Hematological Malignancies

3 – 5 September 2015
London, United Kingdom

NOTE TO THE PARTICIPANTS

The present slides are provided to you as a basis for taking notes during the course. In as many instances as practically possible, we have tried to indicate from which author these slides have been borrowed to illustrate this course.

It should be realised that the present texts can only be considered as notes for a teaching course and should not in any way be copied or circulated. They are only for personal use. Please be very strict in this, as it is the only condition under which such services can be provided to the participants of the course.

Programme

Thursday, 3 September		
Time	**Lecture Topic**	**Lecturer**
08.20-08.30	Welcome and Practical Information	Specht
08.30-09.00	The role of the radiation oncologist in the multimodality treatment of lymphomas	Specht
	General principles of treatment	
09.00-09.45	Radiotherapy	Specht
09.45-10.30	Chemotherapy	Engert
10:30-10:45	*Coffee or Tea*	
10:45-11:10	Immunotherapy	Engert
11:10-11:35	Radioimmunotherapy and new immunological approaches	Illidge
11:35-12:20	Combined modality treatments	Engert
12:20-13:05	*Lunch*	
13:05-13:50	Long term toxicity	Aleman
13:50-14:05	Hodgkin lymphoma: Lymphocytic predominance, the role of radiotherapy	Mikhaeel
	Classic Hodgkin lymphoma, the role of radiotherapy	
14:05-14:35	Early stage	Illidge
14:35-14:55	Advanced stage	Engert
14:55-15:05	Advanced stage, comments on radiation therapy	Yahalom
15:05-15:20	*Coffee or Tea*	
15:20-15:40	Relapsed/refractory disease	Yahalom
15:40-15:50	Relapsed/refractory disease, comments on chemotherapy	Engert
15:50-16:20	Radiotherapy volumes, doses and techniques	Ricardi
16:20-17:20	Hodgkin case discussion	**Ricardi** Yahalom/ Aleman/ Engert

Friday, 4 September		
Time	**Lecture Topic**	**Lecturer**
	Indolent nodal non Hodgkin lymphoma, the role of radiotherapy	
08.00-08.20	Early stage	Illidge
08.20-08.40	New agents for advanced stage	Illidge
08.40-08.50	Advanced stage, comments on radiation therapy	Mikhaeel
08.50-09.10	Role of radiation therapy in relapsed/refractory disease	Yahalom
09.10-09.30	Volumes, doses and techniques	Ricardi
09.30-10.30	Indolent nodal non Hodgkin case discussion	**Mikhaeel** Illidge/ Specht
10.30-10.50	*Coffee or Tea*	
10.50-11.20	Motion management and deep inspiration breath hold DIBH technique	Aznar
11:20-11:50	Contouring - Guideline Presentation	Specht
11:50-12:40	Contouring Group 1 - *Lunch Group 2*	De Bari/ Specht/ Berthelsen/ Aleman
12:40-13:20	Contouring Group 2 - *Lunch Group 1*	De Bari/ Specht/ Berthelsen/ Aleman
13:20-14:20	Presentation and Discussion of Participant Contours	Specht/ Berthelsen/ Aleman
	Aggressive nodal non Hodgkin lymphoma, the role of radiotherapy	
14:20-14:50	Early stage	Ricardi
14:50-15:20	Advanced stage	Aleman
15:20-15:40	*Coffee or Tea*	
15:40-16:10	Relapsed/refractory disease	Mikhaeel
16:10-16:30	Volumes, doses and techniques	Aleman
16:30-17:30	Aggressive nodal non Hodgkin case discussion	**Illidge** Mikhaeel/ Ricardi/ Davies
	Other indications: Role of radiotherapy, special techniques	
17:30-17:50	Myeloma - Solitary & Disseminated	Ricardi
17:50-18:00	Granulocytic sarcoma (Chloroma)	Yahalom
18:00-18:10	Total body irradiation as part of the conditioning regimen for transplant	Yahalom
18:10-18:15	Splenomegaly, hypersplenism	Specht

Saturday, 5 September		
Time	**Lecture Topic**	**Lecturer**
08.00-09.00	Pathology: WHO Classification (morphology, immunophenotype, genetics)	Wilkins
09.00-09.45	Imaging for radiotherapy of lymphomas	Mikhaeel/ Berthelsen
	Extranodal lymphomas: Characteristics, the role of radiotherapy, volumes doses and techniques	
09.45-10.15	Head and neck	Specht
10.15-10.35	Thyroid	Mikhaeel
10.35-10.55	*Coffee or Tea*	
10.55-11.25	Orbital (ocular adnexae)	Ricardi
11.25-11.55	Gastric	Yahalom
11.55-12.25	Skin	Specht
12:50-13:50	*Lunch*	
13:50-14:05	Testicular	Aleman
14:05-14:20	Breast	Aleman
14:20-14:35	Lung	Ricardi
14:35-14:55	Systemic approaches to early and advanced marginal zone lymphoma	Davies
14:55-15:10	Bone	Ricardi
15:10-15:40	CNS	Yahalom
15:40-16:00	Other, rarer sites	Mikhaeel
16:00-16:20	*Coffee or Tea*	
16:20-17:20	Extranodal lymphoma case discussion	Yahalom Specht/ Aleman/ Davies
17:20-17:40	Evaluation and farewell	All

”There is no doubt that radiation remains the most active single modality in the treatment of most types of lymphoma”

James O. Armitage

- Its role has changed
- Now part of combined modality treatment in most situations
- Often as consolidary treatment after primary chemotherapy

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Challenges in lymphoma treatment

- > 70 different diseases, classified on the basis of morphology, immunophenotype, genetic and clinical features:

  Expert pathology is needed

- The diseases may be localized or disseminated, nodal or extranodal, anywhere in the body:

  Expert imaging is needed

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Challenges in lymphoma treatment

- Modern treatment includes:
  - Radiotherapy
  - "Classical" chemotherapy
  - Antibodies
  - Small molecules

Expert radiation and medical oncology are needed

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Role of radiotherapy

Primary treatment for early stage indolent lymphomas

Consolidation therapy for early stage aggressive lymphomas (inc. HL)

Treatment of bulky or residual mass in advanced aggressive lymphoma

Treatment of recurrent disease +/- systemic treatment

Part of conditioning for autologous transplant for recurrent/refractory disease

Palliative treatment in advanced indolent lymphoma

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Role of radiation (and medical) oncology

- Close collaboration from the outset between systemic treatment (medical oncologist/ hematologist/clinical oncologist) and local treatment (radiation oncologist/clinical oncologist)
- The entire treatment strategy must be planned from the outset to allow optimal treatment
- Treatment modifications during treatment must be decided with due regard to both local and systemic treatment options
- Treatment interactions must be considered

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Responsibilities of the radiation oncologist

- Ensure that all information necessary for optimal target definition is available for radiotherapy planning
- Relevant imaging of all lymphoma involvement before chemotherapy (and operation)
- Optimally see the patient before any treatment

Responsibilities of the radiation oncologist

- Ensure that the advantages that can be obtained with modern radiotherapy are used to the benefit of the patient:
  - Optimal target coverage
  - Lowest target dose necessary for the highest chance of local lymphoma control
  - Lowest possible risk of significant long-term side effects

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Ensure that the unique biology of lymphoid malignancies is exploited in RT planning and delivery

In general no survival advantage has been demonstrated with the extended fields of the past

The unique radiosensitivity of lymphoid malignancies means that dose constraints for normal tissues used for solid tumours are not applicable

Modern conformal techniques should be used for lymphomas, not primarily as in solid tumours to allow a high target dose to be delivered, but to minimize the risk of long-term complications

Different techniques are applicable to different disease localizations and disease volumes, no two patients are the same

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Constraints, are they useful for lymphomas?

Organ at risk	Limiting dose/volume
Brain stem	If whole organ irradiated, $D_{max} < 54$ Gy to any part of the volume If partial volume irradiated, $D_{1-10\ cm^3} \leq 59$ Gy
Breast	Minimise volume inside PTV, particularly in young women ≤30 years. Mean dose ≤ 2 Gy
Cochlea	Mean dose ≤ 45 Gy
Coronary artery	Minimise volume inside treatment field and keep doses as low as possible without compromising on PTV coverage
Heart	Mean dose < 26 Gy; $D_{100} < 30$ Gy $V_{30} < 46\%$; $V_{33} < 60\%$, $V_{38} < 33\%$, $V_{42} < 20\%$
Kidney	Single kidney irradiated: V_{15} of 65–70%, Both kidneys irradiated: V_{15} of 20–25% for each kidney; mean dose < 18 Gy. Partial kidney irradiation (all constraints are for combined kidneys): mean dose < 18 Gy $V_{28} < 20\%$, $V_{23} < 30\%$, $V_{20} < 32\%$, $V_{12} < 55\%$. If mean dose to one kidney >18 Gy, V_6 for remaining kidney <30%
Lens	Maximum dose of 6 Gy to any part of the volume unless compromising PTV coverage
Liver	Mean dose < 32 Gy; V_{40} of 30–35%; D_{100} of 25 Gy, D_{66} of 28 Gy, D_{33} of 38 Gy
Lung (whole)	$V_{20} \leq 30\%$, Mean lung dose (MLD) ≤ 20 Gy
Oesophagus	Mean dose < 34 Gy, $V_{35} < 50\%$
Optic chiasm	$D_{max} < 55$ Gy to any part of the volume
Optic nerve	$D_{max} < 55$ Gy to any part of the volume
Ovary	D_{max} <10 Gy to any part of the volume outside PTV. If inside PTV discuss individual case with clinician
Parotid	Bilateral irradiation: mean dose < 25 Gy. Unilateral irradiation: mean dose < 20 Gy to the contralateral parotid
Small bowel	For individual loops $V_{15} < 120\ cm^3$ For whole peritoneal cavity $V_{45} < 195\ cm^3$
Spinal cord	$D_{max} \leq 50$ Gy to any part of the volume
Stomach	$D_{100} < 45$ Gy
Testis	Maximum dose of 2 Gy to any part of the volume
Thyroid	$D_{100} < 45$ Gy

General principles of treatment: Radiotherapy

Lena Specht MD DMSc
Professor of Oncology, University of Copenhagen, Denmark
Chief Oncologist, Depts. of Oncology and Haematology, Rigshospitalet, Copenhagen
Vice-chairman, International Lymphoma Radiation Oncology Group

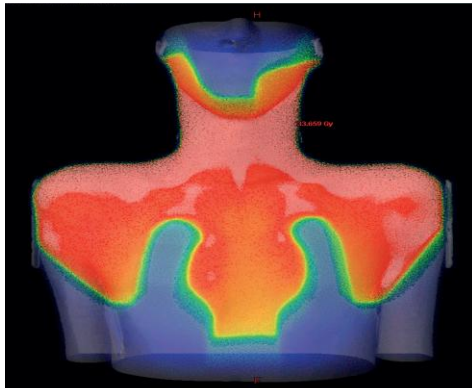
Facts about radiotherapy in lymphomas

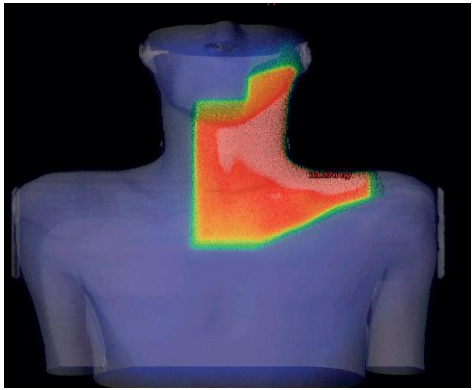
- Most lymphoma types are highly radiosensitive
- Radiotherapy was the first modality to cure lymphomas
- Radiotherapy has serious long-term sequelae
- Modern highly conformal limited and fairly low dose radiotherapy has markedly decreased these risks

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

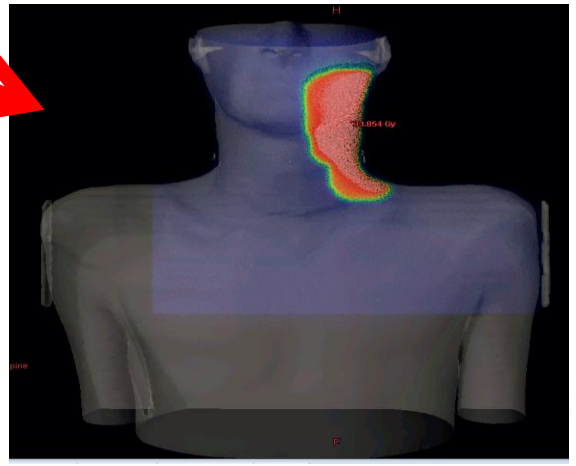
Mantle field (EFRT) or involved field (IFRT)





Based on:
- 2 D planning
- Regions
- Bony landmarks defining fields
- ”Fixed” margins

Involved site (ISRT) or involved node (INRT)



Based on:
- 3 D planning
- Actual lymphoma involvement
- Contouring of volumes (GTV, CTV, PTV)
- Margins (GTV CTV) based on clinical judgement and (CTV PTV) based on internal and setup uncertainties

Target volume for radiation therapy depends on lymphoma type and stage

- Aggressive lymphomas
  - Effective chemotherapy deals with microscopic disease (true for B-cell lymphomas, less so for T-cell lymphomas)
  - Target in early stage disease is only the tissue volume which initially contained macroscopic lymphoma
  - Target in advanced disease is only residual disease, or intially bulky or extranodal disease
- Indolent lymphomas
  - Incurable with chemotherapy only
  - In early stage disease RT is the primary treatment. Target is the macroscopic lymphoma and adjacent nodes in that site with a generous margin
  - In advanced disease RT is palliative. Target is localized symptomatic disease

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Extranodal lymphomas

Aggressive lymphomas

- Same principles as for nodal lymphomas
- In many organs (e.g., stomach, salivary glands, thyroid gland, CNS) lymphoma is multifocal. Hence, the whole organ is treated even if apparently only partially involved
- Even with modern imaging it may be difficult to accurately define the exact extent of disease in many extranodal sites. Hence, the whole organ is treated even if apparently only partially involved

Indolent lymphomas

- Same principles as for nodal lymphomas
- Whole organ is usually treated even if apparently only partially involved (for the same reasons as for aggressive lymphomas)
- Uninvolved nodes are not routinely included in the CTV. First echelon nodes of uncertain status close to the primary organ may be included

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Modern radiotherapy guidelines developed by

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

- Previous wide field and involved field replaced by limited volumes based solely on detectable involvement at presentation
- ICRU concepts of GTV, CTV, ITV, and PTV are used
- New concept, Involved Site RadioTherapy (ISRT), defines CTV on this basis
- Previous doses were higher that necessary, replaced by lower doses in most lymphoma types

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP
ESTRO School

Gross tumor volume (GTV) (ICRU 83)

- Gross demonstrable extent and location of the tumor (lymphoma)
- Original (before any treatment) lymphoma: pre-chemo GTV
  - Seen on CT: pre-chemo GTV(CT)
  - Seen on FDG-PET: pre-chemo GTV(PET)
- Residual (after systemic treatment) lymphoma: post-chemo GTV
  - Seen on CT: post-chemo GTV(CT)
  - Seen on FDG-PET: postchemo GTV(PET)

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Clinical target volume (CTV) (ICRU 83)

- Volume of tissue that contains a demonstrable GTV and/or subclinical malignant disease with a certain probability of occurrence considered relevant for therapy
- Encompasses the original (before any treatment) lymphoma (pre-chemo GTV), modified to account for anatomic changes if treated with chemotherapy up front
- Normal structures (e.g., lungs, kidneys, muscles) that were clearly uninvolved should be excluded
- Residual lymphoma (post-chemo GTV) is always part of the CTV

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Internal target volume (ITV) (ICRU 83)

- Defined in ICRU 62, optional in ICRU 83
- CTV + margin for uncertainties in size, shape, and position of the CTV
- Mostly relevant when the target is moving (chest and upper abdomen)
- Margins may be obtained from 4-D CT, fluoroscopy or from expert clinician
- Margins should be added quadratically: $\sigma' = \sqrt{(\sigma^2_m + \sigma^2_s)}$

Equation for right-angled triangle

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Planning target volume (PTV) (ICRU 83)

- Accounts for set-up uncertainties in patient position and beam alignment during planning and through all treatment sessions
- Function of immobilization device, body site, and patient cooperation
- Geometrical concept introduced to ensure that CTV and/or ITV are properly covered
- Applied by clinician or treatment planner

ISRT scenarios

- Optimal pre-chemo imaging of all the initially involved lymphomas is available and image fusion with the planning CT-scan is possible:
  - INRT
- Pre-chemo imaging (CT, PET, or MR) of all the initially involved lymphomas is available, but image fusion with the planning CT-scan is not possible:
  - Contour with pre-chemo images as a visual aid, allowing for uncertainties of the contouring and differences in positioning
- Pre-chemo imaging not available:
  - Gather as much information as possible from the pre-chemo physical examination, location of scar tissue, patient's and family's recollections, making generous allowance for the many uncertainties in the process

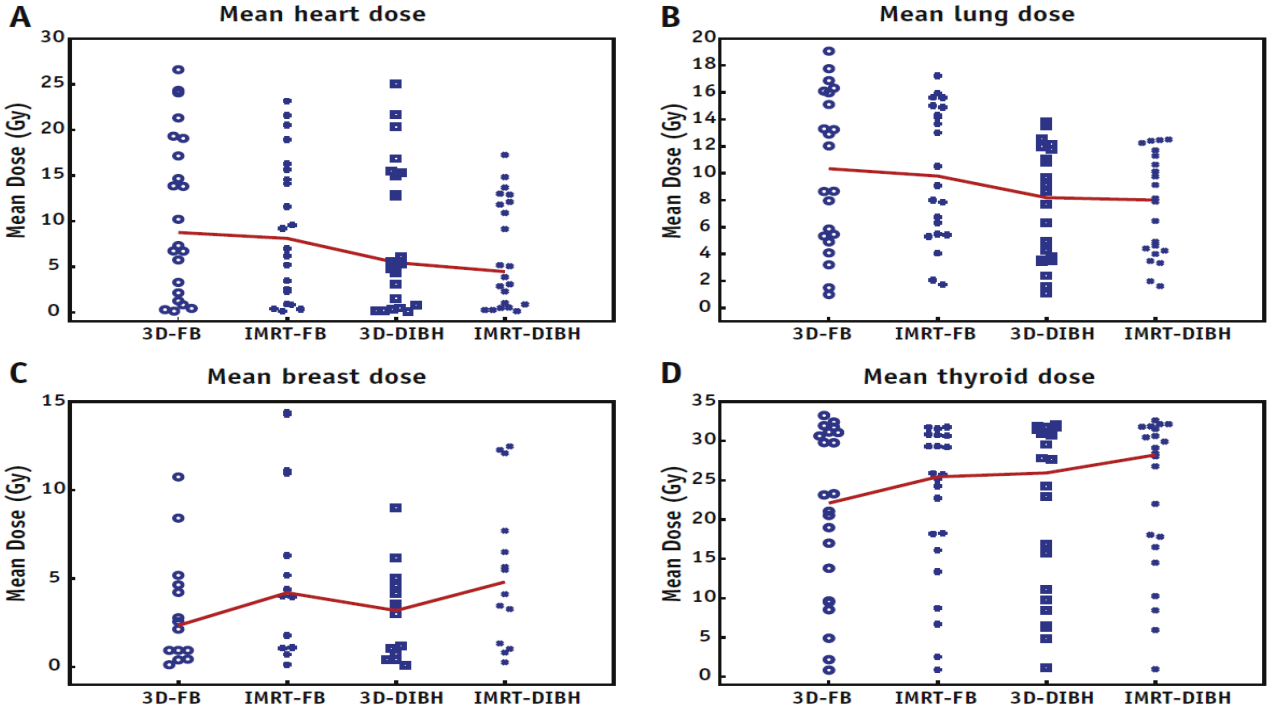
Breathing adaptation and highly conformal treatment (IMRT), what can we achieve?



Aznar et al. IJROBP 2015; 92: 169-74

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Which technique is preferable?

- Depends on the location of the target
- Dose plans for different alternatives should be compared
- Considerations of normal tissue toxicity varies between patients depending on:
  - Age
  - Gender
  - Comorbidities
  - Risk factors for other diseases
- Even low doses to normal tissues, previously considered safe, result in significant risks of morbidity and mortality in long-term survivors
- Doses to all normal structures should be kept as low as possible, but some structures are more critical than others

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Constraints, are they useful for lymphomas?

Organ at risk	Limiting dose/volume
Brain stem	If whole organ irradiated, $D_{max} < 54$ Gy to any part of the volume If partial volume irradiated, $D_{1-10\ cm^3} \leq 59$ Gy
Breast	Minimise volume inside PTV, particularly in young women ≤30 years. Mean dose ≤ 2 Gy
Cochlea	Mean dose ≤ 45 Gy
Coronary artery	Minimise volume inside treatment field and keep doses as low as possible without compromising on PTV coverage
Heart	Mean dose < 26 Gy; $D_{100} < 30$ Gy $V_{30} < 46\%$; $V_{33} < 60\%$, $V_{38} < 33\%$, $V_{42} < 20\%$
Kidney	Single kidney irradiated: V_{15} of 65–70%, Both kidneys irradiated: V_{15} of 20–25% for each kidney; mean dose < 18 Gy. Partial kidney irradiation (all constraints are for combined kidneys): mean dose < 18 Gy $V_{28} < 20\%$, $V_{23} < 30\%$, $V_{20} < 32\%$, $V_{12} < 55\%$. If mean dose to one kidney >18 Gy, V_6 for remaining kidney <30%
Lens	Maximum dose of 6 Gy to any part of the volume unless compromising PTV coverage
Liver	Mean dose < 32 Gy; V_{40} of 30–35%; D_{100} of 25 Gy, D_{66} of 28 Gy, D_{33} of 38 Gy
Lung (whole)	$V_{20} \leq 30\%$, Mean lung dose (MLD) ≤ 20 Gy
Oesophagus	Mean dose < 34 Gy, $V_{35} < 50\%$
Optic chiasm	$D_{max} < 55$ Gy to any part of the volume
Optic nerve	$D_{max} < 55$ Gy to any part of the volume
Ovary	D_{max} <10 Gy to any part of the volume outside PTV. If inside PTV discuss individual case with clinician
Parotid	Bilateral irradiation: mean dose < 25 Gy. Unilateral irradiation: mean dose < 20 Gy to the contralateral parotid
Small bowel	For individual loops $V_{15} < 120\ cm^3$ For whole peritoneal cavity $V_{45} < 195\ cm^3$
Spinal cord	$D_{max} \leq 50$ Gy to any part of the volume
Stomach	$D_{100} < 45$ Gy
Testis	Maximum dose of 2 Gy to any part of the volume
Thyroid	$D_{100} < 45$ Gy

Current approaches and emerging therapies in the treatment of malignant lymphoma

Andreas Engert, MD

Chairman, German Hodgkin Study Group
University Hospital of Cologne

Chemotherapy of malignant lymphoma

- History of and principles of chemotherapy
- Hodgkin lymphoma
- Diffuse large B-cell lymphoma (DLBCL)
- Follicular lymphoma
- Summary

Mechlorethamin

The first cytostatic drug in lymphoma

Name	**Mechlorethamin**	**Strukturformel:**
Other names	**N,N-Bis(2-chlorethyl)-N-methylamin** **Chlormethin** **Stickstofflost** **N-Lost** **HN2**	
Mechlorethamin (Stickstoff-Lost) is an alkylating agent, and is mainly used in the chemotherapy of Hodgkin lymphoma (trade name *Mustargen*®, USA, CH)

Mustargen and the history of alkylating agents

- **Mustargen as antitumor agent evolved from observed effects of mustard gas in ww1**
- **Depression of the hematopoietic system was observed in survivors**
- **Nitrogen mustard is an alkylating agent**
- **First non-hormonal chemical demonstrating clear clinical antitumor activity**
- **Studies published in 1946 demonstrated regression especially of lymphomas**
- **Nitrogen mustard (mechlorethamine, mustargen) and other less toxic and more clinically effective derivatives were developed**

Colvin OM. History of the alkylating agents; 19(3):363-371.
Cancer Principley & Practice of Oncology, de Vita V, et al (eds), 2001

MOPP

Combination chemotherapy

(M)ustargen (also known as mechlorethamine, mustine, or nitrogen mustard)
(O)ncovin (also known as Vincristine or VCR)
(P)rocarbazine (also known as Matulane or Natulan)
(P)rednisone (also known as Deltasone or Orasone)

Drug	Dose	Mode	Days
(M)ustargen	6 mg/m^2	iv bolus	1 + 8
(O)ncovin	1.4 mg/m^2 (max 2)	iv bolus	1 + 8
(P)rocarbazine	100 mg/m^2	po qd	1 - 14
(P)rednisone	40 mg/m^2	po qd	1 - 14

MOPP

Major Side effects

Alopecia (hair loss)

Skin sensitivity

Nausea, vomiting

Chills, constipation

Sterility (dose and age dependent)

Second cancer

https://en.wikipedia.org/wiki/MOPP

COPP

Combination chemotherapy

Drug	Dose	Mode	Days
(C)yclophosphamide	600 mg/m^2	iv infusion	1 + 8
(O)ncovin	1.4 mg/m^2 (max. 2 mg)	iv bolus	1 + 8
(P)rocarbazine	100 mg/m^2	PO qd	1 - 10
(P)rednisone	40 mg/m^2	PO qd	1 - 14

Major side effects of COPP

Myelosuppression

Hair loss

Nausea and vomiting

Infection

Fatigue

Bleeding

Peripheral neuropathy

Gonadal toxicity

Infertility

ABVD

Combination chemotherapy

(A)driamycin (also known as doxorubicin/(H)ydroxydaunorubicin, designated as H in CHOP)
(B)leomycin
(V)inblastine
(D)acarbazine (similar to (P)rocarbazine, designated as P in MOPP and in COPP)

Drug	Dose	Mode	Days
(A)driamycin	**25 mg/m²**	**iv bolus**	**1 + 15**
(B)leomycin	**10 IU/m²**	**iv bolus**	**1 + 15**
(V)inblastine	**6 mg/m²**	**iv bolus**	**1 + 15**
(D)acarbazine	**375 mg/m²**	**iv infusion**	**1 + 15**

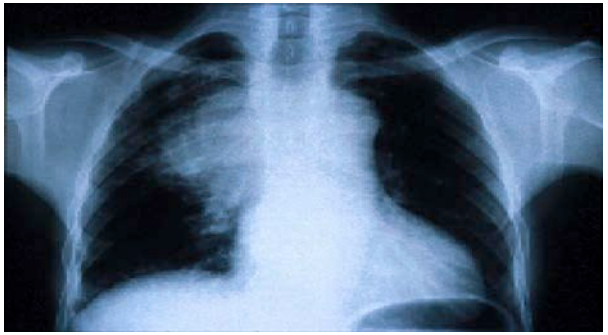
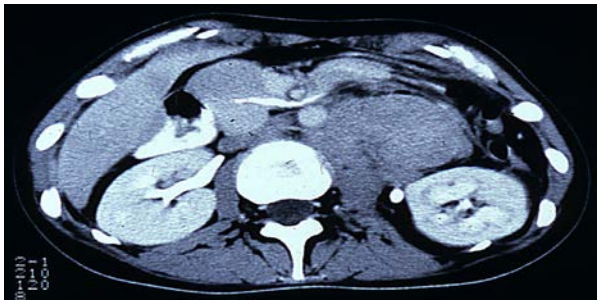
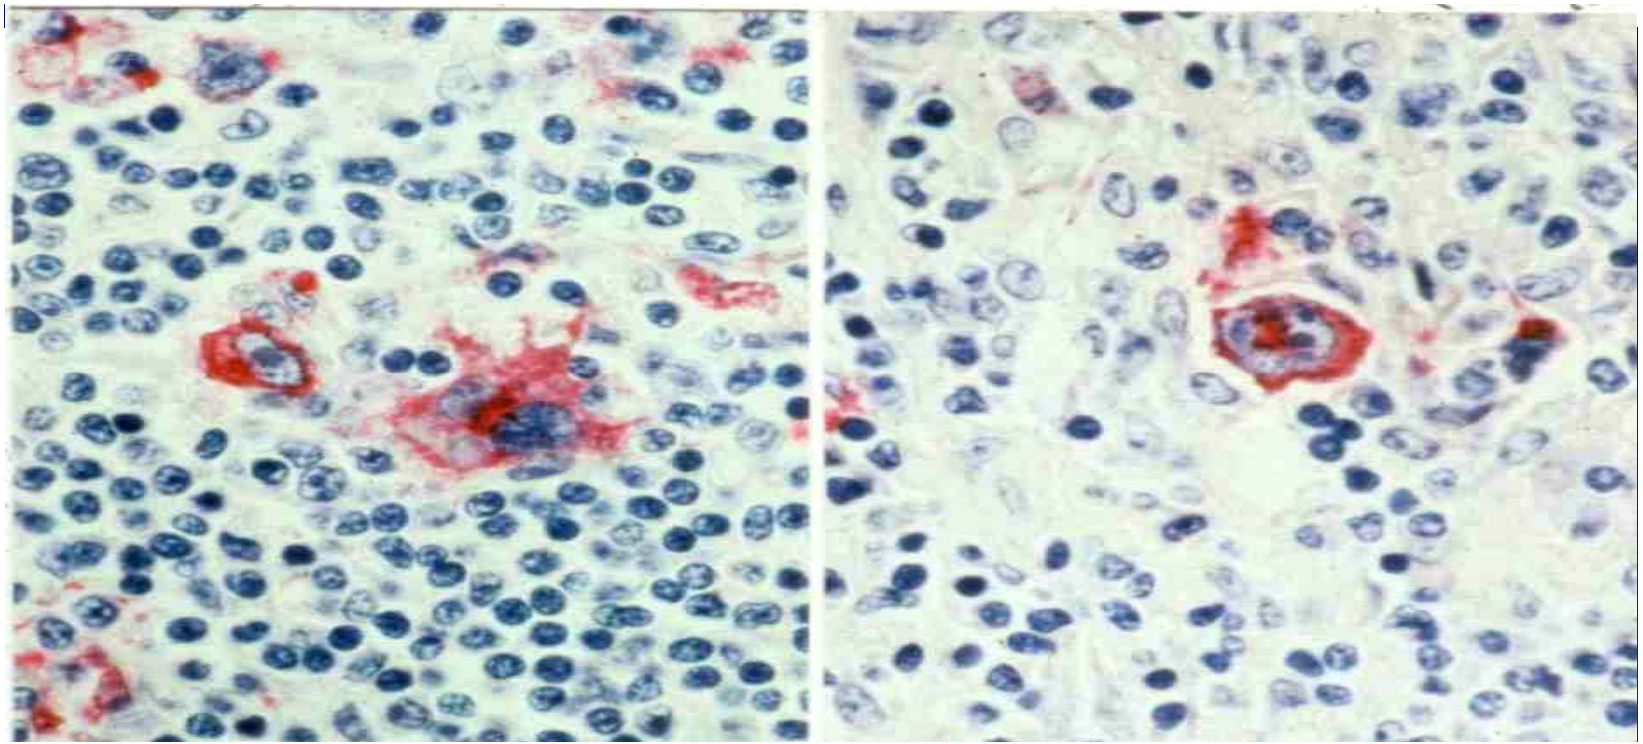
- Follicular lymphoma
- Summary

Hodgkin Lymphoma
Clinical Presentation





Hodgkin Lymphoma
Immunohistology



WHO Classification for HL (2001)

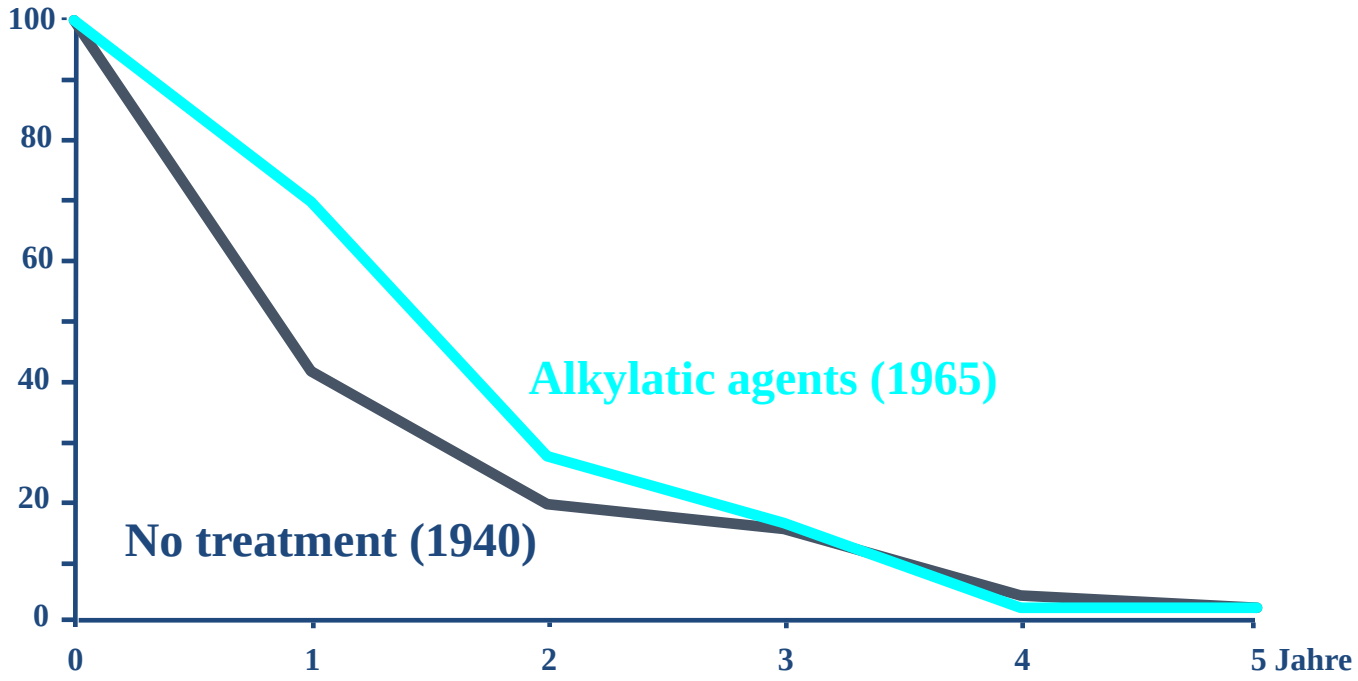
Classical HL (cHL)

- **Lymphocyte-rich classical HL (5%)**
- **Nodular Sclerosis (60-80%)**
- **Mixed Cellularity (25-30%)**
- **Lymphocyte Depletion (1%)**

Nodular Lymphocyte predominant HL (5%)

Hodgkin Lymphoma

Historical prognosis in advanced stages

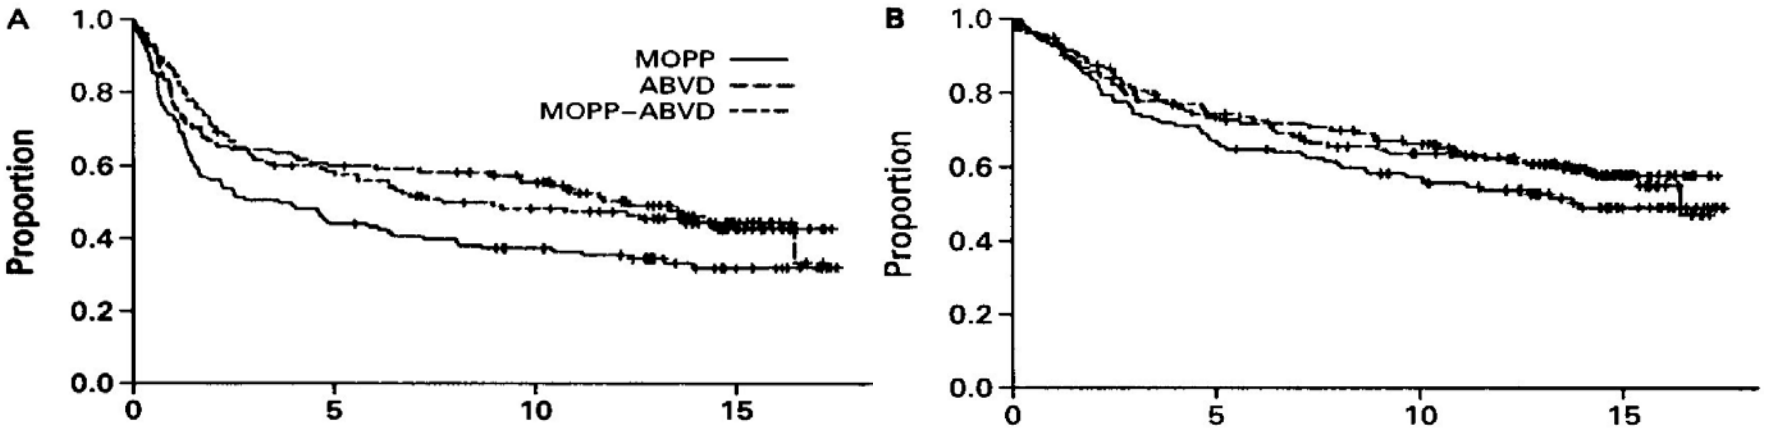


HL treated with MOPP and ABVD

Patients in advanced stages

FFTF

OS

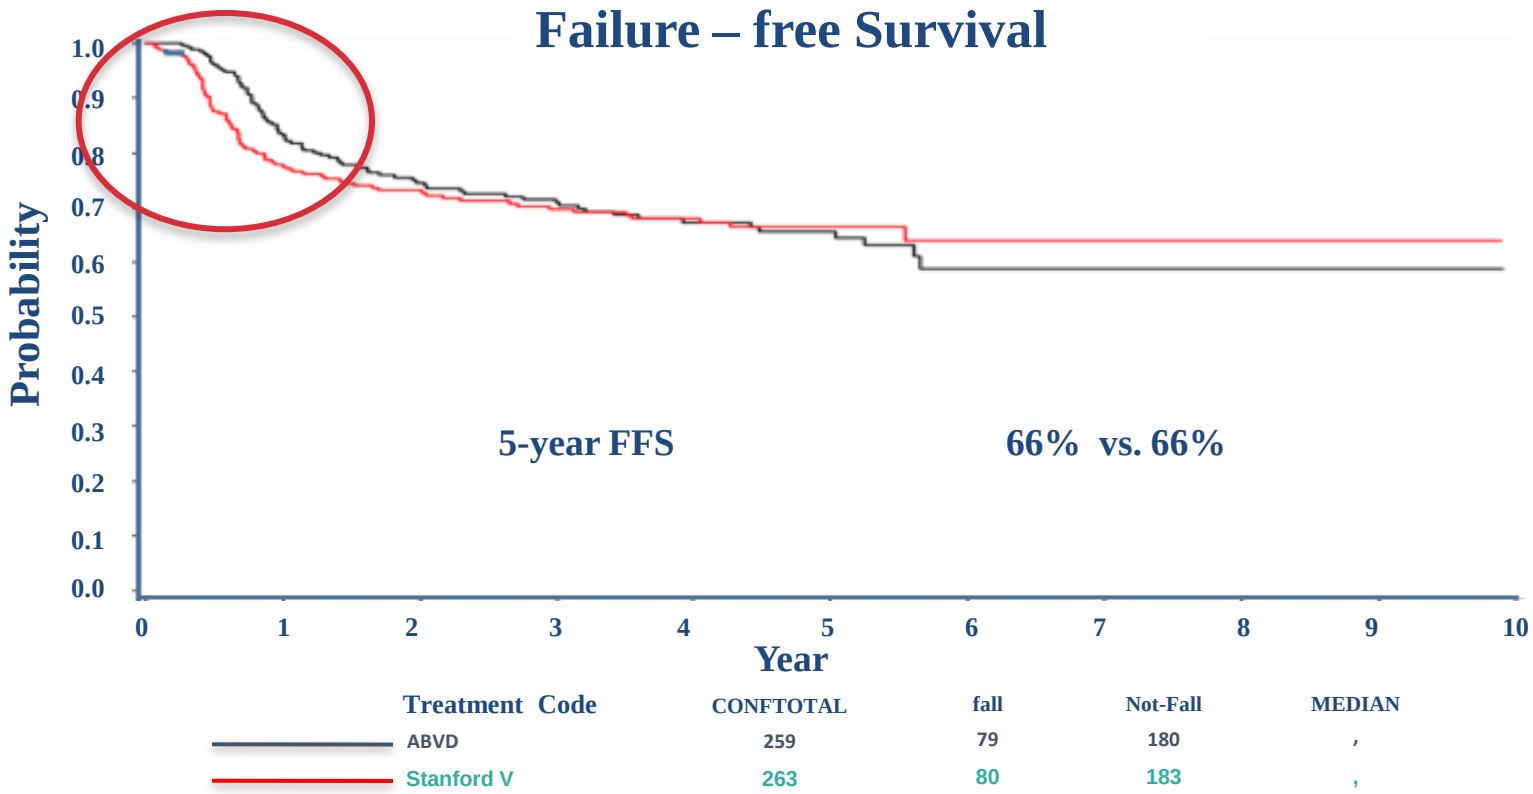


Years after study entry

Canellos G et al NEJM 2002

US Intergroup Trial E2496

ABVD vs Stanford



Gordon et al; JCO 2013

What about ABVD needs improving?

- **Bleomycin lung toxicity with ABVD**
- **Efficacy of ABVD is decreased in certain subgroups**
  - **In patients with stage III/IV disease, the 5-year FFS is about 65%**
  - **In patients >60 years, the 5-year FFS is poor**
  - **In patients with IPS 3-7, the 5-year FFS is about 65%**
- **Long-term tumour control of 70% not good enough**

Improve efficacy!

BEACOPP

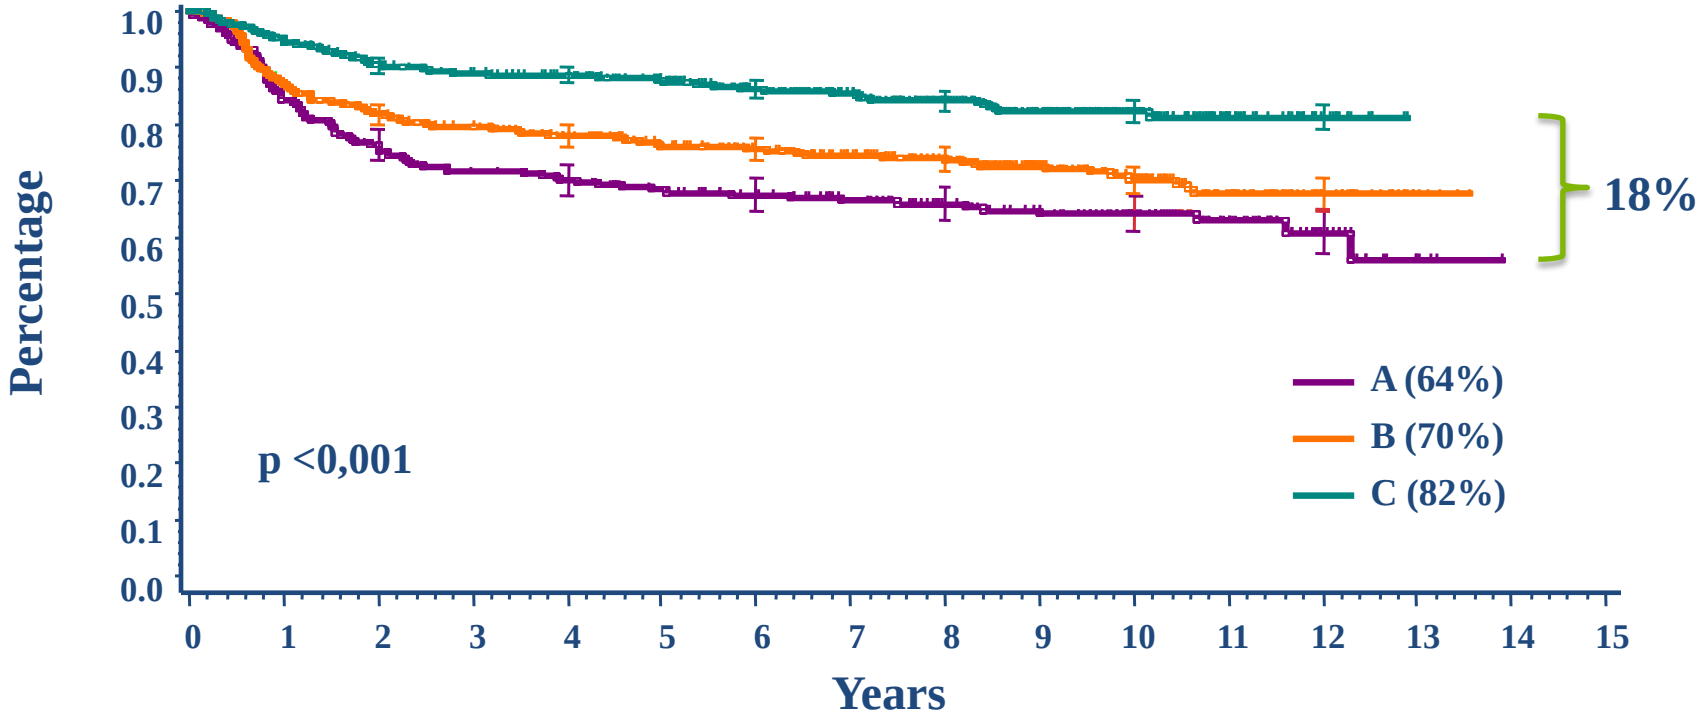
Baseline (base) and escalated (esc)

Drug	base[2]	esc[2]	Route	Schedule
Bleomycin	10	10	iv	8
Etoposide	100	200	iv	1-3
Adriamycin	25	35	iv	1
Cyclophosphamide	650	1250	iv	1
Vincristine	1.4[1]	1.4[1]	iv	8
Procarbazine	100	100	po	1-7
Prednison	40	40	po	1-14
G-CSF	-	+	sc	8-14

[1]max. 2,0mg
[2]mg/m^2

GHSG HD9 trial

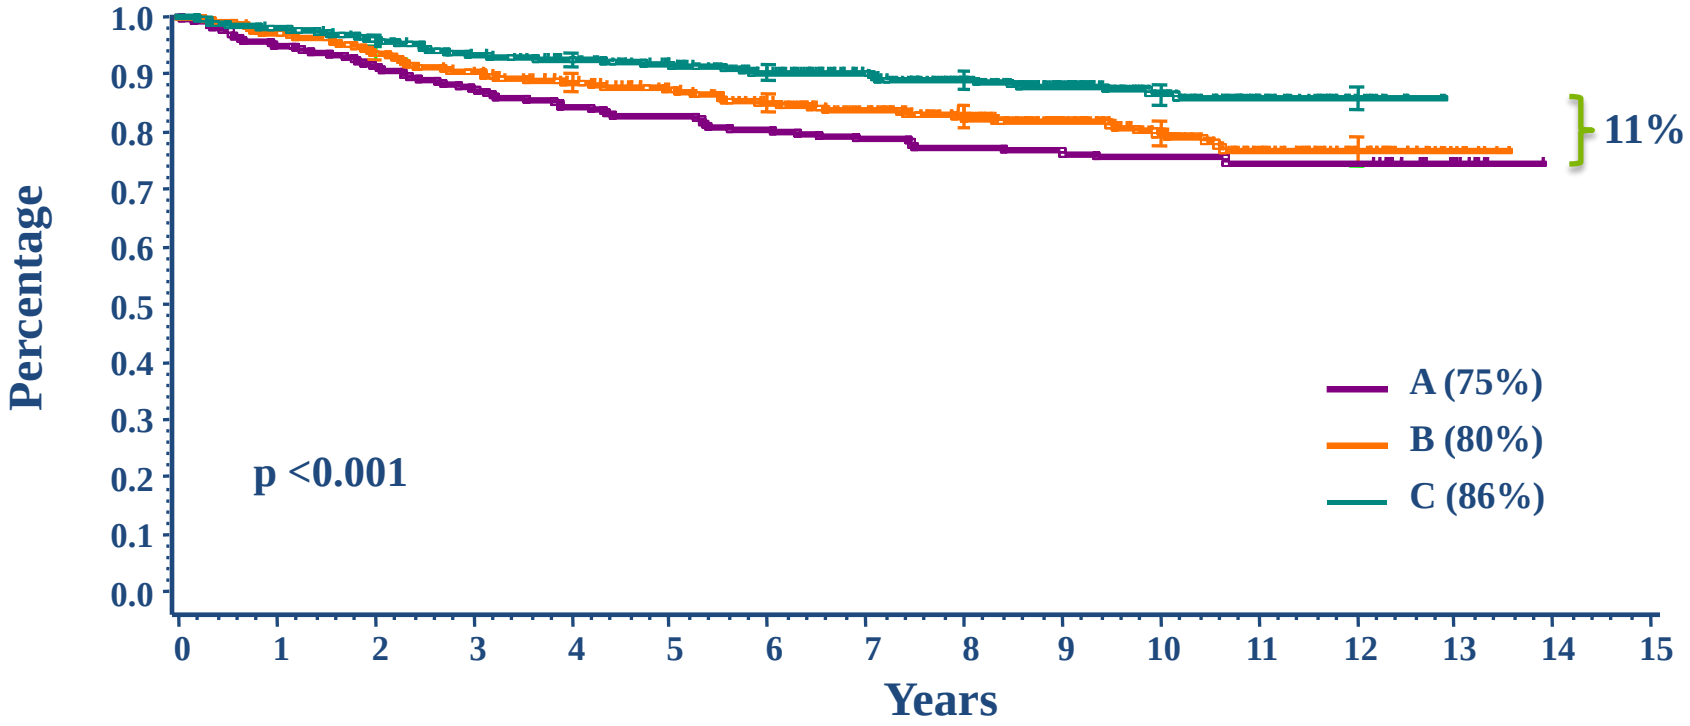
FFTF by treatment arm



Engert A et al, JCO 2009

GHSG HD9 trial

OS by treatment arm



Engert et al; JCO 2009

GHSG HD9 Trial

Causes of death at 10 years (% of all pts)

	C/ABVD n=261	BEAbase n=469	BEAesc n=466
HL	11.5	8.1	2.8
Acute tox. (first-line)	1.9	1.5	1.7
Acute tox. (salvage)	1.9	1.5	0.6
Second malignancy	3.1	3.6	3.2
Cardio-respiratory	1.2	0.9	0.9
Pulmonary	0.4	0.4	0.2
Other/unknown	3.8	3.0	2.1
All deaths	25	20	14

Engert et al; JCO 2009

How can we improve BEACOPP$_{escalated}$?

Early mortality	linked to dose-intensity and Kairos principle, not to a specific drug
sAML/MDS	cyclophosphamide, etoposide, **procarbazine**
Infertility	cyclophosphamide, **procarbazine**
Organ toxicity	**bleomycin**: lung, **vincristine**: PNP, **steroids**: infections

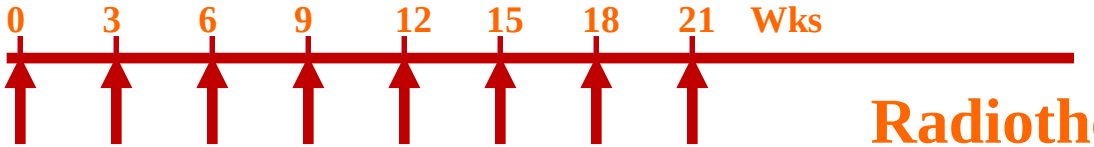
Standard Regimen for DLBCL Patients

R-CHOP

R-CHOP 21



Radiotherapy?

Aggressive NHL:
Prognostic factors - aaIPI

- Poor performance status (ECOG 2-4)
- Elevated lactate dehydrogenase (LDH)
- Stage III or IV disease

- **Risk groups:**
- 0 : low risk
- 1 : low-intermediate
- 2 : high-intermediate
- 3 : high risk

The International Non-Hodgkin's Lymphoma Prognostic Factors Project
N Engl J Med 1993; 329:987–994.

Results with R-CHOP in DLBCL

- **5-year survival according to aaIPI & age**
  - **aaIPI score = 0: >85%**
  - **Young, aaIPI score = 1: >80%**
  - **Young, aaIPI score >1: 60%**
  - **Elderly, aaIPI score >0: 50%**
  - **Very old: 30%**
- **For 30-40% of patients, R-CHOP is not satisfactory**

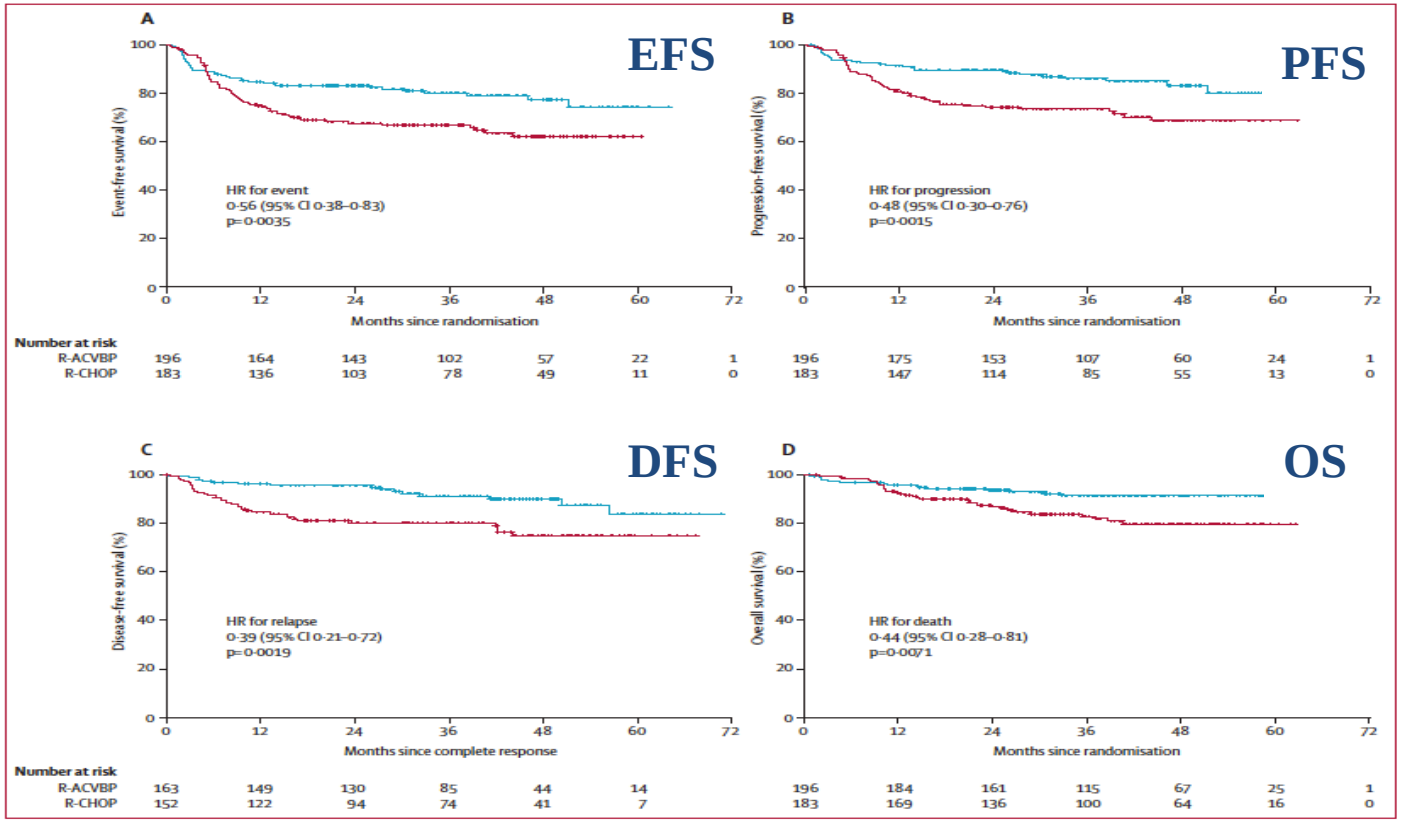
How to further improve DLBCL

- Refractory
  - Use new drugs
  - Subgroup of patients with high risk
- Relapse
  - Higher dose chemotherapy
  - Prevent relapse
- At time of relapse
  - Better salvage regimens

DLBCL: Higher dose regimen

LNH03-2B study

R-ACVBP
R-CHOP



C Rechert et al. Lancet 2011;378:1858

DLBCL: Salvage therapy

- No good regimen
  - R-DHAP, R-ICE, R-ESHAP, R-GDP
  - All identical, few CR, particularly for early relapses
- Necessity to design a New Regimen
  - With all/some new drugs
  - Plus rituximab or another antibody
  - Plus chemotherapy
- Before autologous transplant

DLBCL: Conclusions

- **Medical need: new combinations for poor risk patients**
  - **If possible to identify them**
- **Particularly for refractory/early relapse**
- **New drugs combination at time of relapse**
- **Look at cure**

Chemotherapy of malignant lymphoma

- History and principles of chemotherapy
- Hodgkin lymphoma

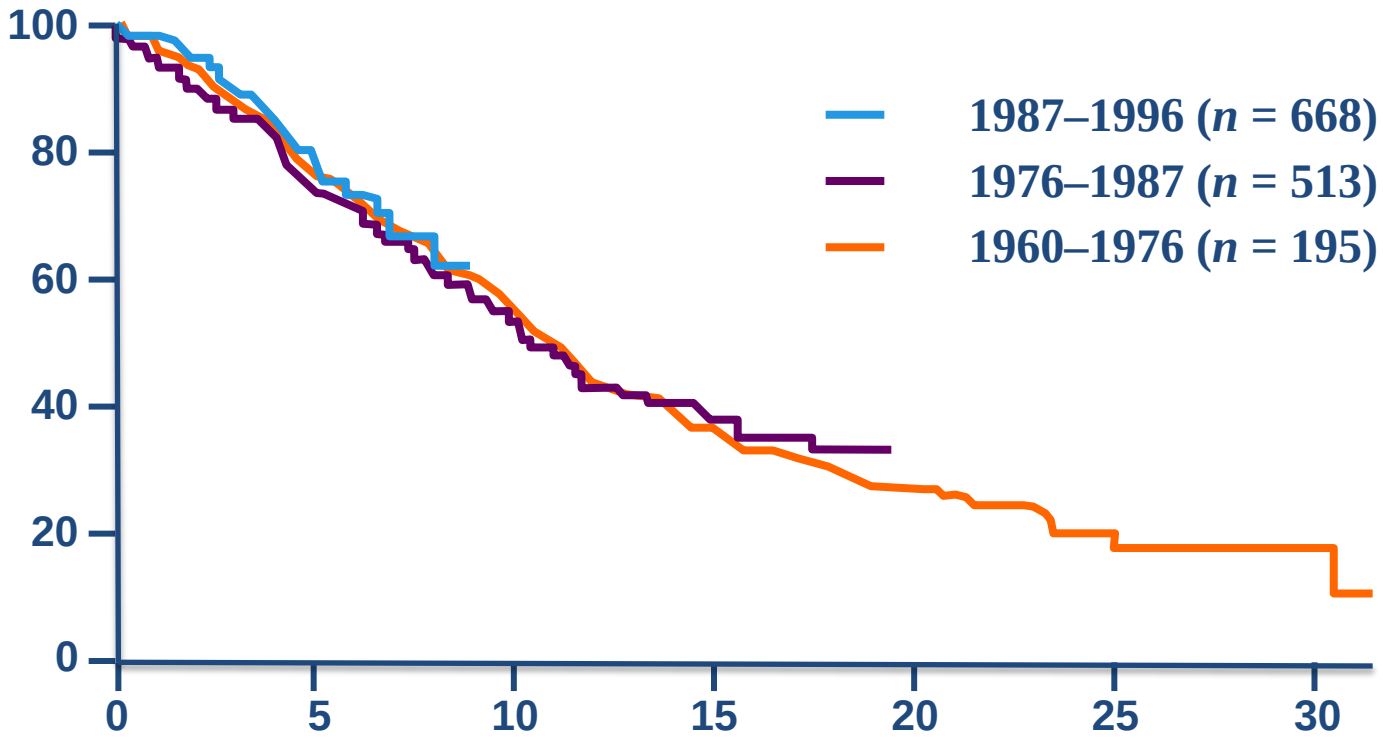
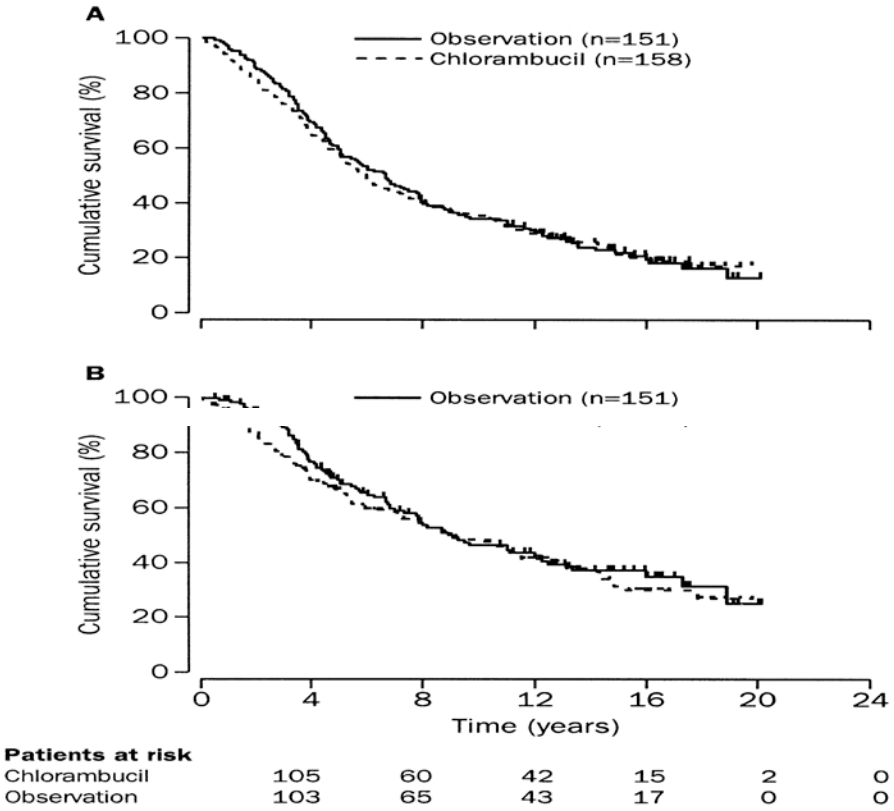
- Follicular lymphoma
- Summary

Indolent NHL – Overall Survival



Horning. *Semin Oncol*. 1993; 20(suppl 5): 75–88

FL: Watch & wait or early treatment?



Overall survival

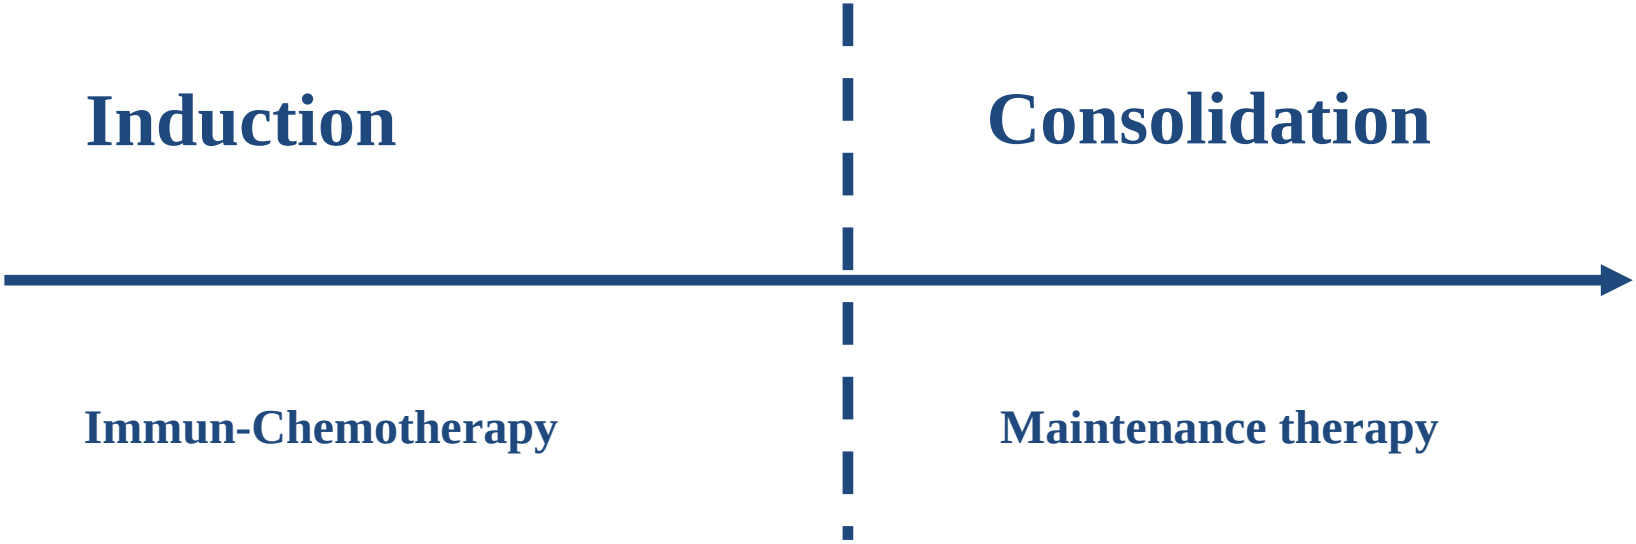
Disease-associated survival

Ardeshna KM et al. Lancet 262: 516, 2003

FL: Reasons to initiate treatment

- **B-symptoms**
- **Hematopoietic failure**
  (Hb<11g/dl, granulocytes <1.500/µl, platelets <100.000 /µl)
- **Large tumor burden**
  (3 areas >5 cm or 1 area >7.5 cm)
- **Rapid progression**
  (increase of tumor mass >50% within 6 months)
- **Complications due to disease**
  (pain, infarction of spleen, hyperviscosity syndrome, etc.)
- **No role for FLIPI, LDH, B2M, age, stage, or bone marrow involvement**

Treatment strategies in indolent lymphomas



Standard of care in pts with indolent lymphomas

- Still a role for watch & wait in asymptomatic pts
- Wait for indication of treatment
- Combined R-chemo standard; R-CHOP most often used
- No clear superiority of R-CHOP over R-CVP
- BR with longer PFS and lower toxicity
- R-chemo plus R-maintenance current best option in follicular particularly in relapsed disease
- No relevant role for high-dose chemo and ASCT
- Perspectives: Bortezomib, Lenalidomide, Obinutuzumab (GA101), Ofatumumab, Temsirolimus, Ibrutinib, Idelalisib, ABT-199

Chemotherapy of malignant lymphoma

- History and principles of chemotherapy
- Hodgkin lymphoma
- Diffuse large B-cell lymphoma (DLBCL)
- Follicular lymphoma
- Summary

Chemotherapy of malignant lymphoma

- **Development of multi-agent chemo led to cure in lymphoma patients**
- **Most frequently used today are CHOP, ABVD and BEACOPP**
- **Typical side effects include alopecia, aplasia, infection, neuropathy, fatigue and infertility**
- **Major long-term effects are 2nd neoplasia and organ failure**
- **Prognosis of pts much worse at relapse (DLBCL, HL)**
- **New less toxic drugs have become available and might improve the long-term prognosis**

ESTRO School

WWW.ESTRO.ORG/SCHOOL

Immunotherapy of malignant lymphoma

Andreas Engert, MD

Chairman, German Hodgkin Study Group
University Hospital of Cologne

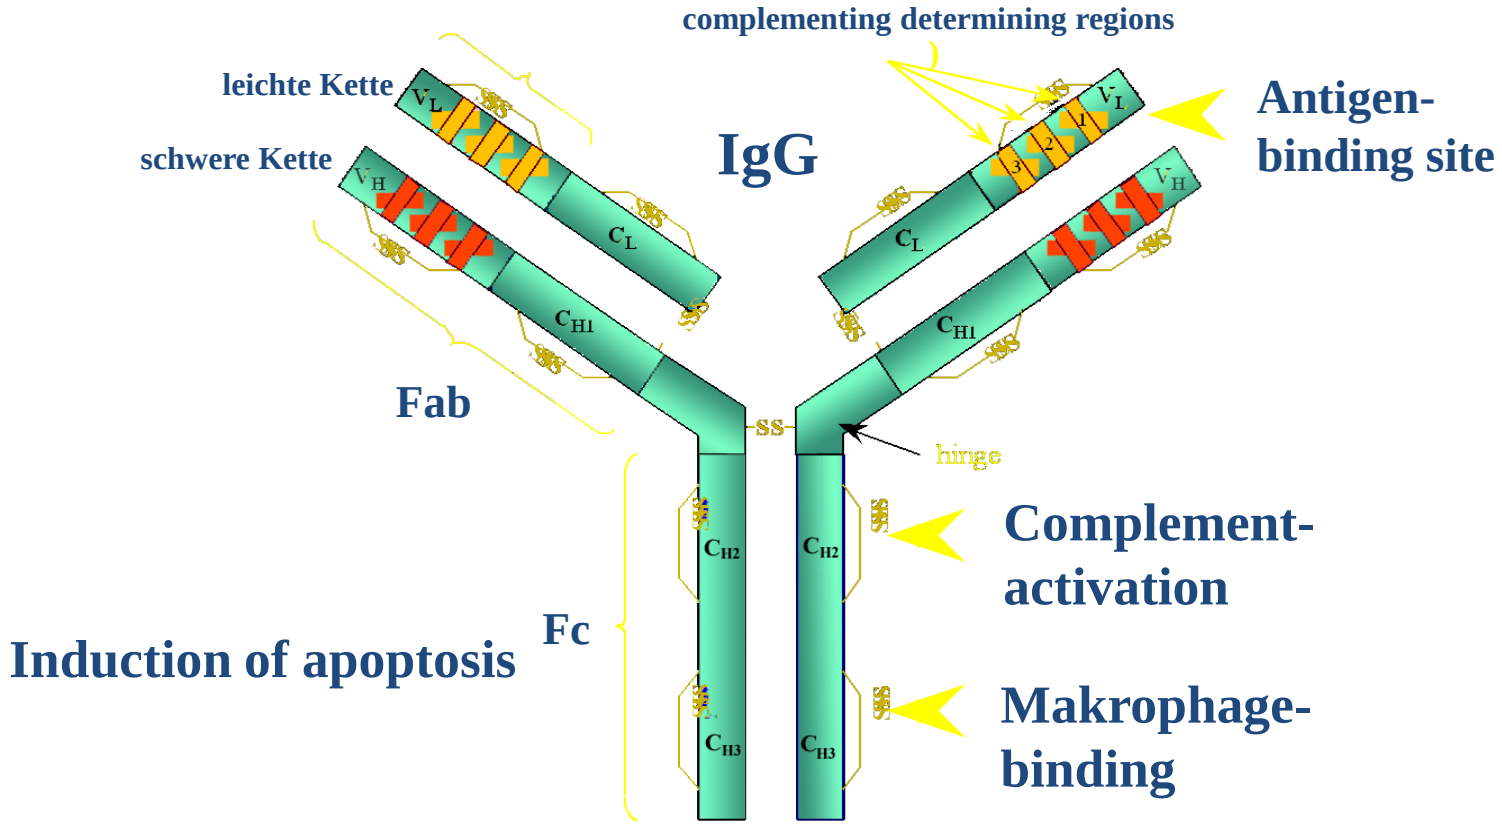
Rationale for immunotherapy of malignant lymphoma

- Long term side effects of chemo- and radiotherapy
- Poor prognosis of patients with relapse or refractory disease
- Small amount of malignant cells (Hodgkin)
- Residual dormant cells lead to relapse
- Good target antigens (CD20, CD30, others)
- Lymphoma well vascularized

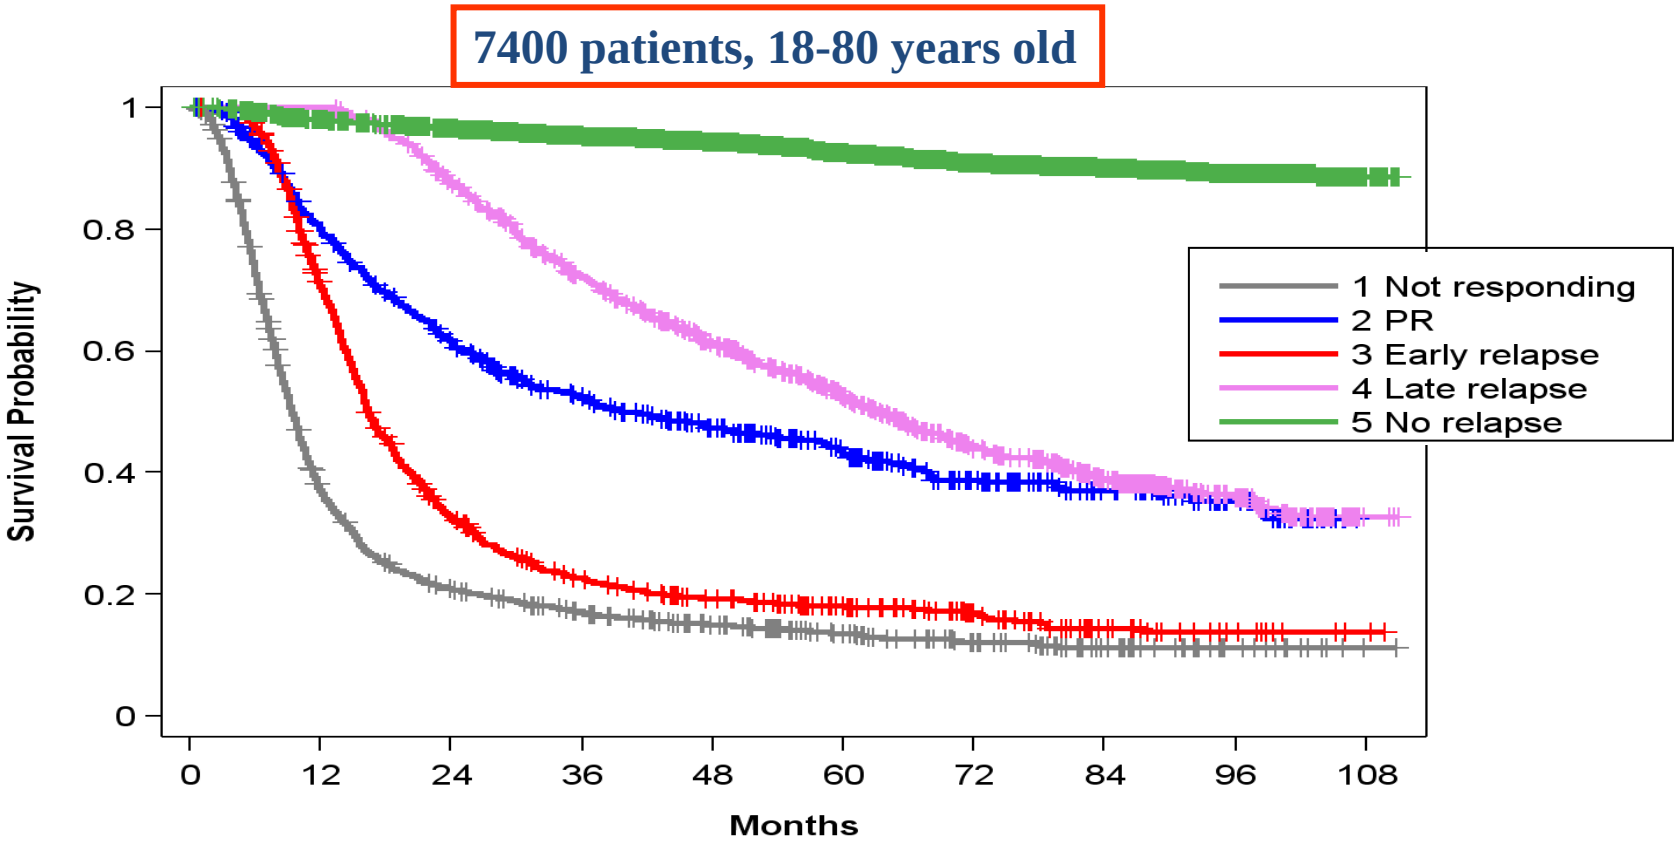
Immunotherapy of malignant lymphoma

- **Diffuse large B-cell lymphoma (DLBCL)**
- **Follicular lymphoma**
- **Hodgkin lymphoma**
- **Summary**

Structure of a monoclonal Antibody



DLBCL in Gela trails: OS



R-CHOP + X

- **RA-CHOP: stopped due to Avastin tox**
- **R2-CHOP: lenalidomide (phase II, not better)**
- **R-CHOP + bortezomib**
- **R-CHOP + enzastaurin**
- **R-CHOP + ibrutinib**
- **R-CHOP + idelalisib**
- **R-CHOP + ABT-199**

Maintenance in DLBCL

- **Rituximab**
  - **3 studies → No benefit**
- **Enzastaurin**
  - **2 studies → No benefit**
- **Lenalidomide**
  - **2 studies → Possible benefit**

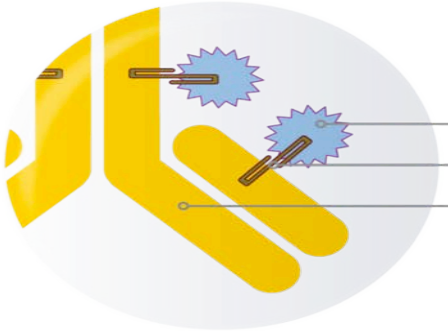
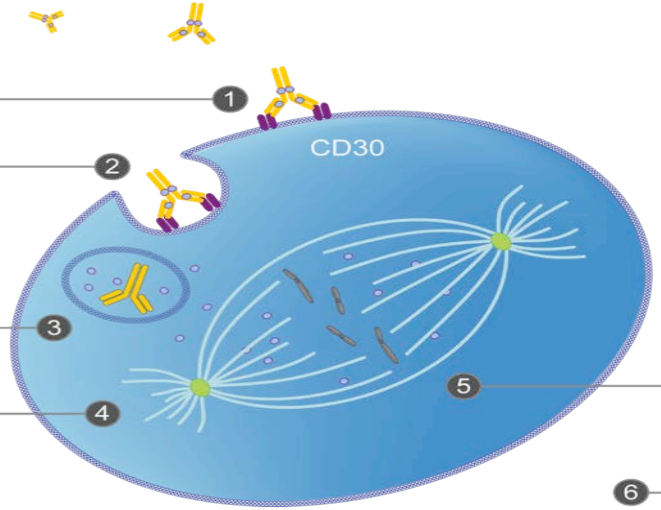
Brentuximab Vedotin (SGN-35)

Mechanism of action



Brentuximab vedotin (SGN-35) ADC

- monomethyl auristatin E (MMAE), potent antitubulin agent
- protease-cleavable linker
- anti-CD30 monoclonal antibody



1. ADC binds to CD30
2. ADC-CD30 complex traffics to lysosome
3. MMAE is released
4. MMAE disrupts Microtubule network
5. G2/M cell cycle arrest
6. Apoptosis

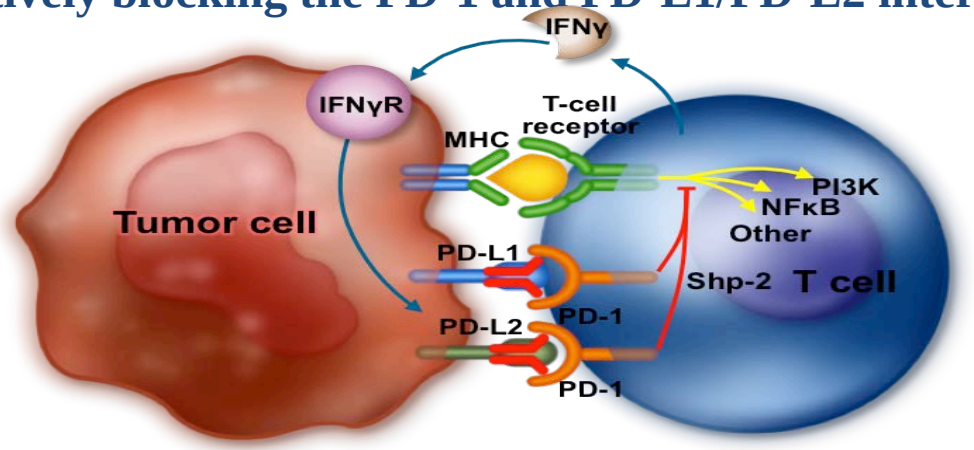
PD-1 Blockade

- PD-1 engagement by its ligands results in transient down-regulation of T-cell function (T-cell exhaustion).
- Nivolumab (BMS) and Pembrolizumab (MSD) fully human/humanized anti-PD-1 antibody selectively blocking the PD-1 and PD-L1/PD-L2 interaction.



- PD-1 blockade through monoclonal antibody therapy has single-agent activity in a range of solid tumors

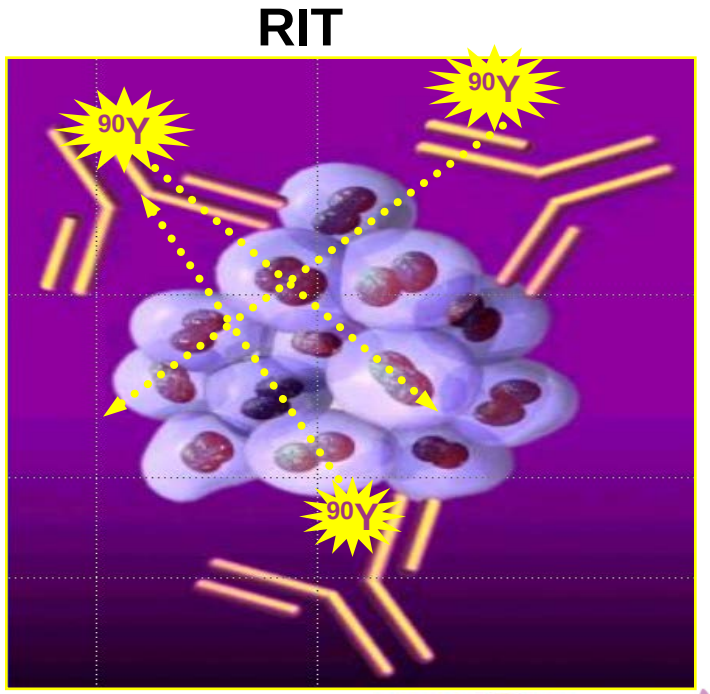
Radioimmunotherapy – a unique tool targeting radiosensitivity

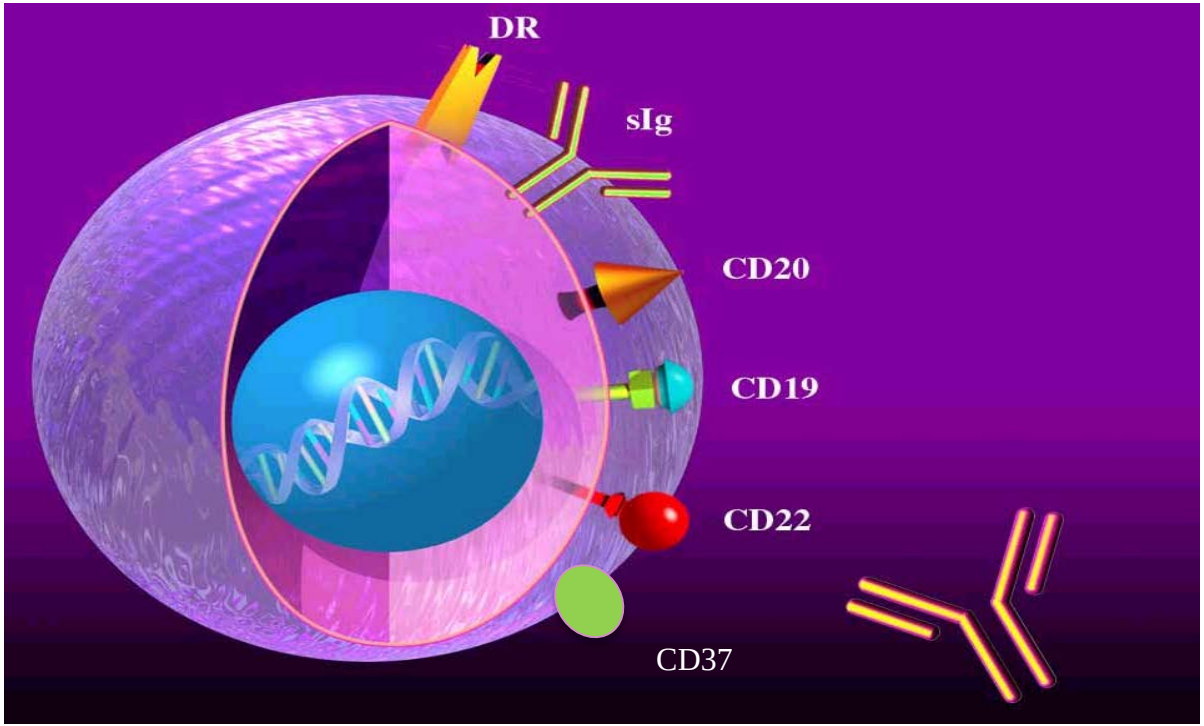
- Lymphoma cells are inherently sensitive to radiation
- Radiotherapy effective in chemotherapy-refractory patients
- Continuous delivery of low-dose radiation and antibody effector mechanisms
- Radiation also destroys tumour cells distant from targeted tumour cell



ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

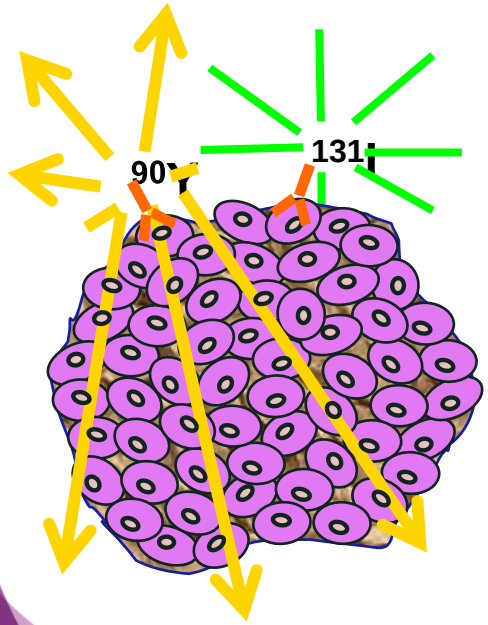
ESTRO School

B-cell lymphomas express several antigens that can be targeted



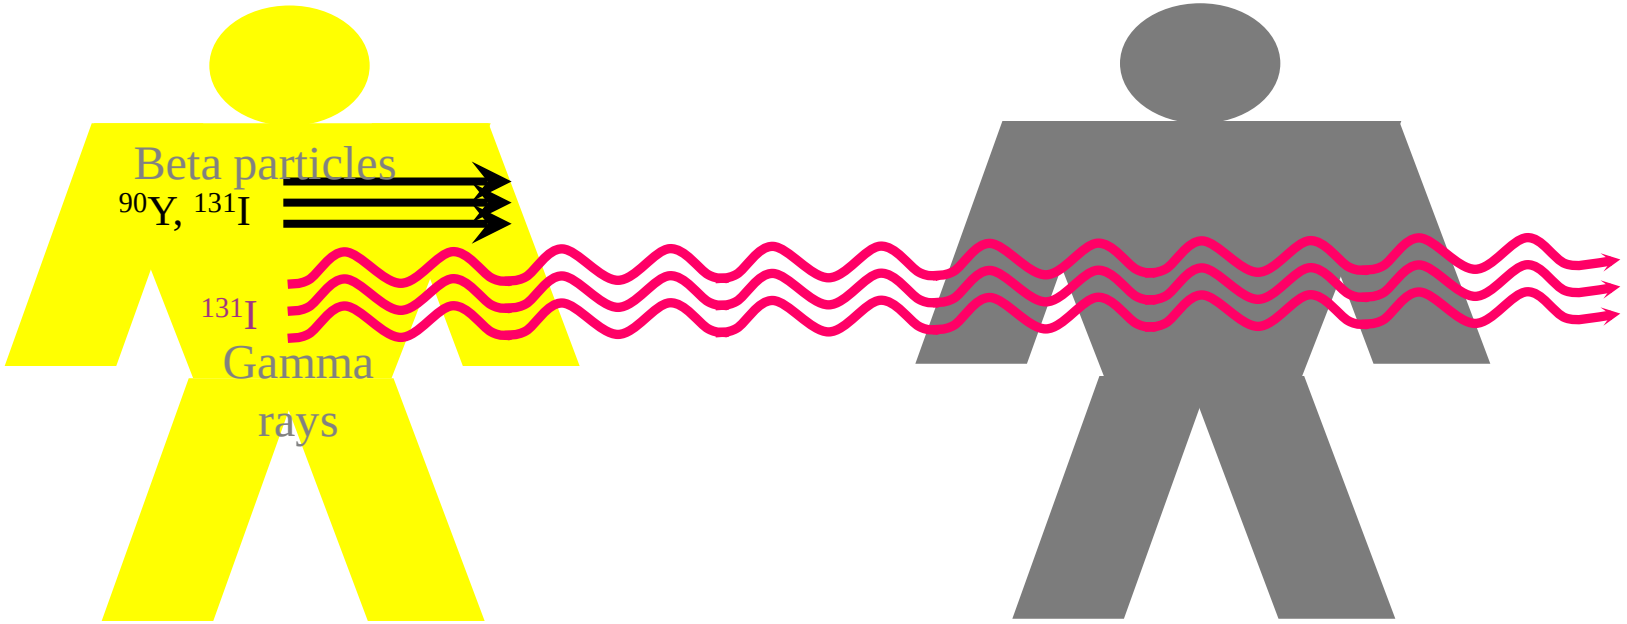
Adapted from Press, OW. *Semin Oncol* 1999; 26: 5(Suppl 14) 58–65

Choice of radioisotope



Properties	^{90}Yttrium	^{131}Iodine
Half-life	64 hours	192 hours
Energy emitter	Beta (2.3 MeV)	Gamma (0.36 MeV) Beta (0.6 MeV)
Path length	χ_{90} 5 mm	χ_{90} 0.8 mm
Urinary excretion	Minimal 7% in 7 days	Extensive/variable 46 - 90% in 2 days
Dosing	Based on weight and platelet count	Clearance based dosing using whole body dosimetry
Administration	Outpatient	Inpatient or restrictions to protect family/public

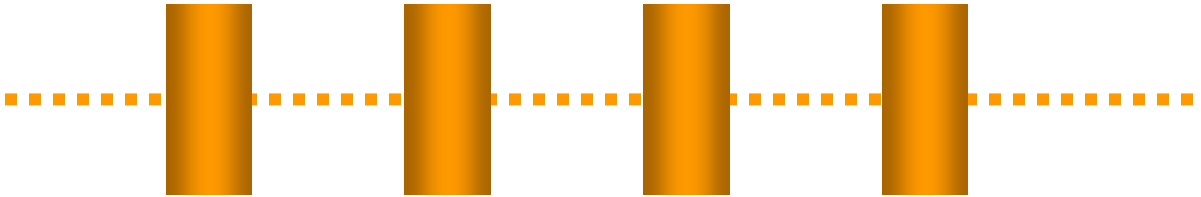
Penetration of Particulate and Electromagnetic Radiation



Radiation delivery profile of conventional radiotherapy versus targeted radiotherapy

Radioimmunotherapy delivers radiation at a lower rate, and continuous delivery may provide less opportunity for DNA repair

Fractionated external beam radiotherapy



Targeted radiotherapy

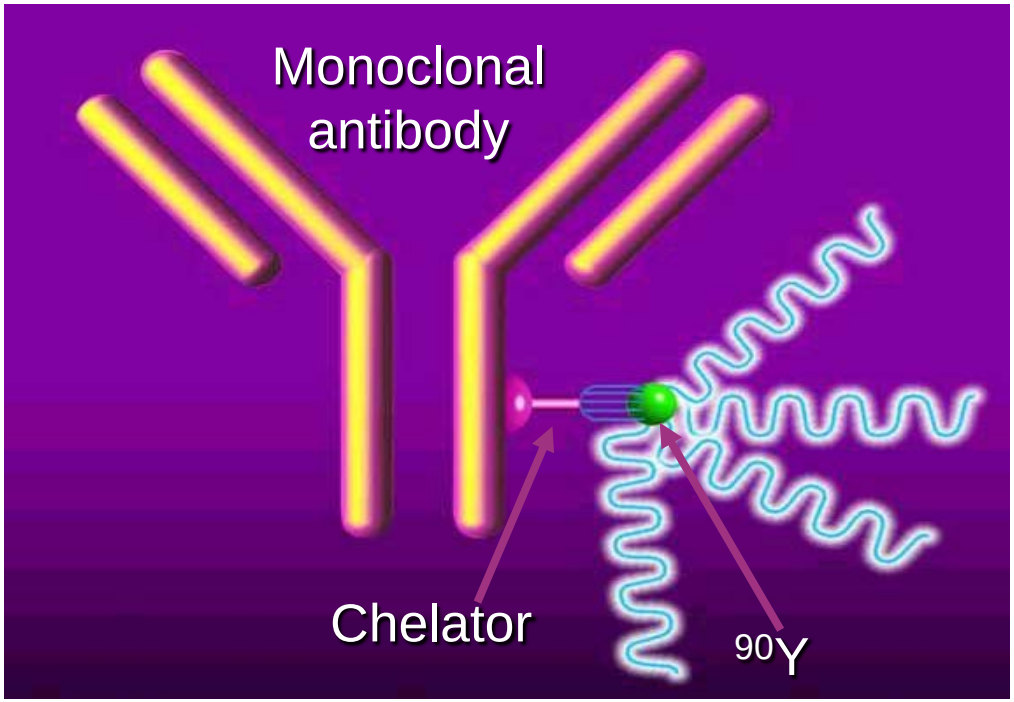
Yttrium-90 Ibritumomab tiuxetan (Zevalin™)



- Ibritumomab
  - Murine monoclonal antibody parent of Rituximab
- Tiuxetan

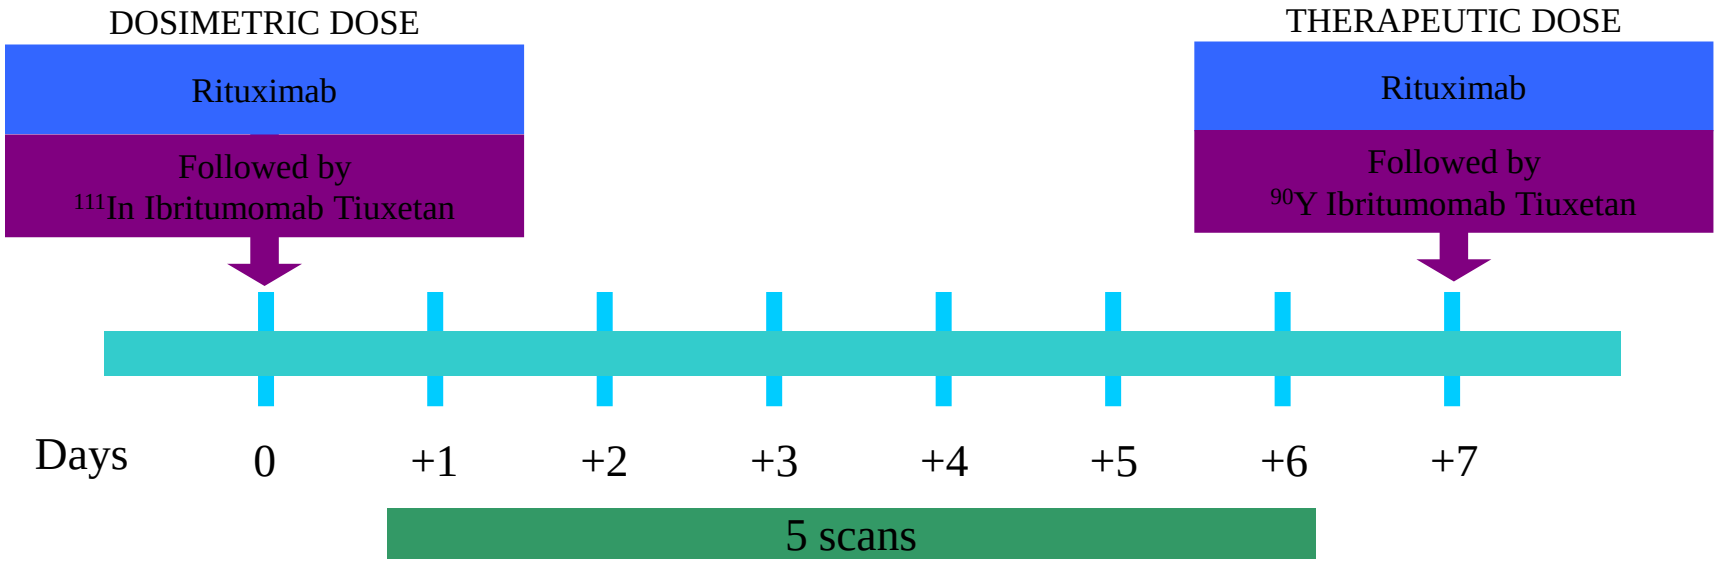
  Conjugated to antibody, forming strong urea-type bond

  Stable retention of ^{90}Y
- 90Y – Beta emitter

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

^{90}Y Ibritumomab Tiuxetan treatment is completed in 7 days



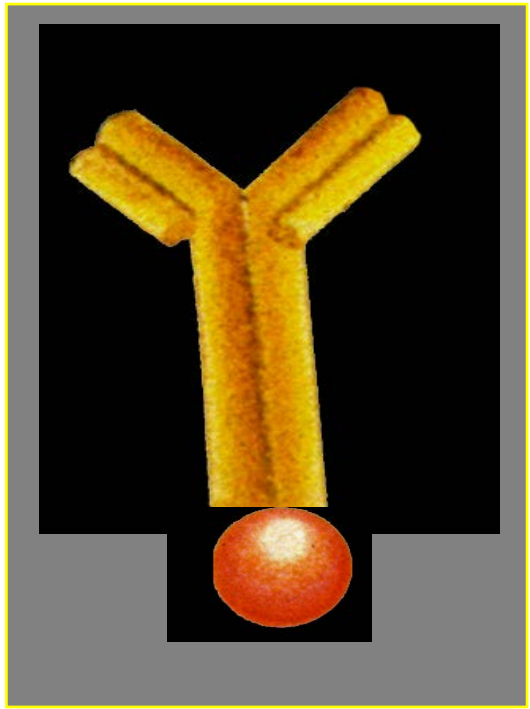
Dosimetric dose: Rituximab 250 mg/m^2; ^{111}In Ibritumomab Tiuxetan 5mCi ^{111}In, 1.6 mg Ibritumomab Tiuxetan

Therapeutic dose: Rituximab 250 mg/m^2; ^{90}Y Ibritumomab Tiuxetan 0.4mCi ^{90}Y for patients with platelet count >150,000 cells/mm^3 or 0.4 mCi/kg for a platelet count 100,000–149,000 cells/mm^3

Wiseman GA, *et al*. *Eur J Nucl Med* 2000; 27: 766–77

^{131}I Tositumomab (Anti-B1): Mechanism Of Action

- **Tositumomab**
  - Murine IgG2a anti-CD20 mAb
  - Triggers apoptosis, via unique epitope
- **Iodine-131 radioisotope**
  - Beta emission
    - Short pathlength “crossfire” effect (~1 mm)
  - Gamma emission
    - Allows individual dosimetry
    - Essential component of treatment



ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Treatment Regimen for ^{131}I Tositumomab (Licensed in USA – no longer available)

Thyroprotection: Day -1 continuing through 14 days post-therapeutic dose

Day 0

Dosimetric dose
(450 mg tositumomab,
5 mCi ^{131}I tositumomab
[35 mg])

- Unlabeled predose infused over 1 hour
- Dosimetric dose used to determine individual pharmacokinetics

→ Whole body counts x 3 →

Day 7–14

Therapeutic dose
(450 mg tositumomab,
mCi dose of
^{131}I tositumomab [35 mg] to deliver
desired cGy TBD)

- Unlabeled predose infused over 1 hour
- Administered mCi activity determined by gamma counts

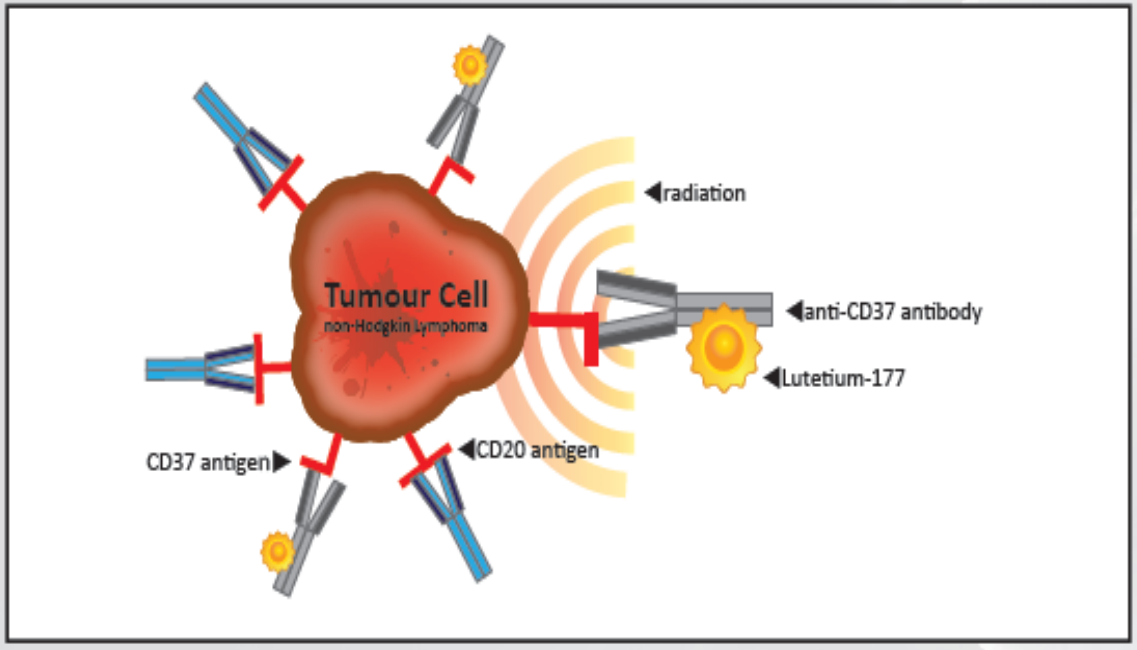
Results of a phase 1 study of ^{177}Lu-DOTA-HH1 anti body radionuclide (Betalutin) conjugate for patients with relapsed CD37+ non-Hodgkin lymphomas – Lugano 2015



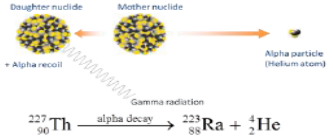
177Lu-DOTA-HH1 (Betalutin)

- Murine mAb HH1
- Chelate to chemical linker DOTA
- Beta emitting lutetium-177 (t1/2= 6.7 days)

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

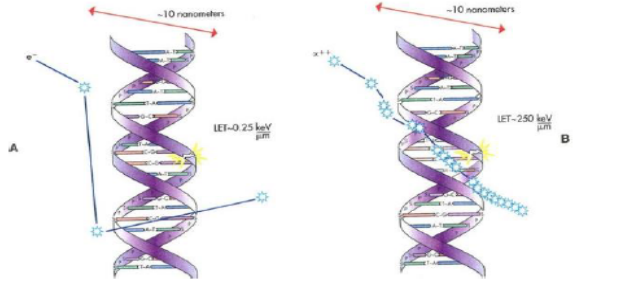
ESTRO School

Alpha: Mechanism of Action



- The alpha-particle: a high energy, heavy charged particle
  - High Linear Energy Transfer (LET) = energy deposited per unit path length
  - High Relative Biological Effectiveness (RBE) = ratio of the effectiveness of one type of ionising radiation relative to another given the same amount of absorbed energy
- Alpha-particles deposit all their energy over a very short distance (2-10 cell diameters)
  - High propensity for Double Strand Breaks (DSB) due to direct DNA damage
  - No special shielding requirements when administering the dose

Low LET radiation vs. High LET radiation



LET: Beta (~0.2 keV/µm) Alpha (>100 keV/µm)

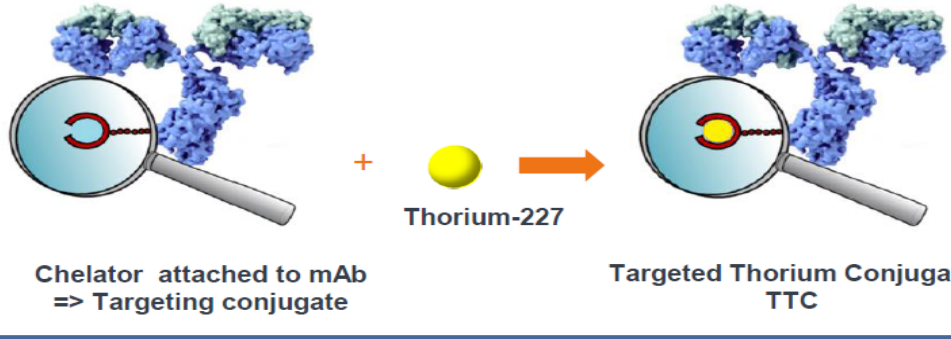
β-RIT for B-Cell Non-Hodgkins Lymphoma

- **Epratuzumab**: humanised mAb to CD22
- Clinical studies performed in NHL patients using naked mAb, beta emitters ^{131}I and ^{90}Y
  - 90Y-epratuzumab; 53% ORR (N=17) in DLBCL (3 median prior treatments), 5 of 6 at MTD (6 mCi/m^2)

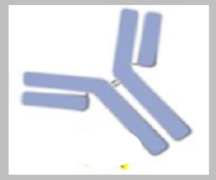
Thorium-227 anti-CD22

What Makes Thorium-227 Unique?

