAM E. HUNT, M.D., COLLIN S. MACCARTY, M.D., M. STEPHEN MAHALEY, JR., M.D., JOHN MEALEY, JR., M.D., HORACE A. NORRELL, M.D., GUY OWENS, M.D., JOSEPH RANSOHOFF, M.D., CHARLES B. WILSON, M.D., EDMUND A. GEHAN, PH.D., AND THOMAS A. STRIKE, PH.D.

The Brain Tumor Study Group and the National Cancer Institute, National Institutes of Health, Bethesda, Maryland

A controlled, prospective, randomized study evaluated the use of 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU) and/or radiotherapy in the treatment of patients who were operated on and had histological confirmation of anaplastic glioma. A total of 303 patients were randomized into this study, of whom 222 (73%) were within the Valid Study Group (VSG), having met the protocol criteria of neuropathology, corticosteroid control, and therapeutic approach. Patients were divided into four random groups, and received BCNU (80 mg/sq m/day on 3 successive days every 6 to 8 weeks), and/or radiotherapy (5000 to 6000 rads to the whole brain through bilateral opposing ports), or best conventional care but no chemotherapy or radiotherapy. Analysis was performed on all patients who received any amount of therapy (VSG) and on the Adequately Treated Group (ATG), who had received 5000 or more rads radiotherapy, two or more courses of chemotherapy, and had a minimum survival of 8 or more weeks (the interval that would have been required to have received either the radiotherapy or chemotherapy). Median survival of patients in the VSG was, best conventional care: 14 weeks (ATG: 17.0 weeks); BCNU: 18.5 weeks (ATG: 25.0 weeks); radiotherapy: 35 weeks (ATG: 37.5 weeks); and BCNU plus radiotherapy: 34.5 weeks (ATG: 40.5 weeks). All therapeutic modalities showed some statistical superiority compared to best conventional care. There was no significant difference between the four groups in relation to age distribution, sex, location of tumor, diagnosis, tumor characteristics, signs or symptoms, or the amount of corticosteroid used. An analysis of prognostic factors indicates that the initial performance status (Karnofsky rating), age, the use of only a surgical biopsy, parietal location, the presence of seizures, or the involvement of cranial nerves II, III, IV, and VI are all of significance. Toxicity included acceptable, reversible thrombocytopenia and leukopenia.

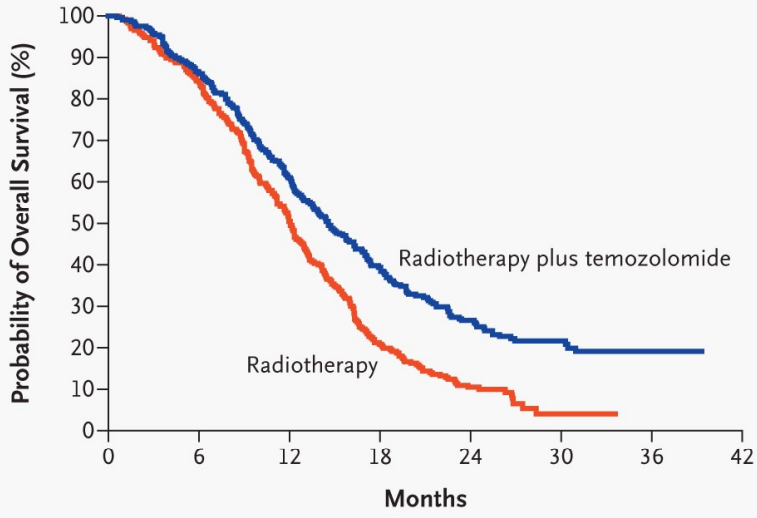
2005



No. at Risk

Radiotherapy	286	240	144	59	23	2	0
Radiotherapy plus temozolomide	287	246	174	109	57	27	4

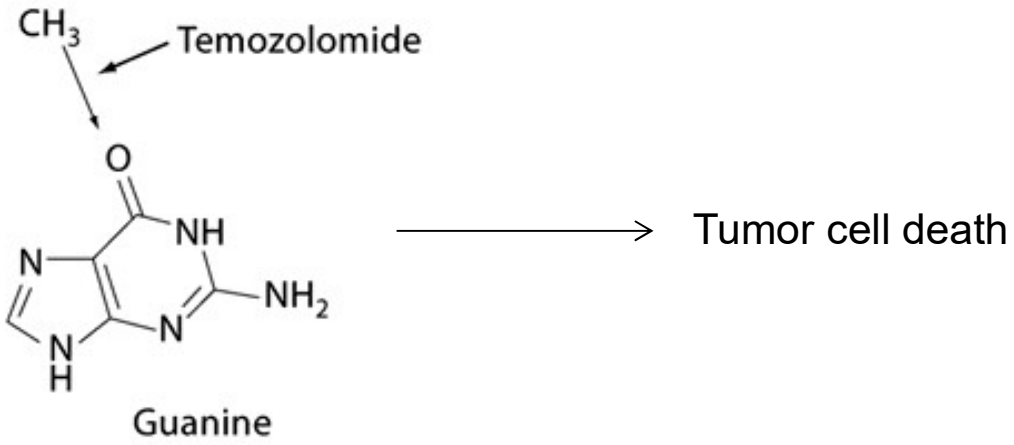
Figure 1. Kaplan–Meier Estimates of Overall Survival According to Treatment Group.

The hazard ratio for death among patients treated with radiotherapy plus temozolomide, as compared with those who received radiotherapy alone, was 0.63 (95 percent confidence interval, 0.52 to 0.75; P<0.001).

ESTRO School

Temozolomide

- Imidazotetrazine derivative of dacarbazine
- Conversion in the systemic circulation at physiological pH to the active compound, 3-methyl-(triazen-1-yl)imidazole-4-carboxamide (MTIC)
- Good BBB penetration
- Oral application (note: there is also an i.v. formulation)
- Methylation of O6 guanine:



Toxicity

Table 4. Grade 3 or 4 Hematologic Toxic Effects in Patients Treated with Temozolomide.

Toxic Effect	Concomitant Temozolomide Therapy (N=284)	Adjuvant Temozolomide Therapy (N=223)	Entire Study Period* (N=284)
	number of patients (percent)		
Leukopenia	7 (2)	11 (5)	20 (7)
Neutropenia	12 (4)	9 (4)	21 (7)
Thrombocytopenia	9 (3)	24 (11)	33 (12)
Anemia	1 (<1)	2 (1)	4 (1)

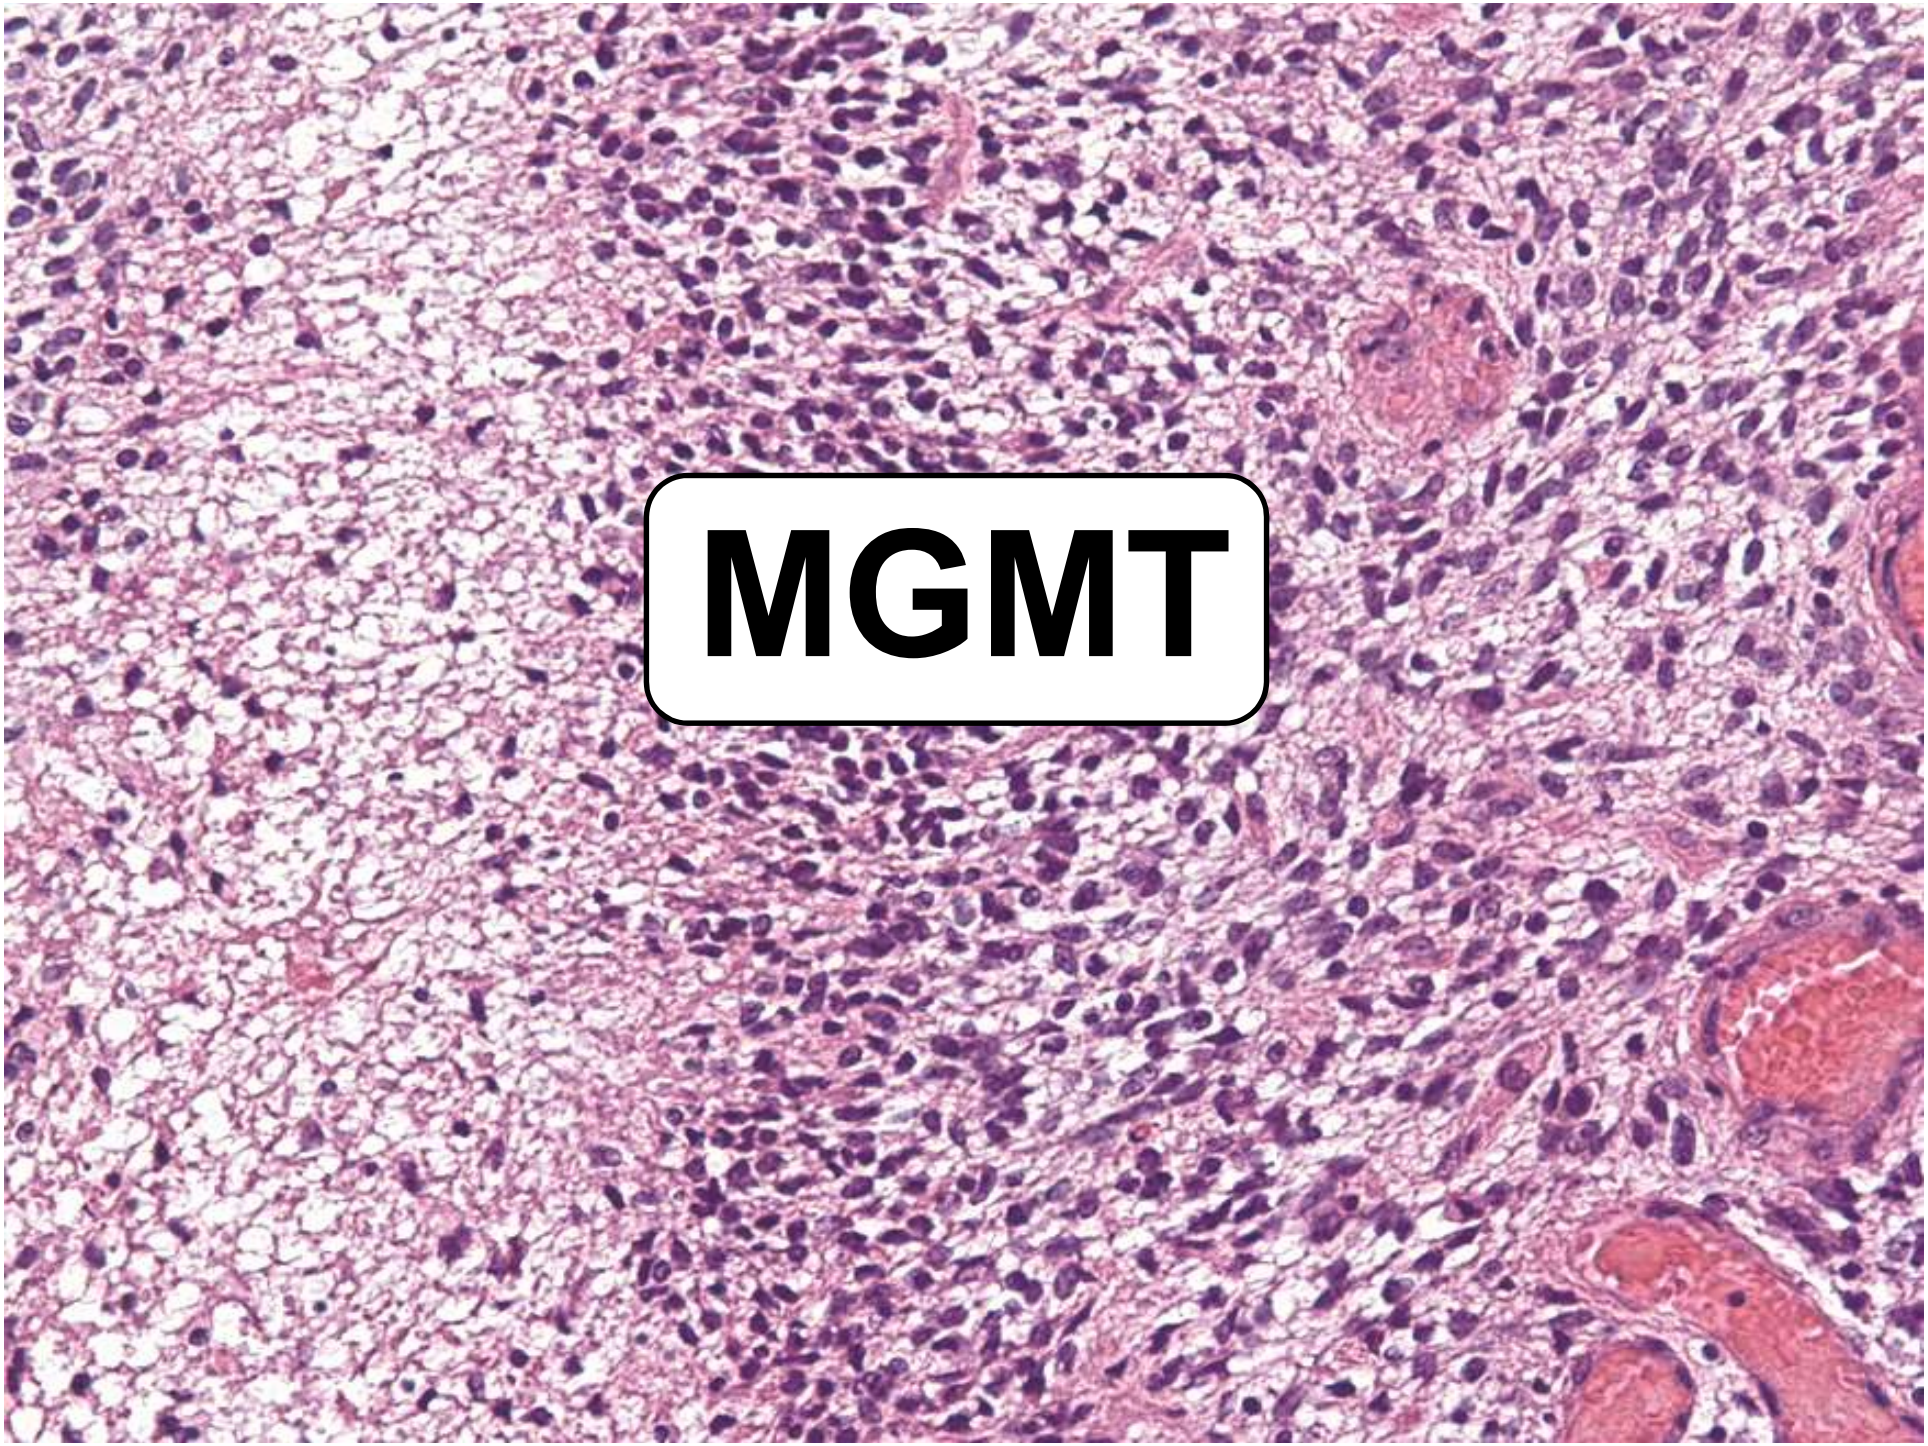
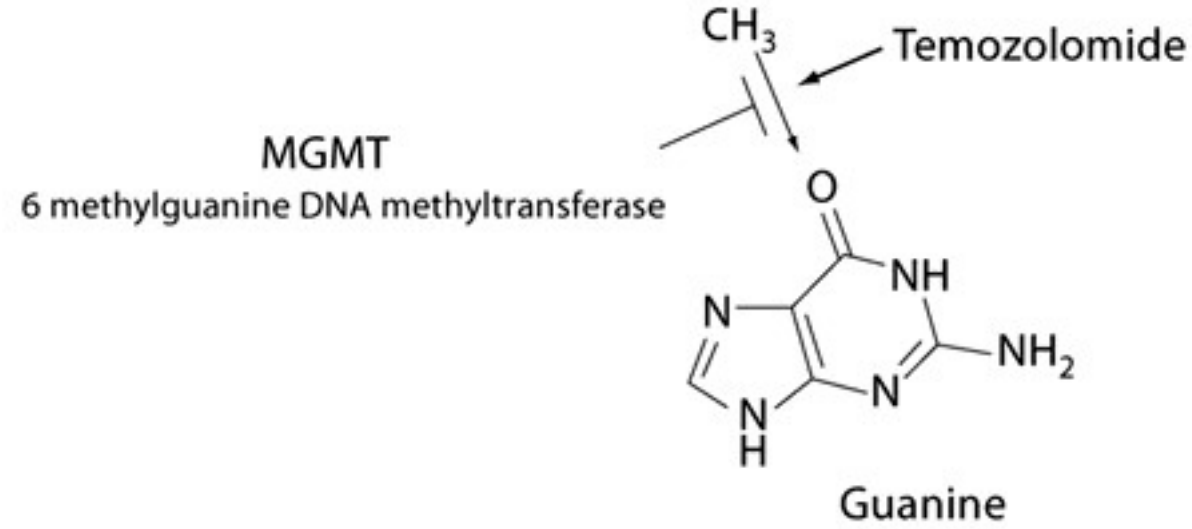
ESTRO School



MGMT

What is MGMT?

- O6-Methylguanin-Methyltransferase (= MGMT)
- DNA repair protein
- MGMT removes methyl group from O6 position of guanine („protects tumor cell DNA from damage by chemo- and radiotherapy“)



ESTRO School

Inactivation of MGMT gene by promoter methylation

Beware! Before you start testing….

… you need a reliable MGMT test!

Essential properties of clinical biomarkers

Clinical performance

= the prognostic or predictive value of a given candidate biomarker

Analytical performance

= the reliability of the results yielded by a particular assessment or test

Problem: results may vary between tests and investigators

Systemic treatment of brain mets

Basic considerations

There is no specific chemotherapy (or any specific medical treatment) for brain mets

Most brain mets derive from chemo-resistant primary tumors

The best chemotherapy for the primary tumor is also the best choice for brain metastases

Brain mets have (probably) no blood-brain barrier (BBB)

Drugs that cross the BBB may be helpful for the prevention of metastasis to the brain and/or for the treatment of „micrometastases“

ESTRO School

Good old chemotherapy

ESTRO School

Chemotherapeutic drugs used to treat brain mets in NSCLC patients

- **Cisplatin / Carboplatin**
- **Vinorelbine**
- **Paclitaxel / Docetaxel**
- **Gemcitabine**
- **Pemetrexed**

Treatment of brain mets

- **Cerebral response rates of about 40% have been reported for NSCLC patients with BM following treatment with platinum and pemetrexed**

- **These results are not inferior to the local response rates typically seen with WBRT**

Barlesi et al. Ann Oncol 2011
Bailon et al. Neuro Oncol 2012

Chemotherapeutic drugs: BBB crossing

Drug levels in brain metastases and neighboring tissues, measured at time of resection or at autopsy

Drug	Tumor level: necrotic lesion	Tumor level: viable lesion	Neighboring normal brain level
Etoposide (63)	5.9 µg/g	3.4 µg/g	1.4 µg/g adjacent, 0.1 µg/g 2 cm distance
Cisplatin (64)			
20 to 25 mg/m^2	Not reported	1.29 µg/g	0.25 to 0.65 µg/g, 2 to 5 cm
60 to 100 mg/m^2		2.97 µg/g	0.7 to 1.11 µg/g, 2 to 5 cm
Vinorelbine (65)	Not reported	68 ng/g	22 ng/g adjacent, 5 ng/g >4 cm
Mitoxantrone (66)	15 to 322 ng/g	25 to 29 ng/g	Not reported

=> but: drug levels in brain mets lower than in extracranial mets

Deeken and Löscher, Clin Cancer Res 2007

ESTRO School

WBRT + Temozolomide

WBRT +/- temozolomide:

- Patients with NSCLC and ≥ 1 newly diagnosed brain metastasis
- Poor accrual
- WBRT alone: median OS: 5.7 months
- WBRT + temozolomide: median OS 4.4

Daily low-dose temozolomide:

- Patients with advanced NSCLC; many of them with brain mets
- “minimal activity as salvage therapy in patients with advanced NSCLC”

Chua et al. Clin Lung Cancer 2014
Kouroussis et al. Oncology 2009

ESTRO School

Targeted therapy

…the ultimate solution?

Targeted therapy

- **Bevacizumab**
  => probably no need to cross the BBB
- **EGFR inhibitors (erlotinib, gefitinib…)**
  => only in patients with sensitizing EGFR mutation
- **ALK inhibitors (crizotinib, ceritinib…)**
  => only in patients with EML4-ALK translocation

Bevacizumab

- Only low risk for CNS hemorrhage in patients with NSCLC and brain mets who are treated with bevacizumab
- Potentially strong anti-edema activity
- Bevacizumab alone or in combination with chemotherapy in patients with brain mets from NSCLC:
  - Median PFS: 7.8 months
  - Median OS: 14.1 months
- WBRT + bevacizumab in patients with brain mets (REBECA):
  - Safe, but clinical benefit remains unclear

Socinski et al. J Clin Oncol 2009
De Braganca et al. J Neurooncol 2010
Lévy et al. Ann Oncol 2014

EGFR inhibitors

- Activating EGFR mutations particularly commmon in adenocarcinomas of the lung
- EGFR mutations may be overrepresented in brain mets of lung cancer patients
- Clinical activity of EGFR inhibitors in patients with activating EGFR mutations has been shown in several large trials
- Modest BBB penetration of EGFR inhibitors

Lynch et al. N Engl J Med 2004
Paez et al. Science 2004
Matsumoto et al. Int J Cancer 2006
Park et al. Lung Cancer 2012
Maemondo et al. N Engl J Med 2010
Rosell et al. Lancet Oncol 2012

CNS response rates in NSCLC patients treated with EGFR-TKI

EGFR mutation status	Therapy	Response rate (%)
Unselected	EGFR-TKI	60%
		43%
		10%
		32%
		33%
		70%
	EGFR-TKI + WBRT	81%
		71%
EGFR mutation	EGFR-TKI	83%
		82%
		89%
		75%
	EGFR-TKI + WBRT	84%

Berger et al. Lung Cancer 2013

ESTRO School

Addition of EGFR inhibitors to WBRT does (probably) not prolong survival

WBRT + gefitinib or temozolomide

- Gefitinib: median OS **6.3** months
- Temozolomide: median OS **4.9** months
- Fatigue as major side effect

WBRT and SRS + erlotinib or temozolomide in patients with ≤ 3 brain mets

- WBRT and SRS: median OS **13.4** months
- Addition of temozolomide: median OS **6.3** months
- Addition of erlotinib: median OS **6.1** months
- Increased toxicity in the gefitinib and temozolomide arm

Pesce et al. Eur J Cancer 2012
Sperduto et al. Int J Radiat Oncol Biol Phys 2013

ALK fusion genes

- Found in around 5% of NSCLC
- Encountered more frequently in never smokers, the adenocarcinoma subtype, and in younger patients
- NSCLC patients with ALK rearrangement have improved OS after radiotherapy for brain metastases compared with EGFR or KRAS mutations

  => Subsequent receipt of targeted therapy is associated with additional improvement in OS
- Crizotinib first approved ALK inhibitor

Shaw et al. J Clin Oncol 2009
Mak et al. Neuro Oncol 2015
Shaw et al. New Engl J Med 2013

Brain mets: a particular challenge?

DOR, median (months) [95% CI]	6.9[4.8, 8.5]	NE[b][5.5, NE]	7.0[5.5, 9.7]
PFS, median (months) [95% CI]	6.7[4.9, 8.5]	8.3[4.6, NE]	6.9[5.4, 8.4]

=> Promising treatment for patients with brain mets?

Kim et al. Lancet Oncol 2016

ESTRO School

Conclusions

- Systemic therapies can improve outcome in brain tumor patients
- Blood brain barrier can be a limiting factor
- Insufficient understanding of tumor biology as one limiting factor
- Emerging targeted agents with putative activity in brain tumors
- Predictive factors may help to tailor systemic therapies
- Need for more research

How large should be the margin? Which technique should be used?

- Several series analyzed the pattern of failure after radiotherapy for LGG
- In the NCCTG 86-72-51 trial 92% of the failures occurred in the treatment field, 3% within 2cm and 5% more than 2 cm
- Radiosurgery remains investigational but margins may be reduced
- Protons may reduce the integral dose and can result in reduction of late toxicity

Improved accuracy of dose delivery

reducing margin for inaccuracy & microscopic spread

Long-term efficacy of early versus delayed radiotherapy for low-grade astrocytoma and oligodendroglioma in adults: the EORTC 22845 randomised trial

M J van den Bent, D Afra, O de Witte, M Ben Hassel, S Schraub, K Hoang-Xuan, P-O Malmström, L Collette, M Piérart, R Mirimanoff, A B M F Karim, for the EORTC Radiotherapy and Brain Tumor Groups and the UK Medical Research Council

Summary

Background Postoperative policies of "wait-and-see" and radiotherapy for low-grade glioma are poorly defined. A trial in the mid 1980s established the radiation dose. In 1986 the EORTC Radiotherapy and Brain Tumor Groups initiated a prospective trial to compare early radiotherapy with delayed radiotherapy. An interim analysis has been reported. We now present the long-term results.

Methods After surgery, patients from 24 centres across Europe were randomly assigned to either early radiotherapy of 54 Gy in fractions of 1·8 Gy or deferred radiotherapy until the time of progression (control group). Patients with low-grade astrocytoma, oligodendroglioma, mixed oligoastrocytoma, and incompletely resected pilocytic astrocytoma, with a WHO performance status 0–2 were eligible. Analysis was by intention to treat, and primary endpoints were overall and progression-free survival.

Findings 157 patients were assigned early radiotherapy, and 157 control. Median progression-free survival was 5·3 years in the early radiotherapy group and 3·4 years in the control group (hazard ratio 0·59, 95% CI 0·45–0·77; $p<0·0001$). However, overall survival was similar between groups: median survival in the radiotherapy group was 7·4 years compared with 7·2 years in the control group (hazard ratio 0·97, 95% CI 0·71–1·34; $p=0·872$). In the control group, 65% of patients received radiotherapy at progression. At 1 year, seizures were better controlled in the early radiotherapy group.

Interpretation Early radiotherapy after surgery lengthens the period without progression but does not affect overall survival. Because quality of life was not studied, it is not known whether time to progression reflects clinical deterioration. Radiotherapy could be deferred for patients with low-grade glioma who are in a good condition, provided they are carefully monitored.

ESTRO School

RT RCT- *summary*

- Radiotherapy is effective at a dose of 45 to 54 Gy
- Higher dose could be dangerous (late toxicity seen more often in the HD arm of the NCCTG trial)
- Early postoperative radiotherapy determined significant improvement in progression free survival from 3.4 to 5.3 years in the EORTC 22845 trial
- Deferring radiotherapy did not impact adversely on overall survival, but the effect on PFS and Freedom from seizure may substancially impact on quality of life
- *Those trials were carried out between the 80s and the 90s, with quite simple radiotherapy techniques also including Cobalt*

Favourable prognostic factors

- Age<40
- Longer duration of symptoms
- Radiation *(PFS ok; OSR n.s.)*
- Tumor size ≦5cm
- Resection *vs* Biopsy
- Histology (OD vs A)

Temozolomide chemotherapy versus radiotherapy in high-risk low-grade glioma (EORTC 22033-26033): a randomised, open-label, phase 3 intergroup study

Brigitta G Baumert, Monika E Hegi*, Martin J van den Bent, Andreas von Deimling, Thierry Gorlia, Khê Hoang-Xuan, Alba A Brandes, Guy Kantor, Martin J B Taphoorn, Mohamed Ben Hassel, Christian Hartmann, Gail Ryan, David Capper, Johan M Kros, Sebastian Kurscheid, Wolfgang Wick, Roelien Enting, Michele Reni, Brian Thiessen, Frederic Dhermain, Jacoline E Bromberg, Loic Feuvret, Jaap C Reijneveld, Olivier Chinot, Johanna M M Gijtenbeek, John P Rossiter, Nicolas Dif, Carmen Balana, Jose Bravo-Marques, Paul M Clement, Christine Marosi, Tzahala Tzuk-Shina, Robert A Nordal, Jeremy Rees, Denis Lacombe, Warren P Mason, Roger Stupp**

Summary

Background Outcome of low-grade glioma (WHO grade II) is highly variable, reflecting molecular heterogeneity of the disease. We compared two different, single-modality treatment strategies of standard radiotherapy versus primary temozolomide chemotherapy in patients with low-grade glioma, and assessed progression-free survival outcomes and identified predictive molecular factors.

Low grade astrocytoma

- Chemotherapy can be a therapeutic option to defer, or an alternative to RT at progression, but, deferring RT must be balanced with the lower control of seizures and shorter PFS [1,2]
- Long term results of athe RTOG 9802 trial showed a survival advantage of 5.5 years by addition of chemotherapy to RT in patients with adverse prognostic factors[2]
- The same experience indicates that treatment of LGG patients, immediately after surgery or at progression, should be tailored according to specific prognostic factors [1-5]
- Patients' subgroups should be treated and trials should be designed according to specific biomarkers, being IDH mutation and 1p/19q codeletion the most relevant[1-5]

Interim analysis is ready…

Interim results from the CATNON trial (EORTC study 26053-22054) of treatment with concurrent and adjuvant temozolomide for 1p/19q non-co-deleted anaplastic glioma: a phase 3, randomised, open-label intergroup study

Martin J van den Bent, Brigitta Baumert, Sara C Erridge, Michael A Vogelbaum, Anna K Nowak, Marc Sanson, Alba Ariela Brandes, Paul M Clement, Jean Francais Baurain, Warren P Mason, Helen Wheeler, Olivier L Chinot, Sanjeev Gill, Matthew Griffin, David G Brachman, Walter Taal, Roberta Rudà, Michael Weller, Catherine McBain, Jaap Reijneveld, Roelien H Enting, Damien C Weber, Thierry Lesimple, Susan Clenton, Anja Gijtenbeek, Sarah Pascoe, Ulrich Herrlinger, Peter Hau, Frederic Dhermain, Irene van Heuvel, Roger Stupp, Ken Aldape, Robert B Jenkins, Hendrikus Jan Dubbink, Winand N M Dinjens, Pieter Wesseling, Sarah Nuyens, Vassilis Golfinopoulos, Thierry Gorlia, Wolfgang Wick, Johan M Kros

Summary

Background The role of temozolomide chemotherapy in newly diagnosed 1p/19q non-co-deleted anaplastic gliomas, which are associated with lower sensitivity to chemotherapy and worse prognosis than 1p/19q co-deleted tumours, is unclear. We assessed the use of radiotherapy with concurrent and adjuvant temozolomide in adults with non-co-deleted anaplastic gliomas.

Summary for Anaplastic Astrocytoma

- Upfront chemotherapy with PCV resulted in improved survival in patients treated for oligodendroglioma and oligoastrocytoma, with 1p/19q co-deletion[1,2]
- Interim results from EORTC 26053-22054 demonstrated a signigicant survival benefit in patients with non co-deleted anaplastic astrocytoma adding adjuvant TMZ to RT[3]
- The question of concomitant RT/TMZ remains open until the final analysis of the CATNON trial
- Repeated surgery and Re-irradiation is still an option for recurrent disease in combination with systemic therapy (CHT and BEV)

Conclusions

- Brain gliomas still represent a major challenge due to the complexity of the medical management and impact on patients' life
- The use of surgery, radiotherapy and chemotherapy need to be tailored according to histology and molecular biology as well as the clinical situation
- Trials are ongoing in the attempt to answer relevant open questions, as are the correct sequence/combination of chemo-radiotherapy in some particular tumor subtypes and the role of biologic targeted agents

* Of the indicated tumors, 6 secondary and 60 primary glioblastomas were previously described in Parsons et al.[16] Copy-number changes in *EGFR*, *CDKN2A*, and *CDKN2B* were determined by quantitative real-time polymerase chain reaction. For such assays, copy-number levels of more than 6 or less than 0.3 were considered amplifications or losses, respectively. NA denotes not analyzed, and ND not determined because of limited sample size and status of data censoring.
† Tumors were graded according to histopathological and clinical criteria established by the World Health Organization.
‡ Patient age refers to age at which the study sample was obtained.
§ Alterations included mutations in *TP53* and *PTEN*, loss of heterozygosity in 1p and 19q, amplification in *EGFR*, and deletion in *CDKN2A* or *CDKN2B*.
¶ Secondary glioblastoma designates a tumor that was resected more than 1 year after a previous diagnosis of a lower-grade glioma (grade II or grade III).

1p/19q co-deletion: what is the therapeutic impact?

Two trials – one result:

Adjuvant procarbazine, lomustine, and vincristine chemotherapy in newly diagnosed anaplastic oligodendroglioma: long-term follow-up of EORTC Brain Tumor Group Study 26951.

van den Bent et al., J Clin Oncol 2013

Phase III trial of chemoradiotherapy for anaplastic oligodendroglioma: long-term results of RTOG 9402.

Cairncross et al., J Clin Oncol 2013

PCV

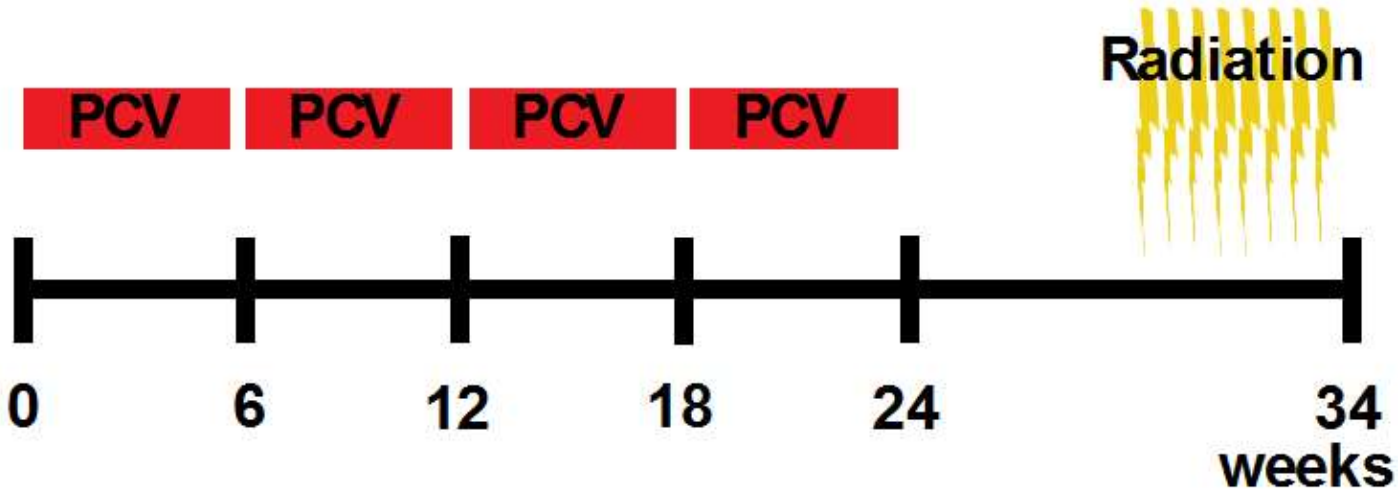
- Established in 1980s
- Combination not used in other tumor entities
- Differing schedules
  - PCV +/- radiation therapy
  - PCV before/after radiation therapy
  - Dose intensity

What is PCV?

Procarbazine	Lomustine (CCNU)	Vincristine
p.o.	p.o.	i.v.
Alkylating agent Breaking of DNA strands	Alkylating nitrosourea compound Breaking of DNA strands	Vinca alkoid Mitotic inhibitor – inhibiting the assembly of microtubule structures
Good penetration trough blood-brain-barrier	Good penetration trough blood-brain-barrier	Moderate to low penetration trough blood-brain-barrier
Molecular weight: 258 Da	Molecular weight: 233 Da	Molecular weight: 923 Da
Dose limiting side effects: Hematotoxicity High (>90%) emetogenic	Dose limiting side effects: Hematotoxicity	Dose limiting side effects: Peripheral neuropathy

ESTRO School

RTOG 9402



AO or AOA, age >=18, KPS >=60

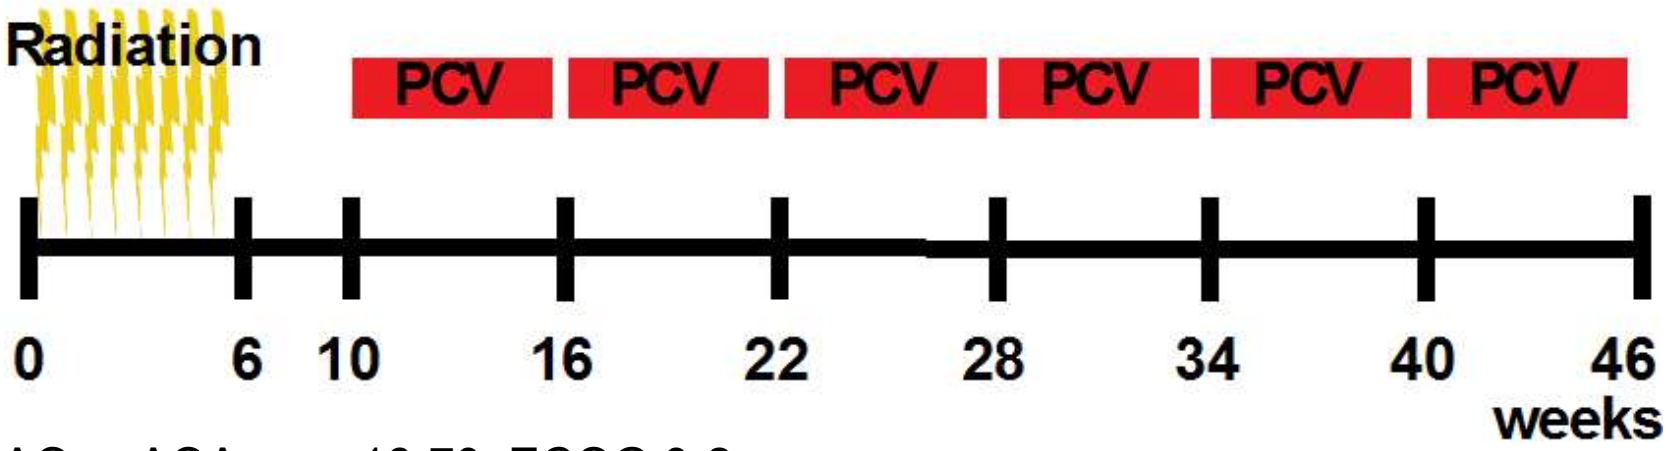
Intensive PCV followed by immediate involved-field RT (experimental arm) or RT alone (control arm).

RT: 59.4 Gy in 33 fractions (1.8 Gy each), 5 days a week. Patients randomly assigned to PCV plus RT began RT within 6 weeks of the last chemotherapy dose.

Cairncross et al., JCO 2013

ESTRO School

EORTC 26951



AO or AOA, age 16-70, ECOG 0-2

RT was to begin within 6 weeks from surgery and consisted of a dose of 45 Gy to be delivered to the planning target volume (PTV-1). Thereafter, a boost of 14.4 Gy (up to a cumulative dose of 59.4 Gy) was delivered to PTV-2

PCV chemotherapy consisted of up to six cycles of standard PCV chemotherapy and had to start within 4 weeks after the end of RT.

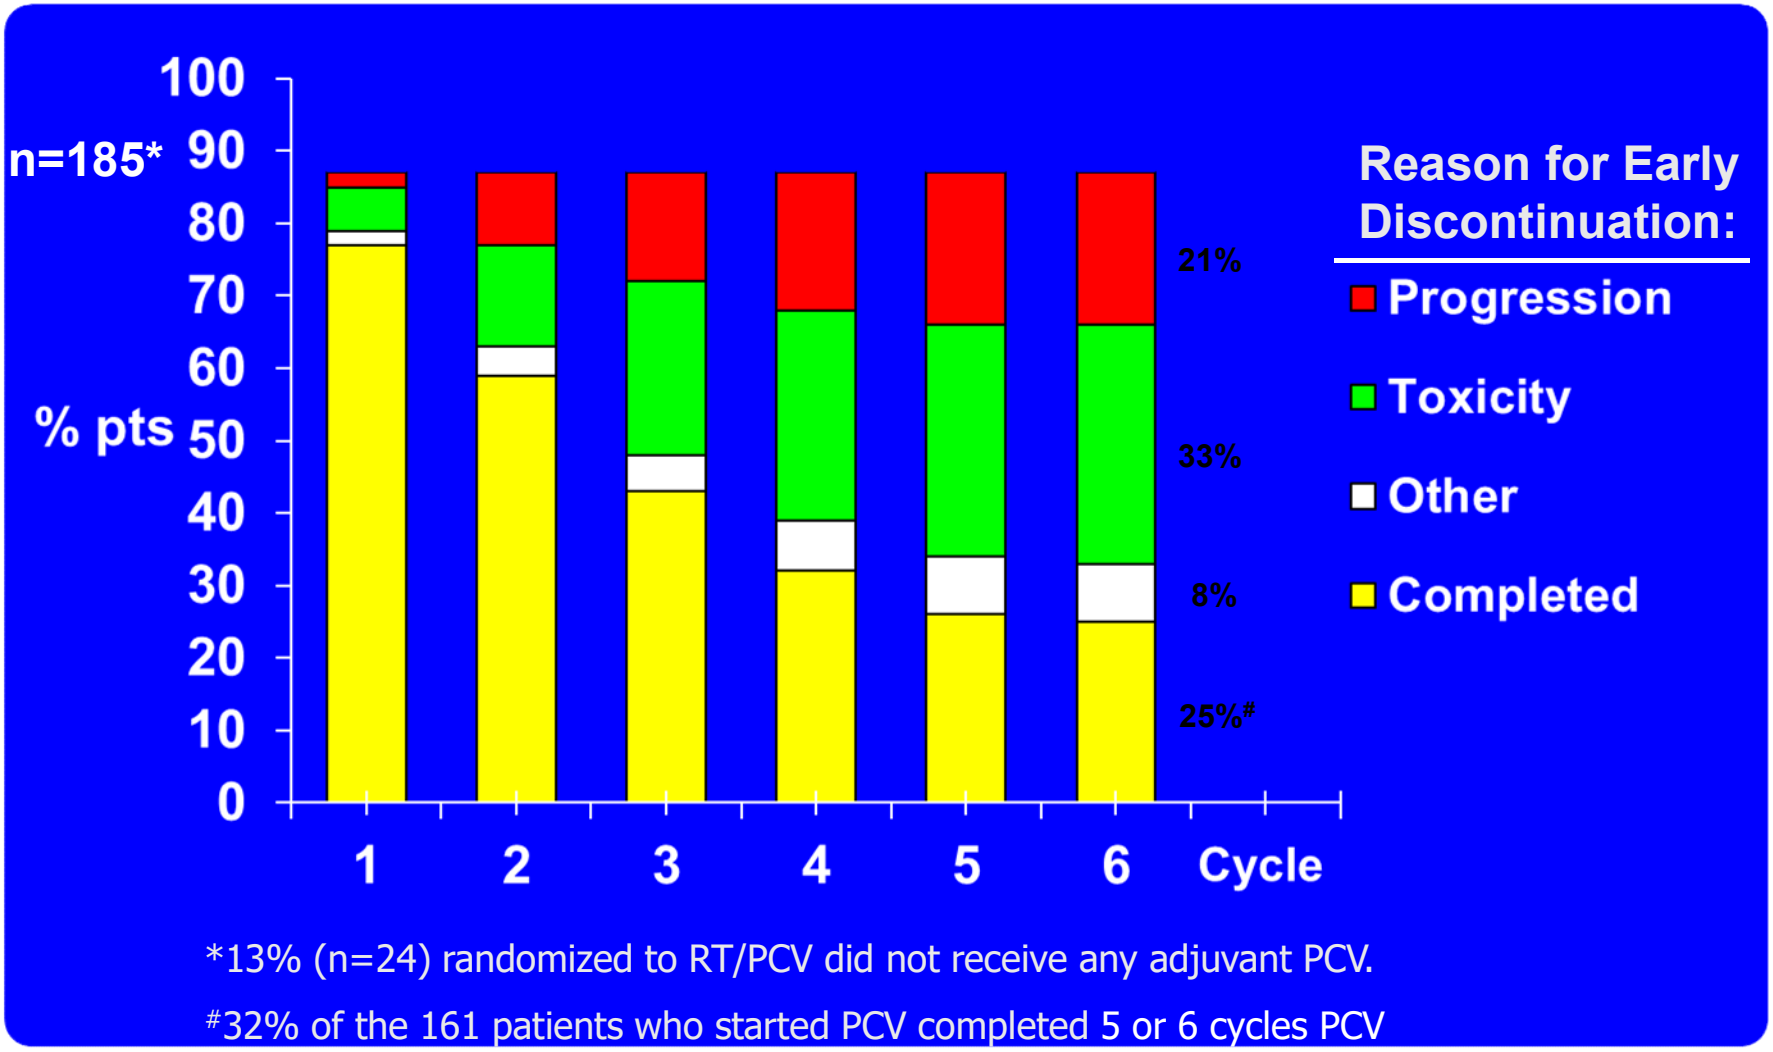
Van den Bent et al., JCO 2013

ESTRO School

PCV toxicities EORTC 26951 vs RTOG 9402

Toxicities (Grade 3/4)	EORTC 26951	RTOG 9402
Hematologic, any	46%	56%
Neutropenia	32%	42%
Thrombocytopenia	21%	37%
Anemia	7%	5%
Peripheral neuropathy	2%	8%
Nausea/vomiting	6%	8%
Toxicity leading to treatment stop	38%	20%

Reasons for discontinuation of PCV in EORTC 26951



*13% (n=24) randomized to RT/PCV did not receive any adjuvant PCV.

#32% of the 161 patients who started PCV completed 5 or 6 cycles PCV

Conclusions: 1p/19q co-deleted anaplastic gliomas

- The combination of RT and PCV may be regarded as standard of care for newly diagnosed 1p/19q co-deleted anaplastic gliomas
- RT → PCV and PCV → RT are both feasible options
- Temozolomide instead of PCV? => no final answer so far

And in patients with low-grade gliomas…?

Feasible options:

- Watch and wait
- Surgery
- Radiotherapy
- Chemotherapy
- Combined radiochemotherapy

And in patients with low-grade gliomas…?

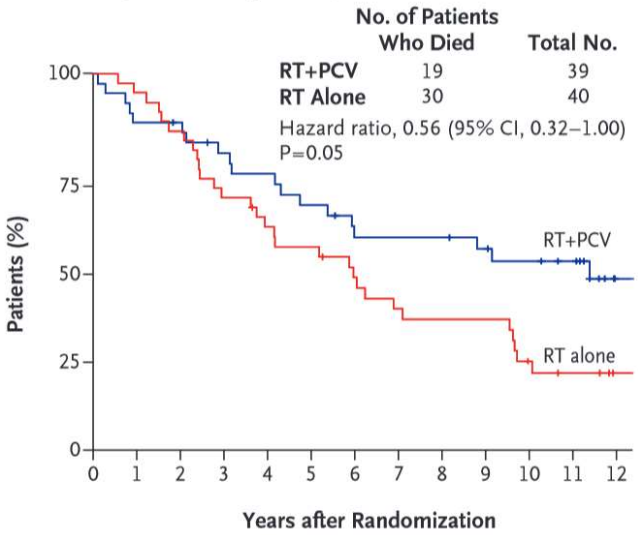
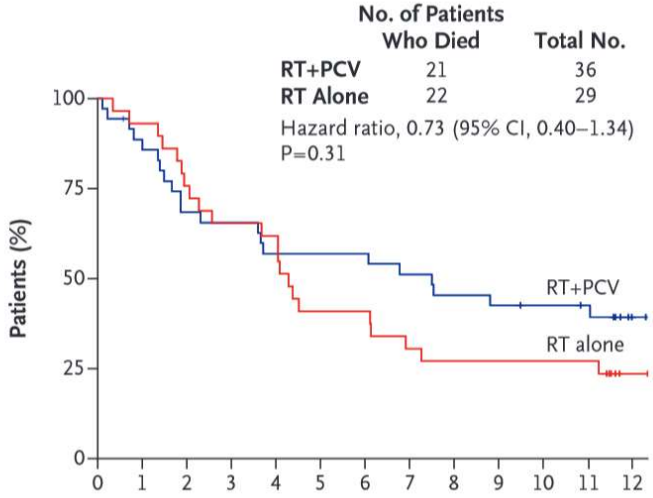
RT alone	57	56	53	53	50	45	45	40	35	31	28	24	11

C Overall Survival, Grade 2 Oligoastrocytoma



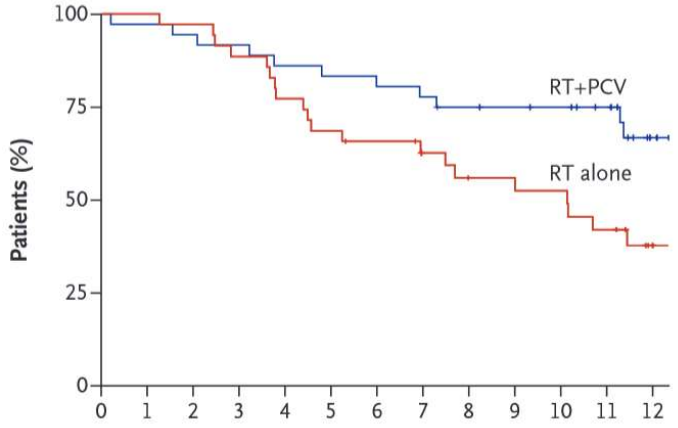
No. at Risk													
RT+PCV	39	34	33	29	27	24	21	20	20	18	16	14	6
RT alone	40	38	34	27	23	21	18	14	13	13	9	6	3

D Overall Survival, Grade 2 Astrocytoma



No. at Risk													
RT+PCV	36	31	24	23	20	20	20	18	16	15	14	14	9
RT alone	29	27	22	19	18	12	12	10	8	8	8	8	2

E Overall Survival among Patients with *IDH1* R132H Mutation



No. at Risk													
RT+PCV	36	35	34	33	31	30	29	28	26	25	24	21	12
RT alone	35	35	34	31	27	24	22	19	16	15	15	12	5

Conclusions

- Long-term data from **EORTC 26951** and **RTOG 9402** suggest RT + PCV as standard of care for patients with anaplastic glioma and 1p/19q co-deletion
- **NOA-04** data do not support an attempt to achieve comparable outcomes with monochemotherapy in patients with 1p/19q co-deleted tumors
- **RTOG 9802** long-term data suggest a benefit from RT/PCV compared to RT alone in the entire cohort of grade II tumors
- PFS and OS gain in the RTOG 9802 dataset is most prominent in patients with oligodendroglial (= **1p/19q co-deleted**?) tumors
- Whether **PCV** can be replaced by **temozolomide** remains unclear

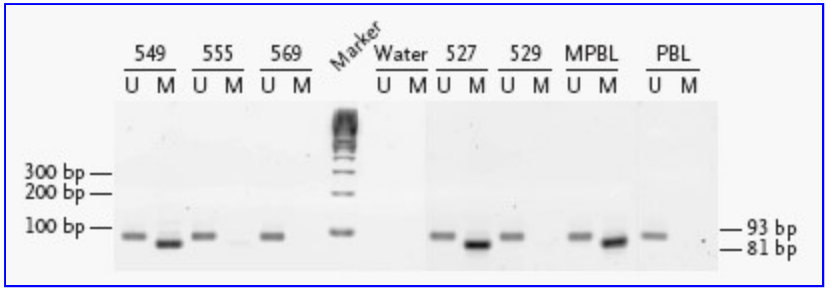
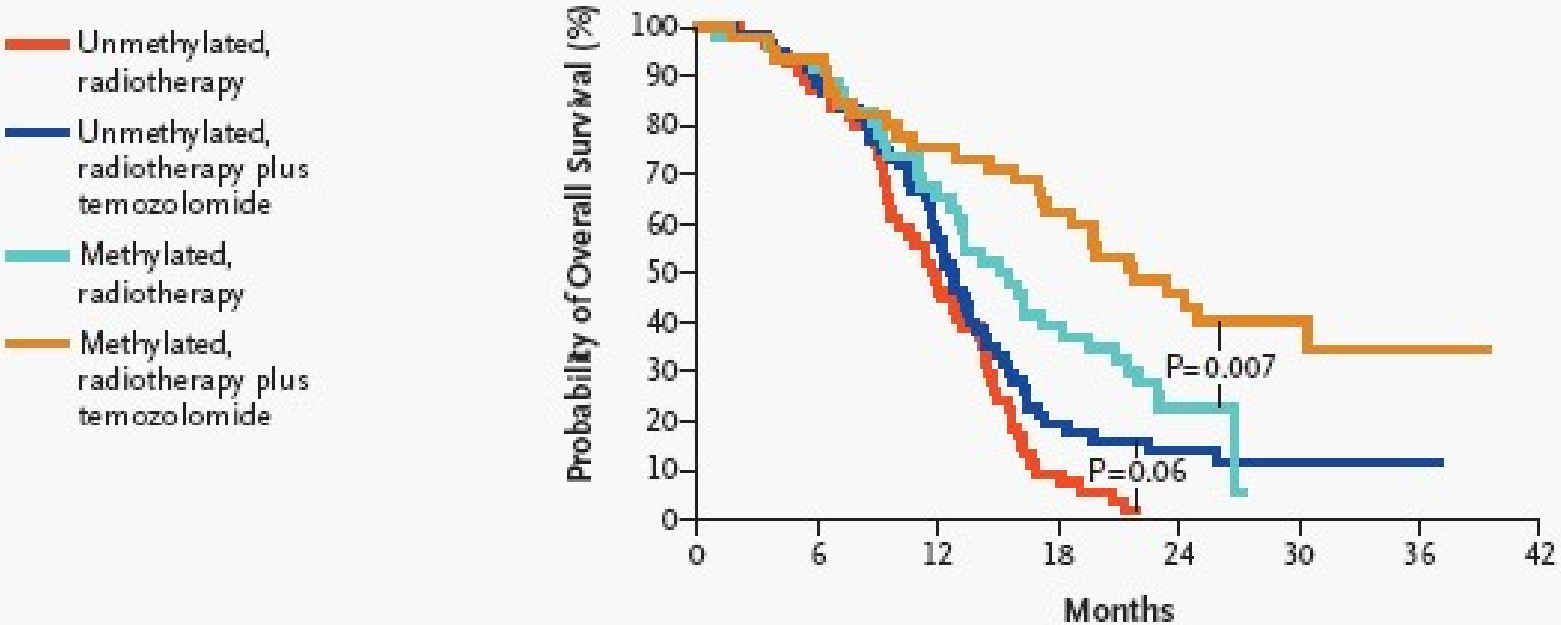
MGMT Gene Silencing and Benefit from Temozolomide in Glioblastoma

Monika E. Hegi, Ph.D., Annie-Claire Diserens, M.Sc., Thierry Gorlia, M.Sc.,





No. at Risk

Unmethylated, radiotherapy	54	47	25	5	0	0	0
Unmethylated, radiotherapy plus temozolomide	60	53	34	11	7	4	1
Methylated, radiotherapy	46	42	30	18	8	0	0
Methylated, radiotherapy plus temozolomide	46	42	34	28	16	7	1

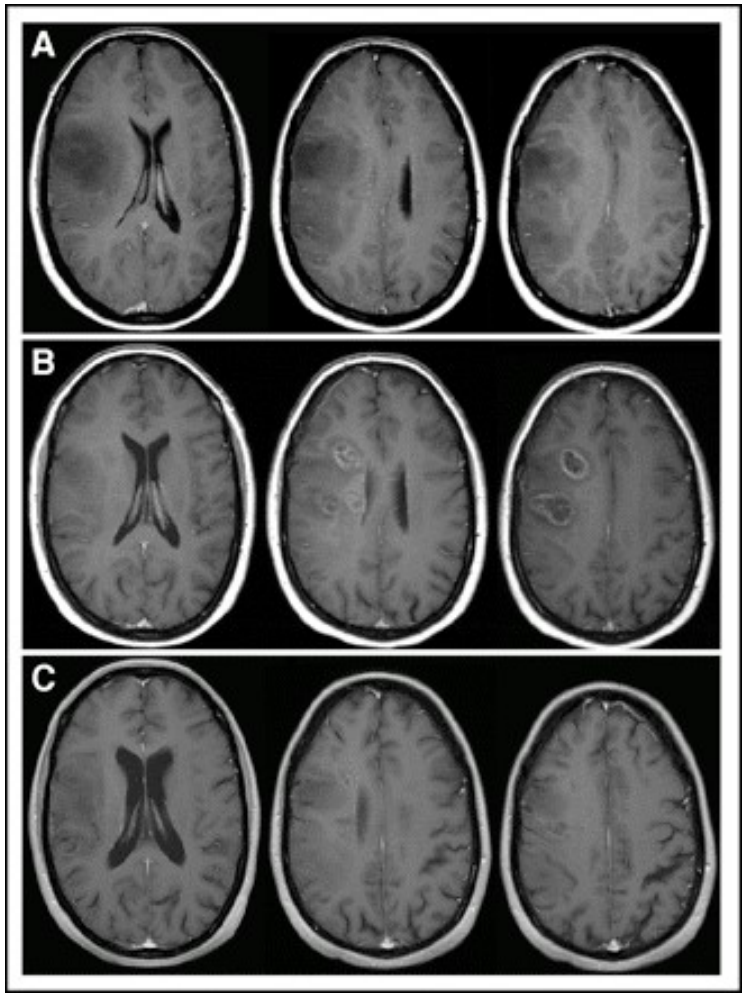
Chemoradiation for GBM: common issues

- continuous temozolomide associated with **lymphopenia**
  - exacerbated by prior and concomitant steroid treatment
  - prophylactic co-trimoxazole or pentamidine recommended if lymphocyte count <0.5
- occasional patients experience pancytopenia during concomitant treatment
- adjuvant temozolomide associated with **neutropenia, thrombocytopenia and fatigue**
- no increase in **late neurotoxicity** documented to date
- **'pseudoprogression'** on post-RT imaging
  - may reflect treatment related inflammation or necrosis
  - no validated imaging methods for discriminating progression from pseudoprogression

Post-op, pre-CRT

1 month post-CRT

6 months post-CRT



Lesion enlargement, evidenced at the first MRI scan in 50 of 103 patients, was subsequently classified as psPD in 32 patients and early disease progression in 18 patients.

