To evaluate the safety and efficacy of short-course hypofractionated whole-breast irradiation (HWBI) on Japanese women after breast-conserving surgery (BCS), a prospective single-arm confirmatory trial (JCOG0906, UMIN000003200) has been conducted in 25 hospitals.

#### Material and Methods

Japanese women who had invasive breast cancer with clinical tumor size of 3 cm or less, no or one to three pathologically positive lymph nodes and pathologically negative inked margin were prospectively registered after BCS with or without adjuvant chemotherapy. The HWBI of 42.56Gy/16fr was delivered to the whole-breast without regional nodal irradiation, and a boost irradiation (BI) of 10.64Gy/4fr to the original tumor bed was added when the surgical margin was 5 mm or less. The recommended treatment period was within 29 days for HWBI and 33 days for HWBI and BI. The primary endpoint was the proportion of pre-specified eight items of grade 2 or higher late adverse reactions (ARs) including telangiectasia, ulceration, fibrosis-deep connective tissue, fracture, pneumonitis, cardiac ischemia/infarction, pericardial effusion and pain-breast occurring between 91 days and three years from the start of HWBI. The sample size was set as 310 patients with one-side alpha of 5%, power of 90%, threshold value of 8%, and expected value of 4%, estimated from the proportion of the late ARs on the historical control including 703 patients followed up for three years or more after conventional fractionated whole-breast irradiation (CWBI) in our pilot survey prior to

the present trial. Secondary endpoints included the proportion of treatment completion within the recommended period, early adverse events (AEs) occurring during 90 days from the start of HWBI, overall survival (OS), disease-free survival (DFS), ipsilateral-breast relapse-free survival (IB-RFS), and the proportion of breast cosmetic change. Early AEs and late ARs were evaluated using CTCAE ver3.0. Survival time was estimated by the Kaplan-Meier methods.

#### Results

Between 2010 and 2012, 312 women were registered. 306 patients received HWBI and 66 patients received HWBI with BI, but six chose CWBI prior to the start of irradiation. 301 patients (96.5%; 95%CI: 93.8-98.2) were treated within the recommended period. Evaluation of early AEs found that 38 patients (12.4%) had grade 2, including 25 patients (8.2%) with radiation dermatitis, and no patients had grade 3/4. On 306 patients receiving HWBI, 3-years OS, DFS and IB-RFS were 99.7% (95%CI: 97.7-100), 95.7% (95%CI: 92.7-97.5) and 99.0% (95%CI: 97.0-99.7). Among 303 (97%) patients, evaluation of late ARs found that 13 patients (4.3%; 90%CI: 2.6-6.7) had grade 2/3, including one of grade 3 pneumonitis. None had grade 4 or treatment-related death.

#### Conclusion

Short-course HWBI is considered as one of the standard treatments for Japanese women with margin-negative invasive breast cancer after BCS. Further follow-up is continued and cosmetic outcome will be analyzed.

#### EP-1157 Serial changes of post-lumpectomy seroma during MRI-guided partial breast irradiation

S.H. Jeon<sup>1</sup>, K.H. Shin<sup>1</sup>, S.Y. Park<sup>1</sup>, J.M. Park<sup>1</sup>

<sup>1</sup>Seoul National University Hospital, Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

After breast conserving surgery, the volume of post-lumpectomy seroma changes by time. We analyzed serial changes of seroma volume (SV) using magnetic resonance image (MRI) to investigate the possible benefit of adaptive radiation therapy during partial breast irradiation (PBI).

#### Material and Methods

From October 2015 to July 2016, 37 patients were prospectively included in the study. A total dose of 38.5 Gy in 3.85 Gy fractions once daily was prescribed to the planning target volume (PTV). The PTV was defined as unequal margins of 1-1.5cm added according to the directional safety margin status of each seroma. Treatment was done using MRI-guided radiation therapy (ViewRay system). During the 10 fractions of treatment, MRI scans were acquired at the time of simulation, 1st, 6th and 10th fractions.

#### Results

The average time intervals of surgery-simulation, simulation-1st, 1st-6th, and 6th-10th fractions were 23.1, 8.5, 7.2, and 5.9 days, respectively. SV was smaller during treatment than at simulation in 34 patients. Mean SV decreased from 100% at simulation to 65%, 55%, and 47% at each MRI scan. Age, body mass index, tumor size, seroma location, SV and delivery of radiotherapy did not showed association with SV change ( $p > 0.05$ , student's t-test). In 34 patients with decreased SV, mean PTVs were 84.7 cm<sup>3</sup> and 56.9 cm<sup>3</sup> at simulation and 6th fraction, respectively, and their difference was proportional to SV at simulation ( $r = 0.832$ ,  $p < 0.001$ , pearson's correlation test).

#### Conclusion

During PBI, rate of SV change is associated with time elapsed from surgery. Frequent monitoring of seroma change with MRI seems helpful for all patients receiving PBI.

**EP-1158 Vmat radiation induced nausea/vomiting in adjuvant breast cancer radiotherapy: dosimetrical issues.**

G. Lazzari<sup>1</sup>, A. Terlizzi<sup>1</sup>, B. Turi<sup>1</sup>, M.G. Leo<sup>1</sup>, D. Becci<sup>1</sup>, G. Silvano<sup>1</sup>

<sup>1</sup>Azienda Ospedaliera SS. Annunziata Presidio Osped, Radiology, Taranto, Italy

**Purpose or Objective**

Breast radiotherapy is associated with a minimal emetogenic risk in MASCC/ESMO guidelines. Although the emetogenic potential risk is estimated < 30%, VMAT adjuvant radiotherapy may induce an unexpected acute toxicity defined radiation induced nausea and vomiting (RINV) as we observed in our experience. Aim of our report is to find a correlation between dosimetrical factors and RINV occurrence in our patients (pts).

**Material and Methods**

In our institution from January 2013 to May 2016 106 breast cancer pts were treated with adjuvant radiotherapy (RT) in VMAT modality. All pts had surgery (conservative or radical). Mean age was 54 years. Neoadjuvant or adjuvant chemotherapy was given in 6 pts and 68 pts respectively (62 pts had high risk emetogenic agents combination, 12 pts had CMF). Left side breasts were treated with in 95 pts, right breast RT occurred in 11 pts. CT planning included all the chest from C6 to D12-L3 vertebrae. PTV consisted of residual breast or chest wall and nodal sites. According ICRU 83, the prescribed dose was 50 Gy total dose (2 Gy/25) to breast-chest wall and internal mammary chain (10 pts). Supraclavicular nodes (36 pts) were treated simultaneously, 1.92 Gy/25 fractions to 48 Gy total dose. VMAT was planned on treatment planning system Oncentra Masterplan® (collapsed cone algorithm) or Monaco® (Monte Carlo photon algorithm) and consisted of dual arc plan (170°/340° for left breast; 190°/20° for right breast) and 6 MV photons beams. In all the pts we retrospectively contoured on CT planning a volume containing the anatomical structures of emetic vagal-sympathical afferent pathways as the celiac plexus and gastroesophageal junction (GEJCPs). This area was identified as an organ at risk (OAR) for which the total volume, Dmax, Dmean and D1cc were calculated. Univariate analysis with  $\chi^2$ , t-test and Pearson covariance were used for statistical analysis.

**Results**

On 106 pts, 68 (64%) patients complained acute RINV according CTCAE v.3 criteria G1 nausea in 46 pts (43%), G2 nausea in 13 pts (12%), G1 vomiting in 8 pts (7%) were recorded. Symptoms occurred at 34 Gy delivered dose (mean 30 Gy, range 20-34). In right side irradiated breasts RINV occurred in 3 pts (27%), in left side RT in 65 pts (60%). RINV was related to a Dmax >10 Gy on GEJCPs ( $p < 0.005$ ). G1 vomiting and G2 nausea were related to a Dmax > 17 Gy ( $p < 0.005$ ) and to a Dmax > 15 Gy ( $p < 0.005$ ) respectively. Radiation breast side, age, systemic therapy, nodal radiation and PTVs volume values were not statistically significant for RINV.

**Conclusion**

RINV in breast radiation is not a common acute side effect. VMAT in breast radiation is responsible for a low dose bath to nearest structures as the GEJCPs and this may explain RINV in our cases. A useful constraint as Dmax < 10 Gy on GEJCPs like a serial structure may be considered in VMAT breast planning to avoid RINV.

**EP-1159 Hypofractionated adjuvant radiotherapy and concomitant trastuzumab for breast cancer: 5-year results**

M. Pasetti<sup>1</sup>, A. Fodor<sup>1</sup>, C. Sini<sup>2</sup>, F. Zerbetto<sup>1</sup>, P. Mangili<sup>2</sup>, P. Signorotto<sup>2</sup>, I. Dell'Oca<sup>1</sup>, C. Gumina<sup>1</sup>, M. Bolognesi<sup>1</sup>, N.G. Di Muzio<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Department of Radiotherapy, Milano, Italy

<sup>2</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy

**Purpose or Objective**

To report 5-year outcomes and toxicity in early breast cancer pts treated with whole breast hypofractionated adjuvant radiotherapy (HRT) and concomitant trastuzumab after breast conservation surgery (BCS).

**Material and Methods**

From February 2009 to October 2011, 442 pts with breast cancer pTis-T2 pN0-N1 (up to 3 positive lymph nodes) underwent forward planned intensity modulated HRT to a TD=40 Gy/15 fr at our institution, and reached 5 year median follow up; 31/442 pts presented c-erb B2 overexpression and were treated with HRT and concomitant trastuzumab. Acute toxicity during HRT was evaluated using the RTOG scale, while late side effects were assessed using SOMA-LENT score.

**Results**

Patients' median age was 60,5 (28-75) years; tumor breast side: 20 left and 11 right. Histology: DCI: 24 pts; DCI+DCIs: 6 pts; DCI+ LCIs: 1 patient; apocrine carcinoma: 1 patient. With a median follow-up of 63,8 (42,5-79,2) mts 3/31 pts (9,7%) presented a local relapse, 2/31 pts (6,5%) a lymph nodal relapse and 4/31 pts (12,9%) a distant relapse, confirming the higher propensity for loco-regional and distant relapse of c-erb B2 positive tumors. All pts were alive at the last follow up. Acute toxicity was G0 in 7 pts (22,6%), G1 in 20 pts (64,5%) and G2 in 4 pts (12,9%) with no G3 toxicity. Late G1 edema and hyperpigmentation persisting up to 18 mts after HRT was observed in 7 pts (22,6%). Two persistent late toxicities were registered only in pts treated with FEC chemotherapy before HRT: one G2 fibrosis, starting 36 months after the end of HRT, with breast volume of 1812 cc (cut-off observed in our series: 866 cc), and one G3 teleangiectasy with breast volume of 596 cc. Two cardiac toxicities were registered, both in left sided breast cancers, one in a patient treated with AC x3 cycles+TXT x 12 weeks +trastuzumab x 12 mts, another in a patient treated with FECx5 cycles+trastuzumab x 12 mts, which presented a mediastinal relapse, treated with salvage chemotherapy. The same patient presented BPCO exacerbations, again after the salvage chemotherapy. While chemotherapy and breast volume were important predictors for acute toxicity, the association of trastuzumab was not statistically significant for both acute and late toxicity at the multivariate analysis.

**Conclusion**

HRT after BCS demonstrated good outcomes and low toxicity. The association of hypofractionated radiotherapy with trastuzumab does not increase acute and late toxicity.

**EP-1160 T4s for T4 small Breast cancer: a new TNM classification subgroup proposal**

W.S. Zrafi<sup>1</sup>, S. Tebra<sup>1</sup>, H. Ouaz<sup>1</sup>, N. Bouaouina<sup>1</sup>

<sup>1</sup>Farhat Hached University Hospital, Radiation oncology departement, Sousse, Tunisia

**Purpose or Objective**

T4 breast cancer are tumors of any size with direct extension to the chest wall and, or the skin, including inflammatory breast cancer. Non inflammatory T4 breast cancer are a considerably heterogeneous group of tumors with a subgroup of small-sized tumors.

Our aim is to evaluate the prognosis of small sized (under 3 cm) non inflammatory T4 breast cancer, comparing them with larger T4 tumors and inflammatory breast cancer.

### Material and Methods

We had undertaken a retrospective study of T4 tumors treated by radiotherapy in the departments of radiation oncology in the Farhat Hached University Hospital and Medical Centre Ibn Khaldoun

### Results

250 patients classified as T4 tumors by our Committee for Gynecologic Oncology were treated in our departments between January 1995 and December 2013.

From these 250 patients, 79 were classified as T4d breast tumors and 171 non-inflammatory breast cancer. From these, 11 cases the primary tumor size is unknown, 20 patients had small tumors under 3 cm at presentation, and 140 patients had tumors of 3cm in size or larger. Seventeen were classified as T4a, 127 as T4b and 27 as T4c.

148 patients had underwent neoadjuvant chemotherapy, mastectomy, and adjuvant radiotherapy.

The median age was 50 years (ranging from 23 to 78). The median size at presentation was 5 cm. the median follow-up period was 42 months (ranging from 0 to 231).

The 5 years Disease free survival was 89% for small tumors versus 59% for non-inflammatory larger tumors and 48% for inflammatory breast cancer. With statistically significant difference  $p = 0.037$  (fig 1).

The overall survival was 89% versus 70% for non-inflammatory larger tumors and 62% for inflammatory breast ( $p = 0.28$ ).

These finding support the fact that small T4 tumors had a different behavior and better prognosis than other locally advanced tumors, thus it should be considered as a distinct entity. Indeed we propose that these tumors should be classified T4"s" ("s" as small).

Although the actual T4 TNM subgrouping is lacking of discriminative power, actually we did not find a significant difference comparing the DFS ( $p = 0.34$ ) or OS ( $p = 0.7$ ) according to the T4 TNM subgrouping (fig 2).

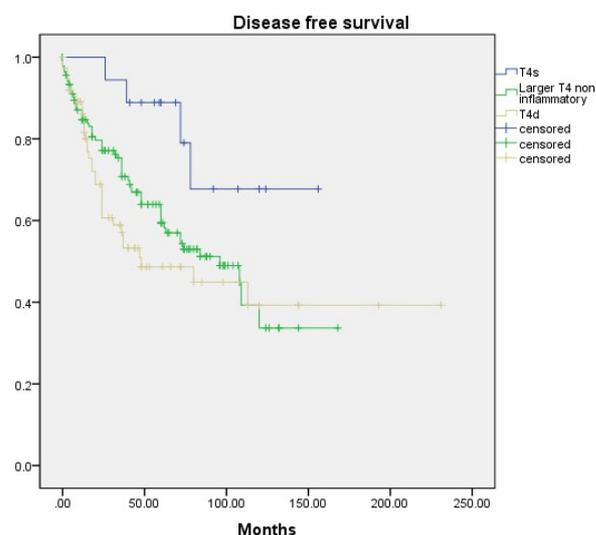

Fig 1: Disease free survival of the T4 s subgroup compared with larger T4 non inflammatory breast cancer and T4d

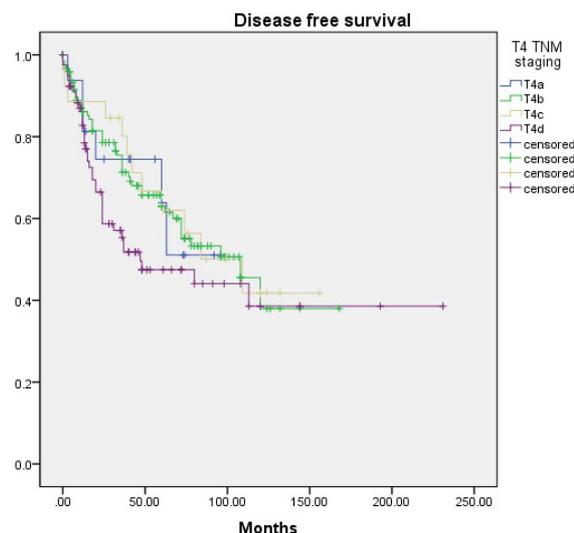

Fig 2: Disease free survival according to TNM staging system

### Conclusion

Many authors are pointing the lack of uniformity and discriminating power of the T4 subcategory of TNM classification. The subgroup of T4 small tumors have a better OS and DFS in our retrospective study.

We hope that adding the T4s subcategory to the TNM classification, will encourage providing more data about its prognosis.

### EP-1161 Hypofractionated Radiation Therapy in Breast Cancer: retrospective analysis of late toxicity

P. Ferrazza<sup>1</sup>, F. De Renzi<sup>1</sup>, T. Iannone<sup>1</sup>  
<sup>1</sup>Ospedale Civile San Martino, Radioterapia, Belluno, Italy

### Purpose or Objective

Various randomised trials have established the role of hypofractionated radiotherapy (HRT) in breast cancer. The aim of our retrospective analysis is to evaluate late toxicity and cosmetic results in patients treated with hypofractionated radiotherapy after breast conserving surgery followed or not by chemotherapy.

### Material and Methods

We included in this analysis patients (pts) treated with breast conserving surgery and HRT with a follow-up of at least 4 years. From January 2007 to September 2012, 239 pts with early breast cancer (TNM stage pTis pT1-2 and N0-N1mic) were treated with adjuvant hypofractionated radiation therapy. 40 pts underwent anthracycline-taxane based chemotherapy before HRT, 161 pts received only hormone therapy and 38 pts received no other therapies. Total dose delivered to whole breast was 45.66 Gy/16 fx in 233 pts and 42.4 Gy/16 fx in only 6 pts. 36 pts received a sequential boost on tumor bed (10 Gy/5 fx).

Late toxicity was recorded according RTOG/EORTC Late Radiation Morbidity Scoring Schema.

### Results

Median age was 61 years (range 36-86 years). 38/239 had DCIS, 158/239 pts had stage I disease and 43/239 had stage II disease. Median follow-up was 61 months. Most common acute toxicity was skin grade 1 (56%) and grade 2 (36.8%). Only 1 pts presented grade 3 skin toxicity.

112 pts presented grade 1 skin late toxicity (58 pts grade 1 edema, 38 pts grade 1 pigmentation changes, 7 pts telangiectasia, 9 pts grade 1 atrophy and 6 pts both edema and pigmentation change). No >grade 3 events were reported. Only 3 grade 3 fibrosis occurred.

The cosmetic results were excellent in 76% pts, good in 19% pts and fair in 5% pts.

No pulmonary or cardiac toxicity was observed. Although the series is not homogeneous, there was no significant difference in the incidence of acute or late toxicity in pts that underwent or not to chemotherapy.

#### Conclusion

In our series HRT is well tolerated with a good toxicity profile and a good cosmetic result. There is no clear evidence that chemotherapy has an impact to acute or late skin toxicity after HRT.

In our analysis we can not evaluate the role that have sequential boost in causing late toxicity.

#### EP-1162 Non surgical breast conserving treatment using a new radiosensitizer

T. Shimbo<sup>1</sup>, K. Yoshida<sup>1</sup>, N. Yoshikawa<sup>1</sup>, H. Yoshioka<sup>1</sup>, M. Nakata<sup>1</sup>, Y. Narumi<sup>1</sup>, T. Komori<sup>1</sup>, H. Matsutani<sup>1</sup>, T. Hamada<sup>1</sup>, Y. Uesugi<sup>2</sup>

<sup>1</sup>Osaka Medical College, Radiation Oncology, Osaka, Japan

<sup>2</sup>Kansai University of Welfare Sciences, Medical treatment for health, Kashihara, Japan

#### Purpose or Objective

The purpose of this clinical study was to clarify a non-surgical breast-conserving therapy (BCT) using a new radiosensitizing agent for the early stage breast cancer patients who rejected surgery. This new radiosensitizer, named KORTUC (Kochi Oxydol-Radiation Therapy for Unresectable Carcinomas) containing 0.5% hydrogen peroxide and 0.83% sodium hyaluronate has been developed for intra-tumoral injection in various tumors. Hydrogen peroxide is the only agent known to be capable of inactivating antioxidative enzymes and producing oxygen when applied topically to tumor tissues. By the addition of sodium hyaluronate, which makes the solution more viscous and slows the degradation of hydrogen peroxide, allowing long-acting radiosensitization of the local tumor tissue.

#### Material and Methods

A total of five early stage breast cancer patients (stage I, 2; stage II, 3) who rejected surgery were enrolled in the KORTUC trial after providing a fully informed consent. The mean age of the patients was 67.5 years (range; 38-80). The tumor size was 24.6mm (range; 14-47). A maximum of 6 mL of the radiosensitizer agent was injected into breast tumor tissue twice a week under ultrasonographic guidance. We used hypo-fractionated radiotherapy with conventional linear accelerator. Forty-four Gy in 16 fractions were irradiated for whole breast and ipsilateral axillary region with tangential field, and an additional electron boost of 9Gy in 3 fractions were delivered for primary tumor site.

#### Results

Treatment was well tolerated with minimal adverse effects in all patients. No patients showed any significant complications other than mild dermatitis. Three patients with estrogen receptor-positive tumors were also started on hormone therapy following KORTUC treatment. All patients showed clinically complete response (cCR). The mean duration of a follow-up was 15.6 months (5/23/26/27/44 months), respectively. All patients were alive with no evidence of disease at present. The mean period taken to confirm cCR on the breast contrast-enhanced CT, MRI or PET-CT was approximately 8.2 months. Cosmetically, all patients evaluated as having an excellent appearance in their ipsilateral breast.

#### Conclusion

Non-surgical BCT (KORTUC-BCT) can be performed safely and effectively for patients with early stage breast cancer. KORTUC-BCT can be one of the treatment options to breast cancer patients who rejected surgery.

#### EP-1163 A Prospective Evaluation of Lumpectomy Cavity Volume Changes During Whole Breast Radiotherapy

B. Barney<sup>1</sup>, G. Martinez<sup>1</sup>, R. Hecox<sup>1</sup>, J. Clark<sup>1</sup>

<sup>1</sup>Intermountain Health Care, Radiation Oncology, Provo, USA

#### Purpose or Objective

A significant percentage of female post-lumpectomy breast cancer patients treated with whole breast radiotherapy (WBRT) have a lumpectomy cavity seroma on the initial CT simulation. Our purpose was to prospectively evaluate for changes in the size of the postoperative tumor bed during a course of WBRT, prior to the lumpectomy cavity boost (LCB).

#### Material and Methods

This prospective study was approved by the IRB, and informed consent was given by 20 women prior to study enrollment. All patients underwent breast conserving surgery and received a recommendation for LCB following WBRT by the treating physician. The median patient age was 63 years (range, 41-84). Most patients (n=19, 95%) had Stage 0, I, or II breast cancer. There was no standardized dose or fractionation for WBRT or the boost; these decisions were left to the treating physician's discretion. Regional lymph nodes were treated as per standardized guidelines. When chemotherapy was required, it preceded WBRT.

Each patient underwent initial CT simulation (CT1) at a median 39 days (range, 11-216) from surgery. Twelve women (60%) had a lumpectomy cavity seroma on CT1, and 8 (40%) did not. All patients underwent a second CT simulation (CT2) approximately 1 week before the LCB began. Median time from CT1 and CT2 was 30 days (range, 21-42). The LCB volume was immediately contoured on CT1 based on surgical clips, presence/location of seroma, and surgical findings. Without referencing CT1 LCB contours, the treating physician then contoured a modified LCB volume once CT2 was obtained, using the same factors for CT1 LCB delineation.

We prospectively compared LCB volumes from CT1 and CT2 across the cohort and within seroma/no seroma subgroups. Univariate analysis of several factors potentially associated with a change in LCB volume from CT1 to CT2, including time from surgery to CT1 ( $\leq 40$  days vs  $> 40$  days), time from CT1 to CT2 ( $\leq 30$  days vs  $> 30$  days), and presence of seroma on CT1, was performed.

#### Results

The median LCB volumes on CT1 and CT2 for the entire cohort were 20.1 and 8.5 cm<sup>3</sup>, respectively. Most patients (n=17, 85%) experienced a reduction (rather than increase) in the LCB volume from CT1 to CT2. For patients with seromas, median LCB volumes on CT1 and CT2 were 36.0 and 8.8cm<sup>3</sup>, respectively, representing a volume reduction of  $>75\%$  over the course of WBRT. For patients without seromas, median LCB volumes on CT1 and CT2 were 11.8 and 8.0cm<sup>3</sup>, respectively, representing a volume reduction of 32% during WBRT. On univariate analysis, only the presence of seroma was associated with a significant change in LCB volume during WBRT.

#### Conclusion

Most patients experienced a change in the size of the LCB volume during WBRT. Patients with seroma experienced a more dramatic volume reduction than those without. We recommend that women who will undergo LCB and have a seroma at the time of initial CT simulation undergo a re-simulation to plan the LCB boost towards the end of the WBRT course.

### EP-1164 Improved accuracy in IORT with electron beams by a new measuring system of mammary gland thickness

P. Scalchi<sup>1</sup>, A. Marchesin<sup>2</sup>, G. Scalco<sup>2</sup>, S. Bacchiddu<sup>3</sup>, C. Mari<sup>3</sup>, L. Grandin<sup>3</sup>, P. Francescon<sup>1</sup>, F. De Marchi<sup>2</sup>, C. Baiocchi<sup>3</sup>

<sup>1</sup>Ospedale San Bortolo, MEDICAL PHYSICS, Vicenza, Italy

<sup>2</sup>Ospedale San Bortolo, SURGERY, Vicenza, Italy

<sup>3</sup>Ospedale San Bortolo, RADIO THERAPY, Vicenza, Italy

#### Purpose or Objective

In IORT of the breast cancer using electron beams (IOERT), the beam energy should be properly chosen, as recommended by both ICRU 71 (2004) and AAPM TG72 (2006), to ensure that the entire PTV be covered by the 90% of the maximum dose ( $D_{max}$ ) and the ICRU reference point be positioned as near as possible to  $D_{max}$ . Due to the physical characteristics of these beams, the measurement of the mammary gland thickness can be critical. In fact, usually it is measured before docking using a needle and a ruler ("needle method"), or ultrasounds. Nevertheless the measured thickness can differ from the real one after docking completion, thus affecting the accuracy of the subsequent dose release. To allow accurate measurements of the gland thickness under treatment conditions, a new measurement system (MARK's) was developed at Vicenza Hospital. The aim of this work is to compare the needle method to MARK's in terms of surgeon-surgeon variability and dosimetry impact.

#### Material and Methods

A mobile IOERT-dedicated linac (LIAC,SIT) with four electron energies (4 to 10 MeV) is used at Vicenza Hospital. MARK's is a sterilizable manual pointer with integrated ruler. After radioprotective disk positioning, the surgeon stitches the mammary gland to prepare the PTV. Then he inserts the terminal part of the applicator, after applying a thin patch layer underneath to prevent target herniation and, while keeping it pressed, he inserts the pointer inside the applicator allowing direct thickness measurements in treatment conditions.

14 patients were studied. The measurements were taken first by the needle method, and then by MARK's. Five measurements points were always taken, one at the center of the PTV and four marginal positions (cranio-caudal and lateral). The electron energies were chosen based on the resulting thickness. The two systems were compared in terms of both the choice of the electron energy, as resulting by following ICRU and AAPM recommendations, and the surgeon-surgeon variability.

#### Results

As shown in the following Table, the needle method systematically overestimates the PTV thickness and surgeon-surgeon reproducibility is better for MARK's. Following ICRU71 and AAPM TG72 the needle method

would cause 11 erroneous energy choices and 5 treatments to be wrongly canceled.

N. of erroneous energy choices (needle method)	N. of possible treatment cancelations following ICRU 71 and AAPM TG 72 method (needle method)	Surgeon-surgeon variability (needle method)	Surgeon-surgeon variability (MARK's)	Thickness difference between methods
11	5	2 mm	1 mm	0.0 ÷ 20.0 mm (5.4 mm on the average)

#### Conclusion

A new system for measuring the mammary gland thickness prior to IOERT developed at Vicenza Hospital was compared to a traditional needle method. The former shows better reproducibility and accuracy, because it reproduces the same target thickness as it exists after the docking. Regarding both treatment decisions and dosimetric accuracy, the found differences are critical when the international recommendations are followed.

### EP-1165 Short and long term safety of a post-mastectomy conformal electron beam radiotherapy (PMERT)

N. Grellier-Adedjouma<sup>1</sup>, M. Chevrier<sup>2</sup>, H. Xu<sup>1</sup>, N. Fournier-Bidoz<sup>1</sup>, F. Campana<sup>1</sup>, F. Berger<sup>2</sup>, A. Fourquet<sup>1</sup>, D. Peurien<sup>1</sup>, D. Lefeuvre<sup>2</sup>, Y.M. Kirova<sup>1</sup>  
<sup>1</sup>Institut Curie, Radiation Oncology, Paris, France  
<sup>2</sup>Institut Curie, Statistics, Paris, France

#### Purpose or Objective

To evaluate short and long-term safety of a chest wall irradiation after mastectomy with our previously published PMERT technique, depending on patient characteristics and treatments received.

#### Material and Methods

We included all women irradiated after mastectomy for a non-metastatic breast cancer with PMERT between 2007 and 2011 in our Department of Radiation Oncology. Acute and late toxicities (CTCAE v3.0) were evaluated with a weekly clinical examination during irradiation and then with monitoring consultations at least every 6 months. We also conducted a dosimetric analysis of 100 consecutive patients irradiated on the chest wall and lymph nodes (LN) (50 right and 50 left), to assess the doses to organs at risk.

#### Results

Among the 796 women included, mean age was 53.2 years (22.1-90.8), 47.6% of them had at least one cardiovascular risk factor, regardless of age, 49% were post menopausal, 8.3% were obese (BMI ≥ 30) and 6.9% and 11.9% had cardiac and pulmonary comorbidities respectively. Internal mammary chain (IMC) was irradiated in 85.6% of cases, supra, infraclavicular LN and axilla in 88.3%, 77.9% and 14.9% of cases. Mean chest wall dose was 49.4Gy (39-56) over 40 days (30-119). Energies of 6 and/or 9 MeV were used in 84.7% of cases.

The maximum acute skin toxicity was grade 1 in 58.5% of patients, grade 2 in 35.9%, and grade 3 in 4.5% of them. There was no grade 4 toxicity. Concomitant chemotherapy was associated with an increased risk of grade 3 toxicity (p < 0.001).

With a median follow up of 64.1 months (5.6-101.5), 29.8% of patients had, temporarily or permanently, hyperpigmentation, fibrosis or telangiectasia (grade 1: 23.6%, grade 2: 5.2%, grade 3: 1%), which tended to be promoted by smoking (p = 0.06); 274 patients (34.4%) underwent breast reconstruction, on average 19.7 months after the end of irradiation (3.6-86.8), which was

considered as satisfactory or very satisfactory in 90% of cases.

Lymphedema occurred in 17.1% of patients (minor: 14.4%, severe: 2.7%), related to axillary radiotherapy ( $p < 0.001$ ) and obesity ( $p = 0.017$ ).

Long-term pulmonary toxicity reached 4% and was related to the irradiated volume. Among the 95 patients with pulmonary comorbidities, 9% experienced increased respiratory symptoms after radiation therapy; it is not possible to distinguish between radiation toxicity and respiratory disease evolution.

Late cardiac events were reported in 21 patients (2.7%), of which 17 had received anthracyclines and 9 trastuzumab. Three patients developed ischemic heart disease, within 5 to 7 years after radiotherapy; all of them had received anthracyclines and were irradiated at the left chest wall and LN, but also had many cardiovascular risk factors (2 to 4).

Mean heart doses were 4.35Gy (2.1-6.6) and 1.7Gy (0.5-2.9) and mean ipsilateral lung doses were 13.9Gy (10.8-17) and 12.4 (8.6-16.1), in case of left and right chest wall and LN irradiation respectively.

#### Conclusion

This series shows that our PMERT technique is well tolerated at short and long term.

#### EP-1166 Patterns of post-operative radiotherapy in breast cancer patients after neoadjuvant chemotherapy

K.M. Lopes<sup>1</sup>, T.B. De Freitas<sup>1</sup>, H.A. Carvalho<sup>1</sup>, A.A. Pereira<sup>2</sup>, S.B. Silva<sup>2</sup>, S.R. Stuart<sup>1</sup>, M.S. Mano<sup>2</sup>, J.R. Filassi<sup>3</sup>, G.N. Marta<sup>4,5</sup>

<sup>1</sup>Faculdade de Medicina da Universidade de São Paulo, Radiation Oncology, Sao Paulo, Brazil

<sup>2</sup>Faculdade de Medicina da Universidade de São Paulo, Clinical Oncology, Sao Paulo, Brazil

<sup>3</sup>Faculdade de Medicina da Universidade de São Paulo, Breast Division, Sao Paulo, Brazil

<sup>4</sup>Hospital Sirio-Libanês, Radiation Oncology, São Paulo, Brazil

<sup>5</sup>Instituto do Câncer do Estado de São Paulo ICESP - Faculdade de Medicina da Universidade de São Paulo, Radiation Oncology, Sao Paulo, Brazil

#### Purpose or Objective

Neoadjuvant chemotherapy (NCT) has the same results as adjuvant chemotherapy in regard to disease-free survival and overall survival and may also allow breast conserving surgery for patients with locally advanced breast cancer. Indications for adjuvant radiotherapy (RT), as well as treatment targets after NCT are not yet well established. The purpose of this study is to evaluate locoregional RT indications and treatment targets in breast cancer patients submitted to NCT.

#### Material and Methods

Retrospective study of 523 patients treated between March 2010 and April 2015 that were submitted to NCT and received post-operative RT. Demographics, tumor and treatment characteristics were evaluated. The variables were submitted to descriptive and frequencies analysis. Comparisons of categorical variables among groups were made with the Chi-square test. Significance level was set at 5% ( $p < 0.05$ ).

#### Results

The mean age was 50 years (range 22 to 84 years). Most patients had stage cT3 or cT4 disease (74.6%) and clinically positive lymph node(s) (81.5%). Luminal "like" tumors comprised 45% of the patients and 27.9% were triple negative. Biopsy for suspected axillary lymph node was performed in 49.5% (32.8% of these were positive). Conservative surgery was performed in 23.1%. All patients received breast or chest wall irradiation; 91.5% supraclavicular fossa (SCF) and axillary levels 2 and 3 irradiation, 1.4% only SCF; 8.7% underwent additional

axillary level 1 irradiation and 8.8% also received internal mammary chain RT; boost was delivered in 21.4% of the patients. Conventional fractionation (25 x 200 cGy) was used in 96.6%. Indication of SCF and levels 2 and 3 axillary lymph nodes irradiation was significantly related to younger age ( $\leq 60$  years) ( $p = 0.03$ ), stage cT3 or cT4 ( $p = 0.027$ ) and clinically compromised lymph nodes at the time of diagnosis ( $p = 0.0001$ ). Internal mammary chain irradiation was also correlated to clinically positive lymph nodes ( $p = 0.01$ ) and stage ypT3 or ypT4 ( $p = 0.028$ ).

#### Conclusion

RT indications and targets were based on tumors characteristics pre-NCT. More advanced disease at the time of diagnosis and age were the main determinants to define RT to nodal targets independently of NCT response.

#### EP-1167 Accelerated Partial Breast Irradiation: A single center analysis.

K. Nugent<sup>1</sup>, D. Kelly<sup>2</sup>, J. McCaffrey<sup>3</sup>, M. Maher<sup>4</sup>

<sup>1</sup>St Lukes Radiation Network, Radiation Oncology, Dublin, Ireland

<sup>2</sup>Cork University Hospital, Medical Oncology, Cork, Ireland

<sup>3</sup>Mater Misericordiae University Hospital, Medical Oncology, Dublin 6, Ireland

<sup>4</sup>Mater Misericordiae University Hospital, Radiation Oncology, Dublin 6, Ireland

#### Purpose or Objective

Our objective was to analyse the use of adjuvant accelerated partial breast radiation (APBI) at our center over a ten year period. We calculated the local recurrence rates, median follow up and overall survival in breast cancer patients who received APBI from 2006 to 2016. In this retrospective cohort, we obtained the average tumour size, histology grade, hormone status and lymphovascular invasion (LVI) presence in order to review the breast cancer characteristics of the patients we selected to treat with this modality.

#### Material and Methods

We conducted a single institution retrospective review of all adjuvant breast cancer patients who received APBI from between January 2006 to September 2016. Patients were identified from a prospectively-maintained dataset of all patients commencing ABPI. A retrospective chart review was conducted as to determine long term follow up outcomes. The following patient details were recorded: median follow up time, demographics, histology, node status, surgery type, adjuvant treatment and local recurrence. Primary outcome was loco-regional recurrence noting if recurrences occurred within the treated breast quadrant.

#### Results

During this period a total of 106 procedures were carried out. The average mean age at time of treatment was 68.2 years. The mean tumour size was 14.65mm, all were estrogen receptor positive and node negative. LVI was present in 8% of the patient cohort. Median follow up was 65 months. The local recurrence rate within the treated breast quadrant was 1.8% (95 CI 0.42-2.44) while the local recurrence rate within the ipsilateral breast was 2.8% (95 CI 1.2-3.3). Overall survival was 97%.

#### Conclusion

Our findings suggest that APBI is a reasonable adjuvant option for selected low risk breast cancer patients.

#### EP-1168 male breast cancer; a review of patients treated from 2004 - 2013 (10yrs)

P. Scott<sup>1</sup>, V. Vanderpuye<sup>1</sup>, J. Yarney<sup>1</sup>, N. Aryeetey<sup>1</sup>, H. Ayettey<sup>1</sup>, M. Dadzie<sup>1</sup>, Z. Meles<sup>1</sup>

<sup>1</sup>Korlebu Teaching Hospital, National Centre for radiotherapy and Nuclear Medicine, ACCRA, Ghana

### Purpose or Objective

Male breast carcinoma (MBC) is rare, and the incidence varies worldwide. It accounts for about 1% of all breast cancers.

Due to the rarity of this disease, there is a lack of prospective clinical trials to define its optimum treatment. Current data consists mostly of small retrospective studies, hence treatment generally follows the principles established for that of female breast cancer.

The purpose of this study was to review and analyse breast cancer in men managed from 2004 to 2013.

### Material and Methods

Men with histologically confirmed breast cancer from 2004-2013 were studied. Information regarding patient demographics, presenting symptoms, tumor characteristics, treatment and outcomes were analysed.

### Results

Over the 10 year period, 41 patients were studied, making 1.6% of all breast cancer cases managed. Median age at diagnosis was 66 years, ranging 36-89.

Majority, 87.8%, self-detected a lump in the breast. The median time from onset of symptoms to diagnosis was 12 months, ranging 3-48.

The commonest histology was invasive ductal carcinoma, 70.7%.

Stage III disease represented 47.58%, while stage I, II and IV disease made up 7.32%, 19.61% and 25.49% respectively. Hormone receptor (HR) status was unknown in 63.4%, 14.6% were estrogen receptor (ER) only positive, 7.3% were progesterone receptor (PR) only positive, 4.9% were ER and PR positive, and 9.8% were ER and PR negative.

Of those who had their HR status checked, 73.2% were HR positive.

Modified radical mastectomy was the most common surgical procedure, 46.3%, mastectomy only in 14.6% and breast conservation in 7.3%. 46.3% of patients received adjuvant radiotherapy. 48.8% did not receive adjuvant radiotherapy because they were metastatic, defaulted or presented late after the surgery. 40.3% received chemotherapy in adjuvant, neoadjuvant or metastatic setting.

Hormone receptor positive patients had Tamoxifen. Median follow up duration was 7 months, ranging 0-64. Median survival was 13 months and 5 year overall survival of 2%.

### Conclusion

MBC makes up 1.6% of all breast cancer presenting to our centre, consistent with worldwide findings of about 1%. Majority presented with locally advanced or metastatic disease. Outcomes are poor and could be due to late presentation. Screening programs may translate into better outcomes.

MBC is frequently hormone receptor positive and may be more sensitive to hormonal therapy, hence receptor status testing is recommended.

Low survival and poor follow up made disease free survival difficult to determine.

### EP-1169 Preoperative CT scan in tumor bed delineation after breast conserving surgery and oncoplasty

T. Saxena<sup>1</sup>, V. Goel<sup>1</sup>, G. Kadyaprath<sup>2</sup>, D. Arora<sup>3</sup>, A.K. Verma<sup>1</sup>, P. Agarwal<sup>1</sup>, P. Kumar<sup>1</sup>, J. Jain<sup>1</sup>, R. <sup>3</sup>Max Hospital- Delhi- India, Medical Physics, Delhi, India

<sup>4</sup>Max Hospital- Delhi- India, Radiation Therapy

Technologist, Delhi, India

### Purpose or Objective

**Background:** Tumor bed (TB) boost, in addition to whole breast radiation therapy (WBRT) improves local control rates as compared to WBRT alone after breast conserving surgery (BCS). There are several pitfalls in localizing TB accurately. Surgical clips are generally placed over pectoralis muscle, even if the tumor is superficial and hence not truly representative and there is always a concern of clip migration. Mammogram and MR mammogram are not quite useful as they are done in a non-anatomic position. Problem of accurate TB identification is further compounded in patients with oncoplastic reconstruction. In oncoplastic surgeries (OPS), scar is often not representative of tumor location. Seroma cavity is generally obliterated by tissue repositioning. Hence, TB delineation is sum total of information from surgical notes, surgical clips, postoperative changes on radiation therapy (RT) planning scans, histopathology report and some calculated guess work.

**Objective:** To determine utility of preoperative CT scan in TB delineation after BCS.

### Material and Methods

This pilot study was conducted in Department of Radiation Oncology, Max Hospital, Delhi, India, on 21 breast cancer patients in whom prior to BCS, preoperative CT scan was done in treatment position on a flat couch, in CT simulator. A radio opaque fiducial was also placed at the centre of palpable lump. After BCS & chemotherapy (if any), RT planning CT scan was taken with similar set up as pre-operative CT scan. Both the scans were co-registered using non-deformable registration on Eclipse Version 10.0. TB was contoured on RT planning CT using surgical clips (TB1) and also on preoperative CT scan (TB2). Tumor bed on all RT planning scans were scored for Cavity Visualization Score (CVS). Relative shift in position of TB on both the scans was compared in all three [lateral (RL), cranio caudal (CC) and Antero-posterior (AP)] directions.

### Results

In our patients, median age was 59 years (Range 42-71). Median of maximum tumor size was 2.5 cm (Range 1.0-5.0). All patients underwent BCS with oncoplastic reconstruction. Median time between preoperative and RT planning scan was 4.6 months. CVS 1 and 5 was observed in 6 patients each and rest patients were having CVS 2, 3 or 4. Mean preoperative, postoperative and combined tumor volume were 10.9cc, 10.9cc and 23.4cc respectively. On evaluating relative positions of tumor bed on pre-operative vs RT planning scan, mean ( $\pm$  SD) RL shift was 2.8 cm ( $\pm$  1.8), which was larger than for the other directions (CC shift 1.2 cm, SD  $\pm$  0.9; AP shift 1.6 cm, SD  $\pm$  1.1). When relative shifts of TB were co-related with tumor location, RL & CC shifts were more in outer quadrant tumors ( $p=0.0005$  &  $0.016$  respectively), while in AP direction,  $p$  value ( $0.26$ ) was not statistically significant.

### Conclusion

Preoperative CT scan in treatment position is an additional useful tool in calculated guess work of TB delineation and helps in improving the accuracy of target volume delineation for TB boost.

### EP-1170 Hypofractionated radiotherapy for ductal carcinoma in situ using VMAT: acute toxicity and cosmesis

F. De Rose<sup>1</sup>, A. Fogliata<sup>1</sup>, D. Franceschini<sup>1</sup>, C. Iftode<sup>1</sup>, A.M. Ascolese<sup>1</sup>, T. Comito<sup>1</sup>, L. Di Brina<sup>1</sup>, A. Tozzi<sup>1</sup>, C. Franzese<sup>1</sup>, E. Clerici<sup>1</sup>, G.R. D'Agostino<sup>1</sup>, P. Navarra<sup>1</sup>, F. Lobefalo<sup>1</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

### Purpose or Objective

To evaluate acute skin toxicity and cosmesis in DCIS patients enrolled in a phase II trial of hypofractionated breast irradiation using VMAT.

### Material and Methods

Patients treated for DCIS with breast-conserving surgery were eligible for a phase II trial of hypofractionated breast irradiation. All DCIS patients underwent VMAT technique to irradiate the whole breast with a total dose of 40.5 Gy delivered in 15 fractions over 3 weeks, without tumor bed boost. Acute skin toxicities were recorded according to RTOG scoring criteria, and late skin toxicities according to CTCAE v4.0. Cosmetic outcomes were assessed as excellent/good or fair/poor according to the Harvard scale.

### Results

From May 2013 to March 2016, 123 DCIS patients accrued. Median age was 56 year (range 30-82 years). The median follow up was 18 months (range 6-63). Most of the tumors were moderately differentiated (51 %) with a no comedo subtype with necrosis DCIS histology (73 %). Sentinel node biopsy was performed in 57 patients (46,3 %). Concomitant hormonal therapy was administered in 16 %. At the end of RT treatment skin toxicity profile was G1 in 56% of the patients, G2 in 14%, no patients presented G3 toxicity. At six months of follow up skin toxicity was G1 in 25% of patients, no G2-G3 cases; cosmetic outcome was good/excellent in 92% of patients. At one year skin toxicity was G1 in 24% of patients; no G2-G3 toxicity was recorded; cosmetic outcome was good/excellent in 94% of patients. After an early evaluation of clinical outcomes we have found 3 cases of local relapse.

### Conclusion

These results evidence that hypofractionated radiotherapy using VMAT is a safe option for DCIS. A longer follow up is needed to assess clinical outcomes and late toxicity.

### EP-1171 Thermography and association to high-grade radiation dermatitis: a prospective trial on 64 patients.

N. Leduc<sup>1</sup>, V. Atallah<sup>2</sup>, A. Petit<sup>1</sup>, S. Belhomme<sup>1</sup>, P. Sargos<sup>1</sup>, V. Vinh-Hung<sup>3</sup>

<sup>1</sup>Institut Bergonié, Radiation Oncology, Bordeaux, France

<sup>2</sup>University Hospital of Bordeaux, Radiation Oncology, Bordeaux, France

<sup>3</sup>University Hospital of Martinique, Radiation Oncology, Fort-de-France, France

### Purpose or Objective

Thermography has been successfully used for non-invasive imaging of various diseases. Radiation-induced dermatitis characterizes by an inflammatory state and sensation of heat. We designed a prospective, observational, single-center study to acquire data about the bi-dimensional evolution of temperature in the treated breast during the course of radiotherapy, seek possible association with the occurrence of dermatitis and eventually inquire about the predictive value of temperature increase over the future occurrence of radiation dermatitis.

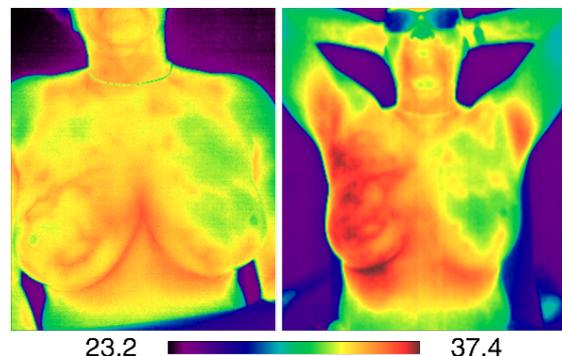

### Material and Methods

All consecutive patients treated for localized breast cancer at the University Hospital of Martinique between May and September 2016 were eligible for inclusion. Included patients were examined weekly by trained investigators for the occurrence of radiation dermatitis. A high-resolution frontal image of torso was taken every week. Treated and contralateral areas were compared.

### Results

64 patients were included. All demonstrated an increase in local temperature over the course of treatment. The occurrence of high grade radiation-induced dermatitis was significantly associated to a higher increase of local average temperature (1.88 vs. 1.15 °C,  $p < 0.0001$ ).

Preliminary results analyzing the predictive value of prior temperature elevation over subsequent occurrence of high-grade radiation dermatitis showed highest sensitivity and specificity of respectively 75% and 69% with a temperature threshold of 1.4°C. Figure 1 demonstrates typical thermal images of torso at 0 and 50 Gy. Temperature is plotted in °C.

### Conclusion

This study demonstrated the feasibility of capturing local temperature elevation over the course of adjuvant radiotherapy for breast cancer. Maximal and average local temperature increased for all patients, confirming the intensity of inflammatory phenomena linked to irradiation. Patients suffering from high-grade radiation-induced dermatitis radiated noticeably more heat. Furthermore, they started doing so before the occurrence of clinical signs of dermatitis. As such, thermography showed promising results as a predictive tool for the occurrence of acute skin toxicity.

### EP-1172 Post-mastectomy radiotherapy with patient-tailored bolus using 3D printing for left breast cancer

K. Yang<sup>1</sup>, Y. Chung<sup>1</sup>, W. Park<sup>1</sup>, S.G. Ju<sup>1</sup>, S.J. Huh<sup>1</sup>, D.H. Choi<sup>1</sup>, H. Cha<sup>1</sup>, J.Y. Park<sup>1</sup>, C.H. Na<sup>1</sup>

<sup>1</sup>Samsung Medical Center, Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

Radiation exposure to the heart during radiotherapy for left breast cancer patients has a chance to increase the risk of cardiovascular disease. Also, radiation pneumonitis and decreased lung function associated with thoracic radiotherapy have been reported. The purpose of this study is to reduce heart and ipsilateral lung doses using an optimized chest wall electron beam therapy with patient-tailored bolus (PTB) using 3D printing technology for left breast cancer patients after mastectomy.

### Material and Methods

Five patients with left breast cancer underwent computed tomography (CT) simulation for irradiation of left chest wall and supraclavicular fossa after mastectomy. We designed a virtual bolus on the chest wall to compensate the surface irregularities on CT images and developed a plan for chest wall electron beam therapy. Also, a rival plan for conventional tangential technique was done on the same CT. For both plans, supraclavicular field was planned using photon beam. For planning, virtual bolus was overridden by a density of material which would be used to make PTB with 3D printer. Dosimetric comparisons for target and organs at risk such as heart and ipsilateral lung were performed between the 3D PTB applied electron beam plan and tangential plan. Wilcoxon signed-rank test was used for statistical analysis.

### Results

For cardiac dose, PTB applied electron plan showed lower  $D_{mean}$ ,  $D_{max}$ ,  $V5_{Gy}$  and  $V30_{Gy}$  than tangential plan ( $p=0.080$ ,  $0.043$ ,  $0.686$  and  $0.068$ , respectively). For ipsilateral lung,

$D_{\text{mean}}$  and  $V20_{\text{Gy}}$  of electron plan were lower ( $p=0.080$  and  $0.043$ , respectively) than those of tangential plan, while  $D_{\text{max}}$  between two plans were less different. For target coverage, all of  $D_{\text{mean}}$ ,  $D_{\text{max}}$ ,  $D_{\text{min}}$ , conformity index (CI) and homogeneity index (HI) of electron plan were higher than those of tangential plan ( $p=0.043$ ,  $0.043$ ,  $0.043$ ,  $0.225$ ,  $0.034$ , respectively).

#### Conclusion

Chest wall electron beam therapy with PTB reduced high dose exposed cardiac and lung volume with clinically acceptable target coverage compared with tangential technique. Postmastectomy radiotherapy using PTB might be effective for left breast cancer patients to reduce risk of cardiac disease and lung morbidity.

#### EP-1173 Understanding variations in the use of hypofractionated radiotherapy for breast cancer

<sup>12</sup>Hospital de la Santa Creu i Sant Pau, Radiotherapy, Barcelona, Spain

<sup>13</sup>Hospital Universitari Germans Trias i Pujol, Radiotherapy, Badalona, Spain

#### Purpose or Objective

Radiation oncology guidelines favour hypofractionated whole-breast radiotherapy (HWBRT) over more conventional schemes in the conservative treatment of breast cancer, but its adoption still varies in clinical practice. This study assessed the patterns of HWBRT use and adoption in Catalonia (Spain).

#### Material and Methods

We used a mixed-methods approach based on an explanatory sequential design, first collecting and analysing quantitative data on HWBRT use ( $> 2.5$  Gy per fraction) in 11 public radiotherapy centres (2005-2015) and then performing 25 semi-structured interviews with all department heads and reference radiation oncologist/s.

#### Results

Of the 34,859 patients fulfilling the study criteria over the study period, just 12% were hypofractionated, reaching a rate of 29% in 2015 ( $p<0.001$ ). Our analysis showed a narrowing age gap between patients receiving conventional fractionation and hypofractionation in centres leading adoption. However, there were important differences in clinicians' interpretation of evidence and selection of patients for specific indications, both within and between departments. Clinical management of radiotherapy departments played a major role.

#### Conclusion

In tackling inequitable access to HWBRT, a rational, evidence-based approach should ideally converge with professional perspectives, the factors influencing the interpretation of the evidence, and the organisational context, including existing dissemination channels.

#### EP-1174 impact of radiotherapy to posterior supraclavicular and posterior triangle area in breast cancer

S.H. Liu<sup>1</sup>, Y.C. Huang<sup>2</sup>, Y.J. Chen<sup>1</sup>

<sup>1</sup>Mackay Memorial Hospital, Department of Radiation Oncology, Taipei, Taiwan

<sup>2</sup>Graduate Institute of Chinese Medical Science, China Medical University, Taichung, Taiwan

#### Purpose or Objective

For patients with 4 or more lymph nodes involvement, regional nodal irradiation (RNI) is associated with increased locoregional control and overall survival (OS). The main radiotherapy (RT) volume for RNI includes axillary, supraclavicular, and/or internal mammary nodes. However, whether the posterior supraclavicular area and the posterior triangle of the neck (PSPT) should be included in RNI remains unclear. The object of this study was to retrospectively review our clinical experience of RNI to PSPT or not in N2-3 breast cancer patients as a reference for target delineation.

#### Material and Methods

Patients with N2-3 breast cancer who received definitive surgery and/or neoadjuvant/adjuvant therapy during 2006-2013 were reviewed. The delivery of adjuvant RT and the coverage for RNI were at the discretion of treating physicians. To ensure precise delineation and dosimetry, only patients treated using the technique of intensity-modulated radiotherapy (IMRT) to regional nodal area were enrolled. The patterns of recurrence including the PSPT region were examined. The locoregional control rate (LCR), distant metastasis-free rate (DMFR), disease-free survival (DFS), and OS were analyzed using Kaplan-Meier method, and survival estimates were obtained with log-rank test and the Cox proportional hazard model.

#### Results

Of 256 N2-N3 breast cancer patients who were diagnosed and received operation in a medical center, 184 cases were eligible for the study. Among these women, 62 received RNI according to the recommended volume by RTOG consensus (RC group), 57 had additional volumes of PSPT (RC+PSPT group), and 65 did not have adjuvant RT (NRT group). Median follow-up was 62.8 months for the entire cohort. There was higher LCR ( $p=0.006$ , 90.8% vs. 78.5% at 5 years) and OS ( $p=0.007$ , 82.7% vs. 64.8% at 5 years) for the patients with adjuvant RT (RC and RC+PSPT) compared to those without RT (NRT). No difference in DMFR ( $p=0.508$ , 69.6% vs. 63.4% at 5 years) and DFS ( $p=0.243$ , 68.2% vs. 69.2% at 5 years) were noted. Among women with adjuvant RT, there was no statistical difference between RC and RC+PSPT groups (LCR:  $p=0.693$ , 93.1% vs. 89.9% at 5 years; DMFR:  $p=0.501$ , 66.2% vs. 73.9% at 5 years; DFS:  $p=0.606$ , 66.2% vs. 71.6% at 5 years; OS:  $p=0.548$ , 83.5% vs. 83.5% at 5 years). In details, locoregional recurrence was found in 4 (6.5%), 6 (10.5%), and 17 (26.2%) patients in the RC, RC+PSPT and NRT group, respectively. Among these patients, no PSPT recurrence was noted in RC+PSPT group, whereas there were 2 (50%) in the RC group and 11 (64.5%) in the NRT group.

#### Conclusion

Adjuvant RNI significantly increased LCR and OS for N2-N3 breast cancer patients. Local recurrence specifically noted in PSPT might be diminished by additional inclusion in the regional nodal irradiation volumes. This impact may not translate to the changes in LCR, DMFS, DFS, and OS in our experience. Further prospective investigation is

needed to validate these results with exclusion of possible selection bias.

#### EP-1175 Impact of body-mass index on setup displacement in patients with breast cancer

Y.C. Tsai<sup>1</sup>, C.Y. Chen<sup>2</sup>, J.T. Tsai<sup>1</sup>

<sup>1</sup>Taipei Medical University-Shuang Ho Hospital, radiation oncology, New Taipei City, Taiwan

<sup>2</sup>Wan Fang Hospital- Taipei Medical University, Radiation oncology, Taipei, Taiwan

##### Purpose or Objective

To determine the impact of body-mass index factors (BMIF) on daily setup variations for patients with breast cancer treated with adjuvant radiotherapy with daily image guidance before radiotherapy and changes during radiotherapy on the magnitude of setup displacement in patients with breast cancer.

##### Material and Methods

The clinical data of 117 patients with breast cancer was analyzed using the alignment data from daily on-line on-board imaging from image-guided radiotherapy between 2013 and 2015. All patients received cone beam computed tomography (CBCT) at the first 5th fraction, then once per week at least. BMFs included body weight, body height, and the circumference and bilateral thickness of the neck. The shifts of each fraction were collected in superior-inferior (SI), anterior-posterior (AP), and medial-lateral (ML) directions respectively, and the absolute distant of shifts was also calculated. The shifts of patients were grouped by factors of BMI, body weight, height, age, operation method and acute toxicities respectively. For grouping of BMI, body weight and height, the median values were used as cut off. The impact of factors was assessed by compare the shifts using independent t-test within each groups.

##### Results

Median BMI was 24.3, and median body weight was 59kg. A higher body weight before radiotherapy correlated with a greater shift in ML ( $p = 0.0088$ ), and SI ( $p = 0.0004$ ) direction. A larger BMI ( $\geq 24.3$ ) was associated with a greater shift in SI ( $p = 0.0005$ ) direction. Comparison of patients undergoing breast-conserving surgery (BCS) and modified radical mastectomy (MRM), BCS group was associated with a larger shift in SI and ML ( $p = 0.028$  and  $p = 0.0051$ , respectively).

##### Conclusion

Larger body weight ( $\geq 59$ kg, larger BMI ( $\geq 24.3$ )) and BCS may be a significant risk factor for daily shifts.

#### EP-1176 Helical tomotherapy in chest wall/breast and draining node irradiation after breast cancer surgery

V. Lancellotta<sup>1</sup>, M. Iacco<sup>1</sup>, S. Chierchini<sup>1</sup>, E. Perrucci<sup>1</sup>, I. Palumbo<sup>1</sup>, L. Falcinelli<sup>1</sup>, S. Saccia<sup>1</sup>, S. Nucciarelli<sup>1</sup>, A. Milletti<sup>1</sup>, C. Aristei<sup>1</sup>

<sup>1</sup>Ospedale Santa Maria della Misericordia, Radiation Oncology, Perugia, Italy

##### Purpose or Objective

Three dimensional conformal radiotherapy (3DCRT) to the chest wall/breast and draining nodes has long been standard treatment for patients at high-risk of relapse after mastectomy or conserving surgery (BCS). Given the complex target shape, other radiotherapy techniques such as intensity modulated RT (IMRT), volumetric modulated arc therapy (VMAT), helical (HT) or direct (DT) tomotherapy were developed. The present study evaluated the toxicity of HT for treating the chest wall or breast plus level III and IV lymph nodes after mastectomy or BCS.

##### Material and Methods

From January 2013 to August 2016, 43 consecutive patients with breast cancer underwent helical

tomotherapy. Table 1 reports their demographics and clinical details. Computed tomography (CT) scans without contrast medium were acquired with patients supported by breast board in the treatment position. CT data were acquired with 2.5 mm slice thickness and were transmitted to the Pinnacle<sup>3</sup> TPS V9.8. One radiation oncologist contoured the clinical target volume (CTV) i.e. chest wall or breast, level III and IV lymph nodes and organs at risk. The chest wall was not expanded to obtain the planning target volume (PTV); the breast and nodes were expanded 0.5 cm in all directions to obtain the PTV breast and PTV ln. Dose prescription was 50 Gy to the PTVs in 25 fractions. In 7 patients treated with BCS a simultaneous integrated boost (SIB) was delivered to the tumoral bed. Dose constraints were defined by an internal protocol following the QUANTEC directive and more recent reports. HT treatment plans were generated using Tomotherapy HD System commercial planning software (TomoTherapy Inc., Madison, WI). Daily set-up corrections were performed for all patients. Toxicity was reported following CTCAE 4.0. Statistical analysis: The Chi-square and the Mann-Whitney's U-tests compared continuous (age and body mass index) and categorical variables (comorbidity, chemotherapy, hormone therapy, trastuzumab and chest wall/breast and lymph nodes volumes).

##### Results

All patients completed treatment. HT provided good target-coverage for the breast, chest wall and lymph nodes, with respectively mean D90% 47.8Gy and 48.55Gy, mean D95% 46.64Gy and 47.99Gy, mean D98% 45.20Gy and 47.3Gy, and mean V107% 0.65Gy and 0.315Gy. All constraints for OARs were respected (i.e. ipsilateral lung: median V5: 70.93 Gy, V20: 24.2Gy and V30: 11.89Gy; contralateral lung: V5: 24.17Gy and V15: 2.15Gy; heart: Dmean 6.6 Gy). G1-G2 acute toxicity developed in 42 patients and G3 acute toxicity in only 1 (Table 2). The only risk factor for desquamation and oedema was chest wall/breast volume ( $p = 0.003$  and  $p = 0.011$  respectively). At a median follow-up of 12.5 months (range 2-29), all patients were alive and 41/43 (95.3%) patients were disease-free.

##### Conclusion

HT is associated with low acute toxicity and appears suitable for treating the chest wall or breast plus level III and IV draining nodes in patients with breast cancer.

#### EP-1177 Late radiation skin effects after breast conserving surgery: possible predictive clinical factors.

A. Romano<sup>1</sup>, A. Rese<sup>1</sup>, E. Toska<sup>1</sup>, L. Faraci<sup>1</sup>, M. Conson<sup>1</sup>, A. Farella<sup>1</sup>, R. Solla<sup>2</sup>, R. Liuzzi<sup>2</sup>, L. Cella<sup>2</sup>, R. Pacelli<sup>1</sup>

<sup>1</sup>University of Napoli Federico II, Section of Radiation Oncology, Napoli, Italy

<sup>2</sup>National Council of Research, Institute of Biostructure and Biomechanics, Napoli, Italy

##### Purpose or Objective

Previously we have shown that dose to surface and psoriasis were predictive factors for radio-induced acute skin toxicity in patients affected by breast cancer treated with breast conserving therapy (BCT). In this study we assessed in the same group of patients the late skin toxicity, evaluating possible relation with acute skin toxicity, dosimetric and clinical factors.

##### Material and Methods

One Hundred Forty patients treated with BCT between 2011 and 2012 in our department were considered for the study. Median age was 57 year (range 32-85). All patients were treated after surgery with 50 Gy to the whole breast delivered with 25 daily fractions in 5 weeks. A boost dose of 10 Gy in 5 days was delivered by electrons to the tumoral bed. Late skin toxicity was assessed by physical inspection during the oncological follow up of the patients

and was described and graded according to the RTOG classification. Relation to previous acute skin toxicity, clinical and dosimetric factors was assessed by univariate analysis.

#### Results

At a median follow up of 54 months (range 50-60), sixteen patients (11%) developed late skin toxicity. Fifteen grade G1-2 (dyschromia and telangiectasia), while 1 patients had nipple necrosis (G4) at the the site of the surgical scar. Interestingly, no significant relation with previous radio-induced acute skin toxicity was found.

#### Conclusion

Our study suggests that late radioinduced skin toxicity appears in a small but significant portion of patients treated by BCT and seems to be unrelated to previous acute skin toxicity.

#### EP-1178 Breast radiotherapy without nodal irradiation in pT1-2 pN0-1 stage: prognostic factors and outcomes.

C. Di Carlo<sup>1</sup>, M. Nuzzo<sup>1</sup>, L.A. Ursini<sup>1</sup>, M. Trignani<sup>1</sup>, L. Caravatta<sup>1</sup>, G. Di Girolamo<sup>1</sup>, M. Di Nicola<sup>2</sup>, D. Genovesi<sup>1</sup>

<sup>1</sup>*Ospedale Clinicizzato S.S. Annunziata, Radiotherapy, Chieti, Italy*

<sup>2</sup>*Biostatistic laboratory, Clinical Sciences, Chieti, Italy*

#### Purpose or Objective

The aim of study was to evaluate loco-regional recurrence (LRR), overall survival (OS), disease free survival (DFS), prognostic influence of the number of positive lymph nodes and others variables in treatment of early breast cancer patients.

#### Material and Methods

From December 2005 to December 2013, 377 female patients with pT1-T2 pN0-N1 were treated in our Radiotherapy Institute and retrospectively evaluated. All patients received conservative surgery with sentinel-lymph node and/or axillary dissection followed by whole breast radiotherapy. According to our institutional protocol nodal region irradiation was not performed. Four cohorts were analyzed according to the number of involved lymph nodes: N0, N1<sub>n1</sub> (1 lymph node +), N1<sub>n2</sub> (2 lymph nodes +), N1<sub>n3</sub> (3 lymph nodes +). Actuarial rates of total LRR, DFS and OS were calculated by the Kaplan-Meier method. Comparisons of clinical and pathologic characteristics between patients groups were calculated using the log-rank test.

#### Results

From a total of 377 patients, 284 patients with pT1 tumors and 93 with pT2 tumors were evaluated. The median age was 58 years (range 31-82 years). The absence of involved lymph nodes has been assessed in 276 patients while N1 was reported in 101 patients: 63 N1<sub>n1</sub>, 19 N1<sub>n2</sub>, and 19 N1<sub>n3</sub>. The median follow-up was 4 years with a LRR rate of 3.4% (13/377). In particular a nodal recurrence rate of 1.06% (4/377) was observed: 2 occurred in the axillary region, 1 in supraclavicular region and 1 within internal mammary chain. Estrogen receptor, menopausal status, adjuvant chemotherapy, Her2neu, margin status and grading were not significantly associated with OS and DFS, whereas progesterone receptors were significantly correlated with DFS and tumor size (T>2 cm) with DFS, LRR and OS. Furthermore, a significant correlation between 3 metastatic lymph nodes and OS was found (N1<sub>n3</sub> p-value 0.024, N1<sub>n1</sub> p-value 0.175, N1<sub>n2</sub> p-value 0.369).

#### Conclusion

In our series, adjuvant radiotherapy after breast-conserving surgery led to low rates of LRR and high rates of OS and DFS in pT1-T2 pN0-N1 breast cancer patients. Moreover, although the retrospective design, the limited sample size and given the low rate of nodal recurrence, the results observed from our study seem suggest that nodal irradiation in patients presenting 1-3 positive

axillary nodes could be not necessary to improve outcome.

#### EP-1179 Target Volume Definition after Lumpectomy for Accelerated Partial Breast Irradiation (APBI) or Boost

I.F. Ciernik<sup>1</sup>, A.M. Greiß<sup>2</sup>

<sup>1</sup>*Dessau City Hospital, Radiation Oncology, Dessau, Germany*

<sup>2</sup>*Deaconess Hospital, Department of Surgery, Dessau, Germany*

#### Purpose or Objective

After tumor resection and surgical manipulation during lumpectomy or oncoplasty, the tumor cavity and the tissue at risk for local relapse is often not clearly definable during radiation therapy planning. Metal clips placed at the thoracic fascia are used to better define the former tumor location. Here we investigated the ability of a liquid tissue marker (BioXmark®, Nanovi®, Copenhagen, DK) to define the local cavity for the purpose for defining a boost volume or a target volume suitable for APBI.

#### Material and Methods

Preclinical investigations how to apply BioXMark® liquid marker best for visualization by computer tomography were performed. Subsequently, thirteen patients underwent lumpectomy for limited stage breast cancer disease and the tumor cavity was marked with the liquid marker as well as a surgical clip. All patients were older than 50 yrs, and all patients presented with hormone-receptor positive disease less than 3 cm, pN0 and all were potentially suitable for APBI. The tumor cavity was marked immediately after resection with BioXmark® and surgical clips. The liquid marker was placed before any oncoplasty-manipulation was performed in three patients analysed. A planning CT was performed 4-5 weeks after surgery. The boost volume was defined, according to the metal clips and the area marked by BioXmark.

#### Results

In preclinical studies a phantom was used to see that the liquid marker sprayed over several square centimeters achieved best imaging qualities on computer tomography. Thus, applying a film of liquid marker over the surface of interest was chosen for further clinical investigations. Seven patients were analysed by the time of submission. The tumor cavity was clearly marked for the purpose of tumor cavity segmentation in six out of seven cases. In one patient, the marker was not reliably discriminated from the glandular tissue. The mean volume of the tumor bed was 22,69 ml (range 8,1 - 40,96). In respect to the metal clips placed on the thoracic wall after lumpectomy, considerable displacement of the boost target volume after oncoplasty was visualized.

#### Conclusion

Visualization of the tumor cavity can improve on the accuracy of the target volume definition for APBI and may allow optimizing PTV margins. Further investigation is justified to reveal clinical utility of liquid-marker-based target volume definition after lumpectomy.

#### EP-1180 Whole breast radiotherapy in Lateral Decubitus position : efficacy and toxicity

E. Bronsart<sup>1</sup>, S. Dureau<sup>2</sup>, H. Xu<sup>1</sup>, F. Berger<sup>2</sup>, F. Campana<sup>1</sup>, E. Costa<sup>1</sup>, A. Chilles<sup>1</sup>, A. Fourquet<sup>1</sup>, Y. Kirova<sup>1</sup>

<sup>1</sup>*Institut Curie, Radiation therapy, Paris, France*

<sup>2</sup>*Institut Curie, Biometrics, Paris, France*

#### Purpose or Objective

To evaluate whole breast 3D conformal radiotherapy (RT) delivered in lateral decubitus position (Isocentric Lateral Decubitus ILD) and report the acute and the late cardiac and pulmonary toxicity of a cohort of patients treated with ILD.

### Material and Methods

From 2006 to 2010, 832 patients with early-stated breast cancer treated by conservative surgery underwent 3D-conformal whole breast RT in the lateral decubitus position at Institut Curie. All types of cup size was included. The acute toxicity of treatment was evaluated weekly using NCI CTC v3.0 scale, and the late toxicity was evaluated once a year and started one year after the end of RT. A dosimetric study was performed to analyse the mean cardiac dose and the mean homolateral and contralateral lung doses.

### Results

Median of follow up is 6.4 years, median age is 61,5 years (min29-max90), and median body mass index is 26.3. 51% have left breast cancer and 49% have right breast cancer. Different type of fraction/dose were performed : 46.5% 66Gy in 33 fractions, 17.9% 50Gy in 25 fractions, 26.1% 40 or 41.6Gy in 15 or 13 fractions and 30Gy in 5 fractions. Acute epidermitis was present in 93% with a median of apparition of 4 weeks, and only 2,8% grade 3. In multivariate analysis, the cup size has significant influence ( $p=0,0004$ ) and the fractionation has a significant influence ( $p=0,0001$ ). After one year 94.1% had no epidermitis. No cardiac or pulmonary toxicity was reported. For normofractionation (2Gy fractions, 50 Gy on the whole breast and 16Gy boost on the tumor bed) : Mean dose to homolatéral lung (HL) is 1,4 Gy (min 0,63 Gy-max 3 Gy), mean dose to contralateral lung (CL) is 0,07Gy (min0,37Gy-max1Gy) mean cardiac dose is 1,14 Gy (min0,54 Gy - max4 Gy). In hypofractionation : for 41,6Gy in 13 fractions schedule : mean dose to HL is 0,87Gy (min0,38 Gy-max5 Gy), mean dose to CL is 0,03 Gy (min0,3 Gy-max3 Gy) mean cardiac dose is 0,77 Gy (min0,38 Gy-max9 Gy). For 40 Gy in 15 fractions schedule : mean dose to HL is 0,96 Gy (min0,38 Gy-max4 Gy), mean dose to CL is 0,04 Gy (min0,02 Gy-max2,28 Gy) mean cardiac dose is 0,74Gy (min0,3 Gy-max1 Gy). In the 28,5Gy en 5 fractions schedule : Mean dose to HL is 0,53Gy (min0,26Gy-max3Gy), mean dose to CL is 0Gy (min0 Gy-max0,4 Gy) mean cardiac dose is 0,37Gy (min0,6 Gy-max5 Gy). Median overall survival is not reached, there is no influence of fractionation on overall survival. Relapse-free survival is not reached, with only 36 relapses without influence of fractionation.

### Conclusion

Whole breast radiotherapy in the lateral decubitus position provides excellent results with very low mean cardiac dose and mean pulmonary dose. There is no cardiac or pulmonary toxicity in this study. And it's also very well tolerated with very good acute toxicity profile.

### EP-1181 dose to non-routinely delineated risk organs in post left conservative surgery conformal breast RT

M. Abdelwahed<sup>1</sup>, M.A.H. Mohamed Abdelrahman Hassan<sup>2</sup>  
<sup>1</sup>As-Salam International Hospital, oncology, Cairo, Egypt  
<sup>2</sup>Kasr Alaini Center of Clinical Oncology & Nuclear Medicine NEMROCK, clinica oncology, cairo, Egypt

### Purpose or Objective

This is a dosimetric study aiming at evaluation of radiation doses to risk organs particularly (brachial plexus, coronary artery & thyroid gland) in previously treated breast cancer cases at Kasr Alaini Center of Clinical Oncology & Nuclear Medicine after left Breast Conservative Surgery (BCS). Our aim was to identify the patients' subgroups in need for routine delineation of these risk organs to avoid toxic doses to them.

### Material and Methods

Twenty five female patients with left BCS treated with external beam radiotherapy to the left breast and supraclavicular region. Delineation of the coronaries was done according to the University of Michigan Medical Center; while the brachial plexus was delineated

according to the RTOG guidelines. Patient measures like body mass index (BMI), mid beam cut separation, Central lung distance, Maximum heart distance (MHD) and doses to risk organs were documented (Heart  $V_{30}$  & heart  $D_{mean}$ , brachial plexus  $D_{max}$ , thyroid gland  $D_{mean}$ ,...)

### Results

Age of the patients ranged from 35years to 70 years (median=54years). BMI ranged from 22.1 to 47.6 (mean=34.2±6.7). MHD mean value was 2.9±1.1cm while the heart  $V_{30}$  mean value was 3.44±3.59% with heart  $D_{mean}$  range from 1.2 up to 9.00Gy (mean=3.92±2.02Gy). The anterior descending coronary artery (ADCA)  $D_{max}$  was 41.9±6.60Gy while the ADCA  $D_{mean}$  was 23.4±10.9Gy. ADCA  $D_{mean}$  increased from 18.5±10.9Gy with MHD ≤3cm to 27.9±9.1Gy with MHD >3cm ( $p$ -value 0.030). ADCA  $D_{mean}$  was also related to  $V_{30}$  of the heart as the ADCA  $D_{mean}$  was 16.9±10.5Gy with  $V_{30}$  <2% while ADCA  $D_{mean}$  was 29.5±7.3Gy with  $V_{30}$  ≥2% ( $p$ -value=0.005). BMI showed borderline significance on ADCA  $D_{max}$  when the BMI was <30, the ADCA  $D_{max}$  was 37.3±10.0Gy while it was 43.7±43.7Gy when BMI ≥30 with a  $p$ -value 0.074. None of the outcome parameters had clinical significance related to the thyroid gland or brachial plexus, The brachial plexus  $D_{max}$  was 46.7±3.0Gy with median value 46.0Gy while the thyroid gland  $D_{mean}$  was 20.6±5.3Gy with median value 20.0Gy.

### Conclusion

A significant dose may be received to non-routinely delineated organs at risk (brachial plexus, coronary artery & thyroid gland) in post-operative loco-regional radiotherapy of patients with left breast cancer after BCS. A significantly higher dose was received to left ADCA in cases with high MHD & heart  $V_{30}$  while borderline significance on ADCA in obese patients where obesity is a known risk factor for developing coronary artery diseases.

### EP-1182 Locoregional treatment of breast cancer with IMRT: a single center experience

I. Ratoso<sup>1</sup>, A. Jenko<sup>2</sup>, R. Hudej<sup>2</sup>, F. Kos<sup>2</sup>, A. Gojkovic Horvat<sup>1</sup>, D. Golo<sup>1</sup>, T. Marinko<sup>1</sup>, M.S. Paulin Kosir<sup>1</sup>, J. Gucic<sup>1</sup>

<sup>1</sup>Institute of Oncology Ljubljana, Department of Radiation Oncology, Ljubljana, Slovenia

<sup>2</sup>Institute of Oncology Ljubljana, Department of Radiation Oncology- Section of Medical Physics, Ljubljana, Slovenia

### Purpose or Objective

To evaluate implementation of breast/chest wall and locoregional lymph nodes irradiation with inverse-planned IMRT in patients with challenging anatomy.

### Material and Methods

Since 2014, 13 patients with challenging anatomy (8 left-, 5 right-sided) were treated with locoregional IMRT on institutional protocol because standard mono-isocentric 3D-CRT was insufficient in sparing organs at risk (OARs). Dose prescription to planning target volume (PTV) was 50 Gy in 25 daily fractions; 3 patients were also prescribed boost dose 10–16 Gy. Treatment planning was done on Elekta Monaco TPS with Monte Carlo calculation algorithm. In the IMRT plan 9 beams with the energy of 6 MV were positioned so that the first two beams were placed tangentially on the PTV (as in a 3D-CRT plan) and the rest were redistributed equidistantly between the tangential pair. The cranial part of beams that would pass through the shoulder into the PTV was blocked with jaws. Two segmentation methods were used, Step-and-Shoot for the first 7 patients and Dynamic MLC (dMLC) for the rest. The primary endpoint in treatment planning was CTV coverage. Radiation was delivered on Elekta Synergy™ Platform linac for Step-and-Shoot mode and Elekta Versa HD™ for dMLC mode.

**Results:** 12 patients had mastectomy and 1 patient had lumpectomy. 7 patients had immediate reconstruction: 2 tissue expanders, 5 autologous deep inferior epigastric perforator flaps. All patients received systemic chemotherapy. Toxicity was evaluated once weekly. 84 % (11/13) of patients had G1 skin toxicity, while 15 % had G2-G3 (2/13) toxicity. In one patient with G3 toxicity skin dose was intentionally increased with a bolus. 1 patient had G1 esophagitis and there was no acute lung toxicity. CTV coverage was within limitations for all patients ( $V_{93\%PD} > 99\%$ ). For evaluation PTV (target volume reduced by 5mm buildup region) the selected target dosimetric metrics were the following: for left-sided breast treatment  $V_{95\%PD} = 96.8\%$  (standard deviation - SD 3.7%),  $V_{107\%PD} = 3.7\%$  (SD 5.4%) and for right-sided breast treatment  $V_{95\%} = 96.3\%$  (SD 4.7%),  $V_{107\%PD} = 1.0\%$  (SD 0.7%). Dosimetric metrics for OARs for the whole group were: heart  $D_{mean} = 5.6$  Gy (SD 3.2 Gy),  $V_{20 Gy} = 4.9\%$  (SD 6.4%), for both lungs  $D_{mean} = 9.6$  Gy (SD 1.7 Gy),  $V_{20 Gy} = 15.9\%$  (SD 3.4%), for contralateral lung  $V_{5 Gy} = 8.7\%$  (SD 16.8%) and for contralateral breast  $D_{mean} = 1.7$  Gy (SD 1.0 Gy). Dose to the OARs and restrictions are presented separately for left and right side in table 1.

Organ at risk	Left side	Right side
<b>Lung</b>		
$V_{20 Gy} < 20\%$	14.2% (SD 2.5%)	19.3% (SD 1.9%)
$V_{5 Gy} < 65\%$ (55%)	29.5% (SD 2.93%)	34.6% (SD 2.5%)
$D_{mean} < 20$ Gy	9.0 Gy (SD 1.6 Gy)	10.7 Gy (SD 1.7 Gy)
<b>Ipsilateral lung</b>		
$V_{20 Gy} \leq 35\%$	31.1% (SD 4.7%)	33.5% (SD 2.2%)
$D_{mean} < 18$ Gy	16.3 Gy (SD 1.9 Gy)	17.3 Gy (SD 1.5 Gy)
<b>Contralateral lung</b>		
$V_{5 Gy} \leq 10\%*$	12.6% (SD 20.8%)	2.1% (SD 1.9%)
$D_{mean}^\#$	2.2 Gy (SD 0.3 Gy)	1.9 Gy (SD 0.2 Gy)
<b>Heart</b>		
$V_{40 Gy} \leq 5\%$	1.8% (SD 1.8%)	0.0%
$V_{20 Gy} \leq 10\%$	8.0% (SD 6.5%)	0.0%
$D_{mean} < 8$ Gy (5 Gy)	7.4 Gy (SD 2.9 Gy)	3.0 Gy (SD 0.9 Gy)
<b>LADCA</b>		
$D_{max} \leq 20$ Gy*	37.4 Gy (SD 12.2 Gy)	2.8 Gy (SD 0.4 Gy)
<b>Humeral head</b>		
$V_{25 Gy} < 1\%*$	4.7% (SD 2.32%)	0.8% (SD 0.69%)
$V_{15 Gy}^\#$	32.2% (SD 20.02%)	4.5% (SD 3.90%)
$D_{mean}^\#$	12.4 Gy (SD 5.6 Gy)	5.1 Gy (SD 1.2 Gy)
<b>Contralateral breast</b>		
$V_{3 Gy} \leq 20\%$	14.9% (SD 10.2%)	19.6% (SD 17.5%)
$D_{mean} < 2$ Gy	1.8 Gy (SD 1.29 Gy)	1.4 Gy (SD 0.2 Gy)
<b>Spinal cord</b>		
$E_{QD_{max}} < 30$ Gy	16.7 Gy (SD 6.3 Gy)	18.0 Gy (SD 2.6 Gy)
<b>Thyroid gland</b>		
$V_{30 Gy} \leq 30\%$	5.9% (SD 5.6%)	12.2%
<b>Liver</b>		
$V_{15 Gy} < 15\%$	1.1% (SD 1.7%)	6.6% (SD 6.3%)
$D_{mean} < 28$ Gy	4.3 Gy (SD 3.7 Gy)	4.8 Gy (SD 3.3 Gy)

SD = standard deviation; \* unmet constraints for organs at risk (OARs)

in left sided radiotherapy; # not yet defined

## Conclusion

**Conclusion:** IMRT of breast/chest wall and regional lymph nodes in patients with challenging anatomy is feasible with acceptable short term toxicity. We had some difficulties in balancing constraints for OARs and target coverage especially in left-sided breast treatment. Better results may be achieved with the introduction of deep inspiratory breath hold (DIBH) combined with IMRT or even VMAT technique.

## EP-1183 Initial Clinical Experience with a Noninvasive Breast Stereotactic Radiotherapy Device: the GammaPod

S. Feigenberg<sup>1</sup>, E. Nichols<sup>1</sup>, Y. Mutaf<sup>1</sup>, W. Regine<sup>1</sup>, S. Becker<sup>1</sup>, Y. Niu<sup>2</sup>, C. Yu<sup>1</sup>

<sup>1</sup>University of Maryland School of Medicine, Radiation Oncology, Baltimore, USA

<sup>2</sup>Xcision Medical Systems, Research, Columbia- MD, USA

## Purpose or Objective

GammaPod™ is a new stereotactic radiotherapy device dedicated to the treatment of breast cancer. It creates a radiation focal spot with sharp dose fall-off at the isocenter by using 36 non-overlapping rotating cobalt-60 beams, and creates a uniform dose coverage by dynamically moving the focal spot within the breast in the prone position. A US FDA approved clinical study is being conducted at the University of Maryland. Herein reported is the initial experience with this novel device.

## Material and Methods

The purpose of this clinical study is to evaluate the feasibility and safety of using the GammaPod™ system to deliver a focal dose of radiation to a target in the breast. Of the 17 planned enrollments, 6 patients have been completed and we expect to complete this trial by the end of 2016. A single 'boost' dose of 8 Gy is delivered post-operatively to the tumor bed plus a 10mm margin using the GammaPod™, followed by whole breast irradiation with either hypofractionation of 15 fractions or a conventional fractionation scheme of 25 fractions. Eligibility criteria include minimum age of 60, with Stages I or II breast cancer, lumpectomy volume less than 30% of the whole breast volume, and the lumpectomy within the immobilized breast. Prior to treatment, the affected breast is immobilized with a patented vacuum-assisted breast cup and imaged on a CT simulator with 1 mm slice thickness. Once the cup is placed, the negative pressure is maintained until the treatment is delivered. An inversely optimized treatment plan is generated while the patient is transported and positioned in the treatment room. Typical time between the imaging session and completion of treatment is about 60 minutes.

## Results

5 of the first 6 enrolled patients completed the treatment. One patient's lumpectomy cavity extended outside the immobilized portion of the breast and therefore did not meet the inclusion criteria for the study. With the sources near its half-life, the treatment time ranged from 17 minutes to 26 minutes. Dosimetrically, for the 5 patients who completed their treatment, more than 95% of the prescription dose covered the clinical target volume, and the maximum dose ( $D_{2\%}$ ) varied from 13% to 20% of the prescription dose (see figure of sample dose distribution). With a median follow-up of 3 months, none of the patients developed treatment related toxicity.

## Conclusion

Initial results indicate that the GammaPod system can deliver a focal dose of radiation to the breast safely. The vacuum-assisted breast cups were able to maintain the immobilization between imaging and treatment. With dynamic dose painting, the dose uniformity rivals that of external beam partial breast irradiation, but with more rapid dose fall-off outside the target, leading to substantially reduced radiation dose to the normal breast. The ability of delivering a focal dose of radiation opens the opportunity for single pre-operative irradiation as an alternative to intra-operative irradiation and pre-operative radioablation.

## EP-1184 HDR boost decreases the risk of breast failure in invasive breast ca. with close or involved margins

J.L. Guinot<sup>1</sup>, M.I. Tortajada<sup>1</sup>, M.A. Santos<sup>1</sup>, F. Romero<sup>1</sup>, A. Moreno<sup>2</sup>, V. Campo<sup>3</sup>, L. Oliver<sup>3</sup>, P. Santamaria<sup>1</sup>, J. Fernandez<sup>4</sup>, L. Arribas<sup>1</sup>

<sup>1</sup>Fundación Instituto Valenciano de Oncología, Department of Radiation Oncology, Valencia, Spain

<sup>2</sup>Fundación Instituto Valenciano de Oncología, Department of Radiation Oncology, Alcoy Alicante, Spain

<sup>3</sup>Fundación Instituto Valenciano de Oncología, Department of Radiation Physics, Valencia, Spain

<sup>4</sup>Fundación Instituto Valenciano de Oncología, Department of Radiation Oncology, Cuenca, Spain

### Purpose or Objective

The risk of breast failure after breast-conserving treatment is two-fold higher in invasive carcinoma with positive surgical margins than in free margins, (between 12 and 34% at ten years) (1). A new resection is recommended, with risk of fair cosmetic result, or mastectomy. With close margin total dose should be higher to avoid local recurrence. Twenty years ago, we started with a high dose rate (HDR) boost after whole breast irradiation in cases with close or positive margin. We review the long-term outcome in these high risk cases

### Material and Methods

Between 12.1996 and 12.2011, 248 patients were included, with a median age of 55 (22-90). Mean FU 127 months. By T stage 179 T1, 62 T2 and 6 T3. By margin status, 120 was positive, 76 close until 2mm, 52 close >2mm and <5mm. All of them were treated with whole breast irradiation (WBI) 50Gy plus HDR boost with 3 fractions of 4.4Gy to 85% isodose in two days, with rigid needles. The contour of CTV was decided by clinical assessment, no CT planning was used. Chemotherapy was used in 52%, and hormonal treatment in 76%. Survival was calculated by Kaplan Meyer method.

### Results

In the whole population, actuarial breast failure at 10 and 15 years was 6.5% and 11.6%. With positive margin: 6.8% and 14.8%, with close margin  $\leq 2$ mm: 9.8% and 9.8%, with margin >2mm <5mm, 2% and 2%. By age, in 90 patients aged 50 or younger, was 11.9% and 17.8%, between 51-70, 3.8% and 8.2%, and no failures over 70. In young women under 50 with positive margin, breast recurrence was 13.1% and 24% at 10 and 15 years. By T stage, no differences between T1 and T2, no failures in T3. No differences if margin was due to invasive carcinoma or DCIS, in G3, or depending on hormonal receptors. Fibrosis or induration were registered in 26.7%, breast edema 6.5%, volume reduction 6.5%, telangiectasia 3.4%, hyperpigmentation 2.1%. Cosmetic outcome was excellent/good in 85.8%.

### Conclusion

Long-term breast control of patients with positive or close surgical margin using WBI plus a HDR boost is similar to that achieved with free margins in the EORTC 22881-10882 trial, in all groups of age, but in young women with positive margin where a new resection is recommended. This approach is useful to avoid a second intervention, in women over 50 with positive surgical margin, or with close margins in all ages.

### Purpose or Objective

Skin sparing mastectomy (SSM) and nipple-sparing mastectomy (NSM) have entered routine surgical practice for breast cancer, though their oncologic safety has not been established in randomized controlled trials. The aim of this study was to evaluate breast surgeons' opinions concerning the indications of post-operative radiation after SSM and NSM.

### Material and Methods

Breast surgeons from North America, South America and Europe were invited to contribute in this study. A 22-question survey was mailed to participating breast surgeons to evaluate their opinions. The indications of post-operative radiation after SSM and NSM.

### Results

A total of 252 breast surgeons answered the questionnaire. Most of them had at least 10 years of post-residency practice. The majority of breast surgeons affirmed that post-operative radiation should be performed in early-stage (stages I and II) breast cancer for patients who present with risk factors for relapse after SSM and NSM (85.0% and 81.0%, respectively). They considered age, lymph node involvement, tumor size, extracapsular extension, involved surgical margins, lymphovascular invasion, triple negative receptor status and multicentric tumor as major risk factors. Considering tumor size, lymph node involvement and age as recurrence risk factors, the most-often suggested cut-off thresholds of those features were 5 cm, > 3 lymph nodes and 40 years old, respectively. Considering that after SSM and NSM, residual breast tissue can be left behind, the residual tissue considered as acceptable in the context of an oncologic surgery were 1 to 5 mm and 6 to 10 mm for 55% and 21% of the responders, respectively. There is no consensus for the necessity of evaluating residual breast tissue through breast imaging.

### Conclusion

Although the indications of post-operative radiation therapy after SSM and NSM are not well defined, all standard relapse risk factors were considered as important, by surgeons, with regards to referring for post-operative radiation therapy.

### EP-1186 Real-time intrafraction motion in breast radiotherapy using an optical surface scanner

D. Reitz<sup>1</sup>, S. Schönecker<sup>1</sup>, P. Freislederer<sup>1</sup>, M. Pazos<sup>1</sup>, M. Niyazi<sup>1</sup>, U. Ganswindt<sup>1</sup>, C. Belka<sup>1</sup>, S. Corradini<sup>1</sup>

<sup>1</sup>LMU University of Munich, Radiation Oncology, Munich, Germany

### Purpose or Objective

Intrafraction motion is of special interest in modern breast cancer radiotherapy. Respiratory motion during intensity-modulated radiotherapy (IMRT) can cause problems in inadequate planning target margins or IMRT delivery. To date, only few data exist on real-time measured intrafraction motion in breast cancer patients. Continuous surface imaging using visible light offers the possibility to monitor patients' movements in 3D-space without any additional radiation exposure.

### Material and Methods

We observed thirty-one patients during 629 fractions that underwent postoperative radiotherapy following breast conserving surgery or mastectomy. During each treatment session the motion of the patient was continuously measured using the Catalyst™ optical surface scanner (C-

RAD AB, Sweden) and compared to a reference scan taken at the beginning of each session. The Catalyst™ system works through an optical surface scanning with LED light (blue:  $\lambda = 450$  nm) and reprojection captured by a CCD camera (green:  $\lambda = 528$  nm; red:  $\lambda = 624$  nm), which provide target position control during treatment delivery. For 3D surface reconstruction, the system uses a non-rigid body algorithm to calculate the distance between the surface and the isocenter and using the principle of optical triangulation. Three-dimensional deviations and relative position differences during the whole treatment fraction were calculated by the system and analyzed statistically.

#### Results

Overall, the magnitude of the deviation vector showed a mean change of 1.3 mm +/- 0.4 mm (standard deviation) and a median change of 1.1 mm during dose application (beam-on time only). Along the lateral and longitudinal axis changes were quite similar (0.9 mm +/- 0.3 mm vs. 0.9 mm +/- 0.5 mm), on the vertical axis the mean change was 1.1 mm +/- 0.3 mm. The mean net beam-on time of radiation therapy was 2.8 minutes. There was no linear correlation between the length of the fraction and the magnitude of deviation. Pearson's correlation coefficient between mean time and mean magnitude of deviation vector over all patients was 0.25 (p-value= 0.175).

#### Conclusion

Mean real-time intrafraction motion was within two millimeters in all directions and is therefore of minor clinical relevance in postoperative radiotherapy of breast cancer.

#### EP-1187 Heart dose evaluation in two free-breathing and deep-breathing modes of breast cancer patients

R. Anbiae<sup>1</sup>, A.R. Tajiri<sup>1</sup>, A. Ahmari<sup>1</sup>, Z. Siavashpour<sup>2</sup>, M. Beigi<sup>1</sup>

<sup>1</sup>Shahid Beheshti Medical University, Radiation Oncology, Tehran, Iran Islamic Republic of

<sup>2</sup>Shahid Beheshti University, Medical Radiation Engineering, Tehran, Iran Islamic Republic of

#### Purpose or Objective

To investigate how much respiratory manner of breast cancer patients during external beam radiotherapy would affect their heart dose.

#### Material and Methods

21 patients with left breast cancer underwent CT simulation without contrast in one day and two positions; breath hold and free breathing, prospectively. Two CT image sets were imported to treatment planning system (Eclipse, version 6). Volumes of PTV (that included breast and chest wall), heart and ipsilateral lung in both image sets were contoured by an individual radiation oncologist. An experienced physicist designed the plans for both CTs. Prescribed dose was 50 Gy in 25 fractions for all included cases. Plans were then confirmed by the oncologist and heart and lung dose volume parameters were exported. Lung and heart Volumes, their V30 and V22.5 and also mean heart dose (MHD) in two condition were studied and analyzed.

#### Results

Mean age of patients was 46.9±12.1. Twelve patients had done MRM and 9 of them had done BCS. Mean heart volume, its V30, V22.5 and MHD in two breathing conditions, breath hold and free breathing, were 519±108 and 526±107 (P=0.545), 1.89±2.41 and 62.88±2.04 (P=0.030), 2.41±2.68 and 4.35±3.42 (P=0.048) and 0.98±0.7 and 1.42±0.5 (P=0.002), respectively. Also left lung volume and V30 of lung in breath hold and free breathing modes were 1763±315 and 1114±219 (P<0.001) and 8.72±3.27 and 8.92±4.29 (P=0.819) respectively. Person correlation did not show linear relation between lung volume and its mentioned DVH parameters; for MHD obtained r=-0.421 (P=0.057), for heart V30 and V22.5

obtained r=-0.500 (P=0.021) and obtained r=-0.371 (P=0.097) and also, for heart volume r=0.032 (P=0.889).

#### Conclusion

All MHD and heart V30 and V22.5 variables were significantly higher with deep breathing in our study. It was shown that irritated heart volume was reduced significantly in this condition. V30 of lung were lower in deep breathing so deep breathing can be efficient method in left breast teletherapy.

#### EP-1188 DIBH radiotherapy in left-sided breast cancer patients using an optical surface scanning system

S. Schönecker<sup>1</sup>, M. Pazos<sup>1</sup>, P. Freislederer<sup>1</sup>, D. Reitz<sup>1</sup>, H. Scheithauer<sup>1</sup>, S. Corradini<sup>1</sup>, C. Belka<sup>1</sup>

<sup>1</sup>LMU University of Munich, Radiation Oncology, Munich, Germany

#### Purpose or Objective

There is a potential for adverse cardiovascular effects in long-term breast cancer survivors following adjuvant radiotherapy (RT). For this purpose, the deep inspiration breath-hold technique (DIBH) has been introduced into clinical practice, to maximally reduce the radiation dose to the heart. In the present study radiotherapy in DIBH was applied using the optical surface scanning system Catalyst™/Sentinel™.

#### Material and Methods

A total of 38 patients with left-sided breast cancer following breast conserving surgery were analysed. Normofractionated and hypofractionated radiotherapy protocols were eligible for this prospective clinical trial. Patient surface data and respiratory parameters were acquired using the laser surface scanner Sentinel™ (C-RAD AB, Uppsala, Sweden) during CT acquisition in free breathing (FB) and DIBH. Dual treatment plans were created and dosimetric output parameters of organs at risk were compared using Wilcoxon signed-rank test. For treatment application the optical surface scanner Catalyst™ (C-RAD AB, Uppsala, Sweden) was used and gating control was performed with an individual audio and video glasses-based feedback system. The Catalyst™ is interconnected to the LINAC systems via a gating interface and allows for a continuous and touchless surface scanning.

#### Results

Following initial patient training and treatment setup, radiotherapy in DIBH with the Catalyst™/Sentinel™ system was time-efficient and reliable. 30 of 38 patients were treated using normofractionated treatment protocols. In these patients, the reduction of the mean heart dose for DIBH compared to FB was 43.2 % (2.45 to 1.39 Gy; p < 0.001). The maximum doses to the heart and LAD were reduced by 47.2 % (41.3 to 21.8 Gy; p < 0.001) and 61.7 % (31.2 to 11.9 Gy; p < 0.001), respectively. For 8 hypofractionated regimes the reduction of the mean heart dose for DIBH compared to FB was 50.1 % (2.13 to 1.06 Gy; p = 0.012). The maximum doses to the heart and LAD were reduced by 49.7 % (38.8 to 19.5 Gy; p = 0.012) and 77.3% (29.9 to 6.8 Gy; p = 0.012), respectively. Overall, also the mean lung dose and the V20 of the ipsilateral lung were significantly lower (-16.1 % and -17.8 %) for DIBH (Lung<sub>Mean</sub> 6.64 Gy; Lung V<sub>20</sub> = 11.7 %) compared to FB (Lung<sub>Mean</sub> 7.92 Gy; Lung V<sub>20</sub> = 14.2 %; p each <0.001).

#### Conclusion

The Catalyst™/Sentinel™ system enabled a fast and reliable application and surveillance of DIBH in daily clinical routine. Furthermore, the present data confirm that using the DIBH technique during RT could significantly reduce high dose areas and mean doses to the heart.

### EP-1189 Right Coroner Artery Assessment in Radiotherapy of Breast Cancer

A. Altınok<sup>1</sup>, O. Askeroğlu<sup>2</sup>, M. Çağlar<sup>1</sup>, M. Doyuran<sup>1</sup>, E. Cantürk<sup>3</sup>, C. Erol<sup>4</sup>, N. Bese<sup>2</sup>

<sup>1</sup>Medipol University, Radiation Oncology, Istanbul, Turkey

<sup>2</sup>Acıbadem University, Radiation Oncology, Istanbul, Turkey

<sup>3</sup>Medipol University, Cardiovascular Surgery, Istanbul, Turkey

<sup>4</sup>Medipol University, Radiology, Istanbul, Turkey

#### Purpose or Objective

The risk of developing coronary ischemic heart disease and the radiation doses to heart and left anterior descending coronary artery (LAD) have been very well documented in breast cancer patients who underwent radiotherapy (RT). On the other hand, there is limited information regarding the right coronary artery (RCA) doses which feeds the heart in 48% of the human population. In this study proximal RCA (pRCA) doses are evaluated in the treatment plans of breast cancer patients who underwent RT.

#### Material and Methods

RCA was contoured with a radiologist in 40 patients. Group A included patients with right-sided breast cancer who underwent only tangential breast RT. Group B included right-sided breast cancer patients who received internal mammary (IM) chain RT in addition to breast. Group C included left-sided breast cancer patients with only tangential breast RT and Group D included left-sided breast cancer patients who received IM chain RT in addition to breast. The distribution of the number of patients in each group was equal. 3D conformal radiotherapy planning technique was used for all patients. The mean and maximum point doses of RCA, LAD and heart were calculated in the final dose volume histogram. One-way ANOVA test was used to determine the independent group variances and Tamhane's T2 test was used for comparison of pairwise differences.

#### Results

The mean and maximum (max) doses for Group A, Group B, Group C and Group D are calculated in cGy as 131mean-202max, 192mean-284max, 64mean-113max and 113mean-174max, respectively. In pairwise comparisons, pRCA mean doses for right breast group are statistically higher than left breast and not different than left breast with IM. pRCA mean doses for right breast with IM group are the highest. There is no difference in mean pRCA doses between left breast and left breast with IM. However, mean pRCA doses for left breast with IM is lower than right breast with IM. pRCA max values for right breast and right breast with IM are statistically higher than only left breast, there is no difference between them and left breast with IM.

The doses for heart and LAD is higher, as expected, in Group C and Group D than Group A and Group B. Figures are listed in Table-1.

#### Conclusion

pRCA receives 130 to 190 cGy when Group A and Group B are irradiated. Especially, when IM is included in RT field with right breast (Group B), pRCA doses are at the highest. But, increase in pRCA dose is not observed in left breast with IM (Group D). Furthermore, pRCA doses for Groups A and B are not as high as LAD doses in left breast and left breast with IM is irradiated. It may be necessary, as in the case for LAD, to include pRCA in planning and constrain the dosage delivered. The correlation between the dosage and ischemic heart disease needs to be established.

Table-1

	Group A	Group B	Group C	Group D
pRCA-mean	131	192	64	113
pRCA-max	202	284	113	174
LAD-mean	7.9	36.8	356	398
LAD-max	28	81	1733	1249
Heart-mean	42	76	121	147

### EP-1190 Assessment of the dose to the heart and the LAD for the left breast radiotherapy

A. Plieskienė<sup>1</sup>, D. Burdulis<sup>1</sup>, J. Remeikienė<sup>1</sup>

<sup>1</sup>Klaipeda University Hospital, Radiotherapy centre, Klaipeda, Lithuania

#### Purpose or Objective

Radiotherapy for left breast cancer may increase risk of cardiovascular diseases. Exposing the anterior portion of the heart and left anterior descending coronary artery (LAD) to the highest radiation dose depends on individual anatomical location of these structures.

The purpose of this work was to assess the radiation doses delivered to the heart and the LAD for the left sided breast cancer patients treated with 3D conformal radiotherapy.

#### Material and Methods

Thirty two randomly selected patients referred for adjuvant radiotherapy after breast-conserving surgery for left-sided breast cancer in 2014-2016: all women, age ranging from 36 to 85 years, median 59 years, at the time of treatment. The radiotherapy target volume typically encompasses the remaining breast tissue after resection of the tumor and, in cases with lymph node metastases, also the regional lymph node areas. Prescribed total radiation dose to the planning target volume (PTV) was 50 Gy in 25 daily fractions (5 fractions a week; delivered in 5 weeks).

The dose to the 5% and 10% of heart volume and average mean heart dose were evaluated. The  $D^{max}$ ,  $D^{mean}$  and  $V^{20}$  (10% of the contoured volume received 20 Gy or more) of LAD in comparison with  $LAD^{arch}$  were assessed.

The acceptability of the radiotherapy plans in this study is then analysed assessing the dose delivered to the whole heart (1), the  $LAD^{arch}$  (2) and the whole LAD (3). The whole LAD is considered to be receiving a high dose when over 10% of the contoured volume received 20 Gy or more.

#### Results

For all 32 patients, the plans are acceptable based on the criteria for whole heart and  $LAD^{arch}$ . The results of this study showed that the mean doses to the three cardiac structures are 1,88 (range, 1,25-3,98 Gy) for the heart, 7,3 (range, 3,82-17,15 Gy) for the  $LAD^{arch}$  and 9,64 (range, 3,24-27,84 Gy) for the LAD.

Most important results shows, that for 11 patients the heart  $D^{mean}$  was only 2,15 (range, 1,37 - 3,98), while a significant dose to the whole left anterior descending interventricular branch being delivered.

We found 4 cases, in which the dose to the  $LAD^{arch}$  was with marginal increase, but significant portion of the heart and whole LAD is included in the field. There were no cases where the dose to the  $LAD^{arch}$ , LAD and whole heart dissociated. But in 7 cases the dose to the  $LAD^{arch}$  was relatively low, however the dose to the whole LAD was significantly higher (14,6-37,6% of the contoured volume received over 20 Gy).

#### Conclusion

Evaluation of the mean dose to the heart only could lead to excessive heart irradiation. The results of the study indicate that it is necessary to assess the dose delivered to the whole heart as well as to the whole LAD for evaluation of the left breast irradiation treatment plan. This is very important to minimise the risk of clinically significant cardiac events after left breast radiotherapy.

### EP-1191 Postmastectomy locoregional irradiation to temporary tissue-expander or permanent breast implant

M.A. Gerardi<sup>1</sup>, D.P. Rojas<sup>2</sup>, R. Ricotti<sup>1</sup>, M.C. Leonardi<sup>1</sup>, G. Riva<sup>2</sup>, D. Ciardo<sup>1</sup>, C.M. Francia<sup>2</sup>, R. Cambria<sup>3</sup>, R. Orecchia<sup>6</sup>, B.A. Jereczek-Fossa<sup>2</sup>

<sup>1</sup>European Institute of Oncology, Department of Radiation Oncology, Milan, Italy

<sup>2</sup>European Institute of Oncology - University of Milan, Department of Radiation Oncology - Department of Oncology and Hemato-oncology, Milan, Italy

<sup>3</sup>European Institute of Oncology, Department of Medical Physics, Milan, Italy

<sup>4</sup>European Institute of Oncology, Department of Plastic and Reconstructive Surgery, Milan, Italy

<sup>5</sup>European Institute of Oncology, Department of Surgery, Milan, Italy

<sup>6</sup>European Institute of Oncology - University of Milan, Department of Medical Imaging and Radiation Sciences - Department of Oncology and Hemato-oncology-, Milan, Italy

#### Purpose or Objective

The aim of the study (partially supported by a research grant from Accuray Inc. entitled "Data collection and analysis of Tomotherapy and CyberKnife breast clinical studies, breast physics studies and prostate study") is to evaluate acute and intermediate toxicity in postmastectomy patients with implant-based immediate breast reconstruction receiving locoregional intensity modulated radiotherapy (IMRT) with a hypofractionated scheme.

#### Material and Methods

Data of the first 121 consecutive post-mastectomy locoregional patients treated with Helical Tomotherapy between May 2012 and May 2015 with a hypofractionated scheme (2.67Gy/fr, 15 fractions) have been prospectively collected. Breast reconstruction was performed with temporary tissue expander implantation in 57% of patients (69/121 expander-patients) and with permanent prosthesis in 43% of patients (52/121 prosthesis-patients). Acute toxicity was evaluated using RTOG/EORTC criteria, while late toxicity was recorded according to LENT/SOMA scale.

#### Results

All patients completed the treatment course without interruption for toxicity. In the expander group, one patient died for leukemia 20.3 months after radiotherapy and two had distant metastasis. Acute toxicity was assessed in 121 patients (mean follow up: 2.4 months, range: 0-8.1 months). No patient experienced grade >2 toxicities (edema, erythema or desquamation). No significant difference (p=0.06) in acute toxicities were observed between the type of allogenic reconstruction: 43.5% (30/69) of expander-patients and 26.9% (14/52) of prosthesis-patients presented toxicities of grade 2. The most common toxicity was edema, which was of grade 2 in 33.3% (23/69) of the expander-patients and 21.2% (11/52) of prosthesis-patients (p=0.141). Grade 2 acute erythema was observed in 14.5% (10/69) of expander-patients and 7.7% (4/52) of prosthesis-patients (p=0.249). Statistically significant (p=0.04) higher incidence of grade 2 edema was found in patients with high BMI. This was found also in the prosthesis-patient subgroup (p=0.05). Intermediate toxicity was evaluated at a median follow up of 14.2 months (range: 5.8-35.0) on 85 patient (54 expander-patients and 31 prosthesis-patients). No grade ≥2 skin dryness, telangiectasia, ulcer, hypo- and hyper-pigmentation were reported (Tab.1).

Tab1. Intermediate toxicity evaluated at a median follow up of 14.2 months (range: 5.8-35.0) on 85 patient (54 belonging to the tissue expander subgroup and 31 belonging to the prosthesis subgroup).

\* The evaluation of fibrosis was performed on 83 patients (52 expander-patients and 31 prosthesis patients).  
\* \*The evaluation of edema was performed on 73 patients (48 expander-patients and 25 prosthesis patients).  
\*\*\* The evaluation of the arm lymphedema was performed on 79 patients (50 expander-patients and 29 prosthesis patients).

#### Conclusion

Acute toxicity of Helical Tomotherapy-based IMRT after immediate breast reconstruction was satisfactory and intermediate toxicity was acceptable. Based on this preliminary analysis, hypofractionation might be considered also in the settings of locoregional treatments, providing advantages for patients' convenience and for fruitful use of resource.

### EP-1192 Assessment of quality of life in phase III clinical trials of radiation therapy in breast cancer

G.N. Marta<sup>1,2</sup>, F.Y. Moraes<sup>3</sup>, E.T. Leite<sup>2</sup>, E. Chow<sup>4</sup>, D. Cella<sup>5</sup>, A. Bottomley<sup>6</sup>

<sup>1</sup>Hospital Sirio-Libanês, Radiation Oncology, São Paulo, Brazil

<sup>2</sup>Instituto do Câncer do Estado de São Paulo ICESP - Faculdade de Medicina da Universidade de São Paulo, Radiation Oncology, Sao Paulo, Brazil

<sup>3</sup>Princess Margaret Cancer Center- University of Toronto, Radiation Oncology, Toronto, Canada

<sup>4</sup>Sunnybrook Odette Cancer Centre- Sunnybrook Health Sciences Centre, Radiation Oncology, Toronto, Canada

<sup>5</sup>Northwestern University, Medical Social Sciences, Chicago, USA

<sup>6</sup>European Organisation for Research and Treatment of Cancer Headquarters, Quality of Life, Brussels, Belgium

#### Purpose or Objective

The aim of this study was to investigate the magnitude to which health-related quality of life (HRQOL) parameters have been used in phase III studies on breast cancer patients who received post-operative radiation therapy, as well as the frequency and correlates of significant HRQOL gains.

#### Material and Methods

A systematic review in accordance with The Cochrane Collaboration Handbook of Interventions Systematic Reviews was performed. Only prospective phase III clinical trials in patients with breast cancer were included. Eligible trials must state radiation therapy as the main element of treatment in at least one of the groups. With regard to HRQOL as an endpoint in the studies, we first attempted to identify any mention in the paper of HRQOL data collection during the trial, or, when no such mention were found, the existence of a companion paper dedicated to HRQOL analysis separately. When HRQOL was a study endpoint, we collected data on the instruments used for HRQOL analysis, assessing if there was formal statistical comparison between study groups and the

results of such comparisons as reported by the authors of the studies.

### Results

The search strategy retrieved 2224 references. Of these, 271 publications, corresponding to 182 trials fulfilled the eligibility criteria and were the subject of this analysis. HRQOL was considered as endpoint in 38 (20.8%) of the included studies and it was used as primary endpoint in 10.9% of them. Most trials (84.0%) focused on biomedical intervention. Of 22 trials that had a positive primary endpoint, 18 had a significant benefit in HRQOL, in favor of the experimental arm. Of 13 trials that had a negative primary endpoint, there were no differences in HRQOL among the study groups. In regards of HRQOL assessment, statistical methods and definition of timing of evaluation were described 32 (84.2%) and 36 (94.7%) trials, respectively. The European Organization for the Research and Treatment of Cancer Quality-of-Life Questionnaire (EORTC-QLQ) (C-30 with or without BR23) alone or plus additional measures was the most frequently used tool in 17 (44.7%) of 38 studies. Eighteen trials (47.4%) used two or more HRQOL assessment tools. The Functional Assessment of Cancer Therapy (global or breast) with or without additional measures were used in 9 (23.6%) of 38 trials.

### Conclusion

This analysis shown that HRQOL has been infrequently investigated in phase III trials of radiation therapy in breast cancer. Statistical methods and timing of evaluation were not always described with sufficient detail. Significant benefit in HRQOL was frequently reported in those trials that reported a positive primary endpoint.

### EP-1193 Hypofractionated external beam radiation therapy for breast cancer. The new standard?

L. Nobre Góis<sup>1</sup>, A. Ponte<sup>1</sup>, J. Casalta-Lopes<sup>1</sup>, T. Teixeira<sup>1</sup>, P. Vicente<sup>1</sup>, M. Borrego<sup>1</sup>

<sup>1</sup>Hospitais da Universidade de Coimbra, Servico de Radioterapia, Coimbra, Portugal

### Purpose or Objective

Hypofractionated external beam radiation therapy (HRT) consists in the administration of higher than conventional dose per fraction, leading to reduced overall treatment time and increased compliance to treatment, at lower costs for hospital and patient. Several randomized phase III trials show HRT as an alternative to conventional fractionation in the adjuvant setting after breast conserving surgery, with similar outcomes regarding local control and side effects. The most commonly used HRT schedules include 42.6 Gy / 16 fractions or 40 Gy / 15 fractions, as stated in international recommendations. In this study we aim to assess toxicity after conservative surgery followed by HRT in breast cancer patients.

### Material and Methods

Prospective inclusion of patients with invasive breast cancer submitted to breast conserving surgery, treated in our Radiation Oncology department between March 2014 and June 2016, aged over 60 years, hormone receptor-positive, HER2-negative, tumor histological grade G1-G2, margins exceeding 1 mm, staged pT1-T2 pN0 cM0, with an adequate dosimetric study. A dose of 40 Gy was delivered in 15 fractions (2.67 Gy / fraction), followed by a boost to the tumor bed of 10 to 16 Gy in 5 to 8 fractions (2.0 Gy / fraction). Acute toxicity (CTCAE4.0 scale) and heart and lung dosimetric parameters were recorded.

### Results

Of the 74 patients accepted for HRT, 2 were excluded due to failure on dosimetric assessment or the presence of complex sclerosing lesion. 72 included patients with a median age of 65 years (60-79 years), tumors mainly located on the left breast (58.3%) and upper quadrants

(65.3%). Invasive carcinoma not otherwise specified (NOS) was present in 91.7%, staged pT1b in 37.5% and pT1c in 52.8%. Boost was prescribed with a dose of 10Gy in 63.9% of patients. The median values of the dosimetric parameters evaluated were Heart V25 of 3.10% (0%-16.68%) and Lung V20 of 11.13% (2.5%-24.38%). All patients completed the originally planned schedule, 97.2% presenting acute cutaneous toxicity (any grade), grade 3 in only 5 patients (6.9%). No other complications were registered during treatment. Median follow-up was 10 months (3-25 months). In the first follow-up visit toxicity was observed in 55.6% patients, with erythema/pigmentation (grade 1-2) in 29.2%, breast edema in 23.5% and fibrosis in 8.3%. One patient had symptomatic radiation related pneumonitis, with full resolution after therapy. Of the 47 patients already observed in subsequent follow-up appointments, there was visible fibrosis in 11 patients, edema in 7 patients, breast shrinkage in one patient and telangiectasia in another patient.

### Conclusion

Hypofractionated radiation therapy schedules allow for excellent treatment compliance with an acceptable toxicity profile and a good cosmetic result. A longer follow-up will allow increased accuracy in late side effects evaluation.

### EP-1194 Dose-volume relationship for acute skin erythema in patients undergoing breast irradiation

F. Badenchini<sup>1</sup>, F. Bonfantini<sup>2</sup>, M. De Santis<sup>3</sup>, S. Gay<sup>1</sup>, F. Palorini<sup>1</sup>, A. Cicchetti<sup>1</sup>, T. Rancati<sup>1</sup>, M. Carrara<sup>2</sup>, T. Giandini<sup>2</sup>, E. Pignoli<sup>2</sup>, R. Valdagni<sup>3</sup>, L. Lozza<sup>3</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milan, Italy

<sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy

<sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milan, Italy

### Purpose or Objective

Standard 3DCRT after breast conserving surgery (BCS) may cause skin toxicity with a wide range of intensity including acute effects like erythema or late effects. In order to reduce these side effects it is advisable to identify potential factors of influence in breast cancer patients undergoing 3DCRT of the breast and modern systemic therapy

### Material and Methods

breast cancer patients consecutively treated in our institution with 3D-CRT after BCS (50 Gy whole breast photon radiotherapy followed in same cases by 10 OR 16 Gy photon OR electron boost to the tumor bed) were evaluated with special focus on documented skin toxicity during RT course.

Acute skin erythema (AE) was visually assessed and recorded using the RTOG scoring system, before RT and every 5 fractions. In this study, grade 2-3 AE during RT was considered as the primary endpoint.

A number of relevant clinical risk factors was prospectively recorded: age, skin phototype, smoking habits, use of drugs, neoadjuvant chemotherapy with anthracyclines and/or taxanes and/or trastuzumab, hormone therapy with tamoxifen or aromatase inhibitors, comorbidities and related drugs, T stage, location of breast surgery.

Dosimetric feature were extracted from the skin dose-volume histogram for the whole treatment (DVH, absolute volume in cc), with skin defined as the difference between the body contour and a 5mm inner isotropic contour from the body.

Dosimetric and clinical variables were included into multivariable logistic regression. Goodness-of-fit was

evaluated through Hosmer-Lemeshow test (HL) and calibration plot.

#### Results

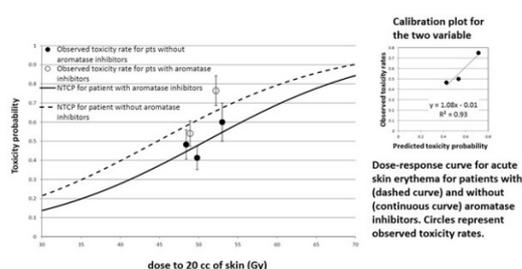

a total of 147 breast cancer patients (median age 55 years, range 34-77) were enrolled.

Grade 1, 2 and 3 AE were 65/147 (44%), 52/147 (35%) and 24/147 (16%), respectively.

At univariate analysis only the dose to 20 cc of breast and use of aromatase inhibitors vs tamoxifen resulted as predictive factors for toxicity (61.8% vs 17.9%,  $p > 0.01$ , for aromatase inhibitors vs tamoxifen, respectively).

ML resulted in a two variable model including the dose to 20 cc of skin (continuous variable,  $OR = 1.09$ ,  $10^{th}$ - $90^{th}$  percentile 1-1.19) and use of aromatase inhibitors ( $OR = 1.7$ ,  $10^{th}$ - $90^{th}$  percentile 1.1-2.7). Calibration was good (HL test  $p = 0.35$ , calibration slope 1.08). Results for model and calibration are presented in the figure.

Smoking also resulted to be a risk factor ( $OR = 4$ ) in a reduced population (87 pts), it was not directly inserted into ML model due to the high prevalence of missing values, but it deserves attention and further analysis

#### Conclusion

this analysis shows that moderate/severe acute skin erythema is related to skin DVH, particularly to the dose to 20cc of skin. In the frame of the here used skin definition, this approximately corresponds to an area of  $6 \times 6 \text{ cm}^2$ . Use of aromatase inhibitors acts as a dose sensitizing factor for kind of toxicity.

#### EP-1195 Regional nodal recurrences after adjuvant breast radiotherapy - are we covering the target?

L.E. Beaton<sup>1</sup>, L. Nica<sup>1</sup>, K. Sek<sup>2</sup>, G. Ayers<sup>1</sup>, C. Speers<sup>3</sup>, S. Tyldesley<sup>1</sup>, A. Nichol<sup>1</sup>

<sup>1</sup>British Columbia Cancer Agency, Radiation Oncology, Vancouver, Canada

<sup>2</sup>British Columbia Cancer Agency, Radiology, Vancouver, Canada

<sup>3</sup>British Columbia Cancer Agency, Breast Outcomes Unit, Vancouver, Canada

#### Purpose or Objective

For all breast cancer patients, adjuvant radiotherapy (RT) reduces locoregional recurrence and for high risk patients, regional nodal irradiation (RNI) improves overall survival. However, there is limited data on the anatomical location of regional nodal recurrence (RNR) after adjuvant RT. Nodal radiotherapy fields have historically been defined using anatomical landmarks but with the advent of 3D radiotherapy planning nodal contouring atlases have been developed. Validation of these atlases is scarce. Our objective was to map the location of RNR in patients previously treated with adjuvant RNI, and assess whether the treating RT fields provided adequate coverage. We also assessed whether these areas of RNR were within the boundaries of the Radiation Therapy Oncology Group (RTOG) nodal atlas.

#### Material and Methods

Between 2005 and 2013, we identified 32 patients previously treated with definitive surgery and adjuvant RNI for breast cancer that developed RNR detected with 18-fluorodeoxyglucose positron emission tomography

(FDG-PET) imaging, before salvage treatment for RNR. FDG-PET positive regional lymph nodes were contoured on each individual PET scan. Deformable registration was used to fuse the FDG-PET scan with the patient's original RT simulation scan, onto which the RTOG atlas had been retrospectively contoured. Each nodal area of recurrence was categorized as: in-field, defined as  $\geq 95\%$  of the RNR volume receiving  $\geq 95\%$  prescribed dose; marginal, RNR receiving  $< 95\%$  prescribed dose; and out of field, RNR not intentionally covered with the original RT plan. RTOG coverage was defined for each RNR as 'inside', 'marginal' or 'outside'.

#### Results

Of the 32 patients, 12 (37%) had limited RNR and 20 (63%) had RNR in addition to distant metastatic disease on FDG-PET imaging. 27 (84%) patients received full axillary RT, 3 (9%) supraclavicular fossa (SCF) only, and 14 (44%) internal mammary node (IMN) RT. Of the 87 nodal relapses, 17 (20%) were out of field. Of those intentionally treated, 10 (33%) patients developed SCF relapse, 18 (66%) axillary relapse and 5 (36%) IMN relapse. 15 (68%) of SCF, 20 (50%) axillary and 1 (14%) IMN nodes were in-field axilla and 0 (0%) of IMN nodal relapses.

Image 1: Areas of regional nodal relapse

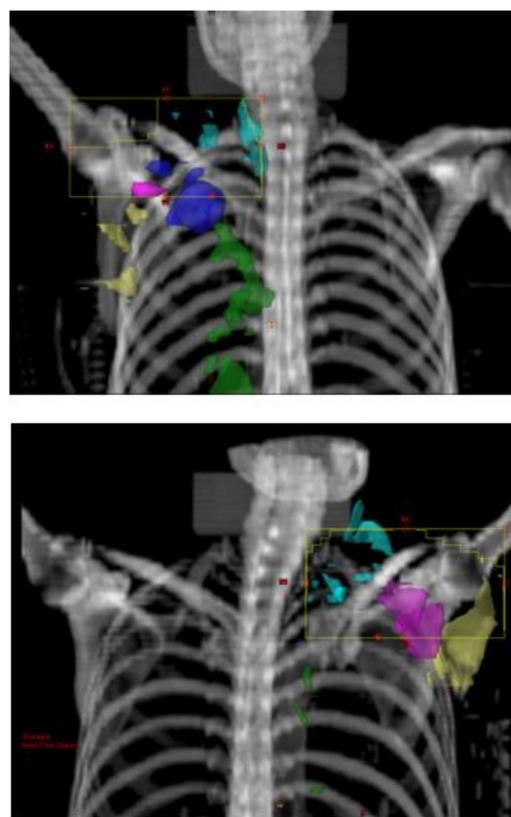

Table 1: Regional Nodal Relapse (RNR)

	SCF	IMN	Axilla 1	Axilla 2	Axilla 3	Axilla (all)
No: patients treated						
RNI	30 (94%)	14 (44%)	27 (84%)	27 (84%)	27 (84%)	27 (84%)
No RNI	2 (6%)	18 (56%)	5 (16%)	5 (16%)	5 (16%)	5 (16%)
No: patients with nodal relapse						
RNI	10 (91%)	5 (36%)	15 (88%)	3 (75%)	5 (71%)	18 (86%)
No RNI	1 (9%)	9 (64)	2 (12%)	1 (25%)	2 (29%)	3 (14%)
Number of FDG-PET nodes						
RNI	22 (96%)	7 (36%)	24 (92%)	5 (83%)	11 (85%)	40 (89%)
No RNI (out of field)	1 (4%)	12 (63%)	2 (8%)	1 (17%)	2 (15%)	5 (11%)
Treating RT fields						
In-field	15 (68%)	1 (14%)	11 (46%)	1 (20%)	8 (72%)	20 (50%)
Marginal	7 (32%)	6 (86%)	13 (54%)	4 (80%)	3 (27%)	20 (50%)
RTOG nodal regions						
Inside	13 (60%)	0 (0%)	15 (63%)	1 (20%)	4 (36%)	20 (50%)
Marginal	3 (14%)	7 (100%)	6 (25%)	1 (20%)	4 (36%)	11 (28%)
Outside	6 (27%)	0 (0%)	3 (12%)	3 (60%)	3 (27%)	9 (22%)

SCF: Supraclavicular fossa  
 IMN: Internal mammary nodes  
 Axilla 1: Axilla level 1  
 Axilla 2: Axilla level 2  
 Axilla 3: Axilla level 3  
 Axilla (all): Axilla levels 1-3.  
 RNI: Regional nodal irradiation

## Conclusion

Despite adjuvant RNI, patients remain at risk of RNR. RNI fields can be optimized, as in our cohort 34 nodes (39%) were marginal, occurring in areas not adequately covered by the prescribed dose. However, 68% of SCF and 50% of axillary relapses were still 'in-field', suggesting that either our prescribed dose to these areas was not adequate to control disease, or that these patients were at a high risk of systemic relapse. Use of the RTOG atlas did not provide improved coverage. The anatomical data from this cohort will be used to generate an atlas of nodal relapse that can assist in defining optimal radiotherapy volumes for RNI. Whether inclusion of such regions will alter relapse patterns and event rates is unknown.

## EP-1196 Possible use of genetic tests: let's consider the opinion of patients

S. Gay<sup>1</sup>, F. Palorini<sup>1</sup>, M. De Santis<sup>2</sup>, S. Frasca<sup>2</sup>, C. West<sup>3</sup>, T. Rattay<sup>4</sup>, T. Rancati<sup>1</sup>, R. Valdagni<sup>2</sup>, L. Lozza<sup>2</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milan, Italy

<sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milan, Italy

<sup>3</sup>University of Manchester, University of Manchester, Manchester, United Kingdom

<sup>4</sup>Christie Hospital, Christie Hospital, Manchester, United Kingdom

## Purpose or Objective

More than half of all women undergoing breast cancer radiotherapy (RT) are anxious about possible changes to appearance of their breast, often causing negative perception of RT.

Aim of this work was to explore patients' views on a potential predictive genetic test that should provide an individual risk probability for toxicity after RT. First, to establish, before any such test is implemented in clinical practice, if such a decision-making tool is acceptable and appropriate for breast cancer pts. Finally, to understand if it would have conditioned the decision-making process with respect the treatment choice (RT + lumpectomy vs mastectomy alone).

## Material and Methods

11 breast cancer pts undergone semi-structured interviews after RT completion. Interviews were conducted by a radiotherapist and a radiotherapy technician.

Thematic analysis was used to analyze the transcripts and identify key themes. Coding was employed to detect common topics and identify sub-themes.

## Results

Characteristic of the 11 pts are reported in figure.

Saturation of themes was reached and 6 themes and relative sub-themes were identified.

1) Comprehension & impressions about benefits of the test: pts well understand the aim of the test, a few pts see in this test a tool for improving RT plans depending on individual predisposition to toxicity, but they do not consider it as a tool to independently choose mastectomy or RT. Nevertheless, they think that the test might make them more confident about treatment since it gives additional information.

2) Preliminary preparation to RT and its side effects: the majority of pts felt prepared to RT even if preparation does not always cancel fear. Many women consider important to have the largest and reliable information. Knowing in advance also negative experiences (about toxicity) is a plus point: women want to be aware about the path they are going to follow.

3) Side effects & hypotheses about protective factors: women propose physical/psychological conditions that would have protected them from strong morbidity, as skin color, use of cream, positive attitude, beloved people, visualization techniques.

4) Thoughts about mastectomy vs RT: mastectomy is felt as a very invasive treatment when compared to RT side effects, furthermore, RT toxicity is felt not so serious as a not suitably treated cancer.

5) Emotions: anxiety and fear are insistent feelings, but they are barely connected to genetic test's result and to the consequent storing of genetic information.

6) Importance of Human Relationships: trust and gratitude versus Hospital/Physician are conditions often more relevant for the treatment choice than the response of a test.

## Conclusion

Pts opinions underlined that a genetic test could help in facing RT and its side-effect in a more conscious manner, and it might help clinician to optimize RT. Nevertheless side-effect are generally perceivable as tolerable, and preferable to mastectomy or tumor control failure

## EP-1197 Results in Breast cancer Patients who Received adjuvant Radiation after Immediate Reconstruction

A. Giraldo Marin<sup>1</sup>

<sup>1</sup>Hospital Universitario Vall d'Hebron, Radiotherapy, Barcelona, Spain

## Purpose or Objective

Prior studies have advocated avoidance of immediate reconstruction (IR) in breast cancer (BC) patients who should receive adjuvant radiotherapy (RT), alluding to worse aesthetic outcomes. Our purpose is to evaluate the complication rates and cosmetic results for patients undergoing postmastectomy radiation therapy (PMRT) after IR.

### Material and Methods

Between June 2010 and March 2016, 25 patients with locally advanced breast cancer, who underwent modified radical mastectomy, IR, and PMRT were treated at our center. RT was delivered to the chest wall ± nodal areas according to stage, with 6MV and total dose of 50 Gy in 25 fractions. Complications were scored following the CTCAE 4.0 criteria. The capsular contracture was evaluated following the Baker classification. Cosmesis was rated as either acceptable or unacceptable to the patient.

### Results

The mean age was 46.7 years (range, 33-65). A total of 20 patients underwent tissue expander and 5 underwent implant (TE/I). Median follow-up (from the start of RT) for all patients was 18 months (m) (4-48m). 40% of the patients were never smokers; 28% were smokers and 32% ex-smokers during RT. 10% and 68% of the patients received neoadjuvant and adjuvant chemotherapy respectively, and 17 patients taking Tamoxifen during RT. After surgery the complications occurred in 15/25 patients: 7 with capsulitis grade (G) 2; 2 with capsulitis G3-4; 3 with cutaneous suffering and mastitis, extrusion and hematoma were presented in 1 patient each. Complications post surgery in 2 patients as were hematoma and extrusion required additional surgery and delayed beginning of RT. All patients completed the RT course without major complications. During RT the only complication presented was skin erythema (SE) G1-2 seen in 20 (80%) and G3 in just 5 patients which were all smokers. During the follow up the major complications were: capsulitis G3 in 5 patients and G4 in 1; skin hyperpigmentation was presented in 4 patients, cutaneous thinning in 6 and 1 patient presented relevant lung toxicity. At the end of the follow-up, TE Exchange have been realized in 12 patients with a mean time after RT of 14,3m (9-22), 3 of them are pending of a new corrective surgery, specially for improve cosmetic outcomes. We reported capsulitis G4 in 2 patients after the Exchange; both were smokers and 1 of them presented extrusion before RT, therefore she was operated twice. Acceptable cosmesis was reported in 60% of the patients

### Conclusion

Our experiences is limited but in our patients undergoing PMRT, RT can be safely delivered after IR, with a low complication rate and good patient satisfaction. In our patients major complications occurred before RT. Further studies are needed to define the factors that may be related to worse aesthetic results.

**EP-1198 Low risk breast cancer patients' supportive care needs and perceptions of follow-up care options**  
J. Kwan<sup>1</sup>, J. Croke<sup>1</sup>, J. Bender<sup>2</sup>, T. Panzarella<sup>1</sup>, K. Ubhi<sup>1</sup>, F. Liu<sup>1</sup>, A. Fyles<sup>1</sup>, A. Koch<sup>1</sup>, R. Dinniwell<sup>1</sup>, W. Levin<sup>1</sup>, D. McCready<sup>3</sup>, C. Chung<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre- University Health Network/ University of Toronto, Radiation Oncology, Toronto, Canada

<sup>2</sup>University Health Network, ELLICSR Cancer Survivorship Centre, Toronto, Canada

<sup>3</sup>Princess Margaret Cancer Centre- University Health Network/ University of Toronto, Surgical Oncology, Toronto, Canada

### Purpose or Objective

Breast cancer is the most common cancer in women and survival following treatment is rising. Although traditional follow-up care has been by oncology specialists post-treatment, literature over the last decade has shown that non-specialist follow-up care is a safe alternative for early-stage breast cancer patients. Barriers in transitioning patients from oncologist follow-up have not been well characterized. This study aims to assess i) the existing follow-up practices at a large institution, ii) met

and unmet supportive care needs, and iii) patient views on alternative care models, particularly involving primary care and eHealth.

### Material and Methods

A cross-sectional survey of well breast cancer patients attending radiation oncology follow-up appointments from August 2012 to May 2013 at the Princess Margaret Cancer Centre (Toronto, Canada) was completed. Eligibility criteria included English-speaking patients with T2 or lower tumor stage, node negative status, and ER/PR-positive breast cancer treated with radiation. Four domains were assessed: health care service use, supportive care needs, perceptions of follow-up care options, and internet usage. Descriptive statistics were completed for all variables and univariable analyses were performed to examine relationships between key variables and domains.

### Results

Response rate was 80% (191/259). Respondents had a mean age of 60 (SD=10.6). Median time since first follow-up was 21 months. The majority of respondents (161/191; 84%) received follow-up care from greater than one cancer specialist and had a median of 3 health care professional visits per year. The most preferred follow-up model was specialist care at a tertiary centre (178/191; 93%) and the least preferred models were specialist care through video conferencing (29/191; 15%) and email (28/191; 15%). Shared care models involving a specialist and family physician were modestly accepted (103/191; 54%). Primary care only follow-up was not well accepted (35/191; 18%), particularly among patients with higher education. Respondents who reported few unmet supportive care needs (p=0.01) or who search online for health information (p=0.02) were more likely to report perceived satisfaction with specialist follow-up via eHealth.

### Conclusion

Specialist health care services continue to be utilized by early-stage breast cancer patients during the post-treatment period. Transitioning patients to alternative follow-up models may be difficult due to strong patient preference for specialist care. Based on this survey, a minority of patients are willing to accept shared care with family physicians or eHealth follow-up via videoconferencing or email at this time.

### Electronic Poster: Clinical track: Lung

**EP-1199 Radiotherapy for pN2 EGFR wide type adenocarcinoma & Squamous Cell Carcinoma lung cancer**  
S.Y. Wu<sup>1</sup>

<sup>1</sup>Taipei Medical University Hospital, No.111- Section 3 Department of Radiation Oncology, Taipei, Chinese Taipei

### Purpose or Objective

There is a lack of large, prospective, randomized studies comparing postoperative radiotherapy (PORT) in pathological N2 (pN2) and surgical resection alone in terms of long-term survival in the setting of lung adenocarcinoma (adenoCA; wild-type [WT] epidermal growth factor receptor [EGFR]) and squamous cell carcinoma (squCA). This national cohort study clarifies the role of PORT in the survival of pN2 lung adenoCA (WT EGFR) and squCA.

### Material and Methods

We analyzed data of patients with adenoCA (WT EGFR) and squCA collected from the Taiwan Cancer Registry database. The patients were categorized into five groups according to the treatment modality: Group 1, comprising

those undergoing surgery alone; Group 2, comprising those undergoing adjuvant chemotherapy (CT) alone; Group 3, comprising those undergoing adjuvant radiotherapy (RT) alone; Group 4, comprising those receiving adjuvant concurrent chemoradiotherapy; and Group 5, comprising those receiving adjuvant sequential CT and intensity modulation RT.

#### Results

We enrolled 588 lung adenoCA (WT EGFR) and squCA patients without distant metastasis. After adjustments for age at surgery, surgical years, and Charlson comorbidity index scores, the multivariate Cox regression analysis demonstrated that adjusted HRs (aHRs; 95% confidence intervals [CIs]) for the overall mortality of female lung adenoCA (WT EGFR) patients were 0.257 (0.111-0.594), 0.530 (0.226-1.243), 0.192 (0.069-0.534), and 0.399 (0.172-0.928) in Groups 2, 3, 4, and 5, respectively. For male lung squCA patients, the aHRs (95% CIs) for overall mortality were 0.269 (0.160-0.451), 0.802 (0.458-1.327), 0.597 (0.358-0.998), and 0.456 (0.265-0.783) in Groups 2, 3, 4, and 5, respectively.

#### Conclusion

Adjuvant CCRT or sequential CT and IMRT  $\geq 5000$  cGy significantly reduced the mortality rate of female lung adenoCA (WT EGFR) and male squCA pN2 patients.

#### EP-1200 Early versus late PORT for pathologic stage IIIA-N2 NSCLC: a multi-institutional retrospective study

M.B. Meng<sup>1</sup>, H.H. Wang<sup>1</sup>, L. Deng<sup>2</sup>, Q.L. Wen<sup>3</sup>, C.Z. Zhang<sup>4</sup>, X.L. Zeng<sup>1</sup>, Y.L. Cui<sup>5</sup>, Z.Y. Yuan<sup>1</sup>, P. Wang<sup>1</sup>

<sup>1</sup>Tianjin Medical University Cancer Institute & Hospital, Department of Radiation Oncology, Tianjin, China

<sup>2</sup>West China Hospital- West China School of Medicine, Sichuan University, Department of Thoracic Cancer, Chengdu, China

<sup>3</sup>Affiliated Hospital of Southwest Medical University, Department of Oncology, Luzhou, China

<sup>4</sup>Nankai University Tianjin People's Hospital, Department of Surgery, Tianjin, China

<sup>5</sup>Tianjin Medical University Cancer Institute & Hospital, Department of Lymphoma, Tianjin, China

#### Purpose or Objective

The aim of this study was to evaluate the effect of the time of postoperative radiotherapy (PORT) in combined modality treatment for pathologic stage IIIA-N2 non-small cell lung cancer (NSCLC).

#### Material and Methods

Between January 2008 and December 2015, patients with pathologic stage IIIA-N2 NSCLC were enrolled and treated with PORT concurrent with or sequential to fewer than three cycles of postoperative chemotherapy (POCT, early PORT) or with PORT administered after at least four cycles of POCT (late PORT) at multiple hospitals. The primary end point was overall survival (OS); secondary end points included pattern of the first failure, locoregional recurrence-free survival (LRRFS), and distant metastasis-free survival (DMFS). Kaplan-Meier OS, LRRFS, and DMFS curves were compared with the log-rank test. Cox regression analysis was used to determine prognosticators for OS, LRRFS, and DMFS.

#### Results

Of 112 included patients, 41 (36.61%) and 71 (63.39%) patients received early PORT and late PORT, respectively. The median OS, LRRFS, and DMFS were longer for those who received early PORT than for those who received late PORT at the median follow-up of 29.6 months (all  $p < 0.05$ ). Uni- and multi-variate analyses showed that number of POCT cycles and the combination schedule of PORT and POCT were independent prognostic factors for OS, LRRFS, and DMFS.

#### Conclusion

Pathologic stage IIIA-N2 NSCLC patients treated with early PORT experienced better OS, LRRFS, and DMFS than those treated with late PORT. Thus, early PORT should be considered as a primary approach for those patients.

#### EP-1201 SLR versus SBRT for high-risk elderly patients with stage I NSCLC

H.H. Wang<sup>1</sup>, M.B. Meng<sup>1</sup>, X.L. Zeng<sup>1</sup>, L. Deng<sup>2</sup>

<sup>1</sup>Tianjin Medical University Cancer Institute & Hospital, Department of Radiation Oncology, , China

<sup>2</sup>West China Hospital- West China School of Medicine- Sichuan University, Department of Thoracic Cancer, Tianjin, China

#### Purpose or Objective

The purpose of this study was to evaluate the efficacy and safety of radiotherapy (RT) for high-risk elderly patients with stage I non-small cell lung cancer (NSCLC) through a meta-analysis of data from published studies comparing sublobar resection (SLR) with RT including conventional fraction radiation therapy (CFRT) and stereotactic body radiation therapy (SBRT).

#### Material and Methods

We searched the Cochrane Library, MEDLINE, CENTRAL, and EMBASE and conducted manual searches. Meta-analysis was performed on the results of homogeneous studies. Analyses subdivided by study design were also performed.

#### Results

Based on our search criteria, we found 16 trials involving 11540 patients. Nine were propensity-score matched (PSM) cohort studies, and 7 were cohort studies. Five studies compared SLR with CFRT, and 11 compared SLR with SBRT. Our results showed that SLR, compared with either type of RT, significantly improved the overall survival regardless in both PSM and non-PSM analyses (all  $p < 0.05$ ). However, the pattern of failure after SLR was similar to that after SBRT (all  $p > 0.05$ ). In addition, RT and SLR were associated with specific complications.

#### Conclusion

These results demonstrated that SLR treatment of high-risk elderly patients with stage I NSCLC resulted in better overall survival compared with RT, including CFRT and SBRT. Considering the strength of the evidence, additional randomized controlled trials are needed before each treatment modality can be recommended routinely.

#### EP-1202 A lot to a little or a little to a lot - dose-volume relationships in thoracic tumors

C. Schröder<sup>1</sup>, R. Engenhardt-Cabillic<sup>2</sup>, A. Buchali<sup>3</sup>

<sup>1</sup>Universität Giessen, Klinik für Strahlentherapie und Radioonkologie- Universitätsklinikum Giessen und Marburg, Giessen, Germany

<sup>2</sup>Universität Marburg, Marburg, Germany

<sup>3</sup>Ruppiner Kliniken GmbH, Klinik für Strahlentherapie und Radioonkologie, Neuruppin, Germany

#### Purpose or Objective

The purpose of this prospective randomized trial was to determine which constellation of dose and corresponding volume of the lung tissue as seen in the dose-volume-histogram (DVH) - either a lot to a little or a little to a lot - should be preferred to ensure the best possible outcome for patients with thoracic carcinomas. To ensure a wider approach we focused on both objective and subjective parameters like clinical outcome, changes in pulmonary function tests (PFT), radiological changes and quality of life (QoL).

#### Material and Methods

From 04/12 to 10/15 81 patients with NSCLC, SCLC or esophageal carcinoma were randomized and treated with either a 4-field-IMRT (Arm A) or a VMAT (Arm B) technique.

Patients with NSCLC were treated with a total dose of 74 Gy, those with SCLC with 60 Gy and those with esophageal tumors with 66 Gy. Fraction dose/day was 2 Gy each. Patients were treated with or without concurrent or sequential chemotherapy according to intradepartmental standards. Data regarding clinical outcome (survival, side effects, local and distant control), PFT (ventilation and diffusion parameters) and quality of life (EORTC QLQ-C30 and QLQ-LC13) were collected before RT, 6 weeks, 12 weeks and 6 months after treatment. QoL data was additionally collected 1 year post RT. Radiological follow-up via CT focusing on lung density changes was done 12 weeks and 6 months after RT.

#### Results

The median follow up was 34,5 weeks. There was no significant difference regarding the local ( $p = 0,954$ ) and distant ( $p = 0,206$ ) outcome, side effects (all  $p > 0,05$ ) or survival ( $p = 0,633$ ) of patients in the two treatment arms at any follow up appointment. The comparison of the PFT showed a statistically significant difference for the DLCO 6 weeks post RT ( $p = 0,028$ ). All other parameters did not differ significantly at any follow up appointment. Regarding the QoL there was no statistically significant difference between the summarized value for the QLQ-C30 and the QLQ-LC13 at any follow up appointment ( $p > 0,1$ ). There was a statistically significant difference between the mean density of the lung parenchyma at 12 weeks ( $p < 0,0005$ ) and 6 months post RT ( $p < 0,0005$ ).

#### Conclusion

Since there was no significant and relevant difference between both treatment arms regarding PFT, clinical outcome and QoL it doesn't seem to be relevant how the DVH is shaped exactly as long as certain established dose constraints are respected. As to whether the difference between the CT density changes is not only significant but also clinically relevant further analysis is needed.

#### EP-1203 Changes in pulmonary function after high dose intrathoracic radio(-chemo)therapy up to 74 Gy

C. Schröder<sup>1</sup>, R. Engenhardt-Cabillic<sup>2</sup>, A. Buchali<sup>3</sup>

<sup>1</sup>Universität Giessen, Klinik für Strahlentherapie und Radioonkologie- Universitätsklinikum Giessen und Marburg, Giessen, Germany

<sup>3</sup>Ruppiner Kliniken GmbH, Klinik für Strahlentherapie und Radioonkologie, Neuruppin, Germany

#### Purpose or Objective

There are numerous ways to examine radiation therapy (RT) related injuries to the lung tissue. Next to obvious factors like treatment induced side effects, the changes in pulmonary function are a simple way to quantify the effects of RT on a patient's lung. In this study we prospectively collected patient-related, dose-related and PFT data before RT and at several follow up visits after RT to analyze the time course of PFT changes and influencing factors.

#### Material and Methods

From 04/12 to 10/15 81 patients with NSCLC, SCLC or esophageal carcinoma were treated with high dose radiation therapy. Patients with NSCLC were treated with a total dose of 74 Gy, those with SCLC with 60 Gy and those with esophageal tumors with 66 Gy. Fraction dose was 2 Gy each. Patients were treated with or without concurrent or sequential chemotherapy according to intradepartmental standards. Data regarding PFT (ventilation and diffusion parameters) was collected before treatment, 6 weeks, 12 weeks and 6 months after RT. The following lung function parameters were analyzed: vital capacity (VC), total lung capacity (TLC), forced expiratory volume in 1 second (FEV1), diffusion

capacity for carbon monoxide (DLCO) and capillary blood gas analysis. Additionally the influence of patient and treatment related factors on PFT was analyzed.

#### Results

The mean FEV1 constantly declined during the follow up ( $p = 0,001$ ). In total 68 % of patients had a reduced FEV1 at 6 months. The general linear model (GLM) with repeated measures determined that the FEV1 differed statistically significant over time ( $p = 0,001$ ). The mean VC didn't change during the follow up ( $p > 0,05$ ). The mean TLC showed a constant decline after RT ( $p = 0,026$ ). At 6 months 60 % of patients showed a decline in VC and 73 % in TLC. The GLM revealed no significant changes of the VC over time. There was a difference between the TLC before RT and at 6 months post RT ( $p = 0,026$ ). The mean DLCO had declined at 6 and 12 weeks but showed a slight recovery at 6 months ( $p < 0,0005$ ). At 6 months 86 % of patients had a reduced DLCO. The GLM determined that there were statistically significant differences of the DLCO over time ( $p < 0,0005$ ). There was an increase in pCO<sub>2</sub> and a decrease in pO<sub>2</sub> after treatment ( $p > 0,05$ ). At 6 months approximately 60 % had a decline in pO<sub>2</sub> and an increase in pCO<sub>2</sub>. Only the pre-treatment PFT classification had a significant influence on the FEV1 after RT. The GLM determined no statistically significant changes of the blood gas parameters over time. Only the pre-treatment PFT classification had a significant influence on the FEV1 after RT.

#### Conclusion

The DLCO seems to be the most reliable indicator for lung tissue damage after thoracic radiotherapy. Although there might be some significance ventilation parameters appear to be less reliable. Only the pre-treatment PFT classification had a significant influence on the FEV1 after RT.

#### EP-1204 Treatment Outcomes and Patterns of Radiologic Injury after Tomotherapy-based SBRT for Lung Tumours

S. Arcangeli<sup>1</sup>, L. Falcinelli<sup>2</sup>, S. Bracci<sup>3</sup>, A. Greco<sup>3</sup>, A. Monaco<sup>1</sup>, J. Dognini<sup>1</sup>, C. Chiostrini<sup>1</sup>, R. Bellavita<sup>2</sup>, C. Aristei<sup>2</sup>, V. Donato<sup>1</sup>

<sup>1</sup>San Camillo-Forlanini Hospitals, Radiation Oncology, Rome, Italy

<sup>2</sup>S. Maria della Misericordia University Hospital, Radiation Oncology, Perugia, Italy

<sup>3</sup>S. Andrea University Hospital, Radiation Oncology, Rome, Italy

#### Purpose or Objective

To evaluate treatment outcomes and patterns of CT lung injury after hypofractionated image-guided stereotactic body radiotherapy (SBRT) delivered with helical tomotherapy (HT) in a series of inoperable lung lesions.

#### Material and Methods

68 medically inoperable patients (69 lesions) without evidence of viable extrathoracic disease were included. Assessment of tumor response was based on the RECIST 1.1 criteria coupled with a 18F-FDG/PET-CT. Toxicity monitoring was focused on treatment-related pulmonary adverse events according to the CTCAE v. 4.0. Acute and late events were classified as radiation pneumonitis (RP) and radiation fibrosis (RF), respectively. Kaplan-Meier survival analysis was used to evaluate the progression-free (PFS) and overall survival (OS).

#### Results

After a median follow-up of 12 months (range, 3-31 months), no instances of  $\geq$  Grade 4 RP was documented and clinically severe (Grade 3) RP occurred in 5.8% of the patients. Two patients (3%) developed a late severe ( $\geq$ Grade 3) symptomatic RF. No specific pattern of CT lung injury was demonstrated, in both acute and late setting. Median OS and PFS for the entire population were 30.8 and

14.1 months, respectively. At MVA, BED  $\geq 100$  and KPS  $\geq 90$  emerged as a significant prognostic factors for OS ( $p = 0.01$  and  $p = 0.001$ , respectively), and BED  $\geq 100$  for PFS ( $p = 0.02$ ).

#### Conclusion

Our findings show that a risk adaptive approach of HT-SBRT based on tumor location is an effective treatment with a mild toxicity profile in medically inoperable patients with lung tumors. No specific pattern of lung injury was demonstrated.

#### EP-1205 The prognostic role of Neutrophil-to-lymphocyte ratio in limited disease small-cell lung cancer

L. Käsmann<sup>1</sup>, L. Bolm<sup>1</sup>, L. Motisi<sup>1</sup>, S. Janssen<sup>1</sup>, S.E. Schild<sup>2</sup>, D. Rades<sup>1</sup>

<sup>1</sup>University of Lübeck, Department of Radiation Oncology, Lübeck, Germany

<sup>2</sup>Mayo Clinic, Department of Radiation Oncology, Scottsdale- AZ, USA

#### Purpose or Objective

Small cell lung cancer is an aggressive cancer type of neuroendocrine origin. Even patients with limited disease have a poor prognosis of 16-24 months. Standard treatment of these patients is radiochemotherapy with cisplatin and etoposide followed by prophylactic cranial irradiation. Systemic inflammation has been suggested an important prognostic factor for outcome in several types of cancer. In this study, we investigated the impact of systematic inflammation represented by the neutrophil-to-lymphocyte ratio (NLR) at diagnosis in patients with limited disease small-cell lung cancer (LD-SCLC) for outcomes.

#### Material and Methods

Data of 65 patients receiving radiochemotherapy for LD-SCLC were analyzed. NLR was obtained from blood samples at diagnosis. NLR plus 12 factors, namely gender, age, ECOG performance score, T-category, N-category, number of pack years, smoking during radiotherapy (RT), respiratory insufficiency prior to RT, haemoglobin levels during RT, EQD2 (<56 Gy vs.  $\geq 56$  Gy), concurrent chemotherapy and PCI, were evaluated for local control, metastases-free survival and overall survival.

#### Results

The overall survival rates at 12, 24 and 36 months were 71%, 45% and 28%, respectively. Median survival time was 20 months. On univariate analysis of local recurrence, lower T-stage (1-2 vs. 3-4) was associated with improved local control at 36 months (62% vs. 41%,  $p=0.04$ ). On multivariate analysis, T-stage was an independent factor ( $p=0.035$ ; HR 1.84 (95% CI 1.04-3.86)). Improved metastases-free-survival on univariate analyses was found for NLR <4 ( $p=0.011$ ), ECOG 0-1 ( $p=0.002$ ), nodal stage N0-1 ( $p=0.048$ ), non-smoking during RT ( $p=0.009$ ), and administration of PCI ( $p=0.006$ ). On multivariate analysis, a trend for improved metastases-free-survival was observed for NLR <4 ( $p=0.063$ ; HR 2.19 (95% CI 0.96-5.06)) and N0-1 ( $p=0.0623$ ; HR 3.4 (95% CI 0.95-21.9)). Improved overall survival rates were found for NLR <4 ( $p=0.001$ ), ECOG 0-1 ( $p<0.001$ ), non-smoking during RT ( $p=0.007$ ), no respiratory insufficiency prior to RT ( $p=0.03$ ) and PCI ( $p<0.001$ ). On multivariate analysis, NLR <4 ( $p=0.03$ ; HR 2.05 (95% CI 1.06-3.95)), ECOG 0-1 ( $p=0.002$ ; HR 3.41 (95% CI 1.57-7.36)) and PCI ( $p=0.015$ ; HR 2.56 (95% CI 1.21-5.34)) were independently associated with improved survival.

#### Conclusion

In this study, NLR was an independent prognostic factor for overall survival in patients with LD-SCLC. NLR can help identify patients with poor prognosis and appears an useful prognostic marker in clinical practice. A prospective analysis is warranted to confirm our findings.

#### EP-1206 FDG-PET/CT predictive parameters of early response after SABR for lung oligometastases

R. Mazzola<sup>1</sup>, N. Giaj Levra<sup>1</sup>, A. Fiorentino<sup>1</sup>, S. Fersino<sup>1</sup>, F. Ricchetti<sup>1</sup>, U. Tebano<sup>1</sup>, D. Aiello<sup>1</sup>, R. Ruggieri<sup>1</sup>, F. Alongi<sup>1</sup>  
<sup>1</sup>Sacro Cuore Don Calabria Cancer Care Center, Radiation Oncology, Negrar-Verona, Italy

#### Purpose or Objective

To investigate the role of 18FDG-PET/CT parameters as predictive of early response after Stereotactic Ablative Radiation Therapy (SABR) for oligometastases lung lesions.

#### Material and Methods

SABR for lung oligometastases was performed when the following criteria were satisfied: a) controlled primary tumor, b) absence of progressive disease longer than 6 months, c) number of metastatic lesions  $\leq 5$ . The prescribed total dose varied according to the risk-adapted dose prescription with a range of doses between 48-70 Gy in 3-10 fractions. Inclusion criteria of the current retrospective study were: a) lung oligometastases underwent to SABR, b) for each patient presence of 18-FDG-PET/CT pre- and post-SABR for at least two subsequent evaluations, c) Karnofsky performance status > 80, d) life-expectancy > 6 months.

The following metabolic parameters were defined semi-quantitatively for each lung lesion: 1) SUV-max, 2) SUV-mean, 3) Metabolic Tumor Volume (MTV), 4) Total Lesional Glycolysis (TLG).

#### Results

From January 2012 to November 2015 fifty patients for a total of seventy lung metastatic lesions met the inclusion criteria of the present analysis. Pre-SABR, median SUV-max was 6.5 (range, 4 - 17), median SUV-mean was 3.7 (2.5 - 6.5), median MTV was 2.3 cc (0.2 - 31 cc). For patients with in-field disease progression median TLG was 17.4 (2 - 52.8), for the remaining the median value was 170.6 (0.5 - 171). For pre-SABR SUV-max  $\geq 5$  a progression/stable metastasis was noted in 88% of cases, while a complete response was observed in 94% of cases for pre-SABR SUV-max < 5 ( $p < 0.001$ , Sensitivity = 88%, Specificity = 94%). A pre-SABR SUV-mean < 3.5 was related to complete response at 6 months after SABR ( $p 0.03$ , Sensitivity = 31%, Specificity = 34%, AUC = 0.32). In cases of in-field failure, a pre-SABR SUV-max > 8 was related to a higher absolute value increase of SUV-max at 6 months of follow up comparing to pre-SABR SUV-max < 8 ( $p 0.005$ ). Delta SUV max 3-6 months was +126% for lesions with in-field progression versus -26% for the remaining ( $p$ -value 0.002). Delta SUV-mean 3-6 months was +15% for lesions with in-field progression versus for the remaining metastases ( $p$ -value 0.008). Finally, 86% of patients with local failure had distant progression versus only 19% in cases without local failure ( $p = 0.004$ ).

#### Conclusion

According to current findings, pre-SABR SUV max and mean seem to predict early response in lung SABR for oligometastases.

#### EP-1207 Outcomes and prognostic factors in solitary brain metastasis from small cell lung cancer

Neurosurgery, Heidelberg, Germany

<sup>5</sup>University Hospital of Heidelberg, Diagnostic and Interventional Radiology with Nuclear Medicine-Thoraxklinik, Heidelberg, Germany

#### Purpose or Objective

Whole brain radiation therapy (WBRT) was historically the standard of care for patients with brain metastases (BM) from small cell lung cancer (SCLC). Even though, for patients from other solid tumours, locally ablative treatments are standard of care for patients with 1-4 BM. The objective of this analysis was to find prognostic factors influencing overall survival (OS) and progression-free survival (nPFS) in SCLC patients with solitary BM (SBM) treated with WBRT.

#### Material and Methods

We identified 52 patients in our cancer center database that had histologically confirmed SCLC and contrast enhanced magnet resonance imaging (MRI) or computed tomography (CT) confirmed SBM between 2006 and 2015. Kaplan-Meier survival analysis was performed for survival analyses. For comparison of survival curves, Log-rank (Mantel-Cox) test was used. Univariate Cox proportional-hazards ratios (HRs) were used to assess the influence of cofactors on OS and nPFS.

#### Results

The median OS after WBRT was 5 months and the median nPFS after WBRT was 16 months. Patients who received surgery prior to WBRT had a significantly longer median OS of 19 months compared to 5 months in the group receiving only WBRT ( $p=0.03$ ; HR 2.24; 95% CI 1.06-4.73). Patients with synchronous disease had a significantly longer OS compared to patients with metachronous BM (6 months vs. 3 months,  $p=0.005$ ; HR 0.27; 95% CI 0.11-0.68). Univariate analysis for OS did show a statistically significant effect for metachronous disease (HR 2.84; 95% CI 1.26-6.38;  $p=0.012$ ), initial response to first-line chemotherapy (HR 0.54; 95% CI 0.30-0.97;  $p=0.04$ ) and surgical resection (HR 0.25; 95% CI 0.07-0.83;  $p=0.024$ ). nPFS was significantly affected by metachronous disease in univariate analysis (HR 14.84; 95% CI 1.46-150.07;  $p=0.02$ ).

#### Conclusion

This analysis revealed that surgery followed by WBRT leads to an improved OS in patients with SBM in SCLC. Further, synchronous disease and response to initial chemotherapy appeared to be major prognostic factors. We propose that locally ablative treatments in combination with WBRT for SBM in SCLC should be considered for therapy. Surgery followed by WBRT should be favored in patients with unknown primary, when pathologic confirmation is required or in patients with large single brain metastasis causing mass effect. The value of WBRT, SRS or surgery alone or the combination for patients with limited number of BM in SCLC must be evaluated in further prospective clinical trials.

#### EP-1208 Concomitant chemoradiotherapy followed by stereotactic ablative boost in non small cell lung cancer

J. Doyen<sup>1</sup>, M. Poudenx<sup>2</sup>, J. Gal<sup>3</sup>, J. Otto<sup>2</sup>, J. Mouroux<sup>4</sup>, B. Padovani<sup>5</sup>, A. Leysalle<sup>1</sup>, C. Guerder<sup>6</sup>, E. Chamorey<sup>3</sup>, P. Bondiau<sup>1</sup>

<sup>1</sup>Centre Antoine Lacassagne, Radiation Oncology, Nice, France

<sup>2</sup>Centre Antoine Lacassagne, Medical Oncology, Nice, France

<sup>3</sup>Centre Antoine Lacassagne, Statistics, Nice, France

<sup>4</sup>CHU Teaching hospital, Thoracic surgery, Nice, France

<sup>5</sup>CHU Teaching hospital, Radiology, Nice, France

<sup>6</sup>Hôpital de la Croix Rouge, Radiation Oncology, Toulon, France

#### Purpose or Objective

The randomized phase III RTOG 7301 trial failed to demonstrate a survival advantage by increasing radiation dose until 74 Gy in locally advanced non small cell lung cancer (NSCLC) treated by concomitant chemoradiotherapy (CRT) and found that mean dose to the heart correlated independently with overall survival (OS). By increasing the dose to the tumor with stereotactic ablative radiotherapy (SABR) one could lead to a greater dose to the target while decreasing the dose to the heart and could improve outcome. A phase I trial was conducted to firstly demonstrate feasibility of this strategy.

#### Material and Methods

After 2 induction cycles with cisplatin (75 mg/m<sup>2</sup>) and docetaxel (75 mg/m<sup>2</sup>) CRT used the same regimen (25 mg/m<sup>2</sup>) in a weekly basis and delivered 46 Gy in 23 sessions; then 3 consecutive fractions of 7 Gy were given with SABR technique with increasing of 1 Gy per session for next dose level (6 dose level; dose escalation with TITE-CRM method). Patients were eligible for the treatment if target volume after 46 Gy was < 6 cm.

#### Results

Twenty-six patients (pts) were treated between March 2010 and June 2015; number of pts for dose level 1, 2, 3, 4, 5 and 6 were respectively of 3, 4, 3, 3, 9 and 4. Median age was of 65.4 years (46-81) with 7 female, 19 male, 1 stage I, 1 stage IIB, 14 stage IIIA, 7 stage IIIB and 3 stage IV disease (oligometastatic). With a median follow-up of 37.1 months (1.7-60.7), limiting toxicities (grade 3 to 5) were as follow: G4 oesophagitis (fistula) at dose level 5; grade 5 (hemoptysis) at dose level 6. Patients mainly presented with grade 1-2 asthenia (n=12) or alveolitis (n=9). There were one complete response (3.8%), 17 partial responses (65.4%) and 7 stabilizations (26.9%). The 2-years local control, metastasis-free survival and overall survival were respectively of 70.3%, 44.5% and 50.8%.

#### Conclusion

The maximal tolerated dose was 3 X 11 Gy after 46 Gy (Biological Effective Dose: 115.3 Gy) and could be tested in a phase II trial.

#### EP-1209 SBRT for lung metastases: retrospective analyses of tumor control and toxicity with a lower BED.

Y. Cremppe<sup>1</sup>, I.P. Barbosa<sup>1</sup>, C.D.O. Rodrigues<sup>1</sup>, E. Gil<sup>1</sup>, P.H. Zanuncio<sup>1</sup>, P.L. Moraes<sup>1</sup>, I. Fagundes<sup>1</sup>, R. Ferrigno<sup>1</sup>  
<sup>1</sup>hospital beneficencia portuguesa de sao paulo, radiation oncology, sao paulo, brazil

#### Purpose or Objective

Many fractionations have been effective on tumor control of primary lung cancer or metastatic lung lesions, most with BED<sub>10</sub> > 100Gy<sub>10</sub>. The aim of this series is to test safety and effectivity of a dose fractionation with a lower BED in the treatment of lung metastatic disease.

#### Material and Methods

Retrospective analyses of 46 patients with metastatic tumor to the lungs treated with SBRT with dose of 40 Gy in 4 fractions (BED<sub>10</sub> = 80Gy<sub>10</sub>), twice a week, from January 2013 to October 2016. The minimal time of follow-up was six months to analyse local control, acute and late toxicity. The most frequent primary site was gastrointestinal (GI) with 15 patients (32,6%), followed by soft tissue neoplasm with 8 patients (17,3 %), genitourinary (6 patients) and melanoma (6 patients).

#### Results

With a median follow-up of 16 months (range 6 to 40 months), the recurrence free survival was 93,2% in 12 months and 88,4% at the time of this analyses. Three patients developed local failure, after 14, 15 and 16 months of treatment. Five patients (10,8 %) had symptoms, including grade III pneumonitis (4 patients), toracic pain (1 patient) and arm paresthesia (1 patient), with a median time of 8,6 months from the end of the

therapy, but only one did not have completely remission of symptoms in 30 days after the beginning, evolving with pathologic rib fracture that got better after four months.

#### Conclusion

This series suggests that SBRT with dose of 40 Gy in 4 fractions (BED<sub>10</sub> = 80Gy<sub>10</sub>) twice a week, is safe and effective for metastatic lung lesions and can be considered for prospective clinical trials to be tested as a reasonable option of dose fractionation.

#### EP-1210 SBRT with FFF Beams and V-MAT for lung cancer. A mono-institutional experience.

F. Martucci<sup>1</sup>, P. Fanti<sup>1</sup>, B. Muoio<sup>1</sup>, S. Cima<sup>1</sup>, C. Azinwi<sup>1</sup>, K. Jordanov<sup>1</sup>, G. Pesce<sup>1</sup>, M.C. Valli<sup>1</sup>, S. Presilla<sup>2</sup>, A. Richetti<sup>1</sup>  
<sup>1</sup>Istituto Oncologico della Svizzera Italiana, Radiation Oncology, Bellinzona, Switzerland  
<sup>2</sup>Ente Ospedaliero Cantonale, Medical Physics Service, Bellinzona, Switzerland

#### Purpose or Objective

Stereotactic body radiotherapy (SBRT) is a method of external beam radiotherapy that accurately delivers a high irradiation dose to an extracranial target in one or few treatment fractions. Based on current evidence, SBRT is a valid and curative treatment for unresectable lung nodules. Aim of this study is to evaluate the efficacy and toxicity of SBRT in pts with early lung cancer and metastatic pulmonary lesions.

#### Material and Methods

We retrospectively analysed data of 41 consecutive pts with lung nodules treated in our centre from September 2011 to December 2015. Demographic patient data and dosimetric data regarding SBRT treatments were collected. Acute toxicity (defined as toxicity < 45 days) and late toxicity (defined as toxicity ≥ 45 days) were reported and graded as per standardized CTCAE 4.0 criteria. Progression free survival (PFS) and overall survival (OS) were also described.

#### Results

The median age was 71 years (range 52-90). Twenty pts were diagnosed with primary or recurrent lung cancer, 21 pts had metastatic lung nodules of varying histologies. Thirty pts had an histologically proven diagnosis, while the remainder were treated after multidisciplinary decision in the face of suspicious PET/CT imaging. The median follow up was 29 months (range 3-56). The treatment was delivered with a Biologically Effective Dose (BED10) ≥ 90 GyE, in 3 to 6 fractions, with volumetric modulated arcs with flattening filter free beams. The median Planning Target Volume (PTV) was 13.1 cm<sup>3</sup> (range 4.6-70). OS at 1 and 2 years was 91.8% and 85.7%, respectively. PFS at 1 and 2 years was 91.7% and 81.5%, respectively. No statistical significant difference in terms of OS e PFS was found between primary and metastatic lesions setting (p=0.098 and p=0.520). Nine of 41 pts had a relapse, and among them only 1 patient showed a recurrence inside the irradiated field. No acute toxicities were registered. Late toxicity was recorded in 2 pts: a grade 2 pneumonitis and a grade 1 rib fracture.

#### Conclusion

SBRT delivered using linac-based flattening filter free volumetric modulated arc radiotherapy is feasible and well tolerated. Our experience confirm excellent long-term local control rates and a very low rate of late toxicity.

#### EP-1211 How selected are patients in clinical trials of radiotherapy for non-small cell lung cancer?

M. Berry<sup>1,2</sup>, K. Neville<sup>1</sup>, J. Ruben<sup>3,4</sup>, L. Holloway<sup>1,2,5,6,7</sup>, S. Vinod<sup>1,2,8</sup>

<sup>1</sup>Liverpool Cancer Therapy Centre, Radiation Oncology, Sydney, Australia

<sup>2</sup>South Western Sydney Clinical School, University of New

South Wales, Sydney, Australia

<sup>3</sup>William Buckland Radiotherapy Centre, The Alfred Hospital, Melbourne, Australia

<sup>4</sup>Monash University, Melbourne, Victoria, Australia

<sup>5</sup>Ingham Institute of Applied Medical Research, Medical Physics, Sydney, Australia

<sup>6</sup>Centre for Medical Radiation Physics, University of Wollongong, Wollongong, Australia

<sup>7</sup>Institute of Medical Physics- School of Physics, University of New South Wales, Sydney, Australia

<sup>8</sup>Western Sydney University, Sydney, New South Wales, Australia

#### Purpose or Objective

Clinical practice guidelines based on evidence derived from clinical trials are used to guide management of patients with non-small cell lung cancer (NSCLC). However patients enrolled in trials must fulfil various eligibility criteria, and may not represent the wider patient population.

The aim of this study was to review eligibility criteria of clinical trials performed in patients with NSCLC and compare the characteristics of an Australian clinical patient cohort against these criteria.

#### Material and Methods

A systematic Medline & Embase search was conducted to identify all randomized clinical trials published in English from 2005-2014 concerning curative radiotherapy for Stage I-III NSCLC. Trials on stereotactic ablative radiotherapy, brachytherapy, post-operative radiotherapy or adjuvant therapy were excluded. Eligibility criteria for entry into these trials were evaluated. A database of contemporaneous NSCLC patients from the Liverpool and Macarthur Cancer Therapy Centres in Sydney, Australia, and from the William Buckland Radiotherapy Centre at the Alfred Hospital in Melbourne, Australia, was reviewed.

#### Results

Twenty-two trials were identified. Performance status was a defined eligibility criterion in all trials, with twelve trials limiting this to ECOG 0-1 and ten to ECOG 0-2. Seventeen trials specified eligibility by age, with five excluding patients >70-80 years. Weight loss was specified in nine trials, being ≤5% in three trials, and ≤10% in six trials. Eight trials excluded patients with cardiac co-morbidity. All trials included use of chemotherapy, so blood test parameters were used for inclusion. Twelve trials had minimum pulmonary function/blood oxygenation requirements for entry. Fourteen trials excluded patients with a history of previous cancer in the past three years.

There were 366 patients treated with curative radiotherapy for NSCLC in the featured cancer centres from 2005-2014. Clinical trial eligibility criteria were not met in 66 patients (18%) because of performance status, and in 60 (16%) because of weight loss. 162 (44%) would have been excluded because of cardiac co-morbidity, and 41 (11%) would have been excluded because of prior cancer.

When considering one of the highest impact trials published during the study period - RTOG 9410 - key inclusion criteria were Stage II, IIIA or IIIB NSCLC patients with ECOG PS 0, 1 or 2, ≤5% weight loss, serum creatinine level ≤1.5g/L, and no prior thoracic or neck radiotherapy. There were 268 clinic patients classified as Stage II, IIIA or IIIB, and trial entry criteria would have rendered 61 (23%) of these patients ineligible for trial enrolment.

#### Conclusion

Patients enrolled in trials for NSCLC are highly selected and do not reflect the clinic population, leading to uncertainty about the applicability of clinical practice guidelines in some patients.

### EP-1212 Parenchymal and functional lung changes after stereotactic body radiotherapy for early-stage NSCLC

J. Rieber<sup>1</sup>, J. Dern<sup>1</sup>, D. Bernhardt<sup>1</sup>, L. König<sup>1</sup>, S. Adeberg<sup>1</sup>, A. Paul<sup>1</sup>, J. Kappes<sup>2</sup>, H. Hoffmann<sup>3</sup>, J. Debus<sup>1</sup>, C.P. Heussel<sup>4</sup>, S. Rieken<sup>1</sup>

<sup>1</sup>University Hospital Heidelberg, Radiooncology, Heidelberg, Germany

<sup>2</sup>Thoraxklinik- University Hospital Heidelberg, Pneumology, Heidelberg, Germany

<sup>3</sup>Thoraxklinik- University Hospital Heidelberg, Thoracic Surgery, Heidelberg, Germany

<sup>4</sup>Thoraxklinik- University Hospital Heidelberg, Diagnostic and Interventional Radiology, Heidelberg, Germany

#### Purpose or Objective

Stereotactic body radiotherapy (SBRT) has been increasingly used for patients with early-stage non-small cell lung cancer (NSCLC) who are classified medically inoperable due to severe pulmonary comorbidities. However, main toxicity following SBRT is detected in the already impaired lung tissue in this patient group and might further influence quality of life and survival.

#### Material and Methods

Parenchymal and functional lung changes were evaluated in 70 patients with early-stage NSCLC treated with SBRT between February 2004 and May 2015 at the University Hospital Heidelberg and for whom more than one year of CT follow-up scans were available. In total, 393 CT scans were examined. Incidence, morphology and severity of lung abnormalities as well as pulmonary function changes were analyzed and correlated with outcome.

#### Results

Median follow-up time was 28.6 months with 2-year and 3-year overall survival (OS) of 75.5% and 54.1% and 2-year and 3-year local progression-free survival (LPFS) of 88.4% and 79.9%.

Regarding acute parenchymal lung changes within the first 6 months after SBRT, 10% of the cases showed no increased density, while 11% were classified as patchy ground-glass opacity, 25% diffuse ground-glass opacity, 25% patchy consolidation and 29% diffuse consolidation. Late CT changes after 6 months were detected in all patients with 10% scar-like fibrosis, 7% mass-like fibrosis and a modified conventional pattern of fibrosis in 83% of the patients. In general, most patients only suffered from mild to moderate CT abnormalities. Maximum severity score for parenchymal changes was significantly associated with ipsilateral lung dose in biological effective dose (BED) ( $p=0.014$ ) and PTV size ( $p<0.001$ ), but not with any further investigated risk factor. Furthermore, patients with no or mild parenchymal lung changes showed significantly improved 2-year and 3-year OS of 79.6% and 61.9%, while moderate to severe changes had 1-year and 3-year OS of 40% and 30%, respectively ( $p=0.043$ ).

Regarding functional lung changes, baseline lung function was generally poor with mean forced expiratory volume in 1 second (FEV1) of 1.5l (predicted 54.1%), mean total lung capacity (TLC) of 5.7 and forced vital capacity (FVC) of 2.7l. SBRT treatment significantly reduced post-SBRT lung function: TLC ( $-0.41$ l;  $p=0.001$ ); FVC ( $-0.17$ l,  $p<0.001$ ), FEV1 ( $-0.8$ l,  $p<0.001$ ), FEV1% ( $-28.2$ %,  $p<0.001$ ) and air way resistance ( $+0.1$ ,  $p=0.003$ ). While pre- and post-treatment lung function parameters did not significantly affect OS ( $p>0.05$ ), higher absolute reduction in FVC was significantly associated with worse OS ( $p=0.005$ ).

#### Conclusion

SBRT was generally tolerated well with only mild toxicity. However, this is the first study illustrating that both parenchymal and functional lung changes following SBRT might impair survival.

### EP-1213 Long-term outcomes of Stereotactic Ablative Radiotherapy for stage I non-small cell lung cancer

S. Lee<sup>1</sup>, S.Y. Song<sup>1</sup>, S.S. Kim<sup>1</sup>, S.W. Lee<sup>1</sup>, S.D. Ahn<sup>1</sup>, S.M. Yoon<sup>1</sup>, Y.S. Kim<sup>1</sup>, J.H. Park<sup>1</sup>, J.H. Kim<sup>1</sup>, E.K. Choi<sup>1</sup>

<sup>1</sup>Asan Medical Center- Univ of Ulsan, Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

To investigate long-term clinical outcomes of stereotactic ablative radiotherapy (SABR) in patients with medically inoperable stage I non-small cell lung cancer (NSCLC)

#### Material and Methods

A retrospective analysis was performed on a total of 169 patients with 178 lesions, 9 patients with synchronous cancer, of stage I non-small cell lung cancer treated with SABR at a single institution from June 2000 to May 2015. Patients with recurrent lung cancer, another primary malignancy, or prior history of RT to chest were excluded. Dose scheme of SABR was 48 Gy in four fractions in early phase, but was escalated to 60 Gy in four fractions from June 2009. CyberKnife™ was also introduced at June 2011. Patterns of failure and survival were evaluated. All failures were identified during total follow-up period, not as initial presentation. Survival was calculated from the date of initiation of radiotherapy. Toxicity was graded using the Common Terminology Criteria for Adverse Events (CTCAE) version 4.03 except rib fracture.

#### Results

Median age was 73 years (range, 40-91). Pathologic diagnosis was done in 173 tumors (97%); Adenocarcinoma in 87 tumors (49%), squamous cell carcinoma in 78 tumors (44%), unspecified NSCLC in 5 tumors (3%) and others in 3 tumors (2%) were identified. There were 39 tumors (22%) with T1a, 70 tumors (39%) were T1b, and 69 tumors (39%) with T2a. Twenty-five (14%) tumors were located at central area. Fractionation schemas were 60 Gy in four fractions (46%), 48 Gy in four fractions (29%), and 54 or 60 Gy in three fractions (16%). Forty-four tumors (25%) were treated with CyberKnife™.

Median follow-up time was 32 months. The 3- and 5-year overall survival rates were 69.5% and 46.7% respectively. The 3-year progression free and cancer-specific survival rates were 62.3% and 86.8%. The 3-year and 5-year actuarial local control rates were 86.3% and 79.3%. Tumor size was an independent prognostic factor for survival. No relapse occurred in tumor  $\leq 2$ cm irrespective of SABR dose. Escalated dose around 60 Gy/4fx (150 Gy<sub>10</sub>) achieved higher local control compared with 48 Gy/4fx (106 Gy<sub>10</sub>), 76.2% versus 60.6% at 5-year ( $p=0.022$ ) in tumors larger than 2cm diameter. However, escalated dose could not reach improved overall survival. Grade 5 toxicities were noticed in two patients; radiation pneumonitis in 1 and fatal hemoptysis in the other patient with centrally-located tumor.

#### Conclusion

SABR provides satisfactory long-term local control and overall survival in medically inoperable stage I NSCLC. Relatively lower dose, 48 Gy/4fx, is enough for T1a tumor, but dose escalation to 60 Gy/4fx improves local control for tumor larger than 2cm diameter.

### EP-1214 Stereotactic Ablative Radiotherapy in Clinical Stage I (<math>\leq 5\text{cm}</math>) Non-Small Cell Lung Cancer

S.J. Ahn<sup>1</sup>, W. Jeon<sup>1</sup>, Y.C. Kim<sup>2</sup>, I.J. Oh<sup>2</sup>, J.U. Jeong<sup>1</sup>, M.S. Yoon<sup>1</sup>, J.Y. Song<sup>1</sup>, T.K. Nam<sup>1</sup>, W.K. Chung<sup>1</sup>

<sup>1</sup>Chonnam National University Medical School, Radiation Oncology, Hwasun, Korea Republic of

<sup>2</sup>Chonnam National University Medical School, Pulmonology, Hwasun, Korea Republic of

### Purpose or Objective

Stereotactic ablative radiotherapy (SABR) has been replacing the role of surgery in the management of operable stage I non-small cell lung cancer (NSCLC). We aim to assess the outcomes of SABR performed in these patients.

### Material and Methods

Fifty-six patients with clinical stage I NSCLC who underwent SABR between Nov. 2006 and Jan. 2015 were analyzed retrospectively. Eligibility for SABR in our practice was tumor size less than 5cm and peripherally located tumors. Age ranged 54 to 87 (median 74) and male to female was 43 to 13. ECOG score was 0 in 16, 1 in 25, and 2 in 15 patients, respectively. Adenocarcinoma was 24 and squamous cell carcinoma was 25. We defined the patients as medically inoperable based on the lung function (baseline FEV1 < 40% predicted, DLCO < 50% predicted), age > 75 yrs & PS >2. Intensity-modulated radiosurgery was planned and delivered consecutively with median 60 Gy (range, 55 - 64 Gy) in 3 to 8 fractions. Median follow-up time was 23.8 months (range, 1.9 - 93.5 months).

### Results

The 3-year and 5-year overall (OS) rate of all 56 patients was 82.9% and 82.9% and progression free survival (PFS) was 54.8% and 45.6%, respectively. The possible prognostic parameters such as tumor size, tumor location (upper vs. lower lobe), gross tumor volume (GTV), SUVmax of the primary tumor, BED, and operability were entered into analysis regarding on OS or PFS. PFS was significantly dependent on the tumor location ( $p=0.047$ ), tumor size ( $>3\text{cm}$ ,  $p<0.001$ ), GTV ( $>19\text{cm}^3$ ,  $p=0.02$ ), and operability. 5-yr PFS of operable ( $n=42$ ) and inoperable ( $n=14$ ) was 52.9% vs. 31.3% ( $p=0.022$ ). OS was significantly dependent on the tumor size ( $p=0.046$ ) and BED ( $>150\text{Gy}$ ,  $p=0.022$ ). 5-yr OS of operable and inoperable patients was 90.1% vs. 67.7% ( $p=0.084$ ), respectively.

### Conclusion

SABR shows the survival outcomes similar to surgery in operable stage I NSCLC. Tumor size ( $>3\text{cm}$ ) was the most significant prognostic factor affecting to OS. We need to increase the BED of SABR over 150 Gy in cases with tolerable lung compliances.

### EP-1215 Risk factors of radiation pneumonitis after SRT: the usefulness of the PTV to lung volume ratio.

T. Ueyama<sup>1</sup>, T. Arimura<sup>1</sup>, K. Takumi<sup>1</sup>, F. Nakamura<sup>1</sup>, R. Higashi<sup>1</sup>, S. Ito<sup>1</sup>, Y. Fukukura<sup>1</sup>, T. Umanodan<sup>1</sup>, M. Nakajo<sup>1</sup>, C. Koriyama<sup>2</sup>, T. Yoshiura<sup>1</sup>

<sup>1</sup>Kagoshima University, Radiology, Kagoshima, Japan

<sup>2</sup>Kagoshima University, Epidemiology, Kagoshima, Japan

### Purpose or Objective

To investigate the risk factors of severe radiation pneumonitis (RP) after stereotactic radiation therapy (SRT) for lung tumors.

### Material and Methods

We retrospectively evaluated 68 lung tumors in 63 patients treated with SRT between 2010 and 2015. RP was graded according to the National Cancer Institute- Common Terminology Criteria for Adverse Events (NCI-CTCAE) version.4.0. SRT was delivered at 7.0-12.0Gy fractions once daily to a total of 48-64Gy (median 50). Univariate and multivariate analyses were performed to assess patient- and treatment-related factors, including age, gender, smoking index, pulmonary function, tumor location, the value of serum Krebs von den Lungen-6 (KL-6), and dose-volume metrics: V5, V10, V20, V30, V40, and V55, V2 of contralateral lung, homogeneity index of PTV (HI), dose of PTV, mean lung dose (MLD), contralateral MLD, PTV volume, lung volume, the PTV/Lung volume ratio (PTV/Lung). The value of PTV/Lung in predicting RP

was also analyzed with receiver operating characteristic (ROC) curves.

### Results

The median follow-up was 21 months. Ten patients (14.7%) developed with RP of symptomatic grade2-5 after completing SRT and three patients (4.4%) died from RP. On univariate analysis, V10, V20, PTV volume, and PTV/Lung were significantly associated with occurrence of RP $\geq$ grade2 ( $P<0.05$ , respectively). On multivariate analysis, only PTV/Lung was statistically significant ( $P<0.05$ ). ROC curves indicated that severe RP could be predicted using PTV/Lung (area under curve: 0.88, CI: 0.78-0.95, cut off value: 1.09, sensitivity: 90.0%, specificity: 72.4%)

### Conclusion

PTV/Lung could well predict the risk for severe RP after SRT.

### EP-1216 Impact of the radiation dose on the pulmonary perfusion assessed using lung scintigraphy

B. De Bari<sup>1</sup>, S. Godin<sup>2</sup>, M. Zeverino<sup>3</sup>, L. Deantonio<sup>4</sup>, T. Breuneval<sup>2</sup>, J. Prior<sup>5</sup>, J. Bourhis<sup>2</sup>, R. Moeckli<sup>3</sup>, M. Ozsahin<sup>2</sup>  
<sup>1</sup>Hôpital Univ. Jean Minjoz, Radiation Oncology, Besançon, France

<sup>2</sup>Centre Hospitalier Universitaire Vaudois, Radiation Oncology, Lausanne, Switzerland

<sup>3</sup>Centre Hospitalier Universitaire Vaudois, Medical Physics, Lausanne, Switzerland

<sup>4</sup>University Hospital "Maggiore della Carità", Radiation Oncology, Novara, Italy

<sup>5</sup>Centre Hospitalier Universitaire Vaudois, Nuclear Medicine, Lausanne, Switzerland

### Purpose or Objective

We aimed at evaluating the impact of the dose of radiotherapy on lung function (LF). LF variations were evaluated by integrating SPECT/CT pulmonary perfusion before and after radiotherapy (RT) in patients treated with radiotherapy +/- chemotherapy for a lung tumor.

### Material and Methods

Between 06.2014 and 09.2015, 15 pts presenting a primary ( $n = 11$ ) or secondary ( $n = 4$ ) lung cancer were treated with radiotherapy +/- chemotherapy (10x3 Gy, 1 pt; 13x3 Gy, 1 pt; 6x8 Gy, 1 pt; 7x7.5 Gy, 1 pt; 3x18 Gy, 1 pt; 12x4.5 Gy, 1 pt; 5x11 Gy, 1 pt; 30x2Gy 4pts; 33x2Gy, 2 pts; 5x12Gy, 1pt; 12x5Gy, 1 pt). Three pts were treated in a context of re-irradiation. All patients received a SPECT/CT to evaluate the LF before and three months after radiotherapy, which was co-registered with the planning phase of the simulation CT-scan. For pts treated with hypo-fractionated regimens, the biological equivalent dose at 2 Gy/fraction (EQD2) was calculated ( $\alpha / \beta = 10\text{Gy}$  for acute toxicity). Isodoses (5, 10, 20, 30, 40, 50, 60, 70, 80, and 90 Gy) were drawn. Then, we calculated the activity (MBq) in these volumes before and after treatment.

### Results

Linear regression analysis showed a significant reduction in LF at three months, which was proportional to the increase of the radiation dose ( $p = 0.00017$ , Figure 1). Our analysis showed a reduction of 0.14% of the LF for each delivered gray. Even with the limits of the small population of this study, the linear equation showed a predictive value in predicting the loss of LF/Gy of 98% ( $R^2 = 0.9807$ ).

### Conclusion

SPECT/CT is a good imaging modality to assess changes in LF after thoracic irradiation. This analysis shows a functional decrease, which is proportional to the delivered dose, reflecting the functional acute toxicity. These function-based approaches could improve our knowledge about the response of the OARs to the radiation, and should be prospectively evaluated.

### EP-1217 Non-small cell lung cancer invading the vertebra: what is the optimal strategy for radiation?

S. Appel<sup>1</sup>, J. Goldstein<sup>1</sup>, Z. Symon<sup>1</sup>, Y. Lawrence<sup>1</sup>, M. Ben aiun<sup>1</sup>, N. Honig<sup>1</sup>, T. Rabin<sup>1</sup>

<sup>1</sup>Chaim Sheba Medical Center, Radiation Oncology, Ramat Gan, Israel

#### Purpose or Objective

Non-small cell lung cancer that invades the vertebra (T4) may cause significant morbidities if uncontrolled locally with limited options for salvage re-irradiation. The spinal foramina and vertebral body are sites of potential tumor invasion and sparing them may compromise local tumor control probabilities. In our institution, we incorporated the strategy of including the entire vertebra and the spinal canal to the allowed dose in two strategies: shrinking fields and integrated boost.

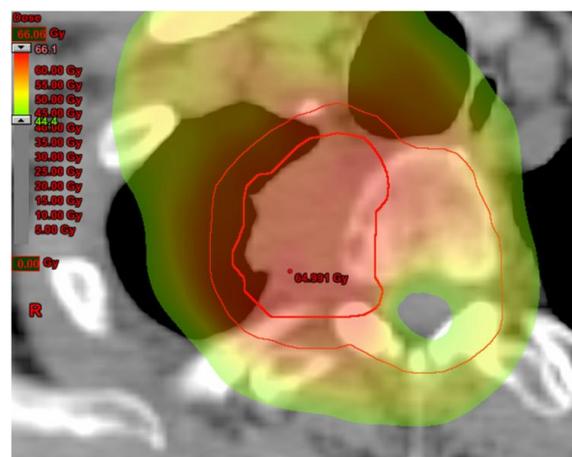

We hypothesized that treating with integrated boost including the spine canal and the vertebral body will result in higher tumor BED than treatment with shrinking fields with off spine boost.

#### Material and Methods

we retrospectively reviewed 14 cases that were T4 and treated with radiation therapy in our institute and included the spine and vertebra, during the years 2013-2016. We searched the radiation plans for mean dose to GTV, spine and fraction size. We calculated the biologically effective doses (BED) per the linear quadratic model, for the GTV using  $\alpha/\beta=10$  and for the spine using  $\alpha/\beta=3$ . In the shrinking fields two calculations were performed for each step, to account for the different doses to the spine.

#### Results

- **Shrinking field:** ( 4 patients) median prescription dose was 59 Gy (55-66 Gy) in 2 Gy per fraction in 29 (26-33) fractions Median GTV dose was 61.3 Gy (57-68.7Gy). The maximal dose to spine with the composite planes, including the exit dose from the boost plan was median of 50.6 Gy (48.4-53.5 Gy). Median BED to PTV was 71Gy (68.1-79.2Gy) GTV was 74.3 Gy (66.6-83 Gy) and to the spine was 82.2 Gy (75.3-86.4 Gy)
  - **Integrated boost:** ( 10 patients) median prescription dose was 61.6 Gy (54-66 Gy) in 2.21 Gy per fraction (1.96-2.28 Gy) in 28 (28-33) fractions. The median GTV dose was 62.6 Gy (55-64.7 Gy). The median maximal dose to the spine was 50 Gy (47.8-52.7Gy), in 1.8 Gy per fraction (1.6-1.9 Gy). Median BED to PTV was 75.2 Gy (64.8-79.2 Gy) GTV was 76.4 Gy (66.6-78.5 Gy), and the median BED to the spine 79.2 Gy (75-85.9 Gy).
1. example of integrated boost treatment color wash. the GTV is bold red and is receiving mean dose of 63 Gy .. the outer red delineates the elective dose and includes the spinal canal and the adjacent vertebra.higher dose is manipulated inside the GTV, to allow higher BED while elective dose is prescribed to the high risk elective area.

2. Table 1: Comparison between treatment strategies: Shrinking fields vs. Integrated boost: Doses prescribed to the PTV, actual doses to the GTV and maximal doses to the spine, and the calculated doses to the GTV and the spine according to the linear quadratic model.

	Shrinking fields	Integrated boost
Prescription to PTV	59 (55-66)	61.6 (54-66)
Dose to GTV median (range) Gy	61.3 (57-68.7)	62.6 (55-64.75)
Fraction size GTV median (range)Gy	2.08 (2.02-2.17)	2.21 (1.96-2.28)
Maximal dose to spine median (range) Gy	50.6 (48.4-53.5)	50 (47.8-52.7)
Number of fractions median (range) Gy	29 (26-33)	28 (28-33)
BED to PTV median (range) Gy	71 (68.1-79.2)	75.2 (64.8-79.2)
BED to GTV median (range) Gy	74.3 (66.6-83)	76.2 (66.2-78.5)
BED to spine median (range) Gy	82.2 (75.3-86.4)	79.2 (75-85.9)

#### Conclusion

Integrated boost strategy resulted in modestly higher BED to the PTV and GTV than shrinking fields, and lower BED to the spine. Thus, the integrated boost strategy should be preferred.

### EP-1218 Prognostic Values of Tumor Markers in Lung Cancer Patients Treated with Definitive Chemoradiotherapy

J.H. Chung<sup>1</sup>, J.S. Kim<sup>1</sup>

<sup>1</sup>Seoul National University Bundang Hospital, Department of Radiation Oncology, Seongnam-si, Korea Republic of

#### Purpose or Objective

Prognostic value of serum carcinoembryonic antigen (CEA), squamous cell carcinoma antigen (SCC), cytokeratin 19 fragment antigen 21-1 (Cyfra 21-1) and neuron specific enolase (NSE) has been investigated in patients with early or advanced lung cancer. However, the role of these markers in patients undergoing concurrent chemoradiotherapy (CCRT) for inoperable lung cancer is unclear.

#### Material and Methods

In this retrospective study, 179 patients (154 men and 25 women; mean age, 62.2±9.7 years) with inoperable lung cancer underwent definitive CCRT at our institution from 2003 to 2014. Histologic classification was as follows: adenocarcinoma 37 (21%), squamous cell carcinoma 62 (35%), other non-small cell lung cancer (NSCLC) 6 (3%), and small cell carcinoma 74 (41%). Age, gender, histology, tumor diameter, clinical N stage, and pre- and post-CCRT

serum CEA, SCC, Cyfra 21-1, and NSE levels were chosen as study variables.

### Results

Increased levels of CEA, SCC, Cyfra 21-1, and NSE levels were detected in 52 (29%), 32 (18%), 61 (34%), and 81 (45%) patients, respectively. According to the histologic subgroup, patients with adenocarcinoma presented significantly higher levels of CEA at baseline than those with other histology. Significantly increased levels of SCC and Cyfra 21-1 at baseline were present in squamous cell carcinoma. Proportion of patients with increased NSE at baseline was higher in small cell carcinoma than other histology. For the group of 105 NSCLC patients, the median survival was 7 months for patients with increased post-CCRT NSE and 26 months for patients with normal post-CCRT NSE ( $p=0.002$ ). For the group of 74 small cell carcinoma patients, the median survival was 7 months for patients with increased pre-CCRT NSE and 27 months for patients with normal pre-CCRT NSE ( $p<0.001$ ). In the multivariate analysis, high level of NSE, histology, and tumor diameter were significantly correlated with worse survival.

### Conclusion

These findings suggest that pre- and post-CCRT NSE levels exhibit prognostic values in patients with lung cancer undergoing definitive CCRT. The combined use of serum NSE may provide additional information for prognosis.

### EP-1219 Concomitant radiotherapy and TKI in EGFR mutant or ALK positive stage IV non-small cell lung cancer

P. Borghetti<sup>1</sup>, M. Bonù<sup>2</sup>, E. Roca<sup>3</sup>, E. Salah<sup>2</sup>, A. Baiguini<sup>2</sup>, S. Pedretti<sup>1</sup>, M. Maddalo<sup>1</sup>, M. Buglione<sup>2</sup>, S. Magrini<sup>2</sup>

<sup>1</sup>Spedali Civili di Brescia, Radiation Oncology, Brescia, Italy

<sup>2</sup>Brescia University, Radiation Oncology, Brescia, Italy

<sup>3</sup>Spedali Civili di Brescia, Medical Oncology, Brescia, Italy

### Purpose or Objective

To investigate the role of radiotherapy (RT) in the management of EGFR-mutant or ALK positive metastatic non-small cell lung cancer (NSCLC) treated with TKI at onset or after standard chemotherapy

### Material and Methods

Clinical data of 50 patients (pts) treated with RT concomitant to TKI for EGFR-mutant or ALK positive NSCLC stage IV were revised. Overall survival (OS) and toxicities were analysed as endpoint of the study. Kaplan-Meier curve and log-rank test were elaborated for analysis of survival, while chi-square test was calculated to compare different variables.

### Results

A description of the series is reported in Table 1. Median age of pts was 65 years. Biological targeted therapy for EGFR-mutant and ALK positive metastatic NSCLC was used in 82% and 18% of cases. Three pts were submitted to 2 TKI. Stereotactic radiotherapy was performed in 9 pts, 8 of them were treated for oligoprogressive disease and 1 for palliation ( $p 0.00$ ). RT was performed within 30 days before TKI, concomitant to TKI and within 30 days after TKI in 8, 33 and 9 cases. Median duration of biological targeted therapy in the whole series was 11.9 (0.4-59.1) months, while was of 9.7 (0.4-33.5), 14.2 (1.7-59.1) and 8.3 (4.6-17.9) months for pts treated with RT before, concomitant and after TKI, respectively. Median OS was 19.3 months and 1 and 2 yrs OS was 71.5% and 36.5%, respectively. Stereotactic RT group showed an apparent significant benefit in term of OS ( $p= 0.043$ ). Fourteen pts reported G1-2 toxicities (7 neurological symptoms, 3 pain and 4 emesis), none determined the suspension of RT. No dermatitis were observed.

Table 1

	n. (%)		n. (%)
Age (median 65 yrs)		RT schedule	
≤ 65 yrs	26 (52)	Stereotactic RT	9 (18)
> 65 yrs	24 (48)	No Stereotactic RT	41 (82)
Performance status		RT target	
0	16 (32)	Brain	27 (54)
1	29 (58)	Bone	19 (38)
2	5 (10)	others	4 (8)
Stage IV presentation		RT aim	
≤ 4	11 (22)	Symptomatic	28 (56)
> 4	39 (78)	Palliative	14 (28)
Previous CHT		Ablative	8 (16)
0	27 (54)		
1	15 (30)		
2	8 (16)		

### Conclusion

Biological targeted therapy with TKI is a recent opportunity to treat stage IV NSCLC with EGFR mutations or ALK translocation but scarce data are available on the effects of combined treatment. Our analysis shows that RT concomitant to TKI is feasible and safe with satisfying OS and RT related toxicities were not higher than expected.

### EP-1220 Sites of recurrent disease and prognostic factors in SCLC patients treated with radiochemotherapy

R. Bütof<sup>1</sup>, C. Gumina<sup>2</sup>, C. Valentini<sup>1</sup>, A. Sommerer<sup>1</sup>, S. Appold<sup>1</sup>, D. Zips<sup>3</sup>, S. Löck<sup>4</sup>, M. Baumann<sup>1</sup>, E.G.C. Troost<sup>1</sup>

<sup>1</sup>University Hospital and Medical Faculty Carl Gustav Carus Dresden, Department of Radiation Oncology, Dresden, Germany

<sup>2</sup>San Raffaele Scientific Institute Milano, Department of Radiotherapy, Milano, Italy

<sup>3</sup>Eberhard-Karls-Universität Tübingen, Department of Radiation Oncology, Tübingen, Germany

<sup>4</sup>OncoRay, National Center for Radiation Research in Oncology, Dresden, Germany

### Purpose or Objective

Concurrent radiochemotherapy (RCHT) is the standard treatment in locally advanced small cell lung cancer (SCLC) patients. Due to conflicting results on elective nodal irradiation (ENI) or selective node irradiation (SNI) there is no clear evidence on optimal target volumes. Therefore, the aims of this study were the evaluation of sites of recurrent disease in patients with limited stage SCLC undergoing radiochemotherapy to assess the feasibility and safety of SNI versus ENI and, moreover, the extraction of prognostic factors for loco-regional control, freedom from distant metastases and overall survival.

### Material and Methods

A retrospective single-institution study was performed in 54 consecutive patients treated with RCHT. After state-of-the-art staging, all patients underwent three-dimensional conformal radiotherapy to a total dose of 45 Gy in twice-daily fractions of 1.5 Gy starting concurrently with the first or second chemotherapy cycle. The gross tumour volume (GTV) consisted of the primary tumour and SNI visualized on CT and/or FDG-PET, or confirmed by cytology. The clinical target volume (CTV) was obtained by expanding the GTV, adjusting it for anatomical boundaries, and electively adding the supraclavicular lymph node stations. Thereafter, the CTV was expanded to a planning target volume based on institutional guidelines. Follow-up consisted of a 3-monthly chest x-ray or CT-scan up to 5 years after RCHT. All sites of loco-regional recurrences were correlated to the initial tumour and dose delivered. The impact of potential prognostic variables on outcome was evaluated using the Cox-regression model.

## Results

After a median interval of 11.5 months, 17 patients (31%) relapsed locally or regionally: six within the initial primary tumour volume, five within the initially affected lymph nodes, three metachronously within primary tumour and initially affected lymph nodes, and three both inside and outside of the initial nodal disease. All sites of loco-regional recurrence had received 92%-106% of the prescribed dose. Thirty-seven patients (69%) developed distant metastases (37.8% liver, 35% brain). Among all investigated co-factors only total GTV revealed a significant correlation with patient outcome.

## Conclusion

In our study most recurrences occurred in the initial primary tumour or lymph node volume, or distantly. We did not register any case of isolated nodal failure, suggesting the use of selective nodal irradiation, possibly with the addition of supraclavicular irradiation in patients with affected lymph nodes in the upper mediastinum, instead of ENI. Among all investigated patient- and tumour-related co-factors only total GTV revealed a significant correlation with patient outcome. Further prospective clinical trials are needed for final determination of optimal irradiation fields in SCLC patients.

## EP-1221 Adherence to lung cancer guidelines and its impact on survival

I. Linares<sup>1</sup>, M. Sánchez<sup>2</sup>, J. Pérez-Alija<sup>3</sup>, E. Molina<sup>2</sup>, Y. Chang-Chan<sup>4</sup>, R. Guerrero<sup>5</sup>, J. Expósito<sup>5</sup>

<sup>2</sup>Escuela Andaluza de Salud Pública. Instituto de Investigación Biosanitaria ibs. Hospitales Universitarios de Granada/Universidad de Granada CIBER de Epidemiología y Salud Pública CIBERESP, Escuela Andaluza de Salud Pública, Granada, Spain

<sup>3</sup>Hospital Plató, Radiation Oncology, Barcelona, Spain

<sup>4</sup>Escuela Andaluza de Salud Pública. Instituto de Investigación Biosanitaria ibs. GRANADA. Hospitales Universitarios de Granada/Universidad de Granada, Escuela Andaluza de Salud Pública, Granada, Spain

<sup>5</sup>Complejo Hospitalario Universitario de Granada, Radiation Oncology, Granada, Spain

## Purpose or Objective

Clinical practice guidelines are tools to improve quality and reduce variability of cancer care. Our objective is to evaluate the concordance between lung cancer guidelines and clinical practice in Granada and its impact on survival.

## Material and Methods

Data were obtained from the population-based cancer registry in Granada (Spain). All cases of newly diagnosed primary lung cancer (non-small-cell lung cancer a small cell lung cancer) in 2011-2012 were included. To describe the adherence to guidelines, 10 indicators regarding diagnostic and treatment were identified. The indicators were assigned according to the pathology, stage and ECOG performance status. For those patients who did not adhere to the indicators, the medical record was reviewed to determine the reason for this. One and two-year relative survival was compared between patients treated according to clinical guide recommendations and those who were treated otherwise.

## Results

685 patients were enrolled; 490 were discussed at a multidisciplinary team meeting. Microscopic verification was available in 81%. 58.6% did not received guideline recommended diagnosis and treatment. Most common non-adherence reasons were a bad performance status and advanced age (16.3%), exitus (8.8%) and patient preference (2.8%). Better adherence was shown in early

stage (62.1% stage I and 66.7% stage II versus 57% stage IV) and women (68.3% versus 44.8% in men). Patients who received guideline recommended diagnosis and treatment had improved survival compared with those who did not: one and two-year relative survival of 51% and 28.2% versus 34.1% and 17.5%.

## Conclusion

Guidelines adherence monitoring can be useful to reduce variability in cancer care. A significant proportion of cases of non-adherence to guidelines are due to unavoidable causes. Alternative guidelines are needed for those cases. Acting in accordance to guidelines improves survival.

## EP-1222 Beclin-1 expression of circulating tumor cells in non-small cell lung cancer patients.

C. Prieto Prieto<sup>1</sup>, D. De Miguel<sup>2</sup>

<sup>1</sup>Hospital Universitario Virgen de las Nieves, Radiation Oncology, Granada, Spain

<sup>2</sup>GENYO. Centre for Genomics and Oncological Research, Pfizer/University of Granada/Andalusian Regional Government-, Granada, Spain

## Purpose or Objective

Non-small cell lung cancer (NSCLC) accounts for 75-80% of the total lung cancer cases, including those at advanced stages IIIA and IIIB, where chemotherapy and radiotherapy are the main recommended treatments. Despite this, recurrence and progression are still present, largely caused by the release of circulating tumor cells (CTCs) into peripheral blood, where they travel up to a secondary organ to establish metastasis. Autophagy is an auto-proteolytic mechanism by which eukaryotic cells can surround intracellular components into vesicles like lysosomes. Beclin-1, whose expression has never been described in CTCs, is plays a critical role in the regulation of autophagy. In spite of this, its role as a risk factor for radiotherapy resistant is not clear yet. Our objective was to identify the prognostic value of the presence of CTCs, from peripheral blood of NSCLC patients undergoing concomitant radiotherapy and chemotherapy treatment, and their characterization with Beclin-1.

## Material and Methods

This prospective and ongoing study included 21 NSCLC patients from Virgen de las Nieves Hospital (Granada, Spain), who have a locally advanced and unresectable disease (stages: inoperable IIIA, IIIB and IV) and were treated with concomitant radiotherapy (total dose of 60Gy with standard fractionation) and chemotherapy (Cisplatin-Vinorelbine mostly). Follow-up was performed by computed tomography (CT) for 3 months after the treatment, however Positron Emission Tomography (PET) was performed in some of them. According to our immunomagnetic selection methodology, CTCs were isolated by epithelial markers from peripheral blood samples before the treatment, and 3, 8 and 48 weeks after and characterized for Beclin-1 expression by immunofluorescence.

## Results

Even though the low number of patients, our results revealed a tendency or an association between presence of CTCs at baseline status with; tumor response observed by CT and PET ( $p=0.99$ ), tumor stage ( $p=0.036$ ) and local and distant progression ( $p=0.088$ ). On the other hand, 19% of the patients showed CTCs<sup>BECLIN1+</sup> but it was not associated with any clinicopathological variables as progression or mortality.

## Conclusion

In conclusion, the presence of CTCs before treatment may be a predictive factor for progression in NSCLC patients, but Beclin-1 may not, however more patients are needed to reach statistical significance.

## EP-1223 Comparing concurrent versus sequential chemoradiotherapy in locally advanced NSCLC

G. Wei<sup>1</sup>, G. Xiaobin<sup>1</sup>, G. Xian-Shu<sup>1</sup>, M. Mingwei<sup>1</sup>, C. Ming<sup>1</sup>, P. Chuan<sup>1</sup>

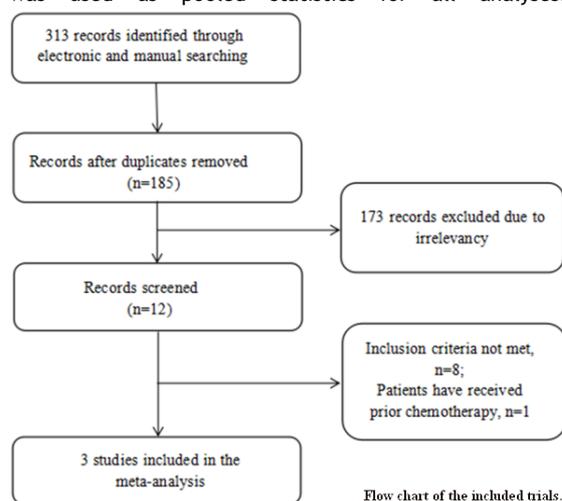

<sup>1</sup>Peking University First Hospital, Department of Radiation Oncology, Beijing, China

### Purpose or Objective

The aim of this study was to compare concurrent (concurrent arm) versus sequential chemotherapy (sequential arm) with hypofractionated radiotherapy in the treatment of inoperable locally advanced non-small cell lung cancer (NSCLC) (stage IIIA or IIIB) by using meta-analysis. The primary objective of this study was to compare the outcomes including tumor response and overall survival (OS) between sequential arm and concurrent arm. The secondary objective was to compare the progression-free survival (PFS) and late adverse event between the two arms.

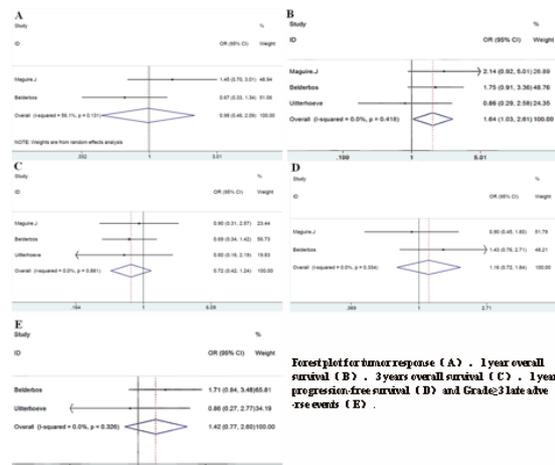

### Material and Methods

Relevant studies were identified through searching PubMed, Embase and Web of Science databases till July, 2016. Odds ratio (OR) with 95% confidence interval (CI) was used as pooled statistics for all analyses.

### Results

The analysis was conducted based on the data from 3 studies with 370 patients. The pooled data showed that 3 years OS was not improved in concurrent arm compared to sequential arm [OR=0.72, 95% CI: 0.42-1.24, P=0.235]. Whereas the combined results for 1-year OS was OR=1.64, 95% CI: 1.03-2.61, P=0.037. There was no significant difference of 1-year PFS [OR=1.16, 95% CI: 0.72-1.84, P=0.542] between these arms. Moreover, no significant difference was found regarding tumor response [OR=1.02, 95% CI: 0.48-2.19, P=0.950] and Grade $\geq$ 3 late adverse events [OR=1.42, 95% CI: 0.77-2.60, P=0.261].

### Conclusion

Our meta-analysis demonstrated that concurrent arm was not significantly better than sequential arm in clinical outcomes.

## EP-1224 Therapeutic effects of accelerated hyperfractionation and conventional fractionation CRT on NSCLC

T. Mitsuyoshi<sup>1</sup>, Y. Matsuo<sup>1</sup>, T. Shintani<sup>1</sup>, Y. Iizuka<sup>1</sup>, W.A. Mampuya<sup>1</sup>, H. Nagai<sup>2</sup>, H. Ozasa<sup>2</sup>, Y.H. Kim<sup>2</sup>, T.F. Chen-Yoshikawa<sup>3</sup>, M. Sonobe<sup>3</sup>, N. Nakajima<sup>4</sup>, A. Yoshizawa<sup>4</sup>, T. Mizowaki<sup>1</sup>, H. Date<sup>3</sup>, M. Hiraoka<sup>1</sup>

<sup>1</sup>Kyoto University Hospital, Department of Radiation Oncology and Image-Applied Therapy, Kyoto, Japan

<sup>2</sup>Kyoto University Hospital, Department of Respiratory Medicine, Kyoto, Japan

<sup>3</sup>Kyoto University Hospital, Department of Thoracic Surgery, Kyoto, Japan

<sup>4</sup>Kyoto University Hospital, Department of Diagnostic Pathology, Kyoto, Japan

### Purpose or Objective

Definitive concurrent chemoradiotherapy (CRT) is a standard treatment for locally advanced non-small-cell lung cancer (NSCLC); however, no consensus exists regarding the most therapeutically effective radiotherapy schedule. In this study, we directly assessed the local and regional pathological effectiveness of CRT using either accelerated hyperfractionation (AHF) or conventional fractionation (CF) by retrospective histopathologic examination of resection specimens after CRT.

### Material and Methods

Data were analyzed from NSCLC patients treated with induction-concurrent CRT followed by thoracotomy between October 2006 and June 2015 in our hospital. All patients received three cycles of induction platinum-based doublet chemotherapy and concurrent radiotherapy using either AHF (42 Gy/1.5 Gy bid) or CF (50 Gy/2 Gy qd). The pathological responses of primary tumor and metastatic lymph nodes after induction CRT were assessed using resection specimens. The differences in pathological responses between the AHF and CF groups were analyzed using Fisher's exact test.

### Results

A total of 51 patients were treated with induction CRT followed by thoracotomy. There were 39 male (76%) and 12 female (24%), with a median age of 62 (range, 43-78) years. All patients had a performance status (PS) score [Eastern Cooperative Oncology Group (ECOG)] of 0. Of the 51 patients, 7 were diagnosed with clinical stage IIB disease, 34 with clinical stage IIIA disease and 7 with clinical stage IIIB disease. The histologic subtypes were adenocarcinoma in 29 patients (59%) and squamous cell carcinoma (SqCC) in 22 patients (41%). No significant

differences existed between the AHF and CF groups in gender, age, clinical stage or histology. A total of 40 patients (78%) had experienced lymph node metastasis before treatment. Patients received radiotherapy using AHF in 17 cases and CF in 34 cases. All patients underwent thoracotomy after induction CRT. The median duration between the last day of radiotherapy and the day of operation was 35 days (range, 16-70). The pathological complete response (pCR) rates in the primary tumor and dissected lymph nodes are shown in Table 1. The pCR rates of adenocarcinoma after induction CRT in the AHF and CF groups were 41% (7/17) and 24% (8/34) in the primary tumor and 50% (8/16) and 50% (12/24) in the dissected lymph nodes, respectively. The pCR rates of SqCC after CRT in the AHF and CF groups were 75% (6/8) and 29% (4/14) in the primary tumor and 63% (5/8) and 64% (7/11) in dissected lymph nodes, respectively. The SqCC in the primary tumor had significantly higher pCR rates under AHF compared to CF ( $p = 0.02$ ). However, the pCR rates of adenocarcinoma after CRT in the AHF and CF groups were similar in both the primary tumor and dissected lymph nodes.

Histology	CF		AHF		p		
	No.	(%)	No.	(%)			
<b>Primary tumor</b>							
	15/51	(29)	8/34	(24)	7/17	(41)	0.21
Adenocarcinoma	5/29	(17)	4/20	(20)	1/9	(11)	1.00
SqCC	10/22	(45)	4/14	(29)	6/8	(75)	0.02
<b>Positive lymph node</b>							
	20/40	(50)	12/24	(50)	8/16	(50)	1.00
Adenocarcinoma	8/21	(38)	5/13	(38)	3/8	(38)	1.00
SqCC	12/19	(63)	7/11	(64)	5/8	(63)	1.00

### Conclusion

Chemoradiotherapy using AHF may achieve a higher pathological therapeutic effect than chemoradiotherapy using CF for squamous cell lung cancer in primary tumors.

### EP-1225 Atlas-based segmentation reduces inter-observer variation and delineation time for OAR in NSCLC

W. Van Elmpt<sup>1</sup>, J. Van der Stoep<sup>1</sup>, J. Van Soest<sup>1</sup>, T. Lustberg<sup>1</sup>, M. Gooding<sup>2</sup>, A. Dekker<sup>1</sup>

<sup>1</sup>MAASTRO Clinic, Department of Radiation Oncology, Maastricht, The Netherlands

<sup>2</sup>Mirada Medical Ltd, Science and Medical Technology, Oxford, United Kingdom

### Purpose or Objective

Tumor and organs-at-risk (OAR) delineations are considered a major uncertainty in radiotherapy. Automatic segmentation methods are currently available that may guide the delineations of OAR. However, the inter-observer variability in OAR delineations are rarely studied and the effect of automated methods on delineation variability has not yet been performed. In this study we systematically quantified the (reduction of) inter-observer variation by providing the delineation expert with an atlas-based generated automatic contour including time spent on delineations.

### Material and Methods

Atlas-based automatic delineations were performed using commercial available software with an atlas derived for 10 stage I NSCLC patients using institutional delineation guidelines with minimal anatomical distortions. In a next step, 20 consecutive prospective stage I-III NSCLC patients were selected from clinical routine. For these patients, 3 experienced radiation technologists independently

created delineations for heart, mediastinum, spinal cord, esophagus and brachial plexus according to the institutional standards. Time taken was also recorded. Next, the automatic atlas-based contour was provided as a starting point for a second round of delineations (blinded for the initial contour). The proposed contour was allowed to be adapted (or discarded) and modified into a clinical acceptable contour. The inter-observer variation was quantified as the non-overlapping volume of the 3 observers for both the initial contours and the adapted contours. Results are expressed as mean±SD, p-values calculated using a Wilcoxon test.

### Results

Comparing the initial contours with the proposed atlas-generated contour, the inter-observer variation volumes reduced significantly for the mediastinum: 253±93 cm<sup>3</sup> to 168±103 cm<sup>3</sup> ( $p < 0.01$ ), spinal cord: 32±10 cm<sup>3</sup> to 17±3 cm<sup>3</sup> ( $p < 0.01$ ) and heart: 211±69 cm<sup>3</sup> to 136±72 cm<sup>3</sup> ( $p < 0.01$ ). For the esophagus there was no reduction inter-observer variation volume ( $p = 0.601$ ), also no clinically significant differences for brachial plexus were observed: 12.9±5.4 cm<sup>3</sup> vs 12.2±5.1 cm<sup>3</sup>. The average delineation time for the above structures was reduced from 18.1±4.8 to 13.2±5.5 minutes ( $p < 0.01$ ), mainly dominated by the reduction in time needed for the mediastinal delineation and heart.

### Conclusion

Besides a reduction in contouring time, the inter-observer variation is also reduced if an atlas-based segmentation approach is used as the initial starting point for delineations. Especially for the larger structures such as the heart and mediastinum the impact on time gain and increase of quality is significant.

### EP-1226 Stereotactic robotic body radiotherapy for patients with pulmonary oligometastases

P. Berkovic<sup>1</sup>, A. Gulyban<sup>1</sup>, L. Swenen<sup>1</sup>, D. Dechambre<sup>1</sup>, P. Viet Nguyen<sup>1</sup>, N. Jansen<sup>1</sup>, C. Mievis<sup>1</sup>, N. Barteley<sup>1</sup>, P. Lovinfosse<sup>1</sup>, M. Baré<sup>1</sup>, F. Lakosi<sup>2</sup>, L. Janvary<sup>3</sup>, P.A. Coucke<sup>1</sup>

<sup>1</sup>C.H.U. - Sart Tilman, Radiotherapy department, Liège, Belgium

<sup>2</sup>Health Science Center- University of Kaposvar, Radiation Oncology, Kaposvar, Hungary

<sup>3</sup>University of Debrecen - Medical Center, Oncology Clinic, Debrecen, Hungary

### Purpose or Objective

To analyse local control (LC), pulmonary and distant progression free survival (pulmonary PFS, DFS), overall survival (OS) and toxicity in a cohort of patients treated by stereotactic body radiotherapy (SBRT) for oligometastatic pulmonary lesions. To evaluate the potential influence of age, histology, controlled primary, performance status, biological effective dose (BED) and other parameters on the obtained results.

### Material and Methods

Consecutive patients with up to 3 synchronous lung metastases were included in this study for Cyberknife at the Liege University Hospital. All patients were referred for stereotactic treatment after a full staging including baseline registration of the pulmonary function, chest and abdominal diagnostic computed tomography (CT) and [18F]-fluorodeoxyglucose (FDG) positron emission tomography (PET)-CT imaging confirming the presence or absence of tumoral activity at the primary tumour site and extra-pulmonary metastases. The intended prescription dose was 60 Gy in 3 fractions, prescribed on the 80% isodose line and adapted based on clinical risk-factors. Local control (LC), lung and distant progression free survival (lung and distant PFS) and overall survival (OS) of patients were generated using Kaplan-Meier survival curves. Age, gender, performance status (PS), primary histology, controlled primary as patient specific, while

total BED10Gy (a/b = 10) prescribed dose as treatment related factors were analysed using log-rank test to determine their impact on outcome.

#### Results

Between 05/2010 and 03/2016, 131 patients with 164 lesions were irradiated. Treatments were delivered 3x/week in a median of three fractions. According to the RECIST criteria a complete or partial response were observed in 86 and 27 lesions, while 12 remained stable. After mean follow-up of 14 months, the 1 and 2-year LC/lung PFS/DPFS/OS were 85.0/62.2/82.6/91.3% and 69.0/44.8/69.8% and 77.9% respectively. Age (>65 years) and controlled primary tumour influenced DPFS (p=0.017) and OS (p=0.02) respectively, while LC and OS differed significantly for BED10Gy (>120 vs. <=120 Gy, p<0.001 and p=0.016) and primary histology (adenocarcinoma or others, p=0.003 and p=0.006) (Figure 1 and 2). Grade 1/2/3/4 fatigue, chest pain and dyspnoea were present in 77/3/0/0, 20/0/0/0 and 26/1/1/0 treatments as acute, while 22/0/0/0, 14/37/0/0 and 18/2/3/1 as late toxicity. One patient died due to RT-induced pulmonary haemorrhage.

Figure 1: Kaplan-Meier curves and log-rank test for LC

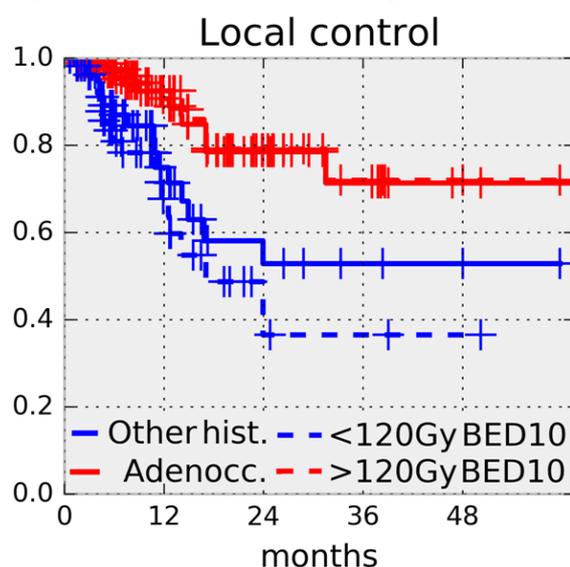

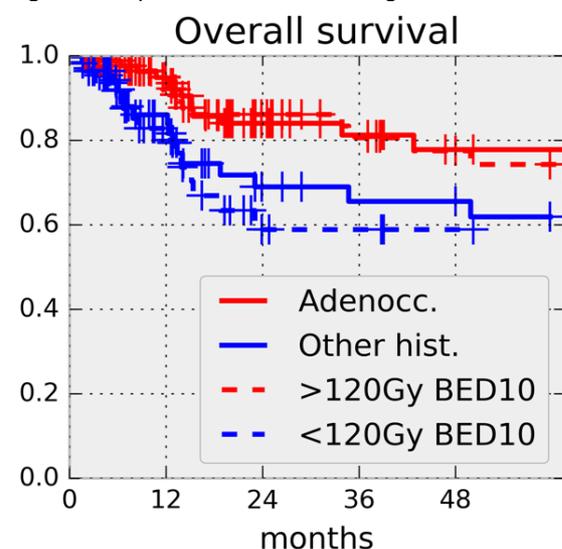

Figure 2: Kaplan-Meier curves and log-rank test for OS

#### Conclusion

Our favourable outcome data reinforces the paradigm shift of SBRT in oligometastatic pulmonary disease. Longer follow-up is required especially concerning patient selection and fractionation schedules to secure adequate dose and to further strengthen the position of this treatment option.

#### EP-1227 Neutrophil-lymphocyte ratio and a dosimetric

Y.H. Lee<sup>1</sup>, H.S. Choi<sup>1</sup>, H. Jeong<sup>1</sup>, K.M. Kang<sup>1</sup>, J.H. Song<sup>2</sup>, W.S. Lee<sup>3</sup>, G.W. Lee<sup>3</sup>, H.N. Song<sup>3</sup>, H.G. Kim<sup>4</sup>, M.H. Kang<sup>4</sup>, D.Y. Rhee<sup>5</sup>, B.K. Jeong<sup>1</sup>

<sup>1</sup>Gyeongsang National University Hospital, Radiation Oncology, Jinju-si, Korea Republic of

<sup>2</sup>Gyeongsang National University Changwon Hospital, Radiation Oncology, Changwon-si, Korea Republic of

<sup>3</sup>Gyeongsang National University Hospital, Internal Medicine, Jinju-si, Korea Republic of

<sup>4</sup>Gyeongsang National University Changwon Hospital, Internal Medicine, Changwon-si, Korea Republic of

<sup>5</sup>Gyeongsang National University Hospital, Emergency Medicine, Changwon-si, Korea Republic of

#### Purpose or Objective

To identify the predictive factors for progression of radiological radiation pneumonitis (RP) to symptomatic RP and to evaluate the usefulness of the neutrophil-lymphocyte ratio (NLR) as a severity and prognosis marker of RP in stage III non-small-cell lung cancer (NSCLC) patients treated with definitive concurrent chemoradiotherapy (CCRT).

#### Material and Methods

The study included 61 patients treated between January 2010 and December 2015. The patient characteristics, tumor factors, laboratory findings, and treatment parameters were recorded. Among patients with radiological RP, the predictive factors associated with progression to symptomatic RP were assessed.

#### Results

Of the 61 patients, 47 (77%) showed radiological RP at a median of 78 days after radiation therapy (RT) completion, and of these, 15 patients (32%) developed symptomatic RP. The interval between RT completion and radiological RP was shorter in patients with progression than in those without progression (p=0.001), and in the latent period within 2 months, progression was highly probable (p=0.002). Stage and the RT technique were related to symptomatic RP (p=0.046 and p=0.046, respectively). Among dosimetric factors, lung volume receiving  $\geq 20$  Gy ( $V_{20}$ ) of >30% was the most significant factor for symptomatic RP (p=0.001). The NLR (NLR<sub>R</sub>) and C-reactive protein level at radiological RP were higher in patients with symptomatic RP than in other patients (p=0.012 and p=0.067, respectively). In multivariate analysis,  $V_{20}>30\%$  and NLR<sub>R}>6</sub> were associated with symptomatic RP development. In receiver operating characteristic curve analysis, the combination of NLR<sub>R}>6 and  $V_{20}>30\%$  improved the predictive power for symptomatic RP.</sub>

#### Conclusion

The NLR at radiological RP is a useful biomarker for predicting symptomatic RP development after CCRT in stage III NSCLC patients. Patients showing early appearance of radiological RP along with the combination of a high NLR and  $V_{20}>30\%$  should be managed with caution as there is a high risk of symptomatic RP.

#### EP-1228 UK NCRI CTRad consensus on drug and radiotherapy combination platform studies in NSCLC

<sup>9</sup>Weston Park Hospital, Department of Clinical Oncology-, Sheffield, United Kingdom

<sup>10</sup>University of Glasgow, Institute of Cancer Sciences, Glasgow, United Kingdom

### Purpose or Objective

Local control and systemic control need to be improved for patients with locally advanced and metastatic non-small cell lung cancer (NSCLC) and novel mechanism based therapies (MBT) drug and radiotherapy (RT) combinations have the potential to achieve this. Current models of early phase clinical trials for these combinations are developed in a piecemeal fashion leading to inefficiency and slow progress. We describe a joint UK National Cancer Research Institute Clinical and Translational Radiotherapy Research Working Group (NCRI CTRad) and Lung Clinical Studies Group (NCRI Lung CSG) initiative to develop two platform studies of MBT/RT combinations in the treatment of NSCLC.

### Material and Methods

NCRI CTRad and the NCRI Lung CSG held a two-day consensus meeting in Glasgow in February 2016 to consider the optimal approach in the development of MBT/RT combinations. Invited participants included UK clinical and medical oncologists, statisticians, methodologists and industry partners active in NSCLC research. The consensus achieved is presented.

### Results

It was agreed to establish 2 platform studies which will run in parallel. In patients with locally advanced NSCLC, a phase 1 study will test novel MBT agents, such as DNA damage repair inhibitors, in combination with curative intent RT in patients with stage 3 NSCLC. We agreed to use conventional fractionation to a dose of 60-66 Gray in 30-33 fractions. In patients with metastatic disease, a phase 2 study will investigate RT in combination with immunomodulating agents. It will investigate the use of RT under two scenarios: 1) palliative radiotherapy delivered for the purpose of symptomatic control; 2) radiotherapy delivered for the purpose of immune stimulation. Both platform studies will involve significant pre-clinical and translational components, will have Patient/Consumer involvement at the core of study development and seek to follow the recent NCRI CTRad Academia-Pharma Joint Working Group consensus for the clinical development of new drug-radiotherapy combinations.

### Conclusion

The UK consortium establishing two platform studies of novel MBT/RT combinations offers a unique opportunity to rapidly improve outcomes for patients with NSCLC in a collaborative fashion.

### EP-1229 Phase II trial of concurrent erlotinib in locally advanced non-small cell lung cancer (LA-NSCLC)

O. Hansen<sup>1</sup>, M. Knap<sup>2</sup>, A. Khalil<sup>2</sup>, C. Nyhus<sup>3</sup>, C. Brink<sup>4</sup>, L. Hoffmann<sup>5</sup>, T. Schytte<sup>1</sup>

<sup>1</sup>Odense University Hospital, Oncology, Odense, Denmark

<sup>2</sup>Aarhus University Hospital, Oncology, Aarhus, Denmark

<sup>3</sup>Vejle Hospital, Oncology, Vejle, Denmark

<sup>4</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

<sup>5</sup>Aarhus University Hospital, Medical Physics, Aarhus, Denmark

### Purpose or Objective

The survival of patients with LA-NSCLC treated with concurrent chemo-radiation (CRT) remains poor. We have performed a phase II study using the tyrosine kinase inhibitor, erlotinib, as radiosensitizer. Due to slow accrual, the study was terminated prematurely. We here report survival and toxicity data from the study.

### Material and Methods

The main inclusion criteria were histological or cytological proven stage IIB-IIIAB NSCLC, PS 0-2. The patients were not candidate for CRT. The prescribed dose was 66 Gy/33F, 5F/week. The radiation technique was IMRT or ARC-therapy. No elective lymph nodes were treated. During RT, oral erlotinib was administered 150 mg daily. No chemotherapy was applied concurrent with RT. The endpoints included overall survival (OS). The results were compared with the survival data from 48 patients treated for LA-NSCLC within the same period and in the same centers in a phase II study using oral vinorelbine (Vino) as radiosensitizer together with radiation 66 Gy/33F. However, the inclusion criteria for this study excluded patients in PS 2, and FEV1<1.

Pt. characteristics		Present study N=15	Vino-study N=48	P-value
Age	Median (range)	75.3 (49.1; 85.0)	64.8 (44.4; 79.4)	0.000
Gender	Male/Female	9/6	27/21	ns
Performance status	0/1/2	3/8/1	28/20	0.000
Histology	Squam/Adeno/NOS	8/6/1	17/32/10	ns
Stage	2B/3A/3B	2/10/3	3/35/10	ns

### Results

From July 2009-August 2013, 15 patients from 3 centers entered the study.

The median OS was 16.9 months; the 1- and 2-year survival was 53% and 40%. In comparison, the survival data from the vino-trial was 21.0 months, 79% and 46% (P=0.11), see Fig 1. However, the patients in the vino-study were younger, and had better PS, see Table 1.

In the erlotinib study, 3 patients (20%) developed pneumonitis grade 3. In the vino-study, 8 patients (17%) developed grade 3 pneumonitis (p=ns).

### Conclusion

This phase II study was prematurely closed. A trend for inferior survival was observed using erlotinib compared to vinorelbine as radiosensitizer, but the small number of patients and differences between the populations treated made the result inconclusive. However, the regimen erlotinib-RT was well tolerate

### EP-1230 Post-operative radiotherapy (PORT) in patients with resected non small cell lung cancer (NSCLC)

T. Schimek-Jasch<sup>1</sup>, M. Kuppler<sup>1</sup>, S. Adebahr<sup>1,2</sup>, A.L. Grosu<sup>1</sup>, U. Nestle<sup>1,2</sup>

<sup>1</sup>Uniklinik Freiburg, Department of Radiation Oncology, Freiburg, Germany

<sup>2</sup>German Cancer Consortium DKTK, Heidelberg, Partner Site Freiburg, Germany

### Purpose or Objective

There is no consensus on the application of PORT in patients with completely resected NSCLC and histologically confirmed mediastinal lymph node involvement. In different institutions, the same patients may be advised to receive PORT or not, e.g. depending on the proportion of involved or resected lymph nodes or on the age and general health of a patient. Therefore our institution takes part in the randomized LUNG ART study (NCT00410683) since 2013. The objective of the presented work was the evaluation of patients consecutively scheduled for PORT in our institution before our participation in LUNG ART.

### Material and Methods

All distant metastases free patients scheduled for PORT after resection of a NSCLC between 2008 and 02/2013 were included in a retrospective analysis. Data on outcome (survival, toxicity) were collected until 07/16.

### Results

58 patients (28% female, 72% male), median 67 years, with a NSCLC (50% SCC, 45% adenocarcinoma and 5% other) and pretherapeutic UICC-stage IIa (2%), IIb (3%), IIIa (93%) and IIIb (2%) were evaluated. The postoperative nodal status was N2 in 50 (86%) patients and N1 and N0 in 4 patients (7%), respectively. Median 2,5 (0-7) lymph nodes stations were histologically involved. 25 (42%) patients received neoadjuvant platinum-based chemotherapy, a downstaging of tumor or lymph nodes could thereby be achieved in 44% and 5% of these patients. 19 (32%) patients received adjuvant chemotherapy. Resection mostly was performed by lobectomy (74%), less common were pneumectomy (12%), sleeve resection (7%), others (7%). In 90% of patients resection was complete, 10% had microscopically involved margins. The median duration between resection and start of PORT were 51 (23-212) days. PORT was applied in 95% of patients by means of 3D-conformal planning, in 5% with IMRT. Median duration of PORT were 39,5 (16-51) days with a median total dose of 52,6 (45-60) Gy. 22% of the patients had a locoregional progression median 7 (2-52) months after PORT, of these 54% within the irradiated area which had received median 50 (45- 59,4) Gy. 62% of patients developed distant metastases median 15,5 (0-88) months after PORT. 75% of patients died, most due to tumor progression (62%). Median actuarial overall survival was 32 (1-88) months, median progression free survival 11 (1-53) months. The evaluation of risk factors for survival and of toxicity data is ongoing.

### Conclusion

These preliminary data show that a fifth of patients after PORT will develop a locoregional recurrence, which complies with data in the literature, and imply that doses of around 50 Gy may not be sufficient to prevent locoregional recurrence in these patients.

### EP-1231 Early Clinical outcome of the first lung SBRT program in a developing country

S. Wadi-Ramahi<sup>1</sup>, J. Khader<sup>2</sup>, F. Abu Hijli<sup>2</sup>, H. Ghatasheh<sup>2</sup>, A. Sulaiman<sup>2</sup>

<sup>1</sup>King Faisal Specialist Hospital and Research Center, Biomedical Physics, Riyadh, Saudi Arabia

<sup>2</sup>King Hussein Cancer Center, Radiation Oncology, Amman, Jordan

### Purpose or Objective

The stereotactic body radiation therapy (SBRT) program at our institution was established through cooperation with an internationally renowned institution and it went clinical in 2012. Until the present day, it stands as the only SBRT program in the entire country with patient population that has increased dramatically in the past few years due to influx of refugees from regional conflicts. Here,

we will present the early clinical outcome of patients treated for lung tumors with SBRT.

### Material and Methods

10 patients were treated to date in the SBRT service. All patients underwent 10-phase 4DCT and PET-CT scans. The internal target volume (ITV) was constructed from the minimum intensity projection (MIP) dataset and expanded, if needed, following PET findings. 5mm margin was added to create the PTV. All patients received a dose scheme of 48Gy/4 fractions except for 2 who received 60Gy/8 fractions due to toxicity concerns. Lung heterogeneity correction was used during planning on Pinnacle<sup>3</sup> (Philips, Netherlands) and treatment delivery was done on Precise linacs (Elekta, Sweden). Positioning was done by using CBCT imaging on every fraction. After completion of SBRT the patient is seen in 2 weeks for clinical evaluation and follow up (FU) for possible acute side effects. The FU is both clinical and radiological with alternating CT Chest and PET/CT scans every 3-4 months for the first 2 years and 6 months interval afterwards.

### Results

All patients treated were males, with age ranging from 50-84 years old, mode of 79. All patients were unfit for surgery except for one who refused surgery. Table 1 summarizes the patients' data showing histology, tumor size, location, and status after last FU. Eight out of ten patients have shown either regression or no evidence of disease (NED) since last FU, while 2/10 have stable disease. One death occurred 15 months from treatment due to unrelated causes, the patient was NED in his last FU. The longest FU period so is 54 months for the first patient treated.

#	age	Pathology	max size from PET/CT	Location	dose regimen	Last day of Tx	# FU	Period of FU, months	Status as of last FU
1	80	PD SCC	2.5	LLL	48Gy/4fx	Mar-12	12	54	Alive NED
2	52	Mets from NSCLC	1.6x1.5	LLL	48Gy/4fx	Jun-14	7	22	Alive NED
3	63	MD SCC	1.3x1.6	RML	48Gy/4fx	Jul-14	5	15	Dead, unrelated to tumor. NED
4	86	MD SCC	1.5x1.9	LUL	48Gy/4fx	Dec-14	5	15	Alive NED

9	79	Adenoca	1.5x2	LUL	48Gy/4fx	May-16	1	3	Alive/Stable tumor
10	74	SCC	2.1	LUL	48Gy/4fx	Jun-16	1	2	Alive /tumor regression

Table 1: Summary of patients treated with SBRT. PD: Poorly differentiated, MD: Moderately differentiated, SCC: Squamous cell carcinoma, LLL/RLL: Left/Right lower lobe, LUL/RUL:

### Conclusion

The newly established SBRT clinical service in our country serves as the only such treatment for inoperable lung tumor for a population of about 10 million, including 2.7 million refugees. We have started recruiting inoperable lung patients to the service at a slow pace to gain more confidence and experience before admitting larger numbers. One of the major unforeseeable difficulties was the long term follow up, this is partly a result of heterogeneity in patient population. Albeit the short FU, early clinical results are encouraging with most treated patients showing tumor regression or NED.

### EP-1232 Patient-reported toxicity in twice-daily (BID) versus once-daily (OD) chemoradiotherapy for LS-SCLC

J. Lodeweges<sup>1</sup>, A. Niezink<sup>1</sup>, H. Elzinga<sup>1</sup>, E. Haan-Stijntjes<sup>1</sup>, N. Dollekamp<sup>1</sup>, O. Chouvalova<sup>1</sup>, J. Ubbels<sup>1</sup>, M. Woltman-van Iersel<sup>1</sup>, A. Van der Leest<sup>1</sup>, J. Langendijk<sup>1</sup>, J.

Widder<sup>1</sup><sup>1</sup>University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands**Purpose or Objective**

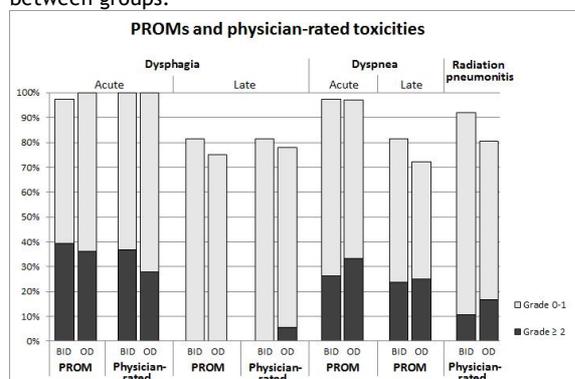

Survival results for limited-stage-SCLC are more favourable for accelerated BID compared with OD chemoradiotherapy (CRT) to nominally equal doses (Turrisi et al. NEJM 1999), but were not further improved by escalating once-daily doses from 45 Gy to 66 Gy (CONVERT-trial). However, concerns regarding acute toxicity with BID CRT do exist. We report prospectively assessed patient-reported outcome measures (PROMs) on dysphagia and dyspnea from an institutional cohort where patients receive BID CRT as preferred treatment, and OD in case of adverse patient- or tumour-related baseline factors suggesting they would not tolerate the accelerated schedule.

**Material and Methods**

All consecutive patients with LS-SCLC treated with VMAT/IMRT or 3D-CRT between 2013 and 2016 within our prospective data registration program (clinicaltrials.gov) were included. The BID schedule was given in 3 weeks to 45 Gy (30\*1.5 Gy), OD CRT was given in 5 weeks to 45-50 Gy (25\*1.8-2.0 Gy), concurrent or sequential cisplatin-etoposide was scheduled with both regimens. The primary endpoint was PROM-dysphagia within (acute) and after 3 months of inclusion (late). Secondary endpoints were PROM-dyspnea, physician-rated dysphagia, radiation pneumonitis, and survival. Toxicities were related with esophageal and pulmonary DVH-parameters, respectively.

**Results**

Out of 74 patients, 38 received BID and 36 received OD CRT with no difference in number of cisplatin-etoposide cycles between groups. In line with the institutional policy, the BID cohort was younger (62 versus 68 years,  $p=0.017$ ), had smaller tumour volumes at planning CT (79 cc versus 127 cc,  $p=0.056$ ), and tended to be in a better general WHO performance status (PS) (45% versus 25% at PS 0,  $p=0.075$ ). At median follow-up of 9.4 months for surviving patients, unadjusted as well as adjusted survival (adjusted for age, WHO PS, stage and GTV) was not significantly better for BID (HR=0.60, 95%CI 0.3-1.4 and HR=0.70, 95%CI 0.3-1.8, respectively). PROMs regarding dysphagia and dyspnea as well as physician-rated toxicities and radiation pneumonitis were not different between groups (figure). Mean esophageal V35 and mean pulmonary V20 were different between BID and OD cohorts (30 Gy versus 41 Gy;  $p=0.027$ , and 20 Gy versus 23 Gy;  $p=0.061$ , respectively), in line with GTV differences between groups.

**Conclusion**

Treatment selection based on tumour volume and patient condition effectively limited PROMs and physician-rated acute and late dysphagia in BID CRT. This can be explained by the significantly lower esophageal V35 due to smaller GTVs in patients receiving BID treatment. Also, acute and late PROM-dyspnea and radiation pneumonitis did not

differ between BID and OD CRT. Treatment allocation could be further improved by dose-volume-fractionation modelling for esophagitis.

**EP-1233 Early results of SBRT as a salvage treatment after thoracic radiotherapy.**A. Navarro-Martin<sup>1</sup>, I. Guix<sup>1</sup>, J. Mases<sup>1</sup>, M. Mutto<sup>2</sup>, E. Nadal<sup>2</sup>, F. Guedea<sup>1</sup><sup>1</sup>Institut Català d'Oncologia, Radiation Oncology, L'Hospitalet de Llobregat, Spain<sup>2</sup>European Oncology Institute, Radiation Oncology, Milano, Italy<sup>3</sup>Institut Català d'Oncologia, Medical Oncology, L'Hospitalet de Llobregat, Spain**Purpose or Objective**

Isolated intrathoracic relapse is common across distinct tumors and especially in lung cancer. Patients who received previous radiotherapy treatment (PRT) are not suitable for salvage surgery and chemotherapy provides poor local control. This study aimed to assess the toxicity and outcome of SBRT re-irradiation (reRT) in patients with solid tumors who developed an intrathoracic relapse.

**Material and Methods**

35p treated with PRT who received salvage SBRT were identified in our database and their medical records were retrospectively reviewed. All patients underwent complete pulmonary function tests (cPFTs) (including DLCO, FEV1 and FVC) and PET-CT scan was performed before and after receiving lung reRT. Treatment planning was based on image fusion with the previous treatment plan and calculating the cumulative total nominal dose. Survival estimations were performed using Kaplan-Meier and differences between PFTs prior and post-reRT were analyzed using Student T-Test. Early toxicity was defined when it occurred up to 6 months.

**Results**

Median age: 68 (r53-81); 29p (83%) were male. The previous treatments SBRT in 17p (49%), 3D-RT 4p (11%) and CT+RT 14p (40%). Mean RT dose 60,4Gy (r34-74). Primary tumors: lung 24 (69%), colorectal 9 (25%), oesophagus 2 (6%). For lung cancer p, the stage distribution was: IA 8 (23%), IB 2 (6%), IIA 2 (5.7%), IIB 1 (3%), IIIA 5 (4%), IIIB 4 (11%), IV 2 (6%). For other primaries, 8p (23%) were non metastatic at diagnosis and developed oligoprogressive disease in thorax which was treated with SBRT and 3 (8.5%) were oligometastatic. The location of reRT site: same lobe 17 (48%), ipsilateral different lobe 7 (20%), contralateral lobes 11 (32%). Median delivered dose of salvage SBRT was 50Gy (50-60) in 10 fractions (r3-10). Median accumulated dose in the lung was 81Gy (r60.10Gy-176Gy).

With a median follow-up of 10m local control rate was 74% (IC95%; 0.59-0.9) and 1-year OS was 84% (IC 95%;0.67-1). The metabolic complete response rate was 23%. No differences in the baseline and post re-irradiation PFTs were observed: FEV1, FVC and DLCO difference and CI95% were 2.41 (-1.79-6.62); 65 (-125-257) and 12.5 (-95 - 121). Asthenia GII in 12p (31%) was the most frequent acute toxicity, no long-term toxicities were detected.

**Conclusion**

Salvage SBRT for treating isolated intrathoracic relapses achieved an outstanding local control and overall survival in selected p. This treatment did not impair post-reirradiation PFT and long-term toxicities were not observed.

**EP-1234 Prophylactic Cranial Irradiation (PCI) in Small-Cell Lung Cancer: a single-institution experience.**M. Konkol<sup>1</sup>, M. Matecka-Nowak<sup>1</sup>, M. Trojanowski<sup>2</sup>, A. Kubiak<sup>2</sup>, P. Milecki<sup>1</sup><sup>1</sup>Greater Poland Cancer Centre, I Radiotherapy Dept., Poznan, Poland

<sup>2</sup>Greater Poland Cancer Centre, Greater Poland Cancer Register, Poznan, Poland

#### Purpose or Objective

In 2013 1.963 (ASR 33,6/10<sup>5</sup>) new lung cancer cases and 1.855 (ASR 31,1/10<sup>5</sup>) lung cancer deaths were reported in Greater Poland. Compared to 1999 the number of new cases rose by 21% and the number of deaths rose by 16%. In the group of lung cancer patients from the Greater Poland population, diagnosed during 2009-2011, 80% were microscopically verified, among them 79,9% were NSCLC and 20,1% were SCLC. Prophylactic Cranial Irradiation (PCI) in SCLC patients remains an important part of the treatment process associated with a reduction of brain metastases and better survival. This paper is a retrospective review of 146 patients irradiated in Greater Poland Cancer Center, Poznan, Poland.

#### Material and Methods

Eighty limited SCLC (LSCLC) and sixty six extensive SCLC (ESCLC) patients irradiated in Greater Poland Cancer Center between 2007-2010 received a standard scheme of 25Gy/10fx with 6MV photons. The qualification based on X-ray post-chemotherapy assessment described as significant partial response or complete response. Mean time from the diagnosis date to the end of treatment was 6 months. The survival data were collected from the national and regional cancer registers.

#### Results

Mean observed survival in our patients was 16,8 months (13,6 months for ESCLC and 19,5 months for LSCLC). The 1-, 3- and 5-year observed survival rates were 74,12%, 9,52%, 4,70% for LSCLC and 48,48%, 1,49%, 1,49% for ESCLC. For our group as a whole respectively: 65%, 8,6%, 3,3%. After radiotherapy, LSCLC and ESCLC patients survived 7,4 and 12,7 months on average. Grade 3 or 4 toxicity has not been noticed.

#### Conclusion

The Concord-2 study results show, that the 5-year net survival rates among lung cancer patients diagnosed during 2005-2009 in Poland (13,4%) and Greater Poland (13,2%) were on the average European level. Similarly, presented SCLC group meets 5-year survival rates of that time. Comparing to other authors, we have noticed slightly better results in 1- year survival - Schild et al: 56% (PCI arm, LSCLC&ESCLC), Slotman et. al: 27,1% (PCI arm, ESCLC).

Nevertheless, in spite of good results shown above, the prospective analysis should be done. Contemporary salvage treatments for intracranial relapse may be underestimated especially if provided before patients become symptomatic.

#### EP-1235 Stereotactic body radiotherapy for lung metastases: retrospective analysis of a single-center

H. Herrmann<sup>1</sup>, C. Proksch<sup>1</sup>, K. Dieckmann<sup>1</sup>  
<sup>1</sup>Universitätsklinik für Strahlentherapie Medizinische Universität Wien, Wien, Austria

#### Purpose or Objective

A significant number of cancer patients with initially localized disease develop distant metastases at follow up. A subset of patients with successful treatment of the primary tumor develop oligometastatic disease months to years after initial treatment. Other patients with metastatic disease present with long-lasting stable disease or remission during systemic treatment and develop progression in single lesions in later course of disease. For these patients with low tumor burden, a semi-curative treatment strategy might be an option. In recent years, stereotactic body radiotherapy (SBRT) of the lung has been shown to provide an alternative to surgical resection of lung metastases. Typically, SBRT in the lung is performed with high single-doses per fraction. High

radiation doses to the lung could result in severe fibrosis, which might especially be relevant for patients with impaired lung function.

#### Material and Methods

We retrospectively analyzed 95 metastatic patients (male, n=64; female, n=31) who underwent SBRT in the lung at our institution from 2005-2015 with a total of 166 lung metastases. The median age was 65 years (range 38-84 years) at initial SBRT treatment. Primary tumors were colorectal cancer (n=35), renal cell carcinoma (n=15), head and neck cancer (n=12), melanoma (n=8), and other malignancies (n=25). Parameters assessed were: local control, survival, lung function test before start of treatment and during follow up, PTV volume, extent of fibrosis on CT scans.

#### Results

The treatment regimen most often used was 12.5 Gy x 3 fractions prescribed to the 65% isodose (n=100; EQD2 for  $\alpha/\beta=10$  Gy: 70.3 Gy at prescribed isodose, 140.5 Gy at 100% isodose) and 15 Gy x 3 fractions prescribed to the 65% isodose (n=33; EQD2 for  $\alpha/\beta=10$  Gy: 93.8 Gy at prescribed isodose, 190.8 Gy at 100% isodose). The median PTV volume was 15.9 ccm (range: 3.6 - 404.5 ccm). Median follow up was 20 months (range 1 - 136 months). The overall survival at 1 and 2 years was 85% and 68%, respectively. We achieved high local control after SBRT treatment at 1 and 2 years which was 95% and 88%, respectively.

Signs of morphologically dense radiation induced fibrotic changes (hounsfield units > 10 as evaluated on CT scans) 4-6 months after treatment was seen in 40 % of all treated lesions. The median diameter of these fibrotic changes were 6.0 cm (range: 2.0 - 10.4 cm). Before SBRT treatment the median baseline FEV1 value of lung function test was 2.5 L (range: 0.96 - 3.96 L). FEV1 values at 1 years after treatment (expressed as mean percentage of baseline FEV1  $\pm$ SD) decreased to 95% ( $\pm$ 8%) which was significant ( $p<0.05$ ) in a paired t-test.

#### Conclusion

SBRT treatment for lung metastases results in high local control rates and can be safely applied. The impact on lung function test at one year after treatment was minimal although high biological doses were delivered. We conclude, that SBRT to the lung can be recommended to oligometastatic patients as an effective alternative treatment to surgical resection.

#### EP-1236 Validation of the clinical diagnostic method for solitary pulmonary nodules before SBRT in Navarra

M. Campo<sup>1</sup>, I. Visus<sup>1</sup>, S. Flamarique<sup>1</sup>, M. Barrado<sup>1</sup>, A. Martin<sup>1</sup>, M. Rico<sup>1</sup>, E. Martinez<sup>1</sup>

<sup>1</sup>Hospital of Navarra, Oncologia radioterapia, Pamplona, Spain

#### Purpose or Objective

In the general practice of the Hospital of Navarra, solitary pulmonary nodules (SPN) are frequently treated with SBRT without cytological confirmation due to patients' comorbidities that heighten the risks associated with transthoracic biopsy. In this analysis we study the reliability of our clinical diagnostic system to better know the accuracy and quality of our protocols.

#### Material and Methods

We analyze retrospectively the pathological results of SPN treated surgically under suspicion of being stage I non-small-cell lung cancer (NSCLC) during 2012 and 2013. The suspicion was based on the criteria of an expert board composed by pneumologists, radiation oncologists, medical oncologists, thoracic surgeons, radiologists and pathologists. The decision of treating was taken according to the FDG-PET features, the morphological characteristics on CT and the growing pattern of the SPN.

We compare our results with previous evidence-based recommendations.

#### Results

A total of 53 patients with SPN and no previous history of cancer were operated. The mean size were 2.67cm; the mean SUVmax was 7.16 and 94% had SUVmax over 2.

The clinical diagnosis before surgery were stage I NSCLC, lung metastases and benign lesion in 58%, 26% and 16% respectively. The diagnosis was confirmed in 89% of the cases.

From the 31 lesions treated with clinical diagnosis of NSCLC, it was confirmed pathologically in 27 (87%).

#### Conclusion

These results validate the clinical criteria of the lung committee in the Hospital of Navarra, as the accuracy of the diagnosis of stage I NSCLC was 87%, exceeding the threshold of 85% previously recommended.

#### EP-1237 Heart dose as a risk factor for dyspnea worsening after multimodality treatment for NSCLC and MPM

A. Botticella<sup>1</sup>, C. Billiet<sup>2</sup>, G. Defraene<sup>3</sup>, S. Peeters<sup>3</sup>, C. Draulans<sup>3</sup>, P. Nafteux<sup>4</sup>, J. Vansteenkiste<sup>5</sup>, K. <sup>3</sup>KU Leuven - University of Leuven, Department of Oncology- Laboratory of Experimental Radiotherapy, Leuven, Belgium

<sup>4</sup>KU Leuven - University of Leuven, Department of Thoracic Surgery and Leuven Lung Cancer Group, Leuven, Belgium

<sup>5</sup>KU Leuven - University of Leuven, Department of Respiratory Medicine Respiratory Oncology Unit and Leuven Lung Cancer Group, Leuven, Belgium

<sup>6</sup>KU Leuven - University of Leuven, Department Imaging and Pathology- Nuclear Medicine and Molecular Imaging, Leuven, Belgium

<sup>7</sup>KU Leuven - University of Leuven, Department of Radiology, Leuven, Belgium

<sup>8</sup>Maastricht University Medical Centre- KU Leuven - University of Leuven, Department of Radiation Oncology MAASTRO, Maastricht, Belgium

#### Purpose or Objective

The purpose of our study is to quantify the influence of heart dose on the early and late onset of dyspnea in a cohort of non-small cancer (NSCLC) and malignant pleural mesothelioma (MPM) patients having multimodality treatment including radiotherapy (RT).

#### Material and Methods

Patient population consisted of: a) stage I-III MPM patients who completed trimodality treatment (induction chemotherapy, EPP and postoperative RT [PORT]); b) stage III (ypN2) NSCLC patients treated with induction chemotherapy, pneumonectomy or lobectomy (+PORT); c) stage I-III NSCLC treated with RT with curative intent (+/- chemotherapy).

In 121 patients with multimodality-treated NSCLC and MPM the maximal dyspnea score (CTCAE 4.0) before RT, at an early (<6 months) and a late (7-12 months) time point were obtained.

Included patients needed to be clinically and radiologically progression-free 9 months after the end of RT. The difference ( $\Delta$ ) between the maximal dyspnea at <6 months and at 7-12 months with the pre-RT dyspnea was calculated.

#### Results

Forty-four percent (50/113) of the patients developed an early worsening of at least 1 point in their dyspnea score

(Adyspnea >1) after the end of RT. Independent predictors of an early worsening were the mean heart dose (MHD) (for  $\Delta$ dyspnea >1: OR=1.032, p=0.04) and the dyspnea score before RT (for  $\Delta$ dyspnea >1: OR=0.40, p=0.0001; for  $\Delta$ dyspnea >2: OR=0.35, p=0.05).

At the later time point, only the dyspnea score before RT (OR: 0.40, p=0.001) was identified as predictor of for  $\Delta$ dyspnea >1.

#### Conclusion

Our results, albeit exploratory, suggest that heart dose may play a role in the early worsening of the dyspnea in a heterogeneous cohort of patients having multimodality treatment including RT, whereas baseline dyspnea plays a major role for both early and later worsening.

#### Electronic Poster: Clinical track: Upper GI (oesophagus, stomach, pancreas, liver)

#### EP-1238 Patterns of recurrence in patients of pT2 esophageal squamous cell carcinoma after radical resection

Y.X. Wang<sup>1</sup>, Y.H. Gao<sup>1,2</sup>, J. Li<sup>1</sup>, R. Qiu<sup>1</sup>, X.Y. Qiao<sup>1</sup>

<sup>1</sup>The Fourth Hospital of Hebei Medical University, Department of Radiation Oncology, Shijiazhuang, China <sup>2</sup>the 2th Central Hospital of Baoding, department of Medical Oncology, Zhuozhou, China

#### Purpose or Objective

To retrospectively investigate the patterns of recurrence and its related factors in patients of stage pT2N0-1M0 thoracic esophageal squamous cell carcinoma (ESCC) after radical resection.

#### Material and Methods

From 2008 to 2011, 222 cases of stage pT2N0-1M0 thoracic ESCC with R0 resection were enrolled. There were 142 males and 80 females. There were 181 in pN1 and 41 cases in pN1. 142 patients has treated with surgery alone and 80 with adjuvant postoperative chemotherapy (POCT). Diagnosis of recurrence was primarily based on CT images.

#### Results

Follow-up ended at 30, Sep, 2014. The overall recurrence rates was 35.1%. Locoregional recurrence (LR) was found in 25.7% of patients, distant metastasis (DM) in 5.9%, and LR plus DM in 3.6%, respectively. The LR occupied about 83.3% of any recurrence, and 87.7% of LR has occurred in mediastinum (91.2% of it located in upper- mediastinum). Multivariate Cox regression analysis showed that the danger of total recurrence, LR and DM for stage pN1 patients was about 7.1, 6.5 and 3.1 folds in compared with stage pN0, respectively; the danger of total recurrence in females was about 49.1% in compared with males. But POCT could not influence total recurrence and LR (P>0.05).

#### Conclusion

The recurrence rate was very high in stage pT2N0-1M0 thoracic ESCC after radical resection, the most common site of recurrence was mediastinum (especially upper-mediastinum), it was probably the main target of postoperative radiotherapy. The recurrence was more frequently occurred in stage pN1 and males. T2N0-1M0 thoracic ESCC with R0 resection were enrolled. There were 142 males and 80 females. There were 181 in pN1 and 41 cases in pN1. 142 patients has treated with surgery alone and 80 with adjuvant postoperative chemotherapy (POCT). Diagnosis of recurrence was primarily based on CT images.

#### EP-1239 SBRT in patients with HCC/CCC or oligometastatic liver disease

S. Gerum<sup>1</sup>, C. Heinz<sup>1</sup>, C. Belka<sup>1</sup>, M. Niyazi<sup>1</sup>, U. Ganswindt<sup>1</sup>, F. Roeder<sup>1,2</sup>

<sup>1</sup>LMU Munich, Department of Radiation Oncology, Munich, Germany

<sup>2</sup>German Cancer Research Center DKFZ, Department of Molecular Radiation Oncology, Heidelberg, Germany

#### Purpose or Objective

To report our experience with stereotactic body irradiation in primary and secondary liver lesions.

#### Material and Methods

We retrospectively analysed 37 patients who had not been eligible for other local treatment options (surgery, RFA) and therefore received SBRT to 1-2 liver lesions (43 lesions in total) in our institution from 2011-2015. Median age was 66 years (31 - 83 years) and 20 patients were male. 16 patients suffered from HCC/CCC, 21 patients had oligometastatic liver disease, mainly originating from colorectal cancer. The majority presented in good performance status (median KPS 90%, range 60%-100%) with adequate liver function (cirrhosis Child A: 13, Child B: 2, Child C: 1, none: 21). Immobilization included a vacuum pillow in all patients and the use of abdominal compression since 2014. Treatment planning was based on 4D-CT (contrast-enhanced since 2014) usually after placement of fiducial markers and rigid registration with diagnostic MRI images. Median ITV to PTV margin was 6 mm.

#### Results

Mean follow-up was 14 months (range 1 - 47) Fiducials were needed in 29 patients (78%). Placement was feasible without any complications in all patients. Abdominal compression was used in 12 patients since 2014 to reduce breathing motion. Dose and fractionation varied dependent on localisation, size, motion and liver function. The most common schemes were 37.5 Gy/65% isodose in 3 fractions, 40 Gy/80% in 5 fx and 54Gy/80% in 9 fx. Median GTV volume on free-breathing CT was 13 ccm (1-247) and median PTV volume was 126 ccm (15-537). Local recurrence (in field) was observed in 6 patients (16%) resulting in a 1-year LC rate of 92%. New lesions in the liver (out-field) occurred in 20 patients (54%), 15 (40%) patients developed extrahepatic progression. 5 patients have died, resulting in a 1-year overall survival of 87% in all patients. No significant differences in any endpoint have been observed between HCC/CCC and oligometastatic patients, although the latter ones had a higher absolute 1-year OS rate (73% vs 87%). Toxicity was generally mild (grade 1: 8 pts., grade 2: 2 pts.), except one patient with Child C cirrhosis who developed hepatic failure shortly after SBRT which was successfully treated by liver transplantation.

#### Conclusion

SBRT is a locally effective and well tolerated treatment method for primary and secondary liver lesions. Given the high rates of intrahepatic outfield failures, careful pretreatment evaluation and patient selection seems mandatory.

<sup>7</sup>Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Department of Radiotherapy, Roma, Italy

<sup>8</sup>University of Bologna, Oncology Center- Department of Experimental- Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

#### Purpose or Objective

In locally advanced pancreatic carcinoma (LAPC) standard radiotherapy and concurrent chemoradiation are able to reduce pain. Stereotactic radiotherapy (SBRT) is an emerging treatment technique but its role in pain palliation is not well known. Therefore, aim of this analysis was to systematically review the palliative effect of SBRT in LAPC.

#### Material and Methods

A systematic review based on PRISMA methodology of papers reporting pain control after SBRT in LAPC patients was performed using PubMed database. Combination with chemotherapy was allowed. Only article published in English were considered.

#### Results

A total of 11 studies reporting data on pain control after SRT in LAPC patients met the inclusion criteria. SBRT was performed using both standard and robotic Linacs. The prescribed SBRT median total dose 24 Gy (range: 14-45 Gy), and the median number of fraction was 3 (range: 1-6). Median EQD<sub>2</sub> using  $\alpha/\beta$ : 10 and  $\alpha/\beta$ : 3 were 65.5 Gy (range 31.3-93.8) and 95.0 Gy (range 40.0-162.0), respectively. Nine of the 11 studies reported different rates pain reduction. Particularly, median pain ORR was 57.0% (range: 44.0-100.0%) with 2 studies reporting pain CR in 48.4% and 81.3% of patients. Reduction of analgesic consumption was recorded in 65.0-100.0% of patients. One study reported no significant pain reduction, while another study reported a significant worsening of pain 2 weeks after SBRT. Acute and late toxicity (grade  $\geq$  3) ranged between 3.3-18.0% and 6.0-8.2%, respectively. All recorded toxicity were GI complications.

#### Conclusion

SBRT was able to achieve pain reduction in most studies with a reasonable rate of side effects. Therefore, further prospective studies on palliative role of SBRT in LAPC seems to be justified. Aim of these trials should be the definition of the optimal dose/fractionation and the best way to combine SBRT with systemic therapies. Finally, being treatment of LAPC patients mainly palliative, quality of life and particularly pain control should be considered as an end point in future SBRT trials.

#### EP-1241 Successful pain relief after a short course of palliative radiotherapy in painful pancreatic cancer.

G. Ebrahimi<sup>1</sup>, C.R.N. Rasch<sup>1</sup>, G. Van Tienhoven<sup>1</sup>

<sup>1</sup>Academic Medical Center, Radiation oncology, Amsterdam, The Netherlands

#### Purpose or Objective

Patients with pancreatic cancer have a high burden of symptoms. At time of diagnosis 30-40% of the patients report pain as a dominant symptom, which rises up to 90% shortly before death. Because of a poor overall survival, the burden of a palliative treatment should be balanced against the expected effect. This study was conducted to assess the effect of a short course of palliative radiotherapy on pain symptoms.

#### Material and Methods

All patients who were treated with palliative radiotherapy because of painful pancreatic cancer between 1998 and 2015 were retrospectively analyzed. Primary endpoint was pain relief and secondary endpoint was overall survival.

## Results

61 patients were treated with a short course of palliative radiotherapy at the Academic Medical Center. A majority had stage four disease (69%) and a minority had local recurrence after surgery (10%). Median age was 62 years, 51% of the patients were male and mean Karnofsky performance score (KPS) was 79%. Median pain score before treatment was 8 on an 11-point numeric pain rating scale. Eighty-five percent of the patients used strong opioids with a mean equivalent oral morphine dose of 147 mg a day. Four radiotherapy dose schedules were given: 3 x 8 Gy (46%), 2 x 8 Gy (39%), both once per week, 1 x 8 Gy (13%) and 1 x 6 Gy (2%). Pain relief after radiotherapy was experienced by 66% of patients. Median time to reduction in pain was 1 week after end of radiotherapy, although this time interval could only be assessed in 25 patients. Information on use of pain medication after treatment was not clearly documented. Four patients had complete pain relief and in 4 patients pain medication was reduced or even stopped. Nausea was a common reported side effect in 51% and vomiting was reported in 21%. Median overall survival was 3.5 months. Patients who had pain relief after treatment had a better overall survival ( $p < 0.0001$ ) compared to non responders.

## Conclusion

A short course of palliative radiotherapy was effective in 66% of the patients with the most frequent given radiotherapy dose schedule of 3 x 8 Gy. Radiotherapy was fairly well tolerated. These results were the basis for a prospective phase-2 study at our institute named PAINPANC (NTR5143). Thirty patients with painful unresectable pancreatic cancer will receive 3 x 8 Gy, one fraction a week, and are prospectively followed with EORTC-QLQ-C15-PAL and Brief Pain inventory questionnaires during and after treatment.

## EP-1242 Palliative EBRT for incurable esophageal cancer and symptomatic dysphagia-single center results

K. Yordanov<sup>1</sup>, A. Richetti<sup>1</sup>, S. Cima<sup>1</sup>, G. Pesce<sup>1</sup>, C. Azinwi<sup>1</sup>, F. Martucci<sup>1</sup>, B. Muoio<sup>1</sup>, P. Fanti<sup>1</sup>, M.C. Valli<sup>1</sup>  
<sup>1</sup>Oncology Institute of Southern Switzerland, Radiotherapy, Bellinzona, Switzerland

## Purpose or Objective

Purpose: to assess the effectiveness and safety of external beam radiation therapy (EBRT) to palliate dysphagia in advanced esophageal cancer patients treated with total dose of 40 Gy/2.5Gy.

## Material and Methods

We retrospectively reviewed the records of 19 patients diagnosed with locally advanced or metastatic esophageal cancer, treated in our institution from 2012 to 2015 with palliative EBRT. All patients had histologically confirmed diagnosis of squamous cell or adenocarcinoma of the esophagus and were symptomatic for dysphagia. Before the start of EBRT the dysphagia was scored according to scale 0-4 (0- no dysphagia, 1 -dysphagia with certain solid foods, 2 -able to swallow semi-solid soft foods, 3-able to swallow liquids only and 4 - unable to swallow saliva). The prescribed total dose to all patients was 40Gy with daily dose of 2.5Gy, 5 fractions per week in sixteen fractions using Volumetric Modulated Arc technique. We evaluated the dysphagia score one month after the end of the EBRT.

## Results

Grade 1 dysphagia was detected before RT treatment in 3 patients (15.8%), grade 2 in 8 patients (42.2%), grade 3 in 6 patients (31.5%) and grade 4 in 2 patients (10.5%). No patient discontinued RT due to acute toxicity. One month after the end of the EBRT 4 patients (21%) experienced complete dysphagia relief.

Fourteen patients (73.7%) experienced improvement of symptomatic dysphagia. Four patients (21%) had no positive effect and one patient died 3 weeks after the end of treatment. **Conclusion** EBRT with mild hypofractionation is an effective treatment for esophageal cancer patients with symptomatic dysphagia. It is well tolerated and can provide symptom relief and quality of life improvement.

## EP-1243 A Study on predictive value of 18F-FDG PET-CT to Chemoradiation of Esophageal Cancer

J. Li<sup>1</sup>, W. Sun<sup>2</sup>  
<sup>1</sup>Fujian Cancer Hospital, radiation oncology, Fuzhou-Fujian, China  
<sup>2</sup>Fujian medical university, Provincial Clinical College, Fuzhou, China

## Purpose or Objective

To evaluate whether the SUVmax and MTV predict short-term clinical curative effect of radiotherapy or chemoradiotherapy in nonoperative esophageal squamous cell cancer.

## Material and Methods

A retrospective analysis was made on 98 cases patients with esophageal cancer from January 2014 to January 2016 in Fujian Provincial Cancer Hospital. All of them had an examination by FDG PET/CT before treatment. Respectively analysis was conducted on SUVmax, MTV's relationship with clinical factors and short-term clinical curative effect.

## Results

There is no difference on SUVmax and MTV of different group of age, gender, morbid position and histology differentiated degree ( $P > 0.05$ ). Significant difference was found on SUVmax and MTV of different group of lesion length, T grade, stage pathologic N stage and clinical ( $P < 0.05$ ). And positive correlation was noticed between the SUVmax, MTV and lesion length, T grade, stage pathologic N stage and clinical stage ( $P < 0.05$ ). Low MTV group and low SUVmax group were higher than high MTV group and high SUVmax group on the percentage of lesion length reduction ( $P < 0.05$ ). And it was negative correlation between SUVmax, MTV and the percentage of lesion length reduction, but the correlation of MTV was stronger than SUVmax.

## Conclusion

There was no significant effect on SUVmax and MTV for age, gender, morbid position and histology differentiated degree ( $P > 0.05$ ), but lesion length, T grade, pathologic N stage and clinical stage were significantly positive correlated with SUVmax and MTV. The SUVmax and MTV can predict short-term clinical curative effect of radiotherapy or chemoradiotherapy in nonoperative esophageal squamous cell cancer, but MTV was more valuable than SUVmax.

## EP-1244 Neoadjuvant Chemo Radiation followed by Surgery in Ca Esophagus - Retrospective Review from India

V. Goel<sup>1</sup>, A.K. Anand<sup>1</sup>, H.K. Chaturvedi<sup>2</sup>, A. Verma<sup>1</sup>, P. Agarwal<sup>1</sup>, T. Saxena<sup>1</sup>, R. Shukla<sup>1</sup>, D. Arora<sup>3</sup>, A.K. Bansal<sup>3</sup>, A. Gulia<sup>1</sup>, C. Garg<sup>1</sup>, U. Mukherjee<sup>4</sup>  
<sup>1</sup>Max superspeciality hospital, Radiation Oncology, Delhi, India  
<sup>2</sup>Max superspeciality hospital, Surgical Oncology, Delhi, India  
<sup>3</sup>Max superspeciality hospital, Medical Physics, Delhi, India  
<sup>4</sup>Max superspeciality hospital, Pathology, Delhi, India

## Purpose or Objective

Neo-adjuvant Concurrent Chemoradiation (NACCRT) followed by Surgery is now the standard of care for middle

& lower third esophageal carcinoma. However this is an intensive treatment regimen. Often there are concerns and doubts about its feasibility in Indian population, who do not have as good nutritional status as western patients. At our institute we have been following this treatment approach since 2009 and have analysed our own outcomes in terms of feasibility, toxicity, mortality and survivals.

#### Material and Methods

We treated 62 patients with NACCRT followed by surgery from October 2009 to December 2015 at Max Hospital, Delhi, India. All patients underwent esophageal endoscopy, biopsy and PETCT scan for diagnosis and staging purpose. Inclusion criteria for NACCRT followed by surgery were, patients with bulky primary tumour, enlarged lymph nodes (LN) on imaging, adherence to surrounding organs and clinical suitability for trimodality therapy. All patients received radiation therapy (RT) with IMRT technique with single/double agent concurrent chemotherapy. PET CT was used in target volume delineation for IMRT in all patients. RT doses were 41.4 Gy/23 fractions and 45 Gy/25 fractions with double & single agent chemotherapy respectively. Patients underwent open transthoracic esophagectomy with 2-Field lymph node dissection; 6-8 weeks after completion of NACCRT.

#### Results

Squamous cell carcinoma was present in 82% patients while only 18% patients had adeno carcinoma. Tumour was located in Middle, Lower and Lower and GE junction in 50%, 23% and 27% patients respectively.

Total 60/62 (96.8%) patients completed NACCRT. Of these 46 (76.6%) were taken up for surgery. Three patients (5%) were considered unsuitable for surgery, 13.3% defaulted for surgery and 5% were lost to follow up after NACCRT. Resectability rate for patients taken up for surgery was 93.4%. Perioperative death occurred in 3 patients (6.6%). Pathological complete response was seen in 37.2% patients. At median follow up of 17.6 months, 3(7%) patients had a mediastinal nodal recurrence and 12% developed distant metastases. In all three patients with nodal recurrence, LN was located in superior mediastinum. Median disease free survival (DFS) and overall survival (OS) is not yet reached. The OS in our study at 1 and 2 year respectively was 76% and 62.8% for all patients.

#### Conclusion

NACCRT followed by surgery is feasible in middle and lower third carcinoma esophagus patients in Indian population and yields high DFS and OS. Most common locoregional pattern of failure was in superior mediastinal nodal station, which needs to be further addressed in terms of RT planning volumes and surgical dissection.

#### EP-1245 A retrospective study for Helical Tomotherapy for Radiotherapy in Esophageal Cancer: is it feasible?

Z. Jastaniah<sup>1</sup>, J.B. Clavier<sup>1</sup>, D. ANTONI<sup>1</sup>, M. Ben Abdelghani<sup>1</sup>, C. Schumacher<sup>1</sup>

<sup>1</sup>centre paul strauss, radiotherapy, Strasbourg, France

#### Purpose or Objective

despite many advances in the treatment of esophageal cancer, local and regional control is a major issue. IMRT showed to be beneficial in terms of reducing the late complication in head & neck cancer. A retrospective analysis to assess the feasibility and the safety of esophageal cancer patients definitively treated with IMRT using Tomotherapy.

#### Material and Methods

Between October 2009 and December 2015, 56 patients with squamous cell carcinoma and adenocarcinoma of the esophagus were retrospectively reviewed.

#### Results

Median age was 67.5 years (47-86). Median radiation dose was 50 Gy (42-66) with 1.8-2 Gy fractions. Median follow-up was 12 months (0-31). The median overall survival and the median progression free survival were 20 months, and 16.8 months, respectively. The 1- and 2-year overall survival is 59% and 41.9% respectively. Patients with elective nodal irradiation have significantly better overall survival and progression free survival. In a univariate analysis, we did not find any significant correlation between incidences of symptomatic respiratory pneumonitis with any clinical or dosimetric parameters.

#### Conclusion

Radiotherapy using IMRT technique is a feasible and secure treatment esophageal cancer. We demonstrated encouraging results in terms of local control and survival with low acute and late side effects.

#### EP-1246 Definitive chemoradiotherapy for esophageal cancer: the impact of histological subtypes on survival

F.E.M. Voncken<sup>1</sup>, R.T. Van der Kaaij<sup>2</sup>, K. Sikorska<sup>3</sup>, J.M. Van Dieren<sup>4</sup>, C. Grootsholten<sup>4</sup>, P. Snaebjornsson<sup>5</sup>, J.W. Van Sandick<sup>2</sup>, B.M.P. Aleman<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute- Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

<sup>2</sup>The Netherlands Cancer Institute- Antoni van Leeuwenhoek Hospital, Surgical Oncology, Amsterdam, The Netherlands

<sup>3</sup>The Netherlands Cancer Institute- Antoni van Leeuwenhoek Hospital, Biometrics, Amsterdam, The Netherlands

<sup>4</sup>The Netherlands Cancer Institute- Antoni van Leeuwenhoek Hospital, Gastrointestinal Oncology, Amsterdam, The Netherlands

<sup>5</sup>The Netherlands Cancer Institute- Antoni van Leeuwenhoek Hospital, Pathology, Amsterdam, The Netherlands

#### Purpose or Objective

Definitive chemoradiotherapy (dCRT) is an established treatment option for irresectable or inoperable squamous cell cancer of the esophagus (SCC). For esophageal adenocarcinomas, the role of dCRT is debated. The adenocarcinoma subtypes (according to the Lauren classification) have shown different pathological response rates after neoadjuvant chemoradiotherapy. Aim of this study was to investigate long-term outcomes of esophageal cancer patients after treatment with dCRT according to the histological subtype.

#### Material and Methods

Esophageal cancer patients treated in the Netherlands Cancer Institute with dCRT between 1999 and 2016 were retrospectively analysed. Treatment consisted of 50Gy/25 fractions with concurrent fluorouracil/cisplatin, or 50.4Gy/28 fractions with concurrent carboplatin/paclitaxel. Patients who refused surgery after completion of neoadjuvant CRT, i.e. 41.4Gy-50.4Gy/23-28 fractions, were also included in the analysis. Patients were grouped by the histological subtype found in the endoscopic biopsy at diagnosis. Biopsies were classified as squamous cell carcinoma (SCC), adenocarcinomas of the intestinal subtype (AC-I) or of the diffuse/ mixed subtypes (AC-D+M). Overall survival (OS), disease-free survival (DFS) and isolated locoregional recurrence (LRR) free interval were compared between patient groups with different histological subtypes. The impact of the histological subtype on OS was evaluated using a Cox regression model.

#### Results

The cohort consisted of 117 patients, including 9 patients who refused surgery after neoadjuvant CRT. Five patients

did not complete dCRT because of comorbidity or toxicity. Median follow up was 56 months. Median OS was 21 months and not significantly different between patients with SCC (20 [95% CI 15-25] months; n=73), AC-I (24 [95% CI 21-27] months; n=34) or AC-D+M (15 [95% CI 7-23] months; n=10). Median DFS was 19 months and, for SCC, AC-I and AC-D+M, DFS was 18 (95% CI 10-30), 21 (95% CI 21-27) and 15 (95% CI 7-23) months, respectively (p=0.29). Median time to isolated LRR was 64 months; for SCC, AC-I and AC-D+M, this was 64 (95% CI 0-129), 47 (95% CI 1-93) and 18 (95% CI 5-31) months, respectively (p=0.61). Multivariable analysis was adjusted for gender, age, completion of radiotherapy (all significantly associated with prognosis in univariable analysis), chemotherapy regimen and Charlson comorbidity score (both p=0.1 in univariable analysis). Age and failure to complete radiotherapy were significant predictors for overall survival. As compared to SCC, overall survival was similar for AC-I; HR 1.22 (95% CI 0.72-2.1) and AC-D+M; HR 1.93 (95% CI 0.9-4.0).

#### Conclusion

In our cohort no significant relationship was found between the histological subtype and long-term outcomes following dCRT for esophageal cancer, although, AC-D+M showed a trend towards poorer outcomes. Not only for SCC, but also for intestinal type adenocarcinomas of the esophagus, dCRT can be considered.

#### EP-1247 Exclusive chemoradiation with Carboplatin-Taxol vs Folfox-4 in locally advanced esophageal cancer.

G. Crehange<sup>1</sup>, A. Bertaut<sup>2</sup>, J.F. Bosset<sup>3</sup>, J. Boustani<sup>3</sup>, M. Rouffiac<sup>1</sup>, F. Ghiringhelli<sup>4</sup>, C. Borg<sup>3</sup>, B. De Bari<sup>3</sup>, J. Buffet Miny<sup>3</sup>

<sup>1</sup>Centre Georges-François Leclerc, Radiotherapy, Dijon, France

<sup>2</sup>Centre Georges-François Leclerc, Biostatistics, Dijon, France

<sup>3</sup>University Hospital Jean Minjot, Radiation Oncology, Besançon, France

<sup>4</sup>Centre Georges-François Leclerc, Medical oncology, Dijon, France

<sup>5</sup>University Hospital Jean Minjot, Medical Oncology, Besançon, France

#### Purpose or Objective

Exclusive chemoradiation delivering 50Gy of external beam radiotherapy (EBRT) combined with Cisplatin and 5-FU remains the standard of care for locally advanced disease since a quarter century. The French PRODIGE 5 phase III trial has demonstrated the safety and the efficacy of FOLFOX-4 combined with exclusive 50Gy EBRT while the Dutch CROSS phase III trial showed an improvement in overall survival with Carboplatin and Taxol when combined with 41.4Gy in the preoperative setting. We sought to determine the feasibility and efficacy of exclusive EBRT with Carboplatin-Taxol compared to FOLFOX-4 regimen.

#### Material and Methods

Patients were matched 1:1 with respect to age at diagnosis ( $\pm 5$  years), stage (I-II vs III-IV), biopsy proven histology (squamous vs adeno) and topography (upper, middle or lower third or cardia). 46 patients followed the above criteria and remained for the final analysis : 23 patients were treated with FOLFOX-4 regimen (group A) and 23 patients with Carboplatin AUC2 mg/mL per min and Taxol 50mg/m<sup>2</sup>, weekly (group B). Comparison between the 2 groups was performed using Mac Nemar test for paired data. Statistical analyses were performed using SAS 9.3 software. All tests were two sided and P values were considered significant when less than 0.05.

#### Results

The mean age in group A was 69.4 years (12.5) and 72.4 years (12.6) in group B (p=ns). In each group, 11 patients

had a stage III disease at diagnosis (47.8%) with only 2 stage IV in group A (8.7%) vs none in group B.

The median delivered RT doses were 50Gy [14-60] in group A while it was 50Gy [20-70] in group B. We found no difference in the compliance with chemotherapy in each group : 6 courses were delivered in 12 patients in group A (52.2%) and 14 patients in group B (60.9%) (p=0.51). No difference in dose reduction was observed between each group for each course of chemotherapy.

After chemoradiation, G1 or higher esophagitis was observed in 5 patients (26.3%) in group A and 3 patients (13.0%) in group B of whom 0 vs 2 G3 were observed in group A and B, respectively. Four patients (21.1%) had a pulmonary infection in group A and 3 in group B (13.0%). Looking at haematological toxicity, 2 patients (8.7%) vs 4 patients (17.4%) had G3 neutropenia, with only 0 and 2 neutropenic fever in group A and B, respectively. No patient had G-CSF. Neither G3 anemia, nor G3 thrombopenia occurred.

After a median follow-up of 17.7 months [0.0-46.9], 25 patients had died, 14 in group A (60.9%) and 11 in group B (47.8%).

The median PFS rates were 14 months in group A [7.7-NR] vs 12.1 months [4.4-NR] in group B (p=0.32).

The median OS rates were 20.3 months in group A [6.2-39.3] vs 17.0 months [4.8-NR] in group B (p=0.82).

#### Conclusion

Exclusive chemoradiation with Carboplatin and Taxol seems feasible with similar toxicity and survival outcomes than FOLFOX-4. The safety and efficacy of the CROSS regimen needs to be tested prospectively with EBRT doses >41.4Gy in a phase II or III trial.

#### EP-1248 Adjuvant radiotherapy for gastric cancer patients underwent gastrectomy and D2 lymph node dissection

Y. Wang<sup>1</sup>, J.M. Hwang<sup>1</sup>, Y.K. Chang<sup>1</sup>, W.Y. Kao<sup>2</sup>, H.L. Wan<sup>2</sup>, S.Y. Chang<sup>2</sup>, C.C. Wu<sup>3</sup>

<sup>1</sup>Taipei Tzu Chi Hospital, Radiation Oncology, New Taipei City, Taiwan

<sup>2</sup>Taipei Tzu Chi Hospital, Medical Oncology, New Taipei City, Taiwan

<sup>3</sup>Taipei Tzu Chi Hospital, General Surgery, New Taipei City, Taiwan

#### Purpose or Objective

The benefit of adjuvant chemoradiation (CRT) has been confirmed by the Intergroup 0116 (INT-0116) study. However, as D2 lymph node dissection has been linked to lower recurrence rate, the role of adjuvant radiotherapy (RT), whether with or without concurrent chemotherapy, following D2 dissection is controversial. The goal of this study is to review the clinical outcome of patients with locally advanced gastric adenocarcinoma underwent gastrectomy and D2 lymph node dissection with or without adjuvant RT.

#### Material and Methods

We reviewed 420 patients who were diagnosed with gastric cancer at Taipei TzuChi Hospital during Jan, 2008 to Sep, 2015, while excluding the following patients: those a) >80 years old, b) didn't undergo gastrectomy and D2 dissection, c) with distant metastases at diagnosis, d) stage IA or IB without nodal metastases, or e) patients who had never been disease-free. The overall survival (OS) and disease-free survival (DFS) rates were compared between patients treated with or without adjuvant RT. Chi-square test or unpaired t-test were used to compare the age, gender, positive lymph nodes (LN) numbers, stage, and chemotherapy status distribution between these two groups.

#### Results

Of those selected patients, thirty-one underwent adjuvant RT and 40 didn't. The characteristics were described in

Table 1. The median follow-up time was 26.87 months. Regional lymph node recurrence alone was only noted in one patient who didn't undergo RT. Distant metastases (DM) were noted in 17 patients (with RT: 8; without RT: 9). Out of those nine patients who developed DM and didn't undergo RT, five had been given chemotherapy. Age is significantly related to worse OS (Pearson correlation coefficient=-0.248, p=.037) but not to DFS (-0.191, p=0.111). Positive LNs number is significantly related to both worse OS (-0.244, p=0.041) and DFS (-0.261, p=0.028). Adjuvant RT didn't significantly improve OS (median: 34.3 vs. 19.7 months, p=0.123) and DFS (median: 30 vs. 17.7 months, p=0.86) (Fig. 1). The patients received adjuvant chemotherapy were with significantly longer OS (median: 31.9 vs. 14.7 months, p=0.007) but not DFS (median: 28.6 vs. 14 months, p=0.42).

#### Conclusion

Although the patients who underwent adjuvant CRT were significantly younger, they were also with more advanced diseases. Most of the recurrent events were distant metastases in our study, indicating that D2 dissection might have largely decreased the locoregional failure rate. Adjuvant RT didn't show significant benefit prolonging OS or DFS. On the other hand, the patients received adjuvant chemotherapy were observed to have significantly longer OS but not DFS. It is possible that the prolonged OS is correlated to the age of patients, rather than a result of chemotherapy. Further randomized controlled trials are required to draw a concrete conclusion.

#### EP-1249 Changes in normal liver volume after high dose radiation in cancer of the liver

K. Rajamanickam<sup>1</sup>, S. Chopra<sup>1</sup>, R. Engineer<sup>1</sup>, V. Ostwal<sup>1</sup>, P. Patil<sup>2</sup>, S. Mehta<sup>2</sup>, E. Dhandpani<sup>3</sup>, K. Joshi<sup>3</sup>, S.K. Shrivastava<sup>1</sup>

<sup>1</sup>Tata Memorial Hospital, Radiation Oncology, Mumbai, India

<sup>2</sup>Tata Memorial Hospital, Digestive Diseases and Clinical Nutrition, Mumbai, India

<sup>3</sup>Tata Memorial Hospital, Medical Physics, Mumbai, India

#### Purpose or Objective

To report liver volume changes and its impact on liver function following hepatic radiation in patients with primary or secondary hepatic malignancies.

#### Material and Methods

From Jan 2015 - April 2016, consecutive patients with unresectable hepatic lesions (hepatocellular cancer (HCC), Cholangiocarcinoma (CCA) or liver metastasis (LM)) who received either high dose radiation (HDRT) or stereotactic radiation (SBRT) and without disease progression were included. All patients were required to have Child Pugh status A-B6 prior to radiation. Total liver volume, gross tumour volume (GTV), normal liver volume (total liver volume- GTV) was determined. Follow up scans were used to determine changes, if any, in normal liver volume. As the dose prescription of each patient was individualised, biologically equivalent dose (BED) were calculated. Univariate analysis was performed to determine impact of total dose, GTV at treatment, use of systemic chemotherapy, primary tumour type, baseline liver function status, age and viral marker status on normal liver volume and liver function during follow up. Reduction in liver volume at follow-ups were analysed with paired t-test. p value of <0.05 was considered significant.

#### Results

Thirteen patients received either SBRT or HDRT. Out of these 6/7 patients with HCC received TACE prior to RT initiation and all received sorafenib while 3/4 with CCA received gemcitabine and cisplatin concurrently with radiation. Another 2 were treated for LM. The Median BED

was 59.5 Gy (48 - 85.5 Gy). The follow up scans were performed at 1 month and 4 months thereafter. The median normal liver volume at baseline, 1<sup>st</sup>, 2<sup>nd</sup> and 3<sup>rd</sup> follow up was 1105 (423-2100) cc, 918 (614 - 1899) cc, 778 (490 - 1746) cc and 816 (576 - 2101) cc for the entire cohort and 1098 (423 - 2100) cc, 886 (614 - 1899) cc, 778 (490 - 1746) cc and 750 (576 - 1136) cc for patients with primary hepatic malignancy (PHM). The reduction in liver volume was statistically significant at 4 months (p=0.05) in entire cohort. In PHM cohort, at 4 and 8 months reduction in liver volume were found significant (p=0.05 and p=0.05, respectively). Deterioration of Childs score was presented in 2/13 patients. This loss in liver function could represent ongoing radiation effects on compensatory liver hypertrophy or hepatocyte regeneration. However no correlation was seen between child score deterioration and loss of liver volume. On univariate analysis, the higher normal liver volume at baseline irradiated shows statistically significantly higher loss of liver volume (p=0.005). None of other tumour or treatment related factors had impact on liver volume changes.

#### Conclusion

The reduction in liver volume at follow up does not correlate with any tumour or treatment parameters other than normal liver volume at baseline. This ongoing loss of hepatic function and reduced hepatocyte regeneration after hepatic radiation needs further investigation.

#### EP-1250 Prognostic impact of post-surgery and post-adjuvant therapy in resected pancreatic adenocarcinoma

G.C. Mattiucci<sup>1</sup>, A. Arcelli<sup>2,3</sup>, F. Bertini<sup>2</sup>, F.A. Calvo<sup>4</sup>, M. Falconi<sup>5</sup>, G.P. Frezza<sup>3</sup>, A. Guido<sup>2</sup>, J.M. <sup>10</sup>S. Raffaele Scientific Institute, Department of Oncology, Milan, Italy

<sup>11</sup>University of Bologna, Department of Medical and Surgical Sciences - DIMES, Bologna, Italy

#### Purpose or Objective

Prognosis of pancreatic adenocarcinoma (PAC) is so dismal that annual mortality and incidence rates overlap. Several studies suggested that preoperative CA19.9 (prCA19.9) could be a useful prognostic marker in patients treated with surgery +/- adjuvant therapies. The purpose of this study was to determine whether post-surgical CA19.9 (poCA19.9) or post-adjuvant CA19.9 (paCA19.9) or a change in prCA19.9 to poCA19.9 could predict pattern of

failure in terms of local control (LC) and metastasis-free survival (DMFS).

#### Material and Methods

We performed a multicenter retrospective study and we selected for this analysis 67 pts Antigen Lewis positive (prCA19.9 > 5U/ml), judged to be secretors of CA19.9. We used the Kaplan-Meier method and the log-rank test to investigate differences in LC and DMFS between groups defined based on clinical and pathological factors, different poCA 19.9 cutoff (37, 100 U/mL), paCA 19.9 cutoff (37 U/mL), and differences (%) between prCA19.9 and poCA19.9 levels.

#### Results

Demographic data and results are shown in Table 1. Median follow-up (FU) was 18 months (2-225). At univariate analysis, levels of poCA19.9 >37 U/ml (p= 0.009) or >100 (p< 0.001) and levels of paCA19.9 >37 U/ml (p= 0.009) were significantly associated with a worse DMFS. A change in prCA19.9 to poCA19.9 did not impact LC and DMFS. CRT did not impact pattern of failure in the whole patients population. Only in patients with poCA19.9 > 37 U/ml CRT significantly affected LC (63.6% for patients treated with CRT vs 40.0% for patients not treated with CRT; p = 0.008).

**Table 1:** Patients' characteristics, median OS and 5-y OS, 5y-LC, 5y-DMFS of the analyzed cohort. CRT: chemoradiotherapy; PD: pancreaticoduodenectomy; DP: distal pancreatectomy; TP: total pancreatectomy

#### Purpose or Objective

To evaluate the safety and efficacy of preoperative chemoradiotherapy and D2 radical resection in patients with locally advanced gastroesophageal junction carcinoma

#### Material and Methods

Gastroesophageal junction carcinomapatients withadenocarcinoma, clinical stage T3-4N0 or any TN1-3M0, Siewert type II and III were enrolled. After exclusion of peritoneal metastasis with laparoscopic exploration, patients were randomly assigned into surgery group and preoperative chemoradiotherapy plus surgery group. The preoperative chemoradiotherapy group received intensity modulated radiation therapy (IMRT) and concurrent chemotherapyS-1 combined with oxaliplatin weekly plan. The prescription dose was GTV 50Gy/CTV 45Gy/25f/35d with concomitant boost. For the concurrent chemotherapy, S-1 was 30mg/m2 bid, five days a week; oxaliplatin was 40mg/m2 per week, with a total of 5 weeks.Laparoscopic exploration was needed 6 weeks after the end of the preoperative chemoradiotherapy. Patients with no peritoneal metastasis underwent D2 radical resection.Postoperative patients received SOX chemotherapy for 6-8 cycles. This trial (PAPER) is a multicenter randomized controlled studyin Beijing, Tianjin and Hebei Province. Primary endpoint is 3-year DFS, the secondary endpointsare safety and effectivity

#### Results

From Sep. 2014 to Jul. 2016,40 cases of 4 centers were enrolled. There were 20 patients in surgery group and 15 cases in the preoperative chemoradiotherapy group. The median age was 61 years (range 33-73).28 were male and 7 were female. Clinical staging were as follows: 20 cT3, 15 cT4; 4 cN0, 8 cN1, 19 cN2, 13 cN3. In the preoperative chemoradiotherapy group ,All patients completed radiotherapy. Six patients cannot tolerate concurrent chemotherapy due to toxicity.There was no grade 4 toxicity.The incidence of grade 3 toxicities were 13.3%: neutropenia. The incidence of grade 2 toxicities were 80%, including: thrombocytopenia (26.7%), neutropenia (6.7%), esophagitis and nausea(13.3%). All patients underwent radical D2 resection. Pathological complete response occurred in 13.3% (2/15) of patients. The T and N downstaging rate were 86.7% (13/15) and 100% (11/11), respectively.

The tumor regression grade (TRG) were1 case of Grade 0, 2cases of Grade 1 and 3 cases of Grade 2, respectively. Surgery-related complications consisted of anastomotic leakage in 2 (13.3%), infection in 1 (6.7%) and hemorrhage in 1 (6.7%) patients. The perioperative mortality was nil. In the surgery group, Surgery-related complications consisted of anastomotic leakage in1 (6.7%), infection in 1 (6.7%) and hemorrhage in 1 (6.7%) patients. The perioperative mortality was nil. Postoperative complications had no significant differences between two groupsConclusion

Preoperative Chemoradiotherapy for patients with locally advanced gastroesophageal junction adenocarcinoma showed an acceptable toxicity, promising efficacy and safety for D2 resection. Further conclusions need to be verified by the mid-term results after the completion of

enrollment

#### EP-1252 Update of Stereotactic body radiation therapy for pancreatic adenocarcinoma: efficacy and safety

<sup>4</sup>Hospital Universitario HM Puerta del Sur, Medical Physics, Madrid, Spain

#### Purpose or Objective

To review feasibility and single center experience with stereotactic body radiation therapy (SBRT) in pancreatic adenocarcinoma.

#### Material and Methods

Since February 2014, 15 (p) patients with a median age of 69.8 years (range 53-86) with histologically proven adenocarcinoma of the pancreas were enrolled on this protocol. Six p (40%) were treated with a radical intent, 5 p (33%) as a part of a neoadjuvant treatment and 4 p (27%) under a palliative intention. Prior to radiation, at least 2 gold fiducial markers were located into the tumor guided by endoscopic ultrasound. All the SBRT treatments included CT or PET-CT for GTV delineation, treatment technique was intensity-modulated radiation therapy (IMRT) and daily image-guided radiation therapy (IGRT) with intrafraction control of tumor motion with a Novalis Exactrac Adaptive Gating System. Total dose: 50 Gy in 10 fractions were prescribed in 13 p (87%), 1 p was treated with 35 Gy in 5 fractions and 1 p was treated with 40Gy in 10 fractions.

#### Results

With a median follow-up of 8 months (range 3 - 24 months), 2 p (13%) are alive without tumor, 4 p (26%) are alive with tumor and 9 p (61%) have died; median overall survival (OS) was 13.4 months (range 8.6 - 30.4 months) and the actuarial 12 and 24 months OS was 79% and 22% respectively. Eleven p (73%) remain locally controlled and median time to local progression (PFS) was 11.4 (range 4.5 - 30.4 months). The actuarial PFS at 12 and 24 months were 85% and 56% respectively. Pancreatic SBRT was well tolerated in our cohort of patients. No grade 3 or higher toxicity was observed. Six p (40%) developed grade 2 epigastric pain and/or grade 2 nausea/vomiting.

#### Conclusion

In our experience, gating SBRT for pancreatic tumor is a feasible and well-tolerated treatment. Most patients are free from local progression, but overall survival remains poor. Prospective studies are needed to define the role of SBRT for pancreatic tumors.

#### EP-1253 Interobserver variability in the target delineation of hepatocellular carcinoma.

<sup>13</sup>University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

<sup>14</sup>German Cancer Consortium DTK, Partner Site Freiburg, Freiburg, Germany

#### Purpose or Objective

To evaluate the inter-observer variability in the gross tumor delineation of hepatocellular carcinoma (HCC) in a multicenter panel.

#### Material and Methods

The analysis was performed within the working group on Stereotactic Radiotherapy of the German Society for Radiation Oncology (DEGRO). A total of 9 German, Austrian and Swiss centers with experience in upper abdominal stereotactic body radiotherapy (SBRT) participated in the study. Sixteen physicians (12 radiation oncologists, 2 liver surgeons, 1 radiologist and 1 nuclear medicine physician) were invited to delineate the gross tumor volume (GTV) of three anonymized HCC cases. A multiphasic CT scan from each patient was distributed to the panel before the annual meeting. In the first case participants were asked to delineate a peripheral well defined HCC. The second case included a patient with a multifocal HCC (1 conglomerate and 1 peripheral tumor). This patient was previously treated with transarterial chemoembolization (TACE) and the peripheral lesion was adjacent to the previous TACE site (lipiodol uptake site). In the last case the participants were given a CT with an extensive HCC involvement with a portal vein thrombosis and inhomogeneous liver parenchyma due to extensive cirrhosis. The inter-observer agreement (IOA) was evaluated according to Landis and Koch.

#### Results

The IOA for the first case was excellent (kappa: 0.85) and for the second case moderate (kappa 0.48) for the peripheral tumor and substantial (kappa 0.73) for the conglomerate. In the case of the peripheral tumor the inconsistency is most likely explained due to the necrotic tumor cavity after TACE caudal to the viable tumor. In the last case the IOA was fair with a kappa of 0.34 with a significant heterogeneity concerning the borders of the tumor and the extent of the portal vein thrombosis (PVT). We did not find significant differences between the different subgroups of experts except for the last case were the physicians who were involved in the diagnosis (radiologists and nuclear medicine physician) showed a better IOA (kappa: 0.64)

#### Conclusion

The IOA was very good among the cases were the tumor was well defined. Yet, in complex cases were the tumor did not show the typical characteristics or in cases with lipiodol deposits inter-observer agreement was compromised.

**EP-1254 DVH analysis of radiotherapy of upper gastrointestinal tumours: a model to predict toxicity.**

<sup>3</sup>Department of Experimental- Diagnostic and Specialty Medicine - DIMES- Università di Bologna- Ospedale S. Orsola-Malpighi, Radiation Oncology Center, Bologna, Italy

#### Purpose or Objective

Tolerance of small bowel is the dose limiting factor in radiation therapy for abdominal neoplasms. Bowel constraints for treatment planning in abdominal radiotherapy derive from scientific publications of pelvic tumors. This study has the aim to evaluate dose tolerance of small bowel and to provide a model detecting acute toxicities in patients with upper gastrointestinal (GI) cancer treated with radiotherapy.

#### Material and Methods

Patients with upper GI cancer treated between 2009 and 2016 with 3D-conformal or intensity modulated radiotherapy (IMRT) with or without concomitant chemotherapy were enrolled in this study. Nausea, vomit and loss of weight, as acute upper gastrointestinal (GI) toxicities, were scheduled using CTCAE v4.03 scale. In all patients small bowel loops, bowel bag, liver and stomach, if present, were contoured by a radiation oncologist on simulation computed axial tomography according to QUANTEC guidelines. Liver, PTVs, Small Bowel, Bowel Bag and Stomach were selected on Dose Volume Histogram (DVH) and their data were extrapolated. DVHs were analyzed for this structures using R statistical software (<http://www.R-project.org>).

#### Results

Data of 143 patients with a median age of 66 years (range 35-84), 79 (55,2%) resected and 64 (44,8%) unresected, were analyzed. All patients selected had primary tumour location cancer in upper GI tract such as pancreas (53%), biliary ducts (15%), stomach (26%), gallbladder (3%), gastroesophageal junction (3%). Prescribed dose ranged between 3000 cGy and 5580 cGy with fractionation ranging between 180 cGy and 300 cGy. Most of patients were treated with 3D conformal radiotherapy (92%) and only 8% received IMRT.

Fiftytwo (36,4%) patients reported no upper GI toxicity; on 27 (18,9%), 36 (25,2%) and 28 (19,5%) patients were observed respectively grade 1, 2 and 3 toxicity. No grade 4 toxicity was recorded.

