This lecture does not aim to provide an exhaustive overview of the methods currently available for the evaluation of tumor oxygenation, however a brief description of the most used techniques is in order. The Eppendorf probes are still considered the gold standard in the assessment of oxygenation and consist in a direct measure of PO<sub>2</sub>. Despite their accuracy, the electrodes are not always applicable in clinics due to their intrinsic invasiveness and the local nature of the measurements. Alternative methods require the use of radioactive tracers and PET scans or functional MRI (e.g. interleaved BOLD-TOLD protocols). Another option is the 3D Doppler ultrasonography, which is inexpensive and non-invasive, although some restrictions reduces the extent of its application.

**Focus on the US Doppler advantages and limitations**

The 3D Doppler technique allows the evaluation of the hemodynamics by exploiting the Doppler effect. The regions containing moving particles will be shown in false colors according to their velocity. Three main indices are provided, namely the vascularization index (VI), the flow index (FI) and the vascularization flow index (VFI). The VI is the percentage of color pixels in the region of interest and represents the amount of vasculature, while FI is the average (%) color-value of the pixels which were recognized as vessels, indicating the mean flow. The rescaled product of the above equals to the vascularization flow index ( $0 < VFI < 100$ ). The vascularization/flow indices are not able to completely define the tissue oxygenation, especially for tumors. This is due to the chaotic development of vasculature in case of rapid angiogenesis promoted by the cancer uncontrolled growth. The vessels are likely to be leaking and immature supplying a reduced amount of oxygen to the cells they drain. The gap between vascularization and oxygenation is also due the lack of knowledge about vessel permeability.

**Example of volume and oxygen-related data integration in tumor evolution models.**

We implemented a macroscale model of tumor development encompassing the tumor evolution where viable and necrotic portion dynamics evolve separately, along with oxygenation changes. The model was set according to the clinical data (volume) of 7 cervical cancer patients undergoing external beam radiotherapy (EBRT) subdivided into 28 fraction (1.8Gy/fraction). For each patient, two expert clinicians performed and manually contoured five Doppler ultrasound tests before, during and after the treatment. The software 4D View® (General Electric Company - Fairfield, Connecticut, United States) was used to compute the tumor volume and the above mentioned vascularization/flow indices (VI, FI, VFI) in the identified tumor region (Fig. 1).

Our algorithm was trained to provide the lowest fitting error on the tumor size evolution, while the oxygenation was allowed to adjust itself freely to cope with the predicted volume. The model-based curves of tumor evolution resulted in over 90% accuracy with respect to the measured volumes. Using the Pearson coefficient (r), the correlation between VI, FI, VFI and the model predicted oxygenation was analyzed. In three cases r 0.9 (strong correlation), while two patients showed an average r value (0.5-0.7). For the remaining two patients, who presented r<0.5, low indices values (especially VFI) and the smallest tumor shrinkage at the end of EBRT (according to data), the model predicted poor average oxygenation.

In conclusion, the relation included in the model to mimic the interplay between tumor volume and oxygenation dynamics was sufficient to provide oxygenation trends correlating to Doppler indices (r>0.5) in five cases out of seven. Although non-responsive tumors were more critical to mimic, the model was able to identify their hypoxic status.

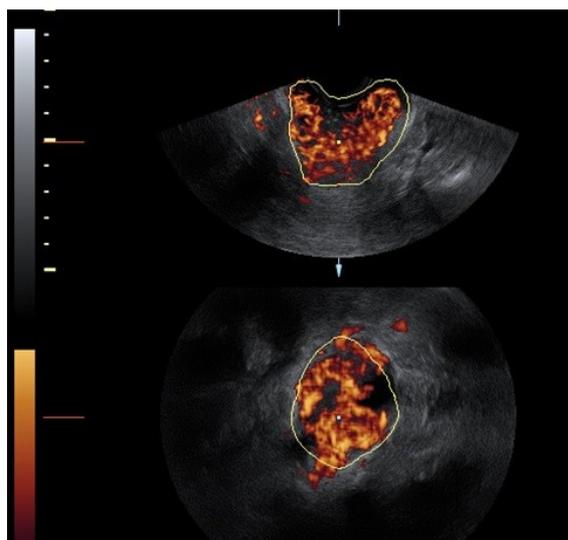

Fig. 1 Example of 3D Doppler image for a cervical cancer patient. Grey scale represents the morphology, while color scale is related to the presence of flow in the corresponding area.

**SP-0596 Machine learning and bioinformatics approaches to combine imaging with non-imaging data for outcome prediction**

O. Gevaert<sup>1</sup>

<sup>1</sup>Stanford University School of Medicine, Biomedical Informatics Research, Stanford, USA

Radiomics and radiogenomics are burgeoning fields of science that put quantitative analysis of medical images (CT, MRI, etc.) central in the analysis towards the goal of precision medicine. The idea is to extract quantitative information from images that can be used for tailoring treatment decisions to the individual patient. More specifically, radiomics is defined as the quantitative analysis of medical images by semi-automatically, and increasingly more automatically, extracting image features from images. Radiogenomics (also known as imaging genomics) is concerned with the mapping of high dimensional molecular data (e.g. transcriptomics, genomics) with quantitative image features that result from radiomics pipelines. Recent developments in both areas of radiomics and radiogenomics are changing the paradigm of precision medicine. While previous work has focused mainly on molecular analysis of cancer, radiomics and radiogenomics propose to harness the power of quantitative medical imaging. This has several advantages, medical images are part of the diagnostic routine, are increasingly more available digitally, and are non-invasive. Especially the latter, the non-invasive characteristic, provides translational opportunities for diagnosis and also in vivo therapy follow-up. For example, radiomics signatures that predict prognosis (e.g. recurrence) can be more easily translated without incurring extra costs. Additionally, radiogenomics allows mapping molecular pathway activities to image signatures for non-invasive assessment of pathway activities, and subsequently hypothesis for targeted treatment. Within the field of machine learning, deep learning and convolution neural networks (CNN) have recently revolutionized analysis of images with many far-reaching applications outside of medicine. More recently, deep learning has entered the medical domain, especially in medical imaging. While most applications have focused on pathological/histological images, applications on medical images are emerging. Currently being used mostly by radiologists to interpret disease and quantitative analysis is still limited. In the meantime quantitative analysis as done in radiomics and radiogenomics research has already

shown that additional information is present that is not necessarily observable by the human eye. Even more, computer vision algorithms have already shown promise in predicting crucial clinical or biological characteristics based on medical images. I will present an update on the latest work in radiomics and radiogenomics for clinical outcome prediction. In addition, I will provide a gentle introduction to deep learning and its potential to rapidly influence quantitative imaging analysis and eventually treatment prediction.

**SP-0597 Tissue classification models for prostate based on imaging and non-imaging data**

U. Van der Heide<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

Imaging data form the basis for target definition in radiotherapy. To attain the best possible understanding of the tissue, increasingly a combination of CT, PET and multiple MRI sequences are used. For dose differentiation treatments, such as dose painting, it is necessary to use the same images to characterize the heterogeneity within the target volume. With quantitative feature extraction, this process reaches a new level of sophistication. Intensity, shape and texture features provide a characterization of the images that can be used to build a classifier that characterizes the disease on a voxel-by-voxel basis.

For prostate cancer, multi-parametric MRI is used routinely for detection of tumors inside the gland. Using feature extraction techniques, we constructed a classifier predicting the presence of cancer. This classifier can be used either to facilitate target delineation or to apply directly for dose painting by numbers. While the performance of image-based classifiers is quite good for the peripheral zone of the prostate gland, it can be challenging to classify tissue between cancer and non-cancerous voxels in the transition zone. Confounders, such as benign prostate hyperplasia, exhibit similar imaging features as cancer and are thus hard to distinguish. In clinical practice, a radiation oncologist has more information about the patient's disease to be used to improve the quality of target delineation. The a-priori prevalence of the distribution of prostate cancer in the gland is well known. For example, prostate cancers mostly occur in the peripheral zone of the gland and less in the transition zone. As part of their diagnostic work-up, patients have received biopsies in the gland, proving cancer presence. The distribution of positive and negative cancer biopsies of a particular patient is available for a radiation oncologist and is considered when defining a GTV delineation. In a study of two independent cohorts of patients, we show that a classifier that combines a-priori prevalence and biopsy data with features derived from multi-parametric MRI, performs significantly better than a classifier based on imaging data alone.

Imaging features are not only used for tissue classification, but also to construct prognostic and predictive models for outcome after treatment. For prostate cancer, similar models are constructed based on T2-weighted MRI, or even multi-parametric MRI. Again, addition of non-imaging data may improve the performance of such models.

**Debate: Debate: Precision in radiotherapy: mission complete!**

---

**SP-0598 Precision in RT: mission completed!**

A. Duffton<sup>1</sup>, C. Dickie<sup>2</sup>

<sup>1</sup>Inst. of Cancer Sciences-Univ. Glasgow The Beatson West of Scotland Cancer Center, Research & Development Radiographer, Glasgow, United Kingdom

<sup>2</sup>Princess Margaret Cancer Centre, Radiation Medicine Department, Toronto, Canada

Over the past two decades, radiation therapy treatment has rapidly changed. Since 2000, Computed tomography (CT) scans have been used for the definition and delineation of target volumes by radiation oncologists. Treatment planning platforms have advanced from 2D to 3D, as well as radiotherapy techniques from 2D conventional approaches to 3D conformal radiotherapy (3D-CRT). Moreover, in just one decade Intensity Modulated Radiotherapy (IMRT) and rotational therapy (Volumetric Modulated Arc Therapy (VMAT), TomoTherapy) have made their appearance. CT simulation is often accompanied by MR simulation or MR fusion for radiotherapy planning purposes and over the next few years, the use of Magnetic Resonance Imaging (MRI) accelerators will become more widespread providing new insights and opportunities. Online megavoltage and/or kilovoltage Imaging before and during radiation treatment is allowing for localization of the target volume to deliver the prescribed dose as accurately as possible.

Each step in the radiation treatment process, from CT to treatment delivery needs to be precise, ensuring the optimal treatment is achieved. In this debate we will focus on this precision, discussing if we have found the highest level of precision in radiation treatment.

Topics for debate will include:

- Modern planning and delivery systems have optimised target coverage.
- Online Cone Beam CT/MR guidance has maximised precision in the preparation of the radiation therapy treatment
- MR/CT imaging during radiotherapy delivery has optimised the precision and accuracy of radiation treatment delivery
- The precision of highly conformal treatment techniques has resulted in improved clinical outcomes with reduced radiotherapy related side effects.

## Poster: Clinical track: Head and Neck

## PO-0603 Metachronous Second Primary Head and Neck Squamous Cell Carcinoma

S.Y. Wu<sup>1</sup><sup>1</sup>Taipei Medical University Hospital, No.111- Section 3 Department of Radiation Oncology, Taipei, Chinese Taipei

## Purpose or Objective

The optimal therapeutic decisions for metachronous second primary head and neck squamous cell carcinomas (mspHNSCCs) are unclear. We examined the treatment outcomes of a national cohort to determine suitable treatments and prognostic factors in patients with mspHNSCCs at different stages and sites.

## Material and Methods

We analyzed data of >20-year-old patients with HNSCC at American Joint Committee on Cancer clinical stages I-IV without metastasis collected from Taiwan Cancer Registry databases. Our protocols were reviewed and approved by the institutional review board at Taipei Medical University (TMU-JIRB No. 201402018). The patients were categorized into four groups based on the treatment modality: Group 1 (control arm, chemotherapy [CT] alone), Group 2 (reirradiation [re-RT] alone with intensity modulation radiotherapy [IMRT]), Group 3 (concurrent chemoradiotherapy [CCRT] alone [irradiation with IMRT]), and Group 4 (salvage surgery with or without RT or CT)

## Results

We enrolled 31 762 HNSCC patients without mspHNSCCs and 1741 mspHNSCCs patients without distant metastasis. Univariate and multivariate Cox regression analyses revealed that surgery, CCRT, Charlson comorbidity index (CCI)  $\geq 6$ , stage of second HNSCC, stage of first HNSCC, and duration from first primary HNSCC of >3 years were significant independent prognostic risk factors for overall survival. After adjustment, adjusted hazard ratios (aHRs; 95% confidence intervals [CIs]) for overall mortality at mspHNSCCs clinical stages I and II were 0.91 (0.42-0.198,  $P = .806$ ), 1.34 (0.78-2.29,  $P = .284$ ), and 0.60 (0.38-0.96,  $P = .033$ ) in Groups 2, 3, and 4, respectively; those for overall mortality at mspHNSCCs clinical stages III and IV were 0.72 (0.40-1.82,  $P = .255$ ), 0.52 (0.35-0.75,  $P < .001$ ), and 0.32 (0.22-0.45,  $P < .001$ ) in Groups 2, 3, and 4, respectively. A Cox regression analysis indicated that a re-RT dose of  $\geq 6000$  cGy was an independent protective prognostic factor for treatment modalities.

## Conclusion

Salvage surgery is recommended for mspHNSCCs if a patient is operable. However, if the patient is inoperable, CCRT is recommended rather than re-RT or CT alone. A re-RT dose of  $\geq 6000$  cGy may be necessary for mspHNSCCs.

## PO-0604 A PET-based nomogram to predict survival in oropharyngeal cancers radiotherapy

J. Castelli<sup>1</sup>, A. Depeursinge<sup>2</sup>, V. Ndoh<sup>1</sup>, J.O. Prior<sup>3</sup>, M. Ozsahin<sup>4</sup>, A. Devillers<sup>5</sup>, E. Chajon<sup>1</sup>, R. De Crevoisier<sup>1</sup>, N. Scher<sup>4</sup>, F. Jegoux<sup>6</sup>, E. Vauleon<sup>7</sup>, B. De Bari<sup>4</sup>, J. Bourhis<sup>4</sup><sup>1</sup>Centre Eugène Marquis, Radiation Oncology, Rennes CEDEX, France<sup>2</sup>University of Applied Sciences Western Switzerland, University of Applied Sciences Western Switzerland, Sierre, Switzerland<sup>3</sup>CHUV, Nuclear Medicine and Molecular Imaging Department, Lausanne, Switzerland<sup>4</sup>CHUV, Radiation Oncology, Lausanne, Switzerland<sup>5</sup>Centre Eugène Marquis, Nuclear Medicine and Molecular Imaging Department, Rennes CEDEX, France<sup>6</sup>CHU Rennes, Head and Neck department, Rennes, France<sup>7</sup>Centre Eugène Marquis, Oncology, Rennes CEDEX, France

## Purpose or Objective

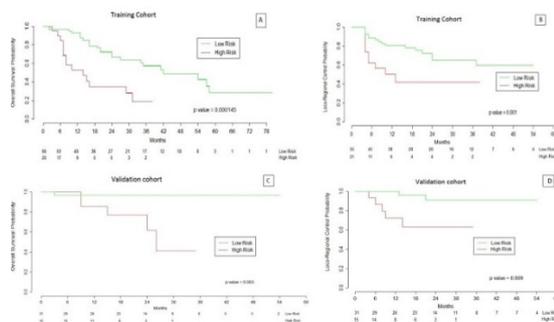

Purpose: In locally advanced oropharyngeal cancer (LAOC) treated with definitive radiotherapy (RT), the aims of this study were: (1) to identify PET-FDG parameters correlated with overall survival from a first training patients and therefore to compute a prognostic score; and (2) to validate this scoring system in a second independent cohort of patients.

## Material and Methods

A training cohort including 76 consecutive LAOC patients treated with chemoradiotherapy or with cetuximab in a first Cancer Center were analyzed. A predictive model of loco-regional control (LRC) and overall survival (OS) was built based on PET-FDG parameters. After internal calibration and validation of the model, a nomogram and a scoring system were developed, and tested in a validation cohort of 46 consecutive patients treated in a second Cancer Center.

## Results

The two populations differed notably concerning age (mean 59.2 vs 63.3 years [ $p = 0.02$ ]) the tumor volume (GTV: 45.8 cm<sup>3</sup> vs 25.6 cm<sup>3</sup> [ $p < 0.001$ ]), p16 status (p16+: 18% vs 37%, [ $p = 0.001$ ]) for the training and validation cohort, respectively. The median follow-up for the training cohort and validation cohort were 38 (range, 2-80) and 23 months (range, 3- 57 months), respectively ( $p < 0.001$ ). The 2-year OS rate was 58% (95% CI: 46-70%) and 85% [74-99%] for the training and the validation cohort, respectively ( $p = 0.001$ ). In multivariate analysis, the metabolic tumor volume (MTV) of the primary tumor and the lymph nodes were independent predictive factors for LRC and OS. Internal calibration showed a very good adjustment between the predicted OS and the observed OS at 24 months. A prognostic score was calculated, based on the B-parameter from the Cox model. A normalization was applied to obtained a score ranging from 0- 5. Using the predictive score, two risk groups (cut-off = 1.33) were identified (median OS 42 vs 14 months,  $p < 0.001$ ) and confirmed in the validation cohort (median OS not reached vs 26 months,  $p = 0.008$ ) (Figure).

## Conclusion

Conclusions: This is the first report of a PET-based nomogram in oropharyngeal cancer. Interestingly, it appeared stronger than the classical prognostic factors and was validated in independent cohorts markedly diverging in many aspects, which suggests that the observed signal was robust.

## PO-0605 Factors associated with late dysphagia and xerostomia in (chemo)radiation for head and neck cancer.

F. Duprez<sup>1</sup>, L. De Witte<sup>2</sup>, S. Nuyts<sup>3</sup>, S. Deheneffe<sup>4</sup>, D. Van Gestel<sup>5</sup>, M. Voordeckers<sup>6</sup>, H. Thierens<sup>2</sup>, W. De Neve<sup>7</sup>, K. De Ruyck<sup>2</sup><sup>1</sup>University Hospital Ghent, Radiation Oncology, Ghent, Belgium<sup>2</sup>Ghent University, Basic Medical Sciences - Medical Physics, Ghent, Belgium

<sup>3</sup>University Hospitals Leuven, Radiation Oncology, Leuven, Belgium

<sup>4</sup>CHU-UCL Namur, Radiation Oncology, Namur, Belgium

<sup>5</sup>Institut Bordet, Radiation Oncology, Brussels, Belgium

<sup>6</sup>University Hospital Belgium, Radiation Oncology, Brussels, Belgium

<sup>7</sup>Ghent University Hospital, Radiation Oncology, Ghent, Belgium

#### Purpose or Objective

To identify patient-related factors, treatment-related factors, genetic variations and dosimetric parameters associated with radiation-induced late dysphagia and xerostomia after (chemo)radiation for head-and-neck cancer (HNC).

#### Material and Methods

Late dysphagia and xerostomia were prospectively scored in 3 prospective academic trials at 6, 12, 18 and 24 months after (chemo)radiation using RTOG/EORTC and CTCAE-scales in 306 HNC patients. Moderate late dysphagia and xerostomia were defined as  $\geq 1$  event of grade 2; severe late dysphagia or xerostomia were defined as  $\geq 1$  event of grade 3 or  $\geq 2$  events of grade 2.

Minimal ( $D_{98}$ ) and maximal ( $D_2$ ) dose, mean ( $D_{mean}$ ) and median dose ( $D_{50}$ ) and volume receiving  $> 50$  Gy ( $V_{50}$ ) for the upper, middle and lower constrictor muscles and esophagus and  $D_{mean}$  and  $V_{27}$  for the parotid glands were derived from dose-volume data. Patient and clinical characteristics included gender, age, smoking status, pack-years, drinking habits, drinks/week, tumor site, T-stage, N-stage, chemotherapy, surgery, neck dissection, radiotherapy modality, tumor dose, fractionation, overall treatment time and baseline and acute dysphagia. Genotyping was performed using restriction length polymorphism or high resolution melting. Univariate association between non-genetic variables and radiation toxicity was assessed using Mann-Whitney-U-test or chi-square-test. Association tests for genetic variants were done by logistic regression.

#### Results

Advanced T-stage, concomitant chemoradiation and grade 3 acute dysphagia are significantly associated with the development of moderate late radiation-induced dysphagia; advanced T-stage and grade 3 acute dysphagia are significantly associated with severe late radiation-induced dysphagia. The  $D_2$ ,  $D_{98}$ ,  $V_{50}$ , the  $D_{mean}$  and  $D_{50}$  to the pharyngeal constrictor muscles and upper esophagus correlated significantly with late dysphagia.

Prediction factors for late moderate and severe xerostomia were female gender, oral cavity/oropharynx primary site and absence of surgery. The  $D_{mean}$  and  $V_{27}$  to the parotid glands were also correlated with late xerostomia.

Carriers of the variant A-allele of rs1800629 G>A (TNF $\alpha$ ) show a higher risk for developing late dysphagia and xerostomia. For xerostomia this association remains statistically significant after multivariate analysis.

#### Conclusion

Besides well-known non-genetic factors, we identified genetic variation in TNF $\alpha$  associated with late dysphagia and xerostomia after (chemo)radiation for HNC.

#### PO-0606 Mandible osteoradionecrosis in oropharynx carcinoma treated with IMRT: Smoking and tumor size matter

F. Caparrotti<sup>1</sup>, S.H. Huang<sup>1</sup>, Y. Song<sup>2</sup>, S. Bratman<sup>1</sup>, J. Ringash<sup>1</sup>, A. Bayley<sup>1</sup>, M. Giuliani<sup>1</sup>, J. Kim<sup>1</sup>, J. Waldron<sup>1</sup>, A. Hansen<sup>3</sup>, L. Tong<sup>1</sup>, W. Xu<sup>2</sup>, B. O'Sullivan<sup>1</sup>, R. Wood<sup>4</sup>, A. Hope<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada

<sup>2</sup>Princess Margaret Cancer Centre, Biostatistics, Toronto, Canada

<sup>3</sup>Princess Margaret Cancer Centre, Medical Oncology, Toronto, Canada

<sup>4</sup>Princess Margaret Cancer Centre, Dental Oncology, Toronto, Canada

#### Purpose or Objective

Osteoradionecrosis (ORN) of the mandible is a late toxicity affecting patients treated with radiotherapy for head and neck malignancies. There is no standardized grading system for ORN and its reporting is based on retrospective findings in heterogeneous patient populations. The rate of ORN in the intensity-modulated radiotherapy (IMRT) era is still unknown.

#### Material and Methods

We report our institutions incidence of ORN from prospectively collected data of 1223 patients diagnosed with squamous cell carcinoma of the oropharynx (OPC) treated with curative intent IMRT, with or without concomitant systemic treatment, from January 2005 to December 2014. Clinical and dosimetric comparisons were carried out between patients with ORN and a matched control cohort of non-ORN patients.

#### Results

The rate of ORN of the mandible was 3% at 1 year, 5% at 3 years, and 8% at 5 years. On multivariate analysis (MVA), smoking (HR 1.92, 95%CI 1.09-3.4; p=0.025) and T category (HR 1.23, 95%CI 1.05-3.16; p=0.033) were statistically significant risk factors. The presence of cardiovascular comorbidities, use of bisphosphonates and pre-IMRT dental extractions were found to be statistically significant differences between our matched cohorts. Mandibular V50(cc) and V60(cc) were predictive of ORN on MVA.

#### Conclusion

Smoking cessation would likely reduce the incidence of ORN. Aside from the commonly used dose constraint of maximum dose to the mandible, minimizing V50(cc) and V60(cc) should be integrated in IMRT planning optimization.

#### PO-0607 Quality of life and xerostomia with IMRT versus 3D-CRT in postoperative head and neck radiotherapy

H.P. Van der Laan<sup>1</sup>, H.P. Bijl<sup>1</sup>, J.G.M. Vemer-van den Hoek<sup>1</sup>, R.J.H.M. Steenbakkers<sup>1</sup>, D.H.F. Rietveld<sup>2</sup>, M.R. Vergeer<sup>2</sup>, C.R. Leemans<sup>2</sup>, J.A. Langendijk<sup>1</sup>

<sup>1</sup>University of Groningen- University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

<sup>2</sup>VU Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

With the introduction of IMRT in head and neck cancer (HNC) a more conformal delivery of dose to the target volumes was possible. A number of randomized studies reported on the added value of IMRT versus 3D-CRT regarding xerostomia, but these studies mainly included patients treated with primary (chemo) radiation. Comparisons between IMRT and 3D-CRT after postoperative radiotherapy (PORT) are very limited. Therefore the purpose of this study was to compare patient reported global quality of life (QOL), swallowing problems, xerostomia and sticky saliva at 6 months and 12 months after PORT with IMRT relative to 3D-CRT.

#### Material and Methods

We performed a retrospective analysis on prospective collected data among 275 HNC patients who received PORT for squamous cell head and neck cancer. Patients were treated at the VUMC (n=132) between August 1999 and September 2003 and at the UMCG (n=143) between May 2007 and February 2015. None of the patients received postoperative chemoradiation. All patients completed the EORTC core quality of life questionnaire (QLQ-C30) and the module for head and neck cancer patients (QLQ-H&N35) prior to RT (baseline) and at 6 and 12 months after completion of PORT. The raw component

scores for QOL and symptoms were linearly converted to a 0-100 scale. Propensity Score (PS) correction and weighting was used to reduce the risk of bias and balance patient and treatment characteristics between the treatment groups (Table). Linear regression analyses were performed with IMRT as independent variable and the patient rated outcome scores as dependent variables. All models were corrected for PS and corresponding scores at baseline.

### Results

With IMRT, the mean PS-weighted QOL scores at 6 months were 9.7 points higher than they were with 3D-CRT (79.5 vs. 69.8,  $p=0.011$ ) and at 12 months they were 9.1 points higher (83.1 vs. 74.1,  $p=0.014$ ). This indicates a significant improvement with IMRT. The lower mean PS-weighted scores for xerostomia (6 months: 34.5 vs. 51.7,  $p=0.007$ , and 12 months: 33.3 vs. 52.0,  $p=0.006$ ) and sticky saliva (6 months: 27.4 vs. 39.6,  $p=0.003$ , and 12 months: 19.8 vs. 33.6,  $p=0.026$ ) also indicate a significant improvement with IMRT (lower symptom scores correspond with less complaints). The mean PS-weighted scores for swallowing problems were similar for IMRT and 3D-CRT (6 months: 19.5 vs. 22.1,  $p=0.532$ , and 12 months: 16.0 vs. 20.6,  $p=0.252$ ).

PS weighted groups	3D-CRT n=154	IMRT n=121	p-value
Male	59%	52%	0.440
Age (mean in years)	61	63	0.203
Larynx/hypopharynx	15%	28%	0.075
Oropharynx	20%	8%	0.075
Oral Cavity	66%	63%	0.749
T3/T4	46%	45%	0.867
N+	48%	49%	0.904
Radical removed tumour	66%	72%	0.476
Extra Nodal Spread	20%	6%	0.017
Laryngectomy	11%	24%	0.084
Bilateral neck PORT	56%	57%	0.898

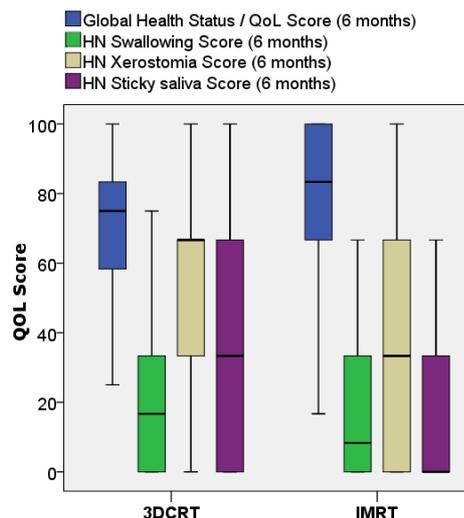

Linear regression*	B	95%CI for B	p-value
<b>Global QOL<sup>(1)</sup></b>			
IMRT (6 months model)	7.957	3.012 – 12.901	0.002
IMRT (12 months model)	6.253	1.243 – 11.263	0.015
<b>Swallowing problems<sup>(2)</sup></b>			
IMRT (6 months model)	1.647	-4.281 – 7.574	0.585
IMRT (12 months model)	-1.920	-8.370 – 4.529	0.558
<b>Xerostomia<sup>(2)</sup></b>			
IMRT (6 months model)	-10.495	-19.821 – -1.168	0.028
IMRT (12 months model)	-9.922	-19.823 – -0.021	0.050
<b>Sticky Saliva<sup>(2)</sup></b>			
IMRT (6 months model)	-11.597	-20.323 – -2.871	0.009
IMRT (12 months model)	-10.133	-19.679 – -0.586	0.038

Propensity Score (PS)-weighting assigns a lower weight to cases that make the characteristics of treatment groups less equal. This may reduce the number of cases and may increase the p-values, even when differences between groups remain the same.

\* All linear regression models are based on unweighted cases and corrected for PS and baseline. B represents IMRT relative to 3D-CRT.

<sup>(1)</sup> Higher global QOL scores indicate a better QOL

<sup>(2)</sup> Higher symptom scores indicate more problems

### Conclusion

This study shows that IMRT significantly reduced patient-reported xerostomia and sticky saliva which translated in significantly improved patient rated QOL compared to 3D-CRT. With IMRT, no significant reduction of swallowing problems was observed.

### PO-0608 Depression, anxiety and claustrophobia in patients undergoing radiotherapy for head and neck cancer

M.E. Pelland<sup>1</sup>, L. Lambert<sup>1</sup>, E. Filion<sup>1</sup>, H. Bahig<sup>1</sup>, M.P. Beaudry<sup>1</sup>, A. Ouellette<sup>1</sup>, P. Bahary<sup>1</sup>, P. Nguyen-Tan<sup>1</sup>  
<sup>1</sup>Centre Hospitalier de l'Université de Montréal, Radio-oncology department, Montréal, Canada

### Purpose or Objective

To assess the prevalence of emotional distress, anxiety, depression and claustrophobia in patients undergoing radiation for head and neck cancer (HNC).

### Material and Methods

This prospective study included patients oriented for treatment for HNC within 6 weeks preceding radiotherapy. Self-reported distress was assessed using the *NCCN Distress Thermometer*, anxiety and depression were assessed using the *Hospital Anxiety and Depression Scale*; and claustrophobia was assessed using the *Claustrophobia Questionnaire*. All questionnaires have been validated and present good psychometric properties. Group differences in outcomes were analysed using both student t-tests and general linear models.

### Results

1346 patients were accrued from May 2009 to April 2016. Median age of patients was 63 years old (18-94). Men represented 74% of patients. Nasal cavity represented 6%; oral cavity represented 11%; oropharynx 49%; hypopharynx 4%; larynx 25% and unknown primary 5%. Of these patients, 46% presented emotional distress, 26% presented anxiety and 9% presented with depression. Moreover, of these patients, 52% presented sub-clinical claustrophobia and 27% presented moderate to severe claustrophobia. Both emotional distress ( $p < 0.001$ ) and depression ( $p < 0.001$ ) were affected by gender, with women scoring significantly higher than men. In regards to anxiety: women were more anxious than men ( $p < 0.001$ ); patients with oral cavity tumors were more anxious than other tumoral sites ( $p < 0.01$ ) and patients with concurrent chemotherapy were more anxious than those with adjuvant chemotherapy and radiation alone ( $p < 0.05$ ). Claustrophobia, in turn, was influenced by gender and marginally impacted by tumor localization, whereas women were more claustrophobic

than men ( $p < 0.001$ ) and patients presenting nasal cavity tumors scored higher than all other tumoral sites ( $p = 0.08$ ).

#### Conclusion

HNC patients undergoing radiation therapy have high levels of emotional distress, anxiety and claustrophobia. Given the high percentage of psychological distress, awareness and management of these issues are primordial as they may have significant impact on treatment acceptance and tolerability as well QOL during and after treatment.

#### PO-0609 <sup>18</sup>F-FDG-PET in Guiding Dose-painting with IMRT in Oropharyngeal Tumours (FiGaRO) - Early Results

<sup>5</sup>Royal Marsden NHS Foundation Trust, Clinical Oncology, London, United Kingdom

#### Purpose or Objective

IMRT ± chemotherapy is an effective treatment for stage III/IVa oropharyngeal squamous cell carcinoma (SCC). Treatment failures occur mostly at the primary site and are difficult to salvage. Dose escalation strategies are being explored, with target volume definition and toxicity considered the main challenges. IMRT can boost doses to selected areas (dose painting) without exceeding normal tissue tolerances. <sup>18</sup>F-FDG-PET/CT can mediate this, by defining areas of metabolic activity for dose escalation. This Phase 1 multicentre study aims to test the feasibility and safety of <sup>18</sup>F-FDG-PET/CT dose-painted IMRT in locally advanced oropharyngeal SCC. We present toxicity results in the first 15 patients.

#### Material and Methods

Patients with ≥T2, HPV-negative or high-risk HPV-positive disease, suitable for radical treatment with neo-adjuvant chemotherapy and chemo-IMRT, are eligible. PET/CT is acquired after one chemotherapy cycle, in the radiotherapy position, in the immobilization shell. The FDG-avid gross tumour volume (GTV-T<sup>18</sup>F-FDG-PET) is manually delineated by a nuclear medicine physician then copied onto the fused CT for direct planning. Thirty daily fractions are delivered in 6 weeks, at 3 dose levels. The radical volume (PTV1) receives 65Gy, the prophylactic volume (PTV2) 54Gy and the GTV-T<sup>18</sup>F-FDG-PET receives 71.5Gy.

#### Results

Fifteen patients (14 male, 1 female; mean age-61, range 49-71) were treated April'14-March'16, at two centres (median follow-up 10 months, range 4-26 months. Eight (53.3%) are HPV-negative, 7(46.7%) are HPV-positive. Average GTV-T<sup>18</sup>F-FDG-PET volume was 11.9cc (range 1.6-67.7cc). Target volume objectives were met in all (median D<sub>95</sub>98.1%, range 96.1-98.9%; Median D<sub>5</sub>102.9%, range 101.1-103.6%), whilst respecting normal tissue tolerances and PTV1 hotspot constraints.

On the CTCAEv.4.0 scale, end of treatment toxicities were: Grade 4-none; Grade 3 - dysphagia-46.7%(n=7), mucositis-26.7%(n=4), pain-13.3%(n=2), salivary gland-6.7% (n=1); Grade 2- dysphagia-53.3%(n=8), mucositis-73.3%(n=11), pain-73.3%(n=11), salivary gland-86.7%(n=13), dermatitis-73.3%(n=11), xerostomia-66.7%(n=10), fatigue-46.7%(n=7). Three month post-treatment toxicities were: Grade 4-none; Grade 3 - dysphagia-20.0%(n=3); Grade 2- dysphagia-20.0%(n=3), mucositis-13.3%(n=2), pain-20.0%(n=3), xerostomia-53.3%(n=8).

On the RTOG/EORTC scale 3-month post treatment toxicities were: Grade 4-none; Grade 3-salivary gland-6.7%(n=1), oesophagus-6.7%(n=1); Grade 2-salivary gland-46.7%(n=7), oesophagus-13.3%(n=2), mucosa-13.3%(n=2), joint(TMJ)-6.7%(n=1). On LENTSOMA categories one patient had a grade 4 toxicity - oropharyngeal dysphagia (gastrostomy dependent). Six (40.0%) had grade 3 toxicities and 13 (86.7%) had grade 2 toxicities. There were 2 local recurrences within 1 year, both underwent salvage surgery with clear margins.

#### Conclusion

<sup>18</sup>F-FDG-PET-guided selective dose escalation is feasible, with acceptable acute toxicity. Late toxicity assessment (3, 6 and 12-months post-treatment) is ongoing.

#### PO-0610 Effects of an oral health promotion program in head and neck cancer patients receiving radiotherapy

E. Kim<sup>1</sup>, H.G. Wu<sup>1</sup>, J.H. Kim<sup>1</sup>, K.S. Kim<sup>1</sup>, T. Yu<sup>1</sup>, C.W.

Wee<sup>2</sup>, N. Choi<sup>1</sup>, B.S. Jang<sup>1</sup>, S.H. Jeon<sup>1</sup>, H.J. Lee<sup>2</sup>, D.H. Han<sup>2</sup>

<sup>1</sup>Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of

<sup>2</sup>Seoul National University College of Dentistry, Preventive and Social Dentistry, Seoul, Korea Republic of

#### Purpose or Objective

To develop oral health promotion program and evaluate its effectiveness in head and neck cancer (HNC) patients receiving radiotherapy (RT).

#### Material and Methods

This was an open-label, non-randomized, prospective study in 84 HNC patients treated with RT. Dental health promotion program consisted of oral exam, oral health education, fluoride varnish and mouthwash. Forty-seven patients were assigned to an experimental group with the dental health care program and 37 to a control group. Clinical benefit was measured by the European Organization for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire head and neck module (QLQ-H&N35) and the oral examination before and up to 6 months after RT.

#### Results

Compared with the control group, the experimental group showed significant improvement in sexuality, use of pain killers, and worried about future ( $p = 0.045$ ,  $p = 0.049$ , and  $p < 0.001$ , respectively). Oral health promotion program did not affect the development of xerostomia. Subgroups of patients with old age ( $\geq 60$  years), stage IV HNC, and radical RT reported significant improvement in quality of life by oral health promotion protocol. Although caries experience significantly increased in a control group ( $p = 0.002$ ), there was no significant change in an experimental group. The experimental group showed significantly decreased plaque score and bleeding on probe ( $p < 0.001$  and  $p = 0.004$ ).

#### Conclusion

Administration of our oral health promotion program decreased dental problems and slightly improved patients' quality of life. We recommend the dental care program for HNC patients receiving RT to reduce treatment related oral toxicities.

#### PO-0611 Long-term prognostic impacts of pretreatment plasma EBV DNA status in nasopharyngeal carcinoma

J.C. Lin<sup>1</sup>, W.Y. Wang<sup>2</sup>, J.W. Huang<sup>1</sup>

<sup>1</sup>Taichung Veterans General Hospital, Department of Radiation Oncology, Taichung, Taiwan

<sup>2</sup>Hung Kuang University, Department of Nursing, Taichung, Taiwan

#### Purpose or Objective

To investigate the prognostic impacts of pretreatment plasma EBV (pEBV) DNA in patients with nasopharyngeal carcinoma.

### Material and Methods

The study population consisted of 931 previously untreated, biopsy-proven, and no distant metastasis NPC patients who finished curative radiotherapy with/without chemotherapy at our department. The pre-treatment pEBV DNA level was measured by the real-time quantitative polymerase chain reaction. We analyzed the relationship between the pEBV DNA status and clinical characteristics. Various survival curves were compared between the patients with detectable and undetectable pEBV DNA by the Kaplan-Meier method.

### Results

EBV DNA signal (> 0 copies/mL) was detected in 90.8% (845/931) NPC patients' plasma before treatment. The percentages in patients with undetectable EBV DNA were inversely associated with presenting stages (24.6% for stage I/II, 8.5% for stage III and 2.8% for stage IV,  $P < 0.001$ ). The pEBV DNA levels were positively correlated with clinical stage ( $P < 0.001$ ). The age, gender, and pathological type between the patients with detectable and undetectable pre-treatment pEBV DNA were similar. However, patients with detectable pre-treatment pEBV DNA had relatively poor performance status, advanced T-classification, advanced N-classification, and advanced overall stage than those with undetectable pEBV DNA. The overall survival (HR=0.4413, 95% CI = 0.29-0.67,  $P=0.0004$ , 10-year rate = 62.2% vs. 90.3%), neck failure-free survival (HR=0.3285, 95% CI = 0.12-0.93,  $P=0.0397$ , 10-year rate = 94.4% vs. 100%), and distant metastasis-free survival (HR=0.3751, 95% CI = 0.23-0.62,  $P=0.0002$ , 10-year rate = 79.9% vs. 97.7%) were significantly lower in patients with detectable pEBV DNA than in those with undetectable pEBV DNA. The local failure-free survival was similar between both subgroups (HR=0.8740, 95% CI = 0.46-1.67,  $P=0.9362$ , 10-year rate = 85.6% vs. 89.2%).

### Conclusion

NPC patients presented with detectable pEBV DNA before treatment were associated with higher clinical stages and significant worse survivals.

### PO-0612 Significance of co-expression of mutant p53 protein and Ki67 in locally advanced HNSCC post chemoradiotherapy

P. Baskaran<sup>1</sup>, Shanmuga<sup>1</sup>, K. Periasamy<sup>1</sup>, S. Sharma<sup>2</sup>, G.K. Singh<sup>1</sup>, V. Yadav<sup>1</sup>, A. Gupta<sup>1</sup>, J. Kaur<sup>1</sup>, A.K. Mandal<sup>2</sup>, K.T. Bhowmik<sup>1</sup>

<sup>1</sup>Safdarjung Hospital, Radiotherapy, New Delhi, India

<sup>2</sup>Safdarjung Hospital, Pathology, New Delhi, India

### Purpose or Objective

To know the significance of the co-expression of mutant p53 protein and Ki67 in locally advanced HNSCC with respect to response to chemoradiation (CRT) and locoregional failure (LRF), distant metastasis (DM) and overall survival (OS) at 1 year.

### Material and Methods

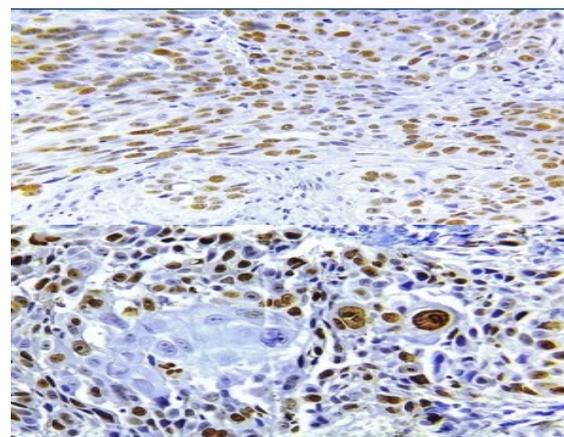

This prospective observational study included 62 patients with stage III-IV non nasopharyngeal HNSCC of which 58 patients completed CRT. Immunohistochemistry was done on the pre-treatment biopsy specimens and the expression of p53 and Ki67 in the tumor were graded based on the degree of nuclear staining. During statistical analysis, patients having co-expression (p53+/Ki67+) were categorised in one group and the rest in the non-co-expressed group (p53-/Ki67-, p53+/Ki67-, p53-/Ki67+). The patients were followed up for a minimum period of 1 year and the association between the co-expression of the markers and the tumor response to CRT and LRF, DM and OS at 1 year were analysed.

### Results

57% (33) patients showed co-expression of mutant p53 and Ki67 while 43% (25) patients fell in the non-co-expressed group. There was a statistically significant association between the co-expression of the markers and the parameters such as age <50 years, N2 stage, TNM stage IVA

and partial response (PR) to CRT at 8 weeks. Similarly, at 1 year, the absence of co-expression was associated significantly with the locoregional control of the disease while the presence was associated with LRF. Even though 8/9 patients with DM showed co-expression, a statistically significant association was not reached on analysis ( $p$ -value 0.064). The relative risk of PR and LRF were 4.16 and 3.59 respectively with p53 and Ki67 co-expression.

On multivariate analysis, the co-expression of the markers was found to be a statistically significant independent predicting factor for PR at 8 weeks post CRT and LRF at 1 year with odds ratio 10.50 and 7.12 respectively, however, the N2 stage was a statistically significant independent factor of DM and mortality at 1 year with odds ratio of 6.16 and 11.14 respectively.

Relative risk	Parameter	Status of markers	Relative Risk	95% confidence interval	'p' Value
	PR to CRT	P53+/Ki67+	4.167	1.644 to 10.561	<0.001
	LRF	P53+/Ki67+	3.598	1.399 to 9.256	0.003
	DM	P53+/Ki67+	6.061	0.810 to 45.363	0.081
Logistic regression	Mortality	P53+/Ki67+	3.030	0.361 to 25.470	0.536
		Variable	Odds Ratio	95% CI	'p' Value
	PR to CRT	P53+/Ki67+	10.50	2.8869 to 38.1899	0.0004
	LRF	P53+/Ki67+	7.1250	1.9954 to 25.4412	0.0025
DM	Nodal stage (N2)	6.1667	1.3336 to 28.5147	0.0199	
Mortality	Nodal Stage (N2)	11.1429	1.1456 to 108.3796	0.0378	

### Conclusion

These results signify that the co-expression of mutant p53 and Ki67 has specific role in the clinical course of locally advanced HNSCC, significant in predicting PR response to CRT and LRF at 1 year. Advanced Nodal stage (N2) has emerged as an independent predictor for DM and mortality at 1 year.

### PO-0613 Effect of geometric GTV-CTV margins in national contouring guidelines

C.R. Hansen<sup>1,2</sup>, J. Johansen<sup>3</sup>, E. Samsøe<sup>4</sup>, E. Andersen<sup>5</sup>, J.B. Petersen<sup>6</sup>, K. Jensen<sup>7</sup>, H.M.B. Sand<sup>8</sup>, L.J. Andersen<sup>8</sup>, C. Grau<sup>7</sup>

<sup>6</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark

<sup>7</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

<sup>8</sup>Aalborg Hospital, Department of Oncology, Aalborg, Denmark

### Purpose or Objective

Danish national guidelines (GL) for head and neck cancer radiotherapy (RT) have been available since 1990 and were revised in 2013. One of the major revision points was the change of GTV to CTV margins from mainly anatomically driven expansions to symmetric geometric expansion. The purpose of this study was to analyse the consistency of generated CTV contours by the new approach and to evaluate the impact on CTVs and any differences between four centres involved in RT before and after the guideline revision.

### Material and Methods

Prior to the GL change in 2013, four centres were asked to delineate CTV1, CTV2 and CTV3 of a stage IV oropharynx patient with three prescription levels: 66 Gy, 60 Gy and 50 Gy in 33 fractions. The contours of the tumour GTV and the lymph node GTV were provided together with the organs at risk (OAR). Each centre made a RT plan from the CTVs. After the new GL was implemented, the centres were asked to repeat the CTV contouring and the dose planning. Likewise, the centres were asked in 2016, three years after the GL, to re-contour and re-plan to test the consistency over time of the GL.

The difference in contouring was evaluated by the difference in CTV volume, Dice Similarity Coefficient (DSC) and average minimum surface distance (MSD) between the CTV contours. The difference in dose plans was evaluated by mean dose to OAR and dose-specific treated volumes ( $V_{62.7Gy}$ ,  $V_{57Gy}$ ,  $V_{47.5Gy}$  and  $V_{25Gy}$ ). The statistical difference was tested with a paired two-sided Student's t-test ( $p < 0.05$ ).

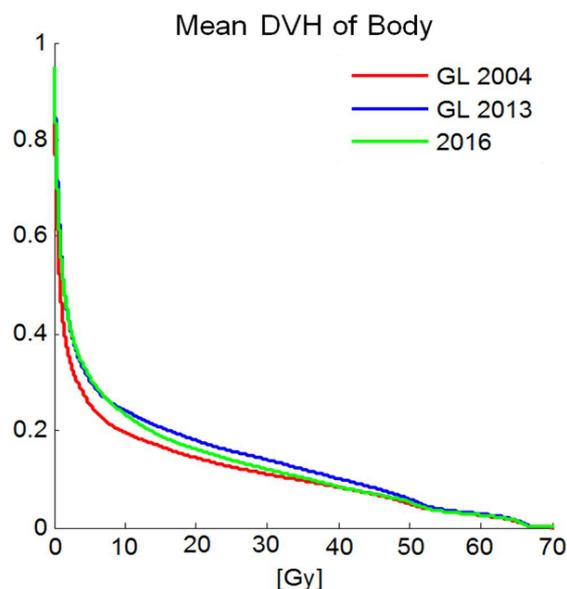

### Results

The contours from GL 2004 were less uniform and showed large volume differences (Table 1). The MSD showed a mean difference of 0.6 cm and a relatively large standard deviation (SD) of 0.45 cm for the CTV1. The GL 2013 provided a more operational margin expansion and hence resulted in a high DSC and very similar volumes, however with a mean increase of 40% and 32% for the CTV1 and CTV2, respectively. The re-contouring in 2016 was similar to 2013 indicating that the interpretation of GL 2013 is not affected by time.

	CTV1						
	GL 2004		GL 2013		2016		GL 2004 vs GL 2013 p-value
	Mean	SD	Mean	SD	Mean	SD	
MSD [cm]	0.63	0.45	0.00	0.14	0.01	0.10	0.07
DSC [index]	0.62	0.34	0.92	0.03	0.94	0.04	0.10
Vol [cm <sup>3</sup> ]	75	79	105	8	106	7	0.52
	CTV2						
	GL 2004		GL 2013		2016		GL 2004 vs GL 2013 p-value
	Mean	SD	Mean	SD	Mean	SD	
MSD [cm]	0.17	0.47	0.00	0.24	0.00	0.15	0.44
DSC [index]	0.66	0.11	0.88	0.01	0.93	0.03	0.004
Vol [cm <sup>3</sup> ]	145	51	191	7	194	2	0.20
Irradiated volume							
$V_{62.7Gy}$ [cm <sup>3</sup> ]	224	111	272	45	271	3	0.37
$V_{57Gy}$ [cm <sup>3</sup> ]	365	104	405	35	384	4	0.40
$V_{47.5Gy}$ [cm <sup>3</sup> ]	772	124	891	80	784	64	0.12
$V_{25Gy}$ [cm <sup>3</sup> ]	1601	219	1940	210	1758	200	0.11
Mean OAR doses							
Parotid left [Gy]	41.8	4.7	44.7	4.0	39.4	2.6	0.20
Parotid right [Gy]	27.0	5.7	28.7	6.6	25.0	6.4	0.52
Oral Cavity [Gy]	30.4	3.5	31.5	1.7	29.5	2.6	0.63

The similarity of the CTV targets in 2013-16 resulted in more uniform dose plans, however, the different planning approaches resulted in only slight difference to the OAR, and the SD of mean doses did not improve significantly. The SD of the irradiated volume improved with the GL 2013 and further improved in 2016 dose plans. It is obvious that the larger CTVs of the GL 2013 increased the

irradiated volume (figure 1), however improved planning and familiarity of the GL reduced this difference in the 2016 plans.

### Conclusion

The GL 2013 showed more uniform CTV1 and CTV2 contouring between centres, which was reproduced in 2016. The more geometric GTV to CTV expansion allows for an easier operational delineation which leaves less room for misinterpretation. This transforms into more uniform treatment plans and very similar irradiated volumes across all centres.

**PO-0614 The prognostic role of 18F-FDG PET/CT in head and neck cancer and the importance of HPV status**  
J.M. Moan<sup>1</sup>, E. Malinen<sup>2</sup>, J.G. Svestad<sup>3</sup>, C.D. Amdal<sup>1</sup>, T.V. Bogsrud<sup>4</sup>, E. Dale<sup>1</sup>

<sup>1</sup>Oslo University Hospital, Department of Oncology, Oslo, Norway

<sup>2</sup>University of Oslo, Department of Physics, Oslo, Norway

<sup>3</sup>Oslo University Hospital, Department of Medical Physics, Oslo, Norway

<sup>4</sup>Oslo University Hospital, Department of Nuclear Medicine, Oslo, Norway

### Purpose or Objective

Standardized uptake value (SUV) and related parameters derived from 18F-FDG PET/CT prior to radiochemotherapy of head and neck cancer have been shown in several studies to correlate with survival. We wanted to validate this finding in our own patient cohort, but also to see the PET parameters together with clinical risk factors including HPV status.

### Material and Methods

We retrospectively reviewed 225 patient cases from 2007 to 2014 with complete sets of 18F-FDG PET/CT and potential clinical risk factors (age, sex, ECOG status, Charlson comorbidity status, pack years of smoking, TNM stage, tumor differentiation, tumor site, HPV DNA status (tested for oropharyngeal cancers [OPC]), treatment duration, days on nimorazole and numbers of weekly cisplatin. All patients received radiotherapy with 68-70 Gy in 2 Gy fractions. Patients older than 70 years or with comorbidity did not receive concomitant cisplatin (26%). Clinical endpoints were overall survival (OS), local control, regional control, distant control, and disease-free survival (DFS). We investigated the image parameters; 1) Gross tumor volume (GTV) based on CT and PET, 2) PET tumor volume delineated by the nuclear medicine specialist, 3) metabolic tumor volume (MTV), 4) total

lesion glycolysis (TLG) and 5) SUVpeak. Univariate and multivariate Cox regression were employed throughout.

### Results

In the univariate analysis, SUVpeak in the primary GTV was associated with local control (HR=1.084;  $p=0.03$ ). The regional nodal SUVpeak was associated with distant control (HR=1.11;  $p=0.003$ ). The other tumor volume and SUV parameters were also associated with clinical endpoints ( $p<0.05$ ). In the multivariate analysis on OS, the model included tumor stage (HR =1.41;  $p=0.02$ ), ECOG status (HR=2.92;  $p<0.001$ ), Charlson comorbidity index (HR=1.37;  $p=0.005$ ), pack years of smoking (HR=1.015;  $p<0.001$ ) and primary GTV volume (HR=1.0074;  $p=0.02$ ). The model on DFS included ECOG status (HR=2.13;  $p<0.001$ ) and the union of all GTV volume (HR=1.0080;  $p<0.001$ ). These models were not improved by including SUV parameters. However, analyzing the subgroup of HPV negative OPC and non-OPC ( $n=77$ ), the model on OS could be improved by including MTV (HR=1.018;  $p<0.001$ ) or TLG (HR=1.0015;  $p=0.007$ ). The model on DFS could be improved by including one of the following parameters: MTV (HR=1.040;  $p<0.001$ ), TLG (HR=1.0036;  $p<0.001$ ) or SUVpeak of regional nodes (HR=1.15;  $p=0.001$ ).

### Conclusion

Accounting for clinical risk factors in the multivariate modeling of survival after radiochemotherapy of head and neck cancer, the SUV parameters appear less important than found in previous studies. The association between the SUV parameters and survival seems to be stronger for HPV negative patients.

### PO-0615 Can diffusion-weighted MRI predict for xerostomia and QoL in head and neck patients receiving RT?

K. Nguyen<sup>1</sup>, M. Min<sup>1,2,3</sup>, L. Holloway<sup>1,2,3,4</sup>, M. Jameson<sup>1,2</sup>, C. Rumley<sup>1,2</sup>, A. Fowler<sup>1</sup>, M. Lee<sup>1,3</sup>, D. Forstner<sup>1,2,3</sup>, R. Rai<sup>1</sup>, G. Liney<sup>1,2,3,5</sup>

<sup>1</sup>Liverpool Hospital, Radiation Oncology, Liverpool, Australia

<sup>2</sup>Ingham Institute of Applied Medical Research, Radiation Oncology, Liverpool, Australia

<sup>3</sup>University of New South Wales, Department of Medicine, Sydney, Australia

<sup>4</sup>University of Western Sydney, Medicine, Sydney, Australia

<sup>5</sup>University of Wollongong, Medicine, Wollongong, Australia

### Purpose or Objective

Diffusion-weighted MRI (DWI) has the ability to identify specific cellular characteristics of tissues. Although DWI has not been traditionally used in RT planning, there is increasing interest regarding its potential worth in predicting RT-related toxicities. Our study aims to investigate 1) serial changes in apparent diffusion coefficient (ADC) maps of salivary glands quantified from DWI and 2) whether DWI can predict for xerostomia and quality-of-life (QoL) in patients with mucosal primary head and neck cancer (MPHNC) receiving primary RT.

### Material and Methods

19 patients with newly diagnosed MPHNC receiving RT were included. DWIs were acquired before, during (week 2,3,5,6) and after RT (post-RT week 4,12). Parotid and submandibular glands were contoured on DWI and corresponding estimated ADCs extracted (Figure1). "Dry mouth" according to Common Terminology Criteria for Adverse Events (CTCAE) v4.0 and "saliva" QoL according to University of Washington QoL (UW-QoL) questionnaire v4.0 were recorded for a follow-up period of 11-23months post-RT. A Spearman Correlation test was used to evaluate associations ( $p\leq 0.05$ =significant) between ADC<sub>mean</sub> of ipsilateral/contralateral/bilateral parotid and submandibular glands and CTCAE, as well as UW-QoL scores.

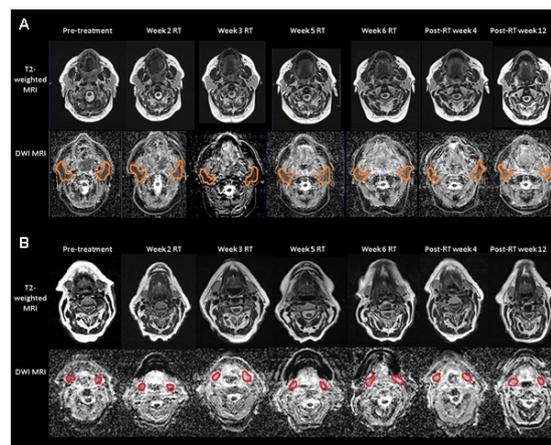

Figure 1. Serial MR (DW and T2-weighted) images of a MPHNC patient with contoured A) parotid glands and B) submandibular glands

### Results

Serial ADC<sub>mean</sub> for parotid and submandibular glands, both ipsilateral and contralateral to primary cancer, showed an increasing trend from pre-RT to post-RT (Figure2).

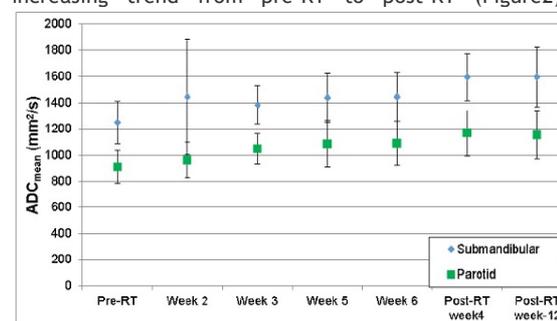

Figure 2: Serial ADC<sub>mean</sub> changes of parotid and submandibular glands from pre-RT to post-RT DWI

On analysis of parotid glands, a statistically significant positive correlation existed between xerostomia and bilateral parotid ADC<sub>mean</sub> on week5 DWI 0.624( $p=0.023$ ), while a statistically significant negative correlation existed between "saliva" QoL and bilateral parotid ADC<sub>mean</sub> on week5 DWI -0.629( $p=0.038$ ). Similarly, on analysis of submandibular glands, a positive correlation existed between xerostomia and bilateral submandibular ADC<sub>mean</sub> on week5 DWI 0.751( $p=0.008$ ), while "saliva" QoL and change in bilateral submandibular ADC<sub>mean</sub> between pre-RT and week5 DWI recorded a significant negative correlation -0.791( $p=0.034$ ).

### Conclusion

Our study shows an increasing trend in ADC<sub>mean</sub> on DWI in salivary glands pre- to post-RT. As ADC is an inverse measure of cellular density, this suggests there is a decrease in the cellularity of salivary glands pre- to post-RT detectable on DWI.

Correlations between ADC<sub>mean</sub> and xerostomia were identified at week5 which suggests ADC<sub>mean</sub> measurements at this time-point (approximately mid-RT) may be most sensitive to predict for late xerostomia, rather than at any other time-point studied. The significant negative Spearman correlation between QoL following RT and change in ADC<sub>mean</sub> suggests a link between worsening QoL and increased ADC<sub>mean</sub> (or decreased cellularity) of salivary glands.

In conclusion, DWI may be a valuable predictive tool for late toxicities in MPHNC patients receiving RT. DWI has potential to aid adaptive radiotherapy which spares salivary glands depending on areas of high cellularity and should be further explored.

#### PO-0616 HPV, CSC marker expression and tumor hypoxia as prognosticators for LRC in patients with HNSCC

<sup>8</sup>University Cancer Center- Medical Systems Biology, TU Dresden- Med. Faculty Carl Gustav Carus, Dresden, Germany

<sup>9</sup>Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology, Dresden, Germany

#### Purpose or Objective

To validate the prognostic impact of HPV status, cancer stem cell (CSC) expression and tumour hypoxia in patients with locally advanced head and neck squamous cell carcinoma (HNSCC), who received postoperative radiotherapy. The impact of these biomarkers has been previously reported in an explorative multicentre, retrospective study.

#### Material and Methods

In this monocentric validation study, 152 patients with squamous cell carcinoma of the oral cavity, oropharynx, hypopharynx and larynx were included. Out of them, 40 patients received postoperative radiochemotherapy and 112 patients received radiotherapy only. All patients were treated between 1999 and 2006. Identical methods for biomarker analysis were applied compared to the previous study. HPV DNA status was investigated by PCR-array based genotyping. Gene expression analysis was performed for hypoxia-associated genes and the potential CSC markers CD44, SLC3A2 and MET using nanoString technology. Cox models presented in the previous study were validated using the concordance index as a performance measure. Primary endpoint was loco-regional control. Results were compared to those previously reported.

#### Results

Loco-regional control and overall survival were lower as in the cohort reported previously. Despite of this, the prognostic value of the combination of HPV status, CSC marker expression (SLC3A2) and tumour hypoxia status could be validated in univariate analyses using this independent validation cohort. For multivariate models, the concordance index was between 0.58 and 0.69 in validation, which indicates a good prognostic performance of the models. The inclusion of the CSC marker CD44 and the 15-gene hypoxia signature improved the performance of the model, when compared to a baseline model without any CSC markers or hypoxia classifiers.

#### Conclusion

The HPV status, CSC marker expression of CD44 and SLC3A2 as well as hypoxia status are potential prognostic biomarkers for patients with locally advanced HNSCC treated by postoperative radiotherapy. While a lower performance of the prognostic models was expected due to the older validation dataset, the significant validation results indicate the robustness of these markers. A

currently recruiting prospective clinical trial will allow further validation of these results and may help to stratify patients for individualized treatment strategies. In addition, these biomarkers are currently being further explored in patients with early-stage HNSCC, who received surgery only and first results will also be presented.

#### PO-0617 Functional Brain Abnormalities in NPC Patients After Radiotherapy

W. Ren<sup>1</sup>, J. Dai<sup>1</sup>, Y. Li<sup>1</sup>, L. Gao<sup>1</sup>, C. Sun<sup>2</sup>

<sup>1</sup>Cancer Hosp.- Chinese Academy of Med.Sciences, Department of Radiation Oncology, Beijing, China

<sup>2</sup>Cancer Hosp.- Chinese Academy of Med.Sciences, Department of Nuclear Medicine, Beijing, China

#### Purpose or Objective

Studies have consistently demonstrated the neurocognitive complications emerge in the survivors of NPC patients who have received RT and greatly affect their quality of life. It is still unclear how the brain functions are affected by radiation and whether these brain functional alterations are related to the radiation dose. This pilot study is aimed at exploring the brain functional alterations by using resting-state functional MRI.

#### Material and Methods

20 NPC patients and 18 normal controls were recruited in this study. All patients were treated with intensity-modulated RT. Resting-state functional MRI scanning and neurocognitive tests including Montreal cognitive assessment (MoCA), Auditory verbal learning test (AVLT), Self-rating depression scale (SDS) and Self-rating anxiety scale (SAS) were administered individually during every patient 1 day before initiation of RT and 1 day after completion of RT. The normal controls also accepted the same MRI scanning and the neurocognitive tests. Amplitude of low-frequency (0.01-0.08 Hz) fluctuations (ALFF) during resting-state functional studies were calculated by Data Processing Assistant for Resting-State fMRI (DPARSF) software package to characterize regional cerebral functions. Paired T test was used to compare the cerebral functional alterations before and after treatment while 2-sample T test was used to compare ALFF values before and after treatment separately with healthy controls. Neurocognitive tests comparison of patients before and after radiotherapy and healthy controls were adopted ANOVA analysis. Significance was set at P=0.05.

#### Results

Compared with the patients before and after radiotherapy, increased ALFF were observed in inferior temporal gyrus, parahippocampal gyrus, hippocampus; decreased in occipital gyrus, inferior and middle temporal gyrus, lingual gyrus, fusiform gyrus, cuneus gyrus, cingulate gyrus, calcarine. Relative to controls, patients showed significantly increased ALFF in fusiform gyrus and inferior temporal gyrus bilaterally, decreased in left frontal gyrus before radiotherapy. After treatment, ALFF were still showed significant changes in these regions and also in parahippocampal gyrus, hippocampus, superior and middle frontal gyrus, decreased in lingual gyrus, cingulate gyrus, calcarine. There were no significant results of neurocognitive tests scores.

#### Conclusion

Our findings firstly revealed that radiation treatment in NPC patients leads to regional synchronous neural activity changed in a short-term while not only in the regions that involved in the target radiation fields, but also in other low dose functional regions of relative neural pathways which may could explain the cognitive deficits in morphological normal-appearing brain of NPC patients after RT. Additionally, the present study offers promising novel neuroimaging approaches for both investigating mechanism of radiation therapy and tracking clinical dosage effects to optimize and individualize patient's

treatment.

#### PO-0618 Role of PET in radiotherapy planning of head and neck tumors: a systematic review

<sup>7</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"- Catholic University of Sacred Heart, Radiotherapy Unit, Campobasso, Italy

<sup>8</sup>S.Orsola-Malpighi Hospital, Medical Physics Unit, Bologna, Italy

#### Purpose or Objective

Use of PET imaging has been proposed in radiotherapy (RT) treatment planning of locally advanced H&N tumors. Some studies showed that most local relapses occur in PET-positive volumes before RT. Therefore, the possibility to define the GTV using PET-imaging has been considered as an opportunity to reduce the irradiated volume allowing Organs at Risk sparing and thus dose-escalation. Some studies analyzed the volumetric differences between the GTV volume evaluated by CT versus PET imaging. Aim of this analysis was to systematically review the available literature on this issue.

#### Material and Methods

From Pubmed database, a literature search ("PET" AND "Radiotherapy Planning") was performed using the PRISMA guidelines including published studies about GTV definition in H&N tumors using CT versus PET imaging. Reviews, editorials, letters and case reports were excluded. Only article published in English were considered.

#### Results

A total of 14 studies reporting data on GTV definition using both CT and PET imaging met the inclusion criteria. The median number of analyzed patients was 26 (range: 6-91). Eight studies included only patients with SCC H&N tumors. PET based GTV delineation was performed by manual contouring (visual method: VM) in 8 studies and by auto-contouring (AC) using 40-50% intensity level for <sup>18</sup>F-FDG PET images in 4 studies. Seven studies reported PET-based GTV-T (primary tumor only), compared to CT-based GTV-T, being larger in 2 studies (1VM, 1 AC), smaller in 3 studies (3 VM), and not different in 2 studies (1 VM, 1 AC). Six studies reported PET-based GTV-N (nodal disease only), compared to CT-based GTV-N, being larger in 1 study (1VM), smaller in 1 study (1 AC), and not different in 4 studies (3 VM, 1 AC). Seven studies reported PET-based GTV-T+N (combined primary tumor plus nodal disease), compared to CT-based GTV-T+N, being smaller in 5 studies (4 VM, 1 AC) and not different in 2 studies (1 VM, 1 AC). In the evaluation of GTV-T+N, PET-based GTV showed a significant reduction in 1/2 AC study and in 4/5 VM studies.

#### Conclusion

Data about the impact of PET imaging in GTV definition in H&N cancers are conflicting although most studies evaluating both tumor and nodes GTV showed a reduced volume using PET. The used PET-delineation methodology seems to influence the results with larger differences (compared to CT-scan) by using VM.

#### Purpose or Objective

A gene signature predicting loco-regional control (LRC) of locally advanced head and neck squamous cell carcinoma (HNSCC) after postoperative radiochemotherapy (PORT-C) will be evaluated using nanoString and RNA microarray data. The prognostic power of the signature as well as the correlation between both methods is evaluated to underline the robustness of the proposed signature.

#### Material and Methods

Gene expression analyses were performed using nanoString technology and the GeneChip® Human Transcriptome Array 2.0 (Affymetrix) on a multicentre retrospective patient cohort of 191 patients with HNSCC who received postoperative radiochemotherapy. The nanoString gene expression panel of 209 genes was composed hypothesis-driven, including genes which are involved in proliferation, invasion and metastasis as well as in radio(chemo)resistance associated with tumour hypoxia, cancer stem cell markers, cisplatin-resistance and DNA repair.

A gene signature which optimally predicts LRC was extracted from the nanoString gene expression data. Different statistical methods for signature selection and outcome prediction were compared. In parallel, this gene signature was evaluated using gene expression data of the GeneChip® Human Transcriptome Array analyses. The prognostic performance of both methods, measured by the concordance index (CI), was compared.

#### Results

The extracted nanoString gene signature contained genes related to cellular proliferation, migration, invasion, and tumour hypoxia. From the different statistical methods, Cox regression performed best and was chosen for outcome prediction. Internal 3-fold cross validation during model building showed a CI=0.7, indicating a good performance of the model. Evaluating the signature using the gene expression data generated with the GeneChip® Human Transcriptome Array led to similar results. The expression values of each gene within the signature were significantly correlated between nanoString and RNA microarray data with  $R > 0.4$ .

#### Conclusion

We determined a gene signature for the prediction of LRC in a cohort of 191 patients with locally advanced HNSCC after postoperative radiochemotherapy based on nanoString gene expression data. The signature showed a good prognostic value and was validated by internal and external validation. Using gene expression data from the GeneChip® Human Transcriptome Array a similar prognostic value was obtained, underlining the robustness of the proposed signature.

#### PO-0620 Partial Laryngeal IMRT for T2N0 Glottic Cancer: Impact of Image Guidance and Radiotherapy Regimen

K. Rock<sup>1</sup>, S. Huang<sup>1</sup>, A. Tiong<sup>1</sup>, L. Lu<sup>2</sup>, W. Xu<sup>2</sup>, A. Bayley<sup>1</sup>, S. Bratman<sup>1</sup>, J. Cho<sup>1</sup>, M. Giuliani<sup>1</sup>, A. Hope<sup>1</sup>, J. Kim<sup>1</sup>, J. Ringash<sup>1</sup>, B. O'Sullivan<sup>1</sup>, J. Waldron<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre, Department of Radiation Oncology, Toronto, Canada

<sup>2</sup>Princess Margaret Cancer Centre, Department of Biostatistics, Toronto, Canada

#### Purpose or Objective

Since 2006 we have used partial laryngeal IMRT due to the ease of sparing the contralateral carotid and arytenoid cartilage. Since then the protocol has undergone two changes. Initially, the matching surrogate for image guidance changed from cervical vertebrae bone (IGRT-bone) to laryngeal soft tissue (IGRT-larynx). Secondly, the IMRT dose/fractionation for T2N0 glottic cancer changed from hypofractionation (RT-hypo) 60 Gy in 25 fractions in 5 wks (60 Gy/25f/5w) to moderate accelerated (RT-acc) 66-70 Gy/33-35f/5.5-6w. This study investigates the impact of these two changes on local control (LC) following partial laryngeal IMRT for T2N0 glottic cancer patients.

#### Material and Methods

All clinical T2N0 glottic patients receiving partial laryngeal IMRT from Jan 2006 to Dec 2013 were reviewed. GTV was delineated based on endoscopic/radiological findings. CTV1 was (GTV +0.3-0.5cm) to high dose and CTV2 (GTV +1cm) to elective dose. PTV was CTV + 0.5cm expansion axially but 1cm superior and inferiorly. LC, overall survival (OS), and grade 3-4 late toxicity (LT) were compared between IGRT-bone vs IGRT-larynx, and RT-hypo vs RT-acc. Univariable analysis (UVA) was used to identify potential factors for local failure (LF). Variables studied included IGRT matching technique (IGRT-bone vs IGRT-larynx), tumor volume and extension (supra- vs sub-glottic), RT regimen, anterior commissure involvement and smoking status. Since IGRT surrogate and RT regimen were highly correlated, two separate multivariable analysis (MVA) models were constructed.

#### Results

A total of 139 patients were identified. T2 category was assigned as follows: supra- or sub-glottic extension (54%); impaired vocal cord mobility (47%); or both (49%). Anterior commissure involvement was present in 72% of patients. IGRT-larynx and IGRT-bone were used in 92 (66%) and 47 (34%) patients, respectively. RT-hypo and RT-acc were given to 71 (51%) and 68 (49%) patients, respectively. Median follow-up was 5.03 yrs. A total of 28 local (IGRT-bone:15/47, IGRT-larynx:13/92), 6 regional, 2 distant failures were identified. Compared to IGRT-bone, IGRT-larynx had higher 5 year LC (85% vs 68%,  $p=0.02$ ) and OS (87% vs 65%,  $p=0.007$ ), but identical LT (7% vs 7%,  $p=0.73$ ). Higher LC was also observed for RT-acc vs RT-hypo (89% vs 70%,  $p=0.008$ ). UVA revealed that IGRT-larynx (HR 0.42,  $p=0.02$ ), RT-acc (HR 0.33,  $p=0.01$ ) were associated with reduced risk for LF while current smoker did not impact LC ( $p=0.49$ ). MVA adjusted for GTV and smoking status confirmed that IGRT-larynx reduced risk of LF vs IGRT-bone (HR=0.40, 95% CI 1.2-5.3,  $p=0.02$ ); RT-acc also reduced risk of LF (HR 0.34, 0.15-0.79,  $p=0.012$ )

#### Conclusion

Moderate accelerated IMRT with laryngeal soft tissue guidance for T2N0 glottic cancers results in high LC (>80%) with minimal toxicity. The transition from bone vertebrae to laryngeal soft tissue matching, together with accelerated schedules and higher biological equivalent dose is safe and potentially shows superior outcomes.

#### PO-0621 Validation of tumor delineation on HE stained sections with cytokeratin staining as gold standard

H. Ligtenberg<sup>1</sup>, S. Willems<sup>2</sup>, E. Jager<sup>1</sup>, C. Terhaar<sup>1</sup>, C. Raaijmakers<sup>1</sup>, M. Philippens<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

<sup>2</sup>UMC Utrecht, Pathology, Utrecht, The Netherlands

#### Purpose or Objective

The extent of microscopic tumor growth determines the clinical target volume (CTV) in head-and-neck tumors. In imaging validation with histopathology, the CTV-margin needed to include all microscopic tumor, can be

determined with microscopic investigation of hematoxylin-eosin (HE) stained whole-mount slices. The purpose of this study is to investigate the accuracy of delineating microscopic tumor growth on HE stained slices by comparing it with the gold standard for squamous cell carcinoma (SCC): immunohistochemical pan-cytokeratin (CKAE1/3) staining.

#### Material and Methods

Twenty-seven patients with laryngeal or hypopharyngeal SCC underwent total laryngectomy (TLE). The laryngeal specimen was fixated and preserved with formalin and sliced up into 3 mm thick slices. For each patient, four subsequent slices with tumor were selected. From each slice, two 4µm-thick whole-mount sections were obtained and stained with HE and CKAE1/3. The tumor was delineated both on the HE and CKAE1/3 stained sections by a dedicated head-and-neck pathologist using a microscope. The stained sections were three-dimensionally reconstructed and rigidly registered to each other. Registration between CKAE1/3 and HE stainings was performed by manually selecting 3-5 corresponding landmarks. The HE-based tumor delineations were compared with the CKAE1/3-based tumor delineations. The maximum distance between HE and CKAE1/3 tumor delineations was measured for each patient. Furthermore, the conformity index (CI) was measured between the corresponding delineations.

#### Results

The 99<sup>th</sup> percentile distance for microscopic disease outside the HE sections was 1.7 mm (0.9-3.4). This distance includes some registration error between HE and CKAE1/3 stained sections. The coverage of the CKAE1/3 delineated volume by the HE volume (sensitivity) was 0.93 (0.85-0.98) and the positive predictive value (PPV) was 0.89 (0.76-0.95). This shows that the tumor volume delineated on HE is larger than on CKAE1/3. As the distances between the contours on HE and CKAE and reversely between CKAE and HE is comparable, the effect on the CTV margin might be considered small. The CI was 0.83 (0.73-0.89), which is smaller than the CI for inter-observer variation in tumor delineation on HE stained sections. This might be partially attributed to the extra registration step which is required for the comparison between HE and CKAE1/3.

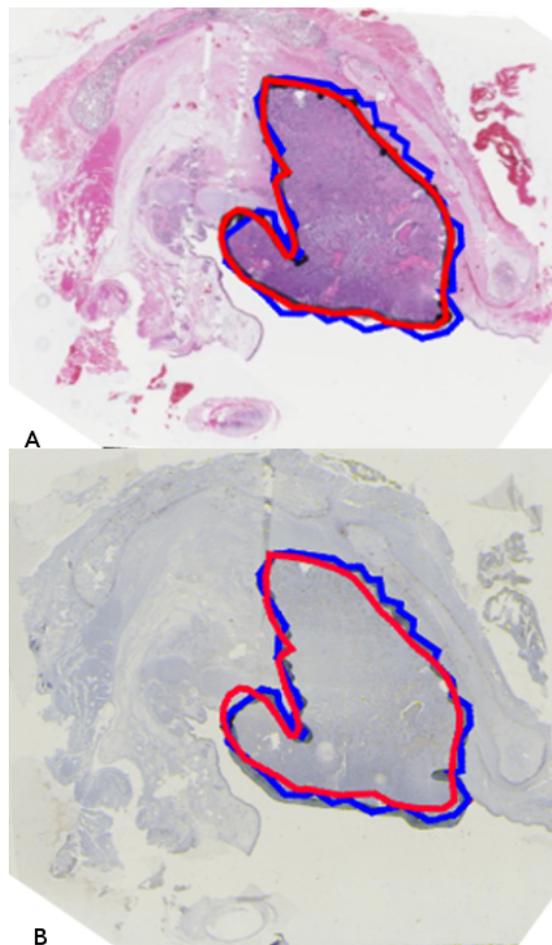

Figure 1: Delineation of tumor on HE (blue) and CKAE (red). Shown on a) HE-stained section and b) CKAE stained section

#### Conclusion

Nearly all tumor is delineated on HE within 2 mm accuracy of the CKAE1/3 delineation. This is comparable with the interobserver delineation accuracy on HE stained sections. Consequently, the effect on the CTV margin for delineations made on MRI or CT is not clinically relevant.

#### PO-0622 Medulloblastoma in adults: a retrospective single institution analysis

I. Hadi<sup>1</sup>, O. Roengvoraphoj<sup>1</sup>, F. Roeder<sup>1,2</sup>, C. Belka<sup>1</sup>, S. Nachbichler<sup>1</sup>

<sup>1</sup>Ludwig-Maximilians-Universität München, Radiation Oncology, München, Germany

<sup>2</sup>German Cancer Research Center DKFZ, Molecular Radiation Oncology, Heidelberg, Germany

#### Purpose or Objective

Adult medulloblastoma is a rare disease. The therapy is based on pediatric treatment protocols. This retrospective analysis investigated the clinical outcomes and prognostic factors of adult patients receiving multimodal therapy in our institution.

#### Material and Methods

Treatment charts of patients with medulloblastoma older than 15 years old, who have been treated in our institution between 2001 and 2014, were analyzed retrospectively. Supratentorial tumors were excluded. Patients' demographic parameters, histology, initial

diagnostics, tumor stadium, risk group, localization, initial symptoms, treatment modalities, toxicities of the treatments, and survival outcomes were investigated.

#### Results

A total of 22 patients were identified. Median age was 30.2 years (16.5-45.6 years). All of the patients had de novo medulloblastoma and good Karnofsky performance status. The most frequent histologies were classic (n=10) and desmoplastic (n=9). 2 patients were high risk and 19 standard risk patients. After tumor resection, all the patients received craniospinal irradiation with a median dose of 35 Gy and a boost to the posterior fossa with a median dose of 19.8 Gy. Simultaneous chemotherapy with vincristine q1w was given to 20 patients. Sequential chemotherapy with cisplatin/vincristine/CCNU was applied in 15 patients. 3 patients with recurrent disease were detected. The median overall survival has not been reached after a median follow up of 92 months. Estimated 5-year OS was 88% and 10-year OS was 80% respectively. Estimated 5-year and 10-year-locregional control was 81% respectively. In univariate analysis shorter locoregional treatment time (interval of tumor resection until end of irradiation) was significantly associated with improved OS ( $p=0.031$ ) and improved locoregional control ( $p=0.049$ ). Furthermore anaplastic histology was associated with worse OS ( $p<0.01$ ). The most common side effects were hematological toxicities, with only 2 patients having had acute grade 3 toxicities.

#### Conclusion

The combined treatment showed a good outcome in patients with adult medulloblastoma. The therapy has been well tolerated. However, further investigations are needed regarding possible prognostic factors.

#### PO-0623 Impact of Interim Events during the Surgery-to-Radiotherapy Interval in Newly Diagnosed Glioblastoma

C.W. Wee<sup>1</sup>, E. Kim<sup>1</sup>, I.H. Kim<sup>1</sup>, T.M. Kim<sup>2</sup>, C.K. Park<sup>3</sup>, J.W. Kim<sup>3</sup>, S.H. Choi<sup>4</sup>

<sup>1</sup>Seoul National University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of

<sup>2</sup>Seoul National University College of Medicine, Department of Internal Medicine, Seoul, Korea Republic of

<sup>3</sup>Seoul National University College of Medicine, Department of Neurosurgery, Seoul, Korea Republic of

<sup>4</sup>Seoul National University College of Medicine, Department of Radiology, Seoul, Korea Republic of

#### Purpose or Objective

To investigate the impact of interim disease progression (PD) and other events occurring during the surgery-to-radiotherapy interval for treatment and outcome in glioblastoma.

#### Material and Methods

A total of 222 patients were planned for radiotherapy (RT) and 173 of them were evaluable for the presence of interim PD by 2 separate MRIs. The size criteria from the updated Response Assessment in Neuro-Oncology criteria was adopted.

#### Results

Of the 222 patients, 1 patient couldn't start the planned RT due to pulmonary complication. All patients with interim events completed the planned RT. Forty-three (24.9%) patients experienced interim PD, and their median survival (MS) was significantly shorter than patients without PD in univariate (13.9 vs. 18.4 months,  $p=.002$ ) and multivariate analysis [ $p=.001$ , HR 2.018 (95% CI, 1.321-3.082)]. Interim non-PD events were observed in 24 (10.9%) patients but did not affect MS compared to those without non-PD events (20.2 vs. 16.4 months,  $p=0.414$ ). Vascular events and infection of the central nervous system occurred in 5 (2.3%) and 9 (4.1%) patients, respectively. Infection significantly prolonged the mean

duration of RT (74.4 vs. 41.2 days,  $p=.005$ ), but did not delay RT (37.8 vs. 31.4 days,  $p=.407$ ) or affect MS (25.5 vs. 16.3 months,  $p=.562$ ). Vascular events did not significantly delay RT (36.7 vs. 31.3 days,  $p=.188$ ), prolong the duration of RT (33.7 vs. 42.3 days,  $p=.127$ ), or affect MS (13.1 vs. 16.7 months,  $p=.915$ ).

#### Conclusion

More aggressive treatment strategies such as reoperation should be investigated in patients with interim PD for survival improvement. Since a significant portion of patients demonstrate interim PD, pre-RT MRI is essential for accurate target delineation. Non-PD events before RT may affect the duration of RT, but not survival.

#### PO-0624 Gammaknife Radiosurgery in patients receiving anticancer immunotherapy: efficacy and safety

D. Greto<sup>1</sup>, M. Loi<sup>1</sup>, S. Scoccianti<sup>1</sup>, M. Baki<sup>1</sup>, I. Desideri<sup>1</sup>, L. Bordi<sup>2</sup>, P. Bono<sup>2</sup>, I. Meattini<sup>1</sup>, P. Bonomo<sup>1</sup>, F. Terziani<sup>1</sup>, V. Carfora<sup>1</sup>, L. Livi<sup>1</sup>

<sup>1</sup>Azienda Ospedaliero Universitaria Careggi- Università di Firenze, Radiotherapy, Firenze, Italy

<sup>2</sup>Azienda Ospedaliero Universitaria Careggi, Neurosurgery, Firenze, Italy

#### Purpose or Objective

Radiosurgery is the treatment of choice for brain metastasis (BMs) in patients with controlled extracranial disease under systemic therapy. In recent years, immune checkpoint inhibitors emerged as a valuable option resulting in unprecedented long-lasting remissions and integrated clinical management in patients affected by metastatic melanoma, lung and kidney cancer. The aim of the study is to assess the safety and the synergistic activity of concurrent immune checkpoint inhibitors and GammaKnife Radio Surgery (GKRS) in a retrospective cohort of patients.

#### Material and Methods

We retrospectively reviewed patients undergoing anti CTLA4 and/or anti PDL1 immunotherapy treated with GKRS at our Institution from January 2014 to March 2016 for BMs. Radiosurgery was delivered within 6 months from the last immunotherapy administration. Response to radiosurgery was evaluated according to RECIST criteria by magnetic resonance (MRI) performed at 45 days, three and six months after procedure. Clinical outcome and toxicity were analyzed and correlated to patient characteristics and treatment modalities.

#### Results

Twelve patients (5 melanoma, 6 lung, 1 kidney) were eligible for a total number of 61 treated lesions for a median number of 3 lesions per patient (1-16). Median age was 55 years (32-77); median GPA was 2 (1-4). GKRS consisted of a single session in all patients for a median dose of 21 Gy (15-24); median treatment volume was 9.45 cm<sup>3</sup> (1.75-220.35). Immunotherapy consisted of Anti CTLA4 (Ipilimumab) in 3 patients, Anti PDL1 (Nivolumab) in 8 patients or both in 1 case, corresponding to 8 (13.1%), 37 (60.7%), and 16 (26.2%) lesions, respectively. No acute neurotoxicity occurred after GKRS. MRI at 45 days showed complete response, partial response and stable disease in 7 (11.5%), 22 (36.1%) and 32 (52.4%) lesions. MRI at 6 months showed progression of treated lesions in 4 (6.6%) cases; five (41.7%) patients experienced distant brain failure. At statistical analysis, local control at 6 months was correlated only to BRAF mutation ( $p=0.029$ ). At a median follow up of 9.6 months (6.3-30.6) we recorded one death due to brain progression while 5 patients died for extracranial disease; radionecrosis occurred in one case.

#### Conclusion

The association of immune checkpoint inhibitors and GKRS is feasible and did not result in severe toxicity. Enhanced local control in GKRS treated BRAF mutated melanoma BMs might result from defective DNA-repair or by

increased antigen load allowing for stronger immune reaction toward mutant clones. Larger series and translational research is needed to elucidate this finding.

#### PO-0625 Accelerated-hypofractionated IMRT plus Temozolomide in Glioblastoma: a phase I dose-escalation study

M. Ferro<sup>1</sup>, G. Macchia<sup>1</sup>, F. Deodato<sup>1</sup>, S. Cilla<sup>2</sup>, A.C. Melone<sup>1</sup>, P. Pagnano<sup>1</sup>, M. Ferro<sup>1</sup>, M. Boccardi<sup>1</sup>, A. #### Purpose or Objective

We performed a dose-escalation trial to determine the maximum tolerated dose (MTD) of Volumetric Modulated Arc Therapy (VMAT) with standard concurrent and sequential-dose temozolomide (TMZ) in patients with resected glioblastoma multiforme.

#### Material and Methods

Histological proven glioblastoma patients underwent VMAT dose escalation. VMAT was delivered over 5 weeks with the simultaneous integrated boost (SIB) technique to the two planning target volumes (PTVs) defined by adding 5-mm margin to the respective clinical target volumes (CTVs). CTV1 was defined by adding a 10-mm isotropic margin to the tumor bed plus any MR enhancing residual lesion; CTV2 was defined as the CTV1 plus 20-mm isotropic margin. Radiation dose was escalated to the PTV1 with the SIB-VMAT strategy. Two dose levels were planned: Level 1 (PTV2: 45/1.8Gy; PTV1: 72.5/2.9Gy) and Level 2 (PTV2: 45/1.8Gy; PTV1: 75/3Gy). All treatments were delivered in 25 fractions. Patients were treated in cohorts of between three and six per group using a Phase I study design. The recommended dose was exceeded if two of the six patients in a cohort experienced dose-limiting toxicity within 3 months from treatment. Concurrent and sequential TMZ chemotherapy was administered according to Stupp's protocol.

#### Results

Seventeen consecutive glioblastoma patients [male/female: 7/10; median age: 58 years) were treated. Six patients were treated at first dose level, with one of them experiencing a dose-limiting toxicity (DLT) (grade 3 neurological toxicity with seizures requiring hospitalization). Being the MTD not exceeded, the PTV1 dose was escalated to the highest planned dose level (75/3 Gy) and 11 patients were treated without any further DLT. After a median follow-up time of 7 months, no grade >2 late neurological toxicity was recorded.

#### Conclusion

The SIB-VMAT technique was found to be feasible and safe at the recommended doses of 45Gy to PTV2 and 75Gy (biological effective dose - BED - of 150 Gy, alpha/beta 3) to PTV1 in the postoperative treatment of patients with glioblastoma.

<sup>3</sup>Centre of Oncological Diagnostics and Therapy, Radiotherapy, Tomaszów Mazowiecki, Poland

<sup>4</sup>Medical University of Lodz, Radiotherapy, Lodz, Poland

#### Purpose or Objective

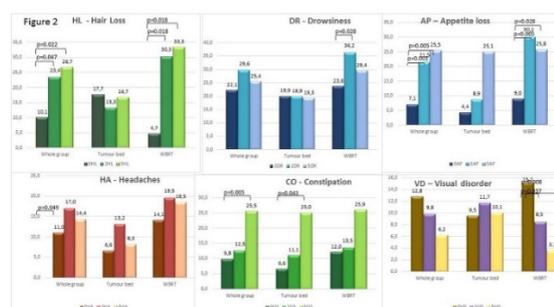

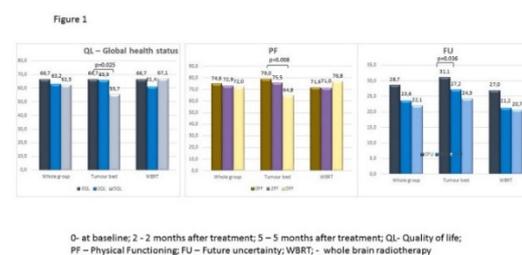

Recently published randomized trial (NCT01535209) demonstrated no difference in neurocognitive function between stereotactic radiotherapy of the tumor bed (SRT-TB) (15Gy/1 fraction or 25Gy/5 fractions) and whole brain radiotherapy (WBRT) (30Gy/10fractions) in patients with resected single brain metastasis. Patients treated with SRT-TB had lower overall survival compared with WBRT arm due to the excess of neurological deaths. We compared study arms for health-related quality of life (HR-QoL).

#### Material and Methods

A self-assessed questionnaire was used to assess the QoL (EORTC QLQ-C30 with -BN20 module) at baseline prior to RT, 2 months after RT and every 3 months thereafter. QoL results were presented as mean scores and compared between arms and time points using the Wilcoxon rank sum test.

#### Results

Of 59 randomized patients, 37 (64%) were eligible for QoL analysis; 15 received SRT-TB and 22 had WBRT. There was no difference in global health status QoL/main function scales/symptoms (except for drowsiness which was worse in WBRT arm 2 months after RT [p=0.048]) between arms. Global health status QoL decreased 2 and 5 months after RT, but significantly only for SRT-TB (p=0.025). Physical function decreased significantly 5 months after SRT-TB (p=0.008). Future uncertainty worsened after RT, but significantly only for SRT-TB arm at 2 months (p=0.036). Patients treated with WBRT had significant worsening of appetite, drowsiness, and hair loss after treatment. Visual disorders improved after RT, significantly for WBRT; constipation worsened after RT, significantly for SRT-TB arm (figures: 1 and 2).

### Conclusion

Despite higher symptoms' burden after WBRT that are attributed to the side effects of RT, like appetite loss, drowsiness, and hair loss, QLQ-C30 global health status, physical functioning and future uncertainty favored WBRT in comparison with SRT-TB in our study. This may be related to the compromised brain tumor control with omission of WBRT; however, we should be aware that in brain metastases patients many factors may influence QoL.

### PO-0627 Prediction of radiosurgery response of brain metastases using convolutional neural networks

Y. Cha<sup>1</sup>, M.S. Kim<sup>1</sup>, C.K. Cho<sup>1</sup>, H. Yoo<sup>1</sup>, W.I. Jang<sup>1</sup>, Y.S. Seo<sup>1</sup>, J.K. Kang<sup>1</sup>, E.K. Paik<sup>1</sup>

<sup>1</sup>Korea Institute of Radiological & Medical Sciences, Department of Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

A deep learning concept based on artificial convolutional neural networks (CNN) is regarded as an emerging radiomics methodology because it uses minimal amount of image preprocessing. Metastatic brain tumor is presumed an appropriate model for radiomics study because of round shape and clear boundary of tumor. The purpose of this study is to predict radiation response of metastatic brain tumor receiving stereotactic radiosurgery (SRS) using the radiomics model based on CNN.

### Material and Methods

CNN is a kind of artificial neural network in which the connectivity pattern between its neurons is inspired by the organization of visual cortex. We implemented a CNN system to process CT images using the numerical computation library 'TensorFlow'. The 110 metastatic brain lesions with longest diameter of 1-3.5 cm treated with SRS between 2007 and 2015 were retrospectively evaluated. Through the radiologic review within 3 months after SRS, all lesions were divided 2 groups: responder (complete or partial response) and non-responder (stable or progression) by Response Evaluation Criteria in Solid Tumor (version 1.1). Responder and non-responder were 57 and 53 lesions, respectively. 110 data-sets which composed of extracted images and matched response classification were randomly assigned to 3 cohorts; training, validation and evaluation cohort. And our CNN system was trained by data-sets of training cohort. Then the system was optimized by adjusting training parameters using data-sets of validation cohort. After sufficient training and optimization, a CNN system reliably predicts classification of the arbitrarily inputted images. We inputted images of evaluation cohort into the trained CNN system. Then the system predicted the response classification of inputted images. The above process was repeatedly performed with changing the number ratio of data-set in each cohort and the assignment of data-sets to cohorts, respectively.

### Results

The range of accuracy of prediction was elevated from 70% to 83% as increasing the number of data-sets of training cohort from 60 to 80. On 80 training data-sets, average 73% sensitivity and 83% specificity in predicting non-responder were achieved.

### Conclusion

CNN based metastatic brain tumor CT image training and classification system was successfully implemented. The prediction of early response after SRS to metastatic brain tumor using the system was achieved effectively. To improve the performance of CNN based prediction system, the number of training data should be increased. This first study of prediction of radiosensitivity using CNN provides initial evidence of potential applicability of CNN based radiomics method to clinical radiation oncology field.

### PO-0628 Correlation between 18F-FDOPA uptake and tumor relapse in recurrent high-grade gliomas

I. Chabert<sup>1,2,3,4</sup>, F. Dhermain<sup>5</sup>, S. Bibard<sup>1</sup>, S. Reuze<sup>1,3,4</sup>, A. Schernberg<sup>5</sup>, F. Orhac<sup>4,6</sup>, I. Buvat<sup>6</sup>, E. Deutsch<sup>3,4,5</sup>, C. Robert<sup>1,3,4</sup>

<sup>6</sup>IMIV, CEA- Inserm- CNRS- Univ. Paris-Sud- Université Paris-Saclay- CEA-SHFJ, Orsay, France

### Purpose or Objective

Patients suffering from high-grade gliomas have a median survival time of 14 months despite various treatment strategies. Our purpose was to investigate whether <sup>18</sup>F-FDOPA PET imaging could predict tumor relapse areas and improve tumor delineation in recurrent high-grade gliomas treated by radio-chemotherapy.

### Material and Methods

This prospective study started in 2015 included 8 patients suffering from recurrent high grade gliomas (grade 4) who received radiotherapy [from 40 Gy to 50 Gy in 2.5 or 4 Gy/fraction] associated with Bevacizumab chemotherapy. Subjects underwent pre-treatment CT, T1-Gd, T2 FLAIR acquisitions and a <sup>18</sup>F-FDOPA scan. All images were registered to the planning CT using a rigid algorithm. One senior radiotherapist delineated Gross Tumor Volumes (GTV) on anatomical MR images. A large region of interest was manually drawn around the first recurrence site on the <sup>18</sup>F-FDOPA images and two thresholds  $t$  of 30% and 40% of the maximum standardized uptake value ( $SUV_{max}$ ) were applied to deduce the regions of high <sup>18</sup>F-FDOPA uptake ( $V_{PET,t}$ ). Follow-up anatomical MR images were used to localize second relapse areas (GTV'). Correlations between all volumes were analyzed using five indexes.  $I_{1,t}$  measures the percentage of  $V_{PET,t}$  not included in the anatomically-defined GTV.  $I_{2,t}$  and  $I_{3,t}$  respectively measure the percentage of GTV' included in GTV and  $V_{PET,t}$ .  $I_{4,t}$  measures the percentage of  $V_{PET,t}$  included in GTV'.  $I_{5,t}$  measures the percentage of  $V_{PET,t}$  not included in the GTV which was predictive of relapse. This index is meaningful only if GTV' and GTV are different.

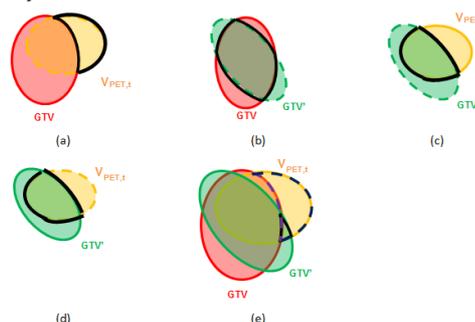

Figure 1: Illustration of (a)  $I_1$ , (b)  $I_2$ , (c)  $I_3$ , (d)  $I_4$  and (e)  $I_5$ . All indexes were obtained by dividing the volume surrounded by a black line by the volume drawn in dashed line.

### Results

Indexes obtained for each patient are presented in Table 1.

Six patients for whom relapse was confirmed anatomically were included in the analysis. For 5 patients,  $I_2$  was lower than 40%, indicating a large progression of the tumor outside the GTV. For 4 patients,  $I_{1,30\%}$  and  $I_{1,40\%}$  values were between 69-82 % and 44-68 %, showing that additional information was provided by <sup>18</sup>F-FDOPA images.  $I_3$  values rapidly decreased when the threshold  $t$  increased (30 % to 40%). For  $t = 30\%$ , values were greater than 50 % for 3 patients. For these patients,  $I_{4,30\%}$  values were between 34

% and 64 % and I<sub>5,30%</sub> values between 22 % to 50 %.