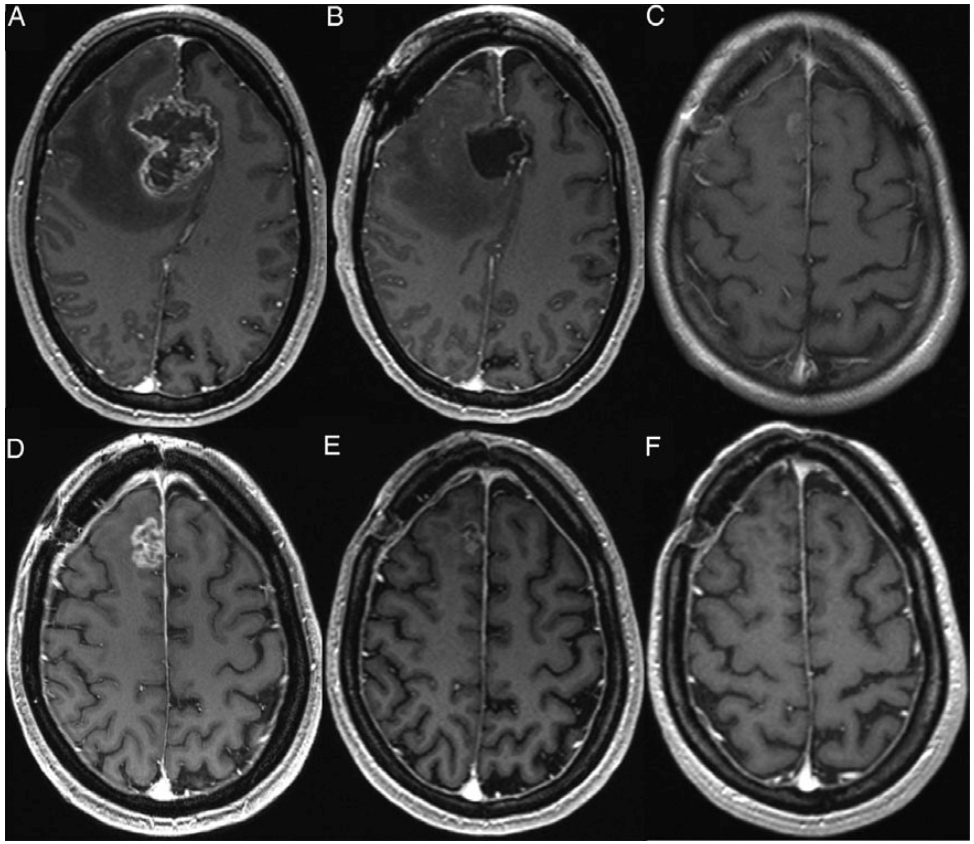
Brandes et al, J Clin Oncol 2008

Pseudoprogression in patients with glioblastoma: clinical relevance despite low incidence

Alexander Radbruch, Joachim Fladt, Philipp Kickingereder, Benedikt Wiestler, Martha Nowosielski, Philipp Bäumer, Heinz-Peter Schlemmer, Antje Wick, Sabine Heiland, Wolfgang Wick, and Martin Bendszus

To qualify for true progression or PsP, patients had to present an enhancement increase of at least 25% of an original lesion with ≥10 mm of perpendicular diameters or a new nodular component ≥10 mm within the radiation field in the first, second, third, or fourth f/u compared with the baseline

Neuro-Oncology 17(1), 151–159, 2015
doi:10.1093/neuonc/nou129



- 548 patients
- 79 fulfilled inclusion criteria
- Only 9 cases of pseudoprogression (11.4%)
- PsP detected at 1, 4 and 7 months

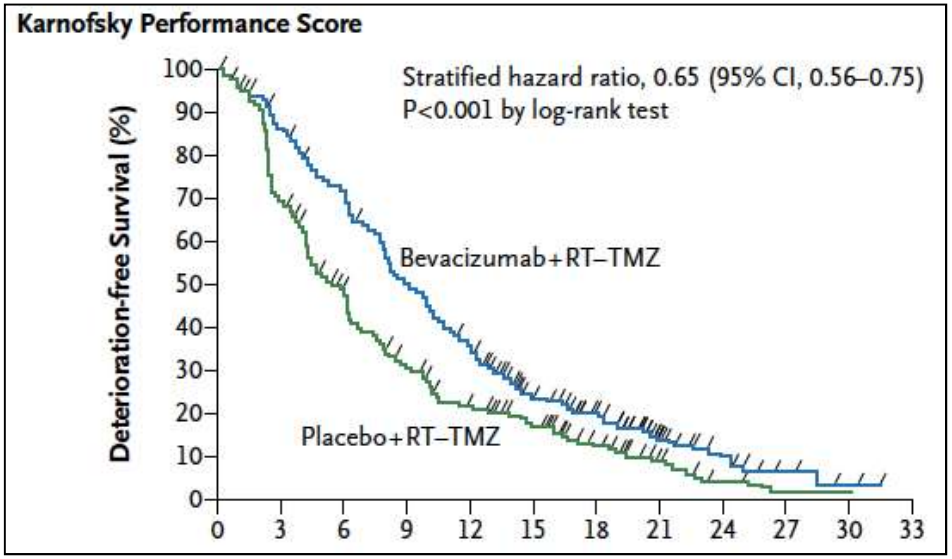
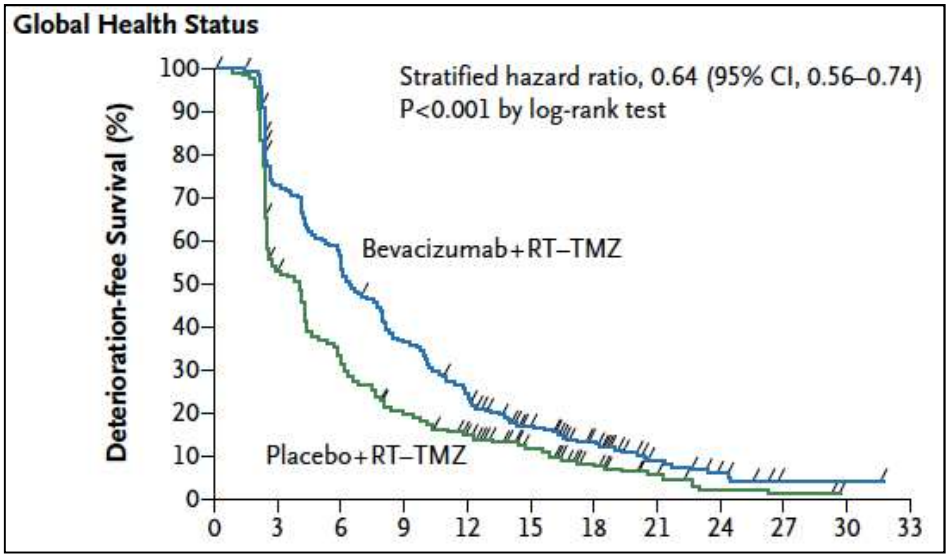
Does bevacizumab maintain QoL?





NET CLINICAL BENEFITS

In the NCB substudy, we found greater deterioration over time in the bevacizumab group than in the placebo group on the basis of the between-group difference in the composite scores on the neurocognitive-function test battery (P=0.05), as well as the scores for the Con-

Longitudinal evaluation also revealed greater deterioration in the bevacizumab group on the basis of the MDASI-BT composite symptom score (P=0.02), composite symptom-interference score (P<0.001), and the scores for activity-related

During the maintenance phase, serious adverse events were more prevalent in the bevacizumab group than in the placebo group, including hypertension (4.2% vs. 0.9%), thromboembolic disease (7.7% vs. 4.7%), wound dehiscence (1.5% vs. 0.9%), fatigue (13.1% vs. 9.0%), visceral perforation (1.2% vs. 0.4%), and serious hemorrhage (1.5% vs. 0.9%).

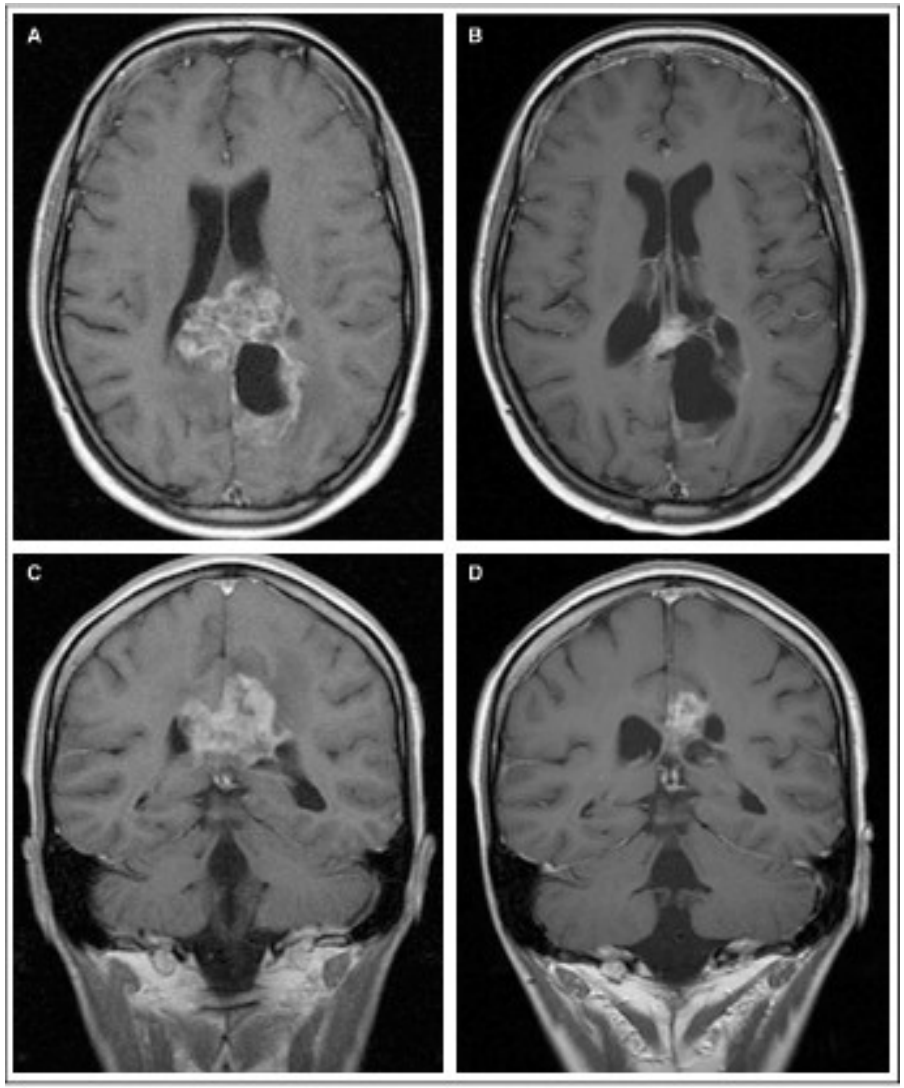
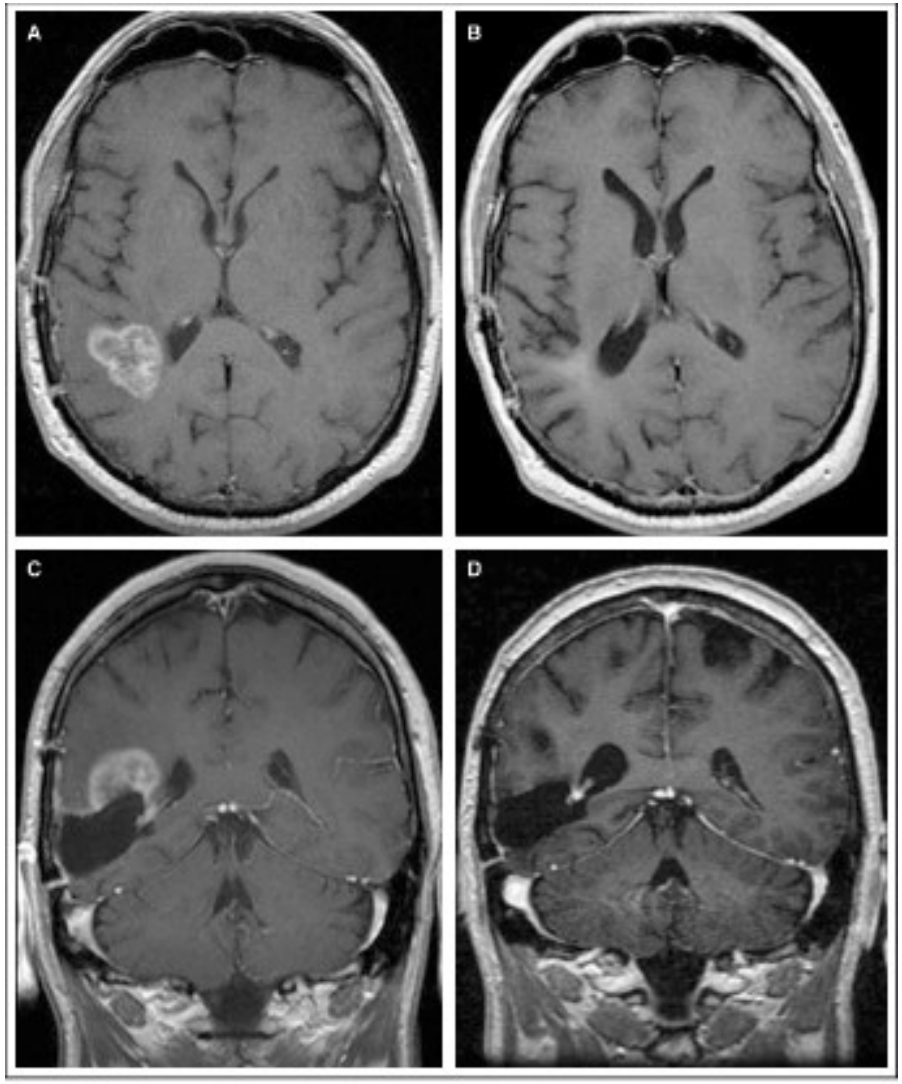
ORIGINAL REPORT

Bevacizumab Plus Irinotecan in Recurrent Glioblastoma Multiforme

James J. Vredenburgh, Annick Desjardins, James E. Herndon II, Jennifer Marcello, David A. Reardon, Jennifer A. Quinn, Jeremy N. Rich, Sith Sathornsumetee, Sridharan Gururangan, John Sampson, Melissa Wagner, Leighann Bailey, Darell D. Bigner, Allan H. Friedman, and Henry S. Friedman

- 35 patients, median 2 progressions
- Median time from diagnosis 14 months
- 57% RR
- 6 month PFS 46%
- 11 patients discontinued because of toxicity

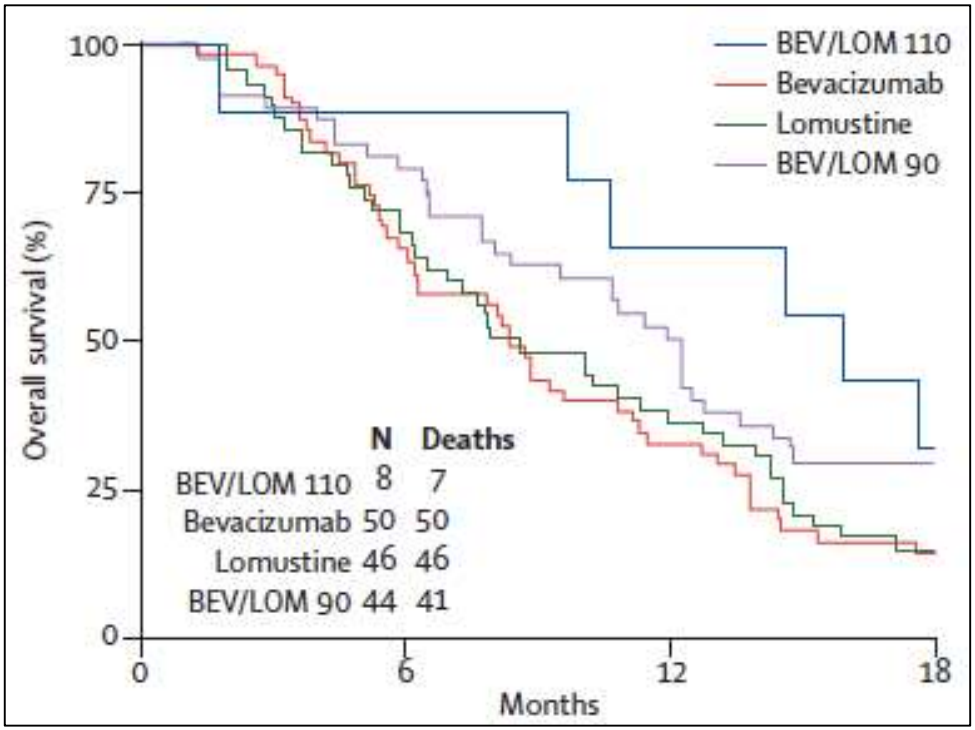




Response v. pseudoresponse?

Single-agent bevacizumab or lomustine versus a combination of bevacizumab plus lomustine in patients with recurrent glioblastoma (BELOB trial): a randomised controlled phase 2 trial

Walter Taal, Hendrika M Oosterkamp, Annemiek M E Walenkamp*, Hendrikus J Dubbink*, Laurens V Beerepoot, Monique C J Hanse, Jan Buter, Aafke H Honkoop, Dolf Boerman, Filip Y F de Vos, Winand N M Dinjens, Roelien H Enting, Martin J B Taphoorn, Franchette W P J van den Berkmortel, Rob L H Jansen, Dieta Brandsma, Jacoline E C Bromberg, Irene van Heuvel, René M Vernhout, Bronno van der Holt, Martin J van den Bent*



PFS-6: 11% MGMT unmethylated
40% MGMT methylated

Immune checkpoint inhibition

"Bristol-Myers Squibb today announced that CheckMate -143, a randomized Phase 3 clinical trial evaluating the efficacy and safety of *Opdivo* (nivolumab) in patients with first recurrence of glioblastoma multiforme (GBM), did not meet its primary endpoint of improved overall survival over bevacizumab monotherapy."

Sativex (GW Pharma)

- Cannabinoid mix
  - 1:1 THC + CBD
  - From *Cannabis sativa*
  - (≠ cannabis)
  - Oromucosal spray
  - Individual dose titration
  - Widely used in MS, cancer pain, nausea, epilepsy

Mechanisms

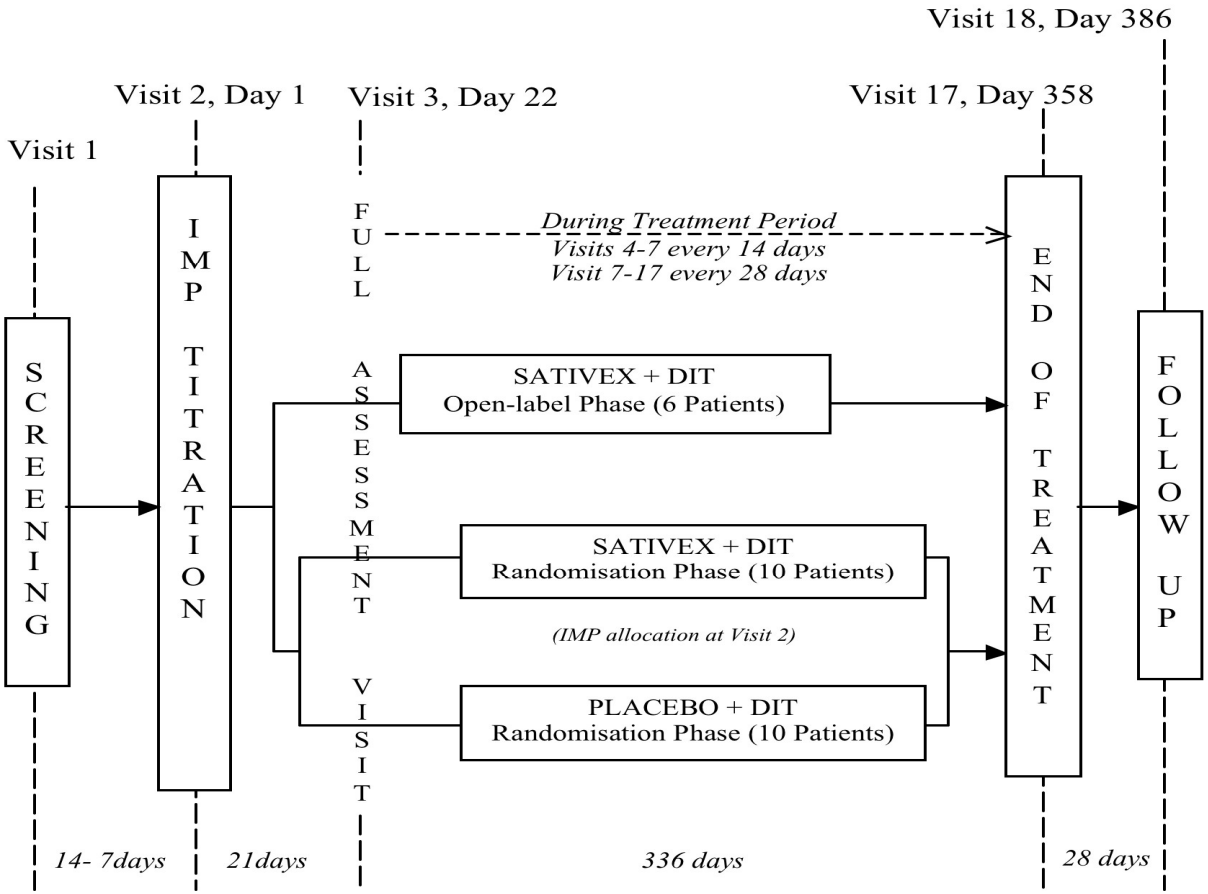
- Pro-apoptotic
- Via ER stress (autophagy) pathways

  - In vitro data in established cell lines
    - GBM stem-like lines
    - Additive/synergism w TMZ and XR

  - In vivo data in standard orthotopic models
    - Enhanced growth delay w TMZ and XR

Study overview

- Open label PhI, run in to randomised, placebo controlled Ph Ib



Dose Intense TMZ: 85mg/m^2 21 q28.

Self titrate Sativex after 7d TMZ: Min 3 max 12 sprays/day

Sativex study – preliminary data

1 year OS 83% vs 44%
PFS-6: 42% vs 33%

PFS-6 from DIRECTOR trial: 21%

Any questions?

Management of ependymoma of the brain and spinal cord

Sarah Jefferies

Overview

- Excellent update on surgery and the recent molecular advances
- Overview of evidence for adjuvant treatment in children
- Overview of evidence for adjuvant treatment in adults

Treatment

- **Surgery**
  - Gross total resection
  - Re-resection for recurrence

- **Adjuvant Treatments**
  - Radiotherapy
  - (+re-irradiation)

  - Chemotherapy

Evidence for surgery

Is gross-total resection sufficient treatment for posterior fossa ependymomas?

LELAND ROGERS, M.D., JEANETTE PUESCHEL, M.D., ROBERT SPETZLER, M.D., WILLIAM SHAPIRO, M.D., STEPHEN COONS, M.D., TERRY THOMAS, M.S., AND BURTON SPEISER, M.D., M.S.

AT-23. A PHASE II STUDY OF LAPATINIB AND DOSE-DENSE TEMOZOLOMIDE (TMZ) FOR ADULTS WITH RECURRENT EPENDYMOMA: A CERN CLINICAL TRIAL

- First randomised study in adult ependymoma
- Patient related outcomes
- Molecular information collected
- 50 patients enrolled
- Await further follow-up

Neuro-Oncology 16:v8–v22, 2014.

So what to do in adults?

Myxopapillary ependymoma

- Gross total resection
  - no need for further treatment
  - imaging follow-up
- Sub-total/recurrence
  - Radiotherapy
- Further recurrence
  - No standard chemotherapy

So what to do in adults?

Grade II Ependymoma

- Gross Total Resection – observation

Grade II subtotal/Grade III

- radiotherapy

Recurrence

- no proven role for chemotherapy
- ? Re-irradiation

Radiation Doses

Radiotherapy Dose

- Children:
  - 54 Gy/30#
  - High risk 59.4 Gy/33#*
- Adult:
  - 54Gy -60GY/30-33#

* Netson KL, Conklin HM, Wu S, Xiong X, Merchant TE. A 5-year investigation of children's adaptive functioning following conformal radiation therapy for localized ependymoma. Int J Radiat Oncol Biol Phys 2012;84:217-23.

Re-irradiation?

Ependymoma recurrence:

~ 40% local

~ 40% metastatic

~ 20% local and metastatic

Survival Benefit for Pediatric Patients With Recurrent Ependymoma Treated With Reirradiation

ESTRO School

Primary CNS lymphoma

- Lymphoma with exclusive manifestation in the CNS
- Median age: ~ 60 years
- Incidence: approximately 0.5/100.000

  => increasing for unkown reasons
- Particular situation: HIV-associated CNS lymphomas

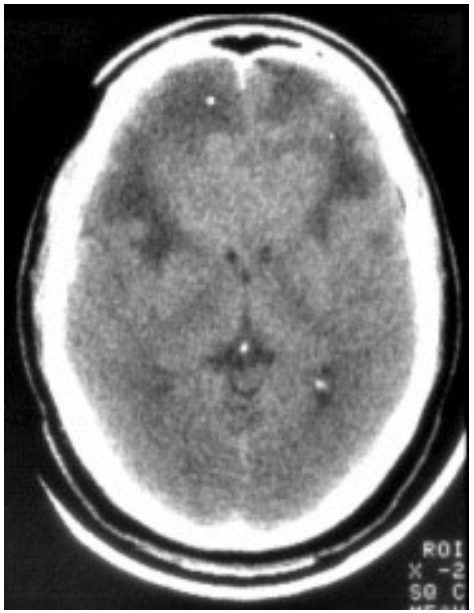
  => incidence decreasing since introduction of HAART
- Unclear pathogenesis => specific CNS tropism?

Clincal presentation

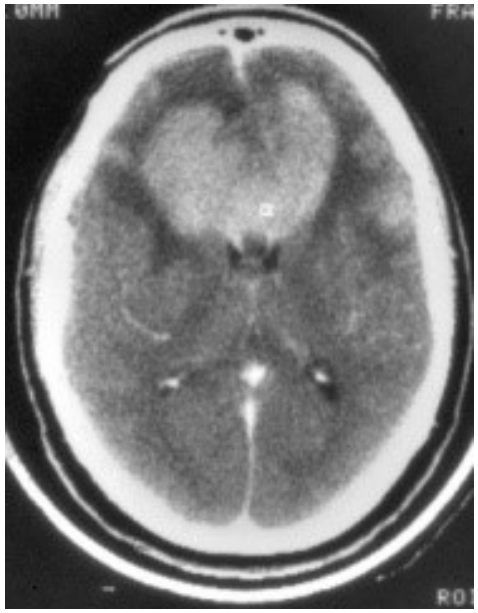
- Personality changes
- Symptoms associated with increased intracranial pressure
- Motor and sensory deficits
- Cranial nerve palsies
- Seizures (rare)
- Cerebellar symptoms

Imaging: CT

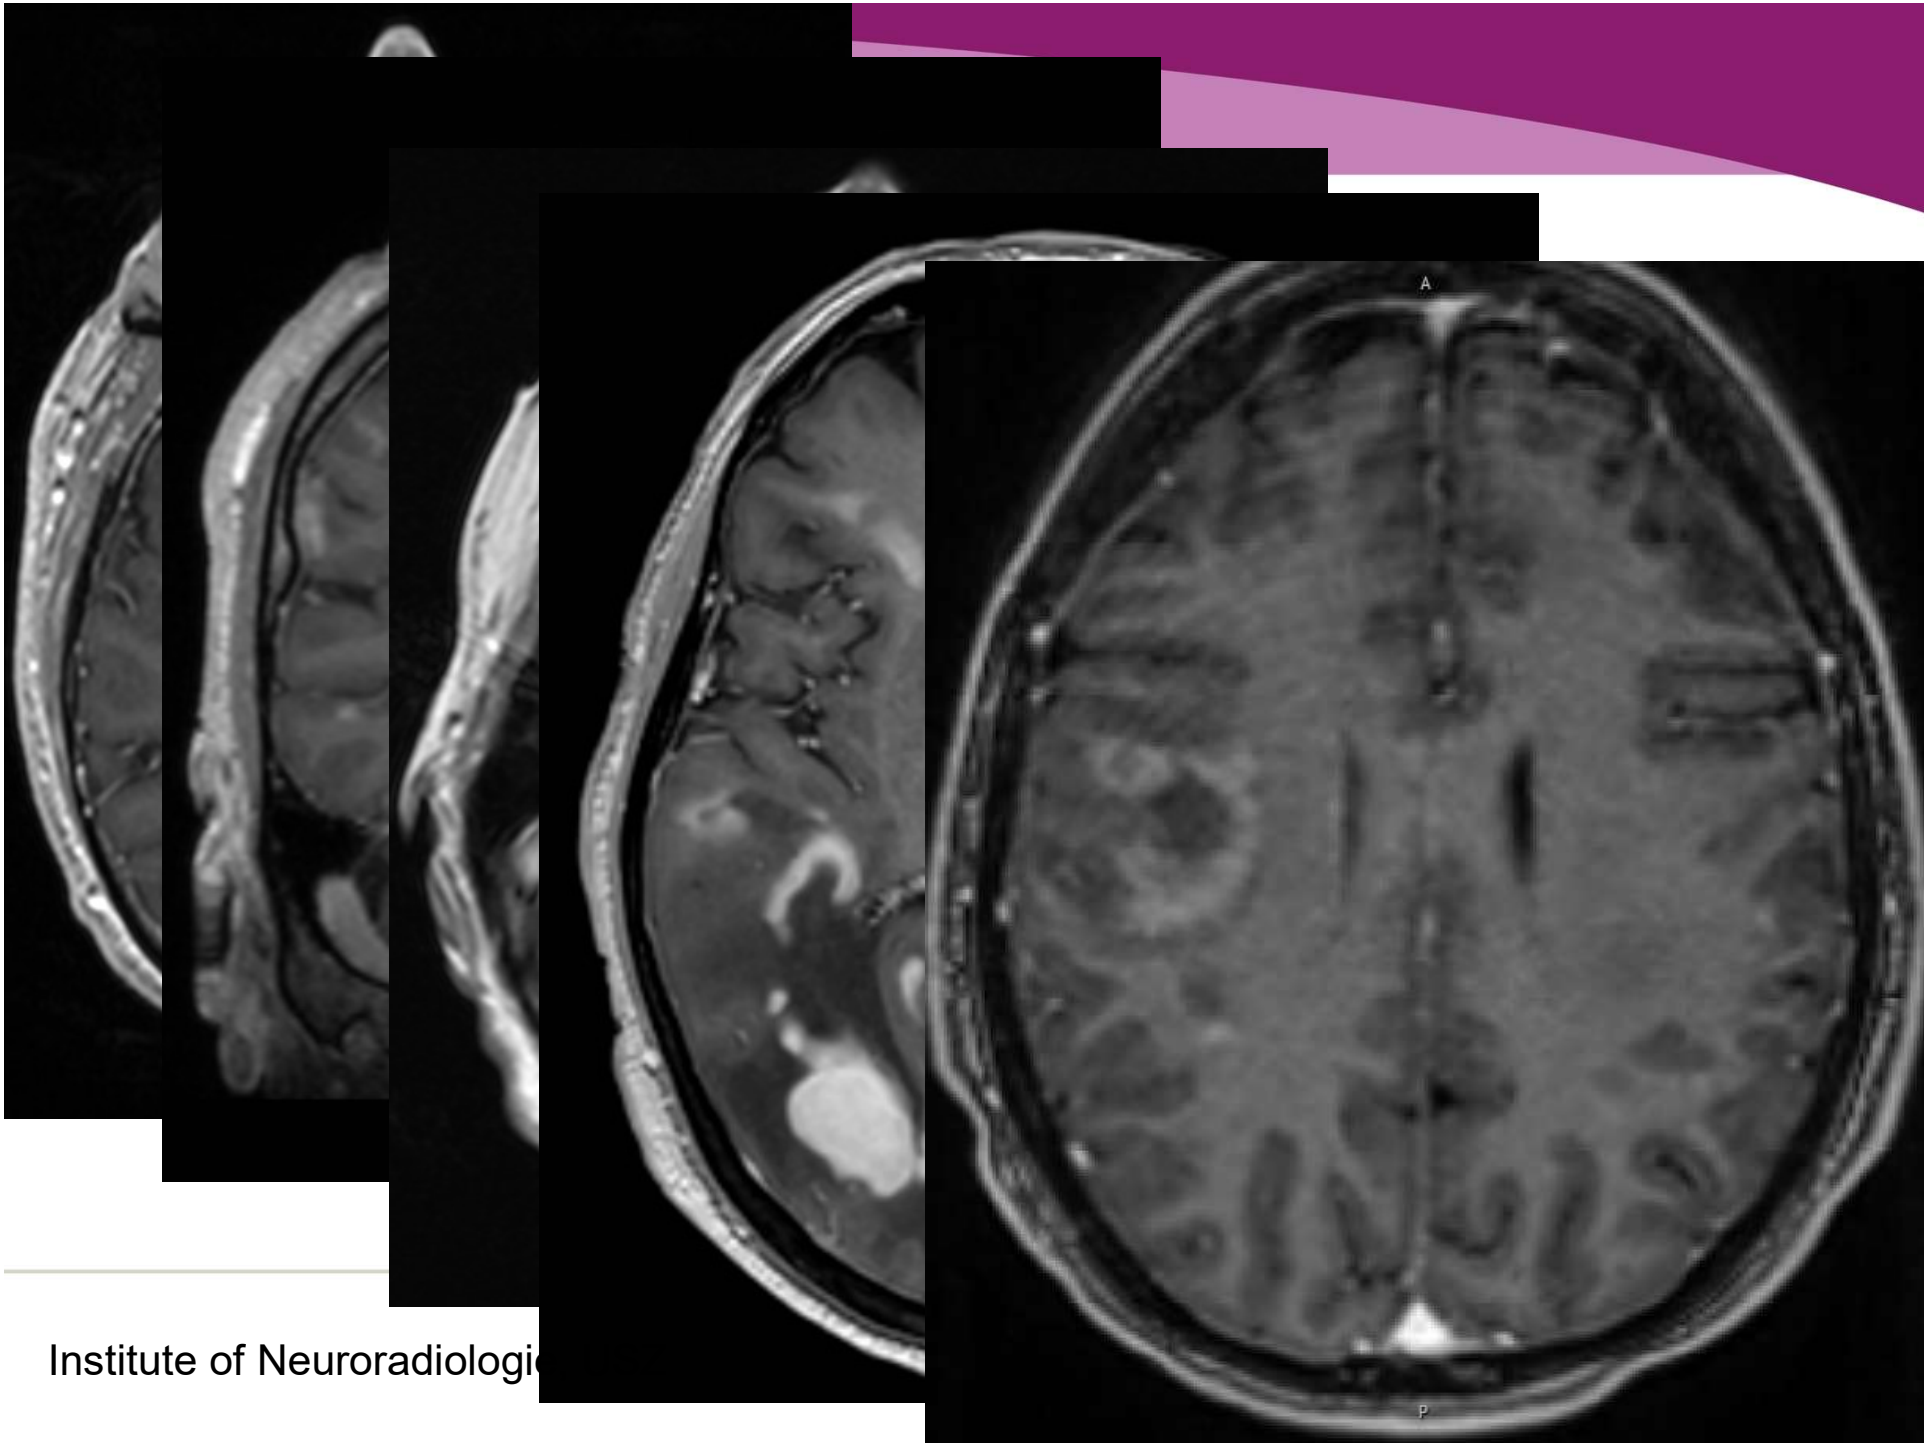
- Iso- or hyperdense mass
- Multiple lesions in about 30-40% of all patients



native



contrast



A
P

How to confirm the diagnosis

- Lumbar puncture: dissemination in the CSF in 20-30% of the patients with newly diagnosed PCNSL

  => Confirmation of a malignant B cell clone (FACS) or clonal IgH rearrangement using PCR

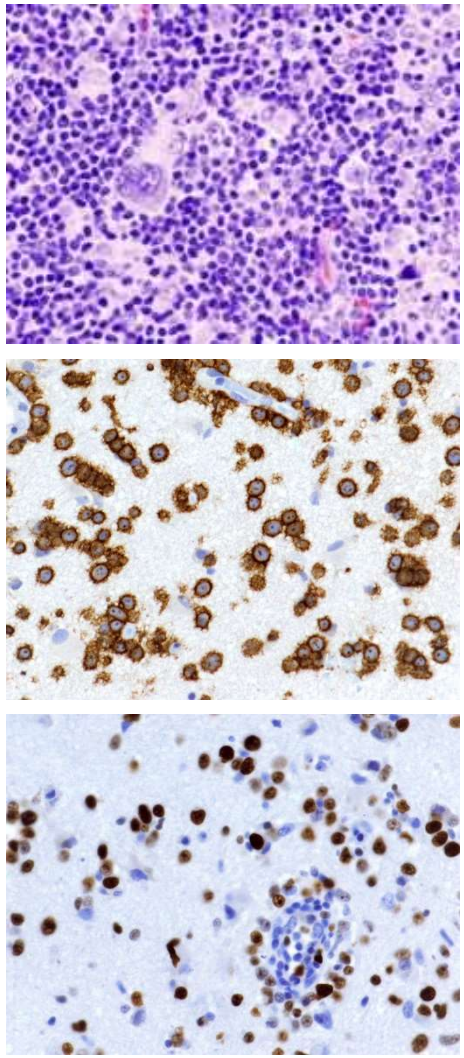
- Stereotactic biopsy: do not administer steroids before!
- Tumor resection does not affect survival – really…?

Staging:

- Slit lamp examination (ocular involvement in 10-15%)
- CT scan chest and abdomen, bone marrow biopsy
- HIV testing

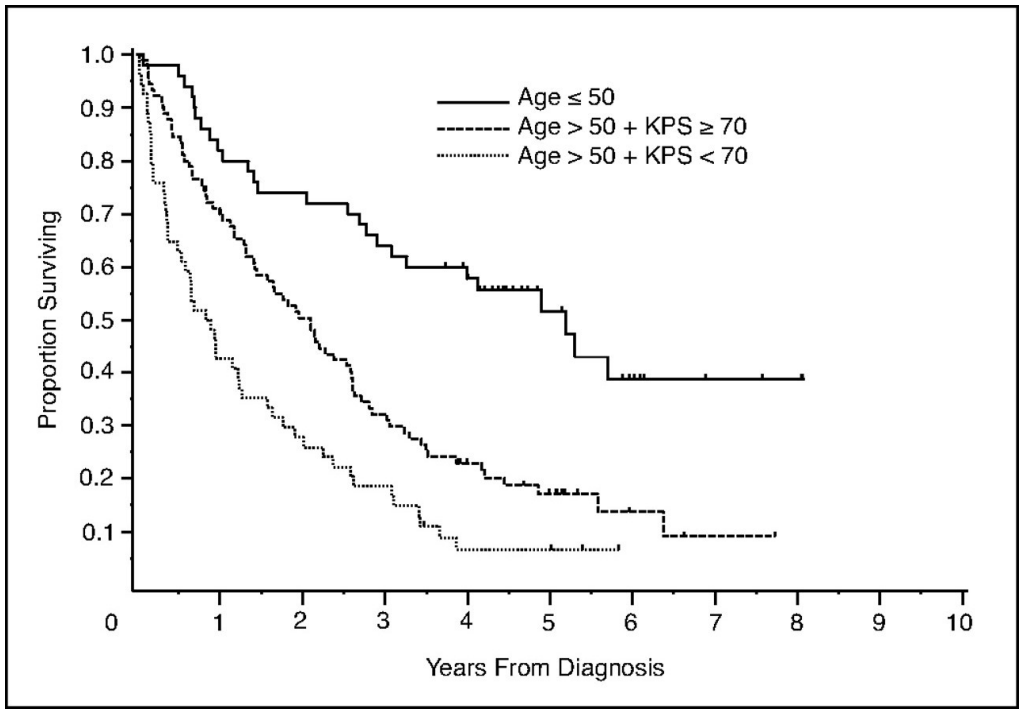
Histology

- Diffuse large B cell lymphoma (98%)
- $CD20^{+}$
- High proliferation index (>50% $Ki\text{-}67^{+}$)



Prognosis

- Survival without treatment: weeks / few months
- Age and performance status are the most important prognostic factors



Abrey et al. J Clin Oncol 2006

- Histological subtype is **not** a prognostic factor

ESTRO School

Treatment of PCNSL: what do we know?

- WBRT (>40 Gy)

  Median OS 12 months, <5% 5-year survival (Nelson et al., 1992)

- High-dose methotrexate (HD-MTX): most active drug

  Median survival approximately 25 months

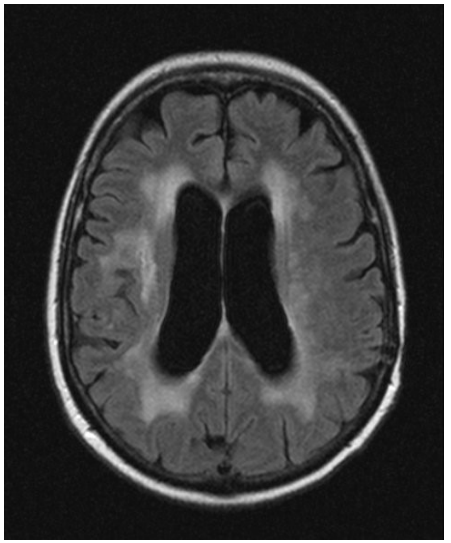
  ~25% surviving 5 years or more (Herrlinger et al., 2005)

- HD-MTX + intrathecal MTX + WBRT

  Median OS 42 months, 25% 5year survival (Abrey et al., 1998, DeAngelis et al., 2002)

  BUT: up to 60% of all patients (and virtually ALL elderly patients) suffer from severe **neurotoxicity** (Abrey et al., 1998; Herrlinger et al., 2001; Harder et al., 2004)

=> no longer appropriate



ESTRO School

IELSG-20: MTX vs. MTX/Ara-C

- Randomized phase II trial, 24 centers, 6 countries
- 79 patients, age 18-75 Jahre
- 4 cycles of MTX, 3.5 g/m^2 alone **OR** MTX plus 4x Ara-C, 2 g/m^2 d2+3, every 3 weeks, followed by WBRT
- CR rate after MTX-based therapy:
  18% (MTX) versus 46% (MTX + Ara-C)
- Hematological toxicity more frequent and severe with combination

No role for resection – for 4 decades

PRIMARY MALIGNANT LYMPHOMAS OF THE CENTRAL NERVOUS SYSTEM

JAMES M. HENRY, MAJ, MC, USA, REID R. HEFFNER, JR, MD,
SAMUEL H. DILLARD, MAJ, MC, USA, KENNETH M. EARLE, MD,*
AND RICHARD L. DAVIS, MD†

Eighty-three cases of primary malignant lymphomas of the central nervous system (CNS) from the files of the AFIP were studied according to various clinical and pathologic parameters. The histologic patterns observed are analogous to those seen in the spectrum of malignant lymphomas arising in the reticuloendothelial system of other organs. The authors favor the diagnosis of primary malignant lymphoma of the CNS rather than that of "reticulum cell sarcoma" or "microgliomatosis" used in the past. Lesions are frequently multifocal, and surgery, other than for diagnostic biopsy, is not usually beneficial. The clinical course can be significantly prolonged by radiation therapy.

Novel agents: PD-1 inhibitors

PD-1 blockade with nivolumab in relapsed/refractory primary central nervous system and testicular lymphoma

Lakshmi Nayak,[1,2] Fabio M. Iwamoto,[3] Ann LaCasce,[1,2] Srinivasan Mukundan,[1,2] Margaretha G. M. Roemer,[1] Bjoern Chapuy,[1] Philippe Armand,[1,2] Scott J. Rodig,[1,2] and Margaret A. Shipp[1,2]

[1]Dana-Farber Cancer Institute, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; and [3]New York Presbyterian Hospital, New York, NY

Key Points

- Genetic analysis reveals frequent 9p24.1/PD-L1/PD-L2 copy-number alterations and increased expression of the PD-1 ligands in PCNSL and PTL.
- PD-1 blockade with nivolumab demonstrated activity in patients with relapsed/refractory PCNSL and PTL.

Primary central nervous system (CNS) lymphoma (PCNSL) and primary testicular lymphoma (PTL) are rare extranodal large B-cell lymphomas with similar genetic signatures. There are no standard-of-care treatment options for patients with relapsed and refractory PCNSL and PTL, and the overall prognosis is poor. PCNSLs and PTLs exhibit frequent 9p24.1 copy-number alterations and infrequent translocations of 9p24.1 and associated increased expression of the programmed cell death protein 1 (PD-1) ligands, PD-L1 and PD-L2. The activity of PD-1 blockade in other lymphomas with 9p24.1 alterations prompted us to test the efficacy of the anti–PD1 antibody, nivolumab, in 4 patients with relapsed/refractory PCNSL and 1 patient with CNS relapse of PTL. All 5 patients had clinical and radiographic responses to PD-1 blockade, and 3 patients remain progression-free at 13^+ to 17^+ months. Our data suggest that nivolumab is active in relapsed/refractory PCNSL and PTL and support further investigation of PD-1 blockade in these diseases. (*Blood*. 2017;129(23):3071-3073)

blood

ESTRO School

Take home messages

- Cure is probably restricted to younger patients
- Standard of care is only poorly defined

  => further trials are urgently needed

- HD-MTX as the therapeutic backbone / rituximab increasingly used
- WBRT should be avoided in the first-line setting

- Open questions:
  - Role for new drugs, e.g. immune checkpoint inhibitors, ibrutinib…?
  - Optimal treatment for elderly/frail patients?

Multicenter pilot study of radiochemotherapy as first-line treatment for adults with medulloblastoma (NOA-07)

Dagmar Beier

- prospective descriptive multicenter single-arm phase II trial to evaluate feasibility and toxicity of radio-polychemotherapy.
- **The NOA-07 trial combined CSI with vincristine**
  Maintenance CT 8 cycles of cisplatin, lomustine, and vincristine.
- Primary endpoint was the rate of toxicity-related treatment terminations after 4 chemotherapy cycles, and the toxicity profile.
- The feasibility goal was reached if at least 45% of patients received at least 4 cycles of maintenance chemotherapy.

Multicenter pilot study of radiochemotherapy as first-line treatment for adults with medulloblastoma (NOA-07)

Dagmar Beier

Results N=30 pts ; 50% showed classic and desmoplastic/nodular histology. 67% were classified into SHH subgroup without *TP53* alterations, 13% in WNT, 17% in non-WNT/non-SHH.

- Four cycles of CT were feasible in the majority (*n* = 21; 70.0%).
- *Hematological side effects and polyneuropathy were prevalent toxicities.*
- The 3-year event-free survival rate was 66.6% at the time of databank lock.

- RT/CT did lead to considerable toxicity in adults, dose reductions through out the first 4 CT cycles
- Modifications on CT have to be performed

Medulloblastoma in adults

Medulloblastoma

Arguments for additional Chemotherapy

⇨ Additional adjuvant CT improves the prognosis in „Standard „ and „High Risk“ Patients

⇨ Additional adjuvant CT allows to reduce the RT-Dose in CSI? (36 Gy to 23.4 Gy) (Reduction of Neurotoxicity)

⇨ Additional adjuvant CT prevent late relapses and the Risk for metastasis outside the craniospinal region.

Medulloblastom in Adults

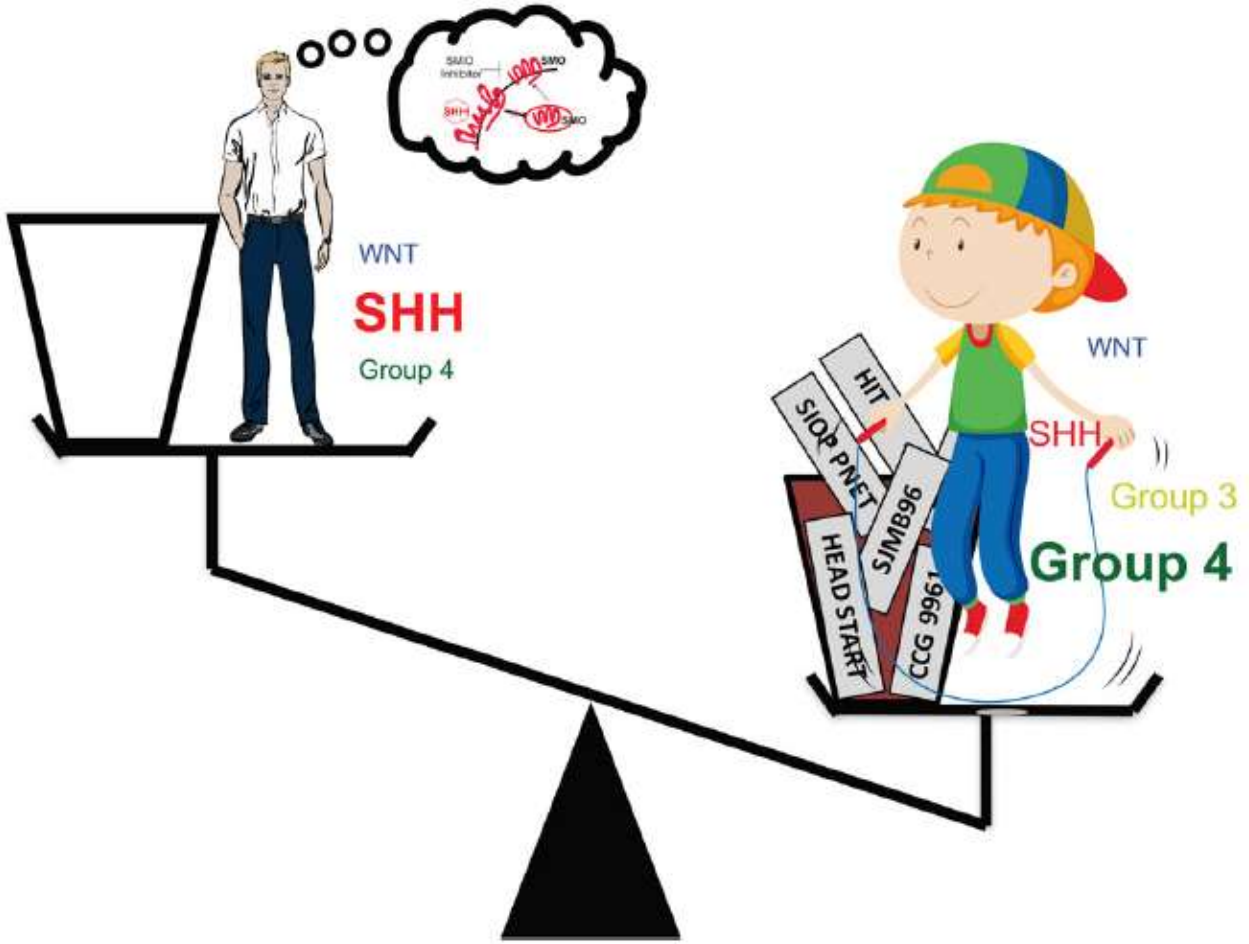
Medulloblastoma
Arguments *against* additional Chemotherapy

⇨ **The additional adjuvant CT is not practible with Standard protokoll („Packer“) for „standard risk „ Patients . Therefore a dose reduction in the spinal axis (von 36 auf 23.4 Gy) should be taken into account. Data Padovani ?**

⇨ **Additional adjuvant CT increases Toxicity without improving the prognosis (Greenberg et al., 2001).**

⇨ **All hyperfractionated RTs for „standard risk“ patients result in identical OS with only minor neurocognitive dysfunction. (M-SFOP 98, Mumbai) im Vergleich mit reduz. kon. RT mit Chx.. eine zusätzl. Chx.ist daher verzichtbar.**

Medulloblastoma in adults: they're not just big kids



Molecular characterisation will be done in Adults and is the Base for individual Treatment

Medulloblastoma in Adults
Conclusion

Actual Standard

postop. RT CSI 36 Gy / 54 Gy boost PF

(Boost only to the Tumor ?)

Dose reduction is not possible at the moment

Chemotherapy for „Standard risk „ ?

Feasibility and effectiveness?

New Concepts ? RT- CT ?

CT- Protocol for „High risk“ ?

Molecular markers for choosing individual MB Therapy

Molecular markers and the concept of biological Risk Profile will Influence MB Therapy .

Treatment concepts of the children cannot be adopted one by one for adults, studies are needed.

Management of medulloblastoma in children

Darren Hargrave

Consultant Paediatric Oncologist,

Neuro-oncology & Experimental Therapeutics

Great Ormond Street Hospital. London, UK.

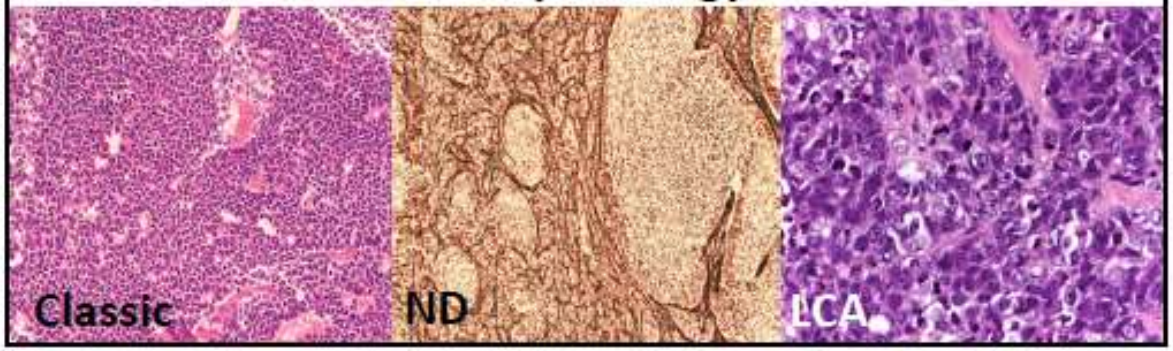
ESTRO School

Medulloblastoma: an aggressive and complex brain tumor

Posterior Fossa Location
20% of all pediatric brain tumors

Metastasis

Histopathology



School

Medulloblastoma

- Most common malignant CNS tumour in children
- Tremendous progress over last 20 years
  - Treatment
  - Biology >>> several distinct subtypes

Medulloblastoma

- 15-20% of all CNS tumors in children

- Bimodal peak incidences at ages 3-4 and 8-9 years

- 10/15% in infancy

- 70% <16 years

- Very rare after age 40

- Rate M:F 1.4 : 1

Medulloblastoma - Aetiology

- Unknown for most patients
- Familial cases
    - SIR 4.1 for siblings

- Genetic susceptibility

Genetic susceptibility
-Seen in several familiar cancer predisposition syndromes (Gorlin syndrome, Turcot syndrome, Li-Fraumeni syndrome, Fragile X syndrome,….)
-Frequency 10% overall, 30% of pts < 3 years
-Genetic counselling/screening of family members

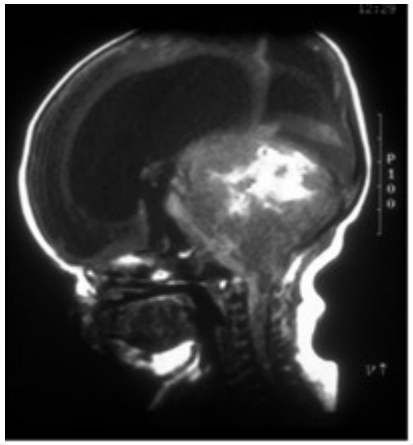
ESTRO School

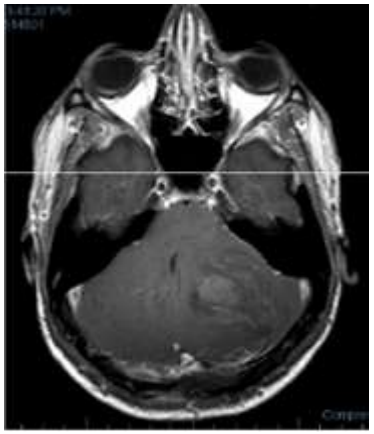
Medulloblastoma - Clinical presentation

- Typical midline location, arising in the vermis, causing IVth ventricle compression (symptoms and signs of raised intracranial pressure)

- In infants increase in head circumference, bulging of the fontanelles

- Hemispheric location more common in very young children and adults (lateralising difficulties with coordination: ataxia and dysmetria)





Medulloblastoma - Spread

- Frequency of leptomeningeal seeding at diagnosis 30-35%
- Greater in infants and very young children
- Extra CNS metastases very uncommon (<5%) [lymph nodes, bone, bone marrow]

ESTRO School

Medulloblastoma - Work-up

- Pre-op craniospinal MR imaging
- Post-op cranial MR 24-48 hours after surgery
- MRI of spine pre or post-op > 14 d
- Lumbar CSF cytology > 14 d post-op

Chang staging system for metastases

- M0: no metastases
- M1: CSF cytology +ve
- M2: macroscopic seeding in subarachnoid space, IIIrd or lateral ventricles
- M3: macroscopic seeding along spinal axis
- M4: extra-CNS spread

Medulloblastoma - Prognosis

Prognosis depends on……..

-Extent of primary tumor/completeness of surgical resection

-Presence or absence of leptomeningeal seeding

Medulloblastoma - Prognosis

Risk groups for management

- Standard risk
  - GTR/residual tumour <1.5 cm² on post-op MRI
  - No leptomeningeal seeding by MRI of the spine or lumbar CSF cytology (M0)
- High risk
  - All others (1/3 to 1/2 all)
- Infants and very young children

ESTRO School

Medulloblastoma - Prognosis

Prognosis depends on…

- Extent of primary tumour/ completeness of surgical resection
- Presence or absence of leptomeningeal seeding

Also…

- Pathologic/molecular subtype

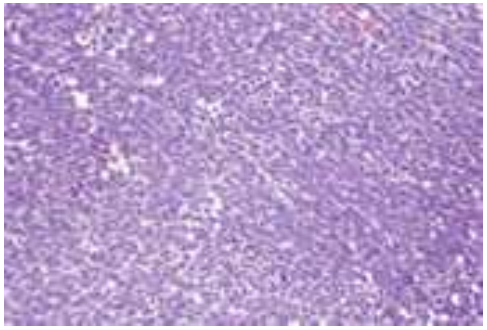
Medulloblastoma
Pathologic subtypes (WHO 2007)

- Medulloblastoma («classic») 70-80% all
- Desmoplastic/nodular medulloblastoma Good
- Medulloblastoma with extensive nodularity (MBEN) Good
- Anaplastic medulloblastoma Bad
- Large cell medulloblastoma Bad

ESTRO School

Classic Medulloblastoma

- 70-80% all
- Prototypical small blue cell tumor
- Densely packed undifferentiated cells



Desmoplastic Medulloblastoma

- Mostly in hemispheres
- Very young children and adults
- Biphasic architecture

Nodules showing neuronal differentiation («pale islands») surrounded by more cellular areas with prominent desmoplasia

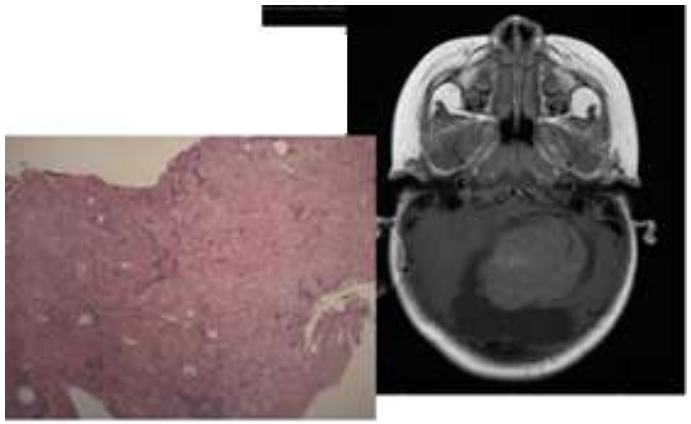
- More favourable

ESTRO School

Medulloblastoma with extensive nodularity (MBEN)

- Overlaps with desmoplastic MB (10-15% of young children)
- Pronounced nodularity (macroscopic)
- Greatly expanded «pale islands» with more advanced neuronal differentiation (neurocytes): previously called “cerebellar neuroblastoma”

MBEN
- Infants (<3 years)
- Strong association with Gorlin syndrome
- Better prognosis than other subtypes (lower frequency of mts, more sensitive to CT and RT)



ESTRO School

Large cell medulloblastoma

- Rare (2-4% of MB)
- Significantly more aggressive
- Large monomorphic cells
- High mitotic rate, extensive apoptosis
- Overlap with anaplastic subtypes

Anaplastic medulloblastoma

- Recently introduced concept

- Problem: many MBs show varying degrees of anaplasia

    - Anaplasia only a significant prognostic factor if severe and diffuse
    - May not be an independent factor….

Redefining subsets

Group A (WNT)

-15%
-Older children
-All had β catenin mutation (not found in other groups)
-Classic histology
-No metastasis
-Prognosis very good

Group B (SHH)

-25%
-Mostly desmoplastic
-Rarely metastatic
-Infants and adults
-Good prognosis for infants, intermediate for adults

Redefining subsets (cont'd)

Group C,D (Group 4), E (Group 3)

-60%
-Young children
-Markers of neuronal and/or photoreceptor differentiation
-Hystology classic or LCA
-Propensity to CSF spread
-Prognosis poor for group E, intermediate for group C,D

Medulloblastoma: the management

- **Standard risk Medulloblastoma**
- High risk medulloblastoma

Medulloblastoma

History of Chemotherapy Clinical Trials:

- 1970s-1980s:
  - -Adjuvant chemotherapy
  - -SIOP I,CCSG 942

Chemo better for high-risk subgroups
Standard dose RT (35-36 Gy established)

- 1980s-1990s:
  - -Pre-RT (Sandwich CT)
  - -SIOP II, SIOP/UKCCSG PNET 3
  - -Pre vs post RT chemotherapy : HIT 91,CCG 921
  - -CCG 9862 adjuvant chemotherapy (CVP)

Intensive sandwich CT better than RT alone (PNET 3)
Immediate RT better than delayed

Cisplatin, VCR,CCNU chemo standard and reduced dose RT (23.4 Gy) established

VIQ	58	96.3	17.1	55-128	55	92.4	20.6	43-145	.28
VIQ (age >8)	31	95.8	17.4	55-128	34	97.1	22.1	47-145	.79
VIQ (age <8)	27	96.8	17.1	60-126	21	84.8	15.7	43-112	.02
PIQ	70	89.7	21	40-140	66	87.1	17.1	40-122	.43
PIQ (age >8)	39	90.4	24.6	40-140	41	88.3	16.8	40-118	.66
PIQ (age <8)	31	88.9	15.8	65-128.5	25	85.1	17.7	41-122	.40
WMI	68	92.3	13.8	55-124	61	89.1	15.3	55-120	.21
WMI (age >8)	38	90	14.8	55-124	39	88.6	16.1	56-120	.69
WMI (age <8)	30	95.2	11.9	65-118	22	90	14.2	55-110	.16
PSI	29	83.3	14.7	50-112	28	75.4	15.5	50-100	.05
PSI (age >8)	18	81.1	15.6	50-112	17	75.1	16.3	50-100	.27
PSI (age <8)	11	86.8	13.1	62-103	11	75.9	14.8	50-96	.08

Abbreviations: FSIQ = full scale intelligence quotient; PIQ = performance intelligence quotient; PSI = processing speed index; VIQ = verbal intelligence quotient; WMI = working memory index. Other abbreviations as in Table 1.

