Broadening the therapeutic band width

Neil Burnet

University of Cambridge Department of Oncology, Oncology Centre, Addenbrooke's Hospital, Cambridge, UK

ATP Barcelona 2017

Introduction

Radiotherapy (RT) is a hugely important cancer treatment

• Improvements will have a major effect to benefit society

• Small improvements in dosimetry translate into significant improvements in outcome for individual patients

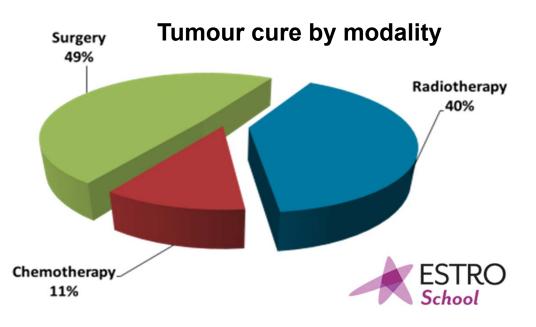

Introduction

RT is potent and cost-effective

- 50% of cancer patients require RT
- 60% treated with curative intent
- UK 66M population
- \sim 100,000 patients receive RT with curative intent in each year

Surgery	£2.1 billion
Chemotherapy	£1.7 billion
Radiotherapy	£0.5 billion

Introduction

- Broadening the therapeutic bandwidth = Improving the therapeutic ratio
- Equivalent to the therapeutic window for drugs
- TCP = Tumour control probability = local control
- NTCP = Normal tissue complication probability = toxicity

• RT is always a balance

VOLUME 28 · NUMBER 18 · JUNE 20 2010

(2010; 28(18): 2996-3001)

JOURNAL OF CLINICAL ONCOLOGY

ORIGINAL REPORT

Critical Impact of Radiotherapy Protocol Compliance and Quality in the Treatment of Advanced Head and Neck Cancer: Results From TROG 02.02

Lester J. Peters, Brian O'Sullivan, Jordi Giralt, Thomas J. Fitzgerald, Andy Trotti, Jacques Bernier, Jean Bourhis, Kally Yuen, Richard Fisher, and Danny Rischin

- Very scary results
- Poor radiotherapy

20%↓ in OS 24%↓ in DFS

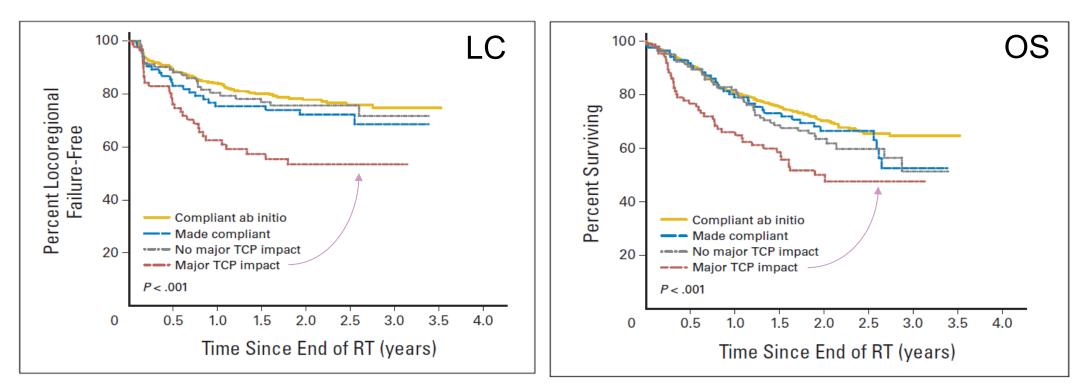

Fig 3. Time to locoregional failure by deviation status

Fig 2. Overall survival by deviation status:

- Poor radiotherapy in 12% of patients in study
 - Considered likely to have a major impact on outcome

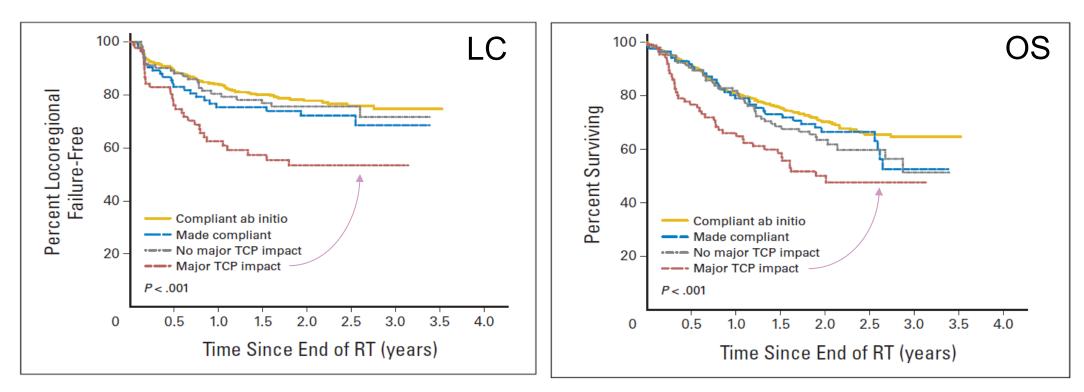

Fig 3. Time to locoregional failure by deviation status

Fig 2. Overall survival by deviation status:

- Poor radiotherapy in 12% of patients in study
 - Considered likely to have a major impact on outcome
 - 3% poor contouring
 - 5% poor plan preparation

- Physical dose distributions individualising treatment
 - > IMRT
 - > IGRT
 - Adaptive RT
 - Imaging including for target volume delineation
 - Proton beam therapy PBT
- Biological strategies
 - Fractionation
 - Exploiting individual variation in normal tissue toxicity
 - Drugs sensitise tumours & protect normal tissues

- Improving the therapeutic ratio is based on *individualisation*
- Focus on physical dose individualisation
 - Integral part of RT for many years actually > 100 years!

- ➢ IMRT is main component of course
- Accurate delivery essential, so IGRT relevant
- Proton beam therapy becoming available

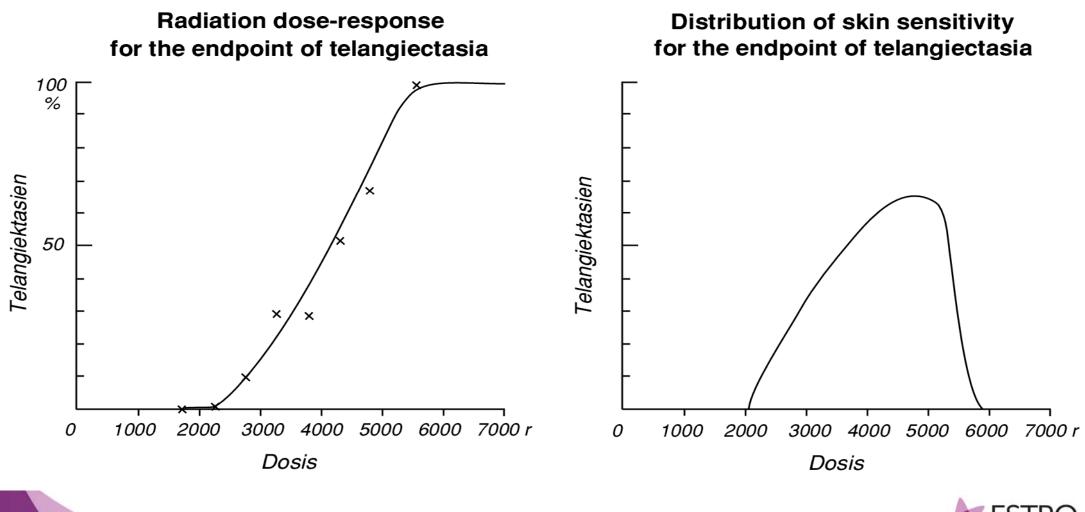

- Local control will translate into overall cure in many patients
 - For breast –1 life saved for every 4 recurrences prevented
- Three variations on improved therapeutic ratio
 - Same cure, lower toxicity
 - Higher cure, same toxicity
 - Higher cure, lower toxicity (if we can !)
- Visually described by dose-response curves (population curves)

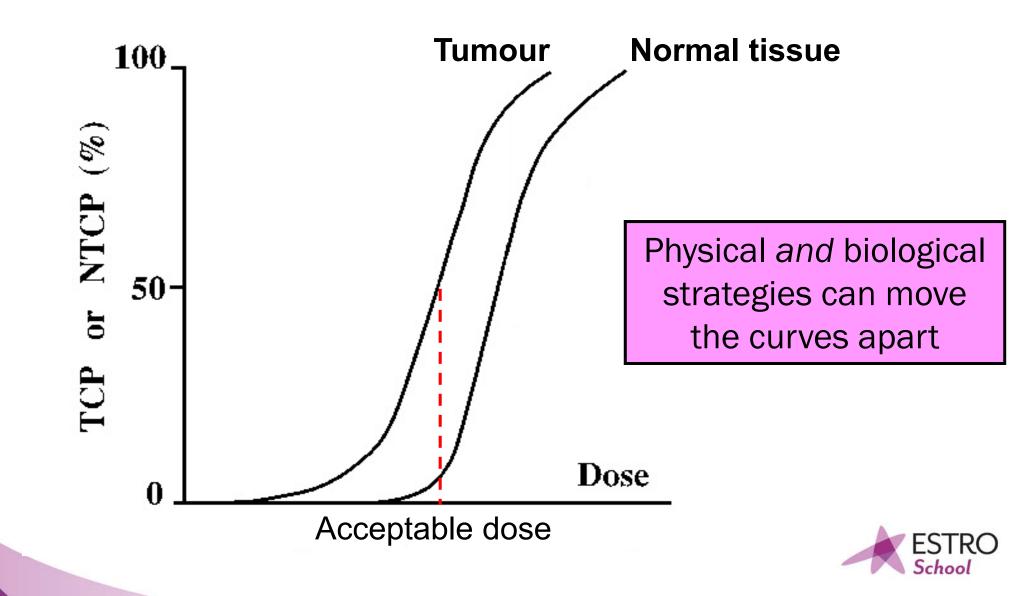

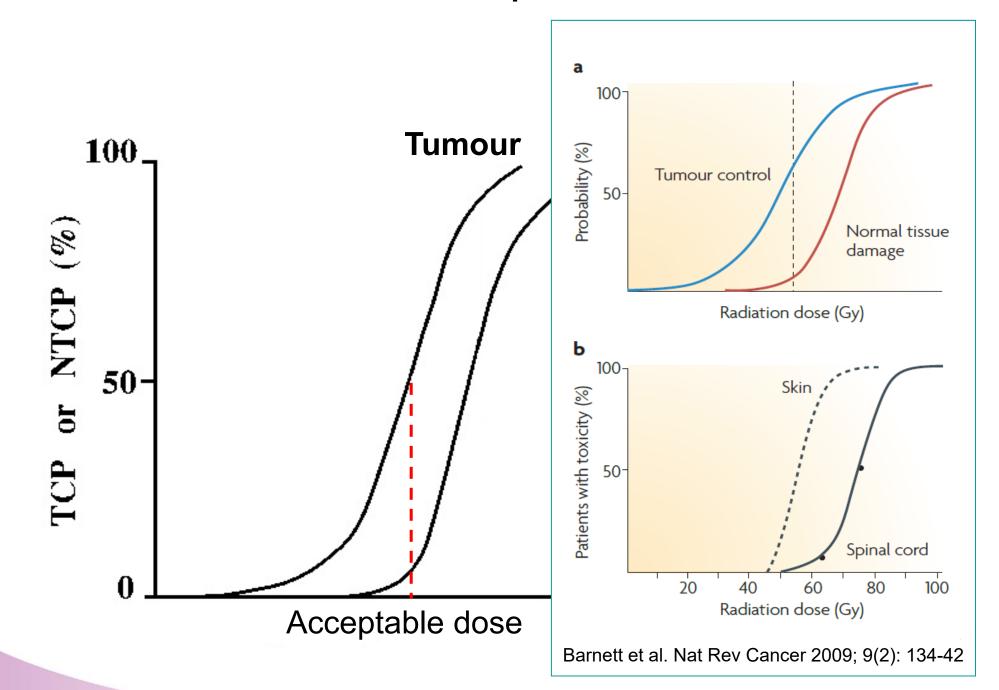

The first normal tissue dose response curve

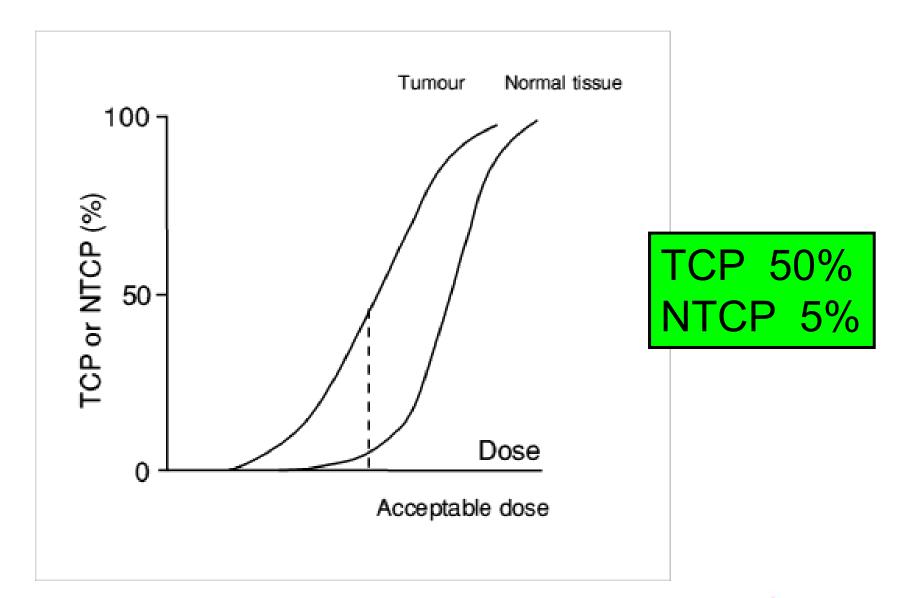

Holthusen - Strahlentherapie 1936

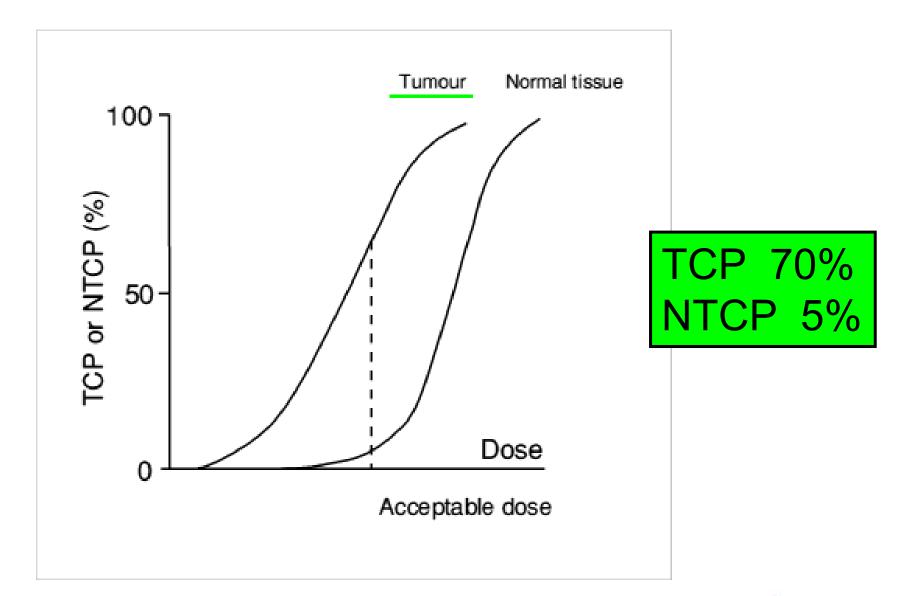

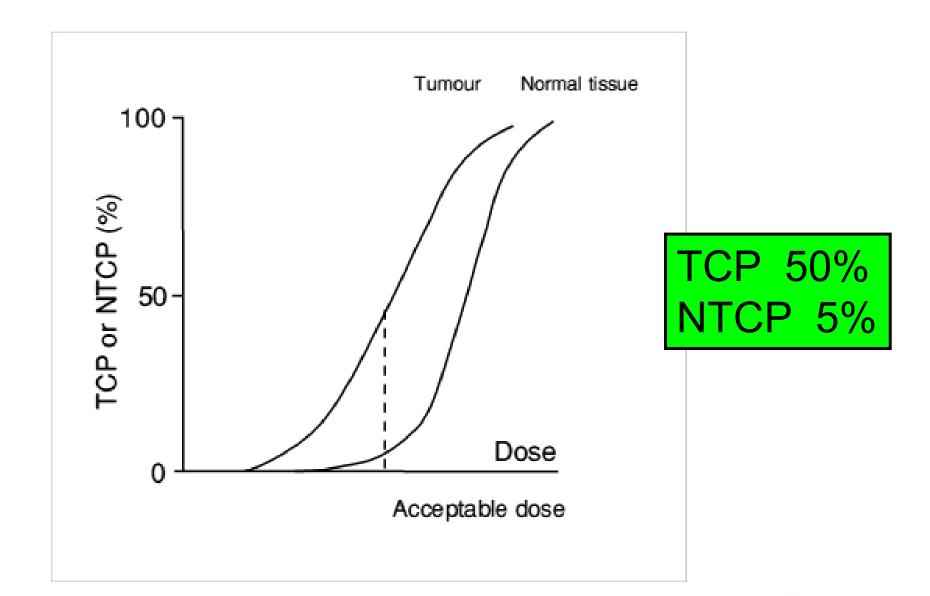

(a)

(b)

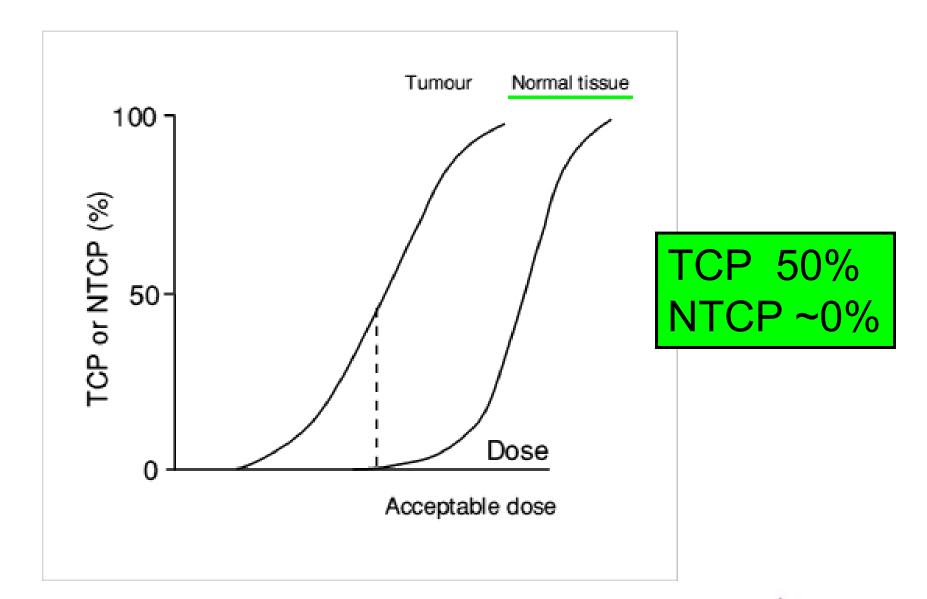

Back to the beginning

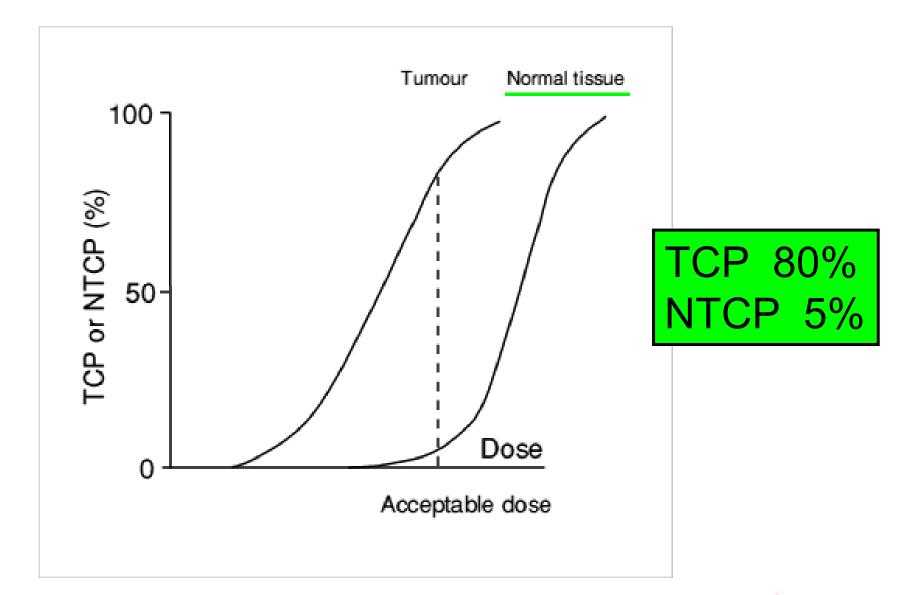

(a)

(c)

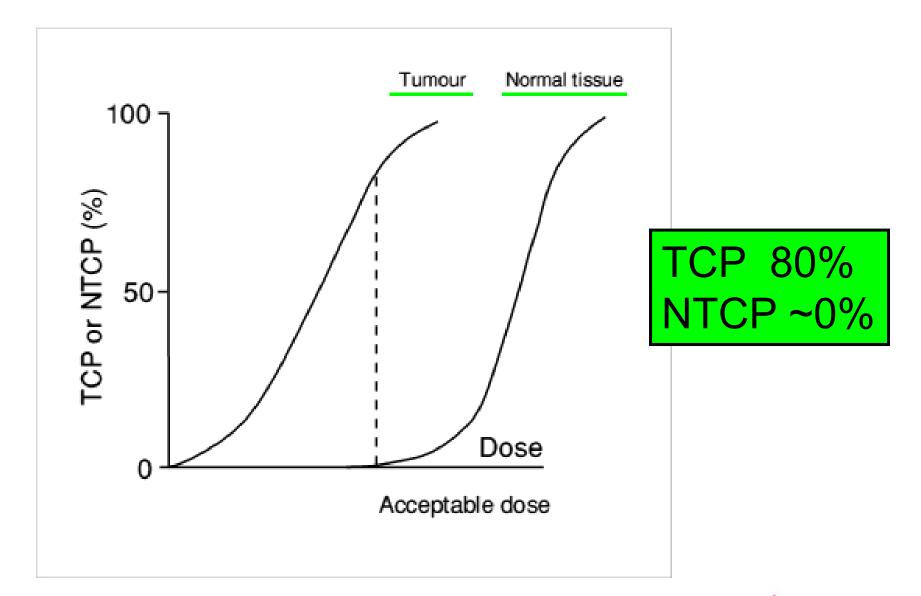

(d)

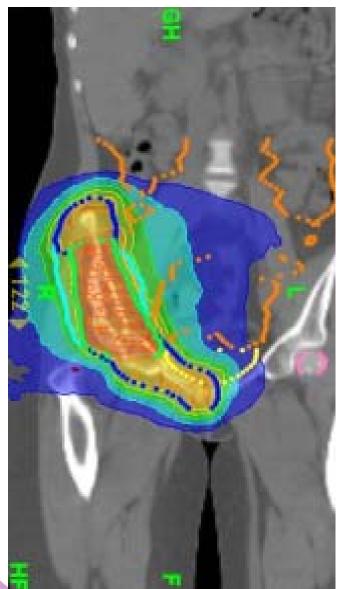

(e)

Normal tissue toxicities

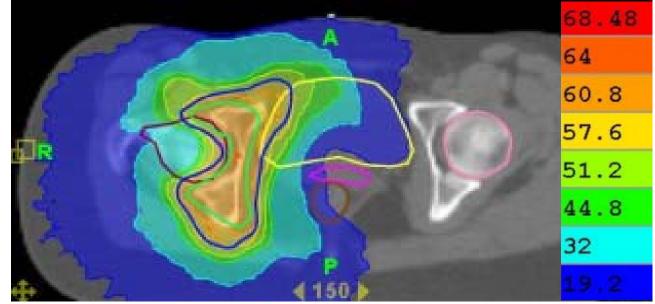

- Toxicity largely relates to **late normal tissue effects**
 - Tissue specific
- Some **acute toxicities** also important
 - Especially applies to concurrent chemo-RT
- Very late effects of second malignancy
 - Difficult to estimate reliably
 - For IMRT, need to balance risk from larger irradiated volume against lower risk of organ damage
 - Role for PBT in children

Pelvic Ewing's sarcoma

- Age 15. Female. Dose 64/60 Gy
- Sparing of central pelvic organs
 Reduced acute & late toxicities

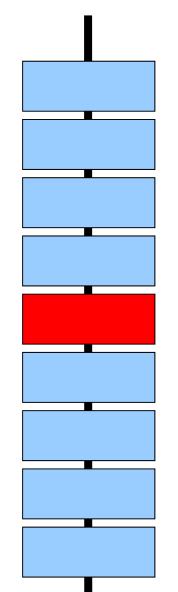

- Toxicity is related to dose
- Volume effect seen in many tissues/organs
- Tissue architecture also relevant
 - ➤ Serial organs eg …
 - > Parallel organs eg ...

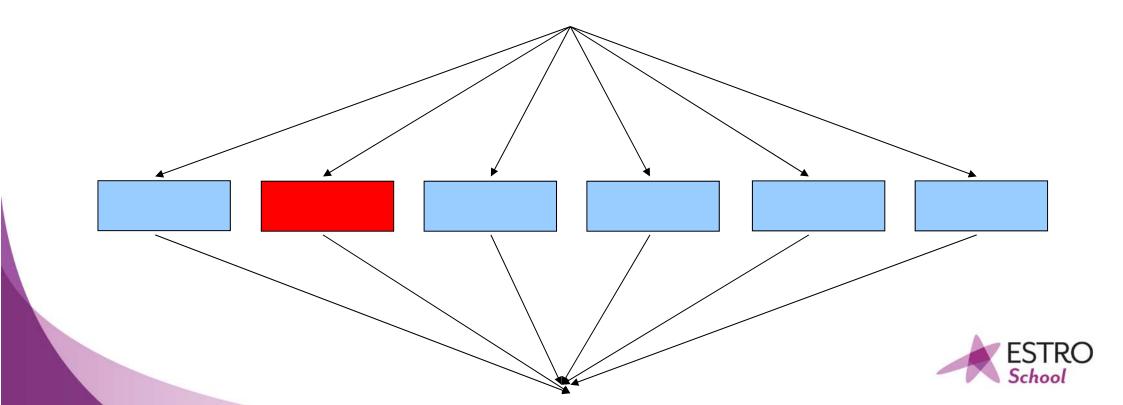

- Serial organ
- Damage to 1 part causes failure
- Serious clinical consequence
- High dose most important
- For example ...
 - ... spinal cord

- Parallel organ
- Damage to 1 part does not compromise function
- Low dose (and volume) usually most important
- For example ...

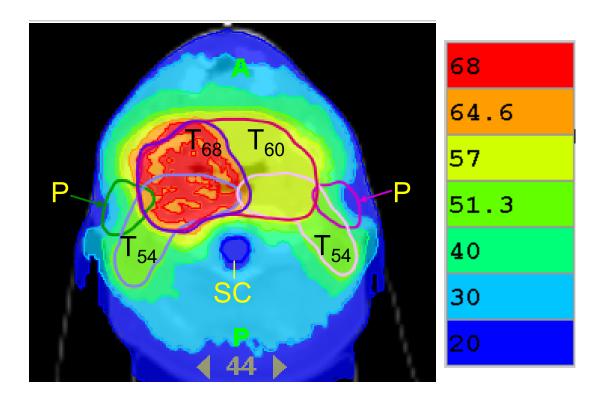

... lung, liver, salivary glands, skin ...

- Volume and architecture important
- If medium dose destroys function, then:
 - Must irradiate only small volume beyond that dose
 - No penalty from higher dose
- If high dose destroys function, then:
 - Avoid high dose
 - Can accept larger volume of irradiation

- IMRT for Head and neck cancer
- Sparing parotids reduces toxicity [¶]
- Restricting dose to spinal cord allows high dose

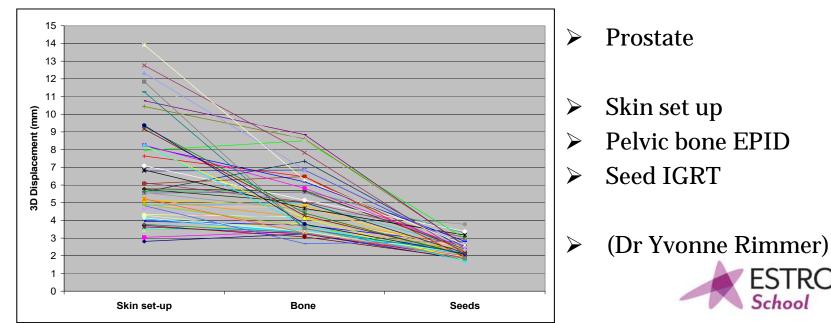

Nutting et al Lancet Oncol. 2011; 12(2): 127-36

Image guidance

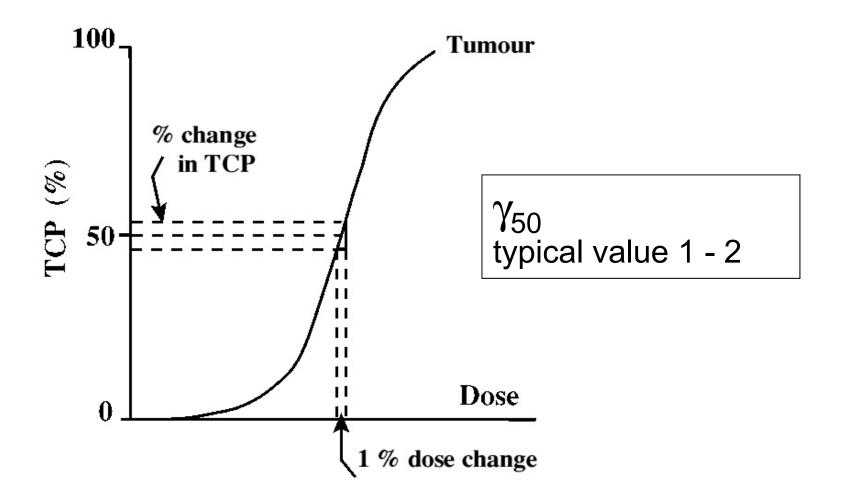

- Patients position less well than we think
- IGRT allows more accurate delivery of dose
 - Deliver the dose to where you planned
 - ? Reduce PTV margins (don't over-reduce)
 - If no reduction of margin, delivers dose more precisely to target and (probably) normal tissue
 - Especially important with steep dose gradients

- Dose response curves are *steep* for both tumour and normal tissue
- Therefore a *small* dose difference can produce a *large* difference in outcome
- This applies to
 ➢ individual patients
 ➢ populations

Gamma 50 and TCP

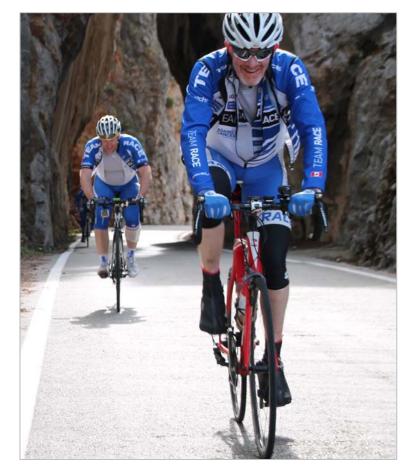

- A 5% dose increase will achieve a 5 10% improvement in tumour control
- Toxicity normal tissue complications show the same effect

- Small steps of improvement are very worthwhile
- Attention to detail will pay dividends

- Small differences matter
- Concept of 'marginal gains'
- Application of the concept has been shown to be *very* successful in cycling

- The same applies to what we do ...
- Attention to details will benefit patients

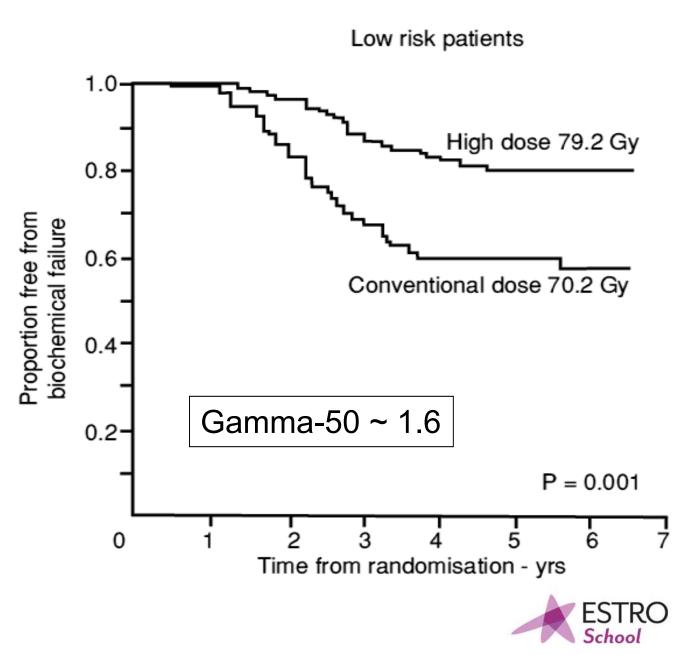

Mike Sharpe 'Mike on his bike'

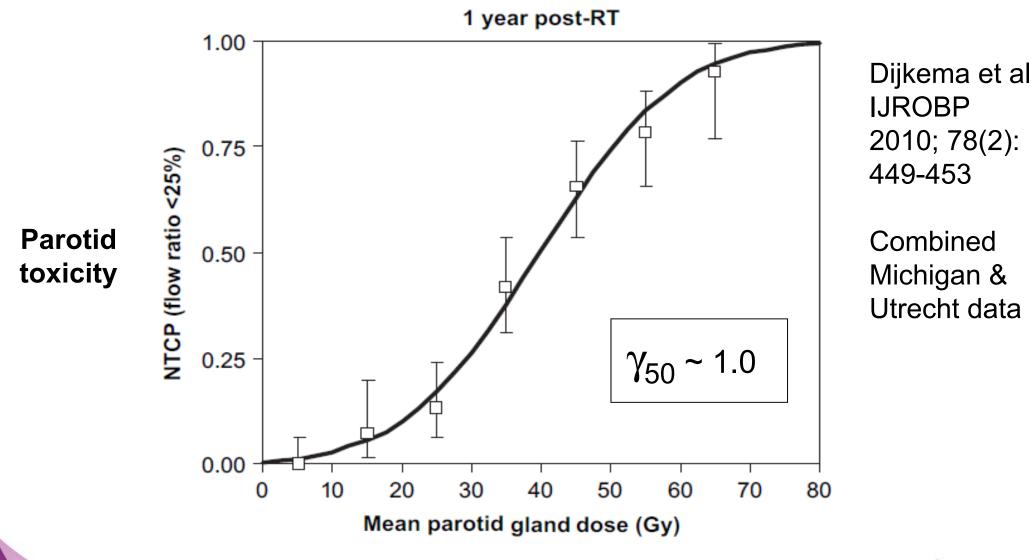

- Prostate cancer, randomised trial
- 70.2 : 79.2 Gy
- 12% dose diff
- Zietman et al
- JAMA 2005; 294(10): 1233-9

• (Used protons in both arms)

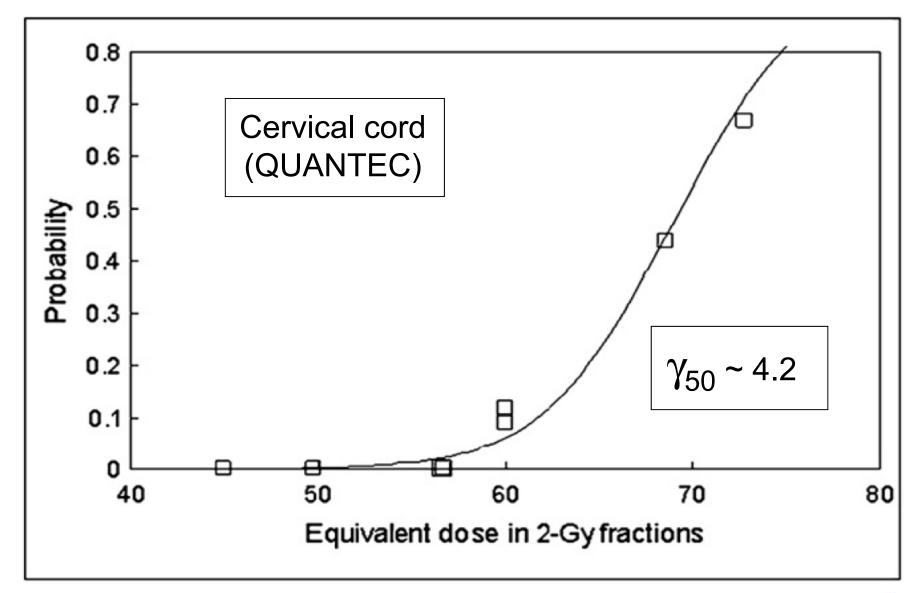

Broadening the band width

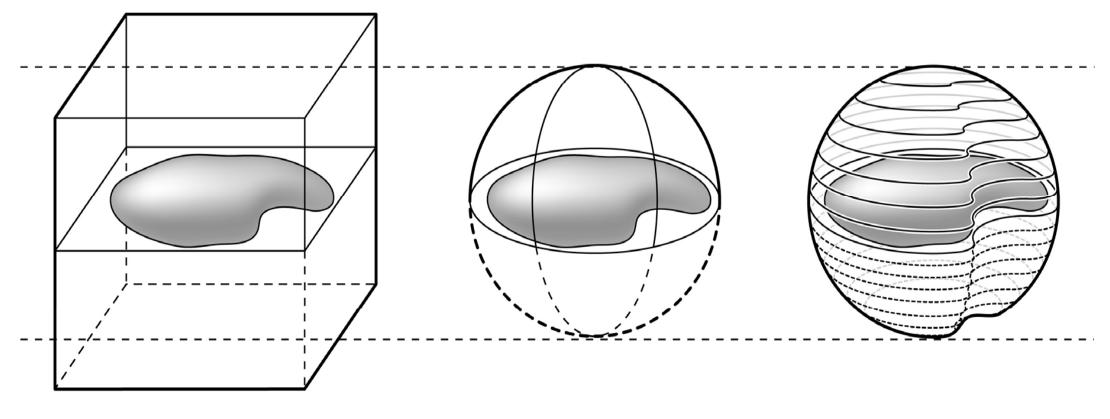

Broadening the band width

Treatment volumes compared

Conventional 'square' plan 3D CRT plan

IMRT plan

Use the best equipment you can!

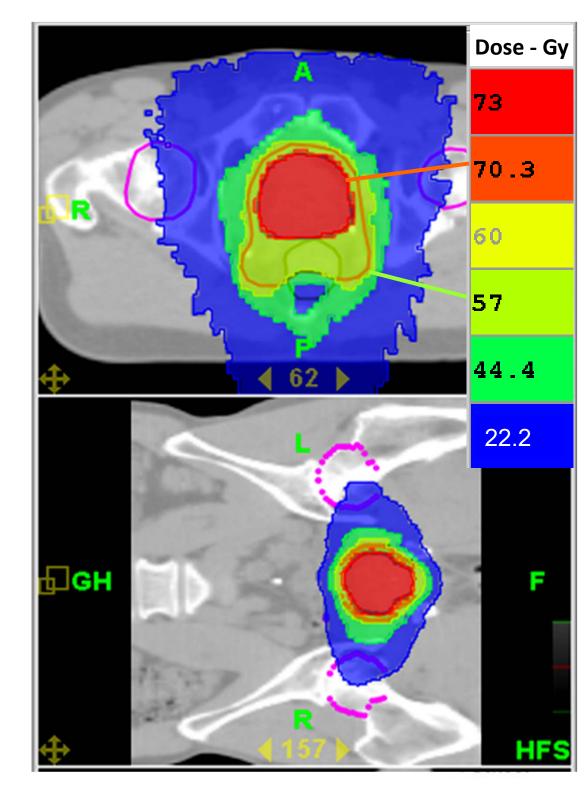

- Old equipment
- Poor maintenance
- Bad choice!

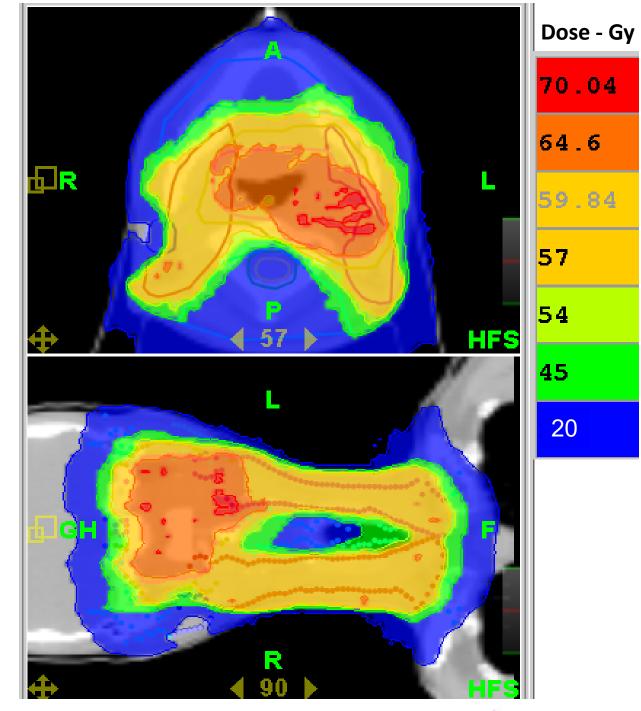

Ca prostate

- Ca prostate
- 74 Gy to primary (37#)
- 60 Gy to seminal vesicles
- Rectal sparing behind PTV

Ca nasopharynx

- 68 Gy to primary (34#)
- 60 Gy to nodes
- Cord dose < 45 Gy
- *No* field junctions
- *No* electrons

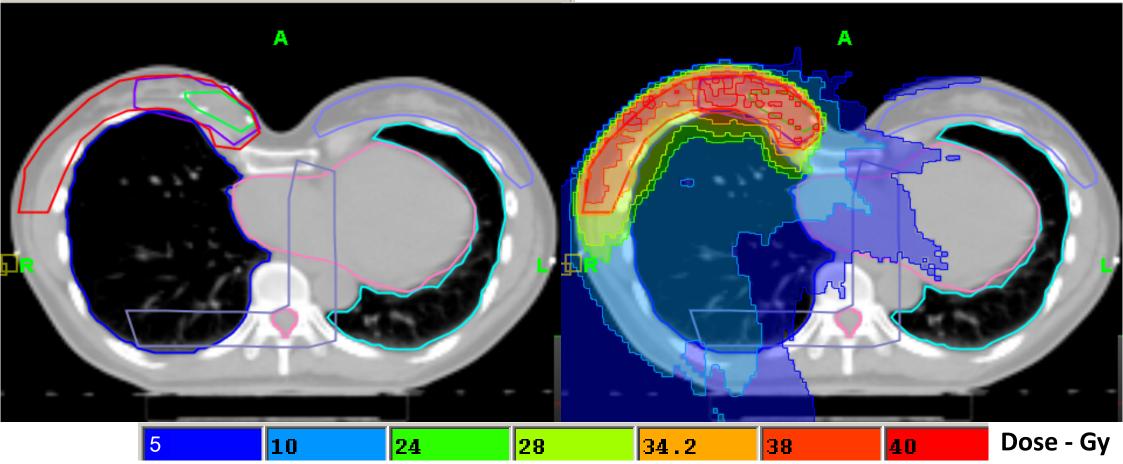

Ca breast

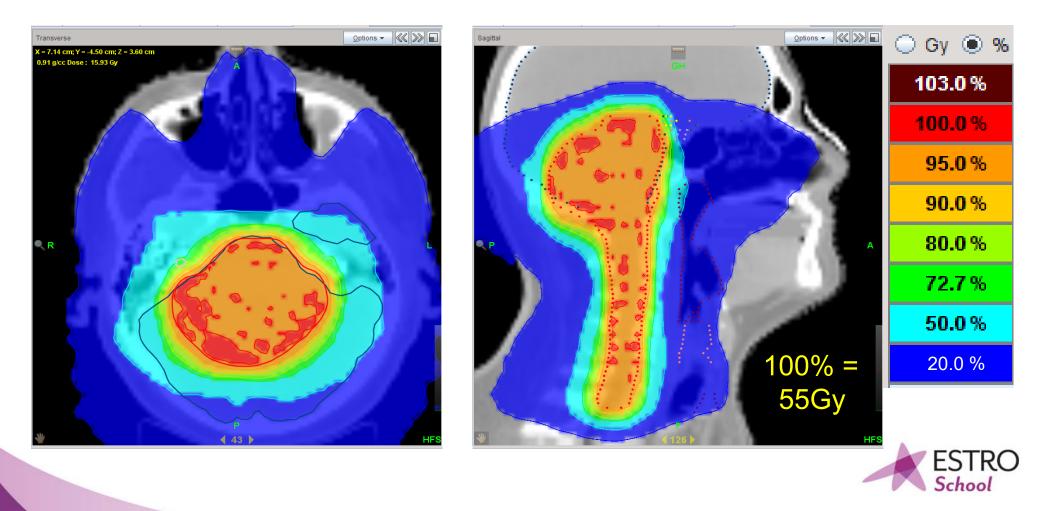

- Ca breast
- Pectus excavatum
- 40 Gy / 15 #

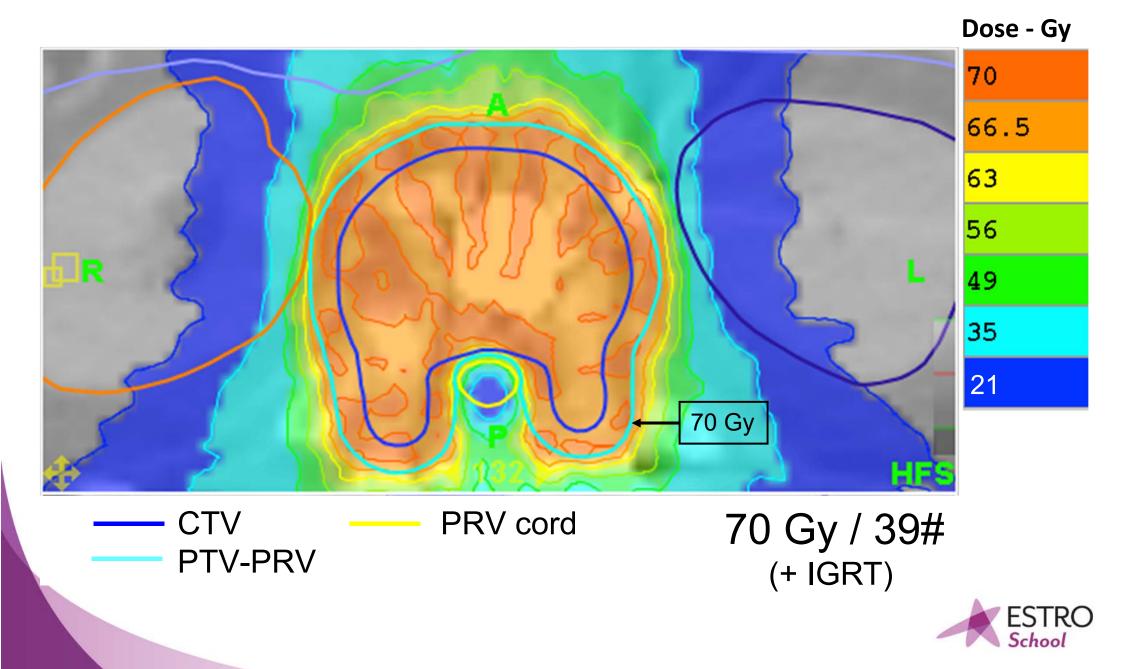

Brainstem + upper cord glioma

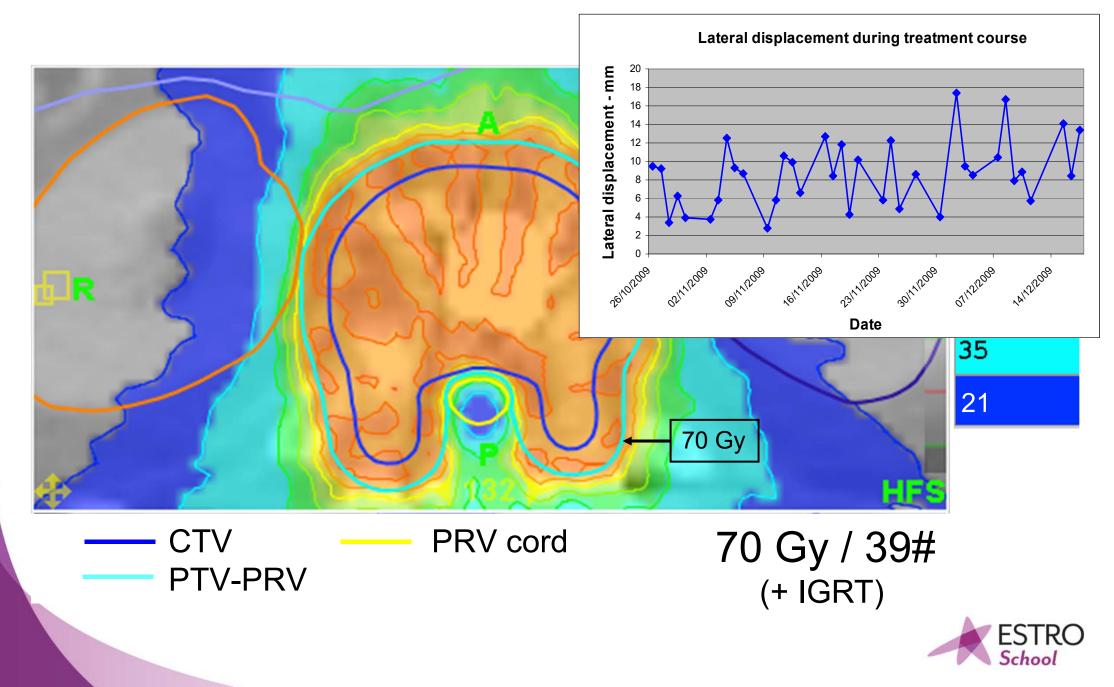

- Low grade glioma (clinical and radiological diagnosis)
- Huge volume, variable body contour
- 55 Gy / 33 #

IMRT for chordoma

IMRT for chordoma

Bandwidth

- Advanced technology is for patient benefit
- Tumour control with minimal toxicity

Conclusions

- Small steps of dose improvement are worthwhile
- Increasing radiotherapy band width requires modern treatment approaches

- Attention to detail translates into clinical advantage for patients
- Lots more to do ...

Extras

Table 1. Normal tissue end points and tolerance parameters

- Values of LKB parameter 'n'
- Describes architecture
- Small value = serial
- Large value = parallel
- Spinal cord n = 0.05
- Lung n = 0.87

Computer-Aided Treatment Planning

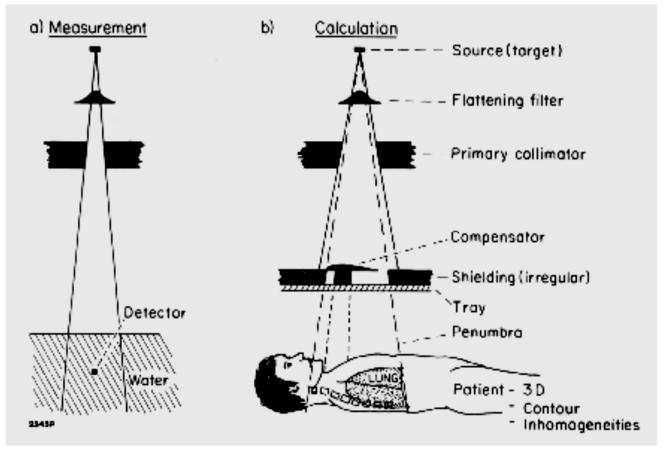

- Patient-specific
 - Delineation of disease
 - Treatment optimization
- Requirements:
 - Anatomical information
 - Simulate treatment approach
 - Estimate dose in vivo under all treatment conditions
- TPS has a long-established role in image interpretation, segmentation, beam placement and shaping.

Dose Calculation Problem

Relate dose calculation in patient to beam calibration conditions

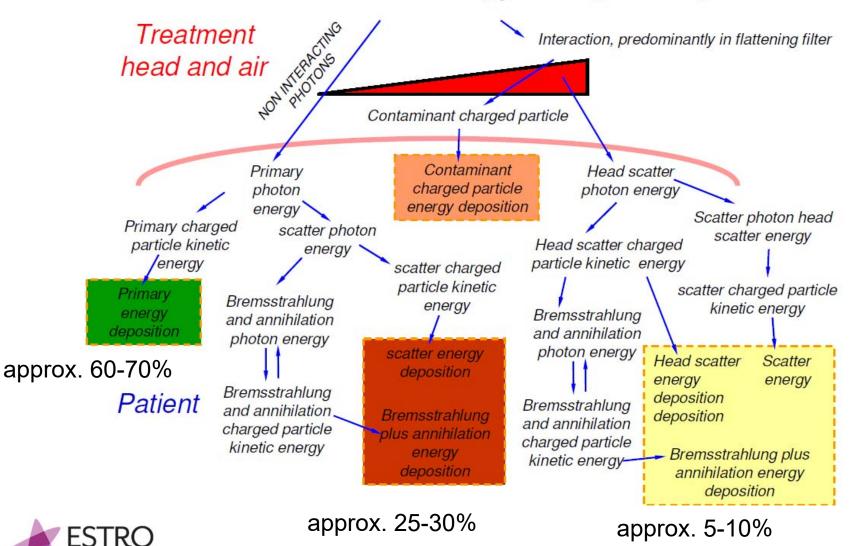

Departice Papanikolaou, et al- 2004 - AAPM Task Group 65

Complexity of dose calculation

Photon radiant energy exiting the target

Expectations

- More demanding treatment techniques require more accurate and predictive dose calculations.
- ICRU 83 recommendation:
 - RTP systems must estimate absorbed dose accurately for:
 - Small fields
 - Tissue heterogeneities
 - Regions with disequilibrium
 - especially high energy photons

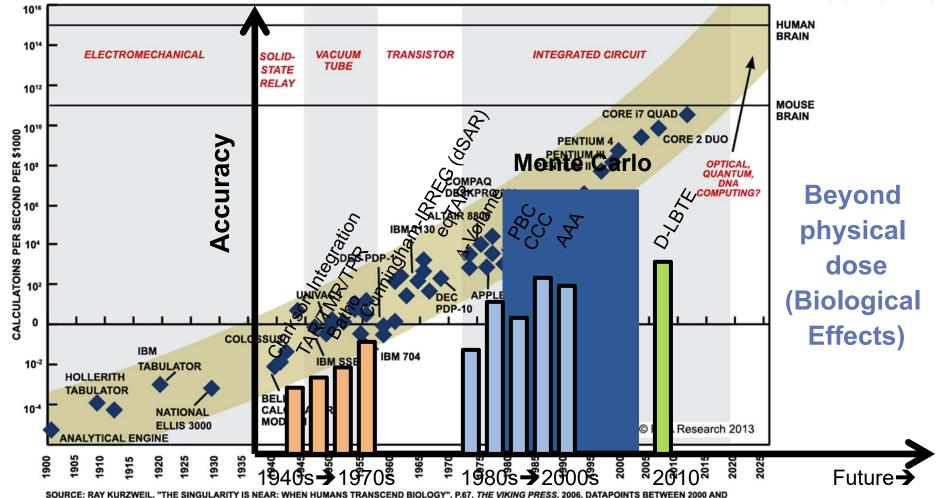

Dose Calculation Methods

Absolute Calibration in water					
Relative Distribution in water					
Tabulate & Interpolate	Model & fit parameters to emulate measurements				
Reconstitute distribution in water by distance, depth, & field size	Compute dose directly from beam geometry & CT images				
Apply correction factors (inhomogeneity, contour)					
"Correction" based methods	"Model" based methods				

Evolution of Photon Beam Dose Algorithms

Adapted from L. Lu IJTCO 1(2) 1 (2013).

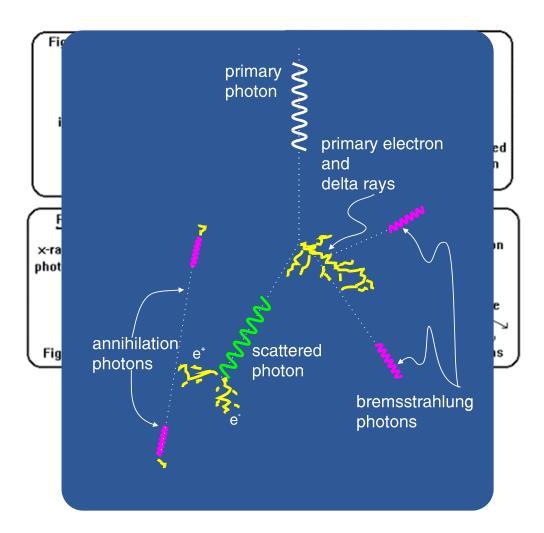

SOURCE: RAY KURZWEIL, "THE SINGULARITY IS NEAR: WHEN HUMANS TRANSCEND BIOLOGY", P.67, THE VIKING PRESS, 2006. D 2012 REPRESENT BCA ESTIMATES.

X-Rays: Energy Deposition in a Nutshell

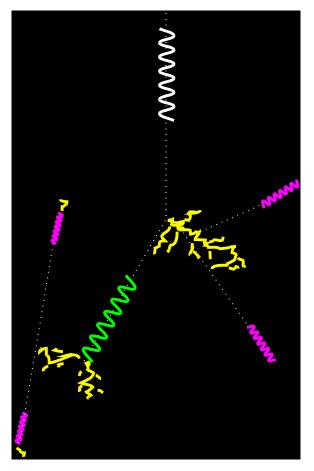

- X rays are ionize *indirectly*.
- On interaction, energy is scattered or transferred to electrons, then absorbed.
- Biological effect depends on the amount of energy absorbed (*dose*).
- Tracking electrons is highly important for accurate dose calculations.
- One treatment (2Gy) requires
 ~10⁸⁻⁹ incident x rays per mm^{2.}

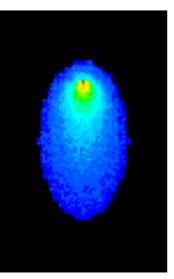

Dose Spread Kernel

Mackie *et al*, PMB **33**(1) (1988).

One incident photon interacts at a point

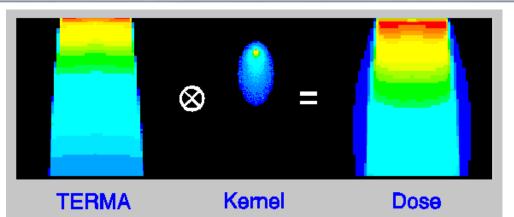

Method: Convolution/Superposition

$$D(\vec{r}) = \iiint \phi(\vec{r}') K_{3D}(\vec{r}', \vec{r}) d^3r$$

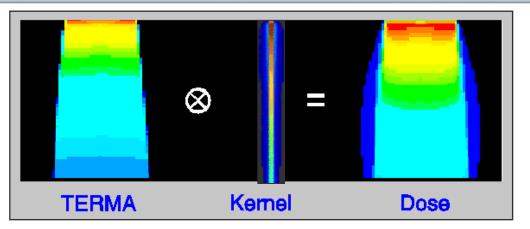

Convolution - Point Kernel

$$D(x, y, z) = \iiint \Phi(x', y', z') K(x - x', y - y', z - z') dx dy dz$$

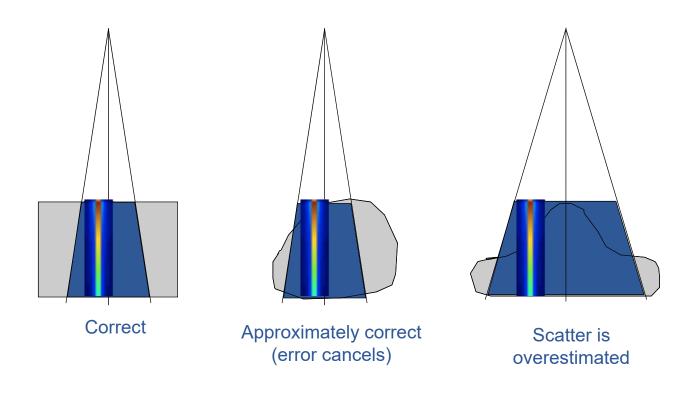

$$D(x, y, z) = \int \int \Phi(x', y', z) K_z(x - x', y - y') dx dy$$

Pencil Kernel Integration

 Pencil kernel methods account for heterogeneity effects along the beam direction but not for lateral effects (penumbra broadening in lungs not modeled).

Pencil beam kernel

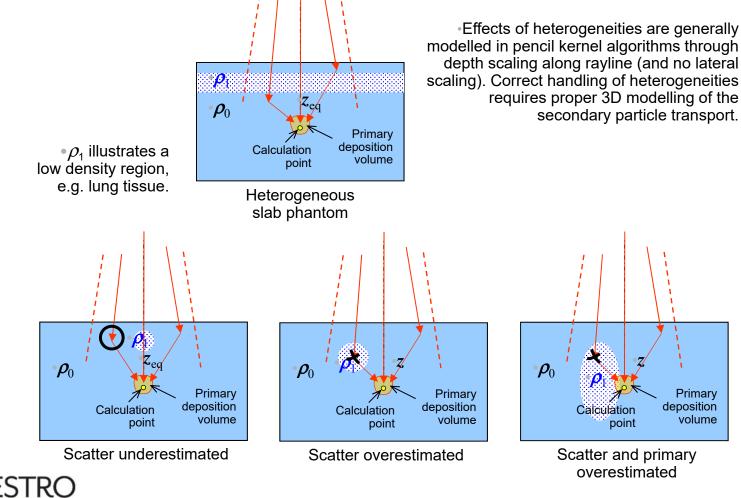

Calculation object approximations

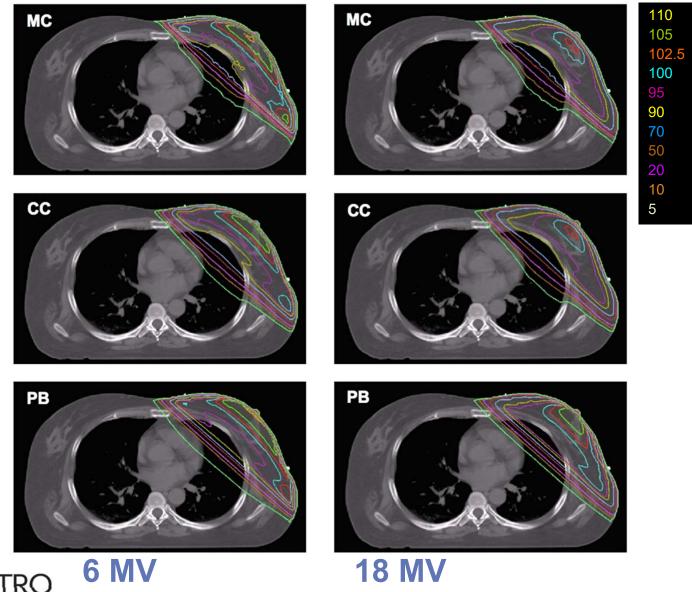

Pencil beam kernel

 Calculation object approximations with heterogeneities

Breast Tangent Example

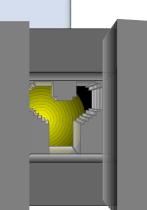

Total Energy Released per MAss (TERMA)

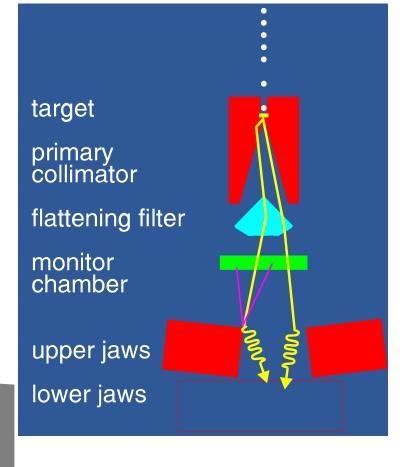

- Radiation is scattered within the treatment head of the accelerator.
- Dose rate "in-air" depends on field size.

$$T(r') = \frac{\mu}{\rho}(\vec{r}')\Psi(\vec{r}')$$

Extra-focal radiation (head scatter) Secondary source

STRO

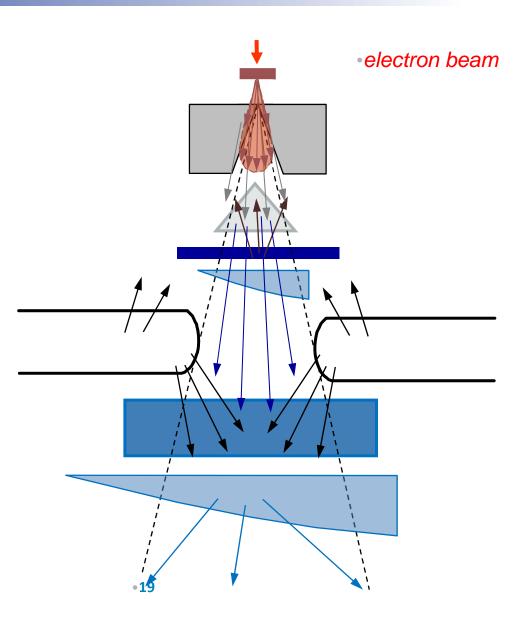

Physics considerations

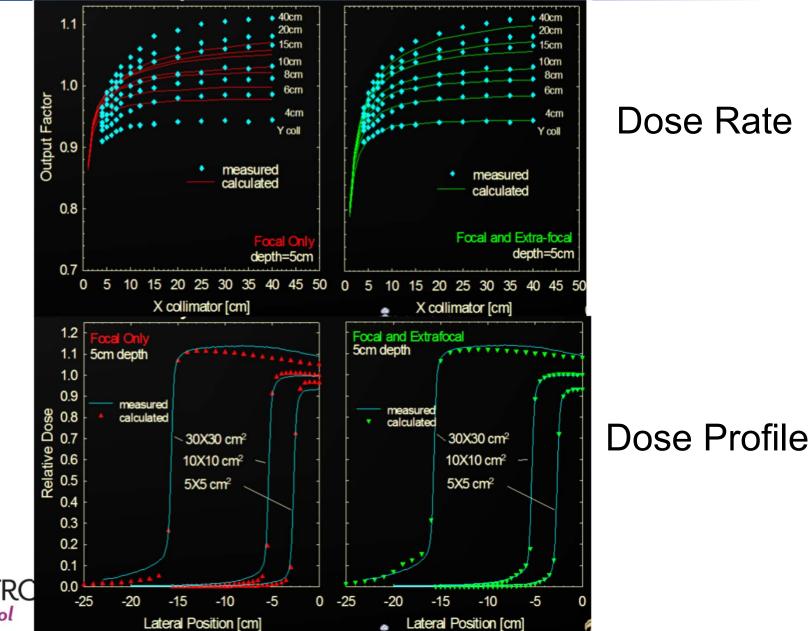

SCATTER SOURCES

- primary collimator
- flattening filter
- collimator scatter
 - (secondary coll., blocks, MLC)
- backscatter into monitor chamber
- wedges, compensators
- blocks, trays,
- □ all effects together determine the incident energy fluence Ψ₀ !!!

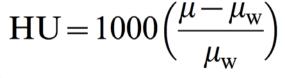

Influence of Head Scatter

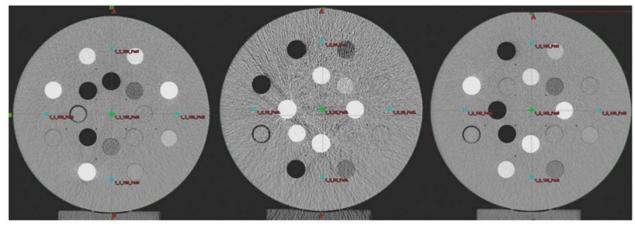

ESTRC

CT Data to Tissue Properties

- Human body: many tissues/cavities
 - Muscle, fat, lungs
 - Bones, teeth
 - cavities (nasal, oral, sinus, trachea)
- Prosthetic devices: metal, plastics
- Different radiological properties.

Images Support Dose Calculations

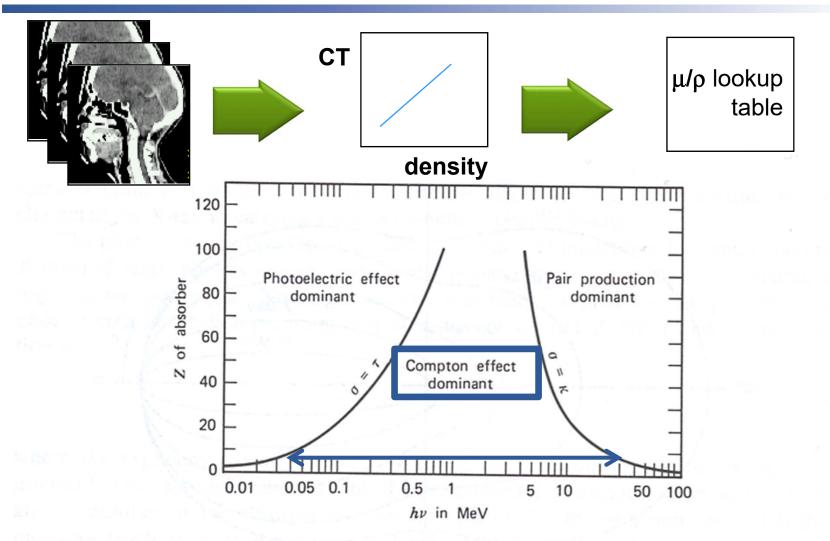

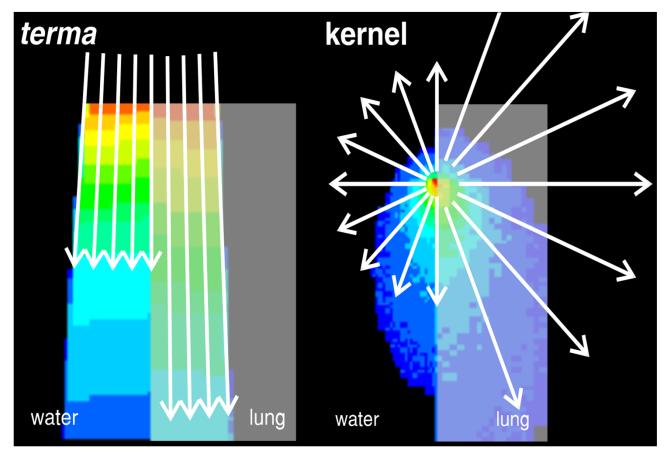

Figure 2-20 The relative importance of the three major types of gamma-ray interaction. The lines show the values of Z and $h\nu$ for which the two neighboring effects are just equal. (From *The Atomic Nucleus* by R. D. Evans. Copyright 1955 by the McGraw-Hill Book Company. Used with permission.)

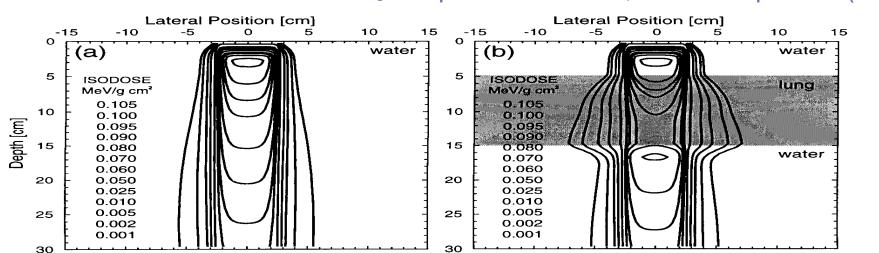

Density Scaling Approximation

 terma and kernel are computed for water and scaled by the average density computed along raylines.