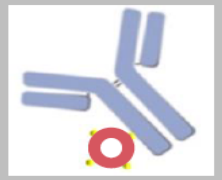
- Half-life (18.7 days) ideal for manufacture and commercial distribution
- Optimal physical half-life for tumor delivery by mAbs
- Radium-223 daughter has a 'clean' well understood clearance route
- Th(IV) forms highly stable complexes with specific chelators at ambient temp.



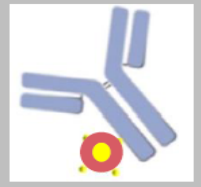
Three principal forms of mAb being injected:



mAb
20%



mAb conjugate
80%



Th-labelled mAb conjugate
<0.1%

Three key components:

- Thorium-227
- Chelator
- Targeting molecule antibody

Defining features of RIT in relapsed Follicular Lymphoma

- High response rates
- Durable remissions
  - in chemo-refractory disease
  - in rituximab-refractory disease

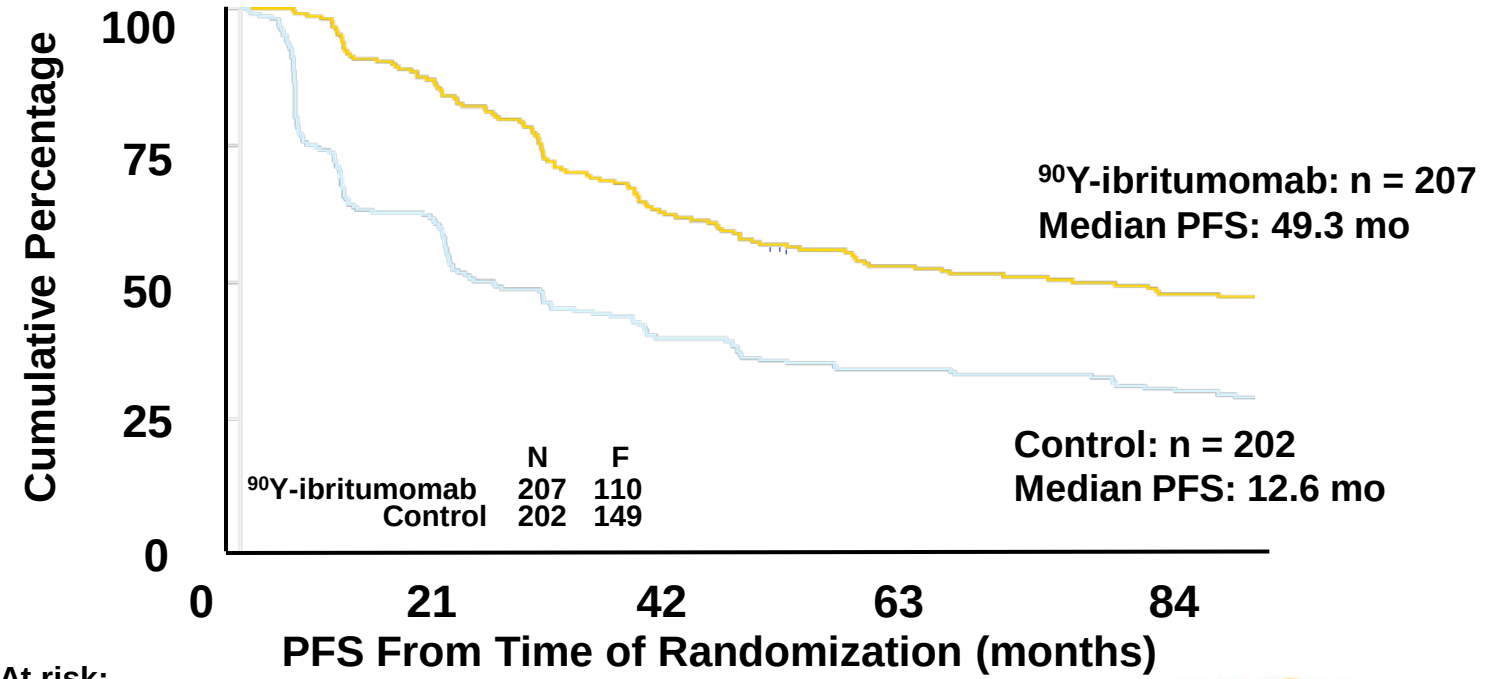
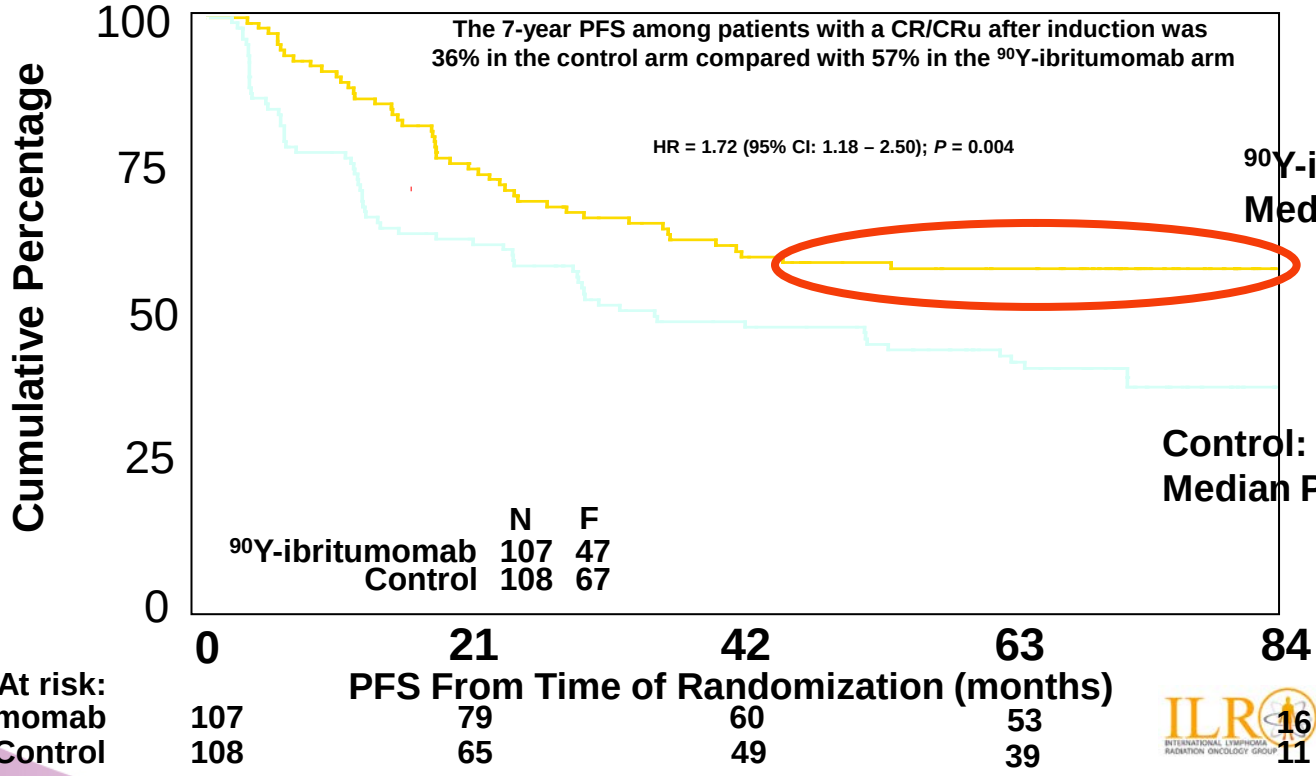
Overall PFS For Treatment Groups



90Y ibritumomab tiuxetan consolidation of first remission in advanced-stage follicular non-Hodgkin lymphoma: updated results after a median follow-up of 7.3 years from the International, Randomized, Phase III First-Line Indolent trial.

Morschhauser F, et al J Clin Oncol. 2013 ;31(16):1977-83.

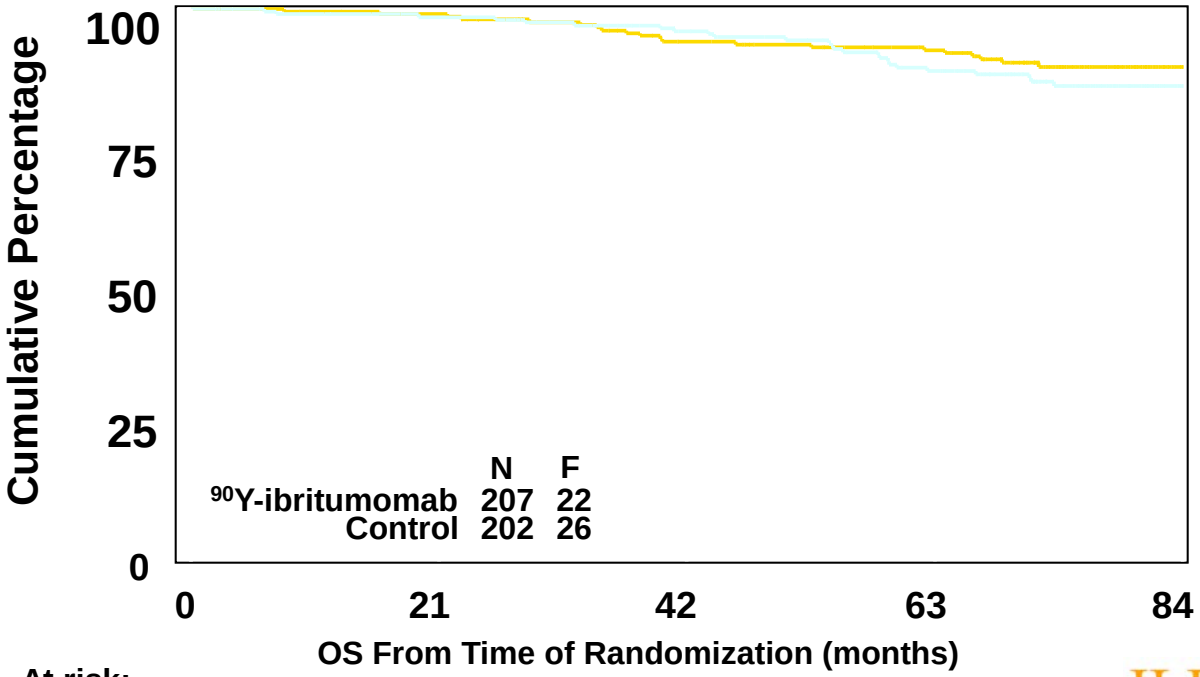


Overall Survival for Treatment Groups

7-year OS 86% in control arm compared with 89% in the ^{90}Y-ibritumomab arm
HR = 1.50 (95% CI: 0.84 – 2.68); *P* = 0.478

^{90}Y-ibritumomab: n = 207
Median OS: > 110 mo

Control: n = 202
Median OS: > 113 mo



At risk:					
^{90}Y-ibritumomab	207	200	178	166	47
Control	202	192	175	152	45

FIT TRIAL
Conclusions after 7 years Follow-up

- ^{90}Y-Ibritumomab consolidation confers a durable PFS benefit for patients with advanced FL
  - 3-year PFS advantage for patients in the ITT population
  - At least a 6-year PFS advantage for patients with a CR/CRu after induction > 5-year advantage in time to next treatment

- No unexpected toxicities emerging

  Annualized rate of secondary MDS/AML was 0.55% in the Zevalin arm

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Does ^{90}Y Ibritumomab Consolidation after first line R-Chemo Induction in Follicular Lymphoma improve outcome?

➢FIT study (R-chemo subgroup; n=59)

- CR rate after Zevalin : 93% (controls: 71%)
- PFS at 84 months: 64% Zevalin vs 23% controls (median follow-up: 71.6 months)

- ECOG 1496 6-8 x chemo - CR/PR/SD randomised 16 cycles of Rituximab – similar results for PFS

➢Randomised (^{90}Y Ibritumomab) vs in Rituximab maintenance (ROZETTA study) no significant difference in PFS

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Responses rates of Zevalin monotherapy versus R-chemo in first line therapy of Follicular NHL

	ORR (%)	CR (%)	Reference
R-CHOP	96	20	Hiddemann et al., 2005
R-CVP	81	41	Marcus et al., 2005
R-MCP	92	50	Herold et al., 2005
Zevalin	84	53	Scholz et al., 2012
Zevalin	96	70	Illidge et al 2014
Bexxar	95	75	Kaminski et al., 2010

Conclusions – Role of RIT in Follicular lymphoma

- RIT simple and effective treatment; most active drug in NHL, unique mechanism of action
  - Effective (high response rate, durable remission) and underused single treatment in relapsed and rituximab refractory disease
  - Patients in ^{90}Y-ibritumomab arm had a greater than 5-year advantage in time to next treatment in FIT trial as consolidation
  - Phase II data as single agents Zevalin RIT in untreated follicular lymphoma show high response rates and durable remission
  - Novel Radioimmunconjugates are being developed but pathways to registration and routine clinical use are challenging.

- Hodgkin lymphoma – early stages
- PET-driven trials
- Chemo-Immunotherapy
- Summary

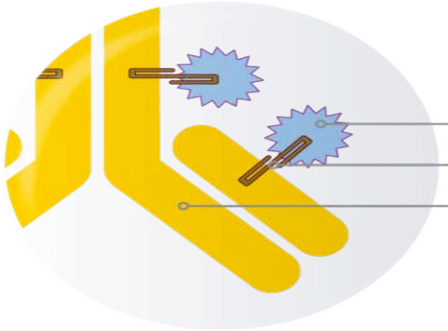
New Antibodies and Molecules
in Hodgkin Lymphoma

- **Brentuximab Vedotin (anti-CD30 ADC)**
- **AFM13 (CD16/CD30 bispecific)**
- **Lenalidomide (IMID)**
- **Everolimus, (mTor-inhibitor)**
- **Rituximab, Ofatumumab (anti-CD20)**
- **Panobinostat, Mocitinostat (H-DAC inhibitors)**
- **TKI´s, JAK2i, PARPi**
- **PD-1 inhibitors**

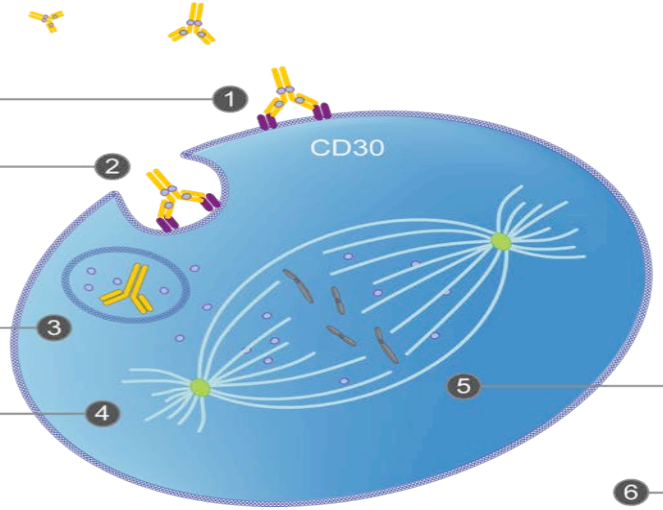
Brentuximab Vedotin (SGN-35)

Mechanism of action



Brentuximab vedotin (SGN-35) ADC

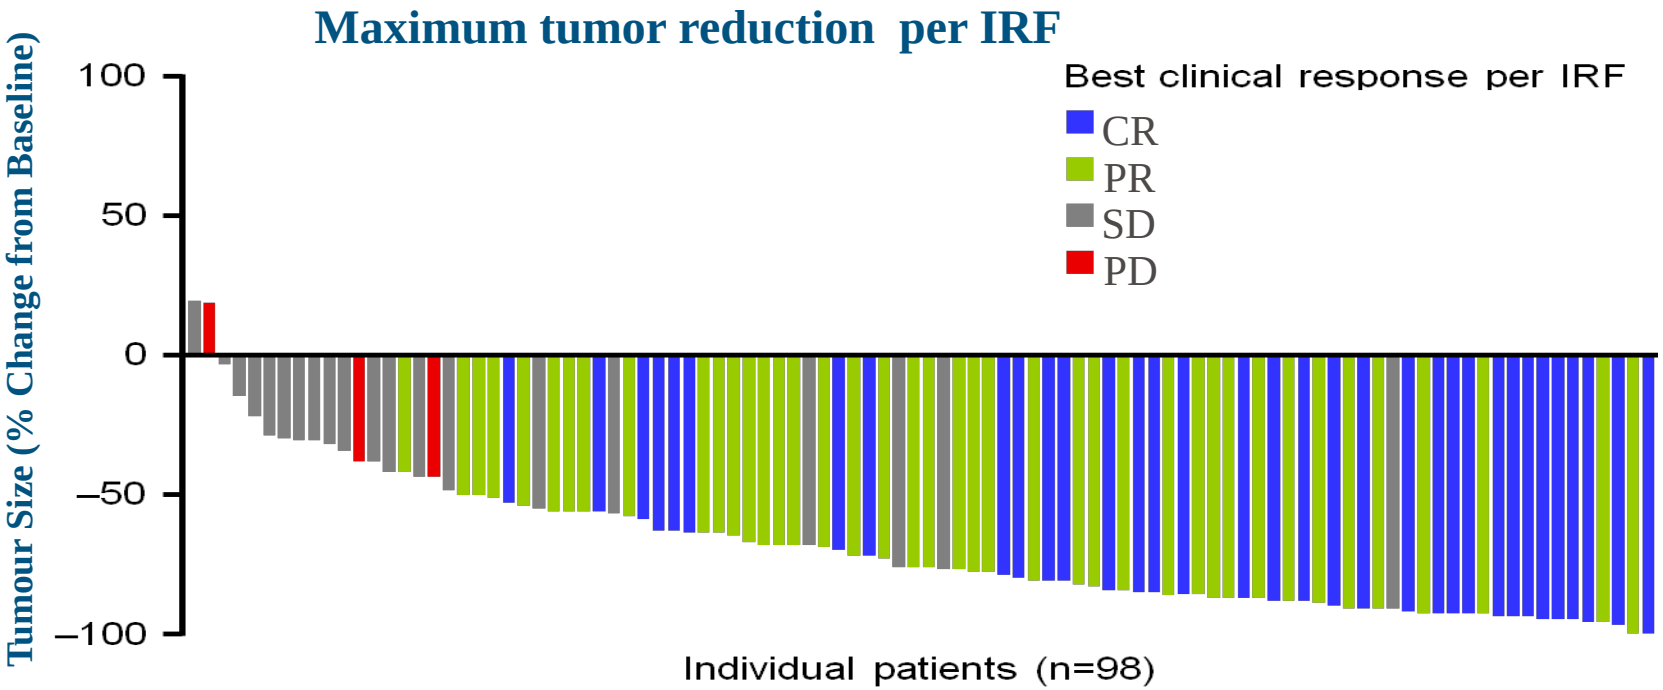
- monomethyl auristatin E (MMAE), potent antitubulin agent
- protease-cleavable linker
- anti-CD30 monoclonal antibody



1. ADC binds to CD30
2. ADC-CD30 complex traffics to lysosome
3. MMAE is released
4. MMAE disrupts Microtubule network
5. G2/M cell cycle arrest
6. Apoptosis

Phase II Pivotal Study of BV

Patients with R/R HL post ASCT



Younes A et al, J Clin Oncol 2012;30: 2183-2189.

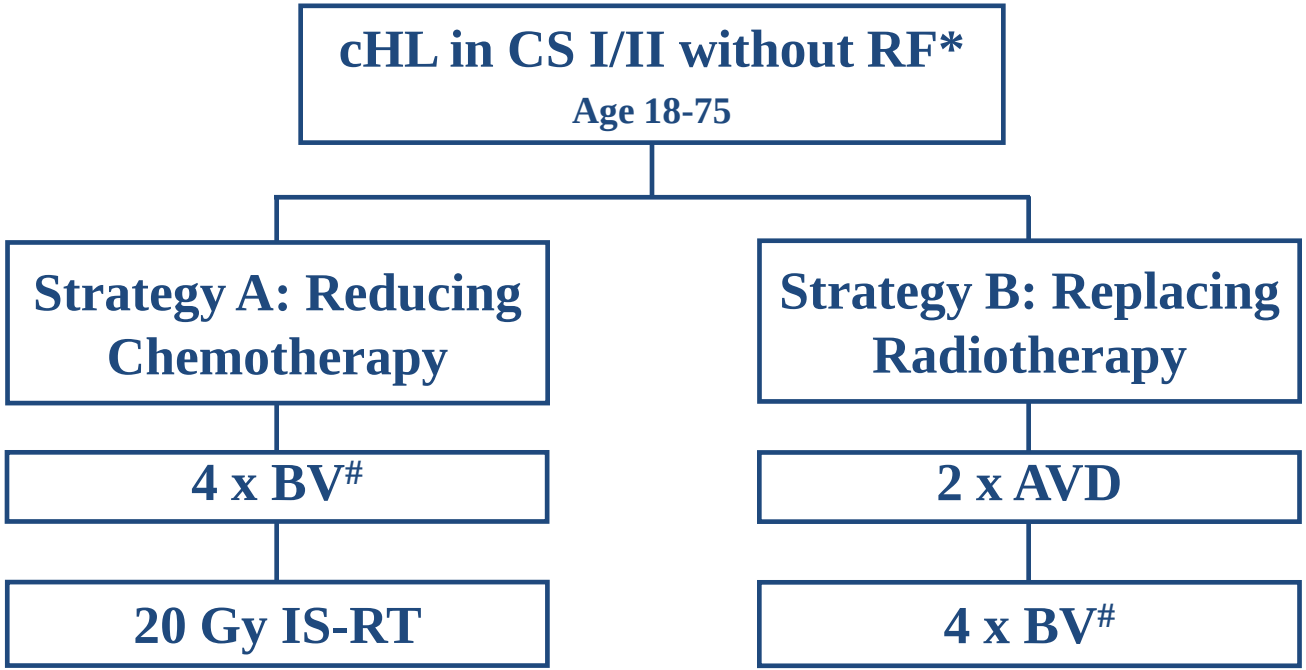
End of therapy and residual nodes > 2.5 cm:

PET positiv: **Rx**

PET negative: **Follow up**

Phase II trial design

BV in early favorable HL

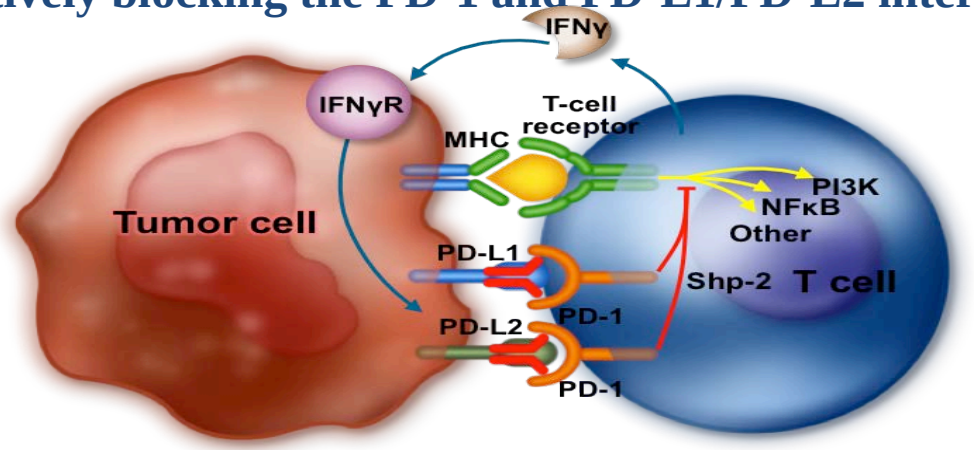


* a) large mediastinal mass b) extranodal disease c) elevated ESR d) ≥3 nodal areas

to be discussed: 1.8 mg/kg every 3 weeks or 1.2 mg/kg every 2 weeks

PD-1 Blockade

- PD-1 engagement by its ligands results in transient down-regulation of T-cell function (T-cell exhaustion).
- Nivolumab (BMS) and Pembrolizumab (MSD) fully human/humanized anti-PD-1 antibody selectively blocking the PD-1 and PD-L1/PD-L2 interaction.



- PD-1 blockade through monoclonal antibody therapy has single-agent activity in a range of solid tumors

Brahmer et al, NEJM 2012;366:2455. Topalian et al, NEJM 2012;366:2443-54

PD-1 Blockade in HL

Background

Pathology of cHL: rare malignant Reed-Sternberg cells within an extensive inflammatory/immune cell infiltrate.

Genetic analyses: frequent 9p24.1 amplification with upregulation of PD-1 ligands and JAK2.

Hypothesis: cHL may have a gene- tically driven dependence on PD-1.

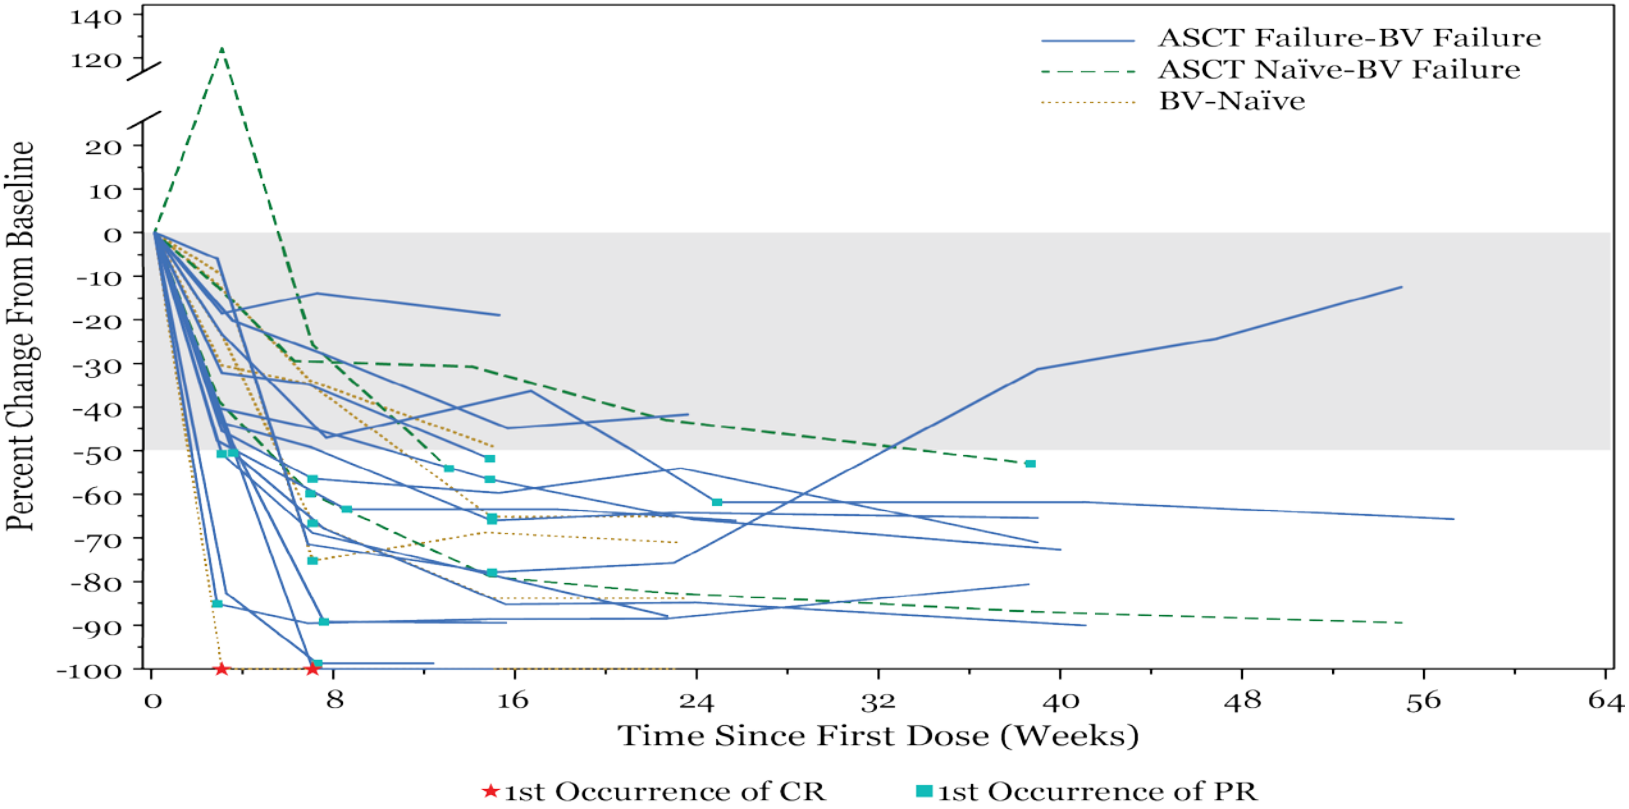
Response Kinetics



Armand P, ASH 2014

Combined Modality Treatment of HL

- Background
- Hodgkin lymphoma – early stages
- PET-driven trials
- Chemo-Immunotherapy
- Summary

Combined Modality Treatment of Lymphoma

- Despite the impressive cure rate in HL, elderly and r&r pts still constitute an area of unmet medical need
- In early favorable, 2xABVD+20Gy IFRT; more chemo not better
- In early unfavorable, 2+2+IFRT or 4xABVD+IFRT; 6x chemo not better (H8U)
- CMT standard of care in early stage HL (OS better!)
- Rapid and H10 gave conflicting results; PET+ pts in H10 benefit from dose escalation with Besc.
- Need to develop less toxic regimen; BV and anti-PD1 might at least in part replace chemo- and radiotherapy in HL

  - Risks of important SMN (breast, GI and lung cancer)
  - 40 year risk of second malignancies after HL
- Cardiovascular disease
- Clinical implications

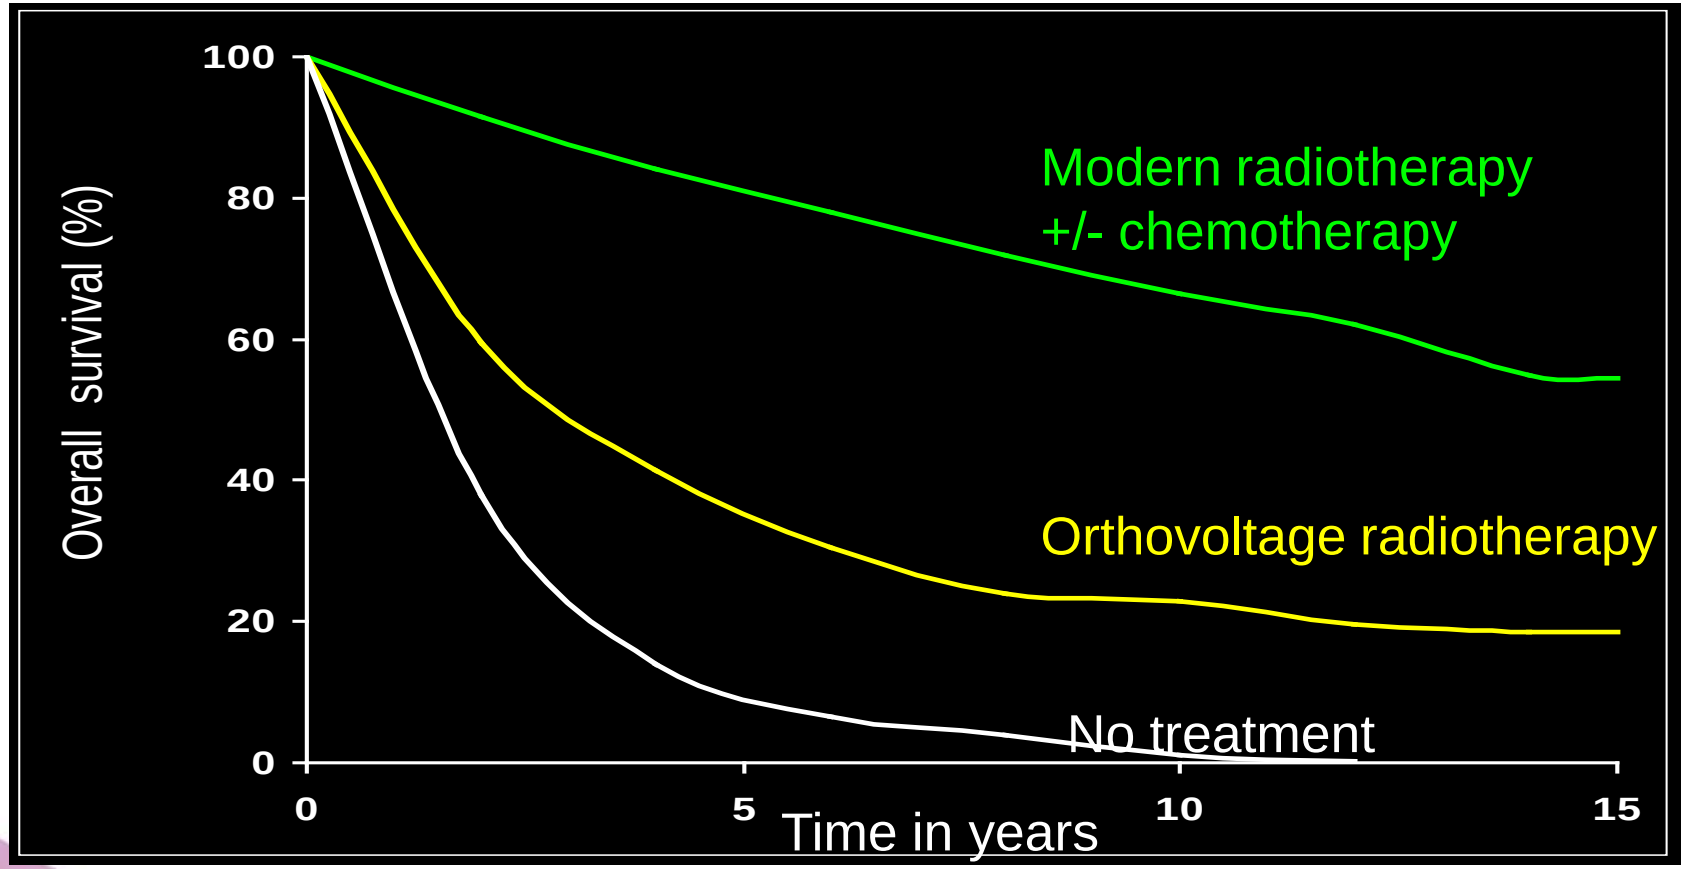
Hodgkin's disease

Nowadays Hodgkin lymphoma

Thomas Hodgkin, 1798-1866

- 0.4% of all new cancers
- 400 new cases per year in NL (16 million inhabitants)
- 67% of all cases below age 45
- Second most common malignancy in young adults
- The prototype of a curable malignancy

Survival after Hodgkin lymphoma



Kaplan 1978

Risk measures in late effect research

- Standardized Incidence Ratio (SIR) =

  Observed / Expected numbers of events =

  Relative risk compared to general population

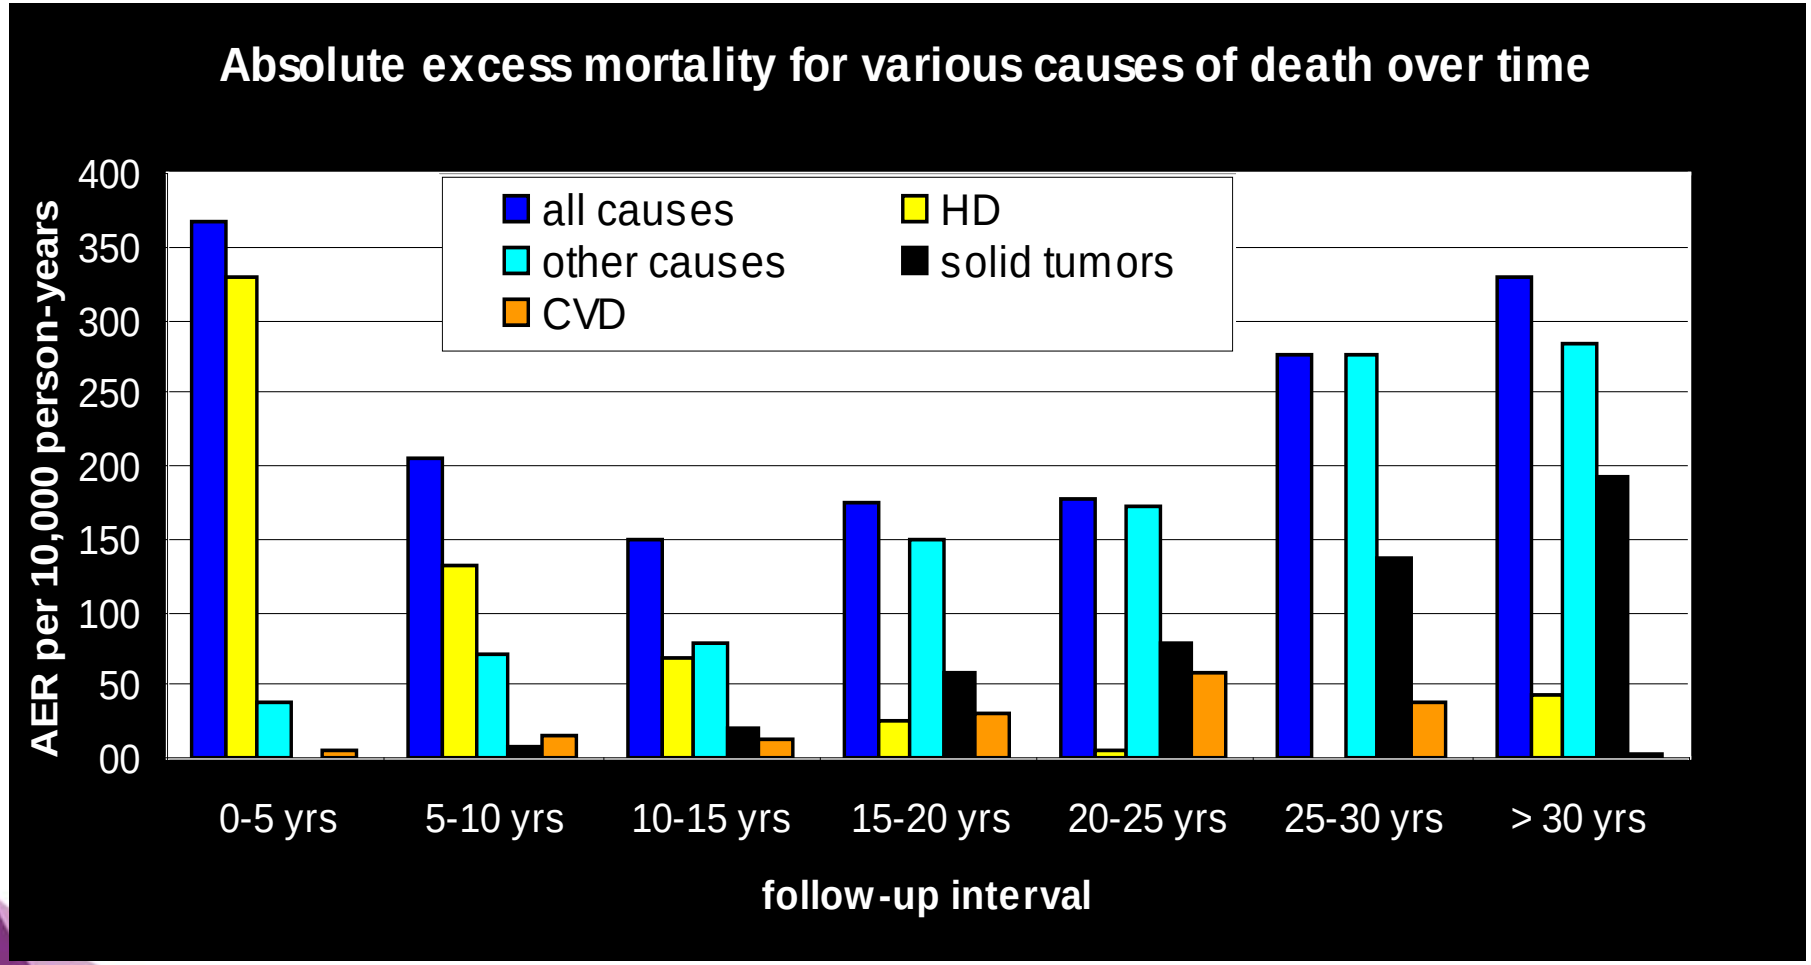
  - High SIR for rare event → low absolute risk

- Absolute excess risk (AER) =

  Excess number of events beyond expected number / 10,000 persons/ year

- Cumulative incidence = % developing event, accounting for death as a competing risk

- Hazard ratio = RR for treatment A vs treatment B



Aleman et al., JCO 2003; 21:3431

Risks of Second Malignancy following HL combined results from 3 large studies* (n=9618)

Site or Type	Obs	SIR	AER

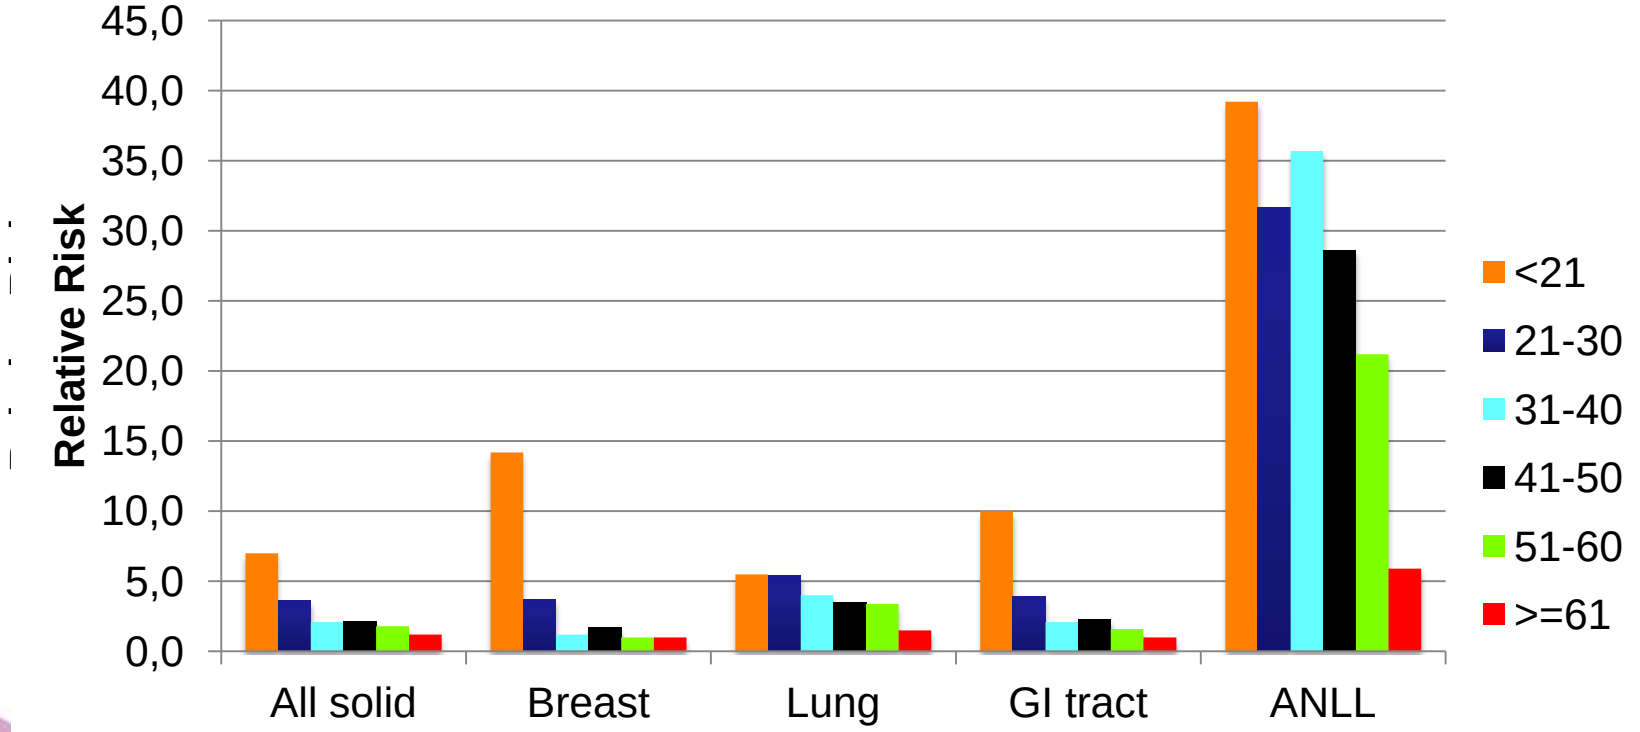
Relative risks of SMN by age at HL diagnosis

International cohort study: 32,591 HL patients

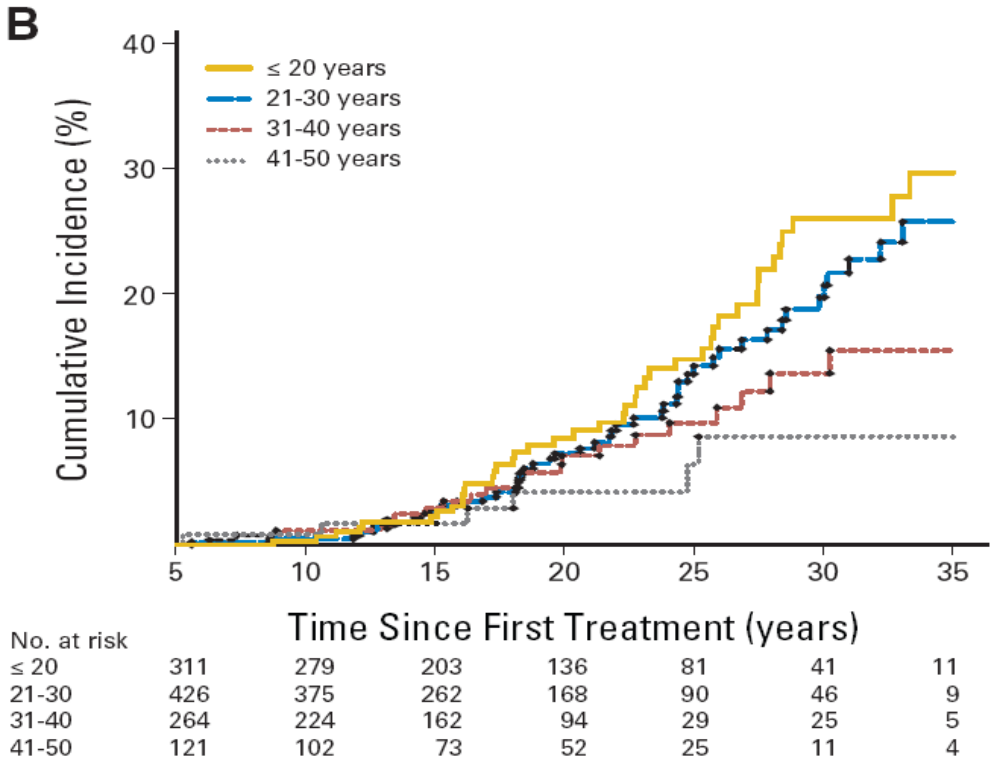
1,111 25-years survivors, population-based



Adapted from Dores JCO 2002; 20:3484

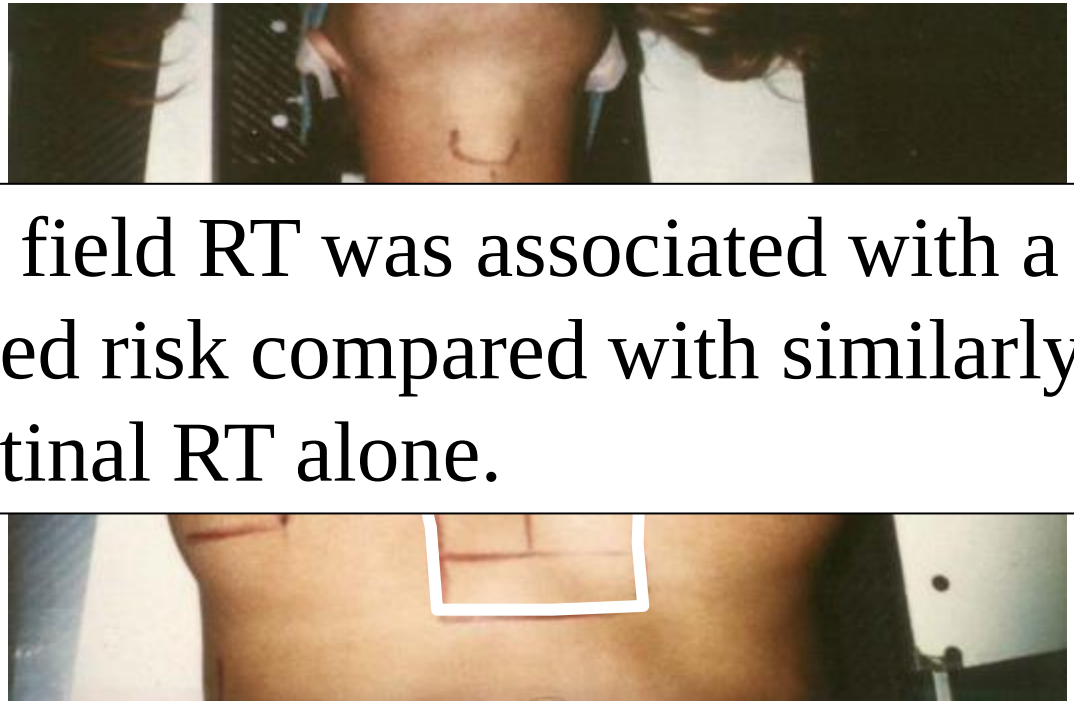
Cumulative incidence of breast cancer by age at HL

(1,122 female 5-year survivors treated for HL <51 years between 1965 and 1995)



De Bruin et al. JCO 2009; 27(26): 4239-4246

From mantle field to IFRT



Mantle field RT was associated with a 2.7-fold increased risk compared with similarly dosed mediastinal RT alone.

De Bruin et al, JCO 2009

Breast cancer following HL

a Dutch case-control study

Radiation dose in Gy (median)	**Cases**	**Controls**	**OR†**	**95%CI**

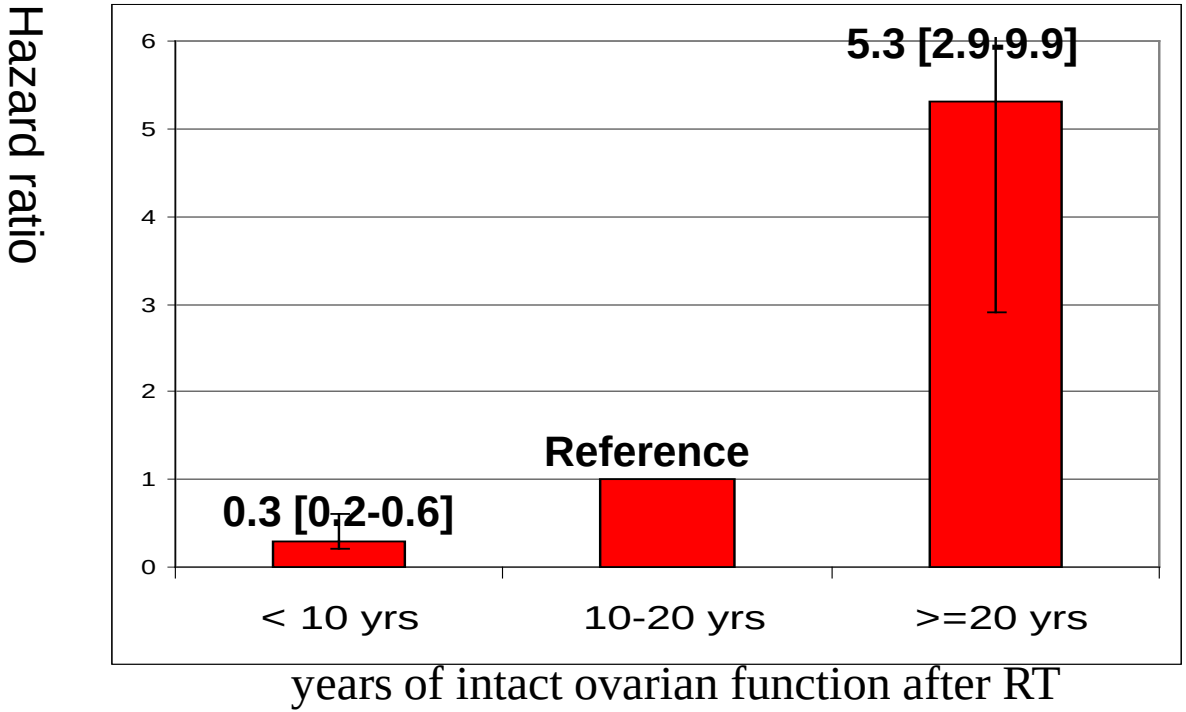
* P trend <0.001; † adjusted for RT dose ovary and CT

- Highest risks in youngest patients
- Induction period: 10-15 years

van Leeuwen JNCI 2003: 95;971

Risk of breast cancer after RT for HL, by duration of ovarian function after RT

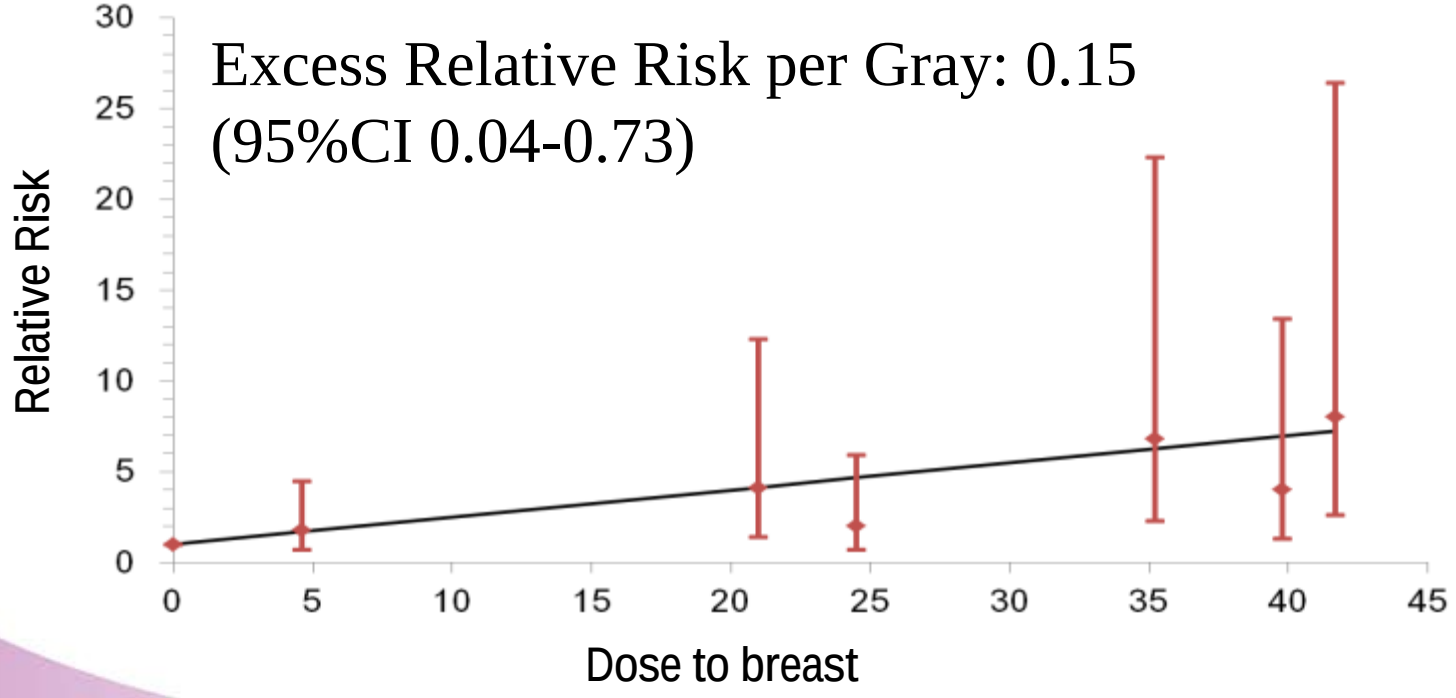


→ Ovarian hormones crucial in radiation-induced breast carcinogenesis

De Bruin et al, JCO 2009

Radiation dose and breast cancer risk in HL survivors (Travis et al. JAMA 2003; 290:465)

International case-control study, 105 breast cancer cases and 266 matched controls; Radiation dose to breast tumor location was estimated.



Literature on CRC risk after HL or childhood cancer and in A-bomb survivors

- Colorectum: important site of excess cancer in HL survivors
- ↑ colon cancer risk after exposure to low RT doses, whereas ↑ rectal cancer risk after higher doses
- Excess CRC risk appears 10 years after exposure

Birdwell et al., 1997; Hodgson et al., 2007; Van den Belt-Dusebout et al, 2009; Henderson et al 2012 (CCS); Nottage et al 2012 (CCS);Life Span Studies; Eggermond work in progress

SIR & AER of CRC

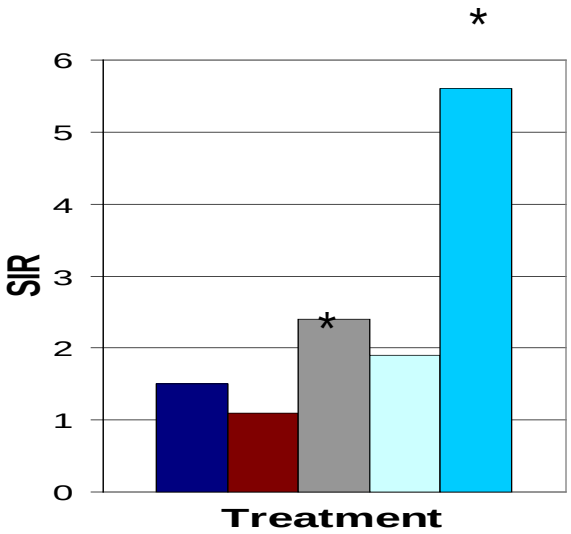
in 2,820 5-year Dutch HL survivors, diagnosed<51 years, treated1965-1995; median fup 21.5 years

Tumor site	O	SIR (95%CI)	AER (95%CI)
Colorectal cancer	49	2.7*	6.3*
Colon	30	2.7*	3.9*
Ascending colon	10	2.3*	1.1
Transverse colon	11	7.5*	2.0
Descending colon	7	1.3	0.4
Colon, NOS	2	5.5	0.3
Rectum	19	2.7*	2.4

SIR = Standardized Incidence Ratio (observed/expected) * p <0.05
AER = Absolute Excess Risk **per 10.000 patients/yr**
NOS = Not otherwise specified

Eggermond, work in progress

Risk of CRC by HL treatment



CT only

Supra RT only

Supra RT + CT

Infra ± supra RT, no CT

Infra ± supra RT + CT

Treatment	Obs	Exp	SIR
CT only	3	2.0	1.5
Supra RT only	3	2.7	1.1
Supra RT + CT	13	5.3	2.4*
Infra ± supra RT, no CT	8	4.2	1.9
Infra ± supra RT + CT	22	4.0	5.6*

* $p < 0.05$

Supra = supradiaphragmatic, infra = infradiaphragmatic

Eggermond, work in progress

Clinical implications

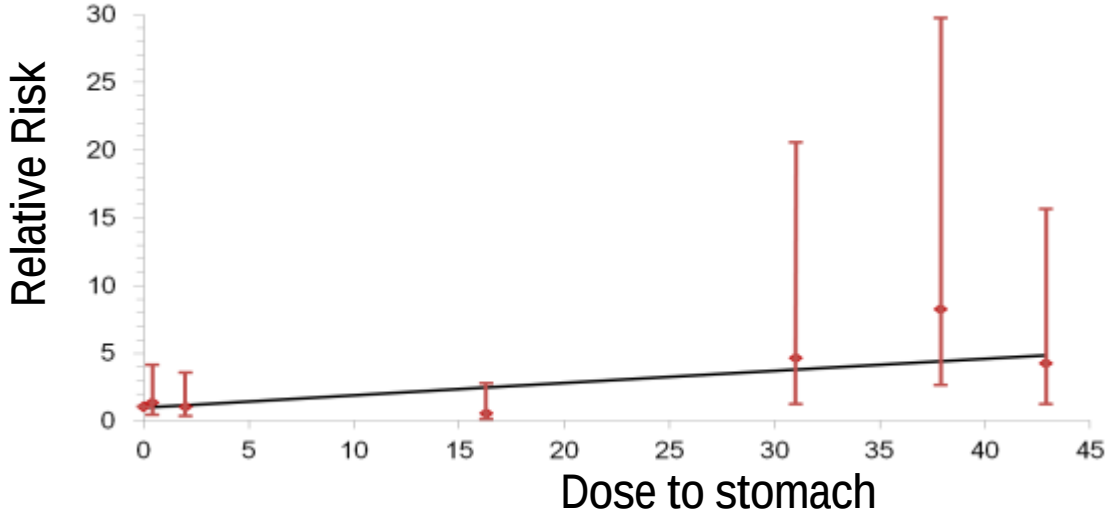
- 47-year old HL survivor (treated < 25 yr) same CRC risk as 55-60 year old person from general population (0.5%)
- Need for screening guidelines for HL survivors
- COG guideline: colonoscopy after ≥ 30 Gy abdominal RT

  10 yrs after RT or at age 35
- Starting age? Also after procarbazine CT?
- Implications for the use of procarbazine in new treatment regimens?

Eggermond, work in progress

Radiation dose and stomach cancer risk in Hodgkin lymphoma survivors

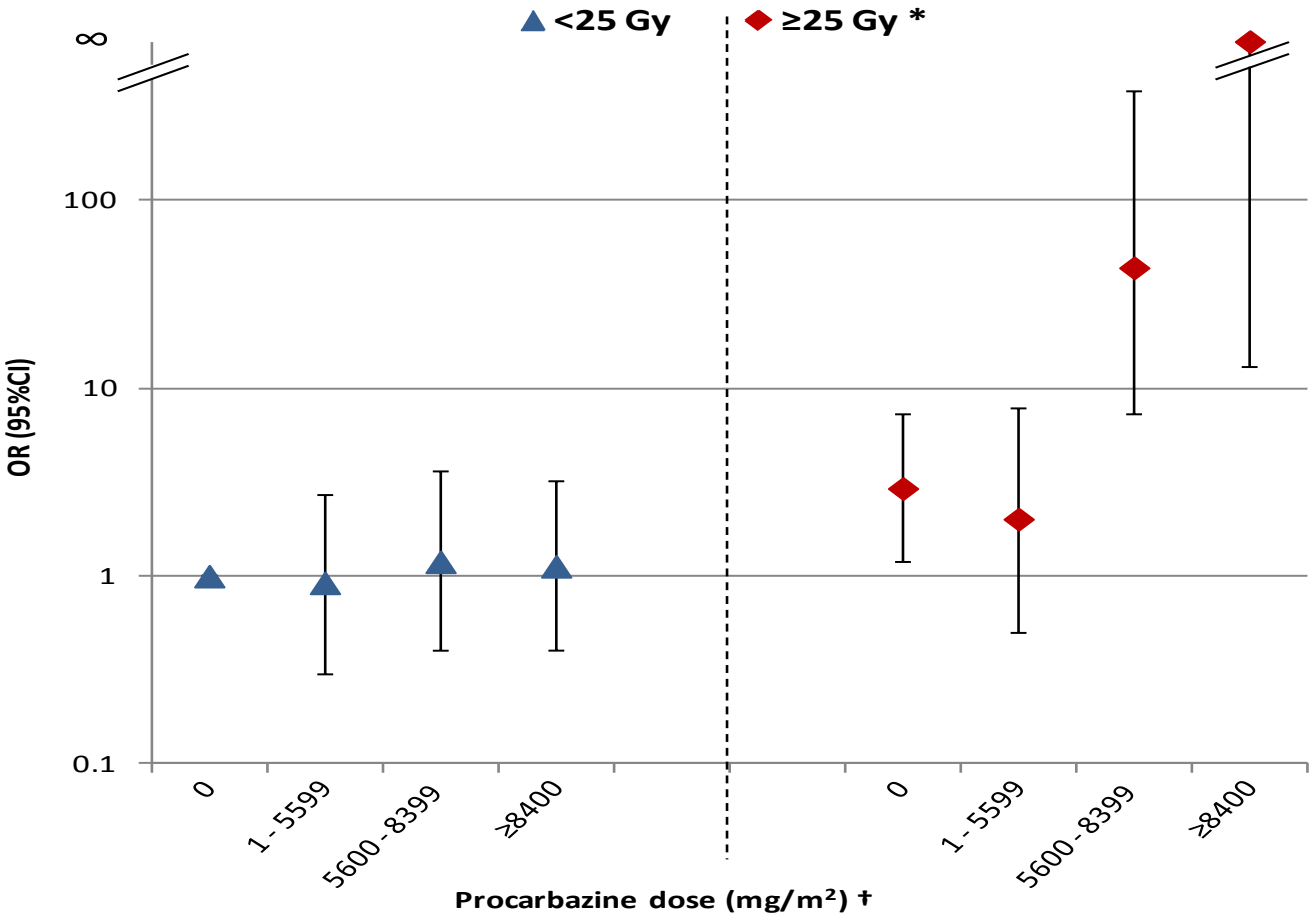
International nested case-control study, 89 stomach cancer cases and 190 matched controls; Radiation dosimetry to estimate dose to area of stomach tumor Morton et al. JCO 2013



RRs adjusted for alkylating agent CT dose

Excess Relative Risk per Gray 0.09 (95%CI 0.04-0.21)

Risk of stomach cancer after HL in relation to radiation dose to the stomach and procarbazine dose.



4.2 g/m^2 procarbazine≈3x MOPP or 6 MOPP-ABV(D)

Morton et al, JCO 2013

Lung cancer after HL
Joint effects of smoking and treatment

- Risks from smoking multiply risks from treatment
- Smoking is the major cause of lung cancer (only 7 out of 222 cases were never smokers)

	RR non/light smokers	RR smokers
No RT (< 5 Gy), no CT	1.0 (ref)	6.0 (1.9-20.4)
RT (≥ 5 Gy), no CT	7.2 (2.9-21.2)	20.2 (6.8-68)
No RT (< 5 Gy), CT	4.3 (1.8-11.7)	16.8 (6.2-53)
RT (≥ 5 Gy), CT	7.2 (2.8-21.6)	49.1 (15.1-187)

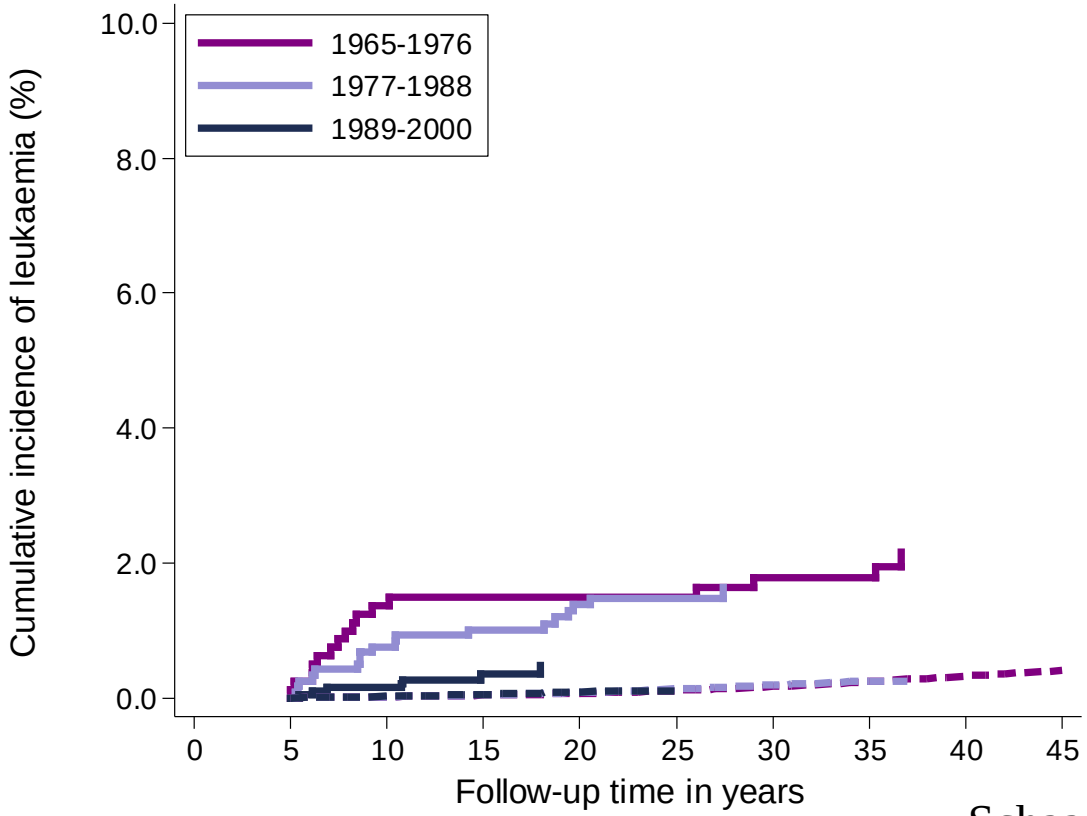
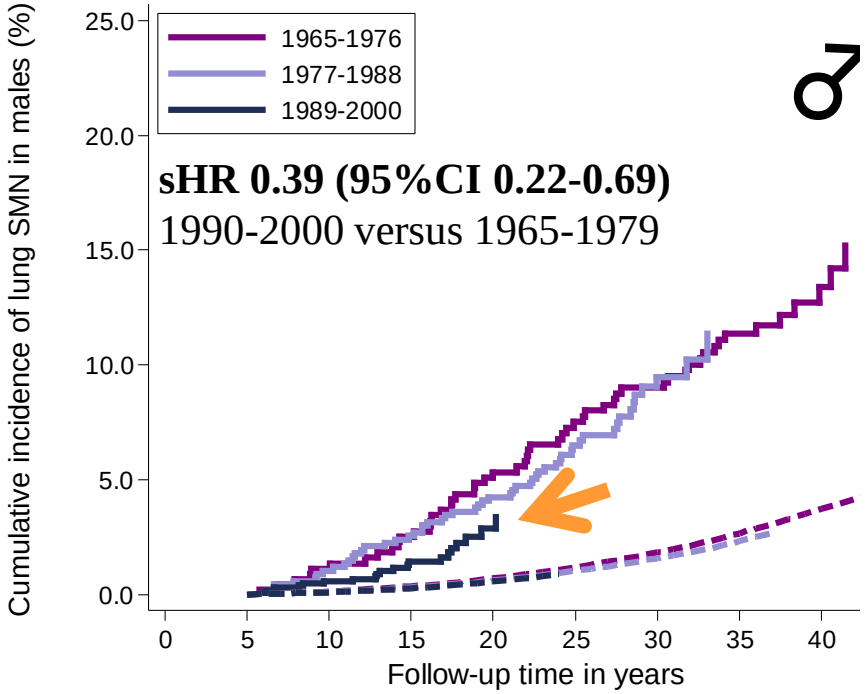
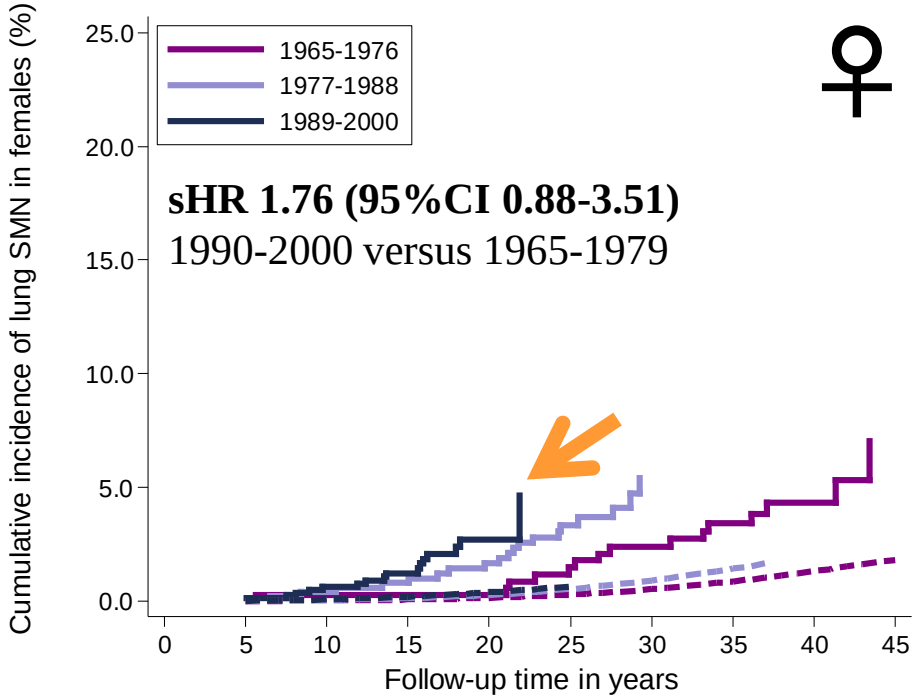
Cumulative incidence of leukemia (excluding MDS)



Schaapveld et al , submitted

Trend in cumulative incidence* of lung cancer by period of treatment and sex in 5 year HL survivors (n=3,905) and the general population





*estimated in the presence of death as a competing risk
Subdistribution HR are adjusted for age and follow-up<20 years

Schaapveld, work in progress

Conclusions

- Risk of hematological SMNs has decreased over time
- Risk solid SMNs does not appear to decrease in patients treated before 2000, potentially due to changes in chemotherapy regimens and more breast cancer screening.
- Awareness of increased SMN risk remains crucial for HL survivors.

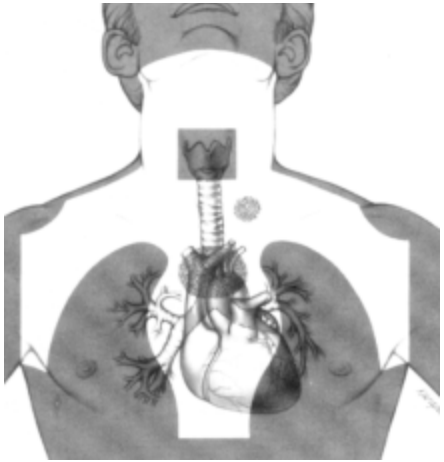
Schaapveld et al , submitted

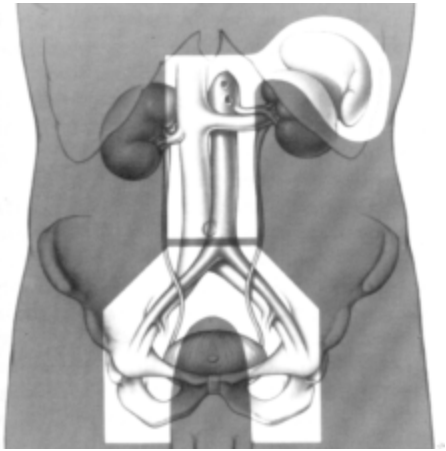
Summary SMN

- Risks of RT associated SMN:
  - Volume related
  - Linear ↑ with dose for most SMN (except thyroid cancer)
- Emerging data on CT related solid ca risks
- Many data on late effects based on outdated treatments
- Imaging and RT techniques have improved → more effective and less toxic treatments

Causes cardiovascular damage

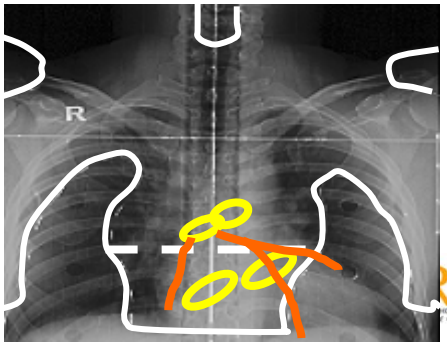
- Chemotherapy (anthracyclines)
- Radiotherapy





RT-associated heart diseases

- Coronary heart disease
- Myocardial dysfunction
- Valvular abnormalities
- Pericardial abnormalities
- Electrical conduction disorders

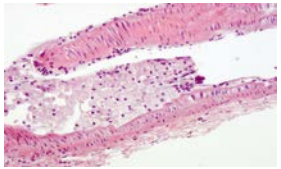


Cardiovascular toxicity

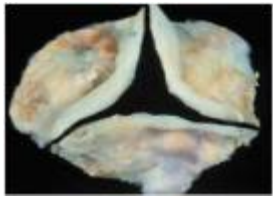
Differences in mechanisms

Radiation

Damage to vasculature (vulnerable plaques*)



Damage to valves



Damage to myocytes

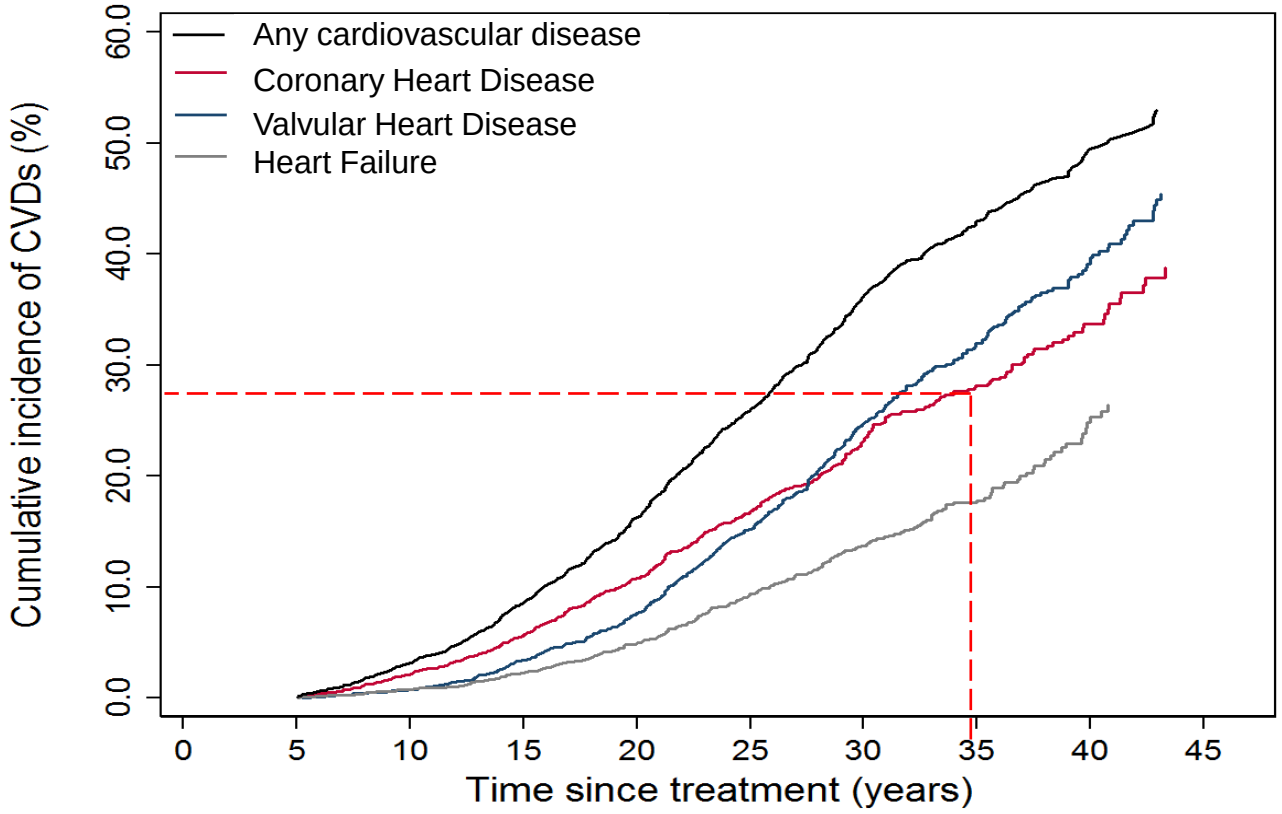
Literature cardiovascular disease after HL

- Mediastinal radiotherapy increases *mortality* of CVD, esp. coronary artery disease
  (Boivin, Cancer 1992; 69:1241; Hancock, JAMA 1993; 270:1949; Swerdlow JNCI 2007; 99:206; Aleman JCO 2003; 21:3431)
- Fewer studies examined CVD *morbidity*
  (Hull JAMA 2003; 290:2831; Aleman, Blood 2007; 109:1878; Glanzmann, Rad Oncol 1998; 46:51)
- Increased mortality for > 25yrs
- Also increased risk for valvular disease *(Aleman, Blood 2007; Hull, JAMA 2003)*

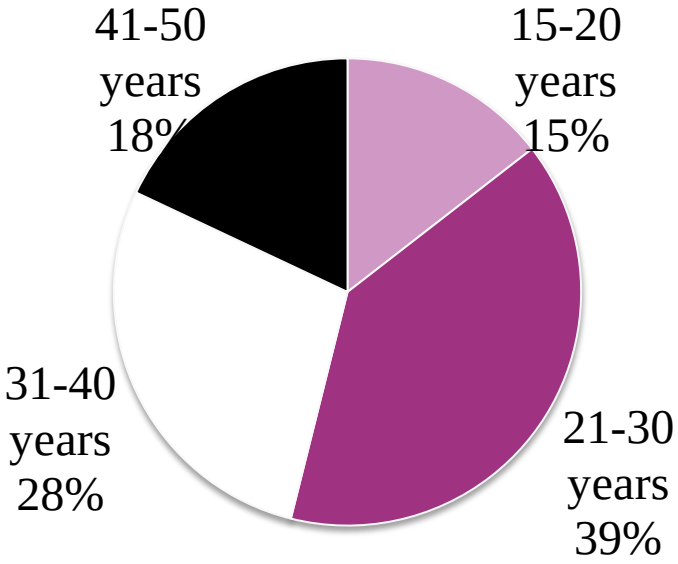
Morbidity of cardiovascular disease

(all events in 2524 5-year survivors of HL treated before age 51 between 1965-1995)

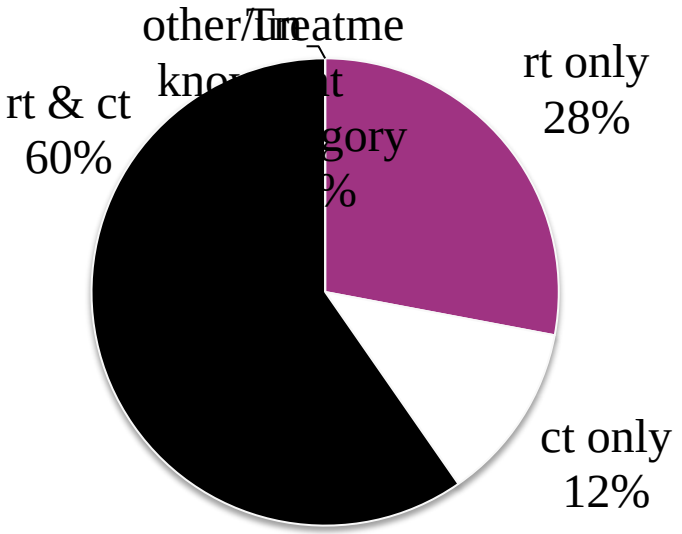


Van Nimwegen et al., JAMA int med 2015

HL age distribution



HL treatment



41% anthracycline-containing chemotherapy

Over time ↓ use mantle field and abdominal RT

Schaapveld, work in progress

Established CVD Risk factors

Risk factor	RR¥	95%CI	p_{trend}
Physical activity at time of questionnaire¤			
Not active (<1 hour a week)	1.0	0.5-2.2	
Moderately active (1-3 hours a week)	0.7	0.5-1.2	
Very active (≥4 hours a week)	0.5*	0.3-0.8	0.136

*p<0.05

¥ adjusted for mediastinal radiotherapy

¤ analyzed in sub-population of patients who filled in the risk factor questionnaire (84 cases and 158 individual controls), adjusted for the matching factors.

Van Nimwegen et al., submitted

Conclusions ischemic heart disease after HL

- Linear dose response relationship with overall risk increase of 7.4%/Gy
  - 2.5-fold increased risk at MHD of 20 Gy
  - Higher ERR for patients treated <27.5 years
- Established risk factors & recent smoking ↑ CHD risk
- High levels of physicial activity ↓ CHD risk
- Results enable risk prediction

Van Nimwegen et al., submitted

Conclusions CVD after HL (literature and Dutch HL cohort)

- After mediastinal RT increased riks of coronary events, valvular disease, CHF
- After 40 yrs: risk of any CVD after mediastinal RT = 50% vs 26% (no mediastinal RT)
- Risk remains increased ≥ 40 yrs
- Younger age at RT → higher risk
- Additive effects of RT and anthracyclines on CHF risk

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Anthracyclines

- Anthracyclines damage myocytes
- Cardiotoxicity may present as ECG changes and arrhythmias, or as cardiomyopathy possibly leading to heart failure
- Dose-effect relationship

Cardiovascular disease after therapy for HL:
A detailed analysis of 9 collaborative EORTC-LYSA trials

- Incidence of CVD was reported during follow-up and updated through a patient-reported questionnaire, mailed in 2009–2010

Maraldo et al, Lancet Hemat in press

Cardiovascular disease after therapy for HL:
A detailed analysis of 9 collaborative EORTC-LYSA trials

Maraldo et al, Lancet Hemat in press

Cardiovascular disease after therapy for HL:
A detailed analysis of 9 collaborative EORTC-LYSA trials

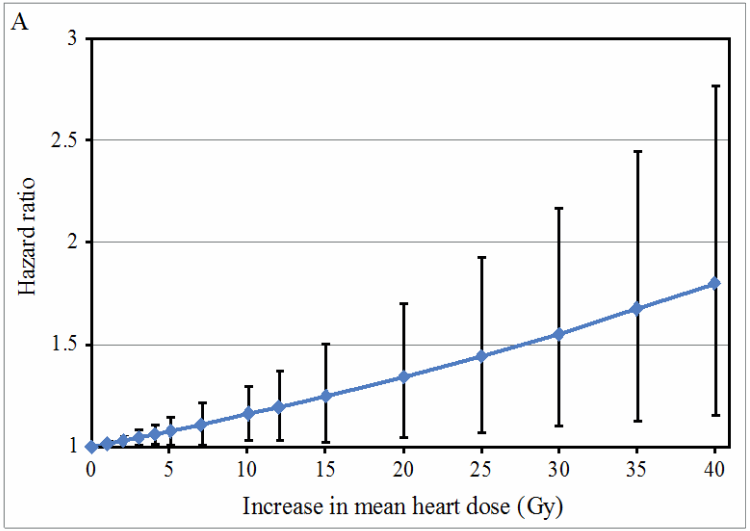
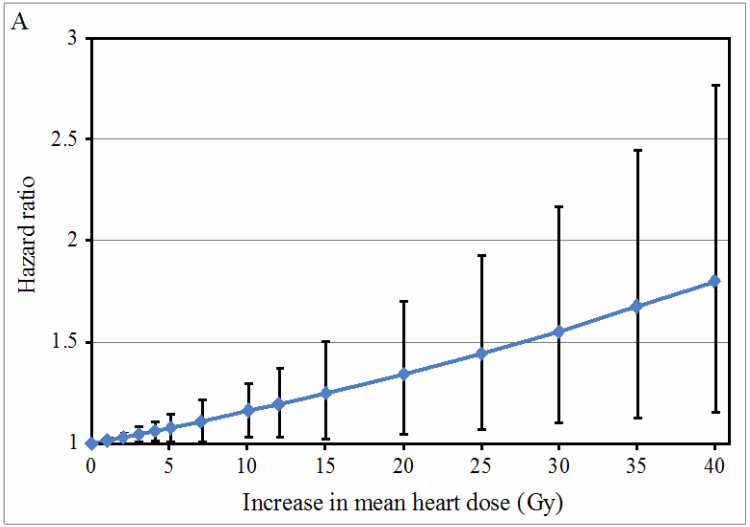
The mean heart radiation dose and the cumulative dose of anthracyclines were significant predictors of CVD, with an increase in hazard rate of 1·5% (95% CI: 0·6–2·4%) per 1 Gy increase in mean heart dose and 7·7% (95% CI: 2·1–13·7%) per 50 mg/m2 increase in cumulative anthracycline dose.





Maraldo et al, Lancet Hemat in press

Optimize treatment ?