Fiftyone patients discontinued radiotherapy and 9 did not complete it, none of them because of GI toxicities. Analyzing VDose for upper GI toxicity grade  $\geq 2$  on DVHs, small bowel loops V31.7, bowel bag V32.7, liver V35.6 Gy and stomach V31.5 Gy resulted as the parameter which most influenced upper GI toxicity ( $p < 0.05$ ). Univariate analysis for  $\geq G3$  grade upper GI toxicity for all structures was not statistically significant ( $p > 0.05$ ). Univariate analysis showed no impact of surgery on upper GI toxicity while female sex and concomitant chemotherapy were associated with likely upper GI toxicity. Multivariate logistic model showed liver V35.6 as best and unique predictor of GI toxicity grade  $\geq 2$  ( $p < 0.01$ ). Relation between dose and toxicity is summarized in figure 1 as empirical cumulative density function plot.

#### Conclusion

In this investigation on patients treated for upper GI cancer, we recommend that V35.6 Liver (relative) should

be held to  $< 22\%$  in order to get upper GI toxicity grade  $\geq 2$  probability below 15%. Further investigations should be done in order to observe significant dosimetric evaluation in patients with grade  $\geq 3$  toxicity.

**EP-1255 Early clinical results for esophageal brachytherapy using a novel multi-balloon HDR applicator**

A.S. Taggar<sup>1</sup>, G.N. Cohen<sup>1</sup>, P.J. Brady<sup>1</sup>, J.J. Cuaron<sup>1</sup>, A. Wu<sup>1</sup>

<sup>1</sup>Memorial Sloan Kettering Cancer Center, Radiation Oncology, New York, USA

#### Purpose or Objective

Management of superficial primary and locally recurrent esophageal cancer (EC) in medically inoperable patients is complex. Endoluminal high-dose-rate (HDR) brachytherapy (BT) has shown mixed results in terms of toxicity and local control (LC). In this study, we assessed the outcomes and toxicities in a set of patients treated in a consistent fashion with a novel multi-balloon HDR applicator (E-app) using CT-based planning.

#### Material and Methods

Five patients were treated with the E-app between November 2015 and August 2016 in a single institution. Their records were reviewed retrospectively under institutional ethics board approval. All patients were treated with HDR brachytherapy using the E-app and 3D CT-based treatment planning, and received a total of 15 Gy in 3 weekly fractions prescribed to tumor volume. All treatments were completed as planned. Four patients had distal esophagus/GE junction tumors, and one patient had mid-thoracic tumor. For one patient who presented with squamous cell (SC) and another with and neuro-endocrine (NE) histology, BT was the primary treatment. Three patients had adenocarcinoma histology and were previously treated with primary chemo/radiotherapy (CRT); two had residual disease after primary CRT and one presented with recurrence 8 years after initial treatment with CRT. Two patients with residual disease received concurrent Capecitabine, whereas all others were treated with BT only.

#### Results

Patients' median (range) age and KPS at the time of BT were 76.6 years (66.0-87.6) and 80 (40-90), respectively. Median length of treatment was 7.0 cm (5.5-9.0 cm). Median dose to the hottest 0.3cc within defined esophageal target volume ( $D_{0.3cc}$ ) was 34.5 Gy (31.8-36.6 Gy).  $D_{0.3cc}$  and  $V_{100}$  of esophagus outside target volume were 14.7 Gy (9.1-21.9 Gy) and 0.8 cc (0.0-3.6 cc), respectively. Median follow-up from BT was 6.1 months (1.7-7.3 months). Observed toxicities included dysphagia (2 patients, grade 1 and grade 2), esophagitis (1 patient, grade 1) stenosis (1 patient, grade 1) and asymptomatic necrosis within the target area (1 patient, prior treatment with 50.4 Gy + FOLFOX chemotherapy); no grade 3 toxicity was observed. Repeat biopsy at 3 months' post BT was done in 3 out of 5 patients: 2 (patients with SC and NE histology) had no evidence of disease and one had persistent disease. One patient developed metastatic disease and died without endoscopic assessment or biopsy after BT.

#### Conclusion

This is the first report of clinical outcomes using a novel multi-balloon HDR brachytherapy applicator (E-App). The E-App appears to provide a safe and effective method of delivering high doses of radiation to localized esophageal cancers. We observed low rate of toxicity with short follow-up and promising clinical and pathological responses in the settings of recurrent and residual disease.

**EP-1256 Local ablative radiotherapy for liver metastasis: factors affecting local control and survival**  
C. Petersen<sup>1</sup>, T. Gauer<sup>1</sup>, T. Frenzel<sup>1</sup>, M. Todorovic<sup>1</sup>, A. Krüll<sup>1</sup>, M. Blaschczyk<sup>1</sup>

<sup>1</sup>University Medical Center Hamburg - Eppendorf UKE, Department of Radiation Oncology, Hamburg, Germany

**Purpose or Objective**

The liver is a common site of metastases from most common solid malignancies. Currently available systemic treatment regimens, result in transient to long-term disease control, raising the question of further local management. Secondary resection and thermo-ablation may contribute to long-term survival or allow at least a relevant chemotherapy-free interval. These approaches are often limited. With stereotactic body radiotherapy metastases can be treated with high efficiency in only a few sessions. Here we evaluate the feasibility of high-dose stereotactic body radiation therapy for liver metastases in patients not eligible for surgery focussing on colorectal cancer patients.

**Material and Methods**

Between July 2012 and December 2015, 33 patients with 56 liver metastases (range 1-4) were treated with SBRT. Primary tumor mostly consists of colorectal cancer (59%) and others (lung-, breast-, pancreatic cancer). Median time between diagnosis of liver metastases and SBRT was 11 months (range 0-57 months). To receive precise information about target localization, 3 gold fiducial markers were implanted in 30 out of 56 lesions (54%). To analyze respiratory tumor motion, 4D-CT scans were performed for all patients. Gross tumor volume contours of 10 breathing cycles were transferred to the average CT of the CD-CT data, forming the internal target volume (ITV). Planning target volume was obtained by adding a 4 mm margin. SBRT was delivered in VMAT technique using Varian TrueBeam linear accelerator. Most common fractionation schedule was 5 x 11 Gy (90% isodose covering the PTV).

**Results**

The median follow-up for all patients was 13 months. The overall local control rate for all 56 metastases was 86% with a total of 7 failures. In univariate analysis, the implantation of fiducial markers was predictive for local control (p=0.029). During follow up period, tumor progression developed in 28 cases (83%). In 13 cases new intrahepatic lesions occurred (47%), in 10 cases extra hepatic lesions (36%) and in 5 cases intra- and extra hepatic lesions (18%). Overall survival rate was 58%, median overall survival was 21 months. Univariate analysis showed statistical significance for OS concerning histology (colorectal vs. other) and gross tumor volume (</> 20 ccm).

**Conclusion**

Liver SBRT is effective and yielded good local control. The SBRT procedure is a valid option for patients with oligometastatic disease and should be considered as an alternative to surgical treatment or other local ablative techniques.

Electronic Poster: Clinical track: Lower GI (colon, rectum, anus)

**EP-1257 A look at pre-operative MRI accuracy at predicting rectal cancer staging post chemoradiotherapy**

K. Nugent<sup>1</sup>, R. McDermott<sup>1</sup>, M. Higgins<sup>1</sup>, B. O'Neill<sup>1</sup>  
<sup>1</sup>St Lukes Radiation Network, Radiation Oncology, Dublin, Ireland

**Purpose or Objective**

Neoadjuvant chemoradiotherapy (CRT) has become standard in the treatment of rectal cancer patients with stage 3 disease. This approach has shown to reduce both local recurrence rates and increase the rate of sphincter preservation procedures. Up to 20% of patients 6 weeks post neoadjuvant CRT have a complete histological response (pCR). PCR has shown to correlate with better and sustained oncological outcomes. The feasibility of the emerging watch and wait management strategy for patients with pCR will depend on the reliability of restaging assessments post CRT. We looked the accuracy of pre-operative MRI in predicting the rectal cancer tumour stage, node status and complete clinical response in patients who have undergone neoadjuvant chemoradiotherapy using histopathologic analysis as the reference standard.

**Material and Methods**

We retrospectively identified all patients who underwent neoadjuvant CRT (50.4 Gy, 1.8 Gy/fraction, in 5.5 weeks, with continuous infusional fluorouracil 225 mg/m<sup>2</sup>daily) for rectal cancer and proceeded to standard TME at our institution over a 16 month period. Their initial cTNM staging was collected as was their restaging ycTNM post CRT (based on diffusion weighted MRI pelvis). The sensitivity and specificity of the latter at predicting tumour, nodal and complete clinical response compared to surgical histology was analysed.

**Results**

43 patients underwent CRT and subsequent TME over the time period at our institution. Overall histopathological response rate was 93% with a pCR rate of 14%. MRI had a sensitivity of 58% and specificity of 94% at assessing complete clinical response, 95 CI 40-93%, 80-99% respectively. At predicting tumour response MRI had sensitivity of 53% and specificity of 85%, 95 CI 45-80%, 74-94% respectively. Accuracy of predicting nodal response were lower with a sensitivity of 43% and specificity of 40% , 95 CI 30-88%,32-58% respectively. The average modal time interval between CRT and MRI was 5 weeks while the average modal time between CRT and surgery was 8 weeks

**Conclusion**

Our study suggests that MRI alone may not be accurate enough in assessing clinical stage post neoadjuvant CRT, and particularly the clinical node status. Imaging alone will likely be needed to be combined with clinical, biochemical and endoscopic assessments in order to improve reliability of post treatment rectal staging.

**EP-1258 High precision SIB-IMRT versus conventional radiotherapy in anal cancer: a propensity score analysis**

F. Arcadipane<sup>1</sup>, A. Lepinoy<sup>2</sup>, P. Franco<sup>1</sup>, M. Ceccarelli<sup>3</sup>, B. De Bari<sup>2</sup>, L. Lestrade<sup>2</sup>, G. Furfaro<sup>1</sup>, M. Mistrangelo<sup>4</sup>, G. Créange<sup>5</sup>, U. Ricardi<sup>1</sup>

<sup>2</sup>Radiation Oncology, Radiation Oncology, Besançon, France

<sup>3</sup>Cancer Epidemiology and CPO Piemonte, Epidemiology, Turin, Italy

<sup>4</sup>Surgery, Surgical Sciences, Turin, Italy

<sup>5</sup>Radiation Oncology, Radiation Oncology, Dijon, France

**Purpose or Objective**

To evaluate clinical outcomes of a simultaneous integrated boost- intensity modulated radiotherapy (SIB-IMRT) approach in patients with non-metastatic anal cancer compared to those of a set of patients treated with 3-dimensional conformal radiation and sequential boost (CRT).

**Material and Methods**

A retrospective cohort of 190 anal cancer patients consecutively treated between March 2007 and October

2015 at 2 academic centres with concurrent chemo-radiation employing either SIB-IMRT or CRT was analysed. The SIB-IMRT group consisted of 87 patients, treated with 2 cycles of Mitomycin and 5-Fluorouracil using a SIB-IMRT based schedule of 42-45 Gy/28-30 fractions to the elective pelvic lymph nodes and 50.4-54 Gy/28-30 fractions to the primary tumor and involved nodes, based on pre-treatment staging.

The CRT group comprised 103 patients, treated with Mitomycin or Cisplatin and 5-Fluorouracil or Capecitabine concurrent to CRT with 36 Gy/20 fractions to a single volume including gross tumor, clinical nodes and elective nodal volumes, and a sequential boost to primary tumor and involved nodes of 23.4 Gy/13 fractions.

We determined colostomy-free survival (CFS) and overall survival (OS), loco-regional recurrence and distant metastases rates for each radiation modality. Cox proportional-hazards model addressed factors influencing OS and CFS. Propensity score-matched analyses were performed to compare SIB-IMRT and CRT.

### Results

Median follow-up for the entire patient group was 32 months. Average overall treatment time was 42 days in the SIB-IMRT group and 59 days in the CRT group. Patients treated with CRT had significantly higher stage and lower grading. The overall survival at the time of analysis was 74%, similarly for the two groups. Three-year colostomy-free survival was 66% for all patients, with no significant difference between the two groups (61% for SIB-IMRT and 74% for CRT, Log-Rank 0.85). The cumulative incidence of colostomies showed that the majority of events occurred within 18 months in both groups. We found no significant difference in terms of outcomes by univariate analysis and a propensity score analysis adjusted for disparities between the groups.

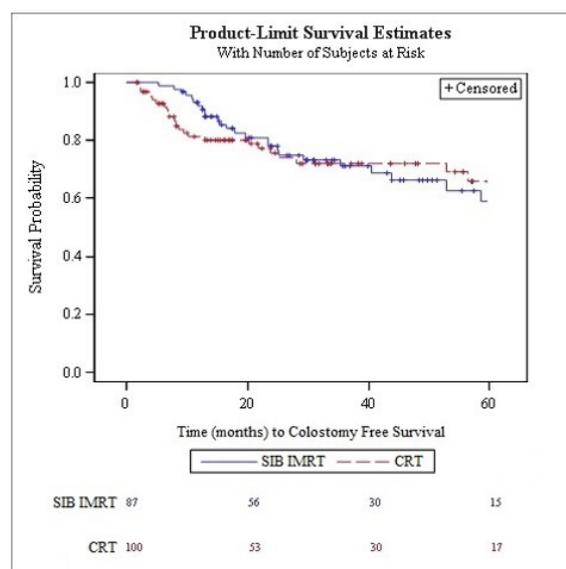

Fig. 1 Colostomy-free survival

### Conclusion

Results of this analysis indicate that 3-year clinical outcomes of SIB-IMRT are similar to CRT. Even if highlighting the retrospective observational nature of the study, these data support the routinely use of SIB-IMRT in clinical practice for anal cancer patients submitted to concurrent chemo-radiation.

### EP-1259 Modern Intensity Modulated Radiotherapy with Daily Image Guidance for Anal Cancer Patients

B. De Bari<sup>1</sup>, L. Lestrade<sup>2</sup>, A. Franzetti-Pellanda<sup>3</sup>, M. Biggiogero<sup>3</sup>, M. Kountouri<sup>2</sup>, O. Matzinger<sup>4</sup>, R. Miralbell<sup>2</sup>, J. Bourhis<sup>5</sup>, M. Ozsahin<sup>5</sup>, T. Zilli<sup>2</sup>

<sup>1</sup>Hôpital Univ. Jean Minjot, Radiation Oncology, Besançon, France

<sup>2</sup>Hopitaux Universitaires de Genève, Radiation Oncology, Genève, Switzerland

<sup>3</sup>Clinica Luganese, Radiation Oncology, Lugano, Switzerland

<sup>4</sup>Hôpital Riviera-Chablais, Radiation Oncology, Vevey, Switzerland

<sup>5</sup>Centre Hospitalier Universitaire Vaudois, Radiation Oncology, Lausanne, Switzerland

### Purpose or Objective

We report the outcomes of the largest populations of anal cancer (AC) patients treated with modern intensity-modulated radiotherapy (IMRT) techniques and daily image guidance.

### Material and Methods

AC patients treated with IMRT +/- chemot herapy in 3 radiotherapy departments were retrospectivel y analysed. They received 36 Gy (1.8 Gy/fraction) on the pelvic and inguinal nodes and on the anal canal, using IMRT (n = 39), volumetric modulated arc therapy (VMAT; n = 15), or helical Tomotherapy (HT; n = 97), and a sequential boost up to a total dose of 59.4 Gy (1.8 Gy/fraction) on the anal and on the nodal gross tumor volumes, delivered with either IMRT (n = 16, until 2011), VMAT (n = 17), HT (n = 61), or 3D-conformal EBRT (CRT, n = 61).

### Results

A total of 151 patients were treated (09/2007 - 03/2015). Of them, 122 presented a stage II - IIIa disease. Chemotherapy was delivered in 138 patients, mainly using mitomycin C and 5-fluorouracil (n = 81). Median follow-up was 38 months (interquartile range, 12-52). Four-year

local control rate was 82% (95% CI: 76-91%). Complete toxicity data were available for 143 patients: 22% of them presented a G3+ acute toxicity, mainly as moist desquamation (n = 25) or diarrhoea (n = 10). Three patients presented a late grade 3 gastrointestinal toxicity (anal incontinence). No grade 4 acute or late toxicity was recorded. Patients treated with standard dynamic IMRT presented a significantly higher risk of acute grade 3 or more toxicity compared to those treated with VMAT or HT (38.5% vs 15.3%, p = 0.049).

#### Conclusion

Modern IMRT (VMAT or HT) with daily IGRT are effective and safe in treating AC patients, and should be considered the standard of care in this clinical setting.

#### EP-1260 Helical Tomotherapy with Daily Image Guidance for Rectal Cancer patients

B. De Bari<sup>1</sup>, A. Franzetti-Pellanda<sup>2</sup>, A. Saidi<sup>3</sup>, M. Biggiogero<sup>2</sup>, D. Hahnloser<sup>4</sup>, D. Wagner<sup>5</sup>, M. Montemurro<sup>5</sup>, J. Bourhis<sup>3</sup>, O. Ozsahin<sup>3</sup>

<sup>1</sup>Hôpital Univ. Jean Minjot, Radiation Oncology, Besançon, France

<sup>2</sup>Clinica Luganese, Radiation Oncology, Lugano, Switzerland

<sup>3</sup>Centre Hospitalier Universitaire Vaudois, Radiation Oncology, Lausanne, Switzerland

<sup>4</sup>Centre Hospitalier Universitaire Vaudois, Surgery, Lausanne, Switzerland

<sup>5</sup>Centre Hospitalier Universitaire Vaudois, Medical Oncology, Lausanne, Switzerland

#### Purpose or Objective

Helical Tomotherapy (HT) has only been recently introduced in the neoadjuvant treatment of locally advanced rectal cancer (LARC) patients (pts). Aim of this retrospective study is to report the results in terms of toxicity and local control of the largest population treated with neoadjuvant HT and chemotherapy (CRT) with daily image guidance (IGRT) followed by surgery.

#### Material and Methods

Data of 117 patients LARC pts treated in 2 Swiss Radiotherapy departments were collected and analyzed. Radiotherapy (RT) consisted of 45 Gy (1.8 Gy/fraction, 5 days/week for 5 weeks) to the regional lymph nodes. Seventy pts also received a simultaneous-integrated boost (SIB) up to a total dose of 50 Gy to the tumor (2 Gy/fraction, 5 days/week for 5 weeks). Chemotherapy consisted of capecitabine 850 mg/m<sup>2</sup>, twice daily, during the RT days. Following a mean interval after completion of CRT of 53 days (range, 13-142), all pts underwent surgery. Ninety-four patients (80.3%) received a low anterior resection (LAR), while 23 pts (19.7%) received an abdomino-perineal resection (APR). The resection status was classified as R0 in 107 patients, and R1 in 3 patients (not reported in 7 patients).

#### Results

The overall rate of G2 or more toxicity was 22% (22/117 patients). Only 3 patients (2.5%) presented a G3 toxicity, as dermatitis (n = 1) or diarrhoea (n = 2). None of the patients presented a G3 (or more) hematologic toxicity and/or G4 non-hematologic toxicity. After a median follow-up time of 23.3 months (range, 4.8 - 66.8), only 2 pts (1.7%) presented a G3-4 late toxicity. The 3-year local control rate was 96.9% (95% confidence interval: 96.4 - 97.3%).

#### Conclusion

CRT delivered with HT and daily IGRT shows excellent rates of local control with few acute toxicity. Longer follow-up is needed to confirm these encouraging results.

#### EP-1261 Hypofractionated radiotherapy for inoperable rectal cancer: A retrospective analysis 2007 to 2015

N. Abdul Satar<sup>1</sup>, A. Sibtain<sup>1</sup>, C. Cottrill<sup>1</sup>, T.M. Richards<sup>2</sup>

<sup>1</sup>Barts and the London NHS Trust, Radiotherapy Dept, London, United Kingdom

<sup>2</sup>Barts and the London NHS Trust- University College London Hospital, Radiotherapy Dept, London, United Kingdom

#### Purpose or Objective

Hypofractionated radiotherapy (HRT) preoperatively improves locoregional control (LRC) for resectable rectal cancer. In addition chemoradiotherapy alone provides complete response rates of 10-20%. For patients with localised disease, unfit for surgery or with metastatic disease, the efficacy of HRT regimens is less clear. We report a single centre study of HRT for non-surgically treated rectal cancer.

#### Material and Methods

We retrospectively reviewed all patients who received HRT between 2007 and 2015. Patients had histologically proven rectal cancer with localised or metastatic disease and were ineligible for surgery. The primary endpoint was overall survival (OS). Secondary endpoints were LRC, toxicity and objective symptom control.

#### Results

Between March 2007 and December 2015 48 patients received pelvic HRT for inoperable rectal cancer, 24 (50%) had locoregional disease. The median (range) age was 78 years (44-93), 17 (35%) patients had performance status 3. Dose/fractionation delivered was 27 Gy/6# in 3 weeks, 31 (64.6%) patients and 25 Gy/5# in 1 week, 12 patients, BED=88 Gy for both regimens. Median (range) time from diagnosis to RT was 2.5 months (0.5-74 months). RT was delivered with a 3D conformal technique in 81% of cases. Two (4%) patients were re-treated with 8 Gy/1# and 16 Gy/4#, after receiving 27 Gy/6# and 25Gy/5# respectively. At a median (range) follow up of 12 months (0.5-76), symptomatic improvement was documented in 19 (39.5%) patients. All patients completed the prescribed regimen. Two (4%) patients died within 30 days of treatment. The 1 and 2 year survival rates for all patients were 45.8% and 16.7% respectively. Median (IQR) OS for patients with localised and metastatic disease were 13.4 months (10.3-25) and 6.2 months (2.5-10.3) respectively. Of the 16 patients alive, 12 (75%) had localised disease with median (IQR) OS in this subgroup of 17.2 months (12.7-27.3).

#### Conclusion

Hypofractionated radiotherapy is efficacious and tolerable for patients with rectal cancer, ineligible for surgery. Long term control of localised disease control can be achieved in a minority. A prospective randomised study would further quantify the benefit of HRT for this poor prognosis rectal cancer subgroup.

#### EP-1262 EBRT And HDRBT in Rectal Cancer Patients Who Are Medically Unfit Or Refuse Surgery

C.L. Chiang<sup>1</sup>, V.W.Y. Lee<sup>2</sup>, C.S.Y. Yeung<sup>1</sup>, M.Y.P. Wong<sup>2</sup>, F.A.S. Lee<sup>1</sup>, S.Y. Tung<sup>1</sup>

<sup>1</sup>Tuen Mun Hospital, Department of Clinical Oncology, Hong Kong, Hong Kong SAR China

<sup>2</sup>Tuen Mun Hospital, Department of Medical Physics, Hong Kong, Hong Kong SAR China

#### Purpose or Objective

TME surgery is the mainstay of treatment for rectal cancer. For those who are either medically unfit or refuse the operation, radiotherapy is frequently recommended but rarely leads to cure. There is recently some evidence suggesting dose escalation by adding HDRBT after EBRT is a feasible and promising strategy for this population. However, optimal dose fractionation regime remains

unclear on how to balance to tumor control and toxicity. Herein we reported our early experience on using EBRT and HDRBT in rectal cancer patients who are either unfit or refuse surgery.

#### Material and Methods

During the period of Jan-2015 to Sep-2016, total 12 consecutive patients treated with EBRT and HDRBT were analyzed; seven patients were because of medical inoperability, while five due to the refusal of surgery. Treatment consisted of EBRT with the regime (1.8Gy x 28, n=2; 5Gy x 5, n=4; 3Gy x 13, n=6) were at the discretion of physicians, followed by HDRBT boost given 8 weeks afterward. The starting dose level was 10Gy weekly x 1 fraction, with escalation to maximum 3 fractions if acute toxicity was acceptable. The primary endpoint was acute toxicity. Secondary endpoints were tumor response, local control, and survival. Tumor responses were assessed based on endoscopy and MRI findings and classified as responding disease (CR + PR), static disease (SD) or progression (PD)

#### Results

At the time of current analysis 9 patients were still alive and, median follow-up time was 13.6 months (range: 5.7-19.2 months). Median age 79 years (range: 70-88), ECOG 2/3 (n=7/5), Charlson co-morbidity score <3 or ≥ 3 (n=6/6); cT3/cT4 (n=11/1), Node positive/ negative (n=6/6), MRI predicted mesorectal fascia threatened (≤1mm) or not (n=7/5). Planned dose of HDRBT 10Gy x 1 / 10Gy x 2 / 10Gy x 3 (n=6/3/3). One patient developed grade 3 toxicity (8.3%). Tumor response was observed in 10 patients (83%). The local control rate at 1 year and 2 years was 100% and 50% respectively. No patients received ≥2 fractions HDRBT boost developed local progression. At 1 year, the cancer specific survival was 81.5%, and the overall survival was 71.3%. Outcome related to dose level was reported in table 1

	10Gy x 1	10Gy x 2	10Gy x 3
Grade 3 acute toxicity	0/6	0/3	1/3
Tumor response	4/6	3/3	3/3
Local progression	2/6	0/3	0/3

#### Conclusion

In our early experience, the combination of EBRT and HDRBT achieves promising tumor response of 83% and 1-year local control rate of 100% with acceptable acute toxicity. Longer follow-up is ongoing. Randomized trials are warranted to determine the optimal dose level of HDRBT.

#### EP-1263 Short course radiotherapy, surgery & chemotherapy for stage IV rectal cancer with liver metastasis.

L. Díaz Gómez<sup>1</sup>, A. Seguro<sup>2</sup>, M. Macias<sup>1</sup>, E. Gonzalez<sup>1</sup>, I. Villanego<sup>1</sup>, L. De Ingunza<sup>1</sup>, V. Díaz<sup>1</sup>, L. Gutierrez<sup>1</sup>, M. Salas<sup>1</sup>, J. Jaén<sup>1</sup>

<sup>1</sup>Hospital Universitario Puerta del Mar, Department of Radiation Oncology, Cadiz, Spain

<sup>2</sup>Hospital de Jerez, Department of Medical Physics, Jerez de la Fra., Spain

#### Purpose or Objective

Resection of primary and liver lesions is the optimal management of Stage IV rectal cancer with liver metastases (Mets). The benefit of neoadjuvant in short course radiotherapy (5x5Gy) in terms of reduction of local recurrences and tumour downstaging have been well established with the publication of the Stockholm studies. Associating the benefit of both treatments by adding the effect of chemotherapy before or after liver surgery (some patients undergoing synchronous resection of the primary tumour and liver) and showing the data of our series of patients between 2014 and 2015 is the aim of our study

#### Material and Methods

16 patients were eligible for this study, 6 women and 10 men in age 50-78 years at the time of treatment. All of them were MRI based stage with 3 patients cT3N1, 5 cT4N2, 2 T4N1, 4 T3N2, 2 T2N2 and 1 to 3 liver Mets. We excluded of our study patients with more than 3 Mets because indication for surgery was ruled at diagnosis and only offered radiotherapy as palliation. Hypofractionated scheme radiotherapy was administered with a total dose of 25Gy and surgery was delayed for 7 days from the start of radiation therapy or at least 4 weeks as literature recommended. Chemotherapy used after surgery of the primary tumour was Folfox or Folfiri scheme with 3 or 6 cycles depending number of liver Mets and patient characteristics.

#### Results

After radiotherapy complexation, 5 patients were into surgical resection in one week, and only 2 had synchronous surgery. Pathological findings showed 12 partial response, 1 complete response and 2 stabilization of rectal tumour. Only 1 patient had a complete liver response after chemotherapy so he was excluded for liver surgery (Mets was not marked) At the time of liver surgery, 4 patients had lung and liver progression so they continued in second line chemotherapy. Until date, we've got 6 patients in follow-up without systemic therapy. The others progressed and are now under chemotherapy treatment. Only one patient died due to neoplastic disease.

#### Conclusion

Combined short course radiotherapy as neoadjuvant treatment in patients diagnosed of Stage IV rectal cancer with liver metastases follow of surgery and chemotherapy with curative intention can be a safe treatment option but must be demonstrated in future clinical trials.

#### EP-1264 Metabolic response and change in CEA level in rectal cancer patients treated with neoadjuvant CRT

T.K. Nam<sup>1</sup>, J. Jeong<sup>1</sup>, K. Ahn<sup>1</sup>, Y. Kim<sup>1</sup>, M. Yoon<sup>1</sup>, J. Song<sup>1</sup>, S. Ahn<sup>1</sup>, W. Chung<sup>1</sup>

<sup>1</sup>Chonnam National University Hwasun Hospital, Radiation Oncology, Hwasun-eup, Korea Republic of

#### Purpose or Objective

We evaluated the significance of both metabolic response using <sup>18</sup>F-fluorodeoxyglucose-positron emission tomography/computed tomography (PET/CT) and change of serum carcinoembryonic antigen (CEA) level before and after preoperative chemoradiotherapy (CRT) as prognosticators for survival in patients with for rectal cancer.

#### Material and Methods

We retrospectively analyzed T3-T4 or N+ rectal cancer 196 patients who underwent preoperative CRT from October 2008 to June 2013. All patients received a median of 50.4 Gy in 28 fractions with 5-fluorouracil or capecitabine. The metabolic response was assessed by determining the maximal standardized uptake value (SUV<sub>max</sub>), absolute difference (ΔSUV<sub>max</sub>), and SUV reduction ratio (SRR) on pre- and post-CRT PET/CT scans. The serum CEA (pre-CRT and post-CRT), absolute difference (ΔCEA), CEA reduction ratio (CRR), and post-operative CEA (post-op CEA) were also determined. Multivariate analysis was performed using above parameters to determine any prognosticator for survival.

#### Results

Median follow-up period was 59 months. 5-year locoregional failure-free survival (LRFS), disease-free survival (DFS), and overall survival (OS) was 80.9 %, 66.0 %, and 86.8 %, respectively. Median pre-CRT SUV<sub>max</sub>, post-CRT SUV<sub>max</sub>, ΔSUV<sub>max</sub>, and SRR were 13.5, 4.9, 11.5, and 0.85, respectively. Median pre-CRT CEA, post-CRT CEA, ΔCEA, CRR, and post-op CEA were 4.42 ng/ml, 2.62 ng/ml, 1.38 ng/ml, 0.34, and 1.55 ng/ml, respectively. On

multivariate analysis, post-CRT  $SUV_{max}$  ( $\leq 6.5$  vs.  $>6.5$ ) was a significant factor for LRFS and DFS. Post-op CEA ( $\leq 2.0$  vs.  $>2.0$ ) was a significant factor for LRFS and OS.

#### Conclusion

This study showed the post-CRT  $SUV_{max}$  was a significant parameter for predicting tumor recurrence. Meanwhile, post-op CEA was the only prognostic factor affecting OS among these parameters.

#### EP-1265 Image-guided SIB-IMRT for the treatment of anal cancer patients

<sup>4</sup>A.O.U. Citta' della Salute e della Scienza, Department of Oncology- Radiation Oncology, Torino, Italy

<sup>5</sup>University of Turin- A.O.U. Citta' della Salute e della Scienza, Department of Medical Sciences- Pathology, Torino, Italy

<sup>6</sup>A.O.U. Citta' della Salute e della Scienza, Department of Oncology- Centre for Gastrointestinal Cancers- Medical Oncology 1 Unit, Torino, Italy

#### Purpose or Objective

Concurrent chemoradiation (CT-RT) has been established as the standard of care for anal cancer patients. We explored intensity-modulated and image-guided radiotherapy (IMRT-IGRT) with a simultaneous integrated boost (SIB) approach reporting on clinical outcomes within a mono-institutional observational study.

#### Material and Methods

Between April 2007 and April 2015, 87 patients with biopsy proven squamous cell anal cancer were treated with SIB-IMRT. Radiotherapy was delivery using a schedule of 50.4/54 Gy to the primary tumor and involved lymphnodes and 42/45 Gy to the elective volumes. Dose prescription varied according to clinical stage, following Radiation Therapy Oncology Group (RTOG) 0529 indications. Concurrent 5-Fluorouracil and Mitomycin-C were given. Clinical data and toxicity are herein reported.

#### Results

A total of 87 patients (stage I 6%; II 56%; III 38%) were treated and observed for median time of 34 months (range: 9-102). CT-RT with MMC and 5-FU was administered in 90.8% of patients. One patient received MMC only, two patients 5-FU only and five patients underwent exclusive RT, after consideration of age, comorbidities and performance status. The 3-year rates of colostomy-free survival, local control, disease free and overall survival were 71% (95% CI 0.59-0.80), 69% (95% CI 0.57-0.79), 64% (95% CI 0.52-0.75), and 79% (95% CI 0.66-0.87) respectively (Figure 1). At the time of analysis 20/87 (23%) patients were dead and 14 death were related to cancer. Up to 23 patients recurred; ten failed locally, 7 failed both locally and distantly and 6 developed systemic failure only. Seventy-seven patients reached a clinical complete response six months after treatment (88.5%). Major acute toxicity events ( $>G3$ ) were recorded for gastrointestinal (6.9%), genitourinary (1.2%) and hematologic (neutropenia: 19.6%) aspects. Borderline significance as prognostic factors with respect to CFS were found for gender and stage (Table 1).

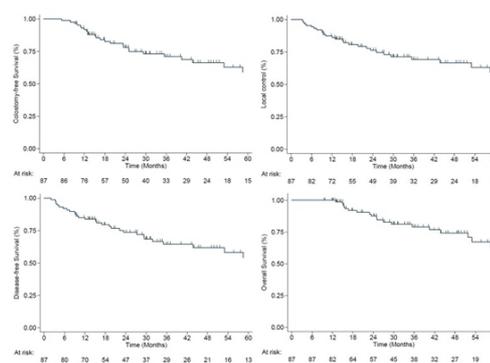

Fig. 1 Colostomy-free survival, local control, disease-free survival and overall survival

	Crude effect			Adjusted effect

<sup>7</sup>Fondazione Policlinico A. Gemelli, TSRM - Gemelli ART - Radiation Oncology, Rome, Italy

#### Purpose or Objective

The MRIdian MRI-<sup>60</sup>Co radiotherapy system (ViewRay, Oakwood, Ohio) combines an open split-solenoid MRI scanner equipped for parallel imaging and three <sup>60</sup>Co gamma-ray sources.

The dose delivered to the subcutaneous tissues of skin by such system should be evaluated: the lower mean beam

energy of the Cobalt source compared to those of clinical X-ray beam lead to increase of the surface dose.

A previous study (SIMBAD 01) investigated the feasibility of comparative planning among different radiotherapy technologies (i.e. IMRT vs VMAT vs MRI-<sup>60</sup>Co) optimizing for target coverage and organs at risk sparing. Hardware and software implementation on MRIdian will be completed at our institution within February 2017. Experimental measurements are planned when the system will become clinically operative. Aim of the present analysis is to quantify the dose delivered to subcutaneous tissues in the SIMBAD 01 planning conditions (without specific optimization for subcutaneous tissues).

#### Material and Methods

Ten patients affected by locally advanced rectal cancer (LARC) were included in this study. For each patient a VMAT RapidArc, a 5-beams sliding window IMRT and one MRIdian treatment plan were performed.

All treatment plans were calculated according to the Quality Assurance protocols adopted in our Institution: the PTV1 was represented by tumor and corresponding mesorectum; the PTV2 by mesorectum in toto and pelvic nodes. Isotropic 0.7 cm margins were added to PTVs. The total prescribed dose for PTV1 was 55 Gy and 45 Gy for PTV2 through Simultaneous Integrated Boost.

All plans were optimized for PTV coverage and sparing of bowel bag and bladder. PTV coverage was evaluated by calculating the V95 and V105 values. For bowel bag V45 and for bladder the mean dose was considered.

The presence of magnetic field has been taken into account during MRIdian MRI-<sup>60</sup>Co planning procedures.

The evaluation of subcutaneous skin dose was obtained calculating the median dose in a 5 mm wide ring dummy structure contoured 3 to 8 mm far from body surface.

The first 3 mm from body surface were not taken into account to avoid inconsistencies related to uncertainties in dose calculation at air-body interface due to different dose calculation algorithms (AAA Collapse Cone for VMAT and IMRT treatments, MonteCarlo for MRIdian TPS).

#### Results

All plans optimized for this study satisfied the constraints on PTV coverage and organs at risk sparing. Dosimetric values obtained in this planning comparison are listed in table 1.

The median skin dose resulted higher using the MRIdian system (1.97 Gy against 1 Gy for IMRT and 0.98 Gy for VMAT)

#### Conclusion

A subcutaneous skin dose increase is observed with the employment of MRI-<sup>60</sup>Co RT when compared to LINAC treatment planning, even if still in clinically acceptable constraints. Considering and contouring such a structure seems useful. Specific study will be performed to define how reducing dose to subcutaneous tissues by optimizing for such structures.

#### EP-1267 In silico Evaluation of the impact of Magnetic Field on dose distribution using of MRIdian MRI- 60Co

<sup>5</sup>Fondazione Policlinico A. Gemelli, KBO Labs - Gemelli ART - Radiation Oncology, Rome, Italy

<sup>6</sup>Fondazione Policlinico A. Gemelli, TSRM - Gemelli ART - Radiation Oncology, Rome, Italy

#### Purpose or Objective

The MRIdian MRI <sup>60</sup>Co radiotherapy system (ViewRay, Oakwood, Ohio) combines an open split-solenoid MRI scanner equipped for parallel imaging and three <sup>60</sup>Co gamma-ray sources.

The quantification of dose distribution perturbations due to the presence of 0.35 T magnetic field represents an issue.

The MRIdian TPS is equipped by two MonteCarlo based algorithms to calculate the dose distribution: the first one has faster calculation time; and does not account for the presence of magnetic field (B<sub>off</sub>). The second one has slower calculation time; and takes into account for the presence of magnetic field (B<sub>on</sub>). Hardware and software implementation on MRIdian will be completed at our institution within February 2017. Experimental measurements are planned when the system will become clinically operative.

Aim of this study was to compare the two algorithms in order to evaluate which could be more accurate in an *in silico* treatment planning study designed for locally advanced rectal cancer (LARC).

This study includes 7 cases of patients affected by LARC. For each patient of the study two plans were developed. Same priority values for the optimization were applied.

The calculation of dose distribution was performed using the two different algorithms object of this study (B<sub>off</sub> and B<sub>on</sub>).

Plans were performed in IMRT modality, adopting same beams geometry consisting in one pseudo-arc composed by three beam triplets.

The treatment plans were optimized according to usual Quality Assurance protocols adopted in our Institution for Linac IMRT treatments: the PTV1 was represented by tumor and corresponding mesorectum; the PTV2 by mesorectum in toto and pelvic nodes. Isotropic 0.7 cm margins were added to PTVs. The total prescribed dose for PTV1 was 55 Gy and 45 Gy for PTV2 through Simultaneous Integrated Boost.

All plans were optimized for PTV coverage and sparing of bowel bag and bladder. For PTVs coverage V95 and V105 were considered. For bowel bag V45 and for bladder the mean dose were considered, respectively. Plans were normalized at target median.

Table 1 summarizes the median values for PTV coverage and organs at risk sparing obtained in the two cases. No significant differences have been reported between the two algorithms.

Table 1

Parameter	B	No B
V95 (PTV1)	98.91	99.20
V105 (PTV1)	0.14	0.01
V95 (PTV2)	98.00	98.20
V100 (PTV2)	59.97	62.00
V105 (PTV2)	14.72	14.80
Mean dose bladder (Gy)	36.30	35.40
V45 Bowel	70.11	59.40
Median dose Skin	1.95	2.05

### Conclusion

The system appears to be able to compensate the dosimogeneities due to the presence of magnetic field through the use of optimizer.

### EP-1268 Tumor response according to NK cell change during preoperative chemoradiotherapy in rectal cancer

J. Heo<sup>1</sup>, Y.T. Oh<sup>1</sup>, O.K. Noh<sup>1</sup>, M. Chun<sup>1</sup>, J.E. Park<sup>2</sup>, S.R. Cho<sup>3</sup>

<sup>1</sup>Ajou University School of Medicine, Radiation Oncology, Suwon, Korea Republic of

<sup>2</sup>Ajou University School of Medicine, Pediatrics, Suwon, Korea Republic of

<sup>3</sup>Ajou University School of Medicine, Laboratory Medicine, Suwon, Korea Republic of

### Purpose or Objective

The objective of this prospective study was to evaluate the relationship between the circulating lymphocyte subpopulation counts during preoperative chemoradiotherapy (CRT) and tumor response in locally advanced rectal cancer.

### Material and Methods

In this prospective study, from August 2015 to June 2016, 10 patients treated with preoperative CRT followed by surgery were enrolled. Patients received conventional fractionated radiotherapy (50.4 Gy) with fluorouracil-based chemotherapy. Surgical resection was performed at 4 to 8 weeks after the completion of preoperative CRT. The absolute blood lymphocyte subpopulation was obtained prior to and after 4 weeks of CRT. We analyzed the association between a tumor response and change in the lymphocyte subpopulation during CRT.

### Results

Among 10 patients, 2 (20%) had evidence of pathologic complete response. In 8 patients with clinically node positive, 4 (50%) had nodal tumor response. All lymphocyte subpopulation counts at 4 weeks after CRT were significantly lower than those observed during pretreatment ( $p < 0.01$ ). A high decrease in NK cell count during CRT (baseline cell count - cell count at 4 weeks) was associated with node down staging ( $p = 0.034$ ).

### Conclusion

Our results suggest that the change of lymphocyte subset to preoperative CRT may be a predictive factor for tumor response in rectal cancer.

### EP-1269 Comparison of 2 and 3 arc VMAT versus fixed field IMRT and proton beam therapy in anal cancer

C. Kronborg<sup>1</sup>, E.E. Wilken<sup>2</sup>, J. Hansen<sup>1</sup>, L. Nyvang<sup>1</sup>, J.B. Petersen<sup>1</sup>, E. Serup-Hansen<sup>2</sup>, K.L.G. Spindler<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Oncology, Aarhus C, Denmark

<sup>2</sup>Herlev and Gentofte Hospital, Oncology, Herlev, Denmark

### Purpose or Objective

Chemoradiotherapy is the standard treatment for squamous cell carcinoma of the anus (SCCA) and is the source of both acute and late toxicity. Advanced radiotherapy treatment techniques aim at reducing dose to organs at risk (OAR) while maintaining target coverage and dose homogeneity. Further, VMAT techniques shorten delivery time considerably. We compared dosimetric advantages of fixed field IMRT, 2 and 3 arc VMAT and additional 3- and 4-field pencil beam scanning proton therapy.

### Material and Methods

Twenty patients with SCCA treated at two different centres were included. Standard treatment was 64-51,2 Gy/32 F or 60-49,5/30 Gy/F delivered with 2 or 3 arc VMAT technique and concurrent chemotherapy according to

local practice. Alternative treatment plans were generated for all patients using 5- or 6- fixed field IMRT and 3 arc VMAT (All Varian Eclipse planning system). Four patients with doses above normal constraints (ex high V40 Gy to the bowel) were selected for additional proton therapy planning; both 3- and 4- field plans were generated (Eclipse ver. 10 Multi Field Optimization (IMPT)). Bowel was delineated as potential bowel cavity and bladder as total circumference.

### Results

Target volume coverage and homogeneity were comparable between the different planning techniques. We compared multiple dose volume parameters to OAR including V40 Gy and V50 Gy to the bowel cavity, V45 Gy to the bladder, mean dose to femoral heads using IMRT, 2 arc VMAT and 3 arc VMAT techniques and found no significant differences in any parameter. Both 3- and 4- field proton treatment plans demonstrated significant sparing on V40 Gy to the bowel cavity: median volume using 2 Arc VMAT was 667 cc, 3- and 4-field proton therapy 522 cc and 535 cc respectively. V45 Gy to the bladder was also considerably lower using protons: 2 arc VMAT 49,3% vs. 23,4% and 28,5% using 3- and 4-field proton therapy. Mean dose to femoral heads was significantly lower with proton therapy while V40 Gy and V30 Gy to the sacral bone were comparable.

### Conclusion

We found dosimetric equality on the selected parameters for OAR when comparing 2 arc VMAT with fixed field IMRT and 3 arc VMAT, and no differences between 2 and 3 arc VMAT either. VMAT reduces overall treatment time and is a feasible option for standard treatment planning in SCCA. In four patients with high V40 Gy to the bowel proton treatment plans proved superior in V40 Gy to the bowel, V45 Gy to the bladder, and mean dose to femoral heads with the potential to reduce subsequent toxicity. Data on acute toxicity will be presented at the meeting.

### EP-1270 Clinical outcome of non-metastatic rectal cancer patients with extremely high CEA level

S.H. YOUN<sup>1</sup>, D.Y. KIM<sup>1</sup>, T.H. KIM<sup>1</sup>, S.Y. KIM<sup>2</sup>, J.H. BAEK<sup>2</sup>, Y.J. CHA<sup>2</sup>, H.J. CHANG<sup>2</sup>, M.J. KIM<sup>2</sup>, S.C. PARK<sup>2</sup>, J.H. OH<sup>2</sup>

<sup>1</sup>National Cancer Center, Proton Therapy Center,

Goyang-si-, Korea Republic of

<sup>2</sup>National Cancer Center, Center for Colorectal Cancer,

Goyang-si-, Korea Republic of

### Purpose or Objective

To investigate clinical outcome of non-metastatic rectal cancer patients with extremely high pretreatment serum CEA level after radical surgery following preoperative chemoradiotherapy

### Material and Methods

A total of 959 patients with clinical stage II-III rectal cancer who underwent preoperative chemoradiotherapy followed by radical surgery between October 2001 and July 2011 were retrospectively analyzed. There were 332 patients with elevated pretreatment serum CEA level ( $> 5\text{ng/ml}$ ) and among them, we defined 23 patients with CEA level of  $> 50\text{ ng/ml}$  as an extremely high pretreatment CEA group. Overall survival rate, relapse-free survival rate, locoregional recurrence-free survival rate and distant metastasis-free survival rate were compared between pretreatment CEA levels of 5-50 ng/ml and  $> 50\text{ ng/ml}$ .

### Results

Median follow-up duration was 69 months (range, 3-165). The five-year survival rate were 80.5% and 73.4%, and the 10-year survival rate were 64.5% and 73.4% in patients with pretreatment serum CEA level of 5-50 ng/ml and  $> 50\text{ ng/ml}$ , respectively ( $p = 0.672$ ). The extremely high CEA group ( $> 50\text{ ng/ml}$ ) had significantly lower relapse-free survival rate (RFS) at 5-year and 10-year than patients with CEA level of 5-50 ng/ml (5-year RFS 70.6% versus.

52.2%, and 10-year RFS 62.1% versus. 52.2%,  $p = 0.048$ , respectively). Also, patients with extremely high CEA ( $> 50\text{ng/ml}$ ) had trend to lower distant metastasis-free survival rate (DMFS) (5-year DMFS 72.0% versus. 55.9%, and 10-year DMFS 67.4% versus. 55.9%,  $p = 0.087$ , respectively), and there were no differences in locoregional recurrence-free survival rate (LRRFS) (5-year LRRFS 89.3% versus. 81.8%, 10-year LRRFS 82.8% versus. 81.8%,  $p = 0.355$ ).

#### Conclusion

This study showed that non-metastatic rectal cancer patients with extremely high pretreatment serum CEA level ( $> 50\text{ ng/ml}$ ) had higher risk of relapse with trend of increasing distant metastasis.

#### EP-1271 Is 3D-CRT still a valid option in radical radiochemotherapy of anal carcinoma in the era of IMRT?

S. Shakir<sup>1</sup>, A. Garant<sup>2</sup>, S. Alshehri<sup>2</sup>, D. Slobodan<sup>3</sup>, T. Alcindor<sup>4</sup>, T. Vuong<sup>1</sup>

<sup>1</sup>Jewish General Hospital, Radiation Oncology, Montreal, Canada

<sup>2</sup>McGill University Health Center, Radiation Oncology, Montreal, Canada

<sup>3</sup>Jewish General Hospital, Medical physics, Montreal, Canada

<sup>4</sup>McGill University Health Center, Medical oncology, Montreal, Canada

#### Purpose or Objective

Intensity Modulated Radiation Therapy (IMRT) is well accepted in our institution as standard radiation technique for patients with anal canal cancer. We are reporting treatment related toxicity profiles recorded during treatment with 3D conformal radiation (3D-CRT) versus IMRT with radical concomitant radiochemotherapy at McGill University Health Center.

#### Material and Methods

This is a retrospective study of all patients' charts diagnosed with squamous cell carcinoma of anal cancer from January 2002 to May 2009. The standard treatment was radical radiation with 2 cycles of chemotherapy using 5-Fluorouracil ( $1000\text{mg/m}^2$  daily for 4 days in a 24 hours continuous perfusion) and Mitomycin-C (at  $10\text{ mg/m}^2$ ). Radiation doses were 50.4 Gy, 54 Gy and 60 Gy in 28, 30, 33 fractions to macroscopic disease for T1, T2/T3, and T4 tumors respectively and 30 Gy in 15 fractions to microscopic nodal disease at risks. Demographic data, treatment modality, different acute toxicities and tolerance as well as outcomes were compared between patients treated with 3D-CRT using conformal diamond diagonal opposing fields [1], and those treated with IMRT.

#### Results

From January 2002 to May 2009, 90 patients (3D-CRT: 40, IMRT: 50) treated with radical intent were included in this study. The median age for the entire cohort was 57 years. Male to female ratio was 0.61. Fifty-four percent ( $n=41$ ) of patients had greater than stage II disease (table 1-A). Acute toxicities were collected prospectively with weekly blood tests, intra treatment weekly evaluation for bowel frequency, skin-reaction and hospital admission for treatment related toxicity. Toxicity grading was based on the national cancer Institute common toxicity criteria version 2.0. The rates of  $\geq$  grade 2 skin, hematological and gastrointestinal toxicities for 3D-CRT group were 65%, 45% and 25% respectively; whereas for IMRT group; 58%, 48% and 20% respectively with corresponding p values of 0.522, 0.834 and 0.617 respectively. Treatment interruption rate was significantly higher (p value: 0.018) with 5% vs 24% rate among patients treated by 3D-CRT vs IMRT, despite a non-significant difference for higher grade 3 hematological rate of 20% versus 28% for 3D-CRT and IMRT groups, respectively, ( $p = 0.46$ ), (table 1-B).

#### Conclusion

Acute toxicity profiles did not differ significantly between the two radiotherapy techniques, but treatment interruption was significantly higher in IMRT group with a trend of higher grade 3 hematotoxicity. Thus, 3D-CRT diamond fields remain a valid option for patients with anal canal cancer. Since May 2009, IMRT has become our standard treatment and we are now looking at its impact on local control in our patient population.

<sup>2</sup>University of Bologna, Radiation Oncology Unit- Department of Experimental- Diagnostic and Specialty Medicine - DIMES- Sant'Orsola-Malpighi Hospital, Bologna, Italy

<sup>3</sup>University of Bologna, Department of Medical and Surgical Sciences - DIMEC, Bologna, Italy

<sup>4</sup>Fondazione di Ricerca e Cura Giovanni Paolo II- Università Cattolica del Sacro Cuore, Radiotherapy Unit, Campobasso, Italy

#### Purpose or Objective

Multimodal therapeutic approach with pre-operative chemoradiation (CRT), conservative surgery +/- adjuvant chemotherapy (CT) is currently the standard treatment in patients with locally advanced rectal ca. The possibility to predict tumor response before chemoradiation could be useful to tailor neoadjuvant treatment. Therefore, aim of this analysis was to correlate the expression of Ki67 with pathological complete response (pCR) rate after CRT in an homogeneous population of patients with cT3N0M0 rectal carcinoma.

#### Material and Methods

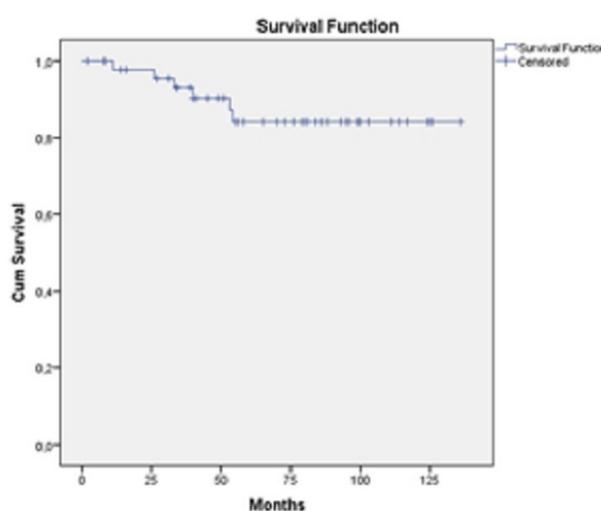

We retrospectively analysed the pre-treatment biopsies of a subgroup of patients (pts) with cT3N0M0 rectal ca. The expression of Ki-67 was evaluated. Radiotherapy was delivered with 3-D conformal technique (total dose: 50.4 Gy, 1.8 Gy/fraction) concurrently with CT (Capecitabine: 31%, 5-Fluorouracil: 17%, 5-Fluorouracil plus Oxaliplatin: 52%). All pts underwent surgery 6-8 weeks after CRT. Adjuvant CT was performed in 37 (76%) pts. DFS and OS were estimated by Kaplan-Meier method. Using as cut-off value the median value of ki-67 expression (91.3%, range

54.1%-99.9%), we stratified pts into two subgroups to test a possible correlation with pCR.

#### Results

Forty-eight pts were treated from March 2002 to October 2011 [M/F: 32/16; median age: 70.5, range: 43-84]. The median follow-up was 61.5 months (range: 2-136). Ten pts achieved a pCR (20.8%). No significant differences were observed based on Ki67 value (lower Ki67: 62.5% pCR; higher Ki67: 37.5% pCR); Fisher's Exact test:  $p=0.345$ ). One-year, 3-year, and 5-year cumulative DFS were 97.9%, 86.0%, and 79.8%, respectively. One-year, 3-year, and 5-year cumulative OS were 97.8%, 93.5%, and 84.1%, respectively (fig.1).

Fig.1: Kaplan-Meier overall survival

#### Conclusion

In this retrospective analysis no significant correlation was observed between Ki67 expression and pCR rate after preoperative chemoradiation. The small sample size and heterogeneity in neoadjuvant and adjuvant treatment could explain this result.

#### EP-1273 Stereotactic body radiation therapy (SBRT) for pelvic re-irradiation

Y. Augustin<sup>1</sup>, C. Chaw<sup>1</sup>, N. Van As<sup>1</sup>, K. Aitken<sup>1</sup>  
<sup>1</sup>Royal Marsden Hospital Trust & Institute of Cancer Research, Radiotherapy, London, United Kingdom

#### Purpose or Objective

Re-irradiation of recurrent pelvic disease remains a challenging clinical problem. SBRT is an attractive modality for re-irradiation which is being increasingly utilised in carefully selected patients. However there remains uncertainty around clinical toxicity, efficacy and maximum safe cumulative doses to pelvic organs at risk (OARs).

The primary aim of this retrospective study was to evaluate treatment related toxicity in patients receiving SBRT with the Cyberknife platform for pelvic re-irradiation at our institution. Secondary objectives were to evaluate efficacy by analysis of local control (LC), distant progression free survival (DPFS) and overall survival (OS) parameters.

#### Material and Methods

Patients receiving re-irradiation with SBRT to pelvic targets within a previously irradiated external beam

radiotherapy (EBRT) field were retrospectively identified. Patients treated with prior pelvic brachytherapy were excluded. Details on primary site, previous EBRT and re-irradiation dose, toxicity, local control and survival were obtained on review of the hospital records. Acute ( $\leq 3$  months) and late toxicity data were retrospectively collected and assessed using CTCAE v4.0. Local and distant progression free survival were calculated from the date of SBRT to the date of radiological progression using standard RECIST criteria (v1.1).

#### Results

22 patients (9 prostate and 13 rectal cancer) received pelvic re-irradiation with SBRT between 25.07.2011 and 20.04.2016. Median age was 66 years (range 30-85 years). Median follow up was 18.5 months (range 3-58 months). The median time between primary EBRT and SBRT re-irradiation was 26 months (range 4-162 months). Median SBRT dose was 30Gy/3# (range 24Gy-44Gy/3-5#). Prior EBRT dose ranged from 20Gy/4#-70Gy/35# (median BED 63.72, range 30-84 assuming  $\alpha/\beta = 10$ ).

55% patients reported no measurable toxicity. No patients experienced  $\geq$ Grade 3 toxicity. 10/22 (45%) patients experienced acute Grade 1/Grade 2 toxicities including fatigue, sciatica, nausea, diarrhoea, rectal haemorrhage and urinary symptoms. Only 1 patient experienced late toxicity (asymptomatic pelvic insufficiency at 21 months post SBRT, not requiring intervention).

The 1 and 2 year LC rate were 90%, 85% and DPFS rate 92%, 71% respectively. OS at 1 and 2 years were 91% and 71% respectively.

#### Conclusion

Pelvic re-irradiation with SBRT is well tolerated and effective at controlling local disease. No  $\geq$ Grade 3 toxicity has been observed to date in our patient cohort although longer term follow up is needed. Further research to establish safe maximum cumulative doses to OARs for pelvic re-irradiation is warranted.

#### EP-1274 Impact of concomitant radiotherapy boost in locally advanced rectal cancer: dose escalation

M.A. Estornell<sup>1</sup>, D. Martinez<sup>2</sup>, V. Morillo<sup>3</sup>, M. López<sup>1</sup>, M. Soler<sup>1</sup>, J.L. Monroy<sup>1</sup>, A.V. Navarro<sup>1</sup>, A. Soler-Rodriguez<sup>1</sup>  
<sup>1</sup>Hospital Universitario de la Ribera, Radiation Oncology Department., Alzira, Spain  
<sup>2</sup>University Hospital.Valladolid, Department of Medical Physics and Radiation Protection., Valladolid, Spain  
<sup>3</sup>Provincial Hospital. Castellon., Radiation Oncology Department, Castellon., Spain

#### Purpose or Objective

The standard preoperative radiation dose for locally advanced rectal cancer (LARC) is 45-50.4 Gy in 25-28 fractions. The aim of this study is to analyze the correlation between escalation radiotherapy dose, pathological complete clinical response (pCR) and downstaging rate or even its relation with other parameters of interest as toxicity, surgical margins, locoregional recurrence-free survival (LRFSD), distant metastasis free survival (DMFS) and overall survival (OS). The efficacy of the dose escalation in terms of pathological tumor response was evaluated as main end-point.

#### Material and Methods

Between 2000 and 2013, 287 patients were treated with preoperative chemoradiotherapy and surgical resection for LARC in our hospital. 233 patients underwent the standard chemoradiation schedule (median age 67 years; stage III 73.3%, stage IV 1.7%; 41.1% low third rectum; 45-50.4 Gy; 1.8-2 Gy/fraction) and 54 patients were treated with simultaneous integrated boost-SIB (median age 66 years; stage III 74.5%, stage IV 1.8%; 21.8% low third rectum; 45 Gy to the pelvis volume with a 2.17 Gy SIB on the tumor and macroscopical nodes).

## Results

Dose escalation radiotherapy treatment reports a benefit in pCR (9.5 % vs 20 % p= 0.029), tumoral downstaging rate (42.7 % vs 60% p=0.020), nodal downstaging rate (62.9% vs 7.7% p= 0.173) and ypT0 rate (10.3% vs 20 p= 0.049). Complete microscopical resection increases on integrated boost group (93.4% vs 98% statistically non-significant). In the comparison between both groups by Contingency Table, no statistically significant differences were found on toxicity (G2 27.5% vs 37%; G3 3.1 % vs 9%) or surgical complications (35.7% vs 40%). With a follow up of 181 months, the study reports a statistically significance on disease free survival (56.1% vs 76.7 % p= 0.036 Kaplan-Meier Test), and overall survival (21% vs 46.65 p=0.02) in the SIB group. Locoregional recurrence-free survival also improves but without statistical significance (88% vs 94.9 % Kaplan-Meier method). Tumoral downstaging was considered as an independent factor on DFS (HR 1.914 p=0.004 Cox model.)

## Conclusion

Escalation dose radiotherapy group achieved statistical differences in pCR (ypT0 yN0), tumoral downstaging rate, overall survival (OS) and distant disease free survival (DFS). pCR could be considered as a prognostic factor on OS. The variable tumoral downstaging demonstrate a great value as an independent factor on DFS.

## EP-1275 Patients with locally advanced rectal cancer (larc): predictive factors of pathological response

S. Montrone<sup>1</sup>, A. Sainato<sup>1</sup>, R. Morganti<sup>2</sup>, C. Vivaldi<sup>3</sup>, B. Manfredi<sup>1</sup>, C. Lalischia<sup>1</sup>, M. Cantarella<sup>1</sup>, G. <sup>1</sup>OSPEDALE SANTA CHIARA, Radiotherapy, PISA, Italy

<sup>2</sup>OSPEDALE SANTA CHIARA, Oncology- Biostatistical Consulting, PISA, Italy

<sup>3</sup>OSPEDALE SANTA CHIARA, Oncology, PISA, Italy

<sup>4</sup>OSPEDALE CISANELLO, Colon-rectal Surgery, PISA, Italy

## Purpose or Objective

Preoperative RTCT followed by total mesorectal excision (TME) is the standard of cure in patients (pts) with LARC. After neoadjuvant RTCT the rate of complete pathologic response (pCR) range between 15%-30% and many studies are trying to find predictive factors of response in order to select pts who could benefit from organ-preserving options (local excision or "wait and see approach"). This study aim to identify predictive factors of T and N response of neoadjuvant RTCT.

## Material and Methods

We analyzed retrospectively the data of 119 pts affected by LARC (all of them cT3-T4 and 90,7% cN+) treated by neoadjuvant RTCT (50.4 Gy in 28 FF + capecitabine 1650 mg/mq/day) followed by TME surgery, between January 2008 and April 2014, in Pisa University Hospital. Based on MR-images, we analyzed T characteristics (clinical stage, site respect to anal verge, cranio-caudal extension, number of involved quadrants, volume, distance from mesorectal fascia) and N characteristics (clinical stage, number of nodes with short axis  $\geq$  5mm and distance from mesorectal fascia), at diagnosis and at restaging (before surgery) and their variations, in order to find a correlation with pathological T and N stage.

## Results

All pts completed planned RTCT. The overall pCR rate was 25,2%. In the multivariate analysis (T parameters) only the number of involved quadrants (p=0,002) and the cranio-caudal extension at diagnosis (p=0,043) resulted to be predictive of pCR. At the pathological findings, the rate of pN+ was 21% compared to 90,7% of the clinical stage. In the multivariate analysis (N parameters) only the number of nodes (short axis  $\geq$  5mm) at diagnosis was shown to be predictive of pN0, both as a continuous variable (p=0,004)

that as dichotomous variable (p<0,0001) with a threshold value of 3 nodes. T and N variations, at pre-surgical restaging, were not significantly correlated to pathological outcomes.

## Conclusion

To know predictive factors of pCR and pN0 after neoadjuvant RTCT could influence the surgical approach. T size and T distance from the anal verge seem to be two well established predictive factors of response. Based on our retrospective analysis, we can add that the number of involved quadrants and the number of nodes ( $\geq$ 5mm) at diagnosis could be additional predictive parameters.

## EP-1276 Clinic and radiobiology of hypofractionated radiotherapy for metastatic liver tumors. Pilot results.

T. Latusek<sup>1</sup>, L. Miszczyk<sup>1</sup>, J. Rembak-Szynkiewicz<sup>2</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy, Gliwice, Poland

<sup>2</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiology, Gliwice, Poland

## Purpose or Objective

Liver metastases are the most common tumor in this organ and majority of them are metastases of adenocarcinomas of the gastrointestinal tract. Radiotherapy is often used as alternative method to surgery. Due to promising results of the extracranial stereotactic radiotherapy used to treat primary metastatic tumors of the lung it is applied also for primary or metastatic liver lesions. The aim was to evaluate the efficacy of hypofractionated radiotherapy for metastatic liver tumors.

## Material and Methods

Clinical material consists of 28 liver malignant liver lesions treated with stereotactic hypofractionated radiotherapy at the Cancer Center, MSC Memorial Institute in Gliwice. Tumor size and volume reflecting initial number of cancer cells were estimated Patient's age was in the range of 33-84 years (median 64). All liver metastases were irradiated with a total dose of 45 Gy given in 3 fractions in 8 days. Method of respiratory gating and CyberKnife were used. Follow-up ranges from 1 to 12 months.

## Results

Early 3-months results show 64% regression (14 cases), 4% stagnation (1 case) and 32% progression (7- cases). However, total dose of 45 Gy does not result in early complete regression. Even in case of „twin tumores” with the same initial volume (the same initial number of cancer cells) surprisingly showed different response: regression vs progression what is difficult to interpret from the radiobiological point of view.

## Conclusion

Total dose of 45 Gy should result in complete regression, but it doesn't. From theoretical calculation it seem that D10 dose may arise even to 21 Gy what seems not very logical. It can not be excluded that reason for such early answer could be „Halo Phenomenon”- inflammation around irradiated area suggesting false stagnation or even regression.

## EP-1277 Optimising RT dose for anal cancer - the development of three clinical trials in one platform

<sup>13</sup>University of Manchester, Department of Surgery, Manchester, United Kingdom

<sup>14</sup>University of Oxford, CRUK MRC Oxford Institute for Radiation Oncology, London, United Kingdom

### Purpose or Objective

Previous phase III trials of squamous cell cancer of the anus have determined radiotherapy with concurrent Mitomycin C and 5FU as the standard of care. This did not change with RTOG 9811 and ACT2. Following the development of IMRT guidance we decided to explore radiotherapy questions in future trials across the loco-regional disease spectrum.

### Material and Methods

We formed a network of UK and international multi-disciplinary trialists and identified the following research questions: - i] can a highly selective policy of involved field CRT result in low locoregional failure (LRF) in small anal margin tumours treated by local excision? ii] can reduced dose CRT using IMRT achieve an acceptably low rate of LRF in early stage anal cancer? iii] can radiotherapy dose escalation reduce the LRF rate with acceptable toxicity in locally advanced disease?

### Results

The PLATO (Personalising Radiotherapy Dose in anal cancer) is a platform trial comprising of the ACT3, 4 and 5 trials and funded by Cancer Research UK. It is due to commence recruitment in Q4 2016. The ACT 3 trial (n=90) is a non randomised phase II study that will evaluate a strategy of local excision for T1N0 anal margin tumours with selective post operative involved field CRT using 41.4Gy in 23 fractions (F) and concurrent capecitabine, reserved for patients with margins <=1mm. An exact single-stage A'Hern design is used. The ACT4 trial (n=162) is a randomised phase II trial (2:1) comparing reduced dose CRT with 41.4Gy in 23F to GTV with 50.4Gy in 28F using concurrent capecitabine for T1-2(<4cm)N0 disease with IMRT and elective nodal irradiation. An exact single-stage A'Hern design is used. The ACT5 trial (n=640) is a seamless pilot (n=60)/phase II (n=140)/phase III trial (n=640 total) that will compare 53.2Gy with 58.8Gy and 61.6Gy using 28 fractions to GTV with either 5FU or capecitabine in T3/4 N1-3 disease. Toxicity and response will be reported for both the pilot and phase II components. Only one of the dose escalated experimental arms will be evaluated for the phase III component. The primary end point for each trial is 3 year LRF.

### Conclusion

The PLATO trial concept is efficient with a single funding application and protocol but supports three separate clinical trials. There are clinical leads for each trial. For the patient there is a single patient information sheet for the specific trial relevant to their disease stage. This approach is increasingly important in the era of personalised medicine. Sharing the details of this concept should assist other investigators to develop similar future studies in other disease sites. It is also a template that

may assist similar parallel trials to be designed in other countries.

### EP-1278 FMISO-PET & perfusion CT at baseline and; week 2 CRT as predictive markers for response in rectal ca

T. Greenhalgh<sup>1</sup>, J. Wilson<sup>2</sup>, T. Puri<sup>1</sup>, J. Franklin<sup>1</sup>, L. Wang<sup>3</sup>, R. Goldin<sup>4</sup>, K. Chu<sup>1</sup>, V. Strauss<sup>5</sup>, M. Partridge<sup>1</sup>, T. Maughan<sup>1</sup>

<sup>1</sup>University of Oxford, Department of Oncology, Oxford, United Kingdom

<sup>2</sup>The Royal Marsden NHS Foundation Trust, Institute of Cancer Research, London, United Kingdom

<sup>3</sup>Oxford University Hospitals NHS Foundation Trust, Department of Pathology, Oxford, United Kingdom

<sup>4</sup>Imperial College London, Centre for Pathology, London, United Kingdom

<sup>5</sup>University of Oxford, Centre for Statistics in Medicine-Oxford Clinical Trials and Research Unit, Oxford, United Kingdom

### Purpose or Objective

Patients with locally advanced rectal cancer are considered for neoadjuvant CRT. Around 15% have a complete response with a similar proportion having minimal response. This study explores the predictive value of FMISO-PET and perfusion CT (pCT).

### Material and Methods

Patients having neoadjuvant CRT for rectal cancer were recruited at a single centre from October 2013-April 2016. FMISO-PET and pCT were done at baseline and in week 2 CRT. Tumour was delineated on MRI by a radiologist, copied to CT using rigid registration and amended for air. FMISO SUVmax in tumour (T) and muscle (M), and perfusion parameters Blood Volume (BV) and Blood Flow (BF) were determined. Pathological tumour regression grade was scored by AJCC 7.0.

### Results

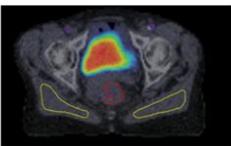

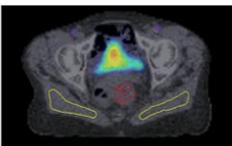

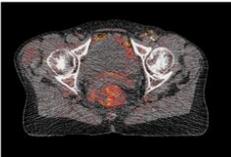

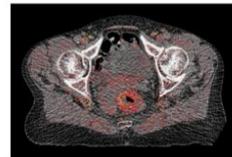

11 patients were recruited with median age 67 (interquartile range (IQR) 19). 9(82%) were male. Staging was T2 in 2 (18%) and T3 in 9 (92%). 4 (36%) were node negative, 6 (55%) N1 and 1 (9%) N2. All had M0 disease. 7 patients had total mesorectal excision. 7 patients were classed as good responders (AJCC 0/1 or good clinical response) and 4 as poor responders (AJCC 2/3 or poor clinical response).

FMISO scans were evaluable in 8/10 patients at baseline and in 8/9 at week 2 CRT (Table 1). Reasons for unevaluability were non-tumour uptake either in the colorectal lumen, which was maximal on the 4 hour scan due to colonic excretion of FMISO, or through spill in from adjacent bladder activity. Using a threshold of T:M SUVmax ratio of > 1.3, a hypoxic tumour volume was identified at baseline in 7/8 and in 5/8 at week 2 CRT. Baseline median T:M SUVmax was 3.1 (interquartile range (IQR) 1.3). In 5/7 patients with paired evaluable scans, the T:M ratio reduced (>=25% reduction in SUV max), however this showed no correlation with outcome in this small dataset.

All patients had evaluable pCT at baseline and week 2 CRT. Neither baseline median BV (3.2, IQR 2.1) nor BF (23.2, IQR 18) showed a relationship with response. There was also no clear trend for change at week 2 CRT in median BV (2.8, IQR 2.2) or BF (21, IQR 38.3)). An example FMISO-PET/CT and BV pCT map at baseline and week 2 CRT is shown in Figure 1.

Patient	Response	T:M SUVmax (Baseline)	T:M SUVmax (Week 2 CRT)	T:M % change from baseline to week 2 CRT
1	Good	1.4	2.2	157%
2	Good	Unevaluabe	Unevaluabe	Unevaluabe
3	Poor	2.4	1.6	67%
4	Poor	2.8	2.1	75%
5	Good	Unevaluabe	1.4	Unevaluabe
6	Poor	1.6	Non-applicable	Non-applicable
7	Good	2.3	1.6	71%
8	Good	2.2	1.3	59%
9	Poor	2.1	1.3	62%
10	Good	Non-applicable	Non-applicable	Non-applicable
11	Good	1.1	1.3	119%

Figure 1: FMISO-PET and pCT blood volume maps at baseline and week 2 chemoradiotherapy  
Poor responder showing reduction in FMISO uptake and BV

	Baseline	Week 2 CRT
FMISO-PET		
pCT BV		

### Conclusion

This pilot study revealed significant challenges in delivery and interpretation of FMISO PET scanning for rectal cancer. Preliminary data does not support the hypothesis that a reduction in FMISO uptake is predictive of response. In addition, no association was seen between pCT parameters and response; larger scale studies would be required to establish the value of this functional imaging modality.

### EP-1279 Tumor response after short course radiotherapy for rectal cancer: immediate versus delayed surgery

M. Cruz<sup>1</sup>, C. Sousa<sup>1</sup>, D. Branco<sup>1</sup>, T. Serra<sup>1</sup>, M. Areia<sup>1</sup>, J. Brandão<sup>1</sup>, G. Melo<sup>1</sup>

<sup>1</sup>Instituto Português de Oncologia de Coimbra, Radiation Oncology, Porto, Portugal

### Purpose or Objective

The aim of this study is to evaluate the influence of time interval between RT and surgery on tumor response after short course radiotherapy (RT) for rectal cancer.

### Material and Methods

This is a retrospective study including patients diagnosed with rectal adenocarcinoma who received neoadjuvant radiotherapy (25Gy/5fractions) between 2012 and 2016. Surgery was performed in our institution. A 4 week interval between RT and surgery was used to compare patients who underwent for immediate or delayed surgery. Tumor response patterns were evaluated according to Ryan's Histopathologic Classification. Groups were statistically correlated using Chi square and ANOVA tests.

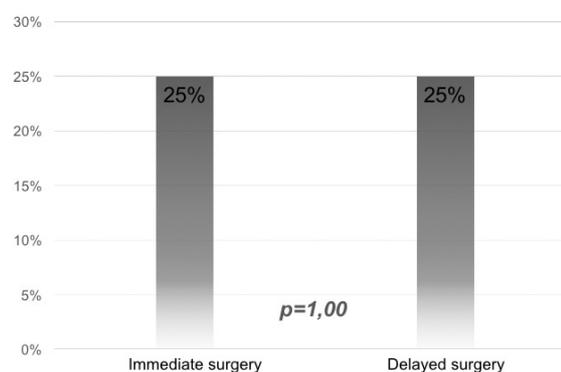

### Results

36 patients were included in this study (61,1% male) with a median age of 77,5 years old ( $\pm 4,9$ ). 75,6% had stage III

disease and median distance to anal verge was 6,0cm ( $\pm 3,4$ ).

The mean interval between RT and surgery was 61 days. 32,4% of the patients had immediate surgery while 67,6% has delayed surgery. Anterior rectal resection was performed in 20 patients and 16 patients had abdominal perineal resection. When analyzing both groups, no differences were found between immediate and delayed surgery regarding tumor downstaging (75% vs. 71%,  $p=1,00$ ) or tumor regression (25% vs. 25%,  $p=1,00$ ). Similar results were observed regarding the proportion of R0 resections (100% vs. 83%,  $p=0,28$ ). Additionally, the number of sphincter preserving surgeries was not statistically superior in the group that underwent for delayed surgery (42% vs 48%,  $p=0,72$ ).

### TUMOR REGRESSION RYAN'S CLASSIFICATION 0 AND 1

### Conclusion

Pathologic response after neoadjuvant therapy for locally advanced rectal cancer is associated with better prognostic results. No correlation between immediate or delayed surgery and tumor regression was observed in this study, suggesting that tumor response depends on other factors besides surgical timing. Further studies should be carried out in order to clearly define predictive factors of tumour response.

### EP-1280 Clinical outcomes of anal squamous cell carcinoma, treated with IMRT, using UK guidance.

S. Sengupta<sup>1</sup>, S. Padmanaban<sup>2</sup>, C. Jacobs<sup>2</sup>, R. Muirhead<sup>3</sup>

<sup>1</sup>School of Medicine, University of Oxford, Oxford, United Kingdom

<sup>2</sup>Oxford Cancer Centre, Oxford University Hospitals, Oxford, United Kingdom

<sup>3</sup>CRUK/MRC Oxford Institute for Radiation Oncology, University of Oxford, Oxford, United Kingdom

### Purpose or Objective

The largest phase III trial of radical chemoradiotherapy in anal cancer to date, the ACT2 study, used a unique radiotherapy dose, fractionation and target volume to other studies and series; delivering treatment using 3D conformal radiotherapy and setting the standard for treatment delivery in the UK. Following the development of intensity modulated radiotherapy (IMRT) UK guidance was produced adapting ACT2 doses and volumes for IMRT delivery. The acute toxicity of delivery using this guidance has been published, confirming reduced toxicity with IMRT; but there is no large series looking at outcome, to confirm maintained outcomes with this new technique. We report a single series centre assessing patient outcomes when utilizing IMRT as per UK guidance.

### Material and Methods

Between April 2013 and July 2016, 87 patients with anal carcinoma were treated with IMRT in the Oxford University Hospital NHS Trust. We retrospectively reviewed clinical notes for patients and tumour demographics, rates of recurrence and colostomy status. Data was collected and analysed using Microsoft Excel, Microsoft Office Professional Plus 2013 and IBM SPSS Software Version 23.

### Results

The median range of the patient population in this study was 61 (range 37-90), with 29:71 male:female ratio. Rates of Tx/T1/T2 and T3/T4 were 62.1% and 37.9% respectively, node negative (N0) and node positive (N+) were 48.8% and 51.2% respectively. 96.6% of patients were free of metastatic disease prior to radiotherapy. The median follow up time after radiotherapy was 15 months (range 3 to 38 months).

The 2 year disease free and overall survival was 76.5% and 83.9% respectively. 94% of patients had a 3 month complete response rate, with 5 patients having an incomplete response, 4 of whom underwent salvage surgery.

At the time of analysis, 5 patients had isolated local relapse following CR at 3 months. Of those, 3 went on to salvage surgery. 7 patients (8%) had distant disease of which 3 patients had both local and distant disease.

2 year colostomy free survival was 75.2%. 12 of the patients had pre-treatment stoma with 7 more patients requiring a colostomy after radiotherapy. **Conclusion** The outcomes in our series suggest that the excellent outcomes achieved with 3D conformal radiotherapy in ACT2 are reproducible with IMRT, delivered according to UK guidance. A larger multicentre audit of outcomes is planned to confirm our findings.

### EP-1281 Feasibility and Toxicity analysis of dose-escalation by SIB/VMAT schedule in rectal cancer patients

A. Re<sup>1</sup>, G. Chiloiro<sup>1</sup>, M.A. Gambacorta<sup>1</sup>, F. Cellini<sup>1</sup>, A. Pesce<sup>1</sup>, D. Marchesano<sup>1</sup>, G.C. Mattiucci<sup>1</sup>, S. Manfredi<sup>1</sup>, V. Valentini<sup>1</sup>

<sup>1</sup>Università Cattolica del Sacro Cuore, Radiation Oncology Department, Rome, Italy

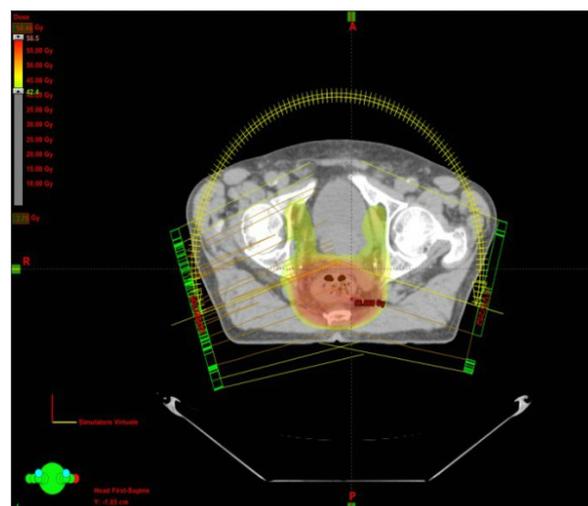

### Purpose or Objective

Evaluation of the feasibility of an intensification of radiation dose by simultaneous integrated boost/Volumetric Modulated Arc Therapy (SIB/VMAT) technique in patients (pts) affected by Locally Advanced Rectal Cancer (LARC) based on toxicity profile.

### Material and Methods

Pts affected by non-metastatic LARC underwent neoadjuvant chemo-radiotherapy (CRT). The CRT was delivered in 25 fractions with SIB-VMAT strategy on two volumes: Clinical target volume (CTV)2 received a total dose of 45 Gy/1.8 Gy/fraction on the total mesorectum and the nodes of drainage; CTV1 received 55 Gy/2.2Gy/fraction as a moderate hypofractionated schedule on the tumor and the corresponding mesorectum.

Surgery was planned at least 8 weeks after the end of CRT. A watch and wait (WW) strategy was considered if restaging exams showed no detectable disease. Adjuvant chemotherapy (CT) was considered according to risk factors. Acute Gastrointestinal (GI), genitourinary (GU) and hematological (HE) adverse events were recorded according to CTCAE scale v4.0. Collaterally CRT efficacy in terms of pathological Complete response (pCR) was analyzed and Tumor Regression Grade (TRG) on the basis of Mandard scale was recorded.

### Results

Thirty-nine pts treated from May 2015 to February 2016 were included in this analysis. The median age was 64 years [range 44-77years]; Male-Female ratio was 2.2. Clinical involvement of mesorectal fascia was detected in 18 pts (46%).

CTV2 included always presacral space and internal iliac nodes, in 30 pts (77%) and in 4 pts (10%) the obturator nodes and the external iliac nodes were added, respectively. 5 pts received CT in the pre-surgical pause. 38 pts received a Total Mesorectal Excision surgery (69% Anterior Resection and 26% Abdominal-Perineal Resection), in 2 pts (5%) a WW approach was preferred. Adjuvant CT was administered to 18 pts. The radiation prescribed dose was entirely delivered in all pts. GI toxicity was recorded in 31 pts (79%): diarrhea and proctitis were most detected. Four cases of grade 3 GI toxicities were registered (6% of all GI toxicities). GU and HE toxicities were less frequent: non infective cystitis (13 pts) and neutropenia (6 pts) were observed. However, none of them presented a toxicity grade  $\geq 3$ . About CT, 8 pts (20%) received less than 4 cycles of concomitant CT because of HE or GI toxicity. pCR was achieved in 10 pts (26%). TRG grade 1 2 3 and 4 was recorded in 11 (28%), 8 (20.5%), 13 (33%) and 5 (13%), respectively. At the median follow-up of 18 weeks the local control, the disease-free survival and the overall survival rates were 100%, 92% and 97%, respectively.

		Grade according to CTCAE v4.0					TOT
		1	2	3	4	5	
Gastrointestinal	Diarrhea	8	6	3			17
	Abdominal pain		3				3
	Rectal hemorrhage	1					1
	Rectal mucositis	3	2				5
	Proctitis	7	7	1			15
	Constipation	1					1
	Rectal pain	1					1
	Fecal incontinence	1					1
	Vomiting	2					2
	Dyspepsia	1					1
Fecal incontinence	1					1	
Genitourinary	Cystitis non-infective	12	1				13
	Urinary tract pain	2					2
	Urinary urgency	1					1
Hematological	Anemia	1					1
	Platelet count disease	2					2
	Neutrophil count decreased	6					6
Skin	Rash maculo papular		1				1
	Radiation recall reaction	2	4				6
Other	Fatigue	1					1
	Fever	3					3

### Conclusion

The SIB/VMAT schedule is well tolerate in LARC. The toxicity was well manageable and the prescribed dose is delivered. Despite the few numbers of patients the rate of pCR is promising. Longer follow-up is required for survival outcomes.

### EP-1282 Clinical and pathological prognostic factors in locally advanced rectal cancer (larc)

S. Montrone<sup>1</sup>, A. Sainato<sup>1</sup>, R. Morganti<sup>2</sup>, C. Vivaldi<sup>3</sup>, C. Laliccia<sup>4</sup>, B. Manfredi<sup>1</sup>, G. Coraggio<sup>1</sup>, M. Cantarella<sup>1</sup>, G. Musettini<sup>3</sup>, D. Delishaj<sup>1</sup>, E. Lombardo<sup>1</sup>, A. Cristaudo<sup>1</sup>, F. Orlandi<sup>1</sup>, G. Masi<sup>3</sup>, P. Bucciatti<sup>4</sup>, A. Falcone<sup>3</sup>, F. Pasqualetti<sup>1</sup>, F. Paia<sup>1</sup>

<sup>1</sup>OSPEDALE SANTA CHIARA, Radiotherapy, PISA, Italy

<sup>2</sup>OSPEDALE SANTA CHIARA, Oncology- Biostatistical Consulting, PISA, Italy

<sup>3</sup>OSPEDALE SANTA CHIARA, Oncology, PISA, Italy

<sup>4</sup>OSPEDALE CISANELLO, Colon-rectal Surgery, PISA, Italy

### Purpose or Objective

Colorectal cancer is the most common gastrointestinal malignancy. More than half of rectal cancer patients (pts) have a LARC at diagnosis and preoperative RT-CT followed by total mesorectal excision (TME) is the standard of cure in these pts. Many studies have analyzed clinical and pathological parameters that could be considered as prognostic factors in pts with rectal cancer. This study aim to identify prognostic factors related to OS and DFS in pts affected by LARC and treated in Pisa University Hospital between January 2008 and April 2014.

### Material and Methods

We analyzed retrospectively the data of 119 pts affected by LARC treated with neoadjuvant RT-CT (50.4 Gy in 28 FF + capecitabine 1650 mg/mq/day) followed by TME-

surgery. In order to identify prognostic factors, we analyzed T and N characteristics at diagnosis and at restaging (before surgery) and their variations (based on MR-images). We also analyzed age, sex and pathological characteristics (surgical approach, ypT, ypN, number of nodes removed, nodal ratio considered as N+/Nresected, histological mucinous aspect, grading, margins, Quirke grade and Dworak's tumor regression).

### Results

All pts completed planned RT-CT. The OS at 2 and 5 years was 97,3% and 88,5%, respectively; 2 and 5 years DFS was 91,5% and 77,5%, respectively. In the multivariate analysis the statistically significant prognostic factors related to DFS were: T-volume (p= 0,046), number of involved quadrants (p= 0,011), distance between T and mesorectal fascia (p= 0,015), pT (p= 0,001), pN (p<0,001), nodal ratio (p<0,0001) and TRG (p= 0,001). Regard to OS, the statistically significant prognostic factors were: number of involved quadrants (p= 0,011), pN (p= 0,009), number of resected nodes (p= 0,042) and nodal ratio (p= 0,002).

### Conclusion

Analyzing our data, we could conclude that clinical T-parameters, pathological T stage and pathological N-parameters are strongly related to an higher incidence of local and distant relapses (DFS). Regard to OS, clinical T-parameters and pathological N-parameters are significantly correlated, while pathological T stage does not seem to have a role as prognostic factor. A better knowledge of these factors related to local and distant relapses will be necessary to decide whether intensify local or systemic treatments.

### EP-1283 Short Course Radiation Therapy For Locally Advanced Rectal Cancer

J. Casalta Lopes<sup>1</sup>, A. Ponte<sup>1</sup>, I. Nobre-Góis<sup>1</sup>, T. Teixeira<sup>1</sup>, M.R. Silva<sup>2</sup>, M. Borrego<sup>1</sup>

<sup>1</sup>Centro Hospitalar e Universitário de Coimbra, Radiation Oncology, Coimbra, Portugal

<sup>2</sup>Centro Hospitalar e Universitário de Coimbra, Pathology, Coimbra, Portugal

### Purpose or Objective v

Locally advanced rectal carcinoma (LARC)v is usually treated with radiotherapy (RT) followed by svurgery. One of the schemes is short course RT (SC: 25Gy / v5 fractions / 1 week) historically followed by immediate surgery. Studies show that a longer interval between SC-RT and surgery may increase downstaging, with the acceptance of this approach in published international guidelines. Intervals from 1 to 4 weeks are associated with higher rates of postoperative complications.

In this study we aim to evaluate toxicity, response to treatment and survival in patients with LARC treated with SC-RT in the neoadjuvant setting.

### Material and Methods

Prospective inclusion of patients with LARC treated by SC-RT between 2002 and 2015. Response was assessed by pathological stage and Ryan modified tumor regression grade (TRG); toxicity was evaluated using CTCAE 4.0 scale. Survival curves were estimated using Kaplan-Meier's method. A type I error of 0.05 was considered.

### Results

73 patients included, 63.0% male. Median age was 80 years, 31.5% with Karnofsky index lesser or equal to 80%. Tumor stage was cT3 in 80.9% and cT4 in 15% of patients; 58.9% were cN+. Perineal acute toxicity grade 2 was described in 2.7%, with no other toxicities. 68 patients underwent surgery with a median RT-surgery interval of 7 weeks (1-22 weeks). Conservative surgery was performed in 79.4% and postoperative complications observed in 33.8%. Complete pathological response (cPR) achieved in 7.4% of patients with TRG 0-1 in 8.9%. Lymphovascular

invasion was observed in 23.5% of surgical specimens and R0 resections in 83.8%. 42 patients underwent surgery more than four weeks after the end of RT (61.7%), with a higher percentage of cPR than those submitted to surgery before, although not statistically significant (3.8% vs. 9.5%). This group also achieved TRG 0-1 more often (3.8% vs. 12.2%). Postoperative complications were higher in the group that underwent surgery up to 4 weeks (42.3% vs. 28.6%), without statistical differences. With a median follow-up of 27 months, at 5 years, locoregional-disease-free survival (LRDFS) was 88.7%, disease-free survival (DFS) was 68.1%, cancer-specific survival (CSS) was 60.8% and overall survival (OS) was 37.0%. Although not statistically significant, cPR showed better outcome at 5 years on LRDFS (100% vs. 87.7%), DFS (100% vs. 65.3%) and CSS (100% vs. 57.5%).

#### Conclusion

In this set of patients, SC-RT was a good option for LARC neoadjuvant treatment, particularly given patient's age and co-morbidities. Although not statistically significant, delayed surgery (over 4 weeks) was associated with a higher cPR rate. In the group of patients with cPR, no local recurrence or distant metastasis were registered. In patients undergoing surgery up to 4 weeks, the higher rate of surgery-related complications may be explained by the existence of surgeries performed in the second and third weeks after RT.

#### EP-1284 Impact of surgical delay after long-course radiochemotherapy in rectal cancer

T.M. Dos Santos Teixeira<sup>1</sup>, A. Ponte<sup>1</sup>, J. Casalta.Lopes<sup>1</sup>, I. Nobre-Góis<sup>1</sup>, M.R. Silva<sup>2</sup>, R. Lebre<sup>3</sup>, A. Barros<sup>3</sup>, M. Borrego<sup>1</sup>

<sup>1</sup>Hospitais da Universidade de Coimbra, Serviço de Radioterapia, Coimbra, Portugal

<sup>2</sup>Hospitais da Universidade de Coimbra, Serviço de Anatomia Patológica, Coimbra, Portugal

<sup>3</sup>Hospitais da Universidade de Coimbra, Serviço de Oncologia Médica, Coimbra, Portugal

#### Purpose or Objective

One of the possible treatments for locally advanced rectal carcinoma (LARC) in the neoadjuvant setting is long course radiotherapy, associated to concomitant chemotherapy (LC-RCT). There is growing evidence that a longer interval between radiation therapy and surgery improves tumor response to LC-RCT. Randomized studies have shown that the achievement of a complete pathological response provides a decrease in local recurrence and an improvement in overall survival. In this study we aim to evaluate the impact of delayed surgery in pathologic complete response rate after neoadjuvant therapy with LC-RCT.

#### Material and Methods

Prospective inclusion of patients with LARC, clinically staged as cT3 or cT4, treated with LC-RCT between 2002 and 2015, with a dose of 50.4Gy / 28 fractions / 5.5 weeks and undergoing surgery afterwards. The response to neoadjuvant therapy was assessed by pathological stage and toxicity was evaluated by using CTCAE 4.0. Survival curves were estimated using Kaplan-Meier's method. A type I error of 0.05 was considered.

#### Results

249 patients included, 64.7% male. Median age was 64 years, 95.2% of patients with Karnofsky index greater than or equal to 90%. Tumor stage was cT3 in 83.9% of patients and cT4 in 16.1%; 90.4% had lymph nodes with criteria for tumor infiltration. During the treatment acute toxicity was observed in 75.1% patients, with 10.0% corresponding to grade 3 or 4. Concomitant chemotherapy was mainly administered using oral fluoropyrimidines (84.7%). 73 patients (29.3%) underwent surgery over 8 weeks after the

end of LC-RCT. 67.1% of patients underwent conservative surgery; there were no differences in postoperative complications regarding time to surgery. Patients undergoing surgery over 8 weeks after the end of LC-RCT showed higher T downstaging (65.8% vs. 56.8%) and pathological complete response (pCR) rate (16.4% vs. 13.1%), although no statistically significant differences were observed. With a median follow-up of 57 months, at 5-years, locoregional-disease-free survival (LRDFS) was 93.4%, disease-free survival (DFS) was 69.5%, cancer-specific survival (CSS) was 77.5% and overall survival (OS) was 70.6%. Patients achieving pCR had better DFS (5-year: 93.3% vs. 65.3%, p=0.003), CSS (5-year: 96.7% vs. 74.5%, p=0.006) and OS (5-year: 88.9% vs. 67.8%, p=0.010). Although not statistically significant, LRDFS was also higher in this group (5-year 100% vs. 92.3%, p=0.100).

#### Conclusion

Although not significantly, delaying surgery over 8 weeks provided greater T downstaging rate and pCR, with no differences regarding postoperative complications. pCR showed significant impact on the DFS, CSS and OS.

#### Electronic Poster: Clinical track: Gynaecological (endometrium, cervix, vagina, vulva)

#### EP-1285 Neutrophilia in locally advanced cervical cancer: biomarker for image-guided adaptive brachytherapy?

C. Chargari<sup>1</sup>, A. Escande<sup>1</sup>, C. Haie-Meder<sup>1</sup>, P. Maroun<sup>1</sup>, S. Gouy<sup>2</sup>, R. Mazon<sup>1</sup>, T. Leroy<sup>3</sup>, E. Bentivegna<sup>2</sup>, P. Morice<sup>2</sup>, E. Deutsch<sup>1</sup>

<sup>1</sup>Gustave Roussy, Radiotherapy department-Brachytherapy unit, Villejuif, France

<sup>2</sup>Gustave Roussy, Department of surgery, Villejuif, France

<sup>3</sup>Oscar Lambret Cancer Center, Radiotherapy department, Lille, France

#### Purpose or Objective

To study the prognostic value of leucocyte disorders in a prospective cohort of cervical cancer patients receiving definitive chemoradiation plus image-guided adaptive brachytherapy (IGABT).

#### Material and Methods

We examined patients treated in our Institution between April 2009 and July 2015 by concurrent chemoradiation (45 Gy in 25 fractions +/- lymph node boosts) followed by a magnetic resonance imaging (MRI)-guided adaptive pulse-dose rate brachytherapy (15 Gy to the intermediate-risk clinical target volume). The prognostic value of pretreatment leucocyte disorders was examined. Leukocytosis and neutrophilia were defined as a leukocyte count or a neutrophils count exceeding 10,000 and 7,500/ $\mu$ l, respectively.

#### Results

113 patients were identified. All patients received a pelvic irradiation concomitant with chemotherapy, extended to the para-aortic area in 13 patients with IVB disease. Neutrophilia and leukocytosis were significant univariate prognostic factors for poorer local failure-free survival (p = 0.000 and p = 0.002, respectively), associated with tumor size, high-risk clinical target volume (HR-CTV) and anemia. No effect was shown for distant metastases but leukocytosis and neutrophilia were both poor prognostic factors for in-field relapses (p = 0.003 and p < 0.001). In multivariate analysis, HR-CTV volume (p = 0.026) and neutrophils count > 7,500/ $\mu$ l (p = 0.018) were independent factors for poorer survival without local failure, with hazard ratio (HR) of 3.1.

### Conclusion

Neutrophilia is a significant prognostic factor for local relapse in locally advanced cervical cancer treated with MRI-based IGABT. This biomarker could help identifying patients with higher risk of local relapse and requiring dose escalation.

### EP-1286 MRI vs clinical assessment in staging and prediction of recurrence in carcinoma cervix treatment

A. Mintu Mathew<sup>1</sup>, S. Aravindh Anand<sup>1</sup>

<sup>1</sup>Government Medical College Trivandrum, Radiotherapy, Trivandrum, India

### Purpose or Objective

This prospective study aimed to evaluate the correlation between MRI and clinical assessment in staging and response evaluation of locally advanced carcinoma cervix. It also aimed to assess the role of MRI as a predictor of recurrence free survival.

### Material and Methods

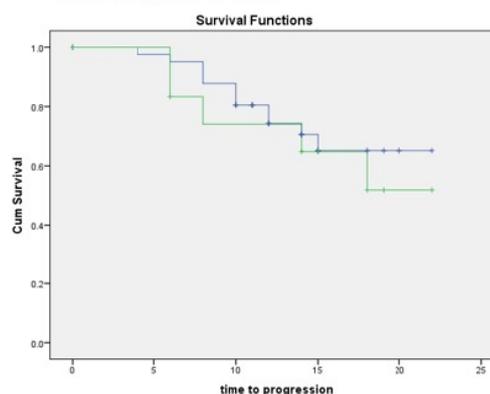

58 women with locally advanced carcinoma cervix were studied from January 2014 to October 2015 after obtaining informed consent. After MRI abdomen & pelvis, patients were started on chemo-radiation. Pelvic External beam radiation (EBRT) to a dose of 45Gy/23 fractions with concurrent weekly cisplatin 40mg/m<sup>2</sup> was given, followed by intracavitary brachytherapy 7Gy/fraction x 3 fractions weekly once. Treatment response was assessed as per RECIST criteria clinically and radiologically with MRI after 4-6 months. Both pre and post treatment radiological evaluation was done by independent radiologists. Any suspected recurrence was subjected to MRI assessment and biopsy for proof.

### Results

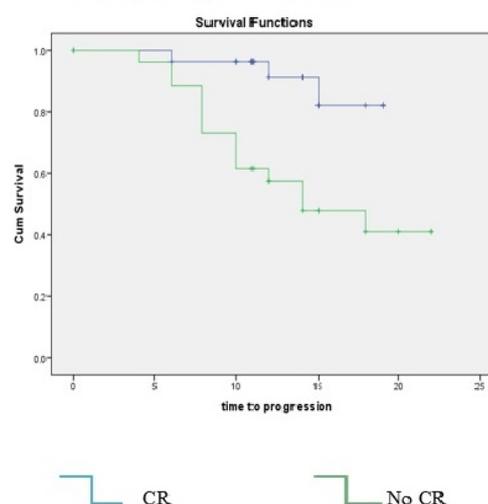

At a median follow up of 12 months, Kaplan Meir survival analysis showed a recurrence free survival of 69.6%. The hazard ratio of recurrence was 8.667 times between non-responders and responders by MRI (p=0.001, 95% CI 2.82 to 35.1) and 1.667 between non responders and responders by clinical assessment (p=0.438).

Kaplan Meir analysis for recurrence free survival separately done for patients who had achieved complete response (on MRI) vs. those who did not, showed only 10.7% percent of the responders and 50 % of the non-responders had recurrence. When assessing the clinical response, it was seen that the 27.9% of the responders and 38.5 % of the non-responders had recurrence showing MRI was more useful in predicting recurrences. The kappa analysis showed a value of 0.18 for initial staging and 0.08 for response evaluation which signified poor agreement between MRI and clinical assessment in both staging and response evaluation. Bland-Altman analysis revealed a mean difference of agreement of 0.28 (0 being complete agreement) between MRI and clinical response evaluation [p= 0.002]

### Clinical Response Evaluation

### Radiological Response Evaluation

### Conclusion

There are significant differences both in staging and response evaluation between FIGO and MRI in carcinoma cervix. In assessment of response to the standard treatment, MRI was found to be a better predictor of recurrence and thus ultimately, the outcome of treatment. This study proves that MRI may be used as a tool in assessment of treatment response thus predicting patients who may go for treatment failure, and may benefit from close follow up and early salvage.

### EP-1287 10-Year outcomes on patients receiving radical radiotherapy for cervical cancer

K. Woo<sup>1</sup>, L. Davis<sup>2</sup>, M. Light<sup>3</sup>, L. Croydon<sup>4</sup>, M. Powell<sup>5</sup>

<sup>1</sup>University College London Hospital, Oncology, London, United Kingdom

<sup>2</sup>Kings College Hospital, Oncology, London, United Kingdom

<sup>3</sup>Guys and St Thomas Hospital, Oncology, London, United Kingdom

<sup>4</sup>Institute of Cancer Research, Oncology, London, United Kingdom

<sup>5</sup>St Bartholomew's Hospital, Radiotherapy, London, United Kingdom

### Purpose or Objective

Cervical cancer is the second most common cancer in women worldwide, 80% of which is treated primarily with radiotherapy. Aim: To evaluate the outcome of patients with cervical cancer treated with radical radiotherapy either as primary treatment or given adjuvantly (+/- chemotherapy) at single cancer centre between 1999 and 2009 in terms of overall survival (OS), acute and late

toxicity, and patterns of local and distant relapse.

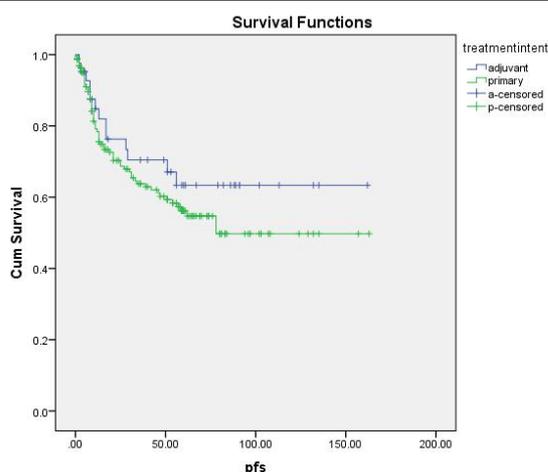

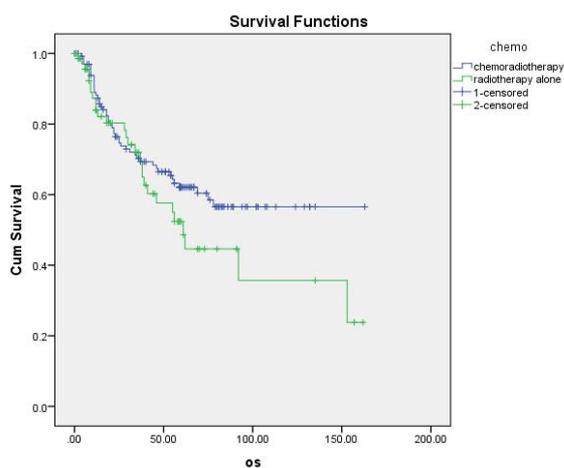

**Standard:** 1. Royal College of Radiologists (RCR) Audit

#### Material and Methods

A retrospective audit of cervical cancer patients treated with radical radiotherapy either in primary or adjuvant setting in a single cancer centre was undertaken. Data was analysed in Excel and SPSS statistical software.

#### Results

Results of 1st Audit Round : 207 patients were included. 79.7% received primary radiotherapy with a 5-year OS of 56%. 20.3% received adjuvant radiotherapy with a 5-year OS of 61%. Patients who received chemoradiotherapy (64.7%) showed a 20% improvement in 5-year OS compared to those who received radiotherapy alone (35.3%). In the acute setting, bowel toxicity was the commonest, (50.2%) followed by urinary (13.5%) and haematological (12.5%). Late toxicity was poorly recorded with only 8 cases documented. There was a 35.7% relapse rate, with 20.2% central recurrences, 9.7% pelvic relapses and 51.3% distant metastases. Of these, distant nodal metastases was most common (34%) followed by lung (26.3%), bone (18.4%) and brain (5%).

#### Conclusion

Survival was comparable with the RCR Audit of 2001-2002 with the exception of patients who received radiotherapy post surgery (61% whereas RCR audit showed 71% 5-year OS). As in the RCR audit, patients who received concurrent chemoradiotherapy had an improved overall survival compared to those who did not. Prospective collection of acute toxicity well recorded but inadequate prospective data collection on late toxicity.

Action Plan:

- Better prospective data collection on late toxicity with assessment sheets at post treatment clinic appointments.
- To reaudit central recurrence rates now that centre has moved from 2-D X-ray guided brachytherapy to 3-d image-guided brachytherapy at a higher fractionation schedule.
- To reaudit acute toxicity in the era of IMRT.

#### EP-1288 Correlation between PET/CT primary tumor FDG uptake and lymph node metastases in cervical cancer

G. Ugurluer<sup>1</sup>, B. Atalar<sup>2</sup>, H.A. Saran Ikizler<sup>3</sup>, N. Sozer<sup>3</sup>, M. Kibar<sup>4</sup>, M. Serin<sup>1</sup>, E. Ozyar<sup>2</sup>

<sup>1</sup>Acibadem University School of Medicine- Acibadem Adana Hospital, Radiation Oncology, Adana, Turkey

<sup>2</sup>Acibadem University School of Medicine- Acibadem Maslak Hospital, Radiation Oncology, Istanbul, Turkey

<sup>3</sup>Acibadem Bursa Hospital, Radiation Oncology, Bursa, Turkey

<sup>4</sup>Acibadem Adana Hospital, Nuclear Medicine, Adana, Turkey

#### Purpose or Objective

In this study, it was aimed to determine the correlation between Positron Emission Tomography/Computed Tomography (PET/CT) primary tumor FDG uptake levels and lymph node metastases in cervical cancer patients.

#### Material and Methods

One hundred and three (103) cervical cancer patients who had pretreatment staging PET/CT were included in the study. Primary tumor maximum standard uptake value (SUVmax) levels, maximum tumor diameter measured on PET/CT, FDG-avid pelvic and paraortic lymph nodes and SUVmax values for FDG-avid lymph nodes were recorded for every patient. Correlation between SUVmax levels and lymph node metastases were evaluated. Statistical analysis were done by SPSS.

#### Results

Median age was 56 years (range; 31-91 years). Mean SUVmax levels for primary tumor and for lymph nodes were 14,3±6,3 (range; 3,9-34,2) and 8,6±3,9 (range; 2,8-19,3), respectively. SUVmax levels for the patients with FDG-avid lymph nodes and non FDG-avid lymph nodes were 15,9 (range; 4,1-34,2) ve 11,9 (range; 3,9-25,5) (P <0,05). Mean levels for the low and high SUVmax groups (according to the median SUVMax level, 13,9) were 9,3 (range; 3,9-13,4) and 18,9 (range; 13,9-34,2). There were lymph node metastases in 46% of patients in low SUVmax group and 70% of patients in high SUVmax groups (p <0,05). Mean SUVmax levels in patients with tumor diameter ≤4 cm and >4 cm were 13,1 (range; 5,5-25,5) ve 17,1 (range; 7,7-34,2), respectively. There were lymph node metastases in 42% of patients with tumor diameter ≤4 cm and 66% of patients with tumor diameter >4 cm. Two groups were statistically different according to the SUVmax levels and lymph node metastases (p <0,05).

#### Conclusion

SUVmax levels in cervical cancer patients might be correlated with high risk for lymph node metastases and might change the prognosis of patients and treatment approach.

#### EP-1289 Use of image guided brachytherapy reduces late toxicity for elderly patients with cervical cancer

D.K. Daijiro Kobayashi<sup>1</sup>, N.O. Noriyuki Okonogi<sup>2</sup>, M.W. Masaru Wakatsuki<sup>3</sup>, H.K. Hiroki Kiyohara<sup>1</sup>, T.O. Tatsuya Ohno<sup>4</sup>, S.K. Shingo Katoh<sup>5</sup>, T.N. Takashi Nakano<sup>1</sup>, T.K. Tadashi Kamada<sup>2</sup>

<sup>1</sup>Gunma University, Radiation Oncology, Gunma, Japan

<sup>2</sup>National Institutes for Quantum and Radiological Science and Technology, Radiation Oncology, Chiba, Japan

<sup>3</sup>Jichi Medical University, Radiology, Tochigi, Japan

<sup>4</sup>Gunma University Heavy Ion Medical Center, Radiation

*Oncology, Gunma, Japan*

<sup>5</sup>*Saitama Medical University International Medical Center, Radiation Oncology, Saitama, Japan*

#### **Purpose or Objective**

Elderly patients with cervical cancer (CC) are commonly treated with radiation therapy (RT) alone because age-related physiologic changes can increase the toxicity of chemotherapy. Thus, brachytherapy (BT) assumes more crucial role for elderly patients with CC. In our institution, treatment technique of BT has moved from 2D-based to CT-based image guided BT (IGBT) in a phased manner. The purpose of this study is to analyze the impact of fraction of IGBT on the clinical outcome for elderly patients with CC.

#### **Material and Methods**

Between January 2001 and September 2014, 104 patients aged  $\geq 70$  years with CC received external beam RT (EBRT) and high-dose rate BT with curative intent in our institution. EBRT (38.0-56.8 Gy) with central shielding after 20-40 Gy was performed for each patient. We compared clinical results of two groups; the patients treated with IGBT only once (single-IGBT group, n=74) or at least twice (multiple-IGBT group, n=30) out of all sessions of BT. Four fractions of BT were administered once a week with a fraction dose of 6 Gy to Point A, basically. Dose adaptation was initially based on dose changes at Point A in IGBT session. If dose adaptation to Point A could not be achieved as intended, manual optimization of dwell positions and dwell weights was performed to improve dosimetry. We predicted that a 6 Gy isodose line would cover the high-risk clinical target volume (HR CTV) in order to achieve a HR CTV D90 (the minimum dose delivered to 90% of the HR CTV) of  $>6$  Gy. The local control (LC) rate, overall survival (OS) rates, and late toxicities were compared in the 2 groups. Late toxicity was defined using the Radiation Therapy Oncology Group late radiation morbidity scoring system as any toxicity occurring 6 months after the initiation of RT.

#### **Results**

The median follow-up period was 59 months in all patients. Twenty-seven patients had stage IB, 45 had stage II, 29 had stage III, and 3 had stage IVA in FIGO staging. The median dose of all BT sessions in total was 24 (7.8-31) Gy at Point A. There was no statistical difference between the two groups in age, FIGO stage, tumor size, Point A dose, and the number of BT. The 4-year LC and OS rates were 89.5% and 70.2% in single-IGBT group, 87.5% and 59.0% in multiple-IGBT group, respectively. There were no statistical differences in survivals between the 2 groups. In regard to late toxicities ( $\geq$  grade 1), 18 patients developed lower gastrointestinal (GI) toxicity and 19 patients developed genitourinary (GU) toxicity in single-IGBT group, whereas 4 patients developed GI toxicity and no GU toxicity were found in multiple-IGBT group. Multiple-IGBT had tendency to reduce GI toxicity and significantly reduced GU toxicity ( $p < 0.05$ ).

#### **Conclusion**

IGBT for elderly patients were performed safely and effectively. Multiple-IGBT, acquiring CT images more than twice, contributes to reduce late toxicity, compared to single-IGBT for elderly patients with CC.

#### **EP-1290 Helical Tomotherapy plus Brachytherapy boost in cervical cancer: a double dose escalation**

G. Cattari<sup>1</sup>, E. Delmastro<sup>1</sup>, A. Mranti<sup>2</sup>, S. Bresciani<sup>2</sup>, S. Squintu<sup>1</sup>, E. Garibaldi<sup>1</sup>, P. Gabriele<sup>1</sup>

<sup>1</sup>*FPO-IRCCS Candiolo, Radiotherapy, Candiolo- Turin, Italy*

<sup>2</sup>*FPO-IRCCS Candiolo, Medical Physic, Candiolo- Turin, Italy*

#### **Purpose or Objective**

Traditionally, curative radiation treatment for squamous cervical cancer (SCC) is associated to concomitant chemotherapy platinum based. Doses on the pelvic volume and on the present disease were limited by tolerance of health tissues, especially by small bowel. The possibility of dose escalation (DE) was achieved by intracavitary brachytherapy (BRT) boost, the most classical and proven hypofractionation technique. More modern technologies and techniques, like Helical Tomotherapy (HT), allowed a safe and concomitant dose escalation in this setting of patients (pts) and we need to show our experience in terms of outcome, tolerance and feasibility

#### **Material and Methods**

From 2011 to 2015 we treated 34 pts affected by SCC, 22 with curative intent (4 recurrences). The mean age was 58 years (range 32-88). Grading was: G2 in 10 pts and G3 in 12pts. Stage was: IIA in 4 pts, IIB in 14 pts, IIIA in 1 pt, IIIB in 2 pts and IV in 1 pt. All pts received concurrent chemotherapy (CHT) with cisplatin and/or taxanes. All patients were treated with Intensity Modulated Radiation Therapy with Simultaneous Integrated Boost Image Guided Radiation Therapy (IMRT-SIB-IGRT) using @Helical Tomotherapy (HT). External beam radiotherapy (EBRT) was planned on PET-CT images acquired in treatment position. Tumor doses ranged from 60 to 70.4 Gy in 30 fractions (fr) with a moderate hypofractionation; dose to the pelvis ranged from 50.4 to 54 Gy. Lumbar-aortic chain was treated in 4 pts (51 Gy); 13 pts received a boost on PET positive lymph nodes with dose ranging from 60 to 66 Gy. All pts were treated with high dose rate BRT boost with dose/fraction of 6-15 Gy in 1-3 fr

#### **Results**

All pts completed the treatment. Mean follow up was 13,6 months (range 1-26). Three pts recurred: 1 pt in lumbar-aortic chain, 2 pts in pelvic region. Mean time to progression was 3,3 months. Overall survival was 82% with a mean time of 10 months. Two pts died for distant metastases, two for peritoneal progression. No acute or late gastro-intestinal (GI) toxicity  $> G2$  were observed; only one pt developed a G3 acute and late genitourinary toxicity. No severe late hematological toxicity was observed; only one pt developed a G4 acute neutropenia requiring medical therapy

#### **Conclusion**

Our experience of double DE by HDR+ EBRT with concurrent chemotherapy, showed to be effective and safe and well tolerate with a low rate of complications

#### **EP-1291 Does concomitant boost using conformal therapy maximize local control in Stage III.B cervical cancer**

R. Santosham<sup>1</sup>

<sup>1</sup>*Cancer Institute WIA, radiation oncology, Chennai, India*

#### **Purpose or Objective**

**BACKGROUND :** This is a prospective study to assess the local control and toxicity profile of concomitant boost using conformal therapy. The role of IMRT to simultaneously boost the primary is unquestionable when small volumes are considered and where more organs are at risk around our target. But in an advanced pelvic malignancy where the target volume is large and where completely avoiding the bladder base or the recto-sigmoid septum are not recommended, 3D CRT may be tried.

**AIM :** To compare the local control and acute toxicity profile of patients treated with concomitant boost and conventional fractionated radiotherapy.

#### **Material and Methods**

29 patients with locally advanced FIGO stage III.B received concomitant boost (Arm A) (190cGy to the pelvis along with 210cGy to the boost volume) using conformal therapy between Sept 2015 and June 2016 of whom 18 patients

received chemotherapy. In the same period, an age matched control group (Arm B) of 29 patients were managed with conventional fractionated radiotherapy of whom 11 patients received chemotherapy. All patients in the concomitant boost arm underwent repeat CT and replan at 36Gy when the response was assessed based on RECIST ver 1.1. Acute toxicity was assessed based on CTCAE 4.0 and RTOG grading of Acute toxicities.

#### Results

Patients who tolerated treatment well without acute radiation or chemotherapy induced morbidity were comparable in both arms (62.06%(A) and 27.7%(B)) and (55.17(A)% 18.1%(B)) respectively. Grade I/II proctitis was seen in 5 patients (17.2%) in Arm A and 4 patients in Arm B (13.7%) Diarrhea requiring medication (Grade II) was seen only in 1 patient conventional group. None of the patients in the concomitant boost group had Genitourinary morbidity while 1 patient developed GU morbidity in the conventional group. Development of Gr I Skin reaction was comparable in both groups. The local control rates were 72.4% vs 51.7% in favor of the control group.

#### Conclusion

The use of concomitant boost in the management of locally advanced cervical cancers is not widely practiced due to the general perception that the toxicity profile may be more due to dose escalation. This study shows that the acute toxicity profile of concomitant boost using conformal therapy is comparable to that of conventional fractionated radiotherapy with better local control rates. Further randomized studies need to be carried out to assess the long term outcome of concomitant boost in locally advanced cervical cancer.

#### EP-1292 Prognostic factors of patients with cancer of uterine cervix in chemo-irradiation era.

F. James<sup>1</sup>, A. Kumar<sup>1</sup>, S. Mathews<sup>1</sup>, J. Joseph<sup>1</sup>, P.S. George<sup>2</sup>, A. Mathew<sup>2m</sup>, M. Anjanappa (India)

<sup>1</sup>Regional Cancer Centre- Trivandrum, Radiation Oncology, Trivandrum, India

<sup>2</sup>Regional Cancer Centre- Trivandrum, Biostatistics and Epidemiology, Trivandrum, India

#### Purpose or Objective

Cancer cervix is the second commonest female cancer in India and accounts for 20.2% cancer mortality in women. Majority of the patients present with advanced stage in our centre. The study aims to identify factors affecting the outcome of cancer cervix treated in Chemo-irradiation era.

#### Material and Methods

From a surveillance study of 1046 cervical cancer patients treated at our centre, between January 2006 to December 2008, data of 790 patients who had radical radiotherapy were taken. Known prognostic factors like stage, age, histological type, use of chemotherapy and overall duration of treatment were taken for the study. The survival rate was analysed using the Kaplan-Meier method. Survival data between groups were compared with the Log-rank test for univariate analysis and Cox regression analysis for multivariate analysis.

#### Results

For the 790 patients, median age was 54.9 years (28-82) with standard deviation (SD) of 10. Median follow up was 59 months (4-93) with SD of 20.5. The five year survival probability is 70.3%. The probability of five year survival is 81.2%, 80.1%, 57.1%, 26.7% for stage 1, 2, 3 and 4 respectively. For patients younger than 40, 40-70 and older than 70 years, the probability of five year survival are 68%, 71.6% and 52.7% respectively. Patients who had squamous cell carcinoma did better with 72% than those with adeno carcinoma with 59.2% survival probability. The patients who had concurrent chemotherapy (two third of patients) also did better

(74.2% compared to 62.3%). Regarding overall treatment time, <8, <9 and <10 weeks were tested. The survival probability decreased significantly when the treatment extended to 9 weeks or more (76.1% vs 63.9%). This remained significant whether chemotherapy was used or not. In univariate analysis, stage, age, histological subtype, use of chemotherapy and treatment duration less than 9 weeks were significant predictors of survival. In the multivariate analysis, earlier stage of disease (stage 2 or less), use of chemotherapy, and duration of treatment less than 9 weeks were significant.

#### Conclusion

For patients receiving radical radiation for cancer cervix, stage, concurrent chemotherapy and finishing treatment within 9 weeks are significant factors for survival.

#### EP-1293 Clinical outcome of prophylactic PAN irradiation for locally advanced cervical cancer

K. Fukuda<sup>1</sup>, Y. Nishimura<sup>1</sup>, K. Nakamatsu<sup>1</sup>

<sup>1</sup>Kindai University Faculty of Medicine, radiation oncology, Osaka-Sayama, Japan

#### Purpose or Objective

The aim of this study is to analyze the outcomes of curative irradiation for locally advanced cervical cancer with or without prophylactic irradiation for para-aortic lymph nodes (PAN).

#### Material and Methods

Between 1999 and 2015, 70 patients with locally advanced cervical cancer treated with curative radiation therapy were analyzed. The median age was 61 years old. From 1999 to 2008, 33 patients were performed prophylactic irradiation for PAN after the treatment of whole pelvic region (PAN+ group). For PAN area, all patients were treated with 2-4 beams using 10-MV X-ray to a total dose of 45Gy /25fr or 50.4Gy /28fr. After 2008, prophylactic irradiation was not performed for 37 patients (PAN-group). Of 70 patients, 44 patients were performed concurrent chemo therapy. All patients were classified according to FIGO staging system. Our cohort includes 47 patients of stage 3 and 23 patients of stage 4. The acute and late complications were evaluated according to CTCAE ver. 4.0.

#### Results

For all patients, 5-year overall survival rate was 53%. For PAN+ group and PAN- group, relapse from PAN area were observed for 3 patients each (9%, 8%). There was no difference between two groups. An acute gastro-intestinal toxicity more than grade 2 were observed in 6 patients from PAN+ group and 1 patient from PAN- group. A late gastro-intestinal toxicity more than grade 2 was observed in 5 patients and 4 patients from PAN+ group and from PAN- group respectively.

#### Conclusion

Prophylactic irradiation for PAN did not prevent local recurrence from PAN area.

#### EP-1294 Interfractional motion of vaginal cuff after hysterectomy in gynecologic cancer

S. Chun<sup>1</sup>, K.Y. Eom<sup>2</sup>, H. Kim<sup>3</sup>

<sup>1</sup>SNUH, Radiation Oncology, SEOUL, Korea Republic of

<sup>2</sup>Bundang Hospital- Seongnam- Korea, Radiation

Oncology, Seongnam, Korea Republic of

<sup>3</sup>Soonchunhyang University Hospital, Department of Radiation Oncology/Cyberknife center, Seoul, Korea Republic of

#### Purpose or Objective

To identify relationship between bladder and rectal volume changes during radiotherapy with vaginal stump movement. Also by calculating vaginal stump movement,

adequate PTV margin for vaginal stump can be determined.

#### Material and Methods

Ten patients with cervical or endometrial cancer were enrolled prospectively. All patients received surgery with curative aim and adjuvant radiotherapy. Patients took cone beam CT (CBCT) once a week with radiocontrast soaked gauze and radiopaque markers to visualize vaginal stump. Each patient underwent total 6 CT imaging acquisition including one simulation CT and 5 CBCTs. All CBCT images of each patient were transported to initial simulation CT images via image registration (MIM software) with bone matching, and by using Computational Environment for Radiotherapy Research (CERR) program, adequate margin covering 95% of combined vaginal cuff volume (MARGIN<sub>95</sub>), rectum and bladder volume, and vaginal cuff movement were calculated. Patients were instructed to keep full bladder and empty rectum before radiotherapy.

#### Results

Average motion change in center of vaginal cuff in 10 patients was Left-Right (L-R) 0.5mm, Anterior-posterior (A-P) 2.2mm, and Superior-Inferior (S-I) 0.4mm, respectively. Correlation coefficient between rectal volume and stump Anterior movement was 0.762 ( $p < 0.001$ ). Also, correlation coefficient between bladder volume and stump posterior movement, left movement was 0.346 ( $p = 0.014$ ), 0.366 ( $p = 0.009$ ), respectively. Mean value and standard deviation of MARGIN<sub>95</sub> was 6.7mm and 3.3mm respectively. Using T distribution, upper 5 percentage value of Margin<sub>95</sub> was 8.6mm

#### Conclusion

Although instructions were given to keep patient rectal volume consistent, large variations in rectal volume was observed. Also correlation between rectal volume and vaginal stump movement was strong ( $p < 0.001$ ). Laxatives and enema may be used to keep rectal volume constant to decrease magnitude of vaginal stump. Suggestive margin for vaginal cuff movement covering 95% of patients' Margin<sub>95</sub> is 8.6mm.

#### EP-1295 Role of postoperative adjuvant radiotherapy in early stage cervical cancer without high risk factors

W. Jung<sup>1</sup>, J. Kim<sup>1</sup>, Y.J. Kim<sup>1</sup>, J. Lee<sup>1</sup>, K. Kim<sup>1</sup>, S. Jeong<sup>1</sup>  
<sup>1</sup>Ewha Womans University Medical Center, Radiation Oncology, Yangcheon-gu, Korea Republic of

#### Purpose or Objective

The aim of this study was to assess and evaluate the rate of adjuvant treatment following radical hysterectomy with pelvic lymphadenectomy in early stage uterine cervical cancer and to suggest the appropriate role of adjuvant radiotherapy among the patients without clinicopathologic high risk factors.

#### Material and Methods

The patients with FIGO stages IB-IIA uterine cervical cancer who underwent radical hysterectomy with pelvic lymphadenectomy between 2001 and 2012 were analyzed. Outcomes and clinicopathologic adverse features of patient groups were compared. High-risk feature was defined as lymph node metastasis, parametrial invasion, or resection margin status, and intermediate-risk feature was defined as tumor size, lymphovascular invasion or depth of invasion. Based on these factors, patients could be divided into high risk group and non-high risk group, and outcome according to adjuvant radiotherapy (RT) or not (non-RT) were evaluated.

#### Results

Total 85 (57.0%) of 149 patients received adjuvant radiotherapy after surgery. Five-year overall survival (OS) and disease-free survival (DFS) rates were significantly different between high-risk group and non-high risk group (86.0% and 78.0% in high-risk group vs 96.5% and 93.9% in

non-high risk group). Among the non-high risk group patients, status more than 2 intermediate-risk factors were statistically associated with lower 5yr OS rate ( $p=0.043$ , HR 9.219, 95% CI 1.076-78.976). In subgroup analysis among the patients with 2 or more intermediate-risk factors, patients who did not receive adjuvant RT showed significantly lower 5yr OS rate compared to <2 risk factors (97.9% vs 81.8%,  $p=0.023$ ), but patients who received adjuvant RT showed no difference (100% vs 96.8%,  $p=0.105$ ).

#### Conclusion

This study was to re-evaluate the findings of risk factors and appropriate role of adjuvant radiotherapy. Adjuvant radiotherapy is not only beneficial to patients with high-risk factors but also to patients with non-high risk factors, especially with more than 2 intermediate-risk factors. Therefore, adjuvant radiotherapy is still important and appropriate modality in patients with adverse features after radical surgery of uterine cervical cancer, despite of potential side effect caused by radiotherapy and desirable high rate of adjuvant treatment after radical surgery in early stage.

#### EP-1296 Adjuvant radiotherapy in endometrial cancer: Volumetric Modulated Intensity Arc Therapy vs 3DRT

C. Iftode<sup>1</sup>, A. Tozzi<sup>1</sup>, E. Clerici<sup>1</sup>, L. Di Brina<sup>1</sup>, G.R. D'Agostino<sup>1</sup>, A.M. Ascolese<sup>1</sup>, T. Comito<sup>1</sup>, D. Franceschini<sup>1</sup>, C. Franzese<sup>1</sup>, F. De Rose<sup>1</sup>, S. Tomatis<sup>1</sup>, P. Mancosu<sup>1</sup>, P. Navarra<sup>1</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

#### Purpose or Objective

To appraise the role of volumetric modulated arc (RapidArc, RA form) in the postoperative treatment of endometrial cancer patients.

#### Material and Methods

A retrospective analysis has been conducted on 36 patients treated with VMAT and image-guided RT (IGRT) since 2011 comparing treatment characteristics and outcome against a group of 24 patients treated with conformal therapy (CRT). Disease specific survival, local control and acute and late toxicity were scored and investigated as well as basic dosimetric characteristics of the treatments.

#### Results

Median age of patients was 64.4 yrs for VMAT and 68 yrs for CRT. All patients had Stage Ib-III. VMAT treatments lead to lower incidence of higher grade of toxicity events (all retrospectively retrieved from charts as worse events). No patient had G3 acute toxicity in both groups of treatment. G2 acute toxicity for patients treated with 3D versus VMAT was as follows: GU 29.17% vs 8.33%; GE 54.17% vs 25%; proctitis 25% vs 5.56%; cutaneous 25% vs 11.11%. Late toxicity in both treatment arms were limited. In the VMAT group 1 patient (2.78%) had G2 GU toxicity as in the 3D group; no patient treated with VMAT had GE G2 toxicity, meanwhile 3 cases (12.5%) were in 3D arm. No VMAT patient had proctitis, but in the 3D group there were 2 cases with G2 (8.33%) and one case (4.17%) of proctitis G3. No statistically significant differences were observed concerning survival or control. With a median FUP of 22.29 and 67.82 months for VMAT and 3D respectively, 4 patients had metastatic progression in the VMAT arm and in 3D arm 2 patients had loco-regional relapse and 3 metastatic progression.

#### Conclusion

The present study demonstrated that VMAT for adjuvant WPRT in endometrial cancer proved to be equally effective as CRT while improves the OAR dose sparing. A significant enhancement of acute toxicity support the use of VMAT technique in this setting of patients.

### EP-1297 Update: Phase III randomised trial on electro-hyperthermia plus chemoradiation for cervical cancer

C. Minnaar<sup>1</sup>, J. Kotzen<sup>2</sup>, A. Baeyens<sup>1</sup>

<sup>1</sup>Johannesburg Hospital- Area 348, Radiobiology, Johannesburg, South Africa

<sup>2</sup>Johannesburg Hospital- Area 348, Radiation Oncology, Johannesburg, South Africa

#### Purpose or Objective

Cervical is the second most common cancer in females in South Africa, with over 5000 new cases reported per annum. Improving outcomes with the addition of affordable radiosensitisers would assist in alleviating the socio-economic burden of the disease in South Africa. Hyperthermia is a known radiosensitiser used to treat cervical cancer with improved clinical outcomes and survivals. The aim of this study is to determine the clinical effects of the addition of modulated electro-hyperthermia to the standard treatment protocols for locally advanced cervical cancer patients in state healthcare in South Africa. late toxicity and 2 year survival.

#### Material and Methods

This ongoing phase III randomised clinical trial is being conducted at the Charlotte Maxeke Johannesburg Academic Hospital. The study aims to enrol 236 female participants with FIGO stage IIB (initial distal parametrium involvement) to IIIB cervical cancer (bilateral hydronephrosis excluded). Participants are being randomised into a 'Hyperthermia' group (electro-hyperthermia plus chemoradiation) and a 'Control' group (chemoradiation alone). Randomisation stratum: HIV status, age and stage of disease. Participants in both groups are receiving 25 fractions of 2Gy external beam radiation, 3 doses of high dose rate brachytherapy (8Gy) and up to 3 doses of cisplatin (80mg/m<sup>2</sup>). Two local mEHT sessions are administered per week prior to radiotherapy in the Hyperthermia group. Local disease control is assessed by Positron Emission Tomography (PET) scans and early toxicity is graded according to the CTCAE version 4.

#### Results

We report on the interim analysis on local disease control and early toxicity of the first half of the recruited participants in our study. Early results show an improvement in local disease control with no unexpected early toxicity in the hyperthermia group.

#### Conclusion

There is a positive trend in the Hyperthermia group suggesting that the addition of hyperthermia may be beneficial in locally advanced cervical cancer patients.

### EP-1298 Radiotherapy in invasive vaginal carcinoma: a systematic review

<sup>6</sup>Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Gynecologic Oncology Unit, Rome, Italy

<sup>7</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Medical Physics Unit, Campobasso, Italy

#### Purpose or Objective

Primary vaginal carcinoma (VC) is rare, accounting for 1-2 % of all gynaecological malignancies. Being rare, most studies are retrospective and few trials are available in literature based on modern radiotherapy (RT) treatments. Therefore, aim of this analysis was to systematically review the recent literature on RT in VC to better define its role.

#### Material and Methods

From Pubmed database, a literature search strategy was performed using the PRISMA guidelines including published prospective and retrospective trials on either form of RT in invasive VC published between 2000 and 2016. Editorials, letters and case reports were excluded.

#### Results

Recorded data were number of patients, period of enrolment, median follow up, treatment characteristics and treatment outcomes. A total of 548 patients (median age 65 years) from 10 studies were analyzed based on selection criteria. Most studies were small retrospective series on patients treated between 1959 and 2014 with different methods in terms of dose, fractionation, treatment techniques, previous surgery, concurrent chemotherapy, combination with brachytherapy (BT), and evaluation modalities. Concurrent chemotherapy was used in 4 studies and 3 papers included postoperative RT. In most studies (8) external beam RT plus BT boost was used. Various RT techniques were used in 6 studies (AP/PA, box-technique, IMRT, VMAT), while in 4 studies the technique was not reported. In only 3 studies IMRT (2) or VMAT(1) were used. Acute and late grade  $\geq 3$  toxicities ranges were 2.4-17.0% and 2.4-17.8%, respectively. Median 5-year DFS was 77.3% (I-II stage; 25.0-92.4%, III-IV stage; 0.0-48.5%). Median 5-year OS was 58.4% (I- II stage; 25.2-83.7%, III-IV stage; 0.0-50.5%) with significant impact of stage on patients outcome.

#### Conclusion

Only few studies have been published in the last decade with large heterogeneity in terms of treatment characteristic and evaluation criteria. Clinical results were strongly influenced by tumor stage. Prospective studies based on advanced RT techniques are needed to better define the role of modern RT in these patients and to improve outcome in advanced stages of VC.

### EP-1299 Nomogram prediction for overall survival of patients diagnosed with cervical cancer.

S. Jagadeesan<sup>1</sup>

<sup>1</sup>Kidwai memorial institute of oncology, radiation oncology, Bangalore- Karnataka, India

#### Purpose or Objective

Nomograms are predictive tools that are widely used for estimating cancer prognosis. The aim of this study was to develop a nomogram for the prediction of overall survival (OS) in patients diagnosed with cervical cancer.

#### Material and Methods

Cervical cancer databases of our institutie were analysed. Overall survival was defined as the clinical endpoint and OS probabilities were estimated using the Kaplan-Meier method. Based on the results of survival analyses and previous studies, relevant covariates were identified, a nomogram was constructed and validated using bootstrap cross-validation. Discrimination of the nomogram was quantified with the concordance probability.

#### Results

In total, 42 consecutive patients with invasive cervical cancer, who had all nomogram variables available, were identified. Mean 5-year OS rates for patients with International Federation of Gynecologists and

Obstetricians (FIGO) stage IA, IB, II, III, and IV were 99.0%, 88.6%, 65.8%, 58.7%, and 41.5%, respectively. two cancer-related deaths were observed during the follow-up period. FIGO stage, tumour size, tumour type histologic subtype, ph, parametrial involvement, endometrial invasion and organ involvement were selected as nomogram covariates. In our study, the total bad prognostic score mean value is 12. So, we derived more than 12 as high risk, more than 10-12 as intermediate risk and; less than 10 as low risk group. Based on predictor Lin's statistic concordance index value is 0.61. The normal value of C index is  $\pm 1$ . In our study we had achieved perfect concordance index value which is suggestive of perfect nomogram.

#### Conclusion

Based on eight easily available parameters, a novel statistical model to predict OS of patients diagnosed with cervical cancer was constructed and validated. The model was implemented in a nomogram and provides accurate prediction of individual patients' prognosis useful for patient counselling and deciding on follow-up strategies

#### EP-1300 Stereotactic radiotherapy for oligometastatic ovarian cancer patients: preliminary results.

S. Ronchi<sup>1</sup>, R. Lazzari<sup>2</sup>, A. Surgo<sup>2</sup>, S. Volpe<sup>1</sup>, S. Comi<sup>3</sup>, F. Pansini<sup>3</sup>, E. Rondi<sup>3</sup>, C. Fodor<sup>2</sup>, R. Orecchia<sup>4</sup>, B.A. Jereczek-Fossa<sup>1</sup>

<sup>1</sup>Istituto Europeo di Oncologia - IEO - University of Milan, radiotherapy - Oncology and Hemato-oncology, Milan, Italy

<sup>2</sup>Istituto Europeo di Oncologia - IEO, radiotherapy, Milan, Italy

<sup>3</sup>Istituto Europeo di Oncologia - IEO, Medical Physics, Milan, Italy

<sup>4</sup>Istituto Europeo di Oncologia - IEO - University of Milan, Scientific Directorate - Oncology and Hemato-oncology, Milan, Italy

#### Purpose or Objective

To retrospectively evaluate response and toxicity of stereotactic radiotherapy (SRT) for oligometastatic ovarian cancer patients (pts).

#### Material and Methods

Between May 2012 and October 2015 we enrolled 57 adult oligometastatic ovarian cancer pts to SRT. Indication criteria were: 1) low tumor burden (1-5 lesions); 2) contraindication to salvage surgery; 3) localized persistent disease after chemotherapy (CT); 4) no CT indication due to hematological toxicity (tox); 5) no more CT lines available or refusal of the patient. Toxicity and tumor response were evaluated using CTCAE and RECIST criteria. CT or PET was performed at 2-3 months (mo.).

#### Results

57 patients/96 lesions underwent SRT. We treated 65 nodal metastases (mets) and 31 visceral mets, 72 and 24 lesions were treated with VERO™ and Cyberknife™ respectively. Median age was 60.3 years (range 45.7-81). All pts had previously received CT and/or ormonotherapy (OT). Concomitant systemic therapy was performed in 10 cases (4 CT, 6 OT). SRT consisted in re-irradiation for 8 lesions. Mean GTV was 13.2 cm<sup>3</sup> (range 0.5 - 90.05). Median dose was 24 Gy (range 16-45 Gy) in 3 fractions (range 2-5). Median follow-up (FU) was 20.9 months (mo.) (range 3.2 - 48.7). Radiological response at first FU (evaluable for 87 lesions) was: complete response, partial response, stabilization and progressive disease (PD) in 52 (59.8%), 18 (20.7%), 12 (13.8%) and 5 (5.7%) lesions, respectively. At last FU (available for 55 pts), 16 pts were alive with no evidence of disease, 26 alive with disease, 13 pts died of disease. Acute and late tox were low: 13 G1 and 12 G1-events (predominantly gastrointestinal), respectively. Pattern of failure was mainly out field (PD out field, in field, in and out field in 41, 3, and 1 cases

respectively). Local control at last FU was observed in 76/87 evaluable lesions (87.4%). Median local progression free survival was 10.6 mo. (range 3.1 - 33.4). Median progression free survival was 3.9 mo. (range 1.5 - 29).

#### Conclusion

In our experience, SRT in oligometastatic ovarian cancer pts has shown excellent local control and toxicity profile. It might be a good alternative to other more invasive local therapies in order to delay systemic therapy especially when temporarily contraindicated, not tolerated, or in chemorefractory disease. The evaluation of site and volumes treated is ongoing. Longer FU and further studies are needed to identify which subgroup of patients may most benefit from this treatment.

#### EP-1301 Early toxicity for image guided adaptive radiochemotherapy including brachytherapy in cervix cancer

K. Majercakova<sup>1</sup>, D. Najjari<sup>2</sup>, M. Buschmann<sup>1</sup>, A. Sturdza<sup>2</sup>, E. Dörr<sup>1</sup>, R. Pötter<sup>2</sup>, D. Georg<sup>2</sup>, Y. Seppenwoolde<sup>1</sup>

<sup>1</sup>Medical University of Vienna, Christian Doppler Laboratory for Medical Radiation Physics for Radiation Oncology, Vienna, Austria

<sup>2</sup>Medical University of Vienna, Department of

Radiotherapy, Vienna, Austria

#### Purpose or Objective

Advanced treatment for locally advanced cervical cancer consists of external beam radiotherapy (EBRT), concurrent Cisplatin combined with Image Guided Adaptive Brachytherapy (IGABT). Recently EBRT adaptive radiotherapy (ART) based on library of plans was implemented in our department for patients with large cervix-uterus motion.

Acute side effects associated with chemo start usually in the first stage of EBRT when the full dose is not yet reached. In the last stage of treatment, combination with IGABT may accelerate toxicity.

#### Material and Methods

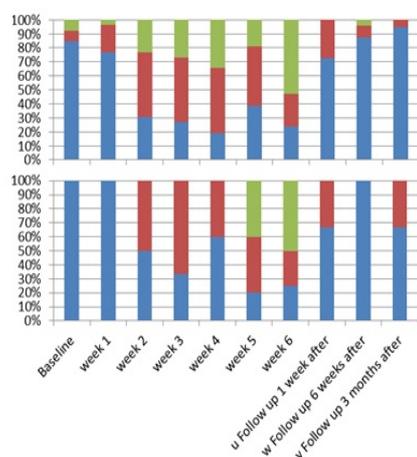

The objective of this study was to evaluate sensitivity, variability and dose-volume correlations of several general, gastrointestinal (GI) and genitourinary (GU) symptoms. These were assessed weekly during treatment and at 3 time points after treatment. A prospective study was performed on 21 non-adaptive EBRT (two 3D-CRT and 19 VMAT) and 5 VMAT ART patients. GI and GU symptoms were evaluated according to CTCAE 4.03.

#### Results

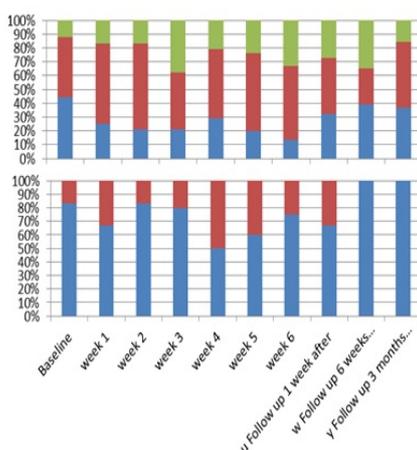

Most parameters did not show much variation throughout treatment and between patient groups. Weight loss showed a slow onset in the first 3-4 treatment weeks and increased after the first IGABT.

The most sensitive GI parameters were stool consistency and diarrhea that were worst in the 3<sup>rd</sup> and 4<sup>th</sup> week of treatment for non-adaptive EBRT patients and had a little later onset for ART patients. For patients treated with Cisplatin, weight loss in the 3-4<sup>th</sup> week of treatment correlated with the irradiated volume to 43Gy ( $\pm 1$  kg weight loss for every 500cc irradiated to more than 1250cc) in combination with severity of vomiting and diarrhea as secondary multivariate components. From the GU toxicity only nighttime micturition seemed to be less for the ART patients. This might be confounded by the coincidence that those patients had a better baseline function to start with and had on average 100 ml more volume in their bladder during the treatment course. Bladder incontinence was worst 6 weeks after treatment and did not correlate with planned EBRT dose volumes. Bladder volumes varied largely throughout the EBRT treatment. The incidence of other side effects like proctitis and cystitis was limited. More patient data is needed to assess the time course.

Time course and severity of diarrhea for non-adaptive EBRT (left panel; n=21) and ART patients (right panel; n=5) according to CTC 4.03; Blue: G1, Red: G2, Green: G3.

Time course and severity of nighttime micturition for non-adaptive EBRT (upper panel; n=21) and ART patients (lower panel; n=5), Blue 0-1x, Red 2-3x, Green: 4-7x.

## Conclusion

Interference of the three different treatment modalities makes it very difficult to unravel dose-effect relations for this patient group. Internal motion of the organs could have induced mismatches between planned and irradiated EBRT dose.

Despite interplay effects of Cisplatin and IGABT, we found some trends i.e. correlation of early weight loss with body V43Gy, severity of vomiting and diarrhea. Consequently, rescanning for the ART patient group is now rescheduled to week 4, to adapt EBRT to reduced body volume if necessary.

For GU toxicity, we recommend the combination of daily bladder volume during EBRT and IGABT to be assessed with non-rigid analyses in a larger patient group.

**EP-1302 Acute toxicity of prophylactic para-aortic chemoradiation for cervical cancer treated in IMAT era**  
N. Ballari<sup>1</sup>, B. Rai<sup>1</sup>, R. Miriyala<sup>1</sup>, A. Bahl<sup>1</sup>, B.R. Mittal<sup>2</sup>, S. Ghoshal<sup>1</sup>

<sup>1</sup>Post Graduate Institute of Medical Education and Research, Radiotherapy and Oncology, Chandigarh, India

<sup>2</sup>Post Graduate Institute of Medical Education and Research, Nuclear Medicine, Chandigarh, India

## Purpose or Objective

Prophylactic paraaortic irradiation is being increasingly advocated for patients of locally advanced cervical cancer. Up to 25% of patients with FDG avid pelvic lymph nodes harbor micro-metastases in paraaortic lymph nodes, corroborating the postulated benefit of prophylactic paraaortic irradiation. However, acute toxicity was a major limiting factor when 2-dimensional extended field radiotherapy planning was used with concurrent cisplatin. With the use of intensity modulated radiotherapy (IMRT) in the form of intensity modulated arc therapy (IMAT), doses to organs at risk could be successfully reduced, limiting the treatment related toxicities. The purpose of our study was to prospectively evaluate the tolerance and acute toxicity in patients of locally advanced cervical cancer undergoing prophylactic extended field paraaortic irradiation by IMAT, with concurrent cisplatin.

## Material and Methods

Patients of FIGO stage IIB-IIIB cervical cancer with FDG avid pelvic lymph nodes, were prospectively accrued between 2014 and 2016. All patients received 45 Gy in 5 weeks to pelvic and paraaortic target volumes, with simultaneous integrated boost (SIB) of 55 Gy in 5 weeks to gross nodal disease by IMAT (Rapida<sup>TM</sup>), with weekly concurrent cisplatin of 40 mg/m<sup>2</sup>, followed by intracavitary brachytherapy. Acute toxicity was monitored twice a week, using CTCAE v 4.03 for gastrointestinal (GI) and genitourinary (GU) toxicity, and RTOG criteria for hematological toxicity. Treatment interruptions were taken as a surrogate for tolerance. Descriptive statistics were used to evaluate acute toxicities; multivariate analysis was used to correlate the toxicities with doses to organs at risk.

## Results

Out of the 15 patients recruited, treatment interruptions due to acute toxicity were observed in none. No grade 3 or 4 acute toxicity was reported in GI, GU or hematological domains.

Among GI toxicities, vomiting and diarrhea of  $\geq$  grade 2 were observed in 13.3%, while nausea, anorexia and dyspepsia of  $\geq$  grade 2 were observed in 6%. Grade 1 proctitis was reported in 26%, while none had  $\geq$  grade 2 proctitis.

Only 6% of patients experienced grade 1 GU toxicity in the form of increased frequency and cystitis, while none had  $\geq$  grade 2 toxicity. Hematological toxicity in the form of  $\geq$  grade 2 anemia was observed in 46%, while 13.3% of patients had  $\geq$  grade 2 leucopenia and 6% had  $\geq$  grade 2 thrombocytopenia.

On multivariate analysis, significant correlation was observed between volume of bowel bag receiving 45 Gy (median, 142 cc) and  $\geq$  grade 2 vomiting (p=0.003). Other dosimetric correlates of toxicity were statistically insignificant.

## Conclusion

Extended field prophylactic para-aortic irradiation with concurrent cisplatin is well tolerated in patients of locally advanced cervical cancer with FDG avid pelvic lymphnodes, treated with IMAT. While none of our patients experienced grade 3 or grade 4 toxicities in GI, GU or hematological domains, proportion of  $\geq$  grade 2 toxicities was within acceptable levels.

**EP-1303 Clinical outcomes of patients with advanced cervical cancer and percutaneous nephrostomy : An audit**

R. Salunkhe<sup>1</sup>, S. Chopra<sup>1</sup>, S. Kulkarni<sup>2</sup>, R. Engineer<sup>1</sup>, U. Mahantshetty<sup>1</sup>, N. Shetty<sup>2</sup>, J. Ghosh<sup>3</sup>, S. Gupta<sup>3</sup>, S.K. Shrivastava<sup>1</sup>

<sup>1</sup>Tata Memorial Hospital, Radiation Oncology, Mumbai, India

<sup>2</sup>Tata Memorial Hospital, Interventional Radiology, Mumbai, India

<sup>3</sup>Tata Memorial Hospital, Medical Oncology, Mumbai, India

#### Purpose or Objective

To determine outcomes of patients with locally advanced cervical cancer who presented with deranged renal functions necessitating urinary diversion with Percutaneous Nephrostomy (PCN) before and during course of pelvic radiation

#### Material and Methods

The retrospective audit was approved by institutional review board. The hospital database from January 2010-June 2015 was reviewed to identify patients with locally advanced cervical cancer and deranged serum creatinine at baseline. Patients wherein PCN was advised at baseline or during treatment were selected for this audit. Pretreatment patient, tumour and treatment related factors that impacted choice of treatment and overall survival in patients undergoing PCN were analysed using univariate and multivariate analysis

#### Results

Over a 5 year study period, 128 patients with primary or recurrent cervical cancer underwent PCN. Of these 56 (44%) underwent PCN before and during treatment and 60 patients (44%) received PCN after completion of primary treatment within the setting of local or distant recurrence that necessitated systemic chemotherapy. Overall 12 (9%) patients did not receive any treatment after PCN due to anticipated poor tolerance. Median serum creatinine before and after a week of PCN was 3.8mg/dl (0.4-7.4) and 1.6 mg/dl (0.6-1.7). Median hospital stay was 13 days(4-67). Overall 62.5% patients developed procedure related urinary infection following PCN and 8% patients died secondary to infective complications.

Of the 56 patients that received PCN before treatment, 54 received either radical (n=31) or palliative radiation (n=23). Of those planned for radical radiation, 34 were stage III, 15 were Stage IV with median tumour size of 4.5 cms. Only 16/54 patients could complete planned concurrent chemoradiation (29%). Median survival for the cohort undergoing PCN prior to treatment was 205 days (7-369) For 16 patients that completed radical chemoradiation the median survival was 254 days (107-380) and 18/54 for those receiving palliative radiation was 146 days (41 - 146). On univariate analysis restricted to cohort of patients receiving radiation Karnofsky performance score <70 at time of PCN (p=0.005), Serum creatinine >3mg/dl (p=0.004), post procedure infection (p=0.002) were factors for poor outcomes of procedure.

#### Conclusion

Conclusion - There is significant fall in serum creatinine and improvement in renal function occurs after percutaneous nephrostomy. Yet the median survival was dismal and patients had considerable procedure related morbidity further adding to the duration of hospital stay. Careful selection of patients to undergo percutaneous nephrostomy is important for the success of the procedure

#### EP-1304 A moderate ipofractionation schedule with IMRT in preoperative locally advanced cervical cancer

R. Autorino<sup>1</sup>, M. Campitelli<sup>1</sup>, A. Martino<sup>1</sup>, A. Nardangeli<sup>1</sup>, G. Mattiucci<sup>1</sup>, V. Frascino<sup>1</sup>, D. Smaniotto<sup>1</sup>, A. Valentini<sup>2</sup>, G. Ferrandina<sup>3</sup>, M. Gambacorta<sup>1</sup>

<sup>1</sup>Polyclinic University A. Gemelli- Catholic University, Institute of Radiotherapy, Rome, Italy

<sup>2</sup>Polyclinic University A. Gemelli- Catholic University, Institute of Radiology, Rome, Italy

<sup>3</sup>Polyclinic University A. Gemelli- Catholic University, Institute of Oncological Gynecology, Rome, Italy

#### Purpose or Objective

To analyze the efficacy and tolerability of intensity modulated radiation therapy (IMRT) simultaneous

integrated boost (SIB) associated to cisplatin based chemotherapy. in preoperative setting of patients with locally advanced cervical cancer

#### Material and Methods

From September 2014 to December 2015, we analyzed patients with locally advanced cervical cancer undergone to neoadjuvant intensity-modulated extended-field chemoradiation plus simultaneous integrated boost. A radiation dose of 39.6 Gy, 1.8 Gy/fraction, was delivered to the pelvis plus a radiation dose to the primary tumor delivered with SIB-IMRT strategy for a total of 50.6 Gy, 2.3 Gy/fraction in 25 fractions. Cisplatin based chemotherapy was delivered associated to radiotherapy. Radical hysterectomy plus pelvic with or without aortic lymphadenectomy was performed within 6 to 8 weeks from CRT. Statistical analysis was performed using Systat program.

#### Results

29 patients (median age: 52 years; The International Federation of Gynecology and Obstetrics (FIGO) stage IB2: 1, IIB: 19, IIIA: 1; IIIB: 5; IVA: 3) were analyzed. The treatment was well tolerated with a good compliance: no patients had grade 3/4 gastrointestinal or genitourinary toxicity; grade 3 leukopenia and neutropenia were reported in only 1 case (stage FIGO IVA) without interruption of the treatment. pCR was documented in 15 cases (51%) and 4 patients (13%) had a microscopic residual disease (persistent tumor foci of 3 mm maximum dimension). At median follow-up of 12.5 months (range: 7-19 months), the 1-year local control was 95%, whereas the 1-year disease-free and overall survival rates were 95% and 100%, respectively.

#### Conclusion

The treatment was globally well tolerated with a good compliance. Results in terms of efficacy were comparable with literature data. Local control and overall survival will be further evaluated with a longer follow-up.

#### EP-1305 Hemoglobin monitoring in Endometrial Carcinoma: how preoperative anemia impacts overall survival.

K. Holub<sup>1</sup>, A. Biete<sup>1</sup>

<sup>1</sup>Hospital Clinic i Universitari de Barcelona, Radiation Oncology Dpt., Barcelona, Spain

#### Purpose or Objective

To investigate the hematological parameters for anemia in relation to survival in endometrial carcinoma (EC) and to audit hemoglobin (Hb) monitoring before, during and after radiotherapy.

#### Material and Methods

We retrospectively evaluated 233 patients (p) out of a total cohort of 248p diagnosed with EC and treated with radiotherapy (RDT) in our center between January 2011 and December 2015. We analyzed the presence of anemia defined as Hb<12g/dL in four specific intervals: pre-treatment (Hb), before RDT(Hb2), during (Hb3) y after RDT (Hb4). We estimated how many patients with basal Hb<12g/dL were monitored for anemia afterwards and if pretreatment Hb level has prognostic value for Overall Survival (OS). Statistics: Ch2, Kaplan-Meier test, T-test.

#### Results

Age at diagnosis (years): mean 64.9 (range 36-90). All patients underwent surgery before RDT, with pelvic lymphadenectomy in 187p (80.3%). Histology: endometrioid 172p(73.8%), non-endometrioid 61p(26.2%). FIGO stage (2009): IA-60p (27.8%), IB-92p(39.5%), II-32p(13.7%), IIIA-9p(3.9%), IIIB-0, IIIC1-20(8.6%), IIIC2-8(3.4%), IVA-9(3.9%), IVB-3(1.3%). Grade: I-50p(21.5%), II-91p(39%), III-88p(37.8%). Majority of patients was treated with combination of EBRT+BT (mean dose 41.2 Gy, range 5-75). Mean follow-up (months): mean 32. Progression was observed in 40p (17.2%): only 1p developed pelvic node

recurrence, 39p developed distant recurrence (4p with vaginal progression, 3p with regional progression and 1p with both vaginal and regional progression, remaining 31p presented exclusively distant progression). Mortality: 31p (13.3%), including 28p (12%) cancer-deaths and 3deaths (1.3%) not related with EC. Remaining 202p were alive (11p in progression status and 191p with no evidence of disease). Anemia monitoring: only 36p (53.7%) of 67p with anemia detected before RDT, underwent subsequent Hb control (during or after RDT). Only 27p of 67p with anemia were previously treated with chemotherapy (40p were anemic with no systemic treatment). Differences between mean Hb levels were statistically significant for Hb1-Hb2 ( $p=,00$ ), Hb1-Hb4 ( $p=,005$ ), Hb3-Hb4 ( $p=,004$ ) and Hb2-Hb4 ( $p=,001$ ).

Patients with pre-treatment Hb level  $<12g/dL$  presented worse overall survival ( $p=,021$ ,  $Chi2$  5.3), with mean OS of 53.39 months (range 45.5-61.3) vs. 61.4 (range 58.4-64.4) in patients with  $\geq 12g/dL$ . **Conclusion**

Despite evidence that anemia is frequent in patients with endometrial carcinoma and determine OS, the follow-up of anemia in cancer patients is still suboptimal. There is a strong need of guidelines for anemia monitoring in cancer patients.

#### EP-1306 New pre-treatment eosinophiles-related ratios as predictive factors for OS in endometrial carcinoma.

K. Holub<sup>1</sup>, A. Biète<sup>1</sup>

<sup>1</sup>Hospital Clínic i Universitari de Barcelona, Radiation Oncology Dpt., Barcelona, Spain

#### Purpose or Objective

To analyze the influence eosinophil levels in prognosis of endometrial carcinoma.

#### Material and Methods

We retrospectively evaluated 233 patients (p) out of a total cohort of 248p diagnosed with endometrial carcinoma and treated with radiotherapy (RDT) in our center between January 2011 and December 2015. We analyzed the prognostic value of pretreatment eosinophiles as well as we described new eosinophils-related ratios in endometrial cancer: Eosinophil-to-Lymphocyte Ratio and Eosinophil\*Neutrophile-to-Lymphocyte Ratio. Statistics: Chi-square, Kaplan-Meier method.

#### Results

Age at diagnosis (years): mean 64.9 (range 36-90). All patients underwent surgery before RDT, with pelvic lymphadenectomy in 187p (80.3%). Histology: Endometrioid 172p (73.8%), non-endometrioid 61p (26.2%). FIGO stage (2009): IA-60p (27.8%), IB-92p (39.5%), II-32p (13.7%), IIIA-9p (3.9%), IIIB-0, IIIC1-20 (8.6%), IIIC2-8 (3.4%), IVA-9 (3.9%), IVB-3(1.3%). Grade: I-50p (21.5%), II-91p (39%), III-88p (37.8%). External beam radiotherapy (EBRT) dose (Gy): mean 44.2 (range 9-65). Brachytherapy (BT) dose (Gy): mean 10.2 (range 5-20). Majority of patients was treated with combination of EBRT and BT. EBRT+BT dose (Gy): mean 41.2 (range 5-75). Mean follow-up (months): mean 32 (SD 17.5). Progression was observed in 40p (17.2%): only one patient developed pelvic node recurrence, 39p developed distant recurrence (4p with simultaneous vaginal progression, 3p with regional progression and one 1p with both vaginal and regional progression, remaining 31p presented exclusively distant progression). Mortality: 31p (13.3%), including cancer-specific mortality: 28p (12%) and 3 deaths not related with endometrial cancer (1.3%). Remaining 202p were alive (11p in progression status and 191p with no evidence of disease).

Eosinophiles-related ratios	Numb in er of	Mean Cu (rang e)	Numb er of Off	Overall p (Chi event surviv 2)
-----------------------------	---------------	------------------	----------------	--------------------------------

pre-treatment analysis	patients	statistics	deaths (hs)	survival (months)
Eosinophils-to-Lymphocytes Ratio (ELR)	131	0.08 (0.0-0.31)	1 vs 3	64.0 vs 52.0 (12.0)
Eosinophiles*Neutrophils-to-Lymphocytes Ratio (ENR)	112	4.6 (1.14-12.5)	4 vs 4	63.0 vs 53.6 (5.86)

#### Conclusion

Tumor-generated inflammation is considered to be one of the principal triggers for tumor progression. Several hypotheses link eosinophilia with cancer, however until now there has not been any evidence of impact of eosinophil levels in combination with other immune cells on prognosis of cancer. To our best knowledge, this is the first publication describing and analyzing the eosinophil-related ratios as a predictive factor in cancer

#### EP-1307 New neutrophils-related ratios as a novel predictive biomarkers for endometrial carcinoma.

K. Holub<sup>1</sup>, A. Biète<sup>1</sup>

<sup>1</sup>Hospital Clínic i Universitari de Barcelona, Radiation Oncology Dpt., Barcelona, Spain

#### Purpose or Objective

To analyze the influence of neutrophils, lymphocytes, monocytes and platelet-related disorders in pre-treatment blood analysis on prognosis of endometrial carcinoma.

#### Material and Methods

We retrospectively evaluated 233 patients (p) out of a total cohort of 248p diagnosed with endometrial carcinoma and treated with radiotherapy (RDT) in our center between January 2011 and December 2015. We analyzed the prognostic value of pretreatment neutrophils and lymphocytes levels as well as Neutrophil-to-Lymphocyte ratio (NLR), Platelet-to-Lymphocyte ratio (PLR), Lymphocyte-to-Monocyte ratio (LMR) and Platelet\*Neutrophil-to-Lymphocyte ratio (Systemic Immune-Inflammation Index, SII) in endometrial cancer. Statistics: Chi2, Kaplan-Meier method.

#### Results

Age at diagnosis (years): mean 64.9 (range 36-90). All patients underwent surgery before RDT, with pelvic lymphadenectomy in 187p (80.3%). Histology: endometrioid 172p (73.8%), non-endometrioid 61p (26.2%). FIGO stage (2009): IA-60p (27.8%), IB-92p (39.5%), II-32p (13.7%), IIIA-9p (3.9%), IIIB-0, IIIC1-20 (8.6%), IIIC2-8 (3.4%), IVA-9 (3.9%), IVB-3(1.3%). Grade: I-50p (21.5%), II-91p (39%), III-88p (37.8%). Majority of patients was treated with combination of EBRT and BT. EBRT+BT dose (Gy): mean 41.2 (range 5-75), median 52. Mean follow-up (months): mean 32 (SD 17.5). Progression was observed in 40p (17.2%): only one patient developed pelvic node recurrence, 39p developed distant recurrence (in 4p with simultaneous vaginal progression, 3p with regional progression and one 1p with both vaginal and regional progression, remaining 31p presented exclusively distant progression). Mortality: 31p (13.3%), including cancer-specific mortality: 28p (12%) and 3 deaths not related with endometrial cancer (1.3%). The remaining 202p were alive (11p in progression status and 191p with no evidence of disease). Neutrophils-related ratio were calculated as follows: NLR-absolute neutrophil count/absolute lymphocyte count, PLR-platelet count/ absolute lymphocyte count, LMR-absolute lymphocyte

count/absolute monocyte count/lymphocyte count. and SII -

Hemogram parameters in pre-treatment blood analysis	Number of patients	Mean (range)	Cut-Offs	Number of events (deaths)	Overall survival (months)	p (Chi2)
Lymphocyte-to-Monocyte ratio (LMR)	112	4.6 (1.14-12.5)	<5.0 vs ≥5.0	8 vs 2	56.5 vs 63.8	.036 (4.42)
Neutrophil-to-Lymphocyte ratio (NLR)	131	3.8 (0.11-22.6)	<2.5 vs ≥2.5	5 vs 10	63.5 vs 56.3	.008 (7.1)
Platelet-to-Lymphocyte ratio (PLR)	129	160 (11.8-647.0)	<30 vs ≥30	9 vs 3	61.5 vs 33.0	.0001 (3.4)
Platelet*Neutrophils-to-Lymphocyte (SII)	129	906.5 (27.2-5094.3)	<20 vs ≥20	9 vs 3	61.4 vs 40.9	.003 (9.1)

#### Conclusion

Preoperative NLR, LMR, PLR and SII are predictive factors for Overall Survival in endometrial carcinoma. To our knowledge, this is the first publication describing predictive value of SII in endometrial carcinoma.

#### Electronic Poster: Clinical track: Prostate

#### EP-1308 A prospective trial of hypofractionation salvage radiation therapy after radical prostatectomy

P. Bulychkin<sup>1</sup>, S. Tkachev<sup>1</sup>, A. Nazarenko<sup>1</sup>

<sup>1</sup>Federal State Budgetary Institution "N. N. Blokhin Russian Cancer Research Center"- the Ministry of Health of the Russian Federation, Department of radiation oncology, Moscow, Russian Federation

#### Purpose or Objective

to estimate and compare local control (LC), disease-free survival (DFS), overall survival (OS) and toxicity of hypofractionation (HF) and classical fractionation (CF) salvage radiation therapy (SRT) in treatment of patients with biochemical and clinical recurrences of prostate cancer (PCa) after radical prostatectomy (RP).

#### Material and Methods

patients with biochemical and clinical recurrences of PCa after RP were divided in two groups. The first one is a group of patients who were treated by HF SRT. HF radiotherapy have been prescribed to the regional lymphatic nodes to 46.8 Gy of 1.8 Gy, to the prostate bed to 61.1 Gy of 2.35 Gy and to recurrent lesions detected by multi-parametric magnetic resonance imaging (MRI) 65 Gy of 2.5 Gy in 26 fractions using simultaneous integrated boost (SIB). The second one is a group of patients who were treated by CF SRT. CF radiotherapy have been prescribed to the regional lymphatic nodes to 44 Gy, to the prostate bed to 66 Gy and if region of clinical recurrence identified to 72 Gy in 33 - 36 fractions.

#### Results

median follow up for all 92 patients was 40 (12 - 78) months. OS - 100%. LC - 100%. The rates of 1, 2 and 3 year DFS were 96 %, 91 % and 86 %. The rates of 1, 2 and 3 year DFS were 98%, 95 % and 89 % in group of patients who were treated by HF SRT. The rates of 1, 2 and 3 year DFS were 95%, 87% and 84% in group of patients who were treated by CF SRT. We have not received statistical significance in

DFS between the two groups (p = 0.125). On multivariate analysis, PSA doubling time ≤ 6 months (p = 0.035) and PSA > 0.5 ng/ml before SRT (p = 0.037) statistical significance associated with biochemical failure. We received a trend to an increase number of patients with symptoms acute gastrointestinal (GI) (p = 0.057) and genitourinary (GU) (p = 0.07) toxicities 2 grade in the group of HF SRT. But we have not received statistical significance in late (3 and more months) GI and GU toxicities between two groups.

#### Conclusion

post-prostatectomy SRT, when using CF, requires 33 - 36 fractions. We would like to suggest a new differentiated approach of hypofractionation radiotherapy for patients with recurrence PCa after RP which demonstrates encouraging efficacy at 3 years without increasing level of late toxicities and reduces the length of treatment by from 21% - 28%.

#### EP-1309 Is it necessary to make a re-plan during IMRT for prostate cancer due to change in prostate size?

O. Tanaka<sup>1</sup>, H. Komeda<sup>2</sup>, T. Iida<sup>1</sup>, M. Tamaki<sup>2</sup>, K. Seike<sup>2</sup>, T. Yokoyama<sup>1</sup>, D. Kawaguchi<sup>1</sup>, S. Hirose<sup>1</sup>, S. Fujimoto<sup>2</sup>

<sup>1</sup>Gifu Municipal Hospital, Department of Radiation Oncology, Gifu, Japan

<sup>2</sup>Gifu Municipal Hospital, Department of Urology, Gifu, Japan

#### Purpose or Objective

Intensity-modulated radiotherapy (IMRT) is a widely used treatment modality for prostate cancer. The technique helps deliver the prescribed dose to the target volume with minimal radiation exposure of the organs at risk (OAR).

Gunnlaugsson et al. reported a significant increase in mean prostate volume (14%) at mid-point of the radiotherapy course as compared to that at baseline. The increase in mean prostate volume tended to persist during the radiotherapy course; the mean prostate volume at the completion of the radiotherapy was 9% higher than that at baseline. The increase in prostate volume was most pronounced in the anterior-posterior and cranio-caudal axes.

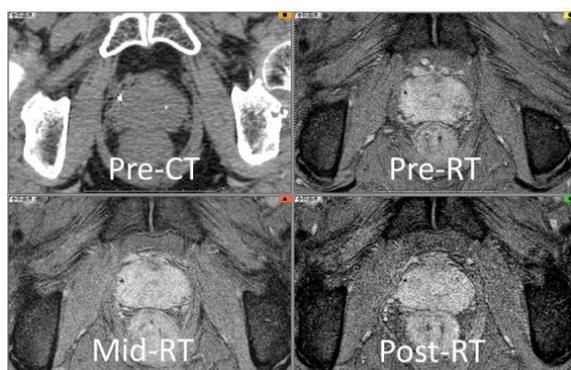

However, most of the data used emanated from studies conducted in Europe and America, while data based on Asian population has been largely lacking. Tanaka et al. measured prostatic size prior to prostate cancer brachytherapy and reported mean prostate volume of approximately 16 cc (including data from patients who had received neoadjuvant hormonal therapy). The implications of change in prostate size for IMRT planning in patients with small prostate glands are not known. Therefore, we evaluated the relatively small changes in size of prostate during IMRT using MRI.

#### Material and Methods

A total of 24 consecutive patients with prostate cancer were enrolled in the study. None of the patients received hormone treatment (neoadjuvant therapy) either prior to or during the course of radiotherapy. Two gold fiducial markers were placed on the prostate before a CT/MRI examination at 3 weeks. MR imaging was performed at three timepoints. The initial MRI was performed prior to the start of radiotherapy. Second MRI was performed at 38 Gy (range: 36-40 Gy), which represented the halfway point of the radiotherapy course. The last MRI was performed at the completion of the radiotherapy course.

An example of the time course of prostate volume change.

Figure 1

## Abbreviations,

Pre-CT; pre-radiotherapy computed tomography; Pre-RT, baseline Magnetic Resonance Imaging (MRI); Mid-RT, MR image at mid-point of the radiotherapy course (about 38 Gy); Post-RT, MR image at completion of the radiotherapy course.

## Results

There was no significant difference between the estimated sizes of prostate during RT in all phases. A retreatment plan was well implemented in all patients.

Table 1

Mean prostate volume at the three study time-points: pre-radiotherapy, mid-radiotherapy and post-radiotherapy

	Pre-RT	Mid-RT	Post-RT	BT
Mean volume of prostate	38	36.9	38.3	33
SD	17.4	20	19.2	16.7

Abbreviations: SD, standard deviation; Pre-RT, pre-radiotherapy; Mid-RT, median time to take MRI and CT examinations (36 Gy, range 34–38 Gy);

Post-RT, completion of radiotherapy (total dose: 74–78 Gy);

BT, brachytherapist, a BT (having 15 years of experience) contoured the prostate using post RT MRI after being blinded to the information.

## Conclusion

In this study, no significant change in prostate size was observed during the course of IMRT. On revising the radiation plan according to change in prostate size, no significant difference with respect to clinical outcomes associated with the use of a revised plan was observed. The mean prostate volume in our study population was 37 cc. The relatively smaller prostate may have led to this result.

EP-1310 <sup>68</sup>Ga-PSMA-PET/CT imaging of localized prostate cancer patients for IMRT with integrated boost

L. Thomas<sup>1</sup>, S. Kantz<sup>2</sup>, A. Hung<sup>1</sup>, D. Monaco<sup>1</sup>, M. Essler<sup>3</sup>, H. Strunk<sup>4</sup>, C. Thomas<sup>1</sup>, W. Laub<sup>1</sup>, R. Bundschuh<sup>3</sup>  
<sup>1</sup>Oregon Health & Science University, Department of Radiation Oncology, Portland, USA

<sup>2</sup>LMU Klinikum der Universität München, Klinik und Poliklinik für Strahlentherapie und Radioonkologie, Munich, Germany

<sup>3</sup>Universitätsklinikum Bonn, Nuklearmedizinische Klinik und Poliklinik für Nuklearmedizin, Bonn, Germany

<sup>4</sup>Universitätsklinikum Bonn, Radiologische Klinik, Bonn, Germany

## Purpose or Objective

The purpose of our study was to show the potential benefits of using <sup>68</sup>Ga-PSMA-PET/CT imaging for integrated boost treatment planning or boost only treatment planning of prostate cancer patients. The potential gain of such an approach is the improvement of tumour control and reduction of the dose to organs at risk at the same time.

## Material and Methods

21 prostate cancer patients (70yrs average) without previous local therapy received <sup>68</sup>Ga-PSMA-PET/CT imaging. Body contour and organs at risk were manually defined on the obtained datasets. A PTV70 and PTV5920 were defined as planning target volumes. A PET active volume GTV<sub>PET</sub> was segmented with a 40% of the maximum activity uptake in the lesion as threshold. Five different treatment plan variations were calculated for each patient (Monaco, Version 5.11.00, Elekta, St. Louis, MO) - Table 1. Analysis of derived treatment plans was done according to QUANTEC with in-house developed software. TCP (Tumor Control Probability) and NTCP (Normal Tissue Complication Probability) was calculated for *Prostate* and *ProstatePET* (TCP) as well as Rectum and bladder (NTCP). Student's t-test method was applied for statistical analysis (paired, two-sided). A p level of smaller 0.05 was considered to be statistically significant.

## Results

The median TCP of the PET-positive volume was found to be (89.9 ± 2.7) % for conventional *Prostate* plans. Comparing the conventional plans to the plans with integrated boost and plans just treating the PET-positive tumor volume, we found that the TCP increased to (95.2 ± 0.5) % for an integrated boost with 75.6 Gy, (98.1 ± 0.3) % for an integrated boost with 80 Gy, (94.7 ± 0.8) % for treatment of the PET-positive volume with 75 Gy, and to (99.4 ± 0.1) % for treating the PET-positive volume with 95 Gy (all p < 0.0001). For the integrated boost with 80 Gy, a statistically significant, but moderate increase of the median NTCP of the rectum was found. Only patients with a tumour directly adjacent to the rectum wall were found to have a significantly higher NTCP<sub>rectum</sub>. At the same time of course, these patient's median TCP of the PET-positive volume was found to be significantly improved as well, if compared to TCPs of conventional plans. For all other plan variations no statistical significant increase of the rectum or bladder NTCP was found.

## Conclusion

Our study demonstrates that the use of <sup>68</sup>Ga-PSMA-PET/CT image information would allow for more individualized prostate treatment planning and better targeting of active tumour volumes. TCP values of identified active tumour volumes can be increased, while rectum and bladder NTCP values either remain the same or are even lower for most plans. Clinical studies should be performed to confirm the theoretical benefits of PET target optimized prostate cancer treatment planning.

Table 1: different plans which were calculated for each patient.

	PTV70 [Gy]	PTV5920 [Gy]	PTV <sub>PET</sub> [Gy]	Ex
<i>Prostate</i>	70.0	59.2		28
<i>ProstatePET</i>	70.0	59.2	75.6	28
<i>PETBoost80</i>	70.0	59.2	80.0	28
<i>PETBoostOnly75</i>			75.0	28
<i>PETBoostOnly95</i>			95.0	35

## EP-1311 Beyond IMRT for Prostate Cancer: The Effect of Modern Technique on Treatment Quality and Outcome

J. Kao<sup>1</sup>, A. Zucker<sup>1</sup>, J. Timmins<sup>1</sup>, A. Wong<sup>1</sup>, A. Woodall<sup>2</sup>, E. Loizides<sup>2</sup>

<sup>1</sup>Good Samaritan Hospital Medical Center, Radiation

*Oncology, West Islip, USA*

<sup>2</sup>*Good Samaritan Hospital Medical Center, Urology, West Islip, USA*

#### **Purpose or Objective**

Radiation technique for prostate cancer has continuously evolved over the past several decades. We describe the effect of utilizing prostate MRI, implementation of strict dose-volume constraints and reducing dose to the uninvolved prostate to <80 Gy on radiation dosimetry and patient outcomes.

#### **Material and Methods**

From 1/10 to 4/12, 48 consecutive patients were treated with standard prostate IMRT (S-IMRT) to 81 Gy. From 5/12 to 4/15, 50 consecutive patients were treated with modern IMRT (M-IMRT) treating the entire prostate to 75.6 to 79.2 Gy while using prostate MRI fusion, dose volume constraints prioritizing normal tissue avoidance above PTV coverage and boosting any dominant intraprostatic masses to 79.2 to 81 Gy. We compared rectal Dmax, V75, V60, V65, V50 and bladder Dmax, V75, V70 and V65 and acute and late toxicity between the S-IMRT and M-IMRT groups.

#### **Results**

The median follow-up for the S-IMRT group was 61 months compared to 26 months (p<0.001). Patient characteristics were well matched except for a higher percentage of NCCN low risk patients in the S-IMRT group. M-IMRT resulted in a significant reduction in median rectal Dmax, rectal V75, rectal V70, rectal V65, bladder Dmax, bladder V75, bladder V70 and bladder V65 (p<0.01 for all). There was no significant difference in rectal V50. There were no significant differences in acute GI or GU toxicity. The 2-year rate of late grade >=2 rectal bleeding was 13% with S-IMRT vs. 3% with M-IMRT (p=0.03). The 2-year rate of late grade >=2 genitourinary toxicity was 11% for S-IMRT vs. 5% for M-IMRT (p=0.21). There were no differences in biochemical control or overall survival.

#### **Conclusion**

While modern MR-guided IMRT for prostate cancer requires increased resources, there is a clear benefit in terms of reduced toxicity without sacrificing disease control implying improved therapeutic ratio.

#### **EP-1312 Long terms outcome in prostate cancer with image guided and intensity modulated radiation therapy.**

C. Salas<sup>1</sup>, L. Gutiérrez<sup>1</sup>, S. Garduño<sup>1</sup>, M. Macias<sup>1</sup>, L. Ingunza<sup>1</sup>, I. Villanego<sup>1</sup>, V. Díaz<sup>1</sup>, E. Gonzalez<sup>1</sup>, L. Díaz<sup>1</sup>, A. Ureña<sup>2</sup>, L. Quiñones<sup>2</sup>, J. Jaén<sup>1</sup>

<sup>1</sup>*Hospital Universitario Puerta del Mar, Comprehensive Care Department Cancer- Radiation Oncology Service- University Hospital Puerta del Mar, Cadiz, Spain*

<sup>2</sup>*Hospital Universitario Puerta del Mar, Clinical management unit Hospital Radiophysics and Radiation Protection- University Hospital Puerta del Mar, Cadiz, Spain*

#### **Purpose or Objective**

The use of gold seeds as radiopaque fiducials (MF) intraprostatic indirectly to locate and visualize the prostate treatment with RT dose escalation, it's called Image Guided Radiation Therapy (IGRT). Combined with Intensity Modulated Radiation Therapy (IMRT), we increased technical precision and high dose to the target volume with dose limiting to the rectum and bladder (OAR).

To report long-term tumor control and late gastrointestinal (GI) and genitourinary (GU) toxicity rates in low, intermediate and high risk prostate cancer (PC) patients, treated with IGRT with fiducial markers and IMRT.

#### **Material and Methods**

Between January 2012 and April 2015, 104 men with PC (T1c-T3a), prostate-specific antigen [PSA] 5-20 ng/dL, or Gleason score [GS] 6 and 7, received normofractionated external radiation therapy and IGRT. 30% received short androgen deprivation (AD) and 70% without AD. The dose was 76 Gy at least 98% the planning target volume in 38 (2 Gy) daily fractions, using IMRT with 6 Mv. Daily image guidance of the prostate was performed with two Electronic Portal Imaging Device (EPID) (antero-posterior and lateral) by automatic matching of the four fiducial markers, in ONCOR. Planning target volume was defined as prostate ± seminal vesicles with 7-mm. margin, except 5-mm. in rectal. Constraints: rectum V70<10%, V50<50%; bladder V70<35%, V65<50%. Biochemical failure was defined according to Phoenix criteria (nadir + 2ng/dL). Follow-up was every 6 months during first 3 years and annually thereafter. GI and GU toxicity were prospectively assessed and scored according to the Radiation Therapy Oncology Group (RTOG).

#### **Results**

Median follow-up was 43 months (range 36-48). Median age was 69 years (range 52-79); 12% had a Gleason score (GS) of 7 and 88% GS of 6. Median initial PSA was 7.8 ng/dL (range 3.6 -19 ng/mL), 79% had low, 15% intermediate and 6% high risk. One patient developed biochemical failure; one patient developed bone metastases, 3 patients died from other causes. Four-year actuarial biochemical recurrence-free, cancer-specific, and overall survival rates were 98%, 98%, and 95%, respectively. The worst grade 2-3 GU or GI late toxicity was 3% and 1%, respectively. At the last follow-up, grade 2-3 late GI and GU toxicity rates were 1% for both groups. No grade 4 or 5 late toxicity occurred.

#### **Conclusion**

IGRT with intraprostatic fiducial markers and IMRT for PSA< 20 ng/ml prostate cancer, is associated with excellent long-term biochemical control with very low late GU and GI toxicity.

#### **EP-1313 18 F NaF PET use in prostate cancer staging in a single centre 2013-2016: retrospective review**

M. Higgins<sup>1</sup>, J. Murphy<sup>2</sup>, K. Nugent<sup>3</sup>, K. O'Regan<sup>2</sup>, P. Kelly<sup>3</sup>

<sup>1</sup>*Cork University Hospital- Cork- Ireland, Radiation Oncology, Dublin, Ireland*

<sup>2</sup>*Cork University Hospital- Cork- Ireland, Radiology, Cork, Ireland*

<sup>3</sup>*Cork University Hospital- Cork- Ireland, Radiation Oncology, Cork, Ireland*

#### **Purpose or Objective**

NaF PET/CT has been in use at Cork University Hospital in staging prostate cancer since March 2013. Its advantage is increased sensitivity and specificity in detecting bone metastases compared with Tc<sup>99m</sup> bone scintigraphy. The detection of occult bone metastases may result in changes to treatment recommendations with potentially significant impact on patient quality of life. Our aim was to assess the impact of NaF PET CT on treatment decisions in our regional cancer centre.

#### **Material and Methods**

A retrospective analysis was performed of NaF PET/CTs undertaken at the PET/CT Unit at CUH from March 2013 to March 2016. Imaging studies on the Picture Archiving and Communication System (PACS) as well as electronic and paper-based patient records were reviewed

#### **Results**

43 NaF PET/CTs were performed on 39 men with prostate cancer in CUH between 20<sup>th</sup> March 2013 and 31<sup>st</sup> March 2016. Indications for NaF PET/CT included:

1. Initial staging of newly diagnosed prostate cancer, mainly with high grade disease (Gleason 8-10) or

discordant standard staging studies (Tc99 bone scan, MRI, CT) [Group 1]

2. Prior treatment and suspected first osseous metastasis [Group 2]

3. Suspected progression of osseous metastatic disease with negative/indeterminate standard imaging [Group 3]

The outcomes of 42 completed NaF PET/CT studies are outlined in Table 1. One patient underwent a NaF PET/CT for staging of an unknown primary.

#### Results

Outcome:	Group 1 N=16	Group 2 N=19	Group 3 N=7	Total N=42
Positive	8	11	7	26
Negative	8	8	0	16
NaF Changed Management	11 (69%)	9 (47%)	5 (71%)	25 (60%)

#### Conclusion

Accurate staging by way of adjunctive imaging is important in the newly diagnosed patient cohort to aid decisions regarding suitability for prostatectomy or radical radiotherapy. Advanced staging beyond CT TAP and bone scan is becoming more important in the metastatic setting as more treatments become available. Determining the burden of metastatic disease to direct treatment is also of great importance.

Our figures showed that NaF PET CT changed the management of 60% of patients overall. A recurring theme, particularly in groups with first suspected osseous metastases or suspected progression of known osseous metastases, was that although NaF PET CT was successful in finding more osseous metastases, oftentimes patients were either not fit for, or refused, further treatment. In addition a number of patients had already commenced chemotherapy, ADT or hormonal therapy prior to NaF PET CT, often based on rising PSA level. In a significant number of cases also patients did not have up to date standard staging i.e. bone scan and/or CT thorax abdomen pelvis within three months of NaF PET, which may have sufficed instead of advanced imaging in certain cases.

NaF PET/CT is a useful additional imaging investigation in clarifying the presence or absence of bone metastases in scenarios of diagnostic uncertainty and it aided the decision-making process regarding further therapeutic strategies. However, care needs to be taken to use advanced imaging in those where there is diagnostic uncertainty and where treatment options still exist.

#### EP-1314 Changes in hormonal therapy during the first 24 months of treatment: a longitudinal cohort study

#### Purpose or Objective

Data are limited showing changes in patients' use of androgen deprivation therapy (ADT) in routine clinical practice. The objective of the study was to describe the number and type of modifications of ADT during the first 24 months of treatment.

#### Material and Methods

In this non-interventional, longitudinal cohort study, we assessed the number and type of modifications of ADT during the first 24 months of treatment in France. At baseline and every 6 months, we collected clinical, biological and therapeutic data and any changes of ADT modality.

#### Results

Between July 2011 and January 2015, 891 pts were evaluable at 24 months. Mean age was 74.1±8.7 years. Indications for ADT were: biochemical relapse after local treatment (21.4%), adjuvant to radiotherapy (RT) (31.6%), metastases (24.2%) and locally advanced tumour without local treatment (20.6%). Gleason score was >7, 7(4+3), 7(3+4) and <7 in 33.6%, 23.1%, 26% and 17.3%, respectively. For the subgroup treated with ADT adjuvant to RT (279 pts), mean age was 71.4±6.9 yrs, and 72.8% had at least one comorbidity. Gleason score was >7, 7(4+3), 7(3+4) et <7 in 28.2%, 23.5%, 32.5% and 15.9% of pts respectively. At 24 months, modification of ADT was reported by 43.8% of the whole population and by 37.6% of the subgroup treated with ADT adjuvant to RT. The main types of modification (% of whole population) concerned the formulation (molecule or duration of action) (61.3%), duration of ADT (10.5%), switch to intermittent treatment (10.0%), addition of chemotherapy (5.6%) or second line hormonal manipulation (9.0%). Modifications of ADT according to indications are summarized in table below. Clear explanation for adaptations was given for only 110 patients (whole population): disease progression: 55.5% ; patient request: 26.4%, tolerance: 12.7% and failure of castration: 7.3%.

Changes in ADT (%) according to Indications of ADT	Adjuvant to RT (n=279)	Locally advanced T. without local trt (n=182)	Biochemical relapse (n=189)	Metastases (n=214)
Mean age (yrs)	71.4	80.6	72.7	72.7
≥3 comorbidities (%)	17.2	10.4	11.6	15.0
Modification of ADT (%)	37.6	38.5	49.7	48.6
Type of modification (%):				
- Modification of formulation	64.8	67.1	58.5	54.8
- Modification of duration or switch to intermittent ADT	14.3	27.1	34.0	11.5
- Addition of another trt (progression)	4.8	12.9	6.4	31.7

#### Conclusion

Change of initial modality of ADT is frequent in the first 24 months of treatment (43.8%) and numerically more frequent in presence of metastases or biochemical relapse than when ADT is added to RT. Surprisingly, the main type of modification is formulation. The main reported reason for modification is disease progression

#### EP-1315 Prostate cancer lymph nodal disease: SBRT only or extensive prophylactic irradiation and boost?

A. Fodor<sup>1</sup>, C. Sini<sup>2</sup>, C.L. Deantoni<sup>1</sup>, C. Fiorino<sup>2</sup>, C. Cozzarini<sup>1</sup>, B. Noris Chiorda<sup>1</sup>, I. Dell'Oca<sup>1</sup>, M. Picchio<sup>3</sup>, P. Mangili<sup>2</sup>, E. Incerti<sup>3</sup>, R. Calandrino<sup>2</sup>, L. Gianolli<sup>3</sup>, N.G. Di Muzio<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Department of Radiation Oncology, Milan, Italy

<sup>2</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy

<sup>3</sup>San Raffaele Scientific Institute, Department of Nuclear Medicine, Milan, Italy

#### Purpose or Objective

Sensitivity and specificity of choline PET/CT is high on a per patient basis, but not on a per lesion basis (positive lymph nodes may be underdiagnosed). We report the outcome of salvage radiotherapy, delivered with TomoTherapy®(TT), in prostate cancer (PCa) patients (pts) previously submitted to radical prostatectomy and presenting persistent/ relapsing PSA and positive(+) lymph-nodes(LN) at 11 C-choline PET/CT(PET), treated

with prophylactic TT on LN areas (pelvic/lombo-aortic, LA) and simultaneous integrated boost(SIB) on PET+ LN.

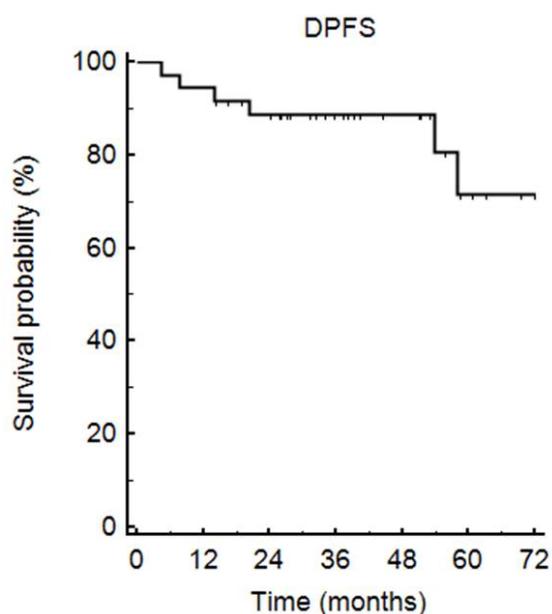

#### Material and Methods

From March 2007-May 2013, 36 PCa pts treated with radical prostatectomy (RP) +/- pelvic/LA LN dissection(LND), and presenting +LN at PET, were treated with TT. Analysis was restricted to oligometastatic treatment-naïve PCa pts satisfying published selection criteria for SBRT (Ost et al, Eur Urol 2016), including also castration resistant and >3 +LN pts (worse prognosis). Pts characteristics were: median age 67(53-78) yrs; median PSA post-surgery/at relapse: 2.74(0.66-23.52) ng/ml; median Gleason score 8(6-10). Five pts underwent RP; 33 RP+LND. Twelve pts were pT2, 22 pT3, 1 pT4, 11 pN1, 1 M1a, 11 R1. Twenty one pts had androgen deprivation(AD) prescription after surgery, 5 were hormonal resistant; 1 patient was treated with chemotherapy(Docetaxel and Estramustine). The interval between surgery and PET was 19.3(3.1-170.2) mts, the median number of PET +LN was 3(1-20). In 23 pts AD was prescribed for a median of 19(0-57) mts. Patients were treated with daily image-guided TT on pelvic/LA LN (51.8 Gy/28 fr), with simultaneous integrated boost (SIB) on prostatic bed (71.4 Gy), and on PET+ LN (65.5 Gy).

#### Results

With a median follow up of 38.1(14.4-82) mts, acute toxicity was low (1 G3 GU acute toxicity; 2 G2 bowel, 2 G2 rectal and 2 G2 GU acute toxicities). Late toxicities were: rectal 3 G2 13.9% (1 pt G3), lymphedema 3 G2 13.9% (1 pt needing surgery), and GU 3 G2: 33.4% (1 pt with salvage cystectomy). At the last control, late toxicities were mild, showing that most events were transitory with no rectal G2, 1 rectal G3; 2 GU G2, 3 GU G3 and 2 Lymphedema G2. A summary of outcome is shown in Table I and Figure 1: Median biochemical relapse free survival (BRFS) was 51.2 months; 3 and 5-year biochemical relapse-free survival (bRFS) was 65.5% and 43% respectively; distant progression free survival (DPFS) was 88% and 70% and Cancer Specific Survival was 92 and 83%.

Alive: Dead	31: 5 3 from Pca 2 other causes
Median PSA (range) 3 months after salvage HTT	0.10 (0.00- 12.88) ng/ml
Median PSA (range) last follow-up	0.05 (0.00-1909.26) ng/ml
Relapse	No: 22; Yes: 14
Site of relapse	Biochemical only: 5 Local: 1 Lymph nodal: 1 LN+ Bone: 4 Bone: 3
Systemic therapy at last follow-up	No: 18; Yes: 18 ADT: 13 CHT: 5

#### Conclusion

Our excellent outcome results suggest that PET-guided prophylactic treatment of LN chains together with SIB to PET+ LN may translate in a substantial increase of bRFS and DPFS compared to reported results after SBRT. A phase III trial comparing these approaches would be suitable. Because of high GU toxicity caused by hypofractionation on post-operative settings the protocol for prostate bed irradiation was modified since 2014 to deliver 70-74 Gy with conventional fractionation.

#### EP-1316 Moderate Hypofractionation RT in post-prostatectomy setting: report on feasibility and acute toxicity

S. Fersino<sup>1</sup>, U. Tebano<sup>1</sup>, R. Mazzola<sup>1</sup>, F. Ricchetti<sup>1</sup>, N. Gaj Levra<sup>1</sup>, A. Fiorentino<sup>1</sup>, G. Sicignano<sup>1</sup>, S. Naccarato<sup>1</sup>, R. Ruggeri<sup>1</sup>, F. Alongi<sup>1</sup>  
<sup>1</sup>Sacro Cuore Don Calabria Cancer Care Center, Radiation Oncology, Negrar, Italy

#### Purpose or Objective

to evaluate the acute toxicity profiles of a moderate hypofractionated regimen with volumetric modulated arcs therapy (VMAT) in prostate cancer (PC) patients underwent to radical prostatectomy (RP).

#### Material and Methods

From December 2012 to February 2016, 125 patients, previously submitted to RP, received adjuvant (64 patients) or salvage (61 patients) radiotherapy (RT) inside an institutional protocol of moderate hypofractionation schedule using VMAT technique (Varian RapidArc, Palo Alto, CA, USA). Eligible patients were < 85 years old, with an ECOG performance status of 0-2, histologically proven adenocarcinoma of the prostate without distant metastases, and pathological stage pT2-4 N0-1, with at least one of the following risk factors: capsular perforation, positive surgical margins, seminal vesicle invasion and/or postoperative PSA > 0,2 ng/ml. Patients were stratified into low (1%), intermediate (9%), and high-risk (90%) groups. The median age was 68 years. The median doses were 66 Gy (range 65.5-71.4) to the prostatic bed and 52.5 Gy (range 50.4-54) to the pelvic lymph nodes, in 28 or 30 fractions. The acute genitourinary (GU) and gastrointestinal (GI) toxicities were scored according to the Common Terminology Criteria for Adverse Events CTCAE v4

## Results

All the 125 patients completed the planned treatment, with good tolerance. After RT, the median follow-up was 15 months. Acute toxicities were recorded for the GU [G0=45/125 (36%), G1=63/125 (50.4%); G2=16/125 (12.8%); G3=1/125 (0.8%)], the GI [G0=42/125 (33.6%); G1=72/125 (57.6%); G2=11/125 (8.8%); no G3]. Analyzing data according to RT intent, a higher rate of GU toxicity  $\geq 2$  was found in the adjuvant setting (17.1%) respect to salvage group (9.8%);  $p=0.01$  at Fisher's exact test. Furthermore, at statistical analysis no difference was found between the type of surgery (Robotic, Laparoscopic or Open) and incidence of urinary incontinence ( $p=0.8$ ). The actuarial Kaplan-Meier for biochemical disease free survival (BDFS) were 94% and 77% for adjuvant and salvage RT, at 36 months.

## Conclusion

moderate hypofractionated postoperative RT with VMAT was feasible and safe with acceptable acute GU and GI toxicities. Longer follow-up is needed to assess late toxicity and clinical outcome

### EP-1317 PET-guided pelvic re-irradiation for nodal recurrences of prostate cancer

P. Dirix<sup>1</sup>, G. De Kerf<sup>1</sup>, B. De Laere<sup>2</sup>, G. Buelens<sup>1</sup>, P. Huget<sup>1</sup>, D. Verellen<sup>1</sup>, P. Meijnders<sup>1</sup>

<sup>1</sup>Iridium Cancer Network, Department of Radiation Oncology, Antwerp, Belgium

<sup>2</sup>Iridium Cancer Network, Translational Cancer Research Unit TRCU, Antwerp, Belgium

## Purpose or Objective

To report our first cases of pelvic re-irradiation using volumetric-modulated arc therapy (VMAT) with a simultaneous integrated boost (SIB) on choline or prostate-specific membrane antigen (PSMA) positron emission tomography (PET) nodal uptake in recurrent prostate cancer, after previous salvage radiotherapy (SRT).

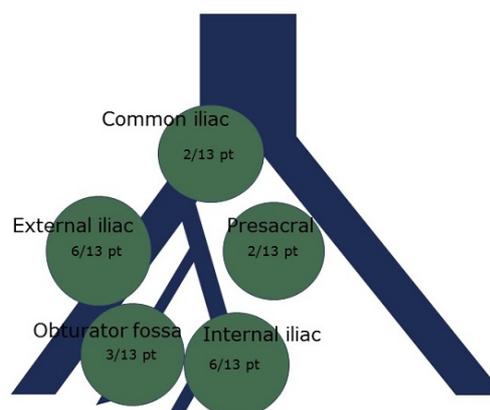

## Material and Methods

Thirteen patients received re-irradiation for a nodal relapse that occurred after initial radical prostatectomy followed by SRT. All patients were initially operated for high-risk prostate cancer between 2007-2014. The initial SRT consisted of radiotherapy of the prostate bed and obturator/iliac lymph nodes to 66.0/52.8 Gy in 33 fractions of 2.0/1.6 Gy, respectively, through intensity-modulated radiotherapy (IMRT). All patients had a consequent pelvic nodal relapse on choline ( $n=6$ ) or PSMA ( $n=7$ ) PET-CT, without extra-pelvic disease. The location of the pelvic recurrences is shown (Figure). The mean PSA at time of nodal recurrence was 2.94  $\mu\text{g/L}$  (range, 0.6 - 7.89  $\mu\text{g/L}$ ). Patients were deemed unfit for surgery and/or surgically inoperable. The re-irradiation was initiated a mean 46 months (range, 8 - 107 months) after SRT. All patients received 66.0/50.0 Gy in 25 fractions of 2.64/2.0 Gy to the PET-positive lymph nodes and elective pelvic nodal regions, respectively. Underdosage of the elective planning target volume (PTV) was allowed (taking the earlier SRT into account), but not of the high-dose PTV. No androgen-deprivation therapy (ADT) was initiated. All toxicity was prospectively scored according to the common toxicity criteria (CTC) version 4.0.

## Results

Acute toxicities were limited: no gastro-intestinal (GI) nor genito-urinary (GU) acute toxicities  $\geq$  grade 2 were observed. Two patients suffered from mild grade 1 diarrhea until 2-3 weeks after radiotherapy, no acute GU toxicities were observed. There was a mean follow-up of 17 months (range, 6 - 27 months) since re-irradiation. Regarding late toxicity, one patient developed grade 1 hematuria at 1 year after re-irradiation which was due to pathologically confirmed cystitis. No other late GI or GU

toxicities were observed. Regarding oncological outcome, all patients developed an initial PSA response, defined as a decline from baseline in PSA level of 80% or greater. Currently, 11 patients remain controlled (without ADT) at a mean of 16 months (range, 6 - 27 months) after re-irradiation, with a mean PSA of 0.34  $\mu\text{g/L}$  (range, 0.17 - 0.63  $\mu\text{g/L}$ ). Two patients progressed within 6 months after the end of radiotherapy and currently receive (chemo-)hormonal treatment. Interestingly, these 2 patients had a PSA doubling time  $< 6$  months. All the other patients had a PSA doubling time  $> 11$  months.

## Conclusion

Pelvic re-irradiation with SIB to the PET-based nodal recurrences is a safe and promising alternative to pelvic lymph node dissection. However, patient selection is crucial and could in the future be guided by biomarkers. Also, concomitant ADT should now be considered based on GETUG-AFU 16.

### EP-1318 Is hypofractionation combined to WPRT effective in high risk prostate cancer patients?

N.G. Di Muzio<sup>1</sup>, A. Fodor<sup>1</sup>, C.L. Deantoni<sup>1</sup>, B. Noris Chiorda<sup>1</sup>, S. Broggi<sup>2</sup>, P. Mangili<sup>2</sup>, I. Dell'Oca<sup>1</sup>, A. Chiara<sup>1</sup>, P. Passoni<sup>1</sup>, N. Slim<sup>1</sup>, M. Pasetti<sup>1</sup>, R. Calandrino<sup>1</sup>, C. Cozzarini<sup>1</sup>, C. Fiorino<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Department of Radiotherapy, Milano, Italy

<sup>2</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy

## Purpose or Objective

Several recent studies have concluded that hypofractionation to prostate/seminal vesicles only cannot be regarded as a standard in intermediate and high-risk prostate cancer. We report here the 5 and 7 year clinical outcomes in high risk (HR) prostate cancer (PCA) patients (pts) treated with hypofractionated TomoTherapy (HT) and routine irradiation of pelvic lymph-nodes (PLN).

## Material and Methods

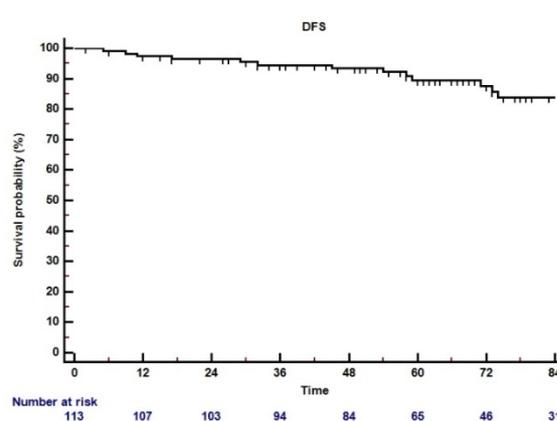

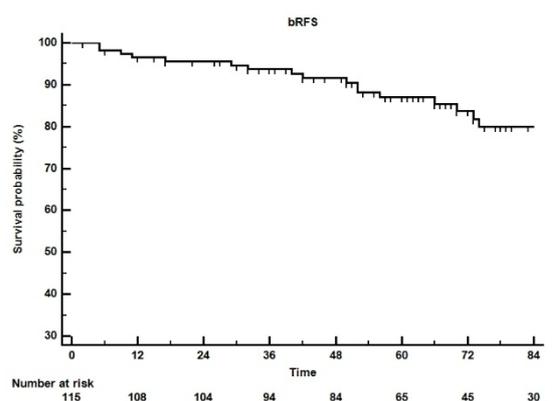

From April 2006-August 2015, 115 HR PCA pts were treated with HT, within a phase I-II study. The dose to PLN, was 51.8 Gy (1.85 Gy/fr), with simultaneous integrated boost (SIB), to prostate and seminal vesicles, up to 74.2 Gy in 28 fr (2.65 Gy/fr). Androgen deprivation therapy (ADT) was prescribed to 104/115 pts for a median of 26 (3-120) months (mos). Median age was 75 (57-90) years, median Gleason Score was 8 (5-10), median initial PSA was 12.4 (1.7-206.0) ng/mL; clinical T stage was: T1c-T2a in 62 pts, T2b-T2c in 35 pts, T3a-T3b in 17 pts and T4 in 1 patient.

## Results

With a median follow up of 68 (2-121) months, 19 pts (16.5%) exhibited a biochemical relapse after a median interval elapsed from the HT end of 64 (2-117) months.

Acute and late toxicity profile was acceptable and is summarized in Table I. Median PSA at the last follow up was 0.09 (0.0-900.0) ng/mL and only 7 pts had ongoing AD. Thirteen pts (11.3%) presented clinical relapse: 2 local, 1 in the mediastinal lymph nodes, 3 combined lymph-nodal (2 mediastinal, 1 para aortic) and bone/visceral metastases, and 7 distant metastases (bone, visceral) only. Twenty-four pts have deceased, but only 3 due to prostate cancer. Five and 7 year actuarial biochemical relapse-free survival (bRFS) was 87% and 80%, respectively (Fig I); corresponding rates of disease-free survival (DFS, accounting for both local and distant failures) were 90% and 84% (Fig. II), of distant metastases -free survival (DMFS) 91% and 89%. overall survival (OS) 89% and 78%, and of cancer specific survival (CSS) 98% and 96%, respectively.

Grading/Toxicity	Acute GU	Acute rectal	Acute bowel	Late GU	Late GI
G0	29 (25.2%)	74 (64.4%)	63 (54.9%)	57 (49.6%)	82 (71.3%)
G1	54 (47.0%)	35 (30.4%)	42 (36.5%)	37 (32.2%)	17 (14.8%)
G2	31 (27.0%)	6 (5.2%)	9 (7.8%)	15 (13.0%)	12 (10.4%)
G3	1 (0.8%)	0	1 (0.8%)	6 (5.2%)	4 (3.5%)

### Conclusion

HR PCa pts treated with a combination of PLN irradiation, high dose to the prostate delivered with image-guided intensity-modulated moderately hypofractionated RT, (EQD2 for a/b=3 roughly 88Gy), showed excellent 5 and 7 year BRFS and CSS. The main cause of biochemical relapse was regional and/or systemic, mostly outside the pelvis, likely due to pre-existent micro-metastatic disease. While such disease cannot be prevented even by the most

extreme dose-escalation, our results suggest that its impact appear to be significantly limited by prophylactic PLN irradiation.

### EP-1319 "Adjuvant"/ radical radiotherapy in prostate cancer patients with synchronous bone oligometastasis

C.L. Deantoni<sup>1</sup>, A. Fodor<sup>1</sup>, C. Sini<sup>2</sup>, B. Noris Chiorda<sup>1</sup>, C. Cozzarini<sup>1</sup>, C. Fiorino<sup>2</sup>, I. Dell'Oca<sup>1</sup>, M. Picchio<sup>3</sup>, E. Incerti<sup>3</sup>, P. Mangili<sup>2</sup>, R. Calandrino<sup>2</sup>, L. Gianolli<sup>3</sup>, N. Di Muzio<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

<sup>2</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy

<sup>3</sup>San Raffaele Scientific Institute, Nuclear Medicine, Milano, Italy

### Purpose or Objective

To report the clinical results, obtained in a monoinstitutional experience, in prostate cancer (PCa) pts with synchronous oligometastatic bone disease treated with radical surgery followed by adjuvant radiotherapy with radical intent.

### Material and Methods

From May 2009 to December 2015, 18 oligometastatic (for the purpose of this analysis, no more than 2 bone metastases) PCa pts underwent radical prostatectomy+pelvic/lombo-aortic (LA) lymph-node dissection. After surgery, all pts were simultaneously treated to bone metastasis (2Gy equivalent dose, EQD2 >40 Gy,  $\alpha/\beta=2.2$ ), as well as "adjuvant" RT to the pelvic  $\pm$  LA nodes (median EQD2 52.2 Gy) and to the seminal vesicle and prostatic bed (median EQD2 60 and 72.4 Gy, respectively,  $\alpha/\beta=1.5$ ), in association with androgen deprivation therapy (ADT). Nine pts were treated with conventional fractionation, while 9 with hypofractionated schedule (2,35 Gy/fr in 5 pts or 2,55 Gy/fr in 4 pts). Patients' characteristics are reported in Table I.

Median ( range) age at diagnosis 58.6 (50.5-76.4) years

Median (range) iPSA 11.44 (2.40-149.00) ng/ml

Median ( range) Gleason Score 9 (7-10)

T Stage  
 pT2: 1  
 pT3a: 7  
 pT3b: 9  
 pT4: 1

N Stage  
 pN0: 4  
 pN1: 14

Bone metastasis number  
 1: 14  
 2: 4

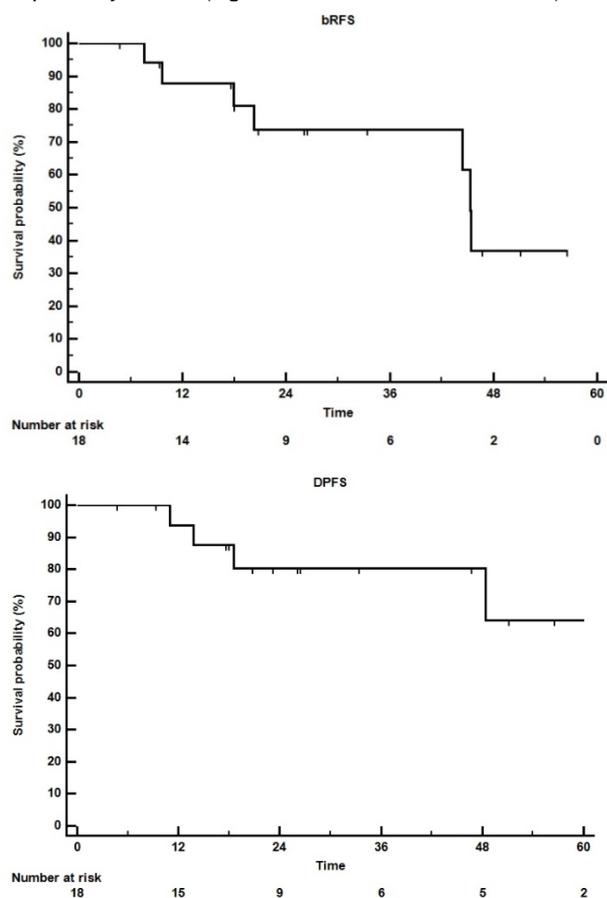

Median (range) PSA before RT 0.19 (0.00-75.83) ng/ml

Median ( range) follow up after RT 26.3 (4.8-79.4) months

### Results

After a median follow up of 26.3 (4.8-79.4) months, only one patient have deceased owing to prostate cancer progression, while 17 are still alive. Seven pts experienced a relapse, whose characteristics are as follows: 2 biochemical only, 1 in the irradiation field and 4 out of field. At the last follow up, 12 pts were under ADT, of whom one in combination with chemotherapy, while 5 ended ADT and were free from relapse, after a median of 28 (range: 13.3-35) months. Acute toxicity was very mild, with no Grade >2 events, and only 2 serious late events, 1 G3 and 1 G4 urinary (salvage cystectomy for gross haematuria) toxicity, in a patient treated with hypofractionation (2,55 Gy/fr). With respect to bone, no Grade $\geq$ 1 toxicity were reported. The median biochemical relapse-free survival (bRFS) was 45.3 months. Actuarial 3- and 5-year bRFS was 73% and 37%, respectively, while the distant progression-free survival (DPFS) was 80% and 64%,

respectively (Fig 1a and b)

### Conclusion

A combination of radical and “adjuvant” radiotherapy in prostate cancer patients with synchronous oligometastatic bony disease at diagnosis and surgically managed show promising results in terms of both biochemical control and distant progression-free survival. The only severe event was probably caused by a previously used hypofractionated protocol for prostatic bed irradiation that was abandoned in 2013.

### EP-1320 Phase II Study of SBRT as Treatment for Oligometastases in Prostate Cancer: Trial in progress.

<sup>11</sup>Fundación Hospital Provincial, BIOSTATISTICS, CASTELLON, Spain

### Purpose or Objective

SBRT-SG 05 (ClinicalTrials.gov NCT02192788 ) is a collaborative (SBRT-SG, GICOR and SEOR) phase II trial testing SBRT and hormone therapy in oligometastatic prostate cancer patients. The aim of this study is to determine response, and biochemical control rates, progression free survival, chemotherapy free survival and impact of treatment on quality of life. We describe here the protocol and first results. This type of studies are currently on the rise worldwide representing interest for this kind of approach.

### Material and Methods

Patients with histologically confirmed prostate cancer (hormone-sensitive or castration-resistant) in an oligorecurrent stage after primary treatment for their disease were assigned to receive SBRT (Vertebral Metastases: 1x16-18Gy or 3x8-9Gy. Lymph node Metastases: 3x10-11 Gy or 6x7,5Gy. Non-spinal bone metastases: 1x16Gy or 3x10Gy). Medical treatment could include LHRH analogues or antiandrogens. The following Inclusion Criteria were established: Time to biochemical recurrence more than 1 year; PSA doubling time > 2 months; Less than 5 bone or lymph node metastases (including spinal) by Choline PET-CT or / and WB-DWI-MRI. To ensure homogeneity in the sample, all patients should have hormone therapy according to current recommendations planning its withdrawal within two years after treatment if biochemical control has been achieved. The percentage of castration resistance patients will be at most 30% and at least 10% of the sample. Concomitant treatment with chemotherapy, abiraterone or enzalutamide is not allowed.

### Results

At present, 38 patients have been recruited in 10 centers, with 47 locations of oligometastases treated. 3 patients have been evaluated at 18 months, 6 have been evaluated at year, 4 at 9 months, 3 at 6 months, 7 at 3 months, 9 at 1 month, 2 just have been received SBRT now and 2 are pending to the initial studies. 2 patients were lost in follow-up. In all there is local and biochemical control. No patient had symptoms related to local progression. 2 (5,5%) of them has disease progression during the follow-up and they are being evaluated for a new SBRT. All of them have not grade >2 toxicity related to SBRT. 9 (25%) patients were included in a state of castration resistance without the need to start second generation hormonal treatment.

### Conclusion

This trial presents a favorable pace of recruitment with good initial figures of biochemical control and local control without the appearance of remarkable SBRT related toxicity at this time.

### EP-1321 Salvage Radiotherapy in locoregional macroscopically relapsed Prostate cancer:retrospective analysis

A. Bruni<sup>1</sup>, G. Ingrosso<sup>2</sup>, E. Mazzeo<sup>1</sup>, L.M. Lamin<sup>1</sup>, B. Lanfranchi<sup>1</sup>, M. Andolina<sup>1</sup>, P. Morelli<sup>2</sup>, I. Turturici<sup>2</sup>, G. Guidi<sup>3</sup>, R. Santoni<sup>2</sup>

<sup>1</sup>AOU Policlinico of Modena, Radiation Oncology Unit, Modena, Italy

<sup>2</sup>Tor Vergata University General Hospital, Radiation Oncology Unit, Rome, Italy

<sup>3</sup>AOU Policlinico of Modena, Medical Physics Department, Modena, Italy

### Purpose or Objective

A subset of patients (pts) with Prostate Cancer (PCa) experiences a biochemical/clinical recurrence following radical prostatectomy (RPP). Even if Salvage Radiation Therapy (SRT) after RPP is recommended as soon as the PSA rises above 0.20 ng/ml, some pts experience a loco-regional macroscopic relapse. Aim of the analysis is to evaluate the role of SRT +/- concomitant androgen deprivation therapy (ADT) in pts with clinical/radiological/metabolic loco-regional relapse.

### Material and Methods

From 2007 to September 2015, fifty-five pts with locoregional macroscopic PCa relapse underwent radical SRT +/- concomitant/adjuvant ADT. Median age at time of SRT was 72 years. At time of diagnosis 32pts had pT2 PCa, 6 pT3a and 19 pT3b according to TNM AJCC Stratification. Only 4 pts had abdominal node involvement (pN+). Gleason Pattern Score was <7 in 8pts, 7 in 35 and >7 in 11 pts. At time of relapse all pts had an elevated PSA: 19 pts <1.0 ng/mL, 22 between 1.1-5 ng/ml and 15 pts >5 ng/mL. Before being submitted to SRT most pts (44/56) were staged with 18F-Choline CT-PET while 18 pts had also pelvic MRI to help with for a better RT planning. At the end of restaging 48/56 had just local relapse (prostatic bed), 3 nodal involvement and 4 pts had both. Due to clinical stage and PSA value, 23 pts were previously submitted to first line ADT, while 6 pts received two or more ADT lines. Finally SRT was delivered in association to concomitant ADT in 25/56 pts in 13 of whom it was continued with an adjuvant approach

### Results

At a median follow up of 36.2 months all pts but 3/56 (5%) were alive. All pts were treated with high dose RT (2.0-2.5 Gy/day, 28-37 total fractions) with or without concomitant ADT. Median RT dose was 70 Gy (range 62-76Gy). Target volume encompassed prostatic bed and macroscopic lesion in 42 pts (75%), while in the other 14 pelvic abdominal RT was performed due to high risk of nodal involvement (in 10 pts with prophylactic intent, in 4 pts using a boost on 18F-Choline CT-PET positive nodes). Three- and 5-year actuarial OS were 97.6%(ES±2.4%) and 88.5%(ES±6.7%), respectively. Three- and 5-year actuarial Biochemical Free Survival were 71.4%(ES±6.9) and 56.7%(ES±9.4) respectively while Metastasis Free Survival 90.5%(ES±4.0%) and 81.2%(ES±6.5%). Nine pts (16%) experienced distant recurrences: bone lesions were found in 6 pts, while extra-pelvic nodes in 5 pts (2/9 pts had both). No grade 4 acute/late toxicities were found, only 1 pt had G3 late Gastrointestinal side effects

### Conclusion

Our results of high dose SRT +/- ADT in pts with loco-regional macroscopic PCa relapse demonstrate an excellent profile in terms of oncological outcomes (OS, DFS, MFS) confirming again the important role of SRT even in this unfavourable subset of pts.

### EP-1322 Performance diagnosis of 11c-choline pet/ct in prostate cancer

P.M. Samper Ots<sup>1</sup>, A. Luis Cardo<sup>1</sup>, M.A. Cabeza Rodriguez<sup>2</sup>, C. Vallejo Ocaña<sup>3</sup>, L.A. Glaria Enriquez<sup>4</sup>, M.L. Couselo Paniagua<sup>5</sup>, J. Olivera Vegas<sup>6</sup>

<sup>1</sup>Hospital Rey Juan Carlos, Servicio de Oncología Radioterápica, Mostoles - Madrid, Spain

<sup>2</sup>Hospital 12 de Octubre, Servicio de Oncología Radioterápica, Madrid, Spain

<sup>3</sup>Hospital Ramon y Cajal, Servicio de Oncología Radioterápica, Madrid, Spain

<sup>4</sup>Hospital La Paz, Servicio de Oncología Radioterápica, Madrid, Spain

<sup>5</sup>Hospital Gomez Ulla, Servicio de Oncología Radioterápica, Madrid, Spain

<sup>6</sup>Fundación Jimenez Diaz, Servicio de Oncología Radioterápica, Madrid, Spain

### Purpose or Objective

To test the performance of 11C-choline PET/CT in staging and change the therapeutic decision in prostate cancer (PC). Correlation of prognostic factors with the detection of disseminated disease.

### Material and Methods

Retrospective observational multicenter study in which 233 patients diagnosed with PC, median age was 68.21 years included. Inclusion criteria: 56 patients (24%) with high-risk localized PC, 102 patients (43.8%) with biochemical failure after surgery and 75 patients (32.2%) with biochemical failure after radiotherapy, all study negative extension (CT and bone scintigraphy). We collected the prognostic factors for PC diagnosis and surgical specimen: PSA, Gleason score, T stage, N stage, percentage of positive biopsies, perineural invasion and margins. And in patients with biochemical failure: the PSA, PSA doubling time (PSADT) and PSA velocity (PSAV) at the time of failure. The study was approved by the Ethics Committee for Clinical Research (CEIC) and meets the standards of data protection. For statistical analysis SPSS version 22.0 was used.

### Results

The 11C-choline PETCT confirmed the diagnosis of the extension study only in 81 patients (34.7%), changed the therapeutic indication in 137 patients (58.8%) and confirmed metastatic disease in 127 patients (54.5%). Prognostic factors of diagnosis of metastasis in 11C-choline PETCT in the univariate analysis were: Primary Gleason <sup>3</sup> 4 (p = 0.002), secondary Gleason <sup>3</sup> 4 (p = 0.039), Gleason score <sup>3</sup> 8 (p = 0.001), perineural invasion in biopsy (p = 0.04), perineural invasion in the surgical specimen (p = 0.029), previous hormone therapy (p = 0.001), the PSA failure (p = 0.023), the PSADT (p = 0.023), and VPSA (p <0.001); in the multivariate analysis: primary Gleason diagnosis (p = 0.001, Gleason score at diagnosis (p = 0.002), PSA in failure (p = 0.005), PSA DT (p = 0.010) and VPSA (p = 0.000).

### Conclusion

11C-choline PET-CT has proven to be cost-effective for the detection of metastatic disease in high risk patients with primary Gleason ≥ 4 and Gleason score ≥ 8 diagnostic, and in patients with biochemical failure and kinetics elevated PSA, which involve a change in the therapeutic indication.

### EP-1323 Role of 68Ga-PSMA PET/CT in radiotherapy for prostate cancer: A single centre experience

N.S. Hegemann<sup>1</sup>, W.P. Fendler<sup>2</sup>, A. Buchner<sup>3</sup>, C. Stief<sup>3</sup>, M. Niyazi<sup>1</sup>, P. Bartenstein<sup>2</sup>, C. Belka<sup>1</sup>, U. Ganswindt<sup>1</sup>

<sup>1</sup>Klinik und poliklinik für Strahlentherapie und Radioonkologie, Radiation Oncology Ludwig-Maximilians-University, München, Germany

<sup>2</sup>Nuclear Medicine, Ludwig-Maximilians-University, Munich, Germany

<sup>3</sup>Urology, Ludwig-Maximilians-University, Munich, Germany

### Purpose or Objective

The aim of this study was to determine the potential role of <sup>68</sup>Ga-PSMA PET/CT in radiotherapy (RT) for prostate cancer.

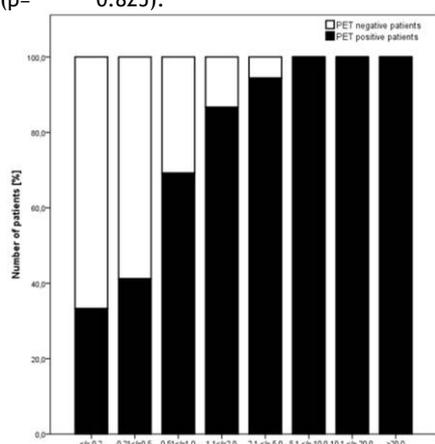

### Material and Methods

A retrospective analysis of 129 patients (pts) with available <sup>68</sup>Ga-PSMA PET/CT (Feb. 2014 - Aug. 2016) was performed. Potentially influencing factors (androgen deprivation therapy at time of PET/CT, injected amount of <sup>68</sup>Ga-PSMA-HBED-CC, PSA doubling time ≤/ > 10 months, PSA before PET/CT, T-/N-category and Gleason score) were evaluated by uni- and multivariate binary logistic regression analysis. The detection rate of <sup>68</sup>Ga-PSMA

PET/CT compared to contrast enhanced CT and its impact on RT management was analysed.

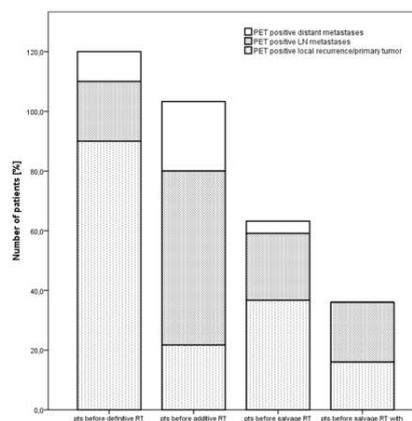

### Results

129 pts (20 at initial diagnosis, 49 with PSA relapse and 60 with PSA persistence after radical prostatectomy) received  $^{68}\text{Ga}$ -PSMA PET/CT prior to RT. The majority of pts (71.3%) had  $^{68}\text{Ga}$ -PSMA PET/CT positive findings (55.1% of pts with PSA recurrence, 75% of pts with PSA persistence and 100% of newly diagnosed pts). The uni- and multivariate analysis found no significant association between PET-positive results and above mentioned factors with exception of PSA before PET/CT: Pts with PSA  $\leq 0.2$  ng/ml had a detection rate of 33.3%, with PSA  $0.21 \leq 0.5$  ng/ml a rate of 41.2% and with PSA  $0.51 \leq 1.0$  ng/ml a rate of 69.2% (figure 1). Median PSA before PET/CT in pts with pathological findings (n=92) was 1.90ng/ml and without (n=37) 0.30ng/ml, in newly diagnosed pts 12.4ng/ml, in pts with PSA relapse 0.49ng/ml and in pts with PSA persistence 0.99ng/ml.  $^{68}\text{Ga}$ -PSMA PET/CT had a high detection rate of PCa recurrence outside the prostatic fossa in pts being considered for salvage RT (figure 2): 22.4% of these pts had PET-positive pelvic lymph nodes and 4.1% distant metastases. In pts considered for salvage RT with a PSA  $< 0.5$  ng/ml  $^{68}\text{Ga}$ -PSMA PET/CT still detected in 16.0% local recurrences within the prostatic fossa and in 20.0% PET-positive pelvic lymph nodes.  $^{68}\text{Ga}$ -PSMA PET/CT had a significantly higher diagnostic value compared to the contrast enhanced CT scan. This resulted in a modification of RT in 56.6% of pts equally observed in high risk (59.2%) as in low/intermediate risk pts (53.8%) (p= 0.825).

### Conclusion

The detection of PCa is strongly associated with PSA level at time of  $^{68}\text{Ga}$ -PSMA PET/CT.  $^{68}\text{Ga}$ -PSMA PET/CT differentiates local, regional and distant metastatic disease with considerable implications for disease management.  $^{68}\text{Ga}$ -PSMA PET/CT narrows the diagnostic gap in post-prostatectomy pts with rising PSA  $\leq 0.2$  ng/ml considered for salvage RT.

### EP-1324 Single-fraction HDR brachytherapy boost in combination to EBRT for prostate cancer

A. Huerta<sup>1</sup>, P. Blanchard<sup>1</sup>, L. Calmels<sup>1</sup>, M. Edouard<sup>1</sup>, A. Bossi<sup>1</sup>

<sup>1</sup>Gustave Roussy, Department of Radiation Oncology, Villejuif, France

#### Purpose or Objective

To describe efficacy and safety of a single-fraction high-dose-rate brachytherapy (HDRBT) boost for patients diagnosed with NCCN intermediate and high risk prostate cancer using real-time transrectal ultrasound (TRUS) based planning in combination to external beam radiation therapy (EBRT)

#### Material and Methods

The records of 146 patients treated with a single-fraction HDRBT boost of 14 Gy using real-time TRUS based planning were reviewed. External beam radiation therapy (46 Gy/23 fractions or 50 Gy/25 fractions) was performed before (76%) or after (24%) HDRBT boost. Genito-urinary (GU) and gastro-intestinal (GI) toxicity were assessed according to CTCAE v4.0 every 6 months after the end of combined treatment, as well as PSA evaluation.

#### Results

The median follow-up was 30 months. Antiandrogen deprivation was administered in 53.6% of the patients. Thirteen patients (8.9%) experienced failure. The biological progression-free survival (bPFS) rate at 24 months was 94%. Ten patients experienced urinary retention within five days after treatment. There were two cases of grade 3 toxicity (rectal bleeding and dysuria). GI and GU toxicity was reported in 14.4% and 54% of the patients respectively.

#### Conclusion

Single-fraction HDRBT boost of 14 Gy using real-time TRUS in combination to pelvic EBRT is a feasible and promising treatment option for intermediate and high risk prostate cancer patients.

### EP-1325 Risk adapted dose-intensified postoperative Tomotherapy RT in prostate cancer using a SIB.

M. Beck<sup>1</sup>, T. Barelkowski<sup>1</sup>, A.H. Thieme<sup>1</sup>, S. Wecker<sup>1</sup>, D. Kaul<sup>1</sup>, W. Włodarczyk<sup>1</sup>, V. Budach<sup>1</sup>, P. Wust<sup>1</sup>, P. Ghadjar<sup>1</sup>

<sup>1</sup>Department of Radiation Oncology, Charité Universitätsmedizin, Berlin, Germany

#### Purpose or Objective

To evaluate a novel risk adapted dose-intensified postoperative radiation therapy (RT) scheme for patients with prostate cancer.

#### Material and Methods

A consecutive series of prostate cancer patients who received postoperative RT after radical prostatectomy (RP) using helical Tomotherapy between 04/2012 and

04/2015 were retrospectively analyzed. RT was administered using a simultaneous integrated boost (SIB) to the area at risk (37 fractions of 1.9 Gy, total dose: 70.3 Gy) being defined based on histopathological findings (T3 region, R1 region) and in a few cases according to additional diagnostic imaging information. The whole prostate bed was treated with a dose of 66.6 Gy (37 fractions of 1.8 Gy). Primary endpoints were acute and late genitourinary (GU) and gastrointestinal (GI) toxicities according to the National Cancer Institute Common Terminology Criteria version 4.0 (CTCAEv4.0). Secondary endpoints included patient reported outcome as assessed by the International Prostate Symptom Score (IPSS) and the International Consultation on Incontinence questionnaire (ICIQ), as well as biochemical recurrence defined as a prostate specific antigen (PSA) of 0.4 ng/ml and rising.

#### Results

A total of 69 patients were analyzed. Sixteen patients underwent adjuvant radiation therapy (ART) and 53 patients salvage radiation therapy (SRT), respectively. The median follow-up was 20 months (range, 8-41 months). Six (8.7%) and four (5.8%) patients experienced acute grade 2 GU and GI toxicity. Two patients (2.9%) had late grade 2 GU toxicity, whereas no late grade 2 GI nor any grade 3 acute or late GU or GI events were observed. When compared to the baseline urinary symptoms ( $p=1.0$ ) and incontinence ( $p=0.9$ ) were not significantly different at the end of follow-up. A total of seven patients (10.1%) experienced a biochemical recurrence with the 2-year biochemical recurrence-free survival (bRFS) being 91%. A persistent PSA  $\geq 0.5$  ng/ml after RP was significantly associated with decreased bRFS ( $p=0.028$ ).

#### Conclusion

Risk adapted dose intensified postoperative RT is feasible and associated with favorable acute and late GU and GI toxicity rates and promising bRFS rates.

#### EP-1326 Long term patients clinical outcome after salvage post-prostatectomy Radiation Therapy (RT)

P. Pietro gabriele<sup>1</sup>, E. Elisabetta garibaldi<sup>2</sup>, A. Angelo maggio<sup>3</sup>, e. Elena delmastro<sup>4</sup>, a. Andrea galla<sup>4</sup>, s. Sara bresciani<sup>5</sup>, D. Domenico Gabriele<sup>6</sup>, M. Michele Stasi<sup>3</sup>

<sup>4</sup>irccs-fpo candiolo cancer center, radiotherapy department, candiolo turin, italy

<sup>5</sup>irccs-fpo candiolo cancer center, medical physics, candiolo turin, italy

<sup>6</sup>sassari university, radiotherapy department, sassari, italy

#### Purpose or Objective

To study the outcome of patients treated for prostate cancer with salvage radiotherapy after radical surgery.

#### Material and Methods

From January 2000 to December 2015 we treated for salvage in our Institution 234 patients (44-75 ys, median 64) affected by prostate cancer operated and with biochemical/clinical recurrences. The pre surgery PSA was 9 (0.36-90) ng/mL, pathologic GS 7 (4-9) and cT1, 2, 3 and 4 were 1, 61, 137 and 1, respectively. Lymph node invasion was presented in 11 patients; the number of nodes removed was 6 (0-40) and positive margins were 64 (27%); post-surgery PSA was 0.10 (0-2). Radiation therapy was performed with Linac from 1999 to 2009 by 3DCRT and with Tomotherapy from 2010 by IMRT-IGRT. Radiation dose were 70.2 Gy (61.6-79.2) to the prostate bed and 54 Gy (45-57.6) to the pelvis, 1.8 Gy per fraction; the pelvis

was irradiated in 46 patients (20%). 66 patients (28%) were treated during RT with hormone therapy (HT). The median time from surgery to RT was 40.7 months (range: 6-212).

#### Results

With a median FU of 117 months (17.6-303) the 10 years prostate Cancer Specific Survival was 88%; Clinical Relapse Free Survival was 67 % and Biochemical Relapse Free Survival only 36%. Cox univariate and multivariate analysis were performed and the results are the following: in multivariate analysis for Cancer Specific Survival are predictive PSA pre RT ( $p=0.0018$ ; HR=1.18), PSA measured at last follow-up ( $p=0.0018$ ; HR=1.04) and nodal invasion ( $p=0.024$ ; HR=5.9); for Biochemical Free Survival are predictive D'Amico classification ( $p=0.002$ ; HR=1.6) and cT( $p=0.007$ ; HR=1.7); for Clinical Relapse Free Survival GS( $p=0.0008$ ; HR=1.7) and last follow-up PSA( $p=0.0001$ ; HR=1.02).

#### Conclusion

In this, based on a large database, it was found that the PSA measured at last low-up was predictor of Prostate Cancer Specific and Clinical Relapse free survival while GS and D'Amico Classification were significantly independent prognostic factors of clinical relapse and Biochemical Free Survival for patients treated with postprostatectomy salvage RT.

#### EP-1327 Decision Support System to implant a rectum spacer during prostate cancer radiotherapy

Y. Van Wijk<sup>1</sup>, B. Vanneste<sup>2</sup>, S. Walsh<sup>2</sup>, S. Van der Meer<sup>3</sup>, B. Ramaekers<sup>4</sup>, W. Van Elmp<sup>2</sup>, M. Pinkawa<sup>5</sup>, P. Lambin<sup>2</sup>

<sup>1</sup>Maastricht university, School for Oncology and Developmental Biology, Maastricht, The Netherlands

<sup>2</sup>MAASTRO clinic, Radio Oncology, Maastricht, The Netherlands

<sup>3</sup>Adelante Zorggroep, Audiology, Maastricht, The Netherlands

<sup>4</sup>Maastricht university, Heath Economics, Maastricht, The Netherlands

<sup>5</sup>University Hospital Aachen, Michael Pinkawa, Aachen, Germany

#### Purpose or Objective

Dose escalation during external beam radiation in prostate cancer patients has been shown to improve progression free survival, but also leads to increased risk of gastrointestinal (GI) toxicity due to high radiation dose in the rectal wall. A method to reduce this dose is implantation of an implantable rectum spacer (IRS) to increase the distance between the rectal wall and the high dose region. Two commercial systems exist: hydrogel spacer (SPA) and Rectal balloon implant (RBI). In this study, a virtual IRS was developed to help identify the patients for whom it is cost-effective to implant an IRS. The research goal was to test whether this virtual IRS is a viable tool to tailor the decision of an IRS implantation to be beneficial for the specified patient.

#### Material and Methods

A virtual IRS was developed using a model based on scans of 11 patients with a RBI. This model was used to create a deformation field (i.e. virtual IRS) that was applied to scans of patients without an IRS. To test the virtual IRS, scans were used of 16 patients before and after the implantation of an IRS: 8 with a RBI, and 8 with a SPA. The real IRS scans were compared to scans with a virtual IRS. IMRT plans were made based on scans before the IRS, after IRS and with the virtual IRS, prescribing 78 Gy to the target volume. These plans were used to compare the rectum dose, the Normal Tissue Complication Probability (NTCP) for GI and the related cost-effectiveness of no IRS compared with the virtual IRS and the real IRS.

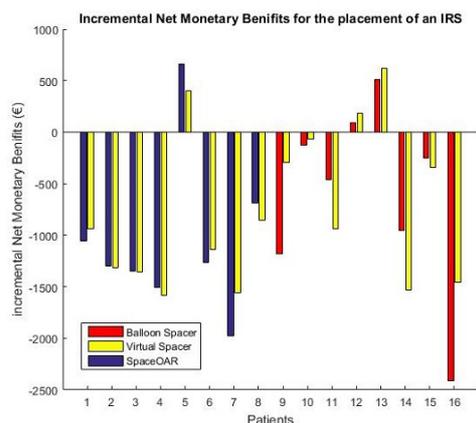

The NTCP model used previously validated dosimetric parameters for late rectal bleeding: mean dose (Gy) and V75 (%) as dosimetric predictors for late rectal bleeding. It also included clinical parameters such as haemorrhoids or use of hormonal therapy. The cost-effectiveness was analyzed using an earlier published Markov model. The incremental net monetary benefits (iNMB) was calculated (assuming a willingness to pay of €80.000/QALY).

### Results

The NTCP for the patients with a RBI and the virtual IRS were 4.1% [range: 3.6-5.0%], and 4.0% [range: 3.4%-5.3%] respectively. For the patients with a SPA the mean NTCP was 4.6% [range: 3.7%-6.1%] while this was 4.4% [range: 3.8%-4.7%] for the virtual IRS (Table 1).

Patient	Real IRS		Virtual IRS		Absolute Difference	
	Mean Dose (Gy)	NTCP (%)	Mean Dose (Gy)	NTCP (%)	Mean Dose (Gy)	NTCP (%)
1	16.1	4.1	15.2	4.1	0.8	0.0
2	13.1	3.6	10.7	3.5	2.5	0.0
3	22.1	4.0	20.4	3.8	1.8	0.1
4	10.2	3.7	7.9	3.7	2.3	0.1
5	31.3	5.0	32.9	5.3	1.6	0.3
6	25.1	3.6	15.6	3.4	9.5	0.2
7	25.5	4.7	8.3	3.8	17.2	0.9
8	11.1	3.9	15.2	4.1	4.0	0.2
9	29.3	5.7	20.7	4.3	8.6	1.3
10	21.3	3.9	19.8	3.8	1.5	0.1
11	21.3	3.9	26.0	4.4	4.7	0.5
12	32.9	4.7	33.8	4.7	1.0	0.0
13	29.3	4.8	27.2	4.6	2.2	0.2
14	24.6	3.7	32.4	4.7	7.8	1.1
15	18.9	4.2	22.0	4.4	3.1	0.1
16	32.9	6.1	23.3	4.5	9.6	1.6

The mean iNMB of the RBI was -€ 1062 [range: -€ 1,974-€ 658]. For the virtual IRS in these patients this was -€ 1042 [range: -€ 1,526.8-€ 400]. The mean iNMB of the SPA was -€ 605 [range: -€ 2,383-€ 427]. For the virtual IRS this was -€ 473 [range: -€ 1,405-€ 528] (Figure 1).

The virtual IRS had a 100% classification accuracy for this study, i.e. when the iNMB of the real IRS was negative, so was the iNMB of the virtual spacer, and vice-versa.

### Conclusion

Individual patient assessment for implantation of an IRS will increase cost-effectiveness of an IRS. The virtual IRS approach in combination with a toxicity prediction model and a cost-effectiveness analyses can serve as a decision support tool for the implantation of either a SPA or a RBI.

### EP-1328 Long term patients clinical outcome after adjuvant postprostatectomy Radiation Therapy

P. Pietro Gabriele (Italy), A. Angelo Maggio, E. Elena Delmastro, E. Elisabetta Garibaldi, S. Sara Bresciani, M. Marco Gatti, A. Andrea Galla, M. Michele Stasi, D. Domenico Gabriele

<sup>1</sup>IRCCS-FPO candiolo cancer center, radiotherapy, CANDIOLO Turin, Italy

<sup>2</sup>IRCCS-FPO candiolo cancer center, medical physics, candiolo Turin, Italy

<sup>3</sup>IRCCS-FPO candiolo cancer center, radiotherapy department, candiolo Turin, Italy

<sup>4</sup>SASSARI university, radiotherapy department, SASSARI, Italy

### Purpose or Objective

To study the outcome of patients (pts) treated for prostate cancer with postoperative radiotherapy (RT) after radical surgery

### Material and Methods

From October 1999 and December 2015, 279 patients (age 42-77ys median 66) operated for prostate cancer were treated in our Institution with conformal radiotherapy (3D or IMRT). Median preoperative PSA was 9 (range: 0.5-104), median pathologic GS 7 (range: 4-10) and number of pts with ct1, ct2, ct3 and ct4 were 1, 60, 207 and 11, respectively. Lymph node invasion was presented in 34 patients; the number of nodes removed was 7 (0-38); the number of patients with positive margins were 195 (69%); post-surgery PSA was 0.073 ng/mL (range: 0-6.22). Radiation therapy was performed with Linac from 1999 to 2009 by 3DCRT and with Tomotherapy from 2010 by IMRT-IGRT. Radiation dose were, 70.2 Gy (range 61.6-75.6 Gy) to the prostate bed and 46.8 Gy (45-50.4) to the pelvis, 1.8Gy per fraction. The pelvis was irradiated in 65 patients (24%). 64 patients (23%) were treated during RT with hormone therapy and 49 (18%) followed the treatment after RT.

### Results

With a median FU of 73.4 (range: 4-212) months from the end of RT the 10 years prostate Cancer Specific Survival was 88%; the Clinical Relapse Free Survival was 72% and Biochemical Relapse Free Survival 60%. Cox univariate and multivariate (MVA) analysis were performed. In MVA, the pathologic Gleason Score ( $p < 0.0001$ ;  $HR > 1.49$ ) and last follow-up PSA ( $p < 0.001$ ;  $HR > 1.0006$ ) were significantly predictors for prostate Cancer Specific Survival, Clinical Relapse Free Survival and Biochemical Relapse Free Survival.

### Conclusion

In this, based on a large database, it was found that the Gleason score and the PSA measured at last low-up were significantly independent prognostic factors of survival for patients treated with postprostatectomy adjuvant RT. **Acknowledgments:** This work was supported by "5 per Mille 2009 Ministero Salute-FPRConlus".

### EP-1329 IG-SBRT for localized prostate cancer: clinical results and late toxicity of a phase-II study

A. Magli<sup>1</sup>, E. Moretti<sup>2</sup>, A. Tullio<sup>3</sup>, C. Foti<sup>2</sup>, M. Crespi<sup>2</sup>, M. Urpis<sup>1</sup>, A. Prisco<sup>1</sup>, M.R. Malisan<sup>4</sup>

<sup>1</sup>ASUIUD, Radiation Oncology, Udine, Italy

<sup>2</sup>ASUIUD, Medical Physics, Udine, Italy

<sup>3</sup>Hygiene and Clinical Epidemiology Institute - University of Udine, Department of Medical and Biological Sciences, Udine, Italy

<sup>4</sup>ICTP, Master of Advanced Studies in Medical Physics, Trieste, Italy

### Purpose or Objective

To evaluate the clinical outcome and late toxicity of a phase II study dealing with SBRT with a total dose of 42 Gy in 7 fractions, in patients with localized prostate cancer at low/intermediate risk (according to NCCN score) and at risk of pelvic lymph node involvement inferior to 17% as evaluated by the Roach formula.

### Material and Methods

This study was based on a prospective analysis of 42 patients enrolled between May 2013 and November 2014. For planning, the GTV included the prostate with the 1/3 proximal seminal vesicles without margin; a margin of 5 mm in all directions around the GTV was applied to define the PTV. All patients were treated with IG-SBRT, utilizing VMAT technique with a 2 full arcs arrangement and photons with beam energy of 6 MV, according to pre-

established treatment dose specifications and DHV constraints: in particular, for PTV, plans were optimised aiming to obtain V95%>95% D98%>94%, V2%<108%; concerning the rectum, the requirements were: mean<18Gy, V20<35%, V32 <10%, V37<5%,D1%<40Gy while for the bladder, the goal was to keep mean dose <14 Gy and V21 <40%, V33 < 30%, V38 <13%,D1%<40Gy. Routine institutional image-based patient position verification protocols foresaw daily on-line matching by CBCT. The acute and late toxicities were recorded using the RTOG/EORTC scale. Additional data were collected by means of I-PSS e IIEF-5 questionnaires. Biochemical failure was determined using the Phoenix definition.

#### Results

The median follow-up duration was 27 months (range: 24 to 36 months). The median age was 74 years (range: 57-80 years). Most dosimetric parameters for the OARs are well within the protocol constraints, with the notable exception of maximal doses to rectum and bladder (exceeding in about 20% of cases), but we did not find any statistical correlation with late toxicities. Acute GU toxicity of grade 2 (increase in urinary frequency) was observed in 7% patients. The incidence rates of late GI and GU toxicity of any grade were 14.2% and 35.7%, respectively. The late GU toxicity of grade  $\geq 2$  was 4.7%. No GE late toxicity  $\geq 2$  was noted. Previous abdominal surgery appeared to be statistically significant ( $p = 0.004$ ; Fisher's test) for the increase of probability of late GE toxicity. The 3-year local recurrence-free survival rate was 98%, only one patient had clinical abdominal lymph node failure. Among the dosimetric data, only V21 (mean value: 22.1%; range: 8.5-55.2%) revealed to be statistically significant for the late GU ( $p = 0.035$ ; Wilcoxon Mann Whitney Test).

#### Conclusion

Our experience with VMAT-based SBRT in low-and intermediate-risk prostate cancer demonstrates favorable efficacy in tumor control and toxicity profile with no decrease in QOL as determined by I-PSS, IIEF. The general good quality of the clinical outcome and the results concerning GI and GU toxicities seem to confirm the robustness of the dosimetric paradigm adopted. Longer follow-up is needed to investigate complete safety and efficacy of the stereotactic treatments.

#### EP-1330 Predictive factors for urinary toxicity in patients treated with radical EBRT for prostate cancer

C. Pisani<sup>1</sup>, A. Galla<sup>1</sup>, D. Beldi<sup>1</sup>, G. Apicella<sup>1</sup>, G. Loi<sup>2</sup>, M. Krengli<sup>1</sup>

<sup>1</sup>University Hospital Maggiore della Carità, Radiotherapy, Novara, Italy

<sup>2</sup>University Hospital Maggiore della Carità, Medical Physics, Novara, Italy

#### Purpose or Objective

Acute and late toxicity scores in patients treated with radical external beam radiotherapy (EBRT) for prostate cancer were correlated with dosimetry and clinical data in order to identify some predictors for urinary (GU) toxicity.

#### Material and Methods

This study enrolled 280 patients (pts) treated with EBRT as primary treatment for prostate cancer in our University Hospital. All patients had at least 24 months follow-up, with a median of 47 months (range: 40-98). According with NCCN risk classification, 18% of pts were at low risk, while the others were at intermediate or high risk. Prescribed dose was 74-78 Gy. Adjuvant androgen deprivation consisting of a luteinizing hormone-releasing hormone analog, was administered in 192 patients (68.6%).

All patients completed a pre-EBRT questionnaire, registering baseline GU symptoms and patients' medical history (diabetes, hypertension, previous surgery, and

smoking) and were assessed by International Prostatic Symptom Score (IPSS). Toxicity was registered following a grading system based on the Radiation Therapy Oncology Group (RTOG). Acute toxicity was defined as toxicity occurring during or within 3 months after the end of EBRT. Late toxicity was defined as toxicity occurring for the first time >3 months after the end of EBRT or as acute toxicity lasting longer than 3 months. Acute and late GU toxicities were correlated with dosimetry and clinical parameters (age, presence of co-morbidities including previous TURP, tumor stage, initial PSA and Gleason Score).

#### Results

Median age was 74 years (range: 64-83); performance status according with Karnofsky scale was 90 (80-100). Fifty percent of pts had cardiovascular disease and 13% of them had undergone TURP before EBRT. Thirty-two percent of pts were treated with IMRT and 20% with IGRT. Median bladder volume at simulation was 263 cc. Thirty-one percent of pts experienced acute G1 GU toxicity, 24% G2 and 3% G3. No G4 GU acute toxicity was reported. Fourteen percent of pts experienced G1 late toxicity and 3% G2. We did not report any G3 or G4 GU toxicity. IPSS baseline value significantly correlated with acute GU toxicity in univariate ( $p=0.009$ ) and multivariate ( $p=0.0002$ ) analysis.

The presence of nocturia ( $p=0.002$ ), bladder urgency ( $p=0.024$ ) and incontinence ( $p=0.024$ ) also significantly correlated with GU toxicity. Bladder volume <200 cc at CT-simulation was also associated with toxicity ( $p=0.014$ ), while maximum dose to bladder was correlated with late toxicity ( $p=0.014$ ). The use of 3D-EBRT was significantly associated both with increased acute ( $p=0.032$ ) and late ( $p=0.03$ ) toxicity.

#### Conclusion

In our study pretreatment IPSS, nocturia, urgency and urinary incontinence at diagnosis, bladder volume < 200 cc during CT-simulation, the use of 3D-EBRT and maximum dose to the bladder was predictive for specific moderate-severe acute urinary symptoms.

#### EP-1331 Efficacy and safety of re-irradiation of locally recurrent prostate cancer with FFF-VMAT

G.R. D'Agostino<sup>1</sup>, C. Franzese<sup>1</sup>, L. Di Brina<sup>1</sup>, S. Tomatis<sup>1</sup>, C. Iftode<sup>1</sup>, D. Franceschini<sup>1</sup>, E. Clerici<sup>1</sup>, G. Reggiori<sup>1</sup>, A. Tozzi<sup>1</sup>, P. Navarra<sup>1</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

#### Purpose or Objective

Despite considerable advances in technologies, especially with the introduction of IMRT, IGRT, and VMAT, re-treatment of locally recurrent prostate cancer with external beams radiation therapy remains controversial because of fear of major complications or unbearable side effects. In this study we report our experience on re-irradiation in a sample of 17 patients previously irradiated for prostate cancer.

#### Material and Methods

Patients affected by prostate cancer and previously submitted to radiotherapy were included in this study, provided that they had an increased PSA, diagnostic for biochemical relapse, and a PET-Choline revealing the presence of a local recurrence of disease. Re-irradiation consisted of a stereotactic treatment delivered by FFF IGRT-VMAT technology in 5 daily fractions. Clinical response was evaluated with PSA and physical examination. Toxicity assessment according to CTCAE (v. 4.01) criteria. During follow-up, PET-Choline was performed in the cases of PSA rising.

#### Results

Between November, 2012 and May, 2016, 17 patients (median age 78 years, range 59-82) were submitted to re-irradiation on prostate (n=10, 58.8%),

prostatic bed (n=5, 29.4%) or prostate and local recurrence (n=2 seminal vesicle, ischium 11.8%). Previous treatment consisted on a median total dose of 74 Gy on prostate or prostatic bed (range 66-76). Ten patients had also received radiotherapy on seminal vesicles, four patients on pelvic lymph-nodes. Median time from previous radiotherapy was 80 months (range 26-116). Median PSA at the moment of recurrence was 3.1 ng/ml (average 4, range 1.2-13.5). As a re-irradiation, a median total dose of 25 Gy (range 25-30) was delivered in a median number of 5 fractions (range 5-6). An immediate biochemical response was observed in all cases. Median PSA nadir after treatment was 0.77ng/ml (average 1.33, range 0.19-6.0, p=0.0004) The sole acute toxicity reported was genito-urinary, mainly represented by pollakiuria and dysuria grade 1 (n=9, 52.9%) or grade 2 (n=2, 11.8%). One patient (5.9%) had a grade 3 hematuria, was hospitalized and submitted to continuous bladder irrigation. A late grade 1 GU toxicity was observed in 3 patients (17.7%). No other toxicities were observed. At a median follow-up of 16 months (range 6-36, calculated from the time of recurrence diagnosis) 8 patients (47.1%), experienced a biochemical recurrence, confirmed by a positive PET-choline in 5 cases (29.4%). Median BFS was 19 months, 1- and 2-year BFS was 84.6% and 32.2%, respectively. Median LC was 24 months, 1- and 2-year LC was 90.9% and 40.4%, respectively. All patients are still alive, 5 of them with measurable disease. Median OS was 96 months from the initial diagnosis (range 59-151).

#### Conclusion

With the technological novelties offered by modern radiotherapy, re-irradiation of patients affected by prostate cancer, and previously treated with radiation therapy, confirms its safety and efficacy. Therefore, it can be considered a valuable option for local recurrence of this disease.

#### EP-1332 Contouring variability with CT and MRI of prostate cancer for radiation planning

A. Otero-Romero<sup>1</sup>, A. Pérez-Rozos<sup>1</sup>, R. Correa-Generoso<sup>1</sup>, I. Jerez-Sainz<sup>1</sup>, M.J. García-Anaya<sup>1</sup>, I. Zapata-Martínez<sup>1</sup>, A. Román-Jobacho<sup>1</sup>, M.D. Toledo-Serrano<sup>1</sup>, R. Ordoñez-Marmolejo<sup>1</sup>, I. García-Ríos<sup>1</sup>, J. Gómez-Millán<sup>1</sup>, J.A. Villalobos-Martín<sup>2</sup>, T. Díaz-Antonio<sup>2</sup>, J.A. Medina-Carmona<sup>1</sup>

<sup>1</sup>Hospital Virgen de la Victoria, Radiation Oncology, Málaga, Spain

<sup>2</sup>Hospital Virgen de la Victoria, Radiology, Málaga, Spain

#### Purpose or Objective

CT (Computer Tomography) is the standard for conformal radiotherapy treatment planning of prostate cancer, however T2-weighted MRI (Magnetic Resonance) allows better definition of apex of prostate, seminal vesicles and the rectum-prostate interface.

Analyse intra and inter-observer variability and whether implementing systematic image fusion with CT and MRI could improve prostate contouring accuracy.

#### Material and Methods

MR was requested to complete tumour staging and performed in a different centre due to the unavailability of MRI scan in our hospital. Planning CT was carried out in our department, slices of 3 mm, with empty bladder and rectum, in supine position using knee and feet immobilization devices. Image fusion was performed with T2-weighted MRI and CT scans matching on bony structures of the pelvis.

We conducted the study in two parts.

First part of the study consisted in contouring the prostate and seminal vesicles of a single patient on CT images and then on MRI fusion images by 9 Radiation Oncologists (including training doctors)

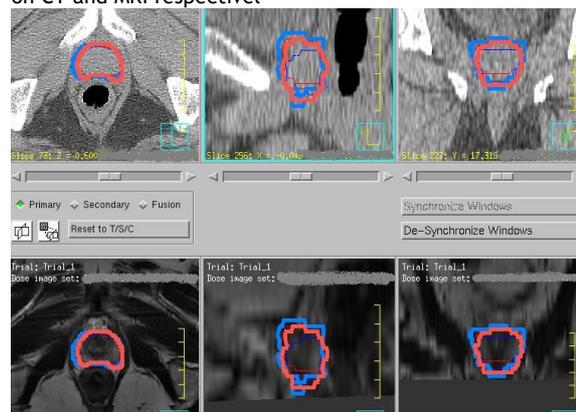

In the second part of the study two Radiation Oncologists, specialized in prostate cancer, and a Radiologist trained in MRI contoured the prostate of 5 patients on CT images and then on MRI fusion images. The contour of the Radiologist was considered the gold standard.

Comparison of volumes measured on CT and MRI using Pinnacle planning system was made. Intraobserver and interobserver variability was assessed taking into account the percentage of coincident volume with the gold standard, analysing the distance of the direction with more differences, and calculating sensitivity (S) and Paccard indexes ( $I_{paccard}$ ; P=delineated prostate; C=gold standard).

#### Results

Accurate CT-MRI image fusion was not always achieved with bony matching due to the different pelvis position and needed soft tissue correction. Volumes of the first part of the study range was 29.1-52.4 cc for prostate and 10.8-16.7 cc for seminal vesicles on CT, and 29.5-57.2 cc for prostate and 11.6-16.1 cc for seminal vesicles on MRI. Comparing CT and MRI volumes the intraobserver ratio was 1.13 (1.02-1.26) for prostate and 1.12 (1.01-1.21) for seminal vesicles.

In the second part of the study mean volumes range on CT scan was 13-21 cm<sup>3</sup> while on MRI was 18-26 cm<sup>3</sup>. Mean volume% comparing to the gold standard volume range was 62%-67% on CT and 81%-86% on MR. Variability in distance in the different directions were 3-9 mm in the longitudinal axis, 3-4 mm in the lateral axis and 2-3 mm in the anterior-posterior axis. Mean sensitivity index was 0.58 on CT and 0.80 on MRI, and mean Paccard index was 0.48 and 0.76 on CT and MRI respectively

y.

#### Conclusion

Prostate MRI enables more accurate planning contouring than CT. In our study CT volumes tend to be smaller than on MRI. The longitudinal axis is the direction where more contouring differences have been found. MRI and CT could be made in the same pelvis position to achieve reduced uncertainty image registration.

#### EP-1333 Impact of 18F-Choline PET scan acquisition time on delineation of GTV in Prostate cancer

C. Parkinson<sup>1</sup>, J. Chan<sup>2</sup>, I. Syndikus<sup>2</sup>, C. Marshall<sup>3</sup>, J. Staffurth<sup>4</sup>, E. Spezi<sup>1</sup>

<sup>1</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom

<sup>2</sup>Clatterbridge Cancer Centre, Clinical Oncology, Liverpool, United Kingdom

<sup>3</sup>Cardiff and Vale University Health Trust, Wales Research & Diagnostic PET Imaging Centre, Cardiff, United Kingdom

<sup>4</sup>Velindre Cancer Centre, Clinical Radiotherapy Trials, Cardiff, United Kingdom

### Purpose or Objective

Dose painting radiotherapy requires accurate outlining of primary tumour volumes in the prostate. T2-Weighted (T2W) Magnetic Resonance Imaging (MRI) is the best imaging method for defining the gross tumour volume (GTV). Choline positron emission tomography (PET) is currently a controversial tracer. The image acquisition differs significantly in published studies. Many used early static imaging. One study found that 18F-choline PET/CT with late image acquisition has superior accuracy to T2W MR and functional MR alone. We investigate whether increasing 18F-Choline PET scan acquisition time from 60 (PET-60) to 90 (PET-90) minutes improves GTV TVD.

### Material and Methods

Analysis was performed on 9 18F-Choline PET scans. Patients were injected with 370MBq of activity. Three clinicians (C1, C2 and C3) independently and without reference to each other contoured GTVs on each of the T2W-MRI, PET-60 and PET-90 scans at differing times. Scans were registered by a clinician using rigid co-registration. The treating clinicians MRI contour was used as a reference contour. The resulting PET and MRI GTVs were transferred to the PET-60 and PET-90 scans after image registration. The Dice Similarity Coefficient (DSC), Specificity (Sp) and Sensitivity (S) were calculated from contour mask voxel analysis.

### Results

Table 1 shows the mean and range DSC, S and Sp scores on MRI, PET-60 and PET-90 for C1, C2 and C3 in comparison to the treating clinicians contour on MRI (C1). A 2 sampled T-test ( $P < 0.01$ ) showed, no significant difference in the Sp, S and DSC between GTVs on PET-60 and PET-90 scans. Further to this, as shown in Figure 1, variability in GTV delineation is significant between observers in a singular case as well as across imaging modalities.

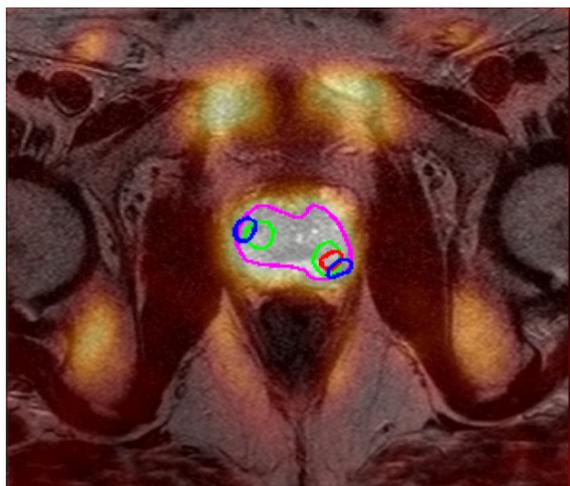

Figure 1: Variability in GTV delineation between imaging modalities and observers. PET-60 derived GTV (Red, Green and Pink) and MRI GTV (Blue).

Table 1: The mean and range of DSC, Sensitivity and Specificity for C1, C2 and C3 for MRI, PET-60 and PET-90

	MRI C2	MRI C3	C1 PET-60	C1 PET-90	C2 PET-60	C2 PET-90	C3 PET-60	C3 PET-90
Mean DSC	0.56	0.65	0.29	0.37	0.35	0.36	0.34	0.33
DSC Range	0.36-0.84	0.39-0.83	0.12-0.59	0.12-0.54	0.15-0.62	0.10-0.61	0.11-0.67	0.13-0.52
Mean Sensitivity	0.59	0.65	0.22	0.35	0.50	0.54	0.34	0.36
Sensitivity Range	0.24-0.92	0.27-0.88	0.08-0.52	0.08-0.90	0.21-0.89	0.12-0.96	0.07-0.54	0.08-0.67
Mean Specificity	0.91	0.92	0.81	0.93	0.93	0.81	0.90	0.89
Specificity Range	0.78-0.99	0.79-0.98	0.66-0.91	0.83-0.97	0.72-1	0.59-0.90	0.80-0.98	0.74-0.97

### Conclusion

Compared to MRI delineated GTVs, 18F-Choline PET GTVs are significantly different. This study found however that

increasing the PET scan acquisition time from 60 to 90 minutes did not improve the performance of GTV TVD in comparison to MRI delineated GTV

### EP-1334 Stereotactic radiotherapy with cyberknife® system in localized prostate cancer

S. Falivene<sup>1</sup>, V. Borzillo<sup>1</sup>, R. Di Franco<sup>1</sup>, G. Totaro<sup>1</sup>, V. Ravo<sup>1</sup>, G. Quarto<sup>2</sup>, D. Sorrentino<sup>2</sup>, S. Perdonà<sup>2</sup>, P. Muto<sup>1</sup>  
<sup>1</sup>Istituto Nazionale Tumori Fondazione Pascale, Radioterapia, Napoli, Italy  
<sup>2</sup>Istituto Nazionale Tumori Fondazione Pascale, Urologia, Napoli, Italy

### Purpose or Objective

Hypofractionated stereotactic radiotherapy (SRT) is an emerging technique in the treatment of localized prostate carcinoma (LPC). Considering that  $\alpha/\beta$  ratio prostate cancer is very low (1.5), SRT is advantageous because consent to deliver higher dose/fraction on target respect conventional radiotherapy. In this study we reported our initial experience with SRT using CyberKnife® System (CK) in the treatment of LPC.

### Material and Methods

From February 2013 to April 2016 ninety-six patients with LPC, mean age 70,6 years, were treated with CK-SRT. All patients were submitted to the eco-guided implants of 4 intraprostatic fiducial markers 7-10 days before the SRT in order to follow, to detect and to correct the intrafraction target movements. The fusion between CT scan and basal RM was made in order to optimize the contouring for treatment planning.

All patients were treated with SRT in 5 fractions of 7-7,25 Gy/fraction for a total dose of 35-36,25 Gy.

It was evaluated acute and late gastrointestinal and genitourinary toxicity using RTOG scale, biochemical control using mean decrease of PSA level during the different phases of follow up.

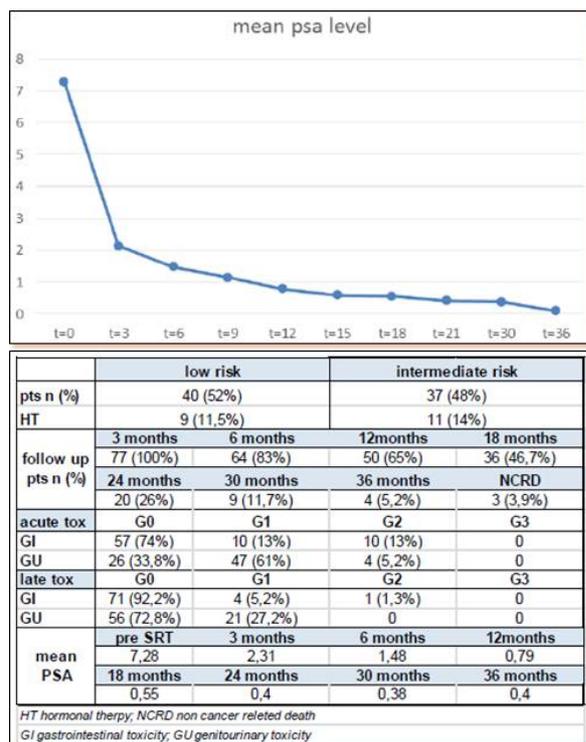

In this study we have analyzed the results in the 77 patients with almost 3 months of follow up.

### Results

All patients have completed CK SRT without severe complication. Median follow up was 17 months. Three patients died for non related cancer causes.

Gastrointestinal acute toxicity G2 for perineal pain and rectal tenesmus was reported in only 13% and was decreased in all patients. Genitourinary acute toxicity G2 for urgency and nicturia was reported in only 4% and G1 for dysuria in 61% of cases which persist in 27,3% of patients. (Table 1)

All patients obtained biochemical response with decrease of PSA. The PSA drop between the start of the therapy and at 21 months of follow up, was significant with  $p < 0,01$  ( $p = 0,00001$ )

### Conclusion

In our experience CK-SRT seem to be safe and reliable in the LPC. No severe toxicities were reported and the patients were very compliant. Careful patient selection is critical to achieve maximum effectiveness by CK SRT. More patients and longer follow up are necessary in order to evaluate the real advantage of SRT respect to standard fractionation in terms of overall survival, biochemical free survival and late toxicity.

### EP-1335 Hypofractionated versus conventional radiotherapy in intermediate- to high-risk prostate cancer

W. Guo<sup>1</sup>, X.S. Gao<sup>1</sup>, X.B. Gu<sup>1</sup>, M.W. Ma<sup>1</sup>

<sup>1</sup>Peking University First Hospital, Department of Radiation Oncology, Beijing, China

#### Purpose or Objective

Prostate cancer is one of the most common cancers in the world, and the population of patients with intermediate- to high-risk localized prostate cancer (PCa) occupies a large proportion. The results of treatment after hypofractionated radiotherapy only have been reported from several small randomized trials. Therefore, we pooled the relevant data and conducted a meta-analysis to compare clinical outcomes of hypofractionated radiotherapy versus conventional radiotherapy in the treatment of intermediate- to high-risk localized PCa.

#### Material and Methods

Relevant studies were identified through searching PubMed, Embase and Web of Science databases till August, 2016. Hazard ratio (HR) or risk ratio (RR) with its corresponding 95% confidence interval (CI) was used as pooled statistics for all analyses.

#### Results

Six clinical cohorts were included with a total of 1621 intermediate- to high-risk localized PCa patients. The meta-analysis results showed that overall survival (HR=1.00, 95% CI: 0.85-1.17,  $p=0.980$ ) and biochemical failure (RR=0.87, 95% CI: 0.68-1.12,  $p=0.274$ ) were similar in two groups. The incidence of acute adverse gastrointestinal event (grade  $\geq 2$ ) was higher in the hypofractionated radiotherapy (RR=1.87, 95% CI: 1.21-

2.91,  $p=0.005$ ). Acute genitourinary adverse event (grade  $\geq 2$ ) was similar among the groups (RR=1.02, 95% CI: 0.92-1.14,  $p=0.671$ ). Gastrointestinal (RR=1.17, 95% CI: 0.90-1.51,  $p=0.238$ ) or genitourinary (RR=1.11, 95% CI: 0.94-1.30,  $p=0.228$ ) late adverse event (grade  $\geq 2$ ) data were not significant differences between two radiotherapy schedules. No publication bias was detected in this meta-analysis (all  $p>0.05$ ).

#### Conclusion

Hypofractionated radiotherapy in intermediate- to high-risk localized prostate cancer was not superior to conventional radiotherapy and showed higher acute gastrointestinal adverse event in this meta-analysis. However, these findings should be utilized cautiously when directed in clinical treatment due to some limitations.

### EP-1336 Effect of bladder, trigone, urethra doses on acute genitourinary toxicity in prostate cancer treatment

L.Z. Arican (Turkey), N. Akturk, K. Meltem, B. Aydin, H. Ellidokuz, I. Bilkay Gorken

<sup>1</sup>Dokuz Eylul Univ. Health Sciences Institute, Department of Radiation Oncology, IZMIR, Turkey

<sup>2</sup>Dokuz Eylul Univ. Health Sciences Institute, Department of Preventive Oncology, IZMIR, Turkey

#### Purpose or Objective

To evaluate the relationship between acute GUS toxicities and the dose/volume values of the bladder, trigone, urethra in prostate cancer (PCa) patients who were treated by volumetric modulated arc therapy (VMAT).

#### Material and Methods

Twenty seven moderate/high-risk PCa patients who were treated between January 2014 and November 2015 were retrospectively evaluated. According to the D'Amico classification 59% of the patients were at high risk. All patients received hormone therapy (2-4 months neo/6-24 months adjuvant). Simulation was performed with a full bladder and empty rectum. Total doses of peripheral lymphatic, seminal vesicle and prostate were 56, 65 and 78 Gy in 37 fractions, respectively. Image guided radiotherapy was performed. The urethra, bladder and trigone were re-contoured respectively on planning CT fused with magnetic resonance images obtained before treatment. The minimum, maximum, mean and Vdose (V20-80) values of the bladder, trigone and urethra were obtained. Acute GUS toxicities were graded according to RTOG. Age, history of previous abdominal surgery, TUR-P, diabetes, smoking, target and bladder, trigone and urethra volumes were evaluated as factors that affect grade  $\geq 2$  GUS toxicity. The Chi-square, ROC, Mann-Whitney U and Wilcoxon regression tests were used in the statistical analyses.

#### Results

The median age is 68 (59-76) years. Grade 2 acute GUS toxicities were observed in 59% of the patients, and there was no grade 3-4 toxicity. The average dose values were 5335 (4337-5995) cGy for the bladder, 7068 (6479-7873) cGy for the trigone and 7901 (7624-7995) cGy for the urethra, respectively. No significant relation was demonstrated between acute GUS toxicities and patient's previous history ( $p>0.05$ ). There was a tendency towards a statistically significant relationship between the trigone V55 ( $p=0.07$ ) and the V60, and a statistically significant association was found between the minimum trigone dose ( $p=0.02$ ) and V65 ( $p=0.02$ ). Due to the low number of patients and events, a cut-off value could not be identified in the ROC analysis.

#### Conclusion

The demonstration of a significant relationship between acute GUS toxicities and increasing trigone doses shows that this structure should be taken into consideration

when planning treatment. Besides this, more patients need to be included in the study to identify a cut-off value that clearly reflects the association between grade  $\geq 2$  GUS toxicity and the trigone volume.

**EP-1337 High hypofractionation using beacon transponders in intermediate-risk prostate cancer: first results**

L. Di Brina<sup>1</sup>, G. D'agostino<sup>1</sup>, C. Franzese<sup>1</sup>, D. Franceschini<sup>1</sup>, T. Comito<sup>1</sup>, F. De Rose<sup>1</sup>, P. Navarra<sup>1</sup>, A. Tozzi<sup>1</sup>, C. Iftode<sup>1</sup>, A. Ascolese<sup>1</sup>, E. Clerici<sup>1</sup>, L. Pasini<sup>2</sup>, A. Benetti<sup>2</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

<sup>2</sup>Istituto Clinico Humanitas, Urology, Rozzano Milan, Italy

**Purpose or Objective**

In the last decades, an improved diagnostic accuracy has led to an increased incidence of early stage prostate cancer(PC). For these patients a traditional course of radiotherapy(RT) remains a critical issue. Furthermore acceleration of RT could improve therapeutic ratio, especially in intermediate risk patients. Therefore we designed a study of hypo-fractionated stereotactic body radiation therapy(SBRT) delivered by Volumetric Modulated Arc Therapy(VMAT) with Flattening Filter Free(FFF) beams and gated using beacon transponders. We report our preliminary results on feasibility and early side effects.

**Material and Methods**

This is a prospective phase II study. Inclusion criteria were: age $\leq 85$  years, PS $\leq 2$ , PSA $\leq 20$  ng/ml and Gleason Score (GS) 7 (NCCN intermediate class of risk), no distant metastases, no previous surgery other than transurethral resection of the prostate (TURP), no malignant tumors in the previous 5 years, IPSS $\leq 7$ . Patients underwent pelvic MRI. Three beacons transponders were positioned transrectally within the prostate parenchyma by an urologist with an ultrasounds-guided procedure that was performed 7-10 days before simulation CT-scan. MR images were registered with those of simulation CT. The RT schedule was 38 Gy in 4 fractions delivered every other day with VMAT and 10MV FFF photons. Toxicity assessment was performed according to Common Terminology Criteria for Adverse Events (CTCAE) v4.0 scale.

**Results**

Between September, 2012 and May, 2016, 23 patients were recruited in the protocol and treated. Median follow-up (FUP) was 16 months (range: 7-27). Median age was 74 years (59-79), Median initial PSA (iPSA) was 7.0 ng/ml (range 3.12-12.7 ng/ml). All patients completed the treatment as scheduled, in a median 8 days (8-11). Median nadir-PSA after treatment was 0.78 ng/ml (range 0.2-4). Acute Toxicities were as follow: three patients (13%) presented G1 proctitis. Genito-urinary toxicity was observed in 57% of patients (n=13): in particular, 6 patients had G1 cystitis (26%) with 4 of these presenting even G1 increased urinary frequency (17%); G2 cystitis was observed in 7 patients (30%) with a G2 urinary frequency observed in two of these patients (9%); in only one patient a G2 urinary retention was observed and it was treated with transient catheterization and oral and rectal medications. No acute gastrointestinal  $\geq$  G2 or genito-urinary  $\geq$  G3 toxicity was found. No other toxicities were observed. At a median FUP of 16 months (range 7-27, from the time of diagnosis), only one patient presented an outfield relapse of disease, that was treated with androgen deprivation therapy (ADT). No other biochemical recurrence or progression of disease was observed.

**Conclusion**

Preliminary findings show that our schedule of hypofractionated radiotherapy, delivered with FFF-VMAT and gated using beacon transponders, is a valid option for intermediate risk PC. Early results in terms of feasibility, toxicity profile and disease control are encouraging to warrant the pursuance of the study.

<sup>5</sup>Istituto Europeo di Oncologia - IEO, Urology, Milan, Italy

<sup>6</sup>Istituto Europeo di Oncologia - IEO, Medical Imaging and Radiation Sciences, Milan, Italy

<sup>7</sup>Istituto Europeo di Oncologia - IEO- Università degli Studi di Milano, Radiotherapy, Milan, Italy

**Purpose or Objective**

To report preliminary results, in terms of acute toxicity, of an innovative hypofractionated treatment with concomitant boost to the dominant lesion for patients with early stage prostate cancer (PCa).

**Material and Methods**

This prospective phase II trial, supported by AIRC (Associazione Italiana per la Ricerca sul Cancro), started in June 2015. Patients with low- and intermediate-risk PCa who met the inclusion criteria underwent hypofractionated radiotherapy (RT) to the prostate with a total dose of 36.25 Gy in 5 fractions (biologically equivalent to a 90.6 Gy, considering a  $\alpha/\beta$  ratio of 1.5 Gy) and a simultaneous integrated boost (SIB) to the dominant intraprostatic lesion (DIL) of 37.5 Gy in 5 fractions (biologically equivalent to a 96.4 Gy, considering a  $\alpha/\beta$  ratio of 1.5 Gy). The DIL was identified by a multiparametric magnetic resonance imaging (mpMRI) co-registered with planning CT. The treatment was delivered using a Varian Trilogy<sup>TM</sup> with RapidArc<sup>®</sup> technology. Toxicity was assessed according to CTCAE v4.0 and RTOG/EORTC criteria. The preliminary evaluation of the first 13 patients was required to assess the feasibility of the treatment before completing the enrollment of 65 patients.

**Results**

The first 13 patients completed the treatment between June 2015 and February 2016. Patients' characteristics are reported in Table 1. An example of dosimetric distribution is shown in Figure 1. With a median clinical follow-up of 5.9 months, ranging from 1 to 6 months, no grade 3 or 4 acute toxicity was reported. At the end of RT, only one patient experienced G2 gastrointestinal (GI) toxicity, and 4 patients had G1 genitourinary (GU) events. After one month, G1 GI toxicity was reported in 2 patients and G1 GU in 4 patients; no toxicity higher than G2 has been recorded. At 6 months from the end of treatment, 8 patients have been evaluated and no events higher than G2 have been experienced: 1 patient had G1 GI toxicity and 3 patients had G1 GU toxicity.

Characteristic	Value
Number of patients	13
Median age (range) [years]	75.4 (62.7-79.9)
Median initial PSA (range) [ng/mL]	5.8 (4.3-17)
Median Gleason Score (range)	6 (6-7)
Risk category (according to NCCN):	
- Low risk	3
- Intermediate	10
Androgen deprivation therapy	1

Table 1 – Patients' characteristics

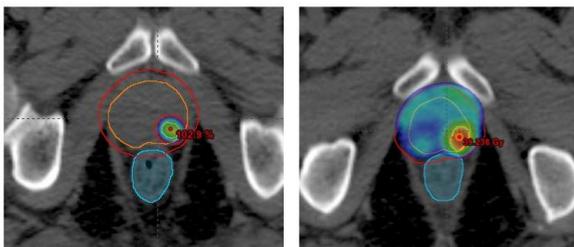

Figure 1 – An example of dosimetric distribution.

### Conclusion

Up to October 2016, 42 patients have completed the treatment. More mature results seem to confirm the presented preliminary ones. Our preliminary data show the feasibility of an extremely hypofractionated schedule with concomitant boost on the mpMRI-identified DIL. The higher number of patients expected for the trial and a longer follow-up are needed to confirm these results. The secondary endpoints of the study, namely the evaluation of late toxicity, patient free survival, overall survival, quality of life and pattern of failure will be investigated when more mature follow-up data will be available.

### EP-1339 Feasibility and efficacy of moderately hypofractionated radiotherapy in high risk prostate cancer

### Purpose or Objective

Prostate cancer (PCa) is the second most common male cancer. The prognosis for patients with a diagnosis of high-risk PCa is poor. No consensus exists on the most effective treatment. In the last decade, hadrontherapy with carbon ions has been considered a suitable strategy for high-risk PCa, in terms of the dose delivery with a resulting increased sparing of organs at risk, based on the promising Japanese results and first Italian data from CNAO.

The aim of this retrospective study was to identify the biochemical progression-free survival and the toxicity profile of localized high-risk PCa patients treated with external beam radiation therapy (EBRT). These results will

constitute a benchmark for a prospective “mixed beam” trial: a boost with carbon ions followed by a pelvic photon intensity modulated radiotherapy (NCT 02672449, registered at clinicaltrials.gov).

### Material and Methods

We retrospectively reviewed the data of 76 patients treated in our Institution with photon EBRT according to the inclusion criteria of the forthcoming “mixed beam” trial: cT3a and/or serum prostate-specific antigen >20 ng/mL and/or Gleason score of 8-10, cN0 cM0. Toxicity, biochemical and clinical progression-free survival were assessed.

### Results

Seventy-six patients treated between 05/2010 and 12/2014 fulfilled our criteria. Median age, initial PSA and Gleason score were 74.9 years, 26.4 ng/mL and 8, respectively. Prostate and vesicles or prostate and pelvis were irradiated in 46 and 30 patients, respectively, using intensity modulated radiation therapy. Moderate hypofractionation was employed (Fox Chase regimen), with a median dose of 70.2 Gy (2.7 Gy for 26 fractions). In 61 patients (80.3%) androgen deprivation therapy (ADT) was added.

The median follow-up was 30.2 months (range 7.2-61.1 months).

Biochemical progression was observed in 22 patients (28.9%) after a median time of 20.2 months (range: 5-58.1) from the end of EBRT. Sixteen patients had clinical progression, always preceded by biochemical progression. Fifty-seven patients (75.0%) are alive with no evidence of disease, 13 patients (17.1%) are alive with clinically evident disease, 6 patients (7.9%) died (3 for PCa).

No grade higher than 2 acute and late toxicity, including urinary and rectal complications, was reported.

### Conclusion

Our results suggest that a more aggressive treatment is necessary. Local treatment intensification based on the “mixed beam” approach combining carbon ions, with its known radiobiological advantages, and photons might really represent a promising strategy in the high-risk PCa and it will be investigated with our prospective clinical trial.

### EP-1340 Comparing dosimetry and toxicity of 5-field IMRT versus VMAT for prostate & pelvic nodal irradiation

P. Turner<sup>1</sup>, S. Jain<sup>1</sup>, D. Mitchell<sup>2</sup>, J. Harney<sup>2</sup>, F. Houghton<sup>2</sup>, J. McAleese<sup>2</sup>, D. Stewart<sup>2</sup>, A. Hounsell<sup>1</sup>, D. Irvine<sup>3</sup>, G. Corey<sup>2</sup>, K. Tumelty<sup>2</sup>, K. Thompson<sup>4</sup>, J. O'Sullivan<sup>1</sup>

<sup>1</sup>Centre for Cancer Research and Cell Biology- Queen's University of Belfast, Advanced Radiotherapy Group, Belfast, United Kingdom

<sup>3</sup>Northern Ireland Cancer Centre, Radiotherapy Physics, Belfast, United Kingdom

<sup>4</sup>Queen's University of Belfast, School of Medicine, Belfast, United Kingdom

### Purpose or Objective

There is emerging evidence supporting the use of prostate and pelvic nodal irradiation in high-risk localised prostate cancer. Recent evidence also suggests a role for local prostate irradiation in metastatic prostate cancer. It is therefore timely to assess different methods of delivering pelvic radiotherapy from the point of view of dosimetry and real world toxicity.

### Material and Methods

The demographics, disease metrics, RTOG graded toxicity and outcome data for 42 patients receiving prostate and pelvic node radiotherapy in our institution over a 2 year

period were retrospectively collected. Dosimetric data were captured including method of treatment delivery: static intensity modulated radiotherapy (IMRT) or volumetric modulated arc therapy (VMAT); dose to prostate and pelvic node volume, as well as a single dose level indicating normal tissue exposure (V50 to bowel, rectum and bladder, that is volume of normal tissue of each receiving  $\geq 50\text{Gy}$ ).

#### Results

The median age was 64 years. 88.1% of patients had Gleason grade  $\geq 8$  cancer and 78.6% had local staging  $\geq \text{T3a}$ . 52.4% of patients were N0 with the remaining 47.6% N1; 1 patient had M1a disease. Treatment was by IMRT in 61.9% of patients and by VMAT in 38.1%. All patients received 74 Gy to prostate. Dose to pelvic nodes was 60Gy in 78.6%, 55Gy in 19% and 56Gy in 1 patient. There was no significant difference in nodal dose received by IMRT vs VMAT groups. All patients had neo-adjuvant and adjuvant hormone therapy. Median follow up was 37 months. Acute bowel toxicity (RTOG) was  $< 2$  in 73.8% and maximally  $= 2$  in 26.2%. Late bowel toxicity was  $< 2$  in 83.3%, and maximally  $= 2$  in 16.7%. Acute urinary toxicity was  $< 2$  in 85.7%,  $= 2$  in 7.1% and maximally 3 in 7.1%. Late urinary toxicity was  $< 2$  in 59.5%,  $= 2$  in 35.7% and maximally 3 in 4.8%. Endoscopy rates during follow up were low: 7 patients had lower GI endoscopy with radiation proctitis confirmed in 5; 8 patients had cystoscopy with radiation related mucosal changes in 3. 14.3% of patients have experienced biochemical failure during follow up.

V50 rectum and bladder are significantly lower in patients treated by VMAT versus IMRT; V50 rectum by VMAT = 48.81% vs by IMRT = 56.19%  $p=0.017$ ; V50 bladder by VMAT = 46.88% vs by IMRT = 58.85%  $p=0.010$ . This has not translated into any significant difference in acute or late toxicities between the groups split by treatment modality. No significance difference was seen between V50 bowel in VMAT vs IMRT treated patients.

#### Conclusion

In high-risk N0 and N1 prostate cancer, treatment by advanced conformal radiotherapy to prostate and pelvis is associated with acceptable levels of toxicity and good biochemical control at 37 months. There is evidence of a dosimetric advantage with VMAT over static field IMRT.

#### EP-1341 Pelvic SABR with HDR boost in intermediate and high risk prostate cancer (spare): early results

H.B. Musunuru<sup>1</sup>, A. Deabreu<sup>1</sup>, M. Davidson<sup>1</sup>, A. Ravi<sup>1</sup>, J. Hlou<sup>1</sup>, L. Ho<sup>1</sup>, P. Cheung<sup>1</sup>, D. Vesprini<sup>1</sup>, S. Liu<sup>1</sup>, W. Chu<sup>1</sup>, H. Chung<sup>1</sup>, L. Zhang<sup>1</sup>, A. Loblaw<sup>1</sup>

<sup>1</sup>Odette Cancer Centre- Sunnybrook Hospital- University of Toronto, Radiation Oncology, Toronto, Canada

#### Purpose or Objective

ASCENDE-RT has provided level 1 evidence supporting the use of androgen deprivation therapy (ADT), external beam radiotherapy and brachytherapy boost in intermediate- and high-risk prostate cancer. The objectives of this study are to report early toxicity and quality of life (QOL) outcomes in patients treated on a hybrid protocol using five-fraction pelvic stereotactic ablative radiotherapy (SABR) with a MRI dose painted HDR brachytherapy boost (HDR-BT).

#### Material and Methods

A phase I/II study was performed where intermediate (IR) and high-risk (HR) prostate cancer patients received HDR-BT 15Gy in single fraction to the prostate and up to 22.5Gy to the MRI nodule. Gantry-based 25Gy SABR was delivered to pelvis, seminal vesicles and prostate in 5 weekly fractions. ADT was used for 6-18 months. Common Terminology Criteria for Adverse Events version 3.0 was used to assess toxicities. QOL was captured using EPIC questionnaire at 3months 6months and then every 6 months. A minimally clinically important change (MCIC)

definition was triggered if the EPIC QOL score at each time point decreases  $> 0.5$  SD, where SD is the standard deviation of baseline scores.

#### Results

Thirty-three patients (NCCN 6.0% low IR, 45.5% high IR and 48.5% HR) completed the planned treatment with a median follow-up of 13.8 months (IQR 12.1, 18.8). The incidence of worst toxicities is shown in Table 1. The 3 grade 3 GU patients were due to temporary urinary catheterization in the acute period following HDR-BT. Mean (95% SD) EPIC urinary QOL scores were 82.5 (16.5), 83.2 (12.9) and 83.7 (16.3) at baseline, 3 months and 12 months and the bowel scores were 95.9 (3.8), 92.6(8.2) and 90.5 (8.3), respectively. Proportion of patients experiencing MCIC at 3 months and 12 months were 20.8% and 14.3% for urinary domain, 47.8% and 53.9% for bowel domain; respectively.

DOMAIN	TIMING	GRADE 2(%)	GRADE 3(%)	QOL MCIC(%)
GENIOURINARY	Acute	45.2%	9.7%	20.8%
	Late	12.9%	0%	14.3%
GASTROINTESTINAL	Acute	9.7%	0%	47.8%
	Late	0%	0%	53.9%

#### Conclusion

This novel treatment protocol incorporating MRI dose painted HDR brachytherapy boost and SABR pelvic radiation for intermediate- and high-risk prostate cancer in combination with ADT is feasible and well tolerated in the acute setting.

#### Purpose or Objective

To evaluate the PSA response, progression free survival (PFS), local control and toxicity of stereotactic body radiotherapy (SBRT) for lymph-node (LN) oligorecurrent prostate cancer.

#### Material and Methods

We retrospectively reviewed 95 patients with LN oligorecurrent prostate cancer treated between 05/2012 and 10/2015. We evaluated biochemical response with

PSA dosage every 3 months after SBRT: considering the pre-SBRT PSA as reference, a decrease in PSA of more than 10% identified responder patient, whereas an increase of more than 10% identified a biochemical progression. The other cases were classified as PSA stabilization. In case of PSA increase during the follow-up, imaging was performed to evaluate clinical progression. Toxicities were assessed with clinical examination every 6-9 months: acute toxicities were reported in the first 6 months after SBRT.

#### Results

A hundred twenty-seven lesions were treated in 95 patients with a median dose of 24 Gy given in 3 fractions. Median pre-SBRT PSA was 3.5 ng/mL. Seventy patients were treated for a single lesion, 25 for 2-4 lesions. In 9 patients SBRT was performed as a re-irradiation. In 35 patients androgen deprivation therapy (ADT) was added to SBRT. Median follow-up was 18.5 months. One patient was not valuable due to short follow-up. Biochemical response, stabilization and progression were observed in 64 (68.1%), 10 (10.6%) and 20 (21.3%) out of 94 patients. In the 57 patients treated with salvage SBRT alone (with no concomitant therapy), biochemical response, stabilization and progression were observed in 38 (66.7%), 9 (15.8%) and 10 (17.5%) cases, respectively. In 17 patients (29.8%) with progressive disease after SBRT, ADT started in a median time of 7.2 months (range 2.4-32.1). Clinical progression was observed in 31 patients (33.0%) after 15 months (median time). In-field progression occurred in 12 lesions (9.4%). 2-year local control and PFS rates were 84% and 30%, respectively (fig. 1-2). Age >75 years correlated with better biochemical response rate. Age >75 years, concomitant ADT administered up to 12 months and pelvic LN involvement correlated with longer PFS. Acute toxicity included urinary (6 and 1 G1 and G2 events, respectively) and rectal events (1 G1 event). Late toxicity included urinary (2 G1 and 3 G2 events). All toxicities were reported in patients treated for pelvic LN. No toxicity were reported in patients with extra-pelvic LN. At the time of the analysis, 32 (34.0%) patients are alive with no evidence of disease, 60 (63.8%) are alive with clinically evident disease, 2 patients (2.1%) died.

Fig. 1. Progression free survival curve, including biochemical and clinical progression (CI - confidence interval)

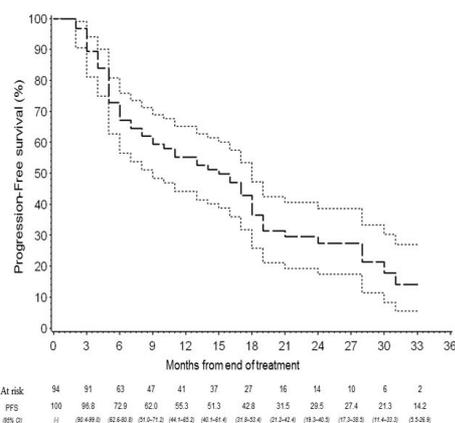

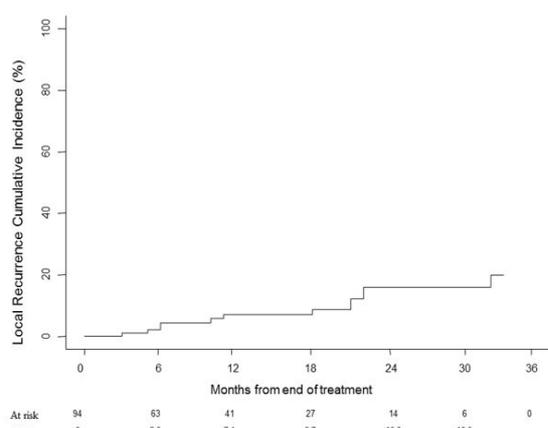

Fig. 2. Local Recurrence Cumulative Incidence (LRci)

#### Conclusion

SBRT is safe and offers excellent in-field control. At 2 years after SBRT, 1 out of 3 patients is progression-free. Further investigation is warranted to identify patients who may benefit most from SBRT and to define the optimal combination with ADT

#### EP-1343 Is stereotactic body radiation therapy a viable option for elderly patients with prostate cancer?

C. Franzese<sup>1</sup>, G. D'agostino<sup>1</sup>, L. Di Brina<sup>1</sup>, L. Cozzi<sup>1</sup>, T. Comito<sup>1</sup>, D. Franceschini<sup>1</sup>, F. De Rose<sup>1</sup>, P. Navarra<sup>1</sup>, E. Clerici<sup>1</sup>, A. Ascolese<sup>1</sup>, A. Tozzi<sup>1</sup>, C. Iftode<sup>1</sup>, S. Tomatis<sup>1</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

#### Purpose or Objective

Data regarding the treatment of elderly patients with prostate cancer show that Radiotherapy (RT) is associated with a cancer specific mortality risk reduction of 2.6% at 10 years, even after adjusting for several confounders including 12 comorbid conditions. The aim of the present study is to evaluate the efficacy and toxicity of Stereotactic body radiation therapy (SBRT) in a group of elderly patients affected by low and intermediate risk prostate cancer.

#### Material and Methods

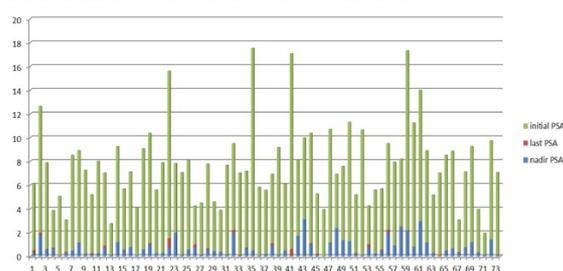

Patients aged  $\geq 75$  years, with biopsy-confirmed prostate cancer were enrolled. Inclusion criteria were: initial prostate-specific antigen (PSA)  $\leq 20$  ng/ml, Gleason Score  $\leq 7$ , International Prostate Symptom Score  $\leq 7$ . Gantry-

based SBRT was performed with Volumetric Modulated Arc Therapy in its RapidArc form and flattening filter free beams. The treatment schedule was 35 Gy in five fractions delivered on alternate days. The PTV included the prostate for low risk and prostate plus seminal vesicles for intermediate risk, with a 5 mm margin in all other directions. Toxicity was recorded according to CTCAE criteria v4.0. Biochemical failure was calculated according to the Phoenix definition. The Expanded Prostate Cancer Index Composite questionnaire was used to record health-related quality of life.

#### Results

From May 2012 to April 2016, 50 patients were enrolled. Twenty-five patients were classified in low risk group and 25 in intermediate risk group. Mean age was 78 years old (range 75 - 84); Gleason score was 6 in 26 and 7 in 24 patients. Median initial PSA was 6.43 (range 2.6 - 17). Median follow-up was 26 months. Acute toxicity was mild. Rectal toxicity was reported as grade 1 in 5 (10%) cases and grade 2 in 1 (2%) cases; grade 1 and grade 2 genitourinary toxicity was described in 13 (26%) and 14 (28%) patients, respectively. In the late setting, 3 (6%) patients reported rectal grade 1 toxicity. Genitourinary late effects were reported as grade 1 in 13 (26%) patients and grade 2 in 2 (4%) patient. Regarding outcome, median nadir PSA was 0.51 ng/ml (range 0.01 - 3.12). Trend of PSA is reported in Figure 1. No biochemical relapses were observed during follow-up and all patients are alive at the moment of the analysis.

Fig. 1 Trend of PSA values. Green: initial PSA; Red: last PSA; Blue: nadir PSA

#### Conclusion

Gantry-based SBRT with VMAT and FFFs can be considered an effective, non-invasive and safe approach for elderly patients affected by prostate cancer at low and intermediate risk. Randomized trials comparing SBRT with other approaches in this setting are necessary.

#### EP-1344 Long-term quality of life after high-dose-rate brachytherapy boost for prostate cancer

W. Busser<sup>1</sup>, I. Korffage<sup>2</sup>, S. Aluwini<sup>1</sup>

<sup>1</sup>Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

<sup>2</sup>Erasmus Medical Center, Public Health, Rotterdam, The Netherlands

#### Purpose or Objective

Quality of life (QoL) of patients treated for prostate cancer (PCa) is relevant because of the long survival of these patients. We aimed to report late toxicity incidences and generic and PCa-specific health-related QoL and to investigate associations between toxicity and QoL in patients treated with high-dose-rate brachytherapy (HDR-BT) boost combined with external beam radiotherapy (EBRT).

#### Material and Methods

264 low- and intermediate risk PCa patients were treated between 2000-2007 with single implant HDR-BT boost (3x6 Gy) combined with EBRT (25x1.8 Gy). Of these, 171 patients with QoL data available with 6-10 years follow-up

(FU) were included. Late grade  $\geq 2$  gastrointestinal (GI) or genitourinary (GU) toxicity was evaluated using physicians charts and EORTC-TOG toxicity questionnaire at 3, 6 and 12 months and yearly thereafter. The highest score of both was used to identify toxicity.

Between 2010-2013, validated self-assessment questionnaires, EORTC QLQ-C30 for health-related QoL and EORTC PR-25 for PCa-specific QoL, were yearly sent to all patients. All C30 functioning domains, global health and fatigue and pain symptoms were evaluated. The evaluated PR25 domains were sexual activity and functioning, urinary and bowel symptoms, and incontinence aid use. Raw scores of each domain were linearly transformed into 0-100 scales. Higher functional scores indicate higher functioning and better QoL, while higher symptom scores indicate lower QoL.

Patients with toxicity were compared to patients without late toxicity. A multi-level linear model was used to statistically assess the QoL differences between the 2 groups over 6-10 years FU. Covariates were included in the analysis to control for their influence: age, PSA, prostate volume and FU time. Clinical relevance of the differences was assessed by means of the minimally important difference (MID): toxicity group mean scores  $\geq 0.5$  standard deviation different from the non-toxicity group, were considered clinically relevantly different.

#### Results

Late grade  $\geq 2$  toxicity was reported by 79 patients (46.2%), of whom 57 (33.3%) had GU and 30 (17.5%) had GI symptoms. Of both C30 and PR25, 364 questionnaires were analysed (mean 2.1 per patient).

Generic QoL (C30) domains did not show any statistically significant differences (Table 1). PR25 PCa-specific QoL for both urinary and bowel symptoms showed clinically relevant worse QoL scores for patients with grade  $\geq 2$  toxicity ( $p < 0.001$  and  $p = 0.01$ , respectively). Of sexually active patients, patients with toxicity reported better sexual function ( $p = 0.001$ ); which was also clinically relevant. The included covariates did not show any associations with QoL score differences.

Table 1: Differences in QoL scores between patients with and without late grade  $\geq 2$  toxicity

Domain	Scale	Toxicity			No toxicity			p-value
		Mean	SD	95% CI	Mean	SD	95% CI	
<b>QLQ-C30</b>								
Global health status/QoL	F	75.6	19.2	72.7-78.5	79.3	16.6	76.9-81.6	0.76
Physical functioning	F	86.6	16.1	84.1-89.0	89.4	15.1	87.3-91.5	0.57
Role functioning	F	87.7	16.9	85.1-90.3	91.6	14.9	89.5-93.7	0.20
Emotional functioning	F	85.2	17.2	82.5-87.8	88.3	14.8	86.1-90.4	0.36
Cognitive functioning	F	84.3	22.4	80.9-87.7	89.1	17.4	86.6-91.5	0.81
Social functioning	F	90.1	18.8	87.2-93.0	93.6	15.7	91.4-95.9	0.19
Fatigue	S	9.0	13.1	7.0-11.0	6.1	9.9	4.7-7.5	0.58
Pain symptoms	S	15.2	20.0	12.1-18.2	9.1	13.3	7.3-11.0	0.51
<b>QLQ-PR25</b>								
Sexual activity	F	73.0	23.0	69.4-76.6	74.0	23.1	70.7-77.3	0.22
Sexual functioning	F	46.5	28.5	39.6-53.4	41.8	28.3	35.6-47.9	0.001
Urinary symptoms	S	24.0	17.7	21.3-26.7	14.4	11.7	12.7-16.1	<0.001
Bowel symptoms	S	6.7	10.3	5.0-8.4	2.7	5.6	1.9-3.6	0.01
Incontinence aid	S	2.2	9.7	0.7-3.6	0.9	8.6	-0.4-2.0	0.35

Note: 95% CI = 95% confidence interval (lower and upper bound values), F = functional scale, S = symptom scale, SD = standard deviation.

#### Conclusion

For patients treated with EBRT and HDR-BT boost, late grade  $\geq 2$  toxicity was not associated with decreased QoL for generic QoL domains, but associations between toxicity and decreased PCa-specific QoL scores were observed. The higher sexual functioning scores in the toxicity group are hard to explain and worth more investigation.

#### EP-1345 Dosimetric effect of seed-based prostate localisation on Pelvic Lymph Nodes in High-Risk Prostate Ca

R. Valentine<sup>1</sup>, E. Miguel Chumacero<sup>2</sup>

<sup>1</sup>NHS greater glasgow and clyde, Department of Radiotherapy Physics, glasgow, United Kingdom

<sup>2</sup>NHS greater glasgow and clyde- University of Glasgow, Department of Radiotherapy Physics, Glasgow, United Kingdom

### Purpose or Objective

Prostate movement is unrelated to pelvic lymph nodes (PLN) location. Therefore, for High-Risk Prostate Cancer radiotherapy, set-up corrections based on image-guided localisation of the prostate might not guarantee that the other nodal PTV receives the intended dose. The aim was to evaluate the impact that couch shifts applied for prostate motion correction have on the dose delivered to the PLN CTV and to determine their ideal PTV margins.

### Material and Methods

Retrospective analysis of 21 VMAT treatments was realized using the interfraction prostate-based couch shifts as new isocentre coordinates in a verification plan. Then each fraction dose was recalculated and the dose coverage of the PLN CTV was assessed with DVHs. To reduce the geometric miss new PLN PTV margins were proposed using the Van Herk formula. Finally treatment plans using current and proposed margins were compared based on the dose to OARs and PTVs.

### Results

The verification plans reported a mean PLN CTV  $D_{99\%}$  of 91.7% and this reduced between 4.8% and 9.0% ( $p < 0.001$ ) compared to the mean of the original plans. 51.3% of the verification plans did not meet the criteria, these showed a prostate vector displacement larger than 0.62 cm. The proposed margins: AP 0.91, SI 0.57, and RL 0.26 cm, reported no significant difference in the dose to OARs and PTVs compared to the current treatment plans margins.

### Conclusion

When daily position correction is made considering only the prostate there is potential dose degradation to the PLN CTV. The proposed new recommended margins, however, are expected to improve dose coverage of the PLN CTV, without significantly affecting the associated OAR doses.

### EP-1346 Oligorecurrent nodal prostate cancer: long-term results of an elective nodal irradiation approach

S. Tran<sup>1</sup>, S. Jorcano<sup>2</sup>, T. Falco<sup>1</sup>, G. Lamanna<sup>1</sup>, R. Miralbell<sup>1</sup>, T. Zilli<sup>1</sup>

<sup>1</sup>Hôpitaux Universitaires Genève, Radiation Oncology, Geneva, Switzerland

<sup>2</sup>Instituto Oncológico Teknon, Radiation Oncology, Barcelona, Spain

### Purpose or Objective

The best strategy to irradiate oligorecurrent nodal prostate cancer (PCa) remains debated with both elective nodal radiotherapy (ENRT) and SBRT considered valid alternatives. Aim of this study is to report long-term results of ENRT in PCa patients (pts) with oligorecurrent nodal disease after primary treatment.

### Material and Methods

Data of 53 oligorecurrent PCa pts (N1 and/or M1a) with  $\leq 5$  nodal metastases ( $n=108$ ) treated with ENRT combined with androgen deprivation (AD) between 2004 and 2016 were retrospectively reviewed. Median age and PSA at diagnosis were 62 yrs (range, 47-77) and 8.6 ng/ml (range, 3.4-92.9 ng/ml), respectively. The primary treatment was RT, radical prostatectomy (RP), RP + postoperative RT and RT + salvage RP in 9 (17%), 23 (43%), 20 (38%) and 1 (2%) pts, respectively. At recurrence (median time after primary treatment of 34 mo, range 2-129 mo), all but one patient were re-staged with 18F-choline PET-CT studies. Median PSA and PSA doubling time (DT) were 3.4 ng/ml (0.2-48.9 ng/ml) and 5 mo (range, 1-35 mo), respectively. At restaging, 45.3% ( $n=24$ ) of the pts presented a single nodal metastasis, while 2, 3, 4 and 5 nodal metastases were found in 30% ( $n=16$ ), 7.5% ( $n=4$ ), 9.5% ( $n=5$ ) and 7.5% ( $n=4$ ) of the pts, respectively. Recurrences were mainly located in the pelvis ( $n=38$ ). A combined N1 and M1a oligorecurrence or extrapelvic nodal progression (M1a) was observed in 10 and 5 pts, respectively. All pts

underwent ENRT between 45 and 50.4 Gy with a boost on positive nodes (median 64.4 Gy, 54-69 Gy) using mainly VMAT ( $n=24$ ) or IMRT ( $n=21$ ) techniques. Concomitant AD was administered to all pts for a median time of 6mo (range, 3-30 mo).