* Student *t* test.

Conclusions: HFRT was associated with marginally higher VIQ in children <8 years of age at diagnosis, consistent with a previous report using questionnaire-based data. However, overall cognitive ability was not significantly different.

SIOP PNET5 MB

EudraCT-Nr. 2011-004868-30

European study (16 countries) for children older than 3 to 5 years

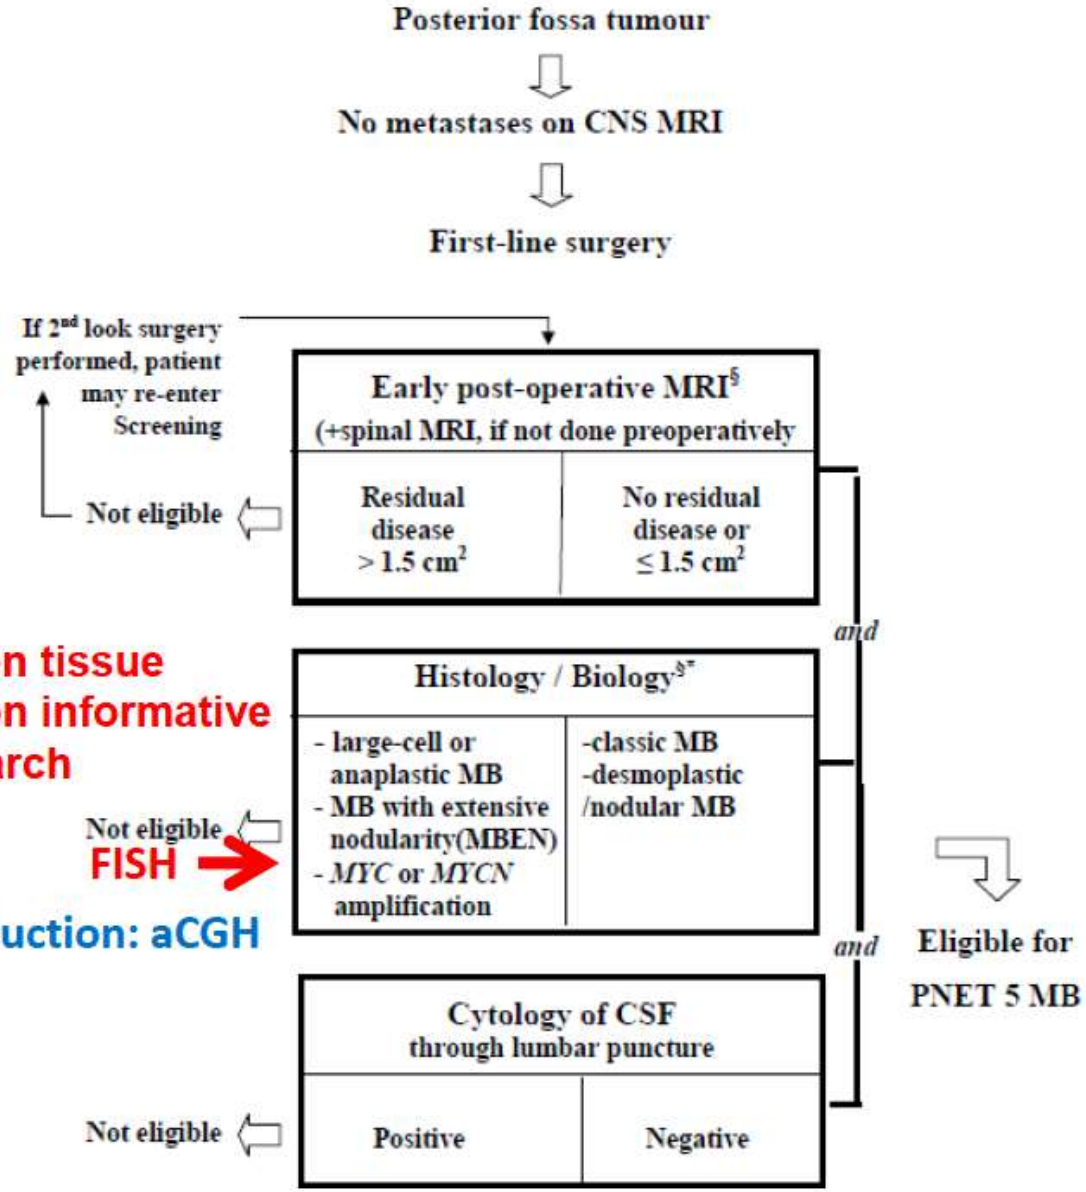
Stratification according to clinical and biological criteria

- LR: Low-risk medulloblastoma (Phase II; Co-PI: F. Doz)
- SR: Standard-risk medulloblastoma (Phase III)

PNET 5 MB substantial amendment

- New definition WNT subgroup
  - ß-catenin mutation analysis mandatory
  - monosomy 6 analysis optional
  - WNT positive patients ≥ 16 years ⟶ PNET 5 MB-SR
- Reduction of CSI dose from 23.4 Gy to 18 Gy in PNET 5 MB-LR
- 40 days period for radiotherapy starts after 1st surgery, even if 2nd surgery was performed.
- Foreseeable inability to start RT within 40 days renders patients ineligible
- Particular per-protocol analysis in LR- arm excluding patients with RT > 40days
- Possibility to add new countries
- Implementation of study board and definition function of study committee
- Use of Health Tracker only for QoS assessments

PNET 5 MB substantial amendment

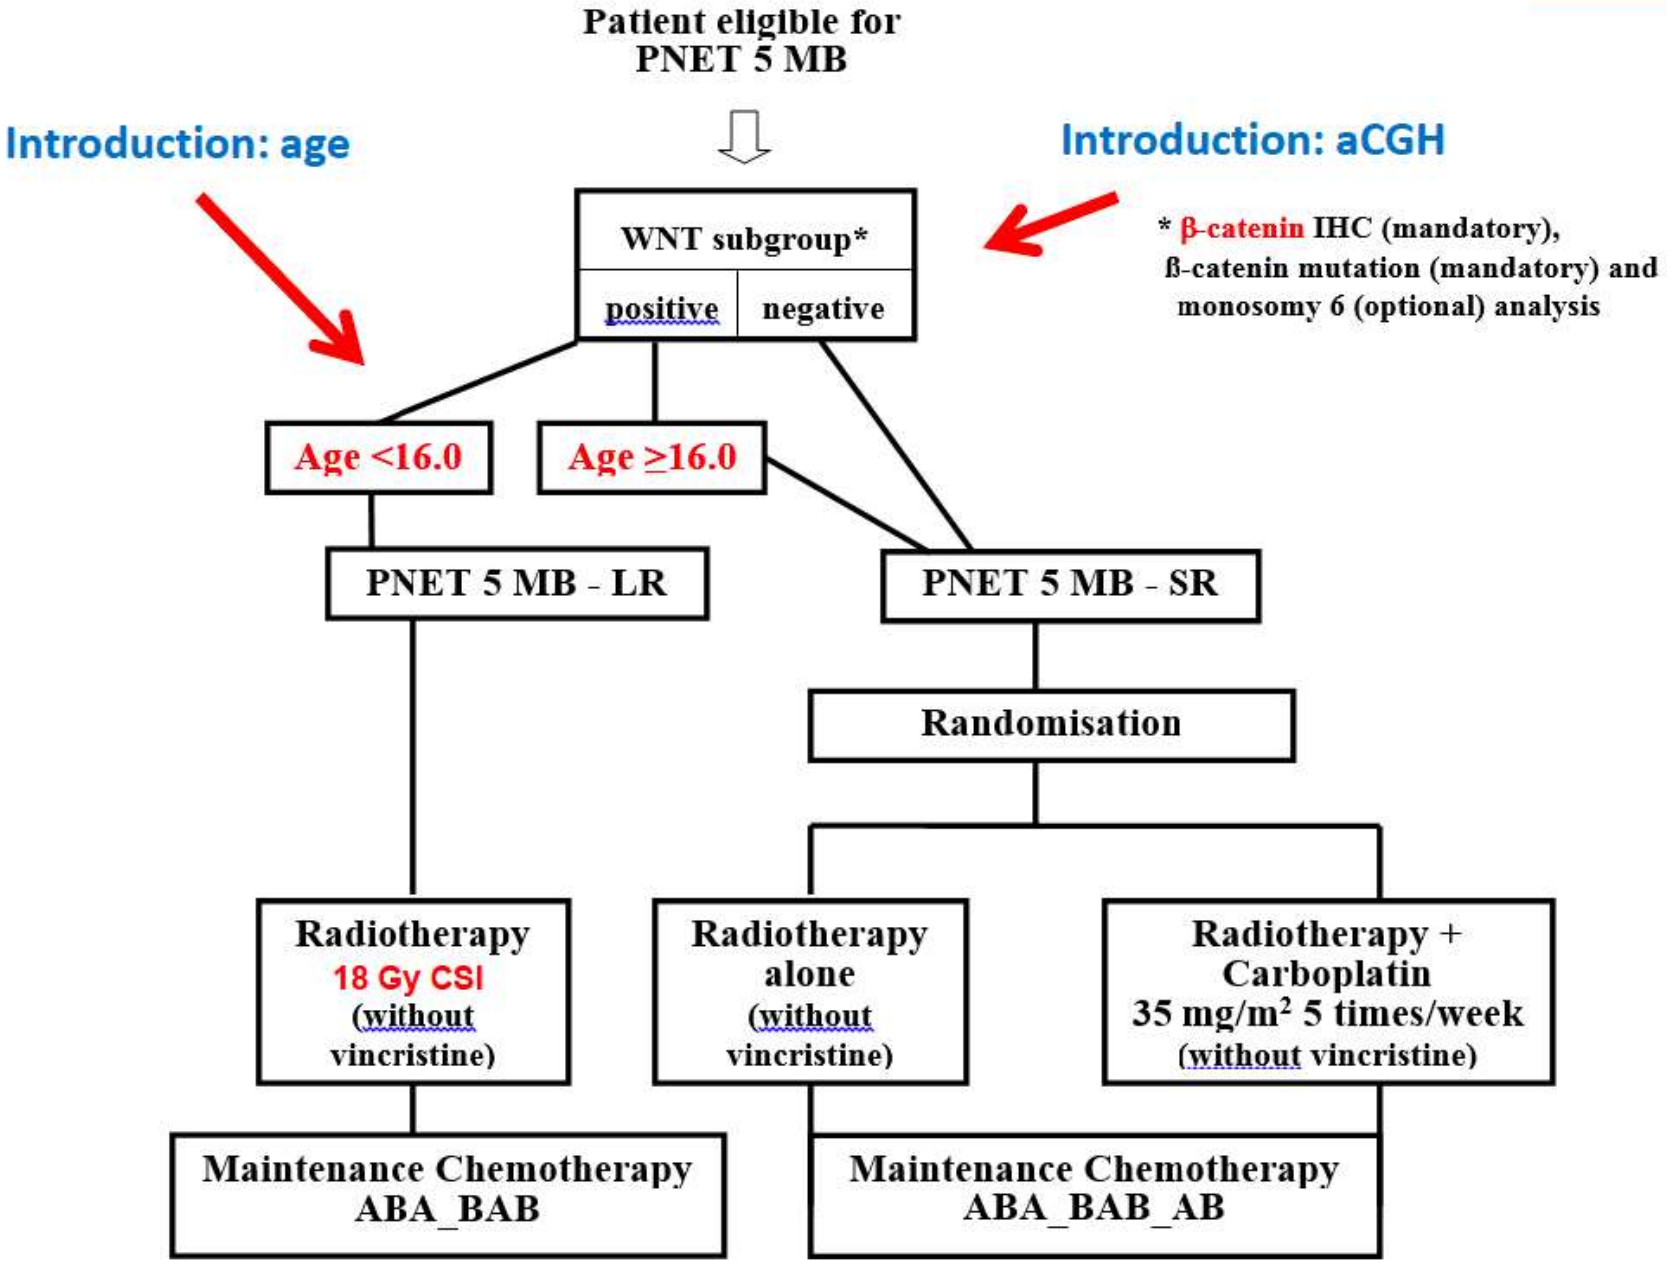


Mandatory frozen tissue

- **20% FFPE non informative**
- **Further research**

Introduction: aCGH

PNET 5 MB substantial amendment



Medulloblastoma: the management

- Standard risk Medulloblastoma
- **High risk medulloblastoma**
- Infant medulloblastoma

Historic outcome for conventional RT and chemotherapy for M2-M3 MB

Study	Entry Period	Outcome at 3 years
SIOP 2	1984-1989	43% EFS
HIT-91	1991-1997	30% PFS
PNET-3	1992-2000	39.7% EFS

High risk MB – Approaches

COG: *Daily Carboplatin with RT* (99701)

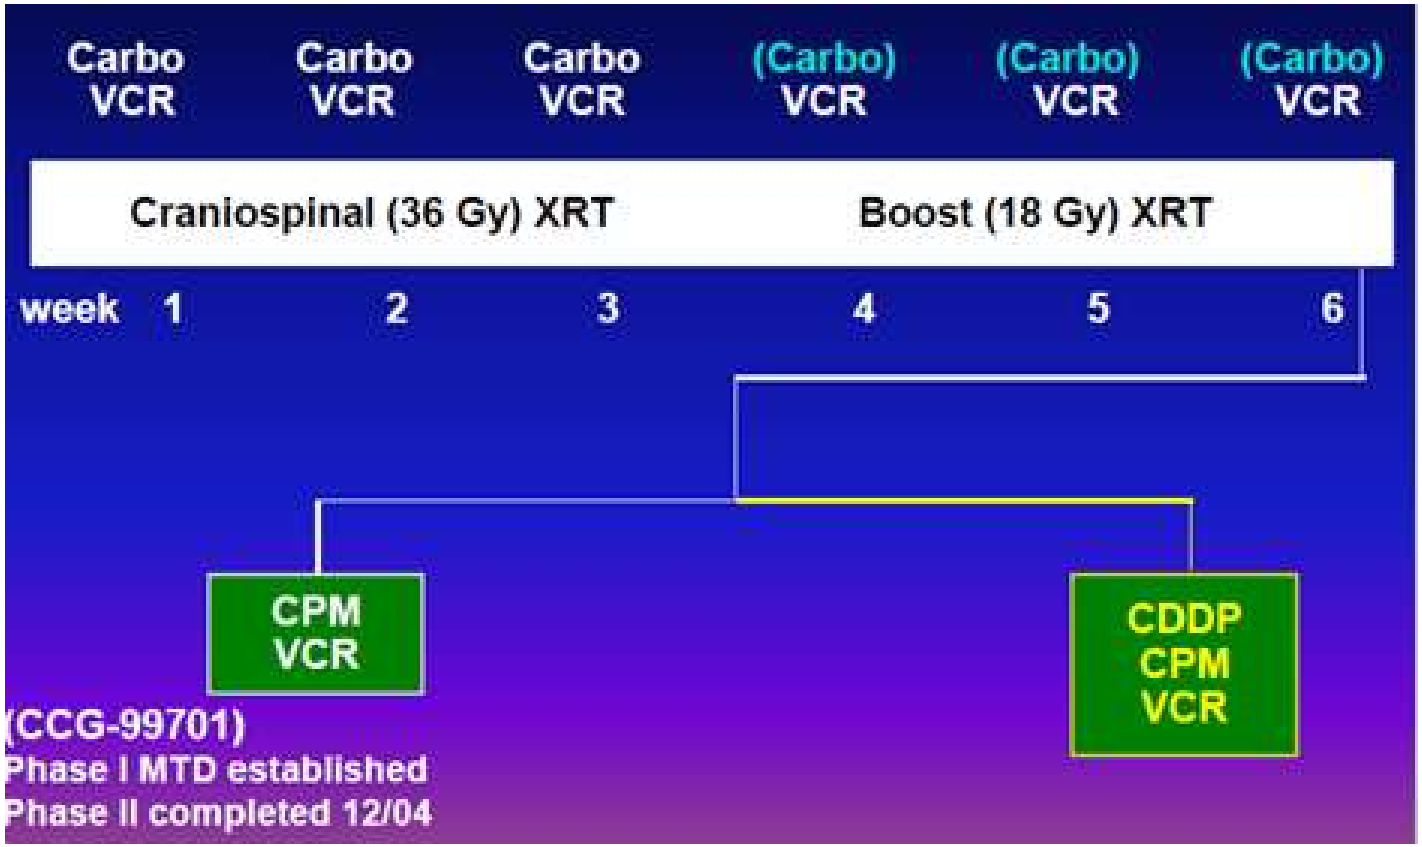
MILAN: *HFRT with HD chemotherapy*

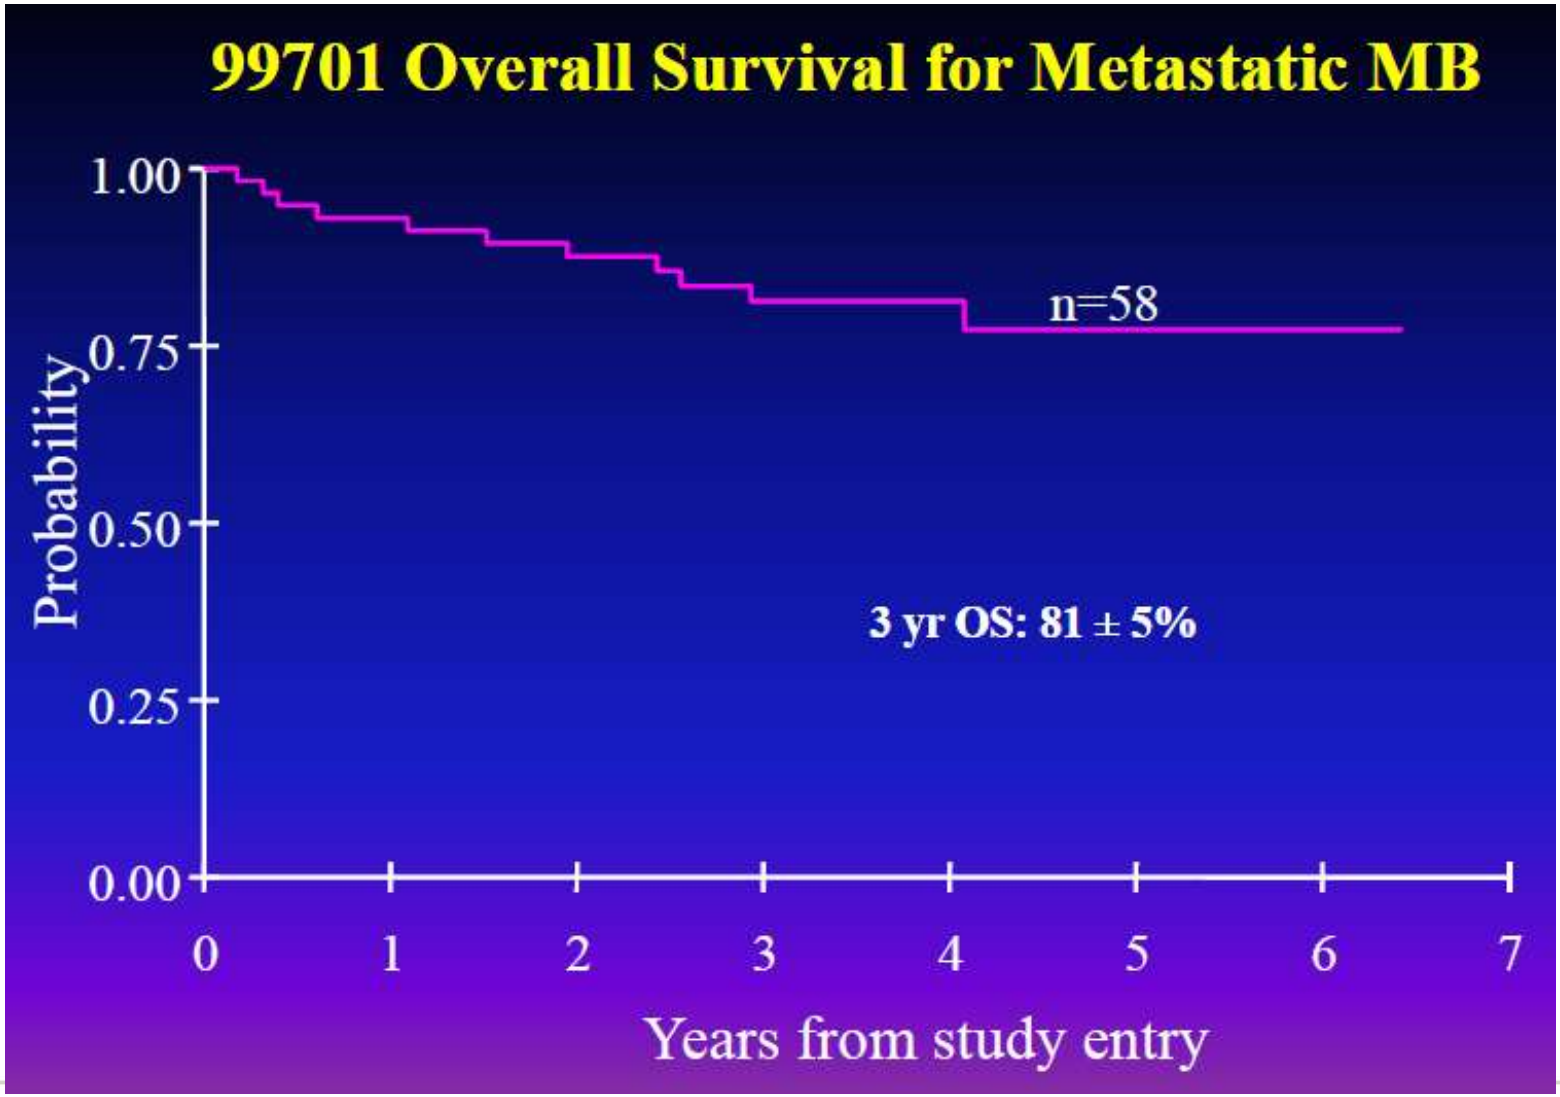
Milan HART Study

- 1998-2007
- 33 pts (M1 9, M2 6, M3 17, M4 1)
- HART: CSI (39 Gy; 1.3 Gy/fraction bid)
  posterior fossa boost up to 60 Gy (1.5 Gy/fraction bid)
- 7 pts aged < 10 yrs who achieved CT after chemo received a lower dose to the neuraxis (31.2 Gy)
- Median 82 months follow-up

- 5 yr EFS 70%
- 5 yr PFS 72%
- 5 yr OS 73%

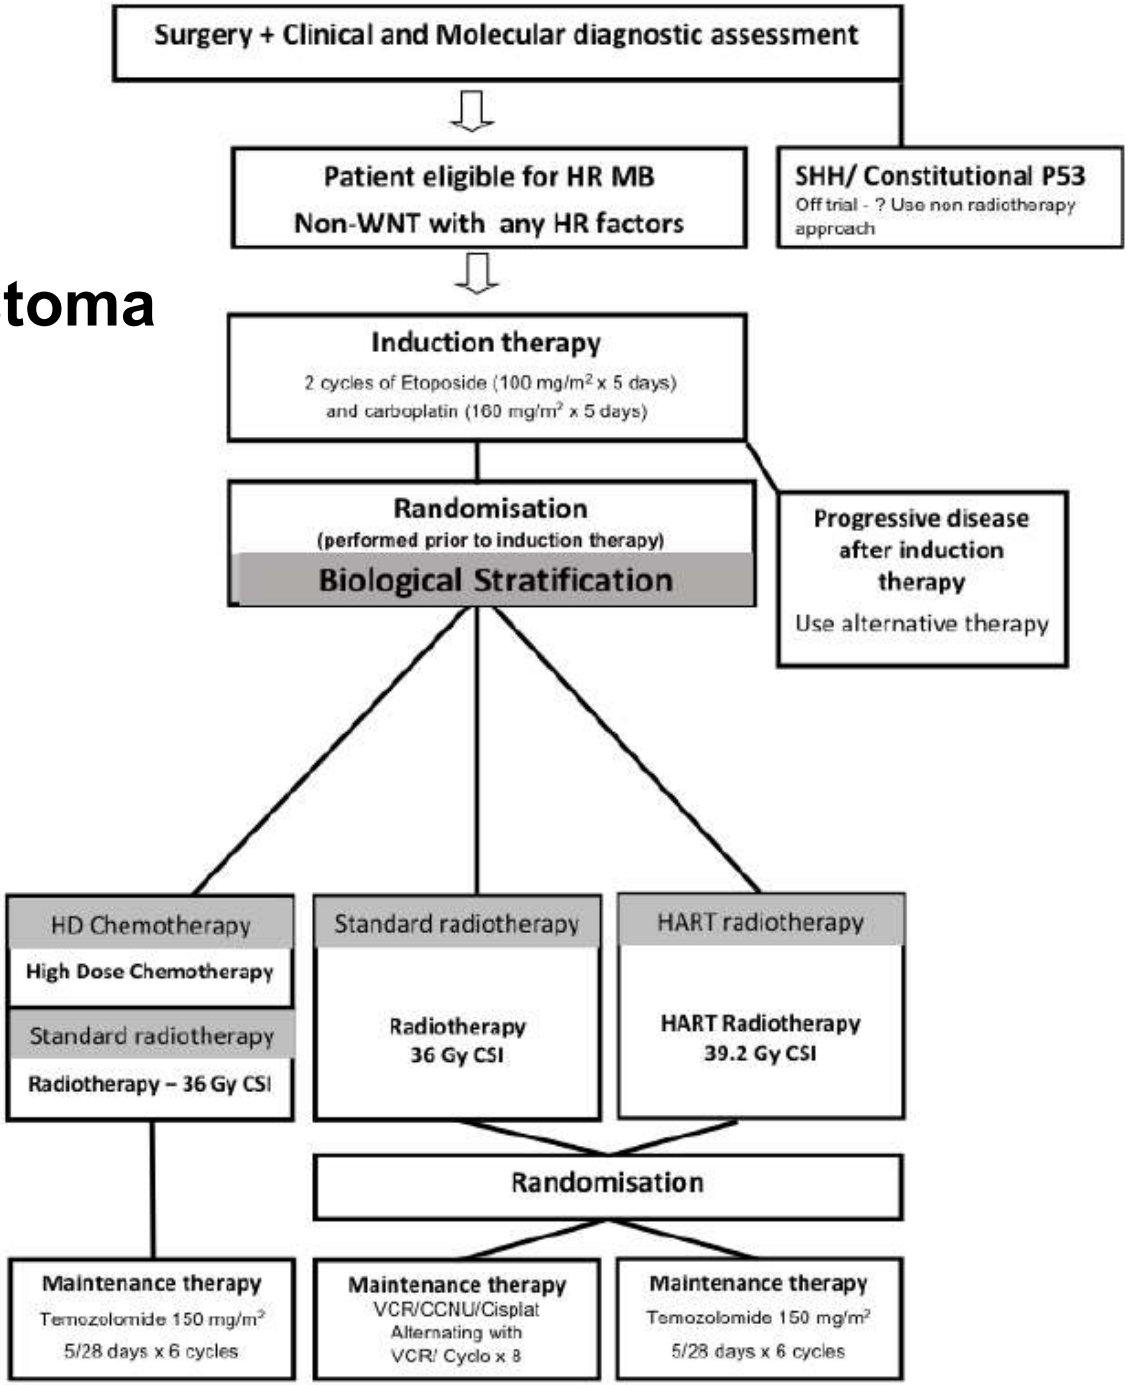
COG High Risk Study
Radiosensitisation study





ESTRO School

SIOP HR Medulloblastoma Trial



Medulloblastoma: the management

- Standard risk Medulloblastoma
- High risk medulloblastoma
- **Infant medulloblastoma**

Infant Medulloblastoma

- Management problematic
- Most protocols involve avoidance (or 1-2 yrs post-poning) of routine CSRT
- Most protocols have accepted impaired outcome and need for RT as salvage, when treatment is more difficult
- Lack of data on long-term quality of life outcome

ACNS1221
A Phase II Study for the Treatment of Non Metastatic Desmoplastic Medulloblastoma in Children Less Than 4 years of Age

Lucie Lafay-Cousin, Eric Bouffet, Arzu Onar-Thomas, Catherine Billups, Cynthia Hawkins, Charles Eberhart, Craig Horbinski, Giles Robinson, Douglas Strother, Linda Heier, Mark Souweidane, Maryam Fouladi, Amar Gajjar

CHILDREN'S ONCOLOGY GROUP

The world's childhood cancer experts

Background/Rational

- Nodular desmoplastic medulloblastoma and medulloblastoma with extensive nodularity (ND/MBEN) have been associated with a more favorable outcome in younger children
- Can be cured without using radiation or consolidation with high dose chemotherapy strategy
- Different toxicity /efficacy profile of regimens used
  - Fertility (CPM, Thiotepa); Ototoxicity (CDDP)
  - Neurocognitive Methotrexate (Intrathecal MTX)

Background/Rational

- Best survival outcome observed with the German HIT SKK regimen: 5y PFS of 95% ± 5%
  - No adjuvant radiotherapy
  - Conventional chemotherapy
  - **With serial intraventricular injections of Methotrexate**
- Can we replicate similar outcome using a modified HIT SKK regimen WITHOUT the IT MTX?

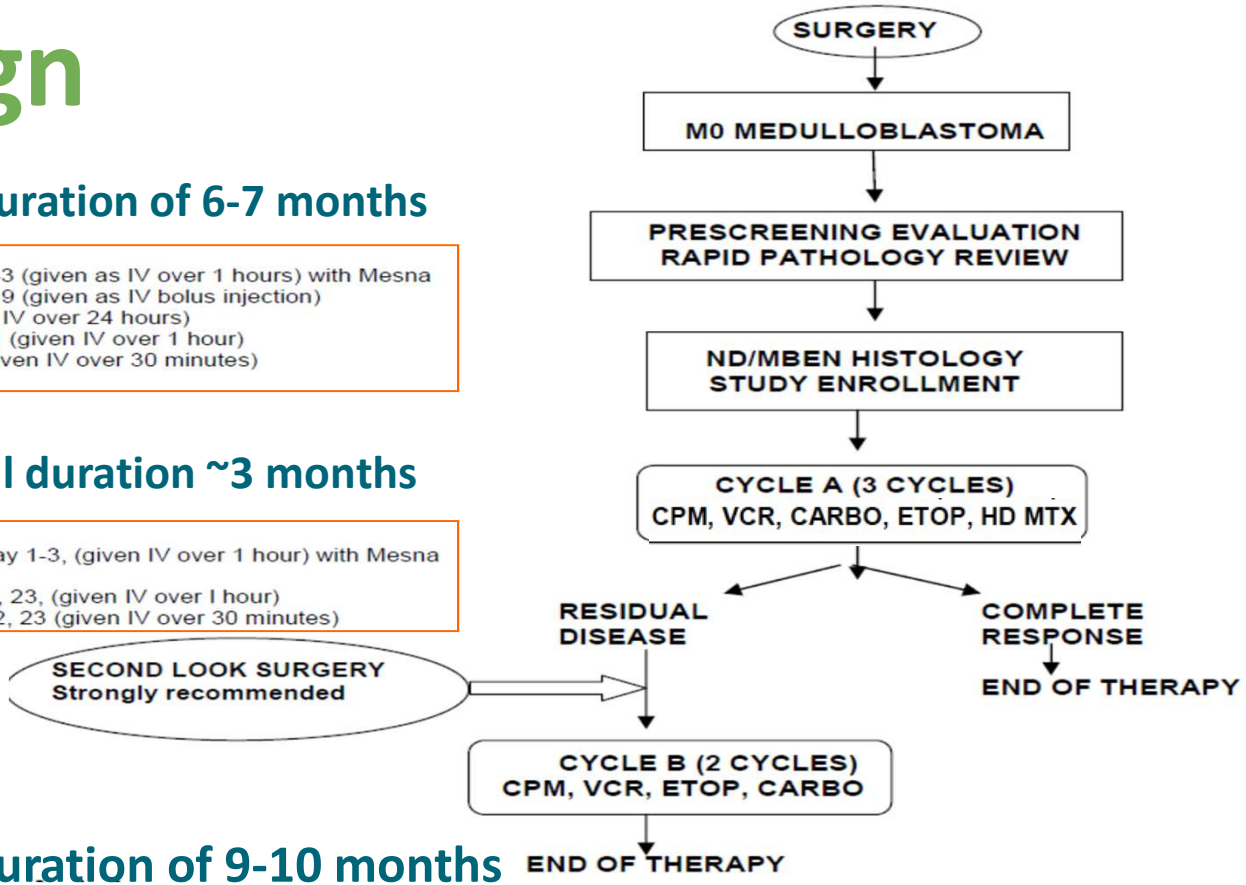
Study Design

Induction (Cycle A) total duration of 6-7 months

Cycle A
Cyclophosphamide (CPM): 800 mg/m^2 on Day 1-3 (given as IV over 1 hours) with Mesna
Vincristine (VCR): 1.5 mg/ m^2 on Day 1, 21, 35, 49 (given as IV bolus injection)
Methotrexate (MTX): 5g/m^2 on Day 21, 35 (given IV over 24 hours)
Carboplatin (CARBO): 200 mg/ m^2 on Day 49-51 (given IV over 1 hour)
Etoposide (ETOP): 150 mg/m^2 on Day 49-51 (given IV over 30 minutes)

Continuation (Cycle B) total duration ~3 months

Cycle B
Cyclophosphamide (CPM): 800 mg/m^2/day on Day 1-3, (given IV over 1 hour) with Mesna
Vincristine (VCR): 1.5 mg/m^2 on Day 1.
Carboplatin (CARBO): 200 mg/m^2 on Day 21, 22, 23, (given IV over I hour)
Etoposide (ETOP): 150 mg/m^2/day on Day 21, 22, 23 (given IV over 30 minutes)



Total planned therapy duration of 9-10 months

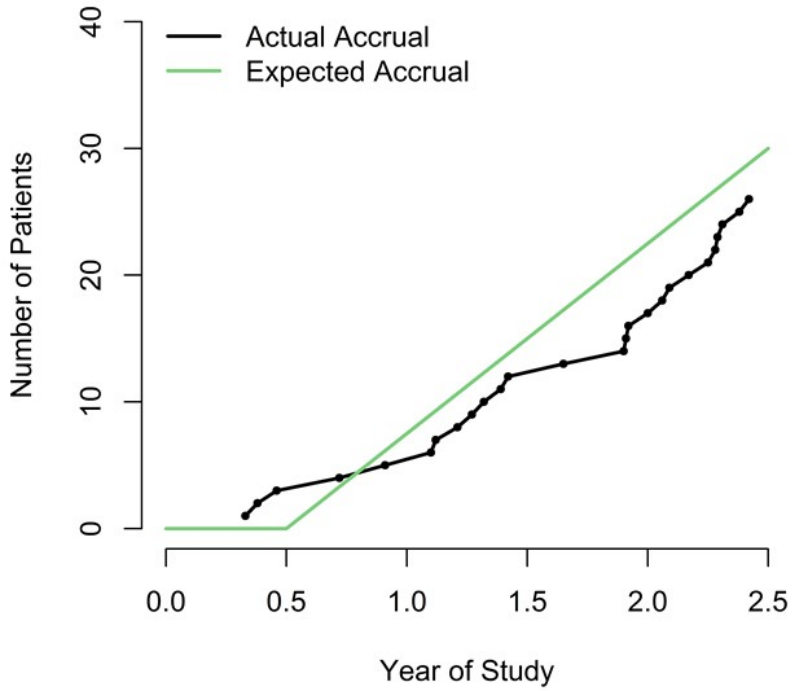
Lucie Lafay-Cousin – ASCO Meeting Chicago June 03rd 2017

Primary Objective

- Estimation of PFS for patients under 4 years of age, with M0 ND/MBEN treated with a modified HIT SKK 2000 regimen (excluding the use of intraventricular MTX)

2-year PFS rate ≥ 90% both desirable for patient and relatively comparable to HIT SKK 2000

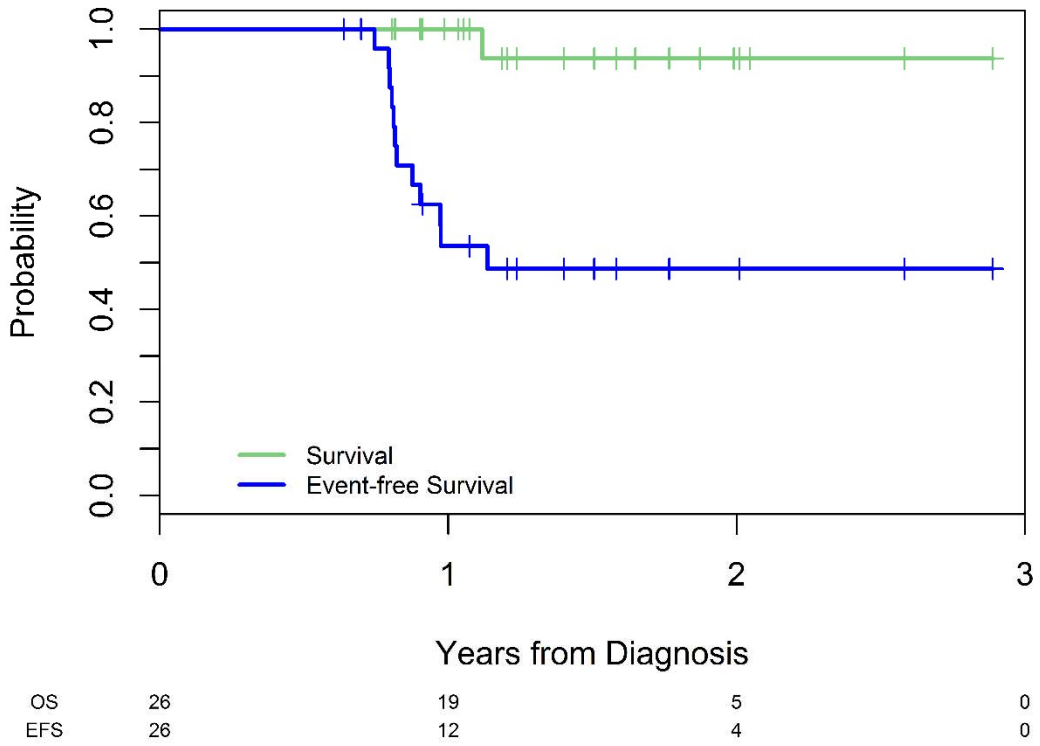
Accrual



- Study opened
  December 23rd, 2013
- Permanently closed
  July 27th, 2016
- 26 patients enrolled out of 37 needed

Lucie Lafay-Cousin – ASCO Meeting Chicago June 03rd 2017

Survival



- Study permanently closed for excess of relapse at interim analysis
- **Estimated 1 y PFS of 53.6% (SE, 10.1%)**
- Median follow up for the 25 survivors was 1.2 years (0.6 to 2.9 y)

Lucie Lafay-Cousin ASCO meeting Chicago June 03rd 2017

Relapses

N	Sex/Age at diagnosis (months)	Residual disease	Time of relapse from diagnosis	Site of relapse	Outcome (months from relapse)	Subsequent treatment
1	M (31.1)	-	9.5	Local	Alive (14.4)	Surgery, CT, SCT
2	M (31.9)	+	9.7	Distant	Alive (14.9)	CT, RT
3	F (32.0)	-	10.5	Distant	DOD (2.9)	na
4	M(21.3)	-	13.7	Local	Alive (8.8)	na
5	F(31.4)	-	9.9	Combined	Alive (9.9)	CT
6	M(27.2)	+	8.9	Combined	Alive (5.3)	CT
7	M(20.8)	-	11.7	Distant	Alive (0.2)	na
8	M(17.2)	-	9.6	Combined	Alive (0.1)	na
9	M(24.4)	-	9.7	Local	Alive (2.9)	CT
10	M(26.7)	-	11.7	Local	Alive (0.7)	na
11	M(26.9)	-	10.9	Local	Alive (at time of relapse)	na
12	M(15.8)	-	9.8	Local	Alive (at time of relapse)	na

Lucie Lafay-Cousin ASCO meeting Chicago June 03rd 2017

Conclusion

- The ACNS1221 regimen without IT MTX failed to achieve the desirable 2y PFS of 90%, leading to premature closure of the study
- None of the MBEN and of the patients under 12 months relapsed
- The molecular characterization of this ND/MBEN cohort is currently been investigated and may help uncover patients who may still benefit from this regimen

ESTRO School

Management of pilocytic astrocytoma in children

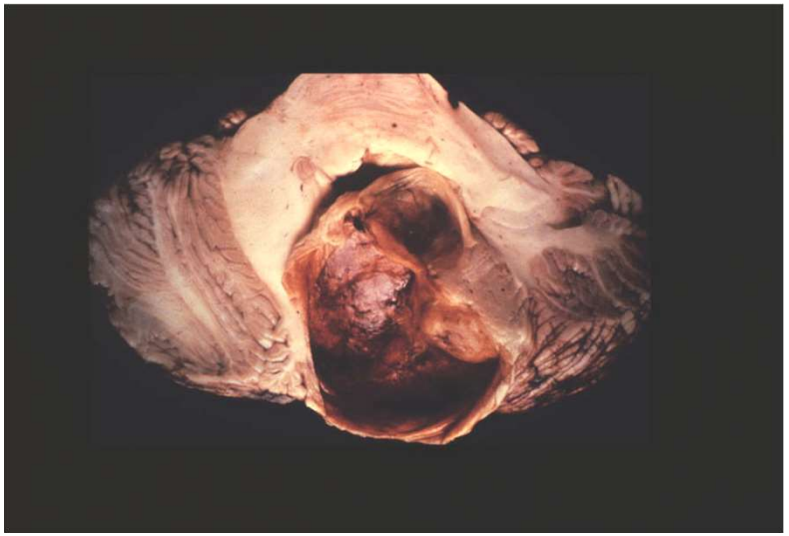
Darren Hargrave

Consultant Paediatric Oncologist,

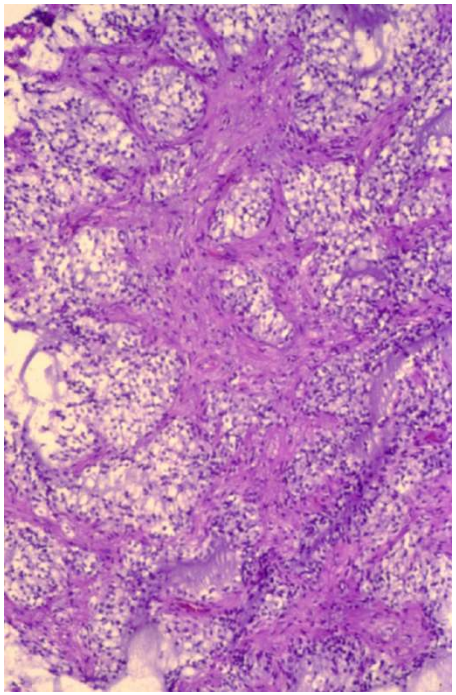
Neuro-oncology & Experimental Therapeutics

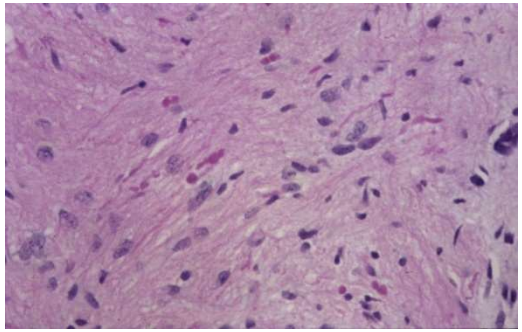
Great Ormond Street Hospital. London, UK.

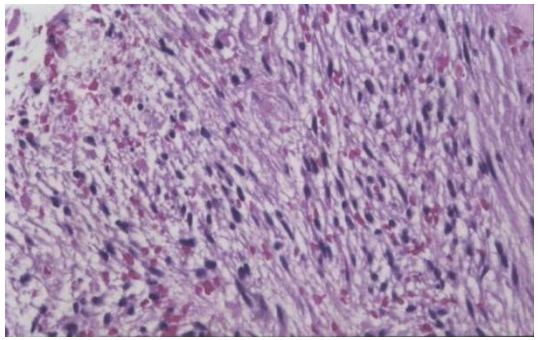
Low Grade Glioma



Pilocytic astrocytoma

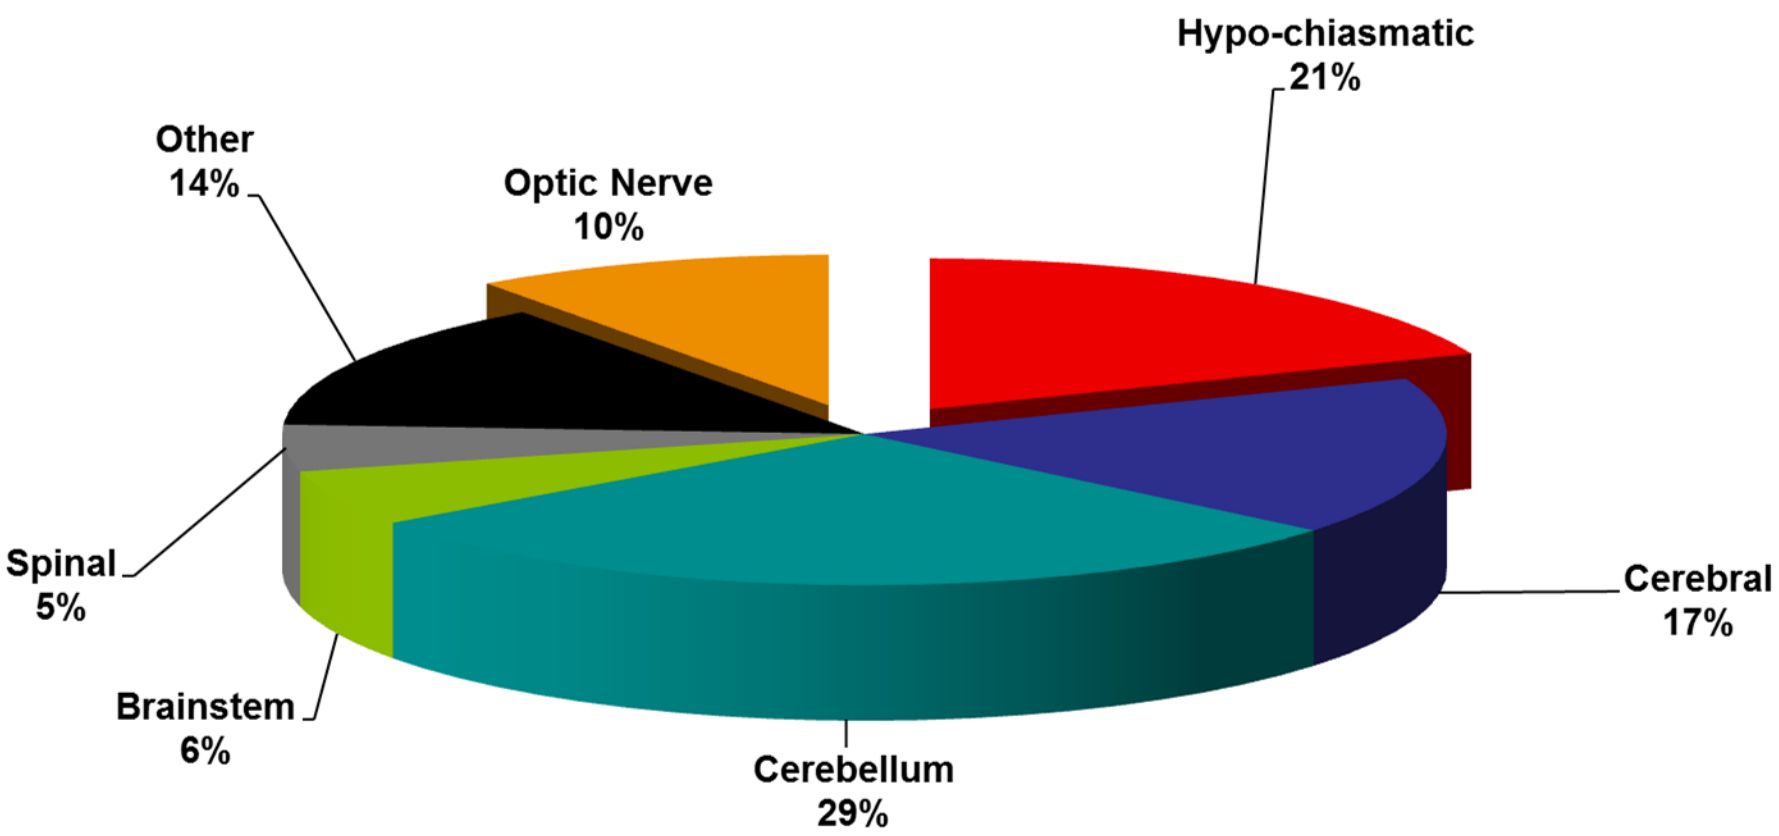






Tumor of cerebellum, often with cyst, biphasic, Rosenthal fibers, piloid cells

Primary Site of Low Grade Glioma



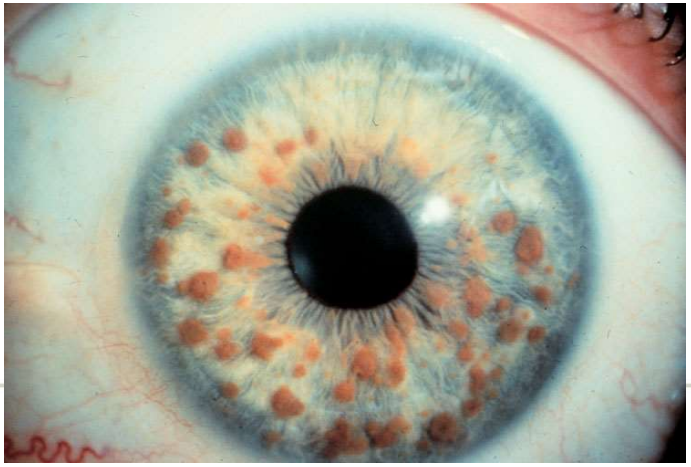
Juvenile Pilocytic Astrocytoma

- Most common type in children
- Seen predominantly in younger children (median ~ 4 years)
- Usually well circumscribed, often partially cystic, with little oedema, no mass effect
- Enhance brightly and uniformly with contrast material
- Gross total resection often possible

Low Grade Glioma in Children

- 30-40% of paediatric brain tumours
- Heterogeneous pathologically, anatomically, clinically and biologically
- < 5% present with leptomeningeal metastases
- Frequently protracted clinical course
- Balance between anti-tumour effects and long-term morbidity of therapy

Aetiology of Childhood LGG



NF-1

RESEARCH ARTICLE

Genetic alterations related to BRAF-FGFR genes and dysregulated MAPK/ERK/mTOR signaling in adult pilocytic astrocytoma

Pankaj Pathak[1], Anupam Kumar[2], Prerana Jha[1], Suvendu Purkait[1], Mohammed Faruq[3], Ashish Suri[2], Vaishali Suri[1], Mehar C. Sharma[1], Chitra Sarkar[1]

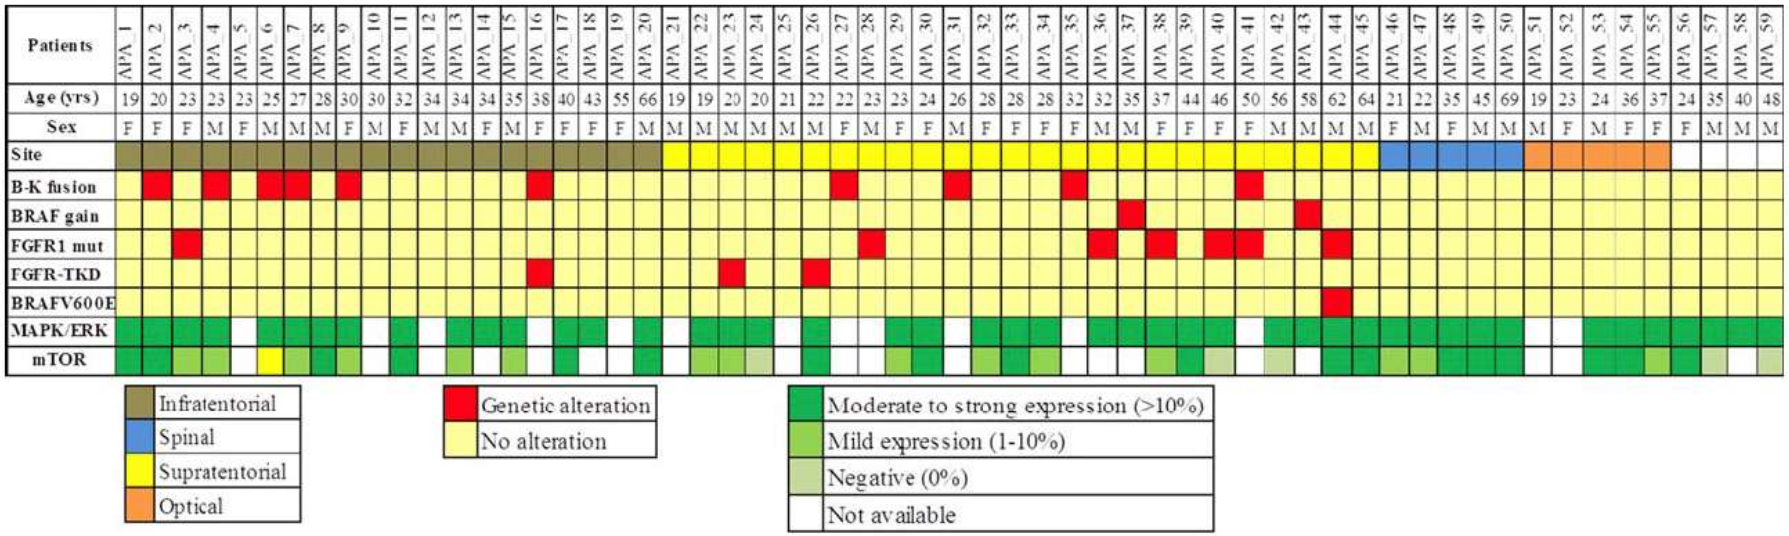

Figure 1. Clinicopathological and molecular genetic features for the 59 adult pilocytic astrocytoma cases with the different genetic and immunohistochemical analyses. (B-K fusion: BRAF-KIAA fusion).

- Surgery remains the mainstay of therapy and GTR is the most consistent prognostic factor for prolonged PFS and OS

- Adjuvant treatment? (CT/RT)

- In case of GTR → no further therapy (10-year OS rates of 90% or greater and rare tumor recurrences)

- In case of PTR → a «wait and see policy» with follow-up brain MRI at 3-6-month intervals and adjuvant treatment postponed until there is either measurable progression by neuroimaging or clinical symptoms

- In case of biopsy/no surgical approach → observation until radiographic progression if there are minimal clinical symptoms

Criteria for non-intervention in LGA

- Asymptomatic and non-progressive lesions in patients with neurofibromatosis

- Lesions in the tectal region

Late Effects of Conformal Radiation Therapy for Pediatric Patients With Low-Grade Glioma: Prospective Evaluation of Cognitive, Endocrine, and Hearing Deficits

Thomas E. Merchant, Heather M. Conklin, Shengjie Wu, Robert H. Lustig, and Xiaoping Xiong

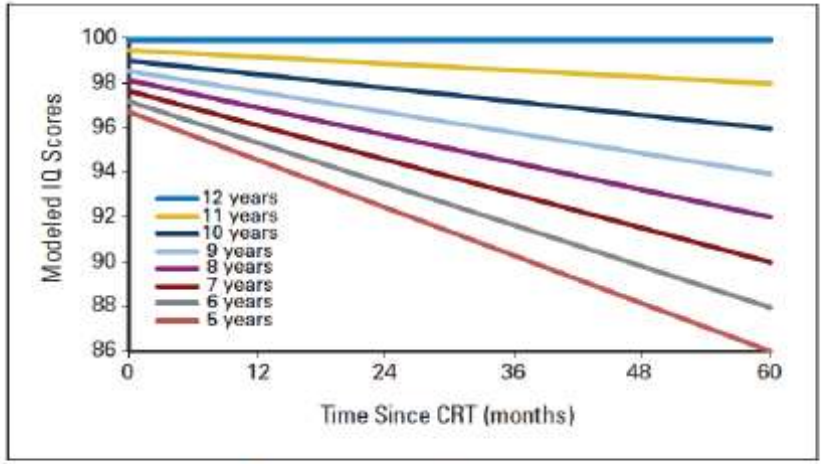

Fig 1. Modeled intelligence quotient (IQ) scores after conformal radiation therapy (CRT) by age for pediatric low-grade glioma. Age is measured in years, and time is measured in months after the start of CRT.

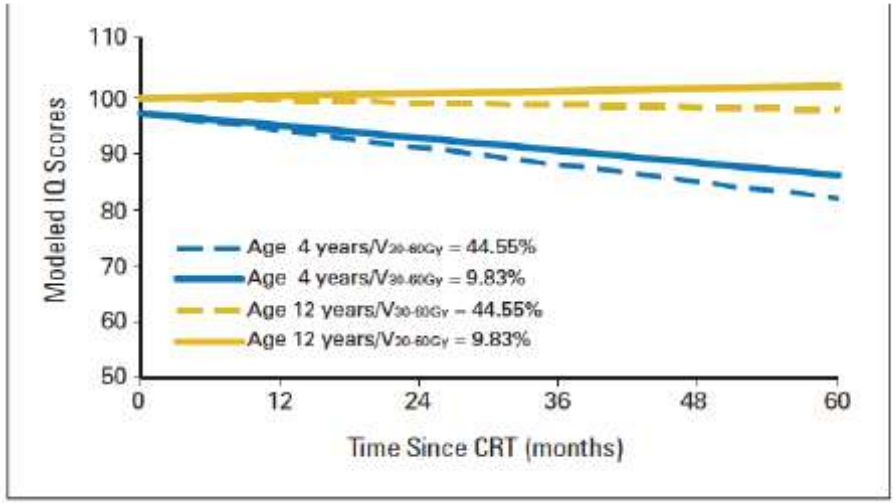

Fig 2. Modeled intelligence quotient (IQ) scores after conformal radiation therapy (CRT) by age and supratentorial brain dose-volume intervals for pediatric low-grade glioma. Age is measured in years, and time is measured in months after CRT. The dose-volume intervals $V_{0\text{-}30Gy}$ and $V_{30\text{-}60Gy}$ represent the percent volume of the supratentorial brain that received dose within the specified interval.