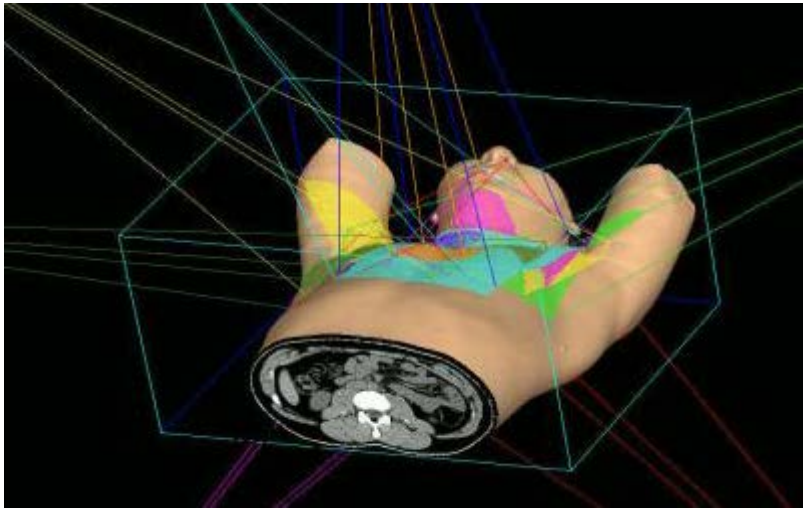
Disease control

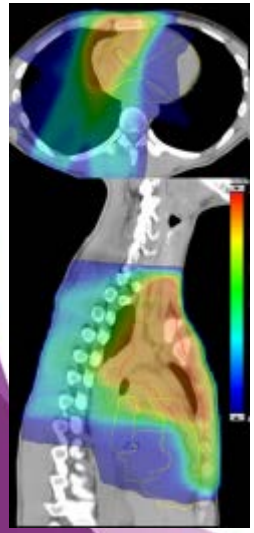
Chance early and late side effects

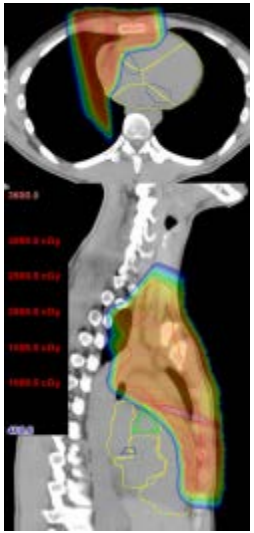
Treatment optimization:

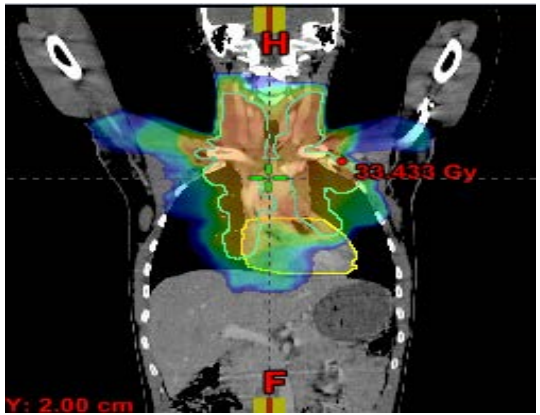
Extensively discussed during course:

- Balancing systemic and local treatment
- Optimal RT technique (including optimal preparation of RT, careful choice target volume, optimal planning, introduction of DIBH, protons etc)

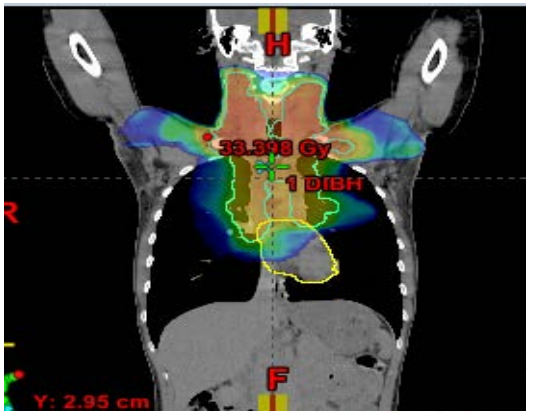








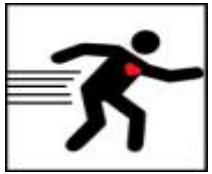
H
33.433 Gy
F
Y: 2.00 cm



H
33.398 Gy
1 DIBH
F
Y: 2.95 cm

Limit risk of (treatment -related) side effects Patient

- Adjust lifestyle - no smoking
- Visit doctor in case of complaints



BETER-project:

A nationwide survivorship care program for adult (non-)Hodgkin lymphoma survivors

Future

- Development of risk prediction models including all available information on late effects
- Improve documentation of applied treatment (including dose to OAR)

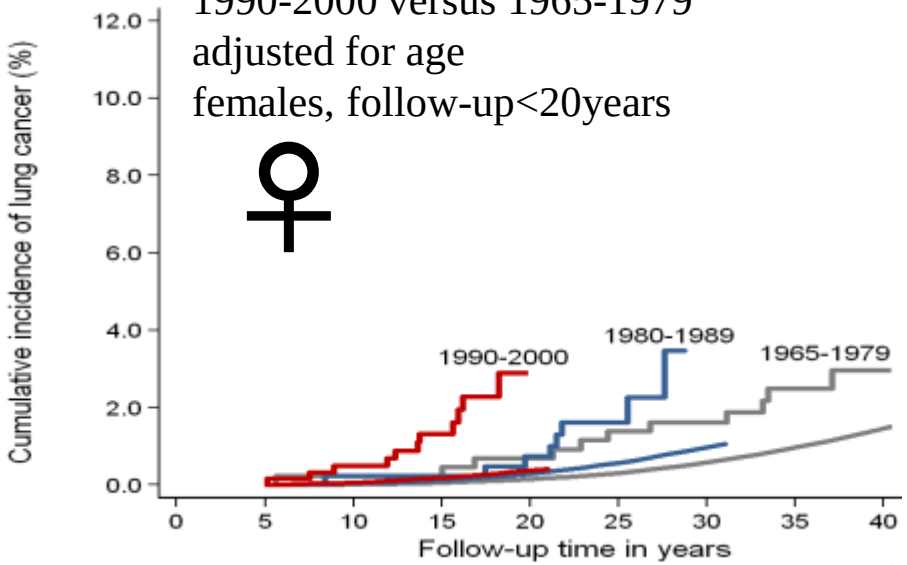
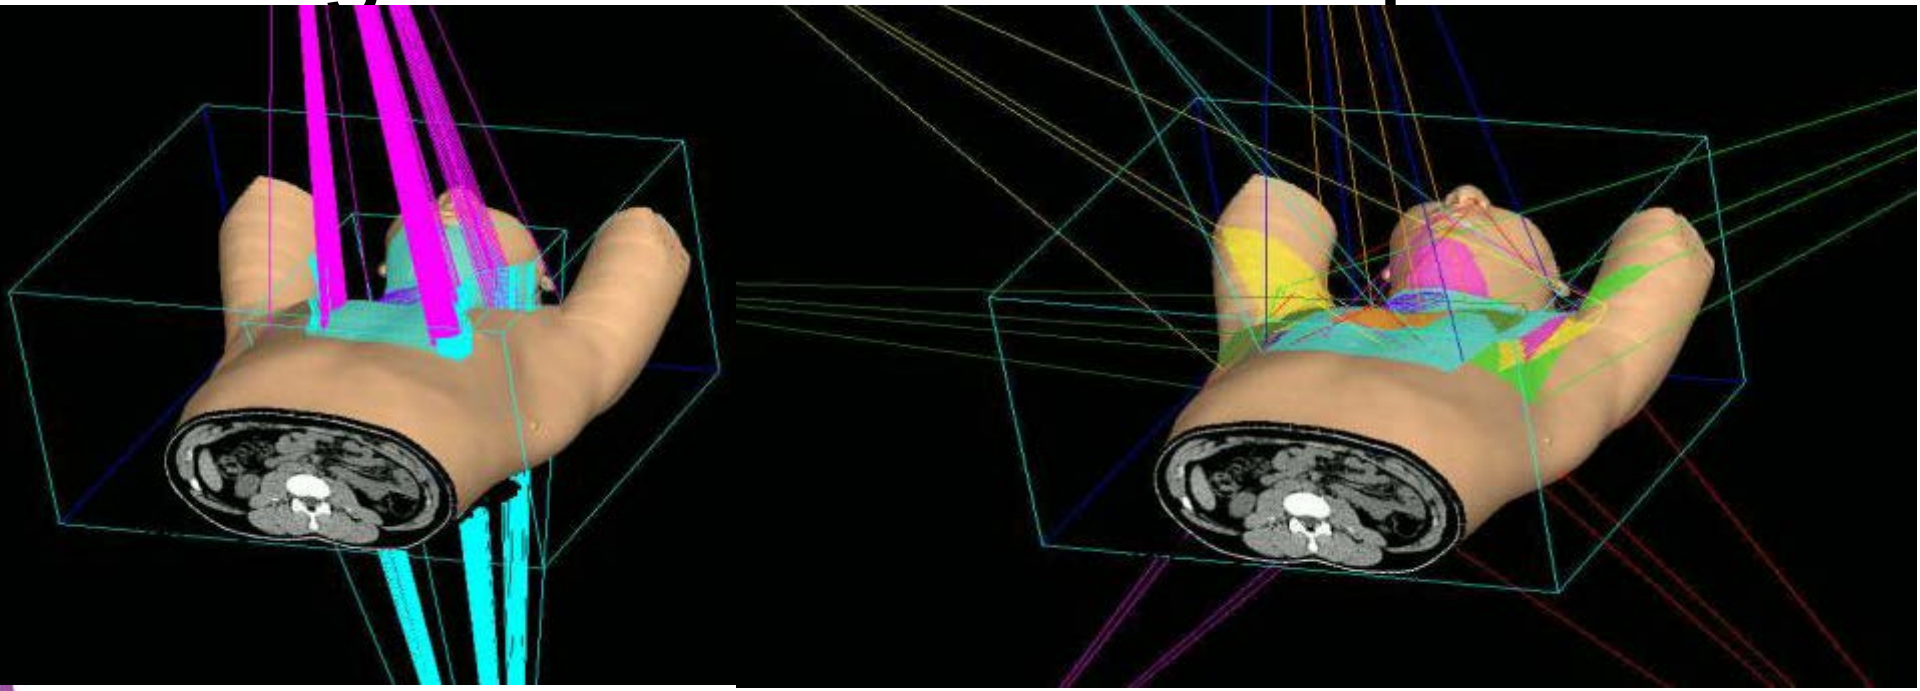
females, follow-up<20years



*estimated in the presence of death as a competing risk

Schaapveld, work in progress

Changes radiation techniques



More (fields) is not always better!

Defining constraints for organs at risk very important

Individualize treatment plan

Screening for second cancers

Breast:

- Women treated with chest RT before age 40
- Start screening 8 years after RT, not before age 25

Colon:

- Screening of colon cancer – under consideration

Lung and stomach:

- No screening for lung cancer or stomach cancer

From current draft Dutch sceening guideline

Future research SMN after HL

- Effects of contemporary RT / systemic therapy
- Interaction between RT and CT (procarbazine)
- Search for susceptibility genes for RT/CT-associated malignancies
- Interaction between treatment and lifestyle
- Risk prediction models
- Efficacy of screening for second malignancies/CVD
- Effect of RT dose/volume on second cancer risk

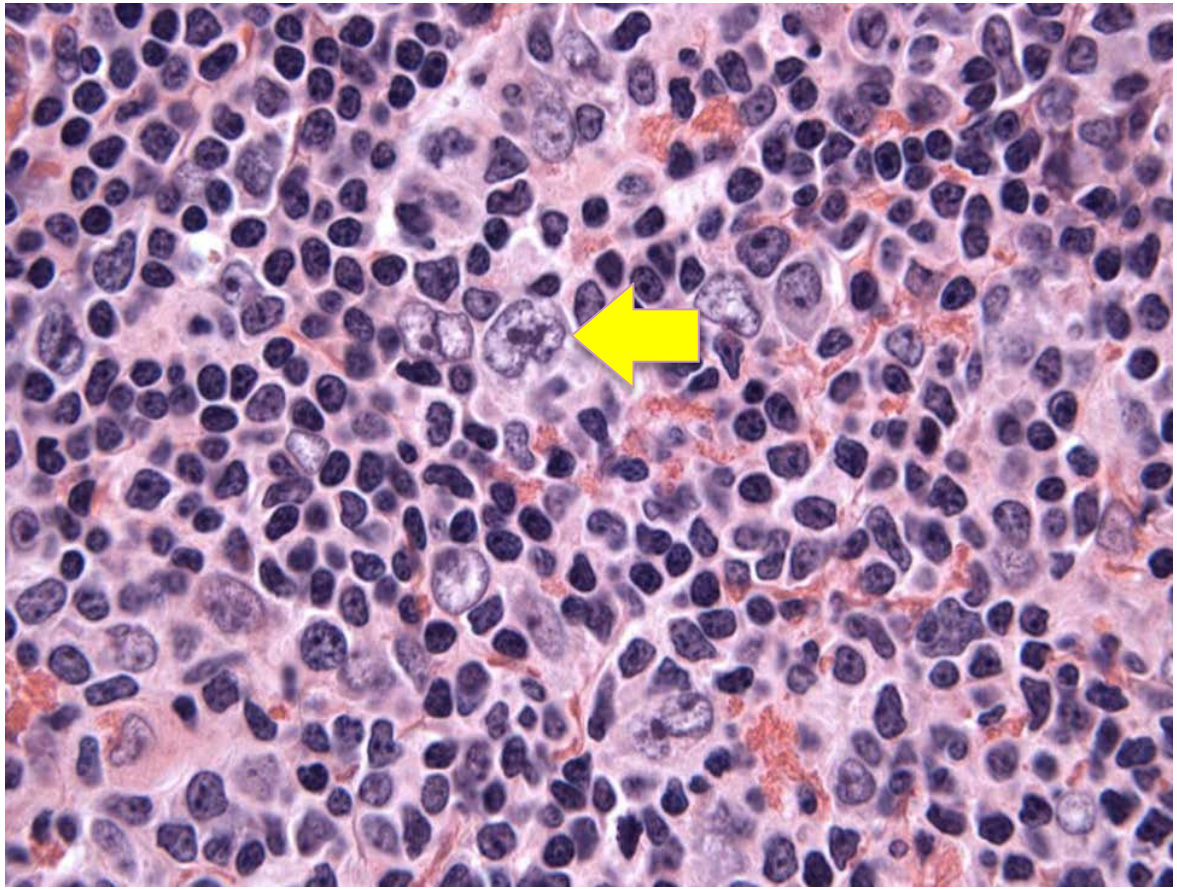
Incidence

- 5% of all HL
- 1.5 / 1m population/ y
- Recently recognized category:
  - 1944: Jackson & Parker: granuloma variant of HL
  - 1994: REAL classification (CD20+ LP, L&H/ popcorn cells)
  - 2001: WHO (separated from cHL as NLP)
- No prospective studies:
  - Re-analysis of previous studies
  - Institutional / registry based retrospective studies

Characteristics

- Histology:
  - LP cells: b-cell markers (CD20, CD79a, CD45) but not CD15, CD30
  - Initially thought: similar to FL, but now thought to be closest to DLBCL (particularly T-cell-rich)
  - NFkB activation
  - DD: progressive transformation of germinal centre.

Popcorn cell



Characteristics (2)

- Clinically:
  - Long history of lymphadenopathy
  - Male predominance (75%)
  - Familial risk described
  - Mediastinal sparing
  - EN sites rare

Characteristics (3)

- Prognosis:
  - Early stage: highly curable
  - Advanced stage: multiply relapsing
  - Transformation to HG-NHL particularly TCR-DLBCL
    - 10 y risk 10-12%
    - 20 y risk up to 30%
    - Risk fs: advanced stage, spleen / abdominal presentation
  - Importance of Bx of every relapse + long FU
  - Death due to NLP is uncommon

Diagnostic work up

- As cHL

- NLP is FDG avid:
  - PET is useful for staging and response assessment.
  - Essential for early stage managed by RT alone (more accurate staging)
  - Useful for RT planning

Management

- Generally:
  - Early stage: RT
  - Advanced stage: systemic treatment
- Important considerations in Treatment:
  - Early:
    - Volume & dose of RT
    - Role of CMT
    - Role of excision alone
  - Advanced:
    - Which chemo
    - Role of Rituximab

CMT / Chemo for early stage

- No RCT
- RT outcome is excellent. Difficult to improve on.
- Limited data on role of CMT in early stage dis
  - *Canadian* data on short course ABVD suggests benefit
  - but other studies (*MDACC, GHSG, Harvard*) show no benefit
  - RT alone remains standard
- Chemo alone strategy in children: limited data
- Rituximab alone: limited data (GHSG 28 pts, Stanford 13 pts):
  - 100% response, but 25% relapse. Not recommended.

Treating limited-stage nodular lymphocyte predominant Hodgkin lymphoma similarly to classical Hodgkin lymphoma with ABVD may improve outcome

Kerry J. Savage,[1] Brian Skinnider,[2] Mubarak Al-Mansour,[1] Laurie H. Sehn,[1] Randy D. Gascoyne,[2] and Joseph M. Connors[1]

[1]Centre for Lymphoid Cancer and Department of Medical Oncology, British Columbia Cancer Agency and the University of British Columbia, Vancouver, BC; and
[2]Centre for Lymphoid Cancer and Department of Pathology, British Columbia Cancer Agency, Vancouver, BC

The appropriate therapy for limited-stage nodular lymphocyte predominant Hodgkin lymphoma (NLPHL) is unclear. In contrast to classical Hodgkin lymphoma (CHL), chemotherapy is often omitted; however, it is unknown whether this impacts the risk of relapse. Herein, we compared the outcome of patients with limited-stage NLPHL treated in an era in which ABVD (doxorubicin, bleomycin, vinblastine, and dacarbazine) chemotherapy was routinely incorporated into the primary therapy to an earlier era in which radiotherapy (RT) was used as a single modality. Using the British Columbia Cancer Agency Lymphoid Cancer Database, 88 patients with limited-stage NLPHL (stage 1A/1B or 2A, nonbulky disease < 10 cm) were identified. Treatment followed era-specific guidelines: before 1993, (n = 32) RT alone; and 1993 to present (n = 56), ABVD-like chemotherapy for 2 cycles followed by RT with the exception of 14 patients who received ABVD chemotherapy alone. Most patients were male (75%) with stage I disease (61%). In an era-to-era comparison, the 10-year time to progression (98% vs 76% $P = .0074$), progression-free survival (91% vs 65% $P = .0024$), and OS (93% vs 84%, $P = .074$) favored the ABVD treatment era compared with the RT alone era. Treating limited-stage NLPHL similarly to CHL may improve outcome compared with the use of radiation alone. (*Blood*. 2011;118(17): 4585-4590)

A B S T R A C T

Purpose
The optimal treatment of stage IA nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is not well defined. Thus, we performed an analysis using the database of the German Hodgkin Study Group.

Patients and Methods
The long-term outcome of 256 patients with stage IA NLPHL was evaluated. Patients had received combined-modality treatment (CMT; n = 72), extended-field radiotherapy (EF-RT; n = 49), involved-field radiotherapy (IF-RT; n = 108), or four weekly standard doses of rituximab (n = 27) within German Hodgkin Study Group clinical trial protocols between 1988 and 2009.

Results
The median age at NLPHL diagnosis was 39 years (range, 16 to 75 years). Most patients were male (76%). The whole patient group had a median follow-up of 91 months (CMT: 95 months; EF-RT: 110 months; IF-RT: 87 months; rituximab: 49 months). At 8 years, progression-free survival and overall survival rates were 88.5% and 98.6% for CMT, 84.3% and 95.7% for EF-RT, and 91.9% and 99.0% for IF-RT, respectively. Patients treated with rituximab had 4-year progression-free and overall survival rates of 81.0% and 100%, respectively. A second malignancy during the course of follow-up was diagnosed in 17 (6.6%) of 256 patients. A total of 12 deaths occurred. However, only one patient died from NLPHL.

Conclusion
Tumor control in this analysis was equivalent with CMT, EF-RT, and IF-RT. Therefore, IF-RT, which is associated with the lowest risk for the development of toxic effects, should be considered as standard of care for patients with stage IA NLPHL. Rituximab alone is associated with an increased risk of relapse in this patient population.

Radiotherapy (cont.)

- Dose:
  - No conclusive evidence of benefit >30Gy
  - 4Gy: inferior outcome *(local relapse 5/8 pts)*
  - NCCN: 30-36 Gy, ESMO: 30 Gy
  - Standard: 30 Gy……36Gy for bulky disease? (uncommon)

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Key points

- Rare, indolent
- Male predominance, mediastinal sparing
- Better prognosis than cHL, rarely cause of death.
- Tendency to transform
- RT alone for early stage: excellent outcome
- Generous ISRT (no chemo)
- Resection is an option only for children

The role of radiotherapy in Early stage stage HL

Tim Illidge MD PhD

Professor of Targeted Therapy and Oncology,

Institute of Cancer Sciences

University of Manchester,

Manchester Academic Health Science Centre,

The Christie NHS Foundation Trust, UK

Overview of talk

1. **Review clinical data on management of early stage HL**

– *Should combined modality treatment still be the standard approach ?*

2. **Recent progress in using FDG PET to guide therapy and delivery of RT in HL**

- *Are we ready to make treatments decisions based on FDG-PET to potentially omit RT ?*

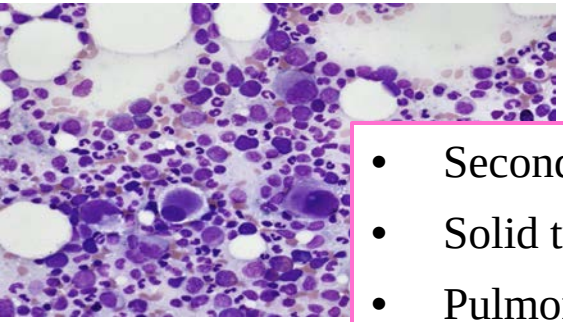
ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

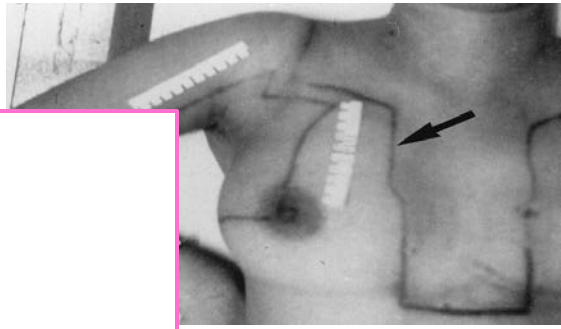
ESTRO School

Overall results of therapy for early disease

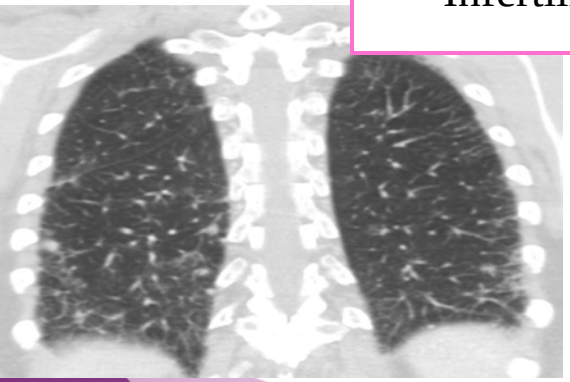
- Up to 90% cures with first line therapy
- About 95% alive at 5 years
- Primary focus of research is to
  - maintain (? improve) this result
  - minimise toxicity

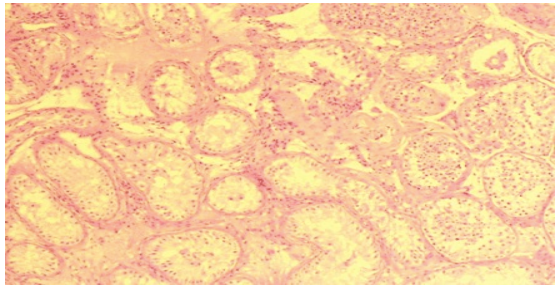
Late effects to avoid as cures increase

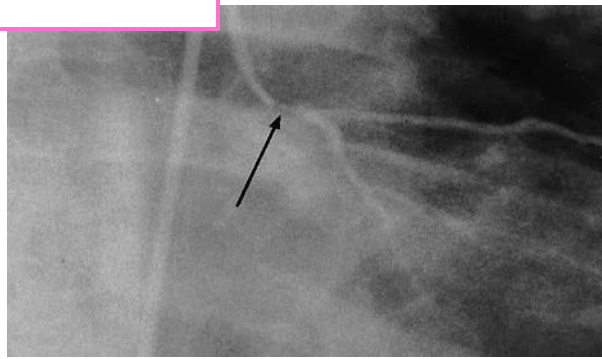




- Secondary MDS/AML from alkylating agents
- Solid tumours from extended field radiation
- Pulmonary fibrosis from bleomycin
- Ischaemic heart disease from mediastinal irradiation and doxorubicin
- Infertility from alkylating agents







Clinical risk-adapted and PET response-adapted approaches

Clinical Risk adapted:

To what degree can we reduce treatment based on clinical prognostic data?

Clinical response adapted:

Is functional imaging response on FDG-PET a better indicator of prognosis?

(and will modifying therapy according to PET CT improve Overall Survival)

Objectives in Early stage Hodgkin Lymphoma

Current standard of care : Baseline risk stratification

	EORTC	GHSG	NCIC/ECOG	NCCN 2010
Risk factors	a) Large mediastinal mass (> 1/3) b) Age ≥50 years c) ESR ≥50 without B-symptoms or ≥30 with B-symptoms d) ≥4 nodal areas	a) Large mediastinal mass b) Extranodal disease c) ESR ≥50 without B-symptoms or ≥30 with B-symptoms d) ≥3 nodal areas	a) Histology other than LP/NS b) Age ≥40 years c) ESR ≥50 d) ≥ 4 nodal areas	a) Large mediastinal mass (> 1/3) or > 10 cm b) ESR ≥50 or any B-ysmptoms c) ≥3 nodal areas d) > 1 extranodal lesion
Favorable	CS I-II (supradiaphragmatic) without risk factors	CS I-II without risk factors	CS I-II without risk factors	CS I-II without risk factors
Unfavorable	CS I-II (supradiaphragmatic) with ≥1 risk factors	CS I or CS IIA with ≥1 risk factors CS IIB with c) or d) but without a) and b)	CS I-II with ≥ 1 risk factors	CS I-II with ≥ 1 risk factors (differentiating between bulky disease and other risk factors for treatment guidelines)

Results from the trials
Early stage disease

- Chemotherapy improves the cure rate over radiation alone (EORTC-H7)
- Sub-optimal chemotherapy (EBVP) needs RT for best results (EORTC-H9)
- Reducing size of the radiation field is safe
- Reducing the radiation dose is possible for good prognosis disease, or after adequate chemotherapy
- Omitting radiotherapy altogether may be possible for some patients: can we predict who they are?

TOTAL	11	23

*Alzheimer disease, drowning, suicide, resp failure, unknown

From Meyer R *et al. NEJM* 2012;366:399-408

NCIC CTG ECOG HD.6 Trial
Small numbers and unusual events

- Unusual deaths correct from statistical point of view - misleading not attributable to radiotherapy.
- No death of "other" causes in chemotherapy alone group or in STNI favourable group. Imbalance misleading in favour of chemotherapy alone group.
- Without these unusual events - negative study without a survival difference but with a significantly better tumor control for the RT group
- Imbalance due to an undersized and incompletely recruited study with a small number of events.

What do we learn from NCIC/ECOG HD6 ?

- Improving long term OS depends on :
  - Effective initial therapy. RT leads to better disease control
  - Developing treatment approaches with less late toxicity (second cancers, lung injury, cardiac toxicity, infertility) is important to improving long term survival
- Small studies with just a few unusual events can influence conclusions much less likely to happen in large studies

What don't we learn from HD6 ?

- How does full course (4-6) ABVD compare with 2 x ABVD and modern small RT field : PFS and OS, patient tolerability and quality of life

- What are the acute and late consequences of replacing 2 x ABVD and modern small RT field versus more cycles of chemotherapy ?

No RCT to address questions

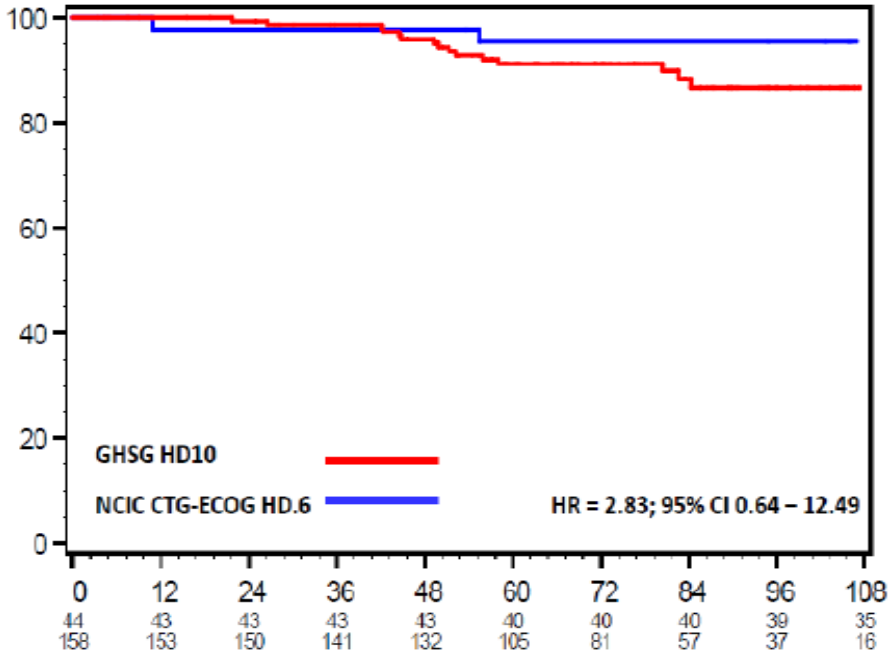
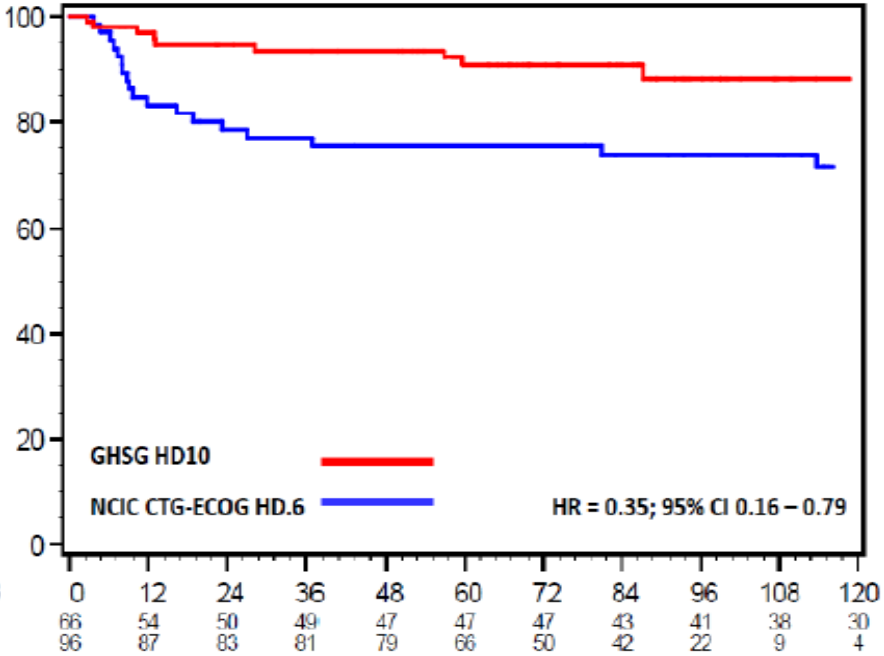
Combined Modality vs ABVD alone

Status after 2xABVD (HD10 eligible pts; PFS)





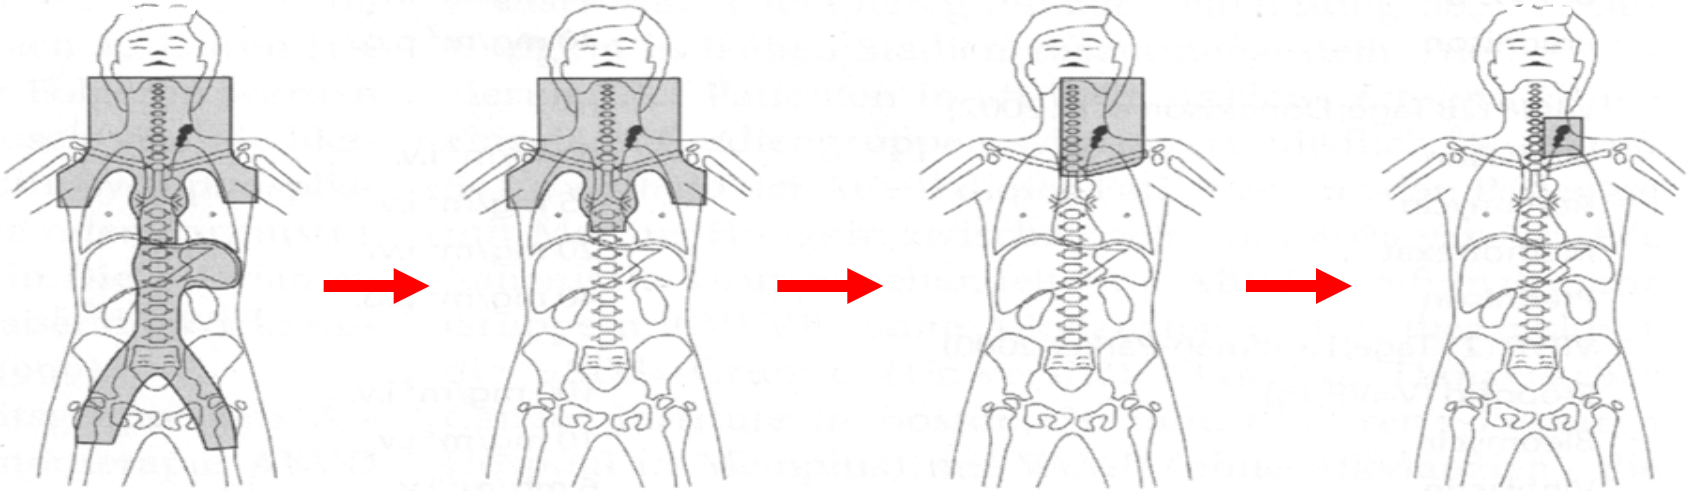
CR/CRu | **No CR/CRu**

Hay A et al, ASH 2012

Key questions in using Combined Modality Treatment in early stage HL

- Is the initial gain in local control with RT offset by the long term risks of RT ?
- Do modern RT approaches with substantial reduction in field size and RT doses maintain excellent initial control and reduce late toxicities leading to improved long term survival over chemotherapy alone ?

Transformation of RT Volumes / Doses in HL
ISRT – Specht L et al IJROBP 2014



Total nodal **Regional nodal** **Involved field** **Involved site**

Dose: 30-44 Gy → **20-30 Gy**

Two thirds of women with early-stage HD do not require radiation of the axillae
Substantial reduction in breast, lung cancer risk, cardiac morbidity

The Challenge of ^{18}FDG PET CT in HL : Converting large SUV numbers into Binary (Positive / Negative) and making sense of it

- Can we use FDG-PET to select patients who can be cured with less chemotherapy and no RT ?
- Primary objective UK NCRI RAPID and EORTC H10 trials
  - Is chemotherapy alone as effective - but less toxic to combined modality treatment in patients with CS I/II HL in terms of PFS in patients who are FDG-PET scan negative* after 3 cycles (UK NCRI) or two cycles (EORTC H10) of ABVD? *(non-inferiority)*

Omitting radiotherapy in early positron emission tomography-negative stage I/II Hodgkin lymphoma is associated with an increased risk of early relapse: Clinical results of the preplanned interim analysis of the randomized EORTC/LYSA/FIL H10 trial.

Raemaekers JM, et al; J Clin Oncol. 2014 Apr 20;32(12):1188-94

- Analysis included 1,137 patients.
  - Favorable subgroup - 85.8% negative early PET scan
  - Unfavourable subgroup - 74.8% negative early PET scan

- IDMC concluded unlikely to show non-inferiority in the final results for the experimental arm and advised stopping random assignment for early PET-negative patients.

- CONCLUSION: CMT resulted in fewer early progressions in clinical stage I/II HL, although early outcome was excellent in both arms. The final analysis will reveal whether this finding is maintained over time.

Conclusions for FDG PET in Early HL

- Using FDG PET may be possible to identify a group of patients with an excellent “early” outcome from chemotherapy alone
- EORTC H10 trial – failed to achieve this goal
  - Favorable subgroup: 14.2% positive early PET scan
- UK NCRI RAPID results were achieved in the setting of
  - Very conservative definition of PET negative 25.3 % PET positive
  - Quality controlled PET image acquisition / Central review of PET images at the Core Lab
  - What is the QA like in your routine clinical practice ?
- Longer follow-up is required to establish the impact of a PET negative approach on 10 and 20 year survival and cause of death

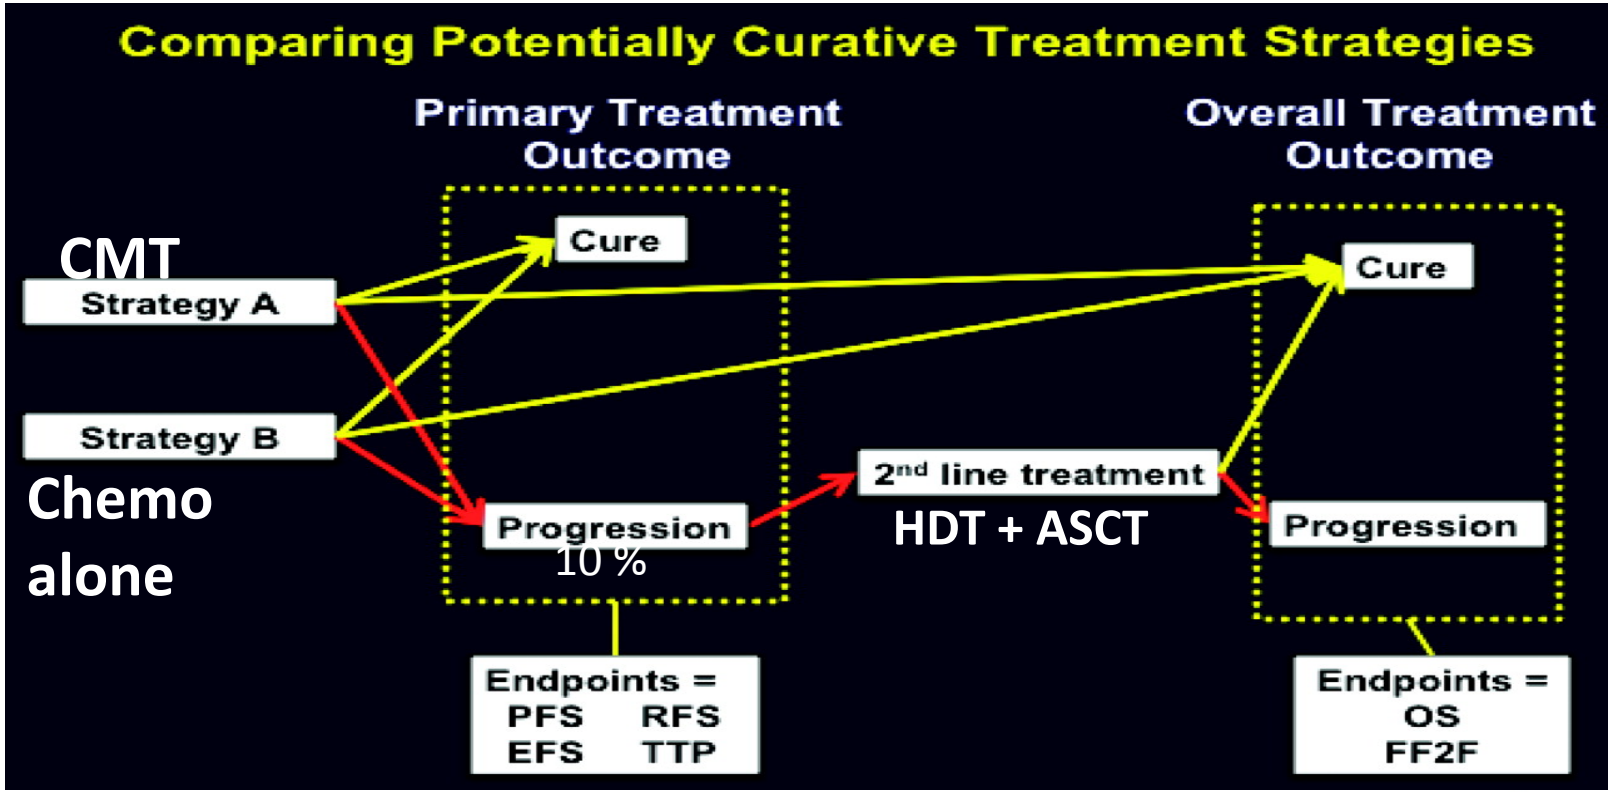
How to compare the effectiveness of two potentially curative treatment strategies.



Connors J M The Oncologist 2012;17:1011-1013

Which Patients with Stage I-II Hodgkin Lymphoma for Contemporary Combined Modality Therapy in PET era ?

- As a treatment option for patients with favorable disease, especially when risk late toxicity of RT considered lower than risk of relapse (Age, site of disease, sex)
- Older patients –risks associated with ABVD
- Definitely for patients with a positive interim PET scan (~25%)
- Definitely for patients with large mediastinal adenopathy - female patients ?

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Conclusions

- Large numbers of well conduction RCT supporting CMT in early stage HL
- Lack of randomised trials comparing chemotherapy alone vs contemporary CMT.
- Recent FDG-PET data inform patient specific discussions about risk of relapse (increased with chemo alone) versus late toxicity (increased with CMT)
- Response adapted treatment using FDG PET - Ongoing challenges to implement in routine clinical practice and QA measures are required to meet Deauville criteria

Treatment of advanced stage HL

- Background
- ABVD, BEACOPP
- Radiotherapy in advanced stage HL
- Summary

Advanced stage HL

Summary

- HL became curable with the introduction of multi-agent chemo
- ABVD associated with 65-70% PFS and 75-80% OS @5yrs
- B.esc gave 15-20% better PFS and 10-15% better OS than ABVD
- Treatment-related mortality and 2nd npl of BEACOPP similar to ABVD; more hematotox and infertility
- 6xB.esc: tumour control 89%, OS 95%; PET-guided RT (HD15)
- B.esc not to be used in pts >40 yrs and poor performance
- Ongoing trials evaluate PET-guided strategies and combining BV with ABVD (enhance efficacy) BEACOPP (reduce toxicity)

ORIGINAL REPORT

Consolidation Radiotherapy in Patients With Advanced Hodgkin's Lymphoma: Survival Data From the UKLG LY09 Randomized Controlled Trial (ISRCTN97144519)

Peter W.M. Johnson, Matthew R. Sydes, Barry W. Hancock, Michael Cullen, John A. Radford, and Sally P. Stenning

Patients and Methods

Patients were randomly assigned between doxorubicin, bleomycin, vinblastine, and dacarbazine and one of two prespecified multidrug regimens. At least six cycles of chemotherapy were planned, with up to eight for patients showing slower response. Involved-field RT was recommended for incomplete response to chemotherapy or bulk disease at presentation. The primary outcome measure was progression-free survival (PFS), landmarked from the end of chemotherapy.

Results

Among 807 patients randomly assigned, 702 achieved objective response. Postchemotherapy RT for consolidation was reported in 300 (43%). With median follow-up of 6.9 years, 161 PFS events and 83 deaths were reported. Baseline characteristics showed more patients with bulk disease having RT (190 [63%] *v* 111 [28%]) and only partial response after chemotherapy (150 [50%] *v* 36 [9%]). Other baseline characteristics were similar. PFS was superior for patients having RT (hazard ratio [HR], 0.43; 95% CI, 0.30 to 0.60) with 5-year PFS 71% without RT, 86% with RT. A similar advantage was seen for overall survival (HR, 0.47; 95% CI, 0.29 to 0.77). There was no evidence of heterogeneity of treatment effect across subgroups.

Response	—		—		—		1.40	1.12 to 1.76
Chemotherapy cycles	—		—		—		0.96	0.72 to 1.27

Conclusion

Patients who received consolidation RT apparently had better outcomes, consistently across all prognostic groups which persisted in multivariate analysis. This suggests that RT contributes significantly to the cure rate for advanced HL, although patient selection for combined modality treatment requires better definition in prospective trials.

J Clin Oncol 28:3352-3359.

Randomized study of consolidation RT vs. Observation in bulky (>5cm) HL patients who became PET-negative after chemotherapy

- 260 pts. with bulky (>5cm) HL received chemotherapy (VEBEP)
- 30 non-responders. 70 CT-negative and PET-negative
- 160 PET negative with CT≥1.3cm RANDOMIZED
- 80 pts. - Observation
- 80 pts.- IFRT (32 Gy)

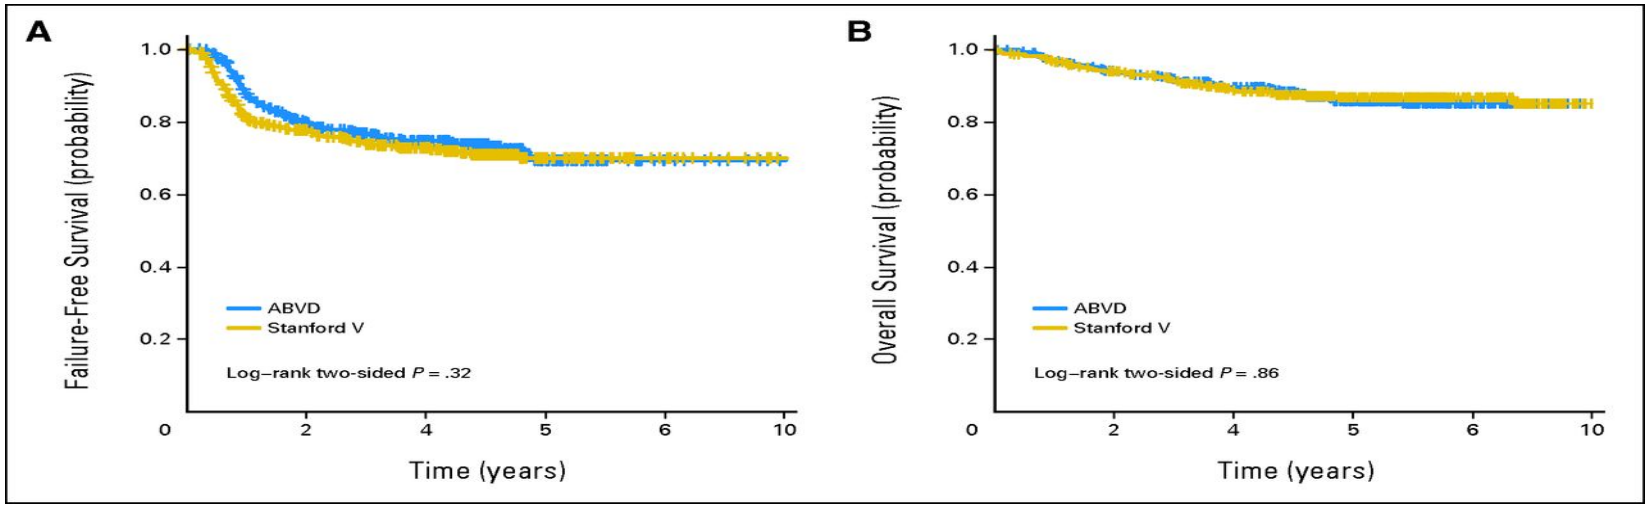
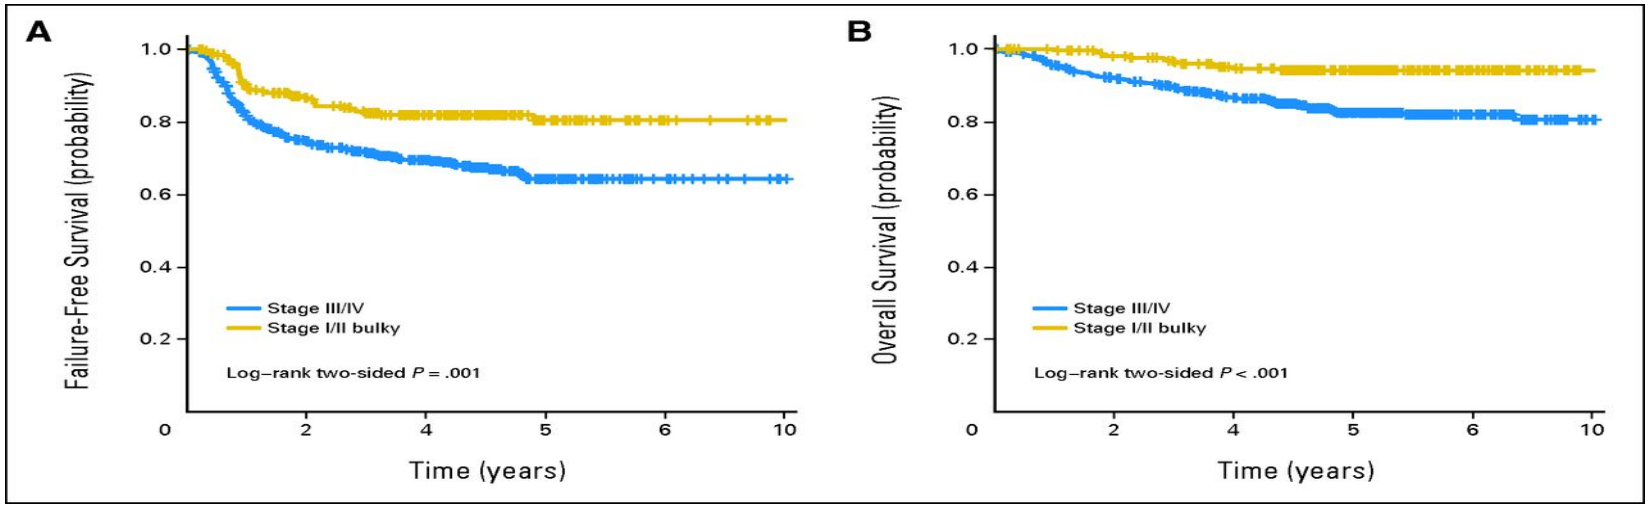
(A) Failure-free (P = .32) and (B) overall survival (P = .86) are shown for all patients, showing no difference between the two arms.



Gordon L I et al. JCO 2013;31:684-691

JOURNAL of CLINICAL ONCOLOGY ASCO

Patients with locally extensive disease (stage I to II bulky) were compared with patients with advanced disease (stage III to IV); patients with locally advanced disease had better (A) failure-free survival (FFS; P = .001) and (B) overall survival (OS; P = ...



Gordon L I et al. JCO 2013;31:684-691

CONCLUSIONS

- There was no significant difference in RR, FFS, OS and 5-year toxicity when ABVD (+RT for BMD) is compared with Stanford V (+ RT for nodal sites >5 cm and macroscopic splenic disease)
- Overall toxicity between the 2 arms was similar, but more lymphopenia and neuropathy was seen in Stanford V
- ***ABVD remains the standard of care***
- Patients with locally extensive disease do better than patients with advanced disease
- For patients with 3-7 IPS risk factors, there is a trend favoring ABVD as measured by FFS

RT in GHSG BEACOPP Studies (1)

- HD 9 established the advantage of escalated BEACOPP. It included 30-40 Gy IFRT to over 2/3 of patients (bulky and/or residual disease).
- In HD 12 esc. BEACOPP cycle reduction and randomization to +/- RT were studied.
- Less esc. BEACOPP was inferior to 8 esc. BEACOPP, but not less toxic.
- FFTP was inferior with no RT particularly if residual CT abnormality. “Our results do not support the omission of consolidation RT for patients with residual disease”.

.

RT in GHSG BEACOPP Studies (2)

- HD15 (Engert et al. Lancet 2012) showed that BEACOPP X6 was as effective and less toxic than BEACOPP X8. OS was better due to less treatment related toxic deaths.
- PET was used for post-chemo evaluation, only if residual CT abnormality (39% of patients).
- There was no randomization to +/- IFRT.
- RT was given only to PET-positive patients (30% of those who had PET). Total receiving RT was 11% compared to 71% in HD9.
- PET- negative patients had outcome similar to CT evaluated CR/Cru and better that those with residual PET.
- The study did not evaluated the contribution to RT to a small remaing number of patents with CT residual mass that remained PET positive, but suggests that with optimal escalated BEACOPP CT-CT patents and PET-CR patients do well with no RT.

.

Reduced-intensity chemotherapy and PET-guided radiotherapy in patients with advanced stage Hodgkin's lymphoma (HD15 trial): a randomised, open-label, phase 3 non-inferiority trial

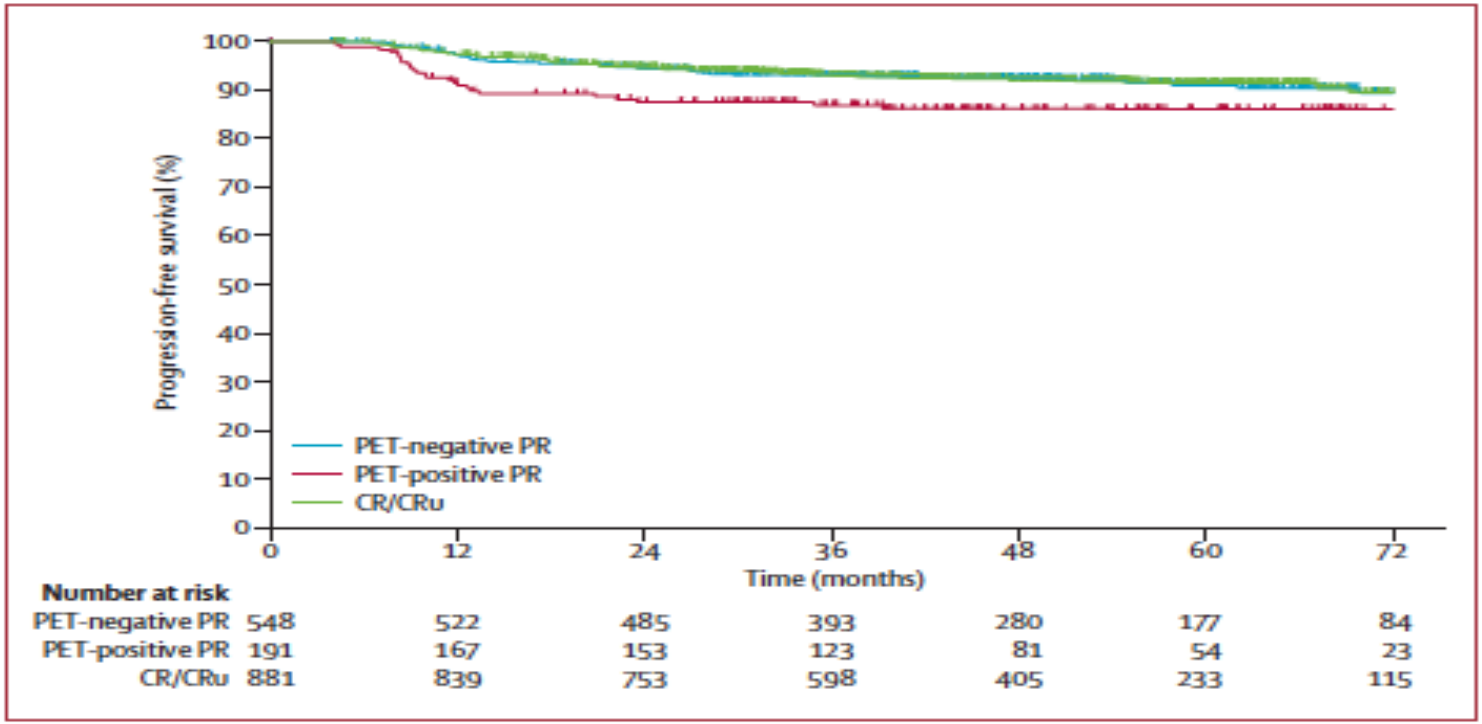


Figure 3: Progression free survival for PET study objective

When RT should be considered in “advanced-stage”?

- With regimens with less excessive chemotherapy (ABVD X6; BEACOPP X6, Stanford V)
- Older patients (>50) tolerate intensive/long chemotherapy poorly.
- Patients with contra-indications for aggressive chemotherapy
- Patients with predominantly bulky site(s)
- Patients with residual disease after chemotherapy
- **Patients with residual disease that remain PET (+)**

RT in Salvage of Refractory or Relapsed patients

- Too many are “salvaged” and re-salvaged without RT and continue to fail in a single site
- NO cross-resistant with chemotherapy (often forgotten)
- RT may (although rarely) be curative as asingle salvage agent
- Best is to design and incorporate RT as part of the salvage protocol
- RT i may be incorporated as:
  - An integral part of the response induction (into PET negative status)
  - As a component of the high-dose transplant regiment (using TLI)
  - As a consolidation post-transplant (to residual or bulky disease)

39 yo woman in CR after ABVD X6 for HL

Radiation Therapy for HD

Recent Trends

- Radiation alone - obsolete
- Combined modality programs
  - Radiation fields – markedly reduced (ISRT by ILROG)
  - Radiation dose – from 40 Gy to 20-30 Gy
- Chemotherapy alone
  - Advanced-stage
  - Early-stage **(>50% of U.S. patients, most women)**

In the United States RT is less commonly used in the management HL
the consequences

- **With the use of PET scans upstaging to stages III/IV is not uncommon; hence less RT is used**
- **How have radiotherapists optimized treatment?**
  - **When administered, Radiation fields are smaller (IF-RT) and doses are lower than in past decades**
  - **More than 2/3 of women do not need axillary irradiation, resulting in minimal (<10%) or no breast exposure**
  - **Bulk decrease by chemotherapy and the benefit of modern imaging allows further radiation field reduction (mediastinum)**
  - **Radiation dose has been cut back from >40 Gy to 30 Gy and more recently to 20 Gy (50% reduction**
- **For unfavorable and bulky stage II HL too many physicians forget that the relapse rate is higher with chemotherapy alone compared to CMT; most failures occur in sites of previous nodal disease!**
- **Most patients who fail chemotherapy alone are still HIGHLY curable but now they need HDT**
  - **Can this paradigm change?**

From medical oncology salvage leader:

- **‘’The fear of RT must stop; it remains the single most effective treatment for HL’’**

HL: the numbers

- 9200 cases estimated in US in 2013-SEER Data

- Approximate numbers based upon MSKCC long term data (GHSG for Early HL, IPI-based for Advanced HL)

  - Favorable Early HL: 15%
  - Unfavorable Early HL: 25%

  - Bulky stage II disease: 20%

  - Favorable Advanced HL (0-3 RF): 30%
  - Unfavorable Advanced HL (4-7 RF): 10%

Memorial Sloan Kettering Cancer Center

High-Dose Therapy Salvage of Hodgkin Lymphoma Enhanced by RT: 30 Years of Experience

MSKCC HL- Salvage with Transplantation Program

- Five consecutive prospective studies (1985, 1994, 1998, 2004, 2011)
- Approx. 500 patients (~18/year)
- Long-term and quality of life study

MSKCC HL- Salvage with Transplantation Program

- All progression/relapses- biopsy proven
- Two-step chemo salvage
  - *Standard dose re-induction*
  - ***High dose***
- Involved-field RT <u>always pre-transplant</u>
- TLI part of the conditioning regimen in previously unirradiated patients

Salvage Therapy of Hodgkin Lymphoma – Why RT?

- Chemotherapy failed in these patients
- Many patients had minimal or no exposure to radiation
- Chemotherapy failures remain responsive to RT
- Previously irradiated sites are amenable to meaningful additional RT by avoiding dose-limiting organs

Integrating Radiotherapy - *Rationale*

- Non-cross-resistant with chemotherapy
- Predictable pattern of relapse
- Unlimited penetration
- Selectivity of dose to site

Integrating Radiotherapy- *Concerns*

- Toxicity
- Treatment delay
- Availability and/or coordination of radiation oncology

Integrating Radiotherapy - *Options*

- ~~Total Body Irradiation~~
- **Post-transplantation RT** to selected sites / patients
  - Delayed or never happens
  - Less effective?
  - Toxic to regenerating marrow (MDS)

Integrating Radiotherapy - *Preferred*

- **Pre-transplantation RT** as part of the response-inducing regimen

✓ Induce maximal tumor reduction when it is most critical

✓ Differential dose to relapse/bulky site vs. all nodal sites (TLI)

✓ Completed within 10 days (36 Gy b.i.d program)

✓ Safe and rarely toxic

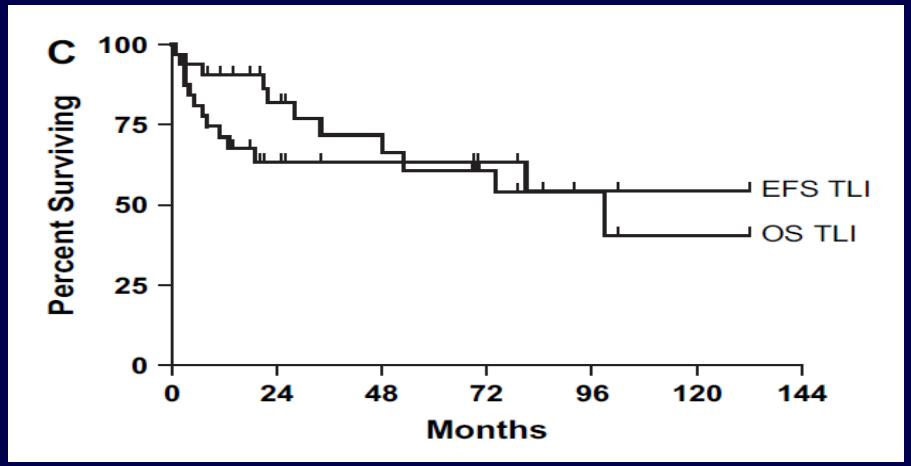
✓ Non-myelosuppressive or leukomogenic

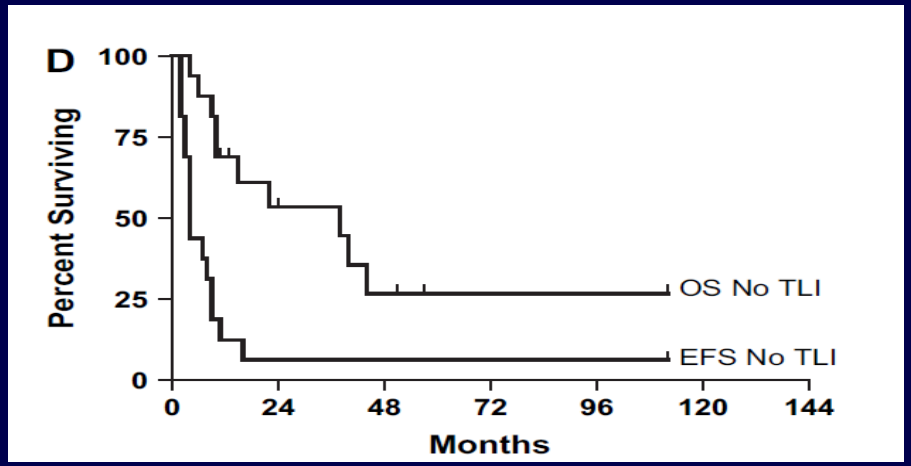
Phase I/II Trial of TLI vs High-Dose Chemotherapy Salvage Regimen

- Patients with primary refractory/relapsed HL (n=48; 1993-2005)
- Conditioning regimen:
  - TLI/chemotherapy
  - Chemotherapy-alone (if prior RT >2000cGy had been given)
- TLI details:
  - Accelerated hyperfractionated TLI 150cGy x10
  - Boost to previous and current disease to 150cGy x10
  - BID regimen
  - Pre-transplant
- Chemotherapy regimen:
  - Carboplatin
  - Cyclohosphamide
  - Etoposide

Evens et al., Ann Oncol 2007

Phase I/II Trial of TLI vs High-Dose Chemotherapy Salvage Regimen





5-year EFS for TLI/chemo vs chemo alone: 63 vs 6% (p<0.0001)

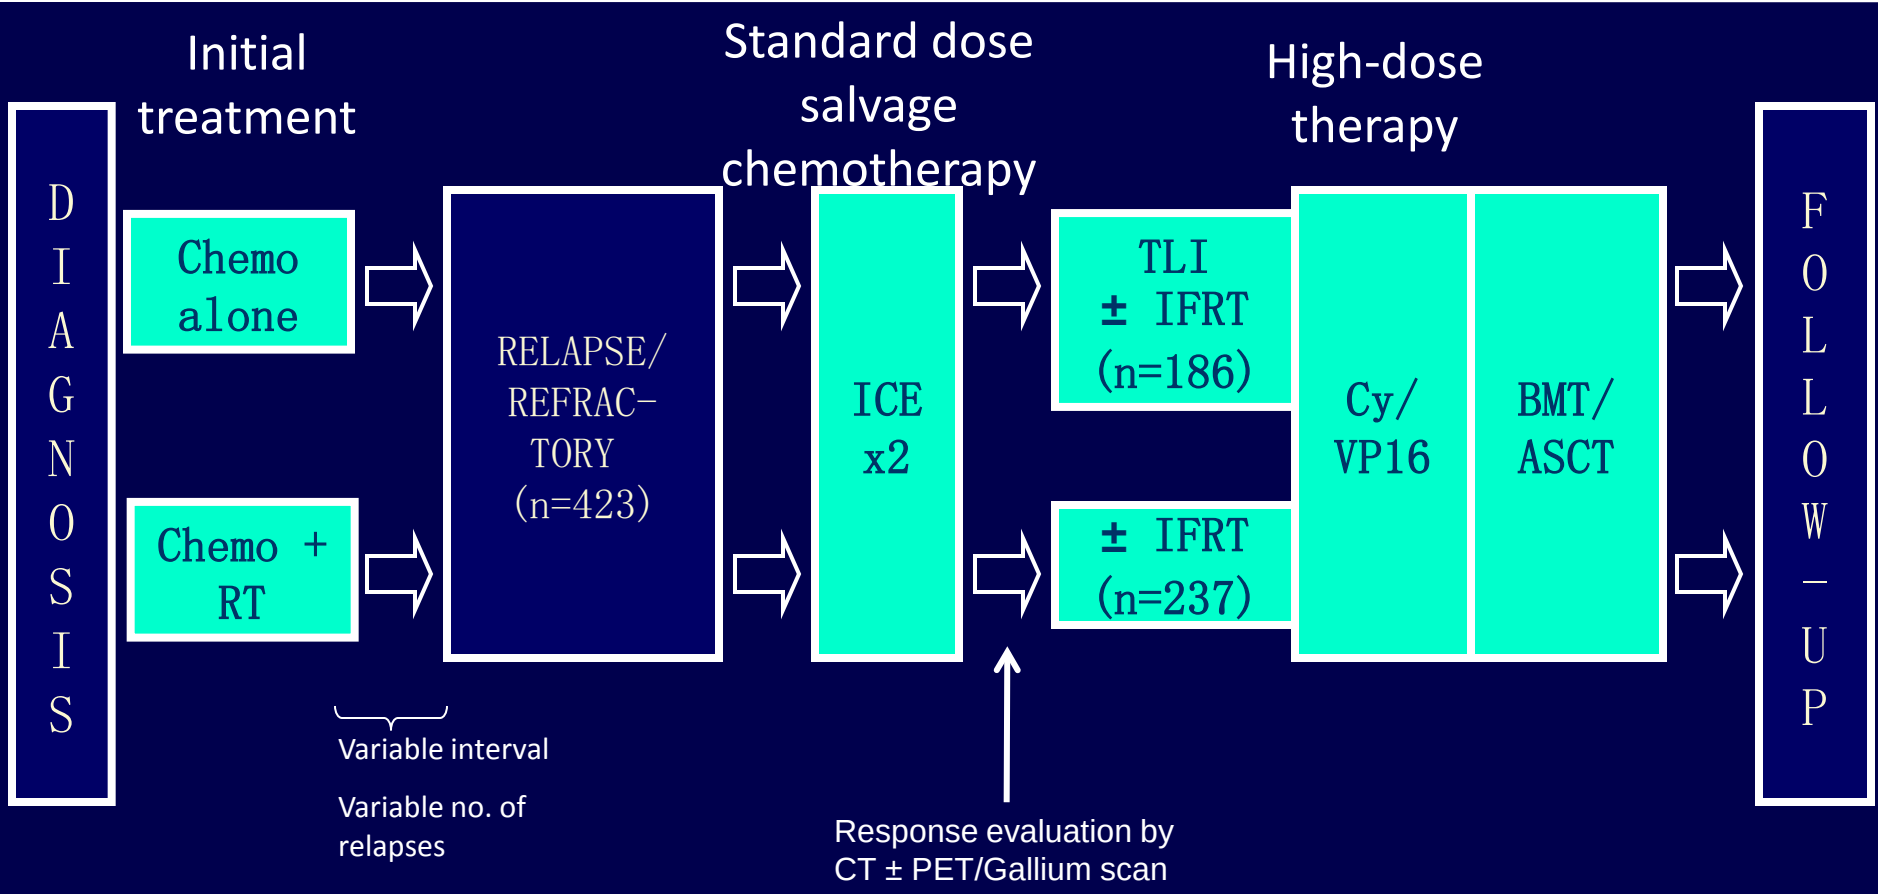
5-year OS for TLI/chemo vs chemo alone: 61 vs 27% (p=0.04)

Predictive factors for EFS: TLI/chemotherapy regimen

Prognostic factors for OS: B-symptoms at relapse

Evens et al., Ann Oncol 2007

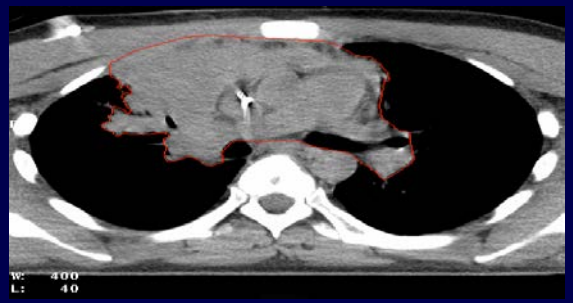
Management of Relapsed HL @MSKCC

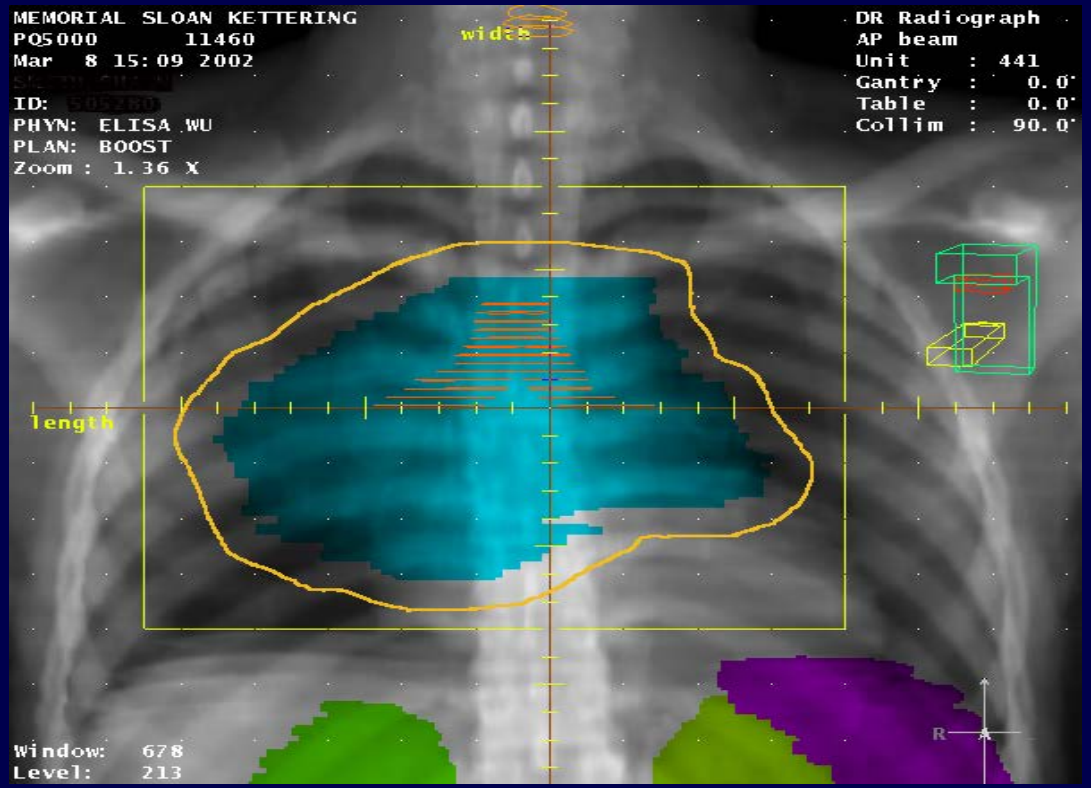


Advantages of Integrated RT in High-Dose Therapy Regimen

- Quick treatment (all treatment delivered over 10 days)
- No interference of RT with salvage chemotherapy and high-dose therapy
- Acute toxicity occurs when patients already admitted for transplantation
- RT pre-ASCT avoids irradiating newly engrafted cells

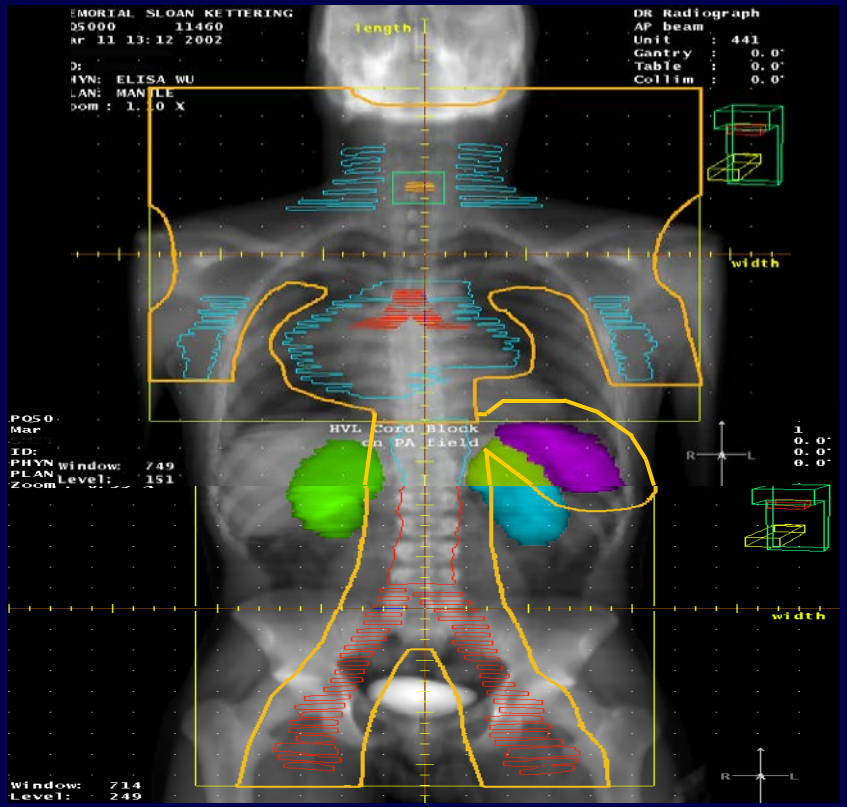
Boost Field (IFRT)





180 cGy x10 fractions
BID

TLI Field



180 cGy x10
fractions BID

MSKCC Clinical Research Program of Salvage for Hodgkin Lymphoma 1985-2015

- First Generation (1985-1994): 146 pts.
  - Various salvage therapy
  - Pre-transplant IF-RT
  - TLI+CV or CBV/BMT
- Second Generation (1994-1998): 81 pts.
  - Intent to treat analysis
  - ICE salvage therapy
  - IF-RT
  - TLI+CV or CBV/ASCT
- Third Generation (1998- 2004): 105 pts.
  - Risk-adapted program
  - Same principles as 2nd
- Fourth Generation (2004- 2009 98 pts.
  - Achieve minimal disease state pre-ASCT
  - Add GND if PET remains positive
  - Same risk-related concept
- Fifth Generation (2011-2014)
  - Brentuximab followed by ICE—ISRT ± STLI – ASCT 45 pts.

Total = 475 pts.

ATHERA trial post-transplant BV maintenance (2010-2014)

Thyroid	1	(0.5%)	0	(0%)

Second Malignancies

Number of deaths from second malignancies: 5

Total incidence of second malignancies: 11

- AML (2)
- MDS (1)
- DLBCL (1)
- NHL (1)
- Thyroid (1)
- Lung (1)
- Stomach (1)
- Colon (1)
- Unknown primary (1)

Summary

- Between 10 and 40% of patients with HL fail after initial therapy.
- Patients failing after chemotherapy alone are candidates for salvage RT.
- IFRT/ISRT followed by TLI integrated with high-dose chemotherapy is an effective, feasible and safe salvage therapy for patients with previously unirradiated, relapsed/ refractory HL.
- On multivariate analysis, CR to standard-dose salvage chemotherapy is the most important predictive factor for long-term OS, EFS and DSS after HDT.
- Primary refractory disease and extranodal disease at relapse are associated with worse outcome.
- Long-term morbidity and second malignancy rates are relatively low.

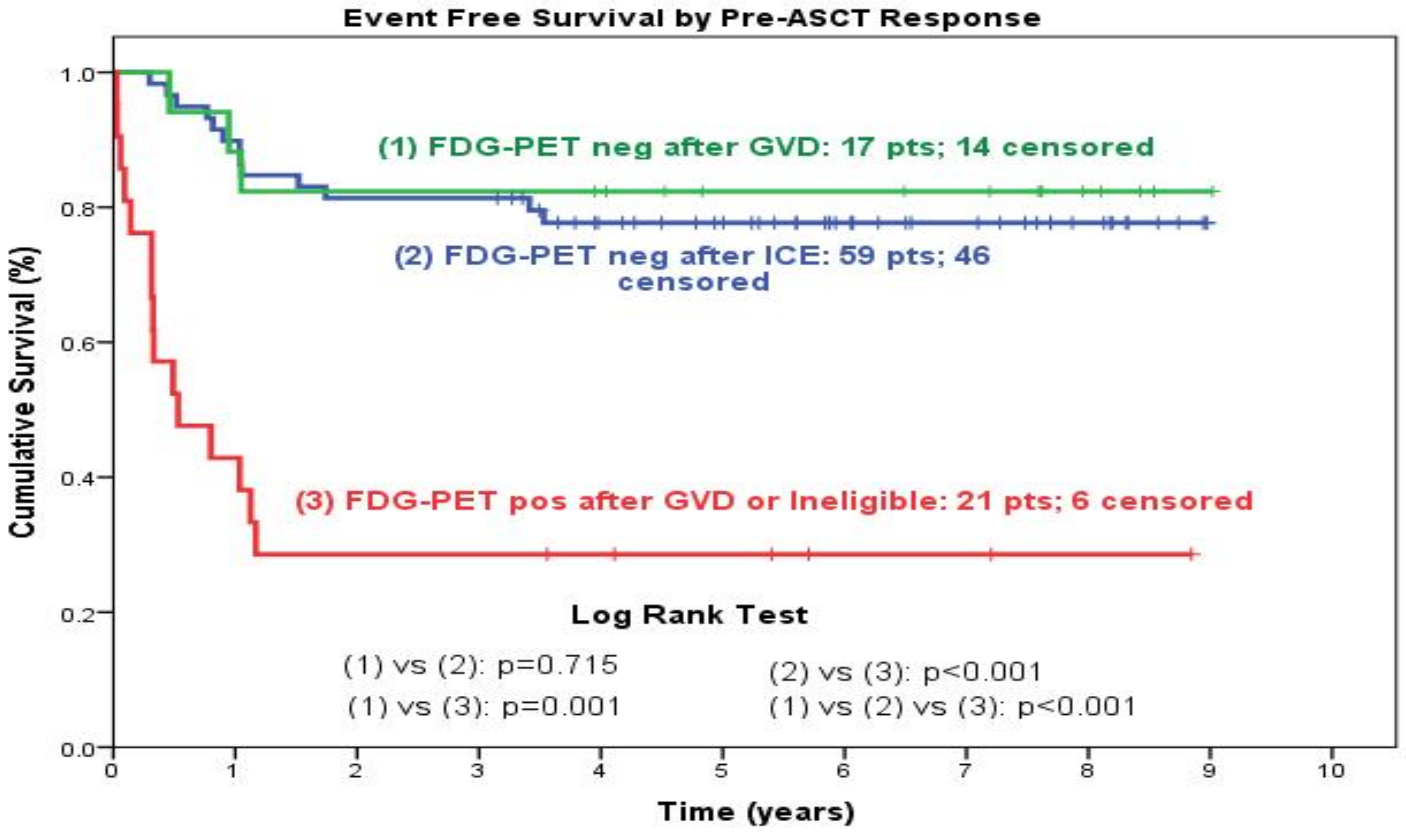
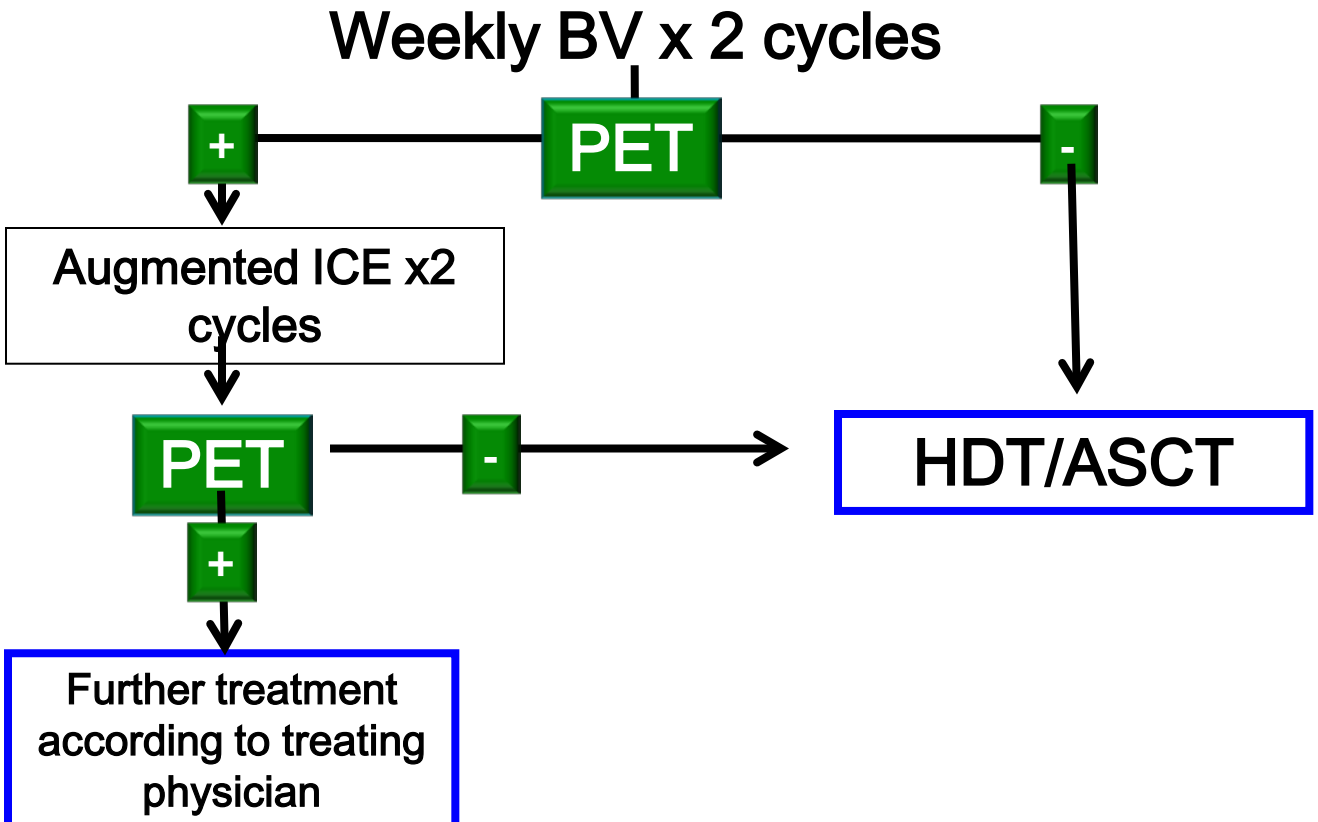
Pre-ASCT Response



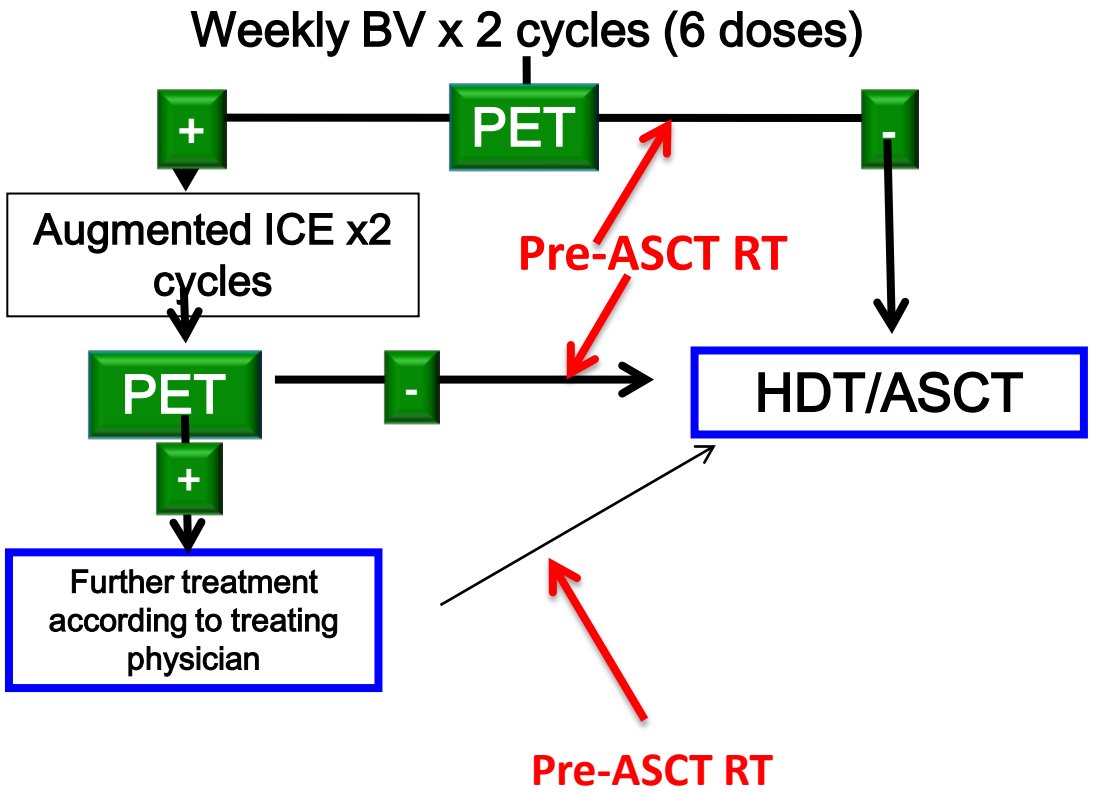
MSKCC 11-142: Relapsed/refractory HL

First TX following upfront therapy

Moskowitz AJ et al Lancet Oncology 16, No 3, 284-292, March 2015



PET-adapted therapy with BV followed by augICE



Summary:

- **45 patients enrolled**
- **27% PET negative after BV alone (avoided ICE)**
- **76% PET negative after whole treatment program**
- **All but 1 patient proceeded to ASCT**

Moskowitz, AJ, et al. Lancet Oncol 2015;16: 284-92

Post-salvage outcome

- 80% CR (Deauville 2) following BV +/- AugICE
- 10 patients did not achieve CR
  - 3 proceeded directly to ASCT (2 deauville 3, 1 deauville 4)
  - 6 received involved field RT followed by ASCT
  - 1 (not eligible for RT) received 3rd AugICE (SD) then ASCT
- Stem cell collection
  - BV alone:
    - Median 6.3 x 10^6/kg (range 2.96-13.29 x10^6/kg)
  - BV-> AugICE
    - Median 9.4 x 10^6/kg (range 5.15-31.43 x10^6/kg)
- Conditioning
  - Chemo (BEAM, CBV): 36
  - TLI/cytoxan/etoposide: 7
  - Pre-transplant IFRT: 17

Conclusions

- Early consolidation post-ASCT with BV demonstrated improved PFS per IRF in HL patients with risk factors for relapse or progression (HR=0.57, P=0.001)
  - PFS benefit was sustained, with 2-year PFS rates per investigator of 65% and 45% on the BV and placebo arms, respectively
  - Consistent benefit was observed across subgroups
- Interim analysis of overall survival did not show a significant difference between treatment arms (P=0.62)
  - Analysis limited by small number of events and the large number of patients on the placebo arm crossing over to BV after progression
  - More patients on the placebo arm received subsequent anti-tumor therapy and/or allogeneic stem cell transplant
- Consolidation therapy was generally well tolerated
  - Peripheral sensory neuropathy and neutropenia were common, and were manageable with dose reductions or delays
  - Two deaths occurred within 40 days of dosing with BV
- BV consolidation therapy is an important therapeutic option for HL patients undergoing ASCT to reduce the risk of relapse or progression

SUMMARY

- APPROACH TO SALVAGE IS STILL EVOLVING
- RT INCORPORATED IN THE SALVAGE REGIMEN IMPROVES OUTCOME – BUT OFTEN FORGOTTEN
- OUR EXPERIENCE SUGGESTS THAT SANDWICHING RT POST STANDARD SALVAGE AND HIGH-DOSE ASCT IS FEASIBLE EFFECTIVE AND SAFE
- GETTING THE PATIENT INTO A PET-CR IS CRITICALLY IMORTANT- RT CAN HELP
- BEST IS TO AVOID RISK OF RELAPSE BY USING COMBINED MODALITY RATHER THAN CHEMO ALONE.

IMIDS: lenalidomide
Others

Relapsed and refractory lymphoma

- Prognosis of r&r lymphoma still to be improved
- DHAP or other reinduction followed by BEAM and autologous TX standard in relapsed lymphoma
- Intensification of chemotherapy not helpful (HDR2)
- Anti-CD30 ADC BV effective and well tolerated; currently being evaluated in combination with chemo and other drugs
- Anti-PD1´s represent a new class of drugs showing very promising activity in r/r lymphoma
- Can new drugs replace radio- or chemotherapy in lymphoma?

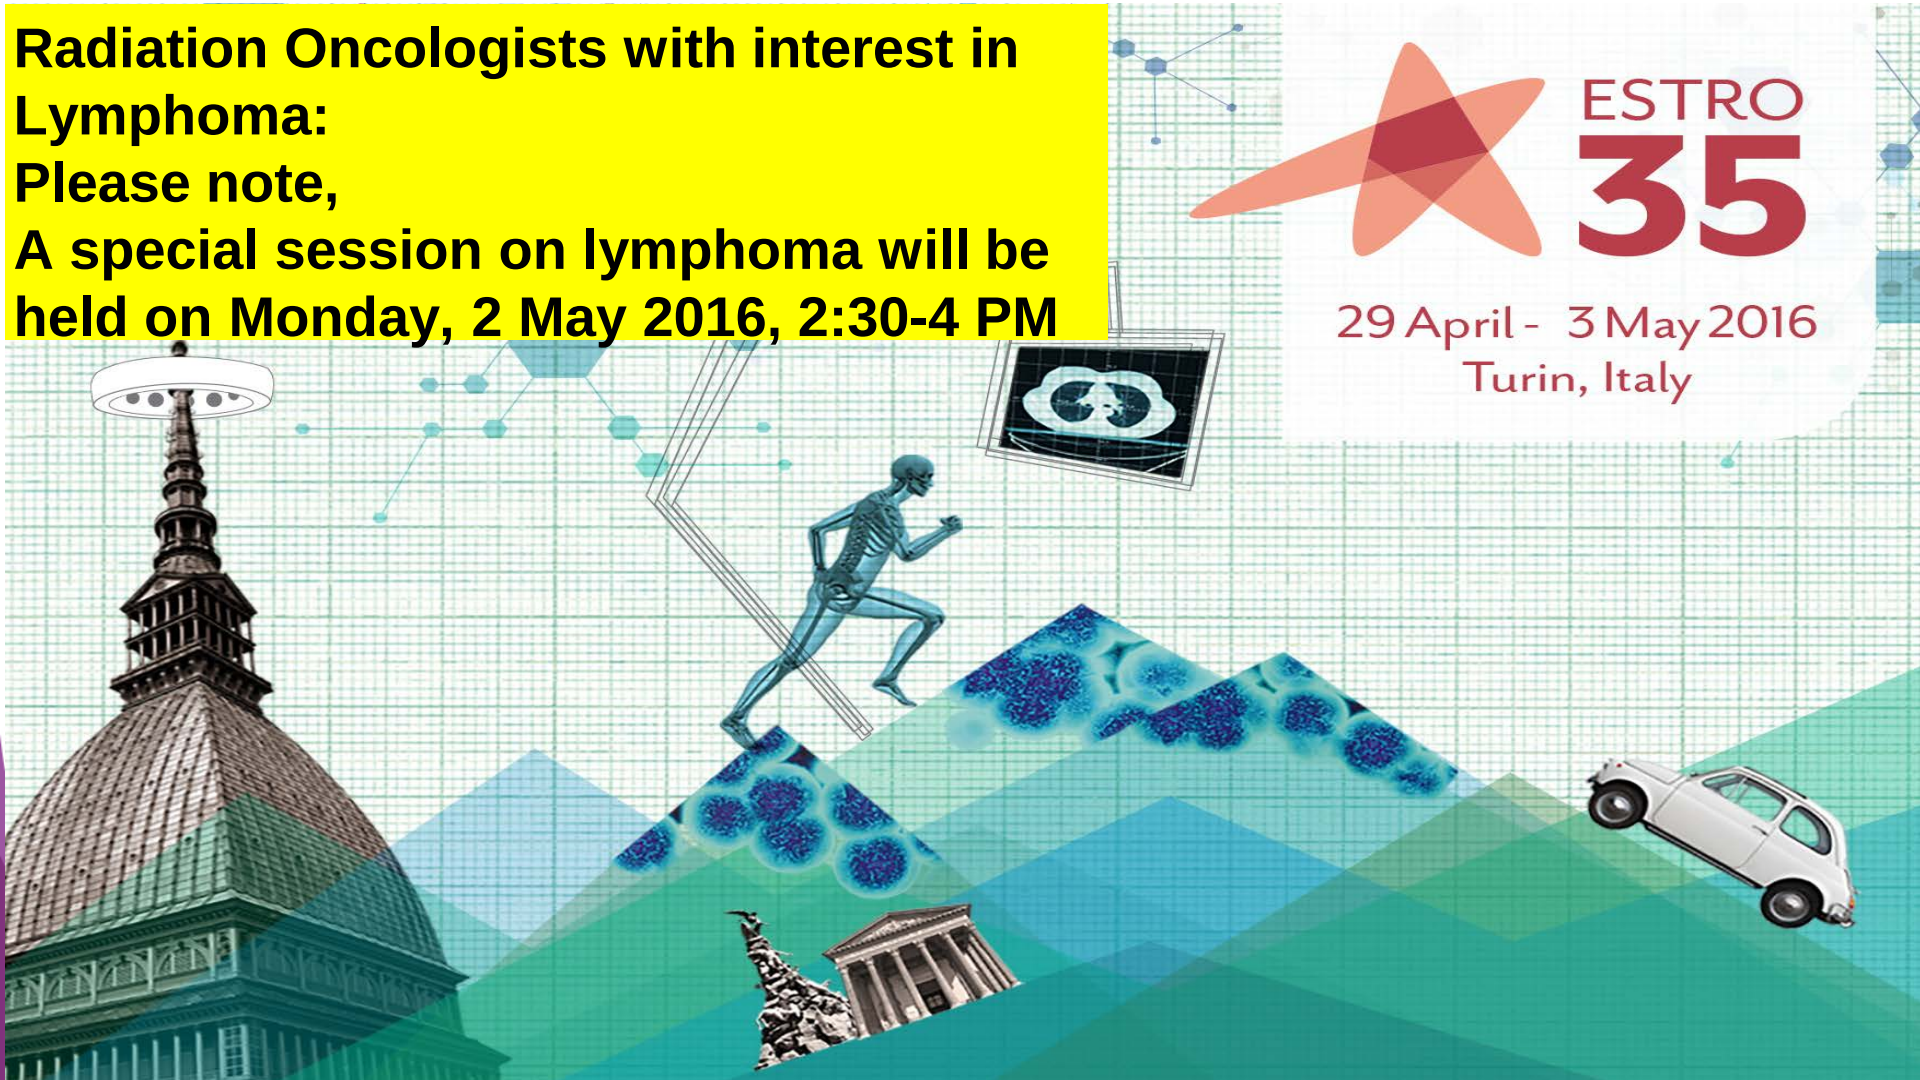
Classical Hodgkin Lymphoma
Radiotherapy volumes, doses and techniques

Umberto Ricardi

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Radiation Oncologists with interest in Lymphoma:
Please note,
A special session on lymphoma will be held on Monday, 2 May 2016, 2:30-4 PM



RT in classical Hodgkin Lymphoma

- In most HL patients, RT is used in combination with chemotherapy
- Chemotherapy has evolved with increasing efficacy to play a major role in the management of HL
- RT continues to have an important place in ensuring locoregional control and improving overall outcome in the combined modality treatment programs for HL

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

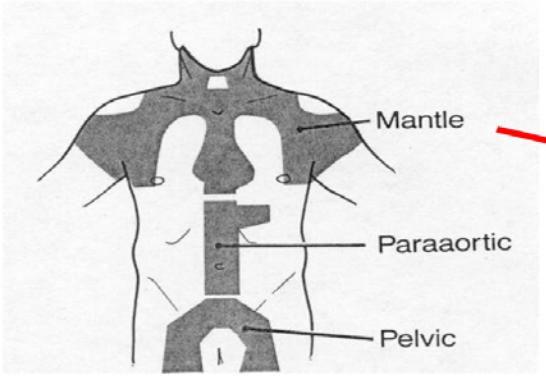
RT in classical Hodgkin Lymphoma

- It is of paramount importance in the delivery of RT to maintain high rates of long-term local control while minimizing radiation exposure to surrounding normal tissues

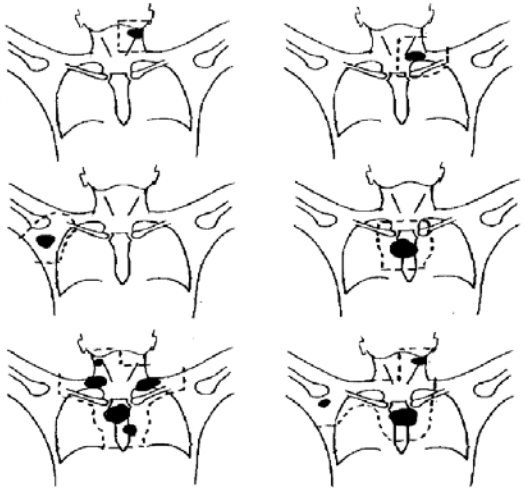
- Furthermore, it is recognized that most recurrences in patients treated for HL occur in sites of previous involvement, and that RT reduces local recurrence

Radiotherapy for Hodgkin lymphoma:
from sole curative treatment to component in combined modality treatment (i.e. no prophylactic radiotherapy for microscopic disease)

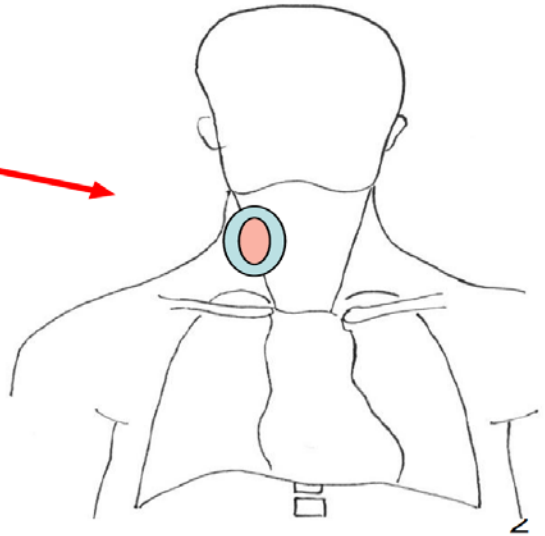
EFRT



IFRT

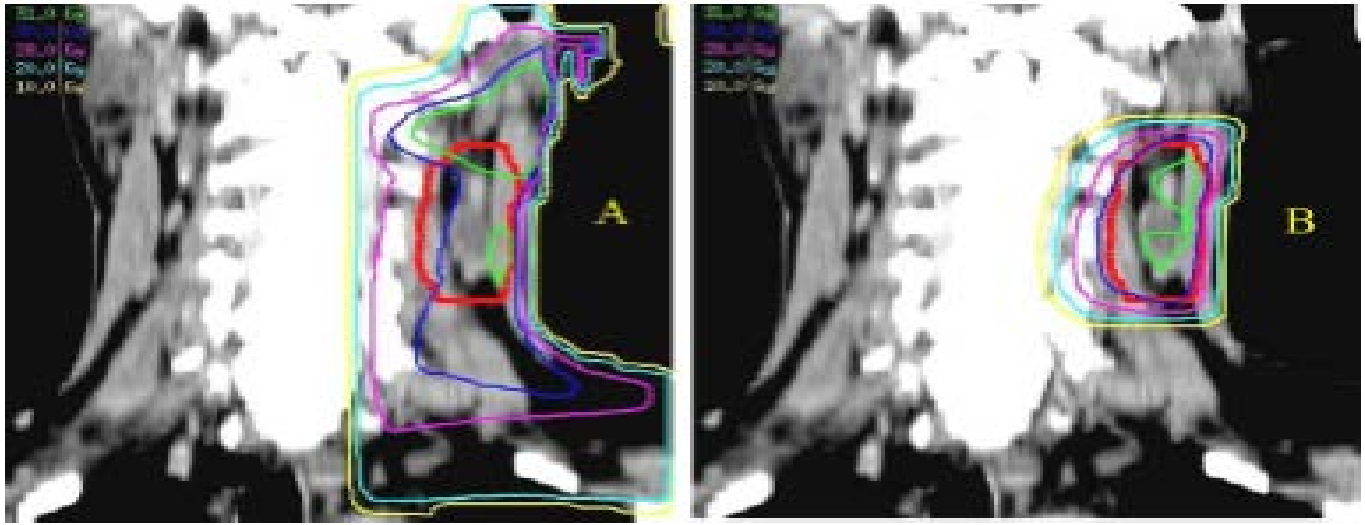


INRT



In the era of combined modality treatment, bigger (radiation fields) is not better !