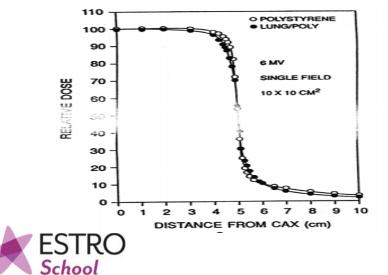

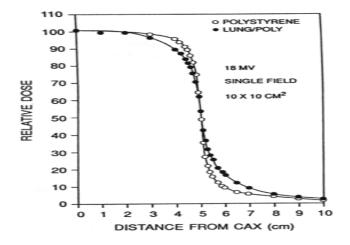

Calculated Data

Measured Data

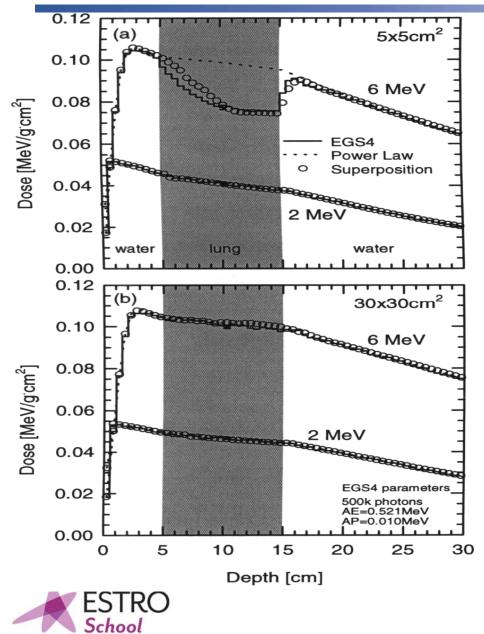

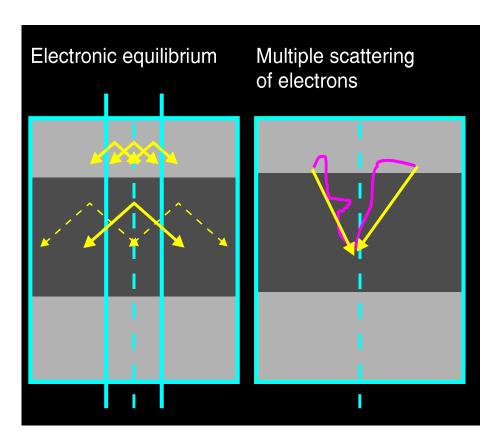

White et al IJROBP 34(5) 1141 (1996)

Papanikolaou et al, AAPM Report 85 (2004)

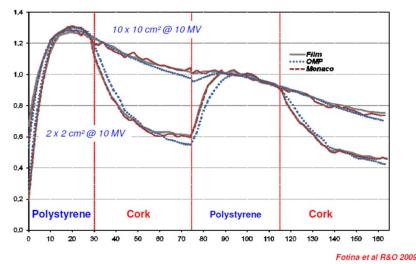

Electronic Disequilibrium

Summary model based & MC approaches

- Point Kernel algorithms much more accurate than Pencil Kernel models - minor deviations versus MC for clinical cases
 - for low density material MC slightly higher accuracy compared to advanced kernel methods
- PK implementations faster than MC
- PK can efficiently use GPU for dose calculations literally in seconds
- MC based dose calculation for high energy photon beams is clinically used

Advanced Kernel Methods

- Collapsed-Cone Convolution, AAA, etc. perform well
 - But Monte Carlo methods are becoming available more widely.

ESTRO School		

Energy Absorbed by an Inhomogeneity

- The absorbed dose within an inhomogeneity, or in adjacent soft tissue is strongly affected by perturbations of the secondary electron fluence generated by the photon beam.
- The absorbed dose in tissue is related to the absorbed dose in water:

med

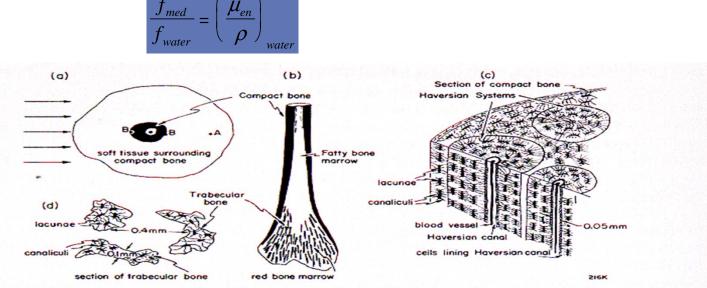

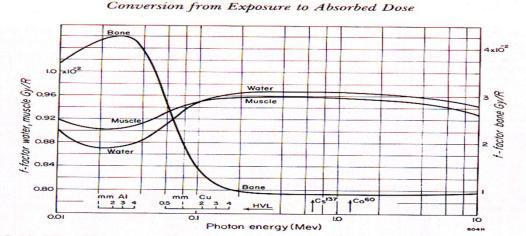

Figure 11-10. (a) Cross section of long bone imbedded in soft tissue. (b) Longitudinal view of lower end of femur. (c) Schematic diagram of Haversian system adapted from Ham (H13). (d) Cross section of trabecular bone.

Energy Absorbed by an Inhomogeneity

287

Figure 8-10. The f-factor as a function of photon energy for water, muscle, and bone taken from data in Table A-7. The auxiliary scale relates the HVL in A1 and Cu to the energy scale.

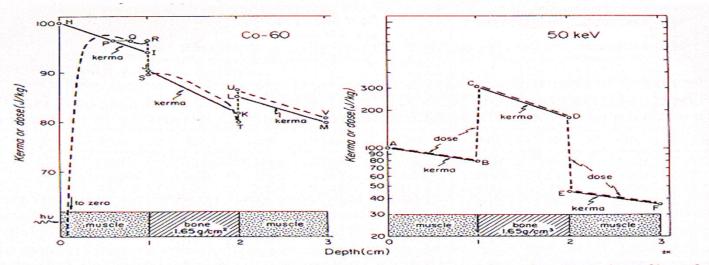

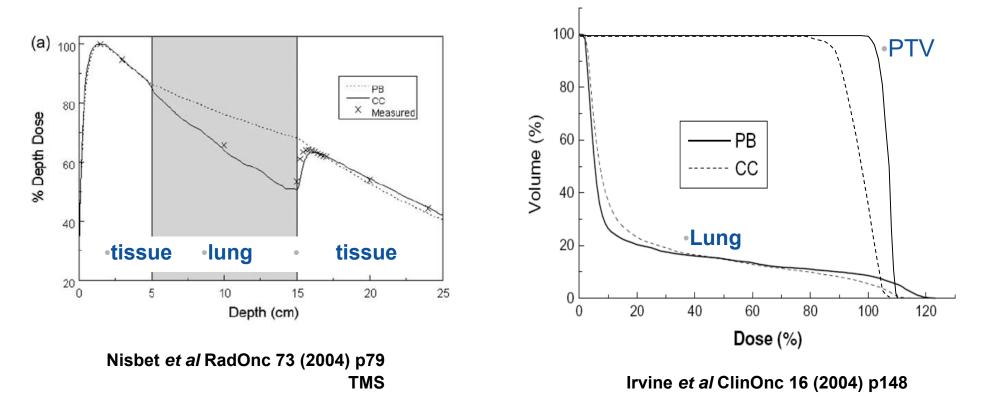

Figure 7-13. Diagram showing kerma and dose in a composite phantom irradiated from the left by cobalt 60 radiation and 50 keV radiation.

BONE

Clinical impact of dose calculation

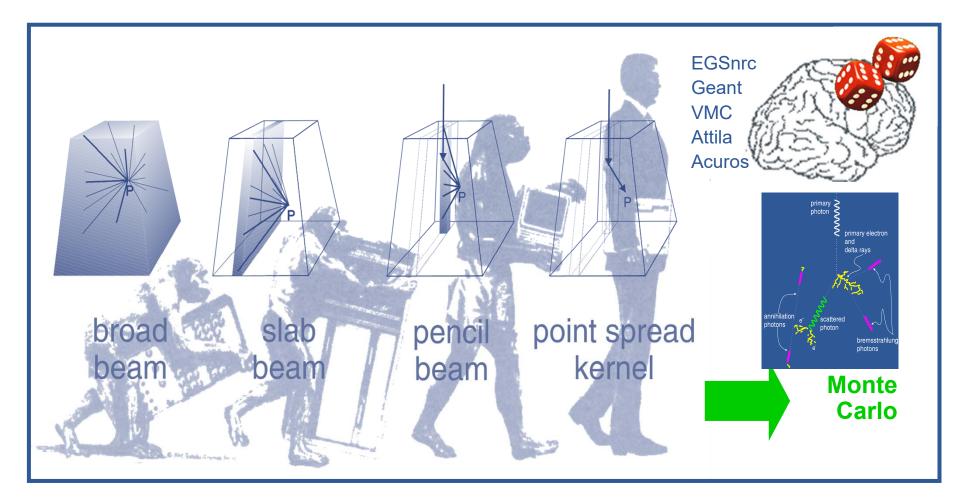

• E.g. inaccurate dose calculation in low density regions (lung)

Summary – Evolution, not Revolution

Modern algorithms are hybrids of deterministic numerical and Monte Carlo methods. They can be expected to predict dose in heterogeneous tissues more accurately

ICRU guidance on planning and prescribing

Neil Burnet

University of Cambridge Department of Oncology, Oncology Centre, Addenbrooke's Hospital, Cambridge, UK

ATP Barcelona 2017

Summary

- Prescribing
- Definition of planning volumes
 - ➢ GTV, CTV, PTV
 - Other volumes
 - Organs at Risk (OARs)
 - Planning organ at Risk Volume (PRV)
- Optimising volumes
- Overlapping volumes
- Questions

The history of radiotherapy

- 1895 Röntgen discovered X-rays
- 1896 first treatment of cancer with X-rays
- 100+ years later the technology has changed!
- ICRU reports are here to help us
- Series began with Report 50 and Supplement 62 (1993 + 1999)
- ICRU 71 (2004) added a few details
- ICRU 83 is designed for IMRT

ICRU guidance

- ICRU 83 specifically dedicated to IMRT
- Recommendations for prescribing changed
- Emphasises need for clear nomenclature for different targets, both GTV and CTV
- Introduces some specific aspects of reporting of dose to normal tissues

ICRU REPORT	Volume 10 No 1 2010	ISSN 1473-6691 (print) ISSN 1742-3422 (online)
AT 83	Journal o	of the ICRU
	ICRU REPORT 83 Prescribing, Record Photon-Beam Inten Radiation Therapy (
Journal of the ICRU Volume	OXFORD JOURNALS	
ume 10 No 1 201	OXFORD UNIVERSITY PRESS	INTERNATIONAL COMMISSION ON RADIATION UNITS AND MEASUREMENTS

ICRU guidance

- Advice on dose planning in the build up region or if PTV extends outside the body contour is given
- Concept of adaptive review introduced
 - > Possible to review dose and dose change during treatment
- Comments on QA given
 - > *Not* discussed here

- Key changes in prescribing
 - Prescribe to *median dose* rather than ICRU reference point
 (≈ isocentre dose)
 - median dose = $D_{50\%}$
 - = dose to 50% of the volume
 - Report *near-maximum* and *near-minimum*, rather than actual max & min
 - Still need to be aware of target coverage

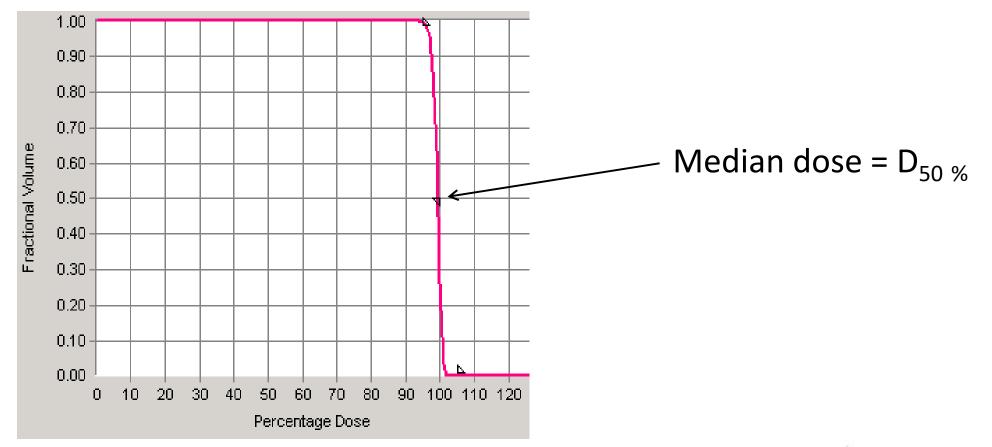

- Specify median dose $D_{median} = D_{50\%}$
 - Corresponds best to previous ICRU reference point dose
 (≈ isocentre dose)
 - Often close to mean dose
 - ➢ Not influenced by 'tails' on the DVH
 - Accurately calculated in TPSs
 - Possible to move from isocentre dose (CRT) to median dose (IMRT) with confidence

• NB useful to add units e.g $D_{50\%}$ or $V_{20 Gy}$

• Median dose = $D_{\text{median}} = D_{50\%}$

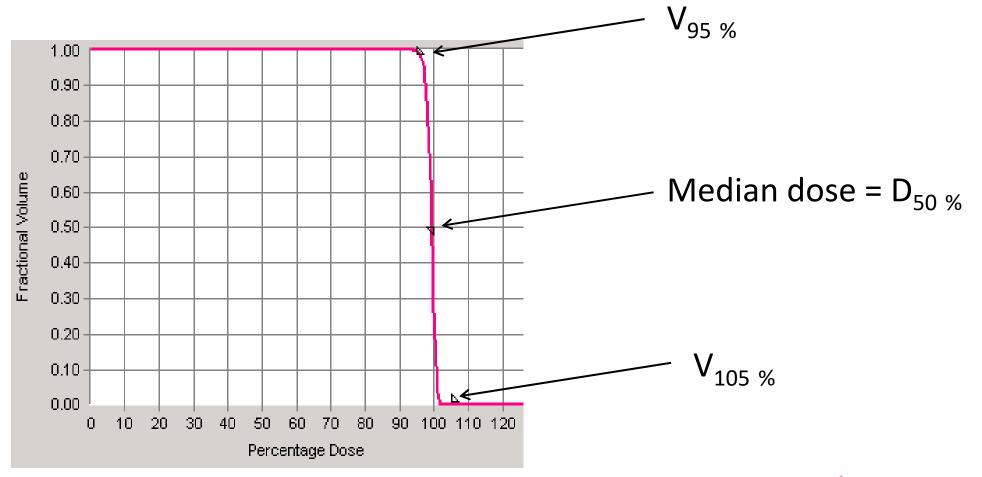

- Prescribing to median dose without some restriction on the slope of the target DVH could allow a shallow slope and low target minimum dose
- Need some agreement on minimum acceptable
 - > At least 99% of the volume $(D_{99\%})$ to receive>95% of dose
 - At least 98% of the volume ($D_{98\%}$) to receive>95% of dose
- Limit on maximum also needed, for example
 - $\blacktriangleright \quad \text{Less than 1\% of the volume >105\% of dose}$

• Dose constraints (objectives) for min & max included (and median)

D_{99 %} >95% (of prescription dose)

V_{95 %} >99% (of target volume)

• Dose constraints (objectives) for min & max included (and median)

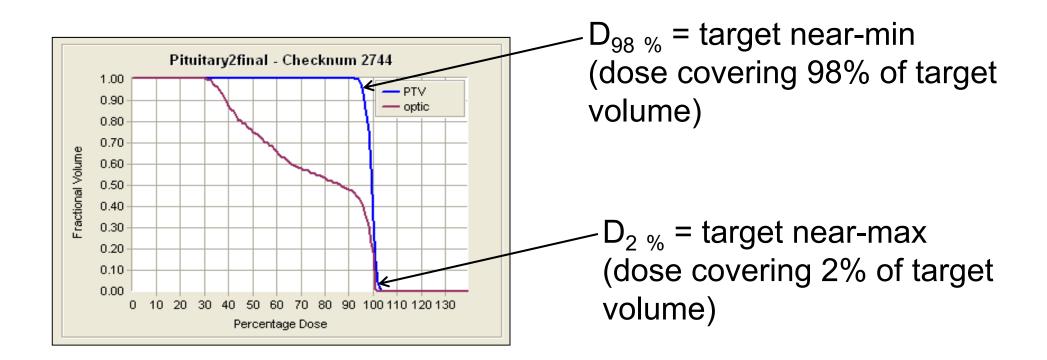

- Report near-maximum and near-minimum in target volume, rather than actual max & min
 - \succ D_{2 %} for near-max, D_{98 %} for near-min

- Report near-maximum and near-minimum in target volume, rather than actual max & min
 - \succ D_{2 %} for near-max, D_{98 %} for near-min

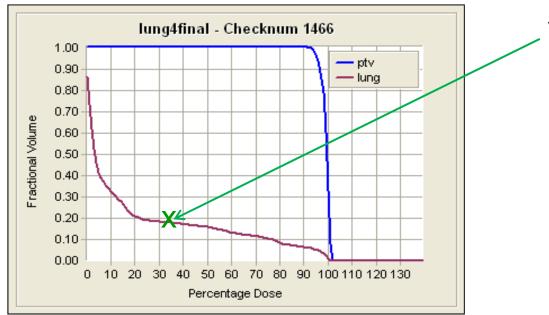

- Clinical relevance of minimum (near-min) dose point may depend on its position within the PTV
 - Minimum dose in edge of PTV may be of marginal significance
 - Minimum dose in centre (in GTV) may be rather important

- Concept of using dose volume histograms for dose specification is introduced in ICRU 83
 - Dose-volume prescribing in place of dose
 - Dose-at-a-point specification is retained for purposes of comparison
- Contains worked examples, which may be helpful

- Add volume parameters where relevant
 - \succ e.g. V_{20 Gy} for lung

 $V_{20 \text{ Gy}}$ Relates to clinical outcome NB $V_{20 \text{ Gy}}$ = $V_{33 \%}$ (for 60 Gy)

- Add volume parameters where relevant
 - \blacktriangleright e.g. V_{20 Gy} for lung
- For parallel structures, worth reporting more than 1 dose point
 - i.e. moving towards dose-volume reporting

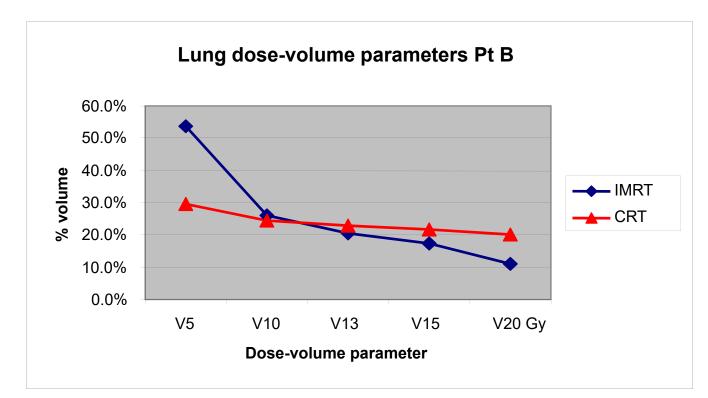

- Essential to add units e.g $D_{50\%}$ or $V_{20 Gy}$
 - $D_{50\%}$ = dose covering 50% of the target volume
 - $V_{20 \text{ Gy}}$ = volume receiving 20 Gy (or less)

Lung doses

- 2 plans compared
 - IMRT : 'CRT'
- Mean lung dose same
 = 9 Gy
- DVH different

• In reporting, the DVH (or some points on it) may be useful

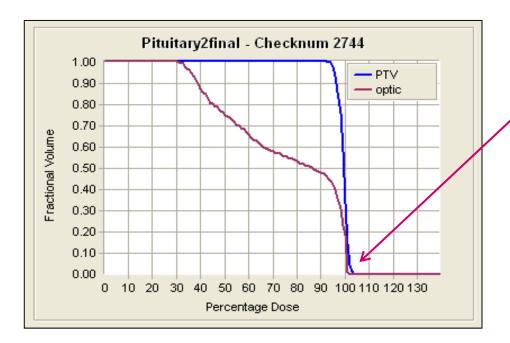

- For serial organs, maximum (near-max) dose is relevant parameter
 - > ICRU recommends D $_{2\%}$ rather than D $_{Max}$ (D $_{0\%}$)
 - Overcomes problem of defining (knowing!) what volume of the structure is important
 - Note that $D_{2\%}$ not validated (yet); caution given !
 - ➢ But ... it is logical
 - However, effect will depend on total volume of structure
 - > In gynae brachtherapy often use $D_{2 \text{ cm}^3}$

Prescribing

- Report near-maximum
 - \succ D_{2 %} for near-max

D_{2 %} = OAR near-max (dose covering 2% of target volume)

No PRV used here because

- OAR enclosed within PTV
- dose < OAR tolerance

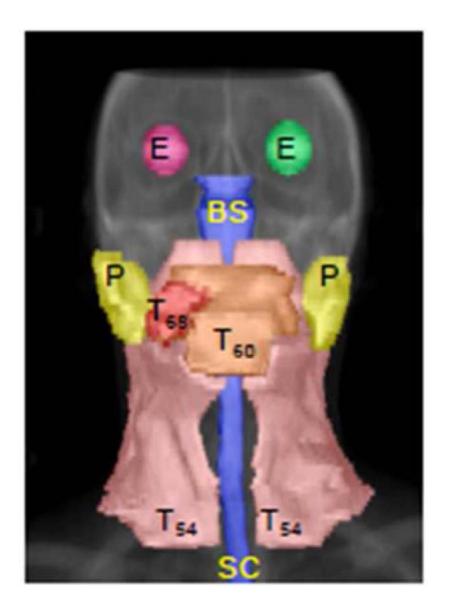

ICRU guidance

- ICRU 83 mentions the possibility of adding some additional parameters relating to dose
- Optional, but may become interesting
 - Homogeneity Index & Conformity Index
 - EUD Equivalent Uniform Dose
 - ➤ TCP, NTCP
 - Probability of uncomplicated tumour control (PUC)
- Some details at end of lecture notes

Target volumes

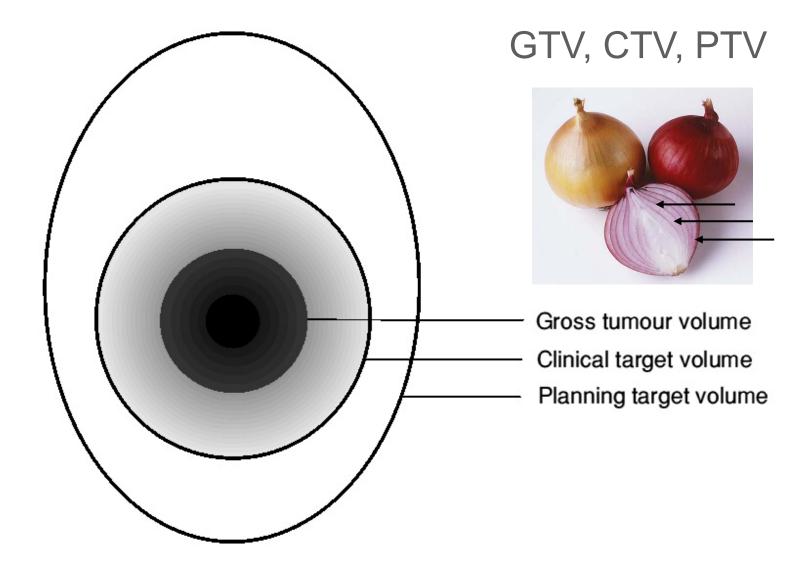

Target volumes

ICRU 50
 target
 volumes

The PTV can be eccentric

Summary

- GTV is tumour you can *See Feel Image*
 - Outline what you see !
- CTV contains GTV and/or sub-clinical disease
 - ➢ Tumour *cannot* be seen or imaged
 - Can be individualised to anatomy
- PTV is a geometric volume
 - Ensures prescription dose is delivered to the CTV
 - Includes systematic + random error components

Target volumes - PTV

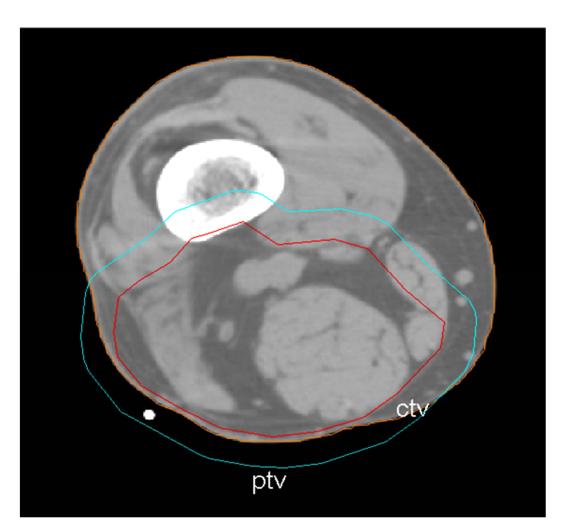

- PTV is a geometric concept designed to ensure that the prescription dose is actually delivered to the CTV
- In a sense, it is a volume in space, rather than in the patient
- PTV may extend beyond bony margins, and even outside the patient
- *Systematic* and *random* errors need to be quantified to produce the PTV margin
 - $PTV = 2.5\Sigma + 0.7\sigma$

Target volumes - PTV

- PTV extends outside the patient
- NB problem of IMRT optimisation
 - in the PTV outside the patient
 - \succ in the build up region

Other volumes - TD

- Treated volume TD
- Recognises that specified isodose does not conform perfectly to the PTV
 - Can be larger or smaller
- $D_{98\%}$ could be used
- Needs to report size, shape & position relative to PTV
 - Can help evaluation of causes for local recurrences

Other volumes - RVR

- Remaining Volume at Risk RVR
- Volume of the patient excluding the CTV and OARs
- Relevant because unexpected high dose can occur within it
- Can be useful for IMRT optimisation
- Might be useful for estimating risks of late carcinogenesis

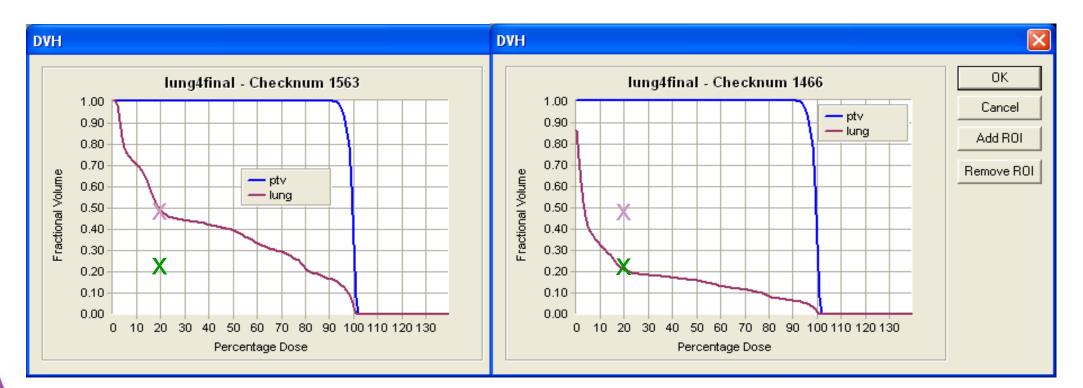

- Organs at Risk are normal tissues whose radiation tolerance influences
 - treatment planning, and /or
 - prescribed dose
- Now know as OARs (not ORs)
- Could be any normal tissue

- Best available data is given in the QUANTEC review
- Marks LB, Ten Kaken R, and guest editors Int. J. Radiat Oncol Biol. Phys. 2010; 76; 3 (Suppl): S1 - 159

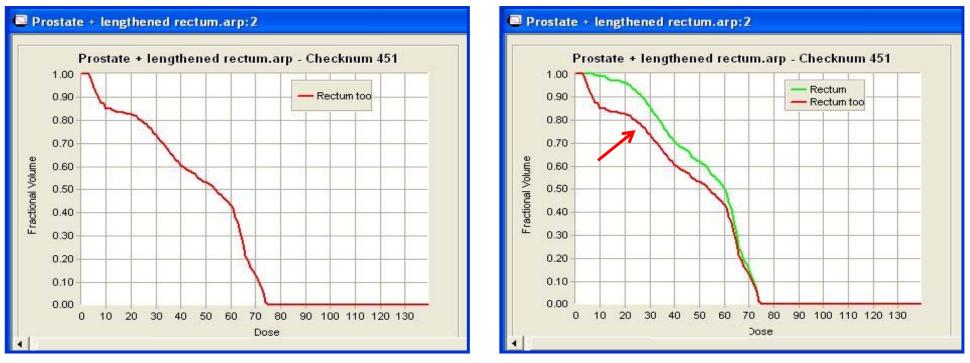

For parallel organs, comparison between plans, patients or centres requires the *whole* organ to be delineated, according to an agreed *protocol*

Better !

Whole lung not outlined

- For other parallel organs, over-contouring may lead to DVHs which appear better but are incorrect
- Rectum– needs clear delineated, according to an agreed protocol

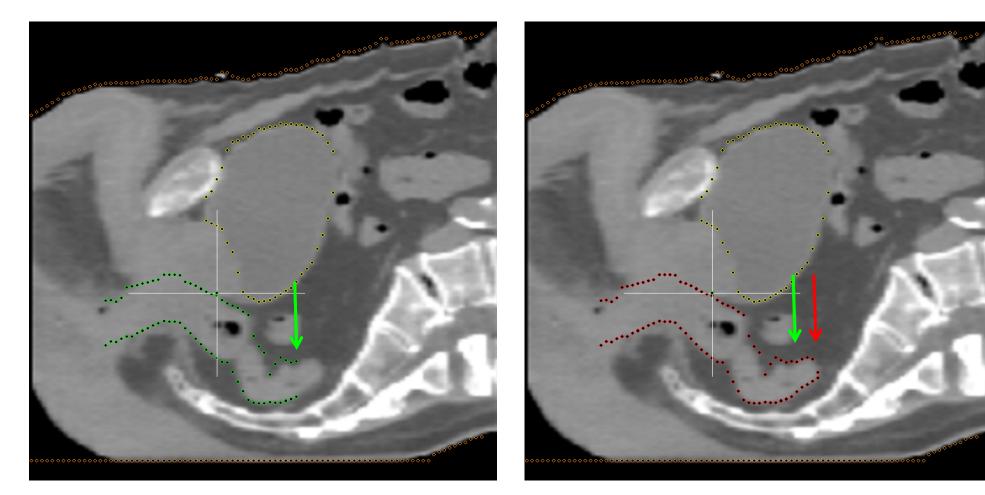

Rectum 'over-contoured'

'Better' DVH is incorrect

• Rectum-clear delineation, according to an agreed protocol

Rectum correct

Rectum on 4 slices more

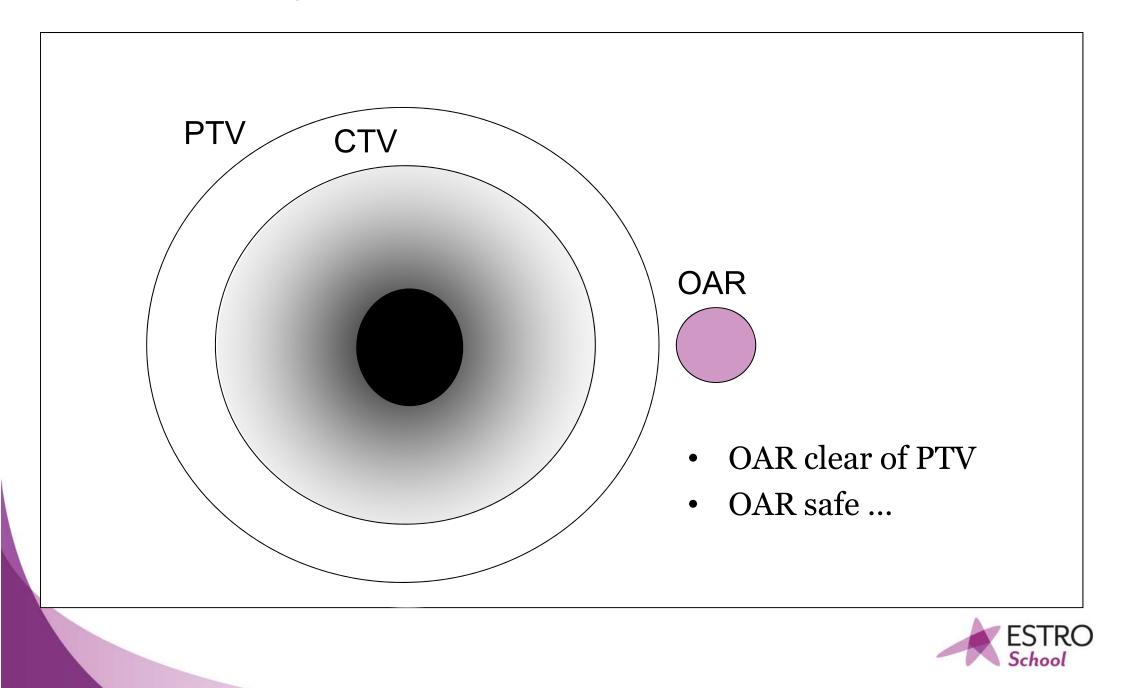

Target volumes – OARs + PRVs

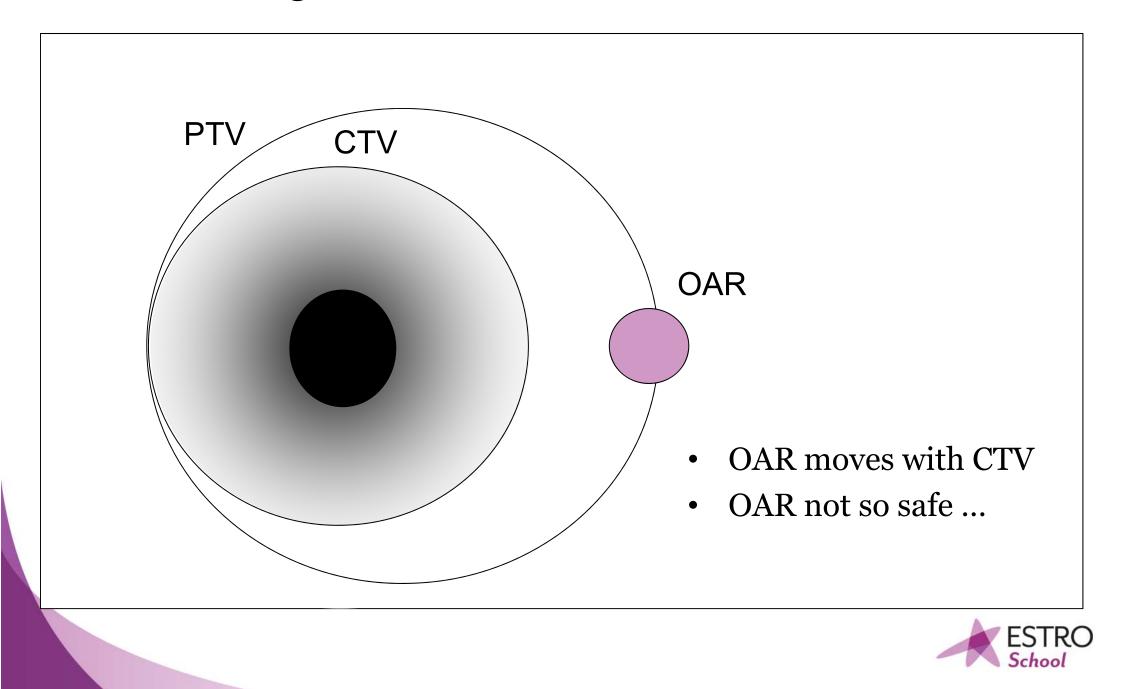

- Uncertainties apply to the OAR ... so a 'PTV margin' can be added around it to give the Planning organ at Risk Volume (PRV)
- But ... the use of this technique will substantially increase the volume of normal structures
- May be smaller than PTV margin
 - Component for systematic error can often be smaller

Target volumes – OARs + PRVs

Target volumes – OARs + PRVs

Target volumes – PRV

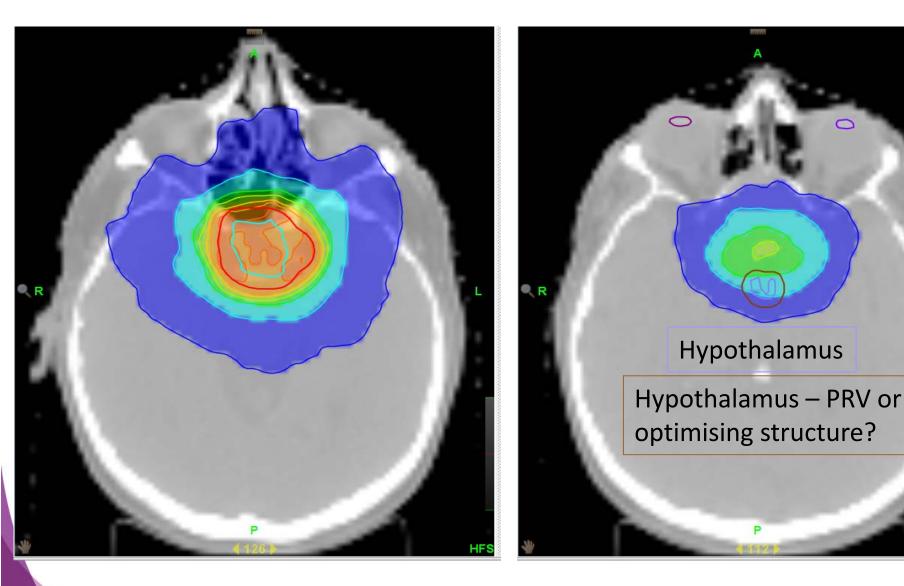

- The use of a PRV around an Organ at Risk is relevant for OARs whose damage is especially dangerous
- This applies to organs where loss of a *small* amount of tissue would produce a *severe* clinical manifestation
- A PRV is relevant for an OAR with serial organisation (almost exclusively)
 - Spinal cord
 - Brain stem
 - Optic pathway
- A PRV is *not* the same as a plan optimising volume

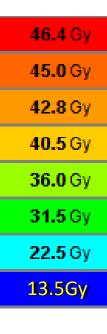

Target volumes – PRV or optimising structure?

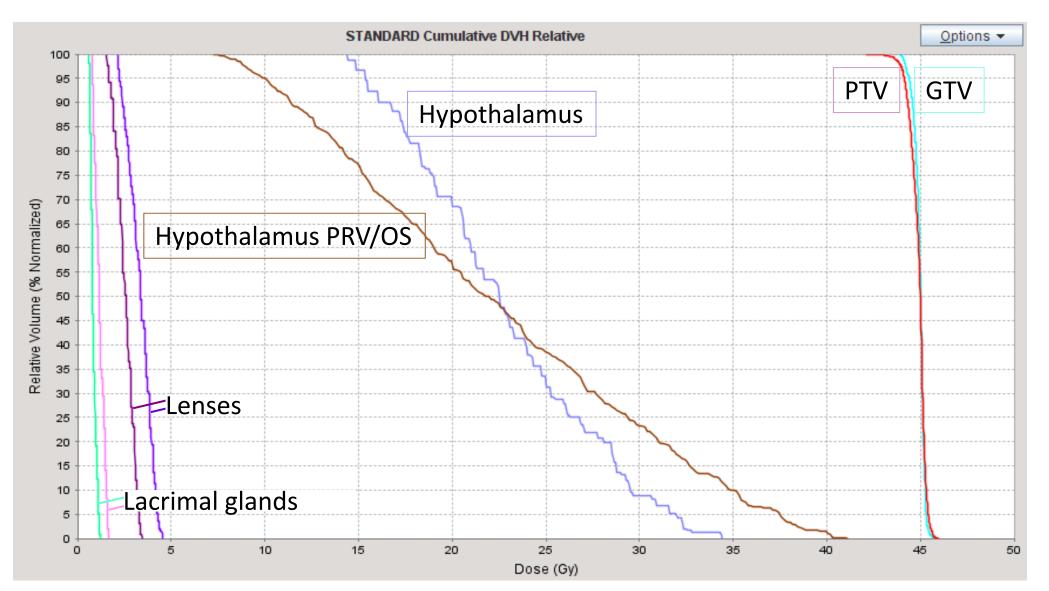

Hypothalamus DVHs

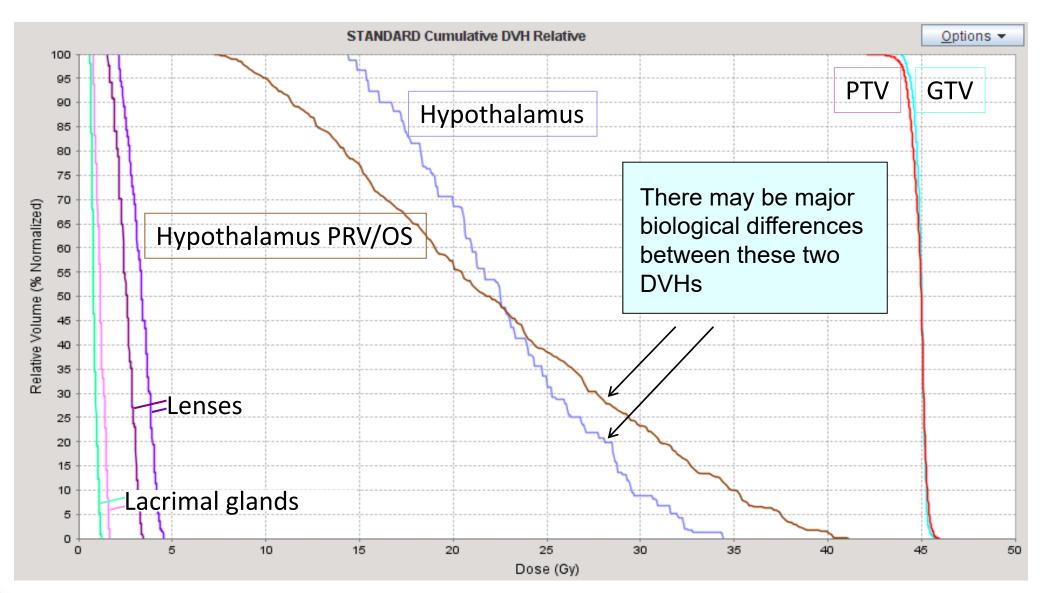

Hypothalamus DVHs

Hypothalamus DVHs

Planning dose limits

Planning limits

- Planning dose limits are either
 - > Objectives
 - Constraints = absolute
- Important to consider dose limits as one or other type
- Not quite as easy as it seems to set values for them

Planning constraints

- Objectives
 - What we would *like* to achieve
 - We should try to meet them
 - Allow greater dose (or volume) if no alternative
- Constraints
 - What we *must* achieve
 - These are like a 'wall'
 - We must meet them
 - Absolute limits (e.g. no areas of higher dose)

Planning constraints

- For a 'class solution' it should be possible to set good values
 - Values are based on experience from other cases
 - > Typically apply to most of the patients
 - > Not fully individualised

Planning constraints

- For an uncommon (challenging) case, there may be no experience
 - > Objective
 - If set too low allows computer (planner) to accept plan less good than is really possible
 - If set too high then effectively fail to guide the plan
 - Constraint
 - If set too low, then drives the plan away from optimal solution
 - If this is a normal tissue constraint then typically drives down dose in PTV
 - If too high then may not protect normal tissue

Prioritising

- Constraints also need to be *prioritised*
 - Primary constraint = PTV dose
 - Primary constraint = normal tissue absolute constraint
 - Balance of prioritisation for different normal tissues may be needed
 - Different solutions may be possible

Planning sheet

- Pre-printed sheet for CNS cases
- 2 clear columns

• Absolute = constraint

Objectives and Priorities

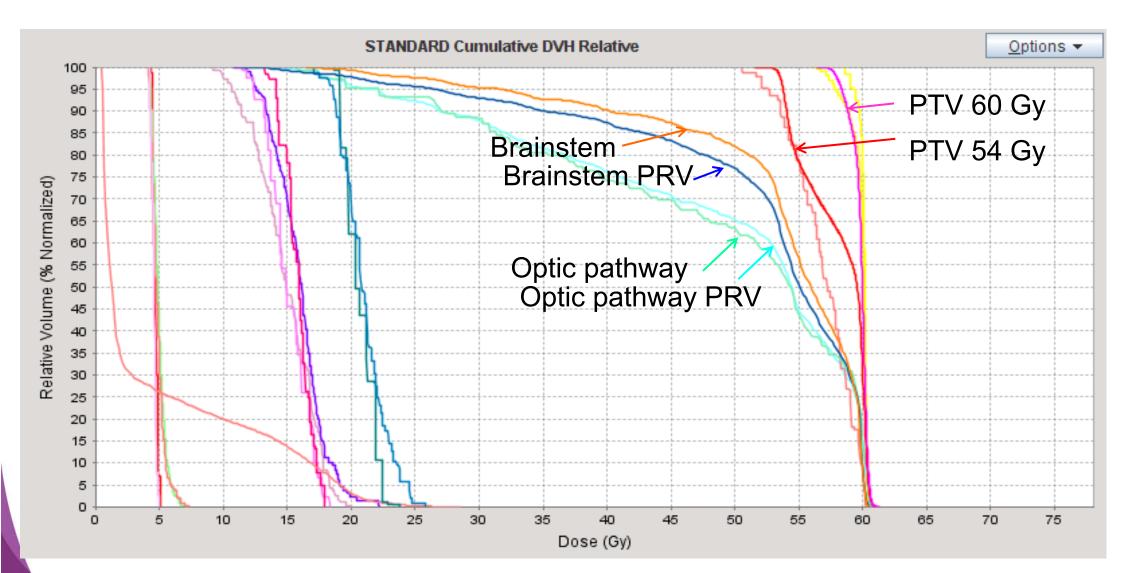

Glioblastoma

Dose - Gy

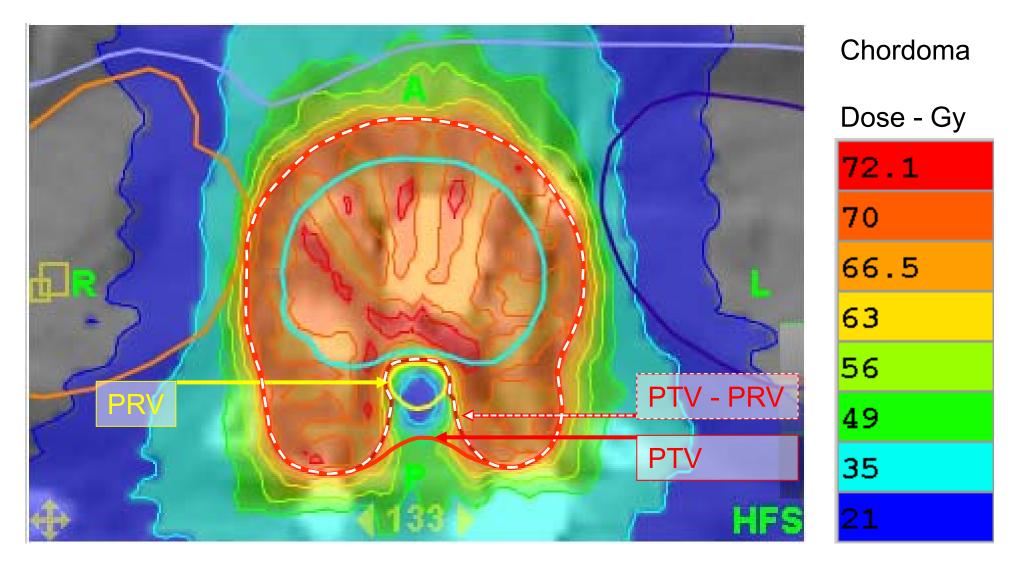

- Objectives for PTV doses
- Constraint for max dose in optic nerves
- Prioritise PTV > PRV

GBM - IMRT plan DVHs

Constraints and Priorities

- Absolute dose constraint for cord PRV (58.6 Gy for 70 Gy/39#)
- Priority PRV > PTV

Target volumes – overlaps

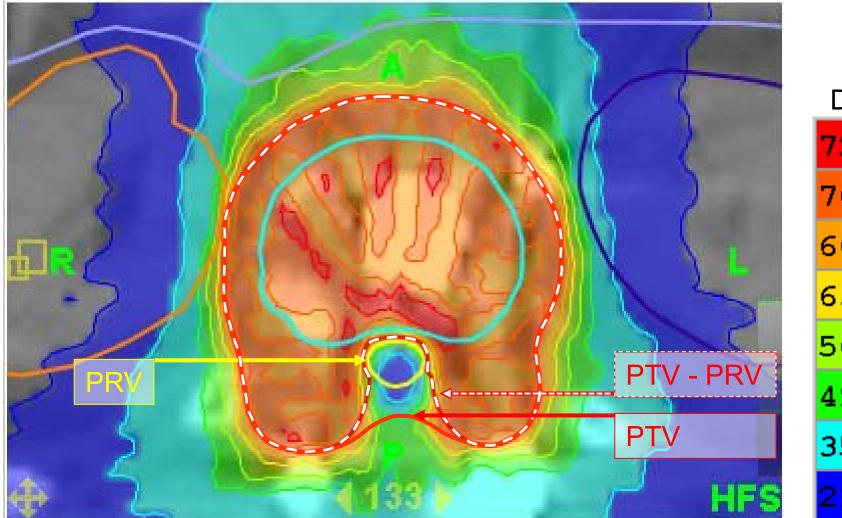

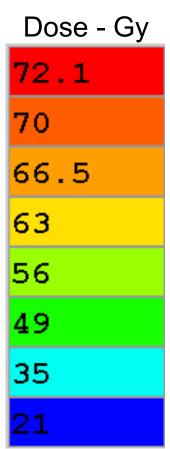

Target volumes – overlaps

- There are always occasions when the PTV and OARs/PRVs overlap
- What is the best strategy?
- The planning concept has changed between ICRU 62 and 83
- In fact it changed completely in ICRU 83
- ICRU 62 edit PTV (even CTV) fine for CRT
- ICRU 83 *do not* edit better for IMRT

Target volumes – overlaps **ICRU 83** ICRU 83 approach for PTV • **IMRT** Add 2nd volume avoiding • Ideal PTV overlap CTV **PTV-PRV** Specify priorities and • doses Cord PRV

- PRV essential here to protect cord (so is IGRT)
- Priority PRV > PTV

- Advantages of not editing PTV (ICRU 83)
 - Clear to planner what is required
 - Clear on subsequent review what target was intended
 - Doses can be adjusted by dose constraints
 - More clearly matches the real clinical objectives
 - Ideal for IMRT delivery

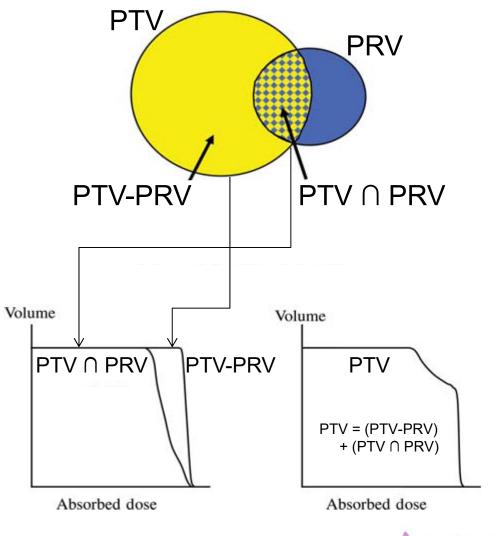

- Overlapping volumes requires:
 - Very clear objective setting
 - Good communication between clinician & planner
 Dialogue (i.e. <u>2 way</u> communication) is recommended !
 - Use of optimiser to deliver different doses to different parts of the target
 - May make assessment of plan using DVH for the PTV more difficult

From ICRU 83

- Review DVHs carefully
- Overall, more robust method

Take home messages

- Median dose closest to 'old' ICRU isocentre prescription point
- Contour OARs carefully with protocol
- Add PRV around CNS structures if giving high doses
- Overlaps can occur between PTV and OAR (or PRV)
 - > Do not edit
 - Construct additional exclusion volumes
 - ➢ Use IMRT

Radiation oncology - a team effort

Additional resources

ICRU guidance

- ICRU 83 mentions the possibility of adding some additional parameters relating to dose
- Optional, but may become interesting
 - Homogeneity Index & Conformity Index
 - EUD Equivalent Uniform Dose
 - ➤ TCP, NTCP
 - Probability of uncomplicated tumour control (PUC)

Homogeneity Index

• Designed to show level of homogeneity

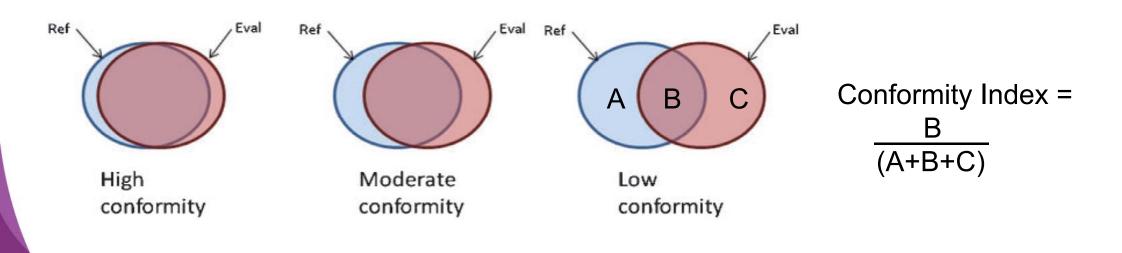

$$HI = rac{D_2 \ \% - D_{98} \ \%}{D_{50} \ \%}.$$

- Difficult to relate to experience (for me)
- Requires further investigation

Conformity Index

- Conformity index
 - Describes how well high dose isodoses 'conform' to the PTV
 - Compares specified isodose to PTV

Equivalent Uniform Dose - EUD

- Reduces an inhomogeneous dose distribution to an equivalent homogeneous dose
- Can then be described by a single dose parameter
- Useful and worth understanding

- Gay HA, Niemierko A. A free program for calculating EUD-based NTCP and TCP in external beam radiotherapy. Phys Med. 2007; 23(3-4): 115-25
- Niemierko A. Reporting and analyzing dose distributions: a concept of equivalent uniform dose. Med Phys. 1997; 24(1): 103-10.

Equivalent Uniform Dose - EUD

• Depends on 'knowing' the value of the exponent 'a'

$$EUD = \left(\sum_i v_i D_i^a\right)^{1/a}$$

v_i = volume of the dose-volume bin D_i
 'a' = response-specific parameter

Equivalent Uniform Dose - EUD

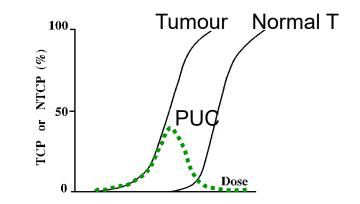

- For tumours 'a' is negative
 - Typical range -5 ('less malignant') meningioma
 - ➢ to -15 ('more malignant') chordoma
- For normal tissues 'a' is positive
 - Parallel near 1
 - Serial larger e.g. up to 20 for spinal cord
 - \succ 'a' = 1/n in the LKB formulation

TCP, NTCP, PUC

- TCP, NTCP
 - Require assumptions and estimates in models
 - An obvious development
 - Requires more hard dose-volume response data
- Probability of uncomplicated (PUC)
 - 'ideal' parameter ?
 - > May suggest lower doses

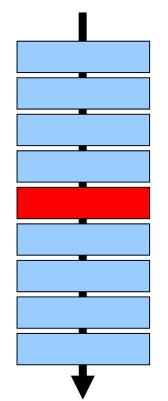

Extra slides

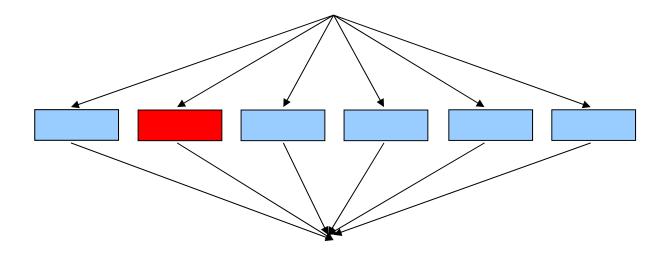

Tissue architecture

• Serial organ

• Parallel organ

• Damage to 1 part (only) does not compromise function

- Damage to 1 part causes failure

 eg spinal cord
- Severe clinical consequence

• Examples ...

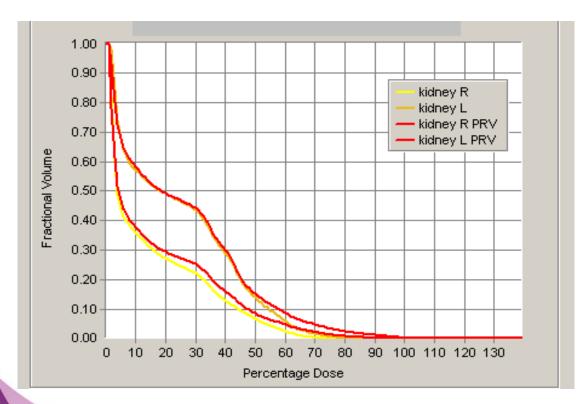

Target volumes – PRV

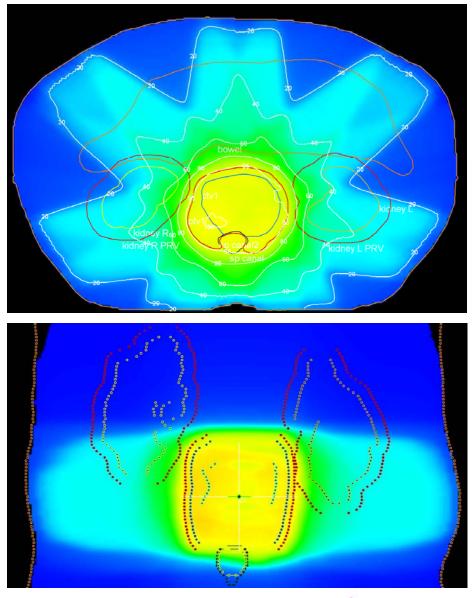

- Spinal cord & optic nerves/chiasm are perfect examples where a PRV may be helpful
 - serial tissue organisation
 - damage is clinically catastrophic
 - Add a PRV, especially if high doses are planned
- Almost no other OARs where a PRV is needed
- PRV may be misleading for parallel organs
- Question of PRV for mixed parallel-serial structures

Target volumes – PRV

- Kidney PRV 10mm
- DVH for PTVs \approx PRVs
- PRV often not of particular value

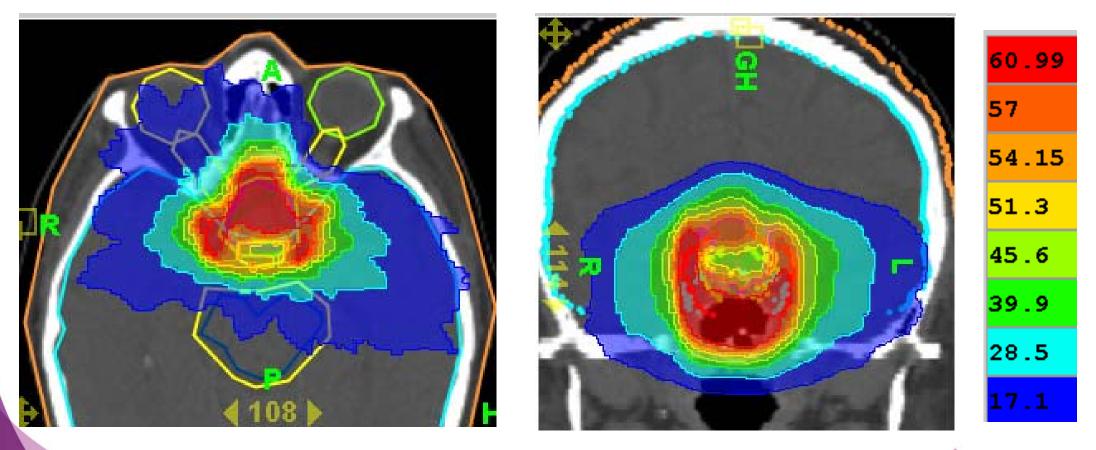

Target volumes – PRV

- PRV around optic nerves and chiasm
- Allows dose escalation not needed for 50 Gy dose

Non-IMRT planning *from simple to complex*

Advanced Treatment Planning Course

3-7 September 2017 – Barcelona, Spain

Markus Stock

Content

- Basics 3D-CRT and IMRT
- General planning aspects
- Clinical examples
 - head and neck:
 - 3D conformal
 - cranio-spinal lesions:
 - beam set-up non-IMRT
 - challenges in planning
- advanced treatment planning how to do it?

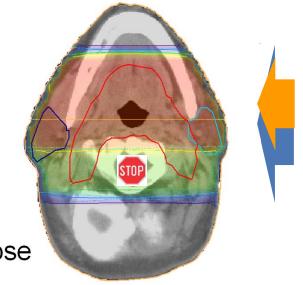

Basics and general planning aspects

Limitations of 3DCRT

- Hard to get acceptable plans for concave targets
- One needs a large number of beams to accomplish dose coverage for complicated target volumes
- limited possible beam directions in regions with large number of critical structures
- optimal beam angles often non- coplanar and can be difficult to apply without collisions, and moreover: difficult to find

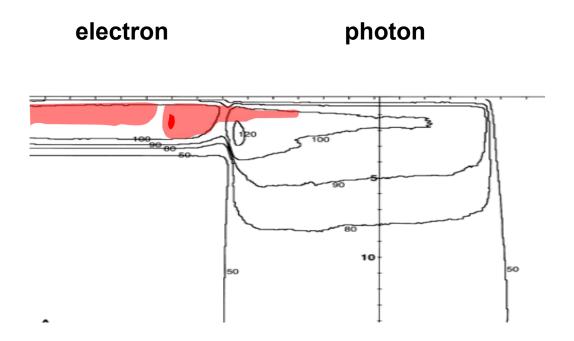

Use of abutting beams

- Electron electron beam matching
 - difficult to match without hot- or cold-spots due to influence on isodose lines of patient curvature
- Electron photon beam matching
 - beams abutted on the surface gives a hot spot on the photon side and a cold spot on the electron side
 - caused by out-scattering of electrons from the electron fields

Choice of optimal beam energy

Aspects

- penetration depth
- dose delivered to normal tissue
- penumbra broadening

4MV		6MV	8MV	10MV	15MV	≥18MV
	Cra	nial				
		HN				
		TI	norax			
				Pelvic		

Higher energy in low density regions

- higher energies means larger penumbra due to increase in lateral electron transport (≥10MV)
- sufficiently accurate planning calculation algorithms are required for decisions on optimal beam energy

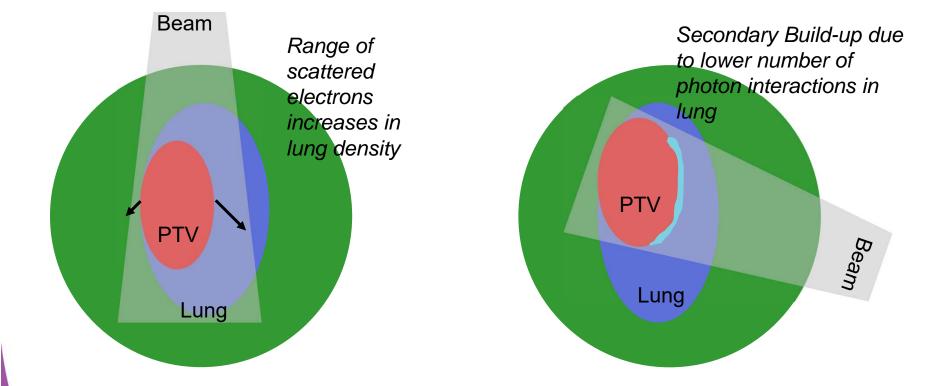

Choice of optimal beam energy in the thorax region

- Low energy beam is preferable
 - tighter margins, sharp dose gradient
 - no significant difference between 6 and 18MV treatment plan (# beams!)
- High energy may be used
 - central tumor location or consolidated lung

Interface effects

 Broadening penumbra in low density area Build-up and build-down in low density area

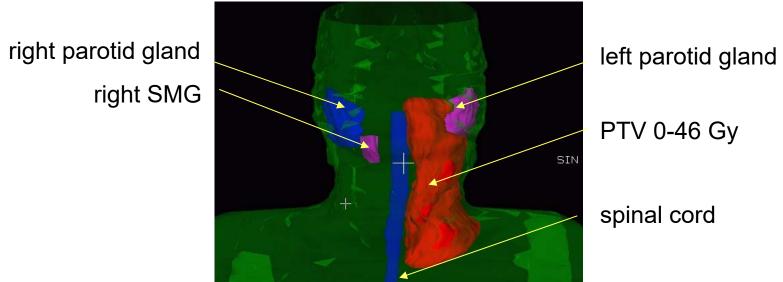

Head & Neck 3D

Head and neck 3D-CRT example: Tonsillar fossa Ca.

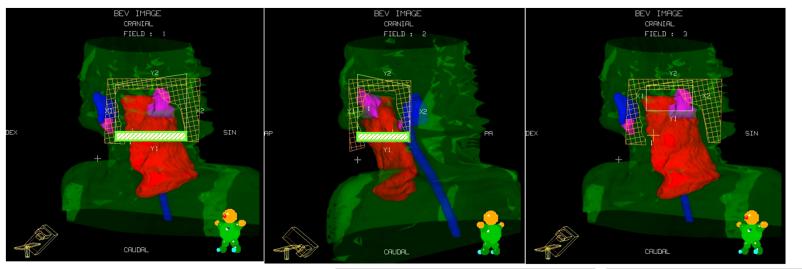

- T1-T3, N0
- CTV = primary tumor + uni-lateral neck (level II-IV)
- 46 Gy 3D-CRT
- BT boost

'simple' 3D CRT plan

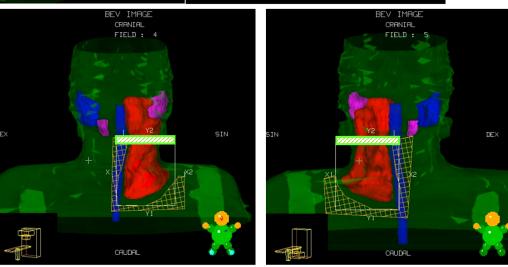

* *

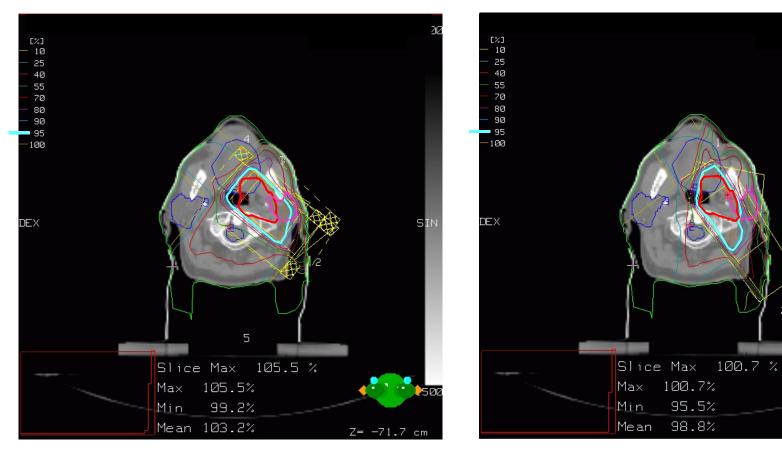

5 fields:3 cranial fields2 caudal fieldssliding junction

* total: 9 fields

9-field 3D-CRT

4-field IMRT

500

SIN

,50e

mean dose (Gy)	3D-CRT	4 field IMRT	
right parotid gland	2.6 Gy	4.0 Gy	
left parotid gland	40 Gy	27 Gy	
ri SMG	18 Gy	10 Gy	
oral cavity	24 Gy	24 Gy	

do we really need IMRT for this case?

no we don't, but application of IMRT results in:

- more OAR sparing
- less treatment planning time
- less delivery time
- no use of a sliding junction, so less risk

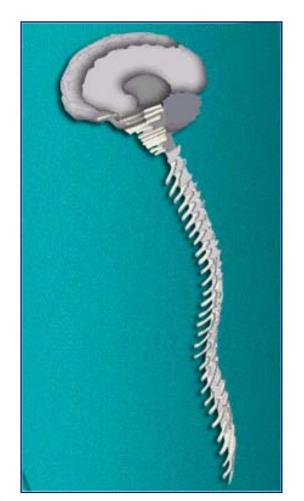

2 identical IMRT plans except for 500 [%] 10 25 40 the isocenter position 55 70 80 90 100 mean dose parotid 27 Gy POS ANT mean dose parotid 30 Gy Slice Max 101.0 % Max 100.9% 1500 95.7% Min 99.3% Mean

position of the isocenter

divergence of the beam in OAR direction

clinical target volume for cranio-spinal irradiation:

- meningeal surfaces of the brain
- spinal cord

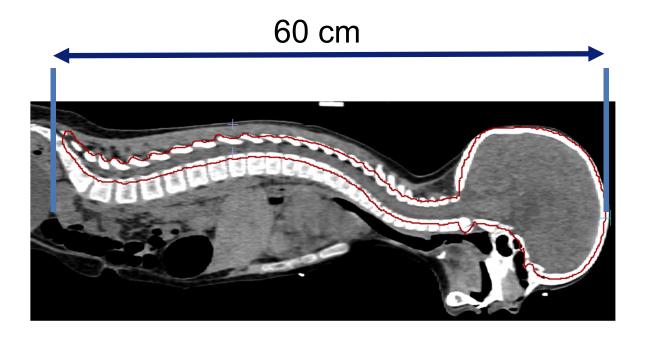

- small number of patients, lack of planning experience
- hardware limitations of TPS?
 - max number of CT slices ? (300+)
 - calculation time / grid size
- beam set-up cranio-spinal treatment
 - need for IMRT? combination 3D-CRT + IMRT?
 - multiple energy, sliding junction etc.

Challenges:

- limitation in maximum field size
- junction area lateral cranial fields posterior spinal field
- dose distribution spinal field?

Λ

Cranio-spinal lesions

Challenges spinal field:

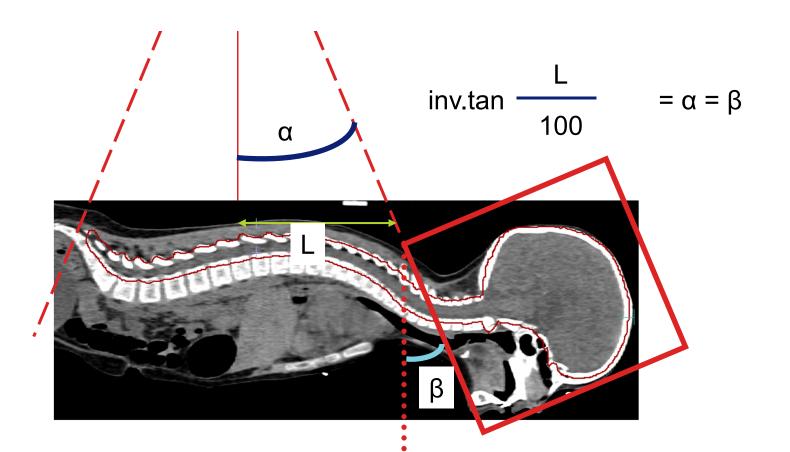

maximum field size: 40 cm at focus isocenter distance 100 cm 1 or 2 spinal fields (1=supine, 2= prone)

collimator angle cranial field = 'half top angle' spinal field

Λ

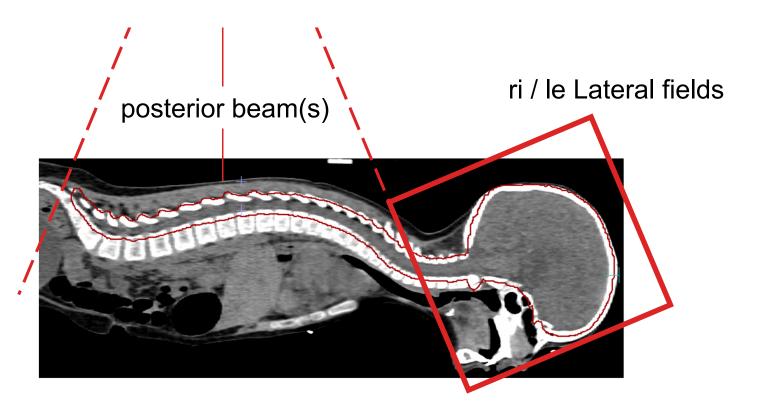

Λ

Cranio-spinal lesions

Challenges non-IMRT:

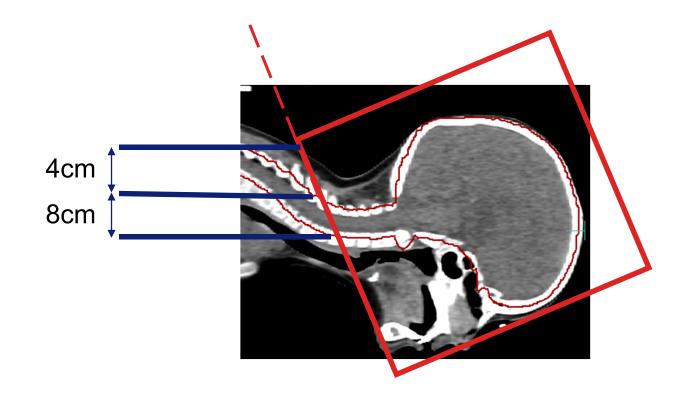

- junction lateral fields - PA spinal field

Challenges non-IMRT:

junction lateral fields – PA spinal field
 difficult due to differences in depth in junction area

additional sub-fields , multiple energies?