CHILDREN'S ONCOLOGY GROUP

Radiation Therapy in Treating Young Patients With Gliomas

NCT00238264 trial

CTV= GTV plus a 0.5 cm margin

Influencing factors

RT related

- Dose: Total tumour dose, but dose to critical structures more important
- Fraction size: Hypo-fractionation or hyper-fractionation
- **Volume**: Whole brain Vs CSI Vs Partial brain
- Technique: Conformal, margins, accuracy of execution
- Energy: Photons Vs particle beam…..Telecobalt
- Planning: Dose constraint models to minimise cognitive impairment

Proton Therapy

Advantages

⇒ **reduction of integral dose to organs at risk (highly conformal even to irregular tumour shapes)**

⇒ **reduction of late effects is expected (neurocog., endocrin., hearing, sec. malignancies..)**

Disadvantages

⇒ **limited information regarding tumour control rates and reduction of late effects**

⇒ **limited access (will change in future)**

Prospective, european wide studies necessary

Marked Recovery of Vision in Children With Optic Pathway Gliomas Treated With Bevacizumab

Robert A. Avery, DO, MSCE; Eugene I. Hwang, MD; Regina I. Jakacki, MD; Roger J. Packer, MD

IMPORTANCE Children with optic pathway gliomas (OPGs) frequently experience vision loss from their tumors. Standard front-line treatment using carboplatin-based chemotherapy typically produces only a modest benefit (eg, stabilization or 0.2 logMAR improvement) in visual acuity (VA). Bevacizumab is a monoclonal antibody that targets vascular endothelial growth factor and acts primarily as an anti-angiogenic agent. Recent reports suggest a qualitative improvement in vision after bevacizumab-based treatment in children with OPGs.

OBSERVATIONS We report 4 cases of pediatric OPGs (2 neurofibromatosis type 1–related and 2 sporadic cases) that received treatment with bevacizumab due to progressive VA or visual field (VF) loss despite prior treatment with chemotherapy or proton-beam radiation. All 4 subjects demonstrated a marked improvement in their VA, VF, or both while receiving bevacizumab-based therapy. Three patients had complete resolution of their VA or VF loss in at least 1 eye—2 of whom had previously received bevacizumab therapy.

CONCLUSIONS AND RELEVANCE Given that most patients with OPG-related visual impairment will show modest or no visual improvement with standard treatment, the incorporation of bevacizumab in these cases may greatly improve visual outcomes and should be considered in appropriate clinical situations.

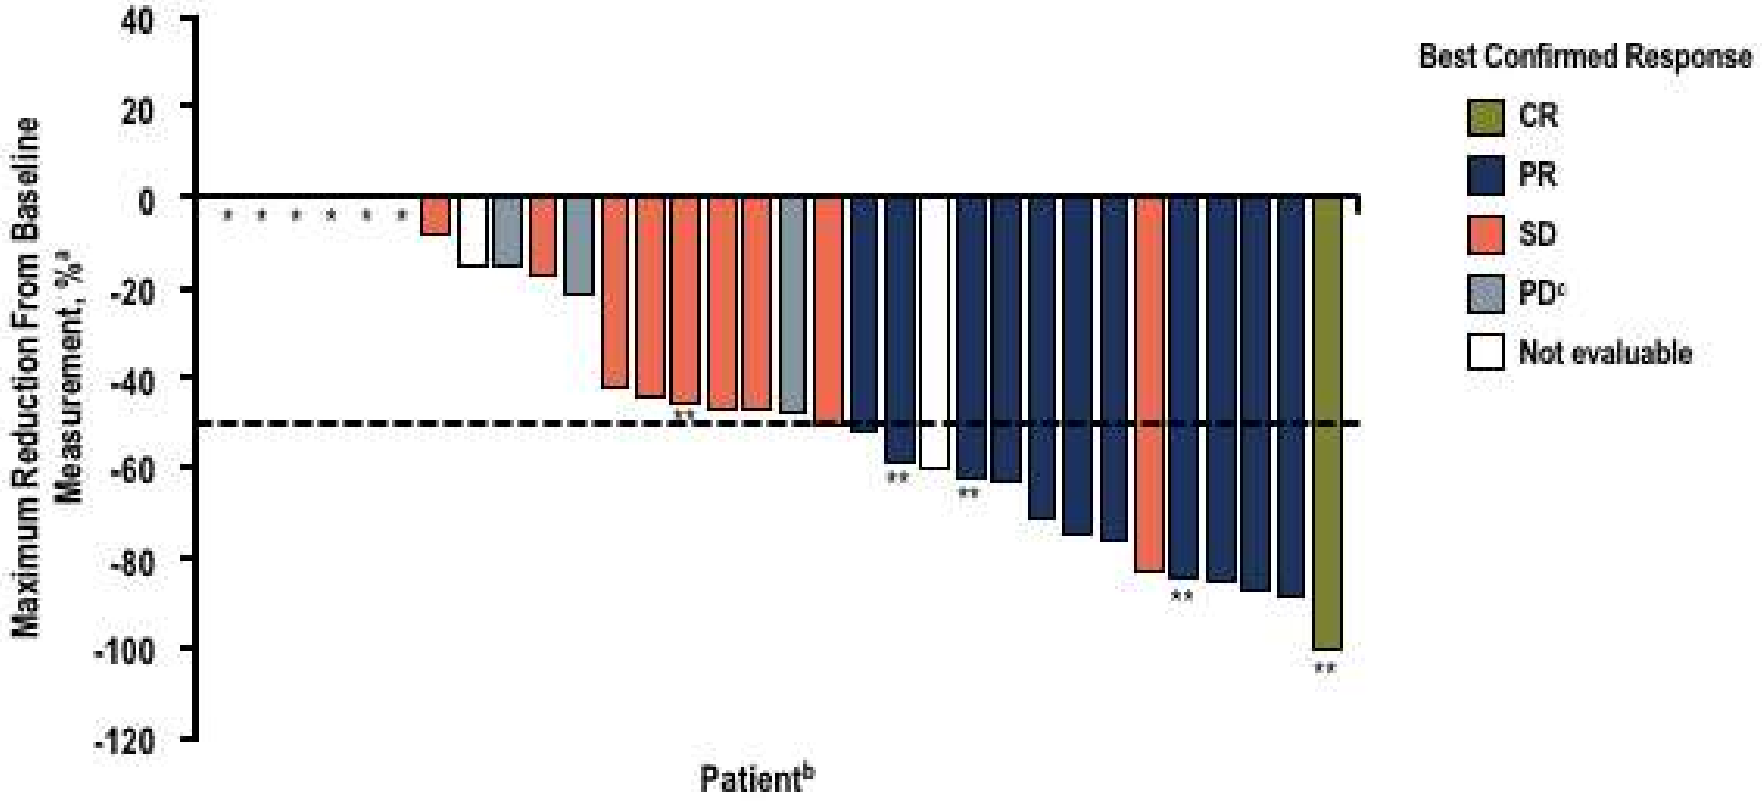
Pilomyxoid astrocytoma treated successfully with vemurafenib

Mary Skrypek MD ✉, Nicholas Foreman MD, Daniel Guillaume MD, Christopher Moertel MD

The first study of dabrafenib in pediatric patients with BRAF V600-mutant relapsed or refractory low-grade gliomas

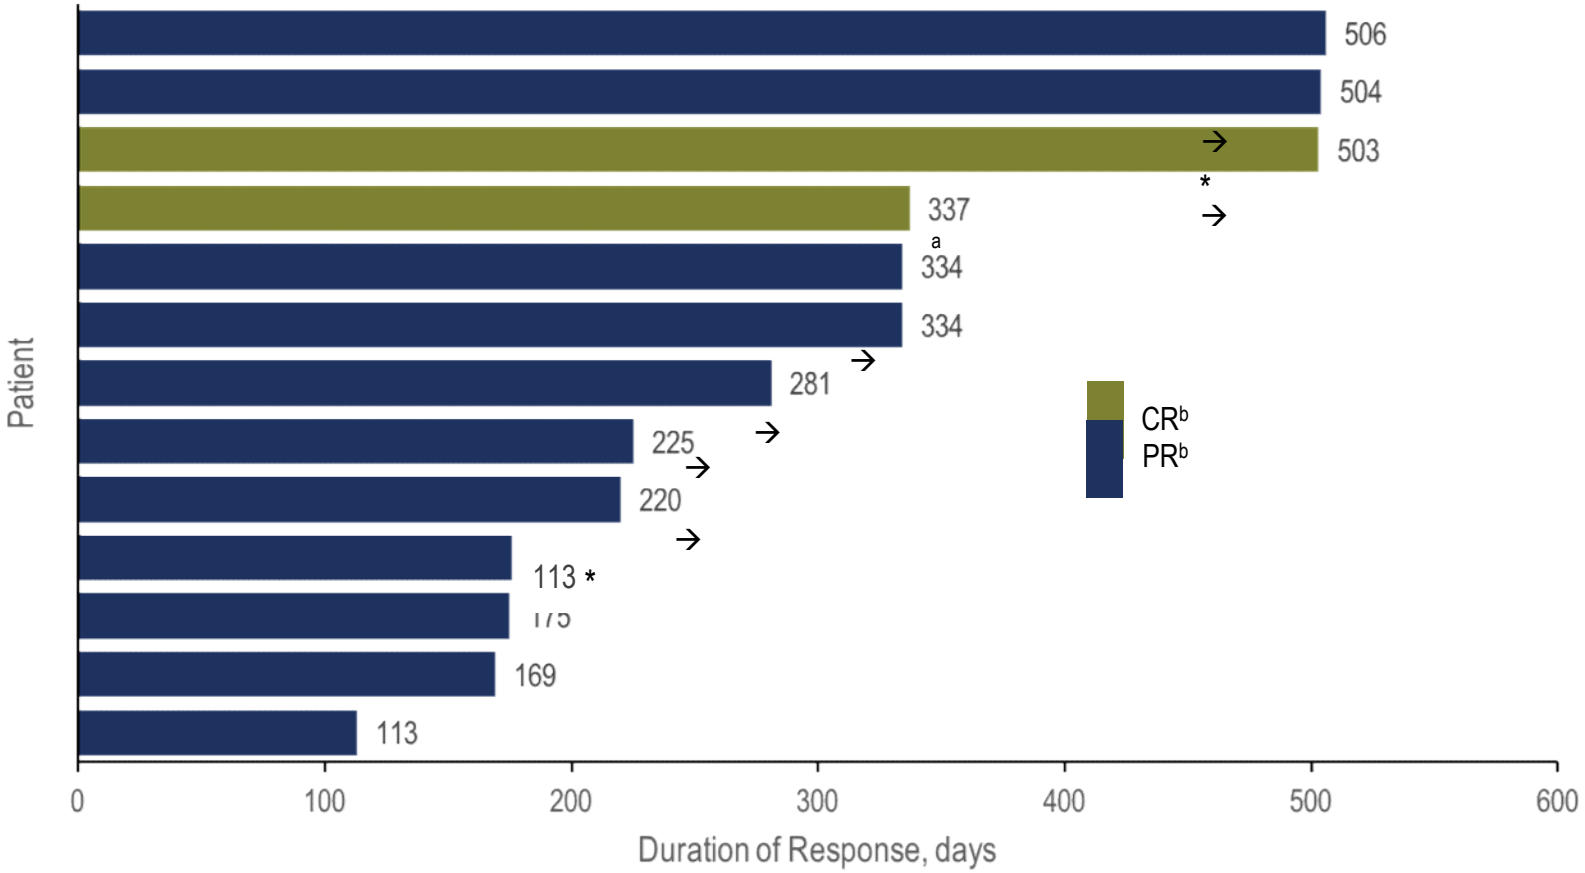
Mark Kieran, Eric Bouffet, Uri Tabori, Alberto Broniscer, Kenneth Cohen, Jordan R. Hansford, Birgit Geoerger, Pooja Hingorani, Ira Dunkel, Mark Russo, Lillian Tseng, Qing Liu, Noelia Nebot, Jim Whitlock, Darren Hargrave

Best response to dabrafenib (independent review)



* Missing patients (SD, n = 4; CR, n = 1 [patient recategorized as SD]; not evaluable, n = 1). ** Patients with no RP2D assigned dose. [a] Percentage change from baseline in sum of products will be of perpendicular diameter of target lesions. [b] Includes all patients with measurable disease and ≥ 1 post-baseline evaluation. [c] Plot shows maximum reduction on study (2 patients with PD previously had SD; 1 PD was due to a new lesion).

DURATION OF RESPONSE (INDEPENDENT REVIEW)



* Censored when discontinued study and patient in response at that time. → Response ongoing as of the data cutoff date (April 1, 2016).
[a] Patient initially assessed as CR and recategorized as SD. [b] Response categorization based on best overall response.

As of the data cutoff, median duration of response and median PFS have not been met

Inclusion Criteria

LOGIC EUROPE

- age: 0 -20.99 years 

- histologically verified LGG 

- collection of **fresh frozen tumor tissue** for biomarker determination **mandatory**.
  Exception: single cases of stereotactic biopsy in which larger biopsy would impose unacceptable risk to patient
- Indication to start chemotherapy: progressive disease on MRI, neurological function, visual function,
- all infants **< 1 year** 

- NO default first line radiation therapy 

Thanks!

Childhood Tumours in Adults

pilocytic astrocytoma /optic nerve glioma

Dr Sarah Jefferies

ESTRO School

Outline

- Review management in children
- Evidence for recommended treatment of adults
- Present some clinical cases

PA in children

- Most common CNS tumour diagnosis – 5-14 years of age
- Sporadic – mainly cerebellar (NFI – optic pathways)
- Well defined tumours
- Lack of invasiveness
- Malignant transformation in <5%

Treatment in children

- Neurosurgical excision:
  - complete **10-year survival > 90%**
  - incomplete **10-year survival ~ 74%***

  *some residual tumours regress after surgery

- Recurrence
  - consider further surgical resection

Chemotherapy – in children

- Chemotherapy often first treatment if progression confirmed and no further surgery feasible
  - Carboplatin/vincristine
  - CCNU/vincristine/procarbazine combinations

Radiotherapy – in children

- Dose and fractionation: 54GY/30#
- Concerns around cognitive deficit and 2nd malignancy
- Minimize with protons?

Radiotherapy – in children

- Mansur et al.,
  - Retrospective review of PA who had received RT
- Median age at diagnosis 10 (3-18)
- Median age for RT 11 (4-25)

Radiotherapy

- 54Gy/30#
- Use RT technique to minimise normal tissue toxicity
- Posterior ON pathway lesions – tend to do less well

Impact of molecular understanding of brain metastases on clinical practice

Assoc. Prof. Dr. Matthias Preusser
Department of Medicine I
Comprehensive Cancer Center Vienna
Medical University of Vienna

Incidence of brain metastases

- Occur in 10-30% of all adult cancers
- Approx. 10 times more frequent than primary brain tumors
- Relative incidence increasing, due to
  - Effective systemic treatments → with longer survival
  - Improved imaging techniques and their increased availability
- Approx. half of all brain mets due to NSCLC, others:
  - Breast cancer
  - Melanoma
  - Unknown primary
  - Renal cell carcinoma

Treatment approaches

- Neurosurgery
- Radiotherapy
  - Whole brain radiotherapy (WBRT)
  - Stereotactic radiosurgery/radiotherapy (SRS/SRT)
- Systemic therapy
  - Chemotherapy
  - **Targeted therapies, e.g. tyrosine kinase inhibitors, antibodies**
- Supportive therapy
  - Edema control
  - Anticonvulsants
  - Pain

Preusser et al, Oxford University Press 2015

Neurosurgery

Typical indications:

- Patients with surgically accessible single brain metastases, no or controlled extracranial tumor burden and good performance status
- Acute decompression on patients with significant mass effect from one or more brain metastases
- **Patients with an unknown primary tumor to obtain tissue for histopathological and molecular tumor (sub-)typing**

Note: unresolved issue of whether or not perform adjuvant irradiation after neurosurgical resection; possible strategies:

- WBRT
- SRS
- Wait and see

Preusser et al, Oxford University Press 2015

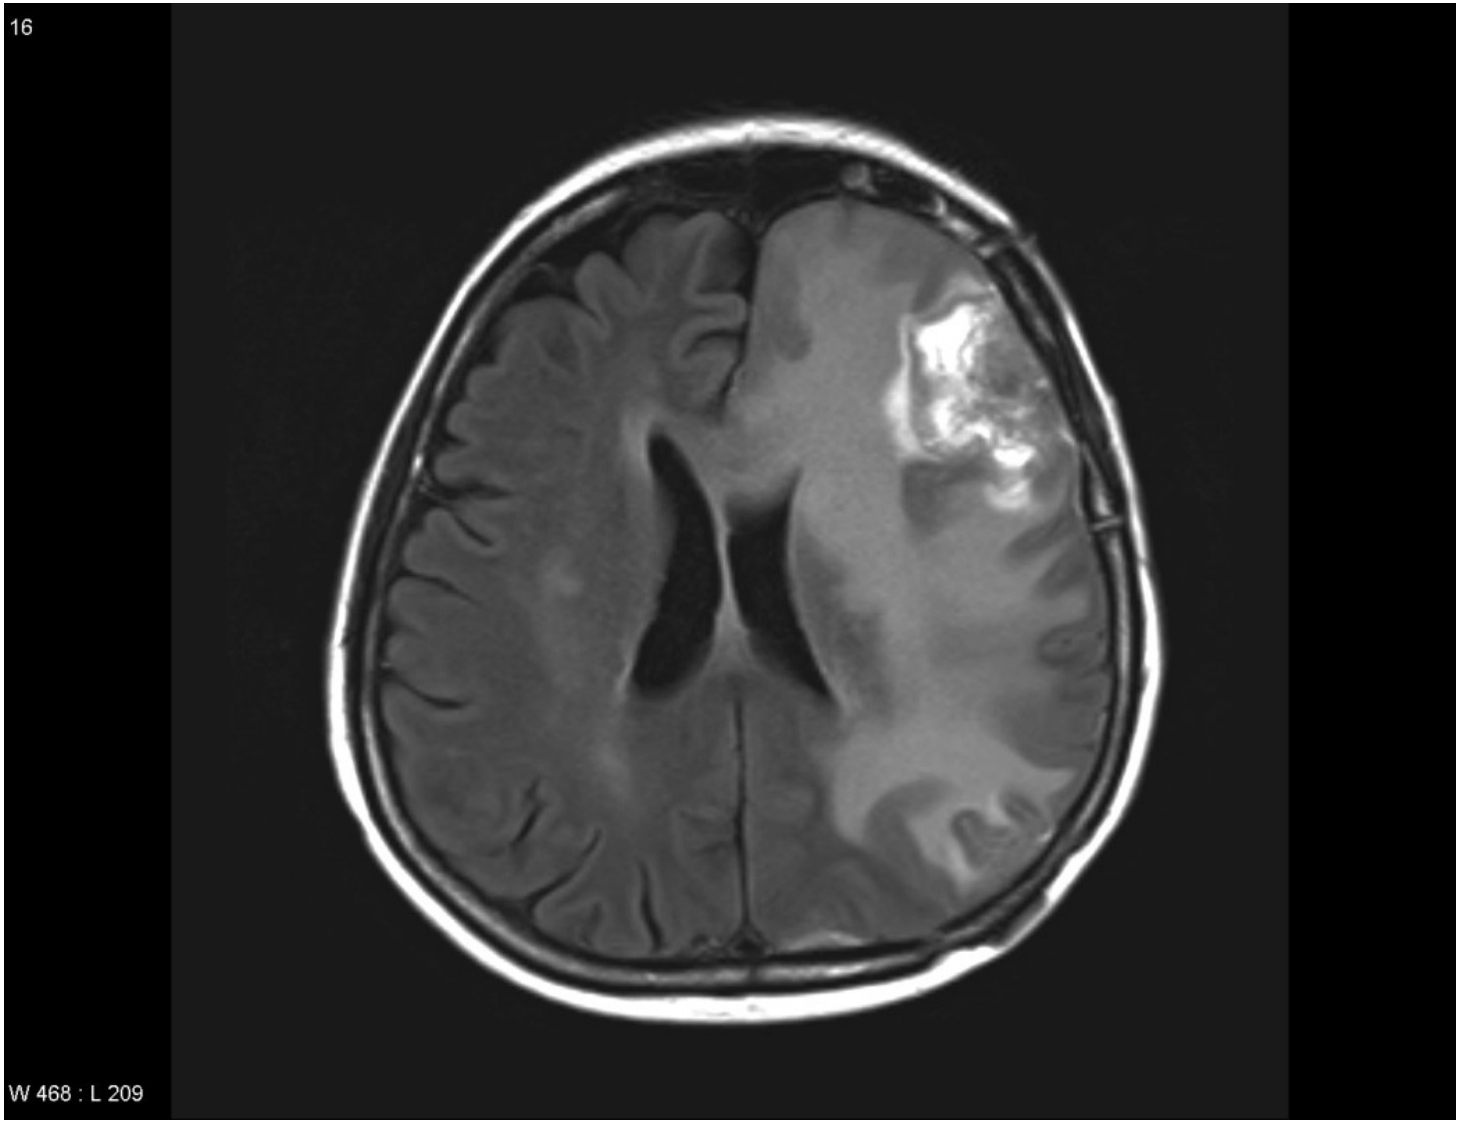
Brain edema

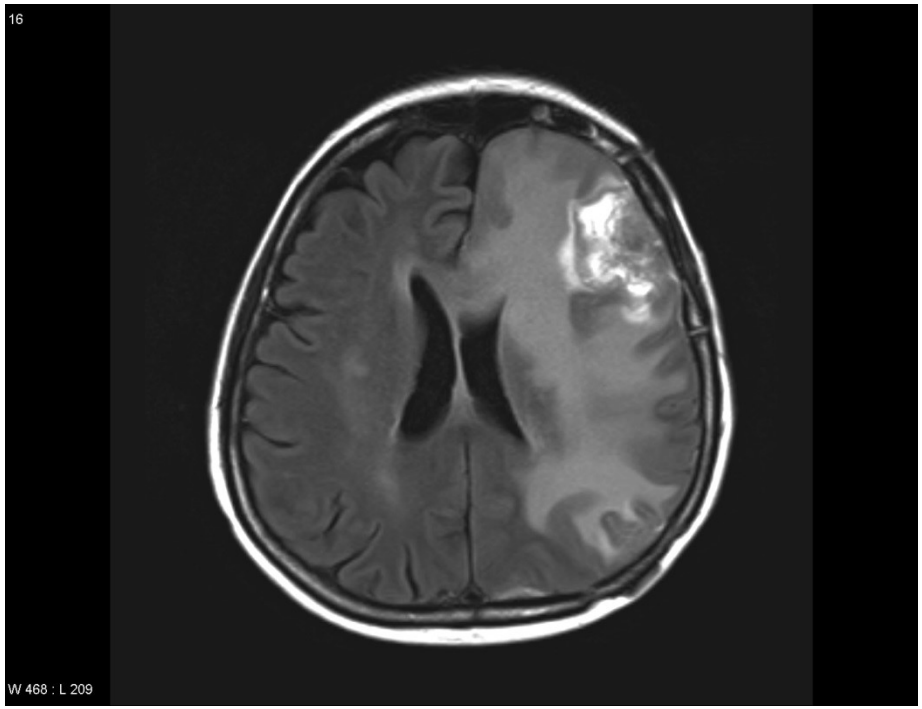


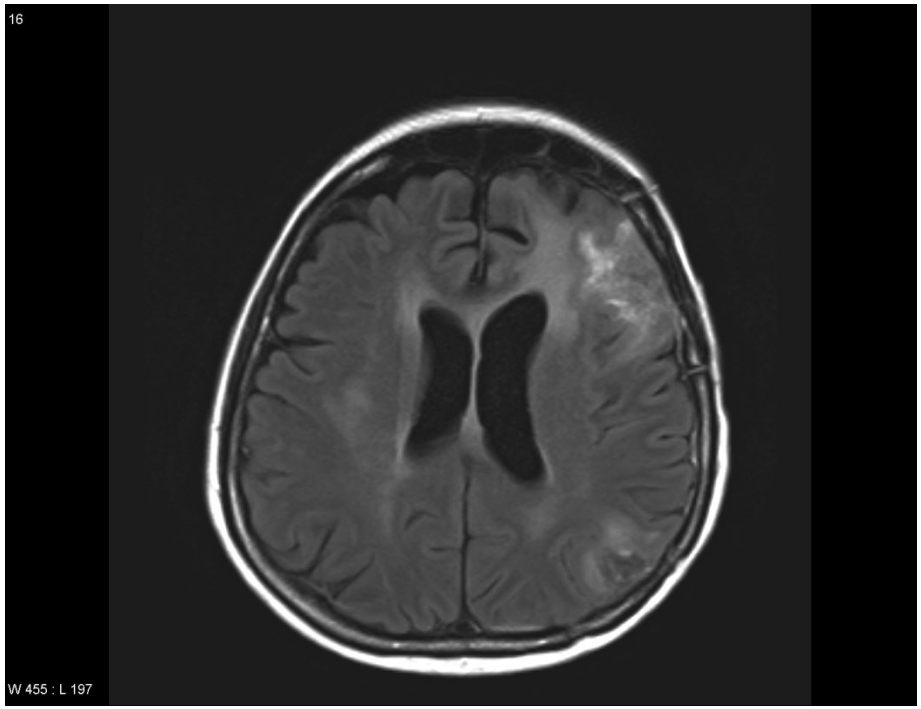
Anti-oedema therapy

- Results from leakage of plasma into the tissue through disrupted BBB
- Detectable of T2-weighted and FLAIR MRI images
- Increased intracranial pressure with headache, vertigo, nausea/vomiting
- May lead to life-threatening brainstem compression and herniation
- Drug of choice: Dexamethasone
  - Initial daily dose usually 12-16 mg
  - Steroid dose should be rapidly reduced and tapered to individual need (“as much as needed, as little as possible”)
  - Withhold corticosteroid in asymptomatic patients and when lymphoma or inflammatory lesion can not be ruled out
- Dexamethasone may be combined with osmotic agents such as mannitol or glycerol
- Obstructive hydrocephalus may be treated with CSF shunt
- Bevacizumab may reduce brain oedema and is associated with decreased corticosteroid need

Bevacizumab for brain edema and radionecrosis

FLAIR





01.12.2012
Before bevacizumab

01.03.2013
After 4x bevacizumab

Conclusions

- Brain metastases are common and a clinical challenge
- Radiotherapy/SRS and surgery are established treatment options
- Brain mets are a promising target for prophylactic and therapeutic intervention based on molecular insights, some mechanisms and drug targets identified and treatmens emerging
- Many open questions that require specifically designed trials (e.g. sequencing/combination strategies)

ESTRO School

Classification of clinical trials

- **Phase 0** Biological proof of concept / biodistribution
- **Phase I** Determination of safety, tolerability and maximum tolerated dose
- **Phase II** Suggestion of efficacy
- **Phase III** Proof of efficacy
- **Phase IV** Optimization of therapy and new patient populations (children, elderly patients)

ESTRO School

Clinical trial endpoints

- Survival
- Survival specified for quality, e.g., “in independence”
- Time to event
- Imaging
- Toxicity
- Quality of life
- Biological endpoints: target inhibition

Typical mistakes of clinical trial designs

- Wrong endpoints
- Inclusion criteria too narrow
- Unrealistic assumptions of effect size
- Sample size too small
- Unrealistic assumptions on accrual

Essentials for planning a clinical trial

- What is my question?
- What are my eligibility criteria?
- What is my primary endpoint?
- What effect size do I expect?
- Which quality measures do I need?
- What is the budget and who will pay?

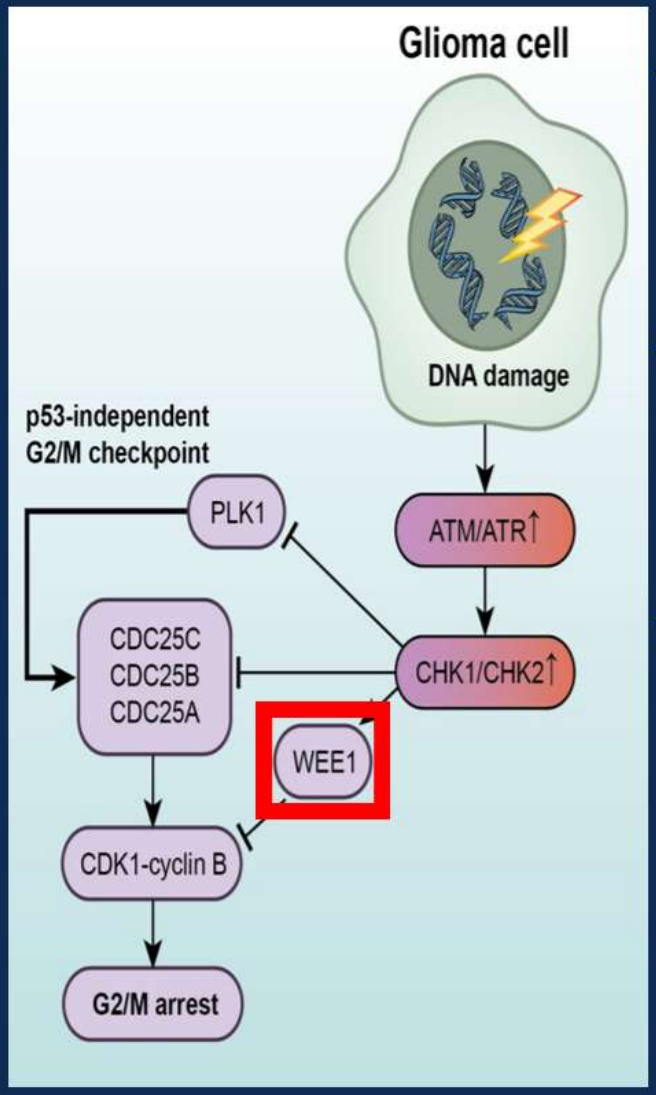
Phase 0 Trial of AZD1775 in Patients with First-Recurrence Glioblastoma

Nader Sanai, Jing Li, Julie Boerner, Harshil Dhruv, Michael Berens, and Patricia LoRusso

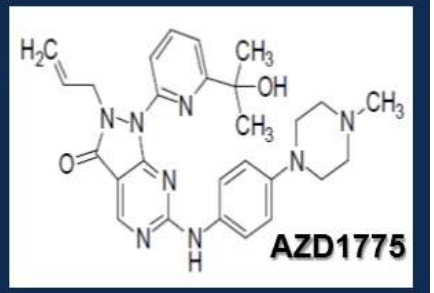
Barrow Neurological Institute, AZ; Translational Genomic Research Institute (TGen), AZ; Karmanos Cancer Institute, MI; Yale University Cancer Center, CT

PRESENTED AT: ASCO ANNUAL MEETING '16

Wee1 Inhibition for Glioblastoma

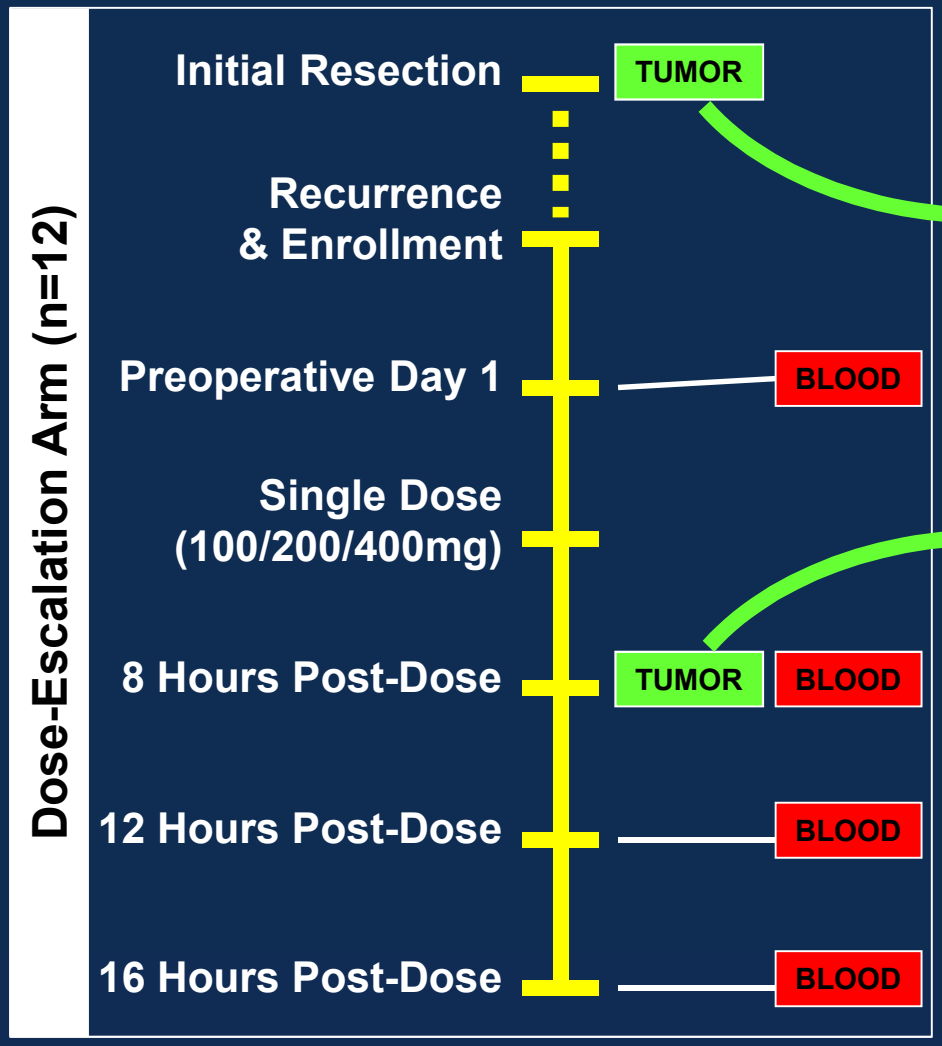


- **Wee1 overexpression in GBM inversely correlates with survival**
- **Wee1 inhibition abrogates G2 arrest and prematurely ends DNA repair**
- **AZD1775 is a potent and selective inhibitor of the Wee1-kinase**



Music *et al. J Neurooncol* 2016 Apr; 127(2): 381-9
Mir *et al. Cancer Cell* 2010 Sep 14; 18(3): 244-57

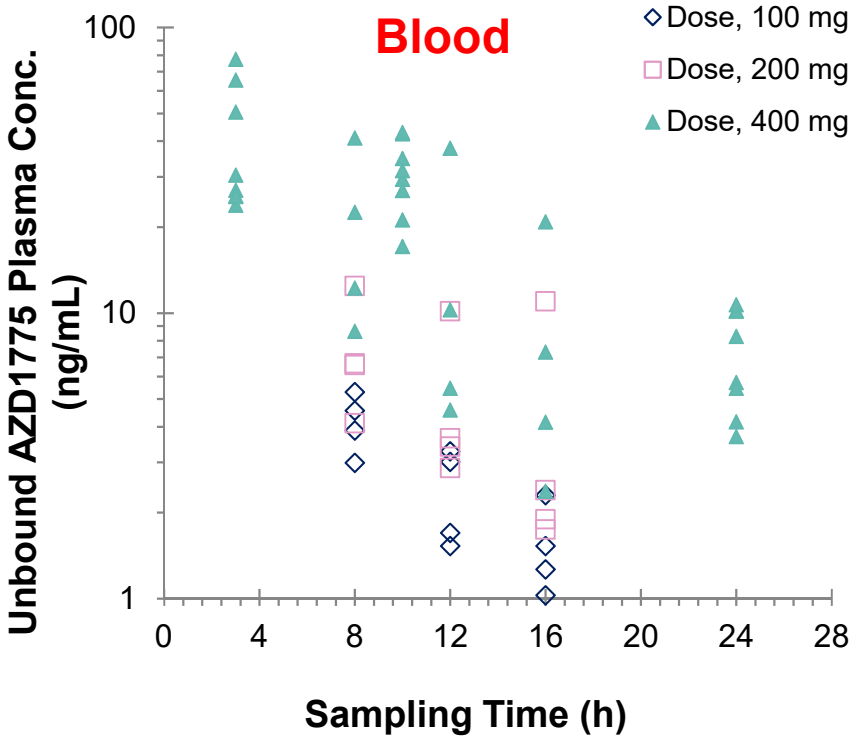
AZD1775 Phase 0 Study for GBM

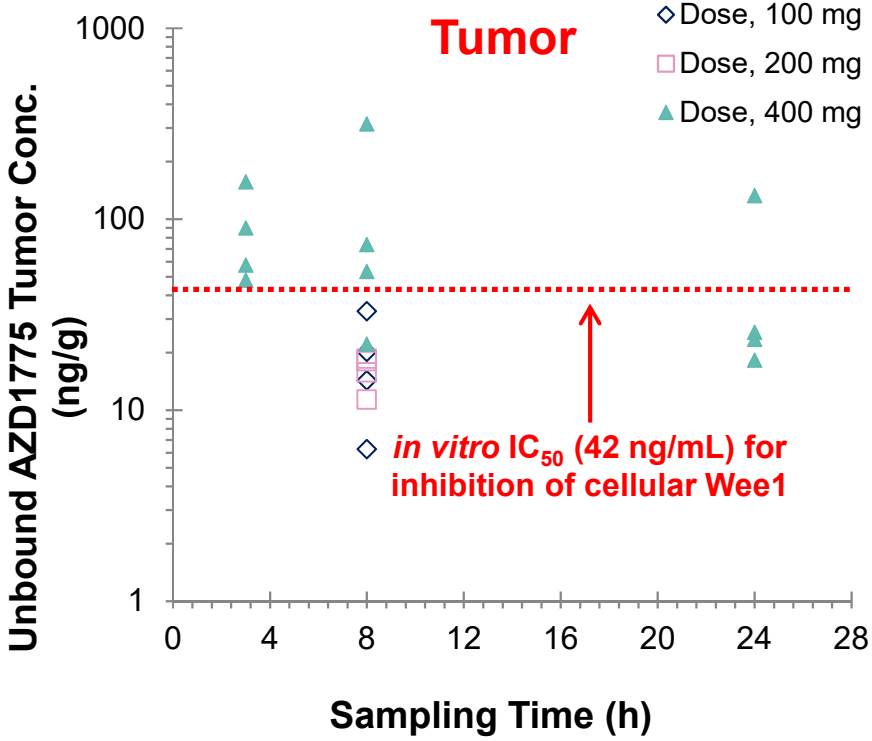


- Phosphorylated H2AX
- Phosphohistone-3
- Cleaved Caspase-3
- Cyclin E
- Phospho-Cdk1
- p53-Status
- Checkpoint Regulators
- Transport Proteins

BARROW Neurological Institute

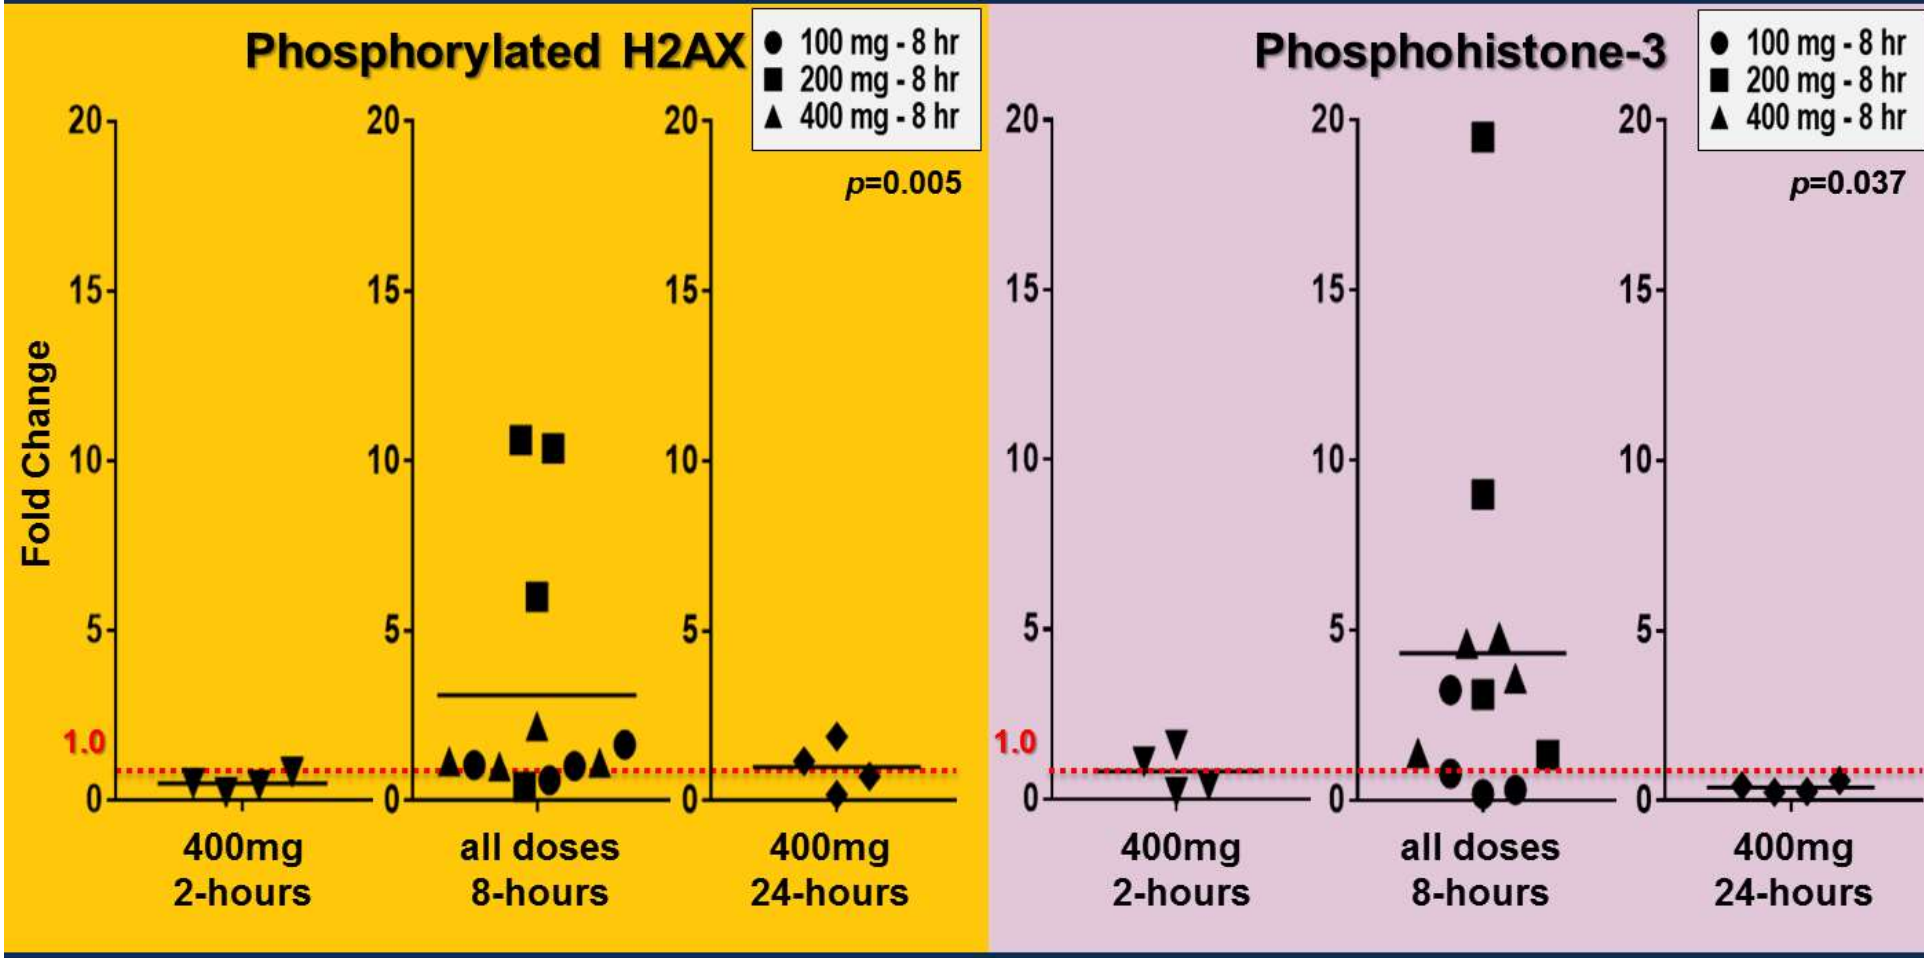
AZD1775 Pharmacokinetics in GBM





- AZD1775 plasma exposure increased with the increase of dose
- 2 to 24 h after 400mg dose, unbound (pharmacologically-active) drug concentrations in tumor ranged from 18 – 315 ng/g, with mean concentration (85 ng/g) > *in vitro* IC_{50} (42 ng/mL) for inhibition of cellular Wee1 activity

AZD1775 Pharmacodynamics in GBM



RT/TMZ→TMZ + marizomib in newly diagnosed glioblastoma

NEWS FOCUS | BRAIN CANCER

A Viral Link to Glioblastoma?

Greg Miller
+ See all authors and affiliations

Science 02 Jan 2009:
Vol. 323, Issue 5910, pp. 30-31
DOI: 10.1126/science.323.5910.30

Circumstantial evidence hints that cytomegalovirus, a common herpesvirus, may play a role in the aggressive brain cancer, but big questions remain.

VIGAS study: design

IJC
International Journal of Cancer

Effects of valganciclovir as an add-on therapy in patients with cytomegalovirus-positive glioblastoma: A randomized, double-blind, hypothesis-generating study

Giuseppe Stragliotto[1], Afsar Rahbar[2*], Nina Wolmer Solberg[2*], Anders Lilja[3], Chato Taher[2], Abiel Orrego[4], Birgitta Bjurman[5], Charlotte Tammik[2], Petra Skarman[2], Inti Peredo[2,6] and Cecilia Söderberg-Nauclér[2]

- 42 patients with newly diagnosed glioblastoma with > 90% tumor resection
- Histologically verified “CMV infection” in the tumor
- Radiotherapy plus concomitant TMZ (no adjuvant TMZ?)
- Addition of valganciclovir or placebo in this trial

ESTRO School

Valganciclovir

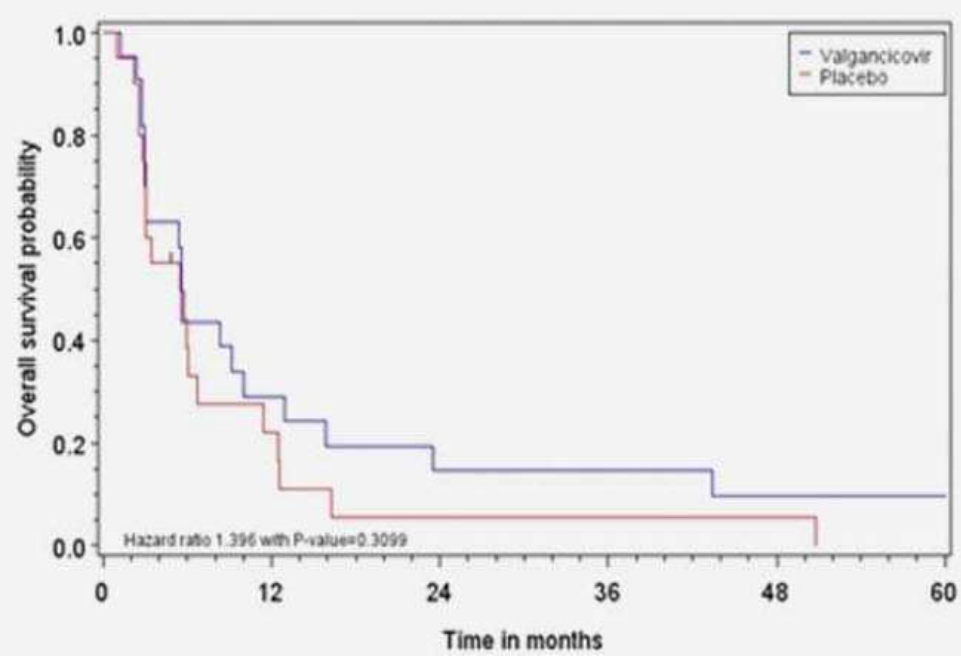
- Approved for the treatment of CMV retinitis in HIV-positive patients or for prophylaxis in immunocompromised subjects
- Side effects: nausea, diarrhea, headache, myelosuppression, fetal toxicity…
- Metabolized to ganciclovir by a CMV-encoded thymidine kinase → concentrates in CMV-infected cells
- Inhibitor of dGTP: incorporated into viral DNA → inhibits viral DNA polymerases which results in chain termination

VIGAS study: outcome

Primary endpoint: tumor size at 3 and 6 months after surgery:

→ **no difference between study arms**

Progression-free survival



Overall survival

Valganciclovir for glioblastoma: surprise!

Survival in Patients with Glioblastoma Receiving Valganciclovir

Cecilia Söderberg-Nauclér, M.D., Ph.D.
Afsar Rahbar, Ph.D.
Giuseppe Stragliotto, M.D., Ph.D.
Karolinska Institutet
Stockholm, Sweden

N ENGL J MED 369;10 NEJM.ORG SEPTEMBER 5, 2013

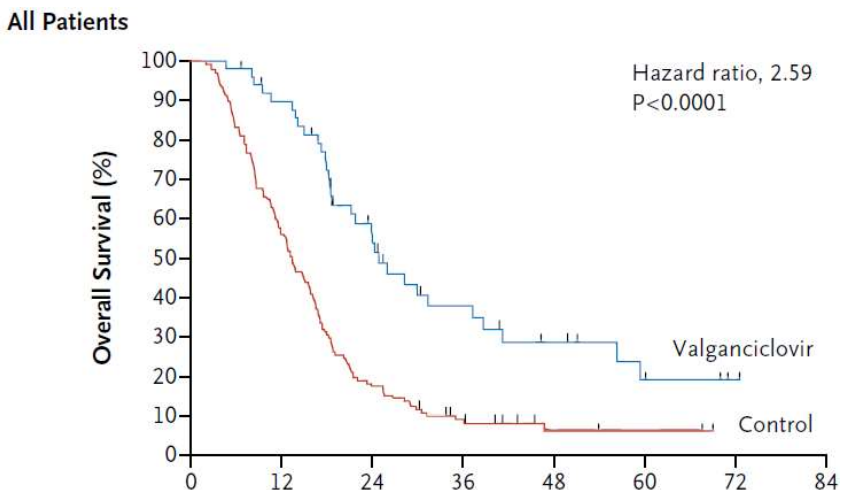
The NEW ENGLAND JOURNAL of MEDICINE

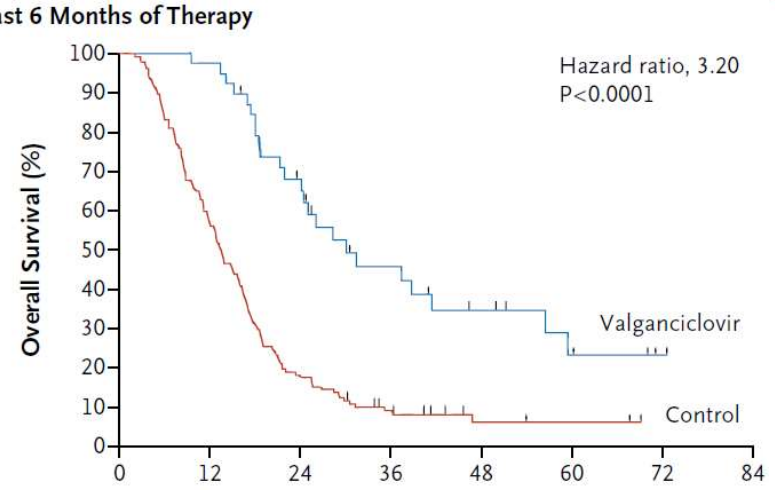
- In exploratory analyses, 22 patients receiving at least 6 months of antiviral therapy, as compared with contemporary controls, had an increased OS at 2 years

- Owing to the promising results of this study, 28 patients at our hospital have received anti-CMV therapy for compassionate use in addition to their standard therapy

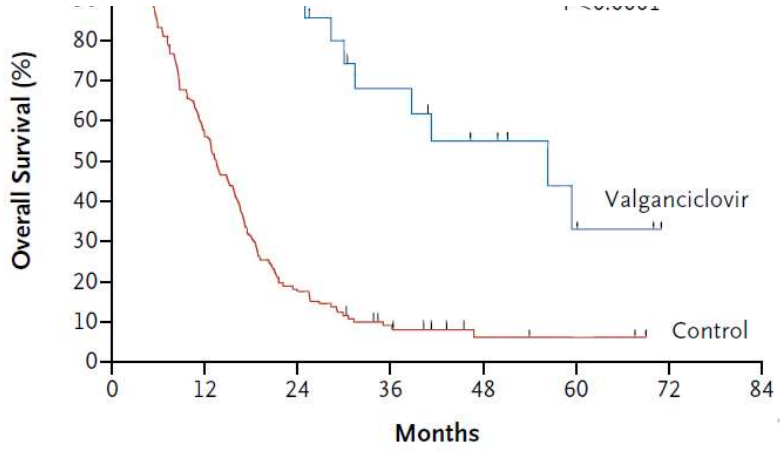
ESTRO School

Valganciclovir-treated patients *vs.* contemporary controls





It is unlikely that any bias in patient selection could have resulted in these high rates of survival



No. at Risk								
Valganciclovir	25	24	18	11	7	3	0	0
Control	137	79	25	10	3	2	0	0

Valganciclovir-treated patients *vs.* contemporary controls

	Valganciclovir treatment			Contemporary controls 2006–2009 (n=137)
	≥1 day (n = 50)	>6 months (n = 40)	>6 months and then maintenance therapy (n = 25)	
Mean age (years) at diagnosis (range)	57 (18–77)	55 (33–75)	56 (33–75)	48.3 (32–83)
Estimated 2-year survival	62% (p<0.0001)	70% (p<0.0001)	90% (p<0.0001)	18%
Median overall survival (months)	25.0 (CI 18.7–37.4, p<0.0001)	30.1 (CI 24.1–56.4, p<0.0001)	56.4 (CI 30.0–, upper 95% limit not reached, p<0.0001)	13.5 (CI 11.8–15.9)

	median OS	2-year OS
Stupp et al., NEJM 2005 (RT/TMZ→TMZ)	14.6 months	27%
Chinot et al., NEJM 2014 (RT/TMZ→TMZ)	16.7 months	30%

ESTRO School

Valganciclovir-treated patients *vs.* contemporary controls

- Heterogeneous cohorts with respect to standard treatment and timing of valganciclovir
- Valganciclovir was given only "**when there was no evidence of progression**"

  → Selection of patients with valganciclovir exposure of 6 months after surgery or after 6 months of standard treatment

  → Enrichment for favorable outcome

  → Creation of a new long-term benefitting sub-group of patients

- No documentation of factors associated with longer survival, e.g. extent of resection, IDH, MGMT etc.

ESTRO School

Conclusions

For a successful clincial trial, you need…:

- A timely question
- An appropriate endpoint
- Sufficient (financial) ressources
- Access to patients and/or a network of collaborators
- Statistical advice

Management of skull base tumours

Dr Sarah Jefferies

Cambridge University Hospitals NHS
NHS Foundation Trust

ESTRO School

Pre-requisites

- Excellent Imaging
- Excellent Surgery
- Anatomical knowledge
- Access to appropriate radiotherapy techniques when needed

Which tumours?

- Primary:
  - **Chordoma/chondrosarcoma**

- Secondary infiltration or involvement:

Intracranial:

Meningioma

Craniopharyngioma

Head and Neck Tumours:

Olfactory neuroblastoma

Adenoid cystic carcinoma

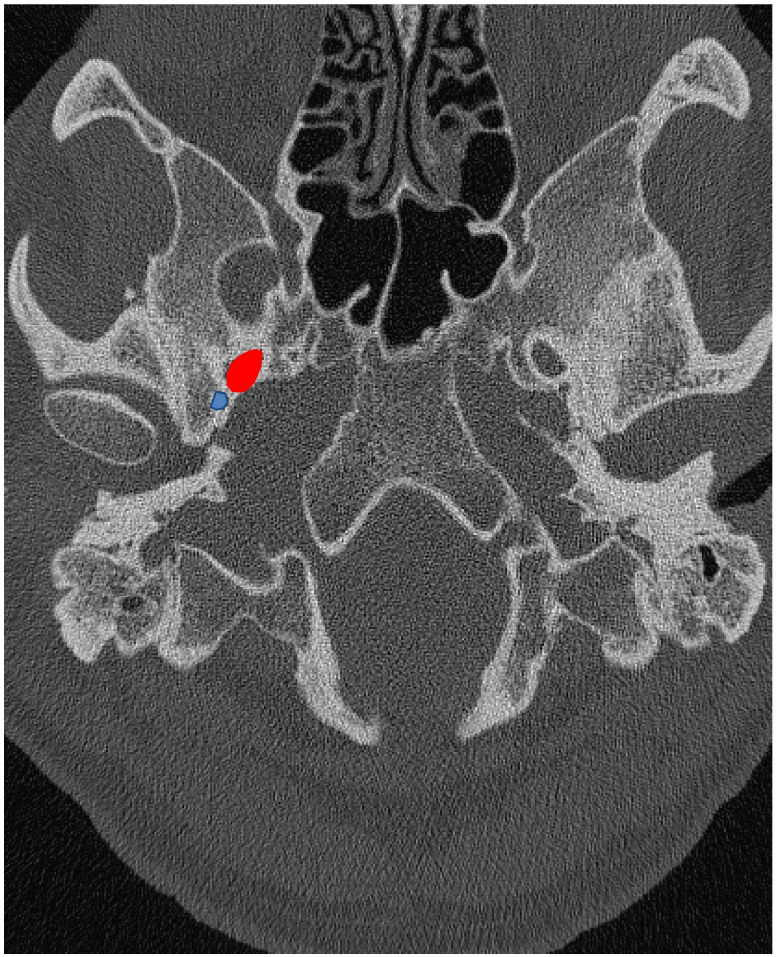
Nasopharyngeal carcinoma

Nasal cavity and paranasal sinus

Sarcoma

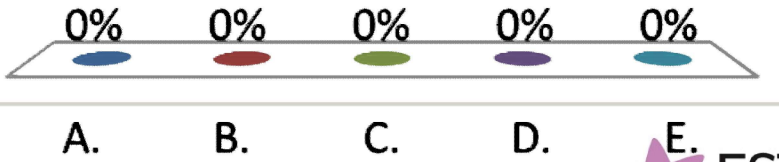
Needs anatomical knowledge

Which Foramen?