### Results

After a median follow-up (FU) after ENRT of 44 mo (range, 2-133), 27 pts (51%) showed PSA progression, with a 5-yr biochemical disease free-survival of  $43 \pm 8.3\%$ . The 5-yr distant progression-free survival (DPFS) rate was  $58.2 \pm 8.5\%$  ( $n=19$  pts with clinical progression). Pts with a PSA DT at relapse  $< 3$  mo showed a worse 5-yr DPFS compared to pts with a PSA DT  $\geq 3$  mo (36.8% vs. 63.6%,  $p=0.029$ ), while a trend towards significance was observed for pts with 1 vs  $\geq 2$  recurrent nodes (71.8% vs. 44.9%,  $p=0.089$ ). Overall survival rate at 5-yr was  $86.4 \pm 6.9\%$  (2 over 4 pts died from PCa). Ten of 19 clinically relapsing pts presented a new oligometastatic progression (7 nodal/2 bone/1 combined). One patient presented a local relapse in the previously untreated prostate bed. Eight out 10 pts were treated with a new RT course, with 3 pts in complete remission at last FU. Only 2 pts presented with a CTCAE v3.0 Grade  $\geq 2$  genitourinary toxicity.

### Conclusion

ENRT combined with concomitant short-course AD is a safe and effective salvage modality for patients with oligorecurrent nodal PCa, able to better delay distant progression compared to historical series using focal SBRT. Prospective randomized studies comparing focal SBRT vs ENRT are warranted to define the best treatment strategy for oligorecurrent nodal PCa.

### EP-1347 Treatment outcomes with hypofractionated high-dose radiation therapy for prostate cancer

D. Candini<sup>1</sup>, F. López Campos<sup>1</sup>, C. Vallejo Ocaña<sup>1</sup>, M. Martín Martín<sup>1</sup>, A. Hervás Morón<sup>1</sup>

<sup>1</sup>Hospital Ramon y Cajal, Radiation Oncology, Madrid, Spain

### Purpose or Objective

To report treatment results, genitourinary (GU) and lower gastro-intestinal (GI) toxicity of a retrospective cohort of prostate cancer patients treated with hypofractionated radiotherapy (hypo-RT) with a high equivalent biological effective dose (BED).

### Material and Methods

From April 2014 to October 2015, 35 patients with histologically confirmed intermediate risk prostate cancer defined by National Comprehensive Cancer Network (NCCN) risk group were assigned to receive hypo-RT with a total dose of 63,4 Gy/20 fractions. Use of image-guided techniques (IGRT) with fiducial markers was required. All patients were given radiotherapy with 6 months of neoadjuvant and concurrent androgen suppression. GI and GU toxicity were prospectively evaluated according to modified RTOG criteria. Toxicity was considered "acute" if occurred during and/or within 3 months after the treatment and "sub-acute" if occurred between 3 and 12 months after the treatment. Biochemical recurrence was defined as a PSA concentration superior than nadir plus 2 ng/mL.

### Results

35 patients with a median age of 76 years (range 61-86 years) were treated in the defined period receiving hypo-RT. The median follow-up was 20.3 months (range 12 - 30 months).

Acute GU toxicity grade I occurred in 20 patients (57.1%), grade II in 2 patients (5.7%). Acute GI toxicity grade I were observed in 6 patients (17.1%), grade II in 3 patients (8.6%). None developed acute GU or GI toxicity grade III or IV.

Sub-acute GU toxicity occurred as follows: grade I in 9 patients (25.7%) and grade II in 1 patients (2.9%). Sub-

acute GI toxicity grade I was observed in 6 patients (17.1%) and grade II in 3 patients (8.6%). No late grade III-IV GU or GI toxicity was detected. For one patient a TURP was planned at 8 months after treatment, for urethral stricture.

Only 1 patient (3%) developed biochemical recurrence after a follow-up of 27 months.

#### Conclusion

Hypo-RT (63,4 Gy/20 fractions) with a high equivalent BED (EQD2Gy\_tumor = 85 Gy) produces acceptable acute and sub-acute toxicity rates with excellent outcomes of biochemical control for intermediate risk prostate cancer. Longer term follow-up should be analyzed to confirm these data.

#### EP-1348 Set-up errors in prostate cancer radiotherapy based on cone-beam computed tomography.

M. Trignani<sup>1</sup>, G. Caponigro<sup>1</sup>, M. Di Biase<sup>1</sup>, P. Bagalà<sup>1</sup>, M.D. Falco<sup>1</sup>, A. Vinciguerra<sup>1</sup>, A. Augurio<sup>1</sup>, M. Di Tommaso<sup>1</sup>, L. Caravatta<sup>1</sup>, D. Genovesi<sup>1</sup>  
<sup>1</sup>*Ospedale Clinicizzato S.S. Annunziata, Radiotherapy, Chieti, Italy*

#### Purpose or Objective

To evaluate set-up accuracy using cone-beam computed tomography (CBCT) in patients with prostate cancer receiving VMAT (volumetric modulated arc therapy) or IMRT (intensity modulated radiation therapy) techniques.

#### Material and Methods

From January 2015 to September 2016, 1199 CBCT referred to 98 prostate cancer patients received radiation treatment at our Institution using Elekta Synergy Agility Linear Accelerator were acquired, recorded and evaluated.

All patients underwent to planning computed tomography (CT) in supine position; knees and ankles were placed in a steady and comfortable position using a footrest. CT scans with slices at 5 mm were acquired at 2 mm in condition of fully bladder (0.75 liter of water, 45 minutes prior to CT scan) and empty rectum. Planning CT was sent to Oncentra Master Plan planning system and then via DICOM to XVI software for co-registration with the CBCT scans. For the CBCT acquisition we used the "pelvis M15"; the Grey level algorithm was employed to obtain 3D-3D co-registration with CT planning. An internal protocol was adopted to reduce interfraction set-up errors and to correct systematic errors. This protocol consisted in the execution of 5 consecutively CBCT during first week of treatment and once weekly CBCT during RT course. On the basis of literature data an on-line correction protocol was adopted: the tolerance level was 3 mm for translation displacements and 3° for rotations; translation displacements were applied in case of values >3 mm, while for rotation >3° patients were repositioned. Then an offline correction was applied with the mean of first 5 scans used to correct systematic errors with 3 mm. Means (m) and standard deviations (SD) of all translational (x, y, z) and rotational displacements were calculated in relation to the first 5 and the following CBCTs. The Wilcoxon test was used to evaluate statistically significant differences between displacements related to first 5 CBCTs and to the following CBCTs.

#### Results

Results are summarized in Table 1. Median values were <3 mm for all CBCTs, for both the first five and following CBCTs, mean values were within 5mm. Greater shifts were observed on z axis. Wilcoxon test showed a statistically significant correlation only for the x (p value = 0.001).

#### Conclusion

In our study, we have analyzed translational set-up uncertainties in prostate cancer treatments using CBCT and we found that all the displacements were within 5 mm, well within the offset established. The action level

of 3 mm currently adopted at our center results safe and it constitutes a good start point to reduce margin CTV-PTV.

#### EP-1349 Adjuvant hypofractionated radiotherapy for prostate cancer: acute toxicity

S. Saldi<sup>1</sup>, R. Bellavita<sup>2</sup>, I. Palumbo<sup>3</sup>, C. Mariucci<sup>1</sup>, E. Arena<sup>1</sup>, M. Lupattelli<sup>2</sup>, M. Mendichi<sup>1</sup>, M. Tenti<sup>1</sup>, F. Tamburi<sup>2</sup>, V. Bini<sup>4</sup>, C. Aristei<sup>3</sup>

<sup>1</sup>*University of Perugia, Radiation Oncology Section, Perugia, Italy*

<sup>2</sup>*Perugia General Hospital, Radiation Oncology Section, Perugia, Italy*

<sup>3</sup>*University of Perugia and Perugia General Hospital, Radiation Oncology Section, Perugia, Italy*

<sup>4</sup>*Perugia General Hospital, Internal Medicine Endocrin and Metabolic Sciences Section, Perugia, Italy*

#### Purpose or Objective

To evaluate acute toxicity and preliminary outcome of hypofractionated adjuvant radiotherapy (Hypo-ART) with helical tomotherapy after radical prostatectomy (RP).

#### Material and Methods

From February 2014 to July 2016, 30 prostate cancer patients received Hypo-ART for pT2-3 N0-1 and/or R1disease. Median age was 67 years (range 53-74). The surgical Gleason score was: <7 in 8 patients (27%), 7 in 10 (33%) and >7 in 12 (40%). Before RP the median PSA was 7.74 (range: 1.13-44.48) which dropped to 0.025 ng/ml (range: 0 -0.53) before Hypo-ART. RT schedule: all 30 patients received 2.25 Gy in 29 fractions (total dose: 65.25 Gy) to the prostate/seminal vesicle bed; 15 (50%) patients also received 1.8 Gy in 29 fractions to the pelvic lymph nodes (total dose: 52.2 Gy). A simultaneous integrated boost (SIB) technique was used. Hormone therapy (LHRH analogue and/or anti-androgen) was administered to 15 (50%) patients with high risk features. Toxicity was graded according to the Common Terminology Criteria for Adverse Events version v4.0. Biochemical failure was defined by ASTRO criteria. The Kaplan-Meier method determined time-to-acute toxicity events. The Mann-Whitney tested compared clinical and dosimetric variables in groups with and without acute toxicity.

#### Results

Median follow-up was 26.5 months (range: 3-31). The median duration of HT was 21 months (range 4-33). Only G1-G2 acute genitourinary (GU) and intestinal (GI) toxicities occurred. Acute grade 1 GU toxicity occurred in 14/30 patients (56%), with 13 (43%) developing cystitis and 1 (3%) hematuria. Acute grade 2 GU toxicity (cystitis) developed in 3/30 (10%) patients, with 1 also affected by urinary retention (3%). Acute grade 1 GI toxicity (proctitis) occurred in 14/30 patients (47%), which was associated with rectal bleeding in 2 (7%) and diarrhoea in 5 (17%). Acute grade 2 GI toxicity (proctitis) developed in 3/30 (10%) patients, which was associated with rectal bleeding in 1 (3%) and diarrhoea in 1 (3%). Post Hypo-ART the median PSA was 0.01 ng/ml (range:0-0.22) and the nadir was 0.005 ng/ml (range: 0-0.2). At the last follow-up no patient presented evidence of biochemical or loco-regional recurrence. The probability of developing acute GU on day 44 and GI toxicity on day 43 was 50% (95% CI 41-46; 95% CI 39-46 respectively). No differences emerged in clinical and dosimetric variables in group with or without acute toxicity.

#### Conclusion

These results suggest that moderate Hypo-ART is safe, effective and well-tolerated. A longer follow-up is needed to assess late toxicity and disease-free survival.

### EP-1350 Stereotactic re-irradiation for prostate cancer recurrence after upfront surgery and radiotherapy

V. Di Cataldo<sup>1</sup>, G. Simontacchi<sup>2</sup>, B. Detti<sup>2</sup>, M. Loi<sup>2</sup>, P. Bonomo<sup>2</sup>, L. Masi<sup>1</sup>, R. Doro<sup>1</sup>, I. Bonucci<sup>1</sup>, S. Cipressi<sup>1</sup>, D. Greto<sup>2</sup>, M. Mangoni<sup>2</sup>, I. Desideri<sup>2</sup>, I. Meattini<sup>2</sup>, S. Scoccianti<sup>2</sup>, E. Olmetto<sup>2</sup>, C. Muntoni<sup>2</sup>, G.A. Carta<sup>2</sup>, L. Livi<sup>2</sup>  
<sup>1</sup>IFCA, Department of Radiotherapy, Firenze, Italy  
<sup>2</sup>University of Florence, Radiation Therapy Department, Florence, Italy

#### Purpose or Objective

Recurrence of prostatic cancer after radical prostatectomy and external-beam radiation therapy (EBRT) is a common occurrence in daily clinical practice. We present our experience of re-irradiation with robotic stereotactic body radiation therapy (rSBRT) for isolated recurrence in the prostatic bed from prostate cancer previously treated with surgery and radiation therapy.

#### Material and Methods

Between June 2012 and February 2016, rSBRT was administered for isolated local relapse to 22 patients previously treated with prostatectomy and adjuvant (9, 40.1%) or salvage (13, 59.9%) EBRT. After primary treatment, all patients experienced a biochemical recurrence with an isolated relapse in the prostatic bed diagnosed with 18F-choline positron emission tomography-computed tomography (PET) with or without pelvic magnetic resonance (MRI). The gross tumor volume (GTV) was defined on the basis of clinical and radiological findings by image fusion of PET and/or MRI. The total dose was 30 Gy in 5 fractions prescribed to the 80% isodose line. PSA was assessed at 2, 6 and every 3 months, following rSBRT. Toxicity was assessed by the Common Terminology Criteria for Adverse Events toxicity scale (CTCAE v.4.03).

#### Results

Twenty-two patients were treated and followed for a median time of 19.5 months (range: 5.9-74.0 months). Prior EBRT had a median total dose of 68 Gy (range 59.4-74.0 Gy) in 1.8-2 Gy for fraction. Median time from EBRT to relapse was 73.3 months (range: 16.9-203.1). Seven patients were receiving androgen deprivation therapy (ADT) following prior biochemical failure; median pre-irradiation PSA value was 1.9 ng/ml (0.4-30). Eighteen patients had biochemical response at 2 and 6 months, with a median PSA decrease of 44.9% and 64.9% respectively; four patients experienced early PSA progression at 2 and 6 months, the median PSA rise was 85.1% and 228.6% respectively. At the time of our analysis, 10 patients showed no evidence of disease, in 2 patients an hormonal treatment was continued with stable PSA levels, while 10 patients had biochemical relapse and four of these had metastatic disease. Biological Progression-free Survival (bPFS) was 81.8% and 68.2% at 6 and 12 months, respectively. Treatment was well tolerated, genitourinary acute and late G1-G2 toxicity occurred in 6 and 5 patients respectively, while two patients experienced late rectal G1-G2 toxicity. At univariate and multivariate analysis of pre-treatment variables, impaired biochemical relapse-free survival (BRFS) was correlated with the use of ADT at the moment of the treatment (p=0.013). Subset analysis in responding patients did not found predictor of BRFS.

#### Conclusion

rSBRT for isolated recurrence in the prostatic bed from prostate cancer previously treated with prostatectomy and EBRT showed favourable results in biochemical control with low and acceptable toxicity, however further prospective studies are needed to confirm these results.

### EP-1351 Stereotactic radiotherapy in recurrent prostate cancer previously treated by radical irradiation

M. Loi<sup>1</sup>, B. Detti<sup>2</sup>, G. Simontacchi<sup>2</sup>, V. Di Cataldo<sup>3</sup>, P. Bonomo<sup>2</sup>, L. Masi<sup>3</sup>, R. Doro<sup>3</sup>, I. Bonucci<sup>3</sup>, S. Cipressi<sup>3</sup>, I. Desideri<sup>2</sup>, D. Greto<sup>2</sup>, M. Perna<sup>2</sup>, V. Carfora<sup>2</sup>, G.

Francolini<sup>2</sup>, I. Meattini<sup>2</sup>, M. Mangoni<sup>2</sup>, S. Scoccianti<sup>2</sup>, L. Livi<sup>2</sup>

<sup>1</sup>Azienda Ospedaliera Universitaria Careggi, Radiotherapy Unit, Firenze, Italy

<sup>2</sup>Università degli Studi di Firenze, Radiotherapy Department, Florence, Italy

<sup>3</sup>IFCA, Radiotherapy Department, Florence, Italy

#### Purpose or Objective

Biochemical recurrence can occur following definitive external beam radiation therapy (EBRT) for localized prostate cancer. Focal robotic stereotactic body radiotherapy (rSBRT) to the recurrent intraprostatic tumor is emerging as a valuable option in this setting. In this retrospective study we evaluated efficacy and toxicity of robotic SBRT for exclusive local failure after primary EBRT.

#### Material and Methods

Data from 28 patients treated at our Institution from September 2012 to December 2015 with rSBRT for prostate cancer recurrence after definitive EBRT were retrospectively reviewed. Local intraprostatic recurrence was assessed by <sup>18</sup>F-choline positron emission tomography-computed tomography (PET); a dose of 30 Gy was delivered in 5 fractions. PSA was assessed at 2 months, 6 months, and every 3 months following rSBRT. Toxicity was assessed by the Common Terminology Criteria for Adverse Events toxicity scale (CTCAE v.4.03).

#### Results

Patients were stratified in low (5, 17.9%), intermediate (9, 32.1%) and high risk group (14, 50.0%) at diagnosis. Median patient age at rSBRT was 78.5 (62-86) years. All patients received prior EBRT for a median total dose of 76 Gy (62-80 Gy) in 2 (1.8-3.1) Gy/fraction. Median time from primary treatment to relapse was 74.1 (19.3-149.2) months. Five patients were receiving androgen deprivation (AD) following prior biochemical failure; median pre-treatment PSA value was 2.7 (2.1-14.4) ng/ml. Twenty-five patients showed biochemical response to treatment at 2 and 6 months, median PSA decline -54.0% (2.2-95.0) and -76.0% (35.9-95.0%) respectively; three patients experienced early PSA progression at 2 and 6 months, median PSA elevation +112.3% (20.0-204.5%) and +267.0% (41.9-309.1%), respectively. At the time of our analysis, after a median follow-up of 20.9 (6.3-49.2) months, 10 patients showed no evidence of disease, 2 patients pursued AD with stable PSA levels, while 10 patients experienced biochemical relapse; among them, metastatic recurrence occurred in 4 cases. Biochemical Progression-Free Survival (bPFS) was 96.4% and 75.0% at 12 and 18 months, respectively. Rectal and bladder acute toxicity grade 1-2 was found in 4 and 1 cases, respectively; grade 1-2 late rectal and bladder toxicity occurred in 1 and 7 cases, respectively. One patient experienced both grade 3 acute and chronic bladder toxicity, consisting of acute urinary retention and hematuria respectively. At univariate and multivariate analysis of pre-treatment variables, impaired bPFS was correlated only with high risk category at diagnosis (HR:13.06, p=0.021). No predictive factor for improved bPFS was found at subset analysis in responding patients, though a trend was observed for PSA decline at 6 months >76.0% (p=0.06).

#### Conclusion

Focal rSBRT can achieve long-lasting remission and delay initiation of medical treatment, in particular in low/intermediate risk patients at diagnosis, with acceptable incidence of acute and late toxicity.

### EP-1352 Single-fraction stereotactic body radiotherapy for nodal oligorecurrent prostate cancer

M. Loi<sup>1</sup>, G. Simontacchi<sup>2</sup>, B. Detti<sup>2</sup>, V. Di Cataldo<sup>3</sup>, P. Bonomo<sup>2</sup>, L. Masi<sup>3</sup>, R. Doro<sup>3</sup>, I. Bonucci<sup>3</sup>, S. Cipressi<sup>3</sup>, I. Desideri<sup>2</sup>, D. Greto<sup>2</sup>, C. Becherini<sup>2</sup>, C. Delli Paoli<sup>2</sup>, R.

Grassi<sup>2</sup>, M. Lo Russo<sup>2</sup>, I. Meattini<sup>2</sup>, S. Scocianti<sup>2</sup>, M. Mangoni<sup>2</sup>, L. Livi<sup>2</sup>

<sup>1</sup>Azienda Ospedaliera Universitaria Careggi, Radiotherapy Unit, Firenze, Italy

<sup>2</sup>University of Florence, Radiotherapy Department, Florence, Italy

<sup>3</sup>IFCA, Radiotherapy Department, Florence, Italy

#### Purpose or Objective

Advances in metabolic imaging allows the detection of oligorecurrent nodal disease in prostate cancer patients after primary surgical or radiation treatment (RT): focal nodal stereotactic RT could be proposed in order to treat the site of recurrence. The aim of the study is to evaluate efficacy and toxicity of single fraction robotic stereotactic radiation therapy (rSBRT) for isolated nodal failure in prostate cancer patients

#### Material and Methods

Twenty-three prostate cancer patients with 27 isolated nodal recurrence were treated by single fraction rSBRT between April 2012 and March 2016. Lymphnodal disease was assessed by <sup>18</sup>F-choline positron emission tomography-computed tomography (<sup>18</sup>F-chol-PET); all patients received single fraction rSBRT. PSA was assessed at 3 months and every 3 months following treatment. Toxicity was assessed by the Common Terminology Criteria for Adverse Events toxicity scale (CTCAE v.4.03).

#### Results

Median patient age at rSBRT was 75 (54-85) years. All patients underwent definitive RT (2, 8.7%) or surgery (21, 91.3%) as primary treatment to the prostate; among operated patients, RT was administered as an adjuvant or salvage treatment in 3 (13.0%) and 3 (13.0%) patients respectively. Median time from primary treatment to relapse was 69.5 (7.6-205.4) months; median pre-treatment PSA value was 2.13 ng/ml (0.35-19.9). Five patients (21.7%) were receiving endocrine therapy (ET) for at least 6 months following prior biochemical failure (BF). Nodal sites of disease were pelvic and lumbosacral nodes in 22 (81.4%) and 5 (18.6%) cases, respectively; four patients were simultaneously treated on a synchronous nodal relapse. Median dose was 24 (20-24) Gy. At 3 months, 12 (52.2%) patients showed biochemical response (median decline -64.6%, 0.8-97.8); 11 (47.8%) patients experienced early PSA progression (median elevation +30.8%, 2.9-390.9). At the time of our analysis, after a median follow-up of 13.6 months (6.0-47.8), 8 patients showed no evidence of disease, 2 patients were continuing ET with stable PSA levels, while 13 patients experienced biochemical progression: among them, 7 patients started ET for <sup>18</sup>F-chol-PET-negative disease, 2 patients had nodal relapse on non-irradiated site and 4 patients developed distant metastasis. At statistical analysis, median time to BF was 10.0 months. Overall Biochemical Relapse-Free Survival (bPFS) was 56.5% at 6 months and 47.8% at 12 months; no predictive factor was related to bPFS. Subset analysis in responding patients showed a median time to BF of 14.7 months; PSA level >4.0 ng/ml showed a borderline predictive value for BF (p=0.054). Grade I bladder toxicity was reported in one case.

#### Conclusion

Isolated nodal relapse of prostate cancer can be safely treated by single fraction rSBRT with excellent tolerance and promising biochemical control; careful selection of patients is mandatory to avoid unnecessary treatment of patient with undetectable advanced disease.

#### EP-1353 Salvage hypofractionated radiotherapy for prostate cancer: acute toxicity

S. Saldi<sup>1</sup>, R. Bellavita<sup>2</sup>, I. Palumbo<sup>3</sup>, C. Mariucci<sup>1</sup>, E. Arena<sup>1</sup>, M. Lupattelli<sup>2</sup>, A. Podlesko<sup>1</sup>, S. Russo<sup>2</sup>, R. Dottorini<sup>2</sup>, V. Bini<sup>2</sup>, C. Aristei<sup>3</sup>

<sup>1</sup>University of Perugia, Radiation Oncology Section,

Perugia, Italy

<sup>2</sup>Perugia General Hospital, Radiation Oncology Section, Perugia, Italy

<sup>3</sup>University of Perugia and Perugia General Hospital, Radiation Oncology Section, Perugia, Italy

<sup>4</sup>Perugia General Hospital, Internal Medicine Endocrin and Metabolic Sciences Section, Perugia, Italy

#### Purpose or Objective

To evaluate acute toxicity and the preliminary outcome of hypofractionated salvage radiotherapy (Hypo-SRT) with helical tomotherapy after radical prostatectomy (RP).

#### Material and Methods

From March 2013 to July 2016, 58 patients underwent Hypo-SRT for biochemical (BR) or local recurrence (LR) after radical prostatectomy (PR). Median age was 67 years (range 52-84). The surgical Gleason score was : <7 in 24 patients (41%), 7 in 22 (38%), >7 in 12 (21%); median PSA pre-SRT was 0.258 ng/ml (range: 0.2-8.65). RT schedule: 24/58 (41%) patients with BR received 2.25 Gy in 32 fractions (Total dose:72 Gy); 34/58 (59%) patients with LR received 2.1 Gy in 33 fractions (Total dose: 69.3 Gy) to the prostate/seminal vesicle bed and 2.25 Gy in 33 fractions to the LR site (total dose:74.25 Gy) using a simultaneous integrated boost (SIB) technique; 6/58 (10%) patients received 1.6 Gy to the pelvic lymph nodes (total dose 52.8 Gy), using a SIB technique. Hormone therapy (HT-LHRH analogue and/or anti-androgen) was administered to 17 patients (29%) with high risk features. Toxicity was graded according to the Common Terminology Criteria for Adverse Events version v4.0. Biochemical failure was defined by ASTRO criteria. The Kaplan-Meier method determined time-to-acute toxicity events and the Mann-Whitney test compared clinical and dosimetric variables in groups with and without acute toxicity.

#### Results

The median follow-up was 12 months (range:3-41).The median duration of HT was 85 months (range 2-168). Only G1-G2 acute genitourinary (GU) and intestinal (GI) toxicities occurred. Acute grade 1 GU toxicity occurred in 28 patients (48%), with 25 (43%) developing cystitis and 3 (5%) hematuria. Acute grade 2 GU toxicity (cystitis) developed in 6/58 (10%) patients, with 1 also affected by urinary retention (2%). Acute grade 1 GI toxicity (proctitis) occurred in 25/58 patients (43%), which was associated with rectal bleeding in 2 (3%). Acute grade 2 GI toxicity (proctitis) developed in 4/58 (7%) patients, which was associated with rectal bleeding in 1 (2%). Post Hypo-ART the median PSA was 0.1 ng/ml (range:0-7.01) and the nadir was 0.03 ng/ml (range: 0-5.67). Biochemical recurrence and /or loco-regional relapse occurred in 10/58 (17%) patients at a median of 19 months after treatment (range: 10-40). Statistical analysis: after Hypo-ART there was 50% probability of developing acute GU toxicity on day 52 and GI toxicity on day 43. Dmax to the prostate/seminal vesicle bed was greater in patients who developed acute GI toxicity.

#### Conclusion

Low grade acute GU and GI toxicity and early biochemical response demonstrated that moderate Hypo-SRT was safe and effective. A longer follow-up is required to confirm these outcomes.

#### EP-1354 Delayed Salvage Radiotherapy for Macroscopic Local Recurrence after Radical Prostatectomy

M. Shelan<sup>1</sup>, S. Odermatt<sup>1</sup>, B. Bojaxhiu<sup>1</sup>, O. Elicin<sup>1</sup>, D.M. Aebbersold<sup>1</sup>, A. Dal Pra<sup>1</sup>

<sup>1</sup>Bern University Hospital, Radiation Oncology, Bern, Switzerland

### Purpose or Objective

Salvage radiotherapy (SRT) is the only potentially curative therapy available for patients experiencing biochemical recurrence after radical prostatectomy (RP), and likely more effective when offered early at low PSA levels. This work aims to retrospectively assess clinical outcome and toxicity of patients treated with delayed SRT to radiologically and/or histologically proven macroscopic local recurrence.

### Material and Methods

We report on a cohort of 56 patients with radiologically detected isolated macroscopic local recurrence on MRI and/or CT scan and treated with SRT between 2001 and 2015. Histological confirmation was available in 35 (63%) patients. A dose of 64-66 Gy (2 Gy/fr) was delivered to the prostatic bed followed by a dose escalation to 72-74 Gy (2 Gy/fr) to the site of macroscopic disease using image-guided IMRT (IG-IMRT). Patients were treated with concomitant short-course (6 months) of androgen deprivation therapy. Biochemical relapse-free survival (PSA nadir + 0.2 ng/ml; bRFS) and clinical relapse-free survival (cRFS) were calculated using Kaplan-Meier method. Baseline, acute and late urinary and gastrointestinal (GI) toxicity rates were reported using CTCAE v4.

### Results

Median age at SRT was 71 years (57-81). Out of 56 patients, 9 (16%) had pT3b disease and 19 (34%) had positive surgical margins. Sixteen patients (29%) had Gleason score  $\geq 8$  at RP. The median time from RP to SRT was 58 months (5-172). Median pre-RT PSA was 2.8 ng/ml (0.2-29). At a median follow-up of 39 months (8-153) post-SRT, 20 patients (36%) had biochemical failure and 8 (14%) developed distant metastasis. Median time to BF after SRT was 30 months (13-116). The 3- and 5-year bRFS were 70.5% and 53.5%, respectively. The 3- and 5-year cRFS was 89.2% and 80%, respectively. High-risk patients (pT3b and/or Gleason score  $\geq 8$ ) had 3- and 5-year bRFS of 54% and 27%, while 3- and 5-year cRFS was 66.7% and 44.4%, respectively. Univariate and multivariate analyses showed that Gleason score  $\geq 8$  and perineural invasion were associated with lower bRFS ( $p=0.005$  and  $0.046$ , respectively). High-risk patients presented lower bRFS and cRFS when compared to lower risk patients ( $p=0.03$  and  $0.001$ , respectively). At baseline, 4 patients (7%) had grade 3 urinary toxicity. Twelve patients (21%) developed grade  $\geq 2$  acute urinary toxicities. Three patients (5%) had grade 2 acute GI toxicities. No grade  $\geq 3$  acute GI toxicity occurred. Nine patients (16%) had grade  $\geq 2$  late urinary toxicities. No grade  $\geq 2$  late GI toxicity was reported.

### Conclusion

Delayed SRT using dose escalated IG-IMRT to isolated macroscopic local recurrence is associated with poor oncological outcomes particularly in high risk patients (i.e. pT3b and/or Gleason score  $\geq 8$ ). Toxicity profile seems to be acceptable at a medium term follow up. Patients with high risk features should be strongly considered for earlier and intensified treatment approaches.

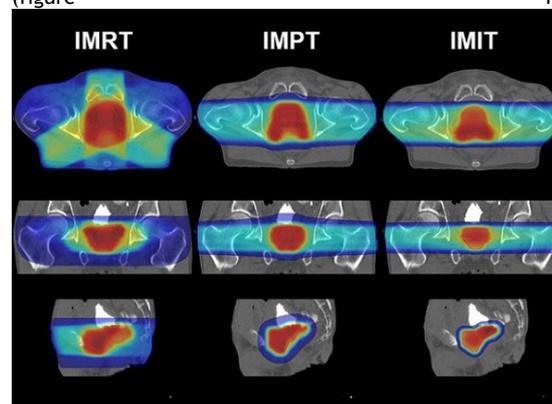

**EP-1355 Comparing toxicity in IMRT and particle therapy of prostate cancer in a ROCOCO in silico trial**  
Y. Van Wijk<sup>1</sup>, E. Roelofs<sup>2</sup>, B. Vanneste<sup>2</sup>, S. Walsh<sup>2</sup>, P. Lambin<sup>2</sup>

<sup>1</sup>Maastricht university, School for Oncology and Developmental Biology, Maastricht, The Netherlands  
<sup>2</sup>MAASTRO clinic, Radio Oncology, Maastricht, The Netherlands

### Purpose or Objective

Studies have shown that dose escalation has positive effect on tumour control probability when treating high

risk prostate cancer. However, due to the higher dose in the rectum, the normal tissue complication probability (NTCP) for gastral intestinal (GI) toxicity is increased. The goal of this study is to investigate whether radiotherapy of high-risk prostate cancer with light-ion particles results in reduced NTCP when compared to IMRT. A comparison between doses and NTCP was made for three modalities: IMRT, proton therapy (IMPT) and carbon-ion therapy (IMIT) (figure 1).

### Material and Methods

Twenty-five consecutive patients with T3-T4 prostatic cancer were included for high-dose radiotherapy. Proton and Carbon-ion treatment planning was performed by the ROCOCO trial partners following a strict clinical protocol, prescribing 78 Gy (biologically equivalent dose) to the target and compared pair-wise to generated IMRT treatment plans. All 75 plans were analysed centrally to compare the dose in the rectum (the main organ at risk) and the NTCP for late rectal bleeding.

A validated multi-factorial NTCP model used the mean dose (Gy) in the rectum and the percentage of the rectum receiving more than 75 Gy (V75) as dosimetric predictors. It also included a set of clinical predictors such as haemorrhoids and hormonal therapy.

**Results**  
An overview of the results is shown in table 1.

Mean rectal Dose (Gy)			V75 rectum (%)			NTCP (%)		
IMRT	IMPT	IMIT	IMRT	IMPT	IMIT	IMRT	IMPT	IMIT
30.8	30	20.8	3.7	2.9	3.9	5.9	5.6	5.3

44.2	30.1	16.1	1.7	1.2	0.7	6.5	5.1	4.3
43.3	23.2	12.5	2	1	1.2	6	4.4	4
43.1	36.6	20.8	0.8	1.7	2.8	6.1	5.8	5

The mean dose in the rectum resulting from the IMRT, proton and carbon-ion plans was 42.9 Gy [range: 30.8-47.2 Gy], 30.8 Gy [range: 23-45.2 Gy] and 18.9 Gy [range: 11.8-33.3 Gy] respectively. The V75 for the IMRT, proton and carbon-ion was 3.2% [range: 0.3-10.8%], 2.1% [range: 0.5-4.3%] and 1.9% [range: 0.6-3.9%] respectively. Both proton and carbon-ion plans showed improvement with respect to the IMRT plans in both dosimetric parameters, and for carbon-ions it showed an improvement when compared to protons.

The NTCP predicted for the IMRT, proton and carbon-ion plans was 8.7% [range: 6-14.5 %], 6.7% [range: 5-9.2 %] and 5.7% [range: 4.7-7.2 %] respectively. On average these treatments didn't show large improvements in NTCP, however, individuals with significant improvement were identified. One patient showed that proton therapy would lower the NTCP with 5.3%, and 4 patients showed that carbon-ion therapy would lower the NTCP with 7.3, 5.2 and twice with 4.1%.

#### Conclusion

Particle therapy offers the opportunity to significantly reduce the NTCP, but require decision support systems, using multi-factorial prediction models and ultimately including cost-effectiveness analyses to choose the optimal treatment modality and justify the accompanying increased costs.

#### EP-1356 SBRT benefit in oligometastatic prostate cancer patients detected by [<sup>18</sup>F]fluoromethylcholine PET/CT

E. Bouman-Wammes<sup>1</sup>, J.M. Van Dodewaard- de Jong<sup>1</sup>, M. Dahele<sup>2</sup>, M.C.F. Cysouw<sup>3</sup>, O.S. Hoekstra<sup>3</sup>, A.H.M. Piet<sup>2</sup>, A.J.M. Van den Eertwegh<sup>1</sup>, H.M.W. Verheul<sup>1</sup>, D.E. Oprea-Lager<sup>3</sup>, V.M. H.<sup>4</sup>

<sup>1</sup>VU University Medical Center, Medical Oncology, Amsterdam, The Netherlands

<sup>2</sup>VU University Medical Center, Radiotherapy, Amsterdam, The Netherlands

<sup>3</sup>VU University Medical Center, Nuclear Medicine, Amsterdam, The Netherlands

<sup>4</sup>VU University Medical Center, Urology, Amsterdam, The Netherlands

#### Purpose or Objective

For patients with oligometastatic recurrence of prostate cancer, stereotactic body radiation therapy (SBRT) represents an attractive treatment option as it is generally safe without major side effects. The aim of this study is to investigate the impact of SBRT in postponing the start of androgen deprivation therapy (ADT), and assess the pattern of recurrence post SBRT

#### Material and Methods

Forty-three patients treated with SBRT for oligometastatic recurrence of prostate cancer were included. Also, a control group of 20 patients not treated with SBRT was identified from other hospitals. Data was retrospectively collected and analyzed.

#### Results

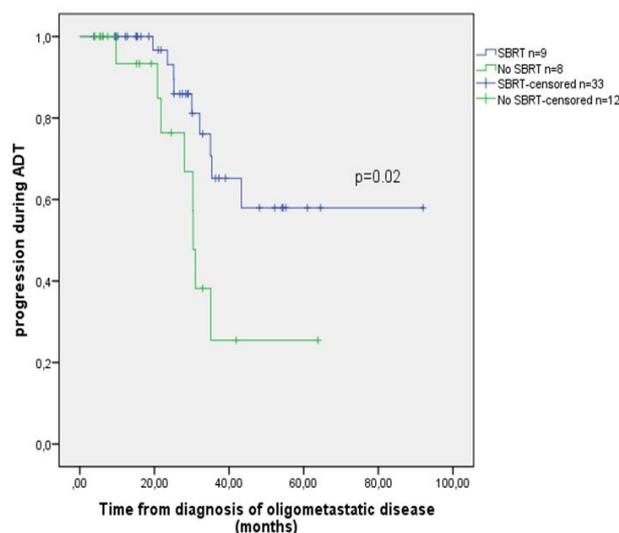

A post-SBRT PSA response was seen in 29/43 patients (67.4%), with undetectable PSA in 6/43 patients (14.0%). The median ADT free survival (ADT-FS), defined as time between the start of SBRT and start of ADT, was 15.6 months (95% CI 11.7-19.5) for the whole group, and 25.7 months (95% CI 9.0-42.4) for patients with an initial PSA response.

Seven patients were treated with a second course of SBRT because of oligometastatic disease recurrence; the ADT-FS in this group was 32.1 months (95% CI 7.8-56.5).

We compared the data of SBRT-treated patients with a group of 20 patients, managed in another hospital, by watchful waiting followed by ADT. Compared to the control group, ADT-FS (from the date of first diagnosis of metastasis until start of SBRT) was significantly longer for SBRT treated patients with 17.3 months (95% CI 13.7-20.9) versus 4.19 months (95% CI 0.0-9.0),  $p < 0.001$ . Once ADT had been started, the subsequent PFS during ADT treatment was comparable between both groups (median 31.5 months for SBRT-treated patients, versus 26.9 months for the control group,  $p = 0.54$ ). This results in a significantly longer period between the diagnosis of oligometastatic disease and development of castration resistant prostate cancer (see figure).

Seventeen patients had a [<sup>18</sup>F]fluoromethylcholine PET/CT performed because of a rising PSA after the first course of SBRT. In 15 patients the rise in PSA could be attributed to lesions which were outside the high-dose SBRT volume, in 2 patients no cause was found, no local failures were identified on these scans. One patient had progressive disease in a previously non-suspicious 3mm lymph node adjacent to the irradiated node. Another patient had persistent disease in a partially irradiated lymph node adjacent to the index node treated at first SBRT. Seven patients (16.2%) had some form of toxicity recorded in their medical chart: 2 of the patients with bone metastases reported a pain flare (grade I), 5 patients with lymph node metastases reported diarrhea (grade I in three patients, grade II in two patients).

Figure: Time from diagnosis of oligometastatic disease until disease progression on ADT (patients not yet using ADT included in the censored group)

#### Conclusion

SBRT might safely and effectively be used to postpone ADT in patients with oligometastatic recurrence of prostate cancer.

#### EP-1357 moderate hypofractionated-imrt of prostate bed after radical prostatectomy : acute toxicity

<sup>8</sup>Hospital University HM Sanchinarro, Radiophysic, Madrid, Spain

#### Purpose or Objective

Hypofractionated radiation therapy as primary treatment for prostate cancer is currently being investigated in large

phase 3 trials. However, evidences in post-operative setting are scarce. We report our experience about feasibility and acute toxicity of a moderate hypofractionated intensity modulated radiotherapy (Hypo-IMRT) schedule for prostate cancer (PC) after radical prostatectomy.

#### Material and Methods

From October 2015 to July 2016, 23 patients (pts) were included for adjuvant (60,9%) or salvage radiation therapy (39,1%). They were classified with *NCCN* criteria in: low (2 pts), intermediate (13 pts) and high risk (8 pts). Median age was 63 years (range 55-77 years). Median PSA pretreatment was 0.31ng/mL (range 0.04 - 4.38ng/mL). Pathological characteristics are summarized in Table 1. Two internal gold-fiducial markers were placed transperineally guided by transrectal ultrasound, in every patient before treatment. CTV was countertered according to RTOG guidelines and expanded 3 mm posteriorly and 5 mm in all other direction to create the PTV. All patients underwent treatment with IMRT up to a total dose of 62.5Gy in 25fx (2,5Gy/day) in a Novalis linac. Daily verification was performed with IGRT-Exactrac®, and 6D-robotic couch. Six (26%) patients received androgen deprivation. Acute toxicity was assessed according to RTOG/EORTC criteria and was recorded weekly during treatment and one month after radiation therapy.

<b>Gleason score:</b>

Gleason score: 6 7(3+4) 7(4+3) 8-10 9% 35% 26% 30%  
 Seminal vesicles invasion: -Yes -No 17% 83%  
 Extracapsular extension: -Yes -No 61% 39%  
 Positive Margin: -Yes -No 48% 52%  
 Perineural invasion: -Yes -No 52% 48%  
 Linfovascular invasion: -Yes -No 22% 78%

**Results**  
 All patients received complete treatment. There were no complications during marker placement. With a median follow-up of 3.7 months (range 1-13 months), the RTOG/EORTC acute urinary toxicities were grade 1 in 34,7% and grade 2 in 21,7%. Neither urinary stress nor incontinence was influenced by radiation therapy. Maximal acute gastrointestinal toxicities were grade 1 in 13%. There was no adverse events  $\geq$  grade 3.

**Conclusion**

Present Hypo-IMRT with IGRT schedule for irradiation of prostate bed after radical prostatectomy reduces the length of treatment by 2 week as compared to other treatment regimens commonly used, is feasible and well tolerated with no severe acute effects side. Longer follow-up is needed to determine late impact of if this low rate of acute toxicity and the biochemical control

**EP-1358 Prostate postoperative hypofractionated radiotherapy: a single institution experience with Tomo S. Gomellini<sup>1</sup>, B. Shima<sup>1</sup>, R. Barbara<sup>1</sup>, C. Caruso<sup>1</sup>, A.D. Andrulli<sup>1</sup>, U. De Pula<sup>1</sup>**  
<sup>1</sup>azienda ospedaliera san giovanni addolorata, specialità radioterapia, roma, Italy

#### Purpose or Objective

During the last decades, many studies of hypofractionated radiotherapy have been published in the prostate cancer field, due to the stronger radiobiological evidences of a low alpha/beta ratio for the prostate cancer ranging around 1.5, demonstrating a trend in improvement in the hypofractionated groups in terms of Local Control and Biochemical Control if compared to the standard fractionation, with a substantial equivalence of acute and late toxicities. Very few publications are at the moment available in the postoperative setting. This is a single institution experience with Tomotherapy of hypofractionated radiotherapy in adjuvant and salvage treatments. We report the preliminary results of acute and late toxicities.

#### Material and Methods

Between February 2012 and October 2015 27 patients underwent an hypofractionated radiotherapy with Tomotherapy in our Institute. Seven pts received adjuvant treatment for the presence of risk factors for local relapse at histological examination at the surgery, while 20 pts underwent a salvage radiotherapy for biochemical relapse after prostatectomy. All patients did a regimen in 23 fractions for a total dose of 57.5 Gy and 59.8 Gy. Patients characteristics are reported in table 1

#### Results

The acute and late urinary and rectal toxicities have been evaluated by the use of the C.T.C.A.E. 4.02 and the SOMALENT modified Scales. We lost 2 patients during the follow up period (1 patients died for other cause and 1 patients was not found anymore). The acute and late toxicities are reported below.

The acute GU-G2 and GI-G2 toxicities were 18.5% and 14.8% respectively. One patient (3.7%) experienced a subacute rectal toxicity  $\geq$  G3, (dilatation for rectal substenosis within 6 months from the end of RT). The late GU-G2 and GI-G2 toxicities were 8% and 0% respectively. Only 1 patient (4%) had a urinary late G3 toxicity (urethral dilations for substenosis) while none patients had a rectal late toxicity  $\geq$  G3.

**Conclusion**  
 Many of the randomized and not randomized trials regarding hypofractionation have been published in the elective treatment setting with very few data available in the postoperative group with the alert for the acute and late toxicities reported in the different published series. Even if this is a very small experience with a limited number of patients, we had very few toxicities but future and larger series are necessary to better understand the real impact of hypofractionated radiotherapy in postoperative prostate cancer setting.

<sup>7</sup>BC Cancer Agency, Radiation Oncology, Prince George, Canada

<sup>8</sup>BC Cancer Agency, Radiation Oncology, Victoria, Canada

<sup>9</sup>BC Cancer Agency, Medical Oncology, Vancouver, Canada

#### Purpose or Objective

Randomized trials have demonstrated the survival and quality of life benefit of Radium (Ra 223) for pts with Castration Resistant Prostate Cancer (CRPC) with symptomatic bone metastases. Alkaline Phosphatase (ALP) level and response is correlated with survival after Ra 223. The British Columbia Cancer Agency (BCCA) is the single provider of Ra223 in BC since 2013. The BCCA also has a provincial Prospective Outcomes and Support Initiative (POSI) using the Brief Pain Inventory (BPI).

Objective: To assess the baseline pain, pain response, and relationship of pain response to ALP response in patients treated with Ra 223 at a population based level.

#### Material and Methods

All patients that started radium 223 between Sep 2013 and Feb 2016 had the required minimum potential to complete 6 cycles at time of analysis. Since June 2015, all patients treated with radium 223 completed POSI questionnaires including BPI at each visit. Pain medication was group as none, non, weak, or strong opioid; a change between groups was categorized as an increase or decrease. ALP and PSA were recorded at consult and prior to each Ra223 dose. A worst pain improvement of at least 2 units on the 10 point scale was considered a pain response. ALP response was defined as a >30% decrease from baseline. Correlation between pain and ALP response was assessed using a Phi statistic.

#### Results

91 patients started Ra223 during the entire study period. 34 patients completed at least baseline BPI, and had at least one follow-up BPI. Of these cases, 90% had pain, 80% had a pain score of at least 3, and 26% scored at least 7 at baseline. Of those with baseline pain of 3 or higher, 37% had a pain improvement of at least 2 units during the course of Ra 223. Of these responding patients, 30% had also received EBRT during Ra223 course, and 90% had stable or improved pain medication group. The ALP response rate was the same in those with and without a pain response (Phi -0.12, p=0.96). Comparing participants with pain response <2 versus at least 2 units, the ALP response (>30%) was similar (58% vs 57%) (0.96). Of note, the median number of prior treatments for CRPCs (abiraterone, enzalutamide, chemotherapy or investigational agents) was 2 (with a range 0-5), reflecting a heavily pretreated cohort.

#### Conclusion

In this population based study of Ra 223, the vast majority of patients have pain at baseline. 37 % of patients had improvement of pain during Ra 223 treatment, although analysis was confounded by use of EBRT. No correlation was observed between pain response and ALP response in this cohort.

**EP-1360 Stereotactic body radiotherapy for oligometastatic prostate cancer recurrence after local treatment.**

P.A. Laurent<sup>1</sup>, E. Martin<sup>1</sup>, F. Cousin<sup>2</sup>, M. Quivrin<sup>1</sup>, F. Bidault<sup>3</sup>, F. Mazoyer<sup>3</sup>, A. Bertaut<sup>2</sup>, G. Crehange<sup>1</sup>

<sup>1</sup>Centre Georges-François Leclerc, Radiation Oncology, Dijon, France

<sup>2</sup>Centre Georges-François Leclerc, Statistics, Dijon, France

<sup>3</sup>Centre Georges-François Leclerc, Medical Physics, Dijon, France

#### Purpose or Objective

To analyse patients treated by stereotactic body radiotherapy (SBRT) for a node or bone oligometastatic recurrence of a prostate cancer (Pca) previously locally treated, and identify possible prognostic factors of early biochemical failure (BF) after SBRT.

#### Material and Methods

In this retrospective study, we analyzed castrate and non-castrate patients treated by SBRT between November 2011 and April 2016 for 1 to 3 metastases, bone or node, diagnosed on a positron emission tomography - computed tomography (PET-CT) or on a bone-scintigraphy with technetium-99, following biochemical recurrence of a prostate cancer after a local curative treatment. Recurrence-free survival (RFS) was the primary end-point defined as the time interval between the first day of SBRT and biochemical failure, defined as 2 consecutive elevations of PSA with last dosage superior to PSA dosage before treatment, or clinical failure, defined as new metastases found on an imaging check-up (PET-CT or scintigraphy). PSA dosage before SBRT, type of metastase (bone or node), number of lesions treated in SBRT, patient's ages, nadir of PSA after SBRT, and concomitant androgen deprivation therapy (ADT) were analyzed in univariate and multivariate logistic regression to identify prognostic factors of poor response to SBRT.

#### Results

With a median follow-up from time of SBRT of 12 months, we treated 40 patients and 56 metastatic lesions, with a local-control rate of 85%. 19 patients were treated for 1 to 3 bone lesions and 21 patients for 1 to 3 node lesions. 8 patients with bone oligo-metastasis and 13 patients with node oligometastasis had a recurrence. The primary involved metastatic sites were lymph nodes (52%) and bone (52%), with 3 patients having both node and bone recurrence. A 2<sup>nd</sup> and 3<sup>rd</sup> course of radiotherapy was delivered in 8 and 1 patients respectively. Median RFS was 345 days (134; 426) in the node metastatic group and 494 days (85; 877) in the bone metastatic group. On bivariate analysis, a PSA nadir up to 0,51 ng/mL after SBRT was identified as a prognostic factor of low RFS. This result was not confirmed in multivariate analysis. There might be a significant difference in RFS between node group and bone group.

#### Conclusion

There might appear that patients treated by SBRT for node oligometastatic prostate cancer recurrence after a local curative treatment could have a lower recurrence-free survival than patient treated for bone oligometastatic disease in the same conditions. This observation justifies further analysis.

#### Ep-1361 Prostate sbrt in 5 fractions, report of 185 patients and late toxicity analysis.

P. Castro Peña<sup>1</sup>, O. Muriano<sup>1</sup>, A. Henao<sup>1</sup>, P. Murina<sup>1</sup>, C. Niño de Guzman<sup>1</sup>, D. Venencia<sup>1</sup>, S. Zunino<sup>1</sup>

<sup>1</sup>Instituto Privado de Radioterapia, Radiation Oncology, Cordoba, Argentina

#### Purpose or Objective

To analyze late urinary and rectal toxicity in patients with prostate cancer who underwent SBRT 5 fractions

#### Material and Methods

Among November'13 and June'15, 185 patients with positive biopsy of prostate cancer were treated; PSA-baseline mean = 14.99 ng / ml [0.42-123.3] and prostate

volume average = 52.6 g [20.6-134]. All were irradiated with SBRT technique in 5 fractions (every other day), according to institutional protocol. IGRT (intra and interfraction) were ExacTrac based, 2 weeks before, 5 intraprostatic titanium fiducial markers were implanted. Virtual simulation based on CT-scan was done every 1mm at prostate level. Drawing volumes and dosimetry planning were done at Iplan-Net system. Prescribed dose at 95% PTV-prostate = 40 Gy or 36.25, depending the risk group. Patients were irradiated with Novalis Tx (BrainLab-Varian) technology, high-resolution multileaf collimator (HDMLC) with leaf of 2.5mm. Planned and irradiated with IMRT-dynamics technique, using 9 portals of 6 MV beams. Genitourinary toxicity (GU) was evaluated using the scale IPSS (International Prostate Symptom Score) and gastrointestinal (GI) according to RTOG criteria.

#### Results

The mean age was 69.1 years [48.1-86.6]. The distribution by risk group was 12.3%, 59.5% and 28.2% low, medium and high respectively. Mean follow-up = 15.1 months [3.8-31.7]. The mean IPSS was before SBRT = 6.2 [0-35]. Post-SBRT = 5.6 [0-34]; 5.1 [0-31]; 5.6 [0-30]; 4.8 [0-22] and 5.6 [0-28] for 2; 6; 12; 18 and 24 months respectively. The rate and extent of post-SBRT rectal toxicity was at 2 months G0 = 80.5%; G1 = 14.1% = 5.4% and G2. At 6 months: G0 = 85%; G1 = 4.1%, 4.9% and G2 = G3 = 1.6. At 12 months: G0 = 92.1%; G1 = 3.3%; G2 = 2.6%, G3 = 0.7 and G4 = 1.6% At 18 months: G0 = 96.4%; G1 = 2.4%; G2 = 1.2. At 24 months: G0 = 97.3%; G1 = 2.7%; G2 = 0

#### Conclusion

According to the presented results we can strongly suggest that Prostate SBRT- Novalis based platform is suitable for a patient acceptable toxicity rate

#### EP-1362 Correlations between dose to small intestine and bladder volume in patients receiving pelvic IMRT

M. Alfayez<sup>1</sup>, A. Sadozye<sup>1</sup>

<sup>1</sup>Beatson West of Scotland Cancer Centre, clinical oncology, Glasgow, United Kingdom

#### Purpose or Objective

#### Background

The use of IMRT to treat various tumour sites has gained wider acceptance in recent years due to its ability to decrease the radiation dose to organs at risk. Various manoeuvres have been implemented to reduce the doses to organs at risk (OAR), such as the small bowel.

#### Aims/Objectives

We evaluated the effect of bladder filling on dose distributions for the small bowel as measured by V20, V30, V40 and V50.

#### Material and Methods

We studied sixty patients undergoing pelvic IMRT (pelvic nodes plus Prostate & Seminal Vesicles) to treat prostate cancer. The minimum dose to the PTV was 95% of the prescribed dose (7200 cGy in 32 fractions). All patients were scanned with a full bladder. PTV and OARs, including the small bowel were contoured by 6 different clinical oncologists to reflect day-to-day practice. Bladder volumes, dose-volume histograms (DVH), V20, V30, V40 and V50 for the small bowel were obtained for each patient.

#### Results

We ran the Pearson correlation coefficient to measure the strength of the linear relationship between the bladder volume and the dose to the small bowel. Results showed a negative correlation between the bladder volume and the dose to the small bowel ( $p < 0.0001$ ).

#### Conclusion

The results demonstrate that bladder filling helps limit dose to the small bowel, and therefore is of paramount importance that every effort is made to ensure

consistency of bladder filling for patients who are undergoing pelvic IMRT.

### EP-1363 Clinical efficacy of a dose escalated and hypofractionated pelvic IMRT study in prostate cancer

<sup>5</sup>Institute of cancer research and Royal Marsden Hospital, Joint Department of Physics, London, United Kingdom

<sup>6</sup>Institute of cancer research and Royal Marsden NHS trust, Department of physics, London, United Kingdom

#### Purpose or Objective

The role of pelvic lymph node (PLN) radiotherapy in high-risk localised prostate cancer remains controversial. The dose to PLN is limited by bowel toxicity and the use of intensity modulated radiotherapy (IMRT) has been developed to improve the therapeutic ratio. The IMRT trial was a phase I/II trial conducted in 426 patients at a single centre, with the aim of exploring dose-escalated and hypofractionated regimes of pelvic irradiation. We report the long term outcomes of this trial cohort.

#### Material and Methods

Eligible patients had high risk (>T3a, Gleason  $\geq$ 8 or PSA  $\geq$ 20) disease with an estimated risk of lymph node involvement of  $\geq$ 30%, or lymph node positive disease. IMRT was inverse planned to give 70-74Gy in 35-37 fractions to the prostate and sequential patient cohorts received 50Gy (n=25), 55Gy (n=70) and 60Gy (n=138) to the pelvis in 35-37 fractions using a simultaneous integrated boost technique. Positive lymph nodes received an additional 5Gy boost. The remaining patients received 60Gy in 20 fractions to the prostate and 47Gy in 20 fractions over 4 weeks (n=64) or 47Gy in 20 fractions over 5 weeks (n=129) with an additional 4Gy boost to positive lymph nodes. All patients received long course androgen deprivation therapy, commencing at least 6 months before radiotherapy. Biochemical failure was defined according to the Phoenix criteria of the nadir +2ng/ml. Local recurrence was confirmed with MRI and/or histological confirmation. Distant staging with CT, MRI, nuclear medicine bone scan or choline-PET CT was performed in patients with biochemical relapse to establish all sites of relapse.

#### Results

426 patients were recruited between 09/08/2000 and 09/06/2010 and the median follow up for the whole cohort at the time of analysis was 7.6 years. Median age was 65 years (IQR 60-70 years) and median presenting PSA was 21.4 ng/ml (IQR10.2-42.8 ng/ml). The total number of failure events was 169. Freedom from biochemical/clinical failure at 5 years was 71% (95% CI 66%-75%). The 5 year prostate cancer specific survival was 92% (95% CI 89%-94%) and overall survival was 87% (95% CI 84%-90%). Table 1 demonstrates the distribution of all documented

sites of relapse in each cohort.

Site of Relapse	50Gy/35 fractions to PLN n=25	55Gy/35 fractions to PLN n=70	60Gy/35 fractions to PLN n=138	47Gy/20 fractions over 4 weeks to PLN n=64	47Gy/20 fractions over 5 weeks to PLN n=129	Total n=426
Local (prostate)	6 (24%)	11 (16%)	12 (9%)	3 (5%)	9 (7%)	41 (10%)
PLN	3 (12%)	5 (7%)	9 (6%)	3 (5%)	6 (5%)	26 (6%)
Other distant LN	3 (12%)	12 (17%)	12 (9%)	5 (8%)	7 (5%)	29 (9%)
Other metastatic sites	13 (52%)	25 (36%)	34 (25%)	9 (14%)	18 (14%)	99 (23%)
Median follow up (years)	13.9	11.2	9.0	7.1	5.7	7.6

#### Conclusion

Pelvic IMRT with dose escalation and hypofractionation is associated with a low rate of pelvic recurrence. Freedom from biochemical/clinical failure, cancer specific survival and overall survival appear favourable, but high dose pelvic IMRT requires testing in a phase 3 trial.

### EP-1364 Substratification of prostate cancer risk groups by core involvement and T stage may alter prognosis

A.B. Hopper<sup>1</sup>, J.P. Einck<sup>1</sup>

<sup>1</sup>University of California San Diego, Radiation Medicine and Applied Sciences, San Diego, USA

#### Purpose or Objective

Stratification of prostate cancer patients into low, intermediate and high risk groups has shown to be an important tool for prognostic outlook and treatment planning. The intermediate and high risk groups have been shown to be quite heterogeneous though, and substratification of these two groups may offer improved guidance. Recent research has shown that a five group risk stratification system may outperform the traditional three group system in predicting prostate cancer specific mortality, though this study did not use detailed staging information or % core involvement (Gnanapragasam et al. PLoS Medicine 2016). We sought to evaluate a five tiered system, specifically substratification of intermediate (IR) and high risk (HR) patients, using more detailed information with regard to stage and biopsy core involvement.

#### Material and Methods

378 intact PCa patients classified as IR or HR were treated with radiotherapy at our institution between Jan 2005 and Dec 2013, excluding any patients with prior metastases or positive nodes on imaging. 48 patients were designated as favorable (fIR) within the IR category with only one IR factor, no predominant Gleason 4 pattern and % of cores involved  $\leq$  50%. 147 patients were unfavorable IR (uIR) with any Gleason pattern 4+3, >50% of cores involved or multiple IR factors. 78 patients were favorable HR (fHR) with only one of Gleason 4+4, PSA > 20, or clinical stage T3. 105 patients were unfavorable HR (uHR) with a combination of multiple HR factors or any Gleason 5 pattern (GS 9 or 10). Recurrence was defined using the Phoenix criteria of PSA nadir + 2 ng/mL. Kaplan-Meier analysis was used to compare biochemical progression free survival (bPFS) between substratification groups. Median follow up was 47 months.

#### Results

Log-rank testing showed no significant difference in total bPFS between fIR and uIR groups (p=0.293). fHR and uHR groups were found to have significantly different bPFS (Figure 1, p=0.036). Overall comparison between the 4 groups showed a significant effect on bPFS (p = 0.038).

Pairwise analysis showed that there was not a significant difference in bPFS between uIR patients and fHR patients ( $p = 0.462$ ). Rates of PSA recurrence in uHR patients were significantly different from fHR, as noted above, as well as with fIR ( $p = 0.031$ ) while not from uIR ( $p=0.070$ ).

#### Conclusion

When taking into account clinical sub-stages and biopsy core involvement there was not a significant difference in bPFS between unfavorable IR patients and favorable HR patients where only one HR risk factor is present. The presence of a single HR risk factor may not be as detrimental to prognosis as previously thought, while multiple IR risk factors or significant core involvement may alter outlook for patients in the IR group. Due to the median follow up of this study biochemical recurrence was used as the primary endpoint which makes direct comparison to studies using prostate cancer specific mortality difficult; additional evaluation using such endpoints is warranted.

#### EP-1365 Pure Hypofractionated Radiotherapy for the Treatment of Low- to Intermediate-Risk Prostate Cancer

R. Stephens<sup>1</sup>, D. Gopaul<sup>2</sup>, D. Panjwani<sup>2</sup>, M. Lock<sup>3</sup>

<sup>1</sup>Grand River Regional Cancer Centre, Oncology, Kitchener, Canada

<sup>2</sup>Grand River Hospital, Oncology, Kitchener, Canada

<sup>3</sup>London Health Sciences Centre, Oncology, London, Canada

#### Purpose or Objective

Radiotherapy for prostate cancer may benefit from hypofractionation<sup>1-3</sup>. Conventional radiotherapy for prostate cancer involves delivering daily 1.8 -2.0 Gy fractions over 9 weeks. All of the hypofractionation studies completed to-date involve delivering fewer fractions of 2.5-3.1 Gy daily for 4 to 5 weeks (i.e., they are accelerated).

The purpose of our prospective phase II clinical trial was to determine whether the use of hypofractionated radiotherapy schedules (i.e., fewer, larger fractions) without acceleration could lead to reductions in the incidence of late toxicity symptoms, while still retaining benefits in disease control.

#### Material and Methods

Prostate cancer patients at Grand River Regional Cancer Centre were screened for the study, and those that met eligibility criteria were enrolled. Written informed consent was obtained. Radiation therapy was delivered using either 3DCRT or IMRT. Patients were categorized as low risk or intermediate risk according to D'Amico criteria<sup>4</sup>. Low risk patients received a total dose of 50 Gy / 15 fx over 7 weeks, and intermediate risk patients received 60 Gy / 20 fx over 8 weeks. Neoadjuvant or adjuvant ADT was not used.

Follow-up involved bi-annual PSA measurements and toxicity grading. Freedom from biochemical failure (FFBF) was determined using the Phoenix definition<sup>5</sup>. Late toxicity scoring was based upon RTOG/EORTC Late Radiation Morbidity Criteria<sup>6</sup>.

Using Microsoft® Office Excel® 2007 (Microsoft, Redmond, WA) demographic information and outcome frequencies were analysed. Actuarial analysis for freedom from biochemical failure (FFBF), late gastrointestinal (GI) toxicity, late genitourinary (GU) toxicity, freedom from evidence of metastatic disease, and overall survival were generated using in IBM® SPSS® Statistics Version 21.0 (IBM Corporation, North Castle, NY).

#### Results

There were 216 prostate cancer patients that met eligibility criteria and were enrolled in the study. 209 patients were included in the long-term analysis after 10 years of follow-up. The median follow-up was 6.5 years. Of the 209 patients enrolled, 53 patients were categorized

as low risk and 156 patients as intermediate risk. Table 1 summarizes the incidence of outcome events at the end of the 10-year follow-up period.

Actuarial analysis (Figure 1) provided 5 year rates of late GI toxicity  $\geq$  RTOG grade 2 of 4.3% in low risk patients and 7.5% in intermediate risk patients. Late GU toxicity rates were 8.6% in the low risk group and 7.6% in the intermediate group. 5 year FFBF rates were 85.1% in low risk patients and 80.1% in intermediate risk patients. The 5 year freedom-from-evidence-of-metastatic disease rates for low and intermediate risk prostate cancer patients were 4.2% and 4.8%, respectively.

#### Conclusion

Compared to accelerated hypofractionated schedules<sup>2-11</sup>, hypofractionation without acceleration resulted in similar rates of late GI toxicities, late GU toxicities, and 5 year FFBF rates (see Table 1).

<sup>13</sup>Toyama Prefectural Central Hospital, Department of Radiation Oncology, Toyama, Japan

<sup>14</sup>National Cancer Research Hospital East, Department of Radiation Oncology, Kashiwa, Japan

#### Purpose or Objective

Small cell carcinoma of the bladder (SCCB) is extremely rare, accounting for less than 1% of malignant tumors in the urinary tract. Because of its rarity, standard therapy has not been established. We conducted the first national survey in Japan on radiotherapy aimed at functional preservation in patients with small cell carcinoma of the bladder.

#### Material and Methods

Data were obtained for treatments and outcomes in patients with a diagnosis of SCCB who received radiotherapy aimed at functional preservation in the period from 1990 to 2010. A multi-center retrospective analysis of 15 eligible cases was performed.

## Results

The median age of the patients was 72 years (range: 44-93 years), and the median follow-up period was 17.4 months (range: 2.7-117.8 months). The median dose was 55 Gy (range: 40.0-61.0 Gy), and a median of 2.0 Gy (range: 1.2-2.0 Gy) was given per fraction. Initial CTV (clinical treatment volume) in most cases was the whole pelvis, and it was shrunk to the bladder or tumor as a boost. Systemic chemotherapy combined with radiotherapy was performed in 10 of the 15 cases. The 1-year and 3-year overall survival rates were 66.7% and 40.0%, respectively, and the 1-year and 3-year local control rates were 70.0% and 60.0%, respectively. Chemotherapy contributed to improvement of overall survival and relapse-free survival ( $p = 0.001$ ). There were no serious adverse events in the observation period. The bladder was maintained in all cases.

## Conclusion

Radiotherapy has an important role from the point of view of the patient's QOL and is likely to become an option for local treatment. Chemotherapy combined with radiotherapy is considered to be essential for systemic tumor control.

### EP-1367 Conservation treatment of Carcinoma Penis with surface mould brachytherapy

M. Anjanappa<sup>1</sup>, A. Kumar<sup>1</sup>, P. Raghukumar<sup>2</sup>, F. James<sup>1</sup>

<sup>1</sup>Regional Cancer Center, Radiation Oncology, Trivandrum, India

<sup>2</sup>Regional Cancer Center, Radiation Physics, Trivandrum, India

#### Purpose or Objective

To assess the rate of organ preservation and to identify factors related to local control in patients treated with surface mould brachytherapy for carcinoma penis.

#### Material and Methods

A retrospective analysis of patients treated with surface mould brachytherapy for carcinoma penis at our institution during the period 2000 to 2011 was carried out. The details of age and date of diagnosis of these patients, tumour size, histology, stage, size of residual disease after biopsy were collected. Further, the treatment details regarding the type of brachytherapy treatment, dose prescribed, response to treatment and recurrences were documented. Local control was calculated from the date of diagnosis to documented date of local recurrence or residual disease. In addition, nodal and systemic relapses were documented separately.

#### Results

A total of seventeen patients were identified from database and the records of sixteen patients were available for the analysis. The mean age was 47.3 years (range 31-73). All patients had histologically verified squamous cell carcinoma. Nine patients had lesion on the glans, six on the prepuce and one on the shaft. Three patients did not have any disease palpable after biopsy and the rest had a tumor size of less than 2cm. Three fourths of the total number had T1 disease. Majority of the patients (fourteen) were treated with pre-loaded LDR source brachytherapy and the rest with remote after loading HDR source. The dose prescribed ranged from 55Gy to 65 Gy at surface for LDR and the HDR dose was 50Gy in 15 fractions and 30Gy in 10 fractions treated twice daily. At a median follow up of 37.5 months (range 9-167), the local control was 75%. Among the twelve patients with T1 disease, one patient had residual disease after brachytherapy and the other had a local recurrence after seven months resulting in local control rate of 83.3%. Three out of sixteen patients had partial response after brachytherapy for which they underwent salvage surgery. The local control with salvage surgery after residual disease or recurrence was 100%. Furthermore, among the

patients with residual disease following brachytherapy, two were having T2 disease. Among them, one patient subsequently developed systemic recurrence (lung and bone) and succumbed to disease. Regional nodal relapse was documented in one patient for whom inguinal block dissection was performed. The nodal and systemic relapses were in T2 patients.

#### Conclusion

Three fourth of patients had local control with organ preservation by mould brachytherapy for Penile squamous cell carcinoma and the rest had surgical salvage to achieve local control. It appeared that the control was better for T1 disease than T2. Mould brachytherapy may be considered as a safe alternative to surgical treatment in patients with early stage penile carcinoma who wish to retain entire penis.

### EP-1368 Impact of post-operative Radiotherapy in bladder cancer after loco-regional relapse.

M.J. Mañas<sup>1</sup>, X. Maldonado<sup>1</sup>, F. Lozano<sup>2</sup>, C. Raventós<sup>2</sup>, R. Morales<sup>3</sup>, V. Reyes<sup>1</sup>, S. Micó<sup>1</sup>, D. SantaMaria<sup>1</sup>, J. Carles<sup>3</sup>, J. Morote<sup>2</sup>, J. Giral<sup>1</sup>

<sup>1</sup>Radiation Oncology. H.U. Vall d'Hebrón, Barcelona, Spain

<sup>2</sup>Urology. H.U. Vall d'Hebrón. Barcelona, Spain,

<sup>3</sup>Medical Oncology. H.U. Vall d'Hebrón. Barcelona, Spain,

#### Purpose or Objective

To assess the role of radiotherapy in bladder carcinoma after loco-regional relapse or pathologic adverse factors in patients previously treated with or without cystectomy after chemotherapy. To evaluate the toxicity of these treatments.

#### Material and Methods

Since September 1998 to September 2016, seventy-eight patients with bladder cancer (68 men, 10 women, median age 53 years, range 37-87 years) have been postoperatively treated with radiation therapy in our department. 63 patients had transitional carcinoma, 7 squamous cell carcinoma and 8 sarcomatoid carcinoma. The aim of the treatment was adjuvant in 27 patients (34.6%), consolidative after nodal relapse post-chemotherapy 19 patients (24.3%) and for local tumor persistence in 32 patients (41.0%).

Mean radiotherapy dose was 50.4 Gy (range 37.5 Gy - 64,8 Gy) 1,8 Gy/fraction, 5 fraction/week (40 Gy to the pelvis and a boost to the GTV up to 55,8 Gy if cystectomy or 64,8 if the bladder was present). RTOG Late Toxicity scale and CTCAEv3.0 were used. Survival was calculated by means the Kaplan-Meier method.

#### Results

Cystectomy was previously performed in 42 patients (53.8%). Clinical prognostic factor were: pT1, 5 (6%); pT2, 29 (37.1%); pT3, 30 (38.4%); pT4 14 (18%); N+, 53 (67.9%); NO 25 (32%).

With a median follow-up of 30.6 months (m). Median time between infiltrative bladder tumor diagnoses and local relapse was 13m (3-77 m), nodal relapse, 11 m (3-39 m). Actuarial survival at 16 m and 36 m were 68% and 51% respectively. At 60 m, actuarial survival post-radiotherapy was 34%.

Median survival after treatment for nodal relapse, local relapse and adjuvant Radiotherapy were 15.5 m(11-92 m), 22.5 m (9-180 m) and 18.5 m (15-84 m) respectively.

Failures after consolidative radiotherapy were: bone metastases (7.7%), nodal relapse (25.6%), local relapse (20.5%), soft tissues metastases (12.8%).

No grade 4 late toxicity has been reported. 8 patients (10%) presented late GI toxicity grade 2 and in 2 was grade 3. In 4 patients (5.1%) grade 2 GU toxicity was reported and grade 3 in 2.

### Conclusion

Post-operative radiotherapy in bladder cancer with loco-regional relapse or with pathological adverse factors is feasible with a low late toxicity profile. Half of our patients are alive at 3 years.

In these patients with loco-regional relapses after radical cystectomy or with macroscopic residual tumor after maximal surgical effort with curative intent, loco-regional control rate is improved with respect to the chemotherapy alone standard treatment.

### EP-1369 Cystectomy with adjuvant radiotherapy for invasive bladder tumors: early results of a phase II study

M. Swimberghe<sup>1</sup>, E. Rammant<sup>1</sup>, K. Decaestecker<sup>2</sup>, P. Ost<sup>1</sup>, S. Junius<sup>3</sup>, P. Dirix<sup>4</sup>, G. De Meerleer<sup>5</sup>, V. Fonteyne<sup>1</sup>

<sup>1</sup>University Hospital Ghent, Radiotherapy, Ghent, Belgium

<sup>2</sup>University Hospital Ghent, Urology, Ghent, Belgium

<sup>3</sup>Centre Hospitalier de Mouscron, Radiotherapy, Mouscron, Belgium

<sup>4</sup>GZA St-Augustinus Hospital, Radiotherapy, Antwerp, Belgium

<sup>5</sup>University Hospitals Leuven, Radiotherapy, Leuven, Belgium

### Purpose or Objective

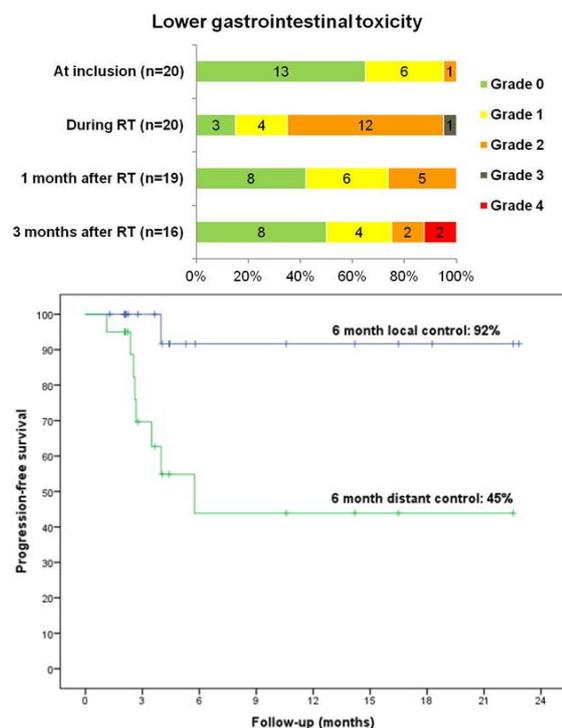

Patients with locally advanced muscle invasive bladder cancer (MIBC) have a high risk of recurrence. Studies have shown a benefit on locoregional control of postoperative radiotherapy (PORT) after radical cystectomy, but its use remains limited due to fear of severe toxicity. With modern radiotherapy (RT) the place of PORT should be reassessed.

### Material and Methods

A phase II study was started to evaluate acute toxicity of PORT with modern RT. All patients underwent radical cystectomy and presented one or more of the following pathological findings: pT3 with lymphovascular invasion, pT4, <10 lymph nodes removed, positive lymph node status or positive surgical margins. A median dose of 50 Gy in 25 fractions is prescribed to the iliac, obturator and presacral lymph nodes. Cystectomy bed is only included in case of positive margins. Treatment is delivered with an arc technique (VMAT). Toxicity is scored at baseline, during, 1 and 3 months after RT using Common Terminology Criteria for Adverse Events version 4.3. Urinary toxicity is scored if a neobladder is present. Local and distal control after treatment were evaluated every 3 months using CT, or earlier on indication.

### Results

Since 2014, 23 patients were enrolled in the study. Due to progressive disease on planning CT 3 patients were excluded. Median follow-up is 4 months (range 1-23). During RT, 4 patients were hospitalized, of which 2 were RT-induced (upper and/or lower gastrointestinal (GI) toxicity). Out of the 5 patients with a neobladder, 4 reported  $\leq$  grade 2 urinary toxicity. One patient developed transient grade 3 nocturia during RT. Three months after RT, 2 patients had surgery for an enterovaginal fistula and obstruction caused by peritoneal metastasis respectively. All other patients had  $\leq$  grade 2 GI and urinary toxicity during follow-up. No isolated local relapse was observed. Seven patients developed distant metastasis of whom 1 patient had simultaneous local and distant relapse and 1 patient had a relapse at the border of the RT-field. Five patients died; 2 were disease-related.

### Conclusion

Using modern RT techniques, PORT for high risk MIBC is feasible and toxicity is acceptable. Preliminary results on locoregional control are promising but long-term follow-up is warranted.

### EP-1370 Simultaneous integrated tumour boost planning in bladder cancer: a comparison of strategies

S. Hafeez<sup>1</sup>, K. Warren-Oseni<sup>2</sup>, H. McNair<sup>1</sup>, V. Hansen<sup>2</sup>, R. Huddart<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Radiotherapy and Imaging, Sutton, United Kingdom

<sup>2</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Dept of Physics, Sutton, United Kingdom

### Purpose or Objective

Partial bladder radiotherapy can be utilized with no adverse effect on local control [1, 2]. We sought to compare partial bladder irradiation using a simultaneous integrated boost (SIB) approach with intensity modulated radiation therapy (IMRT) and volumetric-modulated arc therapy (VMAT) to inform our current image guided adaptive approach.

### Material and Methods

Seven patients with unifocal T2-T3N0M0 MIBC recruited prospectively to an image guided SIB protocol (NCT01124682) were evaluated. Fixed field IMRT and VMAT plans were created treating whole bladder (PTV<sub>bladder</sub>) to 52Gy and tumour (PTV<sub>boost</sub>) to 70Gy in 32 fractions using Pinnacle v9.6, Philips Medical Systems. The same constraints were applied for both planning approaches. Plan quality was assessed by calculating the conformity index (CI= $V_{95\%}/V_{PTV}$ ), homogeneity index (HI= $D_{2\%}-D_{98\%}/D_{50\%}$ ), dose to target and normal structures. Comparisons were made with Wilcoxon signed rank test.

### Results

The mean PTV<sub>bladder</sub> (SD, range) CI for IMRT and VMAT was 1.20 (0.04; 1.14-1.24) and 1.17 (0.06; 1.13-1.30) (p=0.24); mean PTV<sub>boost</sub> (SD, range) CI was 1.20 (0.11; 1.06-1.37) and 1.17 (0.13; 1.03-1.31) (p=0.74) respectively. The mean PTV<sub>bladder</sub> (SD, range) HI for IMRT and VMAT was 0.39

(0.01; 0.37-0.40) and 0.38 (0.02; 0.36-0.40) ( $p=0.61$ ); and mean  $PTV_{Boost}$  (SD, range) HI was 0.08 (0.02; 0.05-0.11) and 0.07 (0.03; 0.05-0.12) ( $p=0.31$ ) respectively.

Structure	Constraint	IMRT			VMAT		
		Mean	SD	Range	Mean	SD	Range
PTV <sub>Bladder</sub>	D <sub>95%</sub>	71.4	0.5	70.7 72.3	71.2	0.7	70.6 72.5
	D <sub>90%</sub>	55.1	1.3	53.8 57.4	55.2	1.8	53.0 57.8
	D <sub>85%</sub>	50.1	0.3	49.7 50.5	50.0	0.4	49.5 50.6
PTV <sub>Boost</sub>	D <sub>95%</sub>	72.3	0.8	71.2 73.5	71.9	0.8	71.3 73.4
	D <sub>90%</sub>	70.1	0.1	70.0 70.3	70.2	0.1	70.1 70.4
	D <sub>85%</sub>	66.8	0.5	66.1 67.6	66.8	1.1	64.7 67.9
Rectum	V30<80%	54.5	10.6	39.8 74.2	54.5	19.0	23.2 80.7
	V50<60%	1.4	1.1	0.0 3.1	0.9	1.0	0.0 2.7
Other bowel	V45<139cc	101.7	47.7	49.9 190.3	104.5	56.3	56.8 219.4
	V50<127cc	73.7	38.1	37.0 150.0	73.5	37.9	38.5 150.9
	V55<115cc	24.4	29.6	2.4 89.3	23.4	21.0	3.9 67.9
	V60<98cc	12.4	17.2	0.0 49.0	11.5	13.8	0.2 40.4
	V65<40cc	6.9	9.5	0.0 27.1	6.4	8.0	0.0 22.5
	V70<10cc	1.6	2.2	0.0 6.0	1.3	1.7	0.0 4.9
Bladder outside PTV <sub>Boost</sub>	V60<80%	23.9	6.4	13.9 32.5	24.7	16.9	10.2 51.5
	V65<50%	8.4	2.5	3.5 11.3	9.3	5.5	2.4 16.3

No statistically significant difference in target volume coverage or dose to rectum, other bowel or bladder outside  $PTV_{Boost}$  was seen between the two plans. Table below summaries the dosimetric outcomes.

### Conclusion

SIB delivery was achieved with comparable target and normal tissue constraints for both techniques. VMAT faster delivery times are likely to mean it is favoured for this group of patients both because of reduction in intra-fraction organ filling opportunity and departmental throughput.

### EP-1371 Primary oesophageal melanoma responds to hypofractionated radiotherapy

K. Griffin<sup>1</sup>, A. Scarsbrook<sup>2</sup>, W. Merchant<sup>1</sup>, G. Radhakrishna<sup>3</sup>, O. Donnelly<sup>3</sup>

<sup>1</sup>St James' Institute of Oncology, Pathology, Leeds, United Kingdom

<sup>2</sup>St James' Institute of Oncology, Radiology, Leeds, United Kingdom

<sup>3</sup>St James' Institute of Oncology, Oncology, Leeds, United Kingdom

### Purpose or Objective

Oesophageal melanoma is rare; current practice would be to consider surgical treatment first, with radiotherapy reserved for unresectable or patients not suitable for oesophagectomy. We report our experience of three consecutive patients who responded to high-dose hypofractionated radiotherapy to localised oesophageal melanoma primaries.

### Material and Methods

Each patient had endoscopic biopsy confirming primary oesophageal melanoma. Prior to treatment whole-body PET scans were performed to aid tumour localisation and exclude nodal or distant metastases. PET scans were repeated after completion of radiotherapy and patients were followed-up clinically thereafter. Each patient gave written consent for publication.

Two patients (A&B) received 50 Gy in 16 daily fractions using a 3D conformal technique. The third patient (C) received 30 Gy in 10 daily fractions followed by intraluminal brachytherapy (16 Gy in 2 treatments, one week apart).

### Results

In all three cases tumours were Braf wildtype, PET-avid on pre-treatment scans and no distant or nodal metastases were identified.

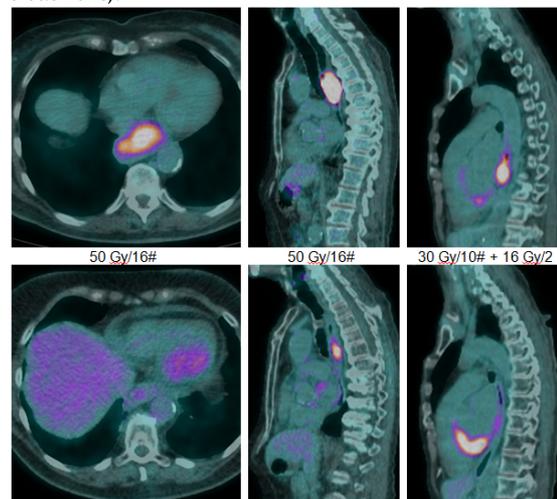

All three patients developed odynophagia requiring analgesia during and for several weeks following treatment and lost weight, though no patient required admission or enteral feeding support.

On post-treatment PET scans all patients had a response in the oesophageal primary;

Patient A had a complete response. She remained disease-free, with normal swallowing, until she died due to myocardial infarction, 30 months after diagnosis (26 months since completion of treatment).

B had a good partial response; pretreatment 6 cm tumour with SUVmax 20.8 - following treatment 2.8 cm, SUVmax 9.7. His swallowing remained normal without further intervention until 24 months after diagnosis (22 months after treatment) - at which point he reported mild dysphagia and a further endoscopy identified residual melanoma. He remains stent-free.

C had complete response of the primary oesophageal melanoma but the post-treatment PET identified metastatic disease in both lungs and peritoneal cavity. She died 12 months after diagnosis (9 months after treatment).

### Conclusion

Oesophageal primaries are a rare site for non-cutaneous melanomas with little evidence to guide management. Based on our series tumours are FDG-avid and PET-CT is likely to be useful in planning treatment. Hypofractionated radiotherapy appears to be effective in achieving local control and should be considered an alternative to surgery for melanoma arising in the oesophagus.

### EP-1372 Preliminary results of fractionated cyberknife stereotactic radiotherapy for uveal melanoma.

I. Bossi Zanetti<sup>1</sup>, M. Pellegrini<sup>2</sup>, G. Beltramo<sup>1</sup>, V. Ravera<sup>2</sup>, A. Bergantin<sup>1</sup>, A.S. Martinotti<sup>1</sup>, I. Redaelli<sup>1</sup>, P. Bonfanti<sup>1</sup>, A. Bresolin<sup>1</sup>, L.C. Bianchi<sup>1</sup>, G. Staurengi<sup>2</sup>

<sup>1</sup>Centro Diagnostico Italiano, Cyberknife, Milano, Italy

<sup>2</sup>Luigi Sacco Hospital - University of Milan, Eye Clinic, Milan, Italy

#### Purpose or Objective

We report our clinical experience of a Hypofractionated Cyberknife Stereotactic Radiotherapy schedule for uveal melanoma treatment.

#### Material and Methods

Between April 2014 and October 2015 12 patients (pts), mean age 65 years (range 36 - 82 years) suffering from uveal melanoma (11 choroidal melanoma and 1 ciliary body melanoma) were treated at Cyberknife Center, Centro Diagnostico Italiano, Milan. All of the pts had received a diagnosis and referral from an ophthalmologist. Cyberknife robot-controlled LINAC radiotherapy was performed delivering a total dose of 54 - 60 Gy (mean 60 Gy) given in 3 or 4 fractions (mean 3) of 15 - 20 Gy (mean 20 Gy) prescribed to the 79 - 82% (mean 80%) isodose surface. All pts underwent orbit MRI with gadolinium for coregistration with the planning CT scans. The planning target volume (PTV) included the contrast-enhancing lesion on MRI plus a 2.5 mm margins in all directions. All pts were irradiated eyelids closed, without peribulbar anesthesia, using a contention with a thermoplastic mask. At presentation the mean PTV volume was 2148 mm<sup>3</sup> (range 701.82 - 5792 mm<sup>3</sup>), mean tumor base measured ultrasonographically 11.75 mm (range 7-15 mm), mean thickness 4.6 mm (range 2.5 - 7.1 mm), with a mean distance of 5.7 mm (range 0 - 15 mm) from fovea and 6.1 mm (range 0 - 13 mm) from optic nerve.

#### Results

After a mean follow-up of 11.5 months (range 3 - 24) local control was achieved in 100% of pts. No patient underwent enucleation and none developed distant metastases (all pts underwent abdomen ultrasound and liver blood examination once every six months and chest CT once a year). We observed a reduction of 17% in median base and of 40% in median thickness that were respectively 10 mm (range 4.8 - 13 mm) and 2.75 mm (range 0.5 - 5 mm) at last follow-up. Visual acuity was reduced in 58% of pts, while in the others no change was found. Three pts suffered of radiation maculopathy, associated in one case with atrophy and in two cases with cystoids macular edema. Moreover radiation-induced optic neuropathy and radiation vasculopathy occurred respectively in 2 and 4 cases. 5 pts developed choroidal ischemia and 3 retinal detachment. At the last follow-up none had corneal anomalies and only one cilia loss.

#### Conclusion

These initial results of our Cyberknife schedule are consistent with data in literature and show a safe, minimally invasive and well tolerated method for treating uveal melanoma. Further follow-up is necessary.

### EP-1373 Will appropriate TSEI timing help to find effective dose for patients with mycosis fungoides?

A. Chourova<sup>1</sup>, M. Doleckova<sup>1</sup>, D. Kralova<sup>1</sup>, P. Berkovsky<sup>1</sup>, T. Juraskova<sup>1</sup>

<sup>1</sup>Hospital Ceske Budejovice, Oncology, Ceske Budejovice, Czech Republic

#### Purpose or Objective

Mycosis fungoides (MF) is the common type of cutaneous T cell lymphoma, CD4+, with great heterogeneity, but incidence is low. TSEI is the most effective single agent for the treatment MF. It is a complex method for

delivering superficial irradiation to entire skin surface. Recommended doses are in range 8-36Gy (The International Lymphoma Radiation Oncology Group, 2015). Presently, the attention is focused on low dose (10-12Gy) TSEI, the complete response rate is lower, but lower are also the complications. Now is the opportunity for retreatment TSEI.

#### Material and Methods

In Department of Oncology, Hospital Ceske Budejovice, Czech Republic, from 1993 to October 2016, 65 patients, who had cutaneous T cell lymphoma, mostly MF, received TSEI.

Different treatment modalities (chemotherapy, PUVA, Interferon, Targretin, local irradiation, ...) have been used prior TSEI for majority of patients.

We have modified TSEI technique developed at McGill University, Montreal (Freeman C.R., 1992) for our condition. The patient is in „ballet dancer“ position and rotates on the carousel, two arc fields produce a uniform treatment field over the total patient height, with SSD 355 cm, 6 MeV electron beam.

The oblique fields achieve with **rotational radiotherapy technique** maximal dose on the surface of the skin, with **stationary radiotherapy technique** there is 88% of max. dose on the surface (max. dose in 9 mm) with PLEXI glass in front of patient, without PLEXI 77% (max. dose in 14 mm). A total dose 18- 40 Gy (10 Gy/week). Dose distribution was monitored by thermoluminescent dosimeters (TLD) with subsequent “patch treatments“ and “boost treatments“.

In the last 2 years (December 2013- June 2016) we used time for complication decreasing in TSEI and better evaluation of MF response to treatment (n=9). TSEI week timing: first week TSEI, second week break, third week TSEI... Fractionation: 2Gy/fraction, 5 fraction/week. Total dose 18-36Gy., median dose 26Gy. Applied dose depended on MF response to TSEI. Median age: 75 years (42-80), T2N0M0B0 (n= 2), T3N0M0B0 (n=3), T3N1M0B0 (n=2), T3N2M0 B0 (n=1), T4N0M0B0 (n=1).

#### Results

- -Complete response: in 100%
  - Relapse: 4 patients in 4, 6, 7 and 12 month
    - 2 patients with relapse - solved by retreatment TSEI (8 a 10 Gy) and Roferon A application, both patients are without MF
    - 1 patient with relapse (4 months) - treated by local irradiation, relapse repeated, become worse, died of reaction GVH.
    - 1 patient relapse (in 6 months) - treated by Targretin
  - - Follow-up: 4 - 20 months, median 14 months
  - - 5 alive without MF
  - -1 alive with MF
  - -3 died
    - 1 patient died of IM without MF
    - 1 patient (non mycosis fungoides) died of GVH reaction, with MF
    - 1 patient died of IM with MF
  - All patients without acute complications of TSEI (erythema, dry desquamation)
- #### Conclusion
- - For all of TSEI patients week timing improves quality of life.
  - - Protraction of the whole time TSEI with week timing allows to get time for treatment effect evaluation.

### EP-1374 Hypofractionated radiotherapy in non-melanoma skin cancer $\geq 3$ cm in elderly PTS .

L. Ferella<sup>1</sup>, S. Parente<sup>1</sup>, G.L. Gravina<sup>1</sup>, P. Bonfili<sup>2</sup>, M. Di Staso<sup>2</sup>, P. Franzese<sup>2</sup>, M.E. La Verghetta<sup>1</sup>, M. Cerasani<sup>1</sup>, D. Di Genova<sup>1</sup>, E. Di Cesare<sup>1</sup>

<sup>1</sup>Università degli studi de L'Aquila, Divisione radioterapia

*e radiobiologia, L'Aquila, Italy*  
<sup>2</sup>*ospedale San salvatore L'Aquila, Uo Radioterapia, L'Aquila, Italy*

#### Purpose or Objective

To evaluate clinical outcome of an Hypofractionated schedule in elderly pts with NMSC  $\geq 3$ cm.

#### Material and Methods

METHOD: From 2010 to 2016 we treated 17 pts, median age 78 years, with diagnosis of NMSC (5/17 basal cell carcinoma, 11/17 squamous cell carcinoma, 1/17 trichilemmal carcinoma),  $\geq 3$ cm (range 3-8 cm diameter), GTV median volume was 32cc (range 5-60 cc). Only 1 pt presented extremity disease (malleolar region) and the others had head region disease. Total dose was 36 Gy in 6 Gy/fractions twice a week. Pts were evaluated 1 month after the end of treatment and then every 3 months. At the follow up pts were assessed for acute and late toxicity according to the Radiation Therapy Oncology Group criteria and treatment response according to Recist criteria.

#### Results

Median follow up was 12 months. We reported CR in 9/17 pts (53%), PR in 8/17 pts (47%) at one month after the end of the treatment. No PD was observed. No pts had acute side effect that required treatment interruption. Acute toxicity was grade 1 RTOG in 3/17 pts. 1/17 had grade 2 RTOG late skin toxicity with moderate fibrosis and discromia.

#### Conclusion

The Hypofractionated schedule of 36 Gy in 6 Gy/fractions 2/week in elderly pts gave good results in term of treatment response and of acute and late side effects even in lesions  $\geq 3$ cm. The treatment was well tolerated in all cases and the shorter regime facilitates compliance of elderly pts reducing the number of Hospital visits.

#### EP-1375 Volumetric-modulated-arc-therapy versus 3D-conformal-radiotherapy for sarcoma of extremities

A.M. Ascolese<sup>1</sup>, P. Navarra<sup>1</sup>, P. Mancosu<sup>1</sup>, S. Tomatis<sup>1</sup>, A. Fogliata<sup>1</sup>, P. Colombo<sup>1</sup>, R. De Sanctis<sup>1</sup>, A. Marrari<sup>1</sup>, D. Franceschini<sup>1</sup>, G.R. D'Agostino<sup>1</sup>, A. Santoro<sup>1</sup>, V. Quagliuolo<sup>1</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

#### Purpose or Objective

To assess the impact of volumetric-modulated arc therapy (VMAT) compared with 3D-conformal radiotherapy (3DCRT) in patients with newly diagnosed soft tissue sarcoma (STS) of the extremities in terms of toxicity, local control (LC) rate and patients overall survival (OS).

#### Material and Methods

The present retrospective study includes patients with newly diagnosed STS of extremities treated at our institution. All patients underwent limb-sparing surgery and adjuvant radiation therapy. 3DCRT was adopted between 2006-2010 and VMAT between 2011-2015. The median total dose prescribed was 66 Gy (range 60-70 Gy) in 33 fractions in both groups. The clinical target volume (CTV) corresponded to the surgical cavity and planning tumor volume (PTV) was generated adding and isotropic margin of 1 cm. All plans were optimized on PTV. Clinical outcome was evaluated by physical examination, contrast-enhanced MRI, thoracic and abdominal computed tomography (CT) scan two months after RT and then every 3 months. The tumor progression was described as local, if it occurred in primary site. Toxicity was evaluated with

Common Terminology Criteria for Adverse Events (CTCAE) scale version 4.0.

#### Results

From January 2006 to December 2015, 147 patients were treated. The greater number of patients had liposarcoma and leiomyosarcoma histology (62%). Preoperative tumor volume was  $> 10$  cm in maximum diameter in 62 (42%) of patients and  $\leq 10$  cm in 85 (58%). Radical surgery was performed in 85 (58%) patients and marginal or closed in 62 (42%). Preoperative or postoperative chemotherapy was administered in 73 (49.6%) patients. The median follow up time was 45.04 months. The 5 years LC rate was 80.79% for the whole cohort, 73.98 for 3DCRT patients and 85.26% for VMAT, respectively. The 5 years OS rate was 68.85% for the entire cohort, 61.1% for 3DCRT group and 80.64% for VMAT, respectively. All but one dosimetric parameters were in favor of VMAT. In detail, PTV V95% was higher for VMAT; bones volume receiving 50 Gy was significant lower for VMAT ( $p < 0.05$ ). For the lower extremities, the maximum dose (i.e. 1cm<sup>3</sup>) to the contralateral leg was smaller for the 3D approach (median: 16Gy vs 7.2Gy). Acute soft tissue G3 toxicity was observed in 10 patients underwent 3DCRT and in 2 received VMAT. G1 fibrosis was recorded in 80% of patients while osteomyelitis conditioning pain and bone fractures in 2 patients in 3DCRT group. Factors conditioning LC and OS, on univariate and multivariate analysis was the tumor size ( $p < 0.01$ ) and the surgical radicality ( $p < 0.01$ ).

#### Conclusion

the availability of modern RT technique permit a better conformity on the target with maximum sparing of normal tissue and lower side effects. This matter is hopeful for prospective study using moderate hypofractionated RT schedule.

#### EP-1376 IOERT combined with EBRT in R1-resected soft tissue sarcomas of the extremities: a pooled analysis

<sup>4</sup>University of Heidelberg, Department of Surgery, Heidelberg, Germany

<sup>5</sup>Centro di Riferimento Oncologico, Department of Surgery, Aviano, Italy

<sup>6</sup>University Hospital Gregorio Maranon, Department of Surgery, Madrid, Spain

<sup>7</sup>University of Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

<sup>8</sup>University Hospital Gregorio Maranon, Department of Radiation Oncology, Madrid, Spain

<sup>9</sup>University of Heidelberg, Department of Orthopedics, Heidelberg, Germany

<sup>10</sup>Helios Clinic, Department of Radiation Oncology, Berlin, Germany

#### Purpose or Objective

To report the results of a European pooled analysis evaluating the use of IOERT combined with EBRT in R1-resected patients with extremity STS.

#### Material and Methods

Three European expert centers participated in the current analysis. Only patients with R1-resection of an extremity STS who received IOERT and EBRT were included. Patient with gross incomplete resections, primary lesions outside the extremities, nodal or distant metastasis prior/at IOERT or missing EBRT documentation were excluded, leaving 68 patients for the analysis. Median age was 59

years and median tumor size 8 cm. 68% of the patients presented in primary situation with 72% of the tumors located in the lower limb. Stage at presentation (UICC 7<sup>th</sup>) was I:12%, II:49%, III:40%. Most patients showed high grade lesions (FNCLCC grade 1:12%, 2:34%, 3:54%, predominantly liposarcoma (38%) and MFH (28%). IOERT was applied to the tumor bed with a median dose of 12.25 Gy using a median electron energy of 8 MeV. IOERT was preceded (16%) or followed (84%) by EBRT with a median dose of 46 Gy in all patients. 22% of the patients received additional chemotherapy.

#### Results

Median follow up was 65 months. We observed 16 local failures, transferring into a 5-year-LC rate of 69%. Median time to onset of a local recurrence was 18 months (6-60 months). LC was significantly influenced by disease situation (primary vs recurrent), T stage and use of additional chemotherapy in univariate analysis. Distant failures were found in 21 patients, resulting in a 5-year-DC rate of 65%. Median time to onset of distant failure was 17 months (3-52 months). Gender, age and type of surgery were significantly associated with DC in univariate analysis. Actuarial 5-year rates of FTF and OS were 44% and 76%, respectively. While FTF was only influenced by use of CHT, OS was significantly associated with type of surgery and timing of EBRT in univariate analysis. However, according to multivariate analysis none of the mentioned factors remained significant for any endpoint. Secondary amputations were needed in 9 patients (13%). Good functional outcome was achieved in 72%.

#### Conclusion

Combination of IOERT and EBRT achieves high local control rates and good overall survival with encouraging rates of preserved limb function even after R1- resections. However, results are worse compared to R0-resections indicating that even IOERT and EBRT cannot fully compensate an unfavourable surgical outcome. Multivariate analysis failed to identify further prognostic factors.

#### EP-1377 Single institutional experience of the treatment of angiosarcoma of the scalp

H. Ihara<sup>1</sup>, K. Katsui<sup>1</sup>, K. Hisazumi<sup>2</sup>, S. Sugiyama<sup>2</sup>, K. Watanabe<sup>2</sup>, T. Waki<sup>3</sup>, T. Kaji<sup>4</sup>, N. Katayama<sup>2</sup>, M. Takemoto<sup>5</sup>, O. Yamasaki<sup>4</sup>, K. Iwatsuki<sup>4</sup>, S. Kanazawa<sup>2</sup>

<sup>1</sup>Okayama University Graduate School of Medicine-Dentistry and Pharmaceutical Sciences, Department of Proton Beam Therapy, Okayama, Japan

<sup>2</sup>Okayama University Hospital, Department of Radiology, Okayama, Japan

<sup>3</sup>Tsuyama Chuo Hospital, Department of Radiology, Tsuyama, Japan

<sup>4</sup>Okayama University Graduate School of Medicine-Dentistry and Pharmaceutical Sciences, Department of Dermatology, Okayama, Japan

<sup>5</sup>Japanese Red Cross Society Himeji Hospital, Department of Radiology, Himeji, Japan

#### Purpose or Objective

To retrospectively analyze the treatment results of angiosarcoma of the scalp.

#### Material and Methods

This study included 22 patients (15 men, 7 women; median age 78.5 years, range 34 - 91 years) with angiosarcoma of the scalp and who received radical radiation therapy between January 2000 and July 2016 at our institution. Four patients had cervical lymph node metastases. One patient had only one lung metastasis. The median radiation dose was 70Gy (range, 52-70), and the fractional dose was 2Gy. Radiation therapy alone or a combination of surgery, radiation therapy, chemotherapy and immunotherapy were administered. Taxane (paclitaxel and/or docetaxel) was used in 17 patients. Concurrent

chemoradiation with taxane was administered in 14 patients. The overall survival (OS), progression-free survival (PFS) and local control (LC) rates were calculated using Kaplan-Meier analysis. Univariate analyses of various potential prognostic factors for OS rate, PFS rate, and LC rate were performed.

#### Results

The median follow-up period was 14.5 months (range, 3.0-102.0). Local recurrence occurred in 6 patients. Distant recurrence was observed in 13 patients. OS rate was 78% at 1 year, 36% at 3 years. PFS rate was 38% at 1 year, 31% at 3 years. LC rate was 72% at 1 year, 62% at 3 years. One patient could not achieve the planned radiation therapy because of grade 3 dermatitis and delirium. In univariate analysis, age $\geq$ 75 was a significant prognostic factor for OS (P=0.015). Cervical lymph node metastasis was a significant prognostic factor for PFS (P=0.006). LC had no significant prognostic factor. In 17 patients without lymph node metastases or lung metastases, concurrent chemoradiation with taxane was a significant prognostic factor for PFS (P=0.018).

#### Conclusion

Multimodality therapies including radiation therapy were effective.

#### EP-1378 The Role of Radiation Therapy in the Treatment of Hemangiopericytoma/ Solitary Fibrous Tumor

Y.Y. Chiang<sup>1</sup>

<sup>1</sup>Chang Gung Memorial Hospital, Proton and Radiation Therapy Center, Taoyuan City, Taiwan

#### Purpose or Objective

Hemangiopericytoma (HPC)/ Solitary fibrous tumors (SFTs) are rare soft-tissue tumors of mesenchymal origin, and originate in a variety of anatomical locations. There is little consensus regarding the role of radiotherapy. Here is a review of treatment approach and clinical outcome from a tertiary referral hospital.

#### Material and Methods

Retrospective analysis was performed. Patients evaluated at Chang Gung Memorial Hospital with diagnosis of hemangiopericytoma/ solitary fibrous tumor between 1996 and 2015 were identified. Patient records were reviewed to collect data on demographics, tumor characteristics, treatment modalities, survival, and length of follow-up. The extent of surgery, tumor diameter, radiation dose and technique were recorded. Patterns of failure were recorded. Local control rate were determined by recurrences after initial surgery or radiotherapy. Patients who had surgery were compared with patients who underwent preoperative or postoperative RT or RT alone.

#### Results

We identified 42 patients with diagnosis of SFT/HPC. Thirty-five patients were available for clinical data and follow up information. Out of 35 patients, 20 (57%) were female and 15 (43%) were male, with a median age of 46.8 years (range, 21-76). Anatomical locations included intracranial 10(29%) and extracranial 25(71%) (head & neck 6, thorax 5, spine 4, pelvis 1, extremities 5, orbit 4). Among 34 patients who received surgery at our institution, 27(80%) patients achieved gross total resection(GTR) and 7(20%) received subtotal resection(STR). The other one patient received palliative chemotherapy at our institution. There are 13 patients who received RT: 5 in adjuvant setting with initial postoperative RT, 7 in salvage setting, and 1 palliative setting. Doses ranged from 40-66 Gy with 2 Gy per fraction, and one of the patient receiving 16 Gy SRS. RT technique included IMRT (7), VMAT (3), 3D conformal (1), electron beam RT(1). Median follow-up time is 73 months (range, 4-252 months).Thirty one (89%) patients were alive, and 4(11%) patients were dead. Five

and 10 years OS were 95.7%, and 82.2%, respectively. Recurrence occurred in 10 patients (29%), 6 locally, 1 distantly and 3 both locally and distantly. Of 10 patients who experienced recurrences, 9 of the cases were intracranial HPC, and 1 were of head & neck origin. Local recurrence occurred in 9 of the pts (26%): 4 after surgery, 5 after surgery and postoperative RT. LC rate at 3 and 5 years were 89.8% and 68.4% respectively. For the group of pts who receive surgery only with comparison to surgery and RT, the 5-year of LC and OS were 74.2%, 64.8% (p=.56), and 90.9%, 100% (p=.73). For the group of pts who receive GTR with comparison to STR, the 5-year of LC and OS were 68.6%, 45.7% (P=.31) and 100%, 100% (p=0).

#### Conclusion

Due to rarity of the disease, our data did not show significant improvement of LC after RT. GTR should be pursued and adjuvant RT after STR is a reasonable approach. Further investigations are needed to determine the optimal therapeutic strategy.

#### Electronic Poster: Clinical track: Paediatric tumours

#### EP-1379 Heart volume reduction in paediatric cancer patients during radiotherapy

I. Van Dijk<sup>1</sup>, J. Visser<sup>1</sup>, J. Wiersma<sup>1</sup>, J. Van Boggelen<sup>1</sup>, B. Balgobind<sup>1</sup>, L. Feijen<sup>2</sup>, S. Huijskens<sup>1</sup>, L. Kremer<sup>2</sup>, C. Rasch<sup>1</sup>, A. Bel<sup>1</sup>

<sup>1</sup>Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands

<sup>2</sup>Academic Medical Center, Pediatric Oncology- Emma Children's Hospital, Amsterdam, The Netherlands

#### Purpose or Objective

Radiation to the heart is associated with adverse cardiac effects in long-term cancer survivors. In adult patients with oesophageal cancer, a decrease in heart volume was observed already early during radiotherapy. Based on this observation we investigated whether similar heart volume changes occur during radiotherapy in paediatric cancer patients as well. Therefore, we retrospectively assessed heart volume change during thoracic radiotherapy in paediatric cancer patients.

#### Material and Methods

We included 13 females and 14 males who received radiotherapy to the thoracic region for a primary paediatric cancer, a recurrence, or metastatic disease between 2010 and 2016; median age at treatment was 11.0 (range 4.0-17.3) years. Median height and weight were 1.4 (range 1.0-2.0) meter and 40 (range 14-69) kilogram, respectively. Primary cancer diagnoses included CNS tumours (n=15), bone tumours (n=4), lymphomas (n=3), rhabdomyosarcomas (n=2), neuroblastomas (n=2), and 1 blastoma.

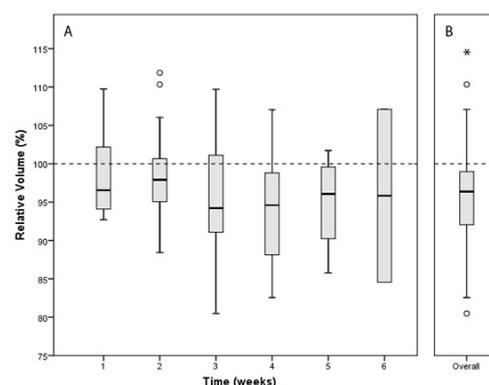

Heart contours were delineated and volumes were measured on cone beam (CB)CTs, considering an interval of at least 3 treatment days between the scans. Relative volume changes were determined by normalizing the volumes with respect to the volume as measured on the first CBCT (i.e., baseline 100%). Cardiac radiation doses were converted into equivalent doses of 2 Gy per fraction (EQD2 for  $\alpha/\beta = 3$  Gy), after which radiation dose parameters were calculated from dose volume histograms. Chemotherapy was administered to 23 of the 27 children (in 13 cases concurrently with radiotherapy), and was categorized as follows: anthracyclines, alkylating agents, vinca-alkaloids, and other.

We tested possible correlations between heart volume change and patient characteristics (gender, age, height, weight), cardiac radiation dose, and category of chemotherapy.

#### Results

Heart volumes were measured on 90 CBCTs (range 2-6 per patient). Figure 1A shows the volume change during the radiation course. The overall median volume reduction from the first to the last CBCT was 3.6% (IQR 0.3-8%) (Figure 1B) this reduction was significant (Wilcoxon signed-ranks tests,  $p < 0.01$ ).

No correlations were found between the reduction of the heart volume and patient characteristics, cardiac radiation dose, or category of chemotherapy.

**Figure 1.** Relative heart volume change in 27 children during radiation therapy involving the thoracic region (A). The overall relative heart volume reduction (B) was significant (\*). Dashed line represents the baseline (100%). Horizontal bars, boxes and whiskers represent median values, 50th and 90th percentiles, respectively. Circles denote outliers.

#### Conclusion

We found a significant heart volume reduction in children during thoracic radiotherapy for cancer. Correlations with patient- or treatment-characteristics were not found. Elucidation of the underlying mechanism and clinical relevance of early heart volume reduction during thoracic radiotherapy require a prospective follow-up study.

#### EP-1380 Impact of radiobiological models in decision making to individualize proton and photon radiotherapy

A. Chaikh<sup>1</sup>, J. Balosso<sup>2</sup>, J. Blouard<sup>3</sup>, J. Bondiau<sup>4</sup>

<sup>1</sup>CHU de Grenoble - A.Michallon, Radiothérapie et physique médicale, Grenoble, France

<sup>2</sup>University Hospital of Grenoble- University Grenoble-Alpes, Department of Radiation Oncology and Medical physics, Grenoble, France

<sup>3</sup>IPNL, France HADRON national research infrastructure, Lyon, France

<sup>4</sup>Centre Antoine Lacassagne, Department of Radiation Oncology, Nice, France

#### Purpose or Objective

The aim of this study is to assess the impact of radiobiological models and their clinical parameters on the medical decisions. This include TCP, NTCP, UTCP (substitute of QALY) and secondary cancer risk estimation in pediatric patients.

#### Material and Methods

17 pediatric patient's cases with medulloblastoma were studied. Two treatment plans were generated with conformal photon radiotherapy and proton therapy. The same dose prescriptions for posterior fossa and craniospinal irradiation were used for both plans. Two radiobiological models were used for NTCP (LKB and Niemierko) and the EUD model for TCP. The organ equivalent dose model was used to estimate secondary cancer risk. The in-silico dose based estimation of toxicity and cancer risk derived from dose volume histogram (DVH). Wilcoxon paired test was used to calculate p-value.

## Results

Overall, proton plans achieved lower dose for most of the OARs. Consequently, the NTCPs were significantly lower,  $p < 0.05$ . However, the variation, due to the model and radiobiological parameters choice, showed a significant impact on UTCP based on TCP/NTCP regarding medical decision. Similarly the variation of TCP/NTCP can reach 20-30% and 100% for secondary cancer, depending on the model.

## Conclusion

The considerable impact of radiobiological model on the radiotherapy outcomes urges us, once again, to measure specific (CTCAE scale) and global (QoL as EQ-5D) clinical outcomes, to tune the parameters of TCP/NTCP radiobiological models. On the other hand, a consensus on radiobiological parameters to compare and rank plans is highly advised in order to initiate real clinical trial instead of solely in-silico comparisons.

### EP-1381 Treatment outcomes of proton craniospinal irradiation for paediatric medulloblastoma

S.Q.E. Ho<sup>1</sup>, L.M. Mullaney<sup>1</sup>, S.A. Barrett<sup>1</sup>

<sup>1</sup>Trinity College Dublin, Applied Radiation Therapy  
Trinity- Discipline of Radiation Therapy- School of  
Medicine, Dublin, Ireland

#### Purpose or Objective

Craniospinal Irradiation (CSI) is the standard radiation therapy treatment for medulloblastoma. Conventional CSI photon therapy (Photon-CSI) delivers significant dose to surrounding normal tissues. Research into paediatric CSI with proton therapy (Proton-CSI) has increased, with the aim of exploiting the potential to reduce normal tissue dose and associated post-treatment complications. This review aims to compare treatment outcomes of paediatric medulloblastoma patients between Proton- and Photon-CSI treatments.

#### Material and Methods

A search and review of studies published between 1990-2015 comparing paediatric (2-18yrs) medulloblastoma Proton- and Photon-CSI in three aspects - normal organ sparing and target coverage, normal organ dysfunction and second malignancy risks - was completed.

#### Results

Fifteen studies were selected for review and the results were directly compared. Proton-CSI reported inconsistent target coverage improvements and improved out-of-field organ sparing was subjected to target volume definition and patient's size. Normal organ dysfunction risks were predicted to be lower following increased normal tissue sparing with Proton-CSI. However, dysfunction can arise from indirect irradiation and predicted risks can be altered according to survivor's future lifestyle habits. Secondary malignancy risks were generally lower with Proton-CSI based on several different risk models. In light of Proton-CSI and Photon-CSI delivering similar neural-axis dose, Proton-CSI might not significantly reduce secondary malignancy risks compared to Photon-CSI as documented secondary cancers were mainly from the brain.

#### Conclusion

Overall, Proton-CSI conferred better treatment outcomes than Photon-CSI for paediatric medulloblastoma patients. This review serves to compare the current literature in the absence of long term data from prospective studies. Proton-CSI should be used with caution while more prospective studies are awaited to reveal its true clinical benefit for paediatric medulloblastoma.

### EP-1382 Feasibility of Proton therapy with concomitant Chemotherapy for atypical teratoid rhabdoid tumors

S. Peters<sup>1</sup>, M. Christiaens<sup>1</sup>, S. Schulz<sup>1</sup>, S. Frisch<sup>1</sup>, P.H.

Kramer<sup>1</sup>, C. Blase<sup>2</sup>, M.C. Frühwald<sup>3</sup>, B. Timmermann<sup>1</sup>

<sup>1</sup>University Hospital Essen, West German Proton Therapy

Center, Essen, Germany

<sup>2</sup>Anästhesie Netz Rhein-Ruhr, Anesthesia, Bochum, Germany

<sup>3</sup>Children's Hospital Augsburg, EU\_RHAB Registry Center, Augsburg, Germany

#### Purpose or Objective

Atypical teratoid rhabdoid tumors (AT/RT) are a rare and highly aggressive disease mostly in infants. Therapy of affected patients requires an intensive multidimensional multimodality treatment concept of surgery, chemotherapy (CTX) and radiotherapy (RT) even in the very young patients. RT takes place either after the end of CTX or concomitant to CTX. Still, there is concern, that intensive combined treatment may not be feasible. We therefore aimed to investigate events of treatment prolongation and hospitalization during proton beam therapy (PT) and concomitant CTX.

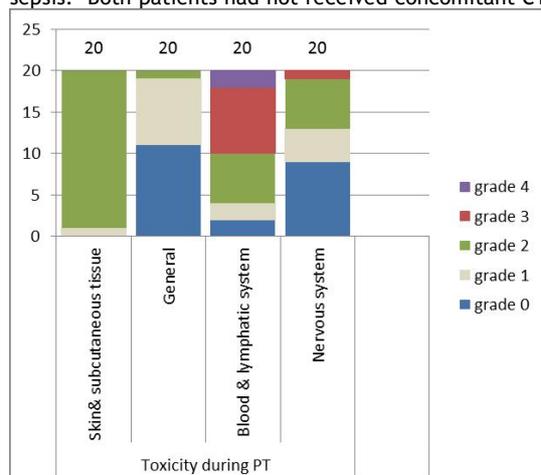

#### Material and Methods

All patients treated at WPE with PT between 2013 and 2016 were prospectively enrolled in the Registry Study for children (KiProReg). Informed consent was obtained from their legal representatives. All patients underwent weekly examinations by radiation and pediatric oncologists. Acute side effects according to CTCAE 4.0., time of hospitalization and prolongation of PT were documented. Hospitalization and treatment interruption was only taken into account if caused by complications.

#### Results

Twenty patients (6 females; 14 males) with a median age of 2.0 years at the start of PT (range, 1.0 - 8.0 years) were enrolled. Twelve patients received local PT up to 54 Gy only; six received an additional boost with a final dose of 59.4 Gy; 2 received craniospinal irradiation plus local boost up to 55.6 Gy. 19 of them required deep sedation during PT. Nine patients had concomitant chemotherapy (RCT) consisting of ifosfamide, carboplatinum, etoposide and/or vincristine, cyclophosphamide. Patients with RCT received an average of 1.4 cycles (range 1.0-3.0). Seven patients (35%) had an episode of fever; four of them received RCT. Acute toxicity during PT is displayed in graph 1. Nine patients (45%) had to be admitted of whom 5 (25%) received concomitant CTX. The duration of hospitalization varied between one and 49 days (average 9.7). Six patients were hospitalized for a period less than five days. Prolonged hospitalization in the three cases was caused by bad nutritional status present already before the start of PT, Norovirus infection and Staphylococcus epidermidis infection, respectively. Average hospitalization of patients with RCT was 3.0 days (range 1.0-21.0 d) with PT only 5.5 days (range 1.0-49.0 d). In two patients (10%) PT had to be interrupted either three or four days. Reasons were viral respiratory infection in one case and bacterial port-a-cath and subsequent

sepsis. Both patients had not received concomitant CTX.

### Conclusion

Our evaluation did not reveal relevant prolongation of treatment due to RCT strategy when administering proton beam therapy in very young patients according to EU-RHAB. However, experienced, multidisciplinary teams have to carefully accompany these very young patients in order to appropriately manage treatment complications and to avoid treatment interruptions potentially jeopardizing treatment efficacy.

### Electronic Poster: Clinical track: Palliation

#### EP-1383 Evaluation of QOL and psychological response in patients treated with palliative radiotherapy

T. Takahashi<sup>1</sup>, T. Yamano<sup>1</sup>, K. Nishimura<sup>1</sup>, N. Utsumi<sup>1</sup>, M. Shimbo<sup>1</sup>, S. Hatanaka<sup>1</sup>, S. Ueno<sup>1</sup>, Y. Iijima<sup>1</sup>

<sup>1</sup>Saitama Medical Center- Saitama Medical University, Radiation Oncology, Kawagoe, Japan

#### Purpose or Objective

Usually, evaluation of palliative radiotherapy is made by physical findings or levels of pain relief. But little is known about patient quality of life (QOL), psychophysiological response, and assessment of adverse effect from the view point of QOL. We evaluated the effects of palliative radiotherapy for cancer recurrence or metastasis on patient QOL and psychophysiology.

#### Material and Methods

A total of 67 patients who received palliative radiotherapy between 2014 and 2015 were enrolled. Patient diseases were bone metastasis in 51 patients, lymph node metastasis in 7 patients, brain metastasis in 2 patients, local recurrence in 3 patients, and the others in 4 patients. Median irradiated dose was 30 Gy in 10 fractions for palliative radiotherapy. We used the questionnaires EORTC-QLQ-C30 and EORTC-QLQ-C15-PAL to evaluate patient QOL and the Hospital Anxiety and Depression Scale (HADS) to evaluate patient mental healthcare at the start and at the end of radiotherapy.

#### Results

As compared to scores at the start of radiotherapy, at the end of radiotherapy, numerical rating scale (NRS) and face scale significantly decreased. On the other hand, Eastern Cooperative Oncology Group Performance Status (ECOG PS) did not show no changes during palliative radiotherapy. In functional scales, average scores of role functioning (RF2) and emotional functioning (EF) also improved. In symptom scales, average scores of fatigue (FA), pain (PA), and insomnia (SL) improved. In bone metastasis group, global health status / QOL (QL2), PA, and SL significantly improved. After palliative

radiotherapy, anxiety score of HADS was elevated below age of 70 years. There was relationship between anxiety improvement and QOL improvement after palliative radiotherapy. Nausea and vomiting scores of EORTC-QLQ-C15-PAL were associated with the irradiated volume of palliative radiotherapy for pelvic region.

#### Conclusion

Patient QOL of was improved by palliative radiotherapy regardless of PS. The possibility of palliative radiotherapy having a positive influence on patient psychophysiology was also suggested in younger age.

#### EP-1384 Concomitant Use of Steroids and Immunotherapy in Cancer Patients: A Comprehensive Review

A. Garant<sup>1</sup>, T. Vuong<sup>2</sup>

<sup>1</sup>McGill University, Radiation Oncology, Montreal, Canada

<sup>2</sup>Jewish General Hospital, Radiation Oncology, Montreal, Canada

#### Purpose or Objective

A large number of clinical trials studying immune checkpoint inhibitors exclude cancer patients who are on corticosteroids. This is based on the biological hypothesis that corticosteroids may antagonize the therapeutic effects of immunotherapy. Corticosteroids are routinely prescribed for their analgesic, antiemetic and anti-inflammatory properties, such as in the palliation of metastatic disease to the central nervous system. We sought to review the literature looking at the clinical outcomes of patients with solid or hematologic cancers who are treated with immunotherapy and concomitant corticosteroids.

#### Material and Methods

Using Medline (via Ovid) and Embase (via Ovid), a literature search was performed from January 2000 to October 2, 2016 with no limits or language restrictions. Identified articles included variations of the terms immunotherapy drugs, steroids and cancer. These were found in the Title/Abstract/Keywords, and in the Medical Subject Headings (MeSH) and Emtree terms thesaurus. A validated adverse effects search filter was used to help with the retrieval of relevant results. A clinician reviewed all titles and abstracts. Full articles of selected studies were retrieved for further analysis of clinical/ radiological disease progression and survival outcomes.

#### Results

Following a retrieval of 3611 unique references, 155 abstracts were retained for review. Twelve articles were retained for final analysis. The first nine articles/ abstracts consisted of case reports, case series and phase I-II trials of patients on CTLA-4 blockade therapy for metastatic melanoma and clear-cell renal cell carcinoma (RCC). Cohorts varied from 1 to 198 patients, including some patients with auto-immune disorders. They reported that the use of corticosteroids for the management of immune-related adverse events (irAEs) did not negatively impact objective clinical response. Of note, the above mentioned articles had not prospectively planned to analyze patient-related outcomes based on the use of corticosteroids. The tenth paper explored the use of colitis prophylaxis with Budesonide in patients receiving CTLA-4 blockade in a randomized phase II trial. In patients treated in the Budesonide arm, there was no statistically significant difference in oncologic outcomes. The final two publications describe objective clinical responses in patients treated with a combination of pembrolizumab, pomalidomide and dexamethasone for heavily treated relapsed/ refractory multiple myeloma patients.

#### Conclusion

The reviewed published data seems to suggest that the addition of corticosteroids to immunotherapy may not

necessarily lead to poorer clinical outcomes. We will consolidate our search with a forthcoming systematic review. Consideration of stratified randomization and treatment sequence evaluations in prospective trials may clarify this controversial topic and perhaps broaden patient access to immune checkpoint therapies.

#### EP-1385 Evaluation of the Spinal Instability Neoplastic Score for spinal metastases

L. Bollen<sup>1</sup>, K. Groenen<sup>2</sup>, W. Pondaag<sup>3</sup>, C. Van Rijswijk<sup>4</sup>, M. Fiocco<sup>5</sup>, Y. Van der Linden<sup>6</sup>, S. Dijkstra<sup>7</sup>

<sup>1</sup>AMC, Radiation Oncology, Amsterdam, The Netherlands

<sup>2</sup>Radboud MC, Orthopedic Surgery, Nijmegen, The Netherlands

<sup>3</sup>LUMC, Neurosurgery, Leiden, The Netherlands

<sup>4</sup>LUMC, Radiology, Leiden, The Netherlands

<sup>5</sup>LUMC, Medical Statistics, Leiden, The Netherlands

<sup>6</sup>LUMC, Radiotherapy, Leiden, The Netherlands

<sup>7</sup>LUMC, Orthopedic Surgery, Leiden, The Netherlands

#### Purpose or Objective

To determine the predictive value of the Spinal Instability Neoplastic Score (SINS) in a cohort of patients treated with radiotherapy for spinal bone metastases.

#### Material and Methods

A total of 110 patients were included in this retrospective study. Time to event was calculated as the difference between start of radiotherapy and date of occurrence of an adverse event or last follow-up, with death being considered a competing event. A competing risk analysis was performed to estimate the effect of the SINS on the cumulative incidence of the occurrence of an adverse event.

#### Results

Sixteen patients (15%) experienced an adverse event during follow-up. The cumulative incidence for the occurrence of an adverse event at 6 and 12 months was 11.8% (95%CI 5.1%-24.0%) and 14.5% (95%CI 6.9%-22.2%), respectively. Competing risk analysis showed that the final SINS classification was not significantly associated with the cumulative incidence of an adverse event within the studied population.

#### Conclusion

The clinical applicability of the SINS as a tool to assess spinal instability seems limited.

#### EP-1386 Mobile health technologies for severely-ill and palliative care patients

G. Theile<sup>1</sup>, V. Klass<sup>2</sup>, G. Tröster<sup>2</sup>, M. Guckenberger<sup>1</sup>

<sup>1</sup>University Hospital Zürich, Department of Radiation-Oncology, Zurich, Switzerland

<sup>2</sup>ETH Zurich, Wearable Computing Laboratory, Zurich, Switzerland

#### Purpose or Objective

**Purpose:** One of the critical phases in severely-ill patients' trajectories is demission from hospital care. Due to a lack of pro-active and low-threshold interventions in the home-care setting, a relevant number of avoidable emergency visits is observed. The idea of this collaboration project of the Clinic of Radiation-Oncology (CRO) USZ and ETH Zurich is an early detection of changes in crucial symptoms by using wireless activity tracking technology. This allows for non-invasive, objective measures; additionally, subjective parameters recorded by questionnaire apps will be captured. Aims of the study are to evaluate and optimize patients' acceptance regarding the supply with a tracking bracelet and a smartphone in order to monitor objective and subjective health data and to evaluate correlations between patient-specific activity patterns and the subjective patients' ratings of pain, distress and quality of life (QoL).

#### Material and Methods

**Methods:** Explorative, descriptive design. Recruitment of 30 participants on the different wards of the CRO (radiation-oncology, palliative). Application of semiquantitative questionnaires and guideline interviews to evaluate patients' usage and acceptance of technical devices. Extraction of sensor data (body motion, social features, heart rate, speech) using signal processing methods from smartphone and wristband. Capturing of subjective health data via electronic version of VAS-pain (daily), of NCCN Distress Thermometer (daily) and EORTC - QLQ C30 (paper version, weekly). First pre-studies on (a) semi-qualitative evaluation of device, app and study acceptance and (b) optimization of patient inclusion criteria and estimation of recruitment as well as (c) a pilot of wireless tracking in three patients have been conducted at time of abstract submission.

#### Results

**Results:** According to the pre-studies severely-ill and palliative patients are willing and able to use smartphones and wristbands and have a positive attitude towards the proposed monitoring systems. Sixty percent of eligible patients declared potential interest to participate. Preliminary data analysis from the pilot support our hypothesis that it is possible to receive exploitable data from mobile devices carried by discharged patients. In May 2017, then having started the main study, we will present more of quantitative evaluation data as well as first data extracted from the activity trackers (smartphone and bracelet).

#### Conclusion

**Conclusion:** Our project will deliver relevant data on patients' acceptance of wireless tracking, as well as correlation between subjective symptom assessment and objective activity data. The study is meant to be preparatory work for an intervention study to test the effect of wireless monitoring on early symptom relief, quality of life and prevention of avoidable hospitalization in the group of the severely-ill and palliative care patients.

#### EP-1387 Time Trends In Opioid Use In Cancer Patients with Pain: Observations from Administrative Data

L. Barbera<sup>1</sup>, C. DeAngelis<sup>2</sup>, C. Earle<sup>3</sup>, C. Atzema<sup>4</sup>, D. Dudgeon<sup>5</sup>, D. Howell<sup>6</sup>, A. Husain<sup>7</sup>, M.A. O'Brien<sup>8</sup>, H. <sup>2</sup>Odette Cancer Centre - Sunnybrook Health Sciences Centre, Pharmacy, North York- Toronto, Canada

<sup>3</sup>Sunnybrook Health Sciences Centre, Medicine, North York- Toronto, Canada

<sup>4</sup>Sunnybrook Health Sciences Centre, Medicine, Toronto, Canada

<sup>5</sup>Queen's University, Medicine and Oncology, Kingston, Canada

<sup>6</sup>University Health Network, Oncology Nursing, Toronto, Canada

<sup>7</sup>Mount Sinai Hospital, Temmy Latner Centre for Palliative Care, North York- Toronto, Canada

<sup>8</sup>University of Toronto, Family and Community Medicine, Toronto, Canada

<sup>9</sup>McMaster University, Oncology, Hamilton, Canada

<sup>10</sup>Juravinski Cancer Centre, Radiation Oncology, Hamilton, Canada

<sup>11</sup>Institute of Clinical Evaluative Sciences, Cancer Research, Toronto, Canada

#### Purpose or Objective

**Objective:** Previous work in Ontario demonstrated that 33% of cancer patients with severe pain (7-10/10) did not receive opioids at the time of their pain assessment. The

objective of this study was to examine temporal trends in opioid prescribing among cancer patients with different pain severity.

#### Material and Methods

Approach: Our study cohort comprised of Ontario residents  $\geq 18$  years with a history of cancer who were eligible for the government's paid pharmacare program and who had a pain assessment using the Edmonton Symptom Assessment Scale (ESAS). Use of ESAS is the result of a population-based provincial initiative to screen ambulatory cancer patients for 9 common cancer symptoms. For each year between 2007 and 2013, we used the date of an individual's highest pain score as the index date to calculate annual opioid prescription rates for claims within -30 days to +7 days of the index date. We evaluated prescriptions for drugs for neuropathic pain as a secondary outcome.

#### Results

Results: During the study period, individuals meeting the cohort inclusion criteria increased over 7-fold with 12,066 individuals aged 18-64 years and 43,715 individuals aged  $\geq 65$  years eligible in 2013. Over time, changes in the distribution of patients across cancer types and pain scores were observed. For example, for those aged 18-64, 33% of patients had pain 7-10 in 2007 decreasing to 22% with pain 7-10 in 2013. Similarly, for those aged  $\geq 65$ , 21% had pain 7-10 in 2007 decreasing to 11% in 2013. In both age groups, opioids were prescribed most frequently for those with pain 7-10 and least frequently for those with no pain. Among 18-64 year olds with pain 7-10, opioid prescription rates decreased from 46% in 2007 to 38% in 2013 ( $p < 0.05$ ). The respective values for those  $\geq 65$  years were 61% to 39% ( $p < 0.05$ ). Prescriptions for drugs for neuropathic pain increased modestly.

#### Conclusion

Conclusion: Over time, pain assessment among cancer patients has increased. However, the proportion with pain who receive an opioid prescription has decreased. This finding may be due to increased detection of non-cancer related pain, but may also be the result of increased scrutiny of opioid prescribing and policy changes intended to decrease prescribing in non-cancer patients.

#### EP-1388 Clinical features of bone metastases and their importance for radiotherapy

N. Bychkova<sup>1</sup>, E. Khmelevsky<sup>1</sup>

<sup>1</sup>Gertzen Moscow Research Oncological Institute, Radiotherapy Department, Moscow, Russian Federation

#### Purpose or Objective

To study the features of bone metastases according to different primary tumors and their importance for radiotherapy

#### Material and Methods

We analyzed 680 cases of symptomatic bone metastases included in the randomized controlled trial and treated with EBRT. The primary breast tumors were diagnosed in 426 (62,6%), prostate in 57 (8,4%), lung in 57 (8,4%), renal in 47 (6,9%), colon in 18 (2,6%), bladder in 11 (1,6%) and other tumors in 64 (9,5%) cases. Patient selection criteria for radiotherapy were pain, risk of pathological fracture/malignant spinal cord compression, increasing neurologic dysfunction. Irradiation of one anatomical area was applied («block concept»). Treatment schedules included 2, 3 and 4 fractions of 6,5Gy and standard treatment schedule with 23 fractions of 2 Gy.

#### Results

The average follow-up period was 70 months. Pain intensity before treatment was significantly higher for bone metastases of prostate and lung cancer compared to breast cancer ( $p < 0,01$ ) and for the men in general ( $p < 0,001$  for non-prostate cases). Average relative lesion length in irradiation's areas was significantly lower for

renal cancer - 1,8 (for the three-level scale) and significantly higher for prostate cancer - 2,28 ( $p = 0,017$ ). The risk of pathological fracture was the lowest only for prostate cancer metastases - 0,21 compared to 0,46 for breast cancer lesions ( $p = 0,0002$ ). Overall effectiveness of EBRT was 96,1%. Complete response rate (CRR) was observed in 59,1% of cases. CRR correlated with the level of total dose. CRR was significantly higher for bone metastases of breast cancer compared to lung and renal cancer (63,6% as opposed to 40,4% and 28,3%,  $p < 0,02$ ) and for melanoma metastases (75%) compared to renal cancer ( $p = 0,036$ ). It is interesting, that bone metastases of melanoma and soft-tissue sarcomas were one of the most radiosensitive. In the multifactorial analysis MANOVA tumor primary site and pain intensity before radiotherapy were the only independent prognostic factors of the effectiveness of radiotherapy.

#### Conclusion

Tumor primary site is a clinical predictor of radiosensitivity of bone metastases, it significantly affect the CRR. Revealed features of bone lesions according to different primary tumors allow to develop individual treatment programs with a view to high efficiency and ease of realization.

#### EP-1389 Superficial hyperthermia with radiotherapy: toxicity and outcome of 62 metastatic lesions

G. Cattari<sup>1</sup>, A.G. Di Dia<sup>2</sup>, M. Gatti<sup>1</sup>, E. Delmastro<sup>1</sup>, E. Garibaldi<sup>1</sup>, G. Belli<sup>1</sup>, A. Salatino<sup>1</sup>, P. Gabriele<sup>1</sup>

<sup>1</sup>FPO-IRCCS Candiolo, Radiotherapy, Candiolo- Turin, Italy

<sup>2</sup>FPO-IRCCS Candiolo, Medical Physic, Candiolo- Turin, Italy

#### Purpose or Objective

The purpose of this study is to evaluate the safety, feasibility and toxicity of radiotherapy-hyperthermia (RT-HT) in the treatment of superficial recurrent and metastatic tumors in this setting of patients

#### Material and Methods

Thirty-nine patients (mean age 69 years; range: 49-93) with histologically confirmed superficial recurrent/metastatic tumours were treated: 19 breast, 10 head & neck, 2 malignant melanoma, 4 sarcomas, 1 uterine, 1 hepatocarcinoma and 2 pancreatic carcinoma. The total number of treated lesions was 62. The mean Karnofsky Index value is 75. Pre-treated patients (70%) received a previous mean RT dose of 50 Gy. Patients underwent RT treatment using 3D-conformal RT (16/39) or Helical Tomotherapy (23/39). External beam RT was delivered in 5-27 fractions of 1.7-5 Gy to a total dose of 20-57.5 Gy (mean external dose: 39 Gy). Hyperthermia (HT) treatment is performed with a double electromagnetic superficial applicators operating at the frequency of 434 MHz. HT session was delivered once/twice weekly during the period of RT, 1-2 hours after RT [mean value: 5; range: 1-9 sessions]. Average, maximum and minimum temperature parameters were recorded during HT treatment. The treatment goal was to reach 40- 42 °C in > 90% (T90) of measured points for a duration of 60 minutes. Acute and late toxicity was evaluated according to the CTCAE criteria. Local control was assessed after the end of the treatment on the basis of the RECIST Criteria

#### Results

During HT treatment the median temperature [range] reached was 40.5 °C [39 - 42.9°C]. Five patients interrupted the treatment: 2 pts (5%) for G3 toxicity, 2 (5%) for poor compliance and 1 (2.5%) for clinical progression disease. Two pts (5%) had acute cutaneous toxicity  $\geq$  G3 at 1 month. Four patients had toxicity > G2 at 3 months, three patients had > G2 at 6 months and only one patients at 12 months. No patients showed toxicity  $\geq$

G2 thereafter. The mean follow-up was 12 months (range 1-50 months). The Local control rate was: 87%, 72%, 65% and 53%, 63% and 75% at 1, 3, 6, 12, 24, 36 months respectively. The time to local progression was ranged between 1 and 12 months (mean: 6 months). The detailed results are reported in Table 1. Five patients are dead (4 for disease and one for vascular accident). Univariate analysis showed that Tmean, Tmax, Tmin, T90 parameters were not associated with local control rate

follow-up (months)	CR (%)	PR (%)	SD (%)	PD (%)
1	20	48	19	13
3	22	28	22	28
6	26	4	35	35
12	20	6	27	47
24	37.5	-	25	37.5
36	25	-	50	25

TABLE 1: response rate in the time (months)

#### Conclusion

RT-HT is useful combined treatment with a good local control rate and patient compliance. The clinical outcome and the time duration of the follow-up is affected by the advanced stage of diseases. A larger pool and a more detailed patient stratification are needed to evaluate the outcome data in the time

#### Acknowledgments

This work was supported by "5 per Mille 2009 Ministero della Salute-FPRC Onlus".

#### EP-1390 Superior target delineation of renal cell carcinoma bone metastases on MRI vs CT

F.M. Prins<sup>1</sup>, J.M. Van der Velden<sup>1</sup>, A.S. Gerlich<sup>1</sup>, A.N.T.J. Kotte<sup>1</sup>, W.S.C. Eppinga<sup>1</sup>, N. Kasperts<sup>1</sup>, L.G.W. Kerkmeijer<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiation oncology, Utrecht, The Netherlands

#### Purpose or Objective

In metastatic RCC (mRCC) there has been a treatment shift towards targeted therapy, which has resulted in a 50% increase in overall survival. Therefore, there is a need for better local control of the tumor and its metastases. Image-guided SBRT in bone metastases provides improved symptom palliation and local control. After SBRT for mRCC, local control rates have been improved from 50% to 85% when compared to conventional fractionation schemes. With the use of SBRT there is also a need for accurate target delineation. The hypothesis is that MRI allows for better visualization of the extend of bone metastases in mRCC for contouring in the context of stereotactic treatment planning.

#### Material and Methods

From 2013 to 2016, nine consecutive patients who underwent SBRT for RCC bone metastases at our center were included. A planning CT and MRI were performed in radiotherapy position according to our clinical protocol. CT images were performed at 1 mm slice thickness on a large bore CT scanner (Philips, The Netherlands). In addition, all patients underwent a 1.5 Tesla MRI scan (Philips Ingenia, The Netherlands) at 1.1 - 4 mm slice thickness. For every patient, T1-weighted images were acquired in transversal and sagittal direction, including a transversal mDIXON scan, as well as T2-weighted images in transversal and sagittal direction, and diffusion weighted images (DWI) according to our clinical MRI protocol. Gross tumor volumes (GTV) in both CT and MRI were delineated. Contouring was performed by a specialized radiation oncologist, based on local consensus contouring guidelines (T1 images were used for target delineation aided by the information derived from the T2 and DWI sequences).

In both CT and MRI the GTV volumes, conformity index (CI) and distance between the centers of mass (dCOM) were compared. Statistical differences in volumes between CT and MRI were tested with Wilcoxon rank sum test.

#### Results

Nine patients with 11 RCC bone metastases were evaluated. The volumes of the lesions on MRI were larger compared to the CT, for all but one lesion (Table 1). This lesion was comparable in size on MRI and CT. Two visual examples of the difference in delineation are shown in Figure 1. The median GTV volume on MRI was 33.39mL (range 0.2mL - 247.6mL), compared to 14.87mL on CT (range 0.2mL - 179.4mL). The difference in volume as delineated on CT and MRI was statistically significant (p=0.005). The CI in the different lesions varied between 0.08 and 0.75. The dCOM varied between 0.78 and 13.34 mm.

Lesions (n)	Location of mRCC	Volume in mL		Difference in mL	CI	dCOM in mm
		CT	MRI			
1	Os ilium left	39.52	50.05	10.53	0.75	2.65
2	Os ilium left	33.56	72.09	38.53	0.43	8.82
3	Os ilium right	179.40	247.6	68.20	0.63	7.59
4	Os ilium right	25.86	75.53	49.67	0.33	8.04
5	Thoracic vertebrae 11	2.58	33.39	30.81	0.08	13.34
6	Thoracic vertebrae 9	14.87	17.44	2.57	0.67	3.30
7	Lumbar vertebrae 2	33.10	42.23	9.13	0.40	9.88
8	Thoracic vertebrae 6	6.07	13.55	7.48	0.40	3.53
9	Thoracic vertebrae 7	1.36	1.755	0.40	0.60	0.78
10	Thoracic vertebrae 8	0.21	0.1784	-0.03	0.41	1.00
11	Acetabulum	1.61	1.64	0.03	0.68	1.76
Mean		30.74*	50.50*	19.76	0.48	5.52
Median		14.87	33.39	9.13	0.43	3.53

Table 1: Volumes, conformity index (CI), distance between the centers of mass (dCOM) in CT and MRI

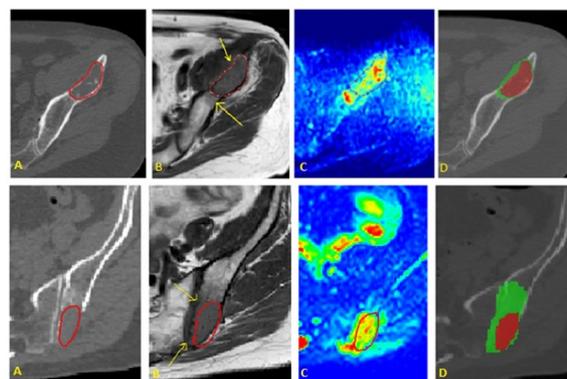

Figure 1: A: Delineations in CT, B: delineations in MRI (T1/T2SE), C: delineations in DWI, D: difference in MRI (green) and CT (red) GTV delineations in lesion 1 and 2.

#### Conclusion

Contouring of RCC bone metastases on MRI resulted in both clinically and statistically significant larger lesions compared with CT. MRI seems to represent the extend of the GTV in RCC bone metastases more accurately, possibly due to improved visualization of bone marrow infiltration. Contouring based on CT-only could result in an underestimation of the actual tumor volume, which may cause an under dosage of the GTV in SBRT treatment plans.

### EP-1391 Digestive toxicity after conformal radiotherapy for palliative cervico-thoracic spinal metastases

G. Peyraga<sup>1</sup>, D. Caron<sup>1</sup>, Y. Metayer<sup>2</sup>, Y. Pointreau<sup>3</sup>, F. Denis<sup>3</sup>, G. Ganem<sup>3</sup>, C. Lafond<sup>3</sup>, S. Roche<sup>3</sup>, O. Dupuis<sup>3</sup>  
<sup>1</sup>Institut de Cancérologie de l'Ouest, Radiation Therapy, Angers, France  
<sup>2</sup>Centre Jean Bernard, Medical Physics, Le Mans, France  
<sup>3</sup>Centre Jean Bernard, Radiation Therapy, Le Mans, France

#### Purpose or Objective

The palliative treatment of cervico-thoracic spinal metastases is based on a conformal radiotherapy (CRT), delivering 30 Gy in 10 fractions (5 days a week for 2 weeks). Digestive toxicities (esophagitis, nausea and vomiting) are common after these radiations and cause a clinical impact probably underestimated in patients. We performed a retrospective monocentric study of early digestive toxicities occurred secondarily to palliative CRT of cervico-thoracic spinal metastases.

#### Material and Methods

All patients receiving palliative CRT at Jean Bernard Center from January 2013 to December 2014 of spinal metastases (all primitive tumors were included) between the fifth cervical vertebra (C5) and 10th thoracic vertebra (T10) for which clinical follow-up was available beyond 3 months were included. Re-irradiations were excluded. CRT was delivered by a linear accelerator (CLINAC, Varian). Premedication to prevent digestive toxicities was not recommended. Adverse events (esophagitis and nausea/vomiting < 3 months) were evaluated according the NCI-CTCae (version 4).

#### Results

From January 2013 to December 2014, 128 patients met the study criteria. The median age was 69.6 years [31.8; 88.6]. The majority (84.4%) patients received a dose of 30 Gy in 10 fractions. The median treatment duration was 13 days [3-33]. Forty patients (31.3%) experienced grade 2 or 3 of esophagitis (35 grade 2 (27.4%) and 5 grade 3 (3.9%)), and 8 patients (6.3%) experienced grade 2 or 3 of nausea or vomiting (6 grade 2 (4.7%), 1 grade 3 (0.8%) and 1 grade 4 (0.8%)). The risk of digestive toxicities seems to be related to spinal localization of metastases (38.5% of grade 2 or 3 esophagitis if radiation from C5 to T4 versus 31.2% if radiation from T5 to T10, and 87.5% of nausea and vomiting concerned T9 or T10) and to the number of irradiated vertebrae (43.9% of esophagitis if more than 5 vertebrae are irradiated versus 25.3% if less than 6 vertebrae are irradiated).

#### Conclusion

The incidence of esophagitis after palliative CRT of cervico-thoracic spinal metastases led to considering static or dynamic Intensity Modulated Radiation Therapy (IMRT) to reduce the dose to organ at risk (esophagus). IMRT could be primarily beneficial if palliative radiotherapy concerns vertebrae between C5 and T4 and if it affects more than 5 vertebrae.

### EP-1392 Prognostic factors for survival in patients with bone metastases

P.M. Samper Ots<sup>1</sup>, M. Hernandez Miguel<sup>1</sup>, E. Amaya Escobar<sup>1</sup>, M.D. De las Peñas Cabrera<sup>1</sup>  
<sup>1</sup>Hospital Rey Juan Carlos, Servicio de Oncología Radioterápica, Mostoles - Madrid, Spain

#### Purpose or Objective

To analyze the prognostic factors for survival in patients with bone metastases.

#### Material and Methods

Retrospective analysis of 104 patients referred for treatment of bone metastases, median age was 59 years, 69 males (66.3%). The most common primary tumors were:

lung 36 cases (34.6%), prostate 24 (23.1%) and breast 13 (12.6%). The mean time diagnosis of bone metastases was 14.55 ± 2 months. 85 patients were treated with 3DRT (81.7%), 9 SBRT (8.7%) and 10 no treatment (9.6%). The study was approved by the Ethics Committee for Clinical Research (CEIC) and meets the standards of data protection. For statistical analysis SPSS version 22.0 was used.

#### Results

70 patients (67.3%) died with a median survival of 14.4 months after the diagnosis of bone metastases. Survival according to the treatment was: 3DRT 13.73 ± 21.3 months, SBRT 20.7 ± 12.0 months and without RT 10.48 ± 10.7 months (p < 0.001). The median survival after end of radiotherapy was 19.4 ± 5.66 months. Prognostic factors for survival were: primary tumor controlled versus uncontrolled 45.3 ± 15.4 versus 7.64 ± 1.09 months (p = 0.001), metastases in other organs 15.23 ± 5.2 versus not 22 ± 4.7 months (p = 0.04), lymph node metastasis 13 ± 5.06 versus not 18 ± 4.3 months (p = 0.007), liver metastases 6.42 ± 1.52 versus not 24.44 ± 7.75 months (p = 0.028), ECOG 0 (49.5 ± 17.1), 1 (7.49 ± 1.38), 2 (8.78 ± 1.97) and 3 (3.88 ± 1) p = 0.003. The primary diagnosis: lung 5.68 ± 1.25 months, breast 59.81 ± 21.12 months, prostate 18.85 ± 5.2 months (p = 0.013). In patients with lung cancer, the histology was a prognostic factor: epidermoid 2.65 ± 0.9 months, adenocarcinoma 7.69 ± 1.8 months and small cell 1.92 ± 1.32 months (p = 0.009). The time to diagnosis of bone metastases was not prognostic factor for survival.

#### Conclusion

In patients with bone metastases, the best prognosis are breast cancer, primary controlled, no other metastases, SBRT and ECOG 0.

### EP-1393 Prognostic factors for survival in patients with brain metastases

P.M. Samper Ots<sup>1</sup>, M. Hernandez Miguel<sup>1</sup>, E. Amaya Escobar<sup>1</sup>, M.D. De las Peñas Cabrera<sup>1</sup>  
<sup>1</sup>Hospital Rey Juan Carlos, servicio de oncología Radioterápica, Mostoles - Madrid, Spain

#### Purpose or Objective

To analyze the prognostic factors for survival in patients with brain metastases.

#### Material and Methods

Retrospective analysis of 87 patients referred for treatment of brain metastases, median age was 62.3 ± 13 years, 56 males (64.4 %). The most common primary tumors were: lung 56 cases (64.4%), breast 12 (13.8 %) and colorectal 9 (10.3%). The mean time diagnosis of brain metastases was 16.3 ± 35.36 months. 63 patients were treated with holocraneal 3DRT (72.4%), 5 holocraneal and boost (5.7%), 6 Stereotactic fractionated radiotherapy (SFR) (6.8%) and 13 no treatment (14.9%). The study was approved by the Ethics Committee for Clinical Research (CEIC) and meets the standards of data protection. For statistical analysis SPSS version 22.0 was used.

#### Results

73 patients (83.9%) died with a median survival of 7.66 ± 0.96 months after the diagnosis of brain metastases. Survival according to the treatment was: holocraneal 6.84 ± 0.97 months, holocraneal and boost 13.06 ± 6.04 months, SFR 7.38 ± 1.5 months and without RT 6.38 ± 2.6 months (p < 0.519). The median survival after end of radiotherapy was 6.47 ± 0.98 months. The time to diagnosis of brain metastases, the situation of the primary, metastases in other organs, number of brain metastases, surgery of metastases, radiosurgery were not prognostic factors for survival. Prognostic factors for survival were: ECOG 0 (8.99 ± 1.43 months), 1 (8.05 ± 2.26 months), 2 (2.78 ± 0.64 months) and 3 (1.24 ± 0.94 months) p = 0.000. Not completing radiotherapy 0.24 ± 0.12 versus

7.27 ± 1.07 months (p = 0.000). The primary diagnosis: lung 6.96 ± 1.34 months, breast 5.38 ± 1.47 months, colorectal 5.72 ± 2.19 months (p = 0.016). The histology: adenocarcinoma 7.93 ± 1.99 months, infiltrating ductal 5.36 ± 1.47 months, small cell 4.94 ± 1.07 months, and epidermoid 3.08 ± 1.0 months, (p = 0.004). In patients with breast cancer estrogen and progesterone receptors, negative 1.54 ± 1.3 months and positive 9.8 ± 1.03 months (p=0.025).

#### Conclusion

In patients with brain metastases, the best prognosis are lung cancer, adenocarcinoma, ECOG 0, and in breast cancer are positive estrogen and progesterone receptors.

#### EP-1394 Prognostic factor for palliative radiotherapy of bone metastases in good performance-status patients

Y. Hamamoto<sup>1</sup>, S. Taguchi<sup>2</sup>, T. Manabe<sup>2</sup>, H. Kanzaki<sup>1</sup>, K. Nagasaki<sup>1</sup>, N. Takata<sup>1</sup>, T. Mochizuki<sup>1</sup>

<sup>1</sup>Ehime University, Radiology, Toon-city, Japan

<sup>2</sup>Saiseikai Imabari Hospital, Radiology, Imabari-city, Japan

#### Purpose or Objective

Performance status is well-known prognostic factor for patients received palliative care. Regarding patients with good performance status, prognostic factors after palliative intent radiation therapy (PIRT) were investigated.

#### Material and Methods

Between Dec. 2009 and Mar. 2014, 148 patients received initial PIRT in our institution. Of these, 100 patients were able to be followed up until death or for more than six months. Among these 100 patients, 63 patients (age, 58-89, median 69; male/female=45/18) were in good performance status (PS 0-1), and were reviewed in this study. Survival time was calculated from the initiation of initial PIRT. Assessed factors were age (<75 vs. >75), sex, primary sites (breast vs. other organs), sites of initial PIRT (bone/soft-tissue/lymph-nodes vs. other organs), and administration of chemotherapy before PIRT (yes vs. no). Univariate analysis was performed by log-rank test and multivariate analysis was performed by Cox proportional hazard model.

#### Results

Regarding all 63 patients, median survival time was seven months and the 1-year overall survival rate was 34%. On univariate analysis, irradiate sites was the only statistically significant factor for survival after PIRT (p=0.0159). Irradiate sites was the statistically significant factor also on multivariate analysis (p=0.0179). The 1-year overall survival rate of the patients who received PIRT to bone/soft-tissue/lymph-nodes was 46% (median survival time, 11 months), while that was 15% for the patients who received PIRT to other organs (median survival time, 4 months).

#### Conclusion

With regard to patients with good performance status, prognosis of patients who received PIRT to bone/soft-tissue or lymph-nodes was comparatively good. Despite small patient number of this study, it seemed that extremely hypofractionated PIRT was not suitable for these patients.

#### EP-1395 CyberKnife treatment of intraorbital metastases: a single center experience on 24 lesions.

G. Riva<sup>1</sup>, M. Augugliaro<sup>1</sup>, G. Piperno<sup>1</sup>, A. Ferrari<sup>1</sup>, E. Rondi<sup>1</sup>, S. Vigorito<sup>1</sup>, R. Orecchia<sup>1</sup>, B.A. Jereczek-Fossa<sup>1</sup>  
<sup>1</sup>Istituto Europeo di Oncologia - IEO, Radiotherapy, Milan, Italy

#### Purpose or Objective

The aim of the study is to evaluate the feasibility, acute toxicity and symptoms control of CyberKnife (Accuray,

Sunnyvale, CA)-based stereotactic radiotherapy (CBK-SRT) on intraorbital metastases.

#### Material and Methods

This retrospective analysis included patients (pts) with symptomatic metastases located wholly within the orbit. Palliative radiation treatment was performed using CyberKnife image-guided technology (using skull-tracking technique). Gross tumor volume (GTV) volume was defined on a pre-radiotherapy magnetic resonance imaging (MRI) with Gadolinium. Treated volumes and dose-volume histograms (DVHs) are discussed. Acute toxicity was recorded according to Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer (RTOG/EORTC) Scale.

#### Results

Between April 2012 and July 2016, 24 metastases (21 pts, 3 treated bilaterally) underwent CBK-SRT for intraorbital lesions (10 intraocular, 14 periocular) from different primary tumors (breast in 13 pts, lung in 3 pts, kidney in 2 pts, lymphoma in 1 pts, thyroid in 1 pts, trunk leiomyosarcoma in 1 pts).

The median treatment dose was 18 Gy (range, 15-24 Gy) given over a median of 3 fractions (range, 2-3 fractions) with a median dose of 6 Gy per fraction (range, 5-10 Gy/fraction). Treated volumes and DVHs are reported in Table 1.

At the end of the treatment, grade 1 toxicity according to RTOG/EORTC score was observed in 8 cases. No change in visual field or loss of vision was documented. 13 lesions of 24 had undergone post-radiotherapy MRI and after median follow-up of 6 months (range, 2.0-26.5 months) no local recurrence occurred. All of these patients reported decreasing pre-radiotherapy symptoms and improvement in quality of life. Longer follow-up (more than 12 months) is available in 4 lesions with complete radiological response in all cases.

Dosimetry	Mean	
	Mean	Median
<b>Vol GTV</b>		
All	3.12 cc	1.50 cc (0.14-17.50)
Intraocular	2.38 cc	0.65 cc (0.14-17.50)
Periocular	3.65 cc	3.65 cc (1.20-12.30)
<b>Eye globe volume</b>		
All	7.60 cc	7.40 cc (5.60-11.30)
Intraocular	7.31 cc	7.30 cc (5.60-8.70)
Periocular	7.84 cc	7.65 cc (5.90-11.30)
<b>D max eye globe</b>		
All	19.85 Gy	20.25 Gy (range 6.90-24.00)
Intraocular	24.00 Gy	24.00 Gy
Periocular	16.80 Gy	17.85 Gy (range 6.90-21.30)
<b>D mean eye globe</b>		
All	6.46 Gy	6.25 Gy (range 1.10-13.50)
Intraocular	8.82 Gy	8.65 Gy (range 6.00-12.80)
Periocular	4.78 Gy	4.55 Gy (range 1.10-13.50)
<b>D max ipsilateral optic nerve</b>		
All	14.06 Gy	16.95 Gy (range 1.55-24.00)

<b>D mean ipsilateral lens</b>		
All	2.17 Gy	1.35 Gy (range 0.30-9.00)
Intraocular	2.60 Gy	3.04 Gy (range 0.79-4.30)
Periocular	1.80 Gy	1.10 Gy (range 0.30-9.00)
<b>D mean optic chiasm</b>		
All	2.98 Gy	2.10 Gy (range 0.50-18.00)
Intraocular	1.46 Gy	1.15 Gy (range 0.50-2.54)
Periocular	4.15 Gy	3.30 Gy (range 0.90-18.00)

Legend: OAR: organ-at-risk; Vol: volume; GTV: gross target volume; D: dose; Max: maximum

#### Conclusion

In our experience, CyberKnife radiotherapy is a well-tolerated, safe and efficacious technique for palliative treatment of intraocular and periocular metastases.

### EP-1396 Versatis® and focal neuropathic pain in cancer patients (screening tool)

C. Prieto Prieto<sup>1</sup>, E. López Ramirez<sup>2</sup>

<sup>1</sup>Hospital Universitario Virgen de las Nieves, Radiation Oncology, Granada, Spain

<sup>2</sup>Oncosur, Oncología Radioterápica, Granada, Spain

#### Purpose or Objective

Lidocaine 5% patch (L5%P) = (Versatis®) represents a novel therapeutic approach to neuropathic pain in cancer patients. The objective of this study is to evaluate its role in treating acute or chronic focal neuropathic pain (FNP) in cancer patients, regardless of its causal relationship with the tumour.

#### Material and Methods

We collected information from 33 cancer patients with focal neuropathic pain (FNP) treated with L5%P. Some interesting data related to L5%P use were analyzed: NP nature, body areas affected, previous and concomitant analgesic treatment, time from patch application to analgesic effect, duration of therapy with L5%P, analgesic efficacy and adverse reactions. Therapeutic indication with L5%P was established in all patients using a validated FNP screening tool (ST) consisting in 4 simple questions.

#### Results

All patients underwent radiotherapy in our Departments. 66.7% of them (n=22) suffered from FNP related with cancer and its therapies. In the other 33.3% of cases (n=11), FNP was not considered related. Potent analgesic effect of L5%P was observed in 23 cases (69.7%), and partial effect in 5 cases (15.2%). It represents an 84.9% of efficacy in our sample. 81.3% of patients did not report adverse reactions at all. 45.5% of patients achieved pain control within one week after starting L5%P treatment. 39.4% of patients did not need concomitant analgesic treatment.

#### Conclusion

Our data support that L5%P (alone or in association with other drugs) may be an effective and safe approach for FNP in cancer patients.

### EP-1397 Dose painting guided by diffusion-weighted MRI applied to recurrent glioblastoma: a phase I protocol

<sup>6</sup>Arcispedale S. Maria Nuova - IRCCS, Neurology Unit, Reggio Emilia, Italy

<sup>7</sup>UNITN, Dipartimento di Fisica, Trento, Italy

<sup>8</sup>UNIMORE, Dipartimento di Scienze e Metodi dell'Ingegneria, Reggio Emilia, Italy

#### Purpose or Objective

Standard treatment for glioblastoma (GBM) is surgery, followed by radio- & chemo-therapy. However, disease recurs in almost all patients and re-irradiation is an option to be considered. Although the topic of re-irradiation is generally controversial because of the toxicity risk, literature provides consistent data supporting both the feasibility and the survival-strengthening capability of radiation, compared to supportive care only. In the

present study, voxel-based re-irradiations guided by magnetic resonance imaging (MRI) were simulated and planned with apparent diffusion coefficient (ADC) used as biomarker for tumor cellularity.

#### Material and Methods

The relapse areas of 6 selected GBM patients treated with STUPP protocol were monitored with MRI. The ADC patterns, considered in the literature as a surrogate biomarker of cellularity was analyzed and chosen to define a signal-to-dose transfer function. This decision, coupled with our clinical data in re-treating GBM with moderate hypo-fractionation regime (Ciammella et al, Clin Neurol Neurosurg, 2013, 115: 1609-14), have formed the basis of a phase I study undertaken on 12 GBM relapse patients, simulated with multi-parametric MRI and re-treated with a dose-painted hypo-fractionated regime. The study foresees dose levels of 30-50Gy/5fr with a cumulative BED<sub>10</sub>>120Gy in an attempt to achieve some changes in the recurrence pattern, without causing excessive radiation necrosis (<12 Gy/fr) inside the irradiated area and respecting the previously irradiated healthy tissue (EQD<sub>2</sub><100Gy). To realise the ADC data extraction and DPBN (Dose Painting By Numbers) planning procedure with RapidArc technique, home-made MATLAB software and automatic scripting procedure on a commercial treatment planning system (TPS) were realised. Nine target sub-volumes were used for the volume-based TPS plan optimisation. Phantom (PTW, Octavius 4D) and portal dosimetry (EPID) based on g-index (2%, 2mm) were applied for the pre-treatment plan evaluation.

#### Results

Considering follow-up data that correlates patient outcomes with histogram changes in the tumour recurrence ADC values of the 6 relapsed patients, a double threshold transfer function was defined. The first patient was enrolled in the study and treated. To a first control to three months after treatment, the first patient has not had acute toxicity, has a performance status of 100%, and has a radiological picture of stable disease albeit associated with signs of pseudo-progression. The pre-clinical check of the delivered treatment, verified with portal and phantom dosimetry, has provided a minimum g-index of 90.7%. The total beam-on time with 4 non-coplanar 6MV FFF arcs was less than 5 min.

#### Conclusion

The phase I protocol, approved by Ethical Committee, has enrolled its first patient. Data on planning, dosimetric and patient follow-up aspects will be presented and discussed.

### EP-1398 Application of radiosurgery in treatment of oligometastases

T. Chebotarova<sup>1</sup>, N. Spizhenko<sup>1</sup>, N. Lisovzka<sup>1</sup>, O. Yarmak<sup>1</sup>

<sup>1</sup>Cyber Clinic of Spizhenko, Radiation therapy, Kapitanyvka -Kyiv region, Ukraine

#### Purpose or Objective

Development of genetic researches in the field of oncology found out proofs of genomic instability in solid tumors which results in their clonal heterogeneity. Oligometastatic disease considered as an intermediate biological state with limited ability of tumor to promote numerous metastases. In this transition stage of growth tumor could give oligometastatic clones expressed with single metastatic lesions. Now it's known, that the cells of oligometastatic tumors expressed specific microRNAs able to block tumor-promoting genes, and as a result make the spread of tumors slower. We are focusing on the group patients with metastatic lesion aiming to detect clinical application for local ablative radiosurgery treatment.

#### Material and Methods

The results of treatment of 335 patients with metastases of brain, lung, liver, renal and epinephrine were analyzed. The localization of primary tumors in this group of patients

was in breast, lung, colorectal and kidney. Performance status of patients was 0-1 according ECOG-scale. All patients have previously radically treated primary tumor and no more than 3-4 distant metastatic lesion by the moment of treatment. Patients receive radiosurgery or hypofractionated irradiation in a single dose 6-20 Gy and total summary dose 20-60 Gy by using CyberKnife system.

#### Results

In 31 patients with distant metastases in brain, lung, liver, renal and epinephrine after local ablative radiosurgery we registered full tumor regression during 2-6 years. The existence of this group of patients clinically confirms molecular differences between higher and low metastatic potential tumors. That is why previously shown genetic features of oligometastatic tumors change our ideas about possibilities of active local treatment in cases of metastatic disease.

#### Conclusion

Thus, our observations clinically confirm the existence of group of patients with oligometastatic tumor disease caused by specific genomic changes in tumor cells. In such cases, local ablative radiosurgery with precision and high doses of radiation could be curative.

#### EP-1399 Rotary-Dual Total Skin Electron Beam Therapy as palliative treatment for mycosis fungoides

A. Jodda<sup>1</sup>, M. Pawlaczyk<sup>2</sup>, M. Fundowicz<sup>3</sup>, T. Piotrowski<sup>4</sup>

<sup>1</sup>Greater Poland Cancer Centre, Medical Physics, Poznan, Poland

<sup>2</sup>Poznan University of Medical Sciences, Skin Diseases Prevention, Poznan, Poland

<sup>3</sup>Greater Poland Cancer Centre, Radiotherapy, Poznan, Poland

<sup>4</sup>Poznan University of Medical Sciences, Electroradiology, Poznan, Poland

#### Purpose or Objective

To retrospectively assess the efficacy and toxicity of a total skin electron beam therapy (TSEBT) in patients with primary cutaneous T-cell lymphoma at various stages of development.

#### Material and Methods

Treatment results of 40 patients (8 female, 32 male) in median age 60 years (from 40-84 years), with primary cutaneous T-cell lymphoma (mycosis fungoides), stage IB-III, treated between 2001 and 2013 were reviewed. All patients were symptomatic. The median total dose was 32Gy (range 12-40Gy), applied with 1,5 Gy per day four times weekly for the whole skin.

#### Results

The median follow-up was 60 months. A clinical complete response was documented in 29 (72.5%) and a partial response in 11 patients (27.5%). The clinical response significantly influenced on the overall survival (OS) ( $p=0.002$ ) and progression-free survival (PFS) ( $p<0.001$ ). The mean OS was 76 months. The mean PFS was 48.9 months and the actuarial one-, two- year PFS were 67.5%, 55%. The statistically significant correlation was found between partial and total remission time and the stages of lymphoma ( $p=0.015$ ). The side effects were observed in all patients during the treatment and include: erythema, skin dryness and desquamation, pruritus, onycholysis and alopecia.

#### Conclusion

For palliation of symptomatic cutaneous lymphoma, total skin electron beam therapy is well tolerated and an efficient treatment.

#### EP-1400 Quality of Life in Responders after Palliative Radiation Therapy for Painful Bone Metastases

L.C. Mendez<sup>1</sup>, J.L. Padilha<sup>2</sup>, K.M. Lima<sup>3</sup>, E. Chow<sup>1</sup>, F.Y.

Moraes<sup>4</sup>, M.D.P.E. Esteves<sup>5</sup>, M.F. Silva<sup>2</sup>, G.N. Marta<sup>6,7</sup>

<sup>1</sup>Sunnybrook Odette Cancer Centre- University of

Toronto-, Radiation Oncology, Toronto, Canada

<sup>2</sup>Universidade Federal de Santa Maria, Radiation Oncology, Santa Maria, Brazil

<sup>3</sup>Faculdade de Medicina da Universidade de São Paulo, Radiation Oncology, Sao Paulo, Brazil

<sup>4</sup>Princess Margaret Cancer - University of Toronto, Radiation Oncology, Sao Paulo, Canada

<sup>5</sup>Instituto do Câncer do Estado de São Paulo ICESP - Faculdade de Medicina da Universidade de São Paulo, Clinical Oncology, Sao Paulo, Brazil

<sup>6</sup>Hospital Sírio-Libanês, Radiation Oncology, São Paulo, Brazil

<sup>7</sup>Instituto do Câncer do Estado de São Paulo ICESP - Faculdade de Medicina da Universidade de São Paulo, Radiation Oncology, Sao Paulo, Brazil

#### Purpose or Objective

Bone metastases cause pain, suffering and impaired quality of life (QOL). Palliative radiotherapy (RT) is an effective method in controlling pain, reducing analgesics use and improving QOL. This study goal was to investigate the changes in QOL scores among patients who responded to RT.

#### Material and Methods

A prospective study evaluating the role of radiation therapy in a public hospital in São Paulo-Brazil recorded patients' opioid use, pain score, Portuguese version of QLQ-BM22 and QLQ-C30 before and 2 months after radiotherapy. Analgesic use and pain score were used to calculate international pain response category. Overall response was defined as the sum of complete response (CR) and partial response (PR). CR was defined as pain score of 0 with no increase in analgesic intake whereas PR was defined as pain reduction  $\geq 2$  without analgesic increase or analgesic reduction in  $\geq 25\%$  without increase in pain at the treated site.

#### Results

From September 2014 to October 2015, 25 patients with bone metastases responded to RT (1 CR, 24PR). There were 8 male and 17 female patients. The median age and ECOG of the 25 patients was 57 years old (range 22 to 89) and 2 (range 0 to 3), respectively. Patient's primary cancer site was breast (11), prostate (5), lung (2), others (7). For QLQ-BM 22, the mean scores of 4 categories at baseline were: Pain site (PS) 39, Pain characteristics (PC) 61, Function Interference (FI) 49 and Psycho-social aspects (PA) 57. At 2 month follow up, the scores were PS 27, PC 37, FI 70 and PA 59. Statistical significant improvement ( $p<0.05$ ) was seen in PS, PC, FI but not PA. In the QLQ-C30, the mean scores were not statistically different for all categories, except for pain that demonstrated a 29 point decrease in the pain score domain (69 to 40).

#### Conclusion

Responders to RT at 2 month presented improvement in BM22 and C30 pain domains, and also improvement in functional interference if BM22 questionnaire. Patients with painful bone metastases may receive palliative radiation therapy to improve both pain and QOL.

#### EP-1401 SBRT for solitary extracranial metastases from gynecologic malignancies

M.C. Repka<sup>1</sup>, N. Aghdam<sup>1</sup>, S. Suy<sup>1</sup>, S.P. Collins<sup>1</sup>, W. Barnes<sup>2</sup>, B.T. Collins<sup>1</sup>

<sup>1</sup>Georgetown University Hospital, Department of Radiation Medicine, Washington, USA

<sup>2</sup>Georgetown University Hospital, Division of Gynecologic Oncology, Washington, USA

#### Purpose or Objective

Solitary extracranial metastases from gynecologic malignancies have historically been treated with either surgery or conventional radiation therapy. We report mature local control, toxicity, and survival for patients

who received five-fraction stereotactic body radiation therapy (SBRT) at our institution.

#### Material and Methods

Patients presenting with biopsy-proven, solitary, small (<5 cm) extracranial metastasis from a gynecologic primary cancer, treated with robotic SBRT, were retrospectively reviewed. Vaginal cuff recurrences or multiple sites of disease were considered exclusion criteria for this analysis. Patients were stratified by the presence or absence of sarcomatous histology. The Kaplan-Meier method was used to estimate local control and overall survival. Durable local control was defined as lasting  $\geq 12$  months. Toxicity was scored per the CTC-AE v4.0.

#### Results

Twenty patients were treated over a five year period from July 2007 to July 2012 for solitary extracranial metastases from gynecologic malignancies. Sixteen patients were noted to have non-sarcomatous histology (six uterine and ten ovarian primary tumors), while four tumors were identified as sarcoma (all uterine primaries). No patients with solitary cervical cancer metastases were identified. Metastases involved the liver, lung, abdomen, spine, pelvis, and extremity. Thirteen patients had fiducials placed for tumor tracking; abdominal and spine metastases were tracked with a fiducial-less spinal tracking system. The median gross tumor volume (GTV) was 42.5 cc (range: 5 - 273 cc). The median dose delivered to the GTV was 35 Gy (range: 30 - 50 Gy) over 5 to 9 days (median: 6 days). At a median follow-up of 56 months (range: 6 - 108 months), the 5-year local control and overall survival rates were 71.2% and 47.5% respectively. However, when stratified by histology, the local control at 5 years was 93.7% in patients with classical histology versus 25.0% in patients with metastatic gynecologic sarcoma ( $p < 0.01$ ) and only 50.0% of the sarcoma patients experienced durable local control. No grade 3 or higher toxicity was observed during or following treatment.

#### Conclusion

Five-fraction SBRT is a versatile, well-tolerated, and highly effective treatment option for small extracranial gynecologic metastases with an excellent 5-year local control of 93.7% in patients with classical ovarian and uterine primary tumors. However, patients with metastatic uterine sarcoma may require a more aggressive or alternative treatment approach.

#### EP-1402 Impact of SBRT on pain and local control for bone metastases: a systematic review and meta-analysis

J.M. Van der Velden<sup>1</sup>, A.S. Gerlich<sup>1</sup>, E. Wong<sup>2</sup>, E. Chow<sup>2</sup>, M. Intven<sup>1</sup>, N. Kasperts<sup>1</sup>, W.S.C. Eppinga<sup>1</sup>, E. Seravalli<sup>1</sup>, M. Van Vulpen<sup>1</sup>, H.M. Verkooijen<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

<sup>2</sup>Sunnybrook Odette Cancer Center, Radiation Oncology, Toronto, Canada

#### Purpose or Objective

Pain due to bone metastases is the most common cancer-related pain syndrome. Besides analgesics, conventional radiotherapy has been the cornerstone in the management of bone metastases. However, control of pain after conventional radiotherapy is modest, approximately 60%. Advances in radiotherapy technique enable the delivery of potentially ablative radiation doses, while respecting healthy tissue constraints under the heading of stereotactic body radiotherapy (SBRT). We conducted a systematic review and meta-analysis to quantify pain response and local control after SBRT for bone metastases.

#### Material and Methods

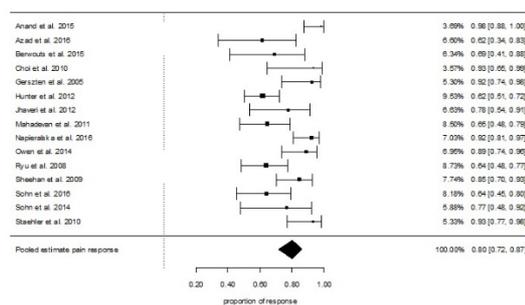

Following the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guideline, Embase, PubMed and Cochrane Libraries were searched with the (synonym) terms 'bone metastases' and 'stereotactic body

radiotherapy'. Studies delivering SBRT in 1 - 6 fractions to patients with or without previous radiotherapy or surgery were included. Information from studies reported in more than one publication was collated, and the most complete or recent article was cited. Study variables, including pain response and local control rates, were extracted from the selected articles. Pain response was defined as a complete or partial (i.e., at least 2 points decrease in pain score) response. To qualify for inclusion in the meta-analysis, outcomes had to be reported on an individual patient or lesion level, follow up had to be recorded at least 45% of the study population, and the size of the study population had to be 10 or more. Pooled estimates using random-effects models were calculated for pain response and local control rates.

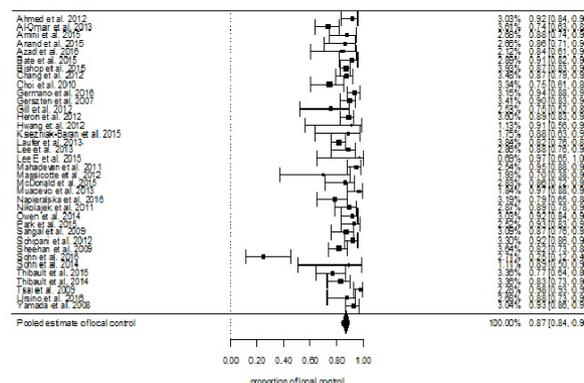

#### Results

After screening of 2619 unique articles, 54 articles (3359 patients) were included in the systematic review. Twenty-six articles (1627 patients/lesions) were included in the meta-analysis for pain response, and 36 articles (2875 lesions) in the meta-analysis for local control. After SBRT, pain response rate ranged from 62% to 98% (see forest plot), and local control rate ranged between 25% and 97% (see forest plot). Excluding the study with the lowest local control rate, which included patients with spinal lesions from hepatocellular carcinoma, the local control rates varied between 74% and 97%. Pooled pain response rate was 80% (95% confidence interval [CI] 72% - 87%) with high heterogeneity ( $I^2 = 77%$ ). Pooled local control rate was 87% (95% CI 84% - 90%) with high heterogeneity ( $I^2 = 76%$ ).

Pain response after SBRT for bone metastases

Local control after SBRT for bone metastases

#### Conclusion

SBRT for bone metastases results in high pain control and high local control rates. This observation needs to be further confirmed within large randomized controlled trials.

### EP-1403 A comparison between 3D and volumetric technique in lumbar vertebral palliative irradiation

N. Ricottone<sup>1</sup>, N. Cavalli<sup>2</sup>, E. Bonanno<sup>2</sup>, C. Marino<sup>2</sup>, G. Pisasale<sup>1</sup>, A. D'Agostino<sup>1</sup>, A. Girlando<sup>1</sup>

<sup>1</sup>HUMANITAS CCO, Radiation Oncology, Catania, Italy

<sup>2</sup>HUMANITAS CCO, Medical Physics, Catania, Italy

#### Purpose or Objective

Lumbar rachis radiation treatment requires to take into account dose to kidneys. Aim of this paper is to evaluate if volumetric techniques can give an advantage when irradiating young patients, patient with a long life expectancy or patients with renal dysfunction. The clinical advantage is to preserve renal function and to not interfere with previous or further medical treatments that make use of renal toxic drugs, as for instance: cisplatin, carboplatin, ifosfamide.

#### Material and Methods

A comparison between four plans were performed: a two fields three dimensional (3D) anterior-posterior plan (3D-2F); a three fields (0°-150°-210°) 3D plan (3D-3F); a VMAT plan and a second VMAT plan spine sparing (VMAT-SS). Dose prescription was 30 Gy in 10 fractions. All plans were calculated with Eclipse 13.6 using AAA algorithm. 3D plans were calculated using MLC shielding and different weighted fields; regarding VMAT plans dose constraints according to QUANTEC were used.

#### Results

Even if dose delivered to kidneys do not exceed QUANTEC dose constraints, VMAT plans achieve better results in term of dose reduction to OARs particularly for kidneys (as showed in the table 1) thus without affecting PTV coverage (figure 1).

	Kidneys						PTV		PTV SPINE Sparing	
	D <sub>mean</sub> (Gy)		V <sub>12</sub> (%)		V <sub>20</sub> (%)		D <sub>mean</sub> (Gy)	D <sub>max</sub> (Gy)	D <sub>mean</sub> (Gy)	D <sub>max</sub> (Gy)
	Dx	Sn	Dx	Sn	Dx	Sn				
3D-3F	12.6	7.9	45.3	22.6	18.8	4	28.1	31.2	-	-
3D-2F	9.7	3.2	33.1	6.9	26.0	3.6	27.5	30.3	-	-
VMAT	6.8	6.1	12.2	3.6	1.9	0	28.9	30.8	28.9	30.9
VMAT-SS	10.8	9.4	27.5	21.7	0	2.2	-	29.6	27.2	30.6

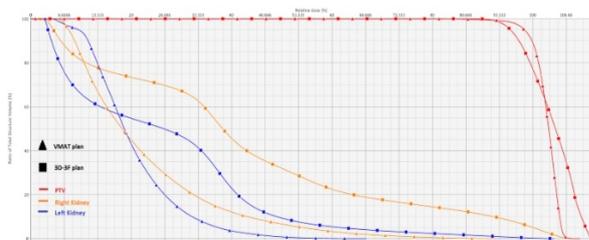

Figure1: DVH comparison between the two plans that gives the best PTV coverage

#### Conclusion

Both 3D plans do not exceed kidneys QUANTEC reference dose constraints. Doses under QUANTEC constraints can cause renal dysfunction in long survivors, young patients and oligometastatic patients. In these situations it is important to consider VMAT planning that gives the opportunity to reduce dose delivered to kidneys decreasing the probability to develop a late renal dysfunction and giving the opportunity for further toxic renal drugs treatments.

### EP-1404 Survival time following palliative whole brain radiotherapy to treat brain metastases

A. Billfalk Kelly<sup>1</sup>, M. Dunne<sup>1</sup>, C. Faul<sup>1</sup>, O. McArdle<sup>1</sup>, I. Fraser<sup>1</sup>, J. Coffey<sup>1</sup>, A. Boychak<sup>1</sup>, B.D. O'Neill<sup>1</sup>, D. Fitzpatrick<sup>1</sup>

<sup>1</sup>St. Lukes Radiation Oncology Network, Radiation Oncology, Dublin 6, Ireland

#### Purpose or Objective

To evaluate the overall survival times of patients with brain metastases who were treated in our institution with WBRT, comparing patients over and under 70 years old, and between fractionation schedules.

#### Material and Methods

A retrospective review was carried out of patients treated with WBRT over a two year period (2013-2014). Data was collected with regards to the time of initial histological diagnosis, dose delivered, age, in-or outpatient basis, extracranial disease status, and time to death, or last known follow up.

#### Results

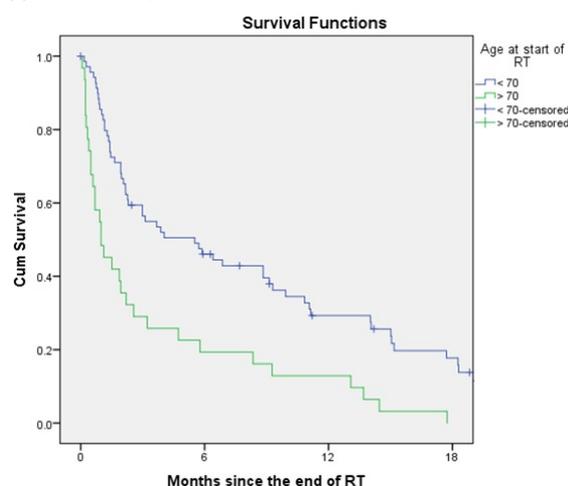

101 patients were identified for analysis. The median age was 64 years (range 32-88).

The radiotherapy was delivered as two opposed 6MV-10MV photon beams, with shielding to the lenses. 50.5% of patients were prescribed 30Gy in 10 fractions, 33.7% 20Gy in 5 fractions and 15.8% patients were prescribed other fractionation schemes. 29.7% were treated as inpatients, and 70.3% as outpatients. The 4 most common histological subtypes were NSCLC 42.6%, small cell lung carcinomas 19.8%, breast adenocarcinoma 14.9%, and malignant melanoma 12.9%. 17.8% of patients had a biopsy or resection of the brain metastases. 11.9% of patients received stereotactic radiotherapy and 2% had already received prophylactic cranial irradiation.

The median follow-up was 2.5 months (range: 2 days-30.5 months) from the end of RT. Median overall survival was 2.6 months (95% CI: 1.1 to 4.0). Overall survival at 1 year was 24%.

All of those aged >70 years died. Overall survival differed significantly between those < 70 years of age and those > 70 (p< .0005). Median overall survival at 12 months was 5.5% for those <70 years and 1.0 months for those >70 years. The hazard (risk of death) is higher and thus the prognosis worse, for older patients controlling for RT dose and Brain surgery or biopsy (p= .011).

Univariate analysis revealed that higher RT doses were significantly associated with longer survival (p< .0005), although this may be due to patients with better performance status receiving 30Gy in 10 fractions as opposed to 20Gy in 5 fractions.

#### Conclusion

Our review shows that survival for most patients is poor in patients who have brain metastases treated with WBRT, which is consistent with international data. 6.9% of patients did not complete the prescribed course of radiotherapy due to clinical deterioration, therefore some patients may be better served with shorter courses of radiotherapy, or treatment with steroids alone, in order to minimise their time in hospital and to ensure maximum quality of life.

While WBRT does have a role in treating some patients with brain metastases, as shown by the long survival of some patients, they should be carefully selected, particularly when considering treating elderly patients.

**EP-1405 A Rapid Access Palliative Radiotherapy Clinic to reduce waiting time in a Regional Cancer Centre**  
M. Morris<sup>1</sup>, T. O'Donovan<sup>1</sup>, B. Ofi<sup>1</sup>, A. Flavin<sup>1</sup>  
<sup>1</sup>Cork University Hospital, Radiation Oncology, Cork, Ireland

#### Purpose or Objective

In September 2014, the Rapid Access Palliative Clinic [RAPC] was set up in the Radiation Oncology Department in Cork University Hospital [CUH] a Regional Cancer Centre in Ireland. Its purpose is to streamline the pathway and facilitate prompt review and timely delivery of palliative radiotherapy [PRT] for symptom relief of patients with terminal cancer.

This study reviews the clinical activity of the RAPC over the initial 3 months and compares it to a second 3 months where the clinic was not available. The purpose of this retrospective review is to evaluate if we are meeting the objectives of the RAPC program.

#### Material and Methods

From the CUH oncology patient information system (Lantis) database, we retrieved the number of patients referred to the RAPC, their demographics, diagnosis and treatment. We calculated the time interval between referral to consultation, consultation to simulation and the percentage of patients who started PRT on the day of their initial RAPC consultation. We calculated the 30-day mortality of patients who received treatment.

We then compared the data from the initial 3 months when the clinic was active from 1<sup>st</sup> September to 30<sup>th</sup> November 2014 against a 3 month period from 1<sup>st</sup> May to 31<sup>st</sup> July, 2016 inclusive, when there was no clinic due to staffing shortages.

#### Results

During the initial 3 month period where the RAPC was active, the number of cases seen in consultation was 129. Patient's ages ranged from 28.4 to 96 years with a mean age of 69.1 years. Most common primary tumour sites were Genitourinary and Lung accounting for 25% and 21% of the patient population. Most common indication for PRT was bone pain accounting for 69% of patients seen in the clinic. Of the 122 patients who received PRT, 57 patients (46.7%) received single fraction PRT whilst 65 patients (53.2%) received fractionated PRT. 98% were seen within 2 weeks of referral (87% within 1 week). The 30-day mortality rate was 13.95%.

When comparing the 2 periods the overall median interval from referral to consultation was 3.9 days with RAPC vs 3.7 days with no RAPC. The median time from consultation to simulation was 0.9 days with RAPC vs 2.7 days with no RAPC. 74% were simulated on the day of their initial consultation with RAPC vs 31.4% with no RAPC. 35% started their PRT treatment on the day of their consultation visit with RAPC vs 23% with no RAPC.

#### Conclusion

The comparison between the initial 3 months of the RAPC vs the 3 months with no RAPC showed the median time from consultation to simulation tripled, the percentage of patients who were simulated on the day of consultation fell by half and only 23% received same day treatment. The 30-day mortality rate is consistent with UK studies and suggests appropriate patient selection. Running a dedicated palliative clinic decreased waiting times, reduced the number of visits to the Regional Cancer Centre and provided prompt PRT to symptomatic patients in the terminal phase of their illness. The RAPC is therefore meeting our objectives.

**EP-1406 Improvement in cancer pain management: the value of a joint approach in a single prospective series**  
V. Masiello<sup>1</sup>, S. Mafrida<sup>1</sup>, F. Cellini<sup>1</sup>, F. Rodolà<sup>2</sup>, G. Cannelli<sup>2</sup>, S. Longo<sup>1</sup>, L. Polidori<sup>2</sup>, M. Balducci<sup>1</sup>, M. Rossi<sup>2</sup>, V. Valentini<sup>1</sup>

<sup>1</sup>Policlinico Universitario Agostino Gemelli- Catholic University, Department of Radiation Oncology - Gemelli-ART, Roma, Italy

<sup>2</sup>Policlinico Universitario Agostino Gemelli- Catholic University, Department of Anesthesiology and Intensive Care Agostino Gemelli Hospital, Roma, Italy

#### Purpose or Objective

Pain management in cancer is a multifactorial challenge for clinicians. Multidisciplinary approach can improve survival and quality of life. In our center we applied a multidisciplinary integrated approach to pain management for outpatients. Purpose of this study was to detect a benefit in terms of quality of life with this approach.

#### Material and Methods

A team represented by radiation oncologist and anesthetist offered a weekly outpatient ambulatory. We enrolled patients (pts) with cancer pain from primitive tumor or metastases. Intervention included RT and/or drug modification/prescription after discussion of both clinicians. Timing of treatment administration was also case-by-case defined. For all the patients we collect performance status (PS), Numeric Rating Scale (NRS), Pain Management Index (PMI) value and Morphine Equivalent Dose (MED) at baseline and after a month of therapy. A complete pain response to radiotherapy was defined as: NRS 0 and no modification in baseline drugs.

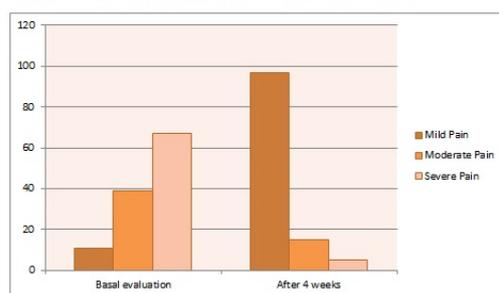

#### Results

From November 2015 to April 2016 we evaluated 85 pts for a total of 122 sites of cancer pain referred. Of this pts, 10% came from consultations, 40% were send from care provider and 50% were on regular follow up. Twenty/85 pts (23.5%) presented cancer pain by primitive tumor. Sixty/85 pts (70.5%) presented bone metastases. At baseline: median PFS: 60% (30-80%); median NRS: 5 (3-10); median PMI: 0 (+1/-3). At first contact 31.8% pts had PMI between -1 and -3 (i.e.: pain not adequately controlled). Moreover, 13% of pts at the baseline didn't assume any therapy and 31.7% assumed only FANS. Pts with a previous cancer pain therapy assumed a median MeQ of 150.5 mg (1-300 mg).

All pts with bone metastases (60/85), underwent palliative RT for a total of 120 irradiated CTVs, as follows: 34/120 (%): 8 Gy/1 fx; 1/120 (%) 4 Gy x 2, 8/120 30 Gy/10 fr, 77/120 CTV with 20Gy/5fr.

After 4 weeks, all the 85 baseline pts was visited/contacted. Median PFS was 60% (40-90), median NRS was 4.5 (0-9) (Figure 1), median PMI was 2 (-1/3). At the first follow up only 2 pts presented a negative PMI (-1) due to pain progression. Complete pain responders were 36%; 5.7% of pts continued to assume FANS only if required and the rest of pts presented a median MED of 150.5 mg (1-300 mg).

Figure 1 – NRS score reported at basal line and after 4 weeks

### Conclusion

In a patient reported outcome era, a joint approach at cancer pain can improve self-report symptoms. Particularly, the non-controlled pain seems to be avoided. Larger series and QoL are required to confirm these results.

### Electronic Poster: Clinical track: Elderly

#### EP-1407 Are future radiation oncologists equipped with the knowledge to manage elderly cancer patients?

L. Morris<sup>1</sup>, N. Thiruthaneeswaran<sup>2</sup>, M. Lehman<sup>3</sup>, G. Hasselburg<sup>3</sup>, S. Turner<sup>1</sup>

<sup>1</sup>Crown Princess Mary Cancer Centre, Radiation Oncology, Westmead, Australia

<sup>2</sup>Peter MacCallum - Bendigo Radiotherapy Centre, Radiation Oncology, Bendigo, Australia

<sup>3</sup>Royal Australian and New Zealand College of Radiologists, Faculty of Radiation Oncology, Sydney, Australia

#### Purpose or Objective

The management of elderly patients with cancer is a significant global challenge as a result of an increasing aging population. Education of future radiation oncologists in geriatric oncology is fundamental to ensuring elderly cancer patients receive appropriate care. This study aims to assess radiation oncology (RO) trainee knowledge, perception and clinical practice in geriatric oncology.

#### Material and Methods

A customised online survey was anonymously administered to 118 RO trainees across Australasia. The survey assessed three domains:

1. Trainee demographics and prior training in geriatric medicine
2. Current clinical practice and attitudes regarding elderly cancer patients and radiation therapy
3. Opinions regarding educational opportunities around geriatric oncology

The survey was developed and reviewed by radiation oncologists with expertise in education and training.

#### Results

A total of 61 (52%) trainees responded to the survey. Over half the respondents had not undertaken a geriatric medicine residency term prior to RO speciality training. 91.8% of respondents had not received teaching during RO training specifically regarding geriatric oncology. The use of geriatric assessment (GA) tools for determining suitability for radiation therapy was uncommon, with 80.3% of respondents rarely or never using them. Over two thirds of respondents reported not seeking or rarely seeking multidisciplinary input from a geriatrician when assessing suitability for treatment. Trainees had low confidence levels in managing complex issues commonly observed in the elderly. Only 39.3% felt they had the confidence to manage these issues with

31.2% not confident/not at all confident. Respondents ranked important factors for deciding treatment options as functional status, assessment of comorbidity, physiological age and cognition. Geriatrician referral scored the least. Of factors influencing dose fractionation schedule, physiological age ranked the highest, whilst performing GA ranked the lowest. The majority of trainees (85.3%) agreed or strongly agreed they would benefit from more training around RO in elderly patients. 65.6% felt the addition of learning objectives to RO curriculum around geriatric oncology would be valuable.

#### Conclusion

RO trainees report inadequate training and experience in geriatric oncology and geriatric medicine. RO trainees rarely use and poorly understand the rationale for GA tools and geriatrician input in clinical practice. Trainees strongly support improved education in geriatric oncology.

#### EP-1408 Nutritional parameters in elderly patients with lung cancer and radiation treatment

J. Monroy Anton<sup>1</sup>, L. Ribes Llopis<sup>1</sup>, E. Molina Luque<sup>1</sup>, M. Soler tortosa<sup>1</sup>, m. Lopez muñoz<sup>1</sup>, a. Soler rodriguez<sup>1</sup>, a. Navarro Bergada<sup>1</sup>, M. Estornell Gualde<sup>1</sup>

<sup>1</sup>Hospital universitario de la ribera, radiation oncology, Alzira, Spain

#### Purpose or Objective

Treatment of lung cancer in elderly patients is increasing in the last years due to the longevity of the population . An important element to consider in these patients is nutritional status, because it can have a major impact on the effects of treatment and compliance Our main objective was to analyze parameters related to feeding and nutrition of elderly in treatment for pulmonary neoplasms

#### Material and Methods

We analyzed 22 patients ; men: 21; women: 1 Age: 70-91 years; mean: 76.9 median: 76.5 Nutritional parameters analyzed :

-Body mass index (BMI)

-Weight loss

-Type of diet: complete solid /oral (standard); deficient or non-solid ; other (parenteral, nasogastric)

-Feeding problems: mechanical, physiological, or any other problems for feeding (due to patient status or treatment administration).

-Nutritional supplements: addition or substitution with nutritional supplementary diets

These parameters were checked at three times:

- T0: before start treatment

- T1: fractions 12-15

- End of treatment

#### Results

##### T0

##### BMI

Mean: 27.95 kg/m<sup>2</sup> median: 27.35 (20.15 - 37.6)

##### Weight loss

<5%: 18 (81%)

5-10%: 3 (13.5%)

>10%: 1 (4.5%)

##### Diet

Standard: 21 (95.5%)

Deficient: 1 (4.5%)

##### Feeding problems

NO problems: 21 (95.5%)

Disphagia gr 1 (RTOG): 1 (4.5%)

##### Nutritional supplements

NO : 21 (95.5%)

YES: 1 (4.5%)

##### T1

##### BMI

mean: 27.7 kg/m<sup>2</sup>; median: 26.75 (20.15 - 37.03)

Weight loss  
 No loss: 12 (54%)  
 <5%: 8 (29%)  
 5-10%: 2 (9%)

#### Diet

YES: 4 (18%)

#### END RADIOTHERAPY

##### BMI

mean: 27.6; median: 26.7 kg/m<sup>2</sup> (20.15 37.34)

Weight loss  
 No loss: 14 (63.5%)  
 <5%: 7 (32%)  
 5-10%: 1 (4.5%)

Diet

Standard: 18 (82%)

Deficient: 4 (18%)

#### Feeding problems

NO problems: 10 (45.5%)

Disphagia: 12 (54.5%)

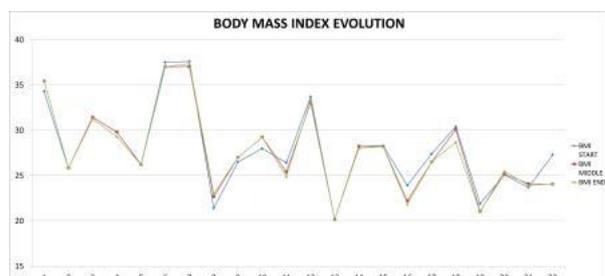

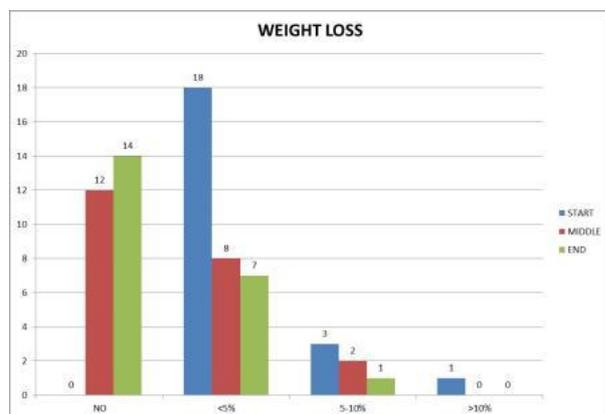

gr. 1: 10 (45.5%)

gr. 2: 2 (9%)

#### Nutritional supplements

NO: 16 (72.7%)

YES: 6 (27.3%)

#### Conclusion

Most elderly patients have a BMI at the start of treatment not indicative of malnutrition, and hardly changes during treatment

All patients have some degree of weight loss at the beginning of treatment. During the treatment and at the end, most do not progress in such loss or it is less than 5%. Patients have a progressive difficulty in feeding, mainly due to dysphagia, but this does not translate for changing the type of diet

It is essential to assess the nutritional status of elderly

patients with lung cancer at the start of oncological treatment, as well as a scheduled monitoring to control feeding problems and give adequate dietary guidelines

#### EP-1409 Prospective study of hypofractionated radiotherapy for elderly patients with High Grade Glioma

E. Clerici<sup>1</sup>, P. Navarria<sup>1</sup>, A.M. Ascolese<sup>1</sup>, F. Pessina<sup>2</sup>, S. Tomatis<sup>1</sup>, L. Cozzi<sup>1</sup>, M. Simonelli<sup>3</sup>, A. Santoro<sup>3</sup>, C. Franzese<sup>1</sup>, L. Bello<sup>2</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

<sup>2</sup>Istituto Clinico Humanitas, Neurosurgery Oncology Department, Rozzano Milan, Italy

<sup>3</sup>Istituto Clinico Humanitas, Oncology and Hematology Department, Rozzano Milan, Italy

#### Purpose or Objective

Published studies showed that a short course of radiation therapy (RT) in elderly and frail patients with diagnosed anaplastic glioma is safe, feasible and better tolerated compared to standard RT fractionation. Based on this background we designed a prospective trial of hypofractionated radiotherapy. The aim of this study was to evaluate patients outcome in terms of progression free survival (PFS) and Overall Survival (OS) rate, and treatment related toxicity.

#### Material and Methods

Elderly patients ( $\geq 70$  years old) with poor Karnofsky performance status and histological confirmed high grade glioma (HGG) were included in this evaluation. All patients underwent hypofractionated radiotherapy with or without concomitant and adjuvant chemotherapy in relation to MGMT status, using temozolomide (TMZ). To precisely define the target volume, computer tomography (CT) scan with and without contrast and magnetic resonance images (MRI) were acquired and images were coregistered. The clinical tumor volume (CTV) corresponded to surgical cavity or to T1 FLAIR abnormality in case of biopsy only. Planning target volume (PTV) was generated adding an isotropic margin of 5 mm from CTV. All plans were optimized on PTV using volumetric modulated arc therapy (VMAT) mode. Dose prescription was 52 Gy in 15 consecutive daily fractions (BED<sub>10</sub> 70.88 Gy). Clinical outcome was evaluated by neurological examination and brain MRI performed, one month after RT and then every 3 months. Response was recorded using the Response Assessment in Neuro-Oncology (RANO) criteria. The tumor progression was described as local, if it occurred in/or within 2 cm from primary site, and distant for new and non-contiguous enhancing or non-enhancing lesions. Hematologic and non-hematologic toxicities were graded according to Common Terminology Criteria for Adverse Events version 4.0.

#### Results

From February 2013 to February 2016, among patients referred to our institution for anaplastic gliomas, 24 patients were included in this evaluation. Biopsy was performed in 13 patients, complete resection in 5 and partial resection in 6. Concomitant and/or adjuvant chemotherapy was administered in 7 patients. The median time and the 6 and 12 months progression-free survival (PFS) rate were 4.4 months, 46% and 12%. The median overall survival (OS) time and the 1 year OS rate were 7.3 months, 70.8% and 16.7%. On univariate and multivariate analysis MGMT status and administration of adjuvant chemotherapy more than concurrent chemotherapy significantly impacted on PFS and OS ( $p < 0.01$ ). The treatment was well tolerated, no severe toxicity was recorded.

#### Conclusion

In our experience, hypofractionated radiotherapy with VMAT-RA in elderly and frail patients could be a safe and

feasible therapeutic option. Adjuvant chemotherapy, in selected patients, can improve survival.

#### EP-1410 Role of PMRT in Elderly Patients with T1-2 and 1 to 3 Positive Nodes Breast Cancer

L. Cao<sup>1</sup>, M.Y. Kirova<sup>2</sup>, C. Xu<sup>1</sup>, K.W. Shen<sup>3</sup>, J.Y. Chen<sup>1</sup>

<sup>1</sup>Ruijin Hospital- Shanghai Jiaotong University School of Medicine, Department of Radiation Oncology, Shanghai, China

<sup>2</sup>Institut Curie, Department of Radiation Oncology, Paris, France

<sup>3</sup>Ruijin Hospital- Shanghai Jiaotong University School of Medicine, Comprehensive Breast Health Center, Shanghai, China

#### Purpose or Objective

Even if evidence of post-mastectomy radiotherapy (PMRT) in patients with T1-2 and 1 to 3 positive nodes breast cancer is increasing, controversies still exist, especially in elderly patients because the risk of treatment-related toxicity. The aim of this study is to evaluate the efficacy and toxicity of PMRT in elderly as well as the place and use of systemic treatment in this population of patients.

#### Material and Methods

We retrospectively reviewed records of consecutive patients with T1-2 and 1 to 3 positive nodes treated with mastectomy at our institution between June 2009 and June 2014. Elderly patients were defined as 65 years or above. Patients who had received neoadjuvant treatment were excluded from the analysis. In total, we analyzed 73 patients, of them only 23 received PMRT. Locoregional recurrence (LRR) was defined as any recurrence within the ipsilateral chest wall, ipsilateral axillary, internal mammary, infraclavicular or supraclavicular lymph nodes. All recurrences at other sites were recorded as distant disease recurrence (DDR). Disease-free survival (DFS) was defined as the time from start of PMRT until recurrence of tumor or death from any cause. Overall survival (OS) is defined as the time from start of PMRT until death from any cause.

#### Results

The median age was 72 years (range, 65-91 years). There were 10 patients with HER2 positive tumors, of them 100% (n=4) received trastuzumab in the PMRT group and 2 of 6 patients in non-PMRT group. All patients with HR positive tumor received endocrine therapy. The patients in the PMRT group were younger (69 years vs. 75 years, P=0.005). Higher number of patients in the PMRT group received adjuvant chemotherapy (82.6 % vs 48 %, P=0.006). At a median follow-up of 48 months (range, 25-85 months), there were 2 LRR diagnosed concurrently with distant metastasis, one in each group respectively. We observed six distant metastases and 5 deaths. In the whole cohort, the 5-year LRR, DDR, DFS and OS were respectively: 3.4%, 13.2%, 84.5% and 92.1%. In the PMRT group, the 5-year LRR, DDR, DFS and OS were 4.5%, 14.1%, 85.9%, and 94.7%, respectively. In the non-PMRT group, the 5-year LRR, DDR, DFS and OS were 2.4%, 12.4%, 84.2% and 92.3%, respectively. In these small single center series, there was no difference in LRR, DDR, DFS and OS between the PMRT and non-PMRT group. There was no significant impact of comorbidity, T-stage, number of positive nodes, HR status, HER2 status and adjuvant chemotherapy on the effect of PMRT.

#### Conclusion

The benefit of PMRT might be limited in the unselected elderly patients with T1-2 and 1 to 3 positive nodes. The intensity of anti-cancer treatment including adjuvant chemotherapy and PMRT tends to decrease in patients with increased age at diagnosis. Larger study is needed to identify elderly patients with relative higher risk of LRR and metastasis, as well as the risk of toxicity to better individualize treatment. Clear biomarkers are needed to

decide patients for whom radiotherapy can be avoided.

#### EP-1411 Chemo-IMRT in elderly head and neck cancer patients

I. Ahmed<sup>1</sup>, S. Kotur<sup>1</sup>, D. Sahoo<sup>2</sup>, D. Sougumarane<sup>3</sup>, R.

Bhise<sup>4</sup>, K. Vinchurkar<sup>5</sup>, M. Kalloli<sup>5</sup>, A. Sanikoppa<sup>6</sup>

<sup>1</sup>Kle's belgaum cancer hospital, radiation oncology, Belgaum, India

<sup>2</sup>Kle's belgaum cancer hospital, radiaiton oncology, Belgaum, India

<sup>3</sup>Kle's belgaum cancer hospital, radiation physics, Belgaum, India

<sup>4</sup>Kle's belgaum cancer hospital, medical oncology, Belgaum, India

<sup>5</sup>Kle's belgaum cancer hospital, surgical oncology, Belgaum, India

<sup>6</sup>Kle's belgaum cancer hospital, pathology, belgaum,India

#### Purpose or Objective

Elderly patients have been underrepresented in prospective clinical trials that have defined standards of care for head and neck cancer. In the era of improved radiation techniques, improved systemic therapy and better supportive care can claim that chemoradiation does, in fact, improve survival for a large segment of this population and should not be denied for fear of poor tolerance.

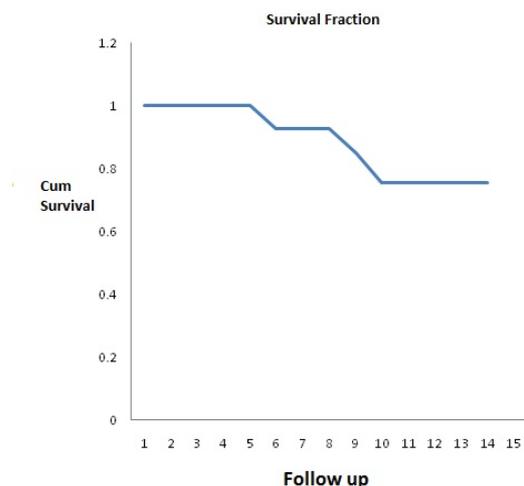

#### Material and Methods

21 patients with locally advanced head and neck cancer treated with SIB-IMRT and concurrent weekly cisplatin were prospectively evaluated. After written and informed consent, all patients were immobilised with head and neck thermoplastic mask followed by CT simulation. Critical structures and Planning Target volumes - high risk receiving 70Gy (PTVHR), intermediate risk receiving 63 or 59.4 Gy (PTVIR) and low risk receiving 56 or 54Gy (PTVLR) in 33-35 fractions over 6.5-7 weeks were defined and planned with Eclipse version 11 planning system using 7-9 field arrangements. Concurrent Chemotherapy was administered using weekly cisplatin 40mg/m2 or carboplatin AUC 2 for 6 cycles. All patients were evaluated for treatment compliance and radiation toxicities weekly. Outcomes were analysed in terms of clinical response evaluation using RECIST criteria, acute toxicities according to RTOG-EORTC and overall survival using Kaplan Meir curve.

#### Results

Median age of presentation was 69 years (range 65-76) with M: F ratio of 16:5. Primary site of presentation were hypopharynx (10), oropharynx (5) and larynx (6). TNM stage status were T1(2),T2(5), T3(11), T4(3); N1(4), N2(1), N3(1); Stage III(10), IVA(10) and IVB(1). All patients received 70 Gy. Median Overall treatment time was 53 days (range 46-65 days) with treatment interruption of 1-9 days (median 3 days). All patients received 4-6 cycles of cisplatin/carboplatin (median 6). Acute toxicities are shown in table. Mean weight loss was 8% (range 4-15%).With a median follow up of 9 months (range 3-15 months), ORR were 71.5% (15 patients) had complete response and 28.5% (6 patients) had partial response. 7 (33%) patients had recurrence with 6 loco regional and 1 distant, out of which 3 expired and 4 are alive with disease. The overall 15 month survival rate is 75.6%.

	GRADE 1	GRADE 2	GRADE 3	GRADE 4
MUCOSITIS	1(5%)	17(80%)	3(14%)	0
DERMATITIS	17(80%)	3(14%)	1(5%)	0
LARYNGITIS	8(38%)	13(62%)	0	0
ANAEMIA	6(28%)	0	0	0
NEUTROPENIA	4(19%)	0	2(10%)	0
THROMBOCYTOPENIA	1(5%)	1(5%)	0	0

### Conclusion

Chemo-IMRT is feasible and well tolerated with acceptable outcomes even in the subset of elderly patients with locally advanced disease.

### Electronic Poster: Clinical track: Other

#### EP-1412 Quality of life of patients after high dose radiation therapy for thoracic carcinomas

C. Schröder<sup>1</sup>, R. Engenhart-Cabillic<sup>2</sup>, A. Buchali<sup>3</sup>

<sup>1</sup>Universität Giessen, Klinik für Strahlentherapie und Radioonkologie- Universitätsklinikum Giessen und Marburg, Giessen, Germany

<sup>2</sup>Universität Marburg, Klinik für Strahlentherapie und Radioonkologie- Universitätsklinikum Giessen und Marburg, Marburg, Germany

<sup>3</sup>Ruppiner Kliniken GmbH, Klinik für Strahlentherapie und Radioonkologie, Neuruppin, Germany

#### Purpose or Objective

Quality of life (QoL) is an important factor in patient care. In this analysis we focused on QoL before and after radio-(chemo-)therapy (RCT) in patients with thoracic carcinomas and its influence on clinical follow up, survival and the correlation with treatment related toxicities.

#### Material and Methods

81 curatively treatable patients with intrathoracal carcinoma (NSCLC, SCLC, esophageal carcinoma) were included in this analysis. They received radio-(chemo-)therapy. Patients with NSCLC were treated with 74 Gy, patients with SCLC with 60 Gy and those with esophageal carcinomas with 66 Gy. Eligible patients received chemotherapy according to intradepartmental standards. For the analysis of the QoL the EORTC QLQ-C30 and the EORTC QLQ-LC13 were used. QoL data was collected before radiation treatment, 6 weeks, 12 weeks, 6 month and 12 month after RT. Additionally factors were analyzed, including clinical outcome, survival, treatment induced side effects.

#### Results

The median follow up was 34,5 weeks. In total 49,4 % of patients had a complete or partial remission and 16,0 % a stable local disease. Local failure occurred in 24,7 % of patients. Distant failure occurred in 44,4 % of patients. Severe dysphagia occurred in up to 9 % of patients, up to 50 % experienced mild dysphagia. The overall rates for RT induced pneumonitis (RP) were low with a maximum of 8 % 12 weeks after RT. The median survival time was 34 weeks with a range from 1 to 220 weeks. All functional

scales showed a variable course but maxed or at least showed a recovery 12 weeks after RT. Symptoms with a high mean symptom score (> 40) were fatigue, dyspnoea and coughing. Insomnia, peripheral neuropathia, appetite loss, dyspnoea (from QLQ-LC13) and all parameters for pain had an intermediate mean score (10 - 40). There were low mean scores of fewer than 10 for nausea and vomiting, diarrhoea, sore mouth and haemoptysis. The GLM revealed no statistically significant difference for any QLQ-C30 parameter over time. For the QLQ-LC13 statistically significant differences over time were found for the peripheral neuropathy ( $p = 0,011$ ) and the dysphagia ( $p = 0,034$ ). There was a highly significant correlation between the clinical dysphagia and the dysphagia scores ( $p < 0,005$ ). The correlation between clinical RP and the scores for dyspnoea and coughing was significant at some follow-up appointments. The EORTC QLQ-C30 and QLQ-LC13 scores did not prove to have a significant influence on the overall survival or distant and local failure.

#### Conclusion

12 weeks after RT the scores of the QLQ-C30 functional scales showed the highest scores or at least a temporary recovery. The symptom scales accurately reflected the common symptoms and treatment related toxicities. There was a significant correlation between clinical dysphagia and pneumonitis and associated QoL scores. QoL did not prove to be a significant predictor for survival or distant and local control.

#### EP-1413 IORT for treatment of recurrent tumors - A single institution analysis.

T.M. Coelho<sup>1</sup>, R.C. Fogaroli<sup>1</sup>, A.C.A. Pellizzon<sup>1</sup>, D.G. Castro<sup>1</sup>, G.R.M. Gondim<sup>1</sup>, M.L.G. Silva<sup>1</sup>, M.J. Chen<sup>1</sup>, A.A. Ambrosio<sup>1</sup>

<sup>1</sup>Accamargo cancer center, Radiotherapy, Sao Paulo sp, Brazi

#### Purpose or Objective

The incidence of recurrent retroperitoneal or pelvic tumors (rRPT) varies from 20% to 77% in literature and requires a multidisciplinary approach. Local control (LC) with isolated salvage surgical resection is dismal, and intraoperative radiotherapy (IORT) can be considered an adjuvant treatment option for selected cases, in special those with previous course of radiation.

This study assessed the feasibility, efficacy and morbidity of IORT as adjuvant treatment of rRPT who underwent to salvage surgical resection.

#### Material and Methods

41 patients with non-metastatic and isolated (one anatomic site) rRPT were treated from 2004 to 2015. All patients were treated with intraoperative electron beam, except one patient who was treated with intraoperative high dose rate brachytherapy. The mean doses were 16 Gy (range 10-21) and 14Gy (range 9-20) for patients without and with previous external beam radiation therapy (EBRT), respectively. The dose was delivered with a 2cm safe margin around the tumor bed. Seventeen (39%) patients had additional EBRT (mean dose 45 Gy) after surgery and IORT. Median survival times were calculated using Kaplan-Meier analysis and differences in survival between groups were tested using log-rank test. The Cox proportional hazards regression model was used to estimate the hazard ratio (HR) for potential predictors of LC, overall survival(OS) and disease-specific survival(DSS). A difference was considered statistically significant if  $p \leq 0,05$ .

#### Results

Twenty-two (54%) patients had pelvic lesions and 19(46%) had retroperitoneal disease. In addition, 3 patients had a second course of RTIO for a second recurrent tumor in different anatomical site, 31 patients (82%) had resection R0 and 8 patients (18%) had resection R1. The most common recurrent tumors were colorectal cancer

(36%) and retroperitoneal sarcomas (50%). With a median follow-up of 70 months (range 12-92), the median DSS was 54 months (range 28-80). The 5-year actuarial OS, LC and DSS were 71%, 68% and 44%, respectively. On univariate analysis margin status of resection significantly affected LC. For patient with resection R0, LC was 83% whereas no patient with R1 resection obtained local control ( $p < 0.01$ ). Toxicity presented in 11 (27%) patients and pain was the most common side-effect (64%) followed by enteritis (18%).

#### Conclusion

IO RT is an efficient method of salvage treatment to improve LC in selected patients with isolated locally recurrent tumors for recurrent pelvic or retroperitoneal tumors, with acceptable incidence of morbidity.

#### EP-1414 Toxicity of concurrent stereotactic radiotherapy and targeted or immunotherapy: a systematic review

S.G.C. Kroeze<sup>1</sup>, C. Fritz<sup>1</sup>, M. Hoyer<sup>2</sup>, S.S. Lo<sup>3</sup>, U. Ricardi<sup>4</sup>, A. Sahgal<sup>5</sup>, R. Stahel<sup>6</sup>, R. Stupp<sup>6</sup>, M. Guckenberger<sup>1</sup>

<sup>1</sup>University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

<sup>2</sup>Aarhus University, Danish Center for Partical Therapy, Aarhus, Denmark

<sup>3</sup>University of Washington School of Medicine, Department of Radiation Oncology, Seattle, USA

<sup>4</sup>University of Turin, Department of Radiation Oncology, Turin, Italy

<sup>5</sup>University of Toronto, Department of Radiation Oncology, Toronto, Canada

<sup>6</sup>University Hospital Zürich, Department of Oncology, Zurich, Switzerland

#### Purpose or Objective

Stereotactic radiotherapy (SRT) and targeted/immunotherapy play an increasingly important role in personalized treatment of metastatic disease. The combined application of both therapies is rapidly expanding in daily clinical practice. Patients may benefit from additive cytotoxic effects, but currently not much is known regarding safety and the potential induction of toxicity. Toxicity data from targeted/immunotherapy combined with conventionally fractionated radiotherapy cannot be extrapolated to SRT because of the differences in physics and biology. The aim of our systematic review was to summarize severe toxicity observed after concurrent treatment.

#### Material and Methods

PubMed and EMBASE databases were searched for English literature published up to april 2016 using keywords 'radiosurgery', 'local ablative therapy', 'gamma knife' and 'stereotactic', combined with 'bevacizumab', 'cetuximab', 'crizotinib', 'erlotinib', 'gefitinib', 'ipilimumab', 'lapatinib', 'sorafenib', 'sunitinib', 'trastuzumab', 'vemurafenib', 'PLX4032', 'panitumumab', 'nivolumab', 'pembrolizumab', 'alectinib', 'ceritinib', 'dabrafenib', 'trametinib', 'BRAF', 'TKI', 'MEK', 'PD1', 'EGFR', 'CTLA-4' or 'ALK'. Studies performing SRT during or within 30 days of targeted/immunotherapy, reporting severe ( $\geq$ Grade 3) toxicity were included.

#### Results

A total of 49 studies were included. Of these, 13 (321 patients) were prospective studies, 27 (653 patients) retrospective studies and 9 (16 patients) case reports. The number of patients per study ranged from 1 to 106 (median 15). Targeted agents concurrent with cranial SRT were tested in 34 studies and with extra-cranial SRT in 19 studies. For cranial SRT, severe toxicity was observed in 14% (89/644) of patients, for extra-cranial SRT in 16% (84/524). Severe toxicity possibly related to cranial SRT or extra-cranial SRT was observed in 6% (5.4% Gr3; 0.6% Gr4; 0% Gr5) and 9% (7.6% Gr3; 0.8% Gr4; 0.6% Gr5),

respectively. Overall, concurrent cranial SRT was well tolerated, except when combined with BRAF-inhibitors (severe toxicity in 20/75 patients (27%)). Furthermore, there is a high risk of morbidity when extra-cranial SRT is combined with EGFR-targeting tyrosine kinase inhibitors and bevacizumab, which was not observed after cranial SRT.

#### Conclusion

The currently available information concerning toxicity after concurrent SRT and targeted/immunotherapy is limited. The focus of published studies lies mainly on concurrent cranial SRT, where the combination generally is well tolerated. For extra-cranial SRT, no definitive conclusions can be drawn. This review underlines the need for clinical studies testing the combination of SRT and targeted drugs/immune check point Inhibitors.

#### EP-1415 Interventions to Address Sexual Problems in People with Cancer

L. Barbera<sup>1</sup>, C. Zwaal<sup>2</sup>, D. Elterman<sup>3</sup>, W. Wolfman<sup>4</sup>, A. Katz<sup>5</sup>, K. McPherson<sup>6</sup>, A. Matthew<sup>7</sup>

<sup>1</sup>Odette Cancer Centre - Sunnybrook Health Sciences Centre, Radiation Oncology, North York- Toronto, Canada

<sup>2</sup>McMaster University, Oncology, Hamilton, Canada

<sup>3</sup>University Health Network, Urology, Toronto, Canada

<sup>4</sup>Mount Sinai Hospital, Obstetrics and Gynecology, Toronto, Canada

<sup>5</sup>CancerCare Manitoba, Cancer and Sexuality Counselling, Winnipeg, Canada

<sup>6</sup>Cancer Care Ontario, Patient and Family Advisory Council, Toronto, Canada

<sup>7</sup>University Health Network, Surgical Oncology, Toronto, Canada

#### Purpose or Objective

Objective: Sexual dysfunction in people with cancer is a significant problem. This guideline aimed to address the following question: "What is the effectiveness of pharmacologic interventions, psychosocial counselling or devices to manage sexual problems after cancer treatment?"

#### Material and Methods

Methods: This guideline was created with the support of the Program in Evidence-Based Care. We searched for existing systematic reviews, guidelines and relevant primary literature from 2003-2015. Men and women were evaluated separately. No restrictions were made on cancer type or study design. When first approaching the guideline the working group chose to focus on sexual disorders commonly known to arise in people with cancer. These included decreased desire, arousal disorders, pain (in women) and erectile dysfunction (in men). Only studies that evaluated the impact of an intervention on a sexual function outcome were included.

#### Results

Results: The panel made one overarching recommendation that there be a discussion with the patient, initiated by a member of the health care team, regarding sexual health and dysfunction resulting from the cancer or its treatment. The Expert Panel felt that this is vital since the additional recommendations cannot be used unless someone has taken the initiative to ask. There were numerous limitations of the existing literature. However, we made additional recommendations on 11 outcomes: 6 for women (sexual response, body image, intimacy/relationships, overall sexual function/satisfaction, vasomotor symptoms, genital symptoms) and 5 for men (sexual response, genital changes, intimacy/relationships, overall sexual function/satisfaction, vasomotor symptoms). There is a role for medication or devices in particular

circumstances. Psychosocial counselling however had the largest evidentiary base for most of the outcomes.

#### Conclusion

Conclusion: To our knowledge this is the first evidence based guideline to comprehensively evaluate interventions to improve sexual problems in people with cancer. The guideline will be a valuable resource to support practitioners and clinics in addressing this important aspect of being human.

#### EP-1416 A new model of care to improve clinical trial participation in radiation oncology

M. Grand<sup>1,2,3</sup>, M. Berry<sup>1,3,4</sup>, D. Forstner<sup>1,3,4</sup>, S. Gillman<sup>1,3</sup>, P. Phan<sup>1,3</sup>, K. Wong<sup>1,4,5</sup>, S. Vinod<sup>1,4,6</sup>

<sup>1</sup>Liverpool Hospital, Cancer Therapy Centre, Liverpool, Australia

<sup>2</sup>Ingham Institute for Applied Medical Research, Clinical Trials, Liverpool- NSW, Australia

<sup>3</sup>Campbelltown Hospital, Cancer Therapy Centre, Campbelltown- NSW, Australia

<sup>4</sup>University of NSW, South Western Sydney Clinical School, NSW, Australia

<sup>5</sup>Ingham Institute for Applied Medical Research, CCORE, Liverpool- NSW, Australia

<sup>6</sup>Western Sydney University, Clinical School, NSW, Australia

#### Purpose or Objective

Clinical trial participation is becoming increasingly recognised as an indicator of quality of care in oncology. Previously, Radiation Oncology (RO) clinical trials at Liverpool and Macarthur Cancer Therapy Centres, Sydney, Australia were managed by a general oncology clinical trials unit. The focus was largely on pharmaceutical and large collaborative group trials, and less on investigator initiated studies. This model was heavily reliant on individual clinicians remembering to screen and recruit patients. Recognising our low rates of participation in clinical trials, we decided to develop and implement a new model of care to support clinical trials in RO.

#### Material and Methods

A new team dedicated to RO clinical trials with specific skill sets in nursing, radiation therapy and clinical research, was formed in December 2014. Strategies were devised to improve performance which included development of standard operating procedures, Good Clinical Practice (GCP) training, and active education and communication. Work processes were changed to be less reliant on clinicians, with more co-ordination by the RO clinical trials team. Active screening was conducted through attendance at multidisciplinary team meetings, screening clinic lists and development of a MOSAIQ screening tool for clinicians. The model involved regular auditing and feedback to clinicians to identify poor recruiters or poorly recruiting trials, and provide clinical trials support to improve this.

#### Results

Across both Liverpool and Macarthur Cancer Therapy Centres, screening activity increased from 51 patients screened in 2014, to 339 in 2015, and to 487 up to August 2016. Participation in clinical trials, as a percentage of new patients seen in RO clinics, increased from 2.6% in 2014, to 12.4% as of August 2016 (Fig 1). The number of RO clinical trials that were open in 2014 was 20, and in 2016, it was 33. Among these studies, the number of investigator initiated studies that were open in 2014 was 8, compared to 15 in 2016. In 2016, the MOSAIQ screening assessment has been completed for 36.6% of new patients across both sites. Completion of GCP certification by all radiation oncology staff involved with clinical trials has reached 100%. The quality of data submission has

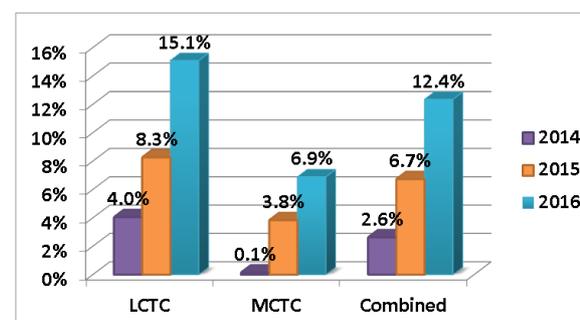

improved through accurate collection of data at the required time points.

#### Conclusion

This new model of care, tailored to the specific needs of RO, has resulted in increased clinical trial screening and participation. The RO clinical trials department has become the chosen model of care across the local health district.

Figure 1: Percentage of patients on clinical trials

#### EP-1417 Clinical evaluation of a fully automatic body delineation algorithm for radiotherapy

T. Fechter<sup>1,2</sup>, J. Dolz<sup>3</sup>, U. Nestle<sup>2,4</sup>, D. Baltas<sup>1,2</sup>

<sup>1</sup>Medical Center - University of Freiburg, Medical Physics - Department of Radiation Oncology, Freiburg, Germany

<sup>2</sup>German Cancer Consortium DKTK, Partner Site Freiburg-Germany, Freiburg, Germany

<sup>3</sup>École de technologie supérieure, Laboratory for Imagery- Vision and Artificial Intelligence, Montréal, Canada

<sup>4</sup>Medical Center - University of Freiburg, Department of Radiation Oncology, Freiburg, Germany

#### Purpose or Objective

The aim of radiotherapy is to deliver the highest possible dose to the tumour and spare surrounding healthy tissue. For high efficacy an accurate delineation of the body outline on planning CT is crucial. On the one hand for dose calculation, on the other hand to reduce the delivered dose to the skin. However, depending on the tumour and treatment type, positioning markers, catheters, breathing belt, fixation mattress, table and/or blankets are directly adjacent to the patient's skin. Algorithms currently employed in clinical settings cannot often distinguish those devices from the patient's body. Consequently, these devices are included in the body segmentation which requires tedious manual corrections. In this work, a fully automatic algorithm for body delineation that can handle structures adjacent to the patient is clinically evaluated for various cancer cases.

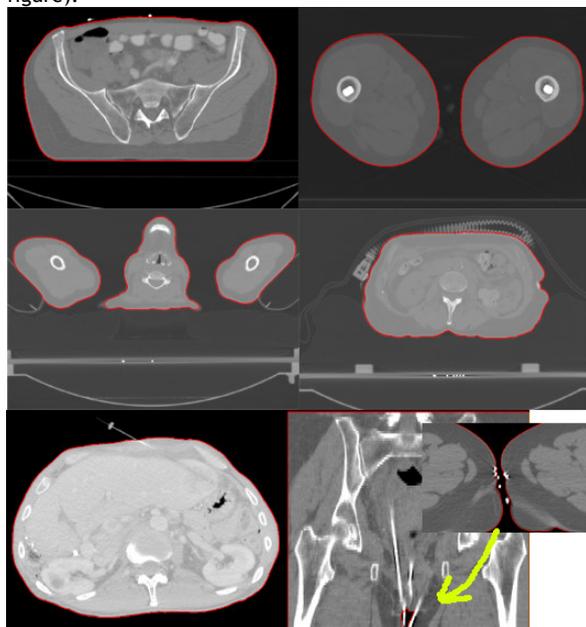

#### Material and Methods

The presented approach is based on a series of threshold and morphology operations, and it was implemented using MITK platform. For evaluation purposes, segmentation was performed on the planning CT of overall 30 patients: 10 lung cancer patients, 10 patients with a prostatic lesion and 10 rectum carcinoma patients. CT scans were acquired on different scanners and with different image resolutions. Body delineations used for real treatment planning served as reference contours. Similarity between reference and generated contours was assessed by computing the volume ratio (VR), Dice's coefficient (DC) and Hausdorff distance (HD) to evaluate differences with respect to volume, overlap and shape, respectively.

#### Results

The mean VR obtained was 0.99 with a standard deviation (SD) of 0.006. The average amount of false ly classified

pixels was around 0.3 %. Overlap analysis yielded a mean DC of 0.99 with SD 0.002 which translates in an excellent agreement. HD calculation resulted in a mean distance of 6.02 mm and a SD of 3.42 mm. For all cases the algorithm was able to successfully separate the body from adjacent parts like breathing belt, blankets, mattress etc. (see figure).

#### Conclusion

We have presented a fully automatic algorithm for body delineation on CT that can handle structures adjacent to the patient. It has been evaluated in a clinical setting, showing an outstanding performance. Particularly, 30 clinical cases including several body locations were segmented. Evaluation demonstrated an excellent agreement with respect to reference contours. For segmentation no user interaction is required. Results suggest the suitability of the algorithm for clinical use with cases of the tested region between thorax and pelvis. Future work will explore the use of the algorithm for other body regions.

#### EP-1418 RandOmized Study Exploring the combination of radioTherapy with Two types of Acupuncture treatment

R. Asadpour<sup>1</sup>, K. Kessel<sup>1,2</sup>, D. Habermehl<sup>1</sup>, T. Bruckner<sup>3</sup>, S. Sertel<sup>4</sup>, S. Combs<sup>1,2</sup>

<sup>1</sup>Technical University Munich TUM, Department of Radiation Oncology, München, Germany

<sup>2</sup>Institute of Innovative Radiotherapy iRT, Department of Radiation Sciences DRS, Neuherberg, Germany

<sup>3</sup>Institute of Medical Biometry and Informatics IMBI, Department of Medical Biometry, Heidelberg, Germany

<sup>4</sup>Bâtiment hospitalier, Department of ORL and Cervical Surgery, Lausanne, Switzerland

#### Purpose or Objective

Acupuncture is known to reduce various clinical signs and symptoms. Often patients treated with radiation therapy (RT) suffer from side effects such as fatigue, nausea/vomiting or reduction of quality of life (QoL). Few randomized data are available to define the role of acupuncture in the context of radiation oncology as a supporting treatment. Therefore, the ROSETTA (RandOmized Study Exploring the combination of radioTherapy with Two types of Acupuncture treatment) trial was initiated as a prospective randomized phase II trial. It examines if traditional (verum-) acupuncture can

reduce RT-related side effects significantly in comparison to sham (false-) acupuncture.

#### Material and Methods

A total of 74 patients are to be recruited. In the experimental arm (n=37) an experienced acupuncture-trained person will treat dedicated acupuncture points. In the control arm (n=37) sham-acupuncture will be performed to provide a blinded comparison of results. The Ethics Committee of the Technical University of Munich (TUM) approved the nature and content of the study with the project number 512/15.

To evaluate quality of life, patients receive a standardized questionnaire (EORTC QLQ C-30) before their first, after their fourth and after their last acupuncture treatment. Further, a study investigator questions patients about their feelings and symptoms as well as documents detailed information regarding their course of disease. The main endpoint of the trial is the improvement of QoL and reduction of fatigue. Secondary endpoints are the reduction of RT-related side effects such as headache, nausea, and pain.

#### Results

The ROSETTA trial is currently recruiting. Initial results from 30 patients (verum acupuncture n=15; sham acupuncture n=15) are presented. All the following items are scaled from 0 to 100. A high score in a symptom scale represents an aggravation of symptoms, whereas a high score in QoL shows an improvement.

Concerning nausea/vomiting and QoL no significant difference can be observed between the sham-acupuncture and the verum group. Thus, patients suffer from a constant level of these side effects during RT. From the first examination to the last visit, fatigue increases in the group receiving sham acupuncture (from 21 to 44). Meanwhile, fatigue remains constant in the verum group (from 40 to 40). Verum-acupuncture shows positive effects in reduction of pain (first visit: 21, last visit: 25) in comparison to the sham-acupuncture group (first visit: 23, last visit: 30).

#### Conclusion

We present first results of the ROSETTA trial, which show preliminary tendencies in 30 randomized patients. Comparing the verum and the sham-acupuncture group, some differences regarding fatigue and pain are apparent. In spite of undergoing RT, patients in both groups do not feel worse concerning the examined features. Our results and ongoing research will generate an excellent data basis on how to include certain complementary medicine methods into high-end oncology treatment.

#### EP-1419 Optimal design and patient selection for interventional trials using radiogenomic biomarkers

<sup>10</sup>University of Rochester, Medical Center, Rochester, USA

<sup>11</sup>University of Manchester, Translational Radiobiology Group I Institute of Cancer Sciences- The Christie NHS Foundation Trust, Manchester, United Kingdom

#### Purpose or Objective

To define the optimal design and patient selection for interventional trials in radiogenomics, as radiogenomics do not give binary information like in e.g. targetable mutation biomarkers. Here, the risk to develop severe side effects is continuous, with increasing incidences of side effects with higher doses and/or volumes.

#### Material and Methods

The most appropriate interventions, endpoints, trial designs, model performance, identification of patient groups that could benefit most from a radio-genomic biomarker, and patient considerations were identified. Patients' advocacy representatives were part of this work.

#### Results

Interventions that can be considered are: alternative treatment, dose modification, altered radiotherapy, mitigation / amelioration and the omission of postoperative radiotherapy in patients with a low risk for tumour recurrence. The optimal intervention is dependent on pre-defined risk factors, which were identified. There is clearly no simple endpoint or time point that can be selected when designing a clinical trial. Composite endpoints should be considered.

Randomised clinical trials and retrospective observational studies have pros and cons in radiogenomics, which will be discussed. As model precision improves, thresholds can be relaxed, e.g., a very precise model could select patients for receiving a higher radiation dose with no risk of undue toxicity. Although more precise models will typically result in more benefit, less precise models might be informative to some degree.

The consequences of the incidence of toxicity/toxicities on the number of patients needed for prospective validation as a function of the prevalence of a genetic profile must be considered. A polygenic risk score will likely be needed as individual genetic variants each contribute only modestly to risk of developing toxicity. Decreasing the standard radiation dose in the most susceptible patients is highly dependent on the dose-effect relationship. These relations are highly dependent on the endpoint, e.g. radiation pneumonitis vs. fibrosis. An in-depth knowledge of the dose-volume relation for a specific endpoint taking into account the clinical usefulness of the dose reduction is needed in order to select the correct patient for this strategy. For the results of a study to be of value for patients, there should be a therapeutic alternative for the standard of care radiotherapy and the quantitative gain should be measurable and relevant. The incidence of peak reactions after radiotherapy is not the only parameter that should be taken into account. It is their severity, reversibility, the possible salvage treatments and the overall influence on quality of life that is also crucial to take into account.

#### Conclusion

The REQUITE and radiogenomics consortium has defined recommendations for the optimal design and patient selection for interventional trials using radiogenomic biomarkers, which will be presented in detail.

#### EP-1420 Effects of Japanese traditional Kampo medicines "Goreisan" for acute radiation enteritis

H. Matsutani<sup>1</sup>, T. Shimbo<sup>1</sup>, H. Yoshioka<sup>1</sup>, N. Yoshikawa<sup>1</sup>, K. Yoshida<sup>1</sup>, M. Nakata<sup>1</sup>, T. Hamada<sup>1</sup>, T. Komori<sup>1</sup>, Y.

Narumi<sup>1</sup>, Y. Uesugi<sup>2</sup>

<sup>1</sup>Osaka Medical College, Radiation Oncology, Osaka, Japan

<sup>2</sup>Kansai University of Welfare Sciences, Medical treatment for health, Kashihara, Japan

#### Purpose or Objective

Goreisan (TJ-17) is one of Japanese traditional Kampo medicine which is composed of five kinds of herbal medicines. TJ-17 has been found to suppress the abnormal water movement through the aquaporin inhibitory effect and an anti-inflammatory effect. Recently, TJ-17 has been indicated for cerebral edema and chronic subdural hematoma, and appears its effects soon. We have investigated whether the TJ-17 is effective in radiation enteritis.

#### Material and Methods

TJ-17 (7.5g/day) was administered 68 patients who received radiation therapy for the whole pelvis. The median age was 64 years old (range; 50-88). Fifty cases were male and eighteen cases were female. Sixty cases (92.6%) were combined chemotherapy (cisplatin and/or gemcitabine), eight cases received radiation alone. When patients showed the diarrhea grade 2 or more in the CTCAE v4.0, we administered TJ-17 without stopping radiation therapy. After prescription, we examined the number of defecation and stool property using a Bristol stool scale.

#### Results

All patients showed grade 2 or more diarrhea during radiation therapy.

At the time of prescription, the median irradiation dose was 23Gy (range; 12-44). Before the administration, the median stool frequency was eight times (range; 4-20). Eighteen cases was type 6 (mushy stool), and fifteen cases was type 7 (watery) in the Bristol stool scale, the median scale was type 7 (average; 6.7). Bloody stools were observed in six cases. After one week administration of TJ-17, fifty-three cases (77.9%) were improved the symptoms. In improved group, the median of decrease in the number of stool frequency was four times (range; 1-19), and the median Bristol stool scale was type 6 (average; 5.4). Bloody stools were disappeared in three of 6 cases (50%). By using the Pearson product-moment correlation coefficient, from the appearance enteritis symptoms, it showed a correlation of moderate to start administering the TJ-17 earlier.

#### Conclusion

Japanese traditional Kampo medicines Goreisan (TJ-17) was effective against in acute radiation enteritis.

#### EP-1421 Outcome by prognostic factors of AVM treated with LINAC: 18 years experience, Spanish Institution

S. Cafiero<sup>1</sup>

<sup>1</sup>Clinica de Occidente, Radiation Oncology, Santiago de Cali, Colombia

#### Purpose or Objective

Outcomes of cerebral arteriovenous malformations (cAVMs) treated with SRS by using LINAC, and results according to the Spetzler-Martin (SM) grading system and the Pollock-Flickinger (PF) score, in a series of patients (pts) from Onkologikoa in Spain

#### Material and Methods

1995 to 2013, 320 pts with cAVMs treated with SRS by using a Clinac 21EX. Mean age 40 years (9-76), 61% men and 39% women. 57% of cAVMs in an eloquent area, 93% at the surface site (hemispheric/corpus callosum/cerebellar) and 7% at a deep site (basal ganglia/thalamus/brainstem). Prior embolization in 36% of pts. A deep venous drainage was in 30% of cAVMs. The cAVM nidus volume PTV was divided into 3 groups: 0-2 cc (30.3%), 2.1

to 5 cc (31.6%), and > 5cc (32.5%). Mean margin dose 15 Gy ( 12-18 Gy) and the maximal 30 Gy

#### Results

##### PF

##### Obliteration

PF<1: complete 60% , partial 35%, no change 4.5%; PF 1.01-1.5: complete 43.5%, partial 47.5% , no change 9%; PF 1.51-2: complete 45%, partial 50%, no change 5%; PF > 2: 1.5% complete, partial 78.5%, no change 6.1%.

##### Rebleeding

PF <1: 2.4%; PF 1.01-1.5: 3%; PF 1.51-2: 3.8% and PF > 2 had no rebleeding,

##### Toxicity

PF <1: acute 13.5%, late 10.6% (clinical 4.7% radiological 3.5%, radiological and clinical 2.4%); PF 1.01-1.5: acute 16%, late 13% (clinical 8%, radiological 2%, clinical and radiological 3%); PF 1.51-2: acute 11.5%, late 12% (clinical 5%, radiological 3.5%, radiological and clinical 3.5%); PF > 2 : acute 17.5%, late 21% (clinical 18%, clinical and radiological toxicity 3%)

##### SM

##### Obliteration

Grade I: complete 65%, partial 35%; Grade II: 50% complete, partial 45%, no change 5%; Grade III: complete 46% , partial 46%, no change 8%; Grade IV : complete 17% , partial 72% , no change 11%, and Grade V: any complete obliteration.

##### Rebleeding

Grade I: 5%, Grade II: 1.4%, Grade III: 3%, Grade IV: 13.%, Grade V no rebleeding.

##### Toxicity

Grade I: acute 12.5%, late 8.6% (clinical 4.3% , radiological 4.3%); Grade II: acute 3.7% , late 14% (clinical 7.5%, radiological 4%, radiological and clinical 2.5%); Grade III: acute 19.5% , late 14%(clinical 4% radiological 3%, clinical and radiological 7%); Grade IV: acute 21%, late 29.5% (clinical 23.5% , radiological and clinical 6%); Grade V: acute 100%, and no late

##### Conclusion

The experience of this single Institution are consistent with those published in the literature , low rate of rebleeding, acceptable toxicity, and obliteration rate that varies with the nidus size and the prognostic factors according to the (SM) and the (PF)

#### EP-1422 Pregnancy outcomes in cancer patients received radiotherapy: a nationwide population-based study

Y.J. Chiang<sup>1</sup>

<sup>1</sup>Chang Gung Memorial Hospital- Linkou, Department of Radiation Oncology, Taoyuan, Taiwan

##### Purpose or Objective

To estimate the risks of adverse maternal outcomes in female cancer patients received radiotherapy (RT) compared with women without malignancy.

##### Material and Methods

We identified 2,350,335 singleton pregnancy using Taiwan National Health Insurance Database and Taiwan Birth Registry between 2001 and 2012, of which 607 pregnancies were in female cancer patients with RT. Odds ratios (ORs) and 95% confidence intervals (CIs) for maternal outcomes were estimated using generalized estimating equation model adjusted by maternal age, Charlson comorbidity index, urbanization, income, occupation and birth of year.

##### Results

From 2001 to 2012, pregnancies in female cancer patients received radiotherapy were associated with an adjusted OR (95% CIs) of 1.46 (1.02-2.09) for severe postpartum hemorrhage compared with women without malignancy. Otherwise there were no significant increasing risks with an adjusted OR of 0.95 (0.84-1.07) for Caesarean section, 0.56 (0.39-0.80) for preterm labor, 0.84 (0.64-1.11) for

antepartum hemorrhage, 0.48 (0.32-0.74) for pregnancy related hypertension, 0.60 (0.38-0.95) for preeclampsia, and 0.62 (0.46-0.85) for gestational diabetes.

##### Conclusion

For female cancer patients received radiotherapy, the risk of severe postpartum hemorrhage might be increased.

#### EP-1423 the evaluation of sleep quality in cancer patients following the diagnosis of a metastatic site

E. Yirmibesoglu Erkal<sup>1</sup>, D. Celik<sup>1</sup>, S. Ozmen<sup>1</sup>, G. Aksu<sup>1</sup>, H.S. Erkal<sup>2</sup>

<sup>1</sup>Kocaeli University, Department of Radiation Oncology, Kocaeli, Turkey

<sup>2</sup>Sakarya University, Department of Radiation Oncology, Sakarya, Turkey

##### Purpose or Objective

The aim of this study was the evaluate the sleep quality in cancer patients receiving palliative radiotherapy for the first time following the diagnosis of a metastatic site and to correlate the sleep quality with the depression status and the level of hopelessness.

##### Material and Methods

Forty-eight metastatic cancer patients about to receive palliative radiotherapy were evaluated using questionnaires for Pittsburgh Sleep Quality Index (PSQI), Beck Depression Inventory (BDI) and Beck Hopelessness Scale (BHS). There were 12 females and 36 males, their ages ranging from 27 to 77 years (median, 60 years). 39 patients were married and 14 patients had at least high school education. Primary tumor site was listed as the respiratory system in 14 patients and the genitourinary system in 14. The time from the diagnosis of cancer to the diagnosis of the metastatic site was less than 1 month in 17 patients, 1 to 6 months in 10 and over 6 months in 21. Radiotherapy was delivered for bone metastases in 34 patients and brain metastases in 9.

##### Results

PSQI scores ranged from 0 to 17 (median, 10) and those with scores over 8 were classified as poor sleepers. BDI scores ranged from 0 to 36 (median, 15) and those with scores over 10 were classified as having mild to severe depression. BHS scores ranged from 0 to 16 (median, 4) and those with scores less than 4 were classified as having no hopelessness at all. Accordingly, there were 30 patients who were poor sleepers, 29 who had mild to severe depression and 25 who were hopeless. There was a strong, positive correlation between PSQI scores and BDI scores which was statistically significant (p=0.002). There was no correlation between PSQI scores and BHS scores. There was a statistically significant association between poor sleep quality and single marital status (p=0.04).

##### Conclusion

Self-administered measurements such as PSQI, BDI and BHS might be used as a simple means to collect data on multiple facets of the sleep quality, the depression status and the level of hopelessness. In this study, poor sleepers were prevalent among metastatic cancer patients. Poor sleep, associated with mild to severe depression, deserves adequate medical attention in terms of supportive care

#### EP-1424 Fertility preserving high precision radiotherapy in non-uterine pelvic malignancies in female

P.S. Sridhar<sup>1</sup>, N. Madhusudhan<sup>1</sup>, K. Roopesh<sup>1</sup>, J. Vijay kumar<sup>1</sup>, M. Praveen kumar<sup>1</sup>, A. Jerrin<sup>1</sup>, A. Pichandi<sup>1</sup>, B. Ajai kumar<sup>1</sup>

<sup>1</sup>Health Care Global Enterprises Ltd, Cyberknife-Radiation oncology, Bangalore, India

##### Purpose or Objective

Fertility is major issue in non-uterine pelvic malignancies in reproductive age requiring radiation. Primary pathology

is most crucial. Malignancies which are potentially curable will always have concern for quality of life and fertility issues. High precision radiotherapy will be able to meet both ends. In this retrospective study attempt had made to reduce the dose to reproductive organs to preserve the reproductive functions.

#### Material and Methods

5 cases of non-uterine malignancies of age between 9-30 years who were treated between 2009-2014 were retrospectively analysed. 2 were sacral tumors, 1 STS of pelvis, 1 Ca rectum, 1 RMS pelvis. All of them had one or combination of surgery, chemotherapy. All of them were required radiation, 4 of them were treated with Intensity modulated radiotherapy and 1 with cyberknife.

Age at diagnosis	Diagnosis	Treatment	Dose to primary	Mean Dose to uterus	Reproductive function	Follow up	
9	RMS pelvis	Chemotherapy, Bladder preserving surgery	50Gy/25Fr IMRT	25Gy	9Gy/12 Gy	Menstruating	6 years 6 months
16	STS sacrum	surgery, chemotherapy	66Gy/33Fr IMRT	28Gy	7.7Gy/46Gy	Not Menstruating	6 years 4 months
28	STS sacrum	Surgery 2 times	60Gy/30Fr IMRT	28Gy	7Gy/10 Gy	Delivered baby	5 years 4 months
25	Ca rectum	Chemotherapy, surgery	IMRT 60Gy/28Fr	28Gy	12Gy/9 Gy	Menstruating	3 years 8 months
26	STS pelvis	Surgery, Chemotherapy	30Gy/5Fr Cyberknife	28Gy	3Gy/8 Gy	Menstruating	3 years 5 months

#### Results

Among 5 cases, all are alive, 4 pts (80%) have no disease 1 pt has recurred in postoperative area. 4 (80%) patients are having menstruation, 1 had delivered healthy baby. 1 patient having primary amenorrhoea is treated with hormones.

#### Conclusion

High precision radiotherapy in non-uterine malignancies will be able to deliver effective dose to the target, able to achieve within tolerance dose to reproductive organs. In highly selective subset of patients fertility preservation can be attempted. However proper randomised trials in this regard is warranted.

#### EP-1425 Permit to enter no-fly-zone: Risk-adapted mediastinal SBRT for oligometastases safe and effective

D. Holyoake<sup>1</sup>, R. Cooke<sup>2</sup>, K. Chu<sup>2</sup>, A. Buckle<sup>2</sup>, M. Hawkins<sup>1</sup>  
<sup>1</sup>CRUK MRC Oxford Institute for Radiation Oncology, Department of Oncology- University of Oxford, Oxford, United Kingdom

<sup>2</sup>Oxford University Hospitals NHS Foundation Trust, Department of Clinical Oncology, Oxford, United Kingdom

#### Purpose or Objective

Stereotactic Body Radiation Therapy (SBRT) to the central chest & mediastinum must be undertaken with caution due to the risks of severe toxicity that may be observed with extreme hypofractionation schedules. A risk-adapted approach uses moderated dose-fractionation schedules and IMRT to meet tolerance constraints of critical normal tissues (even at the cost of reduced coverage of PTV) aiming to achieve disease control with an acceptable safety profile.

#### Material and Methods

We analysed radiotherapy planning, clinical parameters and outcomes for twelve consecutive patients treated at our cancer centre. Nine patients received 60 Gy in 8 fractions delivered on alternate days, and three patients received 45-50 Gy in 10 daily fractions. All treatments were delivered as prescribed on a Varian Clinac iX using daily online CBCT imaging. The most common primary tumour types were colorectal (eight) or renal (two), and mean patient age was 68 years (range 38-89). Eight patients had previously undergone surgical resection (six) and/or ablation (four) of lung metastases, on up to three occasions.

#### Results

Median PTV size was 48.5 cc (range 10.7-111.4 cc) and one patient underwent treatment of two separate lesions (combined volume 42.3 cc). For eleven patients the PTV overlapped with proximal bronchial tree (PBT, comprises trachea and bronchi up to second division), and for the other patient the PTV overlapped the heart and chest wall. For the portion of PTV not overlapping organs-at-risk (OARs), mean D95 was 85.0% of prescribed dose (range 69.6-99.0%), and minimum dose to this volume was between 56.4-86.8% of prescribed dose (mean 67.7%). All mandatory OAR dose constraints were met, however the 'optimal' constraint for PBT was not possible to meet for any patient with overlap of PTV with PBT (Dmax 0.5cc < 32.0 Gy). After median follow-up of 218 days (range 14-389 days) only one patient has had in-field progressive disease; this patient subsequently died of metastatic disease. Four further patients have had distant progressive disease, including one who has died but for whom local disease was controlled at six months. One patient showed complete response on CT at 6 months, and all others have shown partial response or stable disease. No patients suffered acute toxicity affecting delivery of radiotherapy. One patient developed Grade 2 pneumonitis which resolved with steroids.

#### Conclusion

Using moderated dose-fractionation schedules and IMRT to meet tolerance constraints of normal tissues appears to enable safe and effective delivery of SBRT to central chest oligometastatic disease. Treatment resulted in very low incidence of toxicity and excellent rates of local control, though ongoing follow-up will be required to detect late toxicity and record long-term survival outcomes.

#### EP-1426 A model for internal target volume definition based on 4D-cone beam computed tomography.

M. Di Tommaso<sup>1</sup>, A. Allajbeji<sup>1</sup>, L. Caravatta<sup>1</sup>, S. Giancaterino<sup>1</sup>, G. Di Girolamo<sup>1</sup>, M.D. Falco<sup>1</sup>, D. Genovesi<sup>1</sup>  
<sup>1</sup>Ospedale Clinicizzato S.S. Annunziata, Radiotherapy, Chieti, Italy

#### Purpose or Objective

To describe the procedure to build up the internal target volume (ITV) in stereotactic body radiotherapy using 4D three-dimensional cone-beam CT (4D-CBCT) and Simmetry Elekta X-Ray volume imaging system (XVI).

#### Material and Methods

It was employed a dynamic thoracic phantom (CIRS Inc), a ball-shaped polystyrene phantom with a sphere of known volume equipped of a motor-driven platform, simulating a

sinusoidal movement with changeable motion amplitude and frequency. To simulate target motion during a normal breathing to the sphere it was applied a movement of  $\pm 5$  mm in antero-posterior and lateral direction,  $\pm 10$  mm in superior-inferior direction. The frequency of respiratory cycles was set to 1 cycle/3 seconds. A planning CT of the CIRS phantom was performed using a 3 mm slice thickness. CT images were exported to the Oncentra Masterplan (OM) version 4.3. Planning target volume (PTV) was obtained by adding an isotropic expansion of 0.8 cm to sphere (gross tumor volume, GTV) delineated on CT "lung" window and without inclusion of blurring effect. A test VMAT treatment plan with identification of the isocenter at the center of the PTV was created. A verification of the target sphere position by means of Symmetry TM was performed. 4D-CBCT was acquired and subsequently sent to the OM to verify the correspondence between volumes planning CT-based and volumes obtained on CBCT 4D and to obtain ITV-4D. GTVs were delineated on all phases of 4D-CBCT to define ITV.

#### Results

Symmetry XVI software appeared able to follow organ movements. It was found from this study that ITV4D-CBCT and PTV4D-CBCT were overlapped. The margin applied to obtain CTV was reliable.

#### Conclusion

The 4D-CBCT with Symmetry XVI was adequate in providing imaging-guidance for treatment of lung cancer and other tumors occurring in site influenced by organ motion. Symmetry XVI is a valid instrument to perform a respiratory-gated radiation therapy when 4D planning CT is not available. Actually, in our department, the applicability of this procedure on patients continues to be under investigation.

#### EP-1427 Peer reviewed radiation treatment planning process at a university hospital in a developing country

B.M. Qureshi<sup>1</sup>, A.N. Abbasi<sup>1</sup>, N. Ali<sup>1</sup>, A. Hafiz<sup>1</sup>, M.U. Karim<sup>1</sup>, A. Mansha<sup>1</sup>

<sup>1</sup>Aga Khan University Hospital, Radiation Oncology Section- Dept. of Oncology, Karachi, Pakistan

#### Purpose or Objective

The study aimed to evaluate if peer review in weekly simulation review meeting impacts the radiation therapy treatment planning process in a resource limited setting.

#### Material and Methods

The study was done at the Radiation Oncology facility of Aga Khan University, Karachi Pakistan for a period of 2 months. Simulation review meeting (SRM) was held weekly during the study to discuss all the patients being planned for radiation therapy in the presence of consultants and residents. Each patient's contour of organ at risk and treatment volumes or fields, total dose, dose per fraction, number of phases etc are discussed after being planned by primary radiation oncologist. In this study, data was recorded for patients being planned for radiation in weekly SRM in the presence of at least 2 radiation oncologist. Intent was recorded as radical or palliative and discussion for all the patients including 2-D, 3D-CRT and IMRT was noted. The study included patients of primary malignancies of different anatomic regions, treated with external beam radiation therapy at our institute except those who were planned and treated on the same day. Impact of peer reviewed SRM was recorded as 'no change', 'minor change' or major change in contour, dose, field size or intent of treatment. This data was recorded after approval of institutional ethical review committee.

#### Results

Data was collected for a total of 116 patients, out of which 96 we planned with radical intent and 20 for palliation. 61% patients were planned with 3D-CRT technique & 26%

with IMRT. Major primary sites included head and neck (40%), thorax (26%), pelvis (51%) and brain (12%). At least three radiation oncologists were present in two third meetings and changes were mostly made in with gross tumor volume or clinical target volume. It was observed that minor changes were made in 13% patients and major change was done in the plans of 9% of patients.

#### Conclusion

In this modern era of precision radiation therapy treatment planning, peer review of the planning process has a vital role. Peer review of treatment plans among radiation oncologist improves the process and recommended changes can be incorporated in the the treatment plans in a timely manner. The study shows that the review of treatment plans is a necessary quality step in radiation therapy and can be done on a weekly basis for all the patients. Hence, the quality of planning is improved in a resource limited university hospital.

#### EP-1428 Stereotactic body radiotherapy for isolated metastasis from different primitive tumors

A. Lancia<sup>1</sup>, G. Ingrosso<sup>1</sup>, A. Carosi<sup>1</sup>, L. Di Murro<sup>1</sup>, E. Giudice<sup>1</sup>, S. Cicchetti<sup>1</sup>, P. Morelli<sup>1</sup>, C. Bruni<sup>1</sup>, D. Di Cristino<sup>1</sup>, A. Murgia<sup>1</sup>, A. Cancelli<sup>1</sup>, I. Turturici<sup>1</sup>, A. Iadevaia<sup>1</sup>, R. Santoni<sup>1</sup>

<sup>1</sup>Tor Vergata University Hospital, Department of Diagnostic Imaging- Molecular Imaging- Interventional Radiology and Radiotherapy, Roma, Italy

#### Purpose or Objective

The oligometastatic state identifies a subset of patients who might be amenable to curative therapy. In this specific group of patients, Stereotactic Body Radiation Therapy (SBRT) has been shown to reach high levels of local tumor control through the delivery of high doses of radiation in few fractions, without the development of significant toxicity. Any meaningful improvement in survival remains debatable.

#### Material and Methods

From July 2007 to March 2016, 78 patients were treated at our Department with Stereotactic Radiotherapy for isolated body metastasis. The most frequent primary tumor was prostate cancer (28.2%), followed by colorectal cancer (23.1%), and lung cancer (20.5%). All patients received a radical treatment to the primary tumor site. Median time from primary tumor treatment to SBRT for oligometastatic disease was 30.3 months (range 1.07-232.3). No patient had synchronous metastases at the time of SBRT. Median age at diagnosis of oligometastatic disease was 70 years (range 47-88). Median Karnofsky Performance Status (KPS) was 90 (range 70-100). Patients were also evaluated in terms of Charlson Comorbidity Score (CCS). The most used SBRT dose fractionation scheme was 35 Gy in 5 fractions. Overall Survival (OS), Cancer-Specific Survival (CSS), and Local Control (LC) were calculated from the end date of SBRT to the end of follow-up; Progression-Free Survival (PFS) was calculated from the end date of SBRT to the first clinical progression. Treatment related toxicity was evaluated using the CTCAE version 4.0.

#### Results

Median follow-up was 22.68 months (range 1.9-95.73). One year and 2 years LC were 91% and 89%, respectively. At the time of analysis, thirty-one patients (39.7%) were free from local and systemic progression: one and 2-year PFS were 85% and 72%, respectively. CSS at one year was 93% and it was 85% at two years. One and 2-year OS were 92% and 82%, respectively. At the univariate analysis, we found that KPS  $\geq 80$  was a statistically significant prognostic factor for OS, and PFS ( $p=0.001$  for both). OS was also influenced by the primitive tumor ( $p=0.006$ ). 8

(10.2%) patients developed acute toxicity >2, while 5 patients (6.4%) developed late toxicity >2.

#### Conclusion

SBRT is a safe and effective management option for the control of oligometastatic disease. This therapeutic approach can have an important role in delaying disease progression. Toxicity seems to be moderate in most cases

#### EP-1429 maintaining efficacy of low-dose radiotherapy on pain and function in degenerative skeletal diseases

B. Alvarez<sup>1</sup>, A. Montero<sup>1</sup>, E. Sanchez<sup>1</sup>, R. Ciervide<sup>1</sup>, F. Aramburu<sup>2</sup>, M. Hernández<sup>1</sup>, M. López<sup>1</sup>, S. Rodríguez<sup>2</sup>, M. Valero<sup>2</sup>, J.J. Valero<sup>1</sup>, M. García-Aranda<sup>1</sup>, E. Calvo<sup>2</sup>, O. Hernando<sup>1</sup>, X. Chen<sup>1</sup>, R. Alonso<sup>3</sup>, P. García de la Peña<sup>2</sup>, C. Rubio<sup>1</sup>

<sup>1</sup>Hospital universitario hm madrid sanchinarro, Radiation Oncology, Madrid, Spain

<sup>2</sup>Hospital universitario hm Madrid sanchinarro, rheumatology, Madrid, Spain

<sup>3</sup>Hospital universitario hm puerta del sur, radiation oncology, madrid, Spain

#### Purpose or Objective

to evaluate feasibility and duration of response induced by low dose radiotherapy (RT) in patients with painful degenerative diseases comprising enthesiopathies or osteoarthritis refractory to any conventional treatment.

#### Material and Methods

From April 2015 to October 2016, 53 patients with painful skeletal disorders of different locations were treated; 16 (30%) patients were monitored for more than six months. The pain was evaluated before radiotherapy and 6 weeks after treatment according to the visual analogue pain scale (VAS) and the requirements of daily oral analgesic intake.

All patients underwent CT simulation and were treated in a conventional linac. PTV included the affected joint and periarticular soft tissues. Prescribed dose to the PTV was 6 Gy at 1Gy/fraction each two days. If needed, a second course similar to the previous was delivered after 6-8 weeks.

#### Results

All 16 patients were women and the average age was 68 years old. Five treatments were located on hands, 4 on knees, and the 6 remaining at diverse joints. A second course of 6 Gy was required by 50% of patients. Pre-RT median pain score according to VAS was 7.5 (range 4-9); median post-RT pain according to VAS was 1 (range 0-4). There was a reduction of more than 4 points in all patients. Eighty-one per cent of patients reported subjective clinical improvement of their joint pain; 38% of patients reduced their analgesic intake, 6% maintained the same and 31% discontinued oral analgesic.

#### Conclusion

Our results support the efficacy and safety of low-dose anti-inflammatory radiotherapy as an alternative treatment for painful osteoarticular degenerative diseases. Pain response and functional improvement maintained for long time in a substantial proportion of patients on follow-up.

#### EP-1430 Venous thromboembolism in radiation oncology: retrospective trial

M. Cherkashin<sup>1</sup>, N. Berezina<sup>1</sup>, N. Vorobyov<sup>1</sup>, E. Pinelis<sup>2</sup>

<sup>1</sup>Dr Berezin Medical Center, Oncology, Saint-Petersburg, Russian Federation

<sup>2</sup>Albert Einstein College of Medicine, Respiratory Care, New York, USA

#### Purpose or Objective

Venous thromboembolism (VTE) prevention in oncology patients during external beam radiation therapy (RT) in

outpatient setting is the challenging question. There is no clear statement from international societies (ASCO, ESMO, ACCP) and as far it is unclear if RT is an independent risk factor for VTE. Last years a couple of published trials have reported some VTE cases in this group of patients, but lack of evidence is the common problem. The objective of this study is the clear assessment of VTE incidence in these patients

#### Material and Methods

In retrospective analysis 3280 patients' medical records were included (1612 with RT and 1668 with chemotherapy). Inclusion criteria were: RT in outpatient setting, chemotherapy in outpatient setting and exclusion criteria: combined radiochemotherapy, hospitalization, central venous catheter, palliative treatment. 360 patients were selected for the final analysis and were stratified in 3 groups: group I (n=120) 3D-conformal RT for brain tumors or brain metastasis; group II (n=120) RT for body tumors (abdominal, retroabdominal, pelvic, chest, breast); group III (n=120) was control -brain and body tumors on chemotherapy. Mean fraction numbers were 25 (11 - 32), mean total dose - 52 Gy (22 - 66). VTE assessment based on clinical data, venous ultrasound examination (US) and chest CT. Statistical analysis was performed by OpenEpi, Version 3 software pack.

#### Results

Deep vein thrombosis (DVT) was detected in 7 cases (5.8%) in group I, 2 cases in group II and 1 case in control group. VTE patients has a different tumors (right parietal area astrocytoma, brain trunk tumor, skull basis cancer, rectal cancer, breast cancer). 3 patients were available for long-term outcomes assessment (12 months after radiation therapy). During 1-year period we haven't detected thrombosis recurrence. Post thrombotic disease had developed but without severe venous insufficiency. One patient on 11th follow-up month was exposed with repeated course of RT without any complications. The difference between VTE incidence for group I and group III characterized by statistical significance (p=0.018). Risk difference for these groups was 5% (p<0.05).

#### Conclusion

Based on study results we suggest that external beam radiation therapy is potentially an independent risk factor for venous thromboembolism development even in outpatient settings. High degree of clinical suspicion and aggressive diagnostic work-up in case of suspicion is necessary. In our opinion VTE prevention with low molecular weight or unfractionated heparin should be considered in selected patients at least during active radiation therapy

#### EP-1431 Acute toxicity in deep loco-regional hyperthermia

E. Burchardt<sup>1</sup>, A. Roszak<sup>2</sup>, B. Urbański<sup>3</sup>, A. Nowak<sup>3</sup>

<sup>1</sup>Greater Poland Cancer Centre, Department of Oncological Gynecology and Radiotherapy, Poznan, Poland

<sup>2</sup>Greater Poland Cancer Centre, oncological gynecology and radiotherapy, Poznań, Poland

<sup>3</sup>Greater Poland Cancer Centre, Department of Oncological Gynecology and Radiotherapy, Poznań, Poland

#### Purpose or Objective

A series of phase III trials demonstrated the clinical effect of hyperthermia. In January 2016 a new device for deep regional hyperthermia was installed in our cancer centre. The aim of this study was to assess tolerance and acute toxicity of loco-regional hyperthermia given during oncological treatment.

#### Material and Methods

101 patients (pts) were evaluated during treatment in the period of time from January till September 2016. 45 pts

with cervical cancer (CC) were treated with radical radiochemotherapy. 17 pts with CC were treated *palliative with radiotherapy*, 10 pts with hepatic lesions (1 HCC and 9 meta ad hepar) treated with chemotherapy, 7 pts with pancreatic ca treated with chemotherapy, 2 breast ca treated with chemotherapy ( 1 with RT and 1 with CT), 11pts with lung ca treated with chemotherapy , 7 pts with rectal ca. treated with radiotherapy, 4 pts with ca. of sigmoid colon treated with chemotherapy, 2 pts with gastric ca. treated with chemotherapy and 1 with radiotherapy. The Celsius TCS hyperthermia system, an electro-hyperthermia, with a maximum output of up to 500 Watts was used. Two different electrode sizes were applied externally by physical means to the region with tumour in a targeted and controlled manner. The aim was to increase the temperature to 41 °C - 42°C, one session lasted 60min. It was combined with either chemotherapy or radiotherapy twice per week. Toxicity of the skin was evaluated at every session with RTOG/EORTC classification system. The tolerance of treatment was ranged as Group 1: very good if there were 1-2 pauses because of discomfort with no other symptoms, Group 2: good- 3-4 pauses because of discomfort and skin toxicity Grade 1, Group 3: poor- > 4 pauses or shortening of hyperthermia course because of itching and skin toxicity>=Gr 2.

#### Results

Local deep hyperthermia was easily tolerated. 78 pts didn't report any problems and were assigned to Group 1. 16 pts were assigned to Group 2 and only 2 pts to the group "poor". Toxicity was generally mild and never of grade 3. 1/10 pts felt pain in the last few minutes of the session. Acute radiation toxicity was the same with or without hyperthermia. There was a reduced tolerance of hyperthermia in obese persons, with folds of skin on the abdomen. This is primarily due to the fact that between folds of skin sweat is collected what increases negative impression from temperature. All patients with tumours located in pelvis, reported pressure on the coccyx. We haven't observed any increased vaginal bleeding during radical and palliative treatment of CC.

#### Conclusion

Tolerance associated with hyperthermia was very good and most patients felt comfortable during this treatment. Acute toxicity of the skin during the treatment was low.

#### EP-1432 Advantage of butterfly-vmat versus vmat in mediastinal tumors

J. Luna<sup>1</sup>, A. Ilundain<sup>1</sup>, S. Gómez-Tejedor<sup>1</sup>, D. Esteban<sup>1</sup>, M. Rincón<sup>1</sup>, J. Olivera<sup>1</sup>, W. Vázquez<sup>1</sup>, I. Prieto<sup>1</sup>, L. Guzmán<sup>1</sup>, J. Vara<sup>1</sup>

<sup>1</sup>Fundación Jiménez Díaz, Radiation Oncology, Madrid, Spain

#### Purpose or Objective

There is a growing concern about the risks of late adverse effects in young people who receive mediastinal radiotherapy. The amazing technical advance has achieved better planned treatments. At present, the new focus of interest is to minimize the low doses in organs at risks (OARs)

#### Material and Methods

We present our first results of a new protocol in our Department for mediastinal radiotherapy. This protocol includes the comparison of two treatment plannings for every patient: volumetric modulated arc therapy (VMAT), and Butterfly VMAT (a technique developed by the University of Turin, Radiation Oncology Unit). VMAT was performed with a double arc of 360°. B-VMAT consisted of 2 coplanar arcs of 60° (gantry starting angles 150° and 330°) and 1 no-coplanar arc of 60° (gantry starting angles 330°, couch angle 90°).

Until now, five patients have been included: Three mediastinal lymphomas in young women (total dose 36 Gy in two cases and 30 Gy in the other one), one patient diagnosed of hemangiopericytoma located at internal mammary chain (total dose 50 Gy) and the fifth patient diagnosed of thymoma (54 Gy)

In the dose- volume histogram, regarding the PTV, the parameters analyzed were V95, V98, V107, Medium dose, Homogeneity index (HI) and conformity index (CI). For OARS- (heart, lung and breast) and body, several dosimetric parameters were registered.

#### Results

Our results show similar data in PTV coverage, IH and CI. Regarding the OARs, dosimetric parameters were equivalent in lung, heart and body. However, breast doses were clearly lower with B-VMAT, mainly the lowest doses (V4 and V10). For V4 , the medium value was 45.6% (7.8% - 63.1%) for VMAT and 21.5 % (0.7%- 60.1%) for B-VMAT. For V10, the VMAT medium value was 23.2% (0%- 37.2%) and the B-VMAT medium value was 8.9% (0%- 24.4%).

#### Conclusion

B-VMAT for mediastinal tumors is clearly superior to usual VMAT for breast doses, mainly the low doses, and equivalent in the rest of dosimetric parameters. Although the inclusion of more patients is needed, our preliminary results show B-VMAT like a great technical advance in mediastinal radiotherapy.

#### EP-1433 Photoneutron Flux Measurement via NAA in a Radiotherapy Bunker with an 18 MV Linear Accelerator

T. Gulumser<sup>1</sup>, Y. Ceçen<sup>1</sup>, A.H. Yeşil<sup>1</sup>

<sup>1</sup>Akdeniz University- School of Medicine, Department of Radiation Oncology, Antalya, Turkey

#### Purpose or Objective

In cancer treatment, high energy X-rays are used which are produced by linear accelerators (LINACs). If the energy of these beams is over 8 MeV, photonuclear reactions occur between the bremsstrahlung photons and the metallic parts of the LINAC. As a result of these interactions, neutrons are also produced as secondary radiation products ( $\gamma, n$ ) which are called photoneutrons. The study aims to map the photoneutron flux distribution within the LINAC bunker via neutron activation analysis (NAA) using indium-cadmium foils.

#### Material and Methods

The radiotherapy bunker hosts a Philips SLI-25 LINAC which is used for experimental studies. The measurements are taken at the highest energy of the LINAC which corresponds to 18 MeV bremsstrahlung photons. Indium and cadmium foils were used at 91 different points within the bunker. Neutron activation was performed by irradiating the room with 10000 monitor units (MU) at different gantry angles. The field was 40x40 cm<sup>2</sup> open. The activated indium foils are then counted in a High Purity Germanium (HPGe) detector system.

Since indium has a high absorption cross section for thermal and epithermal neutrons, bare indium foil irradiation results in flux information of that region. However cadmium has high absorption cross section in the epithermal and fast region. If one filters the indium foils by cadmium coatings, the difference in the count yields thermal fluxes which are of interest for the doses to the patients in radiotherapy.

#### Results

Result of the analysis shows that the maximum neutron flux in the room occurs at just above of the LINAC head towards to gun direction. This is expected since most of

the neutrons are produced when the electron beam hits the tungsten target and then the primary collimation occurs. Both the target and the primary collimator are located at the top of the gantry head. The maximum thermal neutron flux obtained is  $3 \times 10^5$  neutrons/cm<sup>2</sup>.second which is higher than a standard americium-beryllium (Am-Be) neutron source. At the isocenter plane (SSD=100 cm), the fluxes were  $5.4 \times 10^4$  at the center,  $1.5 \times 10^4$  at 2.5 m away and  $9.9 \times 10^3$  n/cm<sup>2</sup>.s at the room wall which is 3.8 m away from isocenter. The flux at the maze entrance was measured nearly six in a ten thousand less ( $81$  n/cm<sup>2</sup>.s).

#### Conclusion

The neutron flux distribution within the bunker was measured with detail using 91 points. Neutron flux distribution within the bunker found and the graph was plotted. Thus neutron flux can found any desired point in the room by iterations. The flux decreases as we move away the isocenter which is compatible with the literature. The magnitude of the neutron fluxes shows that there is a significant amount of neutron dose within the room. The corresponding neutron dose to the patient however is only 0.1-0.3 % of the total dose. However, neutrons have a high RBE and this unwanted dose is not calculated with the TPS. The future work would be to compare the results with the Monte Carlo simulations.

#### EP-1434 Comparison of small-field output factor measurements

C. Oliver<sup>1</sup>, V. Takau<sup>1</sup>, D. Butler<sup>1</sup>, I. Williams<sup>1</sup>

<sup>1</sup>ARPANSA, Radiotherapy, Yallambie, Australia

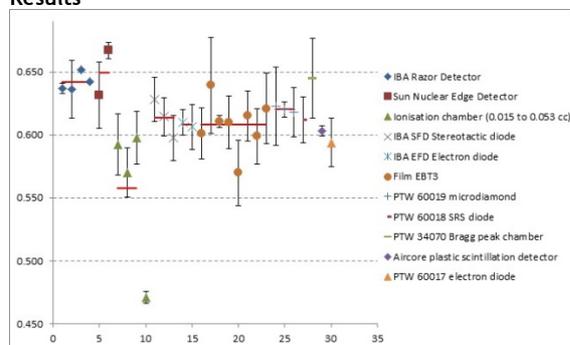

#### Purpose or Objective

The Australian Radiation Protection and Nuclear Safety Agency (ARPANSA) held a comparison in April 2016 whereby participants came to ARPANSA and measured the output factor of a 5 mm cone. The goal of the comparison was to compare the consistency of the small-field output factor measured by independent medical physicists with their own apparatus.

#### Material and Methods

The participants measured the output factor of the 5 mm cone using a 6 MV photon beam at a source to surface distance of 95 cm and depth in water of 5 cm. ARPANSA provided a 3D scanning water tank for detector positioning but all detectors were brought by participants. The participant was asked to measure the output factor as accurately as possible. All post measurement analysis, correction factor determination and uncertainty calculations were supplied by the participant.

#### Results

Fifteen groups travelled to ARPANSA and a total of thirty independent measurements of the output factor were made. The most popular method of measurement was with film but measurements were also made with ionisation chambers, semiconductor detectors, diamond detectors and a scintillation detector. A large volume ionisation chamber measuring dose area product was also used in the

comparison. The standard deviation of all the measurements was 5.6 % with the maximum variation between two results being 42 %.

#### Conclusion

This exercise gave an indication of the consistency of the small-field dosimetry being performed in Australia at the present time. There is no currently accepted protocol for these measurements and a wide range of detectors are being used with correction factors being applied from a variety of sources. The dissemination of the small-field methods and techniques currently being used will aid the consistency of these measurements.

#### EP-1435 Evaluation of single material and multi-material patient-specific, 3D-printed radiotherapy phantoms

D. Craft<sup>1</sup>, E. Burgett<sup>2</sup>, R. Howell<sup>1</sup>

<sup>1</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

<sup>2</sup>Idaho State University, Department of Nuclear Engineering, Pocatello Idaho, USA

#### Purpose or Objective

Anthropomorphic phantoms are used in a variety of ways in radiation therapy for both research and quality assurance purposes. Most anthropomorphic phantoms are of generalized patients, but 3D printing technology can be used to fabricate patient-realistic phantoms for special QA and verification procedures. Most 3D printers, however, can only print in one or two materials at a time, so true patient heterogeneity is limited. In this study, we examined two different patient specific, 3D printed phantoms created based on the same patient to determine the accuracy of single and multi-material phantoms.

#### Material and Methods

The phantoms used in this study were designed from the clinical CT data for a post-mastectomy patient treated at our institution. The CT data was trimmed to remove the patient's head and arms to preserve anonymity and simplify printing. Phantom 1 was designed by converting the trimmed CT data into a 3D model with a CT threshold of >500 Hounsfield units (HU). This model was sliced into 2.5-cm-thick sagittal slices and printed one slice at a time. All slices were printed with polylactic acid (PLA) representing all body tissues, but with air cavities and lower density regions like the lungs left open. Sagittal slices were chosen for their superior fit with each other, and minimal material warping relative to axial slices.

Phantom 2 was designed by converting the CT data into three separate 3D models with a CT threshold of <-147 HU for air cavities, -147 to 320 HU for soft tissue, and >320 HU for bone. The models were sliced into 1-cm-thick axial slices, and printed. The slices were printed from the soft tissue model using a custom formulated high impact polystyrene (HIPS) with the air and bone models left open. After printing, the open bone model sections were filled with a liquid resin polymer with an equivalent density to bone.

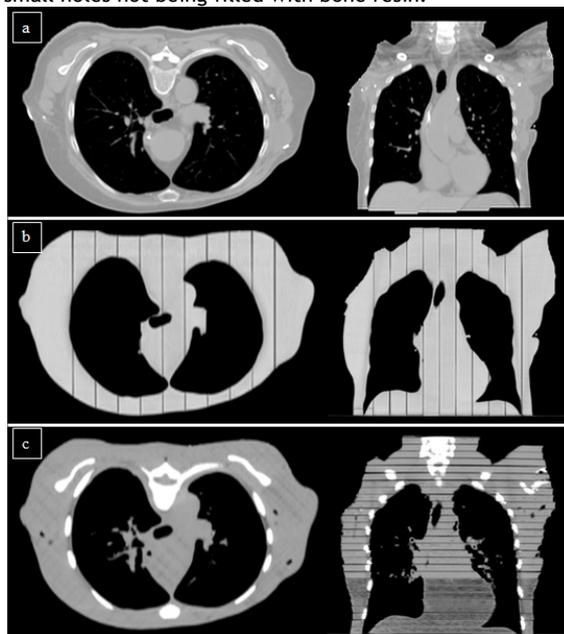

The phantoms were evaluated for their materials and overall accuracy to the original patient CT. Blocks of PLA, HIPS, and the bone resin material were all imaged to determine their average HU. The phantoms were also each imaged and registered with each other and the original patient CT to determine the consistency and accuracy of each phantom.

#### Results

The materials used and their properties are summarized in Table 1. Phantom 1 was fabricated from PLA, which isn't particularly tissue equivalent, but did print relatively consistently. The bone resin and HIPS of phantom 2 more accurately reflect tissue heterogeneity, but have more variations in their printed consistency.

Table 1	Mean HU±SD	Physical Density(g/cm <sup>3</sup> )
PLA	160±12	1.22
HIPS	-127±60	0.98
Bone Resin	680±67	1.48

Figure 1 shows registered images of the original patient image (a), phantom 1 (b), and phantom 2 (c). Tissue density was more accurate in phantom 2, despite some small holes not being filled with bone resin.

#### Conclusion

Two phantoms were created, one with a single material, and a second with two materials (tissue and bone). These two phantoms provide an ability to more closely simulate the patient and provide a means to more accurately measure dose delivered in a patient surrogate.

#### EP-1436 A newly designed water-equivalent bolus technique enables BNCT application to skin tumor.

K. Hirose<sup>1</sup>, K. Arai<sup>1</sup>, T. Motoyanagi<sup>1</sup>, T. Harada<sup>1</sup>, R. Shimokomaki<sup>1</sup>, T. Kato<sup>1</sup>, Y. Takai<sup>1</sup>

<sup>1</sup>Southern TOHOKU BNCT Research Center, Radiation Oncology, Koriyama, Japan

#### Purpose or Objective

The accelerator-based boron neutron capture therapy (AB-BNCT) system was developed in order to enable the installation of safe hospital BNCT. An important feature of AB-BNCT system is its capability of delivering great doses to deep-seated tumors under condition in which a beryllium target and neutron-beam-sharpening assembly are adjusted for production of epithermal neutron that is applicable for more types of tumor localization. Conversely, AB-BNCT is less suitable for superficial cancers, such as malignant melanoma. In this study, we developed a newly water-equivalent bolus technique that has no production of prompt gamma ray and no influence on complicating dose calculation, and we evaluated the effect of this technique on treatment quality for a case of malignant melanoma patient.

#### Material and Methods

A water-equivalent bolus was prepared as follows. Urethane foam was cut down into the size of 3-cm larger than the superficial lesion, infiltrated with distilled water with deaeration, and covered with a thin film. The simulated patient was played by a healthy man and simulated condition was originated from a malignant

melanoma patient with the lesion of 3-cm diameter localized in a sole of right foot. The superficial lesion was bordered by a catheter and covered with a water-equivalent bolus. Using treatment planning system SERA, the tumor is depicted as a region surrounded by the catheter with 5-mm thickness, and also skin is depicted as the other region except for tumor with 3-mm thickness from body surface. A water-equivalent bolus was delineated as water. This was placed into air in calculation in condition with no bolus. For comparison with bolus-like effect of a covered collimator, the outline of an imaginary collimator cover was set as a mass of polycarbonate or a water tank filled with water with 20-50-mm thickness. For calculation of photon-equivalent dose (Gy-Eq), blood 10B concentrations, 10B tumor/blood concentration ration, and CBE factor for 10B(n, $\alpha$ )7Li reaction were assumed to be 25 ppm, 3.5, 4.0. Tolerance dose of the skin was regarded as 18 Gy-Eq.

#### Results

In condition with no bolus, irradiation time was 121.6 min, and tumor Dmax and Dmean were 125 Gy-Eq, and 74.3 Gy-Eq, respectively. In condition with water-equivalent bolus technique, irradiation time was 72.1% decreased (33.9 min) compared with no bolus condition. Also tumor Dmax and Dmean were 54.4 Gy-Eq and 45.0 Gy-Eq, and the dose homogeneity was dramatically improved. Skin Dmax became greatly less than tolerable dose (11.5 Gy-Eq, 59.6% decrease). The bolus-like effect of covered collimator with a mass of polycarbonate or water tank was not sufficient. Dose homogeneity and irradiation time was largely worse than the condition with a water-equivalent bolus.

#### Conclusion

Although this study was examined for a single case of melanoma patient, our results revealed that water-equivalent bolus technique could have a great effectiveness on dose improvement of AB-BNCT for superficial cancers.

#### EP-1437 New Cobalt-60 system for reference irradiations and calibrations

C.E. Andersen<sup>1</sup>

<sup>1</sup>DTU Nutech Technical University of Denmark, Center for Nuclear Technologies, Roskilde, Denmark

#### Purpose or Objective

Cobalt-60 plays an important role as reference beam quality in radiation dosimetry and radiobiology. Only few systems are available on the commercial market for the therapeutic dose range (-1 Gy/min), and it is therefore of interest for research and calibration laboratories that a new irradiator (Terabalt T100 Dosimetric Irradiator) has been introduced by UJP Praha, Czech Republic. In 2013, DTU Nutech in Denmark acquired the first unit of this new model, and the purpose of this contribution is to report on (i) the main characteristics of this gamma irradiator found during the commissioning work, and on (ii) additional developments carried out in order to apply the irradiator for highly precise, automated (i.e. computer controlled) irradiations.

#### Material and Methods

The irradiator has a fixed horizontal beam axis about 110 cm above the floor. A collimator system enables field sizes from 5x5 cm<sup>2</sup> to 40x40cm<sup>2</sup> at the reference point at 100 cm from the source. The irradiator is equipped with a GK60T03 cobalt-60 source having an activity of 250 TBq corresponding to a dose rate of about 1.1 Gy/min at the reference point (Sep. 2016). The source is fully computer controlled. A special rig of 10x10 cm<sup>2</sup> aluminum profiles has been designed in collaboration with UJP Praha. This rig is equipped with a water-tank lift and an xyz-stage for precise positioning of ionization chambers and other dosimeters at the reference point. An optical system is

used for alignment and positioning. The xyz-stage also allows for scanning and accurate field-size measurements at the reference position. The system has been characterized using an ensemble of 11 thimble ionization chambers of the types PTW 30013, IBA FC65G, NE 2571, and NPL2611.

#### Results

Automated procedures were implemented for measurement of absorbed dose to water calibration coefficients. Source irradiations and positioning was found to be highly reproducible. The relative standard deviation of dose-rate measurements with the 11 ionization chambers was less than 0.03% within each specific measurement session carried out over a period of 120 days. The collimator and the shutter systems were characterized using randomized tests run continuously over 24 h periods. Setting the field size to different values in a random order resulted in a relative standard deviation for dose rates within each field size of less than 0.05%.

#### Conclusion

The ability to computer control irradiations has enabled development of automatic calibration and measurement procedures. This in turn has resulted in an improved quality of measurements and implementation of more comprehensive measurement sequences relative to what would have been feasible using an irradiator system with only manual source control. The special rig and the optical alignment system allowed for precise (better than 0.1 mm) positioning of ionization chambers. The system was therefore found to be highly suitable for research and calibrations involving ionization chambers and other dosimeters used in radiotherapy.

#### EP-1438 Experimental determination of correction factors for reference dosimetry in Gamma Knife Perfexion

E. Zoros<sup>1</sup>, E.P. Pappas<sup>1</sup>, K. Zourari<sup>2</sup>, E. Pantelis<sup>1</sup>, A. Moutsatsos<sup>1</sup>, G. Kollias<sup>3</sup>, C.I. Hourdakis<sup>2</sup>, P. Karaiskos<sup>1</sup>  
<sup>1</sup>National and Kapodistrian University of Athens, Medical School - Medical Physics Laboratory, Athens, Greece  
<sup>2</sup>Greek Atomic Energy Commission, Division of Licensing and Inspections, Athens, Greece  
<sup>3</sup>Hygeia Hospital, Gamma Knife Center, Athens, Greece

#### Purpose or Objective

To experimentally determine machine-specific reference

$$K_Q^{f_{msr}, f_{ref}} / Q_0$$

(msr) field correction factors (CFs) for a set of commercially available ion chambers and two dosimetry phantoms which are commonly used for the calibration of the Gamma Knife Perfexion (GK PFX) radiosurgery unit.

#### Material and Methods

Measurements were performed for both plastic spherical phantoms, referred to as acrylonitrile butadiene styrene (ABS) and Solid Water (SW), which are used in GK PFX reference dosimetry. CFs were obtained for IBA CC01, IBA CC13, PTW 31010 and Exradin A1SL ion chambers using the formalism proposed by Alfonso *et al.* (2008) for the dosimetry of small and non-standard photon fields. The determination of absorbed dose to water in phantom material for the msr field (16mm collimator size) was performed using EBT3 radiochromic films and alanine pellets as reference passive dosimeters whose calibration is traceable to a primary standard and do not exhibit substantial beam quality dependence. However, in order to determine absorbed dose to water in water, film and alanine measurements were corrected using phantom-dose conversion factors obtained by Monte Carlo simulations using a recently introduced EGSnrc simulation

model. Special custom made inserts to accommodate ion chambers and alanine pellets were fitted into the inserts of the ABS and SW phantoms. Detectors' central axis was aligned with the z axis of GK PFX stereotactic space for SW measurements, while placed on x-y plane for the ABS phantom. A scanning technique was implemented for the accurate alignment of detectors' reference point of measurement with GK PFX radiation focus. In order to estimate statistical uncertainties of the CFs five measurements were performed for each detector. Regarding ion chambers, measurements were averaged for positive and negative polarity and the obtained readings were corrected for ion recombination, temperature and pressure effects.

#### Results

For the majority of ion chambers in SW phantom CFs were up to 1.01, except of the IBA CC01 were a correction of 4% is needed mainly due to perturbation of the high density central electrode. Regarding ABS phantom larger corrections are needed up to 1.05 for IBA CC01 and CC13 and up to 1.02 for PTW 31010 and Exradin A1SL, attributed to the different orientation of the detectors in GK PFX stereotactic space.

#### Conclusion

An experimental procedure is proposed for the determination of CFs for the GK PFX radiosurgery unit and CFs were determined for a set of ion chambers allowing for accurate dosimetric measurements.

Acknowledgement: This work was financially supported by the State Scholarships Foundation of Greece through the program "Research Projects for Excellence IKY/SIEMENS".

#### EP-1439 Small field dosimetry: preliminary characterization of a nano-chamber with a focus on stem effect

A. Stravato<sup>1</sup>, G. Reggiori<sup>1</sup>, P. Mancosu<sup>1</sup>, F. Lobefalo<sup>1</sup>, L. Paganini<sup>1</sup>, F. Zucconi<sup>1</sup>, V. Palumbo<sup>1</sup>, S. Tomatis<sup>1</sup>, M. Scorsetti<sup>1</sup>  
<sup>1</sup>Istituto Clinico Humanitas, Department of radiotherapy and radiosurgery, Rozzano Milan, Italy

#### Purpose or Objective

Micro and nano-chambers cannot be as small as solid state detectors but present some advantages in terms of energy independence and absolute dose measurement that make them fundamental for small field dosimetry in the SBRT scenario. A preliminary characterization of a nano-chamber prototype (Razor Nanochamber, IBA) was carried out with a particular focus on stem effect. Response under 10 MV FFF beams was observed too.

#### Material and Methods

The study included characterization of leakage, dose rate and dose per pulse dependence, measurement of small beam profiles, and depth dose curves. Profiles were acquired both in orthogonal (i.e chamber axis orthogonal to beam axis) and parallel (i.e chamber axis parallel to beam axis) configuration. Ten repeated inline profile measurements were performed in head-foot and foot-head direction to better quantify the stem effect. Ion collection efficiency and polarity effects were measured. The values of  $P_{ion}$  were verified with  $1/V$  versus  $1/Q$  curves (Jaffé plots). The 6 MV and 10 MV FFF photon beams of a Varian EDGE were used. Output factors for small fields were compared with Razor Diode (IBA) and FOD scintillator values.

#### Results

The 2mm diameter guarantees a very high spatial resolution comparable to some commercially available diodes, with penumbra values 0.5-0.8mm larger than those measured with a Razor Diode for the same fields (Figure 1). When used with the chamber axis perpendicular to the beam axis a strong stem (and cable) effect was observed leading to asymmetric inline profiles

for small fields. Furthermore a difference was observed between profiles performed in head-foot or foot-head direction (Figure 2). Dose rate dependence was found to be <0.3% while dose per pulse dependence showed an increasing trend but still <0.6% for a maximum dpp of 0.2 cGy/pulse. At the nominal operating voltage of 300 V the Razor Nanochamber exhibits a field size dependence of the polarity correction > 2% between the 1x1cm<sup>2</sup> and the 40x40cm<sup>2</sup> field. The OF values were compared with diode and scintillator measurements and show a good agreement for fields >20x20 mm<sup>2</sup>. For smaller fields the volume effect is huge and leads to strongly underestimated values.

#### Conclusion

Razor chamber is an interesting option for small field measurements. Its use in orthogonal configuration raises some stem effect issues evident when measuring inline profiles. More measurements are required in order to fully characterize this ion-chamber.

#### EP-1440 Monte Carlo determination of scintillator quenching effect for small radiation fields

G. Valdes Santurio<sup>1</sup>, C. E. Andersen<sup>1</sup>

<sup>1</sup>Technical University of Denmark, Nutech, Roskilde, Denmark

#### Purpose or Objective

Fiber-coupled organic plastic scintillator detectors are excellent for measurement of the absorbed dose to water in small MV photon fields. This is mostly because their small active volume and their high degree of water equivalence result in an almost negligible perturbation of the radiation field. However, plastic scintillators are less ideal when we consider the signal generation and the signal detection. For the signal generation, it is known that the light yield per absorbed dose for electrons below 100 keV produces less light than electrons with higher energy which is the so-called ionization density quenching. The objective of this work was to investigate the potential implication of this quenching effect for output factor measurements in small 6MV photon beams. Monte Carlo modelling was used to compute changes in light production for different field sizes using Birks formula applied to electrons.

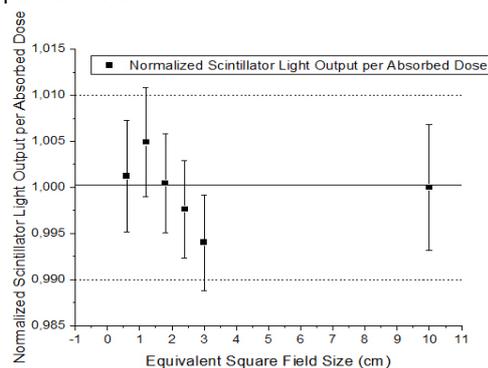

#### Material and Methods

The quenching effect can be predicted by the Birks' formalism which relates the amount of light per distance travelled by a given particle to the ionization density from that particle as expressed by the collision stopping power of the medium (dE/dx). This formalism introduces the quenching parameter (*k<sub>B</sub>*), which describes that the light produced by low energy electrons is not proportional to its deposited energy. We implemented Birks formula in a modified version of the application *egs\_chamber* which is part of the EGSnrc Monte Carlo system. The modified application scored the light output over the absorbed dose for each field size. This ratio will give us how much the quenching effect affects for that specific field size and therefore, differences of the quenching effect when changing the field size can be estimated. Moreover, this ratio will give us how much the scintillator output factor changes when the quenching effect is taken into account. We computed light yields for square field sizes down to 0.6x0.6cm<sup>2</sup> with 10x10cm<sup>2</sup> as reference.

#### Results

The light output over the absorbed dose was calculated for all field sizes. The uncertainty of all values was less than 0.5%. Figure 1 shows the normalized scintillator light output per dose for all field sizes and their respective uncertainties (1 standard deviation). The straight line represents the mean of all the obtained values and the dashed lines represent 1% of deviation with respect to the reference. As can be deduced from the figure, all the

ratios fell inside the range of +/- 1% of the deviation respect the reference.

#### Conclusion

The study shows that for this specific value of *k<sub>B</sub>* studied and all the limitations of the model, the quenching effect will not significantly affect the scintillator output factor measurements in small 6 MV photon fields, and the quenching correction factor will be therefore close to the unity (*u*=1%). The impact of the stem signal (i.e. Cerenkov and fluorescence light produced in the optical fiber cable during irradiations) therefore remains the main influencing factor on such measurements.

#### EP-1441 Repurposing of a small clinical x-ray source for radiobiology irradiations

M. Barry<sup>1</sup>, R. Jones<sup>1</sup>, M. Fay<sup>1</sup>, D. Butler<sup>2</sup>, J. Lehmann<sup>1</sup>

<sup>1</sup>Calvary Mater Newcastle, Department of Radiation Oncology, Newcastle- NSW, Australia

<sup>2</sup>Australian Radiation Protection and Nuclear Safety Agency, Radiation Therapy Section, Yallambie, Australia

#### Purpose or Objective

Around the clock availability of irradiation capability is desirable for creative design of radiobiology experiments. Clinical radiation systems are often only available after hours. Dedicated commercial cell irradiation systems are bulky and expensive. They might not be feasible due to financial or administrative constraints.

This work reports on the repurposing of a retired clinical intraoperative kV irradiation system (Intrabeam™) for cell irradiations.

#### Material and Methods

The Intrabeam system is designed to deliver spherical dose distributions to surgical cavities. The in the adaption for cell irradiations, one of the supplied applicators has been modified to be fitted with custom collimators aiming to deliver a homogenous field across the cell dish. Several collimator designs have been tested and measured using radiochromic EBT3 film. Additionally, measurements without a collimator were done in comparison and to support Monte Carlo simulations. Film calibrations were performed with national standard beams covering the energy range of the device. The BEAMnrc code and the 'NRC swept BEAM' source model have been used to characterize the dose distributions and to aid collimator development.

#### Results

Using the film measurements, the parameters of the Monte Carlo source model (swept angle and beam radius) were tuned to produce the final model. Very good agreement between measured and simulated dose profiles for the open source at 5, 7.5 and 10 cm distance from the tip was observed. (Figure 1)

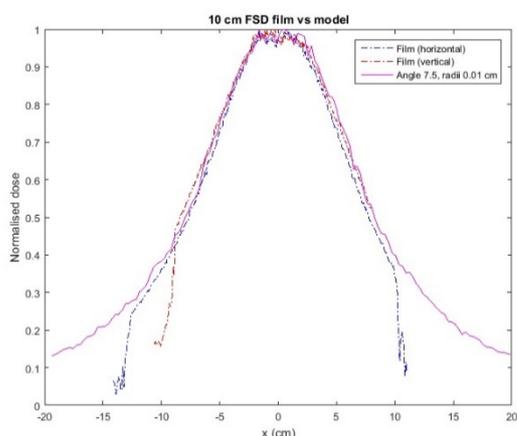

Figure 1: Profiles of the dose distributions 10 cm from the open tip of the source (no collimator) as measured with EBT3 film and simulated using the BEAMnrc Monte Carlo code.

Measurements with steel and aluminum collimator designs identified desirable characteristics for a suitable collimator: a long extension beyond the tip of the source and a diameter beyond the projected field size.

Based on measurements and simulations, a cell culture plate irradiation rig has been designed and built, allowing for radiobiology experiments with different cell dishes and incorporating film measurements to verify dose delivery. (Figure 2)

Figure 2: Cell irradiation rig with Intrabeam, collimator and 96 well cell culture plate.

#### Conclusion

The repurposed x-ray system will allow for flexible irradiation of cell cultures for radiobiology experiments. Future plans include extension to small laboratory animal irradiations, as the unique design with the source of radiation being at the tip of an extended metal tube allows for high dose rates to small fields when in close proximity to the target.

#### EP-1442 Fricke and Polymer gel dosimeters for radiotherapy pre-treatment 3D dosimetry

G.M. Liosi<sup>1</sup>, L. Trombetta<sup>2</sup>, P. Salmoiraghi<sup>2</sup>, M. Mariani<sup>1</sup>, F. Locatelli<sup>2</sup>, E. Bombardieri<sup>2</sup>

<sup>1</sup>Politecnico di Milano, Energy- Nuclear Engineering Division, Milano, Italy

<sup>2</sup>Cliniche Humanitas, Gavazzeni, Bergamo, Italy

#### Purpose or Objective

Pre-treatment dosimetry represents a fundamental step for the verification of radiation therapy outcome, and, in particular, an accurate and precise measurement of the 3D dose distribution with high spatial resolution has become of paramount importance. Aim of this work was the study and characterization of two gel-dosimetry systems (Fricke- and Polymer-gels), suitable for volumetric patient-specific 3D dosimetry.

Fricke-gel dosimeters are based on the dose dependent oxidation of  $\text{Fe}^{2+}$  ferrous ions -dispersed into a tissue equivalent gel matrix- into  $\text{Fe}^{3+}$  ferric ions. Thus, the  $\text{Fe}^{3+}$  concentration is linearly related to the absorbed dose. The MRI acquisition of gels through T1-weighted images permits measurement of  $\text{Fe}^{3+}$  concentration, obtaining at the same time the absorbed dose mapping within the irradiated volume. On the other hand, as regard Polymer-gel dosimeters, a dose-dependent polymerization occurs, hence dose assessment and spatial information can be obtained by means of T2-weighted MRI analysis.

#### Material and Methods

A preliminary optimization of the chemical composition for both Fricke/Polymer- gel dosimeters was performed. Afterwards, the calibration method, MRI (1.5T) acquisition and reconstruction parameters were set for each system to optimize the dose sensitivity and the Signal-to-Noise Ratio. In particular, geometrical distortion, image homogeneity, artifacts, image texture, dose accuracy and resolution, limit of detectability (LOD) and quantification (LOQ),  $\text{Fe}^{3+}$  spatial diffusion (Fricke-gels) and dose rate dependence were evaluated. Finally, a pre-treatment dosimetry of a SBRT plan was acquired and a relative planar profiles comparison with a standard dosimeter (Gafchromic EBT2) was performed. Ad hoc Matlab codes were developed for images analysis.

#### Results

The chemical composition, MRI acquisition and reconstruction parameters were optimized for each gel system. No image correction maps were needed, since geometrical distortion, artifacts and inhomogeneity were always negligible, and no dependence on photon beam dose rate was observed. 3D spatial resolution (voxel dimension) was  $1 \times 1 \times 3 \text{ mm}^3$ . Dose accuracy was under 4% in the range 18-25Gy, but worst for lower doses. Dose resolution was about 1Gy, while LOD was less than 0.5Gy. Differences between gel systems and Gafchromic profiles' FWHMs were in the range 0,5mm - 5,5mm, mean dose deviations in flat region were always around 2%, while penumbra differences were about 2mm. Negligible diffusion and time effects were observed up to 3 hours from irradiation for all gel systems.

#### Conclusion

This study showed that both Fricke/Polymer- gel dosimeter could be a suitable tool to perform pre-treatment QA, with particular focus on SBRT and SRS treatments, thanks to their optimal spatial resolution, their practicability and their capability to perform 3D dosimetry. Further studies are ongoing to standardize a protocol to perform 3D pre-treatment dosimetry.

#### EP-1443 Measurement of 3D dose distributions from an MR Linac with gel dosimetry

Y. Roed<sup>1,2</sup>, L. Pinsky<sup>1</sup>, G. Ibbott<sup>2</sup>

<sup>1</sup>University of Houston, Physics, Houston, USA

<sup>2</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

#### Purpose or Objective

To demonstrate the potential value of polymer gels to measure 3D dose distributions delivered with an MR-image guided radiotherapy delivery machine.

### Material and Methods

Polymer gels were obtained from MGS Research Inc (Madison, CT) in custom-designed glass cylinders of 4 cm height and 5 cm diameter. Irradiations were delivered with a non-clinical MR-linac pilot system (MR-Linac, Elekta AB, Stockholm) that combined a 1.5 T MR scanner with a 7 MV linac. Two dosimeters were positioned separately in a phantom with their midplanes at isocenter distance. A total of 750 MU (~5 Gy) was delivered with 3x3 cm<sup>2</sup> fields at three gantry positions. The gantry was positioned at 0°, 90°, and 180° for the first irradiation and at 0°, 270°, and 180° for the second irradiation. All four cardinal angles weren't feasible due an asymmetric phantom design.

MR images across the entire volume of the dosimeter were acquired with a 3T GE scanner using a 2D spin echo sequence (TR = 1000 ms, TE = 10, 20, 60, 100 ms) 24h after irradiation. Spin-spin relaxation rate (R2) maps were generated. Both field size and penumbra widths were calculated on the central slice. R2 maps were concatenated into a 3D matrix.

The experiment was performed while the magnet of the MR component (B-field) was turned off and will be repeated once the B- field is turned back on.