	I <sub>1,30%</sub> (%)	I <sub>1,40%</sub> (%)	I <sub>2</sub> (%)	I <sub>3,30%</sub> (%)	I <sub>3,40%</sub> (%)	I <sub>4,30%</sub> (%)	I <sub>4,40%</sub> (%)	I <sub>5,30%</sub> (%)	I <sub>5,40%</sub> (%)
1	82.5	44.6	6.4	10.0	1.2	54.3	84.1	51.4	75.3

Table 1: Volume comparison indexes as a function of the threshold applied to the <sup>18</sup>F-FDOPA PET SUV.

## Conclusion

In this cohort, the comparison of GTV, GTV' and V<sub>PET</sub> volumes suggests that <sup>18</sup>F-FDOPA PET images can be useful for predicting tumor recurrence areas in half of the patients with encouraging sensibility and sensitivity values. As a next step, ROC curves will be calculated to define the optimal SUV threshold for radiotherapy delineation purpose. The analysis of all post-treatment MR images will be conducted to better determine the starting points of the recurrence and correlate them to the <sup>18</sup>F-FDOPA PET information.

## Purpose or Objective

Inter-individual variability in terms of treatment outcome and benefit from standard of care treatment is a great challenge in the multimodal therapy of glioblastoma (GBM). In order to recognize patients with particularly poor prognosis a priori and assigning them to alternative treatment approaches, molecular signatures predicting outcome with higher accuracy would be helpful. In our study, we examined whether such a signature could be defined on the basis of miRNA expression analyses.

## Material and Methods

FFPE sections of resected tumours from 36 standard-of-care treated GBM patients along with overall survival follow-up data were collected retrospectively and subjected to low-complexity signature identification from miRNA microarray data. Based on the expression of the signature miRNAs and cox-proportional hazard coefficients, a risk score was calculated and used for classification into higher- and lower-risk patients. The identified signature was validated in a miRNA array data set of a subset of the TCGA GBM cohort which was matched for sex, age and treatment. In order to assess the

functional impact, genes putatively regulated by the signature miRNAs were identified by correlation with global transcriptome data, followed by pathway analysis.

## Results

We identified a prognostic 4-miRNA signature that was independent of MGMT promoter methylation status, age, and sex. A risk score was assigned to each patient that allowed defining two groups significantly differing in prognosis (p-value: 0.0001, median survival: 10.6 months and 15.1 months, hazard ratio = 3.8). The signature was technically validated by qRT-PCR and independently validated in an age- and sex-matched subset of standard-of-care treated patients of the TCGA GBM cohort (n=58). Pathway analysis suggested tumorigenesis-associated processes such as immune response, extracellular matrix organization, axon guidance, signalling by NGF, GPCR and Wnt.

## Conclusion

In the present study, we describe the identification and independent validation of a 4-miRNA signature that allows stratification of GBM patients into different prognostic groups in combination with one defined threshold and set of coefficients. This miRNA signature could be utilized as diagnostic tool for the identification of GBM patients for improved and/or alternative treatment approaches.

<sup>4</sup>Istituto di Cura a Carattere Scientifico Basilicata, Laboratorio di ricerca preclinica e Traslaazionale, Rionero in Vulture, Italy

## Purpose or Objective

Melanocortins are peptides with well-recognized anti-inflammatory and neuroprotective activity. Melanocortin receptor-4 (MC4R) is present in astrocytes and it is expressed in the brain. Given the association of MC4R with antiinflammatory activity, induction of neural stem/progenitor cell proliferation in brain hypoxia, and prevention of astrocyte apoptosis, the aim of this study was to evaluate the possible prognostic, predictive and therapeutic role of the MC4R SNPs on GBM patients.

## Material and Methods

Sixty-one patients with a proven diagnosis of GBM, ECOG PS 0-2, age>18 years, and treated with radiotherapy and temozolomide according to Stupp protocol were enrolled. Genomic DNA was extracted and MC4R gene SNPs were analyzed; the allelic discrimination was performed using an ABI PRISM 7900 SDS (Applied Biosystems, Carlsbad, CA, USA) and with validated TaqMan<sup>®</sup> SNP genotyping assays (Applied Biosystems). Kaplan Meier curves were performed for statistical association with genotypes. The study has been approved by the Comitato Etico di Area Vasta Nord Ovest prot. n. 17013.

## Results

Fifty-six patients were clinically evaluated. The median progression-free survival (PFS) and median overall survival (OS) of these patients were 10.8 months and 23 months, respectively. A relevant finding of our study was the identification of a MC4R genotype that was significantly associated with PFS: patients harbouring the rs489693 AA genotype had a median PFS of 3 months

whereas patients with AC/CC genotypes had a median PFS of 13.7 months ( $P=0.0088$ ). No significant differences in PFS and OS for the other genotypes of the investigated MC4R polymorphisms were found.

#### Conclusion

The rs489693 AA genotype is significantly associated with a shorter PFS in GBM patients treated with radiotherapy and temozolomide schedule.

The present, pilot study may represent the stimulus to prospectively investigate the role of MC4R polymorphisms as a predictive pharmacogenetic marker or as a target for new drug therapies for GBM patients.

#### PO-0631 Molecular subtypes of glioblastoma: immunohistochemical approach and clinical correlations

L. Triggiani<sup>1</sup>, M. Cominelli<sup>2</sup>, E. Tratta<sup>2</sup>, P. Ghirardelli<sup>1</sup>, S. Pedretti<sup>1</sup>, N. Pasinetti<sup>1</sup>, M. Buglione<sup>1</sup>, R. Galli<sup>3</sup>, S. Magrini<sup>1</sup>, P.L. Poliani<sup>2</sup>

<sup>1</sup>Spedali Civili di Brescia, Radiation Oncology, Brescia, Italy

<sup>2</sup>Pathology Unit, Department of Molecular and Translational Medicine- University of Brescia-, Brescia, Italy

<sup>3</sup>San Raffaele Scientific Institute, Neural Stem Cell Biology Unit- Division of Regenerative Medicine- Stem Cells & Gene Therapy, Milano, Italy

#### Purpose or Objective

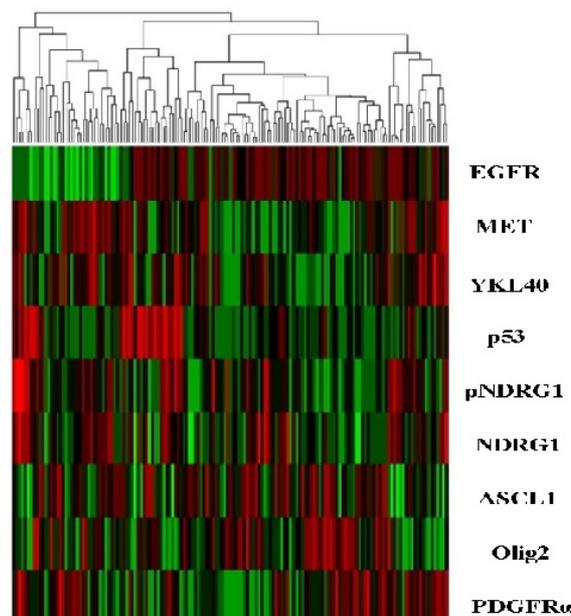

It is currently accepted that Glioblastomas (GBMs) can be classified according to their transcriptional profile in three major molecular subtypes (classic (CL), proneural/neural (PN/N) and mesenchymal (MES)) associated with different gene signature, specific molecular alterations and different prognosis. However, molecular approach is not routinely feasible in daily clinical practice. Thus, assessment of simple tools for GBMs sub-classification is stringently required, particularly for the development of personalized therapeutic strategies. Goal of our study is to investigate the possibility of classifying GBMs by an immunohistochemical approach and correlate the data with clinical information in a large cohort of patients.

#### Material and Methods

We evaluated a wide panel of biomarkers, recognized as subgroup-specific gene classifiers, by IHC on FFPE tissue samples from a large cohort of GBMs (n=151). EGFR amplification and 1p/19q deletion were assayed by FISH. Correlation with histological and prognostic features (including MGMT promoter methylation) were also performed. EGFR status and expression of TP53, IDH1, ASCL1, OLIG2, PDGFRA, PTEN, MET, YKL40 and CD44 were semi-quantitative assayed based on percentage and intensity of expression in immunoreactive cells. Data were also validated at molecular level by mean of RNAseq technology. For statistical analysis, to identify distinct GBM subclasses, we applied consensus clustering to our immunohistochemical data. For clinico-pathological correlations, we retrospectively collected all clinical data, including adjuvant treatment (radiotherapy - chemotherapy).

#### Results

By cluster analysis we identified EGFR, MET, YKL40 and ASCL1 as the most sensitive and specific markers. Their combination allowed to recognize GBM subtypes in 78.8% of cases. Moreover, pleomorphism and epithelioid features were found to be strongly associated to MES subtype (46.2% and 25.7% of MES cases respectively) and small cell component to CL subtype (65.1%). Notably, survival analysis showed that MES GBMs were associated with worst prognosis ( $p=0.079$ ) and CL GBMs is related to a better radio-chemotherapy response.

#### Conclusion

Although GBMs are morphologically defined as unique entity, they are extremely heterogeneous tumours associated with great variability in term of response to treatment (radiotherapy-chemotherapy) and clinical outcome. Our results indicate that using a restricted panel of highly sensitive markers we can identify GBM subgroups with protein expression profiles strongly related to the transcriptional profile.

<sup>4</sup>University of Bonn Medical Center, Division of Clinical Neurooncology and Clinical Cooperation Unit Neurooncology MediClin Robert Janker Klinik, Bonn, Germany

<sup>5</sup>Montreal Neurological Institute and Hospital, Department of Neurology and Neurosurgery, Montreal, Canada

#### Purpose or Objective

The median progression-free survival time after standard-of care therapy for glioblastoma multiforme (GBM) is about 7 months. Most GBM recur locally, suggesting that augmenting local treatments may improve outcomes. We here present the results of a phase I/II trial testing local radiation dose escalation to the resection cavity.

#### Material and Methods

INTRAGO I/II was a monocentric phase 1/2 trial that included patients with resectable GBM. Patients received intraoperative radiotherapy (IORT) with low-energy photons (50 kV) at three dose levels, whereas dosing started at 20 Gy (prescribed to the cavity margin) and was escalated in 10 Gy increments up to 40 Gy. After surgery

and IORT, patients received standard adjuvant therapy, consisting of concomitant external-beam radiotherapy (EBRT; 60 Gy) and temozolomide followed by cycling maintenance temozolomide chemotherapy (5/28 schedule). The primary endpoint was safety as per the occurrence of dose-limiting toxicities (DLT) within 3 months after IORT. Secondary endpoints were progression-free survival (PFS) and overall survival (OS). In addition, we performed an exploratory analysis of the local PFS (defined as tumor recurrence within 1 cm of the resection cavity border). The trial is registered at ClinicalTrials.gov, number NCT02104882.

### Results

Fifteen patients were treated (n=7 at 20 Gy, n=4 at 30 Gy, n=4 at 40 Gy) during surgery. The majority of patients (n=13) underwent incomplete resection. Six patients had unresected multifocal tumors and 3 did not receive per-protocol adjuvant treatment (PPT). Hypermethylation of the MGMT promoter was absent in 10 patients. The median follow-up was 13.8 months. The majority of grade 3-5 adverse events (23 of 27) were deemed related to EBRT, chemotherapy or tumor progression. No DLT occurred and thus the IORT dose was escalated to 40 Gy. Suspected or confirmed radionecrosis was detected in 5 patients of all 3 dose levels. The median PFS was 11.2 months (95%CI: 5.4-17.0) in all and 11.3 months (95%CI: 10.9-11.6) with PPT. The median local PFS was 14.3 m (95%CI: 8.4-20.2) in all and 17.8 m (95%CI: 9.7-25.9) with PPT. The median OS was 16.2 m (95%CI: 11.1-21.4) for all and 17.8 m (95%CI: 13.9-21.7) with PPT. One patient unexpectedly showed distant response of a satellite lesion that was initially not targeted with IORT.

### Conclusion

IORT resulted in a highly relevant increase in PFS and exhibited a manageable safety profile in a cohort with mostly incompletely resected GBM and unfavorable prognostic factors. A multinational randomized phase III trial has been set up to test IORT plus standard of care versus standard of care alone (INTRAGO II; NCT02685605).

### PO-0633 Randomized study of adjuvant temozolomide (6 vs.12 cycle) in newly diagnosed glioblastoma multiforme

A.K. Gandhi<sup>1</sup>, M. Bhandari<sup>1</sup>, D.N. Sharma<sup>1</sup>, P. Julka<sup>1</sup>, G.K. Rath<sup>1</sup>

<sup>1</sup>All India Institute of Medical Sciences, Radiation oncology, New Delhi, India

### Purpose or Objective

The role of adjuvant temozolomide (TMZ) beyond 6 cycles in newly diagnosed glioblastoma multiforme (GBM) is not clear. We did this prospective randomized study with a hypothesis that E-TMZ for a total of 12 adjuvant cycles would improve survival of patients with newly diagnosed GBM as compared to conventional 6 cycles of TMZ (C-TMZ).

### Material and Methods

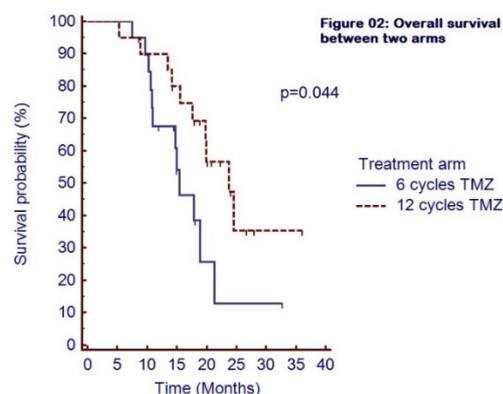

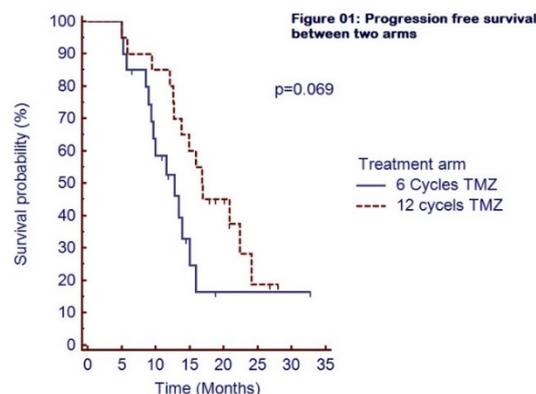

Between January 2012 and July 2013, 40 post-operative patients of GBM between age 18-65 years and Karnofsky Performance Score (KPS)  $\geq$  70 were included. Patients were randomized to receive radiation (60 Gray in 30 fractions over 6 weeks) with concomitant TMZ (75 mg/m<sup>2</sup>/day) and adjuvant therapy with either 6 (C-TMZ arm) or 12 cycles (E-TMZ arm) of TMZ (150-200 mg/m<sup>2</sup> for 5 days, repeated 4 weekly). Toxicity was assessed using CTCAE (common terminology criteria for adverse events) version 3.0. Progression free survival (PFS) was calculated from the time of diagnosis to the time of progression or death. Overall survival (OS) was calculated from the time of diagnosis to the time of death from any cause. Kaplan Meier method was used for survival analysis. P value of < 0.05 was taken as significant and SPSS version 12.0 [SPSS Inc., Chicago, IL, USA] was used for all statistical analysis. All patients signed informed consent before entry into the

study and the study was approved by Institutional ethics committee (IESC/T-027/2011).

### Results

20 patients were treated in each arm. Median age was 49 years and 44 years and median KPS was 90 and 80 respectively in C-TMZ and E-TMZ arms. Gross total resection was possible in 60% and 55% patients and subtotal resection was done in 40% and 45% patients respectively in C-TMZ and E-TMZ arm. 10 and 9 patients respectively in C-TMZ and E-TMZ arm had grade 2 and no patient suffered from grade 3 non-hematological toxicities. 2 patients each had grade 2 hematological toxicity in C-TMZ (both thrombocytopenia) and E-TMZ arm (one neutropenia and one thrombocytopenia) and 1 patient in E-TMZ arm had grade 4 (neutropenia) hematological toxicity during concurrent radiotherapy. Overall, 0% and 5% respectively in C-TMZ and E-TMZ arm had hematological toxicity  $\geq$  3 in grade during concurrent phase.

Median follow up in C-TMZ and E-TMZ arm were 14.65 and 19.85 months. Median PFS was 12.8 months and 16.8 months in C-TMZ and E-TMZ arm respectively (p=0.069). 2 year PFS was 16.4% vs. 18.7% in C-TMZ and E-TMZ arm respectively (Figure 1). Median OS was 15.4 months vs. 23.8 months in C-TMZ and E-TMZ arm respectively (p=0.044). 2-year OS was 12.9% vs. 35.5% respectively in C-TMZ and E-TMZ arm (Figure 2).

### Conclusion

The result of our study suggests that E-TMZ is safe, tolerable as well as confers significant survival advantage as compared to conventional duration of TMZ. Pending results from larger, phase III, multi-institutional studies, it appears prudent for us to suggest use of at least 12 cycles of adjuvant TMZ in patients with newly diagnosed GBM.

### PO-0634 Irradiation of Subventricular Zone in Glioblastoma: Its Impact on Tumor Progression and Survival

F. Sert<sup>1</sup>, S. Hoca<sup>1</sup>, S. Kamer<sup>1</sup>, Y. Anacak<sup>1</sup>

<sup>1</sup>Ege University Medical School&Hospital, Radiation Oncology, Izmir, Turkey

#### Purpose or Objective

Subventricular zone (SVZ) is a paired brain structure situated throughout the lateral walls of the lateral ventricles, a known site of neurogenesis and self-renewing neurons in the adult brain. Some current theories propose that brain tumour stem cells originating from subventricular zone (SVZ) play a role in progression of high-grade gliomas. Since almost all glioblastomas progress locally despite aggressive surgery and radiotherapy, recur within the high-dose irradiation volume in most cases, the theory of tumor cell migration from SVZ is interesting to explore. Irradiation of SVZ supposed to kill brain tumor stem cells which may alter tumour progression and survival. The purpose of this study is to evaluate the impact of the radiation dose to SVZ on progression rates and overall survival in glioblastoma.

#### Material and Methods

Study population consisted of 80 glioblastoma patients (23 females, 57 males) with a median age of 55.5 (21-75) who were treated from January 2012 to December 2014. All patients underwent surgery followed by adjuvant radiotherapy (60 Gy/30 fractions) and concomitant / adjuvant temozolomid. Bilateral SVZ were contoured on MRI images and registered to planning CT slices. Target volumes and organs at risk were also contoured. Conformal radiotherapy with 3-4 fields or IMRT with 1-2 volumetric arcs were used for planning. Median doses for ipsilateral, contralateral and bilateral SVZ were recorded and relations with progression and survival were analyzed using two threshold values at 40 Gy and 50 Gy. Analyses were performed after a median follow-up of 13 months.

#### Results

Median progression free survival (PFS) was 10 months (2-36) and overall survival (OS) was 12 months (3-48). The unfavorable prognostic factors affecting PFS were tumor extending to ventricles ( $p<0.01$ ), ipsilateral SVZ doses  $>50$  Gy ( $p<0.05$ ), and contralateral SVZ doses  $>50$  Gy ( $p<0.05$ ). The unfavorable prognostic factors affecting OS were tumor extending to ventricles ( $p<0.001$ ), contralateral SVZ doses  $>40$  Gy ( $p<0.05$ ) and bilateral SVZ doses  $>40$  Gy ( $p<0.05$ ). In multivariate analysis of prognostic factors, tumor extending to ventricles was the only unfavorable factor for both PFS ( $p<0.001$ ) and OS ( $p<0.001$ ).

#### Conclusion

PFS and OS were shorter in the patients in whom tumor was extending to ventricles and in those where SVZ received at least 40-50 Gy. The data of this study is supports the previous studies showing an inverse correlation between irradiation of SVZ and prognosis. With the present data we can only speculate that those tumors extending deep into the lateral ventricles likely to be larger in size, closer to nearby sensitive structures, and not amenable to total resection. Radiation volumes should cover some parts of SVZ and lateral ventricles to give the prescribed dose to in those unfavorable tumors, which may explain the inverse correlation with SVZ irradiation and survival. Further research is required to clarify the role of brain tumor stem cells locates at SVZ in the prognosis of high-grade gliomas.

### PO-0635 Can psychological support during RT improve distress, mood or quality of life in CNS tumor patients?

L. Dinapoli<sup>1</sup>, S. Chiesa<sup>1</sup>, N. Dinapoli<sup>1</sup>, F. Beghella Bartoli<sup>1</sup>, S. Bracci<sup>1</sup>, M. Massaccesi<sup>1</sup>, A. Tenore<sup>1</sup>, A. Pesce<sup>1</sup>, V. Valentini<sup>1</sup>, M. Balducci<sup>1</sup>

<sup>1</sup>UCSC, Radiation Oncology Department Gemelli-ART, Roma, Italy

#### Purpose or Objective

Patients with CNS tumor often show at diagnosis significant levels of distress, anxiety and depression, which may increase during radiotherapy (RT), for side effects (headache, hair loss, cognitive deficits) or psychological impact on everyday life (absence from work, caregivers' burden). These factors could influence negatively patients' quality of life (QoL) during the entire RT course. The objective of this study is to evaluate the effect of a psychological support offered to patients throughout RT on distress, anxiety, depression and QoL.

#### Material and Methods

Consecutive patients with CNS tumors who underwent RT with radical intent were included between January and September 2016. Psychological support was available for all patients. Distress Thermometer (DT), Hospital Anxiety and Depression Scale (HADS) and Functional Assessment of Cancer Therapy (FACT)-Br were used to evaluate emotional distress, mood and QoL, respectively. The tests were self-administered at the beginning (T0), the middle (T1), the end (T2) of the RT course and three months after the end of RT (T3). Statistical analysis of tests' scores was performed by means of Wilcoxon test for paired samples.

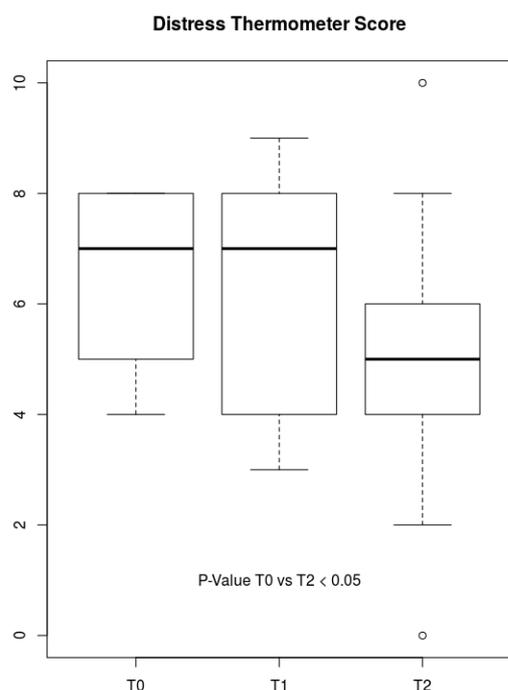

#### Results

Twenty-eight patients (12 male and 16 female, median age 56, range 20-72 years) who underwent radical RT for CNS tumors were included. Radiotherapy was post-operative in all patients and was delivered up to a median total dose of 60 (range 50-66) Gy. Twenty (71.4%) patients received concurrent chemotherapy with temozolomide. All 28 patients underwent the T0, T1 and T2 evaluation. Data collection after three months (T3) is still ongoing.

At T0, 17/28 patients (60.7%) were emotionally distressed (DT score  $\geq 4$ , DT median score=7); at T1, 20/28 (71.4%) patients had significant emotional distress and at T2, 16/28 (57.1%) patients had significant emotional distress. At T0, 9/28 patients (32.1%) showed anxiety/depression (HADS score  $\geq 14$ , HADS median score=20); at T1, 11/28 (39.3%) and at T2, 6/28 (21.4%) patients had significant anxiety and depression.

During RT, in patients who were distressed at baseline (17/28), DT score significantly improved at T2 (median DT score 7 and 5, at T0 and T2 respectively,  $p<0.05$ ) (fig 1).

In patients who were anxious and depressed at baseline (9/28), HADS score did not significantly change during RT. Regarding QoL, statistical analysis on FACT-Br (T0 Vs T2) showed stable scores in Social, Functional, Physical and Symptoms subscales and an improvement in Emotional Well-Being subscale (median Emotional Well-Being score 18 and 19, at T0 and T2 respectively,  $p=0.002$ ).

### Conclusion

In this small series of consecutive CNS tumor patients, psychological support during radiotherapy allows an improvement in distress. Quality of life remained stable with a significant improvement of emotional well-being.

### PO-0636 Impact of DWI-MRI for gross tumor volume definition in patients with recurrent glioblastoma

O. Oehlke<sup>1</sup>, S. Bott<sup>1</sup>, A.L. Grosu<sup>1</sup>, I. Mader<sup>2</sup>

<sup>1</sup>Universitätsklinik Freiburg, Klinik für Strahlenheilkunde, Freiburg, Germany

<sup>2</sup>Universitätsklinik Freiburg, Klinik für Neuroradiologie, Freiburg, Germany

### Purpose or Objective

The low specificity of gadolinium-enhancement in T1-weighted MRI (T1Gd-MRI) in the definition of gross tumor volume (GTV) in recurrent glioblastoma (GBM) is a clinically important problem in the context of treatment planning for re-irradiation. Advanced MR imaging techniques like diffusion-weighted imaging (DWI) have been introduced for diagnosis of tumors. Tumors demonstrate restricted diffusion and thus low apparent diffusion coefficient (ADC), which inversely correlates with tumor cellularity. The goal of this study was to evaluate possible ADC<sub>low</sub>/T1Gd-MRI non-overlap volumes that may have an impact on definition of the GTV in patients with recurrent GBM planned for stereotactic re-irradiation.

### Material and Methods

We evaluated 41 patients treated with stereotactic re-irradiation for recurrent GBM. All patients initially received standard of care with resection followed by radiochemotherapy and adjuvant temozolomide. Progression was diagnosed either by re-resection, biopsy, or RANO criteria in serial MR images. The T1Gd-MRI-GTV was defined as contrast enhancement in 3D T1-weighted sequences. The DWI data were acquired by using a singleshot spin-echo echo-planar imaging sequence ( $b=0$ ,  $1000 \text{ s/mm}^2$ ). ADC values are automatically calculated and displayed as a parametric map. In order to minimize bias, T1Gd-MRI-GTV and ADC<sub>low</sub> areas were determined by different persons.

### Results

The median and mean volumes of T1Gd-MRI-GTVs were 7.71ml (range 0.95-48.27ml) and  $10.67 \pm 9.33\text{ml}$ , respectively. ADC<sub>low</sub> volumes were significantly smaller (median 1.68ml (range 0.27-7.25ml) and mean  $2.43 \pm 1.85\text{ml}$ ,  $p < 0.001$ ). The ADC<sub>low</sub>/T1Gd-MRI overlap volume ranged from 0.03-3.25ml (median 0.62ml) with a mean volume of  $0.84 \pm 0.85 \text{ ml}$ . The corresponding ADC<sub>low</sub>/T1Gd-MRI-GTV non-overlap volume was  $1.46 \pm 1.22\text{ml}$  ( $p = 0.0053$ ) with a median of 1.14ml (range 0.09-5.58ml).

### Conclusion

The results of this study suggest that GTV delineation according to contrast enhancement in T1Gd-MRI in patients with recurrent GBM may lead to target volumes that do not encompass all biologically active tumor detectable in advance DWI MR imaging. Retrospective correlation of ADC<sub>low</sub> areas with the respective isodose distribution and topography of further progression after re-irradiation will help to understand the clinical significance of ADC<sub>low</sub>/non-Gd enhancing areas.

### PO-0637 HFSRT to the resection bed for intracranial metastases: a large retrospective study of 181 patients.

A. Keller<sup>1</sup>, M. Doré<sup>2</sup>, F. Thillays<sup>2</sup>, F. Proust<sup>3</sup>, H. Cebula<sup>3</sup>, I. Darié<sup>3</sup>, F. Lefebvre<sup>4</sup>, G. Noel<sup>1</sup>, D. Antoni<sup>1</sup>

<sup>1</sup>Centre Paul Strauss, Radiotherapy, Strasbourg CEDEX, France

<sup>2</sup>Institut de Cancérologie de l'Ouest, Radiotherapy, Saint Herblain, France

<sup>3</sup>CHU Hautepierre, Neurosurgery, Strasbourg, France

<sup>4</sup>Faculty of Medicine, Laboratory of Biostatistics, Strasbourg, France

### Purpose or Objective

We retrospectively report the outcomes of a large multicenter cohort of patients treated with surgery and hypofractionated stereotactic radiotherapy (HFSRT) to the resection cavities of brain metastases (BM).

### Material and Methods

Between March 2008 to February 2015, a total of 181 patients (189 cavities) with no prior WBRT were treated by HFSRT to the surgical bed of BM, at the dose of 23.1 Gy ( $3 \times 7.7 \text{ Gy}$ ) prescribed to the 70 % isodose line (with 2-mm margin PTV). The primary end-point was local control. Secondary endpoints were distance brain control, overall survival, risks of radionecrosis (RN) and leptomeningeal disease (LMD).

### Results

Of the 189 resected lesions, 44 % were metastatic from a non-small cell lung cancer (NSCLC) primary tumor and 138 patients (76.2 %) had a single metastasis at the time of treatment. The median preoperative tumor volume was 12 mL (0,13 - 92,5), and the median PTV 14.1 mL (0,8 - 65,8). With a median follow up of 15 months (0.6 - 75), the 6- and 12- month local control rates were 92.6 % [95 % CI: 88.8 - 96.3] and 88.2 % [83.6 - 92.9], respectively. On multivariate analysis, PTV (HR = 1.03 [1.01 - 1.05],  $p = 0.005$ ) and GPA (Graded Prognostic Assessment) score (HR = 2.02 [1.11 - 3.66],  $p = 0.021$ ) were predictive of local failure. The 6-, 12-month distance brain control rates were 70.4 % [63.9 - 76.8] and 60.7 % [53.7 - 67.7], respectively. Twenty-six patients (14.4 %) developed signs of LMD, at a median time of 3.8 months (0.13 - 33.6) after HFSRT. Preoperative tumor volume was predictive of LMD (HR = 1.02 [1.0 - 1.04],  $p = 0.029$ ). The median overall survival (OS) was 17.3 months (0.59 - 65.9). The 6-, 12- and 24-month OS rates were 78.8 % [73.2 - 84.9], 62.5 % [55.9 - 69.9] and 39.1 % [32.4 - 47.2], respectively. RPA Class 3 (HR = 2.05 [1.12 - 3.76],  $p = 0.02$ ), piecemeal resection (HR = 1.56 [1.09 - 2.27],  $p = 0.017$ ) and increasing number of BM (HR = 1.71 [1.34 - 2.16],  $p < 0.0001$ ) were independent unfavorable prognostic factors for OS. Fifty-four patients (29.8 %) were subsequently treated with salvage WBRT at a median time of 6.5 months (0.4 - 44.9), and among the patients who developed

distant brain failure, 41 % have been re-irradiated with stereotactic radiotherapy for the additional lesions. Radionecrosis occurred in 35 patients (18.8 %), at a median time of 15 months (3,0 - 38,1) and was associated with the infratentorial location of the metastasis (HR = 2.97 [1.47 - 6.01],  $p = 0.0025$ ).

#### Conclusion

This study demonstrated the safety and efficacy of a 3 x 7.7 Gy HFSRT regimen for irradiation of cerebral metastasis resection cavities. These results compare favorably to historical data undergoing WBRT, SRS or HFSRT. It is an alternative to adjuvant WBRT after surgery, and allow the implementation of salvage therapies.

#### PO-0638 FET PET prior to primary RT of glioblastoma patients - a recurrence pattern analysis

D.F. Fleischmann<sup>1,3</sup>, M. Unterrainer<sup>2</sup>, R. Schön<sup>1</sup>, S. Corradini<sup>1</sup>, C. Maihöfer<sup>1</sup>, P. Bartenstein<sup>2</sup>, C. Belka<sup>1,3</sup>, N.L. Albert<sup>2</sup>, M. Niyazi<sup>1,3</sup>

<sup>1</sup>LMU Munich, Radiation Oncology, Munich, Germany

<sup>2</sup>LMU Munich, Nuclear Medicine, Munich, Germany

<sup>3</sup>German Cancer Consortium (DKTK) German Cancer Research Center (DKFZ) Heidelberg, Germany,

#### Purpose or Objective

<sup>18</sup>F-fluoroethyltyrosine (FET) PET imaging for primary RT treatment planning is of increasing importance. It remains unclear if margin adjustment and reduction is possible through additional FET PET imaging. Margins for FET PET derived biological tumor volumes (BTVs) were compared to MRI-based gross tumor volumes (GTVs) on a recurrence pattern analysis.

#### Material and Methods

Treatment plans and clinical outcome of 36 glioblastoma patients receiving FET PET scans before primary radiotherapy were retrospectively analyzed. The minimal margin including the entire tumor recurrence was calculated for the GTV and a union of GTV and BTV with a threshold of 1.6. Recurrence pattern analysis was performed for the original PTV consisting of the clinical target volume (CTV = GTV + 20 mm) and a 3 - 5 mm PTV margin, the original 95-percent isodose, a synthetic PTV derived from the GTV with a fixed 23 mm margin and a union of GTV and BTV with a 18 mm margin. Treatment planning was performed on OTP-Masterplan® and GTV delineation was based on contrast-enhancing regions on MRI or postoperative resection cavity, respectively.

#### Results

36 glioblastoma patients receiving FET PET before initial RT were included in the recurrence pattern analysis. Median age was 65.5 years and median KPS was 90 at the beginning of RT. Median follow-up time from the start of RT was 47 months, median overall survival 23 months and median progression-free survival 7 months. The minimal margin including the recurrent tumor was smaller for the union of GTV and BTV (median 12.5 mm) than for the GTV alone (median 17 mm) with statistical significance on Wilcoxon-Test ( $p < 0.001$ ). Recurrence pattern analysis revealed 33 (91.6%) central, 1 (2.8%) in-field, 1 (2.8%) marginal, 1 (2.8%) ex-field recurrences for the original PTV, 30 (83.3%) central, 3 (8.3%) in-field, 2 (5.6%) marginal, 1 (2.8%) ex-field recurrence for the 95-percent isodose line, 30 (83.3%) central, 4 (11.1%) in-field, 2 (5.6%) ex-field recurrences for GTV with a 23 mm margin and 32 (88.8%) central, 2 (5.6%) in-field and 2 (5.6%) ex-field recurrences for the union of GTV and BTV with a 18 mm margin. The union of GTV and BTV with a 18 mm margin was smaller than the GTV alone with a 23 mm margin ( $p = 0.053$  in Wilcoxon-Test).

#### Conclusion

FET PET derived BTVs may reduce the minimal margin at the primary RT of glioblastoma patients with an improved delineation of biologically active tumor. The union of GTV and BTV with 18 mm was smaller than GTV with a 23 mm margin and had better results on recurrence pattern

analysis (which corresponds to a 15 mm CTV expansion). These findings have to be prospectively validated.

#### PO-0639 Feasibility of tract based dosimetric analysis in brain tumor patients

M. Conson<sup>1</sup>, L. Cella<sup>2</sup>, E. D'Ippolito<sup>3</sup>, F. Piccolo<sup>3</sup>, S. Coccozza<sup>3</sup>, V. D'Avino<sup>2</sup>, R. Liuzzi<sup>2</sup>, M. Quarantelli<sup>1</sup>, R. Pacelli<sup>3</sup>

<sup>1</sup>Intituto di Biostrutture e Bioimmagini, University of Naples "Federico II"- Department of Diagnostic Imaging and Radiation Oncology- Napoli- Italy, Napoli, Italy

<sup>2</sup>Intituto di Biostrutture e Bioimmagini, National Council of Research CNR, Napoli, Italy

<sup>3</sup>Department of Advanced Biomedical Sciences, University of Naples "Federico II"- Department of Diagnostic Imaging and Radiation Oncology- Napoli- Italy, Napoli, Italy

#### Purpose or Objective

Radiation induced white matter injuries are feared side effects of brain irradiation that may cause cognitive dysfunction. Diffusion tensor imaging (DTI) analysis is a valid tool to evaluate white matter (WM) integrity. A framework for the integrated analysis of tractographic and dosimetric data in brain tumor patients undergoing radiotherapy is proposed. The tool is able to simultaneously measure in specific white matter tracts the diffusion changes due to microstructural alterations and the radiation dose.

#### Material and Methods

Ten consecutive patients affected by high grade glioma were treated by conformal radiotherapy with multiple non-coplanar 6 MV photon beams from a linear accelerator with a total dose of 60 Gy in 30 daily fractions of 2 Gy. Two different time-points were planned for MRI execution (before starting RT and one month after RT). Each MRI study included, beside the DTI, three-dimensional T1-weighted gradient-echo sequence (MPRAGE) before and after i.v. injection of contrast medium, as well as FLAIR and TSE-T2W images in the axial plane. The MPRAGE and the TSE-T2W images were co-registered with the  $b_0$  image and were used for the delineation of the area of parenchymal distortion (deformed area, DA). The DA included the surgical cavity and/or the area of contrast enhancement and/or the area of abnormal signal on TSE-T2W images. Deterministic fiber tracking across the whole WM was then performed using the fiber assignment continuous tracking algorithm. Fractional anisotropy (FA), radial diffusivity (RD) and axial diffusivity (AD) maps were generated. A ROI-based approach was used to select the fiber tracts. All fiber tracts passing through the DA were excluded though belonging to one of the three structures considered. The fiber tracts were converted in DICOM-RT format. The MPRAGE sequences without contrast medium were used as reference images for the co-registration with the corresponding planning CT-scan. The RT structure-set files were transferred from the MRI-space into the planning CT-space using the resulting co-registration matrix. Superimposing the dose map from each patient, the dosimetric evaluation was performed. The detailed scheme of our framework is reported in Figure 1.

VHI had a higher sensitivity for dose inhomogeneities and outperformed traditional indices. Underdosage of WBRT treatment plans as determined by the VHI was associated with decreased overall survival.

#### PO-0642 Influence of Introduction of VMAT and FET-PET on Treatment Outcomes for Glioblastoma Patients

P. Munck af Rosenschöld<sup>1</sup>, I. Law<sup>2</sup>, S. Engelholm<sup>1</sup>, A. Muhic<sup>1</sup>, M. Lundemann<sup>1</sup>, H. Roed<sup>1</sup>, K. Grunnet<sup>1</sup>, H. Poulsen<sup>1</sup>

<sup>1</sup>Rigshospitalet, Department of Oncology, Copenhagen, Denmark

<sup>2</sup>Rigshospitalet, Department of Nuclear Medicine, Copenhagen, Denmark

#### Purpose or Objective

We sought to assess the influence of the clinical introduction of new radiation therapy technologies on the outcome for glioblastoma patients.

#### Material and Methods

Newly diagnosed glioblastoma patients receiving 60 Gy with concomitant and adjuvant temozolomide in the period 2005-2014 were analyzed. Gross tumor volume (GTV) and a clinical target volume by addition of up to 2 cm margin were defined based on MRI. A subset of patients had a biological target volume (BTv) defined based on amino-acid <sup>18</sup>F-FET-PET scanning. The patients' target volumes were treated using conformal radiation therapy (CRT, N=159) or volumetric modulated arc therapy (VMAT) with hippocampal sparing and daily image-guided radiation therapy (IGRT) (N=322). Progression-free survival (PFS) was assessed using the McDonald criteria. Associations between MGMT status, age at RT, performance status, use of steroids, GTV size, BTv size, tumor dose conformity (GTV D95%), mean brainstem dose, mean brain dose, mean hippocampal dose, as well as use of FET-PET and VMAT, for PFS and overall survival (OS) were explored.

#### Results

A total of 521 patients were evaluable, of which 190 patients had FET-PET scanning data. Two patient cases are presented in Fig.1. Average brain dose was lower for patients treated with VMAT compared to CRT (p<0.001, Mann-Whitney). The Kaplan-Meier estimate of PFS (7 months) and OS (15 months) was unaffected by CRT, VMAT and FET-PET technology. Univariate and multivariate Cox regression models for OS are presented in Table 1. Multivariate Cox regression models revealed association of higher mean brainstem dose (p<0.001), BTv (p=0.045), steroid use at baseline (p=0.003), age (p=0.019) and MGMT status (p=0.022) with lower OS. Multivariate Cox models revealed association with increased average brain dose and lower PFS (p<0.001).

#### Conclusion

VMAT and IGRT technology treated patients had lower doses to the brain and hippocampi, which may reduce toxicity and preserve cognition. A combination of clinical, imaging and radiation dosimetry metrics provided the best prognostic model for OS. Reducing the mean brain dose for glioblastoma patients could potentially improve PFS and OS.

#### PO-0643 Scalp-sparing radiotherapy to minimize alopecia in patients with primary brain cancer

S. Scoccianti<sup>1</sup>, G. Simontacchi<sup>1</sup>, C. Talamonti<sup>2</sup>, L. Marrazzo<sup>2</sup>, G.A. Carta<sup>1</sup>, L. Visani<sup>1</sup>, M. Baki<sup>1</sup>, L. Poggesi<sup>1</sup>, D. Greto<sup>1</sup>, B. Detti<sup>1</sup>, P. Bonomo<sup>1</sup>, M. Loi<sup>1</sup>, S. Pallotta<sup>2</sup>, L. Livi<sup>1</sup>

<sup>1</sup>Azienda Ospedaliera Universitaria Careggi, Radiotherapy Unit, Florence, Italy

<sup>2</sup>Azienda Ospedaliera Universitaria Careggi, Medical Physics Unit, Florence, Italy

#### Purpose or Objective

Radiotherapy may induce transient or permanent hair loss with a significant psychological impact on patient's quality of life. Sparing the scalp during focal cranial RT for primary brain cancer is a challenging issue because the scalp is often adjacent to the target and because clear constraints for this structure are not available in the literature. Herein, we report ad-interim results of a prospective clinical study using a scalp sparing technique in primary brain cancer.

#### Material and Methods

Patients treated with focal radiotherapy for primary brain cancer were included. Factors that may have an impact on alopecia (age, cigarette smoking, use of levetiracetam and chemotherapy) were registered. During the simulation CT a wire was used to indicate the hairline of the patient (figure 1). During the contouring process, the scalp volume was defined as a ring region of interest including the tissue between the skin and the skull. For the inverse planning, primary constraint for the scalp was Dmax≤16 Gy, secondary constraint was Dmax≤25 Gy, tertiary constraint was Dmax≤35 Gy. VMAT plans were generated for a prescription dose of 50-60 Gy in 2-Gy daily fractions.

Clinical evaluation was provided at the end of the radiation treatment for assessing the transient alopecia and every 6 months to evaluate the permanent hair loss. During each clinical follow-up evaluation, the patient was asked to wear the thermoplastic mask used during the treatment in order to define with a wire the area of alopecia (figure 2 and 3). Then, a CT scan was performed to the mask and these images are coregistered to the simulation CT to obtain a dosimetric evaluation in the areas of alopecia (figure 4). Alopecia was assessed according to CTCAE version 4.0.

#### Results

Meeting the constraints that we had set for the scalp was not always feasible for cortical and subcortical targets. Dose to the scalp was always minimized as much as possible. A total of sixty patients were enrolled. 46 patients were available for the evaluation of acute alopecia. Three out of 46 had no alopecia; G1 and G2 alopecia occurred in 7 and 36 patients, respectively. The risk of acute alopecia was proportional to the dose received by the scalp

Dose to the scalp	10 Gy	16 Gy	20 Gy	25 Gy	30 Gy	35 Gy
Risk of alopecia	7-31%	45-49%	47-65%	53-74%	55-77%	62-80%

14 patients performed the first trichological follow-up at 6 months: twelve out of 14 (85.7%) completely recovered their alopecia (4 had G1 alopecia, whereas 10 had G2 alopecia when they finished RT).

#### Conclusion

Our preliminary results show that risk of acute alopecia is proportional to the dose received by the scalp. Minimizing the dose to the scalp seems to lead a high probability of alopecia recovery after 6 months. These results need to be confirmed with the long-term follow up of all the enrolled patients. Study of the dose distribution in the areas of alopecia will be the base for the definition of reliable constraints both for transient and permanent alopecia

#### PO-0644 Overall survival following stereotactic radiosurgery (SRS) for breast cancer brain metastases

H. Patel<sup>1</sup>, S. All<sup>2</sup>, A. Keller<sup>2</sup>, B. Dumas<sup>2</sup>, C. Sherrill<sup>2</sup>, M. Mejia<sup>2</sup>, N. Ramakrishna<sup>3</sup>

<sup>1</sup>University of Central Florida College of Medicine,

Medical Student, Orlando, USA

<sup>2</sup>University of Central Florida, College of Medicine, Orlando, USA

<sup>3</sup>UF Health Cancer Center-Orlando Health, Radiation Oncology, Orlando, USA

### Purpose or Objective

We examined the impact of patient and tumor-specific factors on overall survival in patients with brain metastases from breast cancer treated with stereotactic radiosurgery.

### Material and Methods

We performed an IRB-approved retrospective analysis of patients treated at our institution with LINAC-based, image-guided, frameless stereotactic radiosurgery for brain metastases from breast cancer between November 2008 and July 2016. We identified 184 metastatic brain lesions treated in 52 breast cancer patients. Out of the 184 treated brain metastases, 174 had at least one follow up study. Patients were followed with serial brain MRIs with contrast to assess for local progression and recurrence every 2-3 months. Patient characteristics collected included extracranial disease status, Karnofsky performance status (KPS), tumor histology, history of whole brain radiation therapy (WBRT), history of IMRT, history of craniotomy, date of death or last clinical contact, and age at initial SRS treatment. Treatment characteristics evaluated included tumor volume, number of tumors, prescription dose, prescription isodose, and maximum dose. Actuarial patient survival was defined as the time in months from initial SRS treatment to date of death or date of last clinical contact. The overall survival was calculated from date of first SRS treatment session to date of death or progression via the Kaplan-Meier method.

### Results

At the time of initial treatment, 21% of patients were categorized as RPA class I, 69% as RPA class II, and 10% as RPA class III. The median survival was 59.0 months for RPA class I, 14.1 months for RPA class II, and 9.4 months for RPA class III. The median overall survival was 15.0 months. The Kaplan-Meier overall survival estimates at 6 and 12 months were 80.1% and 57.5%, respectively, from the time of initial SRS treatment. The median survival for patients with active extracranial disease was 9.36 months, compared to 59.0 months for patients with inactive extracranial disease (p-value = 0.012). Other factors examined including age, KPS, tumor histology (ductal vs. lobular vs. unknown), ER, PR and Her 2-Neu status, did not have a statistically significant impact on survival.

### Conclusion

Breast cancer patients with brain metastases display a broad range of survival outcomes following SRS, with RPA class I having a median survival of 59 months in our dataset. Those with inactive extracranial disease in our group had the best prognosis following SRS. There was no effect on post-SRS survival based on age, KPS score, pre-SRS WBRT, concurrent WBRT, tumor histology, ER, PR, and Her 2-Neu expression status. These data support the use of SRS in a broad range of breast cancer patients and further reveal no improvement in survival for patients receiving WBRT during their brain metastasis treatment.

**PO-0645** The patterns of the relapses of aggressive non-hodgkin lymphomas after chemoradiotherapy  
V. Sotnikov<sup>1</sup>, G.A. Panshin<sup>1</sup>, N.V. Nudnov<sup>1</sup>, V.A. Solodkiy<sup>1</sup>  
<sup>1</sup>Russian Scientific Center of Roentgenoradiology, Radiation therapy, Moscow, Russian Federation

### Purpose or Objective

Purpose: To study the number and the patterns of the aggressive non-hodgkins lymphomas relapses after

chemoradiotherapy in the subgroups of the patients with different demographic and disease characteristic as well as the different short term results of the chemotherapy and the chemoradiotherapy in its entirety.

### Material and Methods

Material/methods: The study included 676 previously untreated patients with morphologically proven aggressive NHL who received combined modality therapy. The characteristic of the patients: male - 319 (47,2%), female - 357 (52,8%). Age 15 - 86 years (median age 45 years). International prognostic index (IPI) 0-1 (favourable) - 314 (46,4%), 2-3 (intermediate) - 297 (43,9%), IPI 4-5 (unfavourable) - 65 (9,6%); stage I-II - 409 (60,5%), stage III-IV - 267 (39,5%). All patients received initially 6-8 cycles of CHOP or CHOP-like regimens ± Rytuximab and complete remission (CR) or partial remission (PR) was achieved in all of them. Then the radiation therapy was performed. All sites of initial involvement were irradiated in local stages, patients with advanced stages get radiation therapy on PET(+) lesions, partially regressed tumors, sites of initial bulky tumors. Daily doses were 1,8-2Gy, summary doses 30-50Gp. Relapses in the sites of initial involvement were classified as local (true), in initially uninvolved sites - as distant. Mixed relapses (local and distant) were counted in both groups. After completion of the treatment patients were followed up during 1,17-30 years, mean - 5,2±0,2 years, median - 3,1 years.

### Results

Results: The results of the study are presented in the table.

Table 1. Relapses in the different groups of patients with aggressive non-hodgkin lymphoma after chemoradiation therapy

Groups	Number of the patients	Relapses		
		All	Local (true)	Distant
All patients	676	29,9±1,8%	10,2±1,2%	24,8±1,7%
Age <60 years	535	30,3±2,0%	10,1±1,3%	25,8±1,9%
Age>59 years	141	28,4±3,7%	10,6±2,6%	21,3±3,3%
Stage I-II	409	25,4±2,2%*	6,1±1,2%#	22,7±2,1%
Stage III-IV	267	36,7±2,9%* p=0,01	16,5±2,3%# p=0,001	28,0±2,7%

St.III-IV, PR after CT, PR after RT	73	60,2±5,7%* p=0,001	28,7±5,3%* p=0,02	47,9±5,8%# p=0,002

### Conclusion

Conclusion: The probability of relapse of aggressive non-hodgkin lymphoma after chemoradiation therapy is about 30%, but local relapse - only 10%. The probabilities and patterns of the relapses are the same in the young and aged patients. The local and advanced stages have statistically proven differences in the probabilities of all relapses and local relapses (+10%), but the risk of the distant relapse is very close in this groups. Patients from favourable prognostic group (IPI 0-1) have the minimal risk of the relapse, both local and distant in comparison with other IPI prognostic groups. Extranodal lymphomas differ favourably from nodal lymphomas: after chemoradiation therapy the relapses are less common in this group, to the greatest extent - the local relapses (p=0,04). The immediate effect of chemotherapy significantly affects the absolute risk of all relapses and the risk of distant relapse, but only the response to radiotherapy determines the probability of local relapse. At the same time, the partial remission due to the partial regression of the lesion after irradiation) is an additional poor prognostic factor for all relapses and for distant relapses. These

effects persist after the separate analysis of the local and advanced stages.

**PO-0646 Nodular Lymphocyte Predominant Hodgkin's Lymphoma (NLPHL): Early Outcomes**

<sup>2</sup>Tata Memorial Hospital, MEDICAL ONCOLOGY, Mumbai, India

<sup>3</sup>Tata Memorial Hospital, PATHOLOGY, Mumbai, India

<sup>4</sup>Tata Memorial Hospital, NUCLEAR MEDICINE, Mumbai, India

**Purpose or Objective**

To evaluate treatment response, patterns of failure and prognostic factors for patients with NLPHL treated at the Tata Memorial Hospital (TMH).

**Material and Methods**

Between January 2007 & July 2013, 61 patients with histologically proven NLPHL in the age group of 6-70yrs (Median 30.5Yrs) were treated at TMH. Forty four (72%) were males. Majority had Stage I [29 patients (47%)] & Stage II [15 patients (25%)] disease. Fifteen (25%) had bulky disease at presentation. Sixteen (26%) were treated with Involved Field Radiation Therapy (IFRT) alone, 18 (30%) received Chemotherapy (CTh) alone, while 23 (38%) received a combination of CTh followed by IFRT. Four patients underwent surgery as the local treatment. The IFRT doses were in the range of 20-36 Gy. Thirty five (80%) patients received ABVD CTh. Five (8%) patients received Rituximab. Primary MINE CTh was used for 4 (6%) patients.

**Results**

After a mean and median follow-up of 43 and 41 months, the 5 year disease free survival (DFS) and overall survival (OS) were 65% and 93% respectively. Complete response (CR) at completion of primary treatment was 92%. At last follow up 46 (75%) were alive without disease. Two (3%) patients had residual disease, three (5%) patients each had in-field, out of field relapse. Five (8%) had disseminated relapse and one (2%) patient each had transformation to DLBCL and second primary disease (carcinoma tongue). Ten (66%) out of 15 patients with disease relapse received salvage treatment (3 IFRT, 3 CTh, 1 both), of which 7 were disease free at last follow up. Two patients have been planned for autologous stem cell transplantation. On univariate analysis, early stage (75% Vs 27%, p=0.07), absence of B symptoms (67% Vs 57%, p=0.08) and use of IFRT (69% Vs 60%, p=0.38) resulted in superior DFS. For patients with early stage disease (stage I and II), there was no difference in DFS between patients receiving IFRT alone (87%) and CTh + IFRT (80%), however DFS was inferior for patients who received only chemotherapy (55%). All patients tolerated treatment well without any grade III or IV toxicities.

**Conclusion**

NLPHL is associated with excellent overall survival. For patients with early stage disease, IFRT alone results in similar outcomes compared to CTh+IFRT. Early Stage at presentation, absence of B symptoms and the use of IFRT confers superior outcome.

**PO-0647 Factors associated with pulmonary toxicity after conditioning with total body irradiation**

H.K. Byun<sup>1</sup>, H.I. Yoon<sup>1</sup>, H.J. Kim<sup>1</sup>, J. Cho<sup>1</sup>, C.O. Suh<sup>1</sup>  
*Yonsei Cancer Center, Radiation oncology, Seoul, Korea Republic of*

**Purpose or Objective**

To evaluate clinical and therapeutic factors associated with pulmonary toxicity and related to survival outcome after myeloablative conditioning using fractionated total

body irradiation (TBI), followed by allogenic stem cell transplantation (allo SCT).

**Material and Methods**

A total of 58 patients with 43 ALL, 8 AML, and 7 others (1 neuroblastoma, 1 ewing sarcoma, 3 lymphoma, 2 aplastic anemia) who underwent fractionated TBI-based myeloablative conditioning and allo SCT between January 2005 and December 2014 were reviewed retrospectively. Total doses of TBI ranged from 8 Gy to 12 Gy, although most of the patients (91 %) received 12 Gy in 1.5 Gy b.i.d. fractions delivered using a dose rate of 7 to 19 cGy/minute. Patients with clinical symptoms were considered having pulmonary toxicity only if they have radiologic evidence or reduced pulmonary function and were furtherly subdivided based on presence or absence of concurrent infection detected through mediums such as blood or bronchoalveolar lavage. The relationship between the pulmonary toxicity and clinical factors were investigated using univariate and multivariate analysis. In addition, we also performed each survival analysis for treatment-related mortality (TRM) and overall survival (OS) rates.

**Results**

Overall pulmonary toxicities developed in 36 (62%) patients, of which 16 (28%) were proven to have a concurrent infection, and no pathogens were seen in 20 (35%). Median time to onset of pulmonary toxicity from transplantation was 6 months (range 1-31) in patients with infectious pneumonia and 7 months (range 0-26) in patients with the idiopathic pneumonia syndrome (IPS). The leading etiology of infectious pneumonia was bacteria (75%), followed by fungus (37.5%) and virus (12.5%). On univariate analysis, conditioning chemotherapy regimen (p=0.028) was significantly related to infectious pneumonia, while donor type (p=0.021) and transplanted cell type (0.031) was significantly associated with IPS. On multivariate analysis, only the donor type (matched unrelated vs. matched sibling, p=0.021, HR 12.67, 95% CI 1.46-110.30) was an independent factor related to the IPS. Conditioning chemotherapy regimen showed a trend towards significance for the development of infectious pneumonia. Other clinical factors did not have significant impacts on the development of infectious pneumonia or IPS. On survival analysis, patients with infectious pneumonia showed significantly higher rates of TRM (p=0.026) and lower OS rates (p=0.039), whereas patient with IPS did not affect the rates of TRM or OS.

**Conclusion**

Our findings demonstrate that donor type, transplanted cell type and conditioning chemotherapy regimen may have an effect on post-transplant pulmonary toxicity combined with fractionated TBI. Clinicians should consider those clinical factors besides radiation-related factors in deciding on a treatment strategy for individual patients.

**PO-0648 Is age >60 unfavorable prognostic factor in early stage upper aerodigestive tract NK/T-cell lymphoma?**

B. Chen<sup>1</sup>, Y. Li<sup>1</sup>, W. Wang<sup>1</sup>, J. Jin<sup>1</sup>, S. Wang<sup>1</sup>, Y. Liu<sup>1</sup>, Y. Song<sup>1</sup>, H. Fang<sup>1</sup>, H. Ren<sup>1</sup>, S. Qi<sup>1</sup>, Y. Tang<sup>1</sup>, X. Liu<sup>1</sup>, Z. Yu<sup>1</sup>  
*National Cancer Center / Cancer Hospital- Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Radiation Oncology, Beijing, China*

**Purpose or Objective**

The purpose of this study was to determine the survival and prognosis of patients with age>60 in early stage upper aerodigestive tract NK/T-cell lymphoma (UADT-NKTCL), and to estimate whether patients with age>60 have lower survivals than with age<60.

**Material and Methods**

Between December 1979 and December 2014, 544 patients with Stage IE and IIE UADT-NKTCL were treated. Of them, there were 58 patients with age>60. Radiotherapy was the

primary treatment for most of patients. Of those older patients, 37 patients were treated with radiotherapy alone, 17 patients with radiotherapy combined with chemotherapy, 3 patients with chemotherapy alone and one patient with anti-inflammation therapy. Survivals were estimated using the Kaplan-Meier method. Propensity Score Matching (PSM) was applied for 544 patients with ratio 1:2, and covariates included sex, B symptoms, lactate dehydrogenase (LDH), ECOG Performance Status, primary location, Ann Arbor stage and primary tumor invasion. 116 patients with age $\leq$ 60 were eventually matched by PSM.

#### Results

Median follow-up time was 39 months (range, 2-174 months) for 58 older patients and 30 months (range, 1-435 months) for 116 matched patients. Well-balanced pairs of different covariates were established by PSM ( $p < 0.05$ ). After matching, overall survival (OS), cancer-specific survival (CSS), progressive free survival (PFS) and local-regional control (LRC) were no significant difference between patients with age $>$ 60 and with age $\leq$ 60. 5-year OS were 61.4% and 68.9% ( $p = 0.326$ ), 5-year CSS were 69.1% and 71.4% ( $p = 0.902$ ), 5-year PFS were 61.3% and 63.9% ( $p = 0.594$ ), and 5-year LRC were 87.2% and 88.1% ( $p = 0.628$ ), respectively.

#### Conclusion

Older patients with early stage UADT-NKTCL have good prognosis after radiotherapy is the primary treatment. Age $>$ 60 is not unfavorable prognostic factor for early stage UADT-NKTCL. The patients with age $>$ 60 have similar survivals with the patients with age $\leq$ 60.

#### PO-0649 Locoregional Treatment of the Primary Tumor Shows Survival Benefit in De Novo Stage IV Breast Cancer

S.H. Choi<sup>1</sup>, W.J. Rhee<sup>1</sup>, J.W. Kim<sup>1</sup>, C.O. Suh<sup>1</sup>, K.C. Keum<sup>1</sup>, Y.B. Kim<sup>1</sup>, I.J. Lee<sup>1</sup>

<sup>1</sup>Yonsei University, Radiation Oncology, SEOUL, Korea Republic of

#### Purpose or Objective

Although systemic therapy is a mainstay of treatment for metastatic breast cancer, the role of locoregional treatment (LRT) of the primary tumor for an overall survival advantage is still unclear. The aim of this study was to assess the clinical outcomes of patients with de novo stage IV breast cancer after undergoing LRT of the primary site.

#### Material and Methods

From January 2006 to November 2013, a total of 245 patients diagnosed with *de novo* stage IV breast cancer at Yonsei University Health System were included. Among them, LRT of primary tumor (+ systemic therapy) was performed in 86 patients (35%) (Surgery only :  $n = 28$ , surgery + radiotherapy (RT) :  $n = 47$ , RT only :  $n = 11$ ). The remaining 155 patients (63%) received systemic therapies (chemotherapy and/or hormone therapy), while 4 patients (2%) received no treatment. For surgery type, 87% ( $n = 66$ ) received mastectomy, and 12% ( $n = 9$ ) received breast-conserving surgery (BCS). Local recurrence-free survival (LRFS) and overall survival (OS) were investigated, and propensity score matching method was used to balance groups.

#### Results

The median follow-up duration was 40 months (Range, 13 days to 124 months). The 5-year LRFS and OS rates were 27% and 50%, respectively. Total of 188 patients (77%) experienced recurrence, while local recurrence rate was 45% (LRT group 12% vs. no LRT group 47%,  $p < 0.001$ ) and systemic recurrence rate was 95% (LRT group 69% vs. no LRT group 76%,  $p = 0.248$ ). Advanced T stage (T4), liver or

brain metastasis,  $\geq 5$  metastatic sites, no hormone therapy, and LRT(-) were considered significant adverse factors for LRFS, while T4 stage, no hormone therapy, and LRT(-) were considered significant for OS. LRT group demonstrated favorable outcome (5-year LRFS: 55% and 5-year OS: 71%), especially when surgery was performed. Even after matching the baseline characteristics, survival rates were still significantly higher in LRT group than no LRT group (5-year LRFS 55% vs. 22%,  $p < 0.001$ , 5-year OS 71% vs. 43%,  $p < 0.001$ ). Furthermore, LRT (especially surgery) was an important good prognostic factor in patients with  $< T4$  stage tumors, no liver or brain metastasis, and  $< 5$  metastatic sites in subgroup analysis. For the type of surgery, BCS + RT was not inferior to other LRTs, although more patients with early stage tumors or  $\leq 2$  sites, without lung/liver/distant lymph node metastasis, were included. For the role of post-mastectomy RT, treatment results were higher (5-year LRFS 61% vs. 50%, OS 74% vs. 68%) with RT in selected T/N stage ( $\geq N2$ ,  $\geq T3$ , or T2N1) of patients.

#### Conclusion

LRT including RT, together with systemic therapies, is an important option in selected *de novo* stage IV breast cancer patients, especially when the burden of the tumor is low. Furthermore, BCS + RT would be a possible substitute for mastectomy without compromising oncologic outcome in early stage metastatic breast cancer. Post-mastectomy RT should be re-evaluated in light of the advances in systemic therapy, with improving survival in stage IV disease.

#### PO-0650 Omitting radiotherapy in triple-negative breast cancer leads to worse cancer-specific survival

I. Kindts<sup>1,2</sup>, P. Buelens<sup>1,2</sup>, A. Laenen<sup>3</sup>, E. Van Limbergen<sup>1,2</sup>, H. Janssen<sup>1,2</sup>, H. Wildiers<sup>2,4</sup>, C. Weltens<sup>1,2</sup>

<sup>1</sup>University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium

<sup>2</sup>KU Leuven - University of Leuven, Department of Oncology, Leuven, Belgium

<sup>3</sup>KU Leuven - University of Leuven, Leuven Biostatistics and Statistical Bioinformatics Centre L-Biostat, Leuven, Belgium

<sup>4</sup>University Hospitals Leuven, Department of General Medical Oncology, Leuven, Belgium

#### Purpose or Objective

To examine the risk of locoregional recurrence (LRR) and breast cancer-specific survival (BCSS) in triple-negative breast cancer (TNBC) patients after breast conserving therapy (BCT) or mastectomy (ME) with or without radiotherapy (RT).

#### Material and Methods

We retrospectively identified cases with newly diagnosed non-metastatic TNBC between 2000 and 2010 from a prospectively collected single institution database. Patients were excluded in case of no local surgery, no adjuvant RT after breast conserving surgery or in case neoadjuvant chemotherapy was administered. LRR was defined as local and/or regional (axillar, parasternal or supraclavicular region) recurrence. BCSS was defined as death from breast cancer. Patients treated with BCT, ME with RT (ME+RT) and ME only were compared with respect to LRR and BCSS. Cox regression models were used to analyze the association between prognostic factors and outcome.

#### Results

439 patients fulfilled the inclusion criteria. Median follow-up was 10.2 years. Patients in the BCT ( $n = 239$ ), ME+RT ( $n = 116$ ) and ME only ( $n = 84$ ) group differed with respect to age, pT, pN, lymphovascular invasion, lymph node dissection and the administration of chemotherapy. Ten-year LRR rates were 7%, 3% and 8% for the BCT, ME+RT and ME only group, respectively. Patients with a higher pN stage were at higher risk for LRR (HR 1.81,  $p < 0.001$ ). There was a trend towards more LRR in tumors

with lymphovascular invasion. LRR was compared for the three groups in multivariable analysis with correction of pN stage. Patients in the BCT and the ME only group showed a significant higher risk for LRR compared to the ME+RT group (HR 3.29, p 0.037 and HR 4.45, p 0.020 respectively).

Ten year BCSS was 87 %, 84 % and 75 % for the BCT, ME+RT and ME only group, respectively. BC-specific mortality increased with higher pT and pN stages (HR 1.59, p 0.006 and HR 1.82, p < 0.0001, respectively). Patients with an axillary lymph node dissection (HR 2.81, p 0.016) and with lymphovascular invasion (HR 1.72, p 0.053) had lower BCSS. Adjuvant chemotherapy administration was a protective factor for BC-specific mortality (HR 0.58, p 0.024). Multivariable analysis was conducted to assess differences between the three groups with correction for pT, pN, lymphovascular invasion, lymph node dissection and adjuvant chemotherapy. Patients in the ME only group had significant lower BCSS compared to the BCT and the ME+RT group (HR 1.84, p 0.047 and HR 2.88, p 0.003, respectively). No significant differences were observed for the comparison of BCT versus ME+RT. BCSS curves for the three groups as estimated from the multivariable model are presented in figure 1.

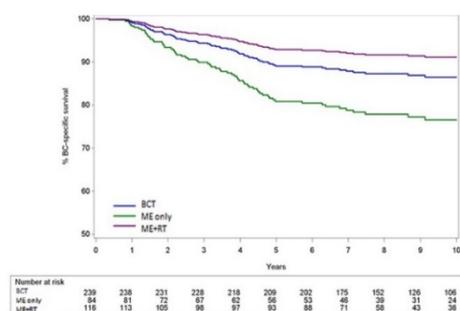

Figure 1: BCSS curves for the three groups as estimated from the multivariable model (with correction for pT, pN, lymphovascular invasion, lymph node dissection and adjuvant chemotherapy). The figure presents the estimated curves for patients with pT2, pN0, no lymphovascular invasion, with adjuvant chemotherapy, without sentinel and with axillary lymph node dissection.

### Conclusion

TNBC patients treated with ME without adjuvant RT showed significant lower BCSS compared to patients treated with BCT or ME+RT and significant more LRR compared to ME+RT when corrected for known clinicopathological prognostic factors.

### PO-0651 Five year outcome and soft tissue toxicity of breast cancer hypofractionated adjuvant radiotherapy

F. Zerbetto<sup>1</sup>, A. Fodor<sup>1</sup>, C. Sini<sup>2</sup>, P. Mangili<sup>2</sup>, M. Pasetti<sup>1</sup>, P. Signorotto<sup>2</sup>, C. Fiorino<sup>1</sup>, I. Dell'Oca<sup>1</sup>, A. Chiara<sup>1</sup>, A.M. Deli<sup>1</sup>, N. Slim<sup>1</sup>, B. Noris Chiorda<sup>1</sup>, C.L. Deantoni<sup>1</sup>, C. Gumina<sup>1</sup>, M. Azizi<sup>1</sup>, G. Rossi<sup>1</sup>, S. Foti<sup>1</sup>, P. Passoni<sup>1</sup>, A. Bolognesi<sup>1</sup>, N.G. Di Muzio<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Department of Radiotherapy, Milano, Italy

<sup>2</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy

### Purpose or Objective

To report the local control and soft tissues toxicity, in breast cancer patients (pts) treated with hypofractionated adjuvant radiotherapy (HRT), 40 Gy in 15 fractions (2,67 Gy/fraction), after breast conservative surgery (BCS), with a 5-years median follow-up.

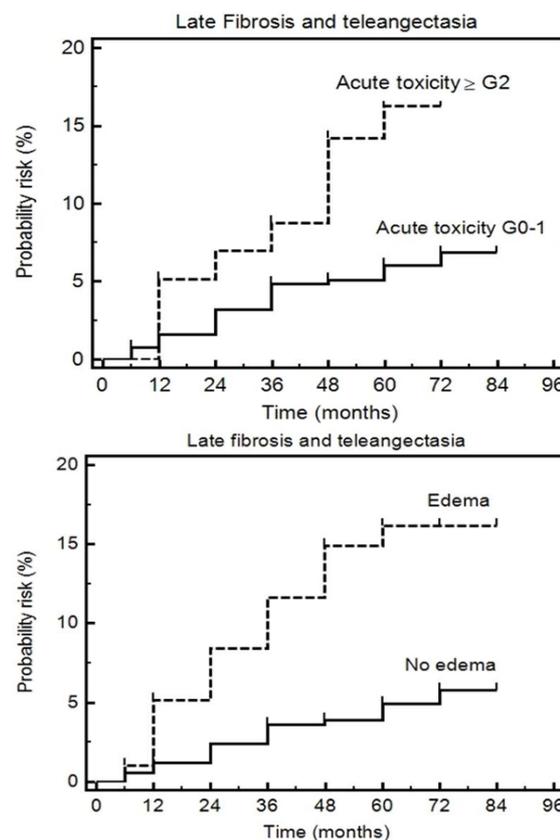

### Material and Methods

From February 2009 and October 2011, 442 pts were treated with HRT after BCS. Local tumor relapse was defined as recurrence of cancer at irradiated breast. The acute toxicity was evaluated during RT treatment by RTOG scale. Late side effects as edema, fibrosis, hyperpigmentation and telangiectasia, were individually assessed, using SOMA-LENT score, at 6 months from the

end of radiotherapy and then every year. The association between possible risk factors and development of early and late complications was identified using multivariate logistic regression analysis.

### Results

After a median follow-up of 65,4 (12-84,8) mos the rate of local failure at 5 years was 2,25%. RTOG acute toxicity was: G0 in 164 pts (37%), G1 in 220 pts (49,8%), G2 in 53 pts (12%) and G3 in 5 pts (1,2%). In 9 pts a delayed toxicity  $\geq$ G2 was detected at 1-3 weeks after the end of radiotherapy. We observed a strong correlation between acute toxicity  $\geq$ G2 and breast volume (p=0,0001), with best cut-off 866 cc derived from ROC analysis. Another important correlation was found with chemotherapy (p=0,003), particularly if concomitant (p=0,017). 99 pts (22,5%) showed edema and/or hyperpigmentation at 6 months after treatment and then the rate decreased over time until disappear, without new events. On the contrary, the rate of pts who presented fibrosis and telangiectasia was neglectable at 6 months (0,68%) but increased over time to become 6.5% at 5 years. The use of build up bolus in more than 7 fractions (p=0,0003), breast volume (p=0,0006), age<56 years (p=0,021), and previous axillary dissection (p=0,0004) were the most important predictable factors for edema and hyperpigmentation, while the development of fibrosis and telangiectasia was correlated with acute toxicity (p=0,0115) (Fig. I) and the presence of edema at 6 months (p=0,0006) (Fig II).

### Conclusion

In our experience HRT is a safe treatment with high rate of 5 year local control, as reported in literature, and low toxicity. The predicting factors of toxicity emerged from our analysis could help to better manage the breast HRT in terms of cosmetic result.

### PO-0652 Risk factors for complications of post-mastectomy radiotherapy on implant-based reconstructed breast

M. Ogita<sup>1,2</sup>, J. Kawamori<sup>2</sup>, K. Sekiguchi<sup>3</sup>, N. Nagura<sup>4</sup>, R. In<sup>4</sup>, A. Yoshida<sup>4</sup>, H. Yamauchi<sup>4</sup>, Y. Iwahira<sup>5</sup>

<sup>1</sup>University of Tokyo Hospital, Radiology, Tokyo, Japan

<sup>2</sup>St. Luke's International Hospital, Radiation Oncology, Tokyo, Japan

<sup>3</sup>Sonoda-kai Radiation Oncology Clinic, Radiation Oncology, Tokyo, Japan

<sup>4</sup>St. Luke's International Hospital, Breast Surgery, Tokyo, Japan

<sup>5</sup>Breast Surgery Clinic, Plastic Surgery, Tokyo, Japan

#### Purpose or Objective

The use of post-mastectomy radiotherapy (PMRT) following immediate breast reconstruction has increased recently. However, its safety has not been well established. We aimed to evaluate the complication rates of PMRT to immediate tissue expander/permanent implant (TE/PI)-based reconstructions for breast cancer and its association with radiotherapy timing.

#### Material and Methods

From Jan 2003 to Dec 2014, breast cancer patients who underwent mastectomy, immediate TE/PI reconstruction and PMRT were retrospectively reviewed. The reconstructed breast and supraclavicular region were treated to a total dose of 50Gy in 25 fractions in most cases. Patients were divided into two radiotherapy timing groups, according to whether they received PMRT to a TE or a PI, to assess the effect of radiotherapy timing on complications. The rates of complications including reconstruction failure (RF), re-operation (unplanned removal or exchange of the TE/PI) and infection were estimated by Kaplan-Meier analysis. The risk factors including radiotherapy timing were analyzed by log-rank test and multivariate Cox proportional hazard model.

#### Results

A total of 81 patients were included. Of these, 32 patients (40%) received PMRT to the TE, and 49 patients (60%) received PMRT to the PI. Median age of patients was 44 years (range, 29-64). Median follow-up was 32 months (range, 2-120). Total RF, re-operation, and infection rates were 12.3% (10/81), 13.6% (11/81), and 11.1% (9/81), and 5-year cumulative RF, re-operation, and infection rates were 16.7%, 16.6%, and 12.2%, respectively. The median duration between PMRT and RF, re-operation and infection were 452 days (range, 14-1120), 474 days (range, 14-825) and 223 days (range, 9-654), respectively. No significant differences were observed in rates of RF, re-operation and infection with respect to radiotherapy timing ( $P = 0.54, 0.73, 0.31$ , respectively). In univariate analysis, age  $\geq 55$  years was a significant factor for re-operation ( $P = 0.009$ ) and infection ( $P = 0.046$ ). In multivariate analysis, age 55 years and older was statistically significant for re-operation ( $P = 0.02$ , HR (95% CI): 4.64 (1.27-16.9)) and infection ( $P = 0.04$ , HR (95% CI): 4.6 (1.08-19.5)).

#### Conclusion

The overall RF rate was 12.3%. There were no significant differences in rates of RF, re-operation, or infection with regard to radiotherapy timing. PMRT to reconstructed breasts of older patients aged 55 years or over can be expected to result in more complications than in younger patients.

#### PO-0653 A heart atlas for breast RT and the influence of delineation education on observer variability

M. Kirlı<sup>1</sup>, D. Akçay<sup>1</sup>, M.M. Barış<sup>2</sup>, I. Bilkay Görken<sup>1</sup>

<sup>1</sup>Dokuz Eylül Univ. Health Sciences Institute, RADIATION ONCOLOGY, IZMIR, Turkey

<sup>2</sup>Dokuz Eylül Univ. Health Sciences Institute, RADIOLOGY, IZMIR, Turkey

#### Purpose or Objective

We developed a heart atlas for cardiac structure delineation for breast RT and intended to evaluate the influence of counting education on contour accuracy and reduction of intra-inter observer variability and cardiac dose reporting.

#### Material and Methods

The data from 16 early left breast cancer patients who received RT with deep breath hold technique in our clinic was analyzed. Heart and cardiac substructures (left (LCA) and right (RCA) coronary arteries, LAD, bilateral atrium and ventricles) were delineated by eight radiation oncologists. Then a cardiac atlas was developed on CT by a cardiac radiologist and experienced radiation oncologist. The whole heart and subunits were delineated for each patient and considered as a gold standard (GS) for this trial. The delineation was repeated on the same patients by observers after the atlas education. Standard tangential fields for RT were created on GS volumes for each patient and dose calculations were repeated for pre/post-atlas contours. The similarity was assessed by using Dice (DSC) and Jaccard (JSC) similarity coefficient indexes. The absolute difference rate was calculated for dose reporting analysis. The pre/post atlas data analyzed using Wilcoxon Signed-Rank test.

#### Results

The inter-observer similarity was increased statistically significant (SS) after education except just for RCA ( $p < 0.05$ ). Also the similarity comparing observers with GS increased in heart and all subunits with education. The increase for both similarity index in left atrium, bilateral ventricles, LCA+LAD has been found SS ( $p < 0.05$ ). There wasn't a significant increase in heart contour similarity after training. We already obtained 94% of heart contour consistency, both pre-post atlas delineation which is higher than other studies in the literature. The intra-observer similarity showed a heterogeneous distribution but most of the observers made a delineation much more similar to GS. The absolute difference rate in dose reporting after using cardiac atlas was SS for bilateral atrium, right ventricle, LAD, LCA+LAD, RCA's maximum (max) doses and bilateral atrium, right ventricle, and RCA's mean doses ( $p < 0.05$ ). Although there was a SS increase for heart and left ventricle similarity rates by using cardiac atlas, it didn't affect the dose reporting consistency. The max dose reporting differences from the GS decreased from 16,97% to 9.31% for LAD ( $p = 0.011$ ); from 14,78% to 9.31% for LCA+LAD ( $p = 0.010$ ). The mean dose reporting differences from the GS decreased from 34,97% to 22,25% for LAD ( $p = 0.07$ ); from 32,36% to 24,47% for LCA+LAD ( $p = 0.056$ ). The atlas usage was found to contribute to a more consisting dose reporting also for max and mean doses of atriums and right ventricle despite being on the edge and/or outside of the RT fields ( $p < 0.05$ ).

#### Conclusion

Cardiac atlas education and using for delineation on heart and subunits reduce the intra-inter observer variability and improves dose reporting consistency for left breast RT.

#### PO-0654 Failure Patterns of Luminal B Breast Cancer Following Postoperative Adjuvant Radiation Therapy

N. Choi<sup>1</sup>, S.W. Lee<sup>1</sup>, Y. Lim<sup>1</sup>, K.Y. Eom<sup>1,2</sup>, E.Y. Kang<sup>2</sup>, E.K. Kim<sup>2</sup>, Y.J. Kim<sup>2</sup>, J.H. Kim<sup>2</sup>, S.Y. Park<sup>2</sup>, I.A. Kim<sup>1,2</sup>

<sup>1</sup>Seoul National University Hospital Bundang Hospital, Radiation Oncology, Seoul, Korea Republic of

<sup>2</sup>Seoul National University Hospital Bundang Hospital, Breast Care Center, Seoul, Korea Republic of

#### Purpose or Objective

The establishment of surrogate definitions for breast cancer molecular subtypes according to IHC has clinically demonstrated prognostic relevance for improved objective risk profiling and individualization of treatment regimens. Defining and stratifying luminal B subtypes, however, still remains indefinite and is in need of more distinct differentiation due to its heterogeneous clinical and molecular characteristics. This study aims to identify prognostic factors for early relapse in luminal B HER2-negative (LB<sub>HER2-}</sub>) and -positive (LB<sub>HER2+}</sub>) subgroups, and to

evaluate failure patterns between the latter and HER2-enriched breast cancer after adjuvant PORT.

#### Material and Methods

Medical records of 516 women diagnosed with luminal B or HER2-enriched breast cancer that underwent surgical resection and PORT at Seoul National University Bundang Hospital (SNUBH) from 2003 to 2012 were retrospectively reviewed. Based on available IHC and FISH results, molecular subtypes were defined according to the 2013 St. Gallen International Expert Consensus recommendation as  $LB_{HER2-}$  in 258 patients (50.5%),  $LB_{HER2+}$  in 136 patients (26.4%), and HER2-enriched in 122 patients (23.6%).

#### Results

Significant differences were observed between the luminal B subgroups, with  $LB_{HER2-}$  demonstrating higher proportions of patients with age younger than 50 years ( $p=0.012$ ), high histologic grade ( $p < 0.001$ ), and positive expression of p53 ( $p=0.007$ ). Patterns of care were also significantly different, with higher rates of systemic therapy omission in  $LB_{HER2-}$  patients ( $p=0.001$ ). After a median follow-up duration of 6.3 years, 10-year OS rates were 87.9% and 97.0% for  $LB_{HER2-}$  and  $LB_{HER2+}$ , respectively ( $p=0.062$ ). On multivariable Cox regression analysis, N stage in  $LB_{HER2-}$  and N stage and histologic grade in  $LB_{HER2+}$  were identified as independent prognostic factors for relapse within 5 years. When compared with HER2-enriched breast cancer,  $LB_{HER2-}$  expressed lower rates of local recurrence ( $p=0.046$ ) and brain metastasis ( $p=0.026$ ).

#### Conclusion

Luminal B breast cancer manifest various patterns of failure among which trends to poorer prognosis is seen in the  $LB_{HER2-}$  subgroup. The majority of  $LB_{HER2+}$  patients undergo some form of systemic treatment and demonstrate relatively better clinical outcomes than  $LB_{HER2-}$  patients. Further stratification of risk prediction, particularly in the  $LB_{HER2-}$  subgroup, and more aggressive systemic treatment are needed to improve treatment outcomes, of which p53 may be a potential marker.

#### PO-0655 Patterns of locoregional failure in women with breast cancer treated by Postmastectomy Radiotherapy

G. Loganadane<sup>1</sup>, Z. Xi<sup>1</sup>, N. Grellier Adedjouma<sup>1</sup>, H.P. Xu<sup>1</sup>, S. Krhili<sup>1</sup>, A. Chilles<sup>1</sup>, F. Campana<sup>1</sup>, A. Fourquet<sup>1</sup>, Y. Kirova<sup>1</sup>  
<sup>1</sup>Institut Curie, Radiation oncology, Paris, France

#### Purpose or Objective

At Institut Curie, PMERT (Postmastectomy Electron Beam Radiation Therapy) is the technique of choice to treat the chest wall for more than 30 years in women with breast cancer because it provides equivalent efficacy but decreases doses delivered to the organs at risk.

#### Material and Methods

From 964 patients with non-metastatic breast cancer treated with this technique between 2007 and 2011 at Institut Curie, data was available for 796 patients. With median follow-up of 64.1 months, locoregional relapse free survival at 5 years, metastases free survival at 5 years and overall survival at 5 years was 90% (IC95%: 88.1-92.4), 83.3% (IC 95% = [80,6 ; 86]) and 90.9% (IC95%: 88.9-93) respectively. Twenty three patients (2.9%) presented locoregional recurrences.

The purpose of this study was to analyze the tumor characteristics and the radiation volumes/doses that could have resulted in failures. Mapping patterns of regional recurrences was also performed.

#### Results

The 23 patients that presented locoregional recurrence had mostly aggressive biologic features: grade III (modified Bloom-Richardson-Elston grading) in 17 patients (74%), high mitotic index in 16 patients (70%) and triple negative status in 12 patients (52%). Vascular embolism was present in 11 cases (48%). There were 4 cT1, 11cT2, 1cT3 and 6cT4. The overall positive nodes found in the lymphadenectomy were p33N+/111N and yp80N+/151N in patients without and with neoadjuvant chemotherapy.

The median age at recurrence was 59. The median locoregional relapse free survival and median overall survival was 28.3 months and 42.8 months respectively. Local recurrence (chest wall) occurred in 12 cases (56%) and infield regional recurrence was observed in 3 cases although sufficient dose was delivered. Marginal or outfield nodal recurrences were seen in 12 cases (56%) and involved level I or II in 9 cases. Interestingly, 3 axillary nodal recurrences occurred outside the ESTRO defined clinical target volumes. Synchronous and metachronous distant metastases were found in 14 and 4 patients respectively.

#### Conclusion

In our series, the local recurrence resulted mostly from of biologic radioresistance whereas regional recurrences were caused by geographical miss. Further follow-up and careful registration of the recurrences is needed to improve the results

#### PO-0656 Reirradiation+hyperthermia after surgery for recurrent breast cancer: 70% 5-year local control

S. Oldenburg<sup>1</sup>, J. Crezee<sup>1</sup>, Y. Kusumanto<sup>1</sup>, R. Van Os<sup>1</sup>, S. Oei<sup>2</sup>, J. Venselaar<sup>2</sup>, P. Zum Vörde Sive Vörding<sup>1</sup>, C. Rasch<sup>1</sup>, T. Van Tienhoven<sup>1</sup>

<sup>1</sup>Academic Medical Center, Radiation Oncology Hyperthermia, Amsterdam, The Netherlands

<sup>2</sup>Institute Verbeeten, Radiation Oncology, Tilburg, The Netherlands

#### Purpose or Objective

Combining reirradiation (reRT) with hyperthermia (HT) has shown to be of high therapeutic value for patients with inoperable locoregional recurrent breast cancer. The purpose of this study was to analyse the therapeutic effect and toxicity of reRT+HT following surgery of locoregional recurrent breast cancer in previously irradiated area.

#### Material and Methods

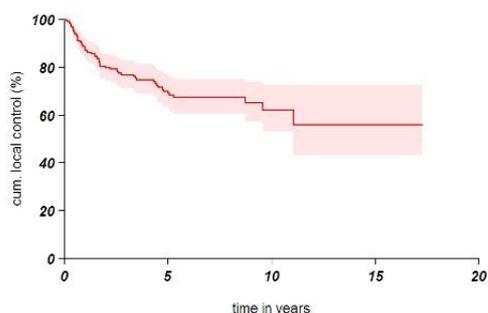

Two hundred and twenty-five patients were treated with re-RT+HT from 1982 till 2006. All patients received previous high dose radiation (median dose 50Gy with or without boost), overlapping with the current reRT field. Forty-two percent of the patients were treated for previous episodes of locoregional recurrent disease using either surgery, radiation, systemic therapy, or a combination of treatment modalities.

At start of reRT+HT there was no macroscopically detectable recurrence after salvage mastectomy, chest wall resection, or local excision in 48%, 6%, and 46% of patients, respectively. ReRT consisted typically of 8x4Gy, twice a week or 12x3Gy, four times a week. Superficial hyperthermia was applied once or twice a week using 434MHz Contact Flexible Microstrip Applicators (CMFA), heating the tumor area to 41-43°C for one hour.

#### Results

The treatment was well tolerated; only 3 patients did not complete treatment as planned due to herpes zoster infection, toxicity and refusal. Median follow-up time was 56 months. The 5-year infield local control (figure 1) and overall survival rates were 70% and 60%, respectively. A longer time interval to current recurrence, concurrent endocrine treatment, breast recurrences compared to chest wall recurrences and smaller recurrence sizes before treatment had a significantly positive effect on the duration of local control in multivariable analyses. Acute  $\geq$  grade 3 toxicity occurred in 10% of patients. The risk of late  $\geq$  grade 3 toxicity was 28% after 5 years and consisted mostly of ulceration (33%). In multivariable analyses the risk of overall late  $\geq$  grade 3 toxicity was 4.6 times higher for patients treated with 4Gy fractions and abutted photon-electron fields ( $P = 0.032$ ).

Figure 1. Local control including confidence interval

### Conclusion

The combination of reirradiation and hyperthermia is well tolerated and results in durable local control. ReRT+HT should be considered a standard adjuvant treatment option following surgery for patients with recurrent breast cancer. Late toxicity might be reduced by decreasing reRT fraction size and/or avoiding photon-electron abutments.

### PO-0657 Breast cancer subtypes and incidence/survival in patients with brain metastases

Y.C. Tsai<sup>1</sup>, M.C. Liu<sup>2</sup>, H.C. Cheng<sup>1</sup>, J.J. Jian<sup>1</sup>, B.L. Yu<sup>3</sup>, C.M. Chen<sup>3</sup>, N.M. Chu<sup>2</sup>, C.F. Horng<sup>4</sup>, M.H. Tsou<sup>5</sup>

<sup>2</sup>Koo Foundation Sun Yat-Sen Cancer Center, Medical Oncology, Taipei, Taiwan

<sup>3</sup>Koo Foundation Sun Yat-Sen Cancer Center, Surgery, Taipei, Taiwan

<sup>4</sup>Koo Foundation Sun Yat-Sen Cancer Center, Clinical Research Office, Taipei, Taiwan

<sup>5</sup>Koo Foundation Sun Yat-Sen Cancer Center, Pathology, Taipei, Taiwan

### Purpose or Objective

Identify incidences and prognosis of breast cancer patients with brain metastases (BM) by breast cancer subtypes. We sought to determine whether a high-risk group could be defined in whom a search of occult BM was justified.

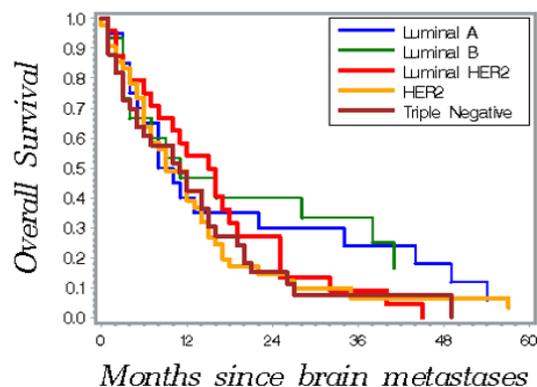

### Material and Methods

Information was obtained from the institutional breast cancer data base. Between 1990 and 2010, 6037 newly diagnosed stage I to III breast cancer patients were included in this study to determine the incidence of brain metastases in different breast cancer subtypes. Retrospective survival analyses were performed in 136 BM per breast cancer subtypes. 90 BM patients had detailed clinical information to define the median time interval from primary diagnosis to development of brain metastases. Estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth receptor-2 (HER2) statuses were tested by immunohistochemical (IHC) staining, and HER2 FISH analysis conducted for IHC 2+.

### Results

With a median follow-up of 80 months. The incidence of CNS relapse was 2.8%. For stage I, II, III, the BM incidence was 0.9%, 2.1% and 6.5% respectively. Incidence of BM were 1% (luminal A), 1.8% (luminal B), 3.9% (luminal/HER2), 6.5% (HER2 enriched), and 4.6% (triple negative) respectively. Among 1503 stage III patients, the incidence of BM were 2.1% (luminal A), 1.5% (luminal B), 9.9% (luminal/HER2), 13.2% (HER2 enriched), and 12.4% (triple negative) respectively. One year survival with BM were 40% (luminal A), 46.7% (luminal B), 54.2% (luminal/HER2), 39.1% (HER2 enriched), and 42.4% (triple negative) respectively. Three-year survival with BM were 24% (luminal A), 33.3% (luminal B), 9% (luminal/HER2),

6.5% (HER2 enriched), and 7.6% (triple negative) respectively. The median time interval from primary diagnosis to development of brain metastases were 99.5 months (luminal A), 58 months (luminal B), 37 months (luminal/HER2), 24 months (HER2 enriched), and 23 months (triple negative) respectively.

### Conclusion

Subtype of breast cancer patients with triple-negative or HER2-positive had an increased risk for the development of brain metastases and shorter 3-year survival. The median time interval from primary diagnosis to development of brain metastases were shorter (2 years) for triple negative and HER2-positive patients. Stage III breast cancer patients with triple-negative or HER2-positive subtype may deserve a search of occult BM in the first 2 years after primary diagnosis.

### PO-0658 impact of breast radiation therapy on complications after alloplastic breast reconstruction

C.D.L.G. Chaves<sup>1</sup>, H.D.A. Carvalho<sup>2</sup>, T.D.C. Saraiva<sup>1</sup>, T.T. Fuzisaki<sup>2</sup>, G.N. Marta<sup>1,3</sup>, R. Casagrande<sup>4</sup>, A. Munhoz<sup>4</sup>, J.A. Brasil<sup>4</sup>, S.R. Stuart<sup>2</sup>

<sup>1</sup>Instituto do Câncer do Estado de São Paulo ICESP - Faculdade de Medicina da Universidade de São Paulo, Radiation Oncology, Sao Paulo, Brazil

<sup>2</sup>Faculdade de Medicina da Universidade de São Paulo, Radiation Oncology, Sao Paulo, Brazil

<sup>3</sup>Hospital Sírio-Libanês, Radiation Oncology, São Paulo, Brazil

<sup>4</sup>Instituto do Câncer do Estado de São Paulo ICESP - Faculdade de Medicina da Universidade de São Paulo, Division of Plastic Surgery, Sao Paulo, Brazil

### Purpose or Objective

To assess the influence of radiation therapy (RT) in local complications in breast cancer patients who underwent breast reconstruction with alloplastic material.

### Material and Methods

Between 2009 and 2013, patients with breast cancer who received alloplastic breast reconstruction with tissue expander (with included or remote valve), prosthesis-expander or breast implant were assessed retrospectively. Patients with at least 2 years of follow-up after the end of treatment were included. Complications were considered when any surgical intervention was required. Early complications, up to three months after surgery and late complications, after 6 months of the end of the surgery or RT. Uni and multivariate analysis were performed to correlate clinical variables with complications.

### Results

In the studied period, 251 patients were evaluated. The mean age was 49.7 years and mean Body Mass Index (BMI) was 27.5 kg/m<sup>2</sup>. Most patients (73%) had diabetes mellitus; 35.5% had hypertension and 10.6% were smokers. Disease was presented in early stage in 78.5%. Modified radical or

simple mastectomy were the main surgical approaches (69.9%). Skin-sparing and nipple-sparing mastectomy were performed in 29.7%. Immediate reconstruction was done in 94% of patients, 85% with tissue expander with included or remote valve. The average volume expansion was 546.2 ml. Post-operative RT was performed in 162 patients (66.4%) with prescribed dose of 50 or 50.4Gy in 92.3%. Early complications were seen in 125 patients (50.8%), of which 25% required reoperation and 18.3% of the patients lost the implant. Local infection was significantly correlated with severe early complications. Only 10 patients (4.1%) had late complications. Of these, 8 underwent post-operative RT (5% of irradiated patients) and 2 (2%) were not irradiated ( $p = 0.327$ ). In the univariate analysis, diabetes mellitus, smoking, neoadjuvant chemotherapy, expander with included valve, age over 50 years, BMI > 25 kg/m<sup>2</sup> were related to early toxicity ( $p < 0.05$ ). In multivariate analysis, besides obesity, diabetes mellitus, expander with included valve and not performing neoadjuvant chemotherapy remained as variables related to early toxicity ( $p < 0.05$ ). No correlation of the studied clinical variables with late toxicities was observed. RT was not related to high risk of early and late toxicities.

#### Conclusion

Approximately 50% of patients with alloplastic breast reconstruction presented early complications. Late complications were low in this population. RT did not increase the risk of severe complications after alloplastic breast reconstruction.

#### PO-0659 Hypofractionated-accelerated concomitant boost in moderate-high risk breast cancer: phase I-II study

<sup>7</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Gynecologic Oncology Unit, Campobasso, Italy

<sup>8</sup>Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

#### Purpose or Objective

To evaluate the results in terms of local control and late toxicity using intensity modulated radiotherapy with concomitant boost in breast cancer (BC). These results were compared with a control group (CG) of patients treated with standard 3-dimensional (3-D) radiotherapy plus sequential boost.

#### Material and Methods

Primary endpoint was local control. Secondary endpoints were late skin and subcutaneous toxicities. Patients with moderate-high risk ( $\geq 3$  axillary nodes and/or pre- or perimenopausal status and/or close resection margins) were enrolled and treated with forward-planned IMRT technique. Prescribed dose to the breast was 50 Gy in 25 fractions (fx) with a concomitant boost to the tumor bed of 10 Gy. In CG group, whole breast received a total dose of 50.4 Gy in 28 daily fx with a sequential boost to the

tumor bed of 10 Gy in 4 fx. Late skin and subcutaneous toxicity were evaluated using Radiation Therapy Oncology Group / European Organization for Research and Treatment Cancer (RTOG/EORTC) scoring scale.

#### Results

Four hundred and fifty one patients were included in our analysis (MARA-2: 321; CG:130). Median follow up was 52 months (range: 3-115). Five-year local control was 96.7% and 97.6% in CG and MARA-2 groups, respectively ( $p=0.676$ ). At univariate analysis, patients treated with concomitant boost (MARA-2) showed a significant increase of late G1 and G2 subcutaneous toxicity ( $p<0.001$ ). Five-year G1 subcutaneous late toxicity free-survival (LTFS) were 73.4% and 38.5% in CG and MARA-2, respectively. Moreover, 5-year G2 subcutaneous LTFS were 96.5% and 80.0% in CG and MARA-2, respectively. Five-year actuarial cumulative incidence of G3 late subcutaneous toxicity was 0.0% and 0.9% in CG and MARA-2, respectively. G1 and G2 late skin toxicities were similar in the two groups and no patients showed G3  $\geq$  late skin toxicity in MARA-2.

#### Conclusion

This study showed the feasibility of concomitant boost using IMRT technique in postoperative radiotherapy of BC with reduction of treatment duration and without significant increase of G > 2 late effects. Local control was excellent despite inclusion criteria.

**PO-0660 Partial breast re-irradiation with IMRT in patients with local failure after conservative treatment**

<sup>5</sup>European Institute of Oncology, Department of Surgery, Milan, Italy

<sup>6</sup>European Institute of Oncology-University of Milan, Department of Medical Imaging and Radiation Sciences- Department of Oncology and Hemato-oncology, Milan, Italy

#### Purpose or Objective

The aim of the study is to evaluate acute and intermediate toxicity and clinical outcome of partial breast re-irradiation (re-PBI) with intensity-modulated radiotherapy (IMRT), using hypofractionation.

#### Material and Methods

This is a prospective clinical study including patients (pts) previously treated with whole breast radiotherapy (WBRT) who experienced in-breast tumor recurrence and underwent a second conservative surgery. Re-irradiation was limited to the tumor bed. Intensity modulated re-PBI was performed using Tomotherapy in helical modality or BrainLab-VERO step-and-shoot modality. Planning target volume (PTV) was generated by clinical treatment volume (CTV) with an isotropic margin expansion of 5 mm. Daily image guided irradiation was performed (megavoltage fan beam computerized tomography (CT) for Tomotherapy and kilovoltage cone beam CT for VERO). Planning objectives for PTV coverage were:  $V_{100\%} \geq 95\%$ ,  $V_{95\%} \geq 98\%$ ,  $D_{0.03cc} \leq 110\%$ . Acute toxicity was evaluated using RTOG/EORTC criteria, while late toxicity was recorded according to LENT/SOMA scale.