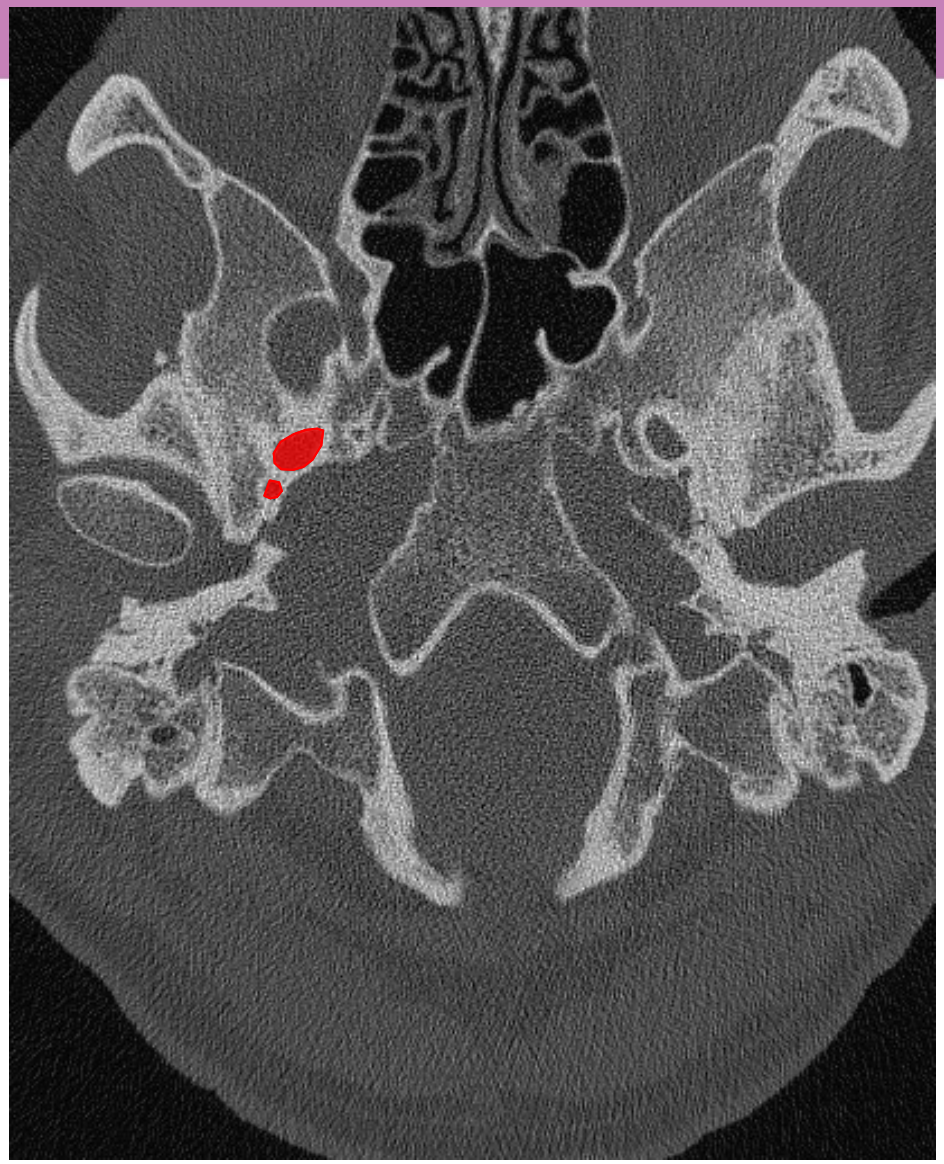
The red shape is overlying:

A. Foramen spinosum
B. Foramen lacerum
C. Jugular foramen
D. Foramen ovale
E. Foramen rotundum



ESTRO School

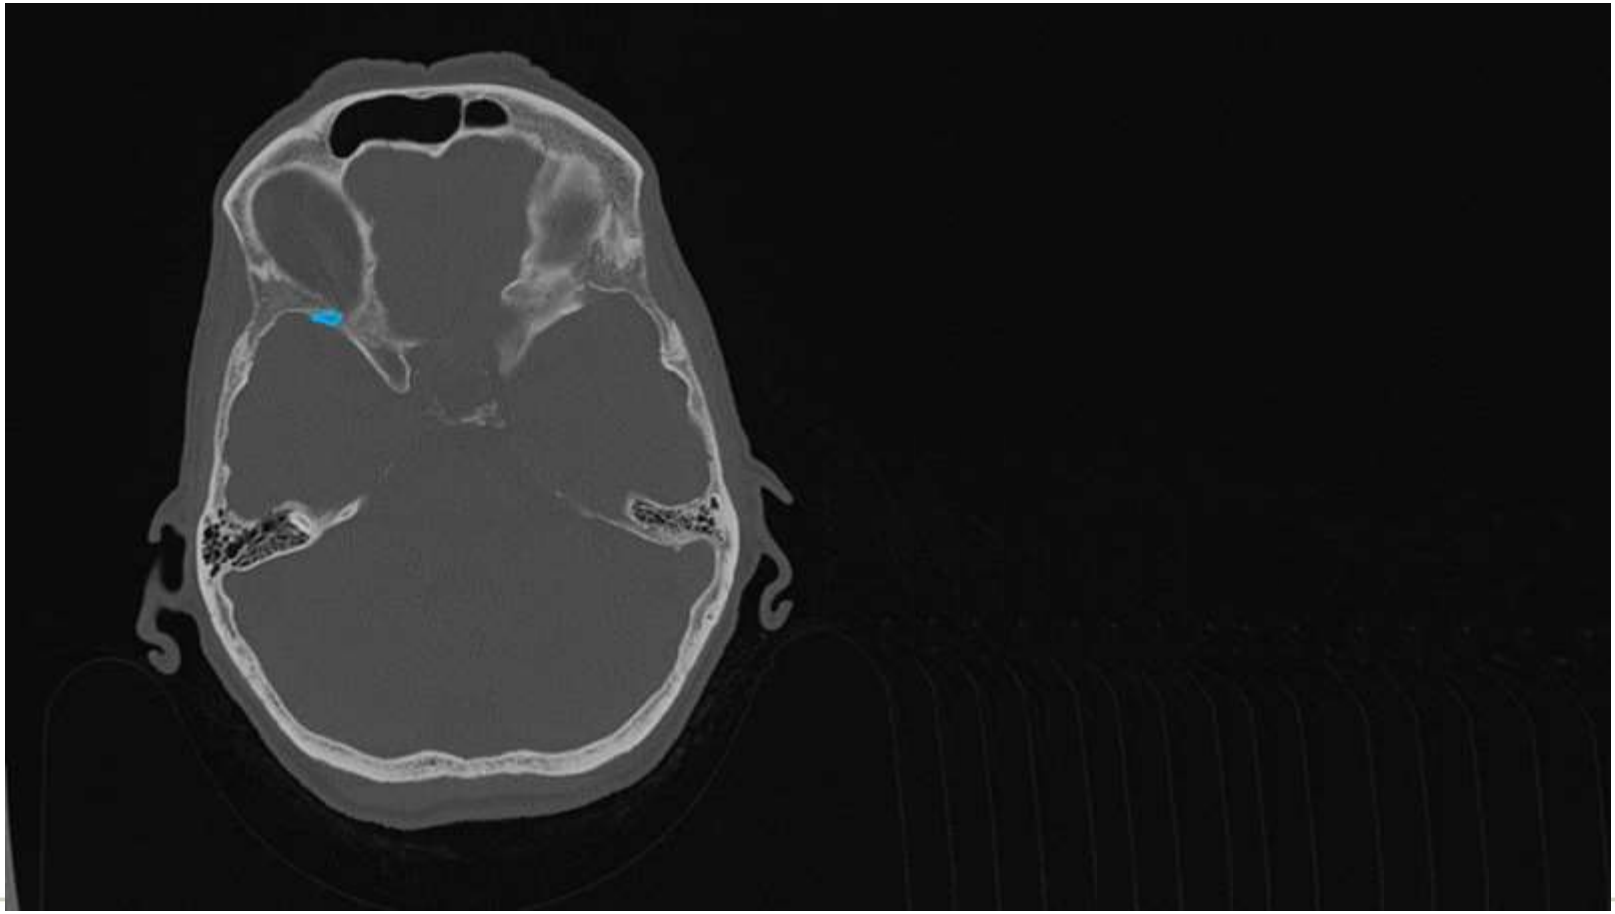
The high-heel footprint sign . . . . .



ESTRO School

RADIOLOGICAL ANATOMY – SKULL BASE FORAMINA

- SUPERIOR ORBITAL
- OPTIC CANAL
- OLFACTORY BULB
- INTERNAL ACOUSTIC
- FORAMEN LACERUM
- CAROTID CANAL
- FORAMEN ROTUNDUM
- JUGULAR FORAMEN
- FORAMEN OVALE
- FORAMEN SPINOSUM
- HYPOGLOSSAL CANAL
- PTERYGOPALATINE FOSSA

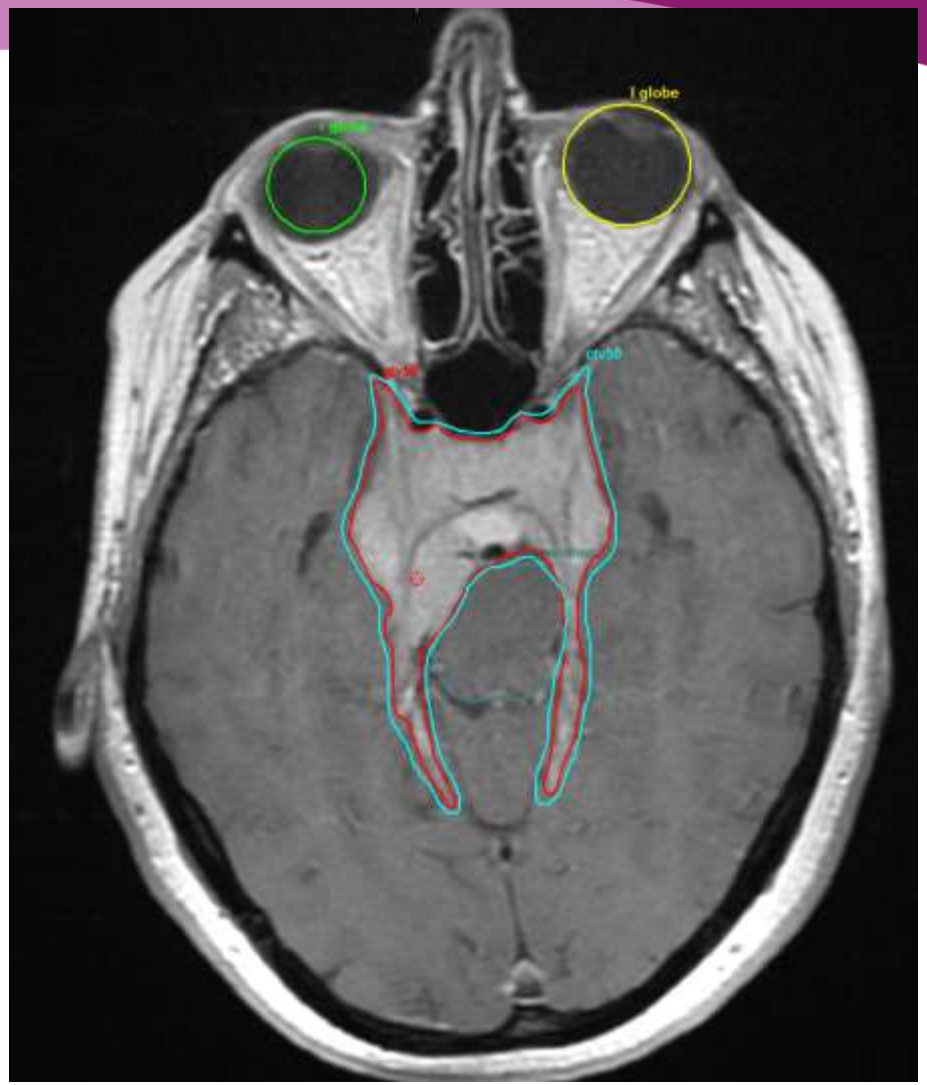


ESTRO School

AN EXAMPLE CASE
DEMONSTRATING (MOST OF!)

55 year old lady.

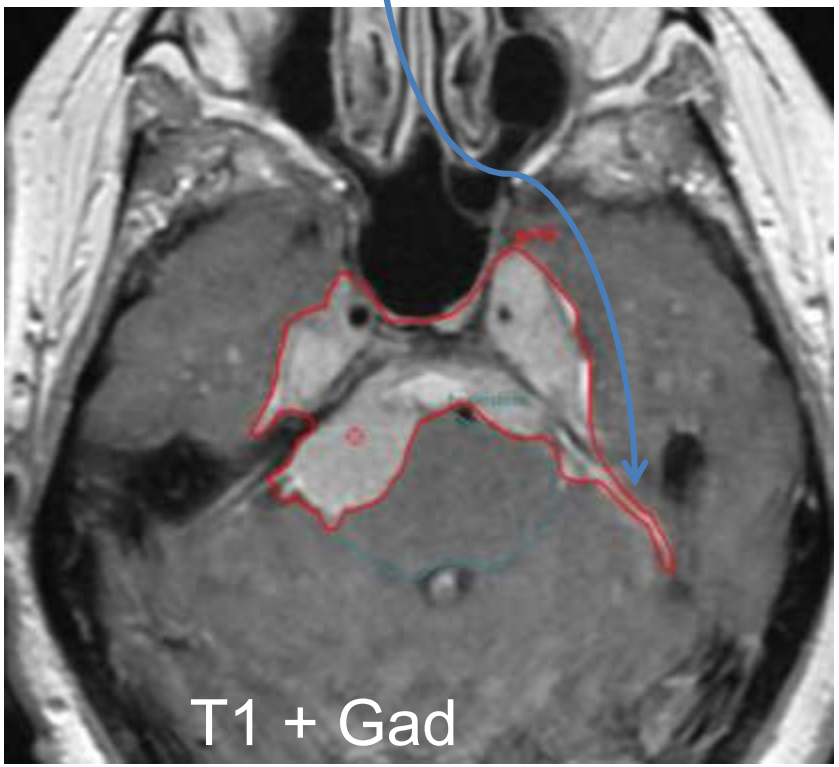
- Presented with a history of gradually worsening left ptosis. No other symptoms
- O/E:
  - left III palsy (ptosis, dilated pupil)
  - left IV palsy
- Otherwise fit and well.



ESTRO School

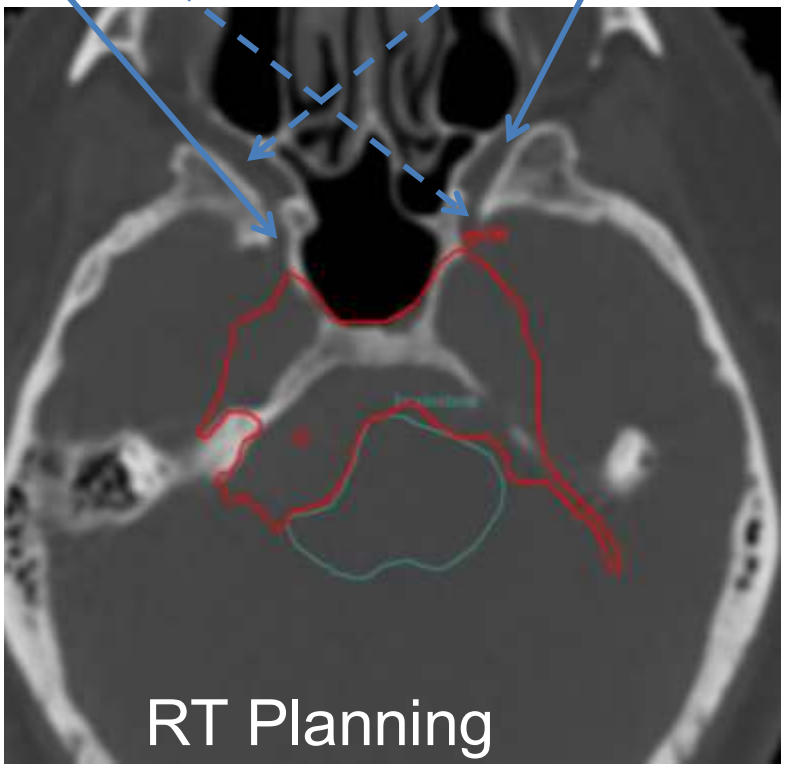
Example case - meningioma

LONG DURAL TAIL ALONG THE PETROUS TEMPORAL BONE CLEARLY VISIBLE ON MRI



FORAMEN ROTUNDUM

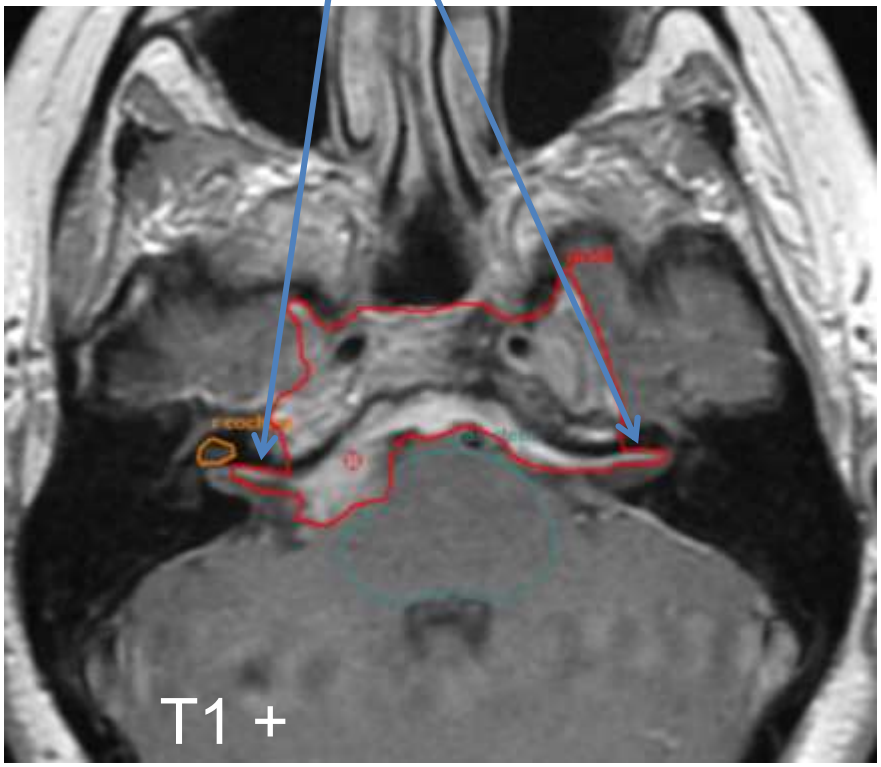
PTERYGOPALATINE FOSSA



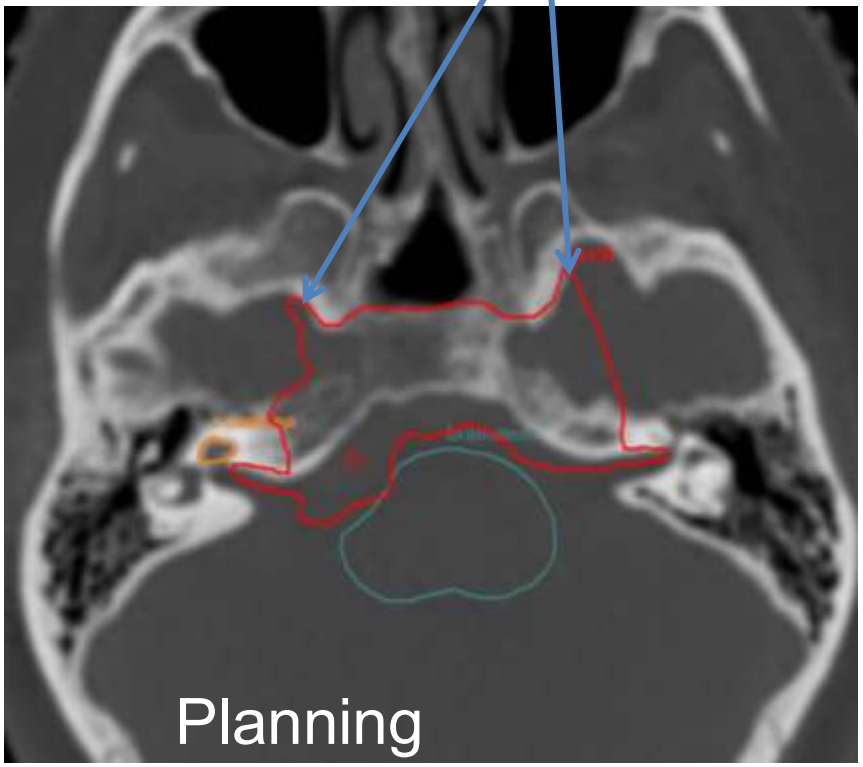
ESTRO School

Example case - meningioma

VISIBALE DURAL TAIL INTO BOTH INTERNAL ACOUSTIC CANALS



DURAL TAIL EXTENIDNG ANTERIORLY AND INFERIORLY TOWARDS FORAMEN OVALE



ESTRO School

Example case - meningioma

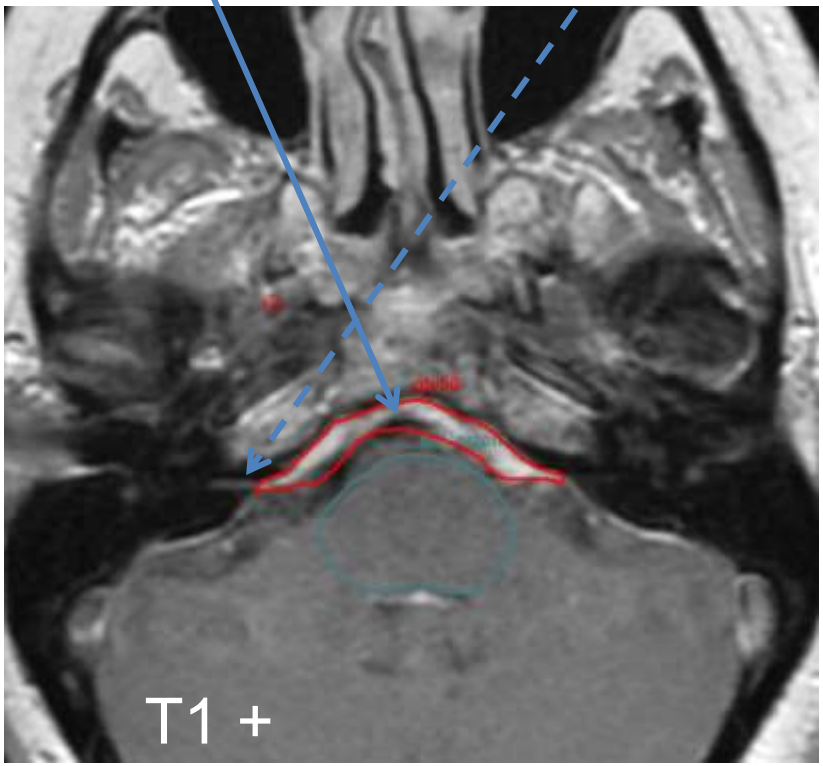
DURAL TAIL EXTENDING INFERIORLY DOWN THE CLIVUS

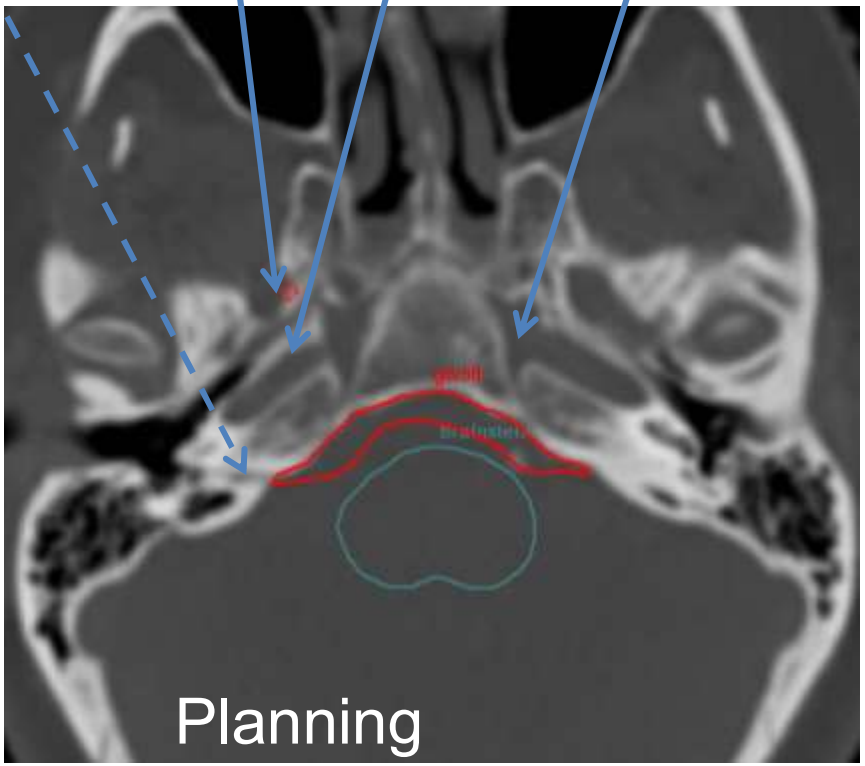
JUGULAR FORAMEN (PARS NERVOSA)

FORAMEN OVALE

CAROTID CANAL

FORAMEN LACERUM





ESTRO School

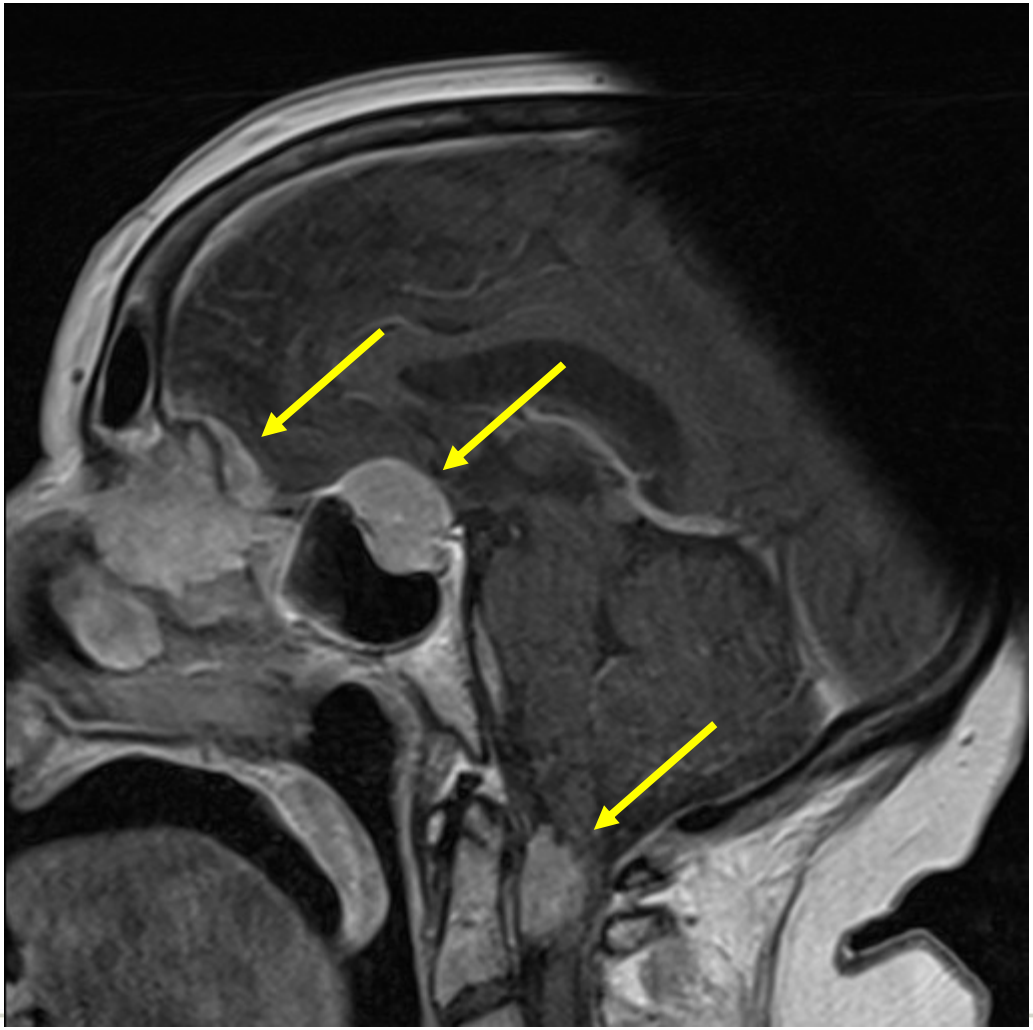
Imaging

Imaging

- Imaging is also an essential prerequisite
  - To show target better
  - For co-registered use in planning

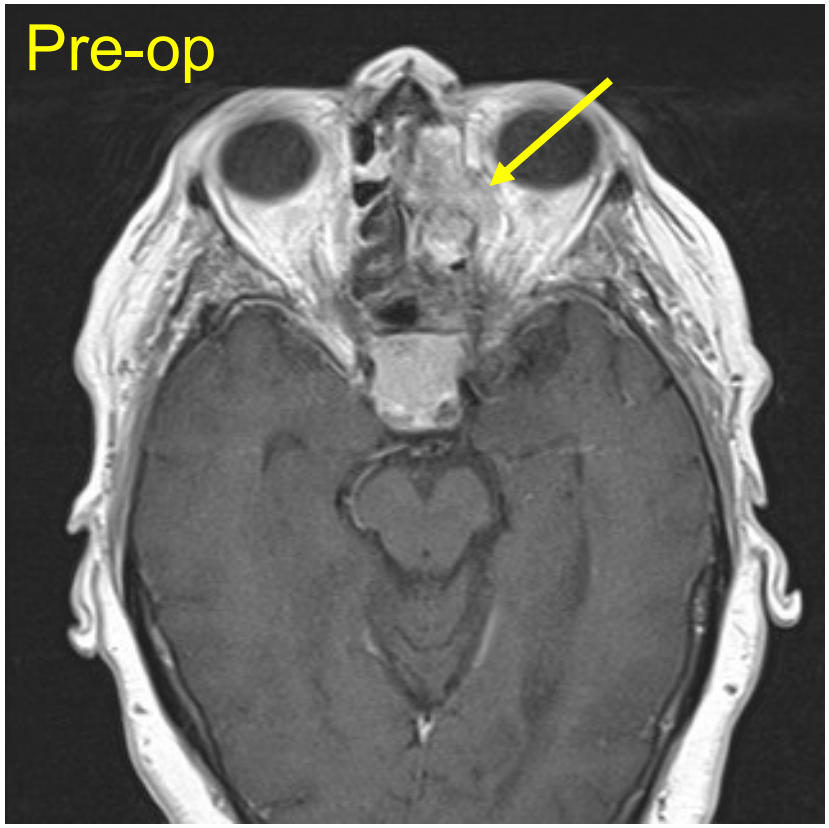
Skull base meningioma

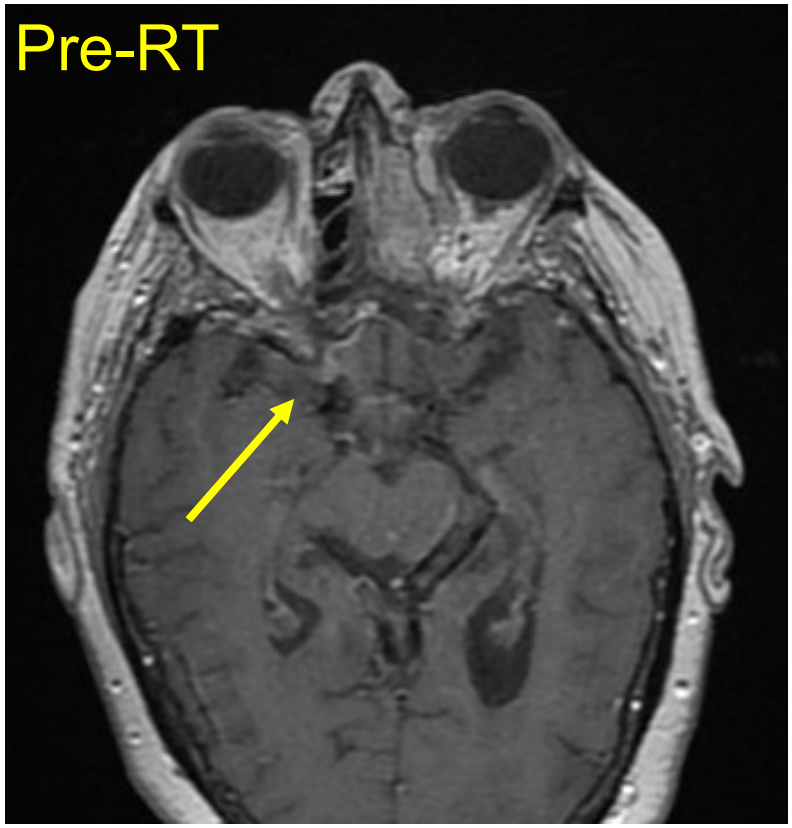
- Note 3 areas of disease
  - 2 areas probably contiguous
  - 3rd at cranio-cervical junction
- Partial resection of suprasellar mass, & biopsy of ethmoid mass



ESTRO School

Skull base meningioma

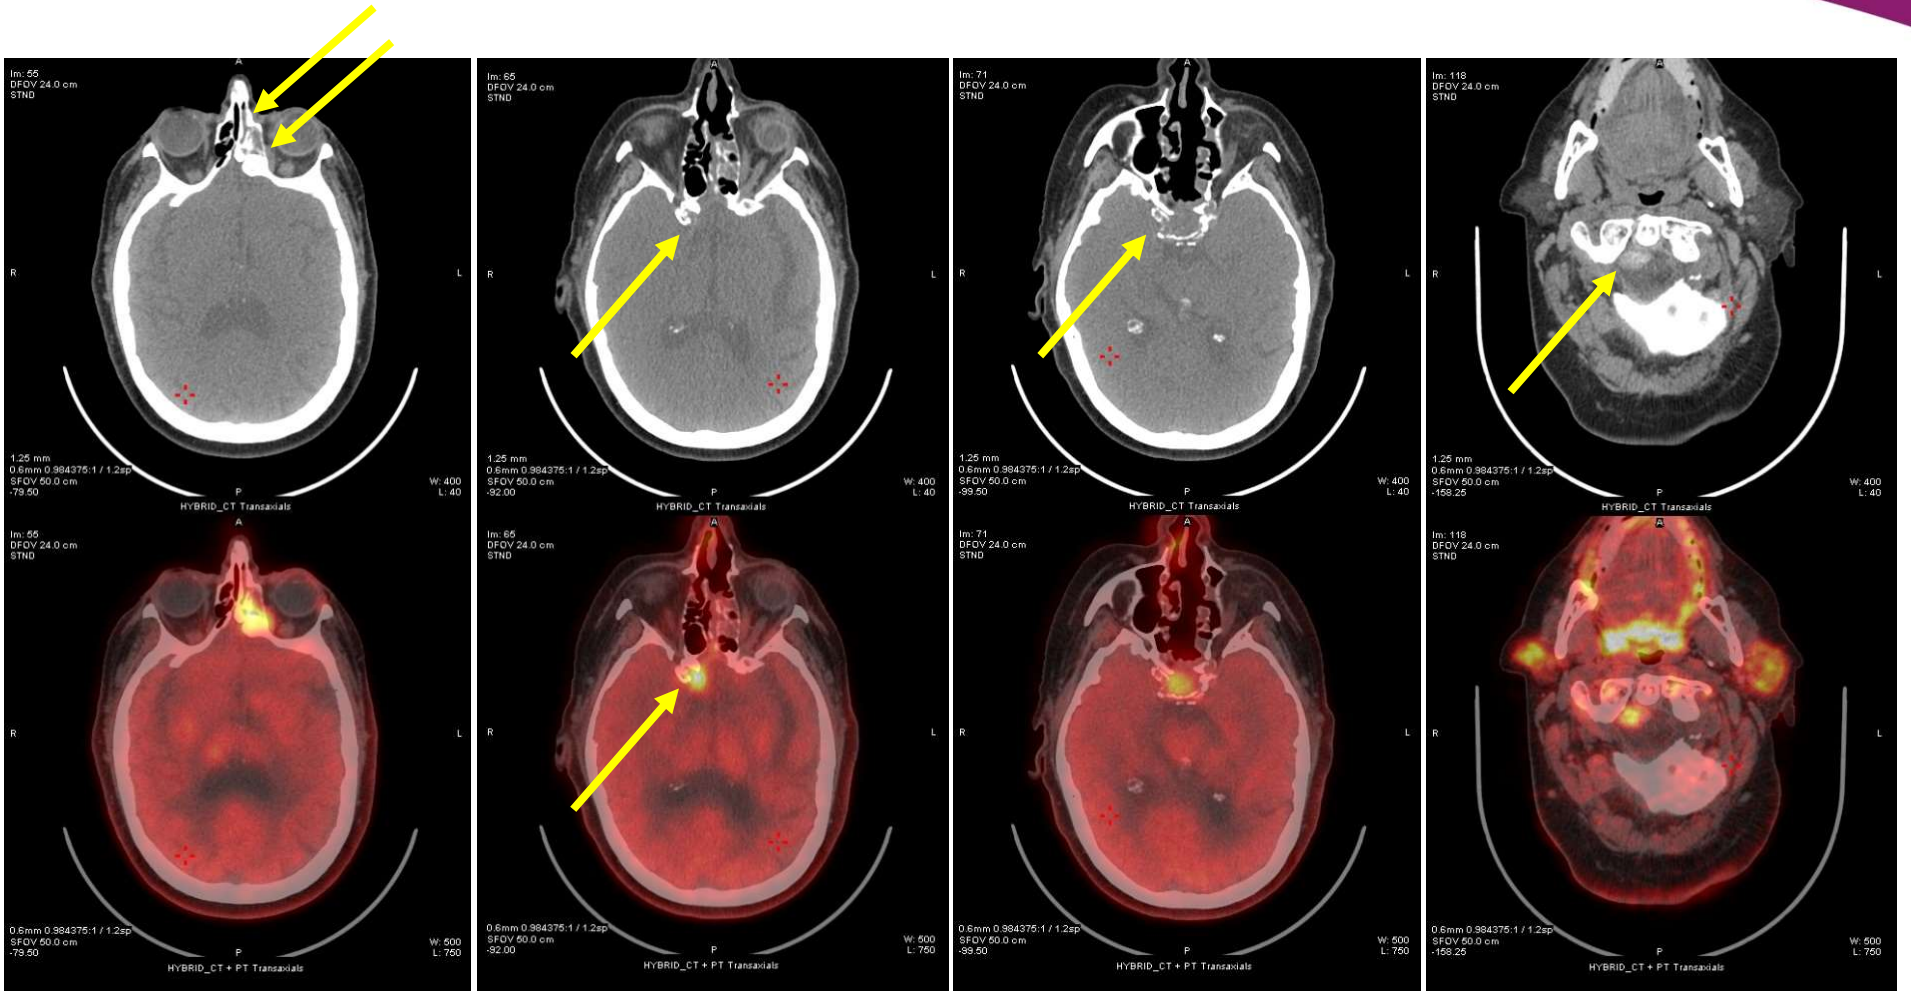




- Definite involvement of L orbit
- Uncertain lesion at R optic foramen

ESTRO School

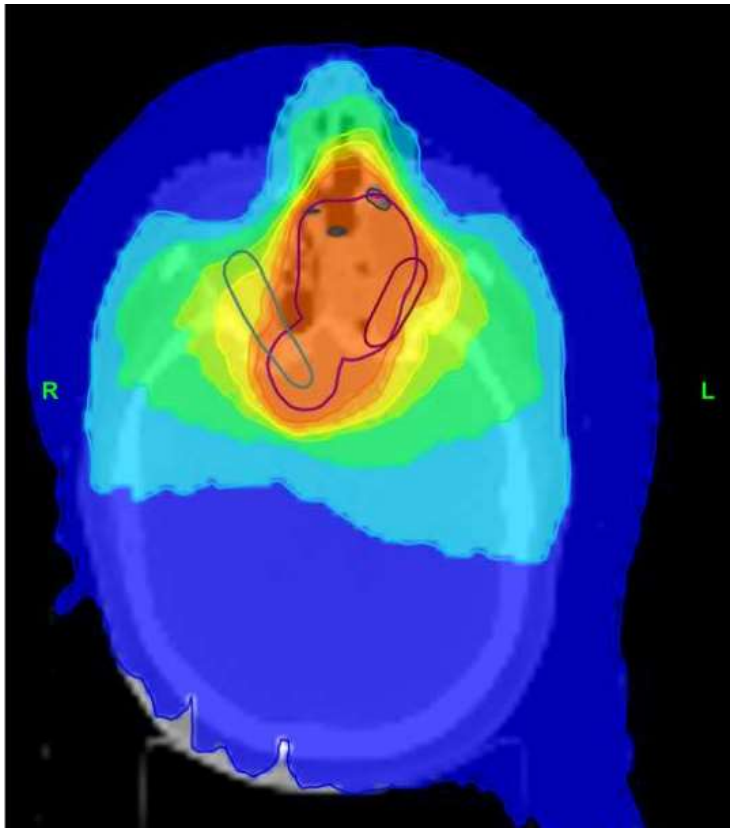
Skull base meningioma

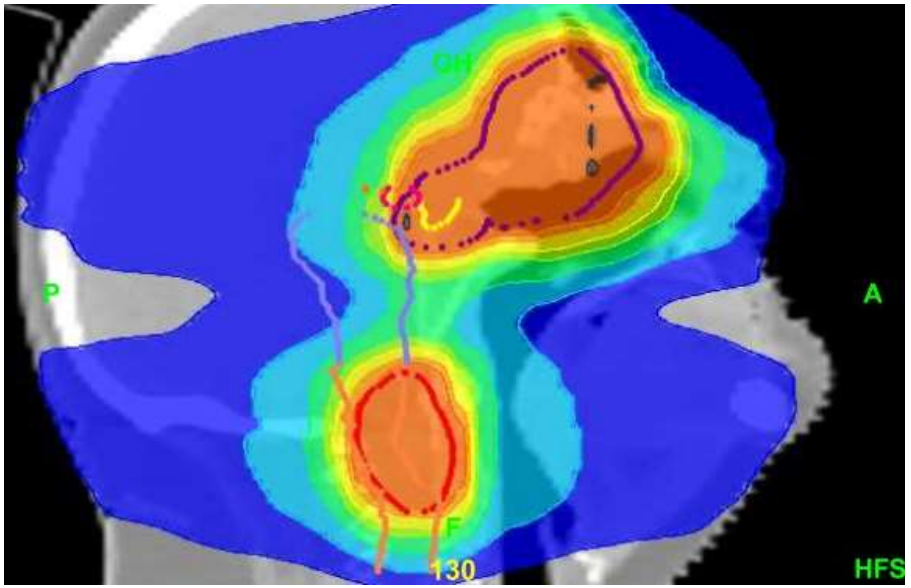


- Methionine PET clarified area at R optic foramen

ESTRO School

Skull base meningioma



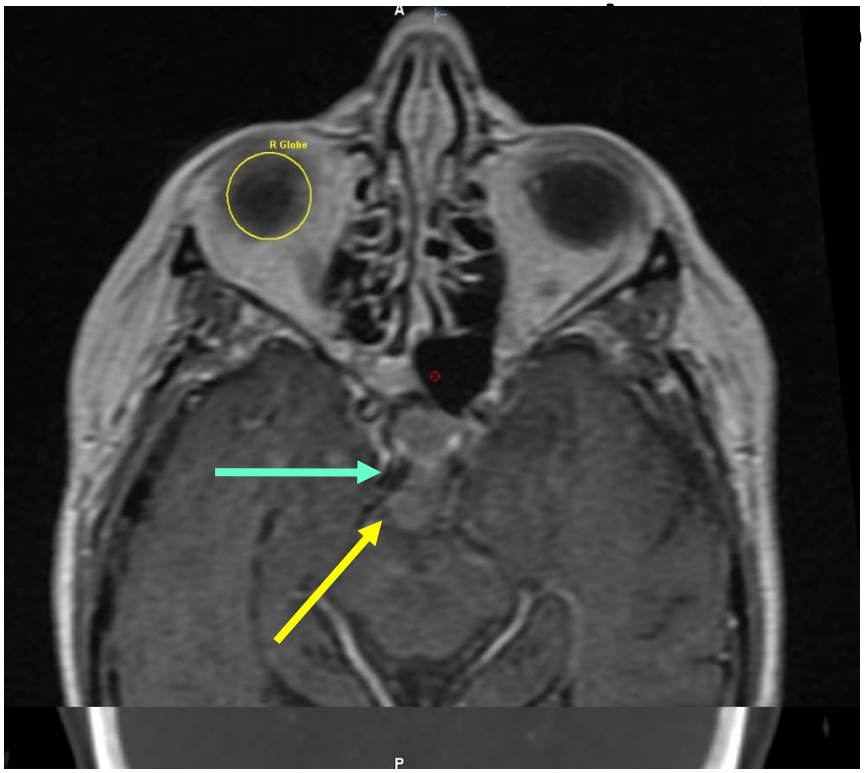


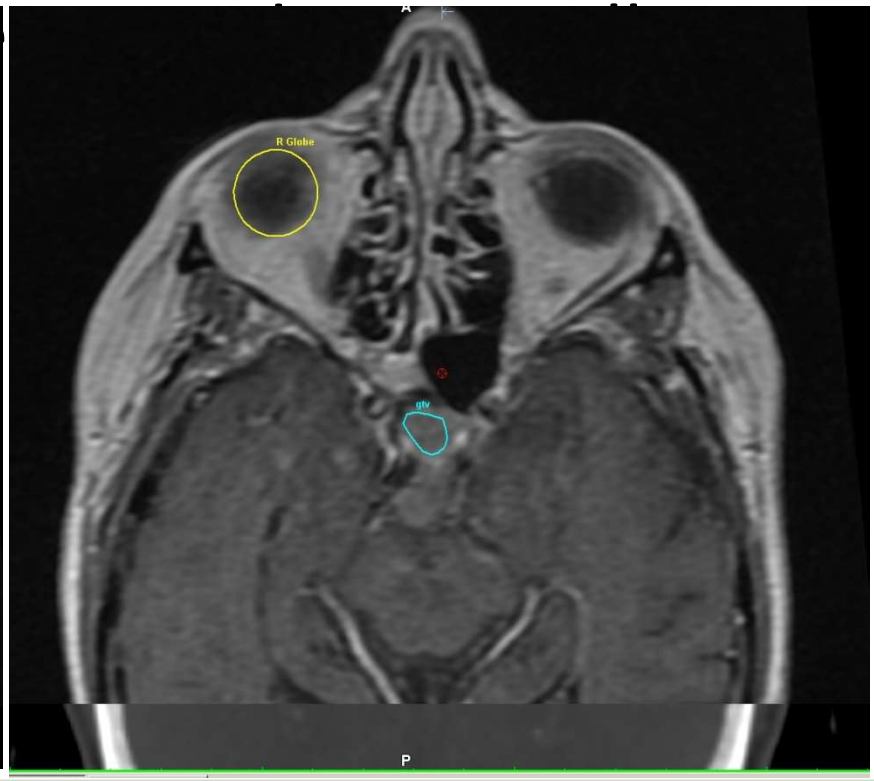
- IMRT plan for all areas
- 50 Gy / 30#

ESTRO School

Imaging for RT planning

- Planning MR for pituitary adenoma

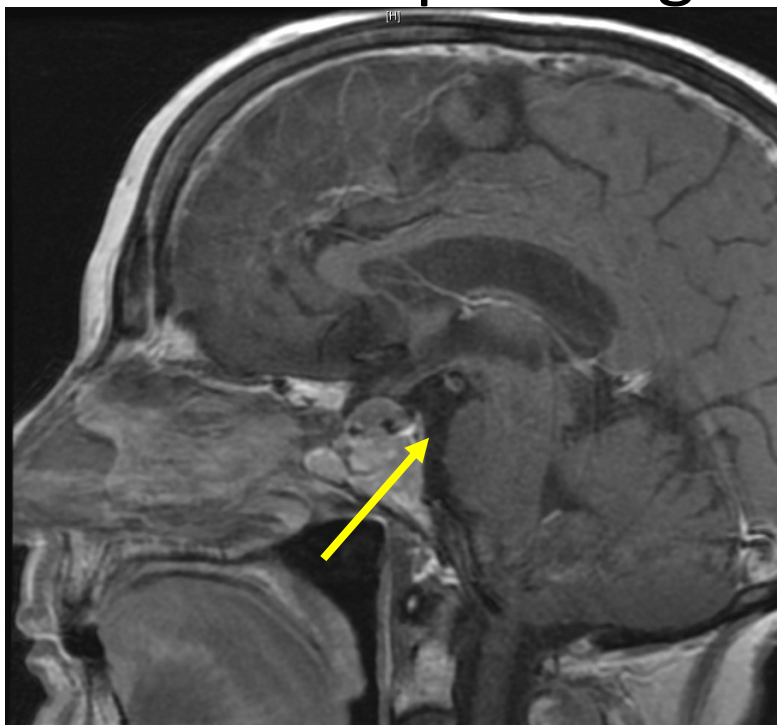




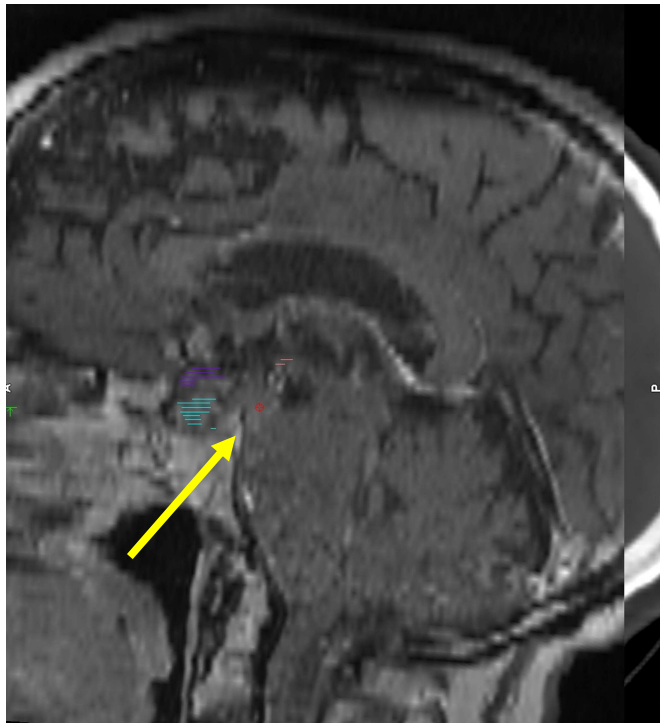
ESTRO School

Imaging for RT planning

- Artefact on planning sequence !



Sagittal T1 + Gd



Axial T1 + Gd planning sequence

ESTRO School

Imaging

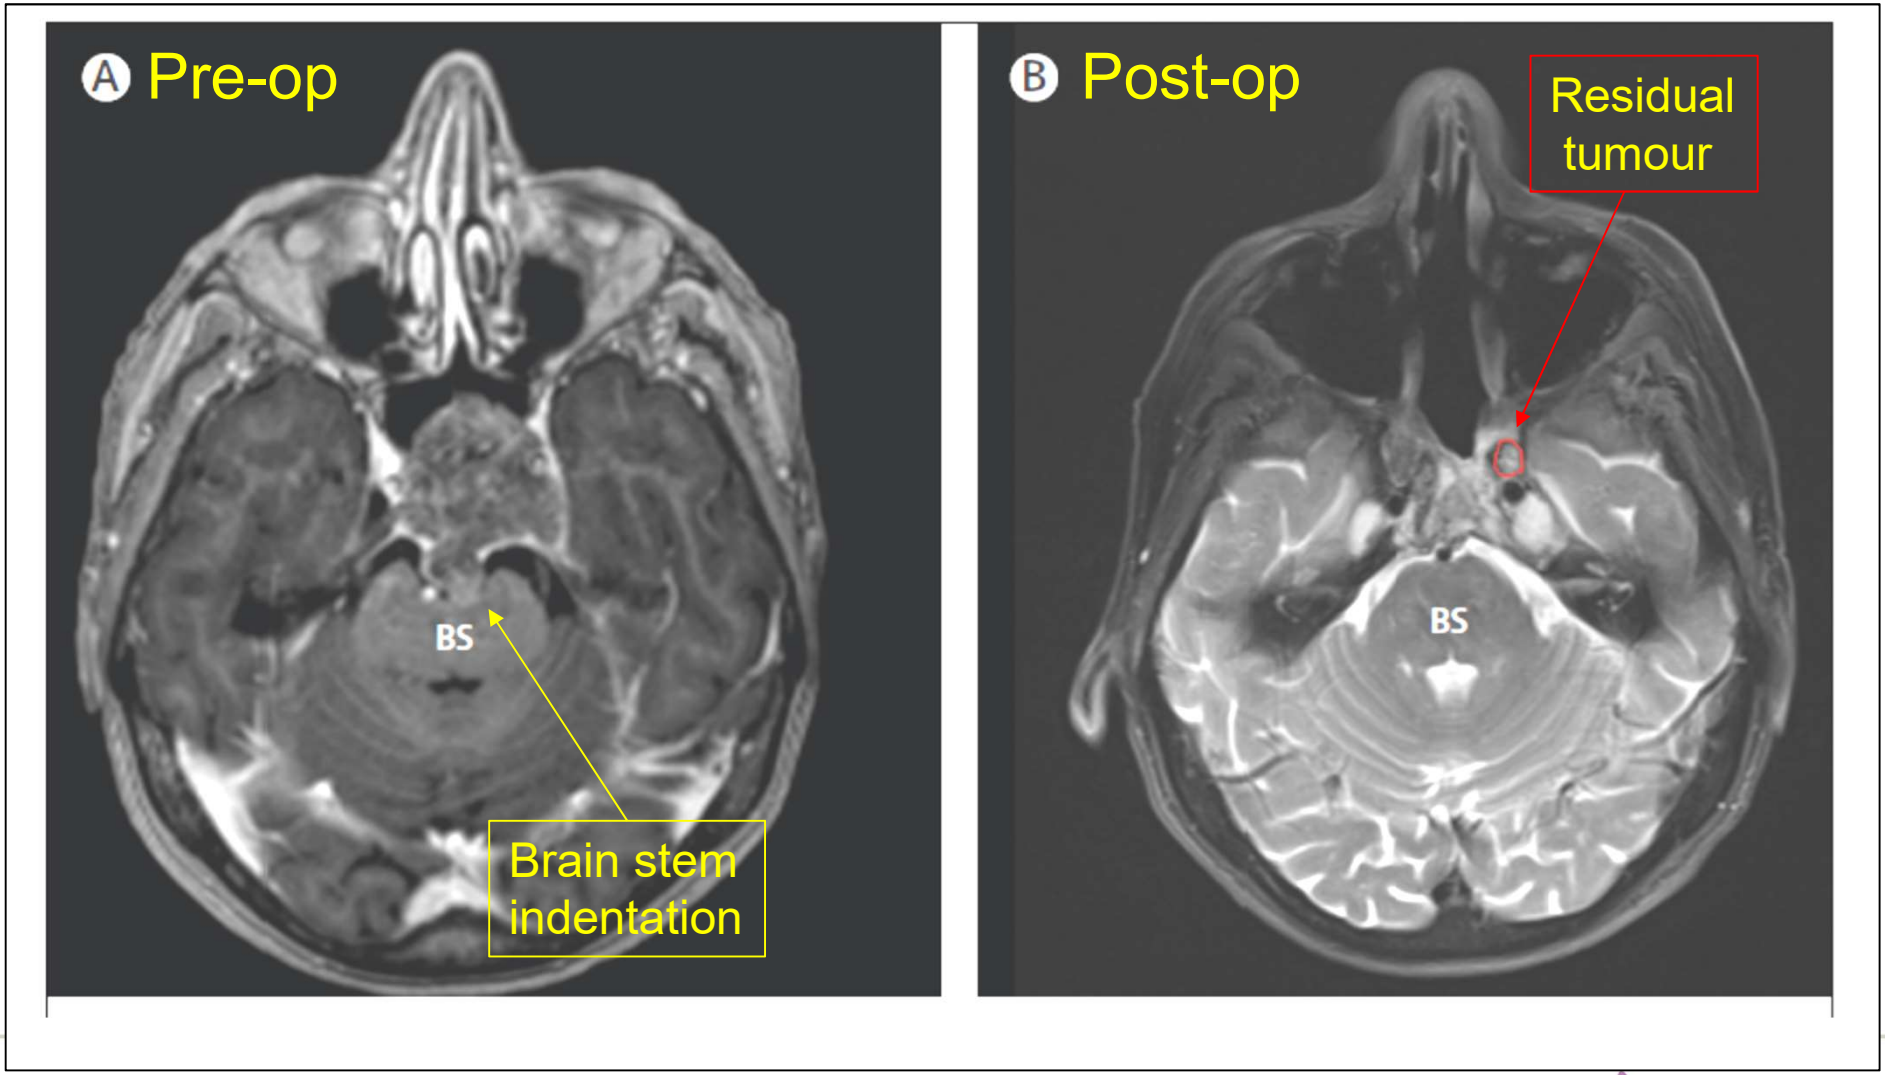
- The best possible imaging is needed for us to make the best of IMRT or PBT
- There is still *much* further to go for diagnostics
- We can still do better with planning imaging

Surgery

Surgery

- Excellent surgery is essential
- Includes
  - Cyto-reduction
  - Decompression
  - Provision of ‘space’
  - Stabilisation
- Needs access endoscopic techniques