Cranio-spinal lesions: cranial fields

Challenges non-IMRT:

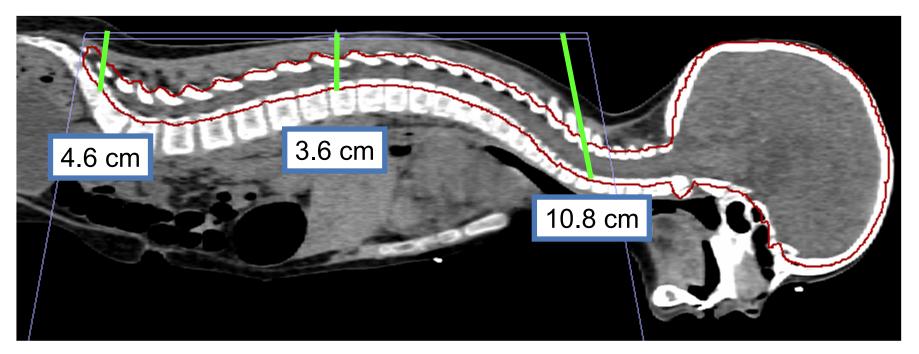

junction lateral fields – PA spinal field better dose-distribution in junction, broader penumbra → sliding junction

Cranio-spinal lesions: spinal field

Challenges Non-IMRT:

- differences in depth of spinal PTV
- different focus skin distances

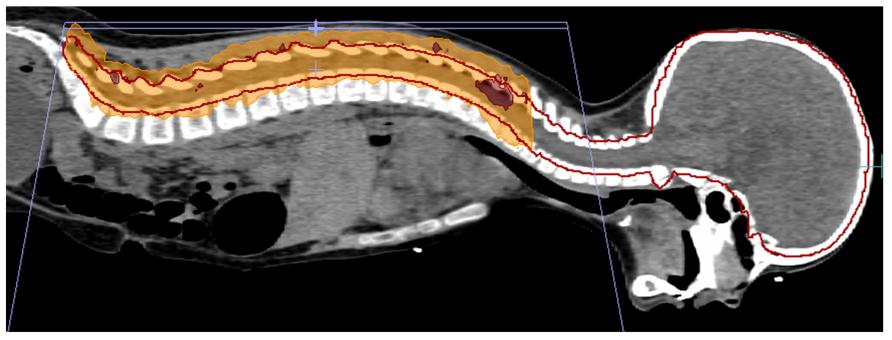

prescribing dose at mean depth, or additional sub-fields needed multiple energy fields

Cranio-spinal lesions: need for IMRT??

IMRT planning:

- differences in depth of spinal PTV
- differences in focus skin distances

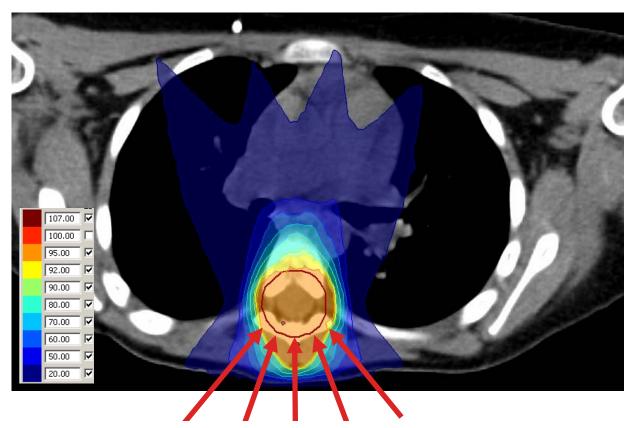

Cranio-spinal lesions: 3D-CRT or IMRT for spinal fields

5 field IMRT / 3D-CRT spinal fields

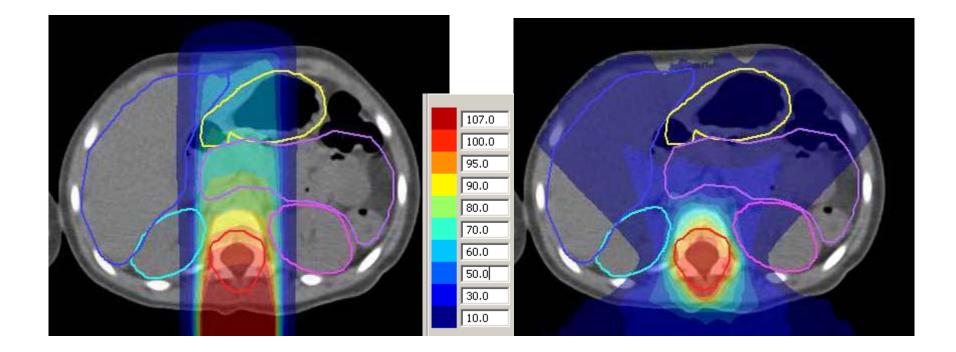

- lower dose in superficial area
- lower dose 'behind' the PTV

Cranio-spinal lesions: 3D-CRT vs IMRT

'simple' 3D-CRT

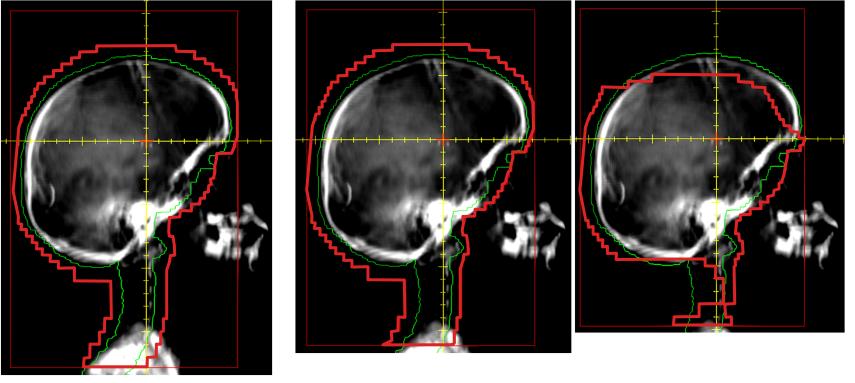

5 field IMRT / 3D-CRT

Cranio-spinal lesions: junction with lateral cranial beams

3D-CRT cranial plan with a broad caudal penumbra

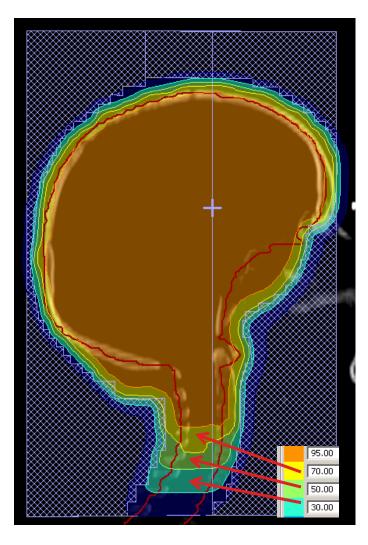

ri lat: 1a

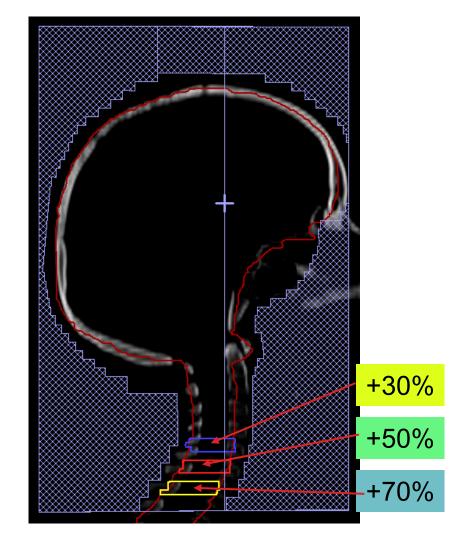

ri lat: 1b

ri lat: 1c

Cranio-spinal lesions: junction with lateral cranial beams

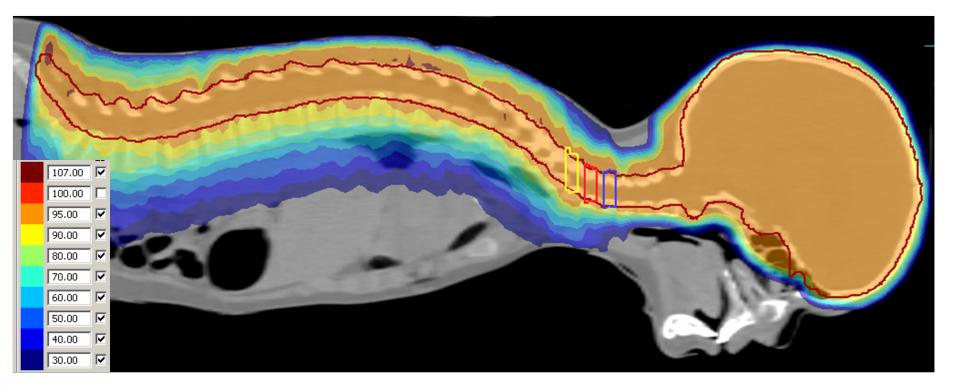

'dose modulation volumes'

Cranio-spinal lesions: 3D-CRT solution

6 3D-CRT cranial beams (start planning) 5 3D-CRT spinal fields (x 3 for broad penumbra)

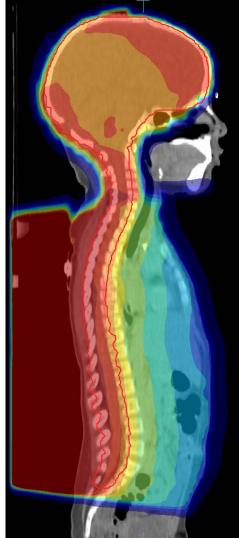

→ so ... 21 fields

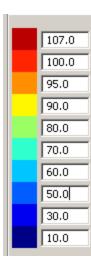

Cranio-spinal lesions: 3D-CRT old vs new

3D-CRT old (single PA)

3D-CRT new

Cranio-spinal lesions: 3D-CRT old vs new

mean dose (Gy)	old	new
thyroid gland	19.1	11.4
heart	7.8	4.4
lungs	3.5	4.7
small bowel	8.1	5.7
liver	4.6	3.8
le kidney	3.2	4.1
stomach	8.1	5.7

General start of a treatment plan

General start of a treatment plan

- where to place the isocenter?
- how to select the proper beam angles?
- how many fields?
- cerrobend blocks or MLC?

Where to place the isocenter?

- high dose region is the most favorite place for the physicist ©
 - (and normally it is a very good choice!)
 - find the best isocenter location with respect to:
 - MLC limits
 - use of wedges
 - build up area, air cavities, bone
 - isocenter position outside the high dose region often results in a more complicated plan

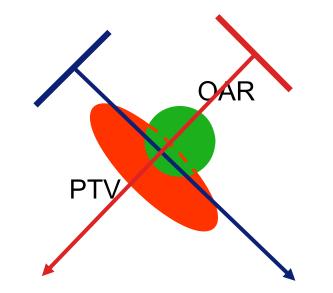

- apply a-priori patient set-up translations if necessary

How to select the proper beam angles?

- think about the dose distribution you want to achieve

- geometrical avoidance

steep dose gradients can only be made using a beam penumbra !

How to select the proper beam angles? Single lung:

Radiotherapy and Oncology 62 (2002) 21-25

www.elsevier.com/locate/radonline

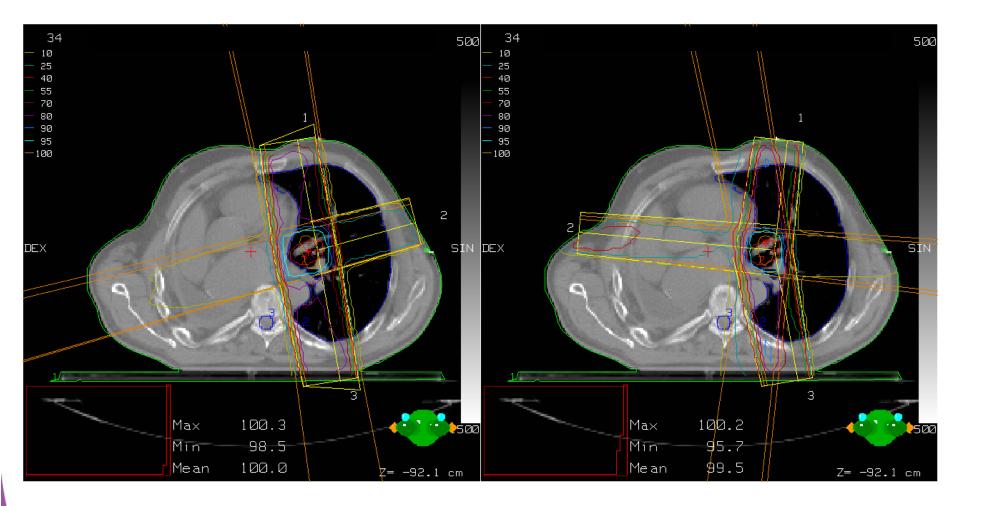

Curative radiotherapy for a second primary lung cancer arising after pneumonectomy — techniques and results $\stackrel{\text{tr}}{\sim}$

Frank J. Lagerwaard, Peter W.J. Voet, Jan P. van Meerbeeck, Sjaak A. Burgers, Suresh Senan*

University Hospital Rotterdam, Groene Hilledijk 301, 3075 EA Rotterdam, The Netherlands Received 15 May 2001; received in revised form 20 July 2001; accepted 7 August 2001

How to select the proper beam angles? Single lung:

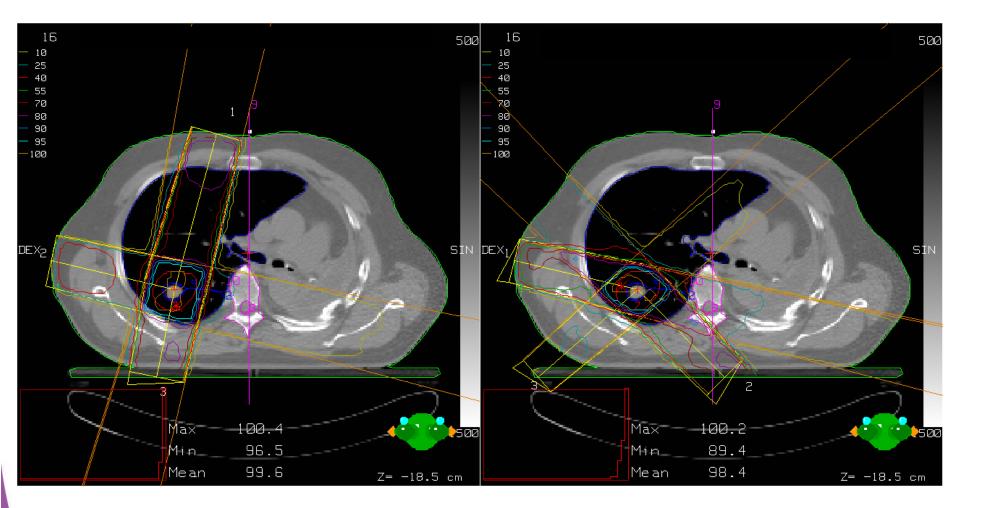

$$V_{20} = 25 \%$$

$$V_{20} = 19 \%$$

How to select the proper beam angles? Single Lung:

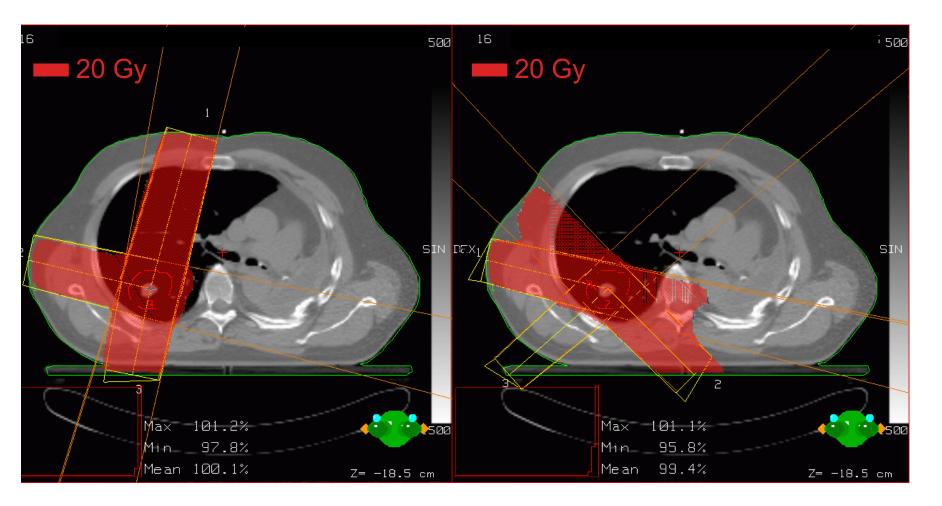

$$V_{20} = 27 \%$$

 $V_{20} = 15 \%$ Lagerwaard et al: R&O, 2001

How to select the proper beam angles? Single Lung:

$$V_{20} = 27 \%$$

 $V_{20} = 15 \%$ Lagerwaard et al: R&O, 2001

How many fields?

- depends on the complexity of the case
- size of the PTV, size of the patient

'Standard' 3D-CRT bladder treatment : 33 x 2.0 Gy:- 3 field (18MV) 3D CRT: CTV bladder + 15mm = PTV

4-5 field technique reduceshigh dose areas....but increases low dose areasdo not be afraid of addingbeams

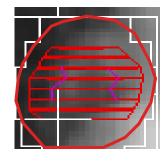

MLC versus Cerrobend blocking

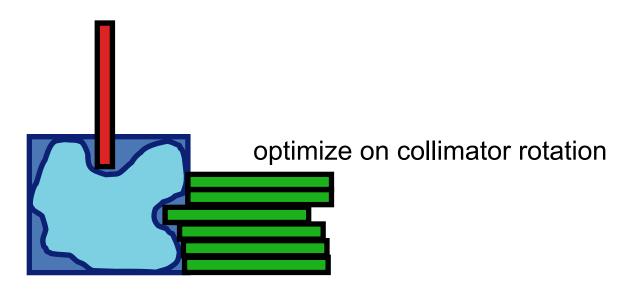

shielding by using cerrobend blocks is always the best

 Δ quality with MLC shielding depends on :

- MLC geometry (1cm, 0.5cm, 0.2cm, ..cm)
- size of PTV
- shape of PTV

'normally' MLC will do just fine, but be aware of it's limitations

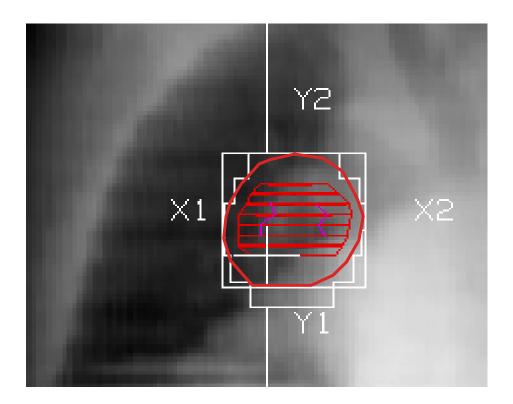

MLC versus Cerrobend blocking:

example early stage lung cancer : field size appr. 5 x 5 cm

MLC versus Cerrobend blocking:

			MLC	Cerrobend	
	1	V20 (%)	15	12	
		Mean lungdose (Gy)	10.3	8.9	
		Conformity-index	0.54	0.56	
	2	V20 (%)	18	16	
		Mean lungdose (Gy)	10.1	9.2	
		Conformity-index	0.46	0.57	
	3	V20 (%)	16	12	
		Mean lungdose (Cy)	10.0	8.6	
		Conformity index	0.55	0.62	
	4	V20 (%)	27	23	
		Mean lungdo se (Cy)	10.0	16.9	
		Conformity-index	0.58	0.63	
-	5	V20 (%)	21	19	
		Mean lungdose (Gy)	14.8	13.9	
		Conformity-index	0,58 - 0,66	0,63 - 0,71	

MLC versus Cerrobend blocking:

N=8		
Mean (1SD)	mlc	cerrobend
V20 (%)	19.9(5.0)	17.3(5.1)
mean lung (Gy)	14.8(3.1)	12.0(3.3)
CI	0.46(0.1)	0.60(0.0)

V ₂₀	Actuarial incidence ≥ grade 2 pneumonitis at 24 months	
<22%	0 %	
22-31%	7 %	
32-40%	13 %	
>40%	36 %	

Ref: Graham MV et al. IJROBP 45, 323-329, 1999

Making the 'best plan'

- finding 'optimal' plans is time consuming
 - plan approach is based on 'common sense' and experience,
 - and allotted time
 - class solutions <u>may</u> generally result into good plans, however,
 - specific patients may benefit from an individual approach
 - do not be afraid of additional beams

Dose volume histograms

1st time shown in 1979!

Proton Radiation as Boost Therapy for Localized Prostatic Carcinoma William U. Shipley. JAMA 241: 1912-1915, 1979

...A quantitative analysis of the posterior rectal-wall dose received by the two treatment techniques is shown in Fig 3...

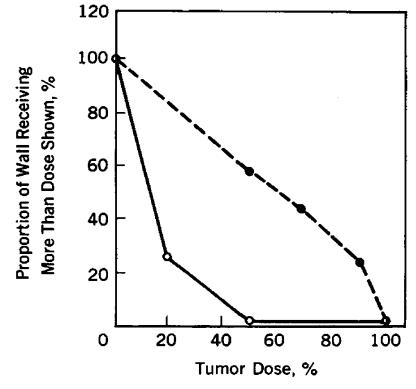

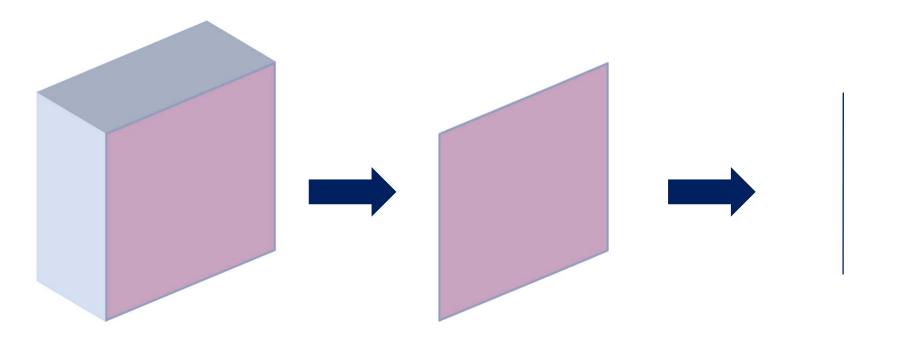

Fig 3.—Comparison of radiation dose to posterior rectal wall by 10-MV x-rays and 160-MV protons. Proportion of the wall is plotted vs dose it received. Dose is expressed as percentage of tumor dose. Solid line indicates protons; dashed line, 10-MV x-rays.

DVH related indicators

- > 3D > 2D
 - Dose distribution

• DVH

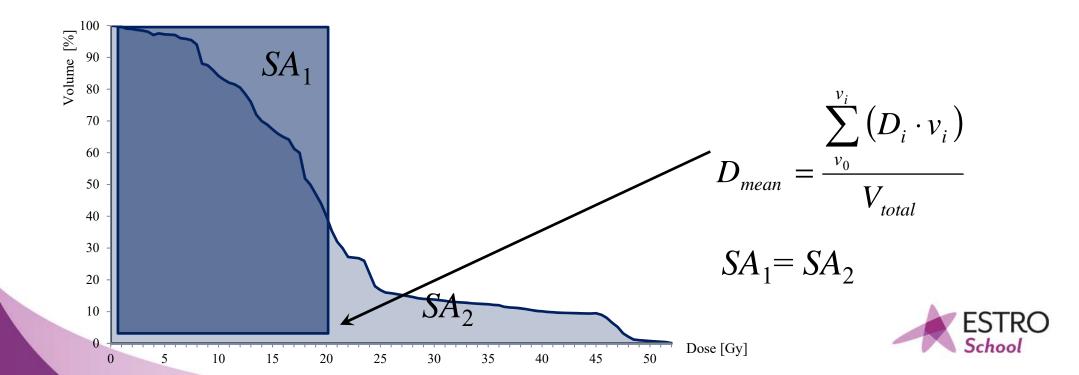

► 1D

- Mean Dose
- Max, Min dose
- $V_{[dose]}$, $D_{[volume]}$

DVH related indicators: mean dose in the OAR

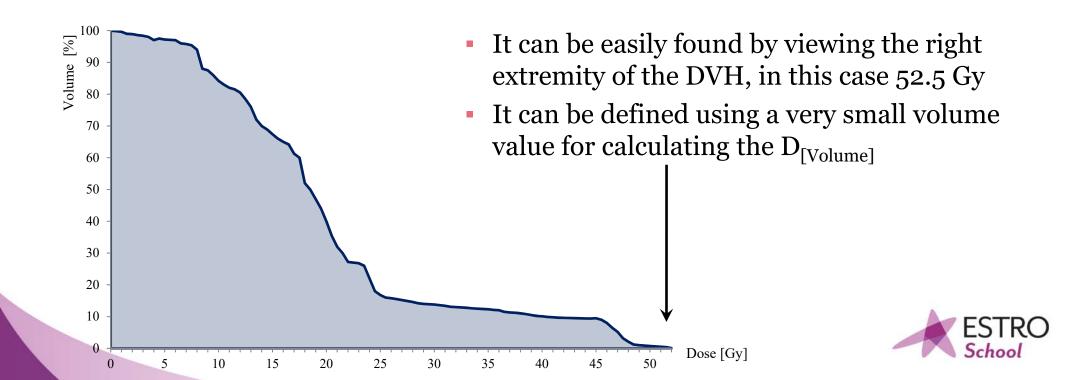

- Mean Dose
 - It "sums" all contributions of the heterogeneous dose distribution
 - It is useful for organs where the impact of the dose is strongly influenced by a parallel radiobiological organization

DVH related indicators: max dose in the OAR

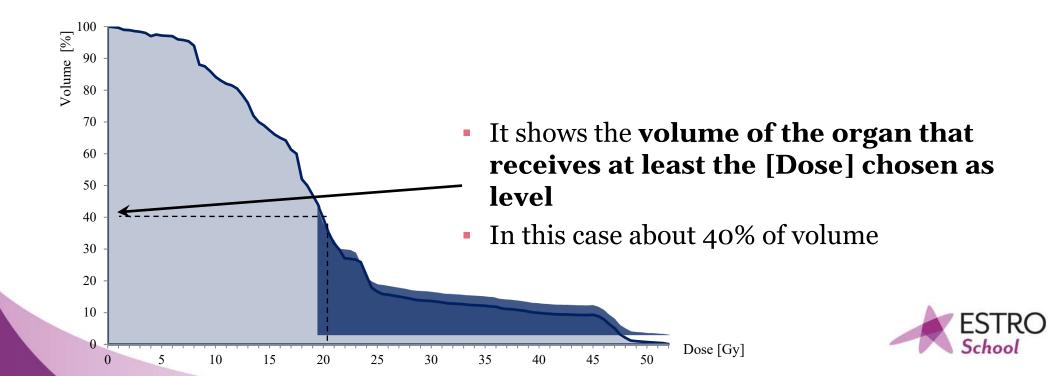

• (Near) Maximum Dose

- It is used when the value of the value of dose is critical relatively independently from the volume
- It is useful for organs where the impact of the dose is strongly influenced by a serial radiobiological organization

DVH related indicators: V[Gy] dose in the OAR

- V[Gy] Dose
 - It is an indicator that is useful when **critical dose levels**, where the clinical effect begins to be significant for the irradiated organ, **are known**
 - It is useful for organ with parallel organization

DVH related indicators: D[cc/%] volume in the OAR

• D[cc/%] Volume

Volume [cc]

 Minimum dose received by the "hottest" x% (or x cc's) of the organ. Usually measured with absolute Volume scale [cc]

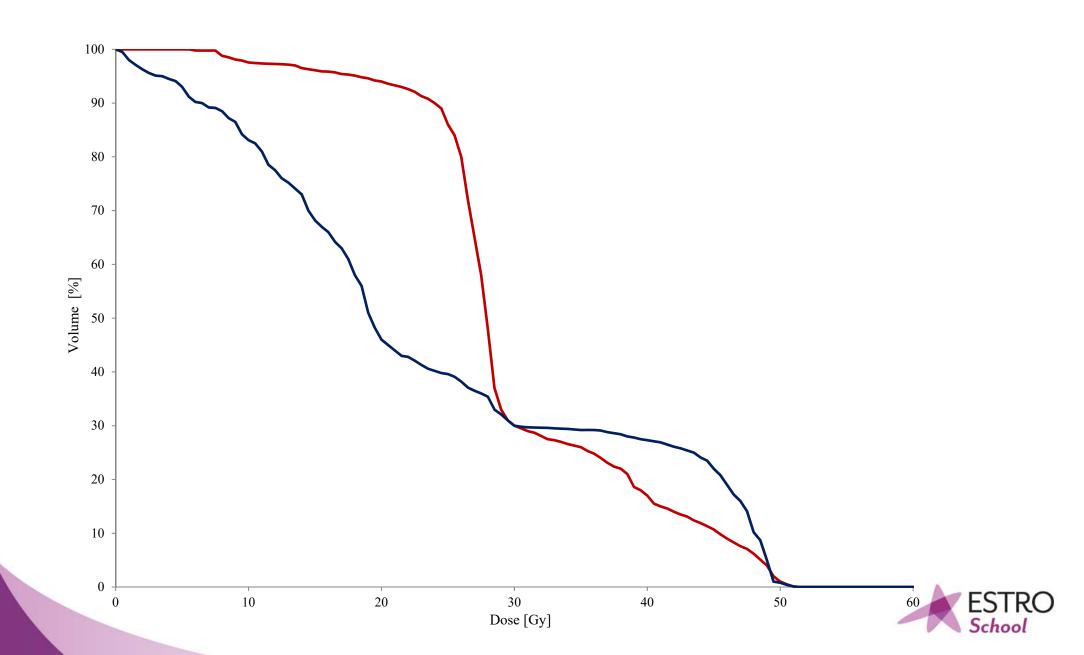

• After choosing the **threshold volume** the corresponding lowest dose is measured

Dose [Gy]

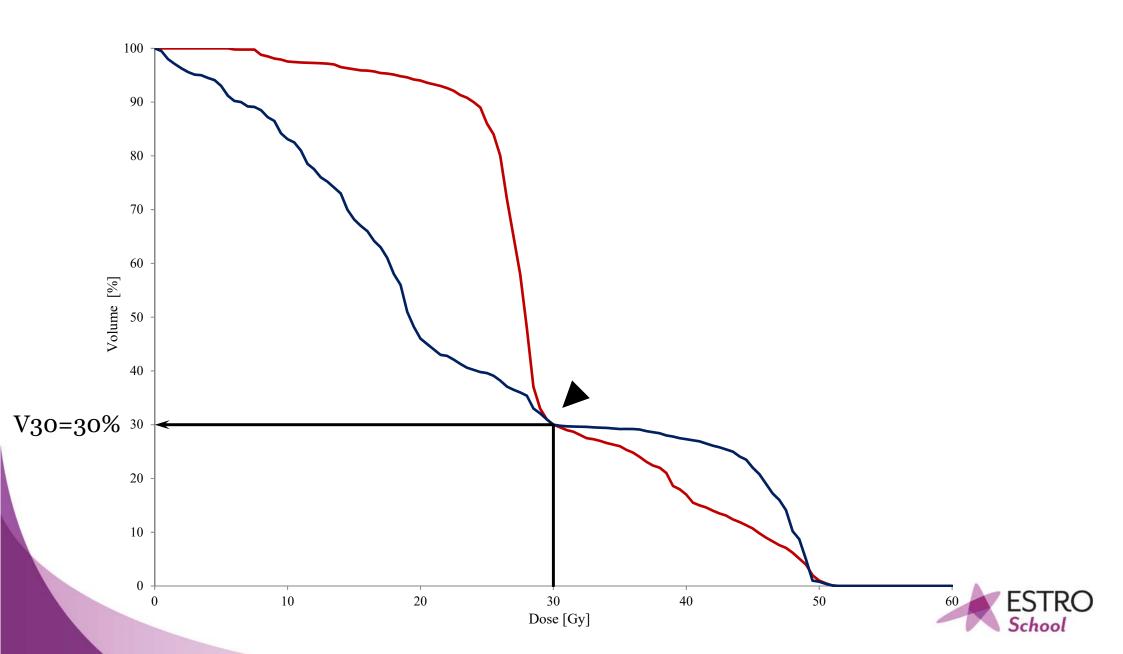

Be careful using single point indicators...

Be careful using single point indicators...

Dosimetry, Biology and Clinic

• Dosimetry: planning related data

 - Treatment related: chemo, hormonal therapy...
 - Prognosis, treatment aim (definitive, local control, palliation)

V-values D-values Mean dose Maximum dose Minimum dose

Dose/response models

• Dose-response models are binary model where the observer has to define some kind of **outcome** that has to be fitted to a sigmoid equation

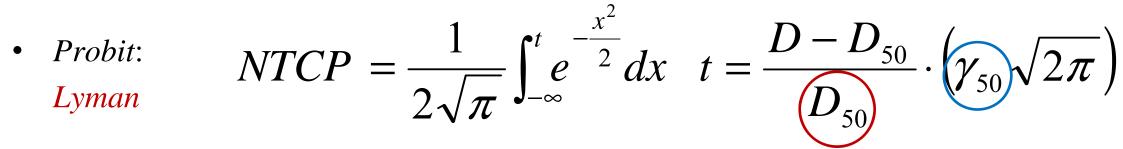

Radiobiology for OAR - NTCP

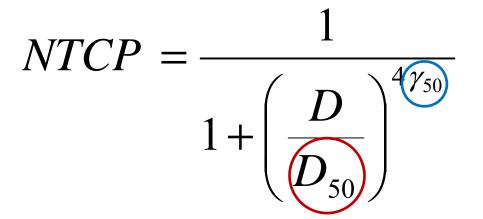

- There are mechanistic derived models for predicting TCP (based on probability of tumor stem cells lost during the treatment)
- There are not convincing mechanistic models for describing all side effect onset
 - Stem cells loss (dry mouth, myelopathy)
 - Abnormal cell growth (fibrosis, telangiectasia)
- Likelihood of side effects onset is proportional to the administered dose
 - Using the probability density function of normal distribution (probit)
 - Using the probability density function of other statistical distribution (logit Log dose)

Deriving NTCP models from dose/outcome data

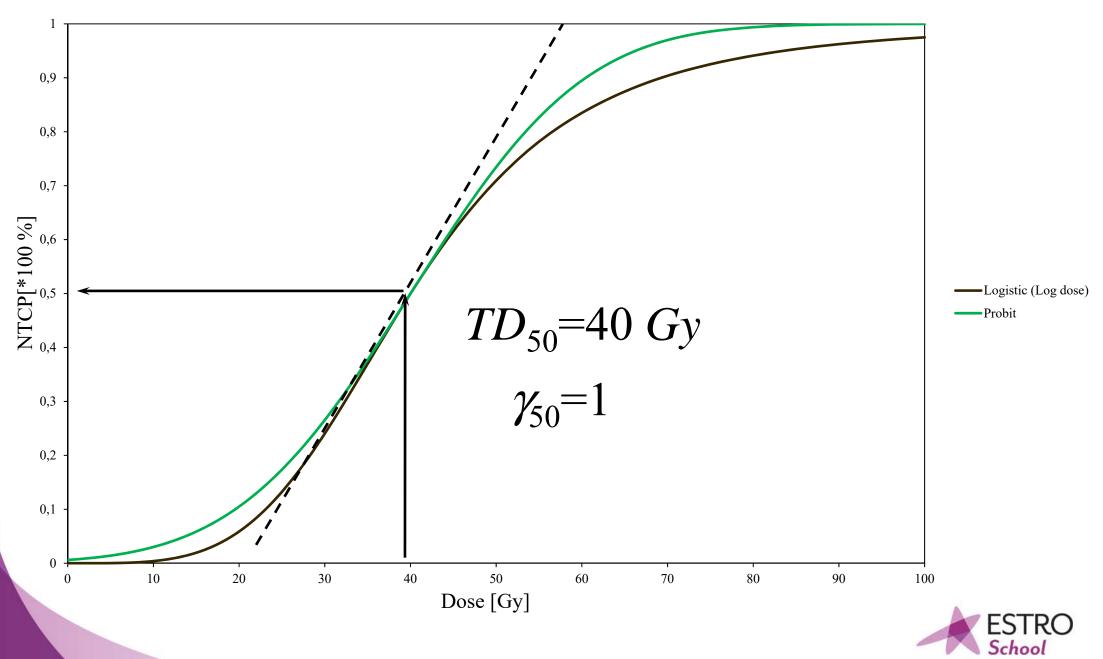

Logistic (log dose):
 Niemierko

NTCP models

Which dose should be used within NTCP models?

- Dose in OAR is usually heterogeneous
- Dose/response relation in OAR changes with the organ considered
- Need to define a number that can summarize the different contribution of dose in the OAR volume

Equivalent Uniform Dose

- The EUD is base on the assumption that two dose distributions are equivalent if they produce the same radiobiological or clinical effect (end-point)
- \succ D_i : the dose in the volum bin
- \succ v_i : volum bin
- ➤ a : parameter that describes the serial/parallel structure of the organ

$$EUD = \left(\sum_{j=1}^{a} v_j D_j^a\right)^{\frac{1}{a}}$$

How to consider the volume effect in dose-response models?

Are DVHs (and DVHs derived indicators) the best tool for evaluating treatments?

Evaluation of treatment plans using target and normal tissue DVHs is no longer appropriate

Christopher F. Njeh, Brent C. Parker, and Colin G. Orton

Citation: Medical Physics **42**, 2099 (2015); doi: 10.1118/1.4903902 View online: http://dx.doi.org/10.1118/1.4903902 View Table of Contents: http://scitation.aip.org/content/aapm/journal/medphys/42/5?ver=pdfcov Published by the American Association of Physicists in Medicine

Are DVHs (and DVHs derived indicators) the best tool for evaluating treatments?

- Point:
 - Long history and huge literature
 - IGRT and modern high precision techniques can be helpful in making DVH estimation more stable
 - Deformable registration could improve the DVH accuracy during treatment
 - Many biological metrics

 (considered very useful) are
 substantially based on (differential)
 DVH data
 - The DVH is not *the* appropriate choice for plan evaluation but it is still *an* appropriate choice

- Counterpoint:
 - Loss of spatial information (from 3D to 2D)
 - The calculation of DVH strongly depends from delineation accuracy (and OAR choices by the doctors)
 - For some structures (e.g. bladder) different metrics can be used (DSH) because of the lack of importance of irradiation of organ content
 - Interpretation of the plot might be subjective
 - It can't carry clinical informations about conditions that could affect the outcome

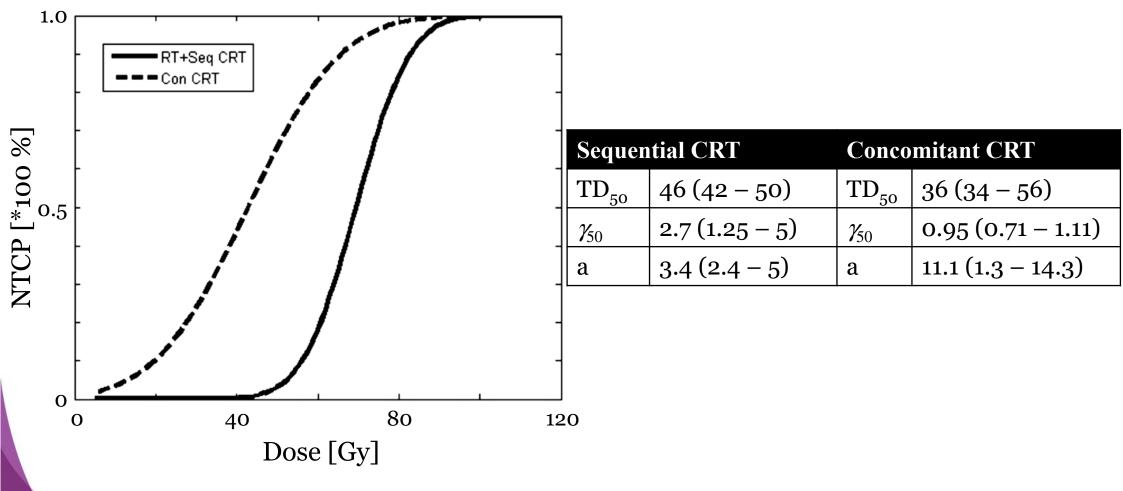

Beyond the DVHs

- DVHs are based only on **anatomy** (knowledge and interpretation) and **dose distribution** reduced to a 2D estimate
- Dose-response model based on few geometrical parameters could **omit clinical conditions** differentiating the patients
- When referring outcome prediction on parameters derived from literature try to compare your evaluation to the same conditions used by publications authors (if available!)
- New methods for **patients classification** are required to achieve a robust and reliable evaluation

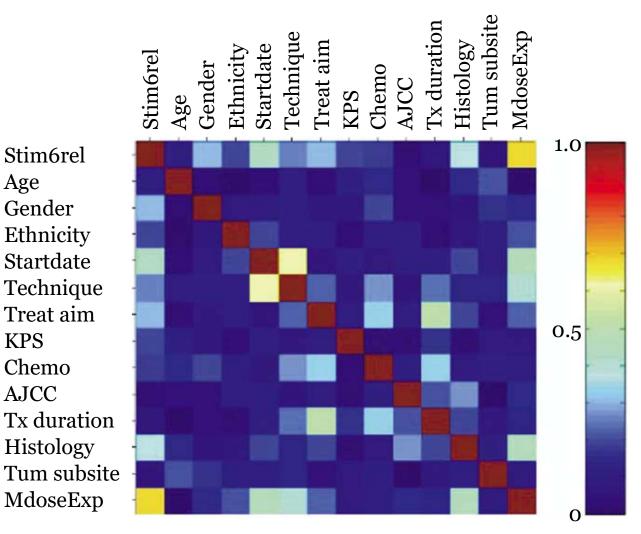

• Solution 1: different populations, different parameters to be used in dose-response model (Lyman)

J Zhu et al. Analysis of acute radiation-induced esophagitis in non-small-cell lung cancer patients using the Lyman NTCP model. Radiother Oncol (2010) 449–454.

• Solution 2: multivariate regression modeling

Age

KPS

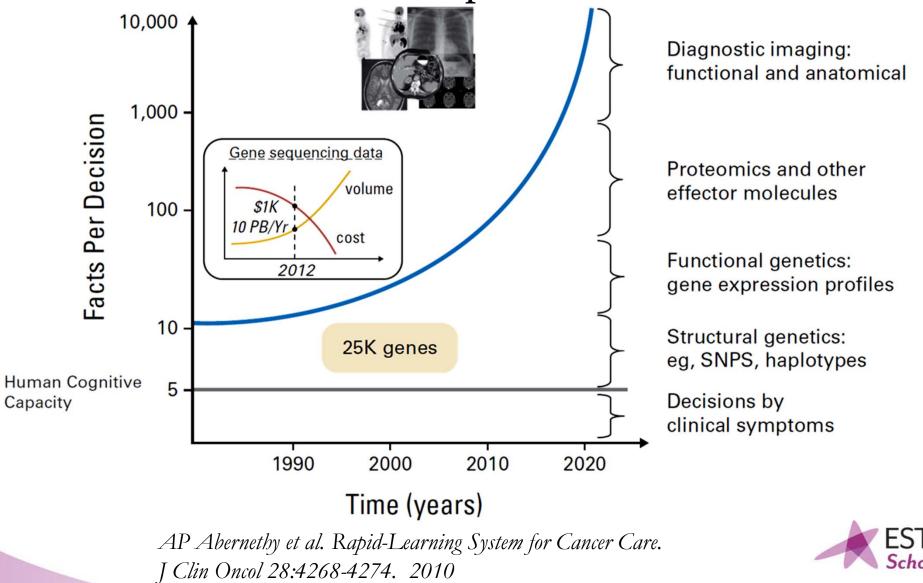

AJCC

Creation of a correlation matrix to establish the relationships among different analyzed factors

J El Naqa et al. Multivariable modeling of radiotherapy outcomes, including dose-volume and clinical factors. Int J Radiat Oncol Biol Phys. 64, (4), 1275–1286, 2006.

• How many variables can be analyzed for treatment evaluation and outcome prediction?

- Possible solutions:
- 1. "Large database" modeling
- 2. Use of automatic computer bots
- 3. Multiparametric modeling
 - Inferential statistics
 - Bayesian approach
 - Use of support-vector-machines
 - ➤ Other...
- 4. Extension of data-mining in multi-centric perspective
- 5. Definition of multi-centric "ontology" for data classification and collection minimizing errors

Int. J. Radiation Oncology Biol. Phys., Vol. 76, No. 3, Supplement, pp. S1–S160, 2010.

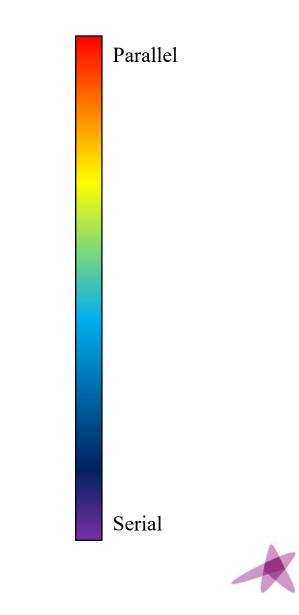

Parameters for clinical outcome prediction and planning evaluation

• Mean Dose

• V[Gy] Dose

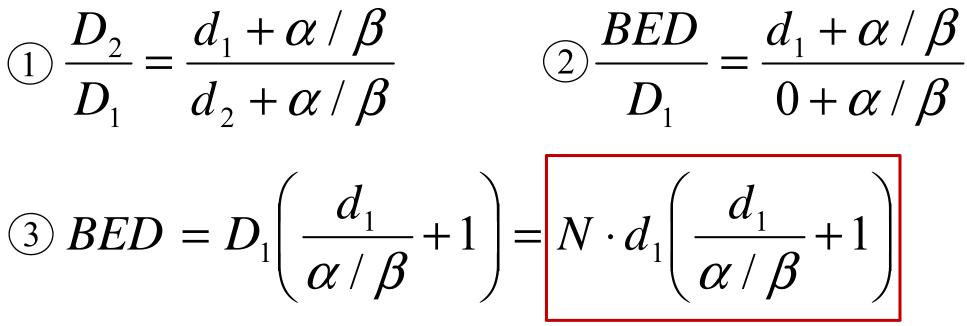

• D[cc/%] Volume

• Maximum Dose

Clinical evaluation: comparison of toxicity data from different protocols

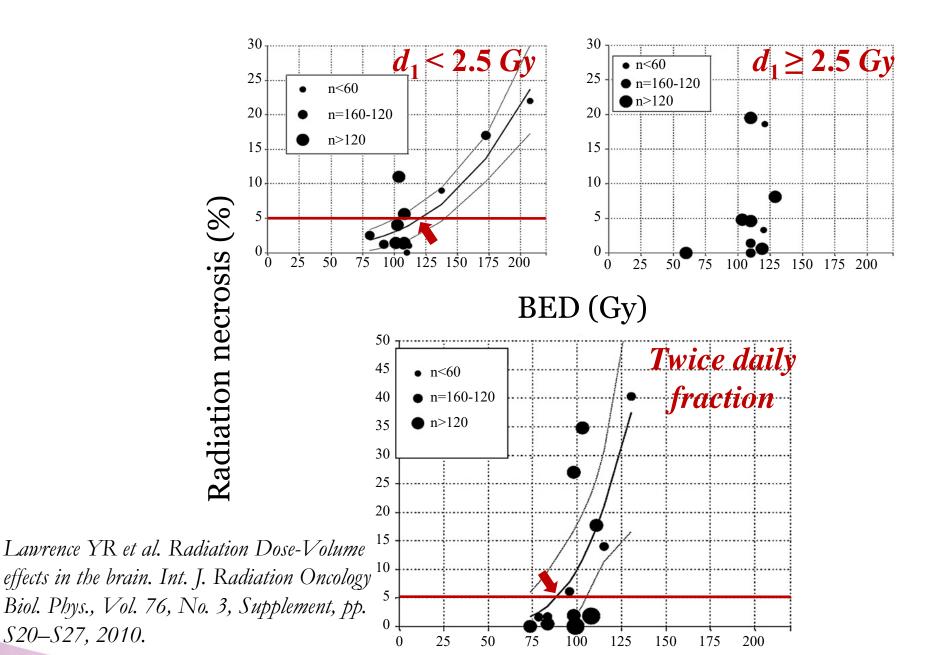

- Biologically Effective Dose
 - A parameter that is independent from the fractionation
 - It doesn't express a real delivered dose

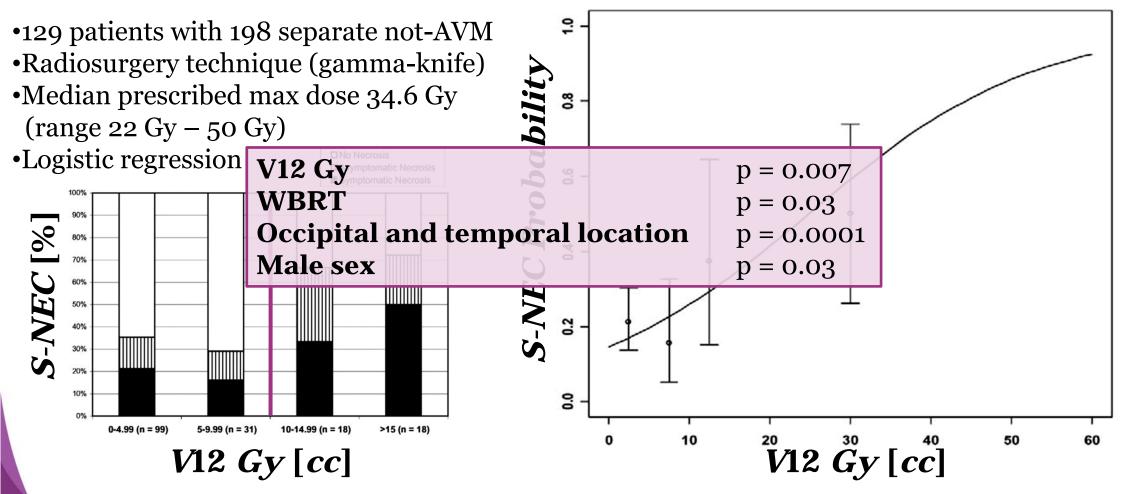

N: fraction number α/β : alfa-beta ratio d_i : fraction number for the given effect

S20–S27, 2010.

Endpoint: Symptomatic necrosis vs Asymptomatic necrosis

T Korytko et al. 12 Gy gamma knife radiosurgical volume is a predictor for radiation necrosis in non-AVM intracranial tumors. Int. J. Radiation Oncology Biol. Phys., ESTRO Vol. 64, No. 2, pp. 419–424, 2006

Volume segmented	Irradiation type (partial organ unless otherwise stated)	Endpoint	Dose (Gy), or dose/volume parameters	Rate (%)	Notes on dose/volume parameters
Whole organ	3D-CRT	Symptomatic necrosis	Dmax < 60 $Dmax = 72$ $Dmax = 90$	<3 5 10	Data at 72 and 90 Gy, extrapolated from BED models
Whole organ	SRS (single fraction)	Symptomatic necrosis	V12 <5–10 cc	<20	Rapid rise when V12 > 5–10 cc

$$BED = N \cdot d_1 \left(\frac{d_1}{\alpha / \beta} + 1 \right) \Longrightarrow 120 = D_1 \left(\frac{2}{2} + 1 \right) \Longrightarrow D_1 = 120 / 2 = 60 Gy$$

- High sensitivity for **fraction doses** > **2** Gy
- High sensitivity for **multi fractions** per day treatments
- Evidence for neurocognitive injury is weak in adults
- For **children** the cutoff for **neurocognitive injury** is about **18-24 Gy** (whole brain irradiation for medulloblastoma)

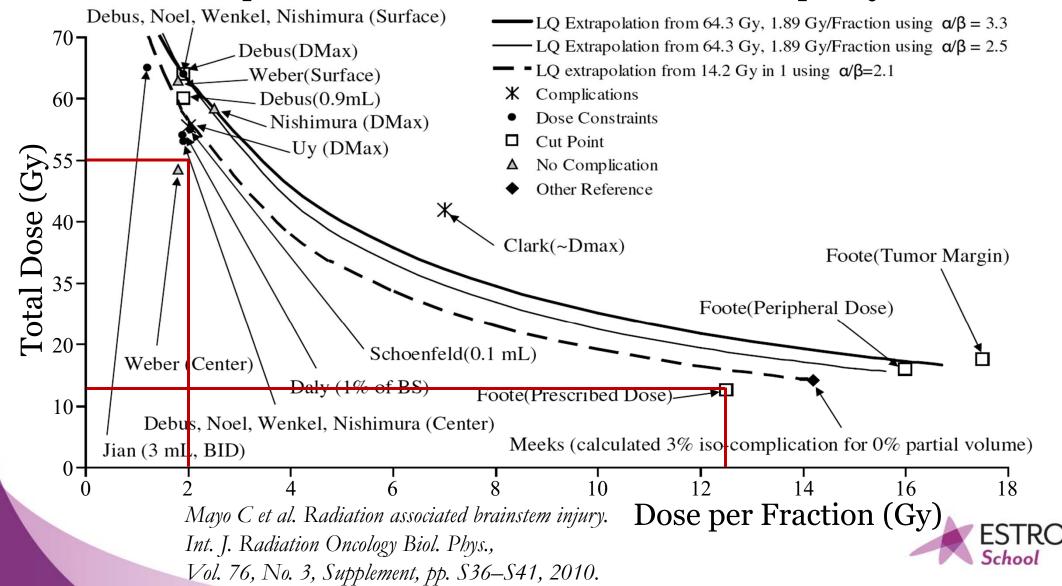

Volume segmented	Irradiation type (partial organ unless otherwise stated)	Endpoint	Dose (Gy), or dose/volume parameters	Rate (%)	Notes on dose/volume parameters
Whole organ	3D-CRT	Symptomatic necrosis	Dmax < 60 $Dmax = 72$ $Dmax = 90$	<3 5 10	Data at 72 and 90 Gy, extrapolated from BED models
Whole organ	SRS (single fraction)	Symptomatic necrosis	V12 <5–10 cc	<20	Rapid rise when V12 > 5–10 cc

$$BED = N \cdot d_1 \left(\frac{d_1}{\alpha / \beta} + 1 \right) \Longrightarrow 120 = D_1 \left(\frac{2}{2} + 1 \right) \Longrightarrow D_1 = 120 / 2 = 60 Gy$$

- High sensitivity for **fraction doses** > **2** Gy
- High sensitivity for **multi fractions** per day treatments
- Evidence for neurocognitive injury is weak in adults
- For **children** the cutoff for **neurocognitive injury** is about **18-24 Gy** (whole brain irradiation for medulloblastoma)

Endpoint: Brainstem necrosis or neuropathy

Volume segmented	Irradiation type (partial organ unless otherwise stated)	Endpoint	Dose (Gy), or dose/volume parameters	Rate (%)	Notes on dose/volume parameters
Whole organ	Whole organ 3D-CRT	Permanent cranial neuropathy or necrosis	Dmax <54 D1—10 cc <u><</u> 59	<5 <5	
Whole organ	3D-CRT	Permanent cranial neuropathy or necrosis	Dmax <64	<5	Point dose <<1 cc
Whole organ	SRS (single fraction)	Permanent cranial neuropathy or necrosis	Dmax <12.5	<5	For patients with acoustic tumors

 Lack of information for dose per fraction in the 4 to 8 Gy range and so there are not affordable recommendations to be followed in the middle fractionations area

• The extrapolation of LQ model to the highest doses may however be incorrect

Mayo C et al. Radiation associated brainstem injury. Int. J. Radiation Oncology Biol. Phys., Vol. 76, No. 3, Supplement, pp. S36–S41, 2010.

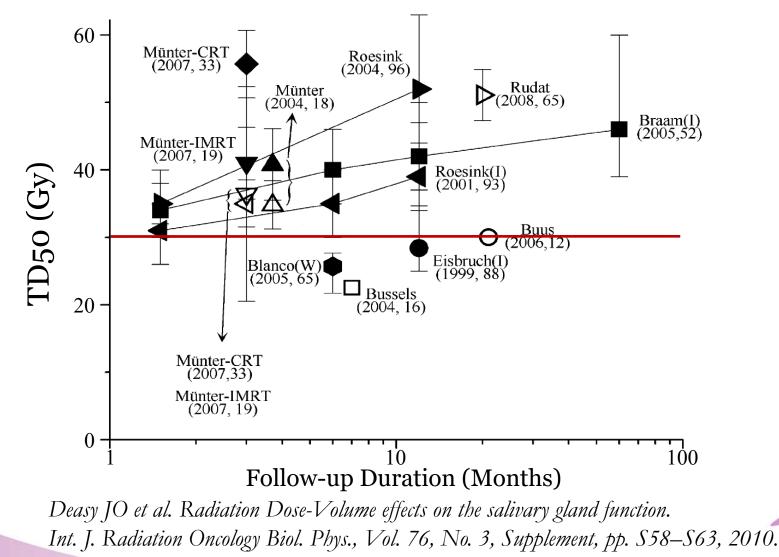

Mean percentage of reduction in stimulated salivery flow rate vs. mean parotid gland dose for different follow-up durations

Deasy JO et al. Radiation Dose-Volume effects on the salivary gland function. Int. J. Radiation Oncology Biol. Phys., Vol. 76, No. 3, Supplement, pp. S58–S63, 2010.

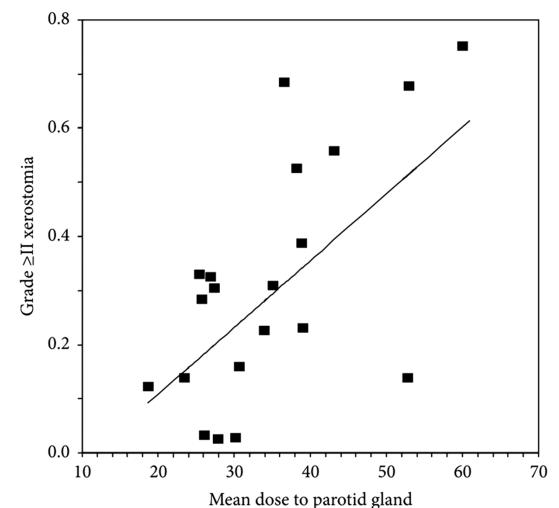

Reported tissue dose required for 50% response for loss of stimulated saliva flow after radiotherapy for <u>single parotid gland</u>

Beetz I et al. Development of NTCP models for head and neck cancer patients treated with three-dimensional conformal radiotherapy for xerostomia and sticky saliva: The role of dosimetric and clinical factors. Radiother. Oncol. Volume 105, Issue 1, Pages 86–93.

Multivariate NTCP model:

Selection of covariates:

Final model:

Baseline xerostomia score is a simple clinical evaluation before the treatment (dummy covariate):

0: no xerostomia

1: a bit of xerostomia

Beetz I et al. Development of NTCP models for head and neck cancer patients treated with three-dimensional conformal radiotherapy for xerostomia and sticky saliva: The role of dosimetric and clinical factors. Radiother. Oncol. Volume 105, Issue 1, Pages 86–93.

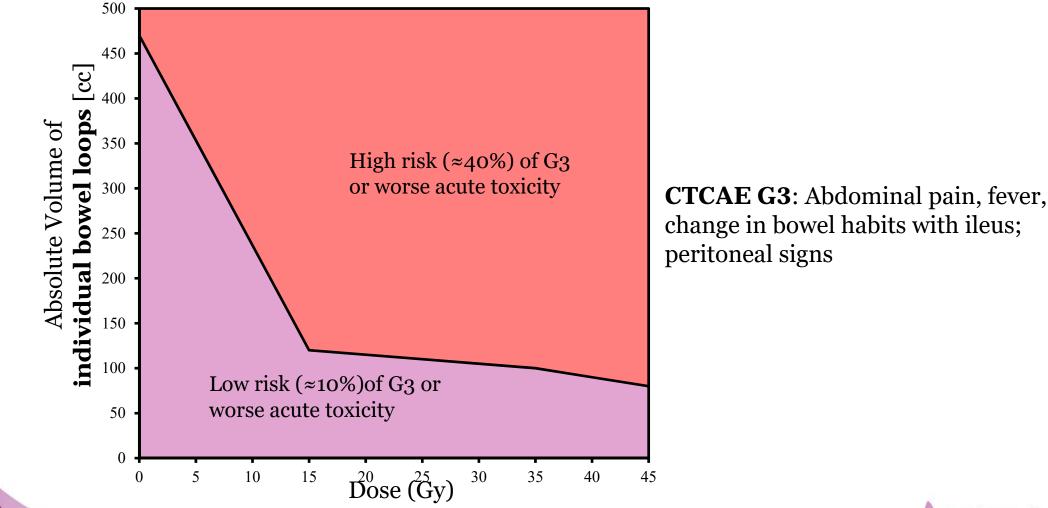

Volume segmented	Irradiation type (partial organ unless otherwise stated)	Endpoint	Dose (Gy), or dose/volume parameters	Rate (%)	Notes on dose/volume parameters
Bilateral whole parotid glands	3D-CRT	Long term parotid salivary function reduced to <25% of pre- RT level	Mean dose <25	<20	For combined parotid glands
Unilateral whole parotid gland	3D-CRT	Long term parotid salivary function reduced to <25% of pre- RT level	Mean dose <20	<20	For single parotid gland. At least one parotid gland spared to <20 Gy
Bilateral whole parotid glands	3D-CRT	Long term parotid salivary function reduced to <25% of pre- RT level	Mean dose <39	<50	For combined parotid glands

- Severe xerostomia is related to additional factors including the doses to the submandibular glands
- But submandibular glands should be included in the CTV for Ib nodes irradiation (oropharynx, oral cavity, N3)

Deasy JO et al. Radiation Dose-Volume effects on the salivary gland function. Int. J. Radiation Oncology Biol. Phys., Vol. 76, No. 3, Supplement, pp. S58–S63, 2010.

Baglan-Robertson threshold model for risk of acute small bowel toxicity

Kavanagh BD et al. Radiation Dose-Volume effects in the stomach and small bowel. Int. J. Radiation Oncology Biol. Phys., Vol. 76, No. 3, Supplement, pp. S101–S107, 2010.

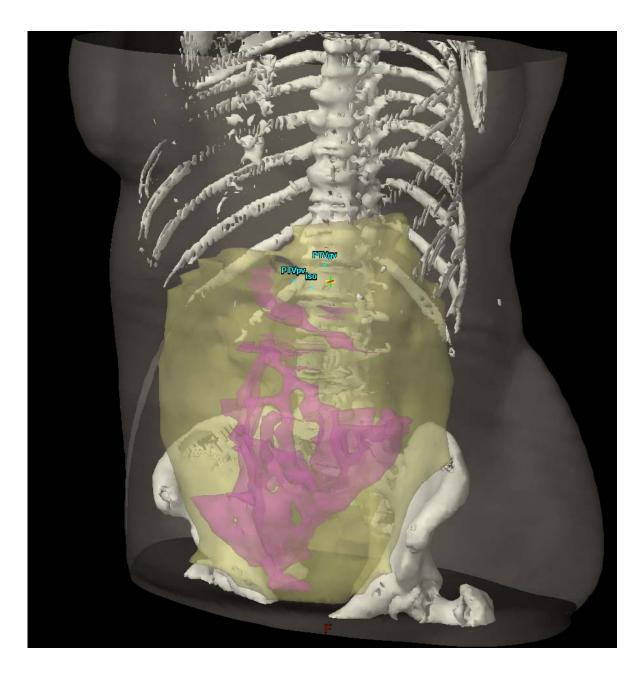

Problems in evaluating small bowel toxicity:

- Different types of treatment can involve small bowel according the primary tumor site (gastric, pancreas, rectum, prostate, cervical cancer)
- 2) Different types of **combined treatment** according to the primary site
 - 1) Chemotherapy (5-Fu, CDDP, Capecitabine, Gemcitabine)
- 3) Intrinsic movements of small bowel (filling, emptying, peristalsis)
- 4) Presence of **surgery** (before radiotherapy)
 - 1) Fixed bowel loops
 - 2) Bowel loops hypovascularization
 - 3) Bowel loops injury

Abbreviations: AUC = area under the curve; SB = small bowel; SE = standard error; PS = peritoneal space.

R Banerjee et al. Small Bowel Dose Parameters Predicting Grade <u>></u>3 Acute Toxicity in Rectal Cancer Patients Treated With Neoadjuvant Chemoradiation: An Independent Validation Study Comparing Peritoneal Space Versus Small Bowel Loop Contouring Techniques Int. J. Radiation Oncology Biol. Phys., Vol. 85, No. 5, pp. 1226–1231, 2013.

Small bowel toxicity in patients with GYN tumors undergone or not to abdominal surgery:

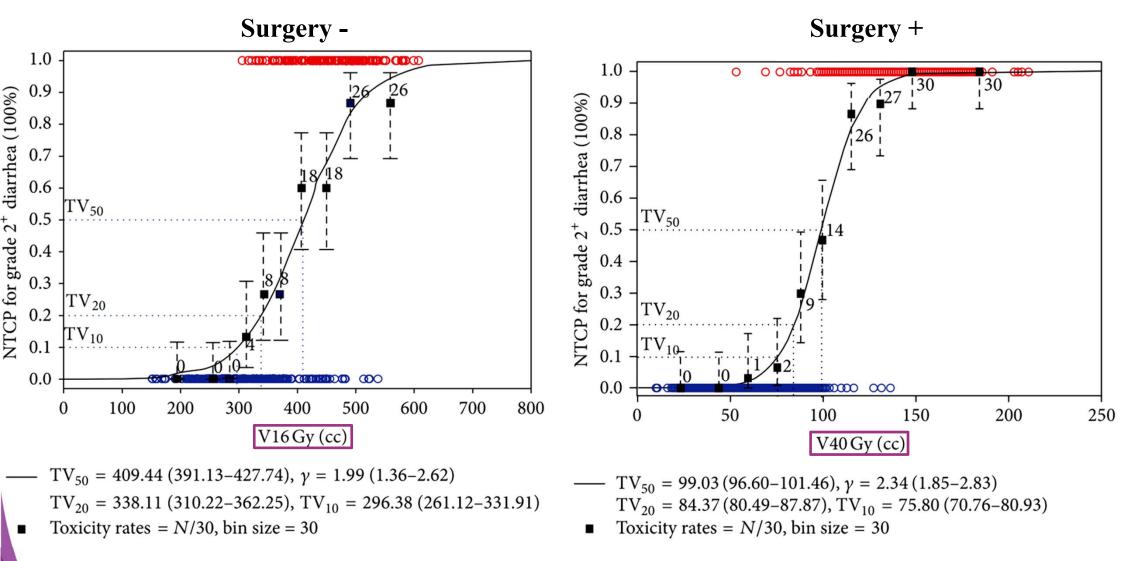

- 1) 95 patients with GYN malignancies
- 2) 34 patients after surgery, 61 patients without prior surgery
- 3) Use of LASSO for modeling logistic regression over Vdose parameters

$$NTCP = \frac{1}{1 + e^{-\hat{\beta}X}} = \left[1 + \left(\frac{TV_{50}}{V}\right)^{4\gamma}\right]^{-1}$$

- TV_{50} = tolerance volume corresponding to 50% incidence of complications V_{50} = volume of small bowel receiving a given dose level
 - = normalized slope of the volume response curve

TF Lee et al. The Different Dose-Volume Effects of Normal Tissue Complication Probability Using LASSO for Acute Small-Bowel Toxicity during Radiotherapy in Gynecological Patients with or without Prior Abdominal Surgery. BioMed Research International Volume 2014, Article ID 143020.

TF Lee et al. The Different Dose-Volume Effects of Normal Tissue Complication Probability Using LASSO for Acute Small-Bowel Toxicity during Radiotherapy in Gynecological Patients with or without Prior Abdominal Surgery. BioMed Research International Volume 2014, Article ID 143020.

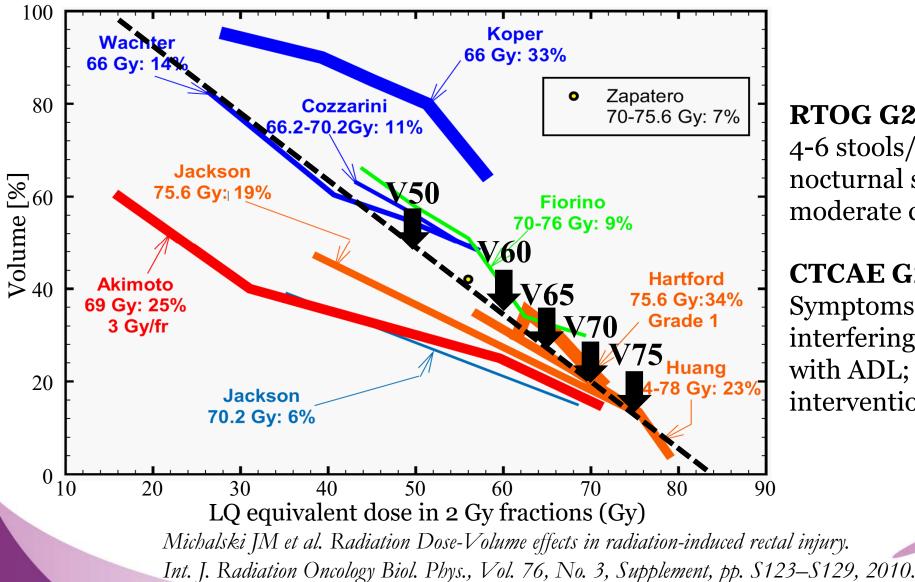

Volume segmented	Irradiation type (partial organ unless otherwise stated)	Endpoint	Dose (Gy), or dose/volume parameters	Rate (%)	Notes on dose/volume parameters
Individual small bowel loops	3D-CRT	Grade <u>></u> 3 acute toxicity	V15 <120 cc	<10	Volume based on segmentation of the individual loops of bowel, not the entire potential peritoneal space
Entire potential space within peritoneal cavity	3D-CRT	Grade <u>></u> 3 acute toxicity	V45 <195 cc	<10	Volume based on the entire potential space within the peritoneal cavity

- All data based on series with **concurrent chemotherapy**
- For single fraction **SBRT** (25 Gy) **data are poor**, but the cutoff seems to set down to V12.5<30 cc without bowel toxicity

Kavanagh BD et al. Radiation Dose-Volume effects in the stomach and small bowel. Int. J. Radiation Oncology Biol. Phys., Vol. 76, No. 3, Supplement, pp. S101–S107, 2010.

Dose-Volume limits for \geq G2 rectal toxicity with LQ corrected doses (α/β = 3 Gy)

RTOG G2: Increase of 4-6 stools/day, or nocturnal stools, or moderate cramping

CTCAE G2: Symptoms not

interfering with ADL; medical intervention indicated

Volume segmented	Irradiation type (partial organ unless otherwise stated)	Endpoint	Dose (Gy), or dose/volume parameters	Rate (%)	Notes on dose/volume parameters
Whole organ	3D-CRT	Grade <u>></u> 2 late rectal toxicity,	V50 <50%	<15	
		Grade <u>></u> 3 late rectal toxicity		<10	
Whole organ	3D-CRT	Grade <u>></u> 2 late rectal toxicity,	V6o <35%	<15	
		Grade <u>></u> 3 late rectal toxicity		<10	
Whole organ	3D-CRT	Grade <u>></u> 2 late rectal toxicity,	V65 <25%	<15	Prostate cancer
		Grade <u>></u> 3 late rectal toxicity		<10	treatment
Whole organ	3D-CRT	Grade <u>></u> 2 late rectal toxicity,	V70 <20%	<15	
		Grade <u>></u> 3 late rectal toxicity		<10	
Whole organ	3D-CRT	Grade <u>></u> 2 late rectal toxicity,	V75 <15%	<15	
		Grade <u>></u> 3 late rectal toxicity		<10	

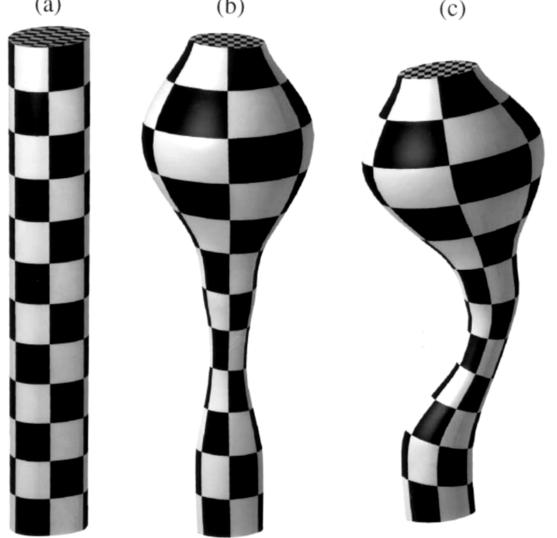

• Rectal segmentation from above the anal verge to the turn into sigmoid colon

- The evaluation of **rectal bleeding** seems to have a *n* value lower than other endpoints (0.09)
- The reduction of V75 from 15% to 10% is more effective than reduction of V50 from 50% to 45% respectively

Michalski JM et al. Radiation Dose-Volume effects in radiation-induced rectal injury. Int. J. Radiation Oncology Biol. Phys., Vol. 76, No. 3, Supplement, pp. S123–S129, 2010.