### Results

The small fields were captured and resolved within each dosimeter. The field width measured along the central cross-plane R2 profile from each dosimeter was 28 mm and 29 mm, respectively. The penumbra widths were 5 mm at both field edges in each dosimeter. The 3D R2 matrix visualized the irradiated volume of the dosimeter well.

In order to study the influence of the B-field on the dose distribution in 3D, the results in the presence and absence of the MR component (B-field) will be compared and presented.

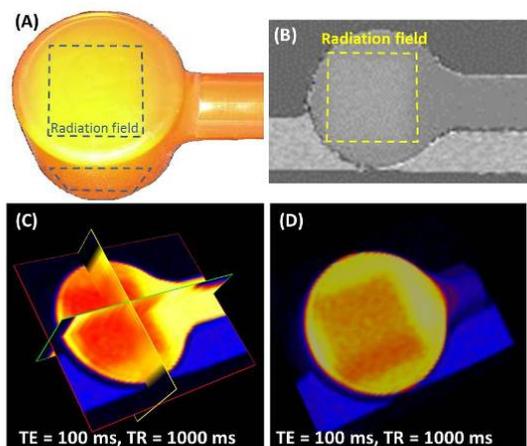

Figure 1: Polymer gels irradiated at three gantry positions:

(A) Un-irradiated (darker) and irradiated (brighter) dosimeter; dashed squares indicate radiation field with gantry at 0° and 90°.

(B) R2 map of central slice; radiation field shown as square.

(C) Cross-sectional slices of the T2 image; un-irradiated (yellow) and irradiated (red) dosimeter; blue – holder for dosimeter, black – air.

(D) 3D volume from concatenated T2 images; yellow – un-irradiated, red – irradiated, black – air, blue – holder for dosimeters

### Conclusion

Polymer gels offer an excellent means to measure 3D relative dose distributions delivered with an MR-Linac in a clinically relevant fashion.

Previous experiments with polymer gels have already shown that steep dose gradients could be measured when irradiated with an MR-Linac. The current study encourages further study of polymer gels for measuring 3D dose distributions in the presence of B-fields.

### EP-1444 Reliable error detection in radiochromic film dosimetry with optimal density curves and corrections

H. Park<sup>1</sup>, Y. Bae<sup>2</sup>, J. Park<sup>3</sup>, M. Kim<sup>1</sup>, Y. Oh<sup>1</sup>, M. Chun<sup>1</sup>, O. Noh<sup>1</sup>, O. Cho<sup>1</sup>, J. Lee<sup>2</sup>

<sup>1</sup>Ajou University Medical Center, Dept. of Radiation Oncology, Suwon, Korea Republic of

<sup>2</sup>Konkuk University Medical Center, Dept. of Convergent Medical Physics and Dept. of Radiation Oncology, Seoul, Korea Republic of

<sup>3</sup>University of Florida, Dept. of Radiation Oncology, Gainesville, USA

### Purpose or Objective

To minimize variation of dosimetric errors caused by correction methods and to suggest optimal conditions in radiochromic film dosimetry using a flatbed scanner, feasible scanning and post analysis procedures were investigated with impacts on error detection in gamma analysis.

### Material and Methods

When a rectangular piece (5 × 4 cm) of EBT3 film was placed at a 5 cm depth of the water-equivalent solid water phantom, doses were delivered to film pieces from 0 cGy to 20 Gy with every 50 cGy under 500 cGy and 100 cGy over 500 cGy. To find an optimal sensitometric curve having a large range of optical density (OD) and linearity in doses of interest, a set of exposed films was scanned in a flatbed scanner with different conditions by adjusting brightness, contrast, and highlight from -50 to 50. Sensitometric curves of a red and a green channel were obtained with each scanning condition and used to compare gamma distributions. In addition, to clarify the effects of applicable corrections, particularly for light scattering and non-uniform responses between a film layer and a panel, dose errors before and after correction were visualized and quantified. Each effect by sensitometric curves and correction methods on detection of dose errors in gamma analysis was evaluated in a square field of 10 cm, a 45° wedged field, and an intensity-modulated field for prostate cancer.

### Results

Both sensitometry curves of the red and the green channel could reach two times higher OD of 2.2 at 20 Gy and the gap of OD was gradually more distinguishable over 4 Gy in scanning with high contrast. The sensitometric curve of green channel showed differentiated linearity in the dose range under 2 Gy. The difference in the gradient of OD brought out maximum 10% difference of gamma passing rate in both wedged and intensity-modulated fields. The primary positions of failed points in gamma analysis were different according to sensitometric curves. When the optimal sensitometric curve was applied, uniformity correction caused maximum 8% difference in gamma passing rate.

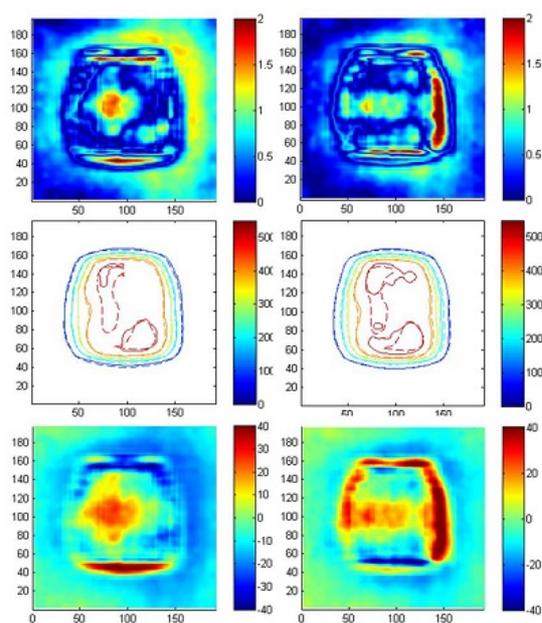

Figure. Effects of sensitometric curves obtained with different scanning parameters on gamma analysis. First and second column show sensitometric curves at high and low contrast. Each row shows gamma distributions, isodose lines of film (solid line) and calculated (dotted line) doses, and dose differences, respectively.

### Conclusion

The application of different sensitometric curves and correction methods caused errors in detected failed points and passing rates in radiochromic film dosimetry. This can lead misinterpret detected dose errors in quality assurance. It is significant to apply the optimal sensitometric curve with appropriate correction methods, especially in modulated radiation fields for reliable and accurate film dosimetry.

### EP-1445 Performance evaluation of scintillators for SiPM PET/MRI Brain Imaging

N. Campos Rivera<sup>1</sup>, B. Seitz<sup>1</sup>

<sup>1</sup>University of Glasgow, School of Physics & Astronomy, Glasgow, United Kingdom

### Purpose or Objective

The combination of PET and MRI has shown a great potential to study the processes and progression of diseases, such as cancer and Alzheimer's, as well as to control and observe novel treatments response. In the last decade, whole-body hybrid systems have been manufactured, such as the Biograph mMR by Siemens. However, this apparatus tend to be very expensive and to have limited performance on the neurological field. Thus, a brain-dedicated portable PET insert with MRI compatibility seems to be worth to investigate

### Material and Methods

Recently, a SiPM with electronics integrated on cell level has been developed: the Philips Digital Photon Counting (PDPC). This device delivers a digital signal of the detected photon counts as well as their timestamp, making it a potential candidate for PET applications. During this work, the performance of several scintillation materials (GAGG, LYSO, LUAG and BGO) coupled with the PDPC was studied. Each PDPC module has 64 channels of 3.2 x 3.8 millimeters, comprising 3200 cells of 59.4 x 64 micrometers and each scintillator crystals is 3 x 3 x 30 millimeters, polished on all faces with five of them covered with a white reflective coating. Analysis on the intrinsic performance of the SiPM (IV curves, temperature dependence, crosstalk) and energy and time resolution for every scintillator was carried out.

### Results

Results showed that LYSO was the best candidate and so detector blocks of this material were manufactured and used to examine the behaviour of a full insert ring. The experimental setup consisted on two 4x4 LYSO arrays coupled to the PDPC. Each crystal of the array was 7 x 7 x 20 millimeters, fitting perfectly the size of the PDPC dies. The detector blocks were placed facing each other and separated by 30 mm with a Na-22 source in the middle and rotating at a 30 degrees steps to imitate the geometry of a ring of the PET insert. The outcome was used to create a GATE simulation that explores the behaviour of this insert in the presence of strong magnetic fields. Such simulation involves the design of a ring device that moves along the patient axis and the calculation of the detection efficiency varying the geometry and speed of the apparatus.

### Conclusion

Our findings show an adequate coupling of the PDPC with the LYSO arrays and the simulation corroborates an appropriate functionality of the detection system inside an MRI machine. The next study phase involves the construction of a prototype for real testing.

### EP-1446 Can parallel plate ion chambers be used for PDD measurements in FFF beams?

S. Vargas Castrillón<sup>1</sup>, F. Cutanda<sup>2</sup>

<sup>1</sup>Lanarkshire Beatson West of Scotland Cancer Centre, Radiotherapy Physics, Airdrie, United Kingdom

<sup>2</sup>Western General Hospital, Oncology Physics, Edinburgh, United Kingdom

### Purpose or Objective

The IAEA TRS-398 code of practice for radiation dosimetry recommends measuring photon percentage depth-dose (PDD) curves with plane-parallel ion chambers. This code of practice was published before flattening-filter free beams became widely used in clinical practice. This choice of detector for PDD measurement should be re-assessed for FFF beams, as the effect of recombination and polarity factors, among others, could lead to differences. The purpose of this work is to assess the use of plane parallel ion chambers for PDD measurements in FFF beams, and to compare them with other chamber types.

### Material and Methods

Beams from Varian TrueBeam linacs, 6 FFF and 10 FFF were used for this study. Depth dose curves (SSD=100cm) were acquired with a PTW 31010 Semiflex, two small volume chambers (Scanditronix-Wellhofer CC04 and PTW 31016 Pin Point 3D), PTW 34001 Roos, Scanditronix-Wellhofer Roos and NACP 02 parallel plate chambers. Measurements were carried out both in a PTW MP3 and an IBA Bluephantom2 water tanks with PTW Tandem, PTW Unidos E and CCU electrometers. PDD scans with plane parallel ion chambers were acquired and corrected for ion recombination. In order to apply this correction, recombination factors were measured with the two voltage technique for different depths and field sizes. The effect of polarity was evaluated using both polarities for measurements. Measurements with different detectors were carried out for a set of field sizes, ranging from 5x5 to 40x40 cmxcm and SSD 100 cm SSD.

### Results

It was found that parallel plate chambers show the closest agreement between PDD curves acquired with different polarities, being the differences below 0.1% for all depths and 40x40 cmxcm.PDDs for one single polarity and different ion chambers have been corrected for recombination and compared. The largest difference in PDD among different ion chambers, once corrected for recombination, has been found for the Scanditronix Roos chamber at 350 mm deep (excluding build up) for all field sizes, which would amount to: 0.7% for 6 FFF and 0.6% for

10 FFF for a 40x40 cmxcm field. Differences between recombination corrected and uncorrected PDDs, and among PDDs measured with different detectors, increase with field size. Differences between recombination-corrected and uncorrected PDDs were found ranging from 1.2% for PTW Semiflex ion chamber to 2.5% for PTW Roos ion chamber, both measured for a 40x40 cmxcm at 350 mm deep.

#### Conclusion

Results show that plane parallel ion chambers can be used for photon PDD measurements, with minimal polarity effects, if recombination effects are corrected for as needed. Medical physicists should use their own clinical judgement to decide about whether or not PDDs must be corrected for saturation effects.

#### EP-1447 Dose Determination in a CT Control Room Using TLD and Monte-Carlo-Method-Based FLUKA Code

A.H. Yeşil (Turkey), M.G. Aksu, Y. Ceçen

<sup>1</sup>Akdeniz University- School of Medicine, Department of Radiation Oncology, Antalya, Turkey

#### Purpose or Objective

Computer Tomography (CT) scan is a diagnostic process where patients are exposed to X-rays on the order of hundred keVs. X-rays interact with different structures of the body such as bone, soft tissue, lung etc. They also interact with other materials present in the room. At the end they are either absorbed or scattered out of the room. The CT rooms are designed with sufficient shielding and licenced by the local authorities however, it is always a good idea to check for weak spots and ensure that the radiologists are working in a safe environment. This study aims to map the radiation dose in the CT control room and determine the weak spots, if any.

#### Material and Methods

The work was carried out with both thermoluminescent dosimeters (TLDs) and Monte Carlo method based FLUKA code. The radiation dose received by the radiologists has been measured by the TLDs and the results were compared with the Monte Carlo simulations.

In this study, a third generation 4-slice helical GE Light SpeedRT CT scanner was used. Scanner has a 80 cm wide gantry opening and its standart operation is at 120 kV.

TLD-600s were used as passive dosimeters. 15 of them were located in different positions within the control room. 30 patients were scanned in a week by 120 kV X-rays for a total of 90 minutes. Calibrations and readouts were performed by PTW-TLDO TLD oven and RADOS RE2000 TLD reader.

FLUKA Code was used to model the CT and the room around. The doses at the TLD locations were obtained by the simulation.

#### Results

The mean value of the TLD measurements was 2.54  $\mu$ Sv/week. FLUKA simulation results had a mean dose of 2.2 $\pm$ 0.2  $\mu$ Sv/week. Maximum X-ray dose in the control room was measured just behind the door 3.73  $\mu$ Sv/week. The FLUKA simulations also agreed with the measurements, 3.4 $\pm$ 0.3  $\mu$ Sv/week.

#### Conclusion

Results of this study show that radiologists receive weekly doses under the limits (0.1 mSv/week) which is compatible with the literature. Study also shows that the CT model of the FLUKA code is accurate and can be used in various X-ray dose studies.

#### Electronic Poster: Physics track: Dose measurement and dose calculation

#### EP-1448 Epid-based in vivo dosimetry for SBRT-VMAT treatment dose verification

S. Cilla<sup>1</sup>, A. Ianiro<sup>1</sup>, M. Craus<sup>1</sup>, P. Viola<sup>1</sup>, A. Fidanzio<sup>2</sup>, L. Azario<sup>2</sup>, F. Greco<sup>2</sup>, M. Grusio<sup>2</sup>, F. Deodato<sup>3</sup>, G. Macchia<sup>3</sup>, V. Valentini<sup>4</sup>, A. Morganti<sup>5</sup>, A. Piermattei<sup>2</sup>

<sup>1</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"-

Università Cattolica del Sacro Cuore, Medical Physics Unit, Campobasso, Italy

<sup>2</sup>Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Medical Physics Department, Roma, Italy

<sup>3</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"- Università Cattolica del Sacro Cuore, Radiation Oncology Unit, Campobasso, Italy

<sup>4</sup>Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Radiation Oncology Department, Roma, Italy

<sup>5</sup>Università di Bologna, Radiation Oncology Center- Department of Experimental- Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

#### Purpose or Objective

In vivo dosimetry (IVD), a direct method of measuring radiation doses to cancer patients during treatment, has shown unique features to trace deviations between planned and actually delivered dose distributions. Extracranial stereotactic radiotherapy (SBRT) involves the delivery of high doses in a few fractions (1-5) for ablative purposes. Then SBRT treatments strongly benefit from IVD procedures, as any uncertainties in dose delivery is more detrimental for treatment goals or patient safety. We assessed the feasibility of EPID-based IVD for complex clinical VMAT treatments for SBRT.

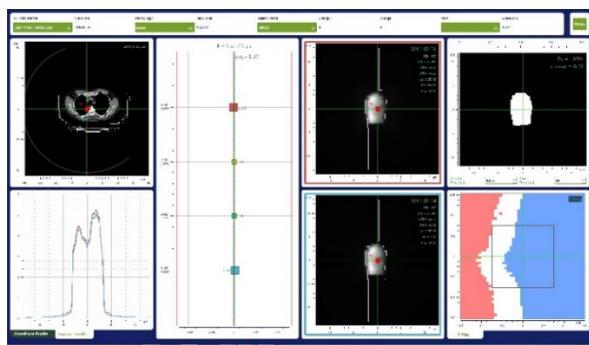

#### Material and Methods

15 patients with lung, liver, bone and lymphnodal metastases treated with Elekta VMAT were enrolled. All plans were generated with Masterplan Oncentra and Ergo++ treatment planning systems (Elekta, Crawley, UK) with a single 360° arc VMAT. All targets were irradiated in 5 consecutive fractions, with total doses ranging from 40 to 50 Gy depending on anatomical sites. All patients passed pre-treatment 3%/3mm g-analysis verification. IVD was performed using SOFTDISO (Best Medical Italy), a dedicated software implemented in our clinic for conformal, IMRT and VMAT techniques. IVD tests were evaluate by means of (i) R ratio between isocenter daily in-vivo dose and planned dose and (ii)  $\gamma$ -analysis between EPID integral portal images in terms of percentage of points with  $\gamma$ -value smaller than one ( $\gamma\%$ ) and mean g-values ( $\gamma$ mean), using a global 3%-3 mm criteria. Alert criteria of  $\pm 5\%$  for R ratio,  $\gamma\% < 90\%$  and  $\gamma$ mean  $> 0.67$  were chosen, the last two in order to accept only 10% of the values to exceed 3%/3mm and an average discrepancy of the order of 2%/2mm, respectively.

#### Results

A total of 75 transit EPID images were acquired. Five images (6.6%) were removed from analysis for image deterioration and/or electronic acquisition failures. The overall mean R ratio was equal to 0.999  $\pm$  0.021 (1 SD) for all patients, with more than 98% of tests within 5% alert criteria. The 2D portal images g-analysis show an overall  $\gamma$ mean of 0.29 $\pm$ 0.13 with 100% of tests within alert criteria, and a mean  $\gamma\%$  equal to 96.9 $\pm$ 5.2% with 96.0% of tests within alert criteria. In contrast to our past experience of patients with head-neck and pelvic treatments, where the systematic use of IVD revealed some discrepancies due to major anatomical variations or random anatomical changes in terms of filling of

rectum/bladder, no relevant discrepancies were detected in SBRT patient. The results are supplied in quasi real-time, with IVD tests performed and displayed after only 1 minute from the end of arc delivery. Figure 1 shows the SOFTDISO user interface.

### Conclusion

The present EPID-based IVD algorithm provided a fast and accurate procedure for SBRT-VMAT delivery verification in clinical routine, with results obtained 1 minute after each arc delivery. This strategy allows physics and medical staff to promptly act in case of major deviations of dose delivery.

### EP-1449 The effect of a build-up screen on superficial dose in total body irradiation

L.S. Fog<sup>1</sup>

<sup>1</sup>Rigshospitalet, The Clinic of Oncology, Copenhagen, Denmark

### Purpose or Objective

In total body irradiation (TBI), a build-up screen is typically positioned between the linac and the patient to reduce the build-up effect in the patient skin. With the implementation of step and shoot TBI (SS TBI), the dose conformity is considerably improved compared with TBI delivered with open fields. Thus, the delivery of an accurate skin dose becomes pertinent. We measured and calculated skin dose for a range of TBI conditions.

### Material and Methods

The dose was measured in a 20 cm thick solid water phantom using a NACP parallel plate chamber, and a PTW Unidos electrometer. The energy response from the chamber contributed no more than 5% to the measurement uncertainty (Phys Med Biol. 2001 Aug;46(8):2107-17).

The dose was measured at a depth of 1 mm in the phantom; for a range of SSDs (340-440 cm); for 6 and 18MV; and for open jaw fields (used in conventional TBI treatments) and MLC defined fields (used in SS IMRT); and with and without a lucite build-up screen of 16 mm thickness, placed 20 cm from the phantom. The MLC fields were created with a 3 cm distance from the phantom edge to the field edge when projected to the isocentre. The chamber was calibrated by measurements under standard reference conditions.

The doses were calculated using Eclipse™ (Varian Medical Systems, Palo Alto), AAA algorithm, v.13.6, with a 1 mm calculation grid.

The difference between measured and calculated doses  $\Delta_{\text{meas, calc}}$ , between jaw and MLC fields  $\Delta_{\text{jaw, MLC}}$ , and with and without build-up screen  $\Delta_{\text{b, no b}}$  were determined.

### Results

For jaw fields,  $\Delta_{\text{meas, calc}}$  is reduced from 0-22% to 0-9% when using a build-up screen (table 1).

For MLC fields,  $\Delta_{\text{meas, calc}}$  increases from 10-31% to 4-48% when using a build-up screen.

With the exception of the scenario with jaws and a build-up screen,  $\Delta_{\text{meas, calc}}$  increased with SSD.

The considerable  $\Delta_{\text{meas, calc}}$  values could arise from inaccurate beam modelling in the build-up region; with the modelling less accurate for MLC fields. For MLC fields,  $\Delta_{\text{meas, calc}}$  increased with increasing SSD, perhaps due to an underestimation of the scatter contribution from MLC fields at extended SSD.

The jaw fields gave rise to a greater dose than the MLC fields. The calculation underestimated  $\Delta_{\text{jaw, MLC}}$  with a build-up screen, while it overestimated it without a build-up screen.

Doses were greater with than without a build-up screen in all the scenarios investigated.  $\Delta_{\text{b, no b}}$  was not considerably different between the calculation and the measurement.

$\Delta_{\text{b, no b}}$  was greater for 18X than for 6X.

Table 1. Measured and calculated doses in a 20x40x40 cm solid water phantom determined 1 mm from the face of the phantom facing the linac, for a range of SSDs, for 6 and 18X, with jaw and MLC defined fields, and with and without a build-up screen.

### Conclusion

The presence of a build-up screen increases superficial phantom dose. However, differences of up to 48% exist between calculated and measured doses at the phantom surface. These differences generally increase with SSD and depend on beam energy and field type (jaw vs MLC) in a complex way. The modelling of scatter from MLC fields at large SSDs appears to be a particular challenge.

### EP-1450 Implementation of dosimetry equipment and phantoms in clinical practice of light ion beam therapy.

L. Grevillot<sup>1</sup>, J. Osorio<sup>1</sup>, V. Letellier<sup>1</sup>, R. Dreindl<sup>1</sup>, A. Elia<sup>2</sup>, H. Fuchs<sup>3</sup>, A. Carlino<sup>4</sup>, S. Vatnitsky<sup>1</sup>, H. Palmans<sup>5</sup>, M. Stock<sup>1</sup>

<sup>1</sup>EBG MedAustron GmbH, Medical Physics, Wiener Neustadt, Austria

<sup>2</sup>EBG MedAustron GmbH / University of Lyon France, Medical Physics, Wiener Neustadt, Austria

<sup>3</sup>EBG MedAustron GmbH / Medical University of Vienna, Medical Physics, Wiener Neustadt, Austria

<sup>4</sup>EBG MedAustron GmbH / University of Palermo Italy, Medical Physics, Wiener Neustadt, Austria

<sup>5</sup>EBG MedAustron GmbH / National Physical Laboratory UK, Medical Physics, Wiener Neustadt, Austria

### Purpose or Objective

QA equipment (water phantoms, films, ionization chambers, anthropomorphic phantoms, etc.) is generally delivered and accepted based on certificates provided by the manufacturer and only minimum testing is performed. At MedAustron, advanced acceptance testing procedures of the QA equipment were additionally developed and implemented by medical physicists. QA equipment passing

the advanced acceptance testing procedure was further commissioned. This work consolidates preliminary understanding for range and spot measurement equipment (Grevillot et al, PTCOG2016), using additional data obtained during beam delivery commissioning (e.g. long term reproducibility of QA equipment). Additional detectors were also commissioned, such as a 2D array of ionization chambers and a diamond detector. The commissioning methods developed allowed determining the accuracy of the QA devices in clinical conditions and better define the QA tolerances for periodic quality assurance of the beam delivery system. The purpose of this work is to guide medical physicists in the implementation of dosimetry equipment and associated phantoms as a pre-requisite to acceptance testing, commissioning and further QA checks of the facility itself.

#### Material and Methods

A x-ray check was carried out for each ionization chamber to verify the integrity of its construction. Positioning accuracy of the water phantom scanning mechanism was evaluated in 3D against laser tracker measurement. Range measurement equipment was carefully calibrated by measuring the entrance WET of the device. Long term reproducibility of a multi-layer ionization chamber detector used for daily QA of beam ranges was determined and used to define morning QA tolerances of the beam delivery system. Spot measurement equipment was evaluated in terms of spot size, position and 2D homogeneity against radiochromic films. Transverse profiles acquired in water with diamond detector were evaluated against pin-point detectors (Figure 1). An ionization chamber-based 2D array was evaluated in terms of effective depth of measurement, recombination, 2D homogeneity and absolute dose against ROOS chamber. Extensive commissioning procedures were developed specifically for each piece of QA equipment, based on its intended use.

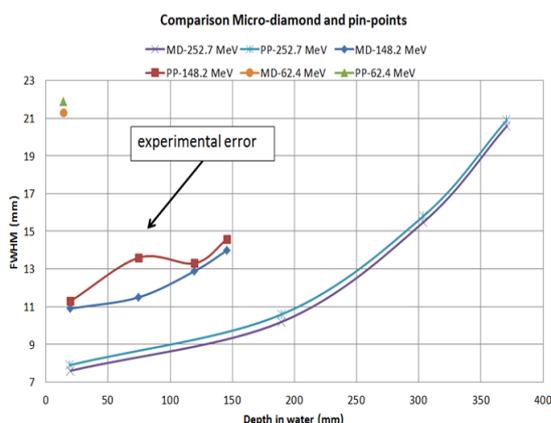

Figure 1: comparison of measured spot sizes between micro-diamond and pin-points in water at 62.4, 148.2 and 252.7 MeV.

#### Results

The advanced acceptance testing procedures developed resulted in the identification of defects in several devices from different manufacturers before clinical use. The commissioning procedures allowed maximizing the performance of the QA equipment and consequently the quality of medical commissioning activities. Main overall uncertainties are presented in Table 1.

Equipment	Parameter	Proton energy range (MeV)	Uncertainty (k=1)
3D water phantom	Absolute range	60 - 250	0.2 - 0.6 mm
	Absolute position in 3D	60 - 250	0.8 mm
	Position reproducibility in 3D	60 - 250	0.1 mm
Water column	Absolute range	60 - 250	0.2 - 0.6 mm
	Reproducibility	60 - 250	<0.2 mm
Multi-layer ionization chamber	Absolute range	60 - 250	0.5 mm
	Reproducibility	60 - 250	<0.3mm
Film dosimetry	Relative dosimetry	60 - 250	2.80%
	Absolute dosimetry	60 - 250	3.60%
Scintillating screen	Absolute spot size	60 - 250	0.2 mm
	Absolute spot position	60 - 250	0.3 mm
	Homogeneity in 2D (10cmx10cm)	60 - 250	<2%
2D array	Homogeneity in 2D (20cmx20cm)	60 - 250	<3.5%
	Homogeneity in 2D (20cmx20cm)	60 - 250	<2%
	Effective depth	60 - 250	0.5 mm

Table 1: Overall uncertainties of range and spot parameters established at MedAustron

#### Conclusion

The procedures implemented at MedAustron significantly improved the knowledge and the performances of the dosimetric equipment and therefore the quality of medical commissioning activities at the facility. Our experience shows that commissioning of QA equipment is a necessary step towards high precision radiation therapy.

#### EP-1451 Validation of local tolerances for VMAT patient specific QA using the IBA Compass system

E. Crees<sup>1</sup>, R. Hulley<sup>1</sup>, G. Kidane<sup>1</sup>, Y. Miao<sup>1</sup>

<sup>1</sup>Queen's Hospital, Department of Medical Physics, Romford, United Kingdom

#### Purpose or Objective

The aim of this study was to review the locally set tolerances for VMAT Head and Neck, Brain and Prostate and Pelvic Nodes patient specific QA using the IBA COMPASS MatriXX<sup>evolution</sup> measurements and computations with the IBA COMPASS<sup>®</sup> system. Radiotherapy treatment planning requires independent verification of both the treatment planning system (TPS) dose calculation and the patient dose delivery system. The verification of the dose delivery system can be carried out independently to the TPS dose calculation (in which case individual treatment plans may be verified using a 2<sup>nd</sup> calculation alone) or can be incorporated into individual patient specific measurements. The pass/fail tolerances of patient specific QA using the Compass system have been set locally. The calculation method verification tolerance was set for the comparison between the Compass dose calculation and the treatment planning system calculation. The measurement method verification tolerance was set by comparing the MatriXX<sup>evolution</sup> measured dose to the treatment planning system calculated dose.

#### Material and Methods

A retrospective study was performed on Head and Neck, Brain and Prostate and Pelvic Nodes VMAT plans that were produced on the Eclipse TPS using the AAA algorithm. Each treatment plan was re-calculated using the Compass software and the dose distribution of each plan was measured using the Compass MatriXX<sup>evolution</sup>. Subsequently, the Compass computed and measured dose distributions were compared to the TPS calculated plan using gamma index analysis. Bland Altman statistical analysis was employed to compare gamma index results of the Compass calculated and Compass measured dose distributions. The analyses were performed based on the agreement between the treatment planning system compared to the measurement and Compass calculations. The tolerances were set on absolute dose difference (2% for computation and 3% for measurement on all points) and global gamma index assessment (2%/2 mm criterion for 98% of points - computation and 3%/3mm criterion for 95% of point - measured).

## Results

Across all treatment sites, the mean gamma index was 99.6% for the calculated dose and 98.3% for measured dose. For each of the treatment sites evaluated, the computed dose typically showed closer agreement with the Eclipse TPS calculation than the measured dose. This study demonstrated that for the Prostate and Node treatment site the average difference in gamma index between the computed and measured dose was within -0.51%. This was -1.22% and -2.02% for Head and neck and Brain treatment sites respectively.

## Conclusion

This result verified that the IBA Compass system is sufficiently accurate and has been adopted for RapidArc treatment plan verification based on either measurements, computation or both.

## EP-1452 Evaluation of a collapsed-cone algorithm in a commercial software for in vivo volumetric dosimetry

J. Gimeno Olmos<sup>1</sup>, V. Carmona<sup>1</sup>, F. Lliso<sup>1</sup>, B. Ibanez-Rosello<sup>1</sup>, J. Bautista<sup>1</sup>, J. Bonaque<sup>1</sup>, J. Perez-Calatayud<sup>1</sup>  
<sup>1</sup>Hospital Universitari i Politecnic la Fe, Radiotherapy department, Valencia, Spain

### Purpose or Objective

Dosimetry Check (DC) (Math Resolutions) commercial software performs pre-treatment and transit EPID-based dosimetry. It provides a verification of treatments, being of interest due to the benefits of the *in vivo* volumetric dosimetry, which guarantee treatment delivery and anatomy constancy.

In this study, the performance of a newly introduced collapsed-cone (CC) dose calculation algorithm is evaluated, as compared with the currently available pencil beam (PB) algorithm and with a conventional Treatment Planning System (TPS) and ionisation chamber measurements.

### Material and Methods

The commercial version of DC (v.4.11) is only CE and FDA cleared for PB algorithm. The CC algorithm is being used as a beta version (v.5.1).

To test if the CC algorithm considers heterogeneities correctly, measurements were done in the IMRT Thorax Phantom (CIRS), which simulates a human thorax. It has several inserts for ionisation chamber measurements.

Six plans were generated, similar to the already published work for the PB commissioning (Phys Med 30: 954-9). Three with the isocentre in the phantom centre (isocentre A, tissue equivalent): (1) four open 10x10 cm static fields in box configuration, (2) 10x10 cm rotational field, (3) typical lung clinical treatment (patient A); and three centred in the phantom's left lung (isocentre B): (4) and (5) equivalent to (1) and (2), (6) typical lung clinical treatment (patient B).

The plans were delivered in a Clinac iX (Varian) accelerator equipped with EPID aS1000, acquiring cine images, which were then converted to fluence by DC to finally calculate dose with PB and CC algorithms. The plans were also calculated in the TPS Eclipse v.13.0 (Varian) with AAA and Acuros XB algorithms.

Calculated point doses were compared against ionisation chamber measurements, performed in the isocentre for each plan with a PinPoint chamber model 31006 (PTW).

DC dose distributions were also evaluated against TPS (Acuros algorithm) using 3D gamma analysis (3% global/3 mm) for the structure defined by the 95% isodose.

### Results

Results are shown in table 1. As expected, CC algorithm improves PB results, mainly in isocentre B where the heterogeneities have greater effects. For isocentre A, the mean difference improves from 0.6% for PB to -0.2% for CC, while for isocentre B, it improves from 6.5% to -0.8%. A very significant improvement in the gamma analysis is

also observed. Figure 1 shows an example of dose distribution.

It has to be mentioned that the calculation time for CC algorithm is of the order of hours, making this algorithm not yet suitable for routine patient verifications. An improvement is expected by the manufacturer to allow GPU calculations.

Table 1. Measured PinPoint doses, relative dose difference (%) for the calculation with DC and Eclipse, and percentage of points passing the 3D gamma analysis (3% global/3 mm) for the structure defined by the 95% isodose.

Iso	Plan #	Plan type	Measured D (Gy)	Relative dose difference (%)				Gamma index (%)	
				Eclipse		Dosimetry Check		PB	CC
				AAA	Acuros	PB	CC		
A	1	Box	6.335	-0.5	-2.7	1.1	-0.2	61.9	89.1
	2	Arc	1.596	-1.5	-2.8	0.2	-0.7	67.2	93.6
	3	Patient A	2.547	-1.3	-0.8	0.4	0.2	65.5	78.2
B	4	Box	6.836	-3.2	-2.2	5.2	-0.8	15.9	99.8
	5	Arc	1.690	-4.4	-2.8	3.6	-2.2	18.5	98.7
	6	Patient B	2.293	-3.3	-4.3	10.6	0.7	11.7	58.7

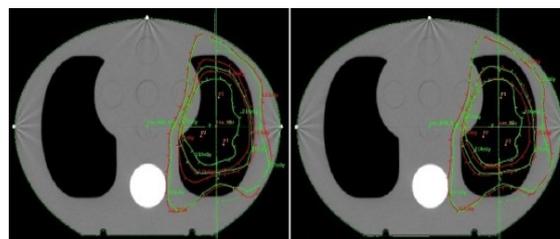

Figure 1. Patient B dose distribution (red = DC, green = Eclipse Acuros). Left, using PB, Right using CC.

### Conclusion

The possibility of *in vivo* evaluation and the potentiality of this new system have a very positive impact on improving patient QA. CC algorithm provides much better results in heterogeneous cases, but it is at the cost of a higher computation time. Improvements are also required in the integration of DC with the R&V system.

## EP-1453 Modeling a carbon fiber couch in a commercial Treatment Planning System

R. Gómez Pardos<sup>1</sup>, D. Navarro Jiménez<sup>1</sup>, A. Ramírez Muñoz<sup>1</sup>, E. Ambroa Rey<sup>1</sup>, M. Colomer Truyols<sup>1</sup>  
<sup>1</sup>Consorci Sanitari de Terrassa CST, Radiotherapy, Terrassa, Spain

### Purpose or Objective

With the increased use of carbon fiber couch tops and the raise of techniques like VMAT with considerable dose delivered from posterior angles, currently their modeling is strongly recommended (Report of AAPM Task Group 176).

The main objective of this work is to model the iBEAM® evo Couchtop in the TPS Monaco. The second goal is to assess the overall impact of not using the couch in VMAT calculations comparing gamma passing rates with an Octavius4D phantom (PTW, Freiburg, Germany).

### Material and Methods

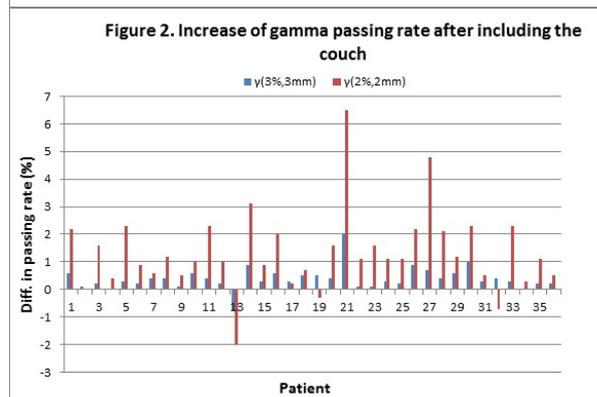

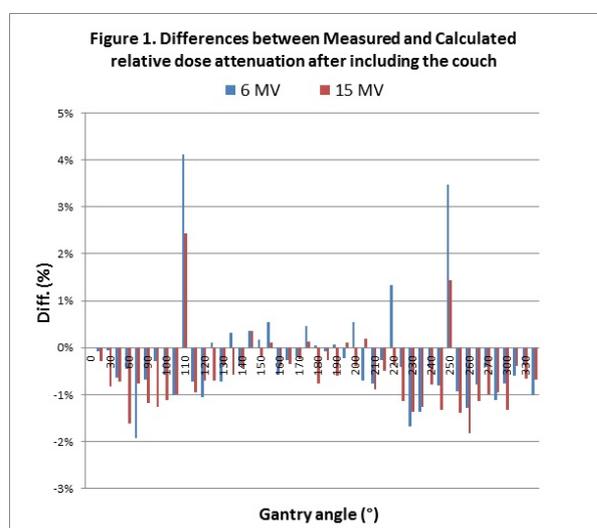

The modeling was made for an Elekta Synergy LINAC with Agility head equipped with the iBEAM couch. The EasyCube homogeneous phantom (Euromechanics Medical GmbH, Nuremberg, Germany) was placed centered on the couch and aligned with the isocentre. The charge was measured with a Farmer ionization chamber every 5 gantry degrees, 100 MU/field, 10x10 cm<sup>2</sup> field size, for both 6 and 15 MV. All the measurements were corrected by pressure and temperature. The relative to zero gantry degree attenuation was calculated for every gantry angle analyzed. Previously the absolute dose at 0 gantry angle was measured.

The couch was modeled by an outer shell of carbon fiber (CF) and an inner part of foam (Foam). The same measured fields were calculated in the Monaco TPS with the Monte Carlo algorithm, 1% Statistical Uncertainty per Control Point, 2 mm grid spacing, dose to water. Then the

relative electron density (rED) of both CF and Foam volumes was adjusted iteratively to match the measured and calculated dose attenuation in several angles. Finally 36 VMAT patients of different pathologies previously irradiated on the Octavius4D phantom were compared with the calculated plans both with and without couch. The gamma passing rates of both cases were compared to determine the overall impact of including the couch in the calculations.

### Results

The rED densities that best reproduced the measured values were  $0.5\rho_{e,w}$  and  $0.1\rho_{e,w}$  for both CF and Foam, respectively (see Figure 1). The agreement between measured and calculated attenuation is good, mainly in the posterior angles, with differences under 1%. At 110 and 250 gantry degrees we measured differences up to 4.2% and 2.4% for both 6 and 15 MV, respectively. These angles match the lateral edges of the couch, where there are many different components, which make this simplified model less accurate.

For the 36 VMAT plans we compared the 3D global gamma passing rates with (W) and without (W/O) the couch, and the average results were (detailed in Figure 2):  $\gamma(3\%,3\text{mm})$ : W/O: 98.9%, W: 99.3%;  $\gamma(2\%,2\text{mm})$ : W/O: 92.5%, W: 93.8%. The median improvement is 0.3% for  $\gamma(3,3)$  and 1.1% for  $\gamma(2,2)$ .

### Conclusion

Relying on the results, it is advisable to implement the treatment couch in the TPS, especially using techniques such as VMAT. In this work we present a successful model of the iBEAM® evo Couchtop in Monaco for both 6 and 15 MV. We plan to implement it for all our both 3D and IMRT/VMAT plans.

### EP-1454 Comparison of Treatment Planning Algorithms and Monte Carlo Simulations in Oesophageal Radiotherapy

D. Johns<sup>1</sup>, E. Spezi<sup>2</sup>, P. Downes<sup>1</sup>, D. Lewis<sup>1</sup>

<sup>1</sup>Velindre Cancer Centre, Medical Physics, Cardiff, United Kingdom

<sup>2</sup>Cardiff University, School Of Engineering, Cardiff, United Kingdom

### Purpose or Objective

Many workers have published comparisons of dose distributions generated by conventional radiotherapy planning systems and those produced by various Monte Carlo (MC) dose calculation packages [1]. However, due to the large computational load involved in producing each MC plan, the number of cases cited in each study is relatively small and hence the statistical power of these studies is low. In this work, distributed computing resources have been used to simulate over fifty oesophageal radiotherapy treatment plans, to provide a more statistically powerful comparison of analytical dose calculations and MC dose calculations.

### Material and Methods

Radical oesophageal radiotherapy plans are routinely produced in our centre according to a protocol originally developed for the national SCOPE trial [2]. Plans were produced using the Pencil Beam Enhanced (PBE) algorithm, and re-calculated using the Collapsed Cone Enhanced (CCE) algorithm, of Oncentra MasterPlan (OMP) v4.3. MC simulations were performed using the BEAMnc package.

### Results

An initial sample of 12 oesophageal radiotherapy treatment plans were simulated using the RTGrid system. The differences between the dose calculation methods, and the variance in the twelve cases, were used to calculate the sample size needed to detect a 3% difference in the proportion of the Planning Target Volume receiving 95% of the prescription dose (PTV V95%) with 90% power, following the method of Altman [3]. The required sample size was determined to be 38, so a further 40 oesophageal cases were subsequently simulated. The volumetric dose data for the different dose calculation methods was used to calculate the Tumour Control Probability (TCP) using the method of Geh [4].

### Conclusion

A statistically significant decrease in the PTV V95% when changing from CCE to MC dose calculations has been demonstrated, in a sample of 40 cases. A statistically significant decrease in the values of TCP calculated based on the CCE and MC dose calculations was also found, suggesting that the differences in physical dose would have clinical significance.

### EP-1455 IGRT kV-CBCT dose calculations using Virtual Source Models and validated in phantoms using OSL

G. Boissonnat<sup>1</sup>, H. Chesneau<sup>1</sup>, J. Garcia-Hernandez<sup>1</sup>, D. Lazaro<sup>1</sup>

<sup>1</sup>CEA-LIST, DM2I/LM2S, GIF SUR YVETTE, France

#### Purpose or Objective

With the growing use of X-ray imaging equipment in Image-Guided RadioTherapy (IGRT), the need to evaluate the dose-to-organs delivered by kV-CBCT imaging acquisition increases. This study aims to propose accurate Monte Carlo (MC) calculations of the patient dose-to-organs delivered by two commercially available kV-CBCT systems: the XVI from Elekta's VERSA HD accelerator and the OBI from Varian's TrueBeam system. Simulations are to be validated using in phantom OSL measurements.

#### Material and Methods

For both kV-CBCT systems, the kV irradiation head geometry was implemented in the MC simulation code Penelope. As a first step, the resulting photon distributions were expressed as Virtual Source Models (VSM) for every standard irradiation condition (kVp, filtration, collimation); it was then validated and adjusted using in water-phantom measurements performed with a calibrated Farmer-type ionization chamber.

In a second step, the validated VSMs were used to simulate the dose delivered by both the XVI and OBI systems in anthropomorphic phantoms, using standard clinical imaging protocols. Simulated dose-to-organs were then confronted to dose measurements performed using OSL inserted into the same phantoms, following a dosimetric protocol for OSLs previously established [1].

In addition, VSM results were confronted to their direct MC counterparts in order to evaluate the benefit of using such technique.

#### Results

The current study highlights the possibility to reproduce OSL dose-to-organ measurements using VSM-driven Monte Carlo simulation with an overall agreement better than 20%. In addition, the use of VSM in the MC simulation enables to speed-up the calculation time by a factor better than two (for the same statistical uncertainty) compared to direct MC simulation. Nevertheless, if direct and VSM calculations are in agreement inside the irradiation field, outside, VSM results tend to be significantly lower (10-30%).

#### Conclusion

The use of a VSM was demonstrated to simplify and fasten MC simulations for personalized kV-CBCT MC dose estimation. In addition, OSLs enable to perform the low dose measurement in the kV range needed for in phantom X-ray imaging equipment dose QA.

This study is to be completed in the near future by the addition of other standard X-ray imaging equipment dedicated to IGRT.

### EP-1456 In-vivo dosimetry using Dosimetry Check: 5-year experience on 345 prostate cancer patients

W.H. Nailon<sup>1</sup>, D. Welsh<sup>1</sup>, K. MacDonald<sup>1</sup>, D. Burns<sup>2</sup>, J. Forsyth<sup>2</sup>, G. Cooke<sup>1</sup>, F. Cutanda<sup>1</sup>, D.B. McLaren<sup>3</sup>, J. Puxeu-Vaque<sup>1</sup>, T. Kehoe<sup>1</sup>, S. Andiappa<sup>1</sup>

<sup>1</sup>Edinburgh Cancer Centre Western General Hospital, Department of Oncology Physics, Edinburgh, United Kingdom

<sup>2</sup>Edinburgh Cancer Centre Western General Hospital, Department of Radiography, Edinburgh, United Kingdom

<sup>3</sup>Edinburgh Cancer Centre Western General Hospital, Department of Clinical Oncology, Edinburgh, United Kingdom

#### Purpose or Objective

It is recommended that all radiotherapy centres in the United Kingdom (UK) have a protocol for in vivo dosimetry

(IVD) and in several European countries IVD is now mandatory. Electronic portal imaging devices (EPIDs), which although developed primarily for the purposes of imaging, are now widely used for IVD and consequently for treatment quality assurance (QA). Here we present results from 5-year clinical experience of using IVD for verification of prostate cancer patients.

#### Material and Methods

Between 2011 and 2016 IVD was performed by Dosimetry Check (DC) (Math Resolutions LLC, Columbia, MD, USA) on 345 prostate cancer patients. Treatment plans were prepared in Eclipse (Varian Medical Systems, Inc., Palo Alto, CA, USA) with 285 patients treated with a volumetric modulated arc therapy (VMAT) technique and 60 patients treated with a three-dimensional conformal radiotherapy (3DCRT) technique. The difference between the dose calculated by Eclipse at a reference point and the dose measured by DC at the same reference point at time-of-treatment was recorded. In cases where the dose difference exceeded  $\pm 10\%$  an alert was triggered and a full three-dimensional gamma analysis (4%/4mm) performed on the treatment plan. This led to either the measurement being repeated or further positional and patient-specific QA checks being performed.

#### Results

Figure 1 shows the percentage difference in point doses calculated by Eclipse and measured by DC for the 3DCRT and VMAT treatments monitored. The mean and standard deviation ( $\mu \pm \sigma$ ) of the percentage difference in dose obtained by DC and calculated by Eclipse was  $1.23 \pm 4.61\%$  in VMAT and  $-3.62 \pm 4.00\%$  in 3DCRT. A total of 12 plans exceeded the  $\pm 10\%$  alert criteria accounting for 3.5% of all prostate cancer treatments monitored. In all of these cases further investigation using 3D gamma analysis and additional patient-specific QA found no reportable treatment errors.

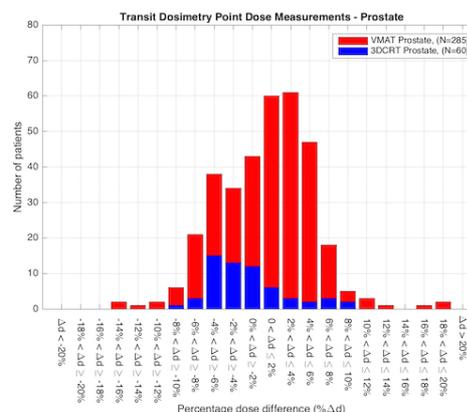

Figure 1: IVD point dose measurements on all prostate cancer patients treated between 2011 and 2016.

#### Conclusion

The preliminary results of this pilot study show that EPID-based IVD using the DC software has the potential to detect errors and identify sub-optimal treatments. With the addition of more data it may also be possible to establish site-specific alert levels, which could improve the quality of radiotherapy.

### EP-1457 Introducing the fraction of penumbra dose in the evaluation of VMAT treatment plans

A. Bäck<sup>1</sup>, F. Nordström<sup>1</sup>, M. Gustafsson<sup>1</sup>, J. Götstedt<sup>2</sup>, A. Karlsson Hauer<sup>1</sup>

<sup>1</sup>Sahlgrenska University Hospital, Therapeutic Radiation Physics, Göteborg, Sweden

<sup>2</sup>University of Gothenburg, Radiation Physics, Göteborg, Sweden

### Purpose or Objective

The overall objective is to develop a 3D complexity metric for VMAT treatments. The complexity scores will be presented as a distribution in a 3D volume and correlate to the fraction of penumbra dose. Regions lacking charged particle equilibrium that might cause dose calculation errors and regions sensitive to multileaf collimator (MLC) positioning errors are located in the penumbra of the MLC opening. The hypothesis is that an increased amount of dose in a voxel that originates from a penumbra region will correlate to the probability of increased difference between planned and delivered dose in that voxel. In this pilot study, 2D distributions are analyzed to validate the correlation to differences between calculated and measured dose.

### Material and Methods

A C# software with dynamically linked MatLab® (Mathworks, Natick, MA) libraries was developed. The input to the software is the DICOM-file of the treatment plan from where the MLC positions are collected, i.e. the appearance of the beams eye view (BEV) plane.

1. The pixels of the BEV plane (pixel size 0.25 mm) is structured binary in open beam (1) or blocked beam (0).
2. The pixels of the BEV plane is also structured binary in field edge (1) or no edge (0).
3. The binary BEV from step 1 is convolved with a Gaussian function normalized to 1. This will weight the complexity score higher in regions with higher dose and lower in the low dose region. This is called a pseudo dose (PD) distribution.
4. The binary BEV from step 2 is convolved with a box function (1 inside box, 0 outside). This will define a region, with the width of the box, as the region of interest where the complexity metric will have a score  $\neq 0$ .
5. The convolution from step 3 is multiplied with the convolution from step 4. This gives a 2D distribution of complexity scores.

The 2D distributions of calculated complexity scores for different box widths and Gaussian sigmas for 30 MLC openings were compared to the 2D distributions of difference (absolute values) between calculated and film measured dose at 10 cm depth in water for the same openings.

### Results

The correlation between the ratios “mean complexity score/mean value of PD distribution” and “mean absolute difference between calculated and measured dose/calculated mean dose” for 30 MLC openings is shown in figure 1. The sigma of the Gaussian and the box width had negligible influence on the correlation. However, those parameters will have influence when the fraction of penumbra dose is evaluated for each pixel separately. They can be chosen to match the dose gradient and width of the region of relevant dose differences at a specific depth, see example of a 2D visual comparison between complexity scores and differences between calculated and measured dose at 10 cm depth in figure 2.

Figure 1

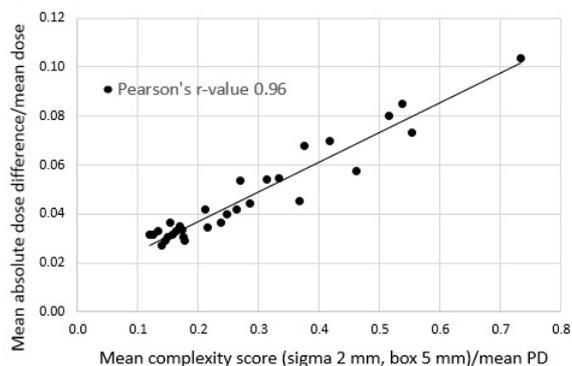

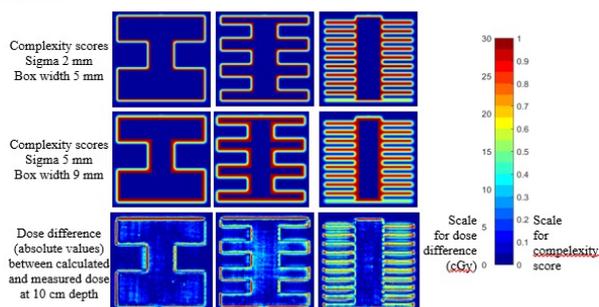

Figure 2

### Conclusion

2D distributions of complexity scores were successfully calculated and compared to 2D distributions of differences between calculated and measured dose with conformities that are promising for further development of calculations in a 3D volume.

### EP-1458 3D dose reconstruction on CBCT for daily monitoring of delivered patient dose

K. Eilertsen<sup>1</sup>, F.C. Vidaurre<sup>2</sup>, Y. Pylypchenko<sup>3</sup>

<sup>1</sup>Eilertsen Karsten, Medical Physics, Lommedalen, Norway

<sup>2</sup>Oslo University Hospital, Medical Physics, OSLO, Norway

<sup>3</sup>Oslo University Hospital, Medical Physics, OSLO, Norway

### Purpose or Objective

The ability to reconstruct the delivered 3D dose distribution using the CBCT acquired on every fraction, can help to verify that the dose to both target as well as organs at risk comply with the treatment intentions throughout the treatment course. The objective of this work has been to study the dosimetric accuracy and feasibility of daily dose monitoring using a novel system for 3D dose reconstruction onto kV CBCT from electronic portal images and machine log data acquired during treatment execution.

### Material and Methods

The tested dose reconstruction engine is based on a collapsed-cone convolution algorithm and is an integrated part of the PerFRACTION3D system (SunNuclear). The method uses a forward projection of MLC leaf position measurements from the EPID, as well as monitor chamber dose rate and output data derived from the associated machine log files. Two different approaches were taken to test the concept: First, kV CBCT of the ArcCHECK measurement array (SunNuclear) was acquired on Varian TrueBeam and Elekta Synergy linacs. Then a number of different patient plans and were delivered to the detector array. The generated EPIDs and log files were imported to PerFRACTION3D, and the dose distributions reconstructed

on the kV CBCTs were compared to corresponding dose distributions derived from the ArcCHECK measurements. Secondly, the PerFRACTION3D reconstructed dose distributions were compared to corresponding RayStation dose calculations (RaySearch) using the kV CBCTs and the original treatment plan data. The comparison was in either case carried out by the use of 3D gamma analysis as well as by comparing traditional dose volume histogram statistics. Following the testing, a clinical deployment into the clinical routine was carried out in order to perform daily dose monitoring of delivered patient dose.

#### Results

A 3D gamma analysis (2%/2mm) showed gamma passing rates >98% when comparing ArcCheck measurements/RayStation plans to the doses reconstructed in PerFRACTION3D for all plans studied. Preliminary results from comparing daily PerFRACTION3D dose reconstructions to planned dose distributions in patients treated for cancer in the head and neck region showed similar agreement.

#### Conclusion

The dosimetric accuracy of the presented method for reconstructing the delivered 3D dose distribution daily CBCT appears very promising. Further studies are however required to study the sensitivity to dosimetric changes from changes in patient anatomy and set-up errors not accounted for by the CBCT based set-up verification procedure.

<sup>10</sup>Ospedale ordine Mauriziano, Fisica Sanitaria, Torino, Italy

<sup>11</sup>AUSL Piacenza, Fisica Sanitaria, Piacenza, Italy

<sup>12</sup>Humanitas, Fisica sanitaria, Milano, Italy

#### Purpose or Objective

The aim of this study was to provide Relative Signal Ratio (RSR) values of three Linac models (Elekta, Elekta Synergy BM and Varian) using measurements performed in a multicenter Italian study. An eventual mathematical description of the RSR curve was proposed in order to calculate RSR for arbitrary field sizes with high accuracy.

#### Material and Methods

Thirty centres with different LINACs joined this project. All measurements were performed using the new IBA unshielded silicon diode RAZOR and the Stealth flat ionization chamber fixed on the gantry as reference. The RAZOR was positioned at 10cm depth in water and SSD=90cm. RSRs were calculated for square field size ranging 0.6-5.0cm. Data were normalized to the 3x3cm<sup>2</sup> field size. In-plane and cross-plane profile were measured to correct RSR for the effective field size (EFS). The error assigned to the experimental points was estimated taking into account the statistical dispersion of the repeated measurements and the error introduced on RSR by the

detector positioning uncertainty. Collected data were clustered by linac model and each group was fitted using the function proposed by Sauer (Med Phys2007). Moreover the obtained curves were compared with the one published by Sauer and Wilbert (SWF) calculated from the fit to the mean values of four solid state detector data series of an ELEKTA linac.

#### Results

The experimental data (blue points) with the fit function (black line) and the SWF (pink dotted line) are shown in figure 1 for each linac model. In all cases, It is evident how the proposed analytical functions fit perfectly to the data for all field sizes and for all the three linac models investigated. Deviations from the SWF are shown in the figure 2. The largest difference of the RSR value respect to the SWF ones are evident below 2cm of effective field size. This is mainly due to the different geometry of the head of the linacs and therefore small changes in the energy spectrum

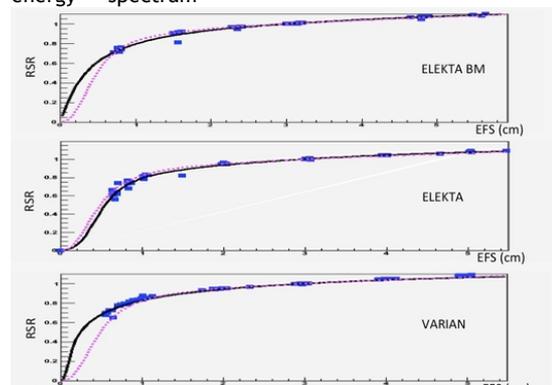

Fig.1 Black line represents the fit of the experimental data ( blue points) while the pink line is the SWF curve

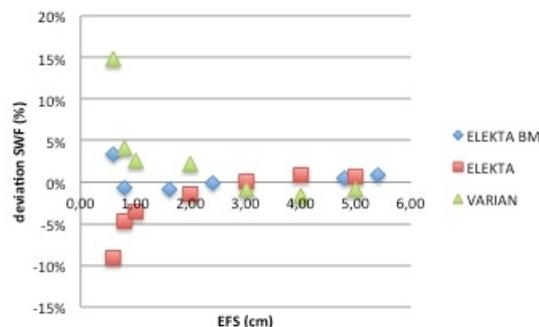

Fig.2 Deviation from the SWF curve of the experimental data fit curve of each linac model

#### Conclusion

In general, the adopted methodology removes much of the ambiguity in reporting and interpreting small field dosimetric quantities and facilitates a clear dosimetric comparison across a population of linacs. Moreover it minimizes the influence of measurement uncertainties and it allows accurate determination of values for non-measured field sizes.

#### EP-1460 Detection of forced errors in VMAT plans using EPID and Epiqa dosimetric system

D. Granero<sup>1</sup>, L. Brualla<sup>1</sup>, A. Vicedo<sup>1</sup>, M. Trinitat<sup>1</sup>, J. Rosello<sup>1</sup>

<sup>1</sup>Eresa-Hospital General Universitario, Department of Radiation Physics, Valencia, Spain

### Purpose or Objective

VMAT treatments in radiotherapy are verified usually by an experimental method, such as, measurement in discrete points with an ionization chamber, radiochromic film, EPID or other dosimetric systems. In this study we did an analysis of the error detection capability in treatment plans of aS1200 EPID of TrueBeam 2.0 linac together with the Epiqa v4.0.12 dosimetric software from EPIDOS. To do this we have introduced forced errors in the treatment plans of 5 different VMAT patients in order to test if the dosimetric system can detect different forced errors introduced in the treatment plans.

### Material and Methods

5 different patients have been selected, a hypofractionated prostate-vesicles treatment, a hypofractionated prostate-vesicles+lymph nodes a head and neck patient, a spine SBRT and finally a treatment of the paraaortic lymph nodes. Treatment plans were designed using 1 or 2 complete arcs. We have introduced forced errors in the Pinnacle treatment plans using excel home made macros. A total of 160 different plans have been irradiated with the TrueBeam 2.0 linac and dose has been measured with the EPID. The errors introduced were: i) collimator angle modified 1°, 2° and 3°, ii) X-jaws modified +2 mm, +5 mm, -2 mm and +5 mm, iii) Y-jaws modified 5 and -5 mm, iv) gantry modified 2° in 4 control points (CP), 1° in 8 CP, 1° in all the control points and finally 2° in all the control points, v) in other plans total UM, that is, total dose, was modified by 1, 2, 3, 5 and 10%, vi) UM for 4 individual CP were modified by 10%, 10% for 8 CP and 20% for 8 CP, vii) the position of all the leaves were modified +0.5, -0.5, +1 and -1 mm, viii) in other plans leaves were modified in each CP in a random way with a maximum displacement of 1, 2 and 5 mm and finally ix) leaves were modified in a random way with a maximum displacement of 2, 5 and 10 mm but using the same displacement for a particular leaf in all the CP. We have compared the dose obtained with the EPID with that calculated by the Pinnacle TPS collapsing the VMAT plans and using the Epiqa software. The gamma 3%/3mm, 2%/2mm and 2%/1 mm have been obtained. We have looked also for visual differences between the dose obtained with the EPID and that obtained with the Pinnacle TPS.

### Results

The analysis of the data shows that some errors can be detected, such as the collimator errors, some X and Y jaws errors, leaves with a systematic displacement, plans with a difference in total dose of 3, 5 and 10% error. Some errors in plans were very hard to detect or undetectable such as that plans with different UM in some control points, different gantry positions, total dose difference of 1 or 2%, and random errors in the leaves in each control point.

### Conclusion

The aS1200 EPID of TrueBeam 2.0 Linac plus the Epiqa software is capable to detect errors in the irradiation of treatment plans although some other errors are undetectable by this system. This makes EPID and interesting dosimetric equipment for the QA of VMAT plans.

### EP-1461 Scintillator dosimetry reveals lung tumor size dependency of 6 MV AAA dose calculations

W. Ottosson<sup>1</sup>, P. Sibolt<sup>1,2</sup>, C.F. Behrens<sup>1</sup>, C.E. Andersen<sup>2</sup>

<sup>1</sup>Herlev Hospital, Radiotherapy Research Unit-

Department of Oncology, Herlev, Denmark

<sup>2</sup>Technical University of Denmark, Radiation Physics-Center for Nuclear Technologies, Roskilde, Denmark

### Purpose or Objective

Radiotherapy for lung cancer generally has a poor prognosis. Motion during imaging and treatment is a major challenge, but also other factors may contribute to the

poor prognosis. One such factor is the ability of current treatment planning systems to accurately compute absorbed dose to tumors in the thorax region where large heterogeneities are present. The current study was designed to experimentally address the question: What is the agreement between actual delivered dose and computed dose using the Anisotropic-Analytical-Algorithm (AAA) in Eclipse treatment planning system for a thoracic-like geometry with tumors of different sizes? This is an important question given the widespread use of AAA and the changes in tumor sizes both over the course of treatment, and from patient-to-patient.

### Material and Methods

An in-house developed thoracic-like phantom, enabling measurements of radiotherapy under well-defined conditions, was used. The phantom has a body of PMMA and can be filled with inserts of various materials, including simulated spherical lung tumors made of PMMA (ranging from 1-8 cm in diameter) which are embedded in low-density balsa wood that simulates lung-tissue. 14 different phantom setups underwent CT scanning, structure delineation, and treatment planning. 56 isocentric treatments of different complexity and phantom configurations were calculated using AAA. Treatment techniques investigated included single conventional field technique, four-field conventional box technique, five-field intensity-modulated radiotherapy and dual-arc volumetric-modulated arc technique. To perform accurate dosimetry under these non-reference conditions, point measurements were carried out using water-equivalent, organic plastic scintillator detectors (PSDs), positioned in the center of the PMMA tumors. Dose differences between measurements and AAA calculations were calculated.

### Results

Considerable tumor-size dependence was observed. For tumor sizes  $\leq 2$  cm, the dose deviations between AAA calculations and PSD measurements were  $7.4 \pm 1.8\%$  (median  $\pm$  1SD). For larger tumor sizes (3-8 cm in diameter) corresponding dose deviations were  $4.2 \pm 1.4\%$ . For the most homogeneous setup, the dose deviations were insignificant ( $0.3 \pm 0.6\%$ ). The results were essentially independent of treatment technique.

### Conclusion

This study suggests a systematic tumor-size dependent dose calculation error for treatment planning on small tumor sizes in heterogeneous setups. This may originate from imperfections in the AAA algorithm. The largest dose deviations were observed for the smallest tumor sizes. Although, it is well known that AAA has issues in heterogeneous regions, we are not aware of any previous experimental study demonstrating a similar systematic tumor-size effect. The effect is large enough to potentially have implications for lung cancer treatment planning. Monte Carlo simulations are currently being conducted in order to verify these findings.

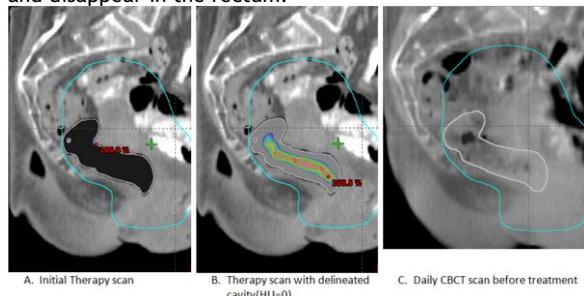

### EP-1462 The impact on VMAT optimization using Type C vs B algorithms for patients with temporary gas pockets

B. Smulders<sup>1</sup>, J. Thomsen<sup>1</sup>, P. Munck Af Rosenschöld<sup>1</sup>  
<sup>1</sup>Rigshospitalet, Department of Oncology, Copenhagen, Denmark

### Purpose or Objective

In our clinic, we have introduced a type C (i.e. Monte Carlo-like) dose calculation algorithm and dose to medium as standard practice. Previous work has shown difference between type B and type C calculation algorithms for dose calculation in high and very low density areas. However, little attention has been given to study the robustness of the treatment plans optimized using type C algorithms during the course of radiotherapy. In particular, the initial

CT scan used for radiotherapy treatment planning can contain temporary gas pockets inside the target volume for patients with tumours in the pelvis that later disappear during the course of radiotherapy. In this study we are interested to explore the dosimetric impact of applying the type C dose calculation algorithm for patients treated in the pelvic area using VMAT, where gas pockets appear and disappear in the rectum.

### Material and Methods

Ten clinical cervix cancer patients were selected for this study. The patients had different sizes of gas pockets on the planning CT. The treatment plans were optimized and calculated using one type B and one type C dose calculation algorithm (Eclipse, AAA and Acuros XB(Dose to Medium), respectively). Gas pockets of these patients were delineated on the planning CT and the contours and CT data was duplicated. On the first series the original CT the HU were kept as is, and on the second CT set the HU on the gas pockets were overridden with HU zero. Thus, we simulate a worst-case scenario where the gas pocket is present on the planning CT but disappear during the course of treatment. The original treatment plan optimized using the type C algorithm was recalculated on both CT data sets. The volume and maximum diameter of these gas pockets were measured and the difference in average and maximum dose in these pockets were calculated.

### Results

The average volume of the pockets was 28.6 cm<sup>3</sup> [range: 1.7-77.7 cm<sup>3</sup>] and the average maximum extent of the gas pocket was 4.2 cm [range: 2.8-5.3 cm]. Volumes up to 20 cm<sup>3</sup> show a decrease about 1 % in the average and maximum dose to the delineated air pocket for type C and an increase of less than 1% for type B algorithm. For volumes larger than 20 cm<sup>3</sup> the average and max dose to the delineated air pocket increases with more than 5% and up to 30%, respectively for the type C algorithm. The type B algorithm shows a decrease up to 2% in average dose and a small increase in maximum dose.

	Vol Air (cm <sup>3</sup> )	Ømax(cm)	Acuros XB (DTW)		AAA	
			ΔDavg(%)	ΔDmax(%)	ΔDavg(%)	ΔDmax(%)
1	1.66	2.8	0.7	-0.9	3.0	0.6
2	11.38	3.2	-1.3	-1.2	0.3	0.6
3	14.70	6.8	-0.4	-0.4	0.0	0.0
4	16.66	3.6	-1.1	-0.7	0.1	0.3
5	17.46	4.4	1.1	-1.4	-0.6	0.0
6	19.72	3.2	4.0	1.3	-0.3	1.1
7	22.41	3.1	5.2	29.5	-0.3	3.5
8	37.90	4.6	5.5	7.2	-1.3	-0.7
9	67.07	5.3	5.2	4.4	-2.1	-0.2
10	77.66	5.3	1.3	-0.8	-2.1	0.5

### Conclusion

Gas pockets above a volume of 20 cm<sup>3</sup> in the initial CT scan can induce dose hotspots during the actual treatment, when using the type C dose calculation algorithm for treatment planning and when deriving dose to medium for VMAT plans. This could increase risk for radiation toxicity in the worst case scenario. This effect is smaller, opposite and probably clinically negligible for the type B algorithm.

### EP-1463 MONET: an accurate model for the evaluation of the ion dose in water

A. Embriaco<sup>1,2</sup>, E.V. Bellinzona<sup>1,2,3</sup>, A. Fontana<sup>2</sup>, R. Alberto<sup>1,2</sup>

<sup>1</sup>Pavia University, Physics, Pavia, Italy

<sup>2</sup>Istituto Nazionale di Fisica Nucleare INFN, Physics Department, Pavia, Italy

<sup>3</sup>Ludwig Maxmilians University, Medical Physics, Munich, Germany

### Purpose or Objective

MONET (Model of ion dose for Therapy) is a code for the computation of the 3D dose distribution for protons in water. MONET accounts for all the physical interactions and is based on well known theories.

### Material and Methods

The first part is the evaluation of the lateral profile.

Our model is based on the Molière theory of multiple Coulomb scattering. To take into account also the nuclear interactions, we add to Molière distribution the Cauchy-Lorentz function, where two free parameters are obtained by a fit to a FLUKA simulation (Bellinzona et al., PMB 2016).

The next step is the passage from the projected lateral distribution to a 2D distribution. The projected distributions are uncorrelated but not independent and we have to use the Papoulis theorem that allows, in case of cylindrical symmetry, to rebuild the radial distribution starting from projected one. We have implemented the Papoulis algorithm in the code.

The second part is the study of the energy deposition in the longitudinal profile.

We have implemented a new calculation of the average energy loss that is in agreement with simulations and other formulas published in the literature.

The inclusion of the straggling is based on the convolution of energy loss with a Gaussian function.

In order to complete the longitudinal dose profile, also the nuclear contributions are included in the calculation using a linear parametrization with only two free parameters for energy.

The total dose profile is calculated in a 3D mesh by evaluating at each depth the 2D lateral distributions and by scaling them at the value of the energy deposition.

### Results

We have compared MONET results with the FLUKA simulations and we have obtained a good agreement for different energy of protons in water.

We have reproduced a lateral scan as a sum of many pencil beams in order to estimate the accuracy of the model focusing on the tails of the distribution that give rise to the low-dose envelope. Also in this case, the agreement between MONET and FLUKA is good.

We have also estimated the calculation time: for each depth, it is about 2 seconds for the single beam and 4 seconds for the beam scan.

### Conclusion

The advantages of MONET are the physical foundation, the fast calculation time and the accuracy.

A possible development of this study is the creation of a dose database of clinical interest and an online fast dose evaluation tool. In the next future, we would like to extend MONET to the case of Helium beam and other ions. Preliminary results for helium ion will be shown.

### EP-1464 Investigation on beam width tolerances for proton pencil beam scanning

B. Ackermann<sup>1</sup>, S. Brons<sup>1</sup>, M. Ellerbrock<sup>1</sup>, O. Jäkel<sup>1,2</sup>

<sup>1</sup>Heidelberg Ion Beam Therapy Center HIT, Medical Physics, Heidelberg, Germany

<sup>2</sup>German Cancer Research Center, Medical Physics in Radiation Oncology, Heidelberg, Germany

### Purpose or Objective

Beside beam spot position and proton range, the beam spot width is one of the central parameters for the correct application of a proton therapy plan utilizing pencil beam

scanning techniques. The aim of this work is to investigate the influence of variations of the nominal beam width on the dose distribution of cubic dose volumes, which are often part of a typical QA program.

#### Material and Methods

For QA purposes, three cubic dose volumes with a spread out bragg peak (SOBP) of  $3 \times 3 \times 3 \text{ cm}^3$  are optimized with the treatment planning system (TPS), syngo PT Planning (Siemens, Germany). The nominal dose in the SOBP is 0.5 Gy. The depth in water of the centre of the cubes is 50, 125 and 200 mm, respectively.

To perform dose calculations on a water phantom with variation of initial beam width, the needed algorithms and base data of our TPS are transferred to MATLAB (The Mathworks Inc., USA). These are mainly the depth dose distributions and the double gaussian parametrization of the beam width. Plans are recalculated with MATLAB with nominal and varied beam width. Dose distributions are analysed performing a 3D gamma index analysis with criterias of 1mm distance to agreement and 5% dose deviation, normalized to global maximum. The maximum negative and positive tolerable beam width deviations are determined where all points still pass the gamma index acceptance criteria (e.g. gamma index < 1).

#### Results

The maximum tolerable beam width variations for the dose cube in a depth of 50 mm amounts to -7% and +10%, while for the dose cube in 125 mm depth the found values are -12% and +17%. The most interesting result is found for the dose cube in 200 mm depth. While the high dose region shows comparable large possible beam width variations of -17% to +25%, the maximum tolerable beam width deviation in the entrance region amounts to -8% and +15%.

#### Conclusion

The QA plan in small depth shows rather small tolerable deviations of the initial beam width. It is observed, that this is mainly affected by the strong variation of the particle numbers per scan spot in each energy slice, optimized by the TPS to achieve lateral penumbras as small as possible. Following this observation, we created a plan with the same field size parameters consisting uniform scanned energy slices. Applying the described beam width variation, resulting tolerable beam width deviations are -13% and +12%.

For the QA plans in medium and large depth, beam width tolerances in the SOBP become larger. One reason is that the additional multiple coulomb scattering in water dilutes the impact of deviations of the initial beam width. Depending on the spot scan pattern, the entrance region can be the region with the highest demands on beam width accuracy for plans in large depths.

For TPS commissioning, the spot scan pattern should be inspected with regard to beam spot width variations.

and 3 mm distance-to-agreement (DTA). The manufacturer specifies a routine for acceptance testing of matched linear accelerators which concerns only the beam quality and field size.

After appropriate MLC calibration, percentage depth dose and beam quality index were evaluated for both linacs, in similar setups. In-plane and cross-plane beam profiles were acquired for field sizes of  $10 \times 10 \text{ cm}^2$ ,  $20 \times 20 \text{ cm}^2$ , and depth of 10 cm. All dosimetric parameters appeared identical for both linacs, within a tolerance of 1%. Beam output calibration differed within 0.5%. The quality of matching was found to be valid for 3D-CRT treatments but not for VMAT. Specific test beams were further performed to compare the two linacs for the accuracy of leave and jaws movement, using the "picket fence" and "sliding-window" methodology at different gantry and collimator angles, using electronic portal imaging device (EPID) dosimetry. The MLC minor leaf and jaw offsets of the second linac was finely adjusted mechanically in order to achieve acceptable accuracy of matching.

38 clinical VMAT plans for various sites and different degrees of modulation were verified on both linacs. The correlation between the GI passing rate and plan modulation, assessed by the number of MU and number of segments, was further investigated using a logistic regression test.

#### Results

The beam quality index was 0.682 for linac 1 and 0.686 for linac 2 after the vendor's matching procedure was performed. GI analysis of the "picket fence" and "sliding window" test beams indicated the need for mechanical adjustment of MLC minor leaf and jaw offsets of linac 2. After the beam matching accomplished, GI analysis of VMAT clinical treatment plans indicated good agreement between the two linacs. The average passing rate between calculated and delivered dose distribution was  $97.7 \pm 2.8\%$  (range: 87.5%-100%) for linac 1 and  $93.4 \pm 4.7\%$  (range: 83%-99%) for linac 2.

Weak correlations were found between the GI passing rate and number of MU ( $R^2=0.043$ ,  $p=0.146$ ) and segments ( $R^2=0.0273$ ,  $p=0.240$ ), indicating that the degree of modulation is not to be considered in setting acceptance criteria for GI analysis.

#### EP-1465 A beam matching procedure for Volumetric Modulated Arc Therapy

L. Abdullah<sup>1</sup>, C. Constantinescu<sup>1</sup>, M.N. Hussein<sup>1</sup>

<sup>1</sup>King Faisal Specialist Hospital and Research center, Biomedical Physics, Jeddah, Saudi Arabia

#### Purpose or Objective

To describe our experience of commissioning and quality control tests, along with the adjustments performed for beam matching in VMAT.

#### Material and Methods

A Synergy linac upgraded to Agility head was matched to a Versa HD linac.

Dose calculation for commissioning tests was performed on Monaco TPS version 5.0, with Monte Carlo algorithm, inhomogeneity correction, calculation grid size of 1mm, and statistical uncertainty of 0.5%/control point. The compliance between dose calculation and measurement was assessed for a gamma-index (GI) of 3% dose difference

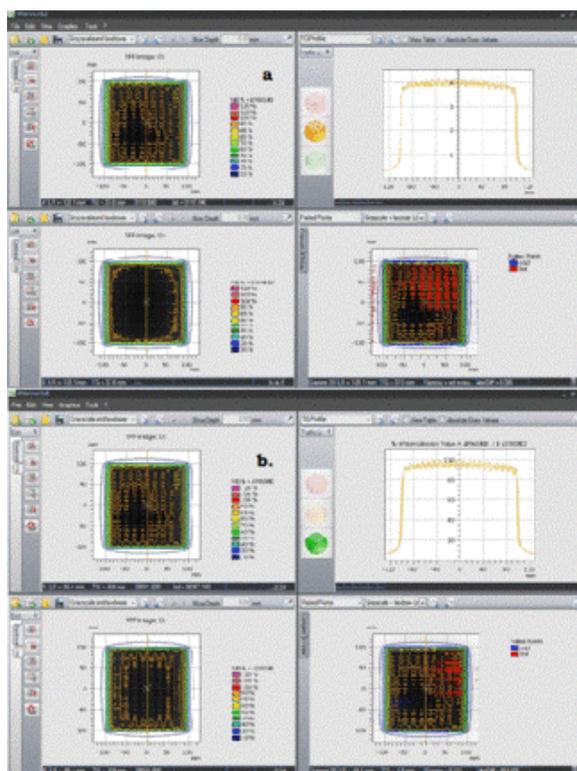

Fig. 1. Analysis of a "sliding window" test beam before (a) and after MLC and jaw offsets adjustment (b), for a gamma-index of 3% dose difference and 3 mm DTA.

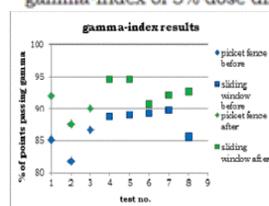

Fig. 2a. Comparison between the passing rate of the calculated and delivered dose distribution before and after MLC and jaw offsets adjustment, for a gamma-index of 3% dose difference and 3 mm DTA.

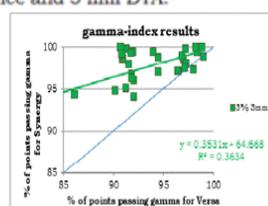

Fig. 2b. Comparison between the passing rate of the calculated and delivered dose distribution of VMAT plans, for a gamma-index of 3% dose difference and 3 mm DTA.

## Conclusion

The manufacturer's defined criteria for beam matching are not strict enough and should be evaluated before to interchange patients between two matched linacs. We described a method of evaluation and a procedure of beam matching for VMAT

## EP-1466 Implementation of a linac head-mounted matrix detector to clinical use for dynamic technique L. Szczurek<sup>1</sup>

<sup>1</sup>International Oncology Centre Affidea Poznan, Medical Physics, Poznan, Poland

## Purpose or Objective

Quality assurance of VMAT plans based on the results in 2D phantom plane is not sufficient. Clinical interpretation of 2D measurements is difficult. The main purpose of this study is transition from 2D QA to 3D dose reconstruction in a patient CT scan which could be achieved using dose reconstruction method from 2D detector array in the Compass system. The first step in the clinical introduction of this system, instead of currently used 2D QA in OmniPro system, is to test reliability of dose reconstructions. In this work we investigated the validation of the method with OmniPro results as a reference. We check whether the Compass QA measurements of VMAT plans fulfill the QA requirements.

## Material and Methods

50 different treatments according to VMAT plans were selected from our database; 20 prostate, 20 gynecology and 10 brain. The QA results were divided based on the mean gamma index and the 3%/3mm and 1%/1mm criteria. Results from OmiPro were compared with Compass and TPS. Additionally, recalculation plan from TPS (Monte Carlo) in Compass system based on the different algorithm (Collapse Cone Convolution) were performed. MLC tests (3ABUT, 7SegA, FOURL plan) were implemented before each set of measurements for evaluation of interleaf leakage, tongue and groove effect.

## Results

Mann-Whitney test showed good agreement between Compass 3D-reconstructed dose and OmniPro results (mean gamma  $0.23 \pm 0.03$  for 3%/3mm and  $0.53 \pm 0.06$  for 1%/1mm criteria). Scatter plot of results from TPS vs. Compass against TPS vs. OmniPro showed small differences in the region of gamma between 0.2 and 0.4. Comparison TPS vs. Compass mean dose in PTV and OAR did not reveal significant differences for prostate  $50.04 \text{ Gy} \pm 0.4$ ,  $50.35 \text{ Gy} \pm 0.33$ , bladder  $32.04 \text{ Gy} \pm 0.41$ ,  $32.45 \text{ Gy} \pm 0.23$ ; gynecology  $45.07 \text{ Gy} \pm 0.34$ ,  $45.02 \text{ Gy} \pm 0.25$ , bladder  $35.04 \text{ Gy} \pm 0.74$ ,  $35.75 \text{ Gy} \pm 0.49$ ; brain  $60.07 \text{ Gy} \pm 0.53$ ,  $60.02 \text{ Gy} \pm 0.71$ , brain stem  $d_{\text{max}} 40.04 \text{ Gy} \pm 0.83$ ,  $39.08 \text{ Gy} \pm 0.33$  respectively.

## Conclusion

Agreement between results obtained from Compass and OmniPro was reached. 3D dose reconstructions in CT patient allowed to evaluate the dosimetric errors and their clinical relevance. Compass reconstruction offers good opportunities to examine dynamic plans and check characteristics of MLC.

## EP-1467 IPEM Code of Practice for proton and ion beam dosimetry: update on work in progress

S. Green<sup>1</sup>, R. Amos<sup>2</sup>, F. Van den Heuvel<sup>3</sup>, A. Kacperek<sup>4</sup>, R.I. MacKay<sup>5</sup>, H. Palmans<sup>6</sup>, D. D'Souza<sup>2</sup>, R. Thomas<sup>6</sup>  
<sup>1</sup>Hall-Edwards Radiotherapy Research Group- Queen Elizabeth Hospital, Medical Physics, Birmingham, United Kingdom

<sup>2</sup>University College London Hospitals, Radiotherapy Physics, London, United Kingdom

<sup>3</sup>Churchill Hospital, Radiotherapy Physics, Oxford, United Kingdom

<sup>4</sup>Clatterbridge Cancer centre, Physics Department, Wirral, United Kingdom

<sup>5</sup>The Christie NHS Foundation Trust, Medical Physics, Manchester, United Kingdom

<sup>6</sup>National Physical Laboratory, Radiation Dosimetry Group, London, United Kingdom

## Purpose or Objective

Current standard methods for reference dosimetry of proton and ion beams typically involve the use of an ionization chamber calibrated in a cobalt-60 beam, with a beam quality correction factor applied to account for the difference between the chamber response in the proton and the calibration beams. This approach gives rise to uncertainties (at 68% confidence level) on the reference dosimetry of 2.4% for proton beams and 3.4% for carbon ion beams when using a plane-parallel ionization chamber. This poster provides an update on the development of a new Code of Practice for reference dosimetry of proton and ion beams, applicable to both scanned and scattered beam configurations. It is aimed to deliver an uncertainty on reference dosimetry for protons of approximately 2% and will utilise a primary standard graphite calorimeter that is robust and portable enough to be used in the end-user facility.

## Material and Methods

This project involves a core team (authors on this submission) plus a group of experts in the field to provide

peer-review. Proposed key elements of the protocol are the use of the NPL portable graphite calorimeter, calibration in a composite field defined to cover what is termed a Standard Test Volume (STV) of delivered dose for scanned beams and calibration in a broad field spread-out Bragg Peak to cover the STV for scattered beams.

#### Results

While for scattered beams the recommendations will be largely in line with those already published, the key steps for scanned beams are proposed to be as follows:

**Step 1:** Derive the curve which defines the number of particles per Monitor Unit (MU) for a range of incident proton/ion energies. This is the Hartmann method and utilises a plane-parallel ionization chamber at a shallow depth in pristine Bragg peaks.

**Step 2:** Input the curve above into the treatment planning system (TPS) for the centre/treatment room and then use the TPS to plan a prescribed dose to the STV in water and deliver this treatment to the calorimeter with its core at the centre of the STV.

**Step 3:** Re-normalise the data obtained in step 1 if necessary, to ensure that the calibration in terms of the number or particles per MU results in the measured dose to the STV.

**Step 4:** Test against alternative STVs to quantify uncertainties in the dose delivered.

In addition, ionisation chambers belonging to the clinical centre will be cross-calibrated against the standard calorimeter at the time of beam commissioning and at regular intervals (to be defined) thereafter.

#### Conclusion

A proton and ion beam dosimetry protocol will be developed which involves direct use of a primary standard level calorimeter in clinical ion beams. This may provide a model to be followed elsewhere, ultimately reducing dose uncertainty for patient treatments worldwide.

The code is under development and due for completion at the end of 2017. This will coincide with beam commissioning at the UK centres during 2018. This poster will describe the proposed methodology with the aim of stimulating wider debate and comments on this approach.

#### EP-1468 Skin dose in radiotherapy: results of in vivo measurements with gafchromic EBT3 films

A. Giuliano<sup>1</sup>, V. Ravaglia<sup>2</sup>

<sup>1</sup>Istituto Nazionale di Fisica Nucleare INFN, Pisa, Pisa, Italy

<sup>2</sup>San Luca Hospital, Medical Physics, Lucca, Italy

#### Purpose or Objective

Clinical side effects to skin are a major concern with radiotherapy patients during the treatment of malignant disease by radiation. As a consequence, it becomes important to accurately determine the dose delivered to a patient skin during radiotherapy owing to complications that can arise. However, the Treatment Planning Systems (TPS) do not accurately model skin dose. The aim of this study is to report the results of surface dose measurements performed during treatments in tomotherapy, at Linac both with 3D-CRT (TPS Pinnacle) and VMAT (TPS Monaco) and in Plesio-Röntgen therapy using EBT3 Gafchromic films.

#### Material and Methods

In vivo measurements were performed with the application of EBT3 film pieces of 2x2 cm<sup>2</sup> directly on the skin of patients or in the inner side of thermoplastic mask, if used during the treatment. The target sites included head and neck (H&N), brain and sarcoma in tomotherapy; breasts at Linac and skin tumors in Plesio-Röntgen therapy. For each patient films were located in 1 to 3 reproducible points (see figure 1 and 2) and measurements were repeated on average in three consecutive fractions. EBT3 films were read with a flatbed scanner Epson

10000XL and images were analyzed using the red channel calibration. In vivo dose evaluations were compared with measurements performed on Cheese phantom both with and without thermoplastic mask at Linac and in Tomotherapy.

#### Results

A total of 117 film measurements were performed on 21 patients. The absolute value of the mean difference between measured and TPS-calculated dose and its standard deviation was 11.3% ± 6.5% for all treatments. A mean absolute difference of 17.7% for Linac plans, 11.6% in Tomotherapy and 4.6% in Plesio-Röntgen therapy were achieved. Both at Linac and in Plesio-Röntgen therapy there was not a clear trend of overestimation of the TPS with respect to measurements. Instead in Tomotherapy there was an underestimation of the TPS (-9.1%) for H&N and brain treatments (in these case measurements were performed with thermoplastic mask) and an overestimation for the sarcoma (9.2%). This trend was confirmed by the measurements made on the Cheese phantom in Tomotherapy, where there was an overestimation of the TPS without mask (28.6% vs -0.7% with mask). Moreover, an improvement of the agreement between EBT3 measurements and Pinnacle and Tomotherapy dose estimation was shown in presence of mask (28.6% to -0.7% in Tomotherapy and -20.7% to -16.3% at Linac).

#### Conclusion

Gafchromic films are suitable detectors for skin dose measurements in radiotherapy. In vivo surface dose measurements with EBT3 are a useful tool for quality assurance in radiotherapy, since the TPS does not give accurate dose values in the first millimeters of skin.

#### EP-1469 Flattening filter free beam profile analysis using two different normalization methods

G. Nicolini<sup>1</sup>, A. Fogliata<sup>2</sup>, E. Vanetti<sup>1</sup>, G. Reggiori<sup>2</sup>, A. Stravato<sup>2</sup>, P. Mancosu<sup>2</sup>, M. Scorsetti<sup>2</sup>, L. Cozzi<sup>2</sup>  
<sup>1</sup>Radiqa Developments, Medical Physics Team, Bellinzona, Switzerland  
<sup>2</sup>Humanitas Research Hospital, Radiotherapy and Radiosurgery Dept, Milan, Italy

##### Purpose or Objective

Flattening filter free (FFF) beams present a profile peaked on the beam central axis (cax), unsuitable for flatness and symmetry description that usually characterize standard beam profiles. Definitions of unflatness and slope have been recently proposed, requiring a preliminar suitable FFF profile normalization. Two main normalization processes as far published are: the inflection point IP (Pönish 2006), and the renormalization factor RF (Fogliata 2012). In both formalisms the FFF dose fall-off at the field edge is superimposed with the corresponding FF profile. The present study aims to compare FFF specific profile parameters using the two normalization procedures.

##### Material and Methods

Dosimetric data from a Varian TrueBeam with 6 and 10 MV, FF and FFF modes, have been collected at SSD 100cm and 5 depths. The cax normalization value N was evaluated for the IP method as  $N = D_{cax} \cdot (D_u/D_r)$ , where  $D_{cax}$  and  $D_r$  are the doses on cax and at the IP of the penumbra region for the corresponding FF beam,  $D_u$  is the dose at the IP of the FFF beam.

The N value for the RF method was evaluated by using the fit dependent on the field size FS and depth:  $N = (a+b \cdot FS + c \cdot \text{depth}) / (1+d \cdot FS + e \cdot \text{depth})$ , where the fitting parameters are taken from published data. The main profile parameters of FFF photon beams were computed: field size, penumbra, unflatness, slope, and peak-position parameters. To systematically investigate the impact of the N value, they were recomputed with a RF value modified of + 1,2,3,5,7,10% (perturbed RF).

##### Results

In terms of cax normalization value, in average, the two methods show an agreement within the 2%, with a tendency of a greater N with IP respect RF method for 10MV. In any case, some outliers are present, with a discrepancy that reaches the 10%; this is expected, since the IP method suffers of the uncertainty of IP position determination in the practice. Beam parameters values derived with the approaches (IP/RF) were computed showing, e.g., for both energies 1.00±0.00 for unflatness and, respectively for 6 and 10MV, 0.99±0.05 and 1.02±0.04 for slope. Analysis with perturbed RF values, shows that with a variation up to 10% of N, the peak position remains within 0.05mm, the unflattens within 0.5% and 1% for 6MV and 10MV beams, while the slope has a variation almost of the same amount of N itself. Field size difference is within 1mm if N variation is within 5%.

##### Conclusion

The two normalization methods are both suitable for subsequent FFF profile description. Unflatness parameter resulted similar when computed using the two different normalization formalisms with no significant differences. Slope values are more sensitive to normalization value, and therefore some outliers were observed due to uncertainty of IP position in the practice. The RF procedure, with the published fitting parameters is easier to use and more robust respect to measurements sampling and detector size.

#### EP-1470 Determination of paramagnetic gel sensitivity in low energy X-ray beam

Y. Ben Ahmed<sup>1</sup>, J. Coulaud<sup>2</sup>, S. Ken<sup>1</sup>, L. Parent<sup>1</sup>  
<sup>1</sup>Institut Universitaire du Cancer Toulouse, Haute

Garonne, Toulouse, France

<sup>2</sup>SIMAD, Haute Garonne, Toulouse, France

##### Purpose or Objective

The INTRABEAM® system is a miniature accelerator producing low energy photons (50 keV maximum). The published dosimetric characterization of the INTRABEAM system for flat and surface applicators was based on detectors (radiochromic films or ionization chambers) not allowing measuring the absorbed dose in the first millimeters of the irradiated medium, where the dose is actually prescribed. This study aims at determining the sensitivity of a paramagnetic gel in order to measure the dose deposited with INTRABEAM surface applicators in the first millimeters of irradiated medium.

##### Material and Methods

The determination of paramagnetic gel sensitivity was performed with irradiations at different dose levels with the INTRABEAM® Carl Zeiss Surgical system (Oberkochen, Germany). The ferrous gel used in this study is a new «sensitis» material which is described by C. Stien et al and V. Dedieu et al. Gel irradiation in tin and capsule containers was carried out for twelve dose levels between 2 Gy and 50 Gy at the gel surface with a 4 cm surface applicators. The applicator was in contact of the gel during irradiation. For the calibration curve, one batch gel was measured without being irradiated. T<sub>2</sub> weighted multi echo MRI acquisitions were performed on a 1,5 T Magnetom Aera MR scanner of Siemens with surface flex head coil technology.

##### Results

The T<sub>2</sub> signal versus echo times can be fitted with a mono-exponential function with 95% of confidence. The first echo time was not considered for the fit. The calibration curve determined from experiments with tins is a linear function (R<sup>2</sup>=0.967) with a sensitivity of  $1.04 \cdot 10^{-4} \text{ s}^{-1} \cdot \text{Gy}^{-1}$ . Gels Sensitivity with capsules are of  $3.67 \cdot 10^{-4} \text{ s}^{-1} \cdot \text{Gy}^{-1}$  (R<sup>2</sup>=0.979) and  $2.54 \cdot 10^{-4} \text{ s}^{-1} \cdot \text{Gy}^{-1}$  (R<sup>2</sup>=0.944). The calibration curve was applied to the irradiation of a surface applicator to obtain the 3D dose distribution in the gel.

##### Conclusion

The dose distribution obtained after irradiation at low energies with an INTRABEAM® miniature accelerator can be measured for the first millimeters thanks to ferrous gels. The determination of gel sensitivity was possible with MRI measurements. Results are relevant but must be confirmed with more irradiations with different dose levels at the surface and different surface and flat applicator diameters.

#### EP-1471 Comparison of the integral dose of IMRT, RapidArc and helical tomotherapy prostate treatments

J. Martinez Ortega<sup>1</sup>, P. Castro Tejero<sup>2</sup>, M. Pinto Monedero<sup>1</sup>, M. Roch Gonzalez<sup>2</sup>, L. Perez Gonzalez<sup>2</sup>  
<sup>1</sup>Hospital Universitario Puerta de Hierro, Servicio de Radiofísica y PR, Majadahonda - Madrid, Spain  
<sup>2</sup>Hospital Universitario de la Princesa, Servicio de Radioterapia, Madrid, Spain

##### Purpose or Objective

Comparison of integral dose (ID) and normal tissue integral dose (NTID) for Helical Tomotherapy (HT), RapidArc and static fields IMRT.

##### Material and Methods

A cohort of ten prostate patients were selected whose prescription was 78 Gy mean dose to the Planning Target Volume (PTV). Seven different plans for every patient were computed. One sliding-window IMRT with XiO planning system and Varian Clinac 21EX, equipped with MLC Millennium 80. Four Intensity-Modulated Radiation Therapy (IMRT) plans were calculated with Varian Eclipse planning system, two step-and-shoot and sliding-window

IMRT for a Varian Clinac 2100 C/D with Millennium 80 and two analogous plans for a Varian Clinac 2300iX with a Millennium 120. For this last machine, a RapidArc plan was also calculated. A HT treatment for Tomotherapy Hi-Art was also planned for every patient.

**Results**

ID and NTID are 27% and 33%, respectively, larger for HT compared to 6MV-IMRT Eclipse treatments. Statistically no difference has been found for ID and NTID values between RapidArc and IMRT treatments.

For IMRT treatments, no influence has been observed on the size of MLC, the delivery technique (step-and-shoot or sliding-window) and the number of fields. However, an ID and NTID increments of 8% and 10%, respectively, are reported when moving a plan from Eclipse to XiO. (Table 1).

The mean DVHs in Fig 1 show some differences depending on the isodose evaluated. Higher values calculated below 20 Gy are compensated by the region from 20 Gy to 30 Gy, where this technique minimizes the volume encompassed by these isodose curves. For HT, there is no compensation, as the volumes below 20 Gy are much higher than for the other techniques. From 20 Gy to 30 Gy, the values are comparable to IMRT, showing no advantage in terms of ID.

**NORMAL TISSUE INTEGRAL DOSE (NTID) ( $\cdot 10^7$  cGy·g)**

Patient	PTV Volume (cm <sup>3</sup> )	IMRT SW80	IMRT ECLIPSE PSE SW80	IMRT ECLIPSE PSE SW120	IMRT ECLIPSE PSE SS80	RAPIDARC	HT
1	181.20	1.29	1.26	1.23	1.25	1.23	1.64
2	140.94	0.98	0.92	0.90	0.91	0.91	1.27
3	228.96	1.44	1.39	1.36	1.39	1.35	1.73
4	180.42	1.31	1.28	1.26	1.28	1.25	1.63

<b>Typical error (k=2)</b>		<b>0.18</b>	<b>0.14</b>	<b>0.14</b>	<b>0.14</b>	<b>0.14</b>	<b>0.18</b>

Table 1. NTID calculated from the dose volume histograms, for every treatment plan, IMRT, RAPIDARC or HT. For IMRT treatments, both delivering technique (SW for sliding-window and SS for step-and-shoot) and MLC characteristics (80 or 120 leaves) are indicated.

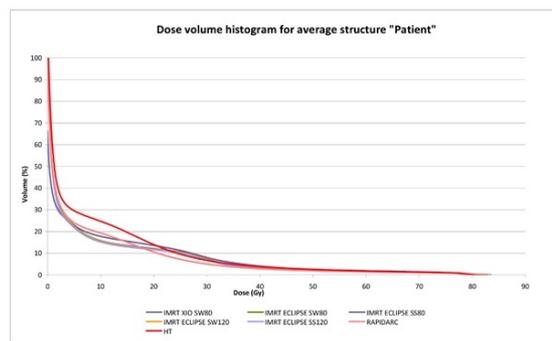

Fig 1. Dose volume histogram for the whole body averaged over the 10 patients of this study, comparing every treatment technique.

**Conclusion**

The source for higher values of ID and NTID for HT is the larger volume receiving dose below 20 Gy. No differences were found in the election of IMRT delivery. For RapidArc plans, ID and NTID values are similar to IMRT.

**EP-1472 Dosimetric E2E verification using 3D printing and 3D dosimeter for brain stereotactic radiotherapy**

M.S. Kim<sup>1</sup>, K.H. Chang<sup>1</sup>, J. Kwak<sup>1</sup>, G.M. Back<sup>1</sup>, T.Y. Kang<sup>1</sup>, S.W. Kim<sup>1</sup>, Y. Ji<sup>1</sup>

<sup>1</sup>Asan Medical Center- Univ of Ulsan, Radiation Oncology, Seoul, Korea Republic of

**Purpose or Objective**

To evaluate the dosimetric accuracy of brain stereotactic radiotherapy (SRT) with a 3D dosimetry system and MRI, we investigated dosimetric end-to-end verification using 3D printing technology and 3D dosimeter.

**Material and Methods**

We implemented an anthropomorphic head and neck phantom with a 3D printed insert made using a 3D printer designed by the Autodesk software and two gel-filled spherical glass flasks as a patient having multiple target brain cancer. For the feasibility study of the gel dosimeter, the dose linearity, dose rate dependence, and reproducibility for the gel dosimeter were verified. Gel-filled vials were irradiated with 6 MV beams to acquire a calibration curve of dose relation to R2 (1/T2) values in 9.4T MR images. Graded doses from 0 to 8 Gy with an interval of 2 Gy were delivered. Two PTVs (PTV1,2) were contoured on the MR images of phantom have dosimetric gel tumor. To evaluate geometric and dosimetric accuracy, a treatment plan was created such that D95s for PTV1 and intentional PTV2 were more than the prescribed dose. The intentional PTV2 was produced by intentionally shifting by 5mm from the true target position. 2 arc VMAT plan was created to deliver 35 Gy in 5 fractions. After irradiation, calibration vials and phantom were scanned by 9.4T MRI and then acquired images were analyzed using an ImageJ and DCMTK software libraries. Scanned MRI images of phantom were imported to a treatment planning system and registered to CT images to compare dose distributions. We also compared the agreement result between the planned and the measured data in 1D (ion chamber), 2D (gafchromic film), and 3D (Gel dosimeter).

**Results**

The best dose linearity was 0.99 (R<sup>2</sup>) at 180 TE (ms). Reproducibility and dose rate dependency were less than 2.2% and 3.5%, respectively for 180 TE. Point dose differences in plan vs. ion chamber were 1.08%, 0.47%, and -2.82%, respectively, for PTV 1, 2, and intentional PTV. And its differences between plan and gel were 0.98%, 1.66% and 3.76%, respectively, for PTV 1, 2, and shifted PTV. Gamma passing rates with 3%/3mm criteria were greater than 99% for all plans. Isodose distributions and

profiles showed qualitatively good agreement between the gel dosimeter, EBT film and RTP data for all PTVs.

#### Conclusion

The results indicate that those processes could effectively evaluate geometric and dosimetric accuracy of brain SRT. This study using 3D dosimetry system was useful to validate the 3D dose distributions for patient-specific QA.

#### EP-1473 Improving the accuracy of dosimetry verification by non-uniform backscatter correction in the EPID

Y. Md Radzi<sup>1,2</sup>, R.S. Windle<sup>2</sup>, D.G. Lewis<sup>2</sup>, E. Spezi<sup>1,2</sup>

<sup>1</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom

<sup>2</sup>Velindre Cancer Centre, Department of Medical Physics, Cardiff, United Kingdom

#### Purpose or Objective

Challenges in improving the accuracy of EPID-based patient dose verification have been widely discussed and remain a key topic of interest for patient safety, as exemplified in the UK by the 'Towards Safer Radiotherapy' 2008 report[1]. In particular, one of which is for every radiotherapy centre to have protocols for in vivo dosimetry (IVD) to be used for most patients as recommended in the Annual Report of the Chief Medical Officer for 2006 and it is already a legal requirement in many European Countries [2]. In this presentation, we report on commissioning and implementation of the commercially available Dosimetry Check (DC) [3, 4] system. Particular emphasis has been given to addressing the significant non-uniform backscatter effect from the VARIAN aSi-1000 EPID arm [5, 6].

#### Material and Methods

A backscatter correction matrix was developed by combination of dosimetric information from a set of segmented fields sampling on different positions around the active area of the imager. The matrix was then used to correct EPID images using MATLAB programming scripts. The corrected image was created in DICOM format and exported to Dosimetry Check to read and analyse. Example treatment fields were generated in our Oncentra MasterPlan (OMP) Treatment Planning System (TPS), with several equidistant dose reference points relative to central axis included. A dose comparison given by DC with reference to the TPS was recorded in an auto-generated report. Assessment and comparison undertaken included the (i) asymmetry evaluation of equidistant points before and after correction being applied with respect to TPS, (ii) improvement in segmented IMRT dose profiles after correction, and (iii) OMP-DC pass rate with gamma criterion 3%/3mm[7], as well as 2-D Gamma Volume Histogram (GVH) evaluation on outlined PTVs.

#### Results

(i) Correction for non-uniform backscatter improved with overall agreement between fields generated in OMP and those recorded in DC from within 3% to better than 1%. (ii) Agreement between OMP and DC for IMRT dose profiles with a sample Head & Neck case was improved by approximately 3% using the correction methodology (Table 1). (iii) For gamma comparison of fields in OMP and DC with 3%/3mm, pass rates were improved from around 80% to around 90% by the correction method. Similarly in GVH evaluation for the outlined PTVs, pass rate has increased from around 80% to 90% after correction being applied.

Segmented beam	Percentage change of dose in DC relative to TPS dose (%)	
	Isocentre	d <sub>max</sub>
B01	-2.65	-2.78
B02	-2.70	-2.76
B03	-2.73	-2.81
B04	-2.75	-2.84
B05	-2.76	-2.89
B06	-2.65	-2.69
B07	-3.26	-3.89
B08	-2.72	-2.80
B09	-3.09	-3.56
B10	-2.70	-2.80
B11	-2.26	-2.32
B12	-3.42	-3.65
Average	-2.81	-2.98
$\sigma$	0.31	0.46

#### Conclusion

The correction method implemented herein for the Dosimetry Check system has proved to be an effective way to reduce verification inaccuracy caused by backscatter from the Varian EPID arm and can be used to enhance the previously established portal verification method for IMRT using this technology.

<sup>5</sup>Tokushima University, Institute of Health Sciences, Tokushima, Japan

<sup>6</sup>Tokushima University, Institute of Bioscience and Bioindustry, Tokushima, Japan

#### Purpose or Objective

Dose delivery error detection of on-line treatments is an important issue for clinical QA practices. The goal of this study was to evaluate a feasibility of the delivery error detection by a new type of on-line transmission detector compared to a 3D detector in patient-specific QA measurements for VMAT treatment.

#### Material and Methods

The Delta<sup>4</sup> Discover system is a transparent, p-type semiconductor diodes detectors, placed in the accessory holder of the treatment head. The system measures the

dose by the accelerator directly and evaluates the dose delivery error to the plan. We have used True-Beam (Varian) with 10 MV photon beams and a QA plan which underwent prostate VMAT. For the QA plan, we prepared seven modified MLC files in which MLC positions were manually shifted between 0 mm to 3 mm, respectively. Then, the dose delivery errors were measured and analyzed dose deviation, distance-to-agreement (DTA) and gamma index by the Delta4 Discover system as well as to the Delta<sup>4</sup> 3D dosimetry system. All measurements were compared against the points that received less than appropriate percentage dose (<10%) were excluded from the gamma index calculation.

#### Results

The results of the Delta4 Discover system and the Delta<sup>4</sup> 3D dosimetry system using all available points for the gamma calculation, 95.7±5.9% and 97.8±3.5% of them passed the criteria (3%/2mmDTA/Th10%), respectively. The two systems also had high correlations of dose deviation and DTA, permitting the routine verification of VMAT patient-specific QA plan as well as permanent in-vivo dosimetry during the patient's treatment course.

#### Conclusion

In this study, we have found that there was high correlation between the pass rate and the intentional dose delivery error, as respect to dose deviation, DTA, and gamma index of the Delta<sup>4</sup> Discover system and the Delta<sup>4</sup> 3D dosimetry system. It was suggested that the dosimetric verification system under investigation could be useful for routine patient specific QA.

#### EP-1475 RBE estimation of different Brachytherapy sources based on micro- and nanodosimetry

M. Bug<sup>1</sup>, T. Schneider<sup>2</sup>

<sup>1</sup>Phys. Techn. Bundesanstalt PTB, 6.5 Radiation Effects, Braunschweig, Germany

<sup>2</sup>Phys. Techn. Bundesanstalt PTB, 6.3 Radiation Protection Dosimetry, Braunschweig, Germany

#### Purpose or Objective

Depth-dependent RBE values of typical photon-emitting Brachytherapy (BT)-sources were determined by a microdosimetric and a nanodosimetric approach. The microdosimetric approach considers a biological endpoint while the nanodosimetric approach is entirely based on the track structure, given by the interactions of the photons and secondary electrons. The track structure characterizes the radiation quality on the nanometric scale.

#### Material and Methods

Within a cylindrical water phantom, isotropically emitting BT-sources were positioned 4 cm below the surface. Studied were Co-60 and Ir-192 representing high-energy photon-emitting sources, I-125 being a low-energy photon-emitting source, and Intrabeam<sup>®</sup>- and Axxent<sup>®</sup>-devices as examples for electronic BT X-ray sources (EBX). Resulting photon spectra were calculated at several points along the cylindrical axis within cylindrical voxels of 0.5 mm depth and 2 mm radius up to a depth of 10 cm.

The microdosimetric calculations of RBE are based on yield coefficients  $\alpha_{dic}$ , representing the linear component of the dose-effect relationship for the dicentric chromosome aberration yield after an irradiation with monoenergetic photons. The RBE for a given source in a given point was determined by convoluting the respective spectrum with the function  $\alpha_{dic}(E)$ , obtained previously by microdosimetric calculations.

The same depth-dependent photon spectra were used to determine nanodosimetric quantities by Geant4-DNA calculations. For each initial photon track, target volumes in size of one DNA convolution which experienced at least 4 ionizations (F4) were identified. Such quantities were previously shown to describe the DSB yield. Based on the

average minimum distance between these volumes within each photon track, the RBE was estimated by normalization to the distance for Co-60 at 0.125 mm depth.

#### Results

Relative depth-dependent RBE based on nanodosimetric quantities are similar to the microdosimetric RBE. For Co-60 and Ir-192, the RBE increases with depth due to an increasing contribution of low-energy photons in the spectra. For the denser ionizing sources, nanodosimetric RBE values were divided by 1.9. Apart from this factor, the constant RBE-dependence up to 10 cm for I-125 and the decrease of RBE for the two EBX sources due to beam hardening are in good agreement with the microdosimetric RBE.

#### Conclusion

RBE based on track structure (nanodosimetric approach) shows that the average intra-track distance between DNA-modelling volumes potentially suffering severe damage is well related to the microdosimetric RBE, based on the formation of dicentric chromosomes, for several BT-sources. Apart from a constant normalization factor for the denser ionizing sources, the depth-dependence is in excellent agreement. This indicates that the nanodosimetric photon track characterization performed in this study is a good descriptor for the radiation quality. Furthermore, the proposed target volume appears realistic. Note, that neither the photon fluence nor biological endpoints were taken into account for this approach.

<sup>3</sup>Università Cattolica del Sacro Cuore, Medical Physics Institute - Fondazione Policlinico Universitario A. Gemelli-, Rome, Italy

#### Purpose or Objective

This study reports in-vivo dose verification (IVD) results elaborated with SOFTDISO software on 300 cancer patients treated with 3D-CRT, IMRT and VMAT techniques. SOFTDISO uses the integral EPID image referred to each single static or dynamic beam providing a quasi- real-time test elaboration.

#### Material and Methods

The selected patients for this study were treated with an Elekta Synergy Agility LINAC at SS. Annunziata Hospital. 3D-CRT, IMRT and VMAT treatment plans of 300 patients were randomly selected. IVD tests were processed with the SOFTDISO software who provides two type of tests: (i) R ratio between the reconstructed isocenter dose and the planned one; (ii) transit dosimetry based on  $\gamma$ -analysis of EPID imaging ( $P_g$  (%) and  $g_{mean}$ ).

#### Results

We identified class-1 errors, derived from inadequate QCs, and class-2 errors due to patient morphological changes. Considering overall (6697) tests, we found out that only 5% of them showed out-of-tolerance mean R values. For gamma index analysis, in 13% of the overall tests were found to be out of tolerance. Ignoring class-2 errors, 100% of patients treated with different radiotherapy techniques (except 3DCRT breast treatment, for which no class-2 errors were observed) reported mean  $P_g$  (%) values within tolerance levels. Thus, the percentage of out-of-tolerance tests decreases from 13% to 7%. However,

considering all the techniques, only 4.4% of mean  $g_{\text{mean}}$  tests resulted out of tolerance. In addition, removing class-2 errors, this percentage decreases to approximately 3%. Actually the workload of IVD procedures on 9 patients is 1 hour per day.

#### Conclusion

IVD performed using SOFTDISO assures: (i) a rapid response of dose delivery alert with a reduced workload; (ii) a large number of patients tested daily and (iii) for out-of-tolerance tests repeating IVD in the subsequent day, the possibility to verify the efficacy of the adopted corrections.

<sup>7</sup>Illawarra and Shoalhaven Local Health District, Illawarra Cancer Care Centre, Wollongong, Australia

<sup>8</sup>University of New South Wales, South Western Sydney Clinical School, Sydney, Australia

#### Purpose or Objective

Pre-treatment dose verification is often performed on dose measuring phantoms with some form of gamma evaluation. However it has been shown that the clinical relevance of a 3% and 3mm pass rate tolerance is questionable. The purpose of this study is to simulate machine errors of clinical significance for nasopharynx patients and test if these errors can be detected on a standard commercial phantom. In this study systematic errors including collimator rotation, gantry rotation, MLC shifts, and MLC field sizes are investigated.

#### Material and Methods

Ten retrospective VMAT patients were planned with a department protocol. Machine errors were deliberately introduced to all plans. Plans were modified by increments using Python to create simulated error plans; -5 to 5° for gantry and collimator angles and -5 to +5mm for MLC shift and MLC field size, considering each parameter separately. Simulated error plans ( $Dose_{\text{error}}$ ) were compared to the original non-error plan ( $Dose_{\text{Baseline}}$ ) utilising equation (1).

$$Dose\ Difference = \frac{Dose_{\text{error}} - Dose_{\text{Baseline}}}{Dose_{\text{Baseline}}} \quad (1)$$

(1)

All error plans doses were then recalculated in Pinnacle<sup>3</sup>. Plans were reviewed against acceptable tolerance limits. Plans were above tolerance and considered unacceptable if PTV D95%, Brainstem D1cc or spinal cord D1cc were beyond a  $\pm 5\%$  deviation in dose. Additionally if either of the left or right parotid mean doses were beyond  $\pm 10\%$ , this was also considered an unacceptable plan.

The smallest unacceptable error plan for each error type (including the Gantry (G), Collimator (C), MLC Shift (S), and MLC Field Size (F) error) was delivered on an Elekta Linac and dose was measured using an ArcCheck. Gamma analysis was performed in SNCpatient version 6.6 utilising a global 3%/3 mm (10% threshold with correction off) gamma pass rate. Before measurement, the Linacs were tested for MLC, gantry and dose accuracy. Only one patient's -5° gantry error was deemed unacceptable and subsequently measured, patient 2 with this error detected (gamma pass rate of 68.8%).

#### Results

The results for 10 patients are shown in Figure 1.

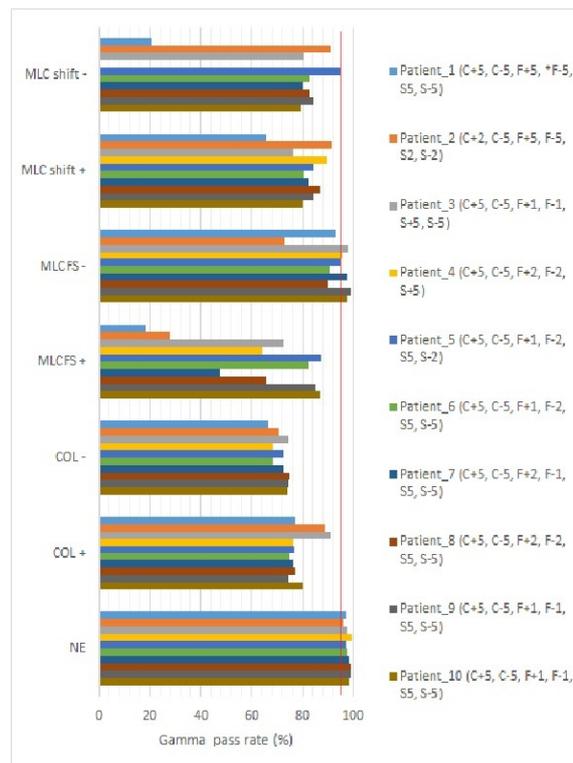

Figure 1. Gamma pass rate (%) for non-error (NE) plans and for deliberately introduced errors (including the Collimator (C), MLC shift (S), and MLC Field Size (F) error), where the latter are selected as exceeding dose tolerances by the smallest magnitude. \*Patient 1 F error of -5 was not deliverable due to machine tolerances, hence an F error of -2 is utilised here.

The global 3%/3mm gamma pass is able to detect the majority of unacceptable plans, however some MLC field size plans still pass. Decreasing the MLC field size by 1mm can result in significantly reduced dose to the PTV, which affects tumour control e.g. patient 3 MLC FS-1 passed, however this plan under-doses the PTV63Gy by -5.4% relative to the original non-error plan.

#### Conclusion

Not all deliberately introduced clinically significant errors were discovered for VMAT plans using a typical 3%/3mm (10% threshold with correction off) gamma pass rate.

#### EP-1478 A split field beam model of Beam Modulator linear accelerator in Pinnacle treatment planning system

M. Chandrasekaran<sup>1</sup>, S. Worrall<sup>1</sup>, M.K.H. Chan<sup>1</sup>, N. Khater<sup>1</sup>, C. Birch<sup>1</sup>

<sup>1</sup>University Hospital Southampton NHS Foundation Trust, Radiotherapy Physics, Southampton, United Kingdom

### Purpose or Objective

The aim of this study was to model a beam modulator linear accelerator in Pinnacle v.14.0 treatment planning system for intracranial stereotactic radiosurgery and radiotherapy.

### Material and Methods

Depth dose, beam profile and total scatter correction factor data were collected for 6 MV photons of Elekta Synergy Beam Modulator™ linear accelerator with 80 leaves each of 4 mm leaf pitch using unshielded IBA stereotactic field diode for field sizes ranging from 0.8x0.8 cm<sup>2</sup> to 4x4 cm<sup>2</sup> and field sizes above 4x4 cm<sup>2</sup> up to 16x21 cm<sup>2</sup> using IBA CC04 pinpoint chamber. The measured data were imported in to the photon physics module of Pinnacle v.14.0 and physical accelerator head specific data such as primary collimator, flattening filter, MLC were input in addition to beam data measurements. The auto modeler of Pinnacle TPS was iteratively used to adjust parameters such as photon beam energy spectrum, Gaussian height and width of the photon source that affect various regions of the depth doses and beam profiles to match measured data. Dose grids of 1 mm and 2.5 mm were used for beam modelling of fields from 0.8x0.8 cm<sup>2</sup> up to an equivalent square field of 6.7 cm<sup>2</sup> and above 6.7 cm<sup>2</sup> respectively. A common photon energy spectrum did not prove sufficient to achieve the required agreement between Pinnacle calculated and measured depth doses and beam profiles for the whole range of field sizes. This was overcome by a split field model that employs field size specific beam energy spectra, with higher relative weights of low energy bins and lower relative weights of high energy bins for small fields and vice-versa for field sizes larger than 6.7 cm<sup>2</sup>. The validity of the model was tested independently using a Standard Imaging Exradin A26 chamber in LUCY phantom for field sizes ranging from 0.8x0.8 cm<sup>2</sup> by comparing calculated and measured absolute doses and relative output factors.

### Results

Optimization of photon beam energy spectrum specific to small field sizes improved the agreement of depth doses both in and beyond build-up region for the small fields. Measured versus calculated absolute planned doses were found to be within 1% for field sizes larger than 1.6x1.6 cm<sup>2</sup> and less than 2.5% for 0.8x0.8 cm<sup>2</sup> field. The agreement between the measured and calculated relative output factors were within 2% for field sizes larger than 1.6x1.6 cm<sup>2</sup> and less than 3.5% for 0.8x0.8 cm<sup>2</sup> fields.

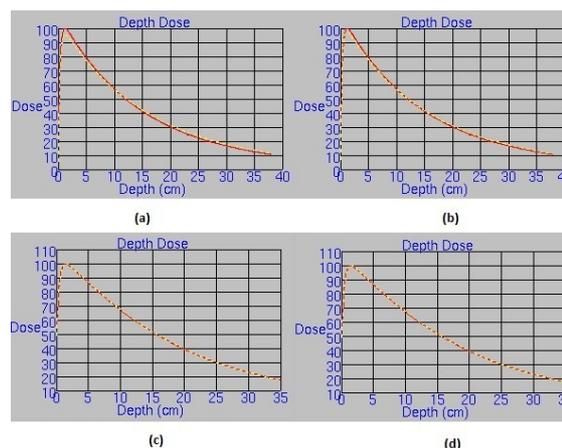

Fig.1. Measured (red) and calculated (yellow) depth doses (a) 0.8 cm and (b) 10.4 cm before energy spectrum optimisation (c) 0.8 cm and (d) 10.4 cm after energy spectrum optimisation

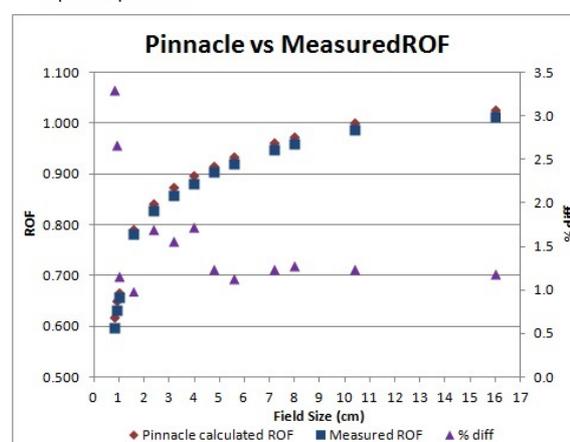

Fig. 2. Pinnacle calculated vs measured relative output factors and percentage differences against field sizes

### Conclusion

A split field model was generated for the whole range of field sizes of a beam modulator linear accelerator from 0.8x0.8 cm<sup>2</sup> to 16x21 cm<sup>2</sup> using field size dependent photon beam energy spectra. The model was successfully validated independently and was found have a good agreement with measured doses and relative output factors.

### EP-1479 Gamma 3D analysis for VMAT treatments using two detector arrays

E.M. Ambroa Rey<sup>1</sup>, D. Navarro Jiménez<sup>1</sup>, A. Ramirez Muñoz<sup>1</sup>, R. Gómez Pardos<sup>1</sup>, D. Amat de los Angeles<sup>1</sup>, A. Gibert Serrano<sup>1</sup>, A. López Muñoz<sup>1</sup>, M. Parcerisa Torné<sup>1</sup>, M. Colomer Truyols<sup>1</sup>

<sup>1</sup>Consorci Sanitari de Terrassa, Medical Physics Unit- Radiation Oncology Department, Terrassa, Spain

### Purpose or Objective

The development of advanced radiation therapy techniques, such as volumetric modulated arc therapy (VMAT), requires a patient-specific pre-treatment quality assurance (QA). Two-dimensional array detectors are widely used for dose distribution verifications and the 3D gamma index is one of the metrics which have been extensively used for clinical routine patient specific QA. The aim of this study is to evaluate the 3D gamma index for different VMAT plans, such as head and neck (H&N) and prostate, with the Octavius 4D system using two 2D-arrays (PTW Octavius4D 1500 and PTW Octavius4D 729).

### Material and Methods

Fourteen H&N and ten prostate VMAT plans were created and their respective QA plans were developed using Monaco 5.1 treatment planning system and delivered by an Elekta Synergy Linac equipped with an Agility 160 MLC system. The cylindrical phantom Octavius 4D was used to measure the dose distribution.

The 2D-array Octavius 729 consists of 729 vented ionization chambers arranged in a 27x27 matrix with a spatial resolution of 10mm. The chamber volume is 0.125cm<sup>3</sup>. The Octavius 1500 array has the same layout and dimensions but with 1405 ionization chambers with a chamber volume of 0.06cm<sup>3</sup>.

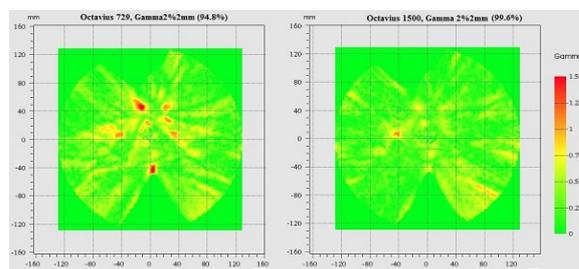

In order to reconstruct and analyze the measured 3D dose from each plan, the PTW VeriSoft 6.2 patient plan verification software was used and a volumetric 3D gamma index analysis (max dose of calculated volume, suppress dose below 10% of max dose of calculated volume) for both 3%3mm and 2%2mm criteria was performed to compare and evaluate the measured and calculated doses for both arrays.

### Results

Table I summarizes the results for both cases. The mean pass rate of global 3D gamma index for all prostate cases was superior to 99% with 3%3mm and 95% with 2%2mm criteria. The Octavius1500 achieves higher results for both criteria. The mean difference was 2.9% for the gamma 2%2mm and 0.6% for the 3%3mm. For the H&N cases, the mean passing rate was lower than prostate cases. Similarly, the Octavius1500 obtain better results for both criteria. The mean difference was 4.2% for the gamma 2%2mm and 0.8% for the 3%3mm.

H&N	Gamma 2%2mm		Gamma 3%3mm	
	Octavius 729	Octavius 1500	Octavius 729	Octavius 1500
Mean (%)	90.6	94.9	98.5	99.3
SD (%)	3.8	3.0	1.0	0.5
Max (%)	94.9	99.5	99.6	100.0
Min (%)	82.5	89.0	96.0	98.3
Prostate	Gamma 2%2mm		Gamma 3%3mm	
	Octavius 729	Octavius 1500	Octavius 729	Octavius 1500
Mean (%)	95.3	98.2	99.3	100.0
SD (%)	1.4	0.3	0.3	0.1
Max (%)	97.1	98.7	99.7	100.0
Min (%)	93.2	97.7	98.7	99.9

Expectedly, the greatest differences between Octavius 1500 and 729 are shown in the gamma 2%2mm criteria. Figure 1 shows a comparison between the gamma 2%2mm for both detectors for a H&N case.

### Conclusion

As we expected, the Octavius 1500 achieves a better result for pre-treatment VMAT plan verification and the results are more remarkable for the gamma 2%2mm criteria. In addition, plans with a higher complexity such H&N can benefit from the superior results of the Octavius 1500.

Moreover, the Octavius 1500 present the possibility to increase the spatial sampling frequency and the coverage of a dose distribution by merging two measurements. We can conclude that Octavius 1500 outperformed Octavius 729 for VMAT pre-treatment QA.

### EP-1480 Patient-specific QA for CyberKnife MLC plans using Monte Carlo

P.H. Mackeprang<sup>1</sup>, D. Vuong<sup>1</sup>, W. Volken<sup>1</sup>, D. Henzen<sup>1</sup>, D. Schmidhalter<sup>1</sup>, M. Malthaner<sup>1</sup>, S. Mueller<sup>1</sup>, D. Frei<sup>1</sup>, D.M. Aebersold<sup>2</sup>, M.K. Fix<sup>1</sup>, P. Manser<sup>1</sup>

<sup>1</sup>Division of Medical Radiation Physics and Department of Radiation Oncology, Inselspital- Bern University Hospital- and University of Bern, Bern, Switzerland

<sup>2</sup>Department of Radiation Oncology, Inselspital- Bern University Hospital- and University of Bern, Bern, Switzerland

### Purpose or Objective

To implement and validate a Monte Carlo (MC) based dose calculation framework to perform patient-specific quality assurance (QA) for multi-leaf collimator (MLC) based CyberKnife treatment plans.

### Material and Methods

In order to calculate dose distributions independently from the treatment planning system (TPS), an independent dose calculation (IDC) framework was developed based on the EGSnrc MC transport code. The framework uses XML-format treatment plan input and DICOM format patient CT data, an MC beam model using phase space files, CyberKnife MLC beam modifier transport using the EGS++ class library, a beam sampling and coordinate transformation engine and dose scoring using DOSXYZnrc.

Validation of the framework was performed against dose profiles of single beams with varying field sizes measured with a diode detector in a water tank in units of cGy / monitor unit (MU) and against a two-dimensional dose distribution of a full treatment plan measured with Gafchromic EBT3 (Ashland Advanced Materials, Bridgewater NJ) film in a homogeneous solid water slab phantom. The film measurement was compared to IDC by gamma analysis using 1% (global) / 1 mm criteria and a 10% global low dose threshold.

Finally, the dose distribution of a clinical prostate treatment plan was calculated and compared to dose calculated by the TPS finite size pencil beam algorithm by gamma analysis using either 2% (global) / 2 mm or 1% (global) / 1 mm criteria and a 10% global low dose threshold.

### Results

Dose profiles calculated with the developed framework in a homogeneous water phantom agree within 3% or 1 mm to measurements for all field sizes. 87.1% of all voxels pass gamma analysis comparing film measurement to calculated dose. Gamma analysis comparing dose calculated by the framework to TPS calculated dose for the clinical prostate plan showed 99.9% passing rate for 2% / 2 mm criteria and 85.4% passing rate for 1% / 1 mm, respectively. Dose differences of up to  $\pm 10\%$  were observed in this case near bony structures or metal fiducial markers.

### Conclusion

An MC based modular IDC framework was successfully implemented and validated against measurements and is now available to perform patient-specific QA by independent dose calculation.

### EP-1481 Testing algorithms in water and heterogeneous medium using experimental designs

S. Dufreneix<sup>1</sup>, A. Barateau<sup>1</sup>, M. Bremaud<sup>1</sup>, C. Di Bartolo<sup>1</sup>, C. Legrand<sup>1</sup>, J. Mesgouez<sup>1</sup>, D. Autret<sup>1</sup>

<sup>1</sup>Institut de Cancérologie de l'Ouest, Medical Physics, Angers, France

### Purpose or Objective

The IAEA Tecdoc 1580 and 1583 suggest several beam configurations for testing, commissioning and ongoing quality assurance of TPS. However, the large number of

tests makes it difficult to implement and results out of tolerance are often left unexplained. Experimental designs are a robust statistical method which minimizes the number of tests to be performed and provides a statistical analysis of the results. They were used to compare computed and measured doses for several algorithms.

#### Material and Methods

Tests were chosen using a Taguchi table L36 ( $2^{11} \times 3^{12}$ ) to enable the quantification of the influence of each parameter. Five algorithms were studied: the AAA (version 11, Varian) is used in clinical routine and the collapsed-cone convolution-superposition (CCCS) algorithm (version 1.5, Mobius Medical Systems) is used as a secondary dose calculation plan check. The AcurosXB (AXB) algorithm (version 11, Varian) was also investigated as well the pencil beam (PB) and Monte Carlo (MC) algorithms available on Iplan (version 4.5, Brainlab). Absorbed dose was first calculated in water for 72 beams with varying parameters: energy, MLC, depth, wedge angle, wedge jaw, X, Y<sub>1</sub> and Y<sub>2</sub> dimensions. Computations were then conducted for 72 beams in a CIRS Thorax phantom with varying parameters: energy, wedge angle, wedge jaw, X and Y dimensions, medium and gantry angle. Calculated doses were compared to measurements conducted on a Novalis TrueBeam STx (Varian) with a CC04 ionisation chamber (IBA).

#### Results

In water, all algorithms gave a mean difference between computed and measured doses centred on zero (within the uncertainty). No studied parameter led to statistically significant deviation. In the thorax phantom, the mean difference between computed and measured doses was  $-0.7 \pm 1.1\%$  for AAA,  $-1.4 \pm 1.4\%$  for CCCS,  $-2.5 \pm 1.0\%$  for AXB,  $2.3 \pm 2.2\%$  for PB and  $0.3 \pm 1.9\%$  for MC. For AAA and CCCS, calculations in bone medium led to a statistically significant underestimation of the computed dose while the other parameters had no influence on the results. For MC, calculated dose was overestimated for gantry angle of  $225^\circ$  which was attributed to the modelization of the treatment table by the TPS.

#### Conclusion

Experimental designs were used as a statistical method to validate the AAA, CCCS and MC algorithms. The PB algorithm was rejected for clinical use because it overestimates the dose in heterogeneous medium. Results showed that the AXB algorithm systematically underestimates the dose in heterogeneous medium which could be linked to the dose to water - dose to medium conversion as referred in the literature. Further investigation is needed before its implementation in clinical routine, especially for modulated beams. The tests described by the experimental designs were also used to define the tolerance levels of the secondary plan check software and are now part of the ongoing quality assurance of the TPS

#### EP-1482 Signal Prediction for an On-line Delivery Verification System

R. Heaton<sup>1</sup>, M. Farrokhkish<sup>1</sup>, G. Wilson<sup>1</sup>, B. Norrlinger<sup>1</sup>, D.A. Jaffray<sup>1</sup>, M.K. Islam<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre University Health Network, Radiation Physics, Toronto, Canada

#### Purpose or Objective

Dynamic radiation delivery techniques like VMAT introduce challenges in treatment verification. Complex treatments, as well as hypofraction and adaptive radiation therapy, require new verification approaches to ensure safe delivered. One approach is the introduction of entrance fluence monitoring device, like the Integral Quality Monitoring (IQM) System (iRT Germany), which provides a spatially encoded dose area product signal as a

unique delivery fingerprint. Complementary to this measurement is the signal calculation based on the treatment plan. This work describes the calculation for the IQM system and examines the impact of selected components on clinical fields.

#### Material and Methods

The calculation models the spatial response of the IQM chamber and the fluence transmitted through the individual collimating elements. The chamber response is modelled as a 2D map. The fluence from the machine is divided into 2 components: a point source at the target and an extended source at the flattening filter, referred to as the primary and extended source, respectively. The primary source is characterized by a radial intensity profile and is attenuated through the jaws and multileaf collimator. Transmission is calculated for a 2D array matching the chamber response map, and area averaged fluence is calculated for moving collimating elements during beam delivery. The extended source is modeled as a Gaussian distributed source with a Compton angular intensity distribution. The contribution of the Gaussian source to each element in the fluence array is raytraced through the collimation to obtain the area averaged fluence. An element-wise multiplication of the chamber response map with the primary and extended source fluence is summed to generate the predicted signal, modified by factors reflecting the chamber volume, the intensity of the primary and extended sources and change in machine output with field aperture. The model has been implemented for Varian and Elekta treatment units, with calculations and measurements compared for clinically relevant fields.

#### Results

Parameters for the model were determined from a series of rectangular field measurements with the IQM chamber combined with ion chamber measurements. Iterative optimization of parameter values to match rectangular field IQM measurement were performed. Similar techniques were used to extract normalization parameters.

The agreement between the calculated and measured signals on a Varian TrueBeam unit for over 300 different IMRT field segments from Prostate and Head & Neck plans show 99% of segments agree within  $\pm 5\%$ ; 95% within  $\pm 3\%$ . Similar results were seen for an Elekta Agility unit in a sample of over 400 different IMRT field segments, with 97% of segments agreeing within  $\pm 5\%$  and 91% within  $\pm 3\%$ .

#### Conclusion

A 2-source calculation model has been implemented for an area-fluence monitor designed for on-line patient QA.

#### EP-1483 Pre-Treatment QA of MLC plans on a CyberKnife M6 using a liquid ion chamber array.

<sup>3</sup>University of Florence, Department of Clinical and Experimental Biomedical Sciences "Mario Serio", Firenze, Italy

<sup>4</sup>IFCA, Radiation Oncology, Firenze, Italy

<sup>5</sup>Azienda Ospedaliera Universitaria Careggi, Radiotherapy Unit, Firenze, Italy

#### Purpose or Objective

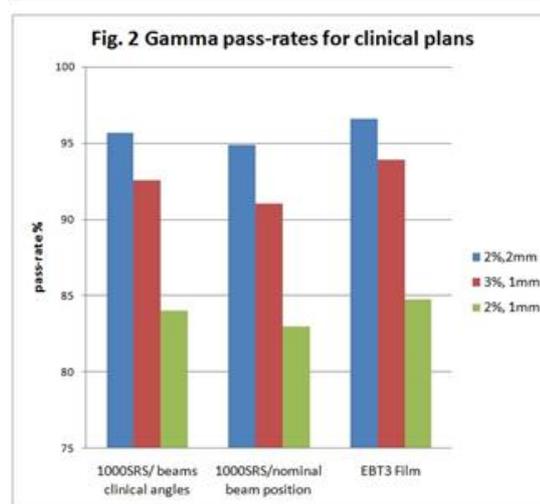

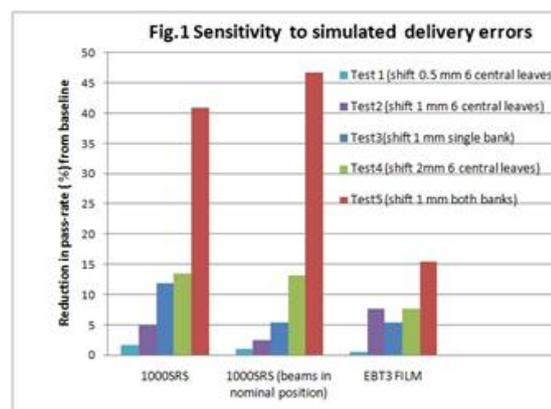

CyberKnife MLC plans require accurate patient-specific QA. The purpose of this study is to validate the use of a liquid ion chamber array for Delivery Quality Assurance (DQA) of robotic MLC plans, using several test scenarios and routine patient plans and comparing results to film dosimetry.

### Material and Methods

Five preliminary sensitivity test scenarios were created from a baseline plan modifying each MLC segment by introducing increasing shifts in leaves positions (0.5 mm - 2 mm). The baseline and test plans were delivered to an Octavius 1000SRS array (PTW) as well as to EBT3 films. An average correction was applied to 1000SRS results to account for the response dependence on source-detector-distance (SDD) [O. Blanck et.al. Phys Med 2016]. The same five test plans were delivered a second time to the 1000SRS re-orienting all beams perpendicularly to the array (nominal position) to eliminate SDD and angle dependence. As a second step 40 clinical MLC plans optimized for various treatment sites (liver, spine, prostate) were delivered to the liquid ion chamber array for patient-specific QA using both the clinical beam orientations and the beam "nominal position". For the latter only a subset of segments(18-21) was selected. Finally, for 15 out of 40 clinical plans a film-based DQA was also performed. All results were analyzed using (2%, 2mm), (3%, 1mm) and (2%, 1mm) gamma index criteria [O. Blanck et.al. Phys Med 2016].

### Results

The pass-rate reductions from the baseline, obtained delivering the five test plans, are shown in fig.1 for (3%, 1mm) gamma criteria. The Octavius 1000SRS showed a good sensitivity to simulated delivery errors with pass-rate reductions increasing from 1.7% to a maximum of 43% with increasing leaves shifts (0.5 mm - 2 mm). Similar sensitivity was observed when the beams were re-oriented in the nominal position geometry. The pass-rate reductions observed with films showed a more irregular trend, and the maximum reduction was 16%. The average pass-rates obtained over clinical plans are shown in fig.2, for the three gamma index criteria. The mean values obtained by the 1000 SRS array, using both the clinical and nominal beam geometry, and by film-dosimetry are all above 92%, when using 3%, 1mm criteria. Differences among the mean pass-rates observed for the three measurement modalities were not statistically significant ( $p > 0.1$ , t-test)

### Conclusion

The results confirm that the 1000SRS array is reliable for pre-treatment QA of CyberKnife MLC plans. The test scenarios highlighted a higher sensitivity to small leaves shifts than what observed by film dosimetry. The gamma pass-rates obtained for clinical plans DQA were comparable to film pass-rates. The possibility to use the beam nominal position was validated and can be an alternative to eliminate SDD and angle dependence.

### EP-1484 Validation of ptw's diamond as alternative method for the imrt-vmat pretreatment verification

A. Niebla Piñero<sup>1</sup>, B.C. Portas Ferradás<sup>1</sup>, P. Rosa Menéndez<sup>1</sup>, J.A. Merino Gestoso<sup>1</sup>, M. Rodríguez Pazos<sup>1</sup>, D. Pardo Calvo<sup>1</sup>, B. Sobral Aspérez<sup>1</sup>

<sup>1</sup>Hospital Universitario Nuestra Señora de Candelaria, Medical Physics, Santa Cruz de Tenerife, Spain

### Purpose or Objective

The aim of the study is the validation of the software DIAMOND, as alternative method to ion chamber point dose measurements to verify prostate's IMRT-VMAT plans. For this purpose, we have selected 109 IMRT and 65 VMAT treated plans between the 12/09/2013 to 08/16/2016. We have compared the results using Diamond with the ion chamber results in the pretreatment verification. Using a ROC analysis we have obtained the new tolerances to apply in our QA program.

### Material and Methods

We have selected 109 IMRT step & shoot plans calculated with CMS XiO and 65 VMAT calculated with CMS MONACO. This plans were calculated over the own patient's CT and also over the IMRT phantom's CT used for the point dose verification. These plans were sent to DIAMOND to make the recalculation in two points: One of them in a high dose-low gradient region (P1), and the other in a high

dose-high gradient region (P2). In our QA program for ion chamber verification, we have established a 3% of deviation in P1 points, and 5% deviation in P2 points.

### Results

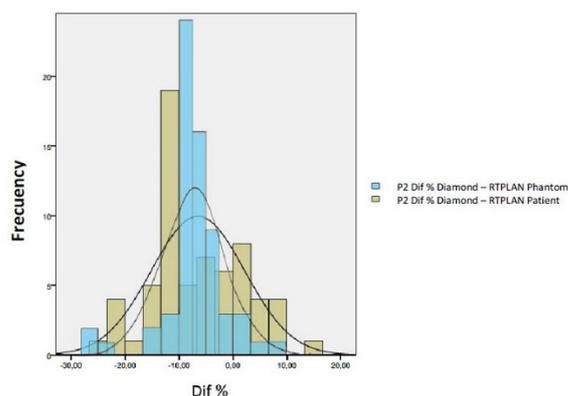

We have recalculated the dose using DIAMOND in P1 and P2 points over the definitive patient plan, and also over the definitive plan simulated in the phantom. The results were compared with the TPS values. Furthermore, we have compared this deviation with the deviation between the measurements and the dose calculated in the TPS. The following table shows some results:

Table 1

	IMRT		VMAT	
	PHANTOM	PATIENT	PHANTOM	PATIENT
P1				
Mean Dif %DIAMOND-RTPLAN	-1.5±0.9	-1±1.3	0.9 ± 3.7	4.8 ± 8
DIAMOND 95% confidence interval (%)	(-1.7;-1.4)	(-1.3;-0.8)	(0.01;1.8)	(3.5;6.3)
Dif% DIAMOND-Measurement	-1.4 ± 1	-	0.4 ± 3.7	-
DIAMOND Tolerance	±3%	±3%	±3%	±7%
P2				
Mean Dif% DIAMOND-RTPLAN	-4.4±1.6	-3.5±2.1	-7.0 ± 5.4	-6.5 ± 8.7
DIAMOND 95% confidence interval (%)	(-4.70;-4.0)	(3.9;-3.1)	(3.5;6.3)	(-8.5;-4.2)
Dif% DIAMOND-Measurement	-5.3 ± 2	-	-8.7 ± 7.5	-
DIAMOND Tolerance	±7%	±7%	±10%	±15%

To establish new tolerances, we have looked into the 95% confidence intervals for dose deviation, and also we have done a ROC analysis between the new method (DIAMOND) and the old (ion chamber). Even though, we show in our results that 95% confidence intervals are asymmetric, we have chosen our tolerances in a symmetric interval. We believe that this decision will make the analysis more clear and will avoid errors in the future.

Figure 1

As we show in figure 1, differences may appear between phantom and patient results for P2 points in VMAT plans. These differences could be associated with different algorithms used in the TPS (Monte Carlo) and the Diamond (Clarkson), and their differences in a heterogeneity medium. Although differences exist, we can correlate the results between the new and the old method, over the phantom's plan and also over the patient's plan. Even though, we have obtained good results in the global plan analysis, we have seen that it's possible to obtain big differences in a field. This can be explained because the calculated point may be in a penumbra region, where the uncertainties in the calculation are bigger than the established tolerances.

### Conclusion

We have checked the DIAMOND's viability to verify IMRT-VMAT plans, also we have calculated tolerances to apply in clinical use. With this new method, we will decrease the time in the verification and also decrease the time between the moment that the plan is calculated and the beginning of the treatment.

### EP-1485 Dosimetric characterization of an high definition MLC for stereotactic radiotherapy treatments.

F. Rosica<sup>1</sup>, F. Bartolucci<sup>1</sup>, C. Fidanza<sup>1</sup>, A. Savini<sup>1</sup>, D. Ciuffetelli<sup>1</sup>, A. Rastelli<sup>1</sup>, G. Orlandi<sup>1</sup>

<sup>1</sup>USL di Teramo Azienda ASL 4, Medical Physics, Teramo TE, Italy

### Purpose or Objective

High definition multi leaf collimators (MLCs) with reduced leaf width are beneficial for treating small lesions in modern stereotactic radiotherapy. In general, leaves have special design details that may have a strong impact on the delivered dose. The aim of this study was to characterize the dosimetric impact of such details in the Varian HD120 MLC for several beam qualities including flattening-filter-free (FFF) modalities.

### Material and Methods

A set of MLC-collimated fields was irradiated using a Varian TrueBeam STx linear accelerator equipped with the HD120 MLC (beam qualities: 6MV, 10MV, 6MV-FFF, 10MV-FFF). These fields were designed using several abutment configurations (e.g. picket fence) in order to enhance the dosimetric impact of the MLC design details such as tongue-and-groove and rounded leaf tip. Dose profile scans were measured in a motorized water phantom using small detectors (IBA-Razor stereotactic diode and PTW-microDiamond 60019). Dose profiles of the abutted fields were summed and compared with the dose profiles of the corresponding open fields. In addition, average MLC transmission was measured using a Farmer ion chamber (IBA-FC 65-G).

### Results

Dosimetric effects induced by leaf details were more pronounced for FFF modalities. Due to the leaf tongue-and-groove, abutments of dose profiles using the leaf borders led to underdosages up to 13.7% (6MV), 12.3% (10MV), 15.5% (6MV-FFF), 14.4% (10MV-FFF), with respect to the open field profile (Fig.1, only 6MV and 6FFF are shown). On the other hand, abutments using the rounded leaf tips caused a dose increment up to 8.5% (6MV), 10.6% (10MV), 9.6% (6MV-FFF), 14.0% (10MV-FFF), with respect to the open field profile (Fig.2, only 6MV and 6FFF are shown). MLC-transmission at central axis was 1.2% (6MV), 1.4% (10MV), 1.0% (6FFF), 1.2% (10FFF). Same values were found in case of leaf interdigitation.

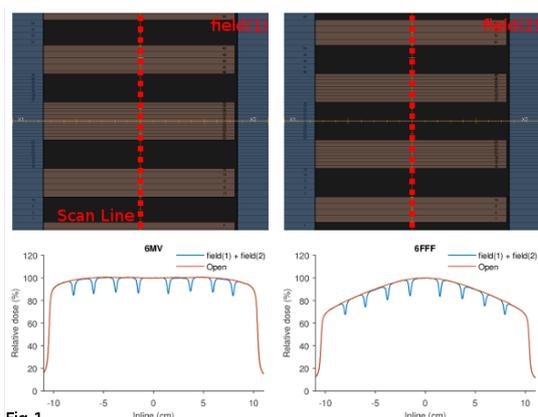

Fig.1

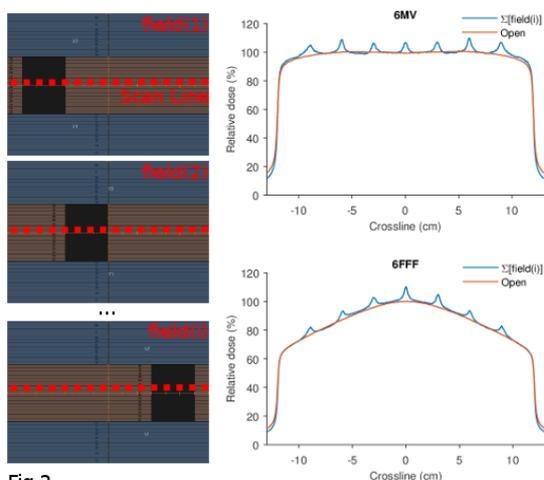

Fig.2

### Conclusion

The Varian HD120 MLC was dosimetrically characterized for several beam qualities. The leaf geometric details have a strong influence on the dose distribution, especially at the location of leaf abutments. These effects need to be considered in treatment planning, especially for intensity modulated techniques. The reported measurements are propaedeutic to the modeling of the observed effects in a treatment planning system for stereotactic radiotherapy.

### EP-1486 Further developments of two complexity metrics to consider clinical aspects of VMAT treatment plans

J. Göstvedt<sup>1</sup>, A. Bäck<sup>2</sup>, A. Karlsson Hauer<sup>2</sup>

<sup>1</sup>University of Gothenburg/Sahlgrenska University Hospital, Radiation Physics, Gothenburg, Sweden

<sup>2</sup>Sahlgrenska University Hospital, Therapeutic Radiation Physics, Gothenburg, Sweden

### Purpose or Objective

The objective of this study is to further develop two aperture-based complexity metrics Converted Aperture Metric (CAM) and Edge Area Metric (EAM) to account for clinical aspects of volumetric modulated arc therapy (VMAT) treatment plans on a control point level.

### Material and Methods

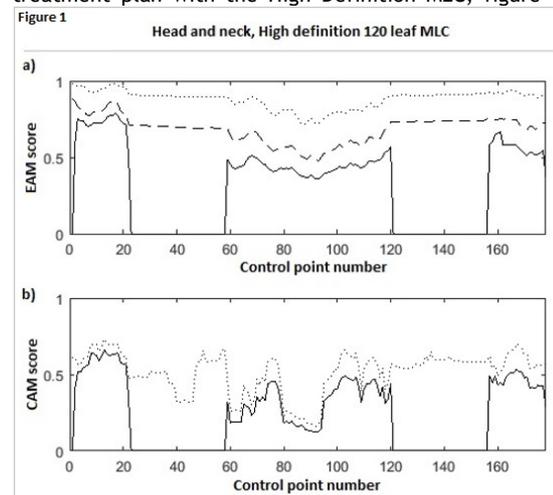

Two complexity metrics, CAM and EAM, have been developed in a previous study<sup>1</sup> where the metrics have been validated using static multi leaf collimator (MLC) openings simulating fix control points in VMAT treatment plans.

In this study, the two metrics have been further developed to be suitable for different types of MLC and adjusted to better differentiate between score values of clinical

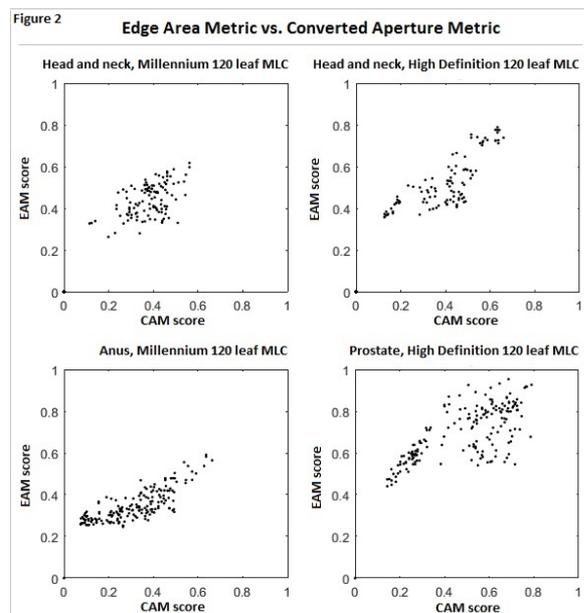

treatment plans. The metrics are also weighted against number of monitor units (MU) for each control point. Four prostate cancer and four head & neck cancer VMAT plans with the High Definition 120 leaf MLC (Varian) and one anal cancer, three prostate cancer and three head & neck cancer VMAT plans with Millennium 120 leaf MLC (Varian) were used in this study.

### Results

The complexity scores on a control point level is illustrated by an example of a head and neck cancer VMAT treatment plan with the High Definition MLC, figure 1.

The dotted lines in figure 1 shows unmodified versions of the metrics for all control points, which have been validated for static fields. The complex region defined in EAM have been reduced from enclosing an area of 5 to 2.5 mm on both sides of the MLC edges (dashed line, figure 1a), to better differentiate between complexity scores. CAM have been adjusted to be suitable for the High Definition MLC. Measurements were taken every 5 mm in both directions to give one measure for each MLC leaf pair<sup>1</sup> for the Millennium MLC. Since the central leaves are 2.5 mm for High Definition MLC the distances are now measured every 2.5 mm. The correlation between dose differences and complexity scores for the static fields<sup>1</sup> were remained for the improved versions of EAM and CAM. The scores were also weighted against number of MU according to an inverse exponential function to mainly lower the impact of the complexity scores for control points with no or very few MU (solid lines, figure 1). In this example the beam was turned off for beam directions coming through the shoulders and those parts should not contribute to the complexity. Larger variations in complexity scores for adjacent control points are seen for CAM compared to more consistent scores for EAM. The correlation between the metrics is shown in figure 2.

### Conclusion

Converted Aperture Metric and Edge Area Metric have successfully been further developed, with retained correlations as previous study, to account for clinical aspects of VMAT treatment plans and provide information about complexity on a control point level.

### EP-1487 Dosimetric aspects in the development of a crawl positioning device for prone breast radiotherapy

L. Paelinck<sup>1</sup>, B. Boute<sup>2,3</sup>, L. Veldeman<sup>1,2</sup>, C. De Wagter<sup>1,2</sup>, B. Speleers<sup>2</sup>, A. Van Greveling<sup>1</sup>, G. Post<sup>2</sup>, W. De Neve<sup>1,2</sup>

<sup>1</sup>University Hospital Ghent, Radiotherapy, Ghent, Belgium  
<sup>2</sup>Ghent University, Radiotherapy and Experimental Cancer Research, Ghent, Belgium  
<sup>3</sup>Ghent University, Industrial Design Center, Ghent, Belgium

### Purpose or Objective

A new prone patient positioning device for breast cancer radiation therapy was developed to treat patients in crawl position. Prototypes showed excellent patient comfort, stability, set-up precision and beam access to the regional lymph nodes. However, two carbon fiber bars of the external frame may be in beam paths in patients with pendulous breasts. In this study, the influence of these carbon fiber bars on the build-up dose and attenuation was investigated.

### Material and Methods

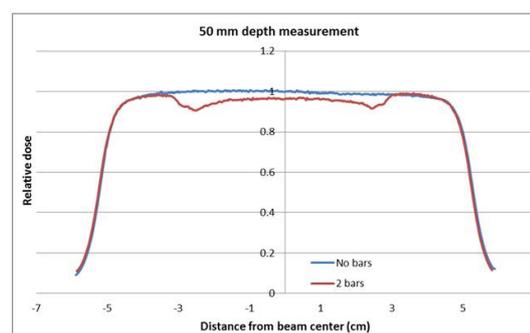

In figure 1 a picture of the patient positioning device is shown. Beams at gantry angles near 90° or 270° will pass through the 1 or 2 pullwinded carbon fiber bars of 37/40 mm upstream from the breast. The average distance between the breast and the closest surface of the medial bar was estimated 19 cm. Radiochromic film (Gafchromic EBT2, Ashland Specialty Ingredients, USA) placed in a slabbed polystyrene phantom was used to measure the influence of the bars on build-up dose and attenuation. Measurements were performed with a 6 MV photon beam at gantry 0° using a distance of 100 cm between the source and the surface of the phantom. A field size of 10 cm x 10 cm was used. Measurements were performed with or

without bars positioned above the phantom. An air gap of 19 cm between the upper surface of the phantom and the undersurface of the (lowest) bar was used. The bars were positioned above each other with parallel longitudinal axes at 95 mm distance between the axes to mimic the lay-out of the positioning device. The set-up with bars was scanned using a large-bore CT scanner (Aquilion, Toshiba Medical Systems, Tokyo, Japan). Measurements were performed at 0, 1, 2, 16, 30 and 50 mm depth in the phantom. Calculations of attenuation were performed using the Pinnacle convolution-superposition algorithm which is used in clinical practice.

### Results

For irradiation through the bars loss of build-up at the beam center, calculated by the formula  $(D-Db)/D$  [for depth >16mm]/ $D$  [depth=16mm] was measured as -3.6%, -2.0% and -1.6% at depths of 0, 1 and 2 mm, respectively. Hereby, D and Db represent the doses without and with irradiation through the bars, respectively. Attenuation at the beam center, calculated by the formula  $(D-Db)/D$  [for depths >= 16mm]/ $D$  [depth=16mm] at depths of 16, 30 and 50 mm depth was measured as 3.6%, 2.7% and 3.2%, respectively. A typical attenuation measurements is shown in figure 2. The attenuation through the bars at the beam center calculated by Pinnacle is 3.7%, 3.1% and 2.8% at 16, 30 and 50 mm depth, respectively.

### Conclusion

Measurements showed that the carbon fiber frame bars have a clinically irrelevant effect on the build-up dose. Attenuation by the bars as calculated using Pinnacle and measurements were in good agreement.

### EP-1488 Evaluation of the Efficacy and Accuracy of Customized bolus by using a 3-dimensional printer

W.K. Choi<sup>1</sup>, S.G. Ju<sup>1</sup>, J.C. Chum<sup>2</sup>, B.J. Min<sup>3</sup>, S.Y. Park<sup>1</sup>, H.R. Nam<sup>3</sup>, D.H. Lim<sup>1</sup>

<sup>1</sup>Samsung Medical Center, Radiation Oncology, Seoul, Korea Republic of

<sup>2</sup>Kyonggi University, Computer Science, Suwon, Korea Republic of

<sup>3</sup>Kangbuk Samsung Hospital, Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

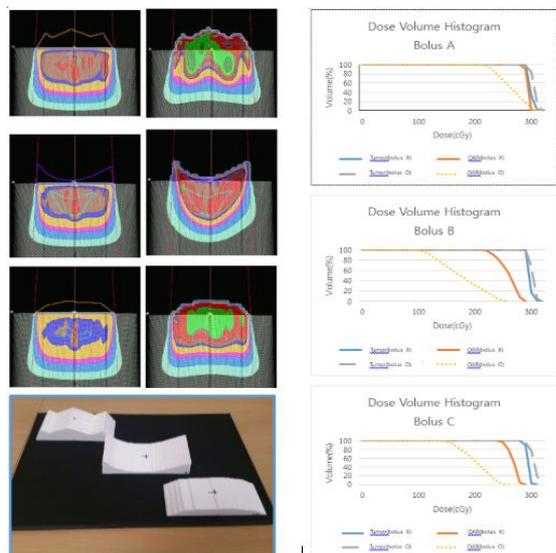

Tissue equivalent material commonly used in the electron radiation therapy was developed its own by using a 3-dimensional printer (3DP). We fabricated a customized bolus using a 3DP and evaluated for usefulness and accuracy of the Customized Bolus.

### Material and Methods

Treatment with an electron beam 20MeV according to the virtual Clinical Target Volume (CTV) and Organ at Risk (OAR) planed with a treatment plan system (TPS). The 3D printed customized bolus was then fabricated Bolus A, B and C, respectively, and its quality and clinical feasibility were evaluated by visual inspection and by assessing dosimetric parameters such as Dose Volume Histogram (DVH),  $D_{max}$ ,  $D_{min}$ ,  $D_{mean}$ ,  $V_{90\%}$ , and  $V_{80\%}$ . Test electron field was measured using Gafchromic<sup>TM</sup> EBT3 film. And then was scanned by using a film scanner and compared with TPS data by applying Gamma ( $\gamma$ ) analysis to verify their geometric accuracy.

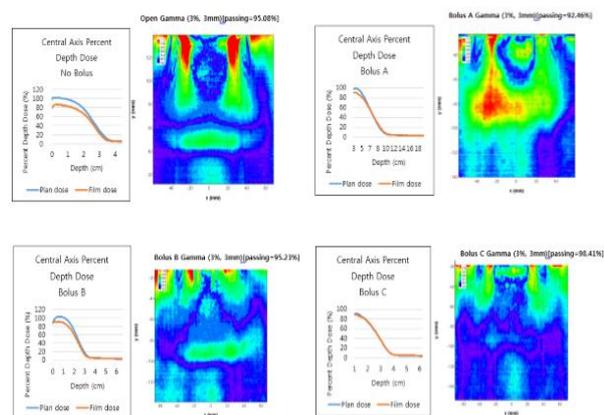

### Results

In all cases, the CTV volume is encompassed within 90% of the prescribed dose 3Gy. There was a difference in the CTV volume,  $D_{max}$  up to 0.12Gy,  $D_{min}$  up to 0.09Gy,  $D_{mean}$  up to 0.12Gy. In the OAR volume,  $D_{max}$  up to 0.29Gy,  $D_{min}$  up to 1.24Gy,  $D_{mean}$  up to 0.66Gy. The dose distribution difference between the measured and TPS dose was within 3%/3mm criteria with Gamma evaluation for EBT3 film. The pass rate for the test were 92.46%, 95.23%, 98.41% for Bolus A, B and C, respectively. It showed a more than 90% pass rate.

### Conclusion

In this study, we fabricated a customized starchy bolus in powdered form using a 3DP to dose build up and evaluated for usefulness and accuracy of the Customized Bolus. The result showed that 3D printed customized bolus could significantly improve the dose homogeneity in the CTV and reduce the dose in the OAR for patients treated with electron therapy effective in clinical trials.

### EP-1489 Effect of the thermoplastic mask on patient skin dose in tomotherapy

V. Ravaglia<sup>1</sup>, A. Giuliano<sup>2</sup>

<sup>1</sup>San Luca Hospital, Medical Physics, Lucca, Italy

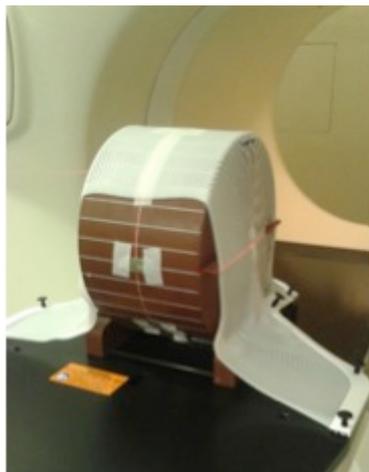

<sup>2</sup>Istituto Nazionale di Fisica Nucleare INFN- Pisa, Pisa, Italy

### Purpose or Objective

The Treatment Planning Systems (TPS) do not accurately model skin dose, and several studies in vivo have demonstrated that the TPS overestimates skin dose in tomotherapy treatments. The bolus effect due to thermoplastic masks, which are commonly used in Tomotherapy head & neck (H&N) treatments, has sometimes been reported in literature. The aim of this study was to report results of in vivo measurements of skin dose in tomotherapy using EBT3 Gafchromic films with and without thermoplastic mask.

### Material and Methods

Surface dose measurements were performed with the application of EBT3 pieces of size 2x2 cm<sup>2</sup>. Films were read with a flatbed scanner Epson 10000XL and images were analyzed using the red channel calibration. Preliminarily, reproducibility of surface dose measurements was assessed on Cheese phantom, then the thermoplastic mask effect was investigated using fine, normal and coarse calculation dose grids on phantom (see Figure 1). Skin doses were measured in vivo with the application of radiochromic film pieces directly on the skin of patients or in the inner side of thermoplastic mask, if used during the treatment. The target lesions included H&N, brain and sarcoma. For each patient films were located in 1 to 3 reproducible points and measurements were repeated on average for three fractions. Measured doses were compared with doses calculated with the TPS using fine grid.

### Results

The reproducibility of film measurements was on average of 2%. Measurements made on the Cheese phantom surface without mask showed an overestimation of the TPS of 28.6% with fine grid, which is commonly used in clinic. In presence of the mask there was an improvement of the agreement between EBT3 measurements and TPS estimated doses, achieving 0.7%. A considerable number of measurements was performed on 8 patients. The mean absolute value of the difference between measured and TPS-calculated dose and its standard deviation was  $11.6\% \pm 2.8\%$  for all treatments. The average differences were 9.1% for brain and H&N (in these case measurements were performed with mask), and -9.2% for the sarcoma. Hence, there was an overestimation of the TPS without the thermoplastic mask.

### Conclusion

In vivo surface dose measurements with EBT3 are a useful tool for quality assurance in tomotherapy, since the TPS does not give accurate dose values in the first millimeters of skin. Measurements performed both on phantom and in vivo have shown a bolus effect due to the thermoplastic mask, that compensates for the overestimation of the skin dose calculated by the TPS.

**EP-1490 A 3-class density method to monitor doses to the parotid glands and spinal cord in oropharynx IMRT**  
 N. Perichon<sup>1</sup>, S. Couespel<sup>1</sup>, C. Hervé<sup>1</sup>, O. Henry<sup>1</sup>, C. Lafond<sup>1,2,3</sup>, J. Castelli<sup>2,3,4</sup>, A. Largent<sup>2,3</sup>, O. Acosta<sup>2,3</sup>, E. Chajon<sup>4</sup>, R. De Crevoisier<sup>2,3,4</sup>

<sup>1</sup>Centre Eugène Marquis, Unité de Physique Médicale, Rennes CEDEX, France

<sup>2</sup>INSERM, U1099, RENNES, France

<sup>3</sup>Université Rennes 1, LTSI, RENNES, France

<sup>4</sup>Centre Eugène Marquis, Radiation Oncology Department, Rennes CEDEX, France

### Purpose or Objective

Within a perspective of dose guided/dose monitoring adaptive radiotherapy, a crucial issue is the possibility to calculate the dose distribution on Cone Beam CT scans (CBCTs). The parotid glands (PGs) and the spinal cord (SC) are among the main organs at risk (OAR) exposed to an overdose during the course of IMRT for oropharynx carcinoma. Dose calculation is particularly complex on non-CT images. One clinically applicable option would be to apply three density classes (soft tissue, air, bone) in the CBCTs, corresponding to the density values of the planning CT. The aim of this study was therefore to estimate the accuracy of the dose distribution calculation within PGs and SC by affectation of three density classes.

### Material and Methods

Fifteen patients receiving IMRT for oropharyngeal cancer had a weekly CT scan along their treatment. OAR and

target volumes were manually delineated in each CT. A 3-class tissue (soft tissue, air and bone) segmentation was performed in each CT scan using a manual threshold method: over 110 UH for the bone and under -150 UH for the air contained into the external patient contours. Soft tissue was deduced by Boolean operation from air, bone and external patient contour. Mean density values were affected to the 3 classes in the weekly CTs, corresponding to those read on the planning CT for each patient. A plan was first generated on each planning CT scan using a 3 dose levels simultaneously integrated boost protocol (70Gy/63Gy/56Gy in 35 fractions). The beam parameters defined on the planning CT scan were transferred to each weekly CT. Two dose distributions were then calculated in these CT using an adaptive convolution algorithm: either based on the "standard reference" CTscan, or based on the 3 density class CT scan. The doses to the PGs (DVH and mean dose) and the SC (D2%) calculated according to the two CT modalities were compared (Wilcoxon test). Finally, 3D gamma index were also calculated to compare the 3D dose distributions. We report the results for the first 5 patients.

### Results

The PGs DVH and mean doses were not significantly different according to the two CT modality based calculation. On average, the difference for the mean dose was 0.1 % (SD=0.7 %). The SC D2% doses were slightly significantly higher when calculation is based on the standard CT with a mean value of 42.94 Gy (SD=3.03 Gy) compared to 42.52 Gy (SD=2.76 Gy) when calculated on the 3 density classes. Figure 1 represents dose distribution in sagittal plane calculated on 3 density class CT. Figure 2 shows the 3D gamma index map on the sagittal plane (criteria DTA/DD 1mm/1% local dose, dose threshold 10 %): 91.7 % accepted point; gamma mean value 0.6. Most differences between the two dose distributions seems to appear on bone volumes.

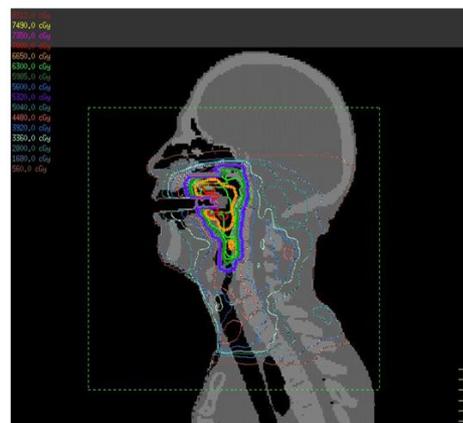

Figure 1: Dose distribution on 3 density class CT scan. Bone appears in white, soft tissue in grey and air in black. CT scan imaging is hidden.

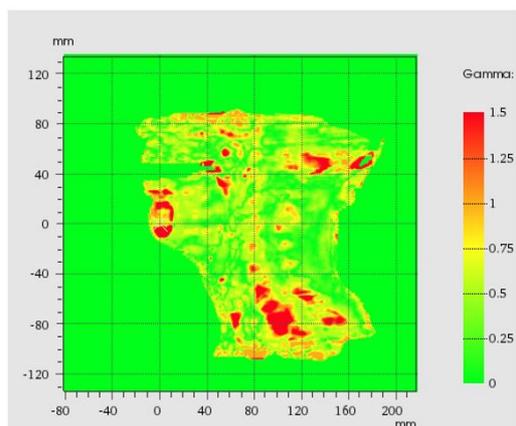

Figure 2: Gamma distribution map for a DTA/DD 1mm/1%, dose threshold 10 % analysis (planning CT scan as reference).

### Conclusion

This 3-class density method can be used to monitor the fraction dose in the PGs during oropharynx cancer IMRT. Small significant differences are observed for the highest dose received in the spinal cord, likely due to the bone heterogeneity.

### EP-1491 Verification of FFF VMAT plans with PDIP and GLAaS algorithms by using the new imager of TrueBeamSTx

T. Ercan<sup>1</sup>, A. Levent<sup>2</sup>, T. Cagin<sup>3</sup>, S.M. Igdem<sup>1</sup>

<sup>1</sup>Gayrettepe Florence Nightingale Hospital, Radiation Oncology, Gayrettepe - Istanbul, Turkey

<sup>2</sup>Medideal Medical Projects and Solutions Inc., Medical Physics, Istanbul, Turkey

<sup>3</sup>Liverpool School of Medicine, Department of Biostatistics, Liverpool, United Kingdom

### Purpose or Objective

Using flattening filter free (FFF) beams shortens the treatment time especially for stereotactic treatment techniques when the high dose rate is used. It is not possible to do quality assurance (QA) with all types of amorphous silicon (aS) detectors because of their saturation limit. In this study, verifications of volumetric modulated arc therapy (VMAT) stereotactic treatment plans were evaluated with PDIP and GLAaS algorithms by using a new unsaturated aS detector and the results were compared.

### Material and Methods

aS1200 image detection unit (IDU) which has aS detector integrated on a Varian TrueBeam STx linac was used (Table 1). Portal Dosimetry (PD) (v.13.0.26) with PDIP algorithm (Varian Medical Systems, Palo Alto) and Epiqa (v.4.0.11) with GLAaS algorithm (Epidos s.r.o., Bratislava) QA tools were configured at SDD: 100 cm with 2400 MU/min dose rate through the detector without saturation issue to use for pre-treatment verification. 10 MV FFF VMAT treatment plans (2400 Dose Rate) of 35 patients with in total 72 arcs were calculated by Anisotropic Analytical Algorithm (AAA, ver.13.0.26) in Eclipse Treatment Planning System. The verification plans were irradiated on the aS1200 imager. The evaluations for both QA tools were done with the technique of gamma analysis (GA). The GA criterias for Distance to Agreement (DTA) and Dose Difference (DD) were defined as 3%/3mm, 2%/2mm and 1%/1mm and applied for "field" (defined with jaws) and "field+1cm" areas. The results were analysed with 2 sample T-test.

Table 1. Specifications of aS1200 IDU

Maximum active field size 43cm x 43cm

Maximum readout speed 20 frame/second

Matrix 1280 x1280

Resolution 0.0336 cm

### Results

Epiqa had dramatically low GA (gamma<1.0) results; less than 95% with the criterias DD:%1, DTA:1mm for field (Average: 85,03, SD:±7,8) and field+1cm (Average: 93,30, SD: ±2,4) comparison areas. There is no significant difference (p>0,05) between PD and Epiqa for GA results of DD:%3, DTA:3mm criterias.

Table 2. Average and standard deviation (SD) results of each method

Evaluated field	Method, DD, DTA	Average value	Standard deviation	p value
Field+1cm	PDIP, %3, 3mm	99.95	0.14	>0.06
	GLAaS, %3, 3mm	99.98	0.05	
	PDIP, %2, 2mm	99.87	0.18	<0.05
	GLAaS, %2, 2mm	99.72	0.30	
	PDIP, %1, 1mm	99.14	0.75	<0.05
	GLAaS, %1, 1mm	93.30	2.44	
Field	PDIP, %3, 3mm	99.92	0.16	>0.707
	GLAaS, %3, 3mm	99.90	0.31	
	PDIP, %2, 2mm	99.59	0.50	<0.05
	GLAaS, %2, 2mm	98.95	1.68	
	PDIP, %1, 1mm	97.03	2.08	<0.05
	GLAaS, %1, 1mm	85.03	7.78	

### Conclusion

We could able to detect more errors with the hardest criterias (DD:%1, DTA:1mm) as expected. Epiqa had better performance for detecting the errors. It could be the result of the differences in workflow. Epiqa compares the dose calculated with clinical algorithm and irradiated image, but PD compares the calculated dose with PDIP and irradiated image. PD and Epiqa can be used for stereotactic VMAT plans with aS1200 detector without saturation problem at SSD: 100cm reliably. If the speed is important for the clinics have high workload, PD could be preferred through being an internal software.

### EP-1492 Influence of induced accelerator' errors on dosimetric verification result and DVH of treatment plan

M. Kruszyna<sup>1</sup>, K. Matuszewski<sup>1</sup>

<sup>1</sup>Greater Poland Cancer Centre, Medical Physics Department, Poznan, Poland

### Purpose or Objective

The commonly used gamma criteria of 3% dose difference (global method) and 3 mm distance to agreement could mask clinically relevant errors. The aim of this work was to evaluate the influence of induced accelerator's errors on 3D gamma method results with the varies criteria and on the patient' dose distribution (DVHs).

## Material and Methods

In the treatment prostate plan with VMAT high-fractionated (2x7.5Gy), FFF technique the errors of dose (differences  $\pm 1\%$ ; 2%; 3%; 5% 7%, 10%), collimator angle (rotations in both directions: 0.5; 1.0; 1.5; 2.0; 2.5; 3.0) and MLC shifts were introduced. For each modified plan, the pre-treatment verification plan was created and measured with 2D-arrays: 729 and SRS 1000 with rotational phantom Octavius® 4D and Verisoft 6.1 software with DVH option (PTW, Freiburg, Germany). Measured (with errors) and calculated (reference plan) dose distributions were analyzed with 3D gamma evaluation method for various tolerance parameters DTA [mm] and DD [%] 1.0; 1.5; 2.0; 2.5; 3.0, by global and local dose methods with a 5% threshold. To detect errors, the achieved score should be less than the assumed tolerance of 95%. Additional the DVHs from error-induced and reference plan were analyzed for CTV D<sub>50</sub>, D<sub>98</sub>, D<sub>2</sub>, and D<sub>25</sub>, D<sub>50</sub> for OARs.

## Results

For 12 error-induced plan with dose discrepancies, proper detection for 729 and SRS 1000 were obtained as follows: 3/12 and 6/12 (G3%/3mm); 8/12 and 6/12 (L3%/3mm); 8/12 and 7/12 (G2%/2mm); 8/12 and 8/12 (L2%/2mm). The rotations of collimator were detected  $>3^\circ$  for 729 and  $>2^\circ$  for SRS 1000. The MLC errors were discovered for plans with 1 leaf (MLC1) and 1 pair of leaves (MLC2) blocked, for all leaves shifted about 0.05cm (MLC3) misalignment weren't indicated so obvious. The clinical relevance of plan with MLC errors and chosen discrepancies for collimator rotation ( $3^\circ$ ) and dose differences (+5%) were presented in the table 1.

Gamma method criteria/DVH parameters	Reference plan [%/Gy]	Error-induced plans				
		MLC1	MLC2	MLC3	+5%	coll 3°
Measured with 729-array - SCORE [%]						
G3%/3mm	99,6	94,7	88,4	99,5	98,4	99,3
L3%/3mm	94,5	72,4	73,3	92,3	85,7	92,3
G2%/2mm	96,8	82	78,7	95,7	92,8	95,8
L2%/2mm	81,3	55,1	59,8	76,6	66	76,8
TPS - differences between reference plan and modified [%]						
D50% [CTV]	15,2	3,9	-7,9	2,0	5,3	0,0
D98% [CTV]	14,7	1,4	-38,1	2,0	5,4	-0,7
D2% [CTV]	15,5	17,4	-1,3	1,9	5,2	0,6
D25% [rectum]	10,3	7,8	-5,8	3,9	4,9	0,0
D50% [rectum]	6,8	13,2	-4,4	4,4	4,4	0,0

The clinical relevance of plan with MLC errors and chosen discrepancies for collimator rotation ( $3^\circ$ ) and dose differences (+5%).

## Conclusion

To more sophisticated analysis the gamma criteria should be less than 3%/3mm or/and local dose method should be used. The resolution of used detector is crucial and should be high for better interpretation of results. Gamma method presents some statistic data, for scrutiny analysis the clinical interpretation should be assessed.

## EP-1493 Machine record parameters or Epid based data for ART QA. A comparison of two scenarios.

P. Haering<sup>1</sup>, C. Lang<sup>1</sup>, M. Splinter<sup>1</sup>  
<sup>1</sup>DKFZ, E040, heidelberg, Germany

## Purpose or Objective

Using machine record files and Epid based dosimetry is popular for machine and patient related QA, as this may also work for adaptive treatment approaches. The Siemens Artiste treatment machine used here, allows a comparison of both methods in one session. Exit images and all relevant machine parameters are included in the image header collected during treatment. Here we present results of a comparison between QA dose recalculations based on the two sources, exit images and machine recorded parameters.

## Material and Methods

A software tool was developed that allows for the extraction of the relevant parameters (MLC-positions, MU,

etc.) from the machine records as well as from the Epid measured exit fluencies. While machine data had to undergo a reformat to be used for recalculation, the exit fluencies need more attention. Here both, the delivered fluence as well as the absorption in the patient do play a role. Therefore both have to be separated to receive reliable MLC positions. The algorithm used first generates an image containing only absorption information for the beam using this to remove this influence on the MLC positions. MUs were used from the parameter file, as the fluence uncertainties on the EPID images have shown to be large to be used for that purpose. The extracted parameters are then inserted in a newly generated Dicom RT-Plan file that then can be used in the treatment planning system (here Raystation, Raysearch) to recalculate the dose. Dose distributions (Epid based, parameter file based and originally planned) are then compared.

## Results

Measuring exit doses with the EPID was a simple task and could be done for all coplanar field sets. The software tool made it simple to extract all the needed parameter from the files and images resulting in 2 new Dicom plan files. Dose recalculation was done by just importing the new plan files to Raystation. Comparing the original dose distribution to the machine file based one showed almost no difference at all ( $< 0.7\%$ ), as MU and leaf position differences were quite small. This might also be grounded in the used calculation grid of 2mm size. MLC positions derived from EPID images show much larger differences. Here detection uncertainties, EPID positioning and the resulting image resolution of 0.3mm do play a major role. This resulted in noticeable differences in the dose gradients regions. Absolute dose differences were below 1.5%.

## Conclusion

Recalculating doses based on EPID and machine based parameters is a possible way for QA in an adaptive treatment approach. As QA parameters are taken from information that is given anyway or that can be easily generated, it does not complicate the procedure of frequent replanning. Results are as expected quite good for the machine file approach while higher discrepancies were found using EPID data. Main problem we face here is that especially for the machine file based version we do not have full independent data sources.

## EP-1494 The MedAustron proton gantry: nozzle design recommendations based on Monte Carlo simulations

H. Fuchs<sup>1,2</sup>, L. Grevillot<sup>2</sup>, A. Elia<sup>2</sup>, A. Carlino<sup>2,3</sup>, J. Osorio<sup>2</sup>, V. Letellier<sup>2</sup>, R. Dreindl<sup>2</sup>, M. Stock<sup>2</sup>, S. Vatnitsky<sup>2</sup>  
<sup>1</sup>Medizinische Universität Wien Medical University of Vienna, Department of Radiation Oncology & Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria  
<sup>2</sup>MedAustron Ion Therapy Center, Department of Medical Physics, Wr. Neustadt, Austria  
<sup>3</sup>University of Palermo, Department of Physics and Chemistry, Palermo, Italy

## Purpose or Objective

MedAustron is equipped with one vertical and three horizontal fixed beam lines and one proton gantry based on the PSI gantry 2 design for patient treatments. This work focuses on simulations and design considerations for the proton gantry nozzle, allowing an optimization of beam delivery properties at isocenter.

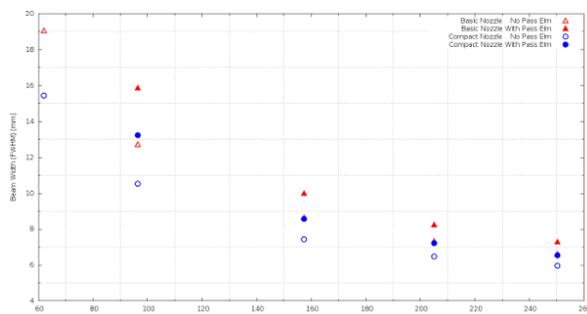

## Material and Methods

Different gantry nozzle designs were evaluated using Gate/Geant4 Monte Carlo (MC) simulations: air filled nozzle, helium filled nozzle, full vacuum nozzle, moving snout, compacting of nozzle elements (vacuum window and monitors). Design considerations were based on the

use of similar components as in the other beam lines as well as a static beam monitoring system. Simulations were performed for 5 representative energies (62, 96.5, 157.4, 205, and 252.3 MeV) also considering the use of range shifter and ripple filter. Nozzle designs were based on the MC model of the MedAustron fixed beam line nozzle, which was verified with measurements at isocenter for 20 representative energies.

### Results

The influence of the gantry nozzle filling with vacuum or helium (as used in some commercial systems) was found to have only a minor impact on spot size (< 2%). Compacting all nozzle elements towards the nozzle exit and reducing the nozzle dimension in beam direction by 25% lead to a reduction of the spot size of up to 20%, depending on the initial energy as depicted in Fig. 1. Using higher energies in combination with range shifter also decreased the delivered spot size for shallow seated tumors, as already demonstrated in other studies (Parodi, et al. PMB 57(12), 2012).

**Figure 1:** Spot size over initial proton energy with (full symbols) and without (empty symbols) passive elements, for the non-optimized (Basic) and the most compacted nozzle.

### Conclusion

The optimum in terms of spot size can be reached if all nozzle elements are as close as possible to the nozzle exit as a reduction in distance to the isocenter proved very effective. Therefore, MedAustron will focus on a compact nozzle design with retractable snout.

### EP-1495 Should we use correction factors for skin dose measurements with radiochromic films?

P. Carrasco de Fez<sup>1</sup>, M.A. Duch<sup>2</sup>, L. Muñoz<sup>2</sup>, N. Jornet<sup>1</sup>, M. Lizondo<sup>1</sup>, C. Cases<sup>1</sup>, A. Latorre-Musoll<sup>1</sup>, T. Eudaldo<sup>1</sup>, A. Ruiz<sup>1</sup>, M. Ribas<sup>1</sup>

<sup>1</sup>Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain

<sup>2</sup>Universitat Politècnica de Catalunya, Institut de Tècniques Energètiques, Barcelona, Spain

### Purpose or Objective

The election of detector for skin dose measurements is critical (see fig. 1a). This work is aimed to study the surface dose in high-energy x-ray beams and to derive potential correction factors (CFs) to be applied for in-vivo skin dose measurements when using EBT3.

### Material and Methods

- 6 and 15 MV x-ray beams from a Clinac 2100 CD (Varian)
- EBT3 radiochromic films + Film QA Pro 2014 software (Ashland) + EPSON EXPRESSION 10000XL scanner
- 30X30X30 cm<sup>3</sup> Plastic Water (PW) phantom (CIRS)
- Low-density polyethylene plastic sleeve
- TLD-2000F (Conqueror)

### Methods

TLDs and EBT3 films were attached to the centre of the PW phantom surface side facing the radiation beam.

The main parameters affecting surface dose as reported in literature were studied (field size and angle of incidence) with both EBT3 and TLDs. The field size was changed between 3.5 and 25 cm, the angle of incidence between 0 and 90°, and the SSD between 75 and 100cm. The effect of a plastic sleeve to be used for in vivo measurements was assessed. Incidence angle and field size CFs for EBT3 films could be derived from comparison against measurements made with TLDs because TLDs are known as not having any dependence on the incidence angle or the field size.

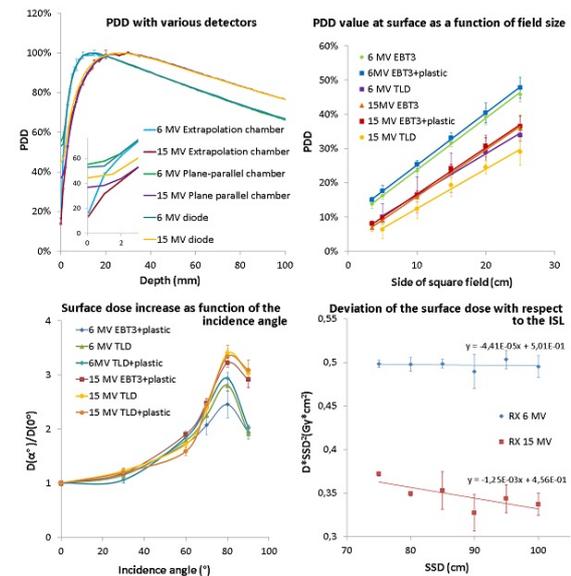

The equivalent depth correction factors (EDCF) for EBT3 films have been determined using measurements made with a PTW 23392 Extrapolation ion chamber in a previous work [1] and measurements made with EBT3 films in this work. EDCF allows determining dose @ the ICRU skin depth (70 µm) from EBT3 measurements (active depth@120µm). The effect of SSD was studied with EBT3.

For film dosimetry, EBT3 films were cut into 3 cm<sup>2</sup> square pieces marked to keep track of their orientation for scanning. Readout of each film corresponded to the mean value within a 1x1cm<sup>2</sup> ROI centred in the film piece. Several pieces for each measurement were read 3 times with random position in the central part of the scanner to account for scanner and film non-uniformity in the uncertainty.

### Results

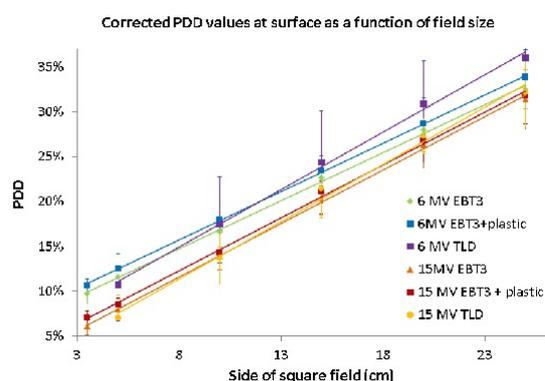

Fig 1b shows surface dose increases linearly as a function of the field size measured with every detector. Fig 1c shows that surface dose increases slowly up to an angle of incidence of 30° and very fast from angles between 60 and 80°.

There is no significant difference between measurements made with EBT3 and with TLD. The effect of the plastic sleeve is negligible considering the uncertainty. SDD: Fig 1d shows deviation to the inverse square law of 0.004% for 6 MV and 0.13% for 15 MV, much lower than EBT3 overall uncertainty (=3%).

EDCF were 0.709±0.044 for 6MV and 0.872±0.127 for 15 MV.

Fig 2 shows the consistency of applying EDCF on data of Fig 1b: EBT3 agree with TLD within the uncertainty. All error bars are k=2.

## Conclusion

No other CFs than the EDCF have to be applied for skin dose measurements with EBT3 films.

This work has been partially financed by the grant *Singulars Projects 2015* of the Spanish Association Against Cancer (AECC).

### EP-1496 A portal dosimetry dose prediction method based on CT images of Electronical Portal Imaging Device

J. Martinez Ortega<sup>1</sup>, N. Gomez Gonzalez<sup>1</sup>, P. Castro Tejero<sup>2</sup>, M. Pinto Monedero<sup>1</sup>, N. Tolani<sup>3</sup>, L. Nuñez Martin<sup>1</sup>, R. Sanchez Montero<sup>4</sup>

<sup>1</sup>Hospital Universitario Puerta de Hierro, Radiofísica y PR, Majadahonda - Madrid, Spain

<sup>2</sup>Hospital Universitario La Princesa, Radioterapia, Madrid, Spain

<sup>3</sup>ME De Bakey VA Medical Center, Radiotherapy Department, Houston, USA

<sup>4</sup>Universidad de Alcalá, Signal Theory and Communications Department, Alcalá de Henares-Madrid, Spain

### Purpose or Objective

In this study, we present a new method for portal dosimetry. CT images of the Electronical Portal Imaging Device (EPID) were used as phantom images for dose calculation. The clinical beam model and beam energy, in the treatment planning system, were used to calculate dose over the EPID.

### Material and Methods

The method was developed for a Varian Clinac 21-EX (Varian Medical Systems, USA), with a nominal photon energy of 6 MV, equipped with a Varian aS1000 EPID. Pinnacle 8.0m (Philips Medical Systems, NL) was used for treatment planning calculations. Matlab® v2012a (Mathworks, USA) was employed to develop code for calculations involving backscatter and output correction factors.

The EPID was calibrated, following the manufacturer procedure, and then unmounted from the linear accelerator and scanned to acquire CT images of the EPID (Fig. 1) on an Aquilion LB (Toshiba Medical Systems, Japan). These CT images were imported into the Pinnacle planning system. The imported images were used as a quality assurance phantom to calculate dose on the image plane, which was considered as the predicted portal dose. Two sliding-window IMRT treatment plans, a prostate and a head and neck case, were delivered, measured and analyzed with both with the EPID and with MatriXX (IBA Dosimetry, Germany), as an independent measurement method.

Matlab code was used to calculate EPID arm backscattering and output factor corrections. Gamma index comparison (3 %, 3 mm) was made for the EPID and MatriXX dose planes versus the calculated dose planes with OmniPro ImRT (IBA Dosimetry).

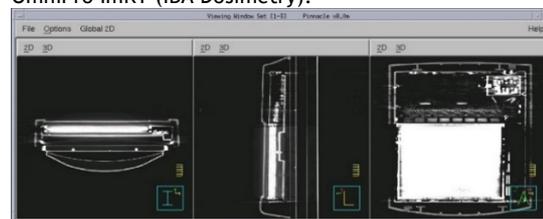

Figure 1. Acquired CT images of the Varian aS1000 EPID. Results

For plans verified with EPID, Gamma index pass rate were 98.6% and 96.5% for prostate (Table 1) and head and neck case, respectively. Dose differences (EPID vs planned) were -0.7% and -0.4%.

For MatriXX measurements, the results are very similar: gamma pass rate of 97.2% for prostate and 97.9% for head and neck, and dose differences (MatriXX vs planned) of -1.4% and -0.8%, respectively.

Field	Gamma (3 %, 3 mm)EPID (%)	Dose diff EPID (%)	Gamma (3 %, 3 mm)MatriXX (%)	Dose diffMatriXX (%)

2	98.6%	-1.0	96.5%	-1.6
3	98.9%	-0.5	98.1%	-1.1
4	98.6%	-0.6	96.0%	-1.5
5	99.0%	-0.3	96.5%	-1.1
6	98.7%	-0.1	99.0%	-1.5
7	98.0%	-0.6	97.3%	-1.2
<b>Average</b>	<b>98.6%</b>	<b>-0.7</b>	<b>97.2%</b>	<b>-1.4</b>

Table 1. Gamma index and dose difference results for prostate treatment.

### Conclusion

The obtained results show the validity of the method presented here. This method can be easily implemented into clinic, as no additional modeling of the clinical beam is necessary. The main advantage of this method is that portal dose prediction is calculated with the same algorithm and energy beam model used for patient treatment planning dose distribution calculations.

### EP-1497 Dosimetric effect of the Elekta Fraxion cranial immobilization system and dose calculation accuracy

C. Ferrer<sup>1</sup>, C. Huertas<sup>1</sup>, R. Plaza<sup>1</sup>, A. Serrada<sup>1</sup>

<sup>1</sup>Hospital universitaria La Paz, Radiofísica y Radioprotección, Madrid, Spain

### Purpose or Objective

Devices external to the patient may cause an increase in the skin dose, as well as modify the dose distribution and hence the tumor dose. This study describes the effect on this parameters caused by the Elekta Fraxion cranial immobilization system. The effect of the inclusion of Fraxion in ElektaMonaco treatment planning system (v. 5.00.00) was also checked.

### Material and Methods

To study the dose attenuation a cylindrical phantom was placed over the Elekta Fraxion with a CC13 Scanditronix-Wellhofer ionization chamber located in the central insert at the linac isocenter. Dose measurements were performed for two open fields, 10x10 cm and other smaller 5x5 cm, as Fraxion is used mainly for radiosurgery treatments. The gantry angles were the ones which cross Fraxion (135° - 225°, 5°-10° increment, IEC gantry angles).

Calculated and measured doses are the average doses of symmetrical angles from 180°. Reference dose without Fraxion was the average dose at 0°, 90°, and 270°. 100 MU were delivered at each angle. All measured doses were compared with the ones calculated with Monaco.

To measure the skin dose and the dose distribution in the Build-up region, several radiochromic Films EBT3 were placed at linac CAX between the slabs of a RW3 phantom placed over Fraxion (SSD= 90 cm) and read using FilmQA Pro software. Films were situated at the surface, 0.5 cm, 1.5cm depth and the linac isocenter. 200 MU were delivered for 10x10 and 5x5 open field sizes and 0° gantry angle. Once irradiated and removed, another set of films were placed under the phantom, in contact with Fraxion, and at 0.5 cm and 1.5 cm from Fraxion, as well as at the linac isocenter. Additional films were located 1 cm away from CAX as in this section Fraxion is wider. Same field sizes and MU at 180° were employed. **Results**

Table 1 shows the comparison between measured and calculated transmitted dose with and without Fraxion in the calculation. Measurements show a 1% attenuation for 180° gantry angle as stated on the Fraxion manual, but this attenuation can be as high as 5 % (5x5 open field) or 6 % (10x10 open field) for 150° gantry angle, as with this angle, the beam traverses the thickest part of the Fraxion. If Fraxion is not included in the calculation, Monaco calculation can result in a 7 % difference between measured and calculated doses, while with Fraxion in the calculation, the maximum difference is 1.5% (10x10, 150°).

Table 2 shows the evaluated skin dose increment caused by Fraxion, and compares calculated and scanned values. Fraxion increases 3.8 times the surface dose, and by 17% at 0.5 cm depth, which can be calculated by Monaco with a difference lower than 1% if Fraxion is included in the calculation.

isocenter, 10cm depth	139.8	55.8	133.4	56.6
Surface dose increment	3.1		3.7	

### Conclusion

It has been shown that the attenuation varies with gantry angle. The inclusion of Fraxion in Monaco improves the calculation from 7% difference to 1% in the worst case (150°, 5x5 open field), furthermore, the skin dose increment and the dose in the build-up region are correctly calculated.

### EP-1498 IMRT and VMAT commissioning for Versa HD linear accelerator using AAPM TG-119

S. Sharma<sup>1</sup>, V. Subramani<sup>1</sup>, P. Kumar<sup>1</sup>, S. Bhaskar<sup>1</sup>, S. Pathy<sup>1</sup>, S. Thulkar<sup>1</sup>, M. Sairem<sup>1</sup>, A. Binjola<sup>1</sup>, P. Agarwal<sup>1</sup>, N. Dhayanethi<sup>1</sup>, P. Kumar<sup>1</sup>, S. Chander<sup>1</sup>

<sup>1</sup>All India Institute of Medical Sciences, Radiation Oncology, New Delhi, India

### Purpose or Objective

The purpose of the study is to evaluate the end to end commissioning accuracy of intensity modulated radiation therapy (IMRT) and volumetric modulated arc therapy (VMAT) for Versa HD linear accelerator using AAPM TG-119 protocol.

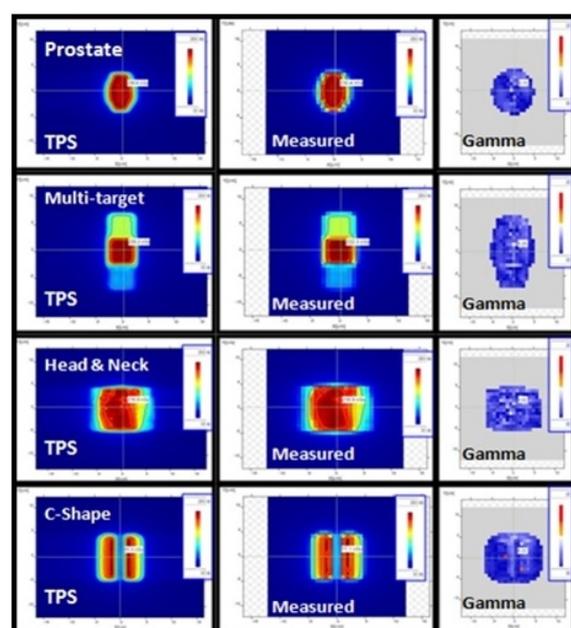

### Material and Methods

Phantom with contoured structure set was downloaded from AAPM website provided with the TG119 report and above structure sets were used as the patient for all plans created in the study. IMRT [step and shoot (SMLC) and dynamic (DMLC)] and VMAT plans were created for TG119 test cases. All the plans were generated using Monaco 5.1 treatment planning system (TPS) for Elekta Versa HD (Crawley UK) linear accelerator. All plans were created using 7-9 beams for IMRT (as per TG119) and single arc for VMAT for energy 6MV, 6MV-FFF & 10MV-FFF (FFF-Flattening filter free). Prescription and planning goals were as kept as per TG119. For point dose measurement CC01 (0.01cc) ion chamber was used and measurements were carried out as per TG119 specified points in high and low dose gradient regions. Point dose difference was calculated as ratio of difference between measured and planned dose with prescription dose. Similarly for planar dose measurement ImatriXX (IBA, Scanditronix Wellhofer, Germany) along with multicube-lite phantom was used and measurement plane was kept at 11cm depth. Planned and measured dose planes were compared using gamma index criteria (dose difference/distance to agreement) of 3%/3mm and 2%/2mm. All measurements were performed by keeping phantom on couch at gantry angle zero. Confidence limit calculation was done as specified in TG119.

**Results**

All planning goals have been achieved as per TG119 report shown in figure-1. At high dose point measurement mean dose differences averaged over different techniques (IMRT/VMAT) planned with different energies for all test cases was  $0.002 \pm 0.020$ , and corresponding confidence limit (mean +  $1.96\sigma$  i.e.  $\sigma$  stand for standard deviation) was 0.041. At low dose point measurement mean dose averaged over different techniques planned with different energies for all test cases was  $-0.004 \pm 0.021$ , and corresponding confidence limit was 0.045. For planar dose measurement gamma passing rate averaged over all test cases was  $99.40\% \pm 0.40$  for 3%/3mm criteria and  $97.82\% \pm 0.13$  for 2%/2mm criteria respectively. Present work overall confidence limit (100-mean +  $1.96\sigma$  i.e.  $\sigma$  stand for standard deviation) for composite planar dose measurement was 1.38(i.e., 98.62% passing) for 3%/3mm and 2.45(i.e., 97.55% passing) for 2%/2mm criteria. Gamma analysis results for a representative measurement are shown in figure-2.

**Conclusion**

Planning and delivery of IMRT/VMAT has been validated using TG119 report. Local institutional confidence limits were established which can be used as baseline for future patient specific quality assurance.

**EP-1499 Additional dose of Image Guided Radiation Therapy in Pediatric Patients**

J. Topczewska-Bruns<sup>1</sup>, T. Filipowski<sup>1</sup>, D. Hempel<sup>1</sup>, B. Pancewicz-Janczuk<sup>2</sup>, R. Chrenowicz<sup>2</sup>, D. Kazberuk<sup>1</sup>, A. Szmigiel-Trzcinska<sup>1</sup>, E. Rozkowska<sup>1</sup>

<sup>1</sup>Comprehensive Cancer Center, Department of Radiotherapy, Bialystok, Poland

<sup>2</sup>Comprehensive Cancer Center, Department of Physics, Bialystok, Poland

**Purpose or Objective**

Kilovoltage cone beam computed tomography (kV CBCT) imaging improves the accuracy of radiation therapy. However, an extra radiation dose is delivered to cancer patients. Instead of default scanning protocol used for adults we prepared individual presets for children undergoing radiotherapy in our Department. The aim of the study was to evaluate additional dose delivered to the pediatric patients being treated according to local protocol for IGRT.

**Material and Methods**

10 children, aged 2-6 years with different type of neoplasms were treated in supine position on linear accelerator (Elekta Synergy) equipped with kV CBCT (XVI v.4.2.) The pretreatment position was evaluated according to our protocol on day 1,2,3 and once in a week thereafter. The individual presets for pediatric patients were prepared for different types of neoplasms and localization of the irradiated area For dose calculation delivered by use of kV CBCT the phantom PMMA 20x20x12 and 16x16x16 with CT chamber TM30009 (PTW) with Unidos (PTW) was used.

**Results**

The modification of IGRT protocols for children includes changes in the acquisition parameters such as frequency, beam energy, voltage, rotational degree, gantry speed, size of field of view, filter with good quality of images (examples of images from the date obtained by collecting of kV CBCT will be presented on the poster). The following presets were prepared (Tab.1). The additional dose delivered to the pediatric patients depends on the number of fractions when the CBCT was performed. Our local protocol for usage of kV CBCT results in delivering of additional dose of 2,52mGy (4 fr. in protocol A) or 2,92mGy (4 fr. in protocol B) for elective brain irradiation in ALL, 3,55 mGy (5 fr. protocol F) for left sided nephroblastoma 3,4 mGy (5 fr. protocol D) or 3,8mGy (5 fr. protocol C) for right sided nephroblastoma, 17,6 mGy (8 fr. protocol E) for RMS in pelvis and 3,45 mGy (5 fr. protocol G) for LGL.

	Field of view (collimator)	Filter	kV	Angle Start	Angle stop	Gantry speed (degree/sek)	Frames	Nominal mAs per frame	Nominal scan dose mGy
Fast head and neck [A]	S 20	F0	100	-130	70	360/60	183	10/10	0,63
Head and neck[B]	S20	F1	100	-130	70	180/60	183	10/10	0,73
Abdomen right [C]	S20	F1	100	-130	70	180/60	366	10/10	0,76
Abdomen Right [D]	S10	F1	100	-130	70	180/60	366	10/10	0,68
pelvis right [E]	S20	F1	100	-130	70	180/60	366	16/16	2,22
Abdomen Left [F]	S20	F1	100	-30	160	180/60	366	10/10	0,71
Abdomen Left [G]	S20	F1	100	-50	130	180/60	366	10/10	0,69
pelvis Left [H]	S10	F1	100	-30	160	180/60	366	10/10	0,63

**Conclusion**

The additional doses of kV CBCT depends on the type of presets used in procedure and number of fractions with IGRT during all treatment. The modified presets enable reducing exposure to irradiation so that IGRT - associated doses seems to be clinically acceptable. However the children's anthropomorphic phantom is needed to further evaluate exposure of normal healthy tissue to irradiation during collecting the date for IGRT.

### EP-1500 Application of RayStretch in clinical cases: Heterogeneity corrections in LDR prostate brachytherapy

J. Vijande<sup>1</sup>, F. Ballester<sup>1</sup>, J. Perez-calatayud<sup>2</sup>, F. Hueso-González<sup>3</sup>, F. Siebert<sup>4</sup>

<sup>1</sup>Universitat de Valencia Dep. de Física Atomica-Molecular Y Nuclear, Atomic Molecular and Nuclear Physics, Burjassot, Spain

<sup>2</sup>University and Polytechnic Hospital La Fe, Physics Section- Radiotherapy Department, Valencia, Spain

<sup>3</sup>Target Systemelektronik GmbH, Wuppertal, Germany

<sup>4</sup>UK S-H- Campus Kiel- Klinik für Strahlentherapie, Radioonkologie, kiel, Germany

#### Purpose or Objective

Tissue heterogeneities and calcifications have significant impact on the dosimetry of low energy brachytherapy (BT). *RayStretch* is an analytical algorithm developed in our institution to incorporate heterogeneity corrections in LDR prostate brachytherapy. The aim of this work is to study its application in clinical cases by comparing its predictions with the results obtained with TG-43 and Monte Carlo (MC) simulations.

#### Material and Methods

A clinical implant (71 I-125 seeds, 15 needles) from a real patient was considered. On this patient, different volumes with calcifications were considered. Its properties were evaluated in three ways by i) the Treatment planning system (TPS) (TG-43), ii) a MC study using the Penelope2009 code, and iii) *RayStretch*. To analyse the performance of *RayStretch*, calcifications located in the prostate lobules covering 11% of the total prostate volume and larger calcifications located in the lobules and underneath the urethra for a total occupied volume of 30% were considered. Three mass densities (1.05, 1.20, and 1.35 g/cm<sup>3</sup>) were explored for the calcifications. Therefore, 6 different scenarios ranging from small low density calcifications to large high density ones have been discussed.

#### Results

DVH and D90 results given by *RayStretch* agree within 1% with the full MC simulations. Although no effort has been done to improve *RayStretch* numerical performance, its present implementation is able to evaluate a clinical implant in a few seconds to the same level of accuracy as a detailed MC calculation.

#### Conclusion

*RayStretch* is a robust method for heterogeneity corrections in prostate BT supported on TG-43 data. Its compatibility with commercial TPSs and its high calculation speed makes it feasible for use in clinical settings for improving treatment quality. It will allow in a second phase of this project, its use during intraoperative ultrasound planning.

### EP-1501 Field-by-field and composite plan pseudo-3D verification of IMRT techniques with radiochromic film

T. Hanušová<sup>1</sup>, I. Horáková<sup>2</sup>, I. Koniarová<sup>2</sup>

<sup>1</sup>Faculty of Nuclear Sciences and Physical Engineering- Czech Technical University in Prague, Department of Dosimetry and Application of Ionizing Radiation, Prague, Czech Republic

<sup>2</sup>National Radiation Protection Institute, Section of medical exposures, Prague, Czech Republic

#### Purpose or Objective

The purpose of this study was to compare field-by-field pre-treatment verification of IMRT dose distributions, which is often performed clinically, to a pseudo-3D method that verifies the global plan dose distribution in several transversal, coronal and sagittal planes.

#### Material and Methods

Sheets of EBT3 film were placed into an IMRT cube phantom into 5 transversal, 5 coronal and 5 sagittal planes close to the isocenter. The phantom was irradiated in this setup with six IMRT step-and-shoot treatment plans. These included one head-and-neck case and five pelvic cases. Two of these plans had not previously met the clinical tolerance criteria and were not used for treatment. Dose distributions obtained with film were compared to predicted dose distributions in OmniPro 1'mRT software. Gamma pass rates were obtained for 3%/3 mm criteria. The same IMRT plans were then measured field-by-field with one EBT3 film sheet placed in the isocentric coronal plane in an RW3 slab phantom, with gantry at 0° for all fields. Again, gamma pass rates were obtained. Finally, the results were compared to clinically performed verification. This was done with a PTW seven29 detector placed in the isocentric coronal plane in an RW3 slab phantom and each field of the plan was tested with gantry at 0°. Gamma pass rates for the PTW array measurements were obtained in VeriSoft with the same criteria 3%/3 mm. Treatment planning was performed in XiO version 4.80 and plan delivery was carried out on a Siemens Artiste linear accelerator at the Thomayer Hospital in Prague.

#### Results

EBT3 film gave higher gamma pass rates than the PTW seven29 array for field-by-field measurements for all patients. If all fields of each plan were averaged out, the average gamma score for both film and PTW detector was above the clinical tolerance limit of 90% for all plans. This was not true for the composite plan measurements with film. While a certain plan met the tolerance limit if measured field-by-field, it could fail to meet the tolerance limit when the global plan dose distribution was measured. Moreover, for a given plan, different gamma score values could be seen with film for the three directions tested. While in some directions the plan met the clinical tolerance limit of a 90% gamma score, it could fail to meet the limit in others. These findings can be influenced by film directional dependence, but this is supposed to be negligible.

#### Conclusion

Field-by-field pre-treatment verification of IMRT dose distributions, both with radiochromic film and an array of ion chambers, gave higher gamma scores than if the global plan dose distribution was measured in a pseudo-3D manner. Field-by-field measurements might be insufficient to detect potential plan errors. More complex investigations are recommended at least when new IMRT techniques are being established in the clinic.

### EP-1502 Dosimetric assessment of brass bolus using radiochromic film

P. Lonski<sup>1</sup>, L. Walton<sup>2</sup>, N. Anderson<sup>2</sup>, J. Lydon<sup>1</sup>, T. Kron<sup>1</sup>, B. Chesson<sup>2</sup>, R. Prabhakar<sup>1</sup>

<sup>1</sup>Peter MacCallum Cancer Centre, Physical Sciences, Melbourne, Australia

<sup>2</sup>Peter MacCallum Cancer Centre, Radiation Therapy Services, Melbourne, Australia

#### Purpose or Objective

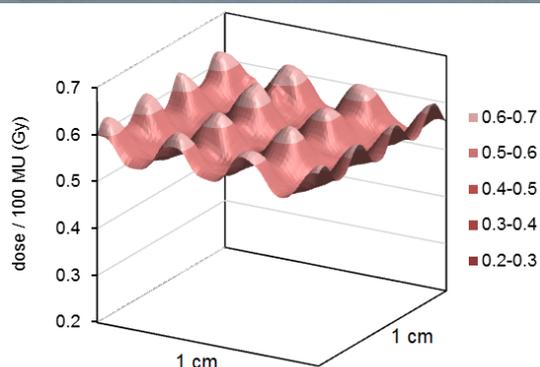

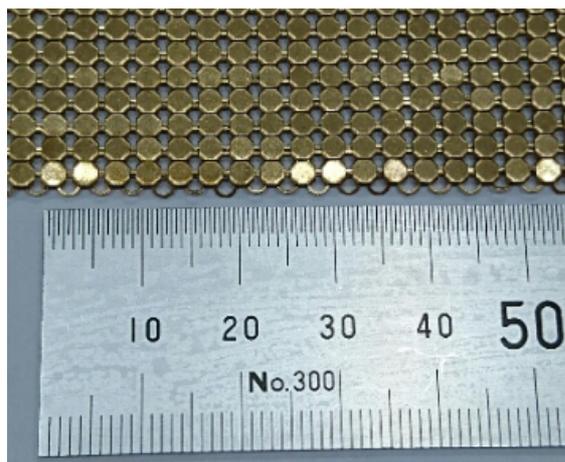

Brass bolus is a new type of bolus designed to enhance surface dose in radiotherapy. Manufacturers claim the impact on other radiation beam characteristics is negligible. The main advantage is the mesh-like grid of brass links can conform to complex patient contours which compared to conventional bolus reduces air gaps between bolus and patient skin. This study aims assess the dosimetric impact of brass bolus on surface dose in megavoltage photon beams.

### Material and Methods

Brass bolus (Radiation Products Design Inc) with a nominal thickness of 1.5mm was used on a tissue equivalent slab phantom (RMI solid water). It was used as single layer and folded over in 2 or 4 layers. Radiochromic film (EBT3) was used to assess surface dose and dose variation on the phantom for a 6 MV and 18MV photon beams (Varian 21iX). Surface dose was measured with and without the brass bolus which was placed on top of the film. A photo of the brass is shown in Figure 1 (a) alongside a 50 mm section of steel ruler. A film calibration curve was derived by exposing samples from the same sheet to various known doses under reference conditions. Film was scanned 12 hours post exposure and manually analysed using ImageJ and MS Excel software.

### Results

Surface dose measured using film in the absence of bolus was 20 % of dose at d-max for a 6 MV beam in a 10 cm x 10 cm jaw-defined square field. Surface dose with a single layer of the brass bolus increased to an average of 57 % of dose at d-max (1.5cm). The mesh-like structure of the brass resulted in a dose enhancement pattern which was non-uniform across the film, as shown for a 1 cm x 1 cm square region in Figure 1 (b), which shows the peaks and troughs resulting from the mesh. The maximum dose (peaks) was 62 % and the minimum (troughs) was 53 % of dose at d-max under reference conditions. Increasing the number of layers of bolus increased the surface dose.

### Conclusion

Brass bolus may be used for surface dose enhancement in external beam radiotherapy with megavoltage photons. The surface dose increased from 20 % to 57 % of dose at d-max for a 10 cm x 10 cm 6 MV field. The non-uniform surface dose distribution should have minimal clinical impact for multi-fraction radiotherapy regimes where multiple layers and the random orientation of brass links relative to skin surface will vary with daily setup.

### EP-1503 The effect of tandem-ovoid applicator on the dose distribution in GYN brachytherapy using Ir-192

M.H. Sadeghi<sup>1</sup>, A. Mehdizadeh<sup>1</sup>, M. Tafi<sup>1</sup>, R. Faghihi<sup>1</sup>, S. Sina<sup>2</sup>, A.S. Meigooni<sup>3</sup>, A. Shabestani Monfared<sup>4</sup>

<sup>1</sup>Shiraz University, nuclear engineering department, Shiraz, Iran Islamic Republic of

<sup>2</sup>Shiraz University, Radiation Research Center, Shiraz, Iran Islamic Republic of

<sup>3</sup>Comprehensive cancer center of Nevada, Las Vegas-Nevada, USA

<sup>4</sup>Babol University of Medical Sciences, Babol, Iran Islamic Republic of

### Purpose or Objective

The dosimetry procedures by simple superposition accounts only for the source shield, and does not take in to account the attenuation of photons by the applicators. The purpose of this investigation is estimation of the effects the tandem ovoid applicator on the dose distribution inside the phantom by MCNP5 Monte Carlo simulations.

### Material and Methods

In this study, the superposition method is used for obtaining the dose distribution in the phantom for a typical GYN brachytherapy. Then the sources are simulated inside the tandem ovoid applicator, and the dose at points A, B, bladder and rectum was compared with the results of supper position. The exact dwell positions, and times of the source, and positions of the dosimetry points were determined from images of a patient. The MCNP5 Monte Carlo code was used for simulation of the phantoms, applicators, and the sources.

### Results

The results of this study showed no significant differences between the results of superposition method, and the MC simulations for different dosimetry points. The difference in all important dosimetry points were found to be less than 4%. The maximum dose differences were found at the tip of the detectors.

### Conclusion

According to the results, the superposition method, adding the dose of each source obtained by the TG-43 algorithm, can estimate the dose to point A, B, bladder, and rectum points with good accuracy.

### EP-1504 Monte Carlo modeling of non-isocentric proton pencil beam scanning treatments

<sup>3</sup>University of Palermo, Department of Physics and Chemistry, 90128 Palermo, Italy

<sup>4</sup>Medical University of Vienna / AKH, Department of Radiation Oncology, Vienna, Austria

<sup>5</sup>Medical University of Vienna, Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

### Purpose or Objective

Monte Carlo (MC) calculation is the gold standard to support dose calculation analytically performed by Treatment Planning Systems (TPS). This work is built upon a preliminary beam model of a fixed beam line based mainly on measurements performed at isocenter. For non-isocentric treatments, accurate description of beam spot size for reduced air-gaps is of paramount importance for accurate treatment planning. This work extends the

previous beam model based on final medical commissioning data, with special emphasis on beam optics modeling in non-isocentric conditions.

#### Material and Methods

GATE 7.2 based on GEANT4 10.02, using physics-builder QBBC\_EMZ and both *range cut* and *step limiter* of 0.1 mm were used. Mean energy and energy spread were optimized in order to match the clinical range (R80) and the Bragg peak width measured in water. An initial set of beam optics parameters (beam size, divergence and emittance) was predicted at nozzle entrance (1.3 m upstream the isocenter) for five key energies. At this step of the study, a symmetrical proton pencil beam was considered. A sensitivity study in order to understand the influence of beam optics parameters at nozzle entrance on the spot size in air for different air gaps was performed. The beam optics parameters were then adjusted empirically, in order to reach 1 mm in absolute deviation or 10% in relative deviation within a treatment area (defined from 58 cm upstream the isocenter to the isocenter). Eventually, optical parameters were extrapolated for 20 clinical energies.

#### Results

Differences obtained between simulated spot sizes and the measured spot sizes seem to be due to systematic differences in the modeling of beam scattering through the nozzle and air gap. These differences are most probably due to combined intrinsic uncertainties from Multiple Coulomb Scattering (MCS) algorithm and nozzle geometry implemented in the simulation. The achieved agreement between measured and simulated spot FWHM is within clinical tolerances of 1 mm in absolute deviation and 10% in relative deviations for five key energies within the treatment area. As an example, FWHM in function of the air gap for three key energies are reported in Figure 1. Deviations observed are presented in Figure 2. Agreement achieved in terms of ranges in water is within 0.1 mm in absolute deviation for all the energies considered.

#### Conclusion

We extended a preliminary beam model based on a first predictions at nozzle entrance. The final beam model describes spot sizes within clinical tolerances of 1 mm/10%, for the treatment area considered. Detailed validation of this MC beam model is on-going and is based on beam scattering of the core pencil beam, transverse dose profiles in the low dose region (nuclear halo), absolute dose in reference conditions, evaluation of the delivery of 3D cubes (depth-dose and transverse profiles). Special emphasis will be given to non-isocentric set-up, including the use of range shifters

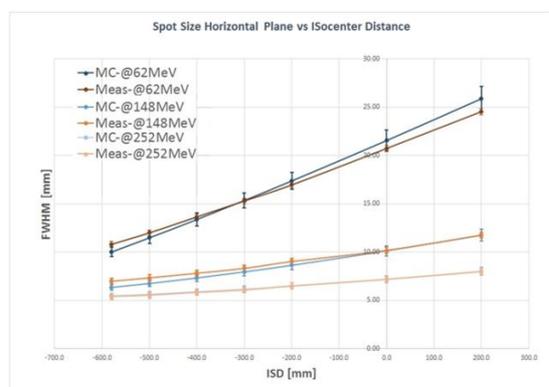

Figure 1. Trend of the simulated FWHM compared to measured values in air for three of the five key energies. In this graph, simulations input parameters were empirically corrected in order to take into account for the scattering due to the air and to the geometry of the nozzle. Error bars on measured values are 0.3 mm while on the simulated values an uncertainty of 5% is considered.

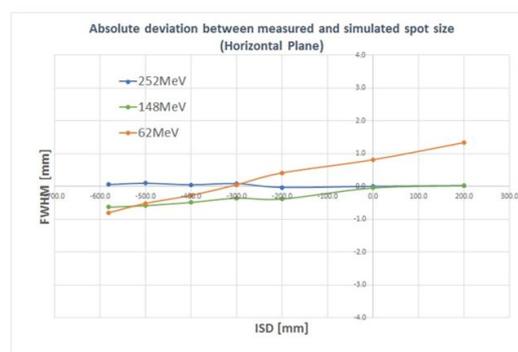

Figure 2. Absolute differences obtained between simulated and measured spot sizes in air considering the full nozzle design. For clarity purpose, in this graph are reported only three out of five key energies used to build the first part of the beam model. Agreement achieved between simulations and measurements is within 1 mm in the treatment region.

#### EP-1505 Use of Portal dosimetry to monitor treatment consistency throughout the course of treatment

S. Deshpande<sup>1</sup>, A. Sutar<sup>1</sup>, S. Naidu<sup>1</sup>, M. Vikram<sup>1</sup>, V. Anand<sup>1</sup>, R. Bajpai<sup>1</sup>, V. Kannan<sup>1</sup>

<sup>1</sup>P.D. Hinduja National Hospital, oncology, Mumbai, India

#### Purpose or Objective

Use of portal dosimetry software to check treatment delivery consistency and to monitor changes in patient anatomy during course of treatment.

#### Material and Methods

Varian portal dosimetry software and Electronic Portal Imaging Device (EPID) aS1200 were used to study consistency of treatment. Patients undergoing VMAT treatment were enrolled in this study. Patient plan was delivered after correcting set up error and transmitted images were acquired by the EPID aS 1200 during the treatment. The transmitted dose images were acquired by EPID after the beam passes through patient. Images were acquired in continuous mode at source to imager distance SID = 150cm on the 1,2,3,5,10,15,20,25 fraction number. Before measuring transmitted dose images cone beam CT was performed to eliminate any set up error. Day one transmitted dose images were defined as base line images. On an average 8 images were acquired during treatment for each patient. These images were compared with base line image. Gamma index evaluation was performed with 1mm and 1% parameter using Varian portal dosimetry software.

#### Results

For the first five images i.e. up to tenth fraction we got average gamma index passing 98.3% which is within action level threshold of 97%. Depending upon the site of treatment we observed gamma passing percentage varies during fog end of treatment

#### Conclusion

Dosimetric measurement during treatment is good tool to investigate error during the treatment. Portal vision is mostly used for patient set up and pre treatment QA of patient. We found that portal dosimetry is useful tool for checking consistency of treatment delivery and monitoring changes in patient contours.

#### EP-1506 Temperature dependent dose readout of Gafchromic EBT3 and EBT-XD film and clinical relevance in SRT

K. Buchauer<sup>1</sup>, L. Plasswilm<sup>1</sup>, J. Schiefer<sup>1</sup>

<sup>1</sup>Kantonsspital St. Gallen, Departement of Radiation Oncology, St Gallen, Switzerland

#### Purpose or Objective

Modern radiation therapy modalities regularly produce SRT/SRS/SBRT plans with highly irregular and steep dose

gradient distributions consisting of many small beam apertures. Accurate verification of such complex treatment fields is still challenging and Gafchromic EBT3 and EBT-XD films play a key role as dosimeter with the highest spatial resolution. Purpose of this work is to evaluate whether well-known temperature dependences of former Gafchromic film media are present with EBT3 and EBT-XD film. The observed systematic patterns of temperature dependence are characterized with respect to relevance in the pre-treatment verification.

#### Material and Methods

An Epson V750 pro flatbed scanner was used to perform scan studies with 125 consecutive scans to purposely warm up the scanner bed. During all scans two temperatures probes were used to measure an average scanner bed temperature. Square film pieces with irradiation dose from 0 Gy to 64 Gy of 1 cm size were placed in the central axis of the scanner bed. Evaluation was performed with the software 'Image J' in all three colour channels in 8100 measurements in total.

#### Results

Temperature dependent relative transmission (%T) readout differences known from former type Gafchromic film media are found to still be present with EBT3 and EBT-XD film type. Higher temperature results in most cases in darker film readout. Interestingly, EBT3 red colour channel changes temperature dependence direction around 16 Gy irradiation dose, meaning that a higher temperature results in less dose readout. Figure 1 and Figure 2 illustrate the relation between the temperature dependent transmission error and irradiation dose for EBT3 and EBT-XD respectively.

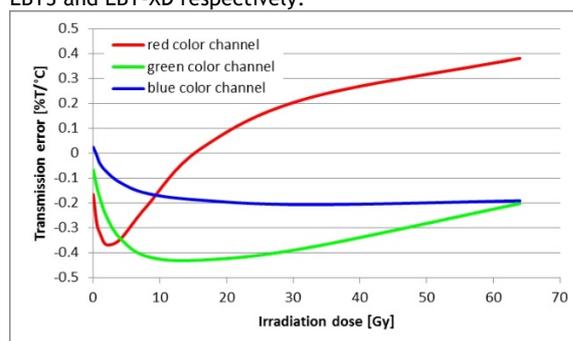

Figure 1 Transmission variation per °C of EBT3 film in dependence of irradiation dose

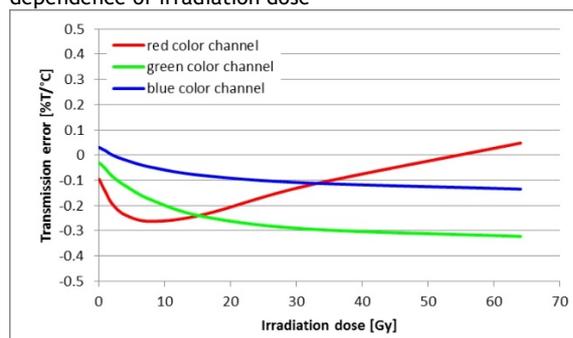

Figure 2 Transmission variation per °C of EBT-XD film in dependence of irradiation dose

#### Conclusion

The results show that all dose levels will be influenced differently by temperature. The common practice of recalibration of a calibration curve with 1-3 film pieces with known dose and the same evaluation temperature is not sufficient to remove temperature dependent readout error. In SRT/SRS/SBRT highest possible precision in dosimetry is not only required in high dose region, but also in medium and low dose areas (OAR relevant) at the same time. For highest precision we therefore suggest to work

in a temperature controlled scanner room in order to achieve the highest possible precision in Gafchromic film dosimetry.

#### EP-1507 Comparison of Pencil Beam Convolution and Analytical Anisotropic algorithms for lung cancer

P. Gkogkou<sup>1</sup>, D. Wills<sup>1</sup>, A. Martin<sup>1</sup>, J. Phillips<sup>1</sup>, N. Solomou<sup>1</sup>, A. Alexandrou<sup>1</sup>, C. Eveleigh<sup>1</sup>, Z. Tassigianopoulos<sup>1</sup>, K. Geropantaz<sup>1</sup>, T. Ajithkumar<sup>2</sup>  
<sup>1</sup>Norfolk and Norwich University Hospital, Oncology Department, Norwich, United Kingdom  
<sup>2</sup>Cambridge University Hospitals NHS Foundation Trust, Oncology Department, Cambridge, United Kingdom

#### Purpose or Objective

Radical radiotherapy using 55Gy in 20 fractions over 4 weeks is an acceptable curative treatment for early-stage medically inoperable lung cancer. The limitation of commonly used Pencil Beam Convolution (PBC) algorithm in terms of inaccurate dose calculation in inhomogeneous tissues such as lung has led to the development of new algorithms such as AAA. However, the true clinical impact of the differences in dose calculations using PBC and Analytical Anisotropic (AAA) algorithms in terms of local control and survival is not known. We compared the clinical outcome of patients with early-stage lung cancer who received radical radiotherapy using either PBC or AAA.

#### Material and Methods

18 patients were treated using PBC and 38 using AAA during 2009-2014. All patients had PET-staged IA or IB disease. None of the patients in this study had received chemotherapy. Residual or recurrent diseases were identified by follow-up imaging. Local failure was defined as tumor recurrence or progression inside the PTV covered by the 95% isodose. This was identified anatomically and volumetrically as PTV-T (Planning target volume around the clinical target volume) = CTV+0.7cm. The minimum follow-up time was 2 years after the completion of the treatment.

#### Results

The median age at diagnosis was 77 years (range 64-87) for the PBC group and 79 years (range 64-94) for AAA. The median follow-up period was 34 months for the AAA vs 26 months for PBC (p=0.006). The median survival was 39 months for AAA vs. 23 months for the PBC group (p=0.008). On univariate analysis, there were no significant prognostic factors for either relapse or overall survival. There were 5 (27.7%) local failures in the PBC group and 8 (21%) in the AAA. No marginal recurrences were found. Using the cox-proportional hazards regression analysis, there were no statistically significant difference in local (p=0.285) or metastatic (p=0.191) recurrence between the two groups.

#### Conclusion

Radical radiotherapy in our cohort study showed an excellent tumor control and low-risk tumor recurrence in the treatment volume. The results of this retrospective study showed that there was no statistical difference between the two algorithms regarding recurrences, whereas AAA gave a significantly better median survival.

#### EP-1508 Quantification of skin dose and photon beam attenuation for the iBEAM couch and Compact accelerator

M.A. Mosleh-Shirazi<sup>1</sup>, F. Arianfard<sup>2</sup>, S. Karbasi<sup>1</sup>, S. Mousavi<sup>1</sup>

<sup>1</sup>Shiraz University of Medical Sciences, Physics Unit-Radiotherapy & Oncology Department, Shiraz, Iran Islamic Republic of

<sup>2</sup>Shiraz University of Medical Sciences, Radiology & Radiobiology Department- School of Paramedical Sciences, Shiraz, Iran Islamic Republic of

### Purpose or Objective

This work aims to accurately quantify the attenuation and skin dose increase for 6 MV photon beams of an Elekta Compact linear accelerator transmitted through the Elekta iBEAM Standard carbon fiber couchtop and related immobilisation devices. A study of this combination of couchtop and linac has not been reported. Other novel aspects of this work include the use of Monte Carlo (MC) simulation in conjunction with thin-buildup diode measurements for better estimation of the clinically-relevant dose to skin basal cell layer, as well as putting the results into context by direct comparison of PDDs in the buildup region and further depths with a typical Co-60 treatment unit utilizing a 'tennis racket' type couch without a Mylar sheet (Theratron Phoenix).

### Material and Methods

Manufacturer-supplied information was used to add an MC model of the couchtop to an existing detailed model of the linac head. Beam attenuation by the couchtop was simulated and measured using an ionisation chamber both in air and in a water-equivalent cylindrical phantom at gantry angles 125°, 135°, 150°, 165° and 180° for field sizes 5×5 cm<sup>2</sup>, 8×8 cm<sup>2</sup>, 10×10 cm<sup>2</sup>, 15×8 cm<sup>2</sup> and 20×8 cm<sup>2</sup>. Also beam attenuations of the head-and-neck (H&N) extension and BreastSTEP boards were measured for an 8×8 cm<sup>2</sup> field. The effect on skin dose was studied by measurement of percentage depth dose (PDD) in the buildup regions of 180° gantry beams of both linac and Co-60 units, using an electron diode in a Perspex slab phantom for 5×5 cm<sup>2</sup>, 10×10 cm<sup>2</sup> and 20×20 cm<sup>2</sup> field sizes, as well as the corresponding linac MC simulations.

### Results

The simulated and measured couchtop attenuation results agreed to within 0.4%, which further validated the MC model. The highest couchtop attenuation (7.6%) was measured at 135° gantry and 5×5 cm<sup>2</sup> field size. The attenuation values of the H&N extension and breast boards at 180° gantry angle were 6.9% and 6.7%, respectively. MC results showed that the couchtop increased dose at various depths of basal cell layer (0.1-0.4 mm) by 55.3%-63.2%. The measured dose increase at 0.4 mm depth ranged between 60.6% and 74.6% with field sizes 20×20 cm<sup>2</sup> to 5×5 cm<sup>2</sup>, the corresponding Co-60 unit increase for a 10×10 cm<sup>2</sup> field being 18.1%. To directly compare two prescribed treatment beams, when the PDDs were normalized at 10 cm depth for a 10×10 cm<sup>2</sup> field, although dose to subcutaneous tissues was always higher with the Co-60 unit, it produced an at least 49.7% lower skin basal layer dose.

### Conclusion

The beam attenuation values should be applied in treatment planning. The obtained skin dose results support and explain the higher observed skin effects in patients treated on the Compact unit compared to those previously treated on the Co-60 unit with similar 180° gantry angle beams. Modifying the treatment techniques to reduce the fraction of the dose delivered through the couchtop and/or the use of a 'tennis racket' type carbon fiber couchtop should be considered.

### EP-1509 Small fields defined by jaw or MLC: evaluation of MU estimation by AAA and Acuros algorithms

F. Lofebalo<sup>1</sup>, A. Fogliata<sup>1</sup>, G. Reggiori<sup>1</sup>, A. Stravato<sup>1</sup>, S. Tomatis<sup>1</sup>, M. Scorsetti<sup>2</sup>, L. Cozzi<sup>2</sup>

<sup>1</sup>Humanitas Research Hospital and Cancer Center, Radiation Oncology, Milan-Rozzano, Italy

<sup>2</sup>Humanitas Cancer Center and Humanitas University, Radiation Oncology, Milan-Rozzano, Italy

### Purpose or Objective

The small field output factor measurements are studied in literature, covering the aspects of lack of charged particle equilibrium, the partial occlusion of the finite source, and

the detector's volume and response. However, the related accuracy of the MU calculation from dose calculation algorithms has not been investigated with similar intensity. Aim of the present work is the evaluation of the MU calculation accuracy for small fields generated by jaw or MLC for two photon dose calculation algorithms in the Eclipse system (Varian): AAA and Acuros. Simple static beam geometries were chosen in order to better estimate the accuracy with no additional biases. Flattening filter free beams (6 and 10 MV) and and flattened 6MV were evaluated.

### Material and Methods

Single point output factor measurement were acquired with a PTW microDiamond detector for 6MV, 6 and 10MV unflattened beams generated by a Varian TrueBeamSTx equipped with HD-MLC. Since the greatest indeterminateness of the measurement accuracy resides in the detector sensitivity correction factors for detector, different corrections, field size dependent, were applied according to different publications on the used detector. Fields defined by jaw or MLC apertures were set; jaw-defined: 0.6x0.6, 0.8x0.8, 1x1, 2x2, 3x3, 4x4, 5x5 and 10x10 cm<sup>2</sup>; MLC-defined: 0.5x0.5 cm<sup>2</sup> to the maximum field defined by the jaw, with 0.5 cm stepping, and jaws set to: 2x2, 3x3, 4x4, 5x5 and 10x10 cm<sup>2</sup>. MU calculation was obtained with 1 mm grid in a virtual waterphantom for the same fields, for AAA and Acuros algorithms implemented in the Varian Eclipse treatment planning system (version 13.6). Configuration parameters as the effective spot size (ESS) and the dosimetric leaf gap (DLG) were varied to find the best parameter setting. Differences between calculated and measured doses were analyzed.

### Results

Agreement better than 0.5% was found for field sizes equal to or larger than 2x2 cm<sup>2</sup>. In the following the results are given for the two extreme detector sensitivity correction factors, with the second value in brackets. A dose overestimation was present for smaller jaw-defined fields, with the best agreement, over all the energies, of 1.6 (0.5)% and 4.6 (3.5)% for a 1x1 cm<sup>2</sup> field calculated by AAA and Acuros, respectively, for a configuration with EES=1 mm for X, Y directions for AAA, and EES=1.5, 0 mm for X, Y direction for Acuros. Conversely, a calculated dose underestimation was found for small MLC-defined fields, with the best agreement averaged over all the energies, of -3.9 (-4.9)% and 0.2 (-0.8)% for a 1x1 cm<sup>2</sup> field calculated by AAA and Acuros, respectively, for a configuration with EES=0 mm for both directions, both algorithms.

### Conclusion

For optimal setting applied in the algorithm configuration phase, the agreement of Acuros calculations with measurements could achieve the 3 (6)% for MLC-defined fields as small as 0.5x0.5cm<sup>2</sup>. Similar agreement was found for AAA for fields as small as 1x1 cm<sup>2</sup>.

### EP-1510 Dosimetric characterisation of stereotactic cones by means of MC simulations

A. Nevelsky<sup>1</sup>, E. Borzov<sup>1</sup>, S. Daniel<sup>1</sup>, R. Bar-Deroma<sup>1</sup>  
<sup>1</sup>Rambam Medical Center, Oncology, Haifa, Israel

### Purpose or Objective

The objective of this work was to employ an MC model of 6MV FFF beam from the ELEKTA VersaHD linac to perform dosimetric investigation of the new ELEKTA stereotactic cones.

### Material and Methods

The BEAMnrc code was used to create detailed model of the linac head and stereotactic cones for the 6MV FFF beam based on the manufacturer data supplied by Elekta. MC simulation with the BEAMnrc code generated the phase-space file which was used in the DOSXYZnrc code to

calculate PDDs, lateral profiles and output factors in a water phantom for stereotactic cones with 5, 7.5, 10, 12.5 and 15 mm nominal diameter. Results from the simulations were compared against measurements performed in water phantom with PTW PinPoint ion chamber and Scanditronix stereotactic diode. Actual cone diameter was found by the best match between the calculated and measured lateral profiles. Sensitivity of output factor to cone diameter variations was investigated. For this purpose, nominal cone diameter was changed by  $\pm 0.3$  mm (which is twice the manufacturer stated uncertainty of 0.15mm).

#### Results

Lateral profiles agreed within 2%/0.5mm for all cone sizes. Actual cone diameters were found to be 5.30, 7.70, 10.15, 12.65 and 15.15 mm. For the actual cone diameter, output factors agreed within 2% for all cones except for cone 5 mm where the difference was 4%. Cone diameter uncertainty of 0.3 mm lead to up to 11% variation in the output factor compared to output factor value calculated for the nominal diameter.

#### Conclusion

The MC model of the VersaHD linac was employed for investigation and characterization of stereotactic cones. Measured data were verified by the MC calculations. Differences between nominal and actual cone diameter were observed. Given the level of manufacturing accuracy and sensitivity of dosimetric parameters to the cone diameter variation, accurate commissioning of stereotactic cones must be performed and comparison with the data from other centers may be misleading.

#### EP-1511 Radiation Dose from Megavoltage Cone Beam Computed Tomography for IGRT

E. Kara<sup>1</sup>, B. Dirican<sup>2</sup>, A. Yazici<sup>1</sup>, A. HICSONMEZ<sup>1</sup>

<sup>1</sup>Onko Ankara oncology center, Oncology Department, Ankara, Turkey

<sup>2</sup>Gulhane Research and Education Hospital, Radiation Oncology, Ankara, Turkey

#### Purpose or Objective

Imaging dose in radiotherapy has generally been ignored due to its low magnitude in comparison to therapeutic dose used to treat patients. However, the total number of fractions can range from 30 to 40 fractions for radical IMRT. The cone beam computed tomography (CBCT) dose to patients can be substantial. Daily imaging results in additional dose delivered to patient that warrants new attention be given to imaging dose. In this study, we try to figure out the organ dose of CBCT for head&neck and pelvis's critical organs with three different CBCT protocols. We also compare the image quality of these protocols and try to find optimum one for dose and image quality.

#### Material and Methods

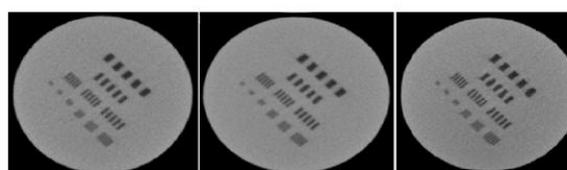

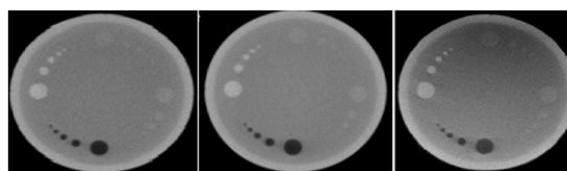

Organ doses were measured for three different megavoltage CBCT protocols on the Siemens Artiste linear accelerator treatment machine. Organ doses were measured by distributing thermoluminescent dosimeters (TLDs) throughout critical organs of an anthropomorphic (RANDO) phantom. The selected organs are rectum, bladder, femoral heads and small intestine for pelvis imaging and spinal cord, brainstem, thyroid and parotid glands for head and neck imaging. The CBCT protocols were 8MU, 15 MU and 8 MU half cycle. Slice size (512x512 pixels), slice thickness (0.54 mm), number of slices (512) and SID (145 cm) were same for each protocol. The numbers of projections are 360 for 8MU&15 MU protocol and 200 for 8 MU half cycle protocol. The placement of TLDs was done with the guidance of an atlas of the anatomy. The TLDs placed RANDO phantom was irradiated by using three different imaging protocol and the doses were compared. We have also performed image quality

tests for each protocol. The used image quality phantom was 20 cm diameter with four 2 cm sections: 1 solid water section for noise and uniformity, 2 sections with inserts for contrast resolution and 1 section with bar groups for spatial resolution. We have performed image quality tests for each CBCT protocols.

#### Results

We have seen that 15 MU protocol has no difference with 8 MU protocols in the means of image quality and the dose of critical organs are much higher than the others as expected. When we compare 8 MU and 8 MU half ring protocols in the means of organ doses, we have seen that the doses of organs changes according to the geometrical placements of organs. Accordingly, while the doses of organs, such as rectum, spinal cord and brainstem, nearby the posterior decreases with the use of 8 MU half protocol, the doses of organs located anterior, such as intestine, thyroid and bladder, increases. It is observed that both the contrast resolution and the spatial resolution of the 8 MU half protocol is better than the 8 MU protocol. It also gives information about position in a shorter time.

	8 MU(cGy)	15 MU(cGy)	8 MU Half(cGy)
<b>Rectum</b>	4.99±0.08	9.27±0.31	3.06±0.39
<b>Bladder</b>	4.64±0.12	8.69±0.24	4.96±0.44
<b>Femur(L)</b>	4.64±0.01	8.38±0.14	4.39±0.37
<b>Femur(R)</b>	4.35±0.54	8.39±0.18	4.92±0.41
<b>Small Intestine</b>	4.53±0.11	8.23±0.13	5.90±0.20
<b>Brainstem</b>	2.10±2.09	3.61±3.64	1.89±1.73
<b>Spinalcord</b>	4.61±0.29	8.39±0.40	3.43±0.86
<b>Parotid(L)</b>	3.64±0.8	6.54±1.55	3.61±0.71
<b>Parotid(R)</b>	3.17±1.56	6.41±2.44	3.36±0.61
<b>Thyroid</b>	5.70±0.09	10.46±0.37	6.65±0.23

#### Conclusion

After obtain all this information about MV CBCT protocols, we figure out that the choice of CBCT protocol should be done after treatment planning by considering of the doses and location of the critical organs. than the others as expected.

#### EP-1512 Comparison between dose transmission detector and 3d dosimetry for lung SBRT treatments.

F.R. Giglioli<sup>1</sup>, E. Gallio<sup>1</sup>, C. Fiandra<sup>2</sup>, O. Hammad<sup>3</sup>, R. Ragona<sup>2</sup>

<sup>1</sup>A.O.U. Città della Salute e della Scienza- Department of Medical Physics- Torino- Italy, Medical Physics, Torino, Italy

<sup>2</sup>University of Turin- Radiotherapy Unit - Torino- Italy, Department of Oncology, Torino, Italy

<sup>3</sup>International Center for Theoretical Physics- Trieste- Italy, ICTP, Trieste, Italy

#### Purpose or Objective

The new IBA Dolphin (IBA Dosimetry, Germany) is a dose transmission detector (DTD) mounted onto the gantry for online treatment verification as well. Aim of this study is to compare the results of the Dolphin/Compass with the traditional 3D dosimetry phantom Delta 4 (Scandidos, Sweden) for lung stereotactic body radiation therapy treatments and to measure the detector attenuation for online dose verification.

#### Material and Methods

At first the two systems were compared in terms of ability of error detection of leaf position. A box treatment was measured three times with introduction of a shift of one leaf bank in steps from 0 to 2 mm and the analysis of gamma index or DVHs was carry out. Afterward ten patients with lung cancer, treated by sbrt, were included in the study. All treatment plans were simultaneously verified with the Dolphin and the Delta 4. The treatment plans were generated by Monaco system (ver.5.0, Elekta AB, Sweden). Dolphin with the Compass software (v. 4.0) permits the 3D dose distribution reconstruction on a patient CT and the Compass itself is a model-based dose computation, with a collapsed cone dose engine; the beam model of the Compass was validated and accepted. For the quantitative analysis parameters of dose-volume based indices for PTV (V80%, D98%, mean dose, D2% and Gamma index 2%-2mm) and OARs doses (Dmax and dose at the threshold volume according to AAPM TG101) were evaluated for Compass calculation and DTD reconstruction. At the same time gamma index (2%-2mm) was calculated based on Delta 4 measurements.

The detector attenuation was estimated in a clinical context comparing the median dose inside the Delta 4 detector with and without the Dolphin mounted.

#### Results

Error detection ability : the fig. 1 shows the variation between difference % of mean dose in a Roi limited to the irradiation beams for DTD versus leaf position shift and the % of points with gamma index > 1 for Delta 4.

Quantitative analysis: table 1 shows the results of the comparison between Dolphin/Compass and Delta 4 phantom. The PTV average gamma was  $0.64 \pm 0.12$ ; the mean percentage differences of V80%, D98%, mean dose and D2% were inferior to 3%. The difference in Gy for OARs were under or equal to 1 Gy, except for D(4cc) of trachea (1.15 Gy). The maximum difference was found for rib D<sub>max</sub> (4.4 Gy). The mean % of point with gamma < 1 for Delta 4 was  $83.2 \pm 0.06$ ; one patient was considered failed with 72% of points with  $g < 1$  in Delta 4.

Detector attenuation : a value of  $10.5 \pm 0.5$  % was found.

Table 1. Comparison between Compass computed and reconstructed doses

Measurement (Compass reconstruction) vs Compass (computed dose) (ref.)

#### Conclusion

The DTD system seems to be more sensitive than 3D detector for error detection ability. The Dolphin/Compass system is a useful tool to perform QA patients in a SBRT context offering more clinically evaluable information than 3D phantoms only. For the online dosimetry, the methodology proposed led to an attenuation correction factor not negligible but constant.

EP-1513 CyberKnife robotic radiotherapy delivery quality assurance using CrystalBall 3D Dosimetry System  
M.A. Al Kafi<sup>1</sup>, A. Al Moussa<sup>1</sup>, M.J. Maryanski<sup>2</sup>, B. Moftah<sup>1</sup>  
<sup>1</sup>King Faisal Specialist Hospital and Research Centre, Biomedical Physics, Riyadh 11211, Saudi Arabia  
<sup>2</sup>MGS Research- Inc., d.b.a. 3D Dosimetry, Madison- CT, USA

#### Purpose or Objective

Stereotactic radiosurgery/radiotherapy (SRS) and stereotactic body radiotherapy (SBRT) deliver high dose to the tumor accurately and precisely. With hypo-

fractionation, even small relative errors can lead to serious complications to the normal tissue or recurrences of the tumor. So delivery quality assurance (DQA) in SRS/SBRT is very critical and poses unique challenges due to extremely high dose gradients and lack of electronic equilibrium. For this reason, dose rate independent dosimeters with precise, high spatial resolution and 3D capabilities are essential as reported by the Council on Ionizing Radiation Measurements and Standards (CIRMS).

#### Material and Methods

The new CrystalBall system (3D Dosimetry, Madison, CT, USA) is designed for DQA with sub-millimeter spatial resolution in 3D. The system is composed of a fast laser CT scanner (OCTOPUS, MGS Research, Inc, Madison, CT) and reusable tissue-equivalent radiochromic polymer gel sphere-mounted on a special QA phantom. Gold fiducial markers are affixed in different locations of the phantom for image guidance with fiducial tracking for CyberKnife (CK) robotic SRS/SBRT system (Accuray, Sunnyvale, CA). The CT images of the CrystalBall gel phantom were transferred to the CK Multiplan treatment planning system. A DQA plan was generated by superimposing a patient plan onto the gel phantom CT data set. The DQA plan was then sent for CK irradiation. The CrystalBall's VOLQA software registers the plan DICOM CT dataset with the laser CT of the irradiated gel, creates OD/cm to dose calibration curve and then compares the CrystalBall irradiation measurements with the Multiplan's DQA plan. It generates QA reports that feature overlays of isodoses in 2D and 3D, profiles, DVHs, voxel statistics, and pass/fail metrics for dose difference and distance-to-agreement according to gamma index criteria. In this study, we performed DQA for four CK patients who received treatment for brain metastasis, spine metastasis and trigeminal neuralgia as recommended by AAPM TG-135. For each patient, the DQA was done three times.

#### Results

Figures 1 and 2 show the CrystalBall phantom setup with OD/cm to dose auto-calibration, 2D and 3D overlay of isodoses for a patient, respectively.

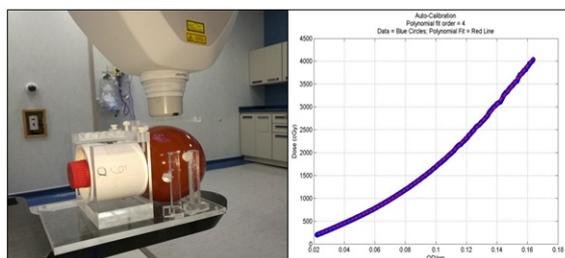

Figure 1. The setup for the CrystalBall phantom system (left) and OD/cm-Dose calibration curve for a plan (right)

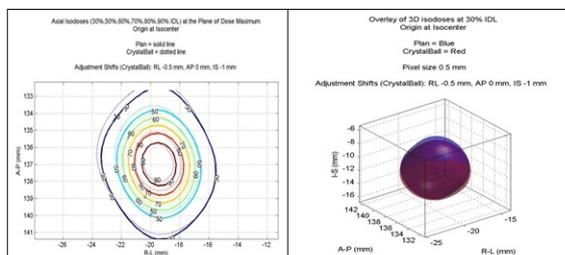

Figure 2. 2D overlay comparison of different isodose lines (left) and 3D overlay comparison of 30% isodose line (right) for the trigeminal patient.

Table 1 shows results of the study for gamma evaluation passing averages for the DQA of the four patients. For all patients studied, we found a passing rate of more than 96% with gamma index criteria of 2 % dose difference and 2

mm distance-to-agreement. For 3 % and 3 mm criteria, the passing rate is found to be above 99%.

Patient No.	Diagnosis	Max Dose (Gy)	Passing ( % )	
			Gamma Index Criteria	
			2%/2 mm	3%/3 mm
1	Brain Metastasis	6.5	99.4 ± 0.5	99.83 ± 0.05
2	Brain Metastasis	8.6	99.46 ± 0.01	99.98 ± 0.02
3	Spine Metastasis	7.3	96.5 ± 0.1	99.13 ± 0.06
4	Trigeminal Neuralgia	77.2	99.99 ± 0.01	99.99 ± 0.01

Table 1: Results of gamma evaluation passing rate for the patients

#### Conclusion

Our DQA results suggest that the newly developed CrystalBall QA phantom system for robotic radiosurgery can be ideal tool for 3D dose verification with isotropic sub-millimeter spatial resolution and film-equivalent accuracy. This 3D tool can offer unique advantage over other existing 2D tools and techniques in terms of high-resolution DQA necessary for radiotherapy with minimal additional physics resources.

#### Electronic Poster: Physics track: Radiation protection, secondary tumour induction and low dose (incl. imaging)

#### EP-1514 Planar kV imaging dose reduction study for Varian iX and TrueBeam linacs

E. Gershkevitch<sup>1</sup>, D. Zolotuhhin<sup>1</sup>

<sup>1</sup>North-Estonian Regional Hospital Cancer Center Radiotherapy, Radiotherapy, Tallinn, Estonia

#### Purpose or Objective

IGRT has become an indispensable tool in modern radiotherapy with kV imaging used in many departments due to superior image quality and lower dose when compared to MV imaging. Since, the frequency of kV images continues to increase (intrafractional imaging, etc.) the reduction of additional dose assumes high priority. Many departments use manufacturer supplied protocols for imaging which are not always optimised between image quality and radiation dose (ALARA).

#### Material and Methods

Whole body phantom PBU-50 (Kyoto Kagaku Ltd., Japan) for imaging in radiology has been imaged on Varian iX OBI 1.5 and TrueBeam 2.5 accelerators (Varian Medical Systems, USA). Manufacturer's default protocols were adapted by modifying kV and mAs values when imaging different anatomical regions of the phantom (head, thorax, abdomen, pelvis, extremities). Images with different settings were independently reviewed by two persons and their suitability for IGRT set-up correction protocols were evaluated. The suitable images with the lowest mAs were then selected. The entrance surface dose (ESD) for manufacturer's default protocols and modified protocols were measured with RTI Black Piranha (RTI Group, Sweden) and compared. Image quality was also measured with kVQC phantom (Standard Imaging, USA) for different protocols. The modified protocols have been applied for clinical work.

#### Results

The default manufacturer's protocols on TrueBeam linac yielded 9.4 times lower ESD than on iX linac (range 2.5-24.8). For most cases it was possible to reduced the ESD on average by a factor of 3 (range 0.9-8.5) on iX linac by optimising imaging protocols. Further ESD reduction was also possible for TrueBeam linac.

### Conclusion

The imaging doses on new TrueBeam accelerator is substantially lower than on previous iX platform. Manufacturer's default IGRT protocols could be optimised to reduce the ESD to the patient without losing the necessary image quality for patient set-up correction. For patient set-up with planar kV imaging the bony anatomy is mostly used and optimization should focus on this aspect. Therefore, the current approach with anthropomorphic phantom is more advantageous in optimization over standard kV quality control phantoms and SNR metrics.

### EP-1515 A novel attachment system for cutouts in kilovoltage x-ray beam therapy

M. Baumgartl<sup>1</sup>, G. Kohler<sup>1</sup>

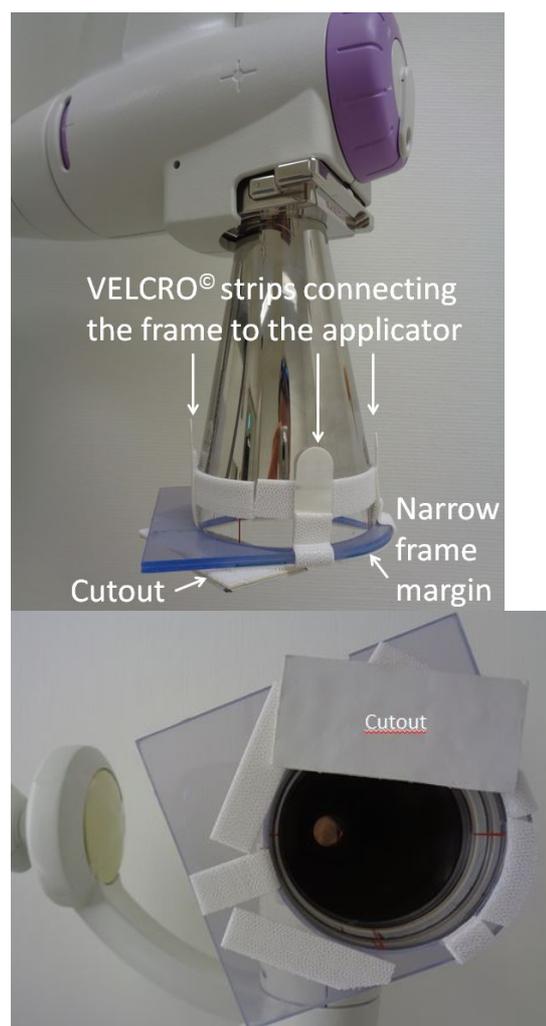

<sup>1</sup>University Hospital Basel, Clinic for Radiooncology, Basel, Switzerland

### Purpose or Objective

Customized shielding in superficial and orthovoltage therapy is a common procedure to spare healthy tissue and is nowadays mainly based on in-house cutouts attached to applicators or patients. However, the production of customized shields could be time consuming and does not always provide a promising result. Inaccuracies during the replacement of cutouts may arise if the same applicator is required to treat different patients or target volumes (TV) immediately one after the other. An adequate, fast and reproducible approach of shielding was developed to treat the TV in the low and medium energy (kV) range for standard applicators.

### Material and Methods

In our department most of the cutouts have a straight-edged shape. Our developed in-house frame-based system can be used to attach and remove the cutouts to the applicator in an easy and fast manner. It is important to note, that the mounted frame must not interfere with the radiation field. Hence, the frame has an identical size as the used applicator. VELCRO® strips were deployed as an attachment modality between applicator, frame and cutout. Those were glued to a PMMA frame with the same size of a standard applicator which attach to VELCRO® strips elongating around the applicator. The skin facing side of the frame is also covered with VELCRO® strips. In addition, cutouts were covered on the one side with VELCRO® strips and on the other side with a plastic foil, respectively. Straight-lined cutouts can be adjusted within seconds to shape TVs.

### Results

All used straight-lined shields from our database could be exactly reproduced contouring 100% of the TV using the developed attachment system. Nevertheless, the system increases the distance of the applicator to the patient skin by non-negligible 8.8mm. This has to be taken into account by an output factor (OF). A comparison of the measured and calculated (by the ISL) OFs shows a maximum deviation of  $\pm 3.6\%$  (12keV) and  $\pm 0.8\%$  (>12keV) for our set-up.

### Conclusion

Shielding healthy tissue in kilovoltage x-ray beam therapy using the reusable frame-based system promises a fast exchange of cutouts. It also ensures a high reproducible accuracy to irradiate multiple TVs in a row with the same applicator but with different frames and cutouts. Moreover, it provides a complete coverage of healthy tissue of straight-lined TVs. Furthermore, a measured OF should be considered to the prescribed dose using the presented frame-based attachment system.

### EP-1516 Prediction of secondary cancer risk from lateral electrons transport from pediatric radiotherapy

A. Chaikh<sup>1</sup>, J. Balosso<sup>2</sup>

<sup>1</sup>CHU de Grenoble - A. Michallon, Radiothérapie et physique médicale, Grenoble, France

<sup>2</sup>University Hospital of Grenoble- University Grenoble-Alpes, Department of Radiation Oncology and Medical physics, Grenoble, France

### Purpose or Objective

Modern dose calculation algorithms in radiotherapy treatment take into account the scattered dose and lateral electrons transport, such as point kernel model. The impact of scattered radiation dose from radiotherapy treatment is more significant for children. In this study, secondary cancer risk (SCR) resulting from scattered dose and the contribution of electrons transport were compared.

### Material and Methods

Clinical examples of treatment plans for pediatric medulloblastoma were used to estimate the SCR for lungs. For each case, two treatment plans with conformal radiotherapy were generated. The same dose prescriptions for posterior fossa and craniospinal irradiation were used for both plans. The dose in first plan was calculated with algorithm taking account only scattered dose. The dose in second plan was calculated taking account scattered dose and lateral electron transport, as point kernel algorithms. The organ equivalent dose (OED) concept with a linear, linear-exponential and plateau dose response curves was applied to dose distributions, dose volume histograms, for lungs to estimate SCR. The excess absolute risk ratio (EAR) was also evaluated as  $EAR = OED$  from scattered dose divided to OED from scattered with lateral electrons transport doses.

### Results

The calculated DVH with algorithm modeling lateral electron transport were significantly increased predicting more average dose for lungs by a factor of 1 to 1.1. The SCR was also increased (8%-16%) depending on model prediction. The EAR ratio were 1.08, 1.2 and 1.13, respectively, using linear, linear-exponential and plateau models.

### Conclusion

The considerable impact of dose calculation methods in radiotherapy, integrated in TPS, can significantly influence the secondary cancer risk prediction and plan optimization, since OED is calculated from DVH for a specific treatment. The modern algorithms such as AAA, Acuros XB or Monte Carlo showed a better prediction of dose distribution. On the other hand, they provided more "trust" DVH metrics, as input in the SCR models, avoiding the uncertainties of dose distribution as well as significantly contribute to better estimations.

### EP-1517 Analysis of radiotherapy risk profile applied to the patient positioning

G. Menegussi<sup>1</sup>, M.M. Vasques<sup>1</sup>, G.R.D. Santos<sup>1</sup>, L. Furnari<sup>1</sup>, L.N. Rodrigues<sup>1</sup>

<sup>1</sup>Hospital das Clinicas -FMUSP, Radiotherapy, Sao Paulo, Brazil

### Purpose or Objective

The purpose of this work is to recognize and understand the risks of the processes of Radiotherapy positioning.

### Material and Methods

Risk analysis methods were applied Failure Mode Effect Analysis (FMEA) to key steps in each sub-step of the positioning process (simulation, initial positioning, displacement, images acquisition and treatment) of patients in the treatment of breast and head&neck (H&N) tumors. This tool enabled us to identify the risks involved in the process, to assess the impact of each sub-step and to rank the most relevant errors by setting a numerical value- Risk Priority Number (RPN) obtained with the scores attributed to the occurrence, severity and detectability by questionnaires submitted to staff (doctors, physicists and therapists).

### Results

For breast the unanimous responses between professional classes were initial placement, lateral displacement in the location of the isocenter and image acquisition. The

causes of positioning errors were during treatment for physicians losses marks on the skin is the most important factor, to the physicists, error in the use of accessories results in major failures and for therapists, changes in the weight of the patient may cause major errors. For H&N cases there was not unanimous response. In simulation-CT scan, doctors point out patients lack of cooperation as the leading cause of errors, physicists an improperly made mask generates the greater number of failures and therapists did not have unanimous answers. In the initial position sub-step, the most important point proved to be the inclusion or exclusion of tracheostomy/nasal probe for therapists and physicists. Physicists also considered non-coincidence of location marks a factor of great importance. In location of the treatment isocenter sub-step, physicists and therapists pointed to the poor positioning of the mask as a cause of failure, but with different impact in the treatment. For physicians, the wrong initial displacement is the main cause of errors. In acquisition of portal sub-step, the most frequent cause of errors was inaccurate comparison of images and mistaken correction, for all. For therapists and physicists, the use of DRR associated with other phases was the root cause of failures in this step. Positioning errors causes during treatment received different answers: for doctors, the main causes of failure are problems with the mask accessories and change in patient weight. For physicists the patient's weight change was the most important failure.

### Conclusion

The FMEA introduces a subjective analysis, since it is dependent on personal judgment criteria relevant points were highlighted in the analysis of positioning routine. To the answers with relevant frequency or high RPN, solutions could be suggested in order to prevent failures and minimizing human errors. Further studies are in progress to other anatomical sites.

### EP-1518 Various activation foils for photo neutron measurements in medical linac

A.H. Kummali<sup>1</sup>, S. Cyriac<sup>2</sup>, S. Deepa<sup>3</sup>, A. BAKSHI<sup>3</sup>

<sup>1</sup>Nanavati Hospital, Medical Physics, Mumbai, India

<sup>2</sup>Apollo Hospitals Navi Mumbai, Medical Physics, Navi Mumbai, India

<sup>3</sup>BARC, RPAD, Mumbai, India

### Purpose or Objective

Photo neutrons produced from medical linear accelerators while operating above 10 MV is a concern for radiation protection and safety for patients and radiation workers<sup>[1]</sup>. Different methods are used to quantify the neutron production in clinical situation. In our study we used various activation foils for the photo neutron measurements in medical LINAC. This study discusses the measurement techniques of neutron absorbed dose for various treatment parameters of clinical importance.

### Material and Methods

Absolute measurements of photo-neutrons using the Indium activation foil<sup>[2]</sup> having both thermal and fast neutron cross-sections through the nuclear reactions<sup>115</sup>In (n,  $\gamma$ )<sup>116m</sup>In and <sup>115</sup>In (n, n')<sup>115m</sup>In, the thermal neutrons using <sup>197</sup>Au(n, $\gamma$ )<sup>198</sup>Au, <sup>63</sup>Cu (n, $\gamma$ )<sup>64</sup>Cu were evaluated in the present study. Photo-neutron measurements for various field size opening using MLC, and for various wedge angles for 15 MV photon beam from a Medical LINAC model Elekta Precise have been carried out in the present study.

### Results

Photo neutrons were measured using 3 foils mentioned above for various field sizes<sup>[3]</sup> such as 10 x 10 cm<sup>2</sup> to 20 x 20 cm<sup>2</sup> and for 40 x 40 cm<sup>2</sup>. Irradiation time for each field size took approximately 10 min and the total MU delivered is 5000 at a dose rate of 590 MU/min. Dose calculated at Dmax is 50Gy and 10 cm back up of PMMA phantom is

ensured for the scattering and to mimic the TPS treatment planning. The result shows that, the total neutron dose increases as the field size increases from  $10 \times 10 \text{ cm}^2$  to  $20 \times 20 \text{ cm}^2$  and for  $40 \times 40 \text{ cm}^2$ . The photo neutron measurements using activation foils for Omni wedged fields in Elekta LINAC is uniquely studied. The irradiation time of about 20 min were taken to deliver 50 Gy at Dmax with the dose rate of 640 Mu/min. Wedged fields were defined for a field size of  $30 \times 30 \text{ cm}^2$  and the wedge used for each set of measurements are  $15^\circ$ ,  $30^\circ$  and  $60^\circ$ . The fast neutron dose decreases and thermal neutron dose increases with wedge angles from  $15^\circ$ ,  $30^\circ$  and  $60^\circ$ . Open beam gives the highest fast neutron dose and the lowest thermal neutron dose.

#### Conclusion

Insensitivity nature of activation foils for gamma/photons and the possibility of absolute measurements using the primary quantity of nuclear reaction cross-section makes activation foil best suited for photon induced neutron measurement. The present results indicate that the total neutron dose represents a small contribution to the therapeutic photon dose, meaning that it is much smaller than 1% of the photon dose delivered to the patient. However, the amount of this extra dose in the vicinity of the patient position cannot be neglected in view of radiological protection assessment related to the patients.

##### EP-1519 Implementation of a hybrid superfast Monte Carlo-Pencil beam dose optimizer for proton therapy

A.M. Barragán Montero<sup>1</sup>, K. Souris<sup>1</sup>, D. Sánchez-Parcerisa<sup>2</sup>, A. Carabe-Fernández<sup>3</sup>, J.A. Lee<sup>1</sup>, E. Sterpin<sup>1,4</sup>

<sup>1</sup>Université Catholique de Louvain- Institute of Experimental & Clinical Research, Molecular Imaging-Radiotherapy and Oncology MIRO, Brussels, Belgium

<sup>2</sup>Universidad Complutense de Madrid, Departamento de Física Atómica- Molecular y Nuclear, Madrid, Spain

<sup>3</sup>Hospital of the University of Pennsylvania, Department of Radiation Oncology, Philadelphia, USA

<sup>4</sup>KU Leuven - University of Leuven, Department of Oncology, Leuven, Belgium

#### Purpose or Objective

Monte Carlo (MC) dose calculation plays an important role in treatment planning for proton therapy due to the limited accuracy of analytical algorithms, especially in very heterogeneous tumor sites. The new dedicated MC engines for pencil beam scanning (PBS) achieve reduced computation times for a single dose calculation. However, computing spot-per-spot doses is still very time-consuming, since typically 10000 to 20000 spots are needed. The presented strategy combines the speed of analytical algorithms and the accuracy of MC to get the best outcome for PBS treatment planning in a reasonable amount of time for clinical practice.

#### Material and Methods

An in-house treatment planning system was used to create the plans. The optimizer combines the analytical pencil beam (PB) algorithm in *FoCa* (Sánchez-Parcerisa et al. Phys Med Biol 2014) and the super-fast Monte Carlo engine *MCsquare* (Souris et al. Med Phys 2016) able to compute a final dose in less than 1 minute.

The hybrid optimization strategy calculates the optimal spot weights ( $w$ ) using the analytical beamlets matrix ( $P_{PB}$ ) and a correction term  $C$ . After a first optimization where  $C = 0$ , the method alternates optimization of  $w$  using  $P_{PB}$  with updates of  $C = D_{MC} - D_{PB}$ , where  $D_{MC}$  results from a regular MC computation (using  $10^8$  protons to ensure good

statistical accuracy) and  $D_{PB} = P_{PB} * w$ . Updates of  $C$  can be triggered as often as necessary by running the MC engine with the last corrected values of  $w$  as input.

The performance of the method is illustrated on two extreme cases: prostate (relatively easy case) and lung (considered to be complex due to the high heterogeneity). For simplicity, we created PTV-based plans but the findings can be equally applied to robust optimized plans.

#### Results

For the prostate case, the recomputed MC dose after initial optimization ( $C=0$ , before correction) revealed a decreased target coverage ( $D95=90\%$  of the prescribed dose,  $D_p$ ) that improved significantly after just one correction ( $D95_{corrected}=97\%D_p$ ).

For the lung case, the difference between MC and PB doses before correction was very large:  $D95=63\%D_p$  and  $D5=137\%D_p$ . But still the hybrid strategy was able to partially improve target coverage ( $D95_{corrected} = 84\%D_p$ ) as well as reducing overdose ( $D5_{corrected} = 111\%D_p$ ), after two updates of  $C$ .

In both cases, further corrections did not lead to better results.

The results proved that the hybrid method allows us to improve dose accuracy even for very complicated cases as lung tumors. However, the success of the correction is limited by the order of magnitude of the term  $C$ , i.e, very large difference between MC and PB doses are only partially corrected.

Figure 1. DVHs for target volumes for prostate and lung case, before ( $C=0$ ) and after one ( $C1$ ) and two corrections ( $C1,C2$ ), respectively.

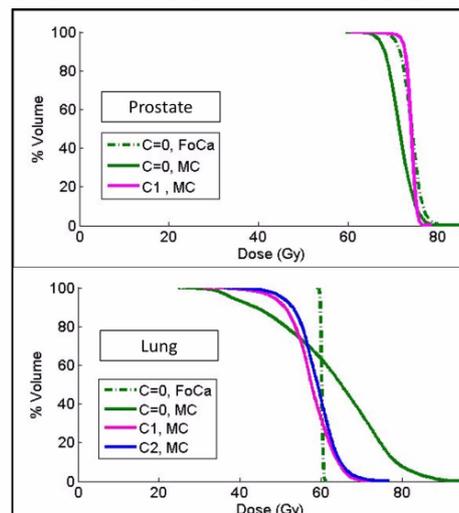

Table 1. DVH metrics (D95, D5 and D5-95 percentile range) and % of prescribed dose ( $D_p$ ) for the target volume of the considered cases. Target prescriptions are 74 and 60 Gy for prostate and lung tumors, respectively.

		Initial optimization ( $C=0$ )		After correction ( $C \neq 0$ )
		<i>FoCa</i>	Re-computed by <i>MCsquare</i>	Re-computed by <i>MCsquare</i>
Prostate	D95 [Gy] (% $D_p$ )	70.69 (95.5%)	67.08 (90.6%)	72.02 (97.3%)
	D5 [Gy] (% $D_p$ )	77.5 (104.7%)	76.16 (102.9%)	75.6 (102.2%)
	D5-95 [Gy]	6.81	9.08	3.58
Lung	D95 [Gy] (% $D_p$ )	59.73 (99.5%)	37.78 (63%)	50.41 (84%)
	D5 [Gy] (% $D_p$ )	60.65 (101.1%)	82.55 (137.6%)	66.71 (111.2%)
	D5-95 [Gy]	0.92	44.77	16.3

### Conclusion

The results showed medium to large differences between the PB and MC doses which could be addressed totally or partially by adding a correction term during the optimization. Since MC beamlets calculation remains time-consuming, this hybrid PB-MC optimization seems a good compromise between accuracy and speed.

### EP-1520 Stereotactic body radiation therapy treatment planning using target volume partitioning

J. Robar<sup>1</sup>

<sup>1</sup>Dalhousie University, Radiation Oncology, Halifax, Canada

#### Purpose or Objective

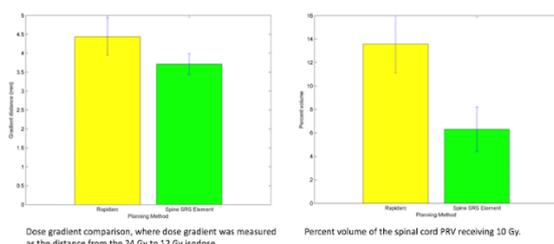

The aim of this study was to evaluate a novel approach to Volumetric Modulated Arc Therapy (VMAT) plan optimization for stereotactic body radiation therapy of the spine involving partitioning of the Planning Target Volume (PTV) into simpler sub-volumes. Treatment plan quality was compared to that provided by a standard VMAT approach.

#### Material and Methods

The new technique investigated in this work relies on a partitioning of the PTV that is dedicated to spinal anatomy. The spine PTV is segmented into multiple sub-volumes using a k-means algorithm, such that each sub-volume minimizes concavity. Each sub-volume is then associated with a separate arc segment for VMAT delivery. The rationale of this approach is that the delivery of dose to multiple, mainly convex target volumes provides flexibility to the VMAT optimizer in prioritizing spinal cord sparing. Treatment plans were established with the novel algorithm using the Spine SRS Element (Brainlab, AG, ver 1.0 beta) and compared to clinical treatment plans generated using standard VMAT planning approach in our centre (Rapidarc, Varian Medical Systems). Test cases included a range of spinal target volumes, including the vertebral body only, vertebral body and pedicles, or spinous process only. Plan quality was compared with regard to PTV coverage, PTV dose homogeneity, dose conformity, dose gradient, sparing of spinal cord PRV and MU efficiency.

#### Results

PTV coverage and dose homogeneity were equivalent, however improved high-dose (90%) conformity was observed for the new approach ( $p=0.002$ ). Sharper dose gradient was produced in 75% of cases but did not reach statistical significance. The percent volume of the PRV spinal cord receiving 10 Gy was reduced ( $p=0.05$ ). Despite the fact that the new method involves delivery of dose to PTV sub-volumes with separate arc segments, MU efficiency was approximately equivalent to the status-quo technique.

### Conclusion

The novel target volume splitting technique offers an efficacious new approach to VMAT optimization, producing high dose gradients in the vicinity of the spinal cord and allowing prioritization of spinal cord sparing.

### EP-1521 Non-coplanar beam orientation and fluence map optimization based on group sparsity

K. Sheng<sup>1</sup>

<sup>1</sup>David Geffen School of Medicine at UCLA, Radiation Oncology, Los Angeles- CA, USA

#### Purpose or Objective

With the increasing availability of non-coplanar radiotherapy systems in clinical settings, it is essential to develop effective and efficient algorithms for integrated non-coplanar beam orientation and fluence map optimization. To achieve this goal, we investigate the novel group sparsity approach for non-coplanar beam orientation optimization.

#### Material and Methods

The beam orientation and fluence map optimization problem is formulated as a large scale convex fluence map optimization problem with an additional group sparsity term that encourages most candidate beams to be inactive. The optimization problem is solved using an accelerated proximal gradient method, the Fast Iterative Shrinkage-Thresholding Algorithm (FISTA). We derive a closed-form expression for a relevant proximal operator which enables the application of FISTA. The beam orientation and fluence map optimization algorithm is used to create non-coplanar treatment plans for six cases (including two head and neck, two lung, and two prostate cases) involving 500 - 800 candidate beams. The resulting treatment plans are compared with 4 treatment plans created using a column generation algorithm, whose beam orientation and fluence map optimization steps are interleaved rather than integrated.

#### Results

In our experiments the treatment plans created using the group sparsity method meet or exceed the dosimetric quality of plans created using the column generation algorithm, which was shown superior to that of clinical plans (Figure shows a head and neck case). Moreover, the group sparsity approach converges in about 5 minutes in these cases, as compared with runtimes of more than an hour for the column generation method. Table shows the PTV dose statistics and runtime comparison.

#### Conclusion

This work demonstrates that the group sparsity approach to beam orientation optimization, when combined with an accelerated proximal gradient method such as FISTA, works effectively for non-coplanar cases with a large number of candidate beams. In this paper we obtain orders of magnitude improvement in runtime for the 'group sparsity' approach to beam orientation optimization by using an accelerated proximal gradient method to solve the  $\ell_{2,1}$ -norm penalized problem. Furthermore, the dosimetric quality of our group sparsity plans meets or exceeds the quality of treatment plans created using a column generation approach to beam angle selection, which has been demonstrated in recent literature to create high quality treatment plans.

### EP-1522 Quantifying the operator variability reduction driven by knowledge-based planning in VMAT treatments

A. Scaggion<sup>1</sup>, M. Fusella<sup>1</sup>, S. Bacco<sup>1</sup>, N. Pivato<sup>1</sup>, A. Roggio<sup>1</sup>, M. Rossato<sup>1</sup>, R. Zandonà<sup>1</sup>, M. Paiusco<sup>1</sup>

<sup>1</sup>Istituto Oncologico Veneto IOV-IRCCS, Medical Physics, Padova, Italy

#### Purpose or Objective

The purpose of this study is to evaluate the potential of a commercial knowledge-based planning (KBP) algorithm to standardize and improve the quality of the radiotherapy treatment. This study evaluates if the predicted DVH constraints generated by the KBP algorithm can reduce the

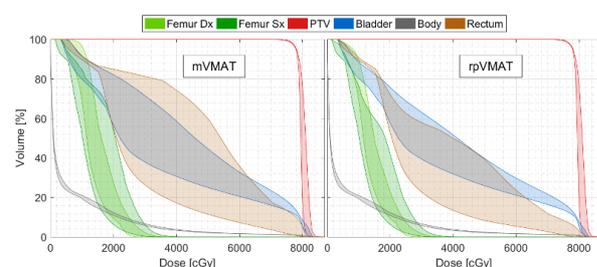

inter-operator variability thus providing a better standard of quality.

#### Material and Methods

Using Varian RapidPlan two models were created for oropharynx and prostate VMAT treatments with respectively 73 and 90 previously treated patients. Five oropharynx and six prostate test patients, not included in the training database, were anonymized and randomized. Four operators, with different planning expertise, were asked to manually obtain a clinical VMAT plan (mVMAT) for each test patient. Subsequently, each operator replied the planning procedure assisted by RapidPlan DVH predictions obtaining a second VMAT plan (rpVMAT). The potential of RapidPlan to reduce the inter-operator variability was evaluated comparing rpVMAT with mVMAT plans in terms of OAR sparing, target coverage and conformity.

#### Results

In the case of prostate treatments mVMAT and rpVMAT plans resulted in similar target coverage while a net reduction in OAR sparing variability was seen for rpVMAT plans (a visual example is given in Figure). For the case in figure, rectum V40Gy resulted  $34.4 \pm 18.1\%$  for mVMAT and  $32.1 \pm 7.6\%$  for rpVMAT. In general, a 40% reduction in inter-planner OAR sparing variability has been registered when planning was assisted by RapidPlan predictions.

For oropharynx treatments RapidPlan-assisted planning leads to more homogeneous target dose distributions, especially for the low-dose target. The low-dose PTV standard deviation obtained in rpVMAT plans was  $2.6 \pm 0.6\%$  while it resulted  $3.2 \pm 1.5\%$  for mVMAT ones. A variability reduction of the order of 10% was also seen in parotids, oral cavity and larynx sparing. For the less experienced planner RapidPlan assistance also induced an overall decrease of OAR mean doses by approximately 15%. Using RapidPlan assistance the overall inter-planner variability is reduced in every single patient and a general improvement of plans statistics is achieved.

#### Conclusion

The use of RapidPlan predictions in VMAT planning driven a homogenization of the planning outcome both in prostate and oropharynx treatment for a group of 4 planners. OAR sparing variability can be reduced as much as 40% maintaining similar target coverage when RapidPlan is employed. This study provide a quantitative measure of the RapidPlan potential as an instrument to improve plan quality.

This findings states that the use of a knowledge based planning system allow for safer treatments.

#### EP-1523 Proton radiography to calibrate relative proton stopping power from X-ray CT in proton radiotherapy

A.K. Biegun<sup>1</sup>, K. Ortega Marin<sup>1</sup>, S. Brandenburg<sup>1</sup>

<sup>1</sup>Kernfysisch Versneller Instituut - Center for Advanced Radiation Technology, Medical Physics, Groningen, The Netherlands

#### Purpose or Objective

To decrease the uncertainty of the relative proton stopping power (RPSP) determination and optimize the clinical calibration curve for individual patients in proton

radiotherapy treatment, by using an alternative novel proton radiography imaging modality.

#### Material and Methods

The optimization of a 'patient-specific' clinical calibration curve for proton stopping power has been performed on a complex phantom (made in-house) with dimensions of  $5.4 \times 9.4 \times 6.0 \text{ cm}^3$ , built of polymethyl methacrylate (PMMA) and filled with 6 inserts of different diameters and contents. It comprises 11 materials (including 5 tissue surrogates) of known composition and density. A CT scan (with SOMATOM Definition AS scanner) of the phantom was done at 120 kV X-ray tube voltage. The image reconstruction was executed with the I40 reconstruction kernel and a slice thickness of 0.6 mm. The Field-Of-View was chosen to be 250 mm, at which (for an image size of  $512 \times 512$  pixels) a spatial resolution was equal to 0.488 mm/pixel. An initial 9-segments calibration curve of RPSP vs. CT number was constructed based on Schneider method and used to obtain a Water Equivalent Path Length (WEPL) map of the phantom,  $WEPL_{DRR}$ .

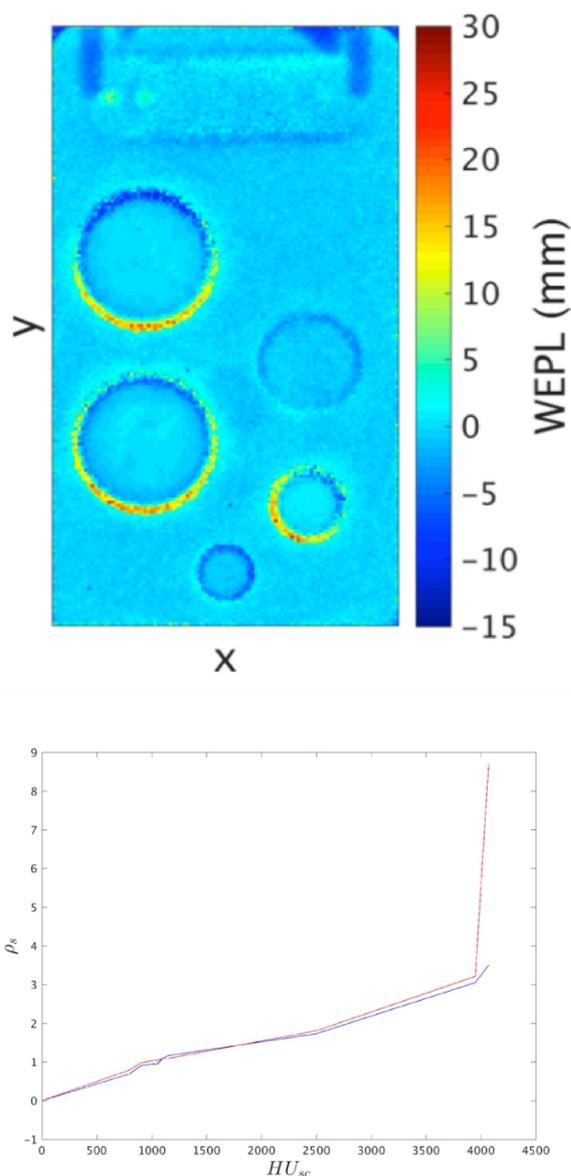

A proton energy loss radiograph of the same phantom was obtained from Geant4 Monte Carlo simulations, in which a novel proton radiography imaging system was implemented. Protons with a large scattering angle due to Multiple Coulomb scattering, causing blurring of the radiography image, were discarded. Thus, only protons traveling along almost straight lines, with scattering angles less than 5.2 mrad, were used to build the radiography image. A WEPL map of the phantom from the proton radiography simulations,  $WEPL_{PRG}$ , was obtained.

The difference between the two maps of  $WEPL_{DRR}$  and  $WEPL_{PRG}$  was evaluated by means of RMSE and  $\chi^2$  statistic. The  $\chi^2$  statistic was used to iteratively modify the segments of the calibration curve.

#### Results

A small difference between  $WEPL_{DRR}$  and  $WEPL_{PRG}$  at the borders of some inserts of the phantom are observed, which are caused by imperfect alignment of the phantom in the CT scanner (figure 1).

Using the iterative optimization on WEPLs, both measures RMSE and  $\chi^2$  statistic decreased significantly. A decrease by 34.33% and 55.01% in RMSE and  $\chi^2$  statistic, respectively, is observed. After discarding PMMA material from the phantom materials, which is not among materials used to construct the clinical calibration curve, a further decrease in RMSE and  $\chi^2$  by 48.34% and 73.18%, respectively, is obtained. The  $\chi^2$  statistic was used to acquire an iteratively optimized calibration curve, and a new  $WEPL_{DRR}$ . A more homogeneous distribution of the difference between  $WEPL_{DRR}$  and  $WEPL_{PRG}$  maps is observed for both cases, with and without PMMA material considered.

### Conclusion

The iterative optimization of the 'patient-specific' CT calibration curve has been performed with the use of the alternative proton radiography imaging technique. An improvement in distribution of the WEPL differences obtained in the two imaging techniques is observed. Further development based on real patient data will be done.

### EP-1524 Automated treatment planning for breast and locoregional lymph nodes using Hybrid RapidArc

M.J. Van Duren - Koopman<sup>1</sup>, J.P. Tol<sup>1</sup>, M. Dachele<sup>1</sup>, P. Meijnen<sup>1</sup>, R. Florijn<sup>1</sup>, B.J. Slotman<sup>1</sup>, W.F.A.R. Verbakel<sup>1</sup>  
<sup>1</sup>VUMC- Afdeling Radiotherapie, Radiotherapy, Amsterdam, The Netherlands

### Purpose or Objective

Breast cancer accounts for a substantial proportion of the workload in many radiotherapy departments. Treatment planning, especially for breast and locoregional lymph nodes (LLNs) can be complex and time-consuming. Automated planning techniques can improve planning efficiency and consistency. Automated planning of tangential field breast-only irradiations has been previously described. We developed a script using the

Eclipse API to automatically plan a more complex hybrid RapidArc (hRA) technique for breast plus LLNs that includes the integration of RapidPlan (RP) into the workflow.

### Material and Methods

The script uses the clinician delineated breast planning target volume (PTV<sub>b</sub>) and LLN PTV (PTV<sub>LLN</sub>) as input to automate field setup (Figure).

The hRA technique consists of two combined plans:

1. Two tangential fields (TFs) with a 2cm cranial slip-zone that deliver 85% of the prescribed dose (PD) to 95% of PTV<sub>b</sub>. Optimal gantry angles and field settings of the TFs are automatically determined by minimizing the organ-at-risk (OAR) surfaces in the beam's eye view. Optimal beam energy is based on PTV dose homogeneity, and field weightings are based on symmetry of dose distribution.
2. Three 80° RA arcs deliver the remaining dose to the PTV<sub>b</sub> and slip-zone, and the full PD to the PTV<sub>LLN</sub>, while sparing tissue outside the PTV. RA fields are positioned automatically using standard gantry angles. Optimization objectives for the relevant OARs (ipsilateral (IL) and contralateral (CL) lung, heart, CL breast, esophagus, thyroid, spinal canal) are automatically placed using dose predictions generated by RP. RA optimization is currently started manually as the scripting API does not yet allow for the inclusion of a previously calculated dose, but interaction during optimization is not required.

### Results

Treatment plans were generated by the script in ~40 minutes (of which 2 minutes were user interaction), while the estimated corresponding manual time was 100-200 minutes. The automated workflow was capable of generating a plan for all patients. However, a number of improvements to the scripting environment have been suggested to the vendor. The dosimetric data was averaged over all 5 patients and was generally comparable between the automated and manual plans (Table), although for individual patients it was evident that the RP model requires further refinements to reduce some OAR doses.

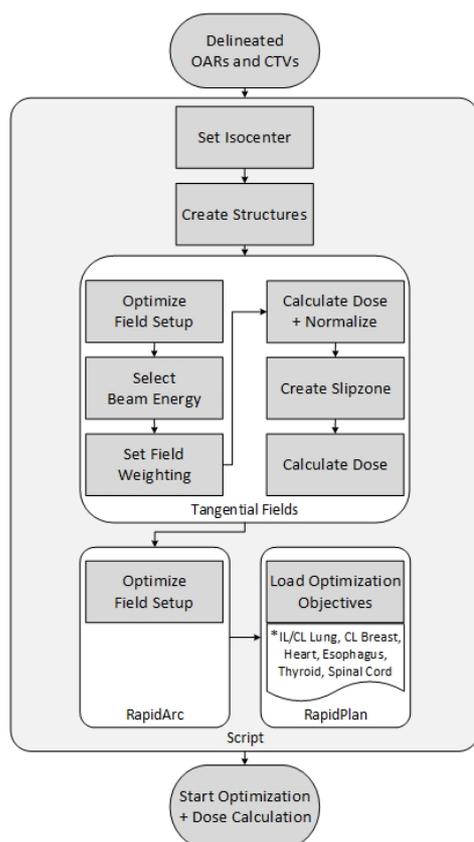

Fig. 1. The flowchart shows the individual steps for the automated treatment plan generation for breast with locoregional nodes.

Table. Averaged dosimetric data of all 5 patients.

MEAN		MANUAL	SCRIPTED
PTV	D98% (Gy%)	41.2 (96.4)	41.3 (96.7)
	D2% (Gy%)	45.6 (106.7)	44.7 (104.6)
HEART	Mean Dose (Gy)	1.3	1.3
CONTRALATERAL MAMMA	Mean Dose (Gy)	0.8	0.9
IPSILATERAL LUNG	Mean Dose (Gy)	12.1	12.9
ESOPHAGUS	Mean Dose (Gy)	4.8	5.0
THYROID	Mean Dose (Gy)	7.0	7.3

### Conclusion

Plan generation for breast with locoregional nodes was successfully automated using the Eclipse scripting API to create a workflow that integrates the RP knowledge-based planning system, and a combination of different techniques: open fields, slip zone, RA. Automated generation of treatment plans is anticipated to lead to more consistent and efficient planning. It may also facilitate the transfer of complex treatment planning techniques between centers.

### EP-1525 Automatic treatment plan generation for Prostate Cancer

S. Agergaard<sup>1</sup>, C.R. Hansen<sup>1,2</sup>, L. Dysager<sup>3</sup>, A. Bertelsen<sup>1</sup>, H.R. Jensen<sup>1</sup>, S. Hansen<sup>2,3</sup>, C. Brink<sup>1,2</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

<sup>2</sup>University of Southern Denmark, Faculty of Health Sciences, Odense, Denmark

<sup>3</sup>Odense University Hospital, Department of Oncology, Odense, Denmark

### Purpose or Objective

Automatic treatment planning is of high interest, since the optimization process is highly complex and the current plan quality is dependent on the treatment planner. In a clinical setting where time for treatment planning is sparse, automatic treatment plan generation would be desirable. This study evaluates automatic treatment planning for high risk prostate cancer in comparison to a current clinical plan quality.

### Material and Methods

All patients (#42) treated for high risk prostate cancer during 2015 at our clinic were replanned using the AutoPlan module in Pinnacle® (ver. 9.10). Similar to the manual plan (MA) the autoPlan (AP) was generated for an Elekta® Synergy linac, consisting of one full VMAT arc and using 18 MV photons. All APs were calculated by the same medical physicist. There was no comparison of the MA and AP in the plan generation process. Using a template model it took on average 90 sec to start autoPlanning, which took approximately 1 hour to complete optimization. Hereafter it took on average 173 sec (range 45 to 550) of active planning for one or two post-optimizations with 15 iterations per run to fine-tune the plan to meet the acceptance criteria.

The plan quality was evaluated by comparing DVHs, dose metrics, delivery time and dose accuracy when delivered on an ArcCheck phantom.

For each patient the MA and AP were blindly evaluated side-by-side by a radiation oncologist, who concluded which plan was better, and if the differences were predicted to be clinically relevant.

All differences were tested for statistical significance with a Wilcoxon signed rank test ( $p < 0.05$ ).

**Results**  
The DVHs show small but significant differences in the doses to both CTV and PTV. The APs spared all OARs significantly. For the rectum the average of the mean doses is reduced from 42.6 Gy to 31.8 Gy. The reduction in rectal dose is significant between 1 Gy and 73 Gy (figure 1). Table 1 shows the results for targets as well as OARs, their standard deviations (std) and the corresponding p-values.

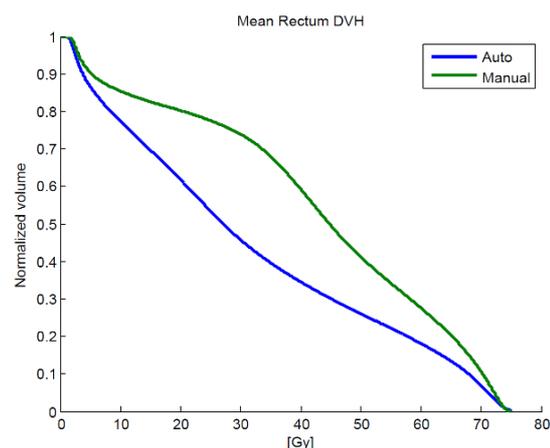

Table 1	Manual plan		Autoplan		p	diff [Gy]
	mean [Gy]	std [Gy]	mean [Gy]	std [Gy]		
PTV	77,2	0,4	78,0	0,3	<0.001	0,8
CTV	78,2	0,4	78,6	0,3	<0.001	0,3
Bowel	9,7	11,3	7,2	8,7	<0.001	-2,5
Rectum	42,6	5,7	31,8	6,2	<0.001	-10,8
Bladder	39,9	12,5	33,8	11,6	<0.001	-6,1
C.femur right	22,4	6,4	18,2	5,8	<0.001	-4,2
C.femur left	23,0	7,1	17,7	6,4	<0.001	-5,3
Penile Bulb	21,9	14,3	16,1	11,8	<0.001	-5,8
External	5,2	0,8	4,8	0,8	<0.001	-0,4
	Delivery					
3%, 3mm	99,7	0,5	99,1	1,6	<0.001	-0,6
2%, 2mm	96,8	2,1	94,3	4,7	<0.001	-2,5
MU	307,3	27,7	403,2	31,8	<0.001	95,9

For two plans the radiation oncologist evaluated the MA and AP to be of equal quality. For 40 of the 42 patients the oncologist chose the AP plan for treatment. Among the 40 plans, 25 of them were predicted to have a clinical relevant benefit. For the ArcCheck measurements the mean global pass rate (3%, 3mm) was reduced from 99.7% (MA) to 99.1% (AP), both well above the clinical acceptance criteria of 95%. Decreasing the margin of the gamma analysis to 2% and 2mm cut the pass rates to 96.5% and 94.3%, respectively.

The MAs had on average 307 MU and took 90 sec. to deliver, while the APs had on average 403 MU and took 110 sec. to deliver. This may be related to an increase in MLC modulation.

#### Conclusion

Autoplan shows a clear clinical improvement in plan quality for high risk prostate cancer treatment planning, delivering both higher doses to the target while sparing all delineated OARs as well as reducing integral body dose. For these reasons the oncologist prefers the AP.

#### EP-1526 Analysis of dose deposition in lung lesions: a modified PTV for a more robust optimization

A.F. Monti<sup>1</sup>, D.A. Brito<sup>1</sup>, M.G. Brambilla<sup>1</sup>, C. Carbonini<sup>1</sup>, M.B. Ferrari<sup>1</sup>, A. Torresin<sup>1</sup>, D. Zanni<sup>1</sup>  
<sup>1</sup>Ospedale Niguarda, Medical Physics, Milano, Italy

#### Purpose or Objective

SBRT in lung cancer is often used to deliver high doses to a small dense nodule (GTV) moving into a low density tissue (the margin generating the PTV).

In order to reach an acceptable degree of accuracy, type B or MC-based algorithms should be adopted.

If a modulated technique (IMRT or VMAT) is used to treat such inhomogeneous PTV, an apparently homogeneous dose distribution is delivered, but high photon fluence is generated inside a 3D shell (PTV-GTV) due to its low electron density (ED). This situation gives the paradox that the dose distribution is apparently uniform, but the GTV, which will move into the PTV, will receive a dose that depends on its position.

This work was designed to evaluate this phenomenon and to suggest a more robust dose optimization.

#### Material and Methods

A TPS Monaco 5.11 (Elekta, SWE) with a MC algorithm was used to simulate a SBRT treatment in a dummy patient (55 Gy in 5 fractions). In a first step, in order to evaluate the dose discrepancy on the target when considering the motion of the high ED GTV, the photon fluence was optimized for the original PTV ED (EDo) and thus used to calculate the dose on a "forced" PTV ED (EDf) in which the ED of the PTV was forced to the mean ED of the GTV.

In a second step the photon fluence was optimized for PTV EDf and then used for the dose calculation on PTV EDo in order to evaluate the dose variation on the lower ED region of the PTV and inside the GTV.

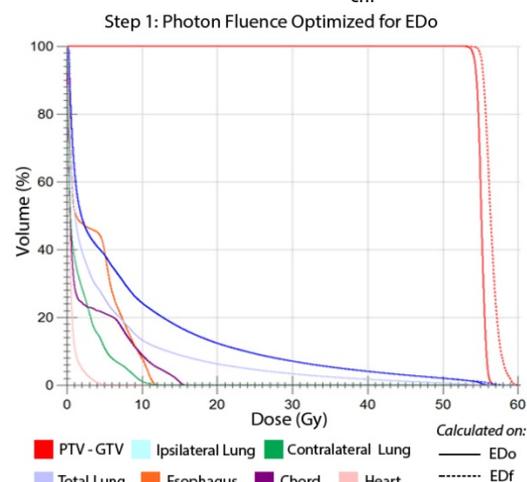

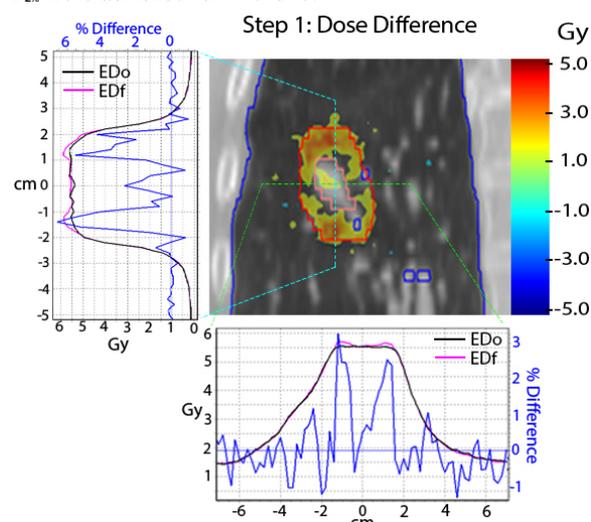

Dosimetric comparisons between the original and recalculated dose distribution were made in each step in

terms of: dose profiles through PTV,  $D_{mean}$ ,  $D_{98\%}$  and  $D_{2\%}$  for PTV-GTV.

#### Results

In step 1 dose profiles, calculated on EDo and EDf, differ up to 6.6%, 3.4% and 3.8% on longitudinal, sagittal and transversal axes along the plan isocenter (center of GTV). Dose increments of 1.6% for  $D_{98\%}$ , 2.5% for  $D_{mean}$  and 5% for  $D_{2\%}$  were obtained for PTV-GTV (see figures 1,2).

In step 2 the maximum difference between dose profiles was -3% for all three axes along the plan isocenter. A reductions of -1.5% for  $D_{98\%}$ , -1.5% for  $D_{mean}$  and -1.4% for  $D_{2\%}$  were achieved for PTV-GTV.

#### Conclusion

If the GTV is static, it should receive a constant dose, but step 1 shows that the dose delivered to GTV, when it reaches a position inside the PTV (where the photon fluence is optimized for low electron densities), is higher than what estimated on the original EDo map. The GTV is thus irradiated in a more homogeneous way in step 2 in which the fluence is optimized for its mean ED everywhere in the PTV. We propose that, in lung small lesions, the PTV is modified in terms of electron density considering the GTV mobility. Optimizing the photon fluence for the "forced" electron density map appears an effective way to evaluate the real dose delivered to the GTV.

#### EP-1527 Pelvic Intensity-Modulated Radiotherapy in prone and supine position in gynaecological cancer

E. Perrucci<sup>1</sup>, G. Montesi<sup>2</sup>, M. Marcantonini<sup>3</sup>, C. Mariucci<sup>2</sup>, M. Mendichi<sup>2</sup>, S. Saccia<sup>1</sup>, A. Cavalli<sup>1</sup>, A.M. Didona<sup>3</sup>, V. Lancellotta<sup>4</sup>, V. Bini<sup>5</sup>, C. Aristei<sup>4</sup>  
<sup>1</sup>Perugia General Hospital, Radiation Oncology, Perugia,

Italy

<sup>2</sup>University of Perugia, Radiation Oncology, Perugia, Italy

<sup>3</sup>Perugia General Hospital, Medical Physics Unit, Perugia, Italy

<sup>4</sup>University of Perugia and Perugia General Hospital, Radiation Oncology, Perugia, Italy

<sup>5</sup>University of Perugia, Internal Medicine- Endocrin and Metabolic Sciences, Perugia, Italy

#### Purpose or Objective

Pelvic radiation is linked to high rate of toxicity, mainly gastrointestinal. In 3D-conformal radiotherapy (3D-CRT), prone position (PP) and a belly-board device are used to reduce the incidence and severity of symptoms. Although Intensity Modulated Radiotherapy (IMRT), over 3D-CRT, allows a better conformal treatment of the targets and to spare the organs at risk (OARs), only a few studies have assessed the role of patient positioning in IMRT planning for OARs sparing. We evaluated the effect of a PP or supine position (SP) with full bladder to spare OARs in pelvic IMRT in gynaecologic malignancies.

#### Material and Methods

A PP and a SP Computed Tomography scan, slice thickness of 3 mm, full bladder and empty rectum, were performed in 13 patients with endometrial or cervical cancer, 8 of whom submitted surgery. Target volumes, nodes and uterus or vaginal cuff, and OARs were delineated by one young in training radiation oncologist and review by a senior radiation oncologist. Step and shoot technique IMRT plans were elaborated for each position. A dose of 50.4 Gy in 28 fractions was prescribed. Dosimetric parameters were compared by non-parametric Wilcoxon exact signed rank test for paired data and for unpaired data with Mann Whitney test and Kruskal-Wallis test (SPSS 22.0, Inc., Chicago, IL). Statistical significance was assumed for  $p \leq 0.05$ .

#### Results

In prone and supine plans the mean PTV volumes were 1374.93 cc for PP and 1413.47 cc for SP, median Dmean were 50.27 Gy in PP and 50.18 Gy in SP, and PTV D50% were 50.4 Gy for PP and 50.3 Gy for SP. Data regarding conformity and homogeneity of IMRT plans for PP and SP gave similar results. All parameters were calculated according ICRU 83. We found that PP permits to spare irradiated rectal volume from 10 to 45 Gy compared with SP, but the difference was not significant. The dose-volume histogram for the bladder was significant better in SP at V45 ( $p = 0.03$ ), V40 ( $p = 0.011$ ), V30 ( $p = 0.033$ ), V20 ( $p = 0.039$ ), V10 ( $p = 0.039$ ). The analysis of tabular dose-volume histograms showed a significant decrease of the small bowel volume at V20 ( $p = 0.005$ ), V30 ( $p = 0.019$ ), V40 ( $p = 0.046$ ), V45 ( $p = 0.028$ ) and V50.4 ( $p = 0.019$ ) in favour of the PP. For V10 the reduction of irradiated bowel was not significant ( $p = 0.055$ ). Dmax and NTCP were significantly lower in PP. In the operated group, a significant difference was observed in small bowel NTCP reduction for both PP and SP ( $p = 0.003$  and  $0.006$ , respectively) compared with non operated group, but not for rectum and bladder.