Surgery

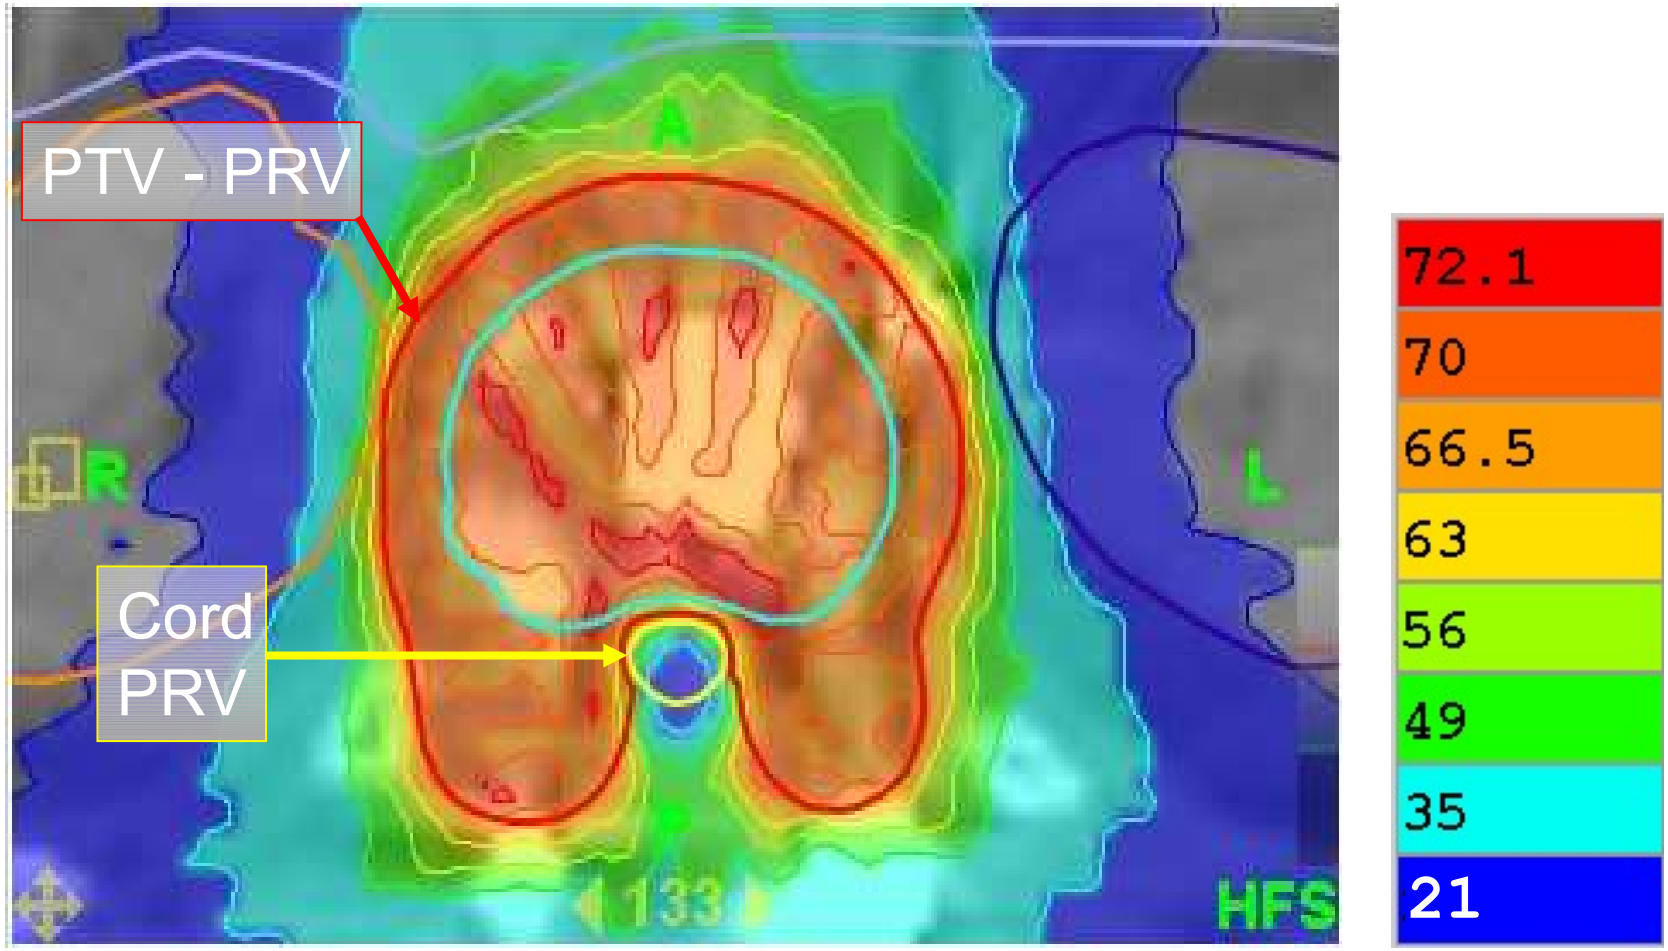


ESTRO School

Image guidance

ESTRO School

Chordoma T12



- 70 Gy median PTV dose. Well at 54 months

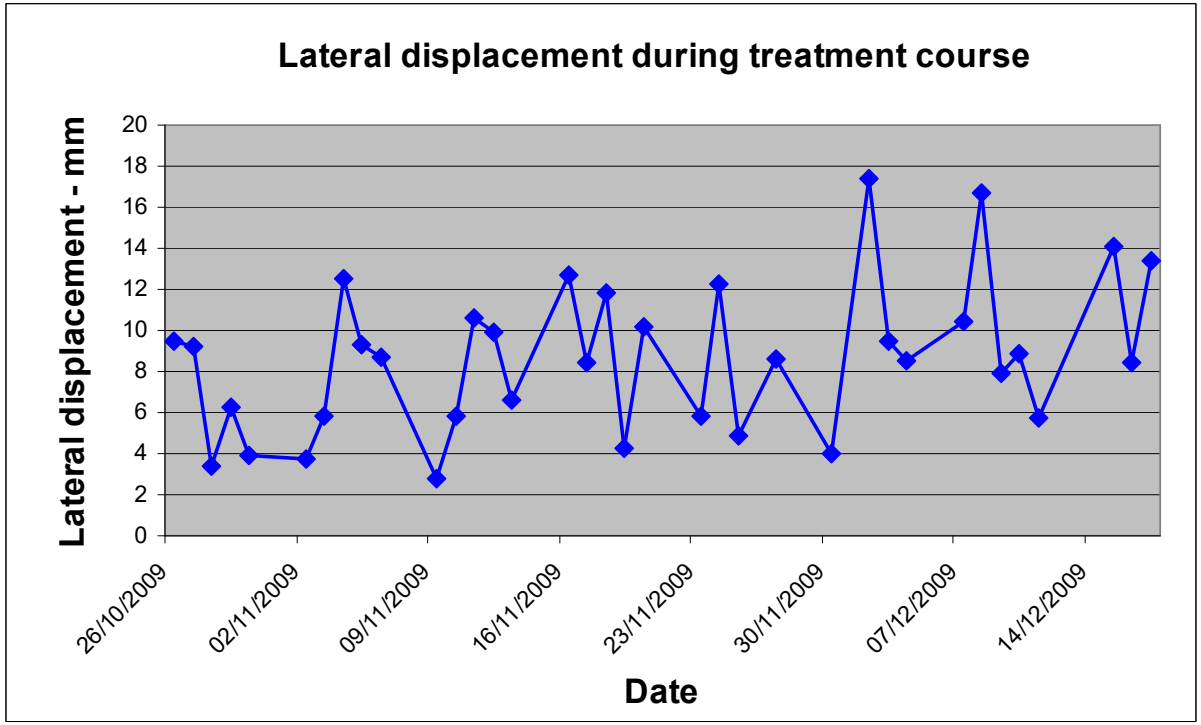
ESTRO School

Image guidance for chordoma

- Daily positional corrections moves – lateral direction

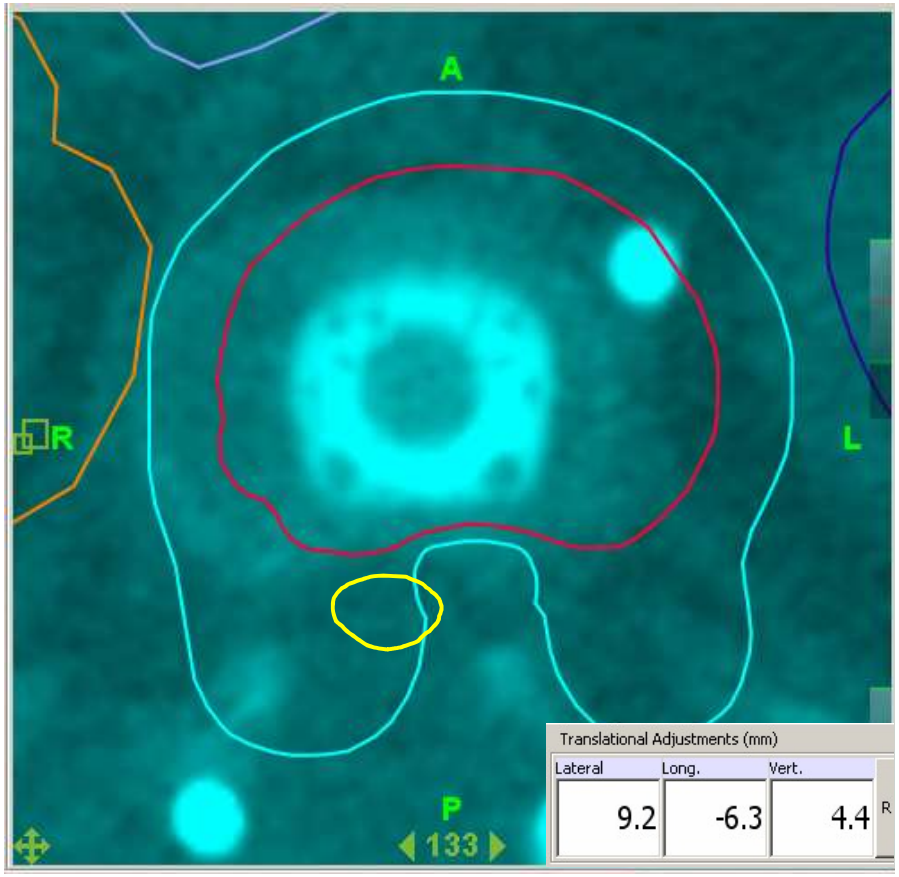
- *All* fractions had significant lateral displacement

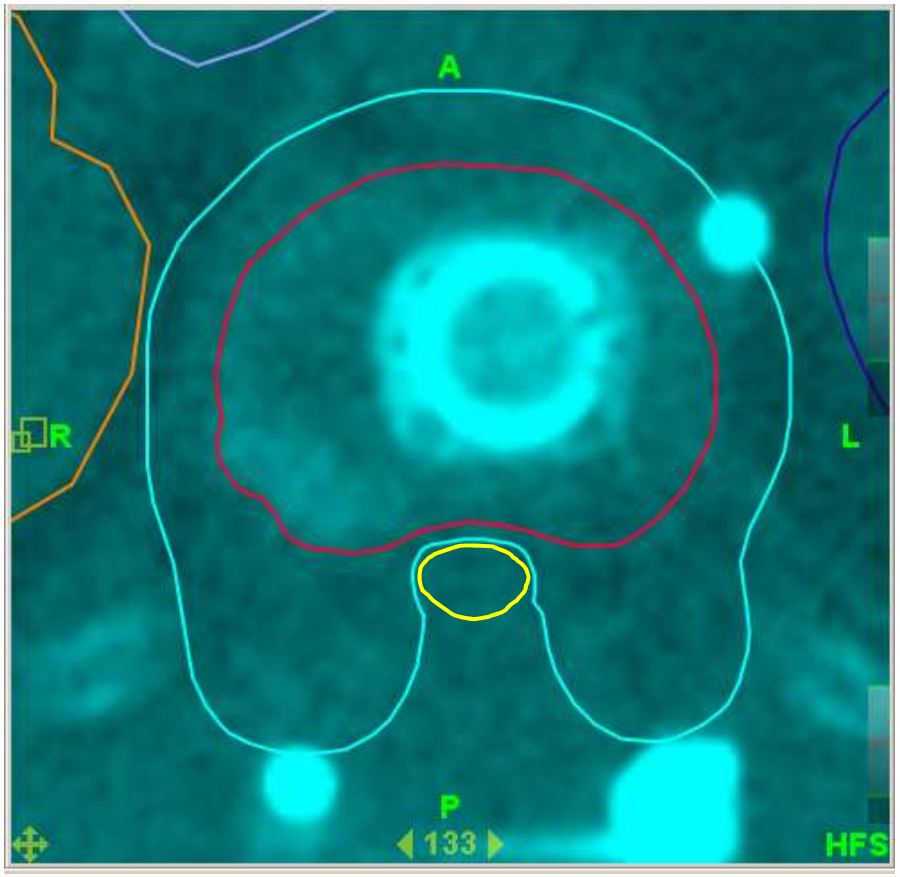
- Note *all* positive – and large



ESTRO School

Image guidance for chordoma



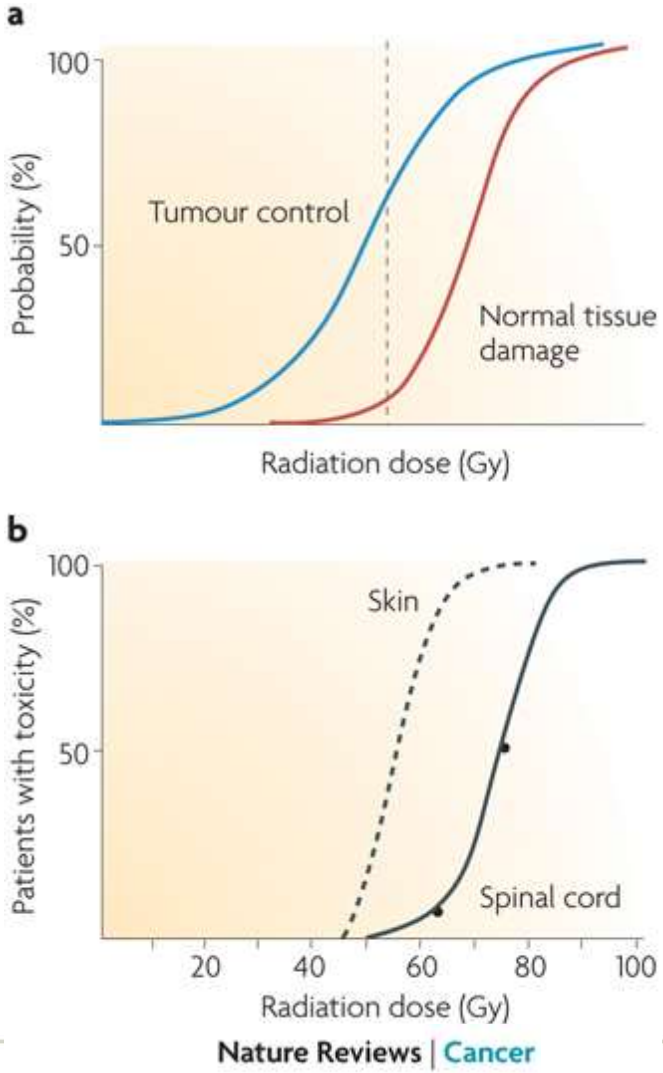


- Imperfect positioning corrected by daily imaging
- 3D positional error 11.1mm

ESTRO School

Radiotherapy

- What we do makes a difference
- Dose response curves are steep
  - Gamma-50 (γ_{50})
    - Tumour 1 - 2
    - Normal tissue 1 – 5
    - Spinal cord ~ 4.2
- Tumour
  - Dose difference of 5%
  - TCP difference 5% – 10%



ESTRO School

Radiotherapy

- Dose matters!
- Dose is an effective biomarker of response
  - Applies to both tumours and normal tissues
  - Current knowledge not very detailed in some tissues
  - This includes CNS tissues and endpoints
- Better conformation delivers better outcome
  - Applies to tumours
  - Applies to normal tissues

IMRT vs CRT

ELSEVIER

Int. J. Radiation Oncology Biol. Phys., Vol. 57, No. 2, pp. 580–592, 2003

0360-3016/03/$–see front matter

doi:10.1016/S0360-3016(03)00587-X

PHYSICS CONTRIBUTION

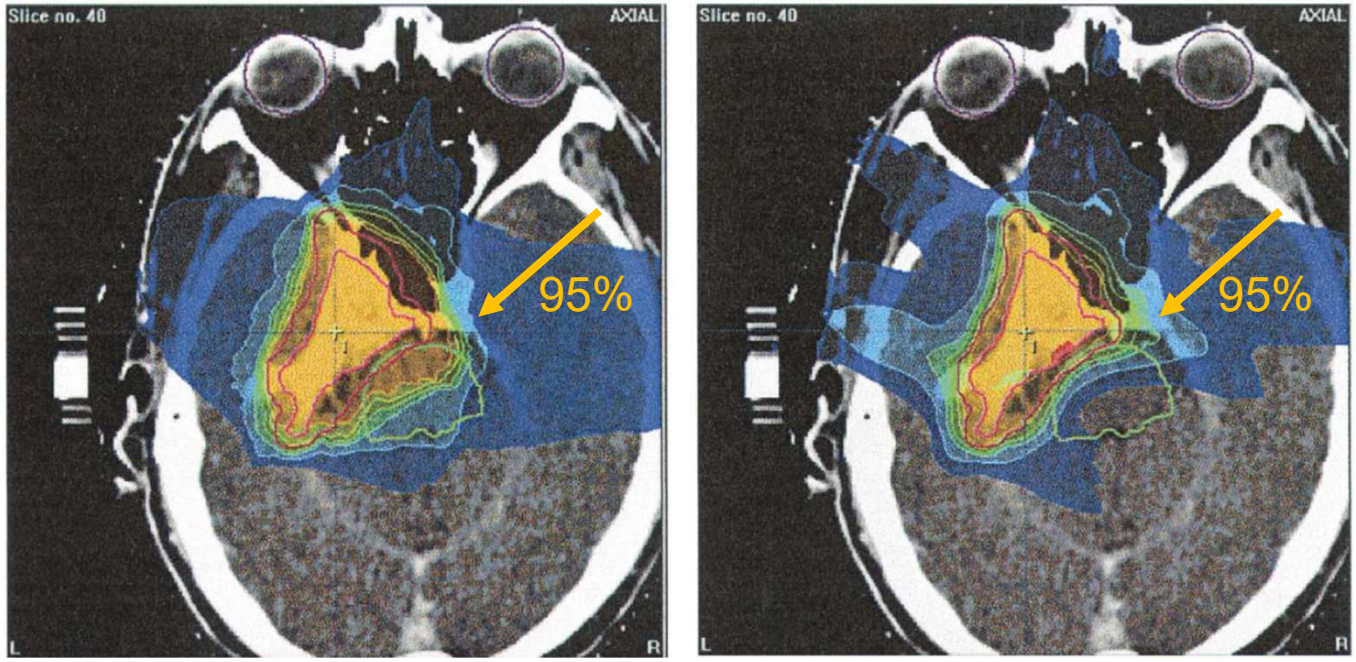
INTENSITY-MODULATED STEREOTACTIC RADIOTHERAPY VS. STEREOTACTIC CONFORMAL RADIOTHERAPY FOR THE TREATMENT OF MENINGIOMA LOCATED PREDOMINANTLY IN THE SKULL BASE

BRIGITTA G. BAUMERT, M.D., IAN A. NORTON, B.SC., AND J. BERNARD DAVIS, PH.D.

- With IMRT, PTV coverage better, esp. for complex shapes
- Lower dose to OARs

IMRT vs CRT

- Dose
  54 Gy/30#
- 95% =
  51.3 Gy

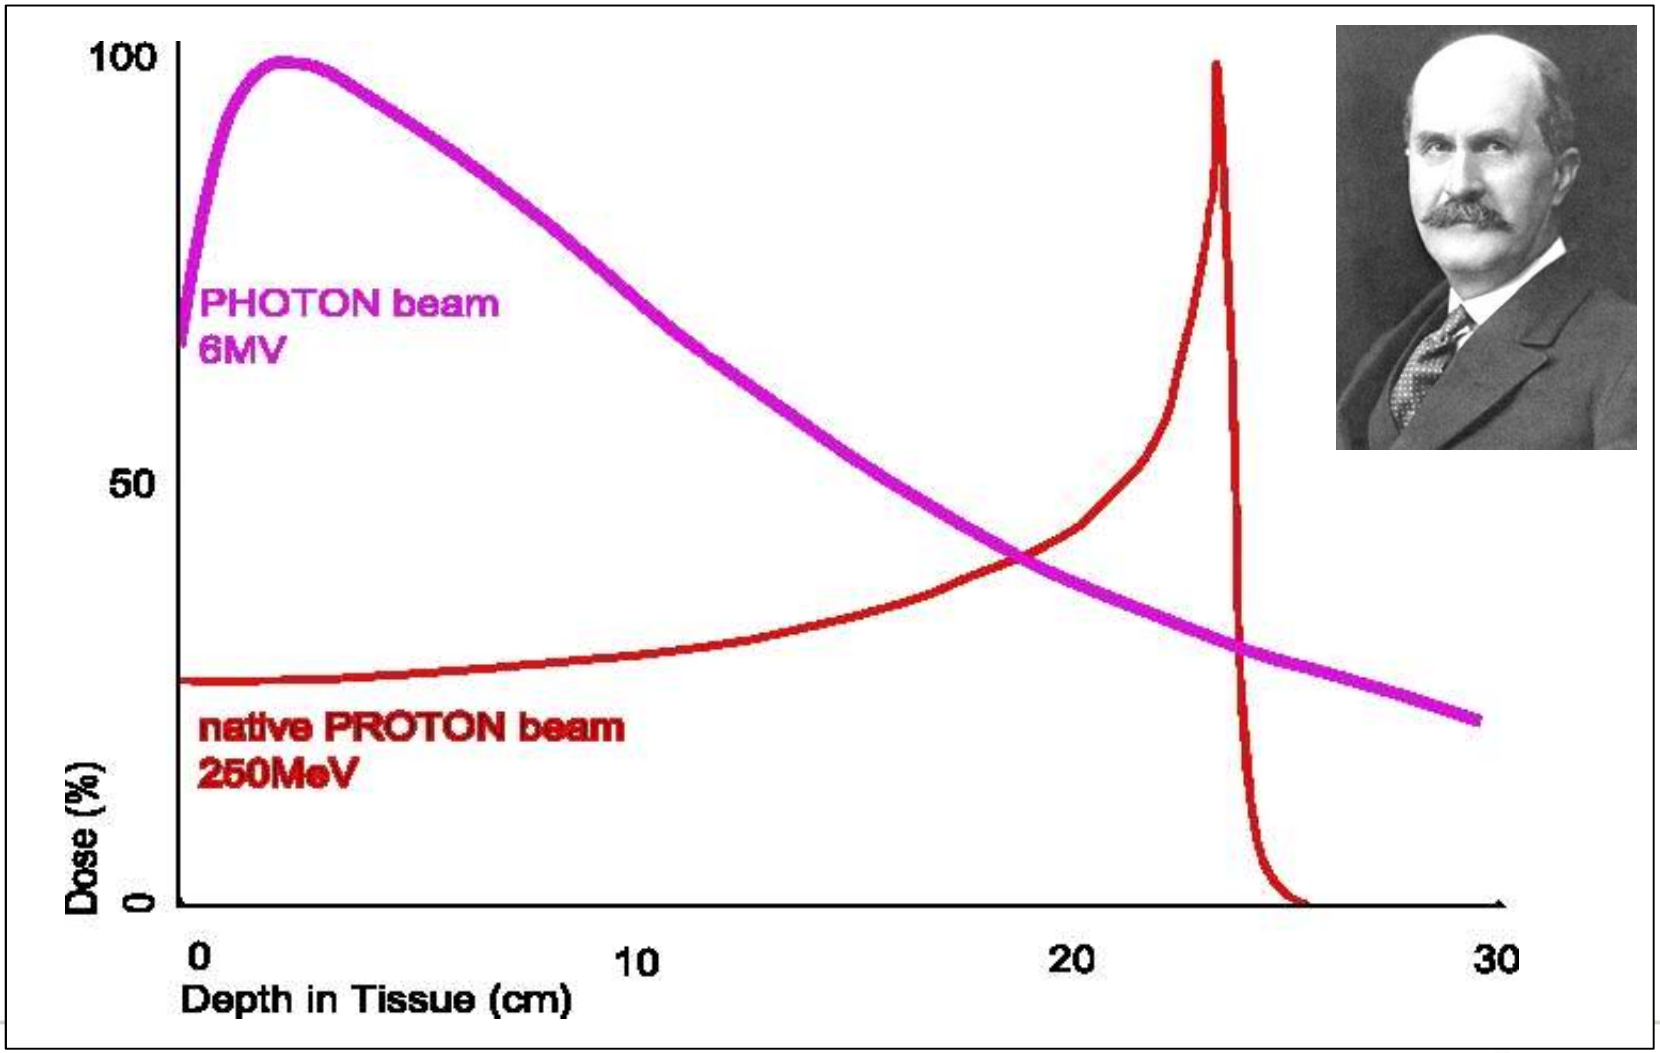


- Reduced dose to brainstem

ESTRO School

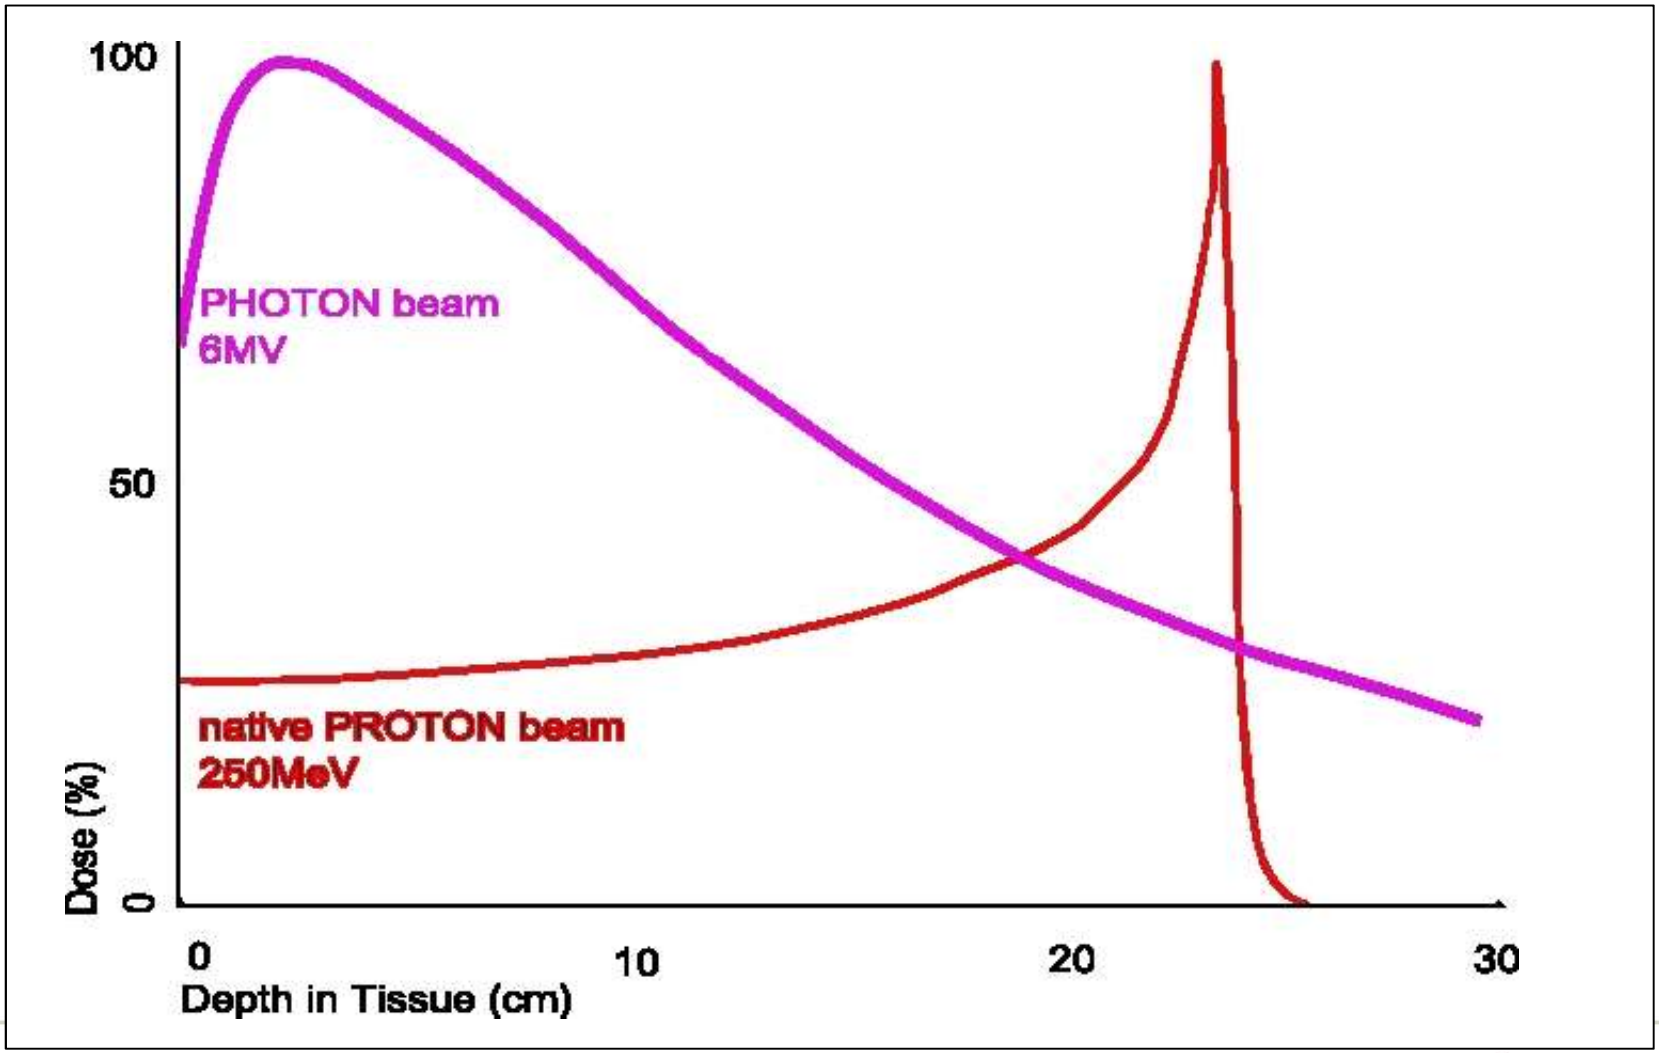
Proton beam therapy - PBT

Proton Bragg peak



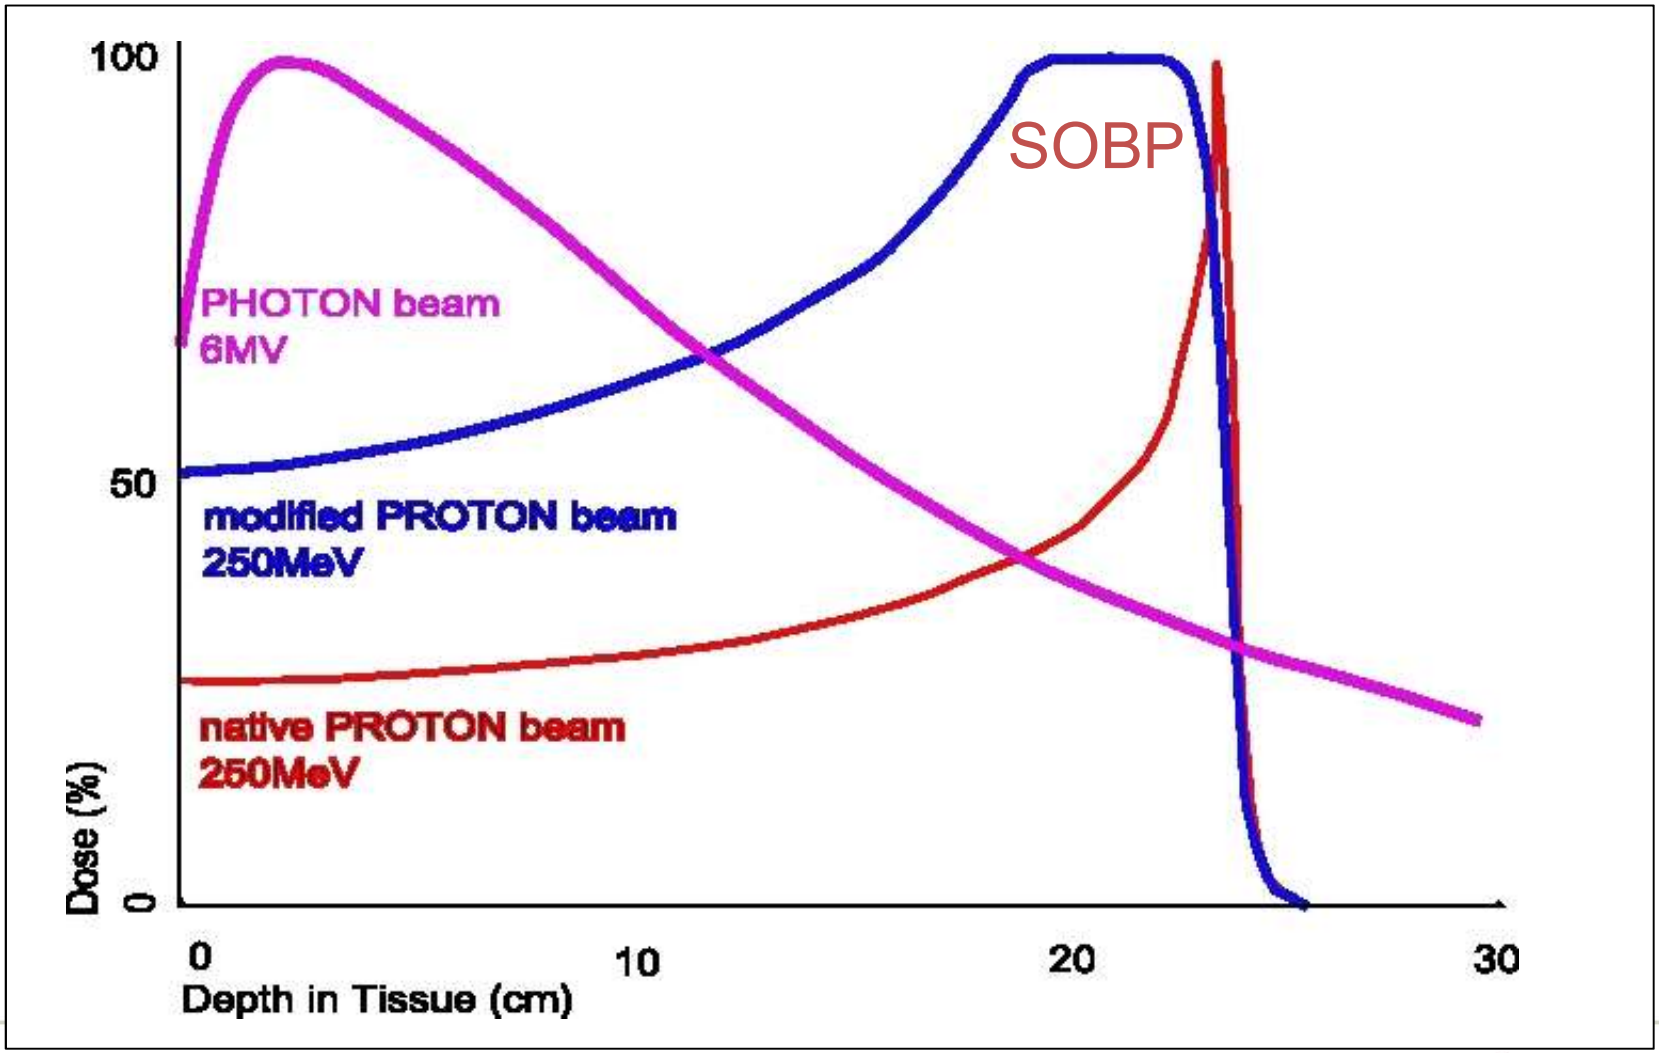
ESTRO School

Proton Bragg peak



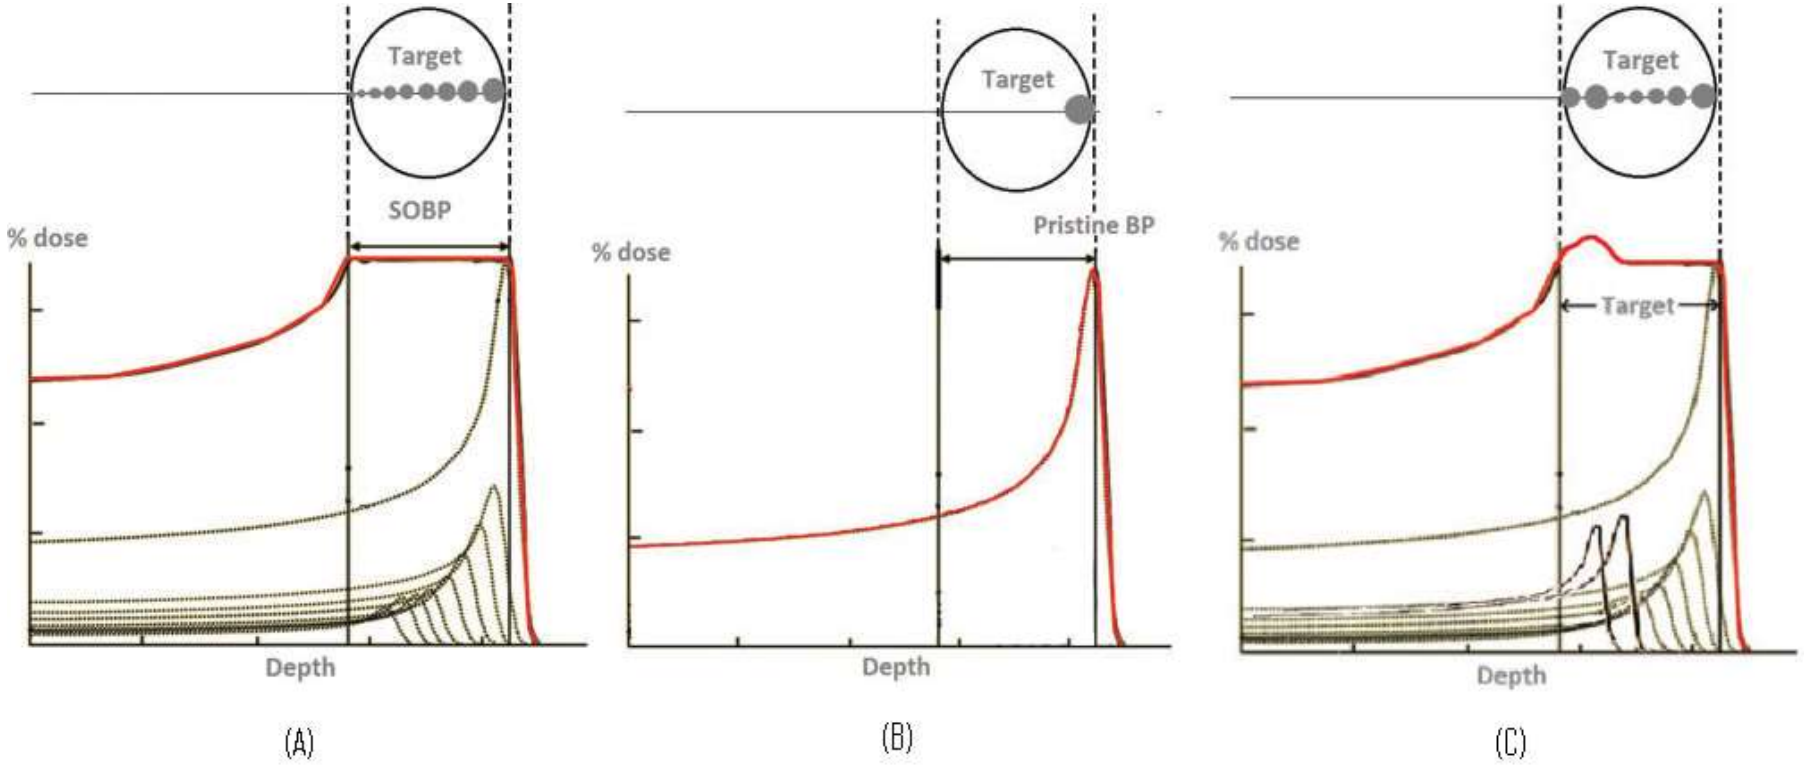
ESTRO School

Proton Bragg peak



ESTRO School

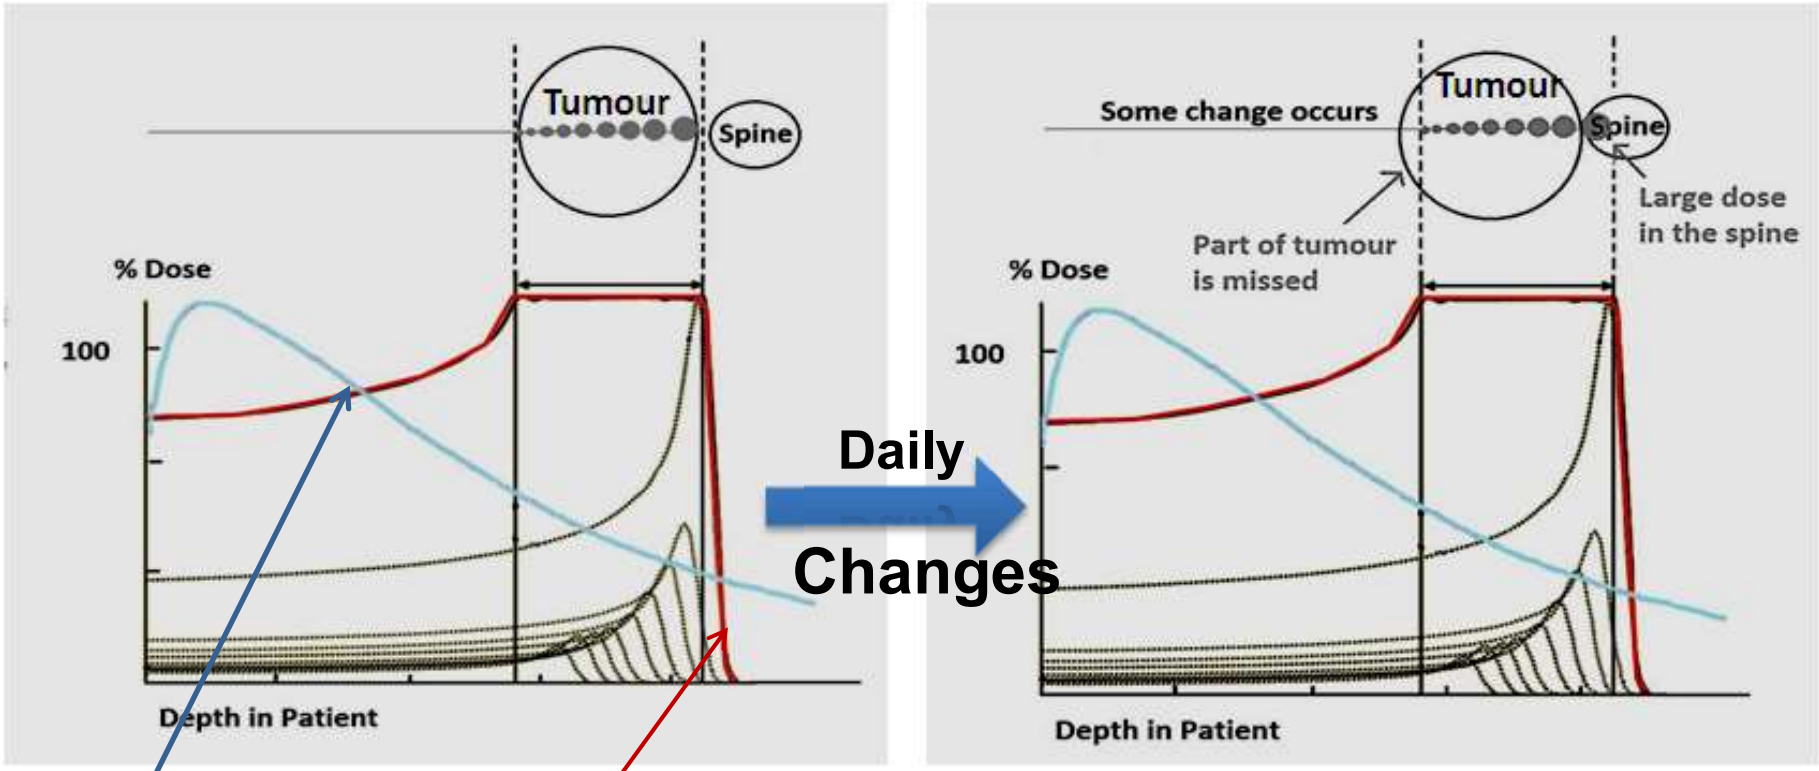
Proton delivery



Active scanning – (a)SFUD, (b)DET IMPT & (c) 3D IMPT

ESTRO School

What are the issues? Range uncertainty



Infinite X-ray fall off

Finite proton range = greater conformity

BUT…
more sensitive to uncertainties

ESTRO School

Skull base meningioma

- Common
- 90% are WHO grade I
- In the skull base – complete resection rarely possible
- Adjuvant treatment should be considered

Skull base meningioma

ESTRO School

How to treat?

- Asymptomatic – need to assess if growing
- Symptomatic – is surgery relevant or indicated
  - Can observe post surgery
- Radiotherapy dose – 50-55Gy/33#
- SRS – only for very specific cases

Complications

- Hypopituitism
- Cranial Nerve Palsies
- Cerebrovascular events
- Neurocognitive decline
- Second Malignancy

ESTRO School

Chordoma and Chondrosarcoma

CHORDOMA

- Presumed to arise from remnants of primitive notochord
- An embryonic precursor replaced by mesodermal elements to form vertebrae and skull base
- 0.84 per 1 000 000 (M>F)
- Median age 58 (3 - 95)
- **Typically Midline**

CHONDROSARCOMA

- Arise from embryonal rests of cartilaginous matrix that escape reabsorption during endochondral ossification
- 5 per 1 000 000 (M>F)
- Median age 51 (1 – 102)
- Appendicular > axial > soft tissue
- **Typically Off Midline**

Natural History

- **CHORDOMA**
  - 5 yr and 10 yr DFS **70% and 45%**
  - Recurrences may be noted many years after treatment
  - Distant metastasis rare (6% - 22%)
  - Metastasis higher in the presence of recurrent disease
  - At recurrence, 3-yr and 5-yr OS ~ **43% and 7%**

CHONDROSARCOMA

- More **indolent** and associate with much more favorable prognosis
- 10-yr local control and disease specific survival **98-99%**
- No relationship between histological subtype and grade

Treatment - surgery

- Goal is to remove as much of the tumour while minimizing complications
- Whenever brainstem compression present – decompress
- Fat graft as spacer to increase distance between clivus and contiguous brainstem to facilitate safe delivery of radiation

Treatment - surgery

Tai et al, Cancer, 1995:
159 patients with cranial chordomas:

Subtotal resection followed by adjuvant radiation had a significantly improved survival over surgery alone (p=0.011)

- No difference when compared to radiation alone (p=0.271)

- The survival curves for the combined treatment separate with follow up and suggest a benefit to include surgery in the management

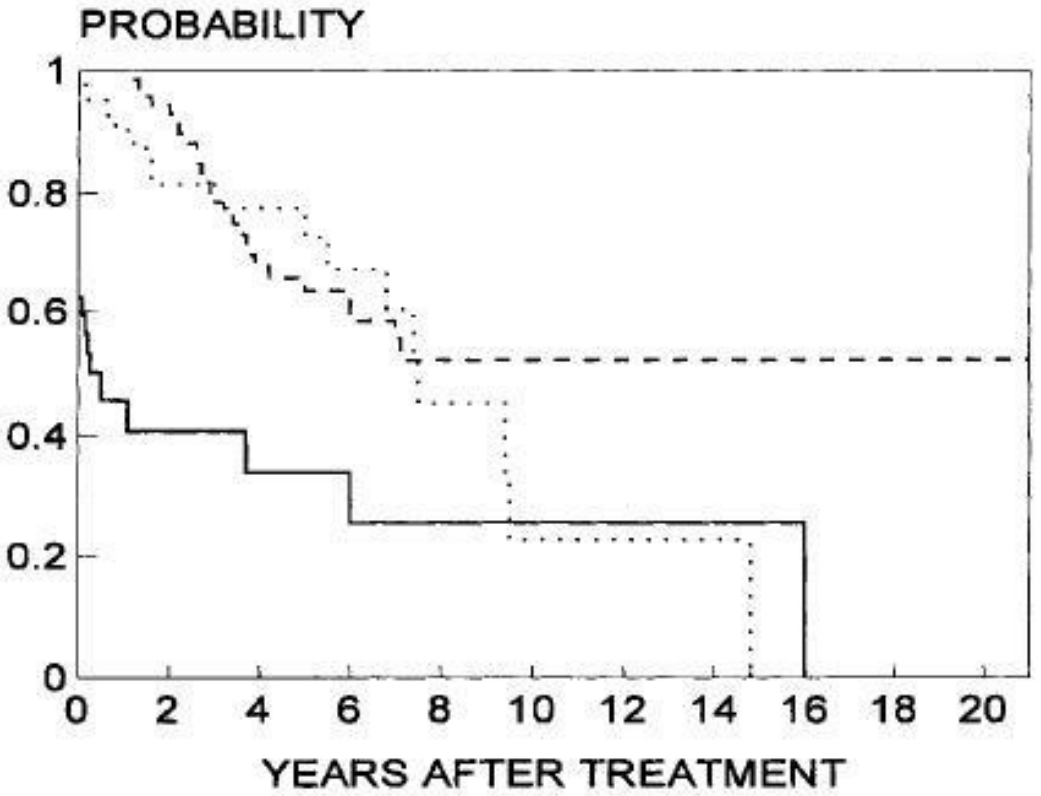

Figure 3. Overall survival according to the three treatments: ——, surgery alone, · · · ·, radiation alone; and – – – –, combined surgery and postoperative radiation.

ESTRO School

Treatment - radiotherapy

Chordoma:

- There have been no randomized studies investigating optimal dose

- Initial results in the 1960s and 1970s suggest an improvement in symptomatic response and local control with increasing dose
- Used antiquated techniques and often included multiple sites in their reports

- In **1970** Pearlman and Friedman: Decrease in local failure with ↑ dose

Dose versus Relapse

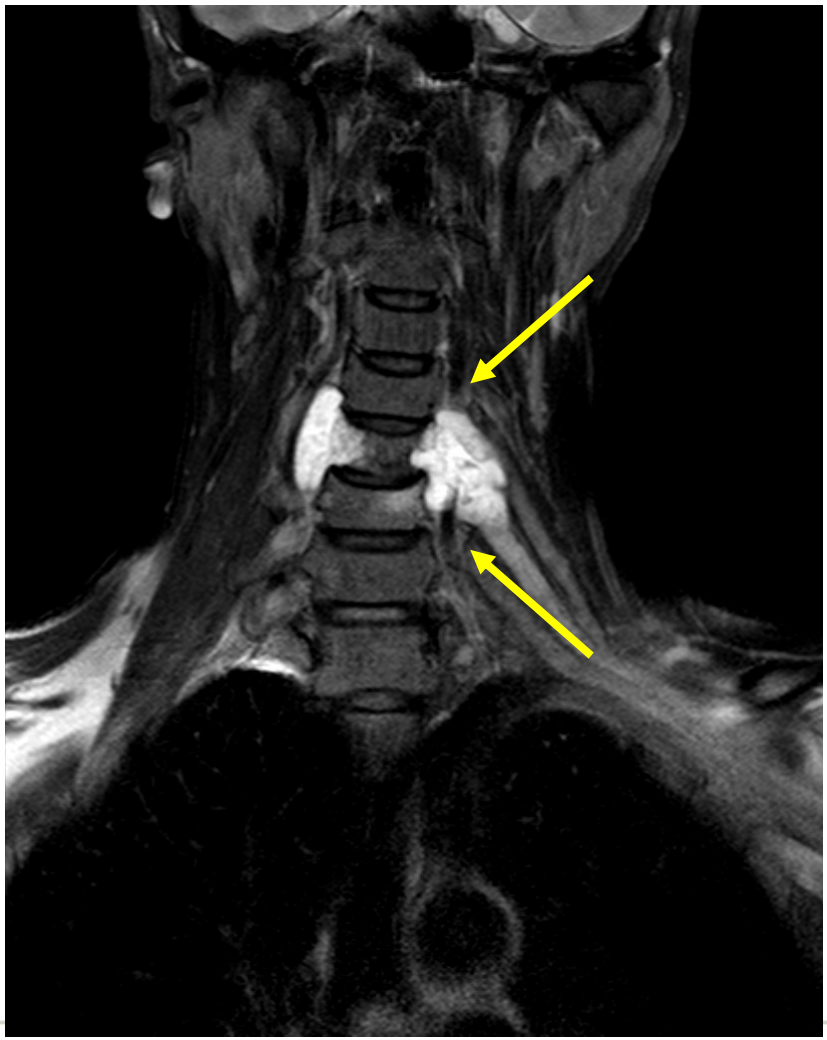
<40 Gy (n=47)	85%
40 – 60 Gy (n=18)	60%
60-80 Gy (n=8)	43%
>80 Gy (n=2)	0%

Chordoma

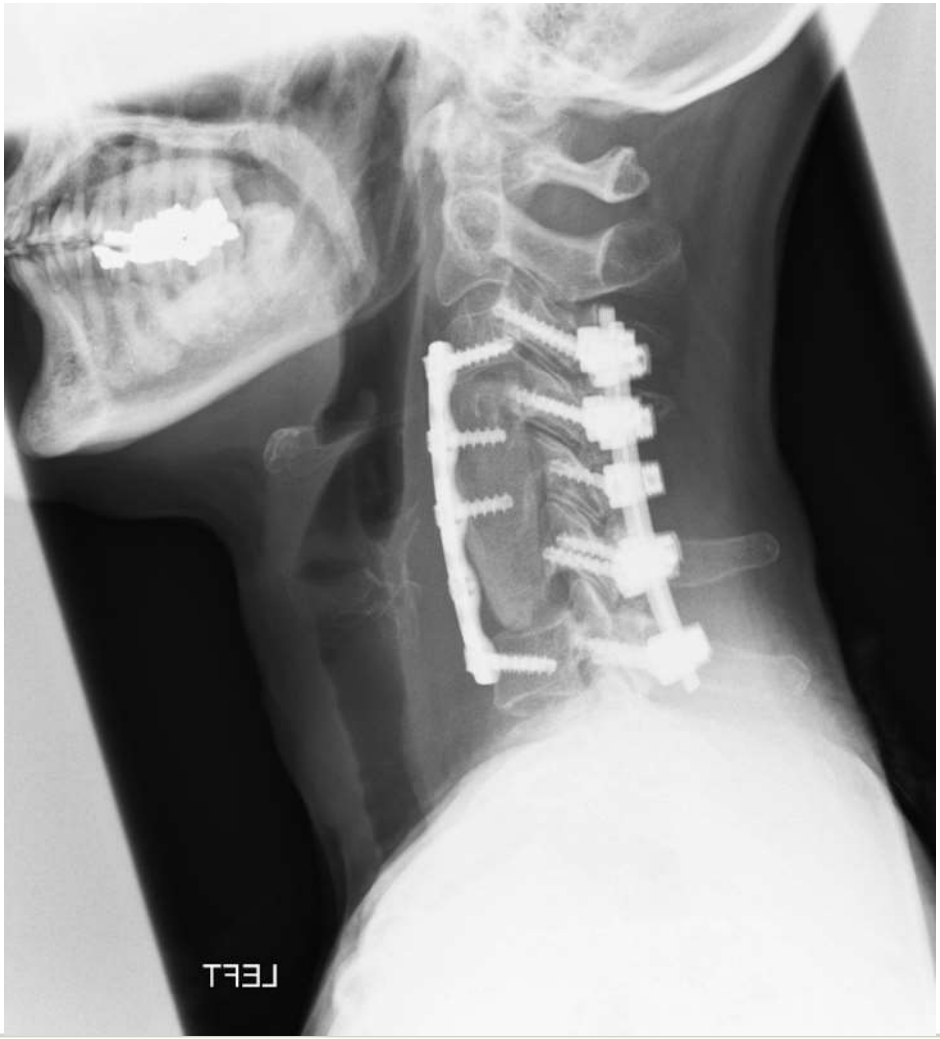
Chordoma - 1

ESTRO School

Chordoma - 1



Chordoma - 1



ESTRO School

Chordoma - 1

- Many normal tissue structures to be considered
- Spinal cord especially important !
- Not suitable for PBT because of metalwork

What can affect outcome

- Other factors affect outcome
  - Tumour volume
  - Brainstem compression
  - Metal

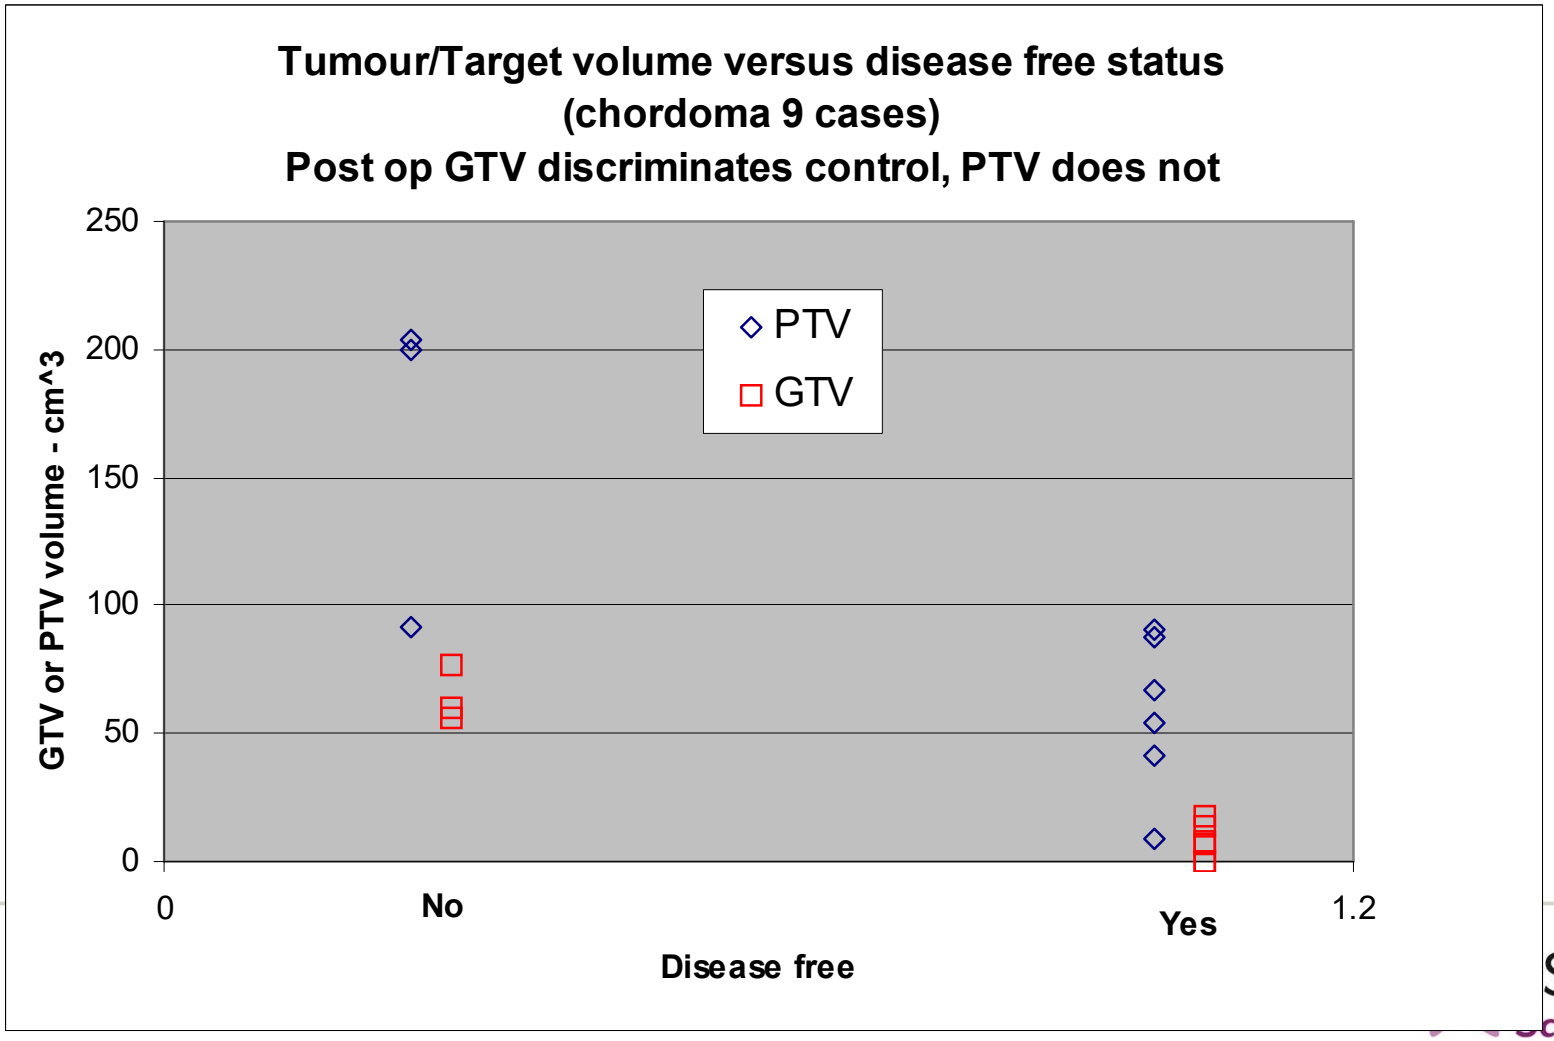
Outcome & Tumour volume

- PSI (mean 73.5 Gy) (Ares et al IJROBP 2009,
  - Local control at 5 years - 81%
  - GTV > 25 cm^3 worse – LC 78% vs 96%

- Cambridge (X-rays – 65 Gy)
  - GTV ≤ 18 cm^3 – LC in 6/6
  - GTV ≥ 60 cm^3 – LC in 0/3
  - Little relation with PTV

Tumour volume

- Cambridge experience



Univariate analysis of risk factors for local failure (LC) and death (OS) in 222 patients with skull base tumors treated with proton therapy. Significant *P* values ($P < 0.05$) are in bold

Prognostic factors		7-year LC (%) [95%CI]	*P* value*	7-Year OS (%)	*P* value*
Compression optic apparatus	Yes	64.6[51.4–81.2]	**0.003**	67.8[53.7–85.6]	**0.016**
	No	85.5[78.8–92.8]		88.3[82.1–95.0]	
Compression Brainstem	Yes	64.0[51.4–79.7]	**0.004**	69.4[56.4–85.5]	**0.008**
	No	86.2[79.3–93.7]		87.2[79.2–95.6]

Gender	Female	72.8[61.4–86.5]	0.63	807[69.8–93.3]	0.79
	Male	83.1[75.7–91.2]		79.4[69.3–91.0]	
Age	⩽40 years	84.4[75.2–94.7]	0.27	89.5[82.2–97.5]	0.12
	>40 years	74.2[64.9-84.8]		72.5[60.9–86.3]	

Tumour volume

- Implications for surgery
  - Major debulking important
  - Small remnant may be acceptable
    - Balance morbidity

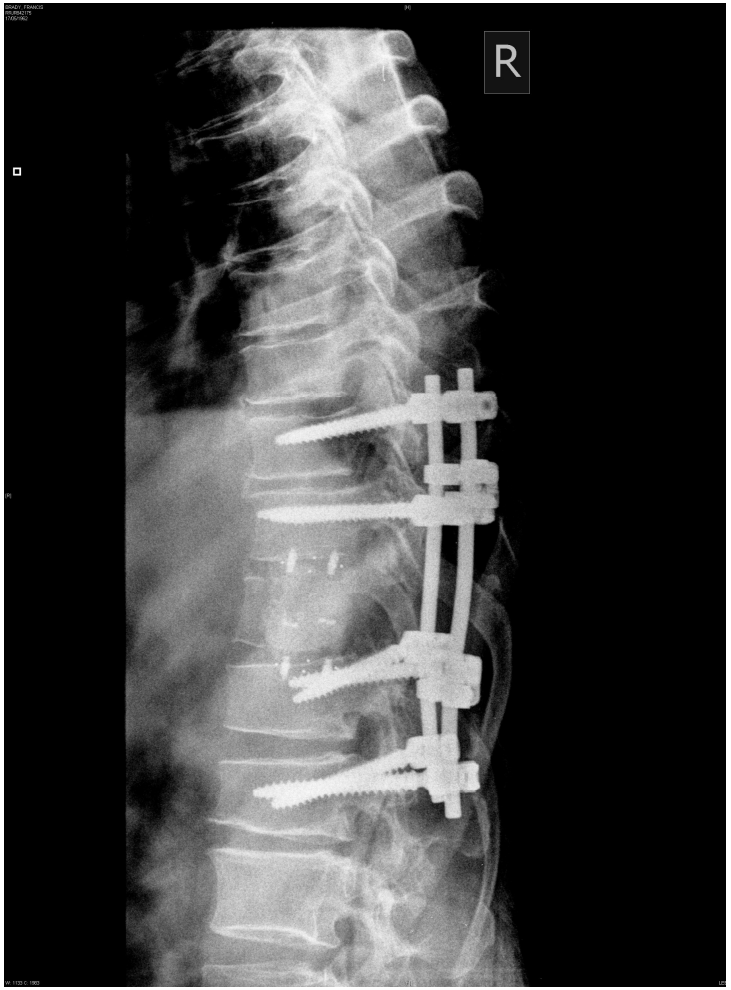
- PSI (mean 73.5 Gy)
- Brainstem/ON compression worse outcome
    - Relates to under-dose at ‘dangerous’ edge