• Dose-Volume histogram (**DVH**) against Dose-Wall Histogram (**DWH**)

Meijer GJ et al. Dose-wall histograms and normalized dose-surface histograms for the rectum: A new method to analyze the dose distribution over the rectum in conformal radiotherapy. Int J Radiat Oncol Biol Phys 1999;45:1073–80.

Dose-Volume histogram (**DVH**) against Dose-Wall Histogram (**DWH**)

Abbreviations: DVH = dose-volume histogram; DWH = dose-wall histogram; NTCP = normal tissue complication probability.

- Toxicity scored with a modified RTOG score
- Endpoint G2 or higher within 2 years from the end of the treatment

Tucker SL et al. Comparison of rectal dose-wall histogram versus dose-volume histogram for modeling the incidence of late rectal bleeding after radiotherapy. Int J Radiat Oncol Biol Phys 2004;60:1589–601.

Multivariate modeling for detecting rectal toxicity (G3 late rectal bleeding)

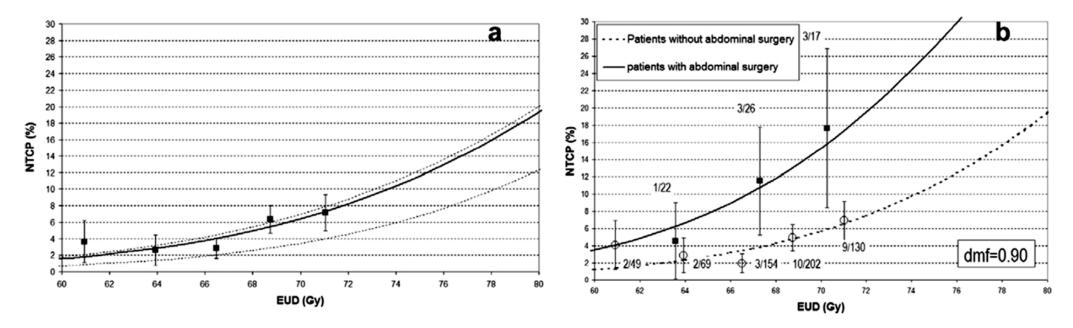

Fig. 2. Incidence of G3 late rectal bleeding vs EUD: (a) unmodified model (without inclusion of clinical risk factor), solid curve predicted NTCP curve, dashed curves 68% confidence interval, see text for the definition of confidence interval; (b) inclusion of previous abdominal surgery. Observed complication rates [symbols] and predicted NTCP curve [continuous lines] are plotted. Description of symbols: (a) solid squares (■) = all patients; (b) open circles (○) = patients without abdominal surgery, solid squares (■) = patients with abdominal surgery.

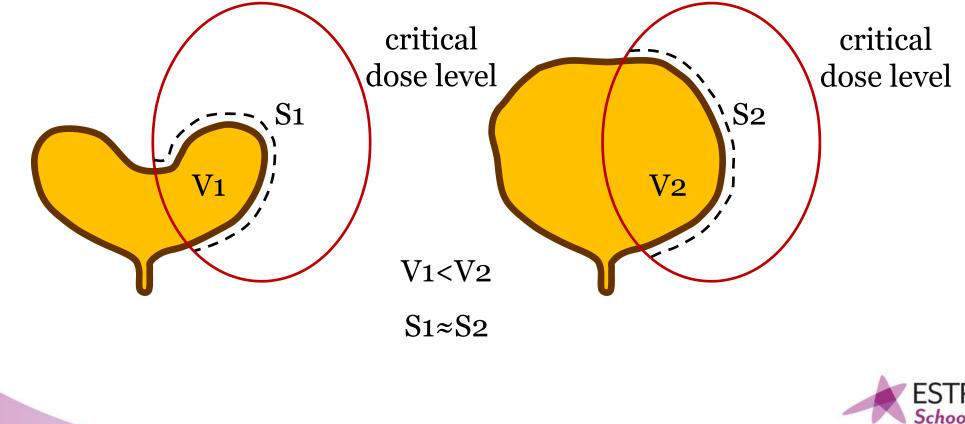

Logistic regression:
$$NTCP = \frac{1}{1 + \left(\frac{TD_{50}}{EUD}\right)^{k}}; EUD = \left(\sum_{i} v_{i} \cdot D_{i}^{\frac{1}{n}}\right)^{n} \frac{n:}{TD_{50}}; \begin{array}{ccc} 0.046\\ 93.1 \ Gy \\ k: \end{array} = \begin{array}{ccc} \frac{TD_{50}:}{93.2 \ Gy} \\ \frac{TD_{50}:}{10.4 \ Gy} \\ \frac{TD_{$$

T Rancati et al. Inclusion of clinical risk factors into NTCP modeling of late rectal toxicity after high dose radiotherapy for prostate cancer. Radiother Oncol 100 (2011) 124–130.

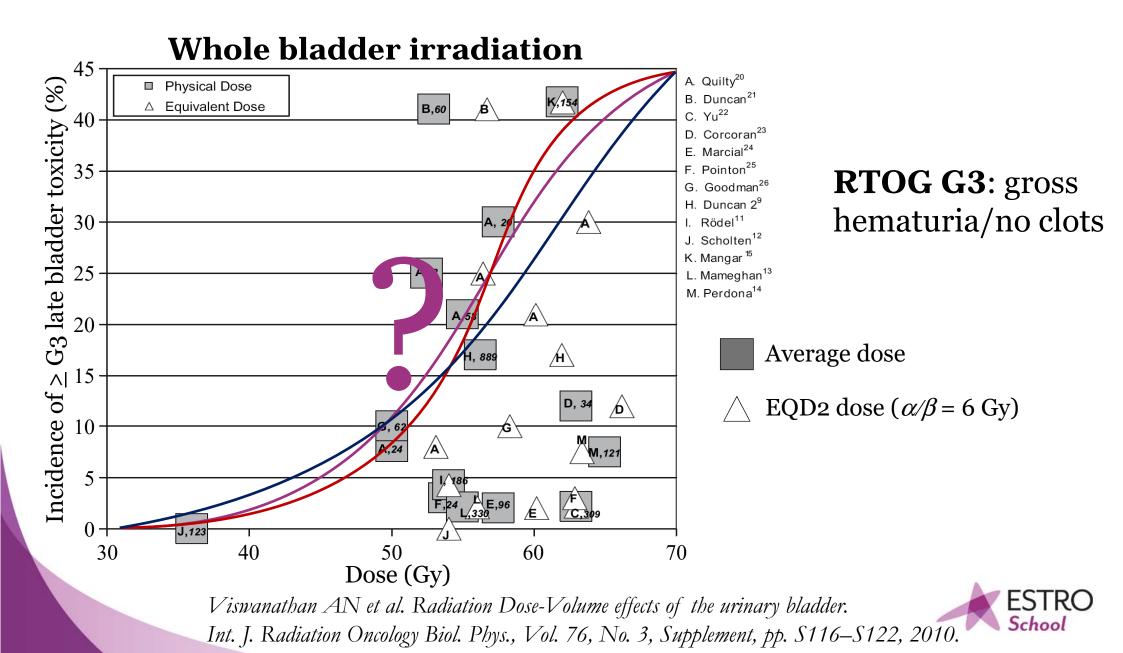

Parameters for clinical outcome: Urinary bladder

Problems in urinary bladder toxicity evaluation:

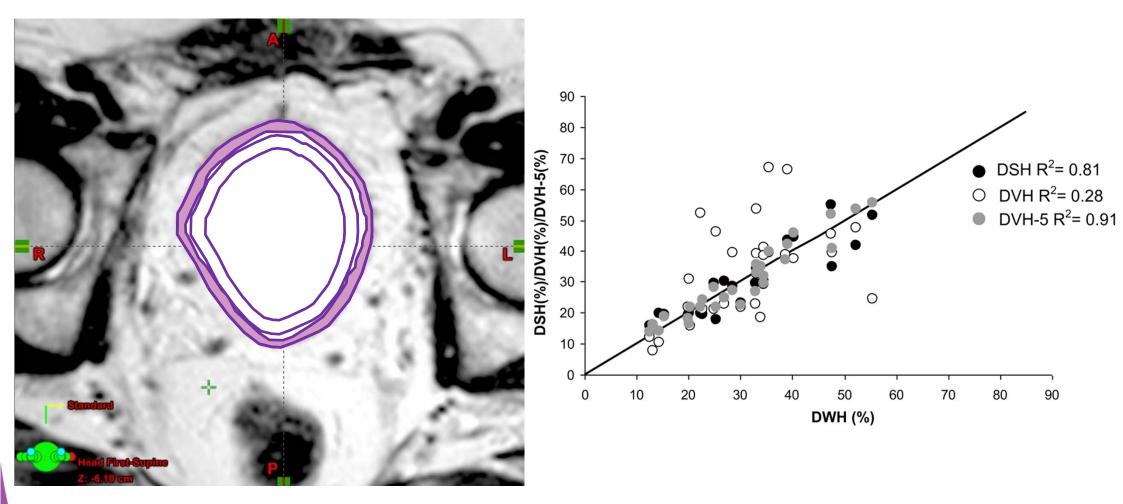

- 1) Heterogeneous evidences
- 2) Poor reliability
- 3) Problems in volume stability during treatment duration:
 - Definition of Vdose and Dvolume not reliable with a single CT scan

Parameters for clinical outcome: Urinary bladder

Is the DVH a good predictor of toxicity in bladder?

Carillo V et al. Correlation between surrogates of bladder dosimetry and dose-volume histograms of the bladder wall defined on MRI in prostate cancer radiotherapy. Radiother Oncol 2012;105:180–3.

Parameters for clinical outcome: Urinary bladder

Multivariate bladder toxicity modeling over clinical factors, DSH and DVH

Table 2

Results of the multivariate logistic analysis for the whole population, endpoint IPSS15end. Discriminative values of the models as measured by the areas under the receiver operating characteristic curve (AUCs) are reported.

Werner-Wasik IRJOBP 2010 76(3) Suppl., S86-S93

Mönchengladbach

Esophagus: late reactions

Fibrosis Stricture < 2% < 60 Gy

Influence factors:

- Dose
- Fractionation
- Volume

Therapy: symptomatic

Kliniken Maria Hilf

Thanks to M. Baumann

Grade 1 radiation-induced esophagitis was observed 1 week after the start of IGRT in 1 patient with metastatic lung cancer who received 48 Gy/8 Fr to the 3.5-cm tumor located posterior to the right main bronchus. The pain resulting from acute radiation esophagitis was relieved at 1 month after IGRT ended. However, this patient suffered from swallowing pain again 3 months after IGRT ended and died as a result of bleeding from an esophageal ulcer 5 months after IGRT ended.

Onimaru IJROBP 2003

Esophagus: planning constraints

conventional fractionation

RTOG 0117:

- V55 < 30%; mean dose < 34Gy

QUANTEC (Werner-Wasik 2010):

- esophagus dose should not exceed prescription dose
- mean dose < 34 Gy
- max dose up to 74 Gy/ 2Gy + CHT

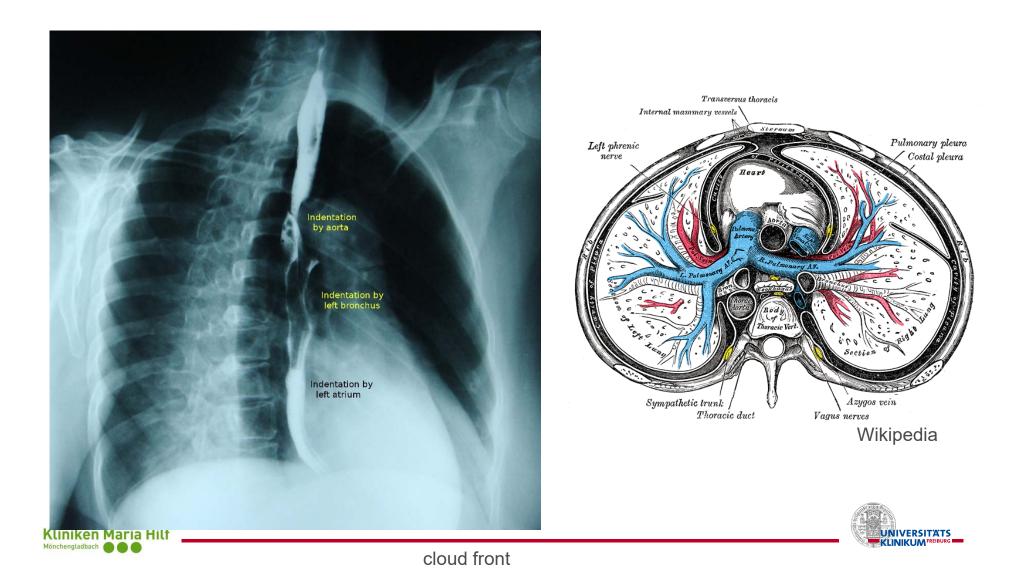

SBRT

Rosel-trial:

maximum dose: 24Gy/3fr or 27Gy/5fr

Esophagus: anatomy

Esophagus: contouring

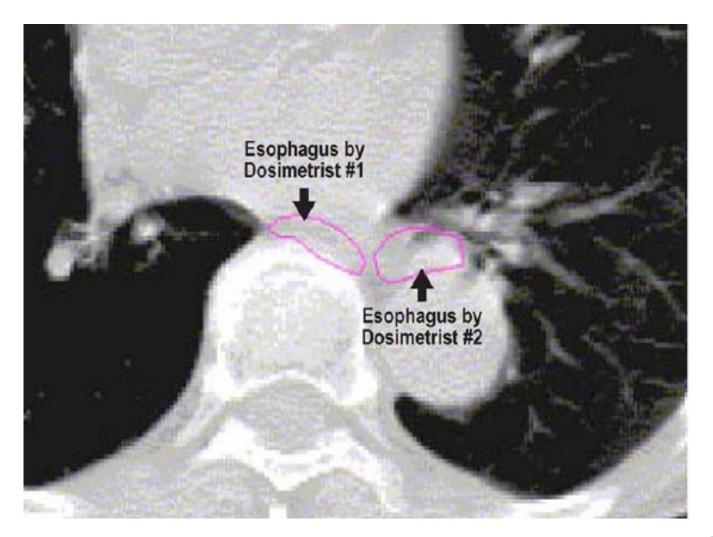

- contour whole organ including its filling from cricoid cartilage to gastroesophageal junction

Challenges: may be difficult to find (search for air) varying filling often collapsed (barium swallow or interpolation may help)

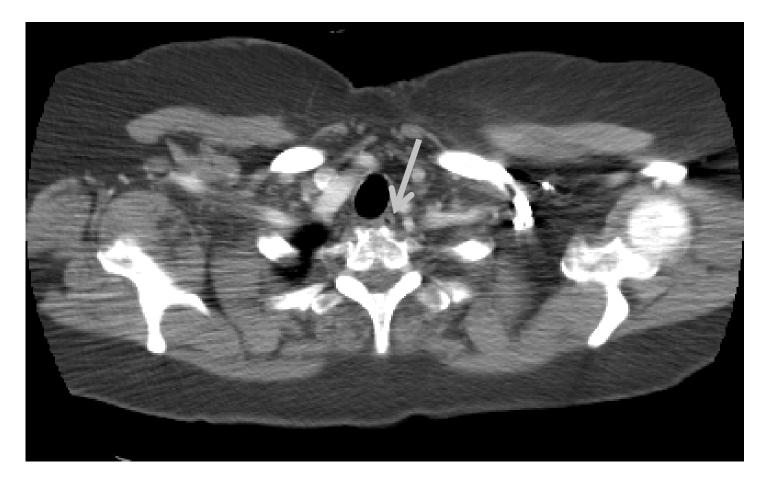

Esophagus: geographic miss

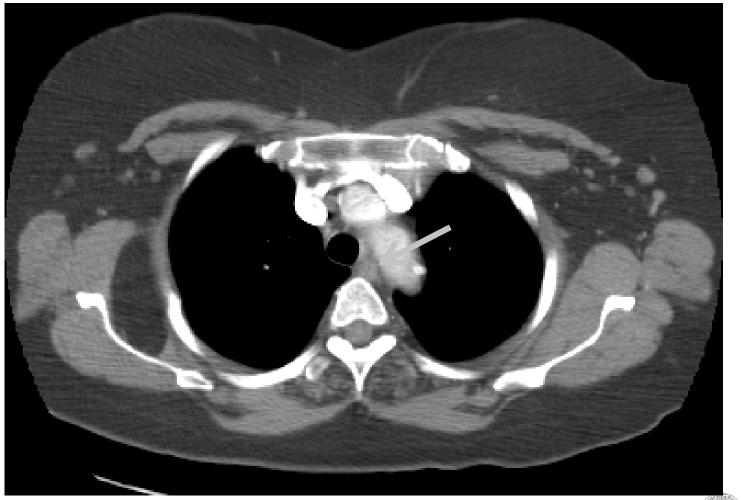

Collier 2003 JACMP 4; 17-24

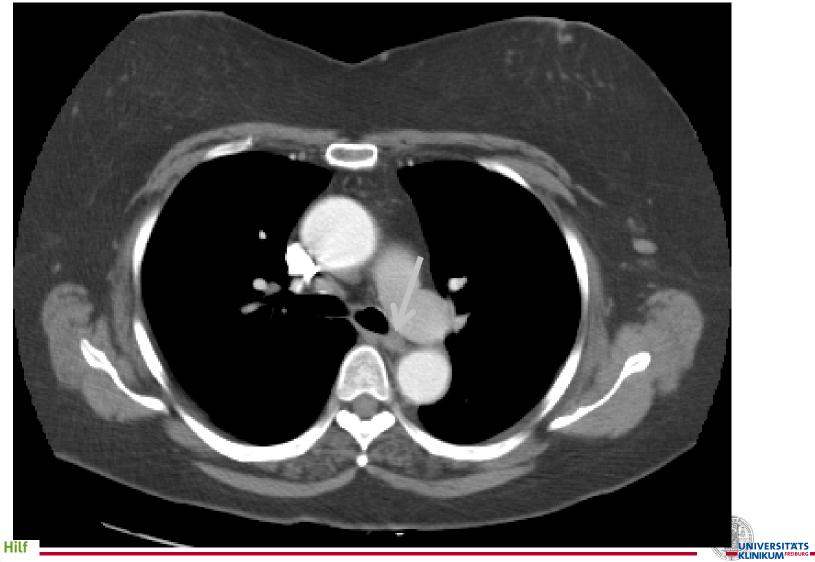

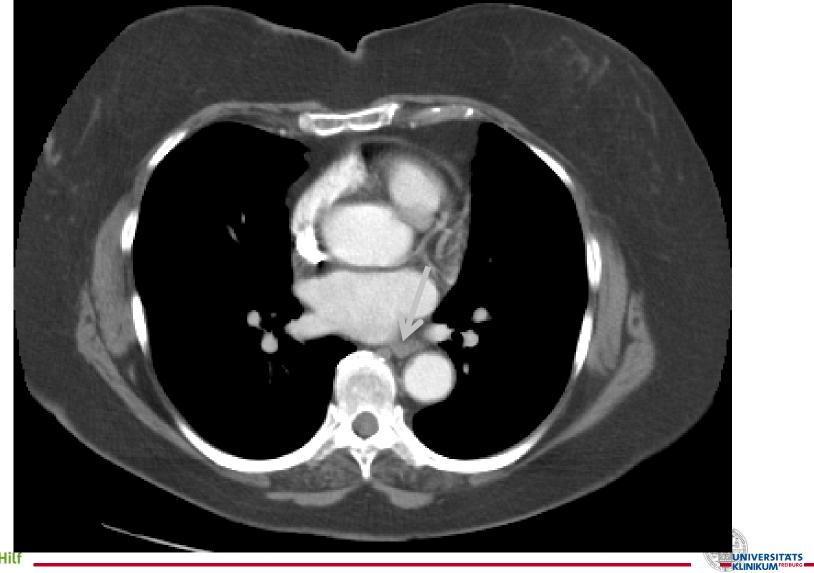

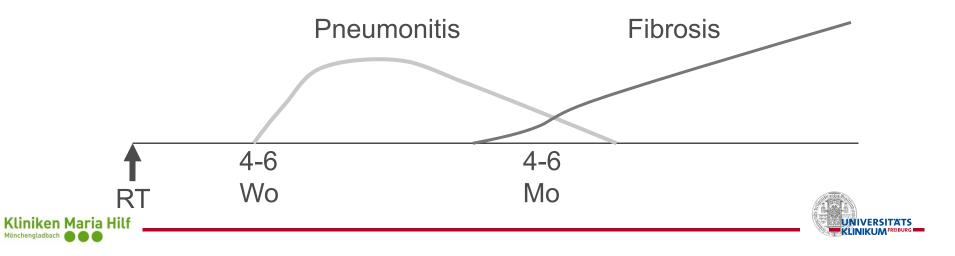

Lung (RILD)

- 1. acute radiogenous Pneumonitis (cough, fever, dyspnea) Treatment: Corticoids
- focal radiogenous fibrosis symptoms depending on volume involved treatment: none prophylaxis: treatment planning

RILD: influence factors

Total dose: clear dose-response relation; tolerance < 25 Gy/2 Gy clear fractionation effect Influence factors: old age, smoking, chemotherapy

Graham et al. IJROBP1999:

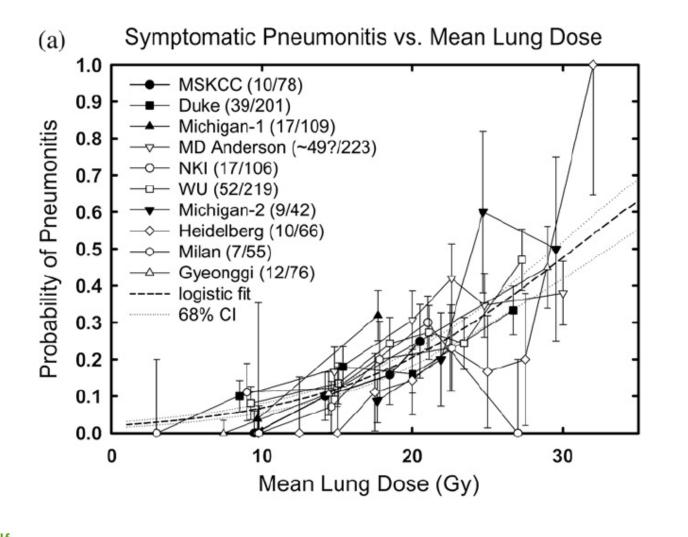

V20 single best predictor of acute pneumonitis (cave: 3D-CRT)

V (%)	Grade 2 (%)	Grade 3–5 (%)
V ₂₀ (%)	(70)	(70)
<22	0	0
22-31	8	8
32-40	13	5 (1 fatal)
>40	19	23 (3 fatal)
nut		

Table 6. Correlation between V_{20} and severity of pneumonitis

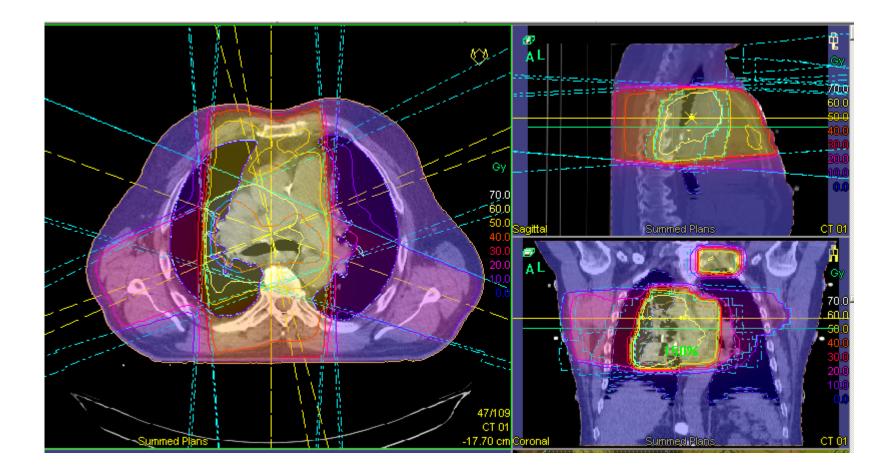

RILD: corelation between MLD and probability of symptomatic pneumonitis

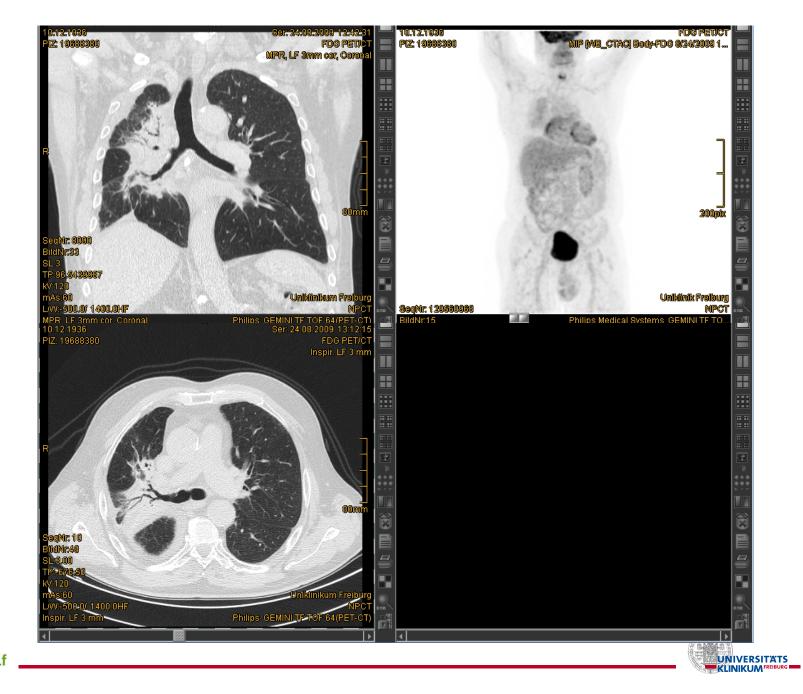

Marks, IJRBOP 76(3) S70-S76 2010

NSCLC IIIb, chemo-radiotherapy; 60 Gy/2 Gy + 2 cycles Cisplatinum V20: 36%; MLD: 20 Gy

Kliniken Maria Hilf

PET/CT 11 mths after RT

Lung: planning constraints I

Conventional RT V20: < 30% (RTOG 0117) < 35% (PET-Plan; Convert) < 31% (LungART, after lobectomy) < 22% (LungART, after pneumonecomy) mean lung dose < 20 Gy (PET-Plan) to be recorded (Convert, LungART)

QUANTEC:

Despite these caveats, it is prudent to limit V20 to \leq 30–35 % and MLD to \leq 20–23 Gy (with conventional fractionation) if one wants to limit the risk of RP to \leq 20% in definitively treated patients with non–small-cell lung cancer.

Lung: what about low doses?

RESEARCH

Open Access

Analysis of clinical and dosimetric factors associated with severe acute radiation pneumonitis in patients with locally advanced non-small cell lung cancer treated with concurrent chemotherapy and intensity-modulated radiotherapy 94 pts, LANSCLC RCT + IMRT CTC 3.0

Anhui Shi, Guangying Zhu*, Hao Wu, Rong Yu, Fuhai Li and Bo Xu

Varibale	Median(Range)	Group	No. of patients	No. of RP	p value*
NTCP	2.33%	≤4.20%	71	1(1.4%)	0.001
	(0.51-9.68%)	>4.20%	23	10(43.5%)	
V10	42.16%	≤50%	70	4(5.7%)	0.005
	(9.91-83.34%)	>50%	24	7(29.2%)	

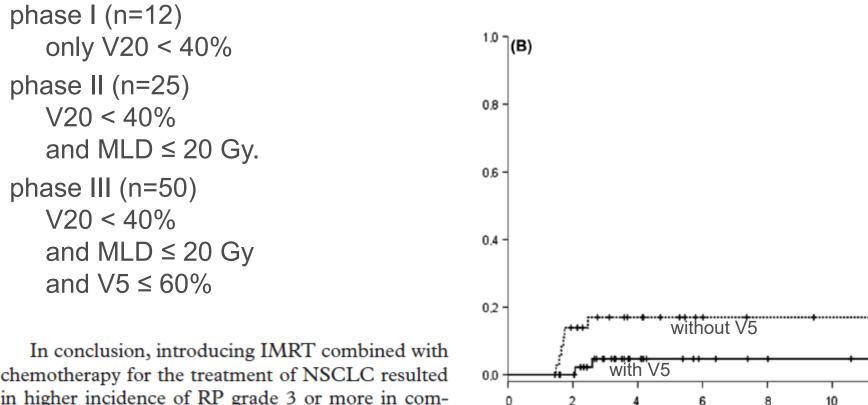

Table 4: Observed rates of SARP as a function of dosimetric parameters (NTCP/V10)

Abbreviation: NTCP = normal tissue complication probability; SARP = severe acute radiation pneumonitis; * Multivariate logistic regression analysis.

Conclusions: NTCP value and V10 are the useful indicators for predicting SARP in NSCLC patients treated with concurrent chemotherapy and IMRT.

Lung: what about low doses?

Khalil et al. Acta Oncol 2015: IMRT, LANSCLC, 87 cases

chemotherapy for the treatment of NSCLC resulted in higher incidence of RP grade 3 or more in comparison to 3D-CRT. Prospectively monitoring patients and introduction of new dose constraints, especially for volume receiving low doses could reduce the incidence of lethal RP in patients treated with IMRT.

Time to develop RP grade 5 (months)

maximum dose 24 Gy/ 3 fr or 27 Gy / 5 fr (ROSEL) 32 Gy / 5 fr < 15 cc (RTOG 0813)

QUANTEC: For partial irradiation, conservative (NTCP) model-based estimates predict that a $V_{25Gy} < 10\%$ (in 2 Gy per fraction) will be associated with a <1% probability of cardiac mortality ~15 years after RT. For this a conservative (*i.e.*, overly safe) model was

Heart: Delineation

there is no present standard for contouring heart

Options:

1. contour relevant structures (CAs, valves, myocardium) problem: movements; no restrictions available due to lack of data

2. contour left ventricle only problem: dose to other relevant cardiac structures not documented

3. contour whole organ problem: no subvolumes available for further optimisation

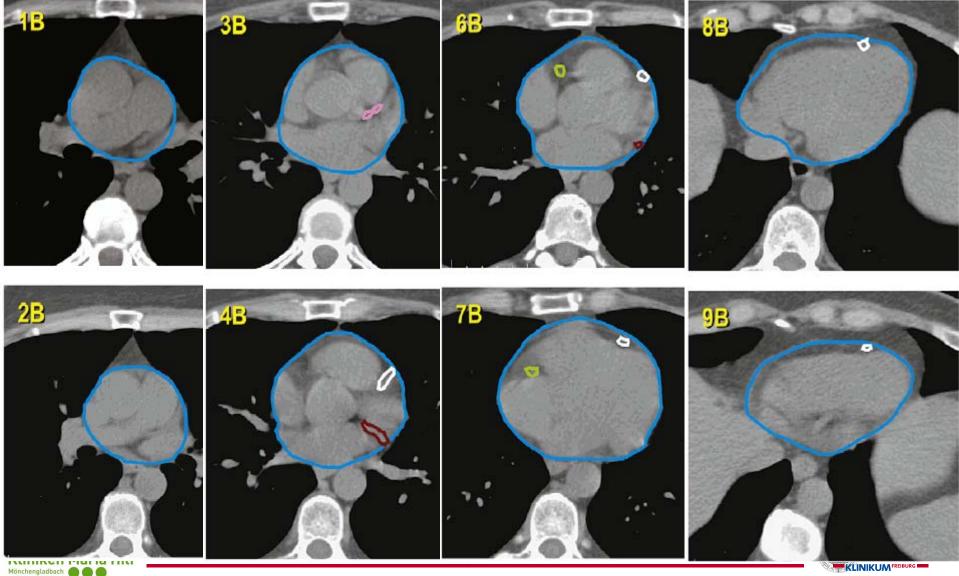

Heart: contouring

Whole Heart and pericardium. Superiorly, the WH starts just inferior to the left pulmonary artery. For simplification, a round structure to include the great vessels as well can be contoured. Inferiorly, the heart blends with the diaphragm. Since cardiac vessels run in the fatty tissue within the pericardium, they should be included in the contours, even if there is no heart muscle visible in that area. If contrast is administered, the superior vena cava (SVC) can generally be contoured separately from the WH. If this is not possible, or when working with a noncontrast scan, the superior vena cava can be included for simplification and consistency.

NA, not applicable.

Forquer, R&O 2009; 93; 408-412

Contouring the brachial plexus

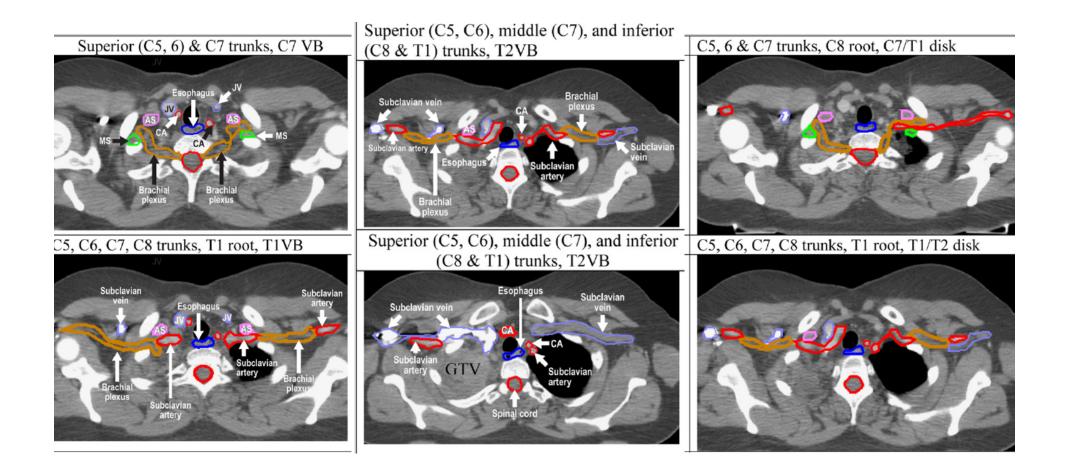

- Locate the neural foramina at the C4-C5 and T1-T2 levels to identify the C5 and T1 roots, respectively
- Locate the subclavian and axillary neurovascular bundle to identify the lateral aspect of the brachial plexus inferiorly
- Locate the anterior and middle scalene muscles from the C5 vertebral level to their respective insertions on the first rib
- 4. Start at the neural foramina at the C4-C5 level and moving caudally; contour the region from the lateral aspect of the spinal canal laterally to the small space between the anterior and middle scalene muscles. At levels at which no neural foramina are present, contour the space or soft tissue between the anterior and middle scalene muscles
- Continue to contour the space between the anterior and middle scalene muscles; eventually, the middle scalene muscle will terminate in the region of the subclavian neurovascular bundle
- 6. Contour the brachial plexus structures inferiorly until the region of the subclavian vascular bundle is identified, the second rib should serve as the medial limit

Practical aspects of IMRT planning part 2

Advanced Treatment Planning Course 3-7 September 2017 – Barcelona, Spain

Markus Stock

Content

- number of beams, class solutions
- beam angle optimization
- energy
- MLC geometry, limitations
- collimator angle
- leaf width
- # of MU in IMRT planning
- isocenter position
- IMRT as efficiency tool for 'simple 3D-CRT'

Number of beams, class solutions

standard number of beams is often applied to specific treatment sites:

- 3,5 or 7 beams in prostate treatment
- 5,7,9 beams in head and neck treatment

class solution = 'group average' set of constraints, number of beams and beam angles (for an 'average' patient!?)

consider class solutions a good starting point look at differences between this patient and the group (different shape, rotations, etc.)

Number of beams, class solutions

when an IMRT plan is getting complicated: try to add a beam!

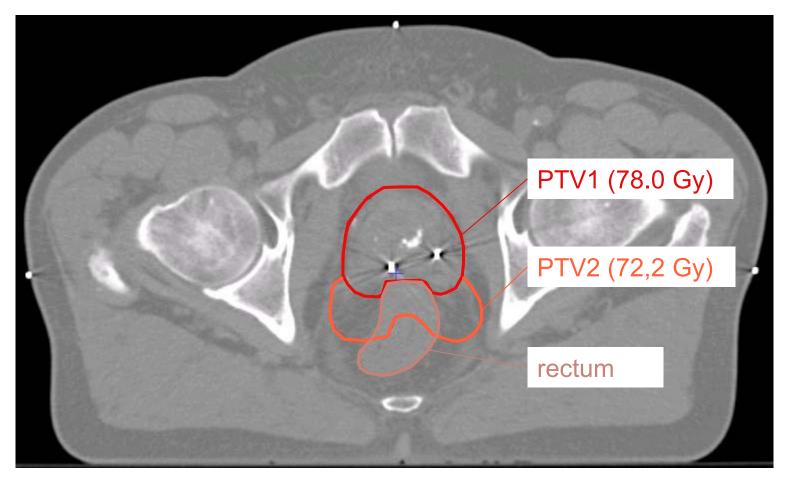

more beams results in:

- more degrees of freedom for the optimizer
- (often) less modulation per field, so easier to segment

more beams will <u>not</u> automatically result in more treatment time!

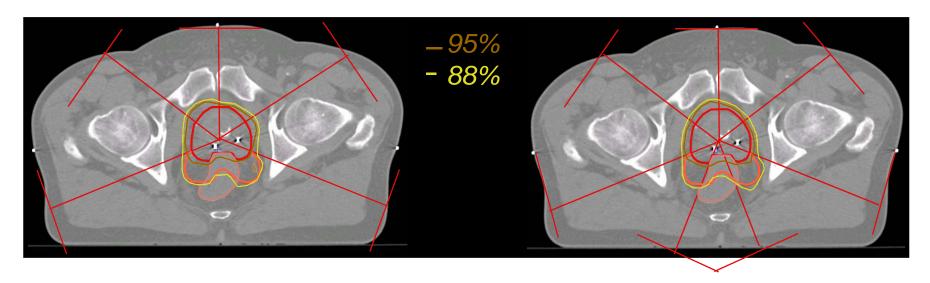

- SIB planning

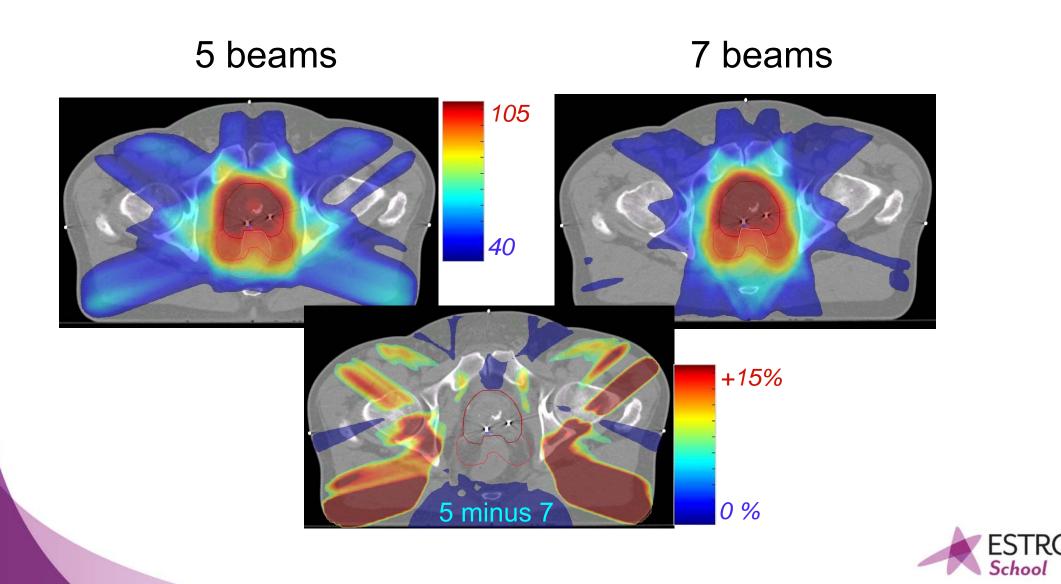

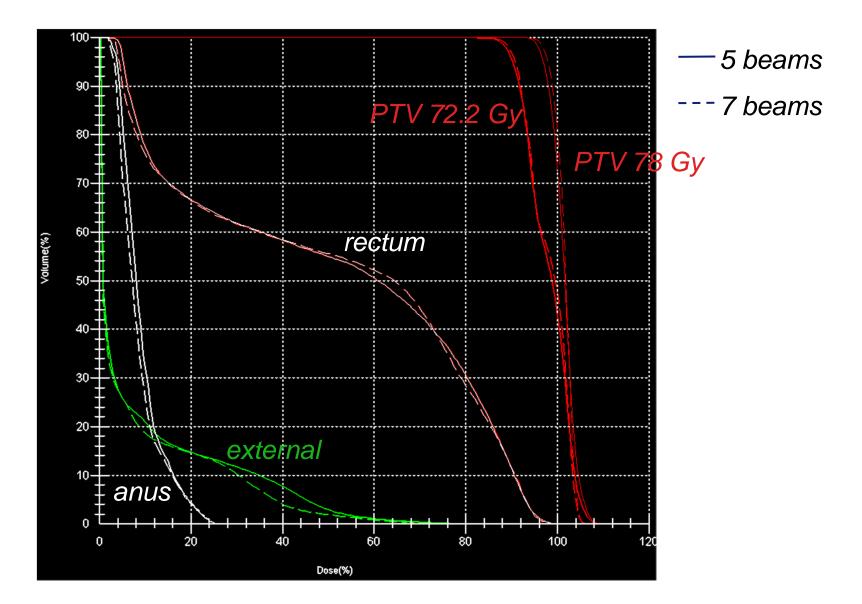

5 beams

7 beams

Monaco		
Mean Dose (Gy)	5 beams	7 beams
External	6.0	5.3
Rectum	39.3	39.2
Anus	6.9	6.3

Monaco		
	5 beams	7 beams
# segments	37	32
# MU's	465	438

beam angle optimization

Beam angle optimization

current status of the clinical use of non-coplanar (nCP) beams and of

beam angle optimization (BAO):

- nCP beams used a lot in cranial SRT and SBRT (liver, lung), generally without IMRT
- Gantry-based units: nCP beams requires couch rotations time consuming, so preferentially avoided
- (Commercial) TPS for BAO + IMRT are generally not available
- Iittle is (and can be) known on the added value of BAO + IMRT and non-coplanar beams

Beam angle optimization

Rotterdam:

 Several years ago start of a program focused on building inverse planning systems for BAO to investigate optimization of both coplanar

and non-coplanar beam setups (initial main focus: liver SBRT)

 new data with strong evidence that both BAO and nCP beams can significantly contribute to treatment plan quality

Med Phys. 2012 Feb;39(2):951-63.

iCycle: Integrated, multicriterial beam angle, and profile optimization for generation of coplanar and noncoplanar IMRT plans.

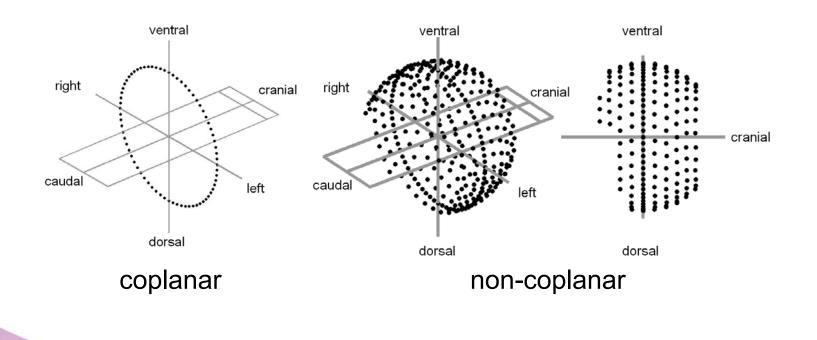

Breedveld S, Storchi PR, Voet PW, Heijmen BJ.

Department of Radiation Oncology, Erasmus MC Rotterdam, Groene Hilledijk 301, 3075 EA Rotterdam, The Netherlands. s.breedveld@erasmusmc.nl

Erasmus-iCycle: main features

- beams are sequentially added to the plan in an iterative procedure
- coplanar beam set-ups: selection from 72 directions (5°)
- non-coplanar set-ups: extend input beam set with noncoplanar beams that avoid collisions (every 10°, ~300)

Example iCycle output

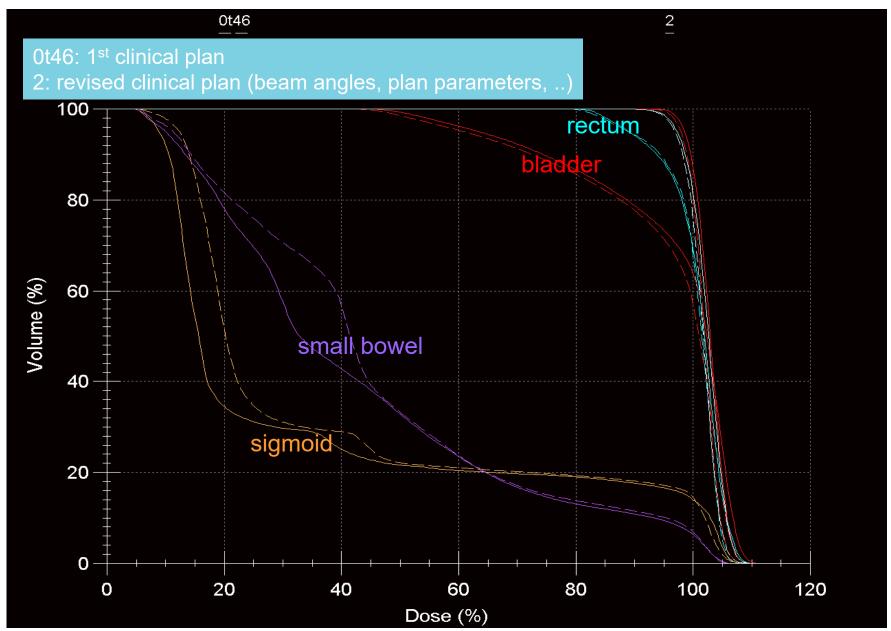

Nr of beams	9	8	7	6
Constraints	and obje	ectives:

Optimality when using small number of beams?

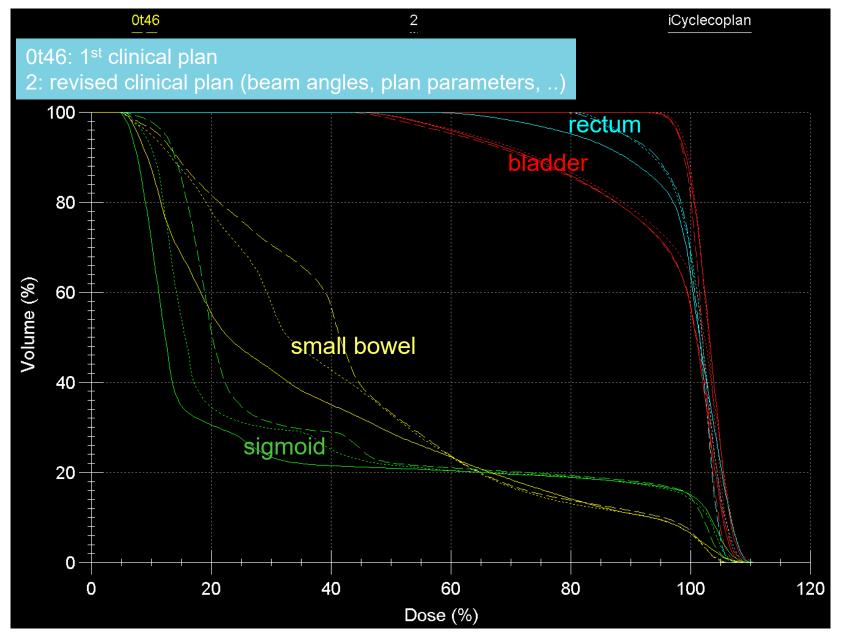

Example: Cervix IMRT Monaco patient

Example: Cervix IMRT Monaco patient

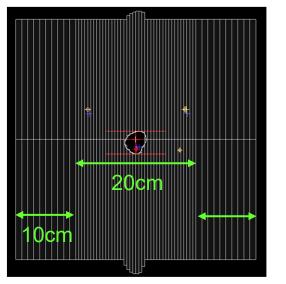

Effect of energy in IMRT planning

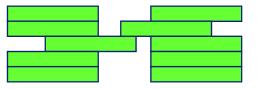

- 6 MV, 10MV, 18MV
 - sharp gradients can only be created using the beam penumbra so, 6 MV often results in the best plan, in terms of OAR sparing
 - however, the volume treated with low dose differs a lot between different energies
 - 6 MV in pelvic region??
 - combination of different energies is a good option (computer based choice?)

MLC geometry: Varian (millenium MLC)

- 120 MLC
- max field size : 40 x 40 cm
 - 20 cm : leaf width = 5mm, outside, 1 cm
- maximum overtravel in (IMRT) fields is 14.3 cm:
 - so, if an IMRT field width ≥ 14.3 cm → splitting beam
 - field width ≈ 28 cm → splitting again ('*carriage positions*')
- inter-digitating MLC's
- closing opposing leaf-pairs

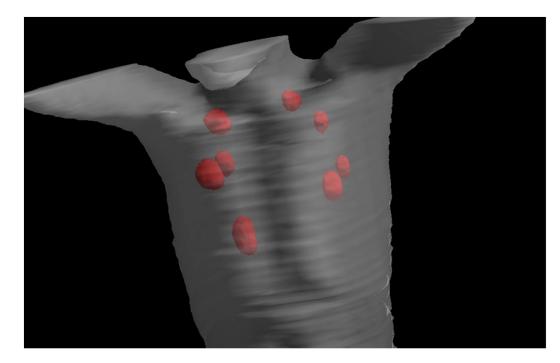

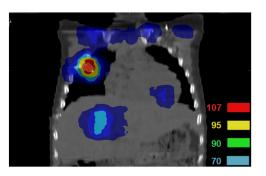

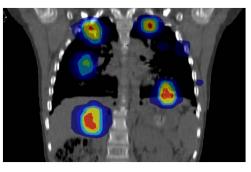

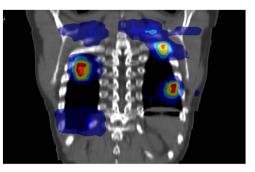

Clinical example multiple PTV case

- 6 year old boy, nefroblastoma, ri.kidney
- boost on multiple metastases (8 in total!)
- 1 isocenter, 6 x 1.8 Gy

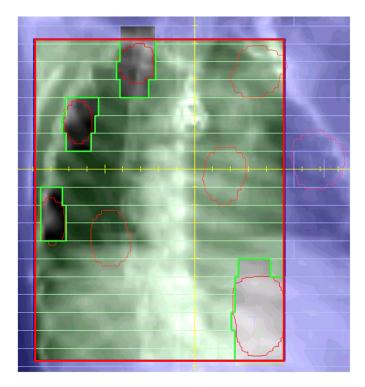

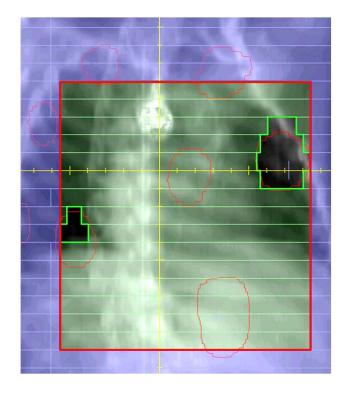

Example multiple PTV (8!) IMRT plan: Varian

segment 1

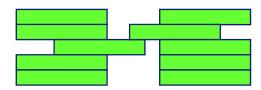

segment x

1.8 Gy / fraction
 8 fields
 38 segments, 555 MU

MLC geometry: Elekta (MLCi, MLCi2)

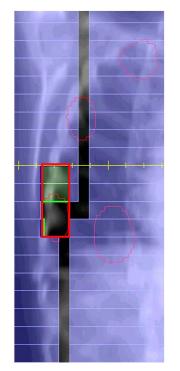

- no splitting of beams
- MLCi : no interdigitating leafs
- MLCi2 : interdigitating leafs

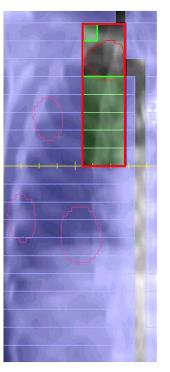

- minimum gap for opposing leaf pairs : 5 mm (MLCi , MLCi2)
- No overtravel on Y-jaws (MLCi , MLCi2)

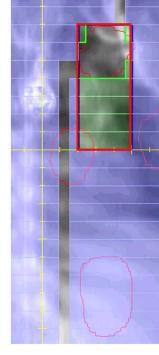

Example multiple PTV IMRT plan: Elekta , MLCi

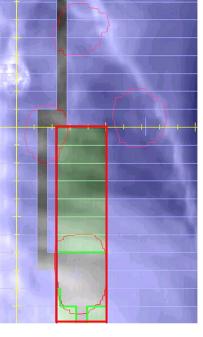

segment 1

segment 2

segment x

1.8 Gy / fraction
 fields
 131 segments, 2239 MU

similar DVH's Varian - Elekta

Example multiple PTV IMRT plan: Elekta versus Varian

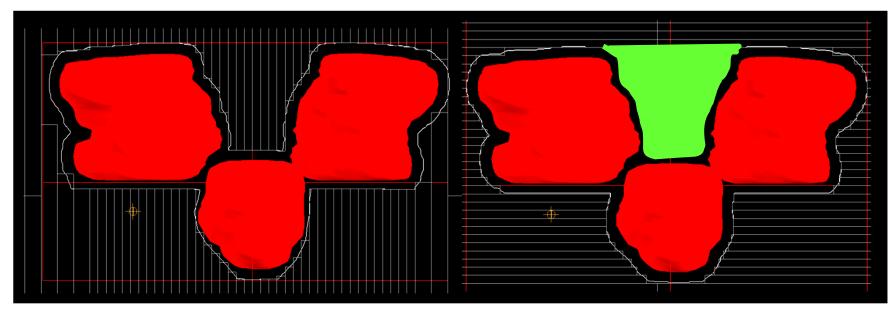

- 3.4 x more # segments
- 4 x more # MU
- in this example the MLC limitations resulted in large differences.
 Step&Shoot IMRT segmentation might not be the best approach on an Elekta linac equiped with MLCi in <u>this specific</u> case

in 'normal' cases not much difference between Varian and Elekta MLCi MLCi2: improved segmentation, similar to Varian MLC

Collimator angle

effect of collimator angle depends on the IMRT restrictions

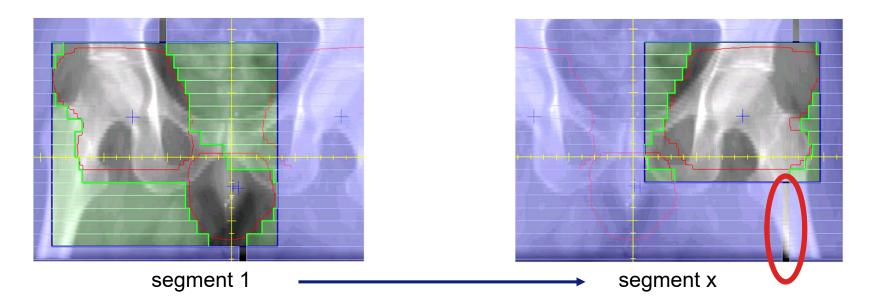

Collimator 90°

Collimator 0°

Effect of collimator angle depends on the IMRT delivery

In step&shoot delivery: block the 'central area'

• in d-MLC delivery:

leafs should be closed when travelling 'across' the central area Elekta MLCi 90° versus Varian / Elekta MLCi2: 0° / 90° or allow for '*move only segments*'

WWW.ESTRO.ORG/SCHOOL

Geometric uncertainties and how to deal with them

Marcel van Herk

Institute of Cancer Sciences Manchester University The Christie NHS Trust

(Formerly at the Netherlands Cancer Institute)

The University of Manchester Manchester Cancer Research Centre

Problems in radiotherapy:

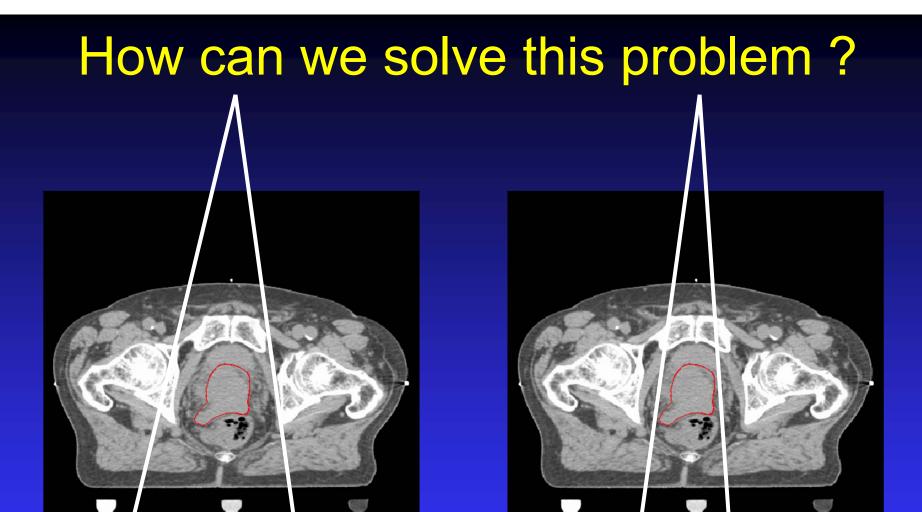

The patient is nervous, did not sleep the night before and lay wriggling on the CT scanner

The physician was in a rush when drawing the target volume

The patients belly flopped from day to day, letting the skin marks move all over the place

The patient was breathing

1. Use large margins, irradiating too much healthy tissues

2. Use small margins, and risk missing the target

3. Or: use image guided radiotherapy

Image Guided Radiotherapy

Increase precision by imaging target and/or healthy tissues just prior to treatment

Image guidance does not solve all geometrical uncertainties and variations and introduces new ones

IGRT Technologies

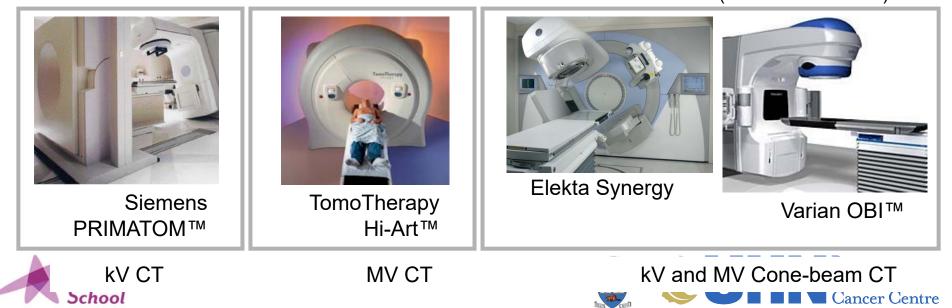

Ultrasound

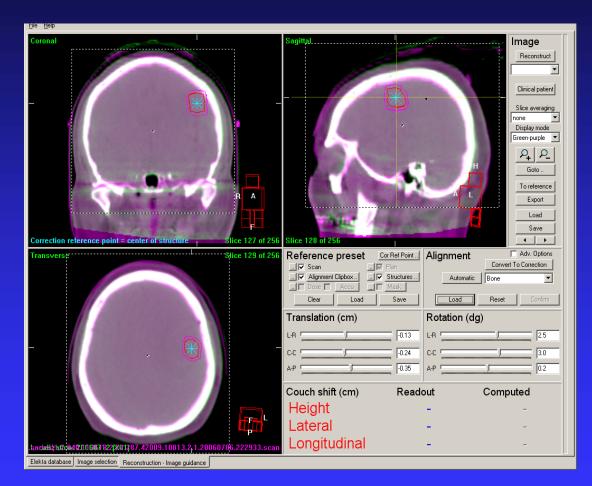

kV Radiographic

Portal Imaging

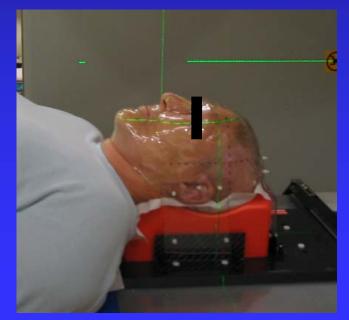

IGRT is brilliant !

Accuracy registration: 0.1 mm SD Accuracy table: 0.5 mm {x, y, z} Intra-fraction motion: 0.3 mm SD

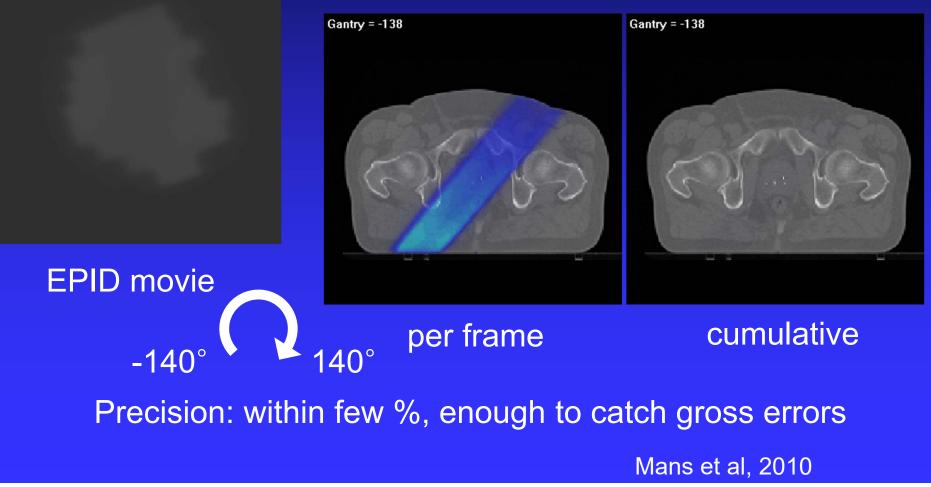

Nomenclature

- Gross error: mistakes, transcription errors, software faults:
 - must be caught by QA
- Error: difference between planned value and its true value during treatment, however small
- Uncertainty: the fact that unpredictable errors occur quantified by standard deviations
- Variation: the fact that predictable or periodic errors occur

EPID dosimetry QA to catch gross errors: used for all curative patients at NKI

Gantry = -138

Reconstructed EPID dose (VMAT case)

Gross errors detected in NKI

2640 Mans et al.: Catching errors with in vivo EPID dosimetry

TABLE I. Errors detected by means of EPID dosimetry from the clinical introduction to July 2009, grouped by (a) treatment site and (b) error type.

(a) Site	Clinical introduction	No. of patients	No. of errors		
Prostate	02-2005	1018	2		
Rectum	07-2006	602	4		
Head-and-neck	06-2007	543	4		
Breast	01-2008	1319 454 401	2		
Lung	01-2008		2		
Others	01-2008		3		
	Total	4337	17		
(b) Error type	No. of errors				
Patient anatomy	7				
Plan transfer	4				
Suboptimally tuned TPS parameter	2				
Accidental plan modification	2				
Failed delivery	1				
Dosimetrically undeliverable plan	1				
Total	17				

0.4% of treatments show a gross error (>10% dose)

9 out of 17 errors would not have been detected pretreatment !!

What happens in the other 99.6%?

- There are many small unavoidable errors (mm size) in all steps of radiotherapy
 - In some cases many of these small errors point in the same direction
 - I.e., in some patients large (cm) errors occur(ed)

This is not a fault, this is purely statistics

- What effect does this have on treatment?
 - We do not really know!

Motion counts? Prostate trial data (1996)

N=185 (42 risk+)

N=168 (52 risk+)

Risk+: initial full rectum, later diarrhea

Heemsbergen et al, IJROBP 2007

The major uncertainties not solved by IGRT

- Target volume definition
 - GTV consistency
 - GTV accuracy
- Inadequacy of surrogate used for IGRT
- Motion that cannot be corrected
 - Too fast
 - Too complex

Delineation variation: CT versus CT + PET

CT (T2N2) SD 7.5 mm CT + PET (T₂N₁) SD 3.5 mm

Consistency is imperative to gather clinical evidence!

Steenbakkers et al, IJROBP 2005

Are prostate markers perfect?

Apex

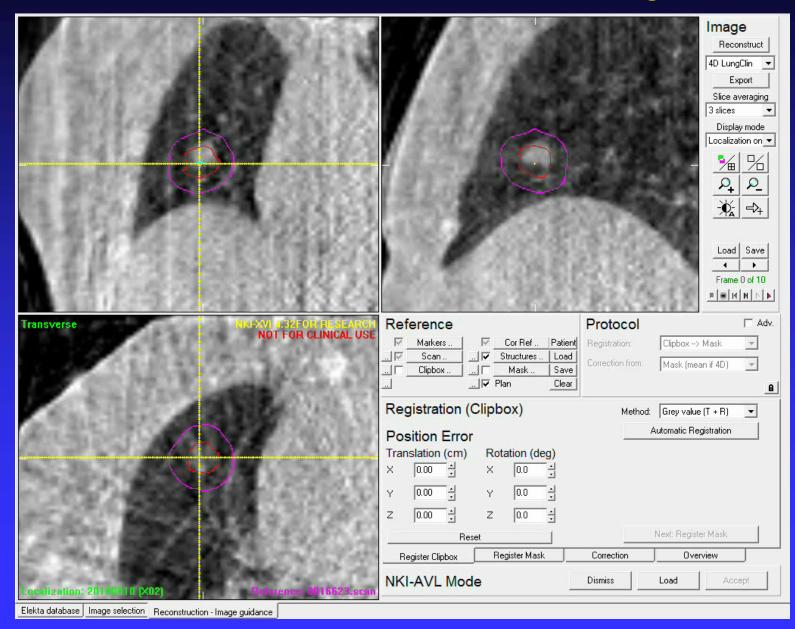

Base

Sem. Vesicles → +/-1 cm margin required

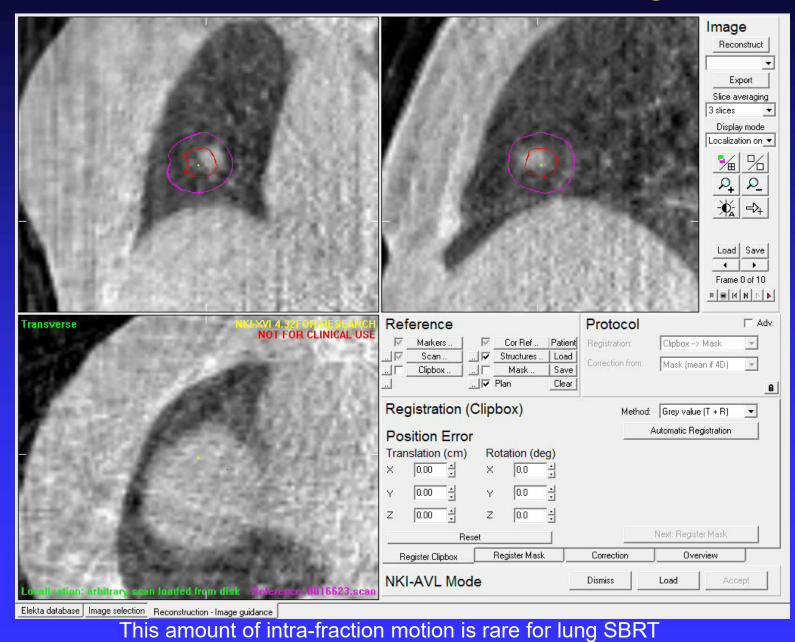

Best: combine markers with low dose CBCT

van der Wielen, IJROBP 2008 Smitsmans, IJROBP 2010

Intra-fraction motion: CBCT during VMAT

Intra-fraction motion: CBCT during VMAT

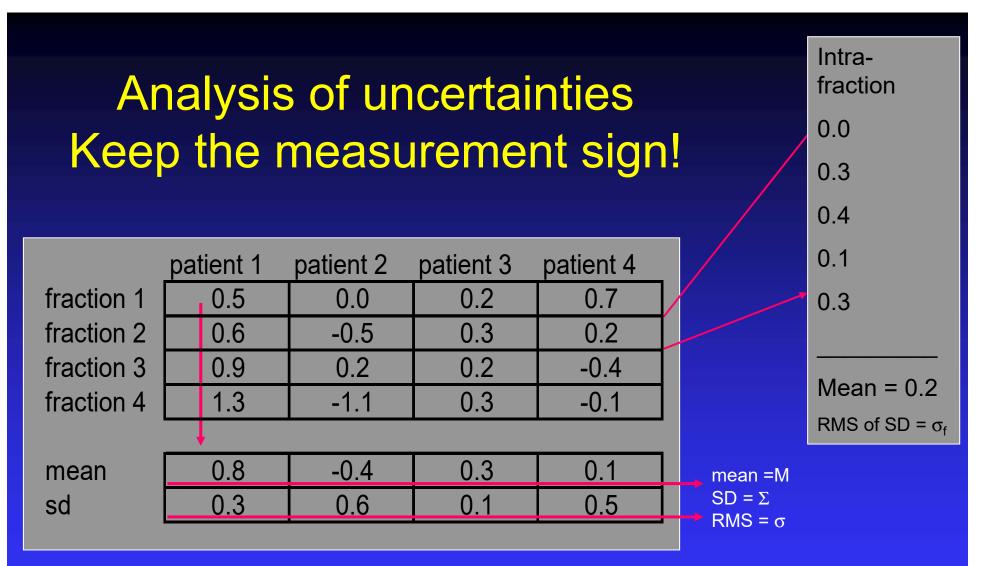

Definitions (sloppy)

 CTV: Clinical Target Volume The region that needs to be treated (visible plus suspected tumor)

 PTV: Planning Target Volume The region that is given a high dose to allow for errors in the position of the CTV

PTV margin: distance between CTV and PTV

. ITV not optimal for external beam! (SD add quadratically)

M = mean group error (equipment)

 Σ = standard deviation of the inter-patient error

 σ = standard deviation of the inter-fraction error

 σ f = standard deviation of the intra-fraction motion

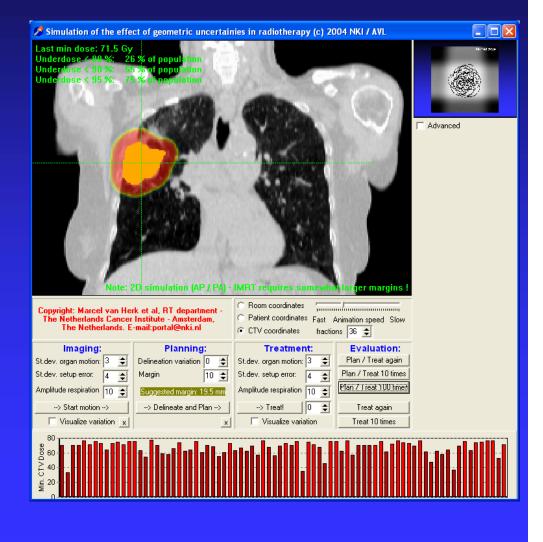

van Herk et al, Sem Rad Onc 2004

Demonstration – errors in RT

 Margin between CTV and PTV: 10 mm

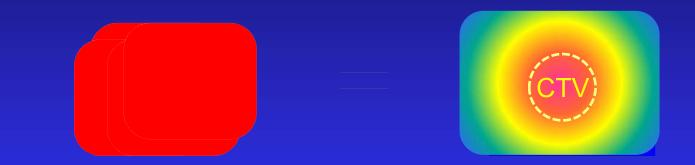

• Errors:

- Setup error:
 - 4 mm SD (x, y)
- Organ motion:
 - 3 mm SD (x, y)
 - 10 mm respiration
- Delineation error: optional

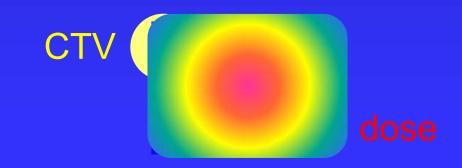

What is the effect of geometrical errors on the CTV dose ?