From IFRT to INRT



•The concept of **IF-RT** which included the whole initially involved lymph node region can now be replaced by the concept of **involved-node RT**, which only includes the initially involved lymph node(s)

RT in classical Hodgkin Lymphoma

- Advances in imaging, treatment planning, treatment delivery, enable irradiation of new volumes with great precision

- The current guidelines for involved field RT based on anatomic landmarks and encompassing adjacent uninvolved lymph nodes are no longer appropriate for modern and more “targeted” RT delivery

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Treatment Volume Principles

- Modern RT planning in lymphoma incorporates the current concepts of volume determination as outlined by ICRU Report 83
- It is based on defining a gross tumor volume (GTV) and a clinical target volume (CTV), that is expanded to a planning target volume (PTV)
- The PTV is then used to define beam coverage
- This approach allows direct comparison with the diagnostic 3D-imaging, increasing the accuracy with which lymph node volumes are defined

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

RT Planning for Lymphomas

- **Role of imaging in radiation planning**
  - 3D imaging (with CT supplemented by functional imaging: PET-CT)
  - The use of diagnostic contrast-enhanced CT is recommended to help to delineate nodal stations and differentiate nodes from vessels
  - Ideally, imaging studies with the patient in the treatment position and using the planned immobilization devices
  - Acquiring high-quality imaging is fundamental to high-quality RT planning

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Gross tumor volume (GTV) (ICRU 83)

- Gross demonstrable extent and location of the tumor (lymphoma)
- Original (before any treatment) lymphoma: pre-chemo GTV
  - Seen on CT: pre-chemo GTV(CT)
  - Seen on FDG-PET: pre-chemo GTV(PET)
- Residual (after systemic treatment) lymphoma: post-chemo GTV
  - Seen on CT: post-chemo GTV(CT)
  - Seen on FDG-PET: postchemo GTV(PET)

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Clinical target volume (CTV) (ICRU 83)

- Volume of tissue that contains a demonstrable GTV and/or subclinical malignant disease with a certain probability of occurrence considered relevant for therapy
- Encompasses the original (before any treatment) lymphoma (pre-chemo GTV), modified to account for anatomic changes if treated with chemotherapy up front
- Normal structures (e.g., lungs, kidneys, muscles) that were clearly uninvolved should be excluded
- Residual lymphoma (post-chemo GTV) is always part of the CTV

ILROG
ESTRO School

Internal target volume (ITV) (ICRU 83)

- Defined in ICRU 62, optional in ICRU 83
- CTV + margin for uncertainties in size, shape, and position of the CTV
- Mostly relevant when the target is moving (chest and upper abdomen)
- Margins may be obtained from 4-D CT, fluoroscopy or from expert clinician
- Margins should be added quadratically: $\sigma' = \sqrt{(\sigma^2_m + \sigma^2_s)}$

Equation for right-angled triangle

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Planning target volume (PTV) (ICRU 83)

- Accounts for set-up uncertainties in patient position and beam alignment during planning and through all treatment sessions
- Function of immobilization device, body site, and patient cooperation
- Geometrical concept introduced to ensure that CTV and/or ITV are properly covered
- Applied by clinician or treatment planner

INRT: guidelines 2008

- FDG-PET scans have to be meticulously analysed to detect lymph nodes that were overlooked on CT imaging (CT assessment can be extremely difficult)
- Any morphological and/or functional asymmetry has to be taken into account
- A decrease in size or the disappearance of initially visible lymph nodes on the pre-CT scan as compared to the POST-CT scan should be considered as surrogate proof of initial involvement
- All the radiological procedures should be performed on patients in the treatment position for proper coregistration
- It is highly advisable that all CT and/or CT/PET scans should be performed with IV contrast

ESTRO School

If prechemotherapy imaging is not optimal…

Involved Site Radiotherapy

ISRT vs INRT

- In both INRT and ISRT, the prechemotherapy GTV determines the CTV, and the irradiated volume is significantly smaller than with IFRT
- However, ISRT accomomodates cases in which optimal prechemotherapy imaging is not available to the radiation oncologist
- In these situations, it is not possible to reduce the CTV to the same extent as with INRT, because the prechemotherapy GTV information may not be optimal
- In ISRT, clinical judgment in conjunction with the best available imaging is used to contour a larger CTV that will be accommodate the uncertainties in defining the prechemotherapy GTV

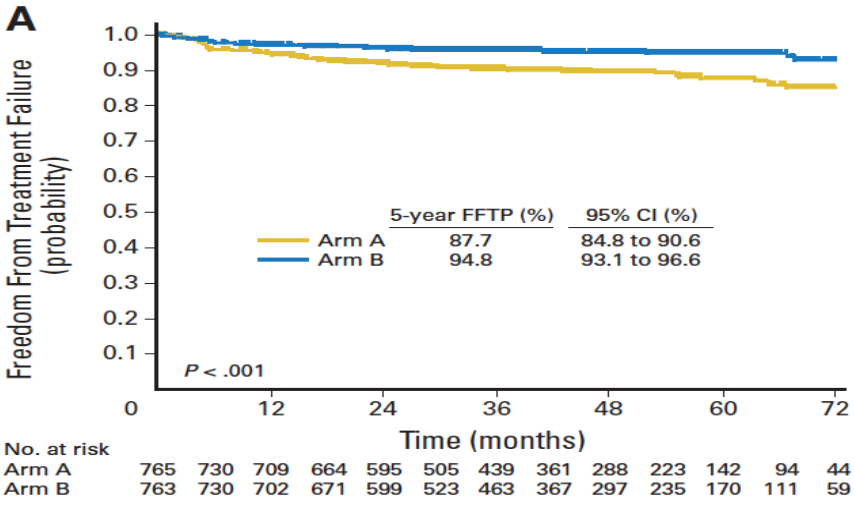
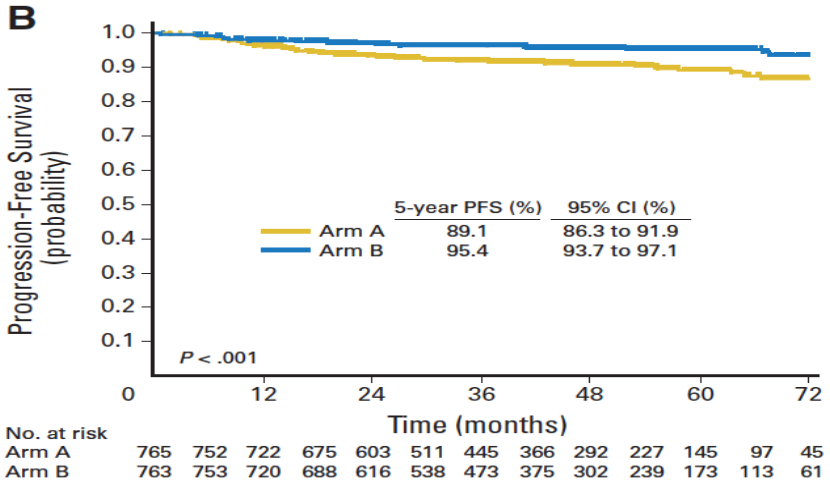
ORIGINAL REPORT

Dose-Intensification in Early Unfavorable Hodgkin's Lymphoma: Final Analysis of the German Hodgkin Study Group HD14 Trial

Bastian von Tresckow, Annette Plütschow, Michael Fuchs, Beate Klimm, Jana Markova, Andreas Lohri, Zdenek Kral, Richard Greil, Max S. Topp, Julia Meissner, Josée M. Zijlstra, Martin Soekler, Harald Stein, Hans T. Eich, Rolf P. Mueller, Volker Diehl, Peter Borchmann, and Andreas Engert



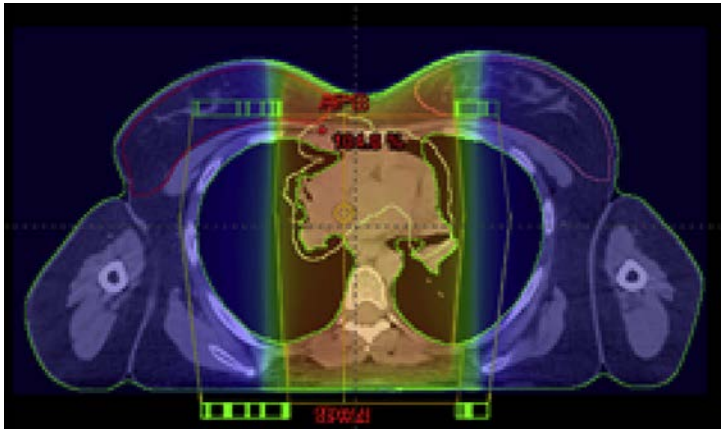


There was more acute toxicity associated with 2+2 than with ABVD, but there were no overall differences in treatment-related mortality or secondary malignancies

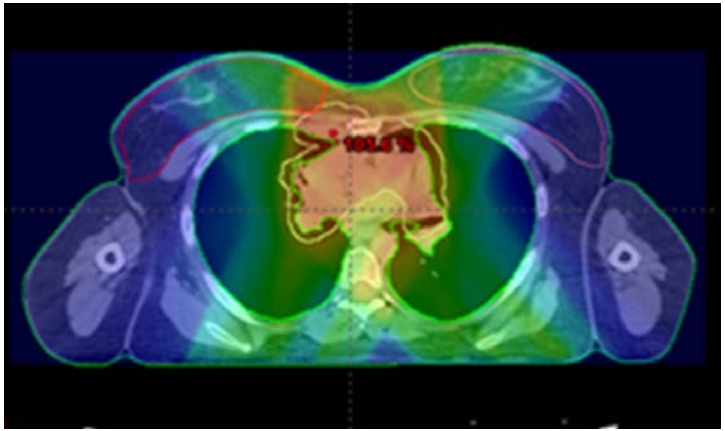
Radiotherapy Techniques

The treating radiation oncologist makes a clinical judgment as to which treatment technique to use, based on comparisons of treatment plans and DVHs with different techniques

3D conformal



IMRT technique



ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

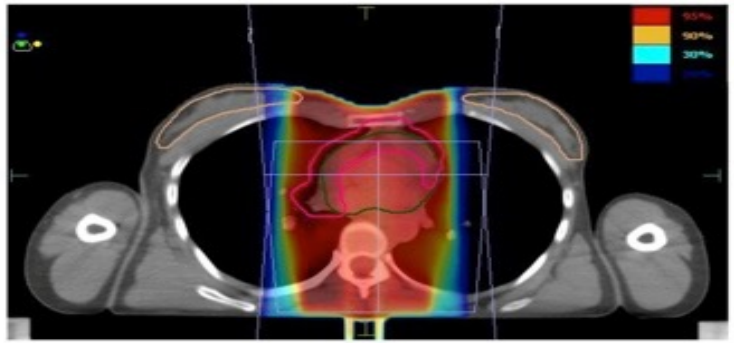
ESTRO School

Dose constraints in lymphoma RT

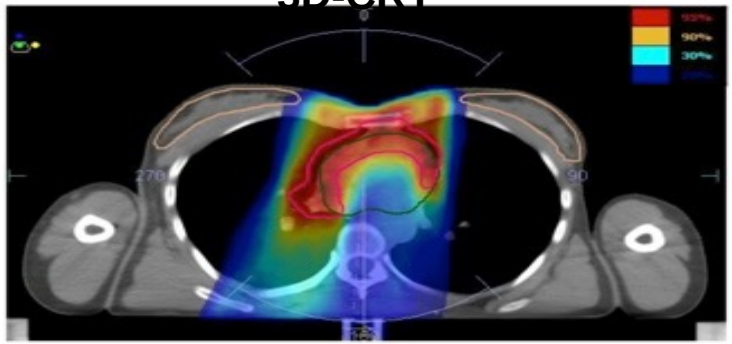
- The relatively low radiation doses needed result in most treatment plans being within the acceptable limits
- Even low doses to normal tissues, previously considered safe, may result in significant risks of morbidity and mortality in long-term survivors
- Doses to all normal structures should be kept as low as possible, but some structures are more critical than others

Highly conformal RT

- Only the target volume is treated to the full dose
- Better sparing of normal tissues



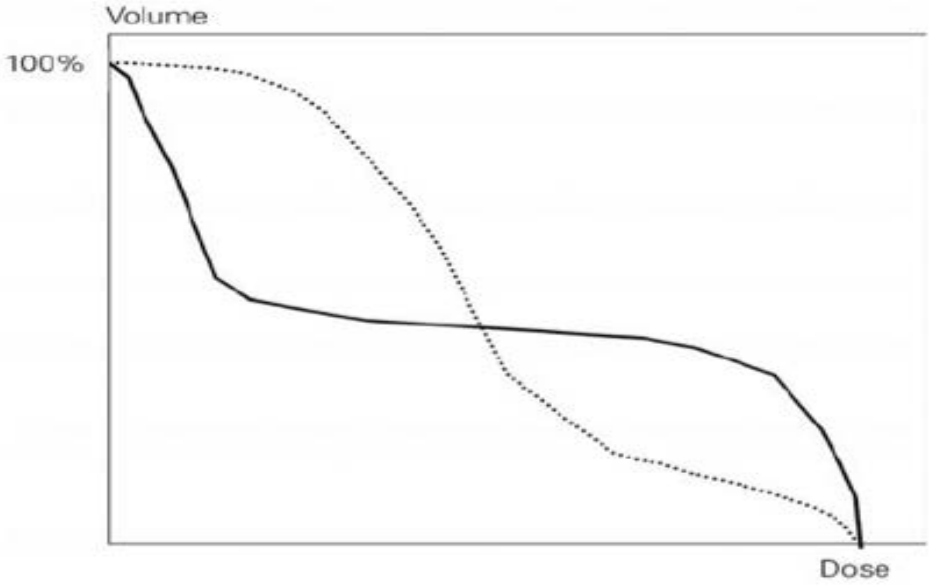
3D-CRT

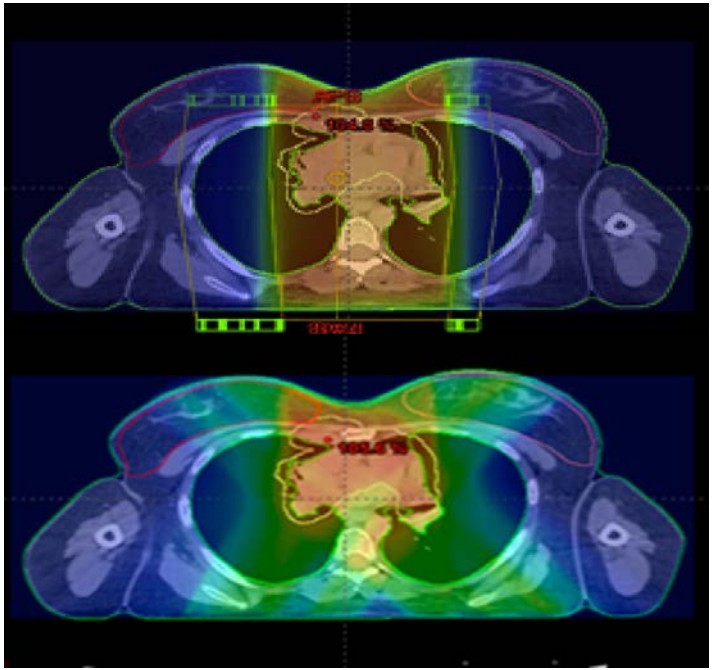


IMRT (VMAT)

A Little to a Lot or a Lot to a Little?

Better sparing of critical normal structures usually at the price of a larger total volume of normal tissue irradiated, albeit to a lower dose





IMRT vs 3D-CRT in lymphoma

- Several published studies investigated the dosimetric profiles of IMRT compared to those of 3D-CRT

- They showed significantly better PTV coverage (V_{90}, V_{95}, conformity index) and/or significantly better sparing effect for different OAR

  - both for the traditional IFRT and for the more recent concept of limited RT (INRT, ISRT)

IMRT in lymphoma RT

IMRT has been thought to be less useful and still not regarded as a standard option in hematological malignancies because:

- Lower prescribed doses, generally well below tolerance dose of normal tissues
- Theoretical increased risk of geographic miss, as the dose gradients are steeper around the target volumes
- Fear of late effects secondary to low-dose exposure of larger volumes of healthy tissues

Estimated risk of cardiovascular disease and secondary cancers with modern highly conformal radiotherapy for early-stage mediastinal Hodgkin lymphoma

27 early stage mediastinal HL patients

Treatment: chemotherapy and INRT delivered as 3D CRT (30 Gy)

Data are means ± SD AER.

Which technique is preferable?

- There is no single proven best planning and delivery RT technique
- No two lymphomas are the same with regard to localization and extent of disease
- The decision should be made at the individual patient level (i.e., what appears the optimal treatment plan for one patient may not be acceptable for another patient)

Which technique is preferable?

- The degree of modulation should be chosen based on individual treatment goals
- The benefits of advanced conformal radiotherapy techniques depend on the individual patient/target geometry
- Their use should therefore be decided case by case, with comparative treatment planning
  - 3D-CRT vs “optimized” VMAT
  - dose plans and DVHs for different alternatives should be compared

Same patient, different solutions

ILROG

ESTRO School

Modern RT in HL

- Radiation therapy has changed dramatically over the last few decades in terms of both irradiated volumes and dose

- Smaller treatment volumes, lower radiation dose and advanced conformal radiotherapy can certainly allow a safer radiation delivery

Modern RT for lymphoma

- Modern RT for HL is a highly individualized treatment restricted to limited treatment volumes

- Radiation oncologists should be involved as part of the multidisciplinary team in the initial management plan and attempt to introduce imaging procedures upfront before the initiation of chemotherapy

Radiotherapy alone for stage I-III low grade follicular lymphoma: long-term outcome and comparison of extended field and total nodal irradiation.

Guckenberger M Radiat Oncol 2012 Jun 24;7**:103.**

- To analyze long-term results of radiotherapy alone for stage I-III low grade follicular lymphoma and to compare outcome after extended field irradiation (EFI) and total nodal irradiation (TNI).

- Between 1982 and 2007, 107 patients were treated with RT alone for low grade follicular lymphoma at Ann Arbor stage I (n = 50), stage II (n = 36) and stage III (n = 21);

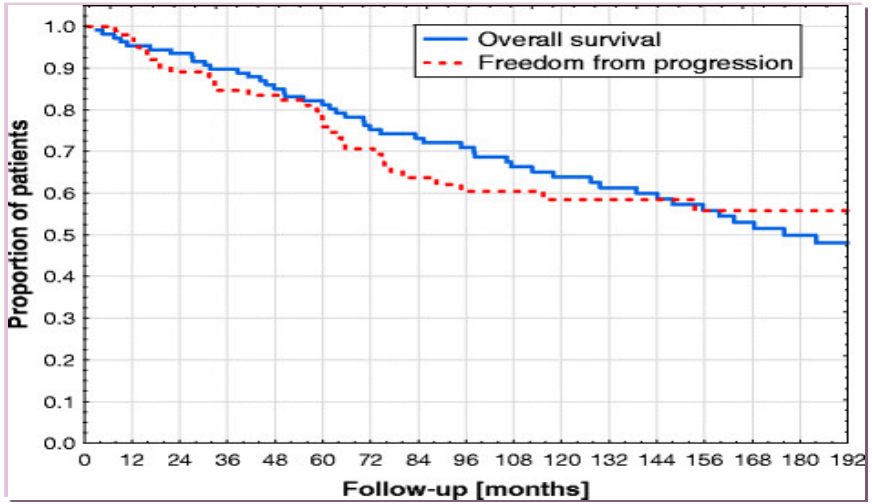
- 48 and 59 patients were treated with EFI and TNI, respectively.

- The median total dose in the first treatment series of the diaphragmatic side with larger lymphoma burden was 38 Gy (25 Gy - 50 Gy) and after an interval of median 30 days, a total dose of 28 Gy (12.6 Gy - 45 Gy) was given in the second treatment series completing TNI.

Radiotherapy alone for stage I-III low grade follicular lymphoma: long-term outcome and comparison of extended field and total nodal irradiation.

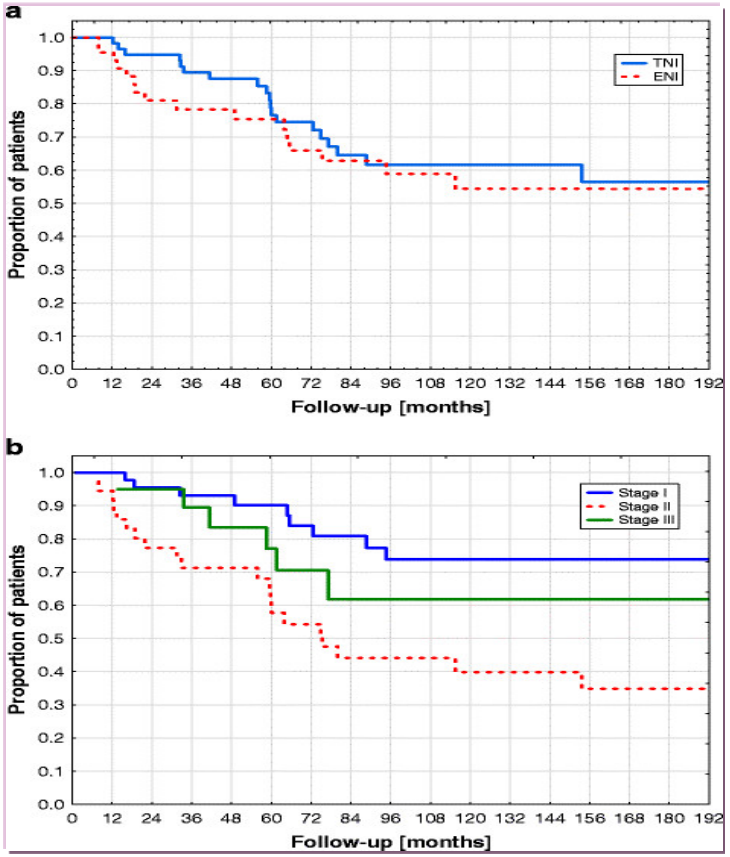
Guckenberger M Radiat Oncol 2012 Jun 24;7:103.

- After a median follow-up of 14 years for living patients, 10-years and 15-years overall survival (OS) were 64% and 50%, respectively.
- Survival was not significantly different between stages I, II and III
- Acute toxicity was significantly increased after TNI compared to EFI with a trend to increased late toxicity as well.



Radiotherapy alone for stage I-III low grade follicular lymphoma: long-term outcome and comparison of extended field and total nodal irradiation.

Guckenberger M Radiat Oncol 2012 Jun 24;7:103.



(a) Kaplan Meier Curves showing **freedom from disease progression** in relationship to TNI versus EFI (no significant difference)

(b) Stage of disease (significant difference between stage I and stage II)

Radiotherapy alone for stage I and II follicular lymphoma resulted in long-term OS with high rates of disease control; no benefit of TNI over EFI was observed.

Is radiotherapy curative for stage I and II low-grade follicular lymphoma?
Should RT alone remain standard of care ?

- US lymphocare 206 of 471 patients stage 1 follicular lymphoma “rigorously staged” - Treatments given
  - R-chemo (28%)
  - RT (27%)
  - Observation (17%)
  - Systemic + RT (13%),
  - rituximab monotherapy (12%), and other (3%).
- Median follow-up of 57 months, 44 (21%) progression events. PFS significantly improved with either R-chemo or systemic and RT. No differences in OS. (Friedberg J et al JCO 2012)

Treatment of limited stage follicular lymphoma with Rituximab immunotherapy and involved field radiotherapy in a prospective multicenter Phase II trial-MIR trial.

Witzens-Harig M, et al BMC cancer. 2011; 11: 87

- Trial aims at testing the combination's efficacy and safety n= 85 patients.
- Primary endpoint of the study is progression free survival.
- Secondary endpoints are :
    - Response rate to Rituximab,
    - Complete remission rate at week 18,
    - Relapse rate,
    - Relapse pattern,
    - Relapse free survival,
    - Overall survival,
    - Toxicity
    - Quality of life.

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Conclusions

- “Rigorous staging” is required to determine appropriate patients to consider IFRT, including BM biopsy and FDG-PET scan
- RT remains treat of choice of stage I/II indolent lymphomas and results in long term progression free survival and possible “cure” for patients still in remission past 10 years
- For early stage disease 24 Gy in 12 fractions remains the standard of care for most patients and provides better local control and 4 Gy in 2 fractions

Decision making in Follicular Lymphoma

- Follicular lymphoma diverse disease, biologically and clinically.
  - Indolent and asymptomatic disease with low tumor burdens
  - More aggressive and symptomatic disease with high tumor burden.
- Decision-making to treat in the frontline therapy based on
  - Histology
  - Disease burden
  - Patient symptoms
  - Patient characteristics, morbidities and choice

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Goals of therapy versus toxicity / tolerability in Follicular Lymphoma

- FL generally considered incurable - most patients will require additional therapy in their lifetime.
- First line treatment options trade off between remission duration versus toxicity. Eg R-CHOP induces more durable remissions relative to R-CVP but carries more short-term toxicity and more risk for late cardiotoxicity
- In absence of proven OS advantage for one choice versus another, no one ‘‘right’’ approach.
- Treatment decision is patient-specific, incorporating goals of treatment with the patient’s unique situation
  - Age, comorbidities, tumour burden, patient preferences.

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

Summary

The *BRAF* V600E mutation has recently been described in all cases of hairy cell leukaemia (HCL). We have developed and validated a rapid and sensitive high-resolution melting analysis (HRMA) assay that detects *BRAF* exon 15 mutations when hairy cells are as low as 5–10% in a sample. All 48 HCL patients were positive for the *BRAF* V600E mutation, while 114 non-HCL cases were all V600E negative. Interestingly, we detected a novel *BRAF* D594N mutation in one patient with multiple myeloma. The HRMA assay offers a useful tool to aid the laboratory diagnosis of HCL.

Novel agents in Follicular NHL

- PI3Kinase inhibition remains leading pathway target
- Idelalisib most mature data, but
  - Copanlisib
  - Duvelisib
  - TG Therapeutics
  - Curis Incorporated – novel tagged PI3K / HDACi

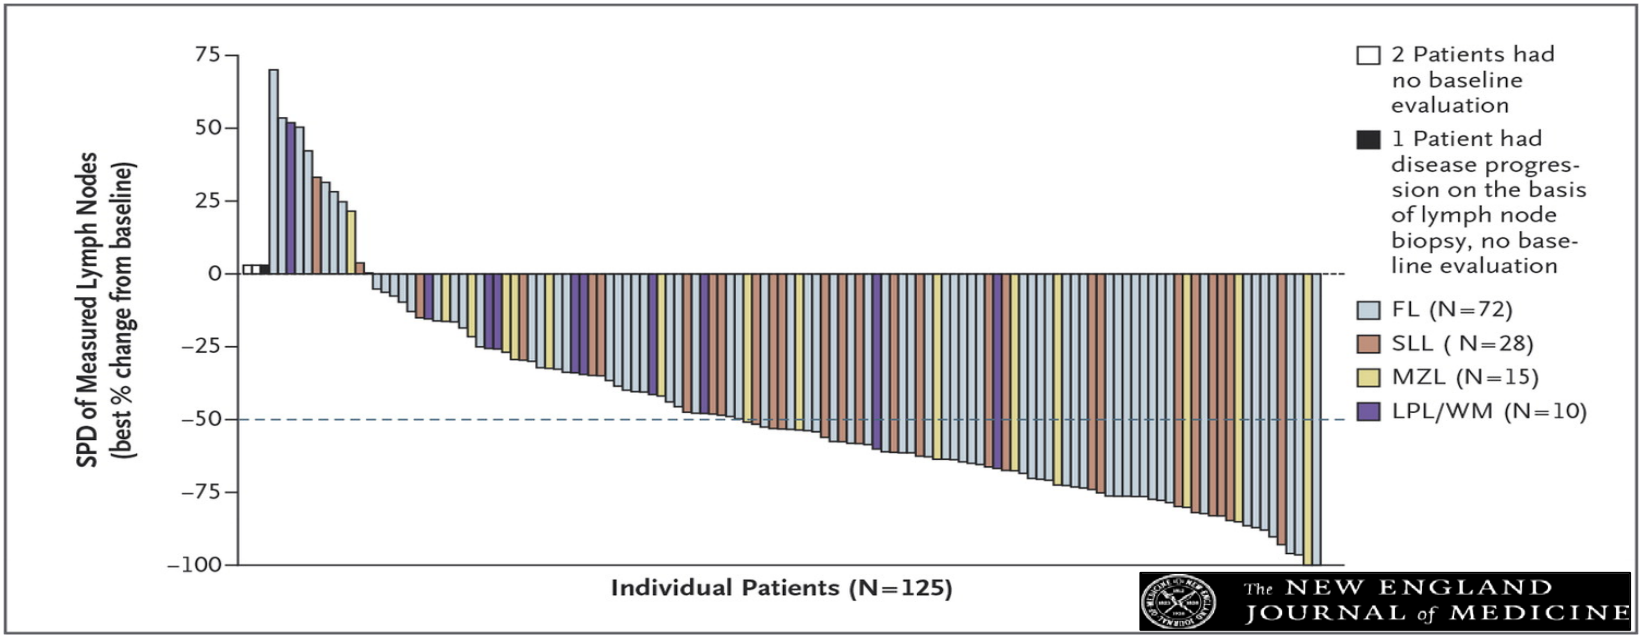
PI3Kδ inhibition by Idelalisib in patients with relapsed indolent lymphoma



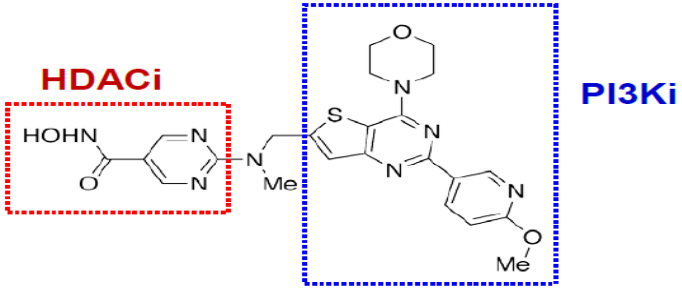
Gopal AK et al. N Engl J Med 2014;370:1008-1018.

Other novel inhibitors in indolent lymphomas

- SYK inhibition
  - GS-9973
- Dual SYK - JAK inhibition
  - PRT062070 – Cerdulatinib
- Combination PI3Ki - HDACi

CUDC-907

- Potent HDAC and PI3K enzyme inhibition in one oral small molecule
- High tissue distribution – significant levels of enzyme inhibition activity
- Active in patients with DLBCL, including transformed follicular DLBCL



IC50 (nM)	HDAC					PI3K			
Enzyme	1	2	3	6	10	Alpha	Delta	Beta	Gamma
IC50 (nM)	1.7	5	1.8	27	2.8	19	39	54	311

Conclusions therapy in advanced stage FL

- Decision-making to treat in the frontline therapy based on; disease burden, patient symptoms, patient characteristics, morbidities and patient choice
- Right choice of initial therapy is the one that gives the best chance of durable remission and lowest toxicity profile for that patient.
- R-Chemo standard of care, randomised studies versus Lenalidomide and Rituximab awaited
- Maintenance Rituximab in responders to induction R-Chemo chemotherapy plus rituximab
- Novel drugs including PI3Kδ inhibition appear effective in relapsed and refractory FL

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Outline

- Role and efficacy
- Clinical trials
- Choice of dose

Role of RT in advanced disease

- Indolent NHL is very radio-sensitive (4Gy)
- Indolent lymphoma is systemic disease with many treatment options
- However, RT is useful for:
  - Localised progression / symptomatic areas
  - Consolidation treatment when local control is important e.g. spinal cord compression
  - Certain sites e.g. CNS / meningeal

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Low dose RT in advanced disease

- 4Gy / 2#
- Advantages:
  - Effective
  - Quick, convenient & cheap
  - Min side effects
  - As low dose; can treat large area or multiple areas
  - Can be repeated with equal efficacy
- Probably underutilized;
  - expansion of systemic Rx options (more expensive, lengthy and toxic!)
  - Availability of radiation oncology opinion

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Patient selection

- Which cases benefit from low-dose RT (4Gy):
  - FL, MZL, SLL, MCL
  - Predominant symptomatic area
  - W&W with localized progression
  - Debulking of residual >R-chemo before maint R (?)
  - Re-irradiation
  - Proximity of vital organs
  - Frail patients
- Which cases may need intermediate dose RT (24Gy):
  - When max chance for OR longer duration of control is desirable / advantageous

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Rapid excellent response with virtually no side effects

General Treatment Options

- Systemic
  - REPEAT RITUXIMAB
  - ANOTHR CHEMOTHEAPY COMIBNATION
  - EXPERIMENTAL AGENTS
  - HIGH-DOSE WITH AUTOLOGOUS OR ALLOGENEIC TRANSPLANT
- Observation
- Palliation and/or local control with RT

Field Design Concept

- Involved site concept
- Limited to palliation need or local control concerns
- Dose and field considerations
- Toxicity to normal organs (including bone marrow reserve)

RT Dose for Palliation

- These are highly radio-responsive lymphomas
- Lower doses are effective
- Range of 4 Gy to 36 Gy (24 Gy commonly used)

Advantages of “Boom-Boom”

- Short treatment duration.
- Minimal morbidity. No myelosuppression.
- High response rate similar to that obtained with primary therapy.
- Effective and simple re-treatment
- Rapid response onset.
- Significant LPFS interval.

FoRT: A phase III multi-centre randomised controlled trial of low dose radiotherapy for follicular and marginal zone lymphoma

Hoskin P, Kirkwood A, Popova B, Brammer C, Diez P, Gallop-Evans E, Jack A, Madhavan K, Robinson M, Syndikus I, Smith P

ELIGIBLE PATIENT

Histologically proven follicular or marginal zone NHL receiving radiotherapy for definitive treatment of stage I/II disease or for palliation by virtue of bulk or anatomical site

RANDOMISATION

Stratified by diagnosis (FL/MZL) and treatment intent (palliative/curative)

ARM A CONTROL
24Gy in 12 fractions

ARM B EXPERIMENTAL
4Gy in 2 fractions

4 weeks:	Local progression and Acute toxicity
12 weeks:	Tumour Response and Late toxicity
Follow up:	Local progression and Late toxicity every 6 months for 2 years, annually thereafter

FoRT: ENTRY CRITERIA

Patient inclusion criteria

- Patients aged over 18 with no upper age limit
- Histologically proven **follicular lymphoma** or **marginal zone lymphoma**
- Biopsy material available for histological review
- Radiation indicated for definitive treatment of stage IA or IIA disease or for palliation by virtue of tumour bulk or anatomical position
- Written informed consent

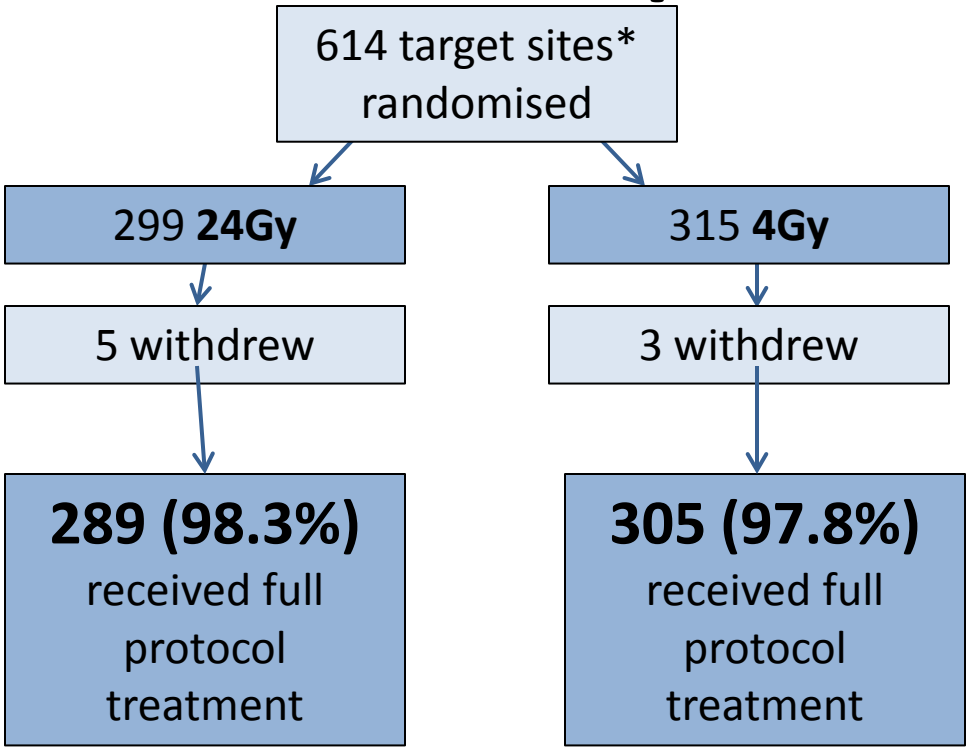
Patient exclusion criteria

- Histological subtypes other than **follicular lymphoma** or **marginal zone lymphoma**
- Predicted prognosis less than 3 months

Statistical considerations

- **Primary Endpoint**
  - Local progression free interval
    (*progression within the radiation field)*
- **Secondary Endpoints**
  - Acute toxicity
  - Late toxicity
  - RECIST response
  - Overall survival
  - Quality of life

Treatment Compliance



* 548 unique patients.

Response to radiotherapy[1]

Response	24Gy N(%)	4Gy N(%)
CR	175 (60.3)	137 (44.3)
PR	60 (20.7)	92 (29.8)
SD	22 (7.6)	44 (14.2)
No progression[2]	20 (6.9)	22 (7.1)
PD	2 (0.7)	9 (2.9)
Missing	11(3.8)	4 (1.3)

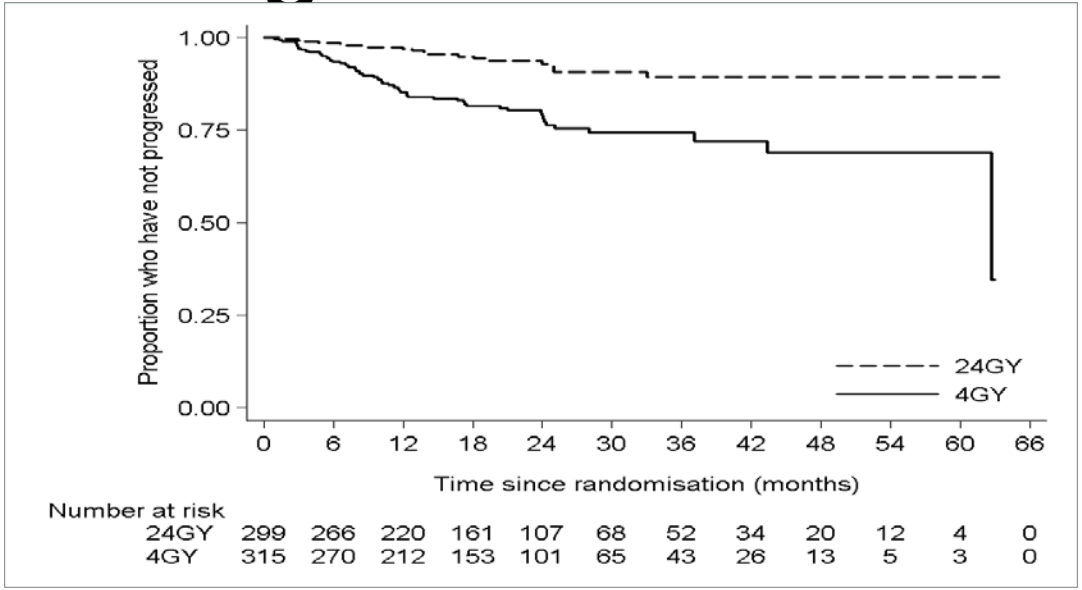
p=0.006

(Chi squared test, response (CR+ PR) vs. No response)

[1] Patients who started treatment only.

[2] No measurable disease at baseline.

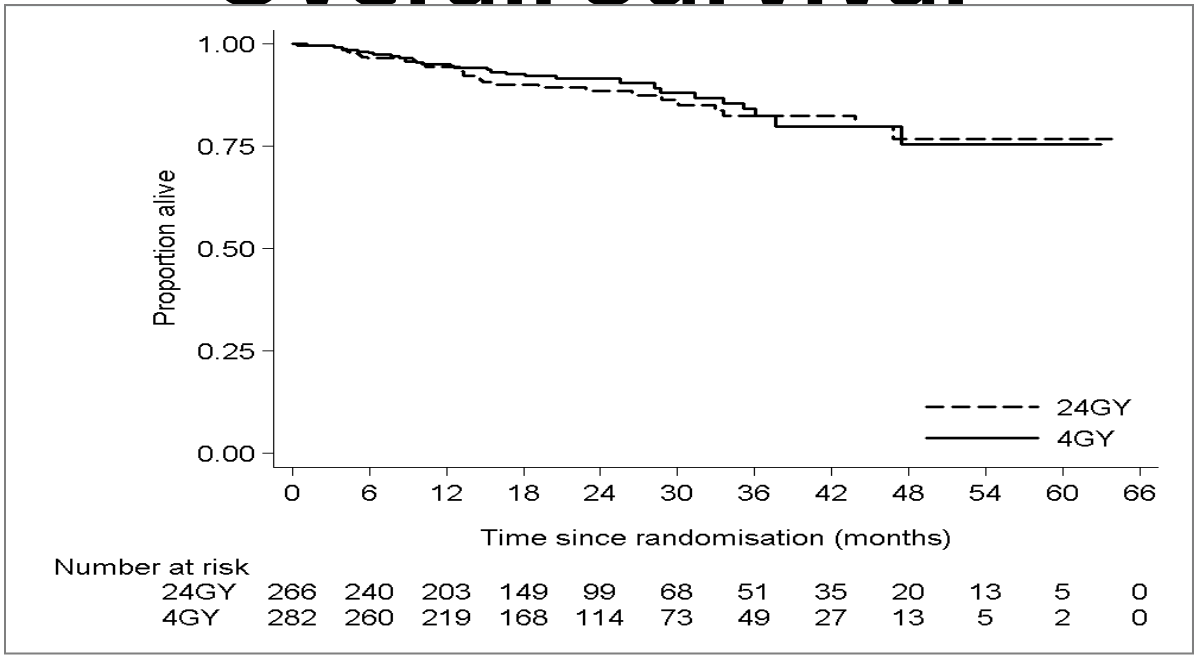
Local Progression Free Interval



Hazard Ratio: 3.49 (95% CI: 2.06 - 5.90), p<0.001

2 Year local progression free rate: 93.7% (24Gy) and 80.4% (4Gy)

Overall Survival



Hazard ratio (each patient counted once): 0.88 (95% CI: 0.53 - 1.46), p=0.61

Median Follow-up time: 22.8 months (0.39 -63.80)

Summary and conclusion

- 4Gy in 2 fractions was inferior to 24Gy in 12 fractions in achieving a durable local progression free interval in follicular and marginal zone NHL.
- 24Gy in 12 fractions should remain the standard schedule for indolent lymphoma.
- 4Gy in 2 fractions is effective (CR rate: 44.3%, PR rate: 29.8%) and may be considered for palliative treatment or retreatment.

Whom to Boom-Boom?

- **Follicular**
- **Mantle-cell**
- **CLL/SLL**
- **Marginal zone**

- **Relapsed, refractory to systemic therapy**

Outliers… ***Outliers…***

Imagine a 10-fold spread in RT dose for prostate cancer…

Our Central Hypothesis:

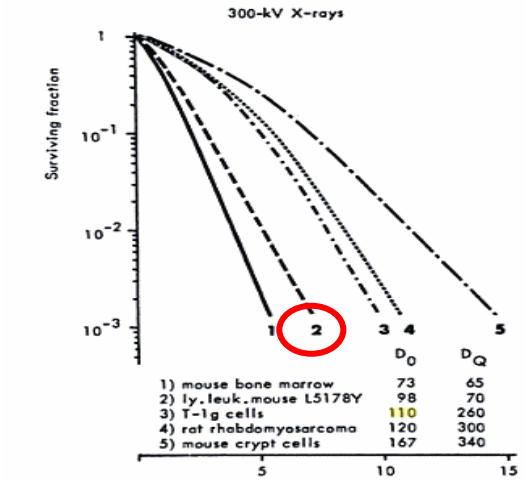
1. Dramatic variations in radiosensitivity can be explained by molecular differences in the tumor
2. Gene expression signatures can be used to predict RT response and to better stratify patients

**Definitive vs. post-op not separated…*
these doses are just for talking points…

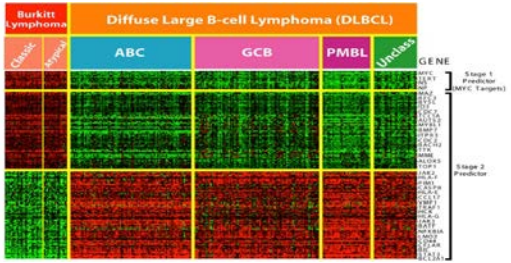
What Drives Radiation Sensitivity in Lymphoma?

The old radiobiology view of RT sensitivity in lymphoma

Lymphoma = Apoptosis = Radiosensitive



RT sensitivity in lymphoma, in the molecular age…



Lymphoma gene expression profiles may predict differences in radiosensitivity

Figure from:
Radiobiology for the Radiologist
By Eric J. Hall, Amato J. Giaccia

It is intrinsic or extrinsic radiosensitivity?

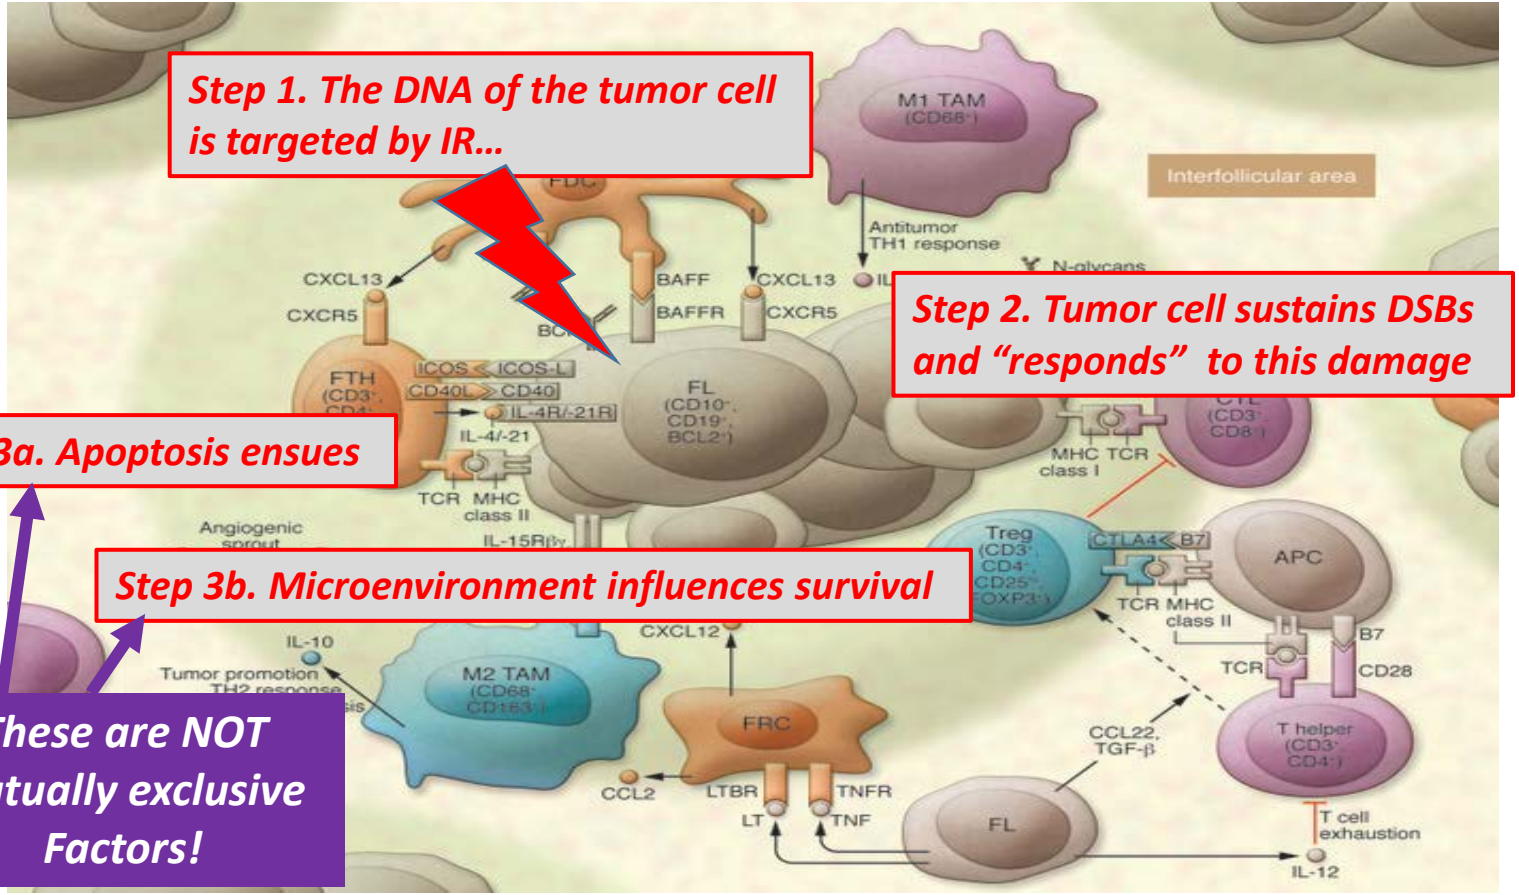


Image from: *J Clin Invest.* 2012;122(10):3424-3431. doi:10.1172/JCI63186.

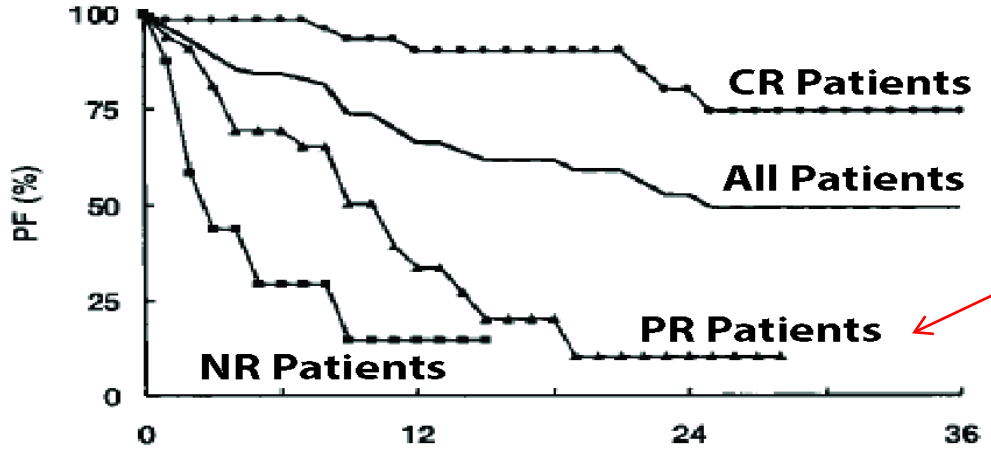
Response to very low dose RT is variable

Our key questions:

1. **Are there molecular biomarkers that can predict these differences?**
2. **What about gene expression profiles?**



Can we identify these patients up-front?

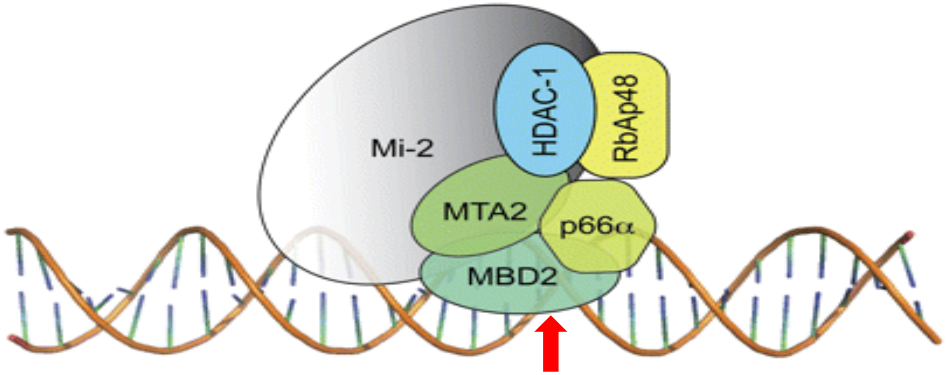
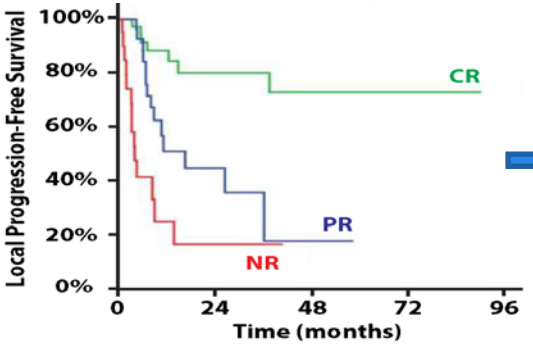
Associated with chromatin modification in cancers

Are the genes relevant to radiosensitivity?



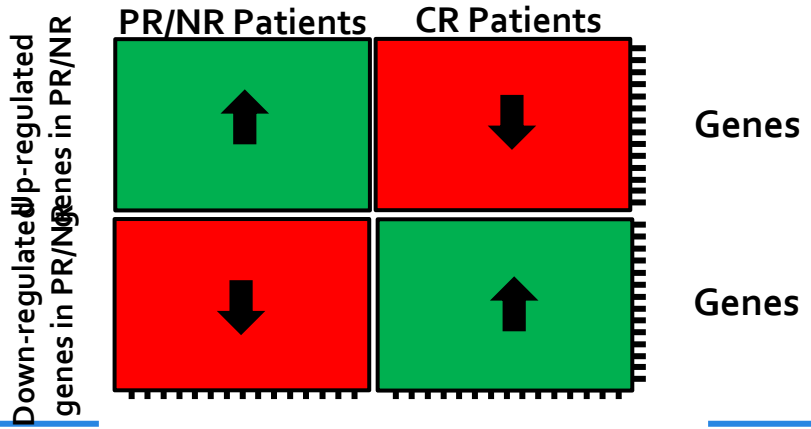
4-fold reduction in MBD2 mRNA in CR patients

What did we do?

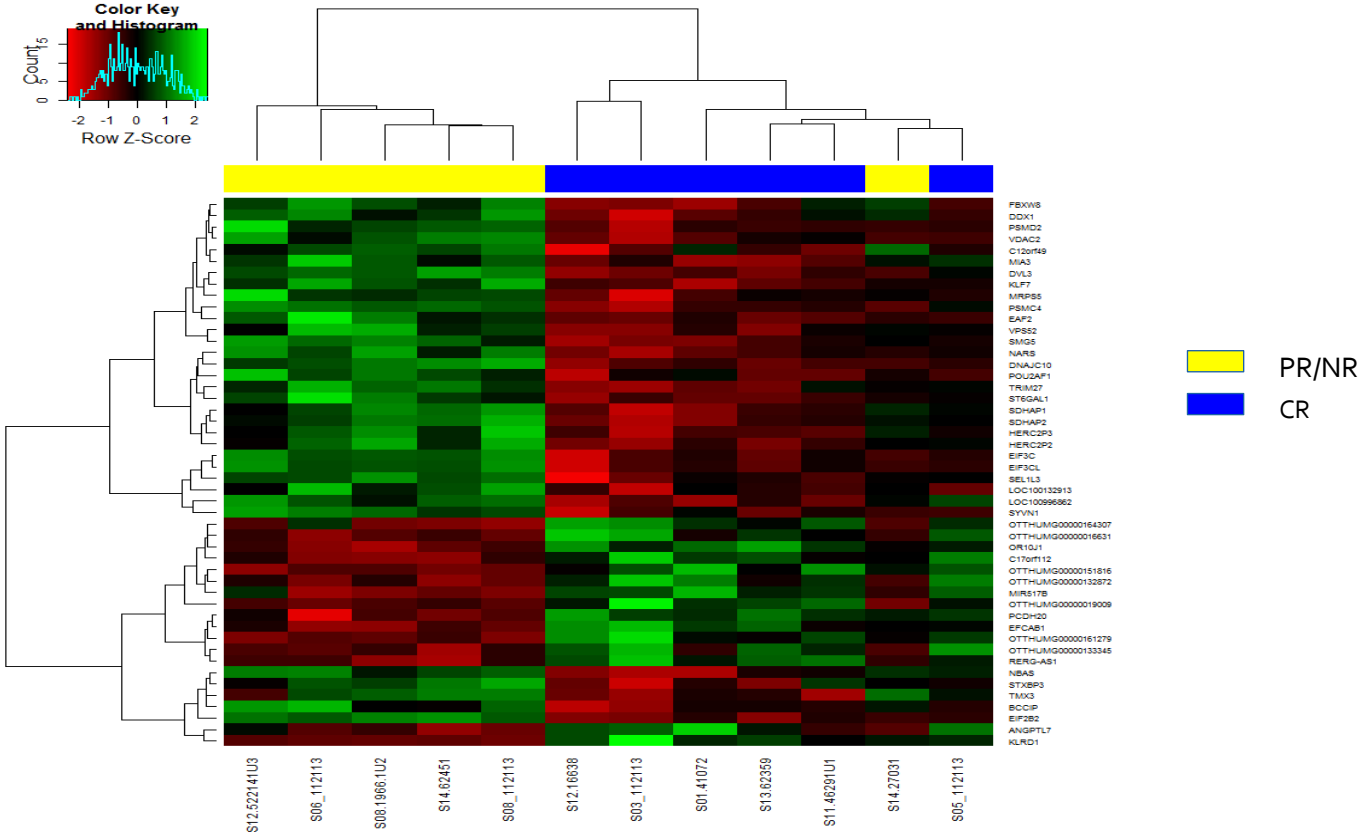


Find FFPE biopsy specimens → Extract RNA → Gene expression profiling → Create an RT response signature

The ideal result



CR vs. PR/NR Gene Pathways



Conclusions

- Intrinsic radiosensitivity exists, but molecular features may trump histology
- "Outlier treatment responders" may provide molecular insights for RT responses
- Archival FFPE tissue now can be used readily for gene expression profiling
- FFPE gene profiling is a viable approach to identify RT response signatures
- RT gene signatures could help better direct treatment choices in lymphoma

Studies are ongoing and we are actively seeking collaborators!

Yale CANCER CENTER
SMILOW CANCER HOSPITAL AT YALE-NEW HAVEN

Sloan Kettering Cancer Center

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

Conclusions

- **Very low dose RT for low grade lymphomas**
  - –Initial response predicts local progression free survival
- **Preliminary microarray profiling studies**
  - –Using FFPE specimens is feasible
  - –Initial studies showed statistically significant changes in relative gene expression between CR and NR groups

Future Directions

1. Expand and validate gene expression signatures in entire low grade lymphoma cohort
2. Translate signatures back to laboratory for functional studies
3. Expand collaboration to other centers/institutes
4. Adapt the proposed workflow to other lymphoma subtypes

Thank you!

Modern RT in Indolent Lymphoma

- Advances in imaging, treatment planning, treatment delivery, enable irradiation of these volumes with great precision

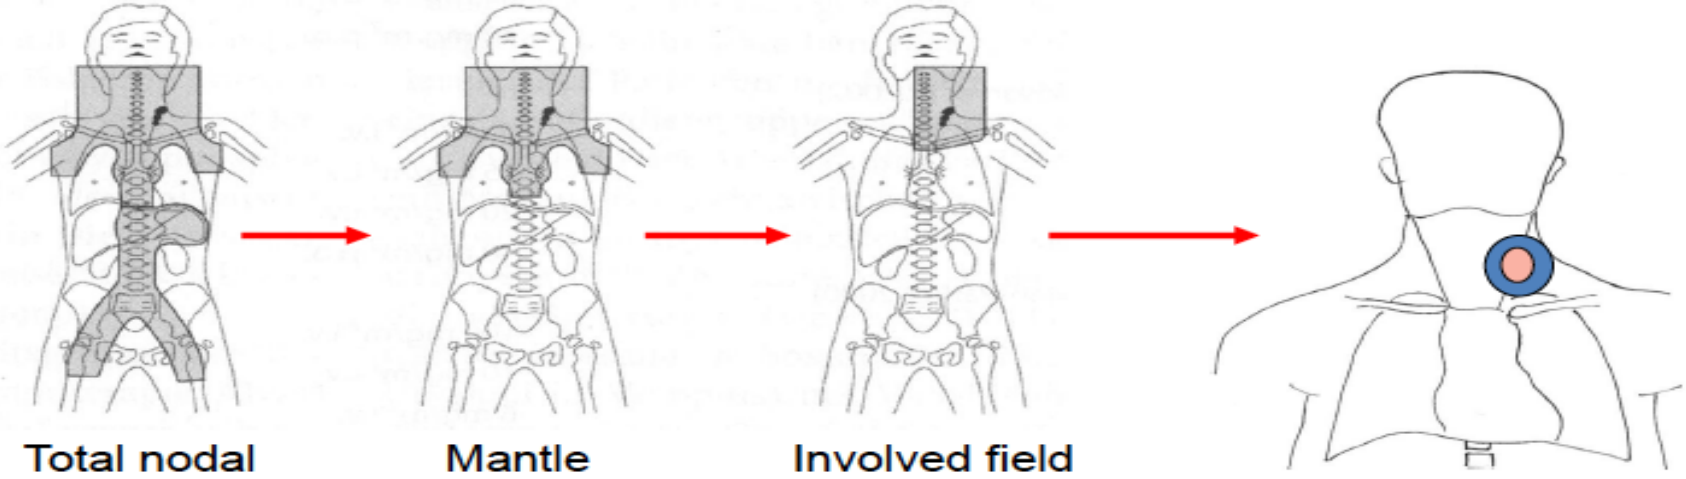
- The current guidelines for involved field RT based on anatomic landmarks and encompassing adjacent uninvolved lymph nodes are no longer appropriate for modern and more “targeted” RT delivery

Modern radiotherapy guidelines developed by

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

- Previous wide field and involved field replaced by limited volumes based solely on detectable involvement at presentation
- ICRU concepts of GTV, CTV, ITV, and PTV are used
- New concept, Involved Site RadioTherapy (ISRT), defines CTV on this basis
- Previous doses were higher that necessary, replaced by lower doses in most lymphoma types

Development of RT volumes



Total nodal Mantle Involved field

2D planning, based on bony landmarks

Involved node

3D planning, based on lymphoma volume

Clinical Investigation: Lymphoma and Leukemia

Modern Radiation Therapy for Nodal Non-Hodgkin Lymphoma—Target Definition and Dose Guidelines From the International Lymphoma Radiation Oncology Group

Tim Illidge, MD, PhD,* Lena Specht, MD,† Joachim Yahalom, MD,‡ Berthe Aleman, MD, PhD,§ Anne Kiil Berthelsen, MD,‖ Louis Constine, MD,¶ Bouthaina Dabaja, MD,# Kavita Dharmarajan, MD,‡ Andrea Ng, MD,** Umberto Ricardi, MD,†† and Andrew Wirth, MD,‡‡, on behalf of the International Lymphoma Radiation Oncology Group

Treatment Volume Principles

- Modern RT planning in lymphoma incorporates the current concepts of volume determination as outlined by ICRU Report 83
- It is based on defining a gross tumor volume (GTV) and a clinical target volume (CTV), that is expanded to a planning target volume (PTV)
- The PTV is then used to define beam coverage
- This approach allows direct comparison with the diagnostic 3D-imaging, increasing the accuracy with which lymph node volumes are defined

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Indolent lymphomas

- In early stage disease, RT is the primary treatment
  - Target is the macroscopic lymphoma AND adjacent nodes in that site with a generous margin
- In advanced disease, RT is palliative
  - Target is localized symptomatic disease

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Role of Radiation Therapy in Indolent Nodal Lymphomas

- **Localized Indolent Lymphoma**

  - For the potentially curative treatment of localized early stage (I and II_1) disease, RT is used as the primary treatment approach

Radiation therapy as primary treatment

In most clinical situations that require RT as primary modality, the GTV should be readily visualized during treatment preparation

The CTV should be more generous in this clinical situation and encompass lymph nodes in the vicinity that, although of normal size, might contain microscopic disease that will not be treated when no chemotherapy is given

Gross tumor volume (GTV) (ICRU 83)

- Gross demonstrable extent and location of the tumor (lymphoma)
- Original (before any treatment) lymphoma: pre-chemo GTV
  - Seen on CT: pre-chemo GTV(CT)
  - Seen on FDG-PET: pre-chemo GTV(PET)
- Residual (after systemic treatment) lymphoma: post-chemo GTV
  - Seen on CT: post-chemo GTV(CT)
  - Seen on FDG-PET: postchemo GTV(PET)

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Volume Definitions for Planning RT for Lymphomas

- **Determination of Gross Tumor Volume**

Imaging abnormalities obtained before any intervention should be outlined on the simulation study and included in the CTV

Volume Definitions for Planning RT for Lymphomas

- **Role of imaging in radiation planning**
  - 3D imaging (with CT supplemented by functional imaging: PET-CT)
  - The use of diagnostic contrast-enhanced CT is recommended to help to delineate nodal stations and differentiate nodes from vessels
  - Ideally, imaging studies with the patient in the treatment position and using the planned immobilization devices
  - Four-dimensional CT imaging in determining the ITV for sites that move with respiration
  - Acquiring high-quality imaging is fundamental to high-quality RT planning

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Clinical target volume (CTV) (ICRU 83)

- Volume of tissue that contains a demonstrable GTV and/or subclinical malignant disease with a certain probability of occurrence considered relevant for therapy
- Encompasses the original (before any treatment) lymphoma (pre-chemo GTV), modified to account for anatomic changes if treated with chemotherapy up front
- Normal structures (e.g., lungs, kidneys, muscles) that were clearly uninvolved should be excluded
- Residual lymphoma (post-chemo GTV) is always part of the CTV

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Role of Radiation Therapy in Indolent Nodal Lymphomas

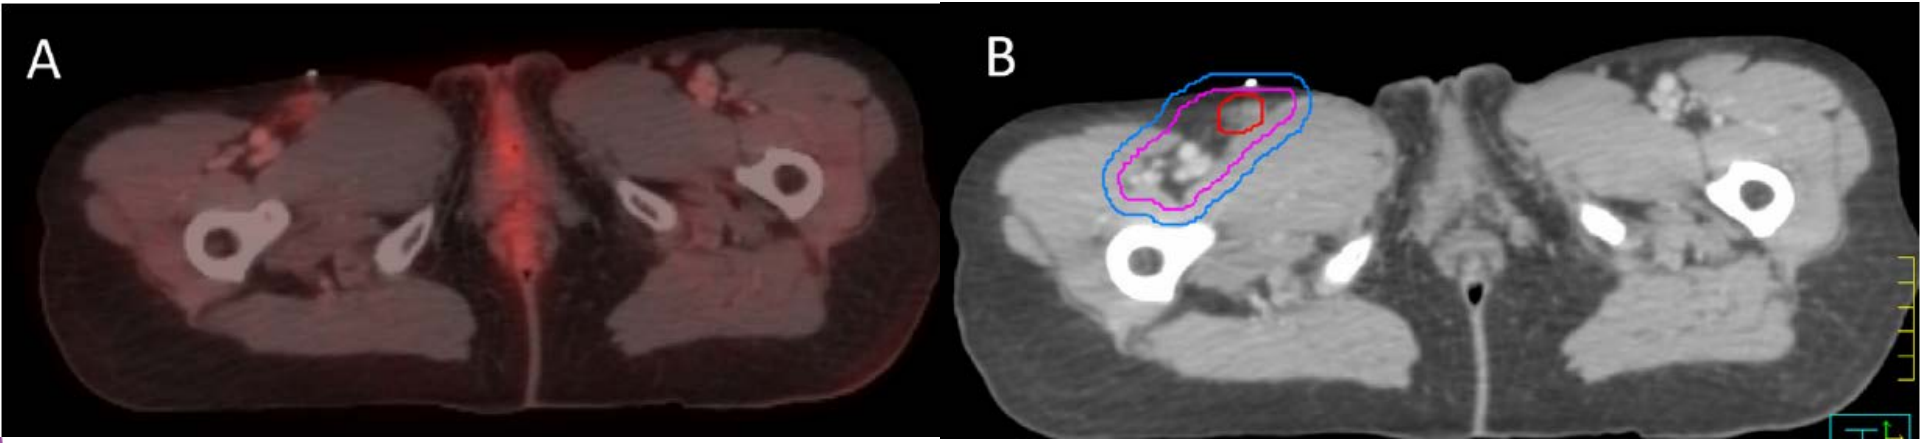
- **Localized Indolent Lymphoma**

  - The CTV must be designed to encompass suspected subclinical disease based on preintervention GTV imaging

  - The CTV should incorporate GTV and include as a minimum adjacent lymph nodes potentially containing microscopic disease in that site, and a generous margin dictated by the clinical situation

Modern Radiation Therapy for Nodal Non-Hodgkin Lymphoma—Target Definition and Dose Guidelines From the International Lymphoma Radiation Oncology Group

ISRT: Localized indolent lymphoma



The CTV must be designed to encompass suspected subclinical disease based on the pre interv
The CTV should incorporate GTV and include adjacent lymph nodes in that site and margin di

Illidge et al, IJROBP, 2014

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Defining CTV relies upon

- knowledge of the spread patterns of the disease
- potential subclinical extent of involvement
- adjacent organ(s) at risk constraints

all of which depend on clinical judgment and experience

Considerations on RT dose

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

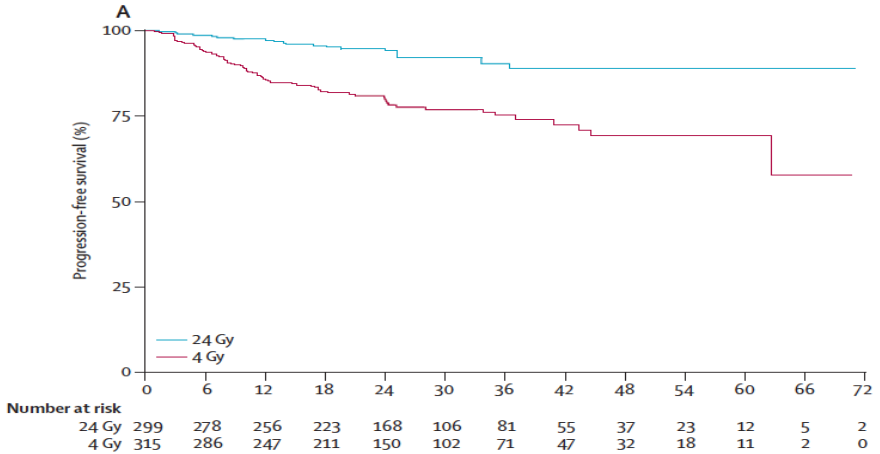
Hoskin et al, Lancet Oncol, 2014

4 Gy versus 24 Gy radiotherapy for patients with indolent lymphoma (FORT): a randomised phase 3 non-inferiority trial

Peter J Hoskin, Amy A Kirkwood, Bilyana Popova, Paul Smith, Martin Robinson, Eve Gallop-Evans, Stewart Coltart, Timothy Illidge, Krishnaswamy Madhavan, Caroline Brammer, Patricia Diez, Andrew Jack, Isabel Syndikus

Lancet Oncol 2014; 15: 457–63

	24 Gy	4 Gy
All patients*		
Complete regression	176 (68%)	137 (49%)
Partial regression (>30%)	60 (23%)	90 (32%)
Stable disease (including <30% regression)	22 (8%)	44 (16%)
Progression	2 (<1%)	10 (4%)
Total	260	281



Interpretation 24 Gy in 12 fractions is the more effective radiation schedule for indolent lymphoma and should be regarded as the standard of care. However, 4 Gy remains a useful alternative for palliative treatment.

Role of Radiation Therapy in Indolent Nodal Lymphomas

- **Advanced-stage Indolent Lymphoma**
  - Patients with advanced or recurrent indolent disease treated with very low doses of only 4 Gy in 2 fractions achieve high response rates
  - RT provides effective palliation for localized symptomatic disease
  - RT to sites of bulky disease where monitoring clinical progression is challenging and progressive disease may lead to organ failure (such as within the retroperitoneum)

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

RT techniques

Dose constraints in lymphoma RT

- The relatively low radiation doses needed result in most treatment plans being within the acceptable limits
- Even low doses to normal tissues, previously considered safe, may result in significant risks of morbidity and mortality in long-term survivors
- Doses to all normal structures should be kept as low as possible, but some structures are more critical than others

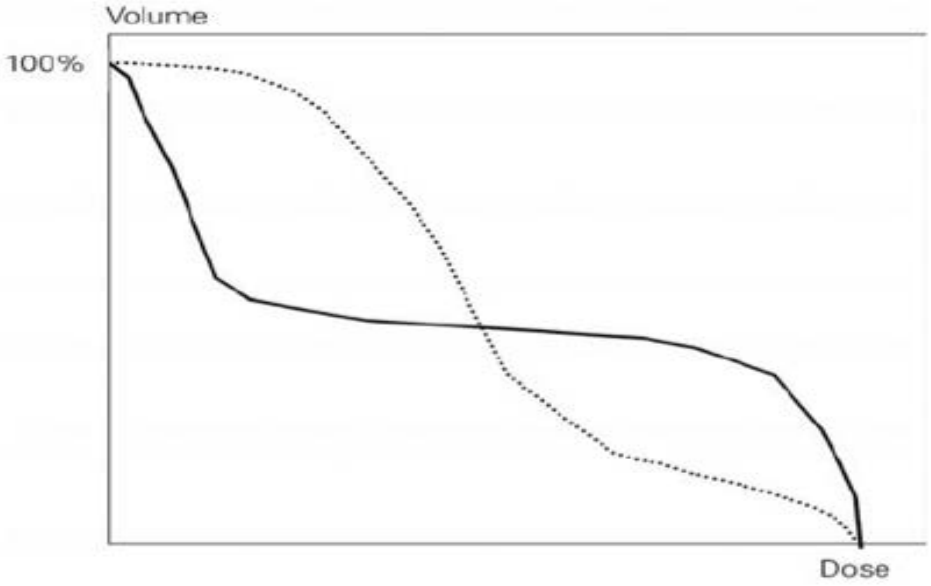
IMRT vs 3D-CRT in lymphoma

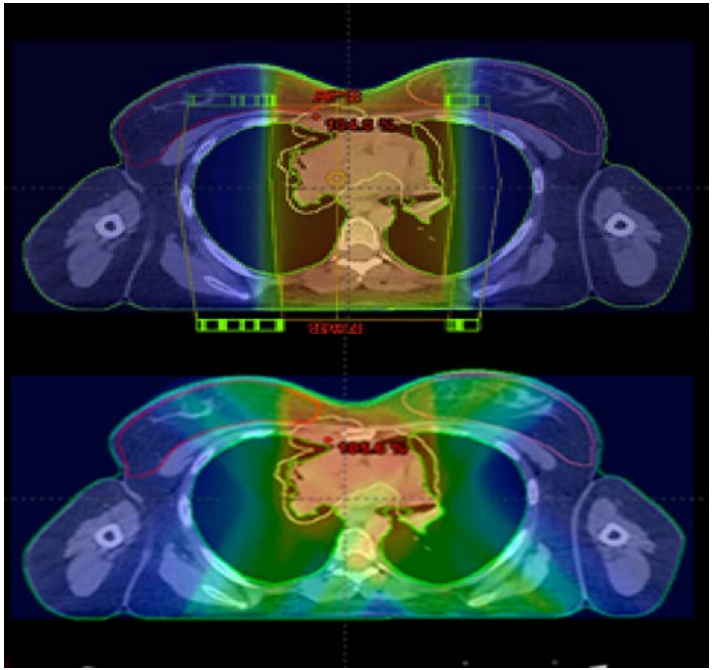
- Several published studies investigated the dosimetric profiles of IMRT compared to those of 3D-CRT

- They showed significantly better PTV coverage (V_{90}, V_{95}, conformity index) and/or significantly better sparing effect for different OAR
  - both for the traditional IFRT and for the more recent concept of limited RT (INRT, ISRT)

A Little to a Lot or a Lot to a Little?

Better sparing of critical normal structures usually at the price of a larger total volume of normal tissue irradiated, albeit to a lower dose

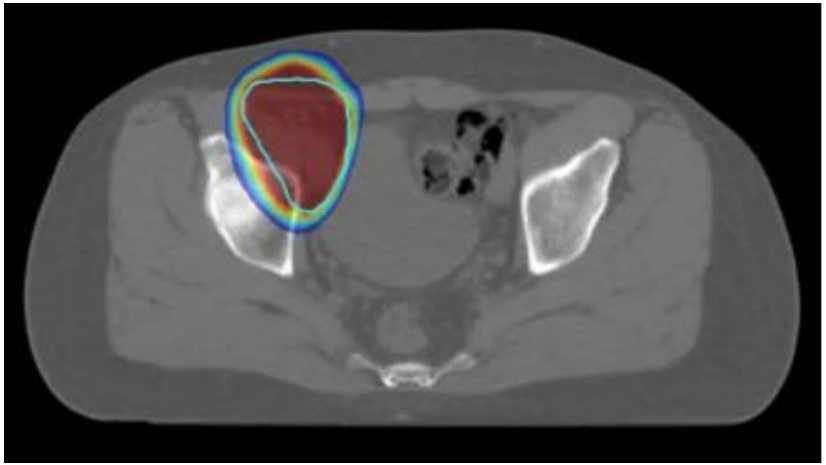


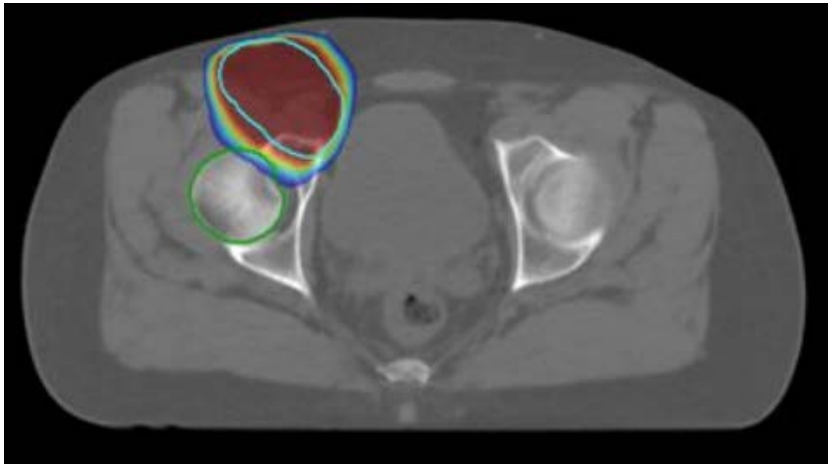


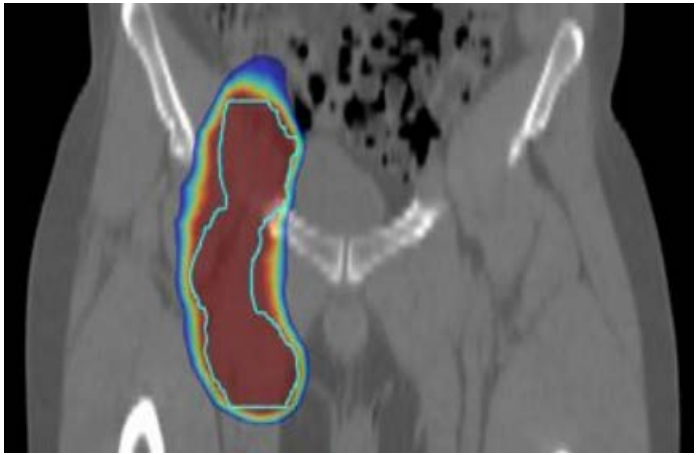
Which technique is preferable?

- There is no single proven best planning and delivery RT technique
- No two lymphomas are the same with regard to localization and extent of disease
- The decision should be made at the individual patient level (i.e., what appears the optimal treatment plan for one patient may not be acceptable for another patient)

M. L., 43 years old, follicular NHL, stage IA







Modern RT in lymphoma

- Radiation therapy has changed dramatically over the last few decades in terms of both irradiated volumes and dose

- Smaller treatment volumes, lower radiation dose and advanced conformal radiotherapy can certainly allow a safer radiation delivery

What is new?

(compared to 2007)

Staging:

- PET/CT for routine staging of FDG-avid Lymphomas
- BMBx not required for HL and most DLBCL
- Simplification of Ann Arbor

Response assessment:

- PET/CT is standard of care for remission assessment
- Standard tool for reporting response is 5-PS (Deauville criteria)
- Deauville Criteria can be used to assign metabolic response categories (CMR, PMR, NMR, PMD)
- Revised CT size criteria

Surveillance:

- Routine scanning discouraged.

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

PET/CT as standard imaging for staging

- PET-CT should be used for routine staging of FDG-avid lymphomas
  - Most lymphomas take up FDG
  - More accurate > CT especially **EN sites**
  - PET results in more **upstaging** > down staging
  - Management change: largest effect in FL (upstaging of early disease)

- PET is important for **RT volumes <IFRT**

- can be used to direct biopsy
  (especially if suspected transformation)

- A baseline PET-CT scan is also desirable for subsequent response assessment

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

Angioimmunoblastic T-cell lymphoma (n = 31)	78 - 100
Enteropathy type T-cell lymphoma (n = 20)	67 - 100
Mycosis fungoides (n = 24)	83 -100
Sezary Syndrome (n = 8)	100 (but only 62% of cutaneous sites)
Primary cutaneous anaplastic large T-cell lymphoma (n =14)	40-60
Lymphomatoid papulosis (n = 2)	50
Subcutaneous panniculitis-like T-cell lymphoma (n = 7)	71
Cutaneous B-cell lymphoma (n = 2)	0

Modified from Weiler-Sagie et al

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Bone Marrow Assessment

- HL: PET/CT only (BMBx no longer required)

High sensitivity and specificity
Large studies showed: v small % of false -ve but no change in therapy

- DLBCL: PET/CT enough in most cases

High sensitivity and specificity
But: small % of **false –ve** (small volume 10-20%)
possibility of missing **LG** component
Histologically +ve BM may be more **prognostically** important
So BMBx indicated only if result may change management

- FL / LG-NHL: BMBx is mandatory

High false negative rate

Recommendations for Bulk

- No agreed definition:
  - HL: 10 cm or 1/3 thoracic diam at any level?
  - DLBCL: 6 – 10 cm? 7.5cm?
  - FL: 6 cm?

- Maximum tumour dimension (MTD) on CT should be recorded at staging*

  * *Term X need no longer be used*

- Methods of Volumetric Measurement of total tumour volume should be explored

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

MTV-0 + DS

	At risk	events	5y-PFS
MTV-0 <400 + DS 4-5	20	1	95%
MTV-0 <400 + DS 1-3	46	5	90.9%
MTV-0 ≥400 + DS 1-3	36	15	58.5%
MTV-0 <400 + DS 4-5	45	29	29.7%

Splenic Involvement

SIZE:

- Wide range of size (race, body size and height)

- Normal size spleen may contain lymphoma and enlarged spleen may be due to other causes

- No agreement on:
  - Single, multiple or volumetric measurement
  - Cut-off

Recommendations for splenic evaluation:

- PET/CT: Best method (diffuse, focal)

- CT: cut-off for splenomegaly is 13cm vertical length

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Simplified Ann Arbor

A / B designation only for HL

Table 2. Revised Staging System for Primary Nodal Lymphomas

Stage	Involvement	Extranodal (E) Status
Limited		
I	One node or a group of adjacent nodes	Single extranodal lesions without nodal involvement
II	Two or more nodal groups on the same side of the diaphragm	Stage I or II by nodal extent with limited contiguous extranodal involvement
II bulky*	II as above with "bulky" disease	Not applicable
Advanced		
III	Nodes on both sides of the diaphragm; nodes above the diaphragm with spleen involvement	Not applicable
IV	Additional noncontiguous extralymphatic involvement	Not applicable

NOTE. Extent of disease is determined by positron emission tomography–computed tomography for avid lymphomas and computed tomography for nonavid histologies. Tonsils, Waldeyer's ring, and spleen are considered nodal tissue.

*Whether stage II bulky disease is treated as limited or advanced disease may be determined by histology and a number of prognostic factors.

Response assessment

Change from IHP to Deauville

- IHP (Juweid):
  - Lesions ≥2cm: CMR is <mediastinum (MBP)
  - Lesions <2cm: CMR is <background
- Deauville:
  - 5 degrees of response
  - MBP and liver thresholds
  - No lesion-size dependence
- Main reasons to change:
  - Change in technology
  - Accumulating data on data on 5PS:
    - Several studies reported improved PPV while maintaining NPP
    - High inter-observer agreement
    - At least 8 studies using DS

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

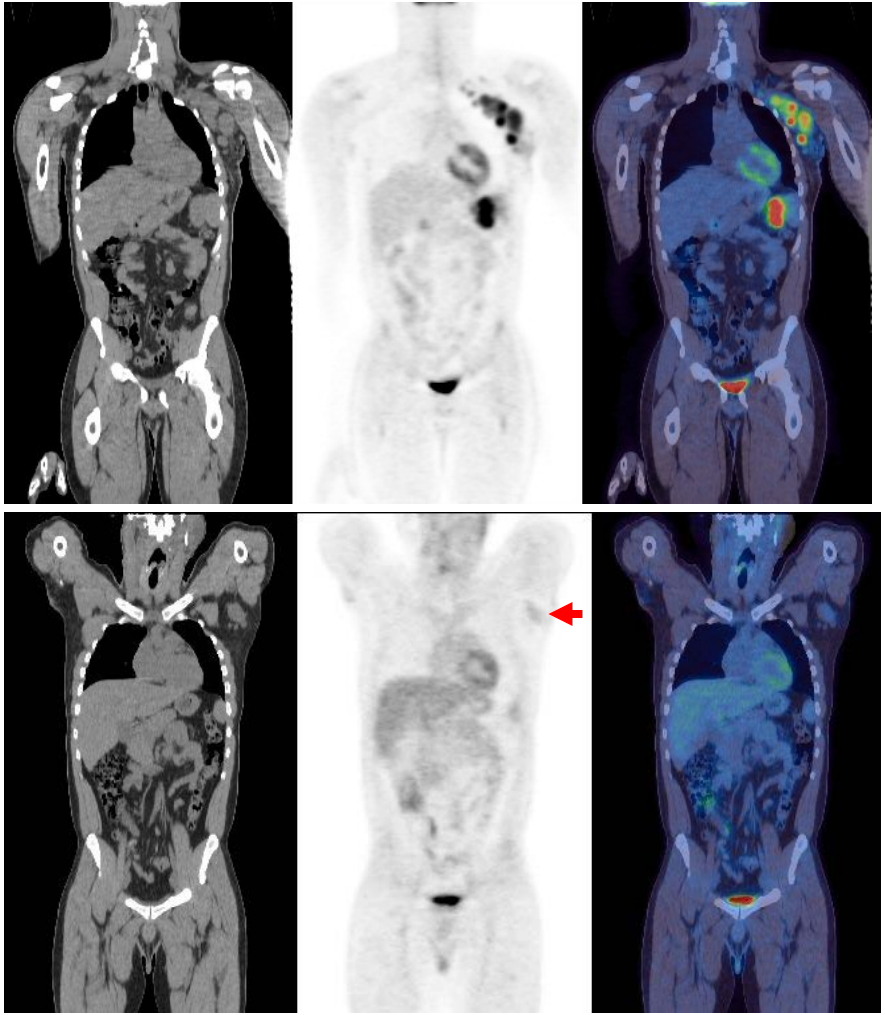
Post



uptake > mediastinum

but < liver

ESTRO School

Score 3

- Main difference with IHP
- Score 3 Definition: uptake > mediast. but ≤ liver
- Is it CMR or PMR? (disease, timing, treatment)

- iPET v ePET:
  - **iPET:** good response (& subsequent Rx planned)
  - **ePET:** CMR?

- Clinical Practice v Trials:
  - Clinical practice: consider prognosis & available options (e.g. RT)
  - Trials: depending on question; escalation v de-escalation

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Score 4 & 5

- Definition:
  - Score 4: **moderately** increased uptake > liver
  - Score 5: **markedly** increased uptake
    OR new lesion(s) likely to be lymphoma

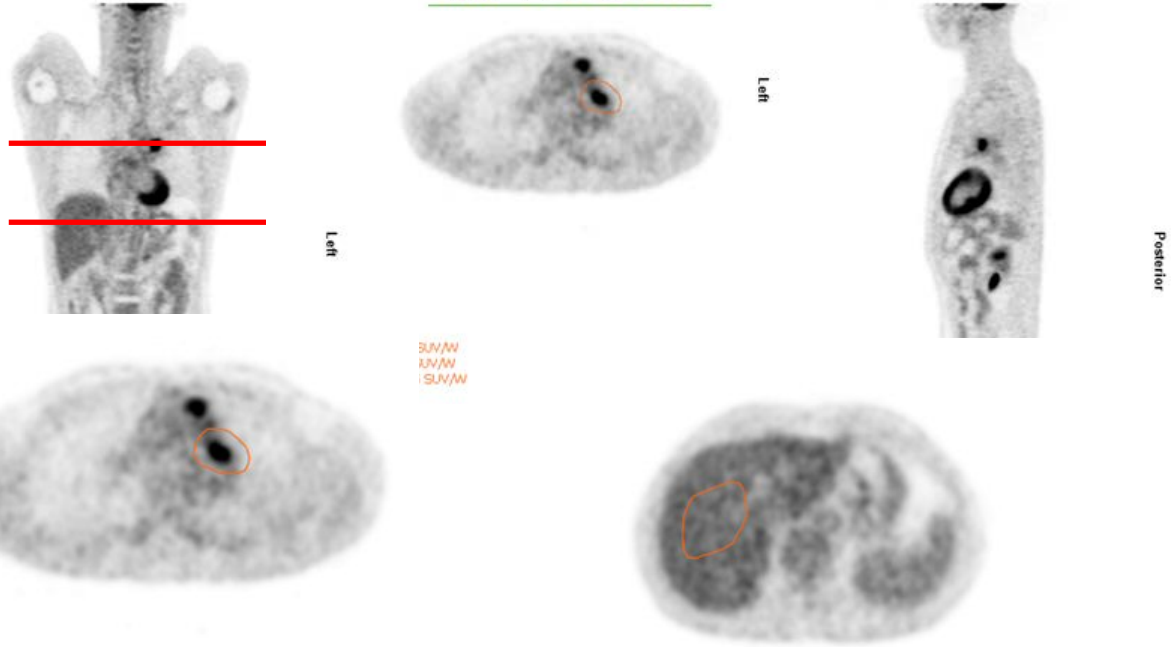
- Difference between “moderate” and “marked”:
  - Moderate: ≥ 130% liver uptake (measured over a large area)
  - Marked: 2 -3 times uptake of liver

- How:
  - Visually
  - SUV aid when close (SUVmax v SUVmean)

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

King's College London & Guy's and St Thomas' PET Centre



SUVmax lesion 8.51

SUVmax liver 2.44

Score 5

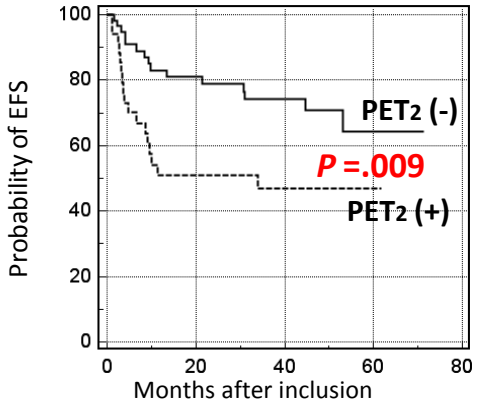
Visual vs. quantitative analysis DLBCL 2 cycles

n = 92 PET 2

Visual analysis

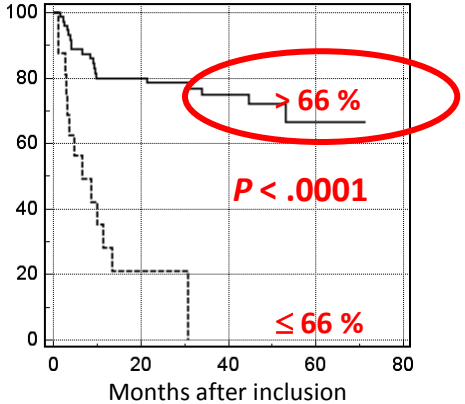


NPV=74%, PPV=50%

n = 80 PET 2

Quantitative analysis

(% reduction SUVmax)



NPV=73.6%, PPV=84.6%

Lin et al al. JNM 2007;48:1626-32

c/o M Meignan, Creteil , France

Challenges with quantitation

Standardised methods :

- PET acquisition
- QC - calibration and monitoring of cameras

Less reliable if low baseline SUV or high residual uptake

Δ SUV cannot always be measured

(17% in Casanovas et al. Blood 2011;118:37-43)

Variation in optimal cut-offs by different groups

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Recommendation:

Quantitation for Response

- Data suggest that Quantitative methods e.g. delta SUV could be used to improve on visual analysis for response assessment in DLBCL but requires further validation in clinical trials [PS: PETAL study ASH 2014]

- Standardisation of PET methods is mandatory for use of quantitative approaches and desirable for routine clinical practice

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Recommendation:

Interim PET-CT

- If mid therapy imaging is performed, PET-CT is superior to CT
- Trials are currently evaluating the role of PET response adapted therapy
- Meantime it is not recommended to change treatment based solely on PET-CT unless there is clear evidence of progression

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Revised criteria for response assessment

	PET-CT BASED RESPONSE	CT-BASED RESPONSE
	Complete Metabolic Response (CMR)	Complete Radiologic Response (CR)
	Partial Metabolic Response (PMR)	Partial Remission (PR)
	No Metabolic Response (NMR)	Stable disease (SD)
	Progressive Metabolic Dis (PMD)	Progressive disease (PD)

	PET-CT BASED RESPONSE	CT-BASED RESPONSE
	Complete Metabolic Response (CMR) ***ALL* of the following**	**Complete Radiologic Response (CR)** ***ALL* of the following**
Lymph nodes and Extranodal sites	**Score 1, 2, or 3* ± a residual mass**	**Target nodes/nodal masses must regress to ≤ 1.5 cm in LDi. No EN sites.**
Non-measured lesion/s	Not applicable	Absent
Organ enlargement	Not applicable	Regress to normal
New lesions	None	None
Bone marrow	No evidence of FDG-avid disease in marrow	Normal by morphology; if indeterminate, IHC -ve
	Partial Metabolic Response (PMR) **ANY of the following**	**Partial Remission (PR)** **ALL of the following**
Lymph nodes and extranodal sites	**Score 4,5** with reduced uptake compared with baseline and residual mass(es) of any size.** *At **interim*** these findings suggest responding disease. *At **end of treatment*** these findings indicate residual disease	**≥ 50% decrease in SPD of up to 6 target measureable nodes and EN sites**
Non-measured lesions	Not applicable	Absent/normal, or regressed but no increase
Organ enlargement	Not applicable	Spleen must have regressed by >50% in spleen length beyond normal
New lesions	None	None
Bone marrow	Residual uptake higher than uptake in normal marrow but reduced compared with baseline	Not applicable

ILROG

Contrast-enhanced CT?