**Tab.1 Late toxicity according to LENT/SOMA**

Chronic side effects (15 pts)	N° of pts (%)
Pain	3 (20%)
Fibrosis	
G1	5 (33.3%)
G2	4 (26%)
Dyschromia	2 (13.3%)
Telangiectasia	2 (13.3%)
Oedema	2 (13.3)
Retraction	9 (60%)

### Results

Between 6/2012 and 11/2015, 48 pts were treated with re-PBI. Median time to recurrence was 137.3 months (range: 25.6-319 months). Prescription dose was 37.05 Gy in 13 fractions. 9 pts were treated with Tomotherapy and 39 pts with VERO. Median age was 60.7 years. The patterns of recurrences were as follows: in 37 cases site of recurrence was the same as the index tumor (true/marginal miss), while in the remaining 17 cases recurrence occurred far from the index quadrant across the breast (elsewhere in breast reappearance). Acute toxicity was moderate: no acute toxicity >G2 was observed at the end of the treatment (erythema G1 in 48% of pts; desquamation G1 in 2% of pts; edema G2 in 8% of pts). Late toxicity according to LENT/SOMA was available for 15/48 patients (Tab.1). All but one had G1-G2 toxicity: one patient experienced G3 retraction. Overall, median follow-up after first relapse was 22.1 months. 45 pts are alive without disease while 3 pts showed distant metastasis (DM). Median time to DM event was 12 months and 3/3 have had true/marginal miss local recurrence with high Ki-67.

### Conclusion

Second conservative surgery combined with additional radiotherapy represents a feasible alternative to mastectomy. None of the patients relapsed locally. Furthermore, good acute toxicity profile and an acceptable early chronic toxicity were observed, although longer follow-up and higher number of pts are needed to confirm these results.

<sup>11</sup>Associazione Italiana Radioterapia Oncologica, intraoperative radiotherapy working group, -, Italy

### Purpose or Objective

To assess the outcome after salvage breast conservative surgery (BCS) and additional partial irradiation (PBI) with intraoperative electrons (IORT) in patients previously treated with BCS and whole breast irradiation.

### Material and Methods

From 1999 and 2015, 115 patients affected by in-breast recurrence (IBTR) were treated with salvage BCS and IORT in 8 Italian centers. Data were collected centrally and entered in a dedicated database. The study was promoted and supported by the IORT Working Group of Italian Association of Radiation Oncology (AIRO). Patients gave informed consent for the use of anonymized data for research and training purposes. Efficacy of re-treatment was evaluated by means of second IBTR and distant metastases (DM) rates. Tolerability was assessed based on the incidence of postoperative complications. Systemic treatment was given according to biologic profile and institution's policy.

### Results

Median time to salvage BCS was 122 months (12-334). Site of IBTR was the same as the index tumor in 44.3% of cases. Median age at first BCS was 56 (37-76), while at salvage BCS was 62 years (40-81). Patients received lumpectomy only in 53% of cases, while axillary dissection was performed in 3.2% of cases. The remaining patients had sentinel node biopsy. In 43.4% of cases, the size of recurrence was comprised between 1 and 2 cm. The majority of patients had positive hormonal receptors, 22.6% had grade 3 tumors and in about half of the cases Ki-67 was higher than 20%.

Regarding technical characteristics, IORT dose was 18-21 Gy in 82.6% of cases, median collimator size was 5 cm (3-6 cm), median electron energy was 7 MeV. Main postoperative complications after IORT delivery consisted of lyponecrosis (4.3%), hematoma (6.9%), seroma (8.7%), edema (6.9%), infection (2.6%). At a median follow-up after IBTR of 56 months (13-124 months), 73.6% of patients were alive. Second IBTR rate was 11.3%. Distant metastases rate was 2.6%. Three patients died of distant disease progression (2.6%). Contralateral breast cancer occurred in 2.6% of cases, while 0.9% developed second new primaries in distant sites.

### Conclusion

The study population included patients from 8 institutions who had resectable IBTR and either refused salvage mastectomy or were offered the second BCS, including PBI, as a valid alternative. Local control obtained with IORT was comparable to that previously described in literature, which ranges between 7% and 32%, with a mean value of about 10%. Multivariate analysis to identify prognostic factors for a better selection of patients is ongoing.

### PO-0662 Target therapy and hypofractionated whole breast radiotherapy: an unexpected protective factor.

### Purpose or Objective

To evaluate the impact of trastuzumab on acute skin toxicity in breast cancer patients treated with hypofractionated radiotherapy to the whole breast and chemotherapy with anthracycline and taxane.

### Material and Methods

From April 2009 to April 2016, we enrolled 632 patients who underwent breast conservative surgery followed by adjuvant hypofractionated whole breast irradiation. Patients received 42.4 Gy in 16 daily fractions, 2.65 Gy per fraction. The boost to the tumor bed was administered only in grade 3 patients and in patients with close or positive margins (< 1mm). Acute and late toxicity was prospectively assessed during and after radiotherapy according to RTOG scale. Multivariable logistic regression models were applied to evaluate the impact of trastuzumab on the occurrence of acute skin toxicity (>=G2).

### Results

In all patients enrolled, the mean age was 74 (range 46-91 yrs). Regression adjusted models showed that chemotherapy (OR= 2.0, p=0.03) and boost administration (OR=2.2, p<0.01) had a significant impact on acute skin toxicity (Figure 1).

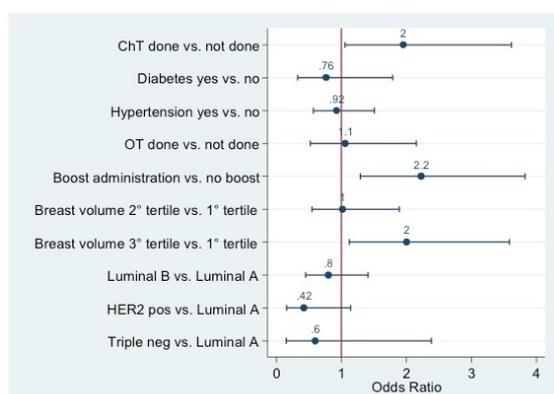

Figure 1: Multivariable Logistic regression analysis of factors associated with the occurrence of acute skin toxicity (>=G2) in 632 T1-2 breast cancer patients.

One hundred and sixty-three patients received chemotherapy. Fifty one of them (30.7%) underwent also trastuzumab therapy. In this group, we found that G1 and G2/G3 acute skin toxicity were 50.4% and 33.9% in patients received only chemotherapy and 64.7% and 21.6% in patients who receive it associated with trastuzumab, respectively. Multivariate analysis showed that patients receiving trastuzumab had decreased risk of acute skin toxicity >=G2 (OR=0.04, p=0.03) (Figure 2).

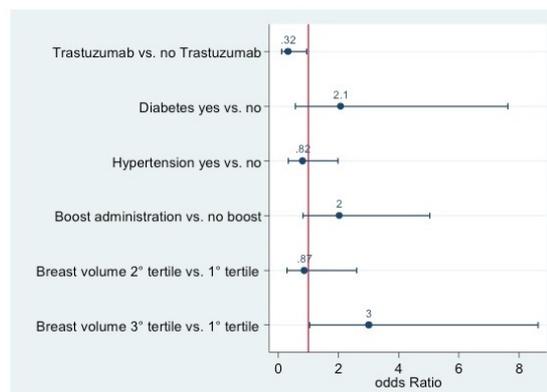

Figure 2: Multivariable Logistic regression analysis of factors associated with the occurrence of acute skin toxicity (>=G2) in 163 T1-2 breast cancer patients who received chemotherapy

### Conclusion

The results of our study demonstrated that chemotherapy impact on acute toxicity in patients undergoing hypofractionated whole breast irradiation, probably due to the recall phenomena. Trastuzumab seems to be a protective factor on acute skin toxicity.

### PO-0663 Early toxicity of 150 patients treated with hypofractionated breast SIB-RT using advanced techniques

F. Lakosi<sup>1</sup>, C. Pirson<sup>2</sup>, P.V. Nguyen<sup>2</sup>, P. Berkovic<sup>2</sup>, S. Ben-Mustapha<sup>2</sup>, F. Princen<sup>2</sup>, S. Cucchiario<sup>2</sup>, A. Gulyban<sup>2</sup>, V. Baart<sup>2</sup>, P. Coucke<sup>2</sup>

<sup>1</sup>Kaposvar University, Radiotherapy, Kaposvar, Hungary  
<sup>2</sup>CHU de Liège, Radiotherapy, Liège, Belgium

### Purpose or Objective

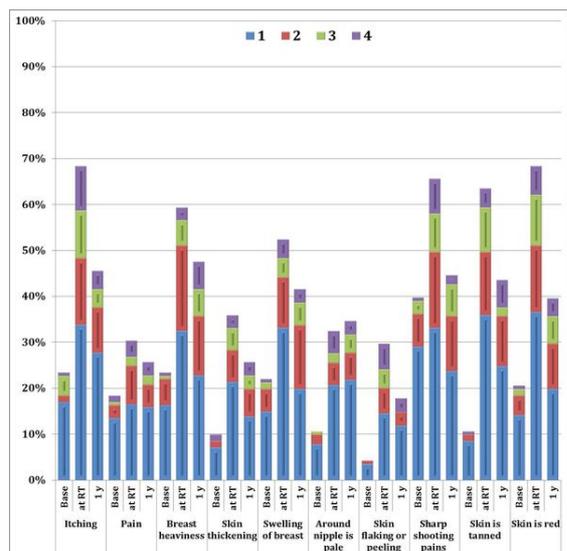

To report physician-and patient reported early toxicity of hypofractionated breast simultaneous integrated boost (SIB) approach with Field-in-Field (breast±nodes) and Volumetric Modulated Arc Therapy (boost) (FiF+VMAT) after breast-conserving surgery.

### Material and Methods

Between November 2013 and July 2016, 150 breast cancer patients with 154 lesions (T1-2, N0-1, M0) were treated with adjuvant radiotherapy using VMAT breast SIB technique. For whole breast irradiation two tangential field-in-field beams were used, while for SIB a full/half arc VMAT between the two tangents were applied. Doses to whole breast and tumor bed were 40.05/45.57 Gy and 48/55.86 Gy respectively, delivered in 15/21 fractions depending whether elective nodal irradiation (n=41) was required. Acute toxicities were scored using the Common Toxicity Criteria for Adverse Events (CTCAEv4). Desquamation was scored as: 0- none; 1- dry and 2- moist. Toxicity was also evaluated with BCTOS and Treatment related symptoms questionnaires. For analysis radiotherapy-related cosmetic and breast specific pain items were selected. Data were recorded baseline, during, 6 weeks and 1 year after treatment.

### Results

The median follow-up was 20 months (range:3-36) and 105 patients remained evaluable at 1 year. The maximum acute toxicities (%) during treatment were the followings: (G0/G1/G2/≥G3): Dermatitis: 8/79/13/-, Desquamation: 69/27/4/-, Pruritus 49/47/4/-, Oedema: 34/59/7/- and Pain: 45/48/7/-, Oesophagitis: 83/16/1-. There were no Grade 3 physician reported acute toxicities. A remarkable incline in Treatment related symptom scores was observed during SIB, which improved thereafter in almost all items, but remained superior to baseline status at 1 year follow up (Figure). The evolution of BCTOS scores showed the same pattern (Table).

	Baseline				1year after RT			
	1	2	3	4	1	2	3	4
Fit of bra	79%	12%	7%	1%	62%	18%	12%	8%
Nipple appearance	65%	22%	12%	1%	55%	32%	10%	3%
Breast pain	79%	19%	5%	0%	56%	30%	12%	3%
Breast shape	57%	29%	10%	4%	38%	42%	18%	3%
Breast swelling	72%	22%	4%	1%	70%	20%	9%	2%
Breast elevation	65%	19%	11%	3%	49%	33%	10%	5%
Breast texture	54%	32%	12%	1%	32%	35%	28%	5%
Breast tenderness	62%	22%	12%	4%	38%	34%	25%	4%
Breast sensitivity	59%	25%	12%	4%	35%	35%	27%	3%
Breast size	53%	26%	17%	4%	24%	47%	27%	3%
Scar tissue	60%	28%	6%	2%	44%	33%	15%	8%

**Conclusion**

Hypofractionated hybrid FiF+VMAT SIB showed to be feasible and was associated with low acute toxicity burden. 1-year follow-up data demonstrated a noticeable decline in radiotherapy related QoL items. Long-term results are needed to assess late toxicity and clinical outcome.

**PO-0664 Standardized Nodal Radiation (RT) through a Breast Clinical Pathway (CP) within a USA Cancer Network**

B. Gebhardt<sup>1</sup>, Z. Horne<sup>1</sup>, G. Ahrendt<sup>2</sup>, E. Diego<sup>2</sup>, D. Heron<sup>1</sup>, S. Beriwal<sup>2</sup>

<sup>1</sup>University of Pittsburgh Cancer Institute, Radiation Oncology, Pittsburgh, USA

<sup>2</sup>University of Pittsburgh Cancer Institute, Surgical Oncology, Pittsburgh, USA

**Purpose or Objective**

ACOSOG Z11 and EORTC AMAROS studies investigated patients (pts) with clinical T1-2 N0 invasive breast cancer (IBC) undergoing breast conserving surgery (BCS) with positive sentinel node (+SLN) biopsy and demonstrated the safety of omitting axillary nodal dissection (ALND). Adjuvant RT fields employed differed between the two trials as regional nodal irradiation (RNI) was mandated in AMAROS and RT fields were heterogeneous in Z11. Furthermore, MA-20 and EORTC RNI trials demonstrated a survival benefit with RNI in pts with positive nodes, leading to wide variation in RT treatment volumes. CPs standardize care when many therapeutic options exist and clinical practice varies unnecessarily. We sought to evaluate the impact of changes to a CP guiding adjuvant RT in pts with +SLNs on practice patterns throughout a large, integrated cancer network.

**Material and Methods**

We implemented a CP for management of IBC with adjuvant RT throughout a network of 22 centers that required entry of management decisions into an online support tool. The CP for treatment of pts with +SLN following BCS was modified in February 2015 to promote

uniform treatment of nodal volumes. The CP recommended modified tangents (MT) including level I/II nodes for pts with micrometastases (pN1mi). For pts with macrometastases (pN1a), CP recommended including level I/II LN in MT and additional field to include level III, supraclavicular (SCV) LN +/- internal mammary nodes for pts with any adverse factor including T2 disease, LVSI, high grade, ER negative, ECE, or age <50. Adjuvant RT fields of pts undergoing BCS with +SLN but not ALND were retrospectively reviewed.

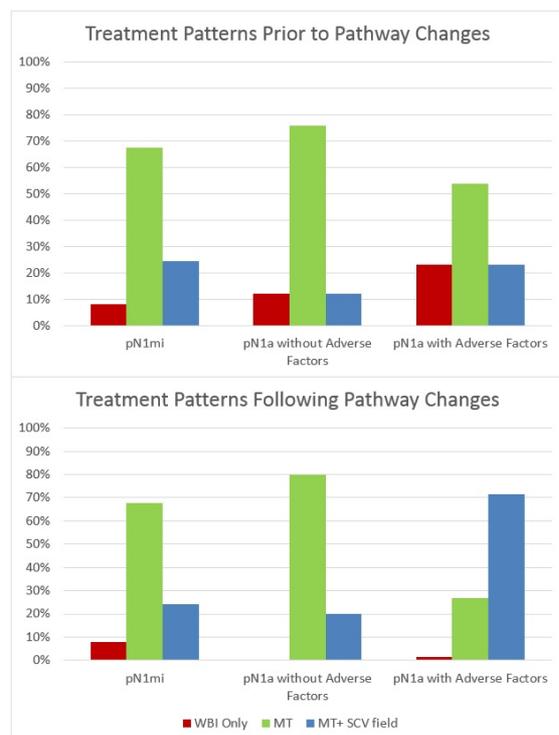

**Results**

The RT fields of 257 pts from July 2011 to August 2016 were reviewed, including 74 (29%) with pN1mi disease & 183 (71%) with pN1a. Of 127 pts treated prior to CP changes, 13 (24%) of 37 pts with pN1mi were treated with whole breast irradiation (WBI) alone and 18 (20%) of 90 pts with pN1a with WBI alone. Following CP changes, 130 pts were treated, including 5 (4%) pts treated with WBI alone, 63 (49%) with MT, and 62 (48%) MT + SCV field. Of 37 pN1mi pts, 3 (8%) were treated with WBI alone. Of 92 pN1a pts, 1 (1%) was treated with WBI alone. A summary of treatment fields relative to pathway change is included in Figure 1. On multivariable analysis (MVA), pN1a disease and treatment after CP changes were associated with use of MT (Table 1). Use of SCV field was associated with pN1a disease with adverse factors and treatment after CP changes.

**Conclusion**

CP's are useful tools for translating published research and guidelines into pt management plans to promote evidence-based care and eliminate unnecessary variations in practice. Recognizing that adjuvant RT treatment volumes were heterogeneous following the publication of Z11 and AMAROS, we modified the CP in 2015 based upon the latest evidence for RNI. After the amendment, pts received standardized RT fields guided by the CP based upon clinical risk factors which will aid in tracking outcomes in future investigations.

<sup>2</sup>Azienda Ospedaliero Universitaria Pisana, Section of Statistics, Pisa, Italy  
<sup>3</sup>Azienda Ospedaliero Universitaria Pisana, Breast Surgery, Pisa, Italy  
<sup>4</sup>Azienda Ospedaliero Universitaria Pisana, Oncology, Pisa, Italy  
<sup>5</sup>Azienda Ospedaliero Universitaria Pisana, Radiology, Pisa, Italy

#### Purpose or Objective

The purpose of the study was to evaluate the outcome of patients (pts) undergone to mastectomy followed or not by post-mastectomy radiotherapy (PMRT) and to investigate the clinicopathological prognostic factors of locoregional recurrence (LRR).

#### Material and Methods

We retrospectively reviewed data of patients underwent total mastectomy and sentinel lymph node examination +/- axillary dissection. Patients were staged according to AJCCU/UICC 7<sup>th</sup> Edition.

According to consensus in literature PMRT was limited to the chest wall (CW-PMRT) in stage pT3 N1 or extended to the lymphatic drainages of apex axilla and supraclavicular nodes (CWLD-PMRT) in stage pT4 N2-3. Patients underwent salvage mastectomy after a previous conservative surgery and RT or with of systemic disease at diagnosis were excluded from the study.

Radiotherapy treatment was performed with linear accelerator and 3DCRT technique using X photons of 6 and/or 15 MV energy. Two tangential beam technique was used for CW-PMRT whereas a half beam technique with the addition of 1-2 anterior-posterior (AP-PA) beam was used for CWLD-PMRT. The prescribed dose was 50 Gy delivered in 25 fractions adding a boost of 20 Gy and 14-16 Gy for positive and close (<2mm) surgical margins, respectively.

Neoadjuvant chemotherapy (CT), adjuvant CT, Trastuzumab, Tamoxifen and systemic endocrine therapy were prescribed according to international guidelines. Radiotherapy was deferred after the completion of adjuvant CT. Univariate and multivariate analyses were performed using SPSS 22 (SPSS Inc., Chicago, IL, USA) technology.

#### Results

Between January 2004 and June 2013 a total of 912 patients underwent to total mastectomy; of whom 269 (29,5%) underwent to PMRT and 643 (70,5%) not. Among PMRT group 77 underwent to CW and 202 to CWLD irradiation. The median follow up was 40 months (range, 3-118). No significant difference in terms of LRR was found between the no-PMRT and PMRT group (p=0,175; HR=1,613; CI95%=0,808-3,219).

The uni and multivariate analysis of LRR for patients not undergone to PMRT showed a significant correlation with the presence of ECE (p=0,049), Mib-1 >30% (p=0,048) and triple negative status (p=0,001). On the contrary, the triple negative status resulted as the only variable significantly correlated to LRR (p<0,0001) in the PMRT group whereas ECE and Mib-1>30% lost the significance. Finally, no significant difference was shown between CWLD and CW-PMRT (p=0,078; HR=0,375; CI95%=0,126-1,116).

#### Conclusion

Based on our data, we strongly confirm the positive impact of PMRT in local advance disease and recommend to carefully consider it in presence of ECE and Mib-1>30% regardless T and N stage. CW irradiation might be a valid option in selected intermediate disease (i.e. less than 3 positive lymph nodes). Future "well designed" prospective studies are needed to properly validate our results.

#### PO-0666 30 Gy single-dose SBRT to lung lesions: outcome in a large series of patients

L. Nicosia<sup>1</sup>, C. Reverberi<sup>1</sup>, L. Agolli<sup>1</sup>, M. Valeriani<sup>1</sup>, V. De Sanctis<sup>1</sup>, C. De Dominicis<sup>2</sup>, G. Minniti<sup>1</sup>, E. Cortesi<sup>3</sup>, M. Martelli<sup>4</sup>, M.F. Osti<sup>1</sup>

<sup>1</sup>Sant'Andrea Hospital- University of Rome "Sapienza", Radiation Oncology, Rome, Italy

<sup>2</sup>Sant'Andrea Hospital- University of Rome "Sapienza", Department of Radiology, Rome, Italy

<sup>3</sup>Policlinico Umberto I- University of Rome "Sapienza", Department of Radiology- Oncology and Human Pathology, Rome, Italy

<sup>4</sup>Carlo Forlanini Hospital- Rome- Italy, Thoracic Surgery Unit, Rome, Italy

#### Purpose or Objective

We conducted a prospective study to evaluate the effectiveness, safety and toxicity of a Stereotactic Body

Radiation Therapy (SBRT) in 30 Gy single dose, for the treatment of lung lesions.

#### Material and Methods

from December 2008 to December 2015 a total of 201 lung lesions in 160 patients affected by lung oligometastatic disease or primary lung cancer were treated at our Institution. All lesions were treated with a 30 Gy single dose SBRT with a stereotactic body frame and a 3-D conformal technique. One-hundred sixty-six (82.5%) lesions were metastases, the remainder were primary lung tumors; main primary tumor sites were lung and colon-rectum (45.2% and 28.8%, respectively). Primary endpoints were local progression-free survival (LPFS) and toxicity, secondary endpoint were disease-free survival (DFS), metastases-free survival (MFS), overall survival (OS) and cancer specific survival (CSS).

#### Results

Median LPFS was not reached; 1- and 2-year LPFS were 88.2% and 77.5%, respectively. Overall response rate was 99.5%, complete response (CR) was achieved in 134 (66.6%) lesions, good or partial response in 43 cases (21.3%), stable disease in 23 (11.4%) cases and progression in one case. Local progression occurred in 34 (16.9%) lesions after a median time of 17 months. Volume <20 cc correlated with survival. Median survival time was 40 months (range 28-51 months) and 1- and 2-years OS were 84.7% and 63.9%, respectively. Median CSS was 48 months (range 38-57 months) and 1- and 2-years CSS were 87.1% and 67.6%, respectively. Median DFS and MFS were 16 and 22 months, respectively, while 1- and 2-years DFS and MFS were 64.4% and 43.1% and 67% and 48.5%, respectively. On the multivariate analysis CR was the most important factor significantly associated with improvement and survival. Acute toxicity occurred in 43 (21.3%) cases, with 10 (4.9%) cases of Grade  $\geq 3$  toxicity. Late toxicity occurred in 80 (39.8%) lesions and the rate of Grade  $\geq 3$  toxicity was 5.9% (12 lesions).

#### Conclusion

our study represents, at our knowledge, the largest series in the literature on the use of SBRT 30 Gy single dose for lung lesions. Our results confirm the safety and effectiveness of this schedule, both in primary tumor and metastases, achieving in selected patients, even long-term survival. Single dose SBRT is characterized by high patients' compliance and it can be easily interfaced with systemic therapies.

#### PO-0667 The differences between two groups of patients with NSCLC depending on the imaging for radiotherapy

A. Masarykova<sup>1</sup>, D. Scepanovic<sup>1</sup>, P. Bires<sup>1</sup>, D. Lederleitner<sup>1</sup>, M. Pobjakova<sup>1</sup>, P. Povinec<sup>2</sup>

<sup>1</sup>National Cancer Institute, Radiation Oncology, Bratislava, Slovakia

<sup>2</sup>BIONT PET Center, Nuclear Medicine, Bratislava, Slovakia

#### Purpose or Objective

Background. - The target volumes of lung cancer are underestimated on a standard three-dimensional positron emission tomography/computed tomography (3D PET/CT) scan when compared to target volumes defined on respiratory gated or four-dimensional (4D) imaging. 4D methods strive to achieve highly conformal radiotherapy for lung tumours, in the presence of respiratory-induced motion of tumours and normal tissues.

Purpose. - The differences between two groups of patients with non small cell lung cancer depending on the imaging for simulation of radiotherapy (3D vs 4D PET/CT), were examined.

#### Material and Methods

A total of 58 patients with NSCLC (45 male and 13 female) underwent an FDG-PET/CT for radiotherapy planning purposes. There were 26 patients who performed 3D PET/CT from 2011 to 2013 and 32 patients had 4D PET/CT

from 2014 to 2016 for the radiotherapy planning. Median age was 63 (range, 49-89). All patients (58) had locally advanced stage of NSCLC. Sixteen percent of patients had atelectasis and 60% mediastinal lymph nodes. Squamous cell lung cancer has been the most represented (72% patients), a remnant was adenocarcinoma. All patients were treated with radical radiotherapy. Dose prescription ranged from 56 to 70.2Gy. Forty eight patients have received chemotherapy sequentially.

#### Results

A comparison of the 3D and 4D volumes has shown that the 4D GTV was on average 58% smaller than the 3D GTV ( $p < 0.01$ ). The 10 mm 4D planning target volume (PTV) was on average 28% smaller than the 10 mm 3D PTV ( $p < 0.01$ ). There was not statistically significant difference between two groups of patients regarding the rate of local recurrence ( $p=0.3188$ ). However, regarding the rate of distant metastases there was statistically significant difference in favour of the 3D imaging group ( $p=0.0455$ ). Seven patients in 3D imaging group and 9 from 4D imaging group lived at the time of analysis. One year disease free survival (DFS) was 42% for 3D imaging group and 37% for 4D imaging group ( $p=0.7903$ ). Also, there was not statistically significant difference regarding 1 year overall survival (OS) between these two groups of patients (3D=69% and 4D=50%,  $p=0.1834$ ).

#### Conclusion

4D PET/CT is clinically a feasible method, to correct respiratory motions in the thorax. Our analysis showed that the definition of GTV and PTV are better in 4D imaging group. However, there was not differences between two groups of our patients regarding local control, as well as DFS and OS.

#### PO-0668 Five-fraction SBRT for central NSCLC in-field recurrences following high-dose conventional radiation

M.C. Repka<sup>1</sup>, N. Aghdam<sup>1</sup>, S. Kataria<sup>1</sup>, S. Suy<sup>1</sup>, E. Anderson<sup>2</sup>, S.P. Collins<sup>1</sup>, B.T. Collins<sup>1</sup>, J.W. Lischalk<sup>1</sup>

<sup>1</sup>Georgetown University Hospital, Department of Radiation Medicine, Washington, USA

<sup>2</sup>Georgetown University Hospital, Division of Pulmonary and Critical Care Medicine, Washington, USA

#### Purpose or Objective

Local treatment options for patients with in-field non-small cell lung cancer (NSCLC) recurrence following conventionally fractionated external beam radiation therapy (CF-EBRT) are limited. Stereotactic body radiation therapy (SBRT) is a promising modality to achieve local control, although toxicity remains a concern. We report our experience using this novel technique.

#### Material and Methods

Patients previously treated with high-dose CF-EBRT ( $\geq 59.4$  Gy,  $\leq 3$  Gy/fraction) for non-metastatic NSCLC who underwent salvage SBRT for localized hilar or mediastinal in-field recurrence were included in this analysis. Total SBRT dose was stratified as low ( $<40$  Gy) or high ( $\geq 40$  Gy). The Kaplan-Meier method was used to estimate local control and overall survival. Durable local control was defined as  $\geq 12$  months. Toxicity was scored per the CTC-AE v4.0.

#### Results

Between November 2004 and August 2014, twenty patients were treated with five-fraction robotic SBRT for central in-field recurrence following CF-EBRT. Twelve recurrences were identified within the mediastinum, and eight were identified within the hilum. One-half of recurrences were adenocarcinoma, while 35% of tumors were classified as squamous cell carcinoma. The median interval between the end of CF-EBRT and SBRT was 23.3 months (range: 2.6 - 93.6 months). The median CF-EBRT dose was 63 Gy (range: 59.4 - 75 Gy), the median SBRT dose was 35 Gy (range: 25 - 45 Gy), and the median total equivalent dose in 2 Gy fractions (EQD2) was 116 Gy (range: 91.3 - 136.7 Gy). At a median follow-up of 12 months for all patients

and 37.5 months in surviving patients, the majority of patients (90%) have died. One-year overall survival and local control were 45% and 30% respectively. However, high-dose SBRT was associated with improved local control ( $p < .01$ ), and the one-year overall survival and local control were 77.8% and 66.7% respectively in this subgroup. Furthermore, an increased mean interval between initial treatment and SBRT was observed in patients who achieved durable local control (41.9 vs. 13.4 months,  $p < .01$ ). While treatment was generally well tolerated, there were two cases of radiation pneumonitis (grade 2) and two cases of recurrent laryngeal nerve paralysis (grade 2 and 3), all of which resolved prior to last follow-up or death. No late esophageal toxicity was noted. A patient who received an SBRT dose of 45 Gy (total EQD2: 129.7 Gy) experienced cardiopulmonary death 35 months following treatment which was attributed to radiation toxicity.

#### Conclusion

Although the overall prognosis for patients with in-field central NSCLC recurrences following CF-EBRT remains grim, five-fraction SBRT was well tolerated with an acceptable toxicity profile. Dose escalation above 35 Gy may offer improved local control, however caution is warranted when treating high-risk recurrences with aggressive regimens. Our findings support the efficacy of five-fraction SBRT re-irradiation reported by Trovo et al. [Int J Radiat Oncol Biol Phys. 2014 Apr 1;88(5):1114-9].

#### PO-0669 Models of pulmonary function changes after thoracic radiotherapy

A.G.H. Niezink<sup>1</sup>, O. Chouvalova<sup>1</sup>, J.F. Ubbels<sup>1</sup>, A.J. Van der Wekken<sup>2</sup>, J.A. Langendijk<sup>1</sup>, J. Widder<sup>1</sup>

<sup>1</sup>UMCG University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands

<sup>2</sup>UMCG University Medical Center Groningen, Pulmonary Diseases, Groningen, The Netherlands

#### Purpose or Objective

Reproducibly measuring pulmonary toxicity remains challenging in thoracic radiotherapy. Pulmonary function tests may render objective parameters to assess pulmonary radiation toxicity. Our aim was to establish a model predicting post-radiotherapy forced expiratory volume in one second (FEV1) and diffusion capacity (DLCO).

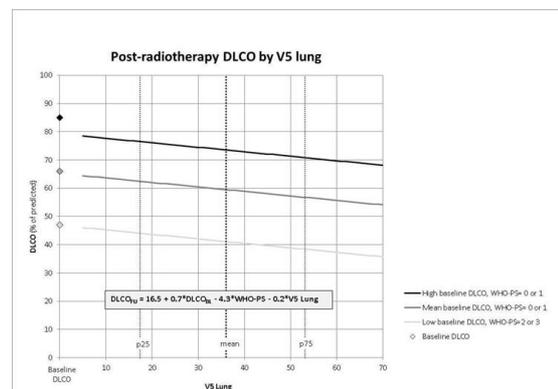

#### Material and Methods

Patients with both baseline and follow-up FEV1 and/or DLCO available were included from a prospective data registry (clinicaltrials.gov). Patient and tumour characteristics as well as dose-volume parameters and survival data were available. Changes in pulmonary function tests were calculated using a paired t-test, and univariable and multivariable linear regression models were built predicting pulmonary function test changes. Multicollinearity was tested using the variance inflation factor and the quality of the models were compared using adjusted R-square and the Akaike information criterion (AIC).

#### Results

Baseline and follow-up FEV1- and DLCO-data were available for 379 and 283 patients, respectively, who were treated between 2013 and 2015 for (N)SCLC stage I-III with (chemo)radiotherapy or SABR. Both FEV1 and DLCO declined significantly after treatment ( $p=0.001$  and  $p<0.001$ ). WHO-performance status (2-3 versus 0-1), chemotherapy (yes versus no), smoking (never versus former or current), technique (SABR versus external beam RT), GTV, lung dose-volume parameters (V5, V20, V30, V40, mean lung dose) and heart volume parameters (V5, V40 and mean heart dose) were significant factors predicting follow-up DLCO after adjustment for baseline DLCO. The best model, based on multivariable linear regression for predicting follow-up DLCO, contains baseline DLCO, WHO-performance status and lung V5 (adjusted R-square=0.71,  $p<0.0001$ ) [Figure 1]. Univariable and multivariable linear regression showed

that baseline FEV1 and lung V40 are significant factors predicting follow-up FEV1 (adjusted R square = 0.21,  $p<0.0001$ ).

**Figure 1:** Baseline DLCO and post-radiotherapy DLCO decline by V5-lung for three different scenarios.

Abbreviations:  $DLCO_{Fi}$  and  $DLCO_{BL}$  = diffusion capacity of carbon monoxide corrected for hemoglobin concentration at follow-up and baseline; WHO-PS=WHO performance score (binary: 2-3 versus 0-1); V5Lung= percentage of lung volume receiving 5Gy or more. p25 / mean / p75 = 25<sup>th</sup> percentile, mean and 75<sup>th</sup> percentile of the V5 Lung.

#### Conclusion

FEV1 and DLCO both decline after thoracic radiotherapy, and DLCO decline is predictable based on a well-performing (adjusted R-square=0.71) linear-regression model including the V5-lung. Limiting post-radiotherapy DLCO decline would require dramatic reduction of low lung dose, which might only be achievable using protons.

#### PO-0670 CPAP ventilation might allow better sparing of normal lung tissue during lung cancer radiotherapy

D. Di Perri<sup>1,2</sup>, A. Colot<sup>2</sup>, A. Barragan<sup>1</sup>, G. Janssens<sup>3</sup>, V. Lacroix<sup>4</sup>, P. Matte<sup>5</sup>, K. Souris<sup>1</sup>, X. Geets<sup>1,2</sup>

<sup>1</sup>Université catholique de Louvain, Center of Molecular Imaging Radiotherapy and Oncology MIRO Institut de Recherche Expérimentale et Clinique IREC, Brussels, Belgium

<sup>2</sup>Cliniques universitaires Saint-Luc, Department of Radiation Oncology, Brussels, Belgium

<sup>3</sup>Ion Beam Applications, Louvain-La-Neuve, Belgium

<sup>4</sup>Cliniques universitaires Saint-Luc, Department of Cardiovascular and Thoracic Surgery, Brussels, Belgium

<sup>5</sup>Cliniques universitaires Saint-Luc, Cardiovascular Intensive Care, Brussels, Belgium

#### Purpose or Objective

Lung toxicity is a major dose-limiting factor in lung cancer radiation therapy (RT). By increasing lung volume, continuous positive airway pressure (CPAP) ventilation during treatment might allow better sparing of the normal lung parenchyma. However, CPAP might also influence respiration-induced tumour motion amplitude and/or tumour position reproducibility. In this study, taking stage I lung cancer patients as a model, we evaluate the effect of CPAP ventilation on lung volume, tumour motion amplitude, and tumour position reproducibility.

#### Material and Methods

Stage I lung cancer patients referred for stereotactic body radiation therapy underwent two 4D-CT scans (with and without CPAP) at two time-points: during the treatment preparation session (T0) and the first day of treatment (T1), resulting in four 4D-CT scans per patient (noCPAP<sub>T0</sub>, CPAP<sub>T0</sub>, noCPAP<sub>T1</sub>, and CPAP<sub>T1</sub>). All images were reconstructed in their time-averaged midposition (MidP) for subsequent analysis. Gross tumour volumes and lungs were delineated on each MidP scan.

First, lung volumes and respiration-induced tumour motion amplitudes were compared between CPAP and noCPAP images at both time-points.

Next, rigid registration based on the bony anatomy was performed between T0 and T1 images (2 registrations per patient: noCPAP<sub>T0</sub>/noCPAP<sub>T1</sub> and CPAP<sub>T0</sub>/CPAP<sub>T1</sub>). Changes in the time-averaged tumour position relative to the anatomy (baseline shifts) were computed in order to assess whether CPAP impacted or not the tumour baseline shift.

#### Results

Patient recruitment is ongoing. Preliminary results based on the first 10 patients (12 tumours) are presented. Mean CPAP was 7 cm H<sub>2</sub>O (range: 6-8). CPAP was well tolerated by all patients.

As expected, CPAP induced a significant increase of lung volumes from 4.62±1.12L to 4.86±1.22L (t(9)=3.41, p<0.01), and from 4.63±0.91L to 4.95±1.03L (t(9)=3.79, p<0.01), at T0 and T1 time-points, respectively.

On the other hand, CPAP had significant impact neither on the tumour motion amplitude (noCPAP<sub>T0</sub>: 11.6±11.0mm vs. CPAP<sub>T0</sub>: 10.8±11.2mm; noCPAP<sub>T1</sub>: 11.5±13.7mm vs. CPAP<sub>T1</sub>: 10.7±11.2mm), nor the tumour baseline shift (noCPAP: 4.1±2.6mm vs. CPAP: 3.6±3.0mm).

#### Conclusion

CPAP is a simple and well-tolerated approach to safely increase the lung volume, without modification of tumour motion amplitude or baseline shift. As a result, CPAP might allow for better sparing of the lungs during RT. Further analysis is warranted to evaluate the actual dosimetric impact of such strategy.

#### PO-0671 Influence of “radioresistant” histologies on SBRT outcome for lung metastases

D. Franceschini<sup>1</sup>, L. Cozzi<sup>1</sup>, F. De Rose<sup>1</sup>, P. Navarra<sup>1</sup>, G.R. D’Agostino<sup>1</sup>, S. Tomatis<sup>1</sup>, C. Franzese<sup>1</sup>, T. Comito<sup>1</sup>, F. Lobefalo<sup>1</sup>, P. Mancosu<sup>1</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

#### Purpose or Objective

Literature data suggest a relevant role of histologies on the outcome of Stereotactic Body Radiation Therapy (SBRT) for oligometastatic disease. We reviewed our experience in the treatment of lung oligometastases from the historically considered “radioresistant” histologies (colorectal, renal, melanoma, sarcoma, hepatocellular and adenoid cystic carcinoma).

#### Material and Methods

Data on oligometastatic patients (less than 5 metastatic sites) treated with SBRT for lung metastases from the above described histologies were analyzed. Primary end point of this study was local control (LC), secondary end points were overall survival (OS) and progression free survival (PFS). Kaplan Meyer analysis was performed. Univariate analysis was done, including many different parameters that could have influenced the outcomes. Toxicity was scored according to CTCAE v. 4.03

#### Results

200 patients treated in our Institution between 2006 and 2015 were included in this analysis. Mean age at SBRT was 66.87 years, (range 22-90). Main characteristics of patients and treatments are showed in table 1.

With a mean follow up of 24.2 months (range 2.2-115.5), 126 (63%) patients were still alive (24 with no evidence of residual disease). In 27 cases (13.5%) patients experienced a local progression of the irradiated lesion during follow up. Local control at 1, 2 and 3 years was 91%, 84.9% and 82%, respectively. Primary histology and the presence of extrapulmonary disease had a significant impact on LC. OS at 1,2 and 3 years was 88.7%, 65.4% and 55%. Primary histology, disease free interval, presence of extrapulmonary disease, number of irradiated lung lesions and age at SBRT all showed a correlation with prognosis at univariate analysis. PFS at 1, 2 and 3 years was 84%, 57.7%

and 47%. Again the presence of extrapulmonary disease and the number of irradiated lung lesions correlated with prognosis. Treatment was well tolerated with no G3-4 acute or late toxicity recorded.

#### Conclusion

In our experience, SBRT remains a valid treatment for lung oligometastases also in the setting of radioresistant histologies. Colorectal metastases showed a higher rate of local relapse. However, the factors mostly influencing prognosis in our experience were the presence of extrapulmonary disease and the number of lung lesions. This means that the selection of “real” oligometastatic patients for local ablative treatments is crucial, in order to have a positive impact on prognosis.

#### PO-0672 Delineation and eye-tracking: How to analyze treatment decisions according physician experience?

F. Legouté<sup>1</sup>, A. Paumier<sup>1</sup>, A. Marquis<sup>1</sup>, J. Blanchecotte<sup>1</sup>, P.J. Mention<sup>2</sup>, P. Gustin<sup>1</sup>, P. Trémoières<sup>1</sup>, D. Caron<sup>1</sup>, C. Cavauro-Ménard<sup>3</sup>

<sup>1</sup>ICO - Paul Papin, Service de Radiothérapie, Angers, France

<sup>2</sup>Centre Hospitalier Universitaire, Médecine nucléaire, Angers, France

<sup>3</sup>Centre Hospitalier Universitaire, Laboratoire Angevin de Recherche en Ingénierie des Systèmes, Angers, France

#### Purpose or Objective

Inter-observer variability (IOV) in target volume delineation is a source of potential dosimetric error in radiation therapy treatment. The main objective of this study was to identify IOV in volume delineation among radiation oncologists in a specialist care center (ICO, Paul Papin, Angers, France) for patients treated for advanced-stage non small-cell lung carcinoma (NSCLC). Then, the potential of automatic segmentation in order to harmonize segmentations was investigated.

#### Material and Methods

Seven observers (six radiation oncologists and one nuclear medicine physician) were recruited. For each of five patients included (twenty-eight preselected cases), GTV (Gross Tumor Volume) were manually and automatically delineated separately with PET registration. To assess the geometric difference between the physicians and automatic segmentations, DICE similarity coefficient (DSC), which measured the geometrical similarity between the two GTVs, was computed. As exploratory aim, eye gaze registrations during an observation task were recorded for ten physicians (residents and specialists).

#### Results

Two PET segmentation methods were used, applying an isocontour at a standardized uptake value (SUV) of 2.5 (GTV2.5) or using fixed thresholds of 41 % (GTV41%) of the maximum intra-tumoural 18FDG activity. The overall mean volume of GTV2.5 was greater than GTV41%, the mean DSC was: 0,70 (± 0,06) versus 0,44 (± 0,18) and the common delineated volume (CDV) was: CDV=0,79 (± 0,13) versus CDV=0,33 (± 0,16). GTV41% led to significant under-contouring errors (-66%), whereas GTV2.5 volume achieved the best predictive value for physicians GTV. The similarity among physicians GTV was suitable in most cases (80%): DSC=0,67 (± 0,08), CDV=0,71 (± 0,13). The feasibility of eye-tracking for cognitive processes analysis in radiotherapy should be taken into account. Rapid and robust data of the eye movement metrics during test tasks helped to define image parameters (colors, contrasts, PET registration, number of slides...) that could influence medical decisions.

Geometrical Similarity Measures									
Physicians versus reference segmentations of GTV									
	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Mean	Min.	Max.	SD
VR - Volume Ratio	0,65	0,94	1,10	1,43	0,90	1,00	0,65	1,43	0,29
DSC - Dice Similarity Coefficient	0,64	0,67	0,58	0,67	0,79	0,67	0,58	0,79	0,08
OV - Overlap volume	0,47	0,50	0,41	0,51	0,65	0,51	0,41	0,65	0,09
CDV - Common Delineated Volume	0,53	0,65	0,60	0,81	0,75	0,67	0,53	0,81	0,11
AV - Additional Volume	0,12	0,29	0,49	0,62	0,15	0,34	0,12	0,62	0,22

Physicians versus automatic segmentations of GTV (isocontour GTV <sub>SUV 2.5</sub> )									
	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Mean	Min.	Max.	SD
VR - Volume Ratio	1,52	1,91	1,08	0,71	1,24	1,29	0,71	1,91	0,45
DSC - Dice Similarity Coefficient	0,71	0,61	0,78	0,67	0,72	0,70	0,61	0,78	0,06
OV - Overlap volume	0,55	0,45	0,64	0,50	0,56	0,54	0,45	0,64	0,07
CDV - Common Delineated Volume	0,90	0,85	0,81	0,57	0,80	0,79	0,57	0,90	0,13
AV - Additional Volume	0,62	1,06	0,27	0,14	0,44	0,51	0,14	1,06	0,36

Table 1 : Comparison of segmentation - Similarity measures.

#### Conclusion

Inter-observer variability in volume delineation can be reduced with the use of PET modality in radiotherapy planning, guidelines and teaching. Eye movement metrics during contours review could be useful for learning sessions in radiation oncology.

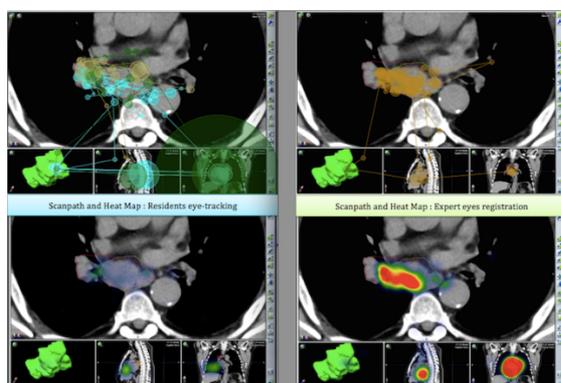

Illustration 1 : Comparison of eye-tracking registrations during segmentation review. Interobservers variability in the identification of anatomical targets and critical structures may explain delineation variability. Greater awareness of this problem, thanks to eye registration ameliorated radiotherapists education.

#### PO-0673 Healing of the bronchial anastomosis and time between neoadjuvant radiochemotherapy and surgery.

A. Koryllos<sup>1</sup>, M. Hammer-Helmig<sup>2</sup>, W. Engel-Riedel<sup>3</sup>, D. Zalepugas<sup>1</sup>, E. Stoelben<sup>1</sup>, C. Ludwig<sup>4</sup>

<sup>1</sup>Krankenhaus Köln-Merheim, Thoracic surgery, Köln-Merheim, Germany

<sup>2</sup>Krankenhaus Köln-Merheim, Radiotherapy, Köln-Merheim, Germany

<sup>3</sup>Krankenhaus Köln-Merheim, Thoracic oncology, Köln-Merheim, Germany

<sup>4</sup>Florence Nightingale Hospital, Thoracic surgery, Düsseldorf, Germany

#### Purpose or Objective

Objective of our retrospective study was to evaluate the healing of the bronchial anastomosis in correlation to the time interval between neoadjuvant high dose chemoradiation (>60Gy) and surgery for non-small-cell-lung cancer patients.

#### Material and Methods

We investigated 485 (2006-2014) patients with NSCLC and bronchus-sleeve-lobectomy in our clinic. n:81 patients had neoadjuvant chemoradiation prior to surgery. n:38 patients had only neoadjuvant chemotherapy and n:366 had noch neoadjuvant therapy. Every bronchial anastomosis was assessed bronchoscopically on the 7th postoperative day. The anastomosis healing was divided in 5 different grades:

Grade I: good healing, without necrosis or fibrin  
Grade II: fokal mucosal necrosis, anastomosis is stable  
Grade III: circular mucosal necrosis and / or ischemia in the depth of the distal bronchus

Grade IV: transmural bronchial necrosis with instability  
Grade V: perforation of the anastomosis, insufficiency

#### Results

The patients with neoadjuvant chemoradiation had in 13,5% a critical anastomosis (Grade IV-V) in comparison to 5.3% for the neoadjuvant chemotherapy group and 6.2% for the non neoadjuvant group.

We investigated the time after the end of chemoradiation and the rate of critical anastomosis using the students t' test. The time between the 6th and 8th postradiation-week was shown to be the optimal time interval for the bronchus healing of the anastomosis (Grade I-II). Patients who were operated before or after the above mentioned time interval had an increased rate of critical bronchus healing (Grade III-IV-V, p:0.003). The postoperative complication rate was 16% after the 42th postradiation day and 34.6% before the 42th postradiation day.

#### Conclusion

- A neoadjuvant radiochemotherapy prior to a bronchial sleeve resection impairs the healing of the anastomosis through a high rate of lokal ischemia.
- On the contrary to the general recommendation, to perform a lung sleeve resection 4 weeks after radiochemotherapy, our data favours an optimal interval of 6 to 8 weeks.
- The neoadjuvant radiochemotherapy raises the complication rate after a bronchial sleeve resection.
- Application and dosis of radiation therapy as a neoadjuvant therapy are handled differently.

#### PO-0674 SABR for lung tumors of 5cm or more: can knowledge-based planning detect high-risk treatment plans?

S. Van 't Hof<sup>1</sup>, M. Dahele<sup>1</sup>, H. Tekatli<sup>1</sup>, A. Delaney<sup>1</sup>, J. Tol<sup>1</sup>, B.J. Slotman<sup>1</sup>, S. Senan<sup>1</sup>, V. W.F.A.R.<sup>1</sup>

<sup>1</sup>VU University Medical Center, radiation oncology, Amsterdam, The Netherlands

#### Purpose or Objective

There is limited data available on the use of stereotactic ablative radiotherapy (SABR) for lung tumors  $\geq 5$ cm. We retrospectively assessed high-risk dosimetric features of treatment plans from patients (pt) with SABR-related toxicity after treatment of such tumors, and studied if dose-volume histogram (DVH) predictions of RapidPlan[Varian Medical Systems], a knowledge based planning system, could identify sub-optimal plans in pt with toxicity.

#### Material and Methods

We retrospectively analyzed outcomes in 54 pt with primary or recurrent non-small cell lung cancer measuring  $\geq 5$  cm, who were treated between 2008-2014 with 5 or 8 fraction SABR using volumetric modulated arc therapy (VMAT). Of these, 15/54(28%) pt had  $\geq G3$  toxicity, most commonly radiation pneumonitis (RP, n=9), fatal lung hemorrhage (LH, n=3) and pleural effusion (n=2). 3/7 pt with interstitial lung disease developed RP. Treatment-related death was considered likely (n=3) or possible (n=8) in 20% of pt. RapidPlan uses a library of different pt plans to generate a model that can be used to identify organs at risk (OARs) which are outliers with respect to the library population. We made a model of all 54 patients and assessed whether pt experiencing toxicity were outliers. A new 'non-toxicity' model was then generated that excluded pt with  $\geq G3$  toxicity, and we assessed if this model could identify any sub-optimal plans in the 15 toxicity pt. This was indicated by at least 1 of the clinical DVHs of relevant OAR (CL, ipsilateral lung [IL], proximal bronchial tree [PBT], esophagus or heart) being located above the DVH prediction range generated by the model.

## Results

RapidPlan DVH analysis of all 54 pt indicated that 4/9 patients with RP had the highest CL doses, and 3 had high IL doses (figure). 2/3 pt developing LH had the highest volumes of PBT receiving high doses >40Gy and Dmax>70Gy. For the 15 pt who developed  $\geq$ G3toxicity, the non-toxicity model showed that 5 of their plans had up to 2.5x higher CL mean dose than predicted, all these pt had RP. For 3 patients, the clinical plans had higher maximum PBT doses(70-82Gy) than the model, 2 of these pt developed LH and 1 post-SABR atelectasis. For the other 8 pt, clinical plans were judged to be good.

## Conclusion

A RapidPlan model identified the potential for plan improvements in nearly 50% of pt undergoing SABR for lung tumors  $\geq$ 5cm, who developed G $\geq$ 3 toxicity. Such plan quality checks are important for this type of higher-risk treatment. They could also help to improve quality of clinical studies.

### PO-0675 Evaluating commercial delineation software in routine clinical practice: analyzing time and quality.

T. Lustberg<sup>1</sup>, W. Van Elmpt<sup>1</sup>, J. Van der Stoep<sup>1</sup>, J. Van Soest<sup>1</sup>, M. Gooding<sup>2</sup>, A. Dekker<sup>1</sup>

<sup>1</sup>Department of Radiation Oncology MAASTRO- GROW, School for Oncology and Developmental Biology- Maastricht University Medical Centre, Maastricht, The Netherlands

<sup>2</sup>Mirada Medical Ltd, Science and Medical Technology, Oxford, United Kingdom

#### Purpose or Objective

Delineation of organs at risk (OAR) and target volumes is vital for treatment planning in radiation oncology. This process is very time consuming and quality of the delineation depends on the skill level of the observer. Automatic delineation software is commercially available but rarely used in clinical practice. The aim of this study to evaluate the quality of automatic delineation of OARs and the time that could potentially be gained by commissioning automatic delineation software for clinical use.

#### Material and Methods

Twenty stage I-III NSCLC patients were selected from routine clinical practice and their CT scans were used to delineate OARs. The following OARs were delineated: left lung, right lung, heart, spinal cord, esophagus, mediastinum, left brachial plexus, right brachial plexus and carina. Each OAR was delineated 3 times, once manually by a technician, once using commercial atlas-based delineation software and once by adjusting the software generated delineation to match clinical guidelines by the same technician. The time needed to perform manual delineation and the adjustments to the automatically generated delineation were recorded. The atlas was derived from 10 stage I NSCLC patients collected from clinical practice. To compare the delineations, the maximum Hausdorff-distance was computed for each patient for each OAR in each CT slice between the manual delineation and the atlas, and between the manual delineation and the adjusted atlas. The mean of these maximums was calculated and presented as a boxplot for each OAR for the two comparisons together with the time required to perform the delineations.

#### Results

Delineation of the left lung, heart, esophagus, left and right brachial plexus and carina was quicker if the automatically generated delineation only needed minor adjustments (Figure 1B). The right lung, spinal cord and mediastinum show a time gain on average, but not for all cases (Figure 1B). The adjustment of the delineation created by the automatic delineation software resulted in a smaller mean maximum Hausdorff-distance for all OARs compared to the manual delineation (Figure 1A), but there was still a difference to the manual delineation.

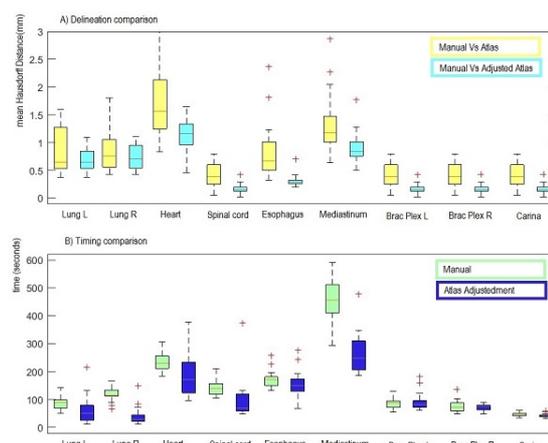

Figure 1: A) Delineation mean maximum Hausdorff-distance for each OAR. B) Time needed to delineate the OARs.

## Conclusion

Based on the results above, we conclude that automatically generated delineations save time for the majority of the cases and after minor adjustment meet clinical guidelines. Further investigation is needed into the quality of the automatic delineation software and inter-observer variability.

### PO-0676 outcomes of synchronous and metachronous pulmonary oligometastasis treated with SBRT

A. Sharma<sup>1</sup>, M. Duijm<sup>1</sup>, E. Oomen-de Hoop<sup>2</sup>, J. Aerts<sup>3</sup>, C. Verhoef<sup>4</sup>, M. Hoogeman<sup>1</sup>, J. Nuytens<sup>1</sup>

<sup>1</sup>Erasmus MC-Daniel den Hoed Cancer Center- Rotterdam- The Netherlands, Department of Radiation Oncology, Rotterdam, The Netherlands

<sup>2</sup>Erasmus MC-Daniel den Hoed Cancer Center- Rotterdam- The Netherlands, Department of Medical Oncology, Rotterdam, The Netherlands

<sup>3</sup>Erasmus MC-Daniel den Hoed Cancer Center- Rotterdam- The Netherlands, Department of Pulmonology, Rotterdam, The Netherlands

<sup>4</sup>Erasmus MC-Daniel den Hoed Cancer Center- Rotterdam- The Netherlands, Department of Surgical Oncology, Rotterdam, The Netherlands

#### Purpose or Objective

The purpose of our study was to evaluate overall survival (OS) and identify factors associated with OS in patients diagnosed with inoperable pulmonary oligometastatic tumors.

#### Material and Methods

Between 2005 to 2015, 326 inoperable pulmonary oligometastasis in 206 patients with  $\leq$  5 metastasis in no more than two organs were treated with stereotactic body radiotherapy (SBRT). Synchronous metastases were defined as presence of metastases within 5 months of diagnosis of primary tumor, otherwise they were assigned to the metachronous group. Risk adapted SBRT was used to treat peripheral lung metastasis with 51 Gy or 54Gy or 60 Gy in 3 fractions or 30Gy in single fraction, central tumors received 50 Gy-55Gy in 5 fractions or 60Gy in 8 fractions and metastasis located close to esophagus or in mediastinum received 6x8 Gy, 7x7Gy or 8x7Gy. Dose to PTV was prescribed at the 70-90% isodose line (median 78%), covering at least 95% of PTV. OS was calculated from date of first SBRT session to date of death or date of last follow up for alive patients. The following variables were assessed for prognosis: age, gender, primary site, metachronous versus synchronous tumors, metastatic burden in body, metastatic burden in lungs, presence of extra pulmonary metastasis, delivery of pre SBRT chemotherapy, disease free interval, biological

equivalent dose (BED), fractionation schedule of SBRT, size of largest metastasis, development of local recurrence after SBRT, delay in initiation of SBRT for > 4 months, presence of comorbidity, location of lung metastasis: central versus peripheral and location of metastasis in lower lobes versus other locations. Primary tumors included 117 colorectal tumors, 36 lung cancers, 11 melanoma, 10 sarcoma, 7 breast carcinoma and 25 tumors were from other sites. Median follow up was 23 months (range 1-100).

#### Results

Median survival in the entire cohort was 32 months. The 2, 3, and 5 year OS rate was 63%, 47%, and 30%, respectively. On univariate analysis, synchronous metastasis and colorectal primary site were significantly associated with improved OS. On multivariate analysis, presence of synchronous metastasis was the only factor independently associated with better OS, adjusted HR=0.57 (95% CI 0.36-0.89). On further categorization, there was significant difference ( $p = 0.048$ ) among synchronous liver metastasis that later developed pulmonary oligorecurrence (median OS 63 months), synchronous pulmonary oligometastasis (Median OS 40 months) and metachronous pulmonary oligometastasis (Median OS 29 months). Local control for the entire group was at 2, 3, and 5 year was 83%, 79% and 73%, respectively. Less than 2% of patients experienced grade 3 acute or late toxicities.

#### Conclusion

SBRT to pulmonary oligometastasis resulted in a 5 year survival of 30%. Synchronous metastases were independently associated with better OS.

#### Prognostic factors on multivariate analysis

	Covariate	HR 95%CI	p-value
1	<b>Primary location</b> o Colorectal (117) o Others (89)	0.69 (0.47-1.02)	0.06
2	<b>Timing of metastasis</b> o Synchronous (60) o Metachronous (146)	0.57 (0.36-0.89)	0.01
3	<b>Pre SBRT Chemotherapy</b> o Yes (100) o No (106)	0.89 (0.60-1.33)	0.57
4	<b>Tumor size</b> o < 3 (144) o ≥ 3 (62)	0.73 (0.50-1.07)	0.73
5	<b>Local control of metastasis</b> o No (33) o Yes (173)	0.79 (0.47-1.33)	0.38

#### PO-0677 Vero SBRT for early stage lung cancer: a phase II trial with dynamic tracking in selected lesions

C. Collen<sup>1</sup>, R. Van den Begin<sup>1</sup>, M. Boussaer<sup>1</sup>, B. Engels<sup>1</sup>, J. Dhont<sup>1</sup>, M. Burghelée<sup>1</sup>, G. Storme<sup>1</sup>, M. De Ridder<sup>1</sup>  
<sup>1</sup>Universitair Ziekenhuis Brussel, Department of Radiation Oncology, Brussels, Belgium

#### Purpose or Objective

To evaluate outcome and toxicity after Vero stereotactic body radiotherapy (SBRT) in early stage lung cancer, and feasibility of dynamic tumor tracking (DTT) with a single fiducial marker in this population.

#### Material and Methods

A prospective trial (NCT 02224547) was started to evaluate SBRT on a gimbaled linac (Vero) for early stage non-small cell lung cancer (T1-3N0M0).

Patients were eligible for DTT if tumor motion on pretreatment 4DCT exceeded 8 mm. A single fiducial marker (Visicoil, IBA) was implanted percutaneously in or near the tumor. Otherwise an internal target volume (ITV) approach was applied, combining GTV's of all 10 respiratory phases on 4DCT. For both approaches, an PTV-margin of 5mm was used from GTV (DTT) or ITV.

#### Results

A total of 73 lesions were treated in 68 patients between Feb 2013 and Feb 2016. Median follow-up amounted to 11 months (2-28 months). Histology was available in 64% of patients, of which 66% were adenocarcinomas and 30% squamous cell carcinomas.

Delivered dose schedules were 48Gy/4 fractions (n= 59), 51Gy/3 fractions (n= 9), 60Gy/8 fractions (n= 5). In 12% of lesions DTT was used. Reasons for omitting DTT were: poor baseline pulmonary function (n=7), deep location not allowing visicoil insertion (n=3), presence of a visicoil in the other lung (n=1) and history of prior pneumothorax (n=1). Mean treatment time for a DTT session was 28.6 minutes, comparable with the mean ITV treatment time (29.5min). Use of DTT resulted in an average PTV reduction of 32% (10-48%) compared to corresponding ITV plans ( $p=0.004$ ).

Two patients needed a temporary chest tube for a small pneumothorax after marker implantation, but no radiotherapy toxicity was observed in the patients treated with DTT. In the ITV group, only 1 patient experienced a grade 2 radiation pneumonitis and 2 patients presented with a COPD exacerbation in the weeks following RT.

In DTT lesions, our results also demonstrated a significant variability in respiration-induced tumor motion: mean craniocaudal motion measured on 4DCT was 13.1mm ± 3.5mm, while during treatment delivery a mean maximum value of 18.9mm ± 8.0mm was observed ( $p=0.04$ ).

One-year Kaplan-Meier outcome analysis shows a local control of 97%, a progression-free survival of 84% and an overall survival of 91%, with no differences between the DTT and ITV groups.

#### Conclusion

Vero SBRT demonstrated excellent outcomes and limited toxicity in early stage lung cancer. Compared to ITV, DTT offered a smaller irradiated volume and allowed adaption to intrafraction movements not covered by 4DCT. DTT by use of a single marker is feasible in primary lung cancer patients, but the need for an implanted marker limits applicability in this population.

#### PO-0678 Health-related quality of life reporting in lung cancer trials: A methodological appraisal.

<sup>2</sup>Ghent University Hospital, Pneumology, Ghent, Belgium

<sup>3</sup>Ghent University Hospital, Medical Psychology, Ghent, Belgium

<sup>4</sup>Ghent University Hospital, Radiation Oncology and Experimental Cancer Research, Ghent, Belgium

#### Purpose or Objective

Health-related quality of life (HRQoL) is an important outcome measurement in locally-advanced non-small cell lung cancer (LA-NSCLC) patients, often presenting considerable comorbidities, hence in clinical trials assessing the role of radiotherapy in this patient population. In addition to the correct execution of these HRQoL studies, it is equally important that the HRQoL data, retrieved from these clinical trials, are reported in a standardized manner, as to draw correct conclusions to support treatment decisions. The aim of this study is to examine the methodological quality of HRQoL reporting in a series of studies retrieved through a systematic review of the literature.

#### Material and Methods

A literature search was performed in PubMed, Embase and Web of Science, with the following inclusion criteria: English language, clinical trial, LA-NSCLC patient population, HRQoL assessment, full-text availability and published between 2005 - 2015. The methodological quality of each study was assessed by the standard checklist for the quality of HRQoL reporting in cancer clinical trials [Efficace et al. J Clin Oncol 2003;21:3502-

11]. This checklist consists of minimum criteria that cancer clinical trials should incorporate to provide reliable HRQoL outcomes. The 11 items are categorized into conceptual, measurement, methodology and interpretation domains. All included studies were scored for adherence to the checklist. Each item that met the criteria received 1 point with a maximum of 11 points. Outcomes range from 'probably robust' (8 - 11) to 'very limited' (0 - 4).

### Results

From 2005-2015, out of 225 publications reviewed, 16 LANSCLC clinical trials (represented in 25 articles) incorporated HRQoL endpoints. Radiotherapy was evaluated, in combination with surgery, systemic therapy or with medication aiming to reduce adverse radiotherapy effects, and impact on HRQoL was assessed.

None of the studies had a methodological quality below 4 ('very limited'). The average quality score of HRQoL reporting in all studies was 7.875, with 13 studies considered to be of high quality ('probably robust'), versus 3 studies of average quality ('limited robust'). No studies fulfilled all criteria.

Particularly, details on a priori hypothesis (n=16) and details on missing data (n=9) were missing. Additionally, clinical significance rather than simple statistical significance was often unaddressed (n=13).

### Conclusion

Qualitative reporting of HRQoL outcomes in scientific articles is a crucial aspect to adequately interpret HRQoL results, with the aim to facilitate daily clinical decision making and support therapy policies. In this review, only the minority of clinical trials fulfilled the minimum criteria for adequate HRQoL reporting. Due to the limited methodological quality and especially the fact that certain crucial aspects of HRQoL data reporting are lacking in the studies, good interpretation of HRQoL data remains difficult.

Poster: Clinical track: Upper GI (oesophagus, stomach, pancreas, liver)

### PO-0679 Role of Chemoradiation Therapy as an Initial Treatment for Esophageal Carcinoma: A Meta-Analysis

M. MA<sup>1</sup>, X.S. Gao<sup>1</sup>, X. Gu<sup>1</sup>

<sup>1</sup>Peking University First Hospital, Radiation Oncology, Beijing, China

#### Purpose or Objective

This study was aimed to compare the therapeutic efficacy of definitive chemoradiotherapy(dCRT) and esophagectomy as initial treatment for resectable oesophageal cancer by meta-analysis.

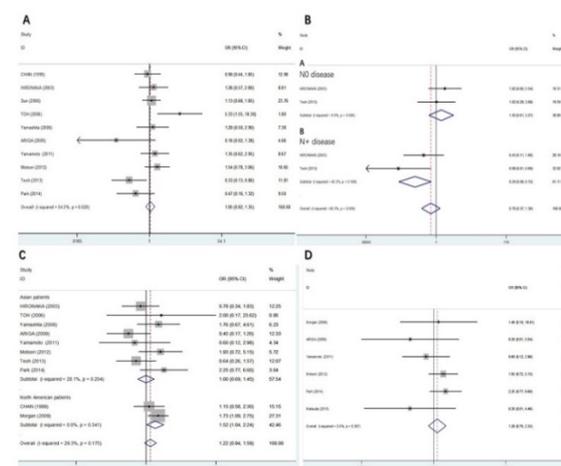

#### Material and Methods

Databases of Pubmed and Web of Science were systematically searched to identify relevant studies. Combined odds ratio(OR) and 95% confidential interval (CI) were computed to assess the comparison effects.

#### Results

A total of thirteen studies (2 RCTs and 11 non-RCTs) with 2071 patients were identified, consisting of the dCRT arm (n=869) and surgery arm (n=1202). There was no statistically significant benefit on 1-year (OR 1.23, 0.67 to 2.24; P=0.50), 3-year (OR 1.022, 0.795 to 1.312; P=0.87) and 5-year overall survival (OR 1.05, 0.82 to 1.35; P = 0.68) for surgery compared with dCRT(Fig.A). As for disease-free survival (DFS), dCRT is relatively inferior than surgery in short term result (OR for 3-year PFS: 1.37, 1.03 to 1.82; p=0.03) but is equivocal with surgery in long-term result (OR for 5-year PFS: 1.06, 0.79 to 1.42; p=0.70). Additionally, patients with positive lymph node could benefit on 5-year OS from dCRT (OR 0.238, 0.079 to 0.717; P=0.011)(Fig.B). Subgroup analysis for Asian and North American patients indicates that surgery is superior on 2-

year OS as compared with dCRT among North American patients(Fig.C). OR of 2-year OS for Asian patients and North American patients were 1.001, (95% CI 0.693 to 1.446; P=0.996) and 1.552, (95% CI 1.035 to 2.238; P=0.033), respectively. Furthermore, we analysed 5 studies consisting a total of 1202 patients which focused on stage I esophageal cancer, no statistically difference was found between dCRT and surgery on 2-year OS (OR 1.279, 0.704 to 2.35; p=0.419)(Fig.D).

### Conclusion

In summary, therapeutic effects of dCRT as the initial treatment is similar to that of surgery on long-term survivals and it remains equivalent with surgical resection for patients with stage I esophageal cancer. Patients with positive lymph node may benefit from dCRT. More randomized trials are needed to confirm our results.

### Purpose or Objective

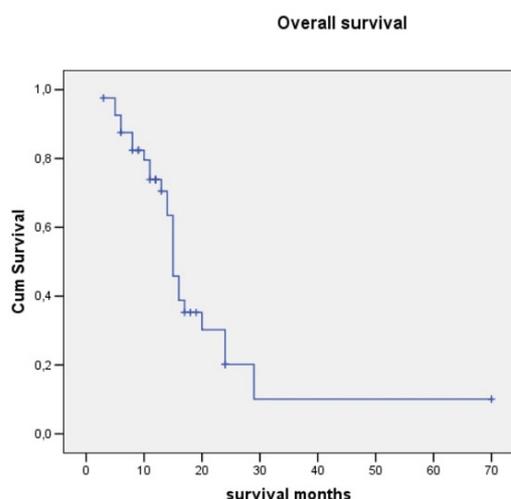

Pancreatic carcinoma is projected to become the 2<sup>nd</sup> leading cause of cancer mortality by 2030. At diagnosis, 30% of patients (pts) present with LAPC involving adjacent structures such as blood vessels, not usually removed because of risk of postoperative complications. Patients with LAPC have an intermediate prognosis between resectable and metastatic pts (median OS ranging from 5 to 11 months). LAPC cause significant pain, obstruction, and other morbidity due to direct extension of the primary tumor. Currently, a treatment option for LAPC is radiochemotherapy (RCT). SBRT is one emerging technique for treatment of LAPC, used by specialized centers to deliver a higher biologically effective dose of precisely targeted radiation in a short course of therapy. Conformity and rapid dose fall-off associated with SBRT offer the potential for dose escalation. We retrospectively review the experience of 5 different centers treating LAPC with SBRT.

### Material and Methods

We included 41 pts with LAPC, undergoing SBRT +/- chemotherapy (CT) with multiagent CT regimens. Exclusion criteria were metastatic disease and radical surgical treatment. Only palliative surgery was admitted. Median dose and median fractionation dose for SBRT were 25 Gy (range: 4-45) and 6 Gy (range: 4-22), respectively. Toxicity was evaluated by CTCAE.4 scale. Overall survival (OS) was estimated and compared by Kaplan-Meier and log-rank methods, respectively.

### Results

We analyzed 41 pts (M/F: 21/20; median age: 71, range: 36-89). Median, 6 months, 1-year, and 2-year OS were: 15 months (range 13.5-16.4), 87.6%, 73.9%, 20.1%, respectively. At univariate analysis a better prognosis was recorded for pts with tumor located at the tail ( $p=0.046$ ), with a histologic grade 2 tumor ( $p<0.001$ ), treated with adjuvant CT ( $p=0.036$ ). There was a trend for improved OS in pts with cT3 tumor stage ( $p=0.085$ ), and in pts treated with biliary stent ( $p=0.066$ ). Nodal stage was not significantly related to OS. Incidence of gastrointestinal (GI) G1-G2 acute toxicity was 40%. Only one case of G3 GI acute toxicity (4%) and only one of G3 GI late toxicity (4.5%) were registered.

### Conclusion

Fractionated SBRT +/- CT results in tolerable acute and minimal late GI toxicity and warrants OS comparable to current standard treatment (RCT). Future studies should incorporate SBRT with more aggressive multiagent CT to optimize pts outcomes.

### PO-0681 SBRT VS standard chemoradiation in locally advanced pancreatic cancer (LAPC): a case-control study

<sup>13</sup>Azienda Ospedaliera San Gerardo, Radiotherapy Unit, Monza, Italy

<sup>14</sup>Fondazione del Piemonte per l'Oncologia FPO- IRCCS Candiolo, Department of Radiotherapy, Torino, Italy

### Purpose or Objective

In the last decades a treatment option for LAPC has been represented by chemoradiation (CRT), however SBRT is considered an emerging option for these patients (pts). Unfortunately, comparison between these two treatment techniques, in terms of toxicity and pts outcome, are lacking. Therefore, aim of this multicentric study is to compare toxicity and outcome between two cohorts of pts treated with SBRT or CRT.

### Material and Methods

A case-control study was performed. Forty-two patients were enrolled (M/F: 25/17; median age: 68.5; range: 36-89). Pts in the two groups were matched according to: age  $</\geq$  65years, tumor diameter  $</\geq$  3 cm, cT, cN, neoadjuvant chemotherapy, adjuvant chemotherapy. Median dose in pts treated with SBRT was 25 Gy (range: 12-30) and median dose in pts treated with CRT was 54 Gy (range: 30-63). Toxicity was evaluated by CTCAE v4.0 scale and survival curves were assessed by Kaplan-Meier method.

### Results

The incidence of GI  $\geq$  G2 acute toxicity was 31% in the SBRT-arm and 37.5% in the CRT-arm, while the incidence of hematological  $\geq$  G2 acute toxicity was 6.3% in both groups. Late GI bleeding was recorded in 6.3% and 8.3% pts treated with SBRT or CRT, respectively. One-year, 2-year and median survival were 50.3%, 30.2% and 13 months (range: 7.3-18.7) in pts treated with SBRT, respectively. One-year, 2-year and median survival were 51.8%, 33.8% and 16 months (range: 7.5-24.5) in pts treated with CRT, respectively.

### Conclusion

This analysis showed that SBRT compared to CRT, is correlated with a similar incidence of adverse effects and with a comparable survival.

**PO-0682 Re-irradiation for oligo-recurrence from esophageal cancer with radiotherapy history**  
K. Jingu<sup>1</sup>, Y. Niibe<sup>2</sup>, H. Yamashita<sup>3</sup>, K. Katsui<sup>4</sup>, T. Matsumoto<sup>5</sup>, T. Nishina<sup>5</sup>, A. Terahara<sup>2</sup>

<sup>1</sup>Tohoku University Graduate School of Medicine, Department of Radiation Oncology, Sendai, Japan

<sup>2</sup>Toho University Omori Medical Center, Department of Radiology, Tokyo, Japan

<sup>3</sup>the University of Tokyo, Department of Radiology, Tokyo, Japan

<sup>4</sup>Okayama University Graduate School of Medicine-Dentistry and Pharmaceutical Sciences, Department of Proton Beam Therapy, Okayama, Japan

<sup>5</sup>Shikoku Cancer Center, Department of Gastrointestinal Medicine, Ehime, Japan

#### Purpose or Objective

to reveal the effectiveness and toxicity of re-irradiation for oligo-recurrence in lymph nodes from esophageal cancer treated by definitive radiotherapy or by surgery with additional radiotherapy

#### Material and Methods

We reviewed retrospectively 248 patients treated with (chemo)radiotherapy for oligo-recurrence in lymph nodes from esophageal cancer in 5 Japanese high-volume centers between 2000 and 2015. Of those 248 patients, 33 patients in whom re-irradiation was performed were enrolled in this study, and the results for patients in whom re-irradiation was performed were compared with the results for other patients. Survival estimates were calculated using the Kaplan-Meier method from the first date of radiotherapy for oligo-recurrence. Toxicity was graded according to the Common Terminology Criteria for Adverse Events (CTCAE v4.0).

#### Results

Median maximum lymph node diameter (MLD) was 22 mm (range, 5-106 mm). Median total radiation dose was 60 Gy (range, 18-70 Gy). Eleven of the 33 patients with a past irradiation history underwent re-irradiation by a hyperfractionation method. Therefore, the median calculated biological effective dose using the LQ model with  $\alpha/\beta = 10$  Gy (BED10) in patients in whom re-irradiation was performed was significantly lower than the median BED10 in others (Mann-Whitney U test,  $p < 0.001$ ). There were no other significant differences than BED10 in patients' characteristics between the group with past irradiation history and the group without past irradiation history. Twenty-nine in the 33 patients performed concurrent chemotherapy with re-irradiation. The median observation period in patients in whom re-irradiation was performed was 14.9 months. The 3-year and 5-year overall survival rates in the 33 patients with a past irradiation history were 17.8% and 0%, respectively, with a median survival period of 16.0 months (95% C.I. = 7.0-17.6). The 3-year and 5-year overall survival rates in 215 patients without past irradiation history were 36.1% and 27.0%, respectively, with a median survival period of 21.5 months (95% C.I. = 16.4-26.6). There was a significant difference between the survival rates in the two groups (log-rank test,  $p = 0.016$ ). The 3-year irradiated field control rates in the 33 patients with a past irradiation history and in 215 patients without past irradiation history were 21.0% and 58.9%, respectively. There was a significant difference between irradiated field control rates in the two groups (log-rank test,  $p = 0.001$ ). Grade 5 toxicity occurred in 4 of 248 patients. Treatment related death, which was gastric hemorrhage, occurred in a patient in whom re-irradiation was performed.

#### Conclusion

Results of radiotherapy with or without chemotherapy for oligo-recurrence in lymph nodes from esophageal cancer in patients with a past irradiation history were insufficient compared with results for patients without a past irradiation history.

**PO-0683 Impact of the radiation dose on hepatic perfusion evaluated using mebrofenin liver scintigraphy**  
B. De Bari<sup>1</sup>, T. Breuneval<sup>2</sup>, M. Zeverino<sup>3</sup>, S. Godin<sup>2</sup>, L. Deantonio<sup>4</sup>, J. Prior<sup>5</sup>, J. Bourhis<sup>2</sup>, R. Moeckli<sup>3</sup>, M. Ozsahin<sup>2</sup>

<sup>1</sup>Hôpital Univ. Jean Minjot, Radiation Oncology, Besançon, France

<sup>2</sup>Centre Hospitalier Universitaire Vaudois, Radiation Oncology, Lausanne, Switzerland

<sup>3</sup>Centre Hospitalier Universitaire Vaudois, Medical Physics, Lausanne, Switzerland

<sup>4</sup>University Hospital "Maggiore della Carità", Radiation Oncology, Novara, Italy

<sup>5</sup>Centre Hospitalier Universitaire Vaudois, Nuclear Medicine, Lausanne, Switzerland

#### Purpose or Objective

We aimed at evaluating the impact of the dose of radiotherapy (RT) on hepatic function (HF). HF variations were evaluated by integrating mebrofenin liver scintigraphy (HBS) before and after RT in patients treated with stereotactic body RT (SBRT) on liver.

#### Material and Methods

Between 04/2015 and 09/2015, 6 patients with primary (3 patients) or secondary liver cancers (3 patients) were treated with SBRT (3x15 Gy: 4 pts, 5x8 Gy: 1 pt or 6x5 Gy 1 pt). All patients received an HBS to assess HF before and three months after RT. HBS was co-registered with the planning phase of the simulation CT-scanner. The biological equivalent dose of 2 Gy per fraction (EQD2) was calculated for each patient with an  $\alpha / \beta = 10$  Gy (acute toxicity). Isodoses (5, 10, 20, 30, 40, 50, 60, 70, 80, and 90 Gy) were drawn. Then, we calculated the activity (MBq) in these volumes before and after treatment.

#### Results

Linear regression analysis showed a significant reduction in HF at three months, which was proportional to the increase of the radiation dose ( $p = 0.0009$ , Figure 1). Our analysis showed a reduction of 0.78% of the HF for each delivered gray. Even with the limits of the small population of this study, the linear equation showed a predictive value in predicting the loss of HF/Gy of 96% ( $R^2 = 0.9605$ ).

#### Conclusion

To the best of our knowledge, this is the first evidence available in the literature showing the utility of HBS in evaluating the variation of HF after SBRT. This analysis shows a functional decrease, which is proportional to the delivered dose, thus predicting the resulting acute toxicity. These functional based approaches could improve our knowledge about the response of the OARs to the radiation, and should be prospectively evaluated.

**PO-0684 Opposite pharmacokinetics of sorafenib modulates by liver irradiation - concurrent versus sequential**

C.H. Hsieh<sup>1</sup>, L.Y. Wang<sup>2</sup>, T.H. Tsai<sup>3</sup>, Y.J. Chen<sup>4</sup>

<sup>1</sup>Far Eastern Memorial Hospital, Radiation Oncology, Taipei, Taiwan

<sup>2</sup>National Taiwan University, School and Graduate Institute of Physical Therapy, Taipei, Taiwan

<sup>3</sup>National Yang-Ming University, Institute of Traditional Medicine, Taipei, Taiwan

<sup>4</sup>Mackay Memorial Hospital, Radiation Oncology, Taipei, Taiwan

#### Purpose or Objective

Sorafenib is a multi-kinase inhibitor that demonstrated a significant improved survival of patients with hepatocellular carcinoma (HCC). The efficacy of radiotherapy (RT) concurrent or sequential with sorafenib in unresectable HCC patients has better effects than single agent. However, the effects of local RT on sorafenib in the plasma system remain unclear. Here, we evaluate the

influence of liver irradiation on the pharmacokinetics (PK) of sorafenib using rats as an experimental model.

#### Material and Methods

Free-moving rat model was used in the current study. Image-guided RT with 2 Gy was delivered to the whole liver of Sprague-Dawley rats. The rats were feeding with sorafenib at 40 mg/kg after RT 1 hour (concurrent model) or post RT 24 hours (sequential model) for the plasma system. The experimental animals were randomized to the sham RT (0 Gy with sorafenib), concurrent group and sequential group, respectively. The PK of sorafenib in the plasma system was calculated. Each group's data was collected from six to eight rats

#### Results

Compared to the sham-irradiated controls, the area under the concentration versus time curve (AUC) of sorafenib (40 mg/kg) was increased by 132% in concurrent group (719 versus 1669 min\*ug/mL,  $p = 0.046$ ). In contrast, the AUC of sorafenib was decreased by 59% in sequential group (719 versus 297 min\*ug/mL,  $p = 0.036$ ). Compared with the concurrent and sequential group, there was a statistically significant difference between both groups (1669 vs 297 min\*ug/mL,  $p = 0.012$ ). There were no differences at T<sub>max</sub> and C<sub>max</sub> between groups.

#### Conclusion

A whole liver RT modulates the systemic PK of sorafenib of the rats. Interestingly, the AUC of sorafenib is increased at concurrent with RT and decreased in sequential model. The RT-PK phenomena are not only noted in chemotherapy agents but also in target therapy drug. The RT-PK phenomena are worth further investigation.

#### PO-0685 The value of postoperative adjuvant therapy for pT2-3 esophageal cancer treated by radical resection

S. Zhu<sup>1</sup>, L. Shuguang<sup>2</sup>, L. Youmei<sup>2</sup>, S. Wenbin<sup>3</sup>, L. Juan<sup>2</sup>, L. Zhukun<sup>2</sup>, S. Jingwei<sup>2</sup>, L. Teng<sup>2</sup>

<sup>1</sup>Fourth Hospital of Hebei Medical University, Department Radiation Oncology, Sijiazhuang- Hebei, China

<sup>2</sup>Fourth Hospital of Hebei Medical University, Department of Radiation Oncology, Shijiazhuang, China

<sup>3</sup>Fourth Hospital of Hebei Medical University, Department of Radiation Oncology, Shijiazhuang, China

#### Purpose or Objective

The aim of this study was to analyze failure modalities and evaluate efficacy of postoperative treatment of pT<sub>2-3</sub>N<sub>0</sub>M<sub>0</sub> esophageal squamous cell carcinoma. The endpoint was to find an efficient way of postoperative adjuvant therapy for this type esophageal cancer.

#### Material and Methods

The clinical data of 702 patients with pT<sub>2-3</sub>N<sub>0</sub>M<sub>0</sub> esophageal squamous cell carcinoma who received radical resection in our hospital from 2007 to 2010 were retrospectively analyzed. Male 482, female 220, median age 60 years. All did not receive any preoperative treatment, were performed with curative esophagectomy included removal of primary tumor and draining lymph nodes, and 343 cases surgical alone. Postoperative adjuvant chemotherapy 279 cases, four courses with an interval of 4 weeks with 80 mg/m<sup>2</sup> of cisplatin on day 1 and 600 mg/m<sup>2</sup>/day of 5-fluorouracil given by continuous intravenous infusion on day1-4. Postoperative prophylactic radiotherapy alone 40 cases with 50.4-59.4Gy of external beam radiation at 1.8-2.0Gy per fraction, and postoperative chemoradiotherapy 40 cases. Analysis of prognostic survival was determined by Kaplan-Meier method and checked by the log-rank test. Cox proportional hazard model was used for multivariate analysis.

#### Results

The overall failure rate of all patients was 48.4%, and surgical alone 54.8%, postoperative chemotherapy alone 42.7%, radiotherapy alone 42.5% and chemoradiotherapy 40.0% ( $\chi^2=11.021, P=0.012$ ). The local regional failure rate

of all patients was 37.5%, and surgical alone 41.7%, postoperative chemotherapy alone 35.5%, radiotherapy alone 27.5% and chemoradiotherapy 25.0% ( $\chi^2=7.430, P=0.059$ ). In 343 cases surgical alone, the overall failure rate 58.5% and the local regional failure rate 46.2% of stage T<sub>3</sub> was significantly higher than T<sub>2</sub> stage 42.4% ( $\chi^2=11.235, P=0.001$ ) and 33.1% ( $\chi^2=5.524, P=0.019$ ). The local regional failure rate 68.0% of thoracic-upper carcinoma was higher than that of thoracic-middle or lower 35.7% ( $\chi^2=17.101, P=0.001$ ). Compared with surgery alone, postoperative chemotherapy, radiotherapy and chemoradiotherapy all improved the 5-year local control rate. Postoperative chemotherapy and chemoradiotherapy significantly increased 5-year PFS ( $P=0.001, 0.024$ ), and 5-year OS rates ( $P=0.001, 0.025$ ). Multivariate analysis revealed that the location, stage of pathology, postoperative adjuvant therapy were independently prognostic factors.

#### Conclusion

The failure rate was high with pT<sub>2-3</sub>N<sub>0</sub>M<sub>0</sub> thoracic esophageal squamous carcinoma after radical esophagectomy alone. Postoperative adjuvant therapy could obviously improve local control, postoperative chemotherapy and chemoradiotherapy could improve PFS and OS.

#### PO-0686 Perfusion imaging of colorectal liver metastases treated with bevacizumab and SBRT

H. Chung<sup>1</sup>, J. Detsky<sup>1</sup>, P. Munoz-Schuffenegger<sup>1</sup>, L. Milot<sup>1</sup>, W. Chu<sup>1</sup>, C. MacDonald<sup>1</sup>, Y. Ko<sup>1</sup>

<sup>1</sup>Odette Cancer Centre - Sunnybrook Health Science, Radiation Oncology, North York- Toronto, Canada

#### Purpose or Objective

SBRT is an accepted alternative to surgical resection of liver metastases from colorectal cancer (CRC). The addition of bevacizumab holds promise as a radiosensitizer and is an active agent in metastatic CRC. There is increasing interest in the use of imaging biomarkers as a method to evaluate and predict response to treatment. Dynamic contrast-enhanced CT (DCE-CT) measures perfusion parameters and has been used to evaluate primary CRC tumors and liver metastases. Contrast-enhanced ultrasound (CEUS) is another method using a microbubble contrast agent to characterize vascular properties of liver lesions. The purpose of this prospective study was to evaluate the temporal evolution of perfusion parameters in CRC liver metastases treated with SBRT and bevacizumab.

#### Material and Methods

Patients with 1 - 3 liver metastases from CRC were prospectively enrolled in this trial. Bevacizumab was administered for 2 doses 2 weeks apart, with the second dose within 48 hours of starting SBRT. SBRT was delivered in 5 fractions. Functional imaging including DCE-CT and CEUS were performed at three time points: at baseline, just prior to SBRT, and within 7 days post-SBRT. DCE-CT output parameters were permeability surface area (PSA), blood volume (BV), and blood flow (BF). CEUS images were used to calculate a quantitative perfusion index (PI). Patients were then followed with physical and imaging assessments every three months.

#### Results

The trial enrolled 11 patients, with 1 dropout. Six patients had a complete set of DCE-CT images (one patient had 2 of 3 scans). Of the 7 evaluable patients, 3, 3 and 1 had evidence of local, distant and simultaneous failure, respectively. Mean PSA and BV decreased in 5 of 6 patients from baseline to post-bevacizumab (-17% ± 37%,  $p=0.22$  and -25% ± 33%,  $p=0.1$  respectively), while BF was not affected. BF and PSA was reduced in all 7 patients pre to post-SBRT (-47% ± 22%,  $p=0.07$  and -40% ± 21%,  $p=0.18$ , respectively) while BV remained stable (0.4% ± 22%,  $p=0.8$ ). CEUS was attempted in 10 patients but adequate image acquisition was only technically feasible in 4. CEUS PI significantly decreased from baseline to post-

bevacizumab ( $-77\% \pm 22\%$ ,  $p=0.048$ ) and had a smaller further decrease after SBRT ( $-34\% \pm 34\%$ ,  $p=0.18$ ). With limited number of patients, there were no differences in changes in any perfusion parameters between patients with and without local failure.

#### Conclusion

To our knowledge, this is the first study in humans that evaluates quantitative CT and US perfusion measures of CRC liver metastases treated with bevacizumab and SBRT. Changes in different measures of perfusion can be detected with these imaging biomarkers. Further study in a larger cohort are needed to better understand temporal changes in perfusion and determine if these changes can be used to predict response to treatment.

#### PO-0687 Spleen dosimetry are associated with lymphopenia during radiotherapy for hepatocellular carcinoma

Q. Zhao<sup>1</sup>, R. Wang<sup>1</sup>, T. Liu<sup>2</sup>, J. Yue<sup>1</sup>

<sup>1</sup>Shandong Cancer Hospital affiliated to Shandong University, Department of radiation oncology, Jinan, China

<sup>2</sup>Shandong Cancer Hospital affiliated to Shandong University, Department of radiology, Jinan, China

#### Purpose or Objective

The decline of peripheral blood lymphocytes induced by radiation would lessen the antitumor effect of the immune response, which might cause immunosuppressive. We aim to investigate the correlation between the decline of peripheral blood lymphocyte and spleen irradiation dose in patients with hepatocellular carcinoma (HCC) during radiotherapy (RT).

#### Material and Methods

Subjects were 59 patients with HCC who had received RT from 2005 to 2014. Min ALC (minimum value of absolute counts for peripheral blood lymphocyte) was collected from the routine workup for each patient before and weekly during RT. Spleen dose-volume variables including mean spleen dose (MSD) and  $V_{n\text{Gy}}$  ( $V_n$ , the percentage of organ volume receiving  $\geq n$  Gy) were calculated from Eclipse Treatment Planning. Potential associations between dosimetric variables and Min ALC were assessed by regression analysis.

#### Results

White blood cells, neutrophil cells, lymphocyte cells and monocyte cells were all declined during RT (all  $P < 0.001$ ). Min ALC were correlated with spleen dosimetric parameters but the other blood cells did not. Min ALC were correlated with MSD ( $P = 0.005$ ), spleen  $V_{5\text{Gy}}$  ( $P = 0.001$ ), spleen  $V_{25\text{Gy}}$  ( $P = 0.026$ ) and spleen  $V_{30\text{Gy}}$  ( $P = 0.018$ ). Controlling patients karnofsky performance status, gender, age, Child-grades and total dose, multivariate linear regression model showed that only spleen  $V_{5\text{Gy}}$  were correlated with the decline of Min ALC (HR= 1.504,  $P = 0.003$ ).

#### Conclusion

Higher spleen irradiation dose were significantly correlated with lower Min ALC during RT for HCC. Maximum sparing for spleen irradiation during RT is recommended to preserve peripheral blood lymphocytes, which may potentially decrease immunosuppression.

#### PO-0688 Unresectable hepatic oligorecurrence SBRT of 55 lesion: Adequate dose coverage improves local control

P. Berkovic<sup>1</sup>, A. Gulyban<sup>1</sup>, P. Viet Nguyen<sup>1</sup>, D. Dechambre<sup>1</sup>, P. Martinive<sup>1</sup>, N. Jansen<sup>1</sup>, F. Lakosi<sup>2</sup>, L. January<sup>3</sup>, P.A. Coucke<sup>1</sup>

<sup>1</sup>C.H.U. - Sart Tilman, Radiotherapy department, Liège, Belgium

<sup>2</sup>Health Science Center- University of Kaposvar, Radiation Oncology, Kaposvar, Hungary

<sup>3</sup>University of Debrecen - Medical Center, Oncology Clinic, Debrecen, Hungary

#### Purpose or Objective

To analyze local control (LC), liver and distant progression free survival (liver PFS, DFS), overall survival (OS) and toxicity in a cohort of patients treated by stereotactic body radiotherapy (SBRT) with fiducial tracking for oligorecurrent liver lesions (Niibe Y, Hayakawa K. Jpn J Clin Oncol. 2010 Feb) from primary colorectal (55.6%), breast (20.4%) and other (24.0%) origins. Influence of lesion size, systemic treatment, physical and biological effective dose (BED with  $\alpha/B = 10$ ) were also evaluated.

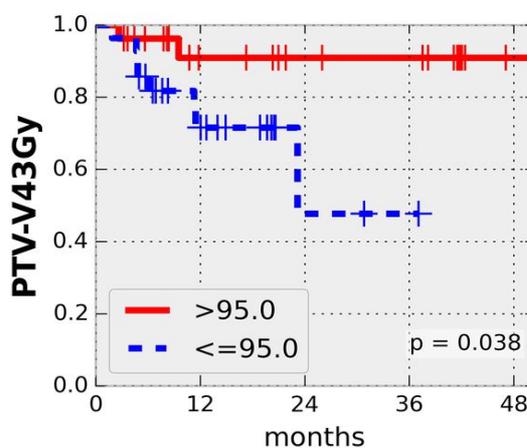

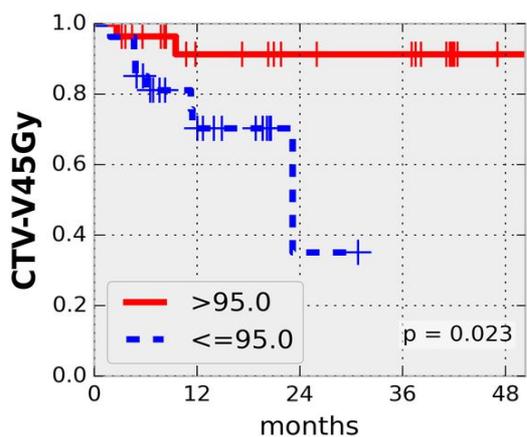

#### Material and Methods

Hepatic oligorecurrent patients ineligible for surgery and with sufficient liver function were included in this study. During the treatment preparation, 18FDG-PET-CT and liver MRI were used to confirm the oligorecurrent nature of the disease and to delineate the gross target volume (GTV), which were expanded to CTV and with a tracking-based margin to the planning target volume (PTV). Intended prescribed dose was 45Gy in 3 fractions on the 80% isodose. Organs at risk dose constraints were respected, if required at the cost of altered fractionation and/or lowered target coverage. All treatments were executed with the CyberKnife platform using fiducials tracking. Patient and treatment data were processed using Kaplan-Meier method and log-rank test for survival analysis.

#### Results

Between 2010 and 2015, 42 patients (55 lesions) were irradiated. The mean CTV and PTV were 67.5 cc and 96.8 cc. Treatments were delivered 3fr/week in a median of three fractions to a PTV median dose of 54.6 Gy. The mean CTV and PTV D98% were 51.5 Gy and 51.2Gy. After median follow-up of 18.9 months, the 1 and 2-year LC/liver PFS/DFS/OS were 81.3/55/62.4/86.9% and 76.3/42.3/52/78.3% respectively. Performance status ( $p=0.005$ ) and histology ( $p=0.040$ ) had significant impact on LC, while age ( $>65y$ ,  $p=0.074$ ) marginally influenced liver PFS. Physical dose of  $V45\text{Gy}>95\%$  for CTV and  $V43\text{Gy}>95\%$  for PTV showed statistically significant effect on the LC (figure 1), similarly to  $gEUD(a=30)>45$  Gy ( $p=0.015$ ),  $BED-V105\text{Gy}>96\%$  ( $p=0.045$ ) and  $gEUD(a=30)>40\text{Gy}$  ( $p=0.040$ ),  $BED85\text{Gy}>98\%$  ( $p=0.037$ ) for CTV and PTV respectively. Acute grade 3 gastrointestinal (GI) and late grade 2 GI and fatigue toxicity were found in 5% and 11% patients.

**Figure 1:** Kaplan-Meier curves and log-rank test for LC with target dose coverage parameters.

### Conclusion

Our favorable survival and toxicity data support the potential paradigm shift whereby the use of SBRT in oligorecurrent liver disease could benefit patients with unresectable or resectable liver metastases. Our study shows the importance of adequate dose coverage and proposes a prescription threshold dose of 45Gy on CTV and 43Gy on PTV to at least 95% of both volumes to significantly improve LC.

### PO-0689 clinical target volume in biliary carcinoma: a systematic review of pathological studies

I. Marinelli<sup>1</sup>, L. Fuccio<sup>2</sup>, A. Guido<sup>3</sup>, A. Farioli<sup>2</sup>, V. Panni<sup>3</sup>, G. Ercolani<sup>2</sup>, G. Brandi<sup>2</sup>, S. Cammelli<sup>3</sup>, A. <sup>2</sup>S.Orsola-Malpighi University Hospital, Department of Medical and Surgical Sciences, Bologna, Italy

<sup>3</sup>S.Orsola-Malpighi University Hospital, Division of Radiation Oncology, Bologna, Italy

<sup>4</sup>Fondazione Giovanni Paolo II, Division of Radiation Oncology, Campobasso, Italy

<sup>5</sup>Sacro Cuore Catholic University, Division of Radiation Oncology, Rome, Italy

### Purpose or Objective

Radiation therapy is a treatment option in both adjuvant and advanced biliary tract cancer. However, lymph nodes target volume delineation guidelines are lacking. Only generic indications are available but without specific recommendations for different primary tumor location (intrahepatic, extrahepatic biliary tract or gallbladder cancer). The aim of this study was to systematically

analyze available literature data to provide guidelines on lymph nodes target volume delineation in unresectable biliary tumor.