Random: Breathing, intrafraction motion, IGRT inaccuracy

Systematic: delineation, intrafraction motion, IGRT inaccuracy

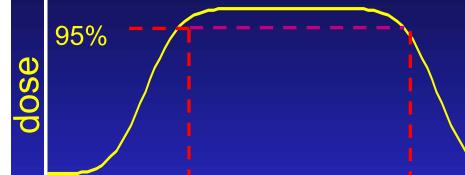

Analysis of CTV dose probability

 Blur planned dose distribution with all execution (random) errors to estimate the cumulative dose distribution

- For a given *dose* level:
 - Find region of space where the cumulative dose exceeds the given level
 - Compute *probability* that the CTV is in this region

Computation of the dose probability for a small CTV in 1D

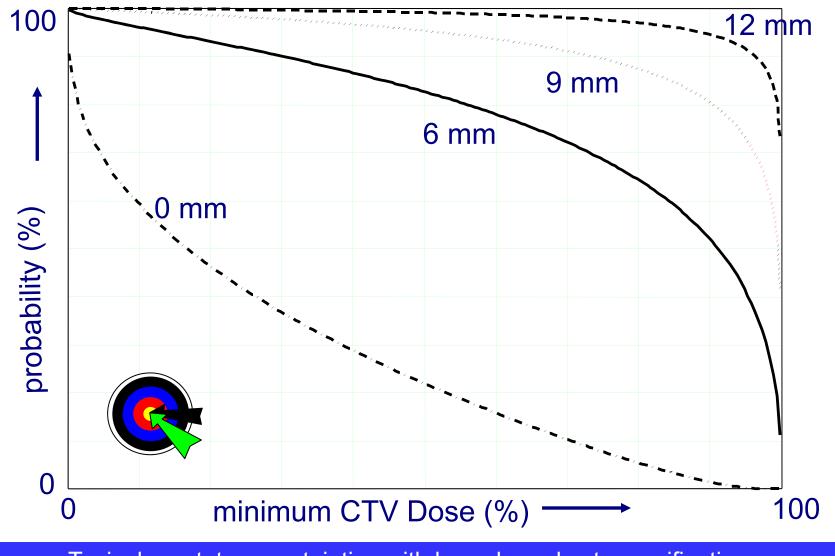

98%

In the cumulative (blurred) dose, find where the dose > 95%

average CTV position

..and compute the probability that the average CTV position is in this area

What should the margin be ?

Typical prostate uncertainties with bone-based setup verification

Simplified PTV margin recipe for dose - probability

To cover the CTV for 90% of the patients with the 95% isodose (analytical solution) :

PTV margin = $2.5 \Sigma + 0.7 \sigma$

 Σ = quadratic sum of SD of all preparation (systematic) errors σ = quadratic sum of SD of all execution (random) errors

(van Herk et al, IJROBP 47: 1121-1135, 2000)

*For a big CTV with smooth shape, penumbra 5 mm

$2.5\Sigma + 0.7\sigma$ is a simplification

 Dose gradients ('penumbra' = σ_p) very shallow in lung → smaller margins for random errors

$$M = 2.5\Sigma + 1.64\sqrt{(\sigma_{p}^{2} + \sigma^{2})} - 1.64\sigma_{p}$$

Number of fractions is small in hypofractionation

- Residual mean of random error gives systematic error
- Beam on time long \rightarrow respiration causes dose blurring
- If dose prescription is at 80% instead of 95%:

$$M = 2.5\Sigma + 0.84\sqrt{(\sigma_p^2 + \sigma^2)} - 0.84\sigma_p$$

Practical examples

Prostate: $2.5 \Sigma + 0.7 \sigma$

Planned dose distribution: hypofractionated lung treatment 3x18 Gy

Realized dose distribution with daily IGRT on tumor (no gating)

9 mm margin is adequate even with 2 cm intrafraction motion

Clinical results with mid-V

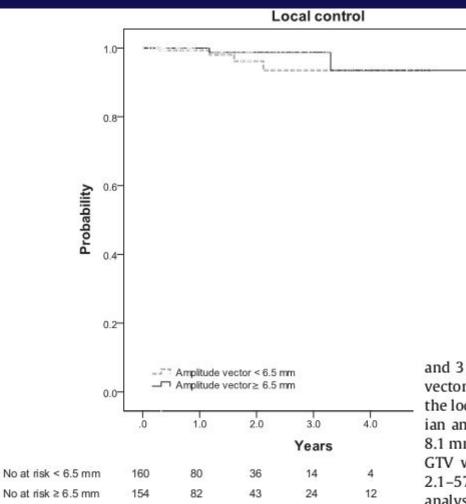

Fig. 3. Local control analyzed per tumor according to respiratory tumor at

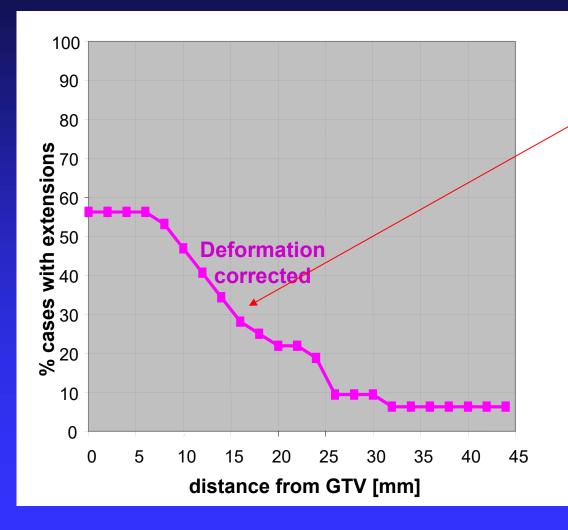

and 3 mm (range 0–18 mm), respectively. The median amplitude vector was 6.5 mm (range 0–39 mm) for all tumors as well as for the locally controlled tumors. In case of local recurrence, the median amplitude vector was significantly *smaller*: 3.0 mm (range 1–8.1 mm) (p = 0.04). In patients with a local recurrence the median GTV was significantly larger with a volume of 16.0 cm³ (range 2.1–57.6 cm³) (p = 0.04). In univariate continuous Cox-regression analysis GTV was predictive for local recurrence (p < 0.001 and HR = 1.08). Amplitude vector was borderline significant (p = 0.08 and HR = 0.77). ROC analysis revealed an optimal cut-off for amplitude vector of 3.5 mm. Additional Cox-regression was significant for LR (p = 0.02 HR = 0.13)

Peulen et al, R&O 2014

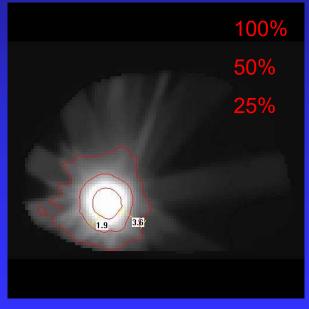

But what about the CTV ?

- By definition disease between the GTV and the CTV cannot be detected
- Instead, the CTV is defined by means of margin expansion of the GTV and/or anatomical boundaries
- Very little is known of margins in relation to the CTV
 - Very little clinical / pathology data
 - Models to be developed

Hard data: microscopic extensions in lung cancer

30% patients with low grade tumors (now treated with SBRT with few mm margins), have spread at 15 mm distance

Having dose there may be essential!

Slide courtesy of Gilhuijs and Stroom, NKI

Conclusions

- In spite of IGRT there are still uncertainties that need to be covered by safety margins
- Margins for random uncertainties and respiratory motion in lung can be very small because of the shallow dose falloff in the original plans
- Important uncertainties relate to imaging and biology that are not corrected by IGRT: The margin with IGRT is dominated by delineation uncertainties
- Even though PTV margins are designed to cover geometrical uncertainties, they also cover microscopic disease
- Reducing margins after introducing IGRT should therefore be done with utmost care (especially in higher stage disease)

Particle therapy planning

Advanced Treatment Planning Course 3-7 September 2017 – Barcelona, Spain

Markus Stock

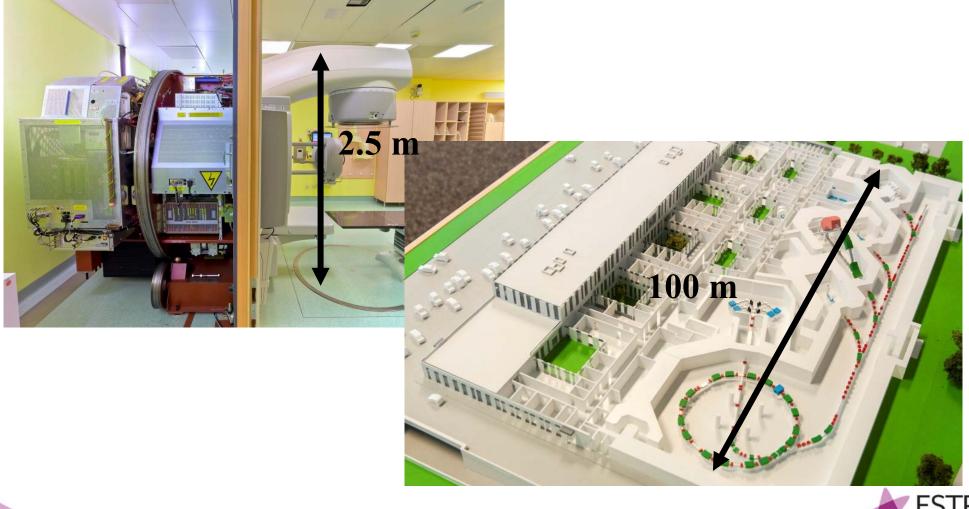

Content

- Photon vs. Protons
- Plan comparisons
- Particle therapy and uncertainties
- Other particle therapy planning specificities
- Short intro to carbon planning

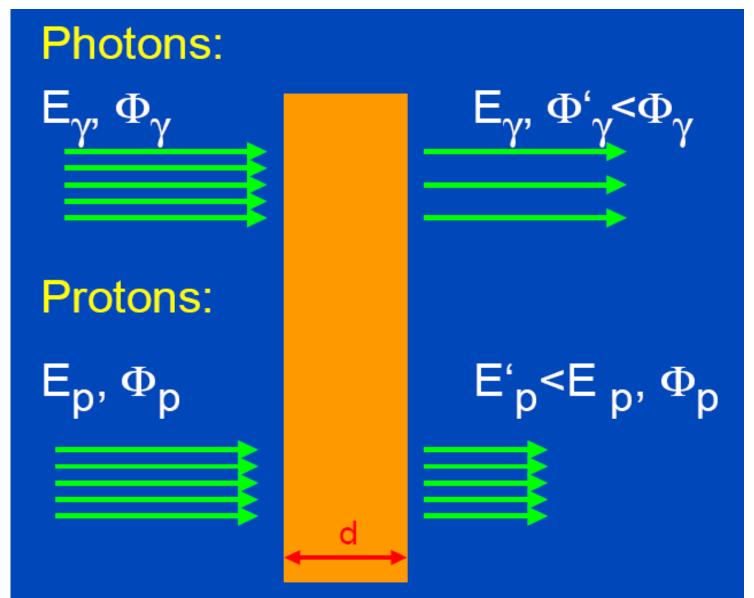

Beam Production

Electron Linear Accelerator vs. p, C Synchrotron

Fundamental Difference in Penetration

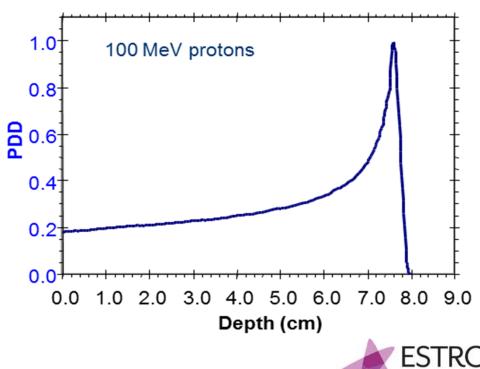

Energy lost = Dose deposition

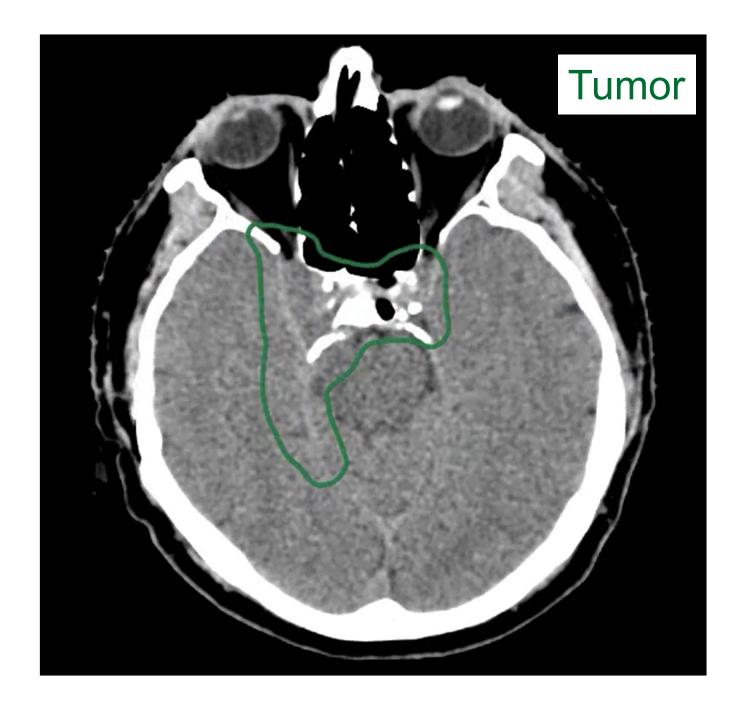

H. Bethe: Annalen der Physik. 397, Nr. 3, 1930

Heavy charged particle follow the Bethe-Bloch formula:

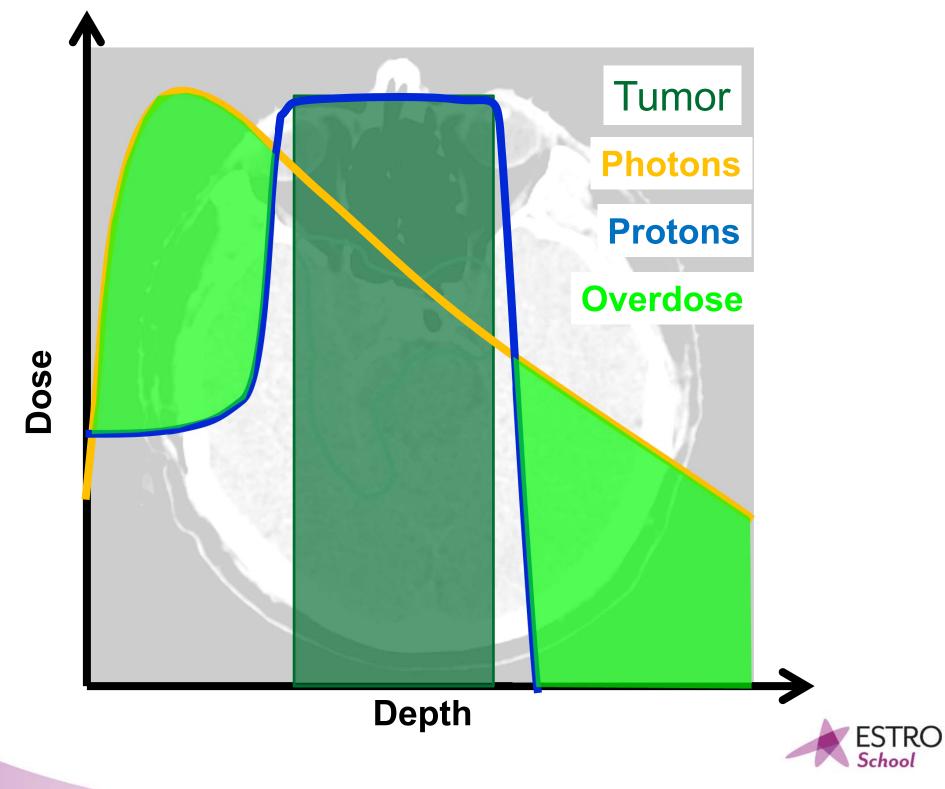

$$-\frac{1}{\rho}\frac{dE}{ds} = \frac{K}{\beta^2} \cdot z^2 \cdot \frac{Z}{A} \left[\frac{1}{2}\ln\left(\frac{2m_e c^2 \cdot \beta^2 \cdot W_{\text{max}}}{\left(1-\beta^2\right) \cdot I^2}\right) - \beta^2 + SDBB\right]$$

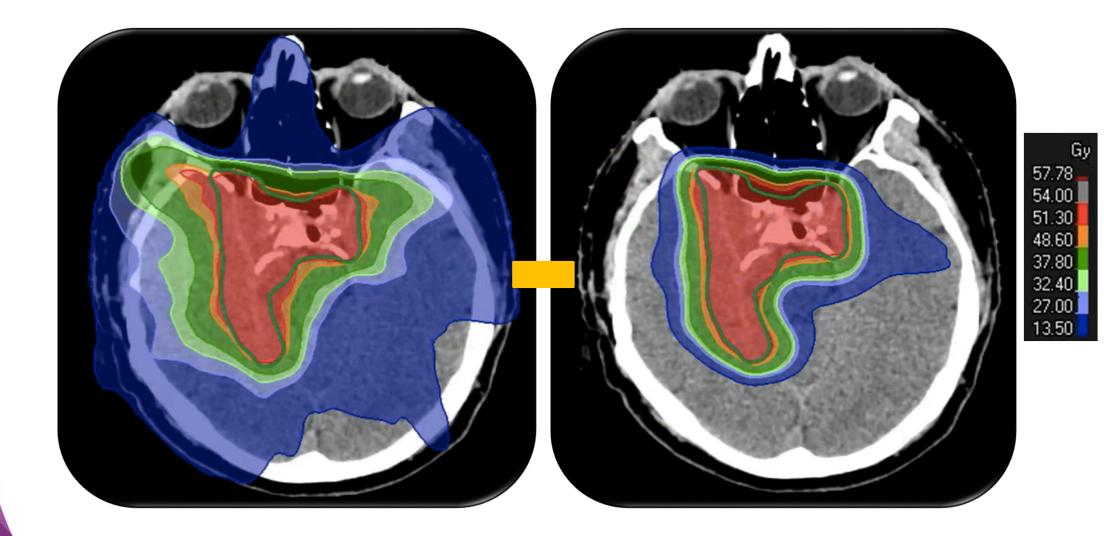

• First approximation: $1/v^2 \rightarrow Bragg peak$

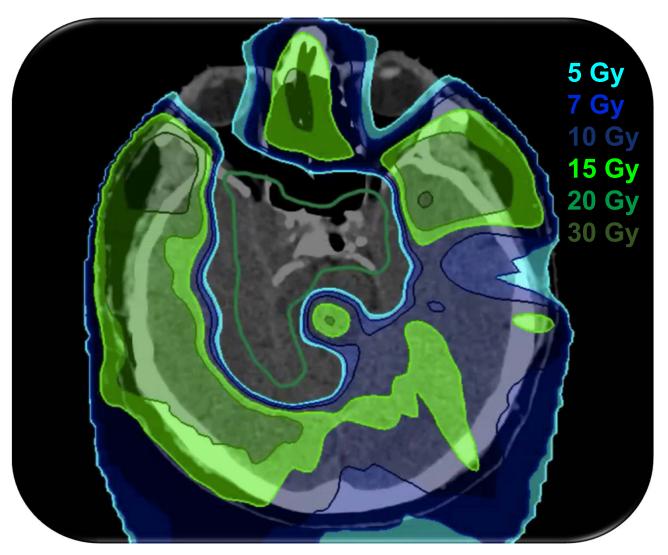

Difference (unwanted dose)

Photons - Protons

Passive vs. active particle beam delivery

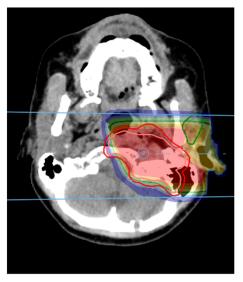

• Mono-energetic pencil beam scanning (PBS) is widely considered superior to passive techniques.

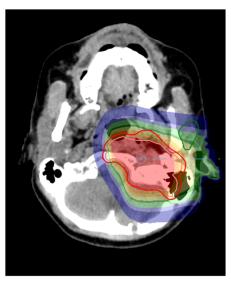

PBS - PROs	PBS - CONs
• less passive elements in the beam line	• penumbra
 no patient customized passive elements 	• (without mitigation strategies) less robust to organ motion
• reduced neutron dose	
• superior dose distribution	
• less fields required	

Planning exercise (single field):

double scattering vs.

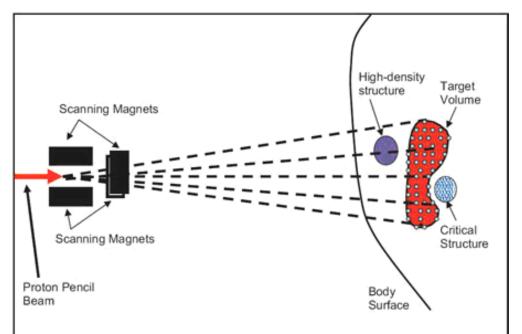

IMPT

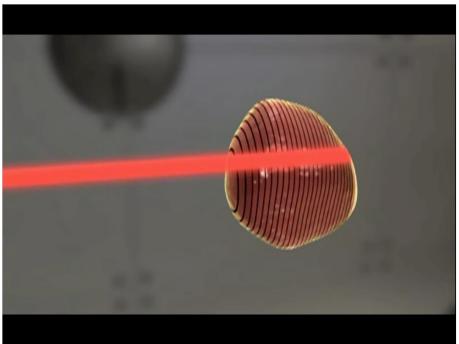

Pencil beam scanning

Effect of range uncertainties

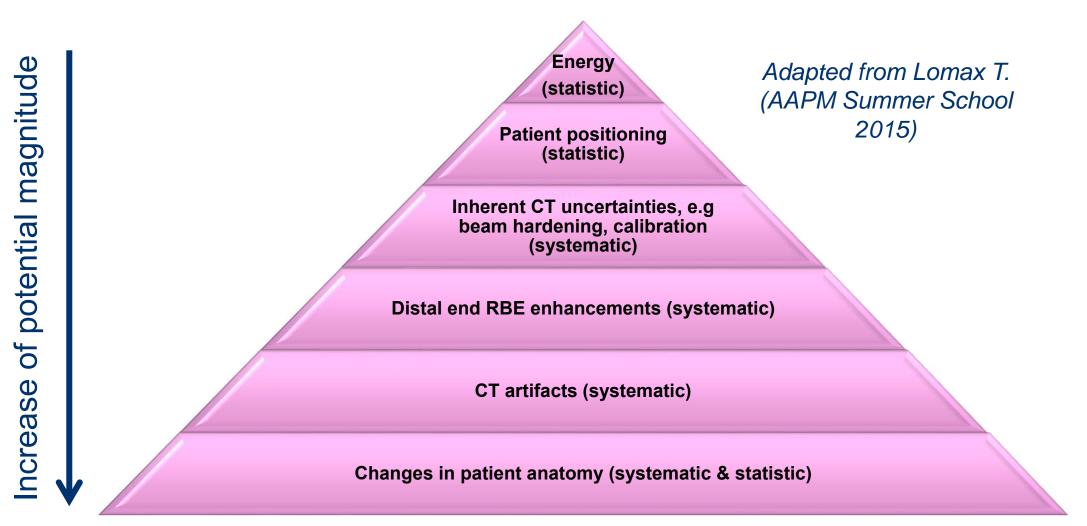

Effect of range uncertainties

Simulation of range uncertainty by HU scaling

Range uncertainty

- ➢ Estimated sum of range uncertainties: ~3 5%
- Range uncertainties are likely to be systematic.

Dealing with uncertainties in TP

- Robust beam arrangement
- Use of PRVs
- Beam specific PTV margins
- Use single beam optimization
- Robust optimization

Evaluation of robustness

(Advanced tools in commercial TPSs required!)

Treatment plan robustness

Robustness of a treatment plan is one of the most important criteria in the plan assessment – complex treatment plans are susceptible to errors Major uncertainties:

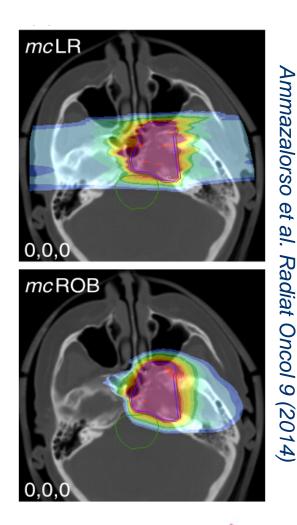

- Ion range
- RBE (fragementation tail of carbon ions)
- Possibilities to achieve a good robustness
 - Beam through most homogenous tissue (avoid areas with larger movement)
 - Avoiding beam angles perpendicular to organ motion

Assessing robustness against set-up errors and patient or organ motion by simulating these variation and their influence on dose distribution Opposing field arrangement is very robust with regard to range uncertainties PTV margins can be optimised in order to maximise the robustness

Robust beam arrangement

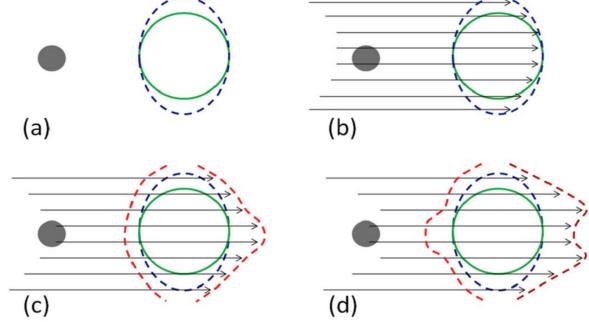

- dose homogeneity: choose beam angles avoiding large density interfaces along the beam axis
- range uncertainty: avoid placing Bragg peaks proximal to critical OARs
 - o beam incidence parallel to OARs
 - spot positioning margins/restrictions around OARs

Beam specific margins

Dealing with the range uncertainty separately by *applying* additional *beam specific margin* on top of positioning uncertainty.

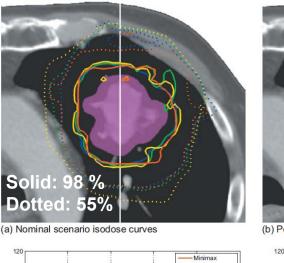

Park et al (2012) IJROBP 82(2):e329-36

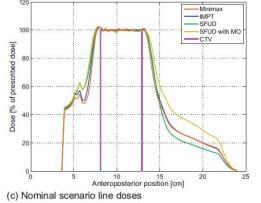

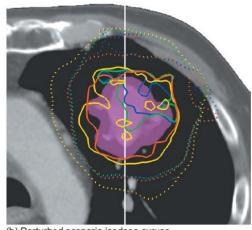

Robust optimisation

MinMax Optimization

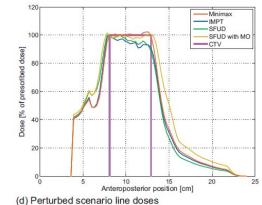

- Minimizing the penalty of the worst case scenario
- Considers only scenarios that are physically realizable
- Accounts for uncertainties in the probability distribution of errors

(b) Perturbed scenario isodose curves

- With robust optimization the traditional margin concepts becomes unsuitable
- Robust methods are discretized into scenarios (choice of scenarios has high impact on the quality)
- Up to ... scenarios have to be calculated in case ... is taken into account

CT artefacts due to metallic implants

Jäkel et al, PMB 2007 reported <5% of patients with neither fillings nor prosthesis

There is no method at the stage of TP which will solve the problem for protons. Try to diminish the effect:

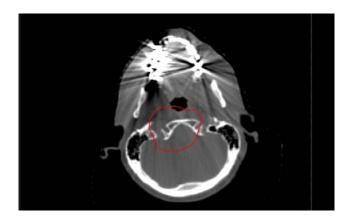

artefact reduction algorithms (HUs are influenced)
 delineation of artefacts (and implants) and HU override

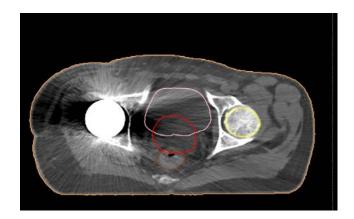

>estimation of related uncertainties required for clinical decisions

In case of less pronounced artefacts:

>avoid parallel incidence to streak artefacts
 >increase margins or use increased uncertainty in robust optimization

≻use multiple beams

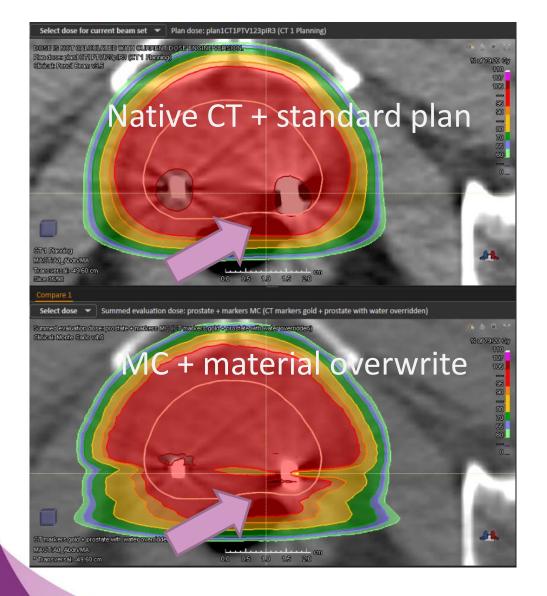

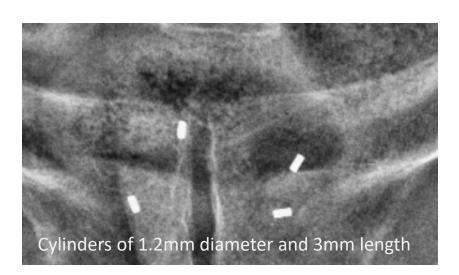

Prostate gold markers

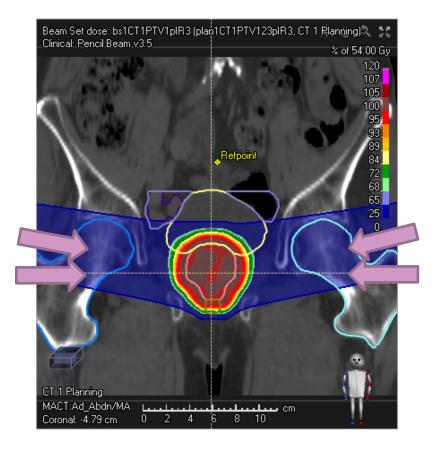

For a standard planning approach evaluated with material overwrite + MC to cause 'dose shadows'

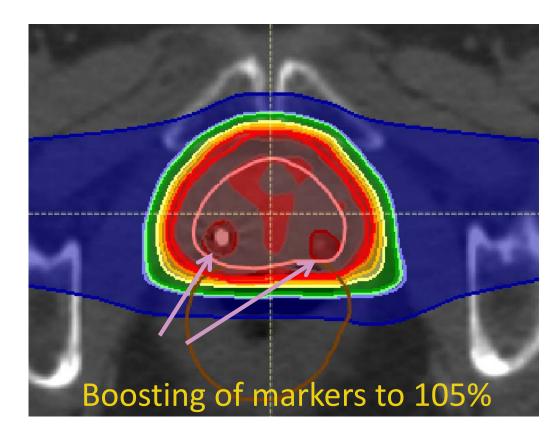

Positioning and orientation of the gold markers quite stable during fxdelivery, but a little smearing due to rotations

Prostate gold markers

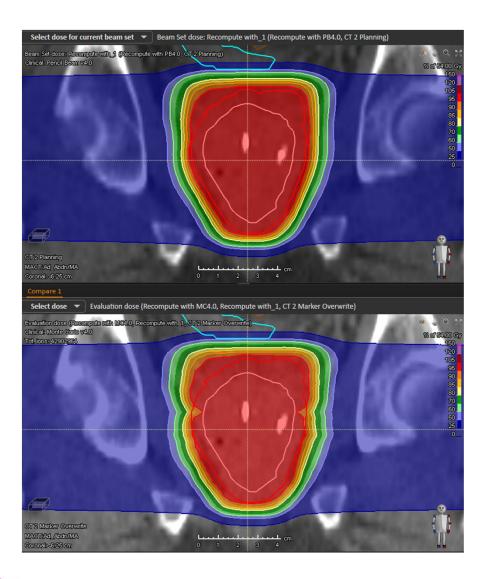

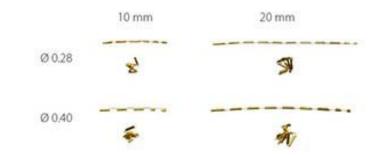

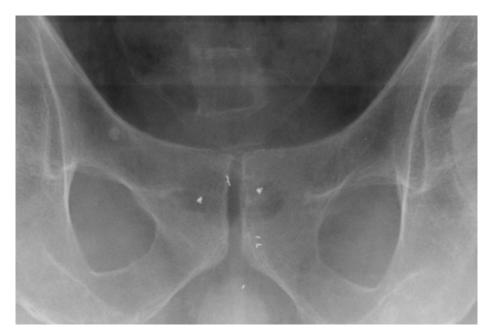

- Using opposite + tilted beams
- Boosting the markers to 105% of prescription FSTR

Impact of markers for PT

Nominal PB plan vs MC recomputation with material overwrite of gold for markers

SBO (SFUD) and MBO (IMPT)

SBO: Single beam optimization

- Possible with passive scattering and active scanning technology
- Spots are weighted in order to achieve a homogenous target dose for every single beam
- OAR sparing only possible by using help structures
- More robust treatment plans

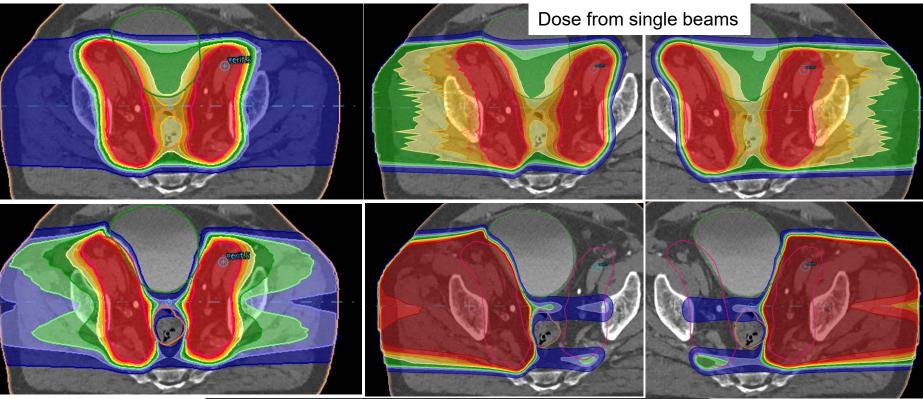

MBO: Multi Beam Optimization

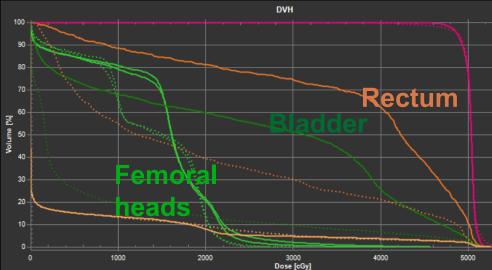

- Active scanning required
- Single beam target doses are not homogenous
- Better OAR sparing possible

SBO vs MBO example prostate case

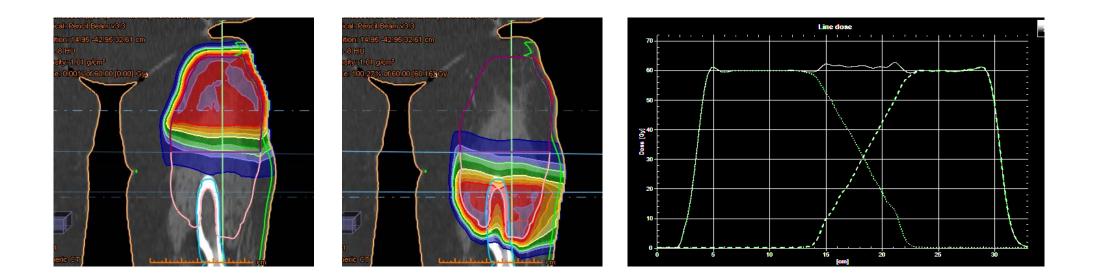

Field matching

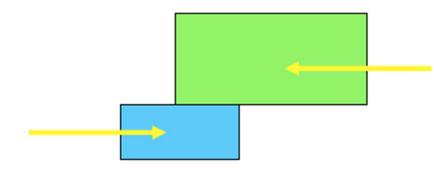

robust optimization for independent beams

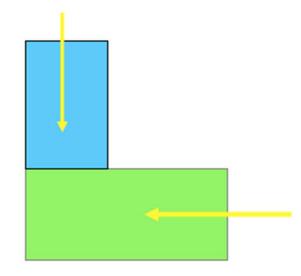

Particle planning basics

Abbuting fields

Patch fields

Lateral penumbra + Lateral penumbra

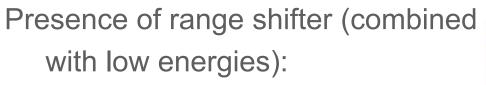

Distal penumbra + Lateral/distal penumbra

Penumbra

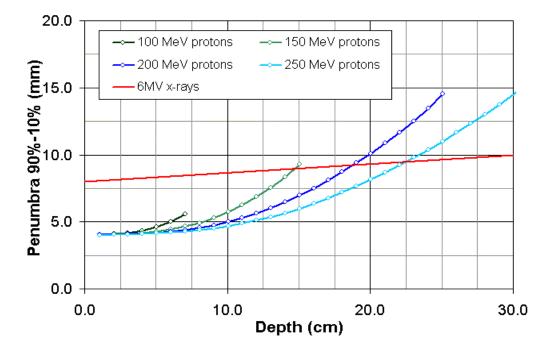

Lateral scattering:

- MCS: penumbra increases with increasing penetration depth.
- Exceeds penumbra of photons at some point.

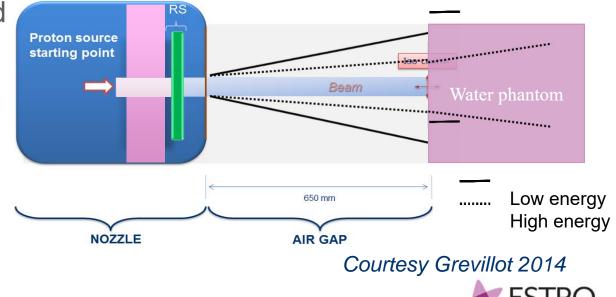

- Substantial increase of spot size.
- Dose calculation accuracy for PB algorithm impaired.

Reduce air gap.

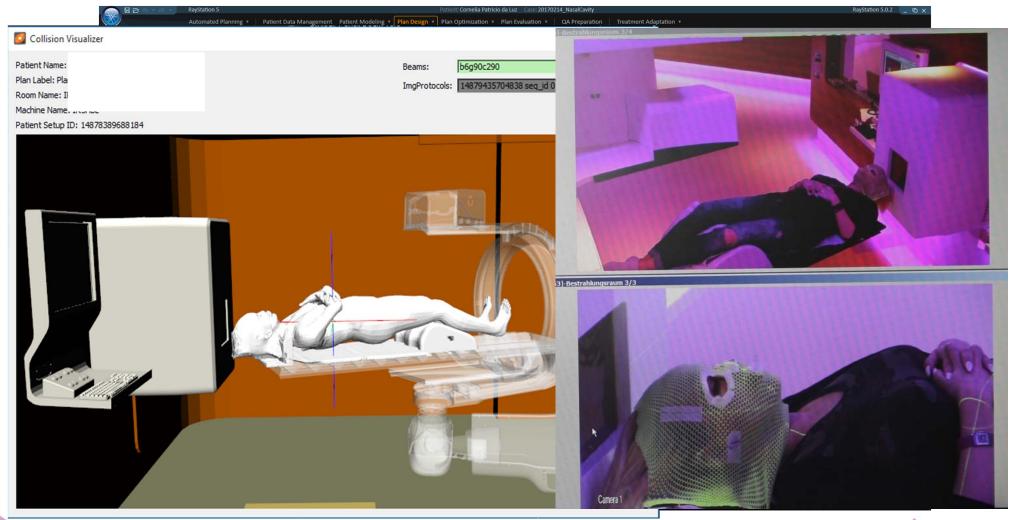

Courtesy Palmans 2006

Reduction of air gap

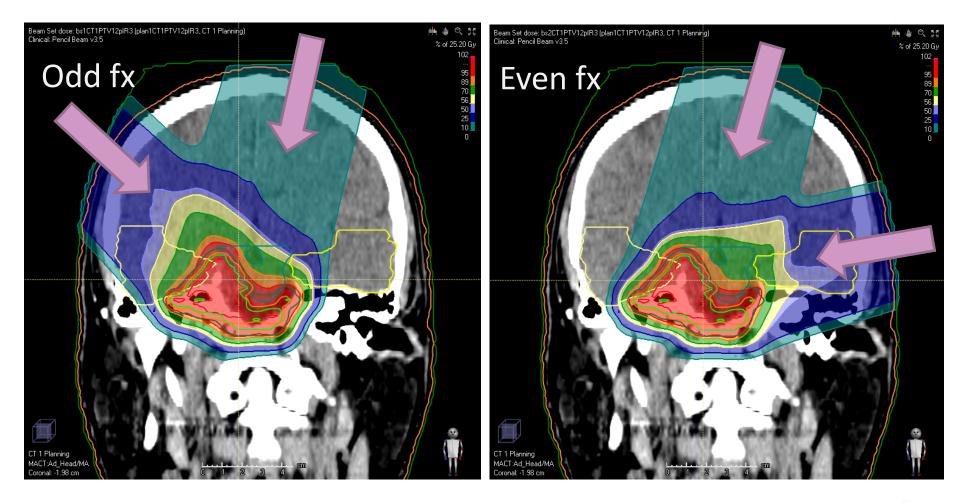

efficient workflow supported by TPS based modelling of room, robot and patient geometries

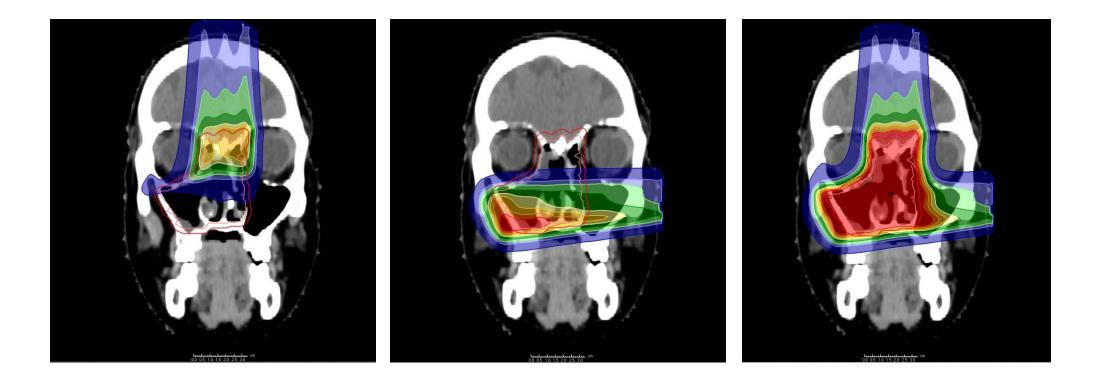

Optimize delivery time per fx

Limited beam angles with horizontal nozzle only Usage of alternating beam sets with each 2 beams

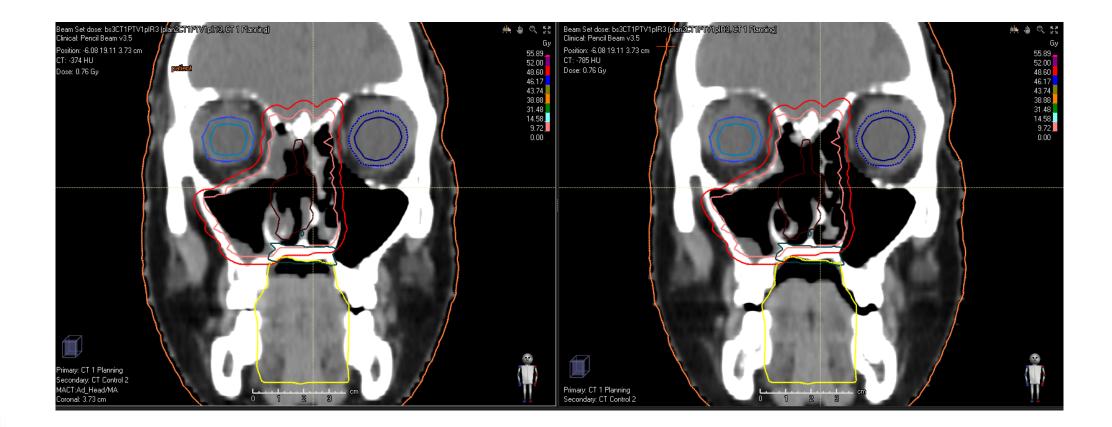

Inter-Ocular Nasal Cavities with horizontal beam only

Patching with smooth matching-gradient + multiple beam sets

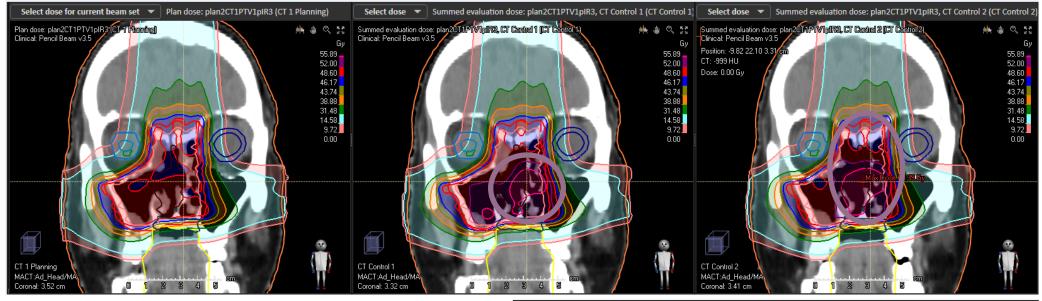

INTER-fx: Nasal Cavity Filling

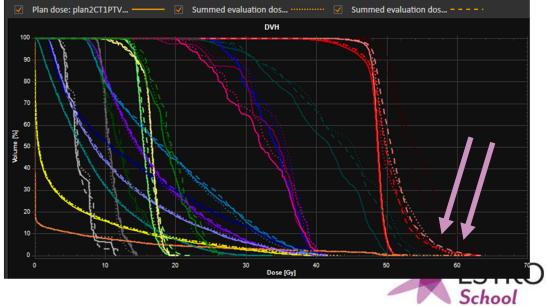

Monitoring filling by control CTs + dose recomputation Alters ranges and dose distribution?

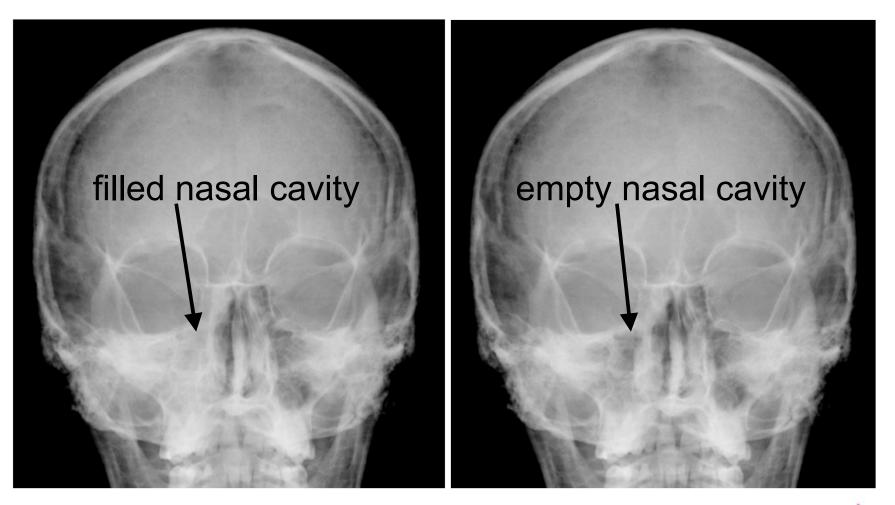

INTER-FX: Nasal Cavity Filling

Dosimetric impact evaluation Palate exposed to higher doses Plan adaption + compensation

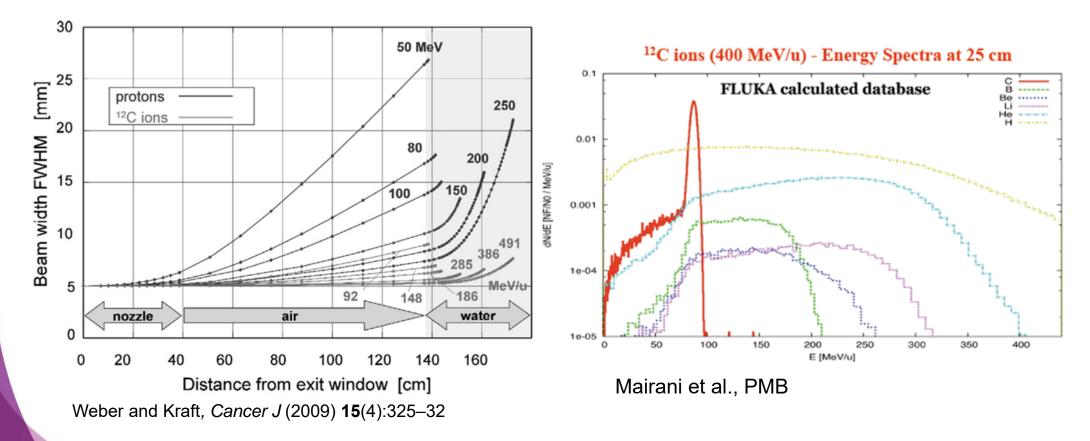

High quality planar imaging

CIBT wrt PT: Some important differences for TP

- Sharper lateral penumbra but tail
- Fragment fluences/LET to be modelled
- No influence of air gap

CIBT wrt PT: Some important differences for TP

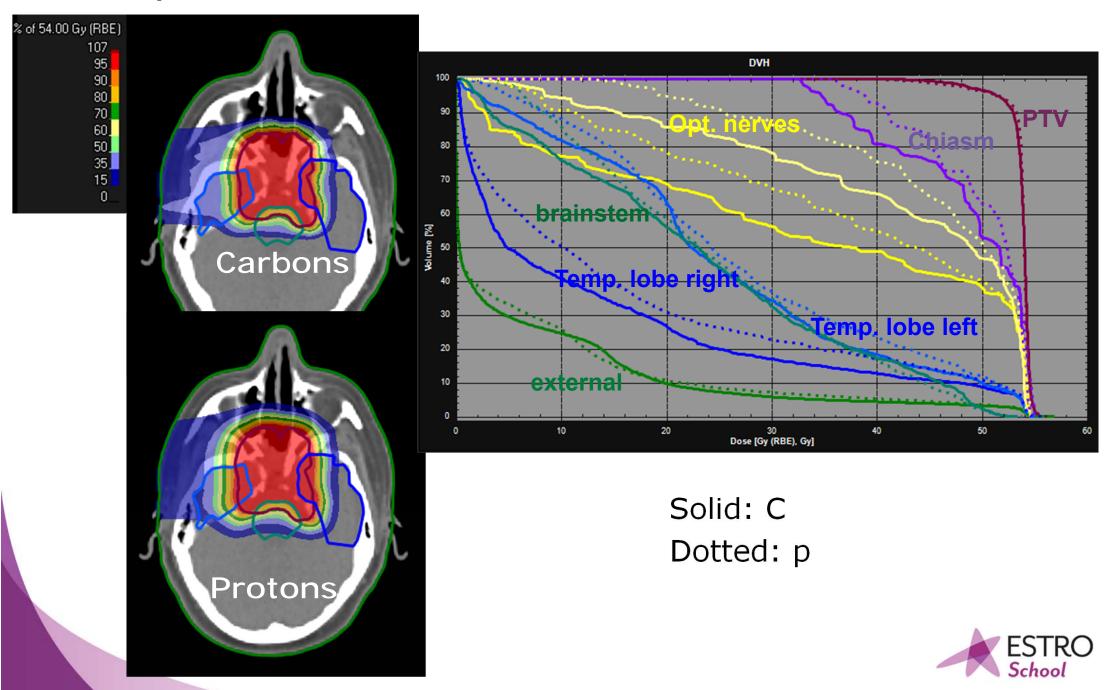

Peculiarities of carbon ion RBE and implications

- RBE-dependence on dose
 - Plan MUs not scalable any longer!
- RBE not constant: How to come up with a robust multibeam plan?
 - SFU(B)D only applicable for single beam per fraction (NIRS)!
- D_{RBE,LEM-I} ≠ D_{RBE,NIRS}, conversion of treatment protocols needed! Is always approximate!
- Approximations and shortcomings in clinical RBEmodels

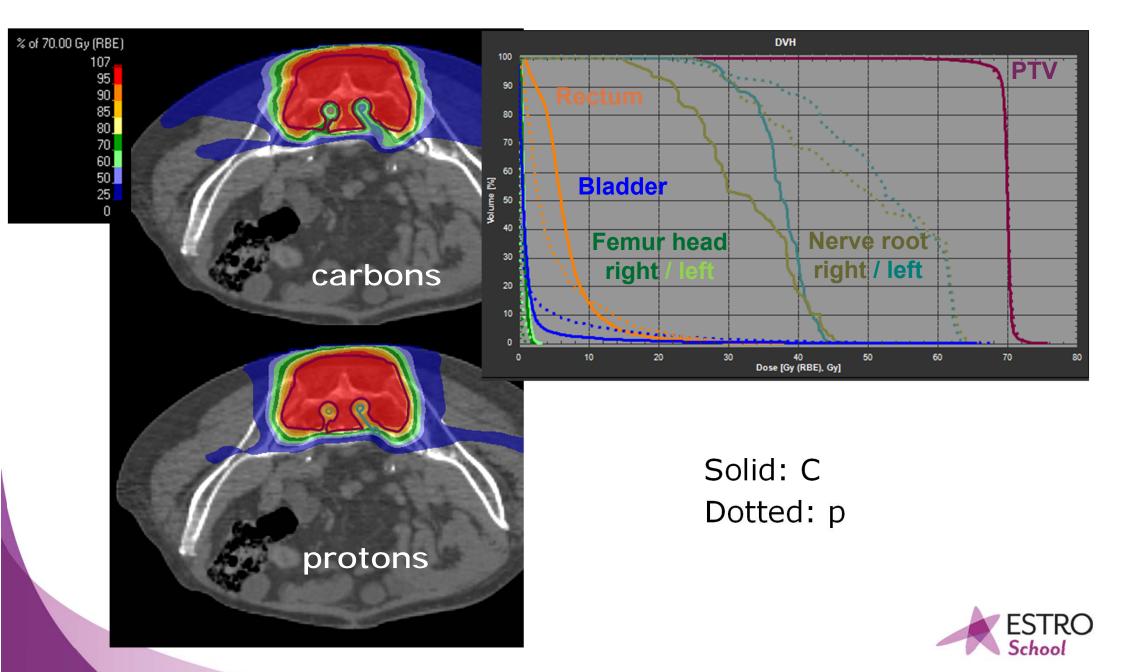

Fossati et al. (2012), PMB

C vs p: Skull base

C vs p: Sacrum

Some practical aspect in ion beam planning For plan creation:

- Limited number of beams should be chosen
- Beam path optimization: Picking "good" beam directions to avoid to pass through heterogeneities or lie tangent to a tissue air-interface
- Intelligent creation of planning help structures for PTV and targets
- Visualization of spot distribution and weighting
- Avoiding corners and edges from positioning devices/ no beam path through shoulders

For plan quality assessment:

- Robust evaluation and optimisation
- Surface dose!
- Hot spots within OARs (position of high dose areas)

Conclusion

- Fundamental difference in beam penetration
- Less beams used in particle therapy
- PBS vs Scattering technique experience
- Robustness optimization major concern
- Limited field size and incidence angles

Basic principles of rotational IMRT planning

Gert Meijer

Rotational IMRT not really new

MAY 1956

Automatic Control of the Tube Current as a Means of Dose Regulation in Tangential Rotation

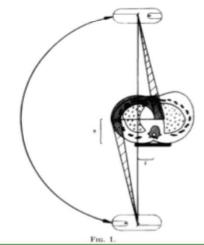

AUTOMATIC CONTROL OF THE TUBE CURRENT AS A MEANS OF DOSE REGULATION IN TANGENTIAL ROTATION

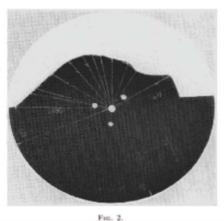

By PROFESSOR H. HOLTHUSEN, M.D., F. GAUWERKY, M.D., and F. HEINZEL, M.D. From the Radiotherapy Department, St. George's General Hospital, Hamburg, Germany (An invited contribution for the Diamond Jubilee Number)

operative X-ray treatment of cancer of the breast by Hare, Trump and Webster in 1952, a lively interest has arisen in Germany, particularly as the result of the publications by Rossmann (1954 and 1955), and Becker, Werner and Kuttig (1954), in this efficient method of irradiation. Tangential rotation offers excellent possibilities for optimum sparing of the

SINCE the introduction of tangential pendulum of the usual commercial moving-beam therapy ap-pliances on a recumbent patient. In this case, according to the design of the pendulum apparatus, either the central ray is set eccentrically by tilting the tube out of the pendulum axis (Rossmann, 1954) or an eccentric tangential X-ray beam is diaphragmed from a tube unaltered in position. For this purpose, using the universal irradiation apparatus TU I of Messrs. C. H. F. Müller, Hamburg, which we have at our disposal, a continuously adjustable tangential slot diaphragm is used with whose aid tumour field

perated Of the two possibilities available in principle to irradiacarry out the desired compensation, namely variable It must speed of the X-ray tube movement during irradiation on the one hand and variation of dose output angle of on the other, the latter was chosen since a regulation e direct of the tube current in accordance with a preradiated determined scheme could be achieved with less >-lateral circumconstructional difficulties. Thus the tube current will have to be reduced in the higher dosed skin rotation areas, and increased in the positions of the tube in l phanin the which the surface areas are lower dosed. For this purpose, distribution schemes for the tube current art near

fan beam vs cone beam

Courstesy of Dirk Verellen

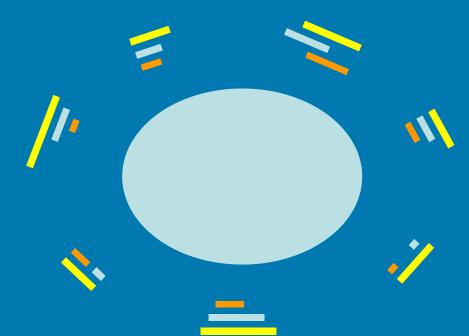

from 3 arcs to a single arc

moving from stacked to spaced

Tang et al. (IJROBP 2007)

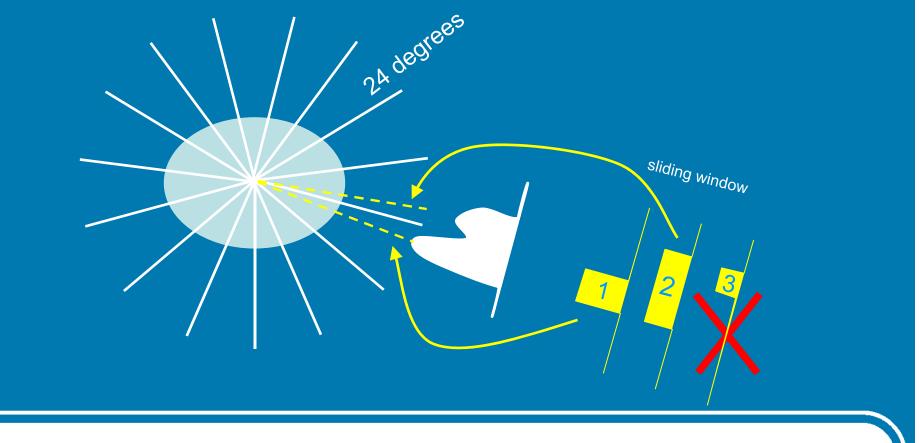

So....

rotational therapy is rather insensitive to angle deviations

but also that cone beam rotational IMRT is not that different from static IMRT

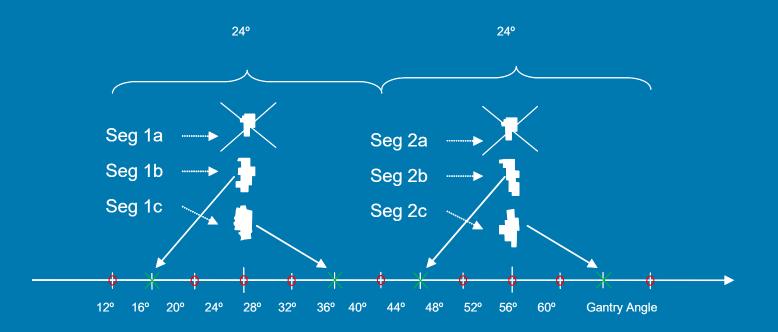

So how does is work in practise?

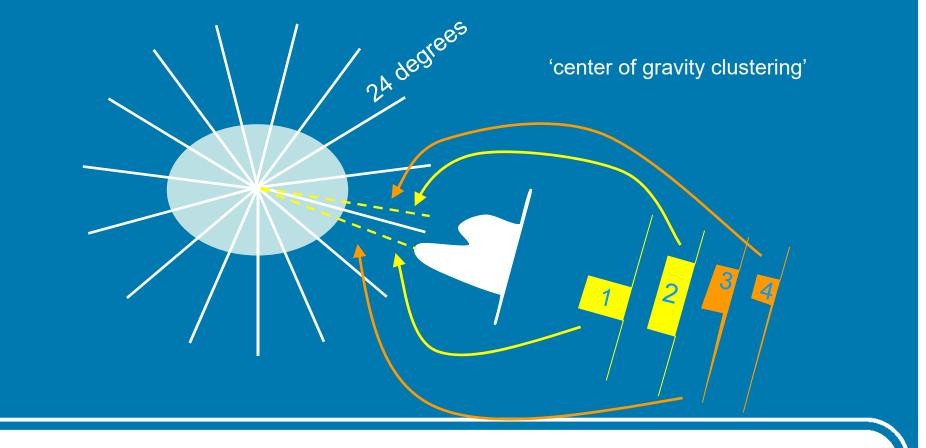

Segmentation

How about dual arcs?

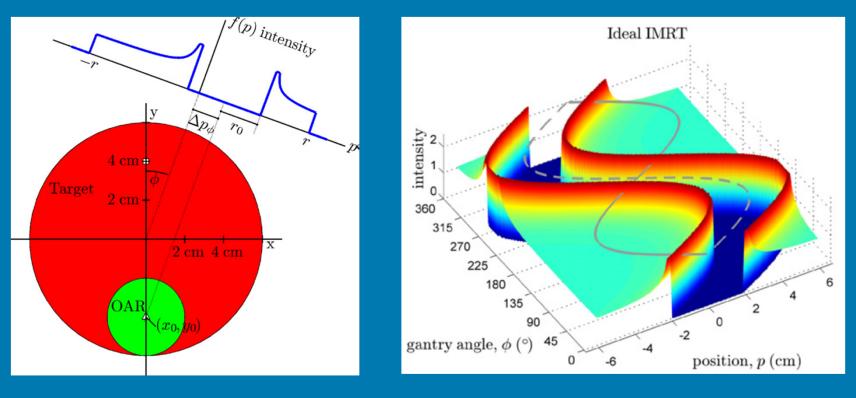

Static IMRT vs VMAT - Conceptual issues

Is there any difference between static IMRT and VMAT?

- Use the same hardware
- Can be virtually 'mapped' onto each other:
 - S-IMRT with infinite number of beams \rightarrow VMAT
 - VMAT with infinitely small gantry speeds (quasi static) \rightarrow S-IMRT

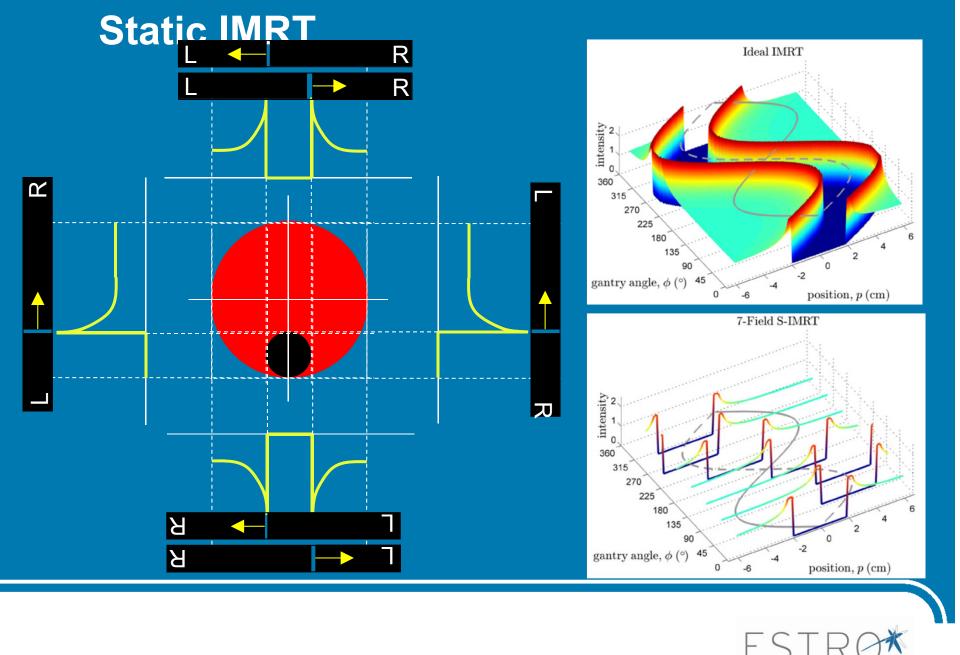

IMRT vs. VMAT - Conceptual differences

Bortfeld and Webb (2009) explaining VMAT by Brahme's IMRT case (1982). Target volume is wrapped around an OAR. Analytical solution is known

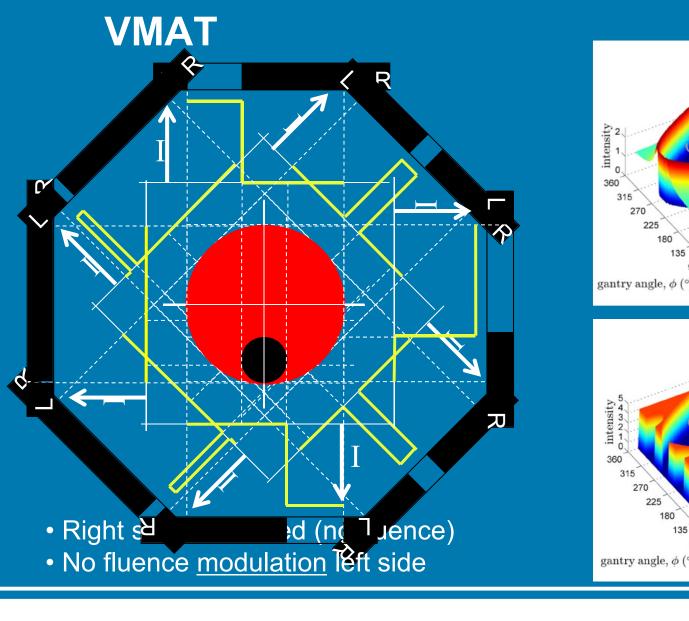

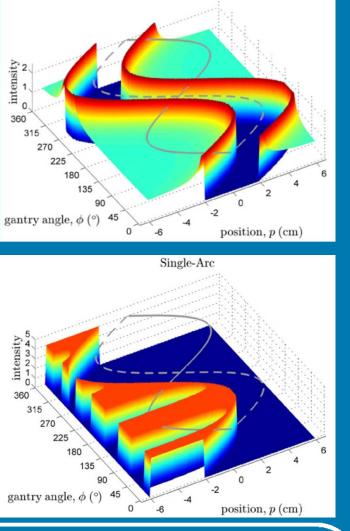

Courstesy of Jochem Wolthaus

Courstesy of Jochem Wolthaus

Ideal IMRT

Courstesy of Jochem Wolthaus

European Society for Therapeutic Radiology and Oncology

IMRT vs. VMAT - Conceptual differences

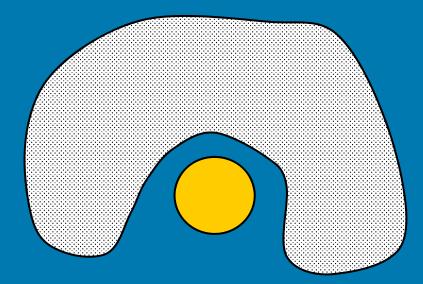

Compromises in different areas:

Static IMRT uses a very coarse sampling of the gantry angle but with full intensity modulation **VMAT** uses all angles but without intensity modulation (per gantry angle)

Courstesy of Jochem Wolthaus

Why need multiple arcs??

Courstesy of Markus Alber

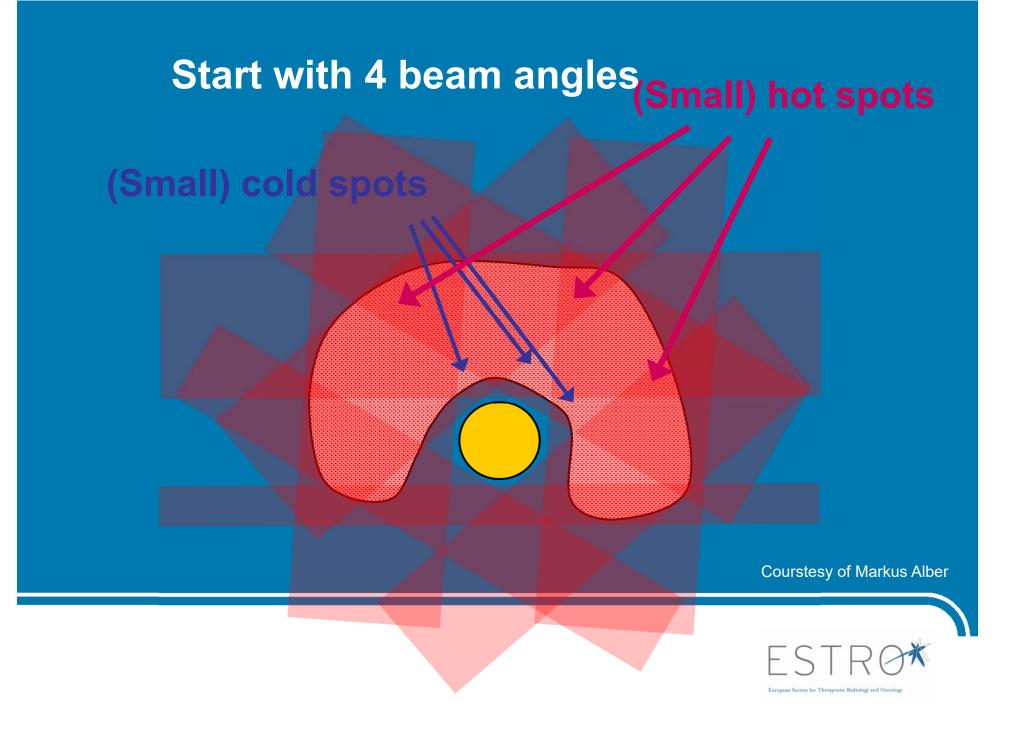

Start with 4 beam angles

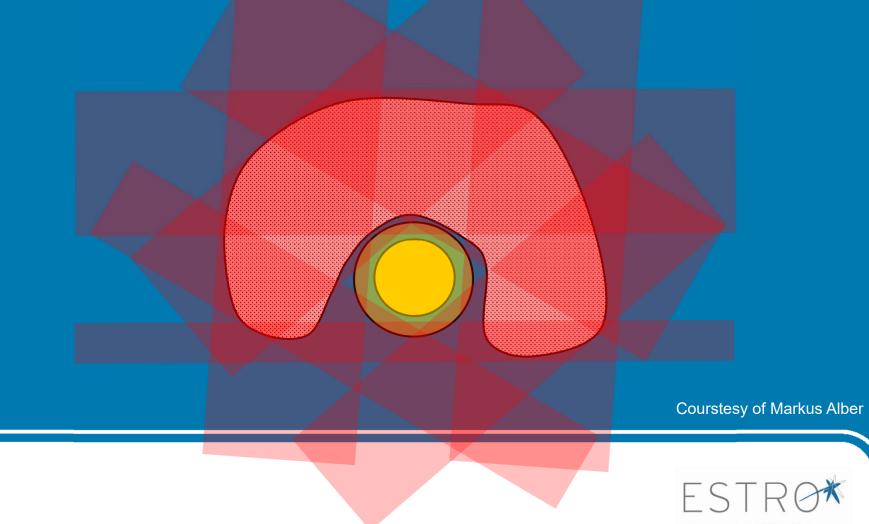

ropean Society for Therapeutic Radiology and Oncology

What if the gradient has to be tighter?

European Society for Therapeutic Radiology and Oncolog

What if the gradient has to be tighter?

(Ice) cold spots

Courstesy of Markus Alber

Use more beam angles!