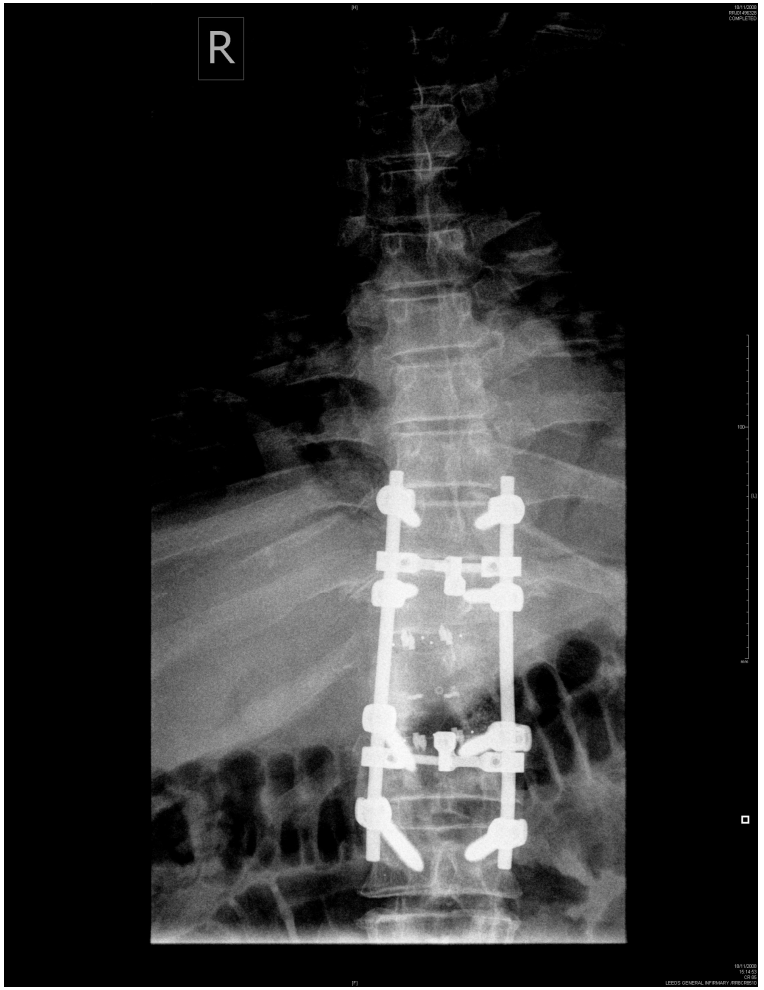
Decompress

- T11

- Relief of compression essential
  - Clinical
  - Dose to target

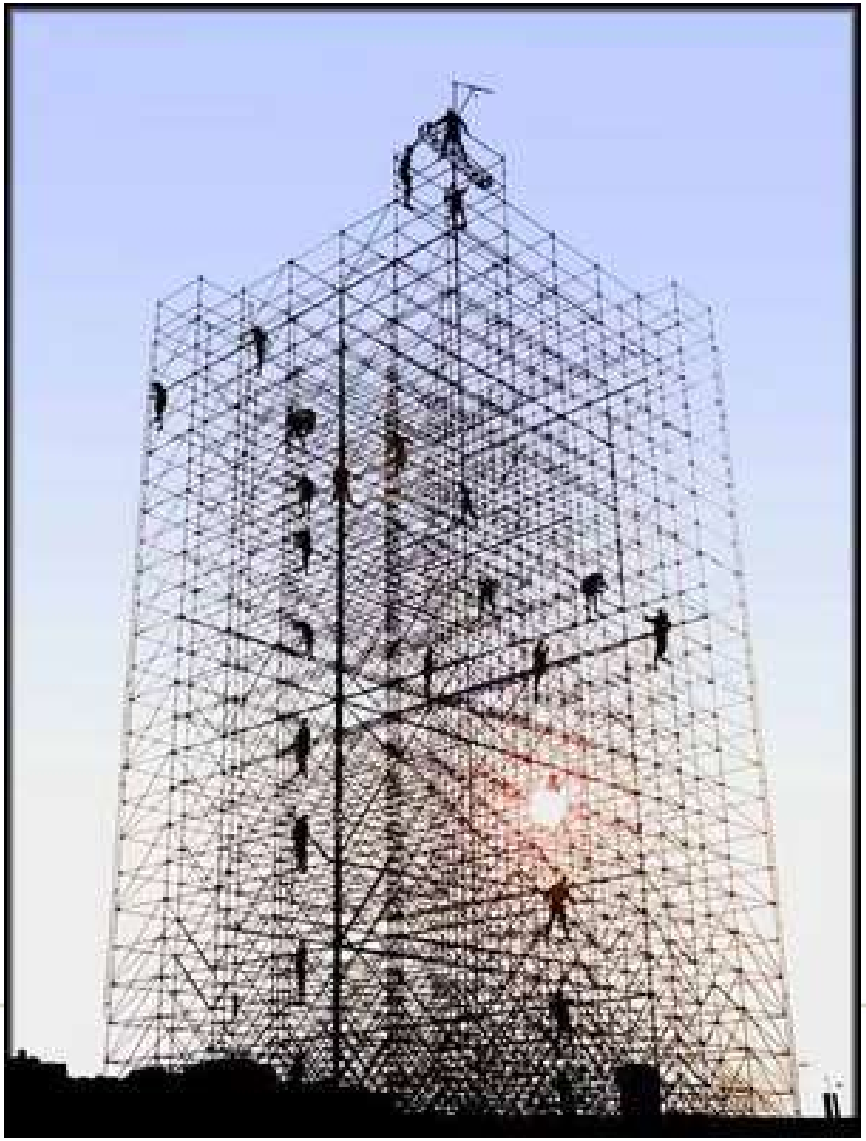
Reconstruction





ESTRO School

RT after metal reconstruction



ESTRO School

RT after metal reconstruction

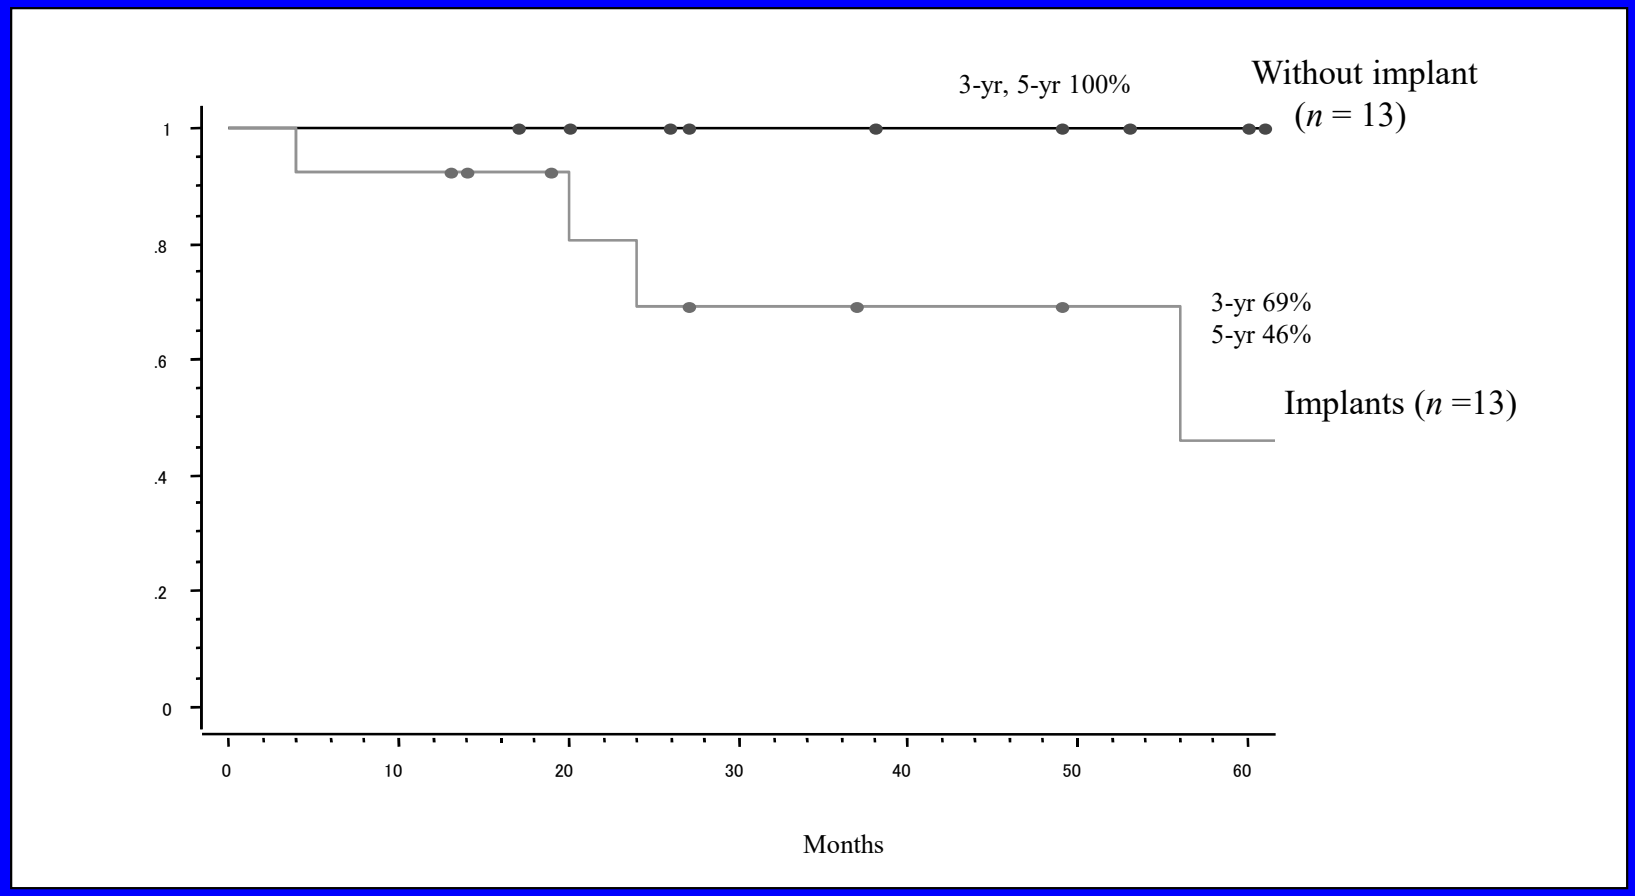
- Metal reduces local control with proton RT
  - Particularly important if metal within GTV
- Issue emerged during 2009
- Result of PSI review of outcomes

RT after metal reconstruction

- Local control at 5 years (PSI – 26 cases, spine)
  - With metal LC = 46%
  - No metal LC = 100%
- Metal reconstruction present in ~ 1/3 spine cases
  - Boston - Delaney et al IJROBP 2009
  - Numerically significant issue
- ? Bigger tumours need reconstruction

Clinical experience at PSI

Chordomas and chondrosarcomas of the spinal axis



Rutz et al 2009

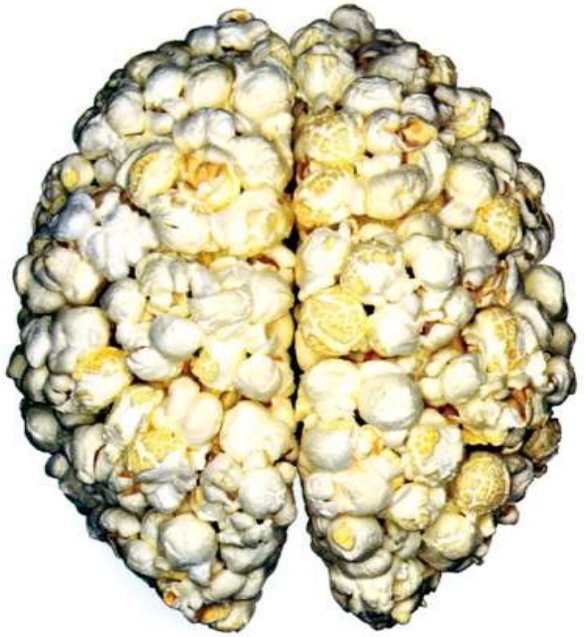
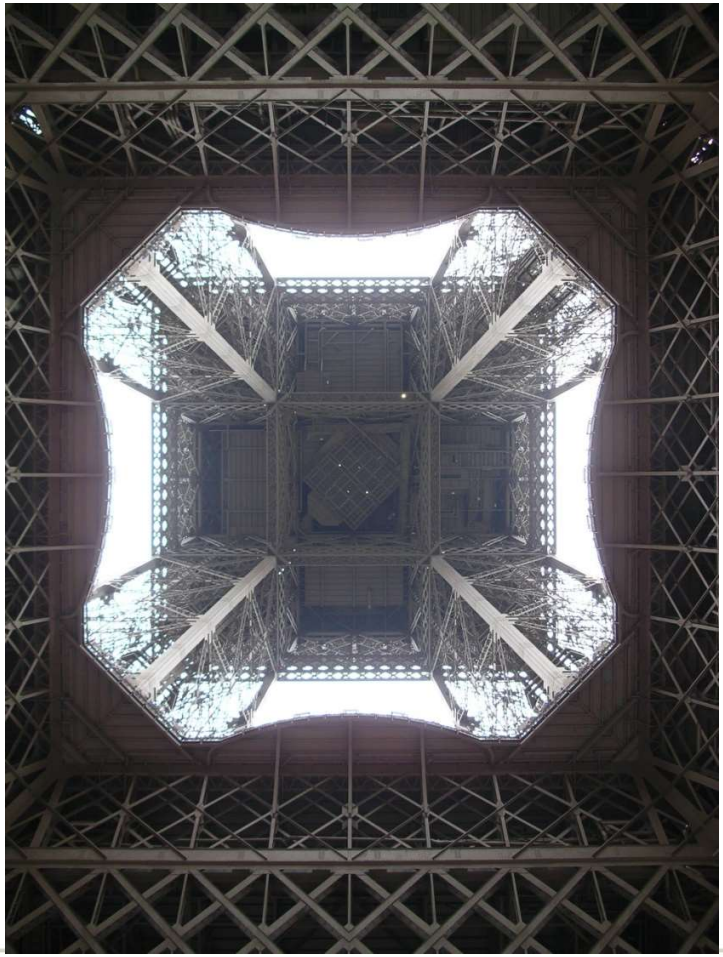
Management of benign tumours



Dr Sarah Jefferies

ESTRO School

Perspective



Risks

Background

- Long natural history
- Often not life-threatening
- Radiotherapy can have a role

Which tumours?

- **Pituitary tumours**
- **Vestibular schwannoma**
- **Craniopharyngioma**
- **Glomus tumours**
- Meningioma

Requirements

- Understand
  - Natural history
  - Imaging
  - Other treatment modalities

Dose-fractionation-radiotherapy

- Fractionated 45-55Gy in 25-33#
- Hypo-fractionated 20-30Gy in 3-10#
- Single fraction (radiosurgery) 10-25Gy in 1#

Pituitary Adenoma

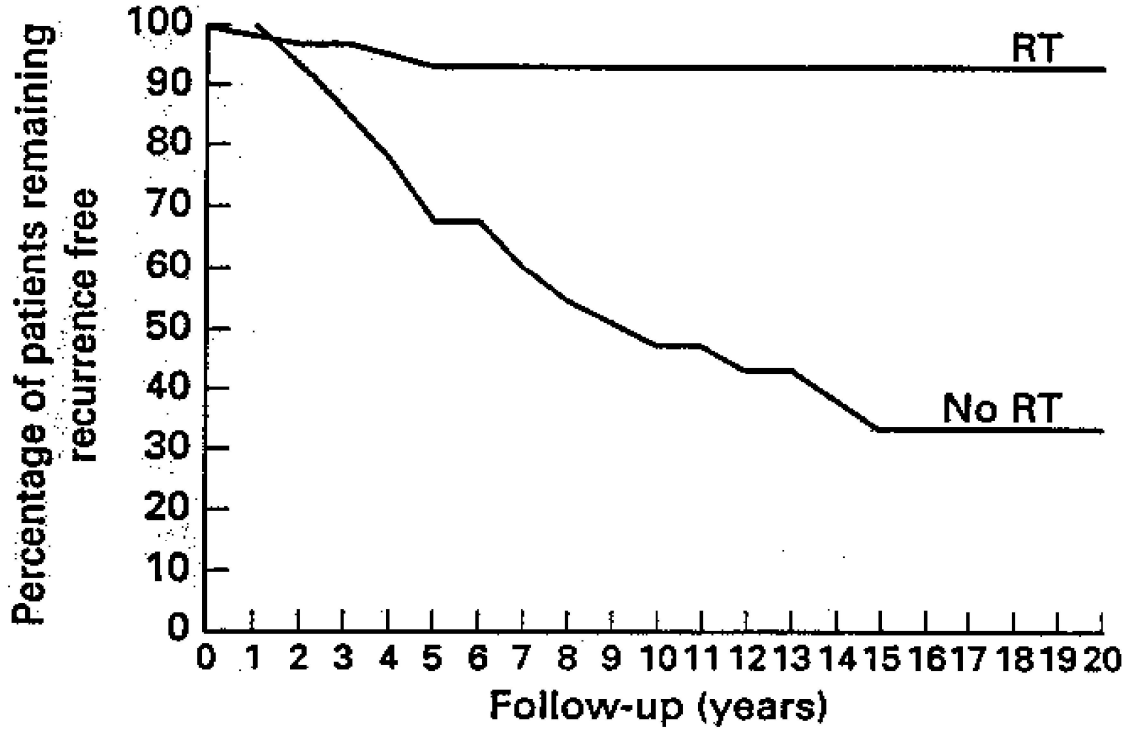
- Radiotherapy is used in patients:
  - with residual or recurrent secreting and nonfunctioning pituitary adenomas after surgery
  - resulting in a long-term tumour control of 80–97%
  - normalization of elevated hormone levels in 40–70% of patients

Int J Radiat Oncol Biol Phys 1995;**33**:307–14.

Clin Endocrinol (Oxf) 1993;**38**:571–8.

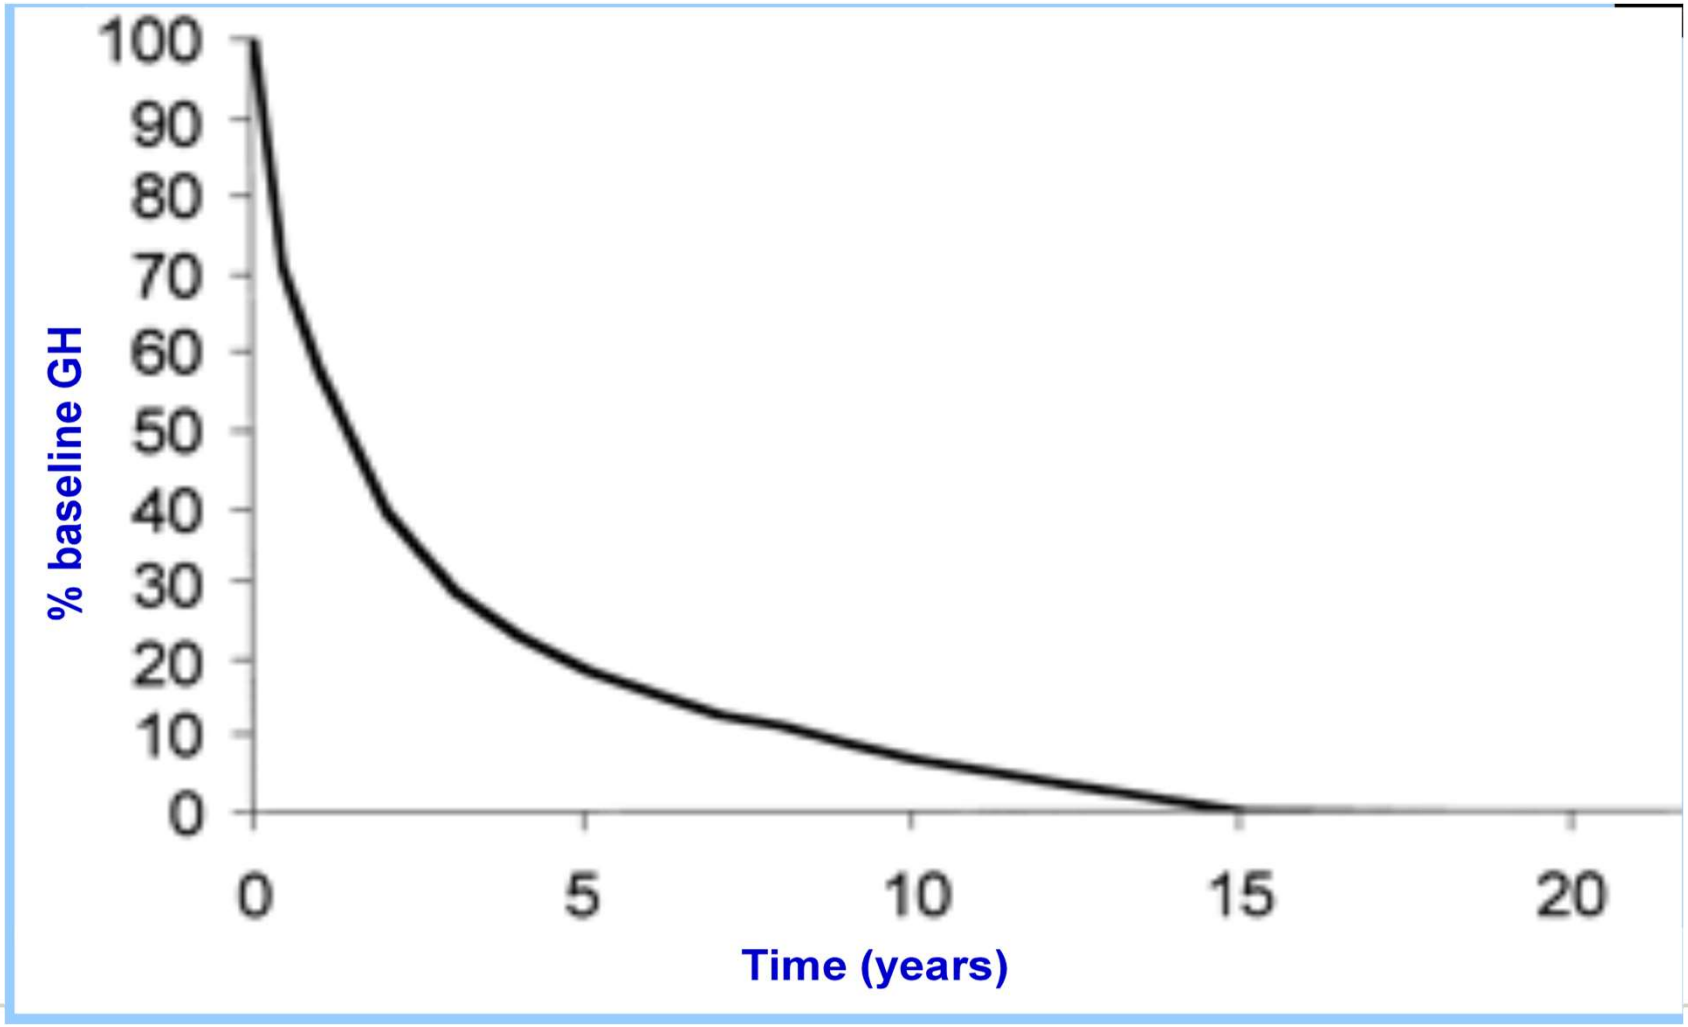
Non-functioning Pituitary Adenoma

No randomised data: 2 centre study – progression post surgery



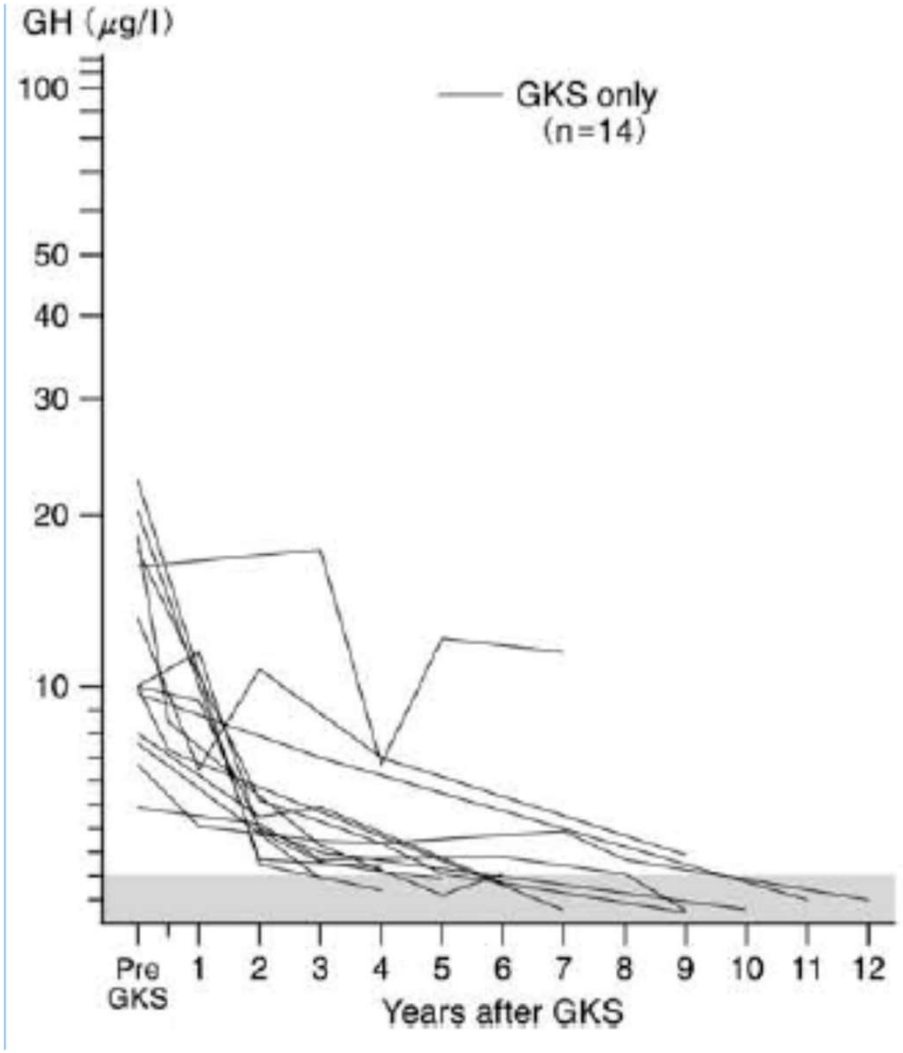
ESTRO School

GH control - acromegaly



ESTRO School

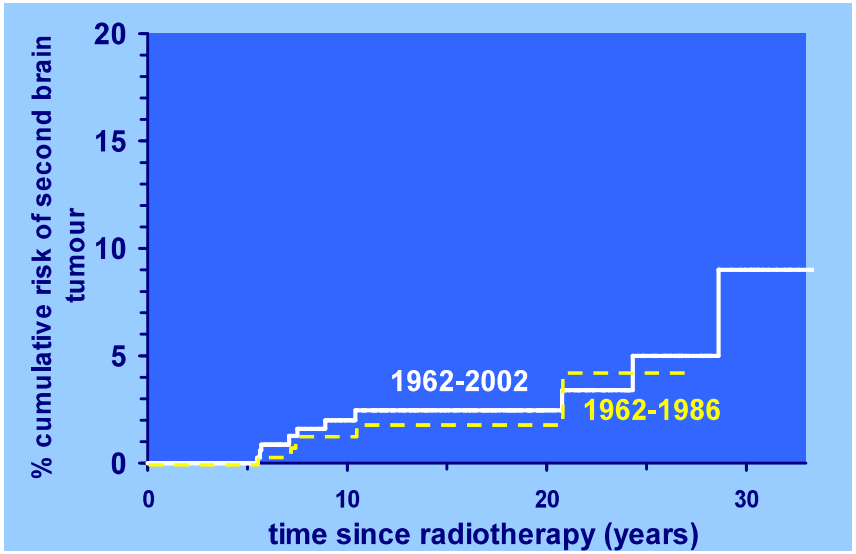
GH and IDH control after GK



ESTRO School

Risks of treatment

- Hypopituitism 30–60% in 5–10 years
- radiation-induced optic neuropathy
- cerebrovascular accidents
- second tumors 0–3%



J Clin Endocrinol Metab 2005;**90**:800–4.

ESTRO School

Which modality of RT to choose?

- SRS retrospective data
- incidence of radiation-induced optic neuropathy:
  - 2% for single doses of 8–12 Gy
  - >10% for doses of 12–15 Gy to the optic apparatus
- cranial nerves in the cavernous sinus:
  - maximum dose is 16–18 Gy
- brainstem
  - maximum dose of 12–13 Gy

Int J Radiat Oncol Biol Phys 2013;**87**:524–7

Table 1 – Summary of recent published results (2000–2014) on SRS for nonfunctioning pituitary adenomas.

What to do?

On the evidence available:

- no data to support the ***superiority*** of SRS over FSRT for patients with pituitary tumours
- Dose and fractionation should be chosen:
  - size
  - position of the pituitary adenoma
- single-fraction SRS at doses of 16–25 Gy ***small*** pituitary adenoma away from the optic chiasm
- FSRT is preferred over SRS for lesions >2.5–3 cm in size and/or involving the anterior optic pathway.

Stereotactic radiotherapy and radiosurgery for non-functioning and secreting pituitary adenomas

Giuseppe Minniti[a,b,*], *Enrico Clarke*[a], *Claudia Scaringi*[a], *Riccardo Maurizi Enrici*[a]

REPORTS OF PRACTICAL ONCOLOGY AND RADIOTHERAPY 21 (2016) 370–378

ESTRO School

Vestibular Schwannoma (VS)

- 6%– 8% of all intracranial tumours
- 80% of cerebellopontine angle tumours
- VSs may remain within the internal auditory canal (IAC) or extend into the CPA
- Symptoms are related to compression of:
  - adjacent cranial nerves
  - brain stem
  - posterior fossa (PF) structures

Differential Diagnosis

- facial nerve schwannoma
- meningioma
- metastasis
- epidermoid cyst
- arachnoid cyst
- aneurysm

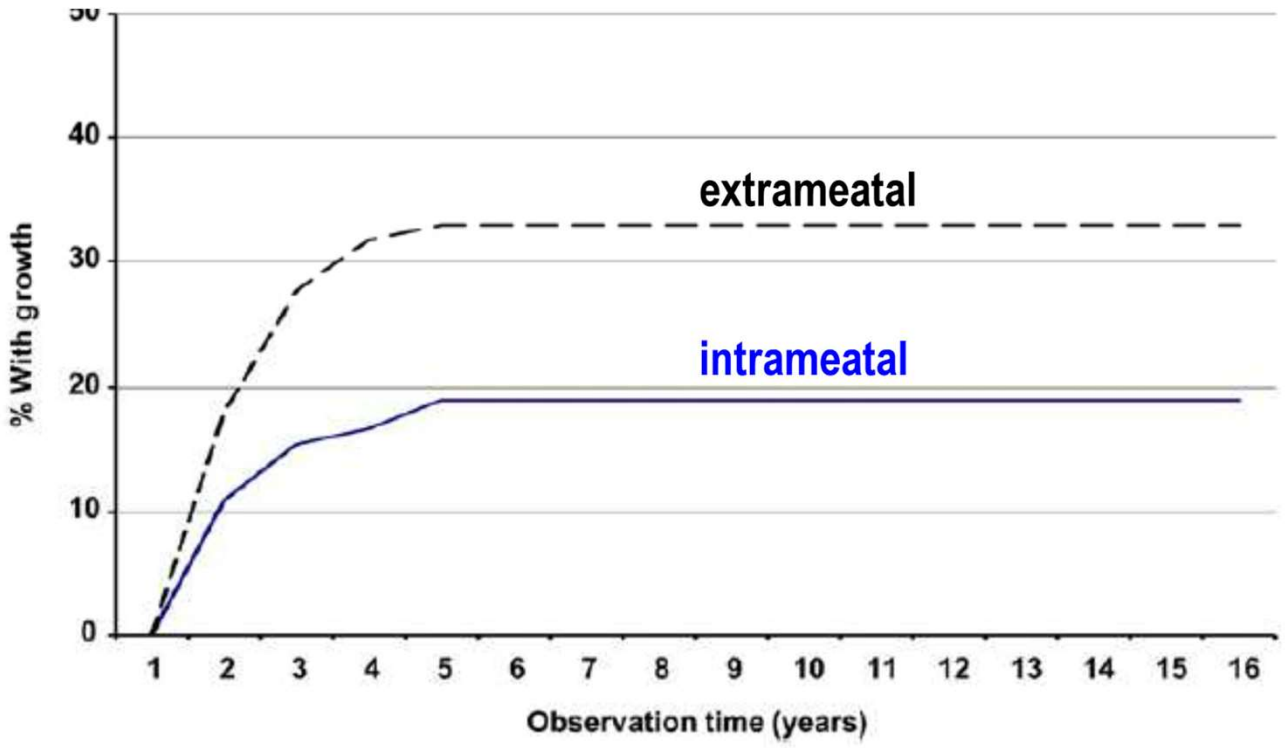
Treatment Options

- Depending on many factors including:
  - patient age
  - tumour size
  - tumour growth
  - and symptoms
- patients can choose:
  - surgery
  - radiation
  - conservative management.

Natural History

- >50% of all VS grow at an average of 2–4 mm/year
- 10% regress
- Extrameatal tumours are more likely to grow compared with intrameatal tumors
- VS of 2 cm is more likely to grow compared with a smaller VS
- Growth rates of 2 mm/year are associated with decreased rates of hearing preservation

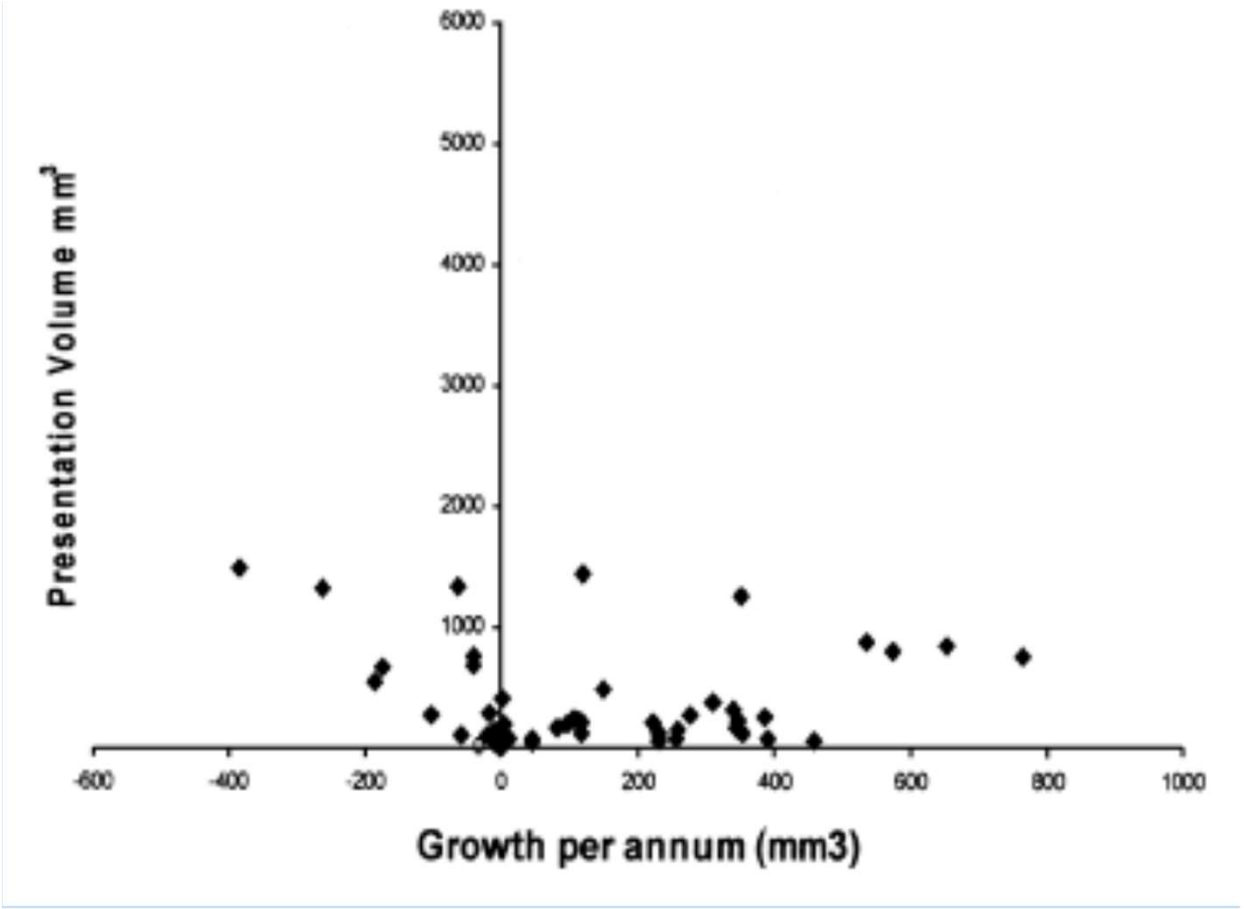
VS - surveillance



Natural history of vestibular schwannoma. *Otol Neurotol* 2006;27:547–52

ESTRO School

VS - surveillance

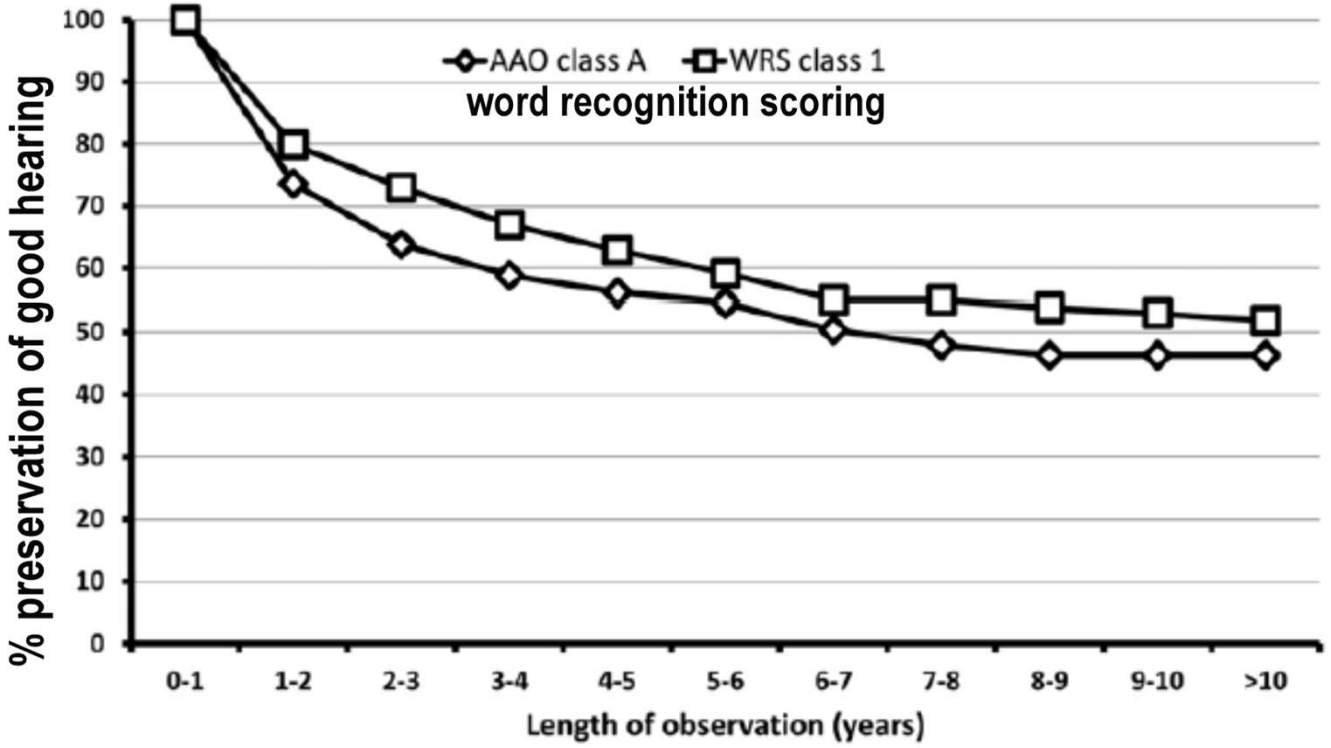


Acoustic neuroma growth: systematic review of the evidence. *Otol Neurotol* 2010; 31:478 – 85

ESTRO School

Hearing Loss – on surveillance

Danish Cohort Study <2cm VS



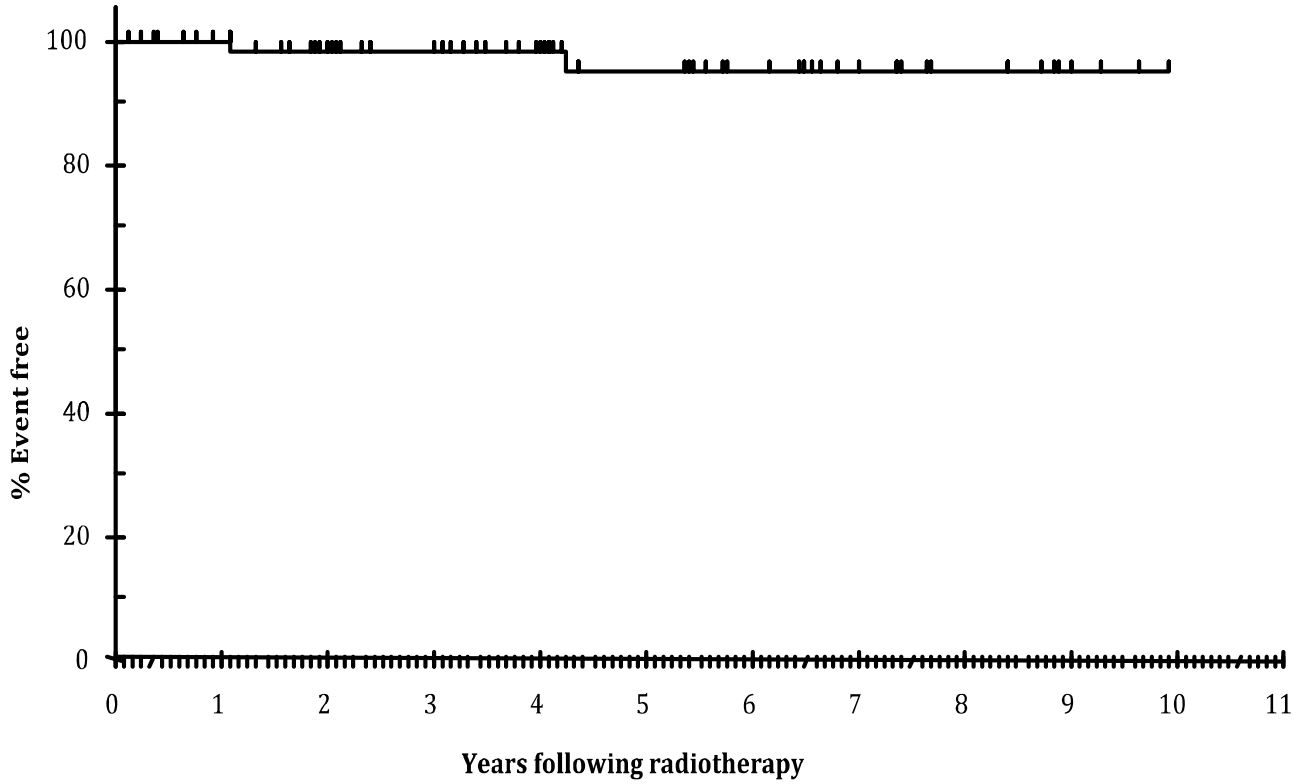
ESTRO School

Radiotherapy

- SRS – single
  - 11–12 Gy
  - 90% tumor control rates
  - 1% risk for permanent facial nerve palsies

- stereotactic fractionated radiation therapy 50/30# - for tumours too large for SRS and surgery not possible

Stereotactic RT



ESTRO School

Hearing

- Hearing preservation rates of 60%–70% initially reported
- Follow-up studies serviceable hearing was preserved in:
  - only 23%–24% patients at 10 years
- Risk Factors:
  - Older age,
  - Larger tumors
  - Poorer pretreatment hearing was found to be a risk factor for progressive post treatment hearing loss

Cystic VS

- 10% of VS are cystic
- Associated with higher degrees of hearing loss
- VS cysts are thought to arise from:
  - recurrent microbleeding or
  - osmosis-induced expansion of CSF trapped in arachnoid tissue
- Cystic VS may rapidly expand
- Surgery is favoured over SRS in the management of cystic VS
- In one study 6.4% of cystic VS treated with SRS required surgery

Neurosurg Rev 2005;28:209 –13

Follow-up

- Post SRS/FSRT the VS may increase in size due to intralesional oedema
- Some tumors will enlarge following SRS
- Most VS treated with SRS will subsequently:
  - decrease or
  - remain stable in size
  - takes time*

Dose and diameter relationships for facial, trigeminal, and acoustic neuropathies following acoustic neuroma radiosurgery. *Radiother Oncol* 1996;41: 215–19

Long-term Toxicity

- Hydrocephalus
- Cranial nerve palsies
- Second malignancy

Craniopharyngioma

Long term results after fractionated stereotactic radiotherapy (FSRT) in patients with craniopharyngioma: maximal tumor control with minimal side effects

Semi B Harrabi[1,2*], Sebastian Adeberg[1], Thomas Welzel[1], Stefan Rieken[1], Daniel Habermehl[1], Jürgen Debus[1,2] and Stephanie E Combs[1]

N = 55

Median age 37 years (range 6–70) (8< 18 years)

RT was indicated:

- progressive disease after neurosurgical resection
- postoperatively after repeated resection or partial resection

Median dose of 52.2 Gy (50 – 57.6 Gy)

Median Follow-up 128 months (2-276)

Harrabi *et al. Radiation Oncology* 2014, **9**:203

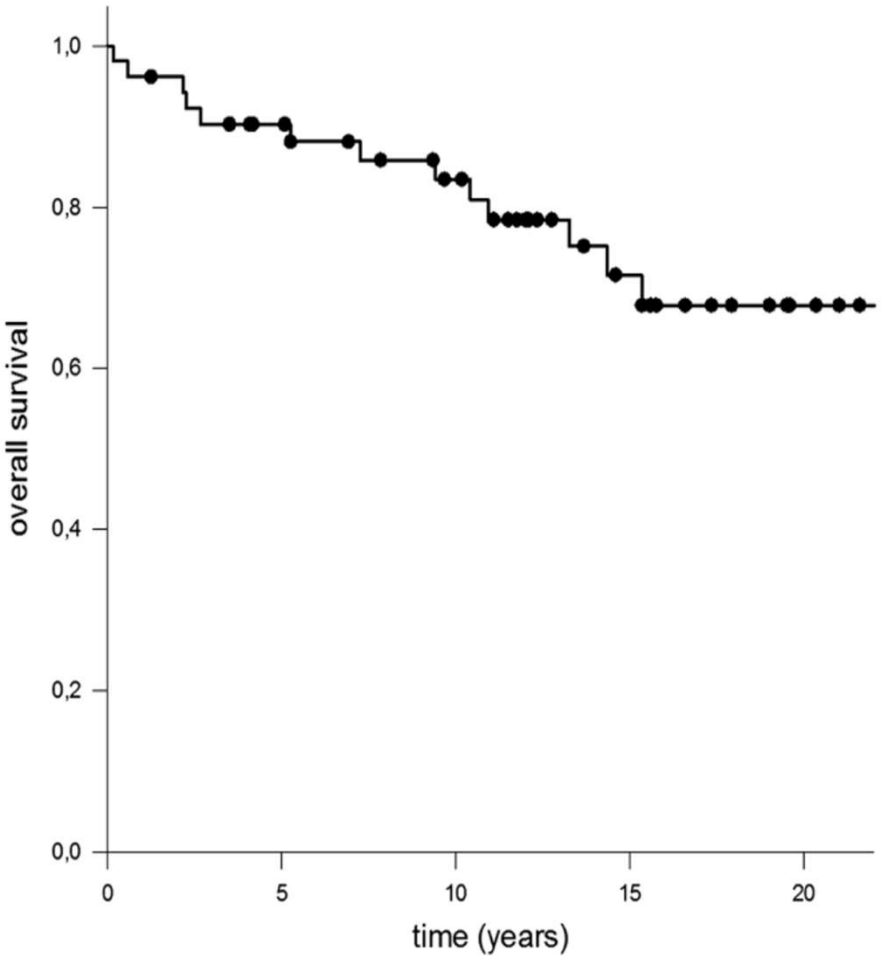

Figure 1 Median overall survival was 90.3% after 5 years respectively 83.3% (10 years) and 67.8% (20 years).

Harrabi *et al. Radiation Oncology* 2014, **9**:203

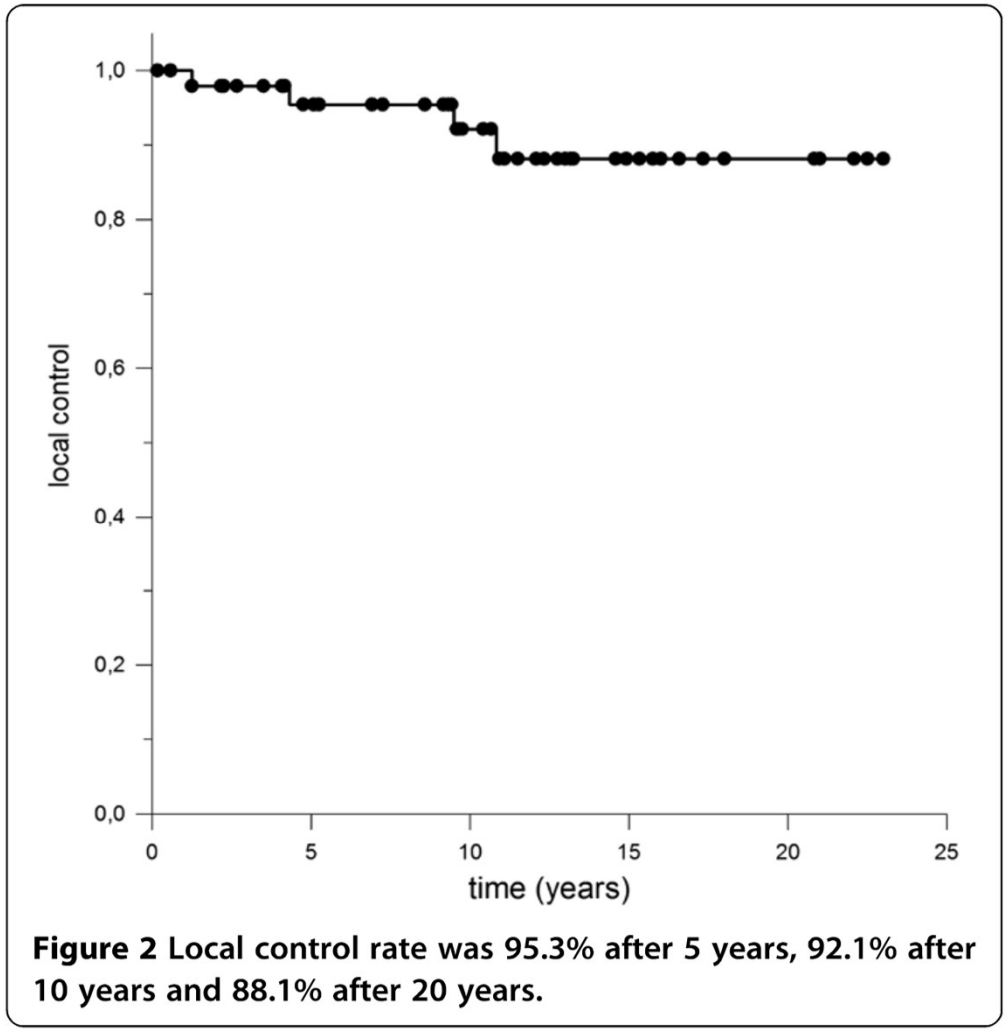

Figure 2 Local control rate was 95.3% after 5 years, 92.1% after 10 years and 88.1% after 20 years.

Harrabi *et al. Radiation Oncology* 2014, **9**:203

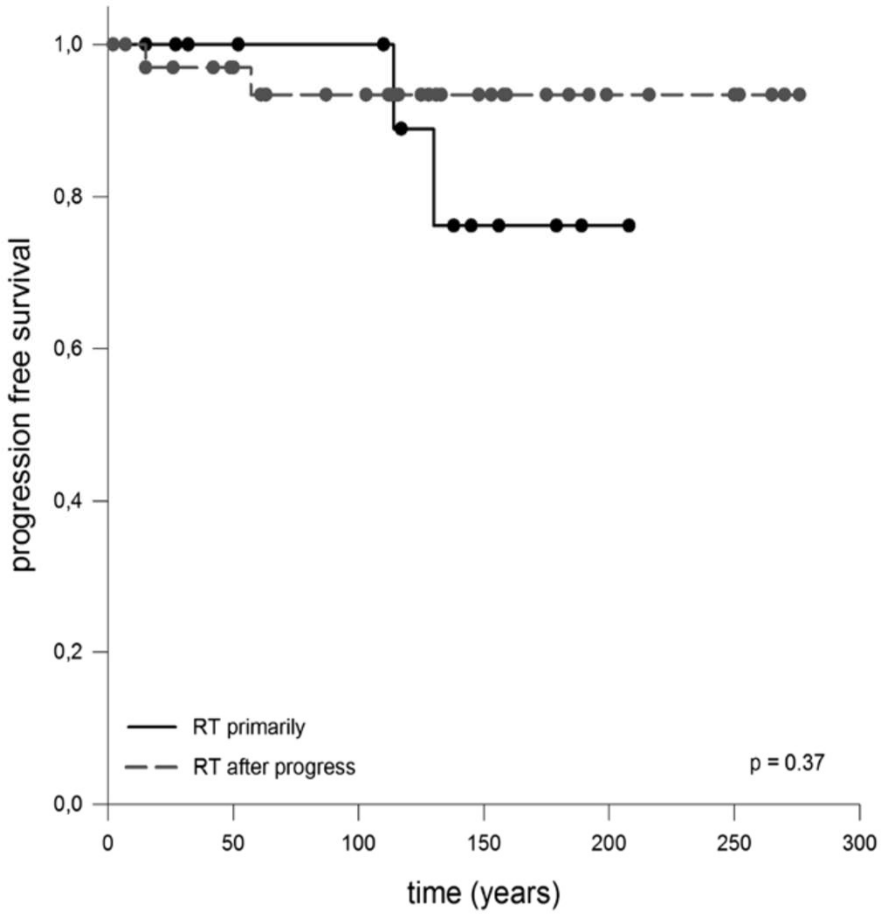

Figure 3 No significant difference was observed for progression free survival whether patients were treated early in the time course or received RT for tumor recurrence, p-value = 0.37.