### Material and Methods

The systematic search of the electronic databases was performed from 1990 through July 2016. Primary outcome measure was the rate of lymph node involvement according to the primary biliary tumor location. Sites with  $\geq 5\%$  incidence of nodal metastases were considered in the clinical target volume for radiotherapy planning.

### Results

Thirteen studies were included. The most frequent site of metastatic lymph nodes in intrahepatic biliary tree carcinoma was along the hepatoduodenal ligament [38.7%, 95%CI=31.0-47.0%]. Other frequently involved lymph nodes were the retroportal [61.1%, 95%CI=50.7-70.6%], the hilar [16.9%, 95%CI=13.2-21.4%] and the nodes along the common hepatic artery [17.0%, 95%CI=8.2-31.9%]. In extrahepatic biliary tree cancer, the most frequently involved lymph nodes were along the hepatoduodenal ligament [40.3%, 95%CI=32.4-48.8%] and the pericholedochal nodes [42.7%, 95%CI=33.8-52.1%]. Other commonly involved nodal regions included retroportal lymph nodes [30.9%, 95%CI=23.0-40.1%], pancreaticoduodenal anterior and posterior nodes [30.1%, 95%CI=12.2-57.1%], paraaortic nodes [15.2%, 95%CI=8.0-27.0%] and nodes along the common hepatic artery [19.7%, 95%CI=11.8-31.0%]. The most common site of metastases in gallbladder cancer were the nodes along cystic duct [23%, 95% CI=16.6-30.8%], the pericholedochal [25.2%, 95%CI=18.6-33.2%] and the retroportal nodes [17.1%, 95% CI=11.6-24.5%].

### Conclusion

Biliary tract cancer has a high propensity for regional lymphatic metastases. An evidence-based nodal target definition of biliary tract cancer based on primary tumor location was proposed.

### PO-0690 An initial result of carbon-ion radiotherapy for metastatic liver tumors.

S. Toyama<sup>1</sup>, H. Suefuji<sup>1</sup>, M. Shinoto<sup>1</sup>, K. Matsumoto<sup>1</sup>, Y. Shioyama<sup>1</sup>

<sup>1</sup>Saga Himat Foundation, Ion Beam Therapy Center, Tosu, Japan

### Purpose or Objective

To evaluate an efficacy and a safety of carbon-ion radiotherapy (C-ion RT) for metastatic liver tumors (MLT).

### Material and Methods

We retrospectively analyzed 22 patients with MLT received the C-ion RT from April 2014 to March 2016. Male and female was 14 and 8, respectively. The median age at the treatment was 68 years old (range; 48-91). Regarding to the primary site, there were 14 patients with colorectal cancer (CRC) and the remaining 8 patients with the different malignancies. The median maximum diameter was 51 mm (range; 10-109). Seventeen patients had a singular disease and 5 had multiple ones. Out of all the patients, 17 patients received 60 Gy (RBE) for 4 fractions in 1 week, and 5 did 60 Gy (RBE) for 12 fractions in 3 weeks; the 12-fraction schedule was chosen when the tumors were close to the organs at risk: the digestive tract, the main trunk of the portal vein, the inferior vena cava, the common bile duct or the skin. The patients were fixed by thermoplastic fixation devices, and the tumor was irradiated from multiple directions with a respiratory synchronization. The overall survival (OS) and the local control rate (LCR) were calculated by a Kaplan-Meier method, and the statistical difference was evaluated by a log-rank test. Adverse events were classified according to the Common Terminology Criteria for Adverse Events version 4.0.

### Results

The median observation duration was 383 days (range; 131-875), the 1-year OS and LCR were 90% and 79%, respectively. At the time of this analysis, 19 patients were

alive, 3 died due to the cancer progression of the tumors except ones received the C-ion RT, 5 developed a local recurrence. The 1-year OS of the CRC group and the non-CRC group, the larger tumor group (> 50mm) and the smaller tumor group, the 4-fraction group and the 12-fraction group were 100% and 75% (p value=0.16), 81 % and 100% (p=0.078), 94% and 80% (p=0.030), respectively. The 1-year LCR of those were 70% and 100% (p=0.13), 56% and 100% (p=0.080), 80 % and 75% (p=0.95), respectively. No Grade 3 and worse adverse reactions were observed. No patients experienced radiation-induced liver disease.

#### Conclusion

It is suggested the C-ion RT for MLT is an effective and safe treatment even in large MLT. This is the initial result thus it is necessary to analyze more number of patients and for longer observation period.

#### PO-0691 Whole-body total lesion glycolysis is an independent predictor of thoracic esophageal cancer

N. Takahashi<sup>1</sup>, R. Umezawa<sup>1</sup>, K. Takanami<sup>2</sup>, Y. Takaya<sup>1</sup>, Y. Ishikawa<sup>1</sup>, M. Kozumi<sup>1</sup>, K. Takeda<sup>1</sup>, N. Kadoya<sup>1</sup>, K. Jingu<sup>1</sup>

<sup>1</sup>Tohoku University Graduate School of Medicine, Radiation oncology, Sendai, Japan

<sup>2</sup>Tohoku University Graduate School of Medicine, Diagnostic Radiology, Sendai, Japan

#### Purpose or Objective

The purpose of this study was to determine whether pretreatment whole-body metabolic tumor volume (MTV<sub>WB</sub>) and total lesion glycolysis (TLG<sub>WB</sub>) are associated with outcomes in patients with thoracic esophageal squamous cell carcinoma treated by definitive chemoradiotherapy (dCRT).

#### Material and Methods

We retrospectively reviewed patients with stage II or III thoracic esophageal squamous cell carcinoma who underwent FDG-PET/CT within 60 days before dCRT at our institution between January 2005 and August 2013. Patients who had massive pneumonia caused by perforation of the tumor at FDG-PET/CT were excluded. Ninety patients were enrolled in this study. We calculated all lesion's SUV<sub>max</sub>, SUV<sub>mean</sub>, MTV and TLG by using MIM maestro™ ver. 6.6.1 (MIM Software Inc. USA). TLG was calculated from MTV × SUV<sub>mean</sub>. TLG<sub>WB</sub> was sum of TLG of primary lesion (TLG<sub>pri</sub>) and lymph-node lesions. MTV<sub>WB</sub> was sum of MTV of primary lesion (MTV<sub>pri</sub>) and lymph-node lesions. Survival estimates were calculated using the Kaplan-Meier method from the first date of dCRT. Predictors were analyzed using Cox's hazards model.

#### Results

The median follow-up period was 64.2 months for survivors. Three-year overall survival (OS), local control (LC) and progression free survival (PFS) were 52.0 %, 42.7 % and 35.2 %, respectively. In univariate analysis, T stage (p = 0.019, hazard ratio [HR]: 1.73), MTV<sub>pri</sub> ≥ median (p = 0.025, HR: 1.95), TLG<sub>pri</sub> ≥ median (p = 0.035, HR: 1.88), MTV<sub>WB</sub> ≥ median (p = 0.004, HR: 2.38) and TLG<sub>WB</sub> ≥ median (p = 0.007, HR = 2.25) were significant unfavorable predictors of OS. TLG<sub>pri</sub> ≥ median (p = 0.016, HR: 1.99), MTV<sub>WB</sub> ≥ median (p = 0.030, HR: 1.86) and TLG<sub>WB</sub> ≥ median (p = 0.012, HR = 2.05) were significant unfavorable predictors of LC. T stage (p = 0.007, HR: 1.65), 1 cycle of concurrent chemotherapy (p = 0.021, HR: 2.14), SUV<sub>max</sub> (p = 0.033, HR: 1.76), SUV<sub>mean</sub> (p = 0.019, HR: 1.85), TLG<sub>pri</sub> ≥ median (p = 0.009, HR: 1.99), MTV<sub>WB</sub> ≥ median (p = 0.006, HR: 2.06) and TLG<sub>WB</sub> ≥ median (p = 0.002, HR = 2.26) were significant unfavorable predictors of PFS. Factors with p < 0.1 in univariate analysis were included in multivariate analysis. In multivariate analysis, MTV<sub>WB</sub> ≥ median (p = 0.016, HR: 2.34) and TLG<sub>WB</sub> ≥ median (p = 0.013, HR = 2.34) were significant unfavorable predictors of OS. TLG<sub>pri</sub> ≥ median (p = 0.023, HR: 2.17), MTV<sub>WB</sub> ≥ median (p = 0.020, HR: 2.18) and TLG<sub>WB</sub> ≥ median (p = 0.007, HR = 2.50) were significant unfavorable predictors of LC. MTV<sub>pri</sub> ≥ median

(p = 0.0495, HR: 1.83), TLG<sub>pri</sub> ≥ median (p = 0.024, HR: 2.01), MTV<sub>WB</sub> ≥ median (p = 0.003, HR: 2.44) and TLG<sub>WB</sub> ≥ median (p = 0.008, HR = 2.79) were significant unfavorable predictors of PFS. SUV<sub>max</sub> was not selected as a predictor of OS, LC or PFS.

#### Conclusion

In multivariate analysis, MTV<sub>WB</sub> and TLG<sub>WB</sub> were independent predictors for OS, LC and PFS. In addition, the hazard ratio of TLG<sub>WB</sub> was highest for OS, LC and PFS in multivariate analysis. TLG<sub>WB</sub> is one of best predictor in patients with stage II or III thoracic esophageal squamous cell carcinoma treated by dCRT.

#### PO-0692 The role of adjuvant chemoradiotherapy in patients with common bile duct cancer after R1 resection

S.W. Kim<sup>1</sup>, S.H. Kang<sup>2</sup>, M. Chun<sup>1</sup>, Y.T. Oh<sup>1</sup>, O.K. Noh<sup>1</sup>, H. Jang<sup>3</sup>, S. Jo<sup>4</sup>

<sup>1</sup>Ajou University School of Medicine, Radiation Oncology, Suwon City, Korea Republic of

<sup>2</sup>Ilsan Paik Hospital- Inje University School of Medicine, Radiation Oncology, Goyang, Korea Republic of

<sup>3</sup>Dongguk University School of Medicine Gyeongju Hospital, Radiation Oncology, Gyeongju, Korea Republic of

<sup>4</sup>Haeundae Paik Hospital- Inje University School of Medicine, Radiation Oncology, Busan, Korea Republic of

#### Purpose or Objective

We investigated the role of adjuvant radiotherapy combined with chemotherapy (CRT) in patients with microscopically positive resection margin after curative resection for extrahepatic cholangiocarcinoma (EHCC).

#### Material and Methods

We included 87 patients with EHCC treated with curative surgery at our institution. Of the 35 patients with microscopically positive resection margin, 22 patients received adjuvant chemoradiotherapy (R1 + CRT group) and 13 received adjuvant radiotherapy alone (R1 + XRT group). We compared treatment outcomes between these patients and 52 patients with negative resection margin who did not receive any adjuvant treatments (S group).

#### Results

Patients in R1 + CRT and R1 + XRT group were younger than those in S group and pathologically positive lymph node was more common in R1 + CRT group. During the median follow-up period of 26 months, the 2-year disease-free survival rates were 55.8% for S group, 54.5% for R1 + CRT group and 9.6% for R1 + XRT group. There was no significant difference in disease-free survival rate between S group and R1 + CRT group (p = 0.225). In contrast, R1 + XRT group had significantly inferior 2-year disease-free survival rate compared with S group (p = 0.013) and R1 + CRT group (p = 0.008). In multivariate analysis, R1 + XRT group had a trend for increased risk of recurrence (HR, 2.049; 95% CI, 0.930-4.514; p = 0.075). The 2-year overall survival rates were 61.5% for S group, 54.5% for R1 + CRT group and 15.4% for R1 + XRT group. There was significant difference in 2-year overall survival rate between R1 + XRT group versus S group (p < 0.001) and R1 + CRT group (p = 0.021). Multivariate analysis revealed that R1 + XRT group had an increased risk of mortality (HR, 2.497; 95% CI, 1.242-5.019; p = 0.010).

#### Conclusion

Adjuvant CRT after R1 resection showed equivalent survival rates to R0 resection without adjuvant treatments, whereas adjuvant radiotherapy alone after R1 resection had significantly worse survival outcomes compared with other groups. As adjuvant CRT had superior outcomes to adjuvant radiotherapy alone in patients with R1 resection, adjuvant CRT might be a better option for controlling microscopic residual EHCC.

<sup>9</sup>Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRST- IRCCS, Radiotherapy Department, Ravenna, Italy

#### Purpose or Objective

Hepatocellular carcinoma (HCC) is a leading cause of cancer death. Experience with stereotactic body radiotherapy (SBRT) for HCC is increasing due to the possibility to deliver ablative doses in few fractions with low rates of toxicity and excellent local control. Furthermore, SBRT can be used in patients unsuitable for other conventional therapies. However, the better way to treat HCC with SBRT has not been defined. Therefore, aim of this analysis was to systematically review the available literature to evaluate treatment and other factors correlated with patients outcome.

#### Material and Methods

Literature search was made in PubMed database. We also checked the references list of five reviews published in the last two year. We included randomized trials or not, excluding case series with less than 8 patients, case reports, and reviews. Only studies published in English were included in this review. The primary endpoint was duration of survival in overall population after SBRT measured by 1-year and 2-year survival rate. Secondary endpoint was toxicity (acute or late) reported as grade  $\geq 3$  toxicity rate.

#### Results

Through the evaluation of titles and abstracts, we selected 70 records. At the end of the screening we included 22 papers fulfilling the inclusion criteria amounting to 1093 patients. All selected studies were published from 2006 to 2015. One-year OS ranged from 23% to 100% (median 75%) while 2-year OS from 23.3% to 100% (median 59%). Twenty records reported toxicity.  $G \geq 3$  toxicity range was 0%-37% (median: 13%). We performed a meta-regression analysis in order to explore whether 1y-OS is correlated to the value of some explanatory variables (Table 1). We observed a direct association between 1-y OS and median age ( $p=0.004$ ,  $R^2=0.31$ ) as well as the presence of solitary lesion ( $p=0.033$ ,  $R^2=0.43$ ), vascular invasion ( $p<0.001$  with  $R^2=0.87$ ) and median tumor size ( $p<0.001$  and  $R^2=0.69$ ). Considering the variables related to treatment, EQD<sub>2</sub> ( $\alpha/\beta=10$ ) affected 1-y OS significantly ( $p<0.001$  and  $R^2=0.72$ ).

**Table 1.** Meta-regression of 1-year survival. Estimates from univariate random effects models.

	N studies	Beta	(95%CI)	P	R <sup>2</sup> analog <sup>d</sup>

Abbreviations: CTP, Child-Turcotte-Pugh score; EQD<sub>2</sub>, equivalent dose in 2 Gy fractions; TACE, transarterial chemoembolization.

<sup>d</sup>R<sup>2</sup> analog describe the proportion of between-study variance explained by the covariate of interest.

#### Conclusion

Use of higher EQD<sub>2</sub> is correlated with improved outcome in HCC treated with SBRT. Prognosis is worse in patients with older age, multiple lesions, larger tumor, and vascular invasion.

### PO-0694 Post-operative Intensity-Modulated hypofractionated Image-Guided Radiotherapy in cholangiocarcinoma

N. Slim<sup>1</sup>, B. Noris Chiorda<sup>1</sup>, C. Gumina<sup>1</sup>, G.M. Cattaneo<sup>2</sup>, M. Reni<sup>3</sup>, L. Aldrighetti<sup>4</sup>, A.M. Deli<sup>1</sup>, F. Zerbetto<sup>1</sup>, P. Passoni<sup>1</sup>, N. Di Muzio<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute- Milano- Italy, Radiotherapy, Milan, Italy

<sup>2</sup>San Raffaele Scientific Institute- Milano- Italy, Medical Physics, Milan, Italy

<sup>3</sup>San Raffaele Scientific Institute- Milano- Italy, Medical Oncology, Milan, Italy

<sup>4</sup>San Raffaele Scientific Institute- Milano- Italy, Surgery, Milan, Italy

#### Purpose or Objective

To evaluate feasibility of post-operative intensity modulated hypofractionated image-guided radiotherapy (Hypo-IGRT) in patients (pts) with extra-hepatic cholangiocarcinoma.

Background: we previously tested Hypo- IGRT in pts with locally advanced pancreatic cancer. The dose of 44.25 Gy in 15 fractions to the whole tumor was feasible and safe (Int J Radiation Oncol Biol Phys, Vol. 87, No. 5, pp. 1000-1006, 2013).

#### Material and Methods

After surgery, pts with histologically proven perihilar and distal cholangiocarcinoma were eligible for this study. Simulation consisted in contrast-enhanced computed tomography (c-e-CT) or <sup>18</sup>F-FDG CT/PET (CTPET) or when possible four-dimensional c-e CT (4D c-e CT), Clinical Target Volume (CTV) consisted in surgical bed and regional lymph-nodes. In Klatskin tumor CTV was defined as the section liver margin and hepatic hilum; the R1 site was identified combining pathological data and surgeon indications. In distal cholangiocarcinoma CTV consisted in the new anastomosis between the biliary tree and the small intestine. The planning target volume (PTV) was defined with standard margins, except in pts who underwent 4D c-e CT where a margin of 5 mm was added isotropically at CTV.

Median delivered dose of RT was 44.25 Gy (40 Gy-48 Gy) in 15 fractions on PTV and was delivered with Volumetric

Modulated Arc-Therapy or Tomotherapy. Concomitant chemotherapy (Cht) consisted in oral capecitabine at a dose of 1250 mg/m<sup>2</sup>/day.

#### Results

From 11/2010 to 09/2016, 24 pts were treated. Characteristics of pts: median age: 69 years (45-83), 12 M and 12 F, median KPS: 90. Eighteen pts (75%) had Klatskin disease, 6 pts (25%) had common and distal bile duct disease (3: intra-pancreatic). Treatment: All pts underwent surgery (19 pts R1, 5 pts R0: 3 pts were N+, 1 pt pT4 and 1 pt had hilary infiltration). Only 3 pts were previously treated with neoadjuvant Cht (2 pts: GEM+CDDP, 1 pt: capecitabine). Four pts received adjuvant Cht (1 pt: PEXG, 1 pt: GEM, 1 pt: GEMOX, 1pt: CDDP+GEM). Seventeen pts (71%) received Cht concomitant to RT. Ten pts (42%) underwent c-e CT and CTPET simulation, 6 pts (25%) underwent 4D c-e CT and 8 pts (33%) only c-e CT. Eight pts (50%) were PET positive. Acute Toxicity: all pts were evaluable. Most toxicities were G1-G2: 2 pts (8%) experienced diarrhea, 14 (58%) nausea/vomiting, 9 (37%) abdominal pain, 3 (12%) cholangitis, 2 (8%) gastric ulcer. Only one pt developed gastro-duodenitis G3. Late toxicity: 20/24 pts were evaluable, no toxicity ≥ G2 occurred. Responses: 23/25 pts were evaluable. Nine pts (39%) had PD (3 local and distant progression, 5 only distant and 1 only local progression). Median TTLP and OS, evaluated using the Kaplan-Meier method, were calculated from start of RT and resulted 31.0, 34.5 months respectively.

#### Conclusion

Adjuvant Hypo-IGRT delivering 44.25 Gy in 15 fractions concomitant to oral capecitabine in patients with extra-hepatic cholangiocarcinoma is feasible with a good toxicity profile.

#### PO-0695 Neo-adjuvant chemoradiotherapy and resection for esophageal cancer: outcomes in daily practice.

E.S.H. Portier<sup>1</sup>, K.J. Neelis<sup>1</sup>, M. Fiocco<sup>2</sup>, W.O. De Steur<sup>3</sup>, A.M.J. Langers<sup>4</sup>, J.J. Boonstra<sup>4</sup>, H.H. Hartgrink<sup>5</sup>, M. Slingerland<sup>6</sup>, F.P. Peters<sup>1</sup>

<sup>3</sup>Leiden University Medical Center, Department of Surgery, Leiden, The Netherlands

<sup>4</sup>Leiden University Medical Center, Department of Gastroenterology, Leiden, The Netherlands

<sup>5</sup>Leiden University Medical Center, Department of Surgery, Leiden, The Netherlands

<sup>6</sup>Leiden University Medical Center, Department of Medical Oncology, Leiden, The Netherlands

#### Purpose or Objective

Since the first results of the Dutch randomized CROSS trial (van Hagen et al, 2012), neo-adjuvant chemoradiotherapy (CRT) followed by resection for primary resectable non-metastatic esophageal cancer (EC) was implemented as standard curative treatment in the Netherlands. We evaluated clinical outcomes with this treatment in daily practice.

#### Material and Methods

We retrospectively studied consecutive patients treated for primary resectable non-metastatic EC between May 2010 and December 2015 at our institution. Patients were included if they started treatment with the intention to undergo neo-adjuvant CRT followed by resection. Patients with neuro-endocrine histology and treatment for recurrent EC were excluded. Treatment consisted of external beam radiotherapy (23 fractions of 1,8 Gy), 5 weekly courses of carboplatin (AUC 2) and paclitaxel (50 mg/m<sup>2</sup>) and transthoracic or transhiatal resection. We recorded patient and tumour characteristics, survival,

disease progression, acute and late toxicity/complications (CTCAE version 4, Clavien-Dindo classification) and send quality of life (QOL) questionnaires (EORTC QLQ-C30 and QLQ-OES18, EQ-5D-5L and a self-developed questionnaire on dumping complaints) to surviving patients.

#### Results

One hundred forty-five patients were included (table 1). Median follow-up was 43 months (95% CI 32.6-53.4 months). All patients completed radiotherapy as intended and 86.9% received the full chemotherapy regimen. One hundred thirty-seven patients underwent surgery, with a resection of the tumour in 130 patients (90%). One patient had a microscopically irradical resection (<1%). Median overall survival (OS) was 35 months (95% CI 29.8-40.2 months, fig. 1). Median progression free survival (PFS) was 30 months (95% CI 19.7-40.3 months). Three-year OS and PFS were 49.6% (95% CI 40.4-58.8%) and 45.6% (95% CI 36.6-54.6%) respectively. Three year cumulative incidence for locoregional progression and distant metastasis were 31% (95% CI 22.9-39.1%) and 45.3% (95% CI 36.5-54.19%). In univariate analysis, tube feeding before start of neo-adjuvant chemoradiotherapy, dysphagia score (0-1 versus 2-4), length of the tumour, clinical T-stage, number of chemotherapy cycles, pathological response (pT- and pN-stage) and extracapsular extension of lymphnode metastases were significantly associated with OS. Tube feeding and extracapsular extension were significant in multivariate analysis. Toxicity and QOL are currently analysed, results will be available at presentation.

1. Ten missing values

## Conclusion

Neo-adjuvant CRT followed by resection for primary resectable non-metastatic EC in daily practice results in a 3 yr OS of 49.6% and PFS of 45.6% compared to 58% and 51% within the CROSS-trial. The lower rates can be attributed to less favourable patient- and tumour characteristics in our study population. Toxicity and QOL results will be presented.

## PO-0696 A predictive nomogram for decision support for patients with pancreatic neuroendocrine tumors

A. Jochems<sup>1</sup>, R. Baum<sup>2</sup>, A. Singh<sup>2</sup>, K. Niepsch<sup>2</sup>, H. Kulkarni<sup>2</sup>, P. Lambin<sup>1</sup>

<sup>1</sup>Maastricht Clinic, Radiotherapy, Maastricht, The Netherlands

<sup>2</sup>Zentralklinik Bad Berka, Nuclear medicine, Bad Berka, Germany

## Purpose or Objective

Pancreatic neuroendocrine neoplasm (NEN) patients may benefit from peptide receptor radionuclide therapy (PRRT). To facilitate treatment decision support for individual patients, accurate statistical models to predict overall survival (OS) are required.

## Material and Methods

414 patients with pancreatic NEN treated at censored, country censored, were included in this study. Variables included in the analysis were age, Karnofsky performance status (KPS), grade of tumor, weight loss (at least 5kg) before PRRT (over last 6 months), presence of bone metastases, presence of liver metastases, hepatomegaly and presence of lung metastases. Few missing data were imputed using the predictive mean matching method. Multivariate analyses were based on Cox proportional hazards regression model. Model results were expressed by the c-index (0.5-1.0; random to perfect prediction). High- and low risk strata were identified by taking median prediction percentage of the model over all patients.

## Results

The nomogram is shown in figure 1. Accuracy of the developed model was tested with internal cross

validation. The discriminative accuracy of the model is 0.67. The nomogram was able to significantly ( $p < 0.001$ ) distinguish low- from high-probability patients for overall survival, as can be seen in figure 2.

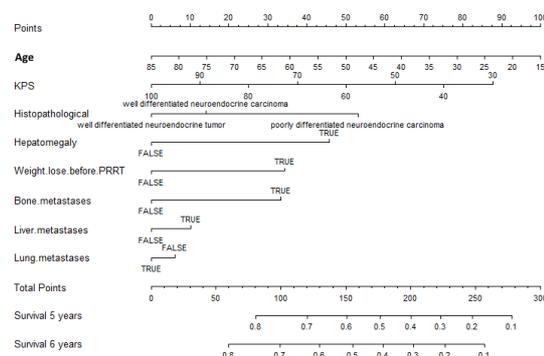

Figure 1: Nomogram of the model PRRT of pancreatic NEN. The nomogram is based on a proportional hazards cox regression. A number of points can be looked up for each variable, the total points can be summed up and mapped to the survival scores on the bottom of the nomogram. The predictive value of each variable is proportional to the points score line length associated with the variable

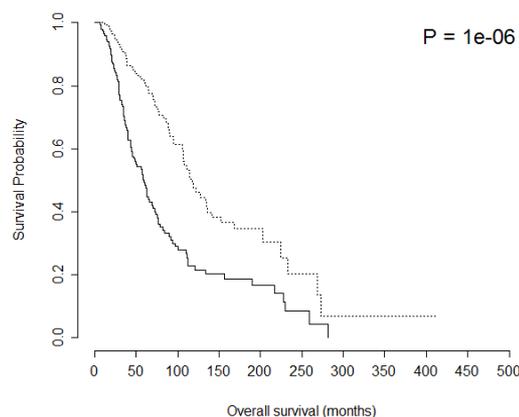

Figure 2: Kaplan Meier curve of model identifying high-risk (solid line) and low risk (dashed line) group. Patients in the high-risk group were identified by the model as above median risk score. Patients in the low-risk group were identified by the model as below median risk score.

## Conclusion

The nomogram is internally validated and able to accurately predict overall survival for pancreatic neuroendocrine neoplasm patients. The model could facilitate decision support in daily clinical practice and can be used for patient counseling and shared decision making, as well as for and generating new hypotheses.

## PO-0697 Reduced inter- and intra-observer variation in esophageal tumor delineation using fiducial markers.

<sup>1</sup>Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands

<sup>2</sup>Academic Medical Center, Radiology, Amsterdam, The Netherlands

<sup>3</sup>Radiotherapy Institute Friesland, Radiation Oncology, Leeuwarden, The Netherlands

<sup>4</sup>The Netherlands Cancer Institute, Radiotherapy, Amsterdam, The Netherlands

### Purpose or Objective

Delineation variation of esophageal tumors remains a large source of geometric uncertainty. Recent studies trying to decrease esophageal tumor delineation variation by adding PET/CT information showed no significant reduction. With future studies focusing on dose escalation, a correct gross tumor volume (GTV) delineation will become more important. In the present study, we investigated the inter- and intra-observer variation in esophageal GTV delineation and the impact of fiducial markers on this variability.

### Material and Methods

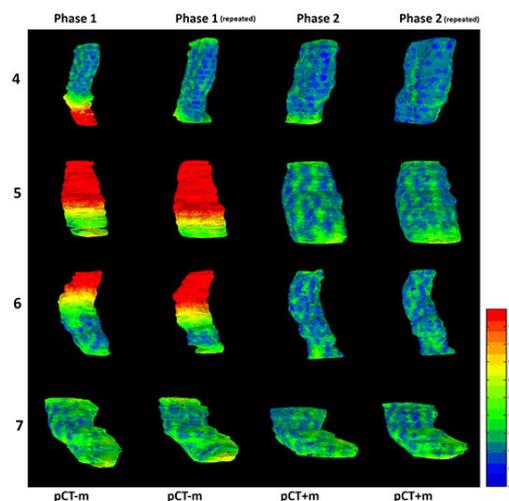

Ten esophageal cancer patients were included in this study, with at least 2 fiducial markers implanted at the cranial and caudal tumor border, visible on planning CT (pCT). Two GTV delineation phases were performed by five dedicated gastrointestinal radiation-oncologists independently. In-house designed software digitally removed the fiducial markers from the pCTs. Phase 1 consisted of a GTV delineation on the resulting marker-less pCTs (denoted pCT-m). Phase 2 consisted of a GTV delineation on the original (e.g., with markers) pCTs (denoted pCT+m). Phase 1 and 2 were executed twice to determine intra-observer variability. As general metrics for inter-observer variability; volumes, generalized conformity indices ( $CI_{gen}$ ; 1 indicating full overlap and 0 indicating no overlap) and delineation variation (cranio-caudal (CC) variation and overall observer variation expressed as standard deviations (SDs)) were calculated. Intra-observer variability was determined in terms of overall observer variation. A Wilcoxon signed-rank test was performed to compare delineation phases (significance level  $\alpha=0.05$ ).

### Results

For all delineated volumes, the results of the mean volumes,  $CI_{gen}$ , CC delineation variation and overall observer variation, of all 10 patients are listed in Table 1. Inter-observer overall observer variation (1SD) was 0.64 cm and 0.28 cm in phase 1 and phase 2, respectively ( $p=0.027$ ). CC delineation variation (1SD) was 1.48 cm for phase 1 and 0.43 cm for phase 2 ( $p=0.004$ ).  $CI_{gen}$  was significantly larger in phase 2 (0.54 vs 0.68;  $p=0.006$ ). Intra-observer overall observer variation (1SD) was 0.44 cm and 0.26 cm, for phase 1 and phase 2 respectively, significantly reduced with the aid of fiducial markers ( $p=0.006$ ).

Patient	Mean volume [cm <sup>3</sup> ]		$CI_{gen}$		CC delineation variation 1SD (cm)		Overall observer variation 1SD (cm)	
	Phase 1	Phase 2	Phase 1	Phase 2	Phase 1	Phase 2	Phase 1	Phase 2
1	13.81	15.53	0.55	0.62	0.63	0.39	0.53	0.50
2	78.06	76.56	0.57	0.58	1.19	0.48	0.69	0.35
3	26.68	52.68	0.31	0.59	2.25	0.19	1.10	0.49
4	10.77	8.97	0.55	0.63	0.97	0.52	0.63	0.45
5	14.49	17.97	0.39	0.69	2.13	0.20	0.84	0.46
6	24.07	20.70	0.33	0.73	2.56	0.41	1.03	0.50
7	27.85	23.43	0.60	0.71	1.24	0.25	0.55	0.55
8	88.22	89.53	0.79	0.73	0.71	0.78	0.53	0.65
9	19.39	19.46	0.62	0.72	0.61	0.40	0.63	0.51
10	34.73	34.38	0.70	0.80	0.70	0.37	0.54	0.47
<b>Overall</b>	<b>33.81</b>	<b>35.92</b>	<b>0.54</b>	<b>0.68*</b>	<b>1.48</b>	<b>0.43*</b>	<b>0.64</b>	<b>0.28*</b>

**Table 1.** Volumetric analysis and inter-observer variation of GTV delineations on pCT-m (phase 1) and pCT+m (phase 2) of 10 esophageal cancer patients for 5 observers. Bold font and \* indicates a significant difference between both phases. Abbreviations:  $CI_{gen}$  = generalized conformity index; CC = cranio-caudal.

**Figure 1.** Overall observer variation (1SD) over the 5 observers projected on the median surface of patients 4, 5, 6 and 7 in anterior-posterior view.

### Conclusion

Large inter- and intra-observer variation in delineation of esophageal tumors was found when using marker-less pCTs. Presence of fiducial markers at CC tumor borders, significantly improved all investigated delineation variation parameters. Since fiducial markers only assist with the determination of the cranial and caudal tumor border, the largest variation reduction (1SD = 1.48 cm to 0.43 cm) was logically seen in the CC delineation variation. Our results endorse the use of fiducial markers in esophageal GTV delineation, consequently reducing geometric uncertainty in esophageal cancer radiotherapy.

**PO-0698 Phase II study of induction chemotherapy followed by radiochemotherapy in pancreatic cancer**  
 M. Fiore<sup>1</sup>, R. D'Angelillo<sup>1</sup>, B. Florenò<sup>1</sup>, P. Trecca<sup>1</sup>, L. Trodella<sup>1</sup>, A. Iurato<sup>1</sup>, L. Trodella<sup>1</sup>, R. Coppola<sup>2</sup>, S. Ramella<sup>1</sup>

<sup>1</sup>Campus Biomedico University, Department of Radiation Oncology, Roma, Italy

<sup>2</sup>Campus Biomedico University, Department of General Surgery, Roma, Italy

### Purpose or Objective

To evaluate the safety and efficacy of induction gemcitabine and oxaliplatin followed by a high weekly dose of gemcitabine-based radiochemotherapy in patients with borderline resectable or unresectable locally advanced pancreatic cancer.

### Material and Methods

From January 2012 through January 2015, 41 patients with pancreatic cancer were included in the study. In all cases an accurate pre-treatment staging was performed. Patients received chemotherapy with gemcitabine 1000 mg/mq and oxaliplatin 100 mg/mq every 14 days for four doses. Patients without disease progression after restaging received conformal radiation therapy and concurrent gemcitabine at the dose of 600 mg/mq weekly.

### Results

Further to the results of the pre-treatment workup, seven patients (17%) were excluded from the protocol because of the evidence of metastatic disease, and thus a total of 34 patients were consequently enrolled. Induction chemotherapy was well tolerated. Five patients (14.7%) experienced disease progression after induction chemotherapy. Twenty-seven patients completed the therapy protocol. Only haematological grade 3-4 toxicities were observed. Nineteen patients were evaluated through surgical exploration and fifteen patients (55.5%) underwent surgical radical resection. With a median

follow-up of 20 months, the median PFS was 20 months. One-year, two-year PFS and three-year PFS were 70%, 53% and 42%, respectively. Two-year and three-year LC were 95% and 79%, respectively. Two-year and three-year MFS were 53% and 42%, respectively (median, 20 months). Median OS was 19.2 months. One-year OS, two-year OS and three-year OS were 77%, 47% and 37%, respectively. The median OS for borderline resectable patients was 21.5 months compared with 14 months for unresectable patients ( $p=0.3$ ). Patients who underwent resection had a significantly longer median OS compared with non-resected patients (37.6 months vs 13 months,  $p=0.03$ ).

#### Conclusion

This protocol treatment represents a well-tolerated promising approach for patients with borderline resectable and unresectable pancreatic cancer. Continued optimization in multimodality therapy and an accurate patient selection are crucial for the appropriate treatment of patients.

#### PO-0699 Is stereotactic radiotherapy following radiochemotherapy useful in local advanced pancreatic cancer?

Deodato<sup>2</sup>, N. Dinapoli<sup>1</sup>, V. Frascino<sup>1</sup>, M. Gambacorta<sup>1</sup>, G. Macchia<sup>2</sup>, A. Morganti<sup>3</sup>, V. Valentini<sup>1</sup>

<sup>1</sup>Università Cattolica del Sacro Cuore- Gemelli ART, Radiation Oncology, Rome, Italy

<sup>2</sup>Fondazione "Giovanni Paolo II"- Università Cattolica del Sacro Cuore, Radiotherapy Unit, Campobasso, Italy

<sup>3</sup>Università di Bologna- Ospedale S. Orsola-Malpighi, Radiation Oncology Center- Department of Experimental- Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

#### Purpose or Objective

To evaluate the feasibility and efficacy of stereobody radiotherapy (SBRT), following radiochemotherapy (RTCT) and chemotherapy (CT), in patients (pts) with unresectable, locally advanced pancreatic carcinoma (LAPC). Primary endpoints were toxicity, local control (LC) and pain-free progression (PFP); secondary endpoints were overall survival (OS) and disease-free survival (DFS).

#### Material and Methods

Patients affected by unresectable LAPC already treated with RTCT (50.4 Gy in 28 fractions (fr) to visible pancreatic tumour and 39.6 Gy in 22 fr to nodal drainage area with concurrent gemcitabine) and chemotherapy (Gemcitabine or Folfirinox), with no evidence of metastatic disease at the restaging imaging, were selected for a SBRT boost on the primary lesion. The pain assessment was defined by Kersh-Hazra scale.

#### Results

From 2003 to 2015, 26 consecutive pts (16 male, 10 female), with a median age of 65.5 years (range 47-80), were enrolled in this study. The 53.8% was a cT4 and the 50% was a N1. The tumor was localized in the head of the pancreas in 53.8% of pts. The SBRT boost was delivered to the primary lesion with a total dose depending on the dose received by the duodenum (maximum dose to the duodenum 90Gy in EQD2  $\alpha/\beta$  2 summing the dose received during RT-CT and SBRT): 20Gy in 5 fr for 4 pts, 20Gy in 4 fr for 5 pts, 25Gy in 5fr for 16 pts and 30Gy in 6fr for 1pt. The median follow up was 25 months (range 15-154). The median interval between RTCT and SBRT was 8 months (range 3-16 months). None Grade 3 or 4 acute or late gastrointestinal toxicities were developed among all pts after SBRT. Pain control was achieved in 19 pts (73.1%) after SBRT boost. After SBRT: 2-years and 3-years LC were 62.4% and 41.6%, with a median of 36 months; 2-years and 3-years PFP were 64.3% and 32.1%, with a median of 25 months; 2-years and 3-years DFS were 27.8% and 18.5%, with a median of 7 months. The 2-years and 3-years OS after SBRT were 57% and 42.7%, with a median of 29

months. Since diagnosis: 2-years and 3-years LC rate were 71.1% and 64.6%, with a median of 45 months; the 2-years and 3-years PFP were 86.3% and 49.3%, with a median of 35 months; 2-years and 3-years DFS were 45.8% and 29.7%, with a median of 23 months; 2-years and 3-years OS were 77.3% and 58%, with a median of 41 months.

#### Conclusion

A SBRT boost on primary lesion after RTCT and CT could be delivered safely and effectively in pts with non-metastatic, unresectable LAPC with acceptable side effects and with promising local and pain control.

#### PO-0700 Significant heart dose reduction by deep inspiration breath hold for RT of esophageal cancer

M. Dieters<sup>1</sup>, J.C. Beukema<sup>1</sup>, A.C.M. Van den Bergh<sup>1</sup>, E.W. Korevaar<sup>1</sup>, N.M. Sijtsema<sup>1</sup>, J.A. Langendijk<sup>1</sup>, C.T. Muijs<sup>1</sup>  
<sup>1</sup>UMCG University Medical Center Groningen, Radiation oncology, Groningen, The Netherlands

#### Purpose or Objective

As survival for esophageal cancer (EC) patients improves<sup>1</sup>, reduction of long term radiation-induced toxicity will become increasingly important. For radiotherapy of left-sided breast cancer patients, deep inspiration breath-hold is used routinely to minimize the radiation dose to the heart<sup>2</sup>. For EC patients, the expiratory phase might be more beneficial to reduce the heart dose, while the inspiration phase might be better for the dose to the lungs, consequently allowing for cardiac dose reduction. Therefore, the main objective of this study was if breath hold in photon radiotherapy of esophageal cancer minimized the dose to the heart, without compromising the dose to the lungs and the target.

#### References:

1. Shapiro J, van Lanschot JJB, Hulshof MCCM, et al. *Lancet Oncol.* 2015;16:1090-1098.
2. Sixel KE, Aznar MC, Ung YC. *Int J Radiat Oncol Biol Phys* 2001;49:199-204.

#### Material and Methods

Ten EC patients were included in this prospective cohort study. All patients received a free breathing (FB) 4D-plannings-CT and additionally a CT-scan in deep inspiration (DIBH) and expiration breath-hold (EBH) using Active Breathing Control (ABC). Treatment volumes and organs at risk were delineated. No ITV margin was used in the breath-hold CTs assuming absence of respiratory movement. Full VMAT treatment plans (3 arcs, per arc <20sec delivery time) were constructed on all 3 planning CTs (FB, DIBH and EBH) with the aim to cover the target with a prescribed dose of 41.4Gy or 50.4Gy, while reducing the cardiac dose, without compromising the dose to the lungs. These plans were compared to the clinically robust partial VMAT /IMRT treatment plans (clinFB), for volume and DVH differences using one way ANOVA with Bonferroni correction.

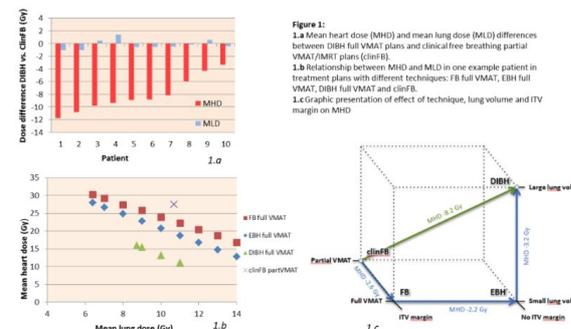

#### Results

Breath-hold, both DIBH and EBH, was feasible in all patients. The GTVs were similar on all 3 CT-scans ( $p=0.99$ ). With DIBH, lung volumes were significantly larger (on average 2800 cc) than with FB and EBH ( $p<0.01$ ). The mean heart dose (MHD) and V30 heart were also significantly different among the 4 types of treatment plans ( $p=0.02$  and  $p<0.01$ ) (table 1). The reduction of the MHD and V30 heart were most pronounced using DIBH and was consistent over the entire range of MHD/MLD, as illustrated by the example in figure 1.b. On average, the MHD and V30 heart reduced from 22Gy in the clinFB plans to 13.8Gy in the DIBH plans (mean difference 8.2Gy, 95%CI 1.2-15.3) (figure 1.a). The reduction in cardiac dose can be explained by: 1) Use of full VMAT instead of partial VMAT/IMRT, 2) the absence of ITV margin when using BH, 3), an increase of lung volume, which allows cardiac doserelation, corresponding to average MHD reductions of 2.8 Gy (1), 2.2 Gy (2) and 3.2 Gy (3), respectively (figure 1.c).

Variable	clinFB (SEM)	FB (SEM)	EBH (SEM)	DIBH (SEM)	F	p
GTV	-	67 cm <sup>3</sup> (14)	63 cm <sup>3</sup> (13)	65 cm <sup>3</sup> (13)	0.014	0.99
PTV	-	764 cm <sup>3</sup> (131)	591 cm <sup>3</sup> (112)	600 cm <sup>3</sup> (117)	0.68	0.57
Lungs	-	4037 cm <sup>3</sup> (294)	4038 cm <sup>3</sup> (288)	6903 cm <sup>3</sup> (356)	22.14	<0.01
Heart	-	899 cm <sup>3</sup> (67)	858 cm <sup>3</sup> (58)	713 cm <sup>3</sup> (86)	0.19	0.83
MLD	7.21 Gy (1.1)	7.44 Gy (1.2)	6.68 Gy (1.1)	7.06 Gy (1.0)	0.084	0.97
V20 lung	10.6% (1.9)	10.05% (2.5)	7.8% (1.8)	9.0% (1.7)	0.36	0.78
MHD	22 Gy (1.8)	19.2 Gy (1.8)	17.0 Gy (1.8)	13.8 Gy (1.8)	3.8	0.02
V30 heart	29.5% (3.2)	21.8% (2.9)	15.4% (2.0)	10.0% (1.7)	11.02	<0.01

Table 1: Mean volumes and DVH parameters on clinical partial VMAT/IMRT, free breathing (FB), deep inspiration breath-hold (DIBH) and expiration breath-hold (EBH) CT-scans and/or treatment plans.

SEM= standard error of the mean.

## Conclusion

A spectacular reduction in mean heart dose of 8,2Gy can be obtained by deep inspiration breath-hold, with similar or even lower mean lung dose, compared to the current standard partial VMAT/IMRT. This may decrease the risk of radiation induced cardiac toxicity.

## PO-0701 Discrepancies between pathological data on nodal spread and the CTVs in RT for biliary tract cancer

J. Socha<sup>1</sup>, M. Michalak<sup>2</sup>, G. Wołakiewicz<sup>3</sup>, L. Kepka<sup>3</sup>  
<sup>1</sup>Regional Oncology Centre Czêstochowa, Radiotherapy, Czestochowa, Poland  
<sup>2</sup>Independent Public Care Facility of the Ministry of the Interior and Warmian & Mazurian Oncology Center, Diagnostic imaging, Olsztyn, Poland  
<sup>3</sup>Independent Public Care Facility of the Ministry of the Interior and Warmian & Mazurian Oncology Center, Radiation Oncology, Olsztyn, Poland

## Purpose or Objective

To compare pathological-surgical data on the pattern of nodal spread in biliary tract cancer (BTC) with nodal CTVs commonly used in adjuvant radiotherapy (RT) for BTC.

## Material and Methods

A comprehensive literature search was performed, using the "PubMed" and "Google Scholar" databases, to select articles on adjuvant RT for BTC, that provided information on the lymph node stations (LNS) included into CTV. Another search was done to extract the surgical and pathological data on the patterns of nodal recurrence and lymph node involvement in BTC. The risk of nodal involvement and the degree of concordance between different RT studies on including each of the LNS into CTV were established with numerical scales presented in Table 1, and compared to show the nodal areas of potential geographical misses as well as unnecessarily irradiated nodal areas, separately for intrahepatic cholangiocarcinoma (IHC), extrahepatic cholangiocarcinoma (EHC) and gall bladder cancer (GBC).

## Results

Out of 59 studies on the use of adjuvant RT in BTC, 19 were finally included: 1 prospective, 15 retrospective and 3 reviews; 14 pathological and/or surgical studies that reported on the lymph node positivity rates in BTC were included. Nodal areas of potential geographical misses include: for right IHC - paraaortic LNS [risk level (R): 3, degree of concordance (C): 1]; for left or hilar IHC - left

gastric LNS [R: 3, C: 0] and paraaortic LNS [R: 3, C: 1]; for proximal EHC - paraaortic LNS [R: 3, C: 1]; for middle EHC - paraaortic LNS [R: 3, C: 1] and superior mesenteric artery (SMA) LNS [R: 2, C: 0]; for distal EHC - paraaortic LNS [R: 3, C: 1], SMA LNS [R: 4, C: 1] and anterior pancreaticoduodenal LNS [R: 3, C: 1]; for GBC - paraaortic LNS [R: 4, C: 1] and SMA LNS [R: 2, C: 1]. Nodal areas that seem to be unnecessarily irradiated include celiac lymph nodes for middle and distal EHC [R: 0, C: 3]. Moreover, the interaorto-caval LNS seems to be the only subsite of the paraaortic LNS that should be included into CTV, which can limit the increase of overall treatment volume caused by inclusion of paraaortic LNS. Similarly, only the posterior group of pancreaticoduodenal LNS should be included into CTV, except for distal EHC - where both posterior and anterior pancreaticoduodenal LNS are at high risk of involvement.

## Conclusion

This is the first study that reports on the nodal areas of potential geographical misses and the unnecessarily irradiated nodal areas in adjuvant RT for BTC. Paraaortic LNS are at very high risk of involvement in all BTC locations - but are almost uniformly omitted, as well as the SMA LNS for middle and distal EHC. Contrarily, celiac LNS are always included into CTV, which seems unnecessary for distal and middle EHC, at least in less advanced stages. In view of some considerable discrepancies between pathological-surgical data and the elective nodal CTVs used in common practice, there is an obvious need for the international consensus guidelines.

## Purpose or Objective

To assess the safety and determine the recommended Phase II dose of anti-EGFR Panitumumab combined with Mitomycin, 5FU and radiotherapy in patients (pts) with locally advanced epidermoid anal cancers.

## Material and Methods

This open prospective, multicentric, single-arm phase I study included patients (OMS: 0 or 1) with histologically proven epidermoid anal cancers T2> 3 cm, T3, T4 or every T-N+, M0. Phase I study was done to determine the Dose Limiting Toxicity (DLT) and the Maximum Tolerated Dose (MTD) of chemotherapy with a conventional 3+3 design. Radiotherapy (conformational 3D or IMRT) was delivered over 5 weeks at 1.8 Gy/fraction to reach a total dose of 45 Gy to the pelvis. After a 2 week break a boost of 20 Gy/2 Gy was delivered to the tumor. Mitomycin was administered on day 1, 29 and 50 at 10 mg/m<sup>2</sup>, 5FU on

days 1-4, 29-32 and 50-53 and panitumumab on day 1, 15, 29, 50 and 65. The doses were as follows: level -1: 5FU at 400 mg/m<sup>2</sup>/j and panitumumab at 3mg/kg; level 0: 5FU at 600 mg/m<sup>2</sup>/j and panitumumab at 3mg/kg. DLT was defined by febrile neutropenia, neutropenia grade 4, thrombocytopenia grade 4 or grade 3 during more than 1 week, GI toxicity grade  $\geq$  3, dermatitis grade  $\geq$  4, first part of treatment non completed (< 75 % doses) according to CTCAEv4, and assessed until 8 weeks after the completion of the treatment Tumor evaluation was performed at 8 weeks, 4 months after end of treatment and every 4 months.

### Results

Out of 10 pts enrolled in this study between June 2012 and March 2015, 9 were treated according to the protocol (one patient was excluded before treatment because the dosimetric plan did not meet the dosimetric constraints). Median age was 57.4 years (range: 52.0-71.1). Tumor characteristics were as follows: T2: one patient; T3: 6; T4: 2; N0: 2 and N+: 7 pts. DLT was observed for the first 3 patients at level 0: febrile neutropenia for one patient, thrombocytopenia and diarrhea grade 3 for the second patient and rectitis, cystitis, dermatitis grade 3 for the third patient. Therefore the protocol was amended to withdraw one mitomycin injection. Six patients were treated on level -1. Out of 6 patients, 2 experienced grade 3 toxicities: asthenia and rectitis for one patient and lymphopenia for the second. Treatment was completed for all 6 pts. Considering all patients treated at level 0 and -1, complete response was achieved for 8 pts whereas one experienced a local recurrence 9 months after the end of the treatment and went through abdomino-perineal resection. All patients were alive with a median follow-up of 18 months.

### Conclusion

In this phase 1 trial, panitumumab (3 mg/kg), mitomycin (10 mg/m<sup>2</sup>) and 5FU (400 mg/m<sup>2</sup>/day) were considered as the tolerable and active doses. These are the recommended doses for the ongoing phase II trial (EudraCT number: 2011-005436-26).

### PO-0703 Bowel dysfunction resulting from different treatment strategies in patients with rectal cancer.

T. Vuong<sup>1</sup>, A. Garant<sup>2</sup>, S. Devic<sup>3</sup>, A. Kezouth<sup>4</sup>

<sup>1</sup>Jewish General Hospital - McGill University, Radiation Oncology, Montreal, Canada

<sup>2</sup>McGill University, Radiation Oncology, Montreal, Canada

<sup>3</sup>Jewish General Hospital- McGill University, Radiation Oncology, Montreal, Canada

<sup>4</sup>Jewish General Hospital- McGill University, Statistics-Epidemiology, Montreal, Canada

### Purpose or Objective

For patients with rectal cancer, sphincter preservation surgery total mesorectal surgery (SPS-TME) is a most important treatment goal after cure. However, beside the body image preservation, bowel function is a major outcome with important impact on quality of life. The Low Anterior resection syndrome (LARS) is well documented with bowel frequency, urgency, clustering, stool and gaz incontinence. A validated LARS questionnaire documented a 40% of severe LARS score after TME alone and 60% after pre-operative Radiation (RT) and TME. In this study, we are proposing to evaluate our population of patients with ano-rectal cancer with various RT regimens.

### Material and Methods

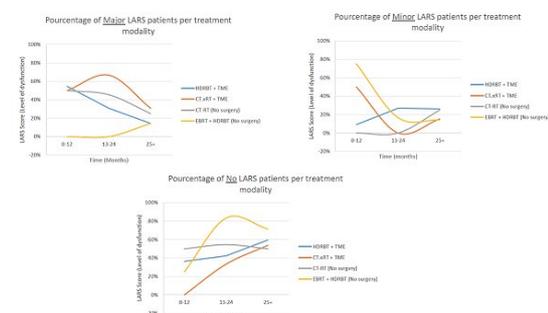

Patients with rectal cancer or anal canal cancer treated between 2013 - 2015 were recruited in this study. IRB approved signed consent was obtained with self administered questionnaires at least in two point times. Patients with LAR with ileostomy closure for at least 3 months. Patients with anal canal treated with chemotherapy (CT) and RT and rectal cancer treated with External beam (EBRT) and high dose rate brachytherapy

(HDRBT) but with no evidence of local recurrence.

	Patient Characteristics			
	HDRBT+TME	CTRT+TME	CTRT (No surgery)	EBRT+HDRBT (No surgery)
Number of patients	88	19	38	23
Age (Median)	59.5	52	56	80
Age (Min)	36	38	39	52
Age (Max)	85	78	91	89
Gender				
Female	26(30%)	8(42%)	30(79%)	8(35%)
Male	62(70%)	11(58%)	6(21%)	15(65%)
	Tumor location based on treatment modality			
	HDRBT+TME	CTRT+TME	CTRT (No surgery)	EBRT+HDRBT (No surgery)
Upper Third	14(16%)	3(16%)	0(0%)	1(4%)
Middle Third	47(53%)	5(26%)	0(0%)	7(30%)
Lower Third	27(31%)	11(58%)	38(100%)	15(66%)

### Results

Patients and tumor characteristics and LARS scoring results by treatment regimen are shown in the Table1 and Figure 1. For the initial 3X4 cross-classified table (3 category-scores: No Lars, Minor Lars, Major Lars, 4 treatment groups: HDRBT-TME, CT-RT-TME, CT-RT (No surgery), EBRT + HDRBT (No surgery)), we computed the Fisher exact test. There is independence between the score category and the treatment group with a p-value of 0.4538. We also considered the Lars score as a continuous variable and we performed an ANOVA which resulted in a non-statistical difference between the score means of the 4 treatment groups. Finally to study the severity of the disease we dichotomized the Lars score into subjects with Lars score  $\leq$ 26 and those  $\geq$ 27 to construct a new 2X4 table. We found a statistical an overall statistical difference between the 4 groups with a p-value of 0.0270. Performing a multiple comparison test, an analogous of a Tukey-type multiple comparison test, we concluded that there is a statistical difference between CT-RT and TME and EBRT + HDRBT (No surgery) group, namely we have more subjects with major Lars in group CT-XRT + TME than group EBRT-HDRBT (No surgery).

### Conclusion

In this study, using the LARS scoring questionnaire, the favorable functional bowel results (lowest rate of severe LARS score) in patients treated with EBRT-HDRBT and no surgery, in the organ preservation approach compared to standard CT-RT and surgery, support the present efforts in developing in organ preservation trials for patients with operable rectal cancer.

### PO-0704 Circulating angiogenesis factors predicting poor chemoradiotherapy outcome in rectal cancer

S. Meltzer<sup>1,2</sup>, L.G. Lyckander<sup>3</sup>, A.H. Ree<sup>1,2</sup>, K.R. Redalen<sup>1</sup>

<sup>1</sup>Akershus University Hospital, Department of Oncology, Lørenskog, Norway

<sup>2</sup>University of Oslo, Institute of Clinical Medicine, Oslo, Norway

<sup>3</sup>Akershus University Hospital, Department of Pathology, Lørenskog, Norway

### Purpose or Objective

Rapid advances in personalised cancer treatment increase the demand for early stratification of tumours and their hosts, which requires easy-to-use, easy-to-interpret biomarkers to assess tumour phenotypes. In this context,

we have applied a multiplex magnetic bead panel (Luminex®) to explore associations between serum proteins and treatment outcome in patients with locally advanced rectal cancer.

#### Material and Methods

Serum samples from 22 rectal cancer patients were collected at the time of diagnosis. All patients underwent neoadjuvant long-course chemoradiotherapy (CRT), according to current national guidelines. Surgery was performed 6-8 weeks after completion of CRT and five patients underwent adjuvant chemotherapy. CRT responses were evaluated by ypTN staging and tumour regression grade (TRG) (College of American Pathologists system) scoring. The median follow-up time was 21 months (range 1-34). Using multiplex magnetic bead technology (Luminex®, R&D systems), a manually selected panel of 86 proteins involved in angiogenesis, hypoxia and metastasis was applied to analyse serum samples. Associations were explored using two-sided Student's t-tests, with p-values < 0.05 considered statistically significant. The STRING (Search Tool for the Retrieval of Interacting Genes/Proteins) database (string-db.org) was used to predict interaction networks. Survival differences were assessed by the log-rank test and visualised by the Kaplan-Meier method.

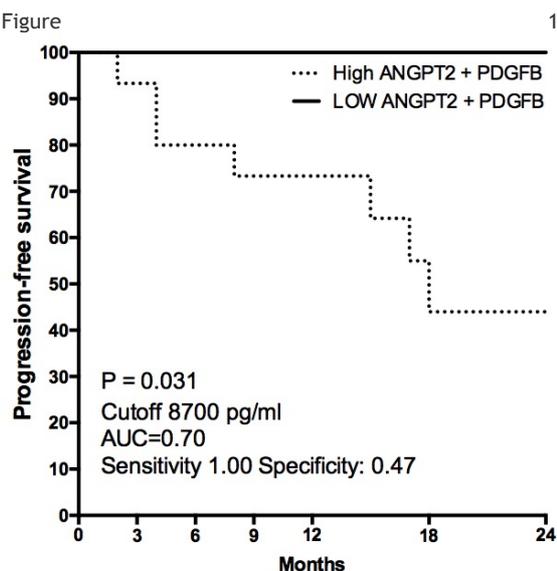

#### Results

Significant associations between several serum proteins and TNM, ypTN, TRG and progression-free survival (PFS) were detected. STRING analysis identified that a majority of these proteins were involved in the PI3K-Akt signaling pathway, and particularly angiopoietin-2 (ANGPT2) and platelet-derived growth factor subunit B (PDGFB) were associated to multiple end-points. By combining ANGPT2 and PDGFB, high levels were associated with both poor histopathologic outcome (ypT3-4 versus ypT0-2: p=0.040; TRG2-3 versus TRG1: p=0.015) (Table 1) and PFS (cut-off 8700 pg/ml, p-value 0.031), with all PFS events being development of liver metastasis (Figure 1).

Table 1 ANGPT2 and PDGFB

		Median (Range)		
Age		63 (48-76)		
BMI		26 (18-35)		
		n (%)	Mean (SD)	P
Gender	Female	7 (32)	10467.488 (4579.561)	
	Male	15 (68)	10568.588 (4486.713)	0.960
TNM stage	T2-3	8 (36)	9393.508 (2931.943)	
	T4	14 (64)	11189.512 (5046.826)	0.372
	N0-1	15 (68)	10145.550 (3615.519)	
	N2	7 (32)	10648.368 (4445.086)	0.671
ypTN stage	ypT0-2	8 (36)	8312.702 (2503.600)	
	ypT3-4	14 (64)	11807.116 (4817.201)	0.040
	ypN0	12 (55)	9666.541 (3822.377)	
	ypN1-2	10 (45)	11580.274 (5022.377)	0.287
TRG score	Good	12 (55)	8625.041 (2388.342)	
	Poor	10 (45)	12830.074 (5254.801)	0.015

Figure

#### Conclusion

Tumour angiogenesis is a major mechanism in sustained tumour progression and the metastatic process. In the current study, our main finding was that high serum levels of the angiogenic factors ANGPT2 and PDGFB identified patients with poor histopathologic response to neoadjuvant CRT, who subsequently progressed rapidly to metastatic disease. These results may point out an escalating tumour aggressiveness paralleled by increasing angiogenesis. The results were achieved in a small cohort and require validation, but may represent an approach for early selection of patients with an aggressive tumour phenotype for intensified treatment strategies, perhaps also with combinatory regimens targeting angiogenesis. The results are currently being validated in an independent patient cohort.

#### PO-0705 Work ability in Dutch rectal cancer patients during the first year of treatment

A.M. Couwenberg<sup>1</sup>, M.P.W. Intven<sup>1</sup>, J.P.M. Burbach<sup>1</sup>, L. Hupkens<sup>2</sup>, W.M.U. Van Grevenstein<sup>3</sup>, H.M. Verkooijen<sup>4</sup>  
<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands  
<sup>2</sup>Blik op Werk, Quality and research institute on workability, Utrecht, The Netherlands  
<sup>3</sup>UMC Utrecht, Surgery, Utrecht, The Netherlands  
<sup>4</sup>UMC Utrecht, Imaging Division, Utrecht, The Netherlands

#### Purpose or Objective

Rectal cancer treatment is associated with substantial morbidity and decreased quality of life. The impact of treatment on workability has hardly been studied. In this study we evaluated workability in rectal cancer patients during the first year of treatment.

#### Material and Methods

All working-aged rectal cancer patients (<67 years) within the Dutch prospective colorectal cancer cohort referred for radiotherapy at the UMC Utrecht between February 2013 and January 2016 were selected. Workability was assessed with the Work Ability Index (WAI) Questionnaire before start of treatment and at 3, 6 and 12 months. The WAI score, ranging from 7 to 49, was calculated for patients with paid employment at time of assessment and who completed at least one questionnaire. Higher scores reflect better workability. Workability was categorized in poor (7-27), moderate (28-36), good (37-43) and excellent (44-49). Results were stratified for treatment strategies and compared with scores of the age-matched Dutch reference population.

#### Results

Of the 156 eligible patients, 133 (85.3%) responded to at least one of the questionnaires. Non-response included patients who didn't return the questionnaires (8.3%) or had missing values in the WAI questionnaire (6.4%). Of the responders, 107 patients (80.5%) had paid employment. These patients had a mean age of 56.2 years and 73.8% were male. All patients underwent neoadjuvant therapy of which 64.5% chemoradiation, 30.8% short-course radiation and 4.7% other regimes. Surgery was performed in 89.7% of the patients, mostly by low anterior (50.5%) or abdominoperineal resection (33.6%). At baseline, the mean WAI score was 32.3, which was substantially lower than the reference population score of 40.9. Workability was poor in 27.5% of the patients, and moderate, good and excellent in resp. 34.1%, 34.1% and 4.4% (Figure 1). Corresponding scores of the Dutch reference population were 2.8%, 14.2%, 47.2% and 35.8% resp. Workability was limited by illness in 82.4% of the patients, and 23.1% completely stopped working. At 3 months, the mean WAI score decreased significantly to 27.1 ( $p < .001$ ) and was poor in 54.7% of the patients. Here after, at 6 and 12 months, the mean WAI score increased to resp. 29.1 and 34.6. At 12 months, 55.3% of the patients reported absenteeism of 100-365 days as result of health problems in the past year compared to 2.3% in the reference population. Only 14.9% of the patients reported no absenteeism. Stratification by neoadjuvant regimen and surgical procedure did not modify the results.

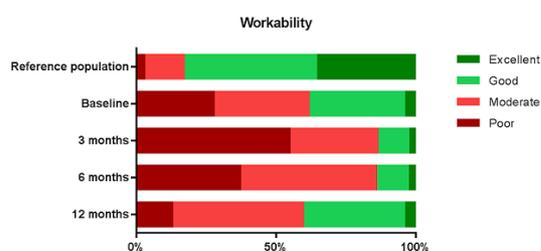

Figure 1. Workability in rectal cancer patient at baseline, three, six and twelve months. The first bar represents the workability of the Dutch reference population.

## Conclusion

Workability in patients with rectal cancer is negatively affected by treatment but seems to recover towards baseline levels at 12 months after diagnosis. Compared to the Dutch population, rectal cancer patients report a much lower workability and a higher level of absenteeism.

## PO-0706 Assessing the impact of sentinel lymph-node and inguinal irradiation in patients with anal cancer

C. Gumina<sup>1</sup>, N. Slim<sup>1</sup>, G.M. Cattaneo<sup>2</sup>, P. De Nardi<sup>3</sup>, C. Canevari<sup>4</sup>, M. Ronzoni<sup>5</sup>, A. Fasolo<sup>5</sup>, C. Fiorino<sup>2</sup>, L. Perna<sup>2</sup>, A.M. Tamburini<sup>3</sup>, R. Rosati<sup>3</sup>, P. Passoni<sup>1</sup>, N. Di Muzio<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Radiotherapy, Milan, Italy

<sup>2</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy

<sup>3</sup>San Raffaele Scientific Institute, Surgery, Milan, Italy

<sup>4</sup>San Raffaele Scientific Institute, Nuclear Medicine, Milan, Italy

<sup>5</sup>San Raffaele Scientific Institute, Medical Oncology, Milan, Italy

## Purpose or Objective

To evaluate the role of sentinel lymph-node biopsy (SLNB) in staging and the impact of inguinal irradiation.

## Material and Methods

Patients with anal squamous cell carcinoma and without gross inguinal lymph-nodes metastases were considered for SLNB after staging with standard imaging procedures and FDG-PET. The Clinical Target Volume (CTV) included the Gross Tumor Volume (GTV: primary tumour and positive lymph-nodes) and pelvic  $\pm$  inguinal lymph-nodes. Planning Target Volume (PTV)1 and PTV2 corresponded to GTV and CTV, respectively, with a margin of 0.5-1.0 cm.

Prescribed dose was 50.4 Gy in 28 fractions to the PTV2 and 64.8 Gy in 36 fractions to the PTV1, delivered with IMRT or VMAT. Concomitant chemotherapy consisted of Mito-C 10 mg/m<sup>2</sup> and continuous infusion 5-FU 1000 mg/m<sup>2</sup> for 4 consecutive days.

## Results

From 03/2008 to 02/2014, 48 consecutive patients were treated. FDG-PET was performed in 42 out of 48 patients. Pathologic inguinal uptake was shown in 15/42 (36%) and 9 of them underwent lymphoscintigraphy: SLNB confirmed inguinal metastases only in 3/8 (37.5%) (SLN not found in 1 patient). FDG-PET did not show inguinal uptake in 27/42 (64%) patients and 17 of them underwent lymphoscintigraphy: SLNB found metastases in 2/17 (12%). Thirty-one patients received prophylactic or curative radiotherapy to the groins (Inguinal RT group) and 17 patients did not (No inguinal RT group). Sixteen/17 patients of the No inguinal RT group had a negative SLNB. At a median follow-up of 41 months no relapse was observed in the "No inguinal RT". No significant differences in terms of toxicities, apart from inguinal dermatitis, were observed between the two groups.

## Conclusion

SLNB improves the PET-based staging and is highly accurate in identifying the true negative patients for which the inguinal irradiation could be avoided. The use of advanced radiotherapy techniques, sparing inguinal lymph-nodes reduces dramatically the inguinal skin toxicity while no differences were found for other side effects.

## PO-0707 Magnetic Resonance Imaging Texture Analysis Parameters for predicting risk of Anal Cancer recurrence

K. Owczarczyk<sup>1</sup>, D. Prezzi<sup>1</sup>, M. Siddique<sup>1</sup>, J. Stirling<sup>1</sup>, G. Cook<sup>1</sup>, R. Glynn-Jones<sup>2</sup>, A. Gaya<sup>1</sup>, M. Leslie<sup>1</sup>, V. Goh<sup>1</sup>  
<sup>1</sup>Guy's and St. Thomas' Hospital NHS Foundation Trust, Department of Cancer Imaging, LONDON, United Kingdom  
<sup>2</sup>Mount Vernon Cancer Center, Department of Oncology, London, United Kingdom

## Purpose or Objective

Despite advances in the management of anal squamous cell carcinoma (ASCC), roughly 25% of patients undergoing standard chemoradiotherapy (CRT) will experience disease recurrence. Currently, there is no established way of predicting disease outcome. Quantitative magnetic resonance (MR) imaging texture analysis (TA) parameters have shown promise in assessing the risk of recurrence in other cancer types. This study was carried out to assess their role in evaluating recurrence risk in patients with ASCC undergoing CRT.

## Material and Methods

We used baseline high-resolution T2-weighted MR images from 42 patients with ASCC undergoing CRT to identify TA parameters with the best ability to predict disease recurrence. Multi-slice regions of interest (ROI) were drawn around the tumours, generating a whole tumour volume. 3D volume statistical and fractal heterogeneity parameters were derived using in-house software. We calculated False Discovery Rate (FDR) p-value for all TA parameters using the Benjamini-Hochberg correction to adjust for multiple tests and used a FDR p-value cut-off of 0.15 to identify candidate parameters. We then analysed baseline T2-W MR images from further 33 patients to independently cross-validate performance of the identified TA parameters. We calculated replication FDR p-values for the validation cohort as well as p values for the pooled cohort.

## Results

Two patients in the test cohort and three patients in the replication cohort had to be excluded based on lack of visible tumour (n=2) and palliative treatment intent (n=3). 40 patients in the test cohort and 30 patients in the replication cohort were included in the final analysis. All

patients had histologically proven non-metastatic ASCC and all underwent curative CRT. There were no statistically significant differences between the test and replication cohorts in terms of baseline demographics and cancer characteristics. The majority of patients had advanced staged disease at presentation - 28/40 patients in the test cohort and 23/30 were AJCC stage III (IIIA or IIIB). 11/40 patients in the test cohort and 7/30 patients in the replication cohort experienced disease recurrence. Median follow-up was 25 months. Using the test cohort, we identified seven baseline TA parameters that were the most influential predictors of disease recurrence at baseline (Figure 1) with FDR p-value <0.15 (<0.02 unadjusted). These parameters were then independently tested using the replication cohort, with four out of seven parameters retaining statistically significant predictive value with replication FDR p-value <0.05. Finally, a pooled analysis of data showed yielded a highly significant FDR p-value <0.01 for five out of seven TA parameters tested.

## Conclusion

Quantitative MR based TA parameters, in particular those previously associated with active inflammation, show promise in assessing the risk of anal cancer recurrence at baseline.

Poster: Clinical track: Gynaecological (endometrium, cervix, vagina, vulva)

### PO-0708 Patterns of Care in the Netherlands for Radiotherapy of Women with Locally Advanced Cervical Cancer

P. De Boer<sup>1</sup>, I.M. Jürgenliemk-Schulz<sup>2</sup>, W. H.<sup>1</sup>, A.C.C. De Leeuw<sup>2</sup>, R. Dávila-Fajardo<sup>2</sup>, C.R.N. Rasch<sup>1</sup>, B.R. Pieters<sup>1</sup>, L.J.A. Stalpers<sup>1</sup>

<sup>1</sup>Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands

<sup>2</sup>University Medical Centre Utrecht, Radiation Oncology, Utrecht, The Netherlands

#### Purpose or Objective

International guidelines as well as the GEC-ESTRO recommendations and ICRU-89 report encourage progression to more advanced techniques, while achieving a uniform registration and reporting of radiotherapy. Do we meet the present clinical standard in cervical cancer radiotherapy? Therefore, supported by the Dutch National Platform for Radiotherapy of Gynaecological Cancer (LPRGT), we investigated the possible variation in current practice for cervical cancer amongst the Dutch radiation oncology centres specialised in gynaecological oncology.

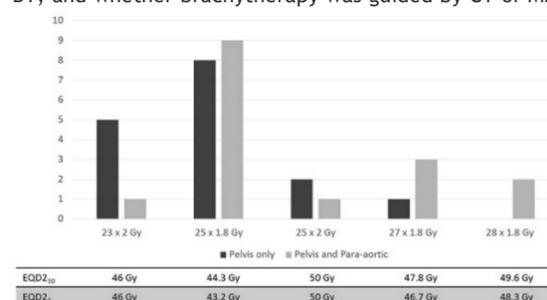

#### Material and Methods

A structured patterns of care questionnaire was completed during a face-to-face interview with radiation oncologists from all sixteen radiotherapy centres in the

Netherlands specialised in gynaecological oncology. The survey addressed important factors that might influence treatment outcome after external beam radiotherapy (EBRT) and brachytherapy (BT): the definition of target volumes, treatment preparation, imaging for treatment planning, treatment planning and IGART for EBRT and BT.

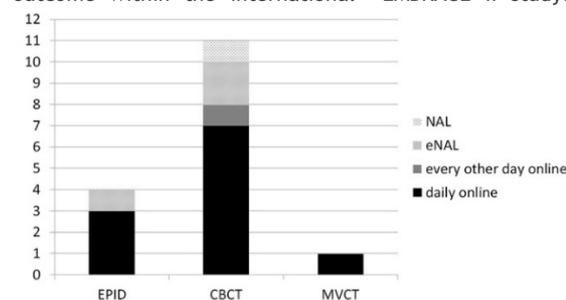

#### Results

All Dutch centres follow and meet the recommendations from the (inter)national guidelines. Within the freedom of the guidelines, we found differences between centres that may have a clinical impact, among others: differences in fractionation size and total dose (with an EQD2 for normal tissue after EBRT varying between 43 and 50 Gy), when or whether to use PET-CT imaging depending on availability of equipment, if para-aortic lymph nodes should be included in the CTV or not, and which technique is used to reduce the dose in OARs (i.e. whether to use box-fields, arc-rotation therapy, IMRT or IGART with a plan of the day strategies), if and when interstitial needles were used for BT, and whether brachytherapy was guided by CT or MRI.

## Conclusion

Most differences in radiation practice for cervical cancer are found at the cutting edge of clinical evidence. The majority of these uncertainties are being addressed in current and future (inter)national studies. For instance, to improve uniformity, the LPRGT organized workshops for all Dutch gynaecologic radiation oncologist, who are encouraged to uniformly treat patients and report outcome within the international EMBRACE II study.

<sup>2</sup>Asan Medical Center- Univ of Ulsan, Obstetrics and Gynecology, Seoul, Korea Republic of

#### Purpose or Objective

To investigate the disease course and identify prognostic factors for survival in patients with residual disease according to post-treatment magnetic resonance imaging (MRI) following definitive concurrent chemoradiotherapy (CCRT) for locally advanced cervical cancer.

#### Material and Methods

We reviewed clinical data from the medical records of 545 consecutive women with biopsy-proven, International Federation of Gynecology and Obstetrics stage IB2-IVA uterine cervical cancer treated with CCRT. Post-

treatment MRI was checked in all patients 3 months after CCRT completion. Out of the 545 patients, 53 with residual cervical cancer based on MRI following definitive CCRT were included in this analysis.

### Results

Thirty-two patients were disease-free at the last follow-up. Of them, 31 had a residual tumor size of  $\leq 2$  cm. Of these 32 women, 30 showed spontaneous regression of residual tumor during follow-up without salvage treatments, whereas the remaining two were alive with no evidence of disease after salvage surgery and chemotherapy. Disease progression was observed in 21 patients, including 7 local, 8 distant and 6 local and distant failures. Of these 21 women, 13 died of disease, 6 were alive with disease, and 2 remained disease-free after salvage treatments. Initial and residual tumor sizes were significant prognostic factors for overall survival; only residual tumor size was significant for local progression-free survival.

### Conclusion

About 60% of patients with residual disease detected on post-treatment MRI remained disease-free without further disease progression. Careful observation without immediate salvage treatments might be feasible in selected patients with a residual tumor size  $\leq 2$  cm.

### PO-0710 Concurrent chemoradiotherapy in locally advanced cancer cervix: Systematic review and meta-analysis

N.R. Datta<sup>1</sup>, E. Stutz<sup>1</sup>, M. Liu<sup>1</sup>, S. Rogers<sup>1</sup>, A. Siebenhüner<sup>2</sup>, D. Klingbiel<sup>3</sup>, S. Singh<sup>4</sup>, S. Bodis<sup>1</sup>

<sup>2</sup>University Hospital Zurich, Oncology, Zurich, Switzerland

<sup>3</sup>Swiss Group of Clinical Cancer Research SAKK Coordinating Centre, Biostatistics, Bern, Switzerland

<sup>4</sup>Sanjay Gandhi Postgraduate Institute of Medical Sciences, Radiotherapy, Lucknow, India

### Purpose or Objective

Concurrent chemoradiotherapy (CRT) is one of the preferred management strategies in cancer cervix. However, unlike early stage cancer cervix, the efficacy of CRT in locally advanced cancer cervix (LACC) (stages IIB-IVA) has been contentious as the therapeutic benefit has not been consistently shown in various randomized clinical trials. A systematic review and meta-analysis was therefore conducted exclusively in LACC to explore the therapeutic efficacy of concurrent CRT vs. radiotherapy (RT) for the endpoints - complete response (CR), long-term loco-regional control (LRC), overall survival (OS), grade III/IV acute and late toxicities.

### Material and Methods

Six databases - Cochrane Library, PubMed, EMBASE, SCOPUS, Google Scholar and Web of Science were searched as per the PRISMA guidelines using MeSH words, "Uterine cervical neoplasms" AND "Radiotherapy" AND "Drug Therapy". This was supplemented by hand-searching and last updated on 29.8.16. The selection criteria included (a) patients exclusively/predominantly in LACC (b) no surgical intervention (c) randomized trials with CRT vs. RT and (d) full length publications in English. Odds ratio (OR), risk ratio (RR) and risk difference (RD) for each of the above endpoints were estimated along with their test for heterogeneity ( $I^2$ ). Subgroup analysis (Q values) and meta-regression (using CT regimes as covariates) were performed for each endpoint to explore the differences in outcomes with different CRT approaches.

### Results

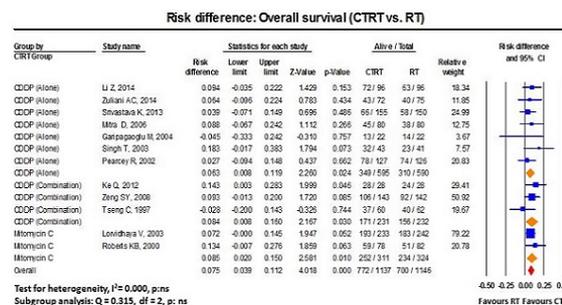

14 articles from a pool of 1788 citations were considered for the final analysis. A total of 2445 patients (CRT: n=1217; RT: n=1228) were included in these trials. 96.6%

of these patients were LACC. A mean teletherapy dose of 48.2Gy (SD: $\pm 2.9$ ) was delivered along with brachytherapy. The brachytherapy doses were variable and depended on the high, medium or low dose-rates of the units as available in each institution. Eight studies used CDDP alone, 4 had multiple agents CT with CDDP (5FU/Taxanes/BLM/VCR) and 2 were based on MMC. The OR, RR and RD for each endpoint is summarized in the Table. CRT improved the CR (+10.2%,  $p=0.027$ ,  $I^2=8.72$ ), LRC (+8.4%,  $p<0.001$ ,  $I^2=0.0$ ) and OS (+7.5%,  $p<0.001$ ,  $I^2=0.0$ , Fig.) over RT alone. However, a 10.4% higher incidence of acute toxicities ( $p<0.001$ ,  $I^2=77.8$ ) was evident with CRT. Late toxicities in both groups were equivocal. Subgroup analysis and meta-regression for each of the 5 endpoints did not reveal any significant difference in outcomes with the 3 different CRT regimes.

Summary of effect measures from 14 randomized studies with chemoradiotherapy vs. radiotherapy in LACC

Effect measures (CRT vs. RT)	Complete response	Long-term loco-regional control	Overall survival	Acute toxicity (grade III / IV)	Late toxicity (grade III / IV)
Odds ratio	Estimate, p value	1.730, p<0.010	1.478, p<0.005	1.386, p<0.001	3.771, p<0.001
	$I^2$ , p value	4.149, pns	0.000, pns	0.000, pns	20.102, pns
	Subgroup* Q value, p value	1.648, pns	2.148, pns	1.127, pns	0.828, pns
Risk ratio	Estimate, p value	1.131, p=0.038	1.130, p<0.001	1.118, p<0.001	3.070, p<0.001
	$I^2$ , p value	34.774, pns	0.000, pns	0.000, pns	20.337, pns
	Subgroup* Q value, p value	1.447, pns	0.541, pns	0.013, pns	1.147, pns
Risk difference	Estimate, p value	0.102, p=0.027	0.084, p<0.001	0.075, p<0.001	10.104, p<0.001
	$I^2$ , p value	8.728, pns	0.000, pns	0.000, pns	77.864, p<0.001
	Subgroup* Q value, p value	1.876, pns	1.112, pns	0.315, pns	0.002, pns

LACC: Locally advanced cancer cervix; \* Chemotherapy subgroups; ns: not significant

### Conclusion

In LACC, although CRT offers a significant benefit over RT alone, it also results in significantly higher grade III/IV acute toxicities. As no specific CT regime was found to be specifically advantageous, the choice of CT agents could be presently based on cost considerations both for primary treatment and management of acute toxicities. This assumes importance especially in most resource constrained developing countries with limited infrastructure and resources but faced with the highest burden of LACC.

### PO-0711 Risk factors for insufficiency fractures in cervix cancer following intensity modulated radiotherapy

A. Ramlov<sup>1</sup>, E. Pedersen<sup>2</sup>, L. Røhl<sup>2</sup>, E. Worm<sup>3</sup>, L. Fokdal<sup>1</sup>, J. Lindgaard<sup>1</sup>, K. Tanderup<sup>4</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

<sup>2</sup>Aarhus University Hospital, Department of Radiology, Aarhus C, Denmark

<sup>3</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark

<sup>4</sup>Aarhus University Hospital, Department of Oncology and Department of Medical Physics, Aarhus C, Denmark

### Purpose or Objective

To investigate incidence and risk factors of pelvic insufficiency fracture (PIF) after definitive chemoradiotherapy for locally advanced cervical cancer (LACC).

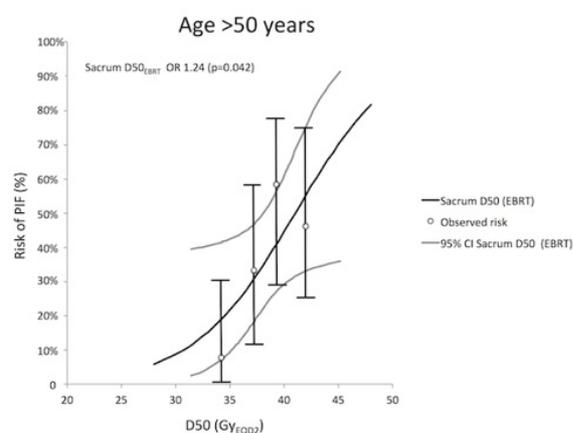

### Material and Methods

101 patients with LACC treated from 2008-2014 were analysed. Patients received weekly Cisplatin, external beam radiotherapy with 45Gy/25fx (node-negative

patients) or 50Gy/25fx with simultaneous integrated boost of 60Gy/30fx (node-positive patients). Pulsed dose rate MRI-guided adaptive brachytherapy was given in addition. Follow-up MRI was performed routinely at 3 and 12 months after end of treatment or at clinical indication. PIF was defined as a fracture line with or without sclerotic changes in the pelvic bones.  $D_{50\%}$  and  $V_{55\text{Gy}}$  were calculated for os sacrum and jointly for os ileum and pubis. Patient and treatment related factors including dose were analysed for correlation with PIF.

### Results

Median follow-up was 25 months. Median age was 50 years. Twenty patients (20%) were diagnosed with a median of 2 (range 1-3) PIFs; half were asymptomatic. The majority of the fractures were located in the sacrum (74%). Age was a significant risk factor ( $p < 0.001$ ), and the incidence of PIF was 4% and 37% in patients below and above 50 years, respectively. Sacrum  $D_{50\%}$  was a significant risk factor in patients  $> 50$  years ( $p = 0.04$ ), whereas  $V_{55\text{Gy}}$  of sacrum or pelvic bone were insignificant ( $p = 0.33$  and  $0.18$  respectively). Risk factors are reported in table 1. A dose-response curve for  $D_{50\%}$  sacrum in patients  $> 50$  years showed that reduction of sacrum  $D_{50\%}$  of from 40  $\text{Gy}_{\text{EQD2}}$  to 35  $\text{Gy}_{\text{EQD2}}$  reduces PIF from 45% to 22% (Figure 1).

	All patients		Patients >50 years	
	OR	P-value	OR	P-value
Age	14.5 (3.1-66.9)	0.001	-	-
BMI	0.62 (0.23-1.67)	0.35	0.77 (0.24-2.52)	0.67
Postmenopausal	8.68 (2.4-32.0)	0.001	-	-
PS	1.25 (0.40-3.90)	0.70	0.82 (0.21-3.2)	0.78
Smoker	1.14 (0.41-3.2)	0.80	0.68 (0.21-2.2)	0.52
Cisplatin	0.49 (0.17-1.43)	0.19	1.26 (0.38-4.3)	0.71
Sacrum $D_{50\%}$ EBRT	2.20 (0.80-6.1)	0.13	4.73 (1.33-16.8)	0.016
Sacrum $D_{50\%}$ EBRT+BT	2.77 (0.96-7.9)	0.057	5.54 (1.47-20.9)	0.011
Pelvic bones $D_{50\%}$ EBRT	2.77 (0.96-7.9)	0.057	5.54 (1.47-20.9)	0.011
Sacrum $V_{55\text{Gy}}$	1.02 (0.33-3.2)	0.98	2.0 (0.49-8.2)	0.33
Pelvic bones $V_{55\text{Gy}}$	1.49 (0.54-4.1)	0.76	2.18 (0.66-7.1)	0.20

Cutpoints: Age  $> 50$  years, BMI  $> 25$ , PS  $> 0$ , Cisplatin  $> 4$  cycles, Sacrum  $D_{50\%}$  EBRT  $> 37.8$  Gy, Sacrum  $D_{50\%}$  EBRT+BT  $> 39.6$  Gy, Pelvic bones  $D_{50\%}$   $> 25.5$  Gy, Sacrum  $V_{55\text{Gy}}$   $> 2$   $\text{cm}^3$ , Pelvic bones  $V_{55\text{Gy}}$   $> 2$   $\text{cm}^3$

### Conclusion

PIF is common after treatment for LACC and is mainly seen in patients  $> 50$  years. Our data indicates that PIFs are not related to lymph node boosts, but to dose and volume associated with irradiation of the elective pelvic target. Reducing prescribed elective dose from 50 to 45 Gy may reduce the risk of PIF considerably.

### PO-0712 Benefit of semi-extended field radiotherapy in patients with locally advanced cervical cancer

J. Lee<sup>1</sup>, Y.J. Chen<sup>1</sup>, M.H. Wu<sup>1</sup>, C.L. Chang<sup>2</sup>, T.C. Chen<sup>2</sup>, J.R. Chen<sup>2</sup>, Y.C. Yang<sup>2</sup>

<sup>1</sup>MacKay Memorial Hospital, Radiation Oncology, Taipei, Taiwan

<sup>2</sup>MacKay Memorial Hospital, Department of Obstetrics and Gynecology, Taipei, Taiwan

### Purpose or Objective

Patients with locally advanced cervical cancer (LACC) are at risk for para-aortic lymph node (PALN) metastasis. The current treatment is pelvic concurrent chemoradiotherapy (CCRT) with reported PALN failure rate of 9% by RTOG 90-01, suggesting that pelvic CCRT might not completely eliminate all microscopic tumours in the PALNs. The pattern of lymphatic spread from the pelvis to the PALN appears orderly. This study aimed to evaluate the role of prophylactic lower PALN irradiation in the era of intensity-modulated radiotherapy (IMRT).

### Material and Methods

We retrospectively assessed 186 patients with stage IB2-IVA cervical cancer and clinically negative PALNs receiving definitive IMRT and concurrent weekly cisplatin (40 mg/m<sup>2</sup>) during 2004-2013. The standard radiation field was the whole pelvis with a prescribed dose of 50.4 Gy in 28 fractions. Brachytherapy was performed at a dose of 30 Gy in six fractions. The decision to use semi-extended field radiotherapy (SEFRT) or extended field radiotherapy was according to physicians' discretion. Patients receiving extended field radiotherapy were excluded. The region targeted by SEFRT included the PALNs below the level of the renal vessels. The acute and late toxicities were scored according to the Common Terminology Criteria for Adverse Events, v3.0. Survival outcomes were calculated using the Kaplan-Meier method. Multivariate analyses were performed with Cox regression models. A p-value  $< 0.05$  was considered statistically significant.

### Results

One-hundred-ten and 76 patients received pelvic IMRT and SEFRT, respectively. The patient and tumour characteristics were not significantly different between the two groups. All patients completed the planned radiotherapy, and brachytherapy. The median follow-up time was 58 months (range, 5-124). The failure patterns are shown in Table 1. The 5-year overall survival, disease-free survival, and PALN failure-free survival for SEFRT vs. pelvic IMRT were 85% vs. 74% ( $p = 0.06$ ), 84% vs. 73% ( $p = 0.08$ ), and 98% vs. 90% ( $p = 0.01$ ), respectively. In the subgroup analysis, the 5-year overall survival for SEFRT vs. pelvic IMRT was 81% vs. 59% ( $p = 0.04$ ) and 87% vs. 82% ( $p = 0.48$ ) in patients with positive and negative pelvic lymph nodes, respectively (Fig. 1). In the multivariable analysis, SEFRT affected the overall survival (hazard ratio, 0.39; 95% confidence interval, 0.19-0.82;  $p = 0.01$ ). No patients had severe late genitourinary toxicities, and three and two patients had late grade 3 gastrointestinal toxicities in the SEFRT and pelvic IMRT groups, respectively ( $p = 0.4$ ).

TABLE 1

Failure pattern between the SEFRT and pelvic IMRT groups.

	SEFRT, N = 76	Pelvic RT, N = 110	p value
No evidence of disease, n (%)	65 (85.5)	84 (76.4)	0.043
Cervical recurrence, n (%)	4 (5.3)	4 (3.6)	0.913
PLN recurrence, n (%)	3 (3.9)	3 (2.7)	0.968
PALN recurrence without systemic recurrence, n (%)	0 (0)	8 (7.3)	0.003
Distant metastasis with PALN recurrence, n (%)	1 (1.3)	4 (3.6)	0.314
Distant metastasis without PALN recurrence, n (%)	7 (9.2)	10 (9.1)	0.745

Abbreviations: PLN, pelvic lymph node; PALN, para-aortic lymph node; RT, radiotherapy; SEFRT, semi-extended field radiotherapy.

Fig. 1 Overall survival curves for the SEFRT and pelvic IMRT in patients

with locally advanced cervical cancer with negative (A) and positive (B)

pelvic lymph nodes.

### Conclusion

For patients with positive pelvic lymph nodes LACC, prophylactic PALN irradiation up to the level of renal vessels could reduce PALN recurrence and improve outcomes with few severe late toxicities. A prospective study investigating the risk stratification based optimal radiation field in patients with LACC is warranted.

**PO-0713 Diffusion-weighted MRI for predicting prognosis after radiotherapy in stage IIIB cervical cancer**  
Y. Watanabe<sup>1</sup>, N. Ii<sup>1</sup>, T. Kawamura<sup>1</sup>, Y. Toyomasu<sup>1</sup>, T. Takada<sup>1</sup>, H. Tanaka<sup>1</sup>, E. Kondo<sup>2</sup>, T. Tabata<sup>2</sup>, H. Sakuma<sup>3</sup>, Y. Nomoto<sup>4</sup>

<sup>1</sup>Mie University Hospital, radiation oncology, Tsu, Japan

<sup>2</sup>Mie University Hospital, Obstetrics and Gynecology, Tsu, Japan

<sup>3</sup>Mie University Graduate School of Medicine, radiology,

Tsu, Japan

<sup>4</sup>Mie University Graduate School of Medicine, radiation oncology, Tsu, Japan

### Purpose or Objective

To investigate the value of the apparent diffusion coefficient (ADC) on pre- and mid-treatment MRI in predicting the prognosis (local recurrence/metastasis) of stage IIIB uterine cervical cancer patients who receive concurrent chemoradiotherapy (CCRT).

### Material and Methods

Twenty-three patients with stage IIIB cervical cancer (the International Federation of Gynecology and Obstetrics, FIGO) underwent 1.5T MRI, including T2 weighted imaging (T2WI) and diffusion-weighted imaging at a b-value of 0 and 1,000 (s/mm<sup>2</sup>) before and 3 weeks after the initiation of treatment. Twenty-two of the 23 patients received standard CCRT (chemotherapy including weekly cisplatin and concurrent radiotherapy including external body radiation therapy and brachytherapy). When measuring the ADCs, the regions of interest (ROIs) were manually drawn to include as much of the tumor as possible in two slices; the two mean values were recorded and averaged. The pre ADCs and mid ADCs were defined as the ADCs measured on pre- and mid-treatment MRI, respectively. The  $\Delta$ ADC values were obtained by subtracting the pre-ADC from the mid-ADC, and the %ADC values were determined by dividing the  $\Delta$ ADC values by the pre-ADC values. The sizes of the tumors were also measured on pre- and mid-treatment T2WI. The %size was defined as the rate of decrease in the longest diameter of the tumor. These parameters were statistically analyzed in relation to the prognosis (local recurrence/metastasis) of the patients. The statistical analyses included the Mann-Whitney U test, Fisher's exact test, and a receiver operating characteristics (ROC) analysis.

### Results

In the study population (n=23), local recurrence or metastasis (R/M) was found during follow-up (12-64 months, median: 40 months) in 7 patients (30%); 2 of these patients had local recurrence, 4 had metastasis and 1 had both. The  $\Delta$ ADC values of the patients with and without R/M were  $0.210 \pm 0.070$  and  $0.331 \pm 0.126$ , respectively, which amounted to a statistically significant difference (p=0.013). The %ADC values of the patients with R/M were significantly lower (mean  $\pm$  SD:  $23.5 \pm 8.25$ ) in comparison to the patients without R/M ( $37.9 \pm 16.4$ ) (p=0.012). The area under the ROC curve of the %ADC was 0.835, and the sensitivity and specificity were 87.5% and 85.7%, respectively, when using an optimal cutoff value of 25.7. The proportion of patients who had %ADC values of <30% was significantly greater among the patients with R/M (6/7, 86%) than it was among those without R/M (4/16, 25%) (p=0.019). The %size values of the two groups did not differ to a statistically significant extent (p=0.483).

	R/M + (n=7)	R/M - (n=16)	P value
Pre ADC (mm <sup>2</sup> /sec)	0.897 $\pm$ 0.095	0.884 $\pm$ 0.069	0.402
Mid ADC (mm <sup>2</sup> /sec)	1.11 $\pm$ 0.13	1.22 $\pm$ 0.12	0.082
$\Delta$ ADC (mm <sup>2</sup> /sec)	0.210 $\pm$ 0.070	0.331 $\pm$ 0.126	<u>0.013</u>
%ADC (%)	23.5 $\pm$ 8.25	37.9 $\pm$ 16.4	<u>0.012</u>
%size (%)	27.3 $\pm$ 12.9	35.0 $\pm$ 14.6	0.483

All data was shown as mean  $\pm$  SD.

Mann-Whitney U test

R: local recurrence, M: metastasis

R/M+: R+ or M+, R/M-: R- and M-

### Conclusion

The  $\Delta$ ADC and %ADC values may be useful for predicting the prognosis of patients with stage IIIB cervical cancer treated with CCRT. Furthermore, the %ADC value of <30% may be an important factor for selecting a stronger treatment strategy in patients receiving radiotherapy after mid-treatment MRI.

### PO-0714 Toxicity and Clinical Outcome of IMRT versus Conventional Radiation Therapy for Endometrial Cancer

L. Vaalavirta<sup>1</sup>, S. Larjavaara<sup>1</sup>, P. Arponen-Esteves<sup>1</sup>, A. Leminen<sup>2</sup>, J. Collan<sup>1</sup>, M. Harrela<sup>1</sup>, M. Kouri<sup>1</sup>, M. Tenhunen<sup>1</sup>, H. Joensuu<sup>3</sup>

<sup>1</sup>Comprehensive Cancer Center- Helsinki University Hospital, Department of Radiation Oncology, Helsinki, Finland

<sup>2</sup>Helsinki University Hospital and University of Helsinki, Department of Gynaecologic Oncology, Helsinki, Finland

<sup>3</sup>Comprehensive Cancer Center- Helsinki University Hospital, University of Helsinki, Helsinki, Finland

### Purpose or Objective

To evaluate toxicity as primary objective and clinical outcome as secondary objective in patients with endometrial cancer (EC) treated with whole pelvic intensity modulated radiation therapy (IMRT) versus whole pelvic conventional radiation therapy (CRT).

### Material and Methods

Between 9/2005 and 6/2008 40 eligible patients with EC were stratified according to stage into two groups: (stage I-II and stage III-IV) and then randomly assigned to receive adjuvant IMRT (n=20) or CRT (n=20). The treatment consisted of 50.4 Gy at 28 fractions. A self-administered symptom scale questionnaire (based on the Common Toxicity Criteria (CTC) v3.0), was being used for patient-reported symptoms with different entities for gastrointestinal (GI), gynecological and urological (GU) symptoms. The questionnaire was filled by the patients prior and after RT course, and at 3, 6, 9, 12, 16, 20, 24, 30, 36, 48 and finally at 60 months after RT. In addition, a physician-reported toxicity questionnaire (based on CTCv3.0) was collected in the beginning, at end of RT, as well as at 3 and 6 months after RT. When evaluating the differences in physician-reported toxicity between the two arms, Fisher's exact test was being used. Hazard ratios (HRs) were estimated for relapse-free survival (RFS) and EC-specific mortality for CRT arm relative to the IMRT arm using Cox proportional hazard model. All statistical analyses were performed using Stata software version 14.2(StataCorp).

### Results

The most noticeable differences between the two study arms were seen for urological symptoms at the end of the given RT, for GI symptoms at 12 months and for gynecological symptoms at 12 months, even though seen throughout the 60-month study period. However the differences remained moderate: patient-reported mean score for urological symptoms at the end of RT was 4.8 (95% CI, 3.0-6.6) with CRT and 2.8 (95% CI, 1.3-4.2) for IMRT, p=0.067; for GI symptoms 1.5 (95% CI, -0.16-3.3) for CRT and 0.4 (95% CI, -0.0080-0.81) for IMRT, p = 0.110 at 12 months; and for gynecological symptoms 1.5 (95% CI, 0.68-2.4) for CRT and 0.2 (95% CI, -0.11-0.51) for IMRT, p=0.0014 at 12 months.