Courstesy of Markus Alber

European Society for Therapeutic Radiology and Oncolog

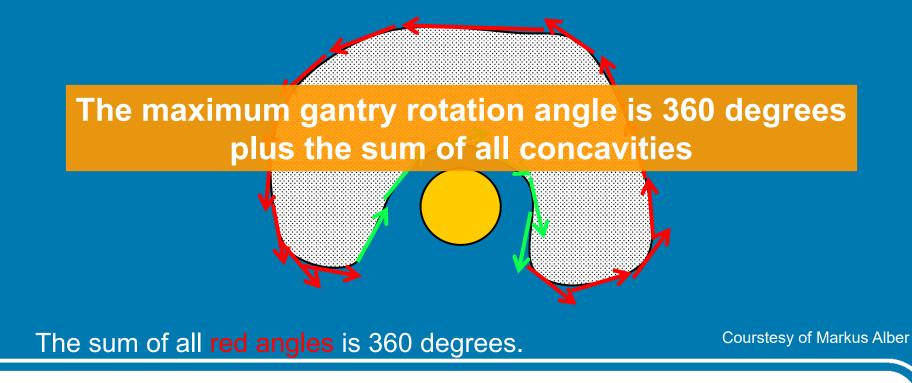

What is the maximum gantry rotation angle needed to paint all gradients for this target??

Courstesy of Markus Alber

What is the maximum gantry rotation angle needed to paint all gradients for this target??

The total gantry rotation is the sum of all red angles (counter-clockwise) and all green angles (clockwise).

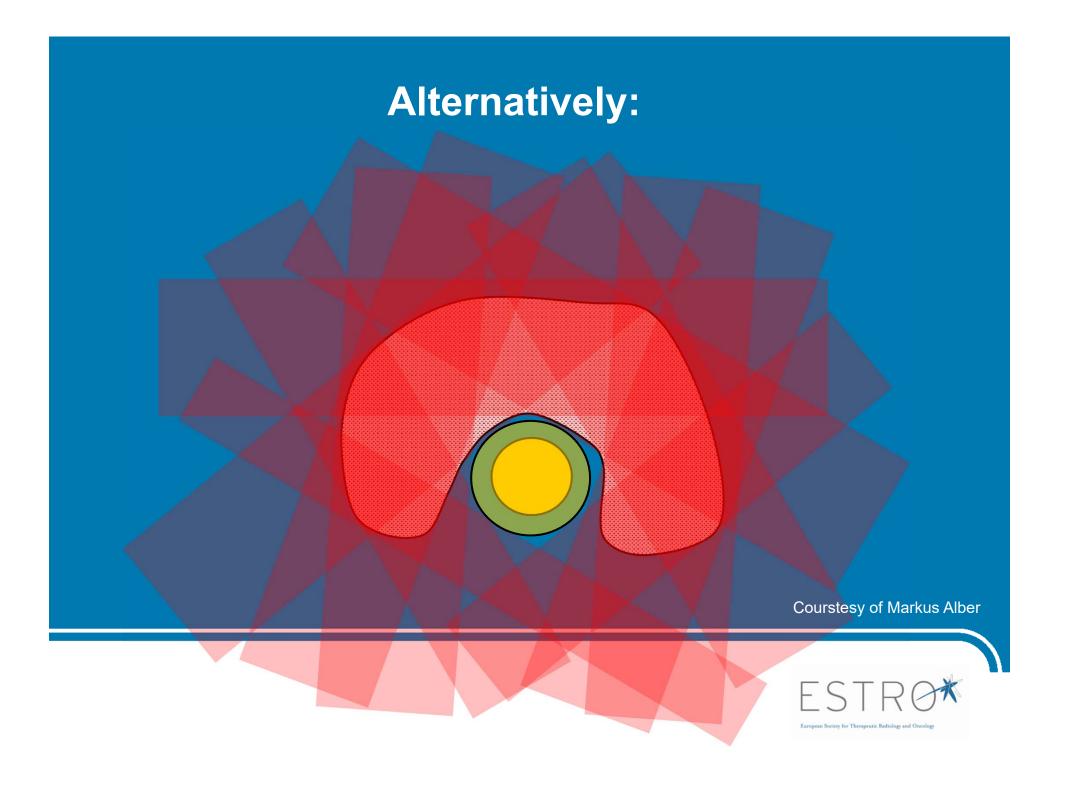

Alternatively:

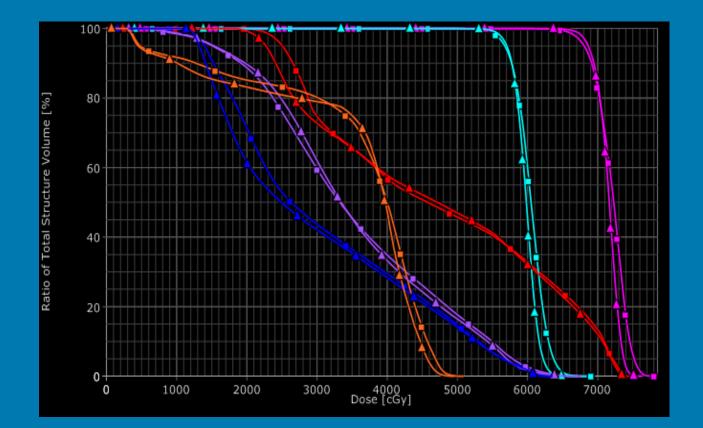

The concavity can be created in one 360 degree rotation plus partial shielding of the beam.

Courstesy of Markus Alber

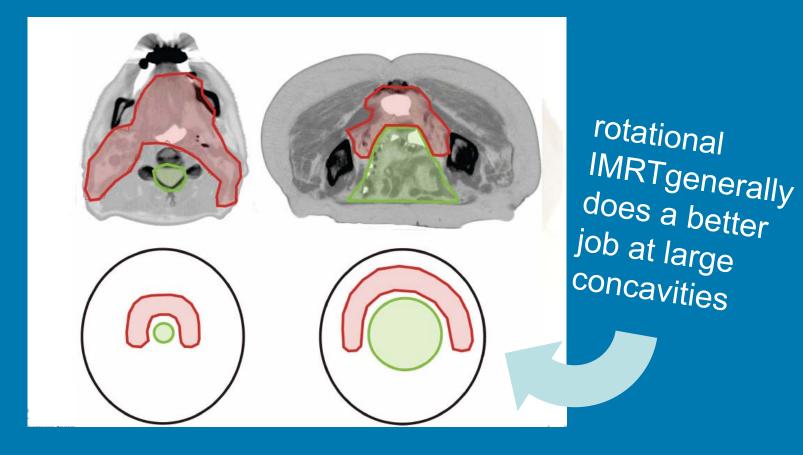

RapidArc single arc versus double arc

De Meerleer et al.

De Meerleer et al.

rotational cone beam IMRT vs static IMRT

- faster delivery
- comparable plan quality

fan beam

cone beam

binary leaves

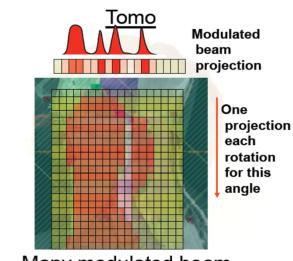

sliding leaves

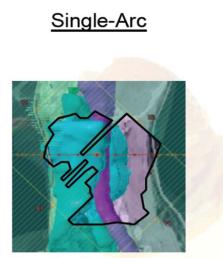

fan beam IMRT offers more modulation than cone beam IMRT

(but comes at cost of longer irradiation time?)

Many <u>modulated</u> beam projections at each angle

One "<u>un"-modulated</u> beam "segment" at each angle

Courstesy of Dirk Verellen

Conclusions

- cone beam rotational IMRT just another flavour but faster because of continuous irradiation but not better (more gantry angles but unmodulated fluence per angle)
- fan beam rotational IMRT (Tomo) offers independent bixel optimisation and therefore more dose shaping functionality
- in both cases fluence enters the patient from all (gantry) angles sometimes requiring different optimisation strategies

Effects of exercise on fatigue, physical functioning, and emotional distress during radiation therapy for breast cancer. V Mock, KH Dow, CJ Meares, PM Grimm... - Oncology nursing ..., 1997 - ncbi.nlm.nih.gov

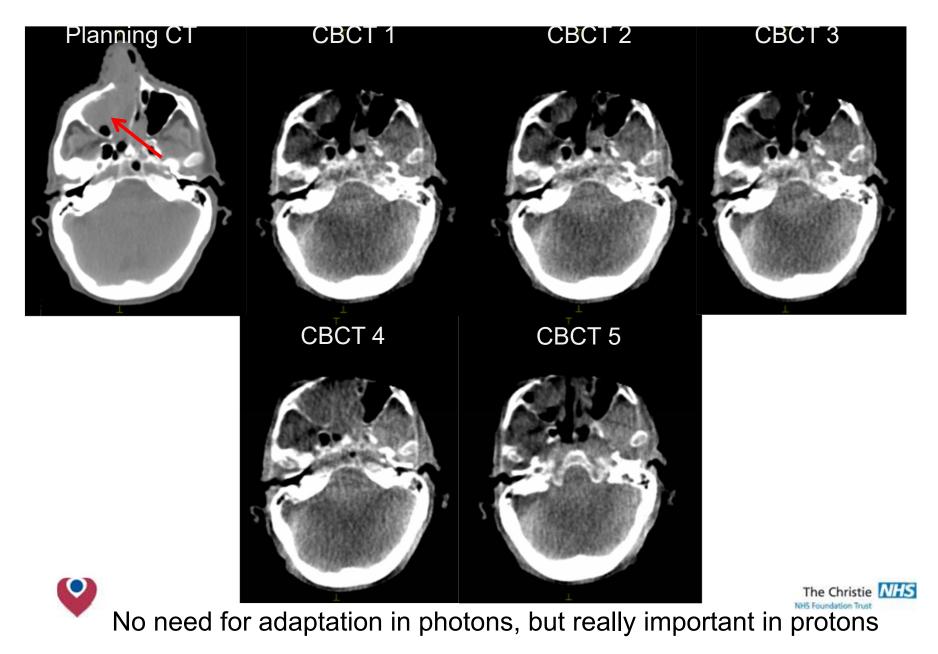

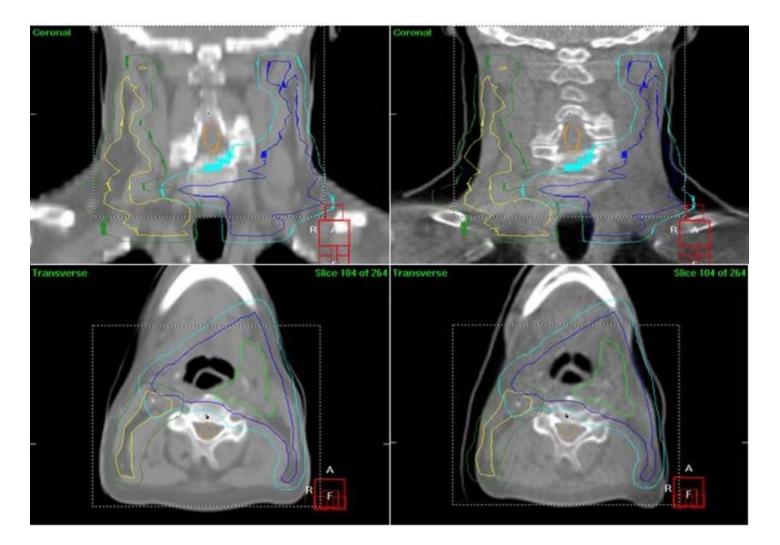

Ad-hoc adaptive radiotherapy

- In the Christie dose is recalculated on CBCT (with density override) based after visual analysis in ~7% of patients
 - mostly lung and H&N
- Actual adaptation in ~1% of patients
 - taking a new CT scan
 - independent new plan
- No special software is used to do this in the clinic just the planning system

Sinus filling and emptying

Weight loss in H&N patient

Adaptation can be done to improve delivery,

but also because the mask no longer fits

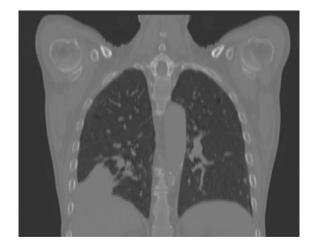

Software for adaptive RT

- To fix the HU of CBCT
 - Density override
 - Deform planning CT to CBCT
 - Shading correction based on planning CT

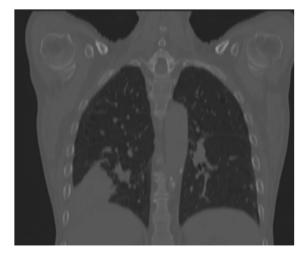

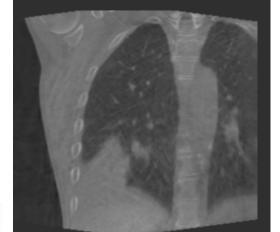

Modify CT to CBCT anatomy

Deformable image registration

modified CT (mCT)
(CT numbers + CBCT anatomy)

Make CBCT suitable for dose calculation

Szeto et al, NK1I 2016

CT

CBCT

Q

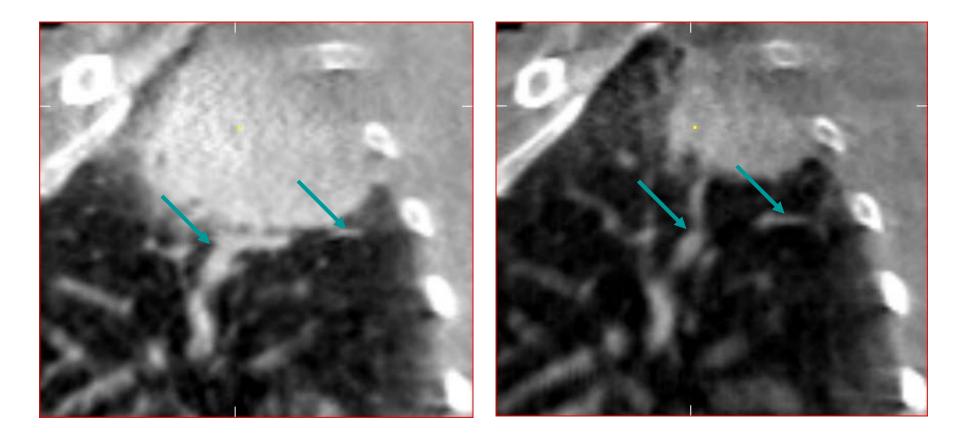

Contour propagation

- Based on deformable registration between planning CT and repeat CT
- May be useful for OAR contours
 - Editing often needed
- Take extreme care with GTV and CTV contours
 Use rigid propagation if unsure

Non-elastic tumour regression

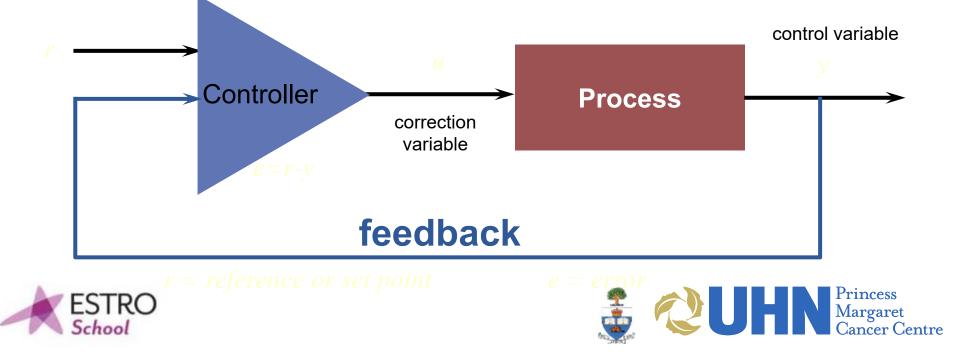

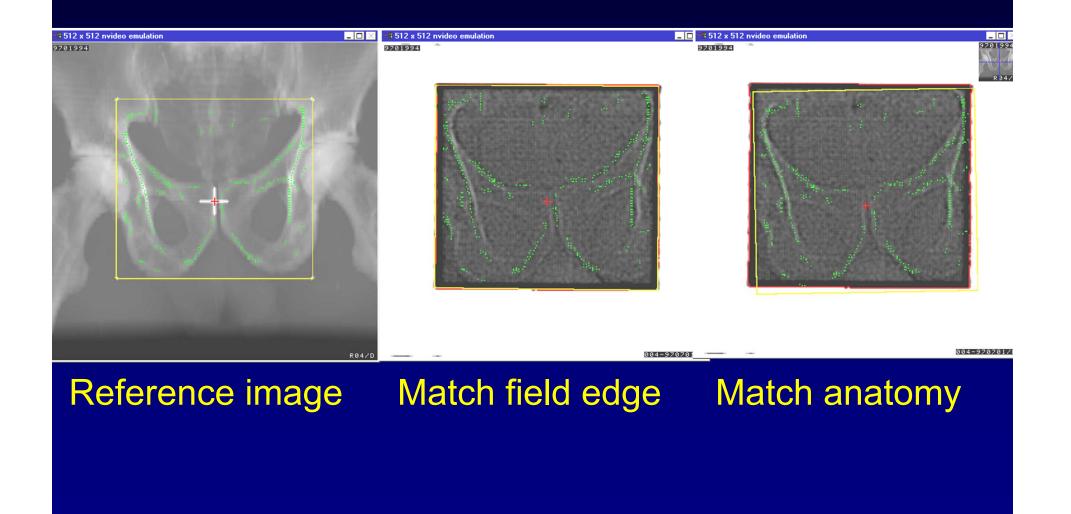

Formal Adaptive Concept

Yan et al., Sem. Rad. Oncol 20(2) 79-83 (2010)

- Origins are informatics and modern control theory.
- IGRT provides *feedback*, statistical treatment deviations are observed.
- Use knowledge to predict and address anatomical (and biological) variation over time.

Portal image analysis - 2D

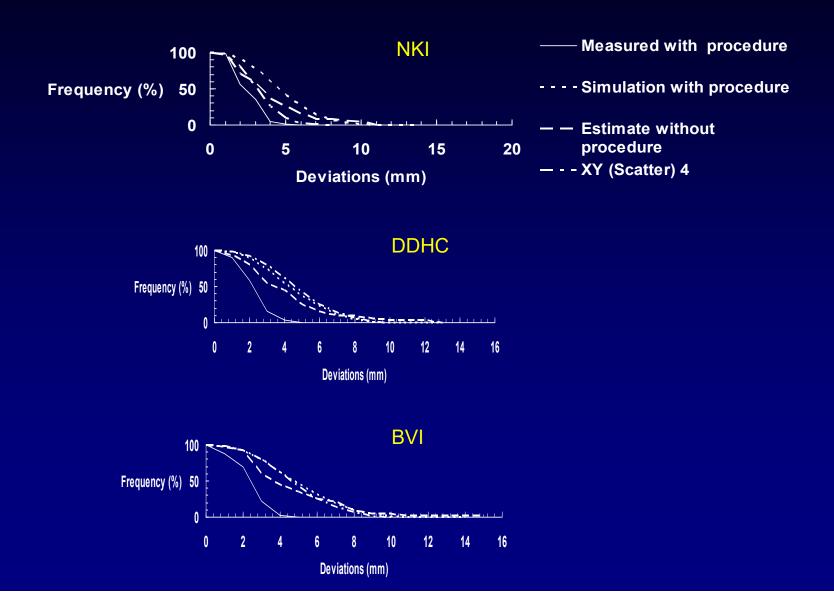

Correction procedures

- No corrections (monitoring)
 - Aimed at determining accuracy of clinical practice
- Ad-hoc corrections
 - danger of overcorrection
- Off-line correction protocols
- On-line correction protocols
 - Aimed at correcting day to day variations

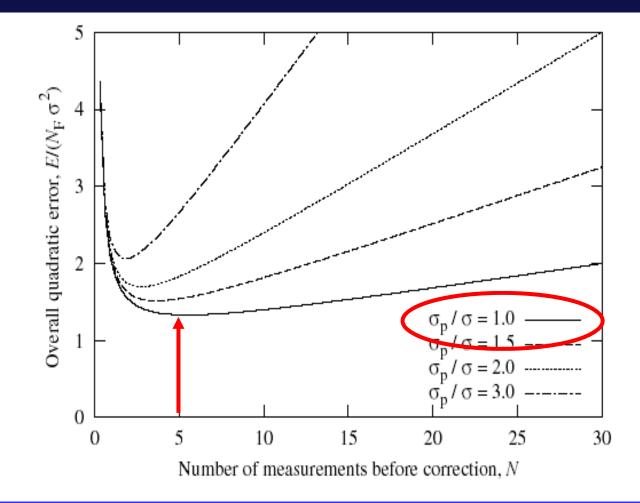

Shrinking action level protocol

- Correct after first fraction if setup error exceeds 6 mm (vector length)
- Correct after second fraction if average error of first and second fraction exceeds 4 mm
- Restart procedure after correction
- Weekly imaging after second uncorrected fraction

Results of correction procedure (150 prostate cases; Bel at el 1997)

When to correct?

Bortfeld at al, PBM 2002

Adaptive Radiation Therapy (Beaumont Strategy)

III Yan et al., PMB 1997 Jan;42(1):123-32

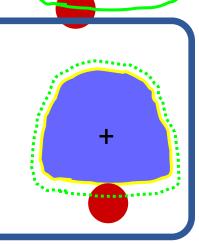

- Extended off-line strategy to account for setup error & organ motion.
- Combine information from EPIDs & multiple CT scans obtained in the first week of treatment.
- Obtain good sense of the average position of organs & targets.
- Personalized margins.

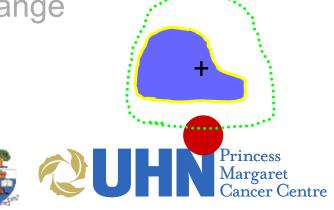

The Evolving Role of IGRT

- Accurate:
 - verify target location and extent
- Precise:
 - tailor PTV margins (patient-specific)

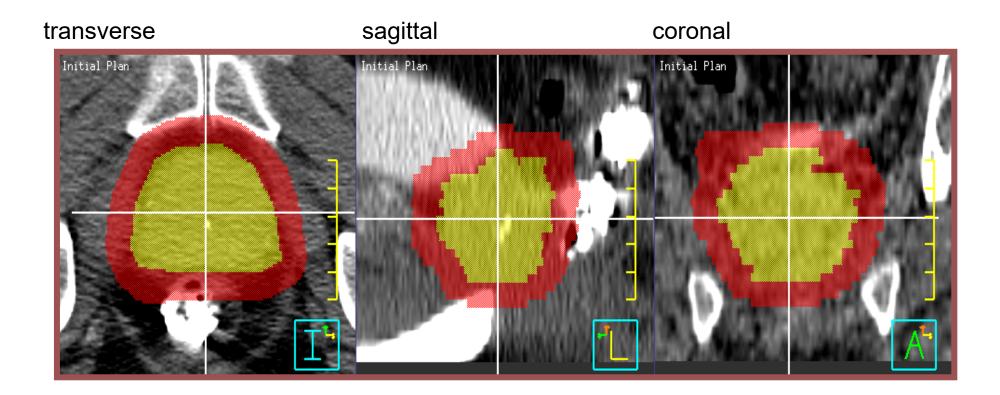

+

Initial PTV

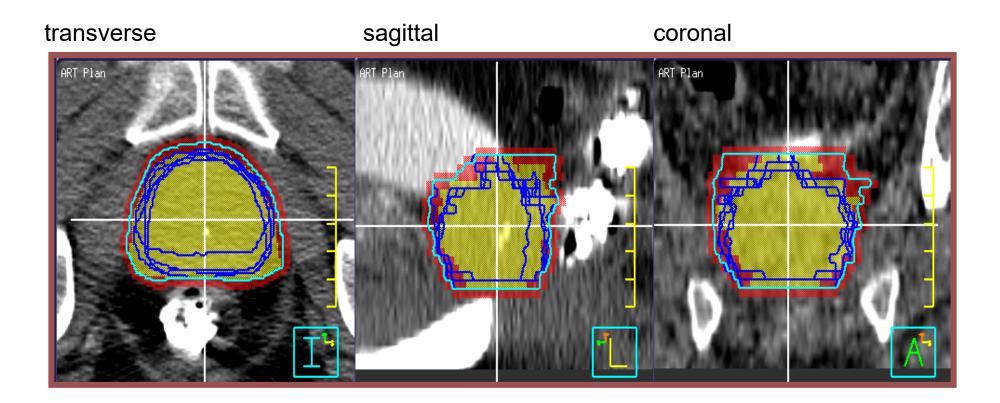

Initial CTV + 10 mm = Initial PTV

Confidence-Limited PTV (cI-PTV)

Initial CTV + 4 CTV_s = ITV (Organ Motion PTV) ITV + Random Setup Error & Measurement Uncertainty = **cI-PTV**

Volume Difference: PTV vs cl-PTV

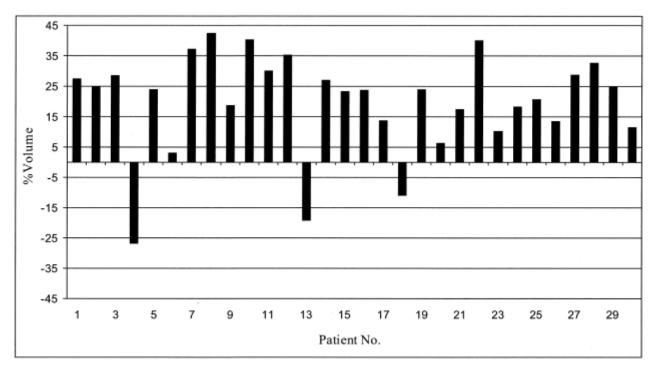

Fig. 5. Distribution of % volume difference between the generic planning target volume (PTV) and the patient-specific confidence-limited planning target volume (cl-PTV, normalizing to the generic PTV).

Martinez, Yan et al IJROBP 50, 1226–1234, 2001

Initial PTV & cI-PTV Do NOT Overlap

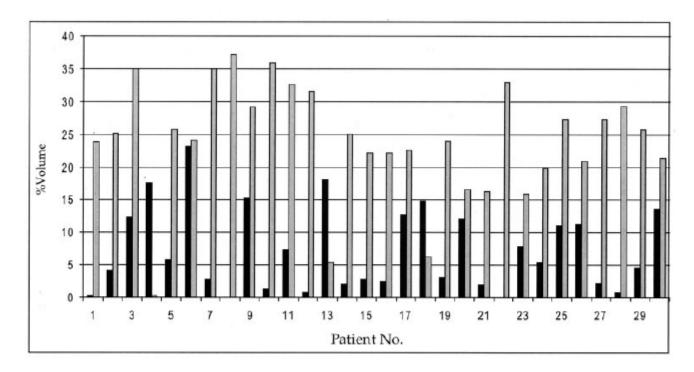

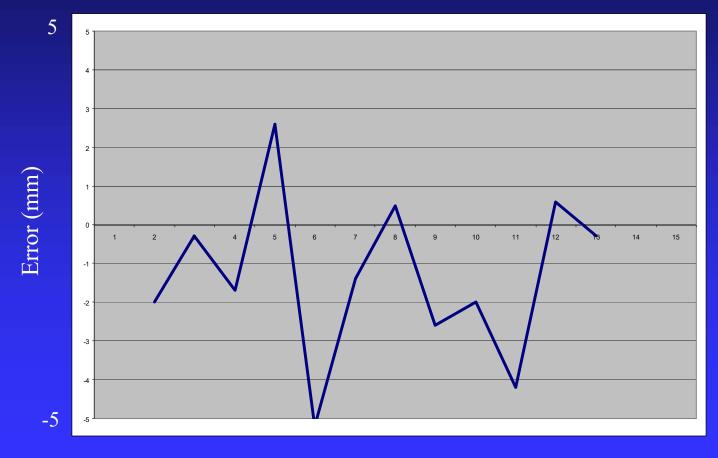

Fig. 6. Solid bars represent the % volume in the confidence-limited planning target volume (cl-PTV) but not in the generic PTV (normalizing to the cl-PTV). The shaded bars represent the % volume in the generic PTV but not in the cl-PTV (normalizing to the generic PTV).

Prostate Adaptive Radiation Therapy

Nuver et al, IJROPB 2007

Methods: average prostate

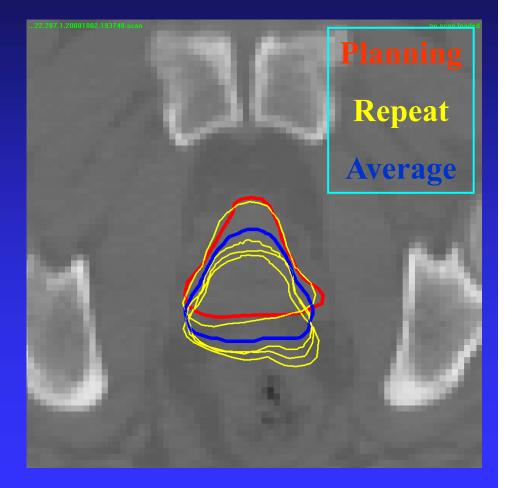

•Plan \rightarrow CBCT1: T1/R1 •Plan \rightarrow CBCT2: T2/R2

•Plan \rightarrow CBCT6: T6/R6

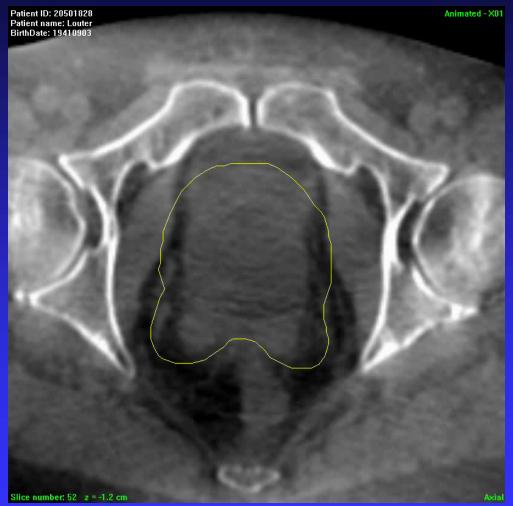

T_{AVG} / R_{AVG}

 T_{AVG} / R_{AVG} puts prostate from plan CT in average position

• With this CTV the margin can be safely reduced from 10 mm to 7 mm

Results: monitoring the treatment

average CTV + 7 mm margin

Nijkamp et al, IJROPB 2007

Results

- 472 out of 483 (98%) follow-up CBCT scans GTV within PTV
- Only 5 out of 67 patients (7%) not enough useful CBCT scans in the first week (moving gas/technical problems)

Downside:

- Procedure took approximately 7 hours extra per patient
 - Prostate registration (0.5 hours)
 - Delineation of rectums on CBCT (2 hours)
 - Planning and paperwork (4 hours)
 - Follow-up (0.5 hours)
- Maximum of 1 patient per week

Kranen et al, IJROBP 2016

Benefits of Daily IG-IMRT

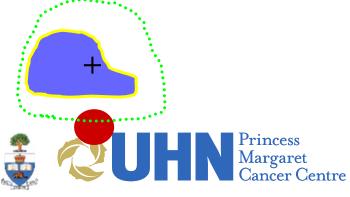

Precision Match PTV to random uncertainty

Adaptation

Assess anatomical changes & update plan

Summary

- Frequent soft-tissue imaging provides feedback & and opportunity to adapt to changing conditions.
- On-line correction combined with off-line adaptation is desirable, but may not be sufficient.
- Adaptive schemes may permit PTV margin reduction, and other opportunities to improve treatment:
 - Assure minimum target dose.
 - Spare more normal tissue volume.

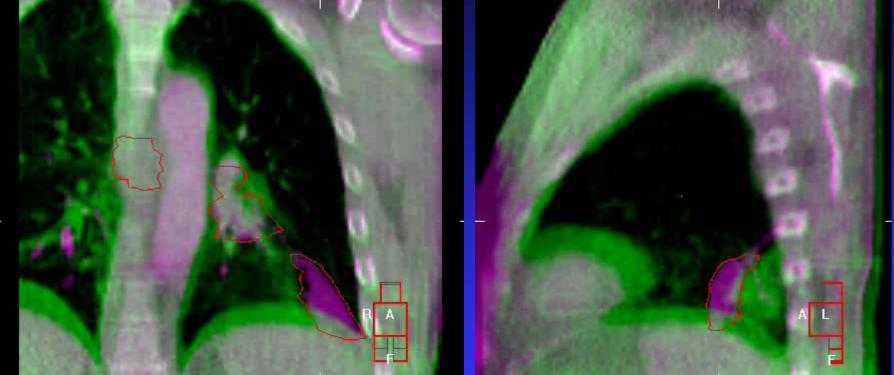

Differential Variability

Planning CT 4D-CBCT CTV

No couch correction can solve this problem

Physical and biological optimisation

Gert Meijer

Physical optimisations

- Input: prescribed dose distribution
- Goal: maximise agreement between prescribed and resulting dose distribution
- **Example**: minimise quadratic difference between

prescribed and calculated dose distribution

Advantages

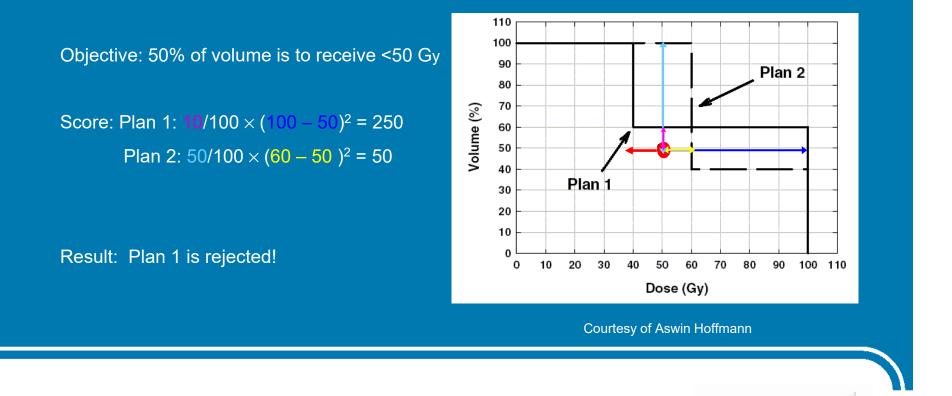

Physical optimisations

- Use of dose and dose-volume objectives is easy and intuitive
- Clinical knowledge is expressed in dose-volume endpoints and can easily be incorporated in the treatment planning recipe
- Objectives are easily and efficiently implemented in computer algorithms

Limitations Physical optimisations

- Quadratic dose difference may not reflect clinical objective
- Properly ranking plans based on dose-volume objectives may fail

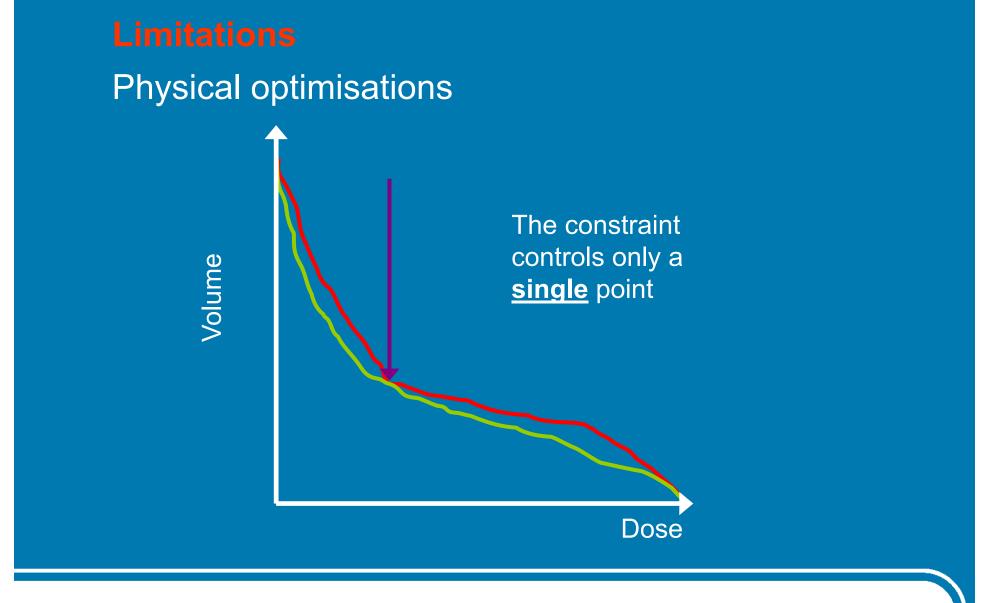

European Society for Therapeutic Radiology and On

Limitations

Physical optimisations

- Objectives do not reflect non-linear dose-response relationship
 - Resulting treatment plan is therefore usually not clinically optimal
- Planning efficiency
 - For each objective a triplet (dose, volume, weight) has to be specified
 - Multiple objectives are needed for the same organ to define a DVH

Optimization in the biology domain

- Rationale: The aim of RT is not to give a required dose to the target, but to accomplish a clinical effect
- Idea: Incorporate radiosensitivity of a tumor and normal tissues in the optimization process
- Method: Use an adequate model to quantify the biological effect of dose deposition

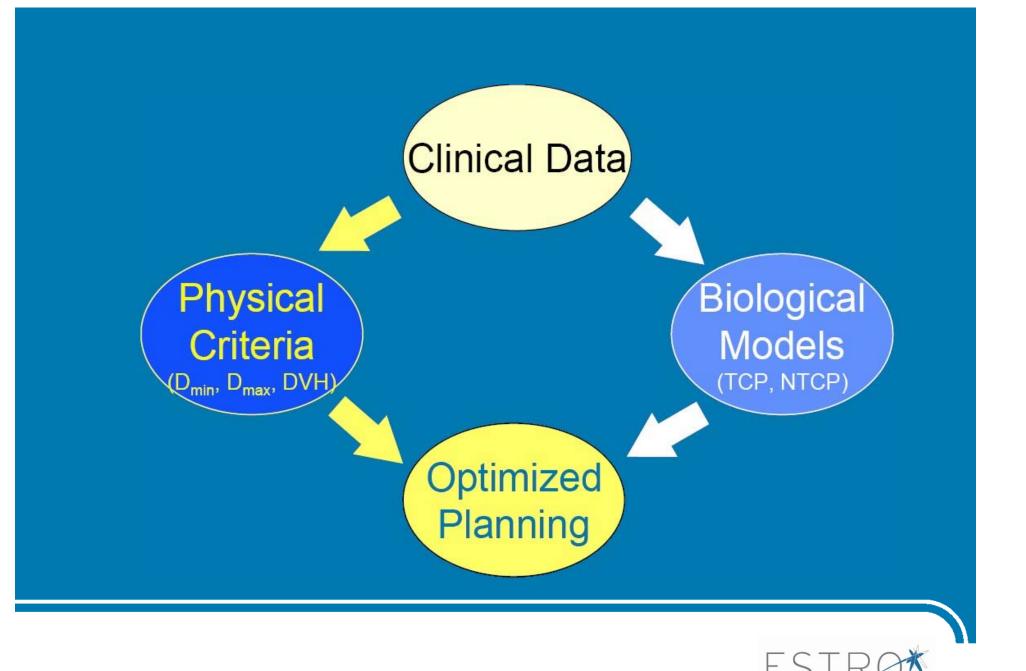

Radiobiological dose-response models

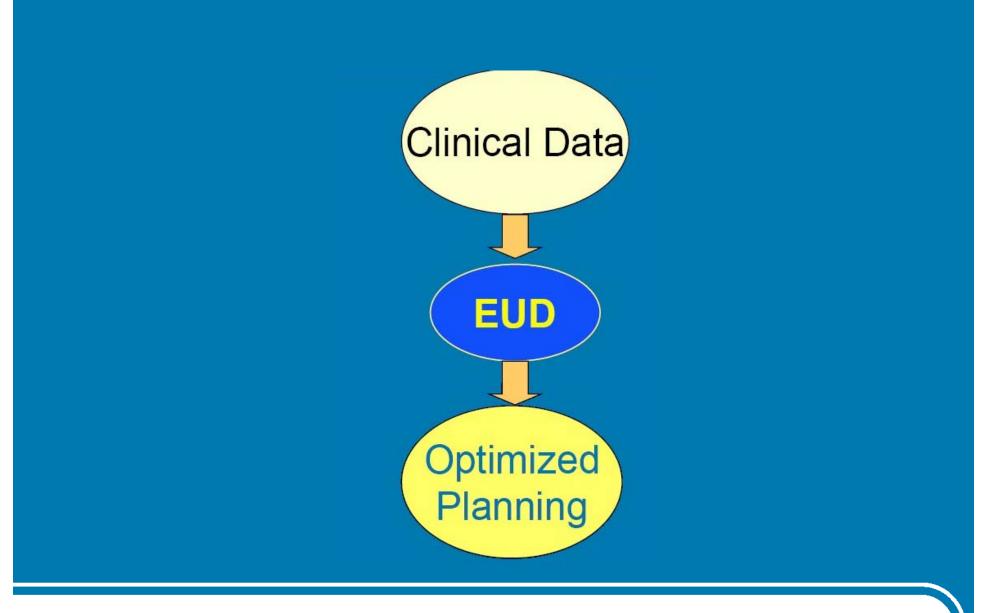

- Mechanistic models: radiobiological basis
 - this is merely a dream ■ energy deposition in tissue → clinical/biologic
 - adequate mechanistic mode

- Empirical/phenomenological models
 - describe observed clinical effect as dose-response relationship
 - find a way to substitute lack of biological knowledge with clinical experience: "let the data speak"

European Society for Therapeutic Radiology and Once

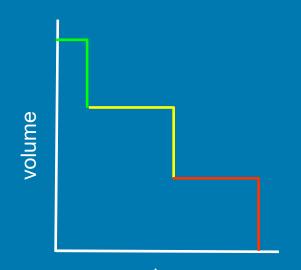

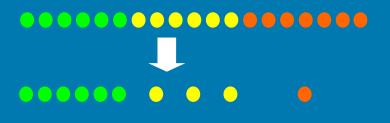

the EUD represents a uniform dose, which leads to the same probability of a radiobiological effect as the corresponding inhomogeneous dose

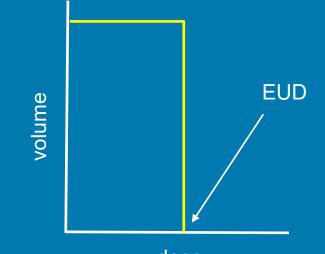

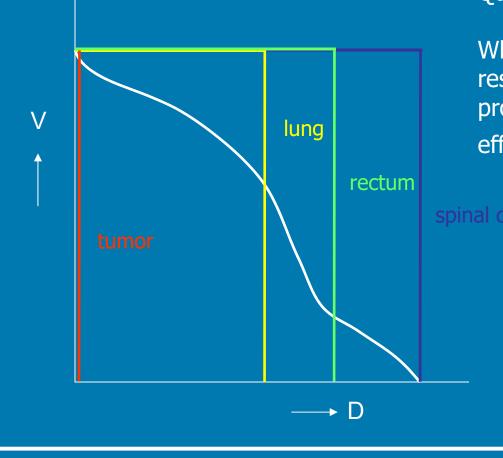

dose

dose

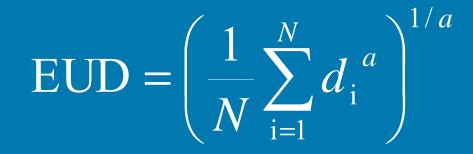

Question:

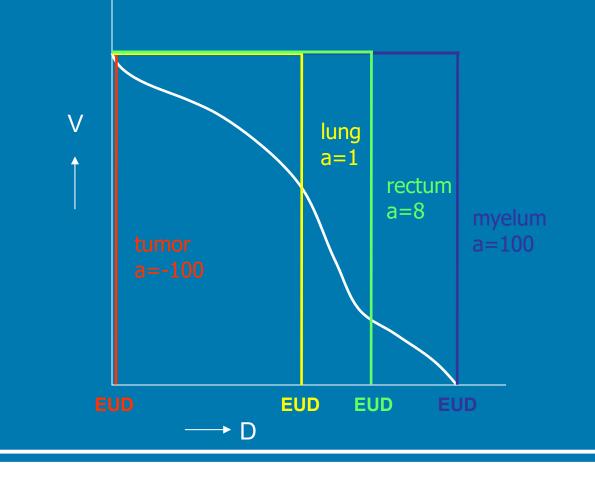

What homogenous dose results in an identical probability of an radiobiological effect?

European Society for Therapeutic Radiology and Onc

		Effect	Suitable organs
	<i>a</i> < 1	Lower doses are given higher weight, so that cold spots affect the EUD to a large extent.	Targets.
$EUD = \frac{1}{N} \sum_{i=1}^{N} d_i$	<i>a</i> = 1	This corresponds to the mean dose. Cold and hot spots are given equal weight.	Parallel organized normal tissue, such as lung and liver.
$N \sum_{i=1}^{n} \alpha_i$	<i>a</i> > 1	Larger doses are given higher weight, so that hot spots affect the EUD to a large extent	Serial tissue, such as the spinal cord.

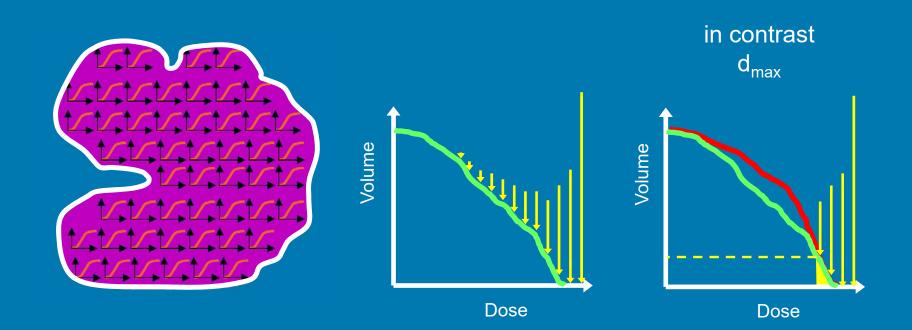

European Society for Therapeutic Radiology and Oncolog

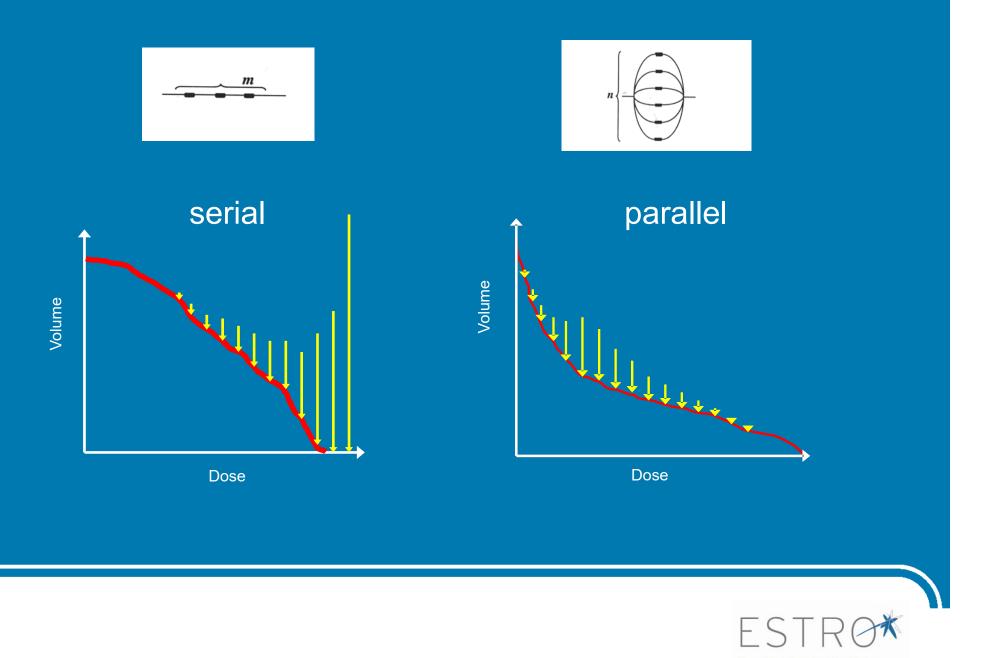

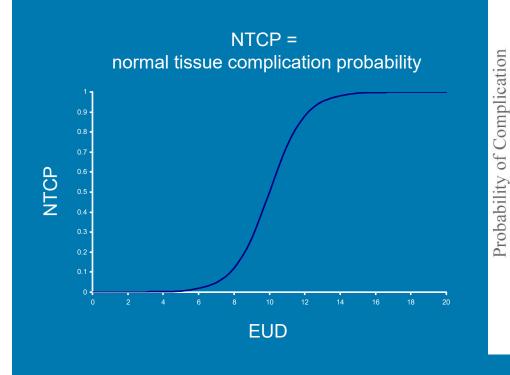

Essentially, a biological cost function is applied to each volume element of a structure The total effect is described in the resulting DVH

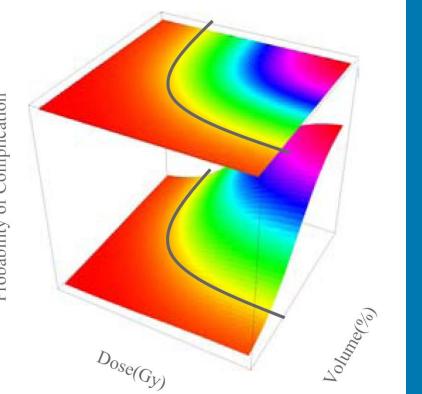

European Society for Therapeutic Radiology and Oncolog

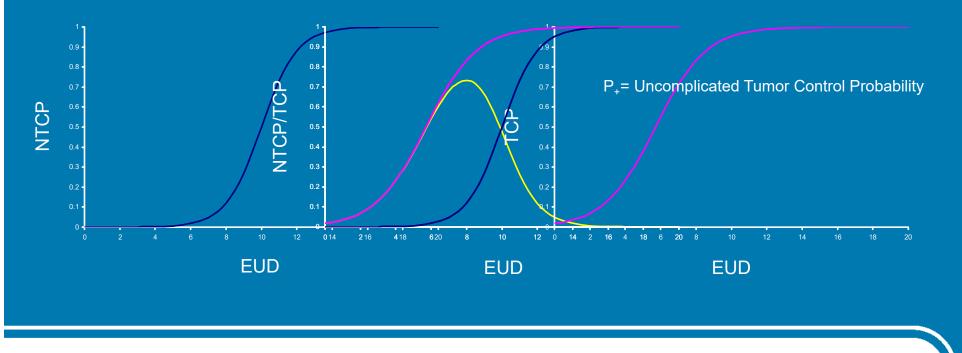

Can we go beyond EUD?

Can we go beyond EUD?

Limitations

Biological optimisations

- Knowledge about biological effects and clinical data is scarce and incomplete
- The models are insufficient and the parameters are uncertain
- Models are not self-limiting: dose distributions can be generated beyond the model's range of validity

Advantages

Biological optimisations

- Both tissue architecture and radiation response are taken into account
- The volume effect is explicitly discounted for in the models used for optimisation
- Sigmoidal models seem to be more clinically relevant than a quadratically scored deviation from the prescribed dose

Conclusions

- Physical optimisation using quadratic cost functions to penalize the dose deviations seems practical, but may be too optimistic in meeting the clinical objective
- Radiobiological optimisation will become more trustworthy by judicious use of more accurate dose-response models
- Physico-biological optimisation can generate plans that are clinically recognized and fulfill the dose and dose-volume constraints based on clinical practice, while outperforming physically optimised plans

MRI in treatment planning

N. Dinapoli

Introduction: MRI – why, where, when?

- Traditional planning procedures use CT images to calculate dose distribution.
- This is because extraction images process of CT is based on X-rays interaction with matter
- The informations that CT can give for planning are of three types:
 - Geometry
 - > Density
 - > Atomic number

- Electron density maps

Dose distribution calculation

Introduction: MRI – why, where, when?

- Advantages of MRI:
 - Better contrast definition
 - Better "chemical" description of the matter structure
 - Better definition of **functional** aspects of the tissues (tumor and OAR) that is **physiology** of the tissues

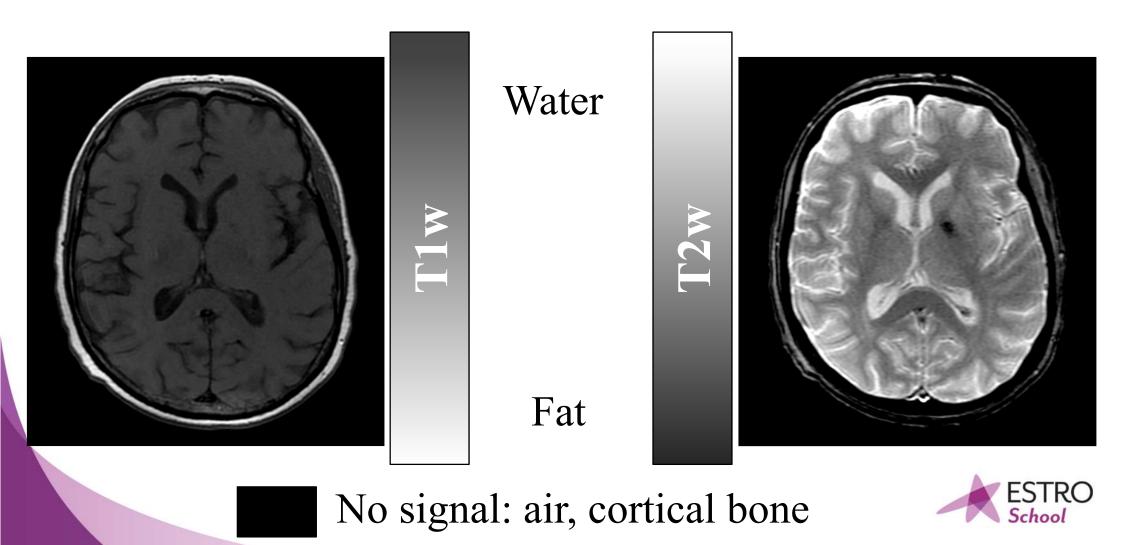

Introduction: MRI – why, where, when?

- MRI sequences
 - Traditional (relaxation time):
 - T1w
 - T2w
 - Functional (post-processing):
 - DWI
 - DTI
 - PWI
 - SMR

Introduction: MRI – why, where, when?

• MRI T1w T2w images:

Functional imaging modalities in MRI

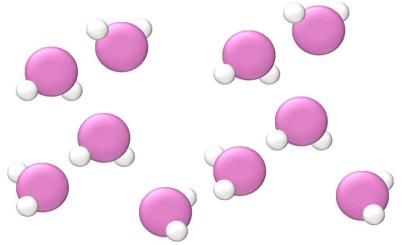

• Functional MRI: imaging modalities that focus on physiological/chemical features of tissues and vascularization, rather than morphology

Diffusion weighted MRI	DWI
Diffusion tensor imaging	DTI
Perfusion MRI	PWI
Spectroscopy MRI	SMR

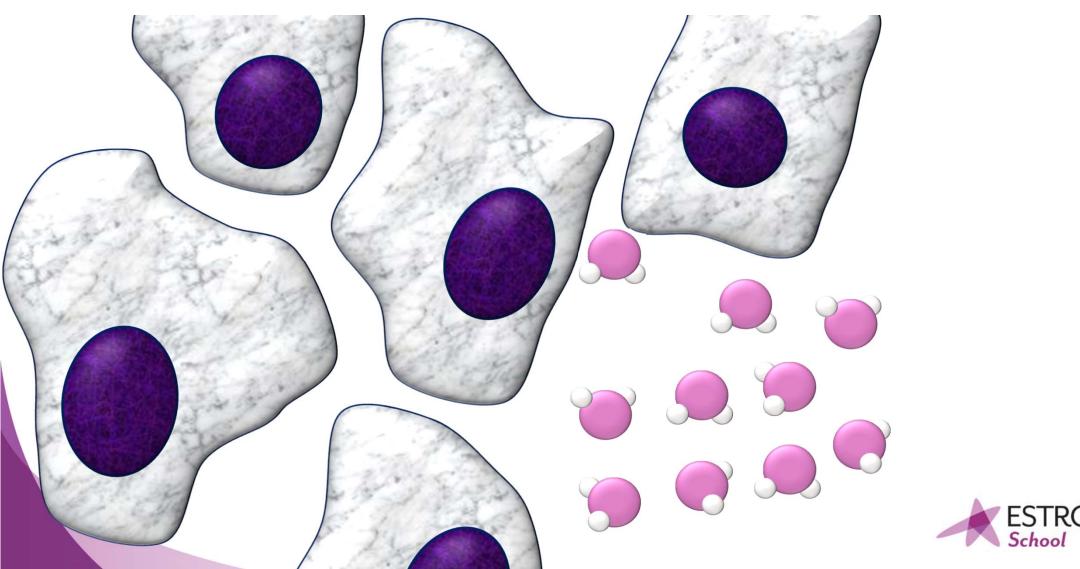

DWI images

- Rationale
 - In biological tissues H2O molecules produce random micro-movements due to the thermal energy (Brownian movements)
 - In DWI images can be obtained by analyzing this kind of movements
 - The micro-diffusion of water molecules gives informations about the normal and pathologic tissues structure

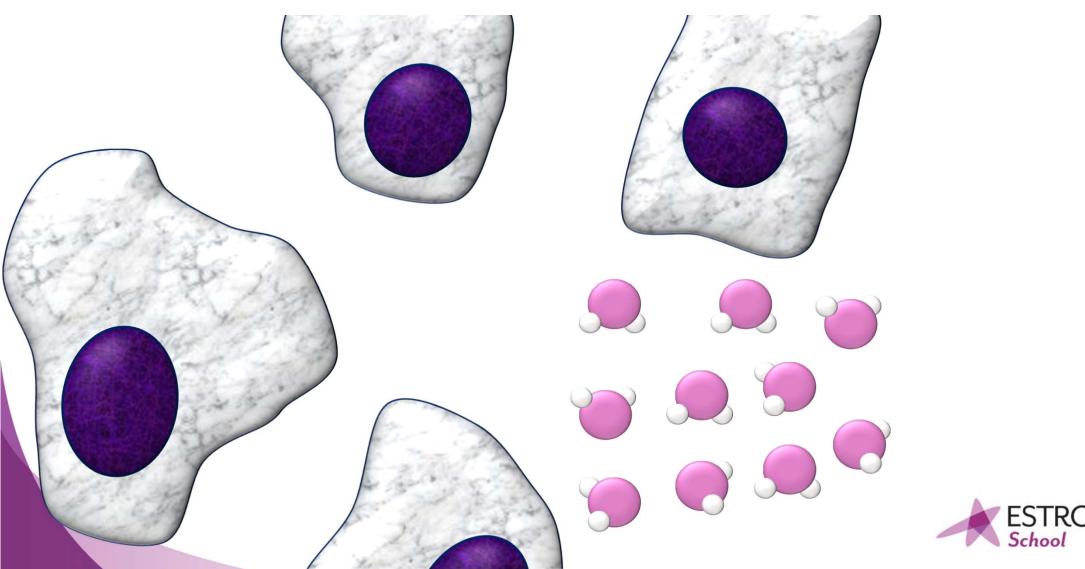

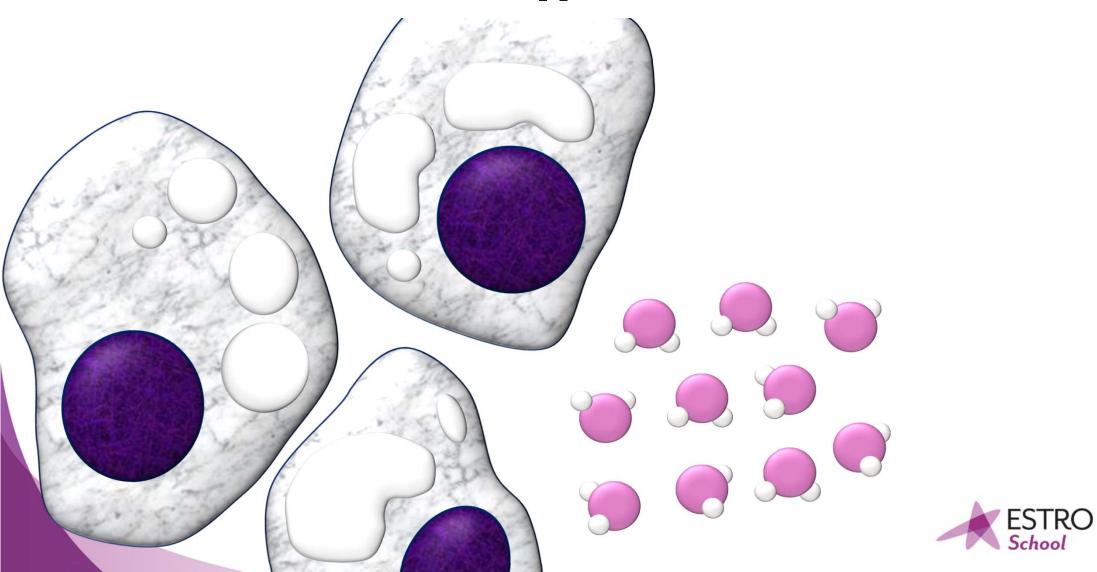

• High cellularity – Lower Apparent Diffusion Coefficient (ADC)

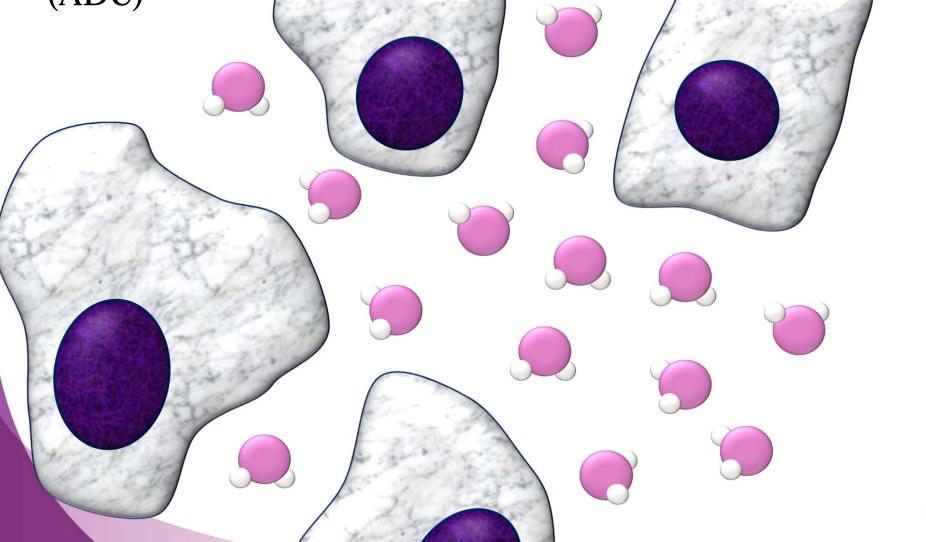

• Low cellularity – Higher Apparent Diffusion Coefficient (ADC)

• Intracellular edema – Lower Apparent Diffusion Coefficient (ADC)

 Extracellular edema – Higher Apparent Diffusion Coefficient (ADC)

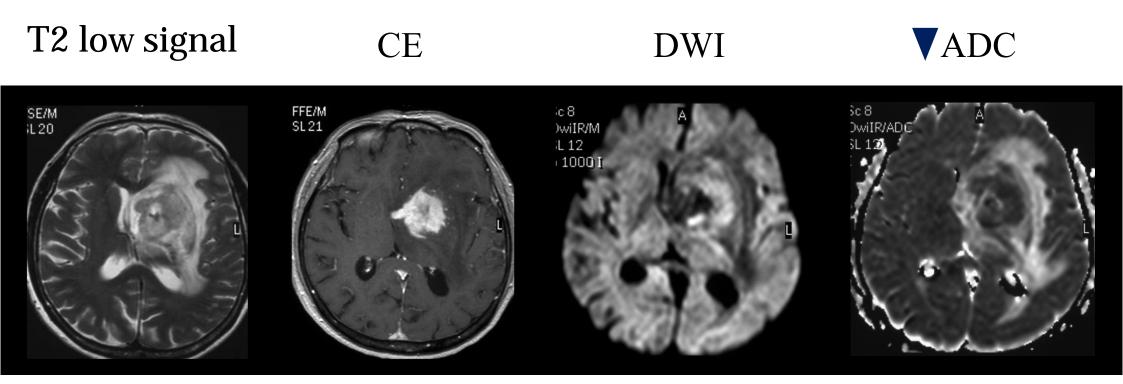

- ADC mapping allows to obtain more informations on the biological "nature" of the tissues
 - $\blacktriangleright \text{ Acute lesion (ischemic)} \qquad \implies \text{oedema} \qquad \implies \mathbf{\forall} \text{ADC}$
 - ➢ Chronic lesion (post-ischemic) →relaxing tissues → ▲ ADC
 - Neoplastic lesions
 - Neoplastic lesions

- \rightarrow high cellularity $\rightarrow \bigtriangledown$ ADC
- \rightarrow necrosis $\rightarrow \land ADC$

I Berry. Imagerie par résonance magnétique. 2004; Masson Editeur, Paris.

Another fatal necrosis after central SBRT...

Case report: Central Airway Necrosis after SBRT

- SBRT to two NSCLC, one of them centrally located
- 8 months later: mediastinal LN recurrence, extensive changes within irradiated bronchus (biopsy: fibrosis)
- Chemo / hemoptysis / intubation

Coradetti et al. NEJM 2012

Died 11 months after SBRT
Kliniken Maria Hilf
Mönchengladbach

SBRT: a knife without suture

Differences in physiological NT-reaction to high dose RT: Fibrosis (lung, liver), necrosis (brain, bone), strictures (esophagus, bronchi)

Difference in clinical consequences: Parallel vs. serial organs

Parallel (lung, liver): small volume of damage no problem (fibrosis)

Serial (esophagus, vessel): small volume of damage may cause life threatening effects

Dose-Limiting Toxicity After Hypofractionated Dose-Escalated Radiotherapy in Non-Small-Cell Lung Cancer

Donald M. Cannon, Minesh P. Mehta, Jarrod B. Adkison, Deepak Khuntia, Anne M. Traynor, Wolfgang A. Tomé, Richard J. Chappell, Ranjini Tolakanahalli, Pranshu Mohindra, Søren M. Bentzen, and George M. Cannon

J Clin Oncol 31:4343-4348.

Conclusion

Although this dose-escalation model limited the rates of clinically significant pneumonitis, dose-limiting toxicity occurred and was dominated by late radiation toxicity involving central and perihilar structures. The identified dose-response for damage to the proximal bronchial tree warrants caution in future dose-intensification protocols, especially when using hypofractionation.

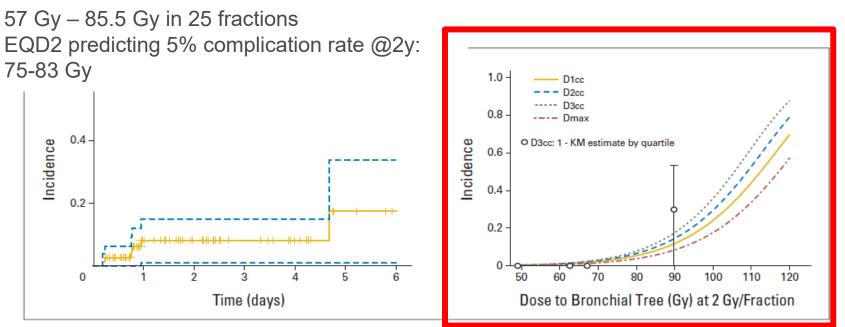

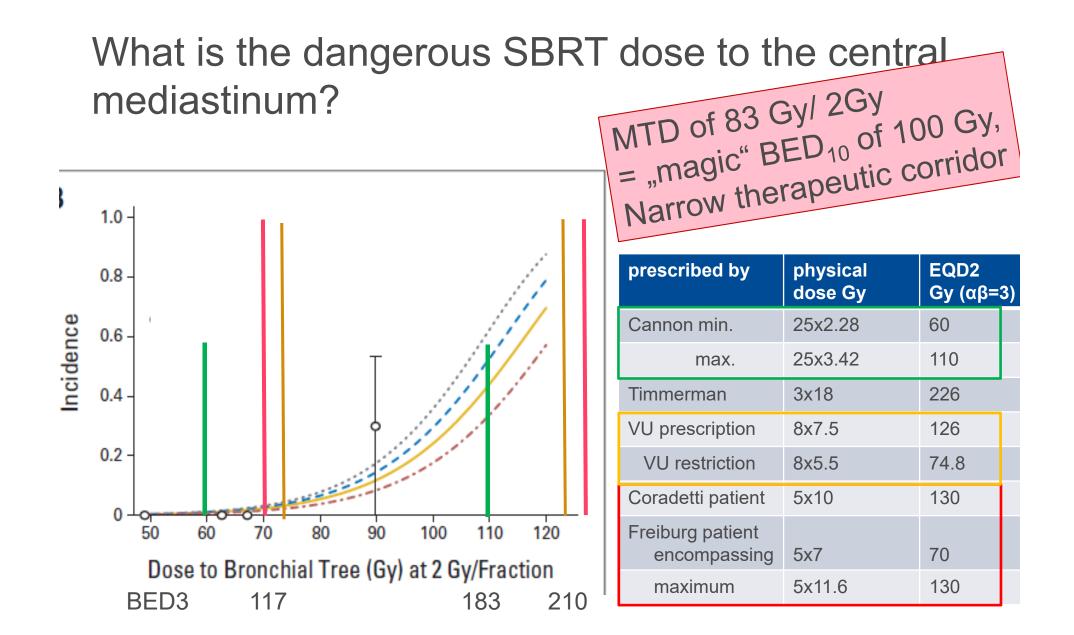

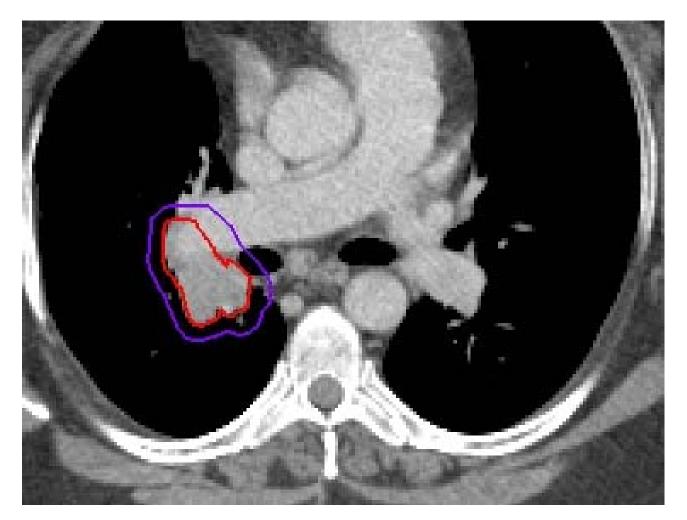

Fig 2. (A) Incidence (1 - Kaplan-Meier [KM] estimate) of any grade 4 or 5 toxicity in patients censored at the time of death or last clinical follow-up. Dashed lines represent the 95% CI. (B) Two-year probabilities of late grade 4 or 5 toxicity according to dose-per-fraction normalized dose (EQD2) to the proximal bronchial tree and estimated using a Cox proportional hazards model. Open circles represent the 1 - KM estimate (± 95% CI) for quartiles of EQD2 D3cc (centered at the quartile mean). Kliniker, DXcc, maximum dose D such that X cm³ of the structure received a dose ≥ D; Dmax, maximum dose to any voxel within structure.SITATS

Esophageal toxicity

Grade 1 radiation-induced esophagitis was observed 1 week after the start of IGRT in 1 patient with metastatic lung cancer who received <u>48 Gy/8 Fr</u> to the 3.5-cm tumor located posterior to the right main bronchus. The pain resulting from acute radiation esophagitis was relieved at 1 month after IGRT ended. However, this patient suffered from swallowing pain again 3 months after IGRT ended and <u>died</u> as a result of bleeding from an <u>esophageal ulcer 5</u> months after IGRT ended.

Onimaru IJROBP 2003

- Very few reports of significant esophagitis
- most centers exclude pts with PTV touching the esophagus from SBRT:

There is more than dose and fractionation...

Beyond prescribed dose, multiple factors influence local control and toxicity after SBRT:

- Imaging in staging and treatment planning (PET-staging? 4Dimaging for TV-delineation?)
- Treatment planning (NT-compromising? PTV-concept? dose calculation algorithms? allowed min/max doses? prescription point ...)
- Immobilisation and image guidance (cbct? 4D-cbct? post treatment scan?