#### Conclusion

PP with a full bladder in pelvic IMRT for gynaecologic malignancies permits a significant bowel sparing for doses > 20 Gy providing similar target coverage and target conformity. This is very useful when higher dose lymph-node boost is planned. SP allows a larger bladder sparing. Small bowel NTCP reduction in both position in operated patients could be linked to the smaller target volume.

#### EP-1528 RapidPlan Head and Neck model: the objectives and possible clinical benefits

y

#### Purpose or Objective

RapidPlan™ is the knowledge based planning process recently implemented in the Varian Eclipse treatment planning system. It estimates, according to the model data, the organ at risk (OAR) DVHs to generate the optimization objectives, tailored on any new patient, for the plan optimization process. Advanced head and neck cancer (AHNC) planning presents complexities due to the anatomy and the low tolerance dose levels for the surroundings OARs. In the present work a RapidPlan (RP) model is configured and subsequently validated to evaluate the RP quality relative to the clinical plans (CP). Secondary, through normal tissue complication probability (NTCP) estimations, the possible effective clinical benefit in planning with RP is evaluated.

#### Material and Methods

83 patients presenting AHNC were selected from the department database. The patients were chosen as their plans were considered as dosimetrically optimal. All plans were optimized for VMAT technique (RapidArc), with 2-4 arcs, 6 MV beam quality, treated on a department linac equipped with Millennium 120-MLC or HD-MLC. Inverse planning used the PRO optimizer, and final calculations were with AAA. Dose prescription was to 69.96 Gy and 54.45 Gy to PTV2 and PTV1, respectively, in 33 fractions. A RP model was generated for the OARs: spinal cord, brain stem, oral cavity, parotids, submandibular glands, larynx, constrictor muscles, thyroid, eyes. To constrain the uninvolved healthy tissue, the 'body' with all the targets subtracted was included in the model. The optimization objectives in the model included the line objective for all OARs with generated priority. For serial organs, an upper objective was added with generated dose at 0% volume with a fixed priority of 90. For parotids and oral cavity, a mean objective was added with generated dose and fixed priority of 60. Targets upper and lower objectives were placed in a very narrow interval, with priority 110 and 120. The automatic Normal Tissue Objective NTO was added with priority 280. The model was validated on a set of 20 similar patients selected from the clinical database. The possible clinical benefit was evaluated through NTCP estimation for some of the OARs, using the biological evaluation available in Eclipse, based on LQ-Poisson model.

#### Results

Regarding target dose homogeneity, the standard deviation was reduced by 0.3 Gy with RP ( $p < 0.05$ ). The mean doses to parotids, oral cavity, and larynx were reduced with RP of 2.1, 5.2, and 7.0 Gy, respectively. Maximum doses to spinal cord and brain stem were reduced of 7.0, and 6.9 Gy, respectively ( $p < 0.02$ ). NTCP reductions of 11%, 16%, and 13% were estimated for parotids, oral cavity, and larynx, respectively, with RP planning.

#### Conclusion

Model validation confirmed the better plan quality with RP plans. NTCP estimation suggests that this dosimetric effect could positively affect also the toxicity profiles for patients receiving RP planning with an adequate model.

#### EP-1529 Reducing total Monitor Units in RapidArc™ plans for prostate cancer

K. Armoogum<sup>1</sup>, M. Hadjicosti<sup>1</sup>

<sup>1</sup>Derby Hospitals NHS Trust, Department of Radiotherapy, Derby, United Kingdom

#### Purpose or Objective

A retrospective planning study was performed on prostate cancer RapidArc (RA) plans to evaluate the use of the 'MU

Objective' optimization tool in Varian Eclipse (v 13.6) incorporating the Photon Optimizer algorithm (v 13.6.23). The RA approach currently used in this study implements two complete arcs to deliver at least 95% of the prescribed dose to the Planning Target Volume (PTV) while minimizing dose to the surrounding Organs at Risk (OAR). In general, RA tends to use fewer MUs per treatment fraction than Intensity Modulated Radiation Therapy (IMRT) with an associated reduction in the risk of secondary induced cancers. The MU Objective tool offers the possibility to further decrease total Monitor Units while maintaining clinically acceptable plan quality.

#### Material and Methods

Thirty clinically approved RA plans (prostate only n=22, prostate and nodes n=8) were selected for re-optimization using the MU Objective tool. This tool allows variation of the Minimum MU, Maximum MU and Strength (S). The 'S' parameter weights the optimizer to reach the MU goal within the defined Min MU and Max MU limits. Based on a previous study [1], the Min MU was set to 0%, the Max MU to 50% of the total clinical plan MUs for the non-optimized RA plan and 'S' was set to the maximum value of 100. The prescribed doses were either 74Gy in 37 Fractions (or 60 in 20), collimator angles were 30° and 330° to minimize the tongue-and-groove effect, jaw tracking was enabled and all plans were treated at 6MV and 600 MU/minute maximum dose rate. The dose/volume objectives for the PTV and OAR were unchanged. Dose calculations were performed using the Anisotropic Analytic Algorithm (v 13.6.23) with a calculation grid size of 2.5 mm, taking into account inhomogeneity correction and disregarding air cavity correction. To determine the quality of the absorbed dose distributions resulting from smoothing, the Paddick Conformity Index (CI<sub>PAD</sub>) and the International Commission on Radiation Units (ICRU) Homogeneity Index (HI) were calculated for all plans [2].

$$CI_{PAD} = (TV_{PI})^2 / (PI \times TV)$$

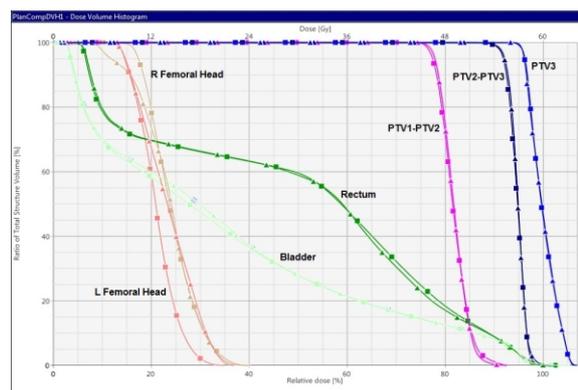

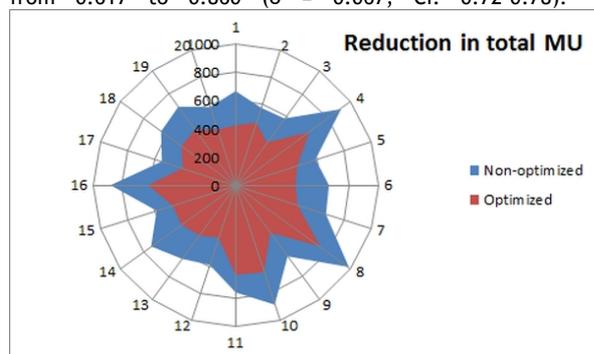

Where PI is the volume of the prescription isodose line (95%), TV<sub>PI</sub> is the target volume within the PI, and TV is the target volume.

$$HI = (D_{2\%} - D_{98\%}) / D_{50\%}$$

Where D<sub>50%</sub> is the dose received by 50% of the target volume and so on.

#### Results

The MU Objective tool resulted in a reduction of total prostate RA plan MUs by approximately 29%. The average ICRU HI for the prostate patients varied from 0.055 to 0.111 ( $\sigma = 0.015$ , CI: 0.07-0.08). The CI<sub>PAD</sub> varied overall from 0.617 to 0.860 ( $\sigma = 0.067$ , CI: 0.72-0.78).

#### Conclusion

The MU Objective tool facilitates the reduction of total prostate RA plan MUs with PTV coverage and OAR sparing maintained. A lower total MU number should translate to lower leakage from the linear accelerator and less scatter within the patient.

#### EP-1530 Validation of RayStation Fallback Planning dose-mimicking algorithm

L. Bartolucci<sup>1</sup>, M. Robilliard<sup>1</sup>, S. Caneva- Losa<sup>1</sup>, A. Mazal<sup>1</sup>  
<sup>1</sup>Institut Curie, Radiotherapy, Paris, France

#### Purpose or Objective

To demonstrate with end-to-end tests the ability of RayStation v5.02 (RaySearch Laboratories AB, Stockholm, Sweden) fallback planning module (RFP) to perform an accurate Helical Tomotherapy (HT) to volumetric modulated arc therapy (VMAT) plan conversion by validating the dose-mimicking algorithm used during the automatic optimization of the fallback plans.

#### Material and Methods

Thirty patient plans of various treatment sites previously treated with HT were switched to 6 MV dual-arc VMAT plans using RFP and default dose-mimicking algorithm parameters. For the purpose of this study no further optimizations were performed and delivery quality assurance (DQA) were designed for each fallback plan. DQA were delivered on a TrueBeam linear accelerator (Varian Medical Systems, Palo Alto, CA) and planar/absolute dose measurements were acquired using the ArcCHECK diode array (Sun Nuclear Corporation, Melbourne, FL) with an insert containing an Exradin A1SL ionization chamber (Standard Imaging, Middleton, WI). 3D dose distributions in the patient geometry were reconstructed within 3DVH software (Sun Nuclear Corporation, Melbourne, FL) by using ArcCHECK Planned Dose Perturbation (ACPD). Agreement between planned and delivered dose was eventually evaluated with global and local 2D/3D gamma-index analysis (3%/3mm and 2%/2mm criteria) and DHV-based comparisons were performed using the following dosimetric parameters: quality of coverage ( $Q = D_{98\%} / D_{ref}$ ), mean dose to target ( $MDT = D_{mean} / D_{ref}$ ) and integral dose to organs at risks ( $ID_{OAR} = \sum D_i \cdot V_i$ ).

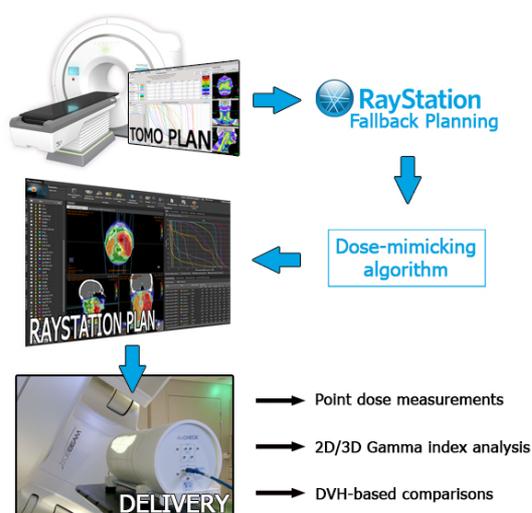

Figure 1 – Methodology implemented to validate the dose-mimicking algorithm used during the automatic optimization of RayStation fallback planning module: DICOM information of HT plans are transferred to RayStation treatment planning system. An automatic HT to VMAT plan conversion is performed by RFP using the dose-mimicking algorithm. DQA of the fallback plans are delivered on the TrueBeam linear accelerator and the ArcCHECK diode array.

## Results

Results of point dose measurements, gamma-index analysis and HDV-based comparisons are listed in table 1. Absolute dose differences were all  $<1\%$  with an average value of  $0.4 \pm 0.4\%$ . Average differences of gamma passing rate (%GP) with a low-dose threshold of 10% of the maximum dose were  $99.9 \pm 0.2\%$  and  $99.2 \pm 1.2\%$  (2D global 3%/3mm and 2%/2mm criteria),  $95.9 \pm 3.4\%$  and  $89.4 \pm 6.5\%$  (2D local 3%/3mm and 2%/2mm criteria),  $99.5 \pm 0.9\%$  and  $97.0 \pm 2.9\%$  (3D global 3%/3mm and 2%/2mm criteria),  $96.9 \pm 2.8\%$  and  $89.2 \pm 6.0\%$  (3D local 3%/3mm and 2%/2mm criteria) respectively. Finally, DVH-based comparisons between calculated and delivered fallback plans showed differences of respectively  $-0.5 \pm 0.8\%$  for the quality of coverage (Q),  $-1.0 \pm 0.7\%$  for the mean dose to target (MDT) and  $0.3 \pm 0.9\%$  for the integral dose to organs at risks (ID\_OAR).

Global %GP (10% threshold)				Local %GP (10% threshold)				% difference: point dose measurements	% difference: DVH-based comparison		
2D		3D		2D		3D			Exradin A1SS	Q	MDT
3%/3mm	2%/2mm	3%/3mm	2%/2mm	3%/3mm	2%/2mm	3%/3mm	2%/2mm				
99.9%	99.2%	99.5%	97.0%	95.9%	89.4%	96.9%	89.2%	0.4%	-0.5%	-1.0%	0.3%
(SD=0.2%)	(SD=1.2%)	(SD=0.9%)	(SD=2.9%)	(SD=3.4%)	(SD=6.5%)	(SD=2.8%)	(SD=6.0%)	(SD=0.4%)	(SD=0.8%)	(SD=0.7%)	(SD=0.9%)

Table 1 – Results of point dose measurements (n=30), gamma-index analysis and HDV-based comparisons for the validation of the dose-mimicking algorithm used by RayStation fallback planning module.

## Conclusion

Fallback planning is an advanced RayStation feature that uses a dose-mimicking function to automatically replicate the DVH and the dose per voxel of a given plan, but for an alternative treatment machine or technique. Results presented here through a Helical Tomotherapy to VMAT plan conversion show a good agreement between planned and delivered dose for point dose measurements, gamma-index analysis and DVH-based comparisons, hence validating the dose-mimicking algorithm used during the automatic optimization of the fallback plans.

## EP-1531 Collimator angle influence on dose coverage for VMAT SRS treatment of four brain metastases

C. Ferrer<sup>1</sup>, C. Huertas<sup>1</sup>, A. Castaño<sup>2</sup>, A. Colmenar<sup>2</sup>, R. Plaza<sup>1</sup>, R. Morera<sup>2</sup>, A. Serrada<sup>2</sup>

<sup>1</sup>Hospital universitaria La Paz, Radiofísica y Radioprotección, Madrid, Spain

<sup>2</sup>Hospital universitaria La Paz, Oncología Radioterápica, Madrid, Spain

## Purpose or Objective

To evaluate the collimator angle influence on the dose coverage of 4 brain metastases treated with volumetric modulated arc therapy (VMAT) stereotactic radiosurgery (SRS).

## Material and Methods

Three brain metastases were prescribed to 18Gy, and a fourth one located in the cerebellar tonsil to 16Gy. Treatment was planned with Elekta Monaco treatment planning system (v. 5.00.00), and optimized using biological and physical based cost functions for mono-isocentric VMAT SRS treatment on an Elekta Synergy linear accelerator equipped with a 160-leaf Agility MLC. Five non coplanar partial arcs were used, plus a full clockwise-counterclockwise arc with 0° couch rotation to modulate only the fourth lesion with different prescription and away from the other three. Planning target volume (PTV) coverage and dose to organs at risk (OAR) have been evaluated for three different collimator angle positions, 5°, 45° and 95°. Treatment constraints were the same for the three plans, one treatment plan for each collimator angle.

## Results

The best plan in terms of target coverage and number of monitor units was achieved with collimator angle set to 95°, with the 95% of the PTV volume receiving more than 95% of the prescription dose for the 4 lesions, with 35.8% less total MU compared with the 5° collimator angle plan (5176 MU versus 8061 MU). The target coverage for the 45° collimator angle plan was lower than for the other two plans. OAR maximal doses were similar for the brainstem, optic nerves and eye lens, but maximum dose to the optic chiasm was 42% and 49.1% lower for the 5° collimator angle plan compared with the 95° and 45° angle plan respectively.

## Conclusion

The choice of collimator angle influences the target coverage as well as the total MU and the doses to OAR. The optimal choice of this angle in VMAT SRS treatments improves the optimization outcome.

## EP-1532 ITV optimization for SBRT lung treatment planning accounting for respiratory dose blurring

C. Cases<sup>1</sup>, A. Latorre-Musoll<sup>1</sup>, P. Carrasco<sup>1</sup>, N. Jornet<sup>1</sup>, T. Eudaldo<sup>1</sup>, A. Ruiz-Martínez<sup>1</sup>, M. Lizondo<sup>1</sup>, P. Delgado-Tapia<sup>1</sup>, M. Ribas<sup>1</sup>

<sup>1</sup>Hospital de la Santa Creu i Sant Pau, Radiofísica i Radioprotecció, Barcelona, Spain

## Purpose or Objective

For SBRT lung treatments accurate 4D dose calculations, accounting for heterogeneities and respiratory motion, are crucial to determine an optimal ITV beyond a purely geometric ITV. We propose a model to predict an optimal ITV from a single figure computed from the Probability Density Function (PDF) of the breathing waveform.

## Material and Methods

We used the QUASAR Respiratory Motion Phantom (Modus Medical Devices) with a cylindrical mobile wood insert as lung substitute and an inner 30mm diameter sphere as tumour substitute (GTV). We acquired 21 independent scans (CT<sub>z</sub>) by axially shifting the mobile insert from  $z = -10$  to  $z = 10$ mm in 2mm steps. We generated 6 ITV: from ITV<sub>0mm</sub> (static case, equal to the GTV of CT<sub>0mm</sub>) to ITV<sub>10mm</sub> (overlap of all GTV from CT<sub>-10mm</sub> to CT<sub>10mm</sub>). We planned a SBRT treatment collimating to each ITV (from PLAN<sub>0mm</sub> to PLAN<sub>10mm</sub>) in Varian Eclipse (AAA v13.5) using a 6MV non-coplanar 3DCRT technique. Due to the *in silico* nature of the study we added no extra margins to the ITV.

We considered 3 breathing patterns: sinusoidal (provided by QUASAR software), free and trained (obtained by the Varian RPM from real patients). We rescaled every

waveform to amplitudes from 2 to 10mm in 2mm steps. We built the actual 4D dose distribution for every PLAN<sub>2</sub> considering all combinations of breathing patterns/amplitudes. We first copied the original treatment (planned at CT<sub>0mm</sub>) to the remaining CT<sub>z</sub> scans and recalculated them by using fixed MU. Then we copied the resulting dose matrices back to the CT<sub>0mm</sub> scan and we shifted them axially by -z. Later, we summed the dose matrices using weights derived from the PDF of the underlying waveforms.

We defined a Quality Index which balances GTV coverage and healthy tissue-sparing as  $QI = (V_{100\%,GTV})^2 / V_{PD}$ , where  $V_{100\%,GTV}$  and  $V_{PD}$  stand for the percentage of GTV covered with the Prescribed Dose (PD) and the volume of the PD isodose respectively. The optimal plan, PLAN<sub>opt</sub>, was the highest QI scoring plan for each breathing pattern/amplitude. Finally, we assessed the PDF's measure of central tendency that best predicts PLAN<sub>opt</sub> irrespective of the breathing pattern/amplitude. **Results** Figure 1a shows the QI for the sinusoidal movement. Every breathing pattern's maximum QI scores project an optimal curve to the x-y plane (figure 1b). For any breathing pattern/amplitude, PLAN<sub>opt</sub> was found to be conformed to an optimal ITV smaller than the purely geometric ITV. We found that the integral of the PDF between  $\pm x$ , i.e., the time fraction on which the GTV is on the central part of the respiratory excursion, was the best predictor of PLAN<sub>opt</sub>. Irrespective of the breathing pattern/amplitude all PDF's integrals collapsed to a unique curve for  $x = 3mm$  (figure 2).

#### Conclusion

Based on 4D dose calculations, we propose a QI to reduce the ITV while maintaining the GTV coverage for SBRT lung treatments. We provide a model to predict the optimal ITV from the integral of the PDF of the breathing waveform. Partially financed by FIS P115-00788 grant.

#### EP-1533 Modulation complexity assessment in VMAT plans from different treatment planning systems.

P. Winkler<sup>1</sup>, A. Trausnitz<sup>2</sup>, J. Schroettner<sup>2</sup>, A. Apfoltner<sup>1</sup>, K. Kapp<sup>1</sup>

<sup>1</sup>Medical University of Graz, Department of Therapeutic Radiology and Oncology, Graz, Austria

<sup>2</sup>University of Technology, Institute of Health Care Engineering, Graz, Austria

#### Purpose or Objective

Modulation complexity (MC) in Linac-based VMAT plans might influence the accuracy of dose calculation and dose delivery as well as the precision of dose delivery. However, MC is not a single-parametric property, but rather consists of several different influencing factors, e.g. average leaf speed (ALS), leaf sequence variability (LSV), mean field aperture area (FAA), aperture area variability (AAV), gantry acceleration (gantry-speed variation, GSV) and dose rate variability (DRV), which might predominantly be correlated with uncertainties in either dose calculation or delivery. In our clinical treatment plans we observed, that different TPS accomplish strong modulation in a noticeably different way, forcing either ALS, LSV and AAV whilst retaining moderate GSV and DRV, or vice versa. The aim of this study is to present several distinct modulation complexity indices (MCI), describing the different aspects of modulation complexity in VMAT plans, and to assess the characteristic ranges of these MCI for different TPS.

#### Material and Methods

We established six MCI, parameterising the magnitude of ALS, LSV, FAA, AAV, GSV and DRV in a VMAT-arc, and implemented their calculation in our automated plan-QA software tool (in-house development). The MCI for 200 randomly selected clinical beams were calculated for the TPS Eclipse (Varian) and Pinnacle (Philips),

respectively. Additionally 20 phantom plans (37 arcs) with increasing modulation complexity were generated for both of the two TPS using best possible matching of optimization criteria, and were subsequently analysed.

#### Results

In the phantom plans, the Pinnacle-optimized arcs showed significantly higher average leaf speed compared to Eclipse-optimized arcs (10.9 and 6.7 mm/sec, respectively). Aperture - opening was 40% larger for the Eclipse-arcs. Consequently, the number of monitor units was smaller in the Eclipse plans (-32%). Whereas the differences for LSV and AAV were rather small (figure 1), DRV and GSV differed significantly, revealing a more pronounced modulation in the Pinnacle plans as far as dose rate and gantry acceleration are concerned. Findings for retrospectively analysed clinical plans and (non-biased) phantom plans were similar.

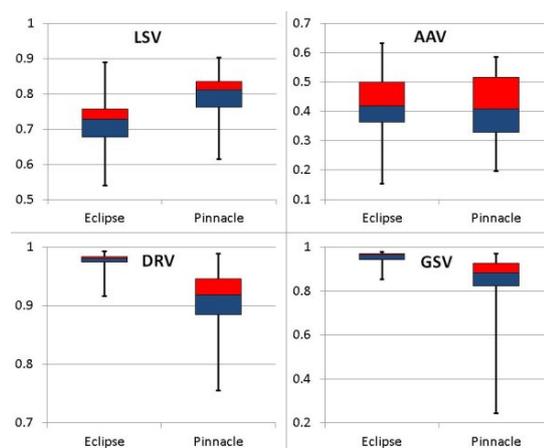

Figure 1: Modulation complexity scores (LSV: leaf sequence variability, AAV: aperture area variability, GSV: gantry-speed variation, DRV: dose rate variability) for 200 VMAT plans, calculated with Eclipse and Pinnacle TPS, respectively. Box-plots showing median, first and third quartile and range.

#### Conclusion

Modulation complexity in VMAT plans has a potential impact on dose-calculation and -delivery accuracy. We found considerable differences for two different TPS in multi-parametric assessment of MC features, indicating the diverging algorithms of the different optimizers. A further investigation of the correlation between particular MC-scores and dosimetric accuracy can be the basis for the definition of tolerance criteria to identify potentially problematic plans.

#### EP-1534 Automate the Complex Stuff: Pathways, Pitfalls and Results of Planning Automation in Raystation

B. Archibald-Heeren<sup>1,2</sup>, M. Byrne<sup>1</sup>, Y. Wang<sup>1</sup>, Y. Hu<sup>3</sup>

<sup>1</sup>Radiation Oncology Centres, Wahroonga, Sydney, Australia

<sup>2</sup>University of Wollongong, Clinical Medical Physics, Wollongong, Australia

<sup>3</sup>Radiation Oncology Centres, Gosford, Sydney, Australia

#### Purpose or Objective

Automation provides the real possibility of providing exceptional plan quality to an enormous population of patients where time constraints or staffing levels may form a barrier. It is thus the authors hope that by openly sharing the constructed methodologies incorporated at Radiation Oncology Centre, Sydney, they may in some way expedite adoption of automation across the greater community. The work will focus on prostate and breast deliveries, but touch on other areas and solutions

### Material and Methods

Atlas Based Segmentation (ABS) was utilized for automatic volume delineation. Volume metrics and DICE coefficient scores were compared between multiple manual delineation, ABS and ABS with post processing. Automatic planning was achieved by python code in the Raystation treatment planning environment. Initial optimization objectives were determined by a min-difference optimization of database entries from previous clinical plans.

Plan evaluation checks against both standard guidelines and previous plan quality scores are produced through python code and inbuilt look up tables. Non-linear scoring systems are incorporated for total plan scores that provide score weighting to crucial structures.

Adaptive planning and dose tracking is achieved in a Varian-Mosaiq-Raystation environment.

In all case time measurements were used to provide comparisons between manual and automated processing of typical radiotherapy planning tasks.

### Results

Contouring of DICE scores showed strong agreement (over 0.90) for the vast majority of regions of interest, with an average DICE coefficient of 77.7 for breast patients and 81.8 for prostate. Results were improved with post processing.

Breast and prostate plans show comparable plan quality with manual planning for both simple single phase and advanced 3-4 target volume techniques with dose volume histogram differences consistently within 5% TD. Point to point comparisons between automatic deformation matches and manual user deformations showed varying results highlighting the current need for visual QA of deformable registrations.

Time improvements over manual processes are recorded for both breast and prostate patients in all areas of testing.

### Conclusion

The possibility of automation to provide efficiency and consistency on a departmental and larger scale is demonstrated. The work represents a step in the correct direction rather than a finished product to radiotherapy automation and the current limitations and problems are opened to the audience for responses and questions.

### EP-1535 knowledge based planning for lung cancer patients with stereotactic ablative radiotherapy

S. Smith<sup>1</sup>, P. Houston<sup>1</sup>, G. Currie<sup>1</sup>

<sup>1</sup>NHS Greater Glasgow & Clyde, Radiotherapy Physics, Glasgow, United Kingdom

### Purpose or Objective

To determine whether a knowledge based treatment planning system can efficiently produce VMAT plans for lung cancer patients treated with SABR and to assess plan quality in relation to different training plan data and model parameters.

### Material and Methods

Three Lung SABR models were developed using the Varian RapidPlan™ DVH estimation algorithm.

1. Model A was trained using 60 plans calculated with both standard and HD MLCs, 6MV flattened /10 MV flattening filter free (FFF) utilising one algorithm (AAA version 10.0.28) with no plans excluded.
2. Model B included data from model A and a further 40 plans; 22 plans with statistical outliers were excluded.
3. Model C included the data from model B. A further 78 plans calculated with a new algorithm version (AAA version 13.6.23) were added to the model. Statistical outliers were excluded.

The resulting models were then used to

generate plans for ten patients who had not been included in the model training process. Comparisons of plans generated by each RapidPlan model with corresponding clinical plans were performed against clinical objectives. Clinical plans were generated by an experienced physicist using 10MV FFF, HD MLC and AAA (version 13.6.23).

### Results

All of the plans generated by each model met the clinical objectives. The PTV V99 (Volume of the PTV receiving at least 99% of the prescription) was comparable between all three model plans and the plan generated by the experience physicist ( $p > 0.05$ ). The R50 (Ratio of the 50% prescription isodose volume to the PTV) and D2cm (the maximum dose at 2cm from the PTV) values were significantly reduced when using the RapidPlan ( $p < 0.05$ ) for all three models. Model B gave the best results and was statistically better than model A ( $p < 0.05$ ). Model B also gave better results for the R100 (Ratio of the 100% prescription isodose volume to the PTV) than the experienced planner ( $P < 0.05$ ). This may be due to the differences in the out of field dose calculation between versions of AAA. OAR doses were comparable between all models and the experienced planner ( $p > 0.05$ ).

### Conclusion

The RapidPlan™ system was able to generate clinically acceptable VMAT treatment plans for lung SABR patients, in a single optimisation, with comparable OAR sparing and equal or better plan conformity than the original clinically acceptable plans, allowing for improved consistency and efficiency in the treatment planning process.

### EP-1536 The advantages of Collimator Optimization for Intensity Modulated Radiation Therapy

S. Pella<sup>1</sup>, B. Brian Doozan<sup>2</sup>

<sup>1</sup>21st Century Radiation Oncology- Florida Atlantic University and Advanced Radiation Physics Inc., Radiation Oncology/Physics, Boca Raton, USA

<sup>2</sup>Florida Atlantic University, Physics/Medical Physics, Boca Raton, USA

### Purpose or Objective

The goal of this study was to improve dosimetry for pelvic, head and neck and other cancer sites with aspherical planning target volumes (PTV) using a new algorithm for collimator angles optimization for intensity modulated radiation therapy (IMRT).

### Material and Methods

A retrospective study on the effects of the collimator optimization for 20 patients was performed by comparing the dosimetric effects, number of monitor units (MU), and the treatment delivery time from optimized plans in Eclipse version 11.0. Keeping all parameters equal, multiple treatment plans were created using four collimator angle optimization techniques: CA<sub>0</sub>, all fields have collimators set to 0°, CA<sub>E</sub>, using the Eclipse collimator angle optimization, CA<sub>A</sub>, minimizing the area of the jaws around the PTV, and CA<sub>X</sub>, minimizing the x-jaw gap. The minimum area and the minimum x-jaw angles were found by evaluating each field beam's eye view of the PTV with *ImageJ* and finding the desired parameters with a custom script. The evaluation of the plans included the monitor units (MU), the maximum dose of the plan, the maximum dose to organs at risk (OAR), the conformity index (CI) and the number of split fields.

### Results

Compared to the CA<sub>0</sub> plans, the monitor units decreased on average by 6% for the CA<sub>X</sub> with a p-value of 0.01 from an ANOVA test. The average maximum dose stayed within 1.1% between all four methods with the lowest being CA<sub>X</sub>. The maximum dose to the most at risk organ was best

spared by the CA<sub>x</sub>, which decreased by 0.62% from the CA<sub>0</sub>. Minimizing the x-jaws significantly reduced the number of split field from 61 to 37. In every field tested the CA<sub>x</sub> optimization produced as good or superior results than the other three techniques. For aspherical PTVs, CA<sub>x</sub> on average reduced the number of split fields, the maximum dose, minimized the dose to the surrounding OAR, and reduced the MU all while achieving the same control of the PTV.

#### Conclusion

For aspherical lesions larger than 100 cc, rotating the collimator to minimize the x-jaw gap produced equal tumor control while reducing the toxicity to the organs at risk with lower monitor units and less split fields compared to keeping the collimator fixed at 0° or with using the *Eclipse* collimator optimization method. Compared to the fixed collimator angle, the monitor units decreased an average of 6% using a CA<sub>x</sub> approach, which was the lowest of the four methods tested. The maximum dose to the organs at risk also showed trends of decreasing, as well as evidence to decrease the peripheral dose. The number of split fields was highly controlled with CA<sub>x</sub> by optimizing the parameter that determines if a field will divide. Of the 20 cases studied, the number of split fields decreased by about 40% with the CA<sub>x</sub> from any other method used. The CA<sub>x</sub> optimization allowed for a rotation of the collimator between each field, which showed positive results in the overall dose shape of the delivered quality assurance tests on an electronic portal imaging device.

#### EP-1537 Iterative dataset optimization in automated planning: implementation for breast radiotherapy

J. Fan<sup>1</sup>, J. Wang<sup>1</sup>, Z. Zhang<sup>1</sup>, W. Hu<sup>1</sup>

<sup>1</sup>Fudan University Cancer Hospital, Department of radiation oncology, Shanghai, China

#### Purpose or Objective

To develop a novel automated treatment planning solution for the breast radiotherapy.

#### Material and Methods

An automated treatment planning solution developed in this study includes selection of the optimal training dataset, dose volume histogram (DVH) prediction for the organs at risk (OARs) and automatically generation of the clinically acceptable treatment plans. The optimal training dataset was selected by using an iterative optimization strategy from 40 treatment plans for breast cancer patients who received radiation therapy. Firstly, the 2D KDE algorithm was applied to predict OAR DVH curves, including the heart and left lung, for patients in group A by considering the other group B as the training dataset. New plans in group A were automatically generated using the Pinnacle<sup>3</sup> Auto-Planning (AP) module (version 9.10, Philips Medical Systems) based on the dose constraints derived from the predicted DVHs. Next the point-wise comparison, taking V<sub>5</sub>, V<sub>20</sub> and mean value as the criteria, between the automatic plans and original clinical plans was performed both objectively and subjectively. Finally the preferred plans in group A got updated after the comparison and were used for the next iteration by considering itself as the training dataset instead. Above steps repeated until search and update for new preferred plans was exhausted. After selecting the optimal training dataset, additional 10 new breast treatment plans were re-planned using the AP module with the objective functions derived from the predicted DVH curves. These automatically generated re-optimized treatment plans were compared with the original manually optimized plans.

#### Results

The proposed new iterative optimization strategy, shown in Fig. 1, could effectively select the optimal training dataset and improve the accuracy of the DVH prediction.

The average of mean dose of the OARs in the iterative process for each group, group A and group B are illustrated in Fig. 2. The dose differences, between the real and prediction, decreased with iterations which indicated the convergence of our proposed technique. As can be seen from Tab. 1, the automatically AP generated treatment plans using the dose constraints derived from the predicted DVHs could achieve better dose sparing for some OARs with the other comparable plan qualities.

#### Conclusion

The proposed novel automated treatment planning solution can be used to efficiently evaluate and improve the quality and consistency of the treatment plans for modulated breast radiation therapy.

#### EP-1538 VMAT craniospinal radiotherapy, planning strategy and results in twenty pediatric and adult patients

F. Lliiso<sup>1</sup>, V. Carmona<sup>1</sup>, J. Gimeno<sup>1</sup>, B. Ibañez<sup>1</sup>, J. Bautista<sup>1</sup>, J. Bonaque<sup>1</sup>, R. Chicas<sup>1</sup>, J. Burgos<sup>1</sup>, J. Perez-Calatayud<sup>1</sup>  
<sup>1</sup>Hospital Universitario La Fe, Radiotherapy Department, Valencia, Spain

#### Purpose or Objective

To describe our VMAT craniospinal radiotherapy planning strategy, to report the dosimetric results for the first 20 patients treated with RapidArc and to compare with previously published data.

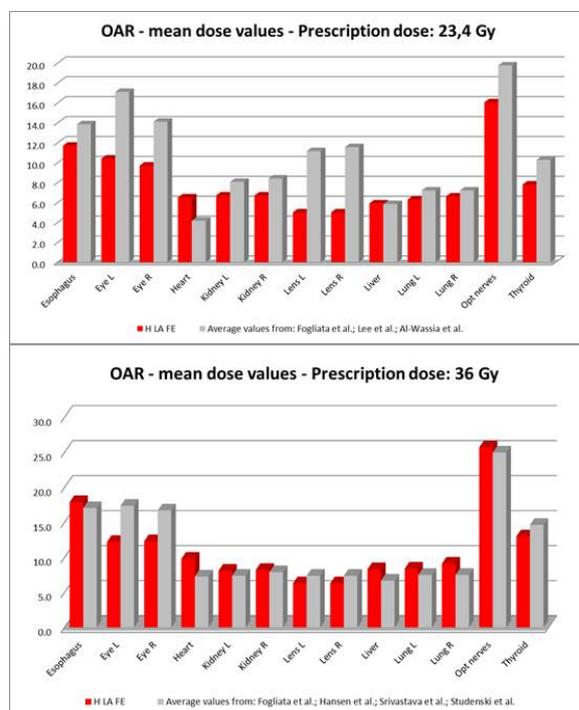

#### Material and Methods

Patients were treated in supine position in Varian Clinac iX linacs (Millennium 120 MLC, OBI) and 6 MV RapidArc, prescription doses (D<sub>prescr</sub>) were 23.4, 30.6 and 36 Gy. Twelve patients were children (3-13 years, avg.: 7.2) and nine adults (23-71 years; avg.: 38.8), the resulting PTV length was 64.8 cm (47-82 cm). The treatment planning was performed with Eclipse® (V 13.0). Depending on the PTV length, 2 or 3 isocenters were used with an overlapping region of about 4cm, all coordinates being equal except the longitudinal one. Two complete arcs were applied in the cranial isocentre, one of them encompassing the cranium plus the superior part of the spinal region, and the other one intended to improve conformity and optic sparing, only encompassing cranium. For the spine, one full arc per isocentre was employed except in 36 Gy cases for which a partial posterior arc was added at lungs level. Collimator angles were set to ±5° except for the second cranial arc (40°). Plans were optimized using Progressive Resolution Optimizer (PROII) and calculated with AAA algorithm, the main goals that at least 95% of the PTV received D<sub>prescr</sub> and also the OAR sparing. The planning objectives were defined at the first step of the optimization. Firstly, optimization weights to PTV, Normal Tissue, lenses and lungs were assigned and, once DVH values were close to the desired ones, the rest of the surrounding OARs were sequentially included (mean doses were employed); in addition, for pediatric patients, homogeneous irradiation of the vertebrae was required; finally, weights to maximum dose to OAR located inside the brain PTV were set to avoid hot spots. After that, the rest of the optimization was carried out using the automatic "Intermediate Dose Calculation" option. Various dosimetric parameters and indices were employed: PTV mean dose; D<sub>1cc</sub>, D2% and D98%; mean and maximum doses for OAR; V5 and V20 for lungs; conformity (CI=Vol<sub>95%</sub>/Vol<sub>PTV</sub>) and homogeneity (HI=D<sub>1cc</sub>/D<sub>prescr</sub>) indices; Normal Tissue mean and V5 dose.

#### Results

We found avg. values for CI, 1.02 (0.98-1.09) and for HI, 1.08 (1.05-1.10) regardless of D<sub>prescr</sub>. OAR mean dose values along with average values reported by different authors are shown in Fig. 1. A great reduction is observed for almost all OAR for 23.4 Gy, while for 36 Gy our results are favorable for eyes and lenses and similar or slightly

poorer to published ones for the rest of OAR, this may be due to the fact that the majority of our cases with 36 Gy were children which are precisely the more complex cases to optimize.

Dosimetric parameters dependent on  $D_{\text{prescr}}$  are presented in Table 1.

$D_{\text{prescr}}$	Lungs		Normal Tissue	
	V20 (%)	V5 (%)	Mean dose (Gy)	V5 (%)
23.4 Gy	0.7	51.5	5.6	38
30.6 Gy	1.4	62.8	6.0	45
36 Gy	6.1	65.2	8.0	50

### Conclusion

A RapidArc planning process for craniospinal axis irradiation has been implemented with significant improvement on conformity, homogeneity, feasibility and efficiency.

### EP-1539 Parameters for estimating and controlling small gaps in VMAT treatments

J. Saez Beltran<sup>1</sup>, V. Hernandez Masgrau<sup>2</sup>

<sup>1</sup>Hospital Clinic i Provincial, Radiation Oncology Department, Barcelona, Spain

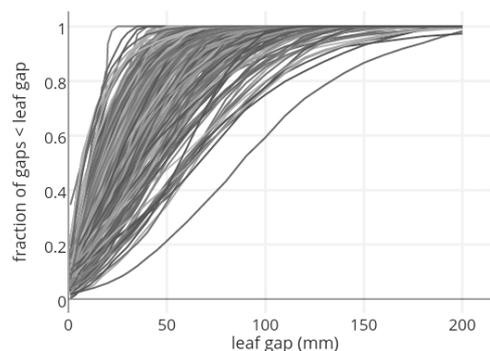

<sup>2</sup>Hospital Sant Joan de Reus, Medical Physics Department, Reus, Spain

### Purpose or Objective

It is well established that dose modelling and calculation of small fields and small MLC gaps is challenging. Indeed, VMAT plans with a large fraction of small MLC gaps are prone to present dosimetric discrepancies due to limitation of the TPS and uncertainties in treatment delivery. On the other hand, there is a growing interest in developing tools to characterize robust class solutions for plans. Our goal was to study leaf gap distributions in terms of descriptive variables and complexity indices.

### Material and Methods

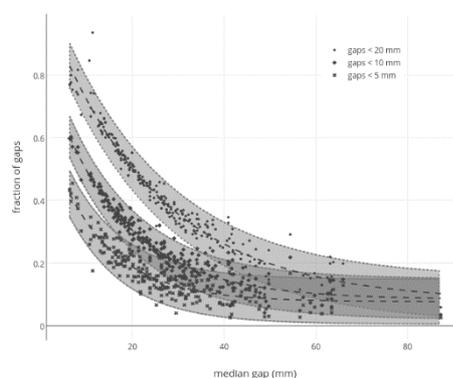

A total of 276 RapidArc plans optimized with Eclipse v13 were exported in DICOM format for this study comprising all locations (HN, prostate, gyne, brain, other). The cumulative histogram of leaf gaps for all plans is shown in figure 1. A set of MATLAB routines was developed to perform the analysis. The following parameters were computed: Total Modulation Index (Mlt) (Park et. al), Modulation Complexity Score (MCS) (McNiven et. al), Beam Irregularity (BI) (Du et. al), mean gap, median gap and MU/Gy. All these parameters were evaluated as predictors of the fraction of small gaps, in particular fraction of gaps smaller than 20, 10 and 5 mm.

### Results

There was a very large variability in the distribution of MLC gaps involved in VMAT plans. A strong exponential relationship between the median gap and the fraction of gaps smaller than 5, 10 and 20 mm was observed ( $r^2=0.8$ , 0.92 and 0.95) (see figure 2). A similar but weaker relationship was observed for the mean gap ( $r^2=0.74$ , 0.87 and 0.94), the MCS ( $r^2=0.55$ , 0.58 and 0.54) and MU/Gy ( $r^2=0.21$ , 0.26 and 0.25). Neither the Mlt nor the BI presented a relationship with any of the gap fractions studied.

For median gaps > 30mm, the fraction of gaps lower than 5, 10 and 20 mm was estimated as  $0.13 \pm 0.07$ ,  $0.20 \pm 0.06$  and  $0.36 \pm 0.07$ , respectively. On the contrary, for median gaps ~10mm, the fraction of gaps lower than 5, 10 and 20 mm was estimated as high as  $0.33 \pm 0.07$ ,  $0.50 \pm 0.06$  and  $0.72 \pm 0.07$ , respectively.

### Conclusion

In general, plan complexity indices exhibit a weak correlation with the fraction of small gaps in VMAT plans. Similarly, setting limits on the number of MUs, or MU/Gy has no clear impact on the fraction of small gaps generated during the optimization process. A good prediction of the fraction of small gaps can be obtained from the median gap of the plan. Thus, tolerance levels for the fraction of small gaps can be defined in terms of the median gap of the plan, which can be useful to generate more robust VMAT plans.

**EP-1540 Optimal fractionation schemes for radiosurgery of large brain metastases**

 J. Unkelbach<sup>1</sup>, H.A. Shih<sup>2</sup>
<sup>1</sup>University Hospital, Radiation Oncology, Zürich, Switzerland

<sup>2</sup>Massachusetts General Hospital, Radiation Oncology, Boston, USA

**Purpose or Objective**

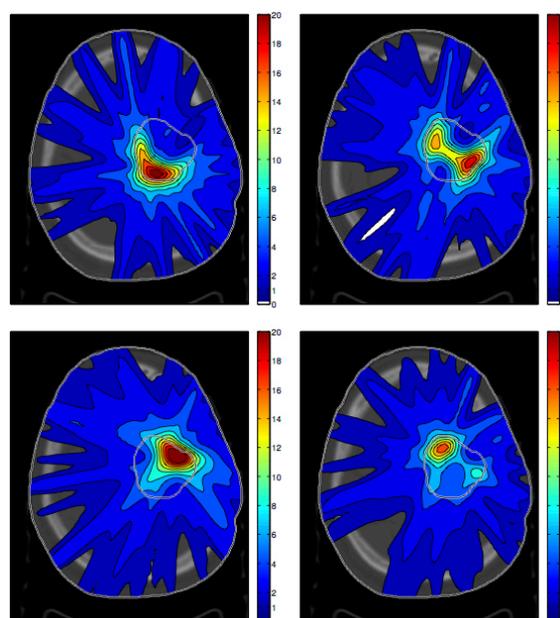

Stereotactic radiosurgery (SRS) is an established treatment option for patients with brain metastases. While small metastases are successfully treated with single-fraction SRS, the optimal fractionation scheme for large lesions is unclear and involves a trade-off between the number of fractions, tumor dose, and dose to normal brain. In this work, we demonstrate that spatiotemporal fractionation schemes, ie. delivering distinct dose distributions in different fractions, may improve the therapeutic ratio for these patients.

**Material and Methods**

Fractionation effects are described using the biologically effective dose (BED) model, assuming alpha-beta ratios of 10 in the tumor and 2 in normal brain. Treatment planning is performed based on objective functions evaluated for BED instead of physical dose. Constrained optimization techniques are used to ensure that all treatment plans have identical target coverage and conformity. Plans are compared regarding integral BED to normal brain, and BED to normal brain adjacent to the tumor.

**Results**

Traditional fractionation schemes deliver the same dose distribution in all fractions. Increasing the number of fractions reduces the BED to normal brain in the high dose region adjacent to the tumor for a fixed tumor BED. However, the integral BED to normal brain typically remains approximately the same. Spatiotemporal fractionation can lower the integral BED via the following mechanism: Distinct treatment plans for different fractions are designed such that each dose distribution creates a similar dose bath in the normal brain surrounding the tumor, ie. exploit the fractionation effect. However, each fraction delivers a nonuniform target dose such that a high single-fraction dose is delivered to alternating parts of the tumor (Figure 1). Thereby, partial hypofractionation in the tumor can be achieved along with relatively uniform fractionation in normal brain, leading approximately to a 10% reduction of BED in normal brain.

*Figure 1: Illustration of spatiotemporal fractionation using 4 fractions for a large brain metastasis (26cc). Treatment planning was performed for rotation therapy (VMAT or Tomotherapy) such that a cumulative BED equivalent to 20 Gy single-fraction dose is delivered to the target, while minimizing normal brain BED. It is assumed that 1x20Gy in the tumor corresponds to 2x13Gy, 3x10Gy, and 4x8Gy. Hence, a uniformly fractionated 4-fraction treatment increases the total physical dose from 20 Gy to 32 Gy. Spatiotemporal fractionation delivers approximately 20 Gy in a single fraction to parts of the tumor. Thereby, the same tumor BED is achieved with a lower physical dose, which translates into a net BED reduction in the normal brain where the dose is relatively uniformly fractionated.*

**Conclusion**

Delivering distinct dose distributions in different fractions may improve the therapeutic ratio. For patients with brain metastasis this may lower integral dose to normal brain and reduce cognitive decline.

**EP-1541 4D dose reconstruction using a standard TPS in combination with a respiratory motion model**

 M. Ziegler<sup>1</sup>, J. Woelfelschneider<sup>1</sup>, H. Prasetyo<sup>1</sup>, C. Bert<sup>1</sup>  
<sup>1</sup>University Hospital Erlangen, Radiation Oncology, Erlangen, Germany

**Purpose or Objective**

Dynamic tracking (DT) is one approach to treat intra-fractionally moving tumors due to a conformal irradiation while sparing of healthy tissue. Clinical tracking systems rely on correlation models to predict the internal tumor position based on external surrogates. However, assessment of the actually delivered dose is still challenging as many treatment planning systems (TPS) do not have the ability to calculate dose on time-resolved (4D) computed tomography images. The aim of this study was to determine the possibility for 4D dose reconstruction of DT patients using a common TPS and a respiratory motion model that is based on external surrogates.

**Material and Methods**

The University Hospital in Erlangen is equipped with a Vero system (Brainlab, Feldkirchen, Germany) that is used to treat patients with intra-fractionally moving tumors by DT. This system further provides the extraction of the patients' surface as a surrogate by external infrared

markers during the treatment. These surrogates are used as an input parameter for a 4D motion model to predict CT volumes at arbitrary positions within the respiratory cycle. Daily CBCT images are used to calculate a baseline shift between the planning CT and the actual anatomy using deformable image registration. Treatment planning was done by the TPS Pinnacle<sup>3</sup> v9.8 (Phillips Radiation Oncology Systems, Fitchburg, WI, USA). The motion model was used to estimate CT volumes in intervals of 100 ms that were imported into the TPS to calculate a partial delivered dose. The Vero system uses rotations of the LINAC head for DT, so the resulting images have to be rotated according to the pan/tilt motion since the TPS is not able to model a non-axial beam line. The partial doses were back-rotated and superposed resulting in the actually delivered 4D dose distribution. In addition, 4D dose-volume-histograms (DVH) were calculated by warping the reference contours onto every respiratory phase using the motion model. The resulting 4D dose distributions were evaluated and compared to phantom measurements using the ArcCheck (Sun Nuclear, Melbourne, FL, USA) in combination with a motion platform jointly developed with QRM, Möhrendorf, Germany.

### Results

The accuracy of the motion model was validated for 20 patients with a geometrical uncertainty of < 3 mm. Dose comparison of the estimated volumes to clinical ground-truth CTs resulted in a pass rate above 98.9% for a  $\gamma$ -criterion of 2% / 2 mm. 4D dose distributions could be reconstructed and were in good agreement to phantom measurements. The actually delivered dose for two liver patients was recalculated and additional patients are currently ongoing.

### Conclusion

The presented approach is feasible to reconstruct 4D dose distributions for DT patients using a common TPS together with the presented motion model. External surrogates to calculate the breathing state are essential as well as daily CBCT or kV images to correct for baseline shifts.

## EP-1542 Can proton therapy for head and neck cancer reduce side effects while maintaining target robustness?

D. Scandurra<sup>1</sup>, R.G.J. Kierkels<sup>1</sup>, M. Gelderman<sup>1</sup>, H.M. Credoe<sup>1</sup>, H.P. Bijl<sup>1</sup>, R.J.H.M. Steenbakkers<sup>1</sup>, J.G.M. Vemer - van de Hoek<sup>1</sup>, J.A. Langendijk<sup>1</sup>

<sup>1</sup>University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

### Purpose or Objective

Head and neck cancer generally consists of targets requiring high doses of radiation in close proximity to vital healthy organs. Proton therapy leads to a reduction of integral dose and therefore can reduce normal tissue complication probabilities (NTCP). The proton range, however, depends on the material along its path and is therefore susceptible to uncertainties, potentially degrading target coverage. These uncertainties can be partially accounted for by conventional target margins (PTV) or robust-optimisation approaches. In this in-silico study, four variations of pencil beam scanning (PBS) proton therapy plans were designed for each patient and compared to the clinical photon plan in terms of robustness and NTCP reduction.

### Material and Methods

Four PBS plans were made for each patient using RayStation (v4.99 RaySearch Laboratories AB, Sweden): 1) PTV based, multi-field optimisation (PTV-MFO), 2) PTV based, single field optimisation (PTV-SFO), 3) CTV robustly optimised MFO (CTV-MFO), and 4) CTV robustly optimised SFO (CTV-SFO). Each plan was designed to a similar target homogeneity

index and normalised to CTV70 D98%. Four beams were used in an 'x' arrangement and a 4 cm range shifter was used where appropriate. The PTV was defined as 5 mm geometric expansion to CTV, identical to current photon plans in our clinic (VMAT). Robust optimisation settings were 5 mm isotropically and  $\pm 3\%$  HU uncertainty. For each plan, robust evaluation was performed for a combination of  $\pm 5$  mm translational,  $\pm 2^\circ$  rotational and  $\pm 3\%$  HU errors (>50 scenarios per plan). The error scenario with the lowest target coverage (V95% to CTV70) is deemed the 'worst-case' scenario.

Organ at risk (OAR) doses and NTCP values of the nominal proton plans and the clinical VMAT plan were compared.

### Results

Robust evaluation showed CTV70 target coverage degraded significantly for PTV based plans, particularly using MFO (-15%) but also for SFO (-5.4%). Robustly optimised plans performed much better, particularly CTV-MFO (-1.7%) which comes very close to matching the robustness of the clinical VMAT plan (-1.2%) (figure 1). CTV-SFO under-performed due to the beam arrangement and the high weighting on OAR dose reduction. OAR doses were significantly better in MFO plans, as this gave the optimiser the most freedom in per-beam dose distribution. In particular, CTV-MFO plans had the lowest OAR doses of all proton and photon plans. NTCP model calculations show that, compared to our clinical VMAT plans, reductions across all patients for xerostomia (-5.9%), dysphagia (-7.0%) and tube feeding (-4.7%) can be expected, but these values varied widely among different tumour sites, stages and individual patients (table 1).

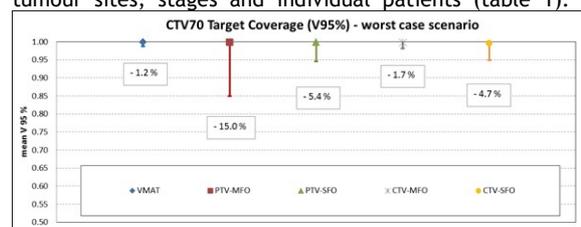

Figure 1: CTV70 target coverage robust evaluation. CTV70 V95% for all nominal plans is approx. 100% (icons). The mean target coverage in the 'worst case' error scenarios can be significantly lower, depending on which plan technique is used (line length).

Site / Stage	$\Delta$ NTCP (%)		
	Xerostomia	Dysphagia	Tube Feeding
Nasopharynx T4N2	-3.6	-8.9	-4.2
Nasopharynx T1N2	-8.4	-10.3	-5.3
Nasopharynx T1N1	-2.8	-7.2	-4.0
Oropharynx T4N2	-6.6	-10.6	-6.7
Oropharynx T3N2	-8.1	-10.0	-11.5
Hypopharynx T2N2	-1.8	-3.9	-2.0
Glottic larynx T3N0	-5.5	-0.9	-0.3
Sphenoid sinus T4N2	-10.9	-6.0	-6.4
Maxillary sinus T4N0	-4.3	-1.3	-0.4
<b>Mean <math>\Delta</math>NTCP (%)</b>	<b>-5.9</b>	<b>-7.0</b>	<b>-4.7</b>

Table 1: Calculated NTCP differences for the CTV-MFO proton plans and the clinical VMAT plans, grouped by tumour location and stage.

### Conclusion

Compared to photon VMAT plans, robustly optimised PBS proton therapy plans reduce OAR doses in head and neck cancer while maintaining a high degree of target coverage robustness. NTCP calculations show a clinical benefit can be expected for a significant proportion of patients.

## EP-1543 Dominant intraprostatic lesions boosting: comparison of tomotherapy, VMAT and IMPT

P. Andrzejewski<sup>1</sup>, A. Jodda<sup>2</sup>, P. Kuess<sup>1</sup>, D. Georg<sup>1</sup>, J. Malicki<sup>3</sup>, T. Piotrowski<sup>3</sup>

<sup>1</sup>Medical University Vienna, Dept. of Radiation Oncology- Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

<sup>2</sup>Greater Poland Cancer Centre, Department of Medical Physics, Poznan, Poland

<sup>3</sup>University of Medical Sciences- Greater Poland Cancer Centre, Department of Electroradiology- Department of Medical Physics, Poznan, Poland

#### Purpose or Objective

For patients with recurring prostate cancer the majority of relapses (around 90%) occur at the location of the primary tumor. That motivates further but local dose escalation to avoid enhanced dose to rectum and bladder. Moreover, boosting the dominant intraprostatic lesions (DIL) is currently explored in clinical studies. The purpose of this study was to assess the feasibility of DIL boosting with tomotherapy and to compare it dosimetrically to previously evaluated VMAT and IMPT strategies.

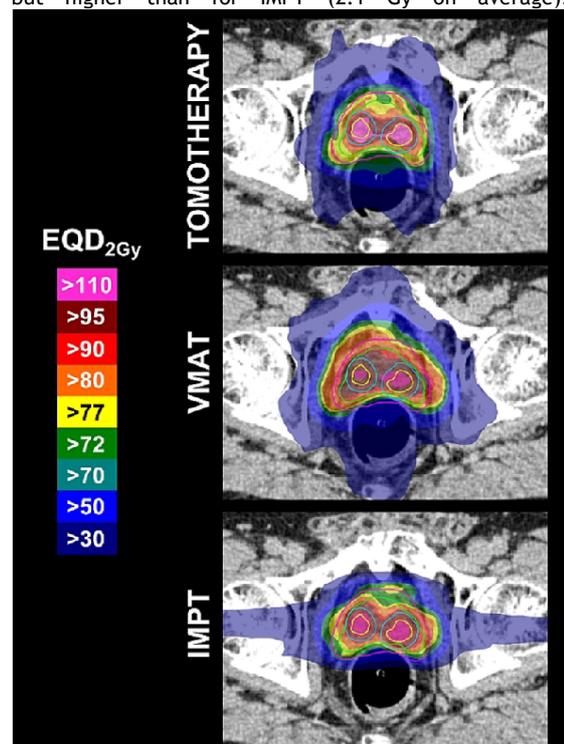

#### Material and Methods

For twelve patients the DILs were defined on multiparametric magnetic resonance scans and propagated to respective co-registered CT images. For each patient a tomotherapy plan (6MV; fixed field width 1 cm; pitch 0.287, modulation factor ranged from 2.5 to 2.9) aiming at the escalation of the physical dose up to 95 Gy to the PTV<sub>DIL</sub> with a dose prescription of 77 Gy to the PTV<sub>prostate</sub>, delivered in 35 fractions. The following hard dose constraints were applied for rectum and bladder:  $V_{72\text{Gy}} \leq 5\%$ ,  $V_{77\text{Gy}} \leq 1\text{cc}$  and  $V_{72\text{Gy}} \leq 10\%$  and  $V_{80\text{Gy}} \leq 1\text{cc}$ , respectively. PTV<sub>DIL</sub> and PTV<sub>prostate</sub> margins were 4/5/4 mm in LR/AP/CC directions, respectively. Resulting tomotherapy treatment plans were compared to VMAT and IMPT plans based on the same objectives and constraints using repeated measures ANOVA test. Furthermore, pelvic floor muscles, femoral heads, urethra and penile bulb dose indices and EUDs were evaluated.

#### Results

The median EQD<sub>2(G/B)</sub> dose to the DIL was 113.4 Gy<sub>(ISOE)</sub> for tomotherapy while it was 2.7 Gy<sub>(ISOE)</sub> less for VMAT and 0.8 Gy<sub>(ISOE)</sub> more for IMPT.  $V_{95\%}$  (of prescribed dose) of 83.4% and 98.1% for PTV<sub>DIL</sub> and PTV<sub>prostate</sub> were best for tomotherapy, while with VMAT and IMPT 64.5, 94.6% and 80.0 and 92.9% was achieved. Mean dose to the rectal wall and bladder wall were 26.4±5.0 and 19.3±5.5 Gy<sub>(ISOE)</sub> for tomotherapy, 30.5±5.0 and 21.0±5.5 Gy<sub>(ISOE)</sub> for VMAT, and 16.7±3.6 and 15.6 ±4.3 Gy<sub>(ISOE)</sub> for IMPT. The EUD for the other delineated organs was significantly lower for tomotherapy in comparison to VMAT (4.3 Gy on average),

but higher than for IMPT (2.1 Gy on average).

#### Conclusion

Tomotherapy is a suitable EBRT modality to deliver DIL boost treatments. It performs better than VMAT in terms of achievable boost doses, target coverage and OARs sparing. However, besides achievable coverage, it does not surpass IMPT. Although the obtained OAR doses were higher than those for a standard treatment approach, the risk levels tend to be reasonably low when comparing doses to the most exposed small volumes of OARs. Further studies on using TomoEDGE™ (that enables dynamic jaws usage) and CyberKnife® for DIL boosting are ongoing.

#### EP-1544 Treatment selection by comparison of patient specific NTCP predictions

J.P. Tol<sup>1</sup>, A.R. Delaney<sup>1</sup>, M. Dahele<sup>1</sup>, I.T. Kuijper<sup>1</sup>, B.J. Slotman<sup>1</sup>, W.F.A.R. Verbakel<sup>1</sup>

<sup>1</sup>VU University Medical Center, Radiotherapy, Amsterdam, The Netherlands

#### Purpose or Objective

A choice between treatment techniques is often influenced by geometric features such as the relative position of the planning target volumes (PTVs) and organs-at-risk (OARs). In practice, treatment plans are created using each technique which are then compared using dosimetric parameters. The plans can be further interpreted using normal tissue complication probabilities (NTCPs). However, this is rarely done due to lack of software to facilitate such comparisons.

We have previously shown that OAR dose-volume histograms (DVHs) predicted by RapidPlan (a commercial knowledge-based planning solution) correspond well with the subsequently optimized plan. Using the scripting application programming interface of the Eclipse treatment planning system we have coded a plan selection program (PSP), which can compare predicted OAR DVHs. PSP also allows calculation of NTCPs to estimate toxicity. As a demonstration, PSP is used to compare proton and photon treatments for ten head and neck cancer patients.

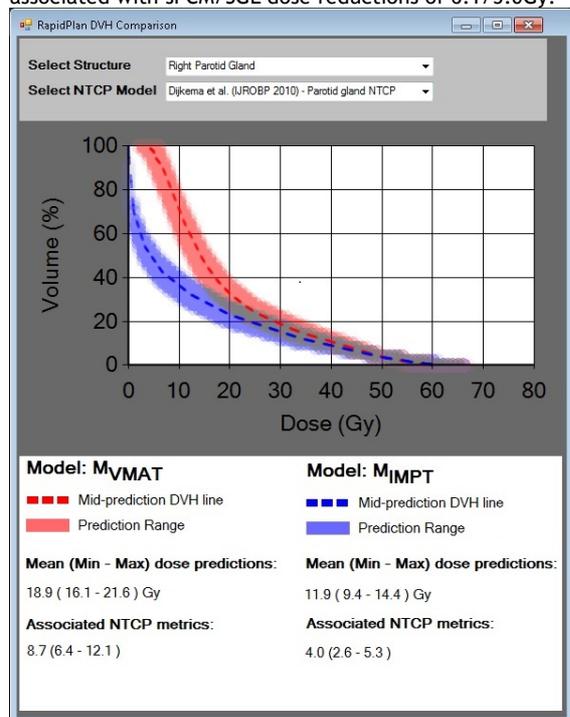

#### Material and Methods

Two RapidPlan models were included in PSP;  $M_{\text{VMAT}}$ , consisting of 101 clinical volumetric modulated arc

therapy (VMAT) plans, and  $M_{IMPT}$ , consisting of 40 intensity modulated proton therapy (IMPT) plans. Modeled OARs included the parotid glands (PGs), submandibular glands (SMGs), oral cavity (OC) and individual swallowing muscles. For 10 evaluation patients, *PSP* was used to derive mean predicted OAR doses generated by  $M_{VMAT}/M_{IMPT}$ , which were further interpreted using NTCP models for the following OARs: 1: PGs (stimulated flow ratio < 25% pre-treatment, Dijkema IJROBP 2010), 2: SMGs (grade 4 toxicity, Murdoch-Kinch IJROBP 2008), 3: OC (grade 3 mucositis, Bhide R&O 2012) and 4: Superior pharyngeal constrictor muscle/supraglottic larynx (sPCM/SGL, grade 2-4 dysphagia, Christianen R&O 2012).

### Results

Figure 1 shows a screenshot of a DVH comparison for the left PG using *PSP*, with the red/blue shaded regions representing the dose predictions by  $M_{VMAT}/M_{IMPT}$ . On average, mean CL/IL parotid gland doses were  $21.3 \pm 3.3 / 33.6 \pm 4.2$  Gy and  $14.5 \pm 6.0 / 28.8 \pm 5.0$  Gy using  $M_{VMAT}$  and  $M_{IMPT}$ , respectively, associated with a 5.0/7.8% reduction in NTCP. Conversely, predicted CL SMG doses were  $33.0 / 31.9$  Gy with  $M_{VMAT}/M_{IMPT}$ , with a 0.3% difference in estimated NTCP. The largest reduction using  $M_{IMPT}$  was noted for the occurrence of oral mucositis (15.6%), with an average OC mean dose reduction of 16.9 Gy. Finally, a 4.5% decrease in dysphagia was predicted using IMPT, associated with sPCM/SGL dose reductions of 6.1/5.0 Gy.

### Conclusion

By including standard dosimetric and NTCP metrics, *PSP* may assist in optimal treatment selection for individual patients. This analysis is based on a DVH line that is predicted by RapidPlan, without requiring the actual (time consuming) creation of treatment plans. This makes the plan comparison process efficient and transparent. Note that the proton versus photon comparison for HNC was solely used as a paradigm, this study was not intended to investigate the accuracy of RapidPlan for protons.

### EP-1545 On mixed-modality radiation therapy optimization using the column generation approach

M.A. Renaud<sup>1</sup>, M. Serban<sup>2</sup>, C. Lambert<sup>3</sup>, J. Seuntjens<sup>1</sup>

<sup>1</sup>McGill University - Downtown Campus Department of Oncology, Physics, Montreal, Canada

<sup>2</sup>McGill University Health Center - Glen Site, Medical

Physics, Montreal, Canada

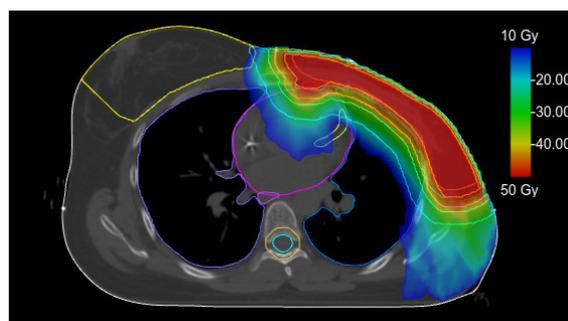

<sup>3</sup>McGill University Health Center - Glen Site, Radiation Oncology, Montreal, Canada

### Purpose or Objective

Despite considerable increase in the number of degrees of freedom with recent radiotherapy optimisation algorithms, treatments are typically delivered using only a single modality. Mixed-modality plans such as electron-photon provide dosimetric advantages for sites with a superficial component. The column generation method, which is an iterative method that finds the aperture with the largest potential to improve the cost function at every iteration, is well suited for mixed-modality optimisation as the aperture generation and modality selection problem can be solved quickly. We assess the performance of the column generation method applied to mixed-modality planning and investigate its behaviour under different modality mixing schemes.

### Material and Methods

The column generation method was applied to a chest wall case (Fig. 1). Photon beamlets were created for a coplanar distribution of beam angles every 20° around the patient. In addition, 5 shortened-SAD (70 cm) electron beam angles were included and beamlets were generated for energies of 6, 9, 12, 16, 20 MeV. A photon MLC acted as the sole collimating device for electrons.

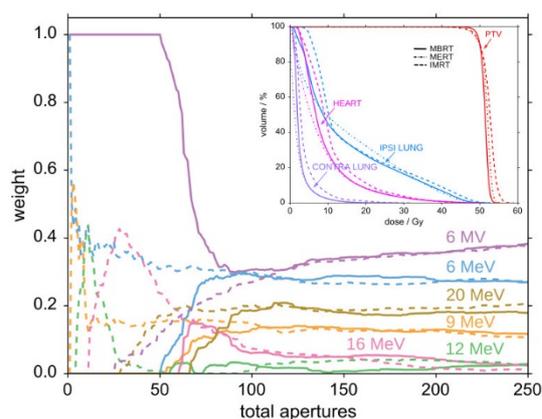

Photon-only (IMRT), electron-only (MERT) and mixed electron-photon (MBRT) treatment plans were created using the same optimisation constraints. To analyse the sensitivity of treatment plans to initial conditions, a perturbation on the original mixed-modality treatment plan was created by forcing the first 50 apertures to be photon apertures before allowing other modalities.

Finally, the efficiency and plan quality of four different modality mixing schemes was analysed by creating treatment plans with more than a single aperture per iteration of the column generation loop.

### Results

The MBRT plan produced better target coverage and homogeneity while preserving the normal tissue-sparing advantages of electron therapy (fig. 2, inset), with a final cost function between 25-30% of the values for IMRT and MERT.

The fraction of total dose among modalities in the treatment plan with the perturbation (fig. 2, full lines) converged to the unperturbed treatment plan (fig. 2, dashed lines) with identical plan quality.

Adding a single aperture per iteration yielded the lowest cost function value per aperture included in the treatment plan. However, adding one aperture per modality every iteration resulted in a plan of comparable quality in only 120 iterations of the column generation loop instead of 580 for the single-aperture scheme. **Conclusion** MBRT planning produced a clinically realistic chest wall plan combining the advantages of photon and electron radiotherapy. The final plan was robust to initial conditions despite the iterative nature of column generation. This work opens the door to robust multi-modality planning and delivery.

#### EP-1546 MR-Linac based single fraction ablative radiotherapy for early-stage breast cancer: a planning study

T. Van 't Westeinde<sup>1</sup>, K.R. Charaghvandi<sup>1</sup>, J.K. Horton<sup>2</sup>, S. Yoo<sup>2</sup>, V. Scholten<sup>1</sup>, B. Van Asselen<sup>1</sup>, H.J.G.D. Van den Bongard<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands  
<sup>2</sup>Duke University Medical Center, Radiotherapy, Durham, USA

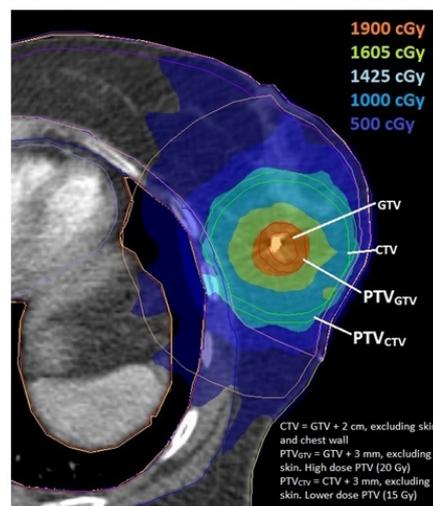

#### Purpose or Objective

Our department is currently working on the implementation of an MRI-linear accelerator (MR-linac) for several tumor sites. Dose distribution in the presence of a magnetic field can be affected by the electron return effect (ERE), which can occur at tissue boundaries like skin and lung. Other MRL settings such as the fixed collimator and isocenter position may also influence the RT plan. We investigated the dosimetric feasibility of single fraction ablative radiotherapy in the prone and supine position for early-stage breast cancer using an MR-Linac approach.

#### Material and Methods

Preoperative contrast-enhanced (CE) CT and MRI scans were used from 10 cT1-2N0(sn) breast cancer patients included in an ongoing clinical trial on preoperative ablative radiotherapy. The gross tumor volume (GTV) was delineated on matched CE MRI- & CT-scans in the supine position. The clinical target volume (CTV) was created by expanding the GTV with 2 cm, thereby excluding skin and chest wall. The planning target volumes PTV<sub>GTV</sub> and PTV<sub>CTV</sub> were created by expanding both GTV and CTV 3 mm, excluding the skin. Prescribed doses were 20 Gy for PTV<sub>GTV</sub> and 15 Gy for PTV<sub>CTV</sub>. Rationale for dose prescription and organs at risk (OAR) constraints for a single fraction ablative RT were previously defined (1). Adequate target coverage was defined as 99% of the PTV should receive  $\geq 95\%$  of the prescribed dose. Intensity modulated radiation therapy (IMRT) plans were made in the presence of a 1.5T magnetic field, using Monaco Research version 5.19.01 planning system. 7 beams with individually chosen beam angles were used for each plan. Dosimetry was evaluated in all simulated plans.

Figure 1. Example of a simulated MR-Linac plan for ablative single-dose radiotherapy

#### Results

For supine positioning the median volume that received at least 95% of the prescribed dose was  $\geq 99\%$  for PTV<sub>GTV</sub> and PTV<sub>CTV</sub>. The median GTV volume was 1.1 cc, the median CTV volume 72.9 cc, the median PTV<sub>GTV</sub> volume 5.3 cc and the median PTV<sub>CTV</sub> volume was 104.9 cc. The median ratio PTV<sub>CTV</sub> to ipsilateral breast was 11.6%. The predefined OAR constraints were achieved in all plans (table 1).

Table 1. Treatment characteristics and dosimetry results of MR-Linac single fraction ablative radiotherapy, in supine position

Characteristics	Number	Median	Range	OAR constraint
<b>Location breast</b>				
Left	5			
Right	5			
<b>Volume (cc)</b>				
GTV (cc)		1.1	[0.6-3.1]	
CTV (cc)		72.9	[33.9-124.9]	
PTV <sub>GTV</sub> (cc)		5.3	[2.9-9.8]	
PTV <sub>CTV</sub> (cc)		104.9	[51.0-171.3]	
Ratio PTV <sub>CTV</sub> to ipsilateral breast (%)		11.6	[1.5-17.9]	
<b>Target coverage (%)</b>				
V19Gy PTV <sub>GTV</sub>		99.3	[98.5-100]	$\geq 99$
V14.25Gy PTV <sub>CTV</sub>		99.0	[98.8-100]	$\geq 99$
Dmax PTV <sub>GTV</sub>		104.3	[102.9-106.8]	<107
Dmean PTV <sub>GTV</sub>		100.3	[100.1-101.1]	100
Dmean PTV <sub>CTV</sub>		107.1	[105.1-112.9]	
<b>OAR dose</b>				
V2 & Gy heart (%)		3.0	[0-9.2]	<10
Mean heart dose (Gy)		0.8	[0.3-1.3]	
Mean lung dose (Gy)		0.9	[0.4-1.2]	<3.6
D1cc skin (Gy)		14.7	[11.2-15.6]	<16
D20cc chest wall (Gy)		12.4	[9.4-14.7]	<16.3
Dmax contralateral breast (Gy)		2.0	[1.2-5.3]	

#### Conclusion

Single fraction ablative radiotherapy in supine position on the MR-Linac is dosimetrically feasible. The feasibility of prone MR-linac treatment will be available at the 36<sup>th</sup> ESTRO conference.

(1) Charaghvandi RK, den Hartogh MD, van Ommen et al. MRI-guided single fraction ablative radiotherapy for early-stage breast cancer: a brachytherapy versus volumetric modulated arc therapy dosimetry study. *Radiother Oncol* 2015 Dec;117(3):477-482.

#### EP-1547 Optimal treatment planning for H&N: evaluation of a predict parotid glands sparing tool

N. Delaby (France), S. Martin, O. Henry, E. Chajon, C. Lafond<sup>3</sup>  
<sup>1</sup>Centre Eugène Marquis, Radiotherapy, Rennes CEDEX, France  
<sup>2</sup>INSERM, U1099, Rennes, France  
<sup>3</sup>University Rennes 1, LTSI, Rennes, France

#### Purpose or Objective

The complexity of the clinical objectives in IMRT yields a variability in treatment planning, especially between operators. A major difficulty is currently to appreciate the

optimality of treatment plans. A previous published model was used allowing to better define the achievable mean dose to organs at risk (OAR) during inverse planning step (Moore et al., Int. J. Radiation Oncology Biol. 2011). This model integrates the overlap volume between the OAR and the PTV. The aim of the present study was to evaluate application of this model adapted to our own data to anticipate the lower dose achievable to the parotid glands (PGs) and its impact in the inter-operator variability in head and neck (H&N) cancer treatment planning.

#### Material and Methods

Twenty patients treated for locally advanced H&N cancer were used to generate the predictive model (PM). Three (70/63/56 Gy) and two (60/54 Gy) dose levels VMAT simultaneously integrated boost treatment plans were generated using Pinnacle v.9.10 (Philips) Treatment Planning System. To test the PM, 10 additional cases were planned with and without the PM (8 patients with 3 levels of prescribed dose 70/63/56 Gy and 2 patients with 2 levels of prescribed dose 60/54 Gy). In a second time, 12 operators with different treatment planning experience performed a treatment planning on the same patient, with and without the PM. Doses to PTVs, PGs, spinal cord PRV, indexes of conformity (CI), homogeneity (HI) and the number of Monitor Units (MU) were compared.

#### Results

Table 1 shows the results for 10 treatment plans with and without the PM. On average, mean doses (Dmean) to PGs decreased of 5.3 Gy [-15.4 Gy; +2.6 Gy] using the model. CI and maximal dose to the spinal cord PRV were similar with both methods. However, plans obtained using the PM show less dose homogeneity into PTV (for middle dose PTV, HI increase by 18% with PM) and had more MU: +13% on average [-3.1%; +32.6%], indicating an increase of plans complexity. Figure 1 shows DVH for homolateral and contralateral PGs with and without PM for the treatment planning generated by 12 operators. With PM use, the dispersion of the data were lower, demonstrating a decrease in inter-operator variability: standard deviation for mean dose delivered to homolateral PG decrease from 2.16 Gy to 1.19 Gy and for contralateral PG from 2.89 Gy to 0.78 Gy.

#### Conclusion

This study showed the utility of a PM to reduce the dose received by the PGs in H&N treatment planning (Dmean decreased of 5.3 Gy). The suggested model guides to the lowest achievable Dmean to the PGs at the beginning of treatment planning step. Integrating this method in the treatment planning workflow reduces significantly the inter-operator treatment planning variability and could potentially allow to a time reduction in treatment planning.

**EP-1548 Dose to risk organs in deep inspiration breath hold non-coplanar VMAT for lung cancer radiotherapy**  
M. Josipovic<sup>1</sup>, G. Persson<sup>1</sup>, J. Bangsgaard<sup>1</sup>, L. Specht<sup>1</sup>, M. Aznar<sup>1</sup>

<sup>1</sup>The Finsen Center - Rigshospitalet, Dept. of Oncology-Section of Radiotherapy, Copenhagen, Denmark

#### Purpose or Objective

Radiotherapy (RT) for locally advanced lung cancer has a high burden on dose to risk organs (OAR), such as lung, heart and oesophagus. Different strategies have been used to decrease the dose to OAR, such as volumetric modulated arc therapy (VMAT) and deep inspiration breath hold (DIBH). In this study we investigated VMAT combined with DIBH and non-coplanar (NC) treatment delivery.

#### Material and Methods

Patients with central lung tumours were selected from a cohort treated in a DIBH RT trial. VMAT plans were made clinically in both free breathing (FB) and DIBH and

consisted of two coplanar (C) partial or full arcs. For NC plans we aimed for RT delivery within 4-6 DIBHs of 20 s, as for the clinically delivered plans. Therefore an approach similar to butterfly VMAT was chosen, with two either 120° or 240° arcs at couch 0°, depending on clinical choice of partial or full arcs, and two 60° arcs at couch 90°. FB arc geometry was kept in DIBH, for both C and NC plans. Dose to OAR was compared between FB C, FB NC, DIBH C and DIBH NC plans.

#### Results

Twelve patients were included, five had central right and seven central left tumours. Total lung volume in DIBH increased by median 48% (range 20-82%) compared to FB. As expected DIBH reduced both mean lung dose (MLD) and lung V20 (median 2.2 Gy and 4.1%). NC VMAT plan decreased MLD and V20 compared to C VMAT with similar amount in both FB and DIBH (median -0.25 Gy and -1.5%). Figure shows impact of techniques on dose to ipsi- and contralateral lung. In right sided tumours, both MLD, lung V20 & V40 were smaller compared to left sided tumours. Mean heart dose (MHD) and heart V50 decreased with DIBH. NC VMAT had the opposite effect, since the two arcs delivered at couch 90° could often not avoid dose entrance through the heart. As anticipated, MHD, heart V50 and heart D2 (minimum dose to the hottest 2% of the heart) were largest in left sided tumours. However, in this small patients group, the observed heart dose parameters were much lower than clinically applied constraints. Still, trying to spare the heart may have resulted in larger lung doses in patients with left sided tumours in all plans (median MLD differences 0.5-2.5 Gy).

Mean oesophagus dose (MED) increased in DIBH, but was not affected by NC technique in either FB or DIBH. However, MED is not a clinically used constraint. Oesophagus V66 was smallest in DIBH C, but in none of the plans it reached close to its limit of 1cm3 (national guidelines' constraint).

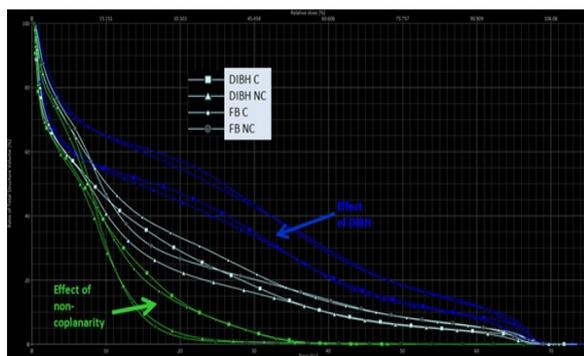

Dose to spinal cord was reduced with both NC and DIBH, with DIBH NC offering the best sparing. See Table for details on dose parameters and clinically used constraints.

Table 1 – dose parameters to organs at risk from conformal or non-conformal VMAT plans presented as median (range)

	FB C	FB NC	DIBH C	DIBH NC	clinical constraints
lung					
MLD [Gy]	16.4 (5.6-23.3)	16.3 (6.3-20.7)	14.2 (4.7-19.5)	13.48 (5.4-19.0)	20

FB = free breathing, DIBH = deep inspiration breath hold, C = conformal, NC = non-conformal, MLD = mean lung dose, MHD = mean heart dose, MED = mean oesophagus dose, Vx = volume receiving more than X Gy, D2 = lowest dose to the hottest 2% of the volume, Dmax = point maximum dose

Figure - Lung dose volume histogram, showing differences in lung dose for different plans:  
 - Non-coplanar (NC) plans reduced dose to the contralateral lung (green arrow) in both FB and DIBH.  
 - DIBH reduced dose to the ipsilateral lung (blue arrow) in both NC and coplanar (C) plans.  
 - Combination of DIBH and NC treatment delivery ensured lowest mean lung dose (white curves).

### Conclusion

Non-coplanar technique can reduce MLD, lung V20 and spinal cord dose in both FB and DIBH. While these reductions were relatively small in our patient group as a whole - and compared to reductions possible by DIBH alone - they were substantial in some patients. Therefore, the NC approach should be exploited in patients not compatible with DIBH for OAR dose reduction.

### EP-1549 Cyberknife Iris based versus InCise based plans for 20 cases of prostate oligonodal metastases

C.L. Chaw<sup>1</sup>, N.J. VanAs<sup>1</sup>, V.S. Khoo<sup>1</sup>

<sup>1</sup>Royal Marsden Hospital Trust & Institute of Cancer Research, Academic Uro-oncology, London, United Kingdom

### Purpose or Objective

To compare dosimetry and delivery efficiency between Iris collimator and InCise multileaf collimator (MLC) (Accuray Inc. Sunnyvale, CA) for patients with oligometastatic nodal disease from prostate cancer.

### Material and Methods

Treatment plans for 20 patients were performed on Multiplan<sup>TM</sup>5.1.3 treatment planning system utilizing MLC and Iris for 30Gy in 3 fractions. To minimize variation between cases, nodal metastases located in pelvis and abdomen with a distance of 0-10mm to organs at risk (OAR; rectum, small bowel and duodenum) were chosen. The clinical target volume (CTV) to planning target volume (PTV) margin is 3mm. Dosimetric evaluation included PTV coverage, CTV coverage, conformity index (CI), Paddick's new CI (nCI), homogeneity index, and gradient index. Treatment delivery efficiency is measured by beam delivery time (start of first beam to end of final beam, including beam-on-time, robot motion, and intra-fraction imaging), number of monitor units and number of beams used. OAR dose sparing were analysed by  $D_{max}$  small bowel dose constrained at D0.5cc: 25.2Gy, D5cc: 17.7Gy,  $D_{max}$  rectal dose constrained at D0.5cc: 28.2Gy and  $D_{max}$  duodenum constrained at D0.5cc: 22.2Gy; D5cc: 16.5Gy and D10cc: 11.4Gy. Statistical significance was tested using Wilcoxon signed rank test.

### Results

There were no statistically significant differences in conformity indices or target coverage, but MLC plans were more homogenous with small but significantly lower mean target dose than Iris (2% difference in PTV mean dose; 4.8% difference in CTV mean dose; all  $P < 0.001$ ). Gradient index was also improved by 13% using MLC plans ( $P < 0.001$ ). All OAR constraints were satisfied by both devices. The small bowel mean dose was significantly lower by 52% using MLC ( $p < 0.001$ ). There was a significant reduction in delivery time by 47% (mean 19.7 mins [range: 13-30 mins] vs 37.0 mins [24-56], total monitor units used by

46%, and 74% reduction in number of beams by 74% with the MLC-based plans (all  $p < 0.001$ ).

### Conclusion

Compared to the Iris, the InCise MLC produced comparable target coverage but was significantly better in dosimetry with significant improved delivery efficiency.

### EP-1550 Investigating the advantages of CyberKnife M6 MLC over Iris collimator for Liver SBRT plans

R. Doro<sup>1</sup>, L. Masi<sup>1</sup>, V. Di Cataldo<sup>2</sup>, S. Cipressi<sup>2</sup>, I.

Bonucci<sup>2</sup>, M. Loi<sup>3</sup>, L. Livi<sup>4</sup>

<sup>1</sup>IFCA, Medical Physics, Firenze, Italy

<sup>2</sup>IFCA, Radiation Oncology, Firenze, Italy

<sup>3</sup>University of Florence, Department of Clinical and Experimental Biomedical Sciences "Mario Serio", Firenze, Italy

<sup>4</sup>Azienda Ospedaliera Universitaria Careggi, Radiotherapy Unit, Firenze, Italy

### Purpose or Objective

The purpose of this study is to evaluate the performance of the CyberKnife M6 systems equipped with MLC for Liver SBRT plans. To this aim, MLC plans were compared to clinical plans generated using circular apertures.

### Material and Methods

21 clinical treatment plans for Liver SBRT created with IRIS variable aperture collimator were optimized again on Multiplan 5.3 TPS using MLC. Plans were created both for first and second treatment cases and were prescribed either in 3 or 5 fractions with prescription doses ranging from 30 Gy to 45 Gy. PTV dimensions ranged from 25.7 cm<sup>3</sup> to 233 cm<sup>3</sup>. The same OAR constraints were applied both for IRIS and MLC plans. Evaluation parameters of each plan included PTV coverage, Paddick's new CI (nCI), homogeneity index (HI), gradient index (GI) and prescription isodose. OAR (duodenum, stomach, bowel, hearth) dose sparing was analyzed using the maximum and mean doses (Dmean). Liver dose sparing was analyzed using mean dose and the volume either inside 15 Gy (3 fractions) or 21 Gy (5 fractions) isodose. The dose delivery efficiency was evaluated on the basis of planned monitor units (MUs) and the reported treatment time per fraction. The dose to the PTV was also summarized by the generalized equivalent uniform dose (gEUD), using  $a=-20$ . The mean values, standard deviation and p-values (two tailed Student's t test) were computed between the two comparison groups and statistical significance set at  $p < 0.05$ .

### Results

The evaluation parameters for the MLC and IRIS plans are shown in table 1. MLC plans achieved equivalent PTV coverage and conformity when compared to IRIS plans and minimized the low dose extension improving significantly ( $p < 0.001$ ) the dose fall-off gradient with GI increasing from 2.65 (MLC) to 3.13 (IRIS). Plans created using MLC were generally prescribed to higher isodose levels (73% vs 70.5%), which resulted in significantly more homogeneous dose inside the PTV (HI=1.37 vs HI=1.42,  $p=0.02$ ). This, however, did not affect significantly the PTV gEUD which was equivalent between IRIS and MLC. No significant difference was observed for OAR dose sparing between the two groups of plans, with the exception of Bowel mean dose which was significantly lower for MLC. Average treatment time was significantly ( $p=0.01$ ) reduced from 34.7 min. to 29.2 min when using MLC. MLC MU mean value was lower than IRIS MU, but statistical

significance was not reached.

Table 1. Comparison between IRIS and MLC over 21 Liver SBRT plans	IRIS	MLC	p
PTV coverage %	97.4 (1.44)	97.7 (1.4)	0.7
PTV gEUD Gy	40.3 (6.5)	40.1 (6.9)	0.9
Prescription isodose %	70.5 % (3.4)	73.2% (3.6)	0.03
nCI	1.15 (0.04)	1.16 (0.05)	0.42
HI	1.42 (0.06)	1.37 (0.07)	0.02
GI	3.13 (0.36)	2.65 (0.21)	< 0.001
Liver Dmean Gy	8.8 (4.0)	7.9 (3.4)	0.46
Liver V 15Gy(21Gy) cm <sup>3</sup>	160.0 (111.3)	138.6 (95.6)	0.53
Duodenum Dmean Gy	2.9 (2.8)	2.4 (2.4)	0.6
Stomach Dmean Gy	3.5 (1.4)	2.7 (1.5)	0.11
Bowel Dmean Gy	1.1 (0.8)	0.4 (0.4)	0.003
Treatment time (min)	34.7 (6.1)	29.2 (6.7)	0.01
MU	27561 (6660)	24044 (6650)	0.11

### Conclusion

MLC plans offer equivalent coverage and OAR dose sparing when compared to IRIS plans for Liver SBRT. An improvement in dose gradient was observed for MLC plans. MLC provided more efficient delivery with a significant reduction in treatment time. The need to prescribe to higher isodose levels when using MLC, requires, however, further investigation.

### EP-1551 Radiobiological optimization and plan evaluation in IMRT planning of prostate cancer

S. Cora<sup>1</sup>, H. Khoulil<sup>1</sup>, M. Bignotto<sup>1</sup>, G. Bolzicco<sup>2</sup>, A. Casetta<sup>2</sup>, C. Baiocchi<sup>2</sup>, P. Francescon<sup>1</sup>  
<sup>1</sup>Ospedale San Bortolo, Medical Physics, Vicenza, Italy  
<sup>2</sup>San Bortolo- Hospital, Radiotherapy Dept, Vicenza, Italy

#### Purpose or Objective

The aim of this study is to compare treatment plans optimized by dose volume objectives (DVO) to plans optimized with radiobiological objectives (RBO) or optimized by combining both DVO and RBO (Mixed)

#### Material and Methods

14 patients with prostate cancer previously treated with IMRT plans (Treatment Planning System: Pinnacle<sup>3</sup>) optimized by Dose Volume Objectives (DVO), were re-planned by radiobiological optimization of gEUD objective functions (RBO) and using combined DVO and RBO, (Mixed Objectives). The prescribed dose to the target of patients varies between 70-78 Gy, delivered in 2 Gy/fraction. The plans were evaluated by dose volume indices (Conformity Index, CI, for PTV and D1%, D15%, D25% and D40% for both rectum and bladder, where Dx is the Dose received by x% of the volume of the OAR) and by radiobiological indices (TCP, NTCP and complication free control probability P+). The Poisson\LQ model and Kallman s-model were used in calculation of TCP and NTCP, respectively.

#### Results

The mean and standard deviation (SD) values of TCP for DVO, RBO and Mixed objectives plans were 0.914±0.05, 0.895±0.07 and 0.912±0.06 respectively. Mean and SD values for NTCP were 0.0413±0.03, 0.0387±0.02 and 0.0365±0.03 for DVO, RBO and Mixed respectively, while P+ mean and SD values for the three objective techniques were 0.872±0.06, 0.8557±0.07 and 0.874±0.05, respectively. The mean value of CI of PTV and D40% for rectum and bladder were 0.805±0.08, 34±0.18Gy, 28±0.6 Gy for DVO, 0.739±0.11, 21.4±0.27 Gy, 21.7±0.72 Gy for RBO and 0.853±0.045, 25.9±0.22 Gy, 22.6±0.72 Gy for mixed objectives.

#### Conclusion

For OAR mean dose values we found that RBO gives the lowest doses compared to both DVO and mixed plans, while TCP values in DVO and Mixed plans were better than RBO. DVO and Mixed plans provide comparable TCP values while RBO gives the lowest TCP values. As to CI, Mixed plans win over both DVO and RBO. In conclusion, by using mixed radiobiological and dose-volume objectives it improves the conformity to the target and also NTCP of

the plan, giving at the same time a comparable TCP as DVO plans.

### EP-1552 Robust optimization for IMPT of pencil-beam scanning proton therapy for prostate cancer

C.L. Brouwer<sup>1</sup>, W.P. Matysiak<sup>1</sup>, P. Klinker<sup>1</sup>, M. Spijkerman-Bergsma<sup>1</sup>, C. Hammer<sup>1</sup>, A.C.M. Van den Bergh<sup>1</sup>, J.A. Langendijk<sup>1</sup>, D. Scandurra<sup>1</sup>, E.W. Korevaar<sup>1</sup>  
<sup>1</sup>University of Groningen- University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

#### Purpose or Objective

Proton therapy for prostate cancer has the potential of delivering high dose to the tumor whilst sparing normal tissue to minimize GI/GU toxicity. In the traditional PTV-based multifield optimized intensity modulated proton therapy (MFO-IMPT) approach to treatment planning for prostate cancer, the PTV is commonly defined through expansion of the CTV to account for setup and range uncertainties. In contrast to this method, the robust optimization approach to IMPT planning does not require the intermediate and somewhat arbitrary step of defining the PTV. Instead, the optimizer is tasked with finding a treatment plan which best meets the clinical objectives under the setup and beam range uncertainties which are explicitly expressed as the input parameters to the treatment planning process. The goal of this study was to apply the robust optimization method for IMPT treatment planning for prostate cancer and evaluate the results against the traditional PTV-based IMPT treatment planning strategy.

#### Material and Methods

For five T<sub>1-3</sub>N<sub>0</sub>M<sub>0</sub> prostate cancer patients two types of MFO-IMPT treatment plans were created in Raystation 4.99 (RaySearch Laboratories AB, Sweden) treatment planning system: a PTV-based plan and a robustly optimized CTV-based plan. The PTV margin for CTV<sub>70</sub> was defined as 5 mm in all directions. The robustness parameters for the robust optimization were set to 5 mm and 3% for setup translational uncertainty and range uncertainty, respectively, and the optimization was performed using the 'minimax' method implemented in Raystation. Treatment plans were normalized to D<sub>98%</sub> of the CTV<sub>77</sub>. The plans were evaluated for robustness by simulating translational and rotational setup errors of the planning CT by ±5 mm and ±2° (yaw and roll), respectively. In addition, the range uncertainty was simulated by scaling the HU of the planning CT by ±3%. By combining the above robustness evaluation modes a total of 260 dose scenarios per plan was obtained. The target coverage robustness was assessed by comparing the voxelwise-minimum (a metric constructed by finding a minimum value of dose in each voxel independently for all the dose scenarios) and average V<sub>95%</sub> of the CTV<sub>70</sub>. To compare dose to the rectum, the entire DVH of the rectum was evaluated for the nominal dose as well as the voxelwise-maximum dose.

#### Results

The V<sub>95%</sub> of the CTV<sub>70</sub> calculated from the voxelwise-minimum DVHs were consistent (>99%). Also, the average V<sub>95%</sub> over all dose scenarios of the CTV<sub>70</sub> were comparable (>99%). The benefit of the robust treatment planning approach was apparent for the rectum dose where the dose is lower for the robustly optimized plan in both the nominal as well as in the perturbed dose scenarios (nominal and voxelwise-maximum dose presented in Figure 1). Only for doses >70 Gy, the CTV-based plans resulted in a slightly higher irradiated rectum volume than the PTV-based plans.

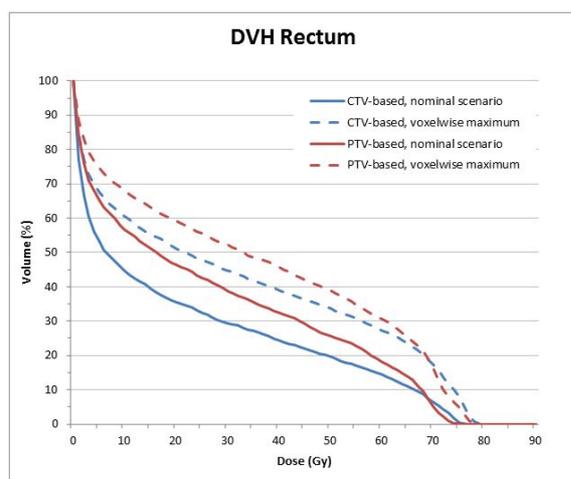

Figure 1. DVH of the rectum for the CTV-based as well as the PTV-based IMPT treatment plan

### Conclusion

The CTV-based robustly optimized treatment plans maintain target coverage, while providing a lower dose to the rectum.

### EP-1553 Dose reduction of femoral heads using volumetric-modulated Dynamic WaveArc for prostate cancer

K. Nakamura<sup>1</sup>, T. Mizowaki<sup>1</sup>, M. Uto<sup>1</sup>, N. Mukumoto<sup>1</sup>, Y. Miyabe<sup>1</sup>, T. Ono<sup>1</sup>, H. Hirashima<sup>1</sup>, K. Yokota<sup>1</sup>, H. Hiraoka<sup>1</sup>  
<sup>1</sup>Kyoto University- Graduate School of Medicine, Radiation Oncology and Image-Applied Therapy, Kyoto, Japan

### Purpose or Objective

Although hip fracture is a rare complication in radiation therapy for prostate cancer (PCa), it is a major cause of morbidity and mortality in elderly patients. Therefore, the femoral heads are the major organs at risk (OARs) in treatment planning of PCa and reduction of doses to the femoral heads could be important. A new irradiation technique, termed volumetric-modulated Dynamic WaveArc (DWA), has been developed. Figure 1 shows the trajectory of DWA beam. An X-ray head with multileaf collimators mounted on an O-ring gantry allows combining simultaneous rotation of the gantry and O-ring, resulting in sequential noncoplanar intensity-modulated beam delivery in a short treatment time, without a couch rotation. Since the bilateral femoral heads were located on the same level as the planning target volume (PTV) in PCa patients, DWA would reduce the doses to the bilateral femoral heads. We performed a planning study using coplanar volumetric-modulated arc therapy (coVMAT) and DWA to compare the dose distribution of PTV and OARs,

beam-on time, and monitor units (MU).

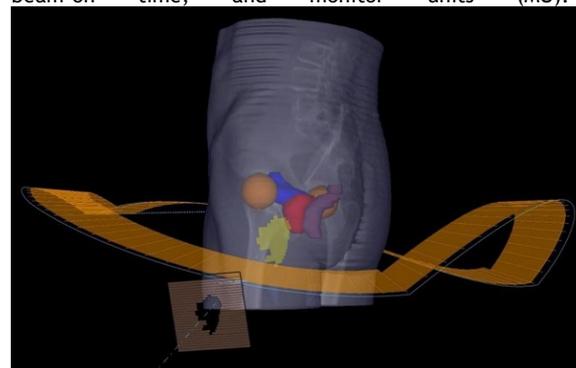

Figure 1 Trajectory of DWA beam.

Red: PTV, Orange: Bilateral femoral heads, Brown: Rectum, Blue: Bladder

### Material and Methods

The coVMAT and DWA plans were created for 20 patients with PCa respectively using RayStation version 4.7 and Vero4DRT. All plans were created using one full arc and the prescribed dose was 76 Gy in 38 fractions as a mean dose to PTV. We compared the dose distributions of OARs (bilateral femoral heads, rectal wall, and bladder wall) and PTV, beam-on time, and MU using a paired t test, and a significance level of less than 5% ( $p < 0.05$ ) was considered statistically significant.

### Results

Table 1 shows the plan comparison between coVMAT and DWA. The mean doses and D1cc of the bilateral femoral heads in coVMAT/DWA plans were 11.8/9.1 Gy ( $p < 0.001$ ) and 21.8/18.5 Gy ( $p < 0.001$ ), respectively. Although the mean volume of bladder wall irradiated greater than 10, 20, 30 and 40 Gy (V10-40) were significantly larger in DWA plans compared with coVMAT, the mean volume of rectal wall irradiated greater than 10, 20, and 70 Gy (V10, V20, and V70) were significantly smaller in DWA plans. The conformity index and homogeneity index were similar in both plans. The mean beam-on time and MU in coVMAT/DWA plans were 70.6/73.5 seconds ( $p = 0.045$ ) and 427/454 MU ( $p = 0.041$ ), respectively.

Table 1 Plan comparison between coVMAT and DWA

	coVMAT	DWA	p-value
<b>Femoral Heads</b>			
Mean Dose [Gy]	11.8	9.11	< 0.001*
D1cc [Gy]	21.8	18.5	< 0.001*
<b>Rectal Wall</b>			
V10 [%]	95.4	91.4	< 0.001*
V20 [%]	86.9	83.4	< 0.001*
V30 [%]	64.6	65.4	0.64
V40 [%]	35.3	35.4	0.82
V50 [%]	25.5	25.7	0.35
V60 [%]	18.7	18.6	0.35
V70 [%]	9.22	8.04	< 0.001*
<b>Bladder Wall</b>			
V10 [%]	52.2	60.1	< 0.001*
V20 [%]	43.2	45.8	0.001*
V30 [%]	33.4	35.2	0.006*
V40 [%]	26.2	26.7	0.03*
V50 [%]	20.9	21.2	0.08
V60 [%]	17.0	17.1	0.80
V70 [%]	13.3	13.2	0.06
Conformity index	89.51	89.48	0.63
Homogeneity index	11.03	11.48	0.42
Beam-on time [sec]	70.6	73.5	0.045*
Monitor unit [MU]	427	454	0.041*

\* Asterisks (\*) indicate the statistical significance of the factors.

## Conclusion

Although DWA increased the V10-40 of bladder wall, beam-on time, and MU, DWA significantly reduced the mean doses and D1cc of the bilateral femoral heads. DWA also significantly reduced the V10, V20 and V70 of rectal wall. DWA seems to be a promising irradiation technique for prostate cancer.

## EP-1554 Partially ablative VMAT for large tumors using simultaneous integrated boost: a proof of concept

<sup>2</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"- Università Cattolica del Sacro Cuore, Radiation Oncology Unit, Campobasso, Italy

<sup>3</sup>Università di Bologna, Radiation Oncology Center- Department of Experimental- Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

<sup>4</sup>Ospedale Bellaria, Radiation Oncology Department, Bologna, Italy

<sup>5</sup>Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Radiation Oncology Department, Roma, Italy

## Purpose or Objective

The aim of this study was to assess the feasibility in the delivery of highly heterogeneous doses to symptomatic large tumor using VMAT technique and simultaneous integrated boost during a short course palliative accelerated radiotherapy.

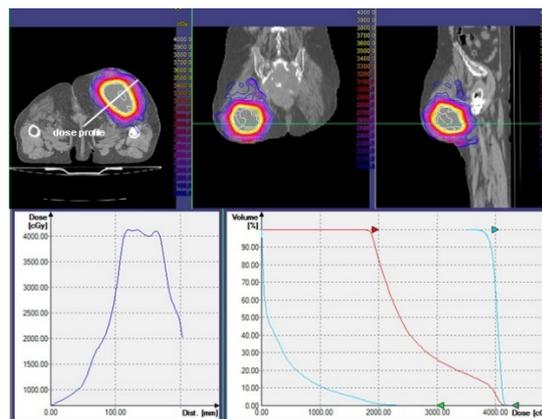

## Material and Methods

For this dosimetric analysis we selected a patient with a large symptomatic sarcoma. A Planning Target Volume (PTV) and a Boost Target Volume (BTV) were defined as the GTV plus and minus 1cm, respectively. Two different doses were simultaneously delivered to the PTV and BTV according to a dose-escalation protocol in 4 fractions. Five dose levels were planned: Level 1 (basal plan: PTV: 20Gy/5Gy), Level 2 (PTV: 20Gy/5Gy; BTV: 25Gy/6.25Gy), Level 3 (PTV: 20Gy/5Gy; BTV: 30Gy/7.5Gy), Level 4 (PTV: 20Gy/5Gy; BTV: 35Gy/8.75Gy) and Level 5 (PTV: 20Gy/5Gy; BTV: 40Gy/10Gy). The aim was to irradiate the central part of the tumor up to 10Gy/fraction while maintaining the border area of the tumor and the surrounding healthy tissues with <5Gy/fraction. SIB-VMAT plans were generated using Oncentra Masterplan TPS, in the dual-arc modality. The mean dose, D98%, D95% and D2% doses were scored for each target. A conformity index, PTV\_CI, defined as the volume encompassed by the PTV 95% isodose divided by the PTV volume, was calculated. A dose contrast index (DCI) was defined as the mean dose to the BTV divided by the mean dose to the PTV (excluding BTV). For healthy tissue, an integral dose, Dint, was defined as the product of mean dose and volume of normal tissue, excluding the PTV. This was reported together with the irradiated volumes at the dose levels of 5, 10, 15 and 20Gy (V5, V10, V15 and V20).

## Results

Overall results are reported in Table 1. When BTV dose escalated up to 200% of PTV prescription, the PTV\_CI increase was <8% (from 1.11 to 1.20), proving that SIB strategy was able to reduce the dose to the BTV surrounding volume despite the major dose escalation. Similarly the percentage increase of ID to normal tissues was 11%. The increase in healthy tissues receiving more than 5, 10, 15 and 20 Gy was about 2%. Deviation from the ideal contrast dose slightly increased with increased BTV dose.

	Dose level 1 basal	Dose level 2	Dose level 3	Dose level 4	Dose level 5	Dose level 5 sequential
<b>PTV (excluding BTV)</b>						
Prescription dose (Gy)	20	20	20	20	20	20

V5 (%)	22	22.5	22.7	23.0	23.5	28.7
V10 (%)	9.1	10.5	10.6	10.8	11.1	11.1
V15 (%)	3.6	5.2	5.3	5.3	5.3	6.3
V20 (%)	0.1	0.44	0.5	0.9	1.0	2.4
<b>Conformity and dose contrast indexes</b>						
CI_PTV	1.11	1.14	1.18	1.19	1.20	1.45
DC	1.00	1.23	1.44	1.50	1.49	1.27
NDC	1.00	0.98	0.96	0.88	0.81	0.89

## Conclusion

We quantified the capability of SIB-VMAT to deliver highly heterogeneous doses in the treatment of large tumors. Despite the major dose escalation in the BTV, the dose conformity to PTV and the integral dose to the normal tissue minimally increased, with a slow increase of dose spillage from PTV to normal tissue. The safe delivery of ablative dose in the central part of the tumor has the potential to greatly improve the palliative effect.

## EP-1555 Improving inter-planner variability in head and neck (H&N) VMAT

H. James<sup>1</sup>, C. Scrase<sup>2</sup>, K. Yip<sup>2</sup>

<sup>1</sup>Suffolk Oncology Centre The Ipswich Hospital, Radiotherapy Physics, Ipswich Suffolk, United Kingdom

<sup>2</sup>Suffolk Oncology Centre The Ipswich Hospital, Clinical Oncology, Ipswich Suffolk, United Kingdom

**Purpose or Objective** Inverse plan optimisation for H&N VMAT is resource intensive. Variation exists between planners when determining optimal solutions. Re-optimisation of sub-optimal plans impacts upon the patient pathway. In our institution class solutions and dose assessment criteria improve consistency in prostate VMAT planning. In this study inter-planner variability was assessed for H&N VMAT. Analysis of plans and shared learning informed the development of optimisation templates to improve consistency and meet clinician expectations. **Material and Methods** VMAT plans for a radical tonsil treatment were created by 10 individuals with varying levels of experience. Plans were expected to meet or exceed pre-defined PTV and PORV dose requirements. Planners used their own judgement to determine optimisation objectives and priorities, define dummy structures and assess whether an optimal plan had been produced. Quantitative dosimetric analysis of the plans covered 3 areas - PTV coverage (conformity index (CI), homogeneity index (HI)), PORV doses and dose spill. Parameters were scored against a gold standard and ranked. Plans were independently reviewed by 2 clinicians

specialising in H&N RT and their assessments were compared with quantitative analysis. Optimisation objectives and priorities and the use of dummy organs were analysed in conjunction with the dose distributions. **Results** Each plan met the pre-defined PTV and PORV doses. There was no significant variation in HI (1.05-1.09) regardless of the priorities applied in the optimisation. A larger variation in CI (1.07-1.18) was attributed to use of the Normal Tissue Objective function. There were variations in dose to normal tissues as planners applied varying dose constraints to keep doses as low as reasonably practicable without compromising PTV coverage. Clinician reviews picked up more subtle but potentially clinically relevant variations between plans - high dose spill, dose spread across mid-line and over-zealous sparing of normal tissues. The plans scored most highly by the clinicians were created by the most experienced planners who took less time to reach an "optimal" solution. **Conclusion** There is a relatively consistent approach to H&N VMAT planning within our institution. This study has highlighted where differences between optimisation objectives and priorities and the use of dummy structures can lead to subtle variations in dose distributions which may not be detected in quantitative analysis but may affect acceptability. More experienced planners familiar with clinician expectations demonstrated improved judgement when determining an optimal plan. Shared learning has enabled a more consistent approach to H&N plan optimisation and an improved understanding of what is achievable and clinically acceptable. This has benefitted both planners and clinicians. In addition, the creation of plan optimisation templates, based on the findings of this study, are aimed at a consistent optimisation resulting in improvements in the patient pathway.

#### EP-1556 Dosimetric commissioning of a TPS for a synchrotron-based proton PBS delivery system

G. Kragl<sup>1</sup>, T. Böhlen<sup>1</sup>, A. Carlino<sup>1,2</sup>, L. Grevillot<sup>1</sup>, H. Palmans<sup>3</sup>, A. Elia<sup>1</sup>, B. Knäust<sup>1</sup>, J. Osorio<sup>1</sup>, R. Dreindl<sup>1</sup>, J. Hopfgartner<sup>1</sup>, S. Vatnitsky<sup>1</sup>, M. Stock<sup>1</sup>

<sup>1</sup>EBG MedAustron GmbH, Medical Department, Wiener Neustadt, Austria

<sup>2</sup>University of Palermo, Department of Physics and Chemistry, Palermo, Italy

<sup>3</sup>National Physics Laboratory, Radiation Dosimetry, Teddington, United Kingdom

#### Purpose or Objective

To provide an overview regarding dosimetric commissioning of the TPS RayStation for proton PBS delivery installed at a synchrotron-based dual particle facility. 1D/2D commissioning consisted of benchmarking the dose calculation algorithm against measured IDD, on-axis lateral spot profiles in air and field size factors as well as comparisons of absolute dosimetry. 3D commissioning consisted of absolute dose comparisons in the SOBP of cubic targets in water as well as the characterization of 3D dose distributions with increasing complexity. A robotic patient positioning system was used rather than extendable snouts to reduce the air gap between patient and nozzle. Therefore, special attention was paid to non-isocentric setups.

#### Material and Methods

Commissioning was performed for the PB algorithm (version 3.5) integrated in RayStation (version 5.0.2). IDDs were acquired with a Bragg peak chamber (PTW) and corrected for insufficient detector size by means of MC simulations (GATE/GEANT4). Spot profiles in air were acquired with a scintillating screen (Lynx, IBA) at 7 air gaps. Absolute dosimetry was performed with a Roos chamber (PTW) in 12 x 12 cm<sup>2</sup> fields (2 mm lateral spot spacing) for 20 energies. Field size factors were acquired

with a semiflex ionization chamber (PTW) at 3 depths in water for field sizes ranging from 2 x 2 to 20 x 20 cm<sup>2</sup>. 3D dose distributions were characterized using 24-PinPoint chamber arrays (PTW).

#### Results

Calculated ranges agreed within 0.2 mm with measured ranges. The integrals of measured and calculated IDDs agreed within 0.5% for clinically relevant ranges. At isocenter, calculated and measured spot sizes (FWHM) differed on average less than 0.4 mm in x- and y-directions. For non-isocentric setups differences were within 0.5 mm. Field size factors always agreed within 4%; deviations were generally low (<1%) and increased only at small field sizes and the highest energies (range >30 cm). For isocentric arrangements, absolute dose agreed within 2.2% in the center of SOBPs of cubic targets with different sizes and at different depths. As expected, the deviations increased for plans with range shifter for non-isocentric arrangements. Variations of up to 3.5% were obtained for modulation widths of 6 cm. Results for more complex geometries are currently under investigation.

#### Conclusion

Clinically acceptable results were obtained for open beams. For plans with range shifter, a scaling of dose distributions might be considered until the upcoming MC dose calculation algorithm is available. Minimizing the air gap to reduce modelling inaccuracies with respect to scattered protons in air is beneficial for these cases and realized by non-isocentric treatments.

#### EP-1557 Minimum prescription concept for dose painting increases robustness towards geometrical uncertainty

S. Korreman<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

#### Purpose or Objective

Dose painting radiotherapy with heterogeneous dose escalation is vulnerable to geometrical errors, which potentially deteriorate the benefits of dose escalation substantially. This study investigates use of a minimum prescription concept to increase plan robustness towards geometrical uncertainties.

#### Material and Methods

Dose escalation was prescribed based on PET Cu-ATSM tracer uptake for a head and neck cancer patient, with a high degree of heterogeneity in the uptake. The minimum dose was 60Gy, and dose escalation was prescribed based on a linear correspondence model to the tracer uptake, with a maximum escalation up to ~90Gy. Dose painting plans were optimized using the Eclipse treatment planning system, using modulated arc therapy technique in a contour-based dose escalation scheme (5 levels). Two planning strategies were tested: (1) Minimum and maximum dose constraints imposed on all subvolumes (exact-map), and (2) minimum constraints on all subvolumes with only one overall maximum constraint (minimum-map). Geometrical error was simulated by displacing the isocenter with up to 2 mm. Quality index metrics were compared for the two planning strategies.

#### Results

For both strategies, optimizations could be performed with good adherence to dose constraints. For the exact-map technique, the fraction of voxels with quality index within plus/minus 5% of prescription dose was ~79%, and the fraction of voxels above 95% of prescription dose was ~93%. For the minimum-map technique, the fraction of voxels above 95% of prescription dose was ~97%. With displacement of 2 mm, the >95% fraction changed to ~85% for exact-map, and ~95% for minimum-map technique.

## Conclusion

Using a minimum dose concept for dose painting with only an overall maximum constraint gives more robust plans than a voxel-by-voxel exact dose prescription, while maintaining maximum dose constraints. Highest adherence to dose painting degree of heterogeneity could be obtained with the minimum-map approach.

**EP-1558 Dosimetric evaluation of incidental radiation of internal mammary chain in breast cancer with 3D RT**  
A.C. Ciafre<sup>1</sup>, J. Castilla<sup>1</sup>, C. Domingo<sup>1</sup>, E. Jorda<sup>1</sup>, D. Dualde<sup>1</sup>, E. Ferrer<sup>1</sup>  
<sup>1</sup>Hospital Clinico Universitario, Oncologia Radioterapica, Valencia, Spain

## Purpose or Objective

The internal mammary chain represents a less common yet important route of lymphatic drainage of breast cancer, constituting a matter of debate in the current clinical practice. Poortmans P. 2015 suggests an improvement of disease-free survival, distant disease-free survival and a reduction of breast cancer mortality when they included the internal mammary and medial supraclavicular lymph-node irradiation. This study intends to determinate the incidental coverage and dose distribution of the internal mammary chain in breast cancer treatment, using tangential and opposite fields with 3D External Radiotherapy.

## Material and Methods

We randomly reviewed 47 female patients treated at one institution between January and December of 2013 with an average age of 62 years. Thirty seven patients (78%) had invasive ductal carcinoma (IDC), and 10 patients (21.2%) other histology types; Her2: Negative (82%), hormonal receptors were positive in all of them, 30 affecting the left and 17 the right breast. The majority of tumours were <2cm (n:41/47). Lumpectomy + Sentinel node biopsy (SLN) was performed in 36 patients, one of them with posterior axillary lymph node dissection due to positivity of SNL and the remaining patients were candidates for axillary lymph node dissection. External radiotherapy was administered exclusively on the breast with tangential and opposite fields with total dose: 50Gy in 5 weeks with 5 fractions per week (200cGy per fraction). Once the treatment was completed, we contour the internal mammary chain according to the Breast Atlas for radiation therapy planning consensus definitions of the RTOG.

## Results

With an average volume of the internal mammary chain of 4.13 cm<sup>3</sup>, the median minimal dose and maximal dose delivered was 278cGy and 4008cGy respectively, this last one corresponding to 8% of Total dose prescribed for the mammary gland. The median V95 was 297.04cGy.

## Conclusion

The radiation of the internal mammary chain on patients of this study have showed minimal incidental doses, therefore we concluded that the contouring, volume delimitation and dose prescription has been appropriated by not affecting unwanted areas. In the other hand unintended radiation of internal mammary chain turns out as insufficient to treat subclinical disease.

**EP-1559 Optimizing the risks for deterministic effects and secondary malignancies in bladder and rectum**

G. Komisopoulos<sup>1</sup>, C. Buckley<sup>2</sup>, S. Stathakis<sup>3</sup>, M. Mavroei<sup>4</sup>, G.P. Swanson<sup>5</sup>, D. Baltas<sup>6</sup>, N. Papanikolaou<sup>3</sup>, P. Mavroidis<sup>4</sup>

<sup>1</sup>University Hospital of Larissa and General Hospital of Larissa- Greece, Medical Physics, Larissa, Greece

<sup>2</sup>Mayo Clinic- AZ, Radiation Oncology, Scottsdale, USA

<sup>3</sup>University of Texas Health Sciences Center at San Antonio, Radiation Oncology, San Antonio- TX, USA

<sup>4</sup>University of North Carolina, Radiation Oncology, Chapel Hill, USA

<sup>5</sup>Baylor Scott & White Healthcare Temple Clinic, Radiation Oncology, Temple- TX, USA

<sup>6</sup>University of Freiburg & German Cancer Consortium DKTK- Partner Site, Radiation Oncology-, Freiburg, Germany

## Purpose or Objective

To use radiobiological metrics to estimate the effectiveness of IMRT and Conformal Radiation Therapy (CRT) modalities in treating prostate tumors. Additionally, to estimate the risk of secondary malignancies in bladder and rectum due to radiotherapy from these treatment modalities.

## Material and Methods

For ten prostate cancer patients, IMRT and CRT plans were developed. For the IMRT plans, two beam energies (6 and 18 MV) and two treatment protocols were used (RTOG 0415 and FCCC). For the evaluation of the deterministic effects of these plans, the tumor control probabilities (TCP) and normal tissues complication probabilities (NTCP) were calculated using the LQ-Poisson and Relative Seriality models. Additionally, the complication-free tumor control probability and the biologically effective uniform dose were calculated for each plan. The risks for secondary malignancies were calculated for bladder and rectum for the different treatment modalities using the LQ model proposed by UNSCEAR.

## Results

The deterministic response probabilities of bladder were lower than those of rectum in all the plans. For bladder, the highest value was for the IMRT FCCC-18X (0.03%) and the lowest for the CRT-18X modality (0.0%). For rectum, the highest value was for the IMRT RTOG-6X (3.52%) and the lowest for the IMRT FCCC-18X modality (0.41%). The average risk for secondary malignancy was lower for bladder (0.37%) compared to rectum (0.81%) based on all the treatment plans of the ten prostate cancer patients. The highest average risk for secondary malignancy for bladder and rectum was for the CRT-6X modality (0.46% and 1.12%, respectively) and the lowest was for the IMRT RTOG-18X modality (0.33% and 0.56%, respectively).

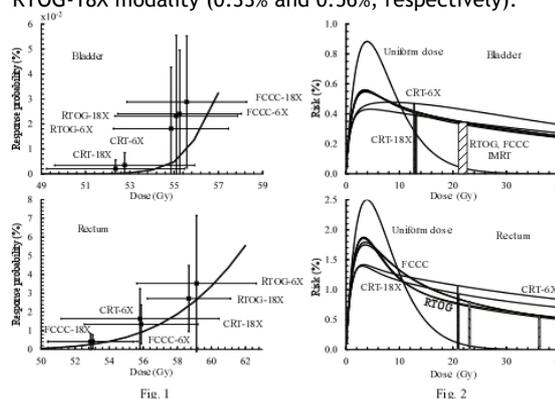

Fig. 1 shows the dose-responses of bladder and rectum for a range of uniform doses for the different radiation modalities. Additionally, the average response of each modality is plotted accompanied by error bars indicating the standard deviations of response and dose within the patient group. In Fig. 2, the average distributions of the risk for secondary malignancy in bladder (upper) and rectum (lower) as a function of dose are presented for the different modalities and protocols. The vertical lines indicate the mean doses that are delivered to the bladder and rectum by the examined treatment plans. The thick solid line corresponds to uniform irradiation of the organ.

## Conclusion

IMRT plans produced using the RTOG 0415 criteria had equivalent dosimetric results with the CRT plans. General

constraints seem suboptimal for sparing rectum when using IMRT. However, tighter dose constraints may result in higher dose inhomogeneities in the PTV. The treatment modalities that had lower NTCP values were inferior in many cases regarding the risk for secondary malignancies. Consequently, the optimization of different treatment modalities and plans should be complemented by the estimation of the corresponding risks for developing secondary malignancies.

#### EP-1560 Left breast cancer planning with VMAT technique: the dosimetric trade-offs

A. Fogliata<sup>1</sup>, J. Seppala<sup>2</sup>, G. Reggiori<sup>1</sup>, F. Lobefalo<sup>1</sup>, V. Palumbo<sup>1</sup>, F. De Rose<sup>1</sup>, D. Franceschini<sup>1</sup>, M. Scorsetti<sup>3</sup>, L. Cozzi<sup>3</sup>

<sup>1</sup>Humanitas Research Hospital, Radiation Oncology, Milan-Rozzano, Italy

<sup>2</sup>Kuopio University Hospital, Cancer Center, Kuopio, Finland

<sup>3</sup>Humanitas Cancer Center and Humanitas University, Radiation Oncology, Milan-Rozzano, Italy

#### Purpose or Objective

: Intensity modulation with volumetric modulated arc therapy (VMAT) for breast cancer treatment has been explored, proving that, as a trade-off of improved target dose distributions, larger volumes of the surrounding tissues receive a more or less pronounced low dose bath. Clinical results demonstrating a detrimental effect of the low-dose bath, related to volume and dose levels, with respect to the two-tangential beam dose delivery, or the associated risk of secondary cancer induction, are currently not available. In the absence of such data, a good approach is to drive the inverse VMAT optimization processes to decrease the dose to all the critical structures as much as possible, and to maximize the target dose homogeneity. This can be primarily achieved by means of adequate beam arrangement, and by highly restrictive planning objectives, more restrictive than the clinical need. Scope of this work is to evaluate the possible trade-offs in breast VMAT planning, exploring the degree of achievable dosimetric sparing of different organs at risk (OAR) by using two quite similar VMAT plan settings.

#### Material and Methods

CT scans of 20 patients presenting left sided breast cancer, in deep inspiration breath hold, were studied. VMAT plans were optimized for the RapidArc technique in the Eclipse treatment planning system (Varian) using the PO algorithm and were calculated with Acuros, to deliver 40.05Gy to mean target dose in 15 fractions. Two partial arcs were arranged for 6MV, Millennium MLC from a TrueBeam linac (Varian). Two plans per patient were optimized: RA\_full, where the optimizer used the entire partial arc trajectory, and RA\_avoid, where sectors (set from -0 to -105 degree) of MU=0 were set. Common dose objectives included a stringent dose homogeneity, mean dose to heart <5Gy, ipsilateral lung <8Gy, contralateral lung <2Gy, contralateral breast <3Gy.

#### Results

RA\_full showed a better dose conformity, lower high dose volumes in healthy tissue and lower skin dose. The NTHD (normal tissue high dose, defined as the uninvolved tissue receiving 90% of the dose prescription relative to the volume of the target) resulted in 18% and 31% for RA\_full and RA\_avoid, respectively. RA\_avoid presented a reduction of the mean doses for all critical structures: 51% to heart, 12% to ipsilateral lung, 81% to contralateral lung, 73% to contralateral breast. All differences were significant with  $p < 0.0001$ .

#### Conclusion

The adaptation of VMAT options to planning objectives reduced significantly the healthy tissue dose levels at the price of some high dose spillage. Evaluation of the trade-

offs to apply to the different critical structures should drive in improving the usage of the VMAT technique for breast cancer treatment, as the choice of the trade-offs would affect the possible future late toxicity and secondary cancer induction risk.

#### EP-1561 Comparison of heart, lung doses, and skin toxicity from different breast cancer RT techniques.

M. Lizondo<sup>1</sup>, N. Jornet<sup>2</sup>, M.J. Fuentes-Raspall<sup>3</sup>, P. Carrasco<sup>2</sup>, A. Latorre-Musoll<sup>2</sup>, A. Ruiz-Martinez<sup>2</sup>, T. Eudaldo<sup>2</sup>, P. Delgado-Tapia<sup>2</sup>, C. Cases<sup>2</sup>, M. Ribas<sup>2</sup>

<sup>1</sup>Institut de Recerca Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain

<sup>2</sup>Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain

<sup>3</sup>Hospital de la Santa Creu i Sant Pau, Servei d'Oncologia Radioteràpica, Barcelona, Spain

#### Purpose or Objective

The aim of this study was to assess whether there are significant differences in lung and heart doses for different breast cancer radiotherapy techniques. This study is based on a plan comparison from the dosimetric and patient data prospectively collected in a breast RT treatment database. Patient and treatment risk factors for acute skin toxicity were analysed.

#### Material and Methods

Patient, treatment variables and treatment-related outcomes were abstracted for 469 breast cancer patients who completed radiotherapy treatment from 2013 to 2016. We selected patients with similar nominal dose to the whole breast (50 Gy) and to the boost (EQD2 66 Gy), patients with no electron boost were excluded. We also included patients with lymph nodes (LN), irradiation (50Gy). The available techniques were 3DCRT and IMRT and from April 2016 onwards, deep inspiration breath hold (DIBH) is used for all left breast patients.

Following our technique decision criteria, all boost areas deeper than the range of our highest e- energy, are treated with integrated boost using IMRT. And till 2016, left breast cancer patient not fulfilling heart and/or lung dose restrictions with 3DCRT were moved to IMRT. For each patient, the technique was chosen in order to maximize PTV coverage and homogeneity while keeping doses to OAR as low as possible.

Heart dose ( $D_{mean}$ ,  $V_{25}$ ) and the ipsilateral lung dose ( $V_{20}$ ) values were compared separately as a function of laterality for patients undergoing 3DCRT (with and without DIBH) or IMRT. Correlation tests were made between maximum acute skin toxicity and technique, season, skin photo-type, breast volume and smoking habits. **Results**

Table 1 shows mean values and significance results. For right-sided breast patients, heart  $D_{mean}$  was significantly lower for 3DCRT techniques than for IMRT techniques, while heart  $V_{25}$  and lung  $V_{20}$  are not significantly different. For left-sided breast patients heart  $D_{mean}$  was lower but heart  $V_{25}$  was higher with the 3DCRT techniques than with IMRT techniques when LN were not included, and heart  $D_{mean}$  also when LN were included. Lung  $V_{20}$  was not significantly different. For those patients treated with DIBH, heart  $D_{mean}$  and heart  $V_{25}$  were considerably lower. Skin toxicity shows a significant correlation with breast volume ( $p=0.01$ ) but not with technique, smoking habits, skin photo type or period of the year in which the patient was treated.

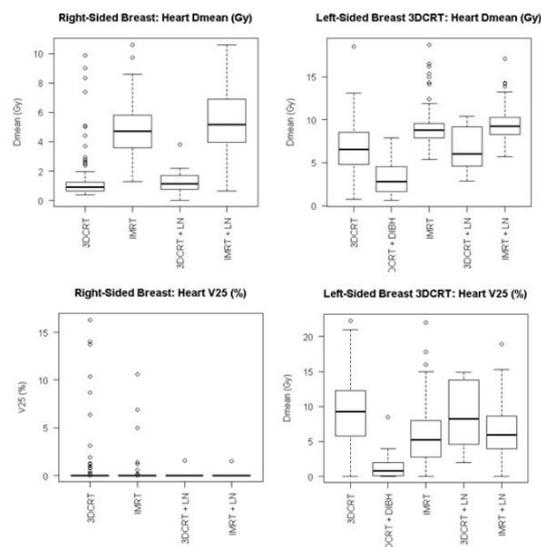

Right						
	3DCRT	IMRT	p	3DCRT+LN	IMRT+LN	p
Heart Dmean (Gy)	1.27	4.97	<0,001	1,33	5,53	<0,001
Heart V25 (%)	0.53	0,57	0,999	0,08	0,27	0,994
Lung V20 (%)	20,21	18,91	0,452	29,17	26,05	0,376
N (No. patients)	153	46		21	11	

Left						
	3DCRT	IMRT	p	3DCRT+LN	IMRT+LN	p
Heart Dmean (Gy)	6,59	9,32	<0,001	6,64	9,71	0,010
Heart V25 (%)	9,01	6,02	<0,001	8,47	6,5	0,642
Lung V20 (%)	18,96	18,66	0,984	28,08	24,62	0,295
N (No. patients)	106	71		10	41	

Left			
3DCRT		p	
DIBH	No DIBH		
Heart Dmean (Gy)	2,54	6,59	<0,001
Heart V25 (%)	1,73	9,01	<0,001
Lung V20 (%)	15,66	18,96	0,079
N (No. patients)	10	106	

### Conclusion

The use of IMRT for SIB in right breast has to be limited to those patients for which electron boost or brachytherapy is not adequate as the mean dose to heart is significantly higher. The use of DIBH in left-sided breast considerably reduces mean and V<sub>25</sub> heart doses. IMRT in left-sided breast shows an increase in D<sub>mean</sub> and a decrease in V<sub>25</sub>, which leads to significant differences in dose distribution over the heart. Heart toxicity could, therefore, have different patterns depending on the technique, being D<sub>mean</sub> a poor surrogate for heart toxicity. Skin toxicity has to be followed-up carefully in patients with high breast volumes.

### EP-1562 A Dose Painting Study Based on CT Intratumoural Heterogeneity vs. FDG PET Uptake in NSCLC

S. Alobaidli<sup>1</sup>, C. South<sup>2</sup>, S. McQuaid<sup>2</sup>, J. Scuffham<sup>2</sup>, I. Phillips<sup>3</sup>, V. Prakash<sup>4</sup>, V. Ezhil<sup>3</sup>, A. Nisbet<sup>2</sup>, P. Evans<sup>1</sup>

<sup>1</sup>University of Surrey, CVSSP-Electronic Engineering, Guildford, United Kingdom

<sup>2</sup>Royal Surrey County Hospital, Medical Physics, Guildford, United Kingdom

<sup>3</sup>Royal Surrey County Hospital, Clinical Oncology, Guildford, United Kingdom

<sup>4</sup>Royal Surrey County Hospital, Nuclear Medicine, Guildford, United Kingdom

### Purpose or Objective

Intratumoural heterogeneity has been reported in the literature to correlate to treatment outcome and overall survival. In this study, a volumetric voxel based map of intratumoural heterogeneity measured from CT images was used to guide dose painting. This approach was compared against dose painting based on FDG PET uptake distributions in regards to the overlap between the boost

volumes and the delivered dose to target volumes and organs at risk (OAR).

### Material and Methods

PET/CT and planning CT images for ten patients diagnosed with advanced inoperable non-small cell lung cancer (NSCLC) were retrieved retrospectively. The gross tumour volume (GTV) contour was used to segment the primary tumour from the CT and PET images. A volumetric voxel based map of intratumoural heterogeneity was generated from tumour CT image using a second-order statistical texture analysis method of grey level co-occurrence matrices. The FDG PET image was converted to SUV map. The low CT intratumoural heterogeneity regions within the generated texture map overlapped with high FDG uptake regions within the PET image (overlap of 65±11%). Hence, two boost volumes were identified, the low CT intratumoural heterogeneity region (Boost<sub>Heterogeneity</sub>) and the high FDG uptake region of >50% SUV<sub>max</sub> (Boost<sub>FDG</sub>). A 3mm margin was added to the boost volumes to account for physical uncertainties and these volumes were labelled PTV<sub>Heterogeneity</sub> and PTV<sub>FDG</sub>. Two volumetric arc therapy plans (VMAT) were created for each patient, with a prescribed dose of 84Gy in 32 fractions to PTV<sub>Heterogeneity</sub> or PTV<sub>FDG</sub> and 64Gy in 32 fractions to the remainder of the clinical PTV. The dose to the boost volumes and OARs (spinal cord, oesophagus, normal lung and heart) was measured and compared between the two plans.

### Results

The dose escalation to the boost volumes in the created plans were shown to be clinically feasible with the dose to OARs within tolerance limits and 95% of the target volume receiving ≥95% of the prescribed dose. When boosting based on PTV<sub>Heterogeneity</sub>, the dose to 95% of PTV<sub>FDG</sub> received ≥95% of the prescribed dose for 3 patients while the other seven patients received 80-92% of the prescribed dose. However, 95% of the Boost<sub>FDG</sub> volume received ≥95% of the prescribed dose for 9 of the 10 patients.

### Conclusion

The results show the feasibility of dose escalation in advanced NSCLC while keeping to normal tissue constraints. Moreover, the preliminary results suggest that boosting based on intratumoural heterogeneity measured from CT images, results in the high 18F-FDG regions receiving a high dose, indicating the potential of using CT intratumoural heterogeneity generated from standard CT images as a surrogate for functional imaging in dose painting.

### EP-1563 Treatment planning for synchrotron microbeam radiotherapy

L. Day<sup>1</sup>, L.M. Smyth<sup>2</sup>, M. Holm<sup>3</sup>, P.A.W. Rogers<sup>2</sup>, P.E. Engström<sup>4</sup>, C. Ceberg<sup>4</sup>, C.M. Poole<sup>1</sup>, J.C. Crosbie<sup>1</sup>, S. Senthil<sup>5</sup>, K. Woodford<sup>5</sup>

<sup>1</sup>RMIT University, School of Science, Melbourne, Australia

<sup>2</sup>University of Melbourne, Department of Obstetrics and Gynaecology, Melbourne, Australia

<sup>3</sup>Lund University, Department of Medical Radiation Physics, Lund, Sweden

<sup>4</sup>Lund University Hospital, Department of Radiation Physics, Lund, Sweden

<sup>5</sup>Alfred Hospital, William Buckland Radiotherapy Centre, Melbourne, Australia

### Purpose or Objective

Synchrotron microbeam radiation therapy (MRT) is a novel radiotherapy modality with significant clinical potential. We have produced a simple dose calculation algorithm for MRT using the Eclipse Treatment Planning System (TPS), by Varian Medical Systems.

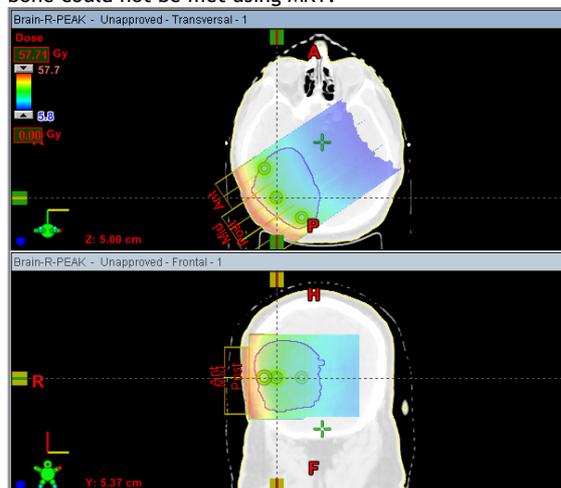

### Material and Methods

The calculation engine in Eclipse was configured to directly evaluate 'peak' doses. Monte Carlo-simulated

Peak-to-Valley Dose Ratios were used to obtain the 'valley' dose displayed in Eclipse. We compared dose profiles generated by Eclipse with Geant4 Monte Carlo simulations and measurements from the Imaging & Medical Beamline at The Australian Synchrotron. We are also in the process of performing a plan comparison study using anonymised patient datasets, comparing kilovoltage MRT plans with clinical megavoltage treatment plans.

#### Results

The Eclipse TPS performed well in calculating 'peak' doses in a water phantom. Considering the simplicity of the algorithm, the 'valley' dose and field profiles were also produced with reasonable accuracy, albeit with some underestimation of the valley dose for larger field sizes. Preliminary studies of megavoltage treatment plan comparisons have been performed. Compared to the clinical megavoltage treatment plans, MRT plans demonstrated adequate target coverage whilst meeting normal tissue dose constraints when target volumes were small and relatively superficial. As expected, planning goals for deep seated tumours and target regions distal to bone could not be met using MRT.

A screen shot of the treatment planning system. The peak dose has been calculated for three treatment fields on a head CT scan.

#### Conclusion

There are real advantages to using the familiar environment of Eclipse with a new radiotherapy paradigm such as MRT. Although, there are limitations to our MRT calculation engine in Eclipse and further work is required, the data generated in this work are overall encouraging and indicate that the potential for this calculation engine to be implemented in the future as part of a Phase 1 clinical trial.

#### EP-1564 Dosimetric assessment of pseudo-CT based proton planning

G. Pileggi<sup>1</sup>, C. Speier<sup>2</sup>, G. Sharp<sup>3</sup>, C. Catana<sup>4</sup>, D. Izquierdo-Garcia<sup>4</sup>, J. Pursley<sup>3</sup>, J. Seco<sup>5</sup>, M.F. Spadea<sup>1</sup>

<sup>1</sup>Magna Graecia University, Department of Experimental and Clinical Medicine, Catanzaro, Italy

<sup>2</sup>Friedrich-Alexander University Erlangen-Nürnberg, Radiation Oncology, Erlangen, Germany

<sup>3</sup>Massachusetts General Hospital, Radiation Oncology, Boston, USA

<sup>4</sup>Athinoula A. Martinos Center for Biomedical Imaging, Radiology- MGH, Charlestown, USA

<sup>5</sup>Deutsches Krebsforschungszentrum - DKFZ, Radiation Oncology, Heidelberg, Germany

#### Purpose or Objective

The aim of this work is to use pseudo-CT (pCT) data, obtained from T1 and T2 weighted MRI, for proton therapy planning.

#### Material and Methods

Data of 15 patients, including T1 and T2 weighted MRI and CT scans, were used in this study. The pCT was generated according to the methodology described in Speier *et al.*, by segmenting the T1<sub>w</sub> and T2<sub>w</sub> MRI volume into 6 tissue classes (grey and white matter, cerebrospinal fluid, bone, skin and air). For each patient, three 18 Gy beams (2 axial and 1 coronal,) were designed on the pCT volume, for a total of 45 analyzed beams. The plan was then copied and transferred onto the CT that represented the ground truth. Range shift (RS) between pCT and CT was computed at R<sub>80</sub> over 10 slices. The acceptance threshold for RS was set to 3.5% of R<sub>80</sub>, according to the clinical guidelines of our Institution.

#### Results

The median value of RS was 0.6 mm with lowest and highest absolute values being 0.08 mm and 3.8 mm respectively. 40 out of 45 beams passed the acceptance test. Largest discrepancies occurred in correspondence of the surgical hole of the scalp containing a metal plate. This happened because the segmentation process did not include metal classification, thus mis-assigning the Hounsfield Unit to skin or air. In this circumstance, the planned range on the pCT was deeper than the actual one detected on the CT.

#### Conclusion

This study showed the feasibility of using pCT, derived from MRI, for proton therapy treatment. The major benefit of MRI acquisition lies in better soft tissue contrast for tumor and organs at risk delineation. Further improvements of the methodology are required for the correct conversion of metal voxels to electron density.

#### EP-1565 Best of both worlds: 3D-CRT-based VMAT for locoregional irradiation in breast cancer.

P.G.M. Van Kollenburg<sup>1</sup>, H.J.M. Meijer<sup>1</sup>, M.C. Kunze-Busch<sup>1</sup>, P. Poortmans<sup>1</sup>

<sup>1</sup>UMC St Radboud Nijmegen, Department of Radiation Oncology, Nijmegen, The Netherlands

#### Purpose or Objective

##### Purpose:

Postoperative locoregional radiation therapy (RT) is increasingly applied in breast cancer patients as it has been demonstrated to decrease the risk of any recurrence and breast cancer mortality in patients with node-positive disease after mastectomy or breast conserving therapy. However RT has also been associated with side effects such as fibrosis, cardiac and pulmonary toxicity, impaired shoulder function and the induction of secondary malignancies.

It is therefore essential to use treatment techniques that enable the delivery of conformal and homogeneous doses, adequately covering the target volumes and limiting the dose to the organs at risk. The technique should also be robust taking into account changes in the position and the shape of the target volumes during treatment. We hereby present the results of the technique as being used in our department.

#### Material and Methods

##### Materials/Methods:

10 breast cancer patients with and an indication for locoregional RT were selected for dosimetric comparison between 3D-CRT and VMAT. All patients underwent a CT-scan with 3-mm slice thickness. Patients with left-sided breast cancer were scanned and treated with voluntary moderately deep inspiration breathhold. The treatment plans were created in the Pinnacle<sup>3</sup> treatment planning system V.9.10 with the Auto-Planning module, using 6 and/or 10MV beams.

For each patient a CTV was delineated based on the ESTRO guidelines. A margin of 7 mm was used to generate a PTV.

The following organs at risk were contoured: thyroid gland, heart, lungs, esophagus and contralateral breast.

Treatment Planning:

Prescription dose was 42,56 Gy in 16 fractions of 2,66 Gy. The 3D-CRT technique consisted of tangential beams for the breast/thoracic wall, one anterior beam (15° or 345°) for the medial periclavicular region and an anterior (15° or 345°) and posterior (165° or 195°) beam for the lateral periclavicular and axillary regions ( Fig. 1.).

For the VMAT technique tangential arcs of 24 degrees were chosen as these provide the best sparing of lung and heart and further minimize the low dose delivery to the rest of the body (integral dose). We analyzed PTV coverage including the conformation number (CN) and dose to the OARs to compare the techniques.

### Results

Results: Table 1 shows the results. Mean V95% for the PTV was 95,3% for 3D-CRT and 97,5% for VMAT.

CN was higher for the VMAT technique, indicating that PTV-coverage has improved at the same time as limiting the volume receiving a lower dose. Coverage was especially better with VMAT for lymph node levels 3-4. This came at a cost of a slightly higher dose to the thyroid gland. Dose to the lungs as well as the heart were lower with VMAT.

### Conclusion

Conclusion: We developed a VMAT-only planning method for locoregional breast irradiation, which is straightforward, robust, can be combined with respiratory control and creates very conformal and homogeneous treatment plans with improved PTV coverage and low doses to the organs at risk.

	Constrain	3D-CRT	VMAT
PTV local	V40.4Gy ≥ 95%	98,7%	97,2%
PTV level 1-2	V40.4Gy ≥ 95%	95,5%	99,5%
PTV level 3-4	V40.4Gy ≥ 95%	70,1%	96,4%
PTV total	V40.4Gy ≥ 95%	95,3%	97,5%
Thyroid	Mean dose <20Gy	16,0Gy	20,6Gy
Esophagus	Max dose 40Gy V30Gy < 1,5cc	34,0Gy 0,6Gy	31,4Gy 0,1Gy
Lungs	Mean dose ≤ 7,5Gy V20% ≤ 12Gy	5,9Gy 12,9Gy	5,5Gy 10,6Gy
Heart	Mean dose <3Gy Max dose V40Gy ≤ 0,6% V20Gy ≤ 3,5% V10Gy ≤ 15% V5Gy ≤ 20%	2,7Gy 40,5Gy 0,4% 3,0% 4,6% 7,1%	2,5Gy 36,3Gy 0,0% 1,6% 4,2% 8,7%
Contralateral breast	Mean dose < 1Gy	0,54Gy	0,70Gy
Conformation number*		0,568	0,687

### EP-1566 Biologically optimized IMRT plans for prostate cancer using population-based tumour biology

E.J. Her<sup>1</sup>, M.A. Ebert<sup>1,2</sup>, H.M. Reynolds<sup>3,4</sup>, A. Kennedy<sup>2</sup>, A. Haworth<sup>5</sup>

<sup>1</sup>The University of Western Australia, School of Physics, Perth, Australia

<sup>2</sup>Sir Charles Gairdner Hospital, Department of Radiation Oncology, Perth, Australia

<sup>3</sup>The Peter MacCallum Cancer Centre, Department of Physical Sciences, Melbourne, Australia

<sup>4</sup>University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia

<sup>5</sup>University of Sydney, School of Physics, Sydney, Australia

### Purpose or Objective

The standard approach to treating prostate cancer with EBRT involves delivery of a high dose of radiation to the entire gland. However, the capability of IMRT planning with dose based objectives fails to exploit the potential to deliver a highly non-uniform dose distribution based on patient/tumour-specific data. A personalised approach to prostate RT is proposed, which aims to deliver a dose distribution sculpted by specific biology, including the spatial distribution of clonogen densities and degree of hypoxia [1, 2], using in vivo multiparametric imaging. The aim of this study was to explore the feasibility and benefits of using a TCP model utilising population-based tumour biology to guide IMRT for prostate cancer, to maximize TCP while simultaneously minimizing NTCP of normal tissues.

### Material and Methods

Four intermediate-risk prostate cancer patients were selected from an established trial patient cohort that underwent conventional 3D conformal radiation therapy (3DCRT). This study compared the delivered 3DCRT plan with a conventional uniform-dose and a biologically-optimized IMRT plan. IMRT planning was carried out on matRad (German Cancer Research Centre, Heidelberg, Germany) and was modified to include biological optimization. The conventional IMRT treatment planning objectives and clinical acceptance criteria were based on the recommendations of Pollack et al [3]. The biologically-optimized plans were created to achieve TCP of at least 0.70. The TCP model included a non-uniform clonogen cell density within the CTV, variation in radiosensitivity parameters within a patient population and repopulation effect. TCP was first calculated for the biologically-optimized plan, then the dose for the other two treatment plans was scaled to match the same TCP. Rectum and bladder NTCP were used for comparison.

### Results

Table 1. Summary of normal structure NTCP for the three treatment plans

Patient	TCP	Biologically-optimized IMRT		Uniform-dose IMRT		3D-CRT	
		Rectum NTCP	Bladder NTCP	Rectum NTCP	Bladder NTCP	Rectum NTCP	Bladder NTCP
Patient 1	0.74	1.4E-05	2.7E-08	1.5E-05	7.0E-05	3.5E-04	7.0E-04
Patient 2	0.81	8.3E-06	5.2E-08	5.4E-05	1.5E-04	6.0E-05	1.3E-04
Patient 3	0.80	5.2E-06	6.6E-08	1.6E-05	1.2E-04	4.6E-04	1.5E-03
Patient 4	0.70	3.2E-05	1.4E-09	8.7E-05	8.8E-06	3.7E-04	6.2E-06

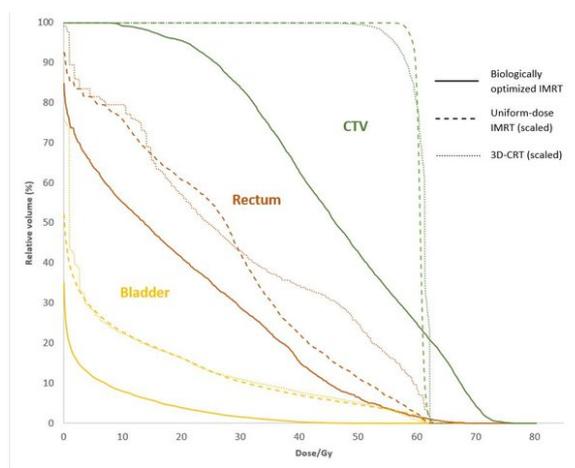

Figure 1. DVH comparison of biologically optimized IMRT, uniform-dose IMRT and 3D-CRT plans for one patient from the study.

Conventional uniform-dose IMRT plans for three patients did not pass the clinical acceptance criteria due to the patient geometry, particularly due to violation of rectal dose-volume constraints. In all cases, biologically-optimized IMRT plans were superior to other treatment modalities on the basis of rectum and bladder NTCP. All comparison results are summarised in Table 1. In Figure 1, the DVH curves for one patient demonstrate the ability of biologically optimized IMRT planning to minimize dose to healthy tissues while maintaining a high TCP.

#### Conclusion

In conclusion, biological optimization of prostate IMRT using a TCP model has the potential to improve the clinical outcome by maximizing TCP and simultaneously minimizing dose to normal structures. This has been demonstrated in the context of population-based tumour cell density distributions. Future work will include the implementation of voxel-level patient-specific data from multiparametric imaging which will allow a personalized approach to IMRT planning with a dose distribution tailored to the specific patient/tumour biology.

#### EP-1567 Inverse planning versus forward planning for orbital lymphoma

E.M. Ambroa Rey<sup>1</sup>, A. Ramirez Muñoz<sup>1</sup>, D. Navarro Jiménez<sup>1</sup>, R. Gómez Pardos<sup>1</sup>, M. Colomer Truyols<sup>1</sup>  
<sup>1</sup>*Consorci Sanitari de Terrassa, Medical Physics Unit-Radiation Oncology Department, Terrassa, Spain*

#### Purpose or Objective

Non-Hodgkin's lymphoma (NHL) of the orbit is an unusual presentation of extranodal NHL and represents 8% of all extranodal NHL and about 1% of all NHL. The purpose of this study is to present a dosimetric analysis between inverse and forward plans for mucosa associated lymphoid tissue (MALT) lymphoma.

#### Material and Methods

Three patients diagnosed with MALT lymphoma were analyzed. Three types of plans (3DCRT, IMRT and VMAT) were created for each patient.

The whole orbital volume was included in the CTV. The organs at risk (OAR), right and left eye, right and left lens, right and left optical nerve, were contoured. Prescription was 27 Gy at 1.8 Gy per fraction.

The 3DCRT plans were elaborated using the treatment planning system (TPS) XiO version 5.1. Five isocentric beams were used. Inverse plans calculations (IMRT and VMAT) were carried out using the Monaco TPS version 5.10. IMRT plans were created based on a five-field arrangement and dynamic MLC delivery method. For VMAT plans, two partial arcs were used. For every plan, the following data for the PTV was recorded: V95%, D50%,

D98%, D2%, CI, HI, MU, number of segments and estimated delivery time. For the principal organs at risk, such as the optical nerve, contralateral eye and contralateral lens, the maximum and mean dose were reported.

#### Results

Table 1 summarizes the results for the PTV.

PTV	3DCRT (mean value/SD)	IMRT (mean value/SD)	VMAT (mean value/SD)
V95% (%)	95.80 [1.63]	99.61 [0.16]	99.30 [0.17]
D50% (Gy)	27.70 [0.31]	27.30 [0.12]	27.20 [0.21]
D98% (Gy)	24.73 [0.71]	26.31 [0.12]	26.12 [0.20]
D2% (Gy)	28.87 [0.23]	28.35 [0.24]	28.76 [0.55]
CI	0.68 [0.03]	0.66 [0.10]	0.59 [0.14]
HI	0.15 [0.03]	0.07 [0.01]	0.10 [0.01]
MU	380.56 [33.54]	411.81 [99.83]	276.41 [25.74]
Segments	-	137.00 [8.89]	85.33 [10.60]
Time (s)	-	140.27 [21.60]	92.46 [27.96]

Table 1. Dosimetric mean values for the PTV.

Inverse planning improves PTV coverage in comparison with forward planning. Also the near-minimum dose D98% is higher for IMRT and VMAT than 3DCRT. In addition the near-maximum dose D2% is lower for IMRT and VMAT. In terms of conformity, the three plans have similar results; meanwhile the 3DCRT technique has a worst homogeneity index. VMAT treatment plans reduce the monitor units and number of segments in comparison with the IMRT plans. For the OAR, the maximum dose (mean value) to the contralateral lens was 4.30Gy for the 3DCRT plans; 3.33Gy for IMRT and 2.86Gy for VMAT plans. For the left optical nerve the maximum dose was 9.39Gy for 3DCRT; 7.31Gy for IMRT and 6.96Gy for VMAT, and for the left eye was 7.20Gy for 3DCRT; 6.37Gy for IMRT and 5.16Gy for VMAT. Dose distribution (axial view) for one representative patient is shown in Fig 1.

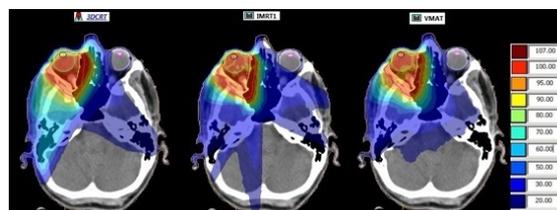

Figure 1. Comparison of the dose distribution in the axial view. Isodoses are in percentage.

#### Conclusion

According to the results, we can conclude that inverse planning is feasible for MALT orbital lymphoma treatment, providing excellent dose coverage of target volume and reduces dose to the organs at risk. Furthermore, we can establish that in terms of coverage and sparing OAR, IMRT and VMAT techniques are very similar, but VMAT technique achieves a faster delivery treatment, resulting in a lower probability of patient movement during the treatment. Despite the fact that the number of examined patients is low, we are sure that inverse planning is an improvement for every patient with this type of malignance, but further investigations, with more cases, between IMRT and VMAT should be done.

#### EP-1568 Benefit of a breath hold radiotherapy technique for breast and internal mammary nodes irradiation

F. Jouvaux<sup>1</sup>, A.L. Blin<sup>1</sup>, I. Lecouillard<sup>1</sup>, M. Benchalal<sup>1</sup>, C. Lafond<sup>1,2,3</sup>

<sup>1</sup>*Centre Eugène Marquis, Radiotherapy, Rennes CEDEX, France*

<sup>2</sup>*Rennes 1 University, LTSI, Rennes, France*

<sup>3</sup>*INSERM, U1099, Rennes, France*

#### Purpose or Objective

Loco-regional radiotherapy of left-sided breast cancer represents a treatment planning challenge when the internal mammary lymph nodes (IMN) are included in the

target volume because of high radiation exposure to the heart. This planning study aimed to quantify the reduction of cardiac and pulmonary radiation dose with moderate deep inspiration breath hold (DIBH) technique compared with free breathing (FB) for irradiation of left-sided breast including IMN.

#### Material and Methods

Ten patients underwent CT simulation scans during FB and DIBH, which was performed with the SpiroDyn<sup>®</sup>RX (Dyn<sup>®</sup>R) spirometer. The clinical target volumes (CTV) included the breast, the ipsilateral IMN, the supraclavicular lymph nodes area and the tumor bed site. Contouring was performed by the same physician, following ESTRO consensus guidelines, on both CT scans. Prescribed doses were 50 Gy in 25 fractions to the breast, the IMN and the supraclavicular area, followed by 16 Gy to the tumor bed site. Treatment plans were calculated by the same physicist with Pinnacle 9.10 (Philips) TPS for both CT scans. Three isocentric beams were used for the 50 Gy volumes: two wide Step and Shoot (S&S) tangents for irradiation of the breast and IMC, and an anterior conformal beam for treatment of the supraclavicular nodes. Three oblique S&S beams were used for tumor bed boost. The resulting averaged dose-volume histograms (DVH) were generated and compared. Mean dose to the heart ( $D_{\text{mean, heart}}$ ) and heart volume receiving 25 Gy or more ( $V_{25\text{Gy, heart}}$ ), mean left lung dose ( $D_{\text{mean, lung}}$ ) and lung volume receiving 20 Gy or more ( $V_{20\text{Gy, lung}}$ ) were evaluated and compared.

#### Results

The average DVHs for FB and DIBH are shown on figure 1.

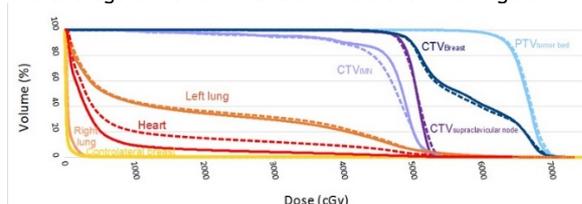

Figure 1: Averaged Dose-Volume Histograms for DIBH (dashed lines) and FB (solid lines) plans

With similar target volumes coverage, average  $D_{\text{mean, heart}}$  was reduced from  $9.7 \pm 2.1$  Gy [range: from 6.1 to 12.7 Gy] to  $5.1 \pm 2$  Gy [range: from 3.2 to 8.9 Gy] in DIBH plans compared to FB. Averaged  $V_{25\text{Gy, heart}}$  was reduced from  $13.5 \pm 4.3\%$  in FB plans to  $4.7 \pm 3.6\%$  in DIBH plans. Figure 2 shows a systematic reduction of  $V_{25\text{Gy, heart}}$  over the 10 patients, superior to 50% for 8 patients.

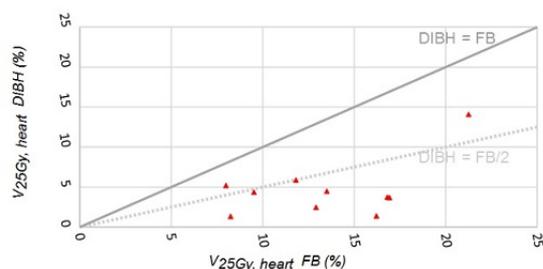

Figure 2:  $V_{25\text{Gy, heart}}$  distribution over the 10 patients: DIBH as a function of FB

Averaged mean  $D_{\text{mean, lung}}$  was reduced from  $18.5 \pm 3.2$  Gy in FB plans to  $17.5 \pm 2.8$  Gy in DIBH plans and  $V_{20\text{Gy, lung}}$  by 7.8% in DIBH plans, but were not systematically inferior.

#### Conclusion

Without compromising target coverage, DIBH treatment plans provided an averaged  $D_{\text{mean, heart}}$  reduction of 4.6 Gy, and a 1.0 Gy reduction of  $D_{\text{mean, lung}}$  on average. Related to the reduction of mean cardiac dose and the demonstrated decrease of cardiovascular toxicities, DIBH may be the preferable treatment technique when radiotherapy of the internal mammary lymph nodes is required for left sided

breast cancer.

#### EP-1569 A comparison of SRS plan quality when using VMAT vs non-coplanar static conformal fields.

R. Brass<sup>1</sup>, L. Howard<sup>1</sup>, M. Gilmore<sup>1</sup>

<sup>1</sup>The Clatterbridge Cancer Centre, Physics, Bebington, United Kingdom

#### Purpose or Objective

To produce a VMAT multi-arc solution in Eclipse for SRS patients with at least equivalent plan quality to previously used static conformal field (SCF) technique. To establish a plan quality tool based on acceptable plan quality metrics for SRS patients.

#### Material and Methods

10 clinical SRS plans were chosen to create a cohort with a variation of indications, target volumes, shapes and positions within the brain (see Table 1). Patients with multiple targets were excluded from the study. The plan quality parameters used were the Paddick conformity index (CI) [Paddick 2000], Paddick gradient index (GI) [Paddick & Lippitz 2006] and normal tissue overdose factor (NTOF: ratio of volume of normal tissue receiving prescription isodose to volume of prescription isodose) along with various dose-volumes (e.g.  $V_{5\text{Gy}}$ ); baseline values were calculated for the SCF plans.

Several arc configurations were considered, ranging from 1 full arc at  $0^\circ$  couch angle to 1 full arc plus 3 half arcs at couch angles of  $45^\circ$ ,  $90^\circ$  &  $315^\circ$ . One of the more complex cases was used to develop a VMAT planning solution by increasing the number of half-arcs used until gains in plan quality became negligible. The *Normal Tissue Objective* (NTO) parameters in Eclipse were then optimised to further reduce the dose to OARs and normal brain tissue. The rest of the cohort was planned using this final solution and plan quality measures calculated and compared to SCF baselines. A final VMAT solution was decided upon consisting of 1 full arc at couch zero plus 2 half arcs at  $45^\circ$  and  $315^\circ$ .

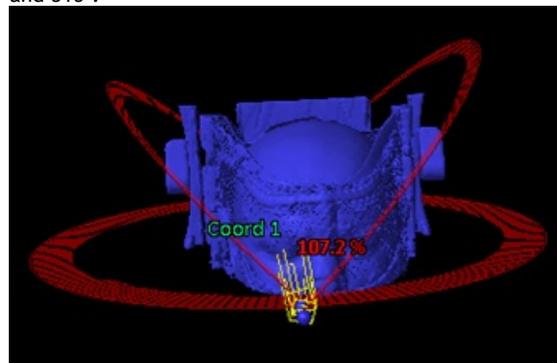

Image 1: 3D view showing final arc arrangement.

The NTO *fall off* parameter was tweaked while fixing the *distance from target*, *start dose* and *end dose* parameters at values suitable for SRS. The final *fall off* value for the VMAT solution was set to 0.50. *Fall off* dictates how quickly the dose should decrease outside the target volume, with a higher value indicating a more rapid decrease. The 0.50 value used here compares to 0.15 used at our centre for VMAT plans.

## Results

Patient	Target V <sub>50</sub> /cc	SCF				VMAT				Notes
		V5Gy/cc	CI	GI	NTOF	V5Gy/cc	CI	GI	NTOF	
Metastasis 1	1.52	17.32	0.78	3.48	0.22	21.90	0.83	4.00	0.00	Regularly shaped, away from OARs
Metastasis 2	2.40	30.02	0.73	3.47	0.24	22.00	0.85	3.39	0.00	Regularly shaped, very inferior, abutting brainstem
Metastasis 3	14.61	125.13	0.79	2.66	0.22	82.80	0.93	2.60	0.00	Large, very superior, away from OARs
Metastasis 4	11.54	77.43	0.73	2.72	0.27	55.50	0.91	2.58	0.01	Regularly shaped, superior, away from OARs
Acoustic neuroma 1	0.41	6.17	0.55	5.92	0.43	4.80	0.80	6.20	0.00	Typical acoustic neuroma, right sided
Acoustic neuroma 2	0.90	9.43	0.58	4.48	0.40	7.40	0.65	4.46	0.09	Left sided, abuts brainstem
Acoustic neuroma 3	1.80	15.60	0.64	3.46	0.18	12.70	0.77	4.10	0.05	Large, left sided, abuts brainstem
Meningioma 1	1.57	21.86	0.61	4.26	0.39	18.70	0.79	4.95	0.11	RTTQA benchmarking case, overlaps brainstem
Meningioma 2	3.21	29.84	0.46	3.23	0.53	19.90	0.76	3.65	0.05	Very irregular in shape, superior and anterior
Meningioma 3	3.76	33.68	0.50	3.46	0.49	19.80	0.83	3.50	0.03	Very irregular, against superior skull

Table 1: Details of each case and results of plan quality tests.

In each case the CI is improved using the VMAT solution. The average CI for SCF plans was 0.64, this increased to 0.81 when using VMAT. The GI appeared to increase in several cases, with improvement only shown in 4 out of 10 cases. In each case, NTOF was reduced to close to zero. Perhaps surprisingly for a VMAT solution, the 5Gy volume was reduced for 9 out of 10 cases. The average 5Gy volume for the SCF plans was 36.65cc; this reduced to 26.55cc when using VMAT.

### Conclusion

Paddick CI has proven to be a reliable metric for conformity, while NTOF gives a good indication of how baggy the prescription isodose is. However, Paddick GI was not found to be a reliable indicator of low dose spread, especially for small volumes. In many cases the 40% and 80% volumes had each been reduced and conformity improved but a higher GI was recorded. The Eclipse VMAT solution is adequate for a wide range of tumour shapes, sizes and locations and can be used for all single-target SRS patients.

### EP-1570 The dynamic jaw mode of tomotherapy: Better neural structure protection for advanced NPC patients?

P.T. Fang<sup>1</sup>, T.Y. Lu<sup>1</sup>, M.N. Wu<sup>2</sup>, M.Y. Huang<sup>1</sup>, C.J. Huang<sup>1</sup>

<sup>1</sup>Kaohsiung Medical University Hospital, Radiation Oncology, Kaohsiung, Taiwan

<sup>2</sup>Kaohsiung Medical University Hospital, Neurology, Kaohsiung, Taiwan

### Purpose or Objective

This study investigated the neural structure protection effects of the dynamic jaw mode of tomotherapy for advanced nasopharyngeal cancer (NPC) by comparing use of the dynamic jaw mode and the fixed jaw mode with different field widths.

### Material and Methods

Twenty patients with locally advanced NPC were selected. All T classifications were T3-4. Plans were using the simultaneous integrated boost technique in 3 dose levels. Four plans were generated utilizing the 2.5 cm dynamic, 2.5 cm fixed, 5.0 cm dynamic, and 5.0 cm fixed jaw modes. Plan efficiency was evaluated in terms of monitor unit and beam-on-time measurements. Plan quality was evaluated using homogeneity index (HI) and conformity index (CI). Dose indices of neural structures such as the optic pathways, temporal lobe, and hippocampus, as well as of other organs at risk (OAR), were compared. Volumetric parameters of the hippocampus and temporal lobe were also assessed. Only plans of the same field width were compared with one another.

### Results

The comparison of the 2.5 cm dynamic jaw plan with the 2.5 cm fixed jaw plan indicated no differences between plan efficiency, HI and CI results, or the dose indices of OARs within the radiation field. However, use of the 2.5 cm dynamic jaw mode significantly improved the

maximum dose to the left optic nerve ( $p=0.005$ ) and chiasm ( $p=0.035$ ). It also lowered the maximum dose and mean dose to the hippocampus (both  $p$  values were 0.035). In addition, the volume receiving 5 Gy (V5) values for the temporal lobe and hippocampus were significantly smaller when the dynamic jaw mode was used ( $p=0.035$ ;  $p=0.013$ ). The comparison of the 5.0 cm dynamic jaw plan with the 5.0 cm fixed jaw plan also indicated no differences between plan efficiency, HI and CI results, or the dose indices of OARs within the radiation field. However, use of the 5.0 cm dynamic jaw mode significantly improved the maximum dose to the left and right optic nerve ( $p<0.0005$ ) and chiasm ( $p=0.005$ ). The mean dose to the temporal lobe was significantly improved using the dynamic jaw mode ( $p=0.013$ ). It also lowered the maximum dose and mean dose to the hippocampus (both  $p=0.035$ ). Finally, the dynamic jaw mode also significantly reduced the V5, V10, and V20 values for the temporal lobe and hippocampus.

### Conclusion

When the same field width, the dynamic jaw mode provided better neural structure protection than the fixed jaw mode, in addition to reducing the low-dose volume to the temporal lobe and hippocampus. These advantages were more pronounced when using a larger field width. There were no significant differences, however, in plan quality and efficiency between the two modes for the same field width. The above results indicate that for the treatment of locally advanced NPC patients, use of the 2.5 cm dynamic jaw mode rather than the 2.5 cm fixed jaw mode currently used in clinical practice would provide better neural structure protection and lower low-dose volumes to the temporal lobe and hippocampus with equal plan efficiency.

### EP-1571 Radiotherapy treatments using a prototype MLC design

P. Nitsch<sup>1</sup>, Y. Li<sup>1</sup>, T. Netherton<sup>1</sup>, P. Balter<sup>1</sup>, S. Gao<sup>1</sup>, M. Muruganandham<sup>1</sup>, S. Shaitelman<sup>2</sup>, S. Frank<sup>2</sup>, S. Hahn<sup>2</sup>, A. Klopp<sup>2</sup>, L. Court<sup>1</sup>

<sup>1</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

<sup>2</sup>The University of Texas MD Anderson Cancer Center, Radiation Oncology, Houston, USA

### Purpose or Objective

We are evaluating the clinical efficacy of a prototype multi-leaf collimator (MLC) design which obviates the need for collimating jaws. The new MLCs are 1.0cm wide, potentially giving increased reliability, and have a maximum speed of 5.0cm/sec. The increased leaf width may reduce the achievable intensity modulation, but the impact of this may be mitigated by the increase in MLC speed and by using IMRT/VMAT treatment planning. Here we evaluate (1) whether clinically acceptable plans can be created using such an MLC design, and (2) the agreement between the planned and delivered dose distributions.

### Material and Methods

IMRT, VMAT, field-in-field and electronic compensator plans were created in the Eclipse treatment planning system using the prototype MLC design and a flattening-filter-free 6MV beam, for the following treatment sites: head/neck, lung (standard fractionation, palliative and SBRT plans), cervix (pelvis and extended fields), intact breast (left and right), prostate (SBRT and involved nodes), and whole brain treatments. The planned dose distributions and DVHs reviewed for clinical acceptability by radiation oncologists, and compared with our original clinical plans (120leaf Millennium MLC, 0.5cm MLCs). Delivered dose distributions for IMRT and VMAT plans were evaluated using the ArcCHECK array.

### Results

In most situations, the plan quality (particularly homogeneity in the target) was highest for IMRT (with

multiple collimator angles), followed by VMAT, electronic compensator, and field-in-field. The optimal IMRT and VMAT plans were typically considered clinically acceptable, while the electronic compensator and field-in-field plans were not (poor homogeneity). Our original clinical plans were generally more homogeneous than those created for the prototype MLC design. The optimal treatment plans for treatments that are typically treated with two beam angles (breast, whole brain) used IMRT with the conventional beam angles. For large breasts, 2 additional IMRT fields were needed to improve coverage and homogeneity (see figure)

The best VMAT plans created with the prototype MLC were typically less homogeneous but more conformal than IMRT plans, when 4 or more arcs were used (see figure comparing IMRT (left) and VMAT (right)). Based on our current experience, we suggest the use of IMRT for this prototype MLC design - because these plans are significantly faster to optimize, and usually give the best treatment plans (for this MLC)

Beam modulation was similar for IMRT and VMAT (3.2 vs 3.4 MU/cGy). When comparing the calculated dose and delivered dose the average gamma passing rate (3%/3mm) was 99.5% (range: 91%-100%) and 99.0% (97.7%-100%) for IMRT and VMAT, respectively.

#### Conclusion

It was possible to plan and deliver clinically acceptable plans for all treatment sites using the prototype 1.0cm MLC design. Initial experience was that IMRT plans outperform the VMAT plans in terms of homogeneity.

#### EP-1572 Feasibility study of prone position in radiotherapy of breast with regional lymph nodes

E. Pawłowska<sup>1</sup>, A. Prawdzik<sup>1</sup>, M. Narkowicz<sup>1</sup>, M. Damińska<sup>1</sup>, R. Zaucha<sup>1</sup>

<sup>1</sup>Medical University of Gdansk, Department of Oncology and Radiotherapy, Gdansk, Poland

#### Purpose or Objective

Prone position radiotherapy has been successfully used to treat breast cancer in women with large, pendulous breasts. The benefit of this technique comes from

decreased doses in organs at risk (OAR). Simultaneous irradiation of regional lymph nodes (RLNs) is done only in supine position, losing this beneficial effect. We have performed a feasibility study of irradiating large (> 780 ml) breasts with RLNs in prone setup.

#### Material and Methods

Target volumes including breast, supra-, infraclavicular, Rotter's, axillary lymph nodes with or without internal mammary (IM) chain were contoured on six tomography scans of 5 patients immobilized in prone position using two commercial breast boards. Delineation was done in accordance with European Society for Radiotherapy and Oncology (ESTRO) consensus. Radiotherapy plans using static (3D CRT) and dynamic (IMRT) conformal techniques were prepared. Dose-volume limits were based on QUANTEC review.

#### Results

In all plans mean doses to the heart, lung (ipsilateral, contralateral and both), left descending artery (LAD) were obtained. Volumes receiving more than 20 and 25 Gy were reported in lungs and heart, respectively. Mean values from all plans are presented in Table 1.

Table 1

		RLN's with IM		
		3D CRT	3D CRT	IMRT
Lungs	MLD (Gy)	6,05	9,1	11,86
	V20 (%)	10,58	16,39	16,37
Ipsilateral lung	MLD (Gy)	12,51	18,50	17,04
	V20 (%)	22,48	27,46	32,11
Contralateral lung	MLD (Gy)	1,98	0,73	7,15
	V20 (%)	0	0	2,24
Heart	MHD (Gy)	7,06	10,75	17,10
	V25 (%)	10,82	16,56	20,60
LAD	Mean dose (Gy)	2,37	7,85	18,72

Radiotherapy to breast and RLNs with IM was associated with significantly higher doses in all OARs independently of the technique used. 3D CRT plans resulted in lower doses than IMRT to nearly all structures.

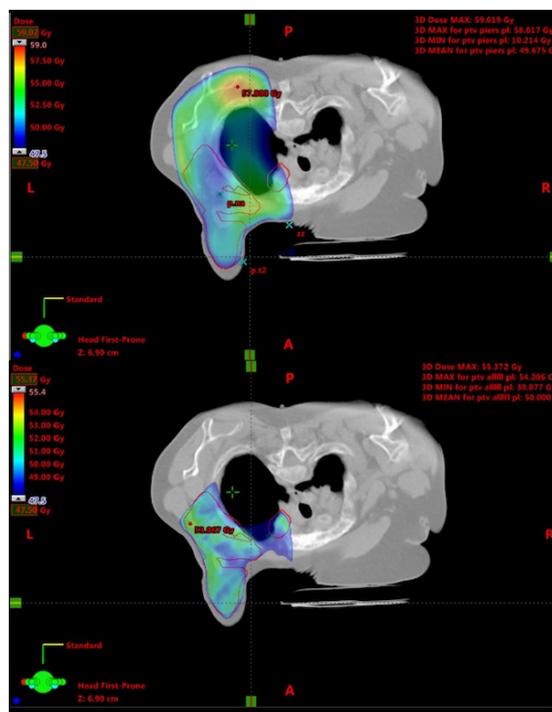

Image 1 presents differences in dose distribution between IMRT (bottom) and 3D CRT (top). PTV includes breast and RLNs with IM

### Conclusion

Irradiation of breast and RLNs without IM in prone position in women with large, pendulous breasts is feasible and safe. Including IM chain in radiotherapy plan significantly increases doses in lungs and heart but acceptable values may be achieved in some of patients. Dynamic techniques show no benefit in comparison to 3D CRT.

### EP-1573 TBI and TMI treatment comparison using bilateral and anteroposterior delivery techniques

E. Sandrini<sup>1</sup>, C.M. Da Silva<sup>1</sup>

<sup>1</sup>*Clinicas Oncológicas Integradas, Medical Physics - Radiotherapy, Rio de Janeiro, Brazil*

### Purpose or Objective

Evaluate doses in organs at risk and target volume coverage of patients undergoing total body irradiation (TBI) or total marrow irradiation (TMI) treatment in supine and lateral decubitus. The TBI and TMI treatment are an old kind of treatment that normally uses 2D calculation. This work used a 3D calculation with heterogeneity correction as the same way of the old technique (two opposite fields), but with a CT it's possible to estimate the dose in OAR and the target coverage.

### Material and Methods

Five partial (3/4) total body CT image were used to plan a TBI treatment with two different setups: supine and lateral decubitus. The plans had two opposite fields with 6MeV and their collimator rotated by 45 degrees, the extended SSD used was 350cm, it was used Acurus XB dose calculation algorithm and the prescription was 12Gy in 6 fractions. For each CT it was drawn the body, bones, lungs, heart, kidneys, liver and eyes. It was investigated the following aspects: (A) body coverage (TBI treatment), (B) bone coverage (TMI treatment), (C) dose homogeneity index (DHI) defined as the ratio of dose received by 90% of the volume (D90) to the minimum dose received by 10% of the volume (D10), (D) mean dose of organs at risk: lungs, kidneys, heart and liver and (E) maximum dose in eyes.

### Results

It was observed that when using supine decubitus instead of lateral decubitus the D95 of body decreases 2%, and D95 of bones didn't change; The DHI of TBI and TMI treatment was reduced by 10%; The crystalline maximum dose and heart mean dose was increased by 20% and 3%, respectively; And the mean dose of kidney, lung and liver was reduced by 10%, 6% and 4%, respectively.

Std. Deviation	23	21	25	25	47	102	25	45	32	38

### Conclusion

This work indicates that the target coverage and DHI aren't significantly affected by the patient positioning. Although the bilateral technique increased the eyes and heart dose, it was observed a decrease in lung, kidney and liver dose. So as the pulmonary complication is renowned as the major causes of mortality following TBI, the best positioning for this kind of treatment is supine decubitus.

### EP-1574 Helical Tomotherapy for Bilateral Breast Cancer Patients: 3-Years Single Centre Experience

F. Ertan<sup>1</sup>, M. Altundag<sup>1</sup>, H. Abanuz<sup>1</sup>, S. Duzgun<sup>1</sup>

<sup>1</sup>*Ankara Oncology Hospital, Radiation Oncology, Ankara, Turkey*

### Purpose or Objective

The present study aims to evaluate dose distribution characteristic using helical tomotherapy (HT) for patients with bilateral breast cancer.

### Material and Methods

From January 2013 to December 2015, 12 patients were treated with tomotherapy. The target volume includes different parts for each patient and was shown in Table-1. During CT simulation, the patient was positioned supine on a breast board and CT slices were obtained at 3 mm intervals extending from the chin to the upper abdomen during free breathing. Tomotherapy planning parameters; the field width, modulation factor and pitch, were assigned to 5cm, 2 and 0.287, respectively, for all plans. To protect critic organs at maximum level, the complete block was applied. The delivered dose was 50Gy within 25 fractions for 11 patients and, simultaneous integrated boost technique was used within 60Gy to boost and 50Gy to PTV in 25 fractions for 1 patient. Treatment planning

objectives were to cover at least 95% of the planning target volume with the 100% isodose. The generated plans were evaluated in terms of dose distribution of PTV(D95,D98,Dmax), doses of total lungs (V20,V10,V5), heart(V30,V20 and mean dose).

Average D98(Gy)	47.22	47.34	48.9	49.00	46.21	46.8	46.70	47.14	47.88	48.2	57.00	58.5
	Average V30 (%)	Average V20 (%)	Average V10 (%)	Average V5 (%)	Average (Gy)							
Heart	1.79	5.5	15.7	42	6.58							
Total Lungs	-	22.5	38.8	55.66	-							

## Conclusion

Bilateral breast treatment is complex and difficult due to the field junction problem with the standard techniques. However, based on the results of this study, HT plans have shown high homogeneity and coverage indexes of target volumes while reducing the lung and heart doses. We expect the increase of low dose region due to helical irradiation. However, by using complete blocking, we provide that the values remained at the tolerance limits.

### EP-1575 Automated VMAT planning for whole brain irradiation with hippocampus sparing

J. Krayenbuehl<sup>1</sup>, M. Di Martino<sup>1</sup>, M. Guckenberger<sup>1</sup>, N. Andratschke<sup>1</sup>

<sup>1</sup>University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

### Purpose or Objective

Whole-brain radiation therapy (WBRT) has been the standard treatment for patient with multiple brain metastases for decades. However, with broader application of stereotactic radiotherapy the use of WBRT has decreased in the past years to avoid possible adverse neurocognitive effects. With the advent of neuroprotective strategies such as hippocampus sparing (HS) the interest in WBRT has been revived. The gold standard constraints for HS WBRT were published by the RTOG 0933 in 2011. In this project, we an automated treatment planning (aTP) approach aiming especially at reduced hot spots in the normal brain.

### Material and Methods

Fourteen consecutive patients treated with HS WBRT were enrolled in this study. The planning target volume (PTV) was defined as the whole-brain excluding the hippocampal avoidance regions defined as the hippocampal expanded by 5mm in three-dimensions. 10 x 3 Gy was prescribed to 92% of the target volume. All patients were planned with VMAT technique using four arcs and two couch kicks (300° and 60°). The plans were optimized for a Trilogy linac

(Varian Medical System) with 5mm leaf width (Millennium MLC). Plan were optimized using Auto-Planning (AP) (Philips Radiation Oncology Systems) and using one single AP template. Plan results were compared to published dose volume histogram (DVH) parameters for HS WBRT. Dose to 2% (D2%) and 98% (D98%) of the target volume and homogeneity index (HI) were evaluated. The hippocampus dose was evaluated based on the minimal dose (D100%) and the maximal dose (Dmax). In addition to DVH parameters evaluation, the effective planning time defined as the working time required between the volumes definition and the end of the plan optimization was evaluated.

## Results

Target and hippocampus DVH parameters are shown in Table 1. The D2% to the brain was reduced on average by > 3Gy [MG1] (34 Gy vs. RTOG 37.5Gy) and the maximum hippocampus dose was reduced by > 1Gy. All the other parameters were similar to published data. The effective planning was kept below 10' for each patient.

	PTV				Hippocampus	
	HI	D98% [Gy]	D2 [Gy]	V30Gy [%]	D100% [Gy]	Dmax [Gy]
RTOG 0933. 2011	-	< 25	37.5	≥ 90%	≤ 9	≤ 16
Gondi et al. 2010	0.3	-	-	-	-	15.3
Nevelsky et al 2013	0.4	25.4	37.3	92.1	8.4	14.4
Gondi et al. 2015	-	26.3	36.0	-	8.6	14.8
Nevelsky et al 2013	0.4	25.4	37.3	92.1	8.4	14.4
<b>Krayenbuehl et al.</b>	<b>0.2</b>	<b>25.8</b>	<b>33.1</b>	<b>92.0</b>	<b>8.1</b>	<b>13.3</b>

## Conclusion

Automated TP for HS WBRT with VMAT achieved significantly decreased maximal brain dose and maximal hippocampus dose while fulfilling all other RTOG 0933 constraints. With this approach, hot spots > 115% could be significantly reduced in contrast to a maximal allowance of 130% in the RTOG protocol.

### EP-1576 Tomotherapy WBRT with SIB planning for patients with brain metastases

D. Synchuk<sup>1</sup>, S. Odarchenko<sup>1</sup>, N. Seryogina<sup>1</sup>, O.

Zinvaliuk<sup>1</sup>, M. Gumeniuk<sup>1</sup>, K. Gumeniuk<sup>1</sup>

<sup>1</sup>Ukrainian center of Tomotherapy, RT department, Kirovograd, Ukraine

### Purpose or Objective

Whole brain radiation therapy (WBRT) is usually the primary treatment option for patients with multiple brain metastases extending median survival time and improving the quality of life. The aim of this study is to develop at our institution the technique for tomotherapy planning of WBRT with simultaneous integrated boost (SIB) for metastases.

### Material and Methods

The target/OAR volume delineation was performed using MIM software. The PTV1 for SIB included GTV for metastases which was defined as the contrast-enhancing lesions on T1-weighted MRI plus 3 mm uniform margin. The PTV2 for WBRT included the whole brain plus 3 mm margin excluding PTV1. The aim of planning was to deliver the 40/30 Gy dose in 10 fractions to SIB/WBRT respectively. Prescription was made to the median dose, also D<sub>99%</sub> should be ≥ 95% D<sub>presc</sub> and D<sub>1%</sub> ≤ 107% D<sub>presc</sub>.

## Results

The development of the standartised planning procedure began after treatment of 8 patients and gaining some experience. For planning purposes an automated workflow to produce additional contours was created: 2 consecutive 5 mm rings around the PTV1 to form the dose falloff; PRV structures as 3 mm outer ring contours for optic nerves, chiasm and brainstem; the structures that overlapped PTV were subdivided into "PTV OAR" and "PTV OAR PRV", the subvolumes created for overlapping regions, and "OAR Plan" and "OAR PRV Plan" for non-overlapping; a special logical volume PTV2\_nR was created by extracting

previously made rings from PTV2 for more clear DVH and statistical analysis.

Being completely involved into the target volume such OARs as optic chiasm and brain stem including their PRVs were added to "Target Constraints" tab along with other PTVs for better dose control in this areas. For the most conformal treatment plan deliverable in a reasonable time, all plans were generated using a 2.5 cm field width, pitch 0.295 and the final modulation factor of 2.1. The template was made within the treatment planning system (TPS).

All previously treated patients were replanned and target coverage was analyzed for PTV1 and PTV2\_nR in terms of homogeneity index (HI) and conformation number (CN),

$$HI = \frac{D_{1\%} - D_{99\%}}{D_{50\%}}; CN = \frac{TV_{95\%}}{TV} \cdot \frac{TV_{95\%}}{V_{95\%}}$$

where  $TV_{95\%}$  - tumor volume covered with 95% isodose, TV - tumor volume,  $V_{95\%}$  - volume of 95% isodose.

The results are shown in the table below.

№	N of mets	GTV vol., ml	PTV1 vol., ml	PTV2_nR vol., ml	Old Tr-t T, min	Tr-t T, min	PTV1		PTV2_nR	
							HI	CN	HI	CN
1	3	30.4	62.55	1543.13	8.4	7.3	0.077	0.827	0.073	0.824
2	4	25	53.09	1353.21	10.5	7.5	0.056	0.743	0.063	0.754
3	2	19.28	38.96	1396.37	8.4	6.8	0.051	0.815	0.063	0.821
4	2	64.93	108.42	1355.34	7.1	6.6	0.078	0.9	0.081	0.808
5	2	67.84	123.26	1133.36	8.7	6.4	0.113	0.863	0.074	0.805
6	3	3.2	12.14	1480.8	7	6.8	0.065	0.738	0.073	0.852
7	1	17.66	37.24	1542.97	8.1	7	0.073	0.783	0.077	0.848
8	2	0.54	3.41	1675.4	6.5	6.4	0.056	0.682	0.075	0.851

### Conclusion

The development and implementation of standard technique for WBRT with SIB allowed us to much faster treatment planning performance using automated workflows for additional structures creation and TPS template for lower machine time used. The treatment time was decreased from 8.09±2.98 min to 6.85±0.95 min (p=0.05). New plans showed good homogeneity (HI 0.071±0.047 for PTV1 and 0.072±0.015 for PTV2\_nR) and conformity (CN 0.794±0.169 for PTV1 and 0.82±0.077 for PTV2\_nR) (p=0.05) with good OAR sparing.

<sup>3</sup>Università di Bologna, Radiation Oncology Center- Department of Experimental- Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

<sup>4</sup>Ospedale Bellaria, Radiation Oncology Department, Bologna, Italy

<sup>5</sup>Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Radiation Oncology Department, Roma, Italy

### Purpose or Objective

High dose irradiation to hippocampus is critical in determining neurocognitive function (NCF) outcomes. We evaluated the feasibility of intensity-modulated whole-brain radiotherapy (IMRT) and simultaneous integrated boost (SIB) to multiple brain metastases (BMs) to generate hippocampus-sparing plans.

### Material and Methods

5 patients with a total of 16 BMs who previously underwent whole brain radiotherapy with boost to multiple

metastases were selected. Radiotherapy was prescribed according to simultaneous integrated boost technique with all targets irradiated simultaneously over 10 daily fractions. Doses of 30 Gy and 50 Gy were prescribed to PTV<sub>whole-brain</sub> and PTV<sub>mets</sub>, respectively. Bilateral hippocampi were delineated according to RTOG 0933 trial suggestions, on T1w MRI co-registered planning CT. Clinical standard plans (s-IMRT) were compared with plans aiming to spare hippocampus irradiation. Two plans were re-optimized for hippocampal sparing using two Elekta MLCs: MLCi2 with 10mm leaf width (hs10-IMRT) and Agility with 5 mm leaf widths (hs5-IMRT). All plans were evaluated using target coverage metrics, homogeneity index (HI) and conformity index (CI). Normal tissue complication probabilities (NTCP) for neurocognitive function impairment (NCF) were calculated using a predictive model developed by Gondi et al.

### Results

Plans aiming to hippocampus sparing demonstrated comparable planning target volumes coverage and no differences in sparing of other organs at risk (brainstem, optic chiasm, eyes, lens). Significant reductions in hippocampal doses relative to standard plans were achieved in all patients. Mean dose to bilateral hippocampi was reduced from 36.5 Gy (range: 34.7-37.7 Gy) to 17.4 Gy (range: 11.2-24.7 Gy) and 16.4 Gy (range: 11.0-24.1) for hs10-IMRT and hs5-IMRT plans, respectively. D40% was reduced from 36.9 Gy (range: 35.3-37.7 Gy) to 18.2 Gy (range: 11.8-25.2 Gy) and 17.2 Gy (range: 11.5-25.0 Gy) for hs10-IMRT and hs5-IMRT plans, respectively. Mean NTCP values for NCF impairment as predicted by Gondi model decreased from 98.0% (range: 97.7-98.5%) to 62.1% (range: 34.8-83.9%) and to 58.2% (range: 33.4-83.5%) for hs10-IMRT and hs5-IMRT plans, respectively. Dose reductions depended mainly on metastases location and distance from hippocampus.

### Conclusion

IMRT plans aiming at sparing bilateral hippocampi can be successfully optimized with SIB-IMRT despite the high-dose irradiation of multiple brain metastases, providing a significant reduction in NTCP for radiation induced NCF decline.

### EP-1578 Frameless intracranial radiosurgery with Helical Tomotherapy: preliminary results.

M. Iacco<sup>1</sup>, C. Zucchetti<sup>1</sup>, M. Lupattelli<sup>2</sup>, C. Aristei<sup>2</sup>, C. Fulcheri<sup>1</sup>, R. Tarducci<sup>1</sup>

<sup>1</sup>Santa Maria della Misericordia Hospital, Medical Physics Department, Perugia, Italy

<sup>2</sup>Santa Maria della Misericordia Hospital, Radiation Oncology Department, Perugia, Italy

### Purpose or Objective

To report the preliminary results of radiosurgery treatments with Helical Tomotherapy (HT) by means of an non-invasive frame.

### Material and Methods

Between April and October 2016, 6 patients underwent radiosurgery with HT for treatment of 10 brain lesions with a median dose prescription of 20 Gy (range 15-22 Gy). The planning target volume (PTV) was created expanding 2mm in all directions the gross tumor volume (GTV). The median PTV was 1.5cc (range 0.6-7.7cc). Treatment plans were performed with the following parameters: field width of 1.05cm, pitch in the range 0.108-0.150, and modulation factor (MF) in the range 1.5-3.5, leading to a final MF of 1.6 on average (range 1.1-2.2). All plans were prescribed according to ICRU83 at the median of PTV, trying to limiting cold ( $D_{98\%}>95\%$ ) and hot spots ( $D_{2\%}<107\%$ ). In addition, 12Gy-volumes ( $V_{12Gy}$ ) of the healthy brain, associated with symptomatic radiation risk of necrosis, was reduced below 10cc. Treatment plans were analyzed recording  $D_{98\%}$ ,  $D_{mean}$  and  $D_{2\%}$  of the PTV. Moreover the

conformity, homogeneity and gradient score indexes were calculated and compared with published reports of HT radiosurgery. Furthermore, the  $V_{12Gy}$  of the healthy brain was also evaluated. A mask-based fixation system has been chosen, because of its high intracranial repositioning accuracy (always <1mm, further details have been discussed in another our work).

### Results

The mean  $D_{98\%}$ ,  $D_{mean}$  and  $D_{2\%}$  of the PTV were  $(90.0 \pm 3.5)\%$ ,  $(99.4 \pm 1.8)\%$ , and  $(106.9 \pm 3.1)\%$  respectively. The minimal dose to the target was slightly lower than the objective, however it was sacrificed in order to have low doses to the healthy brain. The mean values of conformity, homogeneity and gradient score indexes were  $1.4 \pm 0.2$ ,  $1.08 \pm 0.03$  and  $57 \pm 10$  respectively and all indexes were comparable with published results (Table 1). The  $V_{12Gy}$  of the healthy brain was strictly respected except in two cases, where multiple lesions were treated and the prescription was 20Gy and 21Gy. The median  $V_{12Gy}$  was 8.8cc. No acute toxicity of any kind was recorded. The mean treatment time was  $15 \pm 4$  minutes with a maximum of 46 minutes for a patient treated with two consecutive plans irradiating 4 lesions.

Abbreviations: PTV=planning target volume; NA=Not Applicable; not published values or not directly comparable; \* calculated according to ICRU 83

### Conclusion

HT radiosurgery for single and multiple brain metastases appears feasible with satisfying dosimetric results. Moreover, it appears to have encouraging clinical outcomes and the use of non-invasive set-up improves the treatment cosmetic and patient comfort.

### EP-1579 Practical dosimetrical issues in Intraoperative electron radiation therapy

S. Wadi-Ramahi<sup>1</sup>, F. Alzorkany<sup>1</sup>, B. Mofteh<sup>1</sup>, A. Alsuhaibani<sup>2</sup>

<sup>1</sup>King Faisal Specialist Hospital and Research Center, Biomedical Physics, Riyadh, Saudi Arabia

<sup>2</sup>King Faisal Specialist Hospital and Research Center, Radiation Oncology, Riyadh, Saudi Arabia

### Purpose or Objective

Our intraoperative radiation therapy (IORT) service is an active one treating around 50 patients/year. Sarcomas and gastric tumors are the most we treat with IORT. Certain cases pose clinical challenges, such as the use of cone blocking, abutting treatment fields, retreats, and bone partially covering the treatment area. The purpose of this work is to discuss some of these situations and our proposed solutions used clinically at the time.

### Material and Methods

We have the Mobetron® linac (IntraOp, Ca) which can deliver 6, 9 and 12MeV high dose rate electron beams, and an array of cones ranging in diameter from 3 to 10 cm for zero, 15 and 30 deg bevel angles. Only three clinically-faced dosimetrical issues will be discussed here: a) Use of lead shielding to conform to an irregularly shaped tumor, b) The presence of bone in the treatment field as in intraarticular sarcoma and pelvic tumors, c) Abutting two electron cones to treat a long tumor bed.

### Results

a) Following a case requiring ~30% of the area to be blocked, we measured the output for 30% blocked cones using a 0.125cc chamber in water. Each output was normalized to that of the 10cm open cone to calculate

$OF_{blocked}$ . For cones with diameter > 6 cm the  $OF_{blocked}$  was within -5% of the  $OF_{open}$ , for those with diameter <6 cm had a decreased  $OF_{blocked}$  reaching almost to 80% of the  $OF_{open}$ . This behavior was noted for all energies, Fig.1. The use of the  $OF_{blocked}$  for treatment is a physics decision, taking into account the amount of blocked area of the cone, cone size and beam energy. Noting that the  $OF_{blocked}$  were measured for 30% blocked area. b) For a tumor that is partially shielded by bone and treated with a single en face electron beam requires balancing penetration through the bone with exposing normal tissue. The thickness of the bone in a plane parallel to the direction of the beam is measured and then converted to effective depth by using the coefficient of equivalent thickness (CET) using the electron density of bone, 1.65electron/mL. This distorts the shape of the tumor by introducing deep arms, Fig2a. One such case was a sarcoma extending to the intraarticular space and the humeral head covering part of the field. The energy in this case is chosen such that 90% isodose is at the deepest part. Shielding of the normal tissue underneath the shallower parts of tumor is discussed and applied according to practicality of site. C) For long tumors, abutting circular cones at the surface will leave lateral parts under-dosed, while overlapping the cones will introduce high dose, Fig2b. The clinical decision for these cases is to abut at the surface to avoid hot spots in the overlapped area. Overlap of low doses from each cone at depth is deemed acceptable.

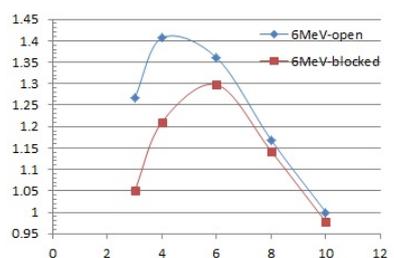

Fig1a: OF vs cone diameter for 6MeV

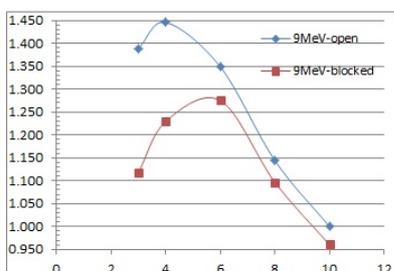

Fig1b: OF vs cone diameter for 9MeV

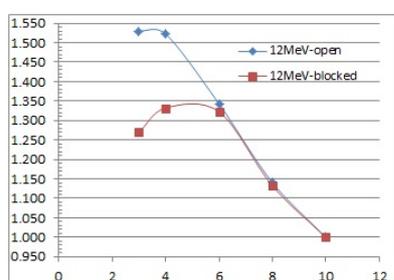

Fig1c: OF vs cone diameter for 12MeV

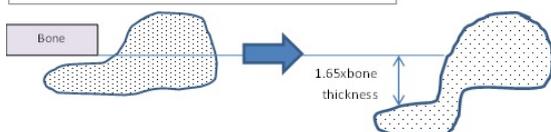

Fig2a: Treating tumors shielded by bone

Fig2b: Treating long area with abutting cones

### Conclusion

Since the start of IORT service in Aug 2013, we have delivered 146 treatment fields to 130 patients with limited toxicity and excellent local control. In a busy service, IORT is not always a straightforward electron treatment, and staff experience and adequate data is important.'

### EP-1580 Dosimetric comparison between 3D-conformal radiation therapy and VMAT in Total Lymphoid Irradiation

C. Ferrer<sup>1</sup>, C. Huertas<sup>1</sup>, A. Escribano<sup>1</sup>, R. Plaza<sup>1</sup>, R. Morera<sup>2</sup>, A. Serrada<sup>2</sup>

<sup>1</sup>Hospital universitaria La Paz, Radiofísica y Radioprotección, Madrid, Spain

<sup>2</sup>Hospital universitaria La Paz, Oncología Radioterápica, Madrid, Spain

### Purpose or Objective

Total Lymphoid Irradiation (TLI) is used in the management of pediatric allogeneic hematopoietic stem cell transplantation (HSCT). This study compares the conventional 3D-conformal radiation therapy (3DCRT)

anteroposterior-posteroanterior (AP-PA) technique with volumetric-modulated arc therapy (VMAT) for TLI.

### Material and Methods

Treatment plan for conventional AP-PA technique was performed with XiO treatment planning system (CMS, v. 5.00.01) and VMAT plan was performed with Elekta Monaco treatment planning system (v. 5.00.00), optimized using biological and physical based cost functions, on an Elekta Synergy linear accelerator equipped with a 160-leaf Agility MLC.

Prescription dose was 8 Gy in 2Gy daily fractions. Patient was in supine position over a custom shaped vacuum bag device, along with an aquaplast mask for head position reproducibility. The arms were extended laterally. VMAT treatment consisted in 2 isocenters, with 4 cm overlap length and 2 partial arcs (290° - 70° and 135° - 210°) each. Linac treatment couch was included in the calculation.

For both techniques, PTV coverage, conformation index (CI), conformation number (CN) and Heterogeneity index (HI) have been compared, as well as doses to organs at risk (OAR) and integral body dose. **Results**

Table 1 shows the results obtained for the PTV and OARs. PTV coverage with both techniques was adequate (V95%= 91.5% and 95.3% for 3DRT and VMAT respectively), HI were similar, but conformation indices were better with VMAT technique. VMAT also improved the doses to the lungs, the heart and the spinal cord. Heart volume receiving 5 Gy or more (V<sub>5Gy</sub>) and receiving 8 Gy or more (V<sub>8Gy</sub>) was considerably lower in VMAT plan. Integral dose, calculated by the product of mean dose to the patient without the PTV and the irradiated volume was 11% lower in the VMAT plan and the mean skin dose 33% lower

ORGAN	PARAMETER	3D-CRT	VMAT
PTV	Mean (cGy)	785,4	801,9
	V <sub>95%</sub> (%)	91,5	95,3
	V <sub>90%</sub> (%)	95,4	98,1
	CI	3,4	0,8
	CN	0,0	0,6
	HI	1,2	1,1
Both lungs	Mean (cGy)	450,0	388,3
	V <sub>5Gy</sub> (%)	44,9	33,7
	V <sub>8Gy</sub> (%)	19,7	0,7
Right lung	Mean (cGy)	388,8	349,1
	V <sub>5Gy</sub> (%)	37,1	28,6
	V <sub>8Gy</sub> (%)	15,0	0,4
Left lung	Mean (cGy)	522,7	438,1
	V <sub>5Gy</sub> (%)	53,8	40,1
	V <sub>8Gy</sub> (%)	24,7	1,0
Heart	Mean (cGy)	723,7	402,9
	V <sub>5Gy</sub> (%)	73,7	29,1
	V <sub>8Gy</sub> (%)	83,5	2,1
Spinal cord	Mean (cGy)	690,7	496,3
Skin dose	Mean (cGy)	586	193

### Conclusion

Although both techniques achieve similar PTV coverage, VMAT plan shows higher level of conformation, with considerably lower mean skin dose and integral dose in spite of the low-dose spread. Doses to OAR are also lower with VMAT, specially the heart. VMAT technique can be very beneficial for pediatric patients undergoing TLI, with lower late organ toxicity.

### EP-1581 Dosimetric comparison of treatment plans for pancreatic cancer: 3DCRT, IMRT and VMAT

P. Trecca<sup>1</sup>, M. Fiore<sup>1</sup>, B. Floreno<sup>1</sup>, R. D'Angelillo<sup>1</sup>, L. Trodella<sup>1</sup>, A. Mameli<sup>1</sup>, E. Infusino<sup>1</sup>, C. Greco<sup>1</sup>, L. Trodella<sup>1</sup>, S. Ramella<sup>1</sup>

<sup>1</sup>Campus Biomedico University, Department of Radiation Oncology, Roma, Italy

### Purpose or Objective

To evaluate conformity, homogeneity and dose distribution to PTV and organ at risk (OAR) of three different types of radiotherapy techniques in pancreatic cancer.

### Material and Methods

Three radiotherapy treatment plans, including 3DCRT, forward-planning IMRT and volumetric arc therapy (VMAT) were created for 18 consecutive patients with pancreatic cancer. Eight postoperative patients with a resectable pancreatic cancer and ten patients with unresectable locally advanced disease were selected for this dosimetric analysis. Dose Volume Histogram (DVH) comparative analysis was performed for PTV and OAR. Paired t-test was used for statistical analysis.

### Results

All plans exhibited similar PTV coverage (V95%) and conformity (all  $p > 0.05$ ). The Homogeneity Index (HI) was acceptable for all plans; in particular, it was higher in VMAT plans than in 3D-CRT and IMRT plans. The mean dose to the liver was 13.5 Gy for 3D, 12.1 Gy for IMRT, 10.9 Gy for VMAT ( $p < 0.001$ ) to the benefit of VMAT. Volumes of kidneys irradiated to doses of 20Gy (V20), 23Gy (V23), 28Gy (V28) by the VMAT plans were significantly less than those of the IMRT and 3D-CRT plans. The volume of kidneys irradiated to a dose of 12 Gy (V12) was not significantly different comparing the three techniques. Mean of the maximum point dose to spinal cord was better in VMAT plans (3D-CRT vs IMRT vs VMAT, 30.6 Gy, 34.1 Gy, 26.5 Gy, respectively;  $p < 0.001$ ).

### Conclusion

VMAT can be a better option in treating pancreatic cancer as compared to IMRT and 3D-CRT. The VMAT plans resulted in equivalent or superior dose distribution with a reduction in the dose to organ at risk.

### EP-1582 Analysis of Risk of a Second Cancer from Scattered Radiation in Acoustic Neuroma Treatment

Y. Oh<sup>1</sup>, D.O. Shin<sup>2</sup>, D.H. Shin<sup>3</sup>, W.K. Chung<sup>4</sup>, M. Chung<sup>4</sup>, D.W. Kim<sup>4</sup>

<sup>1</sup>Kyung Hee University Hospital at Gangdong, Research Institute of Clinical Medicine, Seoul, Korea Republic of  
<sup>2</sup>Kyung Hee University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of

<sup>3</sup>National Cancer Center, Proton Therapy Center, Goyang, Korea Republic of

<sup>4</sup>Kyung Hee University Hospital at Gangdong, Department of Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

This study aimed to compare the risk of a secondary cancer from scattered and leakage doses in patients receiving intensity-modulated radiotherapy (IMRT), volumetric modulated arc therapy (VMAT), stereotactic radiosurgery (SRS), Proton therapy and Tomotherapy.

### Material and Methods

Acoustic neuroma patients were treated with IMRT, VMAT, SRS, Proton therapy or Tomotherapy. Their excess relative risk (ERR), excess absolute risk (EAR), and lifetime attributable risk (LAR) of a secondary cancer were estimated using the corresponding secondary doses measured at various organs by using radio-photoluminescence glass dosimeters (RPLGD) placed inside a humanoid phantom.

### Results

When a prescription dose was delivered in the planning target volume of the 4 patients, the highest organ equivalent doses (OED) was calculated in to Proton therapy, followed by SRS, VMAT, IMRT and Tomotherapy. The OED decreased as the distance from the primary beam increased. The thyroid received the highest OED compared to other organs. A lifetime attributable risk evaluation estimated that more than 0.03% of acoustic neuroma (AN)

patients would get radiation-induced cancer within 20 years of receiving radiation therapy.

### Conclusion

The organ with the highest radiation-induced cancer risk after radiation treatment for AN was the thyroid. We found that the LAR could be increased by the transmitted dose from the primary beam. No modality-specific difference in radiation-induced cancer risk was observed in our study.

### EP-1583 Quantifying Plan Quality Metrics using Conventional and Stereotactic dosimetric indices in Lung SBRT

R. Yaparalvi<sup>1</sup>, M. Garg<sup>1</sup>, W. Bodner<sup>1</sup>, J. Shen<sup>1</sup>, D. Mynampati<sup>1</sup>, H. Kuo<sup>1</sup>, N. Ohri<sup>1</sup>, J. Fox<sup>1</sup>, A. Basavatia<sup>1</sup>, S. Kalnicki<sup>1</sup>, W. Tome<sup>1</sup>

<sup>1</sup>Montefiore Medical Center, radiation Oncology, bronx, USA

### Purpose or Objective

Several metrics have been proposed in literature for evaluating treatment plan quality in conventional and stereotactic planned dose distributions. In this study, we utilized these metrics for characterizing and quantifying Lung SBRT dose distributions. By applying various plan quality metrics available in the literature, we sought to not only characterize Lung SBRT target dose distributions but also evaluate merits of these metrics as tools for lung SBRT plan quality assessment.

### Material and Methods

Treatment plans of 100 Lung SBRT patients treated in our institution were retrospectively reviewed. Dose calculations were performed using AAA algorithm with heterogeneity correction. A literature review on published plan quality metrics in the categories- coverage, homogeneity, conformity and gradient was performed. For each patient, using dose-volume histogram (DVH) data, plan quality metric values were quantified. Data were analyzed using descriptive statistics and two-tailed probability t-test (Wilcoxon signed-rank test). A p-value of  $< 0.05$  was considered statistically significant.

### Results

For the study, the mean ( $\pm$ SD) plan quality metrics in the four representative categories were: Coverage ( $96.4 \pm 2.4$  %); Homogeneity ( $0.21 \pm 0.06$ ); Conformity ( $0.90 \pm 0.06$ ) and Gradient ( $1.27 \pm 0.30$  cm). Geometric conformity strongly correlated with conformity index ( $p < 0.0001$ ). Gradient measures strongly correlated with target volume ( $p < 0.0001$ ). The RTOG lung SBRT protocol advocated conformity guidelines for prescribed dose in all categories were met in  $\geq 94$ % of cases. Evaluating High Dose Spillage, the average cumulative volume of all tissue outside the PTV receiving a dose of  $> 105$ % of prescription dose was  $0.94 (\pm 1.64)$  %. Considering Low Dose Spillage, the maximum % of prescription dose to any point at 2 cm distance in any direction from PTV was  $56.0 (\pm 11.4)$  %. The proportion of lung volume (total lung volume - GTV) receiving doses of 20 Gy and 5 Gy (V<sub>20</sub> and V<sub>5</sub>) were mean  $4.9 (\pm 3.1)$  % and  $16.9 (\pm 9.0)$  %, respectively.

### Conclusion

Our study metrics are valuable tools for establishing lung SBRT plan quality guidelines. Based on our data, we recommend using the following metrics as surrogates for establishing SBRT lung plan quality guidelines- Coverage % (ICRU 62), Homogeneity (HI<sub>ICRU83</sub>), Conformity (CN or C<sub>Paddick</sub>), and Gradient (R<sub>50%</sub>).

### EP-1584 Deformable image registration and dose accumulation for arc-Total Body Irradiation

G. Guidi<sup>1</sup>, N. Maffei<sup>1</sup>, P. Ceroni<sup>1</sup>, G.M. Mistretta<sup>1</sup>, F. Lohr<sup>2</sup>, T. Costi<sup>1</sup>

<sup>1</sup>Az. Ospedaliero Universitaria di Modena, Medical Physics, Modena, Italy

<sup>2</sup>Az. Ospedaliero Universitaria di Modena, Radiation Oncology, Modena, Italy

#### Purpose or Objective

For Total Body Irradiation (TBI) very few experiences of dose calculation using Treatment Planning Systems (TPS) have been reported. The estimation of local dose inhomogeneity and sparing of critical organs is usually performed based spreadsheet calculation fine-tuned by in-vivo measurements. No reports exist for treatment planning with a TPS and dose accumulation based on deformable registration. We report the implementation of these techniques using RayStation<sup>®</sup> commissioned to perform any type of treatment plan and to estimate actual dose distribution as delivered with a Volumetric Modulated Arc Therapy (VMAT)-based TBI technique.

#### Material and Methods

For TPS commissioning, the PTW<sup>®</sup> water tank was positioned at 170cm from the LINAC (Elekta Synergy<sup>®</sup>). PDD, profile and output factors were acquired (8.5x8.5, 10x10, 17x17, 34x34, 51x51, 68x68, 68x8.5, 68x17, 68x34, 68x51 cm<sup>2</sup>). The TBI plan was calculated using a total body CT in supine and prone position and the inverse planning and 3DCRT module available in the TPS. A dose of 600cGy in 6 fractions was prescribed to the midline of the patient outline as contoured in supine and prone position. A longitudinal VMAT-technique with 8 arcs [330°±30° with step of 10°] was simulated using 6MV photons. The ANACONDA algorithm was applied to perform the elastic image registration (0.15cm of grid size) between the two CTs. The deformed vectors fields obtained were used to warp the dose grid allowing, the dose summation between the supine and the prone treatment.

#### Results

The relative weighting factors of the beams were experimentally obtained and confirmed by the calculation of the TSP; a specific MU/fx was set for each gantry angle into the range of [100÷191]MU/fx, based on the previously published VMAT-technique. For the supine and prone treatments, 607cGy and 544cGy were recorded at the respective prescription points in the separate treatment, respectively. The summation of both dose distributions with dose warping using the SumDoses tool developed as described above resulted in an average dose of 1154cGy with quite uniform irradiation.

#### Conclusion

This study assessed the possibility to apply a dedicated TPS with hybrid algorithms to the novel VMAT-TBI technique. A real-time dosimetry was obtained simulating the patient treatment in both supine and prone setup and a cumulative dose was analyzed using deformation and a summation of the dose grids. With this planning approach, lung sparing can be performed as before with individualized lung blocks but this approach would also provide the possibility to directly modulate dose reductions over the lungs (provided appropriate patient positioning can be assured). After full commissioning of the TPS for extended SSD-conditions within the requirements of the TBI-delivery technique, an optimized comprehensive treatment planning approach would be available for this treatment paradigm.

#### EP-1585 A practical method to reduce monitor units in prostate cancer RapidArc plans

D. Sánchez-Artuñedo<sup>1</sup>, S. Jiménez-Puertas<sup>1</sup>, M. Sancho-Navarro<sup>1</sup>, M. Hermida-López<sup>1</sup>  
<sup>1</sup>Hospital Universitari Vall d'Hebron, Servei de Física i Protecció Radiològica, Barcelona, Spain

#### Purpose or Objective

While optimizing a RapidArc (RA) plan with Eclipse Progressive Resolution Optimizer (PRO) algorithm (Varian Medical Systems), it is possible to select a monitor units

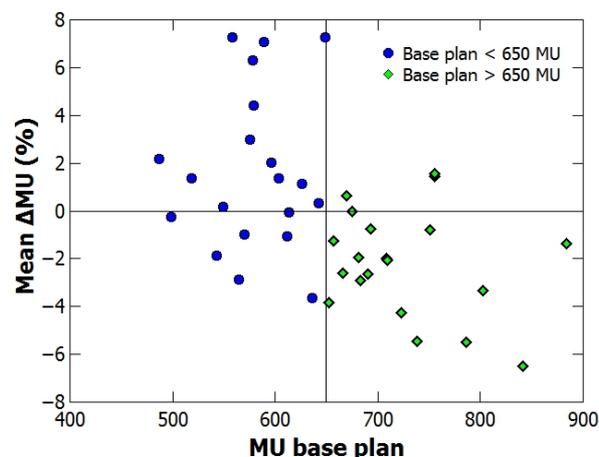

(MU) objective value with the MaxMU dimensionless parameter. We aimed to minimize MU for prostate RA plans as a function of the MaxMU value.

#### Material and Methods

We retrospectively evaluated 40 prostate RA plans optimized with the PRO algorithm of Eclipse v.11. Prescribed doses were 57 Gy/ 59.5 Gy for PTV1 (including prostate and seminal vesicles), and 15 Gy/17.5 Gy for a simultaneous boost to the prostate only, for 30/35 fractions. For each patient, the original plan optimized without a MaxMU constraint (*base plan*) was reoptimized (*reoptimized plan*) for six values of MaxMU: 1000, 800, 700, 600, 500 and 400. Differences in dosimetric parameters of PTV and OAR between the base and reoptimized plans were analyzed with a paired samples t-test. For PTVs the mean dose, D2%, D98%, V95% and (D5%-D95%) were evaluated. For all OAR (rectum, bladder and femoral heads) the mean dose was considered. Furthermore, in rectum, V50, V60, V70; in bladder, D67%, V30 and in femoral heads and bladder, D2%.

#### Results

For MaxMU ≤ 0.75×MU<sub>base\_plan</sub>, the mean reduction of MU was of -2.3% (p<0.001). For MaxMU between 0.75×MU and MU, the mean reduction of MU was -1.3% (p=0.01). For MaxMU ≥ MU, the mean MU increased by 1.2% (p<0.001). Base plans with MU > 650 showed a MU mean reduction of -2.2% (p<0.001). The maximum mean decrease was obtained for MaxMU=500 (-3.7%; p<0.001). Base plans with MU < 650 showed a MU mean increase of 1.7% (p<0.001). However, for some plans the MU decreased (see graph). No clinically relevant differences were found for the analyzed dosimetric parameters.'

#### Conclusion

Prostate cancer Rapid Arc plans may be divided in two groups based on the MU of the base plan. For plans with MU < 650, MU tend to increase if MaxMU parameter is used, but not in all cases (see graph). Due to this variability, we recommend to use this parameter and to compare the obtained plan with the base plan. For plans with MU > 650, a mean MU decrease was obtained being maximum for MaxMU=500. We recommend in this case to reoptimize using this value. The MU reduction was achieved without compromising plan quality.

#### EP-1586 ART and VMAT-the benefits in bone marrow sparing for patients with bladder cancer

M. Poncyljusz<sup>1</sup>, D. Blatkiewicz<sup>1</sup>, J. Chorazy<sup>1</sup>, B. Czyzew<sup>1</sup>, P.F. Kukulowicz<sup>1</sup>, M. Piziorska<sup>1</sup>  
<sup>1</sup>The Maria Skłodowska-Curie Memorial Cancer Centre and Institute of Oncology, Department of Medical Physics, Warsaw, Poland

### Purpose or Objective

The combination of Adaptive Radiotherapy (ART) and VMAT allows to create more conformal plans for patients with bladder cancer without risk of missing target during changes of bladder volume and shape. Relative position of small bowel is influenced by the volume of treated bladder. Recent reviews demonstrated the advantages of using ART in bowel sparing during bladder irradiation. The aim of this study was to assess feasibility of simultaneous sparing of bone marrow, small bowel and rectum using combination of ART and VMAT.

### Material and Methods

The planning CT and 20 CBCT images of each of the five patients were taken into account in this retrospective study to simulate adaptive radiotherapy. The prescribed dose was 52Gy in 20 fractions to the whole bladder. PTV<sub>large</sub> was created by adding isotropic margin of 1,5 cm to the bladder in the planning CT. PTV<sub>small</sub> and PTV<sub>medium</sub> were constructed based on the bladder contours in CBCT images by adding 7-mm margin to the smallest and the largest contour, respectively. The conventional non-adaptive VMAT plans were calculated for PTV<sub>large</sub>. A library of treatment plans for ART was created by generating three VMAT plans linked to the different PTVs for each patient. Simulating the ART treatment, the appropriate plans were selected according to the volume of the bladder registered in CBCT images. The cumulative dose distribution (the ART dose distribution) was calculated as a sum of dose distributions obtained for each fraction. DVHs for pelvic bones, bowel bag and rectum were calculated and compared with corresponding histograms obtained for conventional plans. The following parameters were analysed: V45Gy[cc], V30Gy[cc] for pelvic bones and bowel bag and V50Gy[%], V45Gy[%] for rectum.

### Results

For a cohort of 100 registered CBCT images, 16 of PTV<sub>large</sub>, 66 of PTV<sub>medium</sub> and 18 of PTV<sub>small</sub> were selected to create ART plans. The dosimetric quantities of ART plans and conventional plans were comparable for target coverage. The ART plans resulted in significant reduction in pelvic bones V45Gy[cc], V30Gy[cc], bowel bag V45Gy[cc], V30Gy[cc] and rectum V50Gy[%], V45Gy[%] when compared to conventional plans.

### Conclusion

The ART connected with VMAT technique offers feasibility to create advanced conformal plan without a risk of missing target. It allows better pelvic bones sparing while maintaining bowel bag and rectum dose limits. The lower doses delivered to pelvic bones and thus also to bone marrow allow to expect the lower hematological toxicity.

### EP-1587 feasibility investigation of prone position robotic radiosurgery treatment for dorsal metastasis

E. Kucukmorkoc<sup>1</sup>, N. Kucuk<sup>1</sup>, M. Doyuran<sup>1</sup>, H. Acar<sup>1</sup>, D. Canoglu<sup>1</sup>, R. Rashad<sup>1</sup>, H.B. Caglar<sup>1</sup>  
<sup>1</sup>Medipol University, Radiation Oncology, Istanbul, Turkey

### Purpose or Objective

Treatment of dorsal region tumors with radiosurgery includes different types of problem such as movement of chest, large inhomogeneity region because of lung, exposure risk of arms etc. Decision of patient position before treatment planning is very important to minimize these problems. The purpose of this study is to investigate feasibility of prone position robotic radiosurgery treatment with real time tumor tracking for dorsal region metastasis.

### Material and Methods

10 patients were selected for this study. Planning CT scans were acquired both supine and prone position for all cases. CTV and all critical structures were contoured by same physician. RTOG 0631 protocol criterias were used for

contouring and treatment planning. Multiplan 5.3 (Accuray Inc) with Monte Carlo algorithm was used for all dose calculations. Treatment plan quality indices and organ at risks were compared. Paired Samples T Test was used for statically analysis.

### Results

Mean PTV<sub>min</sub>, PTV<sub>max</sub> and PTV<sub>mean</sub> values are 11.65, 24.49 and 20.90 Gy for supine and 12.40, 23.35 and 20.52 Gy for prone positions, respectively. PTV<sub>min</sub> value in prone plans is significantly higher than in supine plans (p=0.035). There is no significant differences for spinal cord, partial spinal cord, heart, and liver but we found lower values in prone plans for lung (1000cc) and esophagus and statically important (p=0.07 and p=0.031, respectively). Beam on time and MU values in prone plans are significantly lower than in supine plans (p=0.017 and p=0.004 respectively). No significant difference was found in conformity and gradient index. No significant difference in dose outside of the target volume and maximum dose within 1.0 cm from the edge of the target volume.

### Conclusion

Prone robotic radiosurgery with real time tumor tracking has a lot of advantages than supine treatment for dorsal region metastasis. Lower organ doses (esophagus and lungs), beam on time and MU can be achieve with prone setups.

### EP-1588 Dosimetric feasibility of an "off-breast isocenter" technique for whole-breast cancer radiotherapy

J. Casals Farran<sup>1</sup>, J.F. Calvo-Ortega<sup>1</sup>, S. Moragues<sup>1</sup>, M. Pozo-Massó<sup>1</sup>  
<sup>1</sup>Hospital Quiron Barcelona, Radiation Oncology, Barcelona, Spain

### Purpose or Objective

The use of kilovoltage orthogonal setup images has spread in last years in breast radiotherapy. There is a potential risk of collision imaging system-patient when the isocenter is laterally placed. The aim of this study is to investigate the viability of placing the treatment isocenter at the patient midline for breast cancer radiotherapy, in order to avoid the risk of collisions during image-guided setup and treatment delivery.

### Material and Methods

Twenty IMRT plans designed by placing the isocenter within the breast volume ("plan\_ref"), were retrospectively replanned by shifting the isocenter at the patient's midline ("plan\_off-breast"). An integrated simultaneous boost (SIB) technique was used. Multiple metrics for the planning target volumes (PTVs) and organs at risk (OARs) were compared for both approaches using a paired t test.

### Results

Comparing plan\_ref vs. plan\_off-breast, no significant differences in PTV coverage (V95%) were found (96.5% vs. 96.2%; p= 0.361 to PTV<sub>breast</sub>; 97.0% vs. 97.0%; p= 0.977 to PTV<sub>tumor\_bed</sub>). With regard to OARs, no substantial differences were observed in any analyzed metric: V5Gy (30.3% vs. 31.4%; p= 0.486), V20Gy (10.3% vs. 10.3%; p= 0.903) and mean dose (7.1 Gy vs. 7.1 Gy; p= 0.924) to the ipsilateral lung; V5Gy (11.2% vs. 10.0%; p= 0.459), V30Gy (0.7% vs. 0.6%; p= 0.251) and mean dose (2.3 Gy vs. 2.2 Gy; p= 0.400) to the heart; and average dose to the contralateral breast (0.4 Gy vs. 0.5 Gy; p= 0.107).

### Conclusion

The off-breast isocenter solution resulted in dosimetrically comparable plans as the reference technique, avoiding the collision risk during the treatment session.

### EP-1589 A novel integrated biological optimization strategy for cervical carcinoma

C. Tao<sup>1</sup>, Z. Feng<sup>2</sup>, J. Zhu<sup>1</sup>, J. Lu<sup>1</sup>, Y. Yin<sup>1</sup>

<sup>1</sup>Shandong Cancer Hospital Affiliated to Shandong University- Shandong Academy of Medical Sciences, Radiation Oncology, Jinan, China

<sup>2</sup>School of Physics and Electronics- Shandong Normal University, Shandong Province Key Laboratory of Medical Physics and Image Processing Technology, Jinan, China

#### Purpose or Objective

The purpose of this study was to evaluate the quality of intensity-modulated radiation therapy (IMRT) plans optimized by biological constraints for cervical carcinoma. Furthermore, a new integrated strategy in biological planning module was proposed and verified.

#### Material and Methods

In this study, twenty patients of advanced stage cervical carcinoma were enrolled. For each patient, dose volume based optimization (DVBO), biological model based optimization (BMBO) and integrated strategy based optimization (ISBO) plans were produced with the same treatment parameters. Different biological models, including LKB and Poisson model, were also used for organ at risk (OAR) respectively. To evaluate the plan quality of BMBO plans, the dosimetry differences between BMBO plans and their corresponding DVBO plans were evaluated. And ISBO plans were compared with DVBO and BMBO plans respectively to verify the performance of the integrated strategy proposed in this study.

#### Results

Compared with DVBO plans, BMBO plans produced slight inhomogeneity and worse coverage of planning target volume (PTV) (V95=96.787, HI=0.098; p<0.01). However, the tumor control probability (TCP) value were comparable. And BMBO plans produced lower normal tissue complication probability (NTCP) of rectum (NTCP=0.108) and bladder (NTCP=0.144) compared with corresponding DVBO plans (NTCP=0.186 and 0.178 for rectum and bladder, respectively) with significant differences. Better results of V95, D98, CI and HI values could be found in ISBO plans (V95=98.307, D98=54.181Gy, CI=0.762, HI=0.087) compared with BMBO plans (V95=96.787, D98=53.419Gy, CI=0.707, HI=0.098) with significant differences. Furthermore, ISBO plans produced lower NTCP values of rectum (NTCP=0.14) and bladder (NTCP=0.159) than DVBO plans (NTCP=0.186 and 0.178 for rectum and bladder, respectively; with p<0.01 and p<0.01 for rectum and bladder, respectively).

#### Conclusion

For cervical carcinoma cases, BMBO plans produced lower NTCP values of OARs than DVBO plans with a little worse target coverage and homogeneity. And the integrated strategy could produce better coverage, conformity and homogeneity of PTV than BMBO plans, and reduce the NTCP values of OARs compared with DVBO plans.

### EP-1590 Can bolus range shifting improve plan quality in the IMPT of head and neck cancer?

S. Michiels<sup>1</sup>, A. Barragán<sup>2</sup>, K. Souris<sup>2</sup>, K. Poels<sup>3</sup>, W.

Crijns<sup>3</sup>, J. Lee<sup>2</sup>, E. Sterpin<sup>1,2</sup>, S. Nuyts<sup>1,3</sup>, K.

<sup>1</sup>KULeuven - University of Leuven, Department of Oncology, Leuven, Belgium

<sup>2</sup>Université catholique de Louvain, Center of Molecular Imaging- Radiotherapy and Oncology - Institut de Recherche Experimentale et Clinique, Woluwe-Saint-Lambert, Belgium

<sup>3</sup>University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium

#### Purpose or Objective

In intensity-modulated proton therapy (IMPT) of head and neck cancer (HNC), range shifter (RS) air gap is known to widen the pencil beams reaching the patient. The actual effect on dose distributions however remained unassessed. Moreover, emerging technologies such as 3D printing enable to implement RS as bolus, hereby removing the air gap and reducing the risk of collision compared to nozzle-mounted RS. In this study, we assess the impact of clinically applied air gaps on IMPT plan quality, the potential of Monte Carlo (MC) dose calculation plan optimization to mitigate air gap effects, and the potential advantage of bolus RS compared to currently used RS solutions.

#### Material and Methods

Oropharyngeal cancer patients were selected for IMPT based on potential reduction of normal tissue complication probability (NTCP) for xerostomia and dysphagia. Prescription was 54 Gy to the elective neck and 66 Gy to the primary tumor in 30 fractions. Table 1 shows the considered organs-at-risk (OAR). For the treatment planning, a 5 mm CTV-to-PTV-margin was used, and gantry angles 50°, 180° and 310°, with 4 cm of PMMA as RS. Pencil beams from clinical beam data were placed with 5 mm spot spacing and target margin. Beamlets were calculated with a 2x2x2 mm<sup>3</sup> voxel size using the MCsquare fast-MC dose engine. Beamlet weight optimization was performed using the IPOPT non-linear solver. For each patient, 3 different RS cases were compared (Figure 1): applied as bolus, mounted on a 25 cm snout accessory or on a 40x30 cm<sup>2</sup> nozzle. Firstly, the air gap effect was determined by a MC recalculation of the optimal bolus plan (=baseline) on the snout and nozzle case. This represents the scenario in which the air gap is disregarded during optimization. Secondly, the snout and nozzle case were optimized to re-establish the initial clinical goals in the presence of air gap. Finally, differences in OAR dose and NTCP between all optimized RS cases were calculated.

#### Results

Results for 3 patients were compiled in Table 1. Suboptimal planning by disregarding the air gap yielded underdosage ranging from 3.4 Gy to 7.7 Gy for PTV<sub>66Gy</sub> (D<sub>98%</sub>) and from 3.8 Gy to 10.1 Gy for PTV<sub>54Gy</sub>. Case-specific optimization restored PTV coverage, but increased the mean dose to most OARs due to the compromised lateral penumbra of the pencil beams. Compared to the bolus plan, these OAR dose increments translated into xerostomia NTCP increases between 3.9% and 7.1% and dysphagia NTCP increases between 1.5% and 5.0%.

#### Conclusion

The actual effect of RS air gaps in clinical circumstances was quantified for IMPT in HNC. Including the air gap in the plan optimization is essential, but cannot cancel out the impact of spot degradation on OAR dose. In this regard, bolus RS can considerably improve plan quality compared to snout/nozzle mounted RS. NTCP reductions for xerostomia and dysphagia achieved with bolus were not negligible compared to the 10% threshold proposed by the model-based selection of patients for IMPT (Langendijk et al. Radiother Oncol 2013).

Table 1a) Bolus optimal plan recalculated on snout and nozzle cases

D <sub>95%</sub>	Patient 1			Patient 2			Patient 3

<sup>2</sup>Moderate to severe patient-rated xerostomia after 6 months (Beetz et al. Radiother Oncol 2012)  
<sup>3</sup>Physician-rated swallowing dysfunction after 6 months (Christiansen et al. Radiother Oncol 2012)

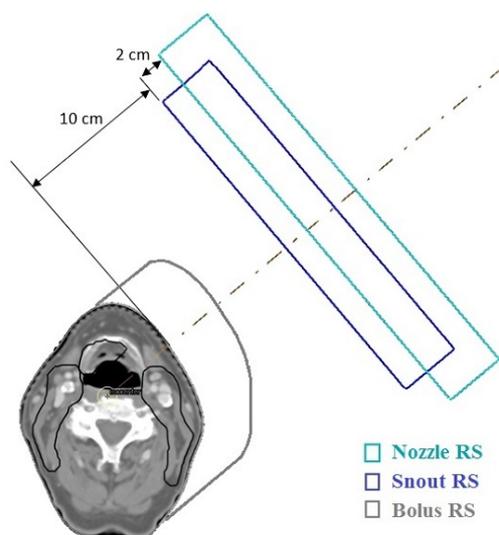

Figure 1. Visualization of the range shifter position when applied as bolus, mounted on a 25 cm diameter snout accessory or on a 40x30 cm<sup>2</sup> nozzle. For the snout and the nozzle, a 3 cm safety distance, i.e. the shortest distance to the patient (typically in the shoulder area), was maintained. For the same safety distance the air gap for the nozzle was 2 cm larger than for the snout.

**EP-1591 Evaluation of noninvasive eye fixation system on Cyberknife radiotherapy of orbital's tumors**

A. Skrobala<sup>1,2</sup>, M. Adamczyk<sup>1</sup>, P. Janiga<sup>3</sup>, A. Jodda<sup>1</sup>, J. Litoborska<sup>1</sup>, E. Czajka<sup>3</sup>, J. Dura<sup>3</sup>, P. Milecki<sup>2,3</sup>  
<sup>1</sup>Greater Poland Cancer Centre, Medical Physics Department, Poznan, Poland  
<sup>2</sup>University of Medical Science, Department of Electroradiology, Poznan, Poland  
<sup>3</sup>Greater Poland Cancer Centre, 1st Radiotherapy Department-, Poznan, Poland

**Purpose or Objective**

Purpose of this study was to evaluate noninvasive eye fixation system on CyberKnife-based stereotactic

radiotherapy (CK-based SRT) by the planning and treatment parameters in patients group suffering from orbital's tumors: ocular melanoma and orbital metastases. Treatment plans for patients with orbital's tumor undergoing CK-based SRT are often challenging due to the close proximity of optic apparatuses.

**Material and Methods**

Feasibility of the eye fixation system was evaluated in the present study using data of 15 patients treated by 1 do 14 with median 5 fractions. The treated PTV volume ranged from 0.73-37.59 cm<sup>3</sup> (median 2.83 cm<sup>3</sup>, mean 7.15 cm<sup>3</sup>, ± SD 11.98). The prescription dose ranged from 20-50 Gy with median value 50 Gy prescribed to the 80% isodose. The eye fixation system was the polymetric device which was attached to the mask system in cranio-caudal orientation and placed in front of the diseased eye (visualization of the system at figure 1 left). The patient was looking at the black point placed at the arm of the eye's fixation system. The proper position of eye during the imaging and treatment was fixed and the position of the system can be easily adjusted and fixed to the suitable position for any patients. The position of the system was defined by CT and used during treatment delivery. CK-based SRT of orbital's tumors were evaluated by PTV coverage, conformity index (CI), total number of monitor units (MU), number of beams and the treatment time and the maximum dose to ipsilateral optic nerve were likewise to assess delivery efficiency.

**Results**

The optical fixation system was well tolerated by all patients and the stable position of the eye was obtained. The system can be used during planning and treatment without any interference with the photon beam, doses to the eye's fixation system ranged from 0.03 - 3.71 Gy (median 0.97 Gy, mean 1.15 Gy, ± SD 1.11). Figure 1 showed the treatment plan of one patient treated on the CK-based SRT using the eye's fixation system. Average treatment parameters of 15 total orbital's lesions (Table 1).

Figure 1. CK-based SRT treatment plan displayed in the axial plane of the patients with a medial orbital tumor in the right eye and multiple beam trajectories.

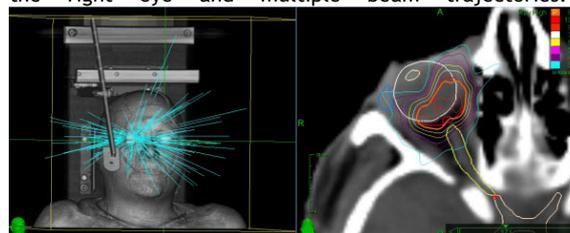

Table 1. Average treatment parameters of 15 total orbital's lesions.

Parameters	Mean	± SD	Range	Median
PTV coverage (%) ≈ ≥ 95%	95.80	1.83	92.74 - 99.05	95.80
Conformity Index	1.16	0.08	1.05 - 1.38	1.16
Total MU	34532	15788	20064 - 78580	31089
No. of beams	117	54	62 - 253	108
Treatment time (min)	32	9	20 - 58	30
Dose max to ipsilateral optic nerve (Gy)	3.46	2.28	0.10 - 7.15	3.97

**Conclusion**

The results of this study and good clinical outcomes demonstrated the feasibility of the eye fixation devices for CK-based SRT without the need of implementing fiducial markers. Two years follow up reported that the salvage therapy (enucleation) was unneeded in all cases. CK-based SRT appeared to be a relatively safe technique in treating orbital's lesions within or near optic apparatuses. CK-based SRT using fixation system provides excellent tumor coverage without delivering excessive dose to critical anterior structure and provided that the dose to the optic apparatuses were limited. The long-term safety of this treatment remains to be confirmed.

**EP-1592 Higher biological dose to heart and lung in IMPT of medulloblastoma patients due to increased LET**  
 E. Rørvik<sup>1</sup>, L.F. Fjæra<sup>1</sup>, C.H. Stokkevåg<sup>2</sup>, S. Thörnqvist<sup>1,2</sup>, K.S. Ytre-Hauge<sup>1</sup>

<sup>1</sup>University of Bergen, Department of Physics and Technology, Bergen, Norway

<sup>2</sup>Haukeland University Hospital, Department of Oncology and Medical Physics, Bergen, Norway

#### Purpose or Objective

For medulloblastoma patients, proton therapy offers increased dose conformity compared to conventional radiation therapy. There is however growing concern about the clinical consequences of the enhanced linear energy transfer (LET) delivered to the normal tissue surrounding the tumor volume. In these patients, the biological dose received to the lung and heart may be higher than reflected by treatment plans based on the clinical practice of using a constant relative biological effectiveness (RBE) of 1.1. The aim of this study was therefore to investigate the biological dose to the heart and lung following craniospinal Intensity-modulated proton therapy (IMPT) using LET-based models for the RBE of protons.

#### Material and Methods

An intensity modulated proton therapy (IMPT) treatment plan was generated in a commercial treatment planning system (Eclipse, Varian Medical Systems) applying two cranial fields and two spinal fields. The dose prescription was 23.4 Gy(RBE) given by 13 fractions. The plan was optimized using a fixed RBE value of 1.1. The IMPT plans were imported into the FLUKA Monte Carlo code where dose and dose-average LET distributions (LET<sub>D</sub>) were calculated. Subsequently, a published LET-based RBE model for proton therapy was applied to these distributions to quantify the biological doses for the heart, lungs and the PTV.

#### Results

The Monte Carlo simulations revealed elevated LET<sub>D</sub> values both in the PTV, heart and lung and correspondingly higher biological doses as compared to the doses obtained with an RBE of 1.1 (Figure 1). The dose volume histograms revealed small elevation in mean dose to the lungs (from 2.0 to 2.4 Gy) and the heart (from 0.7 to 1.0 Gy). However, the variable RBE model calculated a significantly higher max dose in both organs, with a shift from 21.8 Gy to 27.2 Gy for the lungs and 17.2 Gy to 21.2 Gy for the heart.

#### Conclusion

Including LET and biological dose models revealed an increased dose to heart and lung compared to doses calculated with RBE of 1.1, mainly due to the enlarged LET values at the distal dose falloff of the beam. The reproducibility of these results in a larger cohort of patients will be investigated.

**EP-1593 Accuracy of TCP model for nasopharyngeal cancer after more than five years average follow-up**  
 M. Avanzo<sup>1</sup>, J. Stancanello<sup>2</sup>, G. Franchin<sup>3</sup>, S. Barbiero<sup>4</sup>, R. Jena<sup>5</sup>, G. Sartor<sup>1</sup>, E. Capra<sup>1</sup>

<sup>1</sup>Centro di Riferimento Oncologico, Medical Physics, Aviano, Italy

<sup>2</sup>Oncoradiomics, Maastricht, The Netherlands

<sup>3</sup>Centro di Riferimento Oncologico, Radiation Oncology Department, Aviano, Italy

<sup>4</sup>Casa di Cura S. Rossore, Radio-oncology, Pisa, Italy

<sup>5</sup>University of Cambridge, Department of Oncology, Cambridge, United Kingdom

#### Purpose or Objective

A model for radiation therapy (RT) based tumor control probability (TCP) of nasopharyngeal carcinoma (NPC) which includes the effects of hypoxia and chemoradiotherapy was previously developed by fitting TCP to clinical local control data from published randomized studies and tested in a patient dataset with limited follow-up time.

The purpose of this work was to validate the model by comparison of estimated TCP and average overall local control rate in a cohort of patients with long follow-up time.

#### Material and Methods

96 patients treated with intensity modulated RT delivered by LINAC or Helical Tomotherapy and neoadjuvant chemotherapy for histologically proven nasopharyngeal carcinoma were followed for an average time of 5.5 years. TCP was calculated from individual GTV dose-volume histograms, fractionation and overall treatment duration data using a previously established model (Ref. 1) based on the linear-quadratic model and Poisson statistics modified to account for repopulation, chemotherapy, heterogeneity of dose to the tumor, and hypoxia. The model parameters were:  $\alpha/\beta$  of 10 Gy,  $\alpha$  of 0.396 Gy<sup>-1</sup> with  $\sigma_\alpha$  of 0.07 Gy<sup>-1</sup>, density of clonogens 10<sup>7</sup> cc<sup>-1</sup>, fraction of patients showing hypoxia 22%, oxygen enhancement ratio (OER) of 1.417, chemotherapy enhancement factor 1.64, T<sub>pot</sub> of 3 days and T<sub>k</sub> of 28 days.

The average TCP was compared to the local control rate (LCR), defined as the absence of clinical and radiological evidence of disease residuum in the GTV at the last follow-up visit.

#### Results

The average calculated TCP in patients treated at our institution was 86.9% with 95% confidence intervals (95% CI) of 74%-95.0%. At a mean follow-up time of 5.5 years, 15 patients developed local failure in the nasopharynx and three had distant and local recurrences. Three patients developed recurrence outside the treated volume. Local control was therefore obtained in 81% (95% CI: 72-87.8%) patients, and was in agreement with calculated TCP.

#### Conclusion

The TCP model shows was in agreement with LCR in patients treated at our institution after a long follow-up time.

**EP-1594 Development of multivariable models for acute toxicities in nasopharyngeal cancer radiotherapy**  
 A. Cavallo<sup>1</sup>, T. Rancati<sup>2</sup>, A. Cicchetti<sup>2</sup>, N.A. Iacovelli<sup>3</sup>, F. Palorini<sup>2</sup>, C. Fallai<sup>3</sup>, E. Orlandi<sup>3</sup>, E. Pignoli<sup>1</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics Unit, Milan, Italy

<sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milan, Italy

<sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 2, Milan, Italy

#### Purpose or Objective

To investigate the dose-response relationship for acute toxicities in nasopharyngeal cancer (NPC) RT and to build multivariable models aiming at the inclusion of other non-dosimetric factors.

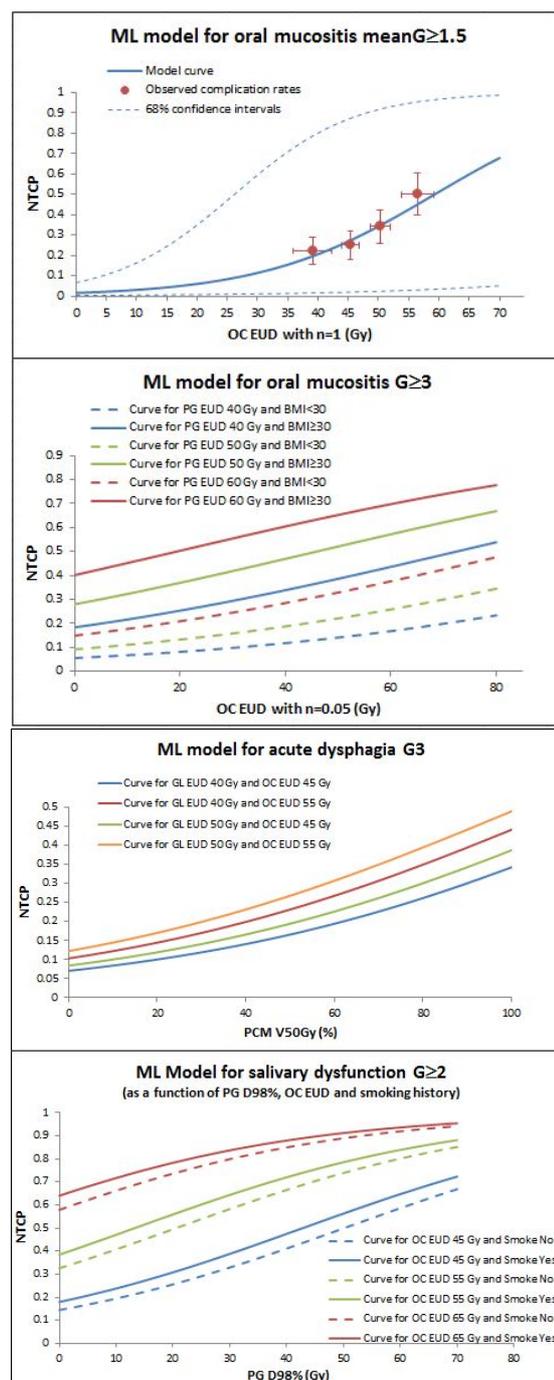

#### Material and Methods

A series of consecutive NPC patients (pts) treated curatively with IMRT/VMAT + chemotherapy at 70 Gy (35-33 fr, 2-2.12 Gy/fr) was considered. Clinical- tumor- and treatment-related data were retrospectively collected: age, gender, BMI, smoking history, histology, staging, comorbidities, RT technique, overall treatment time. Organs-at-risk (OAR) volumes and dose distribution for each pt were also considered. Acute toxicities were

assessed according to CTCAE v4.0 at baseline and weekly during RT. Four endpoints were considered: mean grade (G)  $\geq 1.5$  and G $\geq 3$  oral mucositis (OM), G3 dysphagia and G $\geq 2$  salivary dysfunction (SD). The selected OARs were: oral cavity (OC) and parotid glands (PG) considered as a single organ for OM and SD; OC, pharyngeal constrictor muscles (PCM), supraglottic and glottic larynx (GL) for dysphagia. DVHs were reduced to Equivalent Uniform Dose (EUD); for each OAR the best volume parameter  $n$  was determined through numerical optimization. When this procedure did not converge, we chose to evaluate DVH cutpoint through t-test. EUD was inserted into a multivariable logistic (ML) model together with clinical/treatment features; variables selection was guided by LASSO. Goodness of fit was evaluated with Hosmer-Lemeshow test and calibration plot.

### Results

Data were collected for 132 pts. Mean G $\geq 1.5$  and G $\geq 3$  OM were reported in 40 pts (30%), G3 dysphagia in 50 (38%) and G $\geq 2$  SD in 90 (68%). ML models (figures 1-2) consisted in: a single variable for mean G $\geq 1.5$  OM, i.e. OC EUD with  $n=1$  (mean dose) (OR=1.07); 3 variables for G $\geq 3$  OM including OC EUD with  $n=0.05$  (OR=1.02), PG EUD with  $n=1$  (OR=1.06), BMI $\geq 30$  (OR=3.8, obese pts); 3 variables for dysphagia including PCM V50Gy (OR=1.02), GL and OC EUD with  $n=0.35$  and  $0.15$  respectively (OR=1.02 and 1.04); 4 variables for SD including PG D98% (OR=1.04), OC EUD with  $n=0.05$  (OR=1.11), age (OR=1.08, 5-year intervals), smoke (OR=1.37, yes vs no). Calibration was good in all cases.

### Conclusion

OC resulted to be a parallel organ for mean G $\geq 1.5$  OM, while severe OM was associated to a synergic effect between PG mean dose and high doses received by small OC volumes, with BMI acting as a dose-modifying factor. On the other hand, OC resulted as a fairly serial organ for G $\geq 2$  SD; this could be due to the inclusion of minor salivary glands in OC contour, that the target often overlaps. Older age and smoking history were also associated to a SD increased risk. We did not find a strictly significant association between G3 dysphagia and dosimetric features, but the step trend resulting from our model calibration suggests that the ML model may not describe well the dose-response relationship in this case, with a step function possibly being more suitable. Validation of these models in a larger pts cohort is ongoing.

### EP-1595 NTCP models for early toxicities in patients with prostate or brain tumours receiving proton therapy

<sup>2</sup>Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiooncology, Dresden, Germany

<sup>3</sup>Department of Radiation Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Dresden, Germany

<sup>4</sup>German Cancer Research Center DKFZ, Heidelberg and German Cancer Consortiumion DKTK partner site Dresden, Dresden, Germany

<sup>5</sup>National Center for Tumor Diseases, partner site Dresden, Dresden, Germany

#### Purpose or Objective

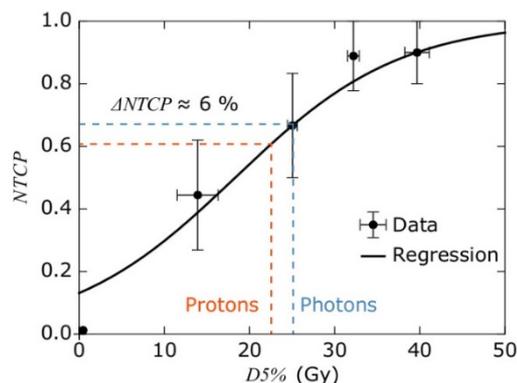

To identify patients who are likely to benefit most from proton therapy, based on the potential reduction in normal tissue complication probability (NTCP) compared to photon therapy. The NTCP models required for this comparison were developed using clinical data on early side effects for patients with brain or prostate cancer having received proton therapy.

#### Material and Methods

Eighty patients with primary brain tumours and 30 patients with adenocarcinoma of the prostate who received proton therapy were included in this study. For the brain tumour patients, the radiation-induced early toxicities alopecia, erythema, pain and fatigue were considered, while for prostate cancer proctitis, diarrhoea, urinary frequency, urgency and incontinence, obstructive symptoms and radiation-induced cystitis were investigated. The occurrence of these side effects was correlated with different dose-volume parameters of associated organs at risk. NTCP models were created using logistic regression. A retrospective comparative treatment planning study was conducted to predict the potential reduction in NTCP of proton therapy compared to volumetric modulated arc therapy using the created models. For patients with brain tumours different subgroups were defined to identify patient groups which show a particularly high reduction in the considered toxicities.

#### Results

For patients with primary brain tumours significant correlations between the occurrence of alopecia grade 2 as well as erythema grade  $\geq 2$  and the dose-volume parameters D5% and V25Gy of the skin were found. Plan comparison showed an average reduction in NTCP for alopecia grade 2 of more than 5 % (see figure) and for erythema grade  $\geq 2$  of about 5 % using proton therapy. For patients with a brain tumour located in the skull base, with a clinical target volume less than 115 cm<sup>3</sup> or with a prescribed dose less than 60 Gy, a potential reduction in NTCP for alopecia grade 2 of about 10 % could be achieved. For patients with prostate cancer significant correlations between obstructive symptoms grade  $\geq 1$  and the dose parameter D30% of the bladder as well as radiation-induced cystitis grade  $\geq 1$  and D20% of the bladder were found. Plan comparison showed an average reduction in NTCP for obstructive symptoms  $\geq 1$  of about 25 % and for radiation-induced cystitis about 15 % using proton therapy.

#### Conclusion

We found significant correlations between the occurrence of early toxicities and dose-volume parameters of associated organs at risk for patients with primary brain tumours or prostate cancer receiving proton therapy. A reduction of NTCP could be predicted for proton therapy based on comparative treatment planning. After validation, these results may be used to identify patients who are likely to benefit most from proton therapy, as suggested by the model-based approach [1].

### EP-1596 Developing and validating a survival prediction model for NSCLC patients using distributed learning

A. Jochems<sup>1</sup>, T. Deist<sup>1</sup>, I. El-Naga<sup>2</sup>, M. Kessler<sup>2</sup>, C. Mayo<sup>2</sup>, J. Reeves<sup>2</sup>, S. Jolly<sup>2</sup>, M. Matuszak<sup>2</sup>, R. Ten Haken<sup>2</sup>, J. Van Soes<sup>1</sup>, C. Oberije<sup>1</sup>, C. Faivre-Finn<sup>3</sup>, G. Price<sup>3</sup>, P. Lambin<sup>1</sup>, A. Dekker<sup>1</sup>

<sup>1</sup>MAASTRO Clinic, Radiotherapy, Maastricht, The Netherlands

<sup>2</sup>University of Michigan, Radiation oncology, Ann-Arbor, USA

<sup>3</sup>The University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom

#### Purpose or Objective

The golden standard for survival prediction in NSCLC patients, the TNM stage system, is of limited quality for patients receiving (chemo)radiotherapy[1]. In this work, we develop an up-to-date predictive model for survival prediction based on a large volume of patients using a big data distributed learning approach. Distributed learning is defined as learning from multiple patient datasets without these data leaving their respective hospitals. Furthermore, we compare performance of our model to a TNM stage based model. We demonstrate that the TNM stage system performs poorly on the validation cohorts, whereas our model performs significantly above the chance level.

#### Material and Methods

Clinical data from 1299 lung cancer patients, treated with curative intent with chemoradiation (CRT) or radiotherapy (RT) alone were collected and stored in 3 different cancer institutes. Two-year post-treatment survival was chosen as the endpoint. Data from two institutes (1152 patients at Institute 1 and 147 at Institute 2) was used to develop the model while data from the 3<sup>rd</sup> institute (207 patients at Institute 3) was used for model validation.

A Bayesian network model using clinical and dosimetric variables was adapted for distributed learning (watch the animation: link censored). The Institute 1 cohort data is publicly available at (link censored) and the developed models can be found at (link censored).

#### Results

A Bayesian network (BN) structure was determined based on expert advice and can be observed in figure 1. Variables included in the final model were TNM stage, age,

performance status, and total tumor dose. The BN model has an AUC of 0.67 (95% CI: 0.59-0.75) on the external validation set and an AUC of 0.65 on a 5-fold cross-validation on the training data. A model based on TNM stage performed with an AUC of 0.49 (95% CI: 0.39-0.59) on the validation set.

#### Conclusion

The distributed learning model outperformed the TNM stage based model for predicting 2-year survival in a cohort of NSCLC patients in an external validation set (AUC 0.67 vs. 0.49). This approach enables learning of prediction models from multiple hospitals while avoiding many boundaries associated with sharing data. We believe that Distributed learning is the future of Big data in health care.

<sup>3</sup>Medical Center - University of Freiburg, Department of Pathology, Freiburg, Germany  
<sup>4</sup>Medical Center - University of Freiburg, Department of Radiology, Freiburg, Germany  
<sup>5</sup>Medical Center - University of Freiburg, Department of Nuclear Medicine, Freiburg, Germany

#### Purpose or Objective

First studies could show an increase in sensitivity when primary prostate cancer (PCa) was detected by addition of MRI and PSMA PET/CT information. On the other side the highest specificity was achieved when the intersection volume between MRI and PSMA PET/CT was considered. Aim of this study was to demonstrate the technical feasibility and to evaluate the tumor control probability (TCP) and normal tissue complication probability (NTCP) of IMRT dose painting using combined <sup>68</sup>Ga-HBED-CC PSMA-PET/CT and multiparametric MRI (mpMRI) information in patients with primary PCa.

#### Material and Methods

7 patients (5 intermediate + 2 high risk) with biopsy-proven primary PCa underwent <sup>68</sup>Ga-HBED-CC-PSMA PET/CT and mpMRI followed by prostatectomy. Resected prostates were scanned by ex-vivo CT in a localizer and prepared for histopathology. PCa was delineated on histologic slices and matched to ex-vivo CT to obtain GTV-histo. Ex-vivo CT including GTV-histo and MRI data were matched to in-vivo CT (PET). Contours based on MRI (GTV-MRI), consensus volume by two experienced radiologist), PSMA PET (GTV-PET, semiautomatic using 30% of SUVmax within the prostate) or the combination of both (GTV-union/-intersection) were created. Three IMRT plans were generated for each patient: PLAN77, which consisted of whole-prostate radiation therapy to 77 Gy in 2.2 Gy per fraction; PLAN95, which consisted of whole-prostate RT to 77 Gy in 2.2 Gy per fraction, and a simultaneous integrated boost to the GTV-union (Plan95<sup>union</sup>)/-intersection (Plan95<sup>intersection</sup>) to 95 Gy in 2.71 Gy per fraction. The feasibility of these plans was judged by their ability to reach prescription doses while adhering to the FLAME trial protocol. TCPs based on co-registered histology after prostatectomy (TCP-histo), and normal

tissue complication probabilities (NTCP) for rectum and bladder were compared between the plans.

#### Results

All plans for all patients reached prescription doses while adhering to dose constraints. The average volumes of GTV-histo, GTV-union and GTV-intersection were 7±8 ml, 9±9 ml and 3±4 ml. In Plan95<sup>union</sup> and Plan95<sup>intersection</sup> the mean doses on GTV-histo were 95.7±1.5 Gy and 90.7±6.9 Gy, respectively (p=0.016). Average TCP-histo values were 63±29%, 99±1% and 90±11% for Plan77, Plan95<sup>union</sup> and Plan95<sup>intersection</sup> respectively. PLAN95<sup>union</sup> had significantly higher TCP-histo values than Plan77 (p=0.016) and Plan95<sup>intersection</sup> (p=0.03). There were no significant differences in rectal and bladder NTCPs between the 3 plans.

#### Conclusion

IMRT dose painting for primary PCa using combined <sup>68</sup>Ga-HBED-CC PSMA-PET/CT and mpMRI was technically feasible. A dose escalation to GTV-union resulted in significantly higher TCPs without higher NTCPs.

#### EP-1598 Modelisation of radiation response at various fractionation from histopathological prostate tumors

V. Aubert<sup>1,2</sup>, O. Acosta<sup>1,2</sup>, N. Rioux-Leclercq<sup>3</sup>, R. Mathieu<sup>4</sup>, F. Commandeur<sup>1,2</sup>, R. De Crevoisier<sup>1,2,5</sup>  
<sup>1</sup>INSERM, U1099, Rennes, France  
<sup>2</sup>University Rennes 1, LTSI, Rennes, France  
<sup>3</sup>Rennes Hospital and University, Department of Pathology, Rennes, France  
<sup>4</sup>CHU Pontchaillou, Department of Urology, Rennes, France  
<sup>5</sup>Centre Eugène Marquis, Department of Radiotherapy, Rennes, France

#### Purpose or Objective

Using simulation from histopathological cancer prostate specimen, the objectives were to identify the total dose corresponding to various fractionations necessary to destroy the tumor cells (50% to 99.9%) and to assess the impact of the Gleason score on these doses.

#### Material and Methods

Histopathological specimen were extracted from 7 patients having radical prostatectomy. A senior uropathologist manually delineated all tumor foci on the hematoxylin and eosin-stained axial slides and assigned Gleason scores (GS) to each individual focus. Antibodies CD31 were used as blood vessel markers. Three slide samples per patient, corresponding to a surface of 2000µm x1200µm, were scanned and used within a simulation model developed in the Netlogo software (Figure 1). The model contained the following cells: tumor cells with a density ranging from 45% to 85%, endothelial cells with a density ranging from 0.3 to 8% and normal cells. The samples were GS:7 (3+4) for 47.6%, GS:7 (4+3) for 28.6% and GS:8 (4+4) for 23.8%. We used the equations of the model simulating the radiation response of hypoxic tumors published by Espinoza et al. (*Med Phys* 2015). The model parameters were adjusted to biological values from the literature: diffusion coefficient (2.10<sup>-9</sup> m<sup>2</sup>/s), Vmax and Km of oxygen consumption (15 and 2.5 mmHg), tumor cells proliferation (1008 hours), half-life of dead cells (168 hours), α (0.15 Gy<sup>-1</sup>) and B (0.048 Gy<sup>-2</sup>) of the linear-quadratic model. Three fractionations were tested, at 2, 2.5 and 3 Gy/fraction at 24h interval. Five simulations were performed by slide sample. The objectives were to identify the total dose, at each fractionation, to kill 50% to 99.9% of the tumor cells.

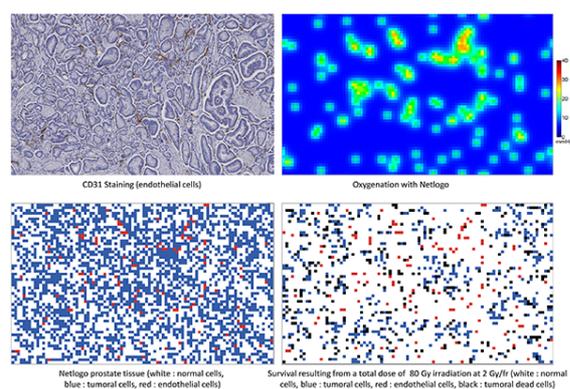

Figure 1

## Results

A total of 315 simulations were performed. Figure 2 shows the total doses necessary to kill 50% to 99.9% of the tumor cells, depending on the fractionation. The mean (SD) doses (Gy) to kill 99% of the tumor cells were therefore 72 ( $\pm 14$ ), 68 ( $\pm 13$ ) and 65 ( $\pm 12$ ) for fractionations (Gy) of 2, 2.5 and 3, respectively. The mean (SD) doses (Gy) to kill 99.9% of the tumor cells were therefore 107 ( $\pm 17$ ), 101 ( $\pm 16$ ) and 94 ( $\pm 15$ ) for fractionations (Gy) of 2, 2.5 and 3, respectively. The foci with GS 7: 4+3 needed significantly higher doses than the foci with GS 7: 3+4 to destroy the tumor cells from 50% to 99.9%, at all fractionations (Mann-Whitney test).

Total dose (Gy)

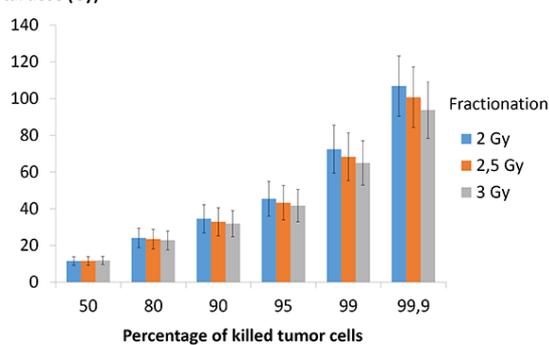

Figure 2

## Conclusion

Our histopathological specimen based simulations allowed to estimate the total doses necessary to kill the tumor cells, depending on the fractionation. GS: 4+3 tissue appears more radioresistant than GS:3+4 tissue.

### EP-1599 Mathematical modeling of the synergistic combination of cancer immunotherapy and radiotherapy

C. Ceberg<sup>1</sup>, J. Ahlstedt<sup>2</sup>, H. Redebrant Nittby<sup>3</sup>

<sup>1</sup>Ceberg Crister, Medical Radiation Physic- Lund University, Lund, Sweden

<sup>2</sup>Lund University, The Rausing Laboratory, Lund, Sweden

<sup>3</sup>Skåne University Hospital, Department of Neurosurgery, Lund, Sweden

### Purpose or Objective

Cancer immunotherapy is a promising treatment modality that is currently under strong development with a large number of ongoing pre-clinical and clinical studies. In an attempt to improve the treatment efficacy combinatorial strategies are explored, and the combination of immunotherapy and radiotherapy is of particular interest, since more than half of all cancer patients already receive radiotherapy as part of their treatment. It is well known that radiation has immunomodulatory effects. In addition to killing off tumor cells as well as immune effector cells,

radiation also affects the release of tumor antigens, the dendritic cell activity and antigen presentation, the presence of immunosuppressive cells in the tumor microenvironment and tumor infiltrating lymphocytes, the regulation of immunogenic cell surface receptors, and immunogenic cell death. However, the balance between pro-tumor and anti-tumor effects is delicate, and the application of immunotherapy in combination with radiotherapy has to be designed very carefully in order to tip the immunomodulatory effect of radiation in the right direction. There are many parameters that can be varied in this equation, including time, dose and fractionation. Therefore, in order to better understand the immunomodulatory effect of radiation, and to be able to optimize the combined treatment, there is a great need for mathematical models.

### Material and Methods

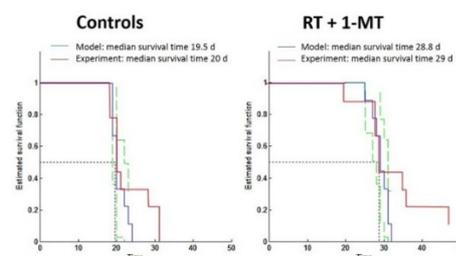

In this work, a mathematical model based on the work by Serre et al.<sup>1</sup> was developed to describe the synergistic effect of immunotherapy and radiotherapy observed in a previous pre-clinical study in glioma carrying rats.<sup>2</sup> Animals with intracranial tumors were given indoleamine 2,3-dioxygenase (IDO) inhibitory treatments with intraperitoneal injections of 1-methyl tryptophan (1-MT), in combination with radiotherapy given as single fractions of 8 Gy.

<sup>1</sup>Serre R, et al. Mathematical model of cancer immunotherapy and its synergy with radiotherapy. *Cancer Res* 76(17):4931-40, 2016.

<sup>2</sup>Ahlstedt J, et al. Effect of Blockade of Indoleamine 2, 3-dioxygenase in Conjunction with Single Fraction Irradiation in Rat Glioma. *J J Rad Oncol* 2(3):022, 2015.

### Results

Using the mathematical model tumor growth and survival curves were simulated, and the parameters of the model were fit to the experimental data. Good agreement for median survival time was achieved both for the two modalities given separately as monotherapies, as well as for the combined treatment, see Figure.

### Conclusion

Conclusion: The simplified mathematical model presented in this work captures the general features of the synergistic combination of IDO-inhibitory immunotherapy and single fraction radiotherapy. The model can be used to explore possible alternative time, dose and fractionation, in order to gain improved insight into the effects of these parameters, and to generate plausible hypotheses for further pre-clinical studies.

### EP-1600 Delta radiomics of NSCLC using weekly cone-beam CT imaging: a feasibility study

J. Van Timmeren<sup>1</sup>, R. Leijenaar<sup>1</sup>, W. Van Elmpt<sup>1</sup>, S. Walsh<sup>1</sup>, A. Jochems<sup>1</sup>, P. Lambin<sup>1</sup>

<sup>1</sup>Department of Radiation Oncology - MAASTRO, GROW School for Oncology and Developmental Biology - Maastricht University Medical Centre MUMC, Maastricht, The Netherlands

### Purpose or Objective

Currently, prognostic information is commonly derived using radiomics features from medical images acquired prior to treatment. However, the potential of delta

radiomics, i.e. the change of radiomic features over time, has not yet been extensively explored. Cone-beam CT (CBCT) imaging can be performed daily for lung cancer patients and is therefore a potential candidate for delta radiomics, which may allow further treatment individualization. In this study we explored delta radiomics using CBCT imaging by investigating the number of features changing at a specific time point during treatment. Moreover, we investigated the differences between patients having an overall survival of less or more than 2 years.

#### Material and Methods

A total of 40 stage II-IV NSCLC patients, receiving curatively intended radiotherapy for a period of at least six weeks, were included in the study. The CBCT images used in this study were 1) CBCT prior to the first fraction of treatment (CBCTfx1), 2) CBCT prior the second fraction of treatment (CBCTfx2), 3) CBCT one week after the start of treatment (CBCTweek2), 4) CBCT three weeks after the start of treatment (CBCTweek4) and 5) CBCT five weeks after the start of treatment (CBCTweek6). For 38 patients CBCTfx1 and CBCTfx2 were available, whereas for 33 patients all weekly CBCTs were available. All patients had a minimal follow-up of 2 years. Per time point, a total of 1046 radiomic features were derived from the primary tumor volume. The images prior to the first and second fraction were used to calculate the variability in imaging features using the coefficient of repeatability (COR), defined as  $1.96 \times SD$ . The weekly images were used to investigate the number of features changing more than the COR with respect to baseline (CBCTfx1).

#### Results

Figure 1 represents the total number of features that changed more than the COR, ranging from 0 to 999 features. The median number of features that changed for the group with overall survival <2 years was 279, whereas this was 500 for the group with overall survival >2 years (Mann-Whitney U test,  $p = 0.06$ ). For 8 out of 10 patients that survived >2 years, more features (31.7%) changed one week after CBCTfx1 than for 13 out of 23 patients that did not survive two years.

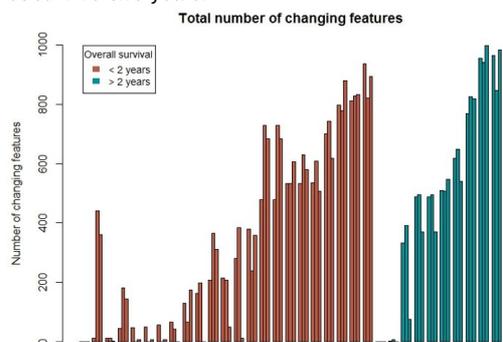

Figure 1: Number of features that change more than the coefficient of repeatability. Each group of three bars belongs to one patient and represents the number of features that significantly change between baseline (CBCTfx1) and CBCTweek2, CBCTweek4 and CBCTweek6, respectively.

#### Conclusion

This study shows that a large proportion of the radiomic features derived from cone-beam CT images change significantly during the course of treatment, meaning that an interval of about two weeks is feasible for a radiomics study using CBCT imaging. The larger number of features that changed in the group with overall survival >2 years could reflect an early response of the tumor to the treatment. In future research, the prognostic value of changing radiomic features (delta radiomics) should be explored in a larger cohort.

#### EP-1601 Do higher CT pixel values outside the GTV predict for poorer lung cancer survival?

M. Van Herk<sup>1</sup>, J. Kennedy<sup>2</sup>, E. Vasquez Osorio<sup>1</sup>, C. Faivre-Finn<sup>1</sup>, A. McWilliam<sup>1</sup>

<sup>1</sup>University of Manchester, Division of Molecular and Clinical Cancer Sciences- Faculty of Biology- Medicine and Health, Manchester, United Kingdom

<sup>2</sup>The Christie NHS Foundation Trust, Department of Informatics, Manchester, United Kingdom

#### Purpose or Objective

Radiomics aims to extract features from medical images that are prognostic for outcome and may help optimize treatment. As far as the tumour is concerned, most work has focused on pixel values *inside* the gross tumour volume (GTV). The aim of this work is to develop a generic methodology to also sample pixels *outside* a tumour volume, assuming that these may carry information about microscopic tumour spread and therefore might predict outcome.

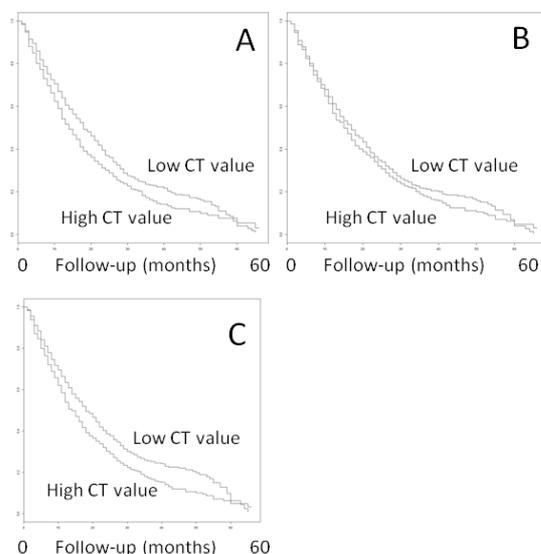

#### Material and Methods

We analysed data from a cohort of 1101 non-small cell lung cancer patients treated with IMRT to 55 Gy in 20 fractions. To evaluate the CT pixel values at various distances inside and outside the GTV, we calculated a signed distance transform of the GTV, which was subsequently used to efficiently collect cross-histograms of the CT density versus distance from the GTV edge. Based on these cross-histograms various pixel statistics were determined as function of the GTV distance, here we report only on the mean pixel value, giving a curve of mean CT value versus distance. The mean of these curves was calculated for patients that were alive (652) and dead (449) at 12 months after start of therapy, censored for follow-up. Significance of the difference was tested by permuting the dead/alive labels 1000 times to create mock differences and counting how often the true difference exceeded the mock difference. Significant regions were defined and the mean pixel value from those regions used as variable in a cox proportional hazard model, splitting the patients on the median of the mean region density, while correcting for age and tumour size. As the outside of the tumour can also include chest wall and mediastinum, we repeated the analysis only analysing pixels inside the lungs.

#### Results

There was a significant different average pixel value in the region 0-1 cm outside the GTV for dead and alive patients (fig. 1) that translated to a hazard ratio (HR) of 1.4,  $p < 10^{-5}$  (corrected for tumour size and age), survival curves split at median density value (fig. 2A). However when only pixels inside the lungs were analysed, the HR reduced to 1.1,  $p = 0.15$ ; i.e. no longer significant (fig. 2B). This finding indicates that the mean pixel values represent mediastinal attachment rather than microscopic disease. Not correcting for tumour size, both signals incorrectly predict outcome significantly (e.g. fig. 2C for lung pixels only).

**Figure 2:** A) Kaplan-Meijer survival curves corresponding to Fig. 1; B) For lung pixels only; C) as B but without correcting for tumour size. These figures highlight the importance of accounting for confounding variables.

### Conclusion

Proper analysis of pixel-based data mining showed that lung pixel density outside the GTV did not predict for survival. The method we proposed allows pixel-based data mining based on distance to an organ. For such analysis, one should be well aware of confounding variables such as tumour size and mediastinal attachment.

### EP-1602 Treatment planning individualisation based on 18F-HX4 PET hypoxic subvolumes in NSCLC patients

E. Lindblom<sup>1</sup>, A. Dasu<sup>2</sup>, J. Uhrdin<sup>3</sup>, A. Even<sup>4</sup>, W. Van Elmpt<sup>4</sup>, P. Lambin<sup>4</sup>, I. Toma-Dasu<sup>5</sup>

<sup>1</sup>Stockholm University, Medical Radiation Physics- Department of Physics, Stockholm, Sweden

<sup>2</sup>The Skandion Clinic, The Skandion Clinic, Uppsala, Sweden

<sup>3</sup>RaySearch Laboratories AB, RaySearch Laboratories AB, Stockholm, Sweden

<sup>4</sup>Maastricht University Medical Center, Department of Radiation Oncology- GROW-School for Oncology and Developmental Biology, Maastricht, The Netherlands

<sup>5</sup>Stockholm University and Karolinska Institutet, Medical Radiation Physics- Department of Physics and Department of Oncology and Pathology, Stockholm, Sweden

### Purpose or Objective

Pre-treatment functional imaging of tumour hypoxia enables the identification of patients at greater risk of treatment failure, and, potentially, allows individualisation of treatment to overcome the increased radioresistance of hypoxic tumours. Treatment individualisation based on tumour hypoxia aims at identifying and prescribing higher doses to radioresistant hypoxic subvolumes based on the relative uptake of hypoxia-specific tracers. This study aimed to perform hypoxic target volume delineation and dose-prescription calculation for non-small cell lung cancer (NSCLC) patients using a novel hypoxic PET tracer, <sup>18</sup>F-HX4.

### Material and Methods

Six non-small cell lung cancer (NSCLC) patients imaged with <sup>18</sup>F-HX4 PET/CT were included in the study. The hypoxic target volumes (HTV) were determined based on

a non-linear conversion between tracer uptake and pO<sub>2</sub>, using a threshold of 10 mmHg. Assuming a clonogenic cell density of 10<sup>8</sup> per cm<sup>3</sup> in the CTV, the HTV doses required to achieve 95% local control (LC) were calculated based on a previously developed radiobiological model (Toma-Dasu et al 2009, 2012) accounting for the dynamic tumour oxygenation due to changes in acute hypoxia not visible in PET images. The total doses were calculated assuming that the treatment involves 24, 30 or 35 fractions.

### Results

The non-linear conversion function and hypoxic threshold of 10 mmHg resulted in hypoxic subvolumes identified in five out of six patients. Three out of six patients had a hypoxic subvolume > 3cm<sup>3</sup>. In two of the patients, the delineated HTV was not entirely confined within the primary CTV. For a treatment delivered in 30 fractions, the prescribed dose required to achieve 95% local control for the two patients with the largest HTVs of 32.74 and 38.29 cm<sup>3</sup> respectively were 75.52 and 75.67 Gy, both corresponding to an EQD2 of almost 79 Gy10. For the third patient with a smaller HTV of only 12.37 cm<sup>3</sup>, the total dose in 30 fractions for 95% LC was 72.35 Gy. If the total dose would be delivered in 35 fractions instead, the prescribed doses would increase with about 2.2% of the dose prescribed in 30 fractions in all three cases. The relative decrease in the total dose if the total dose will be delivered in only 24 fractions is about 3.5% for all three HTVs. For all patients and for all treatment fractionation schemes the dose levels required for achieving 95% tumour control probability accounting for local changes in the oxygenation of the tumour are below the levels of dose boosts proved to be feasible to be delivered without extra dose burden to the OARs on a previous study carried out on the same patients.

### Conclusion

HX4-based delineation of hypoxic target volumes and calculation of required boost doses for a predefined tumour control probability appears to be feasible. HX4 is thus a potentially suitable tracer for the purpose of treatment individualisation in NSCLC.

### EP-1603 Atlas of complication incidence to explore dosimetric contributions to osteoradionecrosis

L. Humbert-Vidan<sup>1</sup>, S. Gulliford<sup>2</sup>, V. Patel<sup>3</sup>, C. Thomas<sup>1</sup>, T. Guerrero-Urbano<sup>4</sup>

<sup>1</sup>Guy's & St Thomas' NHS Foundation Trust, Radiotherapy Physics, London, United Kingdom

<sup>2</sup>The Institute of Cancer Research and Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom

<sup>3</sup>Guy's & St Thomas' NHS Foundation Trust, Oral Surgery, London, United Kingdom

<sup>4</sup>Guy's & St Thomas' NHS Foundation Trust, Clinical Oncology, London, United Kingdom

### Purpose or Objective

Mandibular osteoradionecrosis (ORN) is one of the most severe complications in patients with head and neck cancer undergoing radiation therapy (RT). Potential risk factors include primary tumour site and stage, radiation dose, pre- and post-RT dental extractions and mandibular surgery, chemotherapy, dental hygiene, smoking or alcohol.

This pilot study aims to assess the contribution of radiation dose to the mandible to the incidence of ORN and investigates the effect of different risk factors using the atlas of complication incidence (ACI) method to summarise dose-volume histograms and toxicity data.

### Material and Methods

This retrospective study included 80 patients with head and neck cancer with a median age of 62 (range 35-86) treated with radical IMRT. Primary tumour sites included a majority of oropharynx cases (42), oral cavity (26),

larynx (6), paranasal sinus (4) and two unknown primary cases. Half of the cohort had been diagnosed with ORN of the mandible within a median follow-up time of 3.2 years (range 1.3-5.3) from the end of RT. The toxicity endpoint considered included ORN complication of any grading. The other 40 patients were control cases (no ORN observed) prospectively matched according to primary site and treatment option (PORT or primary RT and chemotherapy type).

For given volume  $v_j$  and dose  $d_i$  levels, the numerical fraction in a cell of an ACI is composed of the number of patients (denominator) and the number of patients with ORN (numerator) that have a mandible percentage volume between  $v_j$  and  $v_{j+1}$  exposed to a dose level between  $d_i$  and  $d_{i+1}$ . Atlases were created for sub-sets of the entire cohort to investigate the effects of pre-RT surgery, chemotherapy, smoking or dental extractions. These risk factors were also tested with univariate statistical analysis. Dosimetric variables including  $d_{max}$  and  $d_{mean}$  were tested with ROC analysis.

### Results

A dosimetric correlation with ORN incidence was observed in cases where treatment modality was primary RT (as opposed to post-operative RT). An increased ORN incidence was observed towards the large percentage volume and high doses region of the ACI, where a large percentage of the mandible volume had received doses of above 40Gy as well as smaller volume percentages receiving doses above 64Gy. A similar incidence pattern was observed for the ACI that included smoking patients only. The ACI for the sub-set of patients that had undergone dental extractions pre- or post-RT also showed a very similar incidence pattern; however, this sub-set included very few cases.

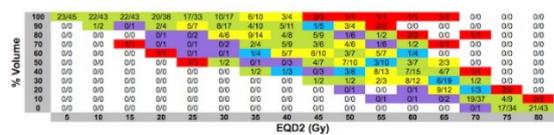

Figure 0: Atlas of complication incidence (ACI) for the sub-set of cases where primary RT was the treatment modality. The percentage volume of mandible is plotted against the EQD2 (Gy) as extracted from the DVHs for all patients. The numerator corresponds to the cases with ORN complication whereas the denominator corresponds to the total number of cases.

### Conclusion

The ACI analysis carried out so far has shown a dose response in patients who received primary RT, patients who smoked at the time of diagnosis and patients who had dental extractions. The limited number of cases did not allow for any conclusive statistical significance of the logistic regression and ROC analysis results. This pilot study will be expanded to include cases from other centres to increase the cohort size.

### EP-1604 Ion induced complex DNA damage: In silico modelling of damage and repair using Geant4-DNA.

J.W. Warmenhoven<sup>1</sup>, N.T. Henthorn<sup>1</sup>, M. Sotiropoulos<sup>1</sup>, R.I. Mackay<sup>2</sup>, K.J. Kirkby<sup>1,3</sup>, M.J. Merchant<sup>1,3</sup>

<sup>1</sup>University of Manchester, Division of Molecular and Clinical Cancer Sciences, Manchester, United Kingdom

<sup>2</sup>The Christie NHS Foundation Trust, Christie Medical Physics and Engineering, Manchester, United Kingdom

<sup>3</sup>The Christie NHS Foundation Trust, Manchester, United Kingdom

### Purpose or Objective

This work uses Monte Carlo simulation to assess and understand the differences in biological response to various radiation qualities in the context of hadron therapy. The current clinical estimator for this is Relative Biological Effectiveness (RBE), offering a biological dose conversion between radiation qualities. A large variability in reported RBE measurements implies that this parameter does not give the full picture. This variability in RBE is a

major source of uncertainty in ion therapy treatment planning. Recently, LET based biological effect models have been proposed, however, among those reviewed there are uncertainties in the behaviour of key biological parameters. We approach the problem on a mechanistic level, linking nanoscale energy deposition to cellular repair.

### Material and Methods

We present a stochastic model to predict ion induced DNA damage and subsequent repair. DNA damage patterns are predicted using nanodosimetric principles applied to track structure simulations within the Monte Carlo based Geant4-DNA toolkit. A section of detailed DNA geometry is irradiated to study specific DNA double strand break structures; building up a library of break models for a given radiation quality. These patterns are then fed into a modified Geant4-DNA simulation where the DNA double strand break ends are explicitly modelled within a simplified cell nucleus. Double strand break ends then progress along the predefined Non-Homologous End Joining repair pathway according to stochastic, time constant based state changes. This allows the prediction of differences in DNA repair for a range of radiation qualities.

### Results

We show that break complexity and repair kinetics are dependent on the particle LET and particle type, with more complex breaks becoming more probable for higher LET (fig 1.). Our simulations predict a greater number of residual DSBs after 24h when higher LET particles are used (fig 2.), which is in good agreement with the literature. We also observe a difference in break complexity for protons and alpha particles at the same LET due to differences in radiation track structure.

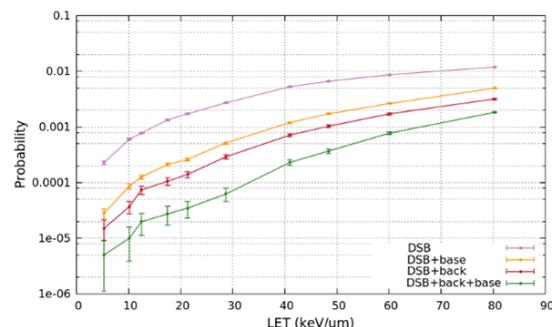

Figure 1: Probability of double strand break complexity with respect to linear energy transfer.

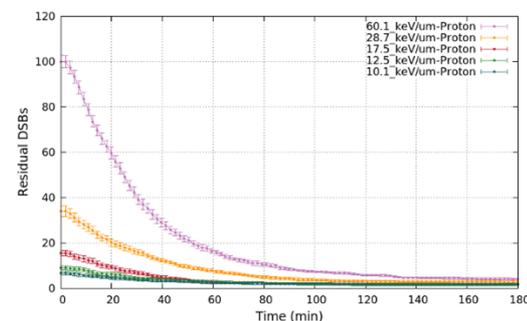

Figure 2: Residual double strand breaks in the simulation at time periods 0 - 3 hours for particles of a given linear energy transfer.

### Conclusion

Monte Carlo track structure simulation coupled to a mechanistic DNA damage repair simulation is a useful tool for modelling biologically relevant endpoints to cellular radiation injury. We have modelled DSB damage and repair with respect to several beam delivery parameters. The complexity of the biological response caused by different ions of the same LET was found to differ due to the

radiation track structure. We suggest that this is as a direct consequence of the complexity of the breaks caused, as similar trends are observed for both repair and break induction. This is of relevance for potential application to LET based treatment plans.

#### EP-1605 Deep learning of radiomics features for survival prediction in NSCLC and Head and Neck carcinoma

A. Jochems<sup>1</sup>, F. Hoebbers<sup>1</sup>, D. De Ruyscher<sup>1</sup>, R. Leijenaar<sup>1</sup>, S. Walsh<sup>1</sup>, B. O'Sullivan<sup>2</sup>, J. Bussink<sup>3</sup>, R. Monshouwer<sup>3</sup>, R. Leemans<sup>4</sup>, P. Lambin<sup>1</sup>

<sup>1</sup>MAASTRO Clinic, Radiotherapy, Maastricht, The Netherlands

<sup>2</sup>Princess Margaret Cancer Centre, Cancer Clinical Research Unit, Toronto, Canada

<sup>3</sup>Radboud University Medical Center Nijmegen, Radiation Oncology, Nijmegen, The Netherlands

<sup>4</sup>VU University Medical Center, Department of Otolaryngology/Head and Neck Surgery, Amsterdam, The Netherlands

#### Purpose or Objective

In order to facilitate personalized medicine in cancer care, predictive models are of vital importance. Radiomics, the high-throughput extraction of large amounts of image features from radiographic images, facilitates predictive model development by providing non-invasive biomarkers. Previous work indicates that radiomics features have high predictive quality<sup>1</sup>. However, these studies used conventional models and the added value of deep learning combined with radiomics features is unexplored. Furthermore, conventional modelling strategies require a selection of features to establish a signature whereas deep learning algorithms do not. In this work we learn a deep learning model on radiomics features and compare it to a previously published cox regression model<sup>1</sup>.

#### Material and Methods

4 independent Lung and Head & Neck (H&N) cancer cohorts (1418 total patients) were used in this study. Radiomic features were extracted from the pre-treatment computed tomography images. The model was learned on the Institute 1 lung cohort (N=422) and validated on the other datasets. The outcome is two-year survival following treatment. A 3 layer deep learning network was used to make predictions.

#### Results

Validation on Institute 2 dataset (N=154) yields an AUC of 0.71 (95% CI: 0.63-0.8) for the deep learning network and 0.66 on the conventional model (95% CI: 0.56-0.75). The difference is not significant (P=0.11). Validation on Institute 3 dataset (N=95) yields an AUC of 0.64 (95% CI: 0.53-0.79) for the deep learning network and 0.75 on the conventional model (95% CI: 0.64-0.86). The difference is not significant (P=0.19). Validation on Institute 4 dataset (N=136) yields an AUC of 0.71 (95% CI: 0.59-0.8) for the deep learning network and 0.74 on the conventional model (95% CI: 0.64-0.83). The difference is not significant (P = 0.24). Validation on Institute 5 dataset (N=540) yields an AUC of 0.58 (95% CI: 0.52-0.63) for the deep learning network and 0.65 on the conventional model (95% CI: 0.59-0.70). The difference is not significant (P = 0.10).

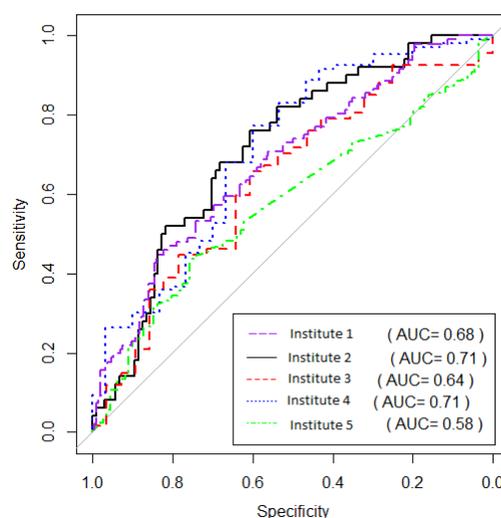

Figure 1: ROC curves of the model validation.

#### Conclusion

The combination of deep learning and radiomics features has similar performance to conventional radiomics modelling strategies. However, feature selection is no longer a required component as all features can be included in the network. This is a major advantage as feature selection is a computationally intractable task for which only heuristic solutions exist.

#### EP-1606 Calculating ion-induced cell death and chromosome damage by the BIANCA biophysical model

M.P. Carante<sup>1,2</sup>, F. Ballarini<sup>1,2</sup>

<sup>1</sup>Istituto Nazionale di Fisica Nucleare INFN, Section of Pavia, Pavia, Italy

<sup>2</sup>University of Pavia, Physics Department, Pavia, Italy

#### Purpose or Objective

To calculate probabilities of cell death and chromosome aberrations following cell irradiation with ion beams of different energy.

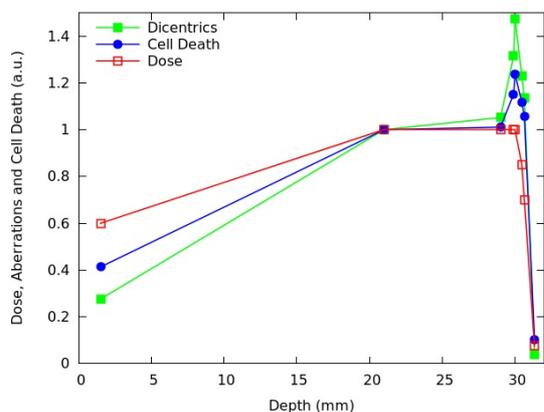

#### Material and Methods

A biophysical model called BIANCA (Biophysical Analysis of Cell death and chromosome Aberrations) [Carante M.P. and Ballarini F. *Front. Oncol.* 6:76 2016] was refined and applied to simulate cell death and chromosome aberrations by therapeutic protons and heavier ions. The model, which assumes a pivotal role for DNA cluster damage, is based on the following assumptions: i) a DNA "Cluster Lesion" (CL) produces two independent chromosome fragments; ii) chromosome fragment un-rejoining, or distance-dependent mis-rejoining, gives rise to chromosome aberrations; iii) certain aberrations (dicentric, rings and large deletions) lead to cell death. The CL yield is an adjustable parameter, as well as the probability that a chromosome fragment remains un-rejoined even if possible partners for rejoining are present. The model, implemented as a MC code providing simulated dose-response curves comparable with experimental data, was applied to different beams, including beams available at the CNAO hadrontherapy centre in Pavia, Italy, and at the CATANA facility in Catania, Italy.

#### Results

The model allowed reproduction of experimental survival curves for cell lines characterized by different radiosensitivity, supporting the model assumptions. Furthermore, cell death and chromosome aberrations

along SOBPs dose profiles were predicted also for depth positions where experimental data were not available. A formula was also derived to predict cell death and chromosome damage for a different cell line exposed to a given ion type and energy, basing on the response of a reference cell line to the same radiation quality. For both endpoints, the increase of effectiveness along the plateau was quantified. A non-negligible increase was found also for protons, associated to high levels of damage beyond the distal dose fall-off, due to the lower energy and thus the higher biological effectiveness.

### Conclusion

In line with other studies, this work suggests that assuming a constant RBE along a proton SOBPs may be sub-optimal. More generally, this work represents an example of therapeutic beam characterization avoiding the use of experimental RBE values, which can be source of uncertainties.

### EP-1607 Secondary cancer risk after particle therapy for organs distal or lateral to the target volume

L. Toussaint<sup>1</sup>, L. Muren<sup>1</sup>, G. Engeseth<sup>2</sup>, C. Stokkevåg<sup>2</sup>  
<sup>1</sup>Aarhus University Hospital, Medical Physics, Aarhus C, Denmark

<sup>2</sup>Haukeland University Hospital, Department of Oncology and Medical Physics, Bergen, Norway

### Purpose or Objective

Proton therapy is the most used particle therapy modality, but carbon ions are also increasingly being applied for specific tumour entities. Particle therapy in general has a known potential of reducing the irradiated volumes of normal tissues, although protons and carbon ions have distinctively different dose distribution characteristics. Protons have a steeper dose fall-off distally while carbon ions have a sharper lateral dose penumbra. In addition, carbon ions have a higher biological effect due to increased cell inactivation, but also for the end-point cell mutation associated with carcinogenic potential. The aim of this study was therefore to compare the risk of secondary cancer (SC) from dose distributions in the thyroid and lungs, particularly radiosensitive organs located distally and laterally to the target volume during craniospinal irradiation (CSI). Since pre-clinical data indicates that the carbon ions RBE for cell mutation may be higher than for cell inactivation, we included this in the models.

### Material and Methods

CSI treatment plans with a prescribed dose of 23.4Gy(RBE) were generated on CT-scans from six pediatric patients (Syngo, Siemens) using pencil beam scanning protons (IMPT) and carbon ions (C-ions). Relative risks (RRs) of radiation induced cancer (IMPT/C-ions) for the thyroid and

the lungs were analysed by applying a bell-shaped dose-response model (J Radiol Prot 2009; 29(2A): A143-157). The model accounts for RBE, fractionation as well as for the competing events of cell mutation and inactivation. The RBE variation for the different end-points was included by introducing and varying the ratio (k) between cell mutation and inactivation for C-ions. The median and range of the patient-specific RRs were calculated from the physical dose distributions and the published input model parameters.

### Results

The dose distributions (Fig 1) illustrated the sharper lateral penumbra of C-ions, which resulted in lower lung doses compared to protons, while the C-ion fragmentation tail contributed to higher doses to the thyroid than from protons. The SC risk estimates strongly depended on the ratio k, and the RR decreased for increasing k for both organs (Fig 2). For the thyroid, the RR was higher from the C-ion plans for the entire scanned range of k. Despite a better sparing of the lungs with C-ions, the carcinogenic potential of C-ions was not consistently lower than for protons: Not including a difference in end-point resulted in RRs in favour of C-ions, while increasing the ratio k gave higher risks for C-ions compared to protons. For the lungs, the median RR turned in favour of IMPT at a threshold value  $k=1.1$ .

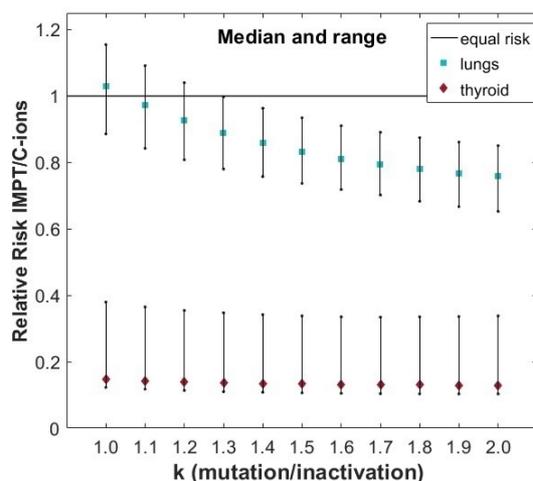

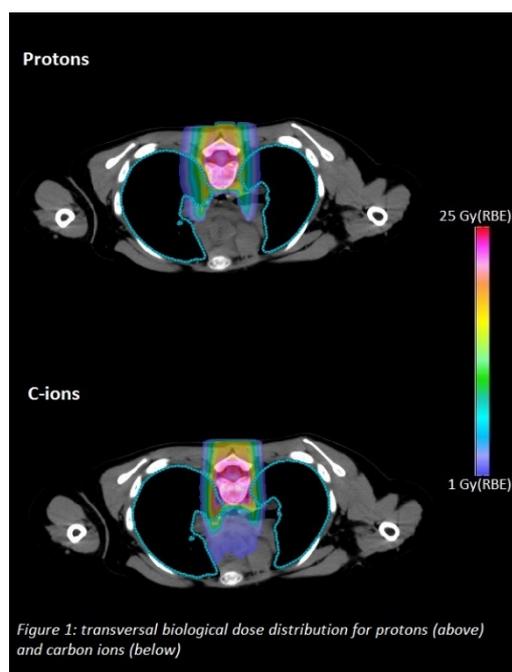

Figure 2: RR IMPT/C-ions estimated as a function of the ratio  $k$ . A RR lower than 1 is in favour of protons.

## Conclusion

Varying the RBE depending on end-point may strongly influence results when estimating carcinogenic risks from C-ion therapy and should be included in modelling risk of radiation-induced SC from C-ion therapy.

## EP-1608 Deriving HPV status from standard CT imaging: a radiomic approach with independent validation

<sup>5</sup>VU University Medical Center, Department of Otolaryngology/Head and Neck Surgery, Amsterdam, The Netherlands

<sup>6</sup>University Hospital Zurich and University of Zurich, Department of Pathology and Molecular Pathology, Zurich, Switzerland

## Purpose or Objective

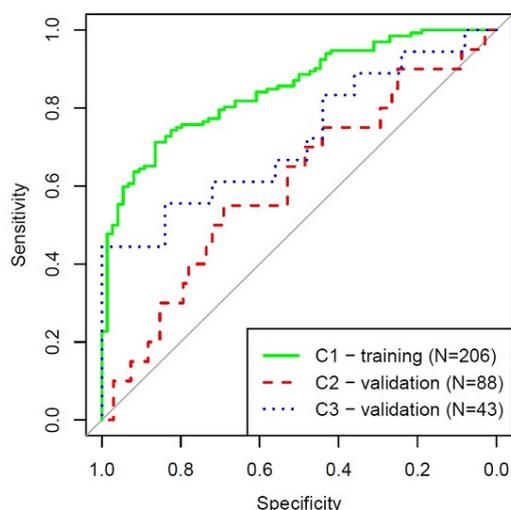

Oropharyngeal squamous cell carcinoma (OPSCC) is one of the fastest growing disease sites of head and neck cancers. HPV positive cancers have been shown to have better tumor control with radiotherapy and increased survival, which makes them interesting for de-escalation protocols. HPV is routinely tested using in situ hybridization for viral DNA, or immunohistochemistry for p16. However, an established, non-invasive, imaging biomarker of HPV status currently does not exist. Radiomics-the high-throughput extraction of large amounts of quantitative features from medical images-has already been shown to be of prognostic value for head and neck cancer. In this study we evaluate the use of a Radiomic approach to identify the HPV status of OPSCC patients.

## Material and Methods

Three independent cohorts, with a total of 793 OPSCC patients were collected: C1 (N=543), C2 (N=159) and C3 (N=100). HPV status was determined by p16 and available for 686 patients. Patients underwent pre-treatment CT imaging and the tumor volume was manually delineated for treatment planning purposes. Images were visually assessed for the presence of CT artifacts (e.g. streak artifacts due to dental fillings) within the GTV, in which case they were excluded from further analysis. In total, 1378 Radiomic features were extracted, comprising: a) first-order statistics, b) shape, and c) (multiscale) texture (Laplacian of Gaussian and Wavelet). The model was learned on the C1 cohort and validated on the remaining cohorts. The Radiomic feature space was first reduced by selecting cluster medoids after hierarchical cluster analysis using correlation ( $p > 0.9$ ) as a distance measure. Multivariable logistic regression was performed using least absolute shrinkage and selection operator (LASSO) model selection (200 times 10-fold cross-validated). The area under the receiver operator curve was used to assess out-of-sample model performance in predicting HPV status.

## Results

Out of the patients with known HPV scoring, we identified 337 (49%) patients without visible CT artifacts: C1 (N=206), C2 (N=88), C3 (N=43), of which 132, 20, and 18 were HPV positive, respectively. The modeling process resulted in a multivariable prediction model, with an AUC of 0.85. External validation in the C2 and C3 cohorts showed an AUC of 0.6 and 0.72, respectively. The receiver operator curves for training and validation are shown in Figure 1.

**Figure 1:** Receiver operator curve for HPV status prediction in OPSCC patients. C1 - training AUC: 0.85 (95% CI: 0.80-0.90). C2 - validation AUC: 0.60 (95% CI: 0.46-0.75). C3 - validation AUC: 0.72 (95% CI: 0.56-0.87).

### Conclusion

We independently validated a radiomic model to distinguish between HPV+ and HPV- OPSCC patients, using standard pre-treatment CT imaging. These results show the potential for a novel quantitative Radiomic biomarker of HPV status to facilitate personalized treatment selection and reinforce the hypothesis that genetic information can be inferred from standard medical images.

### EP-1609 Tolerance doses for detailed late effects after prostate cancer radiotherapy - a post-QUANTEC review

C. Olsson<sup>1</sup>, M. Thor<sup>2</sup>, J.O. Deasy<sup>2</sup>  
<sup>1</sup>University of Gothenburg, Regionalt Cancercentrum RCC väst, Gothenburg, Sweden  
<sup>2</sup>Memorial Sloan Kettering Cancer Center, Medical Physics, New York, USA

### Purpose or Objective

To review tolerance doses for normal tissue toxicity following external beam radiotherapy (EBRT) for prostate cancer in the post-QUANTEC era with a special emphasis on detailed late effects beyond rectal bleeding, and to identify corresponding relationships following brachytherapy (BT).

### Material and Methods

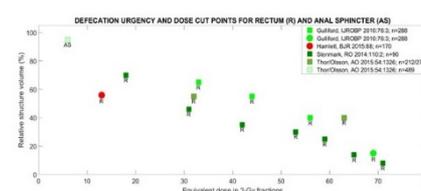

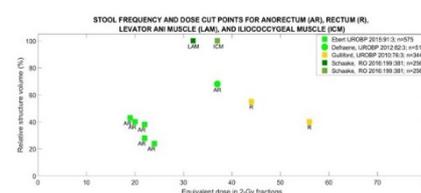

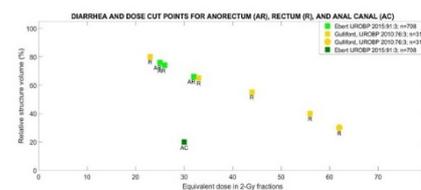

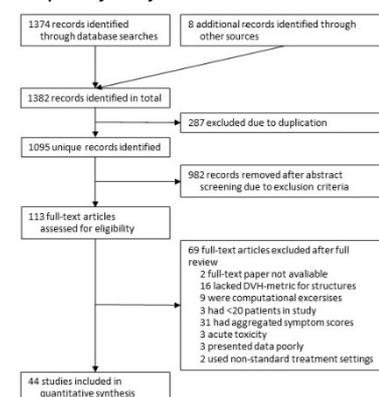

The electronic database PubMed was scrutinized for full-text articles published in English since the publication of the QUANTEC reviews (Jan 1<sup>st</sup> 2010; EBRT only), and since the Emami study (Jan 1<sup>st</sup> 1992; including BT). Studies qualifying for inclusion were randomized controlled/case-control/cohort studies with specific non-aggregated symptom assessments, follow-up >3 months, >20 patients, primary standard treatments for localized prostate cancer with dose-volume based data. Two investigators independently assessed study quality according to eight criteria<sup>1</sup> and an additional study-specific criterion incorporating dose-association complexity. Quantitative synthesis for sufficiently homogenous studies was performed for each treatment modality with dose cut points converted into equivalent doses in 2-Gy fractions ( $\alpha/\beta=3$  Gy). If not explicitly reported, thresholds were derived from suggested models and estimated at a risk level of 10%. The review was registered at PROSPERO

International prospective register of systematic reviews on July 12, 2016.

<sup>1</sup> Agency for Healthcare research and quality, US department of Health in Human services; [https://effectivehealthcare.ahrq.gov/ehc/products/322/998/MethodsGuideforCERs\\_Viswanathan\\_IndividualStudies.pdf](https://effectivehealthcare.ahrq.gov/ehc/products/322/998/MethodsGuideforCERs_Viswanathan_IndividualStudies.pdf)

### Results

The search strategy resulted in 1095 abstracts (Figure 1) of which 44 studies fulfilled the inclusion criteria and were available in full text (one study was excluded based on study quality criteria). The review is expected to include syntheses of dose-response relationships for seven gastrointestinal symptoms (bleeding/diarrhea/frequency/incontinence/pain/proctitis/urgency: n=18/3/4/10/3/4/4), three genitourinary symptoms (hematuria/incontinence/obstruction: n=4/4/3), and one sexual dysfunction symptom (erectile dysfunction: n=3) following EBRT. The corresponding figures for BT±EBRT will be two (bleeding/urgency: n=6/2), four (incontinence/obstruction/pain/stricture: n=4/2/3/2), and one symptom (erectile dysfunction: n=2). Results for diarrhea, stool frequency, and defecation urgency following EBRT are presented in Figure 2. Dose cut points for the rectum and anal canal/sphincter region generally followed the same linear slope for diarrhea/defecation urgency across studies; for stool frequency they were less consistent.