Based on the physician-reported toxicity, grade  $\geq 2$  symptoms were further divided into urological, GI and other symptoms. The differences between study groups remained statistically insignificant, even after pooling all the grade  $\geq 2$  symptoms together at each reported time.

No pelvic in-field relapses were seen in either study arms in a median follow up of 9.1 years. At 9 years there was no statistically significant difference in the cancer-specific mortality between the CRT and IMRT arms. HR in favor of the IMRT was 0.50 (95% CI, 0.14-1.70), p=0.253. No statistically significant difference was found in RFS at

9 years between the study arms. HR in favor of the IMRT was 0.72 (95% CI, 0.24-2.14), p=0.551.

### Conclusion

IMRT reduces patient reported GI and GU toxicity. Survival outcomes at 9 years were not statistically different between study arms.

### PO-0715 A phase II study of chemoradiation with tri-weekly cycles of nedaplatin for uterine cervical cancer.

K. Okuma<sup>1</sup>, H. Yamashita<sup>1</sup>, R. Kobayashi<sup>2</sup>, K. Nakagawa<sup>1</sup>

<sup>1</sup>University of Tokyo Hospital, Radiology, Tokyo, Japan

<sup>2</sup>NTT Medical Center Tokyo, Radiology, Tokyo, Japan

### Purpose or Objective

Chemoradiotherapy based on cisplatin is the standard treatment for locally advanced cervical cancer. Nedaplatin an analog of cisplatin, has been shown to have similar treatment effectiveness for several cancer to cisplatin with less nephrotoxicity, myelotoxicity and gastrointestinal toxicity. This study aimed to assess the acute complication with the maximal dose of nedaplatin for carcinoma of the uterine cervix when administered tri-weekly during pelvic radiotherapy.

### Material and Methods

Nedaplatin, 100mg/m<sup>2</sup>, was administered on days 1, 22, and 43 with a concurrent external beam radiotherapy and intracavitary or intersitial brachytherapy. External beam radiotherapy was delivered with a fraction of 1.8-2 Gy per day for 5 days a week during 5-5.6 weeks and brachytherapy of 24 Gy/ 4 fractions at point A. The efficacy and toxicity of chemoradiotherapy with 100mg/m<sup>2</sup> nadaplatin were evaluated.

### Results

Thirty-four patients with uterine cervical cancer in FIGO stages IB1 to IVA were enrolled in this phase II trial from April 2011 through August 2016. The median follow-up period was 15 (range, 2-56) months. Of the 34 patients enrolled for the trial, only 1 (3%) had grade 4 leukopenia and neutropenia. 18 of 34 patients (53%) developed grade 3 treatment-related hematologic toxicities within 30 days. Without one patient who had to go hospital because of grade 3 diarrhea, there were no grade  $\geq 3$  treatment-related non-hematologic toxicities. Complete response was observed in 94% (32/34) of patients. The 2-year overall survival rate and 2-year progression-free survival rate were 96.7% (95% CI, 50-59%) and 73.5% (95% CI, 27-45%), respectively.

### Conclusion

Chemoradiotherapy with tri-weekly cycles of nedaplatin of 100 mg/m<sup>2</sup> was an effective and tolerable regimen in patients for uterine cervical cancer.

### PO-0716 Pelvic insufficiency fracture after IMRT for gynecologic or anal cancer

L. Bazire<sup>1</sup>, H.P. Xu<sup>1</sup>, M. Amessis<sup>1</sup>, C. Malhaire<sup>2</sup>, K. Cao<sup>1</sup>, A. De La Rochefordière<sup>1</sup>, Y.M. Kirova<sup>1</sup>

<sup>1</sup>Institut Curie, Radiation Oncology, Paris, France

<sup>2</sup>Institut Curie, Radiology, Paris, France

### Purpose or Objective

To summarize results for pelvic insufficiency fracture (PIF) in patients with anal or gynecological cancer treated with pelvic intensity modulated radiation therapy (IMRT).

### Material and Methods

The clinical and morphological (CT and / or pelvic MRI) characteristics of patients treated by IMRT at the Institut Curie, between 2007 and 2014 were analyzed. The overall incidence of pelvic fractures occurred after external beam radiation and the effects of localization (gynecological or anal cancer) were calculated. A retrospective delineation of the pelvic bones (iliac bones and sacrum) was conducted in patients who had a fracture and in 60 patients free of fracture after radiotherapy. Dosimetric study was then performed to compare the patients who had a fracture in patients without fracture.

## Results

Three hundred forty-one patients were treated by IMRT for gynecological or anal cancer between 2007 and 2014. Fifteen patients had at least one pelvic fracture occurred after external radiotherapy, an overall incidence of 4.4%. The age and menopausal status were linked to an increased fracture risk ( $p = 0.0274$  and  $p < 0.0001$ , respectively). The site of the primary tumor (gynecological or anal canal) was not related to an excess risk of fracture. The median maximum dose received at the fracture site was 50.3 Gy (range, 40.8-68.4).

## Conclusion

The incidence of pelvic fracture after IMRT was low but more important after age 50 and postmenopausal patients. The pre-therapeutic assessment of bone density by densitometry could be relevant for these patients.

## PO-0717 Role of Radiation Therapy in Vulvar Cancer Patients with One or More Positive Inguinal Lymph Nodes

M.J. Kanis<sup>1</sup>, N. Ryzewski<sup>2</sup>, E.D. Donnelly<sup>2</sup>, J.R. Lurain<sup>1</sup>, J. Strauss<sup>2</sup>

<sup>1</sup>Northwestern University, Gynecologic Oncology, Chicago, USA

<sup>2</sup>Northwestern University, Radiation Oncology, Chicago, USA

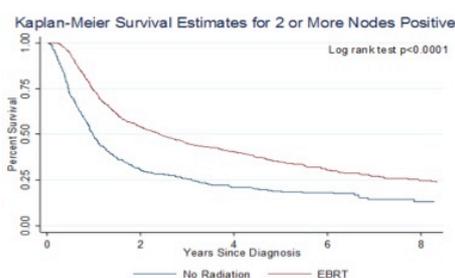

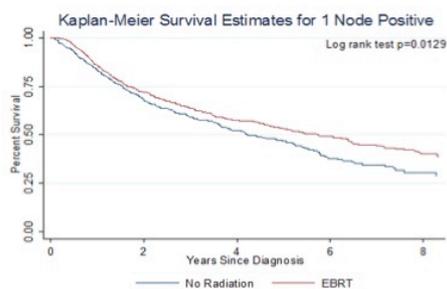

## Purpose or Objective

Using a large national cancer database, we aimed to investigate outcomes for women with one or more than one positive inguinal lymph nodes in squamous cell vulvar cancer who were treated with external beam radiation therapy (EBRT) compared to patients that received no adjuvant radiation.

## Material and Methods

The National Cancer Database (NCDB) was queried to identify women with vulvar cancer that had one or more positive lymph nodes diagnosed between 2004 and 2012. All patients were surgically staged. Chi-square tests and multivariate logistic regression were performed to analyze factors associated with receipt of radiation. Survival analysis was performed using overall survival confidence intervals (CI), log-rank test, Kaplan-Meier estimates, and Cox proportional hazards regression.

## Results

Of 2,859 patients identified, 1,024 (36%) received no adjuvant radiation compared to 1,835 (64%) who received EBRT. Mean number of regional nodes examined was 12.7 for the no radiation group and 12.4 for the EBRT group.

Significant predictors of receiving EBRT over no radiation included age younger than 70 and a closer distance to the hospital. 5-year overall survival (OS) for the entire cohort was 40% (95% CI, 38%-42%). 5-year OS for 1 node positive was 47% (95% CI, 42%-52%) for no EBRT and 53% (95% CI, 49%-57%) in those receiving EBRT. 5-year OS for 2 or more nodes positive was 19% (95% CI, 15%-23%) for no EBRT and 35% (95% CI, 32%-38%) for EBRT. Kaplan-Meier estimates with log-rank test for equality of survivor functions showed improved survival with EBRT in 1 node positive ( $p=0.0129$ ) and 2 or more nodes positive ( $p<0.0001$ ). Cox survival multivariate regression model controlling for confounding variables observed a Hazard Ratio (HR) for EBRT compared to no radiation of 0.88 ( $p=0.122$ ) for 1 node positive, and 0.58 ( $p<0.001$ ) for 2 or more nodes positive. HR without covariates for 1 node positive was 0.82 ( $p=0.008$ ).

## Conclusion

In a large national cancer database, receipt of EBRT was associated with improved survival in woman with vulvar cancer and two or more positive inguinal nodes. In patients with one positive node, a survival advantage was seen using Kaplan-Meier estimates and Cox survival model, but lost statistical significance in a multivariate regression model. These data lend support to the role of EBRT in the management of node positive vulvar cancer. Further research with more detail of other known prognostic factors are needed to validate these findings.

## PO-0718 18-FDG PET/CT parameters to predict survival and recurrence in cervical cancer

N. Scher<sup>1</sup>, F. Herrera<sup>1</sup>, A. Depeursinge<sup>2</sup>, T. Breuneval<sup>1</sup>, J. Bourhis<sup>1</sup>, J. Prior<sup>1</sup>, M. Ozsahin<sup>1</sup>, J. Castelli<sup>1</sup>

<sup>1</sup>Centre Hospitalier Universitaire Vaudois, Radiation Oncology department, Lausanne Vaud, Switzerland

<sup>2</sup>Ecole Polytechnique Fédérale, imaging, Lausanne Vaud, Switzerland

## Purpose or Objective

In the context of locally advanced cervical cancer (LACC) treated with chemo-radiotherapy, the aim of this study was to identify the best predictive 18-FDG PET-based parameters for local-control, disease free- and overall survival, testing different threshold to compute MTV and TLG.

## Material and Methods

Thirty-seven patients treated with standard chemo-radiotherapy followed by brachytherapy underwent a pre-therapy 18-FDG PET/CT. Using different thresholds (from 2.5 to 8 mg/mL and from 30% to 70% of SUVMax), the following PET parameters were computed: maximum standardized uptake value (SUVmax), mean standardized uptake value (SUVmean), metabolic tumor volume (MTV) for primary tumor and lymph nodes, total lesion glycolysis (TLG), and a new parameter combining the MTV and the Euclidian distance between lymph nodes and the primary tumor, namely metabolic nodes distance (MND). Correlation between PET and clinical parameters with clinical outcome (OS, DFS and LRC) was assessed using univariate and multivariate Cox-model. An internal validation of the final model was performed using a cross validation with 5 folds.

## Results

The median follow-up was 52 months (range: 7 - 128). The 3-year OS, DFS and LRC were 71.2 % (95% Confidence Interval (95CI): 56%-86%), 64.1 % (95CI: 48-80) and 69.4 % (95CI: 53 -84) respectively. In univariate analysis, PET/CT parameters associated with OS and DFS were: MTV Tumor, TLG Tumor, TLG Lymph Nodes, and MND. The most predictive threshold segmentation for MTV and TLG was 48 % of SUV max for the primary tumor and 30% for the lymph nodes. In multivariate Cox analysis, the TLG T 48% and MND were the two independent risk factor for OS ( $p<0.01$ ), DFS ( $p<0.01$ ) and LRC ( $p=0.046$ ). The c-index of the model for OS, DFS and LRC (adjusted after cross

validation) were 0.63, 0.68 and 0.66 respectively. Based on this model, 2 groups risk were identified. The 3-year OS, DFS and LRC were 88% (95CI: 67.4 - 100%), 78.7% (63.6 - 97.3%) and 83.6% (95CI: 70.1 - 99.7%) for low-risk group vs 45.5% (95CI: 23.8 - 86.8%), 33.3% (95CI: 15 - 74.2%) and 38.1% (95CI: 17.9 - 81.1%) for high-risk group ( $p < 0.01$ ) (Figure 1 and 2).

#### Conclusion

TLG of the primary tumor and the distance between lymph node and the primary tumor, weighted by the MTV of lymph nodes, were correlated with LRC, DFS and OS. These parameters seem to have a higher predictive value than classical prognostics parameters, and may be useful to tailoring the therapeutic approach in this type of cancer.

#### PO-0719 The use of ultrasound bladder scanning in cervical IMRT to reduce variability of uterine motion

S. Otter<sup>1</sup>, M. Hussein<sup>1</sup>, S. Why<sup>1</sup>, A. Franklin<sup>1</sup>, A. Stewart<sup>1</sup>  
<sup>1</sup>Royal Surrey County Hospital, St Luke's Cancer Centre-Oncology, Guildford, United Kingdom

#### Purpose or Objective

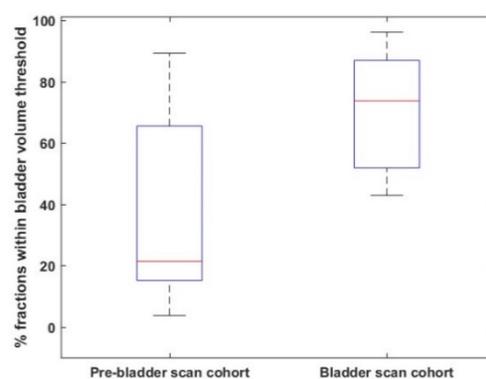

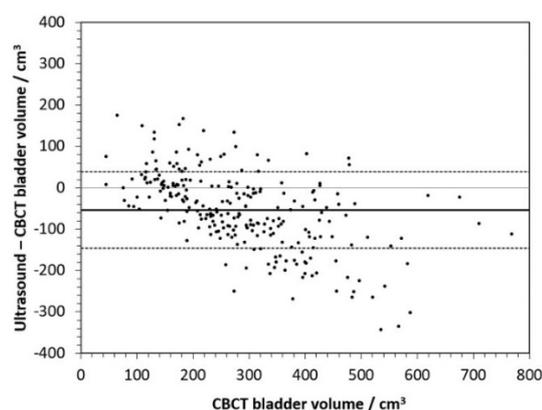

IMRT is being increasingly used over 3D conformal radiotherapy in the treatment of locally advanced cervical cancer. However, the uterus and cervix are mobile structures whose positions vary depending on bladder and rectal filling. The purpose of this study was to assess whether the use of a portable US bladder scanning protocol prior to each fraction of IMRT can reduce bladder filling variability and therefore ultimately reduce cervical / uterine movement.

#### Material and Methods

Patients with locally advanced cervical cancer treated with IMRT received daily CBCT imaging. The bladder was retrospectively contoured on each CBCT. Ten patients were treated using an US bladder scanning protocol (BVI 9400 bladder scan, Verathon). They had a daily pre-treatment bladder scan (BS) and were imaged with CBCT and then irradiated when the bladder volume fell in a pre-determined individualized range based on planning CT scans with empty and full bladder. If the bladder volume was below the target range, patients were rescanned after 15 minutes, if it was above the range, they emptied their bladder and recommenced bladder filling. Nine patients were treated with a standard bladder filling protocol which involved drinking 450ml water in 5 minutes then treatment after 30 minutes. Results were analysed with a Bland-Altman Plot to assess correlation between bladder volume on US and on CBCT. Mann Whitney 1-tailed test was used to assess whether the bladder scanning protocol improved bladder filling consistency (the percentage of radiotherapy fractions where the bladder volume on CBCT fell within the pre-determined range).

#### Results

CBCTs and BS readings were available for 246 fractions of radiotherapy in 10 patients in the BS cohort. 249 CBCTs were available in 9 patients in the pre-BS cohort. The mean difference between BS readings and bladder volume on CBCT was -53.8cc, however the 95% CI band was wide (38.6cc - 146.3cc) and there were a lot of outliers suggesting a lack of statistical significance. This may be related to a combination of: interoperator variability, limited probe size, and differences in the time between the BS readings and the CBCT. The percentage of fractions that had bladder volumes within range were significantly higher in the BS cohort (mean 70.5%) than the pre-BS cohort (mean 38.5%,  $p=0.024$ ). Two patients were excluded from this analysis in the BS cohort as they had empty bladder volumes greater than full bladder volumes on planning CT.

#### Conclusion

The introduction of a bladder scanning protocol has significantly improved the consistency of bladder filling for each fraction of radiotherapy compared to a pre-bladder scan cohort. This may enable a reduction in the CTV-PTV margin in the future which would reduce the volume of irradiated tissue and therefore hopefully reduce toxicity.

#### PO-0720 CTV change during adaptive EBRT for cervix cancer: is mid-treatment plan adaptation required?

D.D. Vignarajah<sup>1</sup>, M.C. Marbán<sup>2</sup>, K.T. Bath<sup>3</sup>, P.J. Hoskin<sup>1</sup>  
<sup>1</sup>Mount Vernon Cancer Centre, Clinical Oncology, Northwood, United Kingdom  
<sup>2</sup>Hospital Universitario Doctor Negrin, Radiation Oncology, Las Palmas de Gran Canaria, Spain  
<sup>3</sup>Mount Vernon Cancer Centre, Radiotherapy Physics, Northwood, United Kingdom

#### Purpose or Objective

Evaluation of clinical target volume (CTV) motion and volumetric changes during cervical cancer external beam radiotherapy (EBRT), to determine the value of mid-treatment plan adaptation compared to pretreatment plan adaptive radiotherapy.

#### Material and Methods

##### Patient Population

Patients undergoing pretreatment adaptive EBRT for cervix cancer were eligible. Consistent bladder and bowel preparation was used as per departmental protocol.

##### Analysis

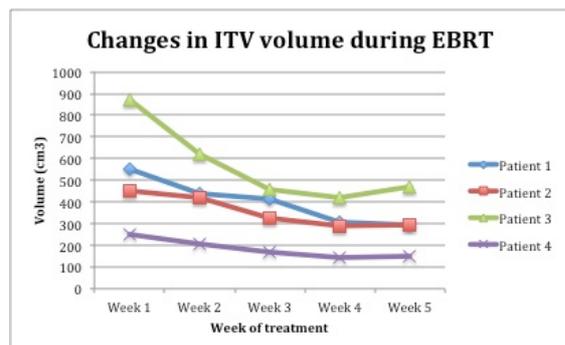

Daily cone beam CT (CBCT) images were reviewed, with the CTV and organs at risk (OARs) delineated on each image set based on GEC-ESTRO guidelines.

Organ motion was assessed in 4 planes (anteriorly, posteriorly, superiorly and inferiorly) at the same anatomical points on each CBCT. Daily CTV volumes were combined to form a weekly internal target volume (ITV), with volume and motion assessed on a weekly basis. Based on the changes noted, new PTV margins were added to the

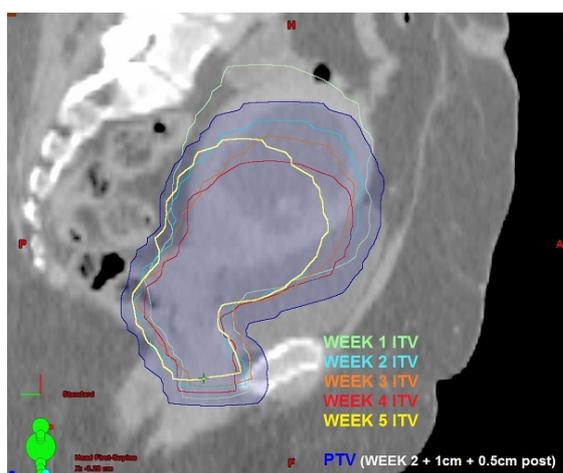

ITVs to ensure adequate coverage of remaining treatments. The adapted mid-treatment PTVs (mtPTVs) were then compared to the pretreatment PTVs (ptPTVs).

### Results

Four patients undergoing adaptive EBRT for cervix cancer were eligible. In total, 100 CBCT images were analysed. The mean CTV volume decrease was 42% by the end of treatment, with 44% of that change (21-63%) occurring within the first week. CTV movement was patient specific, with the largest variations noted anteriorly (1.1cm to 5.5cm) and superiorly (0.67cm-4.3cm). In patients with greater than 1cm variation anteriorly and superiorly, most variation (63%-100%) occurred within the first 2 weeks of treatment.

Given that both volume and movement changes occurred predominantly within the first 2 weeks, mtPTVs were created based on a week 2 ITV. As movement was mainly superiorly and anteriorly, an anisotropic 1cm ITV margin with 0.5cm posteriorly formed the mtPTV. 93% of treatments from week 2 to 5 were covered, with 3 patients demonstrating up to a 28% reduction in volume compared to the ptPTVs. If the mtPTV was created using a 1.5cm anisotropic ITV margin (0.5cm posteriorly), treatment coverage increased to 98%, however treated volume was up to 28% larger than ptPTVs. mtPTV margins based on a week 3 ITV, showed no significant coverage difference from those based on week 2.

Reduced OAR dose was also noted, with treated bowel volume using the mtPTV decreasing by 20.7% compared to the ptPTV.

### Conclusion

Preliminary analyses of patients undergoing adaptive external beam treatment for cervical cancer, shows a dramatic reduction in volume and movement within the first 2 weeks of treatment. mtPTVs based on week 2 ITVs with an anisotropic 1cm margin (0.5cm posteriorly), resulted in adequate treatment coverage in more than 90% of remaining treatments. Treated bowel volume also

decreased by 20%. These results support mid-treatment plan adaptation, although greater patient numbers are required for this to be validated.

### PO-0721 Prediction of local recurrence using pretreatment 18FDG PET/CT radiomics features in cervical cancer

F. Lucia<sup>1</sup>, M. Desseroit<sup>2</sup>, O. Miranda<sup>1</sup>, D. Visvikis<sup>2</sup>, J. Malhaire<sup>1</sup>, P. Robin<sup>3</sup>, O. Pradier<sup>1</sup>, M. Hatt<sup>2</sup>, U. Schick<sup>1</sup>

<sup>1</sup>University Hospital- Brest- France, Radiation oncology, Brest, France

<sup>2</sup>LaTIM- INSERM- UMR 1101- University of Brest, LaTIM- INSERM- UMR 1101- University of Brest, Brest, France

<sup>3</sup>Nuclear Medicine department- University Hospital- Brest- France, Nuclear Medicine department- University Hospital- Brest- France, Brest, France

### Purpose or Objective

Adequate prediction of tumor response to definitive chemoradiotherapy (CRT) in cervical cancer (CC) patients is important to offer a personalized treatment. The aim of this study was to determine if radiomics features in <sup>18</sup>F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) could help in predicting local recurrence in CC.

### Material and Methods

Sixty-nine patients with International Federation of Gynecology and Obstetrics (FIGO) 2014 stage I2B-IVA cervical squamous cell carcinoma receiving synchronous CRT from August 2010 to May 2015 were enrolled in this study. Six (9%), nineteen (27%), thirty-five (51%) and nine (13%) women presented with FIGO stage I, II, III and IV, respectively. <sup>18</sup>F-FDG PET/CT examination was performed on each patient before CRT which consisted of external beam radiotherapy (45 to 50.4 Gy in 1.8-2 Gy per fraction) combined with weekly platinum salts, followed by a high-dose-rate brachytherapy boost (24-26 Gy in 4 fractions). Radiomics (intensity, shape and textural) features of the primary tumor volumes delineated with the fuzzy locally adaptive bayesian (FLAB) algorithm in the PET images were extracted. For textural features three different quantization approaches were considered. The predictive value of clinical parameters and radiomics PET features regarding local recurrence-free survival (LRFS) was evaluated.

### Results

Median follow-up was 1.8 years (0.26-5.6, range). Local relapse occurred in eleven patients (15.9%). In univariate analysis, FIGO stage (I-II vs III-IV)(p = 0.0005), T status (T1-2 vs 3-4)(p < 0.0001), one shape feature (sphericity)(p = 0.001) and two textural features (busyness (p = 0.02), and Grey Level Non Uniformity (GLNU)(p = 0.01) were significantly correlated with local recurrence. The combination of two parameters, such as busyness and sphericity (96.8 % vs 38.2%, HR, 23.51, p<0.0001) or GLNU and sphericity (94.6% vs 23.8%, HR, 20.55, p<0.0001) led to highly accurate models (sensitivity and specificity of 90.9%-77.3% and 81.8%-88.6% respectively).

### Conclusion

In cervical cancer, radiomics features such as sphericity, busyness and GLNU from FDG PET images are significant independent predictor factors for local recurrence. Further research in refining the predictive value of these models is needed to justify dose escalation in these patients, which is already ongoing on a prospective cohort treated at our institution.

### PO-0722 Symptomatic pelvic insufficiency fracture in women after pelvic RT- is there a dosimetric correlate?

Z. Horne<sup>1</sup>, M. Dohopolsky<sup>1</sup>, S. He<sup>1</sup>, B. Gill<sup>1</sup>, S. Beriwal<sup>1</sup>

<sup>1</sup>University of Pittsburgh Cancer Institute, Radiation Oncology, Pittsburgh, USA

### Purpose or Objective

Pelvic insufficiency fractures (PIF) are frequently reported late effect in women who undergo pelvic radiation therapy (RT) for cervical and uterine carcinomas, ranging from 5-15%, though the majority of these are asymptomatic. Other known risk factors include age, pre-existing osteoporosis, and post-menopausal status. Because the majority of PIF are clinically insignificant, we sought to determine predictors of the development of symptomatic PIF in women undergoing pelvic RT.

### Material and Methods

This is a retrospective review of women treated between 1999 and 2013 for uterine or cervical cancer at single institution. All patients received external beam RT with either 3DCRT or IMRT technique to at least 45Gy followed by high dose-rate Intracavitary brachytherapy. Time to symptomatic PIF was calculated as the time from completion of RT to diagnostic imaging demonstrating fracture. Independent t-test and Chi-squared analysis were utilized to determine association between demographic and dosimetric variables and symptomatic PIF.

### Results

253 consecutive patients were identified, 77 (30.4%) of whom had RT plans available for review. The median patient age at diagnosis was 63. The external beam RT dose was 45.0-50. The average mean sacral dose was 37.8Gy (range: 27-44.7Gy). Seven patients (9.1%) were diagnosed with symptomatic PIF at a median time from RT of 23.6 months (range: 7-98 months). Median sacral V20 and V30 were 99.7% and 83.7%, respectively. Sacral V20 was significantly associated with symptomatic PIF ( $p=.008$ ) and V30 trended towards significance ( $p=.054$ ). Sacral V30  $\geq$  83.7% predicted for the risk of symptomatic PIF ( $p=.05$ ).

### Conclusion

This is the first study to correlate symptomatic pelvic insufficiency fracture to dosimetric parameters involved in pelvic RT in women. Limiting sacral V30 < 83.7% is recommended and further study is warranted. We will further validate this data in our larger dataset given the small number of events.

### Poster: Clinical track: Prostate

#### PO-0723 Phase II study with FFF linac-based SBRT in 5 fractions for localized prostate cancer

F. Alongi<sup>1</sup>, U. Tebano<sup>1</sup>, S. Fersino<sup>1</sup>, A. Fiorentino<sup>1</sup>, R. Mazzola<sup>1</sup>, N. Gaj-Levra<sup>1</sup>, F. Ricchetti<sup>1</sup>, D. Aiello<sup>1</sup>, G. Sicignano<sup>1</sup>, S. Naccarato<sup>1</sup>, R. Ruggieri<sup>1</sup>

<sup>1</sup>Sacro Cuore Don Calabria Cancer Care Center, Division of Radiation Oncology, Negrar, Italy

### Purpose or Objective

SBRT is recently considered a potential treatment option in selected prostate cancer (PC) patients. Usually, prostate SBRT has been delivered every other day in order to favour normal tissues recovery, minimizing side effects. Flattening Filter Free (FFF) delivery is a treatment modality able to reduce treatment beam-on time, decreasing patient positioning uncertainties. Aim of the present phase-II study is to evaluate the feasibility, side effects and biochemical control of FFF SBRT delivered in 5 consecutive days in a cohort of localized PC patients.

### Material and Methods

The study, approved by Ethical Committee, started on January 2014. Inclusion criteria were: age  $\leq$  80 years, World Health Organization performance status  $\leq$  2, histologically proven prostate adenocarcinoma, low-intermediate risk according to D'Amico criteria, no distant metastases, no previous surgery other than TURP, no other malignant tumor in the previous 5 years, a pre-SBRT International Prostatic Symptoms Score (IPSS) ranged between 0 and 7.

The SBRT-schedule was 35Gy for low risk and 37.5Gy for intermediate risk PC in 5 fractions, delivered in 5 consecutive days. SBRT was delivered with volumetric modulated radiation therapy (VMAT). Toxicity assessment was performed according to CTCAE v4.0 scale. Neoadjuvant/concomitant hormonal-therapy was prescribed according to risk classification.

### Results

At the time of the analysis, forty-two patients were recruited in the protocol and treated. Median age was 74 years (63-80), Median follow-up was 19 months (range: 12-31). According to risk-category, 31/42 patients were low-risk and 11/42 were intermediate risk. Median initial PSA was 6.1 ng/ml (range, 3.4-12.8 ng/ml). Median Gleason score was 6 (6-7). IPSS pre-SBRT was registered for all patients, with a median value of 4 (range, 0 - 10). All patients completed the treatment as planned. Acute genitourinary toxicity was: G0 29/42 (70%), G1 7/42 (17%), G2 6/42 (13%). Acute gastrointestinal toxicity was: G0 36/42 (86%), G1 4/42 (9%), G2 2/42 (5%). No acute toxicities > G3 were recorded. At the time of the analysis late GU and GI toxicities were: GU-G0 33/42 (78%), GU-G1 7/42 (17%), GU-G2 1/42 (2%), GU-G3 1/42 (2%); GI-G0 39/42 (93%), GI-G1 3/42 (7%) and the median value of IPSS was 4.5 (range, 0 - 20). To date, biochemical control was 100%.

### Conclusion

The present FFF SBRT phase-II study for low-intermediate PC delivered in 5 consecutive days showed to be feasible and well tolerated as well as other series with the same technique and fractionation delivered every other day (Alongi et al Radiation Oncology 2013). Longer follow-up is needed to assess late toxicity profile and clinical outcomes.

#### PO-0724 Moderate hypofractionated radiotherapy in prostate cancer: a meta-analysis from randomized trials

Z. Yin<sup>1</sup>, Z. Yuan<sup>2</sup>, J. You<sup>2</sup>

<sup>1</sup>Tianjin Medical University Cancer Institute & Hospital, Radiotherapy, tianjin, China

<sup>2</sup>Tianjin Medical University Cancer Institute and Hospital, Department of radiotherapy, Tianjin, China

### Purpose or Objective

Conventional radiotherapy (C-RT) with dose more than 75.6Gy was the current standard treatment for patients with localized prostate cancer. While prostate cancer's biological characteristics, low $\alpha$ /Bratio, makes it more radiosensitive to hypo-fractionation. To compare the efficacy and late toxicity of moderate (2.5-3.4Gy) hypo-fractionated radiotherapy (H-RT) in localized prostate cancer with conventional fractionated RT (C-RT), we performed a systematic review and meta-analysis of published randomized trials.

### Material and Methods

Systematic search on published RCTs in English according to Cochrane review guidelines in database of Pubmed, Embase, Cochrane, web of science, and Wiley Online Library were carried out. Outcome of interest was biochemical or clinical disease failure (BCDF), biochemical failure (BF), overall survival (OS) and late toxicities

### Results

6 of 341 studies fulfilled inclusions with 6931 patients. There was no significant difference in BCDF between H-RT and C-RT (RR=0.94, 95% CI: 0.83-1.06,  $p=0.31$ ), with a moderate heterogeneity ( $\text{Chi}^2=6.23$ ;  $\text{df}=4$ [ $P=0.18$ ];  $I^2=36\%$ ). We grouped them into dose-escalated H-RT and no dose-escalated H-RT, dose-escalated H-RT significantly improved BCDF compared with C-RT (RR=0.86, 95%CI: 0.74-0.99,  $p=0.04$ ). Patients who received H-RT showed a lower BF (RR=0.78, 95% CI: 0.63-0.97,  $p=0.03$ ), without heterogeneity ( $\text{Chi}^2=0.86$ ;  $\text{df}=2$ [ $P=0.65$ ];  $I^2=0\%$ ). There was no significant difference in overall survival (RR=0.89, 95% CI: 0.76-1.03,  $p=0.12$ ) between H-RT and C-RT, also no heterogeneity noted ( $\text{Chi}^2=3.53$ ;  $\text{df}=4$ [ $P=0.47$ ];  $I^2=0\%$ ). As

to late toxicity, there is no significant difference in late GI (RR=1.04, 95%CI: 0.88-1.23,  $p=0.63$ ) and GU toxicity (RR=1.10, 95% CI: 0.47- 2.40,  $p=0.26$ ) at 5-years. Since severe heterogeneity were existed, we also divided these studies into dose-escalated and no dose-escalate H-RT group. Dose-escalated H-RT increased in late GI toxicity (RR=1.80, 95%CI: 1.32-2.43,  $p=0.0002$ ) and GU toxicity (RR=1.38, 95%CI: 1.07-1.79,  $p=0.01$ ) significantly, while no dose-escalated H-RT did not (GI: RR=0.82, 95%CI: 0.68-1.00,  $p=0.05$ ; GU: RR=0.92, 95%CI: 0.72-1.16,  $p=0.46$ ).

#### Conclusion

This meta-analysis provides more reliable evidence that H-RT decreased biochemical failure rate, while did not improve overall survival. For dose-escalated H-RT also decreased BCDF rates, and accordingly increased late GI and GU toxicity, while for those without dose-escalated H-RT, there is no difference in BCDF and late GI and GU toxicity.

#### PO-0725 Sigmoid colon is an important organ at risk for high-grade faecal urgency after pelvic radiotherapy

R. Jadon<sup>1</sup>, P. Parsons<sup>2</sup>, L. Hanna<sup>1</sup>, M. Evans<sup>1</sup>, J. Staffurth<sup>1</sup>  
<sup>1</sup>Velindre Cancer Centre, Department of Clinical Oncology, Cardiff, United Kingdom

<sup>2</sup>Velindre Cancer Centre, Department of Medical Physics, Cardiff, United Kingdom

#### Purpose or Objective

Faecal urgency is a common symptom after pelvic radiotherapy negatively impacting quality of life for survivors of pelvic malignancies. Compared with other symptoms such as rectal bleeding and incontinence, dose-volume predictors of faecal urgency are not well established and have not been discussed in the QUANTEC reviews. In this study dose-volume predictors of faecal urgency and constraints to potentially prevent it are sought.

#### Material and Methods

Patient-reported late bowel toxicity data was collected for patients treated with pelvic radiotherapy 12 months post-treatment using the subjective LENT-SOMA patient questionnaire. Treatment plans for these patients were retrospectively analysed with contouring of potential organs at risk including bowel loops, bowel bag, small bowel, large bowel, sigmoid, rectum and anal canal.

Dose-volume predictors for these organs were sought using multivariate logistic regression analysis, with a  $p$ -value of  $<0.05$  considered significant. Constraints from these significant dose-volume predictors were then determined to dichotomise patients into those with and without faecal urgency. Chi-squared analysis was used to assess the 'goodness of fit' of these constraints. The constraints were re-explored on the 24 months post-treatment toxicity data for the same patients.

#### Results

203 patients returned questionnaires including 128 prostate and pelvic node patients, 19 bladder patients, 38 endometrium and 18 cervical cancer patients. 73% were treated with conformal radiotherapy and 27% with IMRT/VMAT. Faecal urgency was reported by 52% of patients, with 41% reporting high grade (grade 3-4 toxicity), defined as 'daily' (grade 3) or 'constantly' (grade 4). There was no clear difference in urgency rates by diagnosis or radiotherapy technique used.

Dose volume parameters of bowel loops, large bowel and sigmoid were predictive of faecal urgency. However only sigmoid parameters (V10, V15, V25) could be used to derive statistically significant constraints below which toxicity would be clinically acceptable. These constraints are detailed in the table below. At 24 months these constraints still demonstrated the ability to dichotomise patients with and without toxicity, although not statistically significantly.

Constraint	Time-point	Rates of High Grade Faecal Urgency		p-value
		Above constraint	Below constraint	Chi-squared
V10<52.6%	12 month	45%	19%	0.03
	24 month	31%	14%	0.3
V15<47.5%	12 month	44%	18%	0.02
	24 month	31%	12%	0.26
V25<36.3%	12 month	44%	23%	0.04
	24 month	32%	11%	0.19

#### Conclusion

These results suggest sigmoid colon to be a responsible OAR for faecal urgency, and reduction of sigmoid dose may improve faecal urgency rates for pelvic radiotherapy patients. Further validation of the constraints derived in an independent sample of patients is required.

#### PO-0726 Dose escalation with HDR brachytherapy for intermediate- and high-risk prostate cancer

R. Chicas-Sett<sup>1,2,3</sup>, F. Celada<sup>1</sup>, J. Burgos<sup>1</sup>, D. Farga<sup>1</sup>, M. Perez-Calatayud<sup>1</sup>, S. Roldan<sup>1</sup>, E. Collado<sup>1</sup>, B. Ibañez<sup>1</sup>, J. Perez-Calatayud<sup>1</sup>, A. Tormo<sup>1</sup>

<sup>1</sup>La Fe Polytechnic and University Hospital, Radiation Oncology, Valencia, Spain

<sup>2</sup>Universidad Católica de Valencia "San Vicente Mártir", Escuela de Doctorado, Valencia, Spain

<sup>3</sup>Recoletas Oncology Institute- Campo Grande Hospital, Radiation Oncology, Valladolid, Spain

#### Purpose or Objective

Dose escalation by the combined therapy between high-dose-rate brachytherapy (HDRB) plus external beam radiation therapy (EBRT) has reported excellent clinical results, strongly supporting its use in high-risk patients. We present our experience of dose escalation using a single-fraction HDRB for intermediate- and high-risk prostate cancer.

#### Material and Methods

From August 2010 to September 2015, 332 patients with National Comprehensive Cancer Network intermediate- (n=59) and high-risk (n=273) prostate cancer were evaluated. Median age was 71 years (range 46-84). The staging was performed via magnetic resonance imaging (MRI) in every case, as is showed in table1. Patients underwent a single-fraction HDRB boost of 15 Gy (n=242) or 9-9.5 Gy (n=90) if seminal vesicles were infiltrated using real-time TRUS based planning. Four gold fiducials markers were implanted immediately after HDRB. EBRT 46 Gy/23fx or 60 Gy/30fx was performed 4 weeks after HDRB to patients who received 15 Gy and 9-9.5 Gy HDRB boost respectively. All patients received EBRT by Volumetric Arc Therapy (VMAT) with imaging guided by CBCT. A total of 148 patients (45%) received a dose of 46 Gy to the pelvis according to the risk pelvic node involvement by ROACH formula. The constraints recommended by GEC/ESTRO have been respected in all brachytherapy plans (Rectum  $D_{2cc} \leq 75$ Gy; urethra  $D_{10} \leq 120$  Gy EQD<sub>2</sub>). GI and GU toxicities were reported according to CTAE v4.0. In all, 290 patients (87%) received neo-concomitant and adjuvant androgen deprivation therapy. Patients were followed prospectively and the Phoenix definition was used to assess biochemical failure

Long term (24 months)	79%
No	9%

## Results

The median follow-up was 33 months (range 2-68). The 5-year biochemical disease-free survival (bFDS) rate was 90% and overall survival (OS) was 86%. Acute genitourinary (GU) toxicity grade 1 and 2 were 37% and 12% respectively, but only 8 patients (2.4%) experienced acute urinary retention (Grade 3). Acute gastrointestinal (GI) toxicity grade 1 and 2 were 16% and 6% respectively. No grade 3 or 4 GI toxicity was observed. Late GU toxicity ≥ grade 3 included 7 patients (2.1%), and the incidence of late GI toxicity ≥ grade 3 was 1% (3 patients) compatible with rectal radiation proctopathy, as is shown in figure 1.

Figure 1. Acute and late toxicities in 332 patients treated with HDRB plus EBRT.

## Conclusion

Dose escalation with a single-fraction HDRB is feasible and well tolerated. The profile of acute and late toxicity is

acceptable, although a longer follow-up is needed to evaluate long-term outcome and toxicities.

## PO-0727 Acute intestinal toxicity after whole-pelvis IMRT for prostate cancer from the patient's perspective

## Purpose or Objective

The aim of this study was to thoroughly analyze patient-reported acute intestinal toxicity (IT) from whole-pelvis RT delivered by means of modern IMRT techniques (IM-WPRT).

## Material and Methods

A multi-Institutional, observational study registered at ClinicalTrials.gov was started in 2014 with the aim of assessing Intestinal, Hematological and Urinary toxicity from IM-WPRT for prostate cancer. Acute IT is evaluated by means of the 10 items of the Inflammatory Bowel Disease Questionnaire pertaining to the Bowel Domain (IBDQ-B) administered to patients (pts) at baseline and at RT mid-point and end: bowel movements (item #1), loose bowel movements (#5), abdominal cramps (#9) and pain (#13), gas passage (#17), bloating (#20), rectal bleeding (#22), urgency to defecate (#24), accidental soiling (#26), nausea and feeling sick (#29). Each item is scored on a 1-7 point scale (most severe symptoms=lower scores). Analyses were performed on the worst variations ( $\Delta$ ) of each item between baseline and RT mid-point or end. This analysis pertains to 242 pts with complete data at all the 3 time intervals, treated with adjuvant, salvage or radical intent (n=91, 104 and 47, respectively), with VMAT, Tomotherapy or static-field IMRT (n=122, 90 and 30, respectively). RT was delivered at conventional (CF, 1.7-2 Gy/fr, n=92) or moderate hypo-fractionation (HYPO, 2.15-2.65 Gy/fr, median 2.35 Gy/fr, n=114). The median EQD2 (for  $\alpha/\beta=3$ ) to prostatic bed and prostate were 72.6 and 77 Gy, respectively; pelvic lymph-nodes/pelvic lymph-nodal area were always treated with conventional fractionation (range 50.4-56.1 Gy, median 51.8; daily dose: 1.7-2 Gy/fr).

## Results

Overall, IM-WPRT was well tolerated, with a median  $\Delta$  with respect to baseline of -2 points for item #1, of -1 points for items # 5, 17 and 24, and 0 for the 6 remaining items (Table 1, Fig. 1). Moreover, the consequent impairment of Emotional, Social and Systemic Domains evaluated by the IBDQ was exceptionally mild (Table 1). Nevertheless, the  $\Delta$  of all the 10 IBDQ-B at RT end with respect to baseline was always statistically significant ( $p \leq 0.02$ ) at the Analysis of Variance (ANOVA). Interestingly, in the 134 patients with complete data at 1 year, ANOVA highlighted a persisting, significant ( $p < 0.04$ )  $\Delta$  with respect to baseline

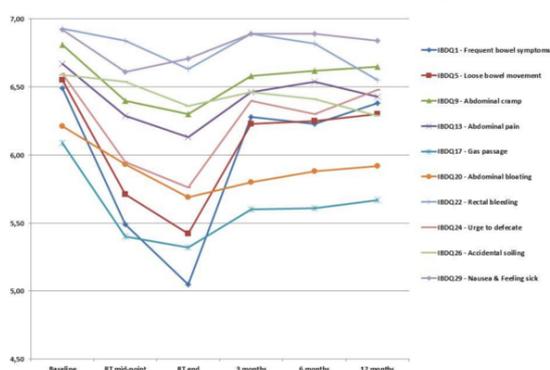

for items # 9, 17, 20, 22, and 26 (Figure 1). Finally, the predictive power of the 10 IBDQ-B items with respect to the acute worsening of the Bowel domain was investigated by means of ROC analyses, setting the 25<sup>th</sup> percentile of the  $\Delta$  with respect to baseline (-1.10, Table 1) as endpoint. The IBDQ items # 1, 5, 13, 20 and 24 showed the highest discriminative power (AUC >80%) in detecting patients with acute IBDQ-B worsening.

IBDQ-B item	1	5	9	13	17	20	22	24	26	29
Description	Frequent bowel symptoms	Loose bowel movements	Abdominal cramp	Abdominal pain	Gas passage	Abdominal bloating	Rectal bleeding	Urge to defecate	Accidental soiling	Nausea & Feeling sick
Lowest (worst)	-6	-6	-5	-5	-6	-5	-6	-6	-5	-5

25th percentile	-3	-3	-1	-1	-2	-1	0	-2	-1	-0.75

IBDQ Domain	Bowel	Emotional	Social	Systemic
Lowest (worst)	-3.6	-2.76	-5.00	-4.00
Highest (best)	+0.80	+1.25	+1.00	+2.50
Mean	0.78	0.36	-0.73	-0.69
Median	-0.80	-0.25	-0.40	-0.60
25th percentile	-1.10	-0.67	-1.20	-1.00

Trend over time of the mean scores of the 10 IBDQ Bowel items

**Conclusion**

Acute, patient-reported, IT from IM-WPRT is mild, but some symptoms seem to persist one year after RT end. Five out of ten questions of IBDQ-B were shown to be more efficient in discriminating patients with larger acute worsening of IBDQ-B.

**PO-0728 BRCA2 mutation predicts poor survival in prostate cancer: A compelling evidence from 8,988 patients.**

M. Cui<sup>1</sup>, X.S. Gao<sup>1</sup>, X. Gu<sup>1</sup>, C. Peng<sup>1</sup>, X. Li<sup>1</sup>, M. Ma<sup>1</sup>  
<sup>1</sup>Peking University First Hospital, Department of Radiation Oncology, Beijing, China

**Purpose or Objective**

To focus on clinicopathological characteristics and prognosis in men with prostate cancer (PCa) with Breast Cancer 2 (BRCA2) mutation and offer some convincing evidence for adding BRCA2 mutation as an early screening biomarker into NCCN and EAU guidelines.

**Material and Methods**

We searched relevant articles from PubMed, Embase, Web of Science and the Cochrane Library databases to evaluate the overall survival (OS) and cancer-specific survival (CSS) difference between BRCA2 mutation and non-carriers in patients with prostate cancer. This meta-analysis was performed following the (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) PRISMA Statement guidelines strictly.

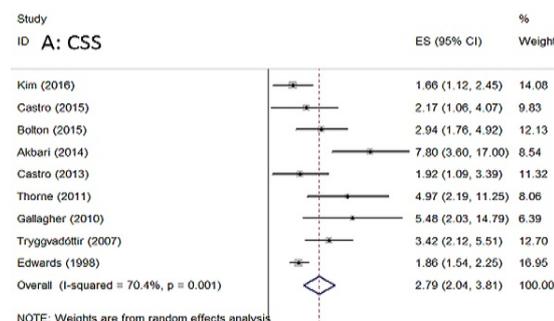

**Results**

We totally incorporated 525 BRCA2 mutations versus 8,463 non-carriers from 10 studies in our meta-analysis. The results showed that BRCA2 mutation carriers was correlated with worse CSS and OS than non-carriers, with pooled Hazard Ratios (HRs) of 2.79 [95% confidence interval (CI): 2.04-3.81, P<0.001] and 2.21 (95%CI: 1.61-3.02, P<0.001) respectively. The results also demonstrated that BRCA2 mutation carriers also harboring

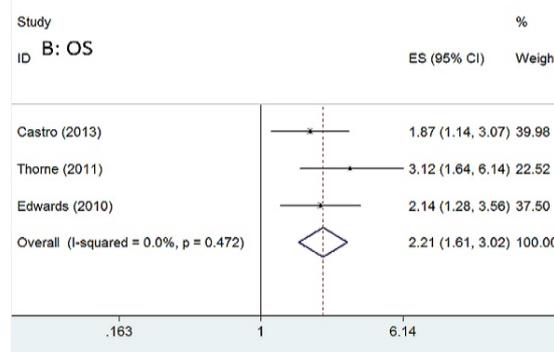

higher Gleason Score(>7), TNM stage(>T3, N1, M1) and risk level than non-carriers.

Table 1: Meta-analysis of the association on clinicopathological features between BRCA2+ and non-carriers with prostate cancer

Variable	No. of studies	No. of BRCA2(+)	No. of Non-carriers	Effects model	OR (95% CI)	P	Heterogeneity I <sup>2</sup> (%)	P <sub>h</sub>	Publication bias P
GS (>7 vs. <=7)	6	231	3,722	Fixed	3.24 (2.36-4.44)	<0.001	21.8	0.27	0.26
T stage (>T3 vs. <=T3)	4	176	2,859	Fixed	1.75 (1.26-2.42)	0.001	0	0.459	0.089
N stage (N1 vs. N0)	3	139	2,367	Fixed	3.90 (2.17-7.03)	<0.001	0	0.593	0.256
M stage (M1 vs. M0)	2	90	1,999	Fixed	2.47 (1.32-4.63)	0.005	0	0.737	1
Risk (high vs. <High)	2	101	2,510	Fixed	1.48 (0.95-2.14)	0.087	0	0.335	1

NOTE: Weights are from random effects analysis

**Conclusion**

Our meta-analysis showed that BRCA2 mutation predicted poor survival outcomes in patients with PCa. Therefore, BRCA2 mutation as a helpful clinical prognostic factor could stratify the high risk patients and provide clinical strategies for more effective targeted treatments.

**PO-0729 Normal Tissue Complication Probability for late urinary toxicities after RT for prostate cancer**

<sup>1</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy

#### Purpose or Objective

The main objective of this work was to fit the Normal Tissue Complication Probability (NTCP) model for the prediction of late urinary symptoms at three years after radical radiotherapy (RT) for prostate cancer. Then, to evaluate the effect of leading clinical risk factors on the NTCP.

#### Material and Methods

Patients were enrolled in a prospective, multicentre, observational trial in 2010-2014. They were treated at different prescription doses with conventional (74-80 Gy at 1.8-2 Gy/fr,) or moderately hypo-fractionated RT (65-75.2 Gy at 2.2-2.7 Gy/fr) in 5 fractions/week.

Urinary symptoms were evaluated through the International Prostate Symptom Score (IPSS) questionnaire filled in by the patients before RT, after RT, and every 6 months until 5 years of follow-up. The incidence of late toxicity at 3 years was defined as the occurrence of an IPSS >=15 at least once between 6 and 36 months after RT. Bladder dose volume histograms were collected for each patient. They were corrected to the equivalent doses in 2 Gy/fraction (EQD2), with  $\alpha/\beta=3\text{Gy}$ , and then reduced to the Equivalent Uniform Doses (EUD), computed at varying n values. Several clinical factors were also collected (comorbidities, drugs, hormone therapies, previous surgeries, smoking, alcohol, age, and body mass index). Maximum likelihood estimation (MLE) was employed for calculating the best-fit NTCP parameters: n (volume parameter summarizing the organ architecture),  $EUD_{50}$  (EUD causing 50% toxicity risk) and k (steepness of the NTCP) [1].

Leading clinical factors associated with urinary toxicity were evaluated with univariable logistic regression ( $p<0.05$ ) and included in the NTCP model as  $EUD_{50}$  modifying coefficients.

#### Results

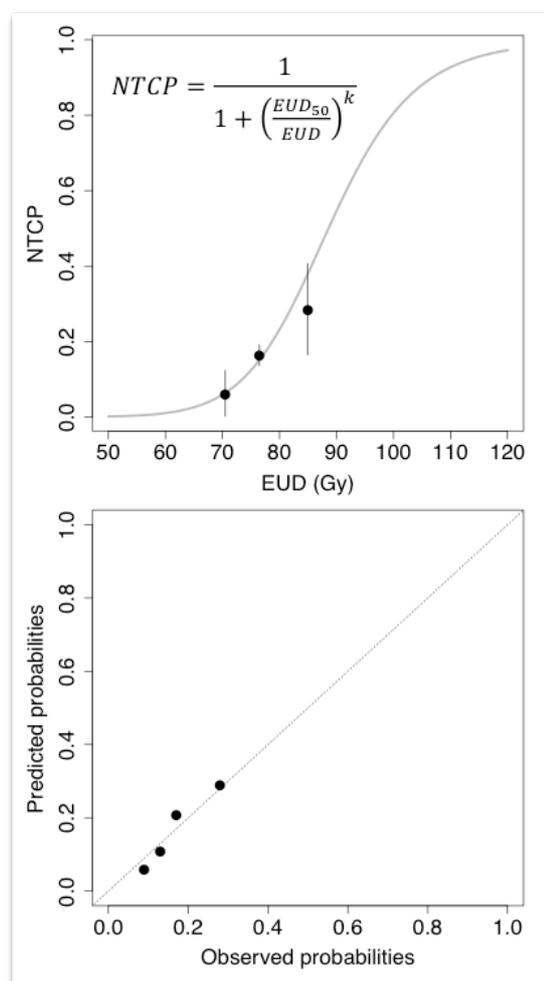

217 patients had complete IPSS questionnaires at 30 or 36 months, at least 3 follow-up evaluations, and did not show urinary symptoms before RT (baseline IPSS <=12). 35/217 patients (16%) showed late urinary toxicity.

MLE pointed toward EUD values with very low  $n=0.01\pm 0.01$ . Thus indicating a serial behaviour of bladder for this toxicity. The best-fit parameter for the NTCP steepness was  $k=12\pm 4$ , while  $EUD_{50}$  was estimated to be  $89\pm 5\text{Gy}$ . The results were confirmed in the hypofractionated population.

The use of antiaggregants was the only clinical risk factor associated with toxicity ( $p=0.02$ , odds ratio = 3.6). Its inclusion in the NTCP model implied a reduction of the  $EUD_{50}$  to  $81\pm 5\text{Gy}$ .

**Conclusion**  
An NTCP model for prediction of late urinary toxicity was determined. Bladder was found to act as a serial organ, so that toxicity risk highly depends on small bladder volumes irradiated with high doses. Patients with antiaggregants exhibit enhanced radiosensitivity. The dose-response relationship points out that hypofractionation (resulting in higher EUDs) should be combined with careful optimization in the bladder-PTV overlap to reduce the risk of late urinary toxicity.

#### PO-0730 The independent benefit deriving from high doses and WPRT in salvage post-prostatectomy radiotherapy

C. Cozzarini<sup>1</sup>, B. Noris Chiorda<sup>1</sup>, C. Fiorino<sup>2</sup>, M. Pasetti<sup>1</sup>, A. Briganti<sup>3</sup>, C.L. Deantoni<sup>1</sup>, A.M. Deli<sup>1</sup>, A. Fodor<sup>1</sup>, N. Fossati<sup>3</sup>, G. Gandaglia<sup>3</sup>, C. Sini<sup>2</sup>, F. Montorsi<sup>3</sup>, N. Di Muzio<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

<sup>2</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy

<sup>3</sup>San Raffaele Vita-Salute University, Urology, Milano, Italy

#### Purpose or Objective

The success rate after salvage radiotherapy (SRT) for biochemical recurrence after radical prostatectomy is still unsatisfactory, possibly owing to inadequate irradiation doses and fields. The few retrospective studies investigating the role of whole-pelvis radiotherapy (WPRT) in this setting have pertained to patients (pts) treated with conventional (60-68 Gy) SRT doses, a factor that may have "diluted" its true effect. The purpose of this analysis was to evaluate the possible clinical benefit of WPRT in addition to high-dose salvage radiotherapy (HDSRT), and to identify the cohort that would benefit most from it.

#### Material and Methods

From 1998 to 2009, 235 node-negative pts underwent HDSRT (median 75.6 Gy, range 64.8-77.4). 149 pts were irradiated to prostatic bed (PB) only, at a median dose of

73.8 Gy (all with 3DCRT), while 86 received WPRT at a median dose of 50.4 Gy (45% by standard 3D box and 55% by static field IMRT), plus a consequential 3D-CRT boost to PB up to 75.6 Gy. The indication of both WPRT and of adjuvant androgen deprivation (AAD), prescribed to 158 pts for a median of 14 months, was at the discretion of each treating physician

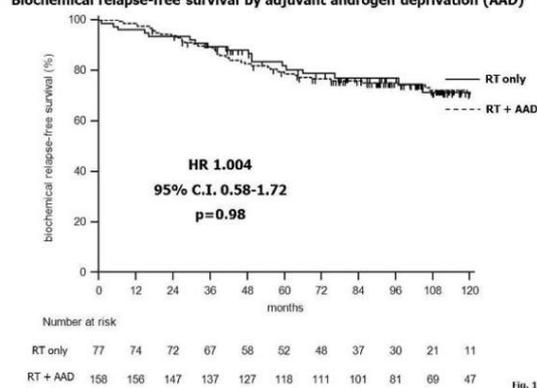

### Results

Median overall FU was 111 months. Owing to the gradual introduction of WPRT over time, the cohort receiving WPRT had a significantly shorter follow-up (90 vs 124 months,  $p < 0.0001$ ) and received significantly higher RT dose (median 75.6 vs 73.8 Gy). All the remaining prognostic variables were evenly distributed. At univariable analysis SRT dose  $\geq 75.6$  Gy was the only variable predictive of significantly increased 7-year bRFS in the overall population and in the two subsets of pts with PSA at SRT (PSA@SRT)  $\leq 0.50$  or  $> 0.50$  ng/mL. WPRT led to a significant improvement in 7-year bRFS in the overall population (84 vs 72%,  $p = 0.02$ ) and in the 144 pts with a PSA at SRT  $> 0.50$  ng/mL (83% vs 64%,  $p = 0.01$ ). At multivariable analysis (MVA) SRT dose  $\leq 73.8$  Gy, pathologic stage  $\geq T3a$ , GS  $\geq 7$  and higher PSA@SRT, but not WPRT, emerged as covariates independently predictive of reduced post-SRT bRFS in the overall population. The independent benefit deriving from higher SRT doses and WPRT was confirmed in the 2 subsets of pts with PSA@SRT  $\leq$  and  $> 0.50$  ng/mL, respectively. No benefit whatsoever emerged from AAD (Fig 1).

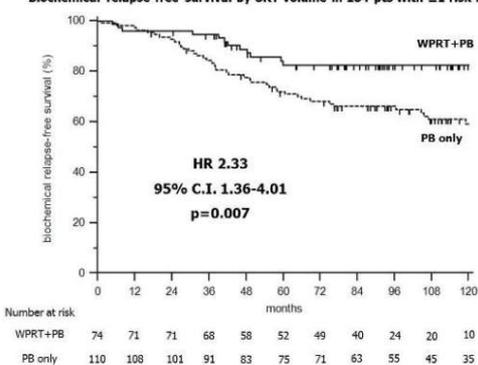

In order to identify the subset benefiting most from WPRT (Fig. 2) and dose-escalation, their roles were investigated in the subset of 184 pts with at least 1 risk factor among those individuated at MVA (GS  $\geq 7$ , pT $\geq 3a$ , and PSA at SRT  $> 0.50$  ng/mL). In this subset MVA confirmed the independent role of WPRT (HR 0.47,  $p = 0.04$ ) and SRT doses  $\geq 75.6$  Gy (HR 0.46,  $p = 0.03$ ).

Neither WPRT nor higher SRT doses led to any significant increase of either acute or late toxicities.

**Biochemical relapse-free survival by adjuvant androgen deprivation (AAD)**

**Biochemical relapse-free survival by SRT volume in 184 pts with  $\geq 1$  risk factor**

### Conclusion

Despite its retrospective nature, this study lends support to the use of both WPRT and SRT doses  $\geq 75.6$  Gy in the salvage setting in node-negative patients with  $\geq 1$  risk factor among PSA at SRT  $> 0.50$  ng/mL, Gleason score  $\geq 7$  and pathologic stage  $\geq T3a$ .

### PO-0731 Comparison of two fractionation schemes in prostate cancer patients treated with robotic SBRT

F. Akyol<sup>1</sup>, P. Hurmuz<sup>1</sup>, G. Ozyigit<sup>1</sup>

<sup>1</sup>Hacettepe University- Faculty of Medicine, Department of Radiation Oncology, Ankara, Turkey

### Purpose or Objective

The aim of this study is to evaluate the long term treatment results of two different fractionation schemes and PSA bounce phenomenon in our patients treated with robotic stereotactic body radiotherapy (rSBRT) for prostate cancer.

### Material and Methods

We evaluated the medical records of 106 patients who were treated between June 2007 and June 2015 for prostate cancer in our department with CyberKnife™. D'Amico risk classification system (1998) was used to group patients. In the low risk (LR) group (n=54) 20 patients received androgen blockade (AB) (for volume reduction or else purposes). In the intermediate risk (IR) group (n=52) 42 patients received neoadjuvant/adjuvant AB. According to our institution's treatment protocol rSBRT was delivered in 5 fractions to a total dose of 36.5 Gy either sequentially (n=58) or every other day (n=48). 'Cavanagh definition' ( $\geq 0.2$  ng/mL) was used to define 'PSA bounce phenomenon'.

### Results

Median follow up time was 56 months. Only one patient died due to pulmonary thromboembolism. Two patients in the LR group and 3 patients in the IR group had PSA relapses. In the whole group 5 year biochemical relapse free survival (BRFS) rate was 93.4% (LR; 97.1% vs. IR; 89.2%;  $p = 0.6$ ). Five year BRFS rate in patients treated with sequential scheme was 92% compared to 100% for every other day scheme ( $p = 0.3$ ). PSA bounce phenomenon was observed in 17 patients (16%) and among them only one patient had PSA relapse. Five year BRFS rate was 89% in patients with PSA bounce phenomenon compared to 94.2% in patients without bounce ( $p = 0.9$ ). There was no difference in the incidence of PSA bounce for different treatment schemes. All of the patients received the planned rSBRT dose without any breaks in the treatment schedule due to toxicity. Late grade III gastrointestinal system toxicity was observed in 4 patients (3 sequential, 1 every other day scheme;  $p = 0.6$ ). No patients reported late grade III genitourinary toxicity.

### Conclusion

Our rSBRT treatment protocol was very well tolerated with high rates of 5 year BRFS rates. PSA bounce phenomenon may also be observed after rSBRT for prostate cancer. We did not find a relation between PSA bounce and biochemical relapse. The fractionation scheme of the rSBRT in our protocol did not affect the treatment results and toxicity.

### PO-0732 Toxicity and outcome in moderately hypofractionated radiotherapy for 590 prostate cancer patients

<sup>4</sup>European Institute of Oncology, Department of Urologic Surgery, Milan, Italy

<sup>5</sup>European Institute of Oncology - University of Milan, Department of Urologic Surgery, Milan, Italy

<sup>6</sup>European Institute of Oncology - University of Milan, Department of Medical Imaging and Radiation Sciences- Department of Oncology and Hemato-oncology, Milan, Italy

### Purpose or Objective

To report toxicity and efficacy of moderately hypofractionated external-beam radiotherapy in a large series of patients treated for prostate cancer in a 9-year period.

### Material and Methods

Between January 2007 and December 2015, 590 T1-T3N0M0 prostate cancer patients received 70.2 Gy in 26 fractions at 2.7 Gy/fraction (equivalent to 84 Gy in 42 2-Gy fractions, considering  $\alpha/\beta$  of 1.5 Gy) using image-guided three-dimensional conformal radiotherapy (3D-CRT) and intensity modulated radiotherapy (IMRT). Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer criteria (RTOG/EORTC) and Houston definition (nadir + 2) were used for toxicity and biochemical failure evaluation, respectively.

### Results

All patients completed radiotherapy. Mean age was 72.6 years (6.5 standard deviation). Fourteen patients were lost to follow-up. Information on gastrointestinal (GI) toxicity was available for 306 (54.4%) patients. Of these, 287 patients (93.7%) reported G0-G1 GI toxicity, with prevalence of G0 (84.6%), 13 (4.3%) G2 toxicity, 6 (2.0%) G3-G4 toxicity (table 2a). Information on genito-urinary (GU) toxicity was available for 306 (54.4%) patients. Of these, 277 patients (91.2%) reported G0-G1 GU toxicity, with prevalence of G0 (68.8%), 26 (8.6%) G2 toxicity, 1 (0.3%) G3-G4 toxicity (table 2b). At univariate analysis, age >80 years, increasing initial risk category, increasing Gleason score, increasing prostate-specific antigen (PSA) and the seminal vesicle involvement were associated with increased mortality. At multivariate analysis, Gleason score was the only predictor of mortality, even after adjustment for age. At univariate analysis, increasing risk, increasing Gleason score, increasing PSA and seminal vesicle involvement were associated with disease progression. At multivariate analysis, Gleason score was the stronger predictor of disease progression, even after adjustment for age.

### Conclusion

The present study confirms that hypofractionated radiotherapy is a viable treatment option for localized

prostate cancer in terms of toxicity and clinical outcome.

### PO-0733 Radium 223: Difference in clinical outcomes between young and old

Y.P. Song<sup>1</sup>, T. Ellis<sup>2</sup>, R. Walshaw<sup>1</sup>, J. Logue<sup>1</sup>, O. Parikh<sup>2</sup>, A. Choudhury<sup>1</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom

<sup>2</sup>Lancashire Teaching Hospitals NHS Foundation Trust, Clinical Oncology, Preston, United Kingdom

### Purpose or Objective

The commonest metastatic site for prostate cancer is the bone. The alpha-emitting radioisotope, Radium 223 (Ra223) has been shown to be effective in symptom management and improving overall survival in patients with metastatic castrate resistant prostate cancer (mCRPC). The balance between clinical benefit and impact of treatment in older patients is important to consider as over 50% of newly diagnosed patients in the UK are over the age of 70. We hypothesized that there would be no difference in outcome between the two groups. The aim of this clinical study is to examine the toxicities and clinical benefits of Ra223 between older and younger patients.

### Material and Methods

Data from all patients treated with Ra223 in two tertiary cancer centres from December 2013 to February 2016 was collected retrospectively. Patients were divided into two groups - those 72 years and above at the time of commencing treatment, and those below 72, as the median age of patients treated in the landmark ALSYMPCA trial was 71. Toxicities were graded with CTCAE version 4. Statistical analysis was carried out using SPSS version 24.

### Results

A total of 129 patients were treated during this period. The median age was 71 (range: 55-89). 65 (50.4%) were below 72 years while 64 (49.6%) were 72 and above. Patients received a median of 5 cycles (range: 1-6) of Ra223 at a dose of 50kBq/kg.

41 (63%) younger patients and 38 (59%) from the older group had had previous abiraterone while 20 (31%) and 15 (23%) respectively had had previous enzalutamide. 41 (63%) from the younger group were previously treated with docetaxel compared to 24 (38%) older patients (p=0.004). 11 (16.9%) of the younger patients and 4 (6.3%) of the older patients had had previous carbazitaxel.

51% of those below 72 and 59% of those 72 and above reported an improvement in symptoms (p=0.326). The median overall survival from starting Ra223 was 8.2 months (0.7-22.4) in the younger group and 8.6 (0.9-23.7) in the older group.

Ra223 was well tolerated with 13 of 129 (10%) patients developing grade 3 (G3) anaemia. This included 11 (17%) from the younger group compared to 2 (3%) from the older group (p=0.009). There was one patient in each group with G3 neutropenia, but no neutropenic sepsis or G3 thrombocytopenia. During the course of treatment, 11 (9%) patients developed a skeletal-related event. This included 3(5%) older patients and 8 (12%) younger patients (p=0.123).

### Conclusion

Ra223 was well tolerated with minimal toxicities. However, a higher percentage of the young patients reported toxicities, with a statistically significant higher incidence of G3 anaemia. This may be associated with previous lines of treatment, since a larger proportion of patients below the age of 72 had had docetaxel in the past. There was no statistical difference between the younger and older patients with respect to symptomatic relief and median overall survival. Older patients had similar clinical benefit with Ra223 and should be considered in appropriate patients.

<sup>10</sup>Istanbul University- Cerrahpasa Faculty of Medicine, Department of Radiation Oncology, Istanbul, Turkey

<sup>11</sup>Istanbul University- Cerrahpasa Faculty of Medicine, Department of Radiation Oncology, Istanbul, Turkey

#### Purpose or Objective

We performed a multi-institutional pooled data analysis as Turkish Radiation Oncology Group (TROG) to evaluate the efficacy of elective pelvic RT and TAB duration in prostate cancer patients with Gleason score (GS) of 8-10 treated with three dimensional conformal radiotherapy (3DCRT) or intensity modulated radiation therapy (IMRT).

#### Material and Methods

A total of 641 eligible prostate adenocarcinoma patients from 11 TROG centers, treated with 3DCRT or IMRT between 1997 and 2013 were evaluated in this study. The eligibility criteria were as follows; T1-3N0M0 according to AJCC 2010 staging system, Gleason score of 8-10, a total RT dose of at least 70 Gy with 3DCRT or IMRT, at least 24 months of follow-up for all surviving patients. TAB duration, elective pelvic RT, T stage, GS, perineural invasion (PNI), total RT dose, RT technique, percent positive core biopsy (PPCB), age, and pre-biopsy PSA level were analyzed as potential prognosticators. ASTRO Phoenix definition was used for biochemical failure (PSA nadir+2 ng/dL). Log-rank test was performed for univariate analyses (UVA), and Cox-regression analysis was used for multivariate analyses (MVA).

#### Results

Median follow-up was 6 years. The median prebiopsy PSA level was 21.3 ng/dL, the median TAB duration was 24 months, and the median total RT dose was 75 Gy. Fifty-one patients were died of prostate cancer, whereas 62 patient died due to other diseases. PSA failure was detected in 171 cases, and distant metastases developed in 99 patients. Five and 10 year biochemical relapse free survival (BRFS) rates for entire cohort were 76.8% and 61.1%, respectively. UVA showed that higher GS, higher PPCB, advanced T stage, PNI presence, elective pelvic RT, younger age, and higher pre-biopsy PSA level were significant poor prognostic factors for BRFS. The duration of TAB ( $\leq 12$  months vs  $> 12$  months), total RT dose and RT technique did not have any significant impact on BRFS. MVA revealed that T stage ( $p=0.002$ ), GS ( $p=0.046$ ), age ( $p=0.01$ ), PNI ( $p=0.04$ ) and PPCB ( $p=0.001$ ) were independent statistically significant predictors for BRFS. We did not found any significant effect of TAB duration ( $\leq 12$  months vs  $> 12$  months) or elective pelvic RT on BRFS in MVA.

**Table 1. The clinical and therapeutic characteristics of 341 eligible prostate cancer patients.**

	Number of patients	%
<b>T Stage</b>		
T1	32	5
T2	357	55.7
T3	252	39.3
<b>Gleason Score</b>		
8	335	52.3
9	276	43.1
10	30	4.7
<b>Pelvic Radiotherapy</b>		
Absent	330	51.5
Present	311	48.5
<b>TAB duration</b>		
$\leq 12$ months	133	20.7
$> 12$ months	489	76.3
No TAB use	19	3

#### Conclusion

In this multi-institutional pooled data analysis, the use of elective pelvic radiotherapy did not improve BRFS in high-risk prostate cancer patients. Similarly, TAB use of more than 12 months in this sub-group did not have any positive impact in BRFS. The optimal duration of TAB in the era of dose escalated prostate IMRT should be determined in further randomized trials to minimize the side effects of 2-3 years of androgen deprivation.

#### PO-0735 HDR-brachytherapy or SBRT for extreme hypofractionation in prostate cancer - long-term results

S. Aluwini<sup>1</sup>, W. Busser<sup>1</sup>, M. Kroon<sup>1</sup>, B. Heijmen<sup>1</sup>

<sup>1</sup>Erasmus MC Cancer Institute- Rotterdam- the Netherlands, Department of radiation oncology, Rotterdam, The Netherlands

#### Purpose or Objective

Hypofractionated radiotherapy for prostate cancer is increasingly used in daily practice because of radiobiological, economic and logistic advantages. Long-term results are still scarce. Here we report on late toxicity of 2 extreme hypofractionation regimens

#### Material and Methods

Between 2007 and 2015, 329 patients with low and intermediate risk prostate cancer (T1a-2b, Gleason score 6-7, PSA  $< 20$  Gy) were treated with either High-Dose-Rate (HDR) brachytherapy (monotherapy) delivered in 4 fractions of 9.5 Gy in 36 hours (206 patients) or with stereotactic body radiotherapy (SBRT) using the Cyberknife (CK), delivering 4 fractions of 9.5 Gy in 4 consecutive days (123 patients). For both regimens, patient follow-up after treatment was performed at 2, 4, 8 and 13 weeks, and at 6, 9, and 12 months in the first year, and 6 monthly thereafter. Validated patient's self-assessment RTOG-EORTC questionnaires (PSAQ) were routinely sent to all patients according this schedule and used to report on late toxicity. We compared late grade  $\geq 2$  toxicity. Moreover, for gastrointestinal (GI) toxicity we analysed stool frequency  $\geq 6$ /day, incontinence, rectal bleeding and pain, and for genitourinary (GU) day frequency  $\geq 16$ , night frequency  $\geq 4$ , haematuria, incontinence and dysuria.

#### Results

Median FU was 36 months with a range of 6-96 months (HDR 36 (6-96), CK 36 (6-84)). There were no significant differences in patient's characteristics between the 2 groups. Based on PSAQ, late grade 2 and 3 GU toxicity was reported in 26.8% and 8.1% of patients in de CK group versus 22.3% and 6.3 respectively (grade  $\geq 2$ :  $p=0.01$ , grade 2:  $p<0.001$ , grade 3:  $p=0.35$ ).

Late grade 2 GI toxicity was reported in 7.3% and 6.8% of patients ( $p=0.98$ ) in the CK and HDR groups, respectively. Late grade 3 GI toxicity was not reported uit the PSAQ.

GU and GI symptoms are compared in Table 1. Only night voiding frequency  $\geq 4$  was statistically significantly higher in the CK group (14.7%) compared to the HDR group (10.0%).

Table 1: Toxicity symptoms HDR vs CK

	HDR	CK	P value
<b>Late GU toxicity incidences (%)</b>			
Day frequency $\geq 16$	0.7	0.4	0.71
Night frequency $\geq 4$	10.0	14.7	0.04
Haematuria	1.6	2.2	0.67
Incontinence	9.9	8.6	0.84
Dysuria	9.0	7.6	0.63
<b>Late GI toxicity incidences (%)</b>			
Stool frequency $\geq 6$	1.6	1.0	0.82
Stool incontinence	2.1	2.6	0.34
Rectal bleeding	4.9	2.0	0.40
Pain	0.4	1.0	0.60

### Conclusion

Extreme hypofractionated radiotherapy, delivering 4 fractions of 9.5 Gy with either HDR-brachytherapy or SBRT, is well-tolerated and safe with comparable late toxicity as other treatment modalities for low and intermediate risk prostate cancer. Compared to HDR, SBRT resulted in a slightly increased grade 2 GU toxicity rate and can therefore be used as an alternative for patients not eligible for brachytherapy.

### PO-0736 Long term outcomes of IG-IMRT dose-escalation to pelvis and prostate for advanced prostate cancer

H. Lieng<sup>1</sup>, T. Rosewall<sup>1</sup>, H. Jiang<sup>2</sup>, A. Berlin<sup>1</sup>, R. Bristow<sup>1</sup>, C. Catton<sup>1</sup>, P. Chung<sup>1</sup>, J. Helou<sup>1</sup>, P. Warde<sup>1</sup>, A. Bayley<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre, Department of Radiation Oncology- Radiation Medicine Program, Toronto, Canada

<sup>2</sup>Princess Margaret Cancer Centre, Department of Biostatistics, Toronto, Canada

### Purpose or Objective

To evaluate late toxicity and long-term biochemical control for men with high-risk or node-positive (N1) prostate cancer treated with image-guided IMRT (IG-IMRT) and dose escalation to both the pelvic lymph nodes and prostate/seminal vesicles.

### Material and Methods

Between 2002 and 2009, men with high-risk or N1 prostate cancer received dose-escalated IG-IMRT to the pelvis and prostate on a phase II clinical trial. The planned prescription dose was 55.1 Gy in 29 fractions to the prostate/seminal vesicles (P/SV) and pelvic lymph nodes (PLN), with a sequential boost dose of 24.7 Gy in 13 fractions to P/SV. Dose reductions were mandated to meet organ at risk constraints. Late RTOG gastrointestinal (GI) and genitourinary (GU) toxicity scores were recorded at each visit and biochemical failure was defined using the Phoenix criteria. Probability of toxicity and biochemical control were estimated using cumulative incidence function. Overall survival was calculated using the Kaplan-Meier method. Difference between groups was evaluated by Gray's test or log-rank test.

### Results

124 men received IG-IMRT to the prostate and pelvic lymph nodes. Median follow-up was 99.7 months (range 5 - 162 months). Men had T3-T4 (45%), N1 (13%), Gleason 8-10 (52%) disease with median PSA 24 ng/mL. The median age was 68 years and 85% received at least 2 years of androgen deprivation therapy. 112 (82%) received the total prescription dose to P/SV, with 67 (54%) receiving the planned dose to PLN of 55.1 Gy, and 106 (85%) receiving at least 50 Gy to PLN.

The 5- and 7-year cumulative incidence of late GI grade  $\geq 2$  was 16.3% and 17.3%, with cumulative incidence of late GU grade  $\geq 2$  toxicity of 8.3% and 13.1% respectively. Late GI grade  $\geq 3$  toxicity at 5 and 7 years was 4.9% and 5.8%

respectively, and late GU grade  $\geq 3$  toxicity was 2.6% and 4.5% respectively. The incidence of GI and GU Grade 3 toxicity was 6% for each. At last follow-up visit there were no GI Grade  $\geq 3$  toxicities and 2 GU Grade 3 toxicities. There was no significant difference in late GI nor late GU toxicity between patients receiving pelvic doses  $\leq 50$  Gy and  $> 50$  Gy.

Five-year biochemical control was 77%, and at 7 years was 67%, with significantly more failures in the node-positive cohort. Biochemical failures occurred in 44 patients (35%) and 14 died from disease (11%). Overall survival was 92% at 5 years and 87% at 7 years and significantly lower in those with nodal metastases.

### Conclusion

IG-IMRT with dose-escalation to both the pelvic lymph nodes and prostate/seminal vesicles results in similar late toxicity to standard dose pelvic irradiation using 2D/3D-conformal techniques. There was no significant difference in toxicity with pelvic doses  $> 50$  Gy compared to  $\leq 50$  Gy. Our biochemical control rates were comparable to that reported in the dose-escalated randomized trials. Patients with nodal metastases at diagnosis had worse outcomes compared to those without nodal disease

### PO-0737 elective pelvic radiotherapy in clinically node-negative prostate cancer: a long-term analysis

F. Catucci<sup>1</sup>, C. Masciocchi<sup>1</sup>, A.R. Alitto<sup>1</sup>, M. Vernaleone<sup>1</sup>, G.C. Mattiucci<sup>1</sup>, V. Frascino<sup>1</sup>, V. Valentini<sup>1</sup>, G. Mantini<sup>1</sup>

<sup>1</sup>Università Cattolica del Sacro Cuore -Fondazione Policlinico A. Gemelli, Radiation Oncology Division- Gemelli-ART, Rome, Italy

### Purpose or Objective

Whole pelvic radiotherapy (WPRT) remains highly controversial in prostate cancer. Although randomized trials failed to show a benefit for patients that received prophylactic irradiation (46-50 Gy) of pelvic lymph-nodes (PLN), elective WPRT could be considered in high-risk patients, based on validated nomograms. Aim of this long-term analysis is to update data about a retrospective analysis, that supported WPRT only for patients with a high risk of Lymphonodal Involvement (LNI), using as threshold 30%, assessed by Roach equation.

### Material and Methods

Patients classified in high- and very high-risk groups (Stage T3 or T4 and/or GS 8-10 and/or PSA level  $> 20$  ng/mL) were analyzed. LNI risk was assessed through Roach equation. RT was performed mainly with 3D technique after 2000. Prone or supine immobilization were used respectively in WPRT and Prostate Only RT (PORT). CTVs were: CTV1 prostate (total dose 7020/1.8 cGy fx until 1999 and 73.8/1.8 cGy fx afterwards), CTV2 seminal vesicles plus CTV1 (total dose 55.8/1.8 cGy fx for cT1-T3a and 64.8/1.8 cGy fx for cT3b-T4), CTV3 PLN, in WPRT (total dose 4500/180 cGy fx). PTVs derived from a common margin of 1 cm to corresponding CTV. Long-term androgen deprivation therapy (ADT) was prescribed. Toxicity was graded according to the CTC v4.03. Statistical analysis was performed using R statistical software 3.2.4.

### Results

Among the 358 patients enrolled between 1994 and 2007, we selected 319 high-risk ones: 20 treated until 1999, by 2D RT, and 299, treated from 2000, by 3D RT; 147 (46.1%) treated with WPRT and 172 (53.9%) with PORT. Median age at diagnosis was 70 years for WPRT (range 42 - 80) and 72 years for PORT (range 56 - 83) group. The two groups were heterogeneous for age, with a statistically significant difference between them ( $p=0.0017$ ). With a median follow-up of 128 months, there were no statistically significant differences between WPRT and PORT groups, in terms of surrogate outcomes. Only OS resulted in a statistically significant difference between WPRT and PORT group, probably due to the initial heterogeneity in age; also among patients younger than 70 years, there weren't statistically significant differences between the

two groups. Then, a subgroup analysis was performed, considering LNI risk, as assessed by the Roach formula, using different cut-off levels (Fig.1, 15%,20%,25%, and 30%). The subgroup analysis confirmed no statistically significant differences between WPRT and PORT for each nodal risk group, either in terms of bDFS, DFS OS, age <70 years ( $p=0.077$ ). Only OS curve showed a better prognosis for WPRT, statistically significant in 15% and 20% nodal-risk groups (Fig.2), but not confirmed by univariate analysis.

LNI risk cut-offs	Treatment	No. of patients (%)
>15	PORT	86 (55,8)
	WPRT	68 (44,2)
>20	PORT	61 (53,5)
	WPRT	53 (46,5)
>25	PORT	46 (52,9)
	WPRT	41 (47,1)
>30	PORT	35 (54,7)
	WPRT	29 (45,3)

Fig.1 LNI risk groups

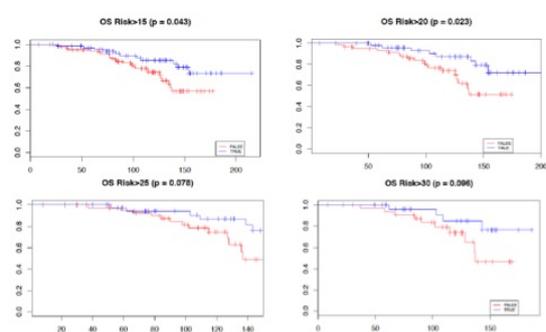

Fig.2 OS stratified by LNI risk (WPRT blue and PORT red)

### Conclusion

This long-term analysis failed to demonstrate a benefit for elective WPRT compared to PORT. Due to retrospective nature, small sample, long accrual and heterogeneity of WPRT and PORT group, new studies need to create performing tools for patients' selection.

### PO-0738 PET with 18F-Choline for evaluation of prostate cancer patients with biochemical relapse/persistence

H. Pérez Montero<sup>1</sup>, M.A. Cabeza<sup>1</sup>, A. Gómez<sup>2</sup>, S.G. Guardado<sup>1</sup>, J.F. Pérez-Regadera<sup>1</sup>

<sup>1</sup>Hospital Universitario 12 de octubre, Radiation Oncology, Madrid, Spain

<sup>2</sup>Hospital Universitario 12 de octubre, Nuclear Medicine, Madrid, Spain

### Purpose or Objective

Current guidelines suggest 18F-choline-PET/CT imaging (18F-Ch-PET) as a diagnostic test for the evaluation of patients with recurrent prostate cancer (PCa). Although it has been shown superior to conventional techniques, the role of 18F-Ch-PET has not been established in clinical practice.

The objective of this study was to evaluate the use of 18F-Ch-PET to restage patients with biochemical relapse (BR) or biochemical persistence (BP), which remains as a controversial issue. Our main goal was to optimize the selection of patients who may benefit the most from this test.

### Material and Methods

It is a prospective study (data collected between February/2014 and October/2016). From the 110 scans performed in our centre, we selected a cohort of 78.

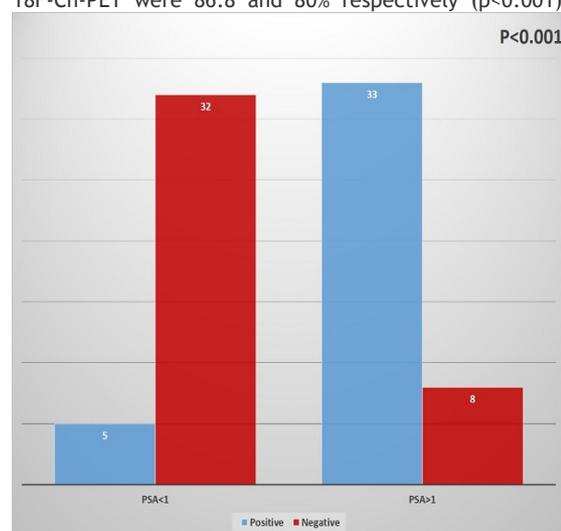

We selected PCa patients with BR or BP after radiotherapy and/or prostatectomy that fulfil certain conditions. Our inclusion criteria were patients in NCCN high-risk group, or also in intermediate risk group with unfavourable features (primary Gleason  $\geq 4$  and  $T \geq 2c$ ). We also selected patients with PSA doubling time (PSAdt) <8 months). Pearson  $\chi^2$  test was performed.

### Results

The mean age of patients was 67 years (range 45-79). Mean PSA was of  $3.4 \pm 5.7$  (0.01-38.8). Mean PSAdt was  $13.4 \pm 24.7$  months (0.7-158.9). Gleason was  $\geq 7(4+3)$  in 50% of cases. Median follow-up after the test was  $13 \pm 9$  months.

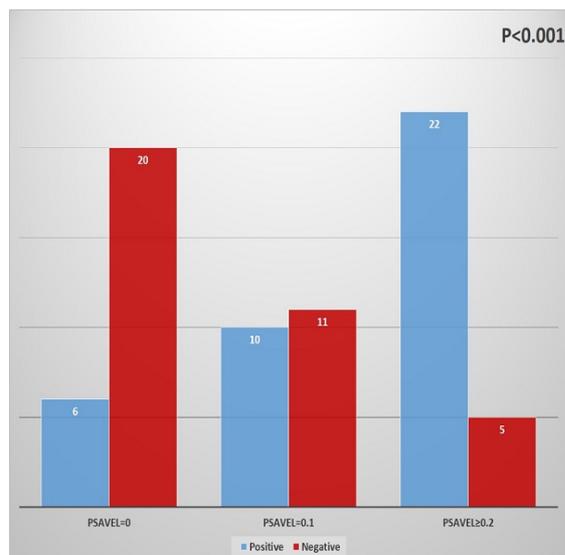

Positive results were obtained in 48.7% of the scans. 57.9% of them showed local and/or regional disease and 42.1% had distant metastases. Tailored treatment was performed in each case.

Scans were positive in 13.5% of patients with PSA <1 ng/mL and in 80.5% of patients with PSA  $\geq 1$  ng/mL. For this PSA level, Sensibility and Specificity for obtaining a positive 18F-Ch-PET were 86.8 and 80% respectively ( $p < 0.001$ ).

In patients with DTPSA <3 months, the test was positive in 87.5% of cases ( $p=0.03$ ). Additionally, 57.1% of them were metastatic. Moreover, 82% of PSAdt >3 cases had negative result or their recurrence were local and/or regional ( $p=0.039$ ).

We stratified 3 groups of patients according of PSA velocity (PSAvel) and observed positivity in 23%, 52% and 81% of cases with PSAvel of 0, 0.1 and  $\geq 0.2$  ng/mL/month respectively ( $p < 0.001$ ).

Results of the test were validated in 72% of the patients. They were confirmed by histology in 14%, by another imaging technique (MRI, Bone scintigraphy or CT) in 23.2%, by another 18F-Ch-PET in 5% and with a biochemical response after a specific treatment in 48% of them. Result of the test was discordant in 9%. According to this data, 18F-Ch-PET has a Sensibility and Specificity of 97% and 81% respectively.

#### Conclusion

18F-Ch-PET seems to be a very useful diagnostic test for restaging recurrent PCa in selected group of patients, allowing all relapse sites to be evaluated at once.

It can also modify treatment management in an important percentage, identifying which ones can be offered a potential curative treatment.

In our series, like in previous literature, PSA level, PSAvel and PSAdt are strong predictive factors for positive 18F-Ch-PET.

#### PO-0739 Phase II Trial of Dynamic Dosimetry for prostate brachytherapy: correlation with post-implant MRI/CT

Abstract withdrawn

Poster: Clinical track: Skin cancer / malignant melanoma

#### PO-0740 Surgery versus Radiotherapy in Uveal Melanoma: SEER Analysis using Propensity Score Matching & IPTW

<sup>3</sup>SMG-SNU Boramae Medical Center, Department of Biostatistics, Seoul, Korea Republic of

<sup>4</sup>Cancer Research Institute- Seoul National University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

The treatment of uveal melanoma includes surgery and radiotherapy (RT). Utilization of RT has been increasing as a strategy for organ preservation, but the survival difference between two modalities has not been reported.

#### Material and Methods

Patients diagnosed with uveal melanoma from 2004 to 2013 were selected from Surveillance, Epidemiology, and End Results (SEER) database. Propensity-score matching with nearest neighbor 1:1 matching method and inverse probability of treatment weighting (IPTW) using propensity score were used to compare the survival outcome between RT only and surgical resection alone for the treatment of uveal melanoma.

#### Results

Overall, 3,291 patients were treated: 2,503 received RT only (RT group) and 788 surgical resections only (surgery group), respectively. After propensity-score matching, 437 patients were identified in each cohort (total N = 874). The RT group had an improved crude 5-year overall survival (OS) rate compared with the surgery group (76 % vs. 60 %, P-value < 0.001) and the 5-year cancer-specific survival (CSS) rate (89% vs. 72 %, P-value < 0.001), respectively. Compared to the surgery group, the RT group was associated with improved OS [hazard ratio (HR) = 0.51, 95% confidence interval (CI) = 0.39 - 0.66, P-value < 0.001] and CSS [HR = 0.37, 95% CI = 0.25 - 0.54, P-value < 0.001] in multivariate Cox proportional hazard analysis, respectively. The survival benefit of the RT group maintained after adjustment with IPTW, both in OS [adjusted HR (AHR) = 0.45, 95% CI = 0.36 - 0.56, P-value < 0.001] and CSS [AHR = 0.27, 95% CI 0.27 - 0.51, P-value < 0.001].

#### Conclusion

To our knowledge, the present study is the first to demonstrate the survival difference according to the treatment modality in uveal melanoma, using both propensity-score matching and weighting methods with the SEER database. The current study suggests that RT might provide a survival advantage over surgery in the treatment of uveal melanoma.

#### PO-0741 Ipilimumab and stereotactic radiosurgery with cyberknife in melanoma brain metastases

<sup>4</sup>Istituto Nazionale Tumori Fondazione Pascale, Struttura Complessa Oncologia Medica Melanoma Immunoterapia Oncologica e Terapie Innovative, Napoli, Italy

<sup>5</sup>Istituto Nazionale Tumori Regina Elena Roma, Biostatistical Unit, Roma, Italy

#### Purpose or Objective

Ipilimumab (Ipi), an anti-cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4) monoclonal antibody, has been shown to improve survival in patients (pts) with advanced melanoma. However, there is a lack of data about the efficacy of Ipi in pts with brain metastases (BMs), as well as about its combination with radiotherapy (RT) and the right sequence of both treatments. The purpose of this study was to evaluate overall survival (OS), local control (LC) of the lesion treated, and intracranial control (IC) in pts with melanoma BMs (MBMs) treated with stereotactic Radiotherapy (SRT)/radiosurgery (SRS) with Cyberknife® and Ipi

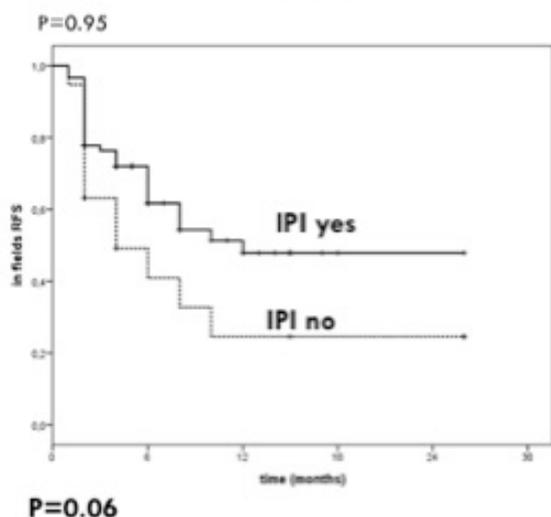

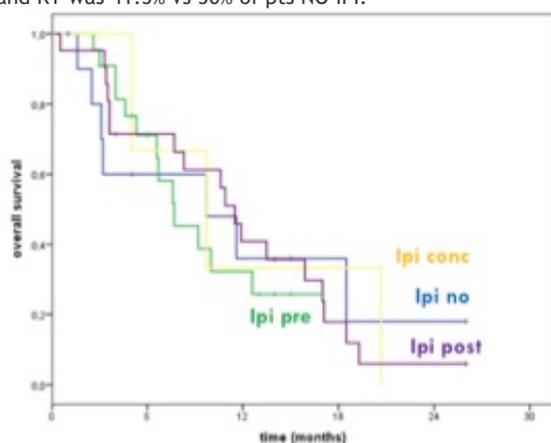

#### Material and Methods

From December 2012 to May 2016 we treated 63 pts (34 M, 29 F) with MBMs. The median age was 61 years (28-81y). 52 pts received Ipi: 24 prior-RT (IPI PRE-RT), 7 concomitant-RT and 21 post-RT (IPI POST-RT). 11 not received Ipi (NO

IPI). Ipi was administered intravenously at a dose of 3 mg/kg over 90 min every 3 weeks for 4 doses. We treated 120 lesions with median diameter size of 8 mm (2-42 mm). 67 SRS(dose range 10-24Gy) and 23 SRT(dose range 18-24Gy). We evaluated the local response according to RECIST criteria. We assessed LC as the sum of CR, PR and SD, IC, and median OS from the date of the SRS/SRT procedure.

#### Results

The median follow-up (FU) was 7 months (m) (range 0-26). 55 pts for a total of 109 lesions were evaluable for FU. The median OS for all pts was 9.7 m and the median OS of 52 pts who received Ipi and RT was 10 m vs 9.7 m of 11 pts IPI NO(P=0.82). The median OS for single group was: 9.7 m for NO-IPI, 7.7 m for IPI PRE-RT, 9.7 m for IPI CONC RT and 11.5 m for IPI POST-RT (p=0.95). The 1-year OS was 41% for IPI POST-RT, 32% for IPI PRE-RT, 36% for NO-IPI and 33% for IPI CONC RT. The 1-year LC of all pts lesions was 43.2%, and the 1-year LC of pts who received Ipi+RT was 48% vs 25% of pts NO IPI(p=0.06). The 1-year LC for single group was 72% for IPI PRE-RT, 36% for IPI POST-RT, 25% for NO-IPI and 33% for IPI CONC RT(p=0.08). The 1-year IC of all pts was 40.1%, and the 1-year IC of pts who received Ipi and RT was 41.5% vs 50% of pts NO IPI.

#### Conclusion

Our experience suggests that the combination of Ipi+SRS/SRT in MBMs pts can obtain a better survival with a low toxicity profile related to combined treatment. The high precision of treatment with Cyberknife allows to reduce radiation of organs at risk. The optimal timing of combination Ipi+RT is not clear, but from our experience it would seem to be a benefit of using the Ipi before SRS/SRT on LC. The recruitment of a greater number of pts and a longer follow-up are needed to demonstrate the

role of Ipi also in the treatment of melanoma pts with BMS and the better sequence with RT.

##### PO-0742 Target delineation conformity in extremity STS within the UK phase II multi-centre IMRiS trial

H. Yang<sup>1</sup>, R. Simões<sup>1</sup>, F. Le Grange<sup>2</sup>, S. Forsyth<sup>3</sup>, D. Eaton<sup>1</sup>, B. Seddon<sup>2</sup>

<sup>1</sup>Mount Vernon Cancer Centre, National Radiotherapy Trials Quality Assurance Group, Northwood, United Kingdom

<sup>2</sup>University College Hospital, Sarcoma Unit, London, United Kingdom

<sup>3</sup>University College London, Cancer Research UK & University College London Cancer Trials Centre, London, United Kingdom

#### Purpose or Objective

Accurate target volume delineation is essential in the use of intensity-modulated radiotherapy, where its role in the treatment of bone and soft tissue sarcoma (STS) is being investigated for the first time within the UK in IMRiS, a prospective multi-centre phase II trial.

As part of radiotherapy trials quality assurance, we determined the conformity of volume delineation of an extremity STS benchmark training case in the post-operative setting, and report target outlining variation in relation to the trial protocol.

#### Material and Methods

The clinical history, operation/histology reports, pre-operative magnetic resonance imaging and planning scans of the training case were made available to participating clinicians, who submitted outlines based on the protocol. Both first and re-submissions were evaluated by two clinicians, where GTV, CTV\_6000 and CTV\_5220 were compared to the reference contours. The volumes were quantitatively assessed using Dice Similarity Coefficient

$$DSC = \frac{2|A \cap B|}{|A| + |B|}$$

(DSC) as:  $\frac{2|A \cap B|}{|A| + |B|}$ , where A and B represent regions of interest. Individual feedback based on trial protocol variations was provided for all submissions.

#### Results

There was a total of 25 submissions from 23 centres. Delineation of GTV, CTV\_6000 and CTV\_5220 were deemed unacceptable according to the protocol in 5(20%), 10(40%) and 5(20%) submissions respectively. The table details the unacceptable variations from the protocol. All unacceptable GTV contours failed to reconstruct the pre-operative disease in its entirety. Incorrect margin expansion constituted the majority of the unacceptable submissions for both CTVs.