Kliniken Maria Hilf

Advanced planning strategies for lung tumours

physical aspects

Gert Meijer

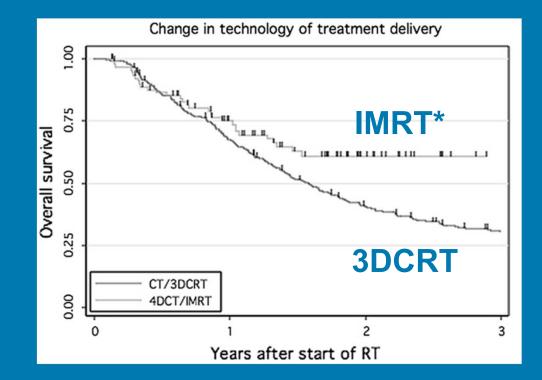

Why use IMRT in lung

better survival

better local control

•less pneumonitis

* in combination with IGRT and 4DCT

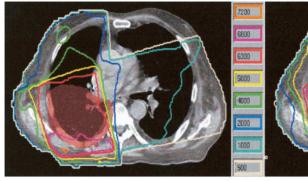

Liao et al. (IJROBP 2010)

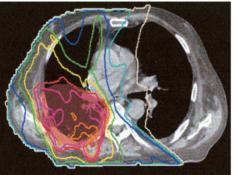

Why use IMRT in lung

43 patients

- more conformal
- better sparing OARs
- lower dose to all lung parameters except V5

		6800	
Parameter	3D-CRT	IMRT	p P
Thoracic normal tissue V_5 (cm ³)	5658 (3040-11596)	6929 (2759-10788)	0.006

3DCRT

IMRT

Murshed et al. (IJROBP 2004)

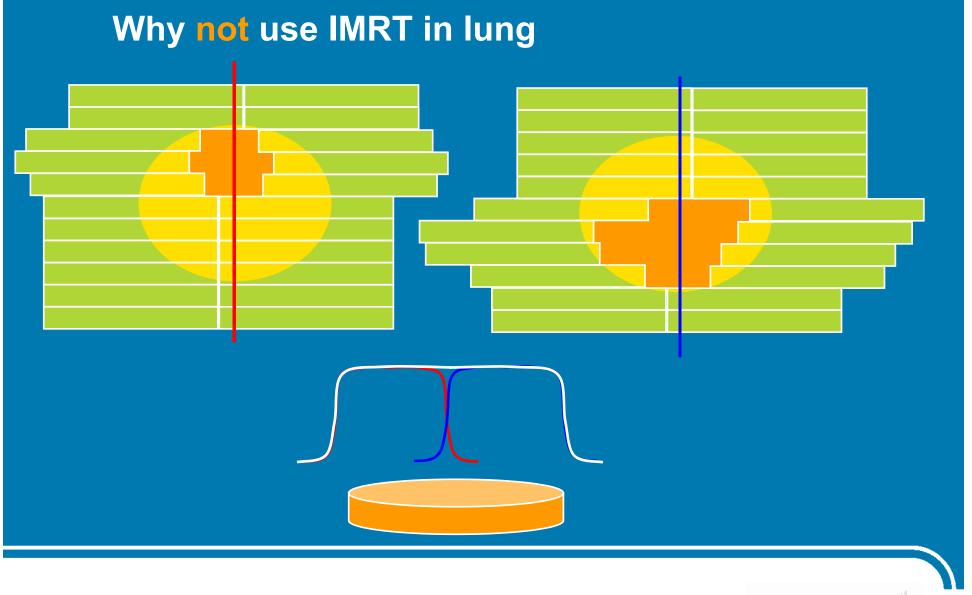

Why not use IMRT in lung

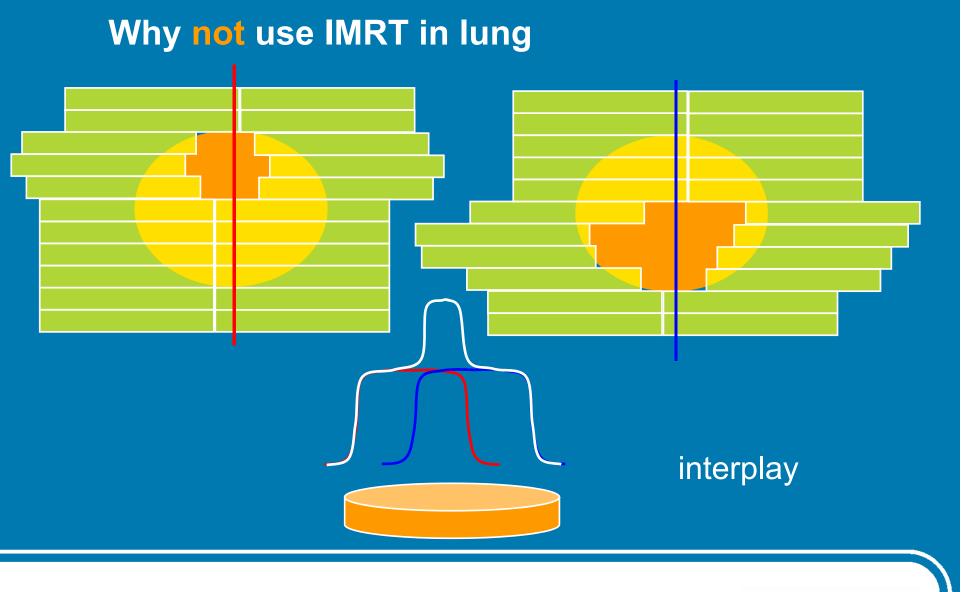

Seppenwoolde *et al.* (IJROBP 2002)

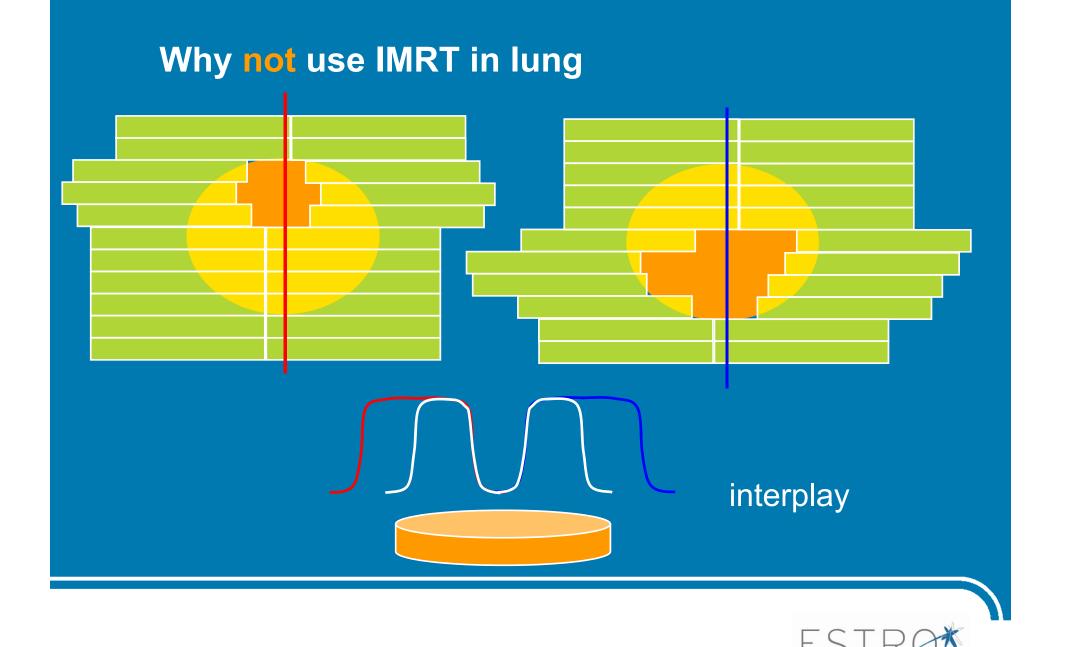

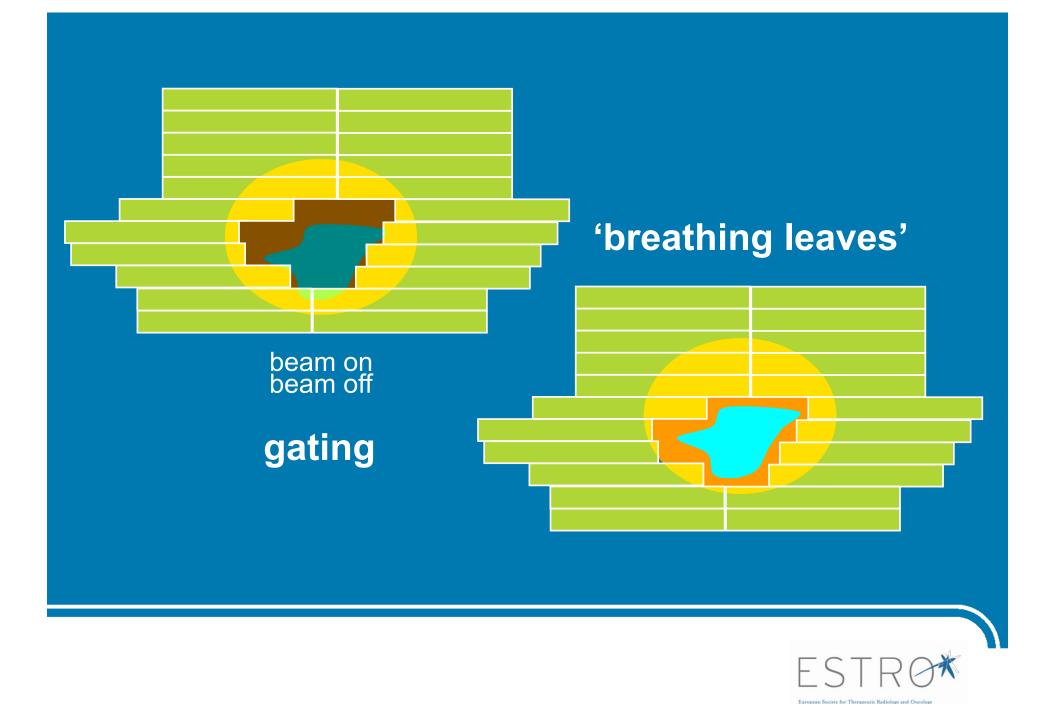

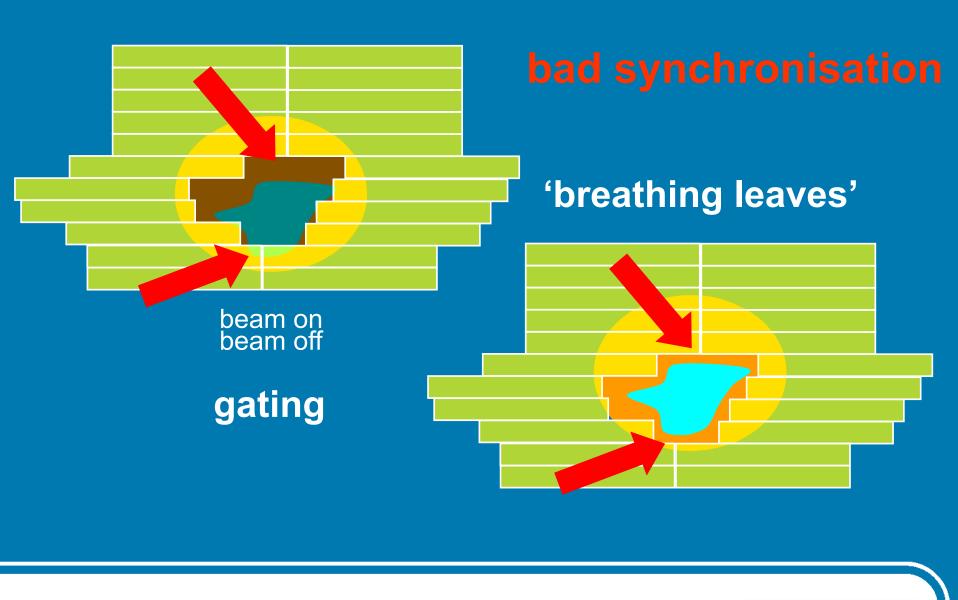

European Society for Therapeutic Radiology and On

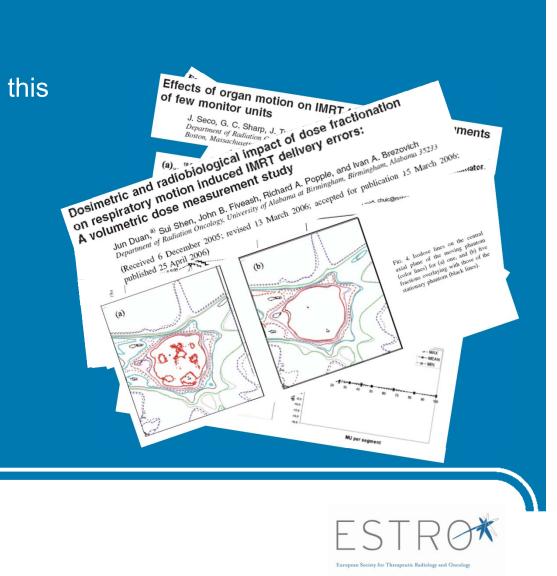

So forget about IMRT for lung if you don't have these fancy tools?

Many studies investigated this phenomenon and

Key findings:

- large potential for interplay effects per fraction
- but cancel out for large fractions or large # MUs
- stability in TCP at 5 fractions
- IMRT for SBRT may even be acceptable
- appropriate margins more important than respiratory control

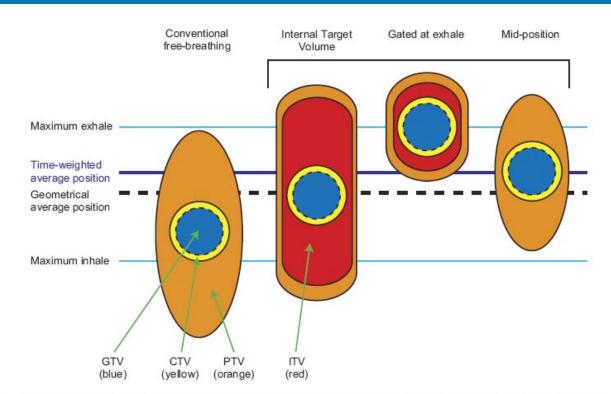

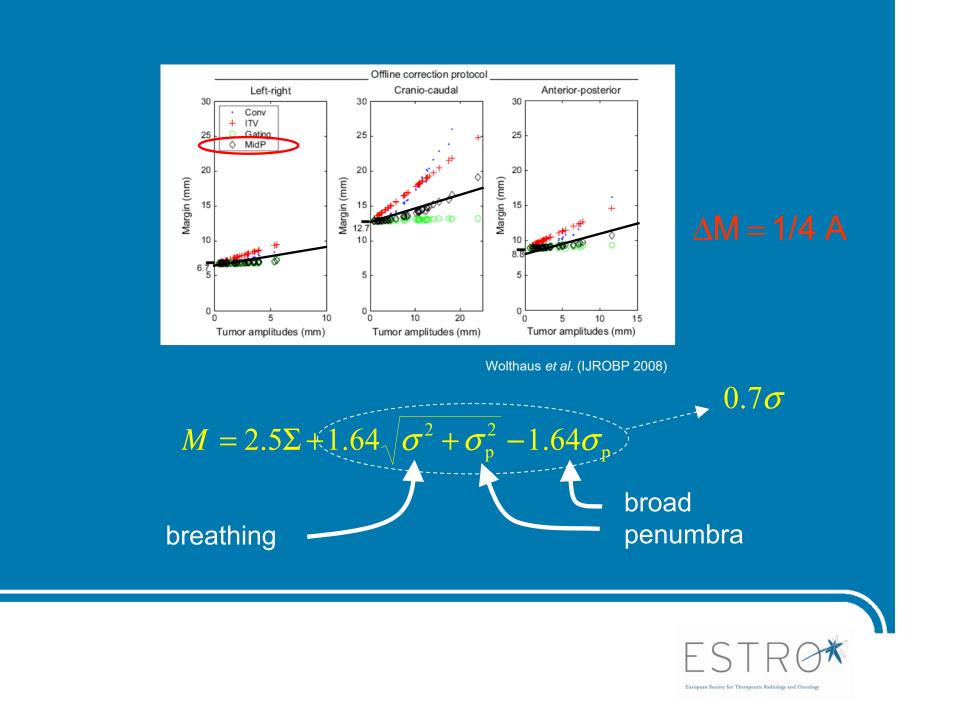

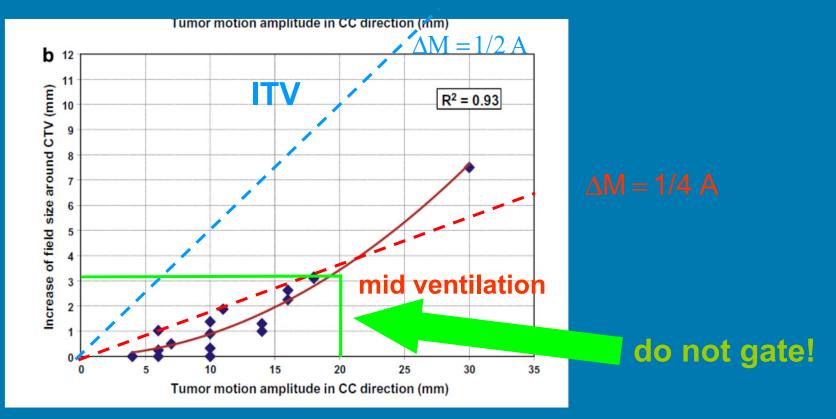

Fig. 1. Schematic overview of different treatment-planning concepts: conventional free-breathing, internal target volume (ITV), gating (at exhale), and mid-position. GTV = gross tumor volume; CTV = clinical target volume; PTV = planning target volume.

Wolthaus et al. (IJROBP 2008)

SBRT

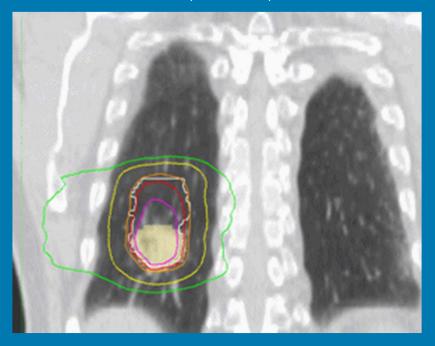

Guckenberger *et al*. (R&O 2009)

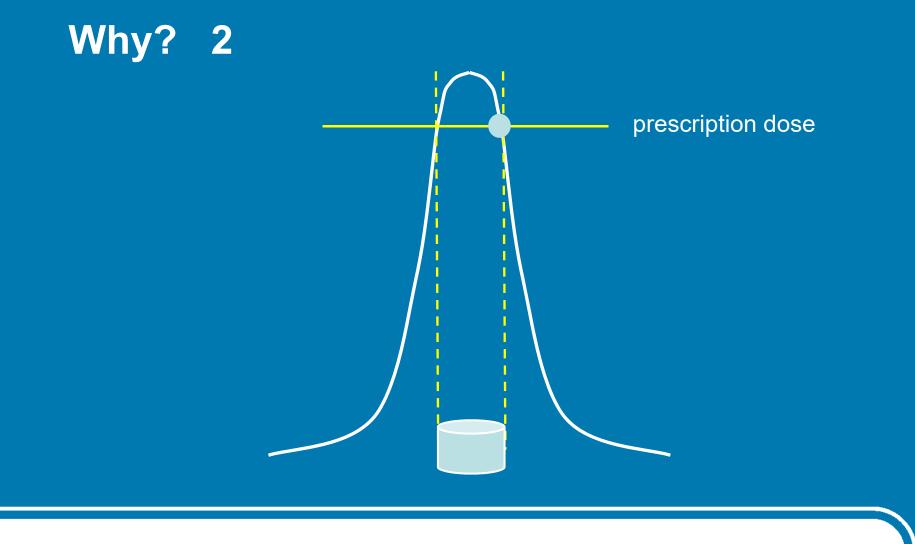

Why? 1

Admiraal et al. (R&O 2008)

because high dose regions move along with the tumour

So

 extra margin for respiration is about ¼ of the breathing amplitude

• how about the other uncertainties?

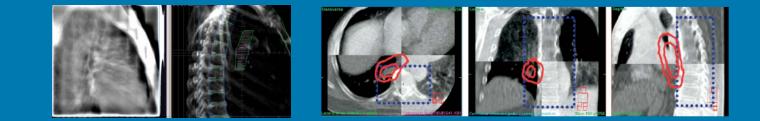

IGRT (not addressed in this course) is key here

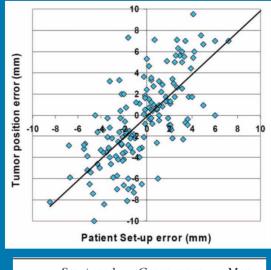

- 4DCT
 - unblurred target delineation
 - tumour movement

• CBCT

 3D soft tissue matching superior to regular 2D bony anatomy matching

	Sys.±rand. error	Group mean error	Max. error
SI	2.1 ± 1.1	0.3 (superior)	8.2
AP	3.3 ± 1.3	1.7 (posterior)	9.1
LR	2.2 ± 1.1	0.7 (left)	6.4

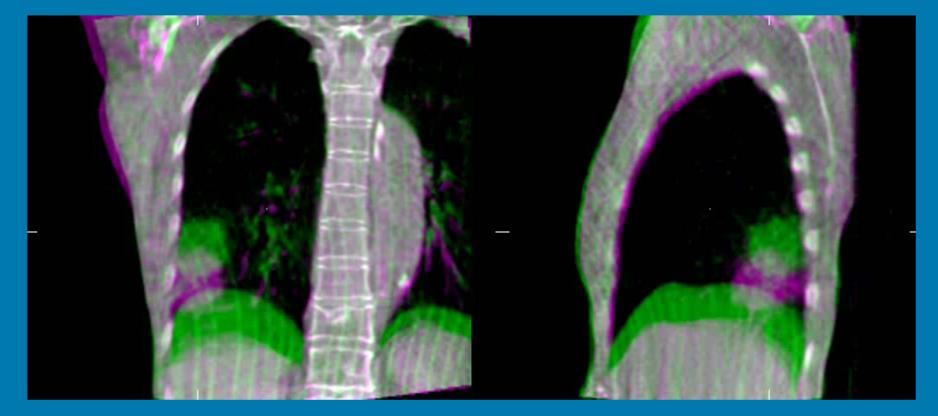

Guckenberger et al. (ActaOncol 2006)

Purdie et al. (IJROBP2007)

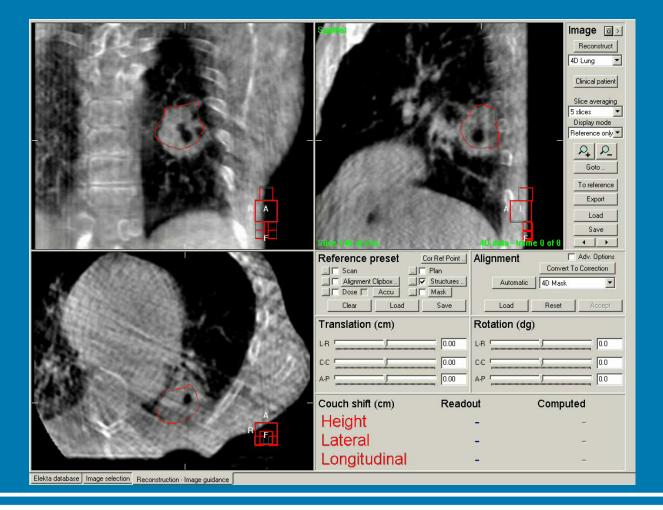

Baseline shifts

Sonke et al. IJROBP 2008

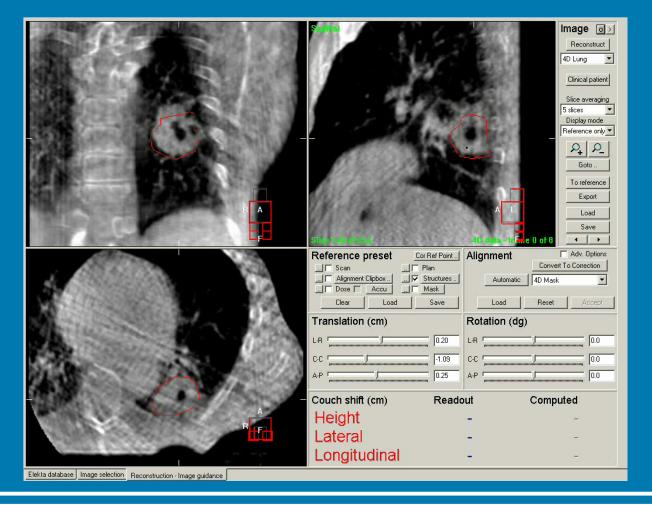

4D CBCT + GTV Contour

Apply Correction

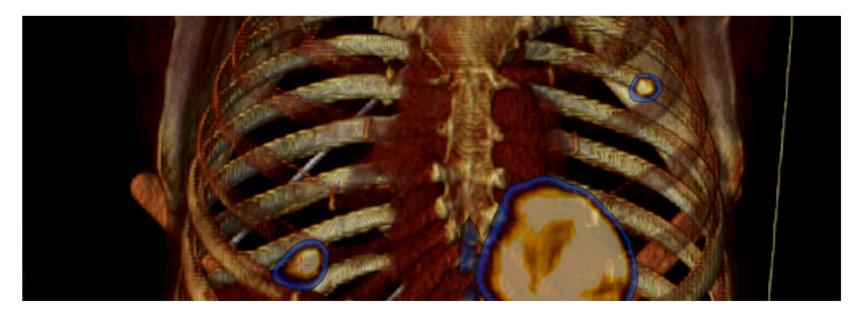

Conclusions

- IMRT superior to 3DCRT for locally advanced NSCLC
 - lower dose to all risk organs except low dose to lungs
- Interplay effects not really critical in IMRT
 - gated delivery not crucial for IMRT
 - but start off with 'simple' plans with large segment shapes
 - additional respiration margin of about ¼ amplitude (if GTV is delineated at mid-vent CT)
- Sound IGRT protocols are crucial

Observer variability vs. method variability

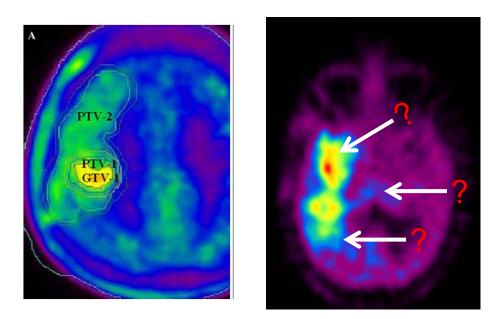

- 1 case, 40 contours
- Experts(A) and teams RO & NM (B)
 → Significantly higher IOV (C)
- IOV Specialists (C) vs. students (D): n.s.
- "PET-years" n.s.
- IMV of automatic algorithms = IOV of students

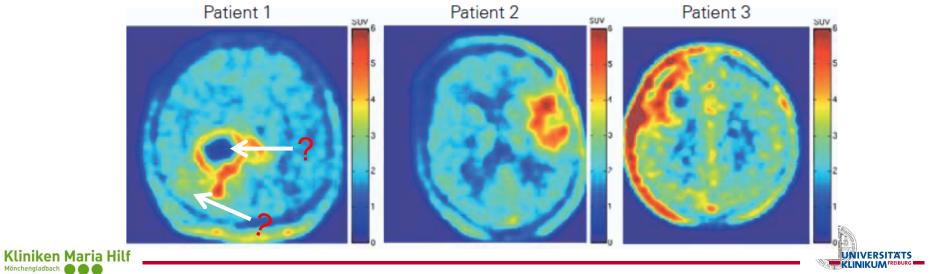

C. Doll et al. Strahlentherapie 2012

Problem: what the hell is the GTV?

Problem: Ground truth

To calibrate a correct contouring method, the knowldedge on the correct tumor borders is essential, e.g. from:

- Phantom-measurements
 Problem: usually homogenous spheres, glass wall, homogenous background
 = not representative for tumors
- simulated images Problem: extremely harmful to produce, proximity to reality depends on assumptions
- image data with histopathology correlation not many datasets available, all have shortcomings: shrinking, distortion, problem of coregistration, diffuse infiltration
- tumor size known from other imaging Problem: reason for second imaging? other problems in size determination

possible surrogates:

- comparison with expert contours, ideally consistent in multiple observers
- visual or mathematical consensus-contour of different methods

Classification and evaluation strategies of auto-segmentation approaches for PET: Report of AAPM Task Group No. 211

M. Hatt¹, J. Lee², C.R. Schmidtlein³, I. El Naqa⁴, C. Caldwell⁵, E. De Bernardi⁶, W. Lu³, S. Das⁷, X. Geets², V. Gregoire², R. Jeraj⁸, M. MacManus⁹, O. Mawlawi¹⁰, U. Nestle¹¹, A. Pugachev¹², H. Schöder³, T. Shepherd¹³, E. Spezi¹⁴, D. Visvikis¹, H. Zaidi¹⁵, A.S. Kirov^{3*}

Conclusions: Based on the large number of published PET-AS algorithms and their relative lack of validation, selecting and recommending an algorithm from among those available is challenging. Available comparison studies suggest that PET-AS algorithms relying on advanced image paradigms perform generally better than simple threshold-based approaches, particularly in realistic configurations. However, this may not be the case for situations with a narrower range of parameters (e.g., a particular body site and/or tumor type), where simpler (e.g., adaptive threshold) methods also may perform well. In either case PET-AS contours need to be critically inspected and edited by a physician. Another

Med Phys, accepted 2017

What have we learned after >10 years searching the holy grail for PET based GTV-segmentation?

- Using molecular imaging for GTV delineation **at all** is more important than finding the right method to include the last voxel
- Maybe drawing one line is not what resembles the information needed for future RT planning
- If we need one line, **visual** delineation is not a bad idea, institutional standardisation makes sense
- Automatic delineation (by something else than simple thresholding)
 speeds up the contouring process but should be used as a starting point for user review
- The use **4D** imaging for TVD will not be possible without automation

Radiotherapy and Oncology

Dose painting in lung cancer

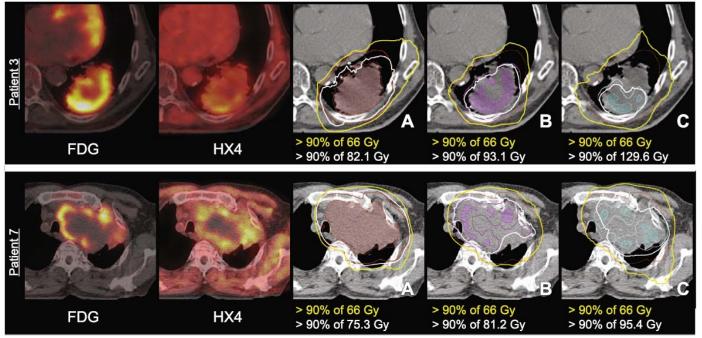

PET-based dose painting in non-small cell lung cancer: Comparing uniform dose escalation with boosting hypoxic and metabolically active sub-volumes

Radiotherapy

Aniek J.G. Even^{a,*}, Judith van der Stoep^a, Catharina M.L. Zegers^a, Bart Reymen^a, Esther G.C. Troost^{a,b}, Philippe Lambin^a, Wouter van Elmpt^a

^a Department of Radiation Oncology (MAASTRO), GROW – School for Oncology and Developmental Biology, Maastricht University Medical Centre, The Netherlands; and ^b Institute of Radiooncology, Helmholtz-Zentrum Dresden-Rossendorf, Germany

Conclusions: Dose escalation based on metabolic sub-volumes, hypoxic sub-volumes and the entire tumour is feasible. Highest dose was achieved for hypoxia plans, without increasing dose to OAR. For most patients, boosting the metabolic sub-volume also resulted in boosting the hypoxic volume, although to a lower dose, but not *vice versa*.

Summary

Radiation Oncology is being revolutionized by new technologies and those are crucially dependent on imaging

Prerequisites for changing concepts are a clinical need and the superiority of the new imaging to traditional methods and may vary significantly between tumors, tracers and clinical scenarios

To seriously show patients benefit by the use of new imaging modalities in different clinical situations, clinical trials are mandatory

Beyond target volume definition, other areas of the use of hybrid imaging in radiotherapy (response assessment, NT-monitoring ...) are presently being investigated

Robust and probabilistic planning

Marcel van Herk Includes slides by Michael Sharpe

Institute of Cancer Sciences Manchester University The Christie NHS Trust

(Formerly at the Netherlands Cancer Institute)

The University of Manchester Manchester Cancer Research Centre

Put more emphasis on robust planning

n Less on breathing stuff

Simplified PTV margin recipe for dose - probability

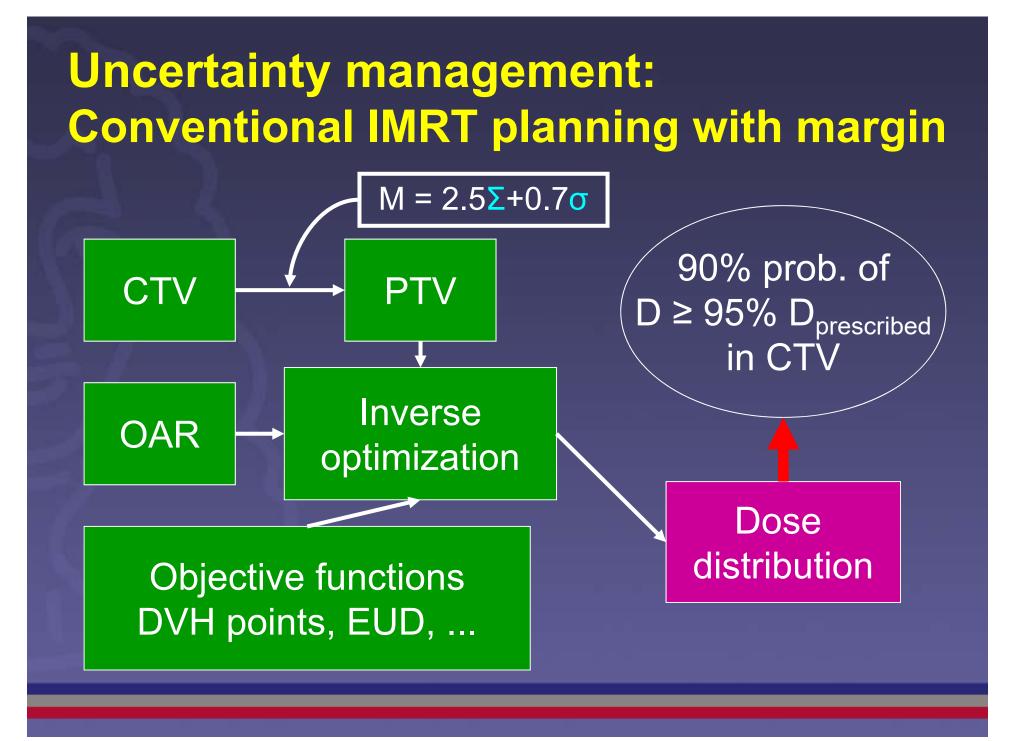

To cover the CTV for 90% of the patients with the 95% isodose (analytical solution) :

PTV margin = $2.5 \Sigma + 0.7 \sigma$

 Σ = quadratic sum of SD of all preparation (systematic) errors σ = quadratic sum of SD of all execution (random) errors

(van Herk et al, IJROBP 47: 1121-1135, 2000)

Margins are an implicit trade off between target coverage and OAR: can we make this explicit?

Uncertainty management: Probabilistic IMRT planning without margin

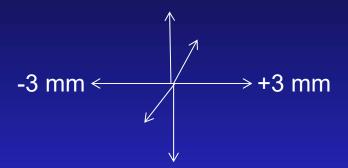

Robust vs probabistic planning

Robust planning:

- Few error scenarios
- Worst case optimization
- No differentiation random/systematic errors

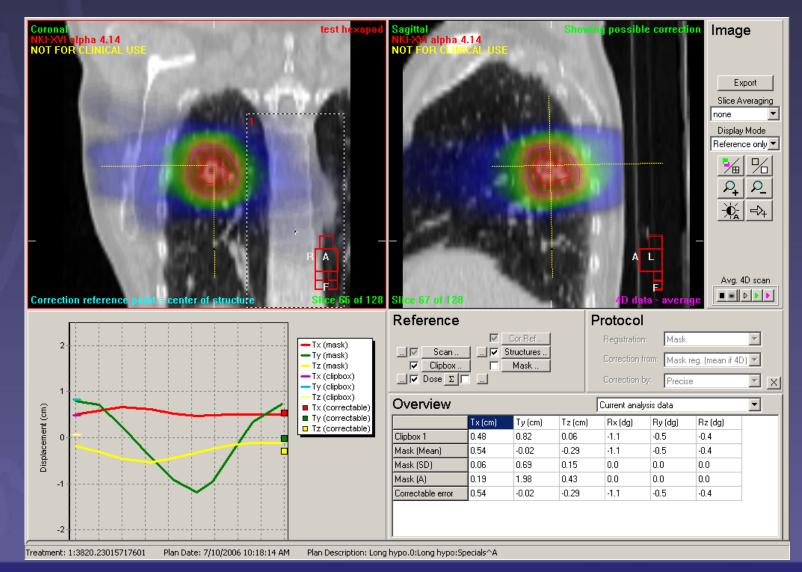

Probabilistic planning

- Hundreds of error scenarios
- Include both random and systematic errors
- Optimize on probability

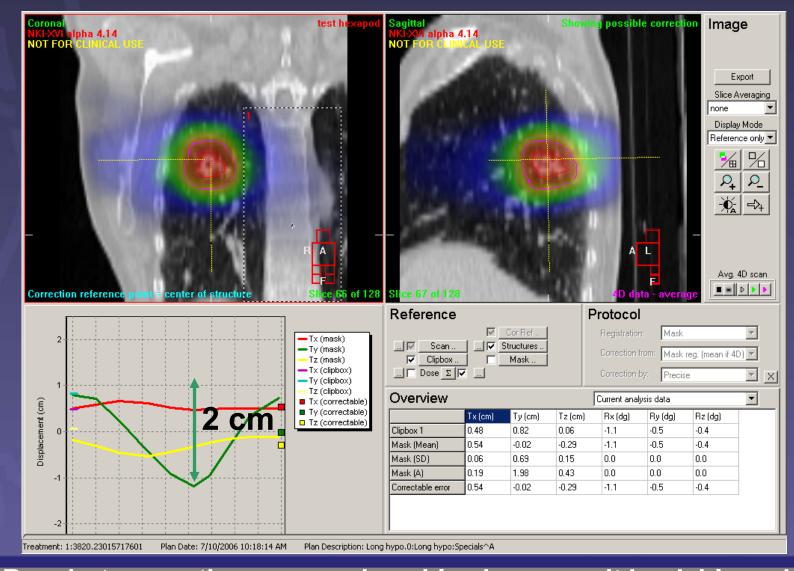

Random errors & breathing

Planned dose distribution: hypofractionated lung treatment 3x18 Gy

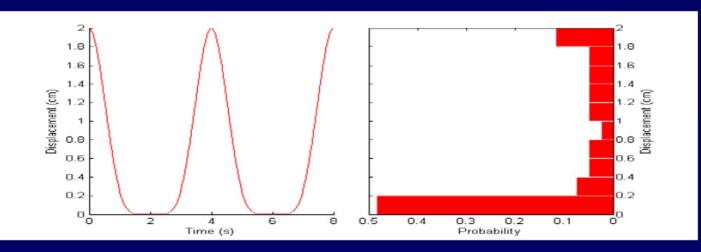

Realized dose distribution with daily IGRT on tumor (no gating)

Respiratory motion causes dose blurring – can it be deblurred ?

• We can get a pmf from sinusoidal data by "horizontal binning"

We can get "error bars" as upper/lower envelopes of many pmfs

Clinical Lung Case

- Tumour in left lung
- Critical structures: left lung, esophagus, spinal cord, heart
- Approx. 100,000 voxels, 1600 beamlets
- Minimize dose to healthy tissue
- Lower bound and upper bound on dose to tumour
- Simulate delivery of optimal solution with 78 "realized pdfs"

Breathing: Margin vs Robust formulation

Courtesy of Tim Chan MIT/MGH

Small gain by taking 'random' motion into account in planning

Systematic errors are much more important - probabilistic planning must include systematic errors

Bohoslavsky et al. PMB 2013

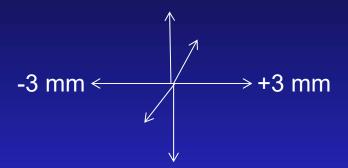

Robust vs probabistic planning

Robust planning:

- Few error scenarios
- Worst case optimization
- No differentiation random/systematic errors

Probabilistic planning

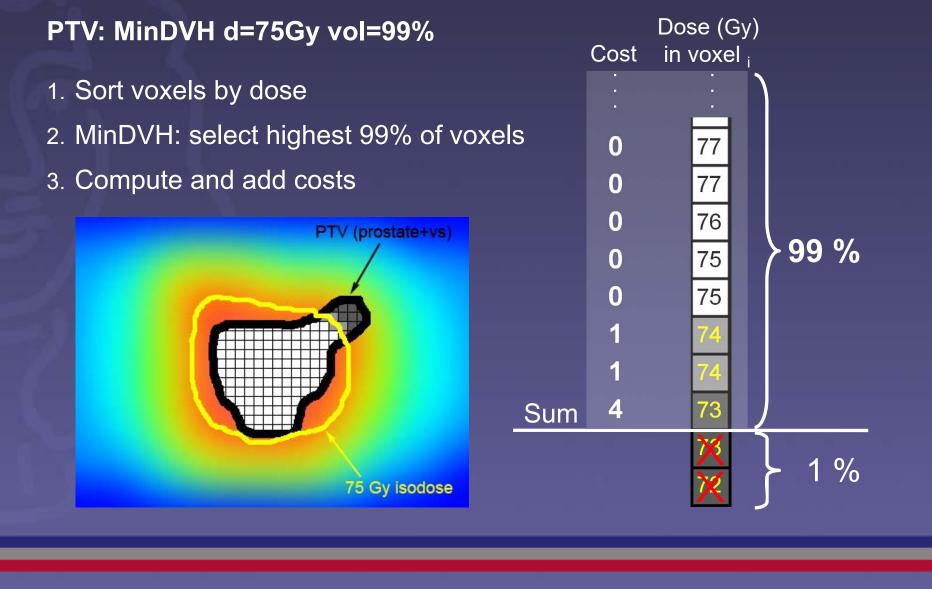

- Hundreds of error scenarios
- Include both random and systematic errors
- Optimize on probability

Regular planning objective functions

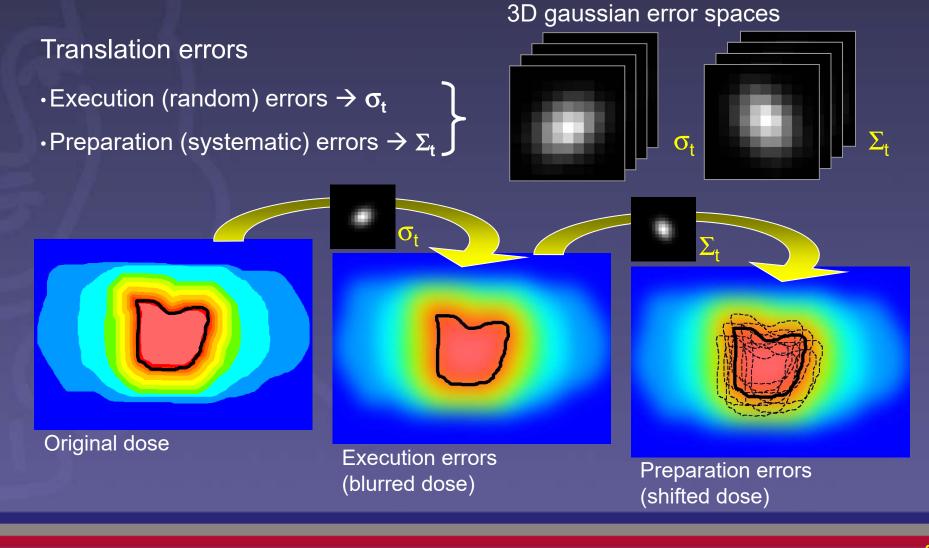

How DVH cost functions are calculated

Probabilistic form of exactly the same cost functions

Pinnacle 8.1v research version

Inclusion of uncertainties in plan optimization

Robust vs probabilistic optimization

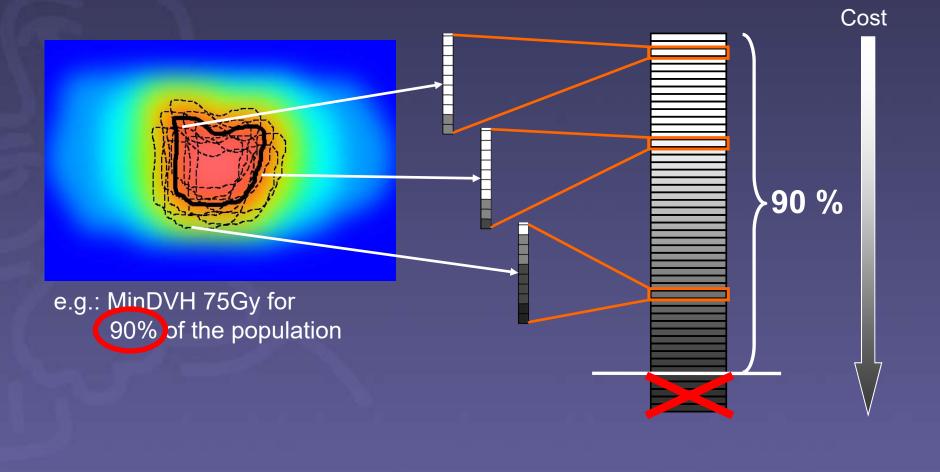

- Robust:
 - Typical 8-24 error scenarios

Commercial \rightarrow

- Weighted average of cost functions
- Do not separate random and systematic errors
- Probabilistic:
 - Hundreds of error scenarios
 - Optimize on probability of meeting constraint
 - Include random and systematic errors

Confidence level of objective functions

- 1. Systematic error simulations are sorted by cost
- 2. The best (lowest cost) cases are selected

Materials and Methods

Six prostate cases were replanned using probabilistic objective functions aiming for identical target coverage

All plans were evaluated using independent geometrical uncertainties simulation software (UNCERT) > 10.000 patients x 39 fractions simulated per plan

Uncertainty values (1SD): setup errors + organ motion

Translation errors (mm)	LR	AP	SI
Preparation (systematic) Σ_{k}	2.6	3.5	2.4
Execution (random) σ_k	2.0	3.0	2.4

Rigid and deformable registration

Marcel van Herk

on behalf of the imaging group

Institute of Cancer Sciences, University of Manchester / The Christie

> With slides from: Netherlands Cancer Institute Academic Medical Center

Image registration

- Find translation....deformation to align two 2D..4D data sets (2.. 100000+ degrees of freedom)
- Allows combination of scans on a point by point basis

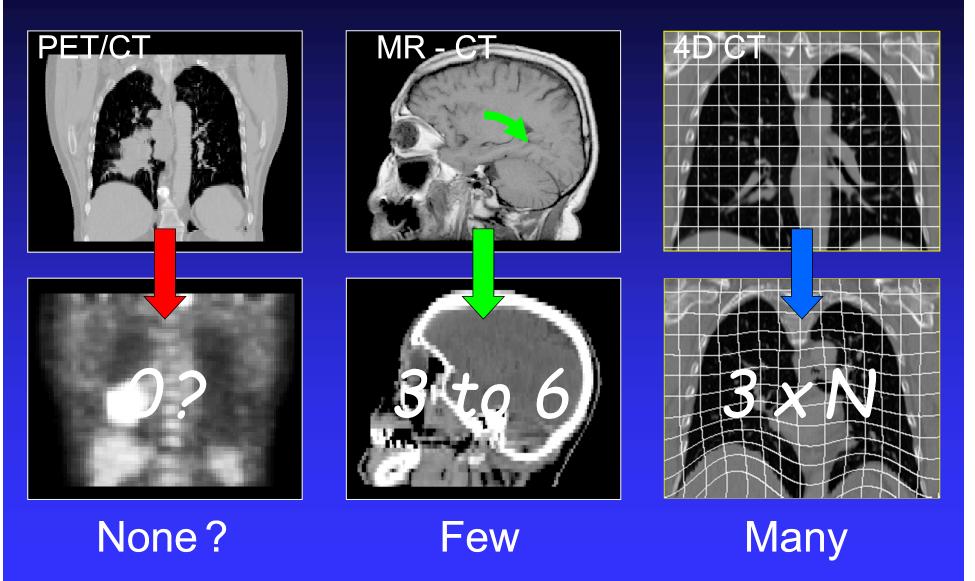

• Applications:

- Complementary data
- Motion tracking and compensation (imaging)
- Image guidance
- Adaptive radiotherapy
- Response monitoring
- Dose accumulation
- Data mining

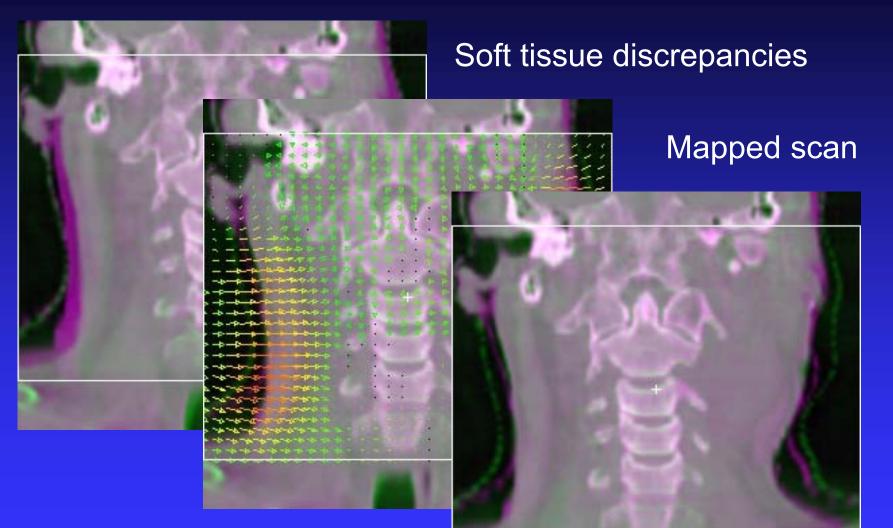

Marc Kessler / UM Degrees of Freedom

By enforcing smoothness the optimization becomes tractable

Demo rigid registration

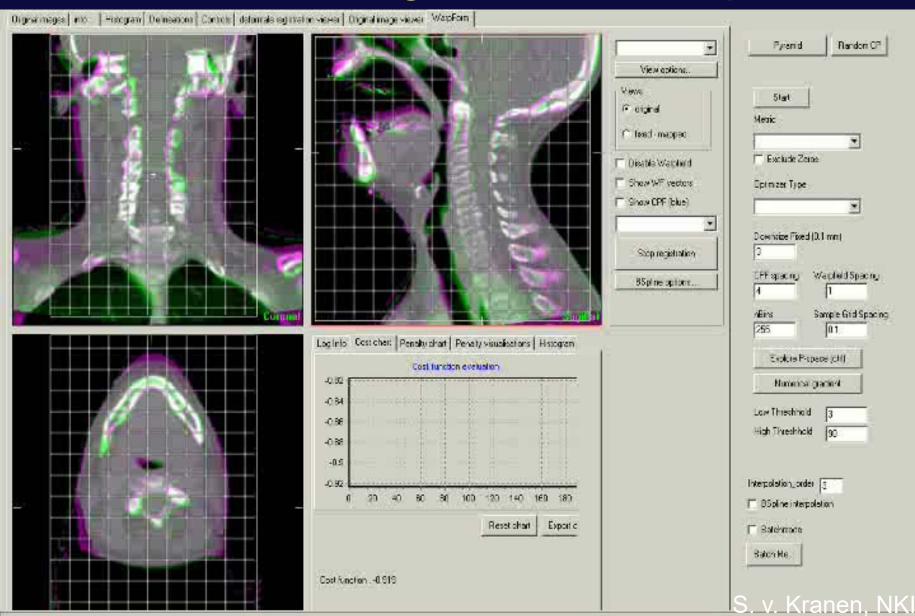

Deformation vector fields

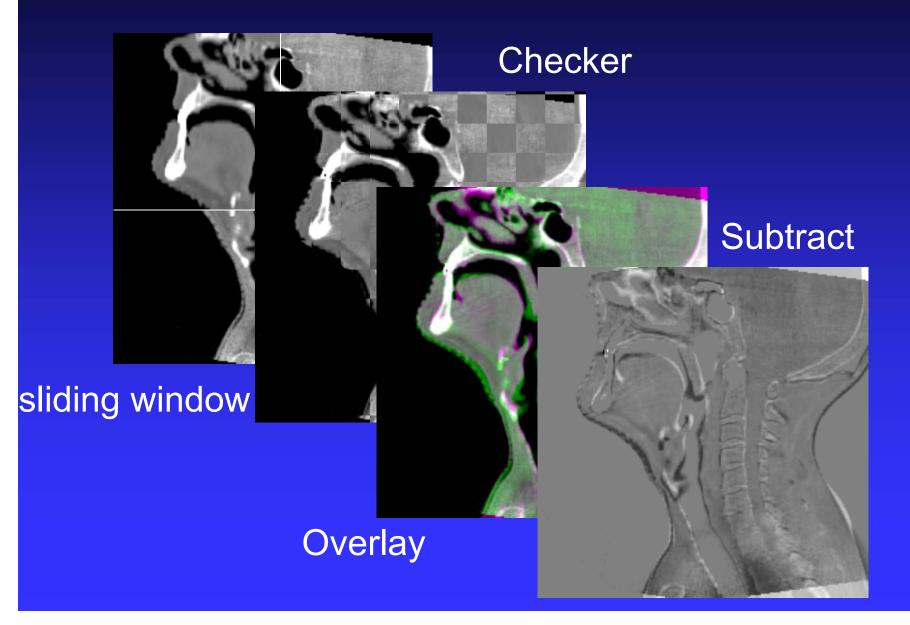

Vector Displacement Field 'Warp field'

S. v. Kranen, NKI

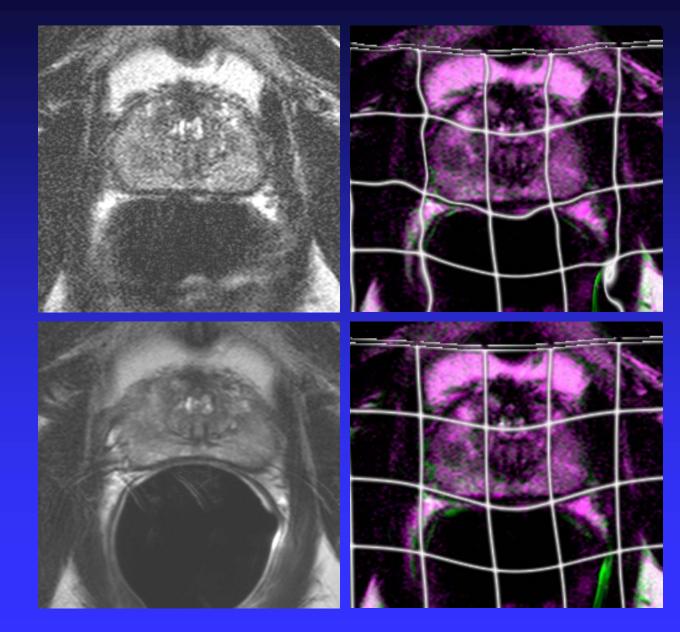

Deformable registration example

Visual verification

Prostate MRI w/wo Endo Rectal Coil

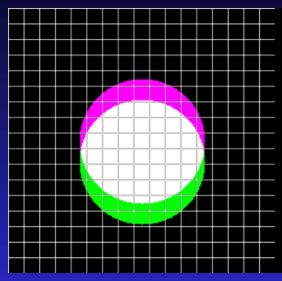

Large effect of parameters on deformable registration

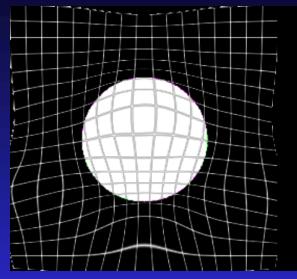

Both solutions are visually correct

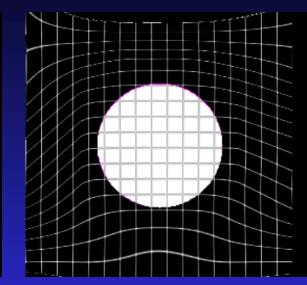

Which answer is right?

S van Kranen, C Kamerling, NKI

Deformable registration classes

Different DVF provide same visual registration result

- Descriptive: it must look good
 - e.g. contour propagation
- Quantitative: it must be an anatomically correct, also inside and at surface of homogeneous organ
 - e.g. dose accumulation

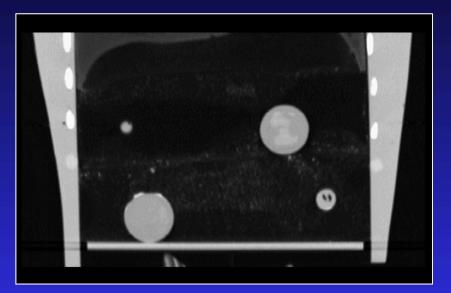

QA methods

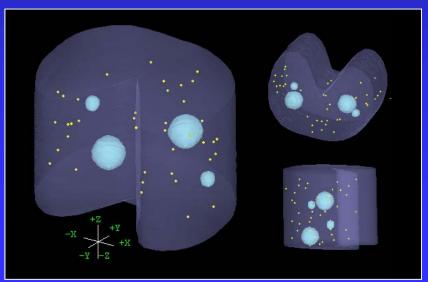

- The algorithm works technically
 - Use phantom or simulated data
- The program works in general
 - Best: use patients with implanted markers (data scarce)
 - Second: compare with human observers
- The program works for this patient
 - Visual verification
 - Consistency, plausibility

Registration of shrinking tumor ?

'elastic' Deformable registation OK

'erosion'
Deformable registration will fail
→ Potential under-dosage of
residual tumor

S. v. Kranen, JJ Sonke NKI

Overconfidence in commercial systems

091709-2 Mayyas *et al.*: Evaluation of prostate deformation and associated dosimetric implications

091709-2

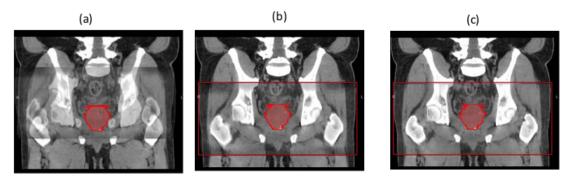

FIG. 1. An example of the registration process in the coronal plane. The rectangular box is the region of interest, which includes the entire CBCT. The contoured structure is the CTV. In (a), CBCT and Simon process in the coronal plane. The rectangular box is the registration fiducial markers. In (c), CBCT is deform Fiducial markers were used to evaluate the registration

Fiducial markers were used to evaluate the registration for each case. The error in the prostate alignment was defined as the average distance between the markers on CBCT and the corresponding SimCT datasets. Alignment error less than 2 mm was considered acceptable. Figure 2 illustrates the workflow with regard to image registration and data anal As shown, out of 200 CBCT-to-CT deformable registration 107 showed alignment agreement within 2 mm.

Conclusions

- QA of deformable image registration is complex
- Deformable image registrations is unsolved problem; algorithms lack biological and biomechanical knowledge
 - Sliding tissue
 - Tumor growth and regression
- This is OK to make pretty pictures and propagate OAR contours
- This is not OK for dose accumulation: it is unsafe to estimate you know where previous dose went
- This is **not OK** for adaptation around 'shrinking' tumors
- I therefore strongly suggest no to optimize dose on top of 'accumulated' dose

Thank you for your attention!

Pareto front analysis in clinical practice: what is it, and what is the gain?

Advanced Treatment Planning Course 3-7 September 2017 – Barcelona, Spain

Markus Stock

Content

- Background: '*planning problem*' in terms of trade off
- *Sweeping* the dose
- Pareto front versus Pareto surface
- Exploring the 'planning problem': Pareto navigation tools
- Published Pareto navigation tools

What is the pareto principle

- The **Pareto principle** (also known as the **80–20 rule**) states that, for many events, roughly 80% of the effects come from 20% of the causes.
- named after Italian economist Vilfredo Pareto showed that approximately 80% of the land in Italy was owned by 20% of the population; Pareto developed the principle by observing that 20% of the peapods in his garden contained 80% of the peas
- Microsoft noted that by fixing the top 20% of the most-reported bugs, 80% of the related errors and crashes in a given system would be eliminated
- Pareto optimality state of allocation of resources in which it is impossible to make any one individual better without making at least one individual worse.

'Planning problem': trade off coverage / sparing

In every treatment plan:

- conflicting OARs how to prioritize / weight them ?
- -dose fall off

Ultimate goal of treatment plan:

- 'optimal' dose coverage
- optimal sparing: as low as possible

Planning problem in manual planning

- It's difficult to make a good estimation of what is achievable in solving the planning problem
- when manually optimizing IMRT plans, one is never sure about the exact quality of the final plan How far away from the 'best' plan,
- and what is defined as the best plan?

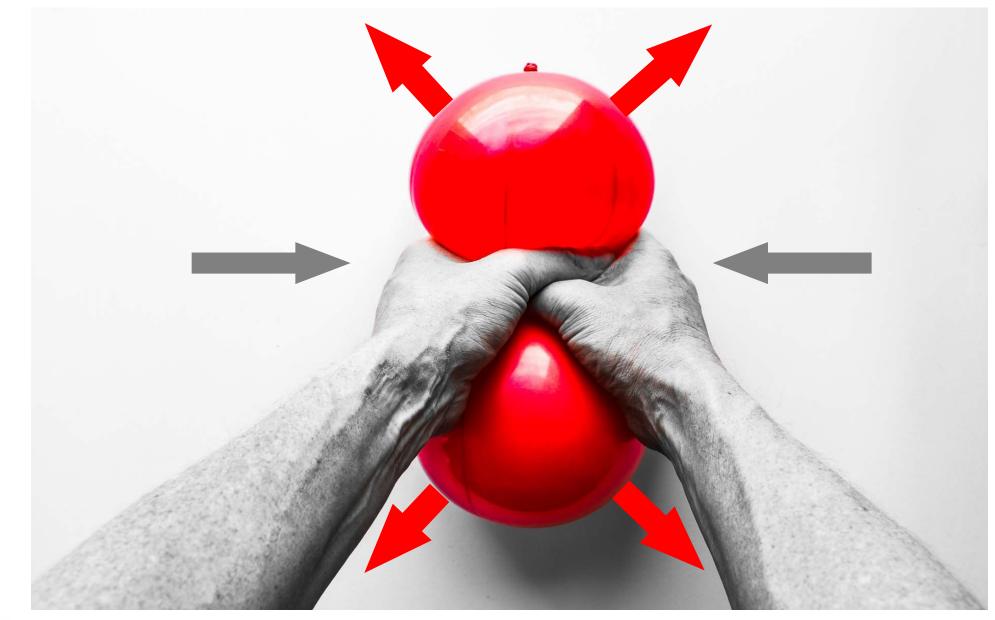

Sweeping dose

- Applying IMRT is nothing more than sweeping dose away from places you put constraints on
- So your IMRT prescription is nothing more than a
- In which you tell the optimizer what to spare

Sweeping the dose : dose *shaping*

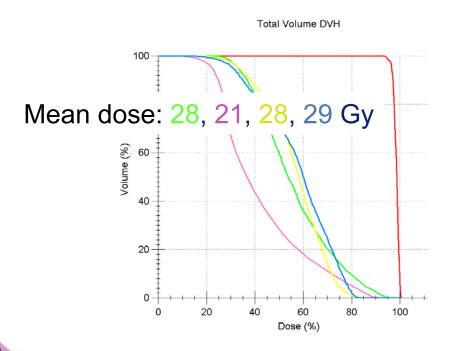

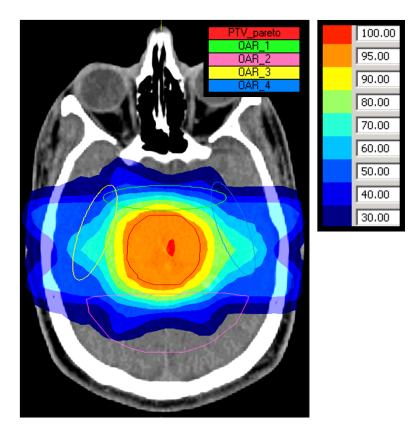

Prescription: PTV = 50 Gy OAR1-4 = minimize mean dose

Option 1: Conformal dose around PTV, no constraints on individual OAR's

'Completely random' shape of dose distribution in surrounding OAR's

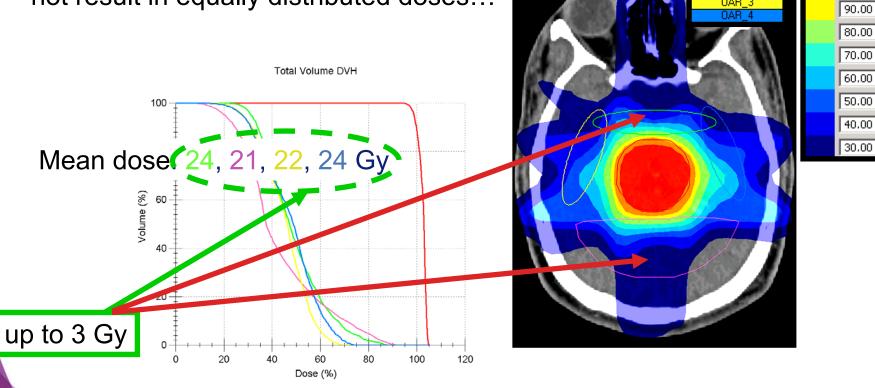

Option 2: Conformal dose around PTV, equally weighted constraints on all OAR's (mean dose = 25 Gy)

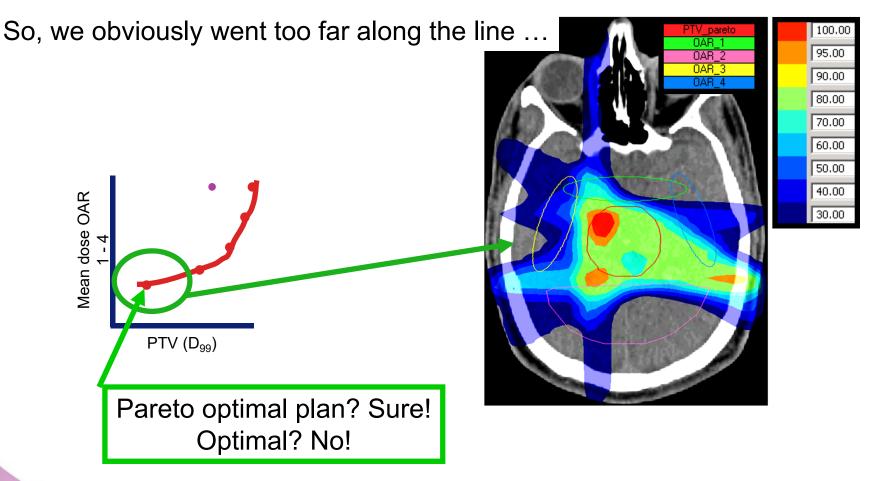

Equally weighted in terms of input, does not result in equally distributed doses...

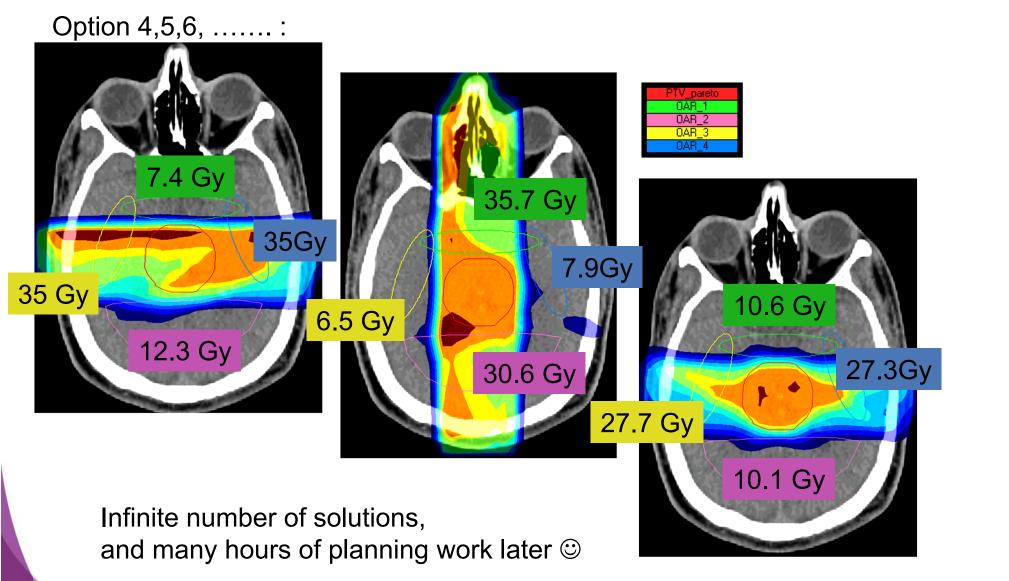

100.00 95.00

Option 3: Conformal dose around PTV, equally weighted constraints on all OAR's (mean dose = 20 Gy)

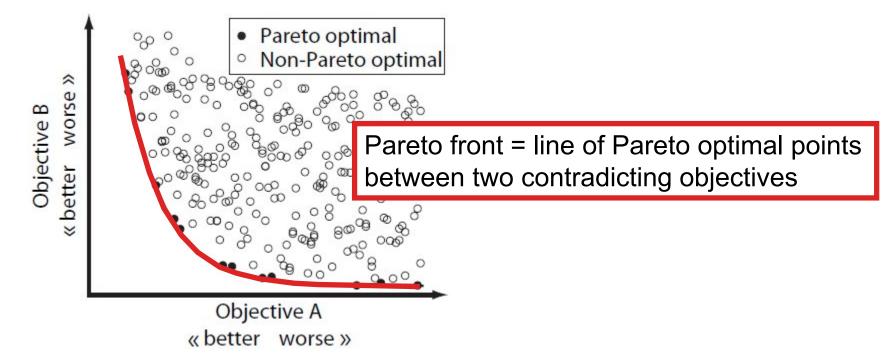

Sweeping dose theoretical example, many options ...