- PET-CT: low-dose non-contrast CT for:
  - Attenuation correction
  - Anatomical localisation

- Pros of Contrast:
  - More **findings** (but rarely change management)
  - Improves **abdo/pelvic** disease detection (bowel physiologic uptake)
  - Shows **vascular** compression/ thrombosis
  - **RT** planning
  - LN **measurement** for clinical trials

- Cons:
  - Additional **radiation**
  - **Resource** implications
  - Small **errors** in FDG measurement in tumours (unlikely to be significant) and 10-15% increase in liver/MBP uptake

Recommendation:

PET –ve Residual masses

- Investigation of significance of PET-negative residual masses should be collected prospectively in clinical trials

- residual mass size and location should be recorded on end-of-

Changes to CT response from 2007

- If a confluent mass splits into discrete nodes when disease is responding, the perpendicular diameters of the nodes should be summed and the combined PPD compared with the PPD of the initial mass
- If nodes later grow the nadir of each node is used to determine progression (or not)
- If target nodes become a confluent mass when disease is progressing, the diameters of those target nodes should be added and the combined PPD compared with the PPD of the subsequent mass
- Splenic enlargement defined as >13cm
- In relapsed disease, CT criteria for PD can be based on increase in a single lesion. SPD eliminated for PD.
- Agents associated with flare reactions may require biopsy or repeat assessment > 2 weeks to determine if there is PD

Follow up

- Clinical judgement, history & examination are cornerstones of FU
- FU freque is determined by histology, if patient is within a trial & clinical setting
- Frequency in curable lymphoma (eg HL, DLBCL) ↓ over time with ↓ likelihood of relapse
- Frequency of FU in other lymphoma (eg FL, MCL) ↑ over time as ↑ likelihood of recurrence
- Surveillance scans should be discouraged
- FP rate > 20% for surveillance PET leads to unnecessary investigations, radiation , biopsies, cost and anxiety

Staging and response criteria

- 1999 National Cancer Institute Working Group
- 2007 International Working Group
- 2211 Lugano imaging

Staging PET/CT

- Flat tabletop
- 2mm slice thickness
- IV-contrast
- Oral contrast
- Arms up if possible
- Both staging and CT for radiation planning

- If suspicion of mediastinal involvment
- Breath hold DIBH

The Copenhagen Model

Staging with CT

- Up to 6 of the largest nodes/nodal masses that are measurable in two diameters, longest and shortest, in different regions, include mediastinal and retroperitoneal disease if involved.
- Node LD longer than 1.5 cm
- Extranodal LD longer than 1.0 cm

PET/CT interpretation

- Indikation :
- Injected dose
- PET interpretation:
- CT interpretation:
- Table of lymphoma measurements:
- Final PET/CT conclusion:

Indikation: Status efter afsluttet kemoterapi for anaplastisk, storcellet ALK negativt lymfom.

18-08-2015 gives i.v. 315 MBq F-18 FDG
mhp. Wb PET/CT FDG. PET 4

Beskrivelse:
PET-scanning:
Sammenholdt med PET/CT-scanning 24.06.15 ses tiltagende metabolisk aktivitet i tidligere beskrevne lymfeknuder periklavikulært og subpektoralt på ve. side samt i ve. aksil. Ligeledes indtryk af tiltagende FDG-optagelse i lymfeknuderne i hø. lyskeregion. Tilkommet moderat øget FDG-optagelse i lymfeknuder langs arcus aortae. Lymfeknuder med den højeste metaboliske aktivitet findes subpektoralt på ve. side og i ve. aksil, hvor aktivitetsniveauet overstiger baggrundsaktiviteten i leverparenkymet. Derudover kan der ikke påvises patologisk øget FDG-optagelse nogetsteds.

CT-scanning af hals, thorax og abdomen efter peroral, men uden i.v. kontrast på baggrund af kendt allergi:
Viser, sammenholdt med CT 24.06.15, tiltagende størrelse af nogle lymfeknuder periklavikulært på ve. side samt i ve. aksil, ligesom der er indtryk af tilkomne, men små, lymfeknuder i mediastinum superius sin. En del af de tidligere sete lymfeknuder i skemaet er dog aftaget i størrelse. Fortsat ikke forandringer i lungeparenkym eller intraabdominale organer. Ossøst uændrede forhold. Tumor 6 målte ved forrige undersøgelse 2,6 x 2,4 cm.

Tumor 1 IMA 102 Ve. halsrod 1,8 x 1,1 cm
Tumor 2 IMA 138 Ve. aksil 3,0 x 1,8 cm
Tumor 3 IMA 155 Distalt i ve. aksil 1,0 x 0,9 cm
Tumor 4 IMA 373 Iliaca externa kar dxt. 1,4 x 0,7 cm
Tumor 5 IMA 390 Hø. ingvinalregion 1,0 x 0,9 cm
Tumor 6 IMA 138 Ve. aksil 3,2, x 3,3 cm.

Konklusion:
Sammenholdt med PET/CT-scanning 24.06.15 samlet set indtryk af progression med tiltagende metabolisk aktivitet i lymfeknuder både over og under diaphragma, hvoraf nogle ses med tiltagende størrelse og andre aftagende.

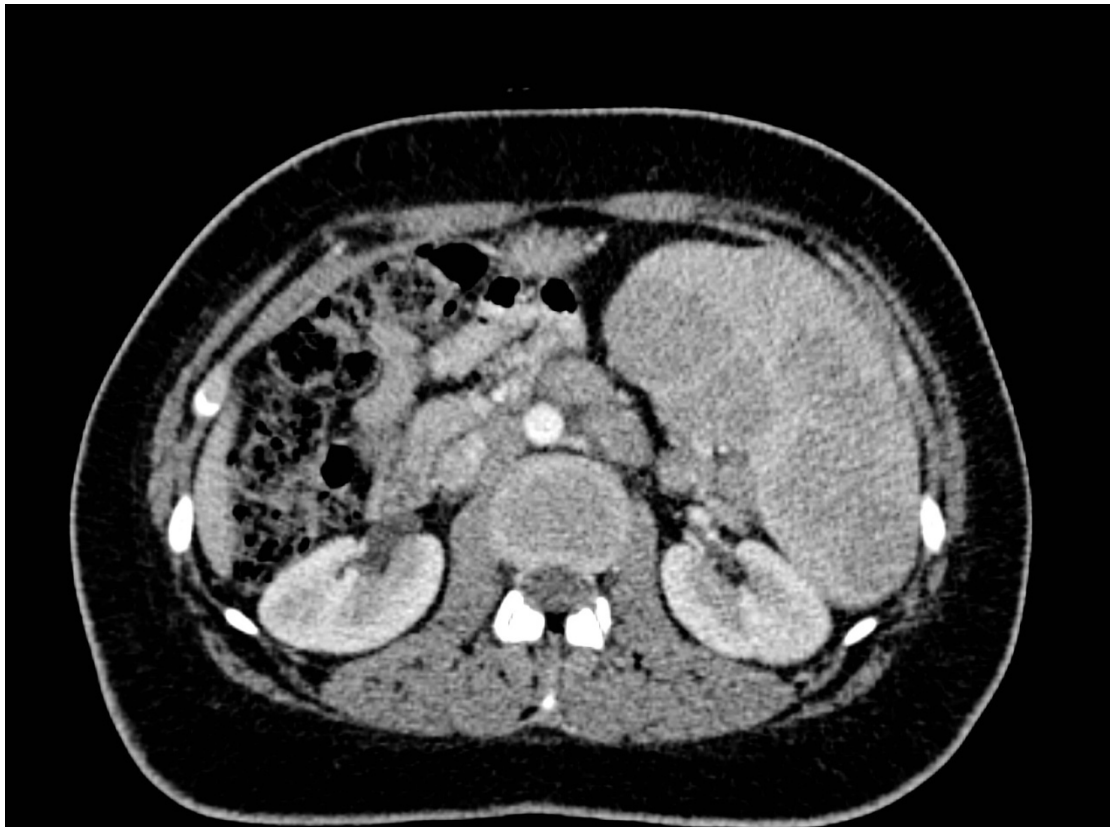
- Diffuse infiltration
- Focal nodular lesion
- Large solitary mass

Spleen – large solitary mass

Spleen diffuse infiltration

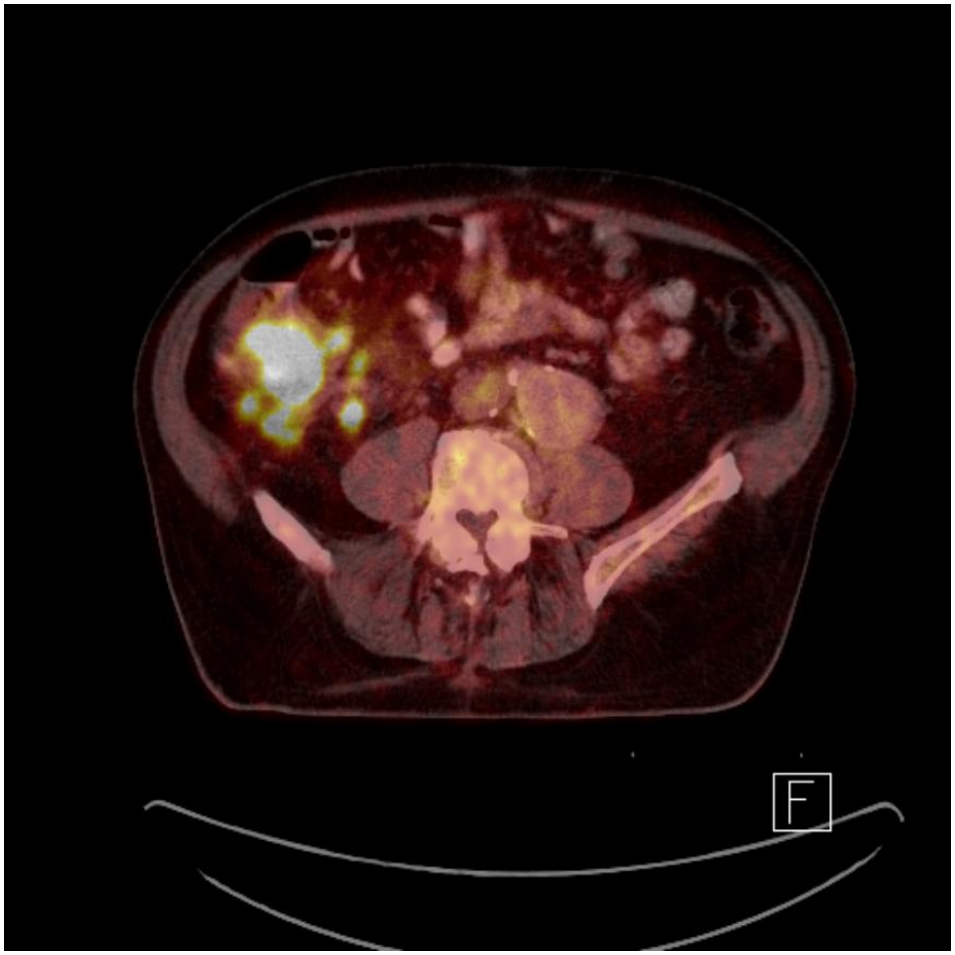
Spleen Focal nodula lesion



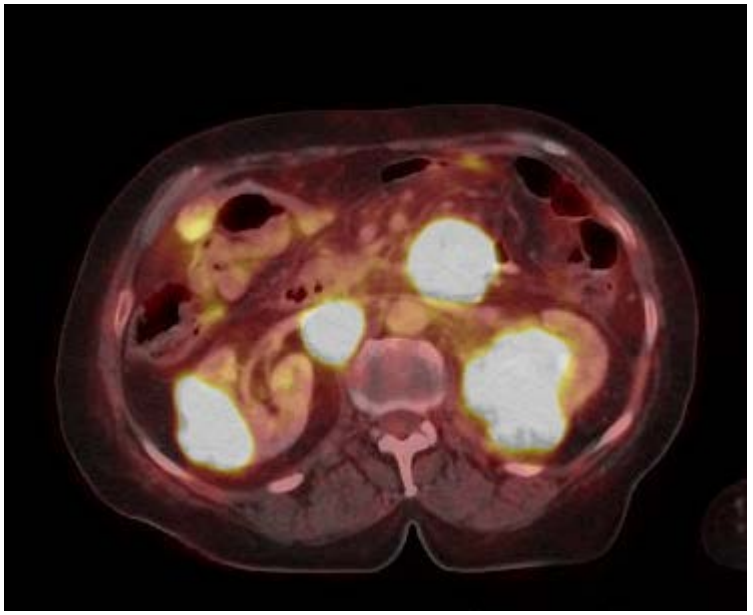
Liver involvement also best detected with PET/CT

Lymphoma in the stomach

Colon



Lymphoma infiltration of the kidneys



Conclusion

- Good images are nescessary for staging as well as treatment planning
- CT and PET/CT are complementary to the clinical examination for treatment planning
- Lymphoma treatment is difficult and collaboration between experts is mandatory

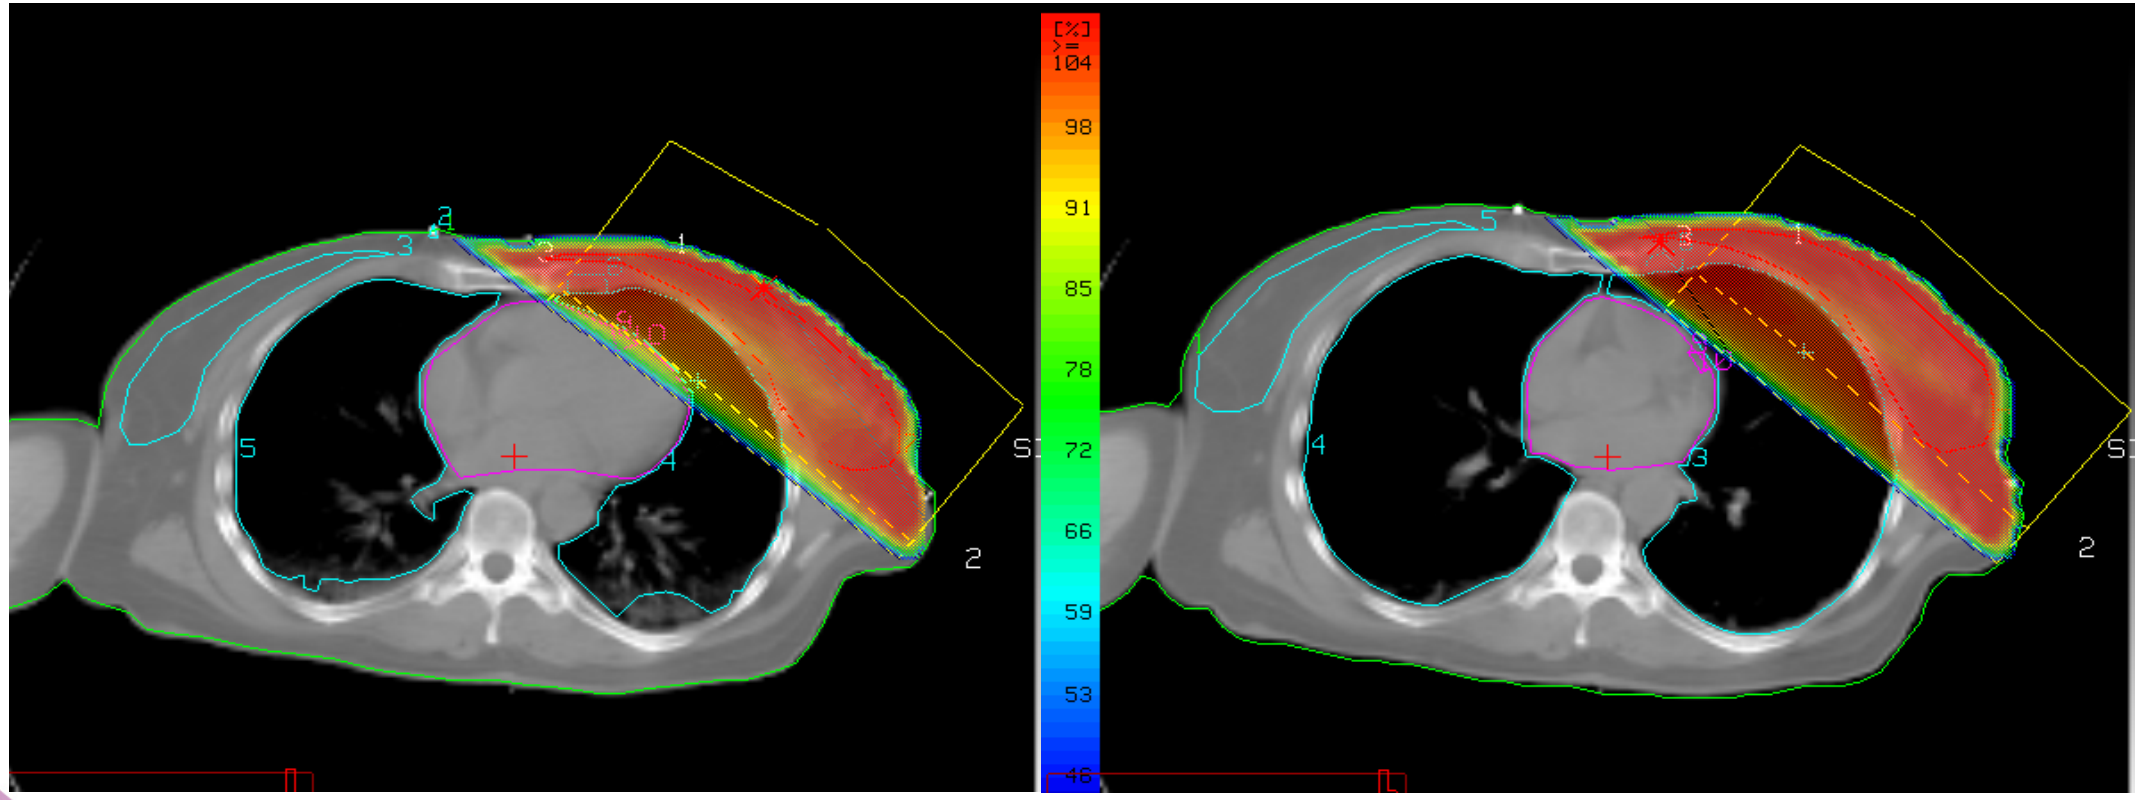
LYMPHOMA: A SPECIAL CASE

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

At Rigshospitalet

- Deep inspiration treatment since 2003 in left-sided breast cancer patients
- > 1000 patients



ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Methods

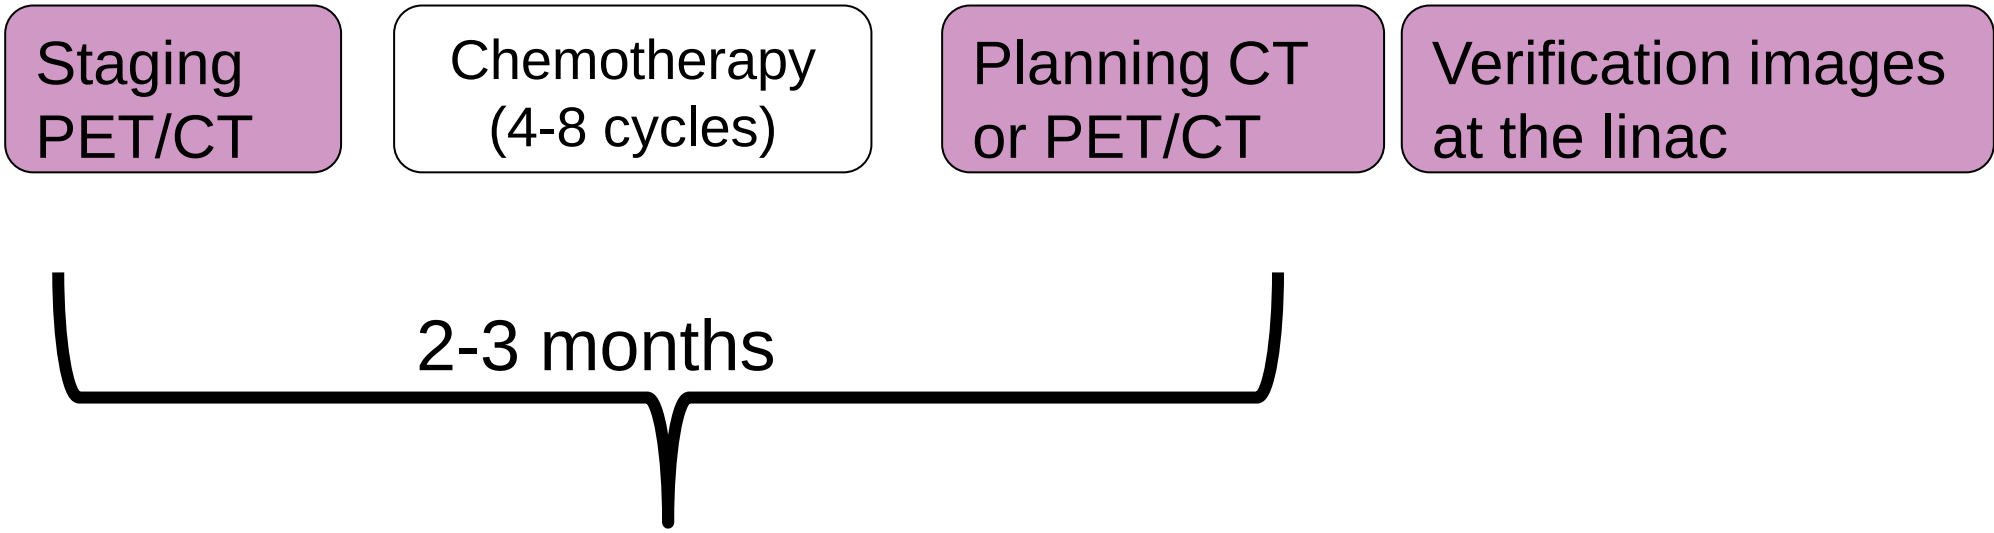
Overall aim:

reduce dose to the heart (heart disease)

And other organs (e.g. Secondary lung cancer)

Prospective phase II trial: 22 patients

All images in DIBH



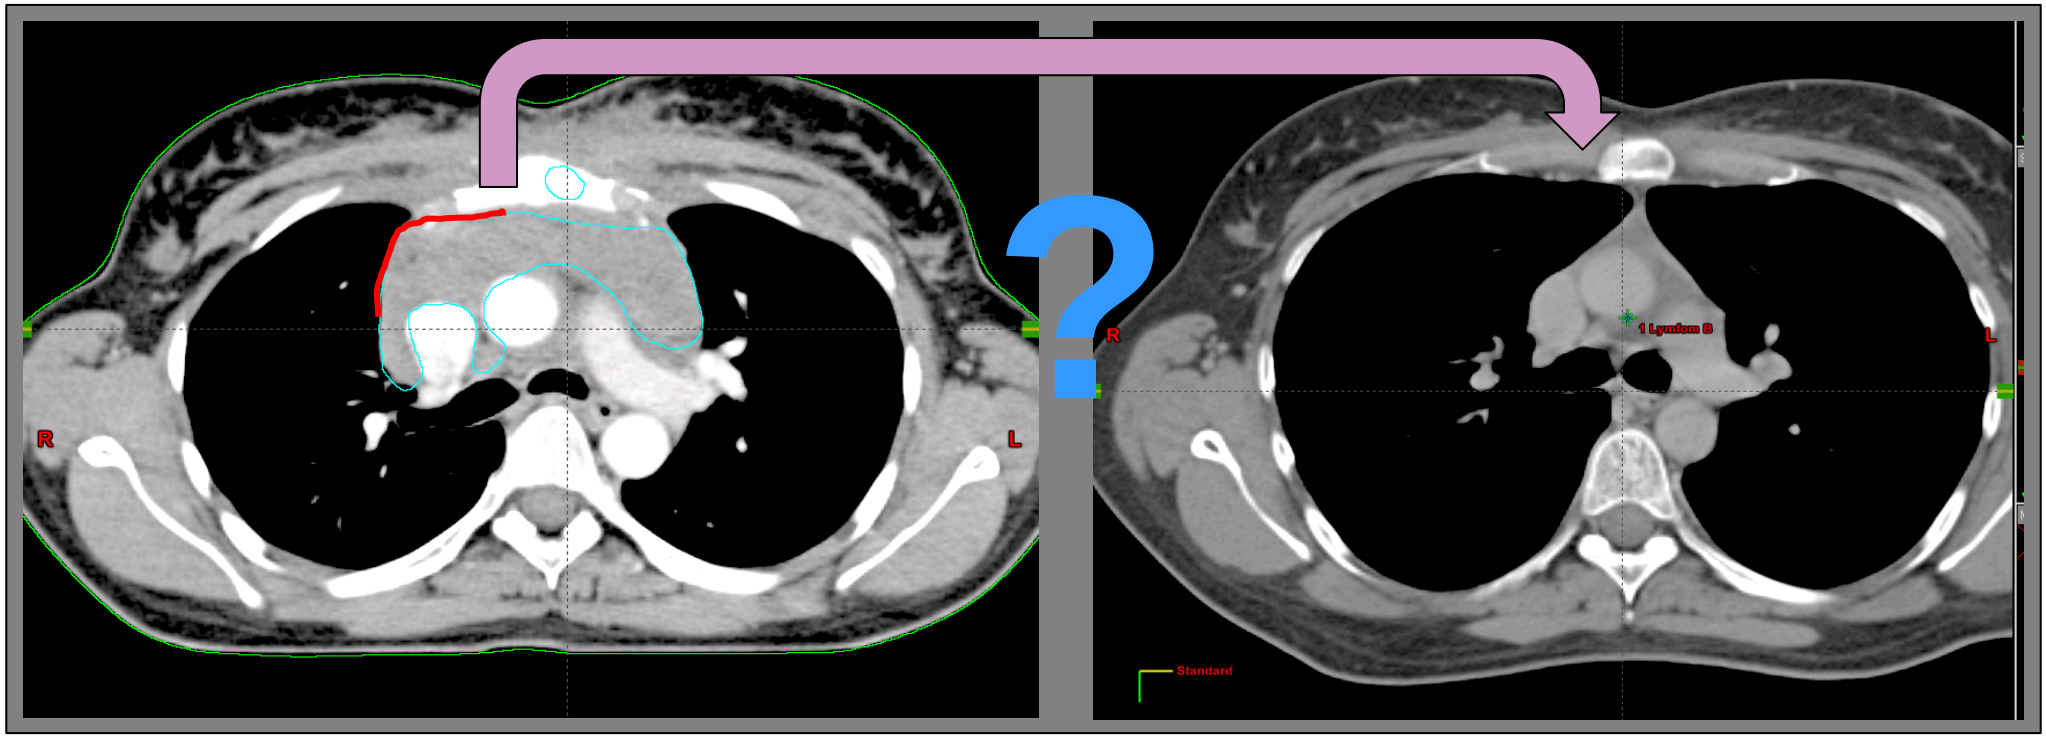
Fusing prechemo and planning images

Pre-chemo PET/CT

free breathing

Planning CT

at deep inspiration



ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

How to handle registration uncertainties ?

- Ensure a treatment-like position already at staging
  - Flat table top
  - Arms up
  - Chest board

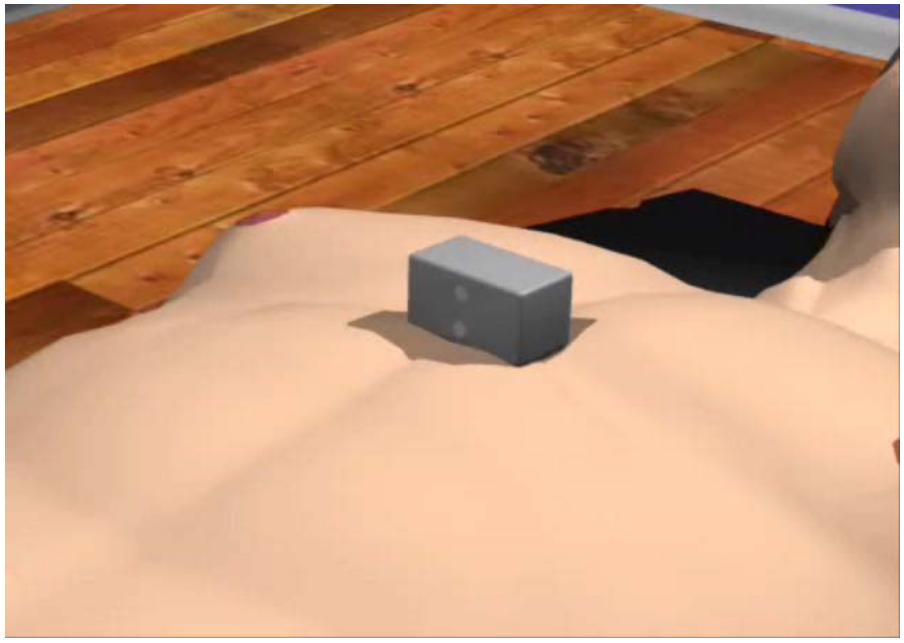
- Provide DIBH PET/CT at staging

- All these take time, logistic effort, and a good collaboration with the PET department!

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Respiration monitoring



<u>Varian RPM system:</u>
Deep inspiration breath hold
Gating
4D CT

On all linacs and scanners

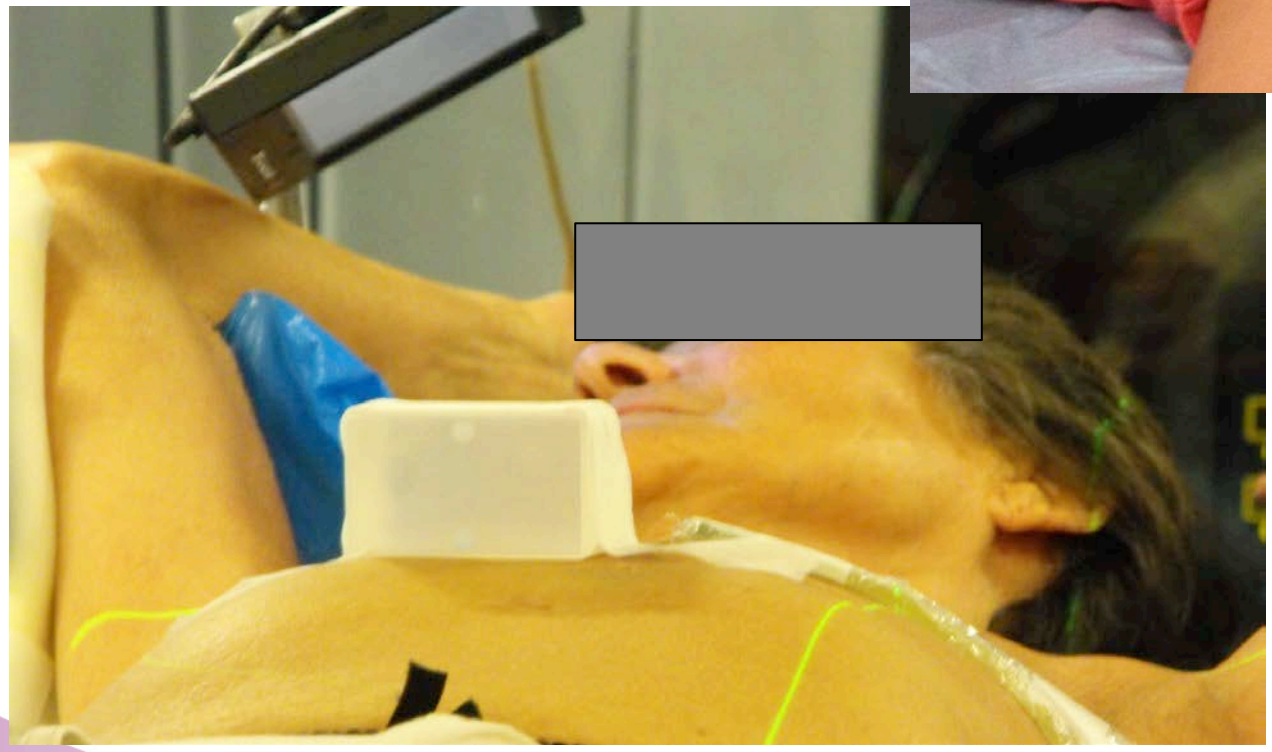
CT + PET/CT

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Visual guidance:

- Scanner
- linac



ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Free breathing

Deep inspiration
breath hold

Take home message (1)

- Keep patient instruction and information as simple as possible
- Coach before scanning (30 min) or directly at the scanner (5-10 min): equivalent results !!
- Extra time necessary at the scanner (install equipment, etc... plus extra acquisition) : 15-30 min
- Good communication with PET extremely valuable !

PET/CT acquisition in practice

Pre chemo scan: *400 MBq* FDG on Siemens Biograph 40 PET/CT (now depending on bodyweight)

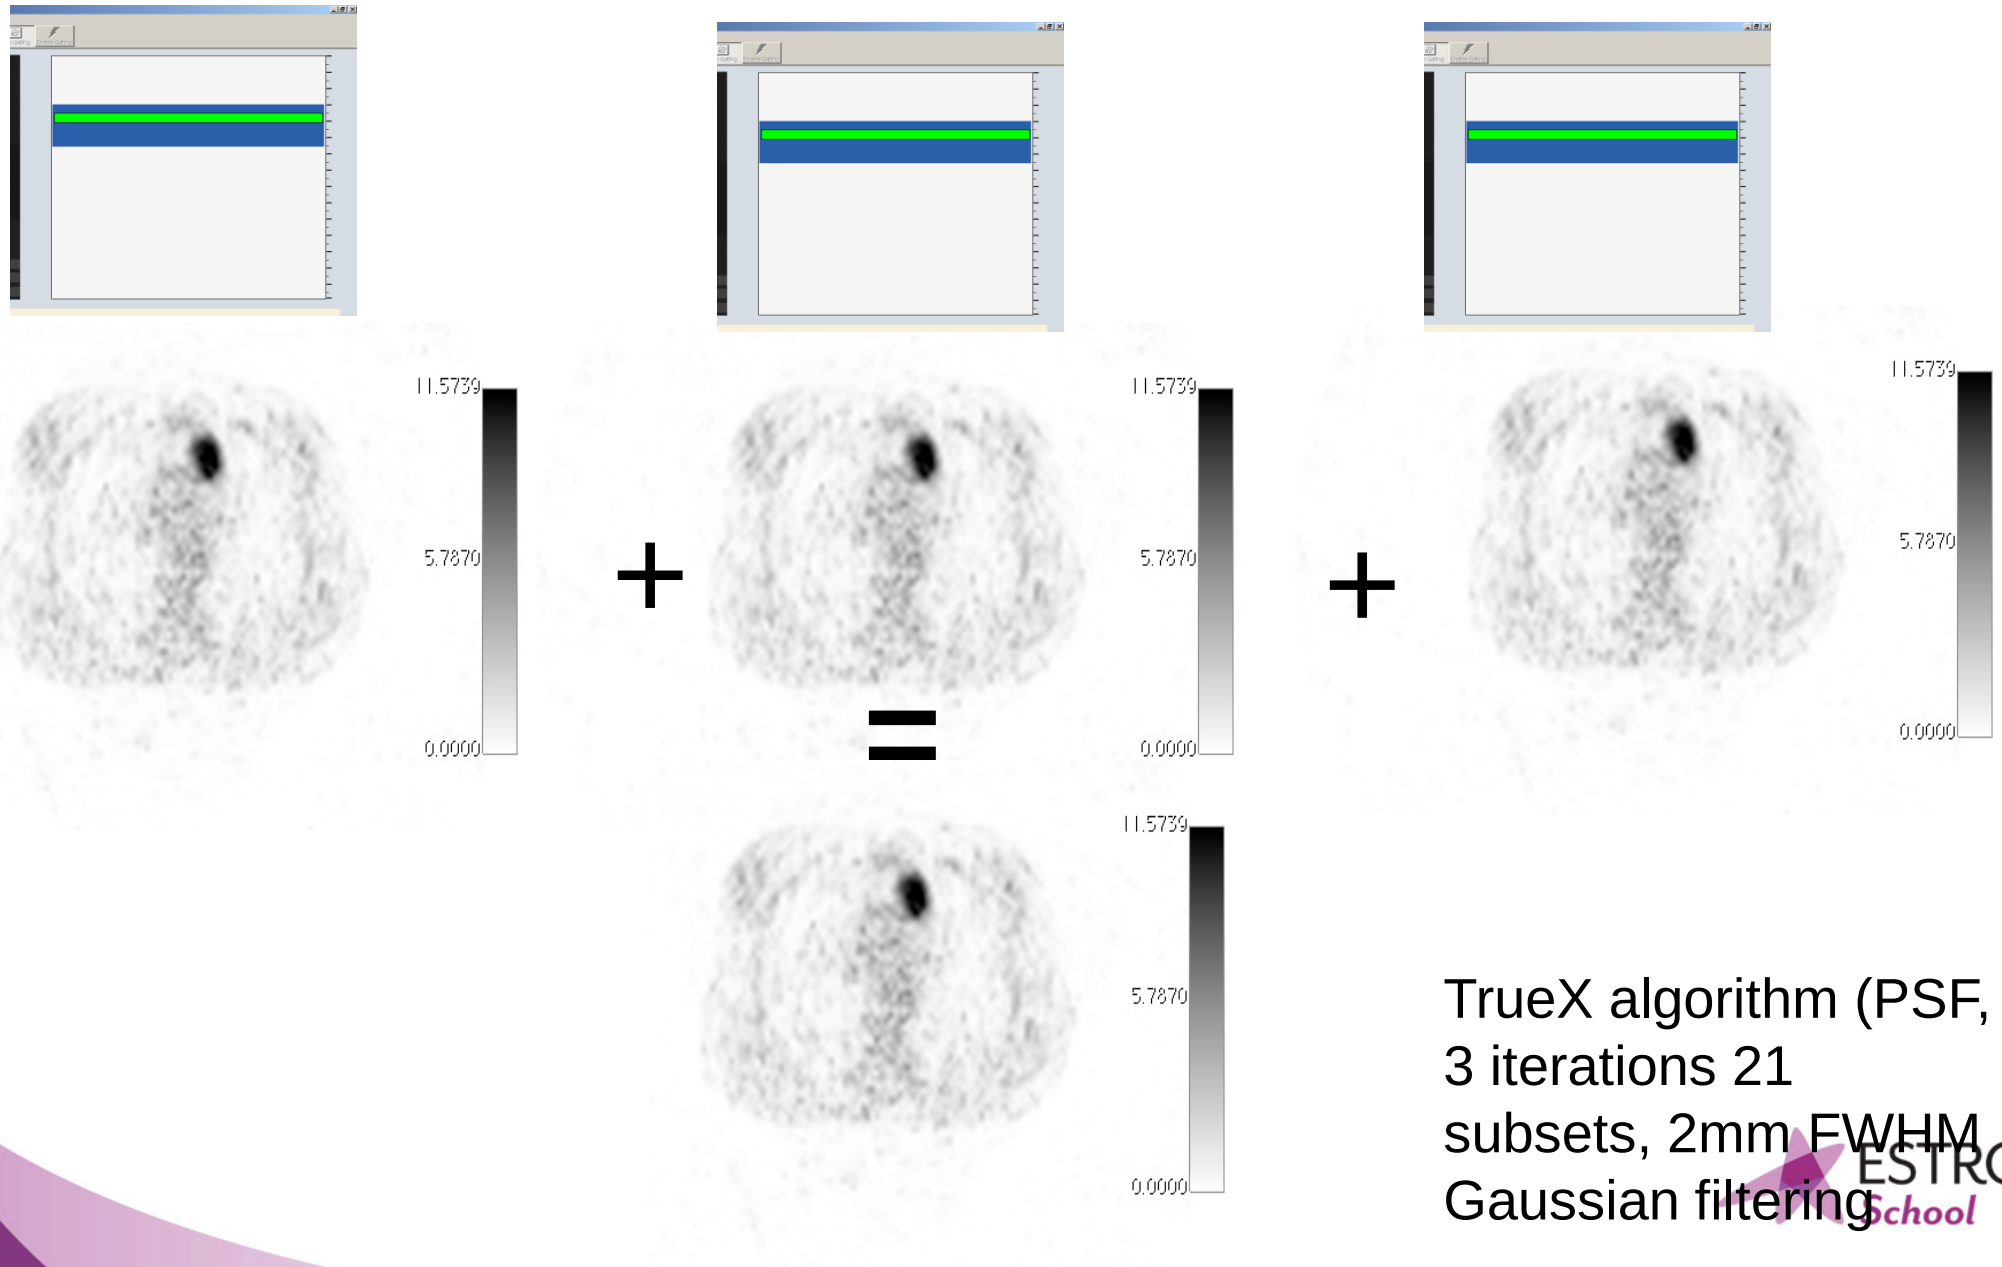
Free breathing scan followed by one FOV scan in breath hold

3 breath holds of 20 seconds each

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

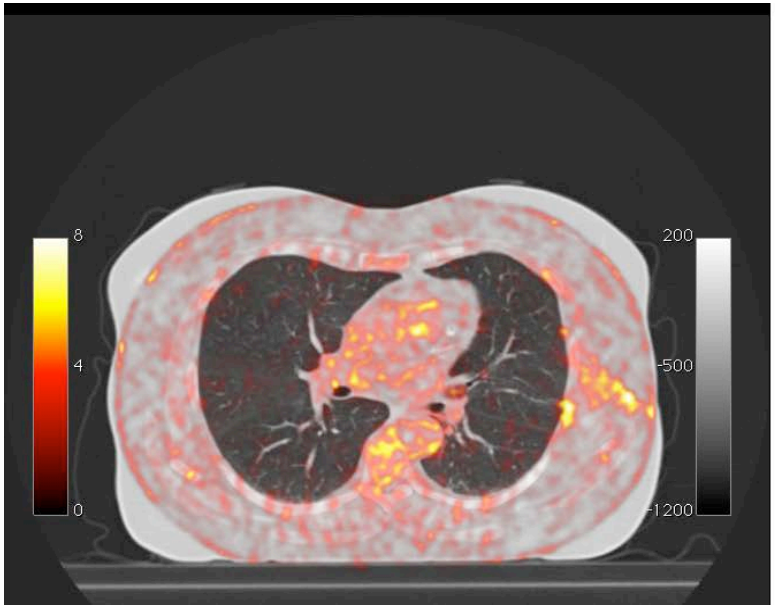
ESTRO School

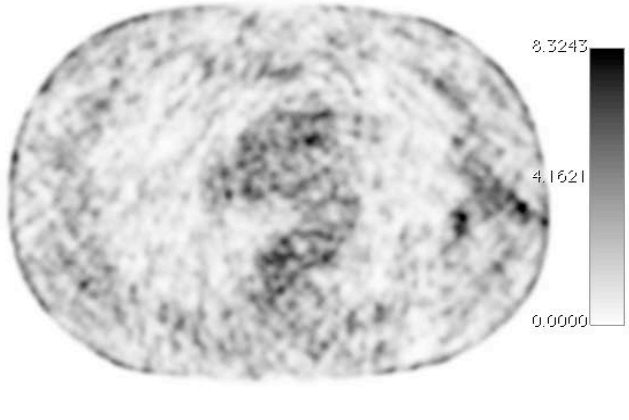
Methods: Image reconstruction

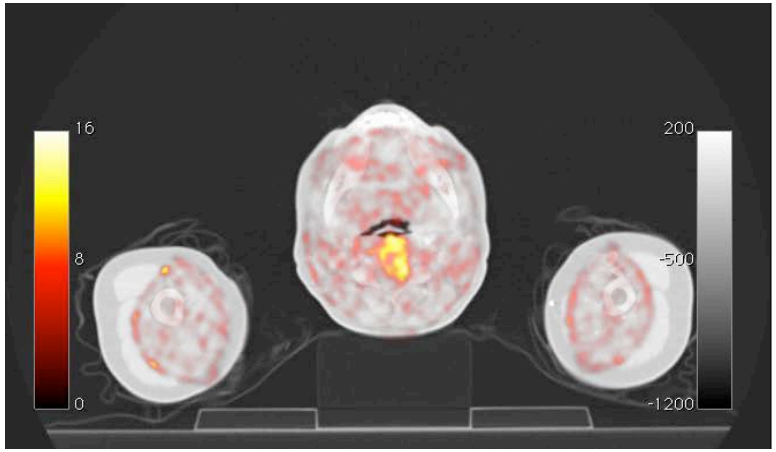


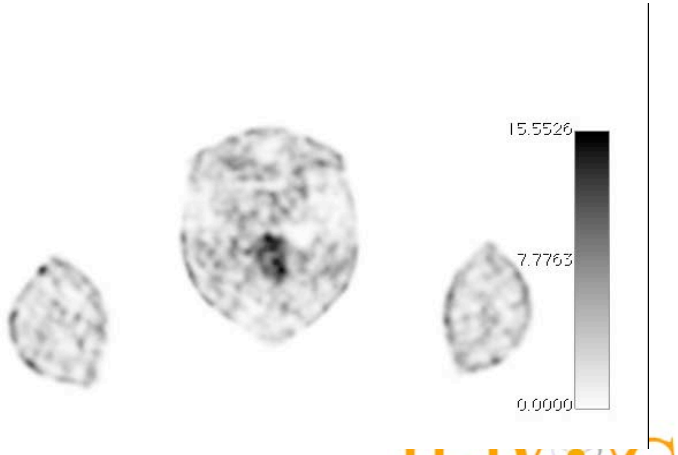
TrueX algorithm (PSF, 3 iterations 21 subsets, 2mm FWHM Gaussian filtering)

Some problems at start-up !!





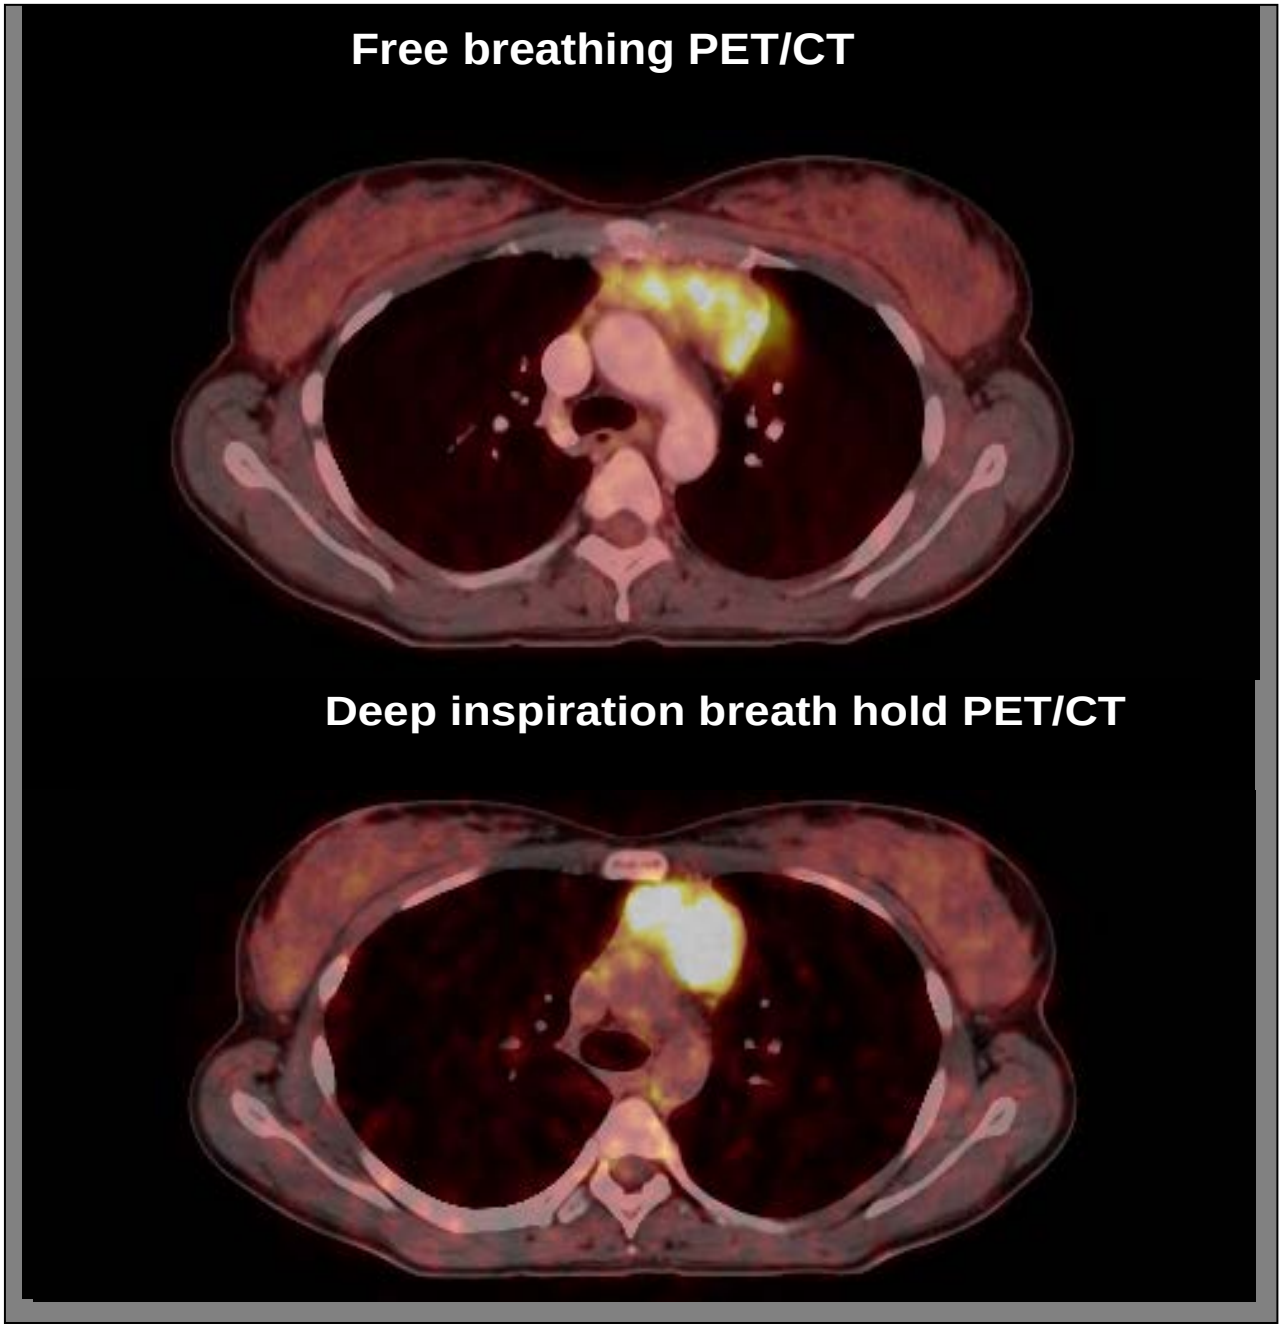




ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

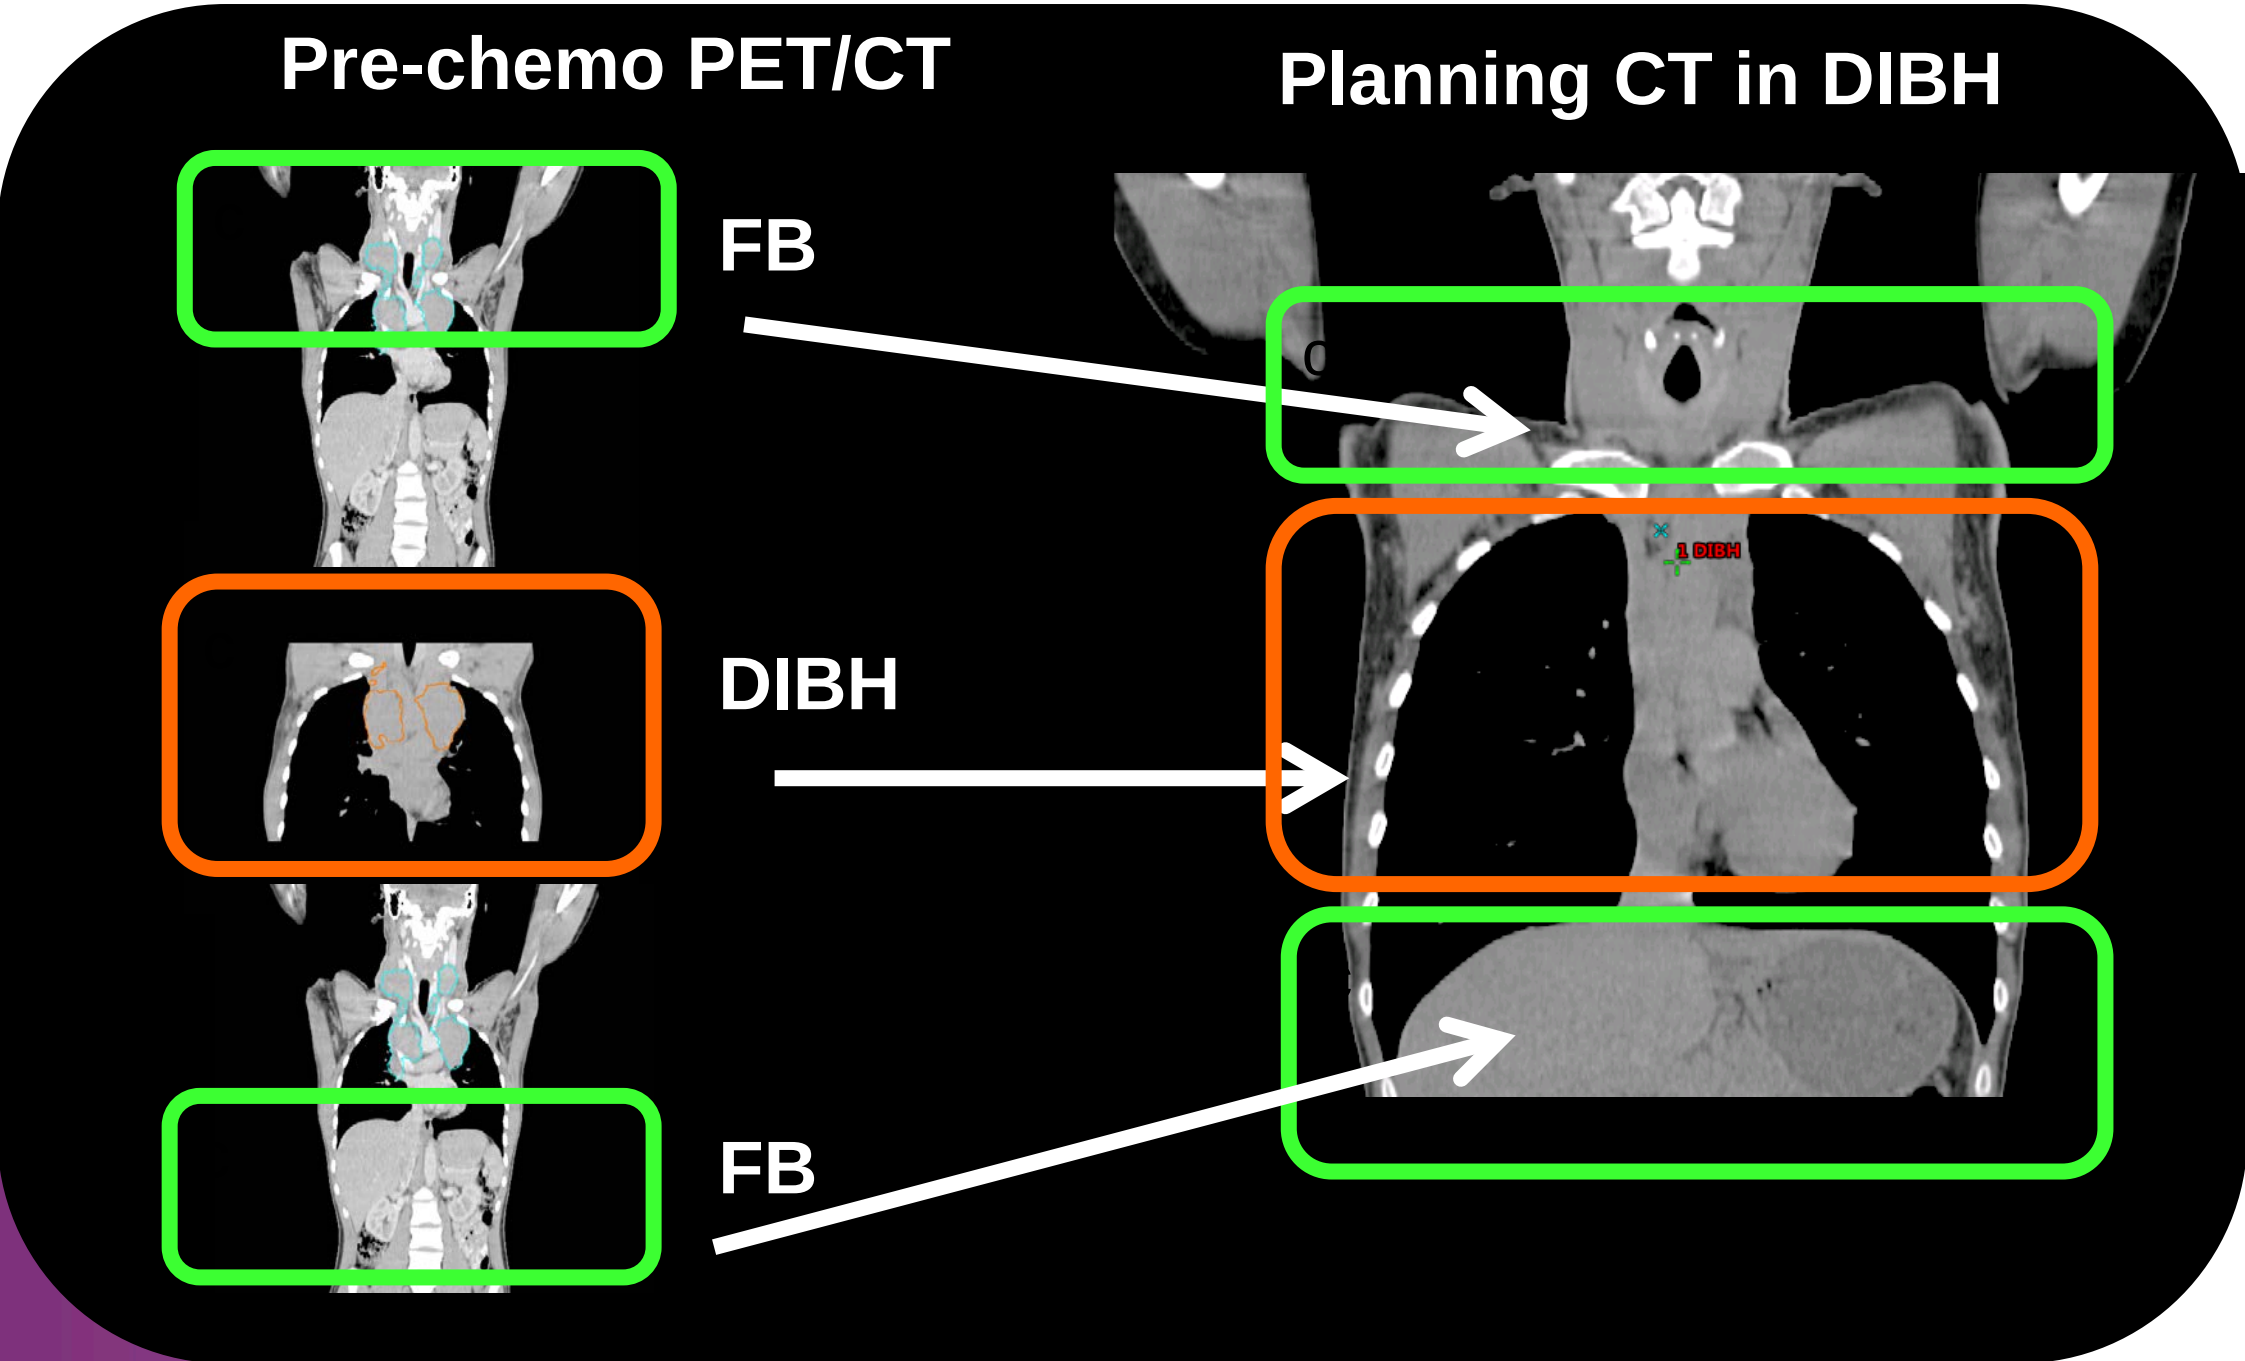
ESTRO School

Results: reduced respiration artifacts

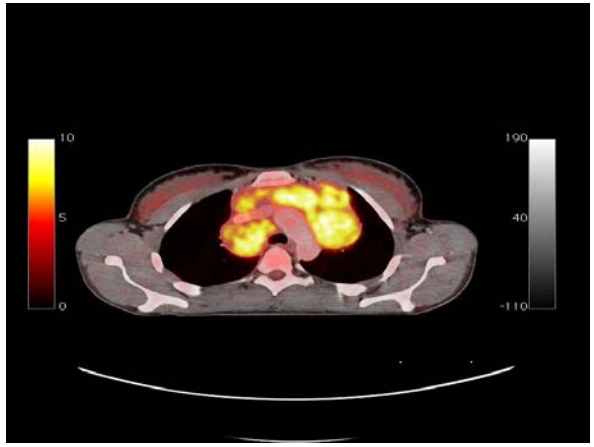


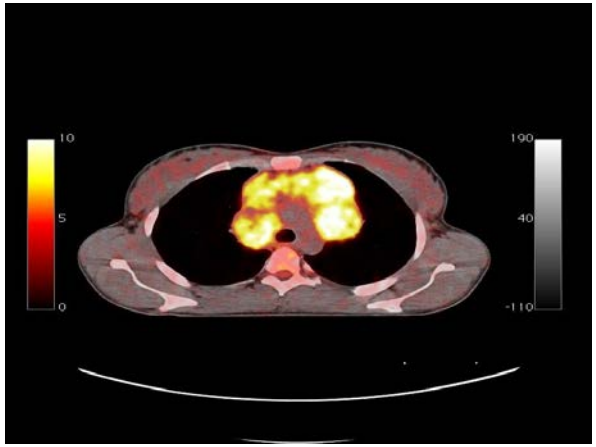
ESTRO School

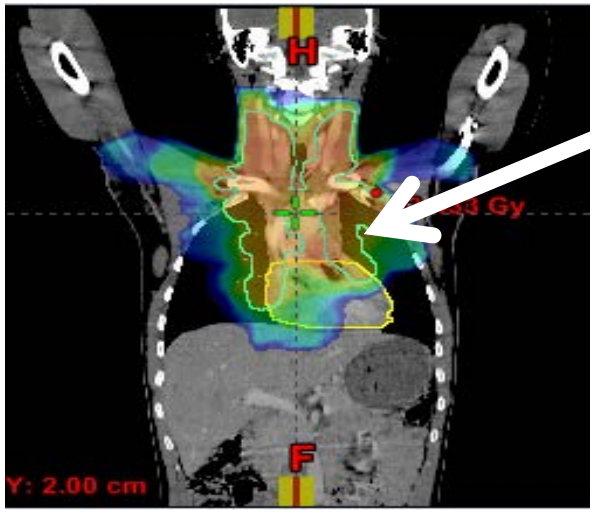
Registration for contouring

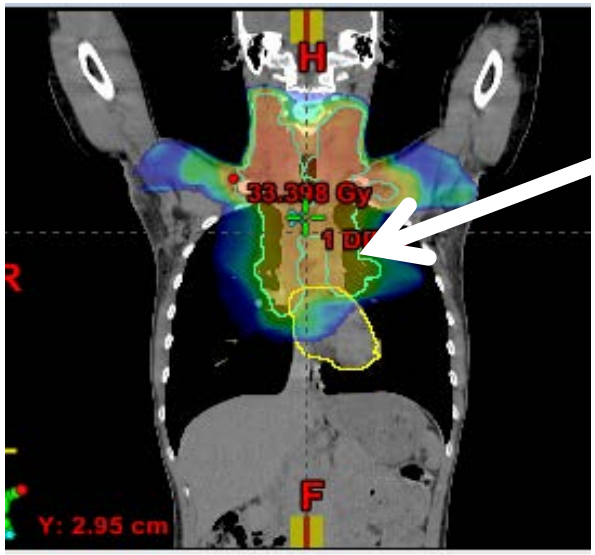


Planning results



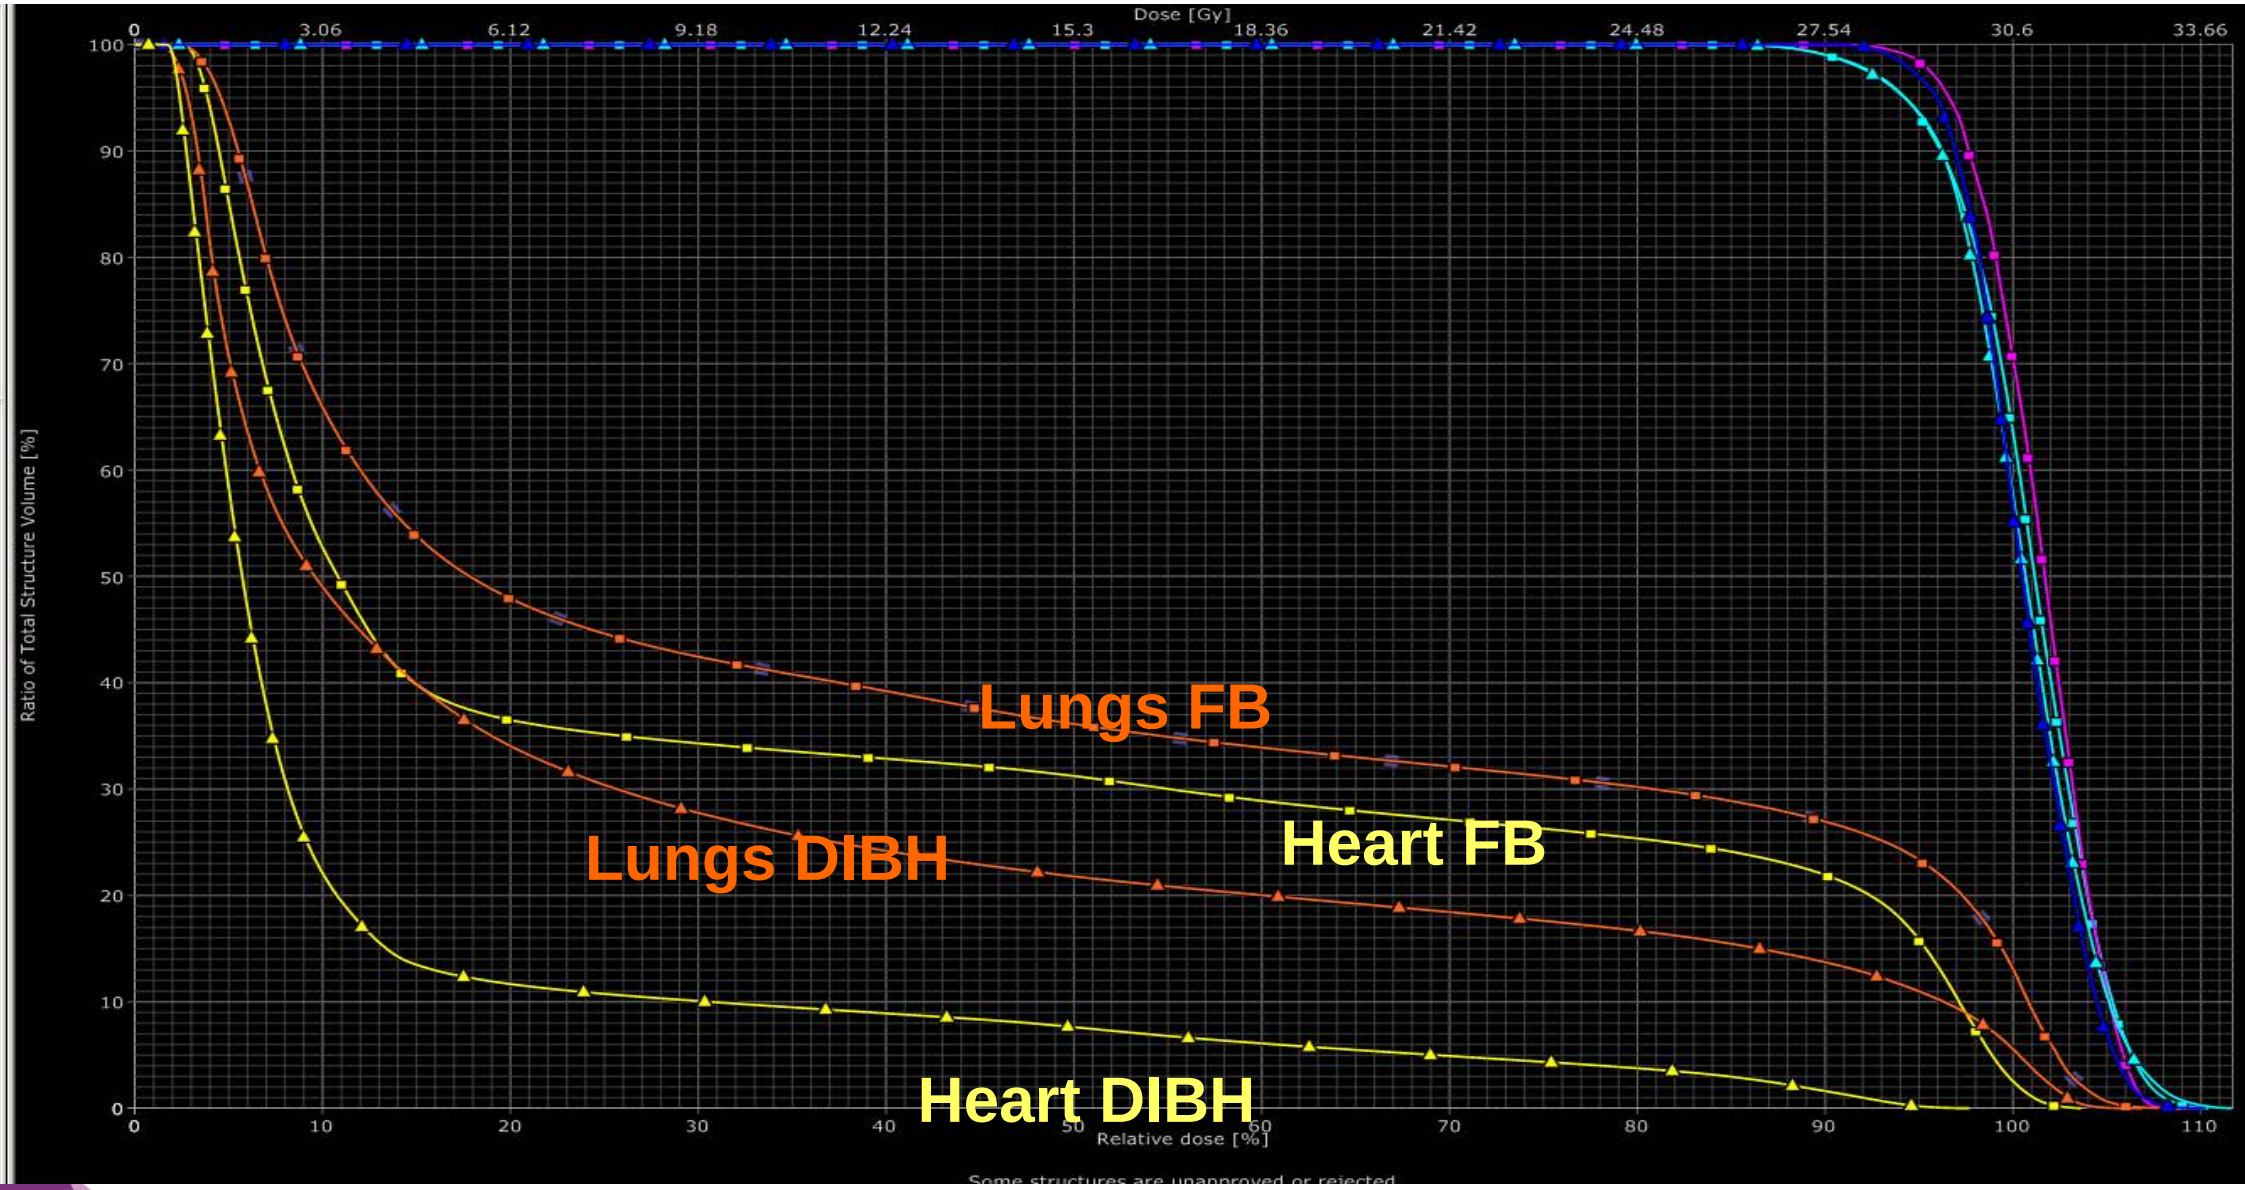




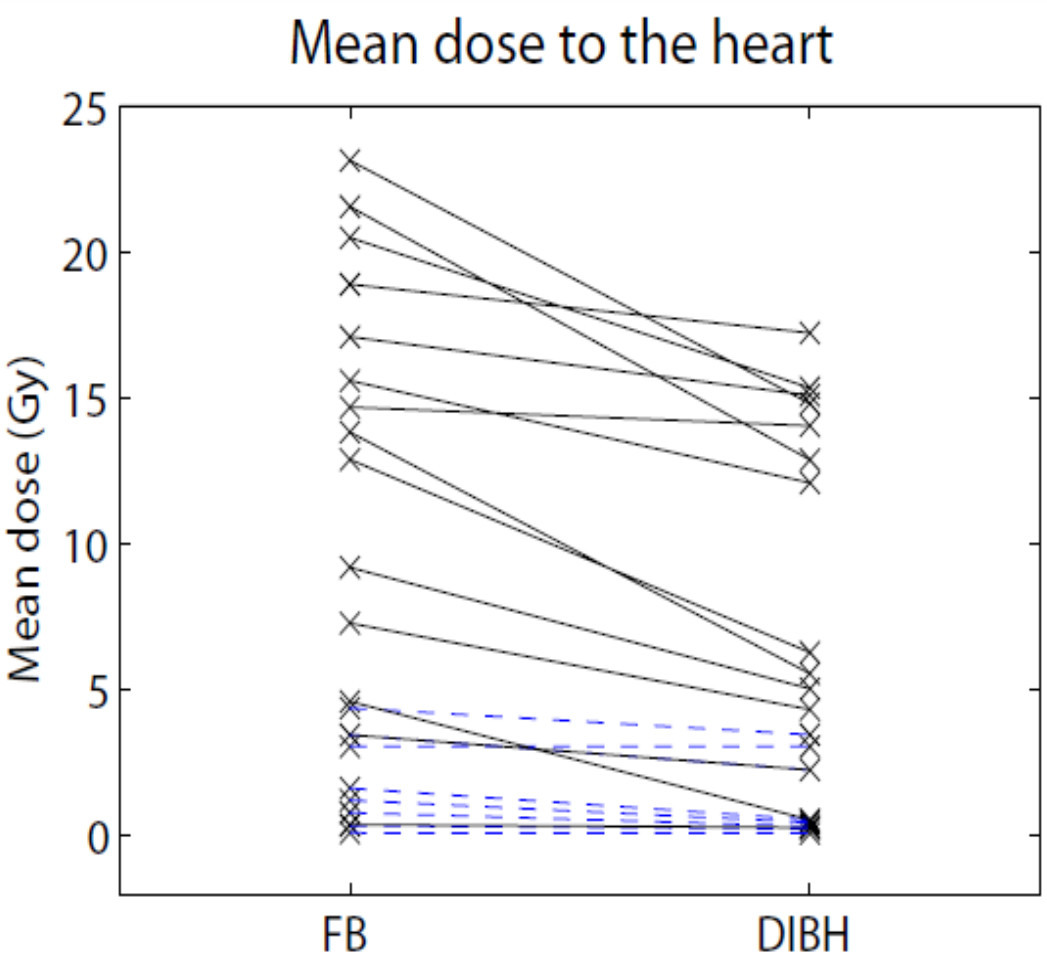


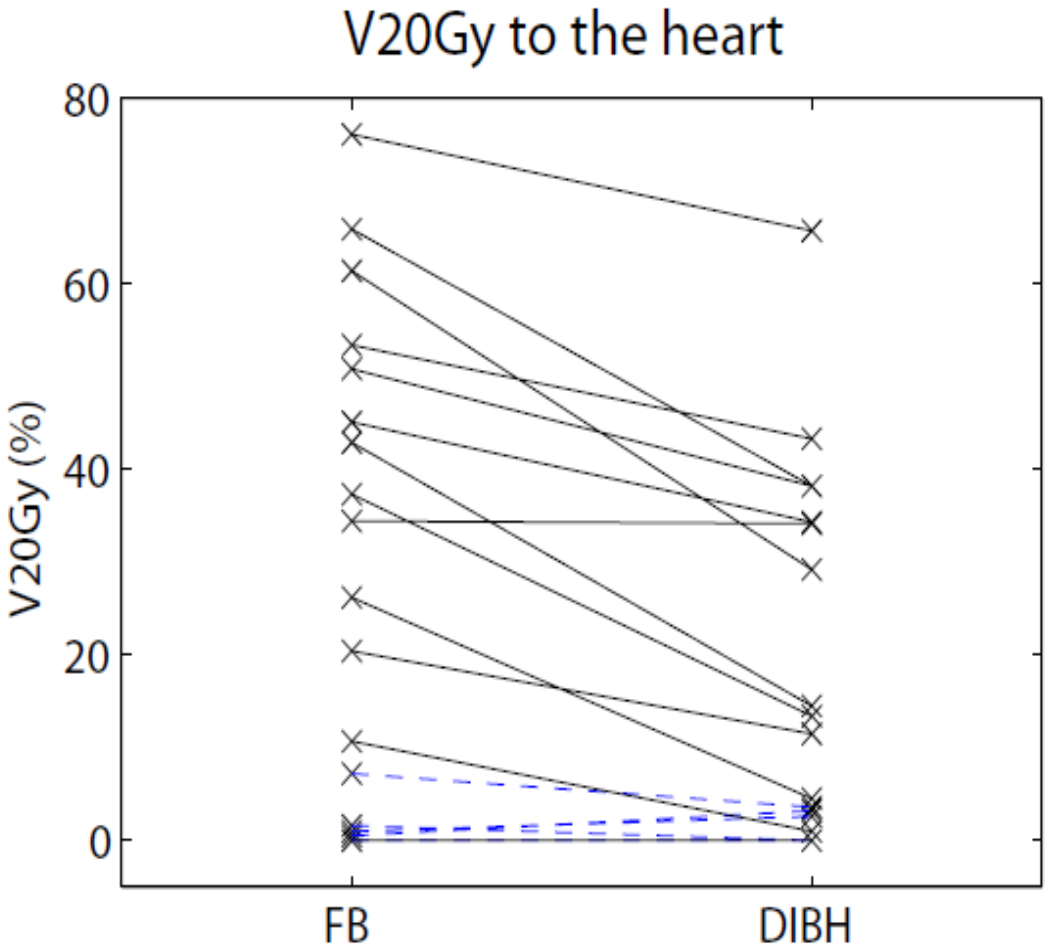
ESTRO School

Mean dose to lungs: 8.5Gy vs 12.8 Gy



Benefit: inter-patient variation



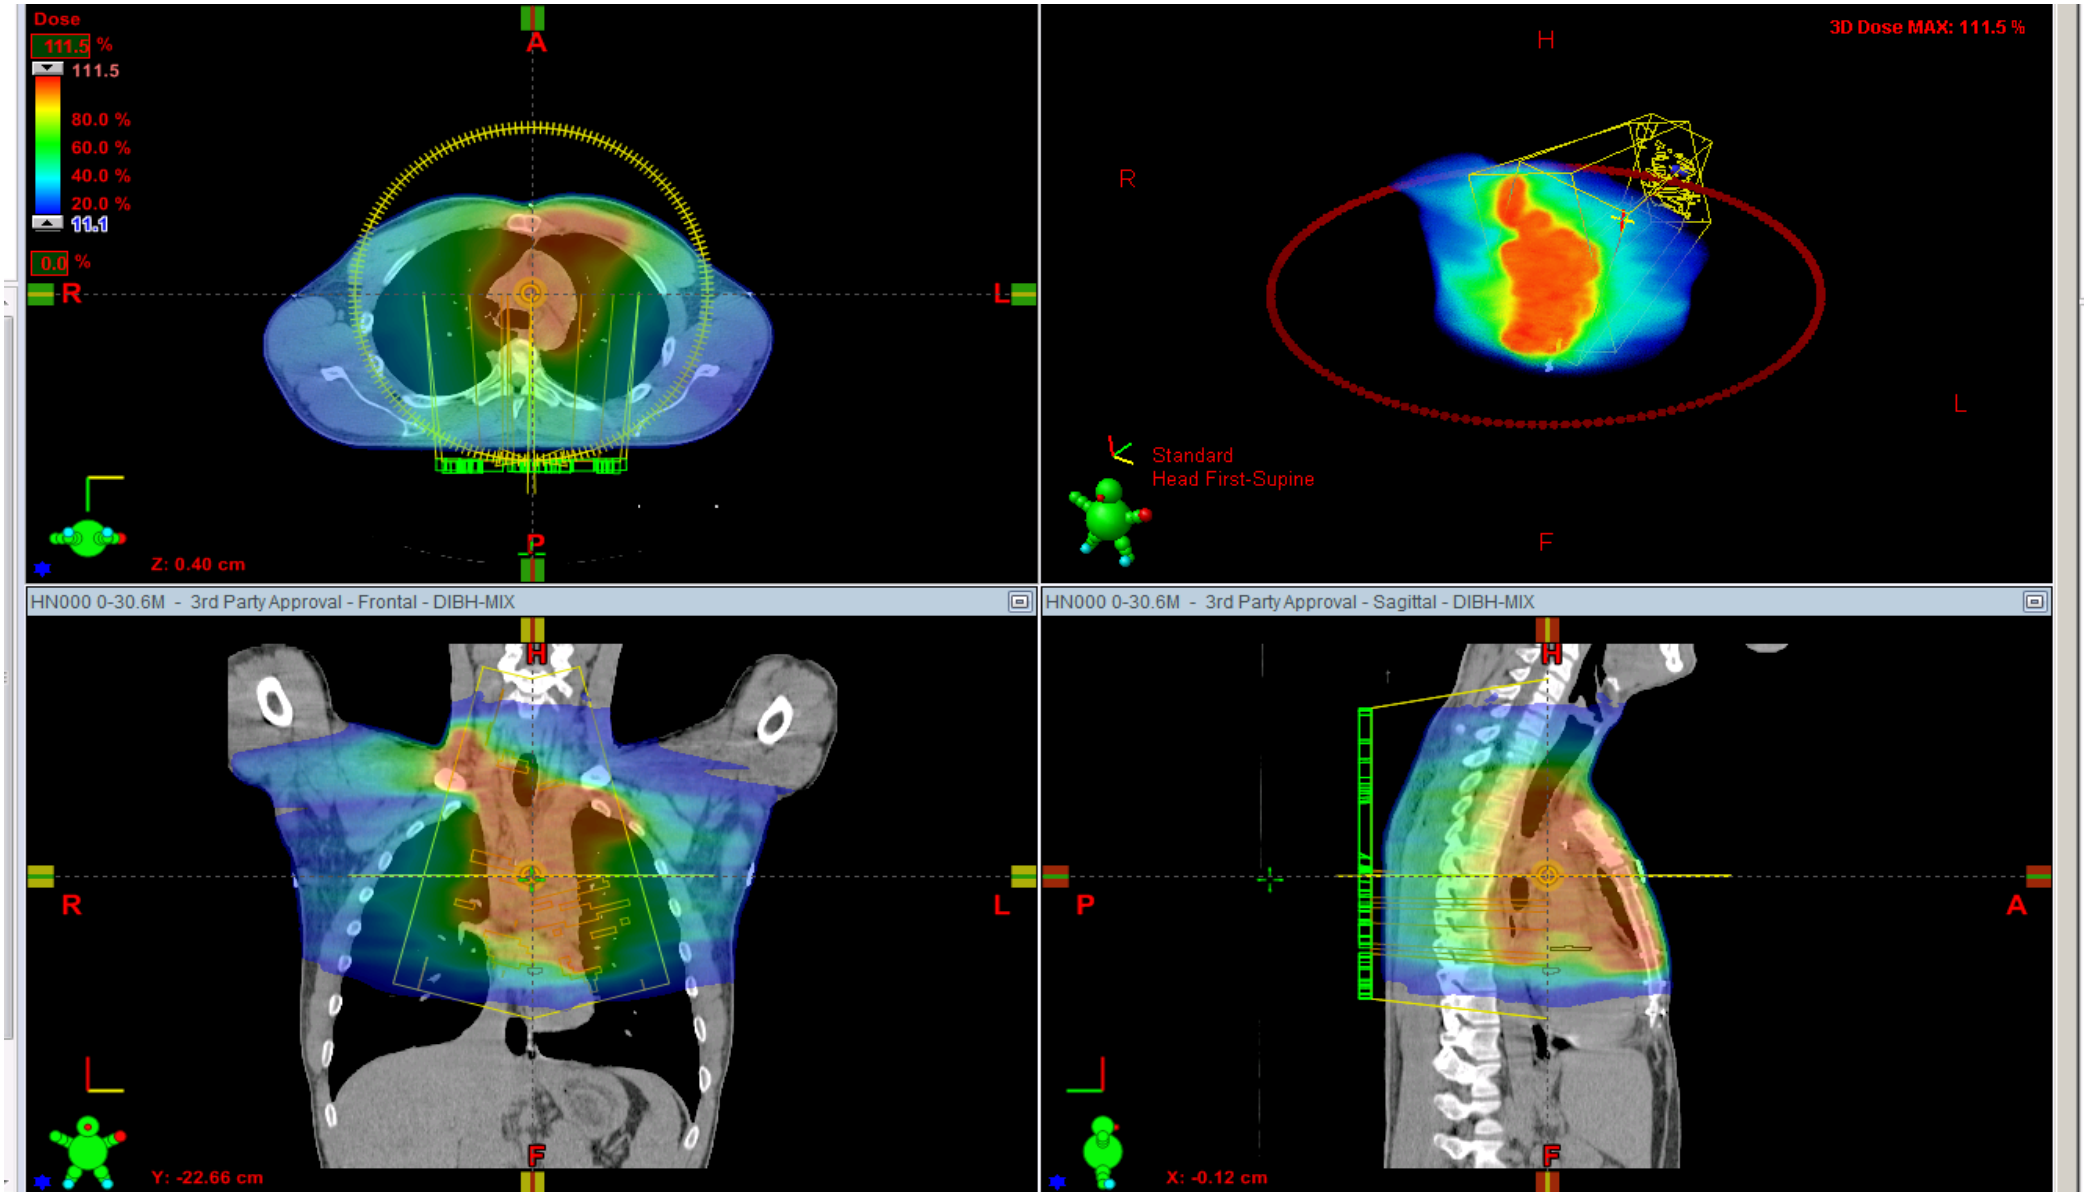


Petersen et al. Acta Oncologica 2015

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

DIBH + VMAT/IMRT



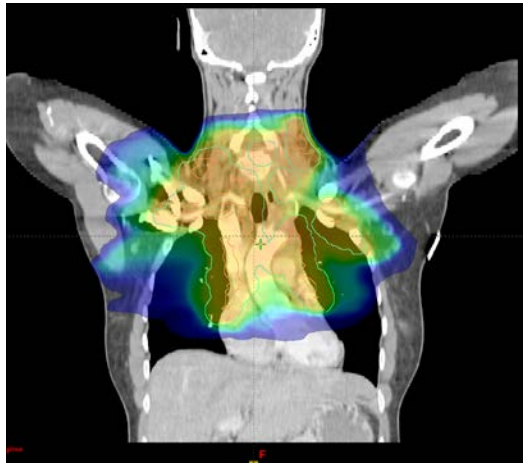
RPM integrated with linac
Beam switches on and off automatically

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

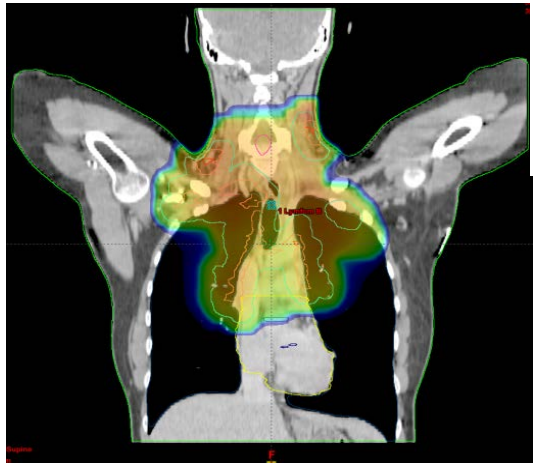
What to choose: IMRT? DIBH or both?

- Free breathing (3DCRT)



•Free breathing (IMRT)

<u>NB: dose bath</u>



- DIBH (3DCRT)

Conclusions DIBH vs IMRT

DIBH-3DCRT was more effective to reduce heart and lung dose
IMRT tended to give a higher mean dose to the breasts

First choice: 3D-DIBH for young women, then IMRT only if the heart dose needs to be further reduced
Men: DIBH+IMRT could be a standard solution

Aznar at al IJROBP 2015

Take home message (2): treatment planning

- Having the staging PET/CT in DIBH increased our physicians' confidence
- The dosimetric benefit was clear enough to make DIBH our standard treatment for HL
- However, we still acquire a free breathing planning CT on top of the DIBH planning CT
- Tendency to combine DIBH with VMAT

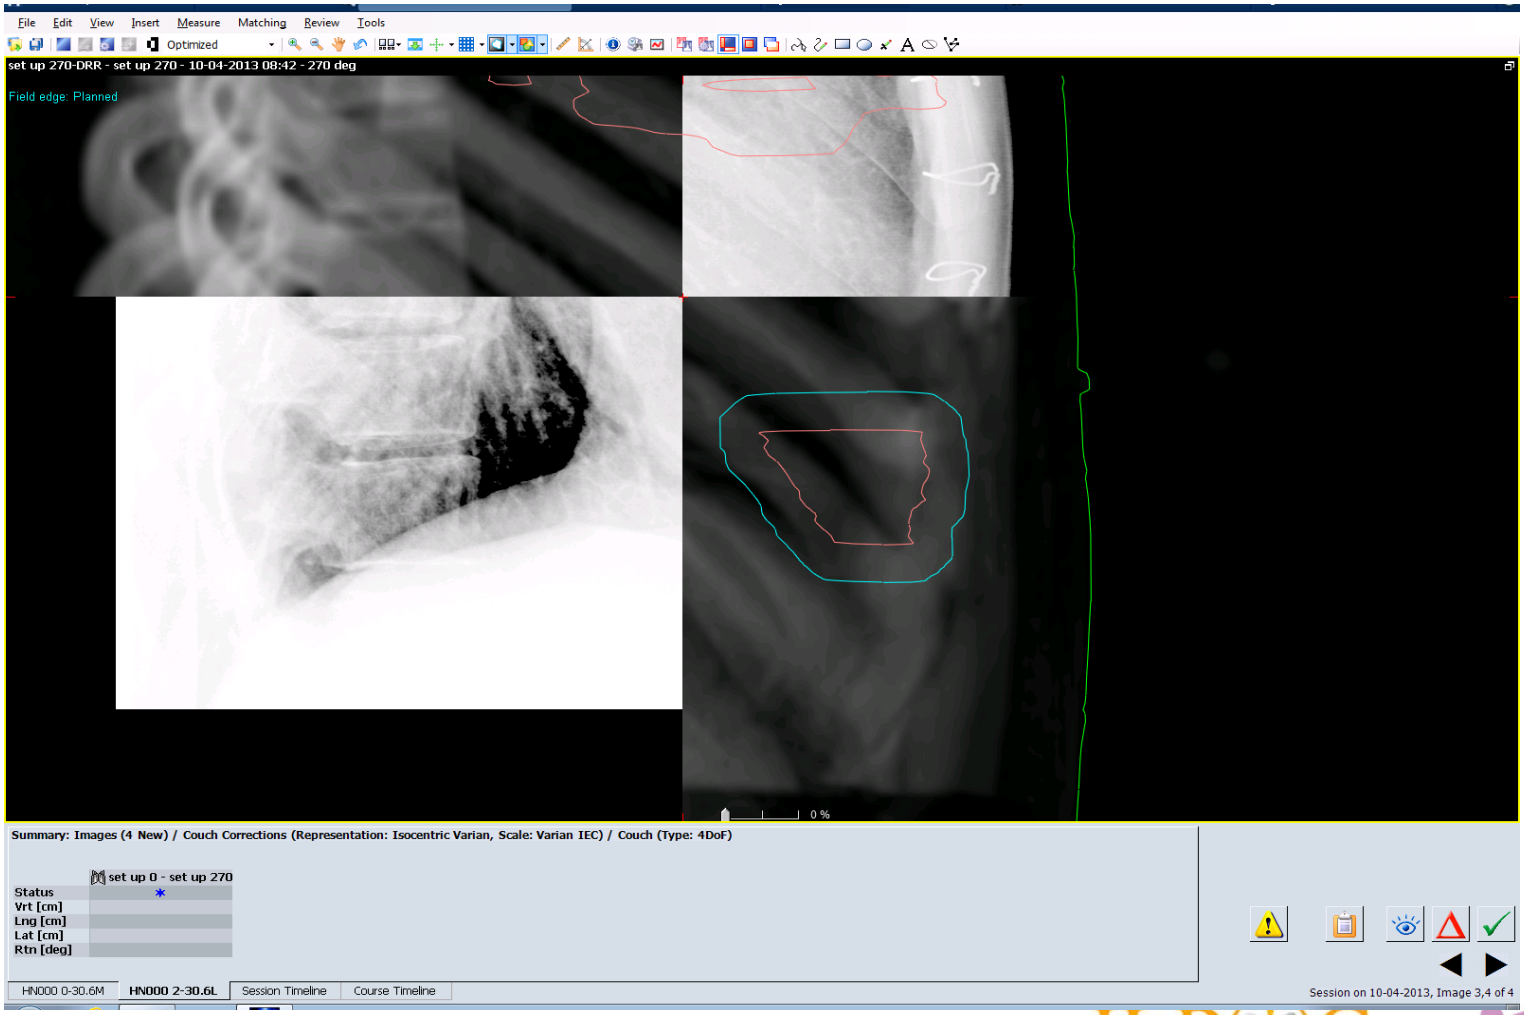
IGRT

POSITION VERIFICATION IN DIBH

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

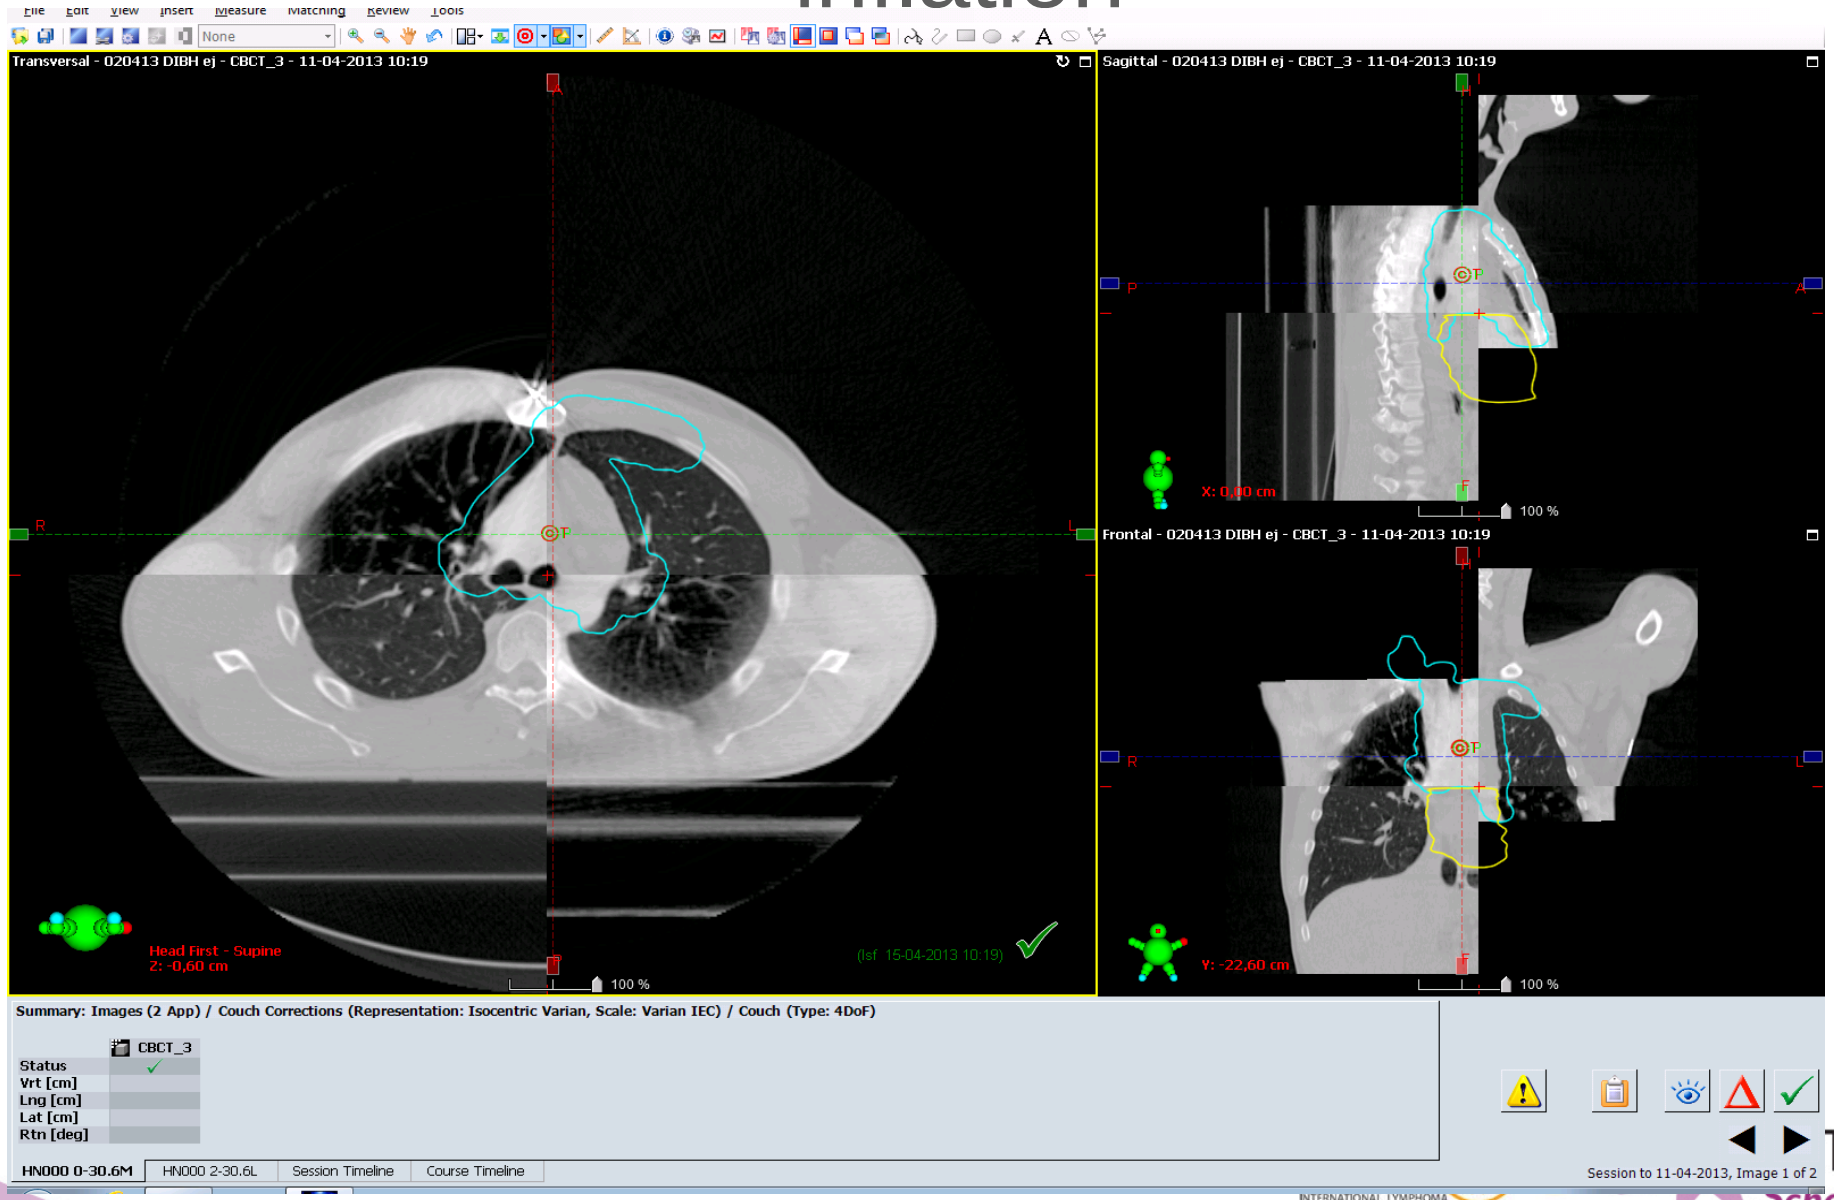
Daily 2D images: fuse on spine, check sternum



ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Can check heart position and lung inflation



Some challenges with CBCT in DIBH

- Requires 2-3 additional breath holds
  - But remember: young/fit patients
- Manually operated
- Some resistance to introduce it as a daily modality !