### Conclusion

Our review demonstrates continuous and innovative activity in the field of late toxicity after prostate cancer

RT since the QUANTEC publications. There is an increased recognition of intra- and inter-structure specific doses, and even though rectal bleeding remains the most studied symptom, there is also a trend towards other non-aggregated symptoms.

#### EP-1610 Predictors for morbidity from planned vs. delivered rectal dose maps in RT of prostate cancer

J. Trane<sup>1</sup>, O. Casares Magaz<sup>1</sup>, L. Bentzen<sup>2</sup>, K. Busch<sup>1</sup>, M. Thor<sup>3</sup>, L.P. Muren<sup>1</sup>

<sup>1</sup>Aarhus University Hospital - Aarhus University, Medical Physics, Aarhus, Denmark

<sup>2</sup>Aarhus University Hospital, Oncology, Aarhus, Denmark

<sup>3</sup>Memorial Sloan-Kettering Cancer Center, Medical Physics, New York, USA

#### Purpose or Objective

Patient-reported gastro-intestinal (GI) symptoms following radiotherapy (RT) for prostate cancer have recently been associated with metrics derived from rectal dose surface maps. In a recent study we developed rectum dose map based normal tissue complication probability (NTCP) models for three common late GI symptoms (at least 20% prevalence in the cohort used for modelling). In the present study we used such dose maps and connected NTCP models to compare the planned, daily and summed rectal dose distributions for patients with repeat volumetric imaging acquired during the course of RT.

#### Material and Methods

The patients included in this study were treated according to a national clinical trial for patients with locally advanced prostate cancer, irradiating concomitantly the pelvic lymph nodes and seminal vesicles to 55 Gy and the prostate to 78 Gy using volumetric modulated arc therapy. The treatment plans were recalculated on weekly repeat cone-beam (CB) CTs (6-8 CBCTs per patient) following Hounsfield Unit override to bone and water. Rectal dose maps were created for the planned dose distribution as well as for the dose distributions re-calculated on weekly CBCTs using a method recently developed by our group. The weekly CBCTs were averaged to provide a measure for the summed/accumulated dose across the course of RT. NTCPs were calculated for the planned, weekly and averaged rectal dose maps using three spatially based response models (based on areas and extents from the rectal dose maps) for three patient-reported GI symptoms: faecal leakage, obstruction and defecation urgency. The study included four prostate cancer patients, one with and three free from late Grade 2+ GI symptoms after RT.

#### Results

Dose differences exceeding +/- 10 Gy (scaled to the full treatment course) were seen in the dose maps for all patients and in all scans (Fig. 1). The largest systematic dose increase in the maps during the course of therapy was seen in the patient that experienced Grade 2+ GI symptoms after treatment. This patient also had higher NTCPs for all three spatial dose metric based models for the average map across treatment compared to the planned dose distribution (e.g. 10% vs 6% for faecal leakage), while smaller differences were seen for the three other patients (Table 1).

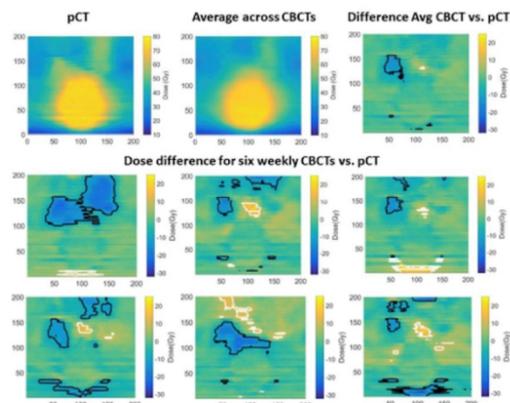

Figure 1: Rectum dose surface maps for the planned dose distribution (pCT) as well as from the averaged dose maps (average across CBCTs). The top right map is the difference maps between these two (Average CBCT vs pCT) where dose differences larger than +/- 10 Gy (scaled to the full treatment dose) are indicated (dose increase during RT in white; dose decrease in black). The six maps in the lower part of the figure are the dose difference maps for six weekly CBCTs relative to the pCT (white/black contour as in the other map).

Table 1: NTCPs estimated for three different GI patient-reported symptoms based on rectal dose surface maps for the planned, weekly CBCTs and averaged dose maps for the patient with Grade 2 GI symptoms.

Patient 2 (Grade 2 GI)	NTCP (Leakage) (%)	NTCP (Obstruction) (%)	NTCP (Urgency) (%)
Week 1	10	47	13
Week 2	14	52	15
Week 3	7	47	15
Week 4	15	55	15
Week 5	13	56	15
Week 6	9	44	13
Week 7	11	55	18
Week 8	15	62	21
Average dose map	10	50	15
Planned distribution	6	45	15
Model input parameters (dose map metrics)	35 Gy lateral extent; 55 Gy central lateral extent	5 Gy upper anterior area; 75 Gy central area; 50 Gy posterior lower area	65 Gy lateral extent; 55 Gy upper lateral extent

#### Conclusion

The rectum dose maps and the connected NTCP models used in this study identified clinically relevant changes in rectum dose distributions caused by organ motion during the course of therapy. This model validation study showed that these maps and models are useful tools to evaluate the risk of normal tissue reactions in the rectum.

#### EP-1611 Dose-response relationships for radiation-induced urgency syndrome after gynecological radiotherapy

E. Alevronta<sup>1</sup>, V. Skokic<sup>1</sup>, U. Wilderäng<sup>1</sup>, G. Dunberger<sup>2</sup>, F. Sjöberg<sup>1</sup>, C. Bull<sup>1</sup>, K. Bergmark<sup>1,3,4</sup>, G. Steineck<sup>1,4</sup>

<sup>1</sup>Institute of Clinical Sciences- Sahlgrenska Academy at the University of Gothenburg, Department of Oncology-Division of Clinical Cancer Epidemiology, Gothenburg, Sweden

<sup>2</sup>Ersta Sköndal College University, Department of Health Care Sciences, Stockholm, Sweden

<sup>3</sup>Sahlgrenska University Hospital, Department of Oncology, Gothenburg, Sweden

<sup>4</sup>Karolinska Institutet, Department of Oncology and Pathology- Division of Clinical Cancer Epidemiology, Stockholm, Sweden

#### Purpose or Objective

To find out what organ and doses are most relevant for 'radiation-induced urgency syndrome' in order to derive the corresponding dose-response relationships as an aid for avoiding the syndrome in the future.

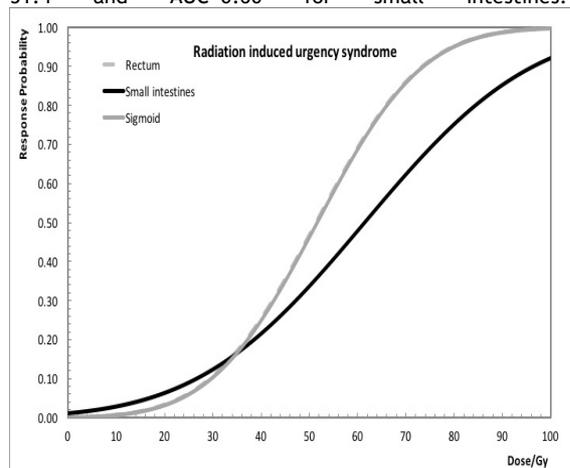

#### Material and Methods

Of the 99 survivors treated with radiation therapy for gynecological cancer, 24 developed 'radiation-induced urgency syndrome'. The survivors included in the study had not received brachytherapy, but other treatment combinations of external radiation therapy, surgery, and chemotherapy at the Karolinska University Hospital, Stockholm or the Sahlgrenska University Hospital, Gothenburg during the period 1991 to 2003. The rectum, the sigmoid and small intestines were delineated and the dose-volume histograms were exported for each patient.

'Radiation-induced urgency syndrome' consists of different self-reported bowel symptoms. To combine the symptoms, factor analyses was used. Dose-response relationships were estimated fitting the data to the Probit model. ROC curve analyses were used to identify which organ at risk is correlated the most with the clinical outcome.

### Results

The maximum likelihood estimates of the dose-response parameters for Probit model, the three organs at risk and 'radiation induced urgency syndrome', the Log Likelihood (LL) value and the AUC are:  $D_{50} = 51.3$  (48.3-54.6),  $y_{50} = 1.19$  (0.98-1.42),  $\alpha/\beta=0.59$  (0.034-1.56), LL = -50.2 and AUC=0.63 for rectum,  $D_{50} = 51.6$  (48.7-54.9) Gy,  $y_{50} = 1.20$  (0.98- 1.44),  $\alpha/\beta=2.02$  (0.85-4.73), LL = -51.0 and AUC=0.66 for the sigmoid and  $D_{50} = 61.4$  (56.4-67.5) Gy,  $y_{50} = 0.90$  (0.73- 1.08),  $\alpha/\beta = 10.3$  (2.1- 1e+06 Gy), LL = -51.4 and AUC=0.60 for small intestines.

### Conclusion

For the studied organs at risk, the dose to the sigmoid is the best predictor of 'radiation-induced urgency syndrome' among gynecological cancer survivors. Dose planners having the ambition to eliminate the syndrome may consider to delineate the sigmoid as well as rectum in order to incorporate the dose-response results.

### EP-1612 Estimates of the $\alpha/\beta$ ratio for prostate using data from recent hypofractionated RT trials.

S. Gulliford<sup>1</sup>, C. Griffin<sup>2</sup>, A. Tree<sup>3</sup>, J. Murray<sup>4</sup>, U. Oelfke<sup>1</sup>, I. Syndikus<sup>5</sup>, E. Hall<sup>2</sup>, D. Dearnaley<sup>3</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom

<sup>2</sup>The Institute of Cancer Research, Clinical Trials and Statistics Unit, London, United Kingdom

<sup>3</sup>Royal Marsden NHS Foundation Trust, Academic Urology Unit, London, United Kingdom

<sup>4</sup>Guy's & St Thomas' NHS Foundation Trust, Department of Clinical Oncology, London, United Kingdom

<sup>5</sup>Clatterbridge Cancer Centre, Department of Clinical Oncology, Wirral, United Kingdom

### Purpose or Objective

The  $\alpha/\beta$  ratio for prostate cancer has been widely studied with growing evidence for a value significantly lower than the standard value for tumours of 10 Gy. Previous studies have also indicated that there may be a time factor whereby tumour repopulation should be considered during the course of radiotherapy[1]. Recent reporting from 4 separate phase III clinical trials comparing hypofractionated schedules with standard schedules for prostate radiotherapy allow for further exploration of the  $\alpha/\beta$  value.

### Material and Methods

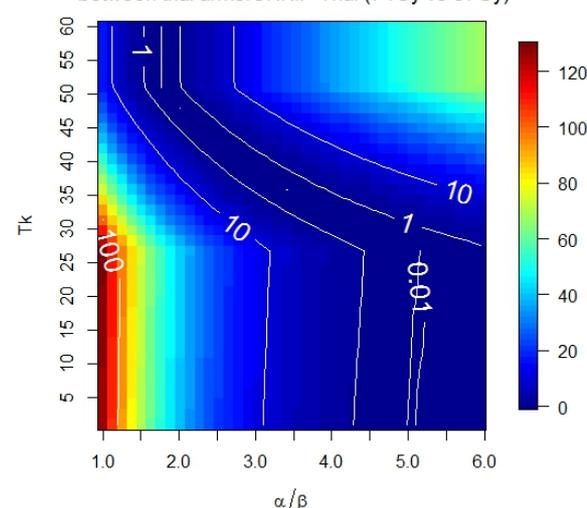

The  $\alpha/\beta$  ratio for prostate was derived independently for each of the CHHiP[2], HYPRO[3], PROFIT [4] and RTOG 0415 studies[5] by comparing the outcomes in the standard and hypofractionated trial arms. This approach ensures that differences between the trials such as use of hormones and outcome metrics are accounted for. It was assumed that the dose response was linear between trial arms. In 3 of the trials, the hypofractionated schedule was compared to 2 Gy per fraction, in the RTOG 0415 study the standard fractionation was 1.8 Gy per fraction. A grid search approach was used to minimise the error for EQD2. Repopulation was included in the model using the term OTT-Tk where OTT is the overall treatment time and Tk is the number of days from the start of treatment when repopulation is assumed to begin. A proliferation rate of 0.31 Gy/day was used [1]. The CHHiP trial had two hypofractionated arms and these were fitted separately.

### Results

Figure 1 is a representative example of the grid search results to minimise the squared difference in EQD2 corrected for outcome between the trial arms. Varying the Tk parameter has 3 distinct phases; i) Tk less than the OTT of the hypofractionated arm, where the  $\alpha/\beta$  ratio varies little ii) Tk between the OTT of the hypofractionated and standard arms, where the  $\alpha/\beta$  ratio transitions steeply and iii) Tk greater than the OTT of the standard arm. This last case reduces to equating the two fractionation schedules. The best fit parameter values for  $\alpha/\beta$  ratio and Tk are shown in Table 1 along with the best fit values for the  $\alpha/\beta$  ratio when repopulation is not considered. For all trials, the overall best fit parameters included a value of Tk that was less than the overall treatment time of the standard arm, indicating an improvement when compared to a model which considered the  $\alpha/\beta$  ratio only.

Figure 1

Squared difference in EQD2 (corrected for outcome) between trial arms: CHHiP Trial (74Gy vs 57Gy)

Table

1

	Best Fit Parameters				No Time factor		
	$\alpha/\beta$ ratio (Gy)	95% CI	Tk (days)	95% CI	$\alpha/\beta$ ratio (Gy)	95% CI	
CHHiP 57Gy	5.2	4.2 - 6.7	25.0	0.0 - 31.5	1.7	1.4 - 2.1	
CHHiP 60Gy	5.4	4.3 - 6.9	17.0	0.0 - 32.2	1.9	1.6 - 2.3	
HYPRO	4.8	4.1 - 5.6	34.0	0.0 - 50.0	3.5	3.1 - 4.1	
PROFIT	3.8	3.1 - 4.6	30.0	0.0 - 34.5	1.3	1.3 - 1.4	
RTOG 0415	31.5	15.2 - >100	44.0	21.5 - 48.5	6.9	5.2 - 10.0	

### Conclusion

The estimation of  $\alpha/\beta$  ratio for prostate cancer presented here included two unknown parameters in the model, as such, no definitive conclusion was reached. However, including  $T_k$  in the model consistently reduced the squared difference and increased the  $\alpha/\beta$  ratio.

### EP-1613 Modelling DNA damage on gold nanoparticle enhanced proton therapy

M. Sotiropoulos<sup>1</sup>, N.T. Henthorn<sup>1</sup>, J.W. Warmenhoven<sup>1</sup>, R.I. Mackay<sup>2</sup>, K.J. Kirkby<sup>1,3</sup>, M.J. Merchant<sup>1,3</sup>

<sup>1</sup>University of Manchester, Faculty of Biology Medicine and Health Division of Molecular & Clinical Cancer Sciences, Manchester, United Kingdom

<sup>2</sup>The Christie NHS Foundation Trust, Christie Medical Physics and Engineering, Manchester, United Kingdom

<sup>3</sup>The Christie NHS Foundation Trust, Manchester, United Kingdom

### Purpose or Objective

Gold nanoparticles have demonstrated a radiosensitization potential under photon and proton irradiation. Most existing studies have attributed the effect to the increased local dose delivered by electrons generated from interactions of the beam protons with the gold nanoparticles. However, the mechanism leading to an increase in the cell killing is yet not clear.

### Material and Methods

To further understand the underlying mechanisms of the radiosensitization at the cellular level, a cell model with detailed nuclear DNA structure was implemented in the Geant4 Monte Carlo simulation toolkit. A realistic gold nanoparticle distribution was incorporated, allowing for the formation of clusters of vesicles filled with the gold nanoparticles. A clinically relevant gold concentration was simulated for the gold nanoparticle size of 6, 15, and 30 nm. Protons with linear energy transfer values found in a spread out Bragg peak (1.3-4.8 keV/ $\mu$ m) were simulated. The event-by-event models available through the Geant4-DNA were used for accurate calculations of DNA damage. Damage to the DNA inducing either single (SSB) or double strand breaks (DSB) was used for the quantification of the radiosensitization effect, for a dose fraction of 2 Gy. Each case was repeated 100 times to get an average number of SSB or DSB numbers.

### Results

For the combinations of gold nanoparticle size and proton energies studied in the present work, no statistically significant increase in the single or double strand break formation was observed. The DSBs induced for the 4.8 keV/ $\mu$ m protons were  $14.93 \pm 0.38$  for the control while ranged from  $15.09 \pm 0.39$  to  $15.76 \pm 0.41$  when the gold nanoparticles were present, depending on the gold nanoparticle size. Similarly, for the 1.3 keV/ $\mu$ m protons the control value was  $12.21 \pm 0.34$  DSBs and in the presence of gold nanoparticle was  $11.94 \pm 0.36$  to  $12.48 \pm 0.33$  DSBs depending on the gold nanoparticle size.

### Conclusion

As gold nanoparticles enhanced proton therapy have been proven experimentally, our results allow hypothesizing contribution from alternative mechanisms of radiosensitization.

### EP-1614 Uncertainty of dose-volume constraints obtained from radiation pneumonitis dose-response analysis

C.M. Lutz<sup>1</sup>, D.S. Møller<sup>2</sup>, L. Hoffmann<sup>2</sup>, A.A. Khalil<sup>1</sup>, M.M. Knap<sup>1</sup>, M. Alber<sup>1,3</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

<sup>2</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark

<sup>3</sup>Heidelberg University Hospital, Department of Radiooncology, Heidelberg, Germany

### Purpose or Objective

Dose planning constraints, such as the volume receiving xGy ( $V_x$ ), are often extracted from clinical outcome data. These data are tainted by uncertainties in dose- and output recording, large patient heterogeneity, small sample size and -variability. Our study is dedicated to the investigation of the fundamental uncertainty with which dose planning constraints can be extracted from clinical radiation pneumonitis data and how this relates to patient number and complication incidence rate.

### Material and Methods

In order to measure the reliability of a  $V_x$  logistic regression model, the dose-response mechanism generating the complication events needs to be known. For this reason, we generated cohorts of patients using real-life dose distributions of patients treated for advanced lung cancer, combined with a postulated  $V_x$  logistic dose-response model. In each of the 1000 cohorts, the patients were randomly assigned complication/no-complication based on the individual risks given by the postulated model. Thus, "alternative reality" cohorts comprised of the same patients, but with different outcomes from the same dose distributions were created. Each cohort thus represented a possible result of a clinical study. They were analyzed with a number of logistic  $V_x$  models, and the best fitting model was selected. This was matched to the postulated model to determine its recognition rate. The postulated model was varied to produce low, intermediate and high incidence rates.

### Results

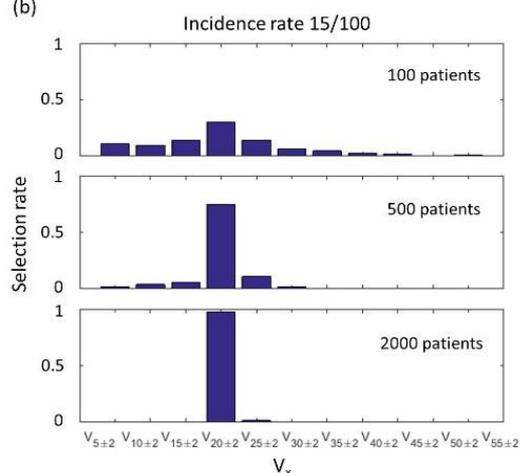

For a patient cohort of 100 individuals, a postulated model with an incidence rate of 15/100 was recognized in 31% of the cohorts. For a cohort size of 500, the correct-recognition rates increased to 75%. For a lower incidence model (7/100), these recognition frequencies dropped to 20% and 56%, respectively.

To ensure a recognition rate >90%, large cohorts of between 500 and 2000 patients were required, see Figure 1(a). Figure 1(b) shows that the distribution width for the 15/100 incidence rate model decreased from a standard deviation of 10Gy for 100 patients to 1Gy for 2000 patients.

(a)

Nr of patients	Incidence rate	7/100	15/100	30/100
	100		20%	31%
500		56%	75%	81%
2000		92%	98%	99%

(b)

### Conclusion

For realistic dose distributions and cohort sizes, a state-of-the-art analysis failed to identify the postulated dose-response in about 2-in-3 cases for the low incidence of the large-volume effect complication radiation pneumonitis. Very large patient cohorts were required to ensure recognition rates above 90%. This fundamentally low success rate could explain the persistent difficulties to derive dose constraints from clinical data for complications in large-volume effect, "parallel" organs.

### EP-1615 Second cancer risk after radiation of localized prostate cancer with and without flattening filter

M. Treutwein<sup>1</sup>, M. Hipp<sup>2</sup>, R. Loeschel<sup>3</sup>, O. Koelbl<sup>1</sup>, B. Dobler<sup>1</sup>

<sup>1</sup>Klinik und Poliklinik für Strahlentherapie- Unive, Regensburg University Medical Center- Department of Radiation Oncology, Regensburg, Germany

<sup>2</sup>Klinikum St. Marien, Department of Radiotherapy, Amberg, Germany

<sup>3</sup>Ostbayerische Technische Hochschule, Faculty of Computer Science and Mathematics, Regensburg, Germany

### Purpose or Objective

Radiotherapy is a standard treatment modality with curative intent for localized prostate cancer. Prostate cancer is a disease of elderly men. Nevertheless these patients have a remaining life span of ten years or more. Radiotherapy compared to surgery may increase the risk for second cancer. Minimizing this risk can be one criterion in deciding for a specific technique. Therefore we compared the organ equivalent dose (OED) and excess absolute risk (EAR) for second cancer for different treatment techniques.

### Material and Methods

For ten patients four different plans were calculated, using a seven field intensity modulated radiotherapy (IMRT) and a single arc volumetric modulated arc therapy

(VMAT) with and without flattening filter. The optimization was performed as simultaneous integrated boost in 33 fractions, aiming for 59.4 Gy minimum dose to the PTV and 71.0 Gy minimum dose and 74.2 Gy maximum dose to the CTV. The OED was computed for the urinary bladder and the rectum from dose volume histograms for the linear-exponential (LEM) and the plateau dose-response model (PM). The EAR can be derived from the OED, taking age modifying parameters into account. The statistical analysis was performed using the Wilcoxon test in IBM® SPSS® Statistics 23 (IBM Corporation).

### Results

Within one technique (IMRT or VMAT) the average value of the OED is lower for the flattening filter free (FFF) mode compared to flat beams (FB) in both organs and for both dose-response models with one exception: In the urinary bladder it is the other way round for IMRT and the LEM. These results are statistically significant (level of significance 5%). The results for VMAT are statistically significant for the rectum only in both models.

Comparing IMRT and VMAT the results are ambiguous: For the LEM the OED is lower with IMRT for both FB and FFF, for the PM lower OEDs are achieved with VMAT. All results are significant, except of one (LEM, FFF, urinary bladder,  $p = 7.4\%$ ).

The average values for the EAR for patients of 71 years at exposure and an attained age of 84 years are given in table 1.

	Urinary Bladder		Rectum	
	EAR <sub>iso-esp.</sub>	EAR <sub>plateau</sub>	EAR <sub>iso-esp.</sub>	EAR <sub>plateau</sub>
IMRT FB	41.66 ± 4.12	49.35 ± 6.04	8.94 ± 0.08	10.64 ± 0.11
IMRT FFF	43.53 ± 5.23	48.93 ± 6.42	9.10 ± 0.09	10.57 ± 0.12
VMAT FB	45.23 ± 5.49	48.33 ± 6.38	9.50 ± 0.09	10.54 ± 0.11
VMAT FFF	44.68 ± 6.17	47.98 ± 6.92	9.36 ± 0.09	10.49 ± 0.12

Table 1. Excess average risk in 10,000 person years Gy.

### Conclusion

Some statistically significant differences have been found for the different treatment techniques and modes. However, they depend on the dose-response model. For the PM the lowest EAR is found for VMAT FFF in both organs at risk, for the LEM IMRT FB shows the minimum values. Plan quality and efficiency should additionally be regarded before the decision for a specific technique and mode.

### EP-1616 Phase II trial of a novel device for DIBH in left-sided breast cancer: preliminary results

I. Romera-Martínez<sup>1</sup>, A. Onses Segarra<sup>1</sup>, C. Muñoz-Montplet<sup>1</sup>, D. Jurado-Bruggeman<sup>1</sup>, J. Marruecos Querol<sup>2</sup>, S. Agramunt-Chaler<sup>1</sup>, J. Vayreda Ribera<sup>2</sup>

<sup>1</sup>Institut Català d'Oncologia, Medical Physics and Radiation Protection, Girona, Spain

<sup>2</sup>Institut Català d'Oncologia, Radiotherapy, Girona, Spain

### Purpose or Objective

To present the preliminary results of the prospective phase II trial of a novel device, called DIFGI, for deep inspiration breathhold (DIBH) in left-sided breast cancer. We will focus on the performance of the device as well as on the dosimetrical benefits of the technique.

### Material and Methods

DIFGI is a simple, friendly, low-priced external respiration-monitoring device developed in our institution that has obtained a utility model protection (Fig.1). The patients hold her breath in supine position until contacting an horizontal bar, which activates an acoustic and a visual signal that offers feedback to the patient and the RTTs,

respectively. DIFGI is benchmarked against Varian's RPM until final validation of the device, but it is compatible with all treatment units and CTs.

Fig. 1

Fifteen left-sided breast cancer patients have been recruited until now. If heart constraints can't be fulfilled in free-breathing (FB), then patients are trained and undergo a second CT scan in DIBH using the DIFGI. The stability, repeatability, reproducibility and reliability of the method are studied. Two radiopaque markers, one on the mediastinum tattoo and another along the back, serve as a reference to measure breath amplitude (Fig.2). The stability and repeatability are measured on the DIBH CT scan. The reproducibility mean value, systematic, and random errors are determined by using daily kV images and weekly CBCTs. The reliability of the device is calculated as the failure ratio compared to RPM.

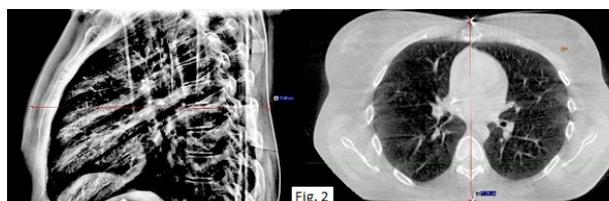

Fig. 2

We also analyse Dmean, V30 (cm<sup>3</sup>), and V25 (%) for the heart in both techniques.

#### Results

Stability and repeatability are below 1.7 and 3.3 mm in all cases, respectively. Reproducibility mean value is 1.7 mm, systematic error is 0.5 mm, and random error is 0.9 mm. DIFGI reliability is 95%. All failures are human errors occurred during the learning period.

Dosimetric benefits compared to FB for the heart are: 3.0 vs 6.7 Gy for mean dose, 14.9 vs 53.4 cm<sup>3</sup> for V30, and 2.8 vs 9.5% for V25.

#### Conclusion

DIFGI is a simple, friendly, low-priced external respiration-monitoring device compatible with all treatment units and CTs. The preliminary results of the stability, repeatability, reproducibility, and dosimetric benefits are encouraging. The reliability of the device depends on human intervention so we plan to interlock it with the treatment unit.

#### EP-1617 Reproducibility and stability of vmDIBHs during breast cancer treatment measured using a 3D camera

M. Kusters<sup>1</sup>, F. Dankers<sup>1</sup>, R. Monshouwer<sup>1</sup>

<sup>1</sup>Radboud university medical center, Academic Department of Radiation Oncology, Nijmegen, The Netherlands

#### Purpose or Objective

To accurately perform voluntary moderately deep inspiration breath hold (vmDIBH) radiation therapy it is essential to determine the position of the chest wall at the start of treatment and to monitor deviations during treatment.

An in-house developed real-time automated monitoring system of the respiratory motion is implemented to verify the reproducibility and stability of the vmDIBH during breast cancer treatments.

#### Material and Methods

Patients with left sided breast cancer are guided to perform vmDIBH assisted by verbal instructions and an additional aid called the 'breathing stick' [1].

A 3D Kinect v2 camera (Microsoft, USA) was mounted in the treatment room to visualize the patient on the treatment couch. Software was developed to track and visualize the anterior-posterior motion of a small area of the surface of the thoracic wall in real time, allowing RTTs in the treatment room to verify the reproducibility and stability of the breath holds during treatment.

The data of ten patients was analysed for reproducibility and stability. The formulas for reproducibility and stability were derived from Cervino et al. with minor adaptations [2]. For reproducibility the standard deviation of the mean of each DIBH level was used. For stability all breath holds were fitted by first order polynomials, the slopes were multiplied by their breath hold lengths to find a range and all these ranges were averaged.

#### Results

A typical example of reproducible and stable vmDIBHs during a treatment fraction of a patient is shown in Figure 1.

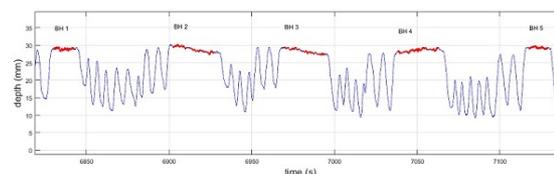

Figure 1: Typical example of five reproducible and stable vmDIBHs for one treatment fraction

The analysed reproducibility and stability of vmDIBH treatment for then patients using the breathing stick is shown in Figure 2. The median reproducibility and stability were 0.9 mm and 1.1 mm, respectively.

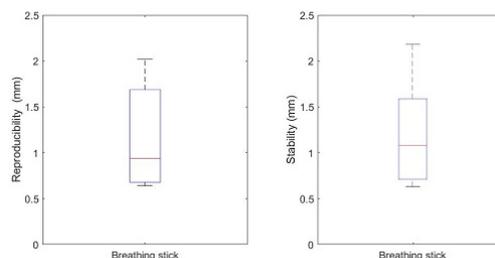

Figure 2: Clinical measurements of the reproducibility and stability of the vmDIBHs for ten patients

#### Conclusion

The reproducibility and stability of the chest wall can be accurately measured using the in-house developed monitoring system. vmDIBH in combination with the breathing stick shows good stability and reproducibility which are comparable to the results in the study of Cervino et al. [2].

In this work the current results are limited to ten patients; we continue to, acquire more data for future analyses. The breathing stick is routinely used in our clinic; currently we use the breath hold monitoring system to test whether using this tool has an added value.

### EP-1618 Can diaphragm motion function as a surrogate for motion of esophageal tumors during treatment?

S.E. Heethuis<sup>1</sup>, L. Goense<sup>1</sup>, A.S. Borggreve<sup>1</sup>, P.S.N. Van Rossum<sup>1</sup>, R. Van Hillegersberg<sup>2</sup>, J.P. Ruurda<sup>2</sup>, S. Mook<sup>1</sup>, G.J. Meijer<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, A.L.H.M.W. Van Lier<sup>1</sup>  
<sup>1</sup>University Medical Center Utrecht, Department of Radiotherapy, Amsterdam, The Netherlands  
<sup>2</sup>University Medical Center Utrecht, Department of Surgery, Amsterdam, The Netherlands

### Purpose or Objective

Esophageal tumors show large motion in cranio-caudal direction (CC), with a Peak-to-Peak (P-t-P) range of 2.7 to 24.5mm [Lever F. et al. (2013)]. In case the motion of the tumor could be followed during radiotherapy treatment, this would enable treatment margin reduction. The aim of this research is to investigate whether the motion of the diaphragm is correlated with breathing motion and drift we can detect in esophageal tumors. As such, the diaphragm could function as a surrogate for esophageal tumor motion during treatment.

### Material and Methods

In total, 46 coronal cine MR scans were obtained from 4 patients whom were treated with neoadjuvant chemoradiotherapy (nCRT) for distal esophageal cancer. In this study, one MR scan was performed prior to nCRT, followed by 5 weekly MR scans during nCRT (in one patient only 4 scans). Cine MR scans included 75 frames acquired in approximately 45 seconds, with a resolution of 2.01x2.01mm. The scan was acquired twice within one session, separated by circa 10 minutes. To estimate motion in the cine MR series an optical flow algorithm (RealTITracker, [Zachiu C. et al. (2015)]) was used to calculate motion fields. The tumor was delineated manually, in which the mean motion for each frame was calculated in CC direction. Motion was also estimated in the diaphragm/liver border within a manually placed rectangle. An in-house tool was designed to find peaks and estimate drifts in the motion curves. Drift was defined as the change in the mean between consecutively found local maxima and minima. Correlation of the CC motion between diaphragm and tumor was calculated. P-t-P analysis was performed on tumor motion curves and tumor motion curves corrected for drift using the diaphragm drift (Fig. 1).

### Results

A strong Pearson's correlation of  $r=0.972$  was found while comparing CC motion in diaphragm and tumor, with a range of 0.849-0.996. The mean P-t-P tumor motion before and after correction for drift was 10.1 and 9.3mm respectively ( $p<0.05$ ). However, for individual scan sessions the effect of drift could be much larger, as is exemplified in Fig. 1a. P-t-P amplitude for each patient before and after drift correction is shown in Fig. 2. Although the amplitude of the diaphragm motion was higher, mean P-t-P motion of 12.6mm, when the tumor motion showed a drift or sudden movement, this was also found in the diaphragm motion (Fig. 1&2).

### Conclusion

In this study it was found that diaphragm motion shows a strong correlation with esophageal tumor motion. Using the diaphragm motion for drift correction resulted on

average in a reduction of the P-t-P range over all patients. This reduction can be used for adaptive treatment strategies, which reduce margins. For example, in case an MR-linac is taken in mind [Lagendijk J.J.W. et al (2008)], MR-based gating to compensate for respiratory motion and/or base-line shift (drifting) detection using the diaphragm as surrogate will be well feasible.

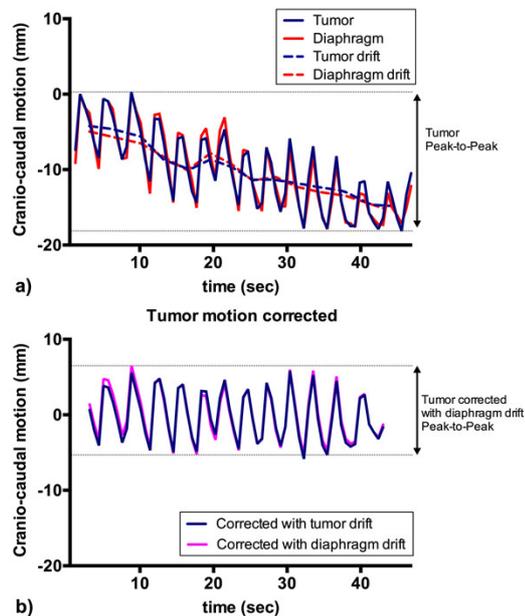

Figure 1: Example of a motion pattern for a patient showing a significant drift. a) Motion (continuous line) and drift curves (dashed line) for tumor (blue) and diaphragm (red) for one scan. b) Tumor motion curve corrected for tumor drift (blue) and diaphragm drift (pink).

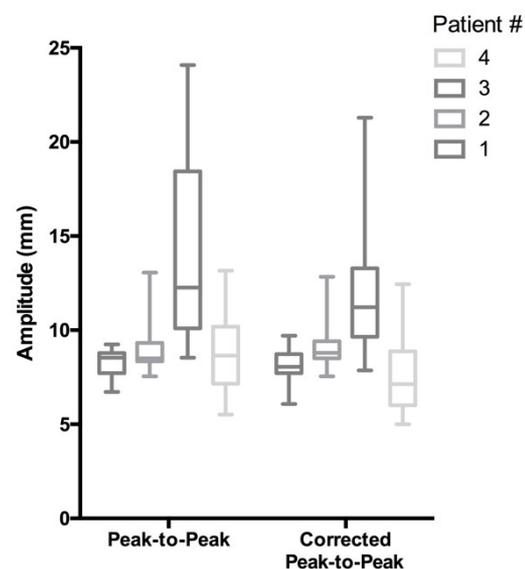

Figure 2: Peak-to-Peak amplitude of tumor motion curves and tumor motion curves corrected using the diaphragm drift. The four patients are indicated separately in boxplots with 25<sup>th</sup> and 75<sup>th</sup> percentile, median and minimum/maximum values shown.

### EP-1619 Determination of Lung Tumour Motion from PET Raw Data used for Accelerometer Based Motion Prediction

<sup>6</sup>Boll Automation GmbH, Research and Development, Kleinwallstadt, Germany

<sup>7</sup>RWTH Aachen University, III. Institute of Physics B, Aachen, Germany

### Purpose or Objective

For precise stereotactic radiation of lung tumours the exact position of the tumour has to be known. A common method for the detection of the tumour position is using fluoroscopy during treatment. This leads to a very precise tracking of the tumour position, but also causes additional dose in the scanned region.

In this work an alternative solution to determine the actual tumour position without additional radiation is introduced. Combined information from FDG-PET scans and an accelerometer based system are used for a patient specific tumour movement prediction.

### Material and Methods

We measured the breathing motions of ten patients in a clinical trial by placing six tri-axial accelerometers on the patient's thorax and abdomen. Each patient is instructed to breathe in up to five different breathing techniques: 'free breathing', 'deep thoracic', 'flat thoracic', 'deep abdominal' and 'flat abdominal'. Simultaneously, a FDG-PET scan was performed to correlate the patient's respiratory states with the tumour positions afterwards. Retrospectively the tumour trajectory was extracted from the PET raw data and afterwards correlated with the information obtained by the accelerometers. The extraction of the respiratory motion was performed using the methods described in [1] and [2]. A verification of the motion extraction algorithm was performed with an in-house developed moving phantom.

### Results

The measurements show a good agreement between real and reconstructed phantom motion. An analysis of a 'deep abdominal' breathing is shown in figure 1. The tumour trajectories are displayed in blue and the low pass filter of the data in red. Combining the information from the accelerometer system and the tumour trajectories a model can be obtained to predict the most likely tumour position for a given accelerometer signal [3]. Figure 2 shows the tumour trajectory in superior-inferior direction of a 'free breathing' instruction in blue and the predicted trajectory in orange. The model shows a good prediction of the real tumour trajectory.

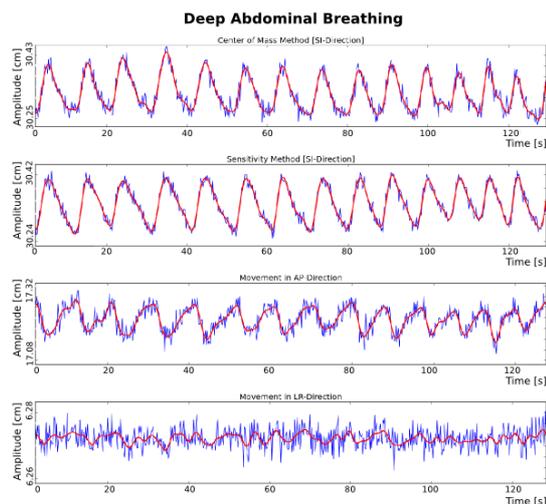

Figure 1: Tumour trajectory (blue) and low pass filter (red)

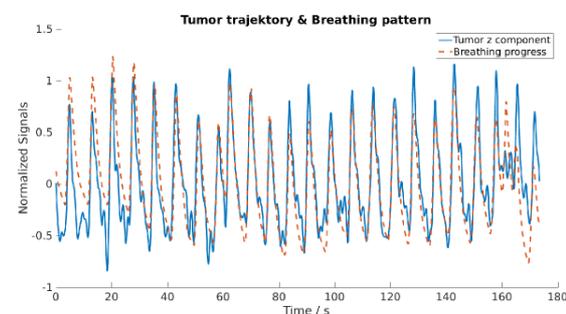

Figure 2: Tumour trajectory (blue) and prediction (orange)

### Conclusion

The algorithm for the tumour trajectory reconstruction was validated in this work.

The presented data show a good agreement of the reconstructed and predicted tumour motion. Thus the accelerometer based system provides the opportunity for tumour tracking from breathing induced motion.

### EP-1620 The immobilizing effect of the vacuum cushion in spinal SBRT and the impact of pain

A.S. Gerlich<sup>1</sup>, J.M. Van der Velden<sup>1</sup>, G. Fanetti<sup>2</sup>, A.

Zoetelief<sup>1</sup>, W.S.C. Eppinga<sup>1</sup>, E. Seravalli<sup>1</sup>

<sup>1</sup>University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands

<sup>2</sup>European Institute of Oncology, Radiation Oncology, Milan, Italy

### Purpose or Objective

The number of patients treated with spinal SBRT is increasing rapidly. This technique requires accurate dose delivery for the optimal treatment effect and protection of organs at risk (e.g. spinal cord). Accuracy can be

challenged by patient motion during treatment delivery. Movement during treatment can be induced by pain. To prevent movement, individualized vacuum cushions are commonly used immobilization devices in SBRT. This study evaluates the impact of the use of a vacuum cushion on intra-fraction movement in patients during SBRT based on cone beam CT (CBCT) data and the impact of pain on motion.

#### Material and Methods

Intra-fraction motion was measured in two groups of patients treated with SBRT: 25 patients with spinal metastases using a vacuum cushion (BlueBAG™, Elekta, Stockholm, Sweden, n= 56 fractions) and 19 patients with lung lesions treated without a vacuum cushion (n= 68 fractions). For the purpose of this study, the comparison group was considered to have a fictive thoracic spine target volume. Intra-fraction motion was assessed by registering the post-treatment CBCT scan to the planning CT, based on the volume of interest around the (fictive) spine metastasis. Translations and rotations were determined based on a CBCT bone density match using the Elekta Medical Systems XVI software. Absolute values of displacements in translations and rotations after each fraction were calculated. Pain at baseline was registered. Treatment time was similar in both groups. Statistical significant differences between the two groups regarding displacements in all directions were tested with Mann-Whitney. This test was also performed for movement in patients with and without pain. Mixed models were used to analyze the differences in movement between two groups because of multiple measurements (i.e. fractions) within patients.

#### Results

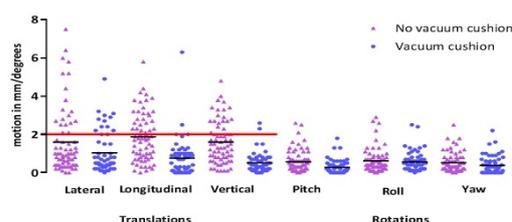

Significant differences in intra-fraction movement were found in 5 out of 6 directions (Table 1) in favor of the vacuum cushion. Mixed models confirmed a significant difference in movement in the longitudinal and vertical direction and pitch axis between patients treated with and without a vacuum cushion. Intra-fraction movement of  $\geq 2$ mm (employed PTV margin) was less frequent in patients treated with a vacuum cushion (Figure 1). In patients treated with a vacuum cushion no significant differences in movement were observed in painful patients versus patients without pain (Table 1).

Table 1: Mean absolute translational and rotational displacements during SBRT measured without vacuum cushion (68 fractions) and with vacuum cushion (56 fractions) in patients with and without pain

	Displacements with and without vacuum cushion			Displacements in patients with and without pain**		
	Without cushion (mean±SD, n=68)	With cushion (mean±SD, n=56)	p-value*	Pain (mean±SD, n=37)	No pain (mean±SD, n=19)	p-value*
Lateral	1.6 ± 1.7 mm	1.0 ± 1.1 mm	0.003	1.2 ± 1.1 mm	0.8 ± 0.9 mm	0.775
Longitudinal	1.9 ± 1.3 mm	0.8 ± 1.0 mm	0.000	0.8 ± 1.1 mm	0.7 ± 0.7 mm	0.821
Vertical	1.6 ± 1.1 mm	0.5 ± 0.5 mm	0.000	0.4 ± 0.3 mm	0.8 ± 0.7 mm	0.122
Pitch axis	0.6 ± 0.6°	0.3 ± 0.4°	0.000	0.2 ± 0.4°	0.3 ± 0.3°	0.965
Roll axis	0.6 ± 0.6°	0.6 ± 0.5°	0.842	0.6 ± 0.5°	0.6 ± 0.6°	0.702
Yaw axis	0.5 ± 0.5°	0.4 ± 0.5°	0.010	0.3 ± 0.3°	0.5 ± 0.6°	0.054

\*Mann-Whitney test \*\*treated with vacuum cushion

Figure 1: Intra-fraction motion with and without vacuum cushion

#### Conclusion

The use of a vacuum cushion resulted in a clinically relevant decrease of intra-fraction movement in multiple directions during SBRT, which results in a more accurate

dose delivery. In these patients, pain did not influence movement during radiotherapy.

#### EP-1621 Intrafraction errors in cranial radiotherapy with standard VMAT mask: implications for SRS/SRT.

F. Azoury<sup>1</sup>, D. Nasr<sup>1</sup>, C. El Khoury<sup>1</sup>, N. Khater<sup>1</sup>, J. Barouky<sup>1</sup>, R. Sayah<sup>1</sup>, N. Farah<sup>1</sup>, S. Achkar<sup>1</sup>, E. Nasr<sup>1</sup>  
<sup>1</sup>Hotel Dieu de France Hospital - Saint Joseph University, Radiation Oncology, Beirut, Lebanon

#### Purpose or Objective

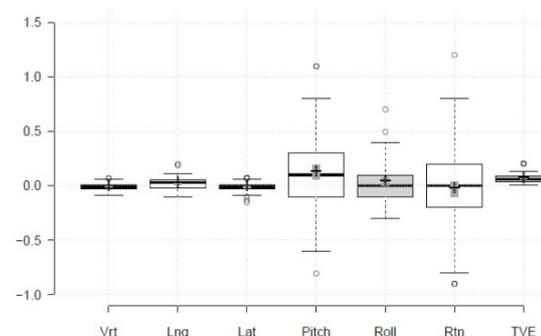

Frameless SRS/SRT for intracranial tumors enhances patient comfort. Reproducibility of setup is assured by systematic CBCT with 6D couch correction before treatment delivery; however concerns of intrafraction motion that could limit the use of frameless reinforced VMAT masks in SRS/SRT still remain. Here we study the magnitude of errors in rotations and translations when using standard reinforced VMAT thermoplastic masks.

#### Material and Methods

We analyzed 100 fractions of patients who underwent cranial VMAT on TrueBeam with Perfect Pitch 6DoF couch (Varian Medical Systems). The patients were immobilized with reinforced IMRT Masks (CIVCO) and standard neck support. For patients requiring additional support to the neck personalized Accuform cushions (CIVCO) were used. Initial repositioning using CBCT before every fraction and 6DoF corrections was performed. Post-treatment CBCT repositioning was also performed to assess intra-fractional motion. Positional errors in all six directions were compiled in addition to 3D total vector errors (TVE).

#### Results

	Vrt	Lng	Lat	Pitch	Roll	Rtn	TVE
Upper whisker	0.06	0.11	0.06	0.80	0.40	0.80	0.13
3rd quartile	0.01	0.05	0.01	0.30	0.10	0.20	0.09
Median	-0.01	0.03	-0.01	0.10	0.00	0.00	0.06
1st quartile	-0.03	-0.02	-0.03	-0.10	-0.10	-0.20	0.04
Lower whisker	-0.09	-0.10	-0.09	-0.60	-0.30	-0.80	0.01
Mean	-0.01	0.02	-0.01	0.13	0.04	-0.03	0.07

Intrafraction translation errors (cm) for the vertical, cranio-caudal and lateral directions were:  $0.01 \pm 0.03$ ,  $0.02 \pm 0.05$  and  $-0.01 \pm 0.04$  respectively (Mean±SD). 3D TVE was  $0.07 \pm 0.04$  (Mean±SD). Intrafraction rotational errors for pitch, roll and rotation were  $0.13^\circ \pm 0.33^\circ$ ,  $0.04^\circ \pm 0.18^\circ$  and  $-0.03^\circ \pm 0.35^\circ$  respectively (Mean±SD) (Table.1). Boxplots presented in Figure.1 show a small variability of the TVE with a range of errors when we eliminate outliers of 0.12cm; however 92% of the cases were within 0.1cm deviation.

#### Conclusion

The use of personalized single layer masks with custom made Accuform cushions produces stable positioning for use on TrueBeam with Perfect Pitch platforms. Intrafraction motion showed a mean TVE of  $0.07 \pm 0.04$ cm. These results suggest that a PTV margin of 0.1cm for SRS cases and 0.2cm for SRT cases is justified to mitigate

intrafraction errors.

#### EP-1622 Intra-fractional isocenter position analysis and dose evaluation of DIBH using surface guided RT

L. Berg<sup>1</sup>, M. Kügele<sup>1,2</sup>, A. Edvardsson<sup>2</sup>, S. Alkner<sup>1</sup>, C. Andersson-Ljus<sup>1</sup>, S. Ceberg<sup>1</sup>

<sup>1</sup>Skåne University Hospital, Department of hematology oncology and radiation physics, Lund, Sweden

<sup>2</sup>Lund University, Medical Radiation Physics - Department of Clinical Sciences, Lund, Sweden

#### Purpose or Objective

The use of surface-guided radiotherapy (SGRT) for deep inspiration breath hold (DIBH) was investigated. Cardiac and pulmonary dose-volume indices were compared during free breathing (FB) and DIBH for left-sided breast cancer patients. In this study, we calculated intra-fractional isocenter shifts based on surface scanning for the first time to investigate potential breathing variations during beam delivery for the individual patient.

#### Material and Methods

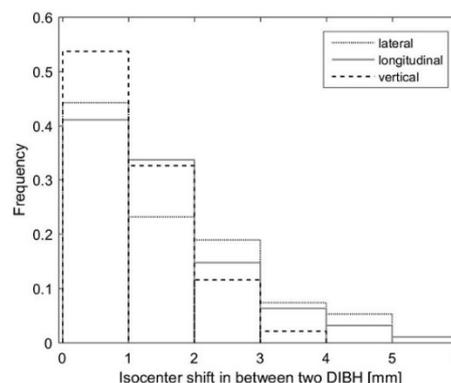

Twenty patients treated with tangential technique, SGRT and DIBH were included. They underwent two computed tomography (CT) scans; one during FB and one during DIBH, which enabled a dose planning study evaluating possible dose sparing with SGRT and DIBH. Target volumes and risk organs were contoured by the same physician in both scans. Individual treatment plans were created and dose-volume indices for the heart, the left anterior descending artery (LAD) and the ipsilateral lung were evaluated.

The optical scanning (OS) systems Sentinel and Catalyst HD (C-RAD positioning AB, Sweden) were used at CT and treatment, respectively. At CT the breathing motion was monitored using an optical tracking point on the skin above the xiphoid process. The size of the gating window was 3 mm and the amplitude of the breath hold was individual for each patient. At treatment the OS system was used for both patient positioning and DIBH delivery. The irradiation was controlled using the tracking point and with the same amplitude and gating window determined during the CT session.

Retrospectively, the coordinates of the calculated isocenter according to the OS system during beam-on was used to investigate intra-fractional motion in between the two separate DIBHs during beam delivery of the two tangential fields. The difference in isocenter position was evaluated for 190 DIBHs from randomly selected treatment fractions.

#### Results

The mean DIBH amplitude was  $10.5 \pm 2.8$  (1 SD) mm. The mean dose for the heart was reduced from  $1.5 \pm 0.8$  Gy for FB to  $0.8 \pm 0.3$  Gy for DIBH, and for the lung from  $5.9 \pm 1.4$  Gy for FB to  $5.5 \pm 1.5$  Gy for DIBH. Dose sparing was also seen for LAD where the mean dose was  $9.6 \pm 7.0$  Gy for FB and  $3.8 \pm 2.9$  Gy for DIBH. The maximum doses, represented as  $D_{2\%}$ , were reduced from  $14.4 \pm 15.2$  Gy for FB to  $3.6 \pm 2.7$  Gy for DIBH and from  $29.0 \pm 18.9$  Gy for FB to  $10.8 \pm 12.3$  Gy for DIBH for the heart and LAD, respectively. The intra-fractional motion of the isocenter between two DIBHs was small and the median values were 1.3 mm, 1.2 mm and 0.9 mm in the lateral, longitudinal and vertical directions, respectively (Figure 1).

**Figure 1.** Histogram of the intra-fractional motion in between two DIBHs. The absolute difference in isocenter position is presented for lateral, longitudinal and vertical direction.

#### Conclusion

For the first time, optical surface scanning was used to evaluate isocenter motion during irradiation. The median intra-fraction motion of the isocenter in the breast during beam-on was less than 1.3 mm in all directions, using a tracking point above xiphoid process and a 3 mm gating window. It was shown, within this study, that the use of SGRT during DIBH for left-sided breast cancer patients results in decreased doses to organs at risk.

#### Purpose or Objective

Stereotactic Body Radiation Therapy (SBRT) requires accurate positioning of the target volume during treatment delivery. In this work we present our initial clinical experience and achieved dosimetric accuracy using an in-house developed position monitoring system, SeedTracker, for prostate SBRT.

#### Material and Methods

A software tool, SeedTracker, was developed in-house to perform real time position verification of prostate markers

during SBRT. SeedTracker, in conjunction with the Elekta XVI system, reads the monoscopic images acquired during treatment and calculates the position of the prostate by auto segmenting the radiopaque markers implanted in it. The accurate performance of the SeedTracker was validated using static and dynamic studies utilising the phantoms implanted with gold seeds. The system also has variable angle stereo image reconstruction functionality for the rapid determination of 3D offsets and position correction of patients in the situations where intrafraction motion is observed during treatment. SeedTracker was utilized for real time monitoring of prostate position for patients undergoing stereotactic boost treatment within the PROMETHEUS trial (UTN: U1111-1167-2997) in Sydney South West Local Health District, Australia. The necessary ethical and legal approvals were obtained from the local health district Human Research Ethics Committee Research Governance Office and Therapeutic Goods Administration, Department of Health, Australian Government before its clinical implementation. The dosimetric accuracy achieved by the utilization of SeedTracker was studied by incorporating the observed position offsets in the planned dose.

### Results

The performance evaluation study of SeedTracker showed that the system demonstrated a minimum True Positive Rate of 88% in studied static and dynamic scenarios with mean ( $\sigma$ ) difference of 0.2(0.5) mm in calculated position accuracy. At the time of writing this abstract SeedTracker had been utilized for the real time position monitoring of twenty six patients' SBRT treatment (consisting of twenty two treatment sessions). Eleven occurrences of position deviations outside the acceptable tolerance limits (3mm) were observed that led to treatment interruption and position correction of the patient. The retrospective dose reconstruction study showed that the V98 to prostate would have decreased by a maximum 20% compared to the planned V98 if real time position monitoring had not been performed and position corrections were not undertaken. The stereo image based position correction available in SeedTracker was shown to be minimum 2 mins faster than the conventional orthogonal image based approach.

### Conclusion

The SeedTracker system has been shown to enable the accurate real time position monitoring and position corrections during prostate SBRT. The occurrence of real position deviations during dose delivery was identified by the SeedTracker leading to improved accuracy of dose delivery to the prostate.

### EP-1624 Respiratory gating of an Elekta linac using a Microsoft Kinect v2 system

D. Edmunds<sup>1</sup>, K. Tang<sup>2</sup>, R. Symonds-Taylor<sup>3</sup>, E. Donovan<sup>1</sup>

<sup>1</sup>The Royal Marsden NHS Foundation Trust, Physics, Sutton, United Kingdom

<sup>2</sup>University of Surrey, Physics, Guildford, United Kingdom

<sup>3</sup>Institute of Cancer Research, Physics, Sutton, United Kingdom

### Purpose or Objective

To investigate whether it is possible to gate radiation delivery from an Elekta linac, using a commercial off-the-shelf (COTS) depth sensor, based on data acquired from patients in a clinical study. The goal of this work is to achieve real time breath-hold monitoring and gating for voluntary breath-hold (VBH) treatments for breast cancer patients.

### Material and Methods

Six participants from the UK HeartSpare trial who had received left breast radiotherapy while performing VBH were recruited for this study. The patients were set up on an Elekta Synergy in a radiotherapy treatment room

exactly as in their original treatment. They then performed a sequence of 3 breath holds for a period of approximately 20 seconds each, during a simulated whole breast treatment with both lateral and medial beams, plus a VMAT delivery. A Microsoft Kinect Version 2 (Kinect v2) commodity depth sensor was used to record breathing traces during this time.

These breathing traces were then used as input to a programmable motion platform carrying a solid water phantom placed on the treatment couch, which was monitored with a Kinect v2. In-house C++ software (see Fig. 1) was used to set a gating threshold, and when the phantom moved outside of this threshold, radiation delivery was paused via signals sent through a fibre optic connection to the linac's gating interface. Radiation dose was verified using a calibrated ionisation chamber and electrometer, with the chamber positioned inside the phantom. A dose measurement was performed for a 200 MU radiation delivery, both with and without gating in place.

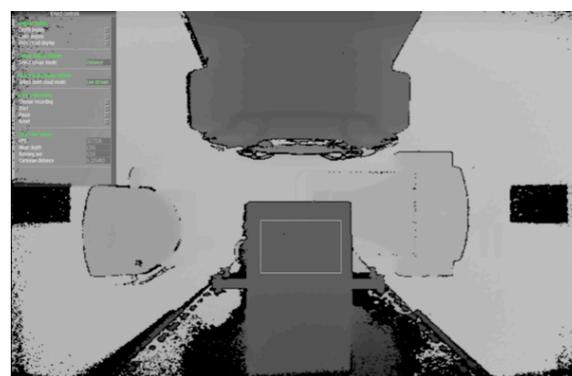

Figure 1: Screenshot of in-house C++ Kinect v2 software, showing a depth image from the camera. The solid water phantom and linac head can be seen in the centre of the image. A region of interest (ROI) is drawn as a white rectangle, and the mean distance of pixels in the ROI is calculated at 60 Hz. Gating threshold can be set with software controls (top left), and a control signal is transmitted to the linac gating interface via fibre-optic cables.

### Results

Kinect v2 was able to acquire all breath holds from each patient successfully. Extracted traces from each patient depth file were sent to the motion platform. In the gating experiments (see Fig. 2), a Kinect v2 was able to track the phantom motion with a root mean square error of between 0.6 mm and 1.3 mm. The latency of our in-house gating software was found to range between 30 and 100 ms. In all cases, the gated radiation delivery dose agreed with the baseline dose measurement without gating to better than 0.4%.

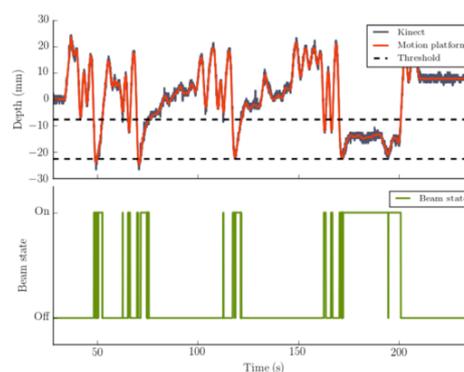

Figure 2: Top: A patient breathing trace programmed into the motion platform, monitored for gating by a Kinect v2 . Bottom: corresponding beam state transmitted to linac.

#### Conclusion

The Kinect v2 provides a cost-effective method of monitoring patients during VBH, and gating the delivery of radiation to only the peak inhale phase. This is a markerless, convenient alternative to manual monitoring.

#### EP-1625 Comprehensive prospective evaluation tool for treatments of thoracic tumours with scanned protons

C. Ribeiro<sup>1</sup>, A. Meijers<sup>1</sup>, G. Janssens<sup>2</sup>, J. Widder<sup>1</sup>, J. Langendijk<sup>1</sup>, E. Korevaar<sup>1</sup>, A. Knopf<sup>1</sup>

<sup>1</sup>University Medical Center Groningen UMCG, Department of Radiation Oncology, Groningen, The Netherlands

<sup>2</sup>Ion Beam Applications IBA, Advanced Technology Group, Louvain-la-Neuve, Belgium

#### Purpose or Objective

Due to the high sensitivity of Pencil Beam Scanning (PBS) to water equivalent thickness (WET) variations, differences between the planned and delivered dose to the CTV (robustness) are of great concern, especially for the treatment of moving targets located in the thorax. Effects that influence the robustness of plans created for patients with moving targets are: machine uncertainties, setup and range errors and the interplay effect, which occurs due to the interference of the time structure of treatment delivery and target motion. The aim of this study is the development and application of a tool that realistically evaluates PBS deliveries to patients with moving targets prior to the actual treatment.

#### Material and Methods

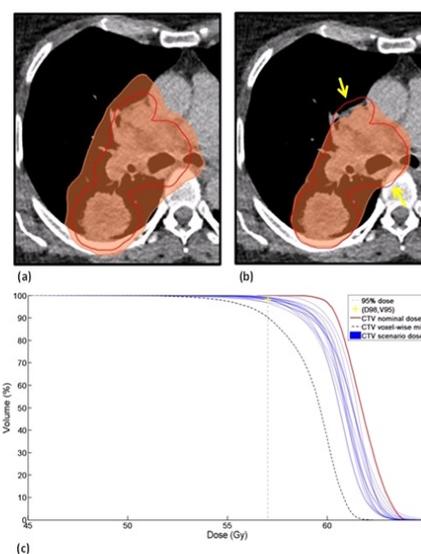

A robustly optimized plan with a nominal dose of 60 Gy to the CTV was created using our treatment planning system for an exemplary lung cancer patient (non-small cell lung cancer (NSCLC) stage III). We considered the delivery of this nominal plan over 8 fractions, which has been shown representative for the clinical delivery over 30 fractions. Our tool simulates (1) machine uncertainties (spot position, dose, and energy errors), (2) setup and range errors (by shifting the patient and 3% scaling the CT intensity values in order to create 14 scenarios representing 14 possible treatment courses), (3) breathing motion (by performing 4D dose accumulation in the planning 4DCT and in repeated 4DCTs), (4) interplay effect (incorporating the time structure of delivery by splitting the nominal plan in 10 different sub-plans with the help of the scanning control system ScanAlgo), and (5) a combination of all previously mentioned effects (1)-(4). To evaluate robustness, the V95 of the CTV was analysed. In case of presence of multiple scenarios ((2) and (5)) the V95 of the voxel-wise minimum dose distribution of the CTV (minimum dose obtained from all the scenarios in each voxel of this structure) was determined.

#### Results

V95 values for the simulation scenarios (1)-(5) are present in Table 1. The V95 for the CTV dropped from 100% (nominal case) to 90.11% when all effects were considered in combination (simulation (5)). Figure 1 shows dose distributions of the nominal plan and the voxel-wise minimum obtained for simulation (5). Furthermore, DVH curves of the nominal plan, all treatment scenarios resulting from the realistic combination of effects and the corresponding voxel-wise minimum dose are shown.

**Table 1** - V95 values for the simulation of all disturbing effects (individually and combined) in a PBS treatment of an exemplary lung cancer patient. For the nominal plan and effect simulations (1), (3) and (4), the V95 value corresponding to a single treatment scenario is shown. For the simulations where 14 treatment scenarios are obtained (effects (2) and (5)), the V95 of the voxel-wise minimum dose is given.

PBS effect	V95 (voxel-wise minimum) [%]
Nominal plan	100
Machine uncertainties (1)	100
Setup and range errors (2)	97,43
Breathing motion (3)	99,97
Interplay effect (4)	99,56
Combination (5)	90,11

**Figure 1** - Dose distributions for (a) the nominal plan and (b) the impact of all disturbing effects of a PBS delivery to a moving target (simulation (5)). In red is the delineated CTV and in orange the 95% dose coverage is shown. The yellow arrows point towards the areas of underdosage of the CTV. In (c) CTV DVH curves for the nominal plan and for all scenarios and the voxel-wise minimum dose obtained after simulation (5) are shown.

#### Conclusion

We developed a realistic and comprehensive tool for a prospective robustness analysis of PBS treatment plans for patients with moving targets. The power of this tool was demonstrated in one exemplary lung cancer patient, showing the significant impact of the combination of PBS delivery effects for target coverage. In clinical practice this tool will help to make decisions concerning the necessity to employ further motion mitigation techniques.

#### EP-1626 Predicting motion of normal tissue using incomplete real-time data during lung radiotherapy.

L.S.H. Bendall<sup>1</sup>, M. Partridge<sup>1</sup>, M.A. Hawkins<sup>1</sup>, J. Fenwick<sup>2</sup>

<sup>1</sup>CRUK MRC Oxford Institute for Radiation Oncology, Department of Oncology- University of Oxford, Oxford, United Kingdom

<sup>2</sup>University of Liverpool, Institute of Translational Medicine, Liverpool, United Kingdom

#### Purpose or Objective

Imaging during radiotherapy treatment has the potential to increase the accuracy and precision of radiotherapy. MR-linacs can produce high quality images during treatment delivery. However, for image acquisition and analysis to be performed in real-time, fast registration techniques based on incomplete data is required. Target motion in lung radiotherapy has been extensively investigated but motion of surrounding organs at risk (OARs) remain relatively uncharacterised. Consequences of irradiating nearby OARs to high doses can be fatal. We have investigated the bronchial tree with the aim of characterising the motion of the whole structure

throughout the respiratory cycle on the basis of an imaged subspace.

#### Material and Methods

4DCT pre-treatment scans of ten NSCLC patients were used to assess the motion of the bronchial tree in order to determine the minimum set of transformations necessary to describe the motion across the respiratory cycle. The bifurcation points (BPs) of the main airways were initially used to characterise the respiratory motion and determine the minimum number of BPs required to be monitored to accurately infer the position of all BPs.

The accuracy of using the transformations resulting from the BP investigation to account for the respiratory motion of the airway sub-structures between the BPs was assessed using the Dice similarity index, maximum Hausdorff distance and the percentage of data points within the structure that are within 0.2/0.5 cm from the baseline structure. Further investigation into the optimal transformation required to minimise the mis-registration of the airway sub-structures throughout the respiratory cycle was performed including aligning the centre of mass of subsections of airways between the BPs.

#### Results

It was found that when the BPs were regionally paired and a single transformation applied to both BPs, the mis-registration errors were reduced from 2.19 to 0.18 cm, suggesting small differential motion between regionally paired BPs. This may also indicate that the transform may reduce the mis-registration of the airway sub-structures between the BPs.

The BP transformations did not always improve the registration of the airway sub-structure in terms of maximum Hausdorff distance. The optimal method found to minimise the maximum Hausdorff distance was by aligning the centre of mass of the sub-structures.

Registration technique	Dice similarity index	Max. Hausdorff distance (cm)	Percentage of points within 0.2 cm	Percentage of points within 0.5 cm
Baseline (no registration)	0.33 - 0.59	0.62 - 1.14	51.3 - 94.7	84.2 - 99.6
BP transformations applied to sub-structures	0.47 - 0.64	0.73 - 0.83	73.8 - 81.4	96.8 - 98.3
Centre of mass of sub-structures aligned	0.54 - 0.58	0.50 - 0.56	85.6 - 89.9	99.8 - 99.9

Table 1 Range of results from registration techniques.

#### Conclusion

Affine transformations have successfully been used to align paired bifurcation points within the bronchus to within 0.18 cm. This demonstrates that it is possible to describe the motion of all the BPs on the basis of a spatial subset of data. Similarly, improvements in the registration of the airway structure has also been achieved, reducing the maximum Hausdorff distance from 1.14 cm to 0.56 cm by using a small subset of information - the centre of mass of sub-structures - at different phases of the respiratory cycle.

#### EP-1627 Anatomical advantages of deep inspiration breath hold for breast radiotherapy: a geometric analysis

L. Conroy<sup>1</sup>, E. Watt<sup>1</sup>, S. Quirk<sup>2</sup>, J.L. Conway<sup>2</sup>, I.A. Olivotto<sup>2</sup>, T. Phan<sup>3</sup>, W.L. Smith<sup>2</sup>

<sup>1</sup>University of Calgary, Department of Physics & Astronomy, Calgary- Alberta, Canada

<sup>2</sup>University of Calgary, Department of Oncology, Calgary- Alberta, Canada

<sup>3</sup>Tom Baker Cancer Centre, Department of Radiation Oncology, Calgary- Alberta, Canada

#### Purpose or Objective

Numerous studies have proven the dosimetric benefits of deep inspiration breath hold (DIBH) for cardiac sparing in left breast radiotherapy; however, the anatomical advantages of this maneuver remain largely uncharacterized on a population basis. We examine the motion of the heart with respect to the target breast and

chest wall (CW) between end-exhalation and DIBH from a tangent *beam's-eye-view* (BEV) perspective.

#### Material and Methods

Two computed tomography scans were acquired for 10 consecutive left-sided breast cancer patients: a DIBH scan and an end-exhalation breath hold (EEBH) scan. Breast and CW were contoured on the DIBH scan according to RTOG consensus guidelines. The heart was contoured on the DIBH scan using a validated heart atlas. Contours were propagated to the EEBH scan using the MIM Maestro™ Adaptive Recontour Workflow and edited where necessary. For all DIBH and EEBH scans, an in-house MATLAB program was used to measure the separation between the heart and CW at an angle approximately perpendicular to the BEV of the medial tangent beam on each axial slice. This is the estimated location of the heart that is at greatest risk of entering the tangent beam. Breath hold amplitudes were measured as the AP distance between DIBH and EEBH body contours at the mid-line/nipple-line intersection.

#### Results

DIBH causes the CW to move superiorly/anteriorly and the heart to move inferiorly/posteriorly. This relative motion facilitates coverage of the whole breast with tangents while sparing the heart (Figure 1). The median (range) breath hold amplitudes (difference between EEBH and DIBH) was 1.3(0.7-2.1) cm in the anterior direction, and the superior border (base) of the heart shifted 1.0(0.2-2.2) cm inferiorly. The relative motion of the CW with respect to the heart in DIBH reduced the amount of heart that would be at risk of entering the tangent field by 1.5(0.6-3.8) cm (Figure 1b). The median maximum increase in heart-CW separation was 1.9(1.2-2.4) cm, at a location 4.8(1.6-6.2) cm inferior to the end-exhale heart base position (Figure 2, colored circles).

#### Conclusion

In contrast to dosimetric evaluations, results from population-based geometric analyses can be applied to a range of breast treatment strategies (e.g., partial breast irradiation, modified wide-tangents). This study provides evidence towards predicting the potential benefit of using DIBH from a free-breathing scan, and can be used to inform treatment planning strategies robust to inter- and intra-fraction motion of DIBH treatments.

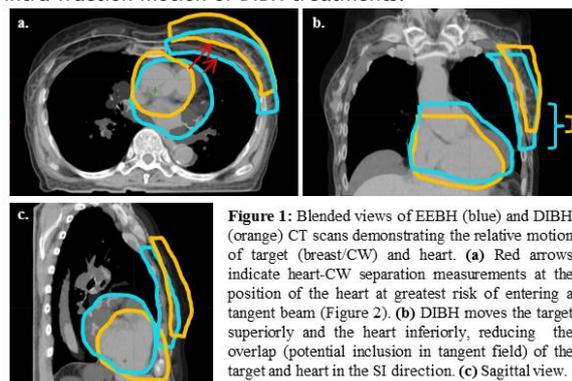

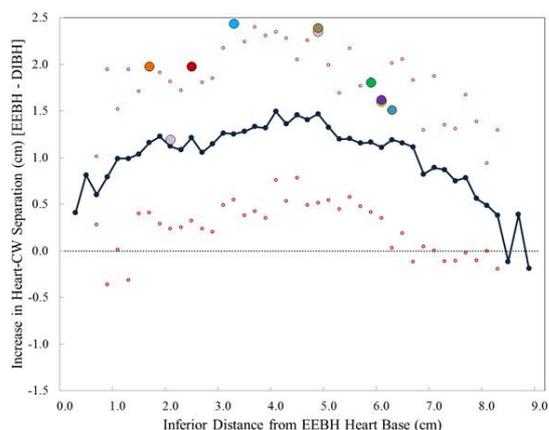

Figure 1: Blended views of EEBH (blue) and DIBH (orange) CT scans demonstrating the relative motion of target (breast/CW) and heart. (a) Red arrows indicate heart-CW separation measurements at the position of the heart at greatest risk of entering a tangent beam (Figure 2). (b) DIBH moves the target superiorly and the heart inferiorly, reducing the overlap (potential inclusion in tangent field) of the target and heart in the SI direction. (c) Sagittal view.

**Figure 2:** Dark blue line shows average increase in the measured heart-CW separation in DIBH compared to EEBH on the same axial CT slice (i.e., difference in length of red arrows in Figure 1(a)). Red dots show minimum and maximum increase in separation over all patients on each axial slice. Coloured circles show the location and magnitude of maximum heart-CW separation for each individual patient (n=10).

### EP-1628 Analysis of prostate SBRT treatments using 3D transperineal ultrasound image guidance methods

M. Szegegi<sup>1</sup>, C. Boehm<sup>1</sup>, B. Ager<sup>1</sup>, V. Sarkar<sup>1</sup>, P. Rassiah-Szegegi<sup>1</sup>, H. Zhao<sup>1</sup>, L. Huang<sup>1</sup>, J. Huang<sup>1</sup>, A. Paxton<sup>1</sup>, F. Su<sup>1</sup>, J. Tward<sup>1</sup>, B. Salter<sup>1</sup>

<sup>1</sup>University of Utah Huntsman Cancer Hospital, Radiation Oncology, Salt Lake City, USA

#### Purpose or Objective

A 2nd generation 3D ultrasound image guidance (USIG) system (Clarity, Elekta Inc), that allows for transperineal (TP) localization and intra-fractional tracking of the prostate has been used in SBRT of the prostate at our institution. We have analyzed 35 patients (175 fractions) regarding the localization and tracking performance of our USIG based prostate SBRT protocol.

#### Material and Methods

Our clinical workflow for prostate SBRT (5 fractions of 7.25 Gy each) involves setting the patient up based on skin tattoos and using TP localization for image guidance. A trans-abdominal (TA) ultrasound study (BAT, Nomos Inc) is also performed to independently check the patient's position once TP-USIG-based shifts are applied. A detailed description of our workflow has been presented before [1].

Once the TP-based alignment has been approved by both a physicist and physician with extensive USIG experience, TP-based tracking is initiated. During the treatment, the beam is manually switched off for any migrations greater than 3 mm in any direction. If this migration occurs for more than 5 seconds, the patient's position is re-adjusted before treatment resumption.

For all 175 treatments in the present cohort, the tracking data was analyzed to determine the number of incidents and duration the target's excursion was greater than 3 mm. Further we evaluate the potential for partial PTV miss, by subtracting couch movement from target movement shown in Figure 1, showing the potential excursion if no corrective action was taken and contrast this with the PTV margins used.

**Results**  
Figure 2 shows the number of instances where the position of a patient had to be corrected. Only 10 of the 35 patients did not require any corrective action. In two patients (cases 29 and 32), the position had to be corrected more than 20 times over the five fractions.

#### Conclusion

With more than 70% of the patients analyzed requiring repositioning, it is clear that intra-fractional tracking should be used when treating with a hypo-fractionated approach, where large excursions should be avoided.

Lastly we will present the early follow up data (average follow up 1.5 years) of rate and type of complications observed and contrast it to our non-tracked SBRT population. This will indicate if SBRT tracking does prevent over-radiation of sensitive structures.  
**References:** [1] Salter BJ et al., 3D Transperineal Ultrasound Image Guidance Methods for Prostate SBRT Radiotherapy Treatment, Radiotherapy and Oncology, 115, S460.

Figure 1: Example of the tracking of one patient in one dimension and the subtraction of table movement. Figure 2: Number of events a corrective positional shift was required during treatment per patient. Each blue dot represents one of the 35 patients. Only 10 patients did not require a corrective action to bring the PTV within tolerance levels (3mm or less).

### EP-1629 Lung tumor tracking using CBCT-based respiratory motion models driven by external surrogates

A. Fassi<sup>1</sup>, A. Bombardieri<sup>1</sup>, G.B. Ivaldi<sup>2</sup>, M. Liotta<sup>3</sup>, P. Tabarelli de Fatis<sup>3</sup>, I. Meaglia<sup>2</sup>, P. Porcu<sup>2</sup>, M. Riboldi<sup>1</sup>, G. Baroni<sup>1</sup>

<sup>1</sup>Politecnico di Milano, Dipartimento di Elettronica Informazione e Bioingegneria, Milano, Italy

<sup>2</sup>Istituti Clinici Scientifici Maugeri, Radiation Oncology Department, Pavia, Italy

<sup>3</sup>Istituti Clinici Scientifici Maugeri, Medical Physics Division, Pavia, Italy

#### Purpose or Objective

The aim was to investigate the use of time-resolved (4D) Cone-Beam CT (CBCT) to build a patient-specific respiratory motion model driven by a surface-based breathing surrogate. The proposed approach was applied for the real-time intra-fraction tracking of lung tumors.

#### Material and Methods

The study included two lung cancer patients treated with stereotactic body radiotherapy. Two CBCT scans, acquired at the beginning and at the end of the first treatment fraction, were analyzed for each patient. Seven passive markers were positioned on anatomical landmarks of the patients' thoraco-abdominal surface. Markers 3D coordinates were continuously acquired during all CBCT scans through an optical tracking system (SMART-DX 100, BTS Bioengineering), synchronized with the acquisition of CBCT projections. A breathing surrogate was obtained from the trajectory of all surface markers. The external surrogate was used to reconstruct the 4D CBCT using the motion-compensated algorithm [1]. A deformable respiratory motion model [2] was built from the 4D CBCT of the first scan. The breathing phase and amplitude given as input to the motion model were estimated from the external surrogate. The accuracy of the proposed tracking approach was evaluated on both the first and the second CBCT scan, after compensating for baseline shifts. Tumor positions estimated in 3D with the motion model were projected at the corresponding angle and compared to the real tumor trajectory semi-automatically identified on CBCT projections.

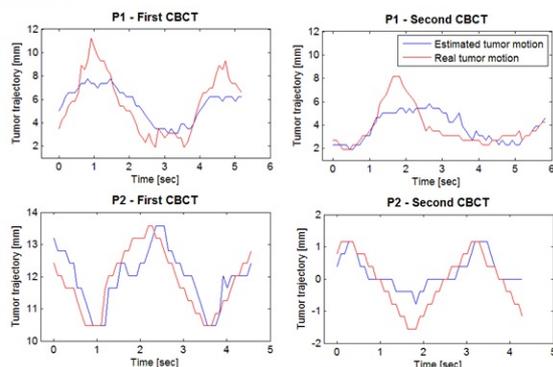

[1] Rit S et al, Med Phys 2009;36:2283-96.

[2] Fassi A et al, Phys Med Biol 2015;60:1565-82.

**Table 1.** Absolute tracking errors (mean ± 1SD) between tumor trajectories estimated from the CBCT-based motion model and real tumor motion identified on CBCT projections along the horizontal and vertical image dimensions.

Patient	Horizontal tracking error [mm]		Vertical tracking error [mm]	
	First CBCT	Second CBCT	First CBCT	Second CBCT
P1	1.7 ± 1.2	0.8 ± 0.5	1.3 ± 0.9	0.9 ± 0.8
P2	0.8 ± 0.4	0.5 ± 0.4	0.5 ± 0.3	0.4 ± 0.3

**Figure 1.** Comparison between real and estimated tumor trajectories along vertical image dimension.

**Results**

Tumor visibility on CBCT images was limited to a small range of projection angles, corresponding to about 5 seconds of each CBCT scan. Table 1 reports the tracking errors measured along the vertical image dimension, i.e. the projection of the superior-inferior tumor motion, and along the horizontal image dimension, combining antero-posterior and medio-lateral tumor motion. The absolute tracking error, averaged over all CBCT scans of all patients, measured  $1.0 \pm 0.9$  mm and  $0.8 \pm 0.7$  mm for the horizontal and vertical image dimensions, respectively. The comparison of real and estimated tumor trajectories along the vertical dimension is depicted in Figure 1. A significant correlation ( $p$ -value < 0.005) was found between real and estimated tumor motion, with correlation coefficients higher than 0.75 and 0.69 for the horizontal and vertical dimensions, respectively.

**Conclusion**

We developed and tested a novel approach for intra-fraction lung tumors tracking, using CBCT-based motion models driven by an external breathing surrogate obtained from non-invasive optical surface imaging. Compared to CT-based motion models, the proposed method does not need to compensate for inter-fraction motion variations that can occur between planning and treatment phases. The validation of the proposed approach on a wider patient population is currently ongoing.

**EP-1630 The impact of DIBH on dose to the junction in loco-regionally treated left-sided breast patients**

M. Van Hinsberg<sup>1</sup>, I. De Bree<sup>2</sup>, E. Osté<sup>2</sup>, D. De Ronde<sup>2</sup>

<sup>1</sup>Zuidwest Radiotherapeutisch Instituut, Klinische Fysica, Vlissingen, The Netherlands

<sup>2</sup>Zuidwest Radiotherapeutisch Instituut, RTT, Vlissingen, The Netherlands

**Purpose or Objective**

Irradiating loco-regional left sided breast cancer patients using a field matching technique is common practice in clinical routine. Possible under- and overdoses at the junction are normally reduced by the natural breathing of the patient. Adding a (deep inspiration) breathhold strategy introduces extra risks of under- and overdosage in this region.

A modified conventional treatment technique for the irradiation of loco-regional left-sided breast patients combined with a voluntary DIBH technique has been introduced in our institute. The objective of this pilot is

to validate that this technique is safe, robust and well tolerated by the patient.

**Material and Methods**

The standard conventional irradiation technique is adapted to become less sensitive to different intrafractional DIBH levels.

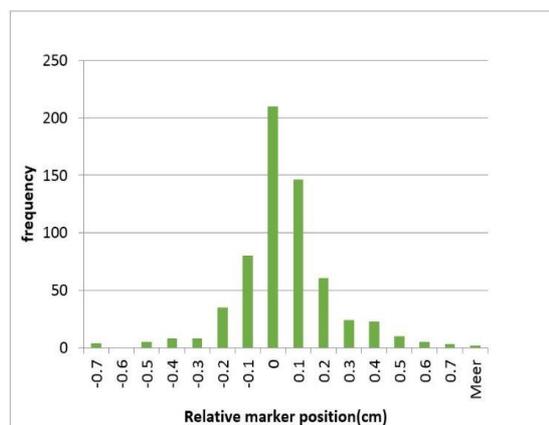

A less steep penumbra at the junction is obtained by creating several subbeams with different MLC-positions. In order to reduce the number of beams, a selection of these beams are grouped to one beam using the Field in Field (FiF) forward IMRT functionality of Varian Eclipse™ TPS. This resulted in treatment plans with 6 to 9 beams.

The study consists of the following steps:

- 1 The field match is validated using film measurements in a phantom.
- 2 Dose distributions and relative movements for 6 patients were assessed in vivo. For this a strip of film (with 6 mm buildup) was placed on the patient skin at the junction. In addition markers were placed on the skin above, on and below the junction, next to the film. Relative movements of the markers in each DIBH were determined using MV-images.
- 3 The relative movements of the marker measured in each DIBH were used to position the beams in the corresponding location in the TPS, resulting in a realistic dose distribution for each fraction and for the total treatment.
- 4 The in-vivo film measurements were used as a validation for the skin dose distribution calculated as explained in 3.

**Results**

The measured relative marker positions of all patients are shown in fig.1.

**Fig. 1** Marker positions relative to the fraction mean. Distribution mean 0.4 mm; sd 2mm; range; -7 to 8 mm. A negative sign means the patient has moved in caudal direction.

Analysing the marker positions of each patient shows no trend between the DIBH level of the first and last beam. No hyperventilating nor exhaustion occurred, indicating that DIBH with 6 to 9 beams is well tolerated.

Planned dose-values and actual, total dose values for the CTU are presented in table 1:

		V95 total	V95 planned	D99 total	D99 planned	dmax any fraction	Dmax total	cc > 107% total	Dmax planned	cc > 107% planned
pat1	borst	90%	84%	83%	81%	113.5%	107.2%	0 cc	107.4%	0 cc
	klier	100%	100%	97%	96%					
pat2	borst	99%	99%	95%	95%	112.9%	107.8%	0 cc	108.3%	0.1 cc
	klier	100%	100%	94%	95%					
pat3	borst+klier	83%	88.4%	62%	63%	113.9%	106.8%	0 cc	107.4%	0 cc
pat4	borst	99.3%	99.3%	95%	95%	123%	107.1%	0 cc	107.7%	0 cc
	klier	95.4%	100%	94%	96%					
pat5	borst	94%	95%	91%	91.4%	108.5%	106.3%	0 cc	106.4%	0 cc
	klier	99%	100%	97%	99%					
pat6	borst	98.9%	98.7%	94%	97.6%	115.5%	110.3%	15cc	108.1%	6cc
	klier	100%	97%	98%	94.6%					

Table 1

The junction in case of pat3 was covered by the 90% isodose (except near the skin). The D99-value shows that this treatment plan was cold compared to the other plans.

#### Conclusion

Measures are needed to prevent the occurrence of extreme hot and cold spots in the junction due to DIBH variation: This modified technique provides a damping effect on the occurrence of dose extremes.

To create an extra buffer against underdosage, D99 of the CTV at the junction should be high enough, eg 95%.

The technique presented is well tolerated by the patient.

#### EP-1631 Reproducibility of DIBH technique guided by an optical system: the florence usl experience

<sup>1</sup>Azienda USL Toscana Centro, Medical Physics Unit, Florence, Italy

<sup>2</sup>Azienda USL Toscana Centro, Radiotherapy Physics Unit, Florence, Italy

#### Purpose or Objective

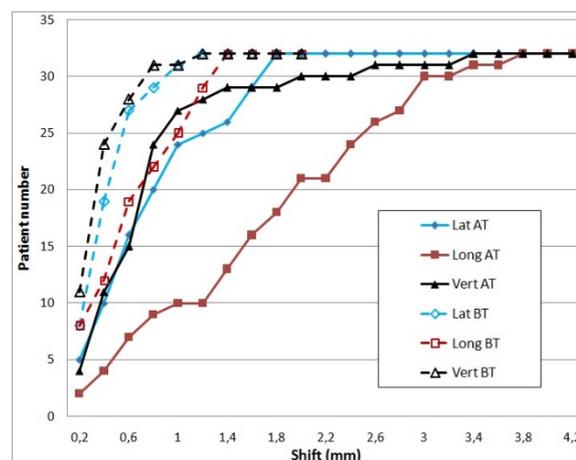

Aim of this work was to evaluate interfraction and intrafraction reproducibility of a deep inspiration breath-hold (DIBH) technique based on optical surface tracking technologies for selected patients undergoing adjuvant RT for left-sided breast cancer.

#### Material and Methods

30 patients that underwent left side adjuvant radiotherapy were included in this study. Prospective gating CT imaging was performed by Sentinel™ (C-RAD Positioning AB, Sweden) laser scanner system and a Siemens BrightSpeed CT scanner. Base line level and gating window amplitude of the respiratory signal was established during CT simulation procedure. Gated treatments delivery was supported by the Catalyst™ system (C-RAD Positioning AB, Sweden) connected with an Elekta Synergy linear accelerator (Elekta AB, Sweden) via the Elekta Response™ Interface. The treatment beam was turned on only when the patient signal is within the previously established gating window. Visual coaching through video goggles were provided to help the patient following the optimal breathing pattern. Treatments were performed in DIBH with 3D conformal tangential beams for 50 Gy median dose to the whole breast in 25 fractions. The reproducibility of the DIBH during treatment was monitored by comparing the reference CT surface with the 3D surfaces captured by Catalyst™ system during BH before and after treatment delivery. Interfraction and intra-fraction variability were quantified in mean and SD displacements in traslation (Lat, Long, Vert) and rotations (Rot, Roll, Pitch) in the isocenter position between the reference and the live surface over all the treatment fractions of the enrolled patients. **Results**

Inter-fraction variability before treatment delivery was extremely reduced: the group mean translational and rotational errors were respectively lower than 0.4 mm and 0.7° in all directions. After treatment delivery the group mean shift was lower than 2 mm in all direction and no difference in rotations was observed.

Intra-fraction variability was <2.1 mm in translations and <1° in rotations. The cumulative distribution of interfraction mean shift during BH before (BT) and after (AT) treatment delivery for the patients undergoing BH treatment is shown in figure. Separate contributions from Lateral, Longitudinal, and Vertical direction were reported.

#### Conclusion

In our experience DIBH procedure guided by optical systems for left breast irradiation is a reproducible and stable technique with a limited inter-fraction and intra-fraction DIBH variability.

#### EP-1632 A motion monitoring and processing system based on computer vision: prototype and proof of principle

N. Leduc<sup>1</sup>, V. Atallah<sup>2</sup>, A. Petit<sup>1</sup>, S. Belhomme<sup>1</sup>, V. Vinh-Hung<sup>3</sup>, P. Sargos<sup>1</sup>

<sup>1</sup>Institut Bergonié, Radiation Oncology, Bordeaux, France

<sup>2</sup>University Hospital of Bordeaux, Radiation Oncology, Bordeaux, France

<sup>3</sup>University Hospital of Martinique, Radiation Oncology, Fort-de-France, France

#### Purpose or Objective

Monitoring and controlling respiratory motion is a challenge for the accuracy and safety of therapeutic irradiation of thoracic tumors. Systems based on the monitoring of internal or external surrogates have been developed but remain costly and high-maintenance. We describe here the development and validation of Madibreast, an in-house-made respiratory monitoring and processing device based on optical tracking of external markers.

#### Material and Methods

We designed an optical apparatus to ensure real-time submillimetric image resolution at 4 m. Using code libraries based on OpenCv, we optically tracked high-contrast markers set on patients' breasts. Validation of spatial and time accuracy was performed on a mechanical phantom and on human breast. A simple graphical interface allowed the user to visualize in real-time the in-room motion of the markers during the session.

#### Results

Madibreast was able to track motion of markers up to a 5 cm/s speed, at a frame rate of 30 fps, with submillimetric accuracy on mechanical phantom and human breasts. Latency remained below 100 ms. Concomitant monitoring of three different locations on the breast showed discrepancies in axial motion up to 4 mm for deep-breathing patterns. Figure 1 displays an example of user

interface.

### Conclusion

This low-cost, computer-vision system for real-time motion monitoring of the irradiation of breast cancer patients showed submillimetric accuracy and acceptable latency. It allowed the authors to highlight differences in surface motion that may be correlated to tumor motion. Madibreat detects and tracks accurately external motion on the breast using low-cost material and accessible open-source, high-level computer vision libraries. It allows immediate monitoring by visually displaying an immediate trace, which can alert that substantial motion could have occurred. Limitations include some remaining failures of the apparatus under low-exposure conditions, as well as considerable CPU occupation.

### EP-1633 Respiratory Motion Analysis using a Surface Guided Radiation Therapy System for Lung SBRT Patients

M. Jermoumi<sup>1</sup>, D. Cao<sup>1</sup>, V. Mehta<sup>1</sup>, D. Shepard<sup>1</sup>

<sup>1</sup>Swedish Cancer Institute, Radiation Oncology, Seattle, USA

#### Purpose or Objective

Surface guided radiation therapy (SGRT) uses a camera/projector pair to create a 3D map of a patient's surface. SGRT can be used to assist in patient set up, real time motion monitoring, and respiratory motion management. In this work, we used SGRT to track the respiratory breathing pattern for lung SBRT patients. An excursion gating approach was employed where the beam delivery was interrupted if the breathing deviated from the expected pattern. The purpose of this work is to evaluate the patients breathing motion during SBRT treatment.

#### Material and Methods

To date, 10 NSCLC patients have been enrolled in this study and treated with stereotactic body radiation therapy (SBRT) using a 12Gyx4 fractionation. Prior to each fraction, each patient was aligned using SGRT. Next, a 4DCBCT scan was acquired to align based on internal anatomy. A virtual respiratory tracking point was then placed close on the patient's surface close to the sternum. The patient's gating window was set based on the end-to-end amplitude measured during the acquisition of the CT at the time of simulation. The gating window was expanded 5 mm beyond the upper level window and 5 mm below the lower level window. In-house developed code was used to evaluate the respiratory data collected from all 40 fractions. The evaluation included an examination of the end-to-end amplitude, the breathing period, and baseline drift. The correlation between baseline drift and the treatment time was assessed over the course of treatment.

#### Results

The mean ( $\pm$  SD) treatment time was 5.3 ( $\pm$  1.34) minutes. The mean ( $\pm$  SD) end-to-end amplitude observed due to inter-fraction and intra-fraction motion were 6.79( $\pm$ 2.51) mm and 6.79( $\pm$ 2.86) mm respectively and the mean ( $\pm$  SD)

breathing period was 4.08( $\pm$ 0.44) s. The coefficient of variance (CV) of the end-to-end amplitude was less than 10% for 50% of the patients and greater than 20 % for 40% of the patients. In 80% of the treatments, the CV of the breathing period was less than 10%. A baseline drift of greater than 2 mm, 3 mm, and 5 mm was observed for 85%, 4%, and 1% of the total treatment times, respectively. The variability (1SD) of baseline drift was within a range of 0.49 to 1.34 mm. The baseline drift versus time showed no correlation ( $r=0.009$ ,  $p=0.24$ ).

#### Conclusion

SGRT provides an excellent tool to track the respiratory signal of lung SBRT patients. The amplitude variability is less than 5 mm which is consistent with other reported studies. These results can be considered as reference data for decision making for subsequent SBRT lung patients.

### EP-1634 Combined 4D and 3D cone beam CT protocol for lung SBRT for reliable and fast position verification

W. Woliner-van der Weg<sup>1</sup>, N. Gelens<sup>2</sup>, V.H.J. Leijser-Kersten<sup>1</sup>, P.M. Braam<sup>1</sup>, J. Bussink<sup>1</sup>, M. Wendling<sup>1</sup>

<sup>1</sup>UMC St Radboud Nijmegen, Radiation Oncology, Nijmegen, The Netherlands

<sup>2</sup>Fontys Paramedische Hogeschool, Medisch Beeldvormende en Radiotherapeutische Technieken MBRT, Eindhoven, The Netherlands

#### Purpose or Objective

In our standard lung SBRT position verification protocol, the use of online 3D or 4D cone beam CT (CBCT) is based on the amplitude of tumor motion as measured on 4D planning CT. This results in about 60% of the patients having 4D CBCT position verification. While 3D CBCT takes only 1 min, 4D CBCT lasts about 4 min. With repetitive imaging, this difference considerably contributes to the time needed for position verification, and the time the patient lies on the treatment couch.

We reconsidered our position verification protocol, to expand the use of 3D CBCT while maintaining reliable position verification for all patients. Therefore, we developed a decision protocol, in which 4D CBCTs of the first treatment fraction are used for further stratification.

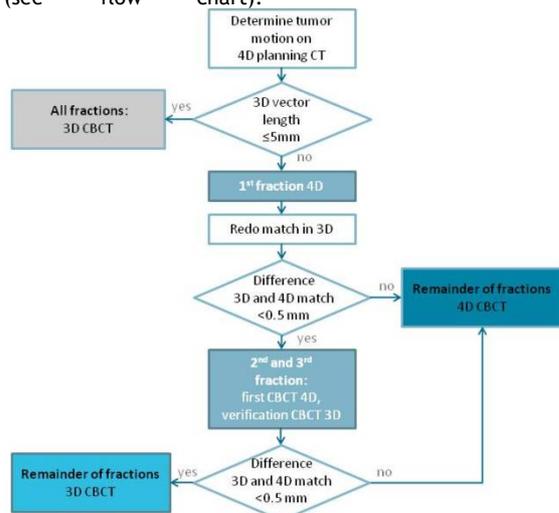

#### Material and Methods

For both 3D and 4D CBCT, the first CBCT has to be within 1 mm in all 3 directions compared to the planning CT, otherwise the positioning error is corrected with the treatment couch and a second CBCT is made for verification. The verification CBCT has to be within 2 mm in all 3 directions, otherwise the procedure is repeated.

Initial selection for 3D or 4D position verification in our department is based on the 3D amplitude of tumor motion measured on 4D planning CT. Patients with a tumor motion vector length >5 mm are positioned based on 4D CBCT.

In the new protocol the choice for 4D CBCT is reconsidered during the treatment course. After the first fraction, the 4D CBCTs are also matched in 3D with the planning CT. Corrections resulting from this match are compared to the corrections resulting from the initial 4D match. If the difference is within 0.5 mm in all 3 directions, for the second and third fraction only the first CBCT is made in 4D, and verification CBCTs are made in 3D. If during the second and third fraction the difference between the 4D and 3D match remain within 0.5 mm in all 3 directions, for the remainder of fractions only 3D online CBCTs are made

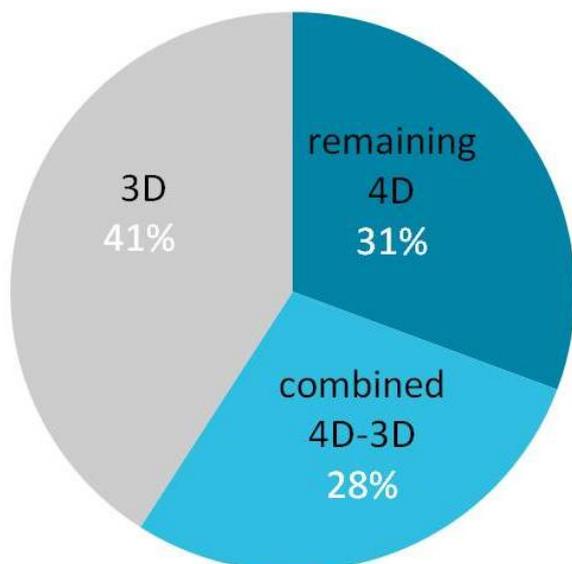

(see flow chart).

We retrospectively applied this protocol to 88 historical treatments (May 2011 - January 2015) performed within our institute to evaluate its effect.

### Results

Of 88 treatments in 86 patients, 36 were initially selected for 3D CBCT in all fractions. From the remaining 52 treatments 25 would have been suitable for 3D CBCT after comparing and combining 4D and 3D CBCT position verification (see pie chart).

### Conclusion

With use of the in-treatment decision protocol for 3D or 4D position verification, the number of patients having 3D CBCT for position verification raised from 41% to 69%. This is not only beneficial for patient comfort, it limits motion related treatment degradation and it also increases treatment capacity. Therefore we propose to use the in-treatment CBCT information and our decision protocol for making optimal use of 3D CBCT.

### EP-1635 Framework for the evaluation of interplay effects between respiratory motion and dose application

A. Von Münchow<sup>1,2</sup>, K. Straub<sup>1</sup>, J. Hofmaier<sup>1,2</sup>, P. Freislederer<sup>1</sup>, M. Reiner<sup>1</sup>, C. Thieke<sup>1</sup>, M. Söhn<sup>1</sup>, M. Alber<sup>3</sup>, R. Floca<sup>4</sup>, C. Belka<sup>1</sup>, K. Parodi<sup>2</sup>, F. Kamp<sup>1</sup>

<sup>1</sup>LMU Munich - Klinikum der Universität München, Department of Radiation Oncology, Munich, Germany

<sup>2</sup>LMU Munich - Faculty of Physics, Department of Medical

Physics, Munich, Germany

<sup>3</sup>Heidelberg University Hospital, Department of Radiation Oncology, Heidelberg, Germany

<sup>4</sup>German Cancer Research Center, Software development for Integrated Diagnostic and Therapy - Department of Radiology, Heidelberg, Germany

### Purpose or Objective

The interplay between respiratory motion of a tumor and dose delivered by complex techniques like IMRT and VMAT can potentially lead to undesirable and non-intuitive deviations from the planned dose distribution. Small field sizes and fluences used in these advanced therapy techniques might amplify the dose deviations. We aim at developing a 4D dose recalculation tool to simulate the dose distribution for a moving target volume more precisely. The impact of interplay effects can be evaluated and compared for different treatment techniques.

### Material and Methods

We developed a workflow combining a Monte Carlo dose calculation and a dose accumulation based on 4DCT images and linac log files. Log data from the linac are retrieved with *Delivery Parameters Log File Converter for Integrity™ R3.2* provided by Elekta. The time information in these log files has a resolution of 0.04 s and is used to divide the original treatment plan into small time intervals correlated to the patient's respiratory phases. All resulting plan fragments (each corresponding to a certain 4DCT phase) are then recalculated using MCverify/Hyperion V2.4 (research version of Elekta MONACO 3.2). As a final step the single doses are sorted and combined to a total dose distribution. Different respiratory cycles, e.g. changes in the breathing frequency or pattern, and treatment methods, e.g. stereotactic treatment or gating, can be simulated and compared for different treatment techniques. The handling and accumulation of the different dose fragments are performed with AVID, a software framework for radiation therapy data processing developed at *Deutsches Krebsforschungszentrum (DKFZ)*. For a first demonstration, implementation and verification, the 4DCT of a *Dynamic Thorax Phantom (CIRS)* is used. A 1D-sinusoidal-rigid-motion with frequency 0.25 Hz and amplitude 2 cm was set.

### Results

A 3D-CRT and an IMRT plan were delivered to the phantom. Fig. 1 shows the resulting DVHs for the GTV using the 3D-CRT and the IMRT plan, respectively. In the plots, two different starting phases are marked ("treatment starting in inhale" and "treatment starting in exhale phase"). The DVHs of the 3D-CRT plan remained unaffected by the respiratory phase shift. Whereas for the IMRT plan (optimized on a dose of 10Gy) the maximal dose changed by 0.27 Gy (2.3%) from 11.95 Gy to 11.68 Gy after the 50% phase shift.

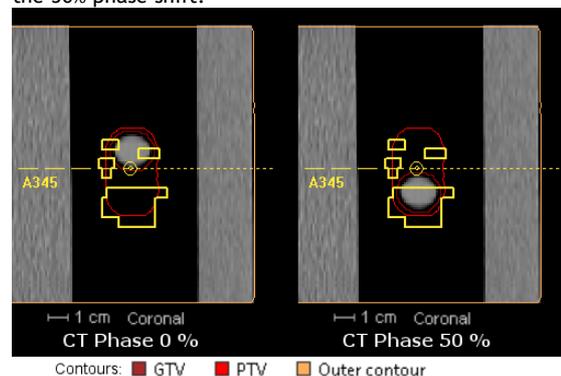

Fig 1: Example for the occurrence of interplay effects: IMRT plan segment on two CT Phases

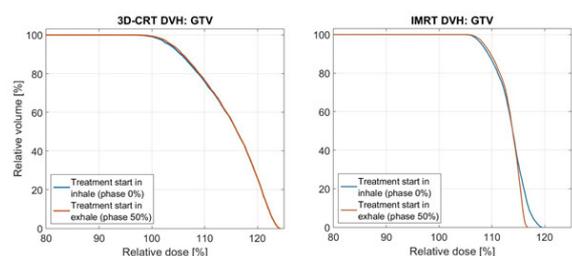

Fig 2: DVHs for the recalculated and accumulated dose distributions. The IMRT plan shows deviations for different initial respiratory phases

#### Conclusion

The presented workflow facilitates the evaluation of time dependencies of the dose application and the impact of interplay effects on the resulting dose delivered to the target volume. In the discussed simplified phantom case, the 3D-CRT plan was more robust in terms of interplay effects than the IMRT plan. The method is going to be applied to real patient data, and first results will be presented.

#### EP-1636 Evaluation of the accuracy in frame-less image-guided radiotherapy and radiosurgery.

M. Iacco<sup>1</sup>, C. Zucchetti<sup>1</sup>, M. Lupattelli<sup>2</sup>, A. Dipilato<sup>1</sup>, C. Aristei<sup>2</sup>, R. Tarducci<sup>1</sup>

<sup>1</sup>Santa Maria della Misericordia Hospital, Medical Physics Department, Perugia, Italy

<sup>2</sup>Santa Maria della Misericordia Hospital, Radiation Oncology Department, Perugia, Italy

#### Purpose or Objective

The study focused on the evaluation of the accuracy of intracranial stereotactic radiosurgery (SRS) and radiotherapy (SRT) treatments, delivered with helical Tomotherapy (HT), by means of mask-based fixation systems.

#### Material and Methods

Firstly, an anthropomorphic phantom was scanned to evaluate the delivery accuracy of the Tomotherapy image guided positioning tool. The megavoltage computed tomography (MVCT), acquired with finest slice thickness (1mm), was automatically registered with the treatment planning CT via the automatic registration algorithm using the "bone and tissue" technique with superfine resolution. After the suggested application of the shifts a second MVCT was acquired and registered with the same procedure. Translational shifts in lateral (IEC-X), longitudinal (IEC-Y) and vertical (IEC-Z) directions and rotations (pitch, roll, yaw), which corresponded to the setup error, were recorded. The same procedure was applied to patients underwent intracranial ipofractionated treatments, for a total of 25 MVCT analyzed. The second MVCT scans, performed at the end of the treatment, were analyzed in order to determine the position accuracy and also to evaluate the intra-fraction motion. Finally, a MVCT post-treatment were also acquired in six patients underwent radiosurgery with HT.

#### Results

Mean setup errors and standard deviations in phantom study were  $0.0 \pm 0.1$  mm,  $0.1 \pm 0.3$  mm,  $0.1 \pm 0.3$  mm, for the IEC-X, IEC-Y, IEC-Z directions and  $0.3 \pm 0.3^\circ$ ,  $0.2 \pm 0.2^\circ$ ,  $0.2 \pm 0.2^\circ$  rotational variations (pitch, roll, yaw), respectively. The mean vector displacement ( $v$ ) was  $0.4 \pm 0.2$  mm. Moreover, the mean rotational variations could be considered negligible. The very low recorded values show that HT system is able to achieve treatment accuracy typical of SRS ( $v < 1$ mm). The mean intra-fraction motions recorded in patients were  $0.1 \pm 0.2$  mm,  $-0.3 \pm 0.6$  mm,  $0.0 \pm 0.5$  mm,  $0.2 \pm 0.3^\circ$ ,  $0.2 \pm 0.4^\circ$ ,  $0.0 \pm 0.3^\circ$  for the

IEC-X, IEC-Y, IEC-Z, pitch, roll and yaw, respectively. The mean vector displacement, in this case, was  $0.8 \pm 0.3$  mm, showing that the mask minimized the intra-fraction motion to a mean value  $< 1$ mm. No dependence on the treatment time was observed.

#### Conclusion

The results of our study demonstrate that a mask-based fixation system have a high repositioning accuracy. Given the small setup error and intra-fraction movement, thermoplastic masks, combined with HT positioning system, may be used for high-precision treatments, like radiosurgery.

#### EP-1637 Critical appraisal of deep inspiration breath hold CBCT for left breast using VMAT

P. Mancosu<sup>1</sup>, G. Nicollini<sup>2</sup>, F. De Rose<sup>3</sup>, F. Lobefalo<sup>1</sup>, D. Franceschini<sup>3</sup>, M. Scorsetti<sup>3,4</sup>, S. Tomatis<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Medical physics unit of radiation therapy department, Rozzano Milan, Italy

<sup>2</sup>Radiqa Developments, Medical Physics Team, Bellinzona, Switzerland

<sup>3</sup>Istituto Clinico Humanitas, radiation therapy department, Rozzano Milan, Italy

<sup>4</sup>Humanitas University, Biomedical Sciences, Rozzano Milan, Italy

#### Purpose or Objective

Voluntary deep inspiration breath hold (DIBH) is a possibility to increase the heart-breast distance and thus to limit the heart mean dose ( $< 4$ Gy) for the left breast radiotherapy. TrueBeam (Varian) -mounted CBCTs provides the possibility to interrupt imaging acquisition allowing the acquisition of a complete volume dataset in DIBH. A critical evaluation of DIBH-CBCT for left breast treatment using VMAT was performed.

#### Material and Methods

A homemade phantom was developed. It consisted of a cylindrical target mounted on a moving phantom with a switch on/off, mimicking a controlled free breathing (FB)/DIBH conditions. Five series of FB-CBCT and DIBH-CBCT were acquired with 8 interruptions, and the images quality was evaluated. Furthermore, 8 patients (136 fractions) with left breast cancer treated with DIBH-VMAT were considered. A simulation DIBH-CT was acquired and the personal breathing curve was recorded using the RPM system (Varian). Plans were optimized according to VMAT technique, adopting a manual flash skin tool to virtually expand the breast boundaries (10mm) and include possible involuntary motions and/or breast shape modification. At the TrueBeam console, the DIBH-CBCT acquisition threshold was set as the reference DIBH curve position  $\pm 2$ mm and delay was fixed to 0.2s. Online shifts in the three directions were recorded. Furthermore, plans were recalculated on the DIBH-CBCT allowing an estimation of the actual daily session dose distribution; session based dosimetric parameters for PTV coverage and organ at risks sparing were compared with the original planned values.

#### Results

On the phantom study, the DIBH-CBCTs were able to freeze the breathing motion, while the correspondent FB-CBCTs showed motion artifacts (figure 1).

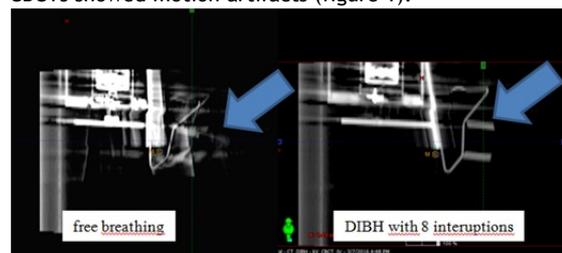

Figure 1: phantom study

Regarding the patients study, mean acquisition time was  $3.2 \pm 1.2$  min (range 1.6-11.5 min); absolute median shifts were  $\leq 3$  mm ( $SD \leq 4$  mm) in the three directions, while the vector shift was  $8.5 \pm 4.4$  mm (range: 0.0-24.2 mm), revealing the necessity of performing a daily CBCT. Differences between the planned PTV and the recalculated PTV coverage (V95%) were within 3.5% proving the feasibility of VMAT in breast cancer treatment (figure 2).

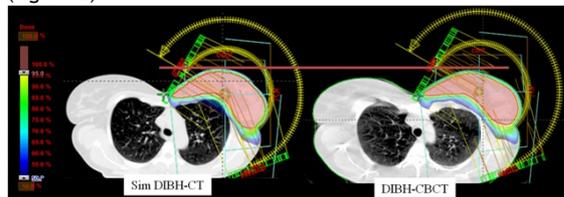

Figure 2: Dose recalculation on a DIBH-CBCT. Similar results were obtained in all cases. **Conclusion** DIBH-CBCT was shown to be feasible with adequate image quality, making possible to evaluate the efficacy of VMAT skin flash tool approach also in DIBH condition. Considering the relative short image acquisition time required, a protocol for DIBH breast SIB treatments in 15 fractions with DIBH-CBCT daily position is starting in our department.

**EP-1638 Comparison dual image registrations for SBRT treatment in central and peripheral tumour lung cancer**  
D. Esteban<sup>1</sup>, M. Rincón<sup>2</sup>, J. Luna<sup>1</sup>, A. Sánchez-Ballesteros<sup>2</sup>, A. Ilundain<sup>1</sup>, L. Guzmán<sup>1</sup>, D. Gonsálves<sup>1</sup>, W. Vázquez<sup>1</sup>, J. Olivera<sup>1</sup>, I. Prieto<sup>1</sup>, J. Vara<sup>1</sup>  
<sup>1</sup>Hospital Universitario Fundación Jiménez Díaz, Radiation Oncology, Madrid, Spain  
<sup>2</sup>Hospital Universitario Fundación Jiménez Díaz, Physical Radiation Oncology, Madrid, Spain

#### Purpose or Objective

Four-dimensional (4D) Cone Beam CT (CBCT) became available in clinics and has been used to quantify localization precision and intrafraction variability of lung tumour. Dual image registration is an option for the 4D-CBCT image registration: a clip-box and mask registration. The clip-box registration is the same as those in 3D CBCT, while the mask registration is a new feature of Elekta XVI CBCT system, which is a soft-tissue registration using a soft-tissue volume called mask.

Published study of 3D CBCT using clip-box with different landmarks led to different registration precisions for peripheral and central lung tumours. The study aims to compare if the different location of the tumour (peripheral and central) has an impact on the precision of the Elekta 4D-CBCT based automatic dual image registrations using clip-box and mask for SBRT treatment of lung cancer.

#### Material and Methods

A sample of 29 patients with diagnosed lung cancer and treated with SBRT from 2014 to 2016 was obtained by purposive sampling. Tumours were classified depending upon his location. They were scanned on a Philips 4D CT scanner and 8-phase images were reconstructed. GTV was contoured on each phase and ITV was generated by including the GTVs. PTV was created from ITV with a 5mm margin. Then a clip-box (place on the spine) and mask (margin of 0.5 cm on the PTV) were created allowing translations.

Elekta XVI CBCT system using a 4D module was used to acquire 4D-CBCT scans of the patients in treatment position prior to radiation delivery and a total of 101 were obtained. These images were registered with reference 4D CT images using dual image registration and a "balance clip-box mask" was generated (Imagen 1). The registrations were reviewed by physicians, choosing the

treatment position in which better coverage of PTV is performed. Possible treatments positions may be clip-box, mask or intermediate values of these. Descriptive analysis and Student t test was performed. Translational shifts calculated from dual automatic registrations were compared with the different standard registrations chosen by the physician, and the possible impact of the different location of the tumours on the precision was studied.

	Clipbox			Mask				Clipbox			Mask				Clipbox			Mask		
	Clipbox	Mask	Ajustar	Clipbox	Mask	Ajustar		Clipbox	Mask	Ajustar	Clipbox	Mask	Ajustar		Clipbox	Mask	Ajustar	Clipbox	Mask	Ajustar
Tx (cm)	0.00	0.14	✓	-0.07	0.07	✓		0.00	0.14	✓										
Ty (cm)	0.00	0.27	✓	-0.13	0.13	✓		0.30	0.57	✓										
Tz (cm)	0.00	0.02	✓	-0.01	0.01	✓		0.00	0.02	✓										
Rx (grad)	0.0	0.0	✓	0.0	0.0	✓		0.0	0.0	✓										
Ry (grad)	0.0	0.0	✓	0.0	0.0	✓		0.0	0.0	✓										
Rz (grad)	0.0	0.0	✓	0.0	0.0	✓		0.0	0.0	✓										

#### Results

There are forty 4D-CBCT from central and sixty from peripheral tumours. Differences of translational shifts between automatic dual registrations and the standard (difference=automatic registration-standard) was obtained. The Table 1 lists the mean and standard deviation of translational shifts directions.

Table 1		Mean [standard deviation] [cm]		
All tumour	x (left-right)		y (superoinferior)	z (anteroposterior)
	Mask	0,048 (1,126)	0,088 (0,159)	0,0897 (0,227)
	Clip-box	0,119 (0,136)	0,288 (0,25)	0,211 (0,199)
	Student T test	0,000	0,000	0,000
Central tumour	x (left-right)		y (superoinferior)	z (anteroposterior)
	Mask	0,033 (0,063)	0,073 (0,138)	0,073 (0,151)
	Clip-box	0,108 (0,094)	0,306 (0,238)	0,244 (0,22)
	Student T test	0,000	0,000	0,000
Peripheral tumour	x (left-right)		y (superoinferior)	z (anteroposterior)
	Mask	0,059 (0,155)	0,098 (0,172)	0,101 (0,266)
	Clip-box	0,127 (0,158)	0,277 (0,358)	0,189 (0,183)
	Student T test	0,000	0,000	0,027

#### Conclusion

Although the clip-box is created from a localized midline structure, the mask is more accurate for central tumours. The outcomes showed that using different dual image registrations resulted in different registration precisions for peripheral and central lung tumours, being favourable in all cases for the mask with statistically significant difference. This difference may be explained because clip-box registration made gross alignments whilst the mask made fine adjustments.

**EP-1639 Does intrafraction motion between vmDIBHs during breast cancer treatment impact on delivered dose?**

M. Kusters<sup>1</sup>, F. Dankers<sup>1</sup>, R. Monshouwer<sup>1</sup>  
<sup>1</sup>Radboud university medical center, Academic Department of Radiation Oncology, Nijmegen, The Netherlands

#### Purpose or Objective

Intrafraction motion simulations were performed in the treatment planning system (TPS) to determine the robustness of the VMAT comprehensive locoregional breast planning technique for residual breathing motion. The simulations are used to determine a threshold for the warning signal of the in-room monitoring system for excessive intrafraction motion deviations.

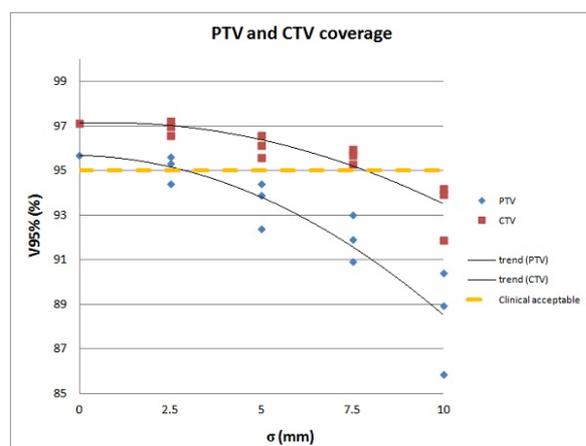

#### Material and Methods

Our current treatment plan technique consists of 6 opposing 24° VMAT beams in latero-medial and medio-lateral direction. A CTV-PTV margin of 7 mm is used and plans with a PTV coverage of V95% > 95% are clinically accepted. IGRT is based on online CBCT.

The influence of the intrafraction breath hold motion on PTV/CTV dose coverage and OARs dose is simulated in Pinnacle TPS (Philips, Madison, WI, USA) with for each beam and each fraction a random shift in the anterior-posterior (AP) direction of each isocenter (with 6 beams for 16 fractions, 96 isocenters are needed). Random shifts were sampled from a Gaussian distribution with standard deviations  $\sigma$  ranging from 0, 2.5, 5, 7.5 and 10 mm. For each standard deviation 3 simulations were performed.

#### Results

Figure 1 shows the results of the simulations. As expected the PTV and CTV coverage decreases for higher  $\sigma$  values. The V95% dose coverage of the PTV and the CTV decreases below the clinically acceptable value of 95% when the  $\sigma$  of the anterior-posterior motion exceeds 2.5 and 7.5 mm, respectively.

**Figure 1:** The V95% coverage (in %) for CTV (red cubes) and PTV (blue diamonds) based on simulations for different  $\sigma$  values. For  $\sigma$  higher than 7.5 mm the V95% of the CTV is below the clinical acceptable value of 95%.

The difference in dose to the OARs  $\sigma \leq 7.5$  mm is negligible.

#### Conclusion

Planning simulations in Pinnacle showed that the plans are robust and the influence of intrafraction breath hold motion on the dose becomes clinically relevant only when  $\sigma > 7.5$  mm.

Clinical data of the chest wall movement of patients in anterior-posterior motion measured using an in-house developed 3D camera breath hold monitoring system (ref abstract) showed a  $\sigma$  of approximately 2.5 mm. This suggests that for most patients residual intrafraction motion during breath hold as achieved in our institute is small enough to assure a good CTV coverage.

In this work only anterior-posterior motion is taken into account for the simulations. Therefore, we need to combine this with other inaccuracies before we can clinically interpret these simulations for reducing the CTV to PTV. Moreover, further investigation is required to determine what threshold should be taken as warning signal of the in-room breath hold monitoring system. Currently we choose to set the threshold value to 7.5 mm (maximum - minimum breath hold).

**Electronic Poster: Physics track: Inter-fraction motion management (excl. adaptive radiotherapy)**

#### EP-1640 Dosimetric consequences of PTV margin reduction in cervix cancer radiotherapy with VMAT and IGRT

T. Berger<sup>1</sup>, M.S. Assenholt<sup>1</sup>, N. Jensen<sup>1</sup>, L. Fokdal<sup>1</sup>, J. Lindegaard<sup>1</sup>, K. Tanderup<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Oncology, Aarhus C, Denmark

#### Purpose or Objective

To evaluate the safety of PTV margin reduction in the elective lymph node target (CTV-E) under condition of Volumetric Arc Therapy (VMAT) and daily IGRT. Furthermore, the benefit of margin reduction for Organs At Risk (OARs) was evaluated.

#### Material and Methods

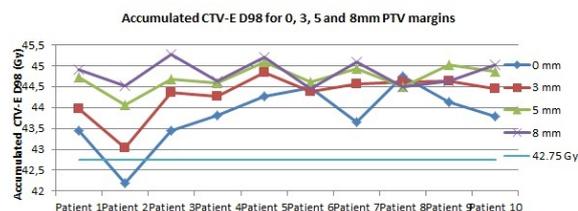

Ten locally advanced cervix cancer patients treated from December 2015 until June 2016, were analysed. The patients were treated with 45Gy in 25 fractions with VMAT and whole pelvic irradiation according to the Embrace II protocol. Patients with para-aortic irradiation were not included in this study. Daily image guidance was performed with CBCT, bony fusion and couch correction (translational and yaw). The ITV-45 defined the combined elective lymph node CTV (CTV-E) and the ITV related to the primary tumour. Four different dose-plans with ITV-45 to PTV margin of 0, 3, 5, and 8mm were evaluated. The target constraints were: ITV-45 D99.99 > 42.75Gy and PTV-45 D95%  $\geq$  42.75Gy. CTV-E was assumed to move as a rigid structure as lymph nodes are located mainly in relation to bone and muscles. CTV-E was transferred from plan CT to each CBCT by rigid bony registration with 6 degrees of freedom. The propagated CTV-E was visually validated and transferred back to the plan CT in the position of the patient during treatment. For each of the 4 plans, the accumulated D98 and D99.9 (average of the DVH of the 25 structures) was evaluated. For the 4 plans, V30 and V40 were extracted for bladder, bowel and rectum as well as PTV volumes and body V43.

#### Results

Figure 1 shows the accumulated CTV-E D98 for all 10 patients with 0, 3, 5 and 8mm PTV margins. Generally, a wider margin allows a better CTV-E coverage. With a 0mm margin, CTV-E D98 is larger than 43.4Gy for 9 patients and reduced to 42.2Gy for one patient. As for the 3mm PTV margin, all 10 patients have an accumulated CTV-E D98 larger than 43Gy. CTV-E D99.9, with a 3mm margin, reaches its lowest value for patient 2 with 39.3Gy. The second lowest value is 40.6Gy for patient 7. For the eight patients left, a 3mm PTV margin allows a minimum of 41.8Gy for CTV-E D99.9.

Table 1 shows for each of the 4 dose-plans the average DVH parameters for the targets and OARs. An 8mm margin (1621cm<sup>3</sup>) results in increased PTV volume of almost 50% compared with a 3mm margin (1114cm<sup>3</sup>). V43 is reduced by 469cm<sup>3</sup> when the PTV margin is reduced from 8 to 3mm, corresponding to a relative volume reduction of about 30%. The average volume of bowel receiving more than 30Gy is decreased by 82 cm<sup>3</sup> when the PTV margin was decreased from 8 to 3mm.

	PTV margins :			
	0mm	3mm	5mm	8mm
PTV volume (cm <sup>3</sup> )	822 ± 149	1114 ± 170	1313 ± 179	1621 ± 204
V43 (cm <sup>3</sup> )	1096 ± 187	1179 ± 168	1346 ± 177	1648 ± 211
CTV-E acc. D99.9 (Gy)	41,82 ± 1,14	42,23 ± 1,30	43,28 ± 0,97	44,16 ± 0,58
CTV-E acc. D98 (Gy)	43,79 ± 0,67	44,30 ± 0,48	44,70 ± 0,28	44,82 ± 0,29
Bowel V30 (cm <sup>3</sup> )	260 ± 87	270 ± 85	291 ± 85	352 ± 87
Bowel V40 (cm <sup>3</sup> )	99 ± 57	106 ± 57	117 ± 63	161 ± 72
Bladder V30 (%)	72,1 ± 12	73,9 ± 13	74,1 ± 12	81,1 ± 11
Bladder V40 (%)	48,8 ± 12	50,7 ± 12	52,7 ± 13	60,0 ± 13
Rectum V30 (%)	75,9 ± 5	76,9 ± 5	80,0 ± 4	84,1 ± 5
Rectum V40 (%)	48,5 ± 5	52,3 ± 8	56,4 ± 11	68,8 ± 9

### Conclusion

The PTV and body V43 are significantly reduced through margin reduction. For all patients, CTV-E D98 was larger than 43Gy for PTV margins  $\geq 3$ mm.

We notice a considerable advantage for the OARs when decreasing the PTV margin from 8 to 5mm. The advantage for OARs of decreasing the margin further to less than 5mm is significant but less pronounced. In particular, the gain for the OARs is small when moving from 3 to 0 mm while a 3mm margin increases the average D98 by 0.51Gy.

### EP-1641 Intra-fractional CBCT validation of a 6D couch to facilitate precision RT of head and neck cancer

A. Bertelsen<sup>1</sup>, C.R. Hansen<sup>1,2</sup>, M. Nielsen<sup>1</sup>, J. Eriksen<sup>2,3</sup>, N. Gyldenkerne<sup>3</sup>, J. Johansen<sup>2,3</sup>, S.L. Krogh<sup>1</sup>, J. Westberg<sup>1</sup>, C. Brink<sup>1,2</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

<sup>2</sup>University of Southern Denmark, Department of Clinical Research, Odense, Denmark

<sup>3</sup>Odense University Hospital, Department of Oncology, Odense, Denmark

### Purpose or Objective

Small planning margins for head and neck (H&N) cancer patients reduces toxicity and can be assisted by stable fixation equipment and IGRT including online corrections for translations and rotations (6D). This clinical study uses intra-fractional CBCT (iCBCT) to investigate the precision and, accuracy of 6D couch usage, and if the patients compensate for the rotational corrections.

### Material and Methods

H&N patients receiving standard fractionated IGRT were included in this study. The inclusion occurred in a three month period after an upgrade of the 6D couch system (Elekta, Hexapod). After online couch correction based on a pre-treatment CBCT (pCBCT) additional setup verification was performed using iCBCT acquired during single arc VMAT.

The residual uncertainty of the 6D couch correction was assessed by comparing the pCBCT and iCBCT registration of the spinal cord.

The residual setup error of the target volume (from the iCBCT) was used to calculate the population-based systematic and random uncertainty given as the standard deviation (SD) of patient mean values and SDs.

Correlations between residual errors and initial setup errors as well as patient specifics (age, weight, BMI, performance status (PS)) were tested using Spearman's R or Kruskal-Wallis (PS) test. For correlations the standard 5% statistical significance level was Bonferroni corrected.

### Results

In total 44 patients were included resulting in 1174 iCBCTs.

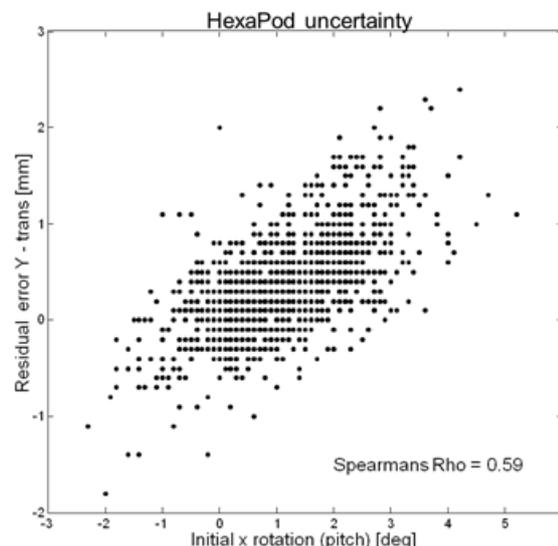

On average, the initial setup errors prior to use of the 6D couch were small, but had statistically significant mean values different from zero (table 1). Deviation in Z is due to standard adjustment of the fixation. The X rotation value is likely caused by the Hexapod calibration performed without load on the couch. Large SD was observed in the initial Y rotation.

The residual error shows that all setup uncertainties are statistically significant reduced (Levens test,  $p < 0.001$ ). However, a large systematic residual error of 0.4mm was observed in the Y-direction. This might be related to a

significant strong correlation between initial X-rotation and residual Y-translation (figure 1). Small SDs for both rotations and translations (table 1) indicate that patient compensation for rotational corrections is modest. The larger SD values for X and Z are related to significant strong correlations to the initial Y rotation ( $R=0.77$  and  $0.68$ , respectively).

No significant correlations were observed between patient-specific parameters and pre or post setup errors. Based the translational systematic and random errors a minimum CTV to PTV margin of 2mm is required (Van Herk et al. IJROBP 2000). However this estimate does not include compensation for rotations of elongated targets.

		Translation [mm]		Rotation [deg]	
		mean	std	mean	std
Initial setup error	X	0,0	2,4	1,1	1,1
	Y	-0,4	2,0	-0,2	1,8
	Z	1,1	2,3	-0,4	1,0
Residual setup error	X	0,0	0,8	-0,1	0,4
	Y	0,4	0,5	-0,3	0,7
	Z	0,0	0,7	-0,1	0,4
Systematic ( $\Sigma$ ) & random ( $\sigma$ ) error	$\Sigma$	$\Sigma$	$\sigma$	$\Sigma$	$\sigma$
	X	0,7	0,3	0,3	0,2
	Y	0,6	0,5	0,4	0,3
	Z	0,4	0,4	0,3	0,1
X	Left - right				
Y	Cranial - Caudal				
Z	Anterior - Posterior				

### Conclusion

The Hexapod system performed well and patients did not seem to compensate for rotational corrections. However due to related uncertainties rotations should be kept at a minimum. The present setup reduces the systematic and random uncertainties which make use of small treatment margins plausible.

### EP-1642 Patient-specific transperineal ultrasound probe setups for image guided radiotherapy

S. Camps<sup>1,2</sup>, F. Verhaegen<sup>3</sup>, P. De With<sup>1</sup>, D. Fontanarosa<sup>2,3</sup>

<sup>1</sup>Eindhoven University of Technology, Faculty of Electrical Engineering, Eindhoven, The Netherlands

<sup>2</sup>Philips Research, Oncology solutions department,

Eindhoven, The Netherlands  
<sup>3</sup>GROW - School for Oncology and Developmental Biology,  
 Department of Radiation Oncology MAASTRO,  
 Maastricht, The Netherlands

### Purpose or Objective

Despite the many advantages of ultrasound (US) imaging (e.g. safety and high-contrast soft tissue imaging) the use of US in image guided radiotherapy (IGRT) workflows is not widespread. This can primarily be attributed to the need of a skilled operator for US volume acquisition. We introduce an algorithm that provides the operator with a patient-specific probe setup that allows good anatomical structure visualization based on clinical requirements. This can potentially minimize operator dependence or even remove the need of the skilled operator.

### Material and Methods

In this study, co-registered CT and 3D transperineal US (TPUS) volumes with corresponding anatomical structure delineations of a prostate cancer patient were available. After preprocessing, a thresholding-based segmentation algorithm was used to extract the bones from the CT scan (Fig. 1A). The retrieved bone mask and the internal perineum boundaries enabled the identification of the patients' perineal area on the skin (Fig. 1A-B-C). Subsequently, the scrotum was localized in order to identify the underlying perineal skin. Finally, the areas on which the US probe could not be positioned in clinical practice (e.g. the region around the anus) were removed. In this way, a skin area accessible for TPUS volume acquisition was automatically identified (Fig. 1D).

All probe setups proposed by the algorithm should allow visualization of the whole prostate and seminal vesicles, as well as the adjacent edges of bladder and rectum, as clinically required. To determine these setups, the accessible skin area, in combination with the structure delineations and an estimation of the potential probe pressure, was used. The setup that also allowed visualization of most of the remaining anatomical structures was considered the best option.

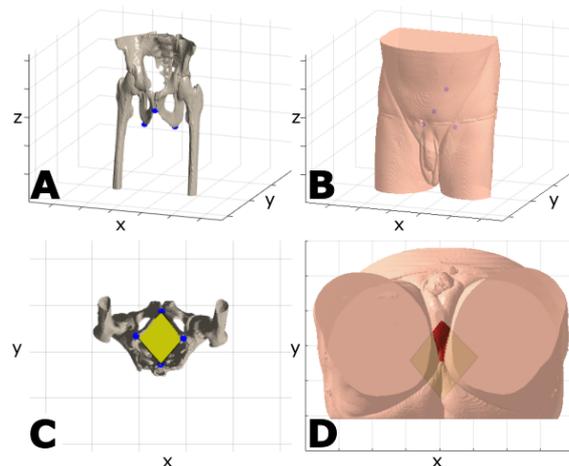

Figure 1. Identification of the perineal area accessible during TPUS volume acquisition. (A) The blue dots superimposed on the extracted bone mask indicate the corners of the perineum. (B) The body contours of the patient with the same corner points positioned inside. (C) The bone mask viewed in cranial direction, with the yellow surface indicating the diamond shaped total perineal surface. (D) The body contours of the patient also viewed in cranial direction. As can be seen, the total perineal surface is partially covered by legs and, in addition, some parts are too close to the anus. These parts were excluded from the total surface, resulting in an accessible perineum on which the US probe could be positioned in clinical practice. This area is indicated in red. The small part of the scrotum that is included in this area can be manually lifted by the patient to enable probe positioning on the perineal skin located underneath.

### Results

By positioning a virtual probe on the patients' virtual skin and subsequently translating it along the Y axis (1 mm step), rotating around Y or Z axes (up to  $\pm 3$  degrees with 1 degree step) or rotating around the X axis (up to  $\pm 15$  degrees with 3 degree step), 12,936 possible probe setups

were identified. In total 108 of these setups allowed visualization of all clinically required structures without the occurrence of blockage by the patients' bones.

In Fig. 2 the sector of the best probe setup is superimposed in yellow on the center slices of the patients' CT volume. If the physician had been provided with this setup prior to the US scan, potentially 96% of the delineated anatomical structures could have been visualized, in comparison with 87% using the current setup (cyan sector in Fig. 2), which was manually determined by trial-and-error.

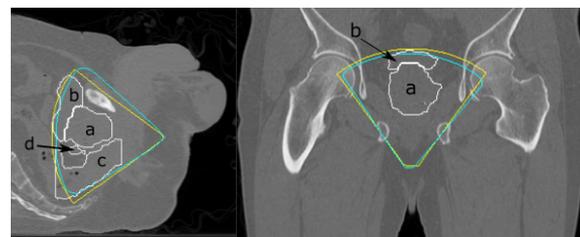

Figure 2. Center slices of the patients' CT volume in both sagittal and coronal direction. The US sector proposed by the algorithm is superimposed in yellow, while the sector actually used by the physician is displayed in cyan. In addition, the anatomical structure delineations are displayed in white: (a) prostate, (b) bladder (c) rectum and (d) seminal vesicles.

### Conclusion

The best probe setup out of 108 possible setups could potentially increase the visualization of the anatomical structures from 87% to 96%, while still fulfilling the clinical requirements. Future steps should focus on enabling skilled and unskilled workers to position the US probe according to the calculated setup.

### EP-1643 Simulate baseline shift uncertainties to improve robustness of proton therapy treatments

K. Souris<sup>1</sup>, A. Barragan<sup>1</sup>, D. Di Perri<sup>1</sup>, X. Geets<sup>1</sup>, E. Sterpin<sup>1</sup>, J.A. Lee<sup>1</sup>

<sup>1</sup>UCL - IREC Molecular Imaging Radiology and Oncology MIRO, Molecular Imaging Radiology and Oncology MIRO, Brussels, Belgium

### Purpose or Objective

Several studies reported both systematic and random variations of the mean position of mobile tumors from fraction to fraction. This so-called baseline shift is a major source of uncertainties for mobile targets and can jeopardize treatment quality. Unlike conventional photon therapy, the inclusion of this error in a PTV margin is inadequate in proton therapy because of the range uncertainties. Accounting for this uncertainty in a robust optimizer is much more appropriate, using for instance population-based estimations of the shifts. We developed a baseline-shift model able to automatically generate modified 4D-CT series used as uncertainty scenarios in the TPS.

### Material and Methods

An average CT scan and a Mid-Position CT scan (MidPCT) of the patient at planning time are generated from a 4D-CT data. The GTV contour in the MidPCT represents the mean position of the tumor along the breathing cycle. Our model can simulate a baseline shift by generating a local deformation field that moves the tumor on all phases of the 4D-CT, without creating any non-physical artifact. The deformation field is comprised of normal and tangential components with respect to the lung wall, in order to allow the tumor to slide within the lung instead of deforming the lung surface. The deformation field is eventually smoothed in order to enforce continuity. Two 4D-CT series acquired at 1 week of interval were used to validate the model.

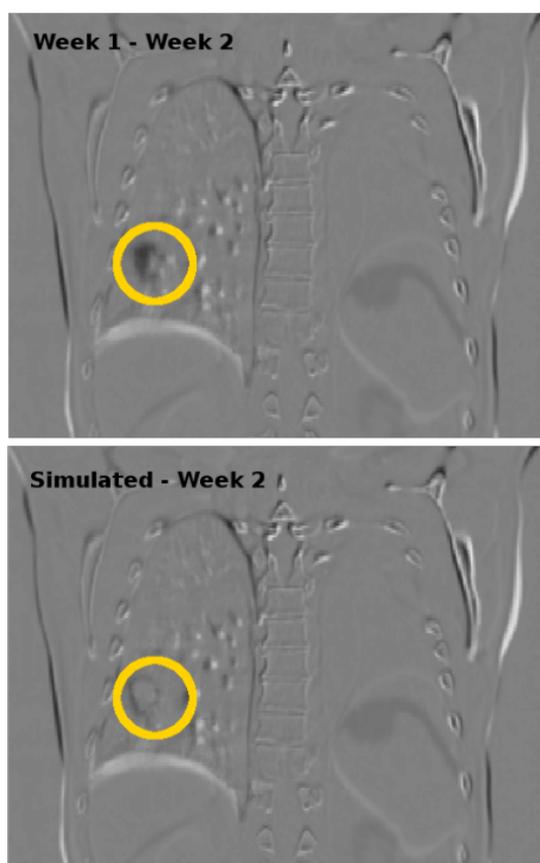

### Results

After rigid registration, a baseline shift of 9.5 mm is measured between the first- and second-week 4D-CT sets (W1-CT and W2-CT). In order to validate our model, a third 4D-CT series (BS-W1-CT) was generated from W1-CT to

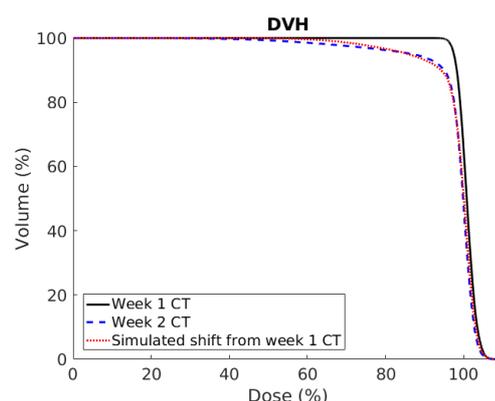

reproduce the measured shift (Figure 1). Water equivalent thickness (WET) has been computed for each voxel of the 3 MidPCTs and revealed that the baseline shift between W1-CT and W2-CT led to a root mean square error (RMSE) of 0.52 mm in the GTV. This WET RMSE was reduced to 0.18 mm between W2-CT and the simulated BS-W1-CT. In addition, a proton therapy plan was optimized on the average W1-CT scan and recomputed on the average W2-CT and BS-W1-CT scans. Figure 2 compares the resulting DVH for all dose distributions. The dose distribution computed on BS-W1-CT reproduces the dose degradation observed on W2-CT. The degradations for D95 are 10.6% and 11.8% for W2-CT and BS-W1-CT, respectively. Similarly, the D90 degradations are 3.2% and 4%.

#### Conclusion

Our model was validated by comparing the WET and dosimetric deviations between a simulated scenario and the real data set. As a future work, we will use our model to automatically generate uncertainty scenarios to feed a TPS for robustness evaluation and optimization of proton therapy plans. For instance, the new 4D robust optimizer of the RayStation can easily consider multiple 4D-CT series during the optimization process.

**Figure 1:** Difference between first- and second-week MidPCTs (top), and difference between simulated shift and week 2 MidPCTs (bottom).

**Figure 2:** Comparison of 3 DVHs on ITV volumes: optimized plan on week 1 images (solid black), degraded dose on week 2 (dashed blue), and simulated baseline-shift (dotted red).

#### EP-1644 Deep inspiration breath hold respiratory gated 3DRT for left breast cancer: Our clinical experience.

M. Pinto Monedero<sup>1</sup>, M. Castanedo Álvarez<sup>1</sup>, J. Martínez Ortega<sup>1</sup>, N. Gómez González<sup>1</sup>

<sup>1</sup>Hospital Universitario Puerta de Hierro Majadahonda, Medical Physics, Madrid, Spain

#### Purpose or Objective

The purpose of this work is to describe Deep Inspiration Breath Hold (DIBH) Respiratory Gated 3D Radiotherapy Treatments (RT) in left breast cancer patients in our clinic and to compare the results to free breathing (FB) treatments.

#### Material and Methods

Patients were trained prior to simulation to evaluate suitability for DIBH technique. Varian Real Time Position Management (RPM) System (Varian Medical Systems, USA) was used to monitor the patients' respiratory motion. They were asked to take a deep breath and hold it repeatedly. A deep breath amplitude was set as a reference level for the treatment sessions. For those patients eligible to this technique, two CT scans were acquired, under FB and DIBH conditions using a Toshiba Aquilion LB CT (Toshiba Medical Systems, Japan). Two treatment plans prescribed to 50 Gy in 25 fractions were computed for each patient: one in FB and one in DIBH conditions with XiO 5.02 treatment planning system (Elekta AB, Sweden). Average dose and V20 for heart and left lung as well as V95 for PTV were evaluated with the physician to decide the treatment technique. Patients were treated in a Varian Clinac-21 EX (Varian Medical Systems, USA) with analogous Varian RPM System. Patient position was verified through AP and lateral planar images in DIBH conditions. The same amplitude which was set as reference level at the simulation must be reached.

#### Results

25 patients underwent this procedure since the technique was introduced at our clinic. Only one patient was found not eligible. 20 of them were finally treated under DIBH conditions, whereas 5 of them were treated in free breathing conditions. Table I summarizes average V20 for heart and left lung as well as V95 for PTV. A significant heart dose sparing was achieved in every patient, as V20 was reduced by 77.4%. Moreover, the left lung benefits of a 24% reduction in V20.

Table I: Main Dose volume histogram results: average PTV V95, V20 Left Lung, V20 Heart.

	V95 PTV	V20 Left Lung	V20 Heart
DIBH	90,0%	21,65%	2,98%
FB	89,0%	28,47%	13,17%

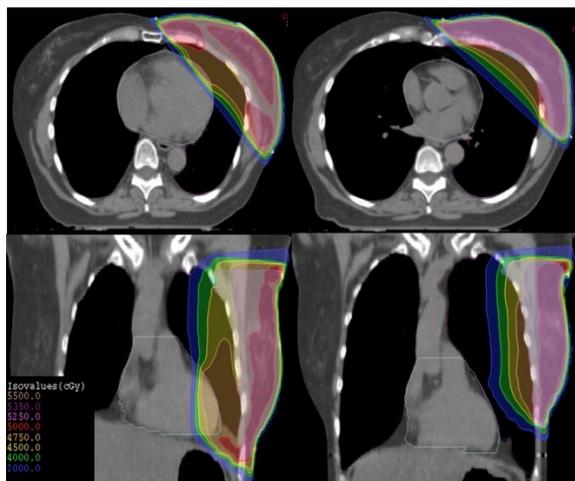

Figure 1: Axial and coronal CT slices of FB (on the left side) and DIBH (on the right side) dose distributions for the same patient.

#### Conclusion

96% of the patients trained were suitable for this technique. In 80% of the cases, DIBH treatment was chosen over FB. DIBH 3D RT for left breast cancer showed significant dose reduction for heart in every patient, and the left lung usually also benefits of it, achieving comparable coverage to PTV.

#### EP-1645 Optimization of on-line setup verification and adaptive radiotherapy for breast cancer patients

M. Essers<sup>1</sup>, S. Hol<sup>2</sup>, I. Maurits<sup>2</sup>, Y. Nijs<sup>2</sup>, T. Donkers<sup>2</sup>, L. Pontzen<sup>2</sup>, S. Toemen<sup>2</sup>, L. Mesch<sup>2</sup>, K. De Winter<sup>2</sup>

<sup>1</sup>Dr. Bernard Verbeeten Instituut, Department of Medical Physics, Tilburg, The Netherlands

<sup>2</sup>Dr. Bernard Verbeeten Instituut, Radiotherapy, Tilburg, The Netherlands

#### Purpose or Objective

In recent years, new imaging modalities besides the long existing megavolt (MV) imaging using an electronic portal imaging device (EPID) have become available at the linac, to ensure accurate patient setup during the course of the radiotherapy treatment. The purpose of this work was to study the usefulness of all possible imaging modalities and to develop the optimal online imaging protocol for breast cancer patients in our institute.

#### Material and Methods

1. kV or MV orthogonal imaging?: The interobserver variation in image registration was compared for 30 MV and 30 kV imaged patients.
2. Is cine acquisition useful, and how?: For 30 patients, cine images ("movieloop" during treatment fields) were acquired and analysed during all treatment fractions.
3. Surgical clips or bony anatomy for image registration?: For 30 patients, the setup changes based on patient anatomy and surgical clips registrations were compared.
4. How to use MV images in the mediolateral tangential direction (ML images) for adaptive radiotherapy? For 30 patients, the ML images during all treatment fractions were analysed
5. Should we use CBCT images?

#### Results

1. The interobserver variation reduced from 0.2mm for MV to 0.1mm (1 SD) for kV image registration.
2. Breath hold is very reproducible and stable within one fraction and during the course of fractions for the majority of patients. 1 of 30 patients was not able to have a stable (< 5mm) breath hold, for every fraction.
3. For 33% of fractions, the difference between anatomy and clip match was > 5mm, due to different patient (breast) posture or seroma or edema, or uncertainties in

anatomy match.

4. On the ML images, the entire breast with a ring structure of 5 mm is projected. For 2 out of 30 patients, the actual patient contour was projected outside the ring structure for several consecutive fractions, resulting in a new CT scan and treatment plan (adaptive RT). For 2.7% of the fractions, the residual deviation in lung wall was > 5mm.

5. CBCT images (if necessary in breath hold) are only acquired and analysed if indicated by the physicist based on deviations on one of the above images.

Based on these results, an imaging protocol for breast cancer patients has been developed. Results of this protocol for (about 450) patients treated in the last half year will be presented.

#### Conclusion

Based on the above results, the imaging protocol for breast cancer patients is now as follows: cine images are acquired during the first treatment fraction, and if breathing motion is > 5 mm, further instructions are given to the patient and extra cine imaging is performed. Everyday, on-line setup verification using clips on orthogonal kV imaging is applied, as well as the use of ML verification images to 1) check and if necessary correct for residual lung wall deviations and 2) apply adaptive radiotherapy using an additional external contour ring structure. CBCT images are acquired only if required by the physicist based on deviations in one of the above images.

#### EP-1646 Impact of interobserver variability and setup uncertainty on dose in organs-at-risk

V. Prokic<sup>1</sup>, F. Röhner<sup>2</sup>

<sup>1</sup>Koblenz University of Applied Sciences, Faculty of Mathematics and Technology, Remagen, Germany

<sup>2</sup>University Hospital Bonn, Department of Radiology, Bonn, Germany

#### Purpose or Objective

Accurate target and organs-at-risk (OARs) contouring and accurate and reproducible patient setup are crucial for success in radiotherapy, in particular when volumetric-modulated radiotherapy (VMAT) with high conformality and steep dose gradients is applied. Interobserver variability in contouring of OARs can have strong impact on dose-volume histograms, as well as possible setup-errors when setup-correction with on-board imaging is not performed daily. The goal of this study is to quantify the impact on delivered dose in parotid gland in patients with head-and-neck cancer irradiated in VMAT technic: (1) due to the interobserver variation in contouring of parotid glands and (2) due to the patient setup without daily image guidance.

#### Material and Methods

We have retrospectively analyzed seven patients who underwent primary definitive radiotherapy for head-and-neck cancer. Patient set-up is verified weekly using kV CBCT. The prescription dose was 50Gy/70Gy to PTV1/2. VMAT plans were generated using Eclipse 13.6 (Varian Medical Systems USA), for TrueBeam Linac with HD-120 MLC and 6MV. Plans were optimized to meet a set of dose constraints to OARs and the prescribed doses to the target volumes. Three radiation oncologist have independently delineated the parotid glands for this analysis. In order to estimate the impact of set-up errors on the dose in parotid glands that would have occurred without correction of patient positioning, for each patient the isocenter of the plan was shifted according to the weekly set-up error and the dose distribution was recalculated in treatment planning system for VMAT plan. Dosimetric impact due to the intraobserver and setup variations was quantified in terms of mean dose in parotid glands.

## Results

In initial plans, the mean calculated dose in parotid glands ranged from 24.1 to 26.2 Gy. There is significant variation in parotid contouring. The degree of variation varied from patient to patient, with maximum differences up to 23% in mean dose to parotid glands. Maximum differences in mean dose to parotid glands due to the uncorrected setup-shifts was up to 12%.

## Conclusion

Intraobserver variability in contouring of OARs and daily variations in patient setup are significant contributors to uncertainty in radiotherapy treatment planning, and consequently in delivered dose. Our analysis indicates that the not-precise contouring can lead to larger difference between delivered and calculated dose.

### EP-1647 Validation of a set up procedure for IMRT/VMAT breast treatment using in vivo dosimetry with EPID

S. Kang<sup>1</sup>, J. Li<sup>1</sup>, P. WANG<sup>1</sup>, X. Liao<sup>1</sup>, M. Xiao<sup>1</sup>, B. Tang<sup>1</sup>, X. Xin<sup>1</sup>, L.C. Orlandini<sup>1</sup>

<sup>1</sup>Sichuan Cancer Hospital, Radiation Oncology, Chengdu, China

#### Purpose or Objective

In vivo dosimetry (IVD) is an important tool able to verify the accuracy of the treatment delivered and its reproducibility. The change of a consolidated existing procedure can be performed if an indisputable evidence of improvement may be proved and the feasibility in a clinical workflow is guarantee. In this work IVD performed with electronic portal imaging device (EPID) was used to evaluate VMAT and IMRT breast treatment performed with a new set up and immobilization procedure.

#### Material and Methods

IVD with EPID was performed over 32 patients that underwent an IMRT or VMAT breast plus supraclavicular treatment. Half of the patients followed the standard set up procedure (SP) of the department, consisting of a thermoplastic mask covering the district to be treated, patient marks over the mask, bolus applied over the mask; the others followed a new procedure (NP) and were immobilized with a breast board and a knee support, patient marks over the skin and bolus applied over the skin. The accuracy of the treatment was evaluated with a commercial software (SOFDISO, Best Medical Italy) that provided two indexes: the ratio R between the reconstructed ( $D_{iso}$ ) and planned ( $D_{tps}$ ) isocenter dose ( $R = D_{iso}/D_{tps}$ ) which can represent the accuracy of the dose delivered, and a  $P\gamma\%$  obtained performing a gamma analysis between the first EPID image and the next ones acquired immobilized. Three consecutive tests were scheduled during the first week of treatment and successively two IVD test per week. The MLC log files of the treatments delivered where analysed with a commercial software and compared with the planned treatment in order to discriminate the deviation coming from the patient (anatomy and set up), from the deviation coming from the linac.

## Results

	IMRT		VMAT	
	SP	NP	SP	NP
P	13	10	6	5
T	105	350	50	40
$P\% (R_{mean})$	100	100	100	100
$T\%(R)$	88	100	94	100
$P\% (P_{mean})$	100	100	80	100
$T\%(P\gamma)$	93	92	79	93

Table 1: Results of 545 IVD tests over 32 patients undergoing IMRT and VMAT breast treatment, with standard set up procedure (SP) and the new one tested (NP). The number of patients (P), IVD tests (T), percentage of patients with  $R_{mean}$  and  $P\gamma_{mean}$  in tolerance  $P\%(R_{mean})$  and  $P\%(P_{mean})$  respectively, percentage of IVD tests with R and  $P\gamma$  in tolerance  $T\%(R)$   $T\%(P\gamma)$ , were reported.

Only the IVD test coming from a delivery with the machines log file in tolerance were considered. The results of 545 IVD tests obtained over 32 patients were reported in Table 1. Every treatment performed with IMRT and VMAT resulted in 100% of the patients with R and  $P\gamma$  indexes in tolerance as for SP as for NP. The percentage of  $P\gamma$  index in tolerance as for VMAT as for IMRT increased with NP. A 10% of, off tolerance tests persisted. The IVD tests off tolerance were reported in the acceptable threshold before the next fraction. **Discussion:** the new immobilization procedure enabled a direct localization of the patient skin and of the bolus positioned over it. The use of the mould mask, positioned over the patient's lead to a non-direct evaluation of the patient rotation and accommodation inside it. The beam can lack of reproducibility if considering its path: air gap between the bolus, the mask and the patient skin not considered in the treatment planning. This aspect is moreover important for IMRT treatment where for some beam entry this situation can be more evident.

#### Conclusion

IVD in is a powerful tool that can be helpful in the validation of new set up and immobilization procedures.

### EP-1648 Thermoplastic mask dependency with interfractional uncertainties for head and neck VMAT treatments

E.M. Ambroa Rey<sup>1</sup>, R. Gómez Pardos<sup>1</sup>, D. Navarro Giménez<sup>1</sup>, A. Ramírez Muñoz<sup>1</sup>, M. Colomer Truyols<sup>1</sup>  
<sup>1</sup>Consorci Sanitari de Terrassa, Medical Physics Unit- Radiation Oncology Department, Terrassa, Spain

#### Purpose or Objective

Volumetric-modulated arc therapy (VMAT) techniques have the ability to deliver a highly conformal dose distribution to the target and high dose gradient at the interface between the tumor and the normal tissues, decreasing the irradiated volume and sparing OARs. However inaccurate alignment of the radiation beam with the patient can lead to critical organs to receive an unwanted high dose or the tumor to receive a reduced dose producing a loss in tumor control. Radiation therapy for head-and-neck (H&N) cancer requires a reliable immobilization for an accurate treatment. The purpose of this study is to establish the interfractional setup error for VMAT H&N patients, using a kilovoltage cone beam CT (CBCT) and a robotic treatment couch (HexaPOD) for accurate patient positioning in six degrees of freedom and analyze the differences between two types of thermoplastic masks (Head mask (H) and Head and Shoulder (HS) mask).

## Material and Methods

Dataset for a total of 945 CBCT scans were obtained from 30 patients (13 with H mask and 17 with HS mask). For each fraction, patients were placed on the HexaPOD robotic couch and a CBCT was performed. For interfraction accuracy evaluation, the daily variations of the three principal axes (X, Y and Z) and three rotational movements (pitch, roll, and yaw) were extracted. Also, the type of thermoplastic mask was recorded. The following parameters were calculated: the mean of the setup corrections ( $M$ ), the standard deviation (random error,  $\sigma$ ), the group random error ( $\sigma$ ) defined as the mean of all the individual patient random error  $\sigma_i$  and the systematic group error ( $\Sigma$ ) defined as the standard deviation of all the means measured for each patient.

## Results

Results are shown in Table 1. The overall mean displacements are larger for the HS mask patients than for the H mask. Also a trend toward a positive antero-posterior direction (1.19 mm) was observed in translational displacements for the HS mask patients. This could be explained taking into account the differences between the simulation and treatment couches as well as the accuracy of the room lasers. The remaining error components did not show any trend. For the rotational directions, the bigger error was in the pitch direction for both the H mask (0.76) and HS mask patients (0.85).

Regarding the systematic group error, we have found a larger error for the HS mask patients (2.34) again toward a positive antero-posterior direction. The random group error shows the same behavior as well.

HEAD MASK						
	X (mm)	Y (mm)	Z (mm)	Pitch (°)	Roll (°)	Yaw (°)
Mean error, M	0,02	-0,32	0,84	0,76	0,03	0,04
Random group error, $\sigma$	1,31	1,47	1,57	0,86	0,92	0,87
Systematic group error, $\Sigma$	1,40	2,04	1,69	0,86	1,17	0,94
HEAD AND SHOULDER MASK						
	X (mm)	Y (mm)	Z (mm)	Pitch (°)	Roll (°)	Yaw (°)
Mean error, M	0,42	-0,11	1,19	0,85	-0,41	-0,16
Random group error, $\sigma$	1,50	1,48	1,71	0,76	0,73	0,75
Systematic group error, $\Sigma$	1,89	1,21	2,34	1,11	1,20	0,94

## Conclusion

We can conclude that the patients with HS mask have larger displacements than the H mask patients, but further investigations should be done.

All errors are below 3mm. This result agrees with the literature for H&N displacements.

In summary, HexaPOD couch in combination with daily CBCT can considerably improve the accuracy of patient positioning during VMAT treatment for H&N treatments.

## EP-1649 Comparison of two thermoplastic immobilization shells for frameless stereotactic radiotherapy

I. Gagne<sup>1</sup>, S. Zavgorodni<sup>1</sup>, A. Alexander<sup>2</sup>, I. Vallieres<sup>2</sup>

<sup>1</sup>BC Cancer Agency - Vancouver Island, Medical Physics, Victoria, Canada

<sup>2</sup>BC Cancer Agency - Vancouver Island, Radiation Oncology, Victoria, Canada

### Purpose or Objective

The primary goal of this study was to compare the inter-fraction 6DOF corrections applied between patients immobilized with an open-face shell system and patients immobilized with a reinforced closed-shell system. The intra-fraction motion was also compared between these two groups of patients.

### Material and Methods

Sixty patients have been treated with frameless radiotherapy on a Varian TrueBeam STx linear accelerator equipped with a six-degree of freedom (6DOF) couch. All patients had a planning CT scan with an immobilization

system that comprised of a CIVCO head cup, a CIVCO customizable pillow and a thermoplastic shell. An open-faced shell from CIVCO was used on the first 15 patients in anticipation of the ALIGN RT optical tracking system installation. A closed-faced shell from AUBO with extra reinforcement was employed on subsequent patients due to delays in the approval of ALIGN RT in Canada and larger than expected setup and intra-fraction motions with the open-faced immobilization system. Two pre-treatment CBCTs were acquired; the first to correct using 6DOF bone anatomy matching the initial inter-fraction setup error, the second to correct using 4DOF the residual setup error following the 6DOF couch moves. A post CBCT was acquired to determine the intra-fraction motion using 6DOF bone anatomy matching.

## Results

Datasets from 12 patients with an open-faced immobilization shell and 29 patients with a reinforced closed-face immobilization shell were obtained for a total of 2451 CBCT scans. Table 1 summarizes the population average of the patient average and largest 6DOF corrections (vrt, lng, lat, pitch, roll, rtn) from CBCT1 for both the open-face and closed-face shells. Also included is the population average of the average and largest intra-fraction motion (vrt, lng, lat, pitch, roll, rtn) recorded from CBCT3 for both the open-face and closed-face shells. A student t-test for uneven sample and variance was applied to determine which parameters had statistically significant differences at the  $p=0.01$  level. No statistically significant differences were found between the two patient populations when patient 6DOF correction averages, however, statistically significant differences were found between the two patient populations when the patient largest rotational corrections were used in the test. Statistically significant differences between the two patient populations were also noted for the patient largest 6DOF pitch and roll intra-fraction motion as well as the patient average 6DOF pitch intra-fraction motion.

Shell type	Population	Vrt (mm)	Lng (mm)	Lat (mm)	Pitch (deg)	Roll (deg)	Rtn (deg)
Open-face	Average of Patient average 6DOF correction	-0.7±1.2	-0.3±1.0	-0.7±0.8	0.1±0.9	0.4±0.6	0.1±0.7
Closed-face	Average of Patient average 6DOF correction	-0.7±1.5	0.1±1.1	-0.4±0.9	0.1±0.7	-0.1±0.4	-0.4±0.6
Open-face	Population largest 6DOF correction	2.5±0.9	3.0±1.3	2.2±0.6	2.3±0.5	2.1±0.5	1.8±0.5
Closed-face	Population largest 6DOF correction	2.2±1.2	2.1±1.0	2.5±1.8	1.1±0.6 ( $p=0.00003$ )	1.2±0.6 ( $p=0.00007$ )	1.5±0.6 ( $p=0.005$ )
Open-face	Population average 6DOF motion	-0.1±0.1	0.1±0.3	0.1±0.1	0.4±0.3	0.0±0.2	0.0±0.1
Closed-face	Population average 6DOF motion	-0.1±0.2	0.1±0.2	0.0±0.1	0.1±0.3 ( $p=0.007$ )	0.0±0.1	0.0±0.1
Open-face	Population largest 6DOF motion	0.5±0.2	1.0±0.7	0.6±0.4	1.3±0.8	0.6±0.3	0.4±0.2
Closed-face	Population largest 6DOF motion	0.4±0.2	0.5±0.3	0.3±0.1	0.5±0.3 ( $p=0.007$ )	0.4±0.2 ( $p=0.007$ )	0.3±0.2

Table 1: Population average of the patient average and largest 6DOF corrections applied post CBCT1 and population average of the patient average and largest 6DOF intra-fraction motion calculated from post-treatment CBCT3.

## Conclusion

Moving to a reinforced closed-face immobilization shell from an open-faced immobilization system has significantly reduced the magnitude of the rotational corrections as well as significantly reduced the magnitude of the pitch and roll motion errors.

## EP-1650 Setup uncertainty in head and neck assessed by a 1.5T MR-sim with thermoplastic mask immobilization

Y.H. Zhou<sup>1</sup>, W.W.K. Fung<sup>2</sup>, J. Yuan<sup>1</sup>, O.L. Wong<sup>1</sup>, G. Chiu<sup>2</sup>, K.F. Cheng<sup>2</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics & Research Department, Happy Valley, Hong Kong SAR China

<sup>2</sup>Hong Kong Sanatorium & Hospital, Department of Radiotherapy, Happy Valley, Hong Kong SAR China

### Purpose or Objective

This pilot study aims to prospectively assess the setup uncertainty in head and neck (HN) using thermoplastic mask immobilization on a dedicated 1.5T MR-sim for radiotherapy based on a cohort of healthy volunteers.

### Material and Methods

11 healthy volunteers received a total of 142 scans (each scanned 4-40 times) on a 1.5T MR-sim in a treatment position immobilized with customized 5-point thermoplastic mask with shoulder fixation to simulate HN-RT fractions. Volunteers were carefully aligned and positioned by RT therapists using a 3D external laser system. The imaging protocol consisted of a T1w SPACE sequence (TR/TE = 420/7.2ms, FOV = 470mm, 256 coronal slices, isotropic voxel size of 1.05mm, acquisition time ~5min, geometric distortion correction ON). Six Degree-of-Freedom rigid body registration based on normalized mutual information (sampling factor = 5%) were used to pair-wisely register images with respect to the first session for each subject. Systematic and random errors of translation and rotation in positional setup were calculated. One sample t-test and box-plot were used to evaluate positional variation of translation and rotation with a significance level of 0.05.

### Results

The overall positional setup repeatability results were presented in Table I. The group mean translation was <1mm and mean rotation was <1°, respectively. The systematic error in LR, AP and SI translation was 0.48mm, 0.23mm and 0.53mm, respectively. The systematic error in roll, pitch and yaw rotation was 0.07°, 0.002° and 0.27°, respectively. The random error in corresponding direction was 1.83mm, 0.62mm and 1.88mm for translation, and 0.36°, 0.01° and 1.09° for rotation, respectively. 20 (-14.0%), 0 (-0%), and 25 (-18.6%) out of all 142 scan sessions had displacements >1mm in the LR, AP, and SI directions, respectively. Displacements >2 mm were seen only in the SI direction in one session (-0.7%). One-sample t-test showed significance of group mean error in AP translation ( $p < 0.001$ ) and all rotations ( $p = 0.02$  in roll and  $p < 0.001$  in pitch and yaw). The box-plot of inter-session translation and rotation was shown in Fig. 1. No significant differences were observed in translation in LR and SI direction, while AP translation was significantly smaller. This could be partially explained by the fixed AP level of the MR-sim couch. The yaw rotation was significantly larger than roll and pitch rotation, which may result from the relatively inadequate immobilization performance in this direction, but yet to be further investigated.

	3D Translation			3D Rotation		
	L-R	A-P	S-I	Roll	Pitch	Yaw
Group Systematic Error (M) (mm)	0.11	0.08	0.21	0.005	0.003	0.08
SD of Systematic Error ( $\Sigma$ ) (mm)	0.48	0.23	0.53	0.07	0.002	0.27
RMS of Random Error ( $\sigma$ ) (mm)	1.83	0.62	1.88	0.36	0.01	1.09

Table I. Population translation and rotation systematic and random error

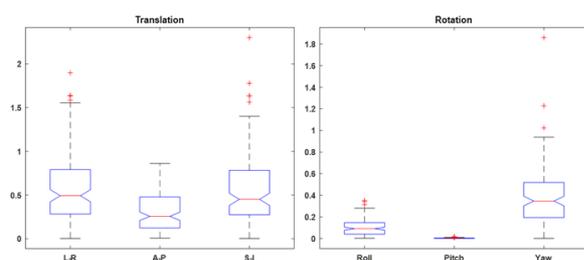

Fig. 1. Box-plot of the inter-session translational and rotational setup variation for all 11 subjects.

### Conclusion

Small head and neck setup uncertainty and thus high positional repeatability could be achieved on a 1.5T MR-sim, suggesting the potentials of MRI for precise HN-RT.

### EP-1651 Dosimetric impact of rotations correction in Stereotactic RT. How much a 6DoF couch is useful?

S. Chiesa<sup>1</sup>, S. Menna<sup>2</sup>, A.R. Alitto<sup>1</sup>, L. Azario<sup>2</sup>, G.C. Mattiucci<sup>1</sup>, M. Ferro<sup>3</sup>, M. Massaccesi<sup>1</sup>, A. Re<sup>1</sup>, A. Piermattei<sup>2</sup>, V. Valentini<sup>1</sup>, M. Balducci<sup>1</sup>

<sup>1</sup>Università Cattolica del Sacro Cuore -Fondazione Policlinico Universitario A. Gemelli, Radiation Oncology Department- Gemelli-ART, Rome, Italy

<sup>2</sup>Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario A. Gemelli, Medical Physics Department, Rome, Italy

<sup>3</sup>Università Cattolica del Sacro Cuore -Fondazione di Ricerca e Cura "Giovanni Paolo II", Radiation Oncology Department, Campobasso, Italy

### Purpose or Objective

Setup accuracy and organ motion control are essential in stereotactic radiation therapy (SRT) due to the use of sharp dose gradients and tight margins around the target volume. PRO-ART Project was designed to evaluate set up errors and dosimetric impact of rotational patient positioning correction using a 6-Degree of Freedom (6DoF) robotic couch.

### Material and Methods

Patients with lung, brain and abdominal lesions were enrolled and immobilized with Uni-frame or trUpoint Arch for brain, Breast board or Body Pro-Lok for chest and abdomen (CIVCO support system) lesions. Eclipse™ Treatment Planning Systems (Varian Medical System®, Palo Alto, CA) was used for dose calculations of VMAT plans. A daily KV-Cone Beam Computed Tomography (CBCT) was performed before each treatment fraction and translational and rotational shifts were identified, recorded and applied on the Protura TM Robotic couch to correct the position. Using MIM 5.5.2 software, the simulation CT was rigidly registered with CBCT, considered as primary CT, for each fraction. After registration, translational errors were applied to correct the CT position, obtaining a tCT, i.e. CT with only translational errors correction. Then, rotational errors were corrected too, obtaining roto-translated CT (rtCT). Reference treatment plan was copied to translated tTP and to roto-translated rtTP and dose distributions were recalculated, obtaining two treatment plans for each fraction. DVHs dosimetric parameters were compared.

### Results

In this study 179 CBCT were performed on 47 patients (14 with primary tumours and 33 with metastatic lesions) and 358 treatment plans were calculated (179 tTP and 179 rtTP). Geometric and dosimetric analysis are reported in Table 1. There was no correlation between translational and rotational shifts. Rotational shifts resulted greater than 1° in 40% of cases. Average variations in PTV and CTV V95% were negligible, but we observed variations of PTV V95% >2% in 30%, 8% and 12% of cases (CBCTs) respectively for brain, thorax and abdomen patients. OARs proximity to the target caused variations >2% and rotations around each axis could determine important changes depending

on the symmetry of the organ.

**Conclusion**

Rotational errors have to be corrected regardless of translations magnitude. Although rotations don't impact on CTV V95%, 6DoF corrections allow better PTV's coverage. Rotational errors could cause considerable dosimetric changes in organs at risk and must be carefully corrected in SBRT to avoid normal tissue complications. An ongoing analysis on setup systems and margin reductions has been planned.

**EP-1652 A new position verification protocol for breast cancer with integrated boost**

K.L. Gottlieb<sup>1</sup>, E.L. Lorenzen<sup>1</sup>, J.D. Jensen<sup>2</sup>, M.H. Nielsen<sup>2</sup>, M. Ewertz<sup>2</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

<sup>2</sup>Odense University Hospital, Department of Oncology, Odense, Denmark

**Purpose or Objective**

The use of integrated boost compared to sequential boost allows shortening of the overall treatment time while maintaining the same biologically equivalent dose to the boost region. However when the target is large as in breast cancer treatments there can be challenges in IGRT registrations between the boost volume and total target volume. The present study proposes and evaluates a protocol for daily IGRT using CBCT of breast cancer patients with integrated boost. A threshold is set for the allowed difference between the whole target match and the boost specific match. If the two matches differ by less than the threshold the boost volume and the total volume is treated in the same setup. If the two matches differ by more than the threshold, the total target volume is matched and treated and then secondly an additional CBCT is performed and matched on the boost volume which is then treated.

**Material and Methods**

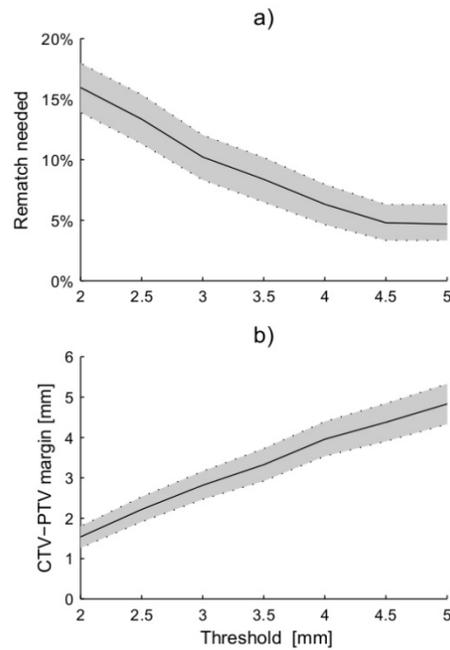

In order to evaluate the match protocol all patients receiving RT during the period 1/1-2016 and 1/7 2016 after breast conserving surgery and with lymph node involvement were retrospectively included in the study. The number of patients eligible for inclusion was 18 (3 was rejected because of missing (2) or faint (1) clips). All patients received daily IGRT with CBCT using XVI from Elekta. CBCT's for the first ten fractions were included resulting in 180 CBCT. Two matches were performed for each patient: First, a chest wall-match were performed, where CBCT images were registered automatically to the planning CT using a grey value translational match of the thorax wall. Secondly, a boost specific match was performed, where the surgical clips were manually registered to their position on the planning CT.

**Results**

The systematic ( $\Sigma$ ) and random errors ( $\sigma$ ) between the thorax wall and the clips based boost matches are seen in the table. The CTV-PTV margins were calculated based on the systematic and random errors using the Van Herk margin recipe. These numbers are found both using no re-matching and a re-matching if there were more than 5 mm differences between the two matches. In the figure the percentage of rematches needed for a given threshold of

allowed difference between the thorax wall and boost match is shown in a). The boost CTV to PTV margin required to account for the difference between chest wall and boost match for a given threshold is shown in b). The grey shaded area shows the 90 percent confidence interval obtained by bootstrapping.

	$\Sigma$ [mm]	$\sigma$ [mm]	CTV-PTV [mm]
<b>No re-matching</b>			
lateral	2,3	1,8	6,9
longitudinal	2,7	2,0	8,1
vertical	2,8	2,1	8,4
<b>5mm treshold for re-matching</b>			
lateral	1,7	1,6	5,3
longitudinal	1,5	1,5	4,9
vertical	1,3	1,6	4,3

**Conclusion**

The presented protocol can reduce the required CTV to PTV margin for the boost region by re-scanning and re-matching the boost region only for patients where the two regions differ by more than a set threshold. Results are presented that can be used for selecting a threshold with the corresponding required CTV-PTV margin. If e.g. a threshold of 5 mm is used, the required CTV-PTV margin can be reduced from approximately 8mm to 5mm and re-scanning and re-matching will be required in only 5% of the fractions.

**EP-1653 Polymark™ fiducial markers migration in Prostate Image Guided Radiation Therapy using CBCT images**

C. Camacho<sup>1</sup>, I. Valdivieco<sup>1</sup>, J. Sáez<sup>1</sup>, A. Herreros<sup>1</sup>, J. García-Miguel<sup>1</sup>, E. Agustí<sup>1</sup>, C. Castro<sup>1</sup>

<sup>1</sup>Hospital Clinic i Provincial, Radiotherapy, Barcelona, Spain

**Purpose or Objective**

Polymer-based fiducial markers, FM (Polymark™) location was analyzed to test the idea that there is no intraseed migration within the prostate, which is fundamental for patient set-up good quality over the entire course of radiotherapy treatment (RT).

### Material and Methods

Six prostate cancer patients with transperineal placement of 3mm-long 1mm-diameter polymer-based fiducials underwent 3mm slice thickness plan CT scan on day 14 after markers implantation, which is considered as a safe waiting time according to the literature.

All patients were managed with the same IGRT protocol: before each daily treatment, two planar KV images were acquired with the OBI 1.4 system (Varian Medical Systems) at 45° and 315°. A manual marker match between the KV images and the planning CT DRRs was performed and automatically transferred to the treatment couch position to correct the patient position in the three translational directions (rotations were not taken into account). Weekly, after patient re-position and just before session delivery, a CBCT scan is acquired, that is used to assess rectum and bladder filling (slice thickness between 1mm and 3mm).

These CBCT images, as being acquired in patient corrected position, have been used to evaluate the FM locations at different times during the course of treatment. A total of 37 CBCT images have been analysed to reconstruct the FM 3D coordinates. The displacement of each FM was calculated relative to its reference position on the reference planning CT, and also shift of the midpoint of each 3 FM set. The distance between markers in each set at the time of planning CT and during specific evaluated treatment have also been computed.

### Results

The average marker migration observed is  $0.68 \pm 0.51$  mm (range between 0 - 3.90 mm). This observation seems independent of the marker position inside the prostate, but not of the spatial coordinate: the antero-posterior direction presents the largest FM average displacement. Although the average migration observed is low, there are cases among the six patients where the migration observed on a specific day was greater than 2mm. This observation may be directly related to the degree of prostate displacement caused by the influence of the rectum and bladder, and also with the possible pelvic rotation in the moment of daily RT (not corrected with the 2D DRR vs KV image comparison).

Changes in distance between pairs of FM in each set have been, on average,  $0.12 \pm 0.11$  mm (range between 0.02 - 4.38 mm).

### Conclusion

The low average FM migration observed is expectable, according to the waiting time between marker implantation and the planning CT scan procedure. A further investigation should be done in order to reduce this waiting time.

The fact of having observed cases among all patients with displacement greater than 2 mm should be taken into account in the CTV-PTV margins: an adequate expansion of margins might compensate for this set-up uncertainty.

### EP-1654 Clinical set up and first results of EPID in vivo dosimetry in an overload Chinese Radiotherapy

J. Li<sup>1</sup>, A. Piermattei<sup>2</sup>, P. WANG<sup>1</sup>, S. Kang<sup>1</sup>, M. Xiao<sup>1</sup>, B. Tang<sup>1</sup>, X. Liao<sup>1</sup>, X. Xin<sup>1</sup>, L.C. Orlandini<sup>1</sup>

<sup>1</sup>Sichuan Cancer Hospital, Radiation Oncology, Chengdu, China

<sup>2</sup>Fondazione Policlinico Universitario Agostino Gemelli, UOC Fisica Sanitaria, Rome, Italy

### Purpose or Objective

In vivo dosimetry (IVD) is an important tool able to verify the accuracy of the treatment delivered. In an environment where several linacs of different types support daily heavy treatment workload over different shifts of therapists, physicists and Radiation oncologists, IVD checks can be strongly recommended to avoid

important dosimetric discrepancies. The work describes the setup of IVD procedure with electronic portal imaging devices (EPID) in an overload radiotherapy clinical workflow, and the preliminary results obtained.

### Material and Methods

64 patients that underwent a VMAT or IMRT treatments for head and neck, brain, breast, lung, thorax, abdomen and pelvis were scheduled for in vivo dosimetry procedure with EPID. A commercial software (SOFTDISO, Best Medical, Italy) was used at this purpose. Two indexes were analysed: the ratio R between the reconstructed (Diso) and planned (Dtps) isocenter dose ( $R = \text{Diso}/\text{Dtps}$ ) and  $P\%$  obtained performing a gamma analysis between the first EPID image and the next ones acquired. The acceptance criteria adopted for the ratio R was  $\pm 5\%$ , while for the 2D  $\gamma$ -analysis in term of  $P\%$  index, we adopted  $P\% > 90\%$  with a passing criteria of 3% global difference and 3mm distance to agreement for head and neck treatment and 5%, 5mm for the others districts. The percentage of patients P% with  $R_{\text{mean}}$  and  $P_{\text{mean}}$  in the tolerance level  $P\%(R_{\text{mean}})$   $P\%(P_{\text{mean}})$  respectively, and the percentage of IVD test T% with R and  $P\%$  in the tolerance level  $T\%(R)$  and  $T\%(P\%)$ , were evaluated. For each district P% take into account the patients with the mean values of the indexes within the tolerance levels, while the T% is referred to the number of tests. If one of the indexes resulted out of tolerance, corrective actions were performed and the test repeated at the next fraction.

### Results

The results of 1211 IVD tests over 64 patients, were reported in Table 1. All the patients analysed shown both indexes ( $R_{\text{mean}}$  and  $P_{\text{mean}}$ ) in tolerance with the exception of breast and thorax treatments. For VMAT and IMRT thorax treatments  $P\%(P\%)$  decreased to 67%. The thorax patients were revised considering the high gradient regions of the isocenter and the positioning set up was optimized. For IMRT breast treatment,  $P\%(P\%)$  decreased to 50%: two (over four) IMRT breast patients were revised adjusting the bolus positioning over the mask in order to realign the reproducibility of the treatment ( $P\%$  index) in the tolerance level. Adopting the appropriate corrections, the successive IVD tests guaranteed at the end of the treatment P% values within the tolerance levels. For thorax and breast treatments, due to the limitation of IVD tests acquired, the mean  $P\%(P\%)$  index values after the correction, were again out of tolerance but the effect of the correction was always efficient.

	Breast	Thorax	Abdomen	Pelvis	H&N	Brain
<b>P</b>	13 (4)	3 (9)	9 (9)	3 (6)	3 (3)	(2)
<b>T</b>	105 (50)	25 (239)	95 (319)	34 (257)	10 (32)	(45)
<b>P%(R<sub>mean</sub>)</b>	100 (100)	100 (100)	100 (100)	100 (100)	100 (100)	(100)
<b>T%(R)</b>	88 (94)	100 (89)	91 (89)	100 (95)	100 (88)	(90)
<b>P%(P<sub>mean</sub>)</b>	100 (50)	67 (67)	100 (100)	100 (100)	100 (100)	(100)
<b>T%(P<sub>γ</sub>)</b>	93 (75)	76 (75)	95 (90)	95 (95)	90 (84)	(93)

Table 1: Results of 1211 IVD tests over 64 patients for different anatomical districts for VMAT and IMRT treatment (in parenthesis). The number of patients (P), IVD tests (T), percentage of patients with  $R_{\text{mean}}$  and  $P_{\text{mean}}$  in tolerance  $P\%(R_{\text{mean}})$ ,  $P\%(P_{\text{mean}})$ , percentage of IVD tests with R and  $P_{\text{mean}}$  in tolerance  $T\%(R)$   $T\%(P_{\text{mean}})$  were reported.

### Conclusion

IVD with EPID, is a powerful tool that can be inserted in an overload radiotherapy department. It can be helpful daily to monitor the accuracy of the treatment and enable a quickly correction of misalignment or discrepancies occurred during the treatment course.

### EP-1655 Improved patient setup for breast cancer patients using the predicted (absolute) couch position.

M. Essers<sup>1</sup>, S. Hol<sup>2</sup>, I. Maurits<sup>2</sup>, W. Kruijff<sup>1</sup>

<sup>1</sup>Dr. Bernard Verbeeten Instituut, Department of Medical Physics, Tilburg, The Netherlands

<sup>2</sup>Dr. Bernard Verbeeten Instituut, Radiotherapy, Tilburg, The Netherlands

### Purpose or Objective

Usually, patient setup is performed by obtaining a reference position at the first treatment fraction ("relative couch position") and then applying on-line or off-line setup protocols. In our institute, a method is used in which the couch position is predicted before the treatment ("absolute couch position")<sup>1</sup>. The purpose of this work was to investigate whether the patient setup for breast cancer patient is improved using the 'absolute couch position' method.

### Material and Methods

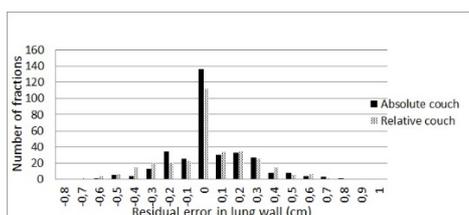

At the time of this study, accurate patient setup was ensured by applying an on-line setup protocol using the patient anatomy (mainly vertebrae, lung tops and sternum) visible on orthogonal (AP and lateral) MV images, and checking the residual deviation of the lung wall on an MV image in the direction of the mediolateral tangential field (ML image).

1. For 83 patients positioned using relative couch positioning as well as 83 patients positioned using absolute couch positioning, the difference in image registration (MV images compared to DRRs) using sternum only or vertebrae only was determined.

2. For the same patients, the residual deviation of the lung wall on the ML image was determined.

### Results

- Using relative couch positioning, the difference between sternum and vertebrae match was smaller than 2 mm for 80% and larger than 5 mm for 12% of the fractions, and for absolute couch positioning, 90% of the fractions showed a match difference smaller than 2 mm and 7% larger than 5 mm. These figures indicate that the patient posture at the linac is slightly in better agreement with the posture at the CT for absolute couch positioning.
- On the ML images, a residual deviation in lung wall position of 5 mm or more was present for 5.1% of the fractions for relative couch positioning and for 2.7% for absolute couch positioning. This also implies a slightly improved patient setup using absolute couch positioning.

### Conclusion

The patient posture as well as patient setup for breast cancer patients is slightly improved using the predicted, or absolute, couch position.

<sup>1</sup> W.J. de Kruijff, R.J. Martens, Reducing patient posture variability using the predicted couch position. *Med. Dosim*, 40:218-21; 2015.

### EP-1656 The inter-fraction variation of the supraclavicular- and the axilla-area in breast cancer patients

S. Gerrets<sup>1</sup>, L. Kroon- van der<sup>1</sup>, M. Buijs<sup>1</sup>, P. Remeijer<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiotherapy, Amsterdam, The Netherlands

### Purpose or Objective

Currently a volumetric modulated arc technique (VMAT) for whole breast irradiation, including the supraclavicular- and axilla-area is being implemented at our institute. In contrast to our currently used tangential fields, VMAT requires a CTV and PTV with corresponding margins. From our clinical experience we know that the setup of the shoulder can be very challenging. The purpose of this study was to quantify the inter-fractional variation of the supraclavicular- and the axilla-area in order to quantify CTV to PTV margins.

### Material and Methods

So far 6 right sided and 6 left sided breast cancer patients, were randomly selected in this ongoing study. Patients were positioned on a Macromedics MBLXI breastboard with upper- and lower- arm trays. During the acquisition of the planning CT skin marks were drawn extended to the humerus to improve reproducibility of the arm positioning. Setup verification and correction was performed based on bony anatomy registration (ribs and sternum) using Cone beam CT and an offline shrinking action level (SAL) protocol. Retrospectively, the residual inter-fraction errors of the supraclavicular area and the axilla were measured by performing bony anatomy registrations using a rectangular region of interest representative for these areas/regions (see Figure 1 'Region of interest'), and determining their difference from the registration on ribs and sternum. From these residual errors, the random and systematic errors were computed and corrected for the use of a SAL protocol (N=3 and  $\alpha=9\text{mm}$ ). Using previously determined setup data from Topolnjak et al [1], Subsequently, the CTV to PTV margins were determined according to the standard margin recipe:  $2.5\sigma+0.7\sigma$ .

### Results

In total 88 Cone beam CT were analyzed; 5-10 scans per patient. Computed residual errors for the supraclavicular region and axilla region are shown in Table 1. The random and systematic residual errors for the axilla regions are larger than the supraclavicular region, as expected. Notable is the small residual error for supraclavicular in LR-direction. The total margins are 0.59cm LR, 0.76cm CC and 0.81cm AP for the supraclavicular region and 0.84cm LR, 0.89cm CC and 0.98cm AP for axilla region.

### Conclusion

For the introduction of a VMAT planning technique for breast and axilla irradiation specific PTV margins adapted for supraclavicular and axilla inter-fraction motion need to be introduced.

### EP-1657 Clinical use of transit dosimetry to analyze inter-fraction motion errors

F. Ebrahimi Tazehmahalleh<sup>1</sup>, C. Moustakis<sup>1</sup>, U. Haverkamp<sup>1</sup>, H.T. Eich<sup>1</sup>

<sup>1</sup>Universitaetsklinikum Muenster, Klinik fuer Strahlentherapie, Münster, Germany

### Purpose or Objective

The aim of this work was to inquire the correlation between the target and organ at risks motions and volume discrepancy with the dosimetric variations at hospital levels. The high resolution, large active area, and effectiveness of the Electronic portal imaging devices offers it to be used for in vivo dosimetry during radiation

therapy as an additional dose delivery check. The transit dosimetry has the potential of testifying dose delivery, the accuracy of MLC leaf positioning and the calculation of dose to a patient or phantom.

#### Material and Methods

In total 42 patients with stereotactic plans were evaluated. Delivery was carried out on a Varian TrueBeam linac equipped with an aS1000 EPID. Continuous portal imaging was performed at each treatment fraction during the delivery of treatment for all beams. To validate the method, we executed treatment plans on a commercial respiratory motion phantom containing plastic spheres as target. Phantom CT scans were made in different phases. First phase were done by applying sinusoidal breathing cycle in different motion amplitudes (-20, -10, 0, 10, 20 mm) in superior/inferior direction and second phase was done by pre-defined breathing simulation with a short pause after exhalation in oscillation mode. Three techniques: 3D-CRT, IMRT and VMAT-SBRT were generated and on board transit dose was collected by EPID during the treatment. The daily obtained portal image were compared with the reference image using the gamma evaluation method with criterion 2% dose difference and 2 mm distance to agreement (DTA) criteria with a threshold value of 5% of maximum value.

#### Results

The area gamma passing rate per arc in most of the plans was higher than the acceptable limit but in some arcs it had lower agreement, the lowest value was 3.7%. Besides irradiating phantom in planned respiratory motion, we re-irradiated the same plans due to displacement of the target by stopping the movement or changing the breathing speed. Gamma parameters such as maximum gamma, average gamma, and percentage of the field area with a gamma value > 1.0 were analyzed. For all the VMAT arcs in phantom measurements, the gamma evaluations were within the tolerance limits ( $\gamma_{max} = 3.5$ ,  $\gamma_{avg} = 0.5$  and  $\gamma\% > 1 = 2\%$ ) though in some measurement 20 mm target displacement was applied. For IMRT fields, measurements were not in good agreement in different tumor motion. 3DCRT fields showed poorest gamma agreement in portal dosimetry analysis.

#### Conclusion

This research increases the need of a tool for monitoring inter-fraction errors by confirming the tumor position within the treatment field over the course of therapy. Using daily EPID images over the course of treatment could potentially provide accurate verification of dose delivery to heterogeneous anatomical regions in patients receiving 3D-CRT and IMRT radiation therapy treatments. However, further studies are required to assess 3D IN VIVO dose verification of VMAT techniques of various treatment sites.

offline protocol where the patient is re-scanned and re-planned two-to-three weeks through treatment. The MR-Linac (Elekta, AB, Stockholm, Sweden) will provide excellent soft tissue contrast which may be desirable for this group of patients. However the electron return effect, caused by the Lorentz force may potentially result in an increased dose to superficial tissues, for example the parotid glands. This effect can be controlled in plan optimisation, however it is unknown whether the presence of a magnetic field makes it necessary to adapt the plan at an earlier stage or more frequently during treatment. The purpose of this abstract is to assess the suitability of the current off-line adaptive radiotherapy workflow for head and neck patients in the presence of a magnetic field.

#### Material and Methods

Ten patients treated with either 66Gy or 60Gy in 30 fractions, were selected from the clinical archive that had shown significant weight loss during treatment which required a repeat CT. Both the initial planning CT (pCT) and the repeat CT (rCT) were fully contoured by an oncologist specialising in head and neck cancer. Two plans were optimised, at 0T and 1.5T using Monaco v5.09 (Elekta AB Stockholm, Sweden) which met the departmental constraints for Target and OAR doses. These plans were copied to the rCT and re-calculated with a 1% statistical uncertainty, allowing the segmentation and delivered MU to remain constant. The magnitude of the change in dose to the target and OARs due to weight loss was compared between the 0T and 1.5T plans. The difference between the dose distribution on the pCT was compared to the distribution on the rCT and how this was affected by the presence of the magnetic field.

#### Results

The percentage difference between 0T and 1.5T plans for the targets showed statistical differences for the D95% for PTV1, PTV2 and PTV3, D50% and mean dose for PTV2, and mean dose and 2cc min for PTV3. The only statistical difference for the OARs was the 2cc max dose for skin which increased by 1.1% for 1.5T plans. However differences between the 0T and 1.5T plans were on average all within 2%, so were considered clinically acceptable.

##### EP-1658 The effect of weight loss in head and neck patients in the presence of a magnetic field

R. Chuter<sup>1</sup>, P. Whitehurst<sup>1</sup>, M. Van Herk<sup>2</sup>, A. McWilliam<sup>2</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Christie Medical Physics and Engineering CMPE, Manchester, United Kingdom

<sup>2</sup>University of Manchester, Manchester Academic Health Science Centre MAHSC, Manchester, United Kingdom

#### Purpose or Objective

Head and neck patients tend to experience weight loss during treatment in a predictable pattern losing between 5-15% of their initial weight over the first two weeks. Adaptive radiotherapy for these patients focuses on an

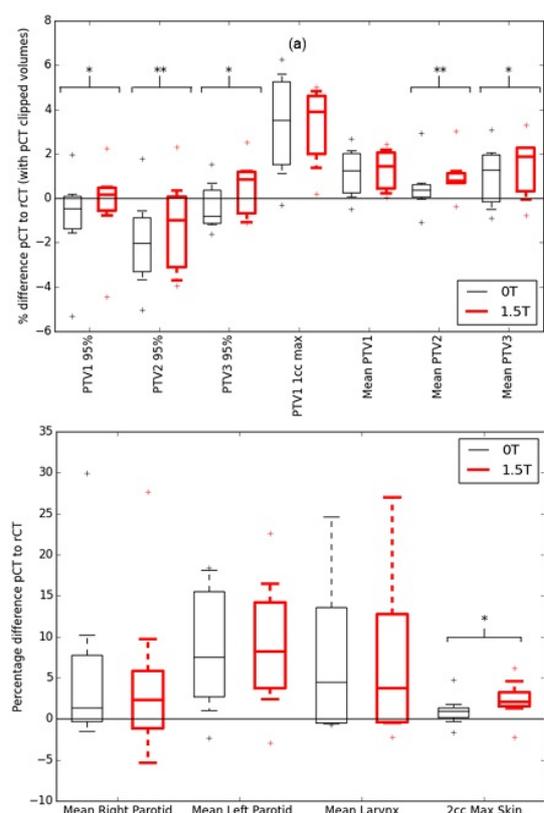

Figure 1. Box plots of the dose statistics for (a) three dose level PTVs illustrating the percentage dose difference between the planning CT (pCT) and rescan CT (rCT) for the magnetic field on (red thick lines) and off (black). The PTVs in the rCT are the PTVs from the pCT copied and clipped to the patient surface by 0.5cm. (b) the percentage dose difference between the pCT and rCT for the magnetic field on (red thick lines) and off (black) for the OARs. Where a \* denotes a significance of  $p < 0.05$  and \*\* a significance of  $p < 0.01$ .

### Conclusion

This work shows that the dosimetric effect of weight loss does not cause any clinically significant changes in the presence of a magnetic field, as the difference between pCT and rCT for 0T and 1.5T are similar. Therefore, current off-line strategies for adaptive planning for head and neck patients are valid for use on the MR-Linac.

**EP-1659 Quantitative triggering of plan adaptation: monitoring plan quality by recalculation on CBCT scans**  
 R. Canters<sup>1</sup>, M. Wendling<sup>1</sup>, M. Kusters<sup>1</sup>, R. Monshouwer<sup>1</sup>  
<sup>1</sup>Radboud University Medical Center, Radiation oncology, Nijmegen, The Netherlands

### Purpose or Objective

Since the introduction of 3D imaging on the linac, anatomical changes observed on CBCT scans regularly lead to plan adaptation. However, adaptation is often triggered by qualitatively assessing anatomical changes between CBCT and planning CT. This regularly leads to unnecessary replanning, disrupting the regular workflow in the clinic. In this study, we created an automated evaluation tool, that recalculates the treatment plan on recorded CBCT scans to indicate if a replanning may be necessary. The aim of this work is to assess its potential for regular clinical use.

### Material and Methods

The recalculation tool imports planning CT and CBCT scan, after which the treatment plan is transferred to the CBCT scan. Subsequently, the plan is recalculated on the CBCT using Pinnacle, and DVH's are compared (Figure 1). The CT-CBCT match is derived from the CBCT match at the linac. Since Hounsfield units (HU) of the CBCT are not

calibrated, a CT to CBCT HU conversion table was created to obtain a reliable CBCT based dose calculation. To validate this approach, we evaluated 11 CT-CBCT registrations of the head with no visible deformations, and compared plan calculations on both scans. To assess the potential to monitor planned dose on the CBCT, 22 patients receiving postoperative head and neck irradiation with 2 or 3 dose levels were evaluated retrospectively for a total of 265 CBCT scans. 5 Patients received a new CT and a replanning during the treatment course. All dose distributions were evaluated on V95% of the PTV, mean dose on parotid glands, mandible, oral cavity, larynx, maximum dose on myelum, and low dose volume (<5Gy).

### Results

Validation on 11 patients of the dose calculation showed an average deviation between planning CT and CBCT scans of less than 1% on all evaluated dose metrics (Figure 2a). Evaluation of 22 patients shows deviations of <5% in PTV coverage in 20 patients over the course of the treatment (Figure 2b). Two patients showed a higher deviation. Patient 14 showed anatomical variation that was not detected during treatment. Patient 18 had a relevant reduction in PTV coverage during treatment course due to weight loss and received a new plan. Four other patients received a replanning because of other considerations, e.g. a deteriorating condition or treatment side effects. In the evaluated OAR's, variations in evaluated metrics of <5% were observed.

### Conclusion

The automated evaluation tool in this study provides a reliable prediction of delivered dose for the daily patient anatomy. Evaluation of a series of fractions shows that it is can detect dose deviations and trigger plan adaptation, with an action level of approximately 5% deviation in V95%. Inclusion of deformable image registration is expected to further increase the reliability of the DVH predictions.

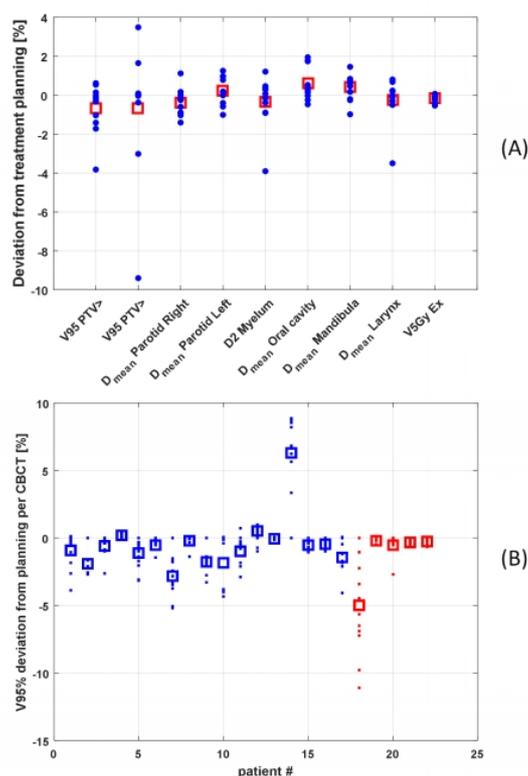

Figure 2: (A) Dose differences on PTV and OAR's for 11 CT-CBCT registrations, in red the averages. (B) Evaluation of variations in V95% of the elective PTV during the treatment for 17 patients without replanning (blue) and 5 patients receiving a new plan (red), with the averages over a treatment series highlighted

#### EP-1660 Improvement in tumour control probability by adapting dose to daily OAR DVCs

D. Foley<sup>1</sup>, B. McClean<sup>1</sup>, P. McBride<sup>1</sup>

<sup>1</sup>St Luke's Reseach Oncology Network, Physics, Dublin, Ireland

##### Purpose or Objective

A technique using analysis of on-board CBCT images to adapt the dose to the target on a fraction-by-fraction basis was developed. This new approach involves using the upper limit of dose volume constraints (DVCs) as the objective to be met at each fraction by tracking and accumulating dose voxels. The aim was to adapt the dose per fraction such that it was optimised each day without any organ at risk (OAR) DVCs being exceeded. The impact on tumour control probability (TCP) and normal tissue complication probability (NTCP) was evaluated.

##### Material and Methods

31 patients who underwent prostate treatment were retrospectively investigated for this study. Initial VMAT plans consisting of 2 arcs were designed to deliver 74 Gy in 37 fractions of 2 Gy each to the target. The patients had on-board CBCT scans taken prior to treatment for between 9 and 33 fractions (436 in total).

An in-house registration algorithm based on phase correlation[1] was used to retrospectively register CBCT images to the planning CT to determine the transformations and deformations in patients' anatomy. This allowed the original plan to be recalculated on the registered CT image that provided the position of the target and OARs for that fraction. By tracking individual voxels throughout treatment, the dose was accumulated and the DVHs and DVC values were determined for each fraction.

The DVCs were then used as limits such that the dose that could be delivered would result in the tightest constraint being just met. Therefore, the dose for that fraction was increased or decreased to ensure that the DVC was on the tolerance limit. The impact of the dose escalation was then evaluated using TCP and NTCP.

##### Results

Thirteen of the patients investigated could have received net higher doses during their treatment without exceeding their OAR DVCs. In the remaining 18 patients, only 20 fractions out of 257 would allow an increase in dose while staying below the DVC limits. The rectum was the limiting structure in 97 % of fractions.

The largest individual increase possible for a given fraction was 87.4 cGy. If all changes were made, the maximum accumulated net increase in dose possible for any patient was 13.58 Gy, assuming the imaged fractions were representative of the patients' entire treatment and scaling to a full treatment. This corresponded to an increase in TCP and rectal NTCP of 13.7 % and 13.6 % respectively. Table 1 shows the results for the 13 patients.

##### Conclusion

Adapting the dose to be delivered to the patient on a fraction-by-fraction basis has the potential to allow for significant dose escalation while staying within institutional DVCs, significantly increasing TCP. This could be particularly useful in the hypofractionation approach to treatments.

[1] Physica Medica, 32(4):618-624, 2016.

#### EP-1661 Adaptive strategy to accommodate anatomical changes during RT in oesophageal cancer patients

T. Nyeng<sup>1</sup>, M. Nordmark<sup>2</sup>, L. Hoffmann<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Medical Physics, Aarhus C, Denmark

<sup>2</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

##### Purpose or Objective

During chemoradiotherapy (chemoRT) in oesophageal cancer (EC), some patients show large interfractional anatomical changes. These changes may affect the dose distribution adversely, demanding adaptation of the treatment plan. The aim of this study was to investigate a decision support system for treatment adaptation based on daily cone-beam CT (CBCT) scans.

##### Material and Methods

Twenty consecutive patients treated with chemoRT for oesophageal and gastro-oesophageal junction cancer were setup to the spinal cord with a tolerance of 5mm using daily CBCT scans. On CBCT, mediastinal structures are barely visible. Therefore, a surrogate structure (SS) was used to evaluate the actual target position. The SS was generated by indicating the borders between dense tissue nearby the clinical target volume (CTV) and lung tissue or air, see Fig1. Geometrical changes above 3mm in the tissue defined by the SS were registered by the radiation therapists (RTTs) for each fraction. Additionally, the RTTs noted changes of the base line diaphragm position above 5mm, the mediastinum above 5mm, the body contour above 10mm, and the shoulder blades above 10mm. Three consecutive registrations in any category triggered an adaptation of the treatment plan, requiring a new CT-scan with IV contrast. Targets and organs at risk were re-delineated, based on deformably propagated contours from the planning CT-scan. We recalculated the original treatment plan on the new CT-scan to evaluate the consequences of the observed anatomical changes.

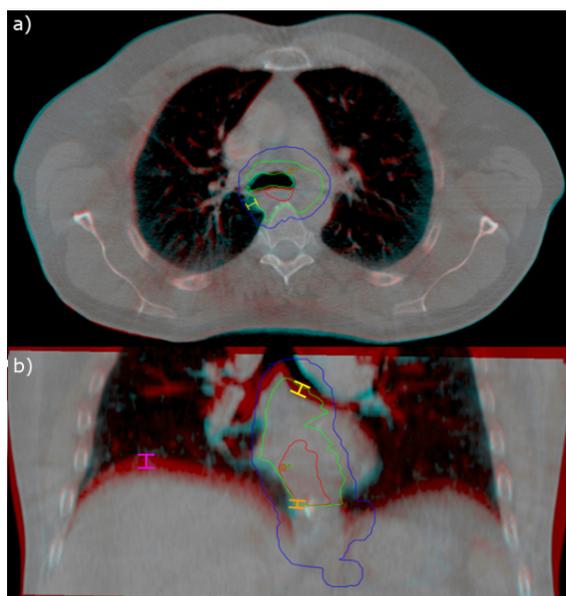

Fig.1: Red outline: Gross tumour volume (GTV); Blue outline: PTV; Green outline: target surrogate structure (SS). Red image: CT; Turquoise image: CBCT. a) Fraction 15 of 23 of RT (25,2Gy delivered in 1,8Gy fractions). Tissue surrounding the GTV has swollen by 6,7mm (yellow marker). This anatomical change is registered as a SS tolerance violation. b) Fraction 16 of 23 of RT (27,0Gy delivered in 1,8Gy fractions). The diaphragm baseline has shifted 8,7mm in caudal direction (magenta marker), stretching the mediastinum 7,9mm in the same direction (yellow marker) and displacing a gold implant near the target base by 5,1mm caudally (orange marker).

## Results

Thirteen patients had their RT plan adapted at least once during treatment. In the first adaptation (13 pts), the median decrease in the CTV receiving 95% of prescribed dose (V95%) and the planning target volume (PTV) was 0.2% [0-6.4%] and 5.2% [0-11.7%], respectively, see Fig2. The largest underdosage was related to interfractional baseline shifts in the diaphragm position (6 pts), with a median decrease in CTV V95% of 0.6% [0-6.4%] and PTV V95% of 8.6% [1.7-11.7%]. Target deviations registered as changes in SS (8 pts), were typically caused by swelling of the target area (7 pts), shrinkage or swelling of the mediastinum (4 pts) and/or compression or stretching of the target due to changed diaphragm position (1 pt). Changes in SS were pooled and showed a median decrease in CTV V95% of 0.2% [0-0.6%] and PTV V95% of 5.0% [0.5-6.9%].

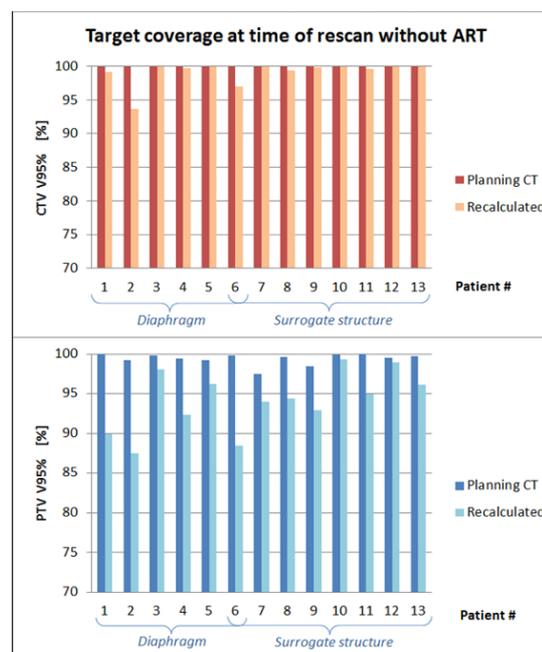

Fig.2: Volumes of CTV and PTV covered by 95% of the prescribed dose (V95%) at planning, compared with the original plan recalculated on the adaptive CT-scan. Patients 1-5 were rescanned due to changes in diaphragm level, whereas patients 7-8 were rescanned due to changes in the surrogate structure. Patient 6 showed changes in both categories. CTV underdosage was most pronounced in patients with diaphragm changes, whereas PTV coverage was sensitive to changes in both categories.

Four pts had a second adaptation during RT. For these pts, changes above tolerance were solely observed for SS. The median decrease in CTV V95% was 0.2% [0-2.1%] and PTV V95% was 4.5% [0.6-7.2%]. None of the twice adapted patients showed changes in anatomy which justified reverting to the original treatment plan - either the changes were further in the same direction or in a different region. **Conclusion**

Target coverage during the chemoRT in EC patients was compromised in some cases due to interfractional anatomical changes. Changes observed during RT persisted and in some cases they increased, making adaptation of the RT plan necessary.

## EP-1662 Interfractional trend analysis of sinograms: a decision-making for adaptive radiotherapy

S. Bresciani<sup>1</sup>, A. Garelo<sup>1</sup>, A. Miranti<sup>1</sup>, A. Maggio<sup>1</sup>, A. Di Dia<sup>1</sup>, P. Gabriele<sup>2</sup>, M. Stasi<sup>1</sup>

<sup>1</sup>Candiolo Cancer Institute - FPO- IRCCS, Medical Physics, Candiolo TO, Italy

<sup>2</sup>Candiolo Cancer Institute - FPO- IRCCS, Radiotherapy, Candiolo TO, Italy

## Purpose or Objective

The aim of this study is to investigate how geometric and anatomical changes can be detected in daily sinogram informations and how this information can be used to examine interfractional trends, building toward a methodology to optimize treatment and support adaptive replanning.

## Material and Methods

Sensitivity of detectors and sinograms complex to detect shift errors and anatomical variations was previously tested on thoracic phantom. In particular systematic variations in shifts (1-5 mm in lateral direction), anatomical variations (adding 1.25-2.5 cm bolus over phantom) were applied.

Subsequently, a total amount of 106 patients treated with Tomotherapy and their related 1573 sinograms were analyzed. The sinograms, measured using Xenon detectors integrated in Tomotherapy unit, were compared with a reference one (usually the first fraction) using both

organ (CTV) and global percentage gamma pass (%GP) evaluation (criteria: 3%/3mm, 2%/2mm and 1%/1mm). For each patient mean %GP, standard deviation ( $\sigma$ ) and angular coefficient of linear fit of %GP were evaluated. In particular  $\sigma$  is used to monitor random set-up and preparation errors while the angular coefficient is used to monitor the target size variation and tumor response during treatment course. The results were correlated to treated pathologies.

### Results

The phantom results showed a sensitivity equal to 100% in detecting all simulated errors.

The obtained results are described in the table

Pathologies	Mean CTV %GP	Standard deviation	Angular coefficient
Gynecologic	84.5	6.5	-0.7
Head & Neck	92.6	4.0	-0.3
Lung	90.5	3.4	-0.4
Rectum	86.6	4.9	-0.2
Breast	94.7	1.9	-0.1

ANOVA analysis pointed out that the significance of the difference between %GP and pathologies exists only when calculating mean %GP,  $s$ , and angular coefficient with the 1%/1mm CTV criterion, obtaining respectively  $p < 0.006$ ,  $p < 0.04$ , and  $p < 0.04$ . Applying the other criteria, the obtained results were  $p > 0.05$ .

The results showed that gynecological patients, followed by lung, head and neck, and rectum pathologies are the most responsive patients.

### Conclusion

Based on these results, we can state a general correlation law between angular coefficient of %GP and treated pathology to search a quantitative parameter to help predict adaptive radiotherapy. This methodology could provide an important element toward informed decision-making for adaptive radiotherapy.

### EP-1663 Automated full-online replanning of SBRT lymph node oligometastases for the MR-linac

D. Winkel<sup>1</sup>, P. Kroon<sup>1</sup>, J. Hes<sup>1</sup>, G. Bol<sup>1</sup>, B. Raaymakers<sup>1</sup>, I. Jürgenliemk-Schulz<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

Diagnostic imaging on the MR-linac most probably provides better visibility of lymph nodes compared to CBCT on conventional linacs. While commercially available plan adaptation methods are feasible, full-online replanning is the preferred method to reach good plan quality. The aim of this study is to investigate the feasibility of fast online replanning on the MR-linac to account for inter-fraction motion for stereotactic body radiotherapy (SBRT) of lymph node oligometastases.

### Material and Methods

Patient imaging data and delineations from seven advanced cervix cancer patients with a combined total of 33 lymph nodes in the abdominal and pelvic region were included. A planning simulation study was performed on these lymph nodes with a 7-field IMRT technique and a prescription dose of 5x 7Gy to 95% of the PTV. Treatment plans were automatically generated using the research version of Monaco by Elekta AB (Stockholm, Sweden) with the use of their research automation API and in-house developed automated treatment planning software. A CTV-PTV margin of 3mm in all directions was applied. To decrease optimization time an additional margin of 5mm around the PTV was applied and only the parts of the OAR's within this margin were considered as OAR during the optimization (Figure 1). All plans were generated using the MR-linac machine model and a 1.5T magnetic field in superior-inferior patient direction. Dosimetric outcomes were evaluated against clinical dose constraints and optimization time was measured. When required, PTV coverage ( $V_{100\%} > 95\%$ ) was sacrificed to meet all OAR dose

constraints.

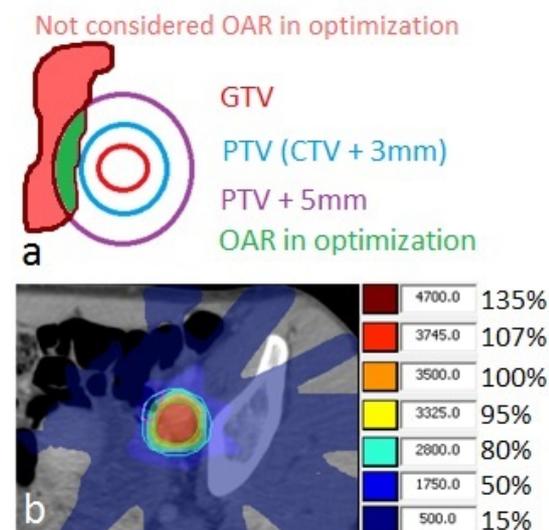

Figure 1: a) A schematic representation of the planning strategy applied in this study to reduce optimization times. b) Resulting dose distribution with isodoses (cGy).

### Results

For 30 (91%) of the 33 cases no clinical dose constraints are violated in combination with sufficient PTV dose coverage. In the other 3 (9%) cases PTV coverage is reduced by  $5.4 \pm 3.0\%$  to meet all dose constraints of the OAR. The average time required for optimization is  $158 \pm 95$  s. The estimated dose delivery time, as reported by Monaco, is  $198 \pm 32$  s. This leads to a total average optimization and delivery times of  $357 \pm 124$  s, which fits well within the proposed 30 minute time limit for treatment on the MR-linac. Both the optimization and delivery time are dependent on the volume of the PTV and increases with increasing PTV. The average PTV is  $6.4 \pm 5.1$  cc (range, 1.8 - 28.3 cc).

### Conclusion

We have shown that automated full-online replanning for the MR-linac to account for inter-fraction motion is feasible for SBRT of lymph node oligometastases. With the planning strategy as applied in this study we are able to automatically generate treatment plans, suitable for clinical use, within a timespan which is clinically acceptable for treatment on the MR-linac.

### EP-1664 Two-step verification of dose deformation in presence of large inter-fraction changes during LACC RT

A. Gulyban<sup>1</sup>, M. Baiwir<sup>1</sup>, S. Nicolas<sup>1</sup>, M. Enescu<sup>2</sup>, V.P. Nguyen<sup>1</sup>, M. Gooding<sup>2</sup>, T. Kadir<sup>2</sup>, J. Hermesse<sup>1</sup>, V. Baart<sup>1</sup>, P.A. Coucke<sup>1</sup>, F. Lakosi<sup>3</sup>

<sup>1</sup>Liege University hospital, Department of Radiation Oncology, Liege, Belgium

<sup>2</sup>Mirada Medical Ltd., Department of Research, Oxford, United Kingdom

<sup>3</sup>University of Kaposvar, Health Science Center, Kaposvar, Hungary

### Purpose or Objective

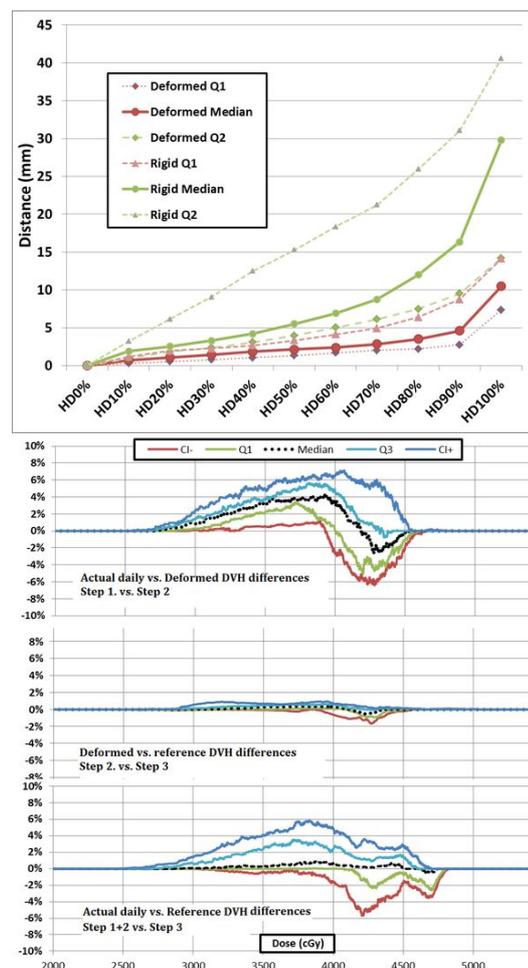

Dose accumulation is one of the most challenging parts of modern radiotherapy, especially in the presence of large inter-fraction motion. Determining actual dose to a given organ during external treatment of locally advanced cervical cancer (LACC) is one of the most prominent examples. In our current investigation we aimed to evaluate the residual dose deformation errors during the summation of dose for clinical target volume (CTV), bladder and rectum.

### Material and Methods

Eleven LACC patients were included in this study treated between 06/2015 and 06/2016. Before each of the 25 treatment session, online corrected CBCT acquisition was performed (XVI 5.0, Elekta Ltd., Crawley, UK). Using the daily CBCTs the CTV, bladder and rectum were delineated (actual position), and the actual dose volume histogram (DVH\_actual) was calculated using the reference dose matrix (rigidly transferred). For a topological co-registration a constraint-based deformation using Radial Basis Function with Robust Point Matching (RBF-RPM) was performed between the current and the reference position of each given organ using Mirada RTx (1.6.3, Mirada Medical Ltd, Oxford, UK). Hausdorff-distance distributions (HDDs) from the reference volume towards the initial and deformed positions were assessed and the accuracy of the RBF-RPM deformation was evaluated. Further two DVHs were generated by deforming the dose matrix (transferred previously to the CBCT) in combination with the actual contour deformed (DVH\_deformed) or with the reference delineation (DVH\_reference). Differences between the relative DVHs were assessed in two steps: 1) the residual error of the deformation (DVH\_actual vs. DVH\_deformed) and 2) the volumetric mismatch sourced from the constraint-based RBF-RPM approximation (DVH\_deformed vs. DVH\_reference). Volume-specific confidence intervals were determined for the separated and combined steps.

### Results

A total of 621 DVHs were generated. The HDDs (Figure 1, from reference) were reduced from the initial 30.5 mm (standard deviation, SD = 16.6) to a reasonably good 10.4 mm (SD = 6.4) confirming a good performance of the constraint-based RBF-RPM (Figure 2, bladder). The initial deformations were responsible for maximum of 3.8%/6.9% and 5.7% errors for CTV, bladder and rectum respectively, reaching a total combined maximum discrepancy of 4.6/7.2/6.2%. For CTV deviations are observed between 40-55 Gy, while for bladder and rectum after 25 Gy errors can be seen. The interquartile errors remained within +/- 5% deviations for the entire dose range.

### Conclusion

Using a two-step clinical verification of the dose deformation confirms the feasibility to perform accurate dose accumulation for CTV, bladder and rectum during LACC RT. These values are within the range of uncertainties originated from dose calculation, residual positioning errors or anatomical changes, confirming the reasonable clinical usage.

**EP-1665 Library of plans approach for bladder cancer radiotherapy including a simultaneous integrated boost**  
 S. Nakhaee<sup>1</sup>, L. Hartgring<sup>1</sup>, M. Van der Burgt<sup>1</sup>, F. Pos<sup>1</sup>, P. Remeijer<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiotherapy, Amsterdam, The Netherlands

### Purpose or Objective

With image guided radiotherapy the positioning of patient can be corrected accurately by a table shift after a registration procedure. However, for large deformations of the target area, for example due to inter-fractional changes in bladder filling, table shift might not fully compensate the variation. Compared to full bladder treatments, the need for accuracy in dose delivery is even more profound for bladder patients receiving simultaneously increased dose to the gross tumor volume (GTV). A daily plan selection from a library of plans is a strategy to tackle this challenge. With this approach, a number of radiation treatment plans are made for a set of anticipated shapes and positions of the target prior to treatment. At every fraction the most suitable plan can then be selected. The purpose of this study was to develop an interpolation method to

generate a library of plans for bladder treatments with a combined target of the total bladder and the GTV.

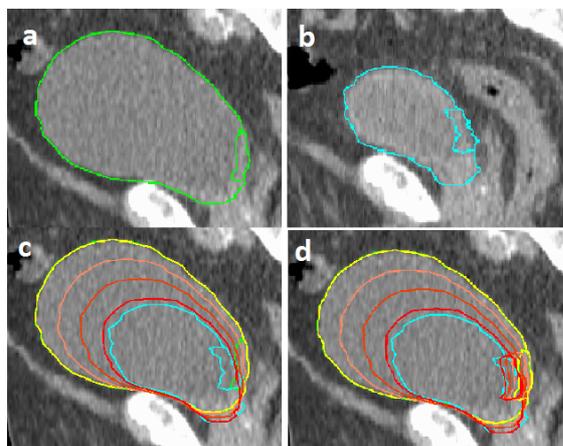

#### Material and Methods

Two CT scans were acquired and registered (empty/full bladder). The bladder CTVs and GTVs were delineated on both CTs. An in-house developed script was developed to calculate intermediate CTVs and GTVs based on the empty and full bladder delineations. The script, which utilizes a Robust Point Matching (RPM) algorithm (Osorio, 2012), yields a deformation vector field that can transform the target structure to the reference structure. The algorithm can be tuned with the following parameters: stiffness, density of points, number of iterations and the final "temperature".

To create intermediates, the deformation can be applied partially, e.g., to create a structure in the middle of the two input structures, a 50% deformation would be applied. Dividing the maximum spacing required between consecutive intermediate plans by the maximum distance between reference and target structure, will give the excitation percentages required to get to equidistant intermediate structures. Bladder CTV and GTV need to be handled by separate RPM processes because the required parameters are very different due to large discrepancy of deformation and size. The number of plans is set by the maximum distance between full and empty CTVs. Therefore first the intermediate structures for CTV are created and then the same excitation percentages are applied to GTV.

#### Results

Figure 1 shows an example of a generated library of plans for CTVs and GTVs. To evaluate the results we create a structure with 100% deformation, which should coincide with the target structure. Using the default stiffness parameter for 10 patients (1000 for CTV and 250 for GTV) we found a success rate of 60%. By tuning the stiffness parameter, intermediate structures were created successfully for the remaining cases. On average it takes 3.50 and 2 minutes for the CTVs and GTVs to be created, respectively.

**Figure 1:** Example of library of plan made for a bladder patient. (a) In green delineation of CTV and GTV on the pre-treatment full bladder CT scan. (b) In blue delineation of CTV and GTV for the empty bladder geometry on the pre-treatment empty bladder CT scan. (c) In shades of orange the library of plans made for bladder CTV. (d) Library of plans made for CTV and GTV is shown simultaneously.

#### Conclusion

We have developed a robust, quick and straightforward method to generate a library of plans for a combined bladder CTV and GTV using delineations of full and empty bladder CTs. The method is able to generate plans at every cm from full bladder.

#### EP-1666 Adaptive radiotherapy in prostate cancer: when and why?

R. Muelas<sup>1</sup>, R. García<sup>2</sup>, L. Vidueira<sup>2</sup>, J. Bonaque<sup>2</sup>, A. Conde<sup>1</sup>, C. Ferrer<sup>1</sup>

<sup>1</sup>Consortio Hospitalario Provincial de Castellón, Oncología Radioterápica, Castellón, Spain

<sup>2</sup>Consortio Hospitalario Provincial de Castellón, Radiofísica y protección radiológica, Castellón, Spain

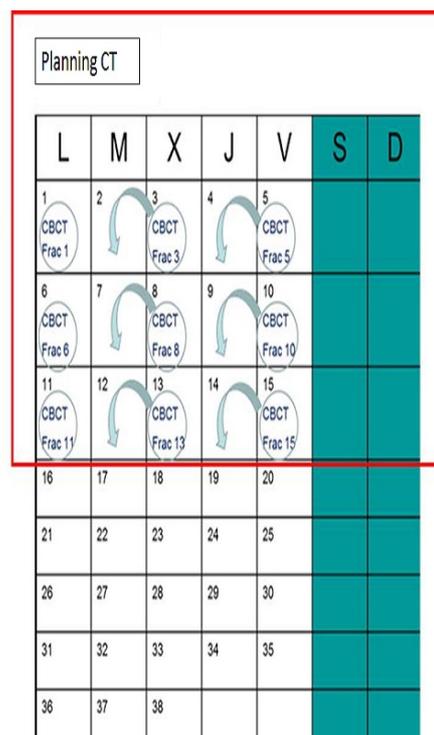

#### Purpose or Objective

To evaluate if planned doses for prostate and rectum are equal to the doses which are actually delivered and to determine adaptation points for the accumulated dose.

#### Material and Methods

Twenty four patients with intermediate and high-risk prostate cancer who were going to be treated with image guided radiotherapy were enrolled. A plan-CT (pCT) and nine treatment kilovoltage conebeam-CT (kVCBCT) scans were acquired prospectively during the first three weeks of a prostate IGRT treatment (a total of 240 CTs). A rectal emptying preparation and a full bladder protocol were used. For each patient, a deformable image registration (DIR) from the pCT to each of the nine kVCBCT was performed with RayStation treatment planning system. All registers were revised and recontoured by a Radiation Oncologist, establishing regions of interest (ROIs) for a second DIR with control of such ROIs. For every patient, a hypofractionated VMAT schedule (15 x 3.82 Gy) was planned and correlated with their kVCBCT images, being able to determine the accumulated and total doses that would have been actually delivered. Since the pCT day, a nutritional evaluation control with anthropometric and biochemical parameters was performed for each of the 24 patients.

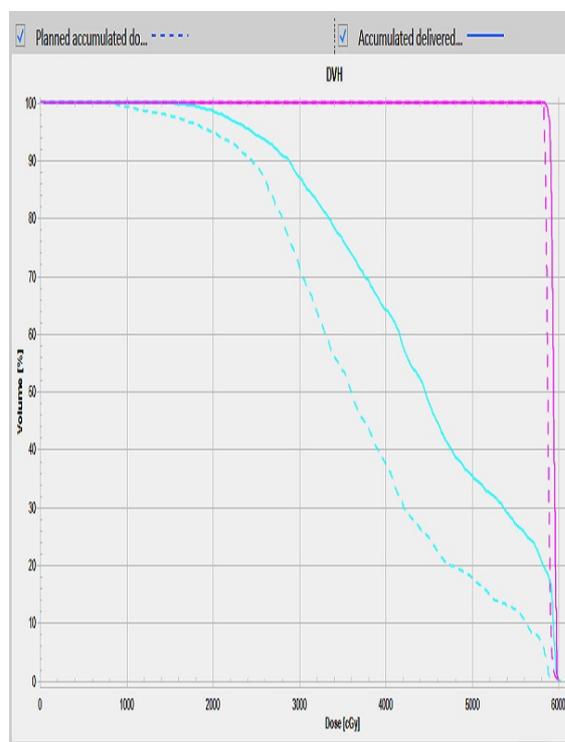

IGART

#### Results

A significant difference between planned and delivered D98 CTV 57 ( $p=0.026$ ) and D2 CTV 57 ( $p=0.005$ ) was observed; however, the average D98 CTV 57 delivered was higher than the prescription dose. Despite not having observed a significant difference in V36.5 of the planned and delivered to the rectum, the delivered doses to 50% of the rectum exceeded the planned constraints in 37.5% of the patients. A significant rectum volume variation was observed during the first week of treatment. An accumulated delivered dose to 50% of rectum > 1194 cGy in fraction five was a significant predictor for exceeding

the rectum constraints. There was an average weight gain of 668 gr between the pCT day and the first day of treatment, but no significant relation with not fulfilling the prescription goals or organ at risk constraints was observed.

### Conclusion

The significant differences between CTV 57 prescribed doses and those actually delivered do not have a clinical impact because the average D98 CTV 57 is higher than the prescribed dose. The V 36.5 delivered to the rectum in 37.5% of the patients exceed the planned constraints, although this difference is not significant. The subgroup analysis has shown significant anatomical variations. The fraction five adaptation point for the accumulated doses in the rectum (1194 cGy) allows to significantly predict when the risk of not fulfilling the rectum V36.5 constraint is high and a plan adaptation is needed. The significant weight gain between the pCT day and the first day of treatment has no significant relation with not fulfilling the prescription goals or organ at risk constraints.

### EP-1667 MR-Guided Radiotherapy of Head and Neck Cancers: Adaptive Planning Strategies

N. Dogan<sup>1</sup>, K. Padgett<sup>1</sup>, M. Duffy<sup>1</sup>, M. Samuels<sup>1</sup>

<sup>1</sup>University of Miami- Sylvester Comprehensive Cancer Center, Department of Radiation Oncology, Miami-Florida, USA

### Purpose or Objective

Adaptive Radiotherapy (ART) with frequent imaging has been used to improve dosimetric accuracy by accounting for anatomical variations, such as primary tumor shrinkage and/or body weight loss, in head-and-neck (H&N) cancer patients. MR-guided radiotherapy technology provides daily real time MR images in the treatment room, hence has a great potential for online adaptive radiotherapy. The purpose of this study is to provide an assessment of different adaptive planning strategies using three-source Co<sup>60</sup> and Magnetic Resonance Imaging (MRI) Guided Radiation Therapy (MR-IGRT) System for treatment of H&N cancer patients.

### Material and Methods

Patients with locally advanced H&N cancers were selected for this study. For each patient, six weekly MR imaging were acquired on the ViewRay MR-IGRT system during the course of radiotherapy. PTVs, parotids, cord, brainstem, mandible, oral cavity and larynx were contoured on planning MR image and all structures were deformably-mapped on the weekly MR images. Three ART planning strategies were explored: 1) A new optimized IMRT plan on each weekly MR image (WeeklyAdapt) 2) A new optimized IMRT plan on week four MR image only (OneAdapt) and 3) Calculating the plan from the planning MR on each weekly MR image (NoAdapt). The PTV coverage for all ViewRay MR-IGRT plans were such that 95% of the PTV received 100% the prescription dose. The differences between accumulated doses on planning MR for all three ART strategies were evaluated using the dose-volume constraints for targets and critical structures.

### Results

For PTV70, PTV60 and PTV54, as compared to the D95 coverage on planning MR, the differences in D95 accumulated doses between three ART strategies were <2%. The maximum dose to both cord and brainstem between WeeklyAdapt and only OneAdapt were very similar and <1% as compared to the planning MR values. However, NoAdapt Dmax for brainstem and cord were >27% and 25% than the original planning MR Dmax values respectively. The mean left and right parotid dose remained very similar both WeeklyAdapt and OneAdapt strategies although there were up to 10.7% increase in the mean dose to the parotids with NoAdapt strategy.

### Conclusion

This study demonstrated that no significant differences in accumulated doses were observed between weekly ART and only one ART at week four during MR IGRT of H&N cancer patients. Further studies are needed to evaluate benefits of daily online ART during MR IGRT.

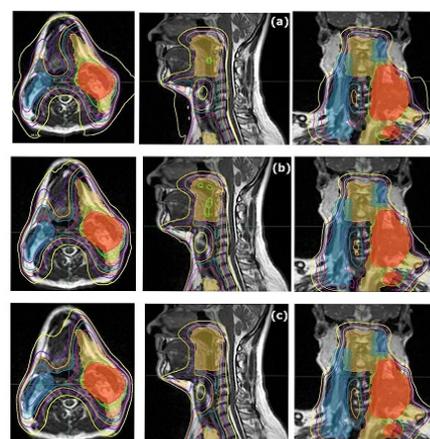

Figure 1: MRI-guided deformable dose accumulation displayed in axial, sagittal and coronal slices for (a) No Adaptation (b) adaptation after 22 fraction and (c) weekly adaptation for one of the head and neck cases included in this study. Note that 70Gy: Green, 60Gy: Pink, and 54Gy: blue. PTV70: Red, PTV60: yellow, and PTV54: blue.

### EP-1668 Dose calculation accuracy using CBCT images for head and neck VMAT

M.A. Carrasco Herrera<sup>1</sup>, B. Quintana<sup>2</sup>, J.M. Nieto<sup>2</sup>, F.J. Luis Simon<sup>1</sup>, C. Santa Marta Pastrana<sup>3</sup>

<sup>1</sup>Hospital Universitario Virgen del Rocío, Medical Physics department, Sevilla, Spain

<sup>2</sup>Hospital Universitario Virgen del Rocío, Radiation Oncology department, Sevilla, Spain

<sup>3</sup>Universidad Nacional de Educación a Distancia UNED,

2U Department of Mathematical Physics and of Fluids,  
Madrid, Spain

### Purpose or Objective

Assessment of the differences between CT and CBCT based dose calculation for a volumetric modulated arc therapy (VMAT) in head and neck radiotherapy treatment.

### Material and Methods

CBCT images of an Alderson RANDO phantom with tissue-equivalent material were acquired in a Varian's On-Board Imager OBI (v1.5) installed on a Varian DHX accelerator, using its standard-dose head protocol (100 kV and 2.5 slice thickness). On the other hand, planning CT images were acquired in a Toshiba Aquilion LB using the same phantom and with our own clinical head and neck protocol (120 kV and 3 mm slice thickness). Different OAR (Body, spinal cord, parotids, mandible, oropharynx, dermis, an inner ring with 1 cm thickness and shoulder) and a PTV were delimited. Additionally, reference points were inserted over all these structures. All defined structures and points were registered with the CBCT images by means of the Varian rigid registration software. Both the delimitation of volumes and the design of the treatment plan have taken into account the limited field of view of CBCT (length 16 cm, diameter 25 cm). A head and neck VMAT plan has been calculated in Eclipse (v10) using both sets of images. For CT images, we only used a standard calibration curve and 3 different calibration sets of curves for CBCT images, i.e., standard, measured with a CATPHAN 504 phantom and measured with a CIRS 062M head phantom placed between head and neck RANDO slices. Dose and HU were calculated in all reference points as well as dose-volume-histograms for the anatomical locations for both CT and CBCT. A gamma analysis was used for HVD comparison.

### Results

The mean HU differences are less than 50 HU and the relative dose differences are less than 3% for all the calibration curves (Table 1) on every reference point over all the structures.

The gamma (2%, 2 mm) DHV analysis shows an excellent agreement for almost all the structures (>95%) (Image1). Ring and dermis have gamma >85%. The non-pass regions correspond to very low dose regions. The worst gamma (>50%) corresponds to the left parotid because it is a very small structure (10 cc) into a high gradient dose zone. Furthermore, there is a difference of 1.8% on its volume as measured on the CBCT and the CT images, probably due to interpolation errors. These results are similar for all the calibration curves analysed.

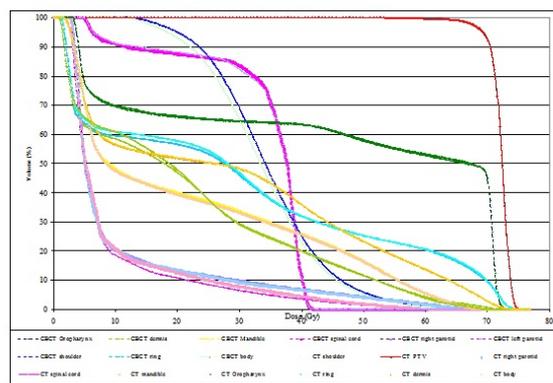

Image1: HDV comparison for CT-CBCT standard calibration curve

		Dif. HU CT-CBCT	Relative dose difference (%) CT-CBCT		
			CIRS	CATPHAN	STANDARD
Oropharynx	Mean	4	-0.94	-1.04	-0.13

	Standard deviation	66	3.43	3.01	3.11

Table 1: HU and relative dose point difference grouped by structures.

### Conclusion

CBCT images for a head and neck VMAT treatment provide accurate dose calculation in adaptive radiotherapy, making them suitable for the assessment of possible changes over the original treatment planning for all the calibration curves analyzed.

### EP-1669 Assessment of the clinical value of off-line adaptive strategies for tomotherapy treatments

D. Dumont<sup>1</sup>, X. Geets<sup>2</sup>, M. Coevoet<sup>2</sup>, E. Sterpin<sup>1</sup>

<sup>1</sup>Université catholique de Louvain, MIRO, woluwe-saint-lambert, Belgium

<sup>2</sup>Cliniques Universitaires Saint-Luc, radiotherapy, woluwe-saint-lambert, Belgium

### Purpose or Objective

This study assessed the clinical potential of offline adaptive strategies based on the dose computed on daily MVCTs (Tomotherapy). We defined clinical indicators that were subsequently used to identify the percentage of plans that should have been adapted due to significant dose deviations to TVs or OARs. Only the consistency of the initial plan throughout the treatment was addressed. Thus, dose was reported to constants TVs and deformed OARs.

### Material and Methods

Cumulative doses were calculated from daily MVCT for 41 lung, 50 prostate and 21 H&N patients, using research versions of off-line adaptive solutions from Accuray and 21<sup>st</sup> century Oncology. All deformed contours were checked by an experienced radiation oncologist, while all dose calculations were crosschecked using our in-house Monte Carlo model (Tomopen). The clinical indicators

were the DVH metrics used during the treatment planning for each considered OAR (e.g.  $D_2$ ,  $V_5$ ) and TVs (e.g.  $D_{50}$ ). Dose constraints were also defined according to the tumor site (e.g.  $D_{mean}$  Parotid < 30 Gy). Two levels of warning were considered:

- red flag: a 10% deviation of the clinical indicator relative to the planned value (e.g. for the parotid  $\Delta D_{mean}$  (cumulated) > 10%  $D_{mean}$  (planned)) AND a violation of a dose constraint (e.g. for the parotid  $D_{mean}$  (cumulated) > 30 Gy)
- orange flag: a 10% deviation of the clinical indicator relative to the dose constraint (e.g. for the parotid  $\Delta D_{mean}$  (cumulated) > 3 Gy).

Both adaptive software evaluated the dose to TVs using deformed PTVs. This approach is questionable because the PTV corresponds to a geometrical (not anatomical) safety margin. Therefore, we reported the dose on rigidly registered PTVs.

### Results

Deformed contours were judged acceptable for all H&N and lung cases. However, registrations failed for most pelvic cases, for which large anatomical deformations occurred (see figure 1). Consequently, pelvic cases were excluded.

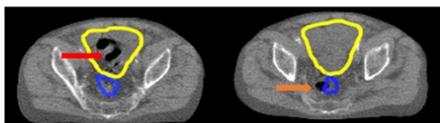

Figure 1: On the left image, an MVCT slice where the deformed bladder (yellow contour) erroneously included a bowel loop (red arrow). On the right image, an MVCT slice (from another fraction) where the deformed rectum (blue contour) failed to include a rectal gas (orange arrow).

Dose calculation of both analytical engines were in good agreement with TomoPen (around 1.5% mean difference on PTV  $D_{50}$ ).

Results are reported in Table 1. For TVs, only 6 flags (out of 62 patients) were reported for the rigidly registered PTV, which was considered as the only relevant volume. The flags reported for lung cases were irrelevant because of the blurring of the tumor density leading to large dose calculation deviations. For the H&N case, the red flag was rejected after analysis (wrong doses in part of the PTV out of the external contour). For the OARs, one H&N was flagged (true flag) with an increase of 11% of the mean parotid dose that exceeded the dose constraint (30 Gy).

Structure/Flag	Red	Orange	Flagged clinical indicator
Deformed PTV H&N	5 (23.8%)	3 (14.3%)	D99
Deformed PTV lungs	10 (24.4%)	8 (19.5%)	D99 and D95
Rigid PTV H&N	1 (4.7%)	2 (9.5%)	D99
Rigid PTV lungs	2 (4.8%)	1 (2.4%)	D99 and D95
Deformed OAR H&N	1 (4.7%)	-	Parotid Dmean
Deformed OAR lung	-	-	-

Table 1: Results of the flagging process (based on the cumulative DVH) for 41 lung and 21 H&N (number and percentage of flagged patients) and the clinical indicator including flag.

### Conclusion

Considering a constant PTV, the impact of treatment adaptation on the quality of delivered plans is minor for the included patients. The conclusion might be different for pelvic cases due to the larger anatomical deformations. Conclusions might also differ for an adapted PTV, but such strategy must address clinical considerations before implementation.

### EP-1670 Couch shifts in NAL protocols: ¿Which is the optimal threshold?

A. Camarasa<sup>1</sup>, V. Hernández<sup>1</sup>

<sup>1</sup>Hospital Universitari Sant Joan de Reus, Servei de Protecció Radiològica i Física Mèdica, Reus, Spain

### Purpose or Objective

The NAL protocols applied to patient positioning in treatments evaluated by CBCT use a threshold regarding couch shifts. If the CBCT demands shifts over the

threshold, the patient must be moved, while shifts below the threshold remain as residual errors. The aims of this study are: (1) to determine the relation between the treatment positioning uncertainty and the corresponding workload, and (2) to obtain the optimal threshold for couch shifts in prostate treatments.

### Material and Methods

The quadratic sum of the uncertainties associated with patient positioning is calculated. If the proposed shifts remain below the threshold, the uncertainties are related to the CBCT matching procedure and to the distribution of residual errors. If the shifts are over the threshold, the uncertainties are due to the couch movement accuracy and, again, the CBCT matching procedure. The relationship between treatment positioning uncertainty and workload was optimized using the threshold for couch shifts as an independent variable. Partial uncertainties were computed based on 811 CBCT clinical cases, together with the historical QA matching results from OBI's equipment and measurements from Varian's couch accuracy. The total positioning uncertainty with  $K = 2$  was calculated for VMAT treatments delivered in 28 sessions with daily CBCT. The workload was estimated from the probability of couch shifts, which was derived from the statistics of the 811 clinical cases.

### Results

The positioning uncertainty and the probability of couch shifts as a function of the chosen threshold are shown in Figure 1. As expected, if a high threshold is used (greater than 12 mm) the workload is minimized but uncertainty is stabilized at an excessively high value. On the contrary, if a very low threshold is used, i.e. between 0 and 2 mm, the probability of couch shifts is very high (between 97% and 100%). In this case, interestingly, the total uncertainty is not significantly reduced due the contribution of the remaining factors. Thus, the chosen threshold should be between 2 and 12 mm. To facilitate the determination of the optimal threshold, the derivations of both functions are shown in Figure 2. It can be observed that uncertainty has a maximum increase when the threshold is raised from 5 to 8 mm. However, if the same procedure is applied to the probability distribution of couch shifts, the maximum decrease takes place for a threshold between 4 and 5 mm.

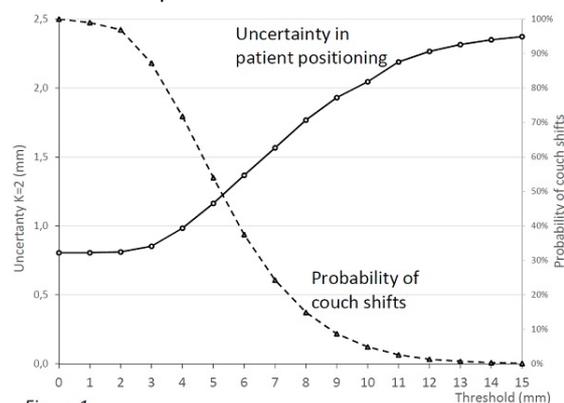

Figure 1

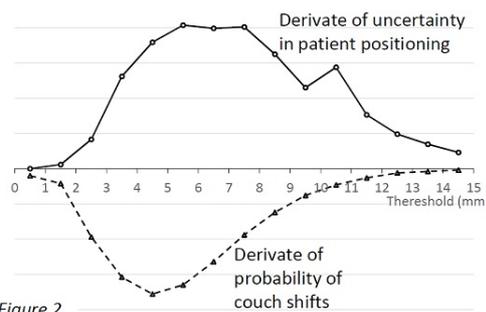

Figure 2

## Conclusion

A compromise between the patient uncertainty positioning and the associated workload is needed. The optimization of the threshold used for couch shifts is subjective and depends on the importance given to both factors. We showed that using a threshold <2 mm doesn't effectively reduce the total uncertainty. We believe that a threshold of 3 or 4 mm is adequate, keeping the positioning uncertainty below 1 mm and a reasonable clinical workload.

## EP-1671 Calculation of the skin dose-of-the-day during Tomotherapy for head and neck cancer patients

M. Branchini<sup>1,2</sup>, C. Fiorino<sup>1</sup>, M. Mori<sup>1</sup>, I. Dell'Oca<sup>3</sup>, M.G. Cattaneo<sup>1</sup>, L. Perna<sup>1</sup>, N.G. Di Muzio<sup>3</sup>, R. Calandrino<sup>1</sup>, S. Broggi<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy

<sup>2</sup>IRCCS Istituto Oncologico Veneto, Medical Physics, Padova, Italy

<sup>3</sup>San Raffaele Scientific Institute, Radiotherapy, Milan, Italy

## Purpose or Objective

Late fibrosis is known to depend on the severity of acute skin toxicity; an increase of skin dose during RT due to anatomy deformation may translate into an increased risk of acute toxicity, suggesting a potential benefit from planning adaptation to counteract this effect. Within this scenario, current study started to explore a previously suggested method for dose-of-the-day calculation in quantifying changes of the skin dose during Tomotherapy (HT) for head and neck (HN) cancer.

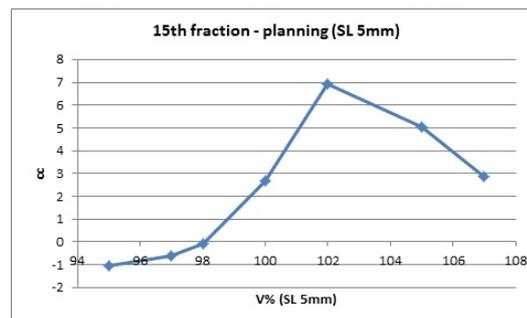

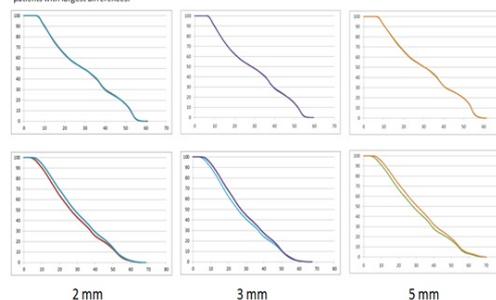

## Material and Methods

Planning CTs of 9 HN patients treated with HT (SIB: 54/66/69 Gy/30fr or sequential boost: 54/66.6-70.2Gy in 37-39 fr) were deformable registered to MVCT images acquired at the 15<sup>th</sup> fraction (processed with anisotropic diffusion filter) using a constrained intensity-based algorithm (MIM software). At the same day, a diagnostic kVCT was acquired with patient in treatment position (CT15) and taken as reference. The original HT plans were recalculated on both the resulting deformed images (CTdef) and CT15 using the DQA (dose quality assurance) HT module. In order to validate the method in computing the dose-of-the-day of the skin, the superficial layers (SL) of the body with thickness of 2, 3 and 5 mm (as a surrogate of the skin dose distribution: SL2,SL3,SL5) were considered in the body cranial-caudal extension corresponding to the high-dose PTV. The SL V95%, V97%, V98%, V100%, V102%, V105% and V107% of the prescribed PTV dose (i.e.: likely to correlate with skin toxicity) were extracted for CT15 and CTdef and compared. In addition, trendlines' R<sup>2</sup> of the graphs with Vd% of CT15 vs CTdef were computed to assess correlation between the two. Then, as a first example of clinical application, skin dose differences between fraction 15 and planning (V95%-V107% of SL) were retrospectively analyzed for 8 patients treated with SIB.

## Results

The differences between SL2/SL3/SL5 V95%-V107% in CT15 and CTdef were very small (<1%/1cc Figure 1). The correlation between SL DVHs parameters estimated on CT15 and CTdef was high (mean R<sup>2</sup>=0.91), with higher correlation for lower doses (i.e.: V95%, R<sup>2</sup>: 0.97, 0.98 and 0.99 for SL2, SL3 and SL5, respectively). When looking to the changes during HT, small average differences between planned vs dose-of-the-day values of SL V95%-V107% were found (< 2 cc), excepting one patient (out of 8) who showed a much more relevant difference between the planned skin dose and the delivered dose at fr 15 (V102%=7cc for SL5, Figure 2).

Figure: analysis of DVH of external layers of CT15 and CTdef, above results of the patient with smallest differences and below result of patients with largest differences.

## Conclusion

The calculation of the skin dose-of-the-day using planning CT-to-MVCT DIR is sufficiently reliable. The method was proven to be able of pointing out early superficial overdosing, to inform adaptive strategies. Preliminary results suggest that clinically relevant changes at half treatment should occur in a minority of patients, reinforcing the utility of our approach to select patients who may really benefit from adaptive replanning.

## EP-1672 Dual energy CT for improved proton stopping power estimation in head and neck cancer patients

V. Taasti<sup>1</sup>, L. Muren<sup>1</sup>, K. Jensen<sup>2</sup>, J. Petersen<sup>1</sup>, J. Thygesen<sup>3</sup>, A. Tietze<sup>4</sup>, C. Grau<sup>2</sup>, D. Hansen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Dept. of Medical Physics, Aarhus, Denmark

<sup>2</sup>Aarhus University Hospital, Dept. of Oncology, Aarhus, Denmark

<sup>3</sup>Aarhus University Hospital, Dept. of Clinical Engineering, Aarhus, Denmark

<sup>4</sup>Aarhus University Hospital, Dept. of Neuroradiology, Aarhus, Denmark

## Purpose or Objective

Pre-clinical and phantom studies have established that dual energy CT (DECT) improves estimation of the proton stopping power ratio (SPR) compared to single energy CT (SECT), leading to increased accuracy in treatment planning dose calculations. However, proton SPR estimation using DECT vs. SECT has only been compared in a single study of tumours in the cranial region with limited anatomical variations, with inconclusive results. We have therefore initiated a clinical imaging study of proton SPR estimation in the head and neck region comparing DECT and SECT. The aim of this study was to investigate if SPR differences between the two CT modalities were found when evaluating heterogeneous tissues of the head and neck region.

## Material and Methods

The patients were CT scanned with a 2<sup>nd</sup> generation dual source CT scanner, SOMATOM Definition Flash (Siemens Healthcare, Forchheim, Germany). DECT images were acquired at 100/Sn140 kVp, and SECT images were obtained as a weighted summation of the low and high DECT images. The DECT scans were acquired at the same day as the control CT scan midway through the treatment course and using the same dose settings as used for the control scan. The CT scans covered the whole anatomical region of the head down to the top of lungs - the SPR comparison was thereby performed over very heterogeneous tissue regions. SPR images were calculated from both the DECT and SECT scans for the four first patients included in the study. For DECT, SPR images were calculated using a noise-robust method previously developed in our group. For SECT, the stoichiometric method was used. Based on SPR images, difference maps were calculated. Seven regions of interest (ROIs) were placed, each covering a single tissue type. Relative SPR differences between the DECT and SECT calculations were extracted from the ROIs.

### Results

For bone, SECT systematically underestimated the SPR compared with DECT, while the reverse was the case for the soft tissues (Fig. 1). The relative SPR differences ranged from -2.2% to 0.9%, with a mean difference of -0.6% (Fig. 2). Large variations of up to 1.5 percentage points were seen for the SPR difference across the patients. However, the differences for the individual patients were systematically either positive or negative for each ROI (Fig. 2).

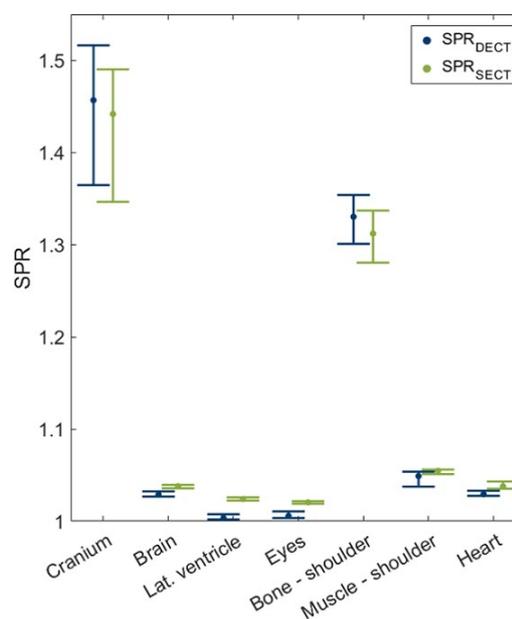

Fig. 1: Mean SPR for the four patients, over seven anatomical regions of interest (ROIs) for the DECT method (blue) and the SECT method (green). Markers show the mean over all patients, and the whiskers show the minimum and maximum of the mean for the individual patients.

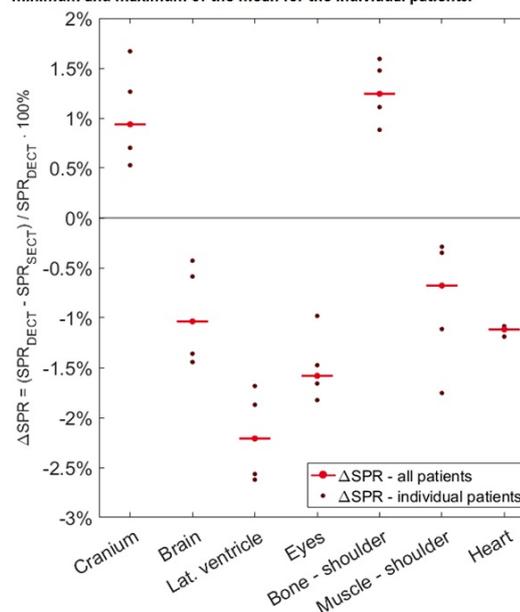

Fig. 2: Relative difference between DECT and SECT method, relative to DECT method. Light red markers with vertical lines show the mean difference over all four patients and dark red markers show the mean difference for each individual patient.

### Conclusion

Large differences in proton SPR estimation were found between DECT and SECT, although these were within the uncertainties which are currently used for dose calculation in particle therapy. These differences indicate that DECT will allow for reduction of treatment margins, resulting in better dose conformity. We are currently performing proton treatment planning for the patients comparing DECT- and SECT-based proton SPRs to investigate the dose difference in the tumour and in the surrounding healthy tissues, as well as potential impact on the range uncertainty margins used in proton treatment planning.

### EP-1673 Electron-density assessment using dual-energy CT: accuracy and robustness

C. Möhler<sup>1,2</sup>, P. Wohlfahrt<sup>3,4</sup>, C. Richter<sup>3,4,5,6</sup>, S. Greilich<sup>1,2</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Division of Medical Physics in Radiation Oncology, Heidelberg, Germany

<sup>2</sup>National Center for Radiation Research in Oncology NCRO, Heidelberg Institute for Radiation Oncology HIRO, Heidelberg, Germany

<sup>3</sup>OncoRay - National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden-Helmholtz-Zentrum Dresden - Rossendorf, Dresden, Germany

<sup>4</sup>Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiooncology, Dresden, Germany

<sup>5</sup>Department of Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Dresden, Germany

<sup>6</sup>German Cancer Consortium DKTK, Dresden, Germany

#### Purpose or Objective

Current treatment planning for essentially every external radiation therapy (photons, electrons, protons, heavier ions) is not able to account for patient-specific tissue variability or non-tissue materials (e.g. implants, contrast agent) which can lead to considerable differences in dose distributions (figure 1). This is due to the conversion of CT numbers to electron density or stopping power using a heuristic Hounsfield look-up table. In contrast, dual-energy CT (DECT) allows for a patient-specific determination of electron density - the only (most important) parameter influencing photon (ion) dose distributions. Among the many algorithms proposed for this purpose, a trend towards increased complexity is observed, which is not necessarily accompanied by increased accuracy and might at the same time militate against clinical implementation. Here, we therefore investigated the performance of a seemingly simple linear-superposition method (Saito, 2012, Hünemohr et al., 2014).

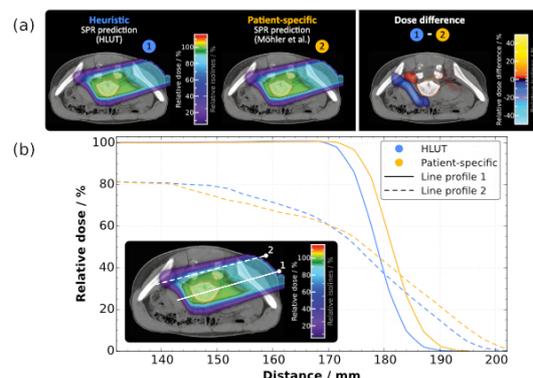

Figure 1: Clinical proton treatment plan of a patient with an implanted metal screw in the vertebral body. Dose distributions of a single beam (a) were calculated using a HLUT-based and patient-specific SPR prediction (Möhler et al., PMB 2016). Dose differences between both approaches are observed at the distal fall-off (blue area) and immediately behind the metal implant (red area). Line dose profiles (b) reveal range differences of about 2-3 mm at the distal fall-off and dose deviations of up to 5% immediately behind the metal implant.

#### Material and Methods

Key feature of the studied approach is a parameterization of the electron density, given by "alpha blending" of the two DECT images. The blending parameter can be obtained by empirical calibration using a set of bone tissue surrogates and a linear relationship between relative photon absorption cross sections of the higher and lower voltage spectrum. First, this linear relation was analyzed to quantify the purely methodological uncertainty (i.e. with ideal CT numbers as input), based on calculated spectral-weighted cross sections from the NIST XCOM database for tabulated reference tissues (Woodard and

White, 1986). A clear separation from CT-related sources of uncertainty (e.g. noise, beam hardening) is hereby crucial for a conclusive assessment of accuracy. Secondly, we tested the proposed calibration method on published DECT measurements of typical tissue-surrogate phantoms and evaluated its uncertainty.

#### Results

The methodological uncertainty of electron-density assessment for the alpha-blending method was found to be below 0.15% for arbitrary mixtures of human tissue. In the case of small abundance of high-Z elements, electron-density results are positively biased, e.g. 0.5% for thyroid containing 0.1% iodine (Z=53) by mass, which is due to the K edge of the photoelectric effect. The calibration parameters obtained from various published data sets, showed very little variation in spite of diverse experimental setups and CT protocols used. The calibration uncertainty was found to be negligible for soft tissue while it was dominated by beam hardening effects for bony tissue.

#### Conclusion

The alpha-blending approach for electron-density determination shows universal applicability to any mixture of human tissue with a very small methodological uncertainty (< 0.15%); and a robust and bias-free calibration method, which is straightforward to implement. We conclude that further refinement of algorithms for DECT-based electron-density assessment is not advisable.

### EP-1674 Experimental investigation of CT imaging approaches to deal with metal artefacts in proton therapy

S. Belloni<sup>1,2</sup>, M. Peroni<sup>1</sup>, S. Safai<sup>1</sup>, G. Fattori<sup>1</sup>, R. Perrin<sup>1</sup>, M. Walser<sup>1</sup>, T. Niemann<sup>3</sup>, R.A. Kubik-Huch<sup>3</sup>, A.J. Lomax<sup>1</sup>, D.C. Weber<sup>1,4,5</sup>, A. Bolsi<sup>1</sup>

<sup>1</sup>Paul Scherrer Institut, Center for Proton Therapy, Villigen PSI, Switzerland

<sup>2</sup>University of Bologna, Department of Physics and Astronomy, Bologna, Italy

<sup>3</sup>Cantonal Hospital Baden, Department of Radiology, Baden, Switzerland

<sup>4</sup>Inselspital, Radiation Oncology, Bern, Switzerland

<sup>5</sup>University Hospital Zurich, Radiation Oncology, Zurich, Switzerland

#### Purpose or Objective

Metal implants are challenging for proton therapy, mainly because of beam hardening artefacts severely compromising image quality of the planning CT. In fact, they result in non-negligible uncertainties in Stopping Power (SP) evaluation and significantly affect VOI delineation accuracy. The aim of this study was to compare different approaches to minimize the artefacts: a manual approach based on delineation of the visible artefacts, which was developed and is used clinically at the Center for Proton Therapy (PSI), and the new tools recently introduced in CT, such as SIEMENS Iterative Metal Artefact Reduction (iMAR) and Sinogram Affirmed Iterative Reconstruction (SAFIRE). Moreover, an experimental verification of direct SP calculation from Dual Energy (DE) images with iMAR has also been considered.

#### Material and Methods

A clinical treatment of a cervical chordoma patient was reproduced on a head and neck anthropomorphic phantom, which presents metal implants (titanium screws and cage) in the area where the PTV was defined. An IMPT plan with two anterior oblique and two posterior oblique fields (dose per fraction 2 GyRBE) was optimized and calculated on 7 different CTs which corresponded to the different imaging approaches: no correction of artefacts, manual correction, iMAR (each of these reconstructed using Filtered Back Projection (FBP) and SAFIRE) and DE

together with iMAR. The delivered dose was measured with EBT3 Gafchromic films, inserted in three sagittal planes of the phantom included in the PTV area, and was compared with the dose calculated on the different CTs from machine log files. Local dose differences and gamma maps were used to evaluate the results, taking into account residual positioning errors, daily machine dependent uncertainties and film quenching.

### Results

We restricted the analyses to the 50% isodose and defined  $A_{+10\%}$  and  $A_{-10\%}$  as the percentage area having percentage differences higher (lower) than 10% (-10%). In general,  $A_{-10\%}$  between calculated and measured dose distributions were below 10% for plane 1 and 2 with the DE approach combined with iMAR (Table 1). Maximum differences were mainly located in the areas of steep dose gradients. Focusing on the SAFIRE algorithms, the three methods showed comparable results to the corresponding FBP algorithms for plane 2 and 3. For plane 1,  $A_{+10\%}$  increased to 24.8% for uncorrected approach, but SAFIRE was again comparable to FBP when iMAR is used.

### Conclusion

DE combined with iMAR shows potential for predicting SP values and reducing metal artefacts. However, all approaches provided comparable, and clinically acceptable, results in terms of dosimetry accuracy. This could be related to the uncertainties in the experimental setup and in the measurements method (mainly use of gafchromic films), which might be comparable to the differences introduced by the metal artefacts correction approaches. The planning approach with multiple fields was robust against errors introduced by metal implants.

		FBP <sub>u</sub>	FBP <sub>m</sub>	FBP <sub>i</sub>	IR <sub>u</sub>	IR <sub>m</sub>	IR <sub>i</sub>	DE
p1	$A_{+10}$ (%)	10.9	12.0	14.2	24.8	18.2	18.5	8.8
	$A_{-10}$ (%)	0.3	0.1	0.0	0.0	0.0	0.0	0.1
	Max (%)	32.6	34.1	38.4	43.1	41.0	43.1	36.8
	Min (%)	-17.2	-13.8	-7.7	-6.8	-9.4	-10.0	-11.8
p2	$A_{+10}$ (%)	12.0	11.0	10.4	10.1	11.5	8.5	6.8
	$A_{-10}$ (%)	0.0	0.1	0.0	0.0	0.0	0.0	0.3
	Max (%)	26.7	30.3	22.7	24.8	25.8	23.2	24.2
	Min (%)	-8.5	-13.9	-10.5	-8.0	-6.3	-9.6	-15.5
p3	$A_{+10}$ (%)	22.5	58.9	41.7	23.5	41.6	26.8	35.7
	$A_{-10}$ (%)	2.3	0.0	0.3	3.1	0.0	1.7	3.3
	Max (%)	31.2	39.7	34.8	31.7	38.4	31.2	32.1
	Min (%)	-22.6	-4.8	-12.5	-18.4	-9.9	-17.5	-21.0

**Table 1** - Quantitative analyses of percentage difference on the 50% isodoses in the three sagittal planes (p1, p2, p3): percentage areas having percentage difference higher (lower) than +10% (-10%)  $A_{+10}$  ( $A_{-10}$ ), maximum and minimum values of percentage difference. None, manual and iMAR are indicated with u, m and i; while FBP and IR stands for Filtered Back Projection and SAFIRE. Finally, DE is the DECT-based SP evaluation combined with iMAR.

### EP-1675 Influence of CT contrast agent on head and neck VMAT dose distributions

L. Obeid<sup>1</sup>, J. Prunaretty<sup>1</sup>, N. Ailleres<sup>1</sup>, L. Bedos<sup>1</sup>, A. Morel<sup>1</sup>, S. Simeon<sup>1</sup>, P. Fenoglietto<sup>1</sup>  
<sup>1</sup>Institut Régional du Cancer de Montpellier, Radiotherapy, Montpellier, France

#### Purpose or Objective

Intravenous contrast agent injection during the patient CT simulation facilitates radiotherapy contouring in the case of head and neck cancers. However, the image contrast enhancement may introduce discrepancy between the planned and delivered dose. The aim of this retrospective study is to quantify the variations of Hounsfield unites (HU) and to investigate their effect on Volumetric Modulated Arc Therapy (VMAT) dose distributions.

#### Material and Methods

Ten patients previously treated by VMAT techniques with identical dose levels (70/60/50 Gy) were selected. For each patient, two CT scans were performed, 2 min. ( $CT_{inj}$ ) and 12 min. ( $CT_{delay}$ ) after Iomeron® 350 biphasic intravenous injection (60 mL, 1mL/s followed by 90 mL, 2 mL/s after 30 s). The treatment planning (optimization and calculation) was performed with  $CT_{inj}$  using the Eclipse TPS and two calculation algorithms (AAA® and Acuros

XB®). Two other treatment plans were recalculated with the same parameters and  $CT_{delay}$ . The mean HU and the iodine distribution were compared between the two scan images in the PTV50, the parotids and the thyroid. A dosimetric comparison using dose-volume histograms in target volumes and OAR (thyroid, parotids) was performed. The maximum ( $D_{2\%}$ ), minimum ( $D_{98\%}$ ) and median ( $D_{50\%}$ ) doses were registered.

### Results

The maximum HU average difference over all the patients was observed in the thyroid ( $81.37 \pm 36.01$  HU) followed by the PTV50 ( $10.76 \pm 15.70$  HU) and the parotids ( $9.39 \pm 16.01$  HU). The differences found with the AAA® algorithm were below 0.1% for  $D_{2\%}$ ,  $D_{98\%}$  and  $D_{50\%}$  in target volumes and between -0.11 and 0.36% in OAR. The differences observed with Acuros XB® Algorithm were less than 0.2% in target volumes and 0.31% in OAR. Moreover, the differences between two algorithms were statistically insignificant ( $p > 0.4$ ).

### Conclusion

This study shows that the use of intravenous contrast during CT simulation does not significantly affect dose calculation in head and neck VMAT plans using AAA and Acuros XB algorithms.

### EP-1676 Comparison of accuracy of Hounsfield units obtained from pseudo-CT and true CT images

N. Reynaert<sup>1</sup>, P.F. Cleri<sup>1</sup>, J. Laffarguettes<sup>1</sup>, B. Demol<sup>1</sup>, C. Boydev<sup>1</sup>, F. Crop<sup>1</sup>  
<sup>1</sup>Centre Oscar Lambret, PHYSIQUE MEDICALE, Lille, France

#### Purpose or Objective

Quality of pseudo-CT (pCT) images used for MRI-only treatment planning is often evaluated using the so-called MAE (Mean Average Energy) curve. Furthermore, a dosimetrical comparison is performed by comparing DVHs using pCT and true CT (tCT). The tCT is always considered as the reference, while uncertainties on these images are neglected. The purpose of the current work is to compare MAE curves for tCT images by varying different scanning parameters and to compare the results with uncertainties on our pCTs.

#### Material and Methods

A Toshiba Large Bore CT was used. Different IVDT curves were determined, for different energies (100-135 kV), FOVs, reconstruction kernel, phantom size, insert positions, using an in-house phantom, with variable size. The IVDT curves were used in our in-house Monte Carlo platform for recalculation of Cyberknife and Tomotherapy plans. pCT images were generated from MRI images (3D T1 sequence) using an atlas-based method. Image quality was determined using MAE, ME and gamma curves.

### Results

Three parameters for tCT had an important impact on the HUs, namely the energy, patient size and reconstruction kernel. These parameters individually modified image values with up to 300 HUs in bone inserts. Furthermore, patient size and energy are often correlated as, it is specifically for small patients that lower energies are used, both leading to higher HUs in bone. The impact of the reconstruction kernel was a surprise (e.g. comparing the FC64 and FC13). For the energy and the reconstruction kernel one can consider introducing specific IVDTs. It becomes more complicated when the IVDT should be modified as a function of patient diameter though. Furthermore, in some TPSs (e.g. Masterplan, Nucletron) only one predefined IVDT is used. Another important problem is the fact that the HUs in the air surrounding the patient are increased when using large phantom sizes (changing from -1000 HU to -910 HU). Depending on the IVDT, this can lead to a largely overestimated air density around the patient ( $0.2 \text{ g/cm}^3$ ) with a possible dosimetric

impact. The dosimetric impact of using different IVDTs when modifying energy, reconstruction kernel and patient size individually are below 2 %, for all Cyberknife and Tomotherapy plans considered. This is also the case for most of our pCT images. In extreme cases for tCT, e.g. when comparing a small patient scanned at 100 kV using the FC64 reconstruction kernel compared to a large patient scanned at 135 kV using the FC13 kernel, HU differences up to 900 (in bone) can be obtained leading to systematic dose differences up to 6 % (DVH shift). Using an “average” IVDT still leads to dose uncertainties > 2 %. Results can be CT scanner specific.

#### Conclusion

Uncertainties on pCT images used for MRI-only treatment planning should be compared to those on tCT images. The uncertainties on tCT images (even when not considering CT artifacts) are non-negligible and are of the same order as those on pCT images generated by e.g. atlas-based methods.

**Electronic Poster: Physics track: (Quantitative) functional and biological imaging**

#### EP-1677 Multicentre initiative for standardisation of image biomarkers

A. Zwanenburg<sup>1</sup>, Image Biomarker Standardisation Initiative IBSI<sup>2</sup>

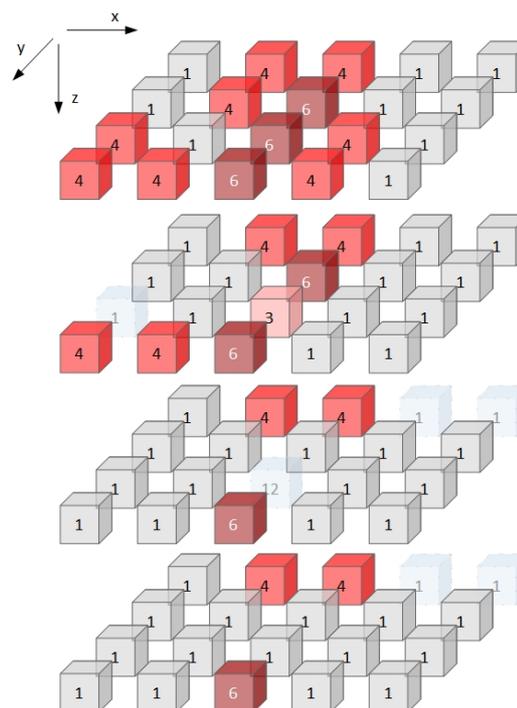

<sup>1</sup>OncoRay - National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus - Technische Universität Dresden - Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

#### Purpose or Objective

Personalised cancer treatment has the potential to improve patient treatment outcomes. One particular approach to personalised treatment is radiomics. Radiomics is the high-throughput analysis of medical images. There are several challenges within the radiomics field which need to be overcome to translate findings into clinical practice. The Image Biomarker Standardisation Initiative (IBSI) addresses the challenge of reproducing and validating reported findings by comparing and standardising definitions and implementation of several image feature sets between participating institutions.

#### Material and Methods

A 5x4x4 voxel digital phantom was devised, with a superimposed region-of-interest (ROI) mask (Figure 1). This volume has characteristics similar to real patient volumes of interest, namely voxels outside of the ROI and missing grey levels. The phantom is moreover sufficiently small to manually calculate features for validation purposes. Because no pre-processing steps (e.g. discretisation) are necessary for calculations on the phantom, feature values may be standardised across all institutions.

A set of definitions for statistical, morphological and textural features was compiled. Commonly used texture matrices were included: the grey level co-occurrence matrix (GLCM), the run length matrix (GLRLM), the size zone matrix (GLSZM), the distance zone matrix (GLDZM), the neighbourhood grey tone difference matrix (NGTDM) and the neighbouring grey level dependence matrix (NGLDM). The definitions and the digital phantom were shared with all participating institutions. The participants then extracted image features from the phantom and reported them. Differences and similarities between participants were discussed to investigate potential errors and necessary changes made to achieve a standard value. Texture matrices can be evaluated per image slice (2D) or in a volume (3D). GLCM and GLRLM are moreover calculated for 4 (2D) or 13 (3D) directional vectors to achieve rotational invariance. GLCM and GLRLM features are then either calculated for every direction and averaged (avg), or after merging the matrices into a single matrix (mrg).

#### Results

17 features were standardised between institutions (Table 1). 58 features are close to standardisation, with one institution with a deviating value. The standardisation of the remaining features is ongoing.

Feature set	# features	# institutions	median CoV [min - max] (%)	# full agreement	# all but 1 agreement
Statistics	17	12	1 [0 - 256]	6	10
Morphology	15	12	48 [22 - 244]	0	0
GLCM	2D avg	25	62 [1 - 373]	0	0
	3D avg	25	42 [1 - 283]	0	2
	3D mrg	25	2 [0 - 31]	1	18
GLRLM	2D avg	16	44 [1 - 122]	0	-
	3D avg	16	34 [1 - 281]	0	2
	3D mrg	16	1 [0 - 158]	1	12
GLSZM	2D	16	54 [0 - 86]	3	-
	3D	16	13 [1 - 314]	0	6
GLDZM	2D	16	-	0	-
	3D	16	22 [0 - 200]	4	10
NGLDM	2D	16	-	0	0
	3D	16	16 [0 - 85]	2	15
NGTDM	2D	5	62 [56 - 127]	0	-
	3D	5	217 [122 - 300]	0	0

## Conclusion

Definitions for a number of image features were devised and evaluated on a digital phantom within an international network. The feature definitions, digital phantom and corresponding feature values will be made available as a standard benchmark database for use by other institutions.

## EP-1678 Are PET radiomic features robust enough with respect to tumor delineation uncertainties?

M.L. Belli<sup>1</sup>, S. Broggi<sup>1</sup>, C. Fiorino<sup>1</sup>, V. Bettinardi<sup>2</sup>, F. Fallanca<sup>2</sup>, E.G. Vanoli<sup>2</sup>, I. Dell'Oca<sup>3</sup>, P. Passoni<sup>3</sup>, N. Di Muzio<sup>3</sup>, R. Calandrino<sup>1</sup>, M. Picchio<sup>2</sup>, G.M. Cattaneo<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy

<sup>2</sup>San Raffaele Scientific Institute, Nuclear Medicine, Milano, Italy

<sup>3</sup>San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

## Purpose or Objective

Radiomic techniques convert imaging data into a high dimensional feature space, guided by the hypothesis that these features may capture distinct tumor phenotypes predicting treatment outcome; it is clear that large multi Institutional studies are needed. The accuracy of tumor contouring based on PET is still a challenge issue in radiotherapy(RT) and this may strongly influence the extraction of radiomic parameters. Aim of current work was to investigate the robustness of PET radiomic features with respect to tumour delineation uncertainty in two clinically relevant situations.

## Material and Methods

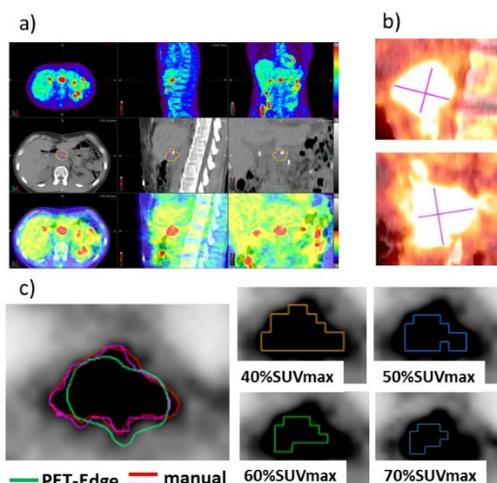

Figure 1

Twenty-five head-and-neck (HNC, with both T and N lesion) and twenty-five pancreatic (with only Tsite) cancer patients(pts) were considered. Patient images were acquired on three different PET/CT scanners with different characteristics and protocol acquisition. Seven contours were delineated for each lesion of the 50pts following different methods using the software MIM(Figure1.a): 2 different manual contours(Figure1.c) 1 semi-automatic ("PET-edge"based on maximum gradient detection, Figure1.b), and 4 automatic (based on a threshold:40%,50%,60%,70% of the SUVmax). The open access CGITAsoftware was used to extract several texture features (TA, e.g. entropy,skewness,dissimilarity,...) divided into different parent matrices (e.g. Co-occurrence,Voxel-alignment,...). Contours were compared in terms of both volume agreement (DICEindex) as well as TA difference (Kruskal-Wallis test). 9 manual contours

were also blinded re-contoured, and the intra-observer variability was also evaluated (DICEindex). Furthermore, the repeatability of semi-automatic contouring was also tested.

## Results

A total of 73 TA were extracted on each contour. A strong disagreement was found between automatic SUVmax threshold contours and manual or semi-automatic contours in terms of both DICE and TA agreement (9/73 TA for HNC and 10/73 for pancreas pts with p-value>0.05,Figure 2). Instead, both the inter-observer as well as the agreement between manual and semi-automatic contour was relatively high, for both volume (median DICE=0.71,range=0.36-0.96) and TA extraction (72/73 with p-value>0.05 for both HNC and pancreas pts). A high intra-observer agreement and a high contour repeatability were found for manual contours (median DICE=0.75,range:0.13-0.92) and for the semi-automatic method for lesions with high uptake values (median DICE=0.95,range=0.42-1.00). No statistically significant difference was found among scanners (p-value=0.12).

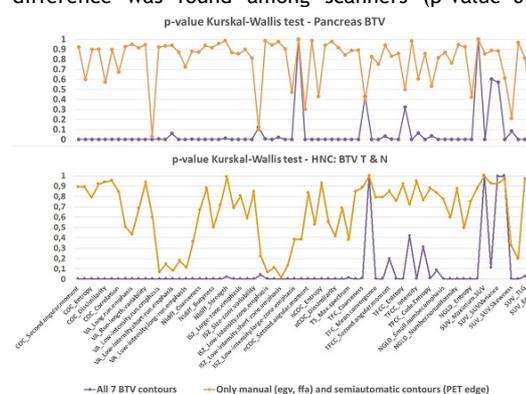

Figure 2

## Conclusion

Almost the totality of the selected radiomic features were sufficiently robust against the delineation when using manual and semi-automatic methods, while threshold based methods resulted to be less robust. The satisfactory results with a semi-automatic PET contouring method suggests, for the two clinically situations considered in this work, possible promising applications for consistent and fast textural feature extraction in multi-centric studies.

## EP-1679 Preliminary functional imaging study on an integrated 1.5T MR-Linac machine

M. Kadbi<sup>1</sup>, Y. Ding<sup>2</sup>, J. Wang<sup>2</sup>, C.D. Fuller<sup>3</sup>

<sup>1</sup>Philips, MR Therapy, Gainesville, USA

<sup>2</sup>MD Anderson, Department of Radiation Physics, Houston, USA

<sup>3</sup>MD Anderson, Department of Radiation Oncology, Houston, USA

## Purpose or Objective

Diffusion-weighted imaging (DWI) is a promising technique in MR guided radiotherapy (MRgRT) to delineate the tumor, predict response to induction chemotherapy, response to radiation therapy, and has been demonstrated as a biomarker of recurrence. This is the first attempt to investigate the performance of DWI technique in an integrated MR-Linac which combines Philips 1.5T MRI with 7 MV photon beam Elekta Linear accelerator (Linac). Conventional EPI-based DWI was compared with Spin-Echo (SE)-based DWI and geometrical distortion of the sequences were benchmarked with CT images as reference for geometric fidelity.

## Material and Methods

Clinical single-shot EPI-DWI sequence is a rapid imaging technique commonly used for functional imaging. However, EPI techniques are very sensitive to hardware and software imperfection (e.g. B0 inhomogeneity and eddy current) as well as susceptibility effect causing geometrical distortion. The system imperfection is more problematic in MR-Linac with split magnet and less homogeneous magnetic field compared to diagnostic MR systems. SE DWI techniques can reduce the geometrical distortion with the penalty of longer imaging time. Split acquisition of fast spin-echo signals for diffusion imaging (SPLICE) is a DWI technique combined with modified spin echo approach in which is insensitive to the phase of the magnetization.

A commercial DWI phantom designed by The Radiological Society of North America Quantitative Imaging Alliance (QIBA) with known Apparent Diffusion Coefficient (ADC) at ice temperature was used in order to determine the optimum ADC measurement sequence for future clinical development. Use of the phantom also allows spatially accurate assessment of geometric distortion compared to CT images acquired using GE Discovery CT 750 HD with Slice thickness of 1.25mm and Voxel size of 0.4883x0.4883x1.25 mm<sup>3</sup>

DWI imaging was performed using SS EPI (TR/TE = 10000/115 ms) and SS SPLICE (TR/TE = 10000/99 ms) with voxel size = 1.72x1.72mm; slice thickness = 4mm; number of slices=25; and b values = 0, 500, 900, 2000 s/mm<sup>2</sup>.

## Results

Qualitative assessment of the geometrical distortion shows significant improvement using SPLICE-DWI against EPI-DWI compared to CT images as shown in figure 1. Quantitative ADC measurement revealed a consistency between measured values using DWI-EPI sequence acquired on Diagnostic MRI system and MR-Linac system in room temperature. The measured values in room temperature are about 33% larger than ADC values measured in 0°C which is in agreement with our previous experiments on diagnostic MRI systems. However, the measured ADC values using SPLICE have larger variations specifically in higher b-values.

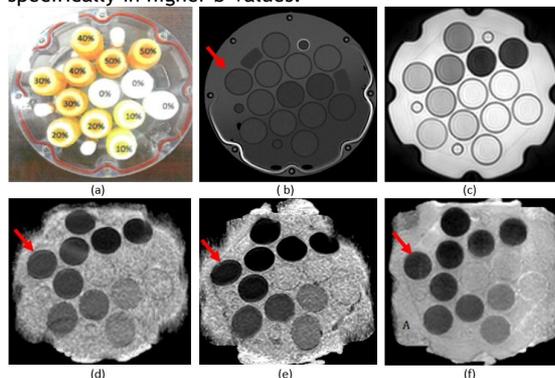

Figure 1: (a) RSNA QIBA DWI phantom (HPD, Inc.); (b) cross sectional view of an acquired CT image; (c) T2W images acquired on MR-Linac; ADC values (b=800) acquired on (d) a diagnostic MRI system using EPI; (e) MR-Linac using EPI; (f) MR-Linac using SPLICE (D). The geometric distortion is decreased significantly using SPLICE compared to the reference CT image (red arrows).

## Conclusion

The SPLICE DWI showed improved spatial fidelity compared to EPI-DWI. This is particularly beneficial in MRgRT due to importance of geometrical fidelity. The SPLICE-DWI sequence needs further modifications and calibrations to achieve more accurate ADC measurement.

## EP-1680 Assessing tumour necrosis in lung cancer with dual energy CT quantitative imaging

V. González-Pérez<sup>1</sup>, E. Arana<sup>2</sup>, J. Cruz<sup>3</sup>, M. Barrios<sup>2</sup>, F. Blázquez<sup>1</sup>, A. Bartrés<sup>4</sup>, L. Oliver<sup>1</sup>, V. Campo<sup>1</sup>, C. Bosó<sup>1</sup>, P. Sanamaria<sup>5</sup>, V. Crispin<sup>1</sup>

<sup>1</sup>Fundación Instituto Valenciano de Oncología, Servicio de

Radiofísica y Protección Radiológica, Valencia, Spain

<sup>2</sup>Fundación Instituto Valenciano de Oncología, Servicio de Radiología, Valencia, Spain

<sup>3</sup>Fundación Instituto Valenciano de Oncología, Servicio de Anatomía Patológica, Valencia, Spain

<sup>4</sup>Onkologikoa, Servicio de Radiofísica y Protección Radiológica, San Sebastián, Spain

<sup>5</sup>Fundación Instituto Valenciano de Oncología, Servicio de Radioterapia, Valencia, Spain

## Purpose or Objective

To assess if dual energy computed tomography (DECT) quantitative imaging can distinguish necrotic tumours in lung cancer.

## Material and Methods

From July 2013 to June 2016, 83 patients who underwent a DECT study were reviewed for their lung tumour necrosis status (33 positive; 50 negative).

Lesion size varied considerably: the mean lesion volume was 15 cm<sup>3</sup> (range 0.05-138 cm<sup>3</sup>). Malignant lesions were predominantly adenocarcinoma (77.1%), squamous cell carcinoma (13.2%) and metastases (7.2%).

DECT examination was performed on a Discovery CT 750 HD scanner (GE Healthcare, WI, USA). Patients were injected with 1.35 ml/kg of body weight of non-ionic iodinated contrast material at 4 ml/s (Iopamidol, 300 mg/ml; Bracco, Italy). A Gemstone Spectral Imaging (GSI) DECT exam of the entire chest was performed at arterial phase.

Lesion volume was semi-automatically segmented using Dexu lung nodule function (ADW4.6; GE Healthcare, USA) by two radiologists. Images for quantitative iodine content  $\rho_i$  (mg/cm<sup>3</sup>) and effective atomic number ( $Z_{eff}$ ) were reconstructed. Maximum, mean and standard deviation values were recorded for both parameters and for conventional HU image. Lesion volume and diameter were also registered. Inter- and intra-observer intraclass correlation coefficient (ICC) was studied.

Bilateral statistical analysis was performed using the Mann-Whitney U test. Due to multiple comparisons, Bonferroni adjustment was made and significance was set at  $p < 0.007$ . Receiver operating characteristic (ROC) curves were generated and diagnostic capability was determined by calculating the area under the ROC curve (AUC). The licensed statistical software package SPSS 20 (IBM, Somers, NY, USA) was used.

## Results

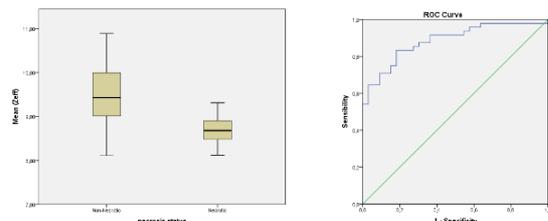

Reproducibility of intraobserver lung lesion the ICC was 0.95 (CI 95% 0.80-0.98) and interobserver ICC was 0.92 (CI 95% 0.70-0.98).

The bivariate analysis for distinguishing necrotic from non-necrotic lesions revealed statistically significant differences. Larger lesions presented more necrosis than smaller ones, as previously known in the literature. Values for  $p$ , AUC and its 95% confidence level interval are shown in Table 1.

Variable	p	AUC	95% C.L.
Mean ( $Z_{eff}$ )	<0.001	0.885	0.814-0.956
$\sigma(Z_{eff})$	0.006	0.680	0.561-0.799
Mean(HU)	<0.001	0.786	0.687-0.884
Maximum(HU)	0.001	0.719	0.609-0.829
$\sigma(HU)$	0.001	0.727	0.617-0.837
Mean( $\rho_i$ )	<0.001	0.784	0.687-0.882
$\sigma(\rho_i)$	<0.001	0.819	0.723-0.916
Diameter	<0.001	0.775	0.676-0.875
Volume	<0.001	0.778	0.679-0.878

Box-whisker and ROC plots are displayed in Fig. 1 for mean  $Z_{eff}$  variable, which presented highest AUC (0.890). Mean

$Z_{eff}$  presented a 84.0% sensitivity and 81.8% specificity for a threshold of 8.96 in ROC curves.

## Conclusion

DECT imaging gives information on tumour necrosis. Quantitative parameters ( $\rho_i$  and  $Z_{eff}$ ) showed better sensibility and specificity compared to standard HU imaging. Mean  $Z_{eff}$  showed better correlation with necrosis status, due to necrotic core absorbs less iodine contrast. Our approach has some advantages. Whole tumour semi-automatic contouring had excellent reproducibility. No cases were excluded due to geometry or mediastinal contact.

This method could be a solid approach to assess necrosis condition. However, we have not studied relationship with the actual location of necrosis, so it would not be useful for dose-painting protocols at necrotic core.

## EP-1681 [C11]Choline PET/MRI for Prostate Cancer: Identify Imaging Characteristics Predicting Metastasis

J.R. Tseng<sup>1</sup>, L.Y. Yang<sup>2</sup>, H.Y. Chang<sup>2</sup>, T.C. Yen<sup>1</sup>

<sup>1</sup>Chang Gung Memorial Hospital at Linkou, Nuclear Medicine and Molecular Imaging Center, Kwei-Shan-Taoyuan City, Taiwan

<sup>2</sup>Chang Gung Memorial Hospital at Linkou, Biostatistics Unit- Clinical Trial Center of Chang Gung Memorial Hospital, Kwei-Shan- Taoyuan City, Taiwan

## Purpose or Objective

Intergraded PET/MRI is a powerful imaging modality for prostate cancer (Pca) in several aspects, from cancer detection, primary staging, to staging of recurrent Pca. The goal of primary staging is to detect metastatic spread from the main tumor. In high risk Pca patients (PSA >20 ng/ml, or Gleason score of 8-10, or clinical stage T3a), intergraded PET/MRI imaging may have great potential to change clinical management. In the current study, we aimed to identify imaging characteristics of main tumor which can significantly predict distant metastasis.

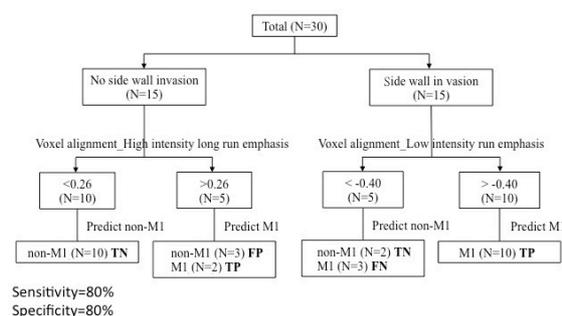

## Material and Methods

This prospective clinical study was approved by the Ethics Committee (approval 102-3271A and 103-4561C). Since January 2015 to June 2016, total 30 Pca patients committed high risk criteria were enrolled to conduct whole body integrated [C11]Choline PET/MRI (biograph mMR, Siemens). The PET and MRI imaging was interpreted independently by one clinically-experienced nuclear medicine physician and radiologist. In the PET imaging analysis, main tumors were segmented using PMOD 3.3 software package. The borders of volumes of interest were set by manual adjustment to avoid physiological [C11]Choline uptake in the urine or intestine. The tumor boundaries were automatically contoured based on the thresholds of SUV 2.65. The gray-level run length encoding matrix (GLRLM) was used for assessing the regional texture features. In the MRI imaging analysis, anatomic (T2-weighted MRI) and functional (diffusion-weighted MRI) imaging features were documented. Multivariate classification and regression tree analysis was used to determine the best combination of variables and the related cutoffs to predict risk for distant metastasis.

## Results

The mean age is 70.1±6.2 years, and the mean PSA level is 91.6 ± 139.4 ng/ml. In these 30 patients, 26 (87%) are categorized as clinical stage IV, 4 (13%) as stage III. Fifteen

(50%) patients have distant metastasis, including 7 (23%) non-regional lymph nodes metastasis, 11 (36%) bone metastasis, 1 (3%) visceral organ metastasis. The individual clinical risk factors (PSA >20 ng/ml, or Gleason score of 8-10, or clinical stage T3a) are not significantly associated with distant metastasis (P-value is 0.493, 0.087, 0.109, respectively). In the multivariate forward analysis, imaging characteristics of main tumor side wall invasion by anatomical T2 MRI is the only significant risk factor predicting distant metastasis (odds ratio 42.25, confidence interval 5.1-346.5, P-value <0.001). The PET regional tumor texture features can further divide patients into with or without distant metastasis by using high intensity long run emphasis value > -0.40 and low intensity run emphasis value <0.26 (Figure 1). The Sensitivity and specificity of the multivariate tree model was 80% and 80%, respectively.

## Conclusion

By providing excellent anatomical, functional, and metabolic information, integrated PET/MR enhances the staging of metastatic disease in high risk Pca. Imaging characteristics including pelvic side wall invasion and tumor metabolic heterogeneity may have crucial role in patient management.

## EP-1682 Comparison of SUV based on different ROIs and VOIs definitions: a multi-center 4D phantom study

M. Lambrecht<sup>1</sup>, K. Ortega Marin<sup>1</sup>, M. La Fontaine<sup>2</sup>, J.J.

Sonke<sup>2</sup>, R. Boellaard<sup>3</sup>, M. Verheij<sup>2</sup>, C.W. Hurkmans<sup>1</sup>

<sup>1</sup>Catharina Ziekenhuis, Physics/Radiotherapy, Eindhoven, The Netherlands

<sup>2</sup>Netherlands cancer institute, Radiotherapy, Amsterdam, The Netherlands

<sup>3</sup>University medical center- university of Groningen, Nuclear medicine, Groningen, The Netherlands

## Purpose or Objective

In the context of the EORTC LungTech trial, a QA procedure including a PET/CT credentialing has been developed. This procedure will ultimately allow us to pool data from 23 institutions with the overall goal of investigating the impact of tumour motion on quantification. As no standardised procedure exists under respiratory conditions, we investigated the variability of 14 SUV metrics to assess their robustness over respiratory noise.

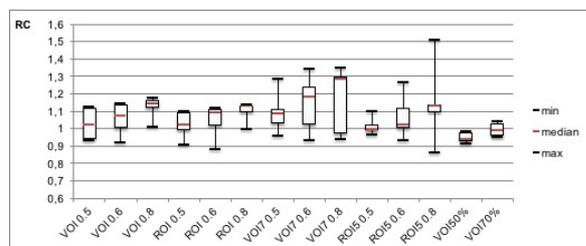

## Material and Methods

The customized CIRS-008A phantom was scanned at 13 institutions. This phantom consists of a 18 cm long body, a rod attached to a motion actuator, and a sphere of either 1.5 or 2.5cm diameters. Body, rods and spheres were filled with homogeneous <sup>18</sup>F-FDG solutions representative of activity concentrations in mediastinum, lung and tumour for a 70kg patient. Three respiratory patterns with peak-to-peak amplitudes and periods of 15mm/3sec, 15mm/6sec and 25mm/4sec were tested. Prior to scanning in respiratory condition, a 3D static PET/CT was acquired as reference. During motion, images

were acquired using 3D or 4D gated PET(average image) according to institutional settings. 14 SUV(mean) metrics were obtained per acquisition varying VOI/ ROI shape and location. Three ROIs and three VOIs with respective radii of 0.5, 0.6 and 0.8cm were investigated. These ROIs/VOIs were first centred on the maximum activity voxel; a second analysis was made changing the location from the voxel to the region (ROI5voxels) or the volume (VOI7voxels) with the maximum value. Two additional VOIs were defined as 3D isocontours respectively at 70% and 50% of the maximum voxel value. The SUV metrics were normalized by the corresponding 3D static SUV. Converting to recovery coefficients (RC) allowed us to pool data from all institutions, while maintaining focus solely on motion. For each RC from each motion setting we calculated the mean over institutions, we then looked at the standard deviation (Sd) and spread of each averaged RC over each motion setting.

### Results

For the institutions visited we found that RCVOI70% and RCVOI50%, yielded over the 14 metrics the lowest variability to motion with Sd of 0.04 and 0.03 respectively. The RCs based on ROIs/VOIs centered on a single voxel were less impacted by motion (Sd: 0.08) compared to region RCs (Sd: 0.14). The averaged Sd over the RCs based on VOIs and ROIs was 0.12 and 0.11 respectively.

### Conclusion

Quantification over breathing types depends on ROI/VOI definition. Variables based on SUV max thresholds were found the most robust against respiratory noise.

### EP-1683 Fractals in Radiomics: implementation of new features based on fractal analysis

<sup>2</sup>Fondazione Policlinico Universitario A.Gemelli, Divisione di Radioterapia Oncologica- Gemelli ART, Roma, Italy

<sup>3</sup>Maastricht University Medical Center, Department of Radiation Oncology, Maastricht, The Netherlands

<sup>4</sup>Università Cattolica del Sacro Cuore, Istituto di Fisica, Roma, Italy

<sup>5</sup>Università Cattolica del Sacro Cuore, Department of Radiotherapy - Gemelli ART, Roma, Italy

### Purpose or Objective

A fractal object is characterized by a repeating pattern that it displays at different size scales: this property, known as self-similarity, is typical of many structures in nature or inside human body (a snow flake and the neural networks are just some examples).

The fractal self-similarity can be measured by Fractal Dimension (FD), a parameter able to quantify the geometric complexity of the object under analysis.

Aim of this study is to introduce in Radiomics new features based on fractal analysis, in order to obtain new indicators able to detect tumor spatial heterogeneity. These fractal features have been used to develop a predictive model able to calculate the probability of pathological complete response (pCR) after neoadjuvant chemo-radiotherapy for

patients affected by locally advanced rectal cancer (LARC). **Material and Methods**

An home-made R software was developed to calculate the FD of the Gross Tumor Volume (GTV) of 173 patients affected by LARC. The software, validated by comparing the obtained results with ImageJ, was implemented in Moddicom, an open-source software developed in our Institution to perform radiomic analysis.

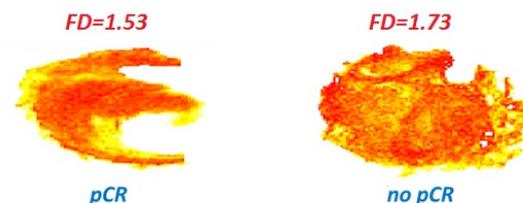

Fractal analysis was performed applying the Box Counting method on T2-weighted images of magnetic resonance. The FD computation was carried out slice by slice, for each patient of the study: values regarding mean, median, standard deviation, maximum and minimum of the FD distribution were considered as fractal features characterizing the patient.

Fractal analysis was moreover extended on sub-populations inside GTV, defined by considering the pixels whose intensities were above a threshold calculated as percentage of the maximum intensity value occurred inside GTV. A logistic regression model was then developed and its predictive performances were tested in terms of ROC analysis. An external validation, based on 25 patients provided by MAASTRO clinic, was also performed. The details on imaging parameters adopted are listed in table 1.

Parameter	Gemelli	MAASTRO
Scanner Type	GE 1.5 T	RM Achieva Scanner 1.5 T
Sequence	Fast spin-echo	Fast spin-echo
Pixel Spacing	0.729 mm	0.7 mm
FOV	18 cm	18
Repetition time	2500-5000 msec	2500-500
Inversion time	100-110 msec	100-110 mse
Echo train length	16-24	16-24
NEX	4	4

### Results

The predictive model developed is characterized by 3 features: the tumor clinical stage, the entropy of the GTV histogram (calculated after the application of a Laplacian of Gaussian filter with  $\sigma=0.34$  mm) and the maximum FD (maxFD) calculated for the sub-population whose intensities are higher than 40% of the GTV maximum value. MaxFD is the most significant parameter of the model: higher maxFD value, typical of a more complex structure, is correlated with less pCR probability. The model developed showed an AUC of ROC equal to  $0.77 \pm 0.07$ . The model reliability has been confirmed by the external validation, providing an AUC equal to  $0.80 \pm 0.09$ .

On the left, maxFD of a patient who has shown pCR, on the right maxFD of a patient who has not shown pCR after chemoradiotherapy. In red the pixel subpopulation with intensity higher than 40% of the GTV maximum

### Conclusion

Fractal analysis can play an important role in Radiomics: the fractal features provide important spatial information not only about the GTV structure, but also about its sub-populations. Further investigations are needed to investigate the spatial localization of these sub-populations and their potential connection with biological structures.

### EP-1684 Optimal window for assessing treatment responsiveness on repeated FDG-PET scans in NSCLC patients

M. Lazzeroni<sup>1</sup>, J. Uhrdin<sup>2</sup>, S. Carvalho<sup>3</sup>, W. Van Elmpt<sup>3</sup>, P. Lambin<sup>3</sup>, A. Dasu<sup>4</sup>, I. Toma-Dasu<sup>5</sup>

<sup>1</sup>Karolinska Institutet, Medical Radiation Physics-Department of Oncology-Pathology, Stockholm, Swede

<sup>2</sup>RaySearch Laboratories AB, RaySearch Laboratories AB, Stockholm, Sweden

<sup>3</sup>GROW-School for Oncology and Developmental Biology-Maastricht University Medical Center, Department of Radiation Oncology, Maastricht, The Netherlands

<sup>4</sup>The Skandion Clinic, The Skandion Clinic, Uppsala, Sweden

<sup>5</sup>Stockholm University, Medical Radiation Physics-Department of Physics, Stockholm, Sweden

#### Purpose or Objective

A previous study has shown that the early response to treatment in NSCLC can be evaluated by stratifying the patients in good and poor responders based on calculations of the effective radiosensitivity,  $a_{\text{eff}}$ , derived from two FDG-PET scans taken before the treatment and during the second week of radiotherapy [1]. However, the optimal window during the treatment for assessing  $a_{\text{eff}}$  was not investigated. This study aims at assessing  $a_{\text{eff}}$  of NSCLC tumours on a new cohort of patients for which the second scan was taken during the third week of treatment. The optimal window for response assessment could be determined by investigating the ability of the method to predict treatment outcome through a comparison of the results of a ROC analysis for the new cohort of patients, imaged at three weeks, with the results of the previous study in which patients were imaged at two weeks.

#### Material and Methods

Twenty-eight NSCLC patients were imaged with FDG-PET before the treatment and during the third week of radiotherapy. The patients received 45 Gy in 1.5 Gy fractions twice-daily followed by a dose-escalation up to maximum 69 Gy in daily fractions of 2 Gy. The outcome of the treatment was reported as overall survival (OS) at two years.  $a_{\text{eff}}$  was determined at the voxel level taking into account the voxel SUV in the two images and the dose delivered until the second scan. Correlations were sought between the average ( $a_{\text{eff}}$ ) or negative fraction ( $nf_{\text{eff}}$ ) of  $a_{\text{eff}}$  values and the OS. The AUC and the p-value resulting from the ROC analysis were compared to the corresponding values reported for the case when the second scan was taken during the second week of treatment.

#### Results

The ROC curves in Figure 1 show the correlation between  $a_{\text{eff}}$  and OS and also the correlation between  $nf_{\text{eff}}$  and OS in the present and the earlier analysis. The results expressed as AUC and p-value show the lack of correlation between either  $a_{\text{eff}}$  (AUC=0.5, p=0.7) or  $nf_{\text{eff}}$  (AUC=0.5, p=0.8) and the OS for the scan at 3 weeks. This contrasts with the case when the second image was taken during the second week of treatment (AUC=0.9, p<0.0001). From the comparison of the ROC curves it results that the values of  $a_{\text{eff}}$  can be used for predicting the OS if the second scan is taken during the second week, but not during the third week.