Pareto front

R. O. Ottosson et al.

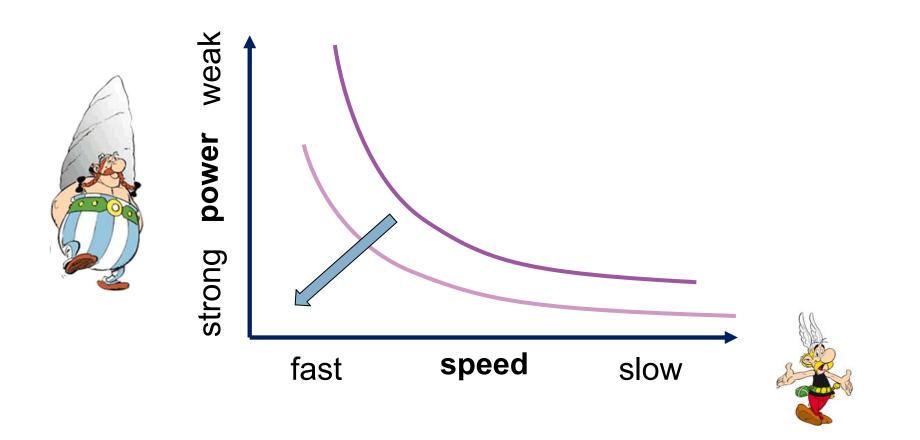

For two mutually contradicting objectives an endless number of solution exists

The solutions where one of the objectives can not be improved without deteriorating the other are <u>*Pareto optimal*</u>

All Pareto optimal solutions lie on the Pareto front

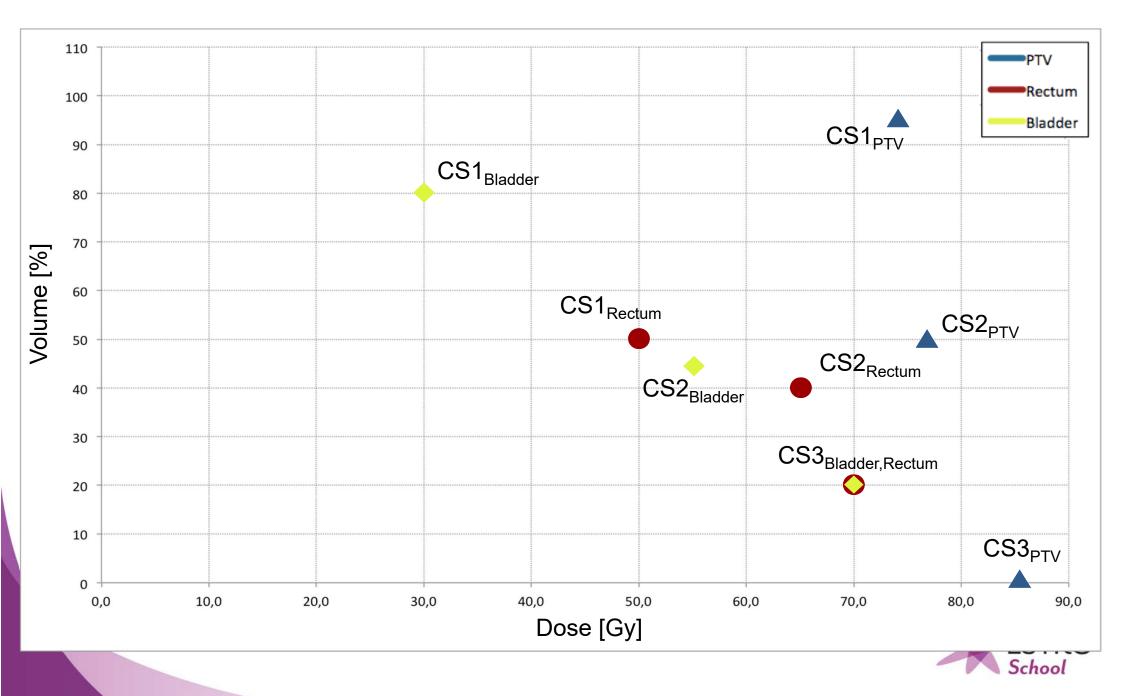

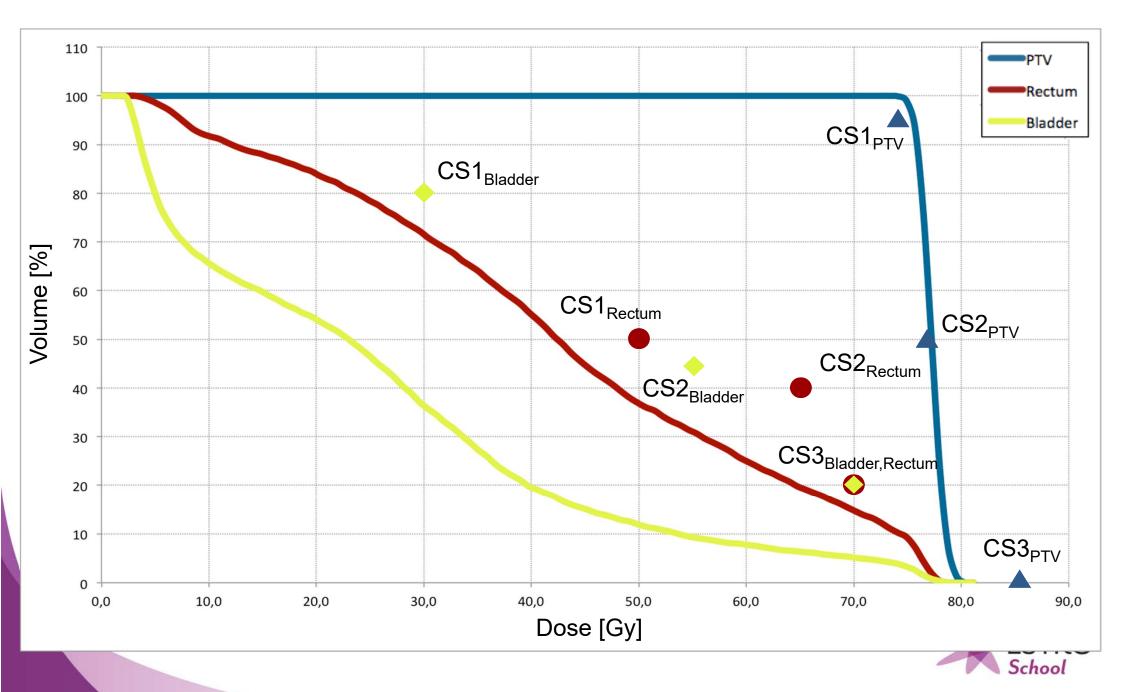

Mnemonic for Pareto front

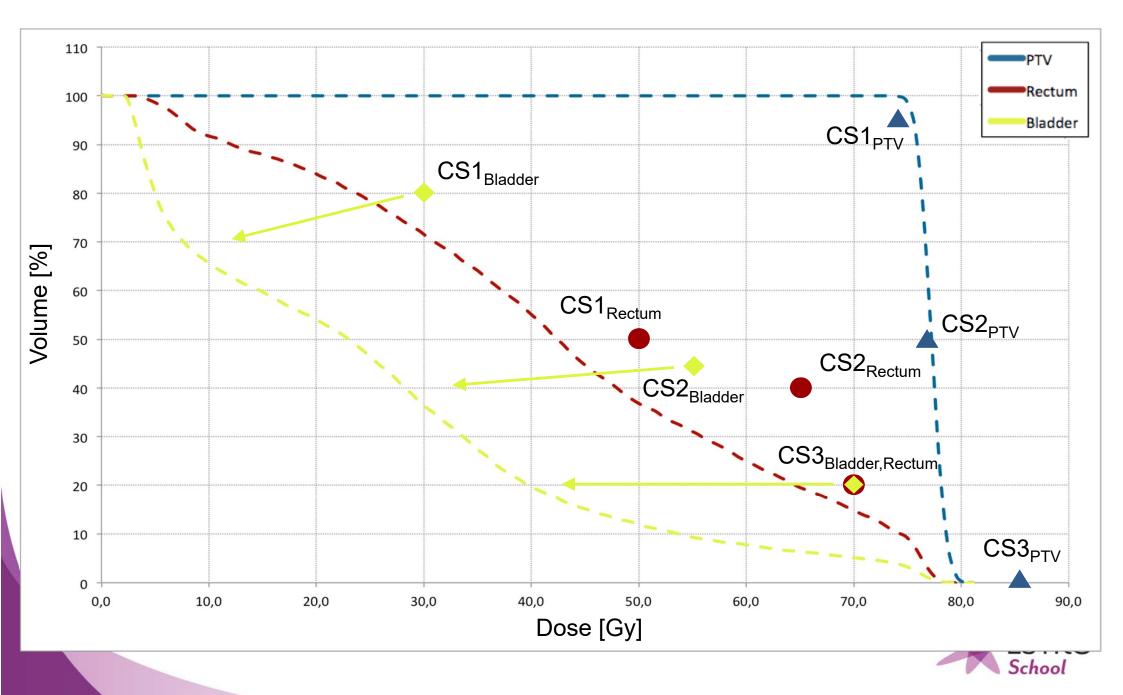

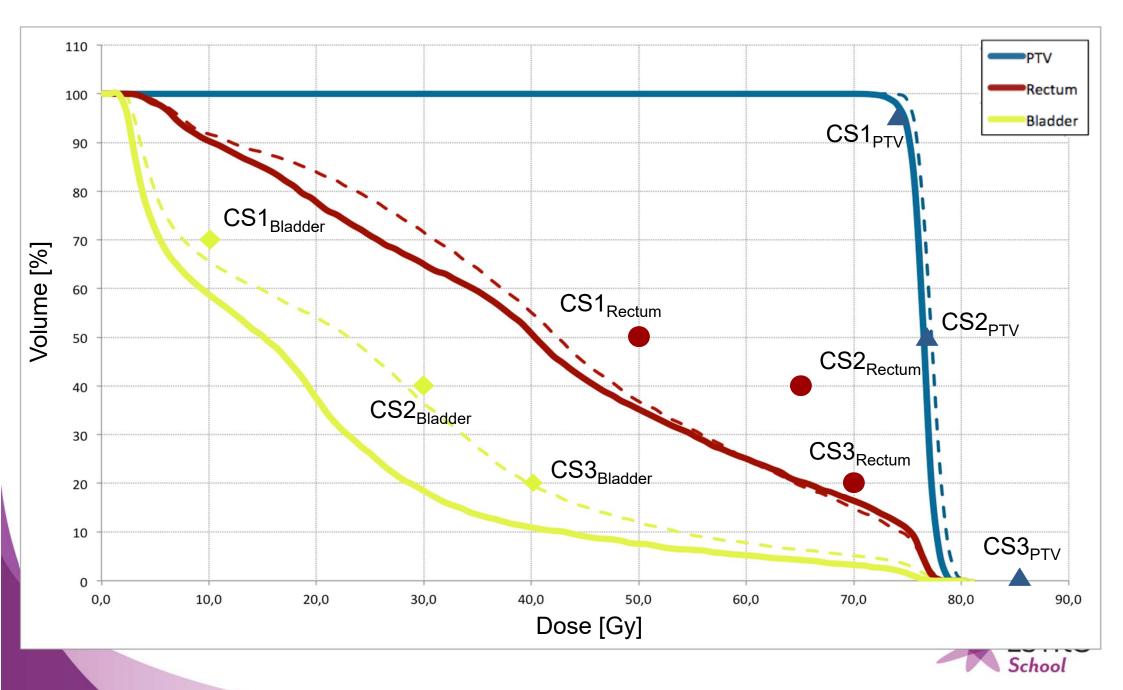

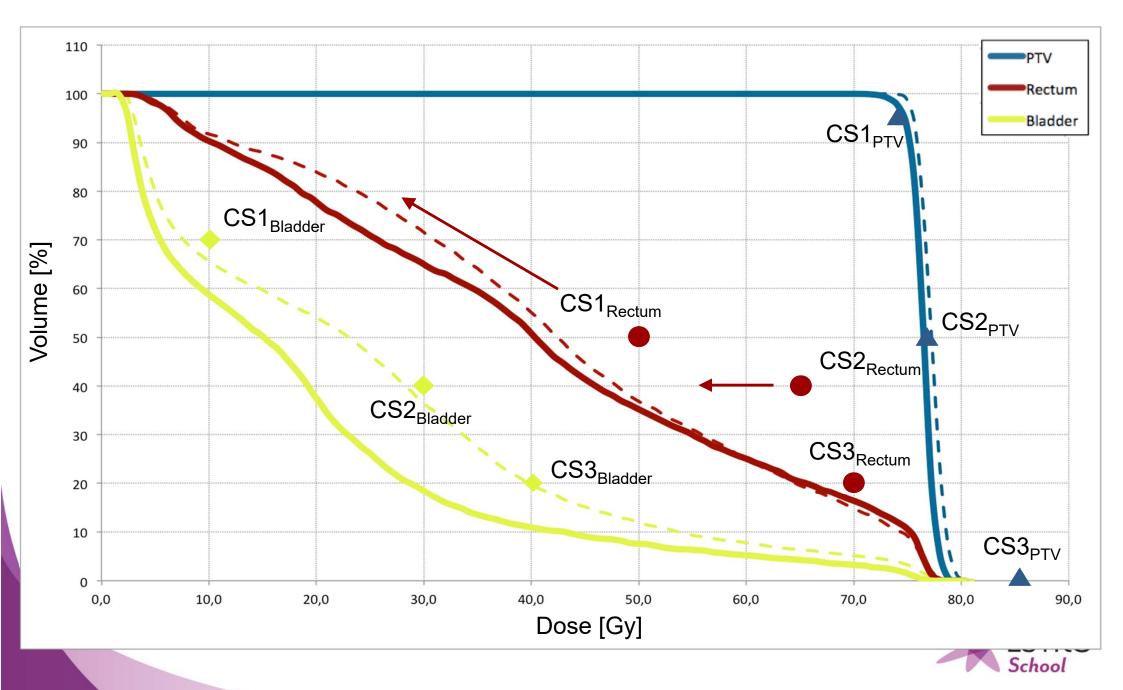

The "manual" way to get there

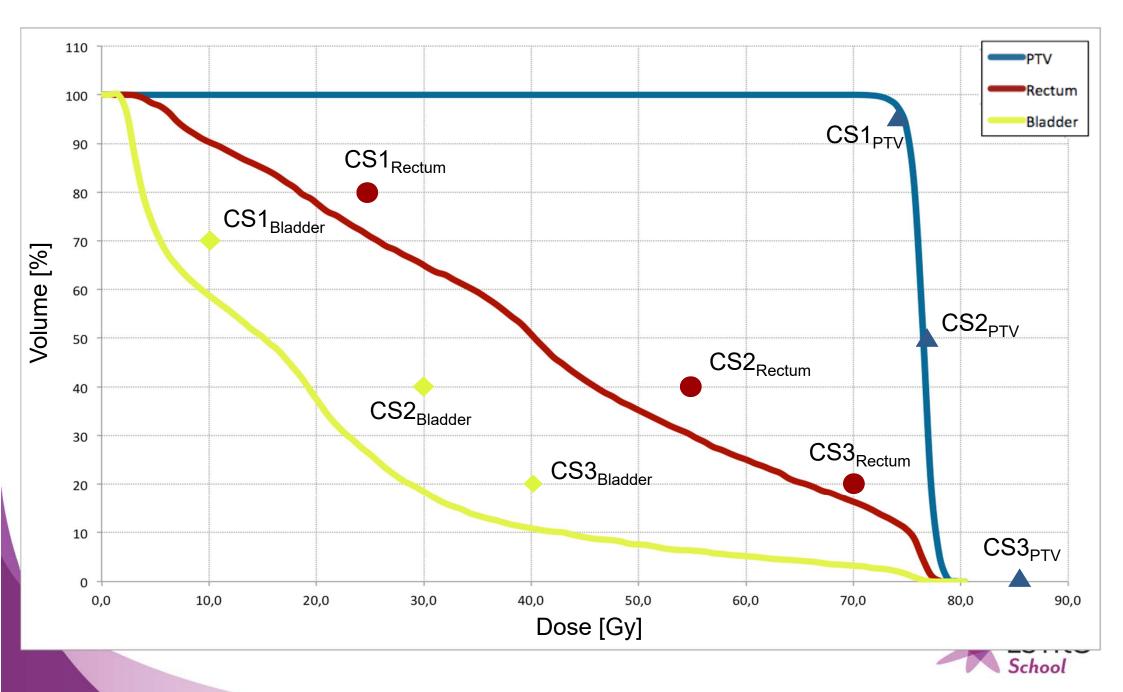

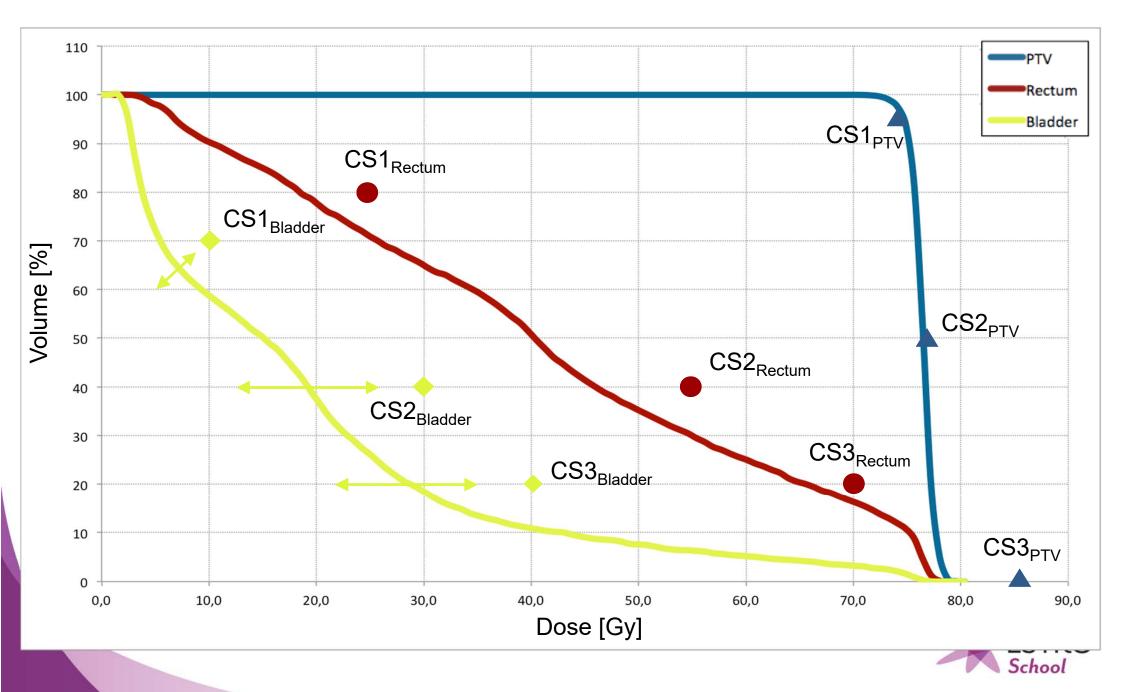

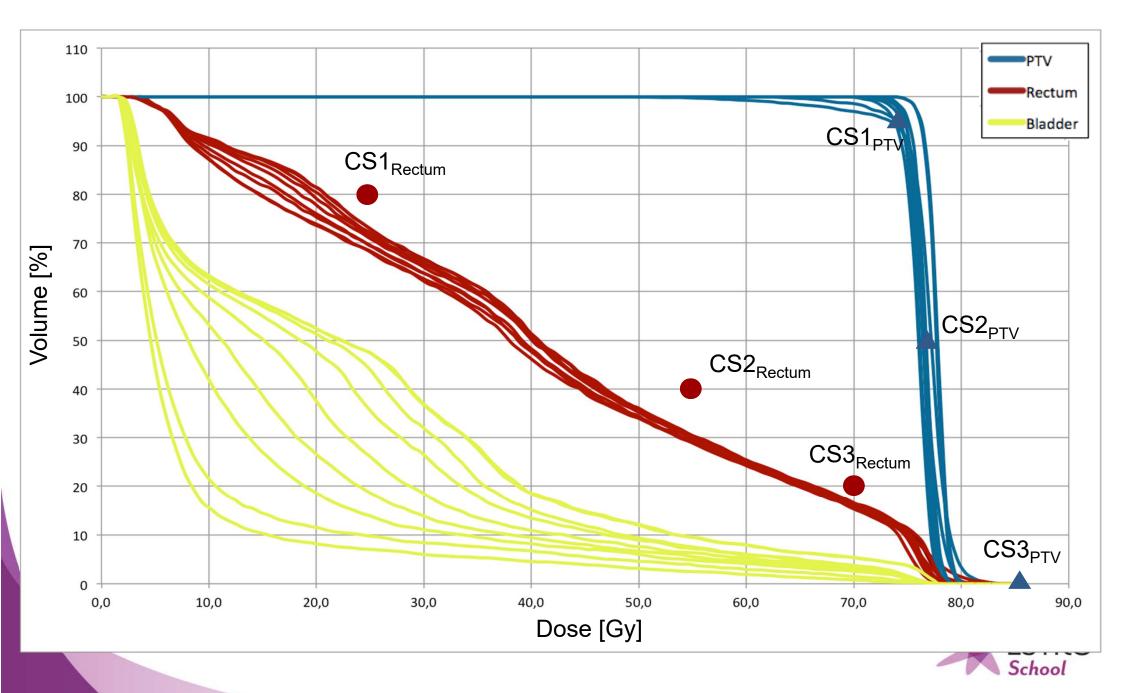

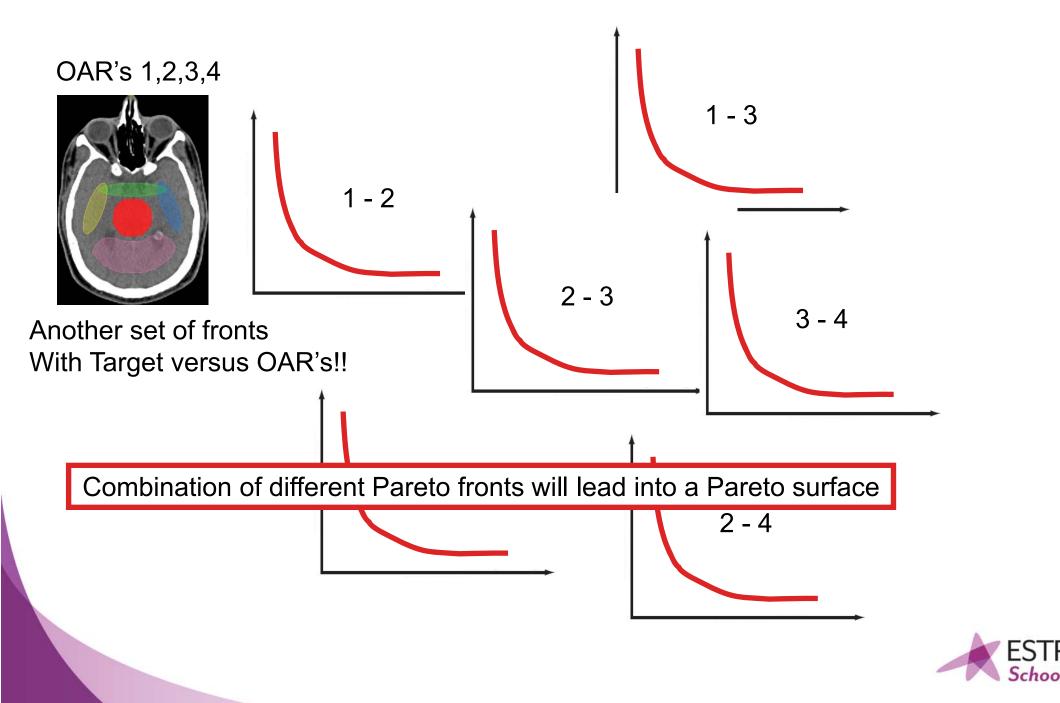

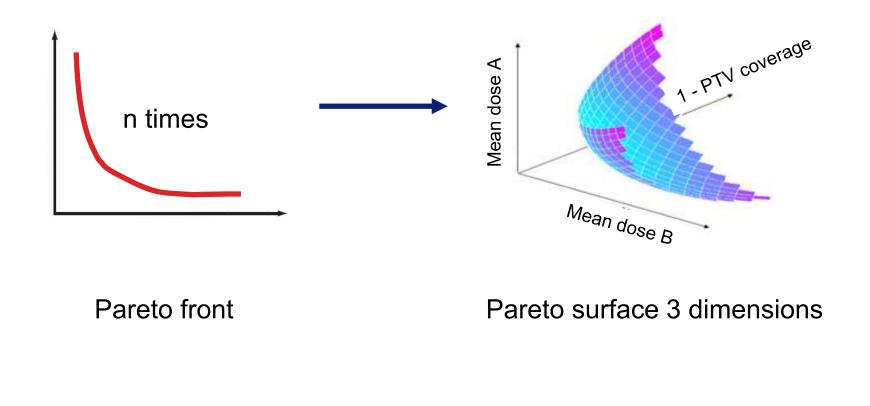

Pareto front versus Pareto surface

Pareto front versus Pareto surface

Pareto surface is a multi dimensional non linear 'landscape' of Pareto optimal solutions

We need tools to *visualize* the landscape and *navigate*

Pareto front navigation in multi-criteria optimization?

To be able to navigate through the landscape we need <u>library of plans</u> "as fine as possible" resolution of the landscape (= <u>many</u> plans)

All 'corner' plans should be part of the library with enough data points along the Pareto surface (so among all individual Pareto fronts), so that any interpolated plan should be as close as possible to an already calculated plan

Pareto front navigation works fine for fluence optimization as long as the landscape is defined with enough detail

Plan library 'around' a class solution

Radiotherapy and Oncology 97 (2010) 561-566

Quality assurance

A practical approach to assess clinical planning tradeoffs in the design of individualized IMRT treatment plans

René Monshouwer*, Aswin L. Hoffmann, Martina Kunze-Busch, Johan Bussink, Johannes H.A.M. Kaanders, Henk Huizenga

Department of Radiation Oncology, Radboud University Nijmegen Medical Centre, The Netherlands

The starting point for building the library of plans was the plan of the initial IMRT class solution. Subsequently, the IMRT parameters (weights and dose levels) of all objective functions, including the PTV, were kept constant and only parameters of the objective functions of the lungs and the oesophagus were varied. The range in which the parameters were varied was chosen such that a broad, but clinically relevant range of IMRT plans was generated.

Class solution = 6 beam configuration divided among ipsi-lateral side

Plan library 'around' a class solution

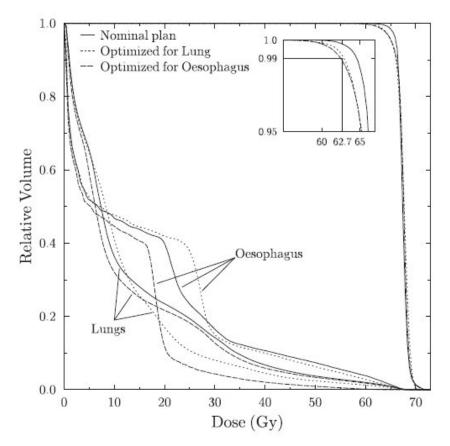

Fig. 1. DVH curves for three different IMRT plans of the same patient (see legend). For the plan optimized for lung sparing, the weight of the lung objective was increased from 1 to 50. For the plan optimized for oesophagus sparing, the dose level of the oesophagus objective function was lowered from 42 to 18 Gy (see text). The inset shows the DVH enlarged around 62.7 Gy (95% of the prescribed dose).

'simple' navigation software, based on DVH's

Another approach to build a library of plans

Simultaneous navigation of multiple Pareto surfaces, with an application to multicriteria IMRT planning with multiple beam angle configurations

David Craft^{a)} Department of Radiation Oncology, Massachusetts General Hospital, Boston, Massachusetts 02114

Michael Monz Department of Optimization, Fraunhofer Institute for Industrial Mathematics, Fraunhofer Platz 1, 67663 Kaiserslautern, Germany

(Received 11 September 2009; revised 19 December 2009; accepted for publication 22 December 2009; published 22 January 2010)

Purpose: To introduce a method to simultaneously explore a collection of Pareto surfaces. The method will allow radiotherapy treatment planners to interactively explore treatment plans for different beam angle configurations as well as different treatment modalities.

2010 American Association of Physicists in Medicine. [DOI: 10.1118/1.3292636]

'Pareto front navigation-tools' of RaySearch TPS: Based on the work of the groups from Boston and Kaiserslautern

Another approach to build a library of plans

<u>A database of plans is</u> automatically generated

- First *n*+1 points calculated on the individual Pareto fronts are the 'anchor-plans' : the best you can do in each objective individually
- The user navigates across the Pareto surface by increasing or decreasing the allowed limits of the objectives
- Beam angle configurations (no optimization!):
 - different beam configurations have different Pareto surfaces
 - based on current point and distance to an other Pareto surface (beam configuration), navigation is switched to the new surface.

How to build a library of plans?

Radiotherapy and Oncology 85 (2007) 292–298 www.thegreenjournal.com

Treatment planning

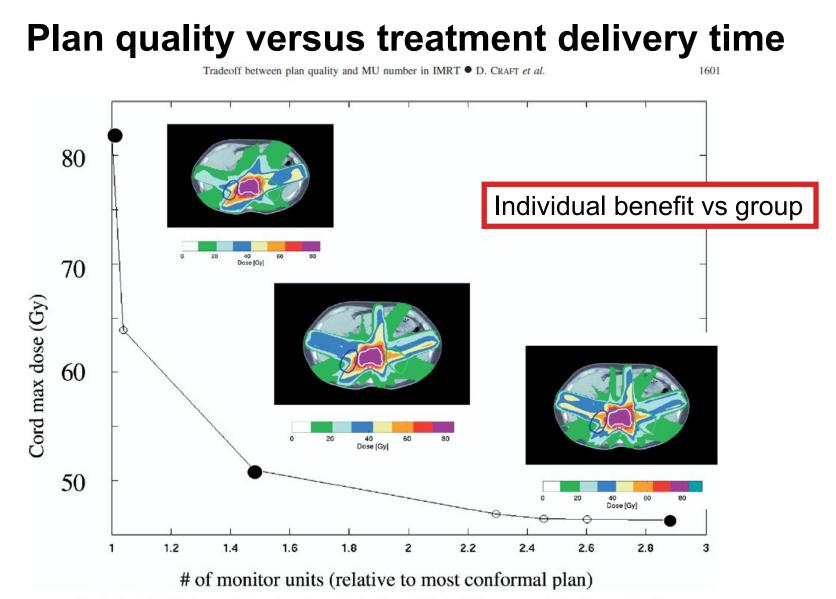

Fig. 3. The tradeoff between spinal cord sparing and intensity-modulated radiotherapy complexity. Dose contours for three points on the Pareto surface show that added complexity is needed to avoid the spinal cord. The clinical target volume is contoured in white.

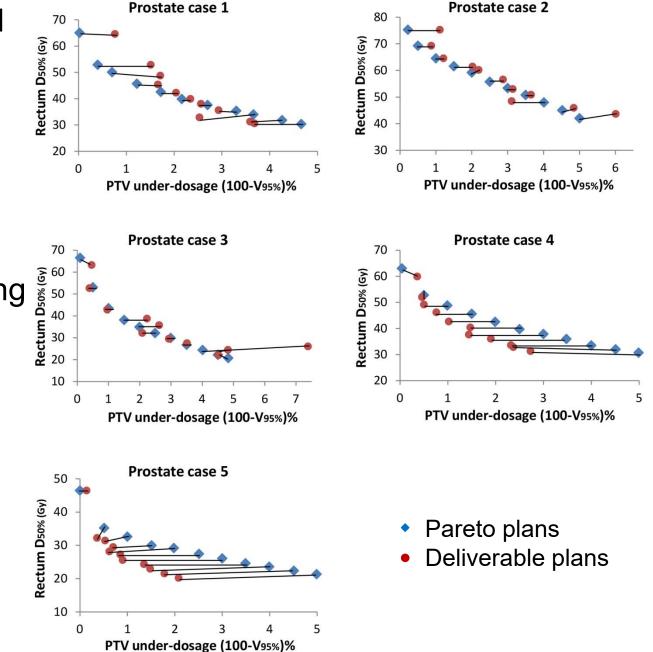

Limitations of this approach

Difference between navigated and delivered plans?

e.g. 5 prostate patients

improvement was achieved partly by compromising other parameters, such as increasing doses to other OARs or by creating small "hotspots"

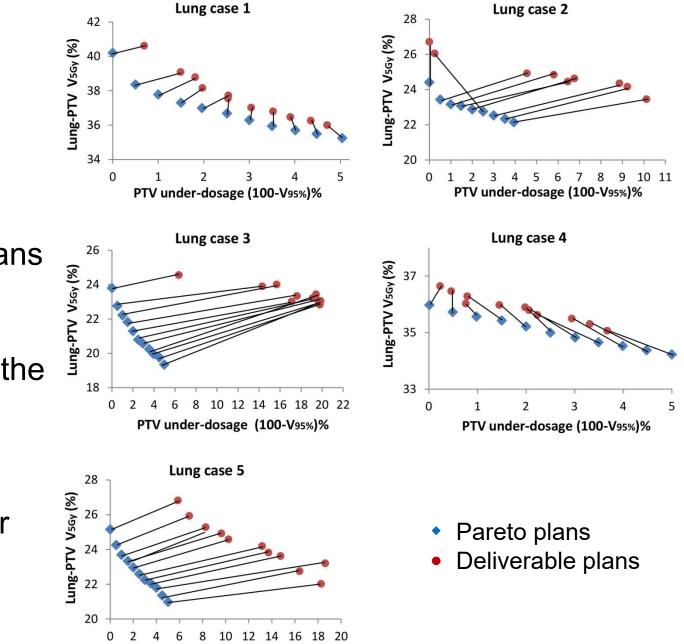

Limitations of this approach

e.g. 5 lung patients

Deliverable plans systematically worse than pareto plans

fluence-based treatment plans does not take into account the effect of lateral electron transport in the presence of heterogeneities

Small PTVs provided bigger differences

PTV under-dosage (100-V95%)%

Conclusion

Finding the 'best' plan is a real challenge

Treatment delivery time should be part of Pareto navigation

Pareto navigation tools are very helpful in exploring the solution area, however, navigation should be done in a sensitive way

Keep track of the end result of each navigation to improve the standard input

Lack of systematic differences between navigated and deliverable plans makes it difficult to predict the dosimetric change, its direction and its magnitude.

ATP Barcelona 2017

Summary

- Small dose differences make a difference (clinically)
 - ➤ (MR linac)
 - (Proton Beam Therapy)
- Keep talking dialogue = 2 way conversation
- Multi-criteria optimisation (MCO) improved individualisation
- More data needed on normal tissue toxicity dose response
- Dose accumulation VoxTox
 - Needs automatic OAR segmentation & other computing
- Biological variation in normal tissue sensitivity
 - Could we convolve a *biological* measure of individual normal tissue radiosensitivity with the *physical* dose plan

Use the best tools for the job !

• "If you want to treat a complex shape ... like this shell ... then you need IMRT"

Jason and Lucy discussing RT techniques ...

Use the best tools for the job !

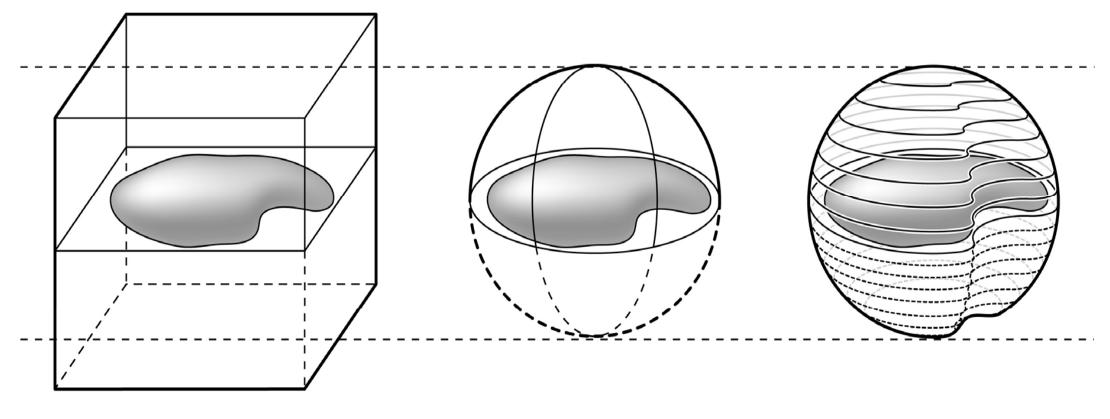

• "If you want to treat a complex shape ... like this shell ... then you need IMRT"

Jason and Lucy discussing RT techniques ...

• And for really good IMRT you also need image guidance

Conventional 'square' plan 3D CRT plan

IMRT plan

• Imaginative use of different beam and arc directions can sometimes improve IMRT plans

• Imaginative use of different beam and arc directions can sometimes improve IMRT plans

• The Mohawk arc !

- Use of IMRT does not guarantee accuracy
- Need image guidance with rational PTV margins

- Use of IMRT does not guarantee accuracy
- Need image guidance with rational PTV margins

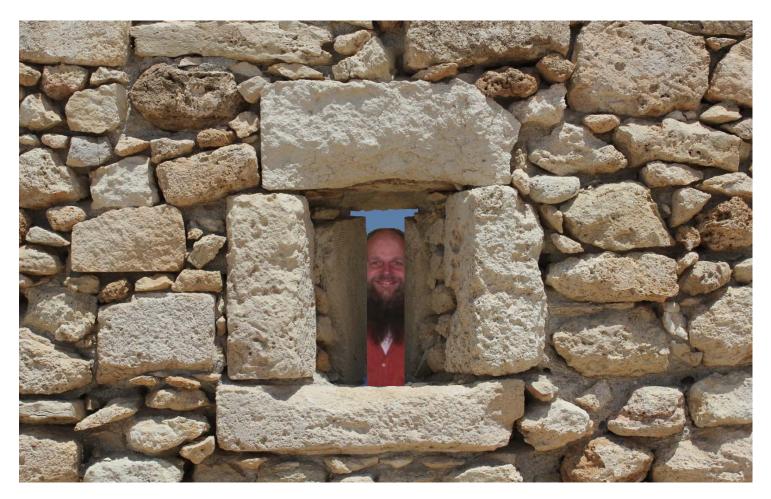

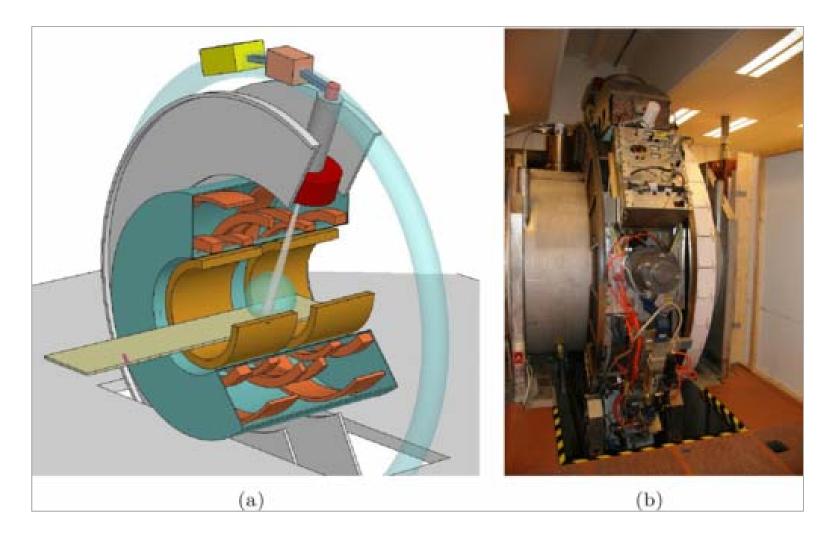

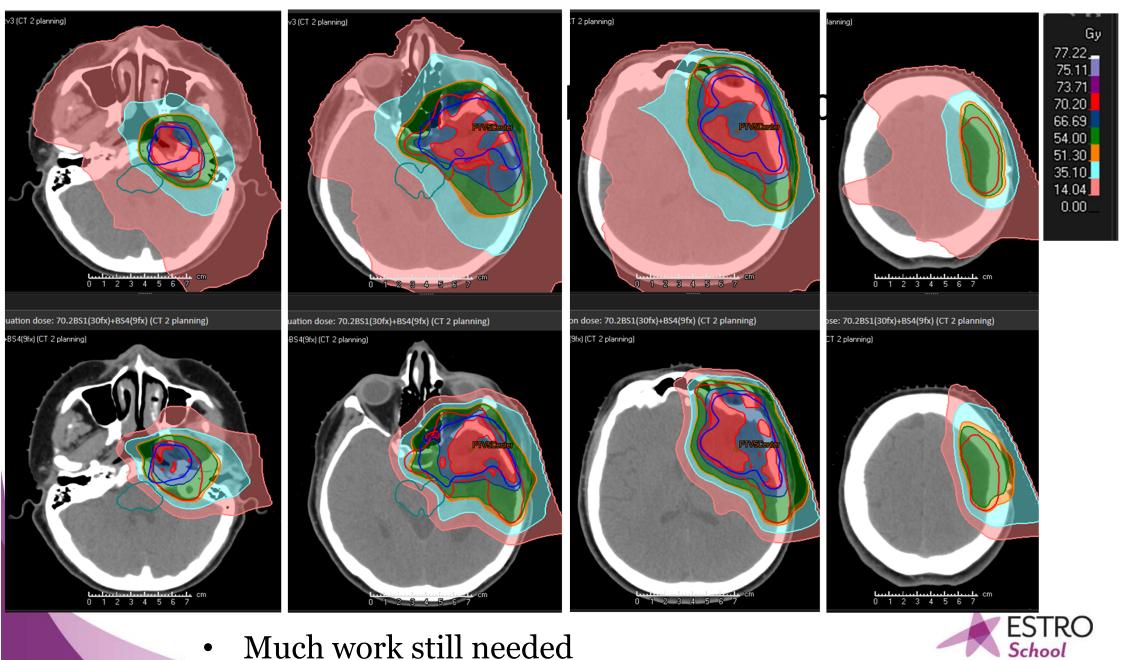

Image guidance - MR linac

Crijns S, Raaymakers B. From static to dynamic 1.5T MRI-linac prototype: impact of gantry position related magnetic field variation on image fidelity. *Phys Med Biol.* 2014 Jul 7;59(13):3241-7

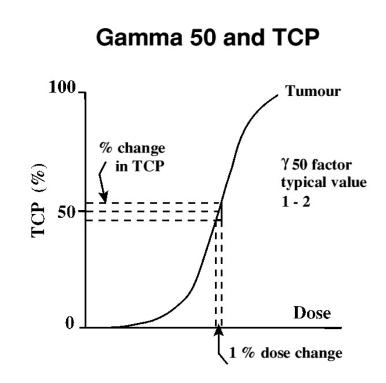

Proton Beam Therapy

Much work still needed •

Small dose differences matter

- Get the details right it's worth it!
- Dose response curves are steep
 - ➢ For tumour
 - ➢ For normal tissue
- A dose change of 5% can lead to a change in <u>TCP of 5 10%</u>
- Small differences are important
 - > To the individual patient
 - \succ To society

Marginal gains

- Small differences matter
- Application of the concept has been shown to be *very* successful in cycling

- The same applies to what we do ...
- Attention to details will benefit patients

Mike on his bike

Dialogue – a key component of happy planning

Dialogue – a key component of happy planning

- As work flows become busier and more tightly programmed, it is less easy to discuss cases
- Often difficult to set Objectives and Constraints perfectly
- Plan review meeting
 - provides review after completion of the plan
 - ➢ It does *not* facilitate discussion *during* its preparation
- Discussions like our course are always valuable

Dialogue – a key component of happy planning

• Talk to your colleagues ...

... and at least I always get an intelligent answer!

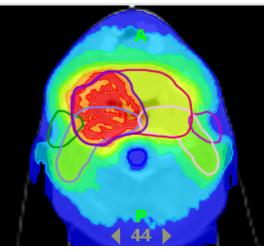

Multi-criteria optimisation (MCO)

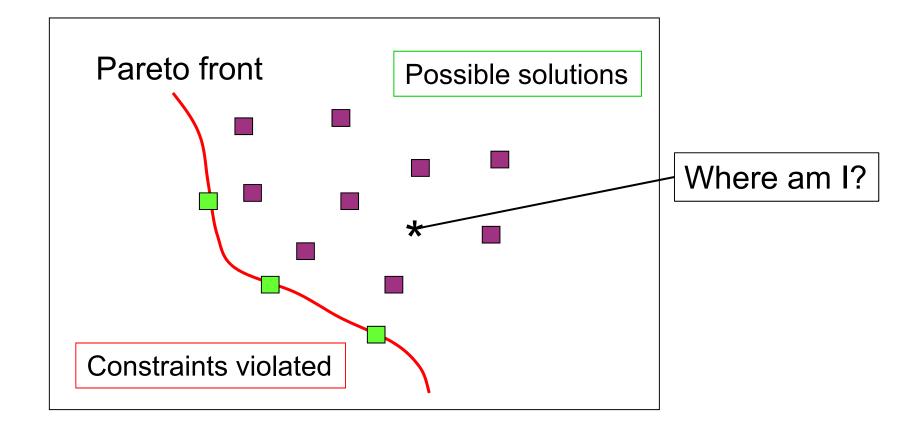

Multi-criteria optimisation (MCO)

- Multi-criteria (MCO) prospect of improved individualisation
- Pareto optimisation is basis for IMRT
- Normally have 1 plan from within solution space
- MCO allows real-time examination of solution space
- This might allow (small) improvements in dose plan for individual patients

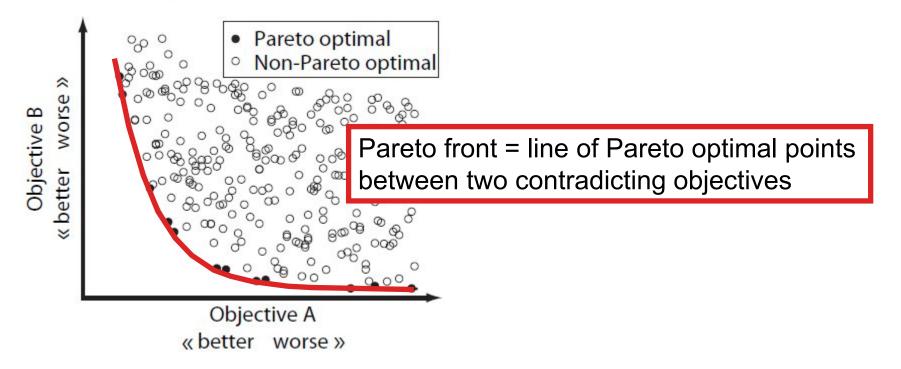

IMRT – Optimisation

Pareto front

R. O. Ottosson et al.

For two mutually contradicting objectives an endless number of solutions exists

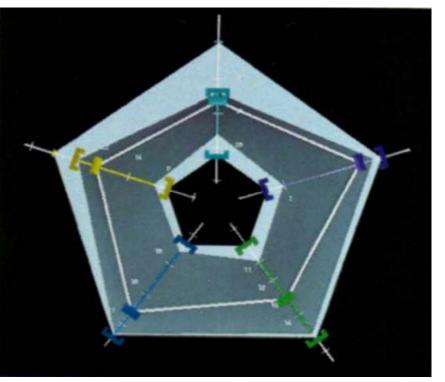

The solutions where one of the objectives can not be improved without deteriorating the other are *Pareto optimal*

All Pareto optimal solutions lie on the Pareto front

Multi-criteria optimisation (MCO)

- Developmental version of MCO system
 - Shows normal tissue structures
 - Bounded limits on dose within solution space
- Real-time exploration possible
- Commercial systems becoming available
- Full value not yet known

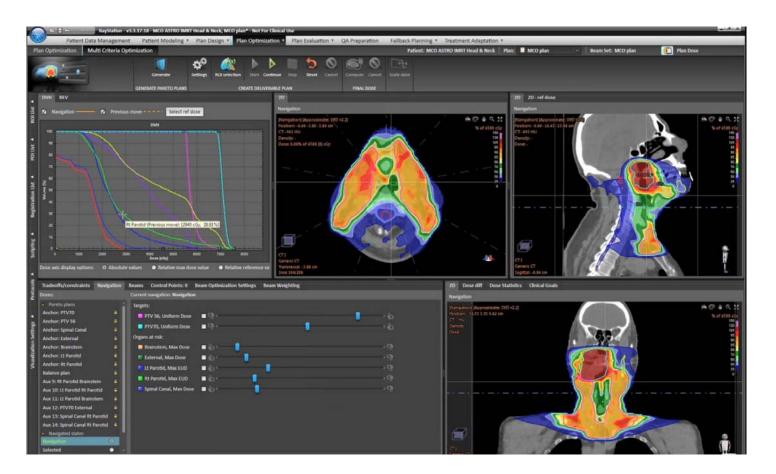

Courtesy of Fraunhofer Institute

Multi-criteria optimisation (MCO)

• Clinical MCO system from RaySearch

• Possibility to refine individualisation of the plan

- More data needed on normal tissue toxicity dose response
- The details of dose response are not known as well as we need
 - Variation in data is considerable
 - Many organs relatively unknown

• Spinal cord - need to avoid events which define tolerance threshold

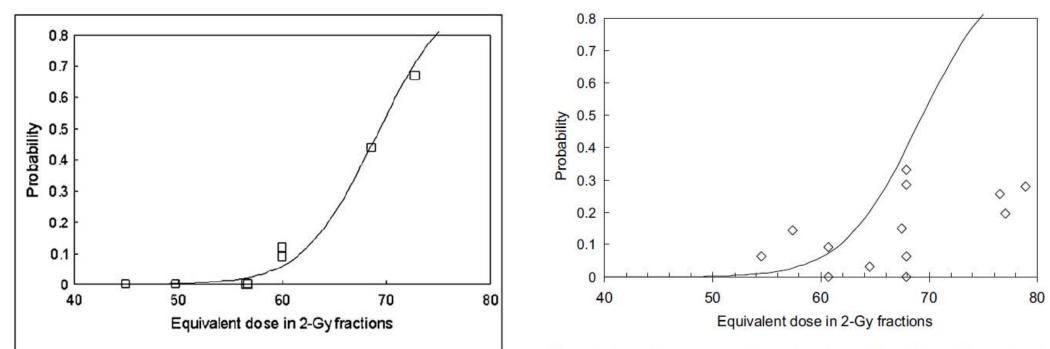

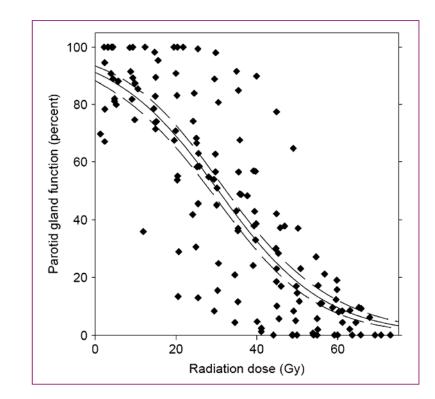

Fig. 1. The dose–response function for the myelopathy of the cervical spinal cord and data points (\Box) derived from Table 1. The probability of myelopathy was calculated from the data in Table 1, adjusted for estimated overall survival per (18).

Fig. 2. The dose–response function for myelopathy of the cervical cord (solid line) and data points for the thoracic spinal cord (\diamondsuit) derived from Table 2. The probability of myelopathy was calculated from the data in Tables 1 and 2, adjusted for estimated overall survival per (18).

QUANTEC - Kirkpatrick et al. IJROBP 2010; 76(3): S42-49 ESTRO

- More data needed on normal tissue toxicity dose response
- The details of dose response are not known as well as we need
 - Variation in data is considerable
 - Many organs relatively unknown

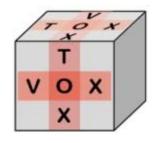

- Parotid dose-response
- Scatter ...

- Standard dose plans are a good approximation to delivered dose
- Dose differences of 10-15% can be detected (eg in trials)
- Further individualisation possible with measurement (estimate) of accumulated dose D_A
- Our research programme is trying to do just this
 - ➢ VoxTox − linking dose at the voxel level with toxicity
 - ➢ Consider rectal toxicity ...

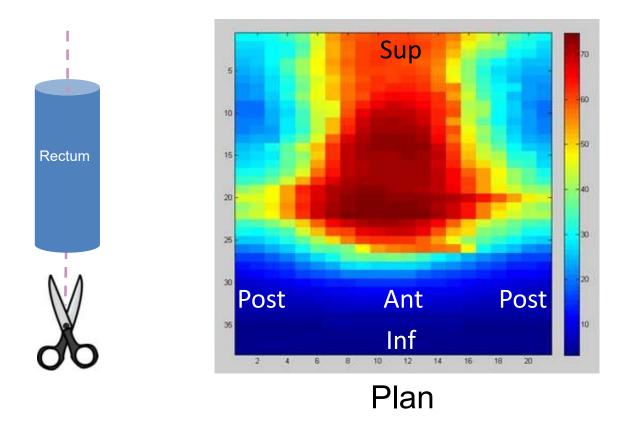

• Rectum dose-surface map (DSM) for prostate RT

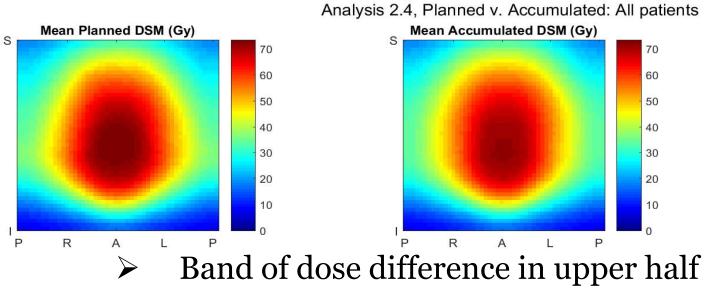

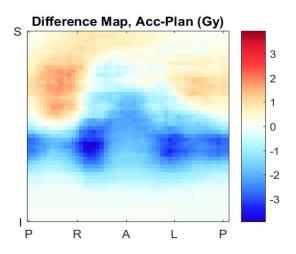

• Early stage only ...

Planned vs Accumulated dose

- Compare dose surface maps (DSMs) ullet
 - Planned dose vs Accumulated dose (D_A)

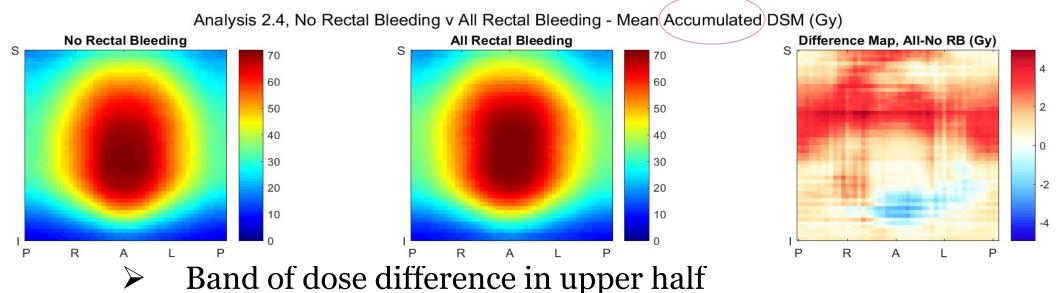

- Postero-lateral in rectal wall >

Accumulated dose DSMs

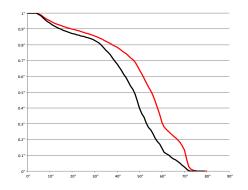

- Compare average D_A
 - > No rectal bleeding vs All rectal bleeding

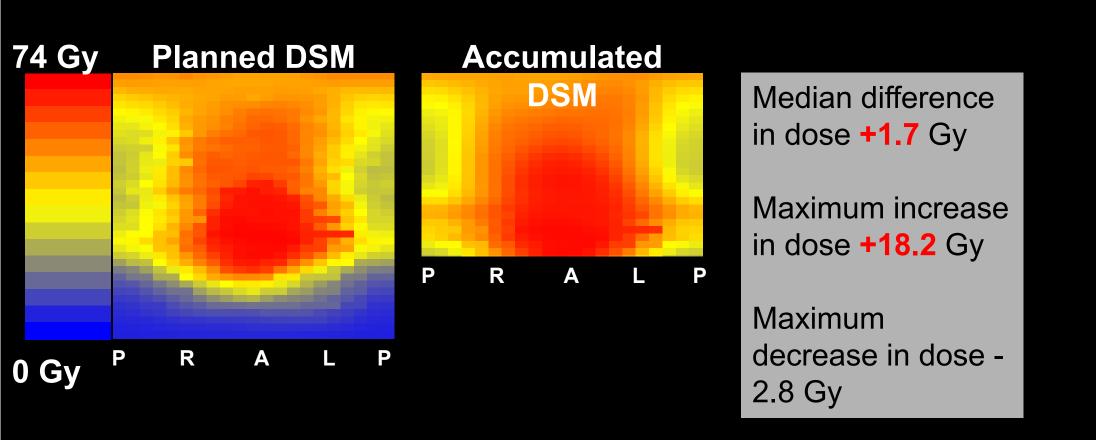

Includes lateral and posterior rectal wall

DSM for <u>highest</u> accumulated compared with planned

Dose accumulation

• Our VoxTox programme is investigating the hypothesis that accumulated dose D_A is a better predictor of toxicity than planned dose

• And we need some computational solutions too !

Dose accumulation

- Our VoxTox research programme is trying to quantify accumulated dose D_A
- There are 500,000 contours to draw
 - > Not possible for human!
 - Computational solutions needed
- Further computing developments will need to be incorporated into work flow

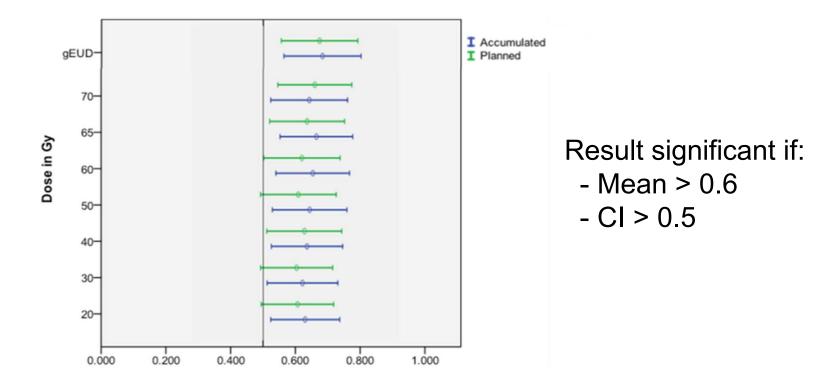

Dose accumulation

- Initial run of 109 prostate patients
 - Rectum auto-contoured on 4033 scans
 - \triangleright D_A recalculated on daily image guidance MV CT scans

VoxTox - results

Dose Surface Map analysis

- DSM D_A predictors mostly better than planned dose
 - \succ EUD accumulated dose (D_A) best predictors

ROC AUC for rectal bleeding (CTCAE Grade \geq 2)

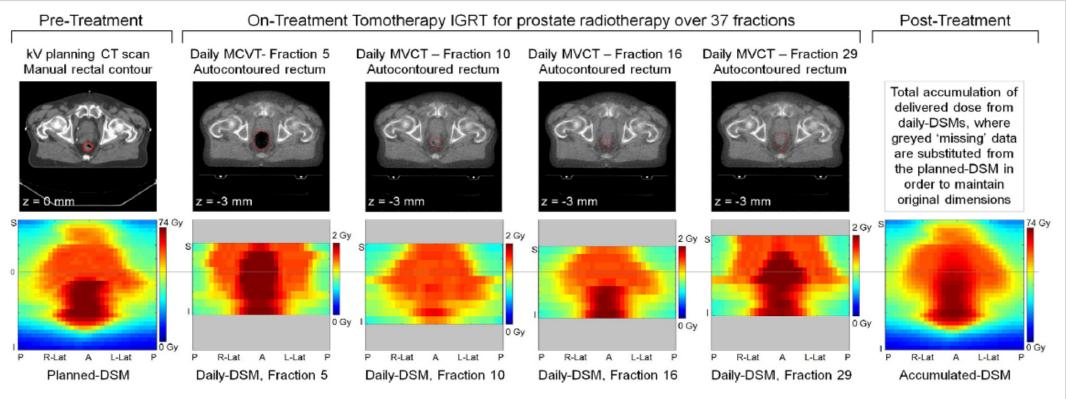

Fig. 1. Generation of planned, daily and accumulated dose surface maps.

• For rectal bleeding

Conclusions: Dosimetric parameters extracted from accumulated DSMs have demonstrated stronger correlations with rectal bleeding and proctitis than planned DSMs.

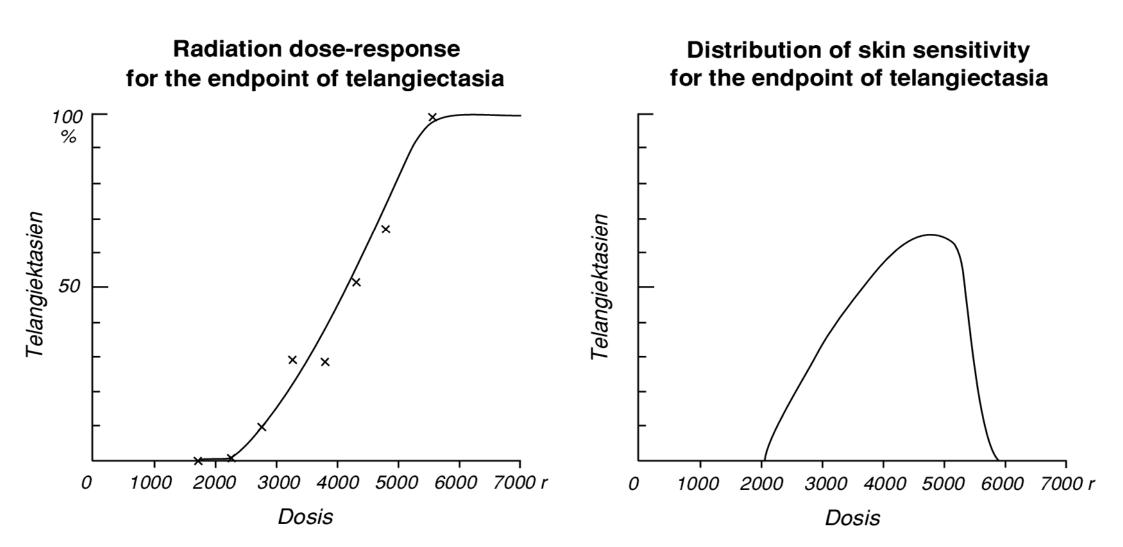

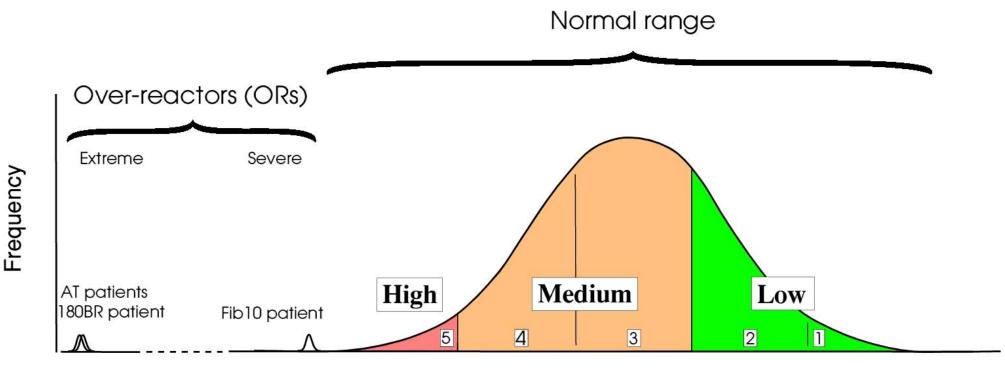

- First formally described in 1936 by Holthusen
 - > Original of the sigmoid dose response curve
- Matches clinical experience since

Holthusen - Strahlentherapie & Onkologie 1936

Idealised normal tissue response - relative scale

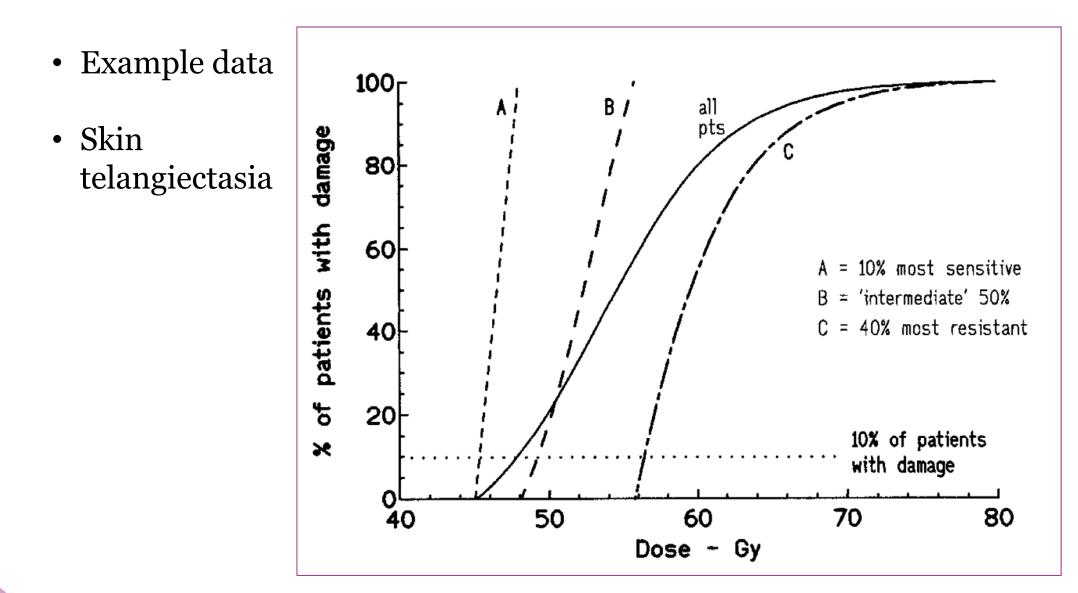

Relative normal tissue radiosensitivity

Resistant

- Sensitive

- Variation in response harder to observe with mega-voltage beams because of skin sparing
- Could be exploited:
 - To avoid toxicity in sensitive patients
 - $\leq 5\%$ of patients
 - > To dose escalate resistant patients
 - 40% of patients dose escalate up to ~15%
- Other methods to measure normal tissue response are needed, to produce more & better dose response data

• Data from Ingela Turesson, Göteborg

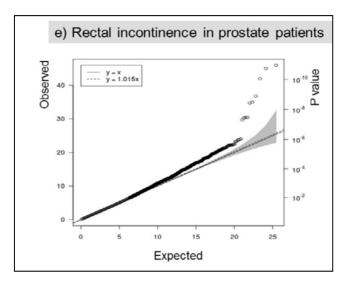

- Definite evidence that *normal* genetic variation is linked to variation in tissue response or toxicity
- Major developments in last 3 years
- Not yet ready for clinical application

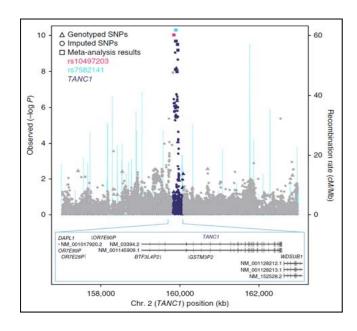

- Radiogenomics of normal tissue toxicity
- Definite evidence of true association between common genetic variants and toxicity¹

- GWAS in prostate cancer ²
- Variation at 1 locus linked to toxicity
- $P = 4.6 \times 10^{-11}$

- 1. Barnett GC et al. Radiother Oncol 2014; 111(2): 178-185
- 2. Fachal L et al. Nature Genetics 2014 Aug; 46(8): 891-4

Radiotherapy and Oncology 2016 Dec;121(3):431-439.

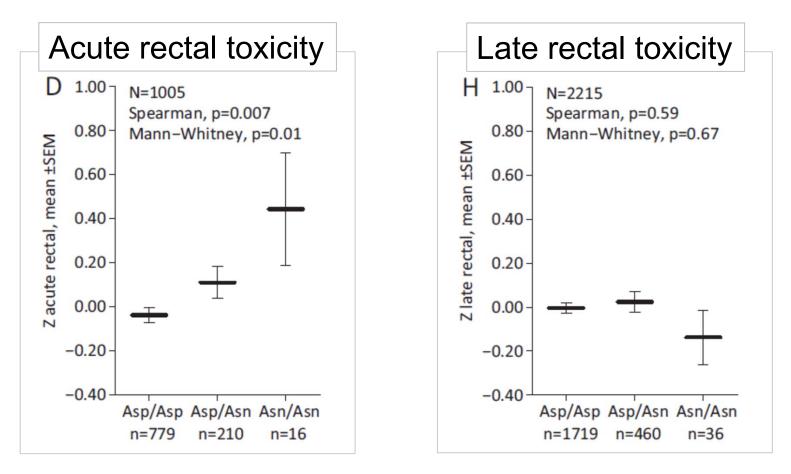

Original article

Individual patient data meta-analysis shows a significant association between the *ATM* rs1801516 SNP and toxicity after radiotherapy in 5456 breast and prostate cancer patients

- Andreassen CN et al. for International Radiogenomics Consortium
- Convincingly shows significant association between specific allele in *ATM* gene and increased risk of normal tissue toxicity from RT

Synergy from physics and biology

- Single SNP change in *ATM* gene
- Association with 7 of 8 endpoints but *not* late rectal toxicity
- Emphasises complexity in biological responses

- Much work still do to identify a 'signature' that might be useable clinically
- Objective is to *combine* individual normal tissue sensitivity measure with individual physical dose plan
 - Biology meets physics

Convolving individual radiosensitivity & individual dose accumulation

- Could we put together a 'signature' of individual normal tissue radiosensitivity and an individual estimate of dose accumulation (D_A) ?
- This develops the concept of individualisation (or personalisation) even more
 - Biology meets more physics

Convolving individual radiosensitivity & individual dose accumulation

Percentages of patient in different risk categories			
Sensitivity	Dose difference (Planned - DA)		
	D _A worse (30%)	D _A same (30%)	D _A lower (40%)
Most sensitive (10%)	3%	<mark>3%</mark>	4%
Average (50%)	<mark>15%</mark>	15%	<mark>20%</mark>
Most resistant (40%)	12%	12%	16%

Scaife JE et al. Brit J Radiol. 2015; 88: 20150172

Doctor's perspective

- Radiotherapy has a crucial role in cancer care
- Many developments still required
- There is always still the physics
- There is always still the margin maths getting more probabilistic
- Small differences make a difference
- Ultimately we are working towards improving patients' outcomes

Doctor's perspective

Better radiotherapy for our patients – a real **team effort**

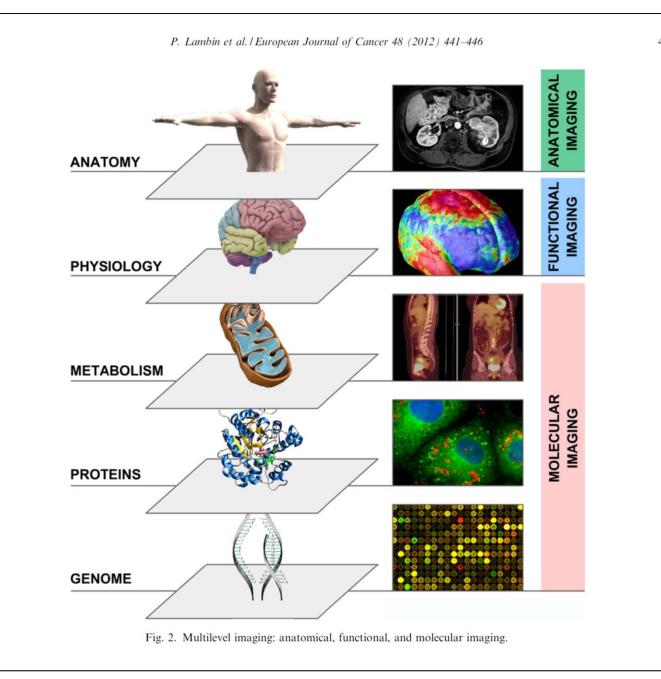

Our first IG-IMRT patient - 31st October 2007

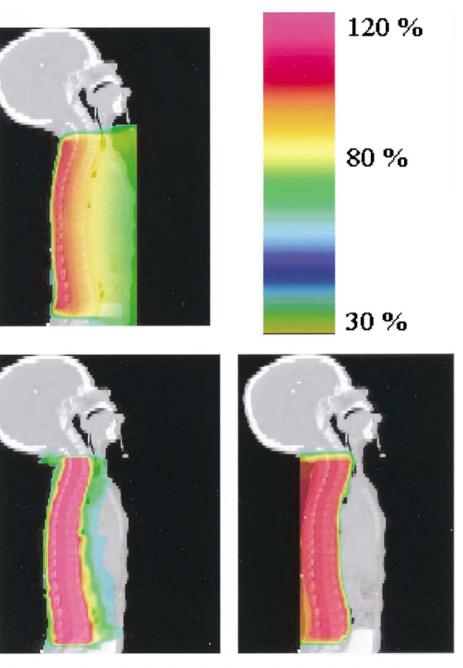

Fig. 3. Isodose distribution in the sagittal projection along the spinal column for (left) X-rays, (center) IMRT, and (right) protons.

Protons

- Proton beam therapy (PBT) can deliver
 - ➢ Lower exit doses − ideal for children
 - Possibly higher doses close to dose-limiting structures
 - Used for skull base and spinal chordoma
- Dose plans 'less tolerant' of variation in shape or density
 - Needs consideration of robustness
- Careful comparison is needed

Spares

Dialogue – a key component of happy planning

- As work flows become busier and more tightly programmed, it is less easy to discuss cases
- Often difficult to set Objectives and Constraints perfectly
- Plan review meeting
 - provides review after completion of the plan
 - ➢ It does *not* facilitate discussion during its preparation
- Case example
 - Pituitary adenoma (ie benign)
 - Absolute dose constraint lens dose <6 Gy</p>
 - Plan would deliver 7.5 Gy
 - ➢ "Oh, I thought we used 8 Gy, so I thought you didn't mean it"
 - Outcome ...

Underpinning science

- Finally
 - There is always still the physics ...
 - There is always still the maths of margins too

Use the best tools for the job !

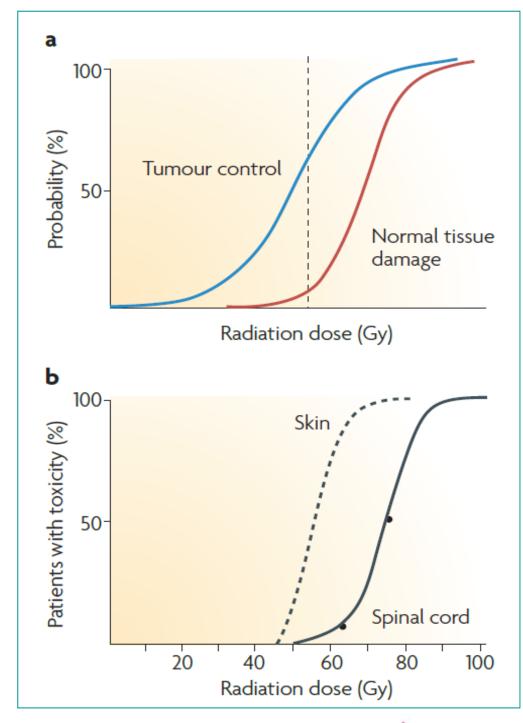

Marginal gains

- Small differences matter
 - To tumour
 - To normal tissues too
- Dose response curves are even steeper for many normal tissues than for tumours

Barnett et al. Nat Rev Cancer 2009; 9(2): 134-42