Some possible compromises…

- Daily 2D DIBH images
- Daily 2D DIBH images + weekly DIBH CBCT (with/without a physicist present)
- Daily DIBH CBCT with a longer treatment slot

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

A note about margins…

- In free breathing: 1cm, 1.5 cm sup-inf
- In DIBH: 1 cm all around ?
- A study of interfraction variation demonstrated that margins could NOT be reduced with DIBH
  - Back to 1cm, 1.5 cm sup-inf

Take home message (3): treatment delivery

- Patient compliance is excellent
- DIBH CBCT is possible, but there is a learning curve

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Conclusion

- DIBH implementation in lymphoma very succesful
- Protocol in lung cancer patients ongoing

- Clear dosimetric benefit, even when using VMAT/IMRT

- Ressource investment: the ”sore points” are
  - PET scanning time
  - IGRT
  - And even then, they remain very manageable !

AGGRESSIVE NODAL NON-HODGKIN LYMPHOMA, THE ROLE OF RADIOTHERAPY

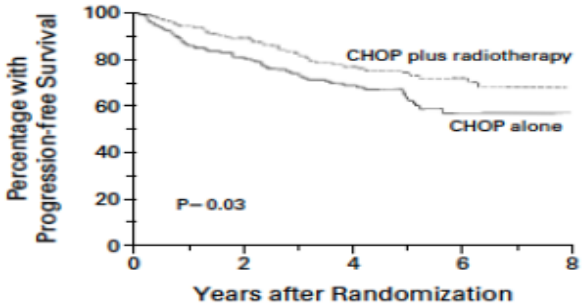
Early Stage

Umberto Ricardi
University of Torino
Department of Oncology

Is there (still) a role for Radiation Therapy in early stage DLCL?

- “Classic” trials investigating the role of CMT in DLBCL (some of them with risk stratification)
- Trials investigating the role of CMT in DLBCL in the Rituximab era
- Data on the role of RT from systematic reviews, retrospective analysis and epidemiologic registry

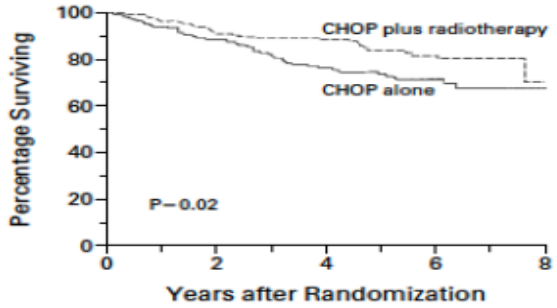
CHOP x 8 vs. CHOP x 3 + IFRT in Stage I/II DLBCL



No. at Risk					
CHOP alone	201	172	111	55	14
CHOP plus radiotherapy	200	178	119	70	17

Figure 1. Progression-free Survival of 201 Patients Receiving Eight Cycles of CHOP Alone and 200 Patients Receiving Three Cycles of CHOP plus Radiotherapy.

Sixty-five patients in the CHOP-alone group died or had progression of their disease, as compared with 45 patients in the CHOP-plus-radiotherapy group. The estimated rates of progression-free survival at five years were 64 percent and 77 percent, respectively.



No. at Risk					
CHOP alone	201	187	120	61	14
CHOP plus radiotherapy	200	185	128	75	17

Figure 2. Overall Survival of 201 Patients Receiving Eight Cycles of CHOP and 200 Patients Receiving Three Cycles of CHOP plus Radiotherapy.

There were 51 deaths in the CHOP-alone group, and 32 in the CHOP-plus-radiotherapy group. The estimated rates of survival at five years were 72 percent and 82 percent, respectively.

Putative beneficial effect of radiotherapy? (the most obvious difference between MInT and GELA trial is the use of additive radiotherapy, i.e. bulky disease and/or extranodal sites)

Which is the current Treatment Strategy?

The results of the MInT study demonstrated a difference between two prognostic groups within the population of young good-prognosis (aaIPI=0,1) patients with aggressive lymphoma: young good-prognosis patients with favourable prognosis (young good-prognosis, favourable) and those with less favourable prognosis (young good-prognosis, less favourable). Therefore, these groups should be treated differentially according to new specific treatment strategies (figure 6).

Background and open questions

- ***R-Chemotherapy plus mediastinal IFRT*** is considered the standard treatment for PMBCL (3-yrs PFS: 80-85%)

- Does mediastinal IFRT still improve the outcome in PMBCL patients treated with R-CHOP/R-CHOP like chemotherapy?

- Is a negative PET-CT scan a reliable indicator of cure following chemotherapy alone, making unnecessary consolidation RT?

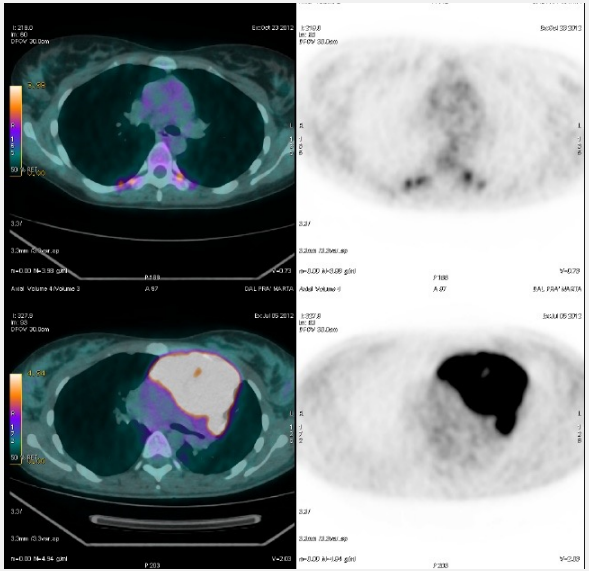
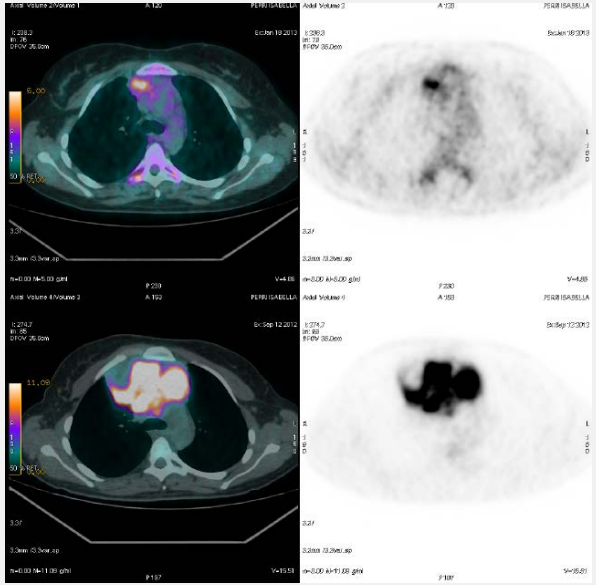
Post-CHT PET



PET-0

Deauville score 2

Post-CHT PET



PET-0

Deauville score 4

Study aim

- *To spare the mediastinal radiotherapy (RT) in patients with "negative PET" after a combined chemo-immunotherapy*

➢ Primary endpoint

- **Progression free survival (PFS) at 2-years from randomization**

➢ Secondary endpoints

- **Overall survival (OS) at 5-years from registration**
- **To define long term toxicities in this patient population**

Cut-off value in the IELSG protocol

- Since the aim of the proposed protocol is **to spare radiotherapy to PET-negative patients**, or, in other words, to de-escalated treatment in favorable-prognosis patients, one should rely on a very sensitive (conservative) threshold to interpret end-therapy scans, in order to avoid false negative results

Score 1: no uptake
Score 2: uptake ≤ mediastinum

→ **NEGATIVE**

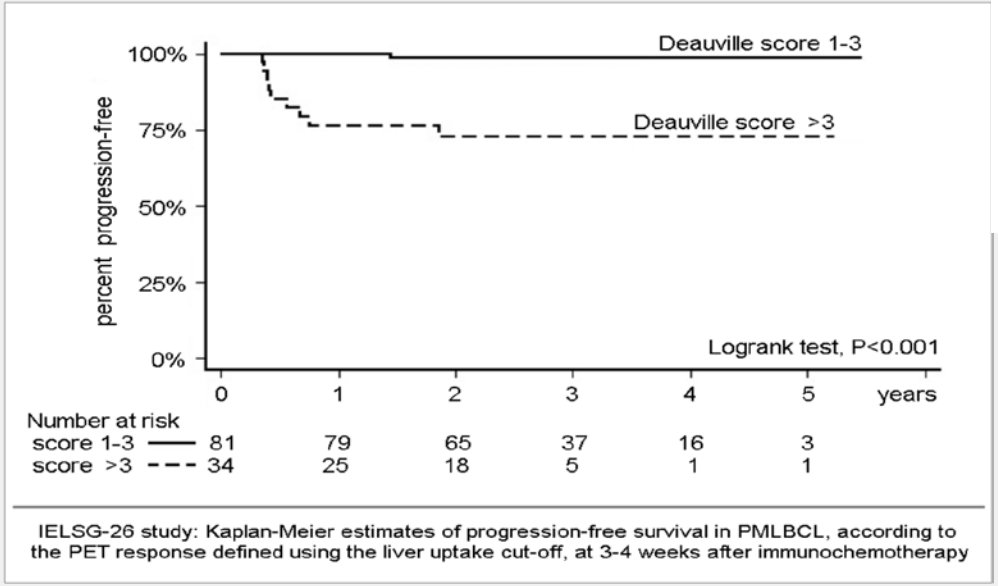
Score 3: uptake > mediastinum but ≤ liver
Score 4: moderately uptake > liver
Score 5: markedly uptake > liver AND/or new sites of disease

→ **POSITIVE**

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Study background:
PFS better defined by liver cut-point



IELSG-26 study: Kaplan-Meier estimates of progression-free survival in PMLBCL, according to the PET response defined using the liver uptake cut-off, at 3-4 weeks after immunochemotherapy

Consolidation RT given to 102 of 115 pts according to local policy irrespectively of the PET score at the end of R-CHT

- ***The IELSG-26 study did not answer the question on the role of mediastinal RT.***

[^{18}F]Fluorodeoxyglucose Positron Emission Tomography Predicts Survival After Chemoimmunotherapy for Primary Mediastinal Large B-Cell Lymphoma: Results of the International Extranodal Lymphoma Study Group IELSG-26 Study

Radiation Therapy After R-CHOP for Diffuse Large B-Cell Lymphoma: The Gain Remains

Joachim Yahalom, *Memorial Sloan-Kettering Cancer Center, New York, NY*

- Clearly, the issue of treatment consolidation after R-CHOP with IFRT, or alternatively with more chemotherapy, has not been resolved
- In an attempt to satisfy all opinions, the National Comprehensive Cancer Network (NCCN) guidelines recommend three cycles of R-CHOP + IFRT for early-stage, non bulky disease, but also allow the administration of six to eight cycles of R-CHOP, with or without IFRT
- The latter is also the NCCN recommendation for bulky disease
- This variety of options in the NCCN guidelines may make everybody happy, but it could be confusing to the nonexpert
- In reality, many hematologists/oncologists simply extend the chemotherapy course and omit radiotherapy (RT)

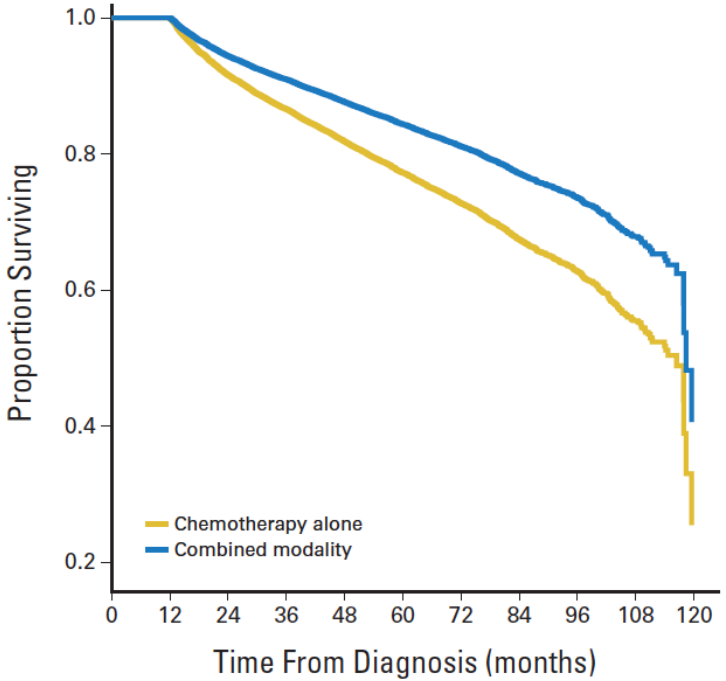
Cox Model With Propensity Score		
Treatment strategy		
Chemotherapy alone	Reference	
Combined modality	0.66 (0.61 to 0.71)	< .001
Sex		
Male	Reference	
Female	0.87 (0.82 to 0.92)	< .001
Income, US dollars		< .001
< 30,000	Reference	
30,000 to 35,000	0.98 (0.88 to 1.10)	.78
35,000 to 45,999	0.94 (0.85 to 1.03)	.19
≥ 46,000	0.81 (0.74 to 0.89)	< .001
Extranodal disease		
Absent	Reference	
Present	1.11 (1.05 to 1.18)	< .001
Propensity score (IPW)*	1.09 (1.02 to 1.15)	.008



Conclusion

Use of consolidative RT after multiagent chemotherapy in DLBCL is decreasing in the modern era. Selection of treatment strategy is affected by both classical prognostic features and socioeconomic factors. Abandonment of combined-modality therapy in favor of chemotherapy alone negatively affects patient survival.

Combined-Modality Therapy for Early-Stage Diffuse Large B-Cell Lymphoma: Knowing When to Quit

Dan L. Longo, *Harvard Medical School, Brigham and Women's Hospital, Boston, MA*

See accompanying article doi:10.1200/JCO.2015.61.7654

Until we have better evidence for changing our current approach, oncologists should stop using radiation therapy as routine treatment in all patients with stage I and II diffuse large B-cell lymphoma

We should stop arguing and agree that current evidence does not support the use of radiation therapy in all of these patients

Rather, we should focus on conducting prospective clinical trials on selected subsets of patients for whom there may be a reasonable chance of demonstrating improved outcomes with radiation therapy

It is important to know when to quit

Aggressive nodal non Hodgkin lymphoma, the role of radiotherapy: Advanced stage - general

Literature:

- No randomized trials on role of RT in advanced disease only
- Limited number of retrospective series in stage III-IV or including stage III-IV (limited numbers of patients)

Duke Experience

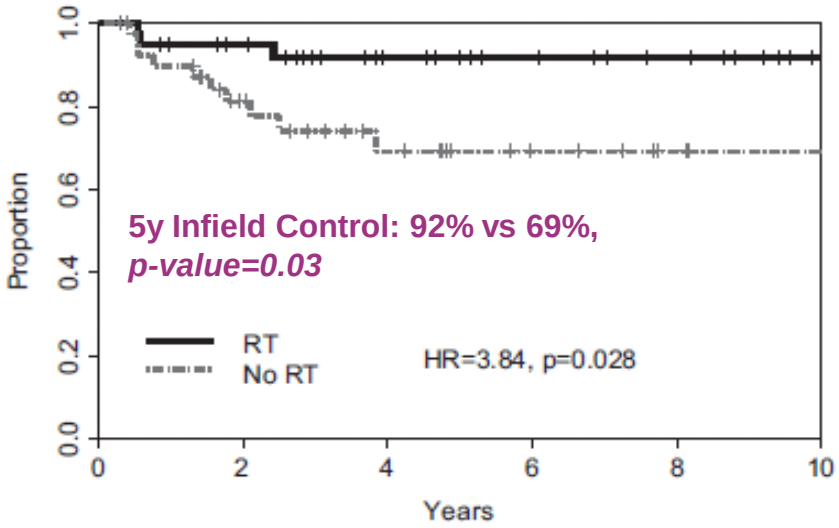
Aim:
Evaluation role of consolidation RT in advanced DLBCL

Patients and methods:

- Retrospective analysis
- 79 stage III-IV DLBCL pts in CR (73% by PET, 14% by gallium) after chemo (65% received R-CHOP) out of a population of 241 patients with DLBCL (any stage) treated between 1991-2009
- 38 (48%) received RT to involved sites (median 25 Gy)

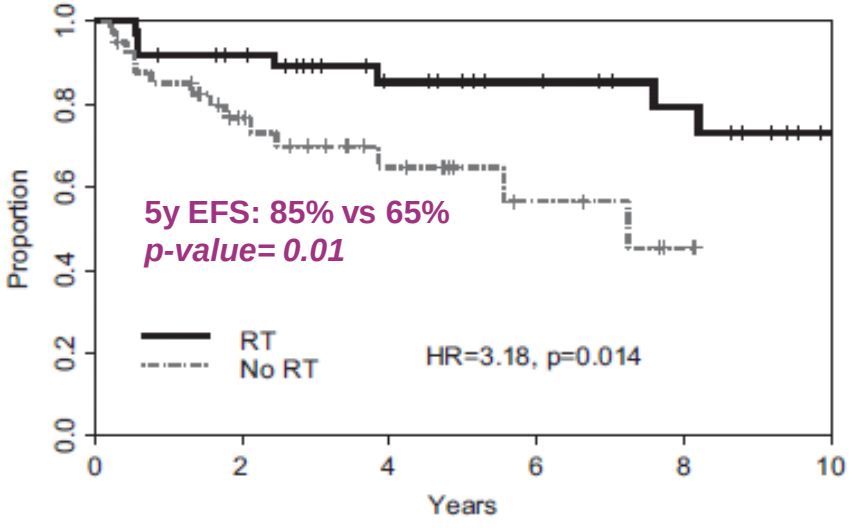
Dorth et al, IJROBP, 2012

Duke Experience
KM curves infield control and EFS



Number of Patients at Risk

RT	38	32	22	17	13	6
No RT	41	24	14	7	3	1



Number of Patients at Risk

RT	38	32	22	17	13	6
No RT	41	23	13	6	2	0

Dorth et al, IJROBP, 2012

Number of Patients at Risk

RT	38	32	22	17	14	6
No RT	41	27	16	8	3	1

Dorth et al, IJROBP, 2012

Duke Experience

Results multivariate analysis:

- No RT associated with significantly higher infield failure *(HR=8, p=0.01)* and event rates *(HR=4.3, p=0.01)*

Conclusion*:*

- Consolidation RT appears to decrease the risk of local disease progression and overall relapse rates in patients with advanced DLBCL having negative functional imaging after chemotherapy.

Dorth et al, IJROBP, 2012

University of Chicago Experience

Patients and methods:

- 211 histologically confirmed stage III-IV DLBCL

patients who received R-CHOP from January 2000 to May 2012 at University of Chicago

- 110 stage III-IV DLBCL pts in CR (86% by PET) after R-CHOP
- 14 (12.7%) received RT

Shi, IJROBP, 2013

University of Chicago Experience

Table 2 Patterns of failure for advanced-stage diffuse large B-cell lymphoma patients treated with R-CHOP chemotherapy alone versus R-CHOP chemotherapy plus consolidative RT

The impact of radiation therapy in patients with diffuse large B-cell lymphoma with positive post-chemotherapy FDG–PET or gallium-67 scans

J. A. Dorth[1], J. P. Chino[1], L. R. Prosnitz[1], L. F. Diehl[2], A. W. Beaven[2], R. E. Coleman[3] & C. R. Kelsey[1]*

Departments of [1]Radiation Oncology; [2]Medicine, Division of Medical Oncology; [3]Radiology, Division of Nuclear Medicine, Duke University Medical Center, Durham, USA

Received 9 December 2009; revised 25 May 2010; accepted 26 May 2010

Background: 2-[fluorine-18]fluoro-2-deoxy-D-glucose–positron emission tomography (PET) and gallium-67 citrate (gallium) response after chemotherapy are powerful prognostic factors in diffuse large B-cell lymphoma (DLBCL). However, clinical outcomes when consolidation radiation therapy (RT) is administered are less defined.

Patients and methods: We reviewed 99 patients diagnosed with DLBCL from 1996 to 2007 at Duke University who had a post-chemotherapy response assessment with either PET or gallium and who subsequently received consolidation RT. Clinical outcomes were estimated using the Kaplan–Meier method and compared using the log-rank test.

Results: Median follow-up was 4.4 years. Stage distribution was I–II in 70% and III–IV in 30%. Chemotherapy was R-CHOP or CHOP in 88%. Median RT dose was 30 Gy. Post-chemotherapy PET ($n = 79$) or gallium ($n = 20$) was positive in 21 of 99 patients and negative in 78 of 99 patients. Five-year in-field control was 95% with a negative PET/gallium scan versus 71% with a positive scan ($P < 0.01$). Five-year event-free survival (EFS; 83% versus 65%, $P = 0.04$) and overall survival (89% versus 73%, $P = 0.04$) were also significantly better when the post-chemotherapy PET/gallium was negative.

Conclusions: A positive PET/gallium scan after chemotherapy is associated with an increased risk of local failure and death. Consolidation RT, however, still results in long-term EFS in 65% of patients.

Timing of peri-transplant RT

PRE- transplant

Pros:

- Cytoreduction if poor salvage chemo response
- Less haematological toxicity
- Ensures administration

Cons:

- Higher risk of pneumonitis
- Delay of HD chemo
- Requires good co-ordination

POST- transplant

Pros:

- Less pneumonitis
- Less GI toxicity / VOD
- No delay in giving HD chemo

Cons:

- More haematological toxicity:
  - Irradiating regenerating marrow
  - MDS / leukemogenic risk
- May be delayed or omitted if recovery is prolonged

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Choice

- Local expertise and practice
- Disease status / response to salvage
- Type & pattern of disease
  - HL v NHL
  - Localised v disseminated
- Site of RT
- Previous chemo, HD chemo

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

(3) Relapse after transplant & transplant ineligible patients

Non transplant eligible

3 groups:

- Age / co-morbidities (up to ½ of relapses)

- Transplant eligible but lack of response to salvage (salvage refractory)

- Relapse after transplant (DFI, dis extent, previous RT)

  e.g. late localised relapse, no RT vs early relapse after RT or dissiminated

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

What can RT achieve in refractory HG-NHL?

Without transplant:

- High response rate: 75-90%
- Durable LC: 50 – 65%
- Durable PFS in a small group, particularly localised disease and low IPI
- LC / cytoreduction may enable SCT in selected patients
- Excellent palliation with min toxicity

Salvage RT for *relapsed / chemorefractory* disease

Implications

- Salvage RT is an option in localized refractory / relapsed DLBCL:
  - Definitive salvage in transplant ineligible pts
  - Additional treatment for transplant eligible pts

- Use of RT in salvage chemotherapy / transplant trials should be controlled for.

- Remaining questions:
  - Can Dose escalation improve outcome of Refractory or Resistant disease?
  - Does higher tumor volume require higher dose?
  - What is the size of ref/rel population that could be salvaged by RT?

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Key points

- Localised PET+ residual disease can be salvaged with RT in selected cases
- Consolidation RT is an option Peri-transplant for selected patients (improves PFS & ?OS)
- Salvage RT is an option for localised chemoresistant disease (durable LC 2/3, PFS 1/3)
- Palliative RT is effective in chemoresistant disease (50 – 80% RR)
- Higher doses are required for resistant disease

Aggressive nodal NHL, the role of radiotherapy: volume, dose and technique

Curative radiotherapy

- Early stage
- Advanced stage
- Relapsed/refractory disease

Palliative radiotherapy

Aggressive nodal NHL – early stage
Target volume

- Past: involved field radiotherapy +/- boost on bulk or residual disease
- Present: involved site radiotherapy +/- boost on bulk or residual disease

Aggressive nodal NHL – early stage
Target volume

CTV:

- Pre-chemotherapy (or pre-surgery) Gross Tumor Volume (GTV)
- Changes in normal anatomy after initial treatment response should be taken into account
- Potential Boost CTV: post-chemotherapy GTV (based op PET-CT-scan)

Illidge et al, IJROBP 2015

Aggressive nodal NHL – advanced stage
Target volume

CTV

- Pre-chemotherapy bulky Gross Tumor Volume (GTV)
- Post-chemotherapy residual mass containing PET positive areas on post-chemotherapy scan
- Potential Boost CTV: post-chemotherapy GTV (on PET-CT-scan)

Illidge et al, IJROBP 2015

Aggressive nodal NHL – refractory disease

Target volume

GTV:

- Site(s) of refractory disease

CTV:

- Usually only site(s) of refractory disease with margin for microscopical disease

Illidge et al, IJROBP 2015

RT Dose

Phase III Trial on RT Dose

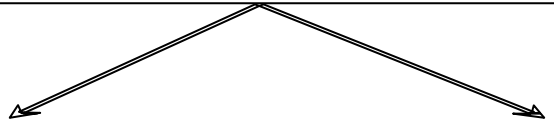
640 Sites of Aggressive NHL

82% DLBCL

86 % stage III-IV

80% as post-chemo consolidative RT

10% received Rituximab



30 Gy in 15 fractions

40-45 Gy in 20-23 fractions

Lowry et al. Rad Onc 2011

30 Gy vs 40-45 Gy

- Median f/u 5.6 years

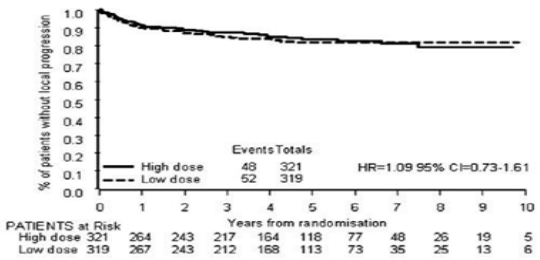
	30 Gy (n=319)	40-45 Gy (n=321)	P-value
5y FFLP	82%	85%	0.66
5y OS	64%	68%	0.29

FFLP: Freedom from local progression; OS: Overall Survival

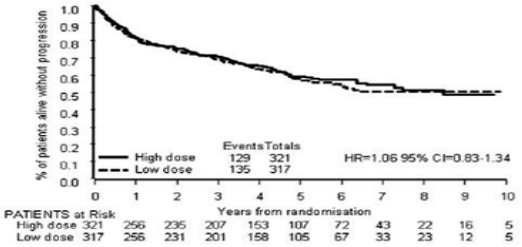
Lowry et al. Rad Onc 2011

Aggressive group

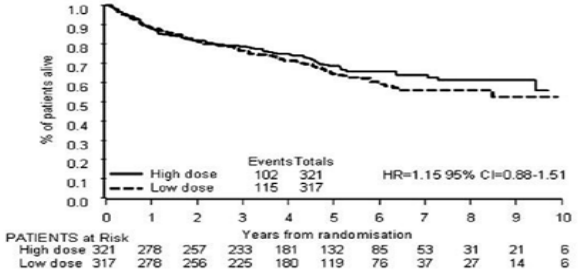
Freedom from local progression



Progression-free survival



Overall survival



Caveats:

- Included pts treated with RT receiving salvage/palliative RT
- No chemo data
- Systemic treatment mostly without rituximab
- Lack of functional imaging of response to chemo

Lowry et al. Rad Onc 2011

CR to Chemo

Study	# Pts in CR	Chemo	Med fu	Response assessment	RT Dose (Gy)	LC
Zinzani, 1999	38	MACOP-B	39 mo	Gallium	30-36	100%

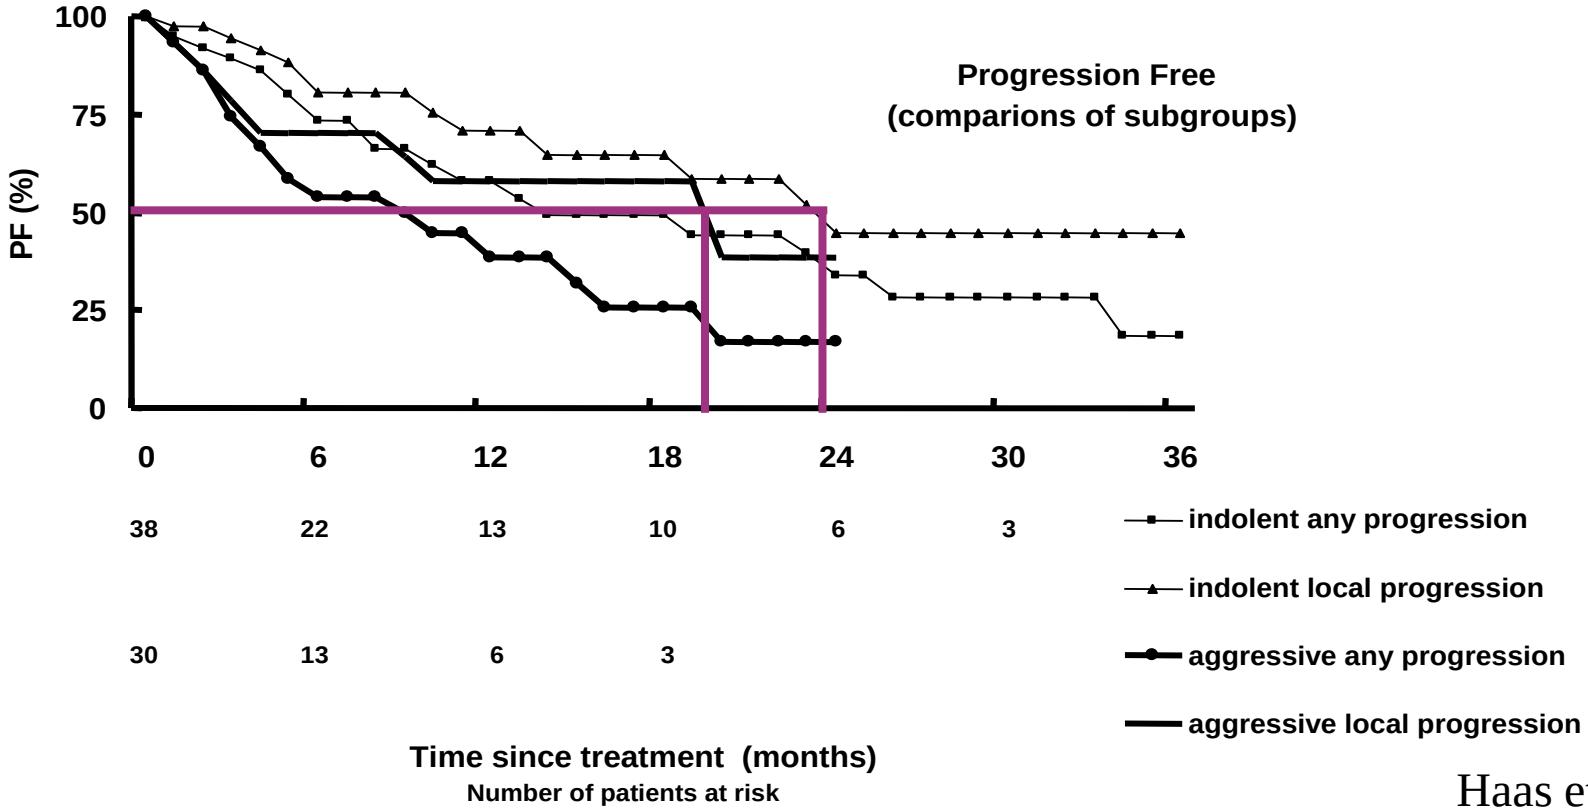
Palliative radiotherapy

- RT of nodal areas in case chemotherapy is not feasible/indicated
  - 2x2 Gy – response rate ±80% (CR ±35%)

Haas et al, EJC 2005

LD-IF-RT in other B-cell malignancies; results according to histological subtype



Haas et al, EJC 2005

Palliative radiotherapy

- RT of nodal areas in case chemotherapy is not indicated
  - 2x2 Gy – response rate ±80% (CR ±35%)
  - Schedule equivalent to 10-12x3 Gy

Summary RT Dose to aggressive Nodal NHL

Setting	RT Dose
CR to Chemo	30-36 Gy (1.8- 2 Gy/Fx)
PR to Chemo	40 Gy (1.8-2 Gy/Fx)
Post-ASCT	30-40 Gy (1.8-2 Gy/Fx)
Primary refractory	45-55 Gy (1.8-2 Gy/Fx)
Palliative	4 Gy (2-4 Gy/Fx) 30-36 Gy (3 Gy/Fx)

RT technical isssues

RT technique

- Same as in Hodgkin lymphoma and indolent NHL

Constraints

- Since many patients are > 60 years second malignancy risk is usually not an issue
- OAR usually lungs, heart, kidneys, bowels

Illidge et al, IJROBP 2015

Aggressive nodal NHL- early stage
Principles of ISRT for Nodal Sites

- CT or PET/CT information of pre-chemotherapy disease (ideally in treatment position)
- Planning requirements: CT-based simulation
- Goal to target site of originally involved lymph node(s)
  - Field encompasses the original volume prior to surgery or chemotherapy
  - Spares uninvolved organs once lymph node has regressed
  - Imaging modalities such as PET and MRI can enhance

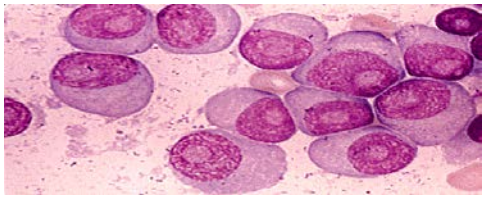
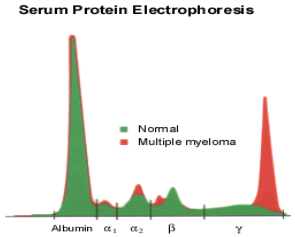
Multiple myeloma

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School



Multiple myeloma



Multiple myeloma is a neoplastic plasma-cell disorder that is characterized by clonal proliferation of malignant plasma cells in the bone marrow microenvironment, monoclonal protein in the blood or urine, and associated organ dysfunction

It accounts for approximately 1% of neoplastic diseases and 13% of hematologic malignancies

In Western countries, the annual age-adjusted incidence is 5.6 cases per 100,000 persons

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

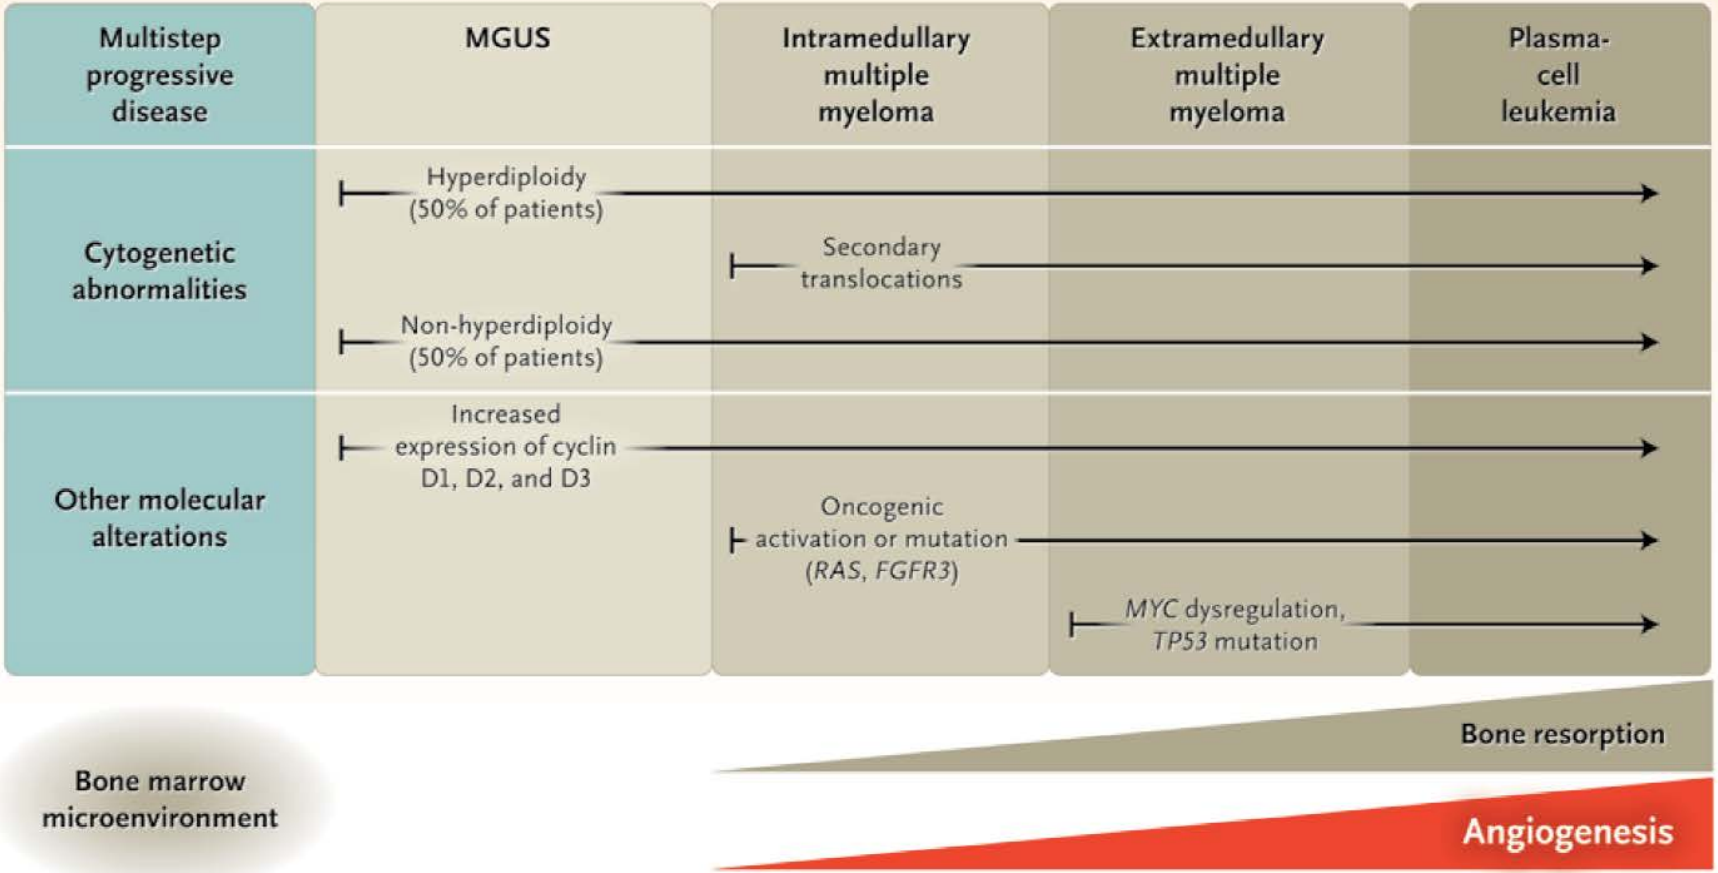
The median age at diagnosis is approximately 70 years; 37% of patients are younger than 65 years, and 37% are 75 years of age or older

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

Myeloma arises from an asymptomatic premalignant proliferation of monoclonal plasma cells that are derived from post-germinal-center B cells

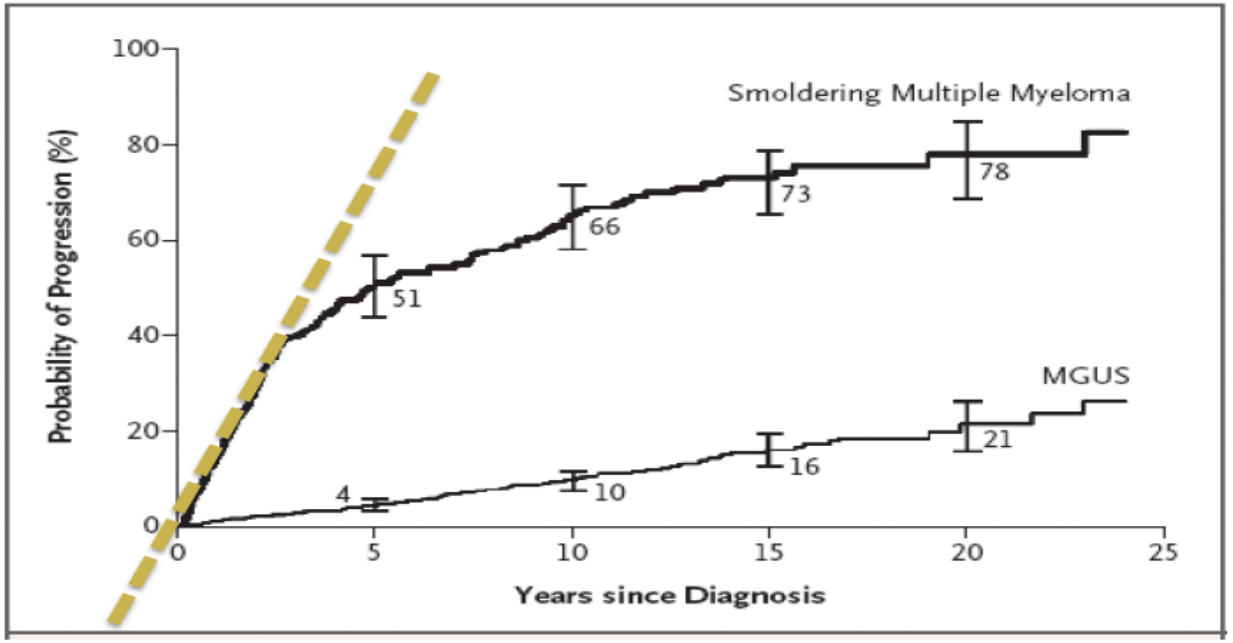
Multistep genetic and microenvironmental changes lead to the transformation of these cells into a malignant neoplasm

Myeloma is thought to evolve most commonly from a monoclonal gammopathy of undetermined clinical significance **(MGUS)** that progresses to **smoldering myeloma** and, finally, to **symptomatic myeloma**



Antonio Palumbo, M.D., and Kenneth Anderson, M.D. **N Engl J Med 2011;364:1046-60.**

High-Risk Smoldering Myeloma Cannot be Ignored*



*Kyle RA, et al. N Engl J Med. 2007;356:2582-2590.

Clinical presentation, diagnosis and staging

The diagnosis of myeloma is based on the presence of at least 10% clonal bone marrow plasma cells and monoclonal protein in serum or urine

In patients with true nonsecretory myeloma, the diagnosis is based on the presence of 30% monoclonal bone marrow plasma cells or a biopsy-proven plasmacytopma

Clinical presentation, diagnosis and staging

Myeloma is classified as asymptomatic or symptomatic, depending on the absence or presence of myeloma-related organ or tissue dysfunction, including:

- hypercalcemia
- renal insufficiency
- anemia
- bone disease

Diagnostic evaluation

Diagnosis

- Medical history and physical examination
- Routine testing: complete blood count, chemical analysis with calcium and creatinine, serum and urine protein electrophoresis with immunofixation, quantification of serum and urine monoclonal protein, measurement of free light chains
- Bone marrow testing: trephine biopsy and aspirate of bone-marrow cells for morphologic features; cytogenetic analysis and fluorescence in situ hybridization for chromosomal abnormalities
- Imaging: skeletal survey, magnetic resonance imaging if skeletal survey is negative

Prognosis

- Routine testing: serum albumin, β_2-microglobulin, lactate dehydrogenase

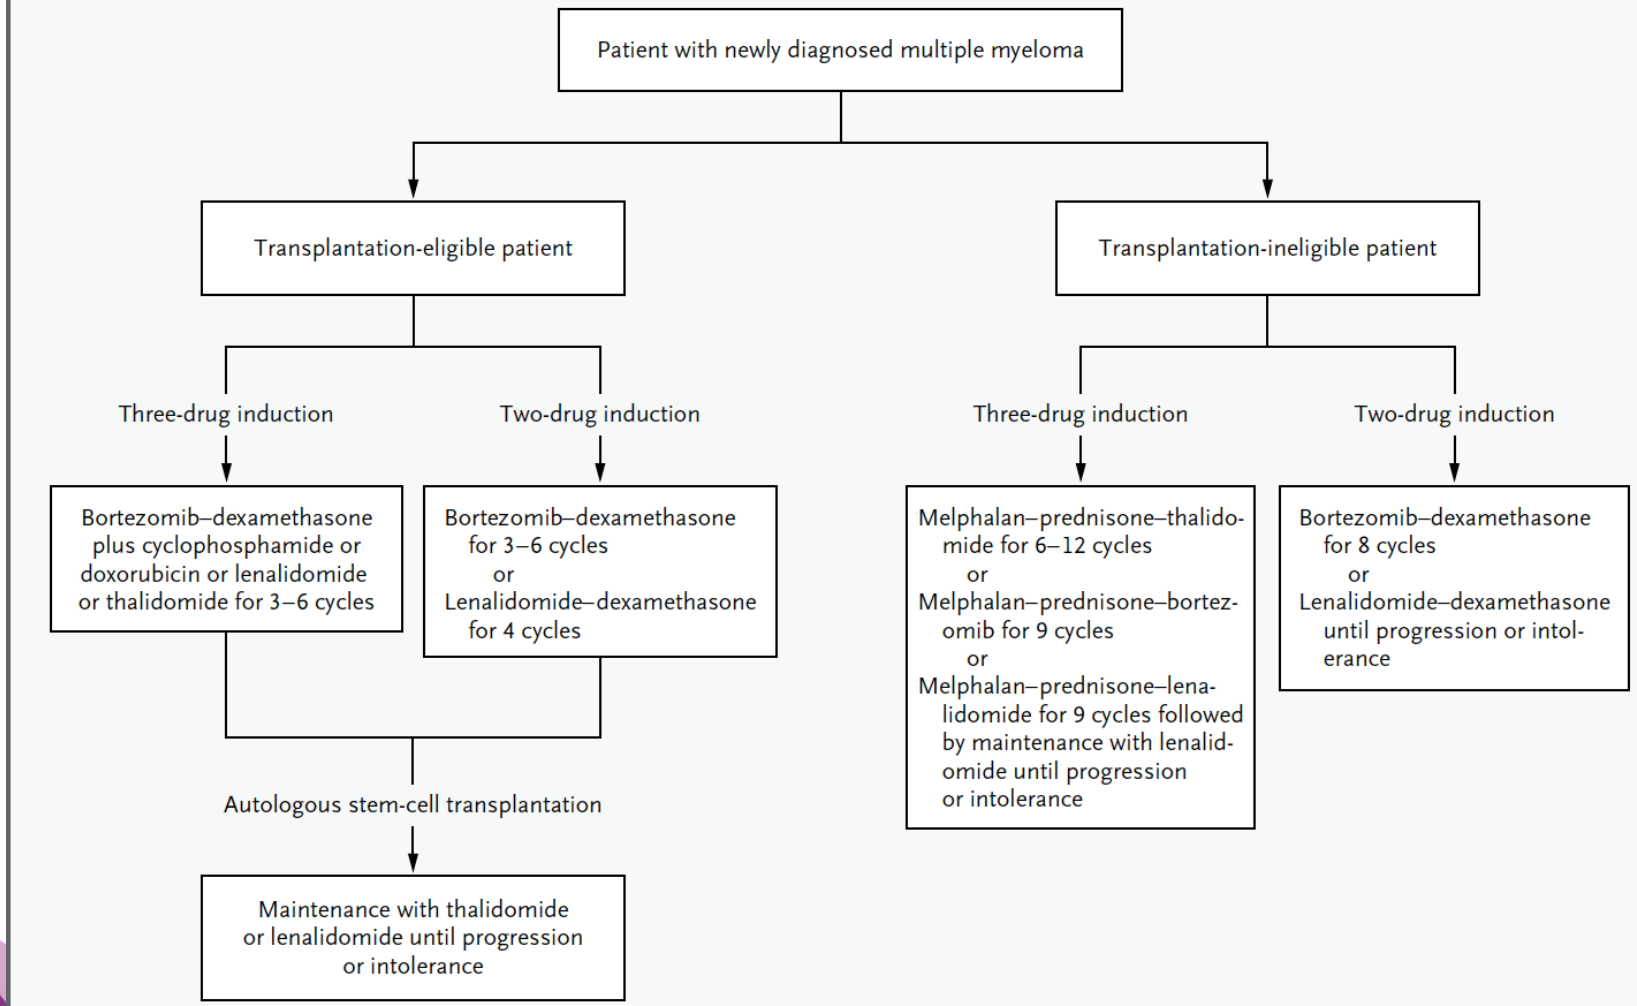
Treatment

Symptomatic (active) disease should be treated immediately, whereas asymptomatic (smoldering) myeloma requires only clinical observation, since early treatment with conventional chemotherapy has shown no benefit

Investigational trials are currently evaluating the ability of immunomodulatory drugs to delay the progression from smoldering myeloma to symptomatic myeloma

The treatment strategy is mainly related to age



Patient with newly diagnosed multiple myeloma
Transplantation-eligible patient
Transplantation-ineligible patient
Three-drug induction
Two-drug induction
Three-drug induction
Two-drug induction
Bortezomib–dexamethasone plus cyclophosphamide or doxorubicin or lenalidomide or thalidomide for 3–6 cycles
Bortezomib–dexamethasone for 3–6 cycles or Lenalidomide–dexamethasone for 4 cycles
Melphalan–prednisone–thalidomide for 6–12 cycles or Melphalan–prednisone–bortezomib for 9 cycles or Melphalan–prednisone–lenalidomide for 9 cycles followed by maintenance with lenalidomide until progression or intolerance
Bortezomib–dexamethasone for 8 cycles or Lenalidomide–dexamethasone until progression or intolerance
Autologous stem-cell transplantation
Maintenance with thalidomide or lenalidomide until progression or intolerance

Treatment

Current data would support the initiation of induction therapy with thalidomide, lenalidomide, or bortezomib, plus hematopoietic stem-cell transplantation for fit patients under the age of 65 years

Autologous stem-cell transplantation with a reduced-intensity conditioning regimen should be considered for older patients or those with coexisting conditions

Conventional therapy combined with thalidomide, lenalidomide or bortezomib should be administered in patients older han 65 years

Less intensive approaches should be considered in patients over 75 years

Radiotherapy in MM

In patients with MM and symptomatic bone disease, significant relief of pain can be achieved with palliative radiotherapy

Radiotherapy can also be used for relief/prevention of neurological symptoms due to spinal cord or nerve root compression

Radiotherapy can be used in MM for prevention - or consolidation after orthopedic stabilization - of a pathologic fracture in the case of severe destruction of the cortical bone (impending fracture)

Radiation doses ranging from 8 Gy in 1 fraction up to 30 Gy in 10 fractions are commonly used

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

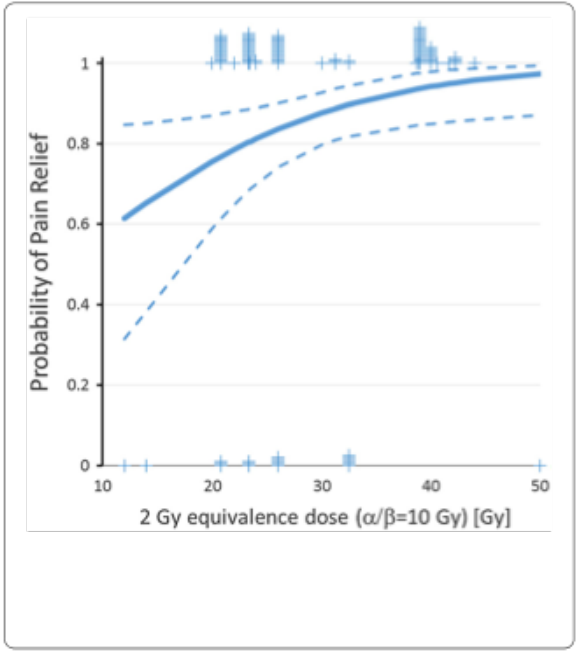
Role of Radiotherapy in MM

- Prompt and highly effective modality in the palliation of of painful bony lesions and mass effects from soft tissue extensions
- Efficacy in the control of lytic bone lesions and in reversing the morbidity of spinal cord and nerve root compression
- 30 Gy in 10 fractions or 40 to 45 Gy in 4 to 4.5 weeks to the lesions with generous margins; 8 Gy/1 fraction may be used

0341582

- solitary vertebral body lesion (C7) in MM

Effects of Radiotherapy in the treatment of multiple myeloma: a retrospective analysis of a Single Institution



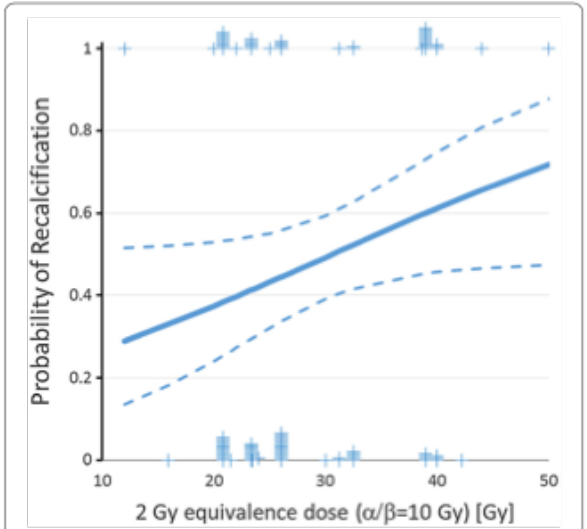


Figure 3 Binary logistic regression analysis of dose effects on recalcification ($\alpha/\beta = 10$ Gy, $p = 0.048$. Dotted lines indicate the 95% confidence limits of the regression line. Tick marks indicate the number of events (0 or 1) at the respective dose.

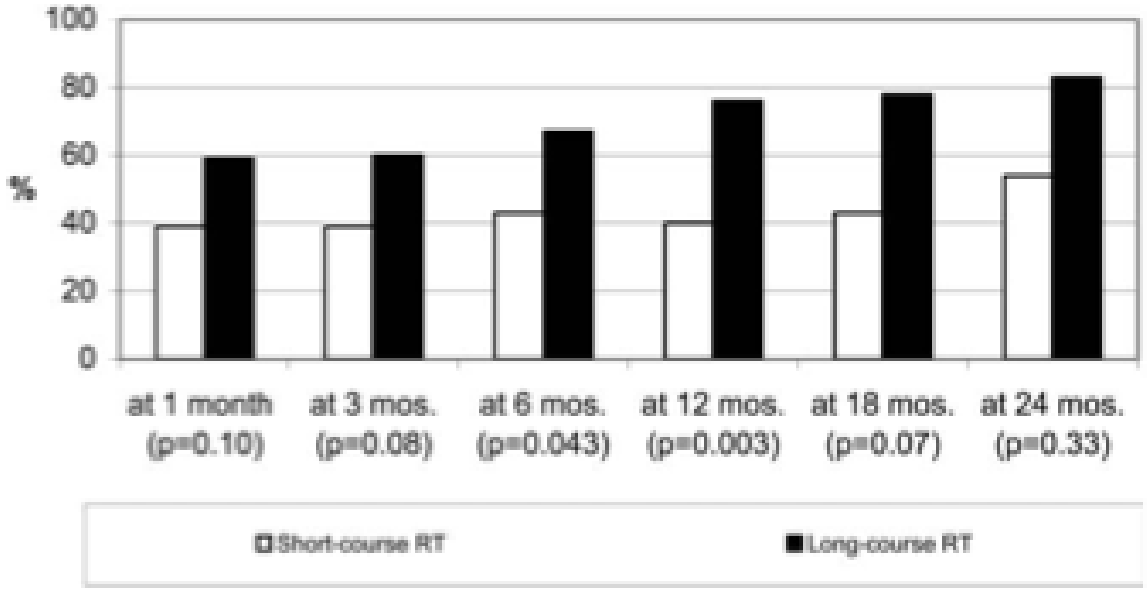
- 153 patients
- 1989-2013

Conclusions:
higher total biological RT dose were associated with better pain relief (**≥30 Gy**) and recalcification (**≥40 Gy**)

Matuschek et al Radiat Oncol 2015;10:71

SHORT-COURSE RADIOTHERAPY IS NOT OPTIMAL FOR SPINAL CORD COMPRESSION DUE TO MYELOMA

IMPROVEMENT OF MOTOR FUNCTION AFTER RADIOTHERAPY



- 172 patients
- 1994-2004

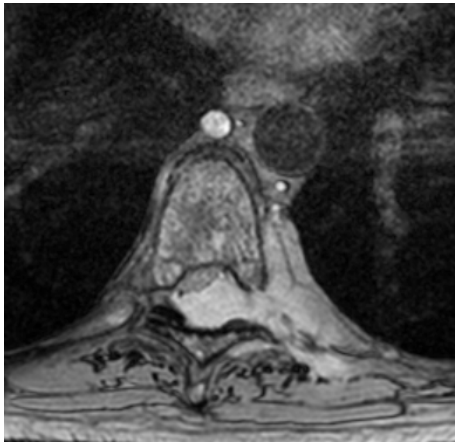
- Short course RT:
  - 8 Gy in single fraction
  - 20 Gy/5 fractions

- Long course RT:
  - **30 Gy/10 fractions**
  - **37.5 Gy/15 fractions**
  - **40 Gy/20 fractions**

Rades et al IJROBP 2006;64(5):1452-1457

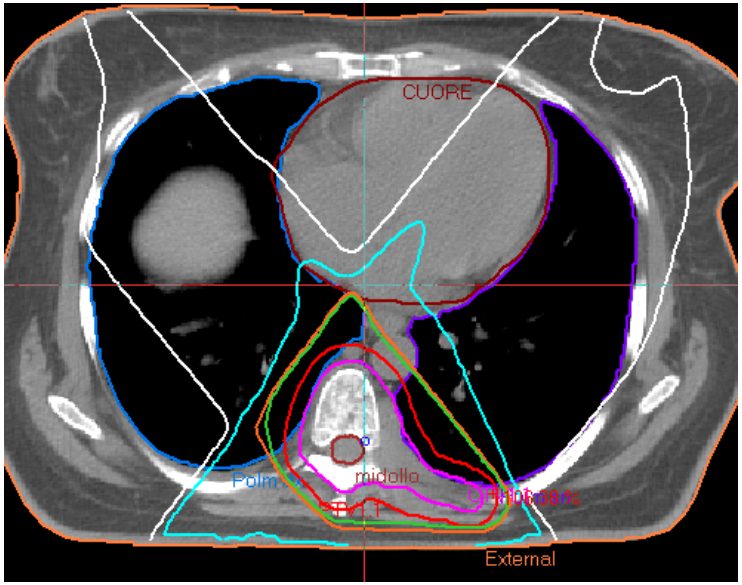
Palliative RT for Multiple Myeloma @ University of Torino

- 40 years old female
- No previous history of cancer.
- Abrupt dorsal pain + left leg weakness and paresthesia that required hospitalization
- Lab: anemia, BJ and M protein elevated
- BM: PC involvement 90%
- **First clinical event of MM**



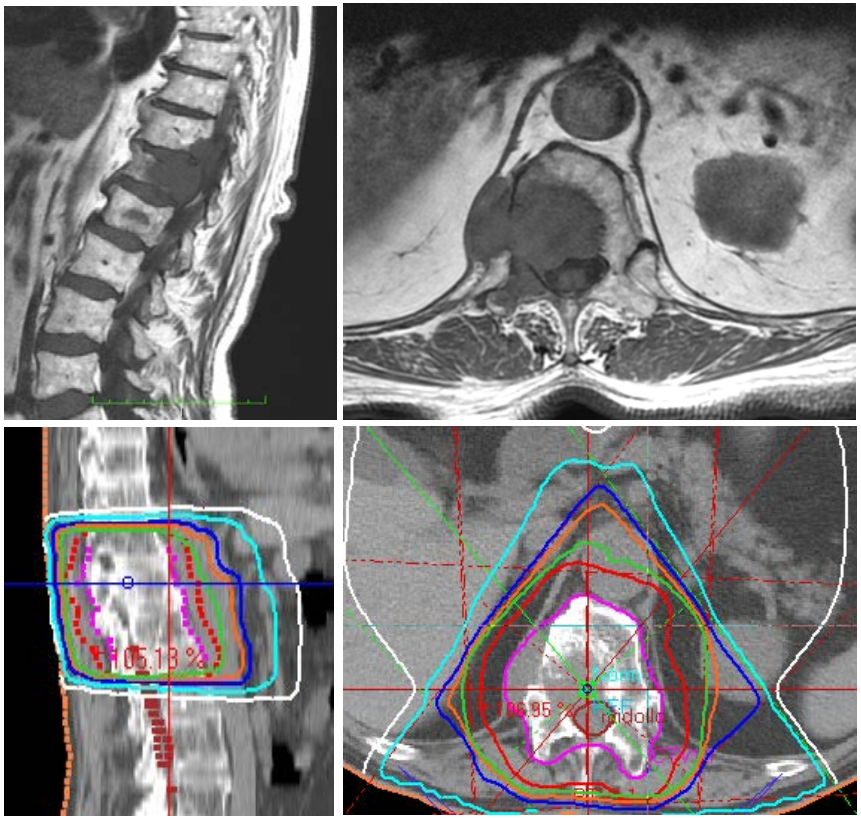
ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School



- 30 Gy/10 fractions
- 3DCRT
- Resolution of neurological symptoms after few sessions of RT

Palliative RT for Multiple Myeloma @ University of Torino



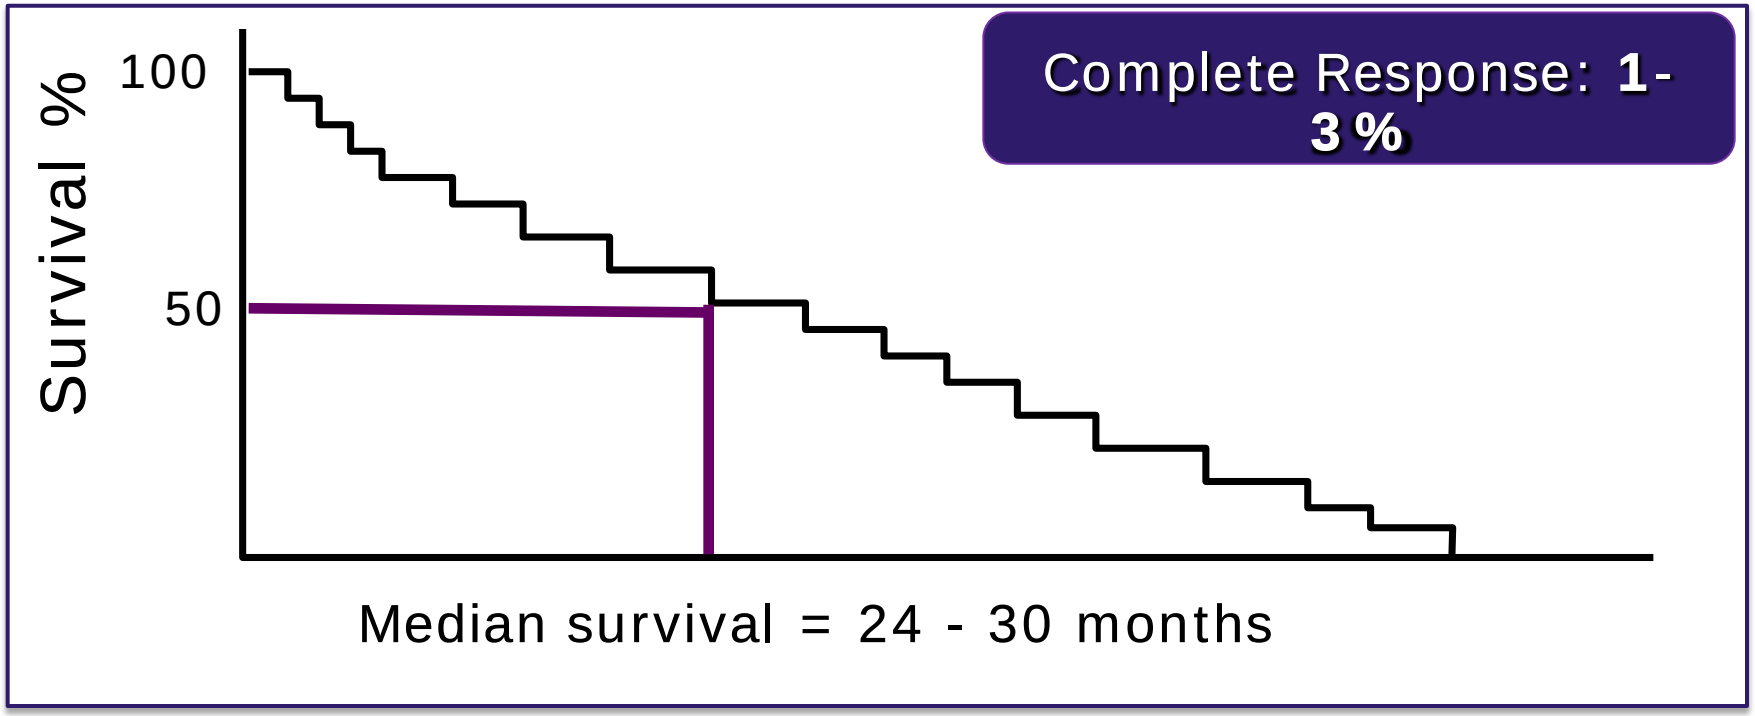
- 72 years old male
- Known history of MM, already treated with multiple lines of chemotherapy
- Osteolytic lesion at D11-D12, determining spinal cord compression, right leg weakness and severe dorsal pain.
- RT dose: 30 Gy/10 fractions
- During treatment neurologic improvement (dorsal pain disappeared and leg weakness significantly reduced)

Systemic radiotherapy in MM:

TBI and HBI

- Bone marrow ablative (allo and/or auto) preparative regimens: drugs alone (Melphalan) (more toxicity with TBI)
- Non myeloablative allogeneic transplantations (mini-allo): single dose 2 Gy TBI, combined with various chemotherapy regimens
- HBI (mainly historical)

Multiple Myeloma - incurable disease



Continuous improvement in overall survival

Solitary plasmacytoma

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

- Solitary or localized plasmacytomas are rare diseases that account for less than 10% of all plasma cell neoplasms

- Similar to MM but without infiltration of the bone marrow, these neoplasms are composed of sheets of plama cells involving bone or soft tissue

- When the lesion is isolated in bone, the disorder is called **Solitary Plasmacytoma of Bone (SPB)** [mostly occurs in the bones of the axial skeleton]

- When in soft tissues, the lesion is called **Extramedullary Plasmacytoma (EMP)**, and is found in the head and neck 80% of the time

- SPBs are found predominantly in men (male-to-female ratio of 2:1) and at a median age of 55 years (younger age than MM), and are slightly more common than EMPs

Diagnosis of SPB requires solitary bone lesion confirmed by skeletal survey, plasma cell infiltration proven by biopsy, normal bone marrow biopsy (< 10% plasma cells), and lack of myeloma-related organ dysfunction (CRAB)

- Treatment of SP is largely composed of retrospective studies on small number of patients

- Currently, the standard of care for SBP is definitive RT, being SBP a highly radiosensitive disease, for which excellent local control rates can be achieved with RT alone (lesion size as prognostic factor; cut off 5 cm)

- In some cases (bone instability, rapidly progressive neurological symptoms) surgical intervention may be required

- Even though the optimal dose of RT has not yet established for SBP, it is recommended a radiation dose of at least 40 Gy in 20 fractions

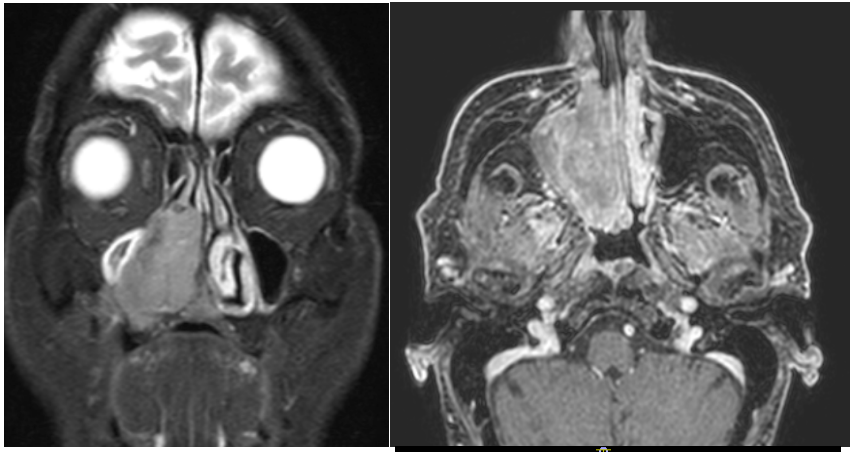
- Local control rates of 94% with doses over 40 Gy, dropped to 64% with doses lower than 40 Gy

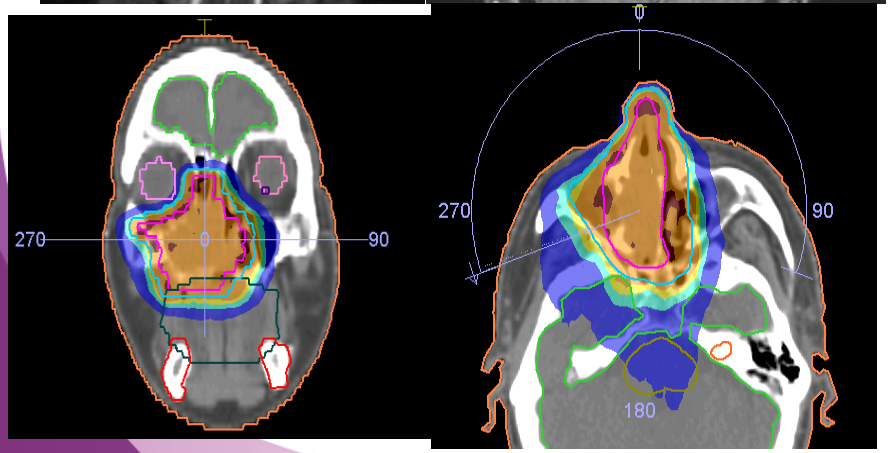
- In clinical practice, a radiation dose of 45-50 Gy with 2 Gy daily fractions is usually recommended

- Since the majority of EMP occurs in head and neck region and radical surgery with curative intent is often a mutilating procedure, radical RT should be preferred

- However, for patients with EMP in other sites, complete surgical removal should be considered, with adjuvant irradiation if appropriate (inadequate surgical margins)

Solitary Plasmacytoma @ University of Torino





- 79 years old patient
- Treatment: Radical RT
- 44 Gy/22 fractions
- IMRT/VMAT

- Although some authors recommend for SPB treatment portals including the entire involved bone (to encompass the entire medullary cavity of the bone), current recommendations favor radiation fields encompassing only the primary lesion, with generous margins (1.5-2 cm) to cover both the osseous and soft tissue extensions of the tumor (shown on CT and/or MRI)

- Prophylactic regional nodes irradiation is not necessary in SPB, as isolated regional node failure is low after local RT without intentional coverage of adjacent nodes

- Elective nodal irradiation is not routinely indicated in EMP patients, unless regional nodes are clinically involved or considered at high risk

Patterns of failure:

- local recurrence
- development of MM
- development of new bone lesions without MM

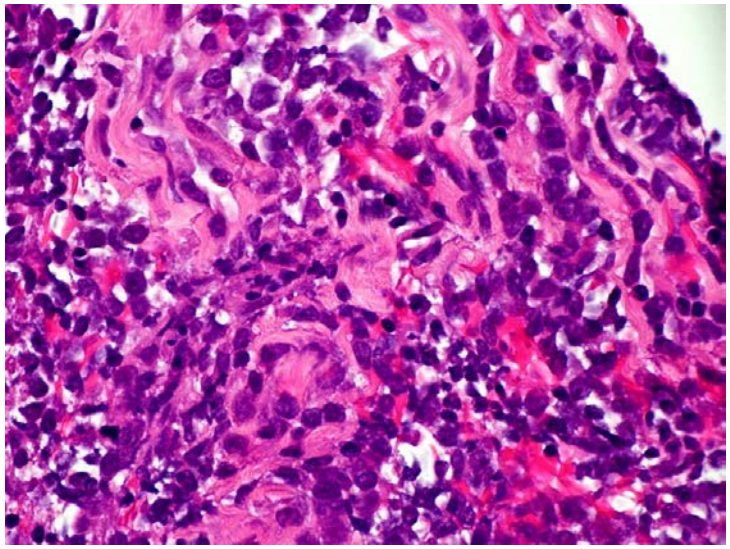
RT for Extramedullary Leukemias

("Granulocytic Sarcomas" –Chloromas) and Leukemia Cutis



Joachim Yahalom, M.D.
Memorial Sloan Kettering Cancer Center
New York, NY, USA

Memorial Sloan Kettering Cancer Center

ILROG International Lymphoma Radiation Oncology Group

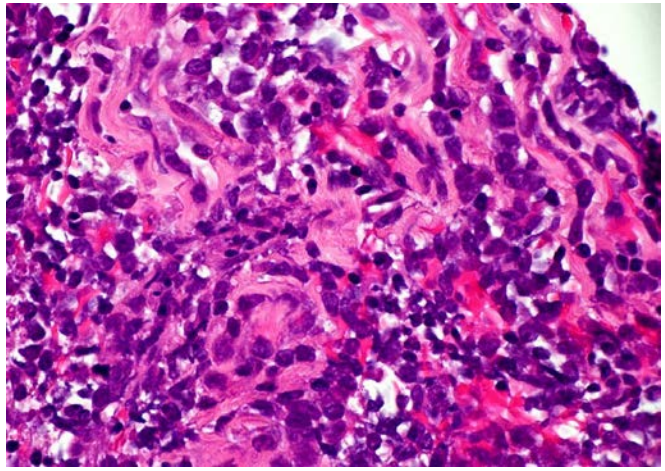
ESTRO School

Background

- Myeloid sarcoma (MS) is an extramedullary tumor of immature myeloid cells

- Leukemia cutis (LC) is the infiltration of the epidermis, dermis or subcutis by neoplastic leukocytes resulting in clinically identifiable cutaneous lesions

Myeloid Sarcoma



Leukemia Cutis

Leukemia Cutis

Leukemia Cutis

Incidence

- Myeloid Sarcoma is reported in 2.5%-9% of patients with AML

  Occurs concomitantly, following, or, rarely, antedating the onset of leukemia

- LC occurs in approximately 3% of patients with AML, and less frequently in chronic leukemias

EXTRAMEDULLARY LESIONS IN NON-LYMPHOCYTIC LEUKEMIA: RESULTS OF RADIATION THERAPY

LINDA Y. CHAK, M.D., MICHAEL D. SAPOZINK, M.D., PH.D.*
AND RICHARD S. COX, PH.D.
Division of Radiation Therapy, Department of Radiology, Stanford University, Stanford CA 94305

Fifty-four courses of radiotherapy were given to 33 patients with symptomatic extramedullary involvement by non-lymphocytic leukemia. Among them were 23 cases of granulocytic sarcoma. Analysis of the treatment response showed that age, hematopathologic type and quality of irradiation did not influence the radiation
($p = 0.003$). We suggest irradiating all extramedullary lesions to at least 1100 ret.

TOTAL SKIN ELECTRON BEAM THERAPY FOR CUTANEOUS LYMPHOMAS AND LEUKEMIAS

LOURDES Z. NISCE, M.D.,[1] FLORENCE C. H. CHU, M.D.,[1] HYUN S. LEE, M.D.,[1]
DANIEL FILIPPA, M.D.,[2] SANFORD KEMPIN, M.D.[3]
AND MORTON COLEMAN, M.D.[4]

Departments of Radiation Therapy,[1] Pathology,[2] Hematology/Lymphoma Service,[3] Memorial Sloan-Kettering Cancer Center, New York, N.Y. 10021, and Medicine, Division of Hematology/Oncology,[4] New York Hospital Cornell Medical Center, New York, NY 10021

Total skin electron beam therapy (TSEB) was used in the treatment of 33 patients with lymphoma and 13 patients with leukemia involving extensive segments of the skin surface. Twenty-two of 23 had skin lesions as a primary manifestation of lymphoma (primary cutaneous lymphoma—PCL) and 11 developed cutaneous lesions following disseminated nodal lymphoma (secondary cutaneous lymphoma—SCL). A once weekly fractionation scheme was employed to irradiate the entire skin surface with 3.5 to 4 MeV electron beam from a 6 MeV linear accelerator. During each weekly session, 400 rad were delivered to the entire skin and a complete course consisted of 4–6 consecutive weekly sessions. The majority of patients have been previously treated elsewhere for various periods and all patients have been at risk for a median of 12 months, range from 12–117 months following TSEB. Striking predominance of the diffuse pattern (76%) was demonstrated in both the PCL and SCL. There was extracutaneous involvement in 63% (13/22) of the PCL, nodal or visceral at onset of TSEB; median follow-up was 24 months, range 6–117 months; 20/22 (90%) of all patients obtained prompt relief of symptoms and complete regression of cutaneous lesions. Duration of cutaneous remission ranged from 6–96 months, median 18 months; in general, duration was adversely influenced by the presence of visceral involvement at onset of TSEB. Although cutaneous response among the patients with SCL and leukemia was equally good, many of these patients were treated for palliation because of rapid progression of their disease. Once weekly treatments were highly effective, well-tolerated and no untoward immediate or late effects have been noted in the bone marrow or normal skin irradiated.

Cutaneous lymphoma, leukemia, total skin electron beam therapy.

Results: Leukemia Cutis

- 13 courses of RT administered
  - 9 TSEB and 4 focal treatments
- Median survival since completion of RT was 5 months
- 1-year LC was 33%
  - All patients who developed a skin relapse had active marrow disease at time of RT or recurrence shortly after
- No significant acute toxicities
  - one case of radiation recall

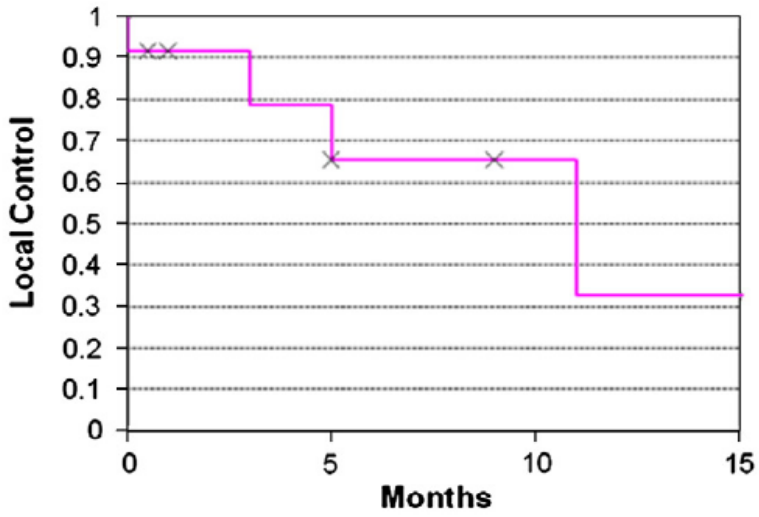

Figure 2 Local control for patients treated with radiation for leukemia cutis.

➢ Bakst R et al Practical Radiation Oncology 2011

Conclusions: Leukemia Cutis

- Patients with LC have aggressive disease with few long-term survivors
- Definitive treatment with TSEB should be utilized only in cases of marrow remission with focal electron therapy reserved for palliation of symptomatic lesions
- Long-term prognosis and durable cutaneous remission is dependent on systemic disease control

Methods: Chloroma

Radiation therapy for leukemia

- Cranial irradiation for CNS disease in ALL
  - To prevent relapse in brain (12-18 Gy/6-12 fractions)
  - To treat disease in brain (18-24 Gy/10-16 fractions, with or without 6-12 Gy/3-8 fractions to spine)
- Testicular irradiation for disease in testes in ALL
  - 24-26 Gy/12-18 fractions
- Splenic irradiation in chronic leukemias
  - 1-10 Gy/10-100 fractions
- Total body irradiation as part of hematopoetic stem cell transplant (for any leukemia, and other diseases)
  - With or without any of the above

Total body irradiation as part of conditioning

- Non-myeloablative:
  - Commonly an outpatient procedure
- Myeloablative doses:
  - >5 Gy in a single fraction
  - >8 Gy in multiple fractions
  - Commonly an inpatient procedure (at MSKCC)
  - Can be performed as an outpatient (if patient is reliable)
  - Keep in mind, this is ***lethal*** therapy!

Indications for HSCT

- Center International Bone and Marrow Transplant most common indications for HSCT in 2005 (most to least common)
  - Multiple myeloma (MM)
  - Non-Hodgkin lymphoma (NHL)
  - Acute myelogenous leukemia (AML)
  - Hodgkin disease (HD)
  - Acute lymphoid leukemia (ALL)
  - Myelodysplastic and myeloproliferative disease (MDS)
  - Chronic myelogenous leukemia (CML)
  - Aplastic anemia (AA)
  - Various other leukemias, cancers, and non-malignant diseases

- National Comprehensive Cancer Network guidelines for HSCT (2009)
  - Acute myelogenous leukemia (AML)
  - Multiple myeloma (MM)
  - Myelodysplastic syndrome (MDS)
  - Chronic myelogenous (CML)
  - Hodgkin disease (HD)
  - Non-Hodgkin lymphoma (NHL)
  - Testicular cancer

Biology of TBI

- Normal and malignant blood cells are the major target in TBI
  - Very sensitive to radiation
  - D_0 of 0.5 – 1.5 Gy
  - Very small shoulder on cell survival curve
  - Other radiobiologic phenomena are ill-defined (repair, reoxygenation, repopulation, redistribution)

TBI effects on blood

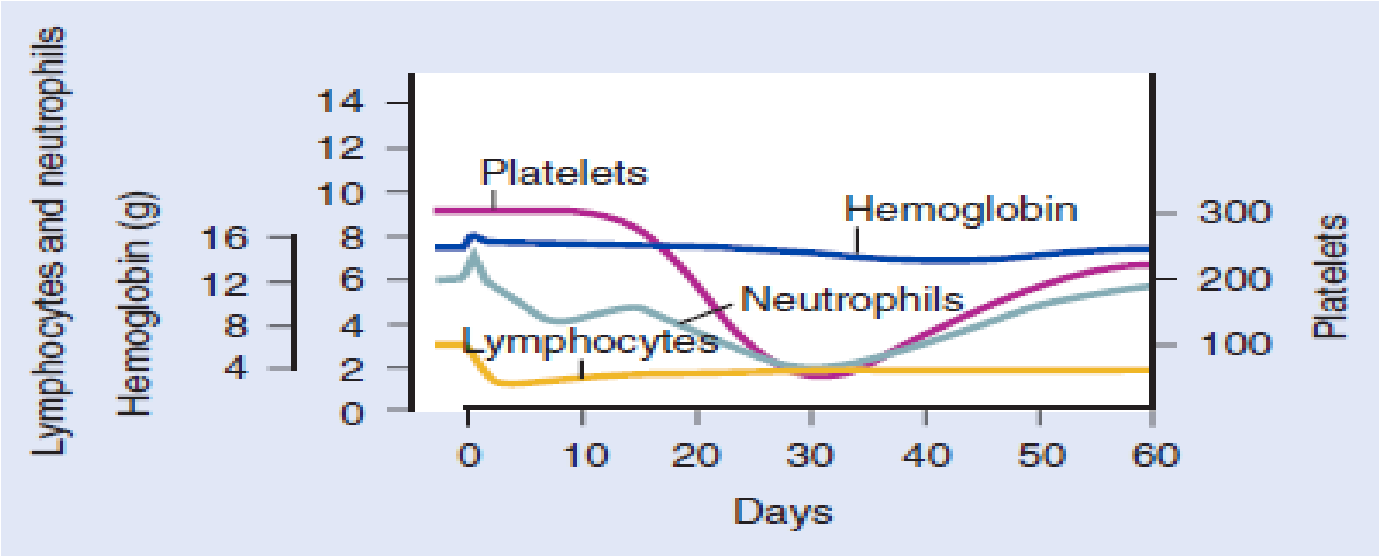

FIGURE 15-3 • Representative hematologic response to total body irradiation, given as a single fraction of 200 cGy on day 0. (From Andrews: Radiation accidents and their management, Radiat Res Suppl 7:390–397, ••••.)

TBI associated with better outcomes in ALL & AML, but not MM

Table 15-3 Randomized Controlled Trials Comparing Hematopoietic Stem Cell Transplant Conditioning Regimens With and Without Total Body Irradiation

Disease	Author (Group) [Reference]	Number of Patients	Type of Transplant	TBI-Based Conditioning	Non-TBI-Based Conditioning	Total TBI Dose Number & Frequency of Fractions Dose Rate	Technique	Conditioning Regimen	OS	EFS	Relapse	Non-Relapse Mortality	TRM	Other Findings
ALL	Bunin et al. (PBMTC) [270]	43	Allogeneic marrow, cord, or peripheral blood	TBI, etoposide 40 mg/kg in 1 day, then Cy 120 mg/kg in 2 days	Bu 16 mg/kg in 4 days, then Cy 120 mg/kg in 2 days	12 Gy 6 bid Dose rate not described	Not described	TBI Non-TBI	3 yr: 67% 3 yr: 47%	3 yr: 58%* 3 yr: 29%*	43%[1] 32%[1]	24%[1] 9%[1]		No significant difference in GVHD, or pulmonary, cardiac, or neurologic toxicity after HSCT; the TBI group had significantly better EFS among patients who received unrelated donor stem cells, and who were under 6 years
ALL AML CML lymphoma	Ringden et al. (NBMTG) [112, 172]	167	Allogeneic marrow	Cy 120 mg/kg in 2 days, then TBI	Bu 16 mg/kg in 4 days, then Cy 120 mg/kg in 2 days	10-12.7 Gy 1-7 given ≥1 times daily 4-12.7 cGy/min	Varied All had lung blocks limiting dose to 9-10 Gy	TBI Non-TBI	7 yr: 63% 7 yr: 54%	7 yr: 62% 7 yr: 51%	7 yr: 29% 7 yr: 29%		7 yr: 14%* 7 yr: 34%*	No significant difference in immunosuppressant use, interstitial pneumonitis, or Karnofsky score, growth, renal, pulmonary, or thyroid function at follow-up; the TBI group had less hepatic VOD, hemorrhagic cystitis, chronic GVHD, death from GVHD, obstructive pronchiolitis, with more cataracts
ALL AML CML	Blume et al. (SWOG) [274]	122	Allogeneic marrow	TBI, then etoposide 60 mg/kg in 1 day	Bu 16 mg/kg in 4 days, then Cy 120 mg/kg in 2 days	13.2 Gy 11 tid Dose rate not described	Not described	TBI Non-TBI	3 yr: ~24% (7 months[2]) 3 yr: ~28% (7 months[2])					No significant difference in GVHD, hemorrhage, sepsis, lung complications, infections, VOD, drug toxicity, relapse, disease free survival
AML	Dusenbery et al. (Minnesota) [261]	35	Autologous marrow	Cy 120 mg/kg in 2 days, then TBI	Bu 16 mg/kg in 4 days, then Cy 200 mg/kg	13.2 Gy 8 bid (4.5 hr apart) 10 cGy/min	6-24 MV photons Bilateral parallel-opposed Head & neck,	TBI Non-TBI	2 yr: 46% 2 yr: 35%	2 yr: 50% 2 yr: 24%	2 yr: 43% 2 yr: 70%	Reported as "not different" Reported as "not different"		No significant difference in time to engraftment, GVHD, time in the hospital, infection, hepative VOD, hemorrhagic cystitis, pneumonitis
AML	Blaise et al. (GEGMO) [260, 262]	101	Allogeneic marrow	Cy 120 mg/kg in 2 days, then TBI	Bu 16 mg/kg in 4 days, then Cy 120 mg/kg in 2 days	10-13.5 Gy 1-6 given 1-2 times daily (6 bid[2]) 3-25 cGy/min (5 cGy/min[2])	Varied All had lung blocks (8.8 Gy[2])	TBI Non-TBI	12 yr: 59%* 12 yr: 43%*	12 yr: 55%* 12 yr: 35%*	12 yr: 25% 12 yr: 37%		12 yr: 16% 12 yr: 27%	No significant difference in time to engraftment, GVHD; the TBI group had less chronic GVHD related mortality
CML	Clift et al. (Seattle) [265, 266]	142	Allogeneic marrow	Cy 120 mg/kg in 2 days, then TBI	Bu 16 mg/kg in 4 days, then Cy 120 mg/kg in 2 days	12 Gy 6 qd 6-7 cGy/min	Dual opposed 60Co sources Geometry not described Blocks not described	TBI Non-TBI	9 yr: 65% 9 yr: 73%	9 yr: 48% 9 yr: 55%	9 yr: 22% 9 yr: 19%	9 yr: 25% 9 yr: 20%		No significant difference in the rate of engraftment, GVHD, hepatic VOD, number of fevers, deaths from infection, mean duration of first hospitalization; the TBI group did have significantly longer fevers, more blood cultures revealing bacteria or fungi, more than one hospitalization in the 100 days after transplant, and higher incidence of grade 2-4 GVHD
CML	Devergie et al. (SFGM) [267]	120	Allogeneic marrow	TBI, then Cy 120 mg/kg in 2 days	Bu 16 mg/kg in 4 days, then Cy 120 mg/kg in 2 days	10-12 Gy 1-24 given 1-8 times daily (bid[2]) 3-25 cGy/min (8 cGy/min[2])	Varied All had lung blocks (8.8 Gy[2])	TBI Non-TBI	5 yr: 66% 5 yr: 61%	5 yr: 51% 5 yr: 59%	5 yr STBI: 11%* 5 yr FTBI: 31%* 5 yr: 4%*	Not reported Not reported	29%[1] 38%[1]	No significant difference in the rate of engraftment, GVHD, hepatic VOD, interstitial pneumonitis, hemorrhagic cystitis, GVHD
MM	Moreau et al. (IFM) [273]	282	Autologous peripheral blood	TBI, then Mel 140 in 1 day	Mel 200 in 1 day	8 Gy 4 qd Dose rate not described	Not described No lung blocks	TBI Non-TBI	3.75 yr: 45.5% 3.75 yr: 65.8%*	21 months[2] 20.5 months[2]			3.6%[1] 0%[1]	No significant difference in growth factor use, cardiac, pulmonary, renal, liver toxicity, or response rates; the TBI group had significantly higher rates of mucositis and hematologic toxicity, and longer hospitalizations

All drug doses given as mg/m² unless otherwise stated.
bid, Twice daily; *Bu*, busulfan; *Cy*, cyclophosphamide; *EFS*, even-free survival; *Mel*, melphalan; *OS*, overall survival; *tid*, three times daily; *TRM*, transplant related mortality; *qd*, once daily.
*Statistically significant difference; [1]observed incidence; [2]median.

TBI used in non-myeloablative regimens for various diseases

Table 15-4 Representative Total Body Irradiation–Based Reduced Intensity Conditioning Regimens for Allogeneic Hematopoietic Stem Cell Transplant

Disease	Author (Group) [Reference]	Number of Patients	Total TBI Dose Number & Frequency of Fractions Dose Rate	Additional Conditioning Therapy	Technique	Type of Transplant
AML	Hegenbart et al. (multicenter) [282]	122	2 Gy 1 ~~0.07 to~~ ~~0.20 Gy~~/min	84% received Flu 90 in 3 days, then TBI	Dual opposed ^{60}Co sources or linear accelerator Geometry not described Blocks not described	Allogeneic marrow (5%) and peripheral blood (95%)
AML	Stelljes et al. (COSTSG) [283]	71	8 Gy 4 given twice daily 8.9-30 cGy/min	TBI, then Flu 120 in 4 days +/- ATG	Not described	Allogeneic marrow (4%) and peripheral blood (96%)
AML	Hallemeier et al. (Washington U.) [284]	32	5.5 Gy 1 27.6-36.4 cGy/min	Cy 120 in 2 days, then TBI	6 MV photons from linear accelerator Parallel opposed lateral fields Arms at side for lung shielding	Allogeneic peripheral blood
CLL	Sorror et al. (Seattle) [285]	64	2 Gy 1 7 cGy/min	83% received Flu 90 in 3 days, then TBI	Dual opposed ^{60}Co sources or linear accelerator Geometry not described Blocks not described	Allogeneic peripheral blood
CML	Kerbauy et al. (Seattle) [286]	24	2 Gy 1 7cGy/min	67% received Flu 90 in 3 days, then TBI	Dual opposed ^{60}Co sources or linear accelerator Geometry not described Blocks not described	Allogeneic peripheral blood
CML	Khoury et al. (Washington U.) [287]	30	5.5 Gy 1 26.4-36.0 cGy/min	Cy 120 in 2 days, then TBI	6 MV photons from linear accelerator Parallel opposed lateral fields Arms at side for lung shielding	Allogeneic peripheral blood
Hematologic malignancy	McSweeney et al. (Seattle) [288]	45	2 Gy 1 7 cGy/min	None	Dual opposed ^{60}Co sources or linear accelerator Geometry not described Blocks not described	Allogeneic peripheral blood
Hematologic malignancy	Baron et al. (Seattle) [289]	221	2 Gy 1 7 cGy/min	77% received Flu 90 in 3 days, then TBI	Not described	97% allogeneic peripheral blood
Lymphoma	Tomblyn et al. (Minnesota) [290]	76	2 Gy 1 Dose rate not reported	Flu + Cy, then TBI or Flu + Bu, then TBI or Bu + Clad, then TBI	Not described	Allogeneic marrow (10%), peripheral blood (46%), and cord blood (43%)
Mantle cell lymphoma	Maris et al. (Seattle) [291]	33	2 Gy 1 7 cGy/min	Flu 90 in 3 days, then TBI	Linear accelerator Geometry not described Blocks not described	Allogeneic marrow (4%) and peripheral blood (96%)
MDS/AML	Schmid et al. (Wiesbaden) [292]	75	4 Gy 1 Dose rate not reported	TBI, then Cy 80-120 in 2 days, ATG	Not described	Allogeneic marrow (19%) and peripheral blood (81%)
MDS/MPD	Laport et al. (multicenter) [293]	148	2 Gy 1 7 cGy/min	97% received Flu 90 in 3 days, then TBI	Linear accelerator Geometry not described Blocks not described	Allogeneic marrow (2%) and peripheral blood (98%)
MDS/secondary AML	Hallemeier et al. (Washington U.) [294]	51	5.5 Gy 1 25.3-37.2 cGy/min	Cy 120 in 2 days, then TBI	6 MV photons from linear accelerator Parallel opposed lateral fields Arms at side for lung shielding	Allogeneic peripheral blood
MM	Maloney et al. (Seattle) [295]	54	2 Gy 1 7 cGy/min	17% received Flu 90 in 3 days, then TBI	Linear accelerator Geometry not described Blocks not described	Allogeneic peripheral blood
MM	Badros et al. (Arkansas) [296]	31	2.5 Gy 2 given twice in 1 day Dose rate not reported	TBI and Mel 100, then Flu 60 in 2 days	Not described	Allogeneic peripheral blood

All drug doses given in mg/kg unless otherwise stated.
AML, Acute myelogenous leukemia; *ATG*, antithymocyte globulin; *Bu*, busulfan; *Clad*, cladribine; *CLL*, chronic lymphoid leukemia; *CML*, chronic myelogenous leukemia; *Cy*, cyclophosphamide; *Flu*, fludarabine; *melphalan*; *MDS*, myelodysplastic syndrome; *MM*, multiple myeloma; *MPD*, myeloproliferative disorder.