Volumes (and brief description from trial protocol)	Unacceptable variations from trial protocol	No. of cases (total 25)
GTV (Reconstructed pre-operative GTV)	Based on post-operative appearance only; pre-operative disease not taken into account	1 (4%)
	Based on post-operative appearance radially; pre-operative disease taken into account for superior/inferior extent but not radially	1 (4%)
	Based on post-operative appearance; pre-operative disease taken into account partially for radial extent but not superiorly/inferiorly	4 (16%)
CTV_6000 (From GTV with margin of 2cm radially, superiorly and inferiorly)	Pre-operative GTV not fully encompassed	3 (12%)
	Incorrect margin expansion (from post-operative appearance)	5 (20%)
	Incorrect margin (<2cm isotropic margin)	5 (25%)
CTV_5220 (From GTV with margin of 2cm radially and 5cm superior and inferiorly, excludes CTV_6000)	Incorrect margin (>2cm isotropic margin)	1 (4%)
	Incorrect margin (<5cm superior/inferior from GTV)	3 (12%)
	Incorrect margin (>5cm superior/inferior from GTV)	1 (4%)
	Volume too narrow due expansion from CTV_6000, where CTV_6000 was tapered longitudinally	1 (4%)

The mean DSCs were systematically lower for the unacceptable contours compared to accepted contours for GTV [0.61 (range 0.55-0.66) vs 0.77 (range 0.60-0.81), p<0.001], CTV\_6000 [0.75 (range 0.53-0.82) vs 0.82 (range

0.77-0.89),  $p=0.036$ ] and CTV\_5220 [0.15 (range 0.02-0.36) vs 0.43 (range 0.11-0.64),  $p=0.002$ ].

CTV\_5220 was incorrectly positioned in 5 submissions due to the contouring inaccuracies of GTV/CTV\_6000. Other variations in the inclusion of the scar/seroma were seen where it was not fully encompassed axially (CTV\_6000: 8 submissions, CTV\_5220: 6 submissions), and where CTV\_6000 was extended beyond margins longitudinally to include it (5 submissions). In addition, some volumes were tapered where the anatomical planes were not followed lengthwise (CTV\_6000: 5 submissions, CTV\_5220: 13 submissions).

There were five re-submissions after feedback, for which all target volumes had either acceptable, or no variation from the protocol (mean DSC GTV: 0.75, CTV\_6000: 0.83, CTV\_5220: 0.48).

#### Conclusion

High numbers of unacceptable variations from the trial protocol were seen in the first submission of the training case; the adherence to the protocol improved following individualised feedback. As the outlining of both CTVs is dependent on the accuracy of the reconstructed GTV in the post-operative setting, this should be done with particular care, with the aid of surgical reports and diagnostic imaging.

#### PO-0743 Retransplantation of bony autografts sterilized by extracorporeal high dose irradiation

L. Saleh-Ebrahimi<sup>1</sup>, A. Klein<sup>2</sup>, Y. Bakhshai<sup>2</sup>, F. Roeder<sup>1,3</sup>, A. Baur-Melnyk<sup>4</sup>, T. Knösel<sup>5</sup>, L.H. Lindner<sup>6</sup>, V. Jansson<sup>2</sup>, H.R. Dürr<sup>2</sup>

<sup>2</sup>LMU Munich, Department of Orthopedics, Munich, Germany

<sup>3</sup>German Cancer Research Center DKFZ, Department of Molecular Radiation Oncology, Heidelberg, Germany

<sup>4</sup>LMU Munich, Department of Radiology, Munich, Germany

<sup>5</sup>LMU Munich, Department of Pathology, Munich, Germany

<sup>6</sup>LMU Munich, Department of Internal Medicine, Munich, Germany

#### Purpose or Objective

Limb-sparing resection of bone tumors requires reconstruction of the bony defect. Retransplantation of the resected bone after sterilisation might be an alternative to prosthetic implants especially in cases with diaphyseal defects. Here we report our experience with this technique using extracorporeal high dose irradiation to sterilize the resected bone.

#### Material and Methods

Extracorporeal irradiation and retransplantation was used in 20 patients (21 lesions) between 2005 and 2015. 13 patients were male and median age was 37 years (10-83) with 4 patients <18 years. Main histologies were Ewing sarcoma (7 pts), Osteosarcoma (5) and metastasis (5). Lesions were located mainly in the lower limb (femur n=12, tibia n=6). After resection and curettage, the tumor-bearing bone was packed into a double sterile bag and transported to the radiation oncology department. To minimize any built-up effect, the bag was wrapped with flap material and placed beneath the LINAC with the lowest possible distance to the head, usually on a tray in the accessory slot. After irradiation with 300 Gy in ap/pa technique, the bone was brought back to the operation room and retransplanted.

#### Results

Median follow up was 33 months (6-129) in the entire cohort and 39 months in survivors. Retransplantation was possible in all patients. An additional fibula augmentation was used in 14 lesions. Surgical revisions (median n=2, range 1-8) were needed in 12 lesions (57%) due to complications or pseudoarthrosis. Complete integration of

the irradiated autograft was finally achieved in 17 of 19 possible lesions (89%). One patient failed with active pseudoarthrosis and in one patient a prosthetic implant was needed secondarily due to a fractured pseudoarthrosis. In two patients with retransplantation of the whole irradiated calcaneus, integration was formally not possible. Median time to complete integration was 10 months (4-35 months). Local control inside the graft and in the affected limb was achieved in 100% and 95% of the patients, respectively. One patient developed recurrence outside the replanted graft, probably due to seeding because of fracture hematoma. Four patients have died, resulting in a 5-year overall survival of 68 %.

#### Conclusion

High dose extracorporeal irradiation is an effective and safe method to sterilize bony autografts during a retransplantation procedure. Local control is achieved in 95%-100%. Complications with the need for surgical revisions occur frequently resulting in a prolonged healing process in more than half of the patients. However, successful integration of the sterilized autografts is finally achieved in the vast majority (roughly 90%). Retransplantation after extracorporeal irradiation seems to be a very promising alternative to prosthetic implants especially in the treatment of diaphyseal or metadiaphyseal lesions.

<sup>8</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Radiotherapy Unit, Campobasso, Italy

<sup>9</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Medical Physics Unit, Campobasso, Italy

#### Purpose or Objective

To evaluate outcomes in patients with primary high grade soft tissue sarcomas (STS), treated with perioperative brachytherapy (BRT) and adjuvant external beam radiation therapy (EBRT) after re-excision of the tumor bed, post unplanned surgery.

#### Material and Methods

The primary aim of this retrospective study was to analyse local control (LC). Secondary objective were metastasis-free survival (MFS), diseases-free survival (DFS) and overall survival (OS) in a large patient population. BRT delivered dose was 20 Gy (15-22 Gy) using Low Dose-Rate or Pulsed Dose-Rate technique. EBRT was delivered with 3D-technique using multiple beams; the median prescribed dose was 46 Gy to the PTV (range 40-60 Gy), conventionally fractionated. Univariate analysis was estimated according to Kaplan-Meier method and log-rank test.

## Results

From 2000 to 2011, 121 patients (median age: 50 years, range 16-86; median follow-up: 54 months), affected by primary high grade STS, underwent unplanned surgery, re-excision of the tumor bed (radicalization) within a maximum of 3-6 months from the previous surgery, perioperative BRT and adjuvant EBRT. Seventeen patients (14.0%) developed metastases, 7 patients (5.8%) relapsed and 9 out of 121 patients died (7.4%). Five-year LC and OS were 93.0% and 91.6%, respectively. At univariate analysis higher 5-year DFS and OS were recorded in patients with lower- limb tumors vs upper-limb and trunk STS (p: 0.053 and 0.041, respectively). Although it wasn't detected any statistical significance related to histologies. Younger patients (< median age) showed improved 5-year LC (97.9% vs 88.1%, p: 0.052), 5-year DFS (88.9% vs 73.9%, p: 0.034) and 5-year OS (96.5% vs 86.6%, p: 0.093).

## Conclusion

The combination of BRT and EBRT is able to achieve satisfactory results, with a high local control rate and overall survival. Prospective studies on combined modality treatment in the adjuvant setting of STS after re-excision surgery or inadequate excision are still needed to improve the results in STS of the trunk and limb.

## Poster: Clinical track: Palliation

### PO-0745 Intrafractional movement of patients with spinal cord compression receiving radiation therapy

E. Ravnkilde<sup>1</sup>, I.M. Jakobsen<sup>1</sup>, A. Appelt<sup>1</sup>, J.P.

Bangsgaard<sup>1</sup>, L.S. Fog<sup>1</sup>

<sup>1</sup>Rigshospitalet, Clinic of Oncology, Copenhagen, Denmark

#### Purpose or Objective

Many palliative radiation therapy patients experience moderate to severe pain. This pain could potentially increase intrafractional movement, requiring planning treatment volume (PTV) margins to be adjusted to account for this. We conducted a prospective study to examine the impact of patient-experienced pain on intrafractional movement and the time needed for treatment delivery.

#### Material and Methods

This prospective study included 18 consecutive patients receiving radiation therapy for spinal cord compression. We recorded the patients' intrafractional shifts, the treatment time, the treatment site and the patients' self-reported pain score. The patients were asked to assess their pain ('pain') prior to radiation therapy fraction, on a scale from 1 to 10 using the NRS (Numerical Ratings Scale) [Pain Pract. 3 (4): 310-6]. Cone beam CT images were acquired before and after all daily treatments. The interfractional shift ('shift'), linac ID number ('linac'), treatment time ('time'), fraction number ('fr number') and treatment site ('site') were recorded. The average and maximum shifts, and the standard deviation (s.d.), were determined.

Spearman correlation coefficients were calculated between: shift and time, fr number, or pain; time and fr number or pain; pain and fr number. Since site was scored by a categorical variable, a Kruskal Wallis test was used to investigate effect of treatment site on shift, time or pain score.

The patients provided informed consent to participation in the study.

#### Results

A total of 113 shifts were measured. The average shift was 0.96 mm, the maximum 4.1mm, and the s.d. was 0.89 mm (fig 1). The only significant correlations (see fig 2) were between

- Shift and pain (patients reporting more pain had greater shifts, p=0.0045, r=0.2699). Patients who report more pain

have greater intrafractional shifts. This may be due to patient discomfort.

- Time and fr number (later fractions were completed more quickly, p=0.0001, r=0.3500). The reduced time for later fractions may be due to the patient becoming more familiar with the treatment procedure.

- Pain and fr number (patients reported less pain in later fractions, p=0.0412, r=-0.1960). While pain score decreased with fraction number, fewer patients provided pain scores for later fractions.

- Site and time (p=0.0044, C<sup>2</sup>=10.87). Treatment site correlates with treatment time.

Patients with pain scores ≤5 had mean intrafractional shift 0.09 cm (s.d. 0.09), while patients with pain scores >5 had mean shift 0.11 (s.d.0.07).

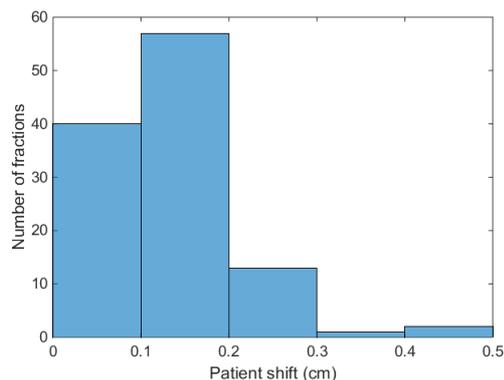

Figure 1. Distribution of intrafractional patient shifts in this work.

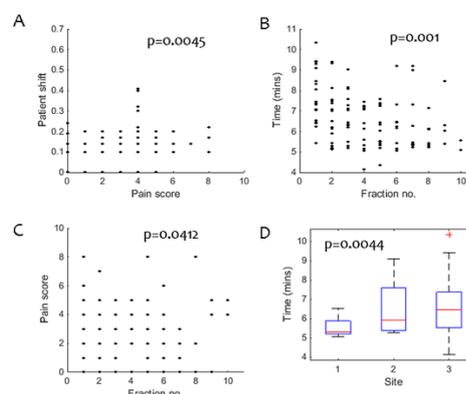

Figure 2. Plots of the four sets of variables which were found to be correlated, and their p values. The patient shift increased significantly with increasing pain (A), the treatment time decreased significantly with increasing fraction number (B), the pain decreased with increasing fraction number (C) and the time correlated with treatment site (D), site=1 is cervical, site=2 is thoracic, site=3 is lumbar).

## Conclusion

A 5 mm PTV margin appears sufficient to account for intrafractional patient movement for spinal cord compression patients imaged daily.

### PO-0746 Inter-observer variation in GTV delineation of bone metastases: a multicenter study

<sup>2</sup>Sunnybrook Health Sciences Centre, Radiation Oncology, Toronto, Canada

<sup>3</sup>European Institute of Oncology, Radiation Oncology, Milan, Italy

<sup>4</sup>University Medical Center Utrecht, Radiology, Utrecht, The Netherlands

<sup>5</sup>University Medical Center Utrecht, Imaging, Utrecht, The Netherlands

### Purpose or Objective

The use of stereotactic body radiation therapy (SBRT) is increasing rapidly in patients with bone metastases. This technique involves high precision dose delivery, for which accurate gross tumor volume (GTV) contouring is crucial. This study compares inter-observer agreement in bone metastases delineated on CT, MR and CT with co-registered MR imaging.

### Material and Methods

Twenty consecutive patients with bone metastases treated with SBRT were selected. All patients received CT and MR imaging in treatment position prior to radiotherapy. CT images were obtained with a Philips large bore CT scanner (1 mm slice thickness). A Philips 1.5 Tesla MRI scanner was used to acquire T1- and T2-weighted images in transversal direction. Coronal and/or sagittal images were acquired, including 3D T1FFE mDIXON scan (slice thickness 1.1mm) and diffusion weighted imaging (slice thickness 4 mm). Five observers from three institutions independently delineated GTV after a training set of two patients and a consensus meeting. First, GTV was delineated on CT images only. A second delineation was based on CT images with co-registered MR images. At least four weeks after the delineation on CT-MR combined, the GTV was contoured on MR imaging only. Average volumes of the contours per patient and imaging modality were calculated. The generalized conformity index (CI) was used to quantify inter-observer agreement. Significant differences between the average volumes and CI were analyzed by Wilcoxon signed rank test. Observer count maps were generated for visual comparison of agreement for each case and imaging modality.

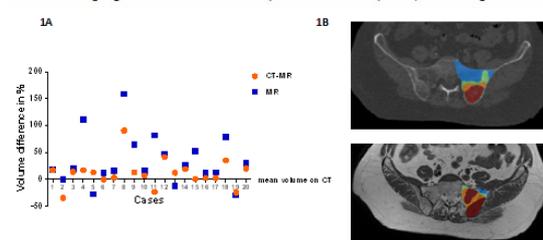

### Results

Mean GTV volume delineated on MR ( $43.4 \pm 49.7 \text{ cm}^3$ ) was larger compared to CT-MR ( $40.2 \pm 49.4 \text{ cm}^3$ ) and CT ( $34.8 \pm 34.8 \text{ cm}^3$ ). Compared to CT, the mean volume of GTV was 11% larger on CT-MR and 35% on MR (Figure 1B). A large variation in CI was found in all imaging modalities: CT (range: 0.15-0.75), CT-MR (range: 0.17-0.71) and MR (0.14-0.80). Mean CI were significantly higher on CT-MR compared to CT (Table 1). An example of a count map is shown (case 18, Figure 1B). For this case, mean volume of the GTV was almost doubled on MR compared to CT, which might be explained by better visibility of the extra-osseous disease on MR imaging.

**Table 1:** GTV Volumes and conformity indices

Case	Primary tumor	Location	Mean volume in $\text{cm}^3$ (SD)			Generalized CI		
			CT	CT-MR	MR*	CT	CT-MR	MR*
1	renal	iliac bone	184.7 (9.2)	216.9 (41.3)	211.4 (19.9)	0.75	0.71	0.80

20	colon	thoracic spine	14.0 (6.7)	16.8 (4.1)	18.2 (2.9)	0.37	0.60	0.66
	mean		34.8 (41.7)	40.2 (49.4)*	43.4 (49.7)*	0.49	0.54*	0.56
	median		24.4	29.8	32.4			

\*MR volumes and conformity indices (CI) in patient 1-14 are based on delineations of 3 observers since data collection is ongoing. The standard deviation is reported in brackets. \*  $p < 0.05$ , Wilcoxon signed rank test

**Figure 1A.** Volume differences of GTV delineations of CT-MR and MR in percentages compared to the mean volume on CT (x-axis). **1B** Observer variation in case 18 visualized in count maps on CT and MRI (transverse T1 weighted). Red = all observers, orange = 3, green = 2 and blue = delineation by 1 observer

### Conclusion

This multicenter contouring study demonstrated large inter-observer variation in GTV delineation for all investigated imaging modalities. Delineation of GTV on MR imaging resulted in larger volumes and marginal better inter-observer agreement compared to CT only delineations. These results suggest that future research should focus on guidelines to improve agreement on GTV delineation in these spine and non-spine bony metastases.

### PO-0747 Setting defaults in palliative radiation: a value-driven approach to improving care

L. Puckett<sup>1</sup>, L. Lee<sup>1</sup>, I. Zhang<sup>1</sup>, P. Zuvic<sup>1</sup>, P. Gilbo<sup>1</sup>, L. Potters<sup>1</sup>, B. Bloom<sup>1</sup>

<sup>1</sup>Northwell Health / Hofstra Northwell School of Medicine, Radiation Medicine, Lake Success, USA

### Purpose or Objective

Single fraction (fx) and hypofractionated (1 or 5 fx) radiation treatment (RT) provide superior value and reduced treatment length in the palliation of bone metastases. Despite data and recent guidelines recommending reduced treatment duration, there has been a slow adoption of this practice in the USA and worldwide. Previous examination of our academic and community multi-center practice from 2004 - 2016 revealed that single fx RT utilization has remained at 16% and hypofractionated courses have remained at 72% since 2012. We hypothesized that enacting evidence-based, treatment-guiding defaults would further increase hypofractionation utilization.

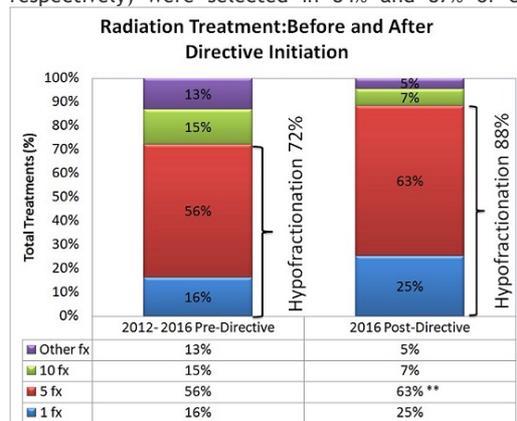

### Material and Methods

Institutionally, palliative bone metastasis treatments are monitored by our Quality Assurance (QA) committee. On 2/29/2016, two distinct consensus-driven and evidence-based clinical directives were created within our electronic health system for use with either simple or complicated bone metastasis, irrespective of primary histology. The simple and complex treatment directives had default prescriptions of 8 Gy/1fx or 20 Gy/5fx,

respectively. The directives were reviewed with physician staff within in the first week of enactment; directives were allowed to be edited at the physician's discretion if an alternative fx was indicated. Patients treated with SBRT were excluded from analysis. Retrospective chart review of patients treated between 1/2012 and 9/2016 revealed 1233 treatment courses (888 unique patients). Statistical analysis included the Chi square test.

### Results

Following implementation, treatment directives were used for 89% of cases (n=125) and were modified to an alternative prescription in 17 cases. Among directive-based treatments, 27% were simple metastases and 73% were complex. Single fx use increased from 17% to 25% among palliative bone metastasis treatments (p=0.02) and hypofractionation (1 or 5 fx) utilization increased from 72% to 88% (p<0.001)(Figure 1). Among simple and complex treatments, the default fractionations (1 fx or 5 fx, respectively) were selected in 84% and 87% of cases.

\*\* NS, p=0.14. All other comparisons with statistical significance (p≤0.05).

### Conclusion

Setting defaults for palliative treatment through an institution-wide adoption of evidence-based, treatment-guiding directives proved to be a straightforward and successful intervention, which significantly increased the utilization of hypofractionation. Our data suggests that treatment directives may be a useful approach in overcoming resistance to other hypofractionated treatment paradigms. Further palliative treatment directive use is planned within our institution for other sites (lung, pelvis). We believe that widespread examination and adoption of evidence-based directives can be used to improve value and reduce overtreatment in palliative oncologic care.

<sup>11</sup>Cruces University Hospital, Clinical Epidemiology Unit, Barakaldo, Spain

### Purpose or Objective

Elderly frequently receive different medical treatments than younger patients because of fear of higher toxicity and expected lower effectiveness. Painful bone metastases have a major impact on quality of life of cancer patients. We investigated whether age is a predictor for pain response after radiotherapy (RT) for painful bone metastases.

### Material and Methods

Between June 2010 and June 2014, 204 patients from ten Radiation Oncology Departments in Spain participated in a prospective observational study\* to evaluate the flare effect in patients with bone metastasis undergoing palliative RT. The pre-treatment evaluation consisted of a full history and physical examination, administration of Brief Pain Inventory (BPI) and record of analgesic consumption within the previous 24 h.

A follow-up visit was scheduled 4-weeks after the end of the RT. At this time the BPI was again administered, and analgesic consumption was recorded.

From this cohort, 128 patients (62.7%) completed the BPI at the first visit and in the follow-up (4-weeks after RT), and therefore were evaluable for treatment response in the present study. Pain response was measured using the International Bone Metastases Consensus from 2002. Worst pain was recorded using the Brief Pain Inventory (BPI): ranged from 0-10.

To identify which variables predicted pain response and in particular to determine whether age is a predictor, Cox proportional hazard models were used. The preselected baseline variables, were age (cohorts ≤65(A)/65-75(B)/>75(C)), gender, Eastern Cooperative Oncology Group (ECOG) performance status scale (0-1/≥2), pain score (≤4/5-7/8-10), treatment schedule (single fraction/multiple), primary tumor (prostate / breast / lung / other cancer types), presence of visceral metastases (yes/no), concomitant systemic chemotherapy (yes/no) and concomitant bisphosphonates (yes/no).

### Results

Table 1 shows patient characteristics. Median age was 66 years (38-89). Overall treatment response (including partial and complete responses) was 61.7%. According to univariate analysis pain response was significantly better in patients > 75(C) years: 53.6% in (A) versus 60.9% in (B) (OR, 1.3; 95% CI, 0.6-2.9; p=0.459) and 80.8% in (C) (OR, 3.6; 95% CI, 1.2-11.0; p=0.022). Patients receiving multiple fractions presented better response (70.5%) that those receiving a single fraction (49.5%) of 8 Gy (OR, 2.8; 95% CI, 1.2-6.1; p=0.01). Moreover, patients presenting a pain score of 8-10 before RT presented better response (70.8%) than those with a pain score <8 (50%) after palliative RT (OR, 2.4; 95% CI, 1.1-5.0; p=0.017). No other factors previously mentioned were found statistically significant.

The multivariate analysis showed that only the treatment schedule (p = 0.005) and the pain score >8 before RT (p = 0.011) were independent factors for pain response. The age was not found a statistically significant factor.

Table 1. Patient characteristics

Characteristic	Patients, n=128*
Age, median (range)	66 years (38-89)
Age groups	
≤65 (A)	56 (43.8)
65-75 (B)	46 (35.9)
>75 (C)	26 (20.3)
Gender male/female n (%)	81(63.3)/47(36.7)

Multiple fraction	91 (77.6)
20 Gy/5 fractions	79 (86.8)
20 Gy/4 fractions	12 (13.2)
Treatment response	
Complete response	15 (11.7)
Partial response	64 (50.0)
Stable disease	35 (27.3)
Progression	14 (10.9)

\*This population corresponds to a subgroup of patients: This study is a subanalysis of a previous multicentric prospective study evaluating the FLARE in patients with bone metastasis receiving palliative radiotherapy:

Gomez-Iruriaga A, Cacicedo J, Navarro A, Marillo V, Willisch P, Carvajal C, et al. Incidence of pain flare following palliative radiotherapy for symptomatic bone metastases: multicenter prospective observational study. *BMC Palliat Care*. 2015 Oct 1;14:48.

## Conclusion

Older patients have a remarkable benefit from palliative RT. A higher age should not be a reason to withhold palliative RT.

## PO-0749 Early impact of pulmonary SBRT on Quality of Life: Benefit for patients with low initial QoL/GHS

S. Adebahr<sup>1,2</sup>, M. Hechtner<sup>3</sup>, N. Schröder<sup>1</sup>, T. Schimek-Jasch<sup>1</sup>, K. Kaier<sup>4</sup>, V. Duncker-Rohr<sup>5</sup>, F. Momm<sup>5</sup>, J. Gärtner<sup>6</sup>, A.L. Grosu<sup>1,2</sup>, U. Nestle<sup>1,2</sup>

<sup>1</sup>University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, Germany

<sup>2</sup>German Cancer Consortium DKTK, Partner Site Freiburg, Freiburg, Germany

<sup>3</sup>University of Mainz, Department of Medical Biostatistics- Epidemiology and Informatics, Freiburg, Germany

<sup>4</sup>Faculty of Medicine and Medical Center - University of Freiburg, Institute of Medical Biometry and Statistics, Freiburg, Germany

<sup>5</sup>St. Josefsklinik Offenburg, Department of Radio-oncology, Offenburg, Germany

<sup>6</sup>Medical Center- Faculty of Medicine- University of Freiburg, Clinic for Palliative Care, Freiburg, Germany

## Purpose or Objective

To determine the early impact of stereotactic body radiotherapy (SBRT) on the quality of life (QoL) of inoperable elderly and comorbid patients with small pulmonary lesions.

## Material and Methods

100 inoperable patients with pulmonary lesion ≤ 5cm (early stage NSCLC or ≤ 2 pulmonary metastases of a controlled primary tumor) were treated with SBRT (3x12.5 Gy or 5x 7Gy to 60% isodose) from 02/2011 to 12/2014 within the prospective, multicenter phase II STRIPE trial. The European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ) C30 and the QLQ LC13 lung cancer-specific questionnaire were used to evaluate quality of life. Assessments were done

before treatment, 2 and 7 weeks, as well as 3 monthly after SBRT for 2 years of follow up (FU) or until death. Here we report on the primary descriptive analysis of early changes from baseline to 7 week-FU. A clinically significant change was defined as a change in HRQL scores of ≥10 points compared with baseline.

## Results

QoL was assessed in 97 patients. Compliance was 92% at baseline and 85% at 7 weeks after SBRT. Overall, regarding the whole cohort, the QoL / Global Health Status (GHS), all function scores, and all inquired symptoms were unchanged from baseline until 7 weeks after SBRT. However, patients who initially scored their QoL / GHS below the median of 50 showed a clinically relevant improvement in QoL / GHS (delta 14), Emotional Function (delta 15.12), and loss of appetite (delta 15.12). In contrary, patients with initial scores of ≥ the median of 50 showed no clinically relevant alterations over time. Patients with an initial low Karnofsky Index (KI) ≤80 revealed a clinical relevant improvement in Emotional Function (delta 10.2), whereas patients with high initial KI >80 did not show any alterations. Univariate, multivariate and further subgroup analysis are object of current investigations.

## Conclusion

In short-term FU QoL is well maintained after pulmonary SBRT for elderly and comorbid inoperable patients. Interestingly, especially patients with initially low QoL/GHS may benefit from SBRT with respect to QoL. Further analysis of predefined predictors are in progress.

## PO-0750 Failure to publish the results of clinical trials in oncology is skewing our medical practice

P. Gallego<sup>1</sup>, J. Perez-Alija<sup>1</sup>, E. Ambroa<sup>2</sup>, I. Linares<sup>3</sup>, A. Pedro<sup>1</sup>

<sup>1</sup>Hospital Plató, Radiation Oncology Department, Barcelona, Spain

<sup>2</sup>Consorci Sanitari de Terrasa, Medical Physics Unit- Radiation Oncology Department, Terrasa, Spain

<sup>3</sup>Institut Català d'Oncologia, Radiation Oncology Department, L'Hospitalet de Llobregat, Spain

## Purpose or Objective

Clinical trials produce the best data available for decision-making in modern evidence-based medicine. Publication of all trials conducted in oncology is needed to fully determine the benefits and risks of treatments currently in use in our clinics. A US Federal law requires responsible parties of all interventional trials to submit summary results to the ClinicalTrials.gov database 12 months after the completion date. We aimed to determine how many of the interventional phase 3 and 4 trials conducted in oncology were in compliance with the law and make their results publicly available. We also analysed if there was any difference when we take into account only radiation oncology trials or molecular oncology ones. Finally we estimated how many of these trials have not published in a peer-reviewed journal (PRJ).

## Material and Methods

As of 6 May 2016, the ClinicalTrials.gov database was searched for interventional phase 3 and 4 trials in Oncology with a primary completion date before 1 January 2013. We determined how many of these registry entries have not published the compulsory deposition of their results in the database. We then categorised our data into a radiation oncology subset and a molecular oncology one. For each trial registered in the database, ClinicalTrials.gov also displayed publication citations either submitted by sponsors or investigators, or automatically indexed by ClinicalTrials.gov. We reviewed

this linked information to evaluate whether or not trials have been published in a PRJ.

#### Results

Of 3479 oncology trials, 2551 (73%) did not deposit a summary result in the registry; only 1096 (32%) had a peer-reviewed publication of their results indexed; only 1596 (46%) had either deposit a summary result in the registry, or published their results in a PRJ, or both. Of 1458 molecular oncology trials, 990 (68%) did not deposit a summary result in the registry; only 514 (35%) had a peer-reviewed publication of their results indexed; only 734 (50%) had either deposit a summary result in the registry, or published their results in a PRJ, or both. Of 483 radiation oncology trials, 414 (85.7%) did not deposit a summary result in the registry; only 154 (32%) had a peer-reviewed publication of their results indexed; only 227 (47%) had either deposit a summary result in the registry, or published their results in a PRJ, or both.

#### Conclusion

Our results show that most trials (70%-80%) in oncology did not report the results in the registry, even though they have been required to do so. More than half of these trials might not have been published in the biomedical literature. Molecular oncology and radiation oncology are no exception to the results found in oncology. Our evidence in oncology is therefore distorted in important ways and this might lead, to say the least, to large inefficiencies in our health care system.

#### PO-0751 Uptake of a novel interactive 3D web-based contouring atlas among the radiation oncology community

E. Gillespie<sup>1</sup>, N. Panjwani<sup>1</sup>, P. Sanghvi<sup>1</sup>, J. Murphy<sup>1</sup>  
<sup>1</sup>University of California San Diego, Radiation Medicine and Applied Sciences, La Jolla, USA

#### Purpose or Objective

In the era of highly conformal treatment techniques, the delivery of safe and effective radiation therapy increasingly relies on accurate target delineation. Current contouring resources are fragmented and cumbersome to use at the point of care. We created a free interactive 3D web-based atlas called eContour ([www.eContour.org](http://www.eContour.org)), which displays best available evidence to guide contour delineation. This study reports on user characteristics, frequency of use, and frequently viewed cases during the first 6 months of dissemination.

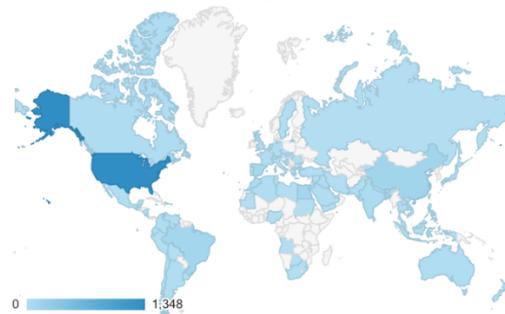

#### Material and Methods

To track individual user data and collect user feedback, visitors to the eContour website are required to register with their email address, profession and hospital affiliation, while the IP address of the computer from which the website is accessed is used to track the user's geographic location. Google Analytics and Mixpanel were employed to track the number and duration of each page view, which was linked to the unique registered user. Descriptive statistics were reported, including frequency of repeat use (primary endpoint) defined as the ratio of users that accessed the website on two different days divided by the total number of registered users. Users in the top quintile were further characterized by profession and geographic location.

#### Results

eContour has 2,616 registered users, of which most (60%) are radiation oncologists (1,092 practicing physicians and 459 residents). Other users include dosimetrists (16%), physicists (9%), radiation therapists (5%), and medical students (5%). Registered users represent 81 countries, with the majority (56%) of users located in the US (see Figure for map). Overall rate of repeat use was 49%, with residents most likely to return to the site (63%) and physicists least likely (36%). Repeat users visited the site on up to 58 different days during the dissemination period, with residents visiting a mean 6.6 different days and practicing physicians visiting a mean 5.4 different days.

Users in the top quintile were primarily physicians (69%) and from the US (67%). Of 33 posted cases in H&N, GI, GYN, GU and lymphoma, the most frequently viewed disease site was H&N (8,171 case views) followed by GI (4,665 case views) and the most frequently viewed cases were nasopharynx, pre-op rectal, pre-op esophageal, anal, post-op endometrial, and intact prostate cancer, each with over 1,000 page views. Users viewed each case page for an average of 3.7 minutes.

#### Conclusion

eContour has a high rate of repeat use especially among radiation oncologists in the US. Users are most frequently looking for help contouring GI and H&N cancers, and they spend fewer than 4 minutes accessing information within a single case. These preliminary data suggest that eContour is a resource that fills a need among radiation oncology professionals. By providing users with updated contouring guidelines at the point of care, eContour has the potential to improve contour accuracy and ultimately impact quality of radiation delivery.

#### PO-0752 Birth outcomes in female cancer patients received radiotherapy: a nationwide population-based study

W.H. Kao<sup>1</sup>, J.H. Hong<sup>1,2</sup>, C.C. Wang<sup>1,2</sup>, Y.J. Chiang<sup>1</sup>, C.F. Kuo<sup>3</sup>

<sup>1</sup>Chang Gung Memorial Hospital, Department of Radiation Oncology, Taoyuan, Taiwan

<sup>2</sup>College of Medicine- Chang Gung University, Department of Medical Imaging and Radiological Sciences, Taoyuan City, Taiwan

<sup>3</sup>Chang Gung Memorial Hospital, Department of Rheumatology- Allergy and Immunology-, Taoyuan, Taiwan

#### Purpose or Objective

For young female cancer survivors who ever received radiotherapy, adverse pregnant outcomes are serious questions not only for themselves but also for their babies. The purpose of this study was to estimate the risks of adverse foetal-neonatal outcomes in female cancer patients received radiotherapy (RT) compared with women without malignancies.

#### Material and Methods

We identified 2,350,335 singleton pregnancies using Taiwan National Health Insurance Database and Taiwan Birth Registry between 2001 and 2012, of which 607 pregnancies were in female cancer patients with RT. Odds ratios (ORs) and 95% confidence intervals (CIs) for foetal-neonatal outcomes were estimated using generalized estimating equation model adjusted by maternal age, income, occupation, Charlson comorbidity index, urbanization, infant sex and birth of year.

#### Results

From 2001 to 2012, the mean age at pregnancy of female cancer patients received radiotherapy was 33.5 years old. There were no significant increasing risks with an adjusted OR (95% CIs) of 0.50 (0.21-1.21) for stillbirth, 0.75 (0.55-

1.02) for low birth weight, 0.6 (0.45-0.80) for prematurity, 0.97 (0.75-1.27) for small for gestational age, 0.82 (0.65-1.04) for large for gestational age, 0.98 (0.69-1.38) for foetal distress, 1.21 (0.92-1.59) for any foetal abnormalities, 1.36 (0.56-3.29) for central nervous system malformation, 1.39 (0.62-3.09) for chromosomal abnormalities, and 1.20 (0.77-1.87) for other/unspecified abnormalities. The risks of Apgar score < 7 in 1 minute and in 5 minutes were not significantly increased with ORs of 0.71 (0.43-1.18) and 0.62 (0.20-1.94).

#### Conclusion

For female cancer patients who received radiotherapy, there were no significant increasing their adverse birth outcomes compared to women without malignancies.

#### PO-0753 Radiation therapy and outcome in cancer patients with acute venous thromboembolism.

J.B. Guy<sup>1</sup>, L. Bertolotti<sup>2</sup>, N. Magné<sup>1</sup>, I. Mahé<sup>3</sup>, C. Font<sup>4</sup>, O. Sanz<sup>2</sup>, J.M. Martín-Antorán<sup>5</sup>, F. Pace<sup>7</sup>, J. Ramón Vela<sup>8</sup>, M. Monreal<sup>9</sup>

<sup>5</sup>Hospital Universitario de Gran Canaria Dr. Negrin, Internal Medicine, Las Palmas, Spain

<sup>6</sup>Hospital Río Carrión, Haemostasis and Thrombosis, Palencia, Spain

<sup>7</sup>Ospedale San Camillo, Medicina d'Urgenza, Rome, Italy

<sup>8</sup>Hospital Universitario Miguel Servet, Internal Medicine, Zaragoza, Spain

<sup>9</sup>Hospital Universitari Germans Trias i Pujol, Internal Medicine, Barcelona, Spain

#### Purpose or Objective

There is lack of evidence on the influence of radiation therapy (RT) on outcome in cancer patients with acute venous thromboembolism (VTE).

#### Material and Methods

RIETE (Registro Informatizado Enfermedad Trombo Embólica) is an ongoing, multicenter, observational registry of consecutive patients with symptomatic, objectively confirmed, acute VTE. We used the RIETE database to compare the rate of VTE recurrences and major bleeding during the course of anticoagulation in cancer patients with or without RT.

#### Results

As of May 2015, 9284 patients with active cancer and VTE were enrolled in RIETE: 4605 with pulmonary embolism (PE) and 4679 with deep vein thrombosis (DVT). In all, 1202 (13%) were receiving RT. During the course of anticoagulant therapy (mean: 181 days), 210 patients presented with PE recurrences (53 fatal), 226 with DVT recurrences and 443 with major bleeding (60 in the brain, 118 fatal). Patients receiving RT had a higher rate of PE recurrences (risk ratio [RR]: 1.56; 95%CI: 1.08-2.21) and a similar rate of DVT recurrences (RR: 0.80; 95%CI: 0.50-1.22) or major bleeding (RR: 1.18; 95%CI: 0.90-1.55) than those not receiving RT. Moreover, patients on RT had a higher rate of cerebral bleeding (RR: 2.05; 95%CI: 1.07-3.71). Multivariable analysis confirmed that patients receiving radiotherapy were at an increased risk for cerebral bleeding (hazard ratio: 2.71; 95%CI: 1.13-6.48).

#### Conclusion

During the course of anticoagulant therapy, cancer patients with VTE receiving RT had a higher rate of PE recurrence and a higher rate of cerebral bleeding than those not receiving RT.

<sup>23</sup>Azienda Ospedaliera di Reggio Emilia, Radiotherapy, Reggio Emilia, Italy

<sup>24</sup>Santa Chiara Hospital, Radiotherapy, Trento, Italy

#### Purpose or Objective

Data from centres active in intraoperative radiotherapy (IORT) were collected within the International Society of Intraoperative Radiotherapy (ISORT) program. The purpose of the present analysis was to analyse and report the main clinical and technical variables of IORT performed by the participating centres.

#### Material and Methods

In 2007, the ISORT-Europe centres were invited to record demographic, clinical and technical data relating to their IORT procedures in a joint online database.

#### Results

The numbers of centres increased from 3 centres in 2007 to 42 centres and 11,025 IORT procedures have been recorded until October, 2016. 96% of treatment was performed with electrons, while 448 treatments were performed with x-rays. Median age of patients was 56.2 years (range: 5 months - 89 years). Gender was female in 81.2% of cases and male in 18.8%. Treatments were curative in 10,482 cases (98.2%) and 2,545 (23.8%) cases were included in study protocols. The most frequent tumour was breast cancer with 8,425 cases (76.4%) followed by rectal cancer with 913 cases (8.3%), soft tissue and bone sarcomas with 348 cases (3.2%), prostate cancer with 165 cases (1.5%), gastric cancer with 120 cases (1.1%) and pancreatic cancer with 117 cases (1.1%). 22% of patients were included in study protocols. Focusing on breast cancer: 96.5% of cases were ductal carcinoma, 99.5% treatments had curative intent and 113 cases were re-treating with IORT.

#### Conclusion

Treatment chronology shows how IORT number of recorded cases increased according with the interest in this ISORT project. This survey gives an overview of

worldwide use of IORT including patient selection criteria and treatment modalities and could represent a basis to design future clinical trials.

#### PO-0755 Implementation of structural patient reported outcome registration in clinical practice

I. Nijsten - van Riesen<sup>1</sup>, L. Boersma<sup>2</sup>, M. Brouns<sup>1</sup>, A. Dekker<sup>3</sup>, K. Smits<sup>4</sup>

<sup>1</sup>MAASTRO Clinic, Projectmanager Datacentre Maastricht Clinic DCM, Maastricht, The Netherlands

<sup>2</sup>MAASTRO Clinic, Director of Patient Care, Maastricht, The Netherlands

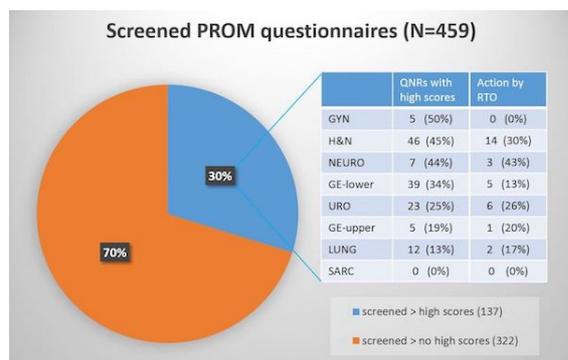

<sup>3</sup>MAASTRO Clinic, Manager Research and Education, Maastricht, The Netherlands

<sup>4</sup>MAASTRO Clinic, Manager of Datacentre Maastricht Clinic DCM, Maastricht, The Netherlands

#### Purpose or Objective

Over the last years there has been an increasing focus on registration and national audits of quality indicators, with the assumption that insights into the quality of a certain treatment will increase outcomes. Within our radiotherapy (RT) institute we have set-up a structural outcome registration, where we first focussed on registration of toxicity, both reported by the doctor and by the patient. The reported toxicity was stored in a data warehouse including dashboards to evaluate toxicity on a population level, and to identify potential targets for improvements in the quality of care. The current study was done to investigate how we can directly improve individual patient care by re-directing the patient-reported outcome measures (PROMs) to the responsible radiation oncologist (RO).

#### Material and Methods

In our regular outcome registration, we score acute toxicity both by the RO and patient, whereas late toxicity is mainly scored by the patient. For the PROMs we handout validated - tumor group specific - questionnaires (QNRs) at baseline. Subsequently we sent out the QNRs at 3 weeks after the end of RT, 3, 6 and 12 months after RT, and thereafter yearly until 5 years after RT. For the current study we manually selected all QNRs scoring  $\geq$  grade 3 symptoms on any item during 2 months. The selected QNRs were sent to the responsible RO by e-mail. The RO reported his/her subsequent actions: 1) Making a note in the Electronic Patient File (EPF); 2) contacting the patient to decide whether analysis and/or treatment of the symptoms was required, or 3) no action. Finally, the RO reported how much time the actions had taken. The type of undertaken actions and the required time was analysed per time-point of the QNR, and per tumor type.

#### Results

All received QNRs during the set period, in total 459, were screened; in 137 (30%)  $\geq$  grade 3 symptoms were reported on any item, which varied between the tumor groups (figure). In 20% of the cases, spread evenly (relatively) between short term and later time points, the RO undertook some additional action, which varied between

discussing the high score in regular follow-up contact with the patient, to referring the patient to the GP, to making a note in the EPF. 90 Out of the 137 (66%) QNRs concerned symptoms between baseline to 3 months after RT; the other 34% concerned late toxicity. The time used by the RO to undertake action varied from 1 - 20 minutes, with an average of 5,8 and a SD of 4 minutes.

#### Conclusion

We found that re-directing the patient-QNRs to the responsible RO improved patient related quality of care, since actions were taken based on information the RO formerly did not acquire. However, the workload for the RO can significantly be diminished by only re-directing QNRs that are returned from 3 months after treatment, since most patients have their follow-up in the referring hospitals. Here PROMs have a substantial added value. The next step is to have the DWH automatically send an alert to the responsible RO.

#### PO-0756 Characterizing tissue equivalent materials used for an end-to-end QA phantom for MR-guided RT

A. Steinmann<sup>1</sup>, D. Followill<sup>1</sup>

<sup>1</sup>UT MD Anderson Cancer Center Radiation Physics, Radiation Physics, Houston- TX, USA

#### Purpose or Objective

Tissue equivalent (TE) materials currently used to simulate tumor and surround tissues for IROC-Houston's anthropomorphic head and thorax QA phantoms cannot be visualized on MR. The purpose of this study was to characterize "dual MR/CT compatible" TE materials that can be used in an end-to-end QA phantom for MR guided radiotherapy (MRgRT) modalities.

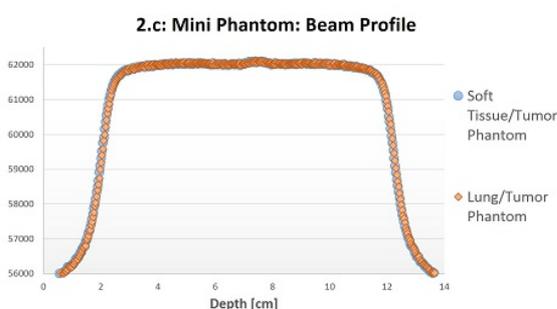

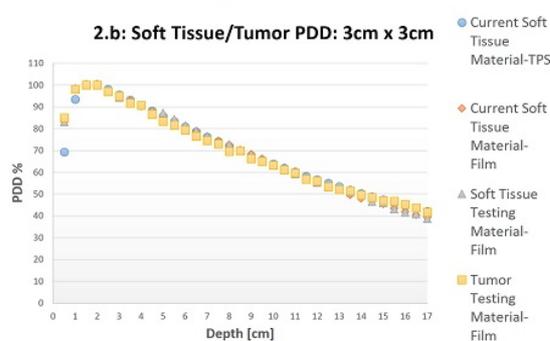

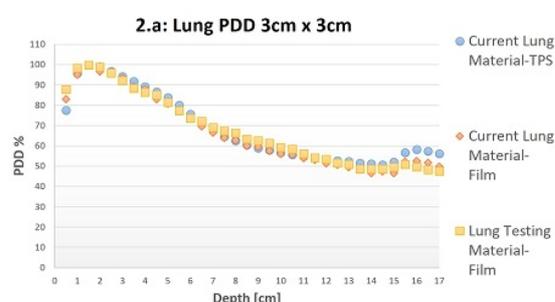

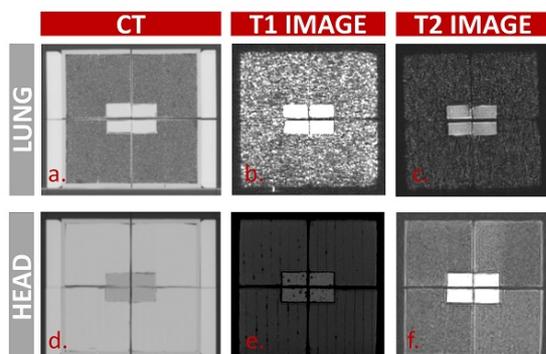

#### Material and Methods

Four materials were characterized for use as TE materials in a QA phantom for MRgRT modalities and were examined based on MR/CT visualization and dosimetric properties. These materials included soft tissue, lung and two potential tumor substitute alternatives. Materials were scanned on Siemens' 1.5T using four sequences, which showed the materials visual contrast between T1 and T2 weighted images. Material's attenuation data were collected using GE's CT Simulator. Dosimetric properties were examined by constructing a 10x10x20 cm<sup>3</sup> PDD phantom that was divided into three sections: anterior, middle, and posterior. Anterior and posterior pieces were composed of polystyrene, whereas the middle section was substituted with the testing materials. EBT3 film was inserted into the phantom's midline and was irradiated using Elekta's Versa 6 MV beam with a prescription of 6 Gy at 1.5 cm and varying field size of: 10x10 cm<sup>2</sup>, 6x6 cm<sup>2</sup>, and 3x3 cm<sup>2</sup>. Relative film measurements were compared with a treatment plan. Two mini-phantoms were constructed out of the four previously studied materials that represented interfaces between tumor/soft-tissue and tumor/lung. These phantoms were fabricated into a 15x15x15 cm<sup>3</sup> cube, where the center-most represented a tumor with dimensions of 3x3x5 cm<sup>3</sup>. Two TLDS were inserted inside the tumor and EBT3 was inserted in the sagittal plane. With a prescription of 6 Gy at 1.5 cm, beam profiles were collected with and without a magnetic field from a 1.5T MR-Linac.

#### Results

The tested TE materials provided great contrasts amongst T1 and T2 weighted images, additionally, they showed attenuation comparable to their respective organ sites. MR/CT compatible lung and soft TE materials had HUs of -685, and 20, respectively, whereas the two potential tumor alternatives showed HU values of -160 and 30. PDD curves were compared with IROC-Houston's conventional lung and soft tissue substitutes. Soft

tissue/tumor equivalent materials show greater PDD curve agreement than lung equivalent materials. While all PDDs showed expected curve shapes, the smallest field size (3x3 cm<sup>2</sup>) showed a deviation of 11.9% and 4.6%, respectively for lung and soft tissue PDD curves. At B=0 and at 6.5 cm in depth of the mini phantom, beam profiles were extracted from the film and were corrected and normalized to the TLDs. It is expected that beam profiles will show similar beam profile results with a 1.5T magnetic field.

## Conclusion

It was determined that the four testing materials were MR/CT compatible, showed expected PDD curves, and preliminary data show expected beam profiles with and without 1.5T on the MR-Linac.

## PO-0757 Variation of mean dose output from 204 UK linacs (Jan-June 2015) and its potential clinical impact.

M. Bolt<sup>1</sup>, A. Nisbet<sup>1</sup>, C. Clark<sup>2</sup>, T. Chen<sup>3</sup>, R. Jena<sup>4</sup>  
<sup>1</sup>St. Luke's Cancer Centre Royal Surrey County Hosp, Radiotherapy Physics, Guildford, United Kingdom  
<sup>2</sup>National Physical Laboratory, Radiation Dosimetry, Teddington, United Kingdom  
<sup>3</sup>University of Surrey, Chemical and Process Engineering, Guildford, United Kingdom  
<sup>4</sup>Addenbrooke's Hospital, Department of Oncology, Cambridge, United Kingdom

### Purpose or Objective

Variation in dose delivered to patients directly impacts the effectiveness of radiotherapy treatments. The drift and daily fluctuations in linac beam calibration (output) is a contributing factor to the cumulative dose received by the patient. Knowledge of the variation in measured outputs on a national scale provides an insight into the uncertainties in dose delivery and its clinical impact.

### Material and Methods

A request for 6MV output measurement data was sent to all UK radiotherapy centres. In total, data was provided for 204 linacs situated at 52 cancer centres across the UK. The data spans 6 months from January to June 2015, totalling almost 25,000 data points. Additional data collected includes: linac model, year of install, measurement equipment and recording method.

The dose response parameter, gamma, is the percentage change in treatment response caused by a percentage change in dose. Gamma values of 2.3 and 5.2 (representative for Head and Neck cancers) were used to estimate the effect on TCP and NTCP respectively [1].

### Results

Based on the collated data, the UK linac outputs had a mean of -0.01% with one standard deviation of 0.88%. There was a wide variety of recording methods, with 8 centres having no form of electronic record for daily checks. Measurement data for both constancy devices and ionisation chambers was provided for 29 linacs. Of these, 8 (28%) had a discrepancy between measurement devices of greater than 0.5%, with 3 linacs (10%) having greater than 1%.

The greatest variation in the mean output of an individual linac was -2.1%, with 90% of linacs having a mean output within 1% of the national mean. No significant variations were observed based on the age of the linac.

The maximum range within a single centre for the mean output for each linac was 2.3% (min: -1.1%, max: +1.2%) - see figure. Assuming patients are treated on a single linac for their treatment duration, this indicates a variation in TCP of 5.3% and a variation in NTCP of 12% dependent on which linac they are treated on at that centre.

### Conclusion

The data collection process indicates that many departments still rely heavily on paper QC records. The variation in treatment outcomes caused by dose variation alone indicates the importance of accurate QC. Output adjustment is one of the simplest ways of maintaining treatment consistency between individual patients, and its significance should not be forgotten with the introduction of more advanced techniques. This variation in dose should be considered when participating in clinical trials. This applies both to small scale local trials in which the technique used may determine the treatment linac, and therefore the dose delivered, as well as large multi-centre trials where the dose variation should be considered for the trial power calculations.

## PO-0758 Development of patient-specific phantoms for verification of SBRT planning using 3D printer

C.S. Hong<sup>1</sup>, D. Oh<sup>1</sup>, S.G. Ju<sup>1</sup>, M. Kim<sup>1</sup>, B.Y. Koo<sup>1</sup>, H.C. Park<sup>1</sup>, D.H. Choi<sup>1</sup>, H. Pyo<sup>1</sup>

<sup>1</sup>Samsung Medical Center- Samsung Biomedical Research Institute- Sungkyunkwan University School of Medicine, Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

A new technique for manufacturing a patient-specific dosimetric phantom (PSDP) using three-dimensional printing (PSDP\_3DP) was developed, and its geometrical and dosimetric accuracy was analyzed.

### Material and Methods

External body contours and structures of the spine and metallic fixation screws (MFS) were delineated from CT images of a patient with MFS who underwent stereotactic body radiation therapy for recurrent thoracic spine metastasis. Contours were converted into a STereoLithography file format using in-house program. A hollow, four-section PSDP was designed and manufactured using three types of 3DP to allow filling with a muscle-equivalent liquid and insertion of dosimetric film and grass dosimeters in the axial and coronal planes, respectively. To evaluate the geometrical and dosimetric accuracy of PSDP\_3DP, CT images were obtained and compared with patient CT data for volume, mean density, and Dice similarity coefficient (DSC) for contours. The dose distribution in the PSDP\_3DP was calculated by applying the same beam parameters as for the patient, and the dosimetric characteristics of the PSDP\_3DP were compared with the patient plan.

Fig. 1. The PSDP\_3DP was printed as 20 separate pieces using three different types of 3D printer with compatible materials (a and b). UV-curable acrylic plastic (UVAP), plastic powder, and titanium were used to create the external body, spine, and metallic fixation screws, respectively, which were then assembled (c and d).

### Results

In comparing between the patient and PSDP\_3DP, the percent differences in volume for the external body, spine, and MFS were -4.1%, 6.4%, and 10.0%, while the DSCs were 0.98, 0.91, and 0.89, respectively. The differences in density between the external body and spine were 7.5% and 15.5%, respectively. In the axial plane at the target center, large dose differences were observed at the border of the external body contour (low-dose region), while most of the center region (high-dose region) was in good agreement, with a dose difference within 5%. The DHVs of both plans were well matched. Specifically, the mean differences in dose for GTV, CTV, spinal cord, and external body were -0.5%, -0.5%, 4.0%, and -2.8%, respectively.

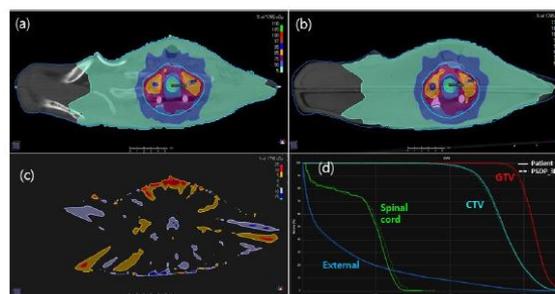

Fig. 2. Plans for the patient (a) and PSDP\_3DP (b) showed very similar dose distributions in the axial plane. Larger dose differences were observed at the border of the external body contour (low-dose region), but was minimal in the center region (high-dose region), the difference of which was within 5% according to an axial dose difference map (c). The DHVs of the both plans were well matched (d).

### Conclusion

The physical accuracy and dosimetric characteristics of the PSDP were comparable with patient data. The ability to manufacture a PSDP representing an extreme patient condition was demonstrated.

### PO-0759 Validation of the influence of M512 substrate resistivity on sensitivity degradation of radiation

N. Stansook<sup>1</sup>, M. Petasecca<sup>1</sup>, K. Utitsarn<sup>1</sup>, M. Carolan<sup>2</sup>, P. Metcalfe<sup>1</sup>, M.L.F. Lerch<sup>1</sup>, A.B. Rosenfeld<sup>1</sup>

<sup>1</sup>Wollongong University, Center for Medical Radiation Physics CMRP, wollongong, Australia

<sup>2</sup>Wollongong hospital, Illawarra Cancer Care Centre, Wollongong, Australia

### Purpose or Objective

The diode detector has been widely used as a quality assurance (QA) tools in radiotherapy. However, the detector is affected by accumulative radiation damage leading to degradation of the sensitivity and dose per pulse dependence. The objective of this study is to investigate the influence of the substrate resistivity on sensitivity degradation of radiation and dose per pulse dependence of M512.

### Material and Methods

The M512 is a monolithic 2D 512 diode array detector fabricated on p-type Si substrate. The detector active area is 52x52 cm<sup>2</sup> with 2 mm pixel pitch. M512 was developed at the Center for Medical Radiation Physics (CMRP) for quality assurance in SRS and SBRT. In this study, two types of Si substrate including M512-Bulk and M512-Epi were investigated. The M512-Bulk has been fabricated on low resistivity bulk silicon with thickness 470 μm while the M512-Epi has been manufactured on an epitaxial high resistivity p-silicon with 38 μm thick grown on a low resistivity of 370 μm thick substrate. Both detectors were irradiated on the <sup>60</sup>Co source in the total dose ranging from 0 to 40 kGy for M512-Bulk and 0 to 60 kGy for M512-Epi detectors. The 6 MV photon beam was used to investigate the sensitivity degradation and dose per pulse dependence. To evaluate the sensitivity degradation, the detector response was measured after irradiation with dose increments of 10 kGy. The dose per pulse dependence was determined by varying the SSD from 100 to 370 cm corresponding to the dose per pulse ranging from 0.278 to 0.021 mGy/pulse. The PDD was measured using a square field size 10x10 cm<sup>2</sup> by fixing the SSD at 100 cm and varying detectors depth in a phantom from 0.5 to 30 cm and comparing with the CC13 chamber.

### Results

M512-Epi demonstrates excellent radiation stability with the sensitivity degradation of 0.3%/10 kGy while M512-Bulk shows the degradation of 1%/10 kGy. The detector response decreases with the dose per pulse decrease. M512-Bulk shows less dose per pulse dependence compare with the M512-Epi with the sensitivity response (pC/Gy) decreasing about 2% while the sensitivity of M512-Epi decreased by 8% at a dose per pulse change of 10 times.

For depth dose measurement, both substrates show a great agreement within  $\pm 2\%$  when compared to the IC response.

#### Conclusion

The difference detector Si substrates show the difference in degradation of the detector sensitivity. The M512-Epi demonstrate 3.5 times better radiation hardness in comparison with M512-Bulk while show more the dose per pulse dependence. However, for typical treatment when SSD <150 cm for all beam angles the sensitivity of the detector decreases within 2% for both substrates making M512 -Epi more preferable choice as QA detector for dosimetry in SRS and SBRT.

#### PO-0760 Investigation of PRESAGE formulation on signal quenching in a proton beam

M. Carroll<sup>1,2</sup>, M. Alqathami<sup>2</sup>, G. Ibbott<sup>2</sup>

<sup>1</sup>University of Texas at Houston, Graduate School of Biomedical Sciences, Houston, USA

<sup>2</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

#### Purpose or Objective

PRESAGE®, a radiochromic polyurethane dosimeter, has shown potential as a 3D dosimetry system for conventional radiotherapy systems. When irradiated by protons, however, signal quenching is observed in high-LET regions. This quenching may result from either (or both) the local saturation of the Leucomalachite green (LMG) or recombination of the radical initiator (RI) along proton tracks. This work studied the magnitude of these quenching mechanisms and the effects of changes to formulaic concentrations of these components to further minimize or eliminate the quenching effect.

#### Material and Methods

Ten formulations of PRESAGE® were manufactured under standardized conditions but with RI concentrations ranging from 3-30 (wt%) and low LMG concentration (2 wt%). Six more formulations were then manufactured with high LMG concentration (4 wt%) and RI concentrations ranging from 6-16%. These formulations were cast in spectrophotometer cuvettes and stored at  $<3^\circ\text{C}$  prior to irradiation. A passively scattered 225 MeV proton beam with a 10 cm SOBP was selected and each formulation of dosimeters was irradiated in a solid water phantom at four depths along the beam profile: one in the dose plateau and three along the SOBP. The photo-absorption spectra were measured for each formulation. The optical attenuation coefficients of the PRESAGE® samples were compared to ion chamber measurements to determine the quenching magnitudes.

#### Results

The photo-absorption spectra demonstrated consistent absorption peaks, and all formulations responded linearly with dose. The dose sensitivity of the dosimeters changed by as much as 42% across all formulations. All formulations with RI concentrations between 10-21% showed quenching less than 3% at the proximal SOBP dose point but increased quenching at other measurement points along the SOBP. Formulations outside this RI concentration range had greater quenching across all measurements. The distal-most points of all formulations showed the greatest quenching. When comparing these points, high LMG formulations had lower quenching than those with low LMG while RI concentrations were 12% or lower, but quenching was greater when RI concentration was above this range. The least quenching in the low LMG formulations was 14.6% which occurred at 12% RI, while in the high LMG formulations this occurred at 10% RI with a maximum under-response of 8.4%. The highest quenching observed was 73.8% in the low LMG, 30% RI formulation.

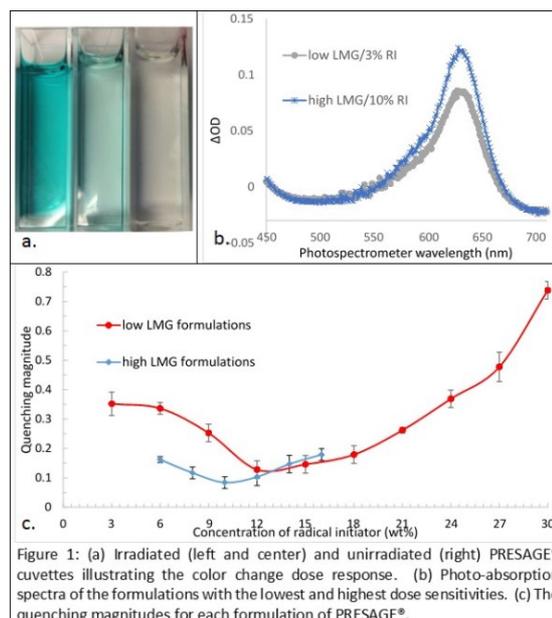

Figure 1: (a) Irradiated (left and center) and unirradiated (right) PRESAGE® cuvettes illustrating the color change dose response. (b) Photo-absorption spectra of the formulations with the lowest and highest dose sensitivities. (c) The quenching magnitudes for each formulation of PRESAGE®.

#### Conclusion

Previous studies have the only investigated the effects of changing RI concentrations on the quenching magnitude of PRESAGE® in a proton beam, but this study has demonstrated that the quenching process is additionally limited by LMG concentration. While a quenching reduction limit for low LMG formulations was before it could be fully eliminated, further reduction of quenching by increasing LMG demonstrates that additional study into PRESAGE® optimization of both of these components may continue to improve accuracy in proton dosimetry.

#### PO-0761 Dosimetry with Farmer ionization chambers in magnetic fields: Influence of the sensitive volume

C.K. Spindeldreier<sup>1,2</sup>, I. Kawrakow<sup>3</sup>, O. Schrenk<sup>1,2</sup>, S. Greilich<sup>1,2</sup>, C.P. Karger<sup>1,2</sup>, A. Pfaffenberger<sup>1,2</sup>

<sup>1</sup>German Cancer Research Center, Medical Physics in Radiation Oncology, Heidelberg, Germany

<sup>2</sup>National Center for Radiation Research in Oncology, Heidelberg Institute for Radiation Oncology, Heidelberg, Germany

<sup>3</sup>ViewRay, Inc, Oakwood Village, USA

#### Purpose or Objective

Ionization chambers exhibit an altered dose response in a magnetic field of an MR-linac due to the deflection of secondary electrons by the Lorentz force. The actual dose response depends on the magnetic field strength as well as on the orientation between chamber axis, beam and magnetic field [Meijssing PMB 54 2009, Reynolds Med Phys 40 2013, Spindeldreier DGMP 47 2016]. The purpose of this study is to investigate the influence of dead volumes, known to exist at the chamber base, on the response of a thimble ionization chamber in the presence of a magnetic field.

#### Material and Methods

The response of a Farmer chamber (PTW 30013) subject to a 6 MV beam was measured in a small water tank [Bakenecker Uni Heidelberg 2015] embedded in an experimental magnet for magnetic field strengths between 0.0 and  $\pm 1.1$  T in the two magnetic field orientations perpendicular to the beam and to the chamber axis. The experimental setup was simulated using the EGSnrc [Kawrakow Med Phys 27 2000, NRC PIRS 898 2009] user code egs\_chamber [Wulff Med Phys 35 2008]. In addition to computing the total dose deposited in the chamber cavity for different sensitive volumes, a high resolution dose map inside the cavity was obtained.

## Results

A maximum of 8.1% and 7.0% increase in chamber response was measured for the two orientations at a field strength of  $\pm 0.9$  T. In contrast, the calculated response was only marginally different, when the entire air volume was considered as a sensitive volume in the simulations. It was possible to reproduce the experimentally observed differences in dose response using a small dead volume close to the chamber stem. The simulated dose distribution within the chamber cavity was found to be highly non-uniform with hot and cold spots at the chamber stem and chamber tip, depending on the field orientation (see Fig. 1).

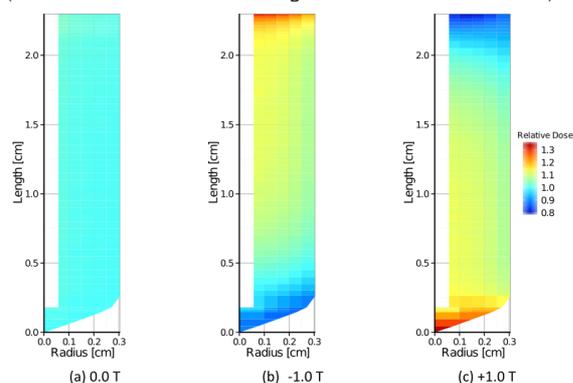

Fig. 1: Dose distribution in the chamber air volume relative to the mean dose in the whole volume without magnetic field, scored in azimuthal rings and projected in Y-R plane, for different magnetic field strengths.

## Conclusion

In the presence of a magnetic field perpendicular to the axis of thimble ionization chambers, the amount of electrons entering the cavity from the tip and stem is increased or decreased, depending on the field orientation. The chamber response is therefore influenced in a significant way by the presence of a dead region known to exist at the chamber base near the stem. Measurements with the chamber axis parallel to the magnetic field are thus advantageous, as in this case the dead volume has less impact due to the Lorentz force acting radially. An optimized chamber design that minimizes the dead volume will also reduce the influence of the magnetic field.

**Acknowledgements:** We thank Dr. E. Schuele as well as R. Kranzer (PTW) for giving detailed information on the chamber geometry.

## PO-0762 Real-time dosimetry with rare earth doped silica

G. Loi<sup>1</sup>, E. D'Agostino<sup>2</sup>, I. Veronese<sup>3</sup>, N. Chiodini<sup>4</sup>, A. Vedda<sup>4</sup>

<sup>1</sup>Azienda Ospedaliera Maggiore della Carità, Medical Physics Department, Novara, Italy

<sup>2</sup>DoseVue NV, R&D, Mol, Belgium

<sup>3</sup>Università degli Studi di Milano and INFN, Dipartimento di Fisica, Milano, Italy

<sup>4</sup>Università di Milano Bicocca, Dipartimento di Scienza dei Materiali, Milano, Italy

## Purpose or Objective

Modern radiotherapy techniques as Cyberknife or VMAT are characterized by high daily doses regimes and steep dose gradient, often associated to small irradiation fields. Optical fiber based dosimetry represents a very attractive alternative to perform measurements under these conditions, thanks to its compactness, real-time response and high sensitivity. The use of such technology has however been hampered by the complex calibration procedures needed to handle the so-called stem signal. Rare earth doped silica, coupled to optical fibers, represent an efficient and robust way to solve this problem.

## Material and Methods

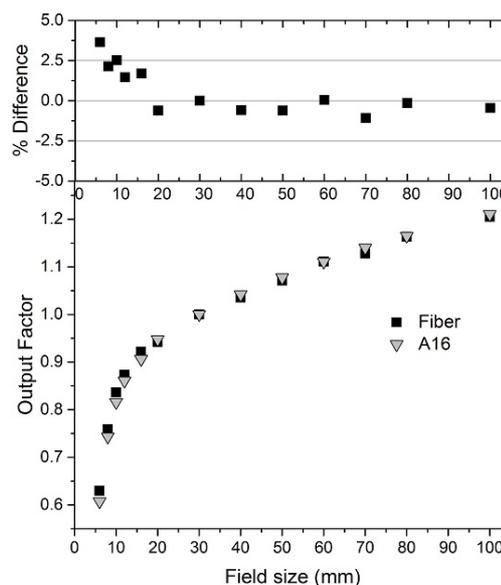

Different types of rare earth doped silica were produced by sol-gel technique. They were coupled to different type of fibers and tested under several conditions.

The radioluminescence and dosimetric properties of Yb-doped silica optical fibers, were studied by irradiating the fibers with photons and electron beams generated by a Varian Trilogy accelerator and comparing its performances with other existing state of the art dosimeters. The scintillation was detected with a laboratory prototype based on an avalanche photodiode (APD).

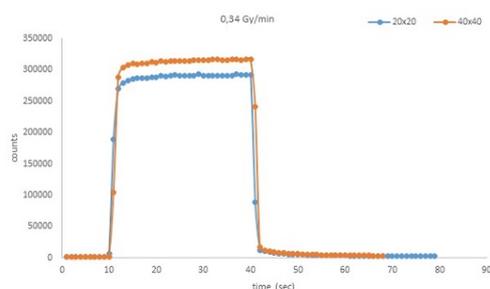

Beside the clinical measurements, a second set of measurements exploiting a cerium-doped silica fiber, was also performed on a preclinical irradiator (Xrad Smart from PXI inc). Measurements were performed during high resolution CT imaging as well as during irradiation.

## Results

The Yb-doped silica system, tested under clinical conditions, showed a satisfactory sensitivity, reproducibility, and a linear dose-rate response. A reliable dose evaluation was obtained independently of the dose rate and of the orientation of the impinging beam, clearly demonstrating that stem signal (and, more specifically, its Cherenkov component) was very efficiently suppressed, even in very unfavorable large field irradiation conditions. The results showed a good agreement with reference dosimeters in terms of relative dose profiles and output factors. Figure 1 shows the outcome of output factor measurements, performed on the linear accelerator, for different field sizes, comparing the Yb-doped fiber to a micro ionization chamber from Standard Imaging (A16).

As for the preclinical irradiations, the very high scintillation yield from the doped silica allows its use without further handling of the stem signal. Figure 2 shows an example of signal obtained for a 20x20 mm<sup>2</sup> and 40x40 mm<sup>2</sup> fields. The difference between the curves is related to the output factor. This was previously determined to be equal to 0.94 for the 20x20 mm<sup>2</sup> field, versus the 40x40 mm<sup>2</sup> field.

### Conclusion

Rare-earth doped scintillating silica, thanks to their high light yield and favorable spectral properties, offer a true alternative to perform optical fiber dosimetry, in different clinical and preclinical conditions, eliminating in a reliable and robust way the influence of the stem effect, without the need of complex and time-consuming calibrations.

### PO-0763 Characterizing the response of Gafchromic EBT3 film in a 1.5 T magnetic field

Y. Roed<sup>1,2</sup>, H. Lee<sup>2</sup>, L. Pinsky<sup>1</sup>, G. Ibbott<sup>2</sup>

<sup>1</sup>University of Houston, Physics, Houston, USA

<sup>2</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

### Purpose or Objective

To assess the influence of a magnetic field (B-field) on the response of radiochromic film. Irradiation at different orientations of the film with respect to the B-field was assessed as well as different durations of exposure of the films to the B-field.

### Material and Methods

EBT3 films were placed at 5 cm depth in an acrylic phantom and irradiated to 2, 4, and 8 Gy using a cobalt source while exposed to the B-field from an electromagnet. The film surfaces were perpendicular to the incident beam while a reference film edge was oriented either parallel (RE0) or perpendicular (RE90) to the B-field. Two B-field strengths of  $B = 0$  T and  $B = 1.5$  T were used. All films were exposed to the B-field for 7 min. A subsequent set of films was irradiated to 4 Gy using the same setup and  $B = 1.5$  T field strength. The films were exposed to the B-field for 6, 10, or 30 minutes.

All films were scanned with an Epson 10000 XL flatbed scanner prior to and 24 hours after irradiation, first with the reference edge parallel (PA) to the scan direction and then perpendicular (PA90).

Red channel pre- and post-scans were analyzed with ImageJ software. Percent differences (%diff) with respect to  $B = 0$  T were calculated for PA and PA90 films. %diff between PA and PA90 were also determined.

### Results

All films exhibited an under-response at each dose level when compared to irradiation at  $B = 0$  T. Less than -2.0 % difference was determined in the PA scan direction at all dose levels for both orientations in the B-field (solid and dashed black in Figure 1). The under-response increased with increasing dose for RE90 films scanned in PA90 direction (dashed grey in Figure 1). For RE0 the maximum %diff was -1.1 % (solid grey in Figure 1).

The %diff in scan direction increased with increasing dose from 11.0 % to 12.4 % in RE0 orientation and from 9.6 % to 11.1 % in RE90 orientation.

Table 1 shows that increasing the time the films remained in the B-field resulted in less than 1.0 % over-response for 6 and 30 min and -0.9 % under-response for 7 and 10 min. The %diff in scan direction was about 12 % for all times.

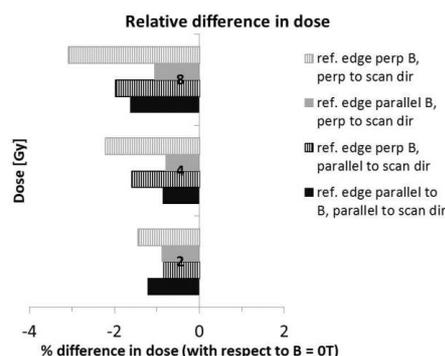

Figure 1: Percent differences in dose with respect to  $B = 0$  T calculated for RE0 and RE90, first for PA scan direction and then for PA90

Table 1: Percent differences in dose with respect to  $B = 0$  T calculated for different durations of exposure to the B-field, first for PA scan direction and then for PA90

Time in B-field [min]	% difference (with respect to $B = 0$ T) [PA scan dir]	% difference (with respect to $B = 0$ T) [PA90 scan dir]	% difference in scan direction
6	0.8	0.5	11.6
7	-0.9	-0.8	12.1
10	-0.5	-0.6	11.9
30	0.7	0.8	12.1

### Conclusion

Radiochromic films can measure doses delivered by a magnetic resonance-image guided radiotherapy treatment unit and can be considered for quality assurance of MR-guided treatment units. The duration of exposure to the B-field did not affect the response of the film and neither did the orientation of the reference edge as all determined %diff were less than the uncertainty of film measurements. However, the orientation of the reference edge with respect to scan orientation did have a significant effect on the response of the film. Maintaining consistent orientation of films both during the irradiation in a B-field and also on the flatbed scanner still remains essential to acquire results with the lowest %diff.

### PO-0764 A study of Tandem systems incorporating three thermoluminescent dosimetry materials.

V. Nelson<sup>1</sup>

<sup>1</sup>Macarthur Cancer Therapy Centre, Medical Physics, Campbelltown, Australia

### Purpose or Objective

Tandem systems, incorporating a pair of TL materials, have been shown to be very useful for the determination of effective energy in radiation beams with unknown radiation energy spectrum. Tandem curves in all these tandem systems exhibits maximum TL response ratio between 40-50 keV and similar TL response ratios on either side of this energy ( $E_{max}$ ), making it difficult to determine if the effective energy is less than or greater than the  $E_{max}$  (Fig.1(a)). However, if a third TL material, with energy dependent TL response different to the other two materials, is included in the tandem, two tandem curves can be obtained. If these two tandem curves significantly differ from each other, the effective energy of the radiation beam can be identified as either less than or greater than  $E_{max}$ , Fig. 1(b), hence improving the dosimetry in this energy range. The aim of this work was to test a number of different TL materials and find a TL material which fulfils this criteria.

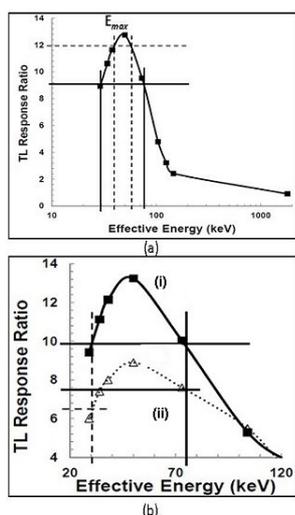

Figure 1. Tandem curves for a two TLD (a) and a three TLD (b) system.

### Material and Methods

Five different TL materials TLD100, TLD100H, TLD200, TLD400 and TLD500, were investigated. Each type of TL dosimeter was irradiated to the eight different qualities of x-radiation. Mean of the response of the 5 dosimeters for a certain x-radiation with effective energy  $E_{eff}$  was taken as the energy dependent TL response of that type of TL dosimeter. For each type of TL detector, energy dependence curves were determined by fitting the experimental results with a polynomial function. Tandem curve pairs for six different combinations were generated; 1. TLD100H, TLD200, TLD400, 2. TLD100H, TLD200, TLD500, 3. TLD100H, TLD400, TLD500, 4. TLD100H, TLD200, TLD400, 5. TLD100, TLD200, TLD500 and 6. TLD100, TLD400, TLD500. TL response ratios at different energies were calculated and compared with two TL material tandem systems.

### Results

All Tandem curves exhibited maximum TL response ratio,  $E_{max}$ , at approximately 45 keV, with reduction in TL response ratios at energies above and below this energy level. All tandem combinations, except the combinations (1) and (4) showed that at energies in the 30 to 80 keV range, where the TL response ratio of tandem pair (i) is same, TL response ratio tandem pair (ii) differs by 20-30%, Figure 2. This will help in determining whether the effective energy of radiation beam is less than or greater than the  $E_{max}$ .

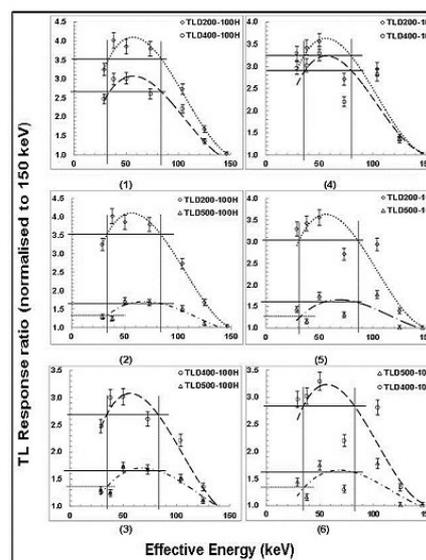

Figure 2. Paired tandem curves for 6 combinations.

### Conclusion

This work presents some possible TLD tandem systems consisting of three types TL materials which are better able to estimate effective energy of a radiation beam in the 30 to 100 keV range than the presently used two TL material tandem systems. This can potentially improve dosimetry in situations where information about the effective energy of radiation is crucial such as personal monitoring. Considering the high sensitivity TLD100H, the TL material increasingly being used in personal dosimetry, tandem combinations of TLD100H, TLD200 & TLD500 or TLD100H, TLD400 & TLD500 are recommended for x or gamma radiation energy discrimination in the 30 to 120 keV range.

### PO-0765 Preparation and Fabrication of a Full-scale Patient-specific 3D-Printed Radiotherapy Phantom

D. Craft<sup>1</sup>, R. Howell<sup>1</sup>

<sup>1</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston- TX, USA

### Purpose or Objective

Phantoms are used in a wide variety of ways for radiotherapy research and quality assurance. Generally, however, these phantoms are limited in size and complexity to represent only small treatment areas or generalized patients. 3D printing technology can make the fabrication and design of patient-specific phantoms simple and inexpensive, but has also been limited by size and complexity due to the limited size of most 3D printers and the tendency of materials to warp while being printed. We aimed to overcome these limitations by developing an effective 3D printing workflow that could be used to design and fabricate large, full-scale, patient-specific phantoms with negligible material warping errors. To demonstrate the viability of our technique we produced a full-scale phantom of a post-mastectomy patient treated at our institution.

### Material and Methods

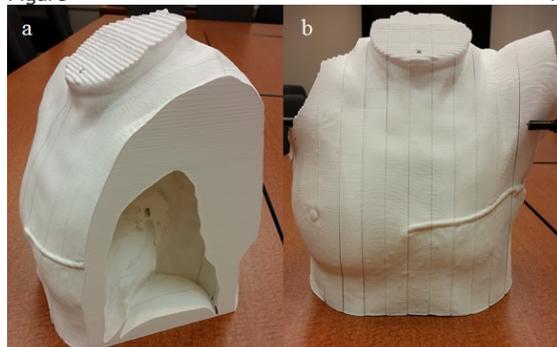

The clinical CT data for a post-mastectomy patient at our institution was converted into a 3D model, and then trimmed to remove the patient's head and arms to simplify printing. The model was next sliced into eleven 2.5-cm-thick sagittal slices, which fit better and have less warping relative to axial slices. Each slice was printed using polylactic acid to represent all body tissues at 100% infill. Air cavities and lower density regions like the lungs were left open and unfilled. The slices were printed on an inexpensive and commercially available 3D printer with

the inferior aspect of the patient on the printing surface. The slices were individually and collectively imaged and examined for printing accuracy. The original patient CT scan and the assembled phantom CT scan were registered together to assess the overall accuracy of the phantom construction.

#### Results

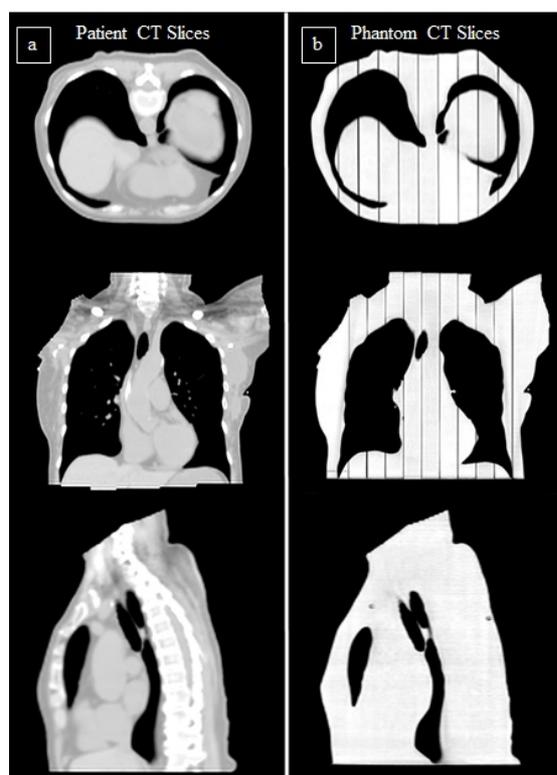

The slices took an average of 24 hours and 19 minutes to print, and the total material cost of the phantom was \$524. Figure 1 shows images of the phantom with the left-most slices removed to show the interior anatomy (a), and the entire phantom assembled (b). As can be seen, the phantom fits together well, and has a high level of detail. Figure 2 shows a comparison of slices in the axial, sagittal and coronal orientations from the original patient CT image (a), and slices from the phantom CT image (b) in the same location and orientation. While material heterogeneity has been lost due to using only one material in the phantom, the anatomical and structural details agree very well between the printed phantom and the source image. The only disagreement is in the lungs, where unsupported nodules were removed prior to printing the phantom. Analysis of individual slices revealed that measurable dimensions were accurate within 0.5 mm, and the average volumetric discrepancy between printed slices and their models was 1.37%.

Figure 1: 1:

Figure

2:

#### Conclusion

The results of our study show that 3D printing technology can be used to fabricate patient-specific, large scale phantoms that could be used for a variety of research, dosimetric, and quality assurance purposes.

#### PO-0766 The effect of air gaps on Magic Plate (MP512) for small field dosimetry

K. Utitsarn<sup>1</sup>, N. Stansook<sup>1</sup>, Z. Alrowaiili<sup>1</sup>, M. Carolan<sup>2</sup>, M. Petasecca<sup>1</sup>, M. Lerch<sup>1</sup>, A. Rosenfeld<sup>1</sup>

<sup>1</sup>University of Wollongong, Center for Medical Radiation Physics, Wollongong, Australia

<sup>2</sup>Wollongong Hospital, Illawara Cancer Care Centre, Wollongong, Australia

#### Purpose or Objective

We evaluate the impact of an air gap on the MP512 irradiation response at depth in a phantom and optimize this gap for accurate small field dosimetry in clinical photon and electron beams.

#### Material and Methods

MP512 is a 2 dimensional silicon monolithic detector manufactured on a p-type substrate. The array consists of 512 pixels with detector size  $0.5 \times 0.5 \text{ mm}^2$  and pixel pitch 2 mm. The overall area of the active part of the detector is  $52 \times 52 \text{ mm}^2$ . The output factor (OF) and the percentage depth dose (PDD) were measured with MP512 in 6MV and 10MV photon beams. The OF was measured at a depth of 10 cm in a solid water phantom for square field sizes ranging from  $0.5 \times 0.5$  to  $10 \times 10 \text{ cm}^2$ . The PDD was measured for field sizes  $2 \times 2 \text{ cm}^2$ ,  $5 \times 5 \text{ cm}^2$  and  $10 \times 10 \text{ cm}^2$  by scanning the MP512 from the depth of 0.5 cm to 10 cm. Both the OF and PDD were measured at all field sizes with an air gap immediately above the detector of 0.5, 1.0, 1.2, 2.0 and 2.6 mm respectively. The PDD for 6, 12 and 20 MeV electron beams with a standard applicator providing  $10 \times 10 \text{ cm}^2$  field size, were measured using an air gap of 0.5mm and 2.6mm.

#### Results

The OF measured by the MP512 reduces with increasing air gap above the detector. The impact of the air gap is largest for the small fields of  $0.5 \times 0.5$  and  $1 \times 1 \text{ cm}^2$  while negligible for field sizes larger than  $4 \times 4 \text{ cm}^2$ . The OF measured by the MP512 detector with an air gap of 0.5 and 1.2 mm show a good agreement with OF measured using EBT3 film and MOSkin for 6 and 10 MV, respectively. Similar results were observed for the PDD measurements in field sizes of  $5 \times 5$  and  $10 \times 10 \text{ cm}^2$ . The PDD for a  $2 \times 2 \text{ cm}^2$  was within  $\pm 3\%$  of the EBT3 for both photon energies. The PDD measured with MP512 is within  $\pm 1.6\%$  and  $\pm 1.5\%$  of that measured using a Markus ionization chamber (IC) for 6 and 10 MV fields respectively. The PDD measured by electron beams demonstrated no significant effect with increasing air gap above the MP512 for all energies. The results for both 0.5mm and 2.6mm gap are within  $\pm 3\%$  of similar measurements made using the Markus IC.

#### Conclusion

The MP512 response with different air gaps immediately above the detector in solid water phantom have been investigated in clinical photon and electron fields. The results confirm that the MP512 monolithic diode array is suitable for QA of small fields in a phantom. The study shows that the air gap size has a significant effect on small field photon dosimetry performance of the MP512 consistent with a loss of electronic equilibrium. The small air gap of 0.5 mm and 1.2 mm is the best air gap for small field dosimetry in 6 and 10 MV photon beams respectively. The effect of air gap on electron beam dosimetry using the MP512 was demonstrated to be not significant due to the electronic equilibrium conditions always being fully established.

### PO-0767 Revisiting EPID design for modern radiotherapy requirements

P. Vial<sup>1,2</sup>, S. Blake<sup>2,3</sup>, Z. Cheng<sup>2,3</sup>, S. Deshpande<sup>1,4</sup>, S. Atakaramians<sup>5</sup>, M. Lu<sup>6</sup>, S. Meikle<sup>7</sup>, P. Greer<sup>8,9</sup>, Z. Kuncic<sup>2</sup>

<sup>1</sup>Liverpool and Macarthur Cancer Therapy Centres and Ingham Institute, Department of Medical Physics, Liverpool BC, Australia

<sup>2</sup>University of Sydney, Institute of Medical Physics-School of Physics, Sydney, Australia

<sup>3</sup>Ingham Institute, Medical Physics, Liverpool, Australia

<sup>4</sup>University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia

<sup>5</sup>University of Sydney, Institute of Photonics and Optical Science- School of Physics, Sydney, Australia

<sup>6</sup>Perkin Elmer, Medical Imaging, Santa Clara, USA

<sup>7</sup>University of Sydney, Faculty of Health Sciences & Brain and Mind Centre, Sydney, Australia

<sup>8</sup>University of Newcastle, School of Mathematical and Physical Sciences, Newcastle, Australia

<sup>9</sup>Calvary Mater Newcastle Hospital, Radiation Oncology, Newcastle, Australia

#### Purpose or Objective

New methods of treatment verification that are in keeping with advances in radiotherapy technology are desirable. The availability of kilovoltage in-room imaging for example has led to a general trend away from the poorer contrast megavoltage (MV) imaging for patient-set-up. The widespread use of intensity-modulated radiotherapy (IMRT) also reduces the utility of treatment beams as a source of imaging for treatment verification. At the same time there has been a steady increase in the use of electronic portal imaging devices (EPIDs) for dose verification. There is however emerging evidence of new roles for MV imaging in real-time target tracking. In this work we address the issue of EPID detector specifications in light of changing clinical requirements. We present a general overview of the detector development work our group has undertaken to design an EPID that better supports applications relevant to current and future clinical practice.

#### Material and Methods

Prototype EPID technologies developed by our group include: a direct detector EPID where the metal/phosphor screen has been replaced by a water equivalent build-up material [1]; a dual detector combining a standard EPID and an array dosimeter [2]; and an EPID comprising a plastic scintillator fibre array (PSFA) in place of the metal/phosphor screen [3]. Our performance specifications were to achieve imaging performance equivalent to standard EPIDs, and a dose response equivalent to standard clinical dosimeters. Quantitative metrics such as detective quantum efficiency (DQE) for imaging and field size response for dosimetry were used in both experimental and Monte Carlo (MC) studies. There are three arms to this project that shall be described; i) MC simulations to characterise and design scintillators; ii) Prototype construction and experimental evaluation, iii) clinical implementation.

#### Results

All prototype detectors exhibited near equivalent dose response with ionisation chambers in both non-transit and transit geometries ( $\pm 2\%$ ), including 2D clinical dosimetry of IMRT fields. The X-ray quantum efficiency of the direct and PSFA detectors is approximately 9% compared to 2% for the standard EPID and dual detector. The imaging performance of the standard EPID and dual detector remains superior to the other prototypes because of the greater efficiency of optical photons detected per incident X-ray and better spatial resolution. MC simulations demonstrate potential improvements in imaging with the PSFA. A model for clinical implementation has been developed that exploits the water equivalence of the detectors. A water equivalent EPID provides more direct and robust verification than can

be achieved with current EPID dosimetry. A water equivalent EPID that retains imaging capability is better suited than current EPIDs for modern radiotherapy.

#### Conclusion

This work demonstrates the feasibility and advantages of alternative EPID designs that better meet the needs of modern radiotherapy.

### PO-0768 Electron Paramagnetic Resonance signal from a new solid polymer material aimed for 3D dosimetry

M.R. Bernal-Zamorano<sup>1</sup>, N.H. Sanders<sup>1</sup>, L. Lindvold<sup>1</sup>, C.E. Andersen<sup>1</sup>

<sup>1</sup>DTU, Nutech, Roskilde, Denmark

#### Purpose or Objective

We have developed a water-equivalent solid polymer dosimeter material aimed for 3D dosimetry in radiotherapy beams. The material responds to ionizing radiation by changes in its optical absorbance and by generation of fluorescence centers. The latter signal is of particular interest as the fluorescence centers facilitate detailed mapping the 3D dose distribution using laser stimulation. However, in addition to the optical signals we also expect that the material could have an electron paramagnetic resonance (EPR) dose response related to the production of stable free radicals. To test this hypothesis, point detector experiments were therefore performed where the material was casted into 5 mm diameter pellets identical in size to the alanine dosimeters that we routinely use for reference EPR dosimetry in our laboratory. The pellets of the new material and alanine were irradiated in <sup>60</sup>Co beams and EPR signals were recorded afterwards.

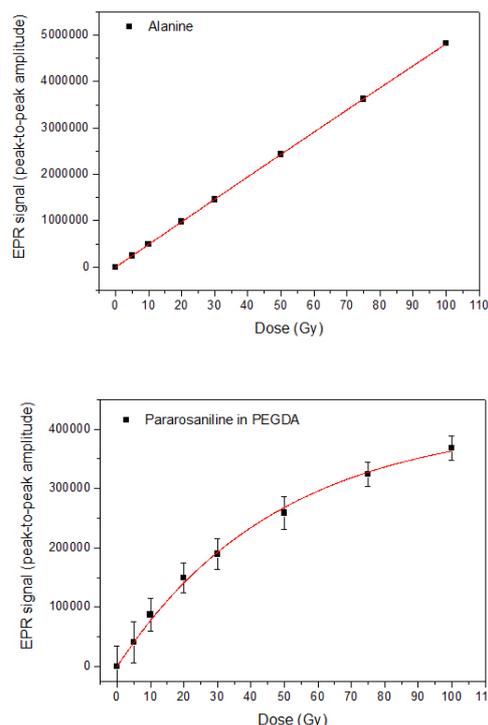

#### Material and Methods

The dosimeter is based in pararosaniline leuco dye, which is chemically transformed into its dye-form by the effect of radiation. The leuco dye is dissolved in a poly(ethylene glycol) diacrylate matrix (PEGDA-575 g/mol) that contains diphenyl(2,4,6-trimethylbenzoyl)phosphine oxide (TPO) used for photocuring. We cured the material in a mold with a 395 nm LED for a few minutes. We made 4 cylindrical pellets of 4.75 mm diameter and 2.78 mm thickness (same size than alanine dosimeters used in this work).

Pellets of the new material and alanine were irradiated in a <sup>60</sup>Co gamma source with a dose rate of about 8 Gy min<sup>-1</sup>. They were given doses of 5, 10, 20, 30, 50, 75 and 100 Gy. The EPR signal for both dosimeters was obtained by a Bruker EMX-micro spectrometer by inserting the pellets into the resonator in a quartz tube. Absorbance and fluorescence signals of the pellets of our material were measured with a Shimadzu UV-2700 spectrophotometer and an Ocean Optics QE6500 spectrometer respectively. Fluorescence was excited with a diode laser.

#### Results

A clear EPR signal was obtained for our material, and this signal increased with dose. The peak-to-peak amplitude of the EPR spectra are shown in the figures. Although alanine and PEGDA have similar characteristics in terms of its water equivalence (similar effective atomic number, mass density and electronic density), their EPR signal is very different.

### Conclusion

We have obtained an EPR signal for our solid polymer dosimeter. The EPR signal increases linearly with dose for the medical dose range, but it saturates for higher doses. Although it is not comparable to the EPR dosimetry using alanine, this signal could be a source of improved understanding of the underlying dosimetric characteristics of this material and it may be a supporting feature to the optical signals from the dosimeter. We further foresee interesting applications in particle therapy beams since the signal production in solid-state dosimeters are generally dependent on the ionization density.

### PO-0769 A microDiamond for determination of absorbed dose around high-dose-rate $^{192}\text{Ir}$ brachytherapy sources

V. Kaveckyte<sup>1</sup>, A. Malusek<sup>1</sup>, H. Benmaklouf<sup>2</sup>, G. Alm Carlsson<sup>1</sup>, A. Carlsson Tedgren<sup>2</sup>

<sup>1</sup>Linköping University, Radiation Physics IMH, Linköping, Sweden

<sup>2</sup>Karolinska University Hospital, Radiation physics, Stockholm, Sweden

#### Purpose or Objective

Experimental dosimetry of high-dose-rate (HDR)  $^{192}\text{Ir}$  brachytherapy (BT) sources is complicated due to steep dose and dose-rate gradients, high dose rates and softening of photon energy spectrum with depth. A single crystal synthetic diamond detector PTW 60019 (marketed as microDiamond) (PTW, Freiburg, Germany) has a small active volume and was designed for such measurements in high energy photon, electron and proton beams. It can be read out directly with standard electrometers used at radiotherapy departments, unlike thermoluminescent detectors, which are currently the most used dosimeters in BT but have to be pre- and post-processed with dedicated equipment. Hence the purpose of this study was to evaluate the suitability of a microDiamond for the determination of absorbed dose to water in an HDR  $^{192}\text{Ir}$  beam quality. The use of three microDiamond samples also allowed for assessment of their individual reproducibility.

#### Material and Methods

In-phantom measurements were performed using the microSelectron HDR  $^{192}\text{Ir}$  BT treatment unit. Oncentra

treatment planning system (TPS) was used to create irradiation plans for a cubical PMMA phantom with a microDiamond positioned at one of the three source-to-detector distances (SDDs) (1.5, 2.5 and 5.5 cm). The source was stepped by 0.5 cm over the total length of 6 cm to yield absorbed dose of 2 Gy at the reference point of the detector. A phantom correction factor was applied to account for the difference between the experimental phantom and the spherical water phantom used for absorbed dose calculations made with the TPS. The same measurements were repeated for all three detectors (mD1, mD2, mD3).

#### Results

Experimentally determined absorbed dose to water deviated from that calculated with the TPS from -1 to +2 % and agreed to within experimental uncertainties for all the detectors and SDDs (Figure 1). The mD2 overestimated absorbed dose to water by up to 2% compared with the estimates by the other two detectors. A decrease in the difference with increasing SDD suggests that it might be related to differences in the position of the active volume inside the detector which is of higher importance closer to the source where dose gradients are steeper. The combined relative uncertainty in experimentally determined absorbed dose to water did not exceed 2% () for all the detectors and SDDs. A variation in raw readings was within 2% over the investigated range.

#### Conclusion

Preliminary results indicate that the dosimetric properties of a microDiamond obviate the need for multiple correction factors and facilitate dosimetry of HDR  $^{192}\text{Ir}$  BT sources. This, together with the convenience of use, shows high potential of a microDiamond for quality assurance of HDR BT treatment units at clinical sites. It must be noted, nevertheless, that individual characterization of a microDiamond is required to achieve high accuracy.