1 patient – anosmia
1 patient worsening vision

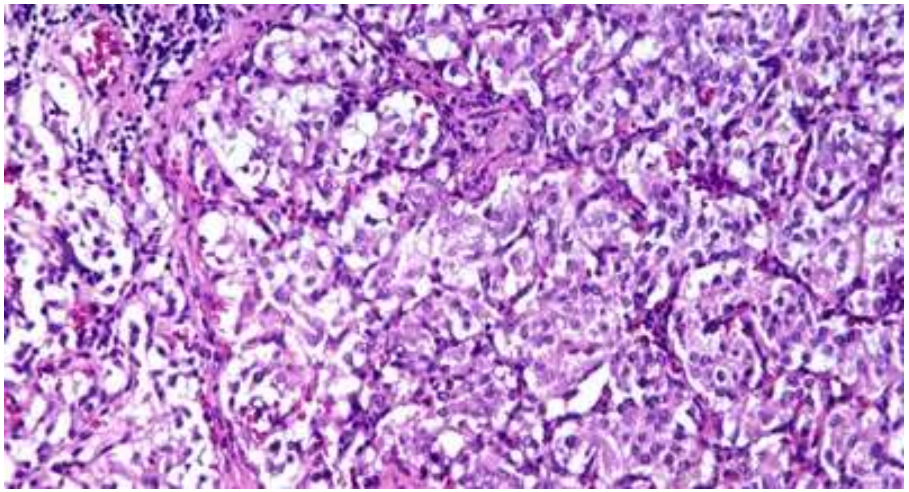
Harrabi *et al. Radiation Oncology* 2014, **9**:203

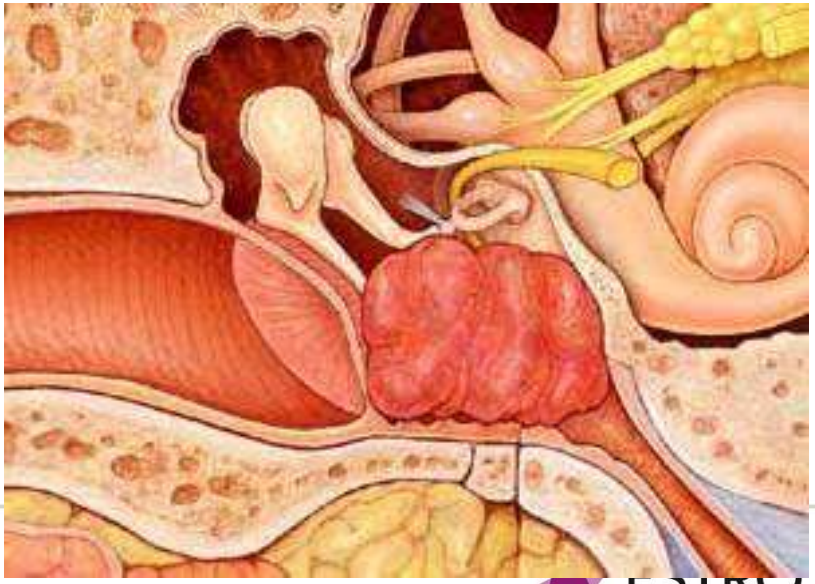
ESTRO School

Craniopharyngioma

- Excellent outcomes from FSRT
- Management requires:
  - Dedicated high quality surgery
  - Support from ophthalmology/endocrinology
  - High quality imaging for planning
  - *alert for cystic enlargement if remnant present

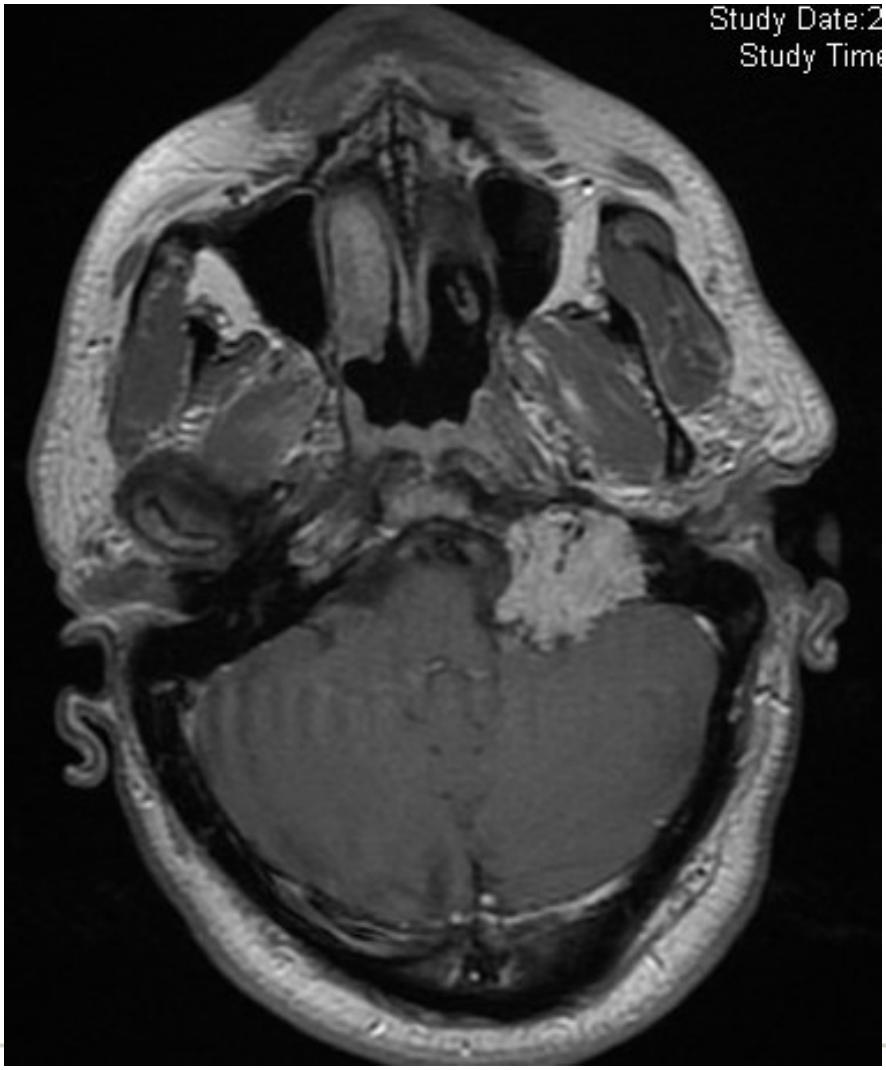
Paraganglioma





Paraganglioma

- Rare
- Need to exclude multiple tumours (SDHD mutations in 10%)
- Can secrete hormones
- Rarely metastasize



ESTRO School

Paraganglioma

- Use optimal imaging
- Plan with radiologist
- Check for multiple tumours

ESTRO teaching course
Management of brain tumours

Patrick Roth

Department of Neurology and Brain Tumor Center
University Hospital Zurich

ESTRO School

Overview

- Management of pain
- Antiemesis
- Treatment of seizures
- Steroids for the treatment of tumor-associated edema

Seizures in brain tumor patients

Background

- Incidence of brain tumor-associated epilepsy
- Tumor-mediated epileptogenesis

Medical treatment

- Available drugs
- Treatment recommendations
    - Interaction with other drugs / tumor-specific treatment
    - Appropriate antiepileptic drugs
- Duration of treatment

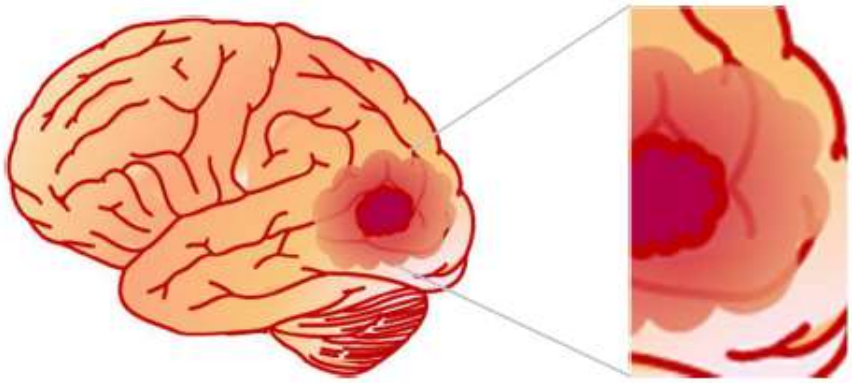
Epilepsy in brain tumor patients

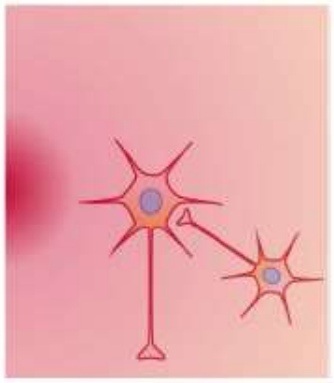
- Approx. 30-50% of all brain tumor patients are affected by seizures
  => frequently first clinical manifestation of a brain tumor

- Seizures are particularly common in slowly growing tumors and tumors of glial origin

• **DNET**	**100%**
• **Ganglioglioma**	**80-90%**
• **Low-grade glioma**	**70-80%**
• **Meningioma**	**30-60%**
• **Glioblastoma**	**30-50%**
• **Metastases**	**20-35%**
• **CNS lymphoma**	**10-15%**

Brain tumors & epileptogenesis





- Blood-brain barrier
- Edema
- Intracranial pressure
- Hemosiderin

- Alkalinization
- Deafferentiation
- Glial excitability ↑

- Glutamate ↑
- GABA-mediated inhibition ↓
- Adenosine ↓

ESTRO School

Impact of tumor-specifc therapy on epilepsy

- **Radiotherapy**: may increase edema, necrotic areas may also enhance the excitability

- **Chemotherapy**: increased risk of infections => fever => may trigger seizures

- **Concomitant medication**:

  Steroids may alter glucose and electrolyte levels

  Neuroleptics may trigger seizures

Which antiepileptic drugs (AED) are appropriate?

Basic considerations

- Antiepileptic activity
- Side effects
- Interaction with other drugs
- Approval for monotherapy

Specifically for brain tumors

- Interaction with tumor-specific treatment
- Direct effects on the tumor
- i.v. administration

Numerous AED are available

Drug	Trade name (CH)	Dose (mg)	costs/day (CHF)
Phenobarbital	Luminal®	50-300	0.1-0.5
Phenytoin	Phenhydan®	200-350	0.15-0.5
Carbamazepine	Tegretol®	600-2000	0.7-2.5
Valproic acid	Orfiril®	1200-2400	1-2
Lamotrigine	Lamictal®	100-300	3-7
Gabapentin	Neurontin®	900-2400	2-5
Topiramate	Topamax®	50-200	2-5
Levetiracetam	Keppra®	1000-3000	4-13
Lacosamide	Vimpat®	100-400	4-13
Zonisamide	Zonegran®	300-500	5-12

ESTRO School

AED in brain tumor patients: where is the evidence?

THE COCHRANE COLLABORATION®

Antiepileptic drugs for treating seizures in adults with brain tumours (Review)

Kerrigan S, Grant R

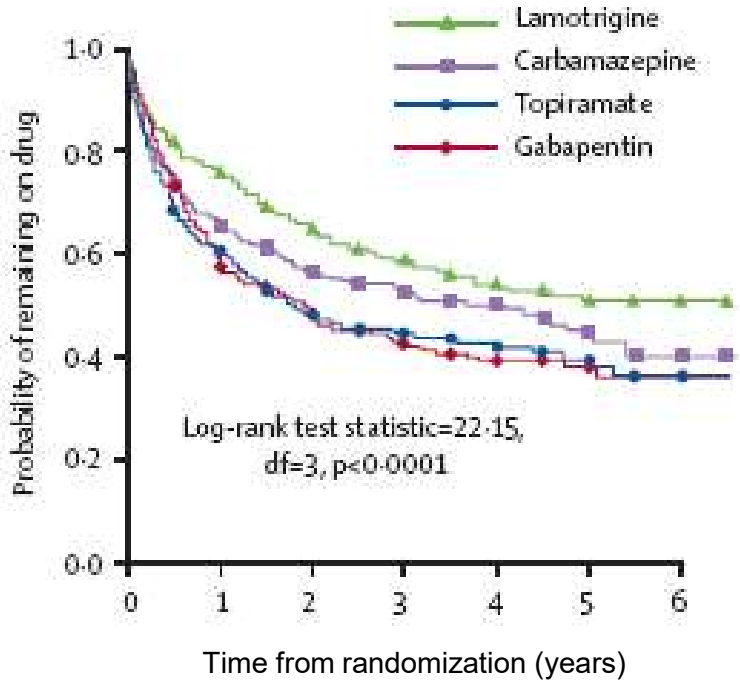
Cochrane Database Syst Rev 2011

"There is a lack of robust, randomised, controlled evidence to support the choice of antiepileptic drug for the treatment of seizures in adults with brain tumors"

"There is a need for further large randomised, controlled trials in this area"

ESTRO School

How to choose the best AED



„time to treatment failure“:
LTG > CBZ, GBP und TPM

Marson et al., Lancet 2007

„seizure control“
LEV = CBZ

Brodie et al., Neurology 2007

1.	Carbamazepine	CBZ
2.	Gabapentin	GBP
3.	Lacosamide	LAC
4.	Lamotrigine	LTG
5.	Levetiracetam	LEV
6.	Oxcarbazepine	OXC
7.	Perampanel	PER
8.	Phenobarbital	Pb
9.	Primidon	PRM
10.	Phenytoin	PHT
11.	Pregabalin	PGB
12.	Topiramate	TPM
13.	Valproic acid	VPA
14.	Zonisamide	ZON

ESTRO School

Old AED: pros and cons

Phenobarbital	Sedation, allergic reactions Enzyme induction (cytochrome P450)
Phenytoin	Vertigo, allergic reactions, liver enzymes ↑, gingival hyperplasia, cerebellar degeneration Enzyme induction (cytochrome P450)
Carbamazepine	Vertigo, Nausea, Ataxia, low blood sodium, nystagmus, allergic reactions, Enzyme induction (cytochrome P450)
Valproic acid	Tremor, gain of weight, coagulation disorders, thrombopenia, teratogenicity Enzyme inhibition

ESTRO School

New(er) AED: pros and cons

Lamotrigine	Skin reactions, tremor, sedation
Gabapentin	Fatigue, vertigo
Pregabalin	Vertigo
Levetiracetam	Fatigue, psychiatric disorders
Topiramate	Fatigue, loss of appetite, cognitive impairment
Lacosamide	Vertigo

Further considerations

- Enzym-inducing drugs may reduce the activity of chemotherapeutic drugs and steroids
- VPA (enzyme inhibition): impact is unclear
- Probably no interaction of lamotrigine, gabapentin, pregabalin, levetiracetam, topiramate or lacosamide with chemotherapeutic agents

1.	Carbamazepine	CBZ
2.	Gabapentin	GBP
3.	Lacosamide	LAC
4.	Lamotrigine	LTG
5.	Levetiracetam	LEV
6.	Oxcarbazepine	OXC
7.	Perampanel	PER
8.	Phenobarbital	Pb
9.	Primidon	PRM
10.	Phenytoin	PHT
11.	Pregabalin	PGB
12.	Topiramate	TPM
13.	Valproic acid	VPA
14.	Zonisamide	ZON

Which drugs are approved for monotherapy?

Monotherapy (CH):

CBZ, GBP, LTG, LEV, OXC, Pb, PHT, PRM, TPM, VPA, ZON

i.v. administration:

LAC, LEV, Pb, PHT, VPA

1.	Carbamazepine	CBZ
2.	Gabapentin	GBP
3.	Lacosamide	LAC
4.	Lamotrigine	LTG
5.	Levetiracetam	LEV
6.	Oxcarbazepine	OXC
7.	Perampanel	PER
8.	Phenobarbital	Pb
9.	Primidon	PRM
10.	Phenytoin	PHT
11.	Pregabalin	PGB
12.	Topiramate	TPM
13.	Valproic acid	VPA
14.	Zonisamide	ZON

Intravenous and oral levetiracetam in patients with a suspected primary brain tumor and symptomatic seizures undergoing neurosurgery: the HELLO trial

Oliver Bähr · Mirjam Hermisson · Sabine Rona · Johannes Rieger · Susanne Nussbaum · Peter Körtvelyessy · Kea Franz · Marcos Tatagiba · Volker Seifert · Michael Weller · Joachim P. Steinbach

Levetiracetam vs. Pregabalin

Table 3. Study endpoints

	Levetiracetam	Pregabalin
Randomized patients	25	27
Composite endpoint	9 (36%)	12 (44%)
Status epilepticus	0	0
2 seizures with consciousness impairment	1 (4%)	1 (4%)
Need to interrupt study drug	7 (28%)	7 (26%)
Need to add on a second antiepileptic drug	1 (4%)	4 (15%)
Seizure free from enrollment until last follow-up	17 (65%)	18 (75%)
Lost to follow-up	0	3 (11%)
Death	7 (28%)	5 (19%)
Survival in the study, days, median (range)	286 (9–431)	166 (0–410)

Who to treat and for how long?

- **Shall all brain tumor patients be treated with an AED?**
  No
- **Prophylaxis in all patient who undergo surgery?**
  No – or only transiently
- **Treatment following a seizure?**
  Yes
- **How long shall patients be treated with an AED?**
  Depends on histology, overall prognosis, tolerance…

Conclusions: brain tumors and epilepsy

- Hardly any data from randomized trials
- **Levetiracetam**: may be overall well tolerated and have good activity against seizures in brain tumor patients
- **Lamotrigine**: no comprehensive testing in brain tumor patients; overall good antiepileptic activity, well tolerated
- **Pregabalin**: may be considered as an alternative drug, probably not approved as monotherapy in most countries
- **Valproic acid**: (very) active, moderate tolerability, teratogenicity!

Overview

- Management of pain
- Antiemesis
- Treatment of seizures
- **Steroids for the treatment of tumor-associated edema**

Steroids in neurooncology: history

CORTISONE AND ACTH AS AN ADJUNCT TO THE SURGERY OF CRANIOPHARYNGIOMAS*

FRANC D. INGRAHAM, M.D.,† DONALD D. MATSON, M.D.,‡ AND ROBERT L. MCLAURIN, M.D.§

BOSTON

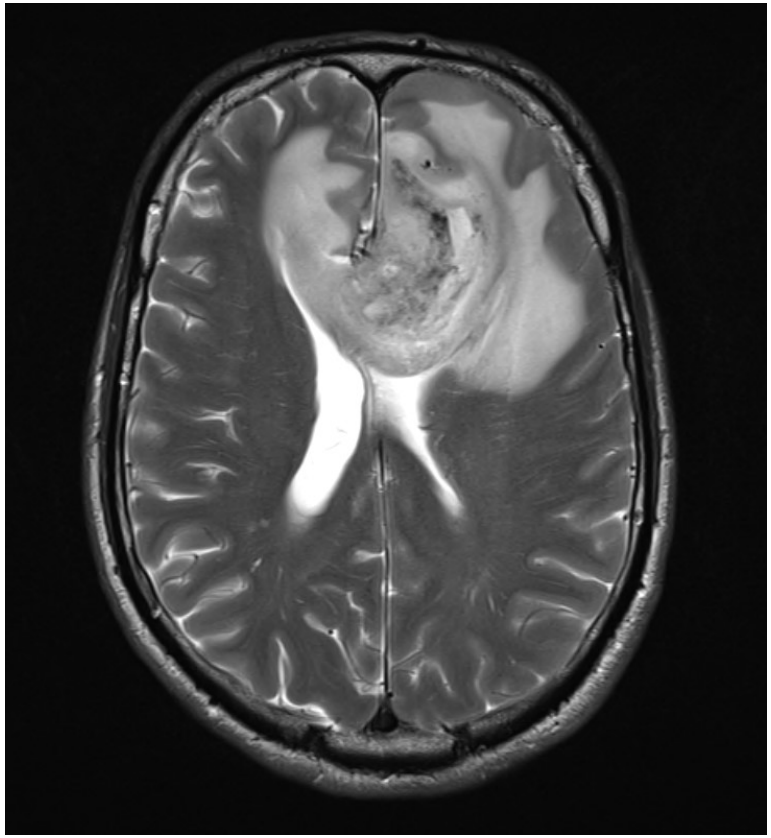
THE surgical management of craniopharyngiomas, whether radical or conservative, has always been hazardous. Gordy, Peet and Kahn[1] reported a series of 51 cases in which the operative mortality was 41 per cent, due principally to severe hypothalamic reactions incident to the surgical manipulation. Grant,[2] in summarizing the results of 40 operations on 30 patients, found a case mor-

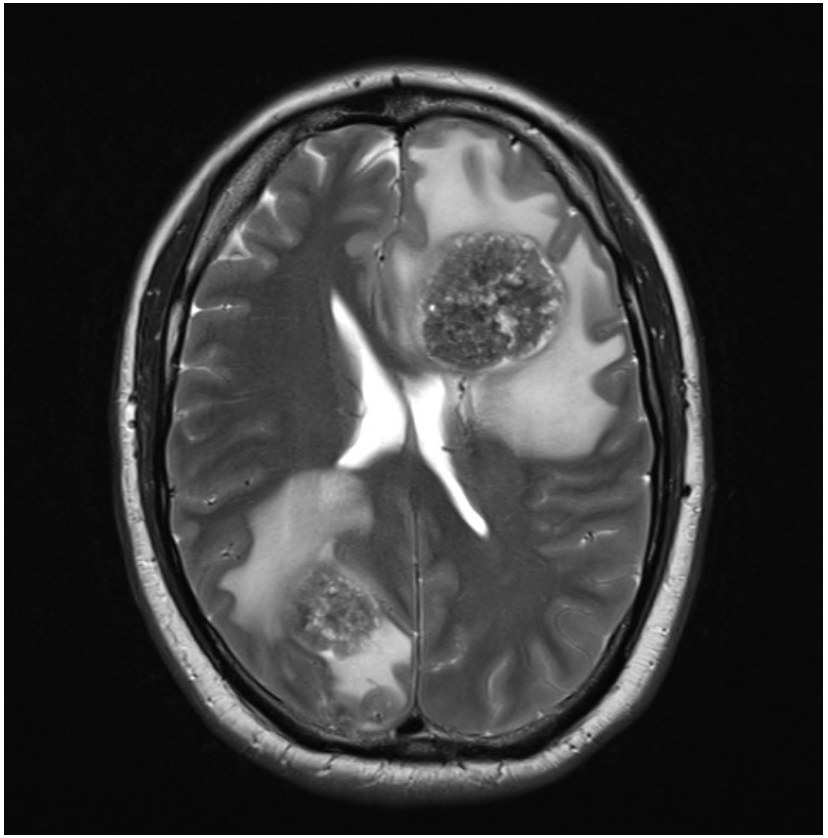
pacity of the pituitary adrenal system were, of course, not employed.

It is apparent that most of the operative complications in the treatment of craniopharyngioma result from the proximity of the lesion to the pituitary gland and the hypothalamus. Manipulation in this region is perilous at all times, but the danger is accentuated in the majority of these cases because

Treatment of edema

Primary or secondary brain tumors with surrounding edema





Anti-edematous therapy

- **70-100% of all brain tumor patients receive steroids during the course of the disease**

- **Commonly rapid effect on tumor-surrounding edema**

  => reduction of mass effect

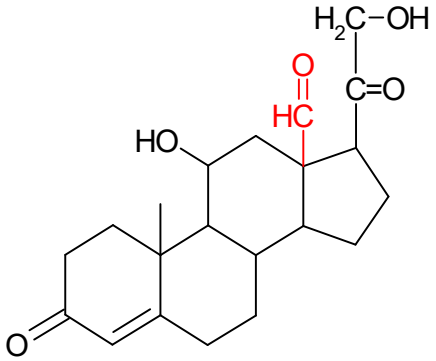
  => considerable clinical improvement is possible

  => maintenance of an acceptable quality-of-life

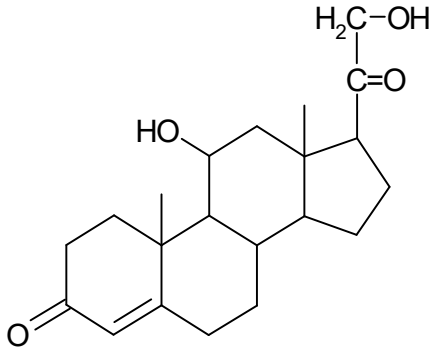
- **Steroid activity may decrease over time**

Physiological steroid hormones

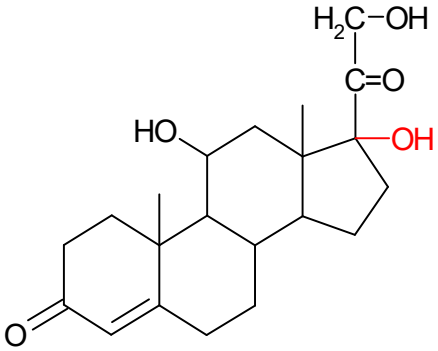
glucocorticoid activity



aldosterone



corticosterone



cortisol/hydrocortisone

mineralocorticoid activity

ESTRO School

Steroids: which compound?

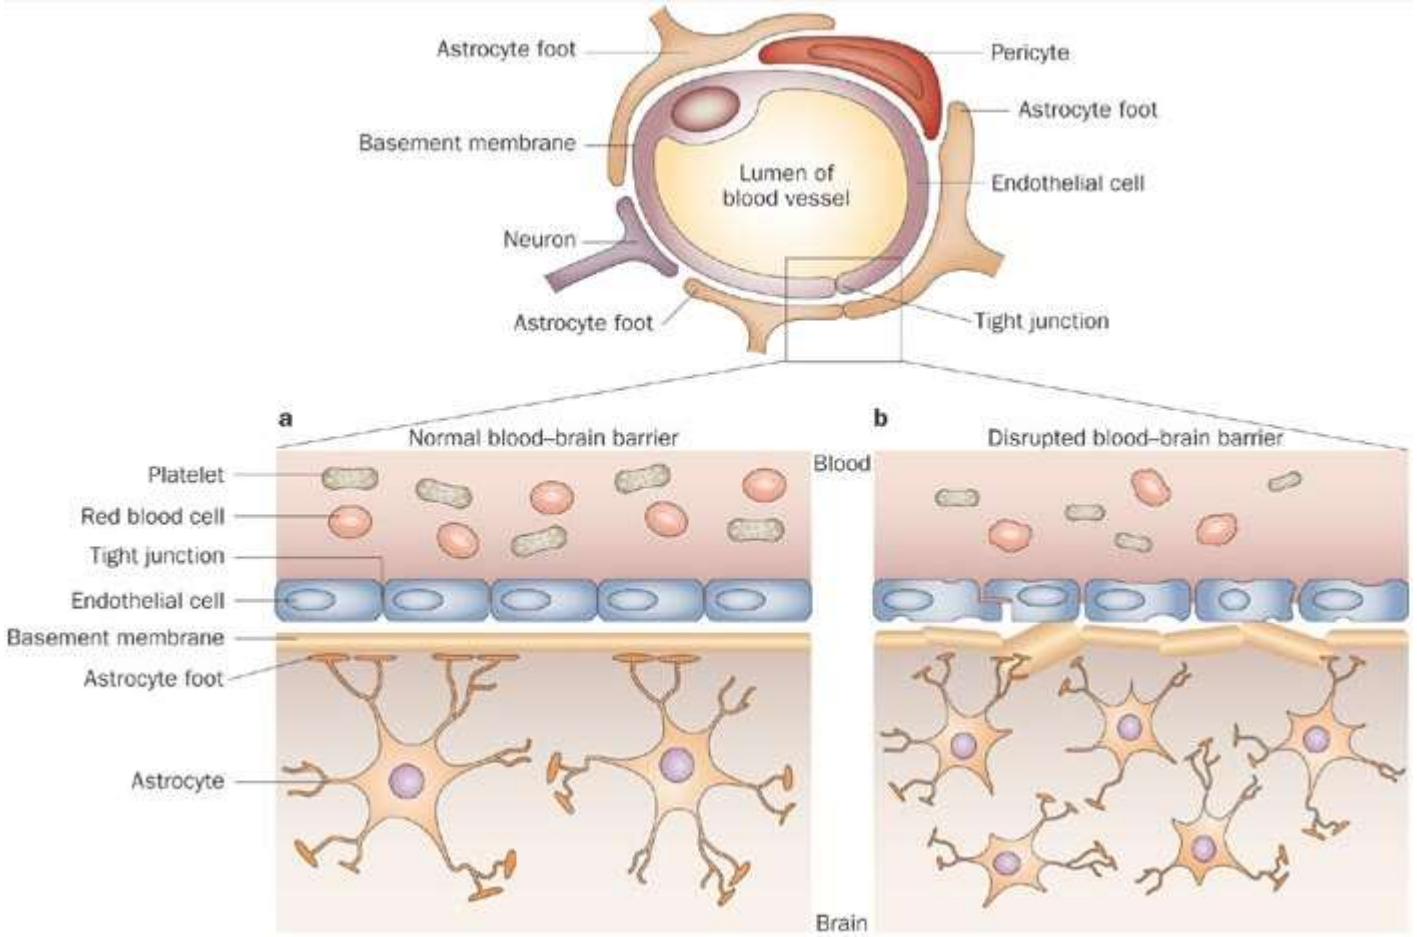
	Glucocorticoid Potency	Plasma half-life (h)	Biological half-life (h)	Mineralo-corticoid effects
Hydrocortisone	1		8-12	1
Prednisone	5	3-4	12-36	0.8
Methylprednisolone	4	1.5-3	12-36	0.5
Dexamethasone	~ 30	2-5	36-54	0

Advantages of dexamethasone:

- Least amount of mineralocorticoid activity
  => Low rate of fluid retention
- Long biological half-life
  => frequent dosing not required

ESTRO School

Brain tumors: vasogenic edema



Tumor-mediated mechanisms:

- VEGF
- Nitric oxide (NO)
- Leukotriens
- Prostaglandins

Cushing's syndrom:

- **Central obesity**
- **"moon face"**
- **Arterial hypertension**

ESTRO School

Osteoporosis & myopathy

Osteoporosis:

- Development of osteoporosis is particularly high in patients taking other osteoporosis-inducing drugs (e.g. loop diuretics, thyroxine)

- Prophylaxis: Calcium, vitamine D, biphosphonates

Myopathy:

- Weakness of the proximal muscles of the upper and lower limbs
- No data supporting the hypothesis that myopathy occurs more frequently when „fluorinated“ steroids are used
- Prophylaxis: physiotherapy

Side effects: many more…

- Gastrointestinal symptoms (peptic ulcers)
- Steroid cataract
- Psychiatric side effects (depression, psychosis, insomnia)
- Increased risk for infections (e.g. Pneumocystis jirovecii) (particularly in patients who receive radio- and/or chemotherapy)

=> Steroid toxicity may reduce the benefit from other treatment modalities, e.g. radio- and chemotherapy

Guidelines for the use of steroids

- Regular check of blood pressure and glucose levels
- Proton pump inhibitor and thrombosis prophylaxis should be considered
- PJP prophylaxis, particularly in patients on radio-/chemotherapy
  - Trimethoprim/sulfamethoxazole (Co-trimoxazole)
  - Pentamidine inhalation
- Check interaction(s) with other drugs

Steroid tapering

- Tapering should be persued as soon as clinically possible
- Short treatment => rapid tapering
- Long duration of therapy => slow tapering

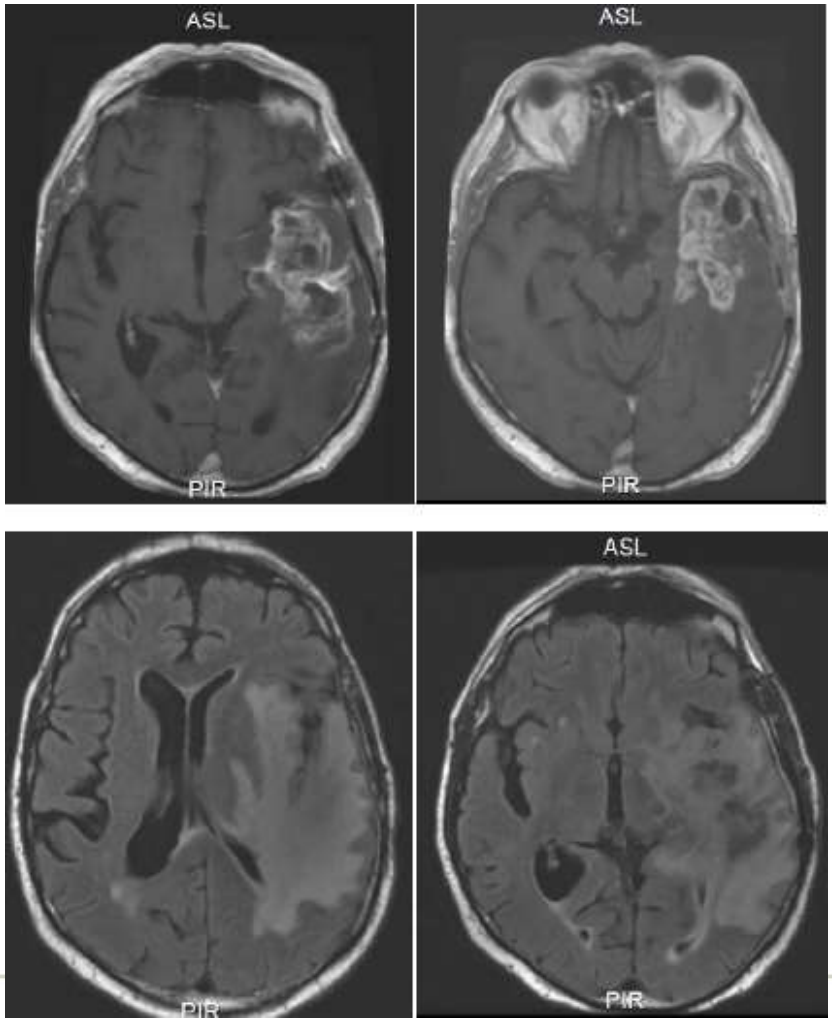
  => Watch for signs of hypocortisolism!

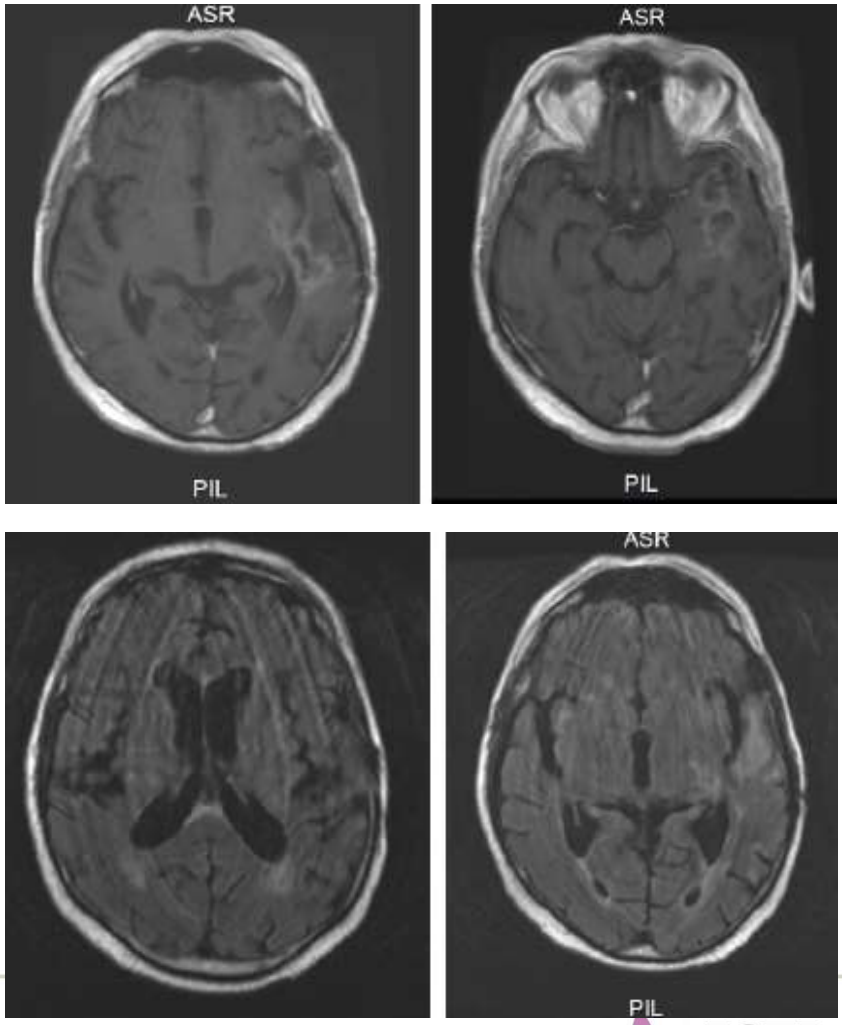
  - Nausea, vomiting, headaches
  - Myalgia, hypotension

- Manifest hypocortisolism: substitution with hydrocortisone

  => average daily dose: 20-30 mg

Bevacizumab





Recurrent glioblastoma

Multidisciplinary management of brain tumours

Cases

Karin Dieckmann, Radiation Oncologist

Johannes Gojo, Pediatric Oncologist

Case 1

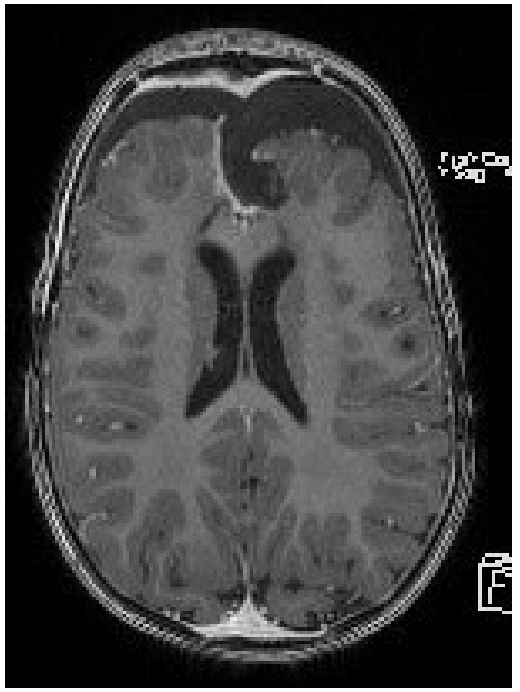
- female
- 2 years 2 months
- Seizure

ETANTR/ETMR

- ETMR = Embryonal tumors with multilayered rosettes
- Characteristic focal amplification of C19mC (chromosome 19)

ETANTR/ETMR

- Biopsy
- 2 blocks CTX :PEI
- gross total resection

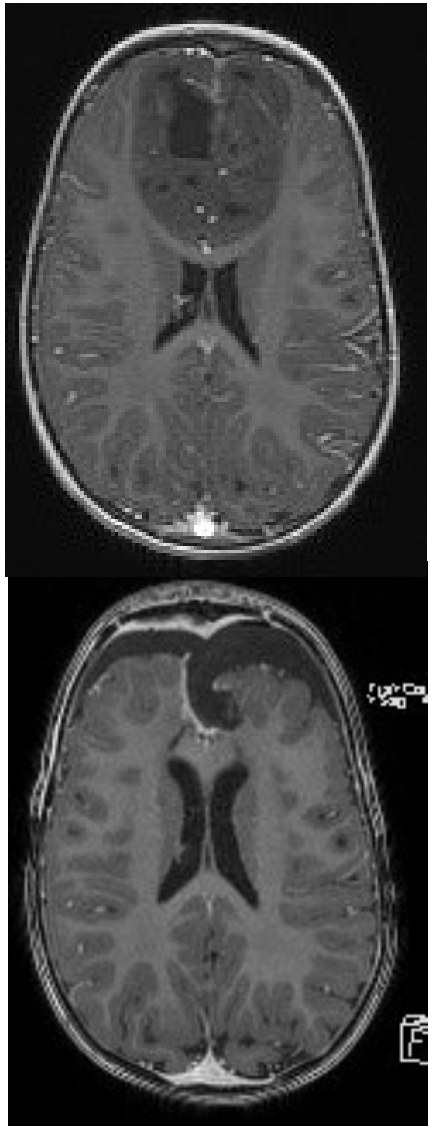


Mozes P., Hauser P., Hortobagyl T. et al., Evaluation of the good tumor response of embryonal tumor with abundant neuropil and true rosettes (ETANTR). J Neurooncol (2016) 126:99-105

ETANTR/ETMR

Proton therapy

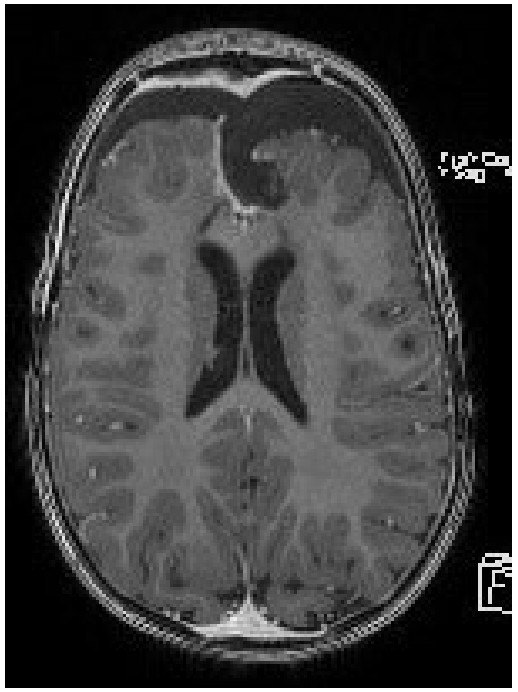
- Focal irradiation (54 Gy)
- concomitant temozolomide (75mg/m2)
- 12 cycles temozolomide (150-200mg/m2)
- + 4 weekly i.th. mit VP-16



Mozes P., Hauser P., Hortobagyl T. et al., Evaluation of the good tumor response of embryonal tumor with abundant neuropil and true rosettes (ETANTR). J Neurooncol (2016) 126:99-105

ETANTR/ETMR

- Biopsy -> 2 blocks CTX -> gross total resection



Proton therapy

- Focal irradiation (54 Gy)
- concomitant temozolomide (75mg/m2)
- 12 cycles temozolomide (150-200mg/m2)
- + 4 weekly i.th. mit VP-16

Still in remission after 18 months

visits kindergarten and shows adequate neurological development

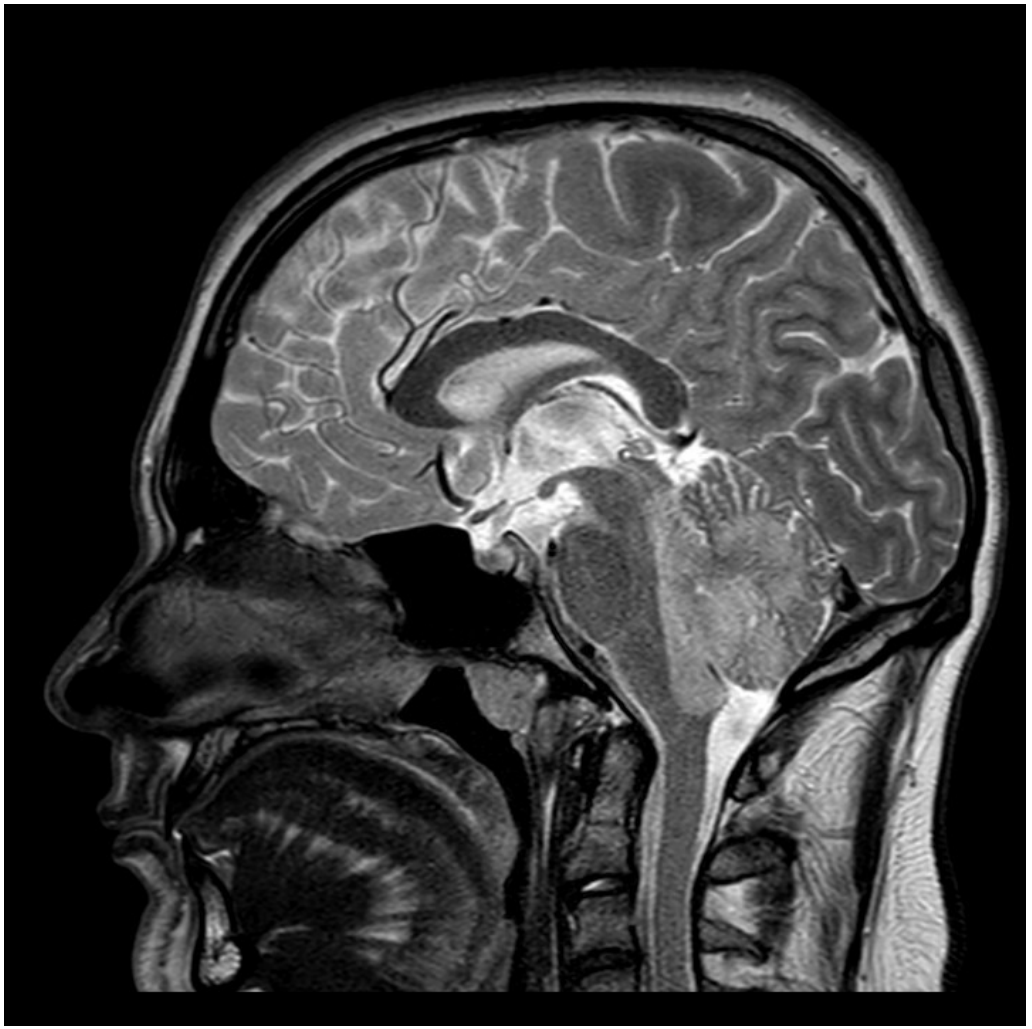
Medulloblastoma

- Male
- 16 years
- Nausea and vomiting



Medulloblastoma

Staging und Biology

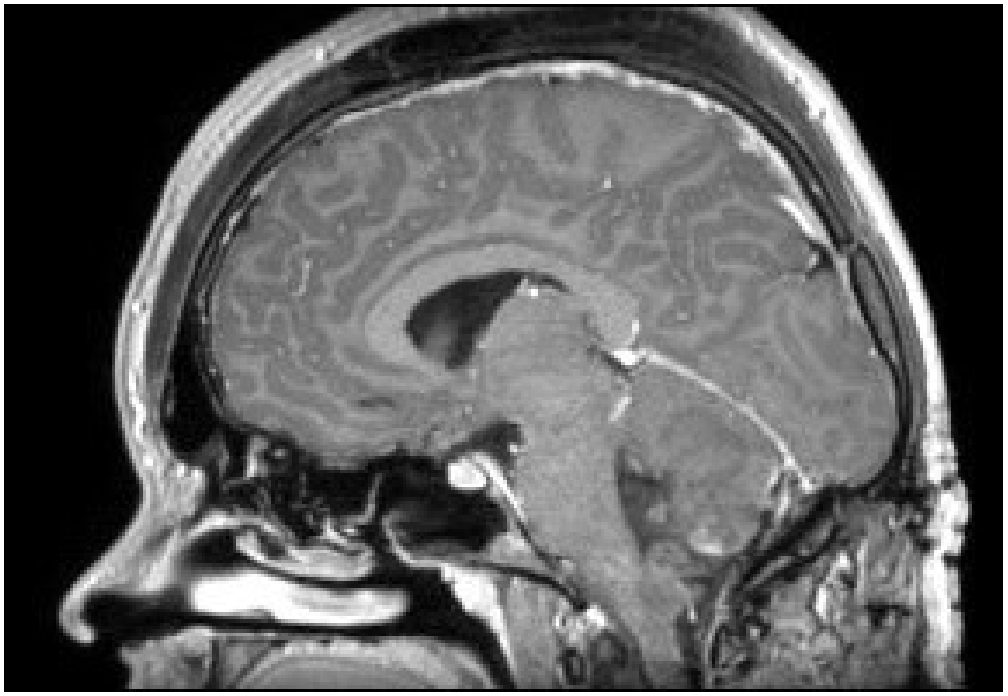
- Metastases – M1-3
- Molecular Subgroup G4
- No MYC amplification

HIGH RISK

OP -> induction CTX -> RTX -> maintenance CTX

Medulloblastoma

- Resection of PF tumor
- Start with Chemotherapy
- intrathekal Chemotherapy



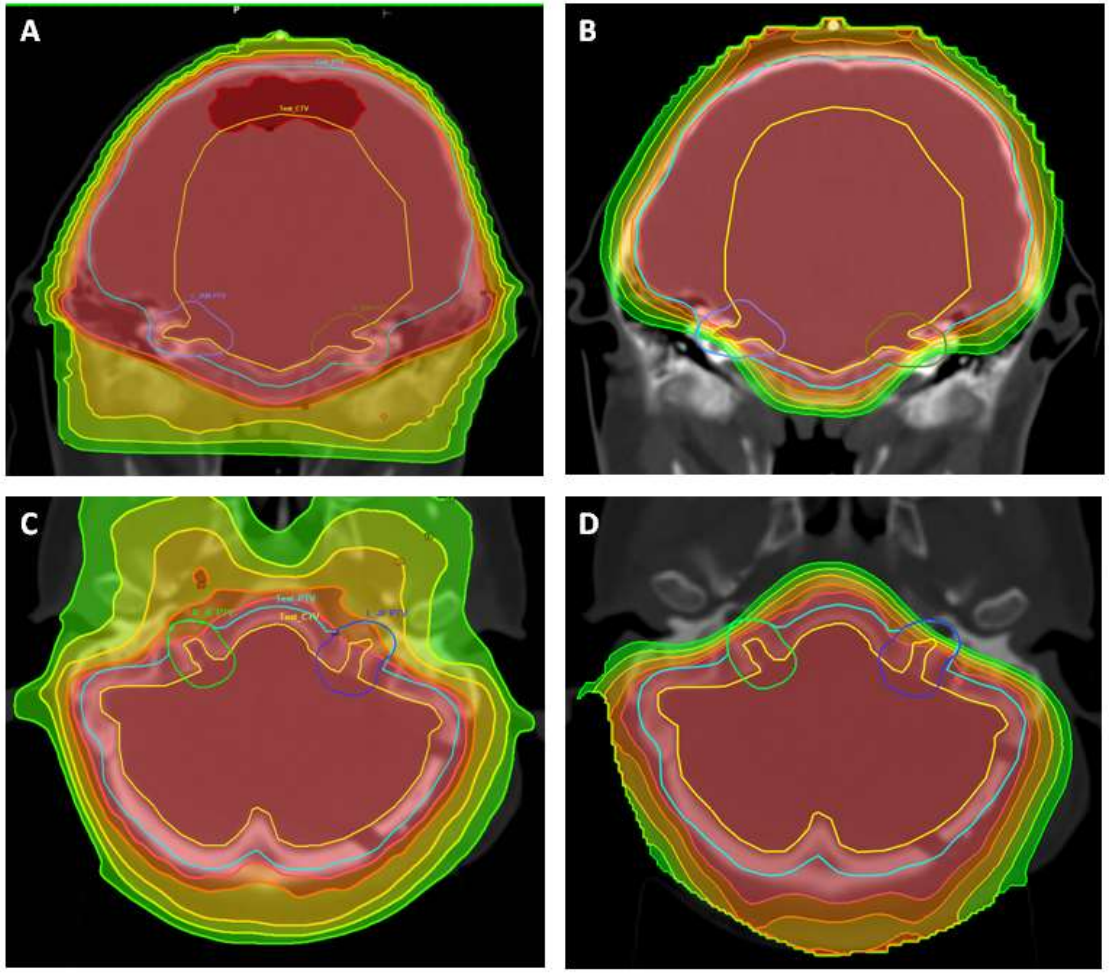
- Radiotherapy - CSI
- Proton therapy

- Less toxicity to vertebral bone marrow if in adolescents that have reached the final height the vertebral bodies can be spared from irradiation resulting in better tolerance of the chemotherapy (subsequent chemotherapy !)
- Less longterm toxicity on cervical/thoracic/abdominal organs

- **Highly Conformal Craniospinal Radiotherapy Techniques Can Underdose the Cranial Clinical Target Volume if Leptomeningeal Extension through Skull Base Exit Foramina is not Contoured.**

- Noble DJ, Ajithkumar T, Lambert J, Gleeson I, Williams MV, Jefferies SJ

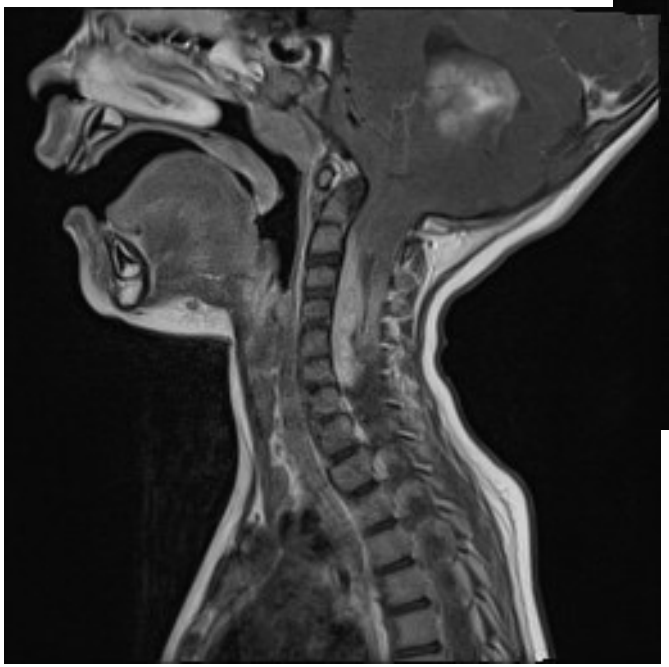
- Clin Oncol (R Coll Radiol). 2017;29(7):439-447



A = Field base, B = Proton, C= Tomotherapy, D = Proton

Ependymoma

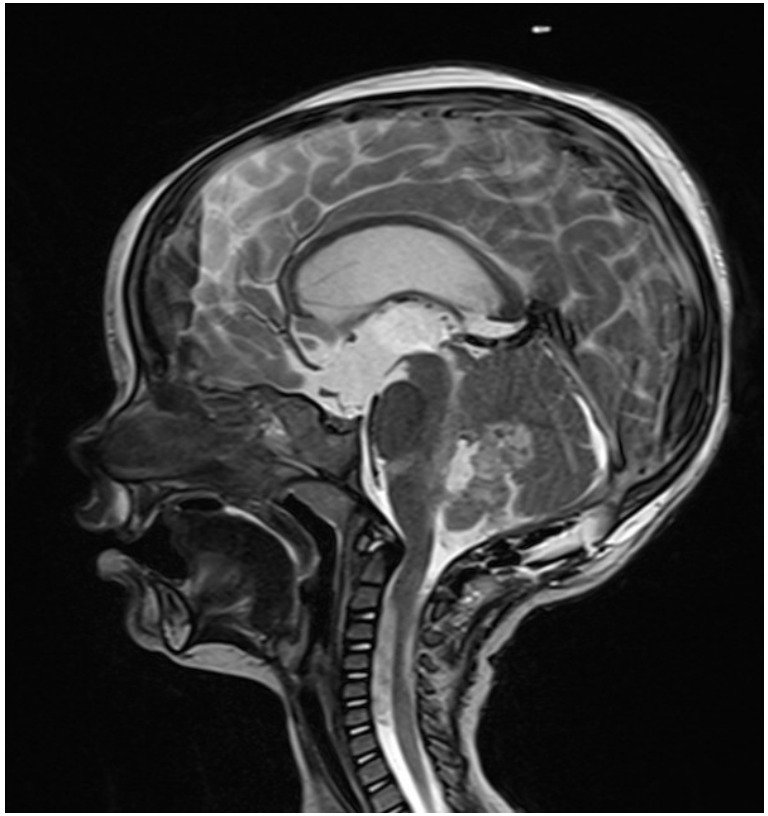
- female
- 3 years 2 months
- long history of ataxia
- PF-EPN-A
- Staging: M0



Ependymoma

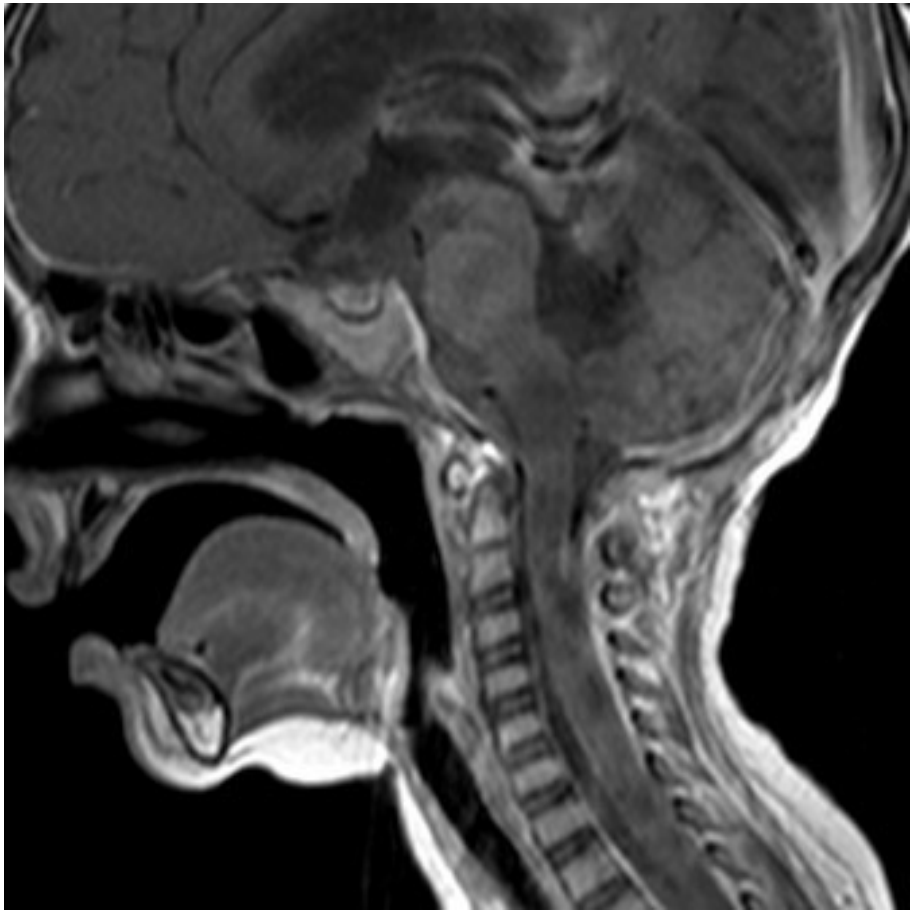
Resection – postoperative residual tumor

WHAT NEXT?

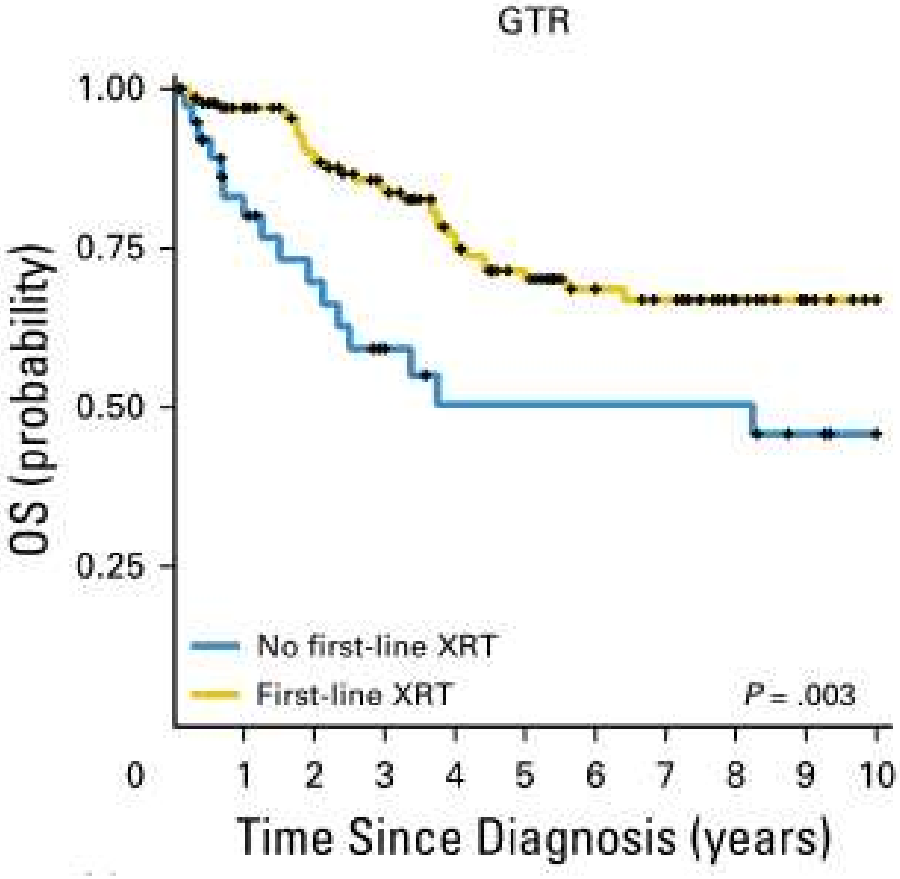


Ependymoma

2nd look surgery -> gross total resection



Ependymoma



No clear benefit of Chemotherapy

Ramaswamy et al., JCO 2016

Ependymoma

Photon therapy:

- local radiotherapy GHD 52,2 Gy in 1,8 Gy ED

- Subsequent chemotherapy 3cycles

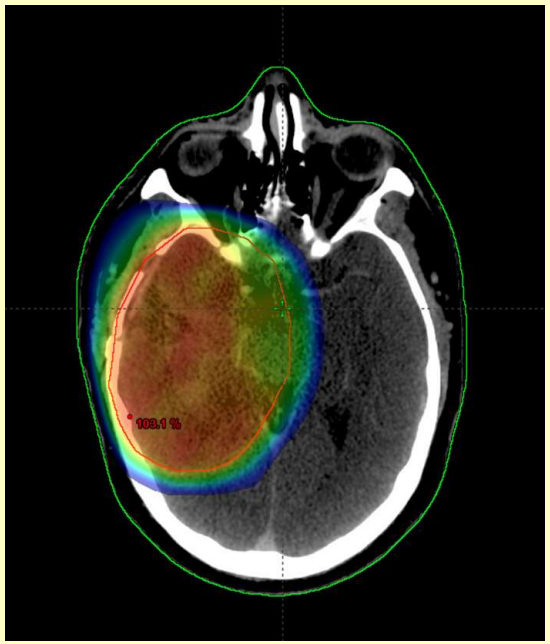
- Patient still in remssion 4 years after diagnosis

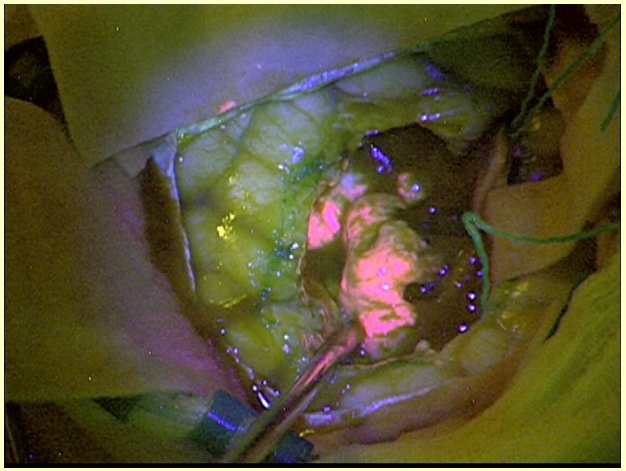
BUT

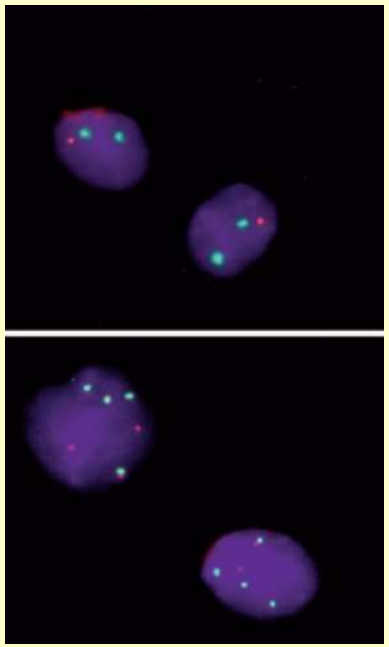
Hypothyroidism, growth hormone deficiency

Young patients with good outcome frequently experience longterm side effects

- Endocrinopathies, neuropsychological deficits, secondary tumors







Elderly patients with glioblastoma