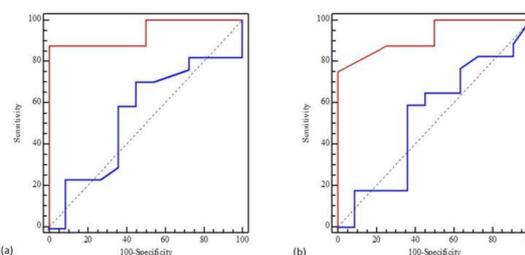

Figure 1. ROC curves showing the correlation between  $a_{\text{eff}}$  and OS (a) and between  $nf_{\text{eff}}$  and the OS (b) for the case when the second FDG-PET image was taken during the second (red) or third (blue) week of treatment, respectively.

#### Conclusion

The optimal window for assessing the responsiveness to treatment based on  $a_{\text{eff}}$  calculations derived from repeated FDG PET scans in NSCLC patients appears to be the second week of the treatment but validation on a larger cohort of patients is warranted.

<sup>3</sup>University Hospital Tübingen, Diagnostic and Interventional Radiology, Tübingen, Germany

<sup>4</sup>University Hospital Tübingen, Radiology - Section of Nuclear Medicine, Tübingen, Germany

<sup>5</sup>University Hospital Tübingen, Radiology - Section of Radiopharmacy, Tübingen, Germany

#### Purpose or Objective

FMISO-PET has proven to capture probabilities of hypoxia in tumors, which may predict risks of local recurrence across patients. On the other hand, Radiomics hypothesizes that heterogeneity of tumors can be extracted from medical images. In this study, we investigate the performance of CT-radiomics features and FMISO PET/CT for prediction of local recurrence in head and neck cancer (HNC) patients.

#### Material and Methods

A cohort of 22 HNC patients who underwent FMISO PET/CT before primary Radiotherapy (RT) treatment was used. Planning CT scans as well as FMISO PET/CT were acquired prior to RT, FMISO PET data was analysed using maximum tumour-to-muscle ratios ( $TMR_{\text{max}}$ ) 4h post injection. 92 Robust radiomics features including intensity-based as well as texture features were extracted from the planning CT images in the gross tumour volume (GTV). Six highly significant radiomics features were selected from a simple filter method based on cumulative distribution function (CDF) in a univariate fashion in addition to a logistic regression classification model (LoG) to build a predictive model. Area under the curve of the receiver operating characteristic curve (AUC-ROC) was computed for  $TMR_{\text{max}}$  and the model including the six selected radiomics Features. Finally, a combined model using FMISO  $TMR_{\text{max}}$  and two radiomics features (one from texture and one from intensity) were constructed.

## Results

Each of the selected six radiomics features (1 texture and 5 first order statistics), which were normalized to be comparable, showed higher predictive power compared to FMISO TMR<sub>max</sub> at the moment of predicting outcomes univariately. AUC-ROC curves demonstrated that a model created out of only six dominant CT-radiomics features can discriminate groups better with respect to local control in HNC using the logistic regression models (AUC = 0.904) than FMISO TMR<sub>max</sub> (AUC = 0.800). Nevertheless, a combination of FMISO-PET TMR<sub>max</sub> values and only two CT-radiomics features (Small Zone Emphasis texture and Minimum Grey Level first-order statistics) can reach an AUC of 0.886 in our classification model.

Simple discriminative analysis CDF index			
Rank	Features	Type	p-Value
1	'Small Zone Emphasis'	Texture GLSZM	0.028
2	'Minimum Grey Level'	Intensity	0.073
3	'Variance'	Intensity	0.093
4	'Root Mean Square'	Intensity	0.095
5	'Mean Absolute Deviation'	Intensity	0.105
6	'Energy'	Intensity	0.106
FMISO			
	TMR <sub>max</sub>		0.120

Table 1: Ranking of CT Radiomics Features and TMR<sub>max</sub> based on p-values in a univariate analysis.

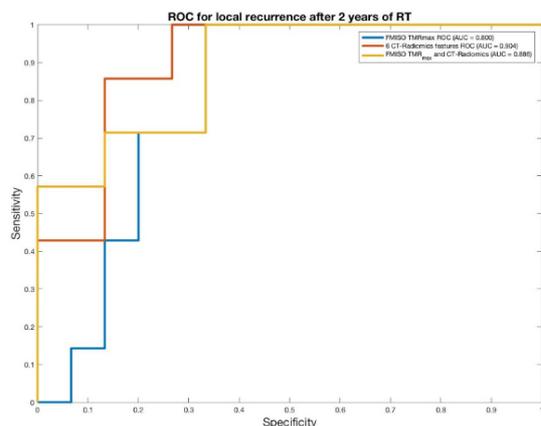

Figure 1: Comparisons of AUC-ROCs using a logistic regression model.

## Conclusion

CT radiomics proved to have better prognostic power with respect to local control in HNC than FMISO-PET TMR<sub>max</sub>. Nonetheless, a combination of TMR<sub>max</sub> and the two most significant features of CT radiomics reaches high prognostic power with fewer features to assess. Consequently, analysing tumour heterogeneity using CT radiomics features may have the power to determine substitute measures of tumour hypoxia and might therefore be used as a basis for personalized RT adaptations in the future.

### EP-1686 Diffusion weighted imaging for treatment response prediction in advanced rectal cancer

H.D. Nissen<sup>1</sup>

<sup>1</sup>Nissen Henrik D., Department of Oncology - Section for Radiotherapy, Vejle, Denmark

#### Purpose or Objective

The standard treatment of locally advanced distal rectal cancer is chemoradiotherapy (CRT) followed by surgery. Based on pathologic examination of the surgery specimen, a significant number of patients are found to be without remaining tumor at the time of surgery. This has led to an increasing interest in whether, for a select group of patients, surgery can be replaced by a wait-and-see

strategy. Several recent studies [1, 2] have shown that this is possible without compromising survival and with significantly reduced comorbidities. A significant challenge in this strategy is selecting the patients who are candidates for this strategy.

We wish to examine whether diffusion weighted MRI (DWI) can be used as an early biomarker for tumor response to CRT.

#### Material and Methods

Here we present data from 25 patients treated for distal T3 or T4 rectal tumors. Patients were treated with long course CRT, including a brachytherapy boost to the tumor, followed by surgery. Patients were DWI scanned before start of CRT and again after 2 weeks of CRT. The DWI sequence included 11 b-values from 0 to 1100. Regions of interest (ROI) were drawn using an algorithm to locate areas with atypically high signal on high b-value images. ROI volumes were then analyzed using a radiomics approach where 67 image features were extracted from each volume. Tumor response to treatment was determined by pathologists examining the surgical specimen and scoring the tumor response using the Mandard Tumor Regression Grade (TRG). Data were analyzed both by visual examination of the data and by applying a decision tree algorithm.

#### Results

From visual inspection of the data we found that using only initial entropy and mean values for the ADC image as well as their change during the first 2 weeks of treatment, we could correctly classify 24 of the 25 patients as either major response (TRG 1 or 2) or minor response (TRG 3 or 4). This was confirmed by building a decision tree for the entire dataset. Applying machine learning techniques where the data are divided into a training and a test sample, we were hampered by the small data set, which meant building a model on only part of the data set and using the remaining patients to test the model gave large variations in both the selected parameters and the ability of the model to correctly predict the response of the remaining patients (from 40% to 100%).

#### Conclusion

DWI imaging can provide information on the tumor response as early as 2 weeks into CRT. Further work is needed to improve the model and especially testing on a larger data set is necessary.

### EP-1687 Texture analysis of 18F-FDG PET/CT predicts local control of stage I NSCLC treated by SBRT

K. Takeda<sup>1</sup>, K. Takanami<sup>2</sup>, Y. Shirata<sup>1</sup>, T. Yamamoto<sup>1</sup>, N. Takahashi<sup>1</sup>, K. Ito<sup>1</sup>, K. Takase<sup>2</sup>, K. Jingu<sup>1</sup>

<sup>1</sup>Tohoku University Graduate School of Medicine, Radiation Oncology, Sendai, Japan

<sup>2</sup>Tohoku University Graduate School of Medicine, Diagnostic Radiology, Sendai, Japan

#### Purpose or Objective

Recently, there are some reports that texture analysis of 18F-FDG PET/CT has better potential to predict outcome of radiotherapy than existing PET parameters such as maximum SUV. We evaluated reproducibility and predictive value of some texture parameters based on gradient-based delineation method and existing

parameters of 18F-FDG PET/CT image in patients with early stage non-small cell lung cancer (NSCLC) treated by stereotactic body radiation therapy (SBRT).

#### Material and Methods

Thirty patients with early stage NSCLC (T1-2N0M0) were retrospectively investigated. SBRT was delivered with total dose of 40-48Gy in 4 fractions for peripheral regions or 50-60Gy in 7-15 fractions for central regions or regions nearby other organ at risk. All patients underwent 18F-FDG PET/CT scan before treatment. Each tumor was delineated using PET Edge (MIM Software Inc., Cleveland) and texture parameters were calculated using open-source code CGITA (Fang, et.al., 2014). From 18F-FDG PET/CT image, three conventional parameters including metabolic tumor volume (MTV), maximum standardized uptake value (SUV) and total lesion glycolysis (TLG) and four textural parameters including entropy and dissimilarity derived from co-occurrence matrix and high-intensity large-area emphasis and zone percentage derived from size-zone matrix were analyzed. Reproducibility was evaluated using two independent delineation conducted by two observers using intraclass correlation coefficients (ICC). The ability to predict local control (LC) was tested for each parameter using Cox proportional hazards model.

#### Results

Median follow-up period was 30.1 month and 8 (23%) patients occurred local relapse. Between two observers, six parameters besides zone percentage (ICC value 0.59) showed ICC value ranged between 0.81 and 1.00. In univariate analysis, there were significant correlations between LC and tumor diameter >30mm (hazard ratio 7.21,  $p=0.02$ ),  $MTV \geq 5.14 \text{ cm}^3$  (HR 9.38,  $p=0.01$ ),  $TLG \geq 59.7$  (HR 5.86,  $p=0.04$ ),  $entropy \geq 34.3$  (HR 0.13,  $p=0.02$ ),  $dissimilarity \geq 2235$  (HR 6.87,  $p=0.03$ ) and treatment biological equivalent dose  $\geq 100 \text{ Gy}$  (HR 0.02,  $p=0.04$ ), respectively. Maximum  $SUV \geq 10.4$  was not a significant predictor for LC ( $p=0.09$ ).

	Groups	Hazard ratio (95% CI)	p value
Sex	female vs. male	1.64 (0.34-6.31)	0.50
Age (years)	$\geq 75$ vs. $<75$	2.24 (0.53-15.3)	0.29
Performance status	0, 1 vs. 2, 3	1.42 (0.25-26.7)	0.73
Tumor diameter	$>30 \text{ mm}$ vs. $\leq 30 \text{ mm}$	7.21 (1.40-33.4)	0.02*
Metabolic tumor volume	$\geq 5.14 \text{ cm}^3$ vs. $<5.14 \text{ cm}^3$	9.38 (1.66-176)	0.01*
Maximum SUV	$\geq 10.4$ vs. $<10.4$	3.51 (0.82-15.0)	0.09
Total lesion glycolysis	$\geq 59.7$ vs. $<59.7$	5.86 (1.12-27.6)	0.04*
Entropy	$\geq 34.3$ vs. $<34.3$	0.13 (0.01-0.72)	0.02*
Dissimilarity	$\geq 2235$ vs. $<2235$	6.87 (1.18-131)	0.03*
High-intensity large-zone emphasis	$\geq 1743$ vs. $<1743$	3.89 (0.91-26.7)	0.07
Zone percentage	$\geq 0.46$ vs. $<0.46$	0.27 (0.01-1.52)	0.16
Biological effective dose	$\geq 100 \text{ Gy}$ vs. $<100 \text{ Gy}$	0.22 (0.04-0.92)	0.04*

Table: Univariate analysis for local control. Asterisk shows significant difference with p value < 0.05. Abbreviation: SUV standardized uptake value.

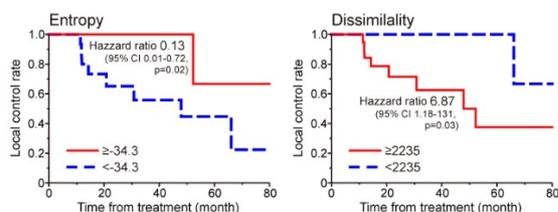

Figure: Local control rate plotted with Kaplan-Meier method.

#### Conclusion

Texture analysis based on gradient-based delineation method has high reproducibility in most parameters. Entropy and dissimilarity calculated from co-occurrence matrix is potentially beneficial to predict LC with reproducibility in patients with NSCLC treated by SBRT. To establish utility of texture analysis in 18F-FDG PET/CT image, further study including prospective trial will be

needed.

#### EP-1688 Voxelbased analysis of FMISO-PET and diffusion-weighted MRI of two different HNSCC models in mice

R. Winter<sup>1</sup>, S. Boeke<sup>2</sup>, M. Krueger<sup>3</sup>, A. Menegakis<sup>2</sup>, E. Sezgin<sup>2</sup>, L. Wack<sup>1</sup>, G. Reischl<sup>3</sup>, B. Pichler<sup>3</sup>, D. Zips<sup>2</sup>, D. Thorwarth<sup>1</sup>

<sup>1</sup>University Hospital Tübingen, Section for Biomedical Physics, Tübingen, Germany

<sup>2</sup>University Hospital Tübingen, Radiation Oncology, Tübingen, Germany

<sup>3</sup>Werner Siemens Imaging Center, Preclinical Imaging and Radiopharmacy, Tübingen, Germany

#### Purpose or Objective

Hypoxia is an important prognostic marker for radiotherapy (RT) response, particularly for head and neck squamous cell carcinoma (HNSCC) and may be measured using PET-tracers such as <sup>18</sup>F-FMISO. Moreover, parameters derived from functional MRI have been correlated with response to RT, such as ADC.

Our hypothesis is that multiparametric PET/MRI, i.e. a combination of different parameters derived from PET and functional MRI, allows a better prediction in terms of RT response than single parameters do.

The aim of this study was to distinguish two different HNSCC cell-lines grown as xenografts in mice, based on voxel-wise image analysis of simultaneously acquired FMISO-PET and ADC data.

#### Material and Methods

11 immunodeficient nude mice were injected into the hind leg with tumor-cells of human HNSCC cell-lines FaDu (n=7) or CAL-33 (n=4). Once a tumor reached its target size (~300 mm<sup>3</sup>), simultaneous PET and MR imaging was performed on a 7T-PET/MR scanner (Bruker) at two time points: before (d0) and after two weeks (d14) of fractionated irradiation (10x 2Gy). The protocol included dynamic FMISO-PET (90min), anatomical T2- and diffusion-weighted MRI.

An image of the FMISO uptake was reconstructed from the last 5 min of the acquired PET data. An ADC map was calculated from a set of 9 diffusion-weighted MR images ( $b=0-800 \text{ s/mm}^2$ ). On the anatomical MR image, tumor and muscle were defined as regions of interest (ROIs). ROIs and ADC map were then resampled to the PET image grid for consistent image analysis on the voxel level. FMISO tumor-to-muscle-ratios (TMRs) were determined at both time points for ROI-based and voxel-by-voxel comparison with ADC values.

#### Results

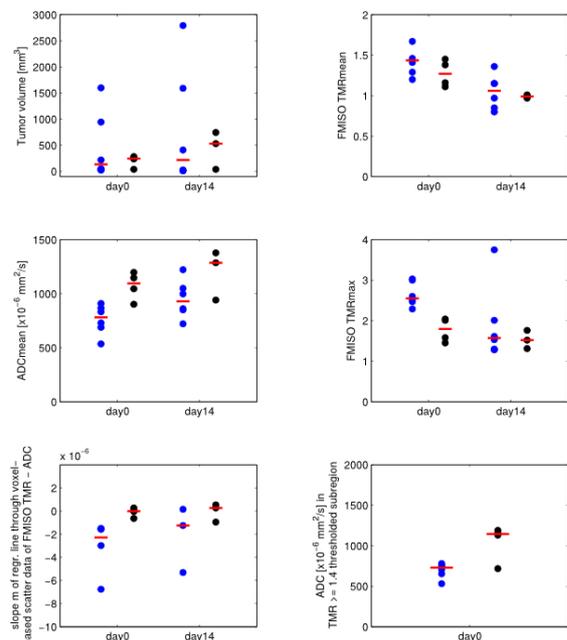

The median (d0/d14) TMRmean was 1.43/1.06 and 1.25/1.00, median ADCmean was 780/929 and 1095/1286  $\times 10^{-6} \text{ mm}^2/\text{s}$ , median FMISO TMRmax was 2.55/1.57 and 1.80/1.52, median slope m of a regression line through voxelbased FMISO TMR and ADC scatter data was -2.29/-1.25 and 0.02/-0.26  $\times 10^{-4}$ , median ADCmean of a thresholded subregion of the tumor where FMISO TMR $\geq 1.4$  was 730 (d0) and 1145 (d0)  $\times 10^{-6} \text{ mm}^2/\text{s}$  for FaDu and CAL-33 tumor ROIs, respectively.

Parameter values for all tumors are presented in Fig1; a scatter plot of voxelbased FMISO TMR and ADC values for one FaDu and one CAL-33 tumor at d0, in Fig2. Out of five parameters, three had strong potential for differentiation of the HNSCC cell-line, when measured at d0: TMRmax, slope m of the regression line and ADCmean of the FMISO positive region (TMR $\geq 1.4$ ).

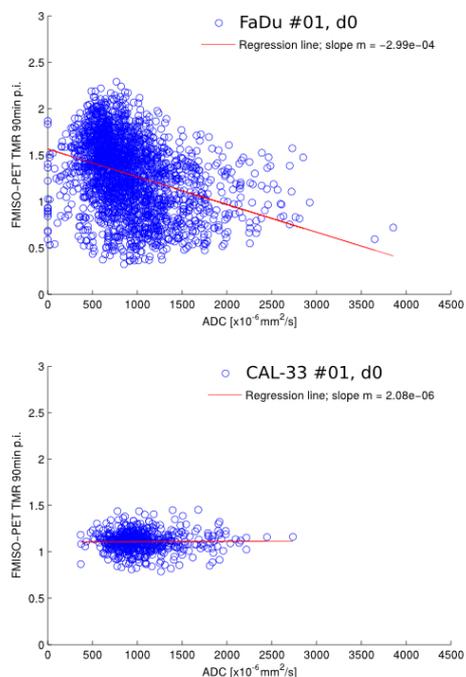

#### Conclusion

Voxelbased analysis of FMISO-PET and ADC data proved to have high potential for discrimination of tumor cell-lines presenting different radiobiological properties. Three parameters were found to be suitable to distinguish the two cell-lines with well-known difference in

radiosensitivity before the start of RT. Additional sets of imaged-derived parameters will be investigated and further cell-lines be measured to identify relations with radiosensitivity for the development of a multiparametric prediction model for personalized RT in HNSCC.

**Fig2:** Values of various parameters derived from the FMISO-PET images (~90min p.i.) and ADC maps for FaDu (blue) and CAL-33 (black) before and after RT are presented. Note that for image and regression analyses a min. tumor size of 10 and 40 mm³ was necessary.

**Fig2:** Characteristic scatter plots of voxelbased FMISO TMR and ADC values for one FaDu (top) and one CAL-33 tumor (bottom) before start of irradiation (d0).

<sup>2</sup>Uppsala University, Experimental and clinical oncology, Uppsala, Sweden

**Purpose or Objective**

To investigate a Gleason driven dose painting approach for high risk prostate cancer patients based on outcome for conventional treatments, and using apparent diffusion coefficient (ADC) MR images for dose prescription.

**Material and Methods**

We based our retrospective study on a total of N=122 high-risk prostate patients treated with radiotherapy, with inclusion criteria to have a pre-treatment PSA<60 µg/L and biopsies analyzed at Uppsala University Hospital. The 5-year local tumor control probability was estimated with Kaplan Meier analysis to TCP<sub>obs</sub>=94.7% (CI 86.4-98.0%). The PSA inclusion condition was used to exclude patients with possible pre-treatment spread. The homogeneous treatment dose D<sub>h</sub> was estimated to 91.6 Gy EQD<sub>2</sub> based on α/β=1.93 for the given proton boost (20Gy in 4 fractions, RBE=1.1) and photon dose (50 Gy in 25 fractions). All patients underwent androgen deprivation therapy. We parameterized the population dose-response TCP<sub>pop</sub>(D) with a logistic function with the parameter γ<sub>50</sub>=2.01 and D<sub>50</sub> chosen so that TCP<sub>pop</sub>(D<sub>h</sub>)=TCP<sub>obs</sub>. The patients' biopsy statements were used to construct simulated prostates with voxelized distributions of Gleason scores G varying per voxel.

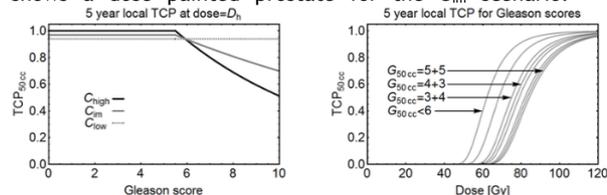

Voxel specific dose-response functions TCP<sub>vox</sub>(D,G) were derived with the logistic parameters γ<sub>50,eff</sub> and D<sub>50</sub>(G) set so that the average TCP<sub>pat</sub> for all patients equals TCP<sub>obs</sub> at D<sub>h</sub>, and the average slope for the patients TCP<sub>pat</sub> equals the slope for TCP<sub>pop</sub>(D) at D<sub>h</sub>. Hence, the voxel specific dose-response functions are described by TCP<sub>vox</sub>(D,G)=1/(1+(D<sub>50</sub>(G)/D)<sup>4γ<sub>50,eff</sub></sup>), where D<sub>50</sub>(G) and γ<sub>50,eff</sub>, for D=D<sub>h</sub>, reconstructs TCP<sub>vox</sub>(D<sub>h</sub>,G<6)=C and TCP<sub>vox</sub>(D<sub>h</sub>,G≥6)=C-k×(G-6).

For G<6 TCP<sub>vox</sub> was set to not vary with Gleason scores since ADC-MRI likely not distinguish G<6 from normal tissue. We used 3 different values of C, a high value C<sub>high</sub>=1 resulting in zero desired dose for G<6 voxels, a low value C<sub>min</sub> resulting in a homogeneous dose distribution (k=0), and an intermediate C<sub>im</sub> for a certain minimum dose.

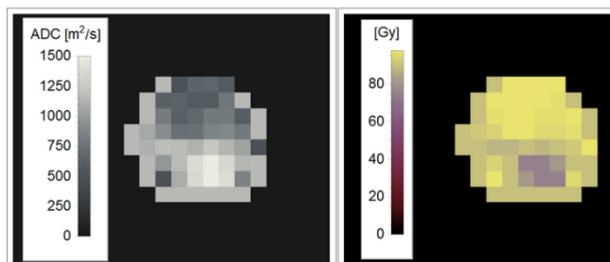

ADC images for a high-risk patient were translated into a 3D-map of Gleason scores based on results published by Turkbey et al. We used the above functions for dose painting to minimize the average dose while keeping the TCP<sub>pat</sub> equal to that for a homogeneous dose of D<sub>h</sub>.

**Results**

For the C<sub>high</sub> scenario the average dose decreased by 9 Gy (max dose 98 Gy). For the intermediate C<sub>im</sub> scenario the average dose decreased by 2 Gy with doses in the range of 74 to 98 Gy. Fig. 1 shows resulting Gleason score to TCP mappings normalized for a 50cc prostate while Fig. 2 shows a dose painted prostate for the C<sub>im</sub> scenario.

**Fig 1.** TCP vs Gleason scores comprising a 50cc prostate volume and corresponding dose-response functions for the intermediate C<sub>im</sub> scenario.

**Fig 2.** ADC in prostate and dose painted prostate for  $C_{im}$  scenario.

### Conclusion

Gleason driven dose painting for prostate cancer using ADC-MRI is feasible to reduce the average dose. The reduction in dose is strongly dependent on the minimum dose assigned to voxels with  $G < 6$ .

### EP-1690 Validating the robustness of PET features in a phantom in a multicenter setting

T. Konert<sup>1</sup>, M. La Fontaine<sup>2</sup>, S. Van Kranen<sup>2</sup>, W. Vogel<sup>1</sup>, J. Van de Kamer<sup>2</sup>, J.J. Sonke<sup>2</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Nuclear Medicine, Amsterdam, The Netherlands

<sup>2</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

PET features may have prognostic or predictive value and could therefore assist treatment decisions. However, PET features are sensitive to differences in data collection, reconstruction settings, and image analysis. It is insufficiently known which features are least affected by these differences, especially in a multicenter setting. Therefore, this study investigates the robustness of PET features in a phantom after repeated measurements (repeatability), due to varying scanner type (reproducibility) and their dependence on binning method and SUV activity.

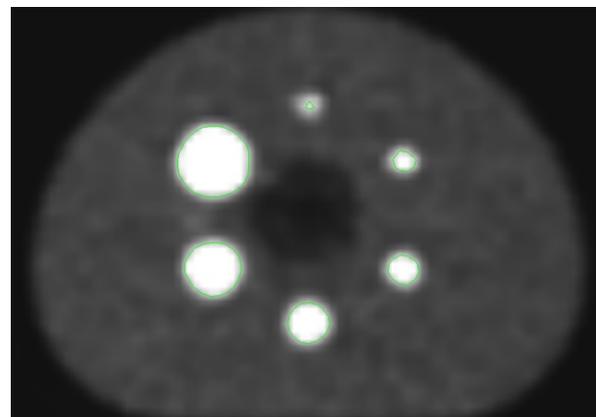

### Material and Methods

PET scans from a NEMA image quality phantom were used for assessment of PET feature robustness. Scans were acquired on a Philips, a Siemens and a GE scanner from three medical centers (see figure 1 and table 1 for more details). Per sphere, a VOI was created by applying a threshold of 40% of the  $SUV_{max}$ . Per VOI, 10 first order statistics and 10 textural features, often reported in literature, were extracted. Two common implementations of image pre-processing, before feature extraction, were compared: using a fixed bin size ( $SUV = 1$ ) versus a number of fixed bins (64 bins). To examine the feature repeatability, measurements were repeated two or three times on the same scanner. The reproducibility was assessed in images by comparing all scanners. The degree of variation was calculated per VOI with the coefficient of repeatability ( $1.96 \times SD/mean$ ), normalized to a percentage ( $CR_{\%}$ ). Features were seen as robust with a  $CR < 30\%$ , matching the level of uncertainty found in response of PERCIST criteria. Wilcoxon signed rank tests were used to estimate the significance of differences due to binning method and p-values  $\leq 0.05$  were considered significant.

### Results

For an overview of the results, see Table 1. The  $CR_{\%}$  of  $SUV_{max}$  in all scans depended on sphere volume, and ranged from 1.1% (largest sphere) to 15.2% (smallest sphere). In the repeatability study, 9 out of 10 PET features were robust with 64 bins in more than one scanner, and significantly higher ( $p < 0.05$ ) when compared to using a fixed bin size, where 7 out of 10 PET features were robust. Reproducibility was achieved in 3 out of 10 PET features when 64 bins were used. PET

features were not reproducible when using a fixed bin size. Dissimilarity ( $CR_{\%}$ : 6.3-24.9), homogeneity 1 ( $CR_{\%}$ : 16.9-22.5), and inertia ( $CR_{\%}$ : 10.2-22.5) were robust to binning method, scanner type, and SUV activity. Coarseness, contrast, busyness, energy, correlation were not robust ( $CR_{\%} > 30\%$ ).

**Figure 1.** A transverse PET image of the NEMA image quality phantom containing six spheres filled with activity. The smallest sphere was excluded from analysis, due to incompatible volume size for feature calculation. Images were acquired following EARL protocol in Siemens and Philips scanners. GE image acquisition was following local protocol.

**Table 1.** The numbers under the PET features represent the mean  $CR_{\%}$  over 5 spheres. Philips 1 = Philips TOF BB, Siemens = Siemens Biograph 40 mCT, ALL = Philips TOF BB, Philips TOF, Siemens Biograph 40 mCT, GE Discovery STE. Coar = coarseness, Cont = contrast, Busy = busyness, Diss = dissimilarity, Homo = homogeneity, Entr = entropy, Ener = energy, Iner = inertia, Corr = correlation.

Scanner type	# of scans	Binning method	Volume	$SUV_{max}$	Coar	Cont	Busy	Diss	Homo1	Homo2	Entr	Ener	Iner	Corr
<b>Repeatability study</b>														
Philips1	2	fixed	23.6	9.1	6.2	15.4	29.6	19.1	12.4	26.9	44.5	30.8	29.4	46.8
Philips1	2	64	*	*	6.2	7.7	7.3	6.7	6.7	14.2	51.0	10.0	5.4	9.5
Siemens	3	fixed	13.6	10.8	11.0	33.9	55.5	12.9	5.8	7.9	5.8	24.6	24.0	108.4
Siemens	3	64	*	*	11.0	12.1	10.5	5.0	5.5	11.1	10.6	11.0	6.4	11.6
<b>Reproducibility study</b>														
ALL	12	64	16.12	167.9	176.1	167.3	166.0	15.5	23.2	39.3	149.2	77.4	21.1	88.0

### Conclusion

This study indicates that not all PET features are robust in a multicenter setting. Care has to be taken in feature selection and binning method, especially if harmonization of methods across centers is not accomplished. Dissimilarity, homogeneity 1, and inertia seem robust and promising PET features for use in a multicenter setting. Use of fixed bin size should be avoided.

### EP-1691 Multi-modal voxel-based correlation between DCE-CT/MRI and DWI in metastatic brain cancer

C. Coolens<sup>1,2,3</sup>, W. Foltz<sup>1,4</sup>, N. Sinno<sup>1</sup>, C. Wang<sup>1</sup>, B. Driscoll<sup>1</sup>, C. Chung<sup>2,5</sup>

<sup>1</sup>Princess Margaret Cancer Centre and University Health Network, Radiation Medicine Program, Toronto, Canada

<sup>2</sup>University Health Network, TECHNIA Institute, Toronto, Canada

<sup>3</sup>University of Toronto, Radiation Oncology and IBBME, Toronto, Canada

<sup>4</sup>University of Toronto, Radiation Oncology, Toronto, Canada

<sup>5</sup>MD Anderson Cancer Center, Radiation Oncology, Houston, USA

### Purpose or Objective

Quantitative model-based measures of dynamic contrast enhanced (DCE) and Diffusion Weighted (DW) MRI parameters have shown variable findings to-date that may reflect variability in the MR acquisition and analysis. This work investigates the use of a voxel-based, multi-modality GPU architecture to include various complimentary solute transport processes into a common framework and

correlate the extra-vascular volume fraction ( $v_e$ ) and apparent diffusion coefficient (ADC) from DCE-MRI/CT and DWI MRI done at the same time points in patients with brain metastases.

#### Material and Methods

A total of 26 tumours in 19 patients were treated under ethics-approved trials with stereotactic radiosurgery (SRS) alone (n=14) or SRS on day 7 of sunitinib (n=12) and underwent multi-parametric imaging at baseline, post drug (if applicable), then 7 and 21 days post-radiosurgery. Each patient received a comparative DCE-MRI scan on the same day as the CT imaging on a Verio 3T System (IMRIS) with Variable Flip Angle (VFA) T1 quantification and 3D-FLASH and Gadolinium injection (Magnevist 20cc); T2-weighted imaging; DWI (echo-planar imaging with TR/TE 7700/110; 3D-diffusion gradient encoding). Volumetric DCE-CT was acquired following a 60cc Visipaque320® injection in an intermittent time sequence up to 3 mins (Toshiba, Aquilion ONE). A temporal dynamic analysis (TDA) method for voxel-based CT perfusion [1] was remodeled to enable using GPU-based optimization on a high throughput cluster to include various complimentary transport processes into a common framework. As DCE-CT is considered a gold standard for tracer-kinetic validation given its signal linearity, we compared extravascular extracellular volume maps from DCE-CT to those from DCE-MRI and ADC values by Pearson correlation on a voxel-by-voxel basis as well as other kinetic parameters using the Modified Tofts model (AUC,  $K_{trans}$ ,  $K_{ep}$ ).

#### Results

Voxel-wise Pearson's analysis showed statistically significant correlations in  $K_{trans}$  ( $P < 0.001$ ) between DCE-CT and DCE-MRI over all imaging time points as well as excellent agreement with very little bias (see Figure 1). The correlation between ADC and  $v_e$  values were strong in the Sunitinib cohort ( $R = 0.6$ ,  $p < 0.01$ , all days) and peaked at day 3 post SRS ( $R = 0.75$ ,  $p < 0.008$ ). No such statistically significant correlation was seen between ADC and  $v_e$  in the SRS alone group. Correlation of ADC histogram parameters between imaging days was highly correlated however, again peaking at Day 7 ( $R = 0.85$ ,  $p < 0.001$ ).

#### Conclusion

Using a common analysis platform has improved the correlations in pharmacokinetic parameters,  $K_{trans}$  and  $v_e$ , obtained from CT and MR than previously reported. Consistent with our hypothesis that ADC and  $v_e$  values would describe a similar physiological effect, the observed correlation between extravascular volume fraction and ADC values was high for the cohort treated with Sunitinib and SRS, but this correlation was not seen for the SRS alone group.

<sup>1</sup>Gustave Roussy, Radiotherapy, Villejuif, France

<sup>2</sup>Univ. Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France

<sup>3</sup>INSERM, U1030, Villejuif, France

<sup>4</sup>IMIV, CEA- Inserm- CNRS- Univ. Paris-Sud- Université Paris-Saclay- CEA-SHFJ, Orsay, France

<sup>5</sup>Gustave Roussy, Nuclear Medicine and Endocrine Oncology, Villejuif, France

#### Purpose or Objective

The aim of this study was to evaluate the possibility of gathering images from 2 different PET devices in a radiomic study, and to propose a signature of local recurrence for locally advanced cervical cancer (LACC).

#### Material and Methods

118 patients with LACC were retrospectively included. All patients underwent a <sup>18</sup>F-FDG PET-CT scan before treatment. They were classified in 2 groups depending on the PET device used for acquisition (G1: Siemens Biograph installed in 2003, N=79; G2: GE Discovery installed 2011, N=39). Treatment consisted in a concomitant chemoradiation delivering 45 Gy in 25 fractions of 1.8 Gy to the pelvis +/- the para-aortic area followed by a pulse-dose rate image-guided uterovaginal brachytherapy of 15 Gy.

The primary tumor was delineated on the PET images using a fixed threshold (40% of  $SUV_{max}$ ) within a manually drawn volume of interest (VOI), called VOI-T. A 73 mL sphere was drawn in the healthy liver considered as homogeneous (VOI-L). For each VOI, 5 conventional indices ( $SUV_{mean}$ ,  $SUV_{max}$ ,  $SUV_{peak}$  in a 1 mL sphere, metabolic volume, tumor lesion glycolysis) and 6 3D textural indices were calculated after resampling the VOI SUV between 0 and 40 using 128 gray levels: Homogeneity and Entropy from the Gray-Level Co-occurrence Matrix, Short-Run Emphasis (SRE), Long-Run Emphasis (LRE), Low Gray-level Zone Emphasis (LGZE) and High Gray-level Zone Emphasis (HGZE).

Wilcoxon's tests were performed between G1 and G2 in VOI-L to determine to what extent technological differences and image properties influence radiomic feature values. A stepwise model selection using the Akaike Information Criterion was applied to determine the best 4-feature signature for local recurrence prediction in both groups, used successively for training and validation. Delong's tests between AUC were performed to evaluate if the signature was more powerful than  $SUV_{max}$  only.

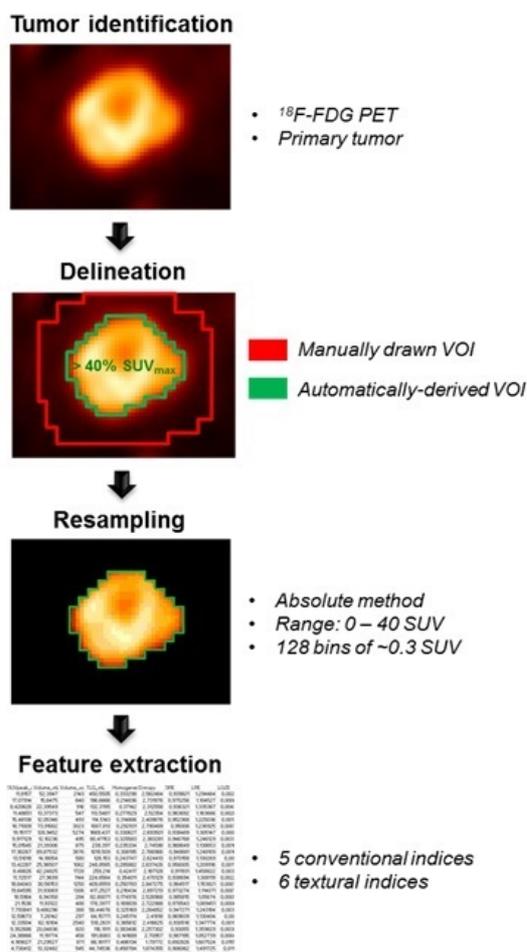

Figure 1: Radiomic pipeline

## Results

SUV<sub>max</sub>, SUV<sub>peak</sub>, Homogeneity and SRE computed in VOI-L were significantly different between the two devices ( $p < 0.05$ ). These p-values suggested that data coming from the two PET devices can therefore not be gathered.

In G1, the best 4-feature signature was a combination of Entropy, SUV<sub>mean</sub>, SUV<sub>max</sub> and SRE (AUC=0.77) and in G2, a combination of SUV<sub>peak</sub>, Homogeneity, LGZE, HGZE (AUC=0.86). G2 signature was validated in G1 with AUC=0.76 and was significantly more powerful than SUV<sub>max</sub> according to Delong's test ( $p=0.02$ ). G1 signature was not validated in G2, yielding to an AUC less than that obtained with SUV<sub>max</sub> only.

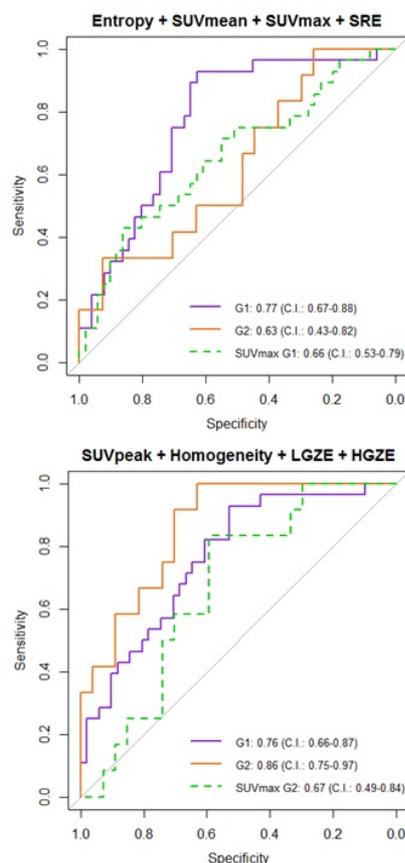

Figure 2: Multivariate analysis using G1 for training, G2 for validation (top) and G2 for training, G1 for validation (bottom) with the best 4-feature signature determined by AIC stepwise algorithm

## Conclusion

Some conventional and textural features are strongly dependent on the PET device and acquisition parameters such as voxel size. A robustness analysis should be performed before each multi-centric radiomic study, to evaluate the possibility of gathering data from different devices. Multivariate analysis showed that radiomic features can predict LACC local recurrence with a better accuracy than SUV<sub>max</sub> for recent PET devices. The creation of an external validation cohort is in progress to confirm the results.

## EP-1693 Functional MRI to individualize PTV margins to seminal vesicles with suspected cancer involvement

S. Damkjær<sup>1</sup>, J. Thomsen<sup>1</sup>, S. Petersen<sup>1</sup>, J. Bangsgaard<sup>1</sup>, M. Aznar<sup>2</sup>, I. Vogelius<sup>1</sup>, P. Petersen<sup>1</sup>

<sup>1</sup>Rigshospitalet, Department of Oncology- Section for Radiotherapy - 3994, København, Denmark

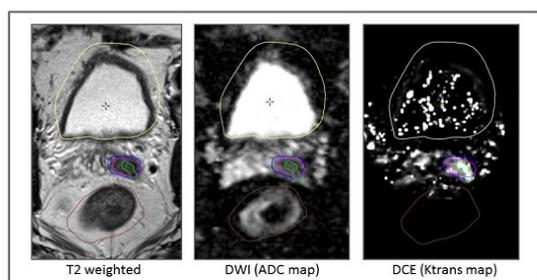

<sup>2</sup>University of Oxford, Clinical Trial Service Unit- Richard Doll Building, Oxford, United Kingdom

## Purpose or Objective

For external beam radiotherapy of prostate cancer patients, the information from pre-treatment MRIs can give patient specific and visual evaluation of suspected pathologically involved volumes in the seminal vesicles (SV) as an important addition to probability based nomograms [1]. We investigate the impact of individualized PTV margins around the SV based on MRI information.

### Material and Methods

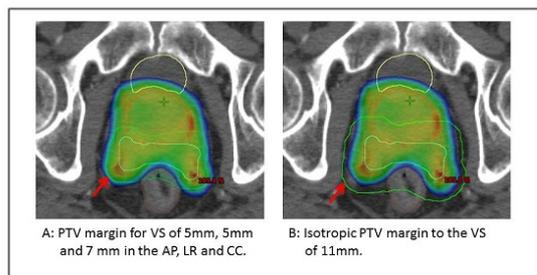

We have obtained CT, T2 weighted (T2w) MRI, dynamic contrast enhanced (DCE) MRI and diffusion weighted imaging (DWI) MRI for 21 high-risk prostate cancer patients with an intact prostate. All patients completed their radiotherapy treatment course of 78Gy in 39 fractions. Our clinical standard margins of 5mm, 5mm and 7mm in the anterior-posterior, left-right and cranio-caudal direction, respectively, were applied to the SV delineation for preparing the clinical plans. MRI scans were then further examined retrospectively. All three MRI sequences were delineated by a radiation oncologist and a suspicious volume on T2W confirmed by an overlap with one of the functional scans (DCR and/or DWI) was assumed to be macroscopically involved, see Figure 1. For patients with confirmed suspicious volume in the SV, we applied a PTV with a margin of 11mm (PTV11mm) to the clinical delineation of SV to account for the mobility of the SV when registering on implanted markers within the prostate as suggested by [2]. Coverage of the PTV used in the clinical dose plan (PTV5mm) and the PTV required for reliable SV coverage (PTV11mm) were extracted from the dose-volume histogram (DVH) of the clinical dose plan.

**Figure 1:** Suspicious volume observed in the SV cranial to the prostate gland in the T2w and confirmed in both functional images. The Ktrans map from the DCE is not calculated in the complete slice and, therefore, information is only available in a limited volume of interest. The contours of the suspicious volume are: T2w (blue), DWI (pink) and DCE (green). The bladder (yellow) and rectum (brown) are contoured in the CT image and transferred to the MRIs.

### Results

For 14 out of 21 patients had a T2w suspicious volume confirmed either by DWI or DCE, with 6 cases having suspicious volumes in all three MRIs. The 14 patients had median (range) of dose to 98% of the PTV volume (D98%) of 73.1Gy (57.6-75.6) and 45.9Gy (39.3-61.7) for PTV5mm and PTV11mm, respectively. In four cases D98% of PTV5mm was below the clinical recommendation of 70.2Gy while all 14 patients had D98% of PTV11mm below 70.2Gy, see Figure 2.

**Figure 2:** The clinical dose plan shown in the transvers slice with 90% dose color wash. In A the clinical margin is shown in dark green (red arrow) and the compromise is seen in dose coverage of SV due to rectum. In B the 11mm margin recommended for ensuring dose coverage of the SV is shown in light green (red arrow) with clearly inadequate coverage. The bladder, rectum, prostate and SV are delineated in yellow, brown, red and cyan, respectively.

### Conclusion

Coverage of the SV to the prescription dose is not guaranteed when using tight margins and highly conformal radiotherapy despite daily match on fiducials in the

prostate. This is a particular concern as studies found a higher rate of failure with highly conformal radiotherapy when comparing to rectangular fields [3], yet uniform wide margins to SV will substantially increase the dose to the rectum. With the current study we used multi-sequence MRI to yield risk-adapted margins to increase coverage of SV for selected patients, while maintaining standard, tight margins for patients without suspicious MRI findings.

<sup>4</sup>CENTRE OSCAR LAMBRET, Department of Medical Physics, Lille, France

<sup>5</sup>INSERM 1189 ONCO-THAI, LILLE University, Lille, France

### Purpose or Objective

To evaluate the feasibility of diffusion-weighted MRI (DWI) as an early biomarker in patients receiving hypofractionated stereotactic boost for intermediate risk prostate cancer

### Material and Methods

Patients with intermediate risk prostate cancer were included in a multicenter CKNO phase II trial. During the first part of the treatment, 23 fractions (2 Gy/session) were delivered over 42 days maximum using 3DCRT. During the second treatment part, hypofractionated stereotactic boost (3 fractions of 6 Gy) was delivered each other day. Median follow up was 26.4 months (range:13.6 - 29.9). Multiparametric (mp) MRI was realized before (M0) and at regular follow-up intervals after radiotherapy (6, 9, 12, 24, 30, 36 and 48 months). This ancillary study included the 24 patients treated in our center (3T MRI). None of them presented with recurrence so apparent diffusion coefficient (ADC) and ktrans variations were correlated to PSA kinetics. GTV was delineated by experienced radiologist and radiation oncologist on baseline and follow-up mpMRI. Mean tumor ADC values (b=0, 1000 and 2000 s/mm<sup>2</sup>) were normalized to obturator muscle (nADC). Spearman's coefficient correlation and non-parametric Wilcoxon Mann-Whitney tests were used for continuous and categorical variables respectively.

### Results

GTV was visualized on MRI in 12 patients. Mean nADC improved from  $1.14 \times 10^{-3}$  mm<sup>2</sup>/s (min 0.49 max 1.53) to  $1.59 \times 10^{-3}$  mm<sup>2</sup>/s (min 1.15 max 1.94) between M0 and M24. The nADC variation between M0 and M12 was correlated with PSA at M18. The nADC increase between M0 and M12 was larger in patients with PSA < 1ng/mL at M18 (p=0.034) (Table). No other correlation was found. Ktrans variation was not associated with PSA kinetics.

	M18	
	PSA < 1 ng/ml	PSA ≥ 1 ng/ml
Median (range)	0.57	0.295
$\Delta$ nADC M12 vs M0	(0.57-0.72)	(0.23-0.53)
		p=0.034
Mean (sd)	0.619 (0.084)	0.22 (0.33)
$\Delta$ nADC M12 vs M0		p=0.034

### Conclusion

These preliminary results show an increase in nADC after stereotactic boost radiotherapy and correlation with PSA nadir. These results should be confirmed with a larger strength and a longer follow up.

### EP-1695 Intra-treatment diffusion MRI for predicting radiotherapy response in head and neck cancer patients

E. Samsøe<sup>1</sup>, F. Mahmood<sup>1</sup>, H.H. Johannesen<sup>2</sup>, C. Maare<sup>3</sup>, R.H. Hansen<sup>4</sup>

<sup>1</sup>University Hospital Herlev, Department of Oncology-Radiotherapy Research Unit, Herlev, Denmark

<sup>2</sup>Rigshospitalet, Department of Clinical Physiology-Nuclear Medicine and PET, Copenhagen, Denmark

<sup>3</sup>University Hospital Herlev, Department of Oncology, Herlev, Denmark

<sup>4</sup>University Hospital Herlev, Department of Radiology-Research group, Herlev, Denmark

### Purpose or Objective

The purpose of this prospective case study is to analyze closely spaced diffusion weighted MRI (DWI) to monitor head and neck squamous cell carcinoma (HNSCC) tumor response throughout the entire course of radiotherapy (RT). The objective is to estimate if and when during RT the percentage (%) changes in apparent diffusion coefficients (ADCs) may be able to predict response to treatment. The % ADC change is expected to be more reproducible across centers than absolute ADC values.

### Material and Methods

Fourteen patients with HNSCC were included in the original study. Three patients were excluded, yielding a total of eleven patients for the analysis. The patients had DWIs before (scan 1), twice a week during (scan 2-12), 2 weeks after (scan 13) and 8 weeks after (scan 14) chemo-RT with 33 or 34 fractions to 66 or 68 Gy in total. Not all patients complied with all planned scans. Patients were scanned with a 1T MRI scanner to acquire DWIs with 7 different b-values (b=50, b=150, b=200, b=500, b=600, b=700 and b=800 s/mm<sup>2</sup>) in addition to T1W + contrast and T2W scans. DWI data based on mean pixel values of the regions of interest (ROIs) were fitted using a mono-exponential model to derive the apparent diffusion coefficient (ADC). The ROIs were delineated by an experienced radiologist using high b-value images (b=800 s/mm<sup>2</sup>).

### Results

This case study presents results from the analysis of two patients with a mean follow-up time of 4 years and 1 month. One of the patients (PT2) achieved complete response from the treatment. The other patient (PT8) had a local relapse 17 months after the last treatment fraction. The DWIs (b=800 s/mm<sup>2</sup>) for PT2 and PT8 with the analyzed gross tumor volumes (GTVs) delineated at scan number 1, 6 and 11 respectively are shown in Fig. 1. The ADC for PT2 increased steadily during treatment, corresponding to a decrease in DWI signal in Fig. 1, with a mean percentage rise in ADC of 27 % from the 1<sup>st</sup> (pre RT) to the 11<sup>th</sup> (5 weeks into RT) scan, see Fig. 2. The mean rise in ADC for PT8 from the 1<sup>st</sup> to the 11<sup>th</sup> scan was only 17 %. These percentage changes in ADCs were +19 % and

+10 % when considering the difference between 1<sup>st</sup> and 6<sup>th</sup> (2.5 weeks into RT) scans for PT2 and PT8, respectively.

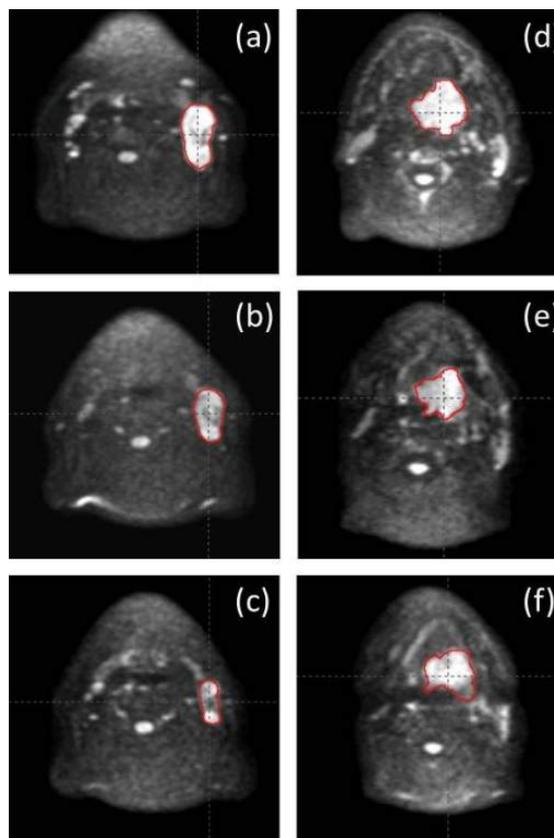

Fig. 1. DWI ROI delineation for PT2: (a)-(c) and PT8: (d)-(f) pre- (upper), 2.5 weeks intra- (middle) and 5 weeks intra-treatment (lower).

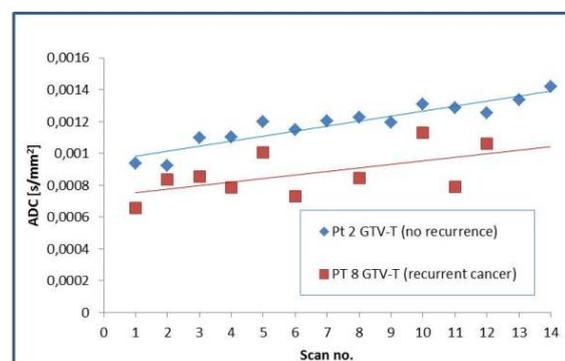

Fig. 2. ADC versus scan number during the two courses of RT for PT2 (diamonds) and PT8 (squares).

### Conclusion

As early as 2-3 weeks into the course of RT, a difference between the percentage rises in ADC was observed between a well responding tumor (PT2) and a tumor which relapsed (PT8). Our results from the case study indicate that the percentage rise in ADC may be a predictor of treatment outcome. These observations comply well with observations from other centers. Further data analysis in this study may reveal an optimum time during RT for response assessment-DWI and eventually a % ADC change threshold for predicting response to treatment.

### EP-1696 Dose-painting planning with uncertainties in dose-response parameters and in patient positioning

M. Balvert<sup>1</sup>, S. Breedveld<sup>2</sup>, J. Unkelbach<sup>3</sup>, D. Den Hertog<sup>1</sup>, S. Petit<sup>2</sup>

<sup>1</sup>Tilburg University, Tilburg School of Economics and Management, Tilburg, The Netherlands

<sup>2</sup>Erasmus Medical Center Rotterdam Daniel den Hoed Cancer Center, Department of Radiation Oncology, Rotterdam, The Netherlands

<sup>3</sup>Massachusetts General Hospital, Radiation Oncology, Boston, USA

### Purpose or Objective

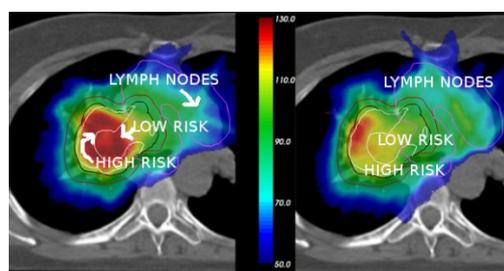

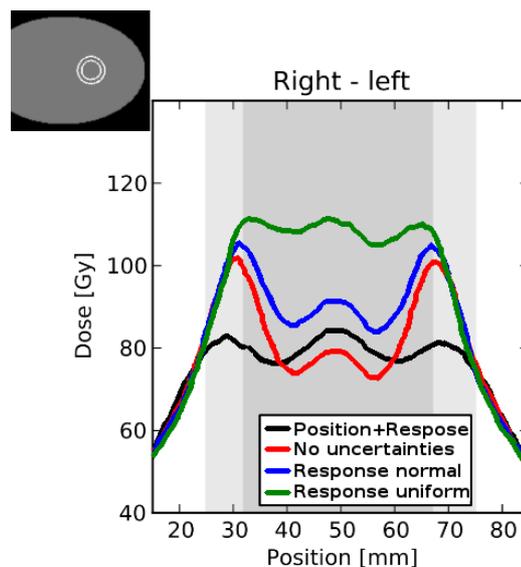

First dose-painting clinical trials are ongoing, even though the largest challenge of dose-painting has not been solved yet: to robustly redistribute the dose to the different regions of the tumor. Efforts to derive dose-response relations for different tumor regions rely on strong assumptions. Without accounting for uncertainty in the assumed dose-response relations, the potential gain of dose-painting may be lost. The goal of this study is to implement an automated treatment planning approach for dose-painting that takes into account uncertainties both in dose-response relations and in patient positioning directly into the optimization. Such that even in the presence of large uncertainties the delivered dose-painting plan is unlikely to perform worse than current clinical practice with homogeneous prescriptions.

### Material and Methods

Dose response relations in TCP (tumor control probability) are modeled by a sigmoid shaped function, using 2 parameters to describe the dose level and cell sensitivity. Each voxel has its own tuple of parameters, and the parameters were assumed to follow probability distributions for which the mean and the variance were known. The expected TCP over all uncertainty distributions was optimized. Random positioning uncertainties were dealt with by convolving the pencil beam kernels with a Gaussian. For systematic geometrical uncertainties, a worst case optimization was implemented, to ensure adequate dose delivery in 95% of the geometrical scenarios. The method was implemented in our in house developed TPS and applied to a 3D ellipsoid phantom with a spherical tumor with a resistant shell and sensitive core and to a NSCLC cancer patient case with 3 subvolumes that were assumed to vary in radio-sensitivity. The effect of different probability distributions for cell sensitivity was investigated.

### Results

As expected, in the absence of dose-response and positioning uncertainties (red line), the dose to the resistant ring of the phantom (light gray in Fig 1) is considerably higher than to the sensitive core (dark gray). However, as the uncertainty in dose response relations increases (blue and green lines), the dose difference between the subvolumes decreases, even though the expected cell sensitivities do not change. Including positioning uncertainties leads to further smearing out of the dose (black line). Fig 2 demonstrates the effect on a real lung patient case with high risk GTV (white), low risk GTV (black), lymph nodes (pink).

### Conclusion

The uncertainties in dose-response relations of different tumor subregions can strongly affect dose-painting treatment plans. Hence, it is crucial to take these uncertainties into account in the optimization to avoid losing any potential gain of dose-painting. To the best of our knowledge this is the first implementation of a dose-painting optimization that is fully automated, and optimizes TCP taking into account both uncertainties in dose-response relations and patient positioning and that can be applied to real world cases

### EP-1697 Does contrast agent influence the prognostic accuracy of CT radiomics based outcome modelling?

S. Tanadini-Lang<sup>1</sup>, M. Nesteruk<sup>1</sup>, G. Studer<sup>1</sup>, M. Guckenberger<sup>1</sup>, O. Riesterer<sup>1</sup>

<sup>1</sup>University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland

### Purpose or Objective

Radiomics is a powerful tool to characterize the tumor and predict treatment outcome. The evaluation of retrospective studies is often hampered due to differences in image acquisition protocols. Whereas planning computer tomography (CT) imaging is standard of care for head and neck squamous cell carcinoma (HNSCC) patients treated with radiotherapy, the use of i.v. contrast depends on the institutional protocol and is not standardized. This was the motivation to study if mixed CT datasets including native CT images and contrast enhanced images can be used in radiomic studies.

### Material and Methods

33 patients with HNSCC that received CT imaging with and without i.v. contrast before definitive radio-chemotherapy were included in the study. The primary gross tumor volume was segmented semi-automatically based on PET images acquired at the same time. 693 radiomic features (17 intensity, 60 texture, 77 in each of the 8 wavelet sub-bands (616 features)) were calculated

in native and contrast enhanced CT images. Radiomic features in the two CT modalities were compared based on the intraclass correlation coefficient (ICC1). The prognostic value of both modalities was assessed using univariable Cox regression. Additionally, in a previous analysis we built a local tumor control prognostic model based on contrast enhanced CT images of 93 patients. It comprised three radiomic features (HHH large zone high grey-level emphasis, LLL sum entropy and LLH difference variance). The performance of this model was comparatively tested in the two new CT datasets.

#### Results

118 out of 693 radiomic features showed a good agreement between native CT and contrast enhanced CT imaging ( $ICC > 0.8$ ). None of the intensity features was stable and only 7 of the texture features in the non transformed map. In the univariable Cox regression 96 and 107 radiomic features in the native and contrast-enhanced CT images had a significant influence on the local control, respectively. 62 parameters were prognostic in both modalities, but only half of them showed a good agreement between native and contrast enhanced CT images ( $ICC > 0.8$ ). Two out of the three features of our previously developed model were stable in respect to the administration of contrast agent in the CT images ( $ICC > 0.8$ ). However, our model was only predictive for the parameter set derived from the contrast enhanced CT images ( $CI = 0.69$ ,  $p = 0.013$ ). Based on this, patients could be divided into 2 risk groups ( $p = 0.02$ , Figure 1).

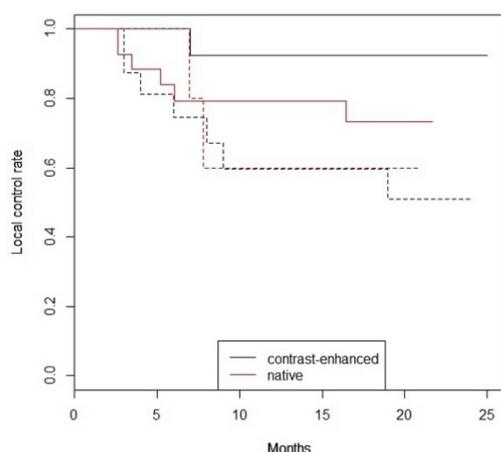

Figure 1: The patients could be divided into two risk groups ( $p = 0.02$ ) based on the radiomics of contrast enhanced CT images and the model derived from our previous training cohort (contrast enhanced CTs). The splitting was not significant for radiomics of native CT images.

#### Conclusion

Radiomic models can be built on a mixed set of native and contrast-enhanced CT images but with a reduced number of suitable radiomic features. A model built exclusively with contrast enhanced CT images cannot be validated in a set of native CT Images.

#### EP-1698 Impact of motion and segmentation on PET texture features: evaluation with heterogeneous phantoms.

M. Carles<sup>1,2</sup>, I. Torres-Espallardo<sup>2</sup>, D. Baltas<sup>1</sup>, U. Nestle<sup>1</sup>, L. Martí-Bonmati<sup>2</sup>

<sup>1</sup>University Medical Center, Department of Radiation Oncology, Freiburg, Germany

<sup>2</sup>Hospital Universitario y Politécnico La Fe, Medical Imaging, Valencia, Spain

#### Purpose or Objective

A major source of error in quantitative PET/CT of lung cancer tumors is respiratory motion. Regarding variability of PET texture features (TF), the impact of respiratory motion has not been properly studied with experimental phantoms. The primary aim of this work was to evaluate the current use of PET texture analysis for heterogeneity characterization in lesions affected by respiratory motion.

#### Material and Methods

Twenty-eight heterogeneous lesions were simulated by a mixture of alginate and 18F-fluoro-2-deoxy-D-glucose (FDG). Sixteen respiratory patterns were applied. Firstly, the TF response for different heterogeneous phantoms and its robustness with respect to the segmentation method were calculated. Secondly, the variability for TF derived from PET image with (gated, G-) and without (ungated, U-) motion compensation was analyzed. Finally, TF complementarity was assessed.

#### Results

In the comparison of TF derived from the ideal contour (VOI\_ideal) with respect to TF derived from 40%-threshold (VOI\_40%) and adaptive-threshold (VOI\_COA) PET contours, 7/8 TF showed strong linear correlation LC ( $p < 0.001$ ,  $r > 0.75$ ), despite a significant volume underestimation. Independence on lesion movement (LC in 100% of the combined pairs of movements,  $p < 0.05$ ) was obtained for 1/8 TF with U-image (width of the volume-activity histogram, WH) and 4/8 TF with G-image (WH and energy ENG, local-homogeneity LH and entropy ENT, derived from the co-occurrence matrix). Apart from WH ( $r > 0.9$ ,  $p < 0.001$ ), no one of these TF has shown LC with Cmax. Complementarity was observed for the TF pairs: ENG-LH, CONT-ENT and LH-ENT.

#### Conclusion

In conclusion, effect of respiratory motion should be taken into account when heterogeneity of lung cancer is quantified on PET/CT images. Despite inaccurate volume delineation, TF derived from 40% and COA contours could be reliable for their prognostic use. The TF that exhibited simultaneously added value and independence of lesion movement were ENG and ENT computed from G-image. Their use is therefore recommended for heterogeneity quantification of lesions affected by respiratory motion.

#### EP-1699 The simulation study of position and biology of target with PET in high energy X-Ray irradiation

Q. Zhang<sup>1</sup>  
<sup>1</sup>Topgrade Medical - Yiren Hospital, Radio-therapy center, BEIJING, China

**Purpose or Objective** To study the possibility of in situ verification of dose distributions and position in radiation therapy with PET imaging based on the activity distribution of <sup>11</sup>C and <sup>15</sup>O produced via photonuclear reactions in patient irradiated by 45MV X ray from the LA45 accelerator.

**Material and Methods** The method is based on the photonuclear reactions in the most elemental composition <sup>12</sup>C, <sup>16</sup>O in body tissues irradiated with high-energy photons with energies up to 45 MeV, resulting primarily in <sup>11</sup>C and <sup>15</sup>O, which are positron emitting nuclei. The induced positron activity distributions were obtained with a PET scanner in the same room of a LA45 accelerator (Top Grade Medical, Beijing, China). The activity distributions of <sup>11</sup>C and <sup>15</sup>O were used to verify the dose distributions and position in target as delivered by the LA45 accelerator.

The experiments were performed with a brain phantom. Radiation beams were delivered to the phantom according to realistic radiation therapy treatment plans. The phantom was immediately transferred to PET and was scanned on the PET after irradiation. The scans were performed at 20 minutes and 2-5 minutes after irradiation for <sup>11</sup>C and <sup>15</sup>O, respectively. The interval between the two

scans was 20 minutes. The activity distributions of  $^{11}\text{C}$  and  $^{15}\text{O}$  within the irradiated volume can be separated from each other because the half-life of  $^{11}\text{C}$  and  $^{15}\text{O}$  is 20 minutes and 2 minutes, respectively. Three x-ray energies were used including 10MV, 25MV and 45MV. The radiation dose ranged from 1.0Gy to 10.0Gy per treatment. The dose distribution can be calculated from the activity distribution of  $^{11}\text{C}$  and  $^{15}\text{O}$ .

#### Results

It was confirmed that no activity was detected at 10 MV beam energy, which was far below the energy threshold for photonuclear reactions. At 25 MV x-ray beams could produce photonuclear reactions and activity distribution images were observed on PET. But it needed much higher radiation dose in order to obtain good quality images. For 45 MV photon beams, good quality activation images were obtained with 2-3Gy radiation dose, which is the typical daily dose for radiation therapy.

#### Conclusion

The PET image and the activity distribution of  $^{15}\text{O}$  and  $^{11}\text{C}$  positron emitter nuclei could be used to derive the dose distribution of 45MV x-ray irradiation at the regular daily dose level. This method can potentially be used to verify in situ dose distributions delivered to the patient using the LA45 accelerator.

#### EP-1700 Prognostic value of FCH PET/CT in response to radical radiotherapy for localized prostate cancer

M. Sepulcri<sup>1</sup>, L. Evangelista<sup>2</sup>, M. Fusella<sup>3</sup>, S. Galuppo<sup>1</sup>, L. Corti<sup>1</sup>, G. Saladini<sup>2</sup>, M. Paiusco<sup>3</sup>

<sup>1</sup>Veneto Institute of Oncology IOV-IRCCS, Radiation Oncology Unit, Padua, Italy

<sup>2</sup>Veneto Institute of Oncology IOV-IRCCS, Nuclear Medicine and Molecular Imaging Unit, Padua, Italy

<sup>3</sup>Veneto Institute of Oncology IOV-IRCCS, Medical Physics Unit, Padua, Italy

#### Purpose or Objective

To assess the value of FCH PET/CT in predicting the outcome of patients with localized prostate cancer treated by radical radiotherapy.

#### Material and Methods

From a mono-centric PET/CT database, we retrospectively reviewed pre-treatment FCH PET/CT scans of 24 patients who underwent radiotherapy for the treatment of localized prostate cancer. For each study, SUVmax, SUVavg and metabolic tumor volume (MTV) were evaluated. Moreover, the value of PSA before radiotherapy (PSAp) was recovered. Regarding radiation therapy, all patients underwent to a radical treatment for a total equivalent dose of 78-80 Gy, reached with a standard fractionation (2 Gy/fraction) or with an hypofractionated schedule (2.5 Gy/fraction). A follow-up period after PET/CT scan, of at least one-year, was required. In accordance with the observational period, patients were classified as disease free (DF) if the increase of PSA value after radiotherapy was less than 2 ng/mL respect to PSA nadir value, conversely with an increase of PSA higher than 2 ng/ml they were classified as recurrent (not disease free, NDF).

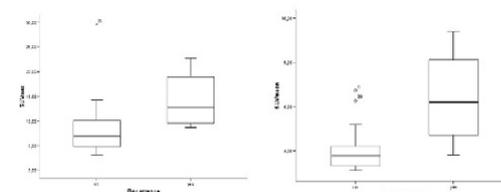

A Kolmogorov-Smirnov test was used to compare the distribution of semi-quantitative PET and PSA data of the two patient groups.

For all patients a simulated plan with a dose escalation on intraprostatic dominant lesion (IDL) was made.

#### Results

Mean, minimum and maximum values of SUVmax, SUVavg, MTV and PSAp were 9 (3.1-29.6), 4.2 (3.1-9.4), 13.3 (0.1-49.1) and 18.3 ng/mL (4.5-88.7 ng/mL), respectively. After one year of follow-up, 20 patients were considered as DF and 4 patients were considered as NDF. The values of DF patients were 8.2 (3.1-29.6), 3.9 (3.1-6.7), 11.6 (0.1-29.7) and 16 ng/mL (4.5-54.8 ng/mL) respectively for

SUVmax, SUVavg, MTV and PSAp. For NDF patients the corresponding obtained values were 14.3 (8.7-22.7), 6.4 (3.8-9.4), 24.8 (7.1-49.1) and 33.7 ng/mL (8.7-88.7 ng/mL). In NDF patients, the mean values of SUVmax and SUVavg were significantly higher than in DF group (both  $p < 0.05$ , fig.1) while MTV and PSAp were not statistically different between the two groups. This data, in accordance with the well known radiobiology of prostate cancer, suggest to increase the dose to the tumor. The analysis of OAR's DVH (bladder and rectum) showed that there are no significant changes between the standard treatment and the simultaneous integrated boost (SIB) approach, reaching a total dose to IDL volume around 105 Gy.

#### Conclusion

High values of FCH SUV's in prostate cancer for patients who are candidates to radiotherapy result predictive of poor outcome after one year of follow-up. Therefore, the SUV values could be useful to identify those patients who could benefit from a boosted radiotherapy dose to the intraprostatic dominant tumor lesion.

#### EP-1701 FDG-PET Background Definition in Rectal Cancer Patients Using Differential Uptake Volume Histograms

J. Schneider<sup>1</sup>, N. Tomic<sup>1</sup>, T. Vuong<sup>1</sup>, R. Lisbona<sup>2</sup>, M. Hickeson<sup>2</sup>, G. Chaussé<sup>2</sup>, F. DeBlois<sup>1</sup>, J. Seuntjens<sup>1</sup>, S. Devic<sup>1</sup>

<sup>1</sup>McGill University, Oncology, Montreal, Canada

<sup>2</sup>McGill University, Diagnostic Radiology, Montreal, Canada

#### Purpose or Objective

According to Erdi et al. [Cancer 1997;80:S2505-9] signal to background ratio (S/B) reflects the activity specific for local normal tissue, rather than making an assumption the activity is uniformly distributed over the whole body and recommended S/B as a quantity of choice for radiotherapy target definitions. In the case of paired organs (lung) Devic et al. [Int J Rad Oncol Biol Phys 2010; 78: 1555-62] sampled background uptake in contra-lateral healthy lung and scaled it by physical densities to obtain S/B for NSLC patients.

#### Material and Methods

Differential uptake volume histogram (dUVH) method [Devic et al. BJR 2016;89:20150388] was used on a group of 20 rectal adenocarcinoma patients that received pre-operative endorectal brachytherapy [Vuong et al, J Cont Brachyther 2015;7:183-8]. All patients had PET/CT scan prior to brachytherapy for staging purposes. Based on post-surgery pathology results half of the patients had complete response after brachytherapy (pT0) while the other half had no or minimal response. Uptake values (in Bq/ml) were sampled on PET images, using CT, and co-registered PET/CT images (Fig.1 top) by placing the sampling region of interest (ROI) over both tumor and healthy rectal tissue, and at the same time by avoiding air (gas) and feces.

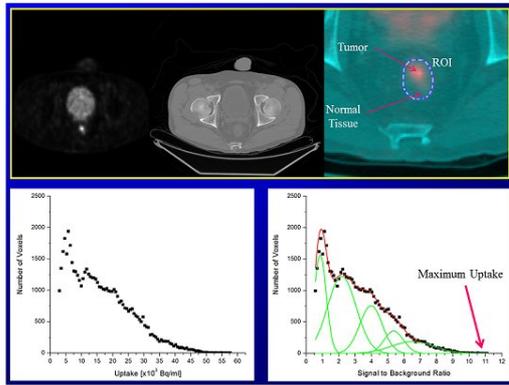

Figure 1: Sampling of FDG uptake within rectal tumor and normal rectal tissue (top); differential Uptake Volume Histogram (dUVH) in terms of uptake values (bottom-left); dUVH normalized to the uptake value of the first peak assuming to represent normal rectal tissue glucose uptake (bottom-right).

**Results**

Once the dUVH was created in terms of uptake values (Fig.1.bottom left) the histogram was normalized to the uptake value of the very first peak assuming to correspond to the normal rectal tissue glucose uptake. Subsequently, the maximum S/B ratios were sampled for all patients (Fig.1.bottom right). Table 1 represents results of two-sample paired t-test indicating that patients with complete response to radiation (pT0) have higher and significantly different S/Bmax when compared to non-responders. While there are some contradictory data in the literature in regards to SUVmax and clinical outcomes, our results are in agreement with notion that more aggressive tumors (that spend longer periods of time in M phase, known to be more radiosensitive) have better response to radiation.

Table 1: Maximum Signal-to-Background ratios (S/Bmax) for patients with complete response (Column A) and with partial omo response (column B), together with results of the two-sample paired t-test.

Case	ADJ	RPV
1	11.9	5.4
2	8.9	6.1
3	18.1	4.4

2. Data1_B	10	5.647	6.8188	2.1525

Difference of Means:		Mean1 - Mean2	>	0
1	10.463			

Null Hypothesis:		MEAN1 - MEAN2	=	0
Alternative Hypothesis:		MEAN1 - MEAN2	<	0
t	12.72272	9	0.00000	

At the 0.05 level, the difference of the population means is significantly different than the test difference (0).

**Conclusion**

While the dUVH method was initially developed to extract different biological sub-volumes (glucose phenotypes) within tumors, results presented here suggest that the same method can help in defining the background uptake on PET images. The method described here shows an alternative to sampling the background (normal) uptake within contralateral (healthy) tissue in the case of paired organs (lung, brain, etc). Furthermore, reconstructed S/Bmax values may prove to represent a prognostic factor of tumor response to radiation and hence allow for tailoring of more patient specific treatment strategies.

**EP-1702 Evaluation of radiation induced MRI intensity change in vertebral bodies after proton beam scanning**  
 L. Placidi<sup>1</sup>, R. Poel<sup>1</sup>, A.J. Lomax<sup>1</sup>, D.C. Weber<sup>1</sup>, M. Peroni<sup>1</sup>  
<sup>1</sup>Paul Scherrer Institute PSI, Centre for Proton Therapy, Villigen PSI, Switzerland

**Purpose or Objective**

This retrospective study aims at evaluating the magnetic resonance intensity bone change (MRiBC) [Gensheimer et al. 2009] induced by pencil beam scanning (PBS) proton treatment. Two fundamental aspects are tackled: (i) the MRI signal reproducibility, especially if the imaging is

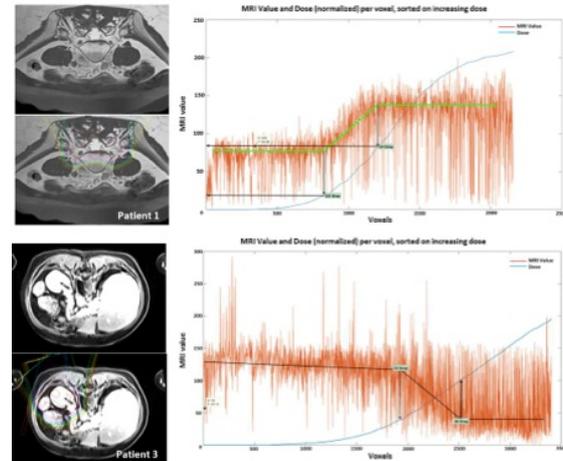

performed at different time points, with the goal of generating differential maps which would enhance/visualize the signal changes; (ii) correlation of MRiBC with the dose distribution, for the purpose of identifying a cumulative dose threshold.

**Material and Methods**

Data of three patients treated at PSI where target was involving or immediately next the spinal cord resulting in an evident bone change (fatty replacement) after the treatment was selected. All patients received a pre- and a post-treatment MRI and a subset of the acquired sequences (T2 space transversal, T1 vixie dixon transversal with contrast media) were included into this analysis. Rigid registration on the bony structure has been performed in the region of interest of the bone change between the planning CT and the MRIs (T1 and T2 sequences), both pre and post treatment. To generate a differential map enhancing only the fatty replacement, it is important that same tissues have the same signal across the different time points. Therefore, we evaluated the stability of MRI signal pre- and post- treatment on vertebral bodies outside the treatment area. Finally, the post treatment MR Intensity was correlated with dose distribution.

**Results**

Variations in signal intensity of the same ROI and in different acquisition days show a mean value of the mean signal intensity difference of 50 and a max-min difference of 130 (grey intensity scale). Therefore, generating a reliable subtraction map is extremely difficult with conventional sequences. For the considered 3 cases, the correlation between the MRiBC and dose distribution looks good for all 3 patients (Fig. 1). In this case, the bone change lies between the 20%-30% isodose line.

**Conclusion**

MRI signals are not quantitative enough to use and it is difficult to manipulate MRI settings to make it more quantitative. Image processing, as normalisation, smoothing, etc., can lead to a substantial variation of the original data set and shows relevant signal histogram differences. A possible common solution could be a quantitative MRI sequences (as a T2 relaxation time map), that is already under investigation and could reduce signal variation of an order of magnitude. As the dataset at our disposal is consisting of pre- and post-treatment MRIs only, it is difficult to say whether bone marrow change is more like a threshold or if there is in fact a useable gradient. In order to monitor the onset of the fatty replacement, track it during the entire process and better correlate it to the delivered dose, periodic MRI acquisition during treatment is necessary. Nevertheless, for these patients, it is clear that there is a correlation between MRiBC and dose.

**EP-1703 Rapid prototyping phantom using LEGO® for MRI distortion correction in MR guided radiation therapy**  
 S. Neppel<sup>1,2</sup>, M. Reiner<sup>1</sup>, M. Peller<sup>3</sup>, C. Belka<sup>1</sup>, K. Parodi<sup>2</sup>, F. Kamp<sup>1</sup>

<sup>1</sup>LMU Munich, Department of Radiation Oncology, Munich, Germany

<sup>2</sup>LMU Munich, Department of Medical Physics, Garching b. München, Germany

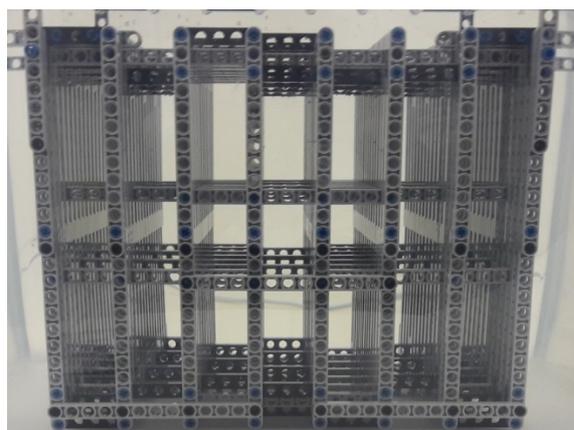

<sup>3</sup>LMU Munich, Department for Clinical Radiology, Munich, Germany

#### Purpose or Objective

An accurate geometry is critical for the use of MR images for dose calculation in MR guided radiation therapy. Therefore, we designed an easily adjustable distortion phantom based on LEGO® technic parts to detect and correct geometrical inaccuracies caused by magnetic field inhomogeneities.

#### Material and Methods

The designed phantom consists of LEGO® technic beam parts with 13 holes, rectangular beam parts with 3+4 holes ("L shape" for stability) and pins to connect 2 or 3 beam parts. The holes within the beam parts have a diameter of 4.85 mm and a center distance of 7.99 mm. The phantom has a size of 24x24x22 cm<sup>3</sup> and is placed in a container filled with water (Fig. 1). The LEGO® parts do not give a signal and are therefore not visible on the MR image in contrast to their water-filled holes. The MR images were acquired on a SIEMENS Magnetom® Aera with a clinically used T1 weighted MPRAGE (Magnetization Prepared Rapid Gradient Echo) sequence with an isotropic voxel size of 1.5 mm, TE = 1.98 ms, TR = 1900 ms, TI = 900 ms and a flip angle of 8°. An automatic hole detection of the Lego parts was developed with the Image Processing Toolbox™ of Matlab® 2016a. First the beam parts are segmented with an adaptive threshold and then a search for circular structures is performed within the beam mask. The centers of the recognized circles are iteratively corrected to the brightest position within the circle. The exact reference hole positions are imported from the CAD model of the phantom.

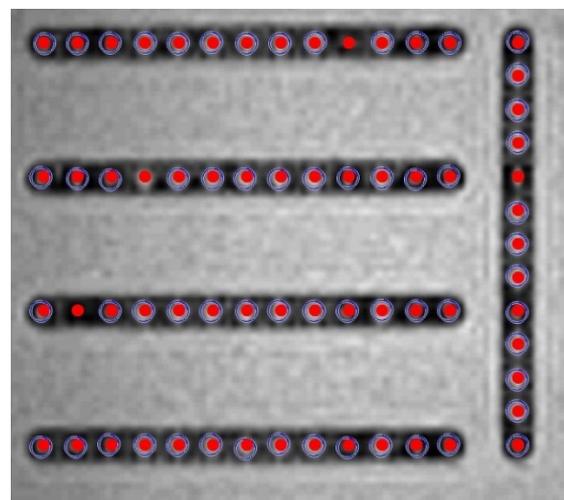

**Figure 1:** Photo of the designed LEGO® phantom in water. This phantom consists of 270 "beam 13 parts" (grey), 85 "beam 3+4 parts" (black), long pins (blue) and short pins (black).

#### Results

A very customizable MRI distortion correction phantom was developed. The beam parts are correctly detected in the inner part of the images. At the edges of the phantom the distinction to the air outside the container and a low contrast leads to undetected holes. The phantom should

hence not be placed at the bottom, but in the center of the water container. More than 90 % of the holes within the recognized beam parts are correctly located by the algorithm (Fig. 2). The main reason for detection failures are the connection pins, which are often filled with air bubbles (no MR signal). The detection rate could be improved using prior knowledge of the shape of the beam parts, available from the CAD model.

**Figure 2:** An exemplary snippet of a phantom MR slice. The blue circles visualize the recognized holes on the MR image and the red dots show the exact positions given by the CAD model.

#### Conclusion

A cheap and extremely customizable phantom was designed using LEGO® technic parts to correct MR images for geometric distortion. For fast prototyping, the size of the phantom can be easily adapted. The hole positions can be extracted correctly and with a high detection rate from the MR images. The shift from their nominal position to the detected position can be used to create a distortion map.

**EP-1704 Breast tumour bed contouring: influence of surgical clips assessed on the same imaging.**

<sup>1</sup>European Institute of Oncology, Department of Radiation Oncology, Milan, Italy

<sup>2</sup>European Institute of Oncology, Unit of Medical Physics, Milan, Italy

<sup>3</sup>Politecnico di Milano, Dipartimento di Elettronica- Informazione e Bioingegneria, Milan, Italy

<sup>4</sup>European Institute of Oncology, Department of Medical Imaging and Radiation Science, Milan, Italy

#### Purpose or Objective

To evaluate the inter-observer variability in the contouring of tumour bed after lumpectomy in breast-conservative surgery patients.

#### Material and Methods

We retrospectively analysed the planning computed tomography (CT) of 47 patients who underwent external radiotherapy (ERT) post-lumpectomy and intra-operative radiotherapy (IORT). Three to 5 surgical clips were positioned to delineate the excision cavity. The CT acquired for ERT planning was modified to obtain a virtual CT scan with hidden clips: in particular, clips were blurred using a fully automated MATLAB script that replaces each voxel of the clip with a value obtained from a normal pseudo-random distribution with mean value and variance

corresponding to the mean value and variance of an outer ring of the clip itself. Two expert and 2 junior radiation oncologists contoured the tumour bed on the original CT and on the processed CT, thus obtaining 376 contours. For each patient, and for all possible pairwise combination of contours, the center of mass distance (CMD), the overlap of volumes according to the Dice similarity coefficient (DSC) and the distance between contours as average Hausdorff distance (AHD) were calculated to estimate the inter-observer variability. The size of volumes obtained with visible and hidden surgical clips was also evaluated.

### Results

A summary of the calculated metrics is reported in Fig. 1, with the boxplot representing the distribution of the metrics obtained from all the possible pairwise operator comparisons. A relative median increase of 48.7% in DSC (absolute difference 0.21) and a relative median decrease of 50.7% and 57.1% in CMD and AHD (absolute difference -0.68 mm and -2.21 mm), respectively, were observed when surgical clips are visible. The differences between “w/o clips” and “with clips” contours were always statistically significant ( $p < 0.001$ ), with the surgical clips showing an important contribute in diminishing the inter-operator variability. Greater volumes were obtained when surgical clips are visible (relative median increased volume +46.4% with visible surgical clips,  $p\text{-value} < 0.001$ ). However, a larger variability in segmented volumes between operators is observed when surgical clips are not visible, as shown in Table 1.

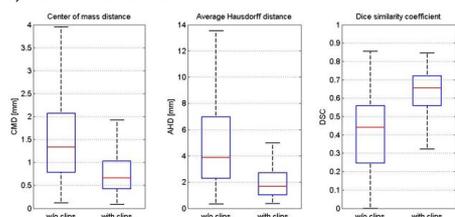

Figure 1 - Boxplot of center of mass distance (CMD), average Hausdorff distance (AHD) and Dice similarity coefficient (DSC) evaluated between all possible couples of operators. For each metric, the boxplots of the results obtained from contours segmented on the modified CT with hidden clips (“w/o clips”) and the original CT scans (“with clips”) are presented.

	Senior 1	Senior 2	Junior 1	Junior 2	<i>p</i> -value
	Median±IQR (cm <sup>3</sup> )	Median±IQR (cm <sup>3</sup> )	Median±IQR (cm <sup>3</sup> )	Median±IQR (cm <sup>3</sup> )	
Hidden clips	52.77±42.30	36.77±33.11	17.39±17.80	16.46±16.64	7.6e-14
Visible clips	47.57±39.23	41.73±22.91	33.35±21.14	37.76±32.50	0.052
<i>p</i> -value	0.77	0.27	3.6e-06	6.4e-07	

Table 1 - Analysis of volumes.

### Conclusion

Discrepancies in contouring target structures can undermine the precision of ERT. The correct identification of tumour bed is important to avoid target miss in the subsequent ERT, to spare this area from the overdosage if the patient underwent IORT and to allow for reliable multi-centric studies. The use of surgical clips supports the radiation oncologist during the contouring process. In this study, we demonstrated that the inter-operator variability decreases with the guidance of surgical clips. A dosimetric analysis will be performed as further development in order to estimate possible underdosage of the target or overdosage of the surrounding normal tissue. [The study was partially supported by AIRC and Accuray Inc.]

**EP-1705 MR imaging of internal mammary lymph nodes and organs at risk in supine breast radiotherapy**  
 T. Van Heijst<sup>1</sup>, E.M. Aalbers<sup>1</sup>, E. Alberts<sup>1</sup>, H.J.G.D. Van den Bongard<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, B. Van Asselen<sup>1</sup>, M.E.P. Philippens<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

Standard radiotherapy (RT) for breast cancer patients is performed with CT guidance. Addition of MRI in breast RT planning is being investigated. We have developed MRI sequences to visualize individual axillary lymph nodes (LNs) [van Heijst et al. 2016, BJR]. The next step is to optimize visualization of internal mammary LNs (IMLNs) and organs at risk (OARs). The purpose of this study is to image the IMLNs, the heart including the coronary arteries (left anterior descending artery (LAD), right coronary artery (RCA), and circumflex artery (CX)) - which are difficult to image due to influence of respiratory and cardiac motion - as well as the brachial plexus, body contour, and chest wall, using MRI in supine treatment position.

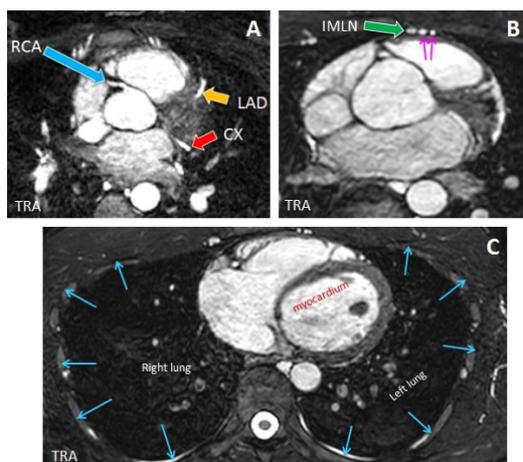

### Material and Methods

Ten healthy volunteers were scanned, arms abducted, on a 1.5 T scanner (Ingenia, Philips). An anterior receive coil was placed on an adjustable bridge, from the abdomen until the mandible without touching the patient; a posterior receive coil was located in the scanner table. No contrast agent was administered. Three MRI sequences were optimized and evaluated qualitatively for structure identification in RT planning:

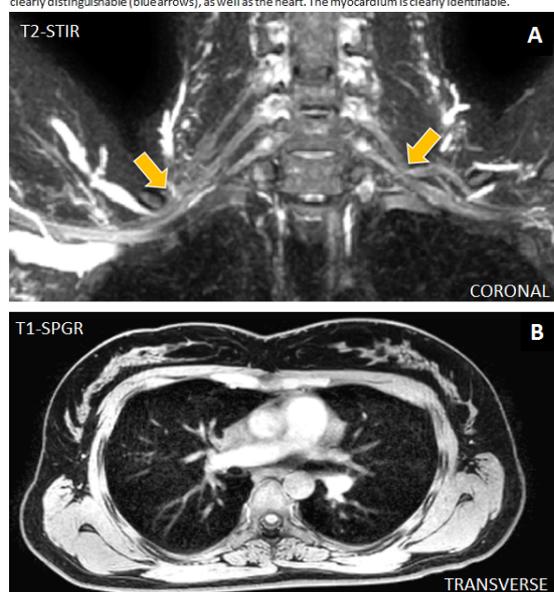

- Coronal 3-dimensional (3D) T2-weighted (T2w) fast spin echo with short-tau inversion recovery fat suppression (T2-STIR), covering the supraclavicular and axillary lymph node regions and the apex of the heart as caudal edge
- Transverse 3D balanced spoiled gradient (bSPGR) covering the heart using: spectral inversion recovery for fat suppression (SPIR); electrocardiography cardiac triggering on the diastolic heart phase; respiratory gating on a 1-D MRI navigator placed on the long-liver interface.
- Transverse 3D T1w SPGR, with mDixon water-fat separation (T1-SPGR) covering the body contour.

### Results

The heart and the RCA, LAD, CX arteries were clearly identified on bSPGR, with high contrast to the surrounding tissues, without apparent motion artifacts [fig 1A]. Small (4 mm diameter) IMLNs located close to the heart were also identified on bSPGR. The chest wall was visualized in bSPGR [fig 1C] and T1-SPGR; the latter distinctly showed the body contour [fig 2B]. The brachial plexus was clearly visualized with T2-STIR, showing intermediate signal intensity (SI), while main axillary arteries showed high SI [fig 2A]. The plexus could be followed from the spinal cord to the axillary nerves into the arm, on both sides.

**Figure 1:** Examples of the b-SPGR MRI scan optimized for visualization of the heart, including the coronary arteries, chest wall, and internal mammary lymph nodes (IMLNs). It is acquired in transverse (TRA) plane, with respiratory gating and cardiac triggering. In (A) a transverse slice is depicted where heart with three main coronary arteries are observed: RCA, LAD, and CX. In (B) the green arrow points to a small (4 mm) IMLN (green arrow) that is clearly visible, located very close to the heart. The parasternal arteries are indicated by the pink arrows. In (C), the chest wall is clearly distinguishable (blue arrows), as well as the heart. The myocardium is clearly identifiable.

**Figure 2:** Examples of MRI scans optimized for organ at risk visualization. In (A) an example of T2-STIR is shown in the coronal plane. The brachial plexus is indicated on both sides by yellow arrows. It can be followed from the spinal cord to the axillary nerves into the arms. In (B), T1-SPGR is shown, in the transverse plane, which clearly shows the body contour.

### Conclusion

Small IMLNs, as well as OARs, such as the brachial plexus, chest wall, heart and coronary arteries, were clearly distinguished on MRI in supine RT position. In current clinical practice, MRI may be used in addition to CT (which lacks soft-tissue contrast) to improve the delineation of targets and OARs in RT for breast cancer patients, with possibly better OAR sparing. Furthermore, together with recent techniques for axillary LN imaging, this may lead to development of MRI-guided stereotactic RT of individual LNs.

### EP-1706 Validation of a novel hybrid deformable image registration algorithm for cervix cancer

M. Buschmann<sup>1,2</sup>, H. Furtado<sup>2,3</sup>, D. Georg<sup>1,2</sup>, Y. Seppenwoolde<sup>1,2</sup>

<sup>1</sup>Medical University of Vienna, Department of Radiation Oncology, Vienna, Austria

<sup>2</sup>Medical University of Vienna, Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

<sup>3</sup>Medical University of Vienna, Center for Medical Physics and Biomedical Engineering, Vienna, Austria

### Purpose or Objective

Adaptive radiotherapy (ART) approaches based on frequent imaging in the planning and/or treatment phase have been proposed for external beam therapy of cervix cancer to account for large organ motion. To use the additional imaging information efficiently in ART, deformable image registration (DIR) is needed for autocontouring, organ deformation and dose deformation. A novel hybrid DIR algorithm that can deform images based on image intensity and contour information was validated for CT-to-CT-registration of the bladder, rectum and cervix-uterus (CTV-T).

### Material and Methods

CT datasets of 10 cervix cancer patients were used in this study. Each patient had one planning CT and 1-5 follow-up CTs in treatment position that were acquired at later time points during treatment. The ANACONDA DIR-algorithm implemented in RayStation v5.0 [1] was used for all registrations. For each patient the planning CT was deformed to all following CTs together with the contours of bladder, rectum and CTV-T, resulting in a total of 28 registrations. DIR was performed in two ways: 1) based only on image intensity information (DIRimg); 2) based on image intensity and controlling structures delineated on both images (DIRstruct). The performance of the DIR was validated by comparing manually delineated, i.e. expert based contours with deformed contours using geometric metrics (Dice coefficient=DSC, 95<sup>th</sup> percentile Hausdorff distance=HD). The overlap metrics resulting from rigid registration were used as baseline. A VMAT dose distribution (prescription: 45 Gy) optimized on the planning CT was recalculated on the follow-up CTs and dose values (D2, Dmean and D98 for CTV) of the delineated and deformed organs were compared.

### Results

The average DSC and HD values over all registrations are presented in figure 1 together with the average improvement compared to rigid registration. The mean structure overlap was slightly improved with DIRimg (0.64) and strongly improved with DIRstruct (0.86) when compared to rigid registration (0.61). Minimum DSC was 0.36/0.04 for DIRimg/DIRstruct. Figure 2 displays the deviation in dose values from the reference contours. No systematic dose difference was observed for both DIR methods. Dose deviations were in general smaller for DIRstruct. The largest absolute dose error was seen in D98 of CTV-T with 10.7 Gy/8 Gy in DIRimg/DIRstruct.

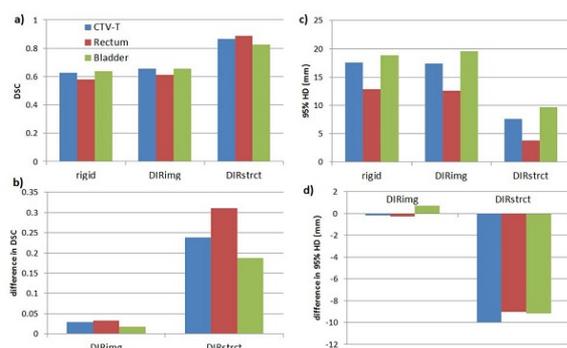

Figure 1: Geometric performance of the DIR algorithm. a) average Dice coefficient (DSC) for rigid registration and the two DIR methods. b) average improvement in DSC over rigid registration. c) average 95% Hausdorff distance (HD). d) average improvement in 95% HD over rigid registration.

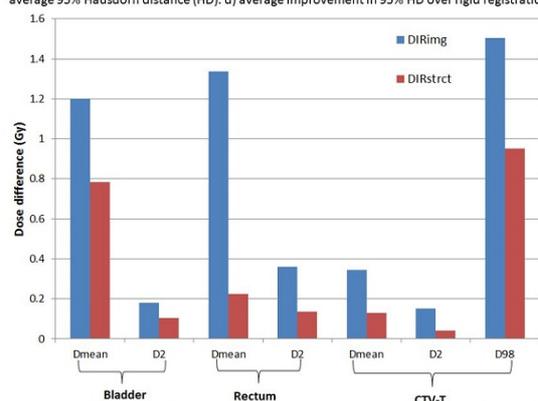

Figure 2: Average absolute difference in dose parameters between reference and deformed contours

## Conclusion

The large deformations occurring in the female pelvis pose a challenge for accurate DIR. The overlap of deformed and delineated organs is generally not satisfactory when using DIR based on image information only, therefore hindering autocontouring. Deformation based on controlling structures delivers improved results, which may make accurate dose accumulation for the mentioned organs feasible, if all available images are manually contoured. Still, in extreme organ motion cases, also this approach led to poor results. Future studies will investigate this DIR method for CT-to-CBCT.

## EP-1707 Dose of the day in Head-Neck cancer Tomotherapy: a DIR-based method's comprehensive validation

M. Branchini<sup>1</sup>, C. Fiorino<sup>1</sup>, L. Perna<sup>1</sup>, G.M. Cattaneo<sup>1</sup>, R. Calandrino<sup>1</sup>, S. Broggi<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy

## Purpose or Objective

The aim of this study is to validate an original method for computing the dose of the day that employs deformable image registration (DIR) of the planning CT to MVCT taken during Tomotherapy (HT) for Head and Neck (HN) cancer, assessing both geometric and dosimetric accuracy.

## Material and Methods

Planning CTs of 10 HN patients treated with HT (SIB: 54/66/69 Gy/30 fr or sequential boost: 54/66.6-70.2Gy/37-39 fr) were deformable registered to MVCT images acquired at the 15<sup>th</sup> fraction (processed with anisotropic diffusion filter) using a constrained intensity-based algorithm (MIM software). At the same treatment fraction, a diagnostic kVCT was acquired with the patient in the treatment position (CT15) and taken as reference. The original HT plans were recalculated on both the

resulting deformable registered images (CTdef) and the CT15. Dosimetric accuracy between CTdef and CT15 was assessed by local dose differences, 2D  $\gamma$  (2%-2mm) and 3D  $\gamma$  (2%-2mm) analysis in body voxels. These results were compared, in terms of 3D gamma, with the accuracy between dose distributions calculated on CT15 and on MVCT calibrated images; the performance was contrasted with the Kruskal-Wallis test. DIR's geometric accuracy was assessed by means of Dice Similarity Coefficients (DSC) between parotids/spinal canal manually contoured on CTdef and on CT15. A further analysis of dose to parotids/spinal canal was carried out for 5 patients by comparing DVHs calculated on the two images and the correlation between parotids mean dose and D5% and D1% to spinal canal values in the two situations (CTdef vs CT15).

## Results

2D and 3D  $\gamma$  pass percentage were 95.4%  $\pm$ 0.8% and 95.0%  $\pm$ 0.7%.  $\Delta D$  was < 2% in 87.9%  $\pm$ 1.3% of voxels. Dose computation on CTdef resulted to be equivalent to calculation on MVCT with correct Image Value Density Table (Kruskal-Wallis p-value = 0.60). The visibility of the anatomical structures, in particular of parotids, on CTdef was qualitatively much better than on MVCT. The agreement of parotid contours between CTdef and CT15 was very good: mean DSC values for L and R parotids were 0.85 and 0.88 (Table). A mean DSC value of 0.81 was found for the spinal canal. DVHs of parotids and spinal canal of CT15 and CTdef were very similar, as shown in Figure for an "average" patient. In particular, linear correlation coefficient  $R^2$  between parotid mean dose, D5%/D1% to spinal canal values calculated on CTdef and the corresponding values calculated on CT15 were 0.93, 0.93 and 0.89 respectively.

## Conclusion

Deforming the planning CT to MVCT with an intensity-based method was proven to be accurate considering both dosimetric and anatomical similarities with respect to diagnostic kVCT. The dosimetry accuracy of the method is equivalent to dose computation on MVCTs, after proper voxel values calibration, with a much better visibility of anatomical structures on CTdef compared to MVCT. DSC values for parotids and spinal canal are comparable with inter-observers' contouring variability on kVCTs reported in literature.

Table: Dice coefficients for parotids and spinal canal.

Patient	Left parotid	Right parotid	Spinal canal
1	0.82	0.92	0.80
2	0.80	0.84	0.77
3	0.83	0.82	0.81
4	0.92	0.90	0.87
5	0.88	0.91	0.81
Mean	0.85	0.88	0.81

## EP-1708 Investigating the reproducibility of geometric distortion measurements for MR-only radiotherapy

J. Wyatt<sup>1</sup>, S. Hedley<sup>1</sup>, E. Johnstone<sup>2</sup>, R. Speight<sup>2</sup>, C. Kelly<sup>1</sup>, A. Henry<sup>2</sup>, S. Short<sup>2</sup>, L. Murray<sup>2</sup>, D. Sebag-Montefiore<sup>2</sup>, H. McCallum<sup>1</sup>

<sup>1</sup>Newcastle upon Tyne Hospitals NHS Foundation Trust,

Northern Centre for Cancer Care, Newcastle upon Tyne, United Kingdom

<sup>2</sup>University of Leeds, Leeds Institute of Cancer and Pathology, Leeds, United Kingdom

<sup>3</sup>Leeds Teaching Hospitals NHS Trust, Leeds Cancer Centre, Leeds, United Kingdom

### Purpose or Objective

MR imaging is increasingly used within radiotherapy due to its superb soft tissue contrast. However MR images can suffer from significant geometric distortions and for MR-only radiotherapy planning, images must be geometrically accurate. It is vital to measure these distortions and the aim of this study was to determine the reproducibility of distortion measurements using a commercial phantom for three different MR scanners from three different centres.

### Material and Methods

Distortion was measured using a Spectronic Medical (Helsingborg, Sweden) large field of view geometric distortion phantom. Three different MR scanners were used: a 1.5 T Siemens Magnetom Espree (1.5T MR), a 3T General Electric Signa PET-MR (3T PET-MR) and a 3T Siemens Prisma (3T MR). To assess reproducibility, two sets of measurements were made on each scanner: three images were acquired without moving the phantom between scans (single set-up) and five images were taken with the phantom re-set up prior to each acquisition (repeated set-up). To investigate set-up sensitivity two separate scenarios were evaluated: one scan acquired with an intentional 1mm lateral offset applied and a second scan with an intentional 1° rotation. Each measurement contained two sequences, a 2D Fast Spin Echo and 3D Gradient Echo.

The phantom consisted of small spherical markers at known locations embedded in a low density foam. The images were analysed using the Spectronic Medical automatic distortion software. Distortion was defined as the magnitude of the vector difference between the known and measured position of each marker in the phantom.

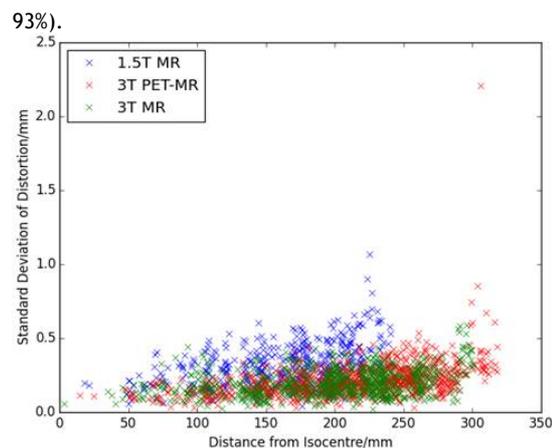

### Results

The mean of the standard deviations of all markers for each scanner, sequence and set-up are given in table 1. The mean standard deviations for the repeated set-up are larger than the standard deviations for the single set-up. All the mean standard deviations are less than 0.4 mm, which is smaller than the minimum voxel size of all acquired scans.

Scanner	Sequence	Mean Standard Deviation of Distortion/mm	
		Single Set-up	Repeated Set-up
1.5 T MR	2D	0.30	0.34
1.5 T MR	3D	0.26	0.32
3T PET-MR	2D	0.32	0.32
3T PET-MR	3D	0.12	0.21
3T MR	2D	0.11	0.21
3T MR	3D	0.11	0.20

Figure 1 shows an example plot of the standard deviation of distortion as a function of distance from the scanner isocentre for each marker.

The set-up sensitivity scans were compared with the repeated set-up scans. For each marker, the measured sensitivity scan distortion was compared to the repeated set-up mean and standard deviation distortion. For the 1mm lateral offset scan 90% of the markers agreed within two standard deviations of the mean of the repeated set-up scan (median of all scanners and sequences, range 78% - 93%). For the 1° rotation scan, 80% of markers agreed within two standard deviations of the mean (range 69% -

### Conclusion

Geometric distortion measurements using the Spectronic Medical phantom and associated software appear reproducible, with smaller than 0.4 mm mean standard deviations for all scanners and sequences tested. Further work needs to be carried out to evaluate the sensitivity to set-up uncertainties.

### EP-1709 Can atlas-based automatic segmentation contour H&N OARs like a physician?

N. Maffei<sup>1</sup>, G. Guidi<sup>1</sup>, E. D'Angelo<sup>2</sup>, B. Meduri<sup>2</sup>, F. Lohr<sup>2</sup>, T. Costi<sup>1</sup>

<sup>1</sup>Az. Ospedaliero-Universitaria di Modena - Policlinico, Medical Physics, Modena, Italy

<sup>2</sup>Az. Ospedaliero-Universitaria di Modena - Policlinico, Radiation Oncology, Modena, Italy

### Purpose or Objective

Radiotherapy requires delineation of organs at risk (OARs). Manual contouring is time-consuming and subject to inter-user variability. A priori information can be used in Atlas-Based Automatic Segmentation (ABAS). Our study evaluates (i) if differences between structures contoured manually and with a Model-Based Segmentation (MBS) tool did not exceed inter-physician variability; (ii) if an unbiased dataset can be used to train and build an improved ABAS template; (iii) if the automatic segmentation is acceptable for all OARs.

### Material and Methods

An analysis of original contours from kVCT of 30 Head and Neck (H&N) patients (pts) was carried out. Original manual contours were compared to the automatic contours performed by the MBS RayStation tool and were then used to train a customized ABAS template. This study is focused on parotids, mandible, spinal cord and brainstem. The analysis was performed using Dice Similarity Coefficient (DSC). The workflow is:

- 2 expert radiation oncologists (ROs), in double-blind mode, gave a score [1÷10] of original manual contours;
- 2 expert ROs, in double-blind mode, gave a score [1÷10] of automatic contours performed by the MBS tool;
- The original manual contours were reviewed/edited to adjust incorrect delineation;
- The edited manual contours were compared with the MBS automatic contours;
- The edited manual contours were used to train a novel ABAS template;
- CTs of 4 new pts were used to test the atlas developed. An expert RO performed a manual contours;

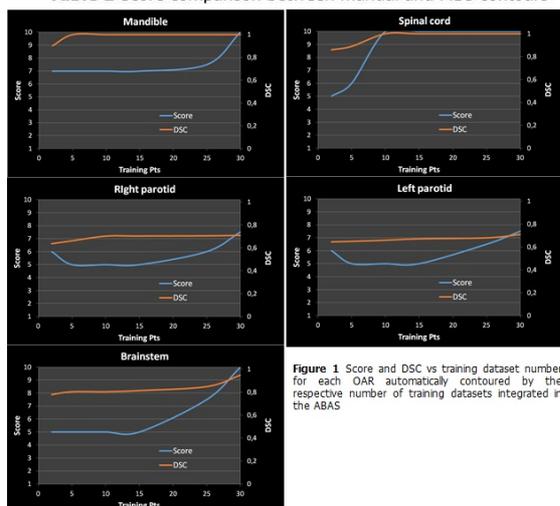

- The manual and automatic contours were compared after every 5 pts added to the atlas at a time up to a total of 30.

## Results

Comparing the mean scores between initial manual and the MBS contours (Table1), the manual approach performed better for spinal cord and parotids with averaged scores of 8.4 (manual) vs 7.2 (MBS). Standard deviation showed comparable intra-organs variability. DSC scores were: 1.0 mandible, 0.71 spinal cord, 0.73 right parotid, 0.72 left parotid, 0.80 brainstem. All 30 pts were then used to build a customized atlas. Contours analysis, tested on 4 new pts, is shown in Figure1. After training, the performance of the ABAS increased for all the OARs automatically contoured. Best outcomes resulted for mandible, spinal cord and brainstem for which the score and DSC are respectively: 10, 1.0; 10, 1.0; 10, 0.95. Parotids showed lower results: 7.5, 0.70 for right parotid; 7.4, 0.71 for left parotid.

ROI	Manual	SD	MBS	SD
Mandible	7,8	1,6	7,7	1,0
Spinal cord	9,0	0,9	7,1	2,7
Right Parotid	8,3	1,5	6,9	1,4
Left Parotid	8,6	1,3	6,2	1,7
Brainstem	8,2	1,4	8,3	0,9
Mean	8,4	1,4	7,2	1,5

**Table 1** Score comparison between manual and MBS contours

**Figure 1** Score and DSC vs training dataset number for each OAR automatically contoured by the respective number of training datasets integrated in the ABAS

## Conclusion

The default MBS tool showed a difference in structure delineation that does not exceed the inter-clinician variability. The customized atlas developed reached performances comparable with the clinical gold standard for mandible, spinal cord and brainstem. To increase outcomes, several atlases trained on specific sub-populations could be created reducing the intra-patient variability and making results closer to optimal segmentation. As a next step, the influence of image quality on automatic segmentation will be analyzed.

## EP-1710 Chemical stability of BioXmark® following normofractionated and single-fraction proton beam therapy

E. Troost<sup>1,2,3,4,5</sup>, S. Menkel<sup>1</sup>, W. Enghardt<sup>1,4,5</sup>, J. Hytry<sup>5</sup>, D. Kunath<sup>1</sup>, S. Makocki<sup>1</sup>, A. Hoffmann<sup>1,4,5</sup>, R. Jølcck<sup>6</sup>

<sup>1</sup>TU Dresden- Med. Faculty Carl Gustav Carus, Radiotherapy and Radiation Oncology, Dresden, Germany

<sup>2</sup>German Cancer Consortium DKTK, Partner site Dresden, Dresden, Germany

<sup>3</sup>National Center for Tumor Diseases, Partner site Dresden, Dresden, Germany

<sup>4</sup>Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiooncology, Dresden, Germany

<sup>5</sup>OncoRay, National Center for Radiation Research in Oncology, Dresden, Germany

<sup>6</sup>Nanovi Radiotherapy A/S, Development, Kgs. Lyngby, Denmark

## Purpose or Objective

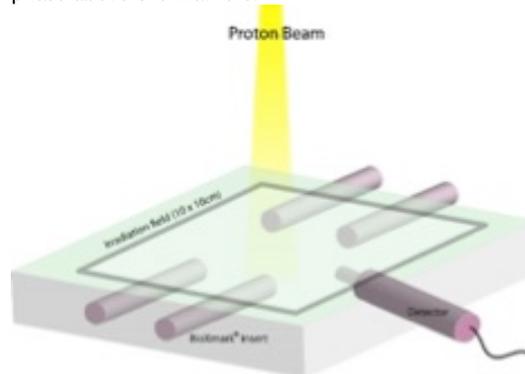

Use of solid fiducial markers in proton radiation therapy has been approached with care as their presence may cause significant local dose perturbations. Recently, a liquid carbohydrate based fiducial marker (BioXmark®) has been introduced with minimal dose perturbation (relative stopping power = 1.164) and visibility properties suitable for use in image-guided proton therapy (IGPT). The purpose of this work was to investigate the chemical stability of the marker for use in both normofractionated and single fraction proton treatment regimes.

## Material and Methods

Ten identical custom-made cylindrical polymethylmethacrylate (PMMA) inserts ( $V = 0.95$  mL,  $d_{\text{outer}} = 10.0$  mm,  $d_{\text{inner}} = 5.0$  mm,  $l = 48$  mm) were prepared. BioXmark® markers ( $150 \pm 30$  mg) were added to the bottom of the inserts and water ( $700 \mu\text{L}$ ) was added on top of the markers. The inserts were sealed with a rubber stopper.

A QA dosimetry phantom was modified to accommodate four PMMA inserts simultaneously by inserting these sideways into the proton irradiation field ( $10 \times 10$ cm) (Figure 1). Four markers (Group A) were irradiated during daily QA for a period of 51 days with 43 fractions ranging from 1.44-1.86 Gy resulting in an accumulated dose of 67.4 Gy. Four other markers (Group B) were irradiated with a single dose of 155.4 Gy and two non-irradiated Control markers were kept on site for the duration of the experiments.

Possible chemical alterations caused by proton irradiation were evaluated by high-performance liquid chromatography (HPLC), electrospray ionization mass spectrometry (ESI-MS), thin-layer chromatography (TLC) and visual inspection of the markers and the aqueous phase above the markers.

**Figure 1.** QA dosimetry phantom setup for proton irradiation of BioXmark® inserts. **Results**

No visual alterations between markers from Group A+B and the Control markers were observed. HPLC and TLC analysis of the markers and the aqueous phase above the markers from all three groups did not indicate chemical degradation of the marker materials (Figure 2). This observation was further supported by ESI-MS analysis, which showed identical m/z fragments for all three groups (Figure 2).

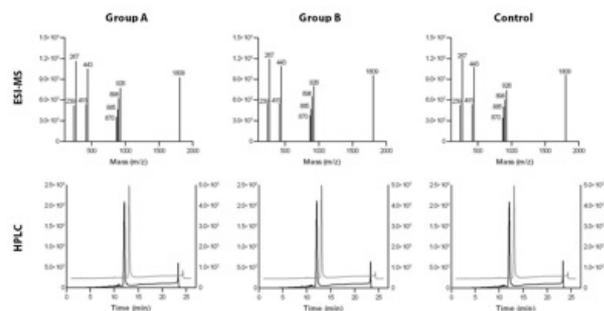

Figure 2. Characterization of BioXmark® markers from Group A (43F/67.4Gy), Group B (1F/155.4Gy) and Control group (non-irradiated) by ESI-MS and HPLC. **Conclusion** The BioXmark® marker showed no chemical degradation after exposure to normofractionated and extremely hypofractionated proton therapy regimes and may serve as a good alternative to solid fiducial markers used for IGPT.

#### EP-1711 Effect of Noise Floor Suppression on Diffusion Kurtosis for Prostate Brachytherapy

Z.G. Portakal<sup>1</sup>, S. Shermer<sup>2</sup>, E. Spezi<sup>3</sup>, T. Perrett<sup>4</sup>, J. Phillips<sup>5</sup>

<sup>1</sup>Cukurova University- Institute of Science and Arts, Physics, Adana, Turkey

<sup>2</sup>Swansea University- Collage of Science, Physics, Swansea, United Kingdom

<sup>3</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom

<sup>4</sup>Velindre Cancer Centre, Physics, Cardiff, United Kingdom

<sup>5</sup>Swansea University- Collage of Medicine, Institute of Life Science, Swansea, United Kingdom

#### Purpose or Objective

Diffusion-weighted magnetic resonance imaging (DW-MRI) and recently diffusion kurtosis imaging (DKI) can be used to characterise prostate tumours and improve the treatment. However, DKI is sensitive to the effects of signal noise due to strong diffusion weightings and higher order modeling of the diffusion weighted signal. The purpose of the study is to evaluate DKI data and the reliability of kurtosis estimates in the existence of noise floor suppression using different sequences and scanners for DW-MRI using gel phantoms with the aim of applying to prostate brachytherapy.

#### Material and Methods

Six plain agar gel phantoms and five agar gel phantoms containing various amounts of glass microspheres were prepared with a volume of 100 cm<sup>3</sup>. Several DW-MRI protocols were tested on the two clinical systems (Optima MR450w 1.5T, GE Medical System, Waukesha, WI and Magnetom Skyra 3T, Siemens Healthcare, Erlangen, Germany) by applying 9 different diffusion weighting 'b values' between 0 and 4000 s/mm<sup>2</sup> in intervals of 500 are summarized in Table 1. Analysis of DKI was performed on a pixel-by-pixel basis in-house software (MATLAB). Table 1. Imaging Protocols for DKI

#### Results

The variation of the apparent diffusion coefficient (ADC) of the gel phantoms with and without the microspheres showed the gels are appropriate to represent healthy and diseased tissues with the aim to applying to the prostate. The results show that we obtain similar values for the ADC in all cases but the values obtained for the kurtosis (K) differ substantially. We observe overestimation of kurtosis with the gels containing microspheres due to the noise floor fitting, especially for the conventional diffusion sequences with EPI readout. This is the result of rapid deterioration of signal and the image quality at high b-value for the EPI readout at both magnetic fields but mostly for 1.5T. As seen in figure 1, there is almost no signal after b = 3000 s/mm<sup>2</sup> for both manufacturers' diffusion product sequences but for modified SE ST scan protocol with FOV 100mm a signal can still be obtained even at b = 4000 s/mm<sup>2</sup>.

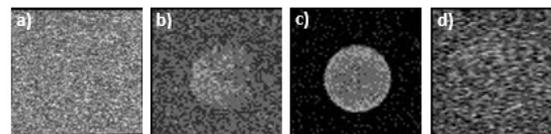

Figure 1. a)SS SE EPI at 1.5T, b)SS SE EPI at 3T, c)SE ST at 3T with FOV=100mm, d)SE ST at 3T with FOV=64mm

#### Conclusion

We demonstrated the effect of noise floor fitting on the estimation of kurtosis using gel phantoms for the assessment of isotropic diffusion kurtosis to investigate its use in the characterization of prostate cancer treated with brachytherapy. We have shown that the rectified noise floor, which exists in standard magnitude data, increases the systematic error of the diffusion coefficients ADC and K. To minimize the impact of noise floor in DKI, high b-values are needed, which appear to be difficult to access with the conventional EPI sequence. Although conventional readout is unfavorable compared to EPI in terms of acquisition times for single slice imaging, significant gains can be made for multi-slice imaging by interleaving the slices. Also, EPI requires multiple averages and lastly getting results fast is useless if they are not accurate.

#### EP-1712 Quantification of radiotherapy-induced mediastinum changes using serial CT imaging

C. Veiga<sup>1</sup>, D. Landau<sup>2</sup>, A. Devaraj<sup>3</sup>, T. Doel<sup>1</sup>, D. Hawkes<sup>1</sup>, J.R. McClelland<sup>1</sup>

<sup>1</sup>University College London, Centre for Medical Image Computing, London, United Kingdom

<sup>2</sup>King's College London, Guy's & St. Thomas' NHS Trust, London, United Kingdom

<sup>3</sup>Royal Brompton Hospital, Department of Radiology, London, United Kingdom

### Purpose or Objective

Radiation-induced lung fibrosis is an unwanted side effect of curative radiotherapy. Radiological findings include changes in the mediastinum such as shift toward the ipsilateral lung due to treatment related volume loss. In this work we investigate building a standardized and semi-automatic method to quantify mediastinum changes as indicator of lung fibrosis.

### Material and Methods

31 patients treated with conventional chemoradiotherapy were included. This was a sub-group of a non-randomized phase I/II isotoxic trial which enrolled stage II and III NSCLC (IDEAL-CRT). Each patient underwent a baseline PET-CT or diagnostic CT before treatment, and a diagnostic CT for follow-up after 12 months (average: 433 days, range: 358-496 days). Rotation and thickening of the anterior junction line were taken as measures of mediastinal change.  $\beta$  was defined as the angle between the posterior-anterior direction and the line that connects the centroid of the spinal canal to the centroid of the anterior junction line at carina level in the follow-up scan; similarly, the thickness of the junction ( $t$ ) was defined as the minimum distance between the two lungs at the same level (Fig. 1). Mediastinum shift was then quantified in terms of the absolute difference between the  $\beta$  measured on the co-registered baseline and follow-up scans (i.e.,  $\Delta\beta = \beta_F - \beta_B$ ), and in terms of the ratio of the thicknesses (i.e.,  $\Delta t = t_F/t_B$ ). This was implemented as a semi-automatic workflow in Matlab using the open-source Pulmonary Toolkit ([github.com/tomdoel/pulmonarytoolkit](https://github.com/tomdoel/pulmonarytoolkit)).

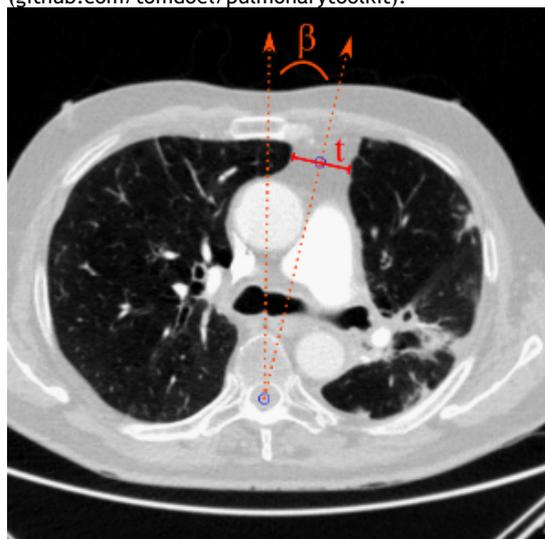

Fig. 1 - Measures of rotation ( $\beta$ ) and thickening ( $t$ ) of the anterior junction line.

### Results

The changes were characterized using the following grading systems: for  $\Delta\beta$ , 0- no/small rotation ( $<4^\circ$ ), 1- moderate ( $4-8^\circ$ ), 2- large ( $>8^\circ$ ); and for  $\Delta t$ , 0- no/small change including moderate shrinkage ( $<1.2$ ), 1- mild enlargement ( $1.2-3$ ), 2- moderate enlargement ( $>3$ ) (Fig. 2). In the presence of disease or toxicities at the junction, the definition of its centroid is unclear; hence six patients were excluded. Significant rotation of the junction line toward the ipsilateral lung occurred in 64% of the patients (36% and 28% for grades 1 and 2, respectively). Significant enlargement of the junction was measured in 56% of the patients (equal occurrence of grades 1 and 2); shrinkage was measured in 16% of the cases. There was no correlation between rotation and thickening of the junction ( $\rho=0.17$ , Pearson's correlation coefficient).

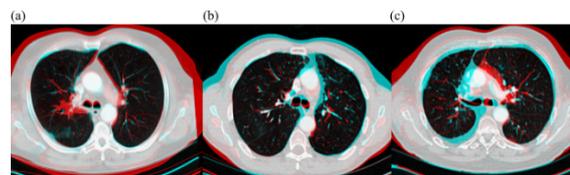

Fig. 2 - Colour overlay of baseline (red) and follow-up (blue) scans. Cases of grades (a) 0 and 0, (b) 0 and 2, (c) 2 and 0 for rotation and thickening, respectively.

### Conclusion

Chronic lung fibrosis manifests radiologically as mediastinal shift. We propose a standardized method to characterize these changes based on the positioning and thickness of the anterior junction line. Further measures are needed to fully describe mediastinum change. We aim to correlate these changes with measures of lung fibrosis.

### EP-1713 Feasibility of low dose 4D CBCT in patients with lung cancer.

A. Bryce-Atkinson<sup>1</sup>, A. McWilliam<sup>1</sup>, T. Marchant<sup>2</sup>, C. Faivre-Finn<sup>1</sup>, G. Whitfield<sup>3</sup>, M. Van Herk<sup>1</sup>

<sup>1</sup>University of Manchester, Division of Molecular and Clinical Cancer Science- Faculty of Biology- Medicine and Health, Manchester, United Kingdom

<sup>2</sup>The Christie NHS Foundation Trust, Christie Medical Physics and Engineering, Manchester, United Kingdom

<sup>3</sup>The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom

### Purpose or Objective

Respiration correlated cone-beam CT (4D CBCT) provides information on the respiratory motion, providing accurate tumour localisation in the lung taking into account breathing motion. This project aims to investigate the potential for 4D CBCT dose reduction, evaluating its effect on image quality, amplitude estimation and registration accuracy.

### Material and Methods

4D CBCT images were reconstructed from 9 lung cancer patients with a minimum of 800 projections (120kV, 16mA, 10-40ms), phase sorted to the nearest projection over 10 phases. The amplitudes of tumour motion ranged from 3.9-20mm. Dose reduction was simulated by reconstructing using 50%, 25%, 16.67%, 12.5% and 10% of projections and varying the number of phase bins, sorting all remaining projections. The image quality of each reconstruction was assessed visually and by testing registration accuracy for bone (3D) and tumour (4D). Registration accuracy was evaluated by comparing results to the standard reconstruction, for both amplitude of motion in the superior-inferior direction and correctable (mean) position.

### Results

Reducing the number of projections had little effect on registration accuracy overall for both bone and soft tissue, despite very poor visual image quality at low number of projections. Reducing the number of reconstructed phases recovered visual image quality (Figure 1) at the cost of underestimating amplitude and 10 phases yielded best registration accuracy (Table 1). When using 10% of projections, motion was reported at less than 5mm for 89% of patients at 3 and 5 phases. Increasing to 10 phases recovered the tumour motion to approximately that of the standard reconstructions. Automatic soft tissue registration required manual preregistration for two patients: one consistently across all reconstructions, and the other only for the 10 phase reconstruction with 10% of projections.

	3 phases		5 phases		10 phases	
	Max. (mm)	≤1mm accuracy	Max. (mm)	≤1mm accuracy	Max. (mm)	≤1mm accuracy
100% projections	3.9	67%	0.3	100%	0.3	100%
25% projections	5.0	89%	4.7	78%	2.0	89%
10% projections	2.7	56%	5.0	56%	4.7	67%

Table 1: Accuracy of low dose 4D CBCT: Maximum position discrepancy and % of patients with discrepancies below 1mm for 100%, 25% and 10% projections reconstructed at 3, 5 and 10 phases. We conclude that 25% lower dose at 10 phases has acceptable accuracy.

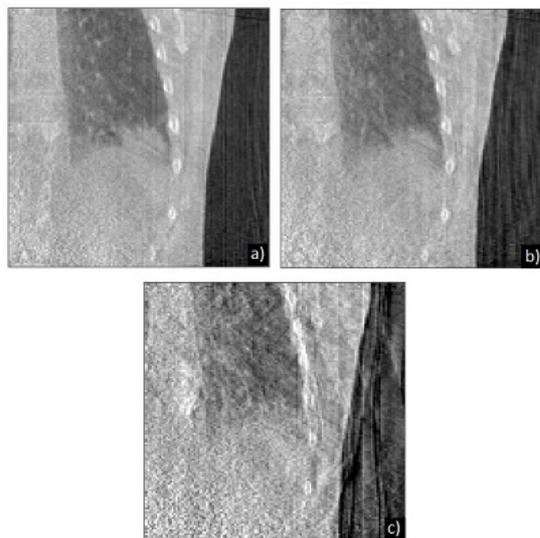

Figure 1: Reconstructions to show image quality for a) standard reconstruction using all projections over 10 phases b) 25% of projections over 3 phases, c) 25% of projections over 10 phases.

### Conclusion

Registration remains accurate even for as little as 10% of projection data, but with significant limitations in visual image quality at 10 phase reconstructions and motion detection at 3 phases. Simulating 25% dose over 10 phases allows for accurate registration without significant loss of image quality or motion detection and is therefore acceptable for 4D CBCT. This result is particularly relevant for patients with a good prognosis as it limits the radiation exposure.

### EP-1714 Automatic delineation of the gross-tumour volume in prostate cancer using shape models

K. Cheng<sup>1</sup>, Y. Feng<sup>1</sup>, D. Montgomery<sup>1</sup>, D.B. McLaren<sup>2</sup>, S. McLaughlin<sup>3</sup>, W. Nailon<sup>1</sup>

<sup>1</sup>Edinburgh Cancer Centre Western General Hospital, Department of Oncology Physics, Edinburgh, United Kingdom

<sup>2</sup>Edinburgh Cancer Centre Western General Hospital, Department of Clinical Oncology, Edinburgh, United Kingdom

<sup>3</sup>Heriot Watt University, School of Engineering and Physical Sciences, Edinburgh, United Kingdom

### Purpose or Objective

Digital models of anatomy have potential for assisting in the segmentation of the prostate and organs at risk (OAR) in radiotherapy planning of prostate cancer. However, manual alteration of automatically generated contours is often necessary to produce an accurate gross-tumour volume (GTV). This is generally the case when the tumour extends beyond the prostatic capsule into the bladder or invades the seminal vesicles (>T3a tumours). The aim of this study was to develop a digital model of the GTV in prostate cancer that incorporates the range of shape variability associated with different T-stages.

### Material and Methods

Computerised tomography (CT) images from 42 prostate cancer patients, which contained a range of T-stages and had the prostate GTV and OARs outlined, were selected.

Three-dimensional (3D) isotropic volumes were created for each data set and the correspondence between points on the GTV surface of each case was established. To fit the model to an unknown data set texture analysis features were calculated in 5x5 volumes perpendicular to the boundary between the interior and exterior of the GTV surface. This estimates the location of the GTV boundary. At each point a search for the GTV shape was conducted by calculating the texture features and moving within the established shape limits until reaching convergence. Training was performed on 32 randomly selected cases and testing on the remaining 10 cases. The Dice similarity coefficient was used to compare the model results with the clinically defined volumes.

### Results

Figure 1 shows an example of a typical GTV produced by the algorithm in which the seminal vesicles have been included in the apical slice (left). Table 1 shows a summary of the results obtained on the 10 test cases. The mean clinical volume of the test cases was 64.5 cm<sup>3</sup> and calculated by the model was 60.3 cm<sup>3</sup>. The largest difference was observed in the cases with the largest GTV.

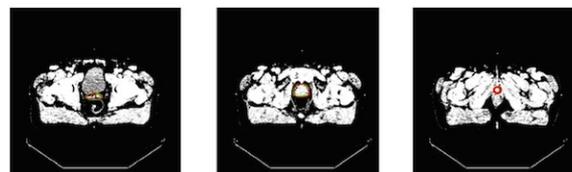

Figure 1: Clinical contour in green, model result in red. Left: apical slice taken from the inferior of the GTV including the seminal vesicles. Middle: central slice of the GTV shape. Right: basal slice from the superior of the GTV.

	1	2	3	4	5	6	7	8	9	10
Clinical vol (cm <sup>3</sup> )	65	67	45	94	50	49	71	59	61	84
Model vol (cm <sup>3</sup> )	65	66	50	52	61	52	67	63	62	65
Dice coefficient	0.91	0.78	0.75	0.71	0.75	0.89	0.82	0.89	0.87	0.75

Table 1: Dice coefficients and volumes obtained on the 10 test cases.

### Conclusion

The proposed model has potential for automatically contouring the GTV when the tumour extends beyond the prostatic capsule into the bladder or invades the seminal vesicles. However, more cases must be included in the model to ensure that the full range of shape variability is represented.

### EP-1715 Differences in delineation uncertainty using MR images only vs CT-MR in recurrent gynaecological GTV

D. Bernstein<sup>1</sup>, A. Taylor<sup>1</sup>, S. Nill<sup>1</sup>, U. Oelfke<sup>1</sup>  
<sup>1</sup>Royal Marsden Hospital Trust & Institute of Cancer Research, Department of Medical Physics, London, United Kingdom

### Purpose or Objective

To build upon previous work [1] to utilise a new contouring concept to quantify the differences in delineation uncertainty when using co-registered CT-MR images vs MRI only for recurrent gynaecological GTVs.

### Material and Methods

A contouring concept was developed in which clinicians draw up to two GTV boundaries per CT slice corresponding to the inner (GTV<sub>i</sub>) and outermost (GTV<sub>o</sub>) possible boundaries the GTV may have and therefore define a boundary interval for the GTV.

Observers contoured centrally recurrent gynaecological GTVs in accordance with this concept first on MRI images

and then on co-registered CT-MR images to allow for their comparison. A rigid soft tissue registration localised around the GTV was used. Observers also contoured the GTV in accordance with local clinical protocols using CT-MR images (GTV\_c) and scored their confidence in these contours on a scale of 1 to 5, 5 being complete confidence. Differences between CT-MR and MR volumes were assessed using paired T-Test. Inter-observer variability was assessed using an analysis of variance. The threshold for significance was  $p < 0.05$ .

### Results

Four observers participated in the study, three of whom had at least 3 years' experience in treating this patient group; two contoured 20 cases, one 19 and one 18. A summary of the results are presented in Table 1.

MR only based volumes were statistically significantly smaller for all observers for each GTV\_i, GTV\_o and GTV\_c, whilst the confidence scores in GTV\_c were higher for all observers, although for one this was not statistically significant.

The magnitude of the offset between the centres of GTV\_i and GTV\_o was calculated and the difference in these offsets compared between CT-MR and MR only contours. An overall difference was detectable for only one observer, in which the distance between GTV\_i and GTV\_o were smaller in the MR only images. For the remaining observers, the agreement in the position of the volumes was not affected by the imaging modality.

Boundary intervals were smaller on the MR only images for all observers, although this difference was not statistically significant for Observer 3.

The impact of multimodality imaging on observer variation for the boundary interval size was tested using 17 cases contoured by all observers, by comparing the ratio of the boundary interval size from CT-MR to MR only between observers. This did not show a statistically significant difference between the observers, with a p-value of 0.507.

Table 1: results comparing MR only based contours with those produced using co-registered CR-MT images.

		Observer 1	Observer 2	Observer 3	Observer 4
		Mean±SD (P-value)	Mean±SD (P-value)	Mean±SD (P-value)	Mean±SD (P-value)
MR Volume f	GTV_i	77.7 ± 24.6 (0.012)	85.4 ± 31.8 (0.041)	77.0 ± 26.2 (0.015)	76.8 ± 43.16 (0.001)
	GTV_c	60.3 ± 16.4 (<0.001)	79.3 ± 24.9 (0.001)	75.4 ± 24.4 (0.004)	73.83 ± 16.4 (<0.001)
CTMR Volume (%)	GTV_o	60.7 ± 17.0 (<0.001)	79.7 ± 19.0 (0.001)	75.8 ± 23.2 (0.002)	73.5 ± 16.6 (<0.001)
	GTV_o - GTV_i	57.2 ± 21.9 (<0.001)	63.2 ± 28.0 (0.001)	68.1 ± 45.2 (0.063)	67.7 ± 20.1 (0.002)
MR Score - CTMR Score		0.2 ± 0.7 (0.215)	0.8 ± 0.8 (<0.001)	1.1 ± 0.8 (<0.001)	0.9 ± 0.6 (<0.001)
Difference between MR and CTMR GTV_o to GTV_i Centre of Volume offset (mm)		-0.2 ± 0.4 (0.028)	0.0 ± 0.2 (0.754)	0.0 ± 0.1 (0.331)	0.0 ± 0.2 (0.946)

### Conclusion

Contouring centrally recurrent GTVs using only MR images, instead of the current practice of co-registered CT-MR images, produces smaller volumes. When using MR images alone, clinicians have a higher confidence in their clinical GTV contours as well as having lower delineation uncertainties overall. The differences between CT-MR and MR only boundary intervals did not vary between observers. This reduction in uncertainties supports an MR-based workflow.

[1] Bernstein, D., et al., *Measurement of GTV delineation uncertainty for centrally recurrent gynaecological cancers*. Radiotherapy and Oncology, 2015. 119(1): p. 5615-5616.

### EP-1716 Semantic PACS deployment enables research in a radiation oncology research environment

M.S. Marshall<sup>1</sup>, H. Beemster<sup>1</sup>, M. Buijter<sup>1</sup>, T. Janssen<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Clinical Physics, Amsterdam, The Netherlands

### Purpose or Objective

Research involving imaging data requires intensive use of costly DICOM operations in order to aggregate the data for research. We installed software SeDI (Semantic DICOM, developed by SOHARD) which creates a database containing all radiotherapy-related DICOM metadata using a Semantic PACS that extracts and stores header tags in a special type of database. The resulting database can be searched with the standardized query language SPARQL using terms from DICOM and a radiation oncology vocabulary. Once all relevant DICOM tags have been extracted by SeDI, DICOM search is significantly accelerated and can often be expressed as a single query. The aim of this work is to show how SeDI helps to quickly resolve typical DICOM queries.

### Material and Methods

In order to quantify the potential speedup for a representative task using SeDI we measured the time spent to retrieve: the UIDs of the RTDose, RTStruct and RTPlan for a set of patients where 1) a relevant organ at risk is delineated and 2) the required DICOM objects exist in the clinical database.

Such a question is relevant if, for example, one wants to calculate DVHs for a large number of patients. Our conventional approach to such a problem would be to use a simple tool that browses through all patients on the DICOM server, find the associated RTStruct, check whether the organ at risk is delineated, and check if the associated RTDose exists in a RTPlan that makes use of the RTStruct. Using the logfiles of the tool that performs these steps, we can estimate the efficiency by using a direct indexing of the relevant DICOM objects using SeDI. Results Using the mentioned logfiles, we found that the above question was asked for 7384 patients. Lookups for 2176 patients found the DICOM objects that met all criteria in a total time of 14.24 hours with an average DICOM lookup time of 23.6 seconds. Lookups for 5208 patients failed to find matching DICOM objects at a total cost of 23.48 hours and an average DICOM lookup time of 16.2 seconds. Since failed lookups would not occur using SeDI, the use of SeDI would save at least the 71% of the search time spent on non-matching queries in our study question, amounting to 23.48 hours saved out of 37.72 total hours. By direct indexing of the relevant objects further time decrease is expected, but the magnitude of this remains open for study.

### Conclusion

We expect that SeDI will enable the researchers to rapidly identify the right DICOM objects for calculations, as well as accelerate ongoing research in outcome prediction, toxicity modelling and radiomics.

### EP-1717 Image Quality Comparison Between Two Radiotherapy Simulators

N. Tomic<sup>1</sup>, P. Papaconstadopoulos<sup>1</sup>, J. Seuntjens<sup>1</sup>, F. DeBlois<sup>1</sup>, S. Devic<sup>1</sup>

<sup>1</sup>McGill University, Oncology, Montreal, Canada

### Purpose or Objective

In this work we compare image quality parameters derived from phantom images taken on two CT simulators most commonly used in radiotherapy departments. To make an unbiased comparison, CT images were obtained with CT scanning protocols leading to the same surface doses, measured using XR-QA2 model GafChromic film reference dosimetry protocol.

### Material and Methods

Two radiotherapy CT simulators GE LS 16 (80 cm bore size) and Philips Brilliance Big Bore (85 cm bore size) were compared in terms of image quality using CATPHAN-504, scanned with Head and Pelvis protocols. Dose was measured at the phantom surface with CT scans taken

until doses during CT scans on both scanners were within 5%. Dose profiles were sampled using XR-QA2 model GafChromic™ film strips placed at four sides of the phantom (top, bottom, left, and right) and taped with a paper tape (Fig.1.a). Table 1 lists scanning and image reconstruction parameters used. To further assure unbiased comparison, we have set geometrical image parameters (highlighted) to be the same. First we scanned the phantom on the GE scanner and measured the surface dose. Table 1 reports averaged surface dose values over four film strips. On each film strip we have taken an average dose over a dose profile along 10 cm. Subsequently, we scanned the phantom 3 times on Philips scanner, each time adjusting mAs setting, until the surface dose reached the dose measured on the GE scanner to within 5%. Then, image quality comparison was performed using CATPHAN-504 modules in terms of spatial resolution (Fig.1.b), low contrast detectability (Fig.1.c), image uniformity (Fig.1.d), and contrast to noise ratio (Fig.1.e).

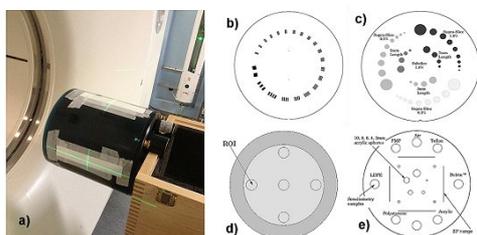

Figure 1: Image quality comparison between two CT-simulators (GE LS 16, and Philips Brilliance Big Bore) using: a) CATPHAN-504 with XR-QA2 film strips attached to the surface of the phantom; b) high resolution module (CTP-528); c) low contrast module (CTP-515); d) image uniformity module (CTP-486), and e) slice width, sensitometry and pixel size module (CTP-404).

## Results

The lower part of Table 1 summarizes results of the image quality comparison. In terms of spatial resolution and low contrast detectability, it appears that the GE scanner is slightly better for both Head and Pelvis protocols. On the other hand, while the uniformity of the images obtained with Head protocol are slightly better for the GE scanner, the Philips scanner has better characteristics for the Pelvis protocol. Also, Philips CT images show significantly less noise for both scanning protocols. Finally, with regards to CNR the Philips CT images appear in general to be better than GE except for high Z material (Teflon) for GE Head protocol.

Table 1: CT scanning techniques and results of image quality comparison for head and body scanning protocols for the two CT-simulators (GE LS 16, and Philips Brilliance Big Bore).

Scanner	GE		PHILIPS		
Protocol	Scanning Protocols				
	Head	Pelvis	Head	Pelvis	
kVp	120	120	120	120	
HVL(mm Al)	6.3	7.4	6.9	6.9	
Pitch	0.562	0.938	0.442	0.817	
Exposure [mAs/slice]	293	26	640	136	
Reconstructed FOV (mm)	240	240	240	240	
Slice thickness (mm)	5	5	5	5	
Pixel width/height (mm)	0.469/0.469	0.469/0.469	0.469/0.469	0.469/0.469	
Image size	512 x 512	512 x 512	512 x 512	512 x 512	
Number of images	37	37	37	37	
Scanning Length (mm)	185	185	185	185	
Displayed CT DIvol [mGy]	99.67	10.53	76.10	9.00	
Displayed DLP [mGy cm]	1992.95	222.09	1151.9	181.1	
Measured Surface Dose [mGy]	81.2	17.3	84.5	18.0	
Image Quality Comparison Results					
Parameter	Head	Pelvis	Head	Pelvis	
MTF10 [ $\mu$ /mm]	6.9	6.7	6.8	6.7	
MTF50 [ $\mu$ /mm]	4.6	4.3	4.2	3.5	
Low Contrast Detectability	Nominal Contrast	1.00%	9	7	8
		0.50%	7	4	6
		0.30%	6	0	2
Integral non-uniformity	0.023	0.030	0.051	0.008	
Uniformity index (%)	-4.55	-5.74	-9.72	-0.84	
SNR	3.93	1.61	7.71	3.79	
Contrast to Noise Ratio	PMP	91.9	37.4	85.6	45.9
	LDPE	64.6	25.9	72.9	24.2
	Acrylic	9.1	3.6	10.7	3.7
	Teflon	311.9	117.9	220.4	122.1

## Conclusion

The GE CT-simulator demonstrated a slightly better image quality in terms of spatial resolution and low contrast detectability, which was expected due to its smaller bore size, and hence lower impact of scattering on the image quality, while Philips CT produced images with better SNR. In the case of CNR values we have found that the Philips scanner provides images of superior image quality than GE scanner for Pelvis protocol. These findings can be explained by the fact that GE uses harder beam quality (HVL=7.4 mm Al) than Philips (HVL=6.9 mm Al) for Pelvis protocol indicating a dependence of image quality parameters on energy spectrum.

## EP-1718 Application of motion compensation in 4D CT of oesophageal cancer.

A. Green<sup>1</sup>, L. Bhatt<sup>2</sup>, R. Goldstraw<sup>3</sup>, H. Sheikh<sup>2</sup>, M. Van Herk<sup>1</sup>, A. McWilliam<sup>1</sup>

<sup>1</sup>The University of Manchester, Department 58-Radiotherapy Related Research, Manchester, United Kingdom

<sup>2</sup>The Christie Hospital NHS Foundation Trust, Consultant Clinical Oncology, Manchester, United Kingdom

<sup>3</sup>The Christie Hospital NHS Foundation Trust, Radiotherapy Physics, Manchester, United Kingdom

## Purpose or Objective

The use of 4D CT has become widespread for treatment planning of lung cancers, and motion compensation is known to be useful for the delineation of targets and organs at risk. To our knowledge, however, motion compensation has not yet been used for oesophageal cancer. Here, as in lung cancers, motion due to respiration induces image artefacts that can make delineation difficult leading to lower quality treatments. In this work, we aim to evaluate the potential benefit of motion compensated CT in oesophageal cancers.

## Material and Methods

Using the ADMIRE (Elekta AB, Stockholm, Sweden) auto-segmentation tool, all 10 phases of the 4D CT scan were deformable registered to a reference phase and averaged, excluding 4 phases displaying the greatest motion velocity.

GTV delineations on motion compensated images of four patients were then compared to those performed according to the SCOPE protocol, in which the GTV is delineated on the inhale, mid-ventilation and exhale phases before being combined. Delineated volumes were evaluated as a surrogate for inter-observer uncertainty, as higher certainty leads to smaller volumes. In addition, the volume delineated on the motion compensated image is compared with the average volume of the SCOPE structures.

### Results

In all cases the volume of the GTV delineated on the motion compensated image was smaller than the average SCOPE volume (figure 1). For two of the four patients, the reduction in volume is significant, however for PT1, the volume delineated on the motion compensated image was slightly greater than the mean volume delineated in the three phases. For the final patient (PT4), the difference is marginal mainly because an extra tumour extension was observed on the higher quality motion compensated image (figure 2), indicating a potential clinical benefit.

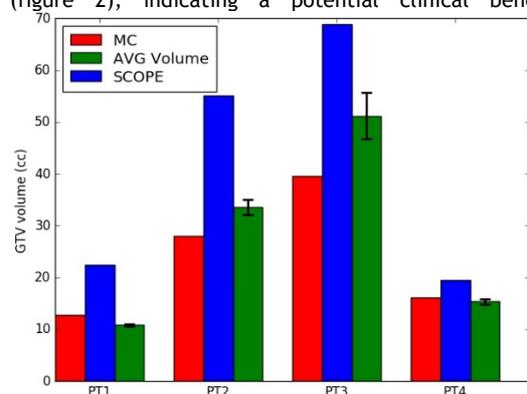

Figure 1: Volume of GTV delineated on patient images. In red, the GTV is delineated on a motion compensated image, in blue the combined GTV created according to the SCOPE protocol is shown. In green, the average volume of the GTV across each of the three phases is shown.

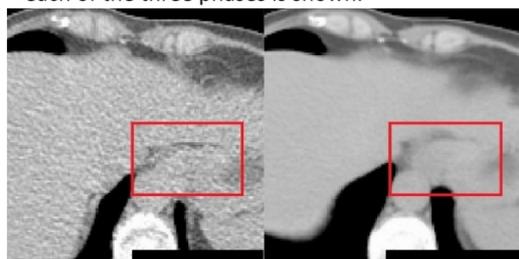

Figure 2: Individual phase CT image (left) compared to a motion compensated image (right) of the same region. The superior quality of the motion compensated image allows delineation of extra tumour extension - highlighted in the red box.

### Conclusion

The use of motion compensation in the delineation of oesophageal cancers reduced delineated volumes in 2 out of 4 patients and would be of benefit to spare surrounding organs at risk.

EP-1719 Diagnostic DSA's, a resource for radiotherapy treatment planning of AVM's

P. Davenport<sup>1</sup>, M. Javadpour<sup>2</sup>

<sup>1</sup>St Luke's Radiation Oncology Center, Physics, Dublin,

Ireland

<sup>2</sup>Beaumont Hospital, Neurosurgery, Dublin, Ireland

### Purpose or Objective

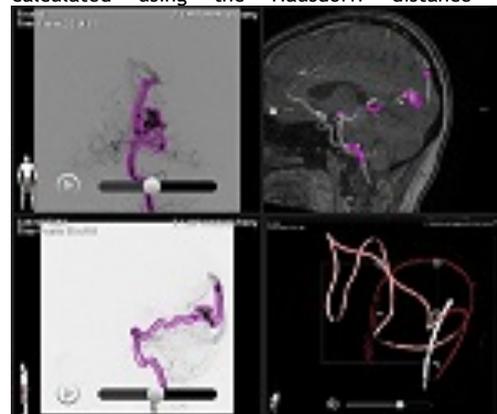

To validate the use of diagnostic digital subtraction angiograms (DSA) for the radiotherapy treatment planning of arterial venous malformations (AVM) using a specialised registration software package.

### Material and Methods

A CT, MRI & DSA compatible phantom was constructed which was used to assist with the calculation of geometric accuracy of the DSA-MRI registration software, SmartBrush Angio supplied by Brainlab. This phantom was imaged using the standard AVM patient care-path for CT, MRI and DSA. The CT and DSA imaging in this case was imaged with a stereotactic localisation frame in place which allowed the scaling of the DSA's to the CT images. An additional set of DSA's were acquired without the localisation frame. In each case the phantom vessels were contoured on DSA, MR and CT, the latter being the reference image set.

Clinical validation of the registration software was completed for two patients. After the registration of both the radiotherapy treatment planning (localised) and diagnostic (non-localised) DSA's to the MR, the feeding arteries and the draining veins were delineated on the localised and non-localised imaging sets.

An analysis of the accuracy of the registrations was calculated using the Hausdorff distance metric.

### Results

The phantom vessels were divided into two sets, the upper loop (UL) and the lower loop (LL) for analysis. The UL consisted of a single vessel traversing the X, Y & Z planes while the LL traversed the X & Z planes only. Using the Hausdorff distance metric a result of 0.41 mm and 0.85 mm displacement for the UL and LL respectively was calculated.

A similar result was found for two clinical cases analysed, a Hausdorff distance of <0.8 mm for the feed artery and drain vein.

Phantom	Dev. (mm)
LL - DSA / MRI	0.78
UL - DSA / MRI	0.41
Clinical	Dev. (mm)
Patient 1 Feed	0.72
Patient 1 Drain	0.71
Patient 2 Feed	0.46
Patient 2 Drain	0.50

### Conclusion

Based on the results of both the phantom study and the clinical data, the use of non-localised diagnostic DSA's could be used to assist with the radiotherapy treatment

planning of AVM's. This negates the need to perform an invasive localised DSA in the majority of cases thereby reducing risks associated with this procedure.

#### EP-1720 Framework for Statistical Cone-Beam CT Reconstruction with Prior Monte-Carlo Scatter Estimation

J. Mason<sup>1</sup>, M. Davies<sup>1</sup>, W. Nailon<sup>2</sup>

<sup>1</sup>University of Edinburgh, Institute for Digital Communications, Edinburgh, United Kingdom

<sup>2</sup>Oncology Physics Department, Edinburgh Cancer Centre, Edinburgh, United Kingdom

##### Purpose or Objective

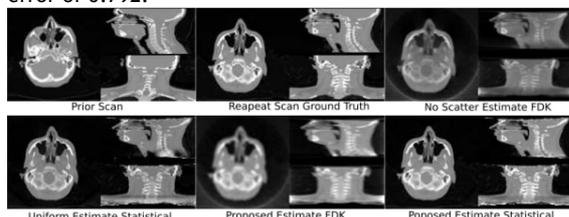

Scatter from the patient and detector leads to significant inaccuracies and artefacts in cone-beam computed (CBCT). Monte-Carlo (MC) methods may allow the scatter signal to be accurately estimated based on a prior scan, but this must be matched and calculated for the new cone-beam measurements, and incorporated appropriately into a reconstruction method. We investigate a framework for statistical reconstruction with these prior MC estimates, under various work-flows.

##### Material and Methods

The framework consists of statistical iterative reconstruction with knowledge of a MC scatter estimate from the planning CT. The estimate can be generated with the scheme proposed by Xu et al. (PMB 2015) with online registration and approximate MC of the prior, or by calculating an accurate scatter off-line and warping to match the new measurements, which will be faster. We supplement the reconstruction with regularisation spatially and between the prior image, hereby utilising the planning image twice.

##### Results

The method was applied to data from repeat CT scanning of a neck cancer patient, with a low-dose repeat CBCT to form the new measurements. The figure shows reconstructions from the framework along with alternative approaches for comparison. The norm of the error in attenuation coefficient through the region containing the specimen is: 2.94 for *no scatter estimate FDK*, which has no scatter correction; 1.74 for *uniform estimate statistical*, which is statistical reconstruction with a simple scatter estimate; 2.41 for *proposed estimate FDK*, with prior scatter estimation; and 0.835 for *proposed estimate statistical*, which is the proposed framework combining double regularised statistical reconstruction with prior scatter estimation. We note that using the estimation strategy of Xu et al. in our framework yields an error of 0.792.

##### Conclusion

We show that the general framework of statistical reconstruction with prior scatter estimation is accurate under low-dose acquisitions. The choice of our off-line scatter estimation or the on-line approximate estimate of Xu et al. is a trade-off in computational time and added accuracy, but either perform well. We suggest this quantitatively accurate method should be suitable for adaptive radiotherapy, and we are planning further testing with more applicable data.

#### EP-1721 A new calibration method of an Elekta XVI (R.5.0.2) system able to achieve superior image quality. D. Oborska-Kumaszynska<sup>1</sup>

<sup>1</sup>Royal Wolverhampton NHS Trust, MPCE Department, Wolverhampton, United Kingdom

##### Purpose or Objective

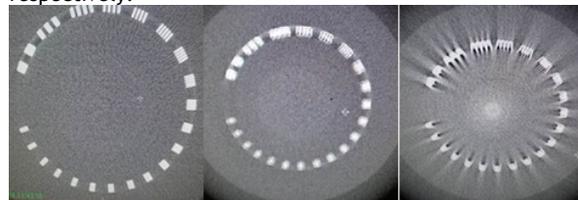

During acceptance testing of an Elekta XVI system, it is standard practice to only test system performance using SFOV. The focus of this work was to develop and introduce an extended customer acceptance test (AT) procedure as a foundation for introducing a new calibration method of an Elekta XVI (R.5.0.2) system. With optimal image quality achieved for all FOVs during AT, more appropriate optimisation of clinical XVI protocols can then be performed.

##### Material and Methods

Following a significant service of the system (X-ray tube replacement and calibration of the detector SDD), it was first calibrated in line with the standard manufacturer procedure. Extended ATs were then performed for all FOVs. A CATPHAN 600 phantom was used to assess spatial resolution, uniformity, contrast and geometry. The parameters used by the reconstruction algorithm can change depending on which AT you are performing (e.g. spatial resolution, uniformity or contrast). It was therefore necessary to assess all combinations of FOVs and each test (e.g. MFOV with spatial resolution, LFOV with uniformity...).

##### Results

The performed ATs showed unacceptable image quality for MFOV and LFOV. Spatial resolution tests revealed images with significant artefacts (Fig.1). The contrast results were worse than 3%. The uniformity test results were worse than 5%. The calibration procedure of the system was repeated a few times but results were still unacceptable. Investigations pointed to a few reasons: very rigid reconstruction algorithm (FDK) with regards to geometry, an exactly defined geometrical relation between X-ray source (focal spot position) and the coordinate system of pixels of the detector for each FOV, and correction of flexmap offset required for each FOV. This led to additional steps in the XVI system calibration: X-ray beam axis alignment perpendicular to the imaging panel surface and to "the centre" of that panel for each FOV; calibration of lateral panel position and re-setting of pots readings; re-calibration of flexmaps, badpixel maps and gains of the imaging panel. The spatial resolution test results showed for SFOV=13 lp/cm, MFOV=12.5 lp/cm, LFOV=13 lp/cm and clear visibility of the spatial pattern. The results for contrast were 1.85%; 2.39%; 2.91%, respectively and for uniformity were 0.52%; 2.00%; 3.64%, respectively.

##### Conclusion

Introducing extended AT for the Elekta XVI (R.5.0.2) system provides full evaluation of the system before introducing it in to clinical practice and ensures that image quality is acceptable for all FOVs. The new calibration procedure was able to realise the full and proper reconstruction of image information and resulted in a significant improvement of image quality for all FOVs, as assessed by the above parameters.

**EP-1722 Inter-observer agreement of ACR MRI phantom Test on a 1.5T MR-Simulator with Flexible Coil setting**  
 J. Yuan<sup>1</sup>, O.L. Wong<sup>1</sup>, S.K. Yu<sup>1</sup>, K.Y. Cheung<sup>1</sup>  
<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Hong Kong, Hong Kong SAR China

**Purpose or Objective**

To evaluate inter-observer disagreement of the ACR MRI phantom test on a 1.5T MR-Simulator (MR-sim) with flexible coil setting for RT simulation scan.

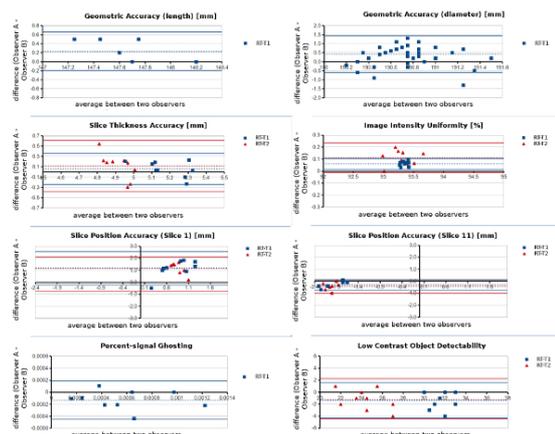

**Material and Methods**

Two 4-channel flexible radiofrequency array coils were wrapped close to a large ACR MRI phantom placed on a indexed flat couch-top in radiotherapy (RT)-setting for image acquisition. The ACR MRI phantom was each time repositioned, aligned and scanned 9 times on a 1.5T MR-sim. The ACR phantom was carefully positioned and aligned using a well-calibrated external 3D laser system for each scan session. Sagittal localizer (TE/TR = 20/200ms), axial T1 (TE/TR = 20/ 500ms) and T2 (TE1/TE2/TR = 20/ 80/ 2000ms) images were acquired following the ACR scanning instructions. Image analysis was conducted by two MRI physicists following the ACR phantom test guidance. Each physicist was blind to the measurement results of the other physicist. Measurement disagreements between two observers were assessed using Bland-Altman (BA) analysis and intra-class correlation coefficient (ICC).

**Results**

All ACR phantom tests passed ACR recommended criteria under RT-setting based on both physicists' analysis in the presence of inter-observer disagreement. Small 95% limit of agreement was noted for all tests (Table 1), of which for geometric accuracy (inside length=0.4mm; diameter=1.0mm), slice thickness accuracy (T1=0.3mm; T2=0.5mm), slice position accuracy (T1 slice 1=1.4mm; T1 slice 11=0.5mm; T2 slice 1=0.9mm; T2 slice 11=0.6mm), intensity uniformity (T1=0.0%; T2=0.1%), percent-signal ghosting (T1=2.9; T2=3.4) and low-contrast object detectability (T1=2.9; T2=3.4) were all much smaller than the corresponding ACR criterion. As illustrated in Fig. 1, all data points fell within the 95% limit of agreement except for diameter accuracy, for which 3 out of 54 (-5.6%) data points fell outside the 95% limit of agreement. Furthermore, small measurement bias close to zero was also obtained for most tests. In terms of ICC, excellent inter-observer agreement (ICC>0.75) was achieved in geometric accuracy (ICC>0.99), spatial resolution (ICC = 1), slice position accuracy (ICC = 0.81), image intensity uniformity (ICC = 0.80), percent ghosting ratio (ICC = 0.85) and low-contrast object detectability (ICC = 0.89). A fair inter-observer agreement was seen in the slice thickness accuracy (ICC = 0.42). Based on both BA-analysis and ICC, excellent inter-observer agreement could be achieved in the ACR MRI phantom test under RT-setting.

Test	series	Slice location	Measurement index	bias	95% limits of agreement
Geometric accuracy (mm)	T1	Localizer	Phantom length	0.2	0.4
		Slice 1	diameter (AP direction)	0.0	1.3
		Slice 1	diameter (LR direction)	0.5	1.0
		Slice 5	diameter (AP direction)	0.4	1.2
		Slice 5	diameter (LR direction)	0.5	0.7
		Slice 5	diameter (phantom's UL to LR)	0.5	0.7
		Slice 5	diameter (phantom's UR to LL)	0.6	0.7
Slice thickness accuracy (mm)	T1	Slice 1	slice thickness	0.1	0.3
	T2	Slice 1	slice thickness	0.1	0.5
Slice position accuracy (mm)	T1	Slice 1	Bar difference	1.1	1.4
		Slice 11	Bar difference	-0.3	0.5
	T2	Slice 1	Bar difference	1.2	0.9
		Slice 11	Bar difference	-0.4	0.6
Image intensity uniformity (%)	T1	Slice 7	Percent integral uniformity (PIU)	0.1	0.0
	T2	Slice 7	PIU	0.1	0.1
Percent-signal ghosting	T1	Slice 7	ghosting ratio	-0.0001	0.0003
Low-contrast object detectability	T1	Slices 8 - 11	Total number of spoke	-1.3	2.9
	T2	Slices 8 - 11	Total number of spoke	-1.1	3.4

**Conclusion**

Our results showed that ACR MRI phantom test under RT-setting was highly reproducible and subject very little to inter-observer disagreement.

**EP-1723 Optimisation of an Elekta XVI (R.5.0.2) system for clinical protocols - image quality vs dose.**

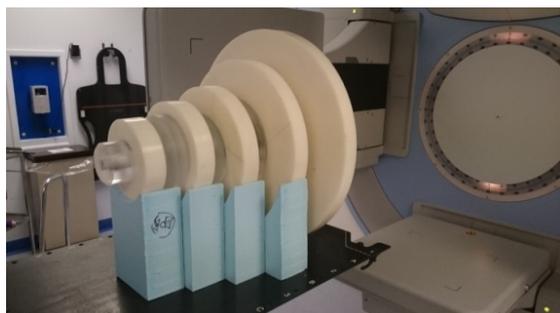

D. Oborska-Kumaszynska<sup>1</sup>, D. Northover<sup>1</sup>  
<sup>1</sup>Royal Wolverhampton NHS Trust, MPCE Department, Wolverhampton, United Kingdom

**Purpose or Objective**

The use of CBCT in radiotherapy has significantly increased in recent times, which has led to an increase in the concomitant dose received by some patients. Often, the generic preset protocols provided by the manufacturers are not optimised for a particular department. This work aimed to optimise image quality and dose for CBCT clinical protocols using an Elekta XVI (R.5.0.2) machine for all clinically relevant treatment sites.

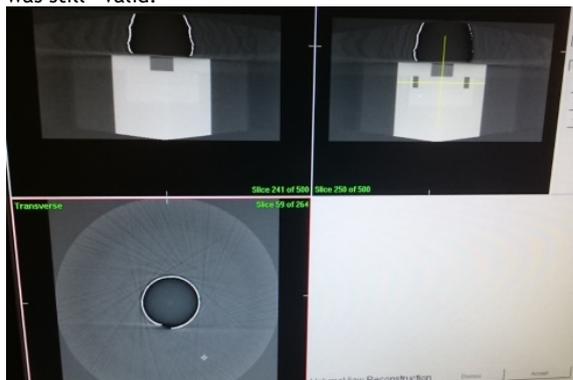

**Material and Methods**

The Elekta XVI system was fully calibrated and Acceptance Tests (AT) were performed for all FOVs before the optimisation procedure. Three different phantoms were used to complete the optimisation: CATPHAN 600, Phillips WEP Phantom Set (PWEPPS) (5 circular objects 15, 20, 26.5, 36.5, 50cm diameter - Fig.1.) and Rando phantom (RP). The optimisation methodology was designed to assess dose vs the following image quality parameters: spatial resolution (SR), uniformity (UN), contrast (CON), CNR, SD, SNR and artefacts. These parameters were evaluated as absolute values and compared to the "standard" image results. These "standard" images were taken for AT presets. The optimisation process was performed by setting the exposure parameters: mA per frame, ms per frame and gantry start/stop angles. The first step involved taking CATPHAN images using varying mA and ms settings. SR, UN, CON, CNR, SD and SNR values were recorded. Final mA and ms settings were chosen based on SNR and UN results, and were no worse than 20% and 5% respectively in relation to the "standard image". Images were also compared using the same mAs but different mA and ms values. The second step involved taking PWEPPS images using the final mA and ms settings for each protocol. SNR and UN were evaluated for phantom diameters relevant to the treatment site in question. The RP was used to assess image quality for the finalised clinical protocols.

## Results

The optimisation process resulted in better image quality in relation to the original presets and “standard images”. Dose was reduced by a factor ranging from 2-4 times. For a given mAs, superior image quality was seen for a higher mA and lower ms, indicating that the detector response was better for a higher dose rate. Saturation artefacts (Fig.2) were visible for 64mA and 10ms when the images included the intersection between the test object and air. The worse UN was seen for LFOV. This was affected by “cutting” from the reconstruction 40 pixel rows at the edge of the panel. It was done because the bad pixel map correction algorithm could not effectively correct the bad pixels. Additionally, for 2D KV images, bad pixel artefacts were visible using the TOR18FDG phantom. The KV detector panel was replaced and the new one was calibrated to get similar gains so the optimisation process was still valid.

## Conclusion

The performed optimisation process allowed us to manage the image quality which met expected quality criteria with significant reduction in dose.

### EP-1724 Phantom image quality evaluation under 3 coil settings for abdominal MR-simulation at 1.5T

O.L. Wong<sup>1</sup>, J. Yuan<sup>1</sup>, S. Yu<sup>1</sup>, K. Cheung<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Hong Kong, Hong Kong SAR China

#### Purpose or Objective

MR-simulation for abdominal radiotherapy often involves the use of customized immobilization vacuum bags and radiofrequency (RF) coil holders. Although several types of RF coils are available for abdominal MR scans, the influence of different RF coils and settings on image quality has rarely been studied. In this study, we aimed to quantitatively compare the quality of image acquired by three different coil settings for abdominal MR-simulation scan on a 1.5T MR-simulator.

#### Material and Methods

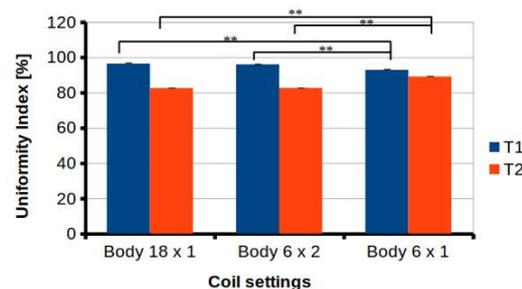

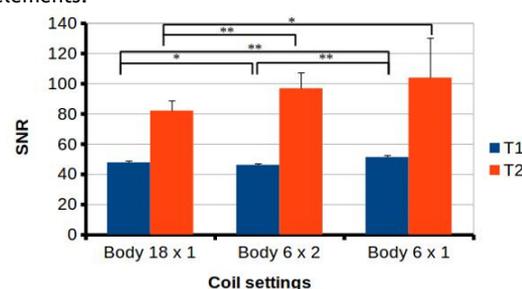

A homogeneous cylindrical water phantom (diameter-21cm, length-35cm, volume-15L) was positioned on a flat couch top with a vacuum-bag. In combination with a spine coil, three sets of scans, with 4 repeats each, were performed under the coil settings

(Fig1) with either a 18-channel body array (Body18x1), two 6-channel body arrays (Body6x2) or a single 6-channel body array (Body6x1) on a dedicated 1.5T MR-simulator (Aera, Siemens Healthineers, Erlangen, Germany). All images were acquired using a 2D spin-echo T1-weighted (TR/TE=500/20ms) and T2-weighted (TR/TE1/TE2=2000/20/80ms) sequences (FOV=448mm, matrix=448x448, slice thickness=5mm, geometric distortion correction and prescan normalization=ON, 11 slices). For all scans, the coil-to-phantom distance remained constant by fixing the coil holder height. SNR was calculated based on AAPM Report 100 using the central slice from each image set. For image uniformity assessment, the percent of pixels with intensity within 10% of the mean signal was calculated as uniformity index (UI). A rank-sum test was performed to compare SNR and UI differences between three coil settings.

## Results

As illustrated in Fig2, the SNR of Body6x1 (T1:51.2±1.3, T2:103.8±26.3) was significantly larger than that of Body18x1 (T1:47.7±1.1, T2:81.9±6.7) for both T1 (P<0.01) and T2 series (P<0.05). Compared to Body18x1, the SNR of Body6x2 (T1:46.1±0.9, T2:96.7±10.5) was significantly lower using T1 series (P<0.05) and larger using T2 series (P<0.01). Significantly larger SNR of Body6x1 was also noted comparing to Body6x2 using T1 series (P<0.01). For image uniformity assessment, UI of Body6x1 (T1:92.8±0.6%, T2:89.0±0.3%) was significantly smaller than Body18x1 (T1:96.4±0.6%, T2:82.5±0.2%) and Body6x2 (T1:96.0±0.2%, T2:82.6±0.2%) using T1 series (P<0.01), and significantly larger than Body18x1 and Body6x2 using T2 series (P<0.01). In terms of SNR and UI, Body6x1 outperformed other two settings for T2-weighted abdominal MR-simulation. However, shorter coverage along SI direction and smaller maximum acceleration factor of Body6x1 might be a limitation for some applications due to its smaller coil size and fewer array elements.

## Conclusion

Our results suggested that Body6x1 might provide better SNR and image uniformity for T2-weighted abdominal MR-simulation scan than other two settings.

## EP-1725 Predicting radiation-induced pneumonitis in NSCLC: a radiobiological and texture analysis study

W. Nailon<sup>1</sup>, W. Lu<sup>2</sup>, D. Montgomery<sup>1</sup>, L. Carruthers<sup>1</sup>, J. Murchison<sup>3</sup>, A.W. Yong<sup>3</sup>, G. Ritchie<sup>3</sup>, T. Evans<sup>4</sup>, F. Little<sup>4</sup>, S.C. Erridge<sup>4</sup>, A. Price<sup>4</sup>, D.B. McLaren<sup>4</sup>, S. Campbell<sup>4</sup>

<sup>1</sup>Edinburgh Cancer Centre Western General Hospital, Department of Oncology Physics, Edinburgh, United Kingdom

<sup>2</sup>School of Engineering University of Edinburgh, Institute of Digital Communications, Edinburgh, United Kingdom

<sup>3</sup>Royal Infirmary of Edinburgh, Department of Radiology, Edinburgh, United Kingdom

<sup>4</sup>Edinburgh Cancer Centre Western General Hospital, Department of Clinical Oncology, Edinburgh, United Kingdom

## Purpose or Objective

In patients with inoperable non-small cell lung cancer (NSCLC) reliably estimating susceptibility to radiation-induced pneumonitis is challenging. Typically dose-volume histogram (DVH) parameters, normal tissue complication probability (NTCP) and changes in lung density are used, however, there is still considerable uncertainty in predicting individual patient susceptibility. The aim of this work was to investigate the presence of patient-specific density patterns that predict the likelihood of pneumonitis based on image analysis of radiotherapy planning CT images. The predictive image analysis measures were compared to NTCP models that predict the risk of pneumonitis.

## Material and Methods

A cohort of 9 NSCLC patients made up of 4 patients (ID 71 to 74) that developed pneumonitis after radiotherapy and 5 patients that remained asymptomatic after radiotherapy (ID 10 to 14) was selected. Radiotherapy planning CT images were acquired at 3 mm slice thickness with a pixel resolution of 1 mm. 6 patients were treated with 55 Gy in 20 fractions and 3 patients with 60 Gy in 30 fractions. Treatment plans were produced on Eclipse using a pencil beam convolution dose calculation algorithm. 7 radiobiological models were used to calculate NTCP on the whole, right and left lungs. Image texture analysis was used to calculate 99 unique features on 32x32 and 20x20 pixel<sup>2</sup> subimages within the whole lung volume. Redundant texture features were removed and a neural network (NN) trained to classify the results.

## Results

The predicted NTCP values are shown in Figure 1 for the analysis of the whole lung volume (normal lung tissue excluding the GTV). Similar results were obtained for the right and left lungs. Although model 5, symptomatic or radiographic pneumonitis <=6 months, showed high NTCP values this was not specific to patients with confirmed pneumonitis. Similar values were obtained in patients showing no signs of pneumonitis. The image texture analysis results identified the risk of pneumonitis most notably in the right lung (87.49%).

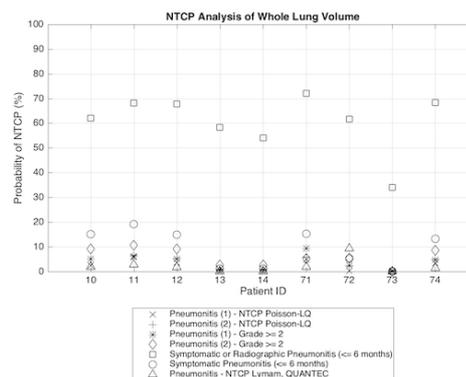

Figure 1: NTCP results on the 9 patients (ID 10-14 asymptomatic, 71-74 symptomatic).

Condition	% Correct Classification Rate (SFS+NN)		
	Whole Lung	Right Lung	Left Lung
No Pneumonitis	90.61	90.90	89.47
Pneumonitis	61.81	80.45	64.21
Overall	80.87	87.49	80.19

Table 1: Texture analysis classification on the whole lung and right and left lung volumes.

## Conclusion

These preliminary results show that it is possible to predict radiation-induced pneumonitis, both prior to treatment and independently of dosimetric evaluation, using image texture analysis of the radiotherapy planning CT images. However further validation on a larger patient cohort is required.

## EP-1726 Efficacy of vendor supplied distortion correction algorithms for a variety of MRI scanners

E.P. Pappas<sup>1</sup>, I. Seimenis<sup>2</sup>, D. Dellios<sup>2</sup>, A. Moutsatsos<sup>1</sup>, E. Georgiou<sup>1</sup>, P. Karaiskos<sup>1</sup>

<sup>1</sup>National and Kapodistrian University of Athens, Medical Physics Laboratory - Medical School, Athens, Greece

<sup>2</sup>Democritus University of Thrace, Medical Physics Laboratory - Medical School, Alexandroupolis, Greece

## Purpose or Objective

Although inherently distorted, Magnetic Resonance Images (MRIs) are being increasingly used in stereotactic radiosurgery (SRS) treatment planning in order to take advantage of the superior soft tissue contrast they exhibit. MR scanner manufacturers have equipped their units with distortion correction algorithms to mainly compensate for gradient nonlinearity induced spatial inaccuracies. The purpose of this study is to assess the accuracy of these algorithms by comparing distortion maps deduced with and without the optional distortion correction schemes enabled for a variety of MRI scanners.

## Material and Methods

A custom acrylic-based phantom was designed and constructed in-house. Its external dimensions were limited to approximately 17x16x16 cm<sup>3</sup> in order to accurately fit in a typical head coil while extending to the edges of the available space. On eleven axial planes, a total of 1978 holes were drilled, the centers of which serve as control points (CPs) for distortion detection. Center-to-center CP distance is 10 mm on x and y axis and 14 mm on z axis, resulting in adequately high CP density. The phantom was filled with copper sulfate solution and MR scanned at 1.5T (SIEMENS Avanto, Philips Achieva) and 3.0T (SIEMENS Skyra) using the corresponding standard clinical MR protocol for SRS treatment planning. All scans were

repeated after disabling the vendor supplied distortion correction scheme. The phantom was emptied and CT scanned to provide the reference CP distribution. In-house MATLAB routines were developed for distortion assessment. Reference and evaluated CP distributions were spatially registered and compared to derive 3D distortion maps. This methodology does not consider uniform geometric distortion as it cancels out during the spatial registration step. This results in omitting uniform susceptibility-induced CP dispositions and thus mainly takes into account machine-related distortions.

#### Results

At central slices, around the scanners' isocenters minimum distortion was detected even with the correction algorithms disabled. However, at the edges of the available space distortion magnitude greatly increases (figure 1) and efficacy of algorithm becomes paramount. Maximum detected distortion reaches 3 mm for the SIEMENS 3.0T scanner but is reduced to less than 1.5 mm if the correction algorithm is enabled. For the 1.5T scanners slightly lower corresponding values were observed.

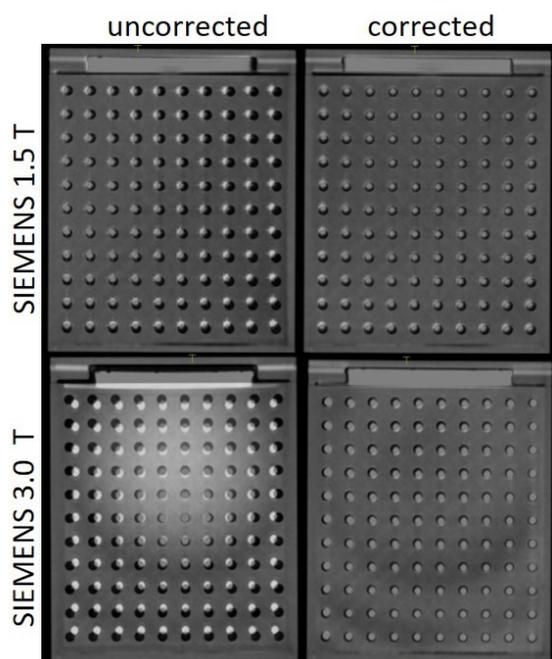

Figure 1: MRIs fused with CT scans of the phantom for a slice lying at the Superior side before and after applying correction schemes.

#### Conclusion

A methodology was developed and implemented to assess the accuracy of vendor supplied distortion correction schemes applied to SRS used MR protocols. Overall results of this work suggest that geometric distortions could be a concern around the edges of the field of view even with the correction algorithms enabled.

<sup>3</sup>. Hospital Son Espases, Radiation Oncology, Palma de

Mallorca, Spain

<sup>4</sup>Hospital Clinic, Radiation Oncology, Barcelona, Spain

<sup>5</sup>Hospital Universitari Sant Joan, Radiation Oncology, Reus, Spain

#### Purpose or Objective

MRI are more and more used in radiotherapy planning so image quality control has become of paramount importance. Diagnostic (DX-setup) and radiotherapy (RT-setup) MRI setups differ in several parameters, v. gr. image protocols, coils used, on top of the need of a flat tabletop to reproduce radiotherapy setup. It is known that these modifications are translated on image deteriorations. Here, we aim to evaluate the signal-to-noise (SNR) variation related to the use of the RT-setup that involved the use of a carbon fibre tabletop.

#### Material and Methods

Two image sets of a phantom and 15 prostate cancer patients were acquired using a DX-setup and a RT-setup. Both image sets were acquired with the same T2w protocol at 1.5T (TR=3000-3900, TE=120 ms; FOV, 180 mm; matrix size, 256 x512; slice thickness, 3 mm; number of signal averages, 4; scan percentage, 80%; TSE factor, 16). The DX-setup involved the use of the usual curved tabletop and a 5-channel coil. The RT-setup involved the use of a flat carbon fibre tabletop and the integrated body coil. SNR was assessed and 3 independent radiologists rated the quality of the images.

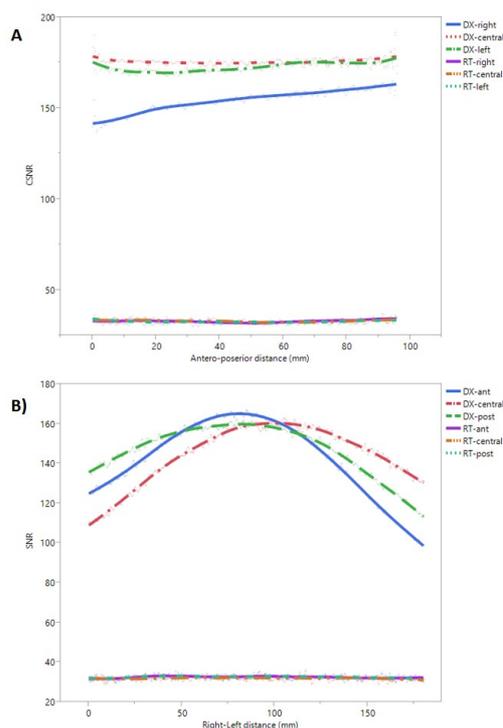

#### Results

Neither burning nor heating issues were associated with the use of the carbon fibre tabletop. Phantom and patient images shown a SNR decrease associated with the RT-setup. An 81% signal loss was observed on the phantom's images. Significant median patients' SNR drops were observed: SNR prostate, DX-setup 8.65, RT-setup 6.61, p=0.015; SNR fat, DX-setup 20.14, RT-setup 16.6, p<0.001. A greater agreement between radiologists was observed on the DX-setup images compared to the RT-setup images (94.4% vs 83.3% when a perfect match was evaluated).

TABLE . SNR and CNR acquired from prostate, fat and muscle ROIs. Data are median and range values. Δ%: mean difference in percent.

	DX-setup	RT-setup	Δ%	P-value
SNR prostate	8.65 (5.03 - 17.46)	6.61 (3.93 - 16.20)	-23.6	0.015
SNR fat	20.14 (17.51 - 25.22)	16.62 (11.11 - 24.38)	-17.5	<0.001
CNR prostate-muscle	6.79 (3.19 - 15.66)	4.5 (1.38 - 12.69)	-33.7	0.005
CNR prostate-fat	10.41 (5.66 - 17.35)	9.42 (4.38 - 15.34)	-9.5	0.252
CNR muscle-fat	18.16 (15.81 - 22.61)	14.21 (8.75 - 21.70)	-21.8	<0.001

Figure . Phantom SNR. A) Antero-posterior SNR profile across the middle and lateral regions of the phantom. B) Right to left SNR profiles across the anterior, middle and posterior region of the phantom. The use of the DX-setup which involved the use of the 5-channel coil was associated to a signal uniformity impairment. To note the perfect uniformity using the body coil.

### Conclusion

The use of different coils at greater distance from the organ of interest and the use of a flat carbon fibre tabletop produced a reduction of the SNR. Even safe under the protocol we used, we believe that the use of more appropriated materials for MRI should be recommended. Nevertheless, this setup could be a low-cost first step for departments who want to start to integrate MRI images into their RT workflow.

### EP-1728 Inter-observer contouring similarity metrics, correlation with treatment outcome for prostate cancer

<sup>9</sup>University of Sydney, Institute of Medical Physics, Sydney, Australia

### Purpose or Objective

To determine the geometric and statistical metrics quantifying inter-observer contouring variation displaying the strongest correlation with simulated treatment outcome for prostate cancer.

### Material and Methods

Data was available for 39 patients with localised prostate cancer, each having undergone CT and MRI scanning prior to radiotherapy. Three observers independently

contoured CTV, bladder, and rectum on T2 MRI. A 7mm margin was applied to each observer's CTV to create observer PTVs. An estimate of the true volume of each structure was generated using the STAPLE algorithm. Geometric and statistical metrics spanning the literature for inter-observer contouring variation studies were calculated for each observer's contours with respect to the STAPLE volume. VMAT treatment plans (78 Gy to PTV) were simulated for each observer's contoured structures, as well as for the STAPLE volumes, for all patients. Radiobiological metrics assessing treatment outcome (TCP, EUD, NTCP, etc.) were calculated for STAPLE CTV, PTV, bladder, and rectum for all treatment plans. Correlations between contouring variation metrics and radiobiological metrics were assessed using Spearman's rank correlation coefficient  $\rho$

### Results

In total 117 observer treatment plans were simulated, resulting in a study with power to detect statistically significant ( $p < 0.05$ ) correlations of  $\rho \geq 0.3$ . No statistically significant correlations were found between contouring variation and radiobiological metrics for CTV and bladder. Figures 1 and 2 observed correlations for PTV and rectum respectively. For both structures volume similarity, sensitivity, and specificity showed moderate levels of correlation with a range of radiobiological metrics, although no correlations were observed between contouring variation and maximum dose within the rectum. Dice Similarity Coefficient (DSC) and Jaccard Index were found to have no significant correlation with simulated outcome for either structure, despite their prevalence within the literature. Centre-of-mass variations in the coronal and sagittal planes for PTV and rectum respectively were the only distance metrics displaying significant correlations to simulated treatment outcome. Euclidean centre-of-mass variations, Hausdorff Distance, and Mean Absolute Surface Distance showed no correlation with any radiobiological metric.

### Conclusion

Results indicate that volume similarity, sensitivity, specificity, and centre-of-mass significantly correlate with simulated treatment outcome within the rectum and PTV for prostate cancer radiotherapy. This information could inform future automated registration and atlas methods, allowing them to be guided on metrics based on clinical significance.

### EP-1729 Air pockets in the urinary bladder during hyperthermia treatment reduce thermal dose

G. Schooneveldt<sup>1</sup>, H.P. Kok<sup>1</sup>, E.D. Geijsen<sup>1</sup>, A. Bakker<sup>1</sup>, J.J.M.C.H. De la Rosette<sup>2</sup>, M.C.C.M. Hulshof<sup>1</sup>, T.M. De Reijke<sup>2</sup>, J. Crezee<sup>1</sup>

<sup>1</sup>Academic Medical Center, Radiotherapy, Amsterdam, The Netherlands

<sup>2</sup>Academic Medical Center, Urology, Amsterdam, The Netherlands

### Purpose or Objective

Hyperthermia is a (neo)adjuvant treatment modality that increases the effectiveness of radiotherapy or chemotherapy by heating the tumour area to 41-43 °C. This has been shown to improve treatment outcome for a number of tumour sites, including the urinary bladder. Hyperthermia may be given both for muscle-invasive bladder cancer, where it is combined with radiotherapy, and for non-muscle invasive disease (NMIBC), where it is combined with chemotherapy. However, some air may be

present in the bladder during treatment, which effectively blocks the microwave radiation used to warm the bladder. This may lead to a lower thermal dose to the bladder wall, which is associated with a lower treatment response. This study investigates the size of that effect.

#### Material and Methods

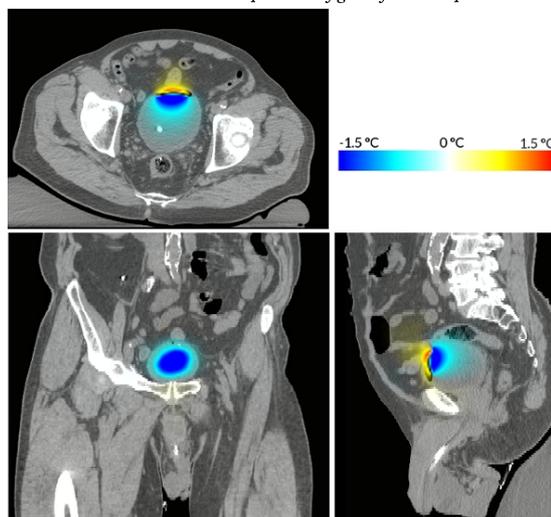

We analysed thirteen NMIBC patients treated at our institute with mitomycin C (40 mg in 50 ml) plus hyperthermia (60 min). Hyperthermia was delivered using our hyperthermia device with four 70 MHz antennas around the pelvis. A CT scan was made after treatment and a physician delineated the bladder on the CT scan. On the same scan, the amount of air present in the bladder was delineated. Using our in-house developed hyperthermia treatment planning system, we simulated the treatment using the clinically applied device settings. We did this with the air pocket delineated on the CT scan, and alternatively with the same volume filled with fluid (urine).

#### Results

The patients had on average 4.2 ml (range 0.8 - 10.1 ml) air in the bladder. The bladder volume delineated by the physician (including air pocket and bladder wall), was on average 253 ml (range 93 - 452 ml). The average bladder volume in which changes exceeded 0.25 °C was 22 ml (range 0 - 108 ml), with the bladder being up to 2 °C cooler when an air pocket was present. There was no evident relation between the quantity of air and the difference in temperature. Although in particular the part of the bladder close to the air pocket absorbs less energy, the temperature in the entire bladder is typically lower because of convective mixing in the bladder contents.

patient #	bladder [ml]	air [ml]	% air	$\Delta T_{\min}$ [°C]	$\Delta T_{\max}$ [°C]
11	262	0.8	0.3	-0.14	0.24
8	197	0.9	0.5	-0.49	0.69
5	245	1.1	0.5	-2.20	3.04
2	93	2.1	2.2	-0.45	0.50
13	161	3.1	1.9	-0.17	0.36
12	188	3.5	1.9	-2.12	2.42
3	452	3.8	0.8	-0.40	1.50
6	277	3.8	1.4	-0.91	1.23
4	196	4.2	2.1	-0.51	0.70
9	265	4.8	1.8	-4.68	3.86
7	257	7.5	2.9	-1.69	1.34
1	285	8	2.8	-2.37	1.32
10	328	10.1	3.1	-0.93	0.90
average	247	4.1	1.7	-1.31	1.39
std dev.	87	2.9	0.95	1.29	1.09

**Table 1.** Bladder volume and air pocket volume per patient, sorted by air volume. Minimum ( $\Delta T_{\min}$ ) and maximum ( $\Delta T_{\max}$ ) temperature differences between the simulations with and without air pocket vary greatly between patients.

**Figure 1.** Temperature difference for patient #1. Because the air pocket shields the electromagnetic field from the top antenna, power absorption is lower in especially the top part of the bladder. Because of heat transport, the effect is noticeable throughout most of the bladder. Axial, coronal and sagittal views.

#### Conclusion

The effect of an air pocket in the bladder during bladder hyperthermia treatment varies strongly between patients, and no relation was visible between effect size and air volume. Generally, this leads to lower temperatures in the bladder, potentially affecting treatment quality, and suggesting that care need be taken to minimise the size of air pockets during hyperthermia treatments.

proton beams. H&N/brain audit is more complex than prostate one, and chamber cavity volume is taken into account more carefully which enables to keep tight tolerances.

#### Results

Centres which participated in the previous run did not perform better than centres which participated for the first time in prostate audit. However, results were sufficient in all cases. There was not significant improvement in results with installations of new linac and TPS. Better MLC performance was observed but CT number to RED was still the problematic point. Differences in planning approaches can be seen. Weakest point for the head audit was the phantom positioning on the couch (despite using IGRT). Tolerances for film evaluation depend on the dose gradient in the direction perpendicular to the film plane. We use 95% or 90% (4%/3mm) for gamma index for prostate/ H&N or brain plans respectively. In future, pseudo-3D gamma analysis will be implemented.

#### Conclusion

It is not straightforward to identify the causes of deviations, especially when they lie within tolerance limits. Nevertheless, it is possible to identify systematic errors which might be vendor dependent, user dependent, or TPS dependent. These can help to optimise the national quality standard in radiotherapy. We recommend not to use rigid marks on phantom but let the centre apply their own fixation and positioning procedure. We recommend to include CT scanning process and identical „patient“ set-up procedure employing RTTs. When designing audit methodology, it is necessary to analyze pilot run results first and then optimise procedure dependent tolerances. This work has been supported by the project No. TB04SUJB001 and by the Ministry of Interior of the Czech Republic, project No. MV-25972-53/OBVV-2010.

#### EP-1732 Treatment planning of dose escalation for anal cancer in the PLATO trial

N.L. Abbott<sup>1</sup>, D. Christophides<sup>2</sup>, M. Robinson<sup>3</sup>, J. Copeland<sup>4</sup>, R. Adams<sup>5</sup>, M. Harrison<sup>6</sup>, M. Hawkins<sup>3</sup>, R. Muirhead<sup>3</sup>, D. Sebag-Montefiore<sup>2</sup>

<sup>3</sup>University of Oxford, CRUK/MRC Oxford Institute for Radiation Oncology, Oxford, United Kingdom

<sup>4</sup>University of Leeds, Clinical Trials Research Unit, Leeds, United Kingdom

<sup>5</sup>Velindre Cancer Centre, Cardiff, United Kingdom

<sup>6</sup>The Hillingdon Hospital NHS Foundation Trust, Uxbridge, United Kingdom

#### Purpose or Objective

*Personalising Anal cancer radiotherapy dose (PLATO)* is a complex integrated protocol, including ACT5 for high risk patients.

ACT5 compares standard and dose escalated radiotherapy. As part of trial development a planning study was carried out by lead centres to determine the impact of dose escalation on OAR sparing. Following this study a benchmark planning case was selected and sent to fifteen UK centres as part of the radiotherapy quality assurance programme (RT QA), co-ordinated by the national QA group. These centres will randomise the first 60 patients in a pilot phase of the trial.

We report the results of the planning study and benchmark planning case with respect to achievable OAR sparing with ACT5 dose escalation.

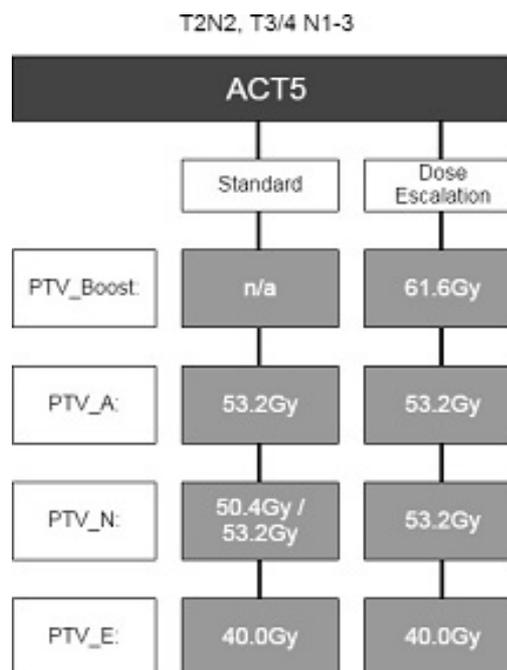

Figure 1: Planning Study target doses

#### Material and Methods

Eight clinical cases were identified as part of the initial planning study and independently re-planned per the RT trial protocol with and without dose escalation by two experienced IMRT planners. A single (female) case was then selected representative of a typical yet challenging case and used as the planning benchmark.

Ten of the fifteen centres participating in the pilot phase of the trial completed the benchmark planning case, planning with dose escalation only. All pilot centre data was processed with CERR<sup>[1]</sup> software enabling dose distribution and dose volume histograms to be assessed.

#### Results

Dose escalated plans for the initial eight cases showed no statistically significant increase in dose to the OAR with dose escalation (p-value>0.1) whilst maintaining PTV coverage (D95%>95%).

Ten centres participating in the pilot phase completed the pre-trial exercise. A range of plan beam configurations were used: 1x 2arc 6 flattening filter free (FFF) MV, 2x 3arc 6MV, 2x 7-field IMRT 6MV, 2x2arc 6MV, 2x Tomotherapy and 1x 4arc 6MV.

All centres met all trial mandatory dose objectives for the benchmark planning case and the vast majority of optimal constraints, see table 1

ROI	Level	Dose Objective		Centres achieving optimal objective	Average [range]
		Optimal	Mandatory		
PTV_Boost [61.6Gy]	D95%	>95%	>90%	9	97.0% [94.3-98.7]

	D35%	<30Gy	<40Gy	7	25.4Gy [14.7-33.9]
	D5%	<40Gy	<55Gy	7	36.3Gy [23.0-42.4]
Bladder	D50%	<35Gy	<45Gy	7	30.6Gy [20.0-36.6]
	D35%	<40Gy	<50Gy	10	33.7Gy [23.5-38.3]
	D5%	<50Gy	<58Gy	10	42.3Gy [40.8-44.7]

Table 1: Optimal and mandatory dose constraints

#### Conclusion

Two sequential planning exercises have demonstrated dose escalation in anal cancer patients is achievable without sacrifice of OAR sparing. This shows OAR sparing is achievable across multiple centres using a variety of planning techniques, giving expectation of consistent quality plans for trial patients.

Over 30 sites will join the trial in the next phase and will complete the same RTQA process.

#### EP-1733 Proton grid therapy (PGT): a parameter study

T. Henry<sup>1</sup>, A. Valdman<sup>2</sup>, A. Siegbahn<sup>1</sup>

<sup>1</sup>Stockholm University, Department of Medical Physics, Stockholm, Sweden

<sup>2</sup>Karolinska Institutet, Department of Oncology and Pathology, Stockholm, Sweden

#### Purpose or Objective

Proton grid therapy (PGT) with the use of crossfired and interlaced proton pencil beams has recently been proposed by our research group. A clear potential for clinical applications has been demonstrated. The beam sizes used in our proof-of-concept study were in the range 7-12 mm, full-width at half maximum (FWHM), representing the typical range of available proton pencil-beam widths at a modern proton therapy facility. However, to further take advantage of the dose-volume effect, on which the grid therapy approach is based, and thereby improve the overall outcome of such treatment, smaller beams are desirable. In this present study, Monte-Carlo (MC) simulations of a simple PGT treatment were performed with varying beam sizes and center-to-center (c-t-c) distances between the beams. The aim was to determine which combinations of those two parameters would produce the most therapeutically desirable dose distributions (high target dose and low valley dose outside of the target).

#### Material and Methods

MC calculations were performed using TOPAS version 2.0 in a 20x20x20 cm<sup>3</sup> water tank. The beam grids were aimed towards a 2x2x2 cm<sup>3</sup> cubic target at the tank center. Two opposing (or 2x2 opposing) grids were used. The target was cross-fired in an interlaced manner. Grids containing planar beams (1-D grids) or circular beams (2-D grids) were

considered. Three beam widths (1, 2 and 3 mm FWHM) and a wide range of c-t-c distances (3-12 mm) were studied. Peak and valley doses outside the target and the minimum, maximum and mean doses inside the target were scored. The objective of the planning was to obtain a nearly homogeneous target dose in combination with low peak doses in normal tissue as well as high peak-to-valley dose ratios (PVDRs) close to the target.

#### Results

The most appropriate c-t-c distances, according to our planning objectives, for 1, 2 and 3 mm beam-element widths, were 7, 8 and 10 mm, respectively. With these c-t-c distances, a very high entrance PVDR was obtained for the 3 beam sizes (>10000). At 1 cm distance from the target, the PVDR was 9, 10 and 14, for the three beam widths studied. Inside the target, a high dose homogeneity could be obtained for these cases ( $\sigma = \pm 4\%$ ). When decreasing the c-t-c distance further, the PVDR decreased dramatically outside of the target. With increasing c-t-c distances, the PVDRs also increased as expected, but the overall target dose homogeneity decreased due to the appearances of cold spots.

#### Conclusion

In this work we studied the possibility to use beam-element widths in the mm range for PGT combined with crossfiring. For each proton beam-element size studied, an optimal c-t-c distance was determined according to the selected planning objectives. With the optimal parameter setting, a high target dose homogeneity could be obtained together with high PVDRs outside of the target.

#### EP-1734 AAPM TG-119 benchmarking of a novel jawless dual level MLC collimation system

D. Mihailidis<sup>1</sup>, R. Schuermann<sup>1</sup>, C. Kennedy<sup>1</sup>, J. Metz<sup>1</sup>

<sup>1</sup>University of Pennsylvania, Radiation Oncology, Philadelphia, USA

#### Purpose or Objective

To study delivery accuracy for fixed beam and volumetric intensity modulated RT (IMRT & VMAT) of a new jawless MLC collimation system mounted on a straight through linac. The AAPM TG-119<sup>1</sup> recommended IMRT commissioning process was used to benchmark the new MLC system and compare it with the TrueBeam Millennium (120-MLC). This new MLC has faster moving leaves that may be more optimum for faster intensity modulated deliveries.

#### Material and Methods

A prototype jawless MLC system with 28 pairs of 1cm leaves provides a 28x28cm<sup>2</sup> field size at 100 cm. The leaves have maximum over-travel, i.e. over 28 cm, and 100% inter-digitization. After acquiring beam data and deducing the dosimetric leaf gaps (DLG) for modeling the MLC in the planning system, we applied the test plans in TG-119 IMRT for fixed IMRT and VMAT delivery. The same test plans, using 6X-FFF (filter-free), were planned and delivered, in an identical way, on a solid water phantom with a cc-13 ion chamber (IC), a MapCheck2 (for IMRT), and an ArcCHECK (for VMAT). Results obtained with the millennium and the new MLC system were compared based on  $\gamma$ -criteria of 3%/3mm-G (global normalization), and a more stringent 2%/2mm-L (local normalization).

#### Results

The TB DLG values (1.3mm) were adjusted to balance the confidence intervals for the IC measurements between IMRT and VMAT. For the new MLC system, the DLG values (0.1mm) were not adjusted. The TG-119 required IC measurements resulted for prototype MLC: 1.19% (mean), 1.28% (SD), 3.71% (CL) and 0.19% (mean), 0.47% (SD), 1.11% (CL) for high dose and low dose regions, respectively. For the TB MLC: 1.93% (mean), 0.5% (SD), 2.91% (CL) and 1.32% (mean), 1.17% (SD), 3.62% (CL) for high dose and low dose regions, respectively. The

comparison of planned to delivered plans for all TG-119 targets for IMRT and VMAT deliveries are shown in Figures 1 and 2 below, and for the two MLC systems. The prototype MLC system produced higher passing rates for both IMRT and VMAT than the TB MLC system for the various test plans. In addition, the prototype MLC system performs equally well for IMRT and VMAT, whereas the TB MLC is less optimum for VMAT delivery compared to IMRT (Fig. 1 and Fig. 2).

Fig. 1

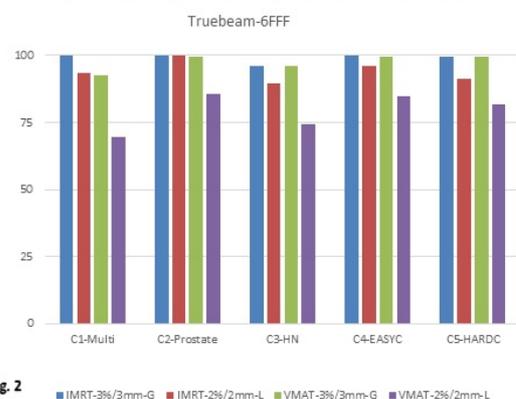

Fig. 2

### Conclusion

The TG-119 test plans were performed on a prototype MLC system in comparison to the well-understood TB Millennium MLC. Our investigation showed, in the context of TG-119, this prototype MLC performs well for both IMRT and VMAT plans.

### EP-1735 Total skin irradiation with helical Tomotherapy: Planning and dosimetry feasibility aspects

A. Haraldsson<sup>1</sup>, P. Engström<sup>1</sup>

<sup>1</sup>Skåne University Hospital, Radiation physics, Lund, Sweden

### Purpose or Objective

Mycosis fungoides (MF) is a lymphatic disease that attacks the skin. The primary treatment for treating MF is total skin electron therapy (TSET). The procedure is technically challenging both in terms of dosimetry and treatment delivery. Helical Tomotherapy (HT) is due to its design especially advantageous when irradiating very long and complex targets. In this study we have explored the possibility of employing HT in the treatment of total skin irradiation (TSI).

### Material and Methods

We used an anthropomorphic whole body phantom (PBU-60 Kyoto Kaguka). The phantom was immobilized with whole body vacuum bag, a five-point open head net mask fixated to the couch and an individual neck rest. The

phantom was covered with a 7 mm thick wet suit made of Neoprene (AquaLung) and CT scanned in two sets; from vertex to thigh and from toes to hip. The CTV was defined as skin with 5mm depth, with PTV as a 7 mm expansion. An optimization bolus was added from the body and 12 mm expansion, defined as mass density 1.0 g/cm<sup>3</sup>. The prescribed dose was 12 Gy delivered in 6 fractions. The dose planning was aimed to keep D<sub>95%</sub> > 95% to PTV and minimizing dose to organs at risk, which was defined as the rest of the body. An optimization structure was used to create a tangential irradiation of the skin, minimizing the dose to normal tissue. We tested the bolus effect of Neoprene with Gafchromic EBT3 film by irradiating slabs of 7mm, dry and soaked in water. To verify skin doses, the phantom with wet suit was irradiated with several 2x2 cm<sup>2</sup> slabs of film taped to the body. The film were evaluated at least 24 hours after irradiation. Corresponding detector array measurements (Delta4, Scandidos) were done and evaluated with gamma analysis. Further, a robustness test was done by moving the phantom 10 mm in the x, y and z directions, to evaluate the effect of mispositioning.

### Results

Results of planning and robustness tests are presented in table 1. Measured data fit to depth dose data yields a dose maximum at 28 mm for Neoprene. Hence, 7 mm is equivalent to 3 mm thick water bolus and lightly soaked Neoprene adds another 1.2 mm thickness of water. Delta4 gamma analysis with 2 mm and 3%, global dose, is clinical acceptable with regards to deliverability (M = 93%, SD = 3%). The verification of 27 film slabs for skin dose gave an average difference from TPS dose of 4% (SD = 3%), figure 1.

Table 1: Dose to organ at risk and target and junction area (PTV-junction), as well as worst case dose coverage to CTV after offset 10mm (CTV<sub>Robust</sub>). All doses are reported in Gy.

Structure	D <sub>2%</sub>	D <sub>98%</sub>	D <sub>mean</sub>
Brain	11.6	0.9	4.6
Heart	4.4	1.0	1.5
Lenses	4.8	4.0	4.5
Liver	6.7	0.9	1.7
Oral cavity	8.8	1.3	4.4
Lungs	11.3	1.3	4.5
PTV <sub>UpperBody</sub>	13.3	11.4	12.2
PTV <sub>Legs</sub>	13.4	10.5	12.2
PTV <sub>Junction</sub>	13.9	10.3	12.6
CTV <sub>UpperBody</sub>	13.0	11.6	12.3
CTV <sub>Legs</sub>	13.4	11.6	12.2
CTV <sub>Robust</sub>	13.5	10.5	12.0

### Conclusion

The difference of measured dose compared to TPS, for both film and Delta4 dosimetry is larger than most types of targets treated with HT which is to be expected considering the technique and size of target. The deliverability is within limit of our clinic action levels (gamma pass rate < 90%) and neoprene is feasible as bolus. The benefits, in comparison with reported electron treatments, are target homogeneity and target coverage with good immobilization and complete irradiation with two positions. The higher dose to organs at risk than reported with electrons needs to be addressed if acceptable with regards to toxicity.

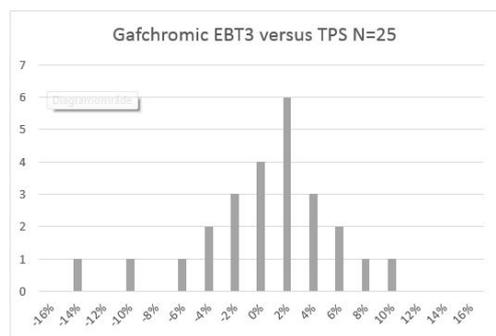

Figure 1: Histogram of film surface measurements, difference presented as measured dose minus TPS dose in percent of subscribed dose to target.

### EP-1736 Radiation and lasers isocenters coincidence with ArcCheck phantom

F. Tato de las Cuevas<sup>1</sup>, J. Yuste Lopez<sup>1</sup>

<sup>1</sup>Hosp. Univ. de Canarias, Medical Physics Dept., Santa Cruz de Tenerife, Spain

#### Purpose or Objective

One tool of Machine QA module of ArcCheck phantom (AC) software checks Radiation and Lasers Isocenters Coincidence (RLIC). The purpose of this work is to evaluate the precision and accuracy of this software tool, comparing it to the same test made with EPID (Electronic Portal Imaging Device).

#### Material and Methods

The LINAC is an Elekta Synergy with Agility MLC and 6 MV energy.

The RLIC with ArcCheck phantom (AC) are obtained following the instructions of the software manual. The measurements are done in continuous gantry movement and for discrete gantry angles. Measurements are made at 9° collimator angle for a 1x25 cm field. A series of measurements were made also in 99° to see the MLC effect, as Agility head has not backup jaws. The AC displacements from laser isocenter in two directions are made in order to check software sensitivity.

RLIC are made with EPID, positioning a Bearing Ball (BB) in the lasers isocenter of a 5x5 cm field and acquiring Images from 0° to 360° gantry angles in 45° steps. The radiation center of the squared field and the center of the BB are calculated with a MATLAB in-house software. BB center is calculated with sub-pixel accuracy in each direction, 3 profiles are obtained and fitted to Gaussian curves, and the mean maximum of the 3 curves is calculated. Radiation field center is obtained calculating the 50% pixel value of a vertical and horizontal profile. The difference between BB center and radiation field center are computed for each gantry angle for in-plane and cross-plane directions. The RLIC for EPID measurements are computed using these values.

#### Results

The RLIC results obtained with AC for each gantry are compared with EPID in the first figure. The mean distance over all gantry angles, for AC (for 9 and 99° collimator degrees) and EPID are: 0.3, 0.6 and 0.7 mm, respectively. The AC results are just distance (because this phantom is not capable of give deviation in in-plane direction for each gantry angle). The results for AC for 9° are higher than for 99° because of the irregular MLC radiation field limit exposed for 9° to the AC diodes. The RLIC for EPID are given in in-plane and cross-plane directions, the distance for each gantry angle is calculated from both directions and show a bigger mean value than for AC, because of being calculated in just one direction in this phantom.

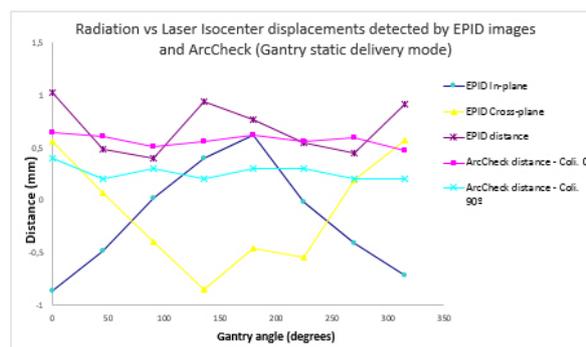

Table 1 shows RLIC results for AC and EPID. AC data is given by phantom software. It can be noticed that the coincidence for both isocenters is lower for the EPID, this can be explained because AC just take into account one direction in each gantry angle

Detector	Displacements		Results			
	X (mm)	Z (mm)	Gantry static delivery		Gantry dynamic delivery	
			X (mm)	Z (mm)	X (mm)	Z (mm)
ArcCheck	none	none	-0.4	-0.5	-0.5	-0.5
ArcCheck	1.0	-1.0	0.5	-1.5	0.4	-1.4
ArcCheck	2.0	-2.0	2.2	-2.1	2.0	-2.0
ArcCheck	-1.0	-1.0	-1.4	0.5	-1.5	0.5
ArcCheck	-2.0	-2.0	-0.5	-0.5	-0.6	-0.4
EPID	none	none	-0.9	-0.9	N/A	N/A

Laser-radiation isocenter coincidence results for some displacements from laser isocenter.

The sensitivity of AC for RLIC is fairly good taking into account the uncertainties of measurement 1 mm between laser positions.

#### Conclusion

ArcCheck software is capable of give a fairly accurate measurement of the laser and radiation isocenters coincidence, taking into account to add about 0.5 mm displacement in X and Z directions.

### EP-1737 Efficient troubleshooting of accelerator faults using the TrueBeam Log Viewer software application

L.H. Praestegaard<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

#### Purpose or Objective

In case of an accelerator fault, the identification of the root cause often takes much longer time than the correction of the fault itself (for example replacement of a component or a calibration). Accordingly, the uptime of an accelerator very much depends on an efficient troubleshooting process. In addition, an overview of existing faults is essential for an efficient planning of service tasks.

#### Material and Methods

The TrueBeam Log Viewer application is an in-house software application developed in C#. For the Varian TrueBeam system all faults occurring during beam on produces an event. With the application all events, for user-selected accelerators and data interval, can be listed including fault details, treatment plan details, mechanical axes, imaging parameters, and imaging arm positions at the time of the event (see figure 1). For each event the TrueBeam system produces a number of node records, each with detailed information about system parameters versus time just before the fault occurred (for example all MLC positions and motor currents at 500 time steps of 10 ms). All node records are readily available in the application from the list of events. In addition, the application can generate an event alarm, including the corresponding event data, each time an event occurs for user-selected accelerators.

For each dynamic beam delivery the TrueBeam system also produces a single log of the main system parameters in a trajectory log text file. The TrueBeam Log Viewer application can list these parameters versus time for user-selected accelerators and data interval. All lists can be sorted with respect to any column, non-clinical events can be ignored, events not matching a user-selected main fault code or fault description string can be ignored, and all lists can be exported to Excel for further analysis.

Figure 1: List of all events for accelerator 01-04 from 3<sup>rd</sup> to 10<sup>th</sup> of October 2016. The selected events are related to the same main fault code 312002.

**Results**

Sorting the list of events with respect to the main fault code provides a fast overview of the number faults for each fault type and accelerator, facilitating an easy prioritization of faults (see figure 1). In addition, treatment plan details and mechanical axes for each event (for example beam energy, the number of monitor units, the patient ID, and the gantry angle) are valuable for the identification of the root cause of the corresponding fault. A more detailed insight into the root cause of a fault can be gained by analyzing node records of the corresponding event in Excel. An example of a node record for a gantry fault is shown in figure 2. Also trending of the main system parameters from the trajectory log text files with Excel is a strong troubleshooting tool.

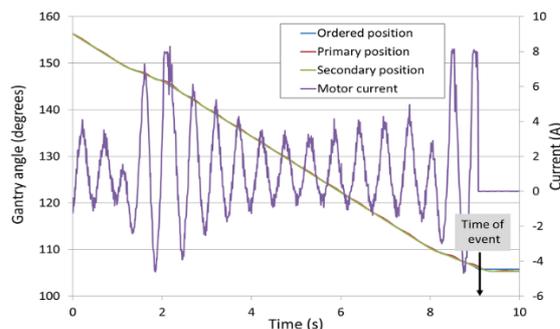

Figure 2: Analysis of a node record for an event with main fault code 312002 (see figure 1). Significant oscillations of the primary gantry readout and gantry motor current strongly indicates a loose gantry chain.

**Conclusion**

The TrueBeam Log Viewer application is an efficient tool both for obtaining an overview of existing faults and for identification of the root cause of faults. In our clinic the application has provided a much more substantiated prioritization of service tasks and faster identification of the root cause of faults. Varian has no service tools with this capability.

**EP-1738 Performance of a new EPID panel and opportunities for a fast MV-CBCT acquisition.**

C. Kennedy<sup>1</sup>, C. Ling<sup>2</sup>, R. Scheuermann<sup>1</sup>, D. Mihailidis<sup>1</sup>, J. Metz<sup>1</sup>

<sup>1</sup>University of Pennsylvania, Radiation Oncology, Philadelphia, USA

<sup>2</sup>Varian Medical Systems, Reserach and Development, Palo Alto- CA, USA

**Purpose or Objective**

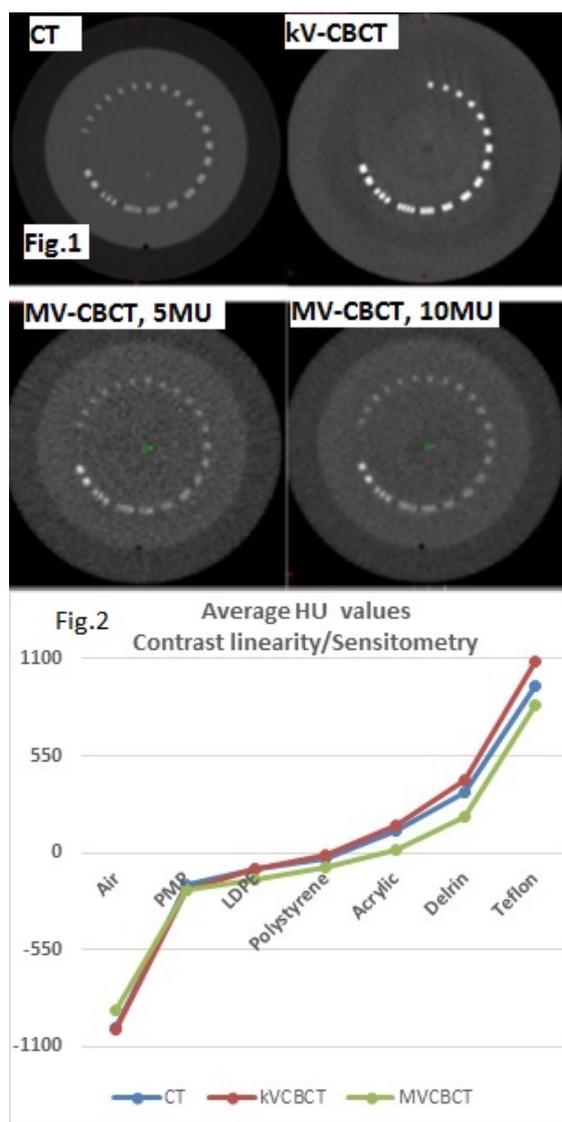

To study the performance, image quality and clinical potential of a novel fast MV-CBCT panel mounted on a straight-through linac with 6X-FFF (filter-free) beam.

**Material and Methods**

A prototype MV imager is mounted in-line with the linac at 154 cm source-to-imager distance. MV-CBCT imaging is performed with 28 cm fixed width (projected at isocenter-100 cm) and variable field length (up to 26 cm max) FOV, 200° arc, 15 sec rotation time, at 5MU and 10MU dose levels. Images of a Catphan® 604 phantom are analyzed in terms of noise, uniformity, spatial and contrast resolution, and contrast linearity. The results are compare with those from Truebeam kV-CBCT imager, and potentially, a Tomotherapy MV-CT imager, all benchmarked to diagnostic CT scanner images. Imaging dose will also be assessed for completeness of testing of the MV-CBCT system.

**Results**

The uniformity and noise of the MV-CBCT was acceptable but not as good relative to diagnostic CT and kV-CBCT, with variation of 32HU from the center to the periphery. Spatial resolution is shown in Fig. 1 with 3lp/mm for 5MU and 4lp/mm for 10MU dose levels, as compared to 7lp/mm for both kV-CBCT and diagnostic CT. The low contrast resolution of the MV-CBCT was >> 1%, compared to 1.0% and 0.5% for kV-CBCT and diagnostic CT. Contrast linearity and sensitometry is shown in Fig. 2, with the MV-CBCT (and 10MU dose level) being the modality that deviates especially for higher density objects like Acrylic, Delrin and Teflon (green data points). Additional tests with varying field length (small, medium and max length) for the MV-CBCT did not show any correlation and/or improvement to the image quality results. Imaging dose will be assessed and presented based on absolute beam output calibration with a 6cc ion chamber and OSLDs. The Tomotherapy data and analysis is underway for comparisons.

### Conclusion

Preliminary image quality tests of a prototype MV-CBCT imaging system that utilizes a 6X-FFF beam and a fast acquisition mode revealed acceptable performance, but as expected, worse than those of kV-CBCT and diagnostic CT. The fast acquisition may potentially be beneficial for motion management treatments such as DIBH for breast and lung tumors. The MV-CBCT also has superior contrast linearity for higher density and metallic materials because of reduced beam hardening, and could be utilized to supplement diagnostic CT images for treatment planning in such cases.

**EP-1739** The feasibility of atlas-based automatic segmentation of MRI for prostate radiotherapy planning  
C. Morris<sup>1</sup>, M.J. Gooding<sup>2</sup>, A. Henry<sup>3</sup>, R. Speight<sup>4</sup>

<sup>1</sup>University of Leeds, Department of Medicine, Leeds, United Kingdom

<sup>2</sup>Mirada Medical Ltd, Mirada Medical Ltd, Oxford, United Kingdom

<sup>3</sup>St James Institute of Oncology, Department of Clinical Oncology, Leeds, United Kingdom

<sup>4</sup>St James Institute of Oncology, Medical Physics and Engineering, Leeds, United Kingdom

### Purpose or Objective

Atlas-based autosegmentation is an established tool for segmenting structures for CT-planned prostate radiotherapy. MRI is being increasingly integrated into the

planning process. The aim of this study was to assess the feasibility of MRI-based atlas-based autosegmentation for organs-at-risk (OAR) and prostate target volumes, and to compare the segmentation accuracy with CT-based autosegmentation.

### Material and Methods

Images were retrospectively selected from 6 prostate patients who received whole field T2 weighted 3D SPACE MRI and CT in the radiotherapy treatment position (at the Northern Centre for Cancer Care, Newcastle). Organs at risk (Bladder, rectum, seminal vesicles, left and right hips, penile bulb) and the prostate were manually delineated on the CT and MRI separately. A 'leave one out' approach was used to automatically segment structures onto the remaining images separately for CT and MRI. Contour comparison was performed using the DICE index and mean distance to conformity (MDC) positional metrics. MDC, DICE and absolute volume were used to assess the performance of the contouring by comparing the automatic to the manual contours. A paired t test was used to determine the statistical significance between MRI and CT.

### Results

The volume analysis (data not presented) showed that manual and automatic contouring on MRI gave smaller contours than CT (significantly so for the hips, prostate and seminal vesicles). The positional analysis results are shown in table 1. MRI autocontouring was more accurate than CT for the bladder (MDC significantly so) and the prostate/penile bulb (although not significantly). There was little difference in accuracy between CT/MRI autocontouring for both hips, rectum and seminal vesicles.

Table key: BL – bladder, LH – left hip, PB – penile bulb, PR – prostate, RE – rectum,

RH – right hip, SV – seminal vesicles, SD – standard deviation

**TABLE 1** – Mean, standard deviation and p-values for MDC and DICE score for automatic contours on MRI and CT. The result was considered significant if the p<0.05.

### Conclusion

Accurate atlas-based automatic segmentation of structures for prostate radiotherapy is feasible using T1-MRI; segmentation of the penile bulb and seminal vesicles was found to be poor. Comparison with CT-based automatic segmentation suggests that the process is equally or more accurate using MRI. Although this study was on a small sample size these results support further translation of MRI-based segmentation methodology into clinical practice.

### EP-1740 Nationwide audit of multileaf collimators performance

K. Chelminski<sup>1</sup>, W. Bulski<sup>1</sup>

<sup>1</sup>The Maria Skłodowska-Curie Memorial Cancer Center, Medical Physics Department, Warsaw, Poland

### Purpose or Objective

The delivery of accurate intensity-modulated radiation therapy (IMRT) or stereotactic radiotherapy depends on a multitude of steps in the treatment delivery process. The proper intensity modulation depends on the proper functioning of a multileaf collimators (MLC). The aim of this audit was the control of the proper collimator leafs positioning.

### Material and Methods

The methodology of the audit of small field output performance was established within the framework of the CRP E2.40.16 project "Development of Quality Audits for Radiotherapy Dosimetry for Complex Treatment

Techniques", run by the Health Section of the International Atomic Energy Agency (IAEA). The participants of the audit were obliged to irradiate provided dosimetric films, in a slab phantom, for a specific leaf arrangement, producing a pattern of five stripes, commonly called a picket fence. The participants had to programme such a pattern so that the stripes are 5 mm wide and are 3 cm distant between themselves. The Gafchromic EBT2 radiochromic films were placed in a slab phantom close to maximum dose depth. The irradiation was 250 MU per stripe.

#### Results

Thirty two Polish radiotherapy centres took part in the audit. They were equipped with various accelerator types and various treatment planning systems. In all cases the 6 MV quality beams were used. The discrepancies between measured and expected stripe positions were in the range 1.2 mm. For particular participants, the leaf position discrepancies were in the range -0,5 mm to 0,5 mm. For particular participants, the mean opening width measured with films for each pair of leafs was between 6 and 8 mm.

#### Conclusion

In the audit, the best performance showed the new type multileaf collimators with 120-160 leafs, The worst performance showed collimators MLC80 from Elekta. The results of the audit are very useful for the participants who should carefully investigate the performance of their multileaf collimators.

#### EP-1741 Commissioning of a robotic patient positioning system equipped with an integrated tracking system

A. Ableitinger<sup>1</sup>, A. Utz<sup>1</sup>, A. Zechner<sup>1</sup>, S. Vatnitsky<sup>1</sup>, M. Stock<sup>1</sup>

<sup>1</sup>EBG MedAustron GmbH, Strahlentherapie, Wiener Neustadt, Austria

#### Purpose or Objective

Robotic patient positioning systems (PPS) used in clinic must consider weight-induced couch bending and must show high reproducibility and stability to achieve the required positioning accuracy. Extensive commissioning of these robotic systems is therefore crucial. The aim of the current work is to determine the positioning accuracy of the PPS, that is equipped with an integrated optical tracking system.

#### Material and Methods

Three different aspects of the PPS were investigated in this study: the basic characteristics including couch bending, reproducibility and stability; the relative spatial deviation in terms of rotation and couch height and the absolute accuracy of the treatment couch.

The treatment volume of the PPS has a dimension of 115cm x 50cm x 40cm. The robotic system enables couch rotations of more than 190°, pitch and roll of ±3° and non-isocentric treatment positions. A photogrammetric camera tracks the treatment couch of the PPS via reflecting markers mounted on the bottom side of the couch (see Fig.1). An iterative position correction loop aligns the couch to the prescribed position.

The reference instrument was a laser tracker with reflecting probes. Drilling holes near the indexing positions (H4-F9) located laterally along the couch every 14cm served as measurement positions for the evaluation of the basic characteristics and the absolute couch position. For the relative deviation the drift of one measurement point on the couch was evaluated.

To determine the bending of the couch it was loaded with six different weights up to 156kg. The reproducible positioning for the same couch position (different axis setting) and the couch stability after 1 hour were measured with the highest payload.

The evaluation of the absolute spatial deviation was based on six measurement points being closest to the room

isocenter. They were compared with their expected coordinates for 1020 different robot positions, poses and payloads.

Figure 1: Setup of PPS with tracking camera and lasertracker in the treatment room is shown on the left. Pattern of reflectors on bottom side of treatment couch are on the right.

#### Results

The basic characteristics of couch-bending, reproducibility and stability were within 0.10mm within the treatment volume (see Fig.2 a, b).

The relative spatial deviation was smaller than 0.40mm for rotations ranging up to 200° (see Fig.2 c). For different vertical positions, the couch drifted less than 0.25mm for 2 different loads and rotations.

The differences between the prescribed and measured absolute position were evaluated in terms of histograms showing the overall 3D deviation. In 95% of all measurement points the 3D accuracy was better than 0.63 mm (see Fig.2 d).

Regarding the weight-induced couch-bending no correlation between the accuracy and payload could be found.

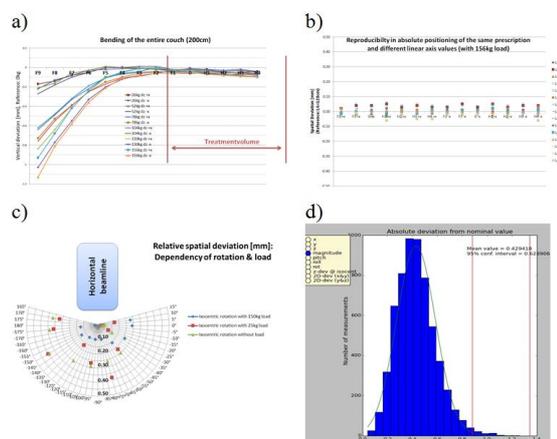

Figure 2: The graphs show in a) the couch-bending and b) the reproducibility. The relative spatial deviation for different rotations is illustrated in c). The histogram in d) shows the 3D deviation of 6120 measurement points equally distributed over the entire treatment volume.

#### Conclusion

The results show that the important spatial properties of the patient positioning system are well within the acceptable clinical tolerances. The very high reproducibility of the PPS allows further optimization of the absolute position. The measured datasets serve as new input for a high accuracy calibration.

#### EP-1742 Optimisation and implementation of brain CBCT templates; an institutional pilot study.

S. Petkar<sup>1</sup>, N. Lalli<sup>2</sup>, F. Solda<sup>1</sup>, C. Gillies<sup>2</sup>, S. Moinuddin<sup>1</sup>, N. Fersht<sup>1</sup>

<sup>1</sup>UCLH NHS Foundation Trust, Radiotherapy, London, United Kingdom

<sup>2</sup>UCLH NHS Foundation Trust, Radiotherapy Physics, London, United Kingdom

#### Purpose or Objective

Volumetric imaging (CBCT) in brain has facilitated the use of volumetric delivery techniques and reduction of

uncertainty margins by quantifying bone set-up variation, and, by inference, OAR position.

The aim of this work is to optimise the current imaging practice on a Truebeam Linac STx(2.5) for adult brain tumour patients by investigating the relationship between CBCT parameters, patient dose and image quality for both bone and soft tissue.

#### Material and Methods

In our institution we currently image this cohort with daily kV imaging and weekly CBCT. A daily 'shift to zero' is applied for set-up variations of less than 3mm with residual error evaluated on a weekly basis via a standard Full-Fan, partial arc CBCT template (Table 1-Template 1) The CBCT image quality was evaluated by comparing three progressive dose-reduction trial imaging templates +/- length reduction (Table 1-Templates 2, 3, 4) with the standard CBCT template.

Initial tests were carried on Catphan® and Rando® phantoms to assess image quality and scan artefact limitations. Three consecutive skull-base meningioma patients were then imaged with the four templates on sequential weekly imaging sessions during treatment.

Each CBCT was reviewed by an expert group of a clinician, two radiographers and two physicists to evaluate, by consensus, the discernibility of the optic nerves, ventricles, cranial bones, temporalis muscle, and the external contour. In addition, the fidelity of the co-registration to the skull-base anatomy (ROI) was assessed. A standard threshold was applied throughout the investigation.

Table 1	Template 1	Template 2	Template 3	Template 4
kV	100	100	80	80
mA	15	15	20	10
ms	20	20	10	10
Length (cm)	16	8*	8*	8*
Dose Reduction Factor	1	1**	0.35**	0.16**

\*Based on mean PTV length plus margin to cover skull base anatomy (ROI);

\*\* 50% less irradiated volume from length reduction

#### Results

A total of 15 CBCT images were acquired and reviewed. All structures were visible for each template except for the ventricles which were assessed as indistinct with templates 3 and 4 (Figure 1).

The fidelity of registration was satisfactory for each template.

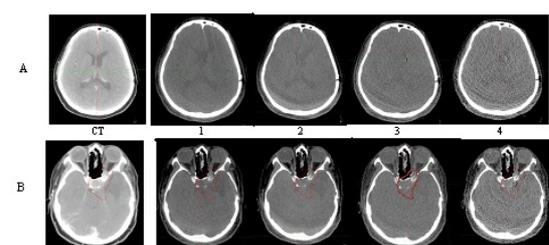

Figure 1. CT planning scan (CT) at the level of the ventricles and ROI (A-B) and corresponding CBCT templates 1-2-3-4 demonstrating the change in discernibility of selected structures with imaging templates.

#### Conclusion

A length-reduction template can be utilised in brain tumours providing the skull-base is included in the CBCT ROI. In cases where the PTV is distant to the skull base, length reduction should be used with care.

A concomitant dose reduction is also feasible unless the discernibility of the ventricles is essential, such as when changes in ventricular volume/position are of concern.

In our institution we will adopt a new imaging strategy for brain tumour patients employing template 4 for all benign skull based tumours and retaining template 1 (standard) for all other lesions.

Further similar work will be carried out to optimise the CBCT protocols in other cohorts of patients (e.g.

paediatrics).

#### EP-1743 Evaluation of proton grid therapy in challenging clinical cases

T. Henry<sup>1</sup>, A. Valdman<sup>2</sup>, A. Siegbahn<sup>1</sup>

<sup>1</sup>Stockholm University, Department of Medical Physics, Stockholm, Sweden

<sup>2</sup>Karolinska Institutet, Department of Oncology and Pathology, Stockholm, Sweden

#### Purpose or Objective

For several decades unidirectional photon-grid therapy has been a useful tool in radiation oncology. Its main advantage is to limit the normal tissue toxicity when irradiating the patients with bulky tumors. In this work we use proton grid therapy (PGT). PGT delivered with a crossfiring technique has been used instead of a unidirectional approach. The physical properties of proton beams allow for the protection of risk organs posterior to the target while the crossfiring technique enables a larger separation between the beams, thus better preserving the normal tissue. Here we evaluate the possibility to use PGT as a therapeutic option in certain clinical situations. For example, due to the ability of interlaced proton-beam grids to significantly spare normal tissue, this technique may be useful in re-irradiation cases not otherwise eligible for radiotherapy treatment because of too high doses to organs at risk.

#### Material and Methods

CT data from patients previously treated with conventional photon therapy at Karolinska Hospital, Stockholm, were reused in order to create PGT treatment plans with the TPS Eclipse (Varian Medical Systems). Patients that could benefit re-irradiations or palliative care were selected. The aim was to deliver a high and nearly homogeneous target dose, while keeping the grid pattern of the dose distribution, made of peak and valley doses, as close to the target as possible. A low grid dose, with low peak and valley doses, was also preferable to better protect the normal tissue. The dosimetric characteristics of those plans were then evaluated, with a focus on the overall homogeneity of the target dose, as well as dose profiles outside of the target (i.e. evaluation of the grid dose distribution through peak and valley doses analysis).

#### Results

All the studied cases presented dose distributions for which the grid pattern was preserved until the direct neighborhood of the targets. When normalizing the minimum target dose to 100%, the valley doses reached around 5%, while the peak doses were approximately 60-70%, depending on the grid geometry used. Inside the targets, a good dose homogeneity could be achieved ( $\sigma = \pm 10\%$ ). The volumes of organs at risk irradiated with high doses remained small and limited spatially to the dose peaks of the grids.

#### Conclusion

PGT produces a combination of nearly homogeneous and high target dose. The grid pattern can be preserved in the normal tissue, from the skin to the direct vicinity of the target, preventing extensive damage to the organs at risk. The PGT approach could present a therapeutic possibility in difficult clinical situations where conventional radiotherapy would fail to provide any suitable option for the patients.

#### EP-1744 Failure modes and effects analysis of Total Skin Electron Irradiation (TSEI) technique

B. Ibanez-Rosello<sup>1</sup>, J.A. Bautista-Ballesteros<sup>1</sup>, J.

Bonaque<sup>1</sup>, J. Perez-Calatayud<sup>1,2</sup>, A. Gonzalez-Sanchis<sup>3</sup>, J.

<sup>2</sup>Clinica Benidorm, Radiotherapy, Benidorm, Spain

<sup>3</sup>General University hospital, Radiation Oncology, Valencia, Spain

<sup>4</sup>General University hospital, Medical Physics, Valencia, Spain

<sup>5</sup>University of Valencia, Physiology, Valencia, Spain

**Purpose or Objective**

A risk analysis of the Total Skin Electron Irradiation (TSEI) technique was performed. The aim of this study was to evaluate the safety and the quality of the treatment process, as well as to adapt the quality assurance program according to the results.

**Material and Methods**

This revision has been executed in a reference center in the TSEI technique, with 80 patients treated following the method Stanford. The risk analysis was made following the methodology proposed by the TG-100 of the AAPM, which is an alternative procedure to the guidelines proposed by the ESTRO in the ACCIRAD project. To this end, a multidisciplinary team developed the process map, outlining the stages of treatment and steps in which each stage is divided. The potential failure modes (FMs) of each step were proposed and evaluated, according their severity (S), occurrence (O) and detectability (D), with a scale from 1 to 10. The product of this factors resulted in its priority number risk (RPN), which enabled ranking the FMs. Then, the current quality management tools were examined and the FMs were reevaluated taking to account these tools. Finally, the FMs with RPN ≥ 80 were studied and new quality management tools to reduce its RPN were proposed.

**Results**

75 steps contained in a total of 12 stages were observed. 361 FMs were evaluated, initially 103 had a RPN ≥ 80 and 41 had S ≥ 8. After, current management tools were considered, only 30 FMs had RPN ≥ 80 (Figure 1). Thereby, new control tools were derived from the study of these 30 FMs. The riskiest FMs were associated to the patient's position during treatment. For the "general body treatment" stage, the position of the screen and the patient was marked on the floor (Figure 2a) and some templates representing the position of the feet were drawn (Figure 2b). In addition, to facilitate positioning of the patient's limbs during "hands treatment" and "feet treatment" stages, the axes must traverse the lasers and the field size within which should position the extremities were marked on the sheet (Figure 2c). These new management tools have begun to be implemented in the facility.

#	Stage	Step	Failure Mode	Cause	Effect	O	S	D	RPN	Notes and examples
227	Hands treatment	Hands positioning	Inadequate distance to the head of treatment equipment	Heavy patient workload	Suboptimal treatment	5	3	5	( 9   9   225 )

Figure 1. The 30 FMs with RPN ≥ 80 after the reevaluation taking to account the current quality management tools.

Figure 2. New QM tools: (a) position of the screen and the patient has been marked on the floor, (b) templates representing the position of the feet have been drawn and (c) the axes must traverse the lasers and the field size within which should position the extremities have been marked on the sheet.

**Conclusion**

Thanks to this analysis, the steps of increased risk have been discovered and new quality management tools have been proposed. However, the multidisciplinary team will perform this analysis periodically to increase the safety and quality of TSEI treatment.

**EP-1745 EPID and Gantry sag characterization in Elekta LINAC**

F. Tato de las Cuevas<sup>1</sup>, J. Yuste Lopez<sup>1</sup>

<sup>1</sup>Hosp. Univ. de Canarias, Medical Physics Dept., Santa Cruz de Tenerife, Spain

**Purpose or Objective**

The EPID (Electronic Portal Imaging Device) is a well-known useful tool for LINAC QA (like MLC QA). The position of the EPID radiation center (RC) is crucial for this kind of tasks. The purpose of this study is analyse the mechanical performance of EPID and Gantry for LINAC QA with EPID.

**Material and Methods**

The LINAC used is an Elekta Synergy equipped with Agility MLC and iViewGT EPID and 6 MV photons energy.

All fields acquired in the study have 20x20 cm size, 5 MU each. To obtain the RC of the EPID at 0° gantry, four fields are used, at 0, 90, 270 and 180 ° of collimator and 0° gantry with a radiopaque crosshair attached to the LINAC head. RC is calculated with two methods: using the radiation field limits and with the radiopaque crosshair center.

Second series of measures are acquired with a BB (bearing ball) placed in laser isocenter and with a tray with four smaller BB fixed in it, in the periphery of the field. Images are obtained over a 360° arc, with 15° gantry steps at 0° collimator angle.

Cross reference of the 4 smaller BB positions with the RC (determined in the first step) are made at 0° collimator and 0° gantry. This gives to the 4 BB the ability to determine RC position in subsequent gantry angles.

EPID sag is calculated for all gantry angles taking into account the laser isocenter BB position in each EPID image and compared with 0° gantry angle. EPID + Gantry sag is determined taking into account the mean position of the BB fixed in the tray. The Gantry sag is obtained after subtraction of EPID sag from EPID + Gantry sag.

Changes in SDD (Source-Detector Distance) are obtained measuring the distance between two tray BB (d) and comparing then to the distance (d<sub>0</sub>) for SDD for 0° gantry angle (SDD<sub>0</sub>) in the way as Eq. reflects.

$$\Delta SDD = SDD_0 \cdot (d/d_0 - 1)$$

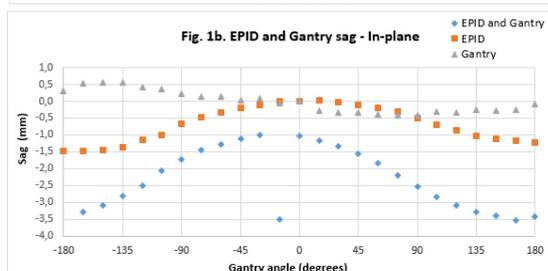

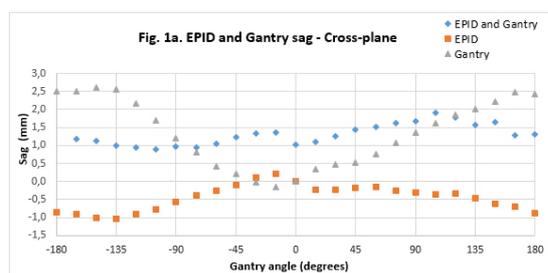

A MATLAB in-house software is developed to make the image analysis. The BBs and the center of radiopaque crosshair is determined in each direction (in-plane and cross-plane) with sub-pixel accuracy, 3 profiles near de BB are obtained and fitted to Gaussian curves, the mean maximum of the 3 curves is calculated. Radiation field center is obtained calculating the 50% pixel value of a vertical and horizontal profile displaced from the center in case of BB in the image center.

### Results

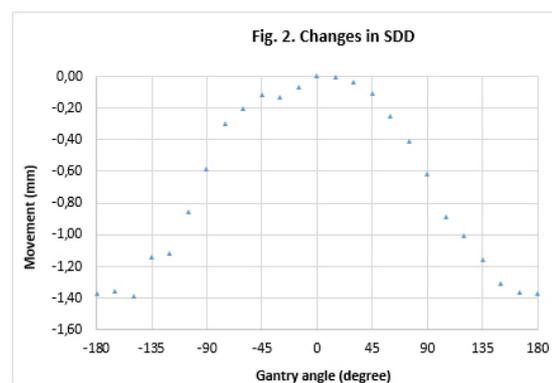

The LINAC measurements take no longer than 2 hours.

The RC for the EPID at 0° gantry obtained with radiopaque crosshair is 1.11 and -1.02 mm for cross-plane and in-plane directions, respectively. The RC using radiation field limits is less than 0.3 mm away from this.

EPID RC is not plotted in Fig. 1 for clarity but is obtained from the EPID + gantry sag measurements after adding the RC for 0° gantry angle.

The major change in SDD is less than 1.4 cm (for 180°) from SDD at 0° gantry angle (see Fig. 2).

### Conclusion

The method presented is a useful, necessary and not too time expending tool to characterize the EPID and Gantry sag of a LINAC when EPID will be used in LINAC QA.

### EP-1746 A new method for exact co-calibration of the ExacTrac X-ray system and linac imaging isocenter

H.M.B. Sand<sup>1</sup>, K. Boye<sup>2</sup>, T.O. Kristensen<sup>1</sup>, D.T. Arp<sup>1</sup>, A.R. Jakobsen<sup>1</sup>, M.S. Nielsen<sup>1</sup>, I. Jensen<sup>1</sup>, J. Nielsen<sup>1</sup>, H.J. Hansen<sup>1</sup>, L.M. Olsen<sup>1</sup>

<sup>1</sup>Aalborg University Hospital, Department of Medical Physics- Oncology, Aalborg, Denmark

<sup>2</sup>Zealand University Hospital, Radiotherapy Department, Næstved, Denmark

### Purpose or Objective

To evaluate a new user independent sub-millimetre co-calibration method between the X-ray isocenter of the ExacTrac® (ET) system and the imaging isocenter of the linear accelerator (linac).

### Material and Methods

The new calibration method was evaluated on five linacs from Varian, three Clinacs with the On Board Imager system and two TrueBeams, all equipped with ET and robotics from Brainlab. A BrainLAB isocenter calibration phantom with five infrared markers attached on the top and a centrally embedded 2 mm steel sphere was used in the setup. Orthogonal MV-kV-image pairs of the calibration phantom were acquired at the four quadrantal gantry angles using the linac imaging system (LIS). In-house made software detected the 2D position of the steel sphere in each acquired image and from this determined the 3D couch translation required to move the steel sphere to the LIS isocenter. To accurately perform the translation, we applied the sub-millimetre real-time readout feature of the ET infrared system, which was set to track the infrared markers of the phantom. Subsequently, the origin of the ET system was calibrated to match the optimal phantom position and hence the LIS isocenter. Regular runs of the Varian IsoCal-routine assured correspondence between the radiation isocenter and the LIS isocenter.

In the standard calibration method former used, the calibration phantom was positioned based on one set of MV-kV-images, manually interpreted by the user.

### Results

The deviation between the ET X-ray isocenter and the LIS isocenter was determined by evaluating the 3D deviation vector for the new user independent optimal positioning of the calibration phantom relative to the LIS isocenter. In ten successive calibrations performed by different users in a time period of nearly half a year, the 3D deviation vector ranged from 0.03 mm to 0.10 mm with an average of 0.07 mm and a standard deviation (SD) of 0.02 mm. Simultaneously, the 3D deviation vector was determined for the standard calibration method, also in ten successive calibrations and performed by different users. Here the 3D

deviation vector ranged from 0.34 mm to 0.82 mm with an average of 0.58 mm and a SD of 0.16 mm. Using the new method of calibration, the 3D deviation vector between the ET X-ray isocenter and the LIS isocenter was on average reduced threefold.

#### Conclusion

Using an in-house made software, a new user independent method of co-calibrating the X-ray isocenter of the ET system with the LIS isocenter was developed. The new method reduced the deviation between the two isocenters threefold and brought them into alignment within one tenth of a millimetre. This may be of clinical relevance in radiotherapy operating with small margins and steep dose gradients i.e. as used in stereotactic radiotherapy.

#### EP-1747 From pre-treatment verification towards in-vivo dosimetry in TomoTherapy

T. Santos<sup>1</sup>, T. Ventura<sup>2</sup>, J. Mateus<sup>2</sup>, M. Capela<sup>2</sup>, M.D.C. Lopes<sup>2</sup>

<sup>1</sup>Faculty of Sciences and Technology, Physics, Coimbra, Portugal

<sup>2</sup>IPOCFG- E.P.E., Medical Physics Department, Coimbra, Portugal

#### Purpose or Objective

Dosimetry Check software (DC) has been under commissioning to be used as a patient specific delivery quality assurance (DQA) tool in the TomoTherapy machine recently installed at our institution. The purpose of this work is to present the workflow from pre-treatment verification with DC comparing it with the standard film dosimetry towards in-vivo patient dosimetry having transit dosimetry with a homogeneous phantom as an intermediate step.

#### Material and Methods

The retrospective study used MVCT detector sinograms of 23 randomly selected clinical cases to perform i) pre-treatment verifications, with the table out of the bore, ii) transit dosimetry for DQA verification plans calculated in a Cheese Virtual Water™ phantom and iii) in-vivo dosimetry using the sinogram of the first treatment fraction for each of the 23 patients. The 3D dose distribution in the phantom/patient CT images was reconstructed in Dosimetry Check v.4, Release 10 (Math Resolutions, LLC) using a Pencil Beam (PB) algorithm. In the pre-treatment mode, Gamma passing rate acceptance limit was 95% using a 3%/3mm criterion. The results have been correlated with the standard film based pre-treatment verification methodology, using Gafchromic EBT3 film with triple channel correction. In transit mode, with the Cheese Phantom, two groups were identified: one with clinical cases in which the longitudinal treatment extension exceeded the phantom limits (group I) and another one with cases where the whole treated volume was inside the phantom (group II). In this mode, a 5%/3mm criterion was used in Gamma analysis. The acceptance limit was again 95%. This was also the criterion for in-vivo dosimetry in the first fraction of each of the 23 patients.

#### Results

There was a good agreement between planned and measured doses when using both pre-treatment and transit mode. In the pre-treatment approach the mean and standard deviation Gamma passing rates were 98.3±1.2% for 3%/3mm criterion correlating well with the results in film. Concerning transit analysis in Cheese phantom, 8 out of 23 cases - group I - presented poor Gamma passing rates of 93.8±2.2% (1SD) on average for 5%/3mm. This was caused by partial volume effect at the edges of the phantom as the longitudinal treatment extension exceeded its limits. Considering the other 15 cases - group II - the global Gamma passing rates were significantly better 99.5±0.7% (1SD), 5%/3mm.

Using the sinogram from the first fraction delivered to each patient, the passing rates were 98.7±1.4% (1SD), on average.

#### Conclusion

The presented results indicate that Dosimetry Check software using either pre-treatment or transit mode is a reliable tool for patient specific DQA in TomoTherapy easily integrable in the routine workflow and without major time allocation requirements. Further investigation needs to be done on DC ability to detect discrepancies during the treatment course, namely if it will be able to alert for re-planning need.

#### EP-1748 Mesorectal-only irradiation for early stage rectal cancer: Target volumes and dose to organs at risk

A.L. Appelt<sup>1</sup>, M. Teo<sup>1</sup>, D. Christophides<sup>2</sup>, F.P. Peters<sup>3</sup>, J. Lilley<sup>4</sup>, K.L.G. Spindler<sup>5</sup>, C.A.M. Marijnen<sup>3</sup>, D. Sebag-Montefiore<sup>1</sup>

<sup>1</sup>Leeds Institute of Cancer and Pathology- University of Leeds & Leeds Cancer Centre, St James's University Hospital, Leeds, United Kingdom

<sup>2</sup>Leeds CRUK Centre and Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, United Kingdom

<sup>3</sup>Department of Radiotherapy, Leiden University Medical Center, Leiden, The Netherlands

<sup>4</sup>Leeds Cancer Centre, St James's University Hospital, Leeds, United Kingdom

<sup>5</sup>Department of Oncology, Aarhus University Hospital, Aarhus, Denmark

#### Purpose or Objective

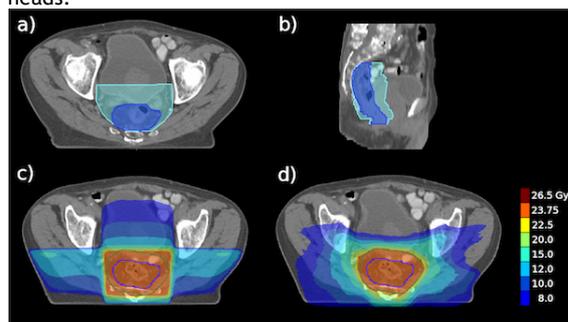

There is increasing interest in radiotherapy (RT)-based organ preservation strategies for early stage rectal cancer. However, standard RT for locally advanced rectal cancer uses a large pelvic target volume, which may represent overtreatment of early cancers with a low risk of nodal involvement and could cause significant morbidity. Thus the international, multi-centre phase II/III STAR-TReC trial, aiming at organ preservation, will use a mesorectal-only irradiation approach for early rectal cancer. Furthermore, in order to limit normal tissue toxicity risk, IMRT or VMAT may be used. We explored the advantages in terms of clinical target volume and organ at risk (OAR) doses of a mesorectal-only target volume compared to a standard target volume for short-course RT, and compared VMAT and 3D-conformal radiotherapy (3D-CRT) for mesorectal-only irradiation. We also aimed at establishing optimal planning objectives for mesorectal-only short-course VMAT.

#### Material and Methods

We conducted a retrospective planning study of 20 patients with early rectal cancer: 15 men, 5 women; 1 high, 10 mid, 9 low tumours; 4 T1, 13 T2, 3 T3a; all N0; 13 treated prone, 7 supine. Standard CTV encompassed the mesorectum, obturator lymph nodes, internal iliac nodes and pre-sacral nodes cranio-caudally from puborectalis to the S2-3 vertebral junction (as per the UK phase III Aristotle trial). The mesorectal-only CTV included the mesorectum only from 2cm caudal of the tumour up to the S2-3 vertebral junction. VMAT plans (6MV FFF, single arc) delivering 5x5Gy to the mesorectal PTV were optimized using a Monte Carlo-based treatment planning system. They were compared to 5x5Gy three-field 3D-CRT plans, for standard and mesorectal targets. We considered target coverage, plan conformity (CI), and doses to bowel cavity, bladder and femoral heads. Metrics were compared using the Wilcoxon signed rank test. VMAT optimization objectives for OAR were established by determining dose metric objectives achievable for ≥90% (bowel cavity) and ≥95% (bladder and femoral heads) of patients.

## Results

Mesorectal-only CTVs were median 59% smaller than standard CTVs (interquartile range 58-63%,  $p < 0.001$ ). All VMAT and 3D-CRT plans had  $V_{95\%} = 100\%$  for the CTVs, while  $V_{95\%}$  of the PTV was comparable for VMAT and 3D-CRT plans (median 99.4% vs 99.6%). Table 1 summarizes doses to OARs and CI. All OAR doses for mesorectal-only irradiation were significantly reduced with VMAT compared to 3D-CRT;  $p < 0.001$  for all metrics. Suggested optimization objectives for OAR for mesorectal-only VMAT were  $V_{10Gy} < 200\text{cm}^3$ ,  $V_{18Gy} < 120\text{cm}^3$ , and  $V_{23Gy} < 90\text{cm}^3$  for bowel cavity;  $V_{21Gy} < 15\%$  for bladder; and  $V_{12.5Gy} < 16\%$  for femoral heads.

**Figure 1:**

**a-b)** Comparison of target volumes: UK standard CTV (light blue) and mesorectal-only CTV (dark blue)

**c-d)** Comparison of mesorectal plans: 3D-conformal (c) and VMAT (d)

	Standard target (3D-CRT)	Mesorectal-only (3D-CRT)	Mesorectal-only (VMAT)
CTV vol [ $\text{cm}^3$ ]	542 (499 – 640)	233 (197 – 252)	233 (197 – 252)
CI	0.70 (0.69 – 0.72)	0.67 (0.66 – 0.70)	0.87 (0.87 – 0.88)
Bladder $V_{21Gy}$ [%]	33.5 (22.0 – 43.3)	10.6 (6.4 – 18.1)	4.6 (2.9 – 10.9)
Bowel cavity $V_{10Gy}$ [ $\text{cm}^3$ ]	335 (231 – 393)	260 (197 – 311)	144 (117 – 187)
Bowel cavity $V_{18Gy}$ [ $\text{cm}^3$ ]	180 (144 – 217)	89 (73 – 111)	75 (65 – 104)
Bowel cavity $V_{23Gy}$ [ $\text{cm}^3$ ]	157 (93 – 184)	64 (55 – 90)	54 (46 – 74)
Femoral heads $V_{12.5Gy}$ [%]	65.2 (47.2 – 81.5)	43.8 (19.6 – 61.0)	3.9 (1.1 – 9.5)

**Table 1:** Volumes and dose metrics for the two target volumes: standard UK volumes (as per the UK phase III Aristotle trial) and mesorectal-only volumes. Conformity index (CI) was calculated as the absolute  $V_{95\%}$  for the PTV relative to the absolute  $V_{95\%}$  for the whole body outline. All values are medians, with interquartile ranges in parenthesis.

## Conclusion

VMAT provides dosimetric advantages over 3D-CRT for mesorectal-only target volumes. The recommended OAR optimization objectives allow for clinical implementation of IMRT/VMAT with improved OAR sparing compared to 3D-CRT standard treatment. These objectives will, after independent validation, be used in the multi-centre STAR-TReC trial.

### EP-1749 The IROC QA Center's Activities Supporting the NCI's National Clinical Trial Network

D. Followill<sup>1</sup>, Y. Xiao<sup>2</sup>, J. Michalski<sup>3</sup>, M. Rosen<sup>4</sup>, T. FitzGerald<sup>5</sup>, M. Knopp<sup>6</sup>

<sup>1</sup>IROC Houston QA Center, ACR, Houston, USA

<sup>2</sup>IROC Philadelphia RT QA Center, ACR, Philadelphia, USA

<sup>3</sup>IROC St. Louis QA Center, ACR, St. Louis, USA

<sup>4</sup>IROC Philadelphia DI QA Center, ACR, Philadelphia, USA

<sup>5</sup>IROC Rhode Island QA Center, ACR, Lincoln, USA

<sup>6</sup>IROC Ohio QA Center, ACR, Columbus, USA

## Purpose or Objective

The Imaging and Radiation Oncology Core (IROC) Cooperative has been active for the past two years supporting the National Cancer Institute's (NCI) National Clinical Trial Network (NCTN), its clinical trials and the details of that support are reported in this work.

## Material and Methods

There are six QA centers (Houston, Ohio, Philadelphia-RT, Philadelphia-DI, Rhode Island, St. Louis) providing an integrated radiation therapy (RT) and diagnostic imaging (DI) quality control program in support of the NCI's clinical trials. The former cooperative group QA centers brought their expertise and infrastructure together when IROC was formed in the new NCTN structure. The QA Center's efforts are focused on assuring high quality data for clinical trials designed to improve the clinical outcomes for cancer patients worldwide. This program is administered through five RT and DI core support services: site qualification, trial design support/assistance, credentialing, pre- and post-case review data management, and case review. IROC also provides educational efforts to improve the understanding of the protocols by participating institutions. IROC monitors over 2000 participating institutions that include nearly 100 participating institutions outside of North America.

## Results

IROC currently provides core support for 172 NCTN trials with RT, DI and RT/DI components. Many of these trials were legacy trial from the previous cooperative group program. IROC monitors nearly 1800 RT photon and 20 proton institutions. Over 28,000 beams outputs were monitored with 8% of the sites requiring repeat audits due to beam out of criteria. As part of credentialing, 950 QA phantoms have been irradiated, 515 imaging modalities evaluated and almost 4000 credentialing letters have been issued. In just year 2, 5290 RT and 4934 DI patient datasets were received (many using TRIAD) by IROC QA Centers to be prepared for review. During the past 2 years, a total of 6300 RT cases and 19,000 DI image sets were reviewed by IROC technical staff. To date, IROC has published 36 manuscripts.

## Conclusion

The QA services provided by IROC are numerous and are continually being evaluated for effectiveness, harmonized across all NCTN Groups and administered in an efficient and timely manner to enhance accurate and per protocol trial data submission. These efforts increase each NCTN Group's ability to derive meaningful outcomes from their clinical trials.

### EP-1750 Enhanced radiotherapy by novel class of radiosensitizers based Bismuth and Gadolinium nanoparticles

S. Farahani<sup>1</sup>, N. Riyahi alam<sup>1</sup>, E. Gorji<sup>2</sup>, R. Rahnamafar<sup>3</sup>, S. Fazli<sup>4</sup>, H. Khosravi<sup>5</sup>, M. Pakravan<sup>1</sup>, V. Shahabian<sup>6</sup>, S. Haghgoo<sup>2</sup>

<sup>5</sup>Tarbiat Modares University, Department of Medical Physics, Tehran, Iran Islamic Republic of

<sup>6</sup>Tehran University of Medical Sciences Radiation On, Sina Specialized and subspecialty Hospital, Tehran, Iran Islamic Republic of

## Purpose or Objective

Recently, the use of nanoparticles with a high atomic number as a new class of radiation sensitizers, to increase the tumor dose and sparing normal tissues has become a hot topic in radiotherapy treatments. Meanwhile, Bismuth and Gadolinium based nanoparticles, can not only be used

in CT and MRI as contrast agents, but also can be feasible radiosensitizers in radiotherapy. Hence they are attractive candidates for multimodal dose enhancement studies. In this study, the ability of dose enhancement of these nanoparticles using MAGIC-f polymer gel under the internal Iridium-192 and the external Cobalt-60 radiotherapy practices were investigated.

#### Material and Methods

The Bi2O3-NPs less than 40 nm in diameter and 0.1 mM concentration were synthesized. To increase the precision of the gel dosimetry a Plexiglas phantom was designed and made, all of the gel filled vials (with and without the nanoparticles) were irradiated to an Ir-192 radioactive source simultaneously. Also, Irradiation was carried out with a Co-60 teletherapy unit.

#### Results

The maximum dose enhancement factors under the internal Iridium-192 radiotherapy were 31% and 22% in the presence of Bi2O3-NPs and Gd2O3-NPs, respectively, whereas these amounts were reduced to 1% in external radiotherapy by Co-60 photons.

#### Conclusion

The results of our research approves the use of Bismuth and Gadolinium based nanoparticles in brachytherapy. Additionally, the polymer gel dosimetry can be a feasible material for verification and estimation of dose enhancements in the presence of nanoparticles.

#### EP-1751 A comparison of tools for Delivery Quality Assurance in TomoTherapy

T. Santos<sup>1</sup>, T. Ventura<sup>2</sup>, J. Mateus<sup>2</sup>, M. Capela<sup>2</sup>, M.D.C. Lopes<sup>2</sup>

<sup>1</sup>Faculty of Sciences and Technology, Physics Department, Coimbra, Portugal

<sup>2</sup>IPOCFG- E.P.E., Medical Physics Department, Coimbra, Portugal

#### Purpose or Objective

A TomoTherapy HD unit has recently been installed in our hospital. The purpose of the present work is to establish an accurate and efficient method of patient specific delivery quality assurance (DQA). Four available tools (EBT3 Grafchromic film, Dosimetry Check -DC -, ArcCHECK™ and RadCalc®) have been tested and compared.

#### Material and Methods

Standard patient plan verification in TomoTherapy is done through film dosimetry in the Cheese Virtual Water™ phantom. Also point dose measurements can be performed inserting ionization chambers in this phantom. A well-established film absolute dosimetry methodology using EBT3 Grafchromic film and applying a multichannel correction method was developed in-house, adapting the standard approach in the DQA Tomo station. The treatment plans of the first 21 patients were retrospectively verified using also Dosimetry Check software (Math Resolutions, LLC) and ArcCHECK™ (Sun Nuclear). A beta version of RadCalc®6.3 (LifeLine Software Inc.) for TomoTherapy has been used for independent treatment time calculation.

DC uses the MVCT detector sinogram to reconstruct the 3D dose distribution. In this work it was used in pre-treatment mode with the couch out of the bore. The transit dose mode where the patient delivered dose reconstruction is obtained was not assessed in this work. ArcCHECK™ records the signal of 1386 diodes embedded as a helical grid on a cylindrical phantom, enabling 4D volumetric measurements.

The Gamma passing rate acceptance limit was 95% using a 3%/3 mm criterion in all cases.

#### Results

All the used QA tools showed a good agreement between measured and planned doses. Film and DC achieved similar

results with mean Gamma passing rates of 98.8±1.6% (1SD) for EBT3 film and 97.9±1.6% (1SD) for DC. Moreover, a correlation was found between those results: when passing rates using film were poorer (<97%), the same happened with DC, while passing rates over 97% for DC corresponded to the same range using film. This correspondence was not verified with ArcCHECK™ where Gamma passing rates were always close to 100% (99.6±0.7% (1SD)).

Concerning the independent treatment time verification with Radcalc®, the percentage difference to the Tomo TPS calculation was 0.2±2.5% (1SD), on average.

#### Conclusion

DC and ArcCHECK™ allow volumetric dose comparisons between calculated and measured doses. Moreover DC displays DVHs and isodose lines for the considered structures in the plan while 3D-DVH in ArcCHECK™ is not available for TomoTherapy.

DC seems to be a valuable tool for performing patient-specific DQA however, considering the present Pencil Beam algorithm and its known limitations, a verification using film dosimetry and ionization chamber measurements should be done in case of any significant discrepancy.

Concerning the beta version for TomoTherapy in RadCalc® software, it seems to be a valid tool for independent treatment time verification, easily incorporable in routine treatment workflow.

#### EP-1752 A simple technique for an accurate shielding of the lungs during total body irradiation

H. Mekdash<sup>1</sup>, B. Shahine<sup>1</sup>, W. Jalbout<sup>1</sup>, B. Youssef<sup>1</sup>

<sup>1</sup>American University of Beirut Medical Center, Radiation Oncology, Beirut, Lebanon

#### Purpose or Objective

During total body irradiation (TBI), customized shielding blocks are fabricated and positioned in front of the lungs at a close distance from the patient's surface to protect the lungs from excessive radiation dose. The difficulty in such treatments is to accurately position the blocks to cover the entire lungs. Any error in the positioning of lung blocks can give higher doses in the lungs than intended and can lead to underdosage in the body/target volume. The conventional technique for the positioning of lung blocks is based on a time-consuming trial and error procedure verified at each trial with radiographic films. A new technique based on CT simulation was developed to determine the exact position of lung blocks prior to treatment for each specific patient. This technique of accurate shield positioning serves the purpose of reducing lung toxicities and most importantly reduces patient's pain and discomfort by minimizing the length of the overall treatment session.

#### Material and Methods

Patients were CT simulated in their lateral recumbent treatment position and lungs were contoured with the aid of a treatment planning system. Horizontal AP/PA fields were designed with MLC aperture conforming to lung contours. The fields were used to project a light field on the patient's skin representing the extent of the lungs, which was subsequently marked on the patient's anterior and posterior skin as seen in Figure 1. Prior to each fraction, the lung blocks were positioned with their shadow matching the lungs' marks. The position of the shielding blocks was radiographically verified prior to the delivery of each beam as per the usual procedure (Figure 2). Three patients underwent TBI with this new technique. Each patient received in total six fractions of AP/PA beams including two fractions with shielded lungs. The lungs received in total 8 Gy and the rest of the body was irradiated with the prescribed dose of 12 Gy. To evaluate the efficiency of this technique, the number of repeated

attempts to correctly position the shielding blocks was recorded for each beam.

Figure 1. The MLC field projected on the patient's body to identify and draw the lungs projections.

Figure 2. Verification of accurate positioning of lung blocks with a radiographic film.

## Results

We succeeded in positioning the shielding blocks from the first attempt in 10 out of 12 beams for the three patients. The position of the shielding blocks was adjusted only one time prior to treatment in 2 out of 12 beams. These results are compared to an average of 3 attempts per beam for each patient using the conventional technique of trial and error. The average time of a treatment session was 29 min with a maximum time of 41 min compared to an average of approximately 60 min in past treatments and a maximum of 120 min.

## Conclusion

Most of TBI patients are pediatric patients and it is difficult to keep them immobilized for a long period of time. This new technique succeeded in reducing the length of the overall treatment session of the conventional TBI procedure and hence reduced patient discomfort while ensuring accurate shielding of the lungs.

### EP-1753 Determining the effect of using lead as electron cutout material compared to low melting point alloy

M. Wanklyn<sup>1</sup>, S. Rizkalla<sup>1</sup>, T. Greener<sup>1</sup>

<sup>1</sup>Guy's and St. Thomas' Hospital NHS Foundation Trust, Radiotherapy Physics, LONDON, United Kingdom

#### Purpose or Objective

The aim of this investigation was to determine whether lead cut-outs are suitable for delivering MeV electron treatments on a Varian TrueBeam which have been planned using the eMC algorithm in Eclipse.

Due to the eMC algorithm beam data being configured using Cerrobend low melting point alloy as the cut-out material it is important to assess the dosimetric differences between the lead and Cerrobend cut-outs.

#### Material and Methods

Unlike the Cerrobend cut-outs which are 1.5cm thick, the lead cut-outs were made to 1cm thickness. This was done to minimise the cost of lead.

Lead versions of all the standard Varian cut-outs were made in house (6x6, 10x10, 6x10, 15x15, 20x20 & 25x25cm<sup>2</sup>). Two regular cut-outs were also made, a 4x8 cm<sup>2</sup> cut-out for the 10x10 cm<sup>2</sup> applicator and a 10x14cm<sup>2</sup> cut-out in a 15x15 cm<sup>2</sup> applicator to determine the out-of-field transmission.

Transmission factors through a 10x10 cm<sup>2</sup> closed end plate were calculated for the lead and Cerrobend materials for a range of energies (6, 9, 12, 16, and 18MeV)

PDDs in water at 100cm SSD and output factors in solid water at  $d_{max}$  at 100cm SSD were measured for the standard applicators with both the lead and Cerrobend inserts for all energies.

Cross line and inline profiles at  $d_{max}$  were taken in water at 100cm SSD for all energies using the two regular cut-outs.

## Results

As can be seen in Figure 1, the transmission through a closed lead endplate is comparable to that for the Cerrobend.

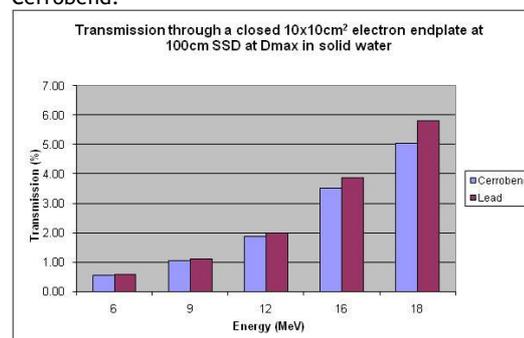

Figure 1: Transmission through a closed endplate in a 10x10cm<sup>2</sup> applicator for both materials.

There is higher transmission through the lead endplate compared to the Cerrobend endplate for all energies but even at the highest energy the difference is only 0.74%.

The measured PDDs agree with each other to within 1.2mm for all energies. The discrepancies were observed near the surface of the PDD curves.

The output factors measured in solid water using the lead inserts agreed with the commissioning values obtained with the Cerrobend inserts to within  $\pm 1\%$  apart from the 6e 10x6cm<sup>2</sup> applicator in which a 1.7% difference in output factor was observed between the lead and Cerrobend. This difference could be due to inaccuracies in the solid water setup as the effective point of measurement of the NACP was estimated to be 1mm.

The profiles measured agreed very well, with the largest discrepancies occurring out of field for the higher energies both crossplane and inplane. This is due to the higher transmission through the lead cut-out at higher energies.

## Conclusion

As there was very good agreement between the lead and Cerrobend inserts and cut-outs for all the tests performed, it can be concluded that using the lead cut-outs is dosimetrically similar to the Cerrobend inserts with which the eMC algorithm was configured.

### EP-1754 Isocentric accuracy of Elekta VersaHD linear accelerators

E. Kouwenhoven<sup>1</sup>, J. Van Egmond<sup>1</sup>, J. Van Wingerden<sup>1</sup>, M. De Goede<sup>1</sup>, M. Mast<sup>1</sup>, J. Van Santvoort<sup>1</sup>

<sup>1</sup>Haaglanden Medical Centre Location Antoniusshove, Radiation therapy, The Hague, The Netherlands

#### Purpose or Objective

The demands on isocentric accuracy are high when accelerators are used for stereotactic treatments. The determination of the optical or mechanical isocenter is inadequate for this purpose, and instead we aim for a procedure to find the megavoltage isocenter. The radius of the smallest sphere through which all rotation axes pass when various collimator, gantry and table angles are applied, is what we use as a measure to quantify the isocentric accuracy. The purpose of the present study is to (1) give an accurate measure of the size of the region containing the megavoltage isocenter, and (2) establish the distance between the rotation axes of table and collimator, respectively. We developed a highly accurate method to determine the isocentric accuracy of Elekta VersaHD linear accelerators.

#### Material and Methods

The tests were performed on all 4 Elekta VersaHD accelerators in our institute. We applied a modified Winston-Lutz test, using a phantom containing a radio-opaque ball, and imaged this phantom onto the EPID using a 10 x 10 cm<sup>2</sup> field. Using the information of a considerable

region of the image, it was possible to find the geometry (i.e., ball center and field outline) in much more detail than just subpixel accuracy. Using a set of at least 8 images with various gantry and collimator angles we could accurately obtain the isocentric accuracy per gantry angle. A consecutive set of 16 images allowed for an analysis giving the distance of the table rotation axis to the collimator rotation axis. We were able to adjust the table position slightly to obtain accuracies necessary for stereotactic application.

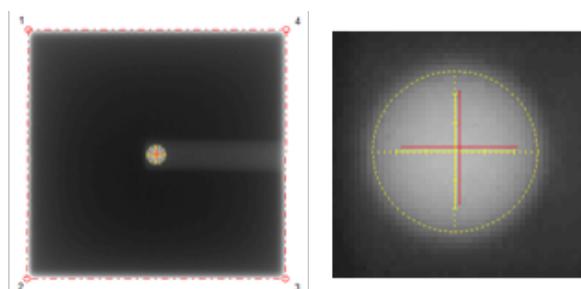

### Results

The method was tested, and we found an accuracy (1 SD) of 0.01 mm. Four new Elekta accelerators (Versa HD) were analyzed according the procedure. The main contribution to isocentric inaccuracy for Elekta linacs is the gantry sag. By adjusting the table rotation axis to a position between the collimator rotation axes at gantry 0° and 180°, isocentric accuracy can be optimized. The table presents the results that were obtained.

Table:  $r_{\text{isoc}}$ : the size of the isocenter quantified by the radius of the sphere containing rotation axes when applying several gantry angles at zero table angle.  $d_{\text{table-coll}}$ : the distance between rotation axis of the table and the rotation axis of the collimator.

Linac	$r_{\text{isoc}}$ (mm)	$d_{\text{table-coll}}$ (mm)
A	0.68	0.20
B	0.53	0.14
C	0.77	0.06
6	0.38	0.01

Figure: an EPID image of a 10x10 cm<sup>2</sup> field and the ball bearing. The field outline and the detected ball are overlaid.

### Conclusion

With our method it is possible to quickly obtain a measure for isocentric accuracy. In combination with table rotation we achieved accuracies better than 0.9 mm, after adjusting the table.

**EP-1755 Multi-modality end-to-end audit by the ACDS**  
 J. Lye<sup>1</sup>, F. Gibbons<sup>1</sup>, M. Shaw<sup>1</sup>, A. Alves<sup>1</sup>, S. Keehan<sup>1</sup>, I. Williams<sup>1</sup>

<sup>1</sup>Australian Radiation Protection and Nuclear Safety Agency, Australian Clinical Dosimetry Service, Melbourne- Victoria, Australia

### Purpose or Objective

The Australian Clinical Dosimetry Service (ACDS) has commissioned a custom phantom and audit incorporating conformal, IMRT, VMAT, and FFF modalities. The design covers future inclusion of small field and SABR modalities. The vision of the ACDS is to provide a comprehensive suite of audit modalities covering all common clinical practice, ultimately to ensure patient safety and to improve national dosimetry. The ACDS also aims to provide dosimetric information that can be used domestically and globally in the clinical trial setting.

### Material and Methods

To ensure efficient delivery of the audit service, all modalities relevant to a facility's clinical practice are measured in a single audit visit. The incorporation of new audit modalities requires a consideration of phantom design suitable for multiple modalities and limitations on facility and ACDS workload. Classification of new modalities and choice of associated cases need to take into consideration the utility for clinical trials.

### Results

The Level III audit is an end-to-end test using a humanoid thorax phantom (CIRS, Norfolk, VA). The custom phantom has a central insert for either conformal modality with two farmer chambers, or for IMRT and VMAT with seven CC13 ion chambers as the primary detectors. The IMRT/VMAT central insert includes a film holder for supplementary measurements. The custom phantom includes removable lungs that are replaced with solid water inserts to investigate the effect of inhomogeneity on IMRT and VMAT deliveries. Figure 1 shows the custom phantom. The CC13 chambers are connected to the TomoTherapy<sup>®</sup> TomoElectrometer, an 8 channel reference class electrometer for simultaneous measurement on all chambers for each audit case.

The IMRT and VMAT planning cases were designed for addition to the current Level III audit. Clinical plans were prepared based on the AAPM Publication TG119 [1] and adapted for use in the ACDS audit program. Table 1 shows an example of how the audit outcomes are reported. Each modality is scored separately, and assigned a Pass (Optimal Level), Pass (Action Level), or Out of Tolerance outcome. Field trials on the IMRT, VMAT and FFF modalities began in September 2016. In 2017 the new modalities scoring criteria will be finalised and the new modalities will go live, and field trials on a SABR modality are scheduled to begin.

**Table 1** Example of modality scoring in the ACDS Level III audit.

Modality	Outcome
3DCRT	Pass (Optimal Level)
IMRT	Pass (Optimal Level)
IMRT FFF	Pass (Optimal Level)
VMAT	Out of Tolerance
VMAT FFF	Pass (Action Level)

**Figure 1** Images of the custom CIRS phantom for the new ACDS Level III audit, showing the removable lungs and removable central insert.

### Conclusion

The ACDS is developing a comprehensive suite of audit modalities aimed at ensuring patient safety across a range of clinical practice. The new Level III (end-to-end) audit joins the integrated range of multi-modality audits provided by the ACDS including the Level Ib audit (on-site linac output) covering reference beams, FFF and small fields and the Level II audit (slab phantom combined with array) audit covering conformal, IMRT, VMAT and FFF treatments plans.

### EP-1756 Treatment planning and dosimetric validation of bone oligomet SABR treatments on TomoTherapy

C. Thomas<sup>1</sup>, T. Burrows<sup>1</sup>, R. Lynn<sup>1</sup>, N. Miles<sup>1</sup>, S. Petty<sup>2</sup>, M. Stenson<sup>1</sup>, K. Blythe<sup>1</sup>, T. Greener<sup>1</sup>

<sup>1</sup>Guys and St Thomas NHS Foundation Trust, Medical Physics, London, United Kingdom

<sup>2</sup>Guys and St Thomas NHS Foundation Trust, Radiotherapy Department, London, United Kingdom

### Purpose or Objective

To establish whether the TomoTherapy helical delivery system can accurately deliver high dose per fraction SABR treatments to bone oligo-metastases within the NHS England Commissioning through Evaluation SABR program.

### Material and Methods

TomoTherapy Volo treatment planning system was used to generate example SABR treatment doses of 10Gy and 15Gy per fraction to a cylindrical PTV within a CT dataset of the Delta-4 phantom. These treatments were delivered to the Delta-4 phantom. Treatment plans for clinical oligo-metastases in bone, with prescription doses of 27Gy/3# and 30Gy/5# were generated and delivered to Delta-4 phantom, ionisation chamber and Gafchromic film. Clinical treatment fractions were delivered in 2 half-fractions in order to allow a mid-fraction imaging scan to assess intra-fraction motion.

### Results

Volo treatment planning system signalled when the treatment planning objectives were not deliverable and suggested modified treatment planning parameters. The test cases measured on Delta-4 passed local gamma analysis at 3%/3mm with >95% pass rate. Paddick and CIRTGO conformity indices were improved with the use of TomoTherapy compared with VMAT solution for the first clinical case, and dose gradient between target and critical structures was improved. For the first clinical case measured on Delta-4, 100% of sampled detectors passed within 3%/3mm gamma analysis and 98.5% passed within 2%/2mm. Initial transverse EBT2 Gafchromic measurement of the first clinical case showed satisfactory qualitative agreement with treatment plan. Subsequent EBT3 GAFchromic film measurements resulted in 97.5% gamma passrate at 3%/3mm and mean dose deviation on representative dose profiles of less than 2.2%. Average intra-fraction motion between half fractions was 0.68mm in X, 0.64mm in Y and 0.84mm in Z with standard deviation of 0.62mm, 0.48mm and 0.79mm respectively.

### Conclusion

GSTFT is the first centre with QA approval under the NHS England CtE programme to treat bone oligometastatic cases using the TomoTherapy treatment planning and delivery system. Volo and Hi-Art systems are capable of generating and accurately delivering homogeneous dose of up to 15Gy per fraction in phantom studies. Clinically approved treatment plans for bone oligomet cases delivering up to 9Gy per fraction have been generated and accurately delivered to diodes, ionisation chamber and Gafchromic film. Intra-fraction motion was small and has permitted the reduction of PTV margin from 4mm to 3mm.

### EP-1757 QA of MLC Elekta Agility for Static fields

F. Tato de las Cuevas<sup>1</sup>

<sup>1</sup>Hosp. Univ. de Canarias, Medical Physics Dept., Santa Cruz de Tenerife, Spain

### Purpose or Objective

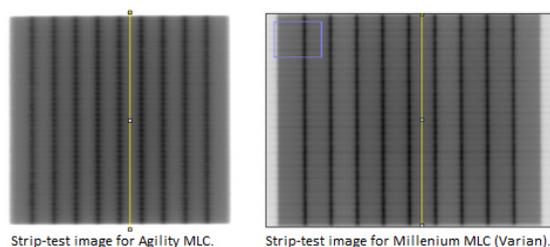

QA of MLC is one of the main points of any LINAC QA program. Agility MLC (Elekta) have different properties than most of the more common MLCs, like less interleaf transmission. The objective is to perform the Agility MLC QA in static mode using the electronic portal imaging device (EPID) and make this process as fast and accurate as possible.

### Material and Methods

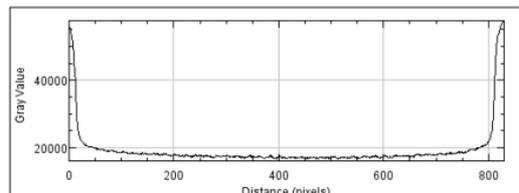

The LINAC is an Elekta Synergy with Agility MLC and 6 MV photons. A software is developed in MATLAB with some remarkable points:

1. Elekta iCOMCAT software was employed to generate and send the strip-test with multiple segments as a unique treatment, as is much faster than creating and irradiating a beam for each segment. With the software of Elekta iView is difficult to acquire a complete image of each full segment as this is not fast enough, so fluency corrections of these segments were performed, in order to avoid erroneous pixel values (PV) in the way: a) In a 23x23 open field is acquired a horizontal profile and measure the % PV (in the center position of each future segment), this % is related to the PV of the position of a reference segment. b) Measure the mean PV in the center of each strip-test segment, and obtain the % PV related to the reference segment PV. c) Rescale the image of each segment in order to obtain the % PV (respect the reference segment). Finally make the sum of all images.
2. Segments of 2 x 20 cm (cross-plane x in-plane) to form series of strip-test images with gaps overlapping from 1.2 to 3 mm are acquired for taking the MLC reference after calibration. The strip-test need bigger gap spread than other MLC in order to detect the gap position correctly, because of the lower penumbra.
3. To correct the collimator angle is used the filtered back projection method, because is very tricky to use the interleaf leakage, as this MLC have much lower interleaf transmission than other MLC, like Millenium (from Varian).
4. To localize the radiation center (RC) of the EPID is used a LINAC tray with centered radiopaque mark. Four 20x20 fields are obtained with this tray at 4 collimator angles. RC is determined for gantry 0° detecting the mark position in each image and obtaining the mean. A vector displacement is created to obtain RC with one image at 0° collimator. Tray images for various gantry angles at 0° collimator are acquired, so that with just one tray image is enough to detect RC exactly. This method is faster than using field edges, where at least 2 images at different collimator angles must be acquired for each gantry angle.

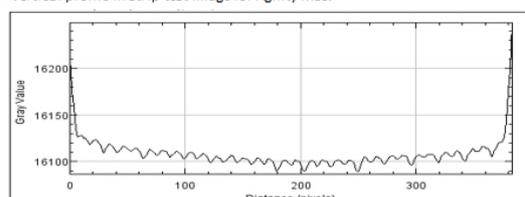

Measurements of leaf positions using light projection are made. Also are obtained strip-test with films and analyzed with RIT software.

Strip-test image for Agility MLC. Strip-test image for Millennium MLC (Varian).

Vertical profile in strip-test image for Agility MLC.

Vertical profile in strip-test image for Millennium MLC (Varian).

## Results

The differences in leaf positions compared with film and light field are beyond 0.1 mm and 1 mm (light field edge detection has a much bigger uncertainty). The acquisition and analysis for one strip-test take less than 4 min.

## Conclusion

The methodology employed analyzes a MLC strip-test in an Elekta LINAC in a fast and accurate way.

## EP-1758 Towards Clinical Implementation of an Online Beam Monitoring System

M. Islam<sup>1</sup>, M. Farrokhkish<sup>2</sup>, Y. Wang<sup>2</sup>, B. Norrlinger<sup>2</sup>, R. Heaton<sup>1</sup>, D. Jaffray<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre and University of Toronto, Medical Physics, Toronto, Canada

<sup>2</sup>Princess Margaret Cancer Centre, Medical Physics, Toronto, Canada

## Purpose or Objective

Continual advancement of Radiation Therapy techniques and consequent complexity in planning and delivery require constant vigilance. To address this, the idea of independent real-time beam monitoring has been proposed. In this presentation, we describe initial steps towards introducing the Integral Quality Monitoring (IQM) system into clinical practice.

## Material and Methods

The IQM system (manufactured by iRT, Germany) consists of a large-area ion chamber mounted at Linear Accelerator's (Linac) accessory slot, which provides a spatially dependent "dose-area-product" per field segment. The system monitors beam delivery in real-time by comparing the expected and measured signals.

Initial evaluation of the system included: reproducibility and stability, agreements between calculated vs. measured signals, sensitivity and specificity for errors. A multiphase approach was considered for clinical implementation. First, IQM data are collected during conventional dosimetric QA tests. Results of the QA tests with and without the IQM chamber in the beam are compared. During this phase a reference dataset of measured IQM signals vs. calculated is generated to help determine the tolerance in the predicated signals. Second, IQM system is introduced as the primary pre-treatment QA tool. Gain in work-flow efficiency and

quality have been assessed. Subsequent real-time monitoring issues have been considered.

## Results

The presence of IQM chamber in the beam path changed the pass rate of MapCheck (IMRT), and ArcCheck (VMAT) within  $\pm 1\%$  when %Dose-DTA criteria were employed, as shown in Table-1. The calculated and measured IQM signals on a Varian TrueBeam Unit for 340 randomly chosen IMRT field segments from clinical plans show good agreements (Fig.1): 95% of segments are within  $\pm 3$ ; total cumulative signals for VMAT delivery were within  $\pm 2\%$ .

By introducing the system as a pre-treatment QA tool 700 hours of staff time and 180 hours of machine time can be saved annually, for a facility treating 240 IMRT and VMAT patients per day. Additionally, the segment by segment dosimetry and independent gantry angle monitoring provides added quality values for pre-treatment QA.

Daily monitoring of beam delivery may save more machine and staff time by eliminating pre-treatment QA, while improving patient safety. However, a number of issues need to be addressed, such as: (1) Modification of TPS beam model to include the effect of the IQM chamber on the beam (2) The TPS should allow an accessory code in IMRT and VMAT (3) The Linac manufacturer should make an accessory code available for the on-line monitor.

Field	Without IQM Chamber		With IQM Chamber		Difference (%)	
	AD (%)	RD (%)	AD (%)	RD (%)	AD	RD
VMAT Plan #1	91.7	98.4	92.4	98.5	0.7	0.1
VMAT Plan #2	91.1	98.8	91.3	99.0	0.2	0.2
VMAT Plan #3	89.9	98.8	87.5	97.1	0.6	0.1
VMAT Plan #4	88.2	97.8	87.3	97.8	-0.9	0.0
Mean	89.5	97.9	89.6	98.1	0.2	0.2

Table-1. Results showing VMAT field dosimetry with ArcCheck in terms of % pass rate (2mm, 3% dose difference) for beams with and without IQM chamber in the beam. AD- Absolute Dose; RD- Relative Dose

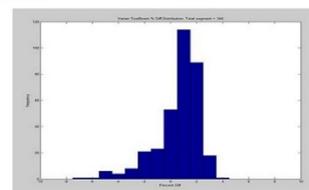

Fig. 1. Calculation vs. measurement of IQM signals for IMRT field segments in Varian TrueBeam

## Conclusion

Clinical implementation of the system in multiple phases helps understanding the performance characteristics of the system, allows smooth transition of QA practices, make overall clinical workflow safe and effective for real-time beam monitoring.

## EP-1759 MLC positioning study based on EPID images analyzed with the Dosimetry Check software

C. Avigo<sup>1</sup>, M. Mignogna<sup>2</sup>, S. Linslata<sup>3</sup>

<sup>1</sup>National Research Council, Institute of Clinical Physiology, Pisa, Italy

<sup>2</sup>Azienda USL Toscana nord ovest- S. Luca Hospital, Radioterapia, Lucca, Italy

<sup>3</sup>Azienda USL Toscana nord ovest- S. Luca Hospital, Fisica Sanitaria, Lucca, Italy

## Purpose or Objective

The IMRT requires extensive knowledge of the MLC position accuracy and repeatability since when accurate leaf positioning is lost significant dose delivery errors can occur. Therefore, the MLC QA is crucial for a complete control of the patient treatment. The use of EPID for this scope can be very helpful in saving time providing images with high spatial resolution and directly digitalized. Dosimetry Check is a commercial software which uses EPID images for pre-treatment verification, in vivo-dosimetry and also MLC QA. The aim of this work was to validate the combined system EPID-Dosimetry Check, in order to control the leaf positioning of an Elekta Agility MLC.

### Material and Methods

The leaf position is defined as the position of the 50% of the dose profile. This measurement depends on relative position of the beam source and of the leaves. In order to validate the EPID measurements of the absolute leaf positions, 10 dose profiles, at the center of different leaf pairs of the same MLC field, were acquired with an Elekta iViewGT EPID and with a diode positioned in a water phantom. The comparison between the two detectors was performed by Matlab. Garden Fence (GF) was chosen as test of the leaf position accuracy and a preliminary study on the gap width was conducted. Leaf position accuracy was checked automatically with DC by acquiring GF at the 4 cardinal gantry angles and with all the beam energies (6, 10 and 15MV), while the reproducibility was tested with 5 GF repeated in one day and 6 repeated in a time interval of 70 days.

### Results

The difference between EPID and diode absolute measurement of the leaf positions was less than 0.8mm for all the analyzed leaves, resulting from the summation of an error due to the isocenter identification (0,5mm) plus the leaf positioning error (0.2mm). The gap width study revealed that, because of the penumbra widening observed in small fields, the leaf position could be accurately measured as the 50% of the edge profile, only if the gap width is equal or larger than 16mm with 6MV beam. Therefore, GF with 20mm gap was chosen as leaf position accuracy test for all the energies in order to distinguish the effect of beam source from that of leaf positioning. For the GF at different gantry angles the difference between the measured and the prescribed position was well within 1.0mm for all the leaves. Moreover, reproducibility of each leaf position resulted to differ from its average value less than 0.4mm.

### Conclusion

This work permitted to assess the accuracy and the repeatability of the Elekta Agility MLC leaf positioning by the combined use of the Elekta iViewGT EPID and the Dosimetry Check software through the acquisition and the analysis of Garden Fence test. This system was validated comparing the EPID with a diode in a water phantom and assessing the minimum gap width necessary for an accurate leaf position measurement at all energies which is useful to distinguish issues related to beam symmetry from those related to leaf positioning.

### EP-1760 A simple method for estimating the longitudinal isocentre shift due to gantry motion

R. Hudej<sup>1</sup>, D. Brojan<sup>1</sup>, S. Pulko<sup>2</sup>, P. Peterlin<sup>1</sup>

<sup>1</sup>Institute of Oncology Ljubljana, Department of Radiophysics, Ljubljana, Slovenia

<sup>2</sup>University Clinical Centre Maribor, Department of Oncology- Radiotherapy Unit, Maribor, Slovenia

### Purpose or Objective

The isocentre as a point of intersection of the three rotational axes (gantry, collimator and treatment couch) ideally remains fixed in space during the rotation of gantry, collimator, or the treatment couch. Due to the mechanical limitations, gantry sags slightly, and consequently the radiation isocentre shifts slightly towards the treatment couch when the gantry rotates from the uppermost to the lowermost position. The purpose of this study is to assess this shift.

### Material and Methods

A strip of radiochromic film embedded in a suitable water-equivalent phantom is irradiated with a cross-line half-slit field from the top (0°). Then the gantry is rotated to the lowermost position (180°) without moving the jaws and the phantom is irradiated again. The film is scanned and analysed with an image analysis script. The central lines of both half-slit images are determined, then the

intersection angle between them is calculated, and finally the distance between the intersections of extrapolated lines with the 'sagittal' plane is calculated.

### Results

This method was tested on 7 linacs of different makes and models (Elekta Synergy Platform, Elekta Versa HD, Varian Unique, Novalis Tx) in the authors' radiotherapy centres. The average distance by which the isocentre moves between both gantry positions was found to be 1.04 mm (SD 0.30 mm), with the whole range covered by the [0.53, 1.48] interval. The two lowest values were achieved on the two single energy Varian Unique linacs. It was found out that the longitudinal isocentre shift is largely independent of the gantry isocentre wobble determined by the star-shot test. We also tested the alignment of the collimator 0° setting with the gantry rotation plane. The average deviation was found to be 0.16° (SD 0.10°), range [0.04°, 0.31°].

### Conclusion

The results appear consistent, but it would be helpful to test the method on a wider pool of treatment machines over a longer period of time. The longitudinal isocentre shift during gantry rotation is a non-negligible parameter which needs to be incorporated into the uncertainty budget which is the basis for the CTV-PTV margin.

### EP-1761 Workflow development for the clinical implementation of an MR-guided linear accelerator

T. Stanescu<sup>1</sup>, A. Berlin<sup>2</sup>, L. Dawson<sup>2</sup>, J. Abed<sup>2</sup>, A. Simeonov<sup>2</sup>, T. Craig<sup>2</sup>, D. Letourneau<sup>2</sup>, D. Jaffray<sup>2</sup>

<sup>1</sup>Stanescu Teodor, Radiation Physics- PMH, Toronto, Canada

<sup>2</sup>Princess Margaret Cancer Centre, RMP, Toronto, Canada

### Purpose or Objective

Development of clinical workflows for the implementation of a new external beam radiation therapy environment which relies on hybrid MR-CBCT in-room imaging guidance.

### Material and Methods

A standard radiation therapy 6X linac (TrueBeam, Varian Medical System, Palo Alto, CA) was integrated with a 1.5 T diagnostic MR scanner (IMRIS, Minnetonka, MN). The MR can move on rails and was tuned up to perform optimal imaging inside the treatment room in the proximity of the linac. The patient load is transferred directly between the MR diagnostic table and the linac IGRT couch via a hovercraft system (Zephyr XL, Diacor, Salt Lake City, UT). No special MR safety requirements were employed regarding the curation of the linac room - the linac/couch can be freely operated mechanically when the MR magnet is present - only typical MR room screening for ferromagnetic content was implemented. Comprehensive testing was completed to confirm negligible magnetic field coupling between the MR and the TrueBeam system (linac and patient table). Since the linac retains its default features and an MR imager is available in the linac vault a combined MR-kV approach can be employed for the patient setup verification and treatment delivery. A new software tool was developed in collaboration with Varian to provide the computation and implementation of treatment couch shifts based on soft-tissue information, i.e. image matching between plan MR and guidance MR. In this study, clinical workflows for liver and prostate were developed and tested. Each site posed challenges from patient image data planning and acquisition to RT planning and in-room guidance. The approach was to integrate the capabilities offered by the new technology in existing processes.

### Results

MR imaging protocols for planning and guidance were established. The guidance scans were optimized to minimize session time with negligible penalty on the accuracy of the image matching process (planned vs. on

demand). MR acquisition was also designed to allow for collection of data needed for CT+MR as well MR-only (or synthetic CT) workflows. This is expected to facilitate access to the in-house adaptive RT implementation in RayStation (RaySearch, Stockholm, Sweden). All MR image data was validated for RT use by means of comprehensive testing for global image quality and correction of spatial distortions. In particular for liver, the management of motion was adapted for the MR environment in the case of potential subjects undergoing either breathhold or abdominal compression (AC). Breathhold was evaluated using Medspira (Minneapolis, MN) whereas AC was implemented using pneumatic pressure belts. Staff requirements and safety for in-room operations was evaluated via simulations and dry runs.

#### Conclusion

Workflows for MR guidance in prostate and liver were designed and preliminary tested. The next step is to enable imaging-only clinical trials in patients. Based on feedback the workflows will be refined to allow for the full implementation of MR-guidance studies.

#### EP-1762 A Comparative Study of 4D and 3D CTSimulation in Esophageal Carcinoma

J. Li<sup>1</sup>, G. Lai<sup>1</sup>

<sup>1</sup>Fujian Cancer Hospital, radiation oncology, Fuzhou-Fujian, China

#### Purpose or Objective

To compare the internal gross target volume (IGTV) and its displacement of primary esophageal carcinoma (EPC) on the base of four-dimensional and three-dimensional computed tomography (4D-CT and 3D-CT) simulation technology.

#### Material and Methods

Twenty-two esophageal cancer patients with pathological proved diagnosis were recruited in this prospective study. Every patient sequentially received contrast enhancement free-breathing 3D-CT and respiration-synchronized 4D-CT simulation chest. Then the target volume and the displacement on three orthogonal directions of three different IGTV planning methods (including IGTV<sub>4D</sub>, IGTV<sub>4D</sub> and IGTV<sub>3D</sub>). The dice similarity coefficient (DSC) and overlap index (OI) between IGTV<sub>4D</sub> and IGTV<sub>4D</sub>, between IGTV<sub>4D</sub> and IGTV<sub>3D</sub> for different segments of esophagus were calculated. Statistical analysis included the Friedman test, analysis of variance on the base of repeated measurement data and paired-samples student t test and the  $P < 0.05$  was set as statistically significant.

#### Results

There were statistical significance of displacement at left-right, anterior-posterior, and superior-inferior directions of primary esophageal tumor GTV of the ten phases originated from medium-thoracic segments and medium-lower-thoracic segments ( $P = 0.005$  and  $P = 0.001$ ). There presented a significant differences of primary tumor volume where appeared  $IGTV_{3D} > IGTV_{4D} > IGTV_{4D}$  ( $P < 0.05$ ). In other words, the implementation of GTV by means of extending position error from based of 3D-CT would lead to unnecessary radiation of the surrounding normal tissues (about 9-24%); However, the application of GTV only by means of integrating end-inhalation and end-exhalation phases would result in uncover target area (about 10-34%).

#### Conclusion

4D-CT simulation technology is superior to 3D-CT simulation technology for IMRT in esophageal cancer.

#### EP-1763 Acute toxicity and in-vivo dosimetry of a two week hypofractionated schedule within the HYPOR study

A. Saha<sup>1</sup>, G. Goswami<sup>2</sup>, S. Mandal<sup>2</sup>, A. Mahata<sup>2</sup>, D. Midha<sup>3</sup>, R. Ahmed<sup>4</sup>, S. Agarwal<sup>4</sup>, S. Ray<sup>5</sup>, J. Das<sup>5</sup>, S.S.

Datta<sup>6</sup>, S. Sinha<sup>7</sup>, S. Chatterjee<sup>2</sup>

<sup>1</sup>Tata medical center, Radiotherapy, Kolkata, India

<sup>2</sup>Tata medical center, Radiation Oncology, Kolkata, India

<sup>3</sup>Tata medical center, Oncopathology, Kolkata, India

<sup>4</sup>Tata medical center, Breast Surgery, Kolkata, India

<sup>5</sup>Tata medical center, Nuclear Medicine, Kolkata, India

<sup>6</sup>Tata medical center, Psycho-Oncology, Kolkata, India

<sup>7</sup>Tata medical center, Statistics, Kolkata, India

#### Purpose or Objective

There are no standard palliative breast radiotherapy regimens for local control but many use the dose equivalent as in the adjuvant setting (40Gy/15 fractions). Within HYPOR study we are exploring a dose of 35 Gy in 10 fractions over 2 weeks prescribed to the breast and supraclavicular fossa (SCF) to palliate advanced incurable breast cancers

#### Material and Methods

A gafchromic RTQA2 film based matching of the junction of tangents and Supraclavicular (SCF) fields (JF) is being carried out to assess the geographical overlap or separation during first 3 fractions. Similarly during the first 3 fractions, in-vivo thermo luminescent dosimetry (TLD) is being performed to confirm received dose by placing a TLD over isocenter of the tangential fields and another at JF. Primary objective for the study has been set to assess the acute toxicity using CTCAE version 4 in 30 total patients

#### Results

Of the required 30 patients, 19 have been recruited. Median dose planned to receive by 95% volume of the breast PTV was 96.3% (range=95.2-98.9%). The median dose max planned to the breast PTV was 106.4% (range=105.4-106.9%). Breast PTV receiving  $\geq 105\%$  of the prescribed dose was planned to be 1.75% (median) with no point dose  $\geq 107\%$ . Organ at risks (OAR) dose constraints were met for all patients. The junction movement range using gafchromic RTQA2 film was between -2mm to +3mm. TLD measured dose (median) and percentage variation of tangential field isocenter dose and field junction dose for first three fractions is summarized in table 1. Median percentage variation for tangential field isocenter dose as measured using TLD was 3 % (Range = -9.7 to 9.4%) and similarly median percentage dose variation for JF as measured with TLD was 1.2 % (Range = -8.5 to 8.9%). At a median follow up of 5 months only 1 patient reported grade 2 acute skin toxicity (others had grade 1). None of the patients complained of dysphagia or acute brachial plexopathy

#### Conclusion

QA measures in the HYPOR study confirm the delivery of the prescribed two week dose schedule with no significant over dosage at the JF. A dose of 35Gy is well tolerated

#### EP-1764 Implementation of a patient specific QA in-vivo dosimetry protocol using the PerFRACTION 3D system

F. Vinagre<sup>1</sup>, P. Rachinhas<sup>1</sup>, P. Simões<sup>1</sup>, A. Cavaco<sup>1</sup>, F. Balau<sup>1</sup>, M. Borrego<sup>1</sup>

<sup>1</sup>Centro Hospitalar e Universitário de Coimbra, Department of Radiotherapy, Coimbra, Portugal

#### Purpose or Objective

The goal of this presentation is to share the experience in implementing an EPID-based in-vivo dosimetry system PerFRACTION™ 3D (PF) from Sun Nuclear Corporation in our center. The results for approximately 50 patients treated with VMAT and IMRT plans in a Truebeam 2.5, Varian Medical Systems, included in a in-vivo dosimetry protocol in clinical routine, are presented and discussed.

#### Material and Methods

About fifty patients treated with a VMAT/IMRT technique were included in this study. In the first 3 fractions of

treatment, *in-vivo* EPID transit images (movie files) were acquired during treatment for every field. After the first 3 fractions, *in-vivo* measurements were repeated on a weekly basis. The PerFRACTION analysis is almost fully automated. Treatment plans were calculated in version 10.6 of Eclipse™ TPS from Varian Medical Systems. The plan, the structure set, the dose distribution and the CT image set are exported to PF server. This server continually searches in R&V and ARIA™ oncology information system, from Varian Medical Systems, for the data of each patient. After each treatment the server gets the recorded log files and the measured EPID Dicom files which are processed and used for the 3D dose distribution calculation. PerFRACTION 3D uses a superposition/convolution type algorithm, the SDC Dose Calculator, to calculate back the dose on the CT image set or on the patient CBCT acquired at the treatment session. Following AAPM TG-218 report, we adopted a tolerance limit (treatable but further evaluation may be warranted) of 95 % of points passing the 3%Global/2mm/10% gamma analysis, and an action limit of 90% (requires additional analysis and may need corrective action). Dose-volume histograms (DVH) analysis obtained by 3D reconstructed dose on the planning CT or CBCT scans allow a clinical interpretation of the deviations and helps to find possible reasons for the discrepancies. PerFRACTION also demands goals definition for specific targets and/or organs at risk which are used to trigger failure email notifications.