### PO-0770 The distortions of the dose response functions of dosimeters in the presence of a magnetic field

H.K. Looe<sup>1</sup>, B. Delfs<sup>1</sup>, D. Harder<sup>2</sup>, B. Poppe<sup>1</sup>

<sup>1</sup>Carl von Ossietzky University, University Clinic for Medical Radiation Physics, Oldenburg, Germany

<sup>2</sup>Georg August University, Prof em. - Medical Physics and Biophysics, Göttingen, Germany

#### Purpose or Objective

The new developments of MRgRT have opened new possibilities for high precision image-guided radiotherapy. However, the secondary electrons liberated within the medium by the primary photon beam are subjected to the Lorentz force. Therefore, the trajectories of the secondary electrons in non-water media, such as an air-filled cavity or a high-density semiconductor, will differ significantly from that in water. In this work we demonstrate, using simple geometries, that the shape of the lateral dose response functions of clinical detectors will depend on the electron density of the detector material, the beam quality and the magnetic field. The dosimetric implications are discussed and correction strategies are proposed.

#### Material and Methods

Based on the convolution model (Looe et al 2015), the one-dimensional lateral dose response function,  $K(x-\xi)$ , acting as the convolution kernel transforming the true dose profile  $D(\xi)$  into the measured signal profile  $M(x)$ , was derived by Monte-Carlo simulation for a simple cylindrical detector placed at 5 cm depth in water using  $^{60}\text{Co}$  and 6 MV slit beams. The cylinder with 1.13 mm radius and 2 mm height was filled with water of normal density ( $1 \text{ g/cm}^3$ ), low density ( $0.0012 \text{ g/cm}^3$ ) and enhanced density ( $3 \text{ g/cm}^3$ ), where the latter two represent the density of an air-filled ionization chamber and a semiconductor detector respectively. Simulations were performed using

the EGSnrc package, and 0.5, 1.0 and 1.5 T magnetic fields were applied.

### Results

Fig. 1 shows the derived kernels  $K(x-\xi)$  without and with magnetic field for the three detector densities and two beam qualities. The shape of  $K(x-\xi)$  without magnetic field has been discussed in Looe et al 2015 in terms of the electron density of the detector material. The effect of the magnetic field on the secondary electrons' trajectories in a non-water equivalent medium is manifested as a distortion of  $K(x-\xi)$ . It is worth mentioning that function  $K(x-\xi)$  for water with normal density (middle panels) does not vary in the presence of a magnetic field, and the shape of this function merely represents the geometrical volume-averaging effect.

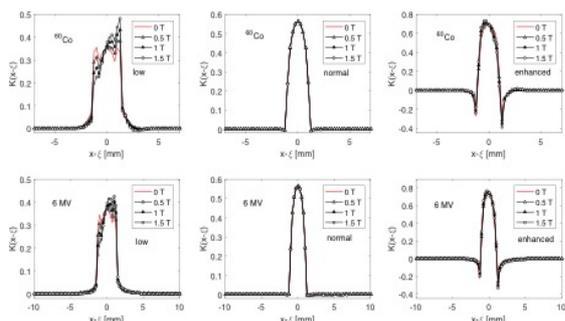

Fig. 1. Area normalized  $K(x-\xi)$  for the cylindrical detector voxels of 'low', 'normal', and 'enhanced' density without and with, 0.5, 1.0 and 1.5 T magnetic field.

### Conclusion

It has been shown for the first time that the lateral dose response functions  $K(x-\xi)$  of non-water equivalent detectors will be distorted by a magnetic field, showing asymmetrical detector response, even if the detector's construction is symmetrical. The distortions are attributed to the differences in charged particle trajectories within the detectors having electron density other than of normal water. The effect of a magnetic field on a detector's response can be characterized by the area-normalized convolution kernel  $K(x-\xi, y-\eta)$ . As previously proposed (Looe et al 2015), corrections based on the convolution model can be applied to account for the detector's volume effect in the presence of magnetic field:

$$p_V(x, y) = \frac{D(x, y)}{\int_{-\infty}^{\infty} K'(x - \xi, y - \eta) D(\xi, \eta) d\xi d\eta} \quad (1)$$

PO-0771 The dose response functions of an air-filled ionization chamber in the presence of a magnetic field B. Delfs<sup>1</sup>, D. Harder<sup>2</sup>, B. Poppe<sup>1</sup>, H.K. Looe<sup>1</sup>

<sup>1</sup>University Clinic for Medical Radiation Physics, Medical Campus Pius Hospital Carl von Ossietzky University, Oldenburg, Germany

<sup>2</sup>Prof em. Medical Physics and Biophysics, Georg August University, Göttingen, Germany

### Purpose or Objective

The development of therapeutic devices combining clinical linear accelerators and MRI scanners for MR guided radiotherapy leads to new challenges in the clinical dosimetry since the trajectories of the secondary electrons are influenced by the Lorentz force. In this study, the lateral dose response functions of a clinical air-filled ionization chamber in the presence of a magnetic field were examined depending on beam quality and magnetic field following the approach of a convolution model (Looe et al 2015, Harder et al 2014).

### Material and Methods

In the convolution model, the 1D lateral dose response function  $K(x-\xi)$  is defined as the convolution kernel transforming the true dose profile  $D(\xi)$  into the disturbed signal profile  $M(x)$  measured with a detector. For an air-filled ionization chamber, type T31021 (PTW Freiburg, Germany), the lateral dose response functions were determined by Monte-Carlo simulation using 0.25 mm wide <sup>60</sup>Co and 6 MV slit beams. The chamber was modelled according to manufacturer's detailed specification and placed at 5 cm water depth in three different orientations, i.e. axial, lateral and longitudinal. For each chamber orientation, a magnetic field oriented perpendicular to the beam axis was applied. Simulations were performed for magnetic fields of 0, 0.5, 1 and 1.5 T using the EGSnrc package and the *egs\_chamber* code.

To verify the simulation results, the lateral dose response functions without magnetic field were compared against measurements with a 5 mm wide collimated 6 MV photon slit beam using tertiary lead blocks following the approach of Poppinga et al 2015.

### Results

Fig. 1 shows good agreement between the simulated and measured dose response functions  $K(x-\xi)$  of the investigated ionization chamber in the three investigated orientations. The structures of the measured functions are not as evident as those of the simulated functions possibly due different scanning step widths used in the experiment and the calculation.

Fig. 2 shows the lateral dose response function  $K(x-\xi)$  with and without magnetic field obtained exemplary for the detector in lateral orientation. The distortion of the dose response function  $K(x-\xi)$  corresponds to the change in the trajectory lengths of the secondary electrons in the air of the ionization chamber due to the Lorentz force, as compared to the trajectories in a small sample of water.

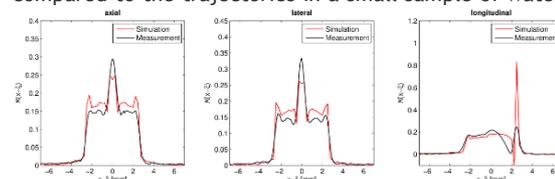

Fig. 1. Area-normalized simulated and measured dose response functions  $K(x-\xi)$

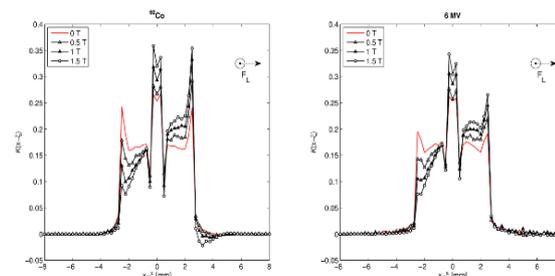

Fig. 2. Area-normalized dose response functions  $K(x-\xi)$  for the T31021 in lateral orientation for magnetic fields of 0, 0.5, 1 and 1.5 T

### Conclusion

The distortions of the lateral dose response function  $K(x-\xi)$  will alter the measured signal profile  $M(x)$  of a detector in magnetic field, as demonstrated in this study. The variety of the possible combinations of detector orientation and magnetic field direction and the strong dependence of the distortion on the magnetic field strength require careful consideration whenever a non-water equivalent detector is used in magnetic field.

<sup>2</sup>Lake Constance Radiation Oncology Center- Martin-Luther-Universität Halle-Wittenberg, Department for Medical Physics- Naturwissenschaftliche Fakultät II, Friedrichshafen, Germany

<sup>3</sup>AOU Careggi, Medical Physics Unit, Florence, Italy

<sup>4</sup>Lake Constance Radiation Oncology Center, Department for Medical Physics, Singen, Germany

<sup>5</sup>University of Florence- AOU Careggi, Medical Physics Unit- Department of Biomedical- Experimental and Clinical Sciences, Florence, Italy

<sup>6</sup>Lake Constance Radiation Oncology Center, Radiooncology, Singen, Germany

### Purpose or Objective

To investigate a new transmission detector for online dose verification. Error detection ability was examined and the correlation between the changes in detector output signal with  $\gamma$  passing rate and DVH variations was evaluated.

### Material and Methods

The integral quality monitor detector (IQM, iRT Systems GmbH, Germany) consists of a single large area ionization chamber which is positioned between the treatment head and the patient. The ionization chamber has a gradient along the direction of MLC motion and is thus spatially sensitive. The detector provides an output for each single control point (segment-by-segment) and a cumulative output which is compared with a calculated value.

Signal stability and error detection sensitivity were investigated. Ten types of errors were induced in clinical VMAT plans for three treatment sites: head and neck (HN), prostate (PC) and breast cancer (MC). Treatment plans were generated with Pinnacle (V.14) for an Elekta synergy linac (MLCi2). Geometric errors included shifts of one or both leaf banks for all control points toward (i) and away (ii) from the central axis of the beam and unidirectional shifts of both leaf banks (iii) by 1 and 2mm, respectively. Dosimetric errors were induced by increasing the number of MUs by 2% and 5%.

Deviations in dose distributions between the original and error-induced plans were compared in terms of IQM signal deviation, 2D  $\gamma$  passing rate (2%/2mm and 3%/3mm) and DVH metrics ( $D_{mean}$ ,  $D_{2\%}$  and  $D_{98\%}$  for PTV and OARs).

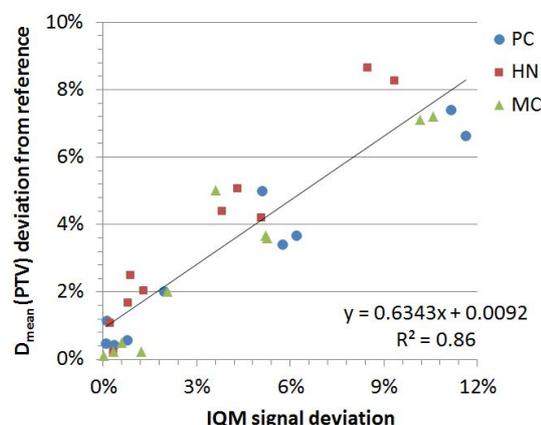

### Results

For segment-by-segment evaluation, calculated and measured IQM signal differed by  $4.7\% \pm 5.5\%$ ,  $-2.6\% \pm 4.6\%$  and  $4.19\% \pm 6.56\%$  for MC, PC und HN plans, respectively. Concerning the cumulative evaluation, the deviation was  $-1.4 \pm 0.25\%$ ,  $-6.0 \pm 0.3\%$  und  $-1.47\% \pm 0.97\%$ , respectively. Signal stability for ten successive measurements was within 0.5% and 2% for the cumulative and the segment-by-segment analysis.

The IQM system is highly sensitive in detecting geometric errors down to 1mm MLC bank displacement and dosimetric errors of 2% if a measured signal is used as reference. Table 1 reports IQM signal deviations for a range of introduced errors.

Regarding MLC errors affecting the field size, large deviations from reference were observed in the IQM signal, while unidirectional shifts introduced deviations below detection limit. A similar behavior was observed for 2D  $\gamma$  and DVH parameters. Figure 1 illustrates the correlation of  $D_{mean}(PTV)$  and IQM signal deviation, indicating that clinically relevant errors can be identified.

Error type		MC	PC	HN
single MLC bank (XZ)	(II) +1mm	2.1%	2.9%	3.4%
	(II) +2mm	4.3%	6.8%	5.8%
both MLC banks	(II) +1mm	5.2%	5.8%	3.8%
	(II) +2mm	10.6%	11.6%	8.5%
	(III) shift+1mm	0.0%	0.1%	-0.3%
	(III) shift+2mm	-1.2%	0.4%	0.9%
Dosimetric errors	2%	2.1%	2.0%	1.3%
	5%	3.6%	5.1%	4.3%

### Conclusion

The deviation between calculated and measured signal is relatively high, therefore a measurement should be defined as reference. With this limitation, the system is not yet capable of treatment plan verification but is a powerful tool for constancy testing.

The detector provides excellent signal stability and is very sensitive regarding error detection. The signal deviation correlates with 2D  $\gamma$  and DVH metric deviations; this information can be used for identifying action limits for the IQM.

### PO-0773 Three-dimensional radiation dosimetry based on optically-stimulated luminescence

M. Sadel<sup>1</sup>, E.M. Høye<sup>2</sup>, P. Skyt<sup>2</sup>, L.P. Muren<sup>2</sup>, J.B.B. Petersen<sup>2</sup>, P. Balling<sup>1</sup>

<sup>1</sup>Aarhus University, Department of Physics and Astronomy, Aarhus, Denmark

<sup>2</sup>Aarhus University Hospital, Department of Medical Physic, Aarhus, Denmark

### Purpose or Objective

Modern radiotherapy employs complex 3D radiation fields to deliver therapeutic doses during treatment, and detailed quality assurance is a prerequisite. Methods based on luminescent passive detectors, such as optically stimulated luminescence (OSL), are widely applied, especially for personal dosimetry and phantom measurements. Reusability is one advantage of using OSL for dosimetry; the OSL particles can be reset by temperature or light-bleaching. Furthermore, the OSL material used in this study has a wide dynamic range and linear dose response, and the dosimeter matrix consists of a flexible material that can be cast into anthropomorphic

shapes and simulate organ deformations during RT. In this abstract we propose a new, reusable 3D dosimetry system based on OSL material embedded homogeneously inside a transparent matrix.

#### Material and Methods

Cuvette-sized prototypes of the dosimeter were produced, consisting of a matrix; 4 g of a transparent silicone elastomer (SE) (Sylgard 184, Dow Corning), and a homogeneously embedded OSL material; 0.3 g of lithium fluoride (LiF) doped with magnesium, copper and phosphorus (LiF:Mg,Cu,P - MCP).

Three samples were prepared in standard OSL-reader aluminum trays; a reference sample with silicone elastomer, and two samples with OSL powder embedded in the SE matrix, containing 0.06 mg and 0.2 mg OSL powder (sample 1 and 2 respectively). They were read-out using a Risø TL/OSL DA-20 reader. Samples were irradiated with 1 Gy beta radiation and stimulated for 100 s with blue light emitting diodes (LEDs), with emission centered at 470 nm and an intensity of  $\sim 80$  mW/cm<sup>2</sup>.

#### Results

The transparency of the dosimeter (see Fig. 1) depended on the concentration of MCP powder, which must be optimized as a compromise between signal level per volume and overall transparency. The refractive-index match between LiF and the SE is quite good for visible wavelengths, which minimizes light scattering from the particles.

Approximately 10,000 and 40,000 counts were detected in 1 second per 1mm<sup>3</sup> voxel from samples 1 and 2, respectively, corresponding to the anticipated signal levels. Also, the silicone matrix in itself did not add to the OSL signal (see Fig. 2). 3D distributions can be obtained without the need for inversion algorithms, for example, by stimulating the OSL dosimeter with a light sheet (from a laser source), and imaging the luminescence intensity across that sheet (by a combination of optical filters and a camera), and shifting this plane across the dosimeter.

#### Conclusion

A new 3D dosimeter system based on OSL material has been presented. It has the potential to verify complex 3D RT doses with high spatial resolution, while maintaining the advantages known from personal-dosimetry use of OSL.

#### PO-0774 Investigation of dose-rate dependence at an extensive range for PRESAGE radiochromic dosimeter

E.P. Pappas<sup>1</sup>, E. Zoros<sup>1</sup>, K. Zourari<sup>2</sup>, C.I. Hourdakis<sup>2</sup>, P. Papagiannis<sup>1</sup>, P. Karaiskos<sup>1</sup>, E. Pantelis<sup>1</sup>

<sup>1</sup>National and Kapodistrian University of Athens, Medical Physics Laboratory - Medical School, Athens, Greece

<sup>2</sup>Greek Atomic Energy Commission, Division of Licensing and Inspections, Athens, Greece

#### Purpose or Objective

The purpose is to investigate dose-rate dependence effects for a recent formulation of the commercially available PRESAGE radiochromic dosimeter (Heuris Inc, NJ) in a wide range of dose delivery rates extending to three orders of magnitude (0.018 - 19 Gy/min).

#### Material and Methods

In order to achieve an extensive dose rate range, this work was divided into two separate studies. Lower dose rates were delivered by <sup>60</sup>Co beams while higher dose rates were achieved by a flattening-filter-free (FFF) linear accelerator. For the low dose rate part of this study, 10 PMMA cuvettes (1×1×4 cm<sup>3</sup>), filled with PRESAGE samples, were irradiated to the same dose with 5 different dose rates. Irradiations were performed with a <sup>60</sup>Co PICKER unit in a secondary standard calibration laboratory. The samples were divided into groups of two and each group was placed at a different distance (56.65 - 427 cm) from the <sup>60</sup>Co source at a 5cm depth within a water phantom. Irradiation times varied in order to deliver the same dose of 1 Gy at the center of all cuvettes with dose rates in the

range of 0.018 - 1.0 Gy/min. For the high dose rate study, a similar methodology was employed. Four couples of PRESAGE cuvettes were placed within a slab in a solid water phantom and irradiated at different dose-rates by varying the dose delivery rate of an ELEKTA Versa HD FFF linac from 2.5 up to 19 Gy/min. Dose delivery of 1 Gy for all dose rates was verified by ion chamber measurements. Irradiation induced optical density (OD) change was measured from pre- and post-irradiation scans with a digital spectrophotometer operated at 633 nm. Mean OD change for each group was normalized to the value for the highest dose rate in each study.

#### Results

Results presented in figure 1 show a trend of increasing PRESAGE dose sensitivity with decreasing dose rate with the over-response reaching up to 16% at 0.018 Gy/min. Although in a first approach such low dose rates could be considered extremely low in external radiotherapy, recent studies have shown that in advanced radiotherapy techniques (e.g. VMAT) dose rate varies drastically across dose distributions delivered and a considerable contribution of the delivered dose could come from very low dose rates (0.01 - 0.1Gy/min). Regarding the high dose rate study, all responses agree within experimental uncertainties, indicating that PRESAGE sensitivity is not significantly affected.

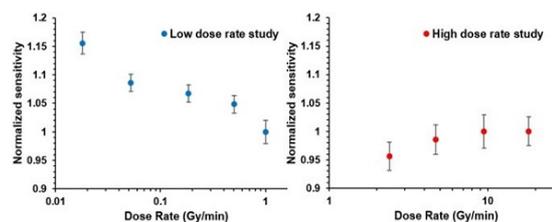

Figure 1: Dose rate dependence of PRESAGE response for both studies included in this work. Error bars correspond to 1 standard deviation of all experimental uncertainties involved.

#### Conclusion

Results of this study indicate a significant over-response of this PRESAGE formulation in very low dose rates that should be considered when they are used in applications involving wide range of dose delivery rates.

#### PO-0775 Contributions to detector response in arbitrary photon fields

S. Wegener<sup>1</sup>, O.A. Sauer<sup>1</sup>

<sup>1</sup>University Hospital, Radiation Oncology, Würzburg, Germany

#### Purpose or Objective

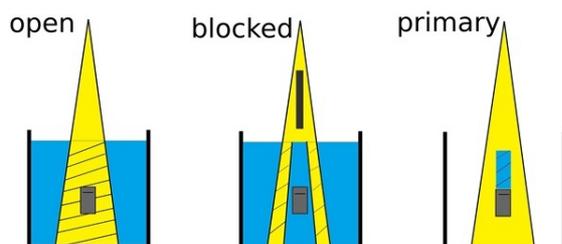

Due to their small active volumes, diodes are often the detectors of choice for many commissioning tasks including the measurement of output factors, especially in small fields. However, high-atomic number material in the chip, detector shielding or other components and a finite active volume size have been found to alter the signal compared to the dose ratios measured in water in the absence of such a detector. As a consequence, correction factors need to be applied to correct the obtained signals. Using three experimental setups (fig. 1), the different contributions to the detector signals were separated and analyzed: the response to scatter, the primary beam and the combination of both.

#### Material and Methods

Signal ratios were obtained for three different experimental setups (fig. 1): First, the standard open field geometry. Secondly, fields in which the central part of the beam was blocked out by a 4 mm aluminum pole and the

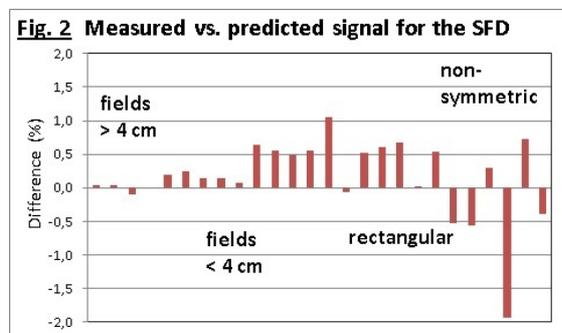

detector was positioned in the dose minimum below. Finally, the detector in air instead of water with a PMMA cap fitted on top. A range of typically used detectors were analyzed, namely a microDiamond, a PinPoint ionization chamber, an EDGE diode, as well as three shielded and three unshielded diode detectors. EBT3 Gafchromic film served as reference. Measurements were carried out on a PRIMUS linac at a photon beam quality of 6 MV with field sizes between 0.8 and 10 cm. Responses in the blocked field and the PMMA setup were combined to calculate the response in the open square fields. The results were interpolated to a general matrix from which responses in any field could be calculated. Examples of such fields were measured for comparison.

**Fig. 1**

## Results

A higher detector overresponse and increasing detector to detector differences were observed when the primary beam was blocked out, whereas almost identical response was seen for all detectors in the primary beam. A combination of the responses in those two setups in a detector-dependent ratio reproduced the values obtained in the open field geometry with less than 1% deviation for all detectors studied and all quadratic field sizes. For rectangular and offset fields the agreement is still almost within 1%. Only when the detector was close to the field edge larger deviations occurred (fig. 2).

## Conclusion

Detector responses in open fields could be calculated from the response to scatter and in the primary beam with 1% agreement in all studied square fields and for all studied detectors. The calculation was extended to rectangular and non-symmetric fields yielding results in agreement with the measurements for a wide range of fields. This method suggests a way to calculate correction factors for arbitrary fields.

## PO-0776 Thermoluminescence Characteristics of Fabricated Ge Doped Optical Fibre for Radiotherapy Dosimetry

M.S. Ahmad Fadzil<sup>1</sup>, N. Tamchek<sup>2</sup>, N.M. Ung<sup>3</sup>, A. Ariffin<sup>4</sup>, N. Abdullah<sup>5</sup>, D.A. Bradley<sup>6</sup>, N. Mohd Noor<sup>1</sup>

<sup>1</sup>Universiti Putra Malaysia, Department of Imaging-Faculty of Medicine and Health Sciences, Serdang, Malaysia

<sup>2</sup>Universiti Putra Malaysia, Department of Physics-

Faculty of Science, Serdang, Malaysia

<sup>3</sup>University of Malaya, Clinical Oncology Unit- Faculty of Medicine, Kuala Lumpur, Malaysia

<sup>4</sup>University of Malaya, Department of Physics- Faculty of Science, Kuala Lumpur, Malaysia

<sup>5</sup>Malaysia Nuclear Agency, Medical Physics Group, Kajang, Malaysia

<sup>6</sup>University of Surrey, Department of Physics, Guildford, United Kingdom

## Purpose or Objective

The dosimetry characteristics of the fabricated Germanium doped cylindrical fibre (CF) and flat fibres (FF) were evaluated including linearity, repeatability, energy dependence, dose rate dependence, angular dependence and fading. The TL kinetic parameters of Ge-doped CF and FF have been investigated using the computerized glow curve deconvolution analysis.

## Material and Methods

A screening process was carried out for the optical fibres with 6 MV photon beam. Optical fibres with sensitivity out of  $\pm 5\%$  mean sensitivity value were discarded in order to ensure the selected dosimeters have constant response. The dosimetry characteristics tests were performed using 6 MV and 10 MV photon beams. The dosimeters were irradiated with doses ranging from 1 Gy to 3 Gy with several dose rates (100 MU/min up to 500 MU/min). Fabricated perspex phantoms were used to study the angular dependency of the optical fibres. Fading rate was studied for 55 days post irradiation. The glow curves were analyzed with a curve fitting computer program known as WinGCF. The glow curves were deconvoluted into five individual peaks in order to figure out the kinetic parameters such as the maximum peak temperature ( $T_{max}$ ), peak integral (PI), activation energy ( $E_a$ ) and frequency factor.

## Results

The screening result revealed that the coefficient of variation was observed to be less than  $\pm 10\%$  for CF and FF. Both CF and FF were found to be linear with  $r^2$  more than 0.99 over the entire dose range explored for both 6 MV and 10 MV photon beams. These fibres provide consistent reading within  $\pm 5\%$  over five repeated measurements. The signal lost was higher in FF (57%) compare to CF (38%) after 55 days of irradiation. Both fibres also offer dose rate- and angular independence. The glow curve for both CF and FF consist of 5 individual glow peaks. The peak height increased with increasing irradiation dose. The  $T_{max}$  of the glow peaks (P1 to P5) is consistent over the dose range used. Peak 1 has the lowest  $E_a$  which lies between 0.544 to 0.636 eV and 0.632 to 0.720 eV for CF and FF respectively, indicating the shallow electron traps. The results also revealed that the PI for both of the fibres will increase as the dose increase. The Ge-doped CF and FF demonstrated a constant glow curves shape with increasing dose. As the dose increases, area under the glow curve increases, suggesting an increasing number of electrons released from its traps.

## Conclusion

CF demonstrated greater TL signal compared to FF. In order to employ these optical fibres in absorbed dose measurement, correction factors for energy dependence and fading should be applied. The Ge-doped CF and FF demonstrated the second-order kinetic model to the high temperature half of the curve is slightly broader than the low temperature half which suggest the possibility of strong electron retrapping. The evaluation on Ge doped optical fibres showed a highly favourable TL characteristics exhibited by CF and FF indicate a great potential in radiotherapy postal dose audit.

## PO-0777 Importance of dosimetry formalism for cells irradiation on a SARRP and consequences for RBE

<sup>2</sup>Institute for Radiobiological Protection and Nuclear Safety IRSN, Department of Radiobiology and Epidemiology SRBE- Research on Radiobiology and Radiopathology Laboratory L3R, Fontenay-aux-Roses- Paris, France

<sup>3</sup>Institute for Radiobiological Protection and Nuclear Safety IRSN, Department of external dosimetry SDE- Ionizing Radiation Dosimetry Laboratory LDRI, Fontenay-aux-Roses- Paris, France

#### Purpose or Objective

Since last three decades, the importance of the dosimetry in radiobiology studies and the standardization of the dosimetry protocols have been highlighted. Nevertheless, most of time, it is very difficult to reproduce experiments described on literature due to a lack of details in the description of dosimetry protocols. As the main objective of radiobiology is to establish links between doses and the radiations-induced biological effects, well-defined dosimetry protocols appear to be a crucial point within the determination of experimental protocols.

In this context, detailed dosimetry protocols for cells irradiation have been implemented on the Small Animal Radiation Research Platform (SARRP). To support the importance of all parameters described on dosimetry protocols, manual protocol changes were performed by modifying the cell growth medium volume and/or the additional filtration for an irradiation at 80 kV. Impacts of modifications of the physical dose induced by these errors/protocols changes were studied on RBE (Relative Biological Effectiveness) using the survival clonogenic assay.

#### Material and Methods

In first, all parameters of the configuration setup (HT, HVL ...) have to be defined. Then, measurements of absolute dosimetry with ionization chamber calibrated in air Kerma free in air condition, converted then in water kerma free in air, and relative dosimetry with EBT3 radiochromic films were performed to determine dose rate and evaluate the attenuation due to the cell growth medium in each containers used for cells irradiation. In order to evaluate the influence of the modification of parameters like cell medium volume (1 or 9 mL instead of 3 mL as the reference condition) and/or the additional filtration, 6 plate wells containing EBT3 films with water were used to determine the impact on the physical dose at 80 kV. Then, experiments with rigorously the same irradiation conditions were performed by replacing EBT3 films by HUVECs. The biological response of HUVECs was assessed by using clonogenic assay.

#### Results

Characterization of the beam quality index in the range of 30 to 220 kV for copper and aluminum filtrations and the homogeneity of the field size have been measured. Then, impact of the cell culture volume and filtration have been evaluated thanks to measurements with EBT3 films and show a variation between 1 to 8% with the copper filtration and 8 to 40% with aluminum filtration compared to each reference condition. HUVECs cells irradiated in the same conditions showed significant differences in cell survival fraction, perfectly corroborating the dosimetric changes observed on physical dose.

#### Conclusion

All together these results strongly support the fact that an accurate dosimetry needs to be performed before an experiment but also to cautiously follow all the defined parameters for one condition of irradiation to avoid errors in the dose delivered on the sample and to be able to properly compare and interpret experiments.

#### PO-0778 New Razor silicon diode for Cyber Knife small beam relative dosimetry: a multi-site evaluation

S. Russo<sup>1</sup>, L. Masi<sup>2</sup>, P.R. Dicarolo<sup>3</sup>, R. Doro<sup>2</sup>, E. De Martin<sup>4</sup>, M.L. Fumagalli<sup>4</sup>, A.S. Martinotti<sup>5</sup>, A. Bergantin<sup>5</sup>, E. Rondi<sup>6</sup>, S. Vigorito<sup>6</sup>, P. Mancosu<sup>7</sup>

<sup>1</sup>Aziend USL Toscana Centro, Fisica Sanitaria, Florence, Italy

<sup>2</sup>IFCA, Radiotherapy, Firenze, Italy

<sup>3</sup>Medical Physycs, Meyer Children's University Hospital-, Florence, Italy

<sup>4</sup>Istituto Besta, Radiotherapy, Milano, Italy

<sup>5</sup>C.D.I., Radiotherapy, Milano, Italy

<sup>6</sup>I. E. O., Radiotherapy, Milano, Italy

<sup>7</sup>Humanitas Research Hospital, Medical Physics Unit of Radiation Oncology, Milan, Italy

#### Purpose or Objective

The aim of this work was to evaluate the suitability of a new unshielded p-type silicon diode (Razor, IBA Dosimetry, Germany) for relative small beams dosimetry over different CyberKnife systems.

#### Material and Methods

Output Factors (OFs) measurements with Razor detector were performed by four Italian Radiotherapy Centers equipped with CyberKnife units for field sizes ranging from 5 to 60 mm, defined by fixed circular collimators. Setup conditions were 80 cm source to detector distance and 1.5 cm depth in water. Measurements were repeated by each center with a PTW-60017 diode. Monte Carlo correction factors reported in literature were applied to PTW-60017 measured data and corrected values were considered as a reference.

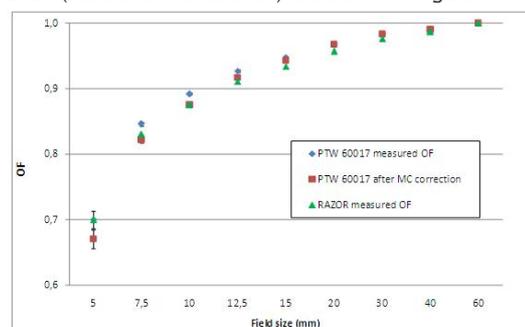

Crossplane and inplane dose profiles ranging from 5-60 cm fixed collimators were measured by Razor detector at a depth of 10 cm in water and SSD 70 cm. The effective field size (EFS), defined as  $EFS = \frac{A+B}{2}$ , where A and B correspond to the in- and cross-line FWHM, were calculated. Penumbra 20%- 80% was also evaluated.

This work has been conducted in the framework of the Italian Association of Medical Physics (AIFM) SBRT working group.

#### Results

Razor OFs measured for fixed collimators in the four enrolled centers showed a variability (relative range) decreasing from 1.2% to 0.4% for field sizes from 7.5 to 60 mm and equal to 2.2% for the smallest cone. The variability obtained for OF measured by PTW-60017 was analogous: lower than 1 % for field sizes from 7.5 to 60 mm and equal to 3.5% for the smallest diameter.

For field sizes down to 7.5 mm Razor measured OFs were lower than PTW-60017 uncorrected measured values. Relative differences between Razor OFs and Monte Carlo corrected PTW-60017 data were below 1% for 60-10 mm cone sizes and within 2 % for 7.5 mm field size over all centers. For the smallest collimator differences ranging from to 2.5% to 6% were observed among centers. Average values and SD of OFs measured by Razor and PTW-60017 diode (MC corrected and not) are shown in figure.

Nominal field size NFS, effective field size EFS and penumbra measurements averaged over the four CyberKnife centers are reported in table. Maximum

difference between NFS and EFS was about 6% for 5 mm field size. Penumbra values were lower than 3 mm for field sizes up to 15 mm.

NFS (mm)	5	7.5	10	12.5	15	20	30	40
EFS (mm)	5.3 ± 0.1	7.7 ± 0.1	10.0 ± 0.2	12.5 ± 0.1	15.1 ± 0.2	20.3 ± 0.1	30.6 ± 0.1	40.9 ± 0.2
P <sub>20%-80%</sub> (mm)	2.1 ± 0.1	2.3 ± 0.1	2.7 ± 0.2	2.8 ± 0.2	2.9 ± 0.2	3.1 ± 0.1	3.3 ± 0.1	3.6 ± 0.2

## Conclusion

**Conclusions:** CyberKnife OFs measured by Razor showed a high consistency among different centers and a comparable variability to data obtained by PTW-60017 routine detector. Comparison between Razor OFs and PTW-60017 measurements corrected by Monte Carlo indicated that correction factors for Razor should be smaller than for PTW-60017 down to 7.5 mm field size. EFS and penumbra measured over the four centers showed a good consistency confirming Razor as a good candidate for small beam relative dosimetry.

## PO-0779 New robotic phantom for evaluation of imaging and radiotherapy of moving structures

H. Arenbeck<sup>1</sup>, L. Eichert<sup>1</sup>, G. Hürtgen<sup>2</sup>, K. Gester<sup>2</sup>, I. Brück<sup>2</sup>, N. Escobar-Corral<sup>2</sup>, M. Fleckenstein<sup>1</sup>, A. Stahl<sup>3</sup>, M.J. Eble<sup>2</sup>

<sup>1</sup>Boll Automation GmbH, Research and Development, Kleinwallstadt, Germany

<sup>2</sup>RWTH Aachen University Hospital, Radiooncology and Radiotherapy, Aachen, Germany

<sup>3</sup>RWTH Aachen University, III. Institute of Physics B, Aachen, Germany

## Purpose or Objective

Four dimensional radiotherapy processes that allow an adaptation to intrafractional motion require increased accuracy of dose application while displaying increased technological and procedural complexity and thus multiplied sources of error. Consequentially, novel 4D phantoms are required that feature anthropomorphic structure and motion. In this work, a prototype of such phantom, which is fit for long term clinical service, is presented.

## Material and Methods

The modular phantom architecture allows different static and moving human equivalent structures and dose measurement devices to be placed into the irradiated region. A new kind of parallel robot generates freely programmable motion in all Cartesian directions. The whole system is portable and features similar extension as a human. Concept, kinematics, construction and software of a previously presented evaluation model have been fundamentally refined.

## Results

The new components of the robotic phantom are presented in figure 1. Major technological advancements with respect to the evaluation model are:

- Robot: A novel kinematic structure has been found, which reduces the number of joints and increases stiffness of the mechanics. A fatigue endurable mechanical construction has been created. Rapid exchange of the Target core and inclusion of tethered measurement devices are now possible via the hollow end effector.
- Modularization: Body and Target can now be assembled manually and rapidly while ensuring an absolute positioning accuracy of < 0.1 mm. Third party phantom structures can be

incorporated and accounted for in a customizable collision control.

- Software: A control software release has been developed featuring extended functions, simplified usage and platform independence.

Figure 2 shows the phantom in a clinical setup. A static and a respiratory gated CT were performed. Respiration surrogates were acquired using the C-Rad Sentinel System. Furthermore, a Cone Beam CT mounted at a linear accelerator was obtained.

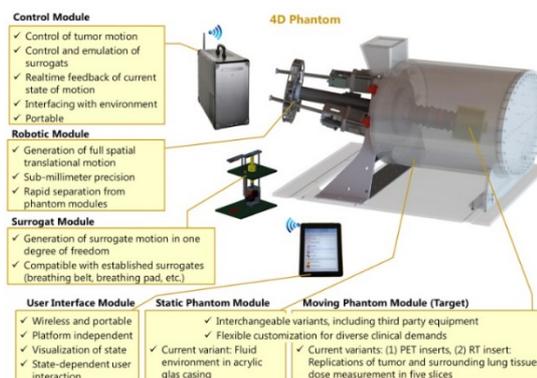

Figure 1: Structure of the robotic phantom

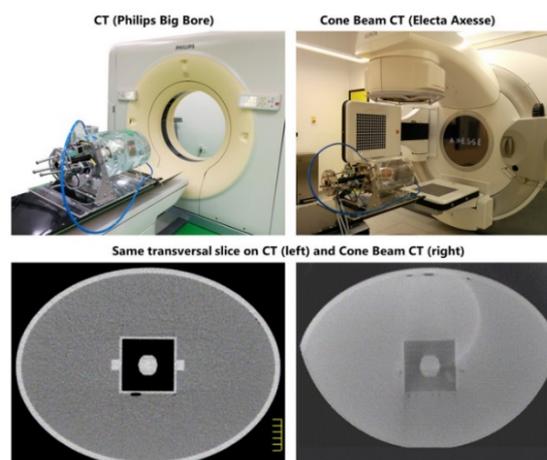

Figure 2: Results of medical imaging

## Conclusion

First applications of the phantom under clinical conditions and purposes revealed feasible physical properties, functional range and applicability. The platform technology of the phantom has reached prototype maturity and can be flexibly adapted to a broad range of clinical scenarios. For example, both little and high complexity of human equivalent structure and motion, both film and ion chamber dosimetry, both air and fluidic environments, optionally containing radioactive tracers, are supported. A unique feature of the phantom is its combination of the described high flexibility with practical feasibility, efficiency and robustness. Next, real time robot control capabilities will be extended and clinical long term studies will be performed.

## PO-0780 Feasibility study of beam monitoring system using AFCRS for proton pencil beam

J.M. Son<sup>1</sup>, M.Y. KIM<sup>2</sup>, M.G. Yoon<sup>3</sup>, D.H. Shin<sup>1</sup>

<sup>1</sup>National Cancer Center, Proton therapy Center,

Goyang-si- Gyeonggi-do, Korea Republic of

<sup>2</sup>Dongnam Inst. Of Radiological & Medical Sciences,

Research Center, Busan, Korea Republic of

<sup>3</sup>Korea University, Bio-convergence engineering, Seoul, Korea Republic of

### Purpose or Objective

PBS, recently developed, scans a tumor with very precise beam of protons that's accurate within millimeters, sparing the healthy surrounding tissues. But it is able to harmful rather than conventional radiotherapy if the beam is not accurately irradiated as planned. It is very important to measure beam width and spot center of the proton pencil beam for the accurate delivery of dose to the target volume with a good conformity. We have developed the beam monitoring system using Array of Fiber-Optic Cerenkov Radiation Sensor (AFCRS), and conducted feasibility study for proton pencil beam.

### Material and Methods

We have developed a fine segmented detector array to monitor PBS. A prototype beam monitor system using AFCRS has been developed for real-time display of the pencil beam status during the PBS mode operation. The x-y monitoring system with 128 channel readout is mounted to the snout for the in-situ real time monitoring. Beam widths and spot centers of various energies are measured. Two dimensional Gaussian fit is used to analyze the beam width and the spot center. The ability of this system to evaluate Lynx system (Scintillator-based sensor with CCD camera) and EBT3 for PBS was compared.

### Results

The measured Gaussian widths using AFCRS changes from 13 to 5 mm for the beam energies from 100 to 226 MeV. The beam widths of PBS using the AFCRS are well matched with the data acquired by a Lynx system and EBT 3 film. In addition, spot centers for 226 MeV PBS beams are also well matched with RTP system.

### Conclusion

The dosimetric performance of the newly developed system based on AFCRS was comparable to that of the Lynx system and EBT3 film. Not only measuring the spot profile but also monitoring dose map by accumulating each spot measurement will be available.

### PO-0781 A characterisation of EBT3 Gafchromic film for relative and absolute dosimetry

I. Billas<sup>1</sup>, H. Bouchard<sup>2</sup>, A. Subiel<sup>1</sup>, I. Silvestre<sup>1</sup>, S. Duane<sup>1</sup>

<sup>1</sup>National Physical Laboratory, Radiation Dosimetry, Middlesex, United Kingdom

<sup>2</sup>Université de Montréal, Département de physique, Montréal, Canada

### Purpose or Objective

The aim of this work is to investigate the variation in dose response of Gafchromic EBT-3 film within each film and across films from different boxes and lots. In this way the uncertainty of relative and absolute dosimetry using EBT-3 film is quantified and its potential for use in small field and MRI-guided radiotherapy is better understood.

### Material and Methods

Sheets of Gafchromic EBT-3 film were uniformly irradiated in a cobalt-60 beam in increments of 1 Gy up to a cumulative dose of 10 Gy. Films were scanned repeatedly before the first irradiation and after each step. Software for image processing and analysis was implemented in MATLAB, allowing determination of the correction for scanner inhomogeneity and calibration of film optical density (OD) response in terms of absorbed dose to water. Regions of interest (ROIs) of various sizes were used to sample image data, quantifying the uncertainty associated with variations within each film, from film to film within the same lot, and from lot to lot. 35 sheets of film were used, taken from 7 boxes across 3 lots. Three channels of optical density (OD) data were analysed statistically, both directly as OD and also in the ratios red/blue and green/blue. Net values were obtained by subtracting pre-irradiation values, and a normalisation correction factor, based on large dose saturation values, was applied.

### Results

The figure shows the net ratio of OD, green/blue, before and after applying the normalisation correction, as a

function of dose, for ROIs which are 10 x 10 mm<sup>2</sup>. The table lists the relative standard deviation of absorbed dose measurements made using EBT-3 in the present work.

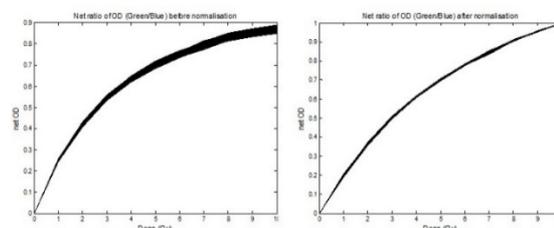

Figure 1: Net ratio of OD (Green/Blue) before (left) and after (right) normalisation correction factor.

Table 1. Relative standard deviation of absorbed dose measurements made using EBT-3 before and after the normalisation correction factor (Green/Blue).

Dose (Gy)	std U before correction	std U after correction
1	1.8%	1.5%
2	1.6%	1.3%
3	1.4%	1.0%
4	1.3%	0.5%
5	1.4%	0.6%

### Conclusion

By combining the subtraction of pre-irradiation values, with a normalisation correction based on large dose saturation values, it should be possible to reduce the contribution to measurement uncertainty arising from intrinsic variations in the characteristics of EBT-3 film to 0.7% ( $k=1$ ) for doses in the range of up to 5 Gy.

### PO-0782 New liquid ionization chamber detector of high resolution for treatment verification in Radiotherapy

<sup>2</sup>Detection And Radiation Technologies SL, Development, Santiago de Compostela, Spain

<sup>3</sup>Instituto de Investigación Sanitaria IDIS, Grupo de Imaxe Molecular, Santiago de Compostela, Spain

<sup>4</sup>Complejo Hospitalario Universitario de Santiago de Compostela, Servizo de Radiofísica e Protección Radiolóxica, Santiago de Compostela, Spain

<sup>5</sup>Universidade de Santiago de Compostela, Laboratorio de Física de Partículas RIAIDT, Santiago de Compostela, Spain

<sup>6</sup>Universidad de Valencia, Departamento de Fisiología de la Facultad de Medicina, Valencia, Spain

<sup>7</sup>Universidade de Santiago de Compostela, Departamento de Física de Partículas, Santiago de Compostela, Spain

### Purpose or Objective

In this work we present a new liquid ionization chamber array prototype for patient treatment verification. The objective of its design is to offer a high spatial resolution with 100% fill factor.

### Material and Methods

The prototype has 2041 liquid ionization chambers of 2.5x2.5 mm<sup>2</sup> effective area and 0.5 mm thickness. The detection elements are arranged in a central square grid of 43x43, covering an area of 107.5x107.5 mm<sup>2</sup>. The central inline and crossline are extended to 227 mm and the diagonals to 321 mm. The active medium is liquid isoootane.

We have studied short- and medium-term stability, dose rate dependence, depth and field size dependence, anisotropy and leaf positioning detectability.

We have measured output factors, tongue-and-groove, garden fence, small field profiles and irregular fields. Finally we have used it for the verification of patient treatments.

## Results

The detector presents dependency on energy that is reflected in the response variation with depth and field size (2.2% under-response for 6 MV, 20x20 cm<sup>2</sup> at 20 cm depth).

The anisotropy study shows important deviations: 28% for lateral incidences and 7% for posterior incidence.

The detector sensitivity for leaf positioning measurement is 1.8 % per tenth of millimeter in the penumbra.

The output factor corresponding to 6 MV and 1x1 cm<sup>2</sup> shows +2% deviation compared with the measurements obtained using a SFD diode and a CC13 gas ionization chamber. The results are normalized to a 5x5 cm<sup>2</sup>. For a 10x10 cm<sup>2</sup> this deviation is -1%. If the energy increases the deviations decrease (+1% for 1x1 cm<sup>2</sup> and -0.5% for 10x10 cm<sup>2</sup> in 10 MV and 15 MV).

In the measurement of small field profiles the gamma comparison between measurements with the liquid ionization array and radiographic film shows 100% passing rates with tolerances 1% - 1mm.

Several patient treatments have been verified. In table 1 the comparison between the treatment planning system and the array measurement for a particular case is shown. We show differences in gamma passing rates when anisotropy corrections are applied or not. Figure 1 shows one of such comparisons.

## Conclusion

A new detector array is presented for the verification of patient treatments of high complexity.

The detector presents a small dependence on energy, which causes a small over-response for the output factors of small fields and an under-response for output factors of large fields. The anisotropy of the device is significant (28% and 7% for lateral and posterior incidences), but can be compensated during treatment verification by using angle-dependent correction factors.

The usefulness for the patient treatment verification has been demonstrated by measuring different patient treatments. The results obtained confirm the validity of this array for dose distribution measurements of complex treatments with small fields and high gradients.

### PO-0783 Planverification in Robotic Stereotactic Radiotherapy with the Delta4-Dosimetry-System

W. Baus<sup>1</sup>, G. Altenstein<sup>1</sup>

<sup>1</sup>Universität zu Köln, Department of Medical Physics, Köln, Germany

#### Purpose or Objective

Stereotactic robotic radiotherapy with the CyberKnife (Accuray, Sunnyvale) might not be fluency modulated radiotherapy (IMRT) in the strict sense. However, the technique is comparable in complexity because of a large number of small (5 to 60 mm), highly non-coplanar fields. Therefore, the manufacturer recommends individual plan verification (DQA, Delivery Quality Assurance), though only on a point dose measurement basis. The report of the AAPM task group on robotic radiotherapy (TG 135) [1] advises the use of film. However, because film dosimetry is rather cumbersome in most cases, it foregoes to demand it for every plan. Film dosimetry provides 2D-measurement, but also laborious calibration, fading and non-linear sensitivity. Arrays of dosimeters have the advantage of comparably easy and direct evaluation, though at a distinctively lower resolution. The aim of this work is to investigate the usefulness of an existing dosimetry system based on diode arrays - the Delta4+ Phantom (ScandiDos, Uppsala) - for DQA of the CyberKnife robotic treatment system.

#### Material and Methods

Several patient plans with PTVs ranging from 5.6 to 112 cm<sup>3</sup> were investigated. The irradiation was performed with a CyberKnife (G4, rel. 9.5, 6 MV photons, no flattening filter), treatment planning system was

Multiplan (rel. 4.5). The Delta4+ dosimetry system consists of a PMMA-cylinder of 22 cm diameter in which two orthogonal silicon diode arrays are housed, adjacent to electrometers. There are 1069 detectors, an inner region with detector spacing of 5 mm (6x6 cm<sup>2</sup>) and 10 mm spacing in the outer region. The measurements were carried out with software Vers. 2015/10. The measurements were compared to film (Gafchromic EBT3 Film, ISP, Wayne) and a high-resolution ion chamber array (Octavius 1000 SRS, PTW, Freiburg). A speciality of the CyberKnife treatment is the fact that correct image guided positioning - using X-ray opaque markers, e.g. - is mandatory. Therefore, special considerations have to be taken for marker placement.

#### Results

Positioning and localisation of the Delta4 was possible and the plan verification could be carried out. The evaluation with the scandidos software produced results with good agreement between plan and measurement (see fig. 1). The evaluation was somewhat compromised by system breakdowns (maybe caused by treatment times of typ.an hour) and the non-complanarity of the plans which prevented the correction for gantry angle usually exploited by the software.

The scandidos software allows for a 3-dimensional evaluation of the dose distribution. The lower spacial resolution compared to film or the 1000 SRS seems to be less important, on the other hand.

#### Conclusion

In principle, the Delta4 dosimetry system seems to be highly suited for DQA of CyberKnife treatment. However, the manufacturer should improve the system in terms of radiaton resistance and a proper implementation of fiducial markers to make it wholly suitable for Cyberknife DQA.

### PO-0784 Volume correction factors for alanine dosimetry in small MV photon fields

H.L. Riis<sup>1</sup>, S.J. Zimmermann<sup>1</sup>, J. Helt-Hansen<sup>2</sup>, C.E. Andersen<sup>2</sup>

<sup>1</sup>Odense University Hospital, Department of Oncology, Odense, Denmark

<sup>2</sup>Technical University of Denmark, Center for Nuclear Technologies, Roskilde, Denmark

#### Purpose or Objective

Alanine is a passive solid-state dosimeter material with potential applications for remote auditing and dosimetry in complex fields or non-reference conditions. Alanine has a highly linear dose response which is essentially independent of dose rate and energy for clinical MV photon beams. Alanine is available as pellets with a 5 mm diameter, and irradiations in flattening filter-free (FFF) beams or other non-uniform beams are therefore subject to volume averaging. In this work, we report on a simple model that can provide volume correction factor for improved output factor measurements in small MV photon beams.

#### Material and Methods

The x-ray beam was delivered by an Elekta Versa HD linac with an Agility MLC160 radiation head. Square field sizes (FS) 0.8, 1.0, 1.4, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0, 20.0, 30.0, 40.0 cm were investigated. The data were acquired at SSD=90 cm, depth 10 cm. The alanine pellets were the standard Harwell/NPL type (Ø4.83x2.80 mm). The pellets were placed in water with a latex sleeve to protect against water. A Bruker EMX-micro EPR spectrometer equipped with an EMX X-band high sensitivity resonator was used to read out the dose deposited in the alanine pellets. The horizontal beam profiles were measured using the IBA Dosimetry photon field detector (PFD) for all FSs while depth dose profiles were measured using the PTW microLion (FS < 8 cm) and PTW semiflex (FS > 8 cm)

detectors. A rotational symmetric Gaussian horizontal beam profile and exponential decaying depth dose profile in the vicinity of the pellet was fitted to the measured profiles. Both 6 MV and 6 MV FFF beams were considered.

### Results

The fit of the beam profile in three dimensions was based on two parameters: the variance for the Gaussian profile and the gradient of the depth profile. The parameters in turn were both changing as function of FS. Using the fitted beam profiles, an analytical model was developed for the calculation of volume correction factors  $k_v$  for given FS (see Table 1).

Table 1: Calculated volume correction factors  $k_v$ , temperature and volume corrected output factors (OF) with SD being one standard deviation (SD) are displayed for the 6 MV and 6 MV FFF beams as function of the field size FS.

Energy FS (cm)	6 MV $k_v$	6 MV FFF $k_v$	6 MV OF $\pm$ SD	6 MV FFF OF $\pm$ SD
0.8	1.063	1.062	0.613 $\pm$ 0.008	0.654 $\pm$ 0.010
1.0	1.019	1.030	0.668 $\pm$ 0.008	0.710 $\pm$ 0.011
1.4	1.010	1.012	0.741 $\pm$ 0.005	0.786 $\pm$ 0.013
2.0	1.004	1.004	0.791 $\pm$ 0.006	0.834 $\pm$ 0.013
3.0	1.001	1.002	0.838 $\pm$ 0.010	0.882 $\pm$ 0.012
4.0	1.000	1.001	0.878 $\pm$ 0.007	0.913 $\pm$ 0.012
10.0	1.000	1.000	1.000 $\pm$ 0.007	1.000 $\pm$ 0.019

### Conclusion

Volume averaging was found to influence the alanine measurements by up to 6 % for the smallest field size. For a cylindrical detector irradiated along the symmetry axis of the detector, simple analytical expressions of the volume correction factors were obtained. The analytical expression gives valuable insight in the volume correction factor  $k_v$  as function of field size and the radius of the sensitive volume of the detector. The method presented here would be applicable for other detectors. With a defined geometry of the sensitive volume of the detector relative to the central axis of the beam the volume correction factor can either be calculated analytically or numerically as function of FS.

Poster: Physics track: Dose measurement and dose calculation

### PO-0785 A pencil beam algorithm for protons including magnetic fields effects

F. Padilla<sup>1</sup>, H. Fuchs<sup>1</sup>, D. Georg<sup>1</sup>

<sup>1</sup>Medizinische Universität Wien Medical University of Vienna, Department of Radiation Oncology, Vienna, Austria

### Purpose or Objective

Magnetic Resonance Image (MRI) has the potential to increase the accuracy and effectiveness of proton therapy. Previous studies on that topic demonstrated that corrections in dose calculation algorithms are strictly required to account for the dosimetric effects induced by external magnetic fields. So far, a real dose calculation possibility including a trajectory corrected approach was missing. In this study, we developed a pencil beam algorithm (PBA) for dose calculation of a proton beam in magnetic fields.

### Material and Methods

MC simulations using the GATE 7.1 toolkit were performed to generate first benchmarking data and subsequent validation data for the PBA. The PBA was based on the theory of fluence weighted elemental kernels. A novel and non-symmetric exponential tailed Gauss fitting function was used to describe the lateral energy deposition profiles in water. Nuclear corrections, multiple scattering and

charged particle drifting were accounted by means of a look-up table (LUT) approach. Longitudinal dose depositions were estimated from the LUT and corrected using a water-equivalent depth scaling. In a first step proton beams in the clinical required energy range 60 - 250 MeV with transverse external magnetic fields ranging from 0 - 3T were analyzed in a 40x40x40 cm<sup>3</sup> water phantom. Next validation simulations were performed for different phantom configurations, e.g. using a simple water box or slab-like geometries with inhomogeneities of different materials and volumes. Percentage depth dose curves (PDD) and two-dimensional dose distributions were calculated to assess the performance of the PBA.

### Results

For PDD in water discrepancies between the PBA and MC of less than 1.5% were observed for all the depth values before the Bragg-Peak (see Figure 1). An increasing value of up to 6% was found in the distal energy falloff region, where dose values represents around 1% of the maximum dose deposition. In all cases, maximum range deviations of the results were less than 0.2 mm. Deviations between two dimensional dose maps obtained with PBA and GATE remained below 1% for almost all the proton beam trajectory, reaching a maximum value up to 4% in the Bragg-Peak region, see Fig. 2. As expected, agreement became worse for high energy protons and high intensity magnetic fields.

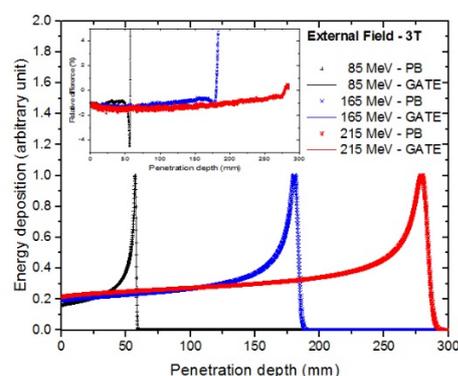

Fig. 1. PDD curves comparing the PB algorithm with MC simulations for proton beams in water. Relative discrepancies are shown in the top region of the graph.

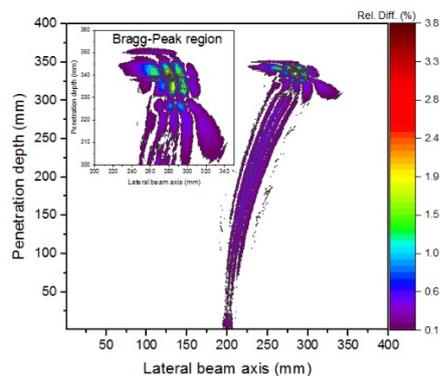

Fig. 2 Relative dose difference map for a 240 MeV proton beam in water exposed to a 3T transverse field.

### Conclusion

The proposed pencil beam algorithm for protons can accurately account for dose distortion effects induced by external magnetic fields. Corrections of dose distributions using an analytical model allows to reduce dose

calculation times considerably, making the presented PBA a suitable candidate for integration in a treatment planning system. The current work demonstrates that proton MRI is feasible from a dosimetric point of view.

#### PO-0786 Energy dependence investigation for detectors used in out-of-field dosimetry

L. Shields<sup>1</sup>, L. Leon-Vintro<sup>2</sup>, B. Mc Clean<sup>3</sup>

<sup>1</sup>St Luke's Hospital, Medical Physics, Dublin, Ireland

<sup>2</sup>University College Dublin, School of Physics, Dublin, Ireland

<sup>3</sup>St. Luke's Radiation Oncology Network, Medical Physics, Dublin, Ireland

#### Purpose or Objective

Traditionally, energy dependence of a range of detectors used in radiotherapy has been investigated mainly in the Cobalt-60 and 6-15MV photon range. However, when considering detectors for use in out-of-field dosimetry, it is more important that the energy dependence is investigated over a much lower range. This study examined (i) the mean incident energy of radiation out-of-field for a 6MV photon beam and (ii) the energy dependence of a range of clinically available detectors to the typical energies experienced out-of-field and (iii) Monte Carlo (MC) calculated and detector measured out-of-field dose profiles.

#### Material and Methods

An Elekta Synergy Linac operating at 6MV and a water phantom at 90cm SSD was defined in BEAMnrc. Phase spaces were scored at 6 different planes in the water phantom - 0.2, 1.4 (dmax), 5, 10, 15 and 20cm. Each phase space file was analysed using the EGSnrc program package BEAMDP to extract energy spectra from each of the phase space files to examine the change in energy spectra with increasing distance from the field edge and depth in the phantom.

The energy dependence of each of the detectors was examined using 70, 100, 125 and 200 kV beams on a Gulmay D3225 Orthovoltage Unit and a 6MV Elekta Synergy beam. The kV energies lied within the range of energies which were found to be dominant out-of-field in a 6MV beam. A dose of 1 Gy was delivered to each detector as determined by their respective calibration protocols, and the signal was recorded for all energies.

In-plane and cross-plane profiles were measured by each detector and compared to MC calculated.

All measurements were performed in an PTW MP3 watertank except for TLDs and Gafchromic EBT3 film which were performed in solid water.

#### Results

Figure 1 displays the results of the energy dependence investigation for each detector in the study. The response of each detector was normalised to 1 at 6MV.

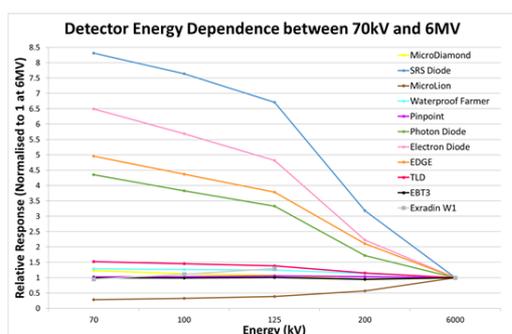

Figure 1 Energy Dependence results for each detector normalised to 1 at 6 MV

Figure 2 displays a comparison between MC calculated versus detector measured out-of-field dose.

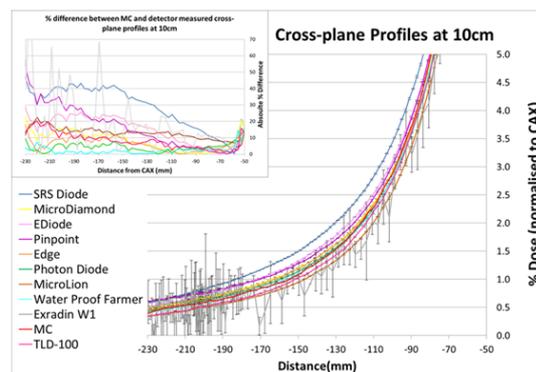

Figure 2 Comparison of Monte Carlo calculated and detector measured cross-plane out-of-field profiles at 10cm deep. Inset: Percentage difference between MC calculated and detector measured cross-plane profiles at 10cm

#### Conclusion

In general the results of the energy dependence investigation predicted the response of the detectors to out-of-field radiation except for the case of the Pinpoint, TLD and microDiamond detectors. Energy dependence was thought to be the leading source of variation in detector response to out-of-field radiation due to the relative increase in low-energy photons. However, dose-rate and angular dependencies can exist in detector responses but were not investigated as part of this study. Other factors such as charge multiplication and cable effects can contribute to a change in response as observed with the Pinpoint detector. This study highlights the need for careful selection of appropriate detectors when accurate out-of-field dosimetry is required and offers a guide and improved understanding of detector response to out-of-field radiation. The waterproof Farmer chamber showed best agreement with MC calculated out-of-field dose and is recommended for out-of-field dose measurements.

#### PO-0787 A compact and complete model for Bra gg peak degradation in lung tissue

R. Dal Bello<sup>1</sup>, C. Möhler<sup>1,2</sup>, S. Greilich<sup>1,2</sup>, O. Jäkel<sup>1,2,3</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Division of Medical Physics in Radiation Oncology, Heidelberg, Germany

<sup>2</sup>National Center for Radiation Research in Oncology NCR0, Heidelberg Institute for Radiation Oncology HIRO, Heidelberg, Germany

<sup>3</sup>Heidelberg Ion Beam Therapy Center HIT, Clinical Research Group Radiotherapy with Heavy Ions, Heidelberg, Germany

#### Purpose or Objective

Due to the lack of a reliable model, current analytical treatment planning for proton and heavier ions cannot account for the degradation of the sharp distal fall-off of the Bragg peak caused by microscopic density heterogeneities, which cannot be resolved by clinical CT. Here, we present a systematic study of Bragg peak degradation in stationary lung parenchyma to provide a comprehensive analytical parametrization for implementation in treatment planning systems (TPS) - aiming at the reduction of dose uncertainties in radiotherapy of the lung.

#### Material and Methods

We developed a compact model describing the lung parenchyma microscopic geometry based on few geometrical and physical variables allowing for flexible Monte Carlo (MC) simulations of lung specific features (alveolar dimension, lung density) and breathing state parameters (air filling state, water equivalent thickness traversed, WET). To benchmark the accuracy of the simulated model, we performed a MC study to assess the specific contributions of the cumulative physical sources of degradation and a series of transmission experiments

on lung-like phantoms with clinical proton and carbon beams at the Heidelberg ion-therapy center (HIT). We adopted the benchmarked model to provide a parametrization of the Bragg peak degradation on the beam and on the previously mentioned lung parameters. Throughout this work, we tested and used a Gaussian convolution of the undegraded Bragg peak (U. Titt et al, 2015) to parametrize the degradation. Furthermore, the model was used to investigate the effects on clinical spread out Bragg peak (SOBP) and on the relative biological effectiveness (RBE).

### Results

Fluctuations in the WET were found the major degradation factor, contributing more than 75% (40%) to the cumulative distal falloff widening for a carbon (proton) Bragg peak. The simulated lung parenchyma model (Figure 1) was capable to reproduce the experimental data with a slight underestimation of the degradation parameters, yet guaranteeing the correct reproduction of all the relevant characteristics in the degraded dose distribution. The Gaussian filtration unified the description for different beam particles and provided a compact and complete characterization with specific dependencies with respect to each lung parameter. Moreover, the description was found independent from the initial beam energy resulting in deviations mainly about the SOBP distal falloff while the plateau remains unaffected. Finally, the impact on the biological dose was mainly driven by changes to the physical dose due to the limited deviations in the RBE.

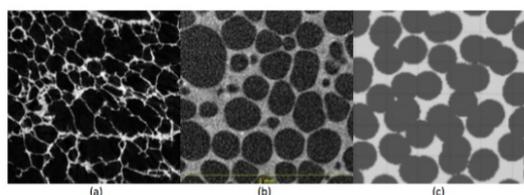

Figure 1: Comparison of micro-CT slices of: (a) a real porcine lung (M. Witt, 2014), (b) the Gammex Lung 455 adopted for the transmission experiments and (c) its benchmarked MC implementation. The air cavities are implemented in (c) as infinite cylinders, which compared to the more complex spherical cavities allow a drastic reduction of the MC simulation time yet guaranteeing a correct reproduction of the Bragg peak degradation.

### Conclusion

We provide a comprehensive characterization of Bragg peak degradation that can readily be implemented in a TPS. Such implementation is crucial for a more complete description of lung treatments, adding to the effect of macroscopic structures (e.g. bronchi, CT resolvable) the contribution of microscopic lung parenchyma (below CT resolution).

### PO-0788 First assessment of Delivery Analysis tool for pre-treatment verification on the new Radixact system

A. Girardi<sup>1</sup>, T. Gevaert<sup>1</sup>, C. Jaudet<sup>1</sup>, M. Boussaer<sup>1</sup>, M. Burghel<sup>2</sup>, J. Dhont<sup>1</sup>, T. Reynders<sup>1</sup>, K. Tournel<sup>1</sup>, M. De Ridder<sup>1</sup>

<sup>1</sup>Universitair Ziekenhuis Brussel, Department of Radiotherapy- Universitair Ziekenhuis Brussel- Vrije Universiteit Brussel- Brussels- Belgium, Brussels, Belgium  
<sup>2</sup>Brainlab AG, BRAINLAB AG Feldkirchen Germany, Brussels, Belgium

### Purpose or Objective

To evaluate the accuracy of the Delivery Analysis (DA) tool for patient-specific pre-treatment verification and the sensitivity to detect discrepancies in dose delivery in comparison with widespread detectors.

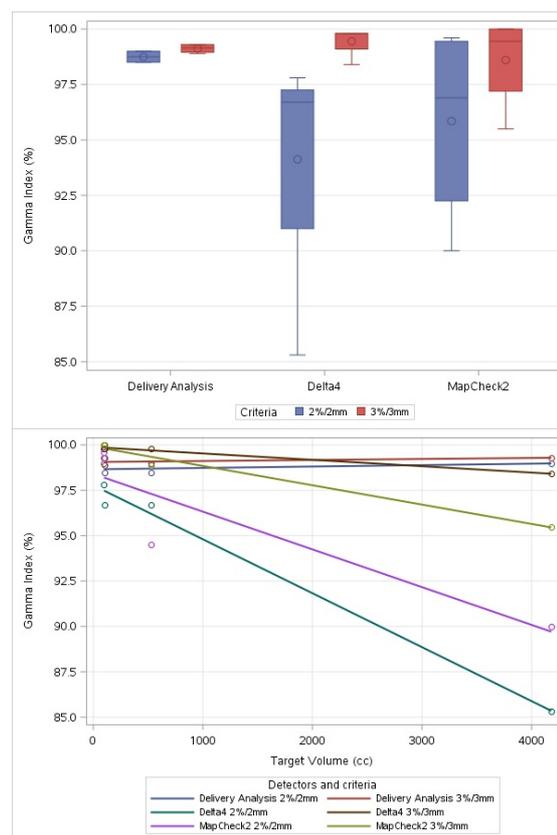

### Material and Methods

The Radixact machine is equipped with the DA device for pre-treatment Quality Assurance (QA) and interfraction verification. This tool is designed to assess the consistency of the delivered treatment through the detector data and to show anatomical changes of the patient. The latter representing a powerful tool to be coupled with Adaptive Radiotherapy. The idea is to use the detector: a) to

measure the Multileaf Collimator (MLC) leaf open time, b) to compare the planned sinogram to the delivered one and c) for dose reconstruction purposes. In this study, we performed pre-treatment verification on the very first twenty heterogeneous patients treated worldwide (target volumes ranging between 98 to 4179 cc) using the DA, the Sun Nuclear MapCheck2 (MC2) and the ScandiDos Delta4 (D4). The Gamma Index was used to show the agreement between dose planning calculations and measurements. To compare the three methods, criteria were set to 2% and 3% in local dose and to 2mm and 3mm in distance, respectively, excluding doses lower than 20% of the maximum doses. The performances of the systems were analysed with a single factor ANOVA test, with a significance level of  $\alpha=0.05$ . A possible dependence of the results from the target volume was furthermore explored with a simple linear regression analysis.

### Results

The ANOVA test showed no statistically significance differences between the performances of the three systems, both for the 2%/2 mm and the 3%/3mm criteria (p-values equal to 0.351 and 0.660 respectively). The linear regression indicated a variation of performance as a function of target volume for the MC2 ( $R^2_{2\%/2mm}=0.819$  and  $R^2_{3\%/3mm}=0.979$ ) and the D4 detectors ( $R^2_{2\%/2mm}=0.991$  and  $R^2_{3\%/3mm}=0.990$ ), which is not highlighted for the DA system ( $R^2_{2\%/2mm}=0.283$  and  $R^2_{3\%/3mm}=0.290$ ). This difference could be related to the missing data due to the larger dimension of the dose map with respect to the detection area of the MC2 and D4 systems.

### Conclusion

This study showed that the performances of the Delivery Analysis tool for the new Radixact machine is not different from those of two other widespread detectors for pre-treatment verification. Moreover, the linear regression test showed that the performances of the system are not correlated with the target volume, as is the case for two other detectors used in the study, proving its sensitivity as a patient specific QA tool.

### PO-0789 Demystifying failed VMAT PSQA measurements with ArcCHECK

P. Kinsella<sup>1</sup>, L. Leon-Vintro<sup>2</sup>, B. McClean<sup>3</sup>

<sup>1</sup>St Luke's Radiation Oncology Center, Physics, Dublin, Ireland

<sup>2</sup>University College Dublin, School of Physics, Dublin, Ireland

<sup>3</sup>St Luke's Radiation Oncology Network, Physics, Dublin, Ireland

#### Purpose or Objective

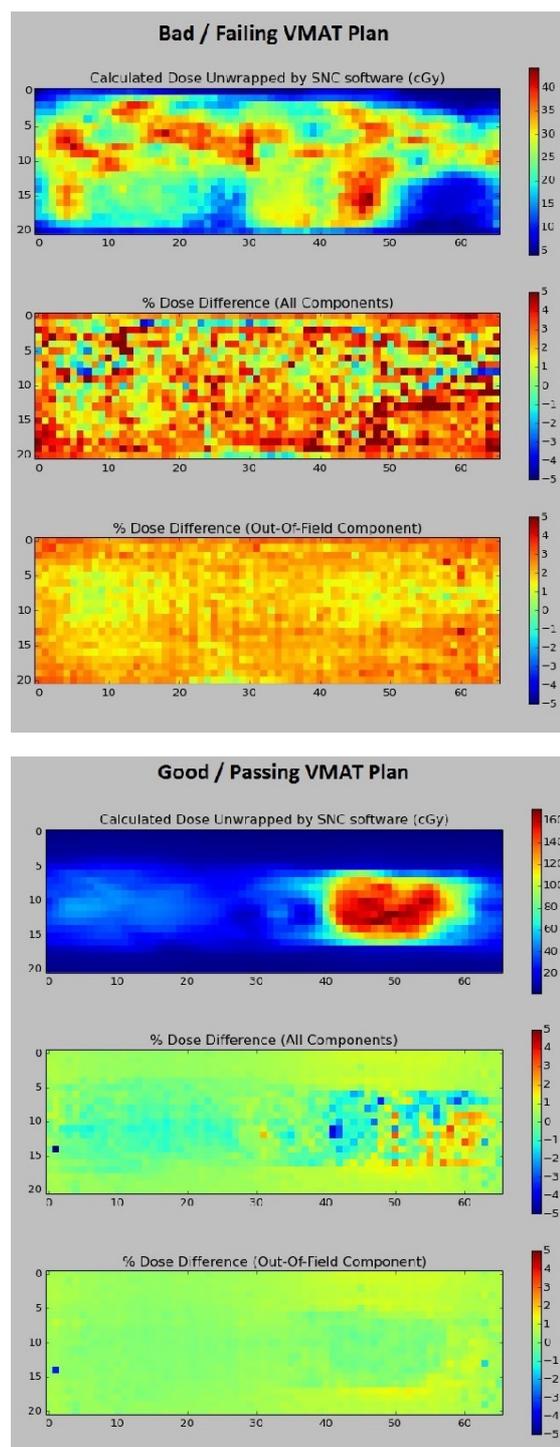

A means of reducing PSQA measurements for VMAT is currently a popular topic of discussion due to the resource burden it generates and the increased use of VMAT. The reluctance to reduce or replace PSQA may be partly due to the difficulty in identifying the cause/s of plan failures. Plans may fail due to a large number of potential factors caused by the TPS, linac or measurement device. The goal of this study was to uncover the reason/s why a selection of VMAT plans have failed.

#### Material and Methods

Five 'bad' plans yielding low (failing) gamma pass-rates and high average gamma-values were selected for analysis. Two 'good' plans yielding high gamma pass-rates and low average gamma values were also used for comparison. The plans were measured with SNC ArcCHECK (1220 Model) cylindrical detector diode array and analysed with gamma analysis in SNC Patient software. The institutional tolerance was  $\geq 95\%$  of the points must pass a gamma analysis with 3% and 2mm gamma criteria, with a 10% threshold and with the Van Dyk option (global gamma analysis) turned on. The control points for each plan were broken up into separate static fields applying the small arc approximation used by TPSs to calculate dynamic arc beams. The fields were then calculated in the Eclipse TPS (AAA) and delivered to the ArcCHECK. The individual static field measurements were compared to the individual calculations using an in-house Python script. Dose-differences were tracked field-by-field for each diode and categorised into 5 components according to the location of the diode in the irradiation geometry: In-field Entrance side, in-field exit side, penumbra entrance side, penumbra exit side and out-of-field. Results presented highlighted the contribution each component had to the overall dose difference.

#### Results

A composite measurement of individual control point fields compared with the conventional PSQA measurement showed minimal difference indicating that the main reason for PSQA fail was not due to the dynamic delivery. The out-of-field component appeared to have the greatest impact on the overall pass-rate as highlighted in the figures below where an example of both a 'good' and 'bad' plan are shown. It has been widely reported that diodes over-respond to low energy photons. A proposed solution to the problem was to use the latest version of the SNC Patient software (v6.7) which provides out-of-beam corrections for this over-response. The impact of applying the out-of-field correction resulted in all previously failed plans passing the gamma criteria stated earlier.

#### Conclusion

Deconstructing failed PSQA measurements proved useful in identifying the main source of error and led to proving that these were false-positive results due to detector limitations. The manufacturers have released a new version of software with the ability to reduce this limitation. The results of this study indicate this correction should be adopted.

### PO-0790 In-vivo dosimetry for kV radiotherapy: clinical use of micro-silica bead TLD & Gafchromic EBT3 film

A.L. Palmer<sup>1</sup>, S.M. Jafari<sup>1</sup>, J. Mone<sup>2</sup>, S. Muscat<sup>1</sup>

<sup>1</sup>Portsmouth Hospitals NHS Trust, Medical Physics Department, Portsmouth Hampshire, United Kingdom

<sup>2</sup>University of Surrey, Physics Department, Guildford, United Kingdom

### Purpose or Objective

kV radiotherapy continues to be an important modality in modern radiotherapy, but has received less research attention in recent years. There remains a challenge to accurately calculate and verify treatment dose distributions for clinical sites with significant surface irregularity or where the treated region contains inhomogeneities, e.g. nose and ear. The accuracy of current treatment calculations has a significant level of uncertainty [1, 2]. The objective of this work was to characterise two novel detectors, micro-silica bead TLDs and Gafchromic EBT3 film, for in-vivo measurements for kV treatments, and to compare measured doses with conventional treatment calculations.

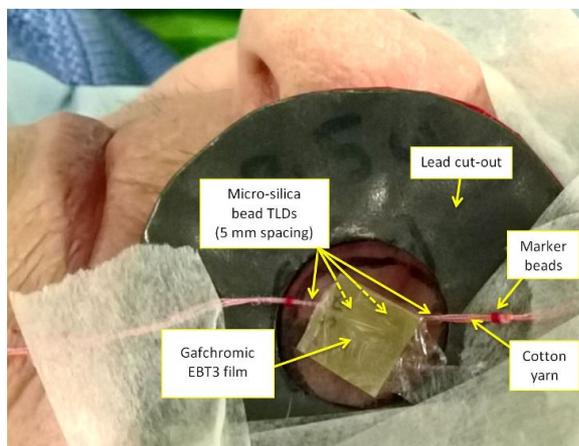

[1. Currie (2007) Australas Phys Eng Sci Med, 2. Chow (2012) Rep Pract Oncol Radiother.]

### Material and Methods

Micro-silica bead TLDs (1 mm diam.) and Gafchromic EBT3 film were calibrated against an NPL traceably calibrated ionisation chamber using an Xstrahl D3300 kV radiotherapy treatment unit. Energy response was evaluated over 70 to 250 kV and compared to 6 MV, useable dose range was evaluated from 0 to 25 Gy, and uncertainty budgets determined. Silica beads were cleaned, annealed, and TL response individually calibrated. EBT3 film was used with triple-channel dosimetry via FilmQAPro® with procedures to reduce uncertainties. Commissioning tests were undertaken in standard conditions using Solid Water blocks and in simulated clinical treatment condition using a custom made 'wax face with nose' phantom. Pilot in vivo measurements were made for a consecutive series of eight clinical patient treatments, including cheek, ear, nose and rib sites, over 70 to 250 kV, and 4 to 18 Gy. Results for the two dosimetry systems were compared to conventional treatment planning calculations.

### Results

Energy response varied by 460% for beads and 9% for film, from 70 kV to 6 MV, necessitating energy-specific calibration. Both dosimeters were useable up to 25 Gy. Standard uncertainty was 3.1% for beads, 2.1% for film. The figure shows typical film and bead positions within the lead cut-out of a kV treatment to the cheek. The table provides calculated and measured doses. Average deviation over 6 patients was -1.3% for beads, -0.9% for film. 3 patients had larger deviations; See table note 1: tumour sitting over the maxillary sinus may reduce dose. Note 2: beads placed along surface of tumour into ear, most distal bead received dose -17.5% from prescription, doctor made compensation. Note 3: Increased uncertainty due to curved surface, film required offset to corner as patient sensitive to contact. Note 4: Uncertainty increased due to large respiratory motion at treatment site.

Dose per #, energy and site	EBT3 Film		Micro-Silica bead		Notes (see text)
	Measured dose, Gy, ( $\pm 2.1\%$ , k=1)	% diff. to calc.	Measured dose, Gy, ( $\pm 3.1\%$ , k=1)	% diff. to calc.	
10 Gy, 100 kV, Cheek	9.176	-8.2	9.090	-9.1	1.
4 Gy, 250 kV, Ear	3.998	0.0	4.030	0.7	2.
4 Gy, 70 kV, Nose	4.015	0.4	3.992	-0.2	
7.5 Gy, 100 kV, Cheek	7.253	-3.3	7.240	-3.5	
10 Gy, 140 kV, Ear	10.154	1.5	10.053	0.5	
8 Gy, 250 kV, Rib	7.053	-8.3	7.528	-5.9	3.
18 Gy, 100 kV, Ear	17.471	-2.9	17.308	-3.8	
4 Gy, 250 kV, Rib	3.861	-3.5	3.721	-7.0	4.

### Conclusion

Both micro-silica bead TLDs and EBT3 film were characterised as suitable for in vivo dosimetry in kV radiotherapy, providing assurance of delivered doses. Film is simpler to prepare, use and read. A line of beads allows conformation to irregular anatomy across the field. A clinical service is now available to verify dose delivery in complex clinical sites.

### PO-0791 Determination of water mean ionization potential for Geant4 simulations of therapeutical ion beams

A. Perales<sup>1</sup>, M.A. Cortés-Giraldo<sup>1</sup>, D. Schardt<sup>2</sup>, J.A.

Pavón<sup>1</sup>, J.M. Quesada<sup>1</sup>, M.I. Gallardo<sup>1</sup>

<sup>1</sup>Universidad de Sevilla, Dpto. Física Atómica- Molecular y Nuclear, Sevilla, Spain

<sup>2</sup>GSI, Biophysics Division, Darmstadt, Germany

### Purpose or Objective

To characterize protons and ion beams to determine the mean ionization potential (I-value) of water to be used in Monte Carlo simulations with the Geant4 Monte Carlo toolkit at energies of interest in particle therapy. The magnitude of this parameter has a strong influence on the Bragg Peak spatial position which, to our knowledge, is a key factor for treatment planning.

### Material and Methods

The energy deposition distributions with respect to depth in water were obtained using an experimental setup (figure 1) which consists in a water tank, which thickness can be varied with micrometric accuracy, and two ionization chambers (ICs), the first one placed downstream the beam exit window (IC1) and the second one just behind the water tank (IC2). The mean energy deposition relative to the mean energy deposition at the entrance as function of depth in water were obtained from the ratio between the ionization produced in IC2 with respect to that of IC1. These measurements were carried out for various ion species covering a range in water between 5 and 28 cm, approximately. The absolute depth in water was determined with an estimated uncertainty of 0.2 mm.

Our Geant4 simulations were done using an ideal geometry (figure 2) composed by a water tank containing cylindrical scoring volumes, with a radius of 28 mm (actual radius of the ICs) and a thickness of 50 microns (similar to the water equivalent thickness of the ICs), to tally the energy deposition.

For the simulation of each particular beam the energy spread was adjusted by fitting the width of the experimental distal fall-off prior determining the optimum I-value by matching our calculated 82% distal depth with the experimental one.

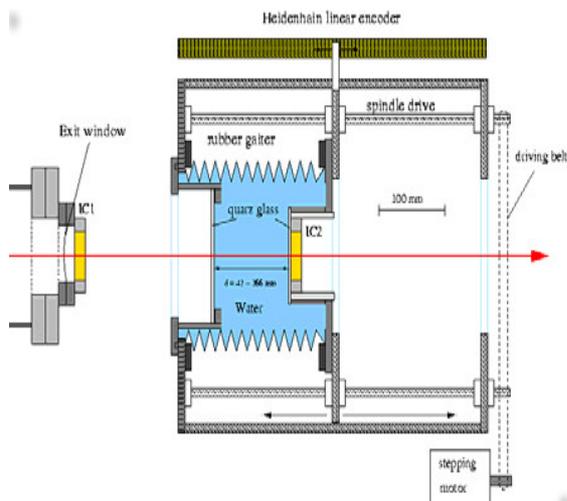

Figure 1. Experimental setup for mean energy deposition in water measurement.

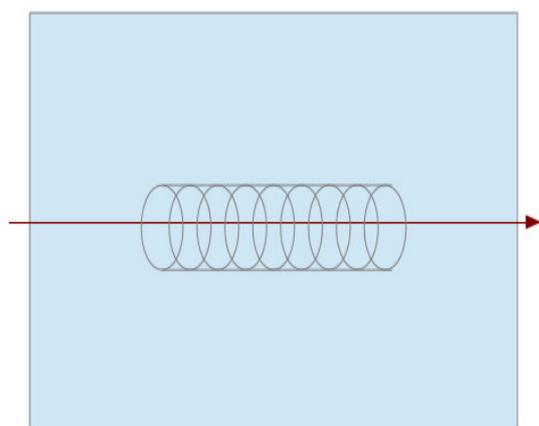

Figure 2. Ideal geometry construct in the Geant4 simulation.

### Results

Our calculations give an optimal I-value of 79 eV for protons, whereas for heavier ions varies from 75 eV to 80 eV. In some cases it was found a dependence of the optimal I-value with respect to the beam energy which is being subject of further work.

### Conclusion

We have calculated the energy deposition distribution as function of the depth in water for proton and ion beams. Our calculations were compared with experimental measurements in order to obtain an overall optimal I-value for simulations with the Geant4 toolkit at therapeutical energies. The values obtained varies from 75 to 80 eV, showing dependences with the particle type and energy of the beam. In fact this variation on the I-value produces a spatial translation of the Bragg Peak in the Geant4 simulation depending on the beam species and energy.

### PO-0792 Monte-Carlo calculated energy deposition and nanodosimetric quantities around a gold nanoparticle

T. Dressel<sup>1</sup>, M. Bug<sup>1</sup>, E. Gargioni<sup>2</sup>

<sup>1</sup>Phys. Techn. Bundesanstalt PTB, 6.5 Radiation Effects, Braunschweig, Germany

<sup>2</sup>University medical center Hamburg-Eppendorf, Clinic for radio oncology, Hamburg, Germany

### Purpose or Objective

Interdisciplinary research on the local DNA damage after irradiation in the presence of high-Z nanomaterials, e.g. gold nanoparticles (GNP), is being performed worldwide

to investigate their application for radiation imaging and therapy. An irradiation of GNP by photons leads to an enhanced secondary electron (SE) yield due to the high photoabsorption of gold. The low-energy SE are absorbed within nanometers around the GNP, thus leading to a higher ionization density and therefore, to an enhanced DNA damage in the surrounding cells. From the physical point of view, the ionization density can be related to DNA lesions via nanodosimetric quantities, such as the ionization cluster-size (ICS) distribution. The purpose of this work is to investigate this correlation by means of Monte-Carlo simulations.

### Material and Methods

The energy deposition and nanodosimetric quantities in water around a single GNP were calculated by means of Geant4 simulations. The related enhancement factors were determined with respect to a water-only environment. The creation and transport of SE inside GNP of different sizes after initial irradiations with mono-energetic kV-photon sources and with three clinical spectra were modeled. The radial energy deposition, the spectrum of the kinetic energy, and the polar angle of the SE were calculated in water shells around the NP. These results were then used as input for the initial state of electrons that were transported through a DNA array of 2250 DNA cylinders, corresponding to one convolution of the DNA. For each cylinder, the ICS and the probability for inducing DNA damage, e.g. double-strand breaks (DSB), was determined. Simulations were repeated without the GNP to determine the enhancement factors for the energy deposition and the DNA-damage probability.

### Results

The enhanced SE yield contributes to the increasing energy deposition in the vicinity of the GNP. For example, for a GNP with a diameter of 30 nm and an incident photon energy of 10 keV the dose enhancement is largest near the surface ( $R_D \approx 1300$ ) but rapidly decreases to a factor of about 30 at a distance of 300 nm. This enhancement shows a maximum for the 50 kVp therapeutic spectrum (about 190 at 300 nm) and decreases for higher energetic sources. For the 12 nm GNP, the enhancement at 300 nm is lower than for the 30 nm GNP by a factor of about 2.5 for all investigated photon spectra. The mean enhancement for the probability of inducing a DSB at 35 nm is approximately 2.4 for 10 keV photons and 12 nm GNP, even though  $R_D \approx 50$ .

### Conclusion

The enhancement of the energy deposition, obtained in this work, is in good agreement with literature data. A comparison of the calculated probabilities for a DSB with literature data about dose enhancement in vitro show that nanodosimetric quantities are more appropriate than absorbed dose for investigating the correlation between physical effects and DNA damage in cells.

### PO-0793 Absorbed dose distributions of ruthenium ophthalmic plaques measured in water with radiochromic film

M. Hermida-López<sup>1,2</sup>, L. Brualla<sup>2</sup>

<sup>1</sup>Hospital Universitario Vall d'Hebron, Servei de Física i Protecció Radiològica, Barcelona, Spain

<sup>2</sup>Strahlenklinik- Universitätsklinikum Essen, NCTeam, Essen, Germany

### Purpose or Objective

Brachytherapy with beta-emitting  $^{106}\text{Ru}/^{106}\text{Rh}$  plaques offers good outcomes for small-to-medium melanomas and retinoblastomas. The measurement of the produced dose distributions is challenging due to the small range of the emitted beta particles and the steep dose gradients involved. Although radiochromic film is a suitable detector for beta dosimetry (high spatial resolution, self-developing, near tissue equivalent, a very thin detection layer and relatively low energy dependence), few publications report measurement data of  $^{106}\text{Ru}/^{106}\text{Rh}$

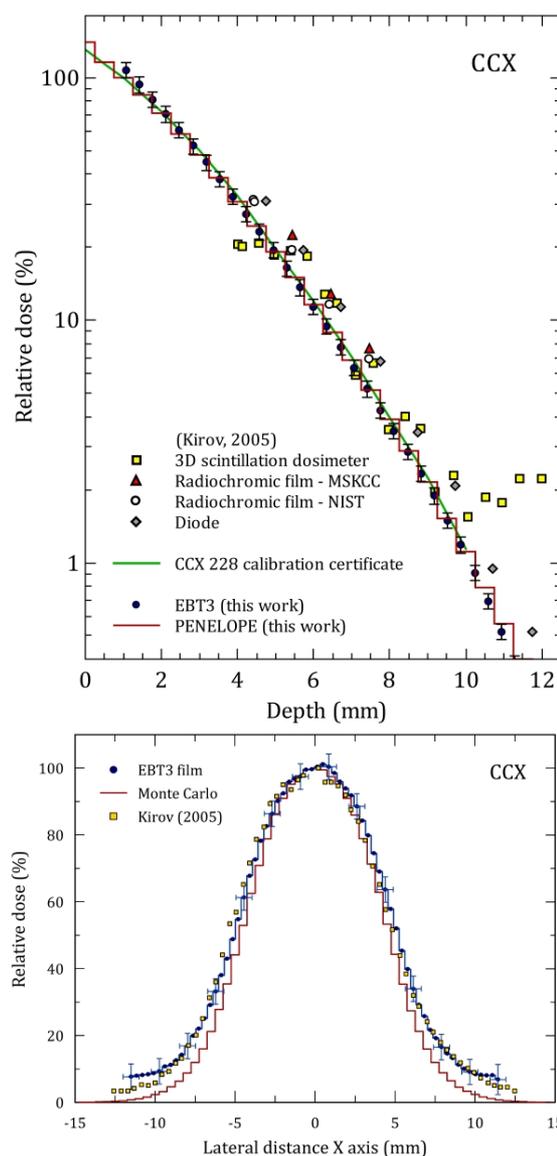

plaques with radiochromic film, and all of them use specifically machined plastic phantoms. We aimed to develop a practical experimental method for measuring the absolute absorbed dose distributions in water produced by  $^{106}\text{Ru}/^{106}\text{Rh}$  plaques using the EBT3 radiochromic film.

#### Material and Methods

Two experimental setups were developed to measure dose planes (1) perpendicular to the symmetry axis of the plaque at 5 mm from the intersection of the symmetry axis with the concave plaque surface, and (2) containing the symmetry axis of the plaques (PDD planes). Both, the plaque and the film, were immersed in water. The required materials are easily affordable by a medical physics department without the need of specifically machined solid phantoms. The setups were tested measuring dose distributions from one CCA and two CCX plaques. Dose distributions were obtained from the irradiated films using the triple-channel dosimetry algorithm implemented in the FilmQA 2015 software. The measured dose distributions were compared with the results of Monte Carlo simulations run with the PENELOPE code, and with published data.

#### Results

The measured absolute dose rates agreed with the values quoted in the calibration certificates of the plaques within the experimental uncertainty, with typical differences below 5%. The relative standard uncertainties obtained were of 3.8% for dose distributions measured at planes perpendicular to the symmetry axis at 5 mm from the surface of the plaque, and of 7.4% for planes containing the symmetry axis. These values are comparable to those reported by other authors using plastic phantoms, but avoiding the uncertainties associated to the conversion from dose-to-plastic to dose-to-water. A good agreement was obtained between measurements and simulations, improving upon published data (see figures for data of depth-dose curves, and lateral profiles at 5 mm from the surface of the plaque, for the CCX plaques).

#### Conclusion

We developed a practical experimental method to measure with the EBT3 radiochromic film the dose distributions in water produced by  $^{106}\text{Ru}/^{106}\text{Rh}$  ophthalmic plaques. The obtained results were of similar or better quality than those obtained using solid phantoms. These setups may ease the quality assurance procedures to the users of these plaques.

#### PO-0794 Comprehensive quality assurance test for high precision teletherapy

S. Wegener<sup>1</sup>, A. Spiering<sup>1</sup>, O.A. Sauer<sup>1</sup>

<sup>1</sup>University Hospital, Radiation Oncology, Würzburg, Germany

#### Purpose or Objective

Modern radiation therapy aims to minimize negative side effects on healthy tissue by tailoring the dose distribution as accurately as possible to each individual tumor. This leads to a progressively increasing complexity of the treatment plans and demands a very high precision of all involved components. Even small errors can significantly compromise treatment techniques which require such an extensive precision as stereotactic radiation therapy. A suitable quality management for such techniques should include a regular end-to-end test that closely mimics the entire procedure of the actual patient treatment while being able to reliably detect a variety of possible errors

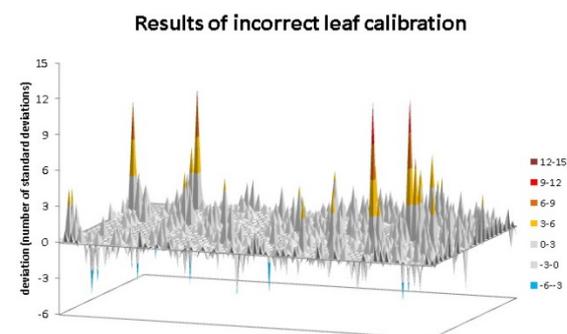

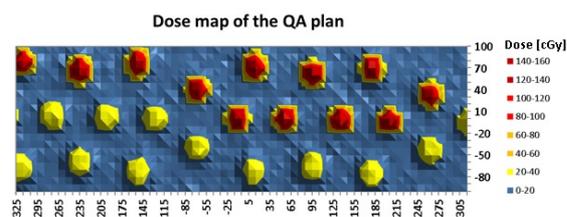

e.g. in calculation, positioning and movement, spatial precision and absolute dose application. We present a test that was introduced into the clinical workflow and evaluated its sensitivity to those errors.

#### Material and Methods

Prior to the irradiation, a custom-built phantom insert for the ArcCHECK (Sun Nuclear, USA) allowed for automatic registration of the cone beam CT to reference data. A 12-field plan including gantry and table rotations targeting a spherical volume of approx. 2 cm diameter was measured weekly using a Synergy accelerator with an Agility MLC (Elekta, Sweden). Signals were obtained from all diodes along the cylinder surface of the ArcCHECK and additional dose was measured with an ionization chamber in the phantom center. For each measurement the plan was compared to the calculation of the treatment planning system via gamma evaluation and every diode reading was compared to the averaged diode readings from previous weeks. Additionally, errors were induced to test the sensitivity for phantom malposition, machine geometry problems and MLC positional inaccuracies.

#### Results

Due to the phantom set up according to the cone beam CT registration, the measurements were very reproducible without any observable user-to-user differences. The typical dose map for the diode cylinder is shown in fig. 1. For all diodes, mean values with small standard deviations were obtained from many consecutive measurements. Any diode deviation observed for the correct application of the test plan never exceeded three standard deviations, while much larger discrepancies could be detected for all induced errors (example: fig. 2).

#### Conclusion

We developed a fast end-to-end test for stereotactic radiation therapy with the ArcCHECK phantom which minimizes user influences for high reproducibility and was easily included into clinical routine. It compares the dose distribution on a helical diode array and a cumulative central dose with the doses from the treatment planning system. By additionally comparing each of the over 1300 diode values to a corresponding average dose derived from previous measurements, the method simultaneously serves as a constancy test of all involved components and is able to reliably detect a vast variety of even very small errors.

#### PO-0795 Comparison of Service graph log and Dynamic linac log of Elekta Linacs for patient QA.

M. Kowatsch<sup>1</sup>, M. Meinschad<sup>1</sup>, G. Leitold<sup>1</sup>, P.

Szeverinski<sup>1</sup>, T. Künzler<sup>1</sup>

<sup>1</sup>LKH Feldkirch, Institut of Medical Physics, Feldkirch, Austria

#### Purpose or Objective

The complexity of intensity modulated radiation therapies (IMAT, IMRT) requires patient specific pretreatment verification of calculated dose distributions which is time consuming. Elekta linacs provide 2 different log files. One is the Service graph (SG) with a resolution of 4 Hz and is directly accessible through the service mode on the linac. The second one is the Dynamic linac log (DLL) with a resolution of 25 Hz. The aim of this study is to compare both types of log files for dose recalculation with Monte Carlo and beam statistics for an Elekta Synergy linac with Agility MLC (Elekta, Crawley).

#### Material and Methods

To compare the log files 2 head & neck, a mamma left side, an abdomen with simultaneous integrated boost, a thoracic spine with 3 dose levels and 1 brain case were chosen. Different parameters like leaf travel (LT), the sum of travel of all leaves between the open jaws, leaf speed (LS), leaf position (LP) and modulation complexity score (MCS) (Masi, Med. Phys. 40, 071718, 2013) were compared between the SG and the DLL. The DICOM RT file was used as reference for comparing LT and MCS. Furthermore log files were converted with an in-house Matlab script to .tel files to recalculate the irradiated plans with Monaco 5.0 TPS (Elekta, Crawley). For recalculation a grid size of 3mm and an uncertainty of 1% per control point were used resulting in a final uncertainty of roughly 0.1%. Isodose and DVH comparison were performed to evaluate equality of recalculated and originally calculated plans.