Hypersplenism, splenomegaly

Lena Specht MD DMSc
Professor of Oncology, University of Copenhagen, Denmark
Chief Oncologist, Depts. of Oncology and Haematology, Rigshospitalet, Copenhagen
Vice-chairman, International Lymphoma Radiation Oncology Group

Splenomegaly

- Seen in CML, CLL, myelofibrosis, other myeloproliferative disorders, hairy cell leukemia, splenic marginal lymphoma
- Caused by:
  - Leukemic infiltration
  - Extramedullary hematopoiesis
  - Important (but sometimes difficult) to tell the difference

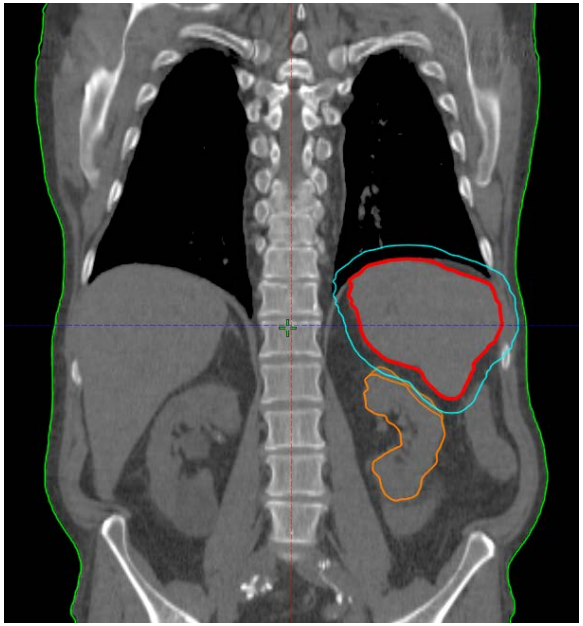
Splenic irradiation

- Used less often than in the past because of more effective systemic treatment
- Indications:
  - Palliative for pain and pressure symptoms
  - Reduction of tumor burden
  - Hypersplenism

Splenic irradiation

- Often significant extramedullary hematopoiesis in enlarged spleen
- Irradiation must be done with caution, risk of severe long-lasting pancytopenia
- E.g., 0.5 Gy x 20, 5 F/W
- Close monitoring of blood counts

Splenic irradiation



70 year old male,
CMMOL, pain

ESTRO School

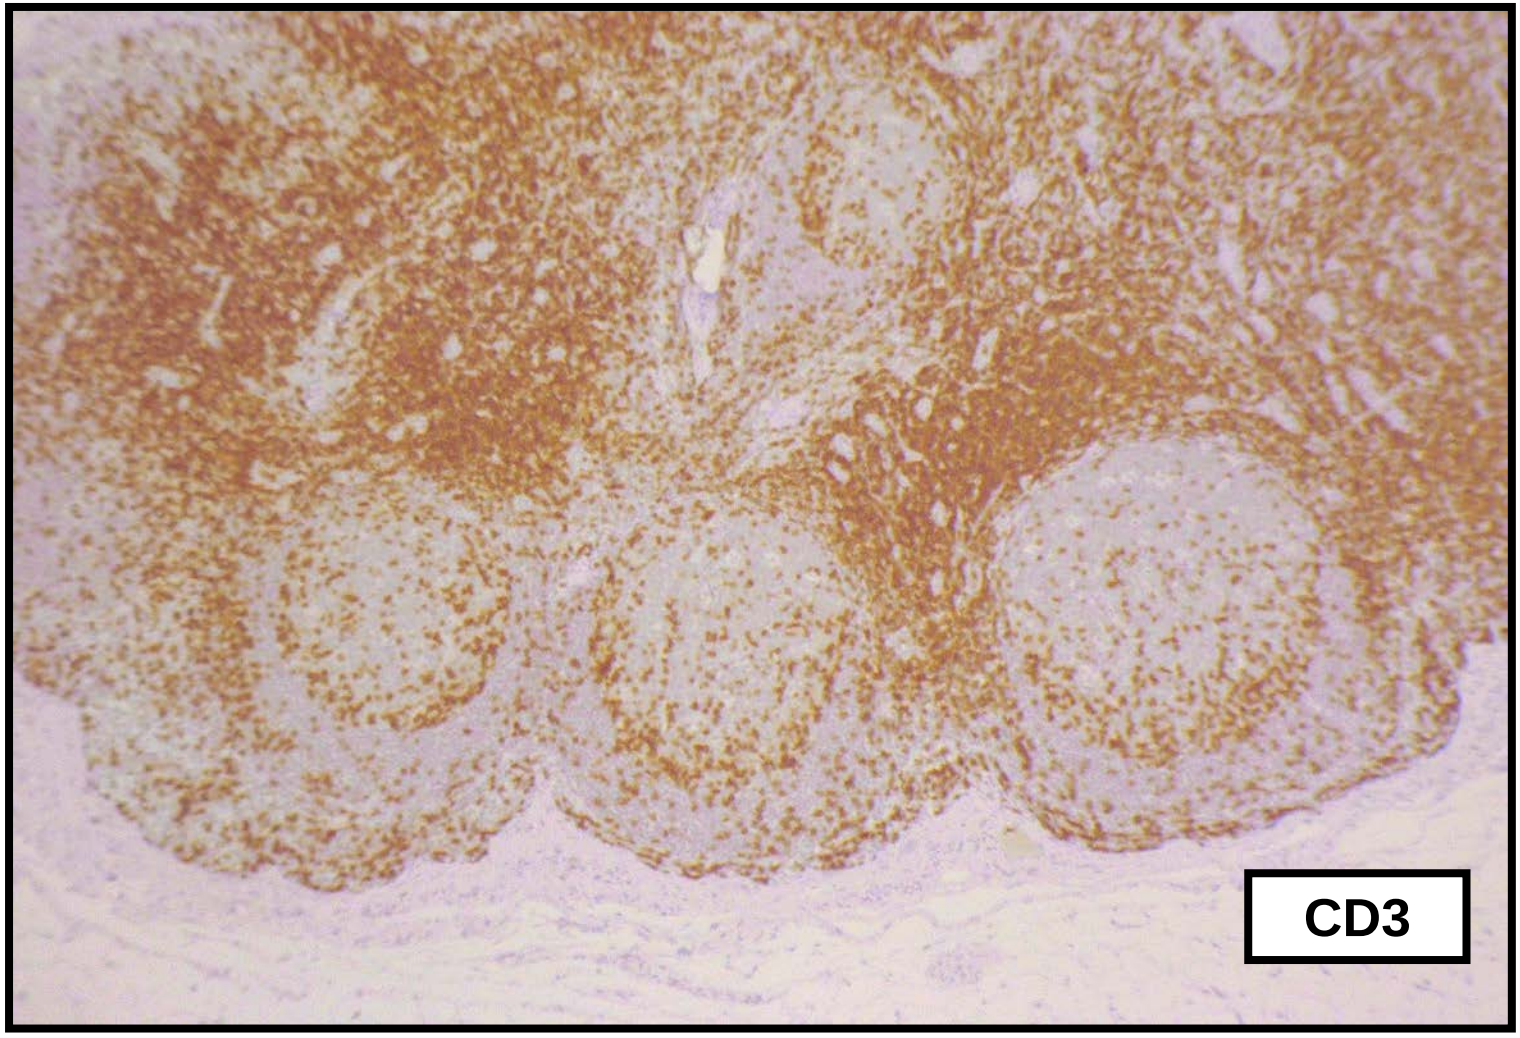
Paracortical T-cell zone and T-cells in follicles



Principles of WHO lymphoma classification

- Aims to define clinically relevant entities
- Diagnosis based on integration of clinical, histological, immunophenotypic and genetic features
- Basic division into ‘precursor’ and ‘mature’ (or ‘peripheral’) lymphomas. Then by lineage (B/T/NK-cell)
- Thymus and bone marrow are primary sites of precursor T- and B-cell development
- ‘Peripheral’ sites are deep and superficial lymph nodes and extranodal (e.g., mucosal) lymphoid tissues

What does histology tell us?

- In the context of clinical information about site(s) of involvement, ‘B’ symptoms etc:
- Small cells (‘-cytes’) vs large cells (-’blasts’) vs mixed small and large
- Presence and extent of accompanying reactions (histiocytes, granulomas, eosinophils, fibrosis, necrosis)
- Architectural features: nodular (potentially follicular) vs diffuse, and mixtures
- Presence of defining cell types; Hodgkin/Reed-Sternberg cells, popcorn cells, hallmark cells...

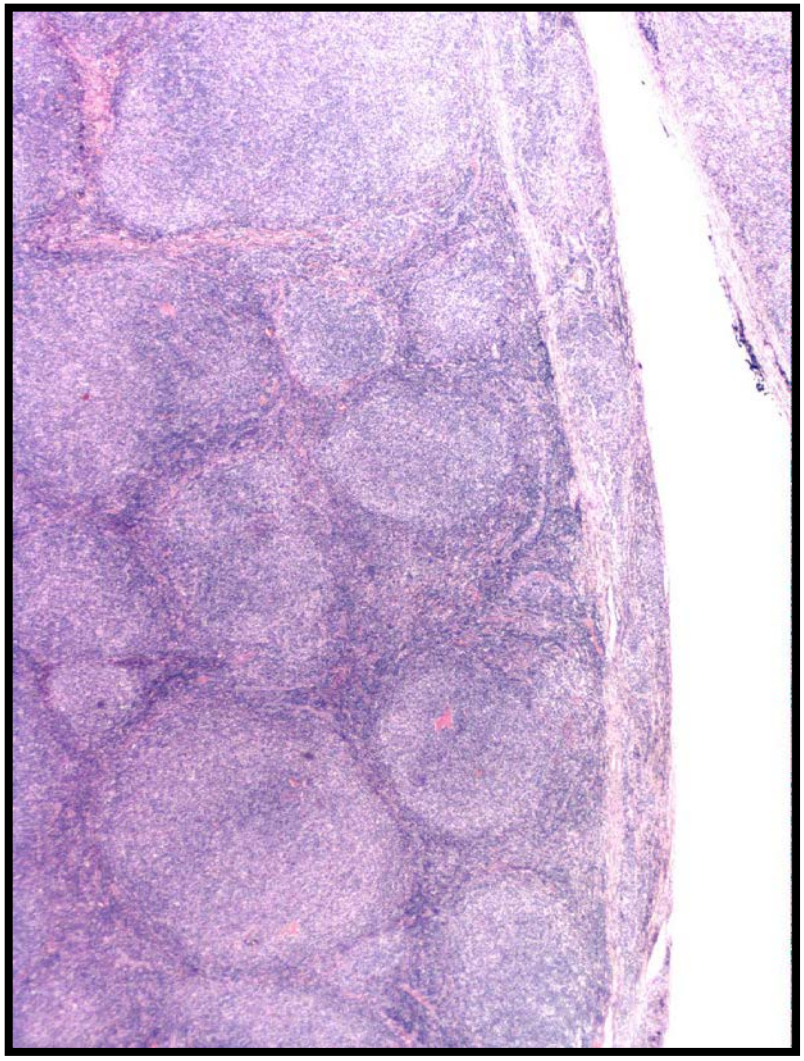
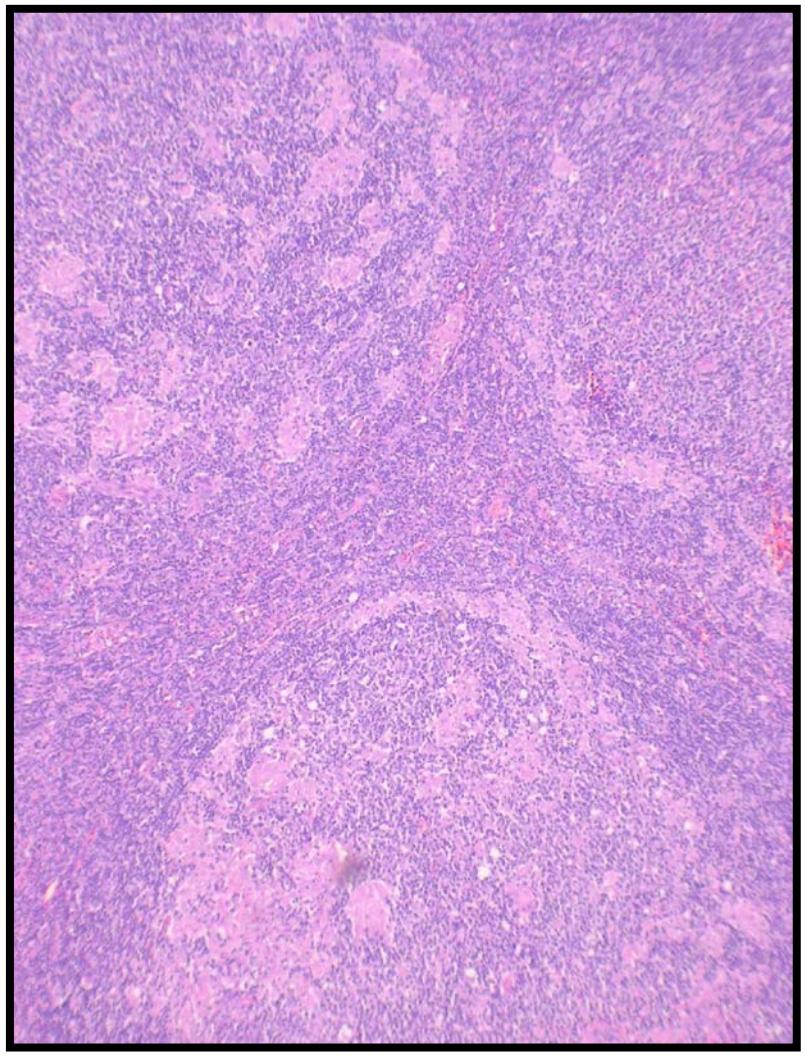
ESTRO School

Nodular/Follicular Architecture

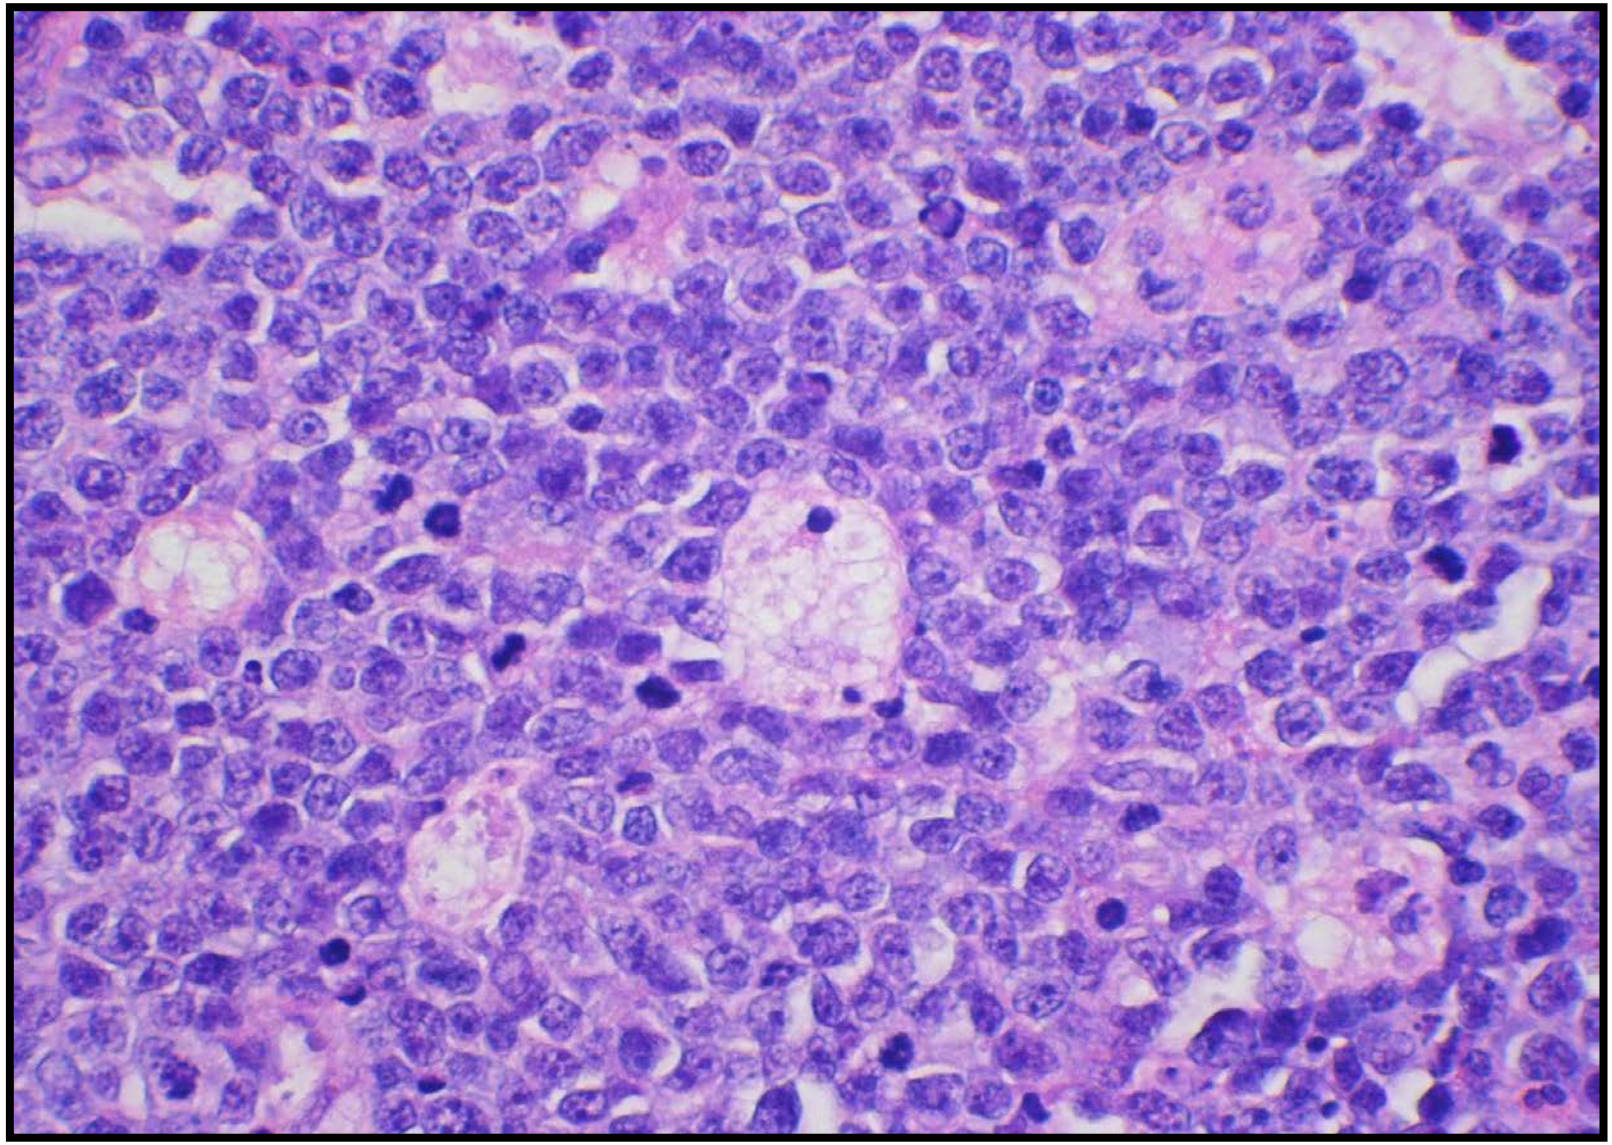




ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

‘Classical’ Morphology in Burkitt Lymphoma



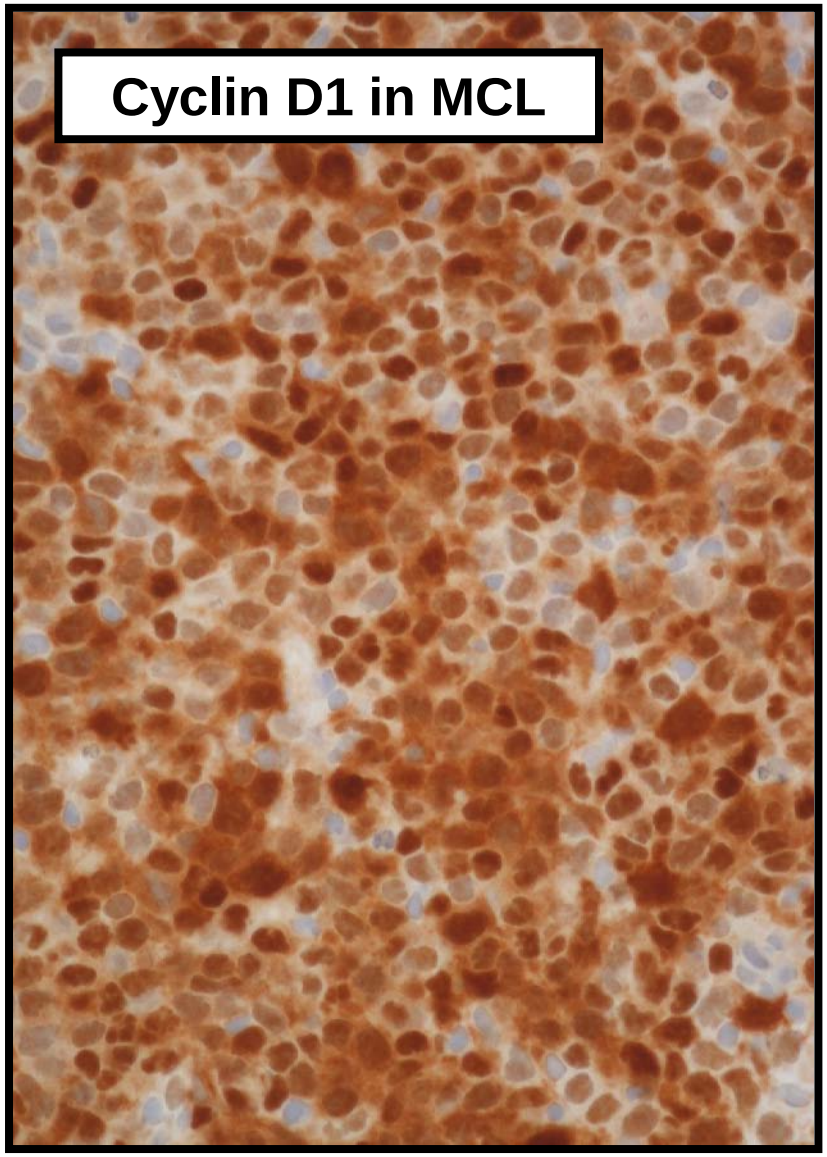
ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

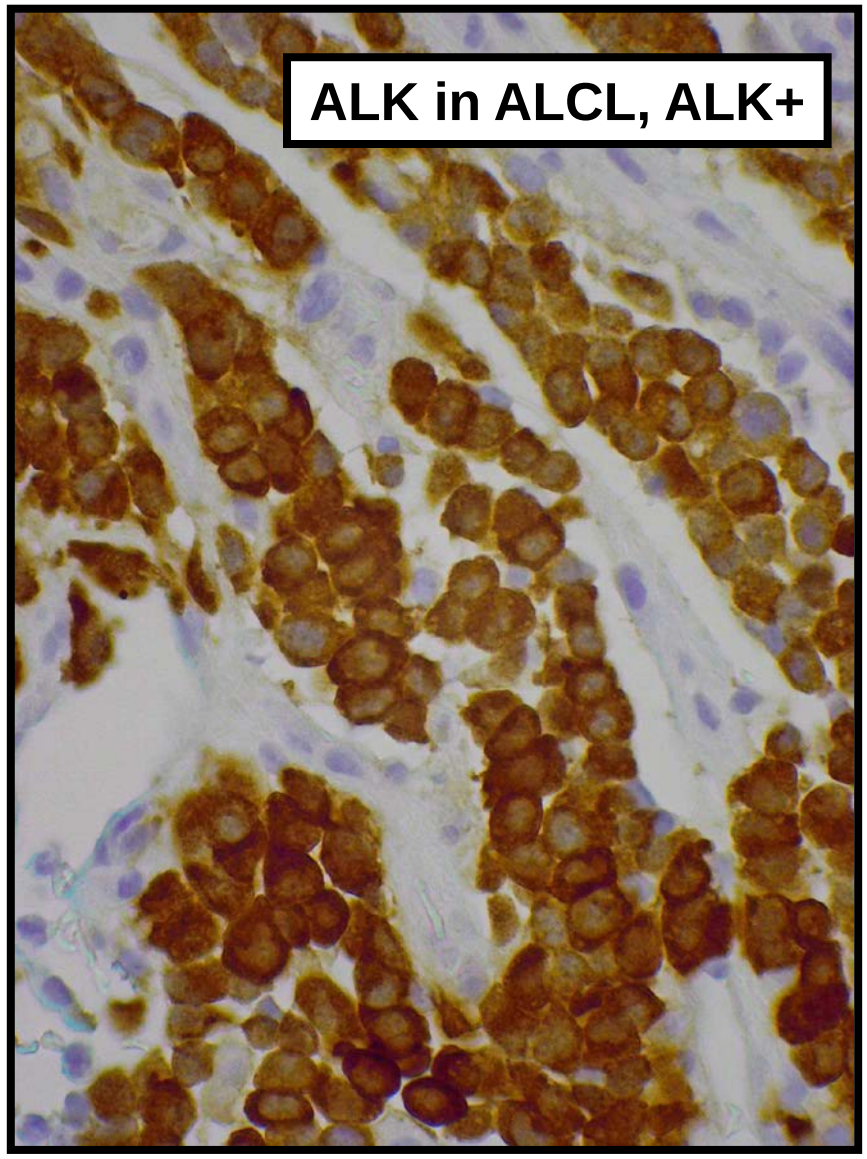
ESTRO School

What does immunophenotype tell us?

- In the context of appropriate (consistent) histology:
- Lineage and sub-lineage: B-/ T-/NK-cell, CD4/CD8 T-cells, CD10+/MUM1+ B-cells
- Characterisation of accompanying reactions (histiocytes and histiocyte-derived dendritic cells, mesenchyme-derived dendritic cells, mucosal lympho-epithelial interactions)
- May reinforce architectural features: e.g. revealing subtle nodularity (potential follicularity)
- Some cellular immunophenotypes are defining

Defining Immunophenotypes





ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

What does genetic information add?

- In the context of appropriate (consistent) histology and immunophenotype:
- Confirmation of monoclonal vs polyclonal lymphoid cell proliferation
- Demonstration of defining rearrangements e.g., *IGH-BCL2, CCND1-IGH, MYC*
- *Rearrangements of prognostic value e.g., MYC, IGH-BCL2 and BCL6, API2-MALT1*

When do we use PCR and when FISH?

- Efficient PCR primer binding requires breakpoints that occur only at restricted, highly consistent areas of the genome.
- Breakpoints in antigen receptor rearrangement (*IGH* and *TCR*) have appropriate properties, favouring PCR.
- IGH-BCL2 breakpoints are variable but partly meet the necessary criteria; CCND1-BCL2 breakpoints are even more variable. MYC rearranges with several partner genes, often unknown.
- FISH probes are much larger and less 'fussy' than PCR primers

Lymphomas that like to circulate - ‘leukaemic’ lymphomas

- Small lymphocytic lymphoma/chronic lymphocytic leukaemia
- Mantle cell lymphoma
- Splenic marginal zone lymphoma
- T-prolymphocytic leukaemia
- T- and NK-cell large granular lymphocytic leukaemia

- Aggressive lymphomas much less likely to circulate except ‘precursor’ types (B- and T-cell acute lymphoblastic leukaemias, and rare variants)

- If they are in the circulation, they are in the bone marrow

Extranodal Lymphomas of Mucosa-associated Lymphoid Tissue

- Mainly indolent, composed of small cells
- Believed to be driven by host immune reactions to chronic infections or auto-immunity
- Form distinctive lympho-epithelial lesions
- Often prominent accompanying reactive lymphoid components

- Enteropathy-associated T-cell lymphoma is classified separately
- Tends to be aggressive, in part due to cytotoxic (perforin etc.) phenotype

Other Extranodal Sites

- Spleen
- Skin
- Testis
- (Ovary)
- Brain
- Bone
- Soft tissue (e.g., extranodal NK/T-cell lymphoma, nasal type)

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

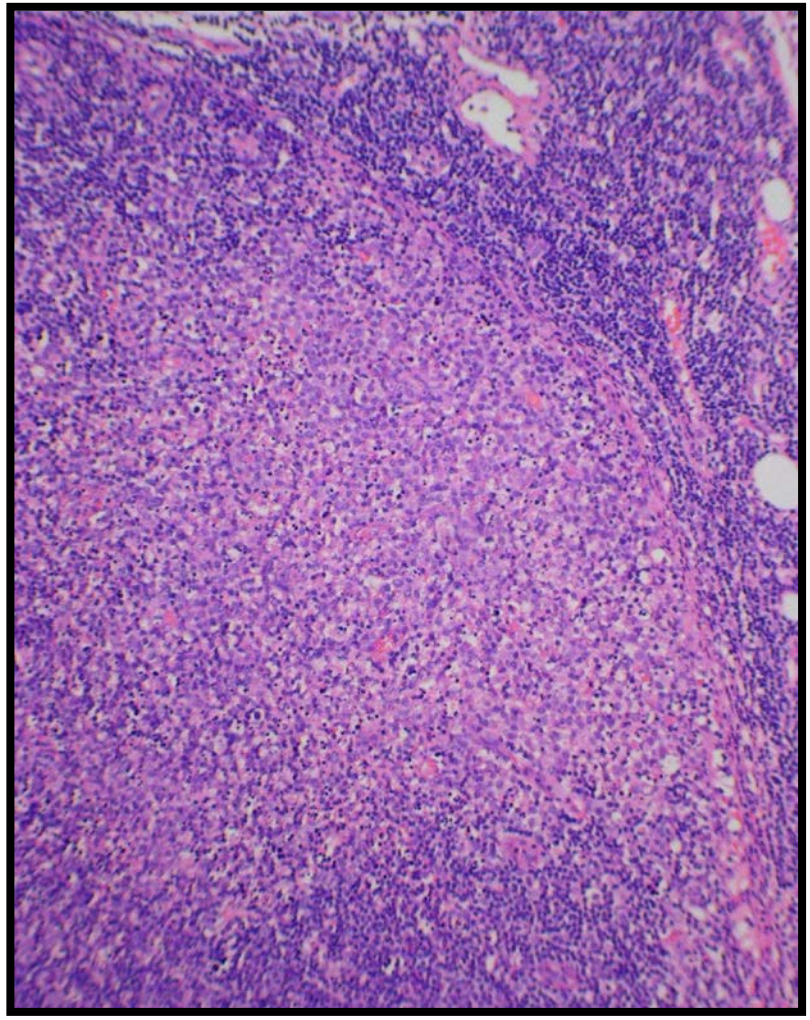
ESTRO School

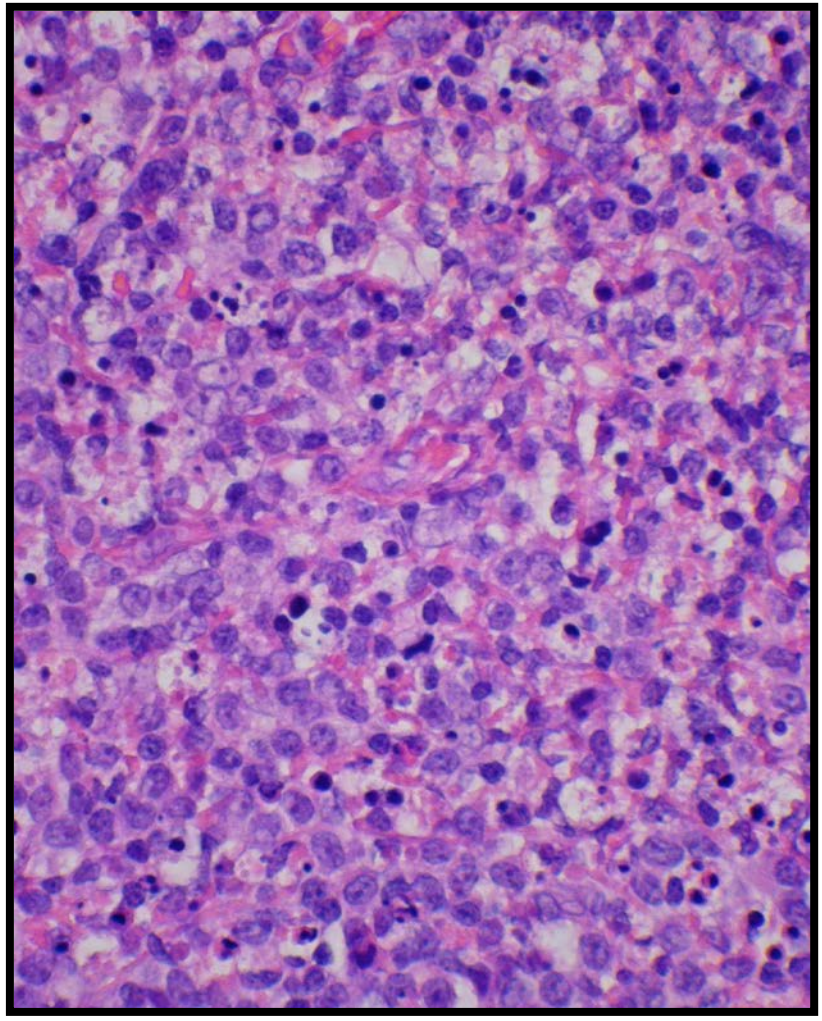
‘Never Events’ in Lymphoma Pathology

- Misinterpreting reactive processes as lymphoma
  - Granulomatous lymph nodes diagnosed as classical Hodgkin lymphoma
  - Histiocytic necrotising lymphadenitis (Kikuchi’s/SLE)

- Misdiagnosing lymphoblastic or Burkitt lymphomas as indolent because the blast cells appear small

Histiocytic Necrotising Lymphadenitis





ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

What's on the Horizon in WHO 2016?

- Further formal recognition of 'grey zone' lymphomas:
  - Large B-cell lymphomas intermediate between DLBCL and Burkitt
  - Large B-cell lymphomas intermediate between DLBCL and cHL
- Revised classification of some examples of nodal 'peripheral T-cell lymphoma, NOS' in recognition of T-follicular helper cell origin
- Reconsideration of surrogates for molecular genetic signals
  - MYC/BCL2 immunostaining
  - Hans classifier (and others)

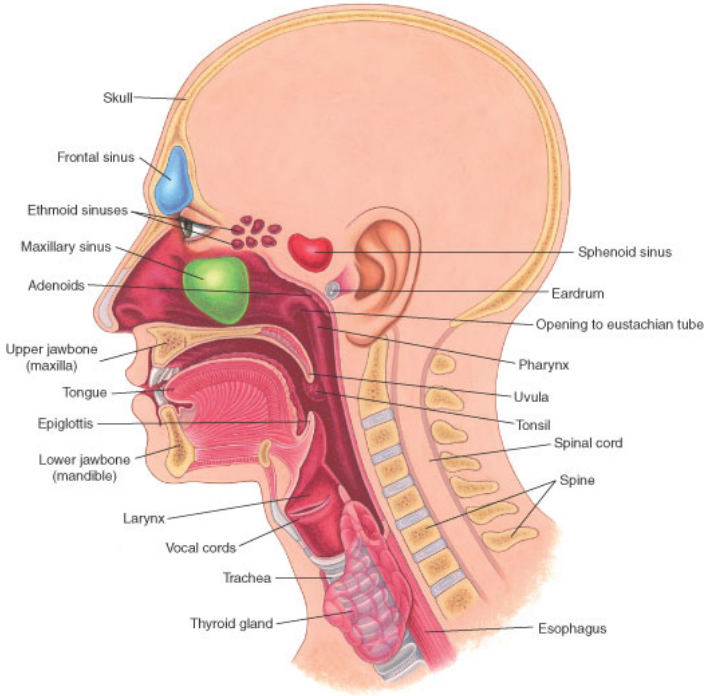
Extranodal lymphomas: Head and neck

Lena Specht MD DMSc
Professor of Oncology, University of Copenhagen, Denmark
Chief Oncologist, Depts. of Oncology and Haematology, Rigshospitalet, Copenhagen
Vice-chairman, International Lymphoma Radiation Oncology Group

Extranodal (not necessarily extralymphatic) sites in the upper aerodigestive tract



- Nasal cavity and paranasal sinuses: NK/T-cell lymphomas (Eastern Asia and South America) and DLBCL (Western countries)

- Pharynx (most often in Waldeyer's ring: lymphatic tissue formed by palatine tonsils, adenoids in posterior nasopharynx, lingual tonsil, and intervening lymphoid tissues): DLBCL

- Oral cavity, larynx and hyphopharynx: rare, include indolent lymphomas, mantle cell lymphomas and DLBCL

- Parotid and other salivary glands: MALT lymphomas

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Head & neck lymphomas, general principles

- Pre-treatment work-up:
  - Detailed ENT examination incl. fiberoptic examination, evt. under general anaesthesia
  - Imaging with PET and CT, MRI for skull base, cranial cavity, cranial nerve, sinuses, and infratemporal fossa

Head & neck lymphomas, general principles

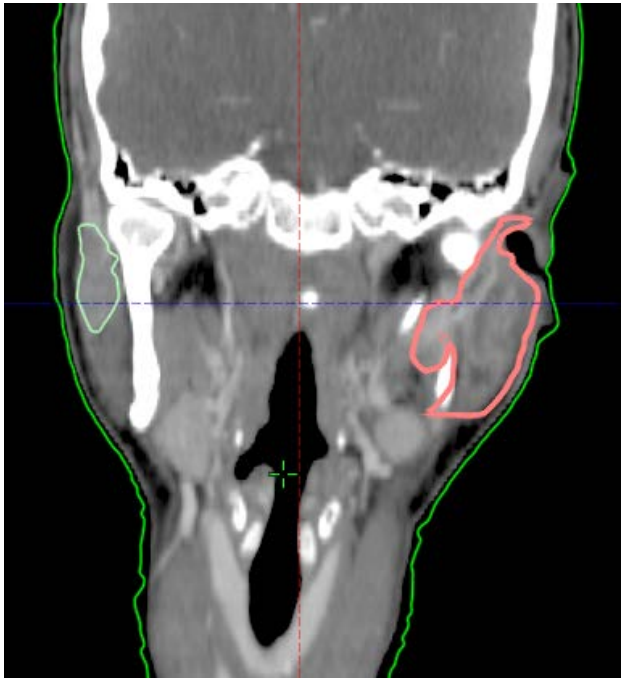
- ISRT to sites of initial definite or suspected involvement
- Prophylactic RT of uninvolved lymph node regions is not routine
- Optimal immobilization, e.g. a 5-point thermoplastic mask
- RT techniques as for solid tumors in the head & neck area often appropriate

Head & neck lymphomas, indolent

- Localized indolent disease: RT primary curative modality, 24-30 Gy
- Lymphoma is often multifocal, and the involved organ is often treated in its entirety
- First echelon nodes of uncertain status close to the primary organ may be included
- Advanced indolent disease: RT may provide effective palliation, 4 Gy effective in most patients

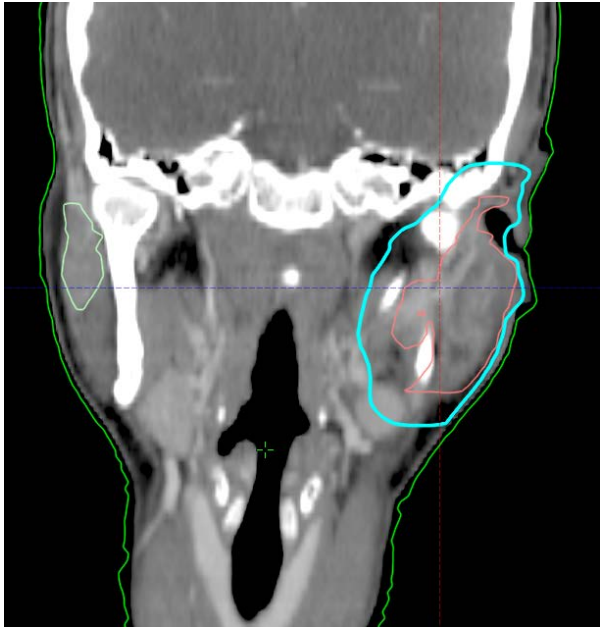
MALT lymphoma in left parotid gland

Post-op images



- 40 year female with swelling in left angular and preauricular area, waxing and waning for two years
- Previous FNA inconclusive
- Excisional biopsy: MALT lymphoma
- No post-op abnormality on PET/CT-scan.

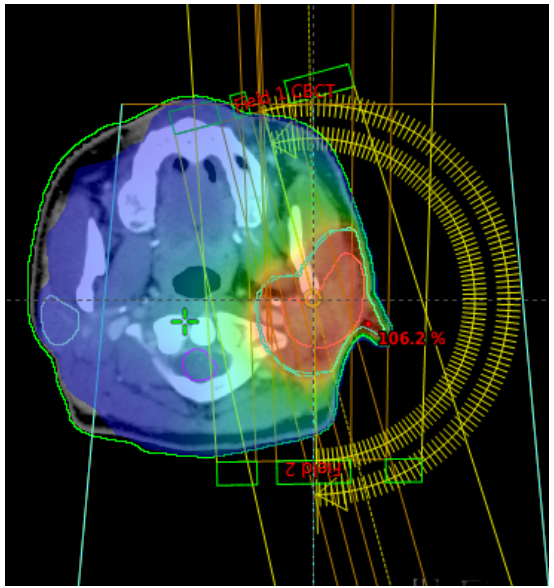
PTV

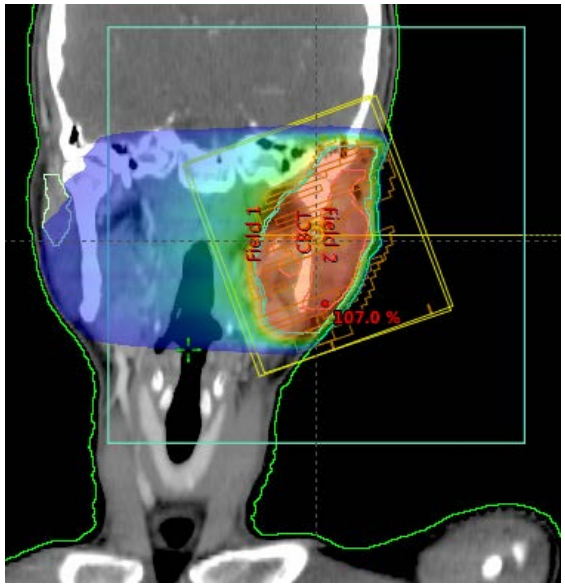


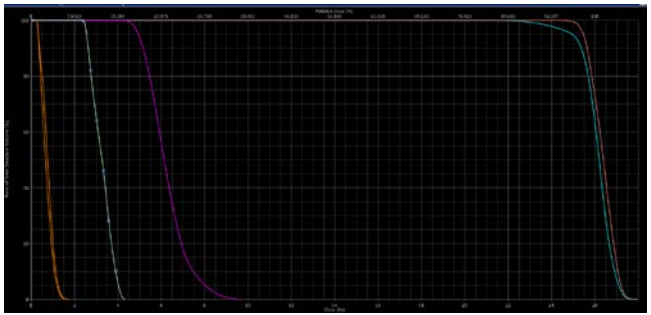
ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Treatment plan (RapidArc)







ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Head & neck lymphomas, aggressive

- Localized aggressive disease: Systemic therapy is the primary treatment. RT is used as consolidary treatment, dose 30-36 Gy after CR, 40-45 Gy if gross residual disease
- Radiation volumes may be limited to part of an organ after excellent response to systemic treatment, which controls microscopic disease
- Advanced aggressive disease: RT to initial bulk according to RICOVER and UNFOLDER studies, extranodal disease unclear (Waldeyer's ring was not considered extranodal in RICOVER)

DLBCL in tonsil

- 74 year old male with DLBCL of the left tonsilla
- Whole body PET/CT (September 4, 2014) showed no signs of lymphoma elsewhere, the patient had no B-symptoms, LDH was normal
- He was in stage IA, and was treated with 3 cycles of R-CHOP followed by ISRT to 30 Gy
- Since then in continuous CR

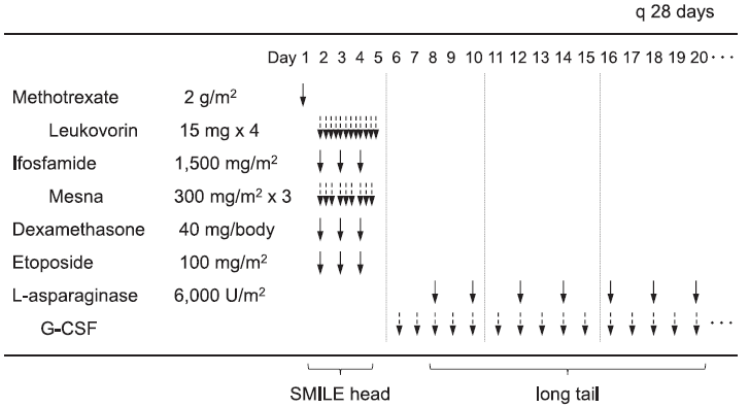
NK/T-cell lymphomas, nasal type

- Associated with Epstein-Barr virus
- More common in Asians and native Americans in Central and South America
- Usually involves nasal cavity and/or paranasal sinuses, Waldeyer's ring may also be involved
- Outside the upper aerodigestive tract it presents in advanced stages and unfavourable prognosis

NK/T-cell lymphomas, nasal type

- Frequently express multidrug resistant P-glycoprotein
- Responds poorly to anthracycline-based chemotherapy (e.g., CHOP-like regimens)
- L-asparaginase is effective: SMILE regimen



NK/T-cell lymphomas, nasal type

- Early stage disease: SMILE (or other effective regimen) x 2
- Radiotherapy is an essential component of treatment and must:
  - Come in early
  - Doses ≥ 50 Gy

NK/T-cell lymphoma, nasal type

Courtesy of Dr. Shunan Qi, Memorial Sloan Kettering Cancer Center, New York, and Chinese Academy of Medical Sciences, Beijing

- **Challenges for GTV contouring**
  - Lesions often associated with mucosa surface
  - Lesions are accompanied with inflammation/necrosis
  - Lesions sit in an area with rich lymphoid tissues
- **Rationales guiding CTV contouring**
  - Experience with chemotherapy is limited (SMILE, non-MDR drugs)
  - RT is the most effective treatment
  - Close association between local control and survival
  - Uncertainty of disease boundaries
  - Local invasiveness of the disease nature

Extended ISRT!

- Irradiate the whole involved cavity and adjacent structures!

Extranodal NK/T cell lymphoma, nasal type, CS IEA, involving left nasal cavity, IPI: 0

- The treatment plan was 2 cycles of SMILE followed by extended involved site radiation therapy (extended ISRT) to 45 Gy
- The patient received 2 cycles of SMILE, and responded immediately with CR on the post-chemotherapy planning PET/CT scan

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Incidence

- 5% of all thyroid malignancies
- 3% of all extra-nodal NHL
- 1-2 cases / million
- F:M = 3 : 1
- Peak: 7th decade
- 2 main subtypes:
  - DLBCL
  - MALT

Pathogenesis

- Link to autoimmune disease and chronic antigenic stimulation

- *Hashimoto's thyroiditis:*
  - Up to 80% of PTL have HT
  - PTL incidence is 40-80 times higher in HT
  - Typically 20-30 years after diagnosis
  - Only 0.6% of HT pts develop PTL

Histological types

- DLBCL 60-70%
- MALT 20-30%

- FL 3-5%
- cHL 2%
- SLL 2-3%
- T-cell very rare

Clinical Presentation

- Enlarging painless goitre:
  - days – 36 months
  - DLBCL : rapid course
- Compressive symptoms (1/3): dyspnoea, dysphagia and hoarseness. Rarely; stridor, SVCO
- B symptoms: not common (10-20%)
- Cervical LN
- Majority are euthyroid

Staging

- IE: Thyroid only 56%
- IIE: + LNs above diaphragm 32%

88%

- IIIE: + LNs below diaphragm 2%
- IVE: + organ involvement 11%

Based on 1048 cases: Graff-Baker, Surgery 2009

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Imaging

- US:
  - Modality of choice for thyroid assessment
  - Useful for DD of rapidly enlarging goitre:
    - Anaplastic thyroid carcinoma
    - Subacute thyroiditis
    - Haemorrhage into cyst or adenoma
  - 3 patterns: nodular, diffuse & mixed
  - Guides Bx

- Radionuclide scanning: not useful

- Cross-sectional imaging (CT + MRI)
  - Assessment of anatomical extent and airways
  - Staging

- FDG-PET/CT:
  - Standard imaging modality for staging

Biopsy

- FNAC
- Core Bx
- Surgical open biopsy

FNAC

- Initial technique of choice for assessment of thyroid lesions
- simple, usually readily available with US
- Traditionally FNAC alone was considered inadequate
- Increasing accuracy with recent adjuncts: flow cytometry, immunoperoxidase studies & PCR.

Role of Surgery

- Primary role is to establish diagnosis
- Surgical resection is not a treatment option
- Airway compromise:
  - Tracheostomy
  - Steroids (after Bx + PET)

Treatment

- Indolent: Primary RT
- Aggressive: CMT
- CTV: whole thyroid + any involved nodes
- Dose:
  - Indolent 24Gy / 12#
  - Agg: 30 – 36 Gy according to response
- Technique:
  - 3D Conformal
  - IMRT / VMAT

Extranodal lymphomas: characteristics, the role of RT, volumes, doses and techniques

Orbital (ocular adnexal) Lymphoma

Umberto Ricardi

Introduction

- 1-2% of all NHL
- 7-8% of extranodal lymphomas
- Ocular adnexa lymphomas (OAL) include:
  - orbit
  - extra ocular muscles
  - conjunctiva
  - eyelids
  - lacrimal gland
  - apparatus
- Increased incidence by 6.3% annually in the period from 1975 to 2001, more rapidly than other extra nodal sites NHL

Introduction

- Most cases of extraocular orbital lymphoma are MZL and involve the conjunctiva, lacrimal gland, eyelid, or retrobulbar soft tissues
- Approximately 15% of such cases are bilateral (synchronous or metachronous)
- Less common: FL and DLBCL

Introduction

- 95% of OAL are B-cell neoplasms
  - Extranodular marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT) type = 35-80%
  - Follicular lymphoma = 20%
  - Diffuse large B-cell lymphoma = 8%
  - Mantle cell lymphoma, small lymphocytic lymphoma and lymphoplasmacytic lymphoma = less common

Ocular adnexae marginal lymphoma (OAML)

Clinical presentation

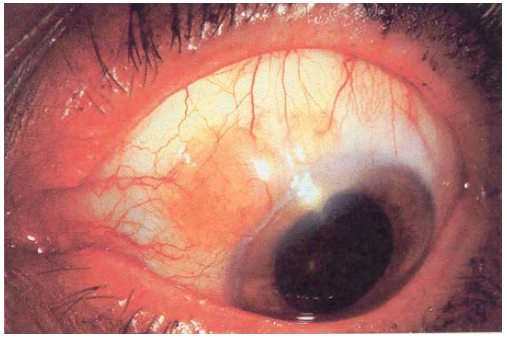
- 5th - 7th decade of life (median age, 65 years)
- female predominance (male:female = 1:1.5/2)
- Korean populations: younger age (median, 46 years) at the time of diagnosis, male rather than female predominance
- Site of origin:
  - orbit = 40%
  - conjunctiva = 35%-40%
  - lacrimal gland = 10%-15%
  - eyelid = 10%
- Bilateral involvement in 10% to 15% of cases (80% simultaneous, 20% sequential events)

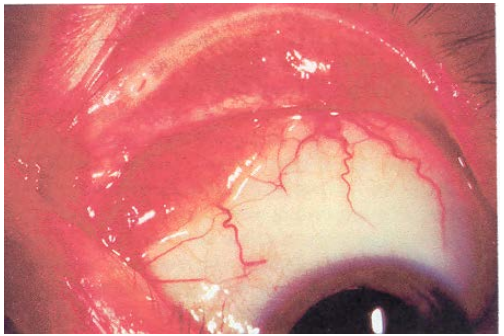
Clinical presentation

- Conjunctival lesions:
  mobile pink infiltrates in the substantia propria (“salmon-pink patch”), causing conjunctival swelling, redness, and irritation

- Orbital lymphoid proliferations:
  palpable, firm or rubbery mass causing progressive proptosis, occasionally associated with periorbital edema, decreased visual acuity, motility disturbances, and diplopia

- Median interval between the onset of symptoms and time of diagnosis:
  7 months





ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Pathology

- Expression of IgM (less often IgA or IgG)
- CD21+, CD35+, CD20+, CD79a+
- CD5-, CD10-, CD23-
- CD43+/-, CD11c+/- (weak).
- t(11;18)(q21;q21) in 15-40%
- t(14;18)(q32;q21) in >38%
- t(1;14)(p22;q34) in <5%
- t(3;14)(p14;q32) in 20%

Chlamidophila psittaci (Cp) infection

- **Cp** = etiologic agent of psittacosis, an infection caused by exposure to infected animals
- Cp infection is detected in tumor tissue in 11% of B-cell lymphomas
- In OAML Cp infection between 47% and 80% in countries like Austria, Germany, Italy and Korea

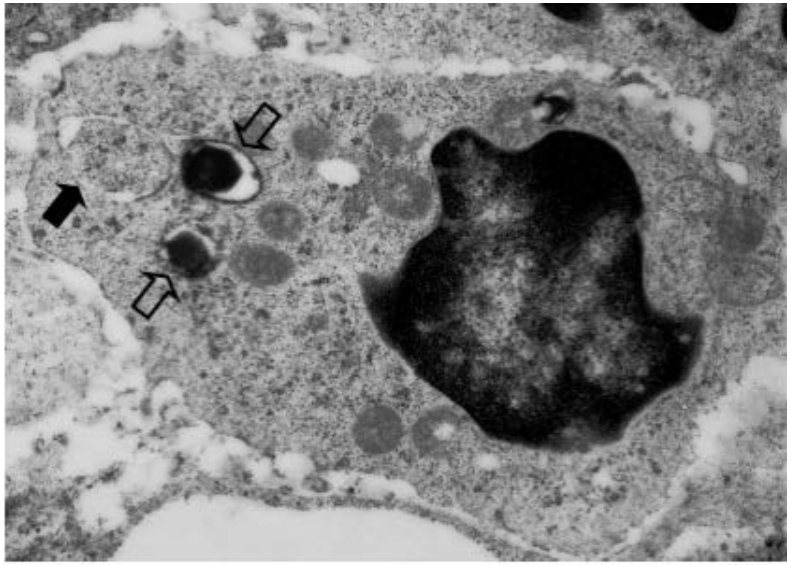


Fig. 2. Elementary bodies (CEB; open arrows) and reticulate body (CRB; full arrow) in an intratumor macrophage of a case of ocular adnexae MALT lymphoma assessed by electron microscopy. Chlamydial infection starts with attachment of a CEB to the host cell, followed by cell invasion. Within eukaryotic cells, chlamydia alternates from a metabolically inactive, highly infective form (*i.e.* the CEB), to a metabolically active, intracellular growing stage form (*i.e.* CRB). Under certain conditions, instead of dividing and differentiating into CEBs, CRBs retain a more stable association within the host cell forming the so-called persistent bodies, an important feature for better understanding the pathogenesis of chronic chlamydial infections.

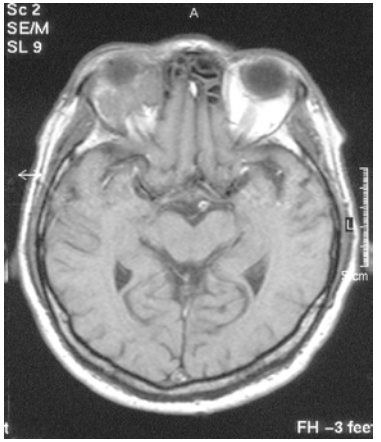
Ferreri et al, Sem Cancer, 2013

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Diagnosis and staging

- Careful ophthalmologic examination
- Adequate tissue sampling
- Complete history and physical examination
- Routine laboratory studies, serum protein electrophoresis, serum LDH, β2-microglobulin
- Chest x-ray
- CT of chest, abdomen, and pelvis
- CT-PET
- Bone marrow biopsy (controversial)
- Orbital CT and MRI with contrast enhancement

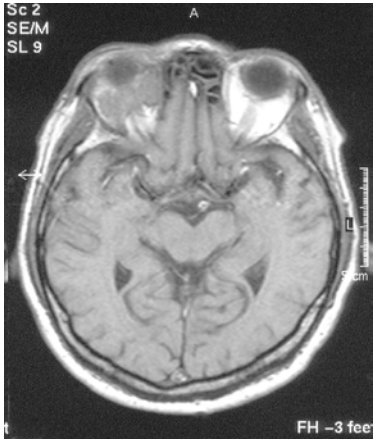


ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Diagnosis and staging

- Careful ophthalmologic examination:
  - To define the extent of conjunctival disease, which is often not fully appreciated on imaging
  - To assess ocular health before irradiation



ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Diagnosis and staging

- Ann Arbor system
- Localized disease (stage I) = 85%-90%
- Nodal involvement = 5%
- Disseminated disease (stage IV) = 10-15%
- Bone marrow involvement in = 5-8%

Treatment
Surgery

- Biopsy: mandatory to determine the histologic subtype of OAL
- Incisional or excisional
- Local relapse has been reported more commonly in patients treated with surgery alone compared with those who also received RT *(Cho et al. 2003; Esik et al. 1996; Lee et al. 2005)*

Treatment

Surgical excision / “Watch and wait”

- 36 patients
- Observation for a median of 7.1 years
- 17 progression (47%)
- 11 required treatment

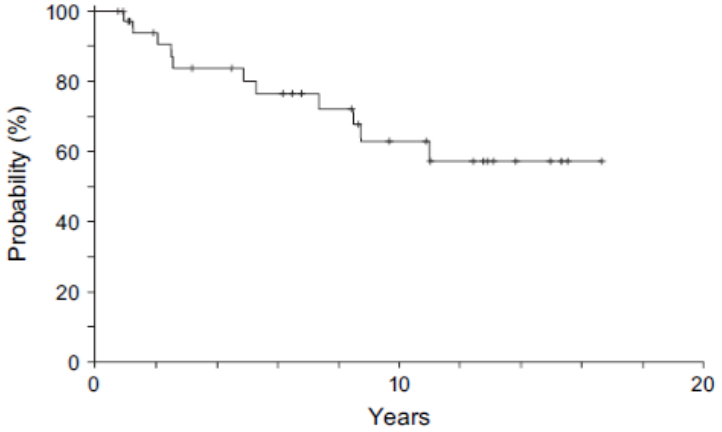


Figure 3. Freedom from requiring treatment. After 5, 10 and 15 years, freedom from requiring treatment was 80%, 63% and 57%, respectively.

This strategy may be appropriate in frail elderly patients with asymptomatic disease or in the setting of severe comorbidities that preclude an aggressive therapeutic approach

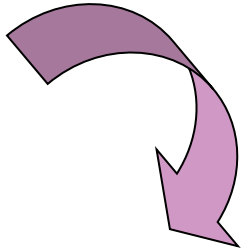
Tanimoto et al, Ann Oncol, 2006

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Treatment
Chemotherapy

- Limited data on chemotherapy for patients with OAML
- Different chemotherapy regimens:
  - COP/CVP
  - CHOP
  - C-MOPP
  - Chlorambucil (frail and/or elderly patients)



Complete response: 67-100%
BUT
Local recurrence: >29%

Treatment
Immunotherapy

- Single agent rituximab in previously untreated patients
  - overall response rates: 50-87%
  - median time to disease progression <1 year

Conconi et al. 2003; Ferreri et al. 2005; Benetatos et al. 2006; Heinz et al. 2007

- 90Y ibritumomab tiuxetan for front line treatment of stage IE indolent OAL in 12 patients:
  - complete response in 10 patients
  - partial response in 2 patients

Esmaeili et al. 2009; Shome and Esmaeili 2008

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Treatment
Cp-eradicating antibiotic therapy

- A prospective phase II clinical trial
- **27 patients** (15 newly diagnosed and 12 relapsed)
- Cp infection in 11 pts
- **Treatment:** doxycycline 100 mg orally twice daily for 3 weeks
- CR/PR in 7 of 11 Cp-positive and 6 of 16 Cp-negative patients
- ORR 48%
- 2-year FFS 66%

Ferreri et al, Ann Oncol, 2006

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Treatment

Cp-eradicating antibiotic therapy

- A meta-analysis including 4 studies with a total of 42 pts
- 20 patients achieved some response, 20 patients had stable disease and 2 progressed during antibiotic therapy

≤ 30	2/18 (11)	0.29	3/32 (9)	0.65
> 30	1/32 (3)	—	3/18 (17)	—

Uno et al, Cancer, 2003

Considerations on RT dose

- A dose of at least 25 Gy is required to provide optimal local control and minimize the rate of local failures in OAML
  (Uno et al. 2003; Ejima et al. 2006; Tsang et al. 2003)

- No differences in local or distal recurrence and survival after radiation with less than or equal to 34 Gy compared with higher doses
  (Le et al. 2002)

- Significant ophthalmologic toxicity with vision loss after doses of more than or equal to 34 Gy
  (Le et al. 2002)

Table III. Results of treatment with doses less than 30 Gy for localized orbital MZL lymphoma.

Author	Patients (orbits)	Dose (Gy)	Local failures	Local control	Technical factors for local failure
Stafford, 2001 [16]	29	15–55.8 (median 27)	0	100%

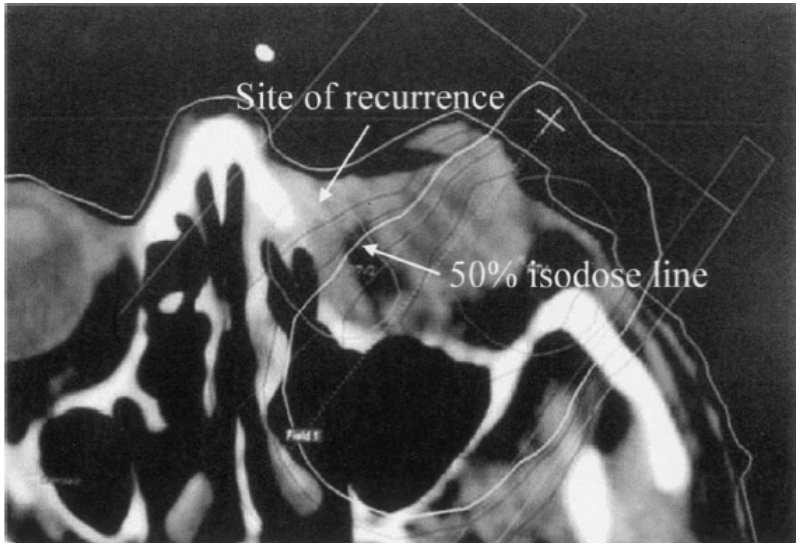
Low	8 (9 eyes)	10
Intermediate/high	3	2
Chemotherapy (n)	2	1
Stage (*n*)		
1E	9 (10 eyes)	11
IV	2	1
Dose (Gy)		
Low grade		
Range	20–30	20–27
Median	25.2	25.2
Intermediate/high grade		
Range	24–39.6	39.6–40
Median	39.6	

Pfeffer et al, IJROBP, 2004

- CR in all pts
- Intraorbital recurrence in previously uninvolved areas not included in the initial target volume: 4 pts (33%) with low-grade lymphoma treated with partial orbit RT



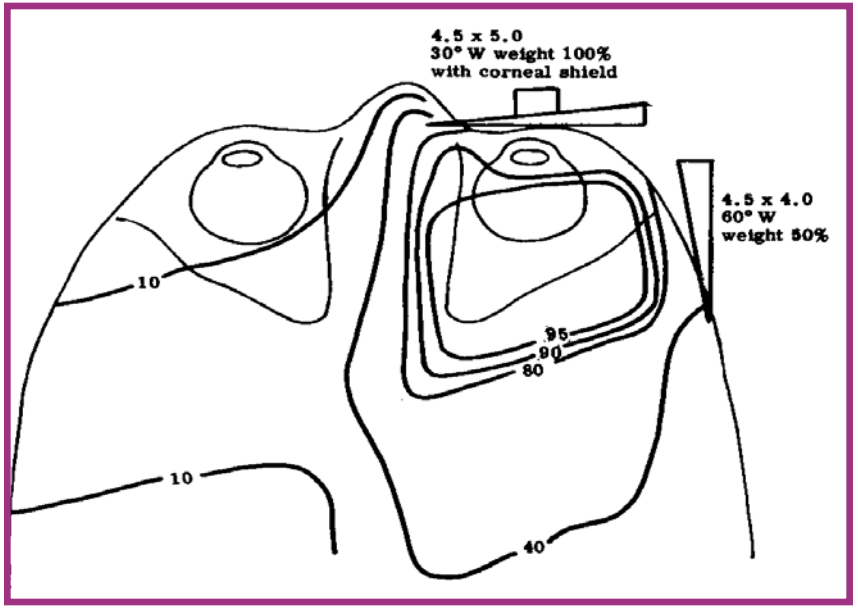
Partial orbital irradiation has been associated with higher risk of local failure

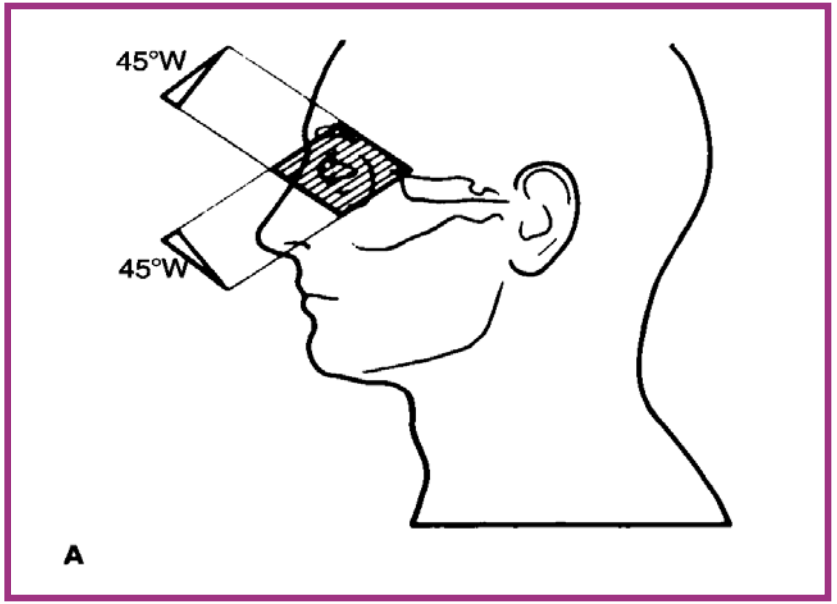
RT technique

- The whole orbit may be treated with 3D conformal or IMRT techniques
- The conjunctival sac and lacrimal gland may be treated with en face electrons
- Bolus should be used in all cases of conjunctival/superficial involvement or definite or suspected extension
- Lens shielding may be used for disease limited to conjunctiva/eyelid, if appropriate and only if there is confidence that disease will not be shielded

RT techniques (3D-CRT)

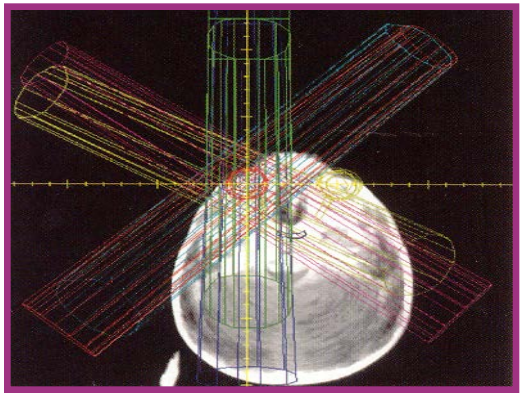
Whole orbit – wedge pair beams

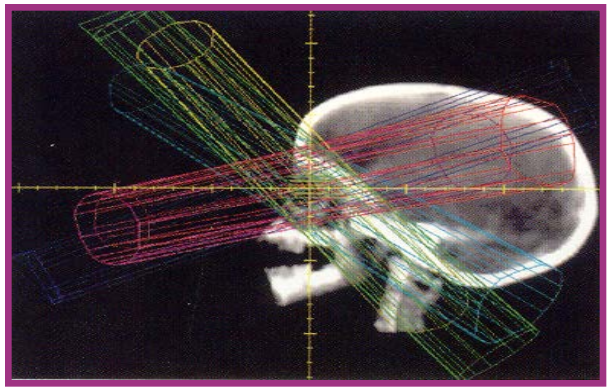


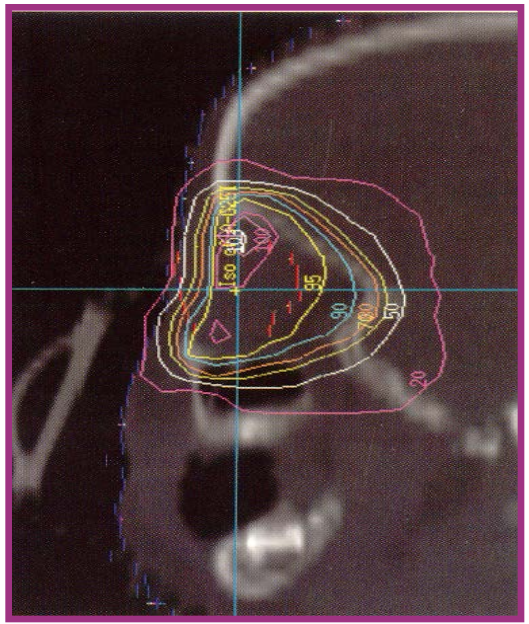


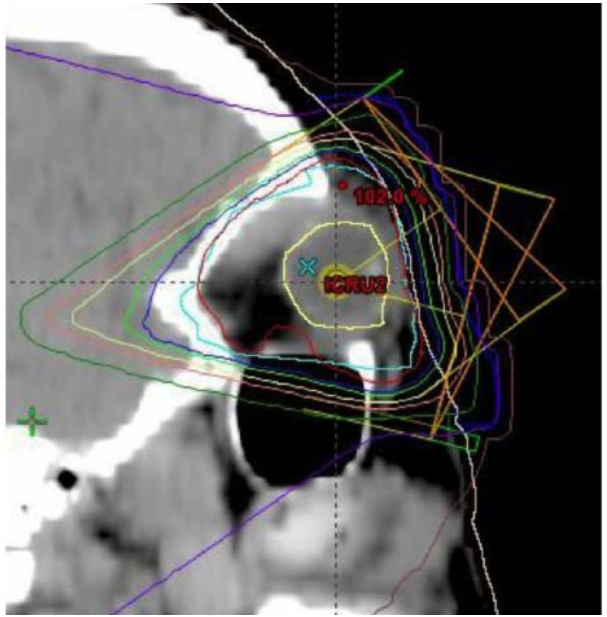
3D CRT

A technique such as a superior-inferior wedge pair has the advantage of sparing the controlateral orbit should metachronous controlateral disease require Rt subsequently





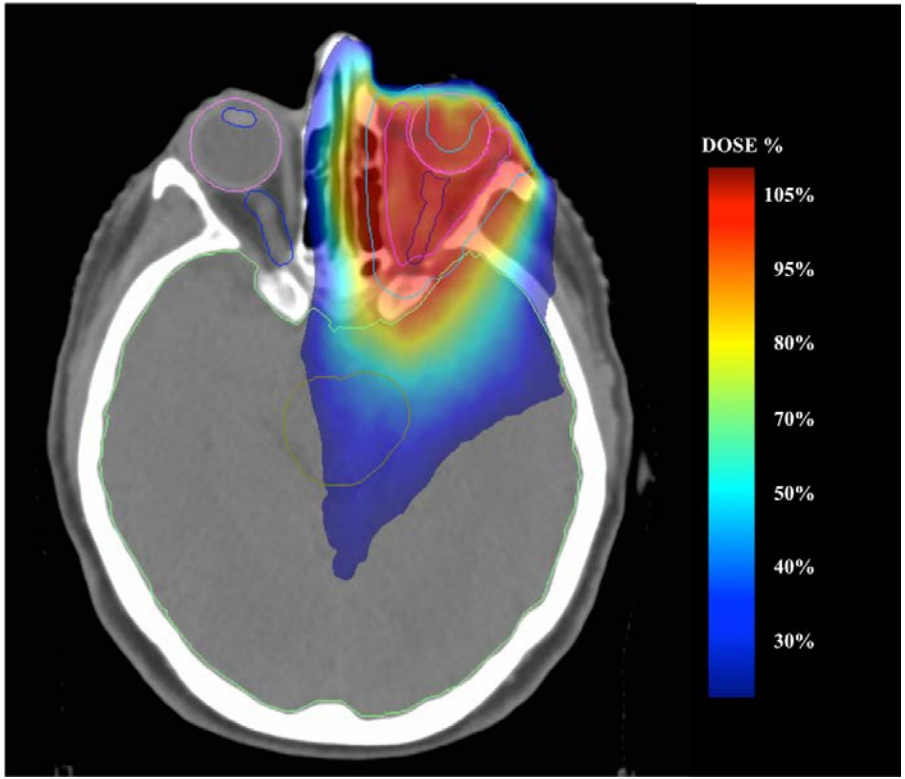




ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

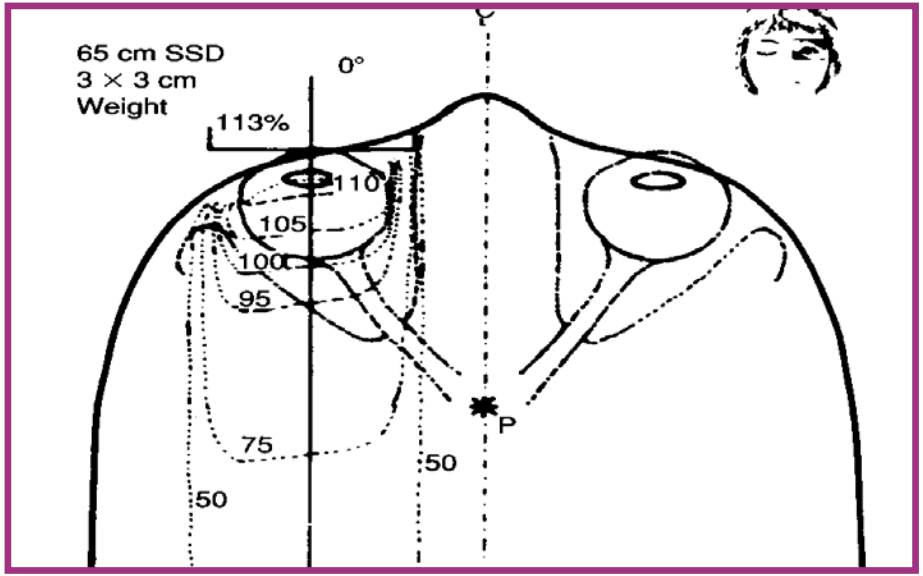
IMRT (VMAT)



Tumors confined to the conjunctiva or eyelid

CTV = entire conjunctival reflection to the fornices (not to include the entire orbit)

Partial anterior orbit – direct electron beam



- This situation is usually approached with a direct electron beam with bolus
- In selected cases, a lens shield may be used to reduce the risk of cataract formation
- Care must be taken not to shield parts of the conjunctiva because the whole conjunctival sac is the CTV

Lens shielding

- Aim: to reduce the incidence of cataract
- Caution: inadvertent tumor under dosing
- Some reports attributed local relapses to inadvertent partial shielding of tumor *(Uno et al. 2003; Fung et al. 2003)*
- Other reports suggest that the careful use doesn't lead to treatment failure *(Le et al. 2002; Martinet et al. 2003; Son et al. 2010; Tran et al. 2013)*
- ILROG guidelines: lens shielding may be used for disease limited to conjuctiva/eyelid, if appropriate and only if disease will not be shielded

Bolus

- Aim: to ensure that conjunctival tumors or other very superficially located lesions receive the full dose of radiation
- In most reports, local failure in superficial disease sites occurred with no mention of the use of bolus *(Uno et al. 2003; Yamashita et al. 2008; Son et al. 2010)*
- In another report bolus was not used routinely unless there was frank skin involvement, without an apparent increase in relapse rate *(Goda et al. 2011)*
- ILROG guidelines: bolus should be used in all cases of conjunctival/superficial involvement or definite or suspected extension

Modern Radiation Therapy for Extranodal Lymphomas: Field and Dose Guidelines From the International Lymphoma Radiation Oncology Group

Volumes: indolent disease

- CTV: for most cases of indolent NHL, the entire bony orbit including definite or suspected extraorbital extensions. When disease is limited to the conjunctiva, the CTV includes the entire conjunctival sac and local extensions to eyelid.
- PTV margin is normally 5 mm.

Dose: indolent disease

Dose: 24 to 25 Gy in 1.5- to 2-Gy fractions.

Yahalom et al, IJROBP, 2015

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Ocular adnexae DLBCL

Role of RT

- Consolidation RT after R-chemotherapy

- Radical RT in patients “unfit” for chemotherapy

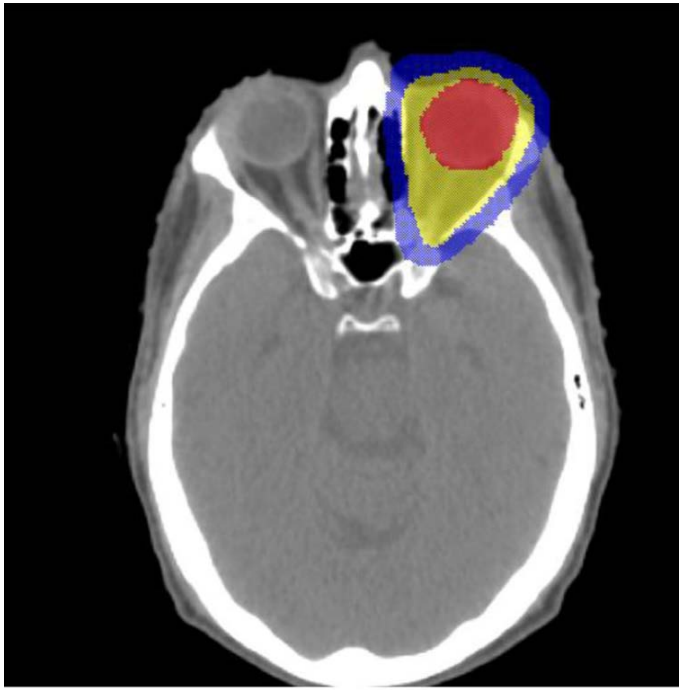
Considerations on RT volume

• **GTV** = residual disease after chemotherapy (if any) for a boost dose

• **CTV** = entire orbit

• **PTV** margin = normally 5 mm

• DLBCL of the lacrimal gland alone
→ CTV for consolidation RT limited to lacrimal gland



Yahalom et al, IJROBP, 2015

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Considerations on RT dose

- CR after chemotherapy → 30 Gy

- PR after chemotherapy
- Relapse
- RT alone (pts “unfit” for chemo)

→ 30 – 36 Gy to whole orbit and extensions

→ 40 – 45 Gy to residual GTV (depending on the volume and proximity to critical structures)

Yahalom et al, IJROBP, 2015

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Toxicity

- Immediate toxicity consists of mild to moderate cutaneous or conjunctival reactions
- Long-term complications are observed in up to 50% of patients
- The complications are relatively minor and include cataract formation (30-50%) and mild xerophthalmia (20-40%)
- RT doses above 36 Gy may result in deleterious ophthalmologic toxicity such as ischemic retinopathy, optic atrophy, corneal ulceration, neovascular glaucoma, associated with significant vision loss

RT of Gastric Lymphomas

- Marginal Zone Lymphoma (MZL) – Most common
  - RT is the standard treatment in North America for "H. Pylori-independent" Gastric MZL (or "MALT")
  - H. pylori -not present
  - H. pylori responded to antibiotics, but MZL persists for a long time
  - H. pylori resistant to multiple antibiotics, MZL persists
  - Failure of antibiotics - MZL progression
  - Failure of antibiotics - difficult symptoms
- Diffuse Large B-Cell Lymphoma (many are transformed MZL)
  - RT consolidation after R-CHOP induced CR

Principles of RT of Stomach

Memorial Sloan Kettering Cancer Center

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Principles of Gastric Lymphoma RT (1)

- For both MZL and DLBCL – The whole stomach constitutes the Clinical Target Volume (CTV)
- The duodenum is included is it was involved with the stomach
- Peri-gastric and adjacent lymph nodes are included only if suspicious by any imaging including endoscopic ultrasound

Memorial Sloan Kettering Cancer Center

ILROG International Lymphoma Radiation Oncology Group

ESTRO School

Principles of Gastric Lymphoma RT (2)

- The final volume also accounts for changes in stomach position during respiration
- The stomach is ideally treated while empty; but slight changes in volume should be accounted for
- The dose rarely exceeds 30 Gy; thus, acute or chronic complications are unlikely.
- Yet, RT exposure of kidneys, heart, lung and liver and bowl should be reduced as much as possible

Memorial Sloan Kettering Cancer Center

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

RT of Stomach: Pre Planning Studies

- Details of endoscopic studies
- Endoscopic ultrasound and directed biopsy in case of thickened wall/suspected transformation
- In patients that may receive RT to large volume of one kidney, renal scan may provide important information

RT of Stomach: simulation

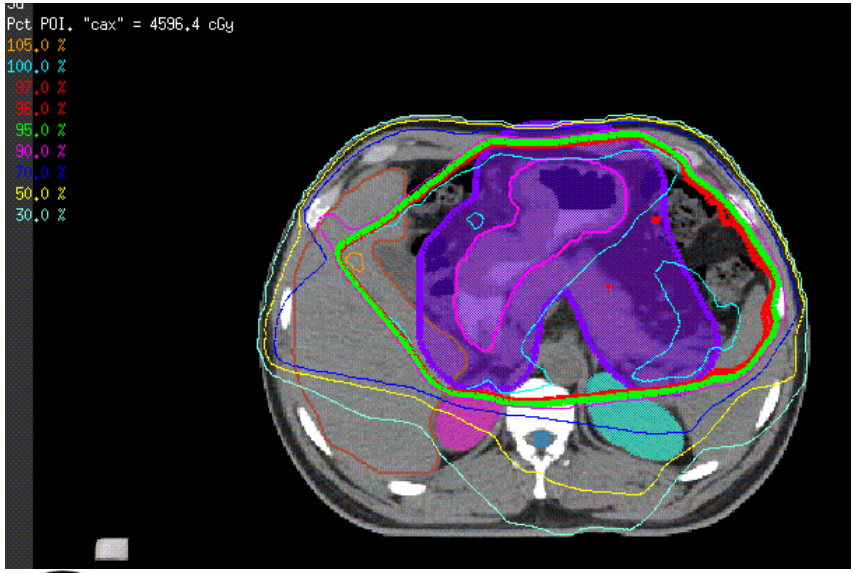
- The stomach volume and position is affected by ingestion of food or liquids. Patients are always simulated and treated with an empty stomach after at least 4 hours/overnight fast.
- Simulate the patient supine with arms up using customized immobilization device.
- A small volume (<50ml) of oral contrast (barium sulfate) should be used in all cases; IV contrast is recommended, if there are suspicious lymph nodes.
- Respiratory motion should be assessed using a 4D-CT scan or fluoroscopy

RT of Stomach: volumes

- **GTV:** Gross disease (if visualized on PET and/or CT) and pathologically enlarged lymph nodes
- **CTV**: GTV + stomach volume outlined from gastroesophageal junction to beyond the duodenal bulb; the whole wall is included (perigastric nodes are encompassed, if visible).
- **ITV** is determined by 4-D CT or by fluoroscopy to track variation of stomach position during respiration. An additional margin of at least 1-2 cm may be added to the CTV to accommodate stomach movement or internal volume changes.
- **PTV** is influenced by set-up variation; in the abdomen 1 cm over final ITV is advised.
- **OAR** volumes for consideration in planning include: kidneys, liver, heart. lungs, bowel, cord.

Treatment Planning

3D-CRT



IMRT

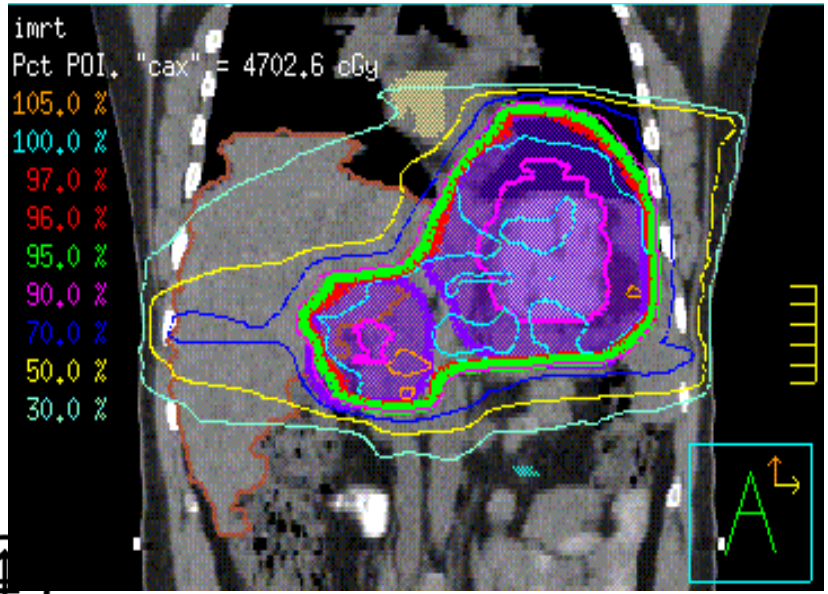
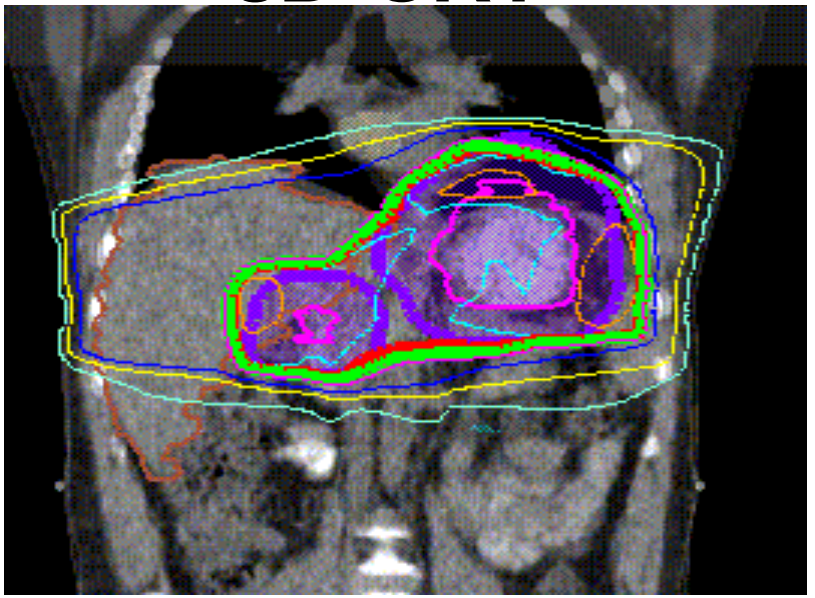
3D-CRT vs. IMRT

IMRT



3D-CRT



Memorial Sloan Kettering Cancer Center

ILROG International Lymphoma Radiation Oncology Group

ESTRO School

Treatment Planning Goals

Conformal therapy is optimal

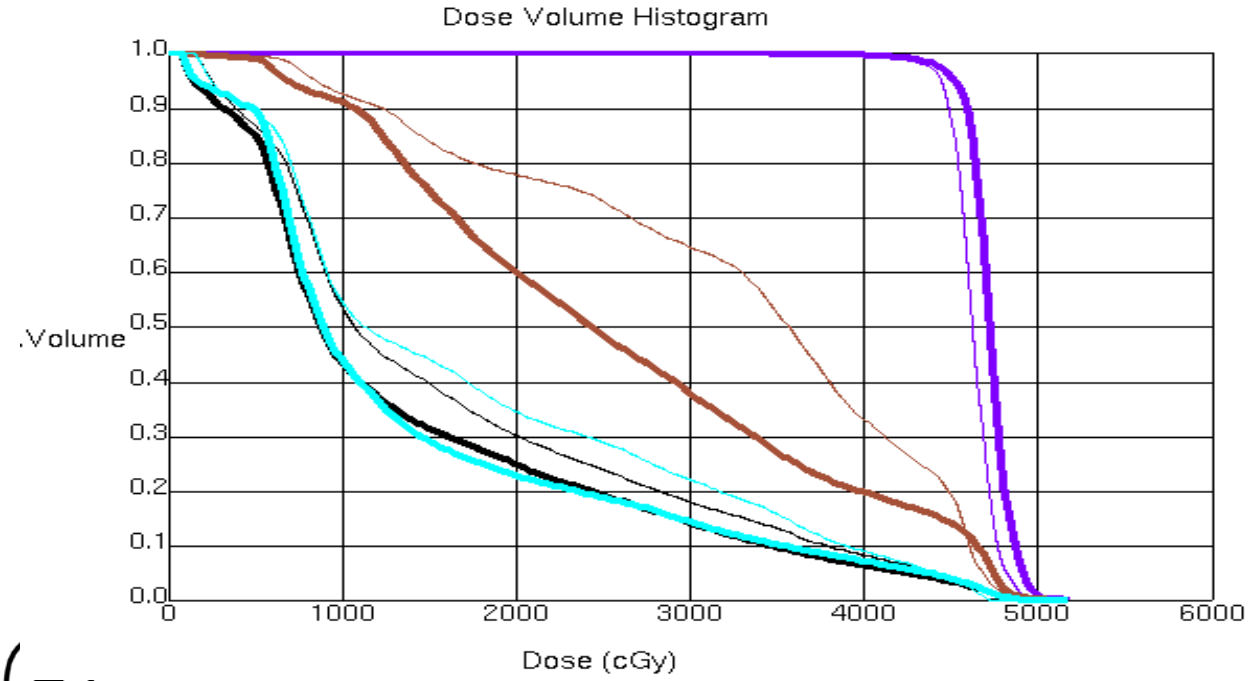
- Della-Bianca et al. compared AP/PA vs. 3D-CRT vs. IMRT
- Advantage to conformal therapy when PTV was in close proximity or overlapped with kidney
- IMRT led to further decrease in left kidney and liver dose

Potential advantages in some cases to IMRT over 3D-CRT
Goal of homogeneous dose delivery (D95 >95%)
Doses to normal structures as low as reasonably achievable (ALARA)

Sparing of kidney and liver

- Kidney dose: limited to <20 Gy to 2/3 of kidney
- Liver dose: Mean dose < 30 Gy

DVH: 3D-CRT vs. IMRT



--- Both Kidneys

--- Left Kidney

--- Liver

--- PTV

Conclusions

- Recommend use of modern radiation techniques
- Target volume of stomach and perigastric nodes in gastric lymphoma
- Margin incorporating 4D CT scan for respiration motion assessment
- Radiation dose of : 30 Gy in 15-20 fractions for Gastric MALT and response-based for DLBCL
- Conformal radiation delivery techniques

Extranodal lymphomas: Skin

Lena Specht MD DMSc
Professor of Oncology, University of Copenhagen, Denmark
Chief Oncologist, Depts. of Oncology and Haematology, Rigshospitalet, Copenhagen
Vice-chairman, International Lymphoma Radiation Oncology Group

Primary cutaneous lymphomas

- Heterogenous group of T- and B-cell lymphomas
- Natural history often more indolent than nodal lymphomas of same histologic subtype
- Solitary or localised skin lesions treated with involved field radiotherapy, long term local control rate generally 80-100 %

(Willemze et al, Blood 1997;90:354-71)

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

European Organization for Research and Treatment of Cancer and International Society for Cutaneous Lymphoma consensus recommendations for the management of cutaneous B-cell lymphomas

Nancy J. Senff,[1] Evert M. Noordijk,[2] Youn H. Kim,[3] Martine Bagot,[4] Emilio Berti,[5] Lorenzo Cerroni,[6] Reinhard Dummer,[7] Madeleine Duvic,[8] Richard T. Hoppe,[9] Nicola Pimpinelli,[10] Steven T. Rosen,[11] Maarten H. Vermeer,[1] Sean Whittaker,[12] and Rein Willemze[1]

(Blood. 2008;112:1600-1609)

Table 1. Overview of previously and currently used classification systems for cutaneous lymphomas and clinicopathologic features of the different CBCL entities

	Previous and current classifications		
EORTC 1997	PCI/ PCMZL	PCFCCL	PCLBCL of the leg
WHO 2001	EMZL	cFCL	DLBCL
		DLBCL	
WHO-EORTC 2005	PCMZL	PCFCL	PCLBCL, LT
WHO 2008	EMZL	PCFCL	PCLBCL, LT
Clinicopathologic features			
Clinical features	Solitary or multiple papules, plaques, or nodules preferentially localized on the extremities	Solitary or grouped tumors presenting on the head or on the trunk	Solitary or multiple tumors presenting mainly on the leg(s) and rarely at other sites
	Sometimes associated with Borrelia burgdorferi infection	Cutaneous relapses in 20%	Frequent relapses and extracutaneous dissemination
	Frequent cutaneous relapses	Extracutaneous dissemination in 5% to 10%	
	Rarely extracutaneous dissemination		
Histopathology	Patchy or diffuse infiltrates composed of small B cells, including marginal zone (centrocyte-like) cells, lymphoplasmacytoid cells, and plasma cells	Follicular, follicular and diffuse, or diffuse infiltrates composed of neoplastic follicle center cells , usually a mixture of centrocytes and variable numbers of centroblasts	Diffuse infiltrates with a predominance or confluent sheets of of centroblasts and immunoblasts
Immunophenotype	Monotypic cIg, CD79a$^+$, Bcl-2$^+$, CD5$^-$, cyclin D1$^-$, Bcl-6$^-$, CD10$^-$, MUM-1$^+$ (on plasma cells)	Monotypic sIg or absence of sIg, CD20$^+$, CD79a$^+$, Bcl-6$^+$, Bcl-2$^-$, MUM-1$^-$, CD10±, FOXP1$^{-(\pm)}$	Monotypic sIg and/or cIg, CD20$^+$, CD79a$^+$, Bcl-6$^{+(-)}$, CD10$^-$, Bcl-2$^+$, MUM-1$^+$, FOXP1$^+$
Prognosis	5-year survival: > 95%	5-year survival: 95%	5-year survival: 50%

PCI indicates primary cutaneous immunocytoma; PCMZL, primary cutaneous marginal zone lymphoma; PCFCCL, primary cutaneous follicle center cell lymphoma; PCLBCL of the leg, primary cutaneous large B-cell lymphoma of the leg; EMZL, extranodal marginal zone lymphoma; cFCL, cutaneous follicle center lymphoma (for cases with a follicular or follicular-diffuse growth pattern); DLBCL, diffuse large B-cell lymphoma (for cases with a diffuse growth pattern); PCFCL, primary cutaneous follicle center lymphoma; and PCLBCL, LT, primary cutaneous diffuse large B-cell lymphoma, leg type.

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Table 4. Recommendations for initial management of the 3 main types of CBCL

Disease type and extent	First-line therapy	Alternative therapies
PCMZL		
Solitary/localized	Local radiotherapy Excision Antibiotics*	IFN-α i.l. Rituximab i.l. i.l. steroids
Multifocal	Wait-and-see Local radiotherapy Chlorambucil† Rituximab i.v. Antibiotics*	IFN-α i.l. Rituximab i.l. Topical or i.l. steroids
PCFCL		
Solitary/localized	Local radiotherapy Excision	IFN-α i.l. Rituximab i.l.
Multifocal	Wait-and-see Local radiotherapy Rituximab i.v.	R-CVP/CHOP‡
PCLBCL, LT		
Solitary/localized	R-CHOP ± IFRT	Local radiotherapy Rituximab i.v.
Multifocal	R-CHOP	Rituximab i.v.

IFRT indicates involved field radiotherapy; i.l., intralesional; and i.v., intravenous.
*In case of evidence for *B burgdorferi* infection.
†Or other single or combination regimens appropriate for low-grade B-cell lymphomas.
‡In exceptional cases or for patients developing extracutaneous disease.