#### Results

PerFRACTION 3D was launched in the beginning of 2016 and is in an early stage of clinical use, with constant software updates and corrections. In the first two months of the *in-vivo* dosimetry QA protocol implementation, 30 transit EPID images were acquired during the treatment fractions of 10 patients. PTV 3D overall gamma passing rate was equal to  $97.3\% \pm 1\%$  (1 SD), with all fractions within the adopted tolerance level of 95%.

#### Conclusion

The preliminary results for *in-vivo* dosimetry using PerFRACTION 3D suggests it as a promising tool for detection of treatment discrepancies and their clinical impact. This *in-vivo* dosimetry approach combined with plan pre-treatment verification can contribute to a more robust patient specific QA as well as to identify more clearly the possible causes of discrepancies such as machine and/or patient related ones.

**Electronic Poster: Brachytherapy: Breast**

#### EP-1766 First experiences using the new Papillon + TM Contact X-Ray Brachytherapy 50Kvp (CXB) unit

J.P. Gérard<sup>1</sup>, C. Dejean<sup>2</sup>, M.E. Chand<sup>1</sup>, D. Lam Cham Kee<sup>1</sup>, J. Doyen<sup>1</sup>, K. Benezery<sup>1</sup>, J.M. Hannoun-Levi<sup>1</sup>

<sup>1</sup>Centre Antoine Lacassagne, Radiotherapy, Nice, France

<sup>2</sup>Centre Antoine Lacassagne, Physics, Nice, France

#### Purpose or Objective

The Papillon 50™ unit was designed in 2009 to perform CXB treatment using 50 KVp X-Rays with short focus distance (FSD <4cm) and high dose rate (> 15 Gy/mn) aiming at replacing the Philips RT 50™ to treat endoscopically rectal cancer. In order to treat breast cancer using an intra-operative radiotherapy (IORT) approach a new Papillon +™ (P+) unit was designed (Ariane cpy. UK) and the first prototype was installed in Centre A Lacassagne in Nice during december 2016.

50 KVp x-ray generator. NBA applicator fixed on x-ray tube-rod (arrow)

#### Material and Methods

The P+ unit is a battery powered mobile X-Ray generator producing an X-Ray beam with a peak energy of 30 or 50 KVp. A tungsten transmission anode is liquid cooled to produce a dose rate of 8-18 Gy/ minute depending on distance and added filtration. The useable beam angle is 310° x360° and is well adapted to breast IORT. The tube incorporates a radiation delivery rod that is 22 cm long and 1.7 cm in diameter. The X ray tube and integrated high voltage generator are mounted on an articulated arm that incorporates electromagnetic brakes on all movements. A separated work station is used to remotely control the system using a wireless connection. Various applicators can be mounted on Treatment Application Adaptors to treat skin, breast and rectal tumors.

Work station  
Papillon+

#### Results

The beam stability is within 3% over 1 hour and the dose homogeneity at a 40 mm diameter breast applicator surface is within  $\pm 5\%$  of the central axis dose. The percentage depth dose at 5 mm is between 35% and 65% depending on the KVP, FSD and applicator diameter. Radiation protection to comply with regulation is easily achieved using a machine mounted shield and the P+ can be used in a room with only 0.3 mm lead equivalent shielding or none if room large ( $> 6\text{ m} \times 6\text{ m}$ ). The P+ can deliver a high dose to small volume in accessible tumors such as skin cancer (especially facial and eyelid) using applicators between 1 and 4 cm, rectum (endoscopic approach) using applicators 2, 2.5 and 3 cm, breast (IORT) using a dedicated spherical Nice Breast Applicator (3 to 5 cm diameter). In the near future it is proposed that vaginal vault irradiation (stepping source) and other IORT sites will be possible using P+.

#### Conclusion

The Papillon +<sup>TM</sup> is a new multipurpose CXB 50 KVP machine with the advantage of a high dose rate and easy radioprotection. First clinical results achieved in Nice will be presented at time of the meeting.

#### EP-1767 The Dosimetric Consequences Throughout The Treatment Time In APBI With SAVI Applicators.

S. Chandrasekara<sup>1</sup>, S. Pella<sup>2</sup>, M. Hyovain<sup>3</sup>, P. Janeil<sup>2</sup>  
<sup>1</sup>Florida Atlantic University, Physics, Boca raton, USA  
<sup>2</sup>Florida Atlantic university, Physics, Boca Raton, USA  
<sup>3</sup>Florida Atlantic University, Physics, Boac Raton, USA

#### Purpose or Objective

To analyze the variation in dose received by the organs at risk (OARs), that occur during treatment time ( 10 treatments) of early stage breast cancers with APBI using SAVI applicators.

#### Material and Methods

A retrospective analysis of 15 patients treated with SAVI applicators at SFRO Boca Raton were considered for this

study. Treatment plan is made based on the initial CT scan that is taken post the insertion of the applicator. Then the patient is treated on outpatient basis on 10 fractions of 3.4 Gy over 5 days. The CT scans of these patients, taken before each treatment were separately imported in to the treatment planning system and registered with the initial CT scan respective to the applicator. Three radio channel markers of the applicator are used as reference points to conduct landmark registration on each CT scan. Difference in Max Dose received by skin, ribs and PTV (Planning target volume) during each treatment is recorded.

#### Results

Contours of any of the OARs were not exactly similar when CT images were fused on each other. Deduction in volumes of PTV and cavity was noticed. There was always a difference between received doses by the OARs and PTVs between treatments. Variations in received dose by Skin and ribs were statistically significant for 3 treatments and 2 treatments respectively under 5% level. Variations were statistically significant for 4 more fractions for both organs under 10% level. Some data indicates, few times patients received more than 145% of prescribed dose that breach the specific guidelines of APBI.

#### Conclusion

The difference recorded in volumes of OARs and iso-doses near the OARs between treatments indicate that the received doses to OARs differ from the prescribed dose in the initial treatment plan. Similarly PTV receiving a lesser dose than the prescribed dose affects the quality of the treatment. It appears that taking a CT scan before each treatment and re-planning is important at this stage to minimize the risk of delivering different doses than the prescribed.

#### EP-1768 What is the proper dose in single fraction HDR brachytherapy as monotherapy for prostate cancer?

S. Ruiz Arrebola<sup>1</sup>, A.M. Tornero-López<sup>2</sup>, J.M. De la Vega<sup>3</sup>, P.J. Prada<sup>1</sup>, D. Guirado<sup>3</sup>

<sup>1</sup>Hospital Universitario Marqués de Valdecilla,

Department of Radiation Oncology, Santander, Spain

<sup>2</sup>Hospital Universitario Dr. Negrin, Unidad de Radiofísica, Las Palmas de Gran Canaria, Spain

<sup>3</sup>Complejo Hospitalario de Granada, Unidad de Radiofísica, Granada, Spain

#### Purpose or Objective

High dose rate brachytherapy (HDRBT) as monotherapy for prostate cancer is applied with several fractionation schedules. Usually the linear-quadratic (LQ) model is used to establish their equivalence. However, using the currently accepted value of  $\alpha/\beta$  for prostate cancer, a significant discrepancy between the LQ model predictions and clinical outcomes is found for the only single fraction schedule in use with long-term results [1].

We aim to determine the value of the absorbed dose for an extreme hypofractionation regime of one fraction in HDRBT monotherapy leading to a biochemical failure rate similar to that of most widely used regimes.

#### Material and Methods

We used available published data from biochemical control at 5 years, for prostate cancer patients of low and intermediate risk treated with exclusive HDRBT: 7 clinical studies with 9 fractionation schedules, from 1 fraction of 19 Gy to 9 fractions of 6 Gy per fraction.

To compare the different schedules, we used the equivalent total dose in 2 Gy fractions, and to describe the biochemical control (BC), we used the LQ model together with the logistics probability function:

$$EQD_2 = D \frac{d + \alpha/\beta}{2 + \alpha/\beta}, \quad (1)$$

$$BC = 100 \left[ 1 + \left( \frac{D_{50} \left( 1 + \frac{2}{\alpha/\beta} \right)}{D \left( 1 + \frac{d}{\alpha/\beta} \right)} \right)^{4\gamma} \right]^{-1}, \quad (2)$$

being D the total dose, d the dose per fraction,  $\alpha/\beta$  the LQ parameter that allows to quantify the sensitivity to the fractionation of prostate cancer,  $\gamma$  the maximum normalized dose-response gradient and  $D_{50}$  the total dose needed to achieve 50% BC.

To fit the model parameters, and to obtain its uncertainties, we used Monte Carlo methods.

### Results

Firstly, the value of  $EQD_2$  of each program was calculated. Figure 1 shows the value of BC versus  $EQD_2$  if the currently accepted value for  $\alpha/\beta=1.5$  Gy is used in equation (1). The black square corresponds to the single fraction schedule [1].

The fit of equation (2) to clinical data produces the results in figure 2. The confidence intervals of the parameters correspond to 95%. Figure 2 also shows BC versus the new  $EQD_2$  values, calculated with  $\alpha/\beta=8.7$ Gy.

From these results, the value of the absorbed dose for an extreme hypofractionation regime with one fraction in HDRBT monotherapy, allows us to obtaining a BC=90% at 5 years, is 21.9 [19.6,26.3] Gy.

Figure 1

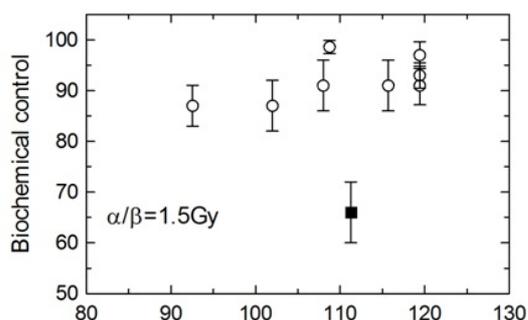

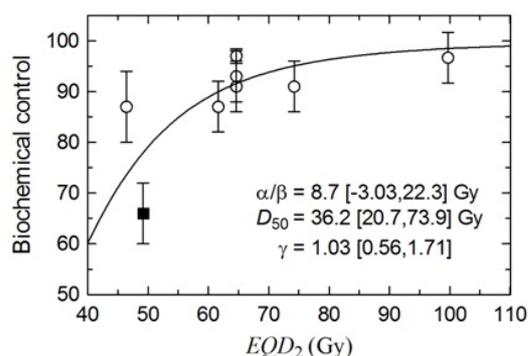

Figure 2

### Conclusion

The  $\alpha/\beta$  value obtained for a range of dose per fraction between 6 and 19 Gy is much greater than the one currently estimated for prostate cancer.

The absorbed dose in HDRBT monotherapy for a regime with one fraction would allow us to obtain a BC=90% is 22 Gy.

The value of  $\alpha/\beta$  obtained here explains well the clinical data in the region of the doses per fraction considered. Nonetheless it is important to take into account some of

the limitations of the model, which may be overcome by adding additional clinical studies, not necessary of brachytherapy as monotherapy. Those limitations are: the fit is over conditioned by the only fraction datum, the data are heterogeneous, and its external validity may be limited, we do not properly know the associated uncertainties nor the dose distributions.

<sup>5</sup>Bialystok Comprehensive Cancer Centre, Physics, Bialystok, Poland

<sup>6</sup>Bialystok Comprehensive Cancer Centre, Physics, Bialystok, Poland

### Purpose or Objective

To evaluate the short term efficacy, early toxicity and dosimetric aspects of combined HDR-BT with EBRT in the radical treatment of prostate cancer patients (PCPs).

### Material and Methods

40 PCPs underwent combined treatment including hypofractionated EBRT (37.5 Gy in 15 fractions over 3 weeks) and conformal HDR-BT between September 2013 and May 2015. The mean age was 69 years with average PSA 6,7 ng/ml and median Gleason score 6,8. T stage was distributed from T1 to T2c. Half of the patients received androgen deprivation. Treatment was delivered using IMRT with an 6- or 15-MV linear accelerator. HDR brachytherapy catheter insertion was performed under spinal anaesthesia. The median number of catheters was 17 (14-18). HDR brachytherapy was delivered using an Iridium-192 source (Nucletron) and treatment planning system: SWIFT 2.11.8 and Oncentra Prostate 3.0.9./4.0. Dose volume constraints included: prostate V100  $\geq$ 95%, V150 and V200 below 40%; maximal urethral dose  $\leq$  120% and average rectal dose  $\leq$  85% of the prescription dose. Patients were monitored weekly during radiotherapy and in 3 months intervals after treatment. Follow-up visit included clinical examination and PSA value assessment. The acute toxicities were graded according to the EORTC/RTOG scales.

### Results

The median V100 was 93% and median D90 was 103%. All patients finished the scheduled therapy without interruption. The most common urinary symptoms were: urgency, frequency, dysuria and nocturia. The rectal symptoms (urgency, frequency) were rare. No grade 3 and 4 acute toxicities were recorded. No patient developed clinical or biochemical progression. The constant decrease of PSA level was observed during follow up.

### Conclusion

Single fraction 15 Gy HDR-BT with hypofractionated EBRT enables dose escalation with excellent dosimetric parameters for the radical treatment of PCPs. The treatment was well tolerated by all patients with satisfactory disease control in the short and medium term.

### EP-1770 Unpredictable PSA failure in intermediate-risk prostate cancer after seed implant brachytherapy

K. Kikuchi<sup>1</sup>, R. Nakamura<sup>1</sup>, H. Kakuwara<sup>1</sup>, S. Yamaguchi<sup>1</sup>, H. Oikawa<sup>1</sup>, W. Obara<sup>2</sup>, H. Ariga<sup>1</sup>

<sup>1</sup>Iwate Medical University, Radiation Oncology, Morioka, Japan

<sup>2</sup>Iwate Medical University, Urology, Morioka, Japan

#### Purpose or Objective

The role of seed implant brachytherapy (BT) in radiotherapy for organ-confined prostate cancer (OPC) is not yet fully established. The aim of this study was to disclose potential factor inducing biochemical relapse (BRFS) after BT for OPC patients (pts) when its strategy modified by D'Amico risk classification.

#### Material and Methods

From December 2004 to June 2014, 691 pts with low (280), intermediate (274), and high (137)-risk were treated with BT by real-time transrectal ultrasound-guided implantation under prescribed dose of 160Gy as monotherapy or 110Gy in combined with external beam radiotherapy (EBRT) delivering to prostate and seminal vesicle of 40Gy or 45Gy of each risk group. Anti-androgen therapy (ADT) of a mean 10.2 months was administered in 336 (49%) pts. All patients were followed at clinics with PSA determinations. The date of biochemical relapse was determined by the Phoenix (nadir + 2 ng/mL) definition. Interval between the date of last radiotherapy day (the RT day) and relapse day were calculated and constructed Kaplan-Meier plots. Differences in plots were evaluated by log-rank test among pts (KM-test) divided by risk classification, history of ADT, or combination of EBRT. In addition, The other proven factors were explored if it dichotomizes pts by different BRFS such as DVH parameters of BT or BT+EBRT, positive core rates of biopsy specimen (PCR), number of D'Amico risk class belong to intermediate or high.

#### Results

A total of 46 pts, 11/ 22/ 13 of each risk group, showed PSA relapse a mean 67.6 (6-135) months after the RT day. It accompanied distant bone metastasis (10), PSA increase >25 ng/ml (3) or regional lymph node metastasis (1). Twenty-four pts died during the study period due to the disease progression (2), cancer other than prostate or other disease (10). The BPFs achieved at 10 years was 91.1% for all patients. KM-test between low and intermediate risk pts showed significant difference (94.7 vs 88.7 %), but not between intermediate and high (88.7 vs 87.5 %). In intermediate pts, there were differences in the mean DVH parameters including pD<sub>90</sub> (179 vs 156 Gy, P=0.000), pV<sub>100</sub> (94 vs 90 %, p=0.001), or PCR (0.30 vs 0.39, p=0.024).

#### Conclusion

Intermediate risk group pts showed a BPFs similar to that of high risk. Those pts who relapsed had a higher risk of BPFs and were treated with RT degraded in dose and coverage. We need a modification in D'Amico intermediate classification and strategy.

### EP-1771 Low dose rate brachytherapy for prostate cancer: A Brazilian Institution experience.

E.T.T. Leite<sup>1</sup>, J.L.F.D. Silva<sup>1</sup>, E. Capelletti<sup>1</sup>, G.N. Marta<sup>1</sup>

<sup>1</sup>Hospital Sirio Libanes, Radiation Oncology, Sao Paulo, Brazil

#### Purpose or Objective

Prostate cancer is the most common type of cancer in men, excluding nonmelanoma skin cancers. The main modalities of treatment are radical prostatectomy (RP), brachytherapy (BT), and external beam radiation therapy (EBRT) with or without androgen deprivation. BT is a treatment option with equal efficacy to EBRT or RP alone in patients with low- or intermediate-risk prostate cancer.

The objective of this study was to estimate biochemical failure-free survival (BFFS), metastasis-free survival (MFS), disease-specific free survival (DSFS), overall survival (OS) and treatment-related toxicities in patients with prostate cancer who underwent LDR-BT alone in a single Brazilian Institution.

#### Material and Methods

Patients treated with Iodine-125 BT with post-implant dosimetry after at least 5 years of follow-up were retrospectively assessed. Patients who received combination therapy (EBRT and BT) and salvage BT were excluded.

#### Results

From 616 patients treated between March 2001 and November 2010, 406 of them were included in the study. 65.5% were low-risk; 30%, intermediate-risk; 4.5%, high-risk. After a median follow-up of 87.5 months, 61 (15.0%) patients developed biochemical recurrence. BFFS at 5 and 10 years was 90.6% and 82.2% respectively. There were no significant differences in the BFFS among the risk groups (p = 0.294). Nadir  $\geq$  1 ng/ml was associated with higher risk of biochemical failure (HR = 5.81; CI 95%: 3.39 to 9.94; p  $\leq$  0.001). MFS at 5 and 10 years was 98.3% and 94% respectively. Three patients (0.3%) died from prostate cancer during follow-up. OS at 5 and 10 years was 96.2% and 85.1% respectively. Acute and late grade  $\geq$  2 and grade  $\geq$  3 gastrointestinal toxicity were observed in 5.6% and 0.5% and 4.6% and 0.5%, respectively. Acute and late grade  $\geq$  2 and grade  $\geq$  3 genitourinary toxicity were 57.3%, 3.6% and 28%, 3.1%, respectively.

#### Conclusion

Iodine-125 LDR-BT is a safety and efficient treatment for well-selected prostate cancer patients.

### EP-1772 HDR Brachytherapy in the treatment of Prostate Cancer - the Vienna Experience

O. Komina<sup>1</sup>, C. Seitz-Kästner<sup>1</sup>, J. Hofbauer<sup>1</sup>, M. Kuntner<sup>1</sup>, J. Wimmer<sup>1</sup>, T. Knocke-Abulesz<sup>1</sup>, E. Nechvile<sup>1</sup>

<sup>1</sup>KH Hietzing mit Neurologischem Zentrum Rosenhügel, Sonderabteilung für Strahlentherapie, Wien, Austria

#### Purpose or Objective

Radiation Therapy (RT) plays a crucial role in the treatment of prostate cancer. The advantage of high dose rate brachytherapy (HDR-BT) as monotherapy or boost to deliver high radiation dose to the tumor and to spare organs at risk (OAR) was recently shown in clinical studies.

#### Material and Methods

We summarized the overall patient data collected in our institution since 2010 when we implemented the real time planning system based on 3D ultrasound imaging. Between 2010 and 2015 a total of 256 patients were treated and 584 implants being performed. 47% of the patients with local disease received HDR-BT alone (4 x 9 Gy on a weekly basis [n= 22], after 2012 3 x 10,5 Gy every other week [n= 99]). 53% of the patients received combination therapy for treatment of intermediate or high-risk prostate cancer. These patients received one or two fractions of HDR-BT with the doses of 9 or 10,5 Gy respectively combined with local external beam RT of the prostate only or additional pelvic lymph node irradiation. 17 patients were treated in terms of salvage therapy after radical prostatectomy (RPE), external beam or brachytherapy.

#### Results

Median age was 69,2 years (range 44,8 - 87,5). The majority of patients (37%) had Gleason 6 histology, 29% Gleason 7a, and 9% 7b. High risk patients receiving exclusively combination therapy had Gleason 8 in 13%, Gleason 9 in 11% and Gleason 10 in 1% of the cases. The median V100 for the prostate was 93,7%. No acute grade  $\geq$ 3 toxicity was observed in the whole cohort of the patients. Late rectal toxicity was observed predominantly

in the patients receiving additional external beam therapy.

#### Conclusion

The feasibility of HDR-BT as a treatment option in low, intermediate and high grade prostate carcinoma was confirmed.

As previously expected, HDR-BT patients treated in a monotherapy setting showed a more favorable profile of detected side effects.

In our experience HDR-BT can be implemented within a radiooncological department of a community hospital.

#### EP-1773 Clinical outcomes in localized prostate cancer treated with HDR Brachytherapy as single fraction

L. Larrea<sup>1</sup>, E. López-Muñoz<sup>1</sup>, P. Antonini<sup>1</sup>, V. González<sup>1</sup>, M.C. Baños<sup>2</sup>, J. Bea<sup>2</sup>, M.A. García<sup>2</sup>

<sup>1</sup>Clinica Virgen del Consuelo, Radiation Oncology, Valencia, Spain

<sup>2</sup>Clinica Virgen del Consuelo, Radiophysics Department, Valencia, Spain

#### Purpose or Objective

To describe the technique and analyze early outcomes in patients with low and intermediate risk prostate cancer treated with high dose rate brachytherapy (HDR) as monotherapy.

#### Material and Methods

From January to December 2015, 8 low and 8 intermediate prostate cancer patients were treated with 20 Gy HDR (Ir 192) as monotherapy, in one fractionation. At diagnosis, mean PSA was 7,42 ng/mL (range 6-16) and mean Gleason score was 6 (range 4-7). Any patient received androgen deprivation therapy. Mean prostate volume was 49 cc (range 21-67,3).

Under rachianesthesia the patient is placed in a dorsal lithotomy position. A balloon catheter is placed into the bladder to correctly visualization of the urethra in transrectal ultrasonography (TRUS). Using a template, plastic needles are placed into the prostate through the perineal skin to the inside of the bladder. The template has needles holes at 5 mm intervals. Mean number of needles inserted was 13 (range 12-15). After implantation of needles TRUS 2 mm spaced axial images are taken for 3D treatment planning. Prostate delineation was done as clinical target volume (CTV) and to evaluate dose constraints. PTV includes the whole prostate gland with a 2 mm posterior wall rectal margin and 5 mm all margins. Urethra was always defined. Dose constraints were: urethra total dose less than 120% and rectal dose less than 70% of the prescription dose. Prescription dose to prostate was 20 Gy. The minimal dose achieved to the 95% of the volume (D95) was 21-23 Gy (105-110%). All the procedure expends about 1-2 hours. Patients stay in hospital for 12 hours with urethral catheter. Genitourinary and gastrointestinal toxicity was evaluated in agreement with Common Terminology Criteria for Adverse Events (CTCAE v4.03). For sexual function the International Index of Erectile Function Questionnaire was used. The global cost is a forfait for all the procedure.

#### Results

With a median follow-up of 15,1 months (range 10-21) all patient survive without progression. Mean PSA after treatment was 1,4 ng/mL (range 0,21-3,37). Three patients presented acute disuria and one patient urinary urgency (grade 1) that were resolved in less that 3 weeks. Erectil function preservation was 87,5%. No gastrointestinal toxicity was observed. One patient was diagnosed of lung cancer two months after brachytherapy treatment. The overall cost treatment was among €-10.000 per patient (€-9.000-14.000).

#### Conclusion

In our experience, HDR brachytherapy using extreme hypofractionation is a safe and well tolerated alternative to permanent-seed implants with a high local control disease and low toxicity rates. Some advantages as "in vivo" prescription, short surgical time and no radioactive procedure were confirmed. However, long-term follow-up is needed to confirm our initial results.

**EP-1774 Randomized phase II trial of IGRT with or without HDR boost in intermediate-risk prostate cancer**  
E. Vigneault<sup>1</sup>, G. Morton<sup>2</sup>, W. Perulekar<sup>3</sup>, T. Niazi<sup>4</sup>, G. Springer<sup>5</sup>, M. Barkati<sup>6</sup>, P. Chung<sup>7</sup>, W. Koll<sup>8</sup>, A. Kamran<sup>9</sup>, M. Montreal<sup>3</sup>, K. Ding<sup>3</sup>, A. Loblaw<sup>2</sup>

<sup>1</sup>CHU de Québec- L'Hôtel Dieu de Québec, Radiation Oncology and Research Centre, Quebec, Canada

<sup>2</sup>Odette Cancer Centre, Radiation Oncology, Toronto, Canada

<sup>3</sup>Canadian Cancer Trials Group, Queen 's University, Kingston, Canada

<sup>4</sup>Mc Gill Jewish General Hospital, Department of Radiation Oncology, Montreal, Canada

<sup>5</sup>Windsor Regional Hospital, Radiation Oncology, Windsor, Canada

<sup>6</sup>CHUM Hôpital Notre Dame, Radiation Oncology, Montreal, Canada

<sup>7</sup>University Health Network Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada

<sup>8</sup>Lakeridge Hospital, Radiation Oncology, Oshawa, Canada

<sup>9</sup>Dr H Bliss Murphy Cancer Centre, Radiation Oncology, St-John's, Canada

#### Purpose or Objective

The purpose of this phase II randomized feasibility study was to assess the ability of Canadian investigators from multiple institutions to randomize patients to IGRT (Image Guided Radiotherapy) or IGRT with HDR (High Dose Rate) brachytherapy boost and to deliver the treatment according to the highest radiation oncology quality assurance benchmarks and standards.

#### Material and Methods

The primary endpoint was to determine the ability to randomize 60 patients over an 18 months period. Arm 1 (IGRT) patients received 78 Gy in 39 fractions or 60 Gy in 20 fractions (physician's preference) while Arm 2 (IGRT + HDR) received 37.5 Gy in 15 fractions with HDR boost of 15Gy. IGRT options were daily imaging with prostate fiducial markers, cone/fan beam CT images, or ultrasound localization system. The secondary endpoints included: acute genitourinary (GU) and gastrointestinal (GI) toxicity, using NCI Common Terminology Criteria for Adverse Events (CTCAE V 3.0) at 3 months, validation of a prospectively defined radiation oncology quality assurance process including real time peer review and treatment compliance. All analyses were descriptive; no formal comparisons between treatment arms were performed.

#### Results

Between April 2014 and September 2015, 57 NCCN defined intermediate risk prostate cancer patients were randomized between IGRT alone (Arm 1) N=29, vs. IGRT plus HDR brachytherapy boost (Arm 2) N= 28. Overall, 93.0% received the treatment as randomized. There were 4 patients (1 on IGRT arm 1 and 3 patients on the IGRT+HDR arm 2) who were treated differently from randomization assignment. For the 29 patients receiving IGRT (arm 1), there were 14 cases reported with minor deviations and 3 with major deviations. For patients on IGRT+HDR (arm 2), there were 18 cases reported with minor deviations and 2 with major deviations. At 3 months in the IGRT group (Arm 1), one patient reported grade 3 diarrhea while in the IGRT+HDR group (Arm 2), two patients reported grade 3 hematuria. No other GI and GU toxicities were reported.

### Conclusion

The pilot study demonstrated the feasibility of randomization between treatment with IGRT alone vs IGRT + HDR boost. Treatment compliance was good including adherence quality assurance.

### EP-1775 Acute toxicity in early cancer prostate patients: low dose rate vs high dose rate monotherapy.

S. Rodríguez Villalba<sup>1</sup>, A. Otal Palacín<sup>1</sup>, J. Richart Sanchez<sup>1</sup>, J. Pérez-Calatayud<sup>2,3</sup>, M. Santos Ortega<sup>1</sup>

<sup>1</sup>Clinica Benidorm, Radiotherapy Department, Benidorm, Spain

<sup>2</sup>Clinica Benidorm and Hospital La Fe, Radiotherapy Department, Benidorm, Spain

<sup>3</sup>Hospital La Fe, Radiotherapy Department, Valencia, Spain

### Purpose or Objective

Brachytherapy (BT) in their two modalities, Low dose rate (LDR) and High Dose Rate (HDR) are used in prostate cancer. At present, all available clinical data regarding these two techniques suggests that they are equally effective, providing high tumor control rates. We compare our experience considering acute toxicity in patients with low or intermediate stages treated with LDR BT or HDR BT in monotherapy.

### Material and Methods

Between January 2004 and June 2016 we have treated 113 patients with BT as an exclusively treatment, 85 patients with permanent LDR with Iodine-125 seeds and 28 with HDR Ir-192. Both modalities were performed using ultrasound based intraoperative techniques.

### Results

**LDR BT PATIENTS:** Median age 68 years (48-81 y), median Gleason 5 (2-7), median value of PSA at diagnosis 7,3 ng/ml (2,5-16,3). 70 patients (82%) low risk (D'Amico classification) and 15 (18%) intermediate risk. In 25 cases (29%) the prescription dose was 145 Gy and in 60 (71%) 160 Gy. Thirty-three (39%) received hormonal treatment.

**HDR BT PATIENTS:** Median age 70,5 years (55-80 y), median Gleason 6 (3-8), median value of PSA at diagnosis 9,08 ng/ml (3-19,75). 12 patients (42%) low risk (D'Amico classification) and 16 (58%) intermediate risk. All patients were treated with 2 applications of 13,5 Gy in monotherapy. Twenty (71%) received hormonal treatment.

We analyze the acute toxicity of both treatments following criteria CTCEV.3 and the results are presented on the table.

There are not Grade 3 o 4 acute toxicity.

	GRADE 0	GRADE 1	GRADE 2	GRADE 3	GRADE 4	
	LDR/HDR	LDR/HDR	LDR/HDR	LDR/HDR	LDR/HDR	
HAEMATURIA	100%/	100%	0%/	0%	0%/	0%
CYSTITIS	35%/	100%	3%/	0%	21%/	0%
INCONTINENCY URYNARY	97%/	87%	0%/	8%	3%/	4%
OBSTRUCCION URYNARY	60%/	100%	15%/	0%	30%/	0%
URINARY FRECUENCY/URGEN CY	41%/	96%	9%/	0%	47%/	4%
URINARY RETENTION	94%/	100%	3%/	0%	3%/	0%
DIARRHEA	94%/	100%	3%/	0%	3%/	0%
RECTAL INCONTINENCY	100%/	100%	0%/	0%	0%/	0%
RECTITIS	94%/	96%	6%/	4%	0%/	0%

### Conclusion

In this analyses the acute genitourinary toxicity was higher when the patient were treated with LDR BT including 2 patients (3%) who needed urinary catheter after the implant. We did not find any differences in gastrointestinal toxicity with and excellent tolerance in both groups.

### Electronic Poster: Brachytherapy: Gynaecology

### EP-1776 Is a single CT plan for vaginal cylinder brachytherapy adequate?

M. Zahra<sup>1</sup>, M. Doak<sup>1</sup>, W. Keough<sup>2</sup>

<sup>1</sup>Western General Hospital- Edinburgh Cancer Centre, Clinical Oncology, Edinburgh, United Kingdom

<sup>2</sup>Western General Hospital- Edinburgh Cancer Centre, medical Physics, Edinburgh, United Kingdom

### Purpose or Objective

To assess if the target coverage and dose to organs at risk (OARs) from a vaginal vault brachytherapy CT plan are representative of dose delivered during the actual treatment.

### Material and Methods

28 patients scheduled for post-operative vaginal vault brachytherapy had an initial planning CT scan (CT1) done a few days before the first fraction, with the vaginal cylinder in-situ to generate a treatment plan. The PTV was the cranial 4cm of the vagina to a depth of 0.5cm, and the OARs outlined included the rectum, sigmoid, small bowel and bladder. On the day of the first fraction the patients has a second CT scan with the vaginal cylinder (CT2) and the PTV and OARs were outlined. Then the plan from CT1 was superimposed on CT2 to assess for variation in V100 and d90 to the PTV and the d2cc to the OARs. Prescribed dose was 21Gy in 3 fractions to the PTV, aiming for a V100 of >95% and d90 of 7Gy per fraction.

### Results

Total of 56 scans were analysed. Mean PTV V100 for CT1: 95.8% (range 99.6% - 83.2%); CT2: 96% (range 99.8% - 90%). Mean d90 for CT1: 7.4Gy (range 7.8 - 6.7Gy); CT2: 7.3Gy (range 7.9 - 6.3Gy). Mean difference in d90 per fraction was 0.23 Gy per fraction (range: 0.56 - 0.01Gy).

	Small Bowel	Sigmoid	Rectum	Bladder
Mean d2cc (Gy) CT1	3.16 (range 7.0 - 0.3)	4.1 (range 6.4 - 1.9)	5.5 (range 7.0 - 3.9)	6.0 (range 6.7 - 4.9)
Mean d2cc (Gy) CT2	3.18 (range 6.8 - 0.3)	3.8 (range 5.9 - 1.4)	5.6 (range 7.1 - 3.6)	6.0 (range 7.2 - 4.9)
Man difference in d2cc between CT1 and CT2	0.8	0.7	0.9	0.5

### Conclusion

The variation in d2cc doses when using the initial CT plan on the second scan taken on the day of the first fraction were minimal and not clinically significant. Differences in PTV coverage are mostly due to slight differences in PTV outlining mainly because of changes in the angle of the cylinder compared to the treatment couch. There does not appear to be the need to plan every single fraction for post-operative vaginal vault brachytherapy as the dosimetry using the initial plan was representative of the dose delivered on the day of treatment.

**EP-1777 Cervical cancer outcomes in the high-dose-rate brachytherapy era: A single institution experience**  
 N. Alyamani<sup>1</sup>, G. Bhattacharya<sup>1</sup>, R. Samant<sup>1</sup>, C. E<sup>1</sup>, T. Le<sup>1</sup>, K. Lupe<sup>1</sup>

<sup>1</sup>The Ottawa Hospital Regional Cancer Centre, Radiation Oncology, Ottawa, Canada

**Purpose or Objective**

Since 2008, the management of cervix cancer with primary radiotherapy at our institution has included the use of HDR (high-dose-rate) brachytherapy; prior to this, LDR (low-dose-rate) brachytherapy was used. The aim of this study is to review our experience with HDR brachytherapy and to evaluate patient outcomes.

**Material and Methods**

A retrospective review of cervical cancer patients treated with curative intent using radical external beam radiotherapy and HDR brachytherapy, from 2008 to 2014 inclusive was performed. Overall survival (OS) and progression-free survival (PFS) were analyzed using the Kaplan-Meier method.

**Results**

A total of 76 patients were treated with radical radiotherapy incorporating HDR brachytherapy during this time period. The median age was 47 years with a median follow-up of 38 months. The histology was squamous cell carcinoma in 88% and adenocarcinoma in 11%. The distribution according to stage was as follows: stage I 16%, stage II 38%, stage III 40% and stage IV 5%. All patients received weekly Cisplatin chemotherapy with a median of 5 cycles delivered. The median dose of external beam radiotherapy was 45Gy delivered in 25 fractions over 5 weeks. The median brachytherapy dose was a total of 24Gy in 3 weekly fractions of 8Gy. The 5-year OS and PFS rates were 74% and 63% respectively. The 5-year locoregional control rate was 82%. There were a total of 25 failure and 12 of these had a component of local failure. However, only 3 of these had exclusively local failure. Of note is that the majority of patients with recurrences had a component of distant failure (19/25; representing 77% of relapses). Using the Common Terminology Criteria for Adverse Events version 4.0 (CTCAE v.4.0), it appears as though severe acute (Grade 3/4) Gastrointestinal (GI) and Genitourinary (GU) toxicity was present in approximately 21% of patients, along with Grade 3/4 Hematologic toxicity seen in 34%. These results are similar to the published literature and compare favorably with our previous LDR brachytherapy experience.

**Conclusion**

There has been a shift towards incorporation of HDR brachytherapy world-wide in the management of cervix cancer and our institutional experience indicates that long-term outcomes for patients remain good, with generally high rates of local control.

**EP-1778 Combined intracavitary-interstitial IGABT of cervical cancer -First dosimetric experience in Hungary**

G. Fröhlich<sup>1</sup>, J. Vízkeleti<sup>1</sup>, N.N. Anhhong<sup>1</sup>, N. Mészáros<sup>1</sup>, T. Major<sup>1</sup>, C. Polgár<sup>1</sup>

<sup>1</sup>National Institute of Oncology, Centre of Radiotherapy, Budapest, Hungary

**Purpose or Objective**

Dosimetric evaluation of combined intracavitary-interstitial high-dose-rate image-guided adaptive brachytherapy (IGABT) of cervical cancer, implemented in Hungary.

**Material and Methods**

Since April 2016, 9 patients with cervical cancer were treated with overall 22 fractions of combined intracavitary-interstitial IGABT. After transrectal US-

guided implantation of Utrecht or Fletcher applicator and needles, High-Risk-CTV (HR-CTV), bladder (b), rectum (r) and sigmoid (s) were contoured on CT, based on the post-teletherapy MRI of the patients. Dose-volume criterions of treatment plans were based on the recommendations of GEC-ESTRO Gyn WG. Treatment plans were compared to the conventional intracavitary 2D plans (the dose was prescribed to point A) and to CT-based 3D optimized plans (without needles) with Friedman and Kruskal-Wallis ANOVA and Spearman rank correlation tests.

**Results**

Median number of implanted needles was 3 (range: 2-4), mean volume of HR-CTV was 39.8 cm<sup>3</sup> (8.3-100.2 cm<sup>3</sup>). For intracavitary-interstitial IGABT, intracavitary 2D and intracavitary 3D optimized plans, difference was found almost in all dose-volume parameters: V100 were 90.4%, 83% and 87.1% (p=0.043), DHI were 0.34, 0.30 and 0.27 (p=0.0137), D2(b) were 4.8 Gy, 6.9 Gy and 5.9 Gy (p<0.001), D2(r) were 3.3 Gy, 6.6 Gy and 3.5 Gy (p<0.001), D2(s) were 3.6 Gy, 5.3 Gy and 4.6 Gy (p=0.045), respectively. Needle number showed inverse correlation with D2(r) (p=0.0264) and D1(r) (p=0.0433) parameters. Volume of HR-CTV correlated with D2(r) (r<sup>2</sup>=0.58) and D2(s) (r<sup>2</sup>=0.71).

**Conclusion**

Dosimetric results of combined intracavitary-interstitial IGABT were comparable to international literature. Dosimetric quality of these plans was significantly higher than intracavitary 2D and 3D optimized plans. Although 3D optimisation improved the quality of conventional 2D plans, IGABT plans resulted in even more homogeneous dose distribution and significantly lower doses to organs at risks.

**EP-1779 High-dose rate brachytherapy for inoperable endometrial cancer: definitive results**

L. Draghini<sup>1</sup>, F. Trippa<sup>2</sup>, M. Casale<sup>2</sup>, P. Anselmo<sup>1</sup>, F. Arcidiacono<sup>1</sup>, S. Fabiani<sup>1</sup>, M. Italiani<sup>1</sup>, E. Maranzano<sup>1</sup>

<sup>1</sup>Radiation Oncology Centre "S.Maria" Hospital Terni, Oncology Department, Terni, Italy

<sup>2</sup>Radiation Oncology Centre- "S.Maria" Hospital Terni, Oncology Department, Terni, Italy

**Purpose or Objective**

**Purpose/Objective:** To report our experience on three dimensional (3D) high-dose rate brachytherapy (HDR-BRT) in patients with stage I-III inoperable endometrial cancer.

**Material and Methods**

**Material/Methods:** Between March 2005 and April 2016 17 patients underwent HDR-BRT or HDR-BRT after external beam radiotherapy (EBRT) as definitive treatment. Median age was 79 years (range, 60-95), median KPS 90% (range, 60-100). Histology was endometrial adenocarcinoma in 14 (82%) and non-endometrial in 3 (18%) patients. In 15 (88%) patients FIGO clinical stage was I and in remaining 2 (12%) III. All patients were evaluated with computed tomography (CT) and endometrial biopsy, in 2 cases also magnetic resonance imaging (MRI) was done. Using the Fletcher applicator, a CT-based planning HDR-BRT was delivered. Follow-up was performed with physical examination, cervical cytology and CT or MRI. Local control (LC) was obtained when there was an interruption of vaginal bleeding.

**Results**

**Results:** All patients had a clinical LC, table 1 shows dose schedules used. After a median follow-up of 36 months (range, 6-131), 3 and 6 years LC rates were 86% and 69%, respectively. Cancer specific survival (CSS) at 1, 2 and 6 years was 93%, 85%, 85%, respectively. Age, stage, dose and type of radiotherapy did not result significant prognostic factors for LC and CSS. Only histology significantly influenced LC: for high risk histology (i.e., non-endometrial carcinoma or grade (G)3 endometrial adenocarcinoma) LC was 73% at 1 year and 36% at 6 years,

for low risk histology (i.e. G1-2 endometrial adenocarcinoma) was 100% at 1 and 6 years ( $p=0.05$ ). Acute toxicity was registered in 2 (12%) patients: G2 nausea and G2 proctitis in 1 patient (6%), G2 diarrhea, G2 anemia and G2 proctitis in 1(6%) patient. Two patients (12%) had G1 late rectal bleeding.

#### Conclusion

Our data show a good LC particularly in patients with stage I low risk histology endometrial cancer. Though number of patients is limited, definitive HDR-BRT could be an alternative treatment option for inoperable elderly patients with good compliance and limited toxicity. Histology is a prognostic factor for LC.

Table 1. Dose schedules

HDR-BRT	Nº of patients (%)	EQD2 ( $\alpha/\beta=10$ )
2 x 7 Gy*	1 (6)	20 Gy
3 x 5 Gy*	1 (6)	19 Gy
3 x 6 Gy*	2 (12)	24 Gy
3 x 7 Gy	2 (12)	42 Gy
3 x 8 Gy	3 (18)	36 Gy
4 x 7 Gy	2 (12)	40 Gy
5 x 6 Gy	5 (28)	40 Gy
7 x 5 Gy	1 (6)	44 Gy
<b>EBRT</b>		
23 x 2 Gy*	1 (6)	46 Gy
25 x 2 Gy*	2 (12)	50 Gy

HDR-BRT = high-dose rate brachytherapy

EQD2: Equivalent dose of 2 Gy per fraction calculated using the equation  $EQD2 = [(d + \alpha/\beta) / (2Gy + \alpha/\beta)]$  derived from linear quadratic model.

Legend: \* patients submitted to external beam radiotherapy and brachytherapy

#### EP-1780 Postoperative endometrium: 68Gy EQD2( $\alpha/\beta=3$ ) at 2cc of vagina is related to G2 late toxicity.

#### Purpose or Objective

To evaluate if EQD2( $\alpha/\beta=3$ ) at 0.1cc, 1cc and 2cc of vagina in cylinder vaginal-cuff brachytherapy (VBT)  $\pm$  external beam irradiation (EBI) is associated with G2 toxicity in postoperative endometrial carcinoma (P-EC).

#### Material and Methods

From June 2014-November 2015, 67 consecutive P-EC patients received VBT $\pm$ EBI: 54 EBI (median 45Gy, range 44-50.4) +VBT (7Gy) and 13 exclusive BT (6Gy x 3 fractions). 2.5cm of vagina was delineated after CT for 3D treatment planning. The active source length was 2.5cm. The BT dose was prescribed at 5mm from the applicator surface. Patients were treated with HDR <sup>192</sup>Ir source using a MicroHDR source projector (Nucletron®). D90, V100 and EQD2( $\alpha/\beta=3$ ) at 0.1cc, 1cc and 2cc were calculated.

The mean follow-up was: 23.2 months (range 7.6-46.8). D90 (cc): median 7.8 (range 4.6-8.9); V100 (Gy): median 7.9 (range 4.4-10.8).

Vaginal toxicity was prospectively assessed using objective LENT-SOMA scores. Late vaginal toxicity: 17/67 (25%) 8 with G1 and 9 G2. For this analysis G0 and G1 patients were considered as no late toxicity (58/67, Group-1) and 9 patients with G2 (9/67, Group-2) were considered as having late toxicity. Statistics: t-Student test and Chi squared, alpha=5%.

**Results**  
The median EQD2( $\alpha/\beta=3$ ) doses were 88.6Gy (62.8-177.6) for 0.1cc, 72.4Gy (57.1-130.4) for 1cc and 69Gy (53-113.4) for 2cc. There were no differences in toxicity and EQD2( $\alpha/\beta=3$ ) between exclusive VBT vs. EBI+VBT. EQD2( $\alpha/\beta=3$ ): The mean EQD2( $\alpha/\beta=3$ ): at 0.1cc was 92.9Gy (SD 17.7) for Group-1 and 96.3Gy (SD 31.6) for Group-2 ( $p=0.62$ ); being 72.3Gy (SD 6) at 1cc for Group-1 and 73.5Gy (SD 5.3) for Group-2 ( $p=0.58$ ); and 67.6Gy (SD 6.2) at 2cc for Group-1 and 73.1Gy (SD 10.8) for Group-2 ( $p=0.03$ ). 20.5% of patients receiving doses  $\geq 68$ Gy EQD2( $\alpha/\beta=3$ ) at 2cc of vagina developed G2 toxicity. All patients with G2 toxicity had received doses  $\geq 68$ Gy EQD2( $\alpha/\beta=3$ ) at 2cc ( $p=0.04$ ).

#### Conclusion

68Gy EQD2( $\alpha/\beta=3$ ) doses at 2cc were related to G2 toxicity in P-EC VBT. In view of these results patients receiving these doses should be informed of their risk and individual characteristics should be considered in treatment planning and follow-up to reduce G2 toxicity. Grant: Spanish Association Against Cancer (AECC) Foundation

#### EP-1781 statistical and dosimetric analysis of air gaps in vaginal cuff brachytherapy

S. Abdollahi<sup>1</sup>, L. Rafat-Motavalli<sup>2</sup>, H. Miri-Hakimabad<sup>2</sup>, M. Mohammadi<sup>1</sup>, E. Hoseinian-Azghadi<sup>2</sup>, N. Mohammadi<sup>2</sup>, N. Rafat-Motavalli<sup>2</sup>, L. Sobhkhiz-Sabet<sup>1</sup>

<sup>1</sup>Reza Radiation Oncology Center RROC, medical physics, Mashad, Iran Islamic Republic of

<sup>2</sup>Ferdowsi University of Mashhad, Physics, Mashhad, Iran Islamic Republic of

### Purpose or Objective

To retrospectively evaluate the incidence, magnitude, and dosimetric impact of any air pockets between the vaginal cylinders and the vaginal mucosa using CT-scan images.

### Material and Methods

120 postoperative vaginal cuff brachytherapy cases were analyzed for receiving the prescribed dose to 5 mm depth from the cylinder wall. CT-Based treatment planning was performed in each fraction. The incidence, vaginal mucosa displacement and air volume were assessed in each treatment. A Monte Carlo study has also been done to evaluate the dosimetric effect of air pockets around the vaginal cylinder.

### Results

In 50 patients, a total of 90 air pockets were observed in 150 procedures. Four patients had pocket free insertion during the whole treatment sessions. The volume of air pockets ranged between 0.01 cm<sup>3</sup> and 4.5 cm<sup>3</sup> with average value of 2.5cm<sup>3</sup>, and the maximum displacement of vaginal mucosa from cylinder surface was between 0.2 and 2 cm with average value of 0.8cm. Thirty patients had no air pockets on their first fraction but in subsequent fractions. Twenty patients had incorrect applicator insertion as they have an air gap between applicator tip and cylinder dome ranged between 0.3 cm and 1.1 cm with average value of 0.8 cm. The Monte Carlo dosimetry also shows that the average dose reduction to the vaginal surface and 5mm-depth, at the air pocket, is respectively about 9.2% and 7.3% per 1 mm of the air thickness.

### Conclusion

Air pockets between vaginal cylinder and the vaginal mucosa are observed in the majority of treatment fractions, and the probability of occurrence varies from patient to patient and procedure to procedure. The dose reduction effect of air pockets needs to be considered especially around the vaginal cuff using imaged based treatment planning in each fraction and the effect on the clinical outcome should be put under more investigation.

### EP-1782 Effect of the amount of bladder filling on normal tissue doses in 3D-HDR vaginal vault brachytherapy

I. Er<sup>1</sup>, S. Kınay<sup>1</sup>, R. Kandemir<sup>1</sup>, F. Obuz<sup>2</sup>, A.N. Demiral<sup>1</sup>

<sup>1</sup>Dokuz Eylul Univ. Health Sciences Institute, Radiation Oncology, IZMIR, Turkey

<sup>2</sup>Dokuz Eylul Univ. Health Sciences Institute, Radiology, IZMIR, Turkey

### Purpose or Objective

In this retrospective study, it was aimed to compare the dose volume parameters of organs at risk for the bladder filling of 50 cc versus 150 cc in high dose rate (HDR) three-dimensional (3-D) vaginal cuff (VC) brachytherapy (BRT).

### Material and Methods

The dosimetric data of the 8 hysterectomized patients with gynecological malignancy who received postoperative pelvic external radiotherapy (RT) + 3-D HDR VC-BRT between March 2015 and August 2015 were analyzed. Computerized tomography (CT) sectional images obtained for VC BRT treatment planning were used for the study. The proximal 1/3 portion of vagina, drawn as a layer of 0.5 cm thickness from the vaginal mucosa (cylinder surface), had been delineated as clinical target volume (CTV). A total dose of 18 Gy (3x6Gy) had been prescribed to the CTV. For the study, bladder, rectum, sigmoid, bowel and CTV were recontoured in a 3-D manner by the same radiation oncology resident. Then the contours were controlled and corrected first by a staff radiation oncologist and then a staff radiologist. Afterwards, treatment planning was performed by the medical physicist using BRT treatment planning system. Mean CTV dose-volume parameters (D90%, D100%,

D50%/D90%, V100%, V150%) for all patients were similar in the treatment plans for two different bladder fillings. Bladder V50%, D50% and D2cc, rectum D2cc, sigmoid D2cc, bowel D50% and D2cc were recorded from the dose-volume histograms obtained in the treatment planning system. Paired comparisons were made for the parameters above for the bladder filling of 50 cc versus 150 cc. Different bladder fillings were compared using Wilcoxon Signed-Rank Test in the SPSS 15.0 statistics program.

### Results

It was observed that as the amount of bladder filling increases, bowel is displaced cranially from the applicator. Bladder D50% decreases (p=0.012) while bladder D2cc increases (p=0.025) in case of 150 cc bladder filling instead of 50 cc. Rectum D2cc shows a statistical trend for increase (p=0.05), however bowel D50% decreases (p=0.012) in 150 cc bladder filling compared to 50cc.

### Conclusion

The statistically significant decrease in bladder and especially bowel D50% parameters supports filling bladder with 150 cc instead of 50 cc in 3D VC-BRT.

### EP-1783 Acute toxicity with Xofigo Axxent Electronic Brachytherapy (XB) in endometrial or cervical cancer

A. Mendez Villamon<sup>1</sup>, A. Miranda Burgos<sup>1</sup>, M. Gascón

Ferrer<sup>1</sup>, M. Puertas Valiño<sup>1</sup>, S. Lozares Cordero<sup>2</sup>, A.

Gandia Martínez<sup>2</sup>, J. Font Gomez<sup>2</sup>, M. Tejedor Gutierrez<sup>1</sup>

<sup>1</sup>H.U. Miguel Servet, RADIATION ONCOLOGY, Zaragoza, Spain

<sup>2</sup>H.U. Miguel Servet, MEDICAL PHYSICIST, Zaragoza, Spain

### Purpose or Objective

To analyze acute toxicity outcomes after treatment with Xofigo Axxent Electronic Brachytherapy (XB) in postsurgical endometrial or cervical cancer patients treated at our medical centre.

### Material and Methods

Prospective study in which we selected 29 patients that received treatment with Xofigo Axxent Electronic Brachytherapy (XB) administered twice a week after endometrial or cervical cancer surgery, with 3D planification. The patients were selected from September 2015 to September 2016. They were divided in two groups: Group 1 (15/29) considered high risk and group 2 (14/29) considered intermediate risk. Group 1 received external beam radiotherapy (46Gy) followed by XB (15Gy in 5Gy fractions) and group 2 received exclusive XB (25Gy in 5Gy fractions). We analyzed the median dose in bladder, rectum and sigmoid D2cc, V50, V35 with XB comparing the doses with Ir-192. The vaginal mucosa, gastrointestinal (GI) and genitourinary (GU) toxicities were analyzed with the Common Terminology Criteria for Adverse Events (CTCAE 4.0) scale.

### Results

The median dose in bladder with XB vs. Ir-192 was: 2cc 66,4% vs. 71.6%, V50 7,2 vs. 11.9 Gy, V35 14.8 vs. 26,6. In rectum XB vs. Ir-192 was: D 2cc 68,4% vs. 73.5% , V50 9.9 vs. 16.7 Gy, V35 19.9 vs. 36. In sigmoid XB vs. Ir-192 was: D 51.4%vs. 59.8%, V50 12.9 vs. 21.3 Gy, V35 28.8 vs. 41.5. The median follow-up was six and a half months (range 3-12 months).

In group 1, acute vaginal mucositis (G1) was observed in 40% of the patients, GI toxicity (G1) occurred in 13% and GU toxicity (G1, G2, G3) was not present.

In group 2, we observed acute vaginal mucositis (G1 and G2) in 57% of the patients, GI toxicity (G1) occurred in 7% and GU toxicity (G1) was present in 29%. There was no grade 3 or greater toxicity in any of the groups. At 3 months follow-up, all of the patients were asymptomatic.

### Conclusion

The dose received by the organs at risk with the Xofigo Axxent Electronic Brachytherapy is less compared to Ir-

192, with a good coverage of the PTV and excellent results as for acute toxicity. The greater toxicity was observed immediately after the treatment was finished reducing in an important way at the third month after treatment.

#### EP-1784 Needle use in cervical cancer brachytherapy using the Utrecht applicator: a single center experience

M. Smolic<sup>1</sup>, C. Sombroek<sup>1</sup>, M. Bloemers<sup>1</sup>, B. Van Triest<sup>1</sup>, M.E. Nowee<sup>1</sup>, A. Mans<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

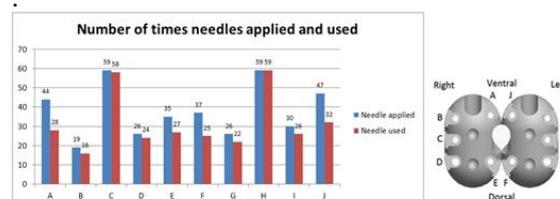

The Utrecht applicator (Elekta, Veenendaal, the Netherlands) used in brachytherapy (BT) for cervical cancer can include up to 10 interstitial needles along with the intra-uterine and ovoid channels. The aim of this study is to examine the clinical use of needles at our institute, and to investigate whether the two needles with largest discrepancy between application and use are essential to treatment planning.

#### Material and Methods

The study included 22 cervical cancer patients treated with 3 fractions of BT. The application of needles per fraction was based on consensus amongst radiation oncologists, medical physicists and RTTs, using the available pre-treatment imaging, physical examination and MRI scan made in the week before BT. We examined how often each of the 10 possible needles (Figure 1) was applied and the frequency of its subsequent use in treatment planning, as well as the average intensity of each needle's use, given by the average ratio of needle channel dwell time to total treatment time. We investigated whether the two needles with lowest frequency and intensity are essential for achieving the planning aims while respecting OAR constraints and yielding an acceptable conformal dose distribution. We did this by removing these needles from the optimized clinical plans (CP) and re-optimizing using the other available needles, intra-uterine and ovoid channels (RP). We aimed to obtain identical HR-CTV D90 values while still trying to achieve similar OAR planning aims and dose distribution conformality as achieved in the CP. We compared RP and CP for DVH parameters (HR-CTV D90 and OAR D2cc's, as well as the ratio D2cc OAR to D90 HR-CTV as a measure of DVH parameter favorability) and dose distributions, characterized by high dose volumes HR-CTV V200% and V300%, the dose homogeneity index (DHI = 1 - HR-CTV V150%/HR-CTV V100%) and conformal index (COIN = HR-CTV V100 (cc)/HR-CTV Volume (cc) x HR-CTV V100 (cc)/Implant V100 (cc)).

#### Results

Needles C, H, J and A are applied most often (in 89%, 89%, 71% and 67% of the cases, respectively) while the needles with the lowest frequency of subsequent use are A (64%), J (68%), F (68%), E (77%). Needles contributing the least to the total treatment time are J (2.9%), E (2.9%), A (3.0%) and F (3.5%). Needles A and J are thus applied often but have the lowest frequency and intensity of subsequent use. Of the 66 clinical treatment plans in this study, 25 made use of both needles A and J. Re-optimizing these clinical plans without using needles A and J leads to minimal differences in DVH parameters and dose distributions between CP and RP (Table 1)

		Clinical plan (CP)		Re-plan (RP)		Difference (RP-CP)	
		Mean	SD	Mean	SD	Mean	SD
HR-CTV	D90 (Gy)	8.7	1.2	8.7	1.2		
	D98 (Gy)	7.2	1.4	7.3	1.5	0.1	0.1
	V100 (%)	98.0	4.1	98.0	4.1	0.1	0.2
	V150 (%)	75.7	5.3	75.1	5.9	-0.5	1.2
	V200 (%)	46.6	7.2	45.5	7.3	-1.8	1.9
	V300 (%)	20.2	4.0	19.3	3.8	-0.9	1.4
GTV	D98 (Gy)	11.9	4.1	11.4	3.8	-0.5	0.9
Bladder	D2cc (Gy)	6.2	0.8	6.1	0.8	0.0	0.2
Rectum	D2cc (Gy)	3.7	1.0	3.8	1.0	0.1	0.1
Sigmoid	D2cc (Gy)	4.5	1.0	4.6	1.0	0.1	0.1
Small bowel	D2cc (Gy)	2.0	1.8	1.9	1.8	-0.2	0.6
Implant	V100 (cc)	79.7	23.3	82.5	23.2	2.8	3.6
D2cc OAR/D90 HR-CTV	Bladder	0.7	0.2	0.7	0.2	0.0	0.0
	Rectum	0.4	0.2	0.5	0.2	0.0	0.0
	Sigmoid	0.5	0.2	0.6	0.2	0.0	0.0
	Small bowel	0.2	0.2	0.2	0.2	0.0	0.1
DHI		0.2	0.0	0.2	0.1	0.0	0.0
COIN		0.4	0.1	0.4	0.1	0.0	0.0

#### Conclusion

Needles C and H are applied and used most frequently and intensely in our clinic. Needles A and J are applied often but have the lowest frequency and intensity of subsequent use. We managed to obtain equally clinically acceptable plans without these needles, indicating that they are not essential to treatment planning and may be discarded in future.

#### EP-1785 use of rectal tube in vaginal cuff HDR-brachytherapy: an unexpected advantage

A. Cerrotta<sup>1</sup>, C. Tenconi<sup>2</sup>, B. Pappalardi<sup>1</sup>, T. Giandini<sup>2</sup>, S. Naimo<sup>1</sup>, D. Mazzeo<sup>2</sup>, E. Mazzarella<sup>2</sup>, S. Grisotto<sup>2</sup>, M. Borroni<sup>2</sup>, C. Fallai<sup>1</sup>, M. Carrara<sup>2</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Department of diagnostic imaging and radiotherapy-Radiotherapy 2, Milan, Italy

<sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Department of diagnostic imaging and radiotherapy-Medical Physics Unit, Milan, Italy

#### Purpose or Objective

Rectal toxicity, both early and late, is a substantial problem in gynecological brachytherapy (BT), occurring in the majority of patients within the first 2 years after the end of treatment. Specific strategies and efforts are needed to limit high doses to the rectal mucosa without reducing the overall target coverage. The aim of our study, following an occasional observation, is to evaluate if the rectal tube we use in our Institute for in vivo dosimetry allows also a reduction of the rectal dose.

#### Material and Methods

In our Institute, adjuvant vaginal BT is always Image Guided (CT/MRI) with a multichannel endovaginal applicator, chosen taking into account both the comfort of the patient and the best contact of the applicator surface with the vaginal mucosa. For all patients, rectal wall in vivo dosimetry is performed with a dedicated rectal tube integrated with dosimeters and rigidly fixed to the endovaginal applicator. Over the time, for technical/clinical problems, two CT scans (acquired within a time interval of 10 minutes) were obtained in 6 patients: one without and one with rectal tube. Each treatment plan was generated and delivered using CT-scan with rectal tube in order to calculate dose to target and OARs (TPS: Oncentra Brachytherapy System). Vaginal cuff, bladder,

rectum and sigmoid were contoured by a single radiation oncologist and the contours were reviewed by all members of the Brachytherapy team. Plan optimization was performed according to International guidelines. Rectum position variation, due to the presence of the rectal tube (diameter: 8.3 mm), attracted the attention of the team. The treatment plan was transferred on CT scan without rectal tube and OARs and target doses were evaluated. For both plans, bladder and rectum DVHs were assessed considering the near maximum dose to 2cc of each organ, D2cc (%). Results are reported as mean ( $\pm$ SD). The Wilcoxon test for pair samples was used for comparison. Differences were considered statistically significant at  $p < 0.05$ .

#### Results

No significant variation was found for bladder D2cc with and without rectal tube: (68.7 $\pm$ 5.9)% vs (68.7 $\pm$ 4.2)%, respectively. D2cc for the rectum systematically increased in all calculated plans without rectal tube: (68.9 $\pm$ 5.7)% vs. (86 $\pm$ 6.7)%. Differences were found statistically significant ( $p=0.031$ ).

#### Conclusion

These preliminary results show that an unexpected advantage of the rectal tube, used for in-vivo dosimetry, is the favorable modification of the rectal anatomy with a consequent significant reduction in terms of D2cc.

#### EP-1786 Intraoperative Brachytherapy (HDR-IOBT) in advanced or recurrence gynecologic cancer..

E. Villafranca Iturre<sup>1</sup>, J. Muruzabal<sup>2</sup>, A. Sola<sup>1</sup>, P. Navarrete<sup>1</sup>, M. Barrado<sup>1</sup>, S. Aguirre<sup>2</sup>, S. La Peña<sup>2</sup>, O. Tarrío<sup>2</sup>, J. Jimenez<sup>3</sup>, M. Ciga<sup>4</sup>

<sup>1</sup>Hospital of Navarra, Radiation Oncology, Pamplona, Spain

<sup>2</sup>Hospital of Navarra, Gynaecology, Pamplona, Spain

<sup>3</sup>Hospital of Navarra, Urology, Pamplona, Spain

<sup>4</sup>Hospital of Navarra, Surgery, Pamplona, Spain

#### Purpose or Objective

Review our initial results in the treatment with surgery and Intraoperative Brachytherapy (HDR-IOBT) in advanced or recurrence gynecologic cancer.

#### Material and Methods

This protocol was designed in 2011 and all cases have been approved in the Committee on Gynecologic Tumors. They included two patient groups: Group 1: patients with advanced cervical cancer with poor response to Radiation and chemotherapy; group 2: patients with pelvic recurrence of gynecological tumors of any origin. In all CT and MRI was performed, in recurrences also PET to exclude metastatic disease. The surgical procedure was pelvic exenteration, enlarged cystectomy or rectal resection or both depending on the extent of disease. After extraction of the surgical specimen, was confirmed in all cases with intraoperative biopsy the absence of macroscopic residual disease. Then, put clips in the surgical bed. Subsequently an applicator Fleipbrup Flap® (Elekta) was placed, with an appropriate number of channels to the extension of the bed. After intraoperative planning, a dose of 10 Gy prescribed at 0.5 cm bed depth was administered. Finally, the applicator was retiring to complete the surgery.

#### Results

In the period between October 2011 and September 2016, 22 patients have been included. In group 1, there were 11 patients with cervical cancer stage IIB in 5 p and IIIB in 6; in group 2 were 11 recurrences of 5p cervix, 3p endometrial carcinoma, 2 sarcoma and 1 vulva. With a median follow-up of 22 months (1-61m), the Local DFS 2 years was 67%: Group 1: 73%; Group 2: 44%; 2 years Disease Free Survival 54.7%: Group 1: 65%, Group 2: 32%; 2 years Overall Survival 56%: Group 1: 76%, Group 2: 44%. The complications were fistula: 1 intestinal, 2 bladder, 1 osteitis pubis in 1p. stenosis sigma 1p.

#### Conclusion

HDR-IOBT associated with pelvic exenteration offers good results of pelvic control and overall survival in patients with gynecologic cancer with a poor prognosis, which usually palliative treatments are offered, although further monitoring is required. However the number of complications, especially fistulas has been important, so we must take it into account for prevention. These results are possible thanks to the multidisciplinary approach to these patients

#### EP-1787 Dosimetric Implications of the organs at risk in Vaginal Cuff Brachytherapy with ML Cylinder

N. Dumitru<sup>1</sup>, M. Shojaei<sup>1</sup>, S. Pella<sup>1,2</sup>, T. Leventouri<sup>1</sup>, J. Pinder<sup>1</sup>

<sup>1</sup>Florida Atlantic University, Medical Physics, Boca Raton, USA

<sup>2</sup>21st Century Oncology, Medical Physics, Boca Raton, USA

#### Purpose or Objective

To develop a method to evaluate the cumulative dose of organs at risk when using the Multi-Channel Cylindrical Applicators in vaginal cuff brachytherapy.

#### Material and Methods

A retrospective analysis of 30 patients treated in 2015 with the Multi-Lumen Cylindrical Applicator with 3 cm diameter, were considered for this study. A total of 150 fractions was received by patients, each of them receiving 5 fractions with 5 Gy each, delivered twice a week and prescribed to the applicator's surface for 2/3 of the vaginal length. The CT scans of these patients, taken for treatment plan were separately imported into the treatment planning system and paired with the initial CT scan after completing the contouring. Two sets of CT images were fused at a time together with respective to the applicator, using landmark registration. Dosimetric evaluations were performed. The maximum doses received by the rectum wall, bladder wall, bowels and PTV were analyzed and traced over the five fractions to determine the total dose distribution over the entire prescribed treatment.

#### Results

No contour of any of the OAR was exactly similar when CT images were fused to each other. Depending on the depth of the insertion the PTV varied minimally. Each plan was performed independently and cumulated 2 at a time until all 5 fractions were added to the initial fraction. There is a difference between the doses received by the OARs between treatments and between the points of maximum doses. The PTV volumes vary from fraction to fraction. The maximum dose varied between 12% and 27% in rectum wall and bladder wall. The minimum dose varied between 2% and 7% in rectum wall and bladder wall. The average dose varied between 9% and 21% in rectum wall and bladder wall. The cumulative treatment does not indicate a total maximum dose exceeding the tolerances for the rectum and bladder.

#### Conclusion

The variation in volumes of OARs and isodoses near the OARs, indicate that the estimated doses to OARs on the planning system may not be the same dose delivered to the patient in all the fractions. There are no major differences between the prescribed dose and the delivered dose over the total number of fractions. Variation in the length of the cylinder part implanted into the vagina and PTV's coverage indicates an inconsistency in the entire vaginal cuff in all five fractions. In some cases, the critical organs will benefit if the consecutive plans will be made after the CT scans are registered with the initial. All the cases studied indicate the need for more detailed study in order to establish a protocol of planning.

### EP-1788 HDR vs LDR Vaginal brachytherapy: a comparison in terms of outcomes and toxicity

R. Autorino<sup>1</sup>, D. Smaniotto<sup>1</sup>, M. Campitelli<sup>1</sup>, L. Tagliaferri<sup>1</sup>, A. Nardangeli<sup>1</sup>, G. Mattiucci<sup>1</sup>, A. Martino<sup>1</sup>, N. Di Napoli<sup>1</sup>, G. Ferrandina<sup>2</sup>, M. Gambacorta<sup>1</sup>, V. Valentini<sup>1</sup>  
<sup>1</sup>Polyclinic University A. Gemelli- Catholic University, Institute of Radiotherapy, Rome, Italy  
<sup>2</sup>Polyclinic University A. Gemelli- Catholic University, Institute of Oncological Gynecology, Rome, Italy

#### Purpose or Objective

To compare the outcomes in terms of survival and toxicity for endometrial carcinoma patients treated with either HDR or LDR vaginal brachytherapy (VBT) after external beam radiotherapy

#### Material and Methods

From January 2000 to December 2014, patients with endometrial cancer after radical hysterectomy +/- pelvic and/or lombo-aortic lymphadenectomy were treated with adjuvant radiotherapy (45 Gy, 1.8 Gy/day on the whole pelvis) and subsequent VBT boost (HDR dose was 7 Gy in one fraction prescribed to 0.5 cm from the surface of the applicator; LDR dose was 25 Gy to the vaginal mucosa). The outcomes of patients were evaluated in terms of local control (LC), overall survival (OS) and toxicity (according to CTCAE v 4.0).

#### Results

We retrospectively analyzed 200 patients treated with external beam radiation therapy followed by a HDR VBT boost in 78 patients and LDR VBT boost in 122 patients. Patients characteristics are summarized in Table 1. With a median follow-up of 25 months (range 1-163), 5-ys overall survival (OS) was 98% vs 97% in LDR and HDR group respectively (p=0.37) and 5-ys local control (LC) was 93%, similar in the two groups (p=0.81). At multivariate analyses, any factors (age, stage, grading) seems to have impact on OS (p=0.37) and LC (p=0.81). Patients treated with LDR VBT after external beam radiotherapy had a higher gastrointestinal acute toxicity; probably, this is due to development of radiation technique over the years of this study. No differences was found in terms of acute genitourinary and hematological toxicity. Late toxicity such as vaginal stenosis was registered during regular follow-up visit by clinical evaluation. We didn't find statistically significant differences between the two modalities (p=0.67).

#### Conclusion

With the limits of a retrospective review, there were no differences in survival and late toxicity outcomes for patients receiving LDR or HDR brachytherapy. HDR is safe technique in comparison to LDR modality. A larger database analysis will confirm outcomes and toxicity of HDR VBT in postoperative endometrial cancer.

### EP-1789 Comparison between MRI based 3D IGABT planning versus standardised BT planning of cervical cancer

M. Hedetoft<sup>1</sup>  
<sup>1</sup>Skåne University Hospital, Department of Radiation Physics, Lund, Sweden

#### Purpose or Objective

The aim of this study was to investigate if the introduction of MRI based Image Guided Adapted Brachy Therapy (IGABT) treatment planning of cervical cancer in our hospital, has improved the target coverage and reduced the dose to Organs at Risk (OAR) in comparison to standard treatment planning with point A dose prescription.

#### Material and Methods

In February 2014 the first brachytherapy treatment of a cervical cancer patient planned with MRI based 3D IGABT technique, was undertaken in Lund. Until the end of August 2016, 38 patients have been treated with this

technique resulting in 142 fractions, all of them included in this study. The tumour stages of the patients included were IB1 (n=5), IB2 (n=5), IIA (n=7), IIB (n=16), IIIB (n=5). Each patient received external beam radiation therapy and 2 or 4 brachytherapy fractions depending on the tumour stage. For brachytherapy treatments the interstitial titanium ring and tandem applicator (Varian Medical Systems) were used. To be able to choose if an interstitial treatment would improve the tumour coverage a pre-plan was always done. 21 patients were selected for intracavitary/interstitial implant and 17 for intracavitary implant only.

Based on the MRI target volumes, GTV, HR-CTV, IR-CTV and OARs (bladder, rectum, sigmoid and bowel) were contoured according to GEC-ESTRO recommendations. The dwell times were optimised for each fraction, 6.5 Gy/fr and the plans were evaluated according to DVH criteria from the EMBRACE II study. For all fractions the optimised 3D plan was compared to a 2D plan with standardised dwell times, the same pre-plan that was used for patient treatments before starting with the IGABT. The standard plan was based on the same MR images, target volumes and OARs as in the optimised plan. The DVH criteria used for evaluation were EQD2 D<sub>90</sub> for HR-CTV, D<sub>2cm<sup>3</sup></sub> for rectum, D<sub>2cm<sup>3</sup></sub> for bladder, D<sub>2cm<sup>3</sup></sub> for sigmoid and D<sub>2cm<sup>3</sup></sub> for bowel.

#### Results

All HR-CTVs with volumes <40cm<sup>3</sup> were covered with >90Gy EQD2 for the standard as well as the optimised plans. For 10 patients the standard plan coverage even exceeded 100Gy EQD2. In the optimised plans the dose to OAR could be decreased for 17 patients while still maintaining the target coverage.

For larger tumours, HR-CTV >40cm<sup>3</sup>, the dose coverage decreased with standard plans while the optimised plans maintained excellent dose coverage for all plans. With optimisation a good target coverage was obtained at the cost of an increased but acceptable OAR dose.

#### Conclusion

In comparison to standardised plans, MRI-based 3D IGABT planning substantially improved target coverage for larger tumours without violating the OAR dose. For smaller tumours the OAR dose was reduced without compromising the target coverage.

### EP-1790 A balloon applicator with adjustable catheters for image-guided endoluminal rectal brachytherapy

M. Heilmann<sup>1</sup>, D. Berger<sup>1</sup>, R. Schmid<sup>1</sup>, J. Bör<sup>1</sup>, B. Wisgrill<sup>1</sup>, R. Pötter<sup>1</sup>, C. Kirisits<sup>1</sup>, M.P. Schmid<sup>1</sup>  
<sup>1</sup>Medizinische Universität Wien Medical University of Vienna, Universitätsklinik für Strahlentherapie, Vienna, Austria

#### Purpose or Objective

To investigate the dosimetric results and first clinical experience with an in-house made balloon-based applicator for endoluminal brachytherapy for patients with locally advanced rectal cancer not undergoing surgery.

#### Material and Methods

The applicator consists of an inflatable rectal balloon with six attached foley catheters used as guidance for brachytherapy plastic needles. The construction of the applicator and the dosimetric profile in terms of representative dose points in 0, 2, 5, 10 mm ipsilaterally and in 0mm contralaterally are described. Feasibility and treatment response in three patients are reported.

## Results

For all three patients the application was well tolerated and could be performed in an ambulant setting. A reproducible dose gradient was achieved in all patients. The surface dose on the target side was  $204 \pm 19\%$  of the normalized dose in 5 mm (100%) tissue depth and  $143 \pm 8\%$  in 2 mm and  $64 \pm 3\%$  in 10 mm. The surface dose on the contra-lateral side was  $20 \pm 8\%$ . After radiochemotherapy with 50 Gy external beam radiotherapy and concomitant chemotherapy with capecitabine, a HDR brachytherapy boost in 2-3 fractions of 7-10 Gy each was delivered. All patients achieved a clinical complete response at 3 months and no major toxicity was observed.

## Conclusion

The use of our balloon based applicator was clinically feasible and resulted in a stable and reproducible dose distribution. The dose gradient is similar to 50 kV contact x-rays. First clinical results are promising.

#### EP-1791 HDR Interstitial Brachytherapy for Head and Neck Malignancies and use of Iridium - 192 implants

V. Pareek<sup>1</sup>, R. Bhalavat<sup>2</sup>, M. Chandra<sup>2</sup>

<sup>1</sup>Jupiter Hospital- Thane, Radiation Oncology, Mumbai, India

<sup>2</sup>Jupiter Hospital, Radiation Oncology, Thane, India

#### Purpose or Objective

To evaluate the treatment outcomes with HDR Interstitial Brachytherapy in Head and Neck Cancers at our Institute with use of Angiocatheters as carrier source of Iridium - 192 wire implants.

#### Material and Methods

58 Patients with Head and Neck malignancies of varying TNM staging as per AJCC staging criteria were analyzed retrospectively between 2008 and 2015. 42 patients (72.41%) received EBRT with HDR - BRT and 26 patients (27.59%) received BRT alone. 23 patients (39.65%) received concurrent Chemotherapy. The age group ranged from 27 to 81 years (Median age 56 years) with 41 patients (70.69%) males and 17 patients (29.31%) females. HDR - BRT was delivered with Iridium - 192 wire implants using plastic bead techniques with varying dose rates. The Biological equivalent doses (BED) were calculated for both BRT and EBRT keeping  $\alpha/\beta = 10$  for tumor and  $\alpha/\beta = 3$  for normal tissue and subsequently median BED doses were calculated and similarly 2 Gy equivalent dose (EQD2) were calculated and loco-regional control and disease free survival was assessed.

#### Results

After completion of HDR - BRT, Patients for followed up one month later and subsequently every 3 months for first 2 years and thereafter every 6 months with median follow up period of 25 months (Range 2-84 months). The DFS probability at year 1 was 82.76% and 68.05% at year 7. The overall survival probability was 91.37% at year 1 and 85.89% at year 5. The local control rate was 67.27% and the control rates according to the stage of disease and T size classification are mentioned in Table 1. The rate of local recurrence was 8.62%, Regional Recurrence was 1.72%, Loco-Regional Failure was 3.44% and Distant metastases following local or regional failure was 17.23%. The Median BED for  $\alpha/\beta = 10$  was 86.775Gy and DFS was 74.07% in patients receiving more than 86.775Gy and DFS was 64.82% in patients receiving less than 86.775Gy and Median BED for  $\alpha/\beta = 3$  was 128.76Gy and DFS was 74.07 in patients receiving more than 128.76Gy as compared to 64.82% in patients receiving less than 128.76Gy. The median EQD2 for  $\alpha/\beta = 10$  was 71.6Gy and for  $\alpha/\beta = 3$  was 75.85Gy. The DFS was 75.86% in patients receiving more

than median dose of 71.6Gy compared to 61.53% in those receiving less than the median dose. The DFS was 78.57% in patients receiving median dose of 75.85Gy as compared to 59.26% in those receiving less than the median dose.

#### Conclusion

The overall outcome in the Patients with oral cavity and oropharyngeal malignancies was good with implementing of HDR - Interstitial Brachytherapy and use of Angiocatheters as carriers of Iridium - 192 wire. The BED10 value of 86.775Gy and BED3 of 128.76Gy showed that the dose received more than the median showed better outcomes in the form of DFS. The EQD2 calculated values suggested the dose received more than 71.6Gy ( $\alpha/\beta = 10$ ) and 75.85Gy ( $\alpha/\beta = 3$ ) showed better outcomes. The role of HDR Interstitial Brachytherapy in Head and Neck cancers is a proven, effective and safe treatment method with excellent long term outcome.

#### EP-1792 Nasal function after exclusive brachytherapy for primary SCCs of the nasal vestibulum

F. Bussu<sup>1</sup>, L. Tagliaferri<sup>2</sup>, G. Mattiucci<sup>2</sup>, G. Di Cintio<sup>1</sup>, N. Dinapoli<sup>2</sup>, J. Galli<sup>1</sup>, G. Almadori<sup>1</sup>, E. De Corso<sup>1</sup>, G. Passali<sup>1</sup>, G. Paludetti<sup>1</sup>, V. Valentini<sup>2</sup>

<sup>1</sup>Universita' Cattolica del Sacro Cuore Policlinico Agostino Gemelli, Head and Neck Surgical Sciences, Rome, Italy

<sup>2</sup>Universita' Cattolica del Sacro Cuore Policlinico Agostino Gemelli, Radiation Oncology, Rome, Italy

#### Purpose or Objective

Squamous cell carcinoma arising from the nasal vestibule is a rare condition accounting for about 1% of head and neck malignancies with several peculiarities concerning both staging and treatment. Exclusive brachytherapy has been proven to be a treatment as effective as surgery under an oncological point of view, with the advantage of much better preserving the complex cartilaginous framework of the nose. The aim of this study is to evaluate, through specific tests, the functionality of the nose after an oncologically effective brachytherapy for SCCs of the nasal vestibulum.

#### Material and Methods

15 consecutive patients diagnosed with primary squamous cell carcinomas of the nasal vestibulum, treated with exclusive brachytherapy between 2010 and 2016, and free of disease since at least 9 months were enrolled. 15 control subjects, matched with the cancer patients as for history of non-neoplastic diseases of the upper airways (mainly chronic rhinosinusitis and asthma), age and sex were selected as well and involved in the study. Both the cases and the controls underwent nose endoscopy, nose cytology, rhinomanometry, olfactometry and saccharin test for mucociliary clearance. Differences between cases and controls were evaluated for each parameter. Statistical analysis was performed using the JMP software version 7.0.1 (SAS Institute).

#### Results

No significant differences between cases and controls for any of the functions evaluated were detected.

#### Conclusion

Squamous cell carcinoma of the nasal vestibulum is a tricky situation for the clinician, as it is often a treatable disease but may harbor significant long term sequelae. On one hand, when planning surgical treatment of these lesions, while obtaining a resection with clear margins is usually quite easy, the achievement of a satisfying aesthetical restoration appears often almost impossible. On the other hand, also external beam radiotherapy is associated to well-known late toxicities: in particular notable alteration in nose cytology and mucociliary clearance, and chronic crusting are associated to the exposure of nose mucosa to EBRT.

The present work demonstrates that brachytherapy has

the advantage of preserving the main nose functions with relevant implication for the quality of life of surviving patients.

#### EP-1793 High-dose-rate brachytherapy for lip and oral cavity tumors

C. De la Pinta<sup>1</sup>, T. Muñoz<sup>1</sup>, A. Montero<sup>2</sup>, J. Dominguez<sup>1</sup>

<sup>1</sup>Hospital Ramon y Cajal, Radiation Oncology, Madrid, Spain

<sup>2</sup>Grupo Hospital Madrid, Madrid, Spain

#### Purpose or Objective

The aim of this study was to evaluate the clinical and cosmetic outcomes and recurrence-free and overall survival in patients treated with high-dose-rate brachytherapy for lip and oral cavity tumors.

#### Material and Methods

All patients referred for interstitial high-dose-rate brachytherapy in our centre from 2007 to 2016 with histologically confirmed squamous cell carcinoma (17p) and basaloid carcinoma (2p) of the lip or oral cavity were retrospectively analysed. Tumor sites included the lips (15p), mouth (3p) and gingiva (1p). Treatment consisted of brachytherapy alone (11p) or recurrence or adjuvant after surgery (8p). All patients were treated with interstitial brachytherapy median implant dose 51 Gy (range 50- 60Gy).

Inclusion criteria were as follows: head and neck location and malignant tumors.

#### Results

With a median follow-up of 55 months (range 3-246 months), local control was achieved on clinical examination or CT scan.

Acute toxicities (11/19p) consisted of epitelitis grade 1 (3p), grade 2 (4p) and grade 3 (4p). Not acute toxicity grade 4 was reported.

Late toxicities (9/19p) were hypopigmentation and fibrosis. One patient had necrosis.

Among 19 patients studied, 2 lost follow-up and they were excluded from the survival analysis.

Preservation of organ functions was in all patients. Using Kaplan-Meier analysis overall survival after minimum follow-up of 55 months was 94,1% and disease-free survival was 89,4%. One patient had a locoregional recurrence and died of tumor.

#### Conclusion

Interstitial brachytherapy is a good choice to deliver high-dose radiation in lip and oral cavity tumor after surgery or as an exclusive treatment. This treatment offers adequate locoregional control with acceptable range of complications.

#### Electronic Poster: Brachytherapy: Physics

#### EP-1794 Intra-op check of ONCURA Rapid Strand (Model 7000) seeds radioactivity in LDR prostate brachytherapy

V. Stserbakov<sup>1</sup>, K. Aru<sup>2</sup>

<sup>1</sup>North-Estonian Regional Hospital Cancer Center Radiotherapy, Department of Radiotherapy and Oncology, Tallinn, Estonia

<sup>2</sup>North-Estonia Medical Centre- Cancer Center, Department of Radiotherapy and Oncology, Tallinn, Estonia

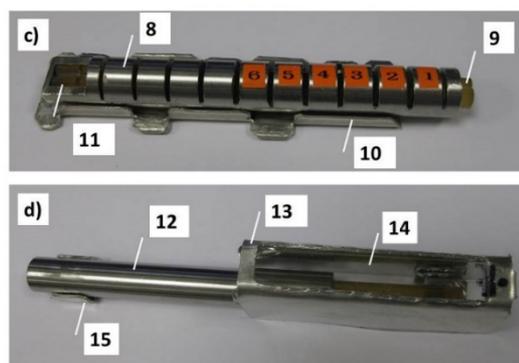

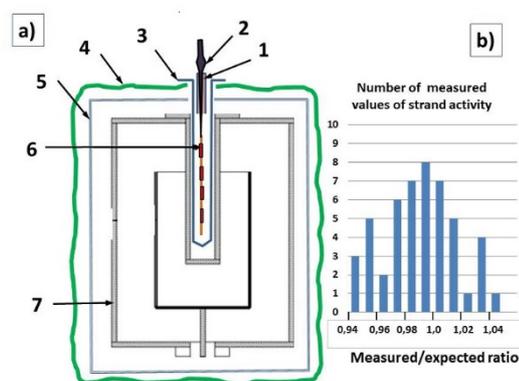

#### Purpose or Objective

To introduce into clinical practice procedure for checking the radioactivity of Oncura rapid strand seeds for LDR prostate brachytherapy deriving the expected value for the strand activity from measurement of activity for each single seed. To perform measurement in possibly more

clean radiation safety conditions with minimal exposure dose to personal by optimizing every step of the procedure.

#### Material and Methods

For measurement the radioactivity of ONCURA single seed, cut off from the strand, it was used well-chamber HDR 1000 Plus (calibration factor for I-125(9011) 2,388 E11  $\mu\text{Gy}\cdot\text{m}^2/\text{h}/\text{A}$  of Standard Imaging) with special insertion for seed. CHARGE mode of Unidos (PTW-Freiburg) electrometer was LOW ( $\leq 230$  pC). Collected time was 1 min. Setting-up for measurement of the radioactivity of rapid strand (containing 4/5/6 seeds) is shown in the figure (a). The well-chamber (7) was placed into plastic container (5), which one then was covered by sterile coating (4) in order to keep external sterile conditions. Plastic container, as well, prevents of not needed external contacts with well-chamber, since its electrometer is working in most sensitive mode. Tweezers (2) with rapid strand (6) and short transport container (1) was mounted into sterile cylindrical tube (barrel) of BBraun Original-Perfusor Syringe® 50 ml (3), which was used as holder for inserting into well-chamber cavity. Devices for performing radiation safely operating with strands are shown on figure (c, d).

On figures:

- a) Assembly for rapid strand radioactivity measurement. 1- short transport container; 2- tweezers to hold strand; 3- cylindrical tube (barrel); 4- sterile coating; 5- plastic container; 6- rapid strand seeds; 7- well-chamber. b) Measured values of Rapid strand seeds radioactivity. c) Strand cutting procedure devices. 8- Transport container with cut-outs for 'safely and clean outside cutting' of required strand; 9- spacing jig; 10- seat for container to prevent its rotation on the table; 11- cut-out for finger in container to prevent rotating of spacing jig inside the container. d) Removing of cut-up strands from container. 12- container; 13- metal shielding cover; 14- lead glass; 15- seat for container.

#### Results

Summarizing the measurement of every single seed activity might be found the intra-op calibration factors for

rapid strand (containing 4/5/6 seeds) inserted into well-chamber. They are: total activity 2,20 mCi<sub>strand of 4 seeds</sub> produce 121,4 pC/10s corrected for pressure and temperature reading of electrometer, overall activity 3,28 mCi<sub>strand of 6 seeds</sub> gives 181,6 pC/10s corrected for pressure and temperature reading of electrometer.

#### Conclusion

Described quality control procedure provide confidence that total seeds radioactivity of implanted into patient in LDR brachytherapy procedure correspond to intended value. Sterile conditions for rapid strands are guaranteed and therefore procedure can be accepted for intra-op using. The exposure dose received by personal during this procedure is negligibly small.

#### EP-1795 A novel MRI markers system in applicator reconstruction for brachytherapy

A. Ota<sup>1</sup>, J. Richart<sup>1</sup>, C. Domingo<sup>1</sup>, S. Rodriguez<sup>1</sup>, P. Rodriguez-Mejjide<sup>2</sup>, I. Fotina<sup>2</sup>, M. Santos<sup>1</sup>, J. Perez-Calatayud<sup>3</sup>

<sup>1</sup>Hospital Clinica Benidorm, Radiotherapy, Benidorm, Spain

<sup>2</sup>Eckert & Ziegler BEBIG GmbH, Marketing, Berlin, Germany

<sup>3</sup>Hospital Clinica Benidorm/Hospital La Fe, Radiotherapy, Benidorm/Valencia, Spain

#### Purpose or Objective

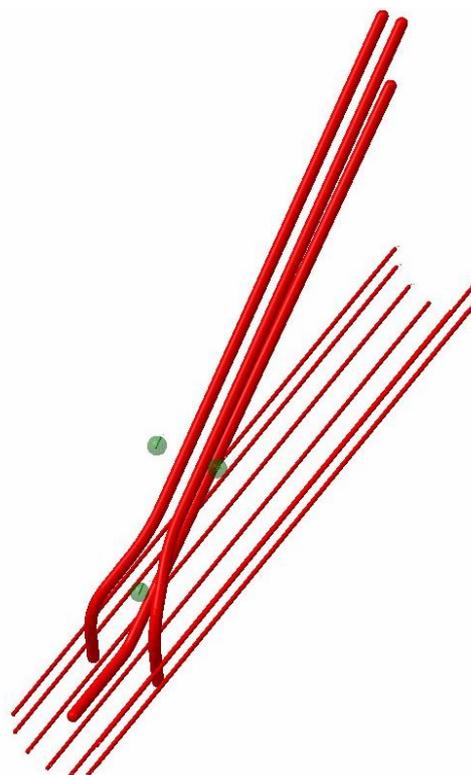

ABS and GEC-ESTRO recommend magnetic resonance imaging (MRI) in T2-sequence as preferable modality in image-guided brachytherapy for gynecological malignancies. On the other hand, widespread availability of the applicator libraries in the brachytherapy treatment planning systems (TPS) allows global approach to the issue of the applicator modeling. The aim of this work is to present a method to incorporate complete applicator geometries in SagiPlan, (not only single channels), based on the technical data available from manufacturer and then develop a marking system which allows recognizing a defined applicator (Vienna-type applicator of Eckert & Ziegler BEBIG) in the MR image series with utmost possible precision for the library reconstruction.

#### Material and Methods

The investigated applicator model is Vienna-type applicator, consisting of tandem with a ring for possible interstitial component from Eckert&Ziegler BEBIG (Berlin, Germany) together with a model available in the library of the SagiPlan® TPS from Eckert&Ziegler BEBIG.

3D model of the applicator was reconstructed independently, using open-source modeling software FreeCAD ([www.freecad.org](http://www.freecad.org)).

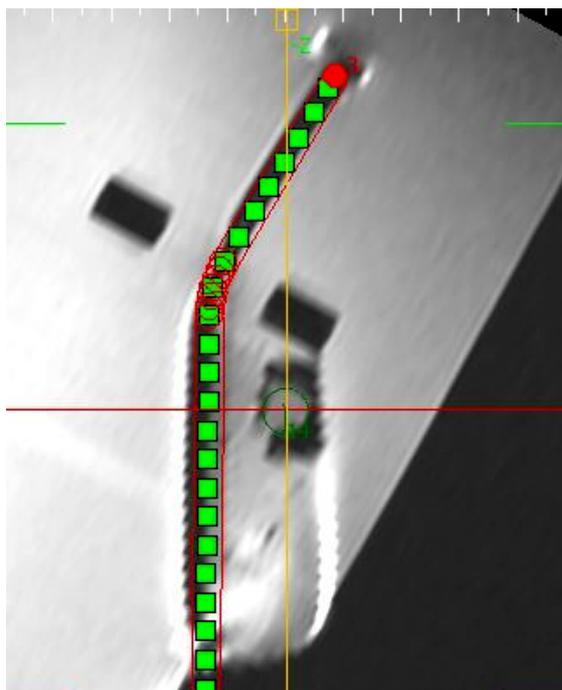

The presented reconstruction technique is based on the placement of three vitamin A capsules, clearly visualized in T2 MRI, embedded in the material layer giving enough contrast for the capsule recognition. The position of the marking capsules with respect to the applicator geometry is known precisely, due to placement of the attachments in 3D model reconstructed in FreeCAD and verified against technical specifications of the applicator. The accessory attachments to the applicator are produced on the 3D printer from polylactide polymer material (PLA) and carry the marking capsules inside.

#### Results

In order to validate the accuracy of the reconstruction with use of the model described above, we acquired T2 MRI sequence of the Vienna applicator in water with accessory attachments in place. The images were entered in the SagiPlan® TPS in order to perform the applicator reconstruction based on the markers and pre-defined template, based on the 3D applicator model, loaded in SagiPlan®.

The presented technique could be expanded to any rigid applicator and other image modalities, under condition of the adequate selection of the markers. It is necessary to mention, that positioning of the accessory attachments on the applicator is very easy and does not affect integrity or other characteristics of the product.

### Conclusion

We designed several accessory attachments for the markers to be placed on Vienna applicator, which allow easy, fast and precise reconstruction. This technique can be expanded for other applicator types. Additionally it permits to resolve the practical issue of the marker availability for the reconstruction in MRI

### EP-1796 Dosimetric comparison between TG43/TG186 algorithms and manual/inverse optimization in brachytherapy

T. Brun<sup>1</sup>, E. Torfeh<sup>1</sup>

<sup>1</sup>Institut Universitaire du Cancer Toulouse - Oncopole, DIPM, Toulouse, France

#### Purpose or Objective

For brachytherapy planning treatment, different types of algorithms are used for calculate and optimize the dose distribution. In Toulouse, reference treatment plans are calculated with the software Oncentra Brachy which is based on the formalism TASK GROUP 43 (TG43) and manual optimization.

The aim of this project is to compare two algorithms dose calculation: TG43, which does not take into account the heterogeneities vs. TG186, which takes into account the heterogeneities. This comparison was realized for gynecological, anal canal, prostate, H&N and skin treatments in order to strengthen clinical practices on the prescribed dose.

Finally, in order to improve the dosimetric quality and harmonize clinical practices, a second study was done to evaluate the difference between a manual optimization and an automatic inverse optimization algorithm with Hybrid Inverse Planning Optimization (HIPO).

#### Material and Methods

For this study, 38 patients dose plans were calculated with the reference dosimetry using the TG43 and a manual optimization. A dosimetric comparison for each plans was done with the dose calculation algorithm based on the TG186 and the optimisation algorithm HIPO. Finally, to study the conformity and consistency of the different algorithms, both COIN and Homogeneity Index (HI) were calculated for the different cases.

### Results

Considering the comparison between the TG43 and TG186 and the most relevant criteria, dosimetric data does not show a significant difference for gynecological, anal canal, prostate, H&N and skin plans. But results for prostate and H&N plans were relevant: a decrease of 13.75% for V50Gy with the TG186 is obtained. This difference is accentuated with the high dose. For the lead, an increase of 21.6% for D25% with the TG186 is obtained (Fig 1).

Regarding the optimization algorithms HIPO/manual and considering the most relevant criteria, there is no significant difference on the target volumes on the D90%. For the two optimizations, the mean value respects the dosimetric constraints for the 5 cases of treatment (difference of 4.3% for the gynecological case, 4.4% for the anal canal case, 1.2% for the prostate case, 0.7% for ENT case, and 6.4% for skin case). Furthermore, the inverse optimization algorithm HIPO shows less fluctuation with respect to manual optimization and results are more homogeneous. The value obtained for the COIN and HI for HIPO were higher than those obtained for a manual optimization in the 5 cases especially for the prostate case (Table 1).

Localisation	COIN				HI			
	TG43-Manuel	TG43-HIPO	TG186-Manuel	TG186-HIPO	TG43-Manuel	TG43-HIPO	TG186-Manuel	TG186-HIPO
Gynéco	0,44	0,5	0,45	0,51	0,37	0,4	0,38	0,38
Canal anal	0,62	0,63	0,62	0,64	0,46	0,39	0,5	0,43
Prostate	0,69	0,82	0,70	0,81	0,54	0,63	0,56	0,66
ORL	0,65	0,68	0,65	0,67	0,5	0,48	0,53	0,51
Peau	0,57	0,67	0,57	0,68	0,36	0,44	0,36	0,47
Mean	0,59	0,66	0,59	0,66	0,45	0,47	0,47	0,49

### Conclusion

The difference between the TG43 and the TG186 is for most clinical cases not significant for target volumes and OARs except sources in the case of the prostate, as well as lead in cases of H&N. The use of HIPO optimization algorithm has shown a real advantage in the robustness of calculation. Moreover, HIPO enables a reduced dwell time by position, so a total treatment time shorter than the ones obtained with manual optimization.

### EP-1797 Dosimetric characterization of MOSFET detectors for Ir-192 and feasibility for in vivo dosimetry.

R. Fabregat Borrás<sup>1</sup>, S. Ruiz-Arrebola<sup>1</sup>, M. Fernández Montes<sup>1</sup>, E. Rodríguez Serafín<sup>1</sup>, J.T. Anchuelo Latorre<sup>2</sup>, M.T. Pacheco Baldor<sup>1</sup>, J.A. Vázquez Rodríguez<sup>1</sup>, M.M. Fernández Macho<sup>1</sup>, D. Guirado<sup>3</sup>, P.J. Prada<sup>2</sup>

<sup>1</sup>Hospital Universitario Marqués de Valdecilla, Radiophysics, Santander, Spain

<sup>2</sup>Hospital Universitario Marqués de Valdecilla, Radiation Oncology, Santander, Spain

<sup>3</sup>Hospital Universitario San Cecilio, Radiophysics, Granada, Spain

#### Purpose or Objective

There is a recognized interest in developing in vivo dosimetry (IVD) as an effective method of independent treatment verification for HDR BT treatments [1]. The purpose of current study was to perform a dosimetric characterization of MOSFET TN-502RDM from Best Medical Canada in order to optimize their use in HDR BT treatments delivered with the Ir-192 source contained in Flexitron afterloader (Nucletron-Elekta).

#### Material and Methods

Dose calculation was made using TPS OncentraBrachy-v4.5.2 (Nucletron-Elekta) and verified with radiochromic films Gafchromic EBT3. Tiny dimensions of MOSFET TN-502RDM (1 mm x 1 mm x 3.5 mm) allow their introduction into common needles used in HDR BT. Steel Trocar point needles from Nucletron with diameter 1.9 mm and length 200 mm were used to place the source and the detectors

within a water phantom specifically designed for this study.

Calibration factors, defined as the ratio between measured dose and detector response (Gy/V), were obtained for five detectors, using a calibration dose of 1 Gy. Calibration factor for each detector was calculated averaging five repeated measures.

Linearity of the response was evaluated until the detector saturation. Temperature dependence within the range of clinical interest, angular dependence and distance-to-source dependence were also assessed. Each dependence was evaluated for three detectors and each experimental measurement was repeated three times. Mathematical models were obtained for each dependence.

### Results

Figure 1 shows a lineal behavior for three detectors evaluated until 155Gy. Maximum variations of detector response were 8.7% with distance-to-source (range of 7 cm), 10% with azimuthal angle and 7.6% with polar angle. Temperature dependence was negligible for interest range. Table 1 shows the results of the parameters describing the mathematical models and their uncertainties, as well as the goodness of fit.

Calibration factors measured were between 8.4-8.6 Gy/V. Calibration factor reproducibility resulted in 2.1% for intra-detector analysis and 0.9% for inter-detector analysis. Finally, estimated global uncertainty associated to our MOSFET measurements is 4.2%.

Figure 1.

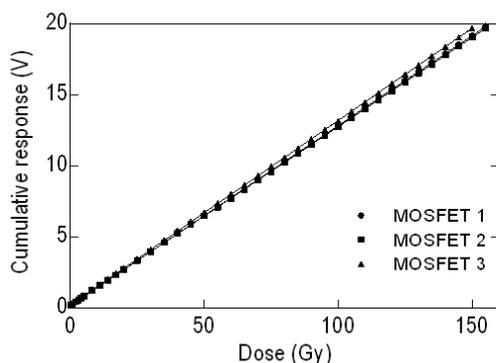

Table 1.

### Mathematical models.

Dependences	Fit	Parameters			$\chi^2/\nu - R^2$
		$b_0$	$b_1$	$b_2$	
Angular polar	$Y=b_0+b_1 \cdot X+b_2 \cdot X^2$	1.099(6)	-6.5e-2(5)	1.03e-2(7)	1.567
Angular azimuthal		6.7e-1(4)	1.23e-1(18)	-1.15e-2(17)	2.374
Distance		9.53e-1(6)	1.53(13)	-	0.9617
Temperature	$Y=b_0+b_1 \cdot X$	1.41(6)	-1.4e-3(2)	-	0.8771
Linearity		1.50e-1(4)	1.2680e-1(5)	-	0.9999

The number between parentheses indicates the uncertainty ( $k=1$ ) in the last significant digit, that is  $-0.093(6) = -0.093 \pm 0.006$

### Conclusion

MOSFET TN-502RDM detectors show a high linearity with accumulated dose and a good inter-detector reproducibility, even better than intra-detector. However, their implementation in a IVD program of HDR BT needs a developed methodology to minimize the impact of the large angular and distance source-to-detector dependence of the MOSFET over their response. This task would be done applying the mathematical models obtained in this study.

<sup>2</sup>King Faisal Specialist Hospital & Research Centre, Biomedical Physics, Rityadh, Saudi Arabia

### Purpose or Objective

In our institution high-dose rate endorectal brachytherapy (HDREBT) is given either as pre-operative downsizing modality or as a boost after external beam therapy (EBT) in patients with rectal adenocarcinoma. In this work, we compare dosimetry between HDREBT and highly conformal external beams therapy (EBT) modalities as an alternative modality.

### Material and Methods

Ten male rectal cancer patients treated with HDRBT boost using the Intra-cavitary Mold Applicator (IMA) have been scanned prior to first treatment fraction firstly without brachytherapy applicator (to be used for EBT planning) Brachytherapy plans were generated using IPSA inverse planning module of MasterPlan treatment planning system which does not provide the impact of the midline shielding used during HDRBT, while the CT data without applicator were used for planning on Cyber Knife (CK, Accuray MultiPlan) and Rapid Arc (RA, Varian Eclipse). In addition to clinical target volume (CTV) various critical structures (contralateral mucosa, bladder, small bowel, sphincter, prostate) were outlined by the same radiation oncologist on two CT datasets; one with applicator for brachytherapy planning, and the second without applicator for planning

for EBT modalities. For the EBT modalities, optimization was performed in such a way to force the exact same CTV coverage as was obtained for each patient treated with HDREBT.

### Results

Comparison of dose distributions in axial, coronal and sagittal planes for one patient are given in Fig.1 (top) for the three modalities investigated. Bottom of the Fig.1 shows comparison between DVH curves for the same patient for CTV and three critical structures (bladder, prostate, and sphincter). Table 1 summarizes averaged (over 10 patients) dose distribution parameters for the three modalities investigated.

Table 1: Summary of averaged (over 10 patients) dose distribution parameters for the three modalities investigated.

	Brachytherapy	Cyber Knife	Rapid Arc
<b>CTV</b>			
Median [%]	156.6	111	106
V100 [%]	89	86	85
V150 [%]	52	0	0
<b>Bladder</b>			
Maximum [%]	26.7	16.0	16.0
Median [%]	6.3	6.0	6.0
<b>Small Bowel</b>			
Maximum [%]	16.1	8.4	5.0
Median [%]	3.2	1.6	0.2
<b>Sphincter</b>			
Maximum [%]	21.4	1.5	2.2
Median [%]	3.2	0.9	0.6
<b>Prostate</b>			
Maximum [%]	79.8	58.6	54.6
Median [%]	18.3	15.0	13.5
<b>Contra lateral mucosa</b>			
Maximum [%]	89.2	85.8	89.4
Median [%]	36.6	34.5	45.3

### Conclusion

From Fig.1 and Table 1 that both EBT modalities provide very conformal dose distribution to the target while providing generally better sparing of surrounding critical structures except for the contralateral rectal wall. The main advantage of brachytherapy is that there is no need for additional PTV margin as the source moves together with the rectum. However, our results suggest that even the addition of PTV margins to sophisticated EBT modalities can produce comparable (if not better) dose distributions to brachytherapy plans. Although, all the EBT modalities possess the image guided radiotherapy (IGRT) systems that allow repositioning of the patient (hence target) just before commencing the treatment fraction, it is difficult to ascertain the impact of daily intra-treatment rectal motility and gas interference on the CTV in this study. The superior dose within HRCTV is best observed with HDRBT and likely the most important factor for achieving complete tumor response in the context of organ preservation [Appelt et al, Int J Rad Oncol Biol Phys 2013; 85: 74-80].

### EP-1799 Feasibility study of in vivo dosimetry with optically stimulated dosimeters for 50kVp Papillon® beam

C. Dejean<sup>1</sup>, A. Mana<sup>1</sup>, M. Gauthier<sup>1</sup>, J. Feuillade<sup>1</sup>, C. Colnard<sup>1</sup>, J. Gérard<sup>1</sup>

<sup>1</sup>Centre Antoine Lacassagne, Academic Physics, Nice, France

### Purpose or Objective

to evaluate optically stimulated luminescence dosimeters (OSL, nanodot Landauer™) to be used for in vivo dosimetry with 50kVp beam.

### Material and Methods

Papillon® mobile xray generator is delivering a 50kVp treatment beam that can be used for skin or rectum treatment. A new machine based on the same beam,

Papillon+® is being launched to add the opportunity of delivering intra operative breast treatment.

OSL principle is to detect light emitted when the luminescence material, which is exposed to radiation, is stimulated with visible light. Associated reader is Microstar ii.

Nanodots were irradiated with Papillon® beam treatment to establish calibration curves and to evaluate attenuation. Attenuation was measured by a second nanodot situated under the first one which is a pessimistic way of determination as both plastic disk infused with Aluminium oxide doped with Carbon Al2O3:C encased in a plastic case.

### Results

Detectors were read after irradiation from 10 to 22.5Gy. No saturation was observed unlikely expected. Results highlight a linear calibration curve with a regression linear coefficient  $R^2=0.9853$ .

Concerning attenuation, results are ranging from 80 to 70% of reference measurements with this methodology.

Discussion: While dose used is in treatment range (around 20 Gy), linear calibration can be used which is different from literature results. It may be linked to the evolution made by Landauer concerning the Microstar reader between (Price, Medical Physics 2013) and today. So, OSL can be used at a time to evaluate skin dose but also delivered dose at applicator surface.

Attenuation methodology needs to be modified to be more relevant according to our clinical use. Gafchromic films may be used to evaluate surface attenuation.

### Conclusion

OSL nanodots are usable with 50kVp Papillon® beam for breast intraoperative radiotherapy for example. OSL reading is fast and without delay. Attenuation surface of the detector is 0.9x0.9cmxcm that has to be clinically validated before replacing thermoluminescence dosimeters (TLD) classically used.

Uncertainties are on the same level as published one concerning TLD (around 17%), they will be determined with Papillon+® beam that permits to treat breast in an intraoperative mode.

### EP-1800 Optical Fibre Luminescence Sensor for Real-time LDR Brachytherapy Dosimetry

P. Woulfe<sup>1</sup>, S. O'Keeffe<sup>2</sup>, F.J. Sullivan<sup>3</sup>

<sup>1</sup>Woulfe Peter, Department of Radiotherapy, Galway, Ireland

<sup>2</sup>University of Limerick, Optical Fibre Sensors Research Centre, Limerick, Ireland

<sup>3</sup>National University of Ireland Galway, Prostate Cancer Institute, Galway, Ireland

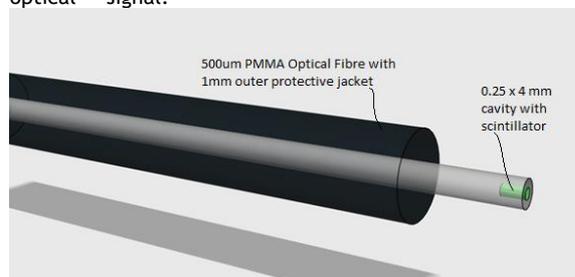

### Purpose or Objective

This paper presents recent advancements in the development of an optical fibre radioluminescence sensor whereby the radiation sensitive scintillator, terbium-doped gadolinium oxysulphide (Gd<sub>2</sub>O<sub>2</sub>S:Tb), is embedded within the core of a 500µm PMMA (Polymethyl methacrylate) plastic optical fibre. The reduced size of the presented optical fibre sensor offers significant advantages for application in brachytherapy. The small dimensions of the sensor (less than 1mm including the outer protective jacket) allows it to be easily guided within existing brachytherapy equipment; for example, within the seed implantation needle for direct tumour dose analysis, in the urinary catheter to monitor urethral dose, or within the biopsy needle holder of the transrectal ultrasound probe to monitor rectal wall dose.

### Material and Methods

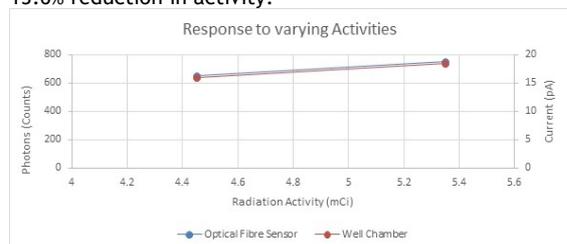

The optical fibre sensor, shown in figure 1, is constructed by micromachining a cavity in the 500µm core of a PMMA (polymethyl methacrylate) plastic optical fibre. The cavity, 250µm in diameter and 4mm deep, is filled with

the scintillating material, terbium doped gadolinium oxysulphide ( $Gd_2O_2S:Tb$ , GOS) and sealed with epoxy. The scintillation material fluoresces on exposure to ionising radiation and the resultant emitted fluorescent light penetrates the PMMA optical fibre core and propagates along the fibre to a Hamamatsu Multi-Pixel Photon Counting Module (MPPC C11208) for monitoring of the optical signal.

### Results

The sensor was further evaluated for its response to different levels of radiation to determine its suitability for brachytherapy applications. The sensor is exposed to a full cartridge, i.e. 15 seeds, corresponding to an activity of 5.35mCi and to a second full cartridge corresponding to an activity of 4.45mCi. Alongside the optical fibre sensor, the charge was also collected within a Standard Imaging HDR 1000 Well Chamber and a reading displayed on the Standard Imaging Max 4000 Electrometer. Fig 2 shows the average photon counts equate to 750 for 5.35mCi and 655 for 4.45mCi, corresponding to a 12.6% reduction in photon counts. The radiation activity of 5.35mCi resulted in a current of 18.47pA and 4.45mCi directly equating to a 13.6% reduction in activity.

### Conclusion

The sensor demonstrates excellent stability, with a standard deviation of 18 counts. The current repeatability, with a maximum percentage deviation of 3.3%, is within accepted limits, however it is envisaged that the future experimental set-up employing a brachytherapy phantom, will significantly improve this.

## Electronic Poster: Brachytherapy: Miscellaneous

### EP-1801 HDR-pleiotherapy for the treatment of extramammary paget's disease. A case report.

M.F. Ropero Carmona<sup>1</sup>, J. Lupiani Castellanos<sup>1</sup>, J. Quirós Rivero<sup>1</sup>, A. Ruiz Herrero<sup>1</sup>, M.A. Gonzalez Ruiz<sup>1</sup>, J. Cabrera Rodriguez<sup>1</sup>, Y. Ríos Kavadoy<sup>1</sup>, J.L. Muñoz Garcia<sup>1</sup>, P. Almendral Manzano<sup>1</sup>

<sup>1</sup>Hospital Universitario Infanta Cristina, Radiotherapy Oncologist, Badajoz, Spain

#### Purpose or Objective

In 1889, Crocker first described extramammary Paget's disease (EMPD). It is considered a rare adenocarcinoma that originates from the skin or skin appendages in areas with apocrine glands. EMPD classification is based on the presence or absence of associated malignancies: Primary or intraepithelial and Secondary. It is more common

postmenopausal women. The main anatomical location is the vulva (65%), followed by the perianal region, scrotum, penis and axilla. The disease presents with well-defined eczematous eruption or leukokeratotic plaque, and a tendency for multifocal lesions.

The standard treatment for local EMPD is surgical resection, although this approach might not be suitable for all patients. Topical treatments such as Imiquimod cream, 5-fluorouracil cream and CO2 laser may also be used, with variable results. Recently, radiotherapy (RT) has been widely used to treat EMPD. RT can be used as the primary treatment in elderly patients with comorbidities who are considered medically inoperable, or in patients who want to preserve body function or structure.

In a review of the literature, we found only three patients of Paget extramammary treated with HDR-pleiotherapy by custom mold.

#### Material and Methods

We present a case of Paget's disease treated by HDR-pleiotherapy with a custom made mold with curative intention. A 80-year-old female presented with a 2-year history of a skin lesion in the glutes, intergluteal folds and vulva, about 11-12 cm, with pruritus, erythema, and punctate bleeding. Positive biopsy for EMPD. Additional exams did not reveal an underlying malignancy.

The patient was treated initially by means of topical applications of imiquimod cream but in the absence of response she was referred to the Radiation Oncology Department. Treated by HDR-pleiotherapy with a custom-made mold with up to a final dose 50 Gy in 10 fractions of 500 cGy, two days a week (EQD2 62.5Gy).

### Results

Acute adverse effects include epithelitis grade 2 and epithelitis small areas grade 3, which resolve with topical measures. After three months of treatment, the patient had complete response and resolution epithelitis.

#### Conclusion

In our opinion, HDR pleiotherapy with a custom-made mold appears to be an ideal alternative for elderly patients with comorbidities, not candidates for aggressive surgical management or who refuse surgery.

### EP-1802 The role of the high dose rate brachytherapy in the conservative treatment of esophageal cancer.

A. Lozhkov<sup>1</sup>, A.V. Vazhenin<sup>1</sup>, T.M. Sharabura<sup>1</sup>

<sup>1</sup>Chelyabinsk Regional Oncol. Centre, Department for Radiotherapy and Radio-Oncology, Chelyabinsk, Russian Federation

#### Purpose or Objective

To evaluate the results of add to EBRT intraluminal HDR brachytherapy.

#### Material and Methods

Between 2008 and 2015, 82 people with cancer of the thoracic esophagus T2-3N0-1M0 and refusal of surgery received radiation therapy.

In the first phase all patients underwent external beam radiotherapy up to 40-50 Gy. Subsequently, the patients were divided into 3 groups. The first group included 30 patients who received concomitant radiotherapy using brachytherapy, in the 2nd group -30 patients who received

EBRT 60-70 Gy, in 3 group -22 patients received EBRT 40-50 Gy. The dose of brachytherapy was 14 Gy in 2 fractions at intervals of one week, which was applied after 40-50 Gy EBRT

#### Results

Reducing dysphagia was observed in 70% of patients in the first group, 54% - in the second group, and 23% - in the third. Two-year overall survival was 36%, 12% and 12% respectively. The median overall survival was 15.7; 9.7 and 6.6 months, respectively.

#### Conclusion

Adding intraluminal brachytherapy to EBRT can reduce dysphagia and improve overall survival.

#### EP-1803 Moderate dose-escalation with perioperative HDR brachytherapy in soft tissue sarcomas

X. Chen<sup>1</sup>, A. Montero<sup>1</sup>, E. Sanchez<sup>1</sup>, J. De las Heras<sup>2</sup>, O. Hernando<sup>3</sup>, M. Lopez<sup>1</sup>, J. Garcia<sup>4</sup>, J.M. Perez<sup>5</sup>, R. Ciervide<sup>1</sup>, J. Valero<sup>1</sup>, M. Garcia-Aranda<sup>1</sup>, R. Alonso<sup>3</sup>, D. Zucca<sup>4</sup>, M.A. De la Casa<sup>4</sup>, B. Alvarez<sup>1</sup>, J. Marti<sup>4</sup>, L. Alonso<sup>3</sup>, P. Fernandez-Leton<sup>4</sup>, C. Rubio<sup>1</sup>

<sup>1</sup>Hospital Universitario HM Sanchinarro, Radiation Oncology, Madrid, Spain

<sup>2</sup>Hospital Universitario HM Sanchinarro, Orthopaedic Surgery, Madrid, Spain

<sup>3</sup>Hospital Universitario HM Puerta del Sur, Radiation Oncology, Madrid, Spain

<sup>4</sup>Hospital Universitario HM Sanchinarro, Medical Physics, Madrid, Spain

<sup>5</sup>Hospital Universitario HM Puerta del Sur, Medical Physics, Madrid, Spain

#### Purpose or Objective

Radiation therapy after conservative surgery improves local control in patients with soft tissue sarcoma. A clear relationship exists between dose and local control. We report our experience about feasibility of perioperative brachytherapy as a moderate dose-escalation approach in the multidisciplinary management of soft tissue sarcoma.

#### Material and Methods

From May 2015 to October 2016, 9 patients (p), 5 men and 4 women, with a median age of 63 years (range 7 - 72 years) underwent perioperative brachytherapy (PoBT). Histology: 4 p (44%) liposarcoma, 2 p (22%) desmoid and 1 p (11%) fusocellular sarcoma, 1 p (11%) pleomorphic sarcoma and 1 p (11%) sarcoma NOS. Tumor staging: 4 p T2aN0M0, 5 p T2bN0M0. Tumor location: thigh 5 p (56%), trunk 2 p (22%), arm 1 p (11%), neck 1p (11%). PoBT procedure was performed by using 6F plastic catheters placed on the surgical bed at the time of excision. Eight patients obtained R0 resection and 1 p R1 resection. Catheters were placed perpendicularly to the surgical incision at 1.5- 2 cm intervals to ensure adequate dosimetry. CT simulation with 1.5 mm slice thickness was done in the fourth or fifth day after surgery once the sewer system was retired. A total 16.5 Gy was delivered to the PTV in 3 fractions of 550 cGy separated at least 6 hours. Catheters were retired after the last fraction.

#### Results

All p received external beam radiotherapy (EBRT) by using intensity modulated radiotherapy (IMRT) at a dose of 50 Gy in 25 fractions of 2 Gy/day. Five p (56%) underwent pre-operative radiotherapy and 4 p (44%) post-operative radiotherapy. Four patients received chemotherapy before or after radiotherapy. One of the biological characteristics of sarcoma is their relatively low  $\alpha$ - $\beta$  ratio. Assuming the alpha- beta ratio of sarcoma cells as 4 our calculation of tumor BED is as following:  $(2\text{Gy} \times 25\text{fx}) + (5.5\text{Gy} \times 3\text{fx}) = 114.19\text{Gy}$  which corresponds to an accumulated EQD2Gy for tumor of 76.12Gy. With a median follow-up of 7.8 months (range 3 - 17.6 months), no local failure nor distance progression has been observed. No grade 2 or higher toxicity was observed.

#### Conclusion

Peri-operative brachytherapy is feasible and well tolerated and allows a moderate dose-escalation in patients with soft-tissue sarcomas.

#### EP-1804 Laparoscopic robot-assisted brachytherapy of muscle-invasive bladder cancer: clinical case report

F. Mascarenhas<sup>1</sup>, F. Marques<sup>1</sup>, K. Maes<sup>2</sup>, R. Formoso<sup>2</sup>, T. Antunes<sup>1</sup>, S. Germano<sup>1</sup>, S. Faustino<sup>1</sup>

<sup>1</sup>Hospital da Luz, Radiation Oncology, Lisbon, Portugal

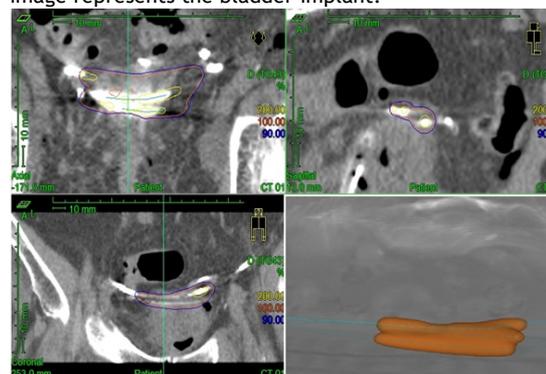

<sup>2</sup>Hospital da Luz, Urology, Lisbon, Portugal

#### Purpose or Objective

The standard treatment of muscle-invasive of the bladder cancer (MIBC) is radical cystectomy. A significant percentage of this population is elderly, with severe comorbidities, or without general conditions to radical cystectomy. Integrated brachytherapy in a multimodality conservative approach for bladder preservation is well established and is considered an alternative therapeutic option in selected cases.

#### Material and Methods

The authors present a clinical case of an elderly patient with a high grade stage T2aN0M0 bladder muscle-invasive carcinoma submitted to laparoscopic robot-assisted brachytherapy (LRAB) according the Arnhem Radiotherapy Institute, that developed specific catheters for this modality. The selection criteria, the clinical evaluation and all phases of the treatment procedure will be presented. Patient was submitted firstly to three cycles of neoadjuvant chemotherapy with carboplatin and gemcitabine followed by intensity modulated external radiotherapy for the pelvis including bladder and pelvic lymph nodes to a total dose of 40Gy in 20 fractions. After 3 weeks patient was submitted to a partial cystectomy and internal iliac lymph nodes dissection. Three Luneray catheters were inserted over the tumor bed in this surgical procedure and brachytherapy was performed beginning in the same day of surgery and completed in the following three days delivering 25Gy in 10 fractions. Following image represents the bladder implant.

The quality of the implant was evaluated using the homogeneity index (HI) and the overdose index (OI), according to the following formulas:

$$HI = (V_{100} - V_{150}) / V_{100} \times 100\%$$

$$OI = V_{200} / V_{100} \times 100\%$$

The first pulse of brachytherapy was administered on the same day of the catheters' implant. After the last pulse, the catheters were removed and then pulled out of the abdomen on the other side.

#### Results

For the present case, HI was 62,3% and OI was 19,7%. The excellent tolerance of the treatment and the absence of complications allowed the patient's hospital discharge the day after the final of brachytherapy. The withdrawal of Foley catheter was performed after 2 weeks. One month after the treatment, the previous symptoms were

completely improved and the patient is actually asymptomatic. The short follow-up ensures excellent acute tolerance and can predict the absence or minimal risk of late toxicity to treatment. **Conclusion**

This clinical case and the previously reported studies of LRAB revealing similar rates of tumor control and survival to radical cystectomy constitute a hope in terms of quality of life for the most minimally invasive conservative treatment in a selected group of patients with localized MIBC.

#### EP-1805 Interstitial and superficial brachytherapy for skin cancer

S. Brovchuk<sup>1</sup>, S. Romanenko<sup>1</sup>, N. Ratushnia<sup>1</sup>, O. Vaskevych<sup>1</sup>

<sup>1</sup>Kyiv Regional Oncology Dispensary, Radiotherapy department, Kyiv, Ukraine

#### Purpose or Objective

The main purpose of this work was to demonstrate the capabilities of brachytherapy in skin cancer treatment. Malignant skin lesions are highly frequent type of cancer. Between two main non-melanoma forms, basal cell carcinoma (BCC) and squamous cell carcinoma (SCC), BCC accounts for about 70%, and SCC of about 30%. And while, in our practice, for treatment of SCC in some cases external beam radiotherapy (EBRT) was required to irradiate regional lymph nodes, BCC, which is almost always local, is perfectly suitable for monobrachytherapy treatment.

#### Material and Methods

In 70% of cases (in our practice more than that) skin tumors are located on head and neck, where high conformity is extremely important. If invasion of a tumor was less than 5 mm deep, accommodated to the surface mold applications were used, if invasion of a tumor 5 mm or more, interstitial implants were used (the examples are presented on Image 1).

Radiation dose was delivered using high dose rate (HDR) afterloader with Ir192 radioactive source and was prescribed in case of BCC at 0.5 cm from visible lesion (growth tumor volume GTV), the enclosed volume corresponds to clinical tumor volume (CTV), in case of SCC at 1-1.5 cm from GTV the enclosed volume corresponds to CTV (planning tumor volume PTV=CTV).

Dose fractionation (every day treatment, 5 days per week):

for BCC cases - dose per fraction (fr) 4Gy in 2 cases and the total dose (TD) of 48Gy (12fr), 5.2Gy per fraction in 39 cases and TD=41.6Gy (8fr), 6Gy per fraction in 5 cases and TD=42Gy(7fr);

for SCC cases - dose per fraction 5.2Gy in 5 cases and TD=46.8Gy (9fr), dose per fraction in 6.3Gy 2 cases and TD=44.1Gy(7fr).

Equivalent dose to standard fractionation was about 58-60 Gy (a/b ratio was taken 6-7Gy (BCC) and 10Gy (SCC)). Treatment planning was performed on CT images, the ratio of CTV that received 150% of the prescribed dose (CTV<sub>150</sub>) to CTV<sub>100</sub> was kept below 0.45 (CTV<sub>150</sub>/CTV<sub>100</sub><0.45), that constrain in interstitial technique, where radiation source is inside the tissue, is achieved when spacing between implants is about 1-1.2 cm.

#### Results

Totally 53 patients (46 - BCC cases, 7 - CSS cases) were treated according to the described method during clinical work in 2013 (clinical example is presented on Image 2); median follow-up 2.5 years (range from 2 to 3 years); 4 patients had local recurrence and one lymph node failure (3-BCC cases and 2 (1 local+1 lymph node) - CSS cases).

#### Conclusion

Brachytherapy method of delivering radiation dose is naturally the most conformal, which also is challenging, but using interstitial implants or, accommodated to the

skin surface, mold applications, gives good results. Dose per fraction of 6Gy and more lead to higher late complications (fibrosis in our experience).

#### EP-1806 HDR brachytherapy for superficial non-melanoma skin cancers.

C. De la Pinta<sup>1</sup>, T. Muñoz<sup>1</sup>, J. Dominguez<sup>1</sup>, A. Montero<sup>2</sup>

<sup>1</sup>Hospital Ramon y Cajal, Radiation Oncology, Madrid, Spain

<sup>2</sup>Radiation Oncology, Madrid, Spain

#### Purpose or Objective

The aim of this study was to evaluate the clinical and cosmetic outcomes in patients treated with high-dose-rate brachytherapy for non-melanoma skin cancer and disease-specific and overall survival.

#### Material and Methods

All patients referred for interstitial brachytherapy in our centre from 2007 to 2016 with non-melanoma skin cancer without distant metastases were retrospectively analysed (n=13). Median age was 7 years (range 54-88). Treatment consisted of brachytherapy alone (10p) or after surgery (3p). Patients with histologically confirmed squamous carcinoma (4p), and basal cell carcinoma (9p). All lesions were macroscopic. Lesions were located on the head and neck: nasal skin (5p), periocular skin (4p) and ear skin (4p). All patients were treated with interstitial brachytherapy median implant dose 53 Gy (range 45-66Gy).

Inclusion criteria were as follows: head and neck location and malignant tumors.

#### Results

From January 2007, 13 patients were treated. Median follow-up was 36 months (range 6-68 months), local control was achieved on clinical examination. Acute toxicities (8/13p) consisted of epithelitis grade 1 (2p) and grade 2 (6p). Cosmesis was good or excellent in 12p. Late skin hypopigmentation were observed in 7 patients. Not acute toxicities grades 3 or 4 were reported. Grade 4 complication rate for all patients was 7,6% (one patient presented skin necrosis)

Among 13 patients studied, 4 lost follow-up and they were excluded from the survival analysis.

Preservation of organ functions were in all patients. Using Kaplan-Meier analysis overall survival after minimum follow-up of 36 months was 93% and disease-free survival was 75%. One patient had a locoregional recurrence.

#### Conclusion

Interstitial brachytherapy is a good choice to deliver high-dose radiation in tumor after surgery or as an exclusive treatment in non-melanoma skin cancers. This treatment offers adequate locoregional control with acceptable range of complications.

#### EP-1765 Volume delineation based on 18FDG-PET and MRI in head and neck cancer treated with IG-VMAT

L. Méndez Blanco<sup>1</sup>, C. Herrero<sup>2</sup>, M. Fueyo<sup>1</sup>, A. Martos<sup>1</sup>, D. Abad<sup>2</sup>, P. Santin<sup>1</sup>, S. Palizas<sup>1</sup>, D. Alonso<sup>1</sup>, A. Rios<sup>1</sup>, M. Vilches<sup>2</sup>, R. Cabanillas<sup>1</sup>

<sup>1</sup>Institute of Molecular and Oncological Medicine of Asturias, Radiation Oncology, Oviedo, Spain

<sup>2</sup>Institute of Molecular and Oncological Medicine of Asturias, Medical Physics, Oviedo, Spain

#### Purpose or Objective

Image Guided-Volumetric Modulated Arc Therapy (IG-VMAT) is being increasingly used to treat locally advanced head and neck cancers. In this context 18-FDG-PET and MRI are becoming especially useful for accurate target volume delineation.

#### Material and Methods

Between November 2012 and October 2015, 38 patients with head and neck carcinomas were treated at our

institution with IG-VMAT. Sites included were the nasopharynx (14), oropharynx (5), hypopharynx (4), larynx (6), paranasal sinuses and nasal cavity (3), thyroid (1), parotid (1) and metastatic neck nodes from an unknown primary (4). Each patient underwent endoscopy, contrast enhanced CT, MRI and 18-FDG PET scans. Plans were generated using two, three or four non-coplanar arcs for tumors originated in the skull base and coplanar arrangements for all other locations. Daily IGRT was performed using Exactrac X-ray 6D system and ConeBeam-CT. The gross target volume (GTV) was defined in imaging studies and a GTVpet was automatically created using a gradient method (42% SUVmax) and registered in planning CT. Diffusion MRI, contrast T1 and T2 were used to create a GTVmri. The clinical target volume (CTV) included all potential areas at risk for microscopic tumor spread, local and regional. PTVs were created adding a margin around GTVs and CTVs of 3-5mm. The average prescription dose to the GTVs was 70Gy and 54-60Gy for the CTVs. All treatment plans were planned with simultaneous integrated boost. Adaptive radiotherapy was used when necessary (17 cases).

#### Results

Mean age of the population was 60 years (24-83). Median follow-up was 30 months (range 12 to 48 months). The 3-year loco-regional control (LRC rates) was 97%. 9 patients died of distant disease progression. The dose delivered was 70Gy, 66Gy, 60Gy and 54Gy to the GTVprimary and positive nodes, GTVsuspicious nodes, CTVhigh risk, and CTVlow risk, respectively. Only 2% of the GTVs and 5% of CTVs received less than 95% of the prescribed dose. Only one patient with a larynx carcinoma (T3N2b) failed in a grossly positive node after definitive chemoradiotherapy. The remaining 37 patients experienced a complete response. No marginal failures have been observed to date. GTV targets delineated in the PET and MRI are different and complementary to each other and relative to the CT contrast, providing safer treatments while preserving the critical organs.

#### Conclusion

Accurate dose delivery is imperative in the setting of intensity modulated radiation therapy because of the sharp dose gradients generated. The proximity of tumors to critical organs requires advanced immobilization devices and the reduction of positional uncertainties. Our multidisciplinary approach in target volume definition and imaged guided radiotherapy resulted in excellent LRC and no marginal failures. The use of PETscan and MRI also demonstrated an improvement in target delineation.

#### EP-1807 Reducing Heart Toxicity In Medulloblastoma Using Proton Therapy

A. Madkhali<sup>1,2</sup>, M. Partridge<sup>1</sup>

<sup>1</sup>University of Oxford, Oncology, OXFORD, United Kingdom

<sup>2</sup>King Saud University, Medicine, Riyadh, Saudi Arabia

#### Purpose or Objective

Radiation therapy is known to cause acute and long term side effects. Some of those side effects are a major reason of mortality in cancer survivors. Heart disease after radiotherapy for Hodgkin and breast cancer patients is a major cause for mortality that it is offsetting the benefits of treatment (EBCTCG, 2016). In this work, potential benefits of using proton therapy in treatment of medulloblastoma to reduce heart toxicity is discussed and compared with benefit gained in reduction of secondary cancer.

#### Material and Methods

Increase in risk for rate of major coronary events for 3DCRT and proton plans for a patient with medulloblastoma (MB) was calculated using published model (Darby et al,2014), the NTCP for cardiac perfusion deficits was modelled using LKB model and relevant parameters (Das et al, 2005), and finally, the mortality risk from ischemic heart disease (IHD) was modelled using relative seriality model and relevant parameters (Kallman et al,1992, Eriksson et al,2000). Risk of mortality from radiotherapy-induced secondary cancer (SC) was modelled as well using voxel-by-voxel dose maps and models that includes cell-kill components, linear quadratic (LQ) and linear model (LIN) (Timlin et al,2015).

#### Results

The heart mean dose in 3DCRT was 16.1 Gy, and 0.1 Gy in the proton plan. Risk of major coronary events were 119% (3DCRT), 0.7% (proton). NTCP was 34.5%(3DCRT), 0.8%(proton). Risk of mortality from IHD was 1.61%(3DCRT) and 0.01%(proton), while mortality from SC was for 3DCRT: 1.08%(LQ), 0.10%(LIN) and for proton: 0.32%(LQ) and 0.03%(LIN)

#### Conclusion

Proton therapy for MB is expected to decrease risk of major cardiac events, mortality due to IHD and mortality from RT-induced secondary cancer significantly, when compared to 3DCRT. With cardiac late side effects being a major and important clinical burden post-RT, and some would say more than secondary cancer risk, these results strengthen the argument to use proton therapy.

**Electronic Poster: Radiobiology track: Normal tissue radiobiology (others)**

#### EP-1808 The response of human induced pluripotent stem cell- derived chondrocytes to ionizing radiation

E. Augustyniak<sup>1,2</sup>, W.M. Suchorska<sup>1,3</sup>

<sup>1</sup>Greater Poland Cancer Centre, Radiobiology Lab, Poznan, Poland

<sup>2</sup>Medical University of Warsaw, The Postgraduate School of Molecular Medicine, Warsaw, Poland

<sup>3</sup>Poznan University of Medical Sciences, Department of Electroradiology, Poznan, Poland

#### Purpose or Objective

The response of stem-derived cells to treatment with ionizing radiation (IR) is a questionable issue. It is worth mentioning that un- and differentiated cells possess different radiosensitivity. It is also unknown, whether the DDR mechanisms of stem-derived cells are more similar to those from 'parental' stem cells (SCs) or perhaps those from completely differentiated cells. Herein, we assume that differentiation process leading to obtaining of specialized cells have a significant effect on mechanisms activated in cells exposed to anticancer agents. We believe that it has a great impact on genetic stability of cells derived from SCs, what has a direct reflection in safety of application of these cells in clinical practice. The main goal of this study was to investigate the DDR of human induced pluripotent (hiPSC)-derived chondrocytes treated with IR.

#### Material and Methods

In the experiment three types of cell lines were used: hiPSCs, human articular chondrocytes and chondrocyte-like cells differentiated from hiPSCs. The investigated cells were treated with IR (0; 1; 2; 5 Gy) and collected 1, 5, 9 and 24 h after IR. Finally, the analyses of  $\gamma$ H2AX, and PARP by flow cytometry were performed. Moreover, we investigated the level of senescence in cells treated with IR.

## Results

These findings show that kinetics of DSBs significantly differ in hiPSCs, chondrocytes, and chondrocyte-like cells differentiated from hiPSCs. Nevertheless, the formation of DSBs in hiPSC-derived chondrocytes is similar to processes occurring in hiPSCs rather than in human articular chondrocytes. The hiPSCs and hiPSC-derived chondrocytes are very prone to DNA damage in comparison with fully mature chondrocytes. However, it is important to point out that hiPSC-derived chondrocytes possess more efficient DNA repair mechanisms resulting in the lower level of DSBs after 24h, in contrast to hiPSCs. Consequently, hiPSC-derived chondrocytes did not easily undergo apoptosis as hiPSCs. Nevertheless, the hiPSC-derived chondrocytes also reveal increased level of cells undergoing senescence.

## Conclusion

The genetic integrity of pluripotent SCs and their derivatives is very relevant due to the unavoidable exposure of SCs to genotoxic and cytotoxic agents during diagnostic procedures, as well as during anti-cancer therapies. For that reason, further studies concerning the safety of stem and stem-derived cells treated with IR are required.

## EP-1809 Effect of thalidomide on radiation-induced urinary bladder dysfunction

J. Kowaliuk<sup>1</sup>, E. Bozaky<sup>2</sup>, S. Sarsarshahi<sup>1</sup>, P. Kuess<sup>3</sup>, W. Dörr<sup>2</sup>

<sup>1</sup>Medical University of Vienna, Department of Radiotherapy- ATRAB - Applied and Translational Radiobiology, Vienna, Austria

<sup>2</sup>Medical University of Vienna, Department of Radiotherapy- ATRAB - Applied and Translational Radiobiology and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

<sup>3</sup>Medical University of Vienna, Department of Radiotherapy - Christian Doppler Laboratory for Medical Radiation Physics for Radiation Oncology, Vienna, Austria

## Purpose or Objective

The urinary bladder represents an important organ at risk during of radiotherapy pelvic tumors. Exposure to significant radiation doses results in the impairment of the biological function, presenting as a decrease in bladder capacity. Patients suffer from dysuria, urgency, incontinence, and increased micturition frequency, including nocturia. The radiation response occurs in three distinct phases: a reversible, biphasic early response, a symptom-free latent phase and an irreversible late phase eventually resulting in fibrosis. Local inflammatory processes are significantly involved in the pathogenesis of radiation response, with a potentially central role of the transcription factor NF- $\kappa$ B. Therefore, thalidomide, a potent NF- $\kappa$ B inhibitor, is studied in a mouse model for its potential to prevent or alleviate bladder dysfunction.

## Material and Methods

This preclinical study was performed in a well-established mouse model. Groups of female mice of the C3H/Neu strain were subjected to local single dose irradiation of the urinary bladder with graded doses in order to generate complete dose-effect curves. Bladder compliance was determined by transurethral cystometry - defining the bladder capacity at an intravesical pressure of 10 mm Hg - in 3-day intervals in the early response phase (day 0-30 p. irr) and subsequently at 4-week intervals until day 360.

The “mouse toilet”, designed to record individual urinations of the mice for analyses of micturition frequency and volume per micturition, was used on a monthly basis. Thalidomide was applied intraperitoneally, at a daily dose of 100 mg/kg over various time intervals in early and latent phase.

## Results

Preliminary results demonstrate that thalidomide clearly reduces radiation-induced functional urinary bladder changes. Daily administration from day 0 - day 15 or day 15 - day 30 significantly reduced the number of responding mice (response: >50 % reduction in bladder capacity). Furthermore, the maximum reduction in bladder capacity was less pronounced in thalidomide treated vs. only irradiated untreated mice.

## Conclusion

The preliminary data indicate that thalidomide has a clear potential to alleviate radiation-induced urinary bladder function impairment in the early phase. This illustrated the crucial involvement of NF- $\kappa$ B in the pathogenesis of the early changes. This will further be confirmed in mechanistic, immunohistochemical investigations. The consequences of the early thalidomide treatment, as well as of administration in the latent phase, on late effects are subject to ongoing studies. Data will be presented.

## EP-1810 Both location and complexity of DNA damage contribute to radiation induced senescence

J. Wang<sup>1</sup>

<sup>1</sup>Institute of Modern Physics- Chinese Academy of Sciences, Biophysics, Lanzhou, China

## Purpose or Objective

Cellular senescence was involved in aging by irreversible loss of proliferative potential. It causes inhibition of cell growth and reduction of cellular function. However, the molecular bases of the DNA damage and their contribution to cellular senescence are not completely clear. The purpose of this study is to investigate the significant role of persistent DNA damage response (DDR) in cellular senescence induced by different kinds of ionizing radiation.

## Material and Methods

By measuring senescence associated- $\beta$ -galactosidase, cell proliferation, activity of Ki67, the number of XRCC1 foci and 53BP1 foci, we identified that heavy ions (including carbon ions, iron ions) and X-rays irradiation could induce senescence in human uveal melanoma 92-1 cells.

## Results

We found that heavy ions were more effective at inducing senescence than X-rays. It was observed that with the repairing of DNA damage, the percentage of 53BP1 foci co-localized with telomeres continually increased and reached to 30% for X-rays at the 5th day after irradiation while the percentage of 53BP1 foci co-localized with telomeres remained steadily around 15% for carbon ions irradiation, implying that the persistent DNA damage induced by X-rays was preferentially associated with telomeric DNA and the telomere-favored persistent DNA damage mainly contributed to cellular senescence induced by X-rays. For heavy ions, less efficient repair of DNA damage was observed and most of the irreparable damage was the complex of single strand breaks and double strand breaks, suggesting that DNA damage induced by heavy ion was often complex and difficult to repair, thus presented as persistent DNA damage and pushed the cells into senescence. In contrast, DNA damage induced by X-rays was mostly repaired in 24 hours.

### Conclusion

In conclusion, both location and complexity of DNA damage contribute to cellular senescence induced by ionizing radiation. These deepening interpretation of cellular senescence following exposure to different kinds of ionizing radiation will provide new insights into the link of DNA damage and aging which is relevant to radiotherapy.

**Electronic Poster: RTT track: Patient preparation, positioning and immobilisation**

### EP-1811 Aligning the chest with a couch improved reproducibility in radiotherapy for head and neck cancers

K. Koiwai<sup>1</sup>, A. Shinoda<sup>1</sup>, T. Ozawa<sup>1</sup>, H. Matsushita<sup>1</sup>, A. Fukazawa<sup>1</sup>, K. Sakai<sup>1</sup>, M. Kadoya<sup>1</sup>

<sup>1</sup>Shinshu University School of Med., Radiology, Matsumoto, Japan

#### Purpose or Objective

In radiotherapy for head and neck cancers, postural reproducibility is sometimes deteriorated due to the non-rigidity of the head and neck. Image-guided corrections cannot completely compensate for the deterioration. We evaluated whether aligning the chest with a treatment couch just before immobilisation improved the postural reproducibility in radiotherapy for head and neck cancers.

#### Material and Methods

Fifty patients with head and neck cancers who underwent radiotherapy from February 2015 to January 2016 were selected for this study. Twenty five patients were treated with the "aligning-the-chest" method, and others not. When we acquired planning CT images of the patients with the aligning-the-chest method, we drew marks on the skin of their anterior chest in line with the fixed marks on the both sides of the couch of the CT scanner which were geometrically the same as on the treatment couch. On the set-up for the treatment, the marks on their chest were aligned with the fixed marks on the both sides of the treatment couch just before immobilisation. For all patients, 2 oblique X-ray images (image 1 and image 2) were obtained on the first session of the treatment. We generated digital reconstructed radiographies (DRRs) representing an ideal posture from the planning CT images with the maximal similarity to the corresponding X-ray images with 6 degree-of-freedom registration. On the both X-ray images and DRRs, we measured the mandibulo-spinal angle that was defined as the angle formed by the line projected parallel to the base of the mandible and the line projected parallel to the alignment of the lower cervical spine. As an index for postural reproducibility, the difference of the mandibulo-spinal angle between the X-ray image and the DRR (DMSA) was calculated in each patient. The raw and absolute DMSA were analysed.

#### Results

In the mean value of the raw DMSA, there was no difference between the patients with the aligning-the-chest method and without the method (image 1 and 2, -0.5° vs. 1.7° and 1.2° vs. 3.0°,  $p = 0.1713$  and  $p = 0.1072$ , respectively). The mean value of the absolute DMSA in the patients with the aligning-the-chest method was significantly smaller than that in the patients without the method (image 1 and 2, 1.3° vs. 4.7° and 2.0° vs. 5.7°,  $p = 0.0004$  and  $p < 0.0001$ , respectively).

#### Conclusion

Aligning the chest with a treatment couch before immobilisation improved postural reproducibility in radiotherapy for head and neck cancers.

### EP-1812 A study on the patient positioning accuracy for stereotactic radiotherapy of brain lesions

O. Pashkovskaya<sup>1</sup>, E. Polovnikov<sup>1</sup>

<sup>1</sup>NSRICP, Oncology and radiotherapy, Novosibirsk, Russian Federation

#### Purpose or Objective

The purpose of this study is an investigation of the patient positioning accuracy (inter-fraction and intra-fraction shifts) for stereotactic radiation treatment of the brain lesions using invasive Leksell Coordinate Frame G®, non-invasive vacuum-activated head frame system HeadFix® and individual thermoplastic masks, and comparison position errors of these systems.

#### Material and Methods

A total of 532 patients, which were treated for benign and malignant brain tumors in our center, represented study population. The invasive Leksell Coordinate Frame G® (LFG), vacuum-activated head frame system HeadFix® (HF) and individual thermoplastic masks (TM) were used to immobilize patients during pre-radiation preparation and radiation treatment. Dose distributions were typically planned with a volumetric modulated arc therapy technique and noncoplanar arcs if needed for optimal dose distributions. Positioning accuracy was estimated using linac-mounted cone beam computer tomography (CBCT) scan system. The target intra-fraction offsets were determined by comparison target positions before and after the irradiation procedures with planning positions. To determine inter-fraction shifts data from daily CBCT scans were used. Statistical samples of target offsets in six coordinates were collected and statistical analysis was carried out.

#### Results

For 386 patients TMs were used, for 31 LFG and for others 115 HF. Analysis of inter-fraction shifts, based on scatterplots, showed no significant correlations and selected systematic errors in patient's positioning. Quantitative estimations of mean values and standard deviations also demonstrated acceptable accuracy. It was concluded that it's necessary to do daily CBCT control, if shifts at least in one direction are greater or close to 5 mm during first four procedures. This is due to patient's specific characteristic and TM doesn't provide sufficient immobilization. Mask remaking does not always solve the problem. As the result of intra-fraction offset estimations, the position errors for LFG and HF were less than 0.3 mm in coordinates and less than 0.3 degrees in rotation.

#### Conclusion

Study of inter-fraction shifts showed that TMs provide acceptable setup reproducibility, as consistent with PTV. With respect to intra-fraction shifts, due to the slight differences of the offset error results, the choice between LFG and HF should be determined by the individual patient characteristics and does not affect on the accuracy of the delivered dose.

### EP-1813 The investigation of the immobilization devices and localization methods for brain cancer in P-SRS.

R.D. Lin<sup>1</sup>, J. Gao<sup>1</sup>, P. Chen<sup>1</sup>

<sup>1</sup>Chang Gung medical hospital, Proton and radiation therapy center, Taoyuan, Taiwan

#### Purpose or Objective

There are two aims of this study: one is to assess the accuracy of the Base of Skull (BoS) immobilization cast and BRW heading for proton stereotactic radiosurgery (P-SRS). The other one is to investigate the accuracy of imaging-guided localization method by using bony structure and fiducial markers as different landmarks.

#### Material and Methods

To assess the accuracy of the immobilization devices, we immobilized the CIRS Radiosurgery Head Phantom with hidden target by BoS cast and heading, respectively. Then we implemented the imaging guidance by using bony structure. Compare to the localization method, the CIRS Radiosurgery Head Phantom with hidden target was immobilized by heading followed by implementation of the imaging guided process using bony structure and fiducial markers, respectively. The overall couch shifts were performed by the radiation therapists, the deviation with respect to the proton isocenter was measured by using the hidden target with paired t-test and 3D vector.

#### Results

For BoS cast and heading, the deviations (mm) were  $0.54 \pm 0.68$  and  $0.48 \pm 0.28$  ( $p=0.412$ ) in right-left (RL),  $0.22 \pm 0.28$  and  $-0.11 \pm 0.34$  ( $p=0.186$ ) in superior-inferior (SI),  $-0.30 \pm 0.11$  and  $-0.15 \pm 0.22$  ( $p=0.167$ ) in anterior-posterior (AP) directions, and  $0.85 \pm 0.42$  and  $0.60 \pm 0.32$  ( $p=0.017$ ) in 3D vector, respectively. For the imaging-guided localization method, the deviations (mm) of bony structure and fiducial markers were  $-0.29 \pm 0.65$  and  $0.19 \pm 0.34$  ( $p=0.002$ ) in RL,  $-0.14 \pm 0.53$  and  $0.01 \pm 0.12$  ( $p=0.126$ ) in SI,  $-0.01 \pm 0.42$  and  $0.10 \pm 0.25$  ( $p=0.219$ ) in AP directions, and  $0.84 \pm 0.48$  and  $0.41 \pm 0.23$  ( $p=0.004$ ) in 3D vector, respectively.

#### Conclusion

Translational deviations were not statistically significant between the immobilization methods or imaging-guided landmarks. However, there were significant differences in 3D vector. The results of our study demonstrated that heading and fiducial markers can achieve good accuracy for brain cancer in proton stereotactic radiosurgery (P-SRS).

#### EP-1814 Is AIO belly board device advantageous in all irradiated rectal cancer patients?

D. Hempel<sup>1</sup>, J. Mandrosz<sup>1</sup>, J. Topczewska-Bruns<sup>1</sup>, D. Kazberuk<sup>1</sup>, A. Szmigiel-Trzcńska<sup>1</sup>, R. Maksim<sup>1</sup>, M. Konopka-Filippow<sup>1</sup>, T. Filipowski<sup>1</sup>, M.Z. Wojtukiewicz<sup>2</sup>, E. Sierko<sup>2</sup>

<sup>1</sup>Comprehensive Cancer Center, Department of Radiotherapy, Białystok, Poland

<sup>2</sup>Comprehensive Cancer Center, Department of Clinical Oncology, Białystok, Poland

#### Purpose or Objective

A prospective study was undertaken to compare prone on flat table position vs on "All in one" belly board device (AIO BBD) by assessment of patients' preferences, irradiated small bowel and bladder volume (SB-V, B-V) as well as setup accuracy in rectal cancer patients (RCPs).

#### Material and Methods

Material and methods: Fifteen RCPs scheduled to irradiation on pelvic area (preoperative,  $n = 11$  and postoperative,  $n = 4$ ) were scanned twice: in prone on flat table and prone on AIO BBD position. Patients were asked to complete an institution-developed questionnaire concerning their perception of the positioning. Using 3D planning system the dose-volume histograms (DVHs) for SB and B were compared in two treatment plans. Setup accuracy of bony anatomy and pelvic organs were analyzed in MV-portals and X-ray volume imaging (XVI) procedures, respectively for on AIO BBD - positioned patients ( $n = 14$ ).

#### Results

AIO BBD was accepted as immobilization method by majority of RCPs and provided better DVHs for SB than prone on flat table position. The setup reproducibility was good, within tolerance limit for patients with BMI  $\leq 29$  kg/m<sup>2</sup>. However, two patients with obesity regarded AIO BBD as uncomfortable and they presented mean setup shifts out of tolerance limit in Y axis - 5.9 mm. The another

obese patient was disqualified from irradiation on AIO BBD due to more beneficial DVH for SB in prone on flat table position.

#### Conclusion

The AIO BBD should be recommended as immobilization method in RCPs with BMI  $\leq 29$  kg/m<sup>2</sup>. Immobilization of obese patients on AIO BBD may be uncomfortable for them, cause worse dose-volume distribution in SB and /or result in unacceptable setup shifts.

#### EP-1815 Technical aspects and setup irradiation of rats using a clinical accelerator

V. SACCO<sup>1</sup>, A. Viale<sup>1</sup>, B. Noris Chiorda<sup>1</sup>, C. Sini<sup>2</sup>, G. Salvadori<sup>1</sup>, C. Fiorino<sup>2</sup>, N. Di Muzio<sup>1</sup>, C. Cozzarini<sup>1</sup>

<sup>1</sup>Nuova Fondazione Centro San Raffaele, Radiotherapy, Milano, Italy

<sup>2</sup>Nuova Fondazione Centro San Raffaele, Medical Physics, Milano, Italy

#### Purpose or Objective

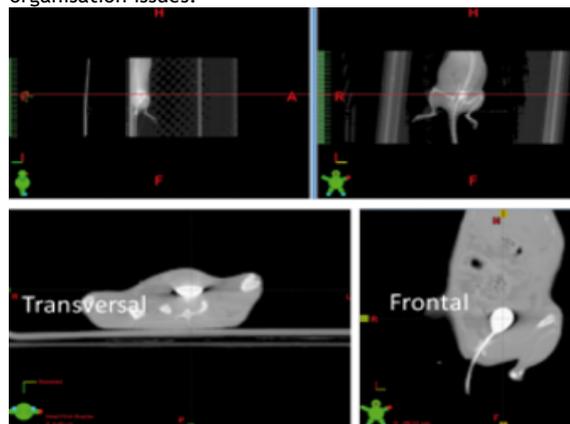

A preclinical study having the aim to test the possible hormone protective role on radio-induced inflammation of the bladder wall has been conceived in our centre using a rat model.

This kind of application usually requires a dedicated microlinac to deliver radiotherapy to small animals. However, this device is not available in our hospital.

The purpose of this study is to set up a system allowing to irradiate rats by a clinical accelerator, with a positioning system that ensures the reproducibility of the treatment.

#### Material and Methods

Eight male rats were surgically catheterized, anesthetized, immobilized within small containers in plastic material, and positioned on the clinical accelerator bed (RapidArc® - Varian Medical Systems). The isocentre was placed on the abdomen of the animals, with a source-to-skin distance (SSD) of 100 cm. A kilovoltage cone-beam CT was acquired in order to image the bladder, previously filled by injecting Gastrografin. The treatment field was defined by assigning an expansion of 3 mm to the bladder on the coronal projection of the cone-beam CT. After positioning of a bolus of 1 cm on the abdomen of the animals, a single fraction of 20 Gy was delivered with 6 MV photons. A single fraction treatment was decided to avoid the need of repeated irradiations that would complicate organisation issues.

#### Results

The animals were successfully treated and well tolerated radiotherapy, being alive after 6 months of irradiation. The shift difference between the cone beam CT reconstruction and the manual correction of the radiotherapist was calculated. The values measured in the group of animals were expressed in three dimensional shifts (along X,Y,Z IEC coordinates, in cm), as mean values  $\pm$  standard deviations: X =  $-0.13 \pm 0.10$ ; Y =  $0.13 \pm 0.08$ ; Z =  $0.13 \pm 0.12$ .

### Conclusion

In absence of a dedicated microlinac, animal radiation treatments with a selective irradiation of the bladder are feasible using a clinical accelerator and a single fraction. The animals well tolerated radiotherapy, and are alive after 6 months of irradiation. The use of animals for experimental purposes has been approved by the Institutional Animal Care and Use Committee (IACUC 698) and by the Ethics Committee of our Institute.

### EP-1816 Neck positioning reproducibility of different pillow types in head and neck cancer patients

W.H. Yu<sup>1</sup>, C.Y. Lin<sup>1</sup>, J.T.C. Chang<sup>1</sup>

<sup>1</sup>*Chang Gung medical hospital, Radiation oncology, Taoyuan, Taiwan*

#### Purpose or Objective

The purpose of this study was to evaluate the angular displacement angle of cervical vertebrae in radiotherapy to head and neck (H&N) cancer patients by using different types of immobilized pillow.

#### Material and Methods

Seventy-four H&N cancer patients were randomized to three different types of immobilized pillow: 28 for routine pillow (Silver Headrests, CIVCO, medical solution), 23 for home-made customized alpha cradle pillow and 23 for Moldcare pillow. On-board images (OBIs) during the first 23 treatment fractions were registered and fused with the digitally reconstructed radiographs (DRRs). The angular displacement of first to fifth cervical vertebrae were recorded.

#### Results

There was no significant difference of the C1-C5 angular displacement in three different types of pillows with  $2.79 \pm 1.72$  degrees in the routine pillow group,  $2.54 \pm 1.68$  degrees in home-made customized alpha cradle pillow group,  $3.17 \pm 2.32$  degrees in Moldcare pillow group.

#### Conclusion

The patients in home-made customized alpha cradle pillow group had smallest neck angular displacement. However there were no significant difference and the reproducibilities of all three pillow types were good. Further evaluation about the clinical use of customized pillows is needed.

### EP-1817 Breast set-up: Assessing two immobilization systems

V. Lancellotta<sup>1</sup>, A.M. Tini<sup>1</sup>, S. Saccia<sup>1</sup>, S. Trinari<sup>1</sup>, S. Dazzini<sup>1</sup>, G. Verzini<sup>1</sup>, N. Mearelli<sup>1</sup>, V. Bini<sup>1</sup>, A. Cavalli<sup>1</sup>, E. Perrucci<sup>1</sup>, C. Aristei<sup>1</sup>

<sup>1</sup>*Ospedale Santa Maria della Misericordia, Radiation Oncology, Perugia, Italy*

#### Purpose or Objective

In breast cancer radiotherapy, an optimal patient set-up is essential to reduce the gap between personalized treatment planning and uncertainties in irradiation administration. In fact, several factors worsen reproducibility, with the most important being poor patient immobilization and lack of a quality assurance system at all steps of the radiotherapy procedure. The aim of our study was to investigate whether the breast board or the arm shuttle provided the best support for a correct patient set-up during irradiation to for breast cancer.

#### Material and Methods

Between November 2012 and December 2014, 28 women, median age 62 years (range 34-88) underwent RT to breast/chest wall plus level III and IV lymph nodes (2 Gy single dose in 25 fractions for a total dose of 50 Gy). Each patient was placed in the same position i.e. supine with arms raised. Thirteen were supported by a non-inclined breast board and 15 by an arm shuttle. The breast board

has several adjustable features to allow for the manipulation of patients arms, wrists, head and shoulders. Furthermore, the presence of head and neck supports in different heights and contours to attain the desired head angulation and/or neck position. Multiple head rest positions in the arm-shuttle provided flexible positions for the head and arms without different heights and contours to attain the desired head angulation and/or neck position. Helical tomotherapy was used to treat all patients. HT planning parameters were: 5 cm field width (FW), 0.287 pitch, and 2.7 - 3 modulation factor (MF). Daily use of CT-MV image-guided RT corrected set-up errors. For each patient, we reported the pitch, yaw and roll values and the x, y and z axis displacements. Statistical analysis used the Mann-Witney test.

#### Results

Table 1 reports pitch, yaw and roll averages and the average displacement on the X, Y and Z axes with the breast board and arm shuttle as well as the significant differences which emerged from the statistical analysis.

#### Conclusion

Compared with the arm shuttle, the breast board provided a better set-up in breast cancer patients undergoing HT irradiation to the breast/chest wall plus draining nodes. Since these results are linked to breast board configuration, its use is now standard in our RT Centre.

### Electronic Poster: RTT track: Imaging acquisition and registration, OAR and target definition

### EP-1818 The rate of a doctor's progress in a learning curve in delineation of hippocampus

M. Konopka-Filippow<sup>1,2</sup>, E. Sierko<sup>1,2,3</sup>, D. Hempel<sup>1</sup>, R. Maksim<sup>1</sup>, T. Filipowski<sup>1</sup>, E. Rożkowska<sup>1</sup>, S. Jelski<sup>4</sup>, B. Kasproicz<sup>4</sup>, E. Karbowska<sup>4</sup>, N. Samolyk<sup>1</sup>, M.Z. Wojtukiewicz<sup>3</sup>

<sup>1</sup>*Comprehensive Cancer Center in Bialystok- Poland, Department of Radiotherapy, Bialystok, Poland*

<sup>2</sup>*Medical University of Bialystok- Poland, Department of Oncology, Bialystok, Poland*

<sup>3</sup>*Comprehensive Cancer Center in Bialystok- Poland, Department of Clinical Oncology, Bialystok, Poland*

<sup>4</sup>*Comprehensive Cancer Center in Bialystok- Poland, Department of Radiology, Bialystok, Poland*

#### Purpose or Objective

Brain radiotherapy (RT) is associated with damage of neural progenitor cells situated in subgranular zone of the hippocampus, which causes neurocognitive decline. Sparing hippocampus during cranial RT could avoid this complication in the group of cancer patients and improve their quality of life (QoL).

Accurate hippocampus contouring is an essential for appropriate brain RT planning with sparing this structure and its an prerequisite of quality assurance in RT.

#### Material and Methods

Ten doctors (7 radiation oncologist and 3 radiologists) delineated left and right hippocampus (LH and RH, respectively) on the 10 patient's virtual axial images of CT brain fusion with the T1 sequence of MRI (1mm) according to the RTOG 0933 atlas recommendations. Two hundred contours of hippocampus were achieved. Deviations in the spatial localization of the structure were described in the three directions: right-left (X), cranio-caudal (Y), forward-backward (Z) in relation to the most adequate contoured hippocampus according to RTOG atlas references, which was delineated by an experienced radiation oncologist.

#### Results

Variability of hippocampus body contouring concerned: the spatial localization, shape, volume and the dimension of the hippocampus in the X, Y and Z axes. The largest

differences were noted in the first three contoured cases: the Z-axis deviation exceeded 5 mm in more than half of hippocampus contours and hippocampal volume were larger than in later defined seven cases. The volume of LH in more than half hippocampus contours was slightly bigger than the RH (1.9 cm<sup>3</sup> vs. 1.8 cm<sup>3</sup>). Most differences in contouring of hippocampus were observed in the area of posterior horn of the lateral ventricle. Contrary, a large number of hippocampal outlines overlapped with each other near brainstem and anterior horn of the lateral ventricle. The average dimension of the hippocampus were 1.7 cm and 0.9 cm in the Z and X axes, respectively.

#### Conclusion

The proper contouring of hippocampus is difficult for the beginner's physicians. The training in delineating this organ at risk under the supervision of experienced radiation oncologist is strongly needed to achieve optimal results in hippocampus sparing procedure, which in consequence would result in improving QoL of the patients.

#### EP-1819 EORTC RTT Delineation Project: improving volume definition of OAR within the EORTC Lungtech trial

M. Van Os<sup>1</sup>, M. Rossi<sup>2</sup>, C. Hurkmans<sup>3</sup>

<sup>1</sup>Erasmus MC Cancer Institute, Department of Radiation Oncology, Rotterdam, The Netherlands

<sup>2</sup>Netherlands Cancer Institute, Radiation Oncology Department, Amsterdam, The Netherlands

<sup>3</sup>Catharina Ziekenhuis Eindhoven, Radiation Oncology, Eindhoven, The Netherlands

#### Purpose or Objective

To accurately evaluate toxicity within a trial, it is important that the delineation of the Organs at risk (OAR) is performed consistently.

The aim of the EORTC ROG/RTT delineation project is to reduce variability in OAR delineation to allow better comparison of toxicity in EORTC trials between institutes. Within the EORTC LungTech trial we evaluated whether provided delineation guidelines are explicit enough to avoid misinterpretation in volume definition of OAR and whether a hands-on delineation workshop adds to this.

#### Material and Methods

A questionnaire was developed and distributed amongst participating institutes requesting feedback after they had completed their benchmark delineation for the EORTC LungTech trial. Difficult areas could be identified. Subsequently two groups were defined: Group A to perform delineation of OAR according to protocol guidelines and with additional visual guidelines. Group B was invited to a delineation workshop where an expert teacher addressed the difficult areas provided from the benchmark cases. The consequent delineations were then evaluated per organ at risk between group A and B and also compared to the benchmark cases. The volume of agreement was calculated.

Our hypothesis is that a delineation workshop prior to launching a trial improves consistent volume definition.

#### Results

Introducing visual guidelines as an extra aid to the written guidelines significantly reduced misinterpretation and greatly improves the consensus of delineation. Although not specifically tested between the groups the RTT's performance in delineating the OARs was deemed as consistent as the clinicians. We aim to demonstrate the additional value of teaching by means of a delineation workshop, but this analysis is still ongoing.

#### Conclusion

The EORTC ROG advised to involve RTTs in future EORTC trials for volume definition of OAR.

In future EORTC trials, a kick-off including a delineation workshop for participating institutes is planned to achieve more consistent delineation of OAR.

#### Electronic Poster: RTT track: Treatment planning and dose calculation / QC and QA

#### EP-1820 RapidArc vs IMRT in adjuvant gastric cancer irradiation: any dosimetric advantage?

K. Mashhour<sup>1</sup>, W. Hashem<sup>1</sup>, R. Fawzy<sup>1</sup>, H. Abdelghany<sup>2</sup>

<sup>1</sup>Kasr el ainy school of medicine-Cairo university, clinical oncology, cairo, Egypt

<sup>2</sup>Kasr el ainy school of medicine-Cairo university, radiation physics, cairo, Egypt

#### Purpose or Objective

The outcome of intensity modulated radiation therapy (IMRT) plans depends on the choice of number of fields, beam orientations, optimization algorithms & planner experience. The RapidArc has the characteristics of both good plan quality as well as high delivery efficiency. The purpose of this work was to compare dosimetric endpoints between IMRT & RapidArc techniques for gastric carcinoma patients in the adjuvant setting.

#### Material and Methods

Twenty gastric cancer patients who had a radical gastrectomy with D2 dissection were eligible. The clinical target volume (CTV) included the gastric bed, anastomosis with 2-cm proximal/distal margins & regional LN areas. The planning target volume (PTV) consisted of CTV plus a 10 mm margin. All plans were created in the Eclipse treatment planning system (v8.6 Varian Medical System). For IMRT, a coplanar seven-field plan was performed. Regarding the RapidArc, plans were done using a double arc plan consisting of 2 co-planar arcs of 360° in clockwise & counter clockwise direction. Dose prescribed was 45 Gy to the PTV in 25 fractions using 6MV photons. The PTV dose coverage criteria were as follows: at least 95% of PTV received 45Gy; The conformity index (CI) & homogeneity index (HI) were calculated. The organs at risk (OAR) were the spinal cord, both kidneys and liver.

#### Results

Target coverage was similar for both techniques. The mean V95 was found to be 94.7% & 94.8% for the IMRT and RapidArc respectively (p = 0.32). The CI for IMRT and RapidArc were 0.93 ± 0.01 & 0.94 ± 0.01, respectively; while the HI was 1.15 ± 0.01 for IMRT & 1.14 ± 0.02 for RapidArc (both p > 0.04). All the plans met the required dose limitations. The maximum spinal cord dose for IMRT and RapidArc was 37.87 Gy vs 36.42 Gy (p = 0.34). For the right kidney, IMRT had significantly lower mean V20 (volume that receives 20 Gy) compared to RapidArc (23.2 vs. 30.3, p = 0.01). The mean V20 to the left kidney were 28.4 and 27.4 in the IMRT and RapidArc respectively (p = 0.01). The IMRT produced a similar liver mean V30 (volume that receives 30 Gy) (24.3 vs. 23.1, p = 0.52) to RapidArc. The treatment delivery time was 193.5 ± 25.0 s (range 157-230 s) to IMRT and 66.0 ± 8.7 s (range 55-77 s) to RapidArc (p = 0.00). The total monitor units (MU) for IMRT and RapidArc were 343.0 ± 94.0 & 363.0 ± 44.0 (p = 0.07), respectively.

#### Conclusion

RapidArc obtained similar dosimetric outcomes to IMRT plans regarding target coverage & OAR sparing with an advantage of shorter delivery time & lower number of MU.

### EP-1821 Air gap between patient surface and immobilization devices: dosimetric impact on H&N IMRT plans

S. Moragues-Femenia<sup>1</sup>, M. Pozo-Massó<sup>2</sup>, J.F. Calvo-Ortega<sup>2</sup>, J. Casals-Farran<sup>2</sup>

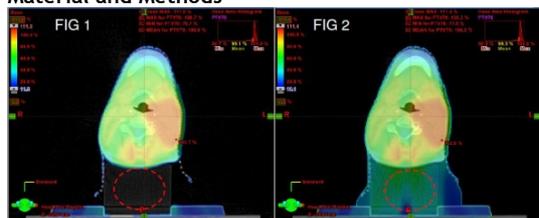

<sup>1</sup>Moragues Femenia Sandra, HOSPITAL QUIRON BARCELONA- Radiotherapy, Barcelona, Spain

<sup>2</sup>HOSPITAL QUIRON BARCELONA- Radiotherapy, HOSPITAL QUIRON BARCELONA- Radiotherapy, Barcelona, Spain

#### Purpose or Objective

In head and neck (H&N) treatments, there is an avoidable air gap between the typical mask-based immobilization device used and the patient surface ("air gap" from now on). Our aim is to evaluate the dosimetric effect of considering the "air gap" on the patient dose distribution on H&N IMRT plans.

#### Material and Methods

A total of 5 H&N patients were selected. The "immobilization" device consisted of a thermoplastic mask covering the head, neck and shoulders, and attached to a board on the linac couch. Targets (PTVs) and organs-at-risks (OARs: spinal cord, brainstem, optic nerves, parotids and oral cavity) were outlined in Eclipse TPS. The posterior aspect of patient skin was also contoured.

Two different approaches were proposed to define the "body structure": 1) the patient outer contour plus the immobilization device (Fig 1); and 2) as previous but also including the air gap between the immobilization device and the patient outer contour (Fig 2). Dose distributions were calculated using identical IMRT plans for each approach. The differences in the minimum (D98%), maximum (D2%) and mean (Dmean) doses to the PTVs and OARs as well as the skin mean doses were compared.

#### Results

Differences within  $\pm 1\%$  were found in the dosimetric parameters analyzed for PTVs and OARs. Mean skin was up to 2% greater when the gap air between patient surface was considered.

#### Conclusion

Little dose differences were observed between the approaches of including or not the air gap existing between the immobilization device and the patient surface.

### EP-1822 Monitoring of parotid gland changes in radiotherapy of NPC with parapharyngeal space involvement

W.C.V. Wu<sup>1</sup>, Y. Zhang<sup>2</sup>, C. Lin<sup>2</sup>, J. Wu<sup>2</sup>

<sup>1</sup>Hong Kong Polytechnic University, HTI, Kowloon- Hong Kong- SAR, China

<sup>2</sup>Sun Yat-sen University Cancer, Cancer Hospital, Guangzhou, China

#### Purpose or Objective

Parapharyngeal space (PPS) involvement is present in over 70% of nasopharyngeal carcinoma (NPC) patients. Since PPS is close to parotid gland, a radical course of radiotherapy for this group of patients may deliver high dose to this organ. The purpose of this study was to evaluate the parotid gland changes of NPC patients with PPS involvement during radiotherapy and up to 3 months after treatment.

#### Material and Methods

Kilovoltage computed tomography (CT) scans of head and neck region of 39 NPC patients with PPS involvement recruited from Sun Yat-sen University Cancer Center between January 2011 and April 2013 were performed at pre-radiotherapy, 10<sup>th</sup>, 20<sup>th</sup> and 30<sup>th</sup> fractions, and 3 months after treatment. All patients were treated with intensity modulated radiotherapy using 6 MV photons with prescribed doses of 66-70 Gy to the target volume. The parotid glands were contoured in pre-radiotherapy planning CT scan and in subsequent scans. At each time interval, DICE similarity coefficient (DSC), percentage volume change and centroid movement between the planning CT and the subsequent CTs were obtained from the contouring software. In addition, the distance between medial and lateral borders of parotid glands from the midline at various time intervals were also measured.

#### Results

The ipsilateral parotid gland received a mean dose of about 5 Gy higher than the contralateral side ( $56.3 \pm 6.2$  Gy vs  $51.7 \pm 9.2$  Gy). The mean DSC for ipsilateral parotid gland decreased to 0.63 at 30<sup>th</sup> fraction and returned to 0.74 at 3 months after treatment. Partial recovery was observed at 3 months after treatment. All differences between each pair of consecutive measurements (such as between 10<sup>th</sup> and 20<sup>th</sup> fractions and 20<sup>th</sup> and 30<sup>th</sup> fractions) were statistically significant ( $p < 0.05$ ). The mean volume change for ipsilateral parotid gland decreased from -15.27% at 20<sup>th</sup> fraction to -37.49% at 30<sup>th</sup> fraction and partially recovered to -23.14% in 3 months. There were no significant differences between ipsilateral and contralateral groups despite the changes in the ipsilateral side being relatively greater. The centroid displacement followed a similar pattern, which moved medially and superiorly by an average of 0.30 cm and 0.18 cm respectively at 30<sup>th</sup> fraction. The changes in ipsilateral gland were slightly greater than the contralateral side.

#### Conclusion

In radiotherapy of NPC patients with PPS involvement, the parotid gland shrank by about 1/3 towards the end of the treatment course. DSC and percentage volume changes of both ipsilateral and contralateral parotid glands decreased during the radiotherapy course and partially recovered in 3 months after treatment. This trend was also seen in the displacements of centroids and the medial and lateral borders of the gland. A re-planning was suggested at around 15<sup>th</sup> to 20<sup>th</sup> fraction so as to reduce the dose to the parotid gland due to the detected movement of this structure during the radiotherapy course.

### EP-1823 DVH- and NTCP-based dosimetric comparison of different margins for VMAT-IMRT of esophageal cancer

S. Münch<sup>1</sup>, M. Oechsner<sup>1</sup>, S.E. Combs<sup>1,2</sup>, D. Habermehl<sup>1</sup>

<sup>1</sup>Klinikum rechts der Isar- TU München, Radiation Oncology, München, Germany

<sup>2</sup>Institute of innovative radiotherapy iRT, Herzmoltz Zentrum, Oberschleißheim, Germany

#### Purpose or Objective

To cover the microscopic, longitudinal tumor spread in squamous cell carcinoma of the esophagus (SCC), longitudinal margins of 3-4 centimetres are used for neoadjuvant and definitive radiotherapy (RT) protocols. Therefore, RT of SCC is often done with large treatment volumes, which lead to high doses to the organs at risk (OAR). However, while the promising results of the CROSS-Trial, that used longitudinal margins of 4 cm, defined a new standard for neoadjuvant chemoradiation (CRT), a smaller margin of 3 cm might be reasonable, especially for early tumor stages.

Purpose of this study was to compare the dose distribution to the organs at risk for different longitudinal margins using a DVH- and NTC-based approach.

#### Material and Methods

10 patients with SCC of the middle or the lower third, who underwent CRT at our institution were retrospective selected. Three planning target volumes (PTV) were created for every patient, with an axial margin of 1.5 cm to the gross target volume (GTV) (primary tumor and PET-positive lymph nodes), analogous to the protocol of the CROSS-trial. The longitudinal margins were 4 cm, 3 cm and 2 cm, respectively. Contouring and treatment planning was performed with the Eclipse 13 planning system (Varian Medical Systems, Palo Alto, CA, USA). For every PTV, volumetric modulated arc therapy (VMAT) plans were optimized. Dose calculation was performed using the AAA algorithm (version 10.0.28) and heterogeneity correction. All plans were normalized to a median prescribed PTV dose of 41.4 Gy with a daily dose of 1.8 Gy. Dose to the lungs, heart and liver were evaluated and compared. Differences of dose parameters were tested for significance with t-test for paired samples.

#### Results

Median tumor length was 6 cm with a range of 3 to 10 cm and 8 of the 10 patients (80%) had lymph node metastasis. When using a longitudinal margin of 3 cm instead of 4 cm, all dose parameters (Dmin, Dmax, Dmean, Dmedian and V5-V35), except Dmax could be significantly reduced for the lungs. Regarding the heart, a significant reduction was seen for Dmean and V5, whereas no significant difference was seen for Dmin, Dmax, Dmedian and V10-V35. When comparing a longitudinal margin of 4 cm to a longitudinal margin of 2 cm, not only Dmin, Dmax, Dmean, Dmedian and V5-V35 for the lungs, but also Dmax, Dmin and V5-V35 for the heart were significantly reduced. Nevertheless, no difference was seen for the median heart dose. In addition, the risk of pneumonitis was significantly reduced by a margin reduction of 3 cm and 2 cm.

#### Conclusion

The reduction of the longitudinal margin from 4 cm to 3 cm can significantly reduce the dose to lungs, while the reduction to 2 cm can also reduce doses to the heart. Despite clinical benefit and oncologic outcome remain unclear, reduction of the longitudinal margins might provide the opportunity to reduce side effects of CRT for SCC in upcoming studies.

#### EP-1824 Elective breast RT including level I & II lymph nodes: A planning study with the humeral head as PRV

J. Van der Leer<sup>1</sup>, K. Surmann<sup>1</sup>, M. Van der Sangen<sup>1</sup>, M. Van Lieshout<sup>1</sup>, C.W. Hurkmans<sup>1</sup>

<sup>1</sup>Catharina Ziekenhuis, Radiotherapy, Eindhoven, The Netherlands

#### Purpose or Objective

The aim of this planning study was to determine a new technique for elective breast radiotherapy and level I and II lymph nodes following the new ESTRO delineation consensus guidelines. According to these guidelines the humeral head should be spared by introducing a planning risk volume (PRV) of the humeral head and connective tissue 10 mm around it.

#### Material and Methods

We included ten left sided breast cancer patients in our planning study in Pinnacle<sup>3</sup> v9.8. Each patient was planned with 16 x 2.66 Gy on the breast PTV (PTVp) and the elective level I and II lymph nodes (PTVn).

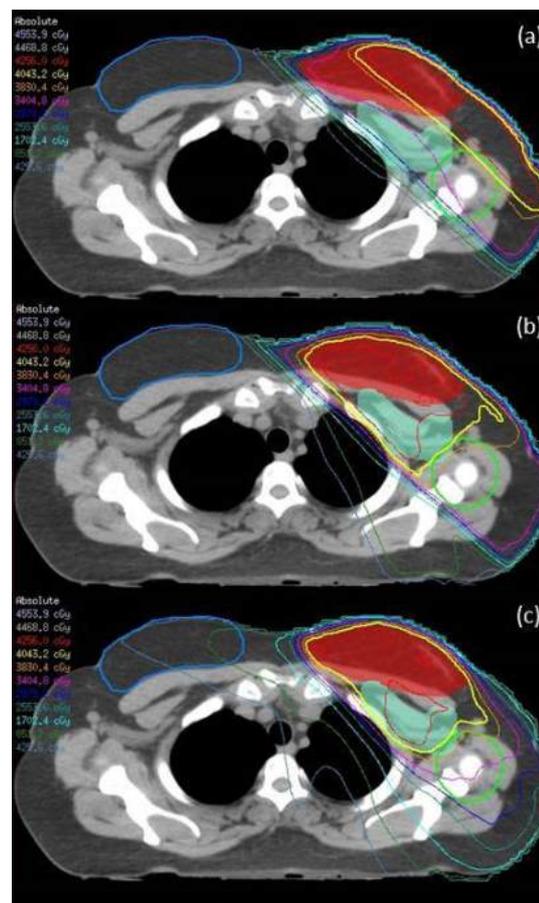

We compared three treatment planning techniques: high tangential field (HTF), 6-field IMRT and VMAT. The HTF technique consisted of two open beams with extra segments and the cranial and posterior border was extended to include PTVn. Some of the leaves were closed

to spare the humeral head + 10 mm around it (hh+10). For the IMRT technique we added four additional fields to the high tangential fields (gantry angle of 330, 30, 80 and 170 degrees) to ensure coverage of the cranial part of the breast and lymph nodes. The caudal border of these additional fields was set 1 cm below the attachment of the clavicle at the sternum. The third technique was a dual arc VMAT from 305 to 180 degrees.

The plans were made by inverse planning, achieving a PTVp coverage of V95%  $\geq$  97% and a PTVn V90%  $\geq$  95%. Additionally, the dose to the lungs, heart and right breast (OARs) has been minimized. hh+10 was included with an objective of V40Gy < 1 cm<sup>3</sup> for all three techniques.

#### Results

HTF resulted in an average PTVp V95% of 97.2% and an average PTVn V90% of 90.4% (see Table 1 and Figure 1). With the additional fields of the IMRT technique the coverage of PTVn increased significantly to on average 98% (p=0.01) while PTVp did not vary significantly (p=0.92). The dose to the OAR was comparable between the HTF and IMRT techniques. When using VMAT the coverage of the PTVn was on average 99.5% (p<0.01 compared to the HTF and p=0.19 compared to IMRT). The dose to the OARs however increased as well. The mean dose to the contralateral breast increased significantly from 0.6 Gy with HTF and IMRT to 2.3 Gy with VMAT (p<0.01 for both).

**Fig. 1:** Dose distributions of (a) HTF, (b) 6-field IMRT and (c) VMAT. PTVp in red, PTVn in turquoise, contralateral breast in blue and humeral head + 10 mm in green. Isodoselines: red: 100%, yellow: 95% and orange: 90%.

Table 1: Dosimetric parameters for the planning target volumes (PTVp and PTVn), planning risk volume (humeral head + 10 mm) and the organs at risk for high tangential fields (HTF), 6-field IMRT and VMAT.

The parameters are given as average (min - max).

	HTF	IMRT	VMAT
PTVp V95% (%)	97.2 (91.8 - 99.5)	97.1 (96.8 - 97.3)	97.0 (96.6 - 97.4)
PTVn V90% (%)	90.4 (73.7 - 98.7)	98.0 (89.5 - 99.9)	99.5 (98.2 - 99.9)
hh+10 V40Gy (cc)	0.45 (0 - 1.02)	0.67 (0 - 1.83)	0.70 (0 - 1.35)
Lungs Dmean (Gy)	4.7 (3.9 - 6.1)	4.8 (3.8 - 5.9)	5.2 (4.2 - 6.8)
Heart Dmean (Gy)	3.3 (1.6 - 6.1)	2.9 (1.6 - 5.7)	3.6 (2.0 - 5.7)
Right breast Dmean (Gy)	0.6 (0.3 - 0.9)	0.6 (0.3 - 0.7)	2.3 (0.6 - 4.2)

### Conclusion

Both the 6-field IMRT and the VMAT technique can be used to spare the humeral head and surrounding tissues as aimed for in the ESTRO guidelines while still achieving proper target coverage. The IMRT technique discussed in our study resulted in a lower dose in the OARs and consequently this technique has been implemented in our institute.

### EP-1825 Evaluation for the usability of the Varian Standard Couch modeling using Treatment Planning System

Y.M. Yang<sup>1</sup>, Y.M. Song<sup>1</sup>, J.M. Kim<sup>1</sup>, J.M. Choi<sup>1</sup>, B.K. Choi<sup>1</sup>  
<sup>1</sup>Samsung Medical Center, Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

When a radiation treatment, there is an attenuation by Carbon Fiber Couch.

In this study, we tried to evaluate the usability of the Varian Standard Couch(VSC) by modeling with Treatment Planning System (TPS)

### Material and Methods

VSC was scanned by CBCT (Cone Beam Computed Tomography) of the Linac(Clinac IX, VARIAN, USA), following the three conditions of VSC, Side Rail Out Grid(SROG), Side Rail In Grid(SRIG), Side Rail In Out Spine Down Bar(SRIOS). After scan, the data was transferred to TPS and modeled by contouring Side Rail, Side Bar Upper, Side Bar Lower, Spine Down Bar automatically. We scanned the Cheese Phantom(Middelton, USA) using Computed Tomography(Light Speed RT 16, GE, USA) and transfer the data to TPS, and apply VSC modeled previously with TPS to it. Dose was measured at the isocenter of Ion Chamber(A1SL, Standard imaging, USA) in Cheese Phantom using 4 and 10 MV radiation for every 5° gantry angle in a different filed size(3X3cm<sup>2</sup>, 10X10cm<sup>2</sup>) without any change of MU(=100), and then we compared the calculated dose and measured dose. Also we included dose at the 127° in SRIG to compare the attenuation by Side Bar Upper.

### Results

The density of VSC by CBCT in TPS was 0.9g/cm<sup>3</sup>, and in the case of Spine Down Bar, it was 0.7g/cm<sup>3</sup>. The radiation was attenuated by 17.49%, 16.49%, 8.54%, and 7.59% at the Side Rail, Side Bar Upper, Side Bar Lower, and Spine Down Bar. For the accuracy of modeling, calculated dose and measured dose were compared. The average error was 1.13% and the maximum error was 1.98% at the 170° beam crossing the Spine Down Bar.

### Conclusion

To evaluate the usability for the VSC modeled by TPS, the maximum error was 1.98% as a result of compassion between calculated dose and measured dose. We found out that VSC modeling helped expect the dose, so we think that it will be helpful for the more accurate treatment.

### EP-1826 Analysis of dose distribution with change of the air gap when proton therapy using line scanning

S. Seo<sup>1</sup>  
<sup>1</sup>samsung medical center, radiation oncology, Seoul, Korea Republic of

### Purpose or Objective

When proton therapy of cranio-spinal irradiation (with prone position) using line scanning technique, there is a motion of spinal code caused by breathing. According to our clinical experience, we could find out the length of breathing motion is up to 20mm. Because of this motion, the air gap(defined as the distance from nozzle to surface) could be changed. In this study, we are going to find out the target dose distribution in various air gap.

### Material and Methods

Sumitomo proton therapy machine(SHI, JAPAN) and robotic couch(Forte, USA) have been used for this study. CT scans were performed using GE Discovery CT-590 RT. In order to measure the target dose, glass dosimeter(AGC Techno, JAPAN) and atom phantom(Norflok, CIRS, USA) were used. For treatment planning, Ray Station(Ray search ver. 5.0, USA) has been used. Mean and D95 were analyzed shifted points from isocenter in PTV of lower spine which has significant effect from patient's respiratory motion. The shifted pitch was ±10mm, ±20mm.

### Results

As a result of analysis, D95 dose at each depth are as follows: iso-center: 2347.4(100%), iso-10mm: 2302.3(98.1%), iso+10mm: 2341.9(99.7%), iso-20mm: 2281.4(97.2%), iso+20mm: 2361.7(100.6%). And mean dose at each depth are as follows: iso-center: 2389.2(100%), iso-10mm: 2355.1(98.6%), iso+10mm: 2394.7(100.2%), iso-20mm: 2335.3(97.7%), iso+20mm: 2415.6(101.1%).

### Conclusion

The main purpose of this study is to confirm that the air gap changes may affect the target dose or not when proton therapy using line scanning. The difference of prescribed dose due to a change of air gap is only D95: -2.8% ~ 0.6%, mean: -2.3% to 1.1%. So even though the air gap changes, it dose not affect to target dose. Therefore, line scanning proton therapy can be seen clinically useful.

### EP-1827 Dosimetric comparison of 3D-CRT, IMRT and VMAT for bilateral breast irradiation

H.M. Hung<sup>1</sup>  
<sup>1</sup>Princess Margaret Hospital, Department of Oncology-Radiotherapy Centre, Kowloon, Hong Kong SAR China

### Purpose or Objective

Breast cancer is the most common cancer worldwide amongst females and ranked the 5th cause of cancer death in 2012. There were 1.67 million new breast cancer cases diagnosed, and contributed to more than 25% of the total number of new cases of cancer diagnosed. The incidence rate of female breast cancer in Hong Kong has been tripled in the past twenty years. Some of the patients may suffered from synchronous bilateral breast cancer which involved a more complex radiotherapy planning as both lungs, the heart and a large irradiated volume are involved. The aim of this study was to evaluate the dosimetric difference between three breast irradiation techniques: 3-Dimensional Conformal Radiotherapy (3D-CRT), Intensity-modulated Radiotherapy (IMRT) and Volumetric-modulated Arc Therapy (VMAT) on bilateral breast radiotherapy.

### Material and Methods

20 breast cancer patients were previously treated with adjuvant radiotherapy, with the prescription of 50Gy over 25 daily fractions to 100% isodose level. 3-dimensional CT-based treatment planning of the three bilateral breast irradiation techniques was performed and all plans were calculated by Acuros External Beam (AXB) algorithm. The cardiac dose, lung dose, conformity, homogeneity, low dose spillage, the overall planning, simulation and treatment time were analyzed and compared.

## Results

IMRT and VMAT significantly improved the conformity to the Planning Target Volume (PTV) and increased the volume of PTV covered with 50Gy. This effect was clearly illustrated in the region of the lateral field edges since it is difficult to achieve in 3D-CRT due to the dose building up effect. The lung volume received 20Gy in IMRT and VMAT were higher than that of 3D-CRT but the result was found to be not significant. The treatment time in terms of number of monitor unit (MU) was found to be significantly lower in 3D-CRT but the time required for setting up the patient to the treatment position was almost doubled to other two techniques.

## Conclusion

IMRT and VMAT are well-accepted techniques and able to provide encouraging dosimetric results for bilateral breast irradiation. VMAT could further reduce the overall treatment time because of the simple setup procedure and the relatively small number of MU. This study suggested that VMAT technique is feasible and is recommended for bilateral breast irradiation.

### EP-1828 Mean Dose in healthy lung for chest tumors treated with Stereotactic Body Radiation Therapy (SBRT)

J.L. Monroy Anton<sup>1</sup>, M. Asensio Martinez<sup>2</sup>, V. Borreda Talon<sup>2</sup>, J. Hernandis Barbera<sup>2</sup>, M. Marco Collado<sup>2</sup>

<sup>1</sup>Hospital universitario de la ribera, radiation oncology, alzira, spain

<sup>2</sup>hospital universitario de la ribera, radiation protection and radiophysics dpt, Alzira, Spain

#### Purpose or Objective

Stereotactic body radiotherapy (SBRT) is considered treatment of choice in patients with pulmonary lesions not candidates for surgical treatment.

High doses of radiation, both total and per fraction, requires a dose limitation in healthy organs at risk (contralateral lung, heart, spine)

Our objectives were:

- To evaluate the mean dose (Dm) received by the contralateral lung in SBRT for thoracic lesions.
- To analyze if PTV volume and/or total dose (TD) are related to the Dm achieved in the contralateral lung.

#### Material and Methods

A total of 26 pulmonary lesions treated with SBRT were evaluated. Simulation was performed with CT 4D respiratory gating and customized immobilization devices. PTV was designed with an isotropic margin of 0.5 cm from the GTV. Treatment was delivered with Linear Accelerator (CLINAC, Varian), and verification done with internal fiducial markers surrogates.

#### Results

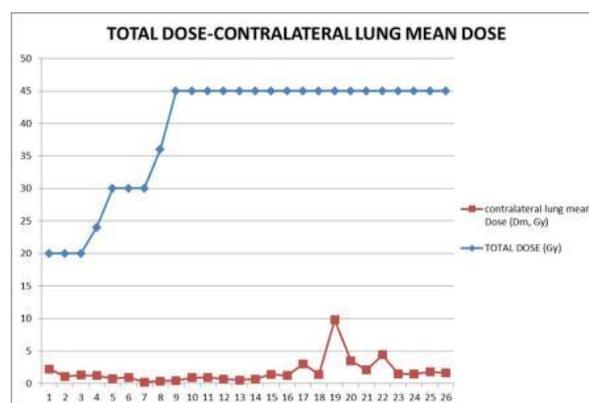

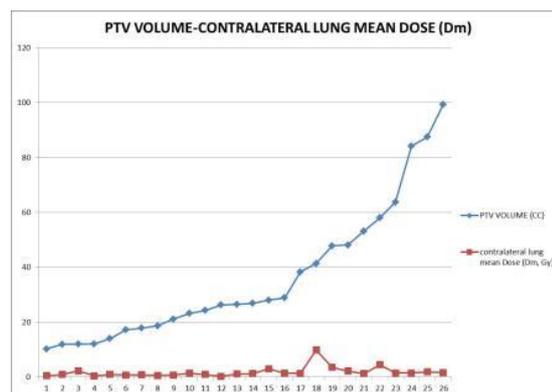

Total Dose (TD) (Gy): range 20 - 45 Gy. Most cases (18; 69%) received a TD of 45Gy.

Dose/fraction: range 10-20 Gy/fr. The most frequent fractionation was 15 Gy (20; 77%).

PTV volumen (cc): range between 10.18 - 99.33cc, with a mean: 36.14cc ; median: 26.65cc

Healthy lung Dm (Gy): range 0.23 - 9.8 Gy; mean: 1.75Gy; median: 1.25Gy

The increase in PTV volume did not associate an increase in the average dose to the contralateral lung. Fig 1 An increase in total dose not involved an associated increase in the dose to the healthy lung. Fig. 2

#### Conclusion

The Mean Dose received by the contralateral healthy lung is minimal.

No relationship was found between the increase in total dose and increased in contralateral lung Dmean. No relationship was found between the volume of PTV and Dmean reached in contralateral lung.

The parameters PTV and TD do not appear to relate to the dose received to the contralateral lung.

We can conclude that SBRT technique can be applied safely largely preserving the healthy lung.

### EP-1829 Dose delivery accuracy in total body irradiation delivered with Step and Shoot IMRT

T. Berlon<sup>1</sup>, L. Specht<sup>1</sup>, P.M. Petersen<sup>1</sup>, L.S. Fog<sup>1</sup>

<sup>1</sup>Rigshospitalet, Clinic of Oncology- Department of Radiotherapy, Copenhagen, Denmark

#### Purpose or Objective

In total body irradiation (TBI) delivered with step and shoot IMRT (SS IMRT), the dose conformity is considerably improved compared with the more widely used TBI delivered with open fields. This conformity is achieved through the use of multiple fields defined by multileaf collimators (MLCs). We aim to quantify the accuracy with which TBI patients treated at our clinic were positioned, and to determine the effect any positioning errors may have had on the delivered dose.

#### Material and Methods

Images acquired as a routine part of the patient treatment with the Theraview™ (Theraview Technology, Leuden, The Netherlands) imaging system were used to determine the positioning shift in the cranio-caudal direction.

Images for 11 consecutive patients, each receiving 6 fractions, were analysed and the shifts recorded (figure 1). For 3 of the patients, only images for 5 of the 6 fractions were available.

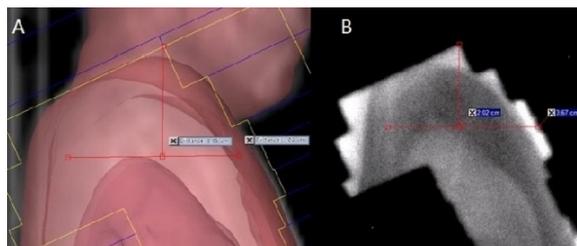

Figure 1: Distances in the craniocaudal and the anterior-posterior directions from the lung apex to an easily-identifiable position in the MLC configuration in the plan (A) and the image acquired during treatment (B)

The plans were then recalculated implementing the shifts using the algorithm used for the clinical plans (Eclipse™, Varian Medical Systems, Palo Alto, AAA algorithm, v 13.6). The mean and maximum doses for the lungs, kidneys, brain and the (body-lungs-5mm) structure were extracted and the difference between the planned and the recalculated doses determined. Results The mean doses change by a maximum of 0.6% (lungs), 0.6% (kidneys), 0.5% (brain) and 0.2% (body-lungs-5mm). The greatest difference between the maximum doses are 8.0% (lungs), 4.8% (kidneys), 2.6% (brain) and 12.0% (body-lungs-5mm).

The standard deviation of the difference between the calculated and recalculated doses are greater for the maximum doses than the mean doses (figure 2). Given that the minimum and maximum doses for SS TBI are typically in the range 90-110% of the prescribed dose, the differences in maximum dose should lead to care being taken when positioning patients for SS TBI.

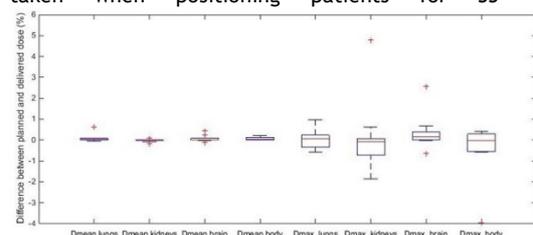

Figure 2. Box and whiskers plots of the mean and maximum doses to the lungs, kidneys, brain and (body-lungs-5mm) for step and shoot TBI, recalculated taking into account craniocaudal shifts during treatment. The red line indicates the median; the box the 25<sup>th</sup> to the 75<sup>th</sup> quantile, the dashed lines includes data not considered to be outliers.

### Conclusion

Patient positioning for a total of 63 fractions of SS TBI is such that the mean delivered doses differs from the planned by less than 0.6%. However, the maximum doses are more sensitive to incorrect patient positioning, differing by up to 12% with the delivered dose being greater than the maximum. Correct patient positioning or SS TBI is pertinent.

### EP-1830 Simple method on bladder filling simulation to improve the soft-tissue evaluation on CBCT

K.L. Jakobsen<sup>1</sup>, K. Andersen<sup>1</sup>, D. Elezaj<sup>1</sup>, D. Sjöström<sup>1</sup>  
<sup>1</sup>University Hospital Herlev, Department of Oncology, Herlev, Denmark

#### Purpose or Objective

The purpose of this study is to present a cost effective method on how to evaluate the robustness of the treatment plan on different bladder fillings during treatment planning. Furthermore the purpose is to evaluate how this method can be used to determine when a bladder is too small during treatment of the patient.

#### Material and Methods

Patients suffering from anal and rectum cancer were enrolled in the study. All patients were instructed to follow our bladder protocol where the patients are asked to empty their bladder 1 hour prior to scan/treatment and then drink 2 glasses of water. The bladder and the bowel

were delineated on the CT image set according to QUANTEC guidelines. At the treatment planning stage different bladder fillings were simulated by cutting off ¼, ½ and ¾ of the bladder in the cranial-caudal direction (Figure 1). By using the different bladder volumes the corresponding bowel volumes were created. The robustness of the treatment plans was evaluated by identifying if the bowel constraint was fulfilled for the different simulated bladder fillings. If bowel constraint wasn't fulfilled the treatment plan was re-optimized to improve the robustness. Before each treatment CBCT was acquired and the true bladder filling was compared to the simulated situations. For the situations where the bladder filling was identified to be too small so the bowel constraint was violated the patients were asked to drink more water. For some of the patients the true bladder was delineated on CBCT and the corresponding bowel was generated and compared to the simulated situation.

### Results

For most of the rectum cancer patients the constraints was fulfilled for all simulated situations. Due to the higher prescription dose and also the location of the target the anal cancer patients didn't match the constraints to the same extent. The study revealed that most of the treatment plans was robust to bladder filling changes but also identified situations where re-optimization could be done to create a more robust treatment plan (Figure 2). The RTTs found it feasible to compare the bladder on the CBCT with the simulations and was also able to identify when additional actions were needed.

### Conclusion

This procedure has shown to be very cost effective as it doesn't require additional imaging and it only takes 10-15 minutes to create the simulated structures. The latter can be optimized further in the future e.g. we consider to only simulating the smallest bladder (largest bowel) for the rectum cancer patients. This should be compared with our previous workflow with unreasonable demands on bladder filling and delineation of the bladder on CBCT with the rather subjective decision when the bladder was considered to be too small. Furthermore this workflow has made it able for the RTTs to get more involved in evaluating and react on differences in soft tissue.

### EP-1831 Entropic Boltzmann closure for MRI-guided radiotherapy

J. Page<sup>1</sup>, J.L. Feugeas<sup>1</sup>, G. Birindelli<sup>1</sup>, J. Caron<sup>1</sup>, B. Dubroca<sup>1</sup>, T. Pichard<sup>1</sup>, V. Tikhonchuk<sup>1</sup>, P. Nicolai<sup>1</sup>  
<sup>1</sup>CELIA, Interaction- Fusion par Confinement Inertiel-Astrophysique, Talence, France

#### Purpose or Objective

The majority of patients affected by cancer are nowadays treated by radiotherapy, which consists in delivering a homogeneous dose with energetic particles. The main goal of this technique is to target and destroy tumoral cells without damaging the surrounding tissue. This treatment possesses a great adaptability to the broad variety of tumors. Therefore, a major effort was made on the last decades to improve technologies involved in the development and the optimization of this treatment. Our work consists on the development and validation of a new model designed to simulate the energy deposition of the particles used in radiotherapy (electrons, photons and protons), within human tissues.

#### Material and Methods

This model is based on a kinetic entropic closure of the linearized Boltzmann equation, which describes the transport of energetic particles in the matter. This equation takes a lot of computation time to be resolved due to the high number of variables. To simplify this, we replace fluences by angular moments, which allows us getting rid of the angular variables and improve the

calculation time. We obtain a set of angular moments equations, and we close this set using the Boltzmann's principle of entropy maximization on the two first equations of the set. We show that this model has an accuracy comparable to references Monte-Carlo (MC) codes (Geant4, MCNPx, Penelope), and is less time-consuming than these ones. We found out this method applies to new approaches, as MRI-guided radiotherapy which consists in irradiating a patient under the influence of a magnetic field. We added the effect of the Lorentz force into our code, and compared it to a reference full MC code FLUKA.

#### Results

We obtain a good agreement between simulations from our model and FLUKA. We are able to highlight some effects that occur on the propagation of particles in the matter, which modify the dose distribution on the interface between materials of different densities in a presence of a magnetic field of a few Tesla. These effects have to be taken into account in order to prevent creation of hot spots or a spread of energy distribution in a human body, within computation times compatible with their use in the clinical environment.

#### Conclusion

Our model could be applied to future clinical cases and would allow a faster and more efficient way to plan a viable treatment for a patient. We plan to validate our results with an experimental campaign. This work takes place in the framework of POPRA (Programme Optique Physique et Radiothérapie en Aquitaine), which involves several laboratories around problematics on the topic of cancer treatment.

**EP-1832 Selecting head and neck cancer patients for proton therapy: the influence of dosimetric thresholds**  
I.T. Kuijper<sup>1</sup>, M. Dahele<sup>1</sup>, A. Delaney<sup>1</sup>, B. Slotman<sup>1</sup>, W. Verbakel<sup>1</sup>

<sup>1</sup>VU University Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

Selecting head and neck cancer patients for proton therapy should be based on objective parameter(s) that indicate a reduced chance of toxicity, for example, on the dosimetric benefit for swallowing and salivary gland structures. We compared volumetric arc therapy photon (VMAT) and intensity modulated proton plans (IMPT) in order to estimate how many patients would be referred for proton therapy using different thresholds of reduction in organ at risk (OAR) dose.

#### Material and Methods

Non-robust IMPT plans were generated for 40 patients with locally advanced head and neck cancer (Varian Medical Systems, 3 fields, multi-field optimization, NUP0/PCS V13.7.14) and compared with the clinical VMAT plans (Varian Medical Systems, RapidArc, 2 arcs, 6MV photons, Acuros V13.6.15). All patients had a simultaneous integrated boost with a fractionation scheme of 35 x 1,55/2 Gy for PTV-elective/PTV-boost. For all plans, the focus was on sparing of all individual salivary and swallowing structures. Patients were categorized according to the amount of additional OAR sparing achieved with proton plans represented by the sum of mean doses to (1) all swallowing structures, (2) parotid gland(s) and (3) submandibular gland(s), if the mean dose was <45Gy for any of these structures using IMPT and/or VMAT.

#### Results

The range for the sum of the three mean doses for photon plans was 37.2-180.8Gy (median 115.4), and for proton plans 21.5-161.9Gy (median 92.1). Differences in total mean dose between photon and proton plans ranged from 1.2-37.2Gy (median 16.9). Assuming a threshold of 10Gy

sparing in sum of mean doses (i.e. proton plan achieved at least 10Gy reduction in total mean dose): 82.5% of proton plans achieved this; threshold 15Gy: achieved by 67.5% proton plans; threshold 20Gy: achieved by 40.0% proton plans; threshold 25Gy: achieved by 17.5% proton plans.

#### Conclusion

The vast majority of patients had a dosimetric benefit with protons as assessed by mean dose to swallowing and salivary gland structures. The results show that the number of patients who would be selected/referred for protons is highly sensitive to the choice of threshold. This has implications for activity levels in proton and photon departments.

**EP-1833 Bowel doses in cervical cancer patients treated with a full bladder during radiotherapy.**

A. Schouboe<sup>1</sup>, E. Kjaersgaard<sup>1</sup>, N. Jensen<sup>1</sup>, L. Fokdal<sup>1</sup>, L. Nyvang<sup>2</sup>, M. Assenholt<sup>2</sup>, J. Lindegaard<sup>1</sup>, K. Tanderup<sup>2</sup>, A. Vestergaard<sup>2</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus N, Denmark

<sup>2</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus N, Denmark

#### Purpose or Objective

Large inter-fractional organ motion is a challenge in cervix cancer radiotherapy. To reduce inter-fractional organ motion, a bladder filling instruction aiming for a comfortably full bladder has been introduced with daily Cone Beam CT (CBCT). The purpose of the study is to evaluate the correlation between bladder filling variation and bowel dose.

#### Material and Methods

Eight consecutive patients with locally advanced cervical cancer treated with chemo radiotherapy, were included in the study. Dose planning and treatment was performed in supine position. Prescribed dose was 45-50 Gy in 25-30 fractions to the pelvis, 5 fractions per week. Daily CBCT with bony fusion and couch correction was performed. A bladder filling protocol was applied with verbal and written instructions, advising patients to drink 450 ml of water in 15 minutes post micturition, 1 hour prior to each treatment. All patients were retrospectively re-planned with a uniform dose of 45 Gy in 25 fractions using VMAT. Target and organs at risk were delineated on CT images for dose planning and on every CBCT (n=210). The clinical target volume (CTV) encompassed the gross tumour volume (GTV), cervix, parametria, uterus, upper vagina and the nodal CTV. A PTV margin of 1.5cm was applied for the GTV, cervix, and uterus and 5mm for the nodal CTV and parametria. Outer extension of bowel loops were delineated including sigmoid in one volume (Bowel) on each of the CBCTs. Based on a bony fusion, all structures were transferred to the planning CT to assess bowel V30 Gy and V43Gy for each fraction. Changes in bowel V30 and V43 of bowel were evaluated as a function of changes in bladder volume compared to the parameters on the planning CT.

#### Results

A large variation in bladder filling was observed and was found to be patient dependent. Large variation in bladder volume and uterus position resulted in large variation in V30 (Table 1). A linear correlation was found between bowel V30 and V43 and bladder volume. Inter-fractional bowel motion was observed due to changes in bladder volume. Linear regression showed that with an increase of 100 cc in bladder volume, the bowel V30 is decreased by a mean of 58 cc (range: 10 - 87 cc). For one patient, the position of the uterus was not affected by bladder filling changes and there was no clear correlation between bladder volume changes and bowel irradiation (Fig 1).

### Conclusion

A correlation between increased bladder filling volume and dose to the bowel were established. Based on these results it is recommended to focus on a uniform bladder filling during planning CT and radiotherapy in order to reduce the dose to the bowel during treatment.

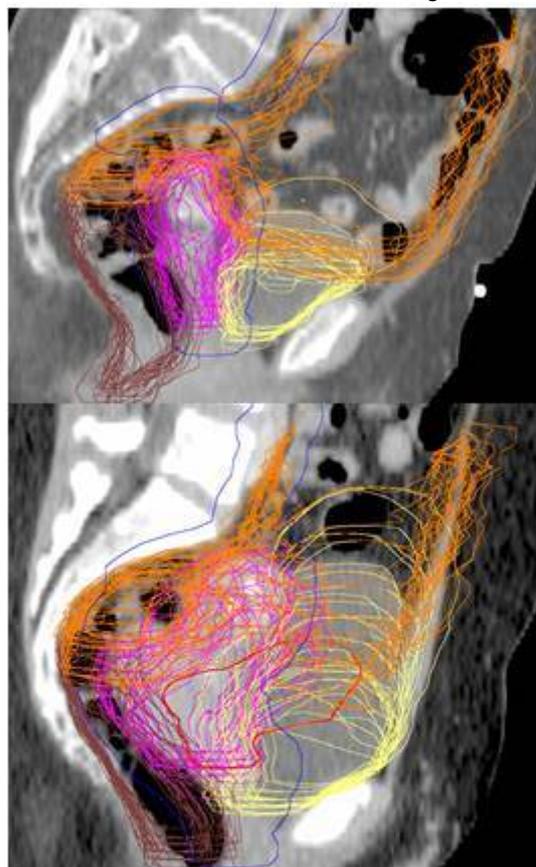

Fig 1. Bowel (orange), Bladder (yellow), uterus (magenta), Rectum (brown) and PTV (blue). Upper panel: Patient with small variation in bladder volume and uterus position resulting in low variation in dose to the bowel. Lower panel: Large variation in bladder volume and uterus position resulting in large variation in bowel V30. The most extreme uterus position is marked in red.

Table 1	Mean $\pm$ SD
Bladder	186 $\pm$ 120cc
Bowel V30	473 $\pm$ 127cc
Bowel V43	234 $\pm$ 81cc
Bowel V30 at bladder vol.100 cc	527 $\pm$ 102cc
Bowel V30 at bladder vol.200 cc	469 $\pm$ 87cc

EP-1834 Dose to internal mammary nodes compared to dose to heart and lung for breast cancer patients

M. Berg<sup>1</sup>, M. Christensen<sup>2</sup>, M. Andersen<sup>2</sup>, N. Kiilerich<sup>2</sup>

<sup>1</sup>Vejle Hospital, Department of Medical Physics, Vejle, Denmark

<sup>2</sup>University College Lillebaelt, Department of Radiology and Radiotherapy, Odense, Denmark

### Purpose or Objective

Prioritization of internal mammary nodes (IMN) over dose to the heart and ipsilateral lung for patients having left-sided radiotherapy (RT) to the residual breast and regional lymph nodes left-sided breast cancer has changed in Denmark after the data from the DBCG-IMN study was released in 2014 [1]. In that study it was shown that in general patients benefit more from having IMN included in the fields compared to the risk of ischemic heart disease. We wanted to evaluate the clinical relevant changes caused by this new practice in our clinic.

### Material and Methods

The dose plans for 45 consecutive patients (20 patients before and 25 after the new practice, respectively) were retrospectively evaluated with respect to V5Gy, V20Gy, V40Gy and mean dose for the heart (MHD), V20Gy and mean dose (MLD) for the ipsilateral lung and V45Gy (prescription dose) for IMN. According to national guidelines the following constraints should be aimed at: V20Gy  $\leq$  10% and V40Gy  $\leq$  5% for the heart, V20Gy  $\leq$  35% for the ipsilateral lung and MLD  $\leq$  18 Gy. After the change according to local guidelines V20Gy should not exceed 40% for the ipsilateral lung.

### Results

Changing the clinical practice trying to increase V45Gy to IMN has resulted in higher median dose to the heart for all parameters investigated - see Table 1. Median MHD increased from 1.50 Gy to 1.85 Gy corresponding to 16.4% and 20.1% increase in rate of major coronary event, respectively [2]. The V20Gy and V40Gy constraints for the heart was violated in one and two cases compared to four and three before and after, respectively. V20Gy for the ipsilateral lung was larger than 35% for one patient before compared to seven patients after the change. V20Gy never exceeded 40% for any patient. MLD was larger than 18 Gy for one patient before and in no cases after. The median volume of IMN receiving the prescription dose (45 Gy) of higher increased from 74.7% to 87.8%.

	Heart				Ipsilateral lung		IMN
	V5Gy (%)	V20Gy (%)	V40Gy (%)	MHD (Gy)	V20Gy (%)	MLD (Gy)	V45Gy (%)
Before new practice	5.59 (1.05-52.65)	0.48 (0-33.47)	0.01 (0.00-26.67)	2.22 (1.45-18.15)	28.84 (20.59-36.70)	14.32 (11.18-18.67)	74.65 (15.10-100.00)
After new practice	7.70 (0.00-32.48)	1.16 (0.00-21.71)	0.13 (0.00-15.47)	2.71 (1.02-11.47)	31.42 (15.54-37.88)	15.46 (8.4-18.13)	87.82 (65.76-100.00)

### Conclusion

Paying more focus to increasing V45Gy for IMN resulted in better target coverage at the expense of higher doses to heart and ipsilateral lung. However the increased dose to heart and lung is believed to be justified by better survival due to better target coverage of IMN. ### EP-1835 Independent verification of treatment planning system calculations

E. Dąbrowska<sup>1,2</sup>, B. Brzozowska<sup>1</sup>, A. Walewska<sup>2</sup>, P. Kukolowicz<sup>2</sup>, A. Zawadzka<sup>2</sup>

<sup>1</sup>Faculty of Physics University of Warsaw, Department of Biomedical Physics, Warsaw, Poland

<sup>2</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Medical Physics, Warsaw, Poland

### Purpose or Objective

In accordance to the EURATOM directive 97/43 (EURATOM, 1997) there must be an independent dose verification procedure for quality assurance in all clinical radiotherapy routines. Referring to Report of AAPM Task Group 114, this procedure can be performed e.g. by second treatment planning system (TPS). The aim of this study was to compare and quantify the differences in dose distribution obtained with two commercially available radiotherapy TPS: the Eclipse (Varian) and the Oncentra MasterPlan (Nucletron).

### Material and Methods

Three dimensional conformal radiotherapy plans (3D-CRT) for patients treated in our hospital were analysed. The analysis and assessment of differences in calculations obtained with two TPS were performed for 160 and 130 patients treated with 6 MV and 15 MV X-rays, respectively. 3D-CRT treatment plans were prepared in the Eclipse TPS (Analytical Anisotropic Algorithm, version 10). Subsequently the DICOM RT data were transferred to the Oncentra MasterPlan TPS (Collapsed Cone Convolution, version 3.3) and dose distribution was calculated. The same number of monitor units were kept. The differences between mean dose in the PTV and dose in the isocenter were compared. For statistical analyses, the Wilcoxon matched-pair signed rank test was used. In addition, the calculations of both TPS were compared with measurements performed in the inhomogeneous phantom.

### Results

The statistically significant ( $p < 0.001$ ) systematic shift between systems, both in the mean dose in the PTV and dose in isocenter was observed. The doses calculated in the Oncentra MasterPlan TPS were always lower than doses calculated in the Eclipse TPS. The average difference of mean dose delivered to the PTV was  $1.4\% \pm 1.0\%$  for 6 MV X-rays and  $2.5\% \pm 0.6\%$  for 15 MV X-rays. The average difference in dose in the isocenter was  $1.2\% \pm 3.5\%$  and  $2.4\% \pm 2.7\%$  for X6 MV and X15 MV, respectively. In most cases the largest differences were caused by air cavities and bone structures. The significant influence of inhomogeneities on dose calculations was confirmed by measurements.

### Conclusion

Estimated differences of dose calculations in most cases did not exceed the action level of 3% recommended by the Knöös et al. publications (2006 Phys. Med. Biol., 51: 5785-5807). Based on this study the independent verification of the Eclipse TPS calculations was introduced in our hospital.

### EP-1836 Study of changes in bowel gas in pelvic radiotherapy

A. Horne<sup>1</sup>, M. Zahra<sup>1</sup>, W. Keough<sup>1</sup>

<sup>1</sup>NHS Lothian, Clinical Oncology, Edinburgh, United Kingdom

### Purpose or Objective

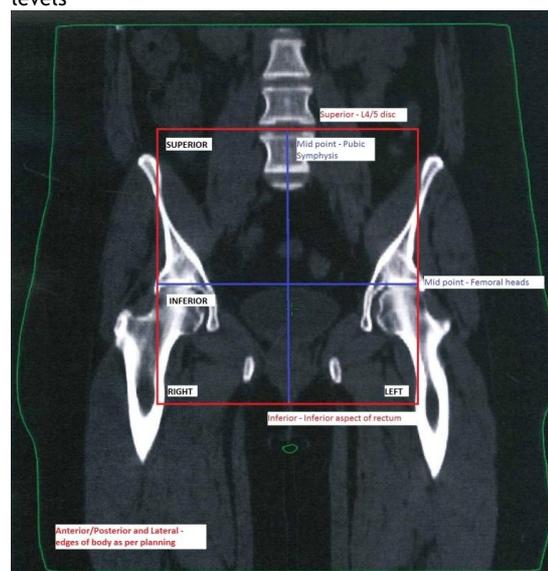

To assess volumetric changes in pelvic bowel gas using serial CT scans in patients receiving pelvic radiotherapy.

### Material and Methods

We performed a retrospective analysis of bowel gas volume and location using planning CT scans for 22 patients. All patients had an initial plan scan (CT1) with a full bladder. In group 1 (n=9) this was compared with a planning scan (CT2) done after about 30 minutes of CT1 with an empty bladder. In group 2 (n=15) CT1 was compared with a CT scan (CT3) done for a phase 2 boost 4 weeks after CT1.

Eclipse™ planning software was used to contour the luminal bowel gas volume within a conventional pelvic radiotherapy field (see figure 1). For each of the 2 groups the total volume and the volume in each quadrant was measured and compared. Significance testing was carried

out using a paired t-test with two-tailed significance levels

at 0.05.

### Results

The results have been summarised in the table below:

	Group 1 (full v.s. empty bladder with 30 minute gap; CT1 v.s. CT 2)	Group 2 (full bladder with 4 week gap; CT1 v.s. CT3)
Sample number	n = 9	n = 15
Median volume (range) c <sup>3</sup>	CT1: 49.8 (4.6 to 171.9) CT2: 82.9 (4.3 to 178.5)	CT1: 30.9 (1.3 to 190.7) CT3: 76.7 (2.8 to 312.8)
Median difference in volume (range) c <sup>3</sup>	-6.6 (-86.8 to 32.9) 6/9 showed an increase in bowel gas	-24.4 (-289.6 to 39.5) 10/15 pts showed an increase in bowel gas
t-test Whole pelvis	-1.48 (p=0.18)	-2.55 (p=0.03)
t-test Superior left	-0.37 (p=0.72)	-2.14 (p=0.05)
t-test Superior right	-1.47 (p=0.18)	-2.46 (p=0.03)
t-test Inferior left	-0.5 (p=0.63)	-0.18 (p=0.85)
t-test Inferior right	-2.36 (p=0.045)	-1.19 (p=0.25)

### Conclusion

In group 1 no significant difference was identified due to changes in bladder volume over a short period of time. In group 2 there was a tendency towards an increase in bowel volume over the 4 week period of radiotherapy more so in the upper quadrants reflecting changes mainly in the colon rather than in the rectum. This is possibly due to the radiotherapy toxicity and associated diet changes. The volume of bowel gas does not appear to be consistent during a course of pelvic radiotherapy and this should be taken into consideration when dosimetry changes are made to the initial planning scan to compensate for bowel gas.

### Electronic Poster: RTT track: Image guided radiotherapy and verification protocols

### EP-1837 Dosimetric effect by rotational error in VMAT on Brain tumor patients

H. Park<sup>1</sup>

<sup>1</sup>Yonsei University, Radiation Oncology, SEOUL, Korea Republic of

### Purpose or Objective

This study is to evaluate the dose effects on whether Hexapod Couch is applied for patient positioning errors to be corrected in the course of VMAT on brain tumor patients.

### Material and Methods

For this study, a total of 1129 cases of CBCT acquired from 46 brain tumor patients with VMAT and Hexapod used are

comparatively analyzed and difference on dose effects is evaluated by dosimetric quality assurance (DQA) and comparison of treatment plans whether Hexapod is applied.

#### Results

The average errors of the patients' position were Lateral (X-axis) direction of  $0.1 \pm 1.4$  mm, Longitudinal (Y-axis) direction of  $0.0 \pm 1.4$  mm, Vertical (Z-axis) direction of  $-0.4 \pm 1.2$  mm Pitch of  $-0.29 \pm 0.61^\circ$ , Roll of  $-0.42 \pm 0.98^\circ$  and Yaw of  $-0.53 \pm 0.98^\circ$ . If the position error takes absolute value, average error on three directions of translation was  $1.06 \pm 0.14$  mm. Rotation error was  $0.82 \pm 0.14^\circ$  which is larger than the translation error.

Through DQA evaluation, the average error rate of point dose in the case of rotational error existed is  $0.89 \pm 0.012\%$ , and in the case without rotational error is  $0.24 \pm 0.015\%$ . Gamma pass rate in the case without rotational error is  $99.71 \pm 0.328\%$  in average and in the case of rotational error existed is  $89.33 \pm 3.874\%$  which is 10% lower so it is statistically significant. ( $p < 0.05$ )

The mean values of dose difference on each ROI before and after rotational error correction in treatment plan are 2.17 Gy of Brain\_max, 0.28 Gy of brain\_mean, and -3.58 Gy, -4.43 Gy of Brain\_stem max and mean respectively. Also, the value of Lt\_Eye\_max is 1.34 Gy and the value of Rt\_eye\_max is -0.71 Gy individually. There is dose difference whether correction of rotational error is existed or not.

#### Conclusion

When VMAT with Hexapod Couch is applied for patients with brain tumors, it is considered to increase reproducibility on patients positioning and treatment efficiency and at the same time, decreases side effects.

#### EP-1838 First IGRT results for SBRT bone and lymph node oligometastases within the pelvic region.

L. Wiersema<sup>1</sup>, G. Borst<sup>1</sup>, S. Nakhaee<sup>1</sup>, H. Peulen<sup>1</sup>, T. Wiersma<sup>1</sup>, M. Kwint<sup>1</sup>, A. Smit<sup>1</sup>, M. Romp<sup>1</sup>, P. Remeijer<sup>1</sup>, A. Van Mourik<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, radiotherapy, Amsterdam, The Netherlands

#### Purpose or Objective

Purpose: There is a growing demand for application of stereotactic body radiation therapy (SBRT) to oligometastatic disease, like bone and lymph node metastases. Based on our clinical experience with common SBRT sites (such as lung, spine and liver), a comprehensive set of treatment execution guidelines was developed for bone and lymph node locations eligible for SBRT. To our knowledge, we present the first combined IGRT positioning data of bone- and lymph nodes SBRT treatments in the pelvic region.

#### Material and Methods

Materials and Methods: The IGRT data for 32 patients treated with SBRT in the pelvic region for oligometastases were reviewed; 16 on gland and 16 on bone. Radiotherapy schedules ranged from 24 -45 Gy in 3 fractions to 25-50 Gy in 5 fractions. These patients were immobilized with a personal vacuum bag, knee-fix, head rest and arm support. The Gross Tumor Volume (GTV) was expanded with a 5mm Planning Target Volume (PTV) margin for bone and 7mm for lymph node treatments. All patients were treated on an Elekta linear accelerator, with 10MV and a coplanar, dual arc, volumetric Modulated Arc Therapy (VMAT) technique. A Cone Beam CT (CBCT) based online imaging protocol was used for set-up, couch correction verification and intra-fraction motion (IFM) assessment. Rigid registrations were performed on the bony anatomy adjacent to the GTV. If the residual translation setup error (i.e. after couch correction) was larger than 2 mm, the correction-verification procedure was repeated and if residual rotation setup errors were larger than  $3^\circ$  the

patient was repositioned. The coverage of GTV within PTV was checked visually. To calculate the IFM, the difference between translation and rotation errors of the inline (i.e. during treatment) or post treatment CBCT and the residual setup errors was calculated.

#### Results

Mean, systematic and random components of residual setup and intra-fraction errors (translations and rotations) are summarized in the table 1 for bone and lymph node cases. The correction-verification procedure was repeated in 3.8% and 10% of the fractions for bone and lymph node cases respectively.

#### Conclusion:

The setup and IFM errors of patients treated with SBRT for oligometastatic disease in the pelvic region (for bone or lymph nodes locations) are very small, demonstrating the reproducibility and robustness of the positioning protocol. Consequently, the contribution of these errors to the GTV-PTV margin is limited and margins may be reduced. For the lymph node locations, research is ongoing to improve image registration methods (e.g. shaped region of interest registration).

#### EP-1839 Towards planning organ at risk volumes for rectum and bladder using cone beam CvT in prostate cancer.

R. Seuntjens<sup>1</sup>, T. Convents<sup>1</sup>, G. De Kerf<sup>2</sup>, A. Sprangers<sup>2</sup>, K. Van Belle<sup>1</sup>, D. Verellen<sup>2</sup>, P. Dirix<sup>2</sup>

<sup>1</sup>Odisee University College- campus T erranova, School of Medical Imaging, Brussels, Belgium

<sup>2</sup>Iridium Cancer Network GZA Sint-Vincentius,

Department of Radiation Oncology, Antwerp, Belgium

#### Purpose or Objective

To analyze planning organ at risk volumes (PRV) for the rectum and bladder using daily cone beam computed tomography (CB-CT) images acquired during prostate radiotherapy.

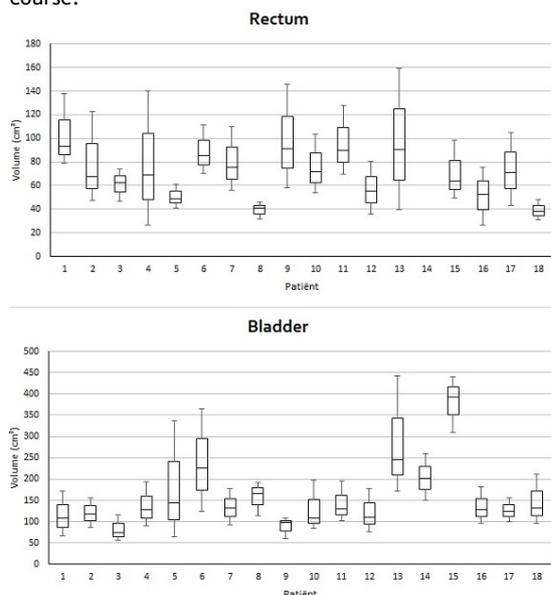

#### Material and Methods

From February 2015 to October 2015, 18 consecutive prostate cancer patients received daily CB-CT imaging after routine set-up imaging. All patients had intermediate- to high risk disease and received 37 fractions of 2.0 Gy to the prostate (CTV\_high) and 1.5 Gy to the seminal vesicles (CTV\_low) through volumetric arc radiotherapy (VMAT). Treatment simulation (with both CT and MRI on the same morning) was performed according to a strict protocol: patients were advised to place a Microlax® Fleet enema 1 hour before the appointment. At the same time, they were asked to empty their bladder and then drink 400 cc of water. Bladder voidance should then be avoided until the CT was taken. First, the CT was taken. If the rectum was too filled and/or the bladder was too empty, the patient was removed from the table and advised to empty the rectum and/or drink some more water. Afterwards, patients were advised to empty the bladder and again drink 400 cc of water. About an hour later, the MRI was performed at the radiology department. Before each treatment, the same protocol was followed but a Glycerin® suppository was subscribed instead of the enema.

#### Results

A total of 666 CB-CT's were evaluated. All CB-CT images were deemed of sufficient quality to identify the CTV's as well as the rectum & bladder. Both CTV's as well as the bladder and rectum (from the lowest level of the ischial tuberosities to the connection anteriorly with the sigmoid) were delineated on all CB-CT's. The manual delineation of each CB-CT took around 18 minutes in total. There was considerable individual variation in rectal and bladder volume on CB-CT's during treatment for each patient (see Figure). The mean rectal volume on daily CB-CT (84.1 cc) was not significantly different from the mean rectal

volume during simulation (86.0 cc) on a paired student t-test. The mean bladder volume on daily CB-CT (160 cc) was significantly larger than the mean bladder volume during simulation (140 cc,  $p < 0.01$ ). There were no significant differences in CTV volumes. PRV margins were generated from the Boolean sum volume of the rectum and bladder obtained from all CB-CT's. For the rectum, the mean  $\pm$  standard deviation displacement was  $0.8 \pm 0.3$  cm. For the bladder, this was  $1.5 \pm 0.5$  cm. In a second step, these contours will be transposed on the original plan and dose-volume histograms (DVH) will be calculated and combined, to produce single mean DVH representative of the dose actually delivered over the entire treatment course.

### Conclusion

Despite a strict treatment protocol, important variation in rectal and especially bladder filling was observed. This resulted in PRV margins of 0.8 and 1.5 cm for rectum and bladder, respectively, which is not clinically possible. Therefore, truly adaptive radiotherapy is needed, depending heavily on automatization.

### EP-1840 Verification of accurate movement of 6DoF Couch using Yonsei QA Set.

D. Jung<sup>1</sup>, H. Park<sup>1</sup>, J. Yoon<sup>1</sup>, S. Lee<sup>1</sup>, J. Kim<sup>1</sup>, J. Cho<sup>1</sup>  
<sup>1</sup>Yonsei Cancer Center, Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

Yonsei QA Set was established to verify the movement accuracy of image-guided 6DoF (Six Degree of Freedom) Couch and to evaluate its usefulness.

### Material and Methods

Two sets of linear accelerators equipped with 6DoF Couch and CBCT were used. Using the established QA Set, each CBCT image was obtained over 15 times through the Penta-Guide Phantom installed with off-set shift values along six translational (Translation; TX, TY, TZ) and rotational (Rotation, Pitch; RX, Roll; RY, Yaw; RZ) directions. Using this method, we compared the reference image and the registration image, and we analyzed the error calculated by measuring the positional accuracy of the modified 6DoF Couch.

### Results

Image-guided comparison of reference image and registration image demonstrated a correlation of 0.993, revealing high calibration accuracy.

Error between the modified off-set value of 6DoF Couch and the measured value along translational directions

were  $0.25 \pm 0.18$  mm in the TX direction,  $0.25 \pm 0.25$  mm in the TY direction, and  $0.36 \pm 0.2$  mm in the TZ direction. Misalignments along the rotational axis were  $0.18 \pm 0.08^\circ$  in the RX direction,  $0.26 \pm 0.09^\circ$  in the RY direction, and  $0.11 \pm 0.08^\circ$  in the RZ direction. The correlation value among the rotational directions was significant at 0.958.

### Conclusion

Using the Yonsei QA Set, we were able to verify the error of 6DoF Couch along both the translational and rotational directions in a very simple method. This system would be useful in performing Daily IGRT QA of 6DoF Couch.

### EP-1841 CASPIR Trial: Interim analysis of prostatic calculi as an alternative to fiducial markers for IGRT

A.G.M. O'Neill<sup>1</sup>, R. King<sup>1</sup>, S. Jain<sup>1</sup>, A.R. Hounsell<sup>1</sup>, J.M. O'Sullivan<sup>1</sup>

<sup>1</sup>Queens University Belfast, Centre for Cancer Research & Cell Biology, Belfast, United Kingdom

### Purpose or Objective

Image guided Radiotherapy (IGRT) for prostate cancer (PCA) frequently employs surgically implanted fiducial markers (FMs). However, it is estimated that up to 35% of prostate radiotherapy patients have prostatic calculi (PC) visible on treatment cone beam CTs (CBCT). PCs represent a potential alternative to implanted fiducials. The purpose of this clinical trial is to directly compare FMs with PCs as an aid to prostate IGRT. Preliminary results are reported.

### Material and Methods

We designed a single institution ethically approved prospective clinical trial investigating the feasibility of using prostate calcifications as natural FMs for IGRT. Patients planned for standard prostate radical EBRT +/- brachytherapy are eligible for the study. Following written informed consent, and prior to CT planning, 3 gold fiducial markers are inserted into the prostate by the trans-perineal route under TRUS guidance. PCs within the PTV are contoured. All participants are aligned for EBRT according to FM positions using daily CBCT image guidance on a Varian TrueBeam linac. Off-line, a single experienced user analyses CBCTs using Image Registration in Eclipse (version 13.6). Random and systematic treatment set-up errors are determined based on FMs, PCs (where present), prostate gland (PG) and bony landmarks (BL) and CTV-PTV margins derived for each data set.

### Results

To date 25 participants have been recruited. 12 participants have PCs contoured, 6 of whom have completed radiotherapy. Based on 2982 individual image registrations the PTV margins required based on each reference structure are summarised in Table 1.

Table

1

	CTV-PTV Margins ( $2.5\sigma + 0.7\sigma$ ) mm		
	X(L/R)	Y(A/P)	Z(S/I)
CTV-PTV <sup>(BL)</sup>	5.0	7.1	3.7
CTV-PTV <sup>(PC)</sup>	4.6	6.3	3.5
CTV-PTV <sup>(FM)</sup>	3.3	6.1	4.3
CTV-PTV <sup>(PG)</sup>	4.4	7.0	3.5

### Conclusion

The maximum difference between the CTV-PTV<sup>(PC)</sup> margin and CTV-PTV<sup>(FM)</sup> margin is 1.3mm in the X or L/R dimension. This is less than the maximum difference between CTV-PTV<sup>(FM)</sup> and CTV-PTV<sup>(BL)</sup> for the same dimension (1.7mm) and comparable to the difference between CTV-PTV<sup>(FM)</sup> and CTV-PTV<sup>(PG)</sup>. Preliminary results from this study demonstrate some evidence to support the use of PCs as an alternative to FMs for prostate IGRT. Recruitment is ongoing with a target of 30 participants with PCs.

### EP-1842 Comparison between infrared marker and surface imaging for DIBH of left-sided breast treatments

A. Tini<sup>1</sup>, I. Pytko<sup>1</sup>, A. Moreira<sup>1</sup>, J. Sharpe<sup>1</sup>, C. Winter<sup>1</sup>, M. Guckenberger<sup>1</sup>, C. Linsenmeier<sup>1</sup>

<sup>1</sup>University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

#### Purpose or Objective

The goal of the study was to compare two different respiratory gating techniques to treat left-sided breast cancer with Deep Inspiration Breath Hold (DIBH): infrared tracking camera with a reflective marker (RPM, Varian) and the optical surface monitoring system (OSMS, Varian) and to improve our daily radiation therapy workflow.

#### Material and Methods

9 breast cancer patients, undergoing DIBH were treated in our clinic using 3D tangential fields. They were positioned supine, on the C-Qual™ Breastboard (CIVCO Medical Solutions). Before the first treatment the patient reference breathing curve was imported to a linac treatment workstation together with calculated thresholds. Additionally, the reference surface from the CT scan in free-breathing (FB) as well as in DIBH were imported to the OSMS and the region of interest was selected. Patients were leveled according to the CT reference marks and then positioned with OSMS using FB surface from CT (5 patients) or acquired FB surface on the first day of treatment (4 patients). After aligning the patient, MV imaging in DIBH based on RPM was done and bone match on the chest wall was used to correct for positioning error. OSMS deltas using the DIBH surface, acquired before performing the couch shifts, were assessed against MV imaging results in the breath hold for every patient to compare the two methods.

#### Results

Positioning based on OSMS was in good agreement with the positioning based on RPM and MV imaging. The mean 3D deviation between the two techniques was within 5mm accuracy. The FB reference surface from CT was found less reliable than the one obtained on the first day of the treatment. For 2 patients, the CT reference DIBH surface shown more than 5mm discrepancy compared to MV imaging with RPM and a new one was taken on the first day of the treatment and used for consecutive treatments. OSMS detected patient pitch of up to 10 degrees.

#### Conclusion

According to our preliminary data, DIBH patient positioning based on OSMS is feasible and reproducible. More data will be collected to confirm these findings and shifts of patients based on the DIBH reference surface, before performing MV imaging, will be implemented into the workflow.

### EP-1843 An audit evaluating the frequency of patient re-preparation after CBCT analysis in prostate IMRT

K. Crowther<sup>1</sup>

<sup>1</sup>Cancer Centre- Belfast City Hospital, Radiotherapy, Belfast, United Kingdom

#### Purpose or Objective

As imaging techniques have advanced and kV-CBCT is now routinely used to verify prostate radiotherapy (RT), changes in bladder and rectal volume affecting the position of the prostate can be seen. The consequences of this can potentially lead to a reduction in PTV coverage, an increase in treatment toxicity, and even biochemical failure. Patients should be treated with a 'comfortably full' bladder and an empty rectum with the aims of reducing rectal distension and minimising prostate movement.

#### Material and Methods

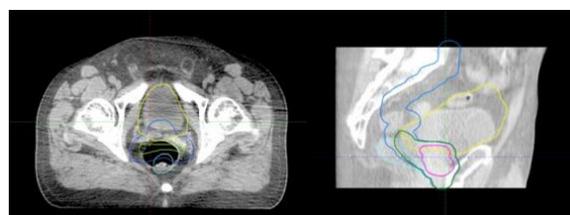

All kV-CBCT images for patients receiving prostate IMRT on a treatment unit were examined over a one month

period. All patients followed the departmental Bladder/Bowel preparation pathway- patients' self-administer daily micro-enemas and follow a simple bladder filling protocol (500 mls of water, 45 mins prior to treatment). The departmental prostate CBCT protocol was used (minimum day 1-3 and weekly). A record of patients requiring re-prep after analysis of CBCT was kept with details of the action taken. The data recorded was reviewed to identify any trends and to quantify the impact on daily workflow.

#### Results

In total 137 scan sets were acquired during this time period. In the majority of cases (89.78%) treatment was delivered as planned after analysis of initial CBCT. In 14 cases (10.22%) after acquiring the CBCT the patient was taken off the treatment couch. Three were due to the patient experiencing urinary urgency and needing to void.

The remaining 11 cases after analysis of the CBCT variation in rectal distension and/or bladder filling was observed and the radiographers did not continue to treatment delivery (Figure 1).

A summary of the results is shown in Table 1. The mean delay caused on the treatment unit was 15 minutes (mins) (range 0-20), this equates to on average 210 mins per month or 21 treatment slots. The time taken from image acquisition to decision to take the patient off the treatment couch mean was 3.21 mins (range 1-6). Scheduled appointment time to time of CBCT acquisition mean was 7.6 mins (range 1-18). A variety of instructions were given to patients with inconsistencies observed with regards to bladder filling.

Patient Number	Observation on CBCT	Impact on plan treatment	Instructions given to patient
1	Inadequate bladder filling	Prostate outside PTV	Drink an extra 'cup' (125ml) of water. Wait 10 mins
2	Inadequate bladder filling, Rectal gas	Seminal Vesicles not within PTV Increase in rectum volume within PTV	Pass wind. Drink 2 cups (250ml) and wait 30mins
3	Rectal gas in PTV	Prostate outside PTV	Pass wind
4	Inadequate bladder filling	Small bowel within PTV Prostate outside PTV	Drink 2 cups (250ml) and wait 30mins
5	Inadequate bladder filling	Prostate outside PTV	Asked to wait- did not follow preparation instructions correctly
6	Inadequate bladder filling	Prostate outside PTV	Asked to wait- did not follow preparation instructions correctly
7	Rectal gas in PTV	Prostate out of PTV	Pass wind
8	Inadequate bladder filling	Prostate outside PTV	Bladder prep emphasised
9	Rectal gas in PTV	Prostate out of PTV	Pass wind
10	Rectal distension	Prostate outside PTV	Asked to pass matter- unable to do so treatment not delivered (Day 1)
11	Rectal distension	Increase in rectum volume within PTV	Did not follow preparation instructions correctly- had not used enema- Asked to re-prep

#### Conclusion

This is a small sample but it has highlighted important issues seen within this patient population. Patient compliance with preparation and the instructions given to patients who require re-prep are important. Guidance and training should be available to ensure consistency in patient instructions. With the introduction of more advanced prostate RT, the demand for IGRT will continue to increase; this will have an impact on the daily workflow with the potential to increase patient waiting times if issues such as patient compliance with preparation instructions are not addressed.

## Electronic Poster: RTT track: Motion management and adaptive strategies

**EP-1844 Clinical introduction of simple adaptive radiotherapy for transitional cell bladder carcinoma**  
 N.J.W. Willems<sup>1</sup>, P.S. Kroon<sup>1</sup>, J.C.J. De Boer<sup>1</sup>, G.J. Meijer<sup>1</sup>, J.R.N. Van der Voort van Zyp<sup>1</sup>, J.L. Noteboom<sup>1</sup>  
<sup>1</sup>UMC Utrecht, radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

Radiotherapy of bladder carcinoma requires substantial CTV-PTV margins to account for day-to-day bladder volume variations. A method to reduce these margins, and hence organs at risk (OAR) dose, is the Plan of the Day method (PotD).

In preparation of a PotD approach, we introduced an offline adaptive radiotherapy (ART) procedure based on ConeBeam CT (CBCT) analysis to select individualized adequate margins for the bladder. Tight PTV margins were defined on a retrospective CBCT analysis (N=9, 56 CBCTs) (table 1).

PTV bladder margin (mm)	cranial	caudal	ventral	dorsal	right	left
wide	15	10	15	15	10	10
tight	10	6	10	10	6	6

Table 1: CTV-PTV margins for initial plan (wide) and adaptive (ART) plan (tight)

### Material and Methods

Pretreatment MRI scans with variable bladder filling were acquired to determine the GTV and the empty, medium and fully filled bladder structure (CTV). During the pretreatment CT planning the bladder was filled according to the medium filled MRI protocol ( $\pm 200$  mL). All patients were treated with a Volumetric Modulated Arc Therapy (VMAT) Simultaneous Integrated Boost (SIB) technique. The prescribed dose was 46 Gy (2 Gy per fraction) to the bladder and 59.8 Gy (2.6 Gy per fraction) to the GTV.

Patients were instructed to perform a comfortably filled ( $\pm 200$  mL) bladder during treatment. Before each treatment session a CBCT was obtained and a manual soft tissue match was performed on the bladder volume. When the PTV did not cover the bladder volume correctly, patients were asked to void their bladder or drink water. The GTV location was decisive for the match. A subsequent 3D online translation correction was applied. The initial 3 treatment fractions were delivered with a plan based on the medium filled bladder with wide PTV margins (table 1). After 3 fractions it was decided if an ART plan could be used. The best fitting CTV (empty, medium or full) (figure 1) and PTV (wide or tight) margins were chosen. The ART plan was delivered from fraction 6 to 23. Daily online CBCT position verification was still performed to monitor adequate bladder coverage by the PTV.

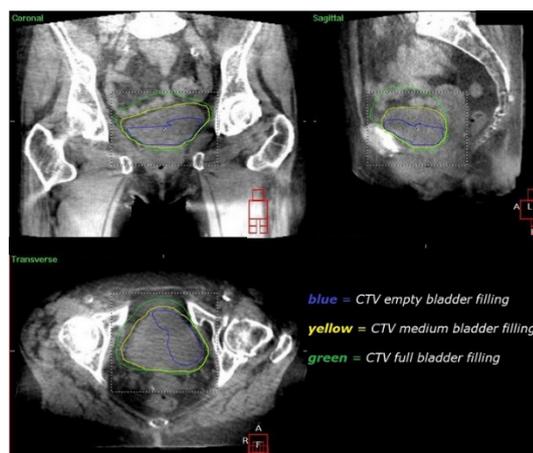

Figure 1: CBCT image of the initial plan. CTV medium bladder filling fits well on CBCT bladder.

### Results

5 patients were treated with our simple ART method since June 2016. For 3 patients the medium bladder filling with tight PTV margins were used. The mean PTV was 28% smaller for the adaptive plans compared to the initial plans.

The other 2 patients were treated with a medium bladder filling and wide PTV margins during the whole treatment. One of these patients could, in retrospect, have been treated with tight margins because the bladder filling became smaller after fraction 3. The other patient showed deformation of the bladder, and the treatment had to be continued with wide PTV margins.

### Conclusion

A simple ART workflow was introduced for bladder carcinoma. By offline selection of a plan based on the most representative treatment bladder volume, tight PTV margins could be applied and OAR doses were thus reduced. Daily verification of the bladder filling is necessary to monitor the GTV and CTV coverage. This approach to ART in bladder carcinoma is a safe and simple method to reduce PTV margins.

### EP-1845 The impact of intra-fractional bladder filling on adaptive bladder radiotherapy

A. Krishnan<sup>1</sup>, Y. Tsang<sup>1</sup>, A. Stewart-Lord<sup>2</sup>  
<sup>1</sup>Mount Vernon Cancer Centre, Radiotherapy  
 Department, Northwood, United Kingdom

<sup>2</sup>London South Bank University, School of Health & Social Care, London, United Kingdom

### Purpose or Objective

To assess the effect of intra-fractional bladder filling on adaptive bladder radiotherapy and investigate if the current departmental adaptive bladder treatment planning margins and plan selection options are appropriate.

### Material and Methods

A retrospective audit was carried out on 38 pairs of pre-treatment and post-treatment cone beam computed tomography scans (CBCTs) from 20 adaptive bladder radiotherapy patients. The bladder was contoured on both pre and post-treatment CBCTs to quantitatively analyse the differences in bladder volume and bladder wall expansion over the treatment fraction. Treatment time was established from acquisition of pre-treatment CBCT to acquisition of post-treatment CBCT. A non-parametric Spearman's Rank correlation test was conducted to investigate if there was a relationship between intra-fractional bladder filling and treatment time.

### Results

A variety of intra-fractional bladder filling and intra-fractional bladder wall expansions were observed. Mean

intra-fractional filling volume was 10.2cm<sup>3</sup> (standard deviation (SD) = 7.1cm<sup>3</sup>; range= 0.3-26.9cm<sup>3</sup>). Average treatment time was 8.9 minutes (SD = 1.8mins; range= 6.5-13.6mins). Intra-fractional bladder filling resulted in expansion of the bladder predominately in the superior and anterior directions with mean translations 2.5mm (SD=1.9mm; range= 0-6mm) and 1.5mm (SD=1.4mm; range= 0-5mm) respectively.

As expected, an increase intra-fractional bladder filling was associated with an increase overall treatment time ( $r_s = 0.323$ ,  $p = 0.048$ ). All plan selection options chosen adequately covered the bladder target treatment volume.

#### Conclusion

Despite the effect of intra-fractional bladder filling, it's suggested that current use of the adaptive bladder treatment planning margins and decision making for all plan selections sufficed. All treatments were delivered within an appropriate time frame for the local hospital department. Due to the limited expansion of the bladder wall laterally, consider reducing the lateral margin requirement if a more conformal plan could be selected whilst minimising dose to the surrounding normal tissue.

#### EP-1846 Verification of latency in respiratory gating with proton beam therapy

I. Maeshima<sup>1</sup>

<sup>1</sup>aiyawa hospital, proton center, Matsumoto, Japan

#### Purpose or Objective

Gating function has been available in our hospital for the proton therapy system since March, 2016. Gating signals generated by a respiratory gating system control the output of proton beam. However, there is latency between gating control signal and proton beam emission/interception and a long latency would affect the treatment accuracy. We verified the latency periods and report the results here.

#### Material and Methods

A globally used respiratory gating system Abches was used for gating signal control. A motion phantom was used for respiratory motion simulation with two modes of motion phantom respiratory speed: 3 sec/fraction and 6 sec/fraction. Gating function was enabled by the Wobbler method in the proton therapy system. The latency between the start of gating signal emission and the start of proton beam generation, and that between the end of gating signal emission and the interception of the proton beam were measured.

#### Results

With the motion speed at 3 sec/fraction, the mean latency at the start of signal emission was 61.75±20.55 msec and at the end of gating signal was 41.4 ± 30.69 msec. With the motion speed at 6 sec/fraction, the mean latency at the start of signal emission was 36.7±27.24 msec and at the end of gating signal was 46.8±28.73 msec.)

#### Conclusion

The results of gating latency between our proton therapy system and the respiratory gating system Abches in this study satisfied the AAPM-TG142 recommended criteria of 100 msec, proving the applicability of the systems.

#### EP-1847 Inter-fraction motion of the uterine cervix during EBRT measured using CBCT and polymer markers

F. Nijeboer<sup>1</sup>, A. Snyers<sup>1</sup>, L. Verhoef<sup>1</sup>, T. Branje<sup>2</sup>, R. Van Leeuwen<sup>1</sup>

<sup>1</sup>Radboudumc, Radiation Oncology, Nijmegen, The Netherlands

<sup>2</sup>Fontys University of Applied Sciences, MBRT, Eindhoven, The Netherlands

#### Purpose or Objective

In external beam radiotherapy of the uterine cervix, large day-to-day movements of the cervix can be seen that are

associated with changes in rectum and bladder filling. These movements should be taken into account in treatment planning, by delineation of an internal target volume (ITV), a careful choice of safety margins, or daily plan selection based on the position of the uterus. In this study, the motion of the uterine cervix was monitored using implanted polymer markers visualized by CBCT. The correlation of this motion to bladder and rectum filling was estimated, and treatment margins were calculated.

#### Material and Methods

234 CBCT images of 10 patients with implanted markers were included. Interfraction motion of the cervix was studied by determining the 3D vector between the center of the markers on CBCT and (full-bladder) planning CT. An inter-observer variability study was determined for this analysis. The correlation between cervix and bladder dimensions and rectum diameter was studied. CTV-PTV margins were calculated using the Van Herk recipe.

#### Results

A strong and statistically significant correlation of cervix motion in the AP direction was found with the rectum diameter (Pearson correlation coefficient  $r = 0.82$  ( $p < 0.001$ )). Correlation with the bladder dimensions in this study was found significant however weak for the AP and SI directions (-0.29 and -0.28 ( $p < 0.001$ ), respectively). Motion of the cervix was largest in the AP and SI directions (Mean (SD of means): 4.1 (11.5) and 5.0 (5.6), respectively) The calculated margins equal 8.7, 33.0 and 18.0 mm in the LR/AP/SI directions.

#### Conclusion

Correlation with bladder and rectum filling, and preferred direction of motion, were shown comparable to previous studies. Calculated CTV-PTV margins were larger than those used in clinical practice. These can be decreased when an ITV is delineated based on multiple CT/MR images with varying bladder/rectum filling, or when a plan-of-the-day approach is used.

#### EP-1848 Dosimetric evaluation of CBCT data in adaptive PoD for cervix cancer

K. Bath<sup>1</sup>, D. Vignarajah<sup>2</sup>, M. Marban<sup>3</sup>, T. Hague<sup>1</sup>, A. Baker<sup>4</sup>, Y. Tsang<sup>4</sup>, P. Hoskin<sup>2</sup>

<sup>1</sup>Mount Vernon Cancer Centre, Radiotherapy Physics, London, United Kingdom

<sup>2</sup>Mount Vernon Cancer Centre, Oncology, London, United Kingdom

<sup>3</sup>Hospital Universitario Doctor Negrín, Radiation Oncology, Palmas de Gran Canaria, Spain

<sup>4</sup>Mount Vernon Cancer Centre, Radiotherapy, London, United Kingdom

#### Purpose or Objective

Adaptive plan of the day (PoD) for cervical cancer has recently been implemented at our centre. PoD using daily CBCT reduces the risk of geometric miss by actively choosing a suitable plan based on a variable CTV position and has the potential of reducing toxicity to organs at risk (OARs). This planning study aimed to assess the potential benefits by recalculating the plan on the daily CBCT datasets, comparing changes to CTV and OAR dose as treatment progressed.

#### Material and Methods

All patients treated with this technique had planning CTs acquired with empty and full bladder and a MRI with mid-bladder filling. Multiple CTVs were outlined on each of the datasets to include uterus and proximal vagina, from which ITVs and PTVs were defined with further nodal volumes as required. VMAT plans were created for each PTV. Online daily CBCT was performed for all patients over the course of 25 treatments and the appropriate PoD was chosen based on the position of the CTV.

The cervix CTV, rectum, bladder and bowel organs were contoured on all CBCTs. Initially the chosen PoD treatment

plan was recalculated on the CBCT for the first and last fractions. Comparisons were made in terms of changes in CTV volumes over the course of treatments. Bladder, bowel and rectum dose was assessed using V30Gy and V40Gy.

#### Results

A total of 100 CBCTs from 4 patients were analysed. All CTVs were within the PTVs chosen for the PoD treatments. The median reduction of CTV volume at the end of treatments was 56%. The CTV reduced over the course of treatment in all patients, and the largest extent of volume reduction was found to be after the first 2 weeks of treatment, with a median reduction of 37%.

The changes of dosimetric parameters on CTV and OARs are summarised in the table below.

Dosimetric parameters	Median % difference between the first and last fraction of treatment
D98%CTV	Increase by 1.15%
D50%CTV	increase by 0.77%
V30Gy Bowel	Increase by 77.66%
V40Gy Bowel	Increase by 129.53%
V30Gy Bladder	Decrease by 0.16%
V40Gy Bladder	Increase by 5.50%
V30Gy Rectum	Increase by 16.30%
V40Gy Rectum	Increase by 51.08%

Given that PTVs remained unchanged, it follows logically that the increased bowel dose can be directly attributed to its anatomical displacement caused by a regressing CTV.

#### Conclusion

This study has shown that consistent CTV coverage is retained through the implementation of adaptive PoD, though, the CTV volume reduces over the course of treatment. As a result, the dose to bowel increases due to the increased amount of bowel within the PTV. It is suggested that proactive replanning of these patients after the first 2 weeks of treatments might be beneficial, in order to reduce bowel dose by taking account of tumour regression.

#### EP-1849 Implementation and verification of DIBH technique for treatment of left-sided breast cancer patients

D. Dupla<sup>1</sup>, K. Konat<sup>1</sup>, M. Janiszewska<sup>2</sup>, A. Maciejczyk<sup>1</sup>, R. Matkowski<sup>3</sup>

<sup>1</sup>Lower Silesian Oncology Center/Wroclaw Medical University, Radiation Therapy/Oncology, Wroclaw, Poland

<sup>2</sup>Lower Silesian Oncology Center, Medical Physics, Wroclaw, Poland

<sup>3</sup>Wroclaw Medical University, Oncology, Wroclaw, Poland

#### Purpose or Objective

The aim of this study was to present specific way of preparation, planning and realization of deep breath-hold (DIBH) technique which is used for treatment of patients with left-sided breast cancer.

#### Material and Methods

283 patients with left-sided breast cancer were irradiated with DIBH technique controlled by Real-time Position Management (RPM) system in Lower Silesian Oncology Center (Wroclaw, Poland) from 2013 to April 2016. Conventional fractionation of 50 Gy for breast with or without regional lymph nodes, and 56,25/60,2 Gy for simultaneous integrated boost in 25/28 fractions were prescribed. 3D, 3D/Intensity Modulated Radiation Therapy techniques were used. Correctness of realization and reproducibility of irradiation was controlled by Image Guided Radiation Therapy protocol. Before each of fractions two orthogonal paired kV images on deep breath

hold to isocenter verification and correction was taken. In addition two MV portal images using the treatment beam to evaluate reproducibility of respiratory motion and to control heart covering in tangential fields was taken. To image analysis an Off-line Imaging Program in ARIA Oncology Information System was used. Reproducibility of movements during respiration under control of RPM system was evaluated after set-up images matching to spine and chest wall. Accuracy of patient positioning and reproducibility of respiratory motion during radiation was evaluated by analysis of tangential field imaging and effectiveness of DIBH technique by presence of heart in tangential fields.

#### Results

The average reproducibility of movements during respiratory cycle controlled by RPM system was in a row -0,07 (±0,2); 0,003 (±0,2); -0,009 (±0,02) cm in vertical, longitudinal and lateral axis. Margin for reproducibility of respiratory cycle was calculated according to van Herk formula and equals: vertical:0,6; longitudinal:0,9 and lateral:0,1 cm. Analysis of tangential field images has shown high accuracy in patients positioning and reproducibility of respiratory motion during radiation therapy with mean systematic setup error  $\Sigma$ :0,037; 0,08; 0,034 cm in vertical, longitudinal and lateral axis. In spite of high reproducibility of respiratory movements and patients positioning part of the heart was included in some tangential field images.

#### Conclusion

DIBH technique is a useful irradiation method to decrease the rate of cardiac complications in left sided breast cancer patients. Developing of detailed protocol of imaging control for DIBH technique and its current analysis is essential for adequate treatment realization. In spite of good reproducibility of respiratory motion controlled by RPM and elimination of set-up error by daily imaging verification, in some cases irradiated field includes heart. It may be caused by insufficient lung expansion caused by wrong diaphragm movement, which is beyond RPM system control. Proper instructions in thoracic and abdominal breathing training are important issues in DIBH technique implementation.

#### Electronic Poster: RTT track: Patient care, side effects and communication

#### EP-1850 Effect on Smoking Behavior, Emotional Distress and Quality of Life in Male H/N Cancer Survivors

H.Y. Kuan<sup>1</sup>, H.X. Zhao<sup>2</sup>, C.Y. Huang<sup>2</sup>, J.T.C. Chang<sup>1</sup>

<sup>1</sup>Chang gung memorial hospital, Department of Radiation Oncology, Taoyuan, Taiwan

<sup>2</sup>Chung Yuan Christian University, Department of Psychology, Chungli, Taiwan

#### Purpose or Objective

To examine the moderation of search for meaning on the relationship between presence of meaning, smoking behavior, emotional distress, and quality of life among male survivors with head and neck cancer.

#### Material and Methods

The head and neck cancer survivors completed the radical cancer treatment longer than 6 months and with smoking history were invited to the study. The participants were interviewed with Substance Use Behavior Questionnaire, Meaning in Life Questionnaire, Short Form Profile of the Mood State, and Functional Assessment of Cancer Therapy Scale-Head and Neck Version in addition to the basic personal characteristic data. Multiple Regression Analysis was used to examine the inter-action effects among different interested outcome.

## Results

Two hundred and four male patients were invited and agreed to participate the study. The median age was 53.9 (30-74). Ninety four (46.1%) patients had buccal cancer, 46 nasopharyngeal cancer, 46 oro-hypopharyngeal cancer and 12 laryngeal cancer. One hundred and thirty (63.7%) patients had previous betel quid chewing and 109 (53.4%) had alcohol drinking. One hundred and three patients had surgery, 191 chemotherapy and all had radiotherapy. Thirty four (16.7%) patients had no religion belief and 30 (14.7%) had no job at interview. Sixty two (30.4%) patients had continuing smoking, 18 (8.8%) patients continued drinking and 6 (2.9%) betel quid chewing. Several relationships had been found after analysis. The presence of meaning had positive effect on global quality of life, emotional well-being and total quality of life. Furthermore, the low presence of meaning and high search for meaning exhibited the lowest levels of general quality of life, emotional well-being and total quality of life. The presence of meaning has negative effect on emotional distress. Furthermore the low presence of meaning and high search for meaning exhibited the highest levels of emotional distress. The longer duration of smoking had less levels of presence of meaning and search for meaning.

## Conclusion

Individuals in the high presence of meaning showed a better adaptation. Compared to those survivors having low presence and low searching for meaning, the head and neck cancer survivors having low presence of meaning and high searching for meaning would have the most poorly emotional distress and quality of life.

## EP-1851 Why is planned palliative radiotherapy often cancelled? A retrospective exploratory study

H. Hansen<sup>1</sup>, M. Skovhus Thomsen<sup>2</sup>

<sup>1</sup>Aarhus University Hospital, Clinic for Radiotherapy and Radiation Oncology, Aarhus C, Denmark

<sup>2</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark

## Purpose or Objective

In our department all appointments are booked when the referral is received, i.e. a 100% pre-booking is performed. In 2014-15 every 7th treatment course for patients referred and booked to palliative treatment in our department was cancelled before the planned start of radiotherapy. This study investigated the reasons for cancellations of palliative treatment courses prior to start of radiotherapy as well as possible common denominators among the cancelled patients.

## Material and Methods

A retrospective exploratory study of reasons for cancelling planned palliative radiotherapy treatment was established. Patients were included if they had been booked for palliative radiotherapy treatment between 1 January 2015 and 30 June 2015. Two sets of data were collected. Firstly, data on age, gender and diagnosis was collected on all planned palliative radiotherapy treatments (n = 787). Secondly, data on all patients who had been cancelled before planned start of treatment (n=105) was obtained. Data on cancelled patients included demographic and clinical data as well as other relevant data recorded in the time between referral to palliative radiotherapy and cancellation. If a patient had been cancelled more than once during the study period data was only collected on the first cancellation.

## Results

Of the 787 planned radiotherapy courses, 106 (13 %) courses were cancelled before planned start of treatment. Of the 106 courses cancelled, one patient accounted for two cancelled treatments. The median time between referral and planned start of treatment for the cancelled

courses was 14 days, showing that the majority of cancelled patients were planned to start radiotherapy much earlier than the maximum time limit of 28 days specified in the Danish legislation. Results of data collected on all planned palliative radiotherapy treatments showed that patients' age, gender and diagnosis did not differ between the courses cancelled before planned start and courses started. Main reasons for cancellation were death before start of treatment, the patient being too weak to start treatment or treatment was no longer relevant. Five of the 33 patients cancelled because they were too weak to receive palliative radiotherapy, died in the time interval between cancellation and the day they were supposed to start treatment. The total number of patients who died before planned start of treatment was 29 (28 %) (Table1).

Table 1: Characteristics of patients with cancelled palliative radiotherapy treatments between 1 January 2015 and 30 June 2015

	No. of patients (%)
<b>Total</b>	105
<b>Gender</b>	
Male	74 (70%)
Female	31 (30%)
<b>Age (years)</b>	
< 40	2 (2%)
40- 69	44 (42%)
≥ 70	59 (56%)
<b>Reasons for referral</b>	
Pain	54 (51%)
Tumour control	47 (45%)
Other	4 (4%)
<b>Reasons for cancellation</b>	
Death	24 (23%)
Too weak to receive treatment	33 (31%)
Treatment no longer relevant	23 (22%)
Other treatment planned	10 (10%)
Patient has declined treatment	12 (11%)
Reason unknown	3 (3%)
<b>Time between referral and planned start of treatment (days)</b>	
< 8	15 (14%)
8 - 14	48 (46%)
15 - 21	39 (37%)
22 - 28	3 (3%)

## Conclusion

The main reasons for cancelling palliative radiotherapy were the patient either being too weak to receive treatment/ dying before beginning of treatment or because treatment was no longer relevant. The other data collected could not explain the number of patients being cancelled. More knowledge is needed about the differences between patients starting palliative radiotherapy treatment and patients being cancelled before start of treatment.

## EP-1852 A research interventional clinic within the NHS to enable participation in prostate clinical trials

K. Crowther<sup>1</sup>, A. O'Neill<sup>1,2</sup>, S. Murray<sup>3</sup>, J. Cousins<sup>3</sup>, O. Stewart<sup>3</sup>, G. Totten<sup>3</sup>, S. Hynds<sup>3</sup>, K. Parsons<sup>3</sup>, P. Shiels<sup>1</sup>, C. Logan<sup>1</sup>, D. Mitchell<sup>1</sup>, C. Lyons<sup>1</sup>, S. Jain<sup>1,2</sup>

<sup>1</sup>Cancer Centre- Belfast City Hospital, Radiotherapy, Belfast, United Kingdom

<sup>2</sup>Centre for Cancer Research and Cell Biology, Queen's University, Belfast, United Kingdom

<sup>3</sup>Belfast City Hospital, Northern Ireland Cancer Trials Network, Belfast, United Kingdom

## Purpose or Objective

Within prostate cancer clinical trials there has been an increasing move towards hypo-fractionated and Stereotactic Ablative Radiotherapy (SABR) regimes. This has led to an increased requirement for Image-Guided Radiotherapy (IGRT). At our centre, it was therefore necessary to implement a service to facilitate the implanting of fiducial markers (FM) and other interventional procedures to enable our participation in such clinical trials.

## Material and Methods

Funding for this service was secured from a research grant. A multi-disciplinary working group of Consultant Clinical Oncologists, Radiographers, Hospital Management, Nurses, Clinical Trials team and Clinical Research Fellows was formed. This group ensured the

service was introduced in a safe and controlled manner by meeting at regular intervals throughout the set-up process, writing protocols and work instructions, and designing and implementing a competency-based training programme for staff undertaking and assisting with the procedures. This service is now a prerequisite for three clinical trials at our centre. Procedures include; prostate FM insertion under Trans Rectal Ultrasound (TRUS) guidance, collection of prostate tissue for research purposes and the insertion of a prostate hydrogel spacer.

#### Results

Since December 2015, there have been 34 patients through this clinic. All patients received FMs and three patients also had prostate biopsies taken and insertion of the hydrogel spacer. As part of service evaluation for the first five months, patients attending this clinic received a post-procedure phone call 72 hours after FM insertion by the Clinical Research Radiographer to monitor for any complications. 11 patients who had attended the clinic for FM insertion received this call; seven patients reported no issues, two reported loose bowels/diarrhoea, one patient reported haematuria and one case of possible prostatitis was also reported.

#### Conclusion

This service has been a significant development in facilitating participation in local and national prostate cancer radiotherapy trials. Patient-reported acute side effects and toxicity resulting from the procedures undertaken would indicate they are well tolerated with minimal complications reported. Demand for this service continues to grow with the opening of further clinical trials. Performance and efficiency of this clinic demands an ongoing collaborative approach by a large multi-disciplinary group working across professional, departmental and institutional boundaries.

#### EP-1853 The Role of Radiotherapist in Prospective Evaluation of Quality of Life of Head-Neck Cancer patients

D. Debojoyti<sup>1</sup>

<sup>1</sup>APOLLO GLENEAGLES HOSPITAL, RADIOTHERAPY, Kolkata, India

#### Purpose or Objective

Cancer and its subsequent treatment may cause physical, emotional, and psychological difficulties for individuals. Quality of life (QOL) indices are as important as the traditional end points of overall survival, disease free survival & tumor response in cancer management. QOL is particularly relevant for patients with head & neck cancer, because social interaction & emotional expression depend to a great extent on the structural & functional integrity of the head & neck region.

#### Material and Methods

During the period, June 2012 to June 2013, 33 head & neck squamous cell cancer patients who received radical chemoradiotherapy were consented and prospectively assessed for quality of life score using European Organization for Research & Treatment of Cancer (EORTC) core Questionnaires version 3 (QLQ-C30) and the EORTC QLQ-H&N35, in any one of three languages (English, Hindi, Bengali). The score was assessed thrice for each patient, before start of radical treatment, just after completion of radical treatment and at the time of first follow up. Follow up QOL score has not been incorporated in this report.

#### Results

There were significant changes in Emotional Function (mean 71.21 vs 79.04,  $p=.04$ , 95%CI -15.53- -.11), Social Function (mean 81.81vs90.90,  $p=.05$ , 95%CI-18.20- .02), Insomnia(mean 22.61vs32.14,  $p=.03$ , 95%CI-18.03- -1.01), Appetite (mean 34.52vs60.71,  $p=0.001$ , 95%CI-40.84- -

11.53) & for Nausea/Vomiting (mean 6.79vs24.69,  $p=.002$ , 95%CI-28.55- -7.25).

#### Conclusion

In accordance with our prospective study of quality of life of patients head & neck cancer, we found there were no deterioration of physical & role function & finally it is remarkable that there was no significant change of global health. This prospective study demonstrates short term deterioration of functional as well as symptomatic scale on the other side we also wanted to seems here, the important role of radiotherapy technologist in quality of life of cancer patients. We thought every radiotherapy technologist should a positive part to collect the EORTC C-30 & EORTC H&N35 QOL questionnaire before & also at the day of completion

#### EP-1854 Information Seeking Patterns of Patients/Carers and Satisfaction with Web-based Resources

A. Craig<sup>1</sup>, D. Dunne<sup>1</sup>, C. Gillham<sup>2</sup>

<sup>1</sup>Trinity College Dublin, Applied Radiation Therapy Trinity- Discipline of Radiation Therapy, Dublin, Ireland

<sup>2</sup>St Lukes Radiation Oncology Network, St. James Hsp., Dublin, Ireland

#### Purpose or Objective

It has been established that a substantial number of patients and their carers use the internet to obtain additional health-related information and several studies have been published analysing the quality of information available on these websites.

The aim of this research was to (1) ascertain the internet usage and information seeking patterns of cancer patients and their carers and (2) identify the possible characteristic demographics of internet users. A secondary aim was to determine if these patients and carers are satisfied with the information available to them on a purpose designed web-based patient information resource, 'Website A' which is affiliated with the Radiation Oncology Network that they were attending

#### Material and Methods

A self- designed anonymous questionnaire consisting of two sections was distributed to patients and their carers within the three radiotherapy departments of a Radiation Oncology Network in Ireland. Participants included patients (n=70) and carers (n=46).

#### Results

A total of 116 surveys were returned, with 73% of participants reporting daily internet usage. 52% of these used the internet for information on general health and 67% of the participants used the internet to search for information on their current cancer diagnosis. Of those participants, only 12% used Website A, the website under evaluation in this study. The remainder were unaware of its existence. Overall, when seeking healthcare information, participants rated medical professionals the most useful, followed by Patient Information Leaflets. Healthcare Information Websites were rated the third most useful resource.

#### Conclusion

Despite medical professionals and information leaflets remaining the most useful sources for patients, physicians need to be aware that many of their patients and their carers are using the internet for information on their diagnosis. This should be acknowledged by recommending quality web-based information resources to ensure that only high quality information is accessed.

Website A offers information specifically tailored to the treatment and support services available within the hospitals of this network- an advantage for patients and carers that cannot be ignored. However, Website A is as the majority of participants were unaware of this website

efforts to promote and advertise this website are warranted.

#### EP-1855 Dedicated Patient Information Cancer Websites: A Usability Comparison

S. Wall<sup>1</sup>, A. Craig<sup>1</sup>

<sup>1</sup>Trinity College Dublin, Applied Radiation Therapy  
Trinity Research Group, Dublin, Ireland

##### Purpose or Objective

In recent years, there has been an explosion in the use of websites for acquiring health information. Usability, or the efficiency, effectiveness, and satisfaction users have with websites, determines whether users will return to the site. As information requirements by patients fluctuate over the course of their disease, health information websites must be usable to ensure they consistently meet patient's information requirements. The purpose of this study was to investigate the usability of one dedicated radiotherapy website, and compare this to 3 other popular patient websites. A secondary aim was to investigate if the websites complied with readability guidelines published by national and international organisations.

##### Material and Methods

The data sources for comparison comprised of websites identified from searching the three most used search engines, using keywords reflecting most common language among patients. The LIDA tool, developed for online health information websites, was used to assess the websites for accessibility, usability and reliability. Readability and quality of online written literature was examined using the HSE/NALA Plain Language Style Guide for Documents and "Making Your Website Senior Friendly" guidelines produced by the National Institute of Aging and the National Library of Medicine in the USA. All data collection methods were analysed using descriptive statistics, to allow for comparison between the websites.

##### Results

Website A scored 88 out of 141 or 62.41% on the LIDA tool, somewhat less than the other 3 popular patient websites. Website A scored highly in consistency of layout, search function and website accessibility, but scored less well for reliability (1 out of 27). Other issues identified with Website A included clarity of information and user interaction. In addition, website A had readability issues, with some content written at a level higher than advised by guidelines. This will impede those with low literacy from effectively using the website.

##### Conclusion

Website A scored lowest of the four websites as a result of issues relating to the reliability of the website. This issue is easy to address, and acting on recommendations from this research, would bring the website in line with other recognised cancer patient information websites, in relation to usability. It is important to remember that the studied websites, while all related to cancer information, are not directly comparable in that they are not specific to radiotherapy, the size of the organisation, the traffic to the site or the country of the sites origin. However steps can be taken as a result of this study to improve the usability of Website A, allowing for greater empowerment of patients through knowledge acquisition which may ultimately lead to improved clinical outcomes.

#### EP-1856 The impact of waiting time on survival of Lung Stereotactic Ablative Body Radiotherapy patients

Y. Tsang<sup>1</sup>, P. Nariyangadu<sup>2</sup>, N. Shah<sup>3</sup>, P. Ostler<sup>3</sup>, P. Hoskin<sup>3</sup>

<sup>1</sup>Mount Vernon Hospital, Radiotherapy, Northwood Middlesex, United Kingdom

<sup>2</sup>Mount Vernon Hospital, Radiotherapy Physics, Northwood Middlesex, United Kingdom

<sup>3</sup>Mount Vernon Hospital, Clinical Oncology, Northwood Middlesex, United Kingdom

##### Purpose or Objective

The introduction of Stereotactic Ablative Body Radiotherapy (SABR) has led to a rapid change in treatment utilization in elderly patients with early stage non-small cell lung carcinoma (NSCLC). This study aims to investigate the impact of waiting time on lung SABR treatment outcomes.

##### Material and Methods

A consultant radiographer has been appointed to lead our institution's SABR service since April 2014. The post holder was expected to streamline the patient pathways that still deliver high quality services but in more resourceful and innovative ways including radiographer led target volume delineations and consent.

Between 2011 and 2015, 105 NSCLC patients were treated with SABR. A retrospective review was done to determine the relationship between overall survival (OS) and intervals between decision to treat and treatment start date (INT). Medians were used to split the distribution of INT into two groups: below and above median. Survival curves for each group were compared using a log rank test. Similar analysis was undertaken comparing patients who were treated before and after the appointment of the consultant radiographer.

##### Results

The median age was 73.9 years (range: 53.0-92.9) and median follow-up was 30.8 months (range: 14.9-74.6). For all patients the median OS was 20.7 months (95%CI: 15.4-26.0) and INT was 1.0 months (range: 0.1-6.9) respectively. No significant difference in OS was found between the below and above median groups ( $p=0.46$ ). The median waiting time has been shortened from 1.4 months to 0.6 months ( $p<0.05$ ) since the joining of the consultant radiographer at our institution although no effect on OS ( $p=0.13$ ) is found.

##### Conclusion

It's suggested that the waiting time has been shortened since the appointment of the consultant radiographer. However no significant effect on OS has been seen. This is contrary to published data using conventional radiotherapy. The short overall time for SABR may be compensating for the difference in waiting time to start. The numbers in this study are small and a significant difference may emerge with a larger cohort.

#### EP-1857 Radiotherapy impairs on the bonding system in primary teeth

A. Queiroz<sup>1</sup>, T. Mellara<sup>1</sup>, P. Nelson-Filho<sup>1</sup>, J. Arid<sup>1</sup>, J. Romano<sup>1</sup>, H. Oliveira<sup>2</sup>, R. Palma-Dibb<sup>1</sup>

<sup>1</sup>University of São Paulo - School of Dentistry of Ribeirão Preto, Department of Pediatric Dentistry, RIBEIRAO PRETO, Brazil

<sup>2</sup>University of São Paulo - School of Medicine of Ribeirão Preto, Department of Medical Clinics, RIBEIRAO PRETO, Brazil

##### Purpose or Objective

When radiotherapy (RT) is performed in the head and neck region, it could lead to structural alteration in enamel and dentin that could influence the behavior of the bonding agents. The present study aimed to evaluate whether the RT interferes in the bonding of two adhesive systems (Clearfil SE Bond e Adper<sup>TM</sup> Single Bond 2) to enamel (E) and dentin (D) of primary teeth, in different times (before and after RT).

##### Material and Methods

Sixty primary molars were cut in a total of 120 fragments of enamel and 120 of dentin, which after the surface polishing were randomly divided into 4 groups ( $n=30$ /group): G1 (control) - enamel and dentin without

RT + restorative procedures; G2 - restorative procedures performed before RT; G3 - restorative procedures performed after RT; and G4 - restorative procedures performed 6 months after RT. Each one of the groups was then divided into 2 subgroups: subgroup A - using the *etch-rinse* Adper™ Single Bond 2; and subgroup B - using the *self-etch* Clearfil SE Bond. The specimens were irradiated in dose fractions of 2 Gy, for 5 consecutive days, until reaching the final dose of 60Gy, in a total of 30 fractions, during 6 weeks. The restorative procedures were done using the Z350 composite, and for standardization of the restorations a matrix was used, so the specimens all presented 4 mm height and 2 mm of diameter. The specimens were submitted to the shear bond strength test (load of 50 kgf and speed of 0.5 mm/minute), the result was obtained in N and then transformed to Mpa. The fracture pattern was analyzed in a confocal microscopy (MC). Five specimens of enamel and 5 of dentin were chosen to the morphological analyzes also by MC, those specimens were evaluated every 10 Gy. As for the bonding interface 3 specimens of each group were chosen, and prepared for scanning electron microscopy (SEM). Enamel and dentin were evaluated separately, data was analyzed by the ANOVA and Post Test Tukey ( $p < 0.05$ ). Significance level was 5%.

### Results

It could be observed that for both substrates the Clearfil SE Bond (E: 20.19 MPa; D: 17.61 MPa) was statically superior than Single Bond (E: 17.21 MPa; D: 15.45 MPa) ( $p < 0.05$ ). As for the time of restoration, group 2 had the worst results, in both enamel and dentin. It was observed that that radiation affected negatively the bonding in enamel and dentin ( $p < 0.05$ ), however, in the group 4 no alterations were observed ( $p < 0.05$ ). The predominant fracture pattern was the adhesive, which had raised its prevalence according to the radiation. In the MC analyses there were morphological alteration in enamel and dentin after the cumulative doses of 40 Gy. It was observed, by SEM, tags formations and alterations on the hybrid layer.

### Conclusion

It could be concluded that RT had affected the morphological surface of enamel and dentin, and that it affected the adhesion of the bonding systems, indicating that it should be waited at least 6 months after RT to perform restorative procedures, in which the Clearfil SE Bond was less affected.

## Electronic Poster: RTT track: Education and training/role development

**EP-1858 Implementation of nursing consultations following adjuvant radiotherapy for breast cancer**  
S. Petri<sup>1</sup>, A.B. Krog<sup>1</sup>, L. Prenter<sup>1</sup>  
<sup>1</sup>The Finsen Center - Rigshospitalet, Department of Oncology Section for Radiotherapy, Copenhagen, Denmark

### Purpose or Objective

The purpose of implementing nursing consultations for women treated with adjuvant radiotherapy for breast cancer was multiple. The primary objective was to enhance the women's experience of continuity and consistency of care during the treatment trajectory. Secondly the aim was to implement a preparation tool "Supporting life with cancer" (fig. 1) in the consultations to address the problems and challenges the women could experience in their everyday lives following the treatment trajectory. The focus of the nursing consultations was therefore on handling the toxicity experienced during the radiotherapy as well as a specific focus on rehabilitation and support in the future everyday life.

**For you and your relatives Supporting life with cancer 1**

**Preparation tool - to help you - prior to an interview about rehabilitation and palliation**

**Problems / challenges in your everyday life that you would like to discuss**

**Challenges regarding activities of daily living**

**Challenges in your social life**

**Physical and mental challenges**

**For you and your relatives Supporting life with cancer 2**

**Distress**

**How is your level of distress in everyday life? Tick on the thermometer**

**What is important to you in your daily life?**

**What should cancer not prevent you from doing?**

**What worries you the most?**

**Other areas you want to talk about**

### Material and Methods

Initially all RTTs (nurses and radiographers) received a generic course regarding the use of the preparation tool "Supporting life with cancer" and assessment of rehabilitation needs during the cancer treatment trajectory. Subsequently the RTTs were divided in smaller groups of 4 to 8 and participated in a course regarding the specific content of the consultations.

The bullet points were:

- Nursing assessment of the radiotherapy induced toxicity
- Advice and guidance to cope with the toxicity in everyday life
- Communication techniques to ensure a patient-centered and patient-driven agenda

These sessions were conducted by the department's clinical nurse specialist, an experienced RTT and MScN. Guidelines for the consultations and tip sheets on communication and rehabilitation services were designed in cooperation with the RTTs to support and simplify the tasks of the consultations. Frequent follow-up sessions with the small RTT-groups and the clinical nurse specialist comprised adjustment and supervision continuously during the implementation period.

In December 2015 the consultations were implemented to a limited number of patients, in order to gain knowledge on challenges that could occur. Small adjustments were made and in February 2016 the consultations were expanded to the entire patient group.

### Results

The consultations were implemented successfully. The results of an audit on 100 patient charts are showed in table 1. Ninety-eight of the first 100 women, whom were scheduled for the nursing consultation, received it. The duration of the consultation was planned to 20 minutes, and the mean duration was 21.5 minutes.

Table 1

Results			
Patient characteristics, N=100			
Age (years), mean [SD, min - max]	59,2 [11,6, 25 - 85]		
Duration of consultations <sup>2</sup> (minutes), mean [SD, min - max]	21,5 [11,2, 5 - 90]		
Questions from audit			
	Yes (%)	No (%)	Unknown (%)
Was the preparation tool handed out?	94 (94%)	2 (2%)	4 (4%)
Was the nursing consultation held?	98 (98%)	2 (2%)	-
Did the patient bring the preparation tool?	46 (47%)	54 (53%)	-

<sup>1</sup> The nursing consultations were scheduled to last 20 minutes

<sup>2</sup> It is the patient's sovereign decision whether to use the preparation tool or not

Furthermore the implementation process was evaluated with the RTTs in smaller groups and statements like; "a meaningful task", "well prepared" and "it's not as difficult as anticipated, I can actually handle this" were frequent statements.

### Conclusion

The successful implementation of this project was particularly due to the deep involvement of the RTTs in

the planning and adjustment of the project. In this way the RTTs felt an ownership of the project while the new tasks were considered meaningful too. Future areas for improvement involve the patients' perspectives of the consultations and the need assessment preparation tool.

#### EP-1859 RTTs challenge's in re-plan decision

D. Radola<sup>1</sup>

<sup>1</sup>Greater Poland Cancer Centre, Radiotherapy Department II, Poznan, Poland

#### Purpose or Objective

Important role of imaging, and verification on medical accelerator depend on RTT team. From the past three years, our Oncology Center develop advance scope of practice dedicated to RTT depend on the level of the education, allowed to managed and build strong team. The priority is quality of the treatment. The main aim of this work is to present changes in responsibility in daily practice of the RTT allowed to improve the quality of treatment, by fast detection of possible residual errors in radiotherapy.

#### Material and Methods

Radiation Technology' tasks included: patient positioning, portal verification, irradiation delivery. The scope of licentiates' responsibilities (equivalent of bachelor's degree -) was extended to include QA dosimetric procedures and the preparation of accelerators. The existing duties of RTT with magister's degree (equivalent of master's degree) were extended and supplemented with new competences. These included the supervision of the work on the accelerator, decisions on replanning, assistance to the radiation therapist in preparing patients for treatment, (immobilisation, iCT, organ at risk contouring, verification of ready treatment plans on the simulator).

#### Results

In 2011/12 number of re-plan was (481) and (523) which correspond with 10% of all treating patient in our Center. In 2013 we start developing idea of advance scope of practice of our RTT. Next two years of experience in Immobilization, treatment preparation, and contouring indicate increasing number of quality control. Number of re-plan in 2014/ 2015 was (581) (566) which corresponding with 11.5% and it was higher by 1,5% according to first two years. Time of patient preparation for treatment (Immobilization, Ct-scan, Contouring, QA) decrease from 5 (days) to 4 (days).

#### Conclusion

Advance role of the RTT significant increasing their academic competency, affect on the quality control in the process of radiotherapy. New role of RTT, allow to increase patient safety, higher standards of the treatment and advance decisions making based on the image registration corresponding with number of re-plan. Further developing of the role should open more advance scope of practice of modern RTT.

#### Electronic Poster: RTT track: Risk management/quality management

EP-1860 A process and human factors engineering paradigm for radiation oncology

K.C. Chan<sup>1</sup>, W.Y. Lee<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Department of Radiotherapy, Hong Kong, Hong Kong SAR China

#### Purpose or Objective

The ever-advancing Radiation Oncology has become a technologically based speciality. The automation-based

advances in radiotherapy bring new challenges to patients and the department in terms of safety and quality. The knowledge of process and human factors engineering was incorporated in the implementation of Radiation Oncology Information System (ROIS) and its integration with the Hospital Information System (HIS) at the department. It aimed to enhance radiotherapy planning and treatment efficiency, quality and safety. Since HIS is the central patient data source of the department, this project also aimed at integrating the two systems to maintain patient record integrity.

#### Material and Methods

Before clinical implementation, a project team was formed in preparation for the implementation of ROIS and its integration with HIS. The end-to-end radiotherapy process was reviewed. A dedicated testing database environment was built to assess usability requirements. Main requirements, risk areas and contingency measures were identified. Application training was given to all stakeholders in the department so as to cultivate understanding of MOSAIQ and ensure familiarity with the use. Integration of ROIS with HIS required analysis of computer information flow. The method of communication and the type of data sent between each component were examined (Figure 1).

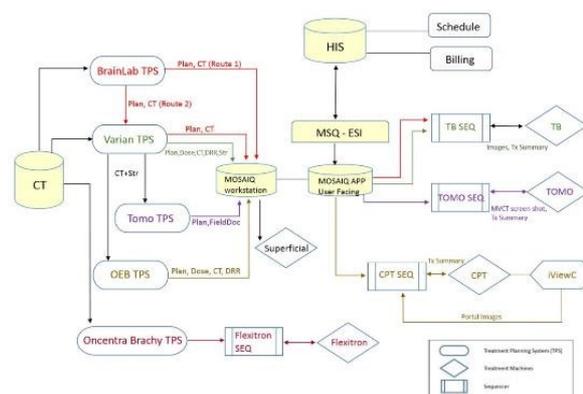

Figure 1. Diagram of information flow between different components within the department.

#### Results

Machine interfacing was completed in August 2014. Since then, our department started treating patients with MOSAIQ as the ROIS. The implementation incorporated key concepts of process engineering. Efficiency, quality and safety could be improved by streamlining processes, removing ambiguity, improving communication and standardizing workflow. The knowledge of human factors engineering, namely automation, forced function, simplification and standardization, was applied to design the new working procedures for safe and effective human use. The implementation of MOSAIQ made process improvement possible by setting code capture mandatory at certain stages within the radiotherapy process. The codes captured set the foundation for clinical data acquisition and statistics purpose. The ROIS was successfully integrated with HIS, which automated patient registration (Figure 2) and charging process.

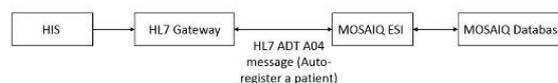

Figure 2. Flowchart showing how auto-registration is done via HL7.

#### Conclusion

To conclude, the enhanced efficiency and quality after implementation of ROIS showed the potential to reduce errors and improve safety. The integration with HIS

centralized patient data into a single user interface accessible across multiple locations. Patient record integrity could be further improved.

**EP-1861 Patient Satisfaction with Radiotherapy Services at Institute of Oncology in Ljubljana (Slovenia)**  
V. Zager Marciuš<sup>1</sup>, M. Križan<sup>1</sup>, A. Oklješa Lukič<sup>1</sup>, I. Oblak<sup>1</sup>  
<sup>1</sup>Institute of Oncology- Ljubljana, Radiotherapy Department, Ljubljana, Slovenia

#### Purpose or Objective

**Purpose/Objective:** The objective of the research was to determine the degree of patients' satisfaction with radiotherapy services at the Institute of Oncology in Ljubljana and to obtain feedback on the quality of performance of various professional profiles and healthcare.

#### Material and Methods

**Material/methods:** The research makes use of the descriptive method, reviewing and analyzing scientific literature. Using a cross-section one-day study, we assessed the satisfaction of patients with various professional profiles (receptionists, nurses, radiology engineers, doctors, radiotherapy oncologists) and with healthcare in general. The instrument used to obtain the study data was a questionnaire utilizing Likert's five-point scale of satisfaction. The questionnaire was first tested on a small group of patients. The surveying, which was implemented over the course of one day, was conducted in November 2015. The study a total of 282 involved patients out of the 359 planned, which adds up to a 78.6 % overall response rate. For the analysis and evaluation of the data obtained, two computer programs were used, namely Microsoft Excel 2010 and IBM SPSS Statistics 22. The study was approved by the Commission for Ethics and Professional Assessment of Clinical Study Protocols at the Institute of Oncology in Ljubljana.

#### Results

**Results:** Out of the 282 participants in the study, 51.4 % were male and 48.6 % female. 80.9 % of the patients participating in the survey were over 50 years old. The older and less educated patients were generally more satisfied with both the medical staff and the services provided. The questions in the questionnaire were divided into three segments: work, provision of information, and kindness. The patients were most satisfied with the work of radiology engineers and the kindness of doctors, radiotherapy oncologists, and nurses. The patients who knew their doctor by name gave higher ratings for their satisfaction with the operation of the radiotherapy department with a statistically significant difference ( $p=0.030$ ). A very strong correlation coefficient (i.e. a correlation coefficient whose value exceeds 0.600) was found in relation to the satisfaction with the operation of the radiotherapy department, namely in terms of work and the provision of information by radiology engineers and doctors' work and kindness. All the correlations obtained were statistically significant in terms of risk (1 %).

#### Conclusion

**Conclusion:** The assessment of a patient's satisfaction level is a generally recognized method of determining the quality of healthcare services. The efficiency of a patient's medical treatment is determined by multiple factors, among them being the working environment, relationships among the medical staff, the methods of leadership and organization, motivation and training of the medical staff. Hence, the opinions of patients represent a vital basis for the planning of changes and improvements that would lead to a quality implementation of work and medical care.

#### EP-1862 Alert issues in the radiotherapy

D. Eyssen<sup>1</sup>

<sup>1</sup>MAASTRO Clinic, Radiation Oncology, Maastricht, The Netherlands

#### Purpose or Objective

There are several report available with information about risky circumstances in healthcare. The ECRI publish a top 10 list from risk in healthcare. The ECRI is an independent, non- profit organization who investigates the best approach for improvement of risk, quality and cost effectivity in patientcare. On their website the top 10 hazard list is presented. According to these lists, alarm management is a top 10 risk. Due to the dominant human-technic relation within the radiotherapy this risk is also an issue in the radiotherapy.

#### Material and Methods

The main focus for this research is advisory towards reliable alerts at the right, risky moment whereby the user will receive an adequate alert and knows how to handle. There will be an comparison of the incident database between the radiotherapy institutes. The cadre for this comparison is: The overkill off reminders / pop-ups / warnings. The lack of reminders / pop-ups / warnings. The process on the linear accelerator. There will also be a tally between radiotherapy institutes. The main focus is to investigate if there are different alerts between the institutes and the way institutes deal with these alerts. For this tally the cadre is the linear accelerator

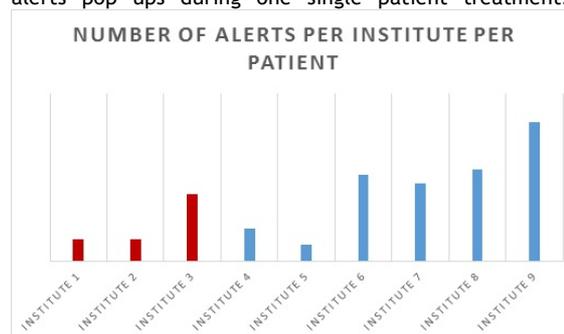

#### Results

Comparison of the database

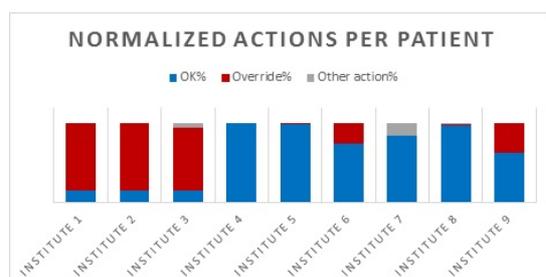

3 institutes checked their database of incidents. Are there any incident related to Alert management? What seems is that there are not that many incident report related to this topic. Although the less reports about alerts management, it was still possible to classify the reports in four groups: Alerts that have less organizational embedding. This can lead to alerts tiredness. No alert present but desirable. Unclear alerts for the user. Alerts whereof not sure what the consequences are

Tally between the radiotherapy institutes

9 institutes have shared their data and tally their alerts on the linear accelerator. The project group collect all the data and processed it into a document. Although there is variation between the number of alerts popups between the different vendors, all the institutes received 1 to 5 alerts pop ups during one single patient treatment.

There also seems a difference between the vendors. In the comparison there is clearly visible that one suppliers presenting less alert pop up than the other. There is no value judgment between the vendors about the alerts and related incidents. Also the action that should be taken by the alerts is different between the two vendors. One vendor is using an override while the other is using the OK button

### Conclusion

Alerts are an issue in the radiotherapy. This research shows that for each patient treatment the user must deal with 1 to 5 alerts depending on the supplier. This indicates that bad alerts management will not lead to false radiation. On the other hand an overkill from alerts will lead to alerts tiredness. A linear accelerator can make over more than one thousand alerts. For the user is unthinkable to deal with all these alerts. But act on a random basic is also not conceivable.

### EP-1863 Risk analysis for image guided lung SBRT

A. Perez-Rozos<sup>1</sup>, I. Jerez-Sainz<sup>1</sup>, A. Roman<sup>1</sup>, A. Otero<sup>1</sup>, M. Lobato<sup>1</sup>, Y. Lupiañez<sup>1</sup>, J. Medina<sup>1</sup>

<sup>1</sup>Hospital Virgen de la Victoria, Radiation Oncology. Medical Physics., Malaga, Spain

### Purpose or Objective

Stereotactic Body Radiotherapy (SBRT) is a complex technique that reduce number of sessions and increase fraction dose, with higher accuracy requirements. In this work we carry out a risk analysis of our lung SBRT simulation, planning and treatment process using Failure Modes and Effects methodology (FMEA).

### Material and Methods

FMEA analysis was performed by a multidisciplinary team integrated by radiographers, nurses, medical physicists, and radiation oncologists. Main steps were: identify flux diagram of whole process, assign risk and probability for every steps, and specific analysis of higher RPN number steps to reduce global risk uncertainty.

### Results

Main analyzed steps include: a. Simulation, b. Prescription and treatment planning c. Preparation and treatment verification d. Treatment delivery. Every step was then described with higher detail. The detail degree has to be enough to allow for clarity, but not too high to loose in small unimportant steps.

In every substep we identified failures modes and effects and risk priority numbers (RPN) were assigned, using a score for severity, occurrence and detection probabilities (scores from 1 to 10). RPN numbers were promediated between team members. Failure modes with the higher scores were given the maximum priority to subsequent study to apply specific QA or to take measurements to reduce RPN number. We have identified 32 events, the 5 with higher scores were selected in a first stage to reduce risk numbers. Critical steps involved isocenter transfer and integrity between image and treatment system, prescription errors between oncologist prescription and electronic one, and mistakes in treatment delivery.

### Conclusion

Risk analysis in radiotherapy process must be a priority to identify weakness and reduce uncertainty. Multidisciplinary teams help to make flux diagrams, identify critical steps and increase global safety.

### EP-1864 Control of patients with pacemaker/implantable cardioverter defibrillator undergo radiotherapy.

M. Puertas Valiño<sup>1</sup>, A. Mendez Villamon<sup>1</sup>, M. Gascon Ferrer<sup>1</sup>, C. Vazquez Sanchez<sup>1</sup>, P. Sanagustin Pedrafita<sup>1</sup>, J. Castillo Lueña<sup>1</sup>, M. Tejedor Gutierrez<sup>1</sup>

<sup>1</sup>hospital universitario miguel servet, radiotherapy, zaragoza, spain

### Purpose or Objective

To establish a few basic criterias of control of the device, in patients submitted to irradiation, without generating an excessive load of work for the involved services and a stress to the patient.

### Material and Methods

There has been created a patient registration sheet, with the clinical information of these and with those parameters relating to the treatment, as well as symptoms suffered by the patient and the information it brings over of the functioning of the device. A protocol of action has been established, so that when a patient of these characteristics is considered to be subsidiary of treatment by ionizing radiation, some procedures are carried out:

1. Consultation to the Service of Cardiology of our center, for the first valuation.
2. Preparation of the treatment , bearing in mind, the distance of the field of irradiation to the device. Make sure that the device does not receive a direct, unshielded irradiation.
3. Schedule of treatment for these patients, making easier the control for the cardiologist of our institution. Once the treatment sessions have finished, the final review is realized and the opportune controls are ruled.

### Results

From the beginning of the project in March 1, 2016, there have been radiated in our department, 16 patients with cardiac implantable devices .

- 5 women and 11 men.
- The middle ages are 76,8 years (66 years to 86 years).
- All of them were non-pacemaker-dependent
- The tumour pathology origin of the need of irradiation has been:
  - Carcinoma of lung 8 patients.
  - Carcinoma of breast 5 patients.
  - Brain Metastasis 1patient.
  - Cancer of rectum patient 1.
  - Cancer of larynx patient 1.
- The dose of radiation the patients has been variable: between 30 Gy (300cGy/sesión) in case of cerebral metastases, to 69.3 Gy (210 cGy/sesión) in case of the carcinoma of larynx or an extreme hipofraccionamiento in the SBRT of lung, with dose of 60 Gy, in meetings of 1200cGy. In two cases, the patients received concomitant chemotherapy. - The used energies have been, in the majority of the patients, photons of 6, 10 and 15 MV. Only in a case of cancer of breast, the irradiation of photons was followed by 3 meetings electrons.

The review of the device, it has not showed alterations of this one in any case. There have been checked the medication, syncopes, IC, as well as all the parameters of the programming of the pacemaker or defibrillator, without some alteration be observing.

### Conclusion

In our patients some alteration has not been targeted in the device after the irradiation, independently of the dose. On balance, RT may be delivered safely in carefully selected patients without the need to remove the PM/ICD from the vicinity of the RT field.

### EP-1865 The utilization of retrospective registry for patient information of access to care

M. Siekkinen<sup>1</sup>, M. Stepanov<sup>2</sup>, A. Hammis<sup>3</sup>, P. Rautava<sup>4</sup>

<sup>1</sup>Turku University Hospital, Cancer Centre, Turku,

Finland

<sup>2</sup>Turku University Hospital, Centre for Clinical Informatics, Turku, Finland

<sup>3</sup>Turku University Hospital, Centre for Clinical Informatics, Turku, Finland

<sup>4</sup>University of Turku, Preventive Health Care, Turku, Finland

### **Purpose or Objective**

Access to care can have a major impact on cancer care outcomes. Therefore hospitals should provide sufficiently rapid access and information of the time to support patients' decision making of treatment unit. The follow up data of the access to care for patients is also a criterion of qualitative cancer care defined by Organization of European Cancer Institute (OEI). The aim was first to describe how a gynecological (gyn) and breast cancer (bc) patient's access to care during their care pathway has occurred in Turku University Hospital (Tyks) Cancer Centre after receiving an admission note and secondly submit it to the electronic portrayal of patient care pathway for patients.

### **Material and Methods**

The study was carried out VIII / 2015 - IX / 2016 in clinical information service unit and treatment units in Turku University Hospital (Tyks) in Finland. The target group was gyn (N=1549) and bc (N=945) patients starting their first cancer treatment. The data collection method was a retrospective registry study. The dates of appointments, phone calls, multidisciplinary meetings, treatment decisions and periods (surgery, radiotherapy, chemotherapy, other treatments) were carried out from WebMarela, Oberon and Aria information system entries. Access to care was analyzed from the admission note to the first treatment unit and to other care contact days. The results were analyzed by statistical methods (the mean time and the standard deviation figures). The accuracy of the results was verified by obtaining a review of experts from treatment units. The recommended time of access to cancer care of Ministry of Social Affairs and Health in Finland were taken into consideration. Results were presented quarterly and linked electrically internet sites to the portrayal of patient care pathway for patients.

### **Results**

In total, access time for gyn patients (n=331) from the first admission note to first treatment unit (gyn surgery outpatient clinic) contact (first appointment) was 11 days (mean; quarterly range 10-12) and to surgery 28 days (mean; quarterly range 24-35) or to radiotherapy/chemotherapy 41 days (mean, quarterly range 39-43). Access time for bc patients (n=661) from the first admission note to first treatment unit (breast surgery outpatient clinic) contact (phone call) was 4 days (mean, quarterly range 2-5), to appointment 14 days (mean; quarterly range 10-15) and to surgery 27 days (mean; quarterly range 21-33) or to radiotherapy/chemotherapy 20 days (mean; n=1). Quarterly, access to care for gyn patients was highest at second quarter 2015 and 2016, and for bc patients increased linearly from first quarter 2015 to third quarter 2016. The increase was not depend on number of patients.

### **Conclusion**

A retrospective registry study could produce up to date information of cancer patients' access to care. It also might increase patients' knowledge of access to care during the care pathway. Further definition models should be produced of variables for management and the development of the cancer care.

# Radiotherapy &Oncology

Journal of the European Society for  
Radiotherapy and Oncology

## INFORMATION FOR AUTHORS

ARTICLES should deal with original research or reviews of topics defined in the aims of the journal. Radiotherapy and Oncology publishes original material only. It is therefore understood that the content of the paper has not previously been published in the same or a similar form and that it is not under consideration for publication elsewhere. The act of submitting a manuscript to the journal carries with it the right to publish that paper.

Radiotherapy and Oncology uses an online manuscript submission and peer review process.

Papers and correspondence should be submitted online at <http://www.ees.elsevier.com/ro> and the instructions on the site should be closely followed. Authors may submit manuscripts and track their progress to final decision. Reviewers can download manuscripts and submit their reports to the Editors electronically.

The full contact details for the Editorial Office are shown below:

**Professor Michael Baumann, Radiotherapy & Oncology Editorial Office, Deutsches Krebsforschungszentrum (DKFZ), Im Neuenheimer Feld 280, 69120, Heidelberg, Germany (E-mail: [ro@elsevier.com](mailto:ro@elsevier.com)).**

### TYPES OF PAPERS

#### 1. Full length original papers (max. 3000 words)

Describe original scientific work in the field of radiation oncology or related areas. The content of the paper should be sufficient to reach valid conclusions. Full papers should include a structured abstract and be divided into sections (Introduction; Materials and Methods; Results; Discussion; References; Tables; Figures) and should not normally exceed 6 printed pages, including references and a maximum of 6 tables/figures. Additional material can be submitted as supplementary files.

#### 2. Short communications and Technical notes (max. 2000 words)

Provide a brief but complete account of a particular piece of work, e.g. Phase I or II study, and should in total be no longer than 4 printed pages, normally including a maximum of 2 figures or tables. A summary of not more than 50 words should be included (not a structured abstract), but the manuscript can have fewer subheadings (e.g. short introduction; materials and methods; results and discussion). Authors are advised to see a recent issue of the journal for size and lay-out.

#### 3. Review articles

Rigorous critical assessment of clinical and/or laboratory research in a field of interest to the journal and its subscribers. Reviews are normally solicited by the editors, and it is suggested that authors wishing to contribute a review article contact the editor-in-chief.

#### 4. Editorials and commentaries

Editorials and commentaries relate to articles in the journal or to issues of relevance for the readership. This type of communication is normally solicited by the editors.

#### 5. Letters to the Editor

On topics of current interest or comment upon material previously or simultaneously published in the journal. They should be limited to 500 words and may include 1 table or figure.

#### 6. Announcements

The inclusion of announcements, etc. is at the discretion of the Editors and the Publisher and subject to space availability. Request for inclusion of meeting announcement should be sent to the ESTRO secretariat (see address in journal).

### Author inquiries

For inquiries relating to the submission of articles (including electronic submission where available) please visit this journal's homepage at <http://www.elsevier.com/locate/radonc>. For detailed instructions on the preparation of electronic artwork, please visit <http://www.elsevier.com/artworkinstructions>. Contact details for questions arising after acceptance of an article, especially those relating to proofs, will be provided by the publisher. You can track accepted articles at <http://www.elsevier.com/trackarticle>. You can also check our Author FAQs at <http://www.elsevier.com/authorFAQ> and/or contact Customer Support via <http://support.elsevier.com>

**Language services.** Authors who require information about language editing and copyediting services pre- and post-submission please visit <http://webshop.elsevier.com/languageediting> or our customer support site at <http://support.elsevier.com>.

**A full and complete Guide for Authors is available online at  
<http://www.thegreenjournal.com>**