ESTRO School

Primary Cutaneous CD30+ neoplasms (lymphomatoid papulosis, ALCL)

- LyP: Chronic, recurrent, self-healing
- In up to 20 % associated with other types of lymphoma

- C-ALCL: 80 % present with solitary or localized nodules
- Local radiotherapy, dose 24-30 Gy

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Localized skin lymphomas: ISRT

- Margin beyond clinically evident erythema/ induration 1-2 cm
- Thickness of lesion must be determined to ensure adequate coverage in depth
- Most lesions can be treated with electrons
- Bolus is required to avoid skin sparing
- Low energy X-rays (100 kV) may sometimes be used
- For deep, bulky or circumferential lesions photons may be needed

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Mycosis fungoides

- Most common cutaneous T-cell lymphoma
- 4 % of all lymphomas, 50 % of all cutaneous lymphomas
- Indolent clinical course
- Limited to the skin for many years
- Patches → Plaques → Tumors
- Skin directed therapies unless extracutaneous

Extranodal lymphomas: Characteristics, the role of radiotherapy, volumes doses and techniques:

Testicular lymphoma

Berthe Aleman

Radiation oncologist

NETHERLANDS CANCER INSTITUTE
ANTONI VAN LEEUWENHOEK

ILROG
INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Testicular lymphoma

General

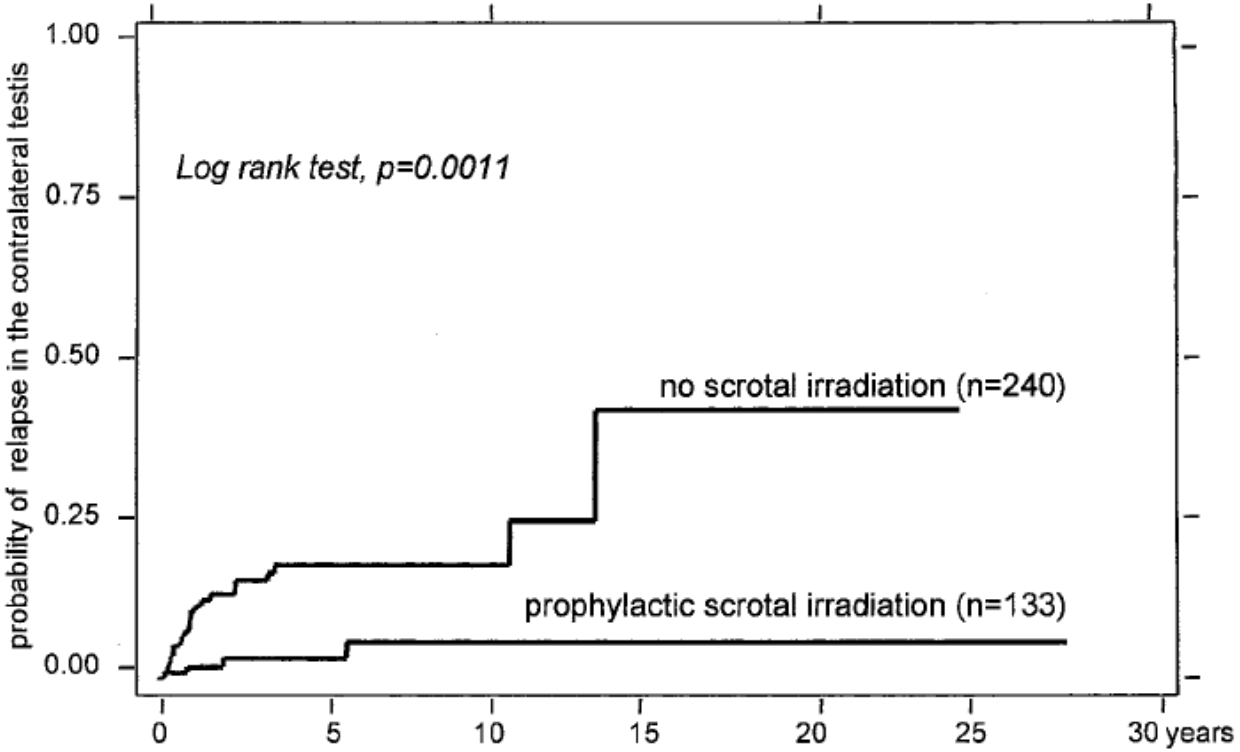
- Primary testicular lymphoma (PTL) is an uncommon and aggressive form of extranodal non-Hodgkin lymphoma (NHL)
- Annual incidence at 0.09 to 0.26 per 100 000 population
- 0,5% of testicular malignancies and 1-2% of all NHL cases
- Median age at diagnosis: 66 - 68 years

Testicular lymphoma

General (continued)

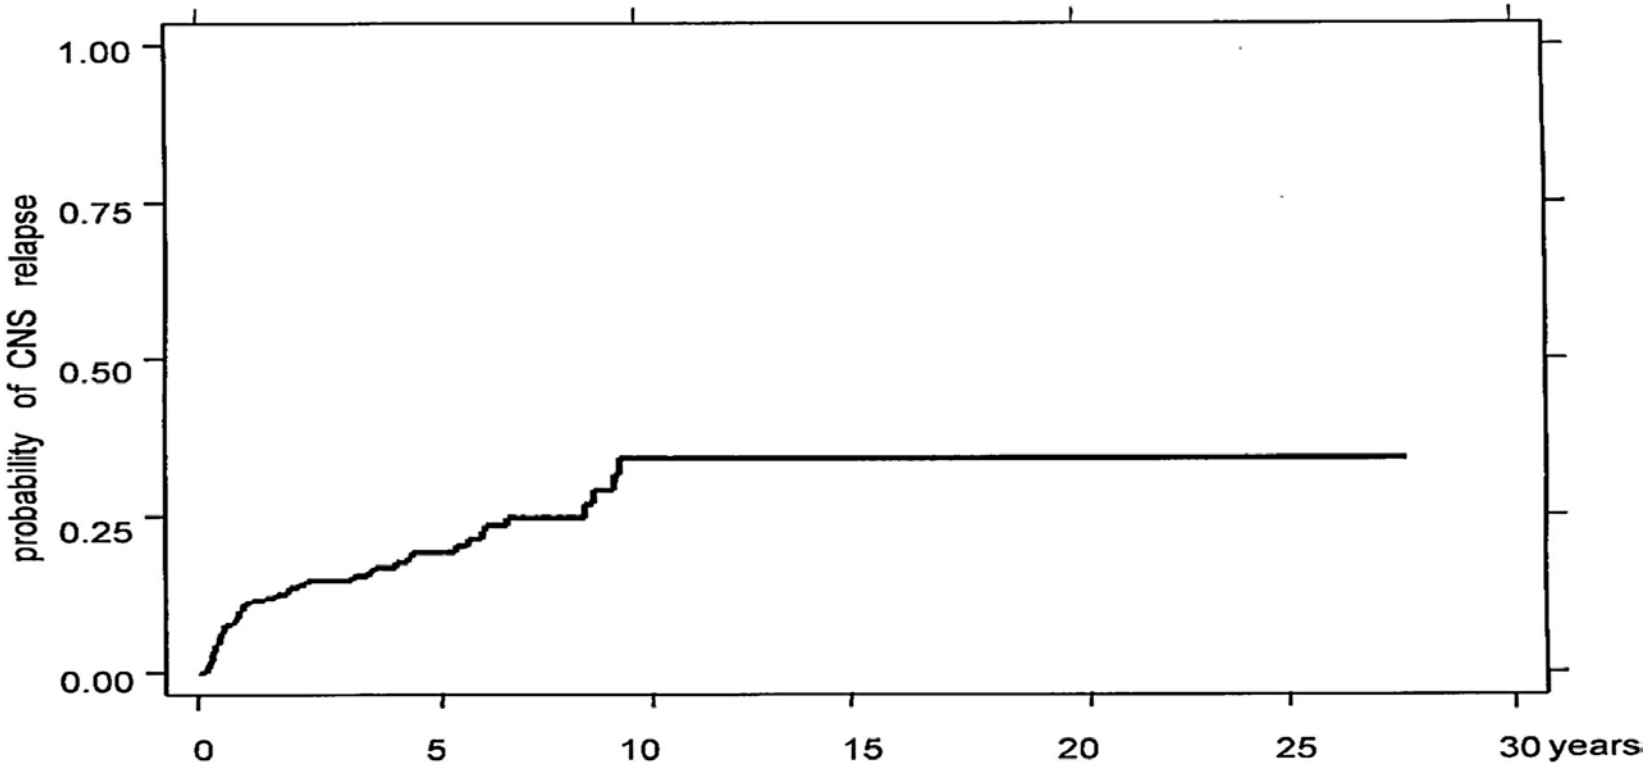
- PTL is both the most common testicular malignancy in men age >60 years and the most common bilateral testicular neoplasm.
- 20-30% present with systemic disease
- Common histology: DLBCL
- Sanctuary sites:
  - Contralateral testicle
  - Central nervous system

Risk of recurrence in contralateral testis



Zucca et al, JCO 2003

Time to CNS recurrence in the IELSG retrospective study, demonstrating ongoing risk of late CNS relapses.



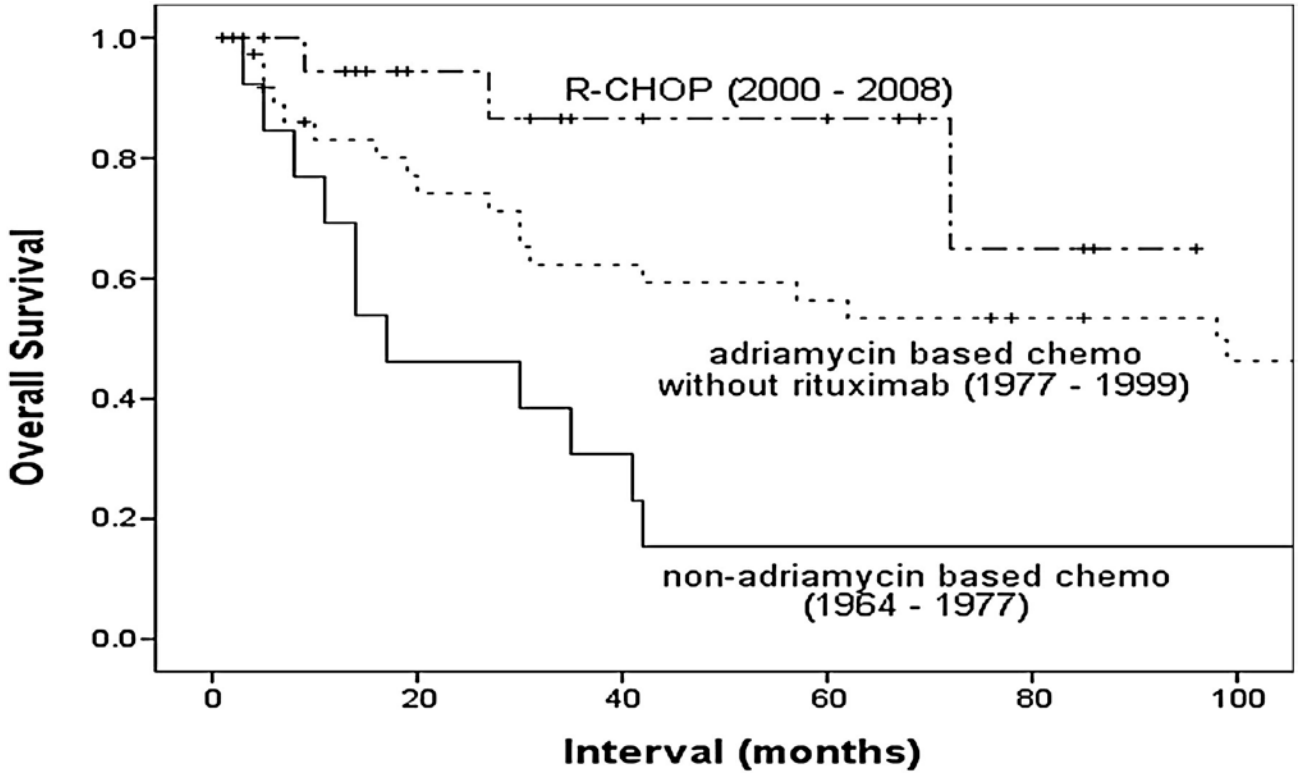
Chan Y. Cheah et al. Blood 2014;123:486-493

Prognostic factors for PFS in PTL

Adverse prognostic factors for PFS in studies of PTL
Age >70 y
Advanced stage
B symptoms
ECOG performance status >1
>1 extranodal site
Involvement of extranodal sites other than testis
Tumor diameter >10 cm
Raised serum LDH
Raised serum β_2-microglobulin
Hypoalbuminemia
Involvement of the left testis

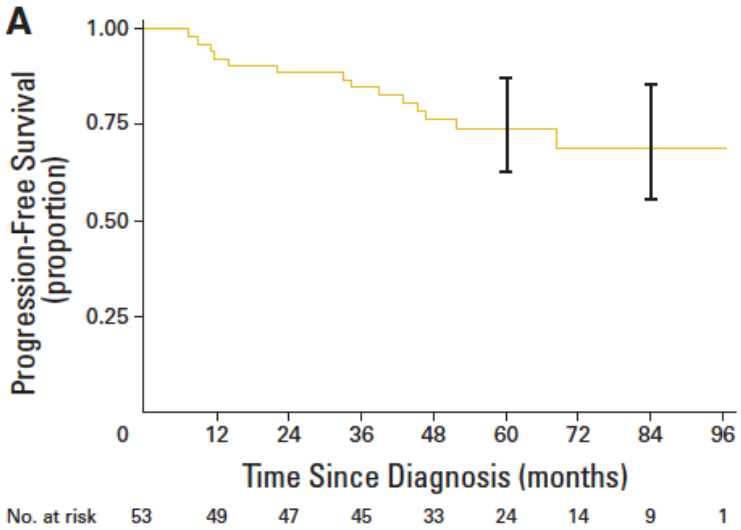
Chan Y. Cheah et al. Blood 2014;123:486-493

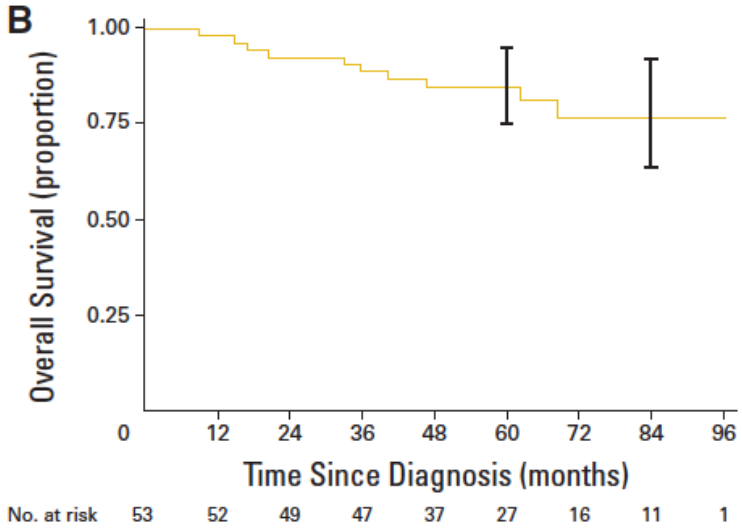
OS of patients with PTL treated at MDACC, by chemotherapy strategy



Chan Y. Cheah et al. Blood 2014;123:486-493

First-Line Treatment for Primary Testicular DLBCL With R-CHOP, CNS Prophylaxis, and Contralateral Testis RT: an International Phase II Trial (n=53, stage I-II)





No testicular relapses following 30 Gy

Vitolo et al, JCO 2011

Testicular lymphoma

Treatment

- R-CHOP (or more aggressive regimens)
- Intrathecal or intravenous methotrexate
- RT is given to the involved testis (if not resected) and to the remaining testis and scrotum
- RT may be given to involved abdominopelvic nodes in stage IIE disease.

Yahalom et al. ILROG guideline, IJROBP 2015

Testicular lymphoma
Prophylactic RT contralateral testicle

Volume

- An anterior electron field with energy calculated according the thickness of the scrotum/testis is set; bolus may be required.

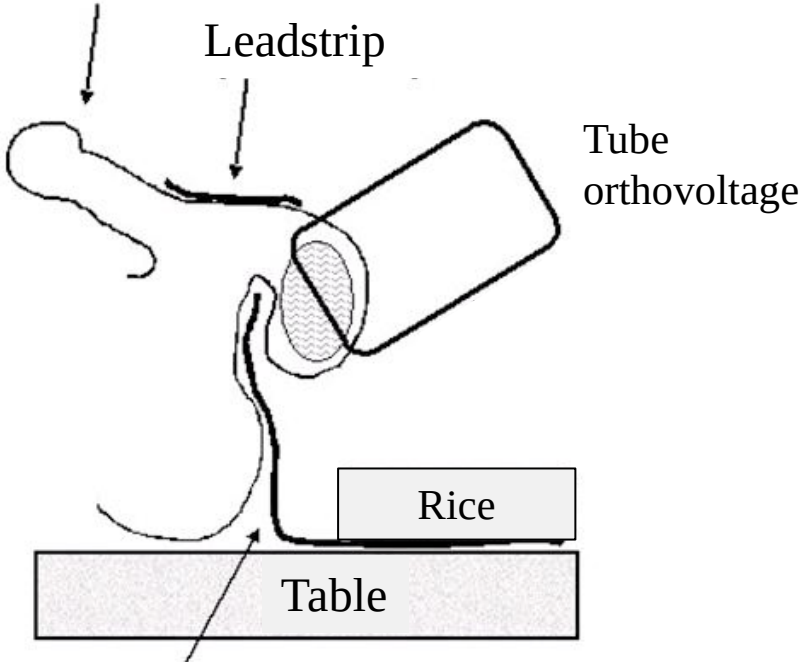
Yahalom et al. ILROG guideline, IJROBP 2015

Setup radiotherapy testicle

With the patient supine in a frog-leg position, the penis is lifted and taped to the abdominal wall, and the scrotum is supported and immobilized with bolus under and around the scrotum.

Yahalom et al. ILROG guideline, IJROBP 2015

Penis taped to the abdominal wall



Leadstrip on perineum and anus

NETHERLANDS CANCER INSTITUTE
ANTONI VAN LEEUWENHOEK

Testicular lymphoma

Dose

- Dose to testis: 25 to 30 Gy in 1.5 to 2 Gy per fraction

Yahalom et al. ILROG guideline, IJROBP 2015

Testicular lymphoma

Questions:

- Is 25-30 Gy safe?
- Could we use a lower dose ? 18 Gy? 20 Gy?
- Could surgery be an alternative?

- What to do during follow up?
  - Lab? Testosterone?

S + RT + CT	42	21
Any surgery	100	49
Any RT	130	64
Any CT	164	80

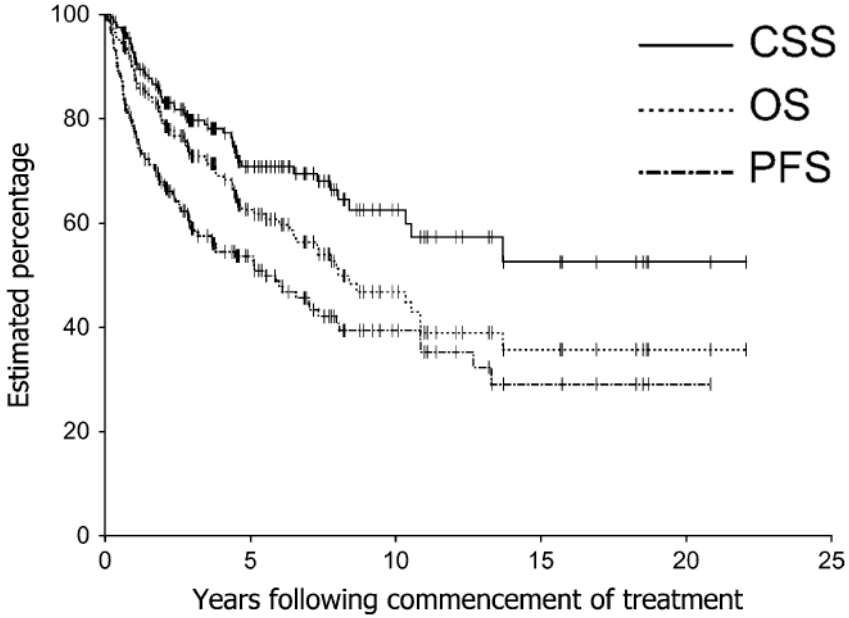
Initially involved breast only: 50%
Initially involved breast + regional lymph nodes: 35%

Median RT dose: 40 Gy
Range RT dose: 4-60 Gy

Ryan et al, Ann Oncol 2008

Primary diffuse large B-cell lymphoma of the breast: a study by the International Extranodal Lymphoma Study Group;

cause specific survival, overall survival and progression free survival



Number at risk

CSS	204	68	25	9	2	0
OS	204	68	25	9	2	0
PFS	204	58	20	6	1	0

Median CSS: not reached

Median OS: 8.0 years

Median PFS: 5.5 years

Ryan et al, Ann Oncol 2008

Primary diffuse large B-cell lymphoma of the breast: a study by the International Extranodal Lymphoma Study Group

Results:

- MFA: favourable International Prognostic Index score, anthracycline-containing chemotherapy, and radiotherapy (RT) were significantly associated with longer OS (each $P \leq 0.03$).
- There was no benefit from mastectomy, as opposed to biopsy or lumpectomy only.
- At a median follow-up time of 5.5 years, 37% of patients had progressed—16% in the same or contralateral breast, 5% in the central nervous system, and 14% in other extranodal sites.

Ryan et al, Ann Oncol 2008

Primary diffuse large B-cell lymphoma of the breast: a study by the International Extranodal Lymphoma Study Group

Conclusions:

- Limited surgery+anthracycline-containing CT +IFRT: best outcome in the pre-rituximab era
- Prospective study needed

Lung Lymphoma

Umberto Ricardi
University of Torino
Department of Oncology

Background

- Primary pulmonary lymphoma is a very rare neoplasm, representing only 2-4% of extranodal non-Hodgkin lymphoma and only 0.4% of all malignant lymphomas

- Most cases are represented by MZL

- Primary pulmonary lymphoma is defined as a clonal lymphoma proliferation affecting one or both lungs in a patient with no detectable extrapulmonary involvement at diagnosis or during the subsequent 3 months

Background

- MZL (bronchial associated lymphoid tissue lymphoma [BALT lymphoma]) may involve any element of the bronchial tree, often as an isolated lesion

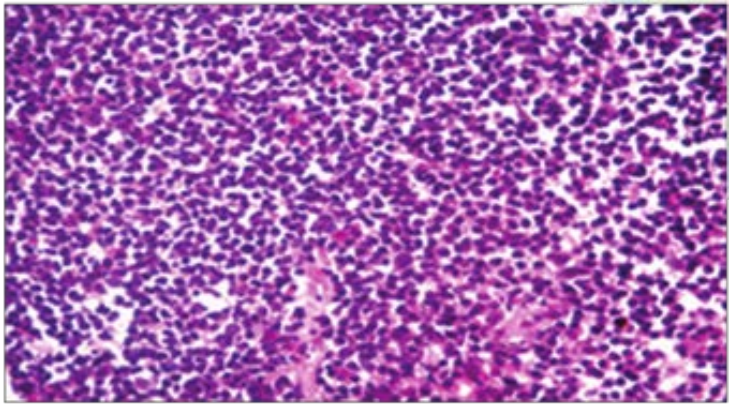
- Surgery as first treatment: pulmonary lesion as a potential lung cancer

Histology

- BALT lymphoma 80-90%
- DLBCL 10%

- Most common immunohistochemical features:

  - CD 20+
  - CD19+
  - CD22+
  - CD10-
  - CD5-
  - Bcl2+



Cytogenetics

- t(11;18)(q21;q21) is documented in 30-40% of BALT lymphoma
- The fusion product , cIAP2-MALT1, may concomitantly contribute to lymphomagenesis both as a tumor suppressor gene and as an oncogene

Bertoni et al. J Clin Invest 2006;116(1): 22-26

- The role of chronic infections, toxic exposure, or underlying autoimmune diseases in BALT lymphoma is unknown

- Achromobacter (Alcaligenes) xylosoxidans, a Gram negative bacterium with low virulence but with high resistance treatment, has been recently detected

- Whether this finding indicates a potential etiopathogenetic role of this bacterium in BALT lymphoma will however require further studies

Clinical presentation

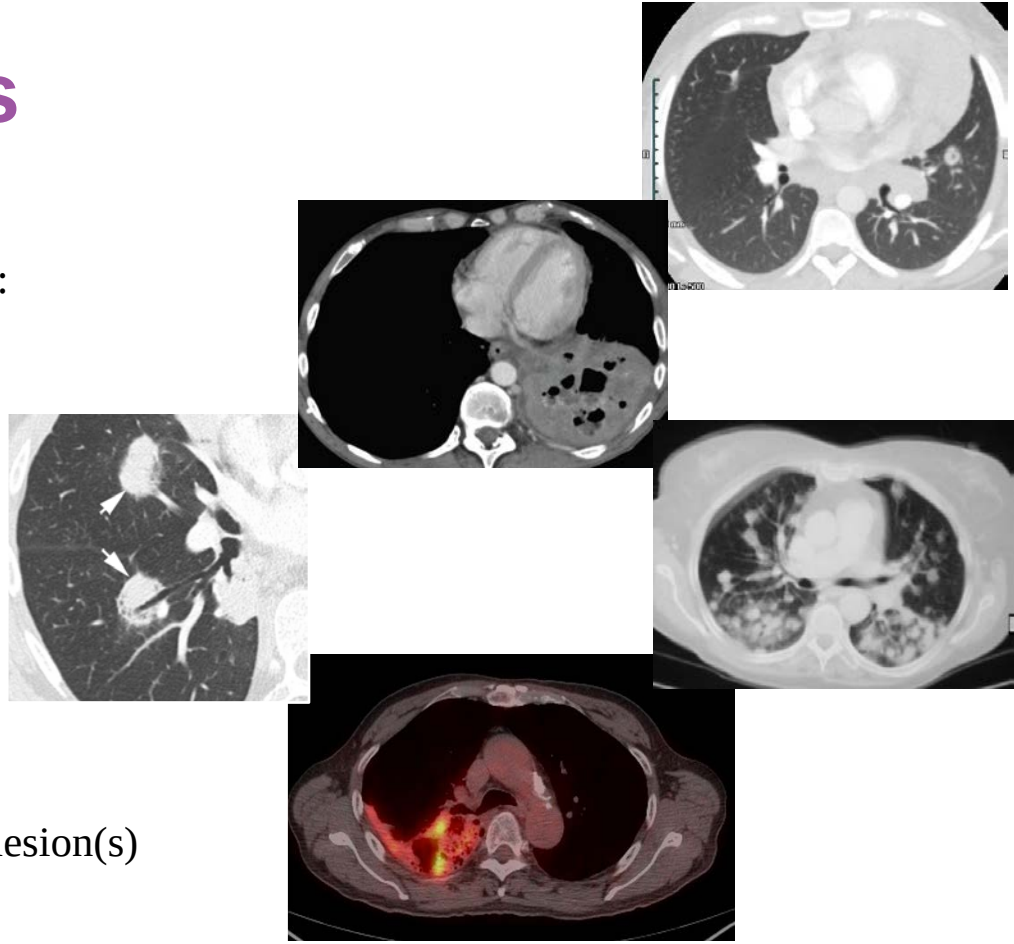
- Most patients (90%) are asymptomatic at diagnosis and disease is incidentally discovered

- When present, symptoms are unspecific, such as:
  - Cough
  - Mild dyspnea
  - Chest pain
  - Hemoptysis

- B symptoms are uncommon

Diagnosis

- Radiologic findings are nonspecific and include:
  - Solitary nodule
  - Multiple ill-defined nodules
  - Mass with air bronchograms
  - Pleural effusion
  - Atelectasis
  - Cavities



- FDG-PET usually reports a mild uptake of the lesion(s)

Staging

Ann Arbor system modified by Ferraro

Stage	Description
I E	Unilateral or bilateral presentation of the lung
II 1E	Lung presentation with hilar lymph node involvement
II 2E	Lung presentation with mediastinal lymph node involvement
II 2EW	Lung presentation with chest wall or diaphragm involvement
III E	Lung presentation with abdominal lymph node involvement
IV E	Lung presentation with extra-lymphatic organs or tissue involvement

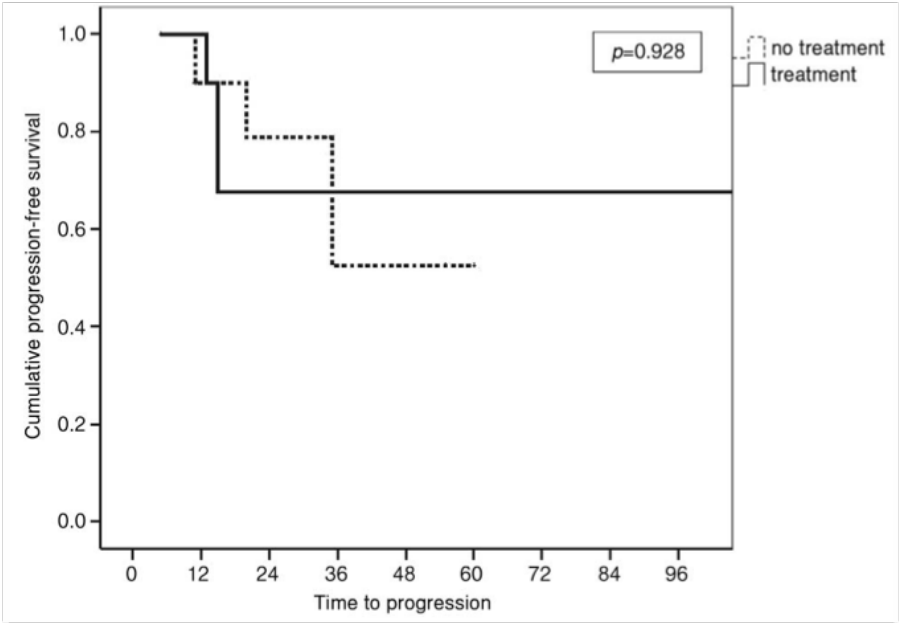
Does MALT Lymphoma of the Lung Require Immediate Treatment? An Analysis of 11 Untreated Cases with Long-term Follow-up



"MALT lymphoma of the lung is a very indolent disease with the potential for spontaneous regression. For this reason, patients diagnosed with pulmonary MALT lymphoma might not require immediate treatment in the absence of symptoms and a watch-and-wait policy could be adopted."

Troch et al. Anticancer Research 2007;27:3633-3638

A retrospective international study on primary extranodal marginal zone lymphoma of the lung (BALT lymphoma) on behalf of International Extranodal Lymphoma Study Group (IELSG)

Abstract

Primary lymphoma of the lung is a rare entity. Clinical features, optimal treatment, role of surgery and outcomes are not well defined, and the follow-up is variable in published data. Clinical data of 205 patients who were confirmed to have bronchus mucosa-associated lymphoid tissue lymphoma from December 1986 to December 2011 in 17 different centres worldwide were evaluated. Fifty-five per cent of the patients were female. The median age at diagnosis was 62 (range 28–88) years. Only 9% had a history of exposure to toxic substances, while about 45% of the patients had a history of smoking. Ten per cent of the patients had autoimmune disease at presentation, and 19% patients had a reported preexisting lung disease. Treatment modalities included surgery alone in 63 patients (30%), radiotherapy in 3 (2%), antibiotics in 1 (1%) and systemic treatment in 128 (62%). Patients receiving a local approach, mainly surgical resection, experienced significantly improved progression-free survival ($p = 0.003$) versus those receiving a systemic treatment. There were no other significant differences among treatment modalities. The survival data confirm the indolent nature of the disease. Local therapy (surgery or radiotherapy) results in long-term disease-free survival for patients with localized disease. Systemic treatment, including alkylating-containing regimens, can be reserved to patients in relapse after incomplete surgical excision or for patients with advanced disease. ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Conclusions

- Most cases of primary lung lymphomas (80-90%) are MALT lymphoma

- BALT lymphoma tends to be an indolent disease with prolonged survival (70-80% @ 10 years), although with frequent relapses (30-40% @ 5 years)

- The optimal management of BALT lymphoma has yet to be clearly determined:

  - **Surgery** is preferable for localized disease
  - **Chemotherapy** is the treatment of choice for extensive disease
  - **Observation** is a good alternative for asymptomatic patients with localized disease

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Conclusions

- Data regarding a precise role for radiotherapy are lacking
- RT can be reserved for patients with a unique small lesion
- Planning procedures with 4D-CT is highly recommended to account for organ motion during the respiratory phases
- Modern radiation techniques (IMRT/IGRT) are recommended to reduce radiation exposure to ipsilateral and controlateral lung
- RT dose should be in the range of 24-30 Gy
- Low dose schedule (2 Gy x 2) has obtained promising results and could be argument of research in future trials

Modern Radiation Therapy for Extranodal Lymphomas: Field and Dose Guidelines From the International Lymphoma Radiation Oncology Group

RECOMMENDATIONS FOR PLANNING AND TREATMENT

VOLUMES:

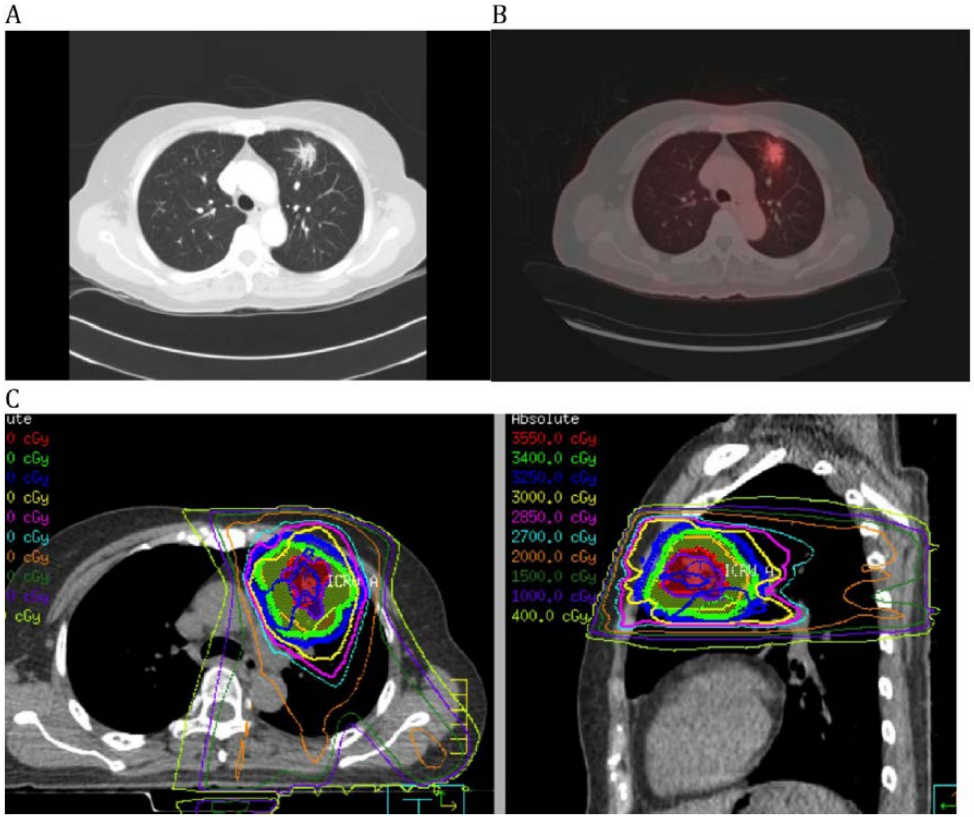
- CTV: preintervention (biopsy, surgery or systemic therapy) GTV, expanded by clinical judgment to accommodate imaging uncertainties and suspected adjacent microscopic infiltration
- ITV: expansion for respiratory motion (use 4DCT if available)

TECHNIQUE:

- 3D conformal or IMRT
- V20 and pulmonary function status should be taken into account

Yahalom et al. IJROBP 2015;92(1):11-31

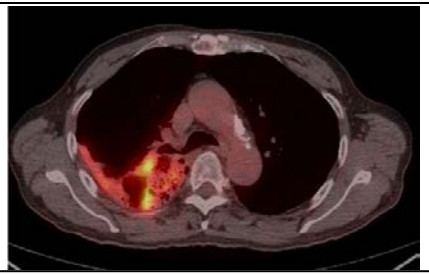
Modern Radiation Therapy for Extranodal Lymphomas: Field and Dose Guidelines From the International Lymphoma Radiation Oncology Group



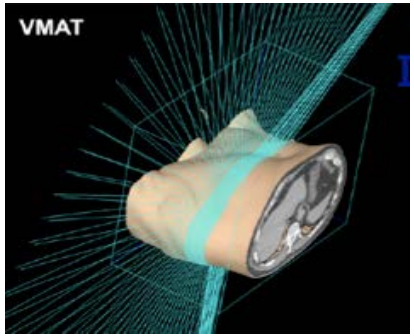
Yahalom et al. IJROBP 2015;92(1):11-31

Modern RT for lung lymphoma

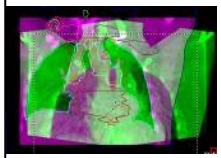
1. **Use of 4D-CT**: accounting for tumor motion during breathing
2. **GTV-Definition**: minimization based on functional Imaging (PET-CT) and shift to smaller CTV volumes

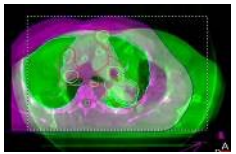


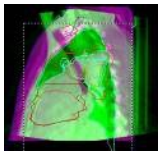
3. Treatment Planning as IMRT based on Monte-Carlo Dose calculation (dose-painting)



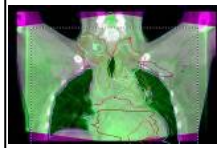
4. Image Guided Radiotherapy Treatment with Cone-Beam-CT at Linac for margins reduction

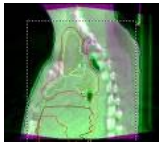






Suboptimal Positioning





Optimal Positioning

Practice guidelines for the management of extranodal non-Hodgkin's lymphomas of adult non-immunodeficient patients. Part I: primary lung and mediastinal lymphomas. A project of the Italian Society of Hematology, the Italian Society of Experimental Hematology and the Italian Group for Bone Marrow Transplantation

Zinzani et al. Haematologica 2008;93(9):1364-1371

RECOMMENDATIONS

MALT lymphomas

- **Surgery** is the treatment of choice for localized presentations
- **Chemotherapy** (anthracycline or fludarabine based regimens) is the treatment of choice for extensive disease
- **Observation** is a good alternative for asymptomatic patients with localized disease
- **Radiotherapy** may be an option (small lesion, histology available)

DLBCL

- **Recommended first line therapy** includes anthracycline based CT (CHOP or MACOP-B like regimens)
- **Surgical resection** requested in some cases
- Rituximab association with CT needs to be evaluated within approved clinical trials
- As for nodal DLBCL, second-line therapy with CT + ASCT is recommended

	t(11;18)	3q and gain 12q	Nil typical
Typical clinical presentation	I_E disease	Abnormal blood count, splenomegaly	Adenopathy

Splenic Marginal Zone Lymphoma

- Prominent splenomegaly: variable involvement of lymph nodes, bone marrow, peripheral blood, Splenic hilar lymph nodes and bone marrow are often involved
- lymphoma cells may be found in the peripheral blood as villous lymphocytes <1%
- Association with hepatitis C infection has been reported, although the prevalence ranges from 36% to less than 10%
- Abdominal discomfort due to splenomegaly
- Modest cytopenias that are primarily due to splenic sequestration (less marrow infiltration).
- Typically diagnose on BM, may need splenectomy
- Intergruppo Italian Linformi 309 patients, 5-year cause-specific survival 76%.

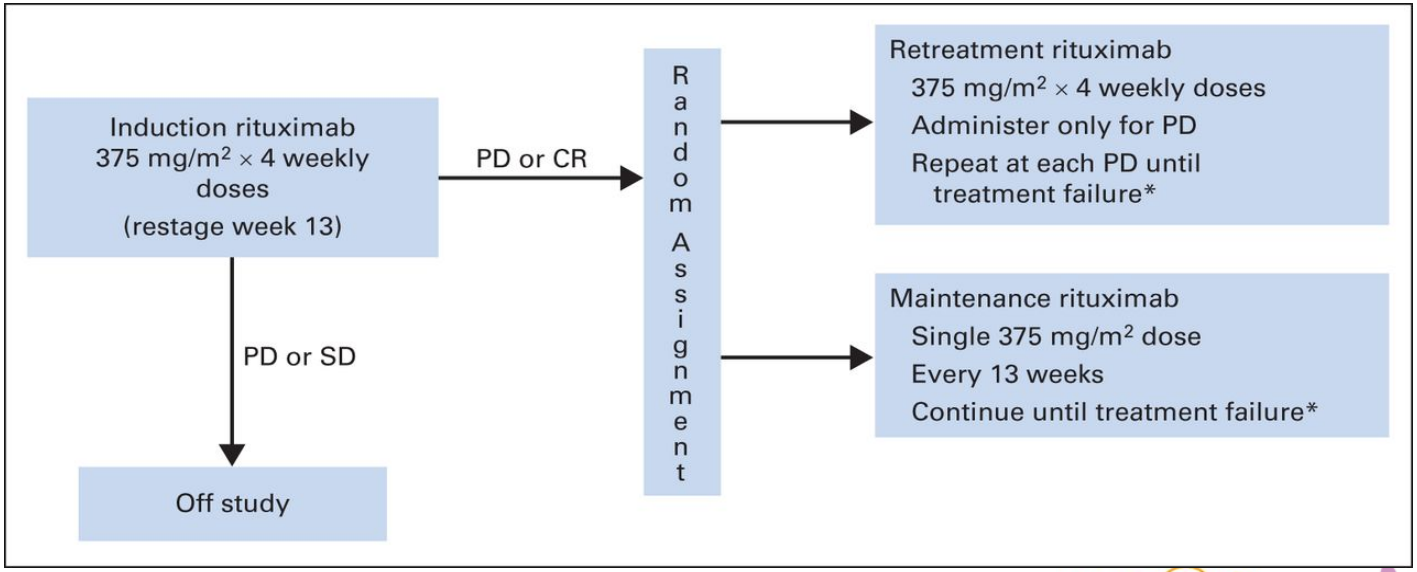
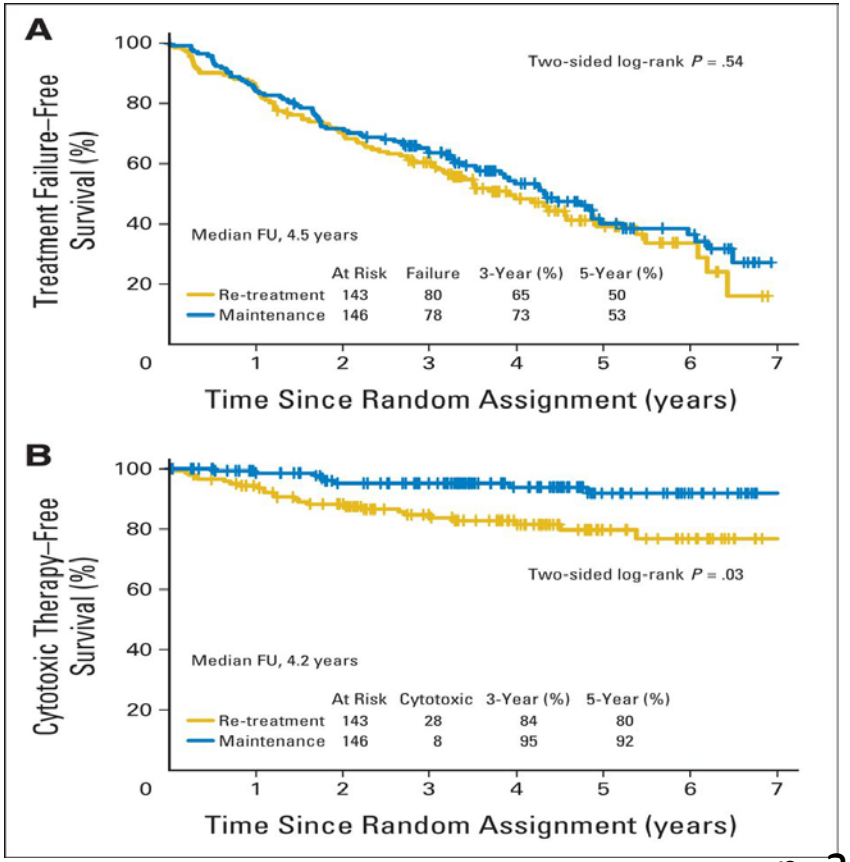
Rituximab Extended Schedule or Re-Treatment Trial

N=289. Previously untreated low burden



Brad S. Kahl et al. JCO **2014;32:3096-3102**



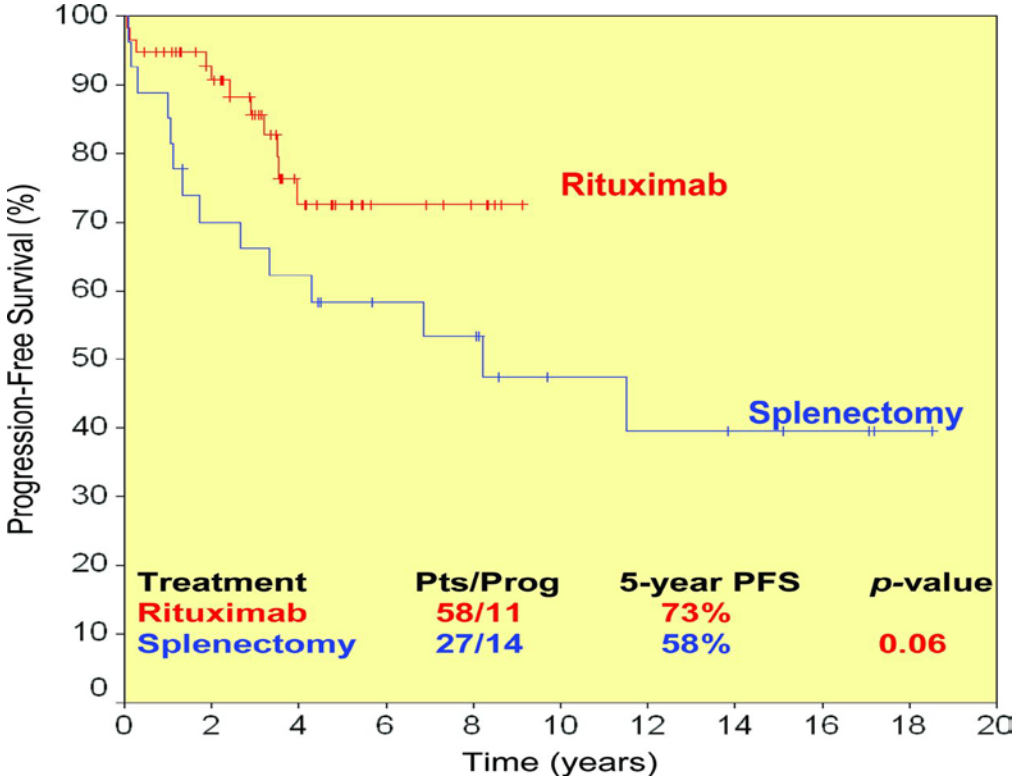
Time to treatment failure

Time to first cytotoxic therapy

n=298

Brad S. Kahl et al. JCO 2014;32:3096-3102

Progression-free survival (PFS) probability in rituximab-treated (red line) and splenectomized patients (blue line) after 5 years.



Christina Kalpadakis et al. The Oncologist 2013;18:190-197

So…first line rituximab…

Maintenance rituximab can be considered, but not standard of care

Splenectomy for poor responders and relapse

Patient specific discussion

Nodal MZL

- <2% NHL median age 60
- Upto 30% have Hep C + serology (variable)
- Generalised asymptomatic LN;
- BM in 30-60%..exclude dissemination of ENMZL
- Few therapeutic trials – same principles as other ‘indolent’ lymphomas..watch and wait
- 60-80% alive at 5 years

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

BR vs. R-CHOP as First Line Treatment in Patients with Indolent and Mantle Cell Lymphomas (MCL): Updated Results from the StiL NHL1 Study

Eligible patients:

- CD20-postiive FL, WM, MZL, SLL, MCL (elderly)
- No previous treatment
- Stage III or IV

(n = 549)

RANDOMISE

Bendamustine-Rituximab (BR)

Bendamustine 90 mg/m² days 1-2
Rituximab 375 mg/m² day 1

CHOP-Rituximab (R-CHOP)

Cyclophosphamide 750 mg/m² day 1
Doxorubicin 50 mg/m² day 1
Vincristine 1.4 mg/m² day 1
Prednisone 100 mg/days days 1-5
Rituximab 375 mg/m² day 1

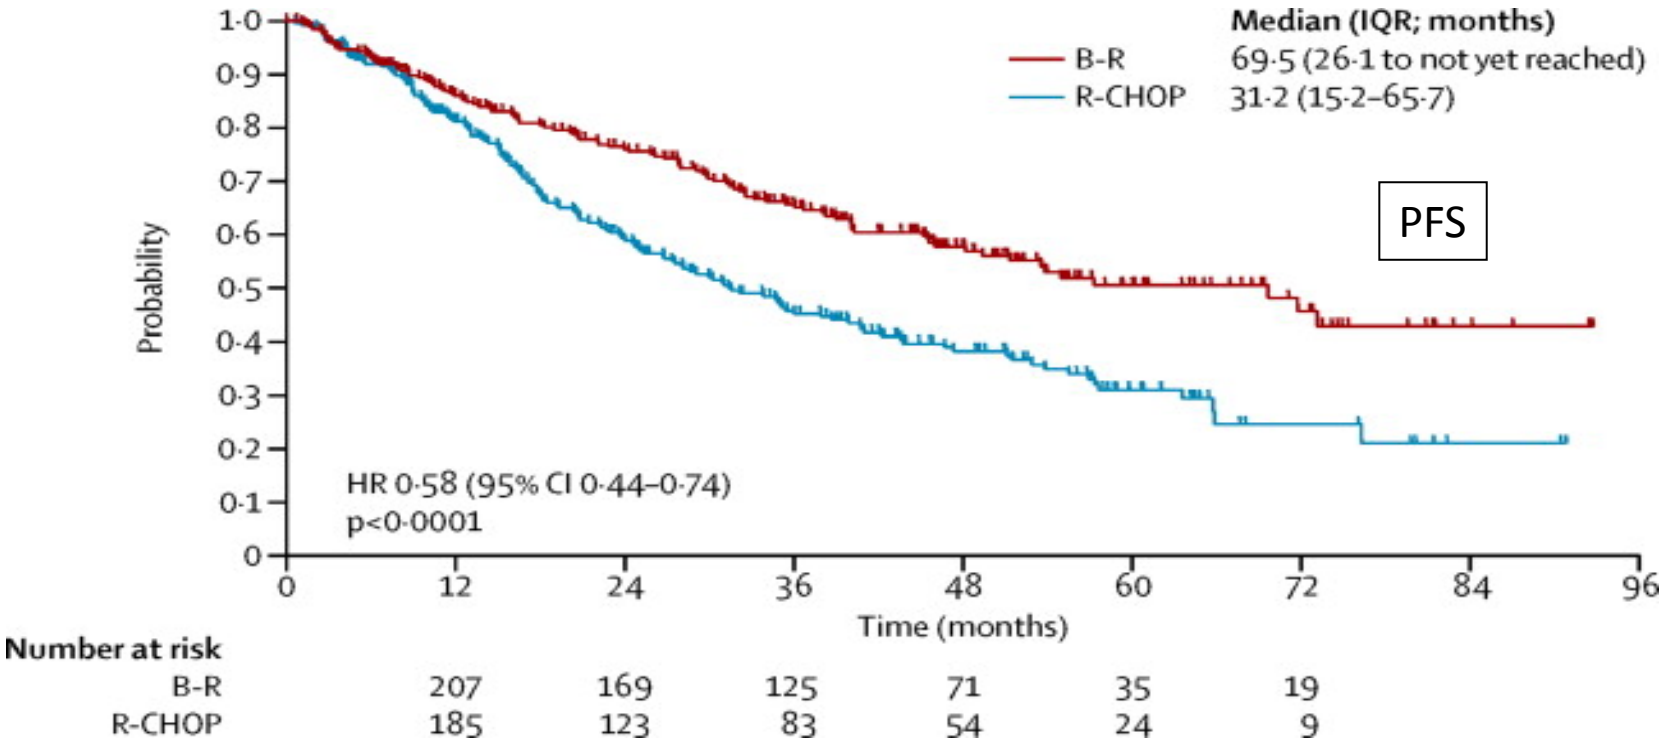
Primary objective

- **To prove the non-inferiority of BR vs. R-CHOP defined as a decrease of < 10% in progression-free survival (PFS) after 3 years**

Secondary objectives

- **Time to next treatment (TTNT), event-free survival (EFS), overall survival (OS)**
- **Acute and late toxicities, infectious complications**
- **Stem cell mobilization capacity in younger patients**

StiL Study



No difference in OS

Rummel et al Lancet April 2013

Lenalidomide

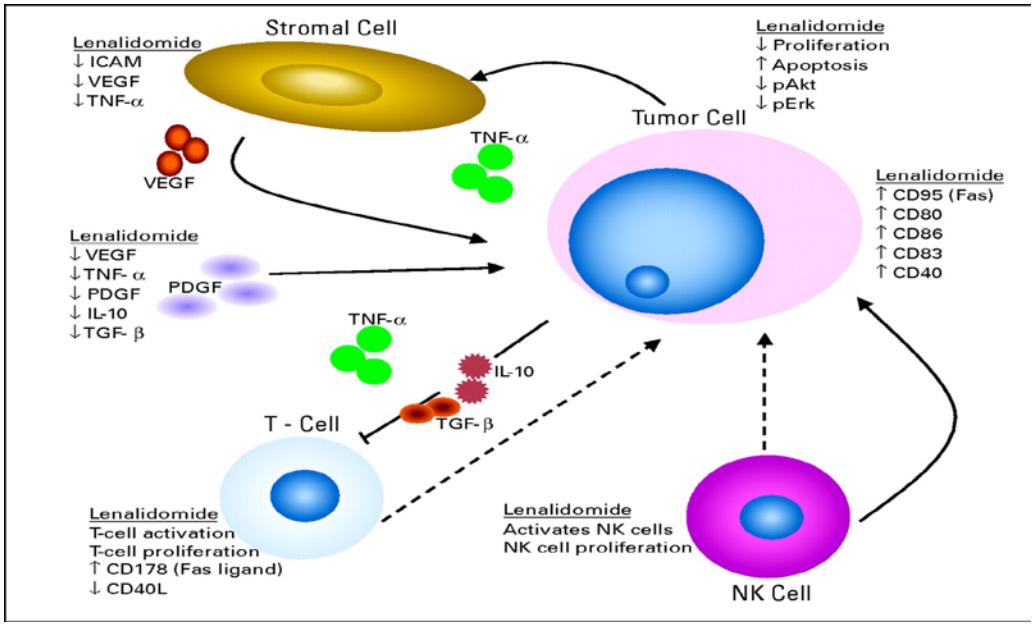
- Immunomodulatory properties
- Modulation of both cellular and cytokine tumour cell microenvironment
- Activates T cell and NK response to tumour cell
- Down regulates pro-survival cytokines
- Approval in myeloma



Chanan-Khan, A. A. et al. J Clin Oncol; 26:1544-1552 2008

The R^2 regimen (Fowler at al. Lancet Oncol 2014)

- Preclinical data suggests that lenalidomide may augment immune effector function and enhance rituximab mediated ADCC
- Previously untreated advanced stage ‘indolent lymphoma’

Lenalidomide	20mg po	Day 1-21 q28
Rituximab	375mg iv	Day 1
6 cycles. Responders continued to 12 cycles		

- n=110 (103 pts. evaluable) 57% GELF criteria for high tumour burden

Chanan-Khan, A. A. et al. J Clin Oncol; 26:1544-1552 2008

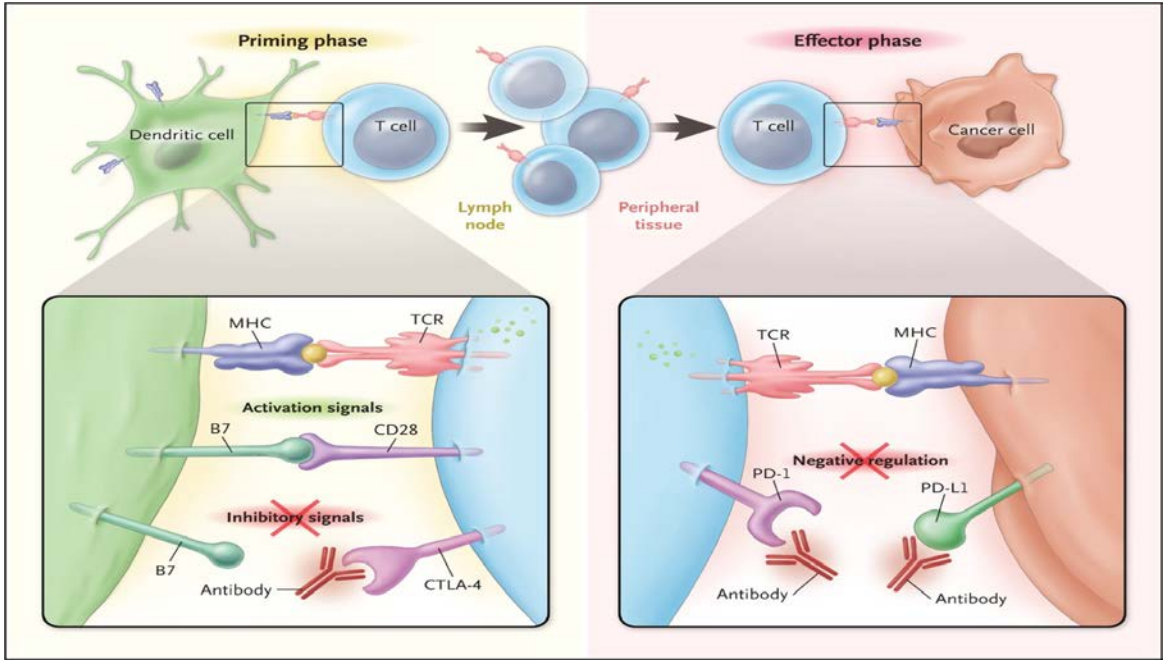
Long term???

Exhausted T-cells

- Blocking immune checkpoints may promote endogenous antitumour activity
- PD1: Inhibitory receptor on activated T-cells, B-cells, NK and myeloid cells. Inhibition of T-cell activation when engaged by ligands (PDL1/2)
- PD1 expressed on T-cells when exposed to tumour, and associated with exhaustion. Blocking can restore function



Ribas A. N Engl J Med 2012;366:2517-2519.

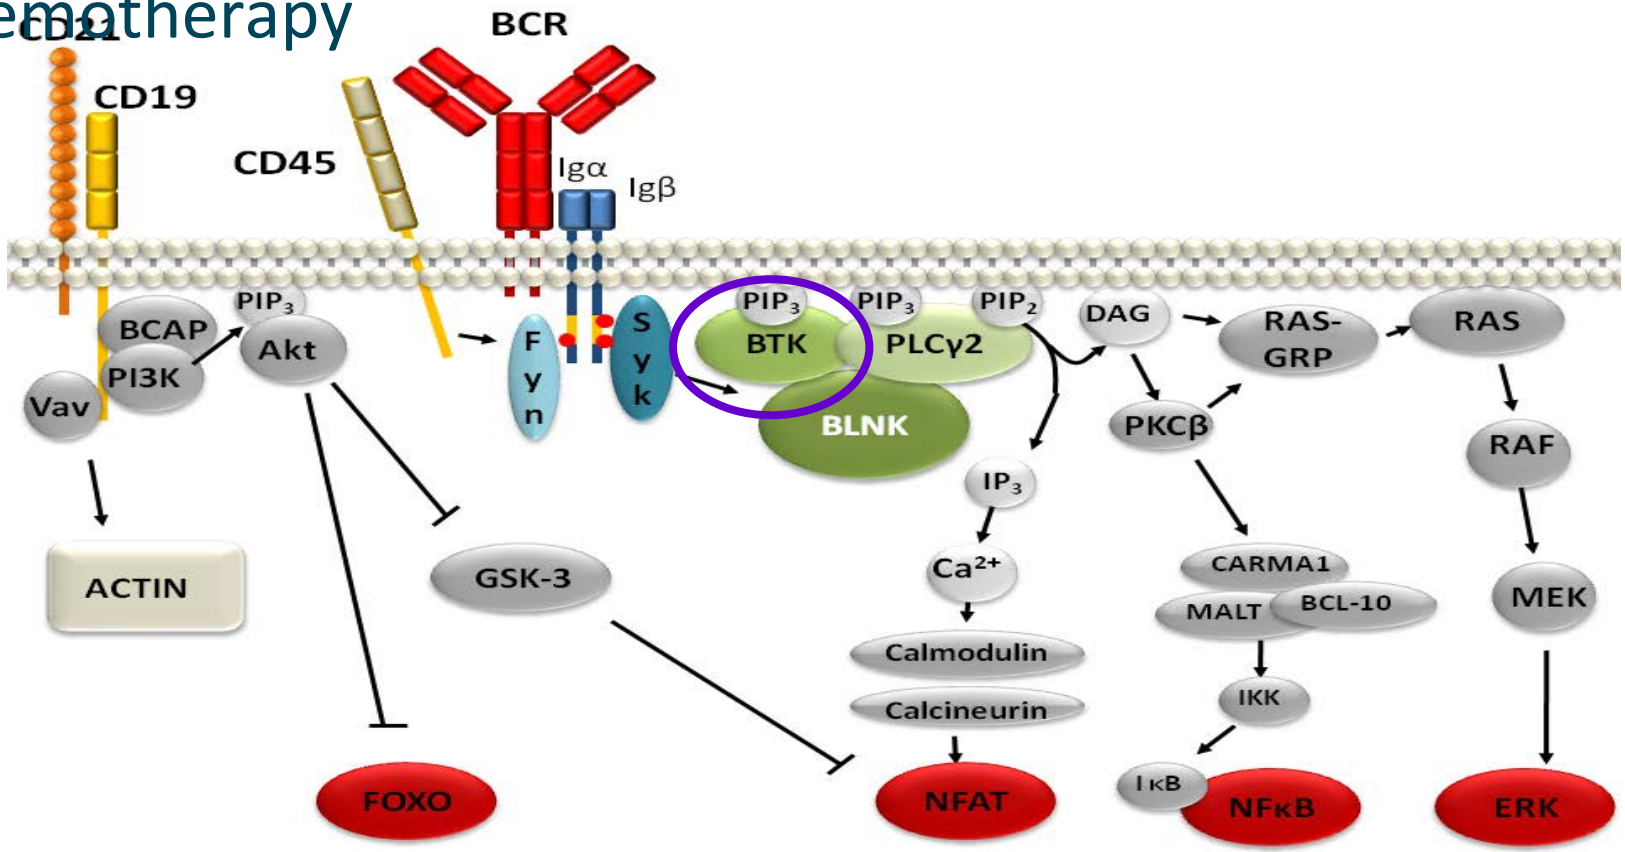
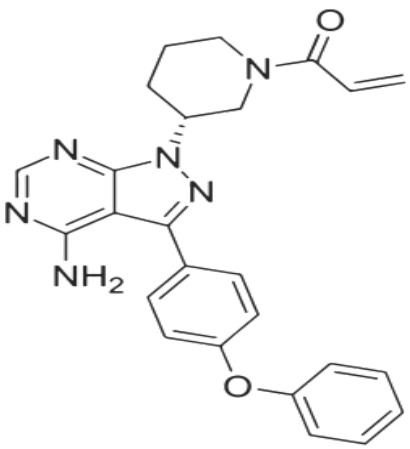
B-cell receptor signalling. ..Inhibit and spare the chemotherapy



Ibrutinib: Mechanism of action



Chemical structure of ibrutinib [4]

Interactions between the tumour microenvironment and malignant B cells play an important role in B-cell homing, adhesion and migration through activation of intracellular pathways in the B cells.[1,2]

BTK's pivotal role in signalling through B-cell surface receptors results in activation of pathways necessary for B-cell trafficking, chemotaxis and adhesion.[3]

Covalent binding in ATP pocket of BTKL….believed to disrupt key malignant processes and:[3,4]

- Induce apoptosis; Inhibit adhesion (may lead to lymphocytosis)

Extranodal lymphomas: characteristics, the role of RT, volumes, doses and techniques

Bone

Umberto Ricardi

Introduction

- Primary bone lymphoma (PBL) constitutes approximately 5% of all extranodal NHLs, <1% of all NHLs, and 3-7% of all malignant primary bone tumours
- Median age at diagnosis: 45 – 60 years old
- A slight preponderance of males over females (male/female ratio 1.5)

Introduction

- Most patients with bone lymphoma have DLBCL (80% of cases)
- Approximately 80% of patients present in stage IE (about 10% of patients have a polyostotic presentation)
- The most common involved bones are femur (most often diaphyseal involvement) and pelvis

Table 1
Patient's characteristics at presentation in the IELSG-14 series.

	Limited stage DLBCL ($n = 161$)	MB-DLBCL ($n = 37$)	Stage IV DLBCL ($n = 63$)
Males	51%	59%	40%
Median age; years (range)	55 (18–99)	53 (17–75)	62 (28–83)
Clinical presentation (%)			
ECOG-PS > 1	15%	38%	62%
High LDH serum level	34%	30%	65%
B symptoms	9%	24%	30%
Pain	82%	92%	90%
Swelling	40%	45%	34%

Cerebrospinal fluid	–	3%	1%
Bone marrow	–	–	35%
Other	4%	–	–

DLBCL = diffuse large B-cell lymphoma; MB-DLBCL = multifocal bone diffuse large B-cell lymphoma; ECOG PS: Eastern Cooperative Oncology Group Performance Status; LDH lactate dehydrogenase.

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Clinical presentation

- Symptoms:
  - pain 80–95%
  - tumour mass 30–40%
  - pathological fracture 15–20%
- Mean time between symptoms and diagnosis: 8 months
- Spinal cord compression: 16%

Radiographic findings

- **Rx:**
  - mostly lytic lesions
  - a mixture of permeative, moth-eaten or destructive patterns of the bone cortex
  - often reactive changes of the periosteum
- **contrast-enhanced CT scan:**
  - demonstrates the boundaries of any extraosseous extension
  - indicates cortical breakthrough by the tumour
  - detects osteolysis, osteosclerosis and fragments of bone sequestra
- **MRI:**
  - more detailed extension of disease
  - evidence of cortical changes, intratumoural fibrosis, replacement of trabecular bone and bone marrow by tumour
- **PET-CT:**
  - recommended for initial evaluation, staging and response assessment

Treatment: CMT as standard approach

• *Dosoretz et al.* treated 30 PBLs with RT alone

5 year-DFS: 53%; OS:63% Cumulative incidence of local recurrence: 14%

No local failures if dose up to 50 Gy

• *Fairbanks et al.* reported on 63 Stage IE PBLs

50 pts received RT alone, 10 CMT, 2 CT alone, 1 surgery alone

Univariate analysis: improved 5-year DFS with CMT vs RT alone (90% vs 57%) Doses over 40 Gy improved OS

• *Bacci et al.* 30 pts with localized PBL with 10 yrs follow-up

26 pts CT with anthracycline-chemo: 3 systemic relapses

4 RT only (30-45 Gy whole bone; 10-15 Gy boost): 1 local relapse

DFS 88 % at 87 months mean follow-up

Excellent cure rates with the addition of CT to RT

Lymphoma

Clinical Features, Management, and Prognosis of an International Series of 161 Patients With Limited-Stage Diffuse Large B-Cell Lymphoma of the Bone (the IELSG-14 Study)

Marta Bruno Ventre,[a] Andrés J.M. Ferreri,[a] Mary Gospodarowicz,[b] Silvia Govi,[a] Carlo Messina,[a] David Porter,[c] John Radford,[d] Dae Seog Heo,[e] Yeon Park,[f] Giovanni Martinelli,[g] Emma Taylor,[h] Helen Lucraft,[i] Angela Hong,[j] Lydia Scarfò,[a] Emanuele Zucca,[k] David Christie,[l] on behalf of the International Extranodal Lymphoma Study Group (IELSG)

The Oncologist 2014;19:291–298

Implications for Practice: Patients with limited-stage diffuse large B-cell lymphoma of the bone exhibit a favorable prognosis when treated with primary anthracycline-based chemotherapy whether followed by radiotherapy or not. In patients treated with chemoradiotherapy, the use of larger radiation fields and doses are not associated with better outcome. Central nervous system dissemination is a rare event in these patients, suggesting that specific prophylaxis is superfluous.

Conclusion. Patients with PB-DLBCL exhibit a favorable prognosis when treated with primary anthracycline-based chemotherapy whether followed by radiotherapy or not. In patients treated with chemoradiotherapy, the use of larger radiation fields and doses is not associated with better outcome. Central nervous system dissemination is a rare event in PB-DLBCL patients. ***The Oncologist*** 2014;19:291–298

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Therapeutic issues

- Anthracycline-based chemotherapy as first line treatment for patients affected with primary bone DLBCL
- A survival benefit of the addition of the anti-CD20 monoclonal antibody rituximab to CHOP in primary bone DLBCL has not been demonstrated

- **The survival benefit of adjuvant irradiation after primary R-chemotherapy is a matter of debate**
- **Optimal radiation volumes and doses**

Considerations on RT volumes

- IELSG-14 study:
  - primary bone DLBCL treated with CHOP followed by RT of the whole bone: 5-year PFS 76%
  - primary bone DLBCL treated with CHOP followed by RT of a part of the affected bone (IF-RT): 5-year PFS of 64%

Radiation volumes

- CTV: Prechemotherapy GTV (preferably on MRI) with margins added to accommodate uncertainties in subclinical tumor extension and quality of imaging, and fusion into simulation CT

- PTV is between 0.5-1 cm, depending on site and immobilization

Modern Radiation Therapy for Extranodal Lymphomas: Field and Dose Guidelines From the International Lymphoma Radiation Oncology Group

Yahalom et al, IJROBP, 2015

Considerations on RT dose

- Radiation dose depends on:
  - the size of the irradiated volume
  - the anatomical area
  - the response to primary chemotherapy

- IELSG-14 study:
  - 47 pts irradiated with a dose ≤ 36 Gy: 5-year PFS 72%
  - 58 pts irradiated with a dose > 36 Gy: 5-year PFS 75%

radiation to a dose of 45 Gy in 25 fractions

Conclusions: Relatively high rates of survival were achieved but the number of local failures suggests that the dose of radiotherapy should remain higher than it is for other types of lymphoma. Disability after treatment due to pathological fracture was not seen.

- 102 patients with primary bone DLBCL
- median age: 55 years (range, 16-87 years)
- most common site of presentation: long bones

- RT: 67 pts (66%)
  - 47 pts stage I – II
  - 20 pts stage III – IV
- median RT dose: 44 Gy

Treatment

- *Combined modality therapy:*

R-CHOP x 6 cycles followed by 30-40 Gy ISRT

Therapeutic issues

- Risk of CNS recurrence associated with skeletal involvement is a matter of debate, with rates of 4% and 0.6% respectively for DLCL patients with and without skeletal involvement

- In the IELSG-14 study, CNS involvement occurred in 2.5% of patients with primary bone DLCL

- Available evidence suggests that CNS prophylaxis is superfluous in primary bone DLCL

Memorial Sloan Kettering Cancer Center

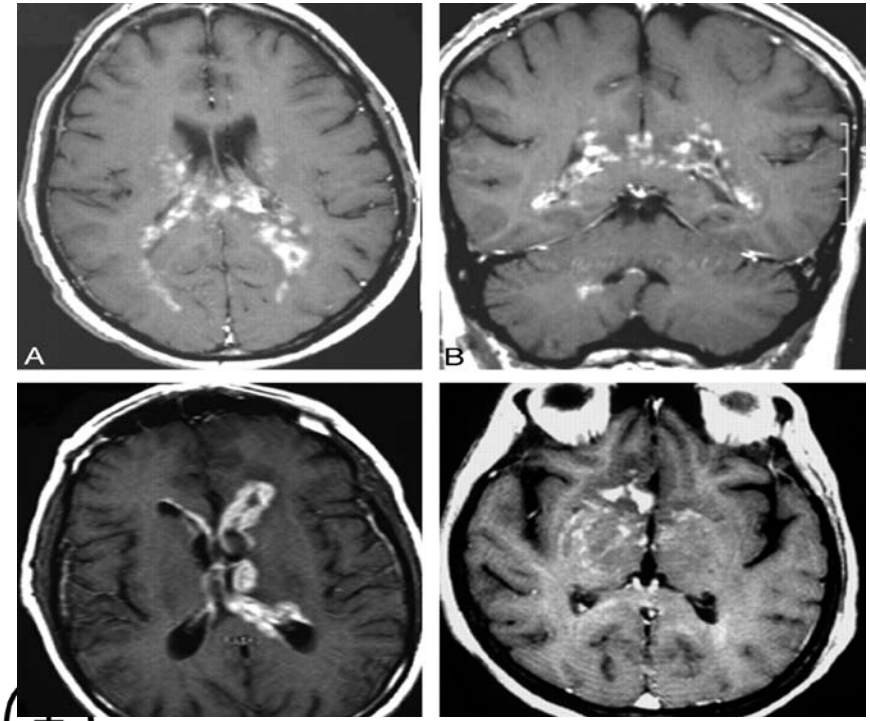
ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

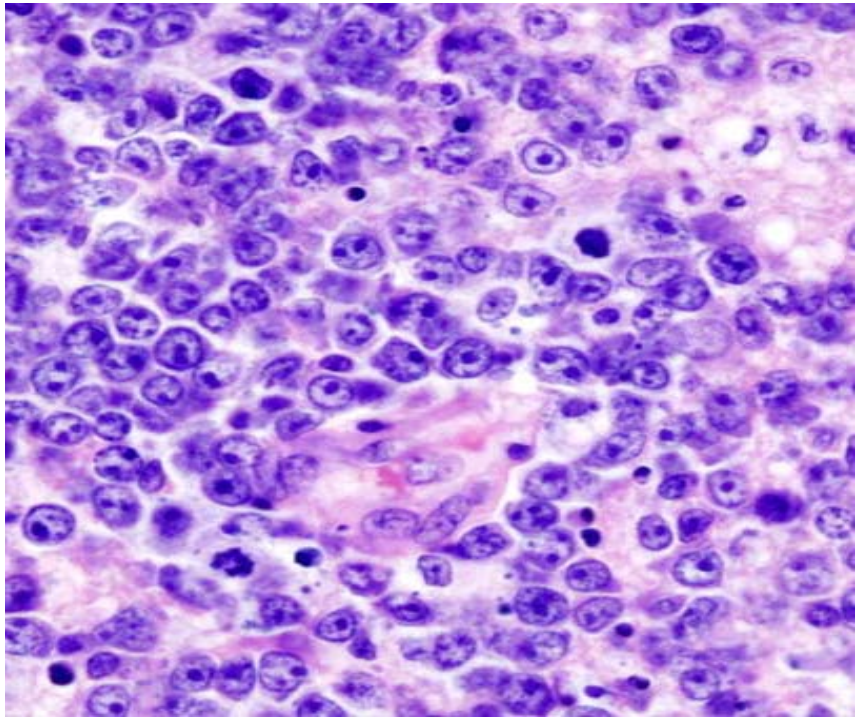
ESTRO School

Definitions

- **PCNSL -** Extranodal non-Hodgkin's lymphoma confined to the cranio-spinal axis without evidence of systemic involvement
- **Secondary Nervous System Lymphoma (SNSL)-** Systemic lymphoma with involvement of the nervous system

Primary CNS Lymphoma (PCNSL)





Memorial Sloan Kettering Cancer Center

ILROG International Lymphoma Radiation Oncology Group

ESTRO School

Primary CNS Lymphoma: A unique lymphoma entity

- Increasing incidence (immunocompetent, older)
- PCNSL- Confined to brain (occasionally to eyes and CSF)
- Systemic spread is very rare
- Multi-centric in the brain in presentation and in relapse (unlike gliomas)
- Resection is not associated with better outcome
- May initially improve and even temporarily disappear with steroids (may mask a diagnosis)

PCNSL

Epidemiology

- ***Central Brain Tumor Registry of the United States (CBTRUS), 1998-2002***
  - Brain Lymphoma
    - 3.1% of all primary CNS tumors
    - 0.46/100,000 person years
    - ~1000-1500 cases per year in the United States
    - Median age at diagnosis = 60
    - Incidence increased ~3-fold from 1973-1984 but recent SEER data suggests plateau of incidence

PCNSL

Epidemiology

- ***Risk Factors***
  - Immunosuppression
    - Congenital (SCID, Wiskott-Aldrich Syndrome)
    - Acquired (HIV)
      - The risk of PCNSL in HIV patients is 3600-fold higher than general population
      - Up to 2/100 HIV infected persons develop PCNSL
    - Iatrogenic (Organ allograft recipients)

PCNSL in “immunocompetent” hosts

(non-HIV)

Primary CNS Lymphoma

- Type

- Primary
  - Brain
  - Leptomeninges
  - Eye
  - Spinal cord
- Metastatic
  - Leptomeninges 4-11%
  - Epidural 3-5%
  - Brain 1%

- Clinical Features

- Mean age = 60
- Gender: men: women - 1:1
- 23% ocular involvement
- 17% positive CSF cytology
- Clinical features
  - 51% behavioral/personality
  - 28% hemiparesis
  - 13% seizure
- DLBCL histology
  - ~85% Non-GC

PCNSL

Symptoms

ESTRO School

PCNSL: A unique treatment challenge

- Rapidly lethal if not treated or responsive
- **RT alone is effective**, but CRs are brief (median survival– 1 yr)
- Adding CHOP or CHOD does not improve RT alone results
- **High-Dose Methotrexate** is the mainstay of effective treatment best for inducing a complete response
- There may be a small benefit from adding rituximab
- High-dose ARA-C has also been used for consolidation and salvage
- High-dose chemotherapy with autologous stem cell rescue has been suggested as an alternative to RT consolidation for fit patients

PCNSL Baseline Evaluation

- **Pathologic Evaluation**
  - Centralized confirmation of pathology with immunopathology when possible
- **Clinical Evaluation**
  - Complete medical, neurological, cognitive examination
  - Determination of prognostic factors (age, PS)
- **Laboratory Evaluation**
  - HIV, lactate dehyrogenase, creatinine clearance
- **Extent of Disease Evaluation**
  - Brain- Contrast-enhanced cranial MRI
  - CSF- Cytology, flow cytometry, IgH PCR
  - Eye- Slit lamp evaluation
  - Body- CT of chest/abdomen/pelvis; BM biopsy + aspirate. Consider testicular US in older men

PCNSL

CT Appearance

The debated role of RT consolidation

- A brief (forgotten) history of WBRT alone
- The breakthrough for cure with MTX followed by WBRT
- The great concern of post-MTX radiation-related neurotoxicity
- Efforts to match the results of combined modality with higher dose chemotherapy alone and effective salvage
- The controversial phase III study
- High-dose chemotherapy with autologous stem cell transplantation
- An alternative combined modality with low-dose RT and rare toxicity

RTOG 83-15 WBRT alone

- 41 patients
- WBRT of 20 RT of 40 Gy + boos
  Gy to lesion (+ 2 cm margin)

- **Overall median survival: 12 months**
  - <60 years: 23 months
  - ≥60 years: 8 months
  - KPS≥70: 21 month
  - KPS<70: 6 months
  - Relapses inside and outside the “boost” area

High-dose methotrexate with or without whole brain radiotherapy for primary CNS lymphoma (G-PCNSL-SG-1): a phase 3, randomised, non-inferiority trial

Eckhard Thiel, Agnieszka Korfel*, Peter Martus, Lothar Kanz, Frank Griesinger, Michael Rauch, Alexander Röth, Bernd Hertenstein, Theda von Toll, Thomas Hundsberger, Hans-Günther Mergenthaler, Malte Leithäuser, Tobias Birnbaum, Lars Fischer, Kristoph Jahnke, Ulrich Herrlinger, Ludwig Plasswilm, Thomas Nägele, Torsten Pietsch, Michael Bamberg, Michael Weller*

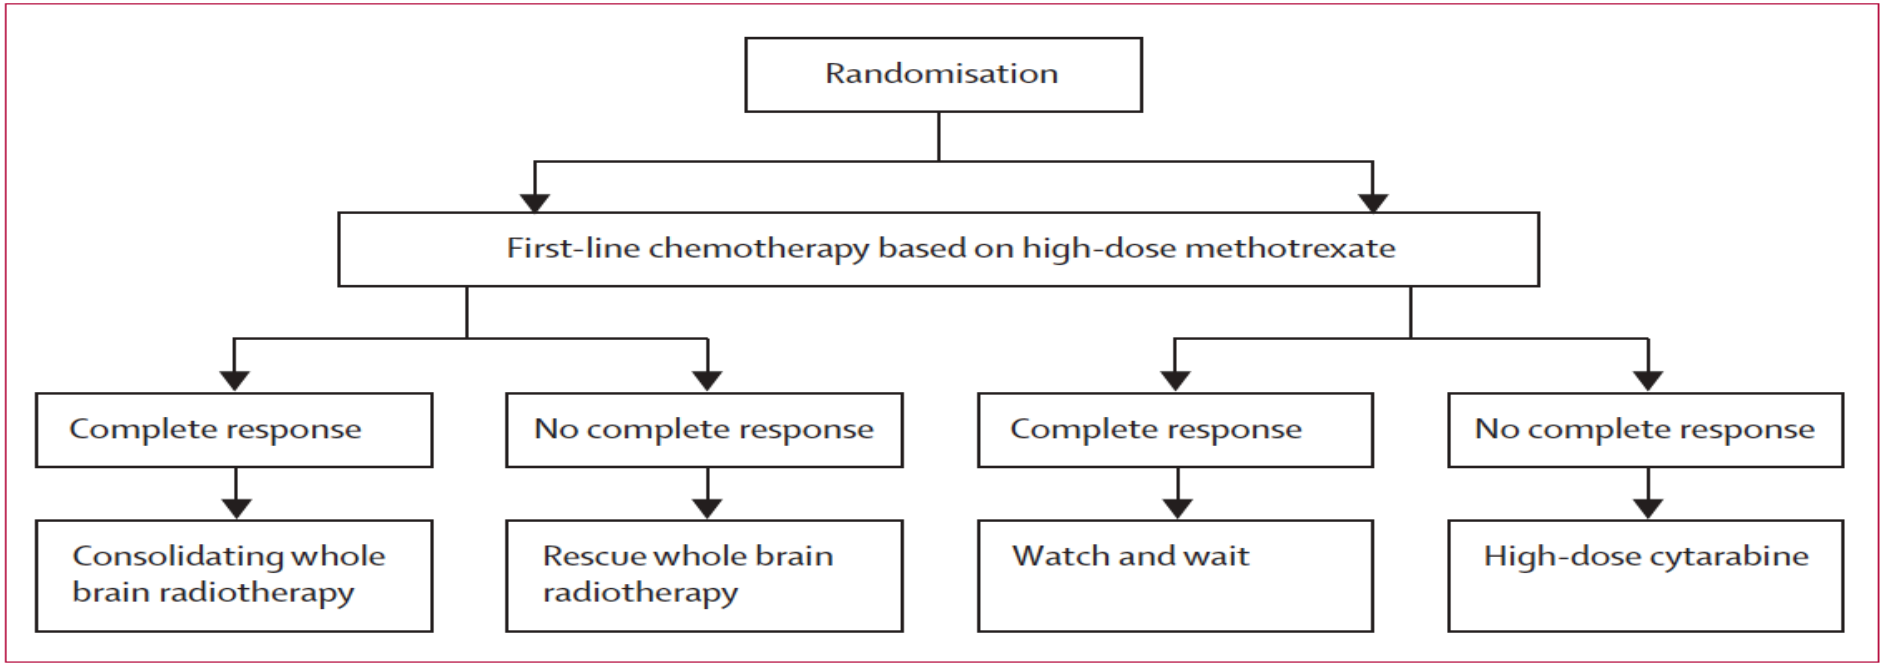

Figure 1: **Trial design**

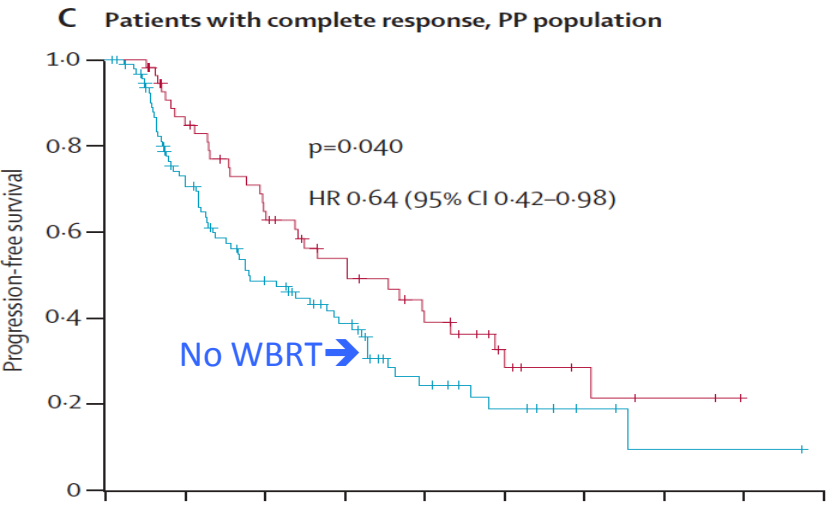

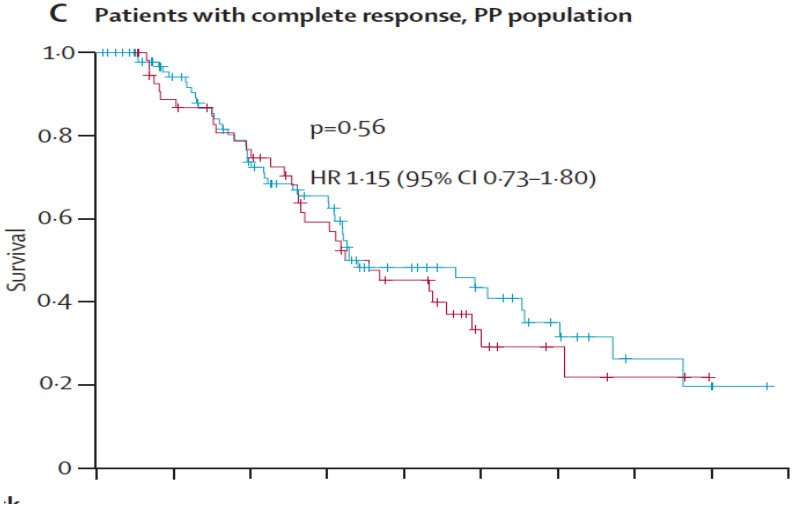

Highly criticized:

- Poor protocol adherence
- Non-inferiority goal in OS not met
- Insufficient toxicity evaluation
- Overall poor results, sub-optimal chemo
- Neurotoxicity even with chemo alone (26%), with RT (49%)
- Salvage improved survival, but carries high QOL/toxicity cost

Hypothesis

Reduced-dose WBRT following effective immuno-chemotherapy will result in lower neurological toxicity while providing adequate disease control in all age groups

Chemotherapy Schedule

- **Day 1**
  - Rituximab 500 mg/m2
- **Day 2**
  - MTX 3.5 gm/m2
  - VCR 1.4 mg/m2
  - Procarbazine 100 mg/m2/d x 7 d. (cycles 1, 3, 5, 7)

X5 cycles (or X7, if PR)

- **Following WBRT**
  - ARA-C 3 gm/m2 (2 cycles)

RT Schedule

- **IF CR** after R-MVP X5 or X7 →**WBRT of 2340 cGy**

- **IF PR** after R-MVP X7 →**WBRT of 4500 cGy**

Exploratory Neuropsychological and Imaging Correlates

Among 31 patients who received rdWBRT, 12 patients (median age, 58 years, including three patients age ≥ 60 years) were progression-free and completed neuropsychological evaluations up to 48 months. At baseline, cognitive impairment was present in several domains. After induction chemotherapy, there was a significant improvement in executive ($P < .01$) and verbal memory ($P < .05$). There was no evidence of significant cognitive decline during the follow-up period, except for motor speed ($P < .05$). Minor fluctuations were observed on memory performance over time. There was no evidence of depressed mood, and self-reported quality of life remained stable during the follow-up period (Table 1).

70 year old lady with severe headaches

Joachim Yahalom, MD
Lauren E. Abrey, MD

ABSTRACT

Background: High-dose methotrexate (MTX) and whole brain radiation therapy (WBRT) prolong survival in primary CNS lymphoma (PCNSL) patients but have been associated with delayed neurotoxicity. Consequently, patients are often treated with chemotherapy alone, and WBRT is deferred until relapse.

Methods: We performed a retrospective study to evaluate the safety and efficacy of salvage WBRT. Radiographic response, survival, and late neurotoxicity were assessed as the main endpoints.

Figure 1 Overall and progression-free survival (PFS) from start of whole brain radiation therapy

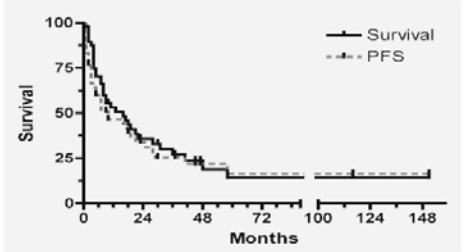

Figure 2 Survival from start of whole brain radiation therapy, separated by age group

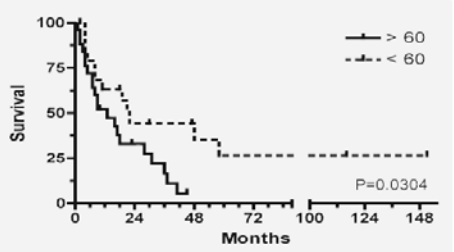

Salvage of chemotherapy alone failures **(MGH)**

- Progression- 17; relapse- 10 pts.
- WBRT- Median- 36 Gy (28-45 Gy)
- CR-37%; PR- 37%
- Median survival- 9.7 from relapse
    - 29 mos from diagnosis
- 33% survived >1 year
- Relapses from CR- 8 pts:
    - Brain- 4
    - Systemic- 4

Results of Whole-Brain Radiation As Salvage of Methotrexate Failure for Immunocompetent Patients With Primary CNS Lymphoma

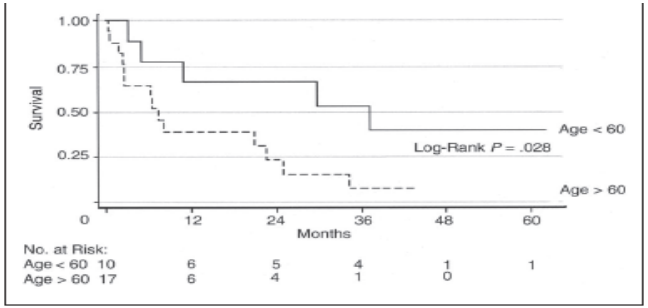

Fig 2. Survival from start of whole-brain radiotherapy, separated by age group.

RT in PCNSL: Field design

- **CTV**: Whole brain including C1 and C2 and the posterior aspect of the eyes.
- The iso-center is set anteriorly and bisects the bony canthi (to reduce divergence in possible future match to ocular field).
  - Alternatively, anterior border of PTV is set with the isocenter 5 mm behind the lens.
- If the eyes were originally involved, both eyes should be included in their entirety in WBRT field.
- The role of tumour site boost is uncertain and is not recommended by most experts
- It is not standard to irradiate the whole cranio-spinal axis

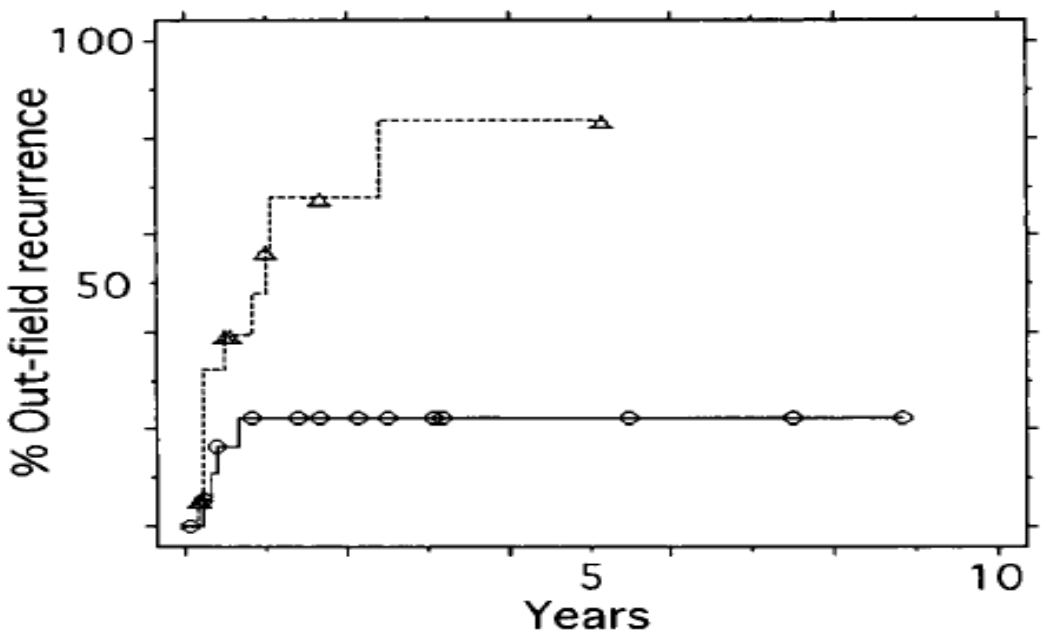

FIGURE 3. Cumulative incidence of out-field recurrences according to the safety margins of the radiation field. —○—: margins ≥ 4-cm; --△--: margins of < 4-cm.

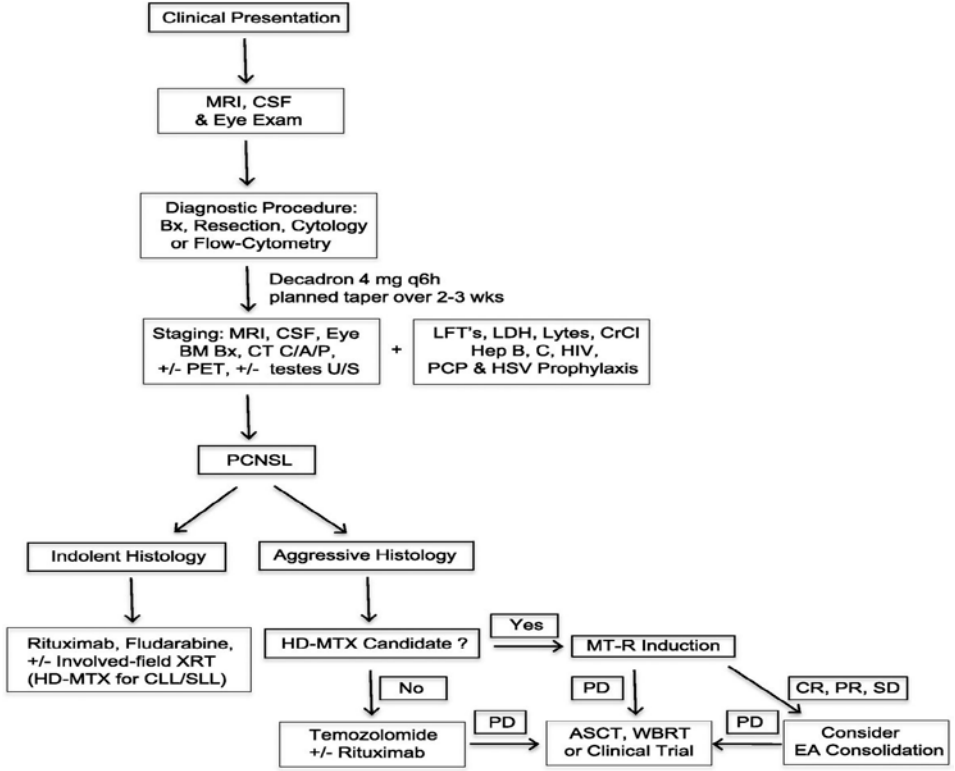
RT in PCNSL: Dose

- Consolidation dose after MRI-CR to chemotherapy: 23.4 Gy in 1.8 Dose per fraction. (13 treatments)
- WBRT after incomplete response to chemotherapy: 36 Gy to 45 Gy (1.5 to 1.8 Gy/fraction)
- WBRT for salvage of chemotherapy failure (progression or relapse) 36 – 40 Gy (1.5 Gy-1.8 Gy/fraction)
- WBRT as primary treatment for non-candidates for chemotherapy: 40-50 Gy
- Whole orbit (if included)- only up to 36 Gy
- For palliation: WBRT dose is 30-36 Gy in 10 or 15 fractions.

How I treat PCNSL. In the diagnostic work-up, an MRI of the spine (± gadolinium) may be useful if warranted by neurologic symptoms or if CSF analysis is contraindicated.



James L. Rubenstein et al. Blood 2013;122:2318-2330

RT in PCNSL – Take home

- WBRT an effective tool in many stages of treatment
- Best use of RET is as low dose (24 Gy) after CR to MTX
- Full dose RT after MTX is toxic in age >60 years
- Chemotherapy alone in “full” MTX doses or with ASCT transplant is also toxic, but is often considered
- Patients respond (yet, temporarily) to salvage with RT alone or with chemotherapy

Histologies

- Most common:
  - DLBCL: virtually any organ
  - Marginal Zone Lymphoma

- Presentation:
  - Main presentation
  - Extra-nodal involvement in context of stage IV disease (not strictly EN lymphoma)

General principles of management

- Early stage:
  - Low-grade: curative RT
  - High-grade: CMT if RT feasible. Full course chemo alone if not.
    - Tolerability of chemo
    - Response to chemo
    - Morbidity of RT
    - Suitability for future salvage

- Advanced stage:
  - Low-grade: systemic Rx ± RT for local control
  - High-grade: systemic Rx ± consolidation RT to sites of EN disease

RICOVER-60: RT to extra-lymphatic tissue

Patients with initial bulky disease (defined as lymphoma masses or conglomerates with diameter ≥ 7.5 cm) or extralymphatic involvement were to receive RT to these areas if complete remission (CR), unconfirmed CR (CRu), or partial remission (PR) was achieved after chemotherapy except when these lymphoma manifestations were completely removed by surgery. Start of RT was planned to be 3 to 6 weeks after the last chemotherapy cycle. A central RT reference panel developed an individual RT plan for each patient. RT to bulky disease was applied as involved-field RT. If a residual tumor remained after chemotherapy, target volume was adapted. If CR was achieved after chemotherapy, the target volume included the lymph node region of the initial bulk. Lymph node regions were defined according Ann Arbor. Target volume of extralymphatic disease included the complete initially involved extralymphatic area. Patients received RT 36 Gy, at 1.8 to 2 Gy per fraction, administered 5× per week. No RT was to be administered in the RICOVER-noRTh cohort.

Abdominal lymphoma

- Duodenum:
  - FL increasingly recognised
  - Obstructive symptoms / pain
  - May be part of multifocal small bowel lymphoma. Small foci in bowel not appear on PET due to physiological FDG in bowel
  - Small bowel capsule endoscopy
  - Local RT is an option for localised indolent disease.

- Small bowel:
  - Indolent (FL, MZL), T-cell, DLBCL
  - Treatment according to histology
  - Sometimes diagnosed after resection
  - Whole abdominal RT has been reported

ILROG INTERNATIONAL LYMPHOMA RADIATION ONCOLOGY GROUP

ESTRO School

Abdominal lymphoma

- Kidneys:
  - Rare as primary presentation
  - High risk of CNS disease
  - Primary treatment: chemo
- Adrenals:
  - High risk of CNS disease

Pelvic Lymphoma

- Bladder: DLBCL or MZL. FL reported
- Prostate: MZL, FL
- Uterus / ovaries: DLBCL. High risk of CNS disease

Considerations:

- Bladder: FDG excretion is urine (PET for staging nodes / others sites)
- Planning: bladder full v empty. Rectal volume. IV contrast
- CTV: whole organ
- Fertility issues

Female patients with DLBCL and involvement of the reproductive organs have poor outcomes and markedly increased risk of CNS relapse with R-CHOP(-like) therapy

Tarec C. El-Galaly,[1] Chan Y. Cheah,[2] Martin Hutchings,[3] George Mikhaeel,[4] Laurie H. Sehn,[5] Kerry J. Savage,[5] Sally Barrington,[6] Jakob W. Hansen,[3] Mette Ø. Jensen,[12] Martin Bøgsted,[1] Hans E. Johnsen,[1] John Seymour,[2] Joseph M. Connors,[5] Peter d.N. Brown,[3] and Diego Villa[5]

- 1,536 patients, 76 (5%): reproductive organ involvement.
- Testicular involvement = 48 (6%) of men
- Female reproductive organ involvement = 28 (4%) of women
  (uterus n=15, ovaries n=11, both n=2).