#### Results

The difference for leaf travel between SG and DLL to the Dicom-RT file was between -9.5% to 2.7% and -0.4% to 6.2%, respectively and between SG and DLL from -2.8 to -11.3%. The differences of the MCI between the two log files was -0.4% to 0.3% and up to 20% compared to the DICOM file (see Table 1). The difference of 20% for plan 6 originates from the definition of LT. In this case, 2 beams with 2 arcs were evaluated. For SG and DLL all beams were evaluated as a single beam, the Dicom RT files were evaluated beam-by-beam. The maximum LT for a particular leaf between 2 control points (CP) showed big discrepancies and was in one case 20.1 mm for the SG and 32.6 mm for the DLL. The differences originate from writing errors between CPs in the SG and these errors are still inexplicable. Random dose errors in DVH up to  $\pm 0.5$  Gy can be seen by recalculation of both log files for the entire plan. For linac parameter statistics (LT, LS, LP) the SG cannot be used because of random writing errors.

LT SG/Dicom [%]	LT DLL/Dicom [%]	LT SG/DLL [%]	MCS SG/DICOM [%]	MCS DLL/DICOM [%]	MCS SG/DLL [%]
2.7%	6.2%	-3.3%	1.2%	0.9%	0.3%
2.4%	-0.4%	2.8%	2.0%	2.0%	0.0%
2.2%	4.1%	-1.8%	1.2%	0.9%	0.3%
0.1%	2.3%	-2.1%	1.9%	1.6%	0.3%
1.5%	6.1%	-4.3%	1.8%	1.8%	0.0%
-9.6%	2.0%	-11.3%	-20.3%	-20.0%	-0.4%

Table 1: Differences in percent for leaf travel (LT) compared between Dicom RT file (Dicom), Servicegraph Log file (SG) and Dynamic Log file (DLL) and the comparison of the Masi Complexity Score (MCS).

#### Conclusion

Both file types are accurate for dose recalculation. The 4 Hz resolution and writing errors of the Servicegraph log are limiting a robust statistical analysis of linac parameters. Dynamic linac logs allow for dose recalculation and for a more detailed statistical analysis of the linac. Both types of log files can be taken for patient QA to decrease the workload of measurements and for

recalculation of delivered dose to the planning CT.

#### PO-0796 Optimisation of plan robustness to sinus filling in a magnetic field.

A. Pollitt<sup>1</sup>, R. Chute<sup>1</sup>, P. Whitehurst<sup>1</sup>, R. MacKay<sup>1</sup>, M. Van Herk<sup>2</sup>, A. McWilliam<sup>2</sup>

<sup>1</sup>Christie Hospital NHS, Radiotherapy, Manchester, United Kingdom

<sup>2</sup>University of Manchester, Division of Molecular and Clinical Cancer Science, Manchester, United Kingdom

#### Purpose or Objective

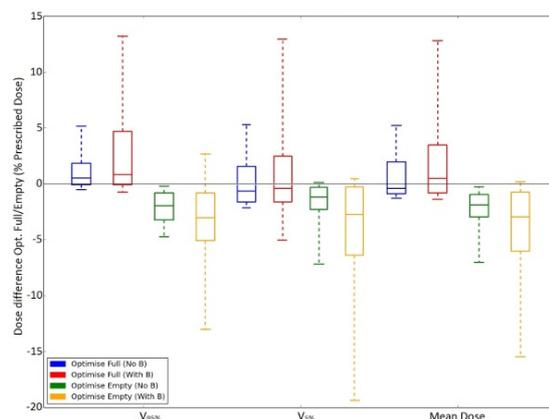

The MR Linac (Elekta AB, Stockholm, Sweden) will provide on-treatment MR imaging allowing for excellent soft tissue imaging. Such a machine will become an integral part of the drive towards daily online adaptive radiotherapy. However, the presence of the magnetic field results in the Lorentz force and will cause an increase or decrease in dose to superficial tissues (Raaijmakers et al. 2007). This is particularly pertinent for sinus cancers, of which 60% are squamous cell carcinoma's and primarily on the surface layer of the nasal cavity. Recent studies (Bol et al 2015, Uilkema et al. 2015) have been performed to determine the effect of the Lorentz force on low density cavities in the body. This abstract aims to investigate the effect of the magnetic field on plan quality and optimisation for varying sinus filling and emptying states.

#### Material and Methods

Ten patients with PTV's overlapping the sinus cavity were selected from the clinical archive. For each patient four plans were optimised at 60Gy in 30 fractions, 2 with no B-field and 2 with the 1.5T B-field present. For each, 1 plan assumed full sinuses with the volume overridden to 1gcm<sup>-3</sup> and the other assumed empty sinuses with the volume overridden to 0gcm<sup>-3</sup>. All plans were created using Monaco (v5.19.07, Elekta AB Stockholm, Sweden) and met the departmental constraints for Target and OAR doses. To investigate the effect of a change in sinus filling, plans were recalculated on their opposite filling state, i.e. plan optimised on a full sinus was recalculated on an empty sinus. The difference in dose between the two plans for target coverage and OARs was calculated. This comparison will determine the magnitude of the effects from sinus filling in each scenario. Investigating the range of dose differences will provide information on how to optimise these plans to minimise the effect of the Lorentz force.

#### Results

The change in dose to the Target for the different filling and magnetic field combinations can be seen in Figure 1. Several of the dose differences for plans optimized on an empty cavity, for both with and without B-field show a shift of the mean of the distribution which is greater than 2% (considered potentially clinically significant). i.e. mean Dose = 2.36%; V<sub>50%</sub> = 2.26%; V<sub>5%</sub> = 3.12%; V<sub>2%</sub> = 3.21%. An OAR which also saw a difference greater than 2% was the Brainstem PRV 1cc max = 2.16 %.

**Figure 1** Dose difference for Target, optimised full and empty both with and without the 1.5T magnetic field. The shift in the median dose from plans optimised without the 1.5T magnetic field (b) to plans with the magnetic field shows the effect of the ERE effect on the dose difference. All of the plans optimised and recalculated with the magnetic field show a greater spread in the dose data than without the magnetic field. This is especially true for the V<sub>5%</sub> optimized empty showing that the recalculated plans (full) are prone to hotspots.

#### Conclusion

This abstract shows greater dosimetric differences due to sinus filling in a 1.5T magnetic field for plans optimised with an empty cavity. Without a B-field plans optimised on full and empty cavities show similar results.

The dose to the PTV is also less conformal optimising on an empty cavity due to hotspots caused by the ERE close to the surface shown by a higher effect for the max dose to 2% of the Target. The results indicate that optimising with a full sinus cavity makes the plan more robust to the Lorentz force and therefore to changes in filling.

#### PO-0797 Studies on optical fiber dosimeters for in-vivo dosimetry in HDR brachytherapy

L. Moutinho<sup>1</sup>, H. Freitas<sup>1</sup>, J. Melo<sup>1</sup>, J.F.C.A. Veloso<sup>1</sup>, P.J. Rachinhas<sup>2</sup>, P.C.P.S. Simões<sup>2</sup>, J.A.M. Santos<sup>3</sup>, A. Pereira<sup>3</sup>, J. Silva<sup>3</sup>, S. Pinto<sup>3</sup>

<sup>1</sup>University of Aveiro, Physics Department, Aveiro, Portugal

<sup>2</sup>CHUC, Radiology, Coimbra, Portugal

<sup>3</sup>IPO-Porto, Radiotherapy, Porto, Portugal

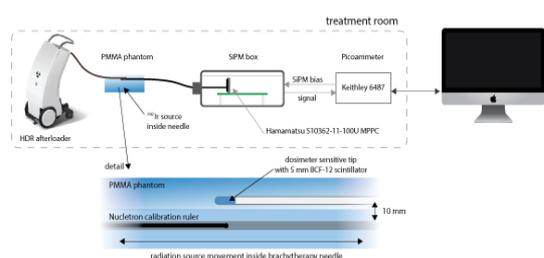

#### Purpose or Objective

Dose verification and quality assurance in radiotherapy should be assessed in order to provide the best treatment possible and minimize risks for patient. Notwithstanding, due technical constraints in certain treatments there's no such tools capable to perform real-time dose measurement. An ideal dosimeter for prostate brachytherapy should provide real-time and in-vivo dose measurement, present high sensitivity and no dependencies on energy, dose and dose rate and temperature. Also should be detectable in the anatomic volume to check its position, easy to use and calibrate and not expensive/disposable use of its implantable part.

#### Material and Methods

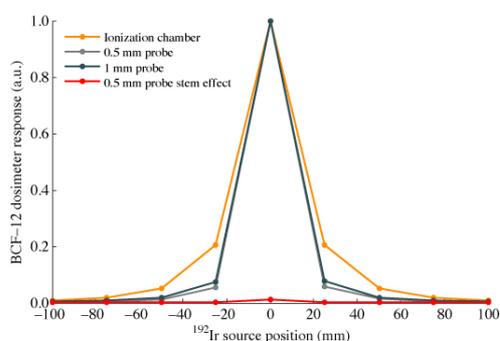

We developed a fiber optic dosimeter suitable for real-time dose monitoring in breast and prostate brachytherapy, thus opening the possibility for real-time dose correction.

The dosimeter comprehends a sensitive optical fiber probe of 1mm or 0.5 mm diameter where a 5 mm length scintillating optical fiber is coupled. The clear optical fiber providing scintillation light guidance into the photodetectors.

## Results

The first round of in-vitro tests in clinical ambient allowed to demonstrate that fiber optical based dosimeters are suitable for dosimetry in regimes such the ones in HDR prostate brachytherapy. The versatility of this kind of device and easiness of use allows application in other radiotherapy modalities. The dosimeter response was evaluated under irradiation with a 10.07 Ci Ir-192 HDR-brachytherapy. The dosimeter shows a linear response with dose and is capable of detecting  $\mu\text{Gy}$  dose variations like an ionization chamber.

## Conclusion

The first round of in-vitro tests in clinical ambient allowed to demonstrate that fiber optical based dosimeters are suitable for dosimetry in regimes such the ones in HDR prostate brachytherapy. The versatility of this kind of device and easiness of use allows application in other radiotherapy modalities.

The dosimeter shows a linear response with dose and is capable of detecting  $\mu\text{Gy}$  dose variations like an ionization chamber.

## PO-0798 Identification of areas of high-risk skin toxicity in SBRT and IMRT treatments

P. Carrasco de Fez<sup>1</sup>, M.A. Duch<sup>2</sup>, N. Jornet<sup>1</sup>, M. Lizondo<sup>1</sup>, T. Eudaldo<sup>1</sup>, A. Latorre-Musoll<sup>1</sup>, C. Cases<sup>1</sup>, A. Ruiz<sup>1</sup>, M. Ribas<sup>1</sup>

<sup>1</sup>Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain

<sup>2</sup>Universitat Politècnica de Catalunya, Institut de Ciències Energètiques, Barcelona, Spain

### Purpose or Objective

The AAPM TG176 shows examples of dramatic unexpected skin effects. This work is aimed:

1. To develop an in-phantom method to identify what areas of skin could be exposed to high doses and are of potential risk in order to decide where to perform skin in vivo dosimetry on SBRT (3DCRT) and IMRT treatments (sliding windows).
2. To assess the impact of 2 table tops for these techniques.

### Material and Methods

- Two Clinac 2100 CD (Varian) with the Exact Couch, one with the Exact Couch top (carbon fiber grid) and one with the IGRT Couch top
- EBT3 films+Film QA Pro 2014 Software (Ashland)+EPSON EXPRESSION 10000XL scanner

- QUASAR phantom (Modus Medical)
- MATLAB R2015b software (MathWorks)

### Methods

4 treatment plans with various prescription doses were selected: liver SBRT [3x20Gy], lung SBRT [3x18 Gy], breast IMRT [27x1.85Gy@breast; 27x2.44Gy@boost] and head-and-neck IMRT [33x2.12Gy@high-risk; 33x1.8Gy@medim-risk; 33x1.6Gy@low-risk]. Plans were copied onto the QUASAR phantom. All treatments were planned with 6 MV RX but the liver SBRT that was planned with 15 MV. All plans had 7-11 fields.

Two 6 cmx25.4 EBT3 film strips were attached to the QUASAR phantom along the axial plane. Plans were delivered on two twin linacs with different table tops. All experiments were repeated thrice.

Films were read with FilmQA software. Dose maps were exported and then imported by MATLAB to apply the equivalent depth correction factors (EDCF) to EBT3 films (on areas not having any direct contact with the table top) to get dose at the ICRU skin depth (70 $\mu\text{m}$ ). EDCFs have been determined from measurements made in a previous work [1] using a PTW23392 Extrapolation ion Chamber and measurements made now with EBT3 films. The application of other correction factors was not required as a result of other study presented by the authors at this meeting where EDCFs for EBT3 are also reported.

We compared dose profiles along the middle of the strips for the two table tops.

### Results

Figure 1 shows one example of the dose maps corresponding to the two strips for one session for each plan and table top. The effect of the Exact Couch grid is visible, and it can increase the dose in contact to the grid up to 180%, but doses in contact to the IGRT Couch are much larger (see for example the two bottom subplots scale).

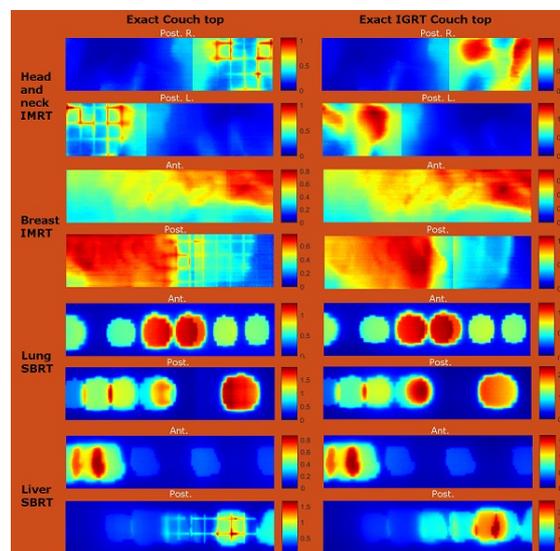

Table I shows the maximum total doses measured on dose profiles along the centre of the strips for the two table tops and the relative increase in dose due to the IGRT couch. For the IGRT couch top there are areas larger than 2 cm with a dose larger than twice the dose measured for the Exact Couch top.

**Table Ia. Maximum total skin dose (Gy) over the whole course of the treatment on a dose profile along the centre of the strip. Mean and standard deviations of three measurements.**

Treatment plan	Dose map	Table top			
		Exact couch top		IGRT couch top	
		Dose	sd	Dose	sd
Head and Neck IMRT	Posterior right	23,4	0,7	<b>35,28</b>	0,2
	Posterior left	23,1	0,7	<b>41,98</b>	0,17
Breast IMRT	Anterior	19,58	0,19	18,3	0,3
	Posterior	19,91	0,17	<b>28,58</b>	0,15
SBRT lung	Anterior	3,73	0,02	3,62	0,02
	Posterior	5,59	0,09	6,85	0,06
SBRT liver	Anterior	5,21	0,13	5,02	0,04
	Posterior	7,1	0,7	11,16	0,12

**Table Ib. Relative increase (I) in skin dose due to the IGRT couch top vs the Exact Couch top on a dose profile along the centre of the strip: Maximum and average values, and size of regions with double dose.**

Treatment plan	Dose map	Max	u(k=2)	Average	Size(I>2)
					(cm)
Head and Neck IMRT	Posterior right	<b>2,8</b>	0,4	1,47	<b>2,8</b>
	Posterior left	<b>2,25</b>	0,12	1,38	<b>4,1</b>
Breast IMRT	Anterior	1,03	0,02	0,95*	-
	Posterior	<b>1,83</b>	0,18	1,27	-
SBRT lung	Anterior	1,9	1,0	0,97*	-
	Posterior	<b>2,7</b>	0,6	1,20	<b>1,6</b>
SBRT liver	Anterior	1,0	0,2	0,94*	-
	Posterior	<b>3,0</b>	0,2	1,41	<b>2,5 &amp; 2,3</b>

\*Average values in anterior dose maps are <1 due to the larger attenuation of the IGRT couch

### Conclusion

- IMRT techniques can deliver skin doses above the threshold for deterministic effects.
  - The main factor affecting skin dose is the table top.
  - The skin dose for the IGRT Couch Top can be the triple than that for the IGRT Couch top.
- This work has been partially financed by the grant *Singulars Projects 2015* of the Spanish Association Against Cancer (AECC).
- [1]Detector comparison for dose measurements in the build-up zone. M.A Duch et al. 3rd ESTRO FORUM. 2015.

### PO-0799 Fast protocol for radiochromic film dosimetry using a cloud computing web application

J.F. Calvo Ortega<sup>1</sup>, M. Pozo-Massó<sup>1</sup>, S. Moragues-Femenía<sup>1</sup>, J. Casals-Farran<sup>1</sup>

<sup>1</sup>Hospital Quiron Barcelona, Radiation Oncology, Barcelona, Spain

### Purpose or Objective

To propose a fast protocol to evaluate plans computed by a treatment planning system (TPS) by using radiochromic film dosimetry.

### Material and Methods

Gafchromic EBT3 films and an Epson V750 Pro scanner were used in this study as dosimetry system. Film dosimetry was conducted using the triple-channel method implemented in a cloud computing application ([www.radiochromic.com](http://www.radiochromic.com)). Batch calibration curve (up to 5 Gy) was obtained using several film pieces that were scanned 24 hours after exposure (24 h-calibration).

So far, radiochromic film dosimetry has been performed in our department for patient specific quality assurance (QA) by scanning the films 24 hours after their irradiation. However, in this study we have investigated the feasibility of a "fast protocol" that enables to obtain measurement results within 1 hour for dose verification. This protocol combines the 24-h calibration and measurements acquired using three film pieces: 1) one is exposed to the clinical plan (verification film); 2) a film piece is homogeneously irradiated to the expected maximum dose of the clinical plan, and 3) an unexposed film piece. The three films are simultaneously digitized in the fast protocol in order to obtain the absolute dose distribution in the verification film.

To evaluate this fast protocol, ten IMRT plans (sites: prostate, breast, brain, lung and head and neck) were delivered onto EBT3 films on a Varian linac. Absolute dose distribution of verification film was derived for each plan

by digitizing simultaneously the three film pieces at 15, 30, 45 minutes and 24 hours after completing irradiation (15 min-protocol, 30 min-protocol, 45 min-protocol, 24 h-protocol, respectively). The four dose distributions obtained for each plan were compared with the calculated one by the TPS (Eclipse v 10.0) to demonstrate the equivalence of results. The comparisons (measured-calculated) were done using a global gamma evaluation (3%/3 mm). Gamma passing rates obtained for 15 min, 30 min and 45 min post-exposure dose maps were compared with those for 24 hours by using a paired t test.

### Results

No significant differences respect to 24 h-protocol were found in the gamma passing rates obtained for films digitized 15 minutes (96.6% vs 96.3%, p= 0.728), 30 minutes (95.6% vs 96.2%, p= 0.640) and 45 min (94.9% vs 96.2%, p= 0.485).

### Conclusion

The 15 min- protocol provides gamma passing rates similar to those that would be obtained if the verification film had been scanned under identical conditions to the calibration films (24 h).

**PO-0800 Log file based performance characterization of a PBS dose delivery system with dose re-computation**  
T.T. Böhlen<sup>1</sup>, R. Dreindl<sup>1</sup>, J. Osorio<sup>1</sup>, G. Kragl<sup>1</sup>, M. Stock<sup>1</sup>  
<sup>1</sup>EBG MedAustron GmbH, Medical Physics, Wiener Neustadt, Austria

### Purpose or Objective

The dose distribution administered by quasi-discrete proton pencil beam scanning (PBS) is controlled via a dose delivery system (DDS). Delivered proton fluences deviate from the planned ones due to limitations of the DDS in precision and accuracy. The delivered particle fluences and resulting dose distributions were evaluated in this study with a special focus on the DDS performance as a function of the number of particles (NP) per spot.

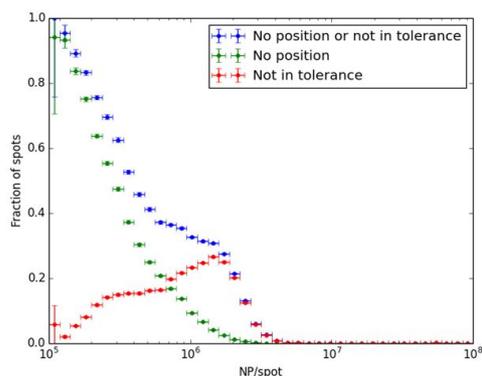

### Material and Methods

Software tools for the DDS performance evaluation based on treatment log files and the re-computation of the corresponding dose distribution in the TPS RayStation (RaySearch Labs, Stockholm) were created. For this purpose, DICOM RT ion plans with the measured spot positions and NP/spot were generated and were imported into the TPS. Re-computing dose for the delivered particle fluences allowed comparing delivered against the planned dose distributions. A set of 95 delivered treatment plans for regular-shaped targets were analysed for this study. The plan set encompassed plans with various spot spacing distances and different values for the allowed minimum NP/spot. Also settings outside the foreseen clinical parameter ranges were included. Notably, a minimum NP/spot of  $1 \times 10^5$  was set for some plans. A configurable DDS spot position tolerance triggers an interlock if spots above a given weight are outside the set tolerance. For low-weighted spots, counts may be so low that the DDS is not able to determine a position.

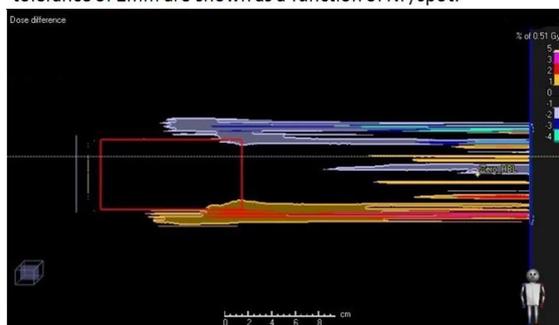

### Results

The DDS performance degrades for lower NP/spot steadily. Figure 1 (left) shows, as a function of NP/spot, the fraction of spots for which no position can be determined and the fraction of spots which are out of a position tolerance of 2mm. For  $NP/spot > 2 \times 10^6$ , a feedback position correction loop improves positioning notably (not shown). Hence, most particles are delivered with a deviation of the spot position smaller than  $\pm 0.1$ mm. For  $NP/spot < 1 \times 10^6$ , a systematic deviation of requested vs delivered particles is observed, up to about 2%. However, contribution of these spots to the total delivered dose is generally small. Figure 1 (right) displays dose differences in % between the planned and delivered dose distributions for a rectangular box irradiated with 0.5Gy. For this plan, a minimum NP/spot constraint of  $0.5 \times 10^6$  was set. Small dose discrepancies were seen specifically for the

penumbra of the proximal end of the SOBP, where NP/spot were generally low and spot position inaccuracies were larger.

The fraction of spots for which no position is determined by the DDS and the fraction of spots which are out of a position tolerance of 2mm are shown as a function of NP/spot.

Dose differences in % between the planned and delivered dose distributions are displayed for a rectangular box (6x6x12cm<sup>3</sup>, shown as red contour) irradiated with 0.5Gy.

#### Conclusion

This study indicates limitations of the DDS used for proton PBS and provides guidance on the selection of adequate treatment planning parameters for clinical application. In particular, it allows choosing an admissible minimum NP/spot which leads to clinically acceptable dose deviations. In future, the established analysis tools may be employed for the analysis of the beam intensity selection, patient-specific log file QA and dose accumulation studies.

#### PO-0801 Benchmarking Gate/Geant4 for oxygen ion beams against experimental data

A. Resch<sup>1</sup>, H. Fuchs<sup>1</sup>, D. Georg<sup>1</sup>

<sup>1</sup>Medizinische Universität Wien Medical University of Vienna, Radiation Oncology, Vienna, Austria

#### Purpose or Objective

Oxygen ions are a promising alternative to carbon ion beams in particle beam therapy due to their enhanced linear energy transfer, which is expected to yield a higher relative biological effectiveness and a reduced oxygen enhancement ratio. In order to facilitate research on oxygen ion beams using Monte Carlo (MC) simulation under well-defined conditions, a benchmark against the existing experimental data was performed.

#### Material and Methods

Several available physical models in Geant4 (version 10.2.p01) were benchmarked using the GATE (version 7.2) environment. The nuclear models recommended for radiation therapy such as the quantum molecular dynamics model (QMD) or the binary cascade model (BIC) were investigated. Integrated depth dose (IDD) distributions of three energies (117, 300 and 430 MeV/u) measured at Heidelberg Ion-Beam Therapy Center (HIT) and partial charge changing cross sections measured at

Gesellschaft für Schwerionenforschung (GSI) were used as reference data.

#### Results

For all physics lists, the relative dose differences up to the Bragg peak were found to be less than 4% compared to measurements. Beyond the Bragg peak, in the so-called fragmentation tail, differences increased notably, by up to one order of magnitude. However, the absolute dose difference in the fragmentation tail was comparable to the absolute difference before the Bragg peak. The QMD model systematically overestimated whereas the other models underestimated the dose in the fragmentation tail. Overall, deviations to the measurement were less than 2% of the maximum dose for all models, disregarding the dose fall off region due to the steep dose gradient. Partial charge changing cross sections simulated with the BIC, BERT and QBBC models deviated up to 60% from the measurements, INCLXX up to 38% and the QMD model up to 24%. However, the significance on fragmentation in particle therapy is limited by the high energy equal to 630 MeV/u used in the measurements.

#### Conclusion

IDDs simulated with Gate/Geant4 agreed well with measurements for all models under investigation, although notable deviations were observed in the fragmentation tail. Measured partial charge changing cross sections could best be reproduced using the QMD model, whereas the BIC model showed considerable discrepancies. Therefore, Gate/Geant4 can be considered a valid dose calculation tool for oxygen ion beams and will further on be used for the development of a pencil beam algorithm for oxygen ions. The QMD model is recommended in order to obtain accurate fragmentation results, which is essential for radiation oncology purposes.

#### PO-0802 Experimental validation of single detector proton radiography with scanning beams

C. Chirvase<sup>1</sup>, K. Teo<sup>2</sup>, R. Barlow<sup>1</sup>, E.H. Bentefour<sup>3</sup>

<sup>1</sup>International Institute for Accelerator Applications, The University of Huddersfield, Huddersfield, United Kingdom

<sup>2</sup>University of Pennsylvania, Department of Radiation Oncology, Philadelphia PA, USA

<sup>3</sup>Advanced Technology Group, Ion Beam Applications s.a., Louvain-la-Neuve, Belgium

#### Purpose or Objective

Proton radiography represents a potential solution to solve the uncertainties of dose delivery in proton therapy. It can be used for in-vivo beam range verification; patient specific Hounsfield unit (HU) to relative stopping power calibration and improving patient set-up. The purpose of this study is to experimentally validate the concept of the energy resolved dose measurement for proton radiography using a single detector with Pencil Beam Scanning (PBS).

#### Material and Methods

A 45 layers imaging field with a size of 30 x 30 cm<sup>2</sup> and energies between 226 MeV and 115 MeV is used to deliver a uniform dose. The dose per spot is 4.25 mGy with spot spacing equal to the beam sigma. The imaging field is first delivered on wedge shaped water phantom to produce calibration library of Energy Resolved Dose Functions (ERDF) between 0 cm and 30 cm. Then, the same imaging field is delivered in three different configurations: a stack of solid water in a stairs shape with thicknesses between 1 mm and 10 mm - that determines the accuracy with which the WEPL (water-equivalent path length) can be retrieved, CIRS lung phantom - that illustrates the accuracy on the density of multiple materials and a head phantom - which represents a realistic case of heterogeneous target.

As shown in Figure 1, proton radiographs are recorded with a commercial 2D detector (Lynx, IBA-Dosimetry, Schwarzenbruck, Germany) which has an active area of 300 x 300 mm<sup>2</sup> with an effective resolution of 0.5 mm.

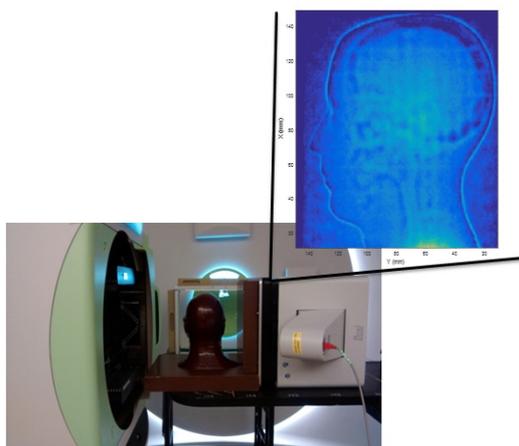

Figure 1. Experimental set-up with an example of proton radiograph imaged at beam energy of 220 MeV.

### Results

In this study we demonstrate the robustness of the energy resolved dose measurement method for single detector proton imaging. It shows the capability to determine the WEPL with sub-millimeter accuracy in a homogeneous target and performs well in heterogeneous target, proving an accuracy better than 2 mm even in most heterogeneous areas of a head phantom. These performances are achieved by using an imaging field with as little as 5 energy layers with spacing up to 10 mm between the layers.

Although the optimization of the imaging dose was not a goal of this study, only  $\sim 21$  mGy per  $\text{cm}^2$  is sufficient to obtain the above accuracies. This dose can be further decreased by using a detector with higher sensitivity and by reducing the number of beam spots per layer of the imaging field.

### Conclusion

Proton radiography with single detector using energy resolved dose measurement did show potential for clinical use. Further studies are needed to optimize the imaging dose and the clinical workflow.

### PO-0803 CloudMC, a Cloud Computing application for fast Monte Carlo treatment verification

H. Miras<sup>1</sup>, R. Jiménez<sup>2</sup>, R. Arrans<sup>1</sup>, A. Perales<sup>3</sup>, M. Cortés-Giraldo<sup>3</sup>, A. Ortiz<sup>1</sup>, J. Macías<sup>1</sup>

<sup>1</sup>Hospital Universitario Virgen Macarena, Medical Physics, Sevilla, Spain

<sup>2</sup>Icinec TIC SL, R&D division, Sevilla, Spain

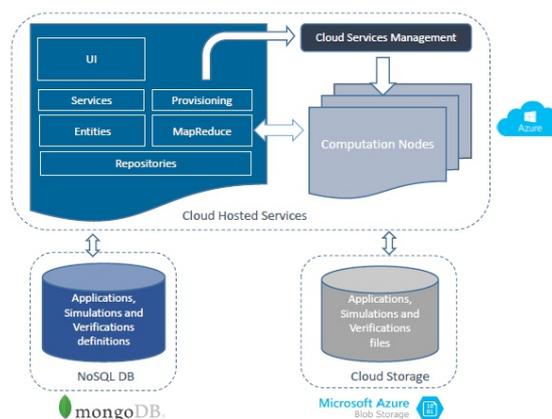

<sup>3</sup>Universidad de Sevilla, Atomic- Molecular and Nuclear Physics Department, Sevilla, Spain

### Purpose or Objective

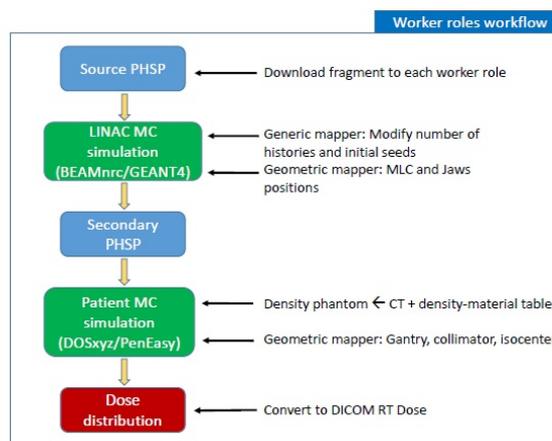

CloudMC is a cloud-based solution developed for reducing time of Monte Carlo (MC) simulations through parallelization in multiple virtual computing nodes in the Microsoft's cloud. This work presents an update for performing MC calculation of complete RT treatments in an easy, fast and cheap way.

### Material and Methods

The application CloudMC, presented in previous works, has been updated with a solution for automatically perform MC treatment verification. CloudMC architecture (figure 1) is divided into two units. The processing unit consists of a web role that hosts the user interface and is responsible of provisioning the computing worker roles pool, where the tasks are distributed and executed, and a reducer worker role that merges the outputs. The storage unit contains the user files, a data base with the users and simulations metadata and a system of message queues to maintain asynchronous communication between the front-end and the back-end of the application.

CloudMC is presented as a web application. Through the user interface it is possible to create/edit/configure a LINAC model, consisting of a set of files/programs for the LINAC simulation and the parametrization of the input and output simulation files for the map/reduce tasks. Then, to perform a MC verification of a RT treatment, the only input needed is the set of CT images, the RT plan and the corresponding dose distribution obtained from the TPS. CloudMC implements a set of classes based on the standard DICOM format that read the information contained in these files, create the density phantom from the CT images and modify the input files of the MC programs with the corresponding geometric configuration of each beam/control point.

A LINAC model has been created in CloudMC for the two LINACs existing in our institution. For the PRIMUS model BEAMnrc is used to generate a secondary phase space, which is read by DOSxyz to obtain the dose distribution in the patient density phantom. For the ONCOR model, a specific GEANT4 program and PenEasy have been used instead. In figure 2 the workflow in each worker role is described.

### Results

IMRT step&shoot treatments from our institution are selected for the MC treatment verification with CloudMC. They are launched with  $2 \cdot 10^9$  histories, which produce an uncertainty  $< 1.5\%$  in a  $2 \times 2 \times 5$  mm<sup>3</sup> phantom, in 200 medium-size worker roles (RAM 3.5GB, 2 cores). The total computing time is 30-40 min (equivalent to 100 h in a single CPU) and the associated cost is about 10 €.

### Conclusion

Cloud Computing technology can be used to overcome the major drawbacks associated to the use of MC algorithms for RT calculations. Just through an internet connection it is possible to access an almost limitless computation

power without the need of installing/maintaining any hardware nor software.

CloudMC has been proved to be a feasible solution for performing MC verifications of RT treatments and it is a first step towards achieving the ultimate goal of planning a full-MC treatment a reality for everyone.

#### PO-0804 Relative dosimetry evaluation for small multileaf collimator fields on a TrueBeam linear accelerator

T. Younes<sup>1,2,3</sup>, S. Beilla<sup>1</sup>, L. Simon<sup>1,3</sup>, G. Fares<sup>2</sup>, L. Vieilleveigne<sup>1,3</sup>

<sup>1</sup>Centre de Recherche et de Cancérologie de Toulouse - UMR1037 INSERM - Université Toulouse 3 - ERL5294 CNRS, 2 avenue Hubert Curien - Oncopole de Toulouse, 31037 Toulouse Cedex 1 - France, France

<sup>2</sup>Université Saint-Joseph de Beyrouth - Faculté des sciences - Campus des sciences et technologies, Mar Roukos, Dekwaneh, Lebanon

<sup>3</sup>Institut Universitaire du Cancer de Toulouse Oncopole, 1 avenue Irène Joliot Curie, 31059 Toulouse Cedex 9, France

#### Purpose or Objective

The aim of our study was to compare the performance of the PTW microdiamond detector 60019 and the E Diode 60017 in homogeneous media to MC calculations for small MLC fields. Two dosimetric algorithms: Acuros XB (AXB) and Analytical Anisotropic Algorithm (AAA) were also evaluated for these cases.

#### Material and Methods

The True Beam linear accelerator STx equipped with a HD120 MLC was accurately modelled with Geant4 application for emission tomography (GATE) platform using the confidential data package provided by Varian<sup>1</sup>. Its corresponding validation was carried out using measurement of depth dose profile (PDD), lateral dose profiles and output factors for 6FF and 6FFF static fields ranging from 5x5cm<sup>2</sup> to 20x20cm<sup>2</sup>. Small MLC fields ranging from 0.5x0.5 cm<sup>2</sup> to 3x3 cm<sup>2</sup> were used for this part of study. The jaws were positioned at 3x3 cm<sup>2</sup> for MLC fields less than 2x2 cm<sup>2</sup> and 5x5 cm<sup>2</sup> for the rest. Measurements, corresponding to these configurations, were performed in a water phantom at a source surface distance of 95 cm using microdiamond and E diode detectors. The dosimetric accuracy of the detectors and the dosimetric algorithms were compared against MC calculations that were considered as a benchmark.

#### Results

Profiles measurements and calculations gave similar penumbras for both detectors and algorithms considering a source spot size of 0 for AAA and 1mm for AXB. Even though microdiamond detector should be less adapted for profile measurements due to the volume averaging effect that is more important than the E diode considering its geometry. Significant differences were observed between measured and calculated PDD for field size under 2x2 cm<sup>2</sup>. The differences in the build-up region between MC and microdiamond detector for the MLC 0.5x0.5 cm<sup>2</sup> field were up to 5.8% and up to 5.6% at 15.5 cm depth. For the MLC 1x1 cm<sup>2</sup> field, smaller differences of 4.3% and 3.6% were observed in the build-up region and at 20.5 cm depth, respectively. The deviations between E diode and MC in the build-up region were up to 4.9% and up to 9.7% at 25 cm depth for a 0.5x0.5 cm<sup>2</sup> field size. Lower deviations of 3.5% and 4.7% were found for the 1x1 cm<sup>2</sup> field size in the build up region and at 20 cm depth, respectively. As for AXB and AAA algorithms, for the 0.5x0.5 cm<sup>2</sup> field size, differences were up to 1.8% and 2% in the build-up region, respectively. For higher depth differences were up to 3.8% and 3.7% for AXB and AAA calculations, respectively.

#### Conclusion

Our study showed that the microdiamond is less sensitive to dose rate dependence and is more accurate than E

Diode for PDD measurements. Correction factors should necessarily be applied for both detectors and calculation algorithms in homogenous medium for fields under 2x2 cm<sup>2</sup>. Further studies on the output factor correction factors are ongoing.

#### PO-0805 Commissioning of the new Monte Carlo algorithm SciMoCa for a VersaHD LINAC

W. Lechner<sup>1</sup>, H. Fuch<sup>1</sup>, D. Georg<sup>1</sup>

<sup>1</sup>Medizinische Universität Wien Medical University of Vienna, Department of Radiotherapy and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

#### Purpose or Objective

To validate the dose calculation accuracy of the Monte Carlo algorithm SciMoCa (ScientificRT GmbH, Munich, Germany) for a VersaHD (Elekta AB, Stockholm, Sweden) linear accelerator. SciMoCa is a recently developed Server/Client based Monte Carlo algorithm, which provides fast and accurate dose calculation for various applications, e.g. independent dose assessment of 3D-CRT, IMRT and VMAT treatment plans or general research purposes.

#### Material and Methods

A beam model of a 6 MV flattened beam provided by a VersaHD was used to calculate the dose distribution of square fields in a virtual 40 x 40 x 40 cm<sup>3</sup> water block. The investigated field sizes ranged from 1 x 1 cm<sup>2</sup> to 40 x 40 cm<sup>2</sup>. For the acquisition of percentage depth dose profiles (PDDs) and for output factor measurements, a PTW Semiflex 31010 was used for field sizes down to 3 x 3 cm<sup>2</sup> and a PTW DiodeE as well as a PTW microDiamond were used for field sizes ranging from 1 x 1 cm<sup>2</sup> to 10 x 10 cm<sup>2</sup>. The measured output factors were corrected for small field effects where necessary. The lateral profiles of all fields were acquired using a PTW DiodeP at depths of d<sub>max</sub>, 5 cm, 10 cm, 20 cm and 30 cm, respectively. A calculation grid size of 2 mm and a Monte Carlo variance of 0.5% were used for the calculations. PDDs and lateral profiles were extracted from the calculated dose cube. These calculated dose profiles were re-sampled to a grid size of 1 mm and compared to previously measured depth dose and lateral profiles using gamma index analysis with a 1 mm/1% acceptance criteria. The mean values of  $\gamma$  indices ( $\gamma_{\text{mean}}$ ) as well as the relative difference of measured output factors (OF<sub>meas</sub>) and calculated output factors (OF<sub>calc</sub>) were used for the evaluation of the calculation accuracy.

#### Results

Table 1 summarizes the results of the gamma analysis of each investigated field as mean and standard deviation for each field. The mean values of  $\gamma_{\text{mean}}$  and the standard deviation of the mean increased with increasing field size. Figure 1 depicts the distribution of  $\gamma_{\text{mean}}$  values with respect to profile type, field size and measurement depth. The majority of  $\gamma_{\text{mean}}$  values were well below 1. The highest  $\gamma_{\text{mean}}$  values were found for the 40 x 40 cm<sup>2</sup> field and for larger measurement depths. The high  $\gamma_{\text{mean}}$  of the 40 x 40 cm<sup>2</sup> field were attributed to the size of the digital water phantom. The  $\gamma_{\text{mean}}$  values of the all PDDs were below 0.5 for all field sizes. The calculated and measured output factors agreed within 1% for field sizes larger and 1 x 1 cm<sup>2</sup>. For the 1 x 1 cm<sup>2</sup> the difference between measured and calculated output factors was 1.5%.

Table 1 Summary of the gamma analysis and output factors for each field

Field size cm <sup>2</sup>	mean( $\gamma_{\text{mean}}$ )	std( $\gamma_{\text{mean}}$ )	OF calc	OF meas	difference
1 x 1	0.28	0.09	0.675	0.665	1.5%
2 x 2	0.31	0.09	0.807	0.801	0.8%
3 x 3	0.30	0.11	0.839	0.844	-0.6%
4 x 4	0.29	0.07	0.880	0.879	0.1%
5 x 5	0.32	0.10	0.908	0.905	0.3%
8 x 8	0.39	0.08	0.967	0.970	-0.3%
10 x 10	0.40	0.15	1.000	1.000	0.0%
15 x 15	0.47	0.18	1.059	1.058	0.1%
20 x 20	0.49	0.28	1.095	1.097	-0.2%
30 x 30	0.39	0.12	1.140	1.144	-0.4%
40 x 40	0.77	0.68	1.172	1.164	0.8%

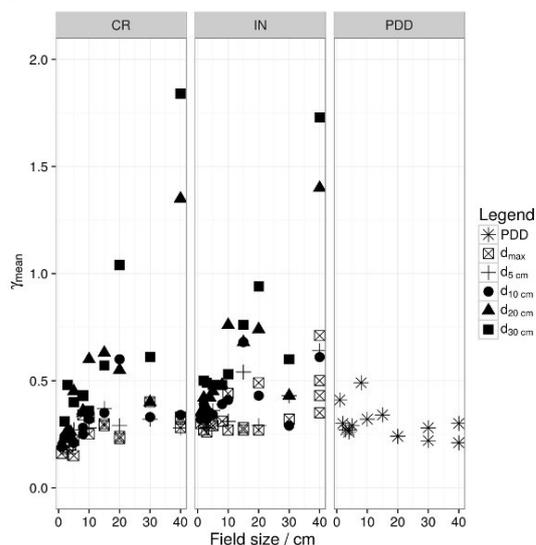

Fig 1  $\gamma_{\text{mean}}$  values of all profiles and measurement depths.  
Abbr.: CR... cross line profile, IN... in line profile,  
PDD... percentage depth dose

## Conclusion

The investigated beam model showed excellent agreement with measured data over a wide range of field sizes and measurement depths with improved agreement for small field sizes. These commissioning results are a solid basis for ongoing investigations focusing on more complex treatment types such as IMRT and VMAT and heterogeneous phantoms.

## PO-0806 Dosimetric end-to-end test procedures using alanine dosimetry in scanned proton beam therapy

A. Carlino<sup>1,2</sup>, H. Palmans<sup>1,3</sup>, G. Kragl<sup>1</sup>, E. Traneus<sup>4</sup>, C. Gouldstone<sup>3</sup>, S. Vatrnsky<sup>1</sup>, M. Stock<sup>1</sup>

<sup>1</sup>EBG MedAustron GmbH, Medical Physics, Wiener Neustadt, Austria

<sup>2</sup>University of Palermo, Department of Physics and Chemistry, Palermo, Italy

<sup>3</sup>National Physical Laboratory, Radiation dosimetry, Teddington, United Kingdom

<sup>4</sup>Raysearch

laboratories AB, Particle therapy, Stockholm, Sweden

## Purpose or Objective

At MedAustron (MA) a quasi-discrete scanning beam delivery with protons has been established. The clinical implementation of this technology requires comprehensive end-to-end testing to ensure an accurate patient treatment process. The purpose of such end-to-end testing is to confirm that the entire logistic chain of the radiation treatment, starting from CT imaging, treatment planning, patient positioning, monitor calibration and beam delivery is operable and leads to the dose delivery within a pre-defined tolerance. We present

dosimetric end-to-end procedures for protons based on customized anthropomorphic phantoms and different dosimetric techniques.

## Material and Methods

A homogeneous polystyrene phantom and two anthropomorphic phantoms (pelvis and head phantom) have been customized to allocate different detectors such as radiochromic films, ionization chambers and alanine pellets. During testing, the phantoms were moving through the workflow as real patients to simulate the entire clinical procedure. The CT scans were acquired with pre-defined scan protocols used at MA for cranial and pelvic treatments. All treatment planning steps were performed with RayStation v5.0.2 treatment planning system (TPS). A physical dose of 10 Gy was planned to clinically shaped target volumes in order to achieve uniformity better than 0.5% on the dose delivered to the alanine pellets. In the treatment room the plans were delivered to the phantoms loaded either with alanine pellets and radiochromic EBT3 films (figure 1) or two Farmer chambers. The alanine pellets (5.0 mm diameter and 2.3 mm thickness) and their read-out were provided by the National Physical Laboratory (NPL). One of the challenges of alanine for dosimetry in particle beams is the known response dependency (quenching) on the charge, the fluence and the energy of the particles constituting the mixed radiation field. Corrections for this were derived by a Monte Carlo dose calculation platform implemented in a non-clinical version of RayStation.

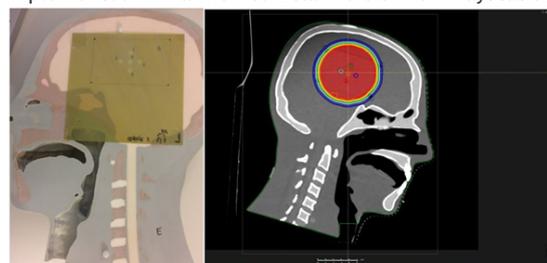

Figure 1: end-to-end test procedure with the head phantom. Top left: the loading of the phantom with alanine pellets and EBT3 films. Top right: the treatment plan preparation in RayStation v5.0. Bottom: the positioning and irradiation with an actively scanned proton beams.

## Results

The measured absolute dose to water obtained with the Farmer chamber in all delivered plans was within 2% of the TPS calculated dose. A lateral 2D homogeneity of 3% inside the treatment field was measured with EBT films. Doses determined with the alanine pellets after correction for the quenching effect showed a mean deviation within 3% and a maximum deviation below 7% in the homogeneous and anthropomorphic phantoms.

## Conclusion

The end-to-end test procedures developed at MedAustron showed that the entire chain of radiation treatment works efficiently and with accurate dosimetric results. Our experience shows that alanine pellets are suitable detectors for dosimetry audits and developed procedures can be used to support implementation of scanning beam delivery technology in clinical practice

### PO-0807 Practical advantages of a transmission chamber in relative dosimetry of Brainlab conical applicators

B. Tang<sup>1</sup>, J. Li<sup>1</sup>, S. Kang<sup>1</sup>, P. WANG<sup>1</sup>, L.C. Orlandini<sup>1</sup>  
<sup>1</sup>Sichuan Cancer Hospital, Radiation Oncology, Chengdu, China

#### Purpose or Objective

The commissioning of a radiosurgery unit requires the acquisition of specific detectors able to characterize the geometry and dosimetry of small fields. The acquisition of the equipment for absolute dosimetry remains the priority for the Hospitals, considering that relative measurements can be performed without a reference chamber using long acquisition time. The commissioning results therefore in a tedious procedure. In this study, a new transmission chamber (Stealth Chamber, IBA Dosimetry) was used as a reference chamber (RC) in relative dosimetry of Brainlab cone applicators. The timing of the practical procedure and dosimetry results with and without the reference chamber, will be analyzed and compared.

#### Material and Methods

IBA SFD3G diode detector was used to measure the 6MV photon beam of a Varian Novalis used with Brainlab cone applicators. Inline and crossline profiles at different depths and central axis depths doses (PDDs) were measured with a motorized water phantom (Blue phantom, IBA Dosimetry) and OmniPro v7.4 software for every cone. The measurements were acquired with the transmission reference chamber positioned on the gantry head in a continuous mode and without RC in a step by step mode. The details of the acquisition parameters were reported in Table 1. The total measurements time for each procedure was registered.

**Table 1** The Acquisition parameters with and without stealth chamber

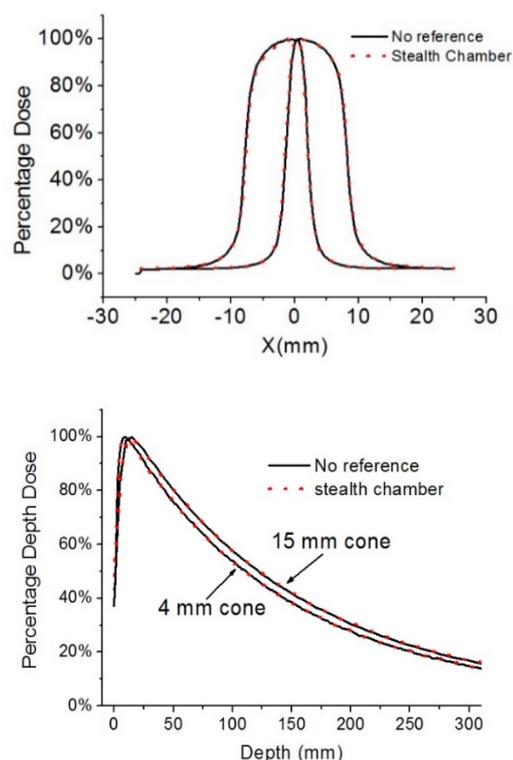

Acquisition parameters/method	No reference	Stealth Chamber
Scan mode	step by step	continuous
Scan speed	-	5 mm/s
In-scan positioning speed	5 mm/s	-
Positioning speed	10 mm/s	10 mm/s
Acquisition time	5 s	-
Stabilization time	1 s	0.08 s

#### Results

Profiles at depth 10 cm for 4/15 mm diameter cones and the depth doses acquired with the two procedures (Figure 1&Figure 2) shown a good agreement. The total measurement time registered was 490 seconds for the PDDs acquisition without RC and only 64 seconds when the scan mode change from "step by step" to "continuous" after stealth chamber was in place. The overall measurement time for 4mm diameter was 575 s and 12 s without and with RC respectively, 735 s and 17 s for the 15 mm diameter cone.

Figure 1

Figure 2

#### Conclusion

Traditionally, there is no way of applying a reference detector when measuring small fields, especially for SRS Brainlab conical collimators. The lack of reference signal usually requires to acquire more signals in each measured point to suppress the linac output fluctuation, which results into a long measurement procedure. However, by the introduction of stealth chamber, "continuous mode" became available to us which substantially shorten the measurement time while a good agreement between measurements with and without stealth chamber for both PDDs and Profiles was still reached. The use of stealth chamber is a good solution to spare time during small field dosimetry measurements. This aspect is important during the commissioning of the stereotactic unit but it becomes fundamental for the frequently quality control performed.

### PO-0808 Comparison of multi-institutional QA for VMAT of Nasopharynx with simulated delivery errors

D.I. Thwaites<sup>1</sup>, E.M. Pogson<sup>1</sup>, S. Arumugam<sup>2</sup>, C.R. Hansen<sup>3</sup>, M. Currie<sup>4</sup>, S. Blake<sup>1</sup>, N. Roberts<sup>5</sup>, M. Carolan<sup>4</sup>, P. Vial<sup>2</sup>, J. Juresic<sup>2</sup>, C. Ochoa<sup>2</sup>, J. Yakobi<sup>2</sup>, A. Haman<sup>2</sup>, A. Trtovac<sup>2</sup>, T. Al-Harhi<sup>1</sup>, L. Holloway<sup>2</sup>

<sup>1</sup>University of Sydney, Institute of Medical Physics-School of Physics, Camperdown, Australia

<sup>2</sup>Liverpool and Macarthur Cancer Treatment Centres, Medical Physics-Radiation Oncology, Liverpool, Australia

<sup>3</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

<sup>4</sup>Illawarra Cancer Care Centre, Medical Physics - Radiation Oncology, Wollongong, Australia

<sup>5</sup>University of Wollongong, Centre of Medical Radiation Physics, Wollongong, Australia

#### Purpose or Objective

Quality assurance of individual treatment plans is often performed using phantom measurement and analysing acceptable delivery accuracy by gamma analysis with a required pass rate. Simplifying a complex treatment plan and measurement into a single number is problematic. This study evaluates the sensitivity of

different equipment to simulated machine errors and explores the role of different planning approaches to this **Material and Methods**

VMAT plans were generated for a selected patient in Pinnacle<sup>3</sup> at three institutions, as per their local protocol. An automated VMAT plan was also generated by institution 3 using Pinnacle<sup>3</sup> Autoplanning. Simulated machine errors were deliberately introduced to the plans utilising Python. These included collimator (°), MLC field size (mm) and MLC shift (mm) errors of 5, 2, 1, -1, -2 and -5 units. Error-introduced plans were then recalculated and reviewed. The DVH metrics listed in Table 1 were deemed unacceptable if their differences relative to the relevant baseline plan were above the tolerances listed. Plans were considered unacceptable if any one or more of the limits were exceeded.

Structure and Metric	Limit
PTV1, PTV2, PTV3 - D95%	±5% deviation
Brainstem - D1cc	±5% deviation
Spinal Cord - D1cc	±5% deviation
Parotids (left and right) - D <sub>mean</sub>	±10% deviation

Table 1. DVH metrics and limits.

For each error type (i.e. in Collimator, C; MLC shift, S; MLC Field Size, FS), the smallest error plans that were deemed unacceptable were delivered within the given institution; on an Elekta Linac, measured using an Arccheck for institutions 1 and 3, and on a Varian Linac, measured using a Delta4 for institution 2. Gamma analysis was performed in SNC Patient version 6.6 or Delta4 software respectively, utilising a 3%/3mm and 2%/2mm global gamma pass rate (10% isodose threshold with correction off). Before each set of measurements, MLC checks and a complex benchmark patient test were used to ensure the Linacs' performances were within normal range.

#### Results

The global 3%/3mm gamma pass is able to detect the majority of unacceptable plans; however some plans with significant errors still pass. Interestingly the error type/s that passed differed at differing institutions (Figure 1).

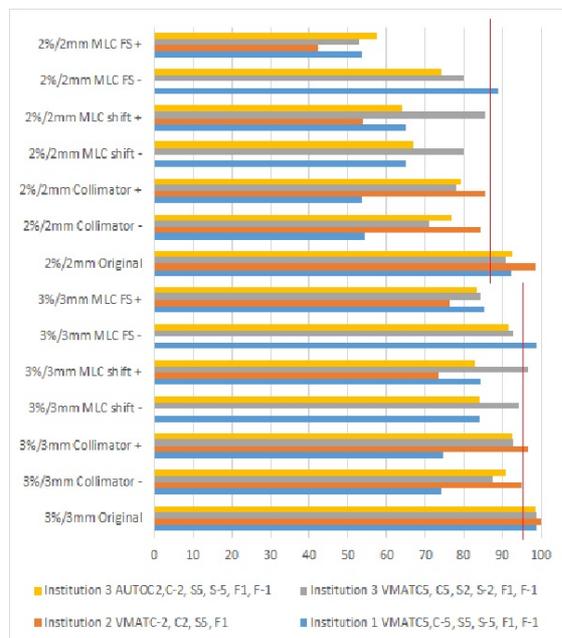

Figure 1. The smallest error plans (including Collimator (C), MLC shift (S), and MLC Field Size (FS) error) which exceeded global gamma pass rates. Errors detected if the gamma pass rate was <math>< 95\%</math> (for 3%/3mm) or <math>< 88\%</math> (2%/2mm). Plans that passed are illustrated above the red

lines. Negative MLC errors were not performed at Institution 2, due to differing equipment.

The automated VMAT plans from institution 3 were similar in pass rate to the manually planned VMAT for collimator errors, despite the difference (higher magnitude for manual VMAT plans) in error magnitude. This could be caused by the higher MLC modulation in the automated plans.

#### Conclusion

Not all deliberately introduced errors were discovered for VMAT plans using a typical 3%/3mm global gamma pass rate (for 10% threshold with correction off). Consistency between institutions was low for plans assessed utilising differing devices and software. A 2%/2mm global analysis was most sensitive to errors.

#### PO-0809 A 3D polymer gel dosimeter coupled to a patient-specific anthropomorphic phantom for proton therapy

M. Hillbrand<sup>1</sup>, G. Landry<sup>2</sup>, G. Dedes<sup>2</sup>, E.P. Pappas<sup>3</sup>, G. Kalaitzakis<sup>4</sup>, C. Kurz<sup>2</sup>, F. Dörringer<sup>2</sup>, K. Kaiser<sup>2</sup>, M. Würll<sup>2</sup>, F. Englbrecht<sup>2</sup>, O. Dietrich<sup>5</sup>, D. Makris<sup>3</sup>, E. Pappas<sup>6</sup>, K. Parodi<sup>2</sup>

<sup>1</sup>Rinecker Proton Therapy Center, Medical Physics, Munich, Germany

<sup>2</sup>Ludwig-Maximilians-Universität München, Department of Medical Physics, Munich, Germany

<sup>3</sup>National and Kapodistrian University of Athens, Medical Physics Laboratory- Medical School, Athens, Greece

<sup>4</sup>University of Crete, Department of Medical Physics, Heraklion, Greece

<sup>5</sup>Ludwig-Maximilians-Universität München, Department of Radiology, Munich, Germany

<sup>6</sup>Technological Educational Institute, Radiology & Radiotherapy Department, Athens, Greece

#### Purpose or Objective

The high conformity of proton therapy (PT) dose distributions, attributed to protons stopping in the target, is also the main source of uncertainty of the modality. PT is sensitive to errors in relative stopping power to water (RSP) uncertainties and to density changes caused by organ motion. The ability to verify PT dose distributions in 3D with a high resolution is therefore a key component of a safe and effective PT program. Existing 2D dosimetric methods suffer from shortcomings attributed to LET dependence, positioning uncertainties, limited spatial resolution and their intrinsic 2D nature. Recent advances in polymer gel dosimetry coupled to 3D printing technology have enabled the production of high resolution, patient specific dosimetry phantoms. So far this approach has not been tested for PT.

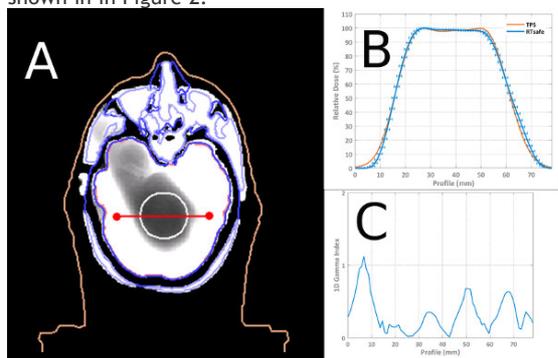

#### Material and Methods

A 3D-printed hollow head phantom derived from real CT data was filled with VIPAR6 polymer gel and CT scanned for pencil beam scanning (PBS) treatment planning, following RSP characterization of the gel and the 3D printer bone mimicking material (see Figure 1). All irradiations of phantoms were carried out at the Rinecker Proton Therapy Center in Munich, which is dedicated for PBS. An anterior oblique SFUD plan was used to cover a centrally located cerebral PTV, following the standard operating procedures of the PT facility. The field was crossing the paranasal sinuses (see Figure 2A) to test the TPS modelling of heterogeneities. 3D maps of the T2 relaxation time were obtained from subsequent MR scanning of the phantom and were converted to relative dose. The dose response linearity and proton range were verified using separate mono-energetic irradiations of cubic phantoms filled with gel from the same batch. Relative dose distributions were compared to the TPS predictions using gamma analysis.

**Figure 1.** 3D printed patient-specific head phantom filled with dosimetric gel during the treatment planning process. **Results**

Results from mono-energetic irradiation of the cubic phantoms showed proton range agreement to the TPS within 1 mm for 90 MeV and 115 MeV, supporting the SPR gel characterization accuracy. Dose-response linearity was confirmed for the delivered dose range, except at the Bragg peak position where a LET dependence was revealed. Gamma index and relative dose distribution profiles showed good agreement between TPS and gel, as shown in in Figure 2.

**Figure 2.** (A) Slice of the 3D SFUD dose distribution converted from a T2 relaxation map obtained from MR scanning

the irradiated 3D printed head phantom filled with polymer gel. The PTV is indicated in white. (B) Gel (RTsafe) and TPS

dose profiles along the path marked in red in (A). (C) 3%/2mm gamma index along the profile. **Conclusion**

In this work we have shown that patient-specific 3D polymer gel dosimetry is applicable to PT using PBS. Further characterization and correction of the LET dependence and comparison to MC dose calculations will be carried out and presented.

**Acknowledgements:** DFG-MAP

#### PO-0810 Absolute dose pre-treatment Portal Dosimetry using the Varian MAASTRO implementation

A. Taborda<sup>1</sup>, J. Stroom<sup>1</sup>, C. Baltes<sup>2</sup>, A. Seabra<sup>1</sup>, K. Dikaiou<sup>2</sup>, C. Greco<sup>1</sup>

<sup>1</sup>Champalimaud Centre for the Unknown, Clinical Department, Lisboa, Portugal

<sup>2</sup>Varian Medical Systems, Varian Medical Systems Imaging Laboratory, Baden-Dättwil, Switzerland

#### Purpose or Objective

Current clinical portal dosimetry from Varian evaluates dose using calibrated units (CU). This work assesses the quality of the first Varian implementation of the MAASTRO algorithm for pre-treatment absolute portal dosimetry (in Gy) of 6X-FF fields.

#### Material and Methods

To achieve the proposed goal, a comparison was made between the gamma analysis results obtained using both Varian's clinical portal dosimetry (PDIP v10.0.28) and the MAASTRO algorithm [1] implementation made available for the authors in the Portal Dosimetry (PD) application accessible through the Varian Citrix Research Environment (CRE). For this study, 10 breast IMRT breast plans and 10 VMAT prostate plans were chosen from the patients' database. In total, 71 IMRT fields and 40 VMAT arcs were compiled for analysis. Each plan was recalculated with gantry zero on a water-equivalent slab phantom, for later comparison of absolute dose at 5cm depth. Verification plans were created for irradiation with 6X-FF beams at the Varian Edge LINAC in order to measure the doses at the Electronic Portal Imaging Device (EPID) level. For each field/arc, the measured doses and the calculated doses were compared by gamma analysis in CU for PDIP and in absolute dose values (Gy) for the PD system on the CRE. [1] Nijsten SM et al, 'A global calibration model for a-Si EPIDs used for transit dosimetry', Med. Phys. 34(10): 3872-84, 2007

#### Results

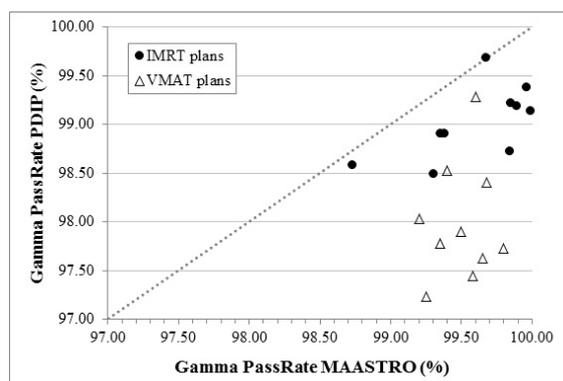

Table 1 presents the summary of the gamma analysis results obtained in the comparison between the measured dose at the EPID and the calculated dose using the MAASTRO algorithm implementation and PDIP. The results show that the analyzed IMRT plans using the MAASTRO algorithm obtained, on average, a higher gamma pass rate, lower mean gamma values and lower dose differences than while using PDIP. The same is observed for VMAT plans. Figure 1 shows the graphical comparison between the gamma passing rate obtained using the MAASTRO algorithm and PDIP, where the black circles represent the comparison of the gamma passing rates for IMRT plans (averaged over all beams) and the open triangles represent the comparison of the gamma passing rates for VMAT plans (averaged over all arcs). One can see that the gamma pass rate obtained using the MAASTRO algorithm is consistently higher than the one obtained using PDIP.

IMRT plans		Gamma (3.0%, 3.0 mm), Threshold: 10%					
Patient plan	Number of fields	MAASTRO (Gy)			PDIP (CU)		
		g-avg	g<1%	ΔDmax (Gy)	g-avg	g<1%	ΔDmax (CU)
1	6	0.22	99.30	0.17	0.26	98.50	28.24

1

### Conclusion

It is shown that the MAASTRO algorithm implementation for gamma analysis based on absolute dose comparison is reliable and provides very good results for both types of plans tested. When compared with the results obtained with PDIP v10.0.28, the MAASTRO algorithm presents at least as good results for the pre-treatment portal dosimetry as the currently available PDIP, while reporting absolute dose results, making it a viable, and even desirable, alternative.

### PO-0811 Monte Carlo simulation of peripheral dose for Gamma Knife treatments

B. Sanchez-Nieto<sup>1</sup>, E. Doerner<sup>1</sup>, A.M. Cardona<sup>1</sup>, F. Bova<sup>2</sup>  
<sup>1</sup>Pontificia U-dad Catolica de Chile, Institute of Physics, Santiago, Chile

<sup>2</sup>Gamma knife Chile, Radiotherapy, Santiago, Chile

### Purpose or Objective

Induction of second cancers after external beam radiotherapy (RT) is associated to the dose deposited outside the treatment field (Peripheral Dose -PD) [1]. New advances in radiation oncology have increased the survival of patients beyond the period of latency of the occurrence of secondary cancer (> 5 years), so that the estimation of PDs has become particularly relevant. Commercial treatment planning systems present a great uncertainty in the dose calculation outside the treatment field (differences up to 50%) [2]; therefore, alternative methodologies for estimation of PD to radiosensitive organs are needed. There are previous studies [3,4] applicable to external RT with linear accelerators. However, no such a model exists for Gamma Knife. The aim of this study was to estimate the peripheral dose associated to radiosurgery treatments using Monte Carlo (MC) and experimental measurements with TLDs.

### Material and Methods

A Leksell Gamma Knife 4C radiosurgery equipment was modeled using the set of C++ libraries Egspp, part of the MC platform EGSnrc. The model includes the entire set of 201 Cobalt-60 sources, along with their respective beam channel. Validation was performed by comparing profiles and dose deposited in depth during irradiation of the Lucy QA Phantom with all sources opened. Then, the photon spectrum and absorbed dose were calculated and measured with TLD-100 pairs, for the plan above, at 14 points of a pseudo-anthropomorphic phantom. TLD-100 had calibration factors for 6 MV nominal energy. TLD readings were corrected by an energy response correction factor due to the change in response from the 6 MV calibration beam to the softened spectrum at the measurement points.

### Results

The simulated geometry was tested using a raytracing method, included in Egspp, which allowed visualization of geometrical details to be compared with the available technical drawings. Difference of just 3.5 % was obtained

for the experimental and calculated FWHM. Mean energies calculated from peripheral photon spectra energies ranged from 0.242 MeV in the mediastinum to 0.171 MeV in the pelvis. Based on these results, an average energy correction factor of 10% was applied to TLD readings. A maximum of 15% difference between calculated and measured peripheral doses were obtained.

### Conclusion

The use of Egspp allowed us to model accurately the Gamma Knife. The level of detail achieved in the modeled geometry is essential for the peripheral dose calculation, since it is dependent on the radiation leakage. The agreement between simulations and measurements is good, with higher discrepancies observed in the points located on the limbs of the phantom. A MC methodology for peripheral dose characterization has been validated and therefore, different scenarios regarding patient size and/or beam geometry can be estimated for future references.

### PO-0812 Dosimetric impact of using Acuros algorithm for stereotactic lung and spine treatments

L. Vieilleveigne<sup>1,2</sup>, T. Younes<sup>1,2</sup>, A. Tournier<sup>1</sup>, P. Graff Cailleaud<sup>1</sup>, C. Massabeau<sup>1</sup>, J.M. Bachaud<sup>1</sup>, R. Ferrand<sup>1,2</sup>

<sup>2</sup>Centre de Recherche et de Cancérologie de Toulouse CRT- UMR1037 INSERM - Université Toulouse 3, Radiophysique- équipe 15, Toulouse, France

### Purpose or Objective

The main aim was to assess the dosimetric impact of calculating with the Acuros (AXB) algorithm instead of Anisotropic Analytical Algorithm (AAA) for stereotactic (SBRT) lung and spine cancer treatments.

### Material and Methods

Ten stereotactic lung patients and ten stereotactic spine patients were selected to investigate the dosimetric impact of using AXB instead of AAA. Dynamic conformal arc was used for SBRT lung patients with a prescription of 50 to 55 Gy in 3 or 5 fractions to the 80% isodose. For the SBRT spine patients, Rapid Arc plans were prepared and 27 Gy was prescribed in 3 fractions to the PTV median dose. The plans were recalculated with the AXB algorithm by using the same beam settings and monitor units as the AAA. Two dose reporting modes of AXB, dose to medium (Dm) and dose to water (Dw) were studied. Relative dose differences between algorithms were calculated for PTV (D98%, D95%, D50% and D2%) and for organs at risk (D2% and mean dose for the ipsilateral lung, the spinal cord or the cauda equina).

### Results

For the 10 SBRT lung patients, the mean lung density was around 0.18 g/cm<sup>3</sup> which corresponded to a normal lung tissue. The dosimetric impact on PTV dose (D98%, D95%, D50%) using AXB instead of AAA was quite small with a maximum underdosage up to 3.1% for D98%. Larger differences were obtained on D2% with a maximum deviation of 7.79%. The average difference on the mean ipsilateral lung dose was 0.22% and 0.44% for AXBDm and AXBDw, respectively. AXBDm and AXBDw presented similar results.

For the 10 SBRT spine patients, large relative dose disagreement of up to -5.02% for the D98% of the PTV was observed with AXBDm. On average, for the D50% of the PTV, AXBDm revealed a relative underdosage of -2.36%, whereas AXBDw lead to a relative overdosage of +1.64%. Concerning the spinal cord or the cauda equina, the average mean dose was reduced up to -6.93% and up to -

4.97% for AXBDM and AXBDw, respectively. For these organs at risk, differences up to -4.56% and to +3.37% were found for the D2% for AXBDM and AXBDw, respectively.

#### Conclusion

The studied lung cases present small mean differences among all calculation modalities; AXBDM and AXBDw calculations are similar. The spine cases show strong difference between AXBDM and AXBDw inside the PTV and the spinal cord or the cauda equina. Acuros is known to provide an accurate alternative to Monte Carlo calculations for heterogeneity management [1] and reporting dose to medium is the preferred choice [2]. Nevertheless, moving from AAA to AXBDM for SBRT treatments, in particular for spine or for lung of low density, has to be carefully evaluated.

<sup>5</sup>University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom

#### Purpose or Objective

We undertook this work to quantify the impact of deep inspiration breath hold (DIBH) and proton therapy, alone and in combination, relative to treatment in free breathing (FB) with IMRT with respect to the estimated risk of cardiac toxicity after radiotherapy for patients with early-stage mediastinal Hodgkin lymphoma (HL).

#### Material and Methods

Treatment plans were generated for 22 patients in both FB and DIBH to 30.6 Gy (Gy(RBE) for proton therapy) in 17 fractions. IMRT plans were created according to the clinical procedure at the presenting author's institution. Proton plans were created with guidance from the authors with clinical proton therapy expertise. Mean doses to the heart, heart valves, and left anterior descending coronary artery (LADCA) were exported and excess relative risks (ERRs) of radiation-induced myocardial infarction, heart failure, and valvular disease were estimated. Dose volume histograms (DVHs) for the heart were extracted and mean DVHs were created for each treatment technique. The Friedman test was used to assess statistical significance, and analysis was performed in Matlab (The MathWorks, Inc).

#### Results

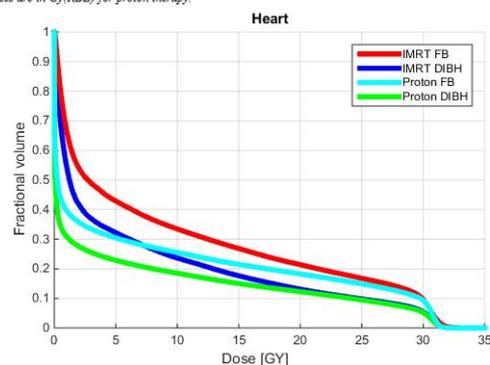

The use of both DIBH and proton therapy were found to reduce the dose as well as the estimated risk to cardiac structures (Table 1). Mean doses to the heart, valves, and LADCA, and the ERRs of radiation induced myocardial infarction, heart failure, and valvular disease were statistically significantly reduced for all other treatment

technique combinations when compared with IMRT in FB, and when proton therapy in DIBH was compared to proton therapy in FB. Heart dose and the ERRs of myocardial infarction and heart failure were significantly reduced when proton therapy in DIBH was compared to IMRT in DIBH. However, when proton therapy in FB was compared to IMRT in DIBH no statistically significant differences were seen for any doses or ERRs. To further analyze the differences between proton therapy in FB and IMRT in DIBH, the paired differences in heart dose from the techniques were calculated (proton therapy in FB minus IMRT in DIBH). The resulting median difference was 0.0 Gy (range -4.3 to 3.5), revealing that the relative benefit of these two techniques with respect to heart dose is patient-specific. Furthermore, mean DVHs for the heart show that, on average, the volume of the heart receiving a dose above about 7 Gy is greater for proton therapy in FB than it is for IMRT in DIBH (Figure 1).

**Table 1:** Doses and excess relative risk (ERR) estimates for 22 patients with early-stage mediastinal Hodgkin lymphoma in FB or DIBH delivered with IMRT or proton therapy. \* indicates a p-value < 0.05 with the Friedman test, post-hoc analysis with Bonferroni correction.

Metric	IMRT FB (1)	IMRT DIBH (2)	Proton FB (3)	Proton DIBH (4)	p-value (n benefited out of 22 by technique on right)					
	Median (Range)	Median (Range)	Median (Range)	Median (Range)	1vs2	1vs3	1vs4	2vs3	2vs4	3vs4
Heart Dose (Gy)	8.0 (0.1-23.2)	3.7 (0.1-17.3)	4.2 (0-17.0)	3.5 (0-13.3)	(21)	(20)	(22)	(11)	(20)	(20)
Valve Dose (Gy)	21.0 (0.3-30.0)	13.4 (0.2-28.8)	16.4 (0-29.9)	9.2 (0-28.9)	*	*	*	*	*	*
LADCA Dose (Gy)	7.7 (0.1-29.5)	4.7 (0.1-24.5)	4.9 (0-29.6)	2.7 (0-24.6)	(20)	(17)	(21)	(12)	(17)	(18)
Heart Failure ERR (%)	41.3 (0.9-161.5)	22.1 (0.7-120.4)	28.0 (0-118.6)	20.3 (0-92.9)	(21)	(20)	(22)	(11)	(20)	(20)
Myocardial Inf- arction ERR (%)	37.7 (0.5-95.0)	15.3 (0.4-79.3)	23.0 (0-71.9)	15.3 (0-69.4)	(21)	(19)	(21)	(10)	(19)	(20)
Valvular Disease ERR (%)	36.7 (0.5-149.2)	23.4 (0.3-130.6)	28.8 (0-147.9)	16.1 (0-131.9)	(21)	(20)	(21)	(8)	(15)	(18)

Abbreviations: FB: free breathing; DIBH: deep inspiration breath hold; IMRT: intensity modulated radiation therapy; LADCA: Left anterior descending coronary artery; n: number of patients.  
Doses are in Gy(RBE) for proton therapy.

#### Conclusion

DIBH and proton therapy both reduced the dose to cardiac structures and the risk of cardiac toxicity, compared to IMRT in FB, but no significant difference was found between IMRT in DIBH and proton therapy in FB. Therefore, with respect to cardiac toxicity, these data suggest that given a choice in techniques, IMRT in DIBH and/or proton therapy should be selected. However, the difference between IMRT in DIBH and proton therapy in FB is variable and should be evaluated on a patient-specific basis.

#### PO-0814 The Influence of scans parameters on effective dose of CBCT scans used for IGRT procedures

Abuhaimeid<sup>1</sup>, C. J. Martin<sup>2</sup>, M. Sankaralingam<sup>3</sup>

<sup>1</sup>King Abdulaziz City for Science and Technology, Department of Applied Physics, Riyadh, Saudi Arabia

<sup>2</sup>University of Glasgow, Department of Clinical Physics, Glasgow, United Kingdom

<sup>3</sup>Beatson West of Scotland Cancer Centre, Department of Radiotherapy Physics, Glasgow, United Kingdom

#### Purpose or Objective

A new software with a version of (V2.5) of On-Board imager (OBI) system, which is utilized in the clinic for image guided radiation therapy (IGRT) procedures, was

released recently by Varian with new scan protocols. This study aimed to investigate the influence of parameters of the new protocols on the effective dose (E) compared to the previous version (V1.6).

#### Material and Methods

Effective dose of three scan protocols (head, thorax, and pelvis) were estimated using Monte Carlo simulations. BEAMnrc and DOSXYZnrc user codes were used to simulate the OBI system integrated into a TrueBeam linac, and to calculate organ doses resulting from the protocols employed. Organ doses were evaluated for the ICRP adult male and female reference computational phantoms. The main differences between the software versions (V1.6) and (V2.5) are: (1) the beam width was extended to 214 mm instead of 198 mm, (2) the mAs values were increased to (150, 270, 1080) compared to (147, 267, 1056) for head, thorax, and pelvis, respectively, and (3) the projections number was increased to 500 for head scan compared to 367, and to 900 for thorax and pelvic scans instead of 660.

#### Results

The use of the scan protocols implemented in V2.5 resulted in increasing E of head scan by 13% and 12%, where E of V1.6 was 0.27 mSv and 0.44 mSv for male and female phantoms compared to 0.31 mSv and 0.49 mSv for V2.5, respectively. Parameters of the new protocols, also, led to rise E of thorax and pelvic scans by 16% and 17% for male, respectively, and by 16% for female. E of thorax and pelvic scans increased from 3.32 mSv and 5.95 mSv to 3.86 mSv and 6.88 mSv for male, respectively, and from 3.97 mSv and 11.38 mSv to 4.65 mSv and 13.16 mSv for female, respectively.

#### Conclusion

CBCT scans play a major role in radiotherapy treatment. The scan protocols with the new parameters were implemented into the new software to improve the image quality acquired with the scans, and to extend the field of view. This helps to improve the patient positioning on the treatment couch and deliver the specified dose to the patient with a high accuracy, and hence optimising the treatment output. The new head, thorax, and pelvic scans only increased E values by 12 - 13%, 16 - 17%, and 16%, respectively, for male and female. These increases are acceptable when compared to improvement of the treatment output.

#### PO-0815 External neutron spectra measurements for a single room compact proton system

R. Howell<sup>1</sup>, E. Klein<sup>2</sup>, S. Price Hedrick<sup>3</sup>, M. Reilly<sup>4</sup>, L. Rankine<sup>5</sup>, E. Burgett<sup>6</sup>

<sup>1</sup>UT MD Anderson Cancer Center Radiation Physics, Radiation Physics, Houston- TX, USA

<sup>2</sup>Northwell Health System, Medical Physics, Lake Success, USA

<sup>3</sup>Provision Center for Proton Therapy, Radiation Oncology, Knoxville, USA

<sup>4</sup>Washington University, Radiation Oncology, St. Louis, USA

<sup>5</sup>The University of North Carolina, Radiation Oncology, Chapel Hill, USA

<sup>6</sup>Idaho State University, Nuclear Engineering, Pocatello, USA

#### Purpose or Objective

Secondary external neutrons are produced within the physical components of the proton beam line e.g., the double scatterer, modulation wheel, compensator, and field aperture. In passive scattered proton therapy, external neutrons account for a majority of neutron dose equivalent for small fields and up to 50 % for large fields. Spectra measurements are needed to fully and accurately understand neutron dose equivalent from external neutrons. Such data should be reported for proton beamlines from each manufacturer. Here, we focused on the single room compact proton system manufactured by

Mevion (Mevion Medical systems, Littleton, MA) whose use is rapidly increasing in the United States and worldwide.

#### Material and Methods

Measurements were performed using a 250-MeV passively scattered proton beam with a range of 20 cm, modulation of 10 cm with the small aperture in place. Measurements were done with a solid brass plates fully filling the aperture opening to achieve a 'closed jaw configuration'. This configuration was selected because it is the most amount of high-Z material that can be in the beamline, thus representing the maximum external neutrons produced for the small field designation.

We performed measurements at isocenter and off axis at 40 and 100 cm from the isocenter with the gantry rotated to 90° or 0° and couch rotated 0° or 270°, Figure 1. All measurements were performed using an extended range Bonner Sphere Spectrometer (ERBS). The ERBS had 18 spheres including the 6 standard Bonner spheres and 12 extended spheres with various combinations of copper, tungsten, or lead. Each set of measurements was performed with all 18 sphere combinations in air with the <sup>6</sup>LiI(Eu) scintillator. Data were unfolded using the MAXED MXD\_FC33 algorithm and normalized per unit proton Gy to isocenter.

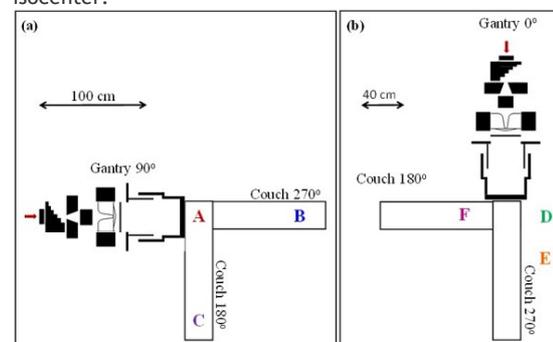

Figure 1: Schematic diagram of measurement locations.

#### Results

The measured neutron spectral fluence at each of the six measurement positions are shown in Figure 1. The average energies, total fluence, and ambient dose equivalents per proton Gy are listed in the table imbedded within figure 1. The average energy, total fluence, and ambient dose equivalent were all highest at isocenter and decreased as a function of distance from isocenter. While the energy distributions for each of the fluence spectra (Figure 1) were similar, with a high-energy direct neutron peak, an evaporation peak, a thermal peak, and an intermediate continuum between the evaporation and thermal peaks, there were a higher fraction of direct neutrons at isocenter compared to 40 and 100 cm from isocenter.

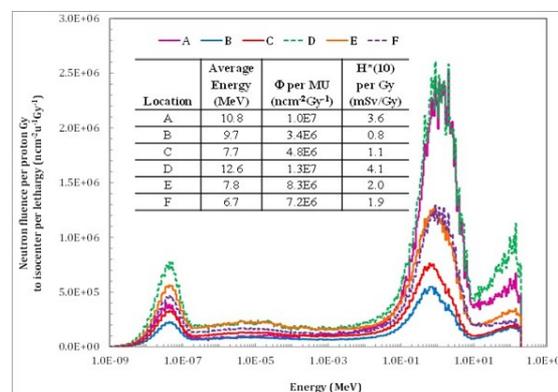

Figure 2: Measured neutron fluence spectra at each of measurement position. For each fluence spectrum, the average energy, total fluence, and ambient dose equivalent  $[H^*(10)]$  are listed in the imbedded table.

### Conclusion

In this study, we measured spectra for external neutrons and characterized neutron dose equivalents for a single gantry proton system, whose use in the United States and worldwide is increasing.

#### PO-0816 LRPM for fast automated high quality treatment planning - towards a novel workflow for clinicians

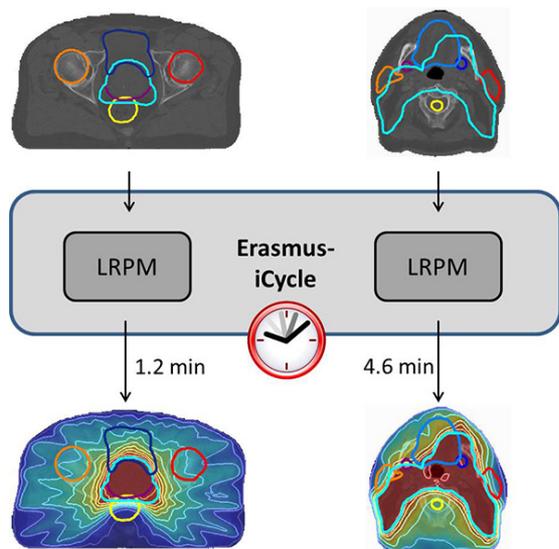

R. Van Haveren<sup>1</sup>, B.J.M. Heijmen<sup>1</sup>, W. Ogryczak<sup>2</sup>, S. Breedveld<sup>1</sup>

<sup>1</sup>Erasmus Medical Center Rotterdam Daniel den Hoed Cancer Center, Radiation Oncology, Rotterdam, The Netherlands

<sup>2</sup>Warsaw University of Technology, Control and Computation Engineering, Warsaw, Poland

#### Purpose or Objective

The aim is to create a novel efficient workflow for clinicians, where high quality treatment plans are ready to be inspected minutes after the delineation is finished. In the current clinical workflow, plans are automatically generated using the in-house developed Erasmus-iCycle optimiser, but planning times can be in the order of hours. Therefore, we propose an extension of Erasmus-iCycle to substantially reduce computation times, but maintain plan quality.

#### Material and Methods

We developed the Lexicographic Reference Point Method (LRPM), a fast algorithm to automatically generate multi-criterial treatment plans in a single optimisation run. In contrast, the currently implemented sequential method in Erasmus-iCycle requires multiple optimisations to generate a plan. We validate the LRPM by comparing automatically generated VMAT plans (mimicked by 23 static beams) with the LRPM and the sequential method for 30 prostate cancer patients and 15 head-and-neck cancer patients. For these treatment sites (and others), Erasmus-iCycle is in clinical use.

#### Results

For the 30 prostate cancer patients, plan differences between the LRPM and the sequential method were found neither clinically nor statistically significant. The LRPM reduced the average planning time from 12.4 to 1.2 minutes, a speed-up factor of 10. For head-and-neck, the LRPM reduced the planning times from 99.7 to 4.6

minutes, a speed-up factor of 22. Plan quality was mostly similar on average. For individual cases however, the LRPM plans showed clinically more balanced trade-offs between OAR doses. In comparison with the plan resulting from the sequential method, relatively large dose reductions were possible for some OAR(s) at the cost of relatively small increases of dose for other OAR(s).

#### Conclusion

The LRPM features very fast automatic multi-criterial generation of high-quality treatment plans, reducing Erasmus-iCycle planning times to the order of minutes. Further research focuses on clinical implementation.

#### PO-0817 Anatomical robust optimization to deal with variation in nasal cavity filling during IMPT

S. Van de Water<sup>1</sup>, F. Albertini<sup>2</sup>, D.C. Weber<sup>2</sup>, B.J.M. Heijmen<sup>1</sup>, M.S. Hoogeman<sup>1</sup>, A.J. Lomax<sup>2</sup>

<sup>1</sup>Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

<sup>2</sup>Paul Scherrer Institute, Center for Proton Therapy, Villigen PSI, Switzerland

#### Purpose or Objective

Intensity-modulated proton therapy (IMPT) for tumors in the sinonasal and skull-base regions can be seriously affected by interfraction changes in nasal cavity filling, resulting in underdosage of the tumor and/or overdosage of organs-at-risk (OARs). The aim of this study was to develop an anatomical robust optimization method that accounts for variation in nasal cavity filling and to compare it with the conventional single-field uniform dose (SFUD) approach and with online plan adaptation.

#### Material and Methods

We included CT data of five patients with tumors in the sinonasal region, for which the clinical target volume (CTV) showed large overlap with the nasal cavity. Based on the planning CT, we generated for each patient 25 'artificial' CTs with varying nasal cavity filling (Figure 1). The minimax robust optimization method available in our in-house developed treatment planning system was extended to account for anatomical uncertainties by including additional (artificial) CTs with varying patient anatomy as error scenarios in the inverse optimization. For each patient, we generated treatment plans using: 1) the SFUD approach (with varying planning target volume (PTV) margins of 0 mm, 3 mm or 5 mm), 2) anatomical robust optimization (including two, three or four artificial CTs, next to the planning CT), and 3) online plan adaptation (generating a new treatment plan for each artificial CT). We used the clinically applied 3- or 4-beam arrangements. Treatment plans were evaluated by recalculating and accumulating the dose for an entire fractionated 50-Gy treatment, assuming each artificial CT to correspond to a 2-Gy fraction. We assessed CTV and OAR dose parameters for the accumulated dose and individual fractions. A treatment planning strategy was considered adequate when  $V_{95\%} \geq 99\%$  and  $V_{107\%} \leq 2\%$  in each fraction.

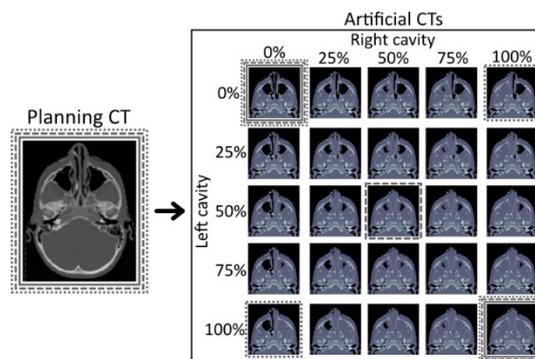

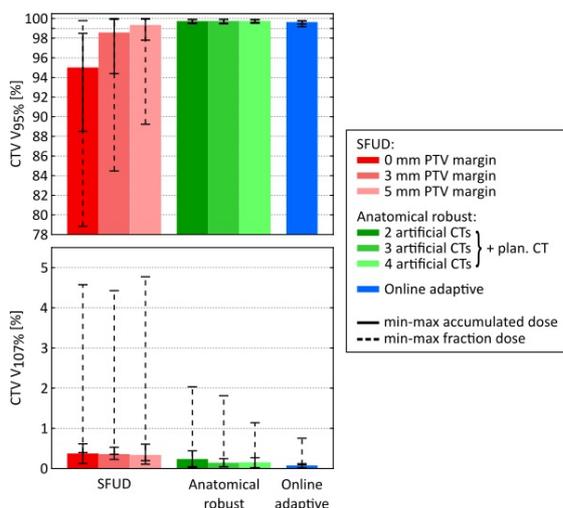

Figure 1. Overview of the CT data available for each patient. Grey boxes indicate the CTs that were included in the anatomical robust optimization: two (solid), three (dashed) or four (dotted) artificial CTs, in combination with the planning CT.

## Results

Anatomical robust optimization resulted in adequate CTV doses if at least three artificial CTs were included next to the planning CT. Online plan adaptation also resulted in adequate CTV irradiation, whereas this could not be achieved using the SFUD approach, even with a PTV margin of 5 mm (Figure 2). Anatomical robust optimization provided considerable OAR sparing compared with the SFUD approach (5 mm margin), with an average reduction in max-dose and mean-dose parameters of 6.0 Gy (17%) and 5.8 Gy (24%), respectively. The use of online plan adaptation resulted in further OAR sparing compared with anatomical robust optimization, reducing max-dose and mean-dose parameters on average by 3.8 Gy (13%) and 3.4 Gy (23%), respectively.

**Figure 2.** Average accumulated-dose CTV V95% and V107% values for the different planning strategies. Whiskers indicate extreme values (solid: accumulated dose, dashed: fraction dose).

## Conclusion

We have developed an anatomical robust optimization method that effectively dealt with the variation in nasal cavity filling, providing substantially improved CTV coverage and OAR sparing compared with the conventional SFUD approach. Online plan adaptation allowed for further OAR dose reduction and we therefore recommend this planning strategy to be pursued for future application in these patients.

## PO-0818 Improving plan quality and efficiency by automated rectum VMAT treatment planning

G. Wortel<sup>1</sup>, J. Trinks<sup>1</sup>, D. Eekhout<sup>1</sup>, P. De Ruiter<sup>1</sup>, R. De Graaf<sup>1</sup>, L. Dewit<sup>1</sup>, E. Damen<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands

## Purpose or Objective

To develop, evaluate, and implement fully automated VMAT plan generation for rectum patients that receive either palliative 39 Gy (13×3 Gy), or curative 45 Gy (25×1.8 Gy, postoperative), 50 Gy (25×2 Gy, preoperative) treatment.

## Material and Methods

The automatic rectum VMAT plan generation is performed by a combination of our in-house developed automation framework FAST and the Pinnacle<sup>3</sup> Auto-Planner. The automatic planning starts after the physician has delineated the rectum target volume(s). FAST starts our TPS Pinnacle<sup>3</sup>, creates a patient record, and imports the CT. The patient's skin and bladder are auto-segmented by Pinnacle<sup>3</sup>'s module SPICE. In addition, the small bowel is delineated using a custom-made FAST module. The

bladder and small bowel are merged to a structure that is used as the single OAR. Next, a density override of 0.5 g/cm<sup>3</sup> is performed on any air pockets in the PTV that are identified using a density threshold. A dual arc VMAT plan is set up and the dose distribution is optimized using the Pinnacle<sup>3</sup> Auto-Planner. After the generation of the Auto-Plan, which takes about 45 minutes, it is presented to the dosimetrist for approval.

The Pinnacle<sup>3</sup> Auto-Planner creates plans based on a set of dose optimization goals and a number of advanced settings called the "treatment technique", which allows (indirect) control over the resulting plan. The main challenge is to develop a single treatment technique that leads to optimal plans, which meet our precise and high clinical demands, for a large patient population.

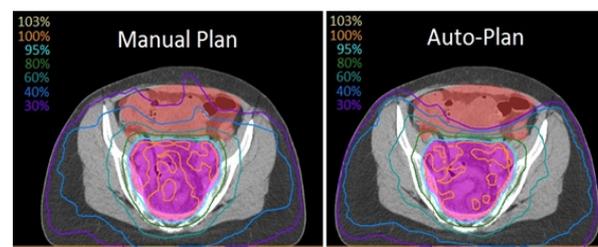

After having optimized the treatment technique using a test set of 30 patients, we evaluated the Auto-Plans by performing a blind test where 4 physicians and 4 planning dosimetrists were asked to compare manual clinical plans with Auto-Plans for 10 new patients.

## Results

The optimized treatment technique is shown in Table 1. On average, the mean dose to the small bowel + bladder is 2.5 Gy lower for the Auto-Plans compared with manual plans, at the expense of having a slightly increased dose in the lateral direction. An example of a manual plan and an Auto-Plan is shown in Figure 1. The result of the blind test was a unanimous preference for the Auto-Plans (20-0), based on a better PTV coverage and a lower OAR dose. The slightly higher lateral dose was considered acceptable.

ROI	Optimization Goal
PTV	Dose of 5033 cGy
Small bowel + bladder - (PTV + 5mm)	Mean Dose of 1000 cGy, priority high, no compromise
PTV ring (from PTV + 0mm to PTV + 5mm)	MaxDose of 4900 cGy, priority medium, no compromise
PTV ring (from PTV + 5mm to PTV + 26mm)	Mean Dose of 1700 cGy, priority low, no compromise
Skin - (PTV + 35mm)	Max Dose of 3000 cGy, priority medium, no compromise
Advanced Settings	Value
Tuning Balance	8%
Dose Fall-Off Margin	1.5 cm
Hot-Spot Maximum Goal	103%
Use Cold-Spot ROIs	Yes

**Table 1:** The Optimization Goals and Advanced Settings of the Pinnacle<sup>3</sup> Auto-Planner technique used for (50Gy) rectum planning. For the other doses, the objective values are scaled physically.

**Figure 1:** Comparison of a Manual Plan and an Auto-Plan. The tomato colored ROI is the small bowel + bladder. In this case, the mean OAR dose is 4 Gy lower in the Auto-Plan.

## Conclusion

We have successfully developed automatic rectum VMAT treatment planning using our automation framework FAST in combination with the Pinnacle<sup>3</sup> Auto-Planner. The Auto-Plans systematically differ from the manual clinical plans (with an average OAR mean dose reduction of 2.5 Gy) and are unanimously preferred by physicians and dosimetrists. This clearly demonstrates how the implementation of an Auto-Planner system, combined with the accompanying reconsideration of plan style and clinical trade-offs, can lead to improved treatment plans. As a result, automatic rectum VMAT planning has been introduced in our clinic as of July 2016.

## PO-0819 Robustness evaluation of single- and multifield optimized proton plans for unilateral head and neck

Dresden, Dresden, Germany

### Purpose or Objective

To compare 4 different proton pencil beam scanning (PBS) treatment approaches for unilateral head and neck cancer (HNC) targets in terms of robustness, including anatomical changes during the treatment course.

### Material and Methods

Eight patients with unilateral HNC treated with double scattered proton therapy were selected. Each patient dataset consists in a planning CT and several control CTs acquired by an in-room CT scanner during the treatment course. Four different proton PBS plans with simultaneous integrated boost and dose prescriptions of 50.3 Gy(RBE) to the low-risk CTV and 68 Gy(RBE) to the high-risk CTV in 34 fractions were calculated: conventional PTV-based single-field (SFO) and multifield optimization (MFO), and robustly optimized SFO and MFO plans on CTV level, considering  $\pm 3$  mm and  $\pm 3.5\%$  of setup and range uncertainty, respectively.

The treatment plans were recalculated on the registered control CTs and the cumulative doses calculated and compared with the nominal plan. For robustness evaluation, perturbed doses using a probabilistic scenario-wise approach obtaining random setup shifts through Gaussian sampling, and range uncertainties of 0, +3.5% and -3.5% were calculated, using planning and control CTs, considering both anatomical changes and uncertainties. Cumulative doses from 30 different perturbed treatment courses were generated for each plan.

### Results

The target coverage for the four nominal plans was similar, fulfilling the clinical specification of  $D_{98} \geq 95\%$  of the prescribed dose (range 96.9-100.5% for low-risk CTV, 97.4-100.8% for high-risk CTV), being slightly lower on the robust optimized plans. The doses to the organs at risk were similar for all plans; however, for the ipsilateral parotid, higher median doses up to 5 Gy were found on the SFO approaches (Table 1), whereas the contralateral parotid is completely spared. The target coverage throughout the treatment course with slightly changing anatomy remains in general constant.

Table 1. Dose statistics (mean  $\pm$  standard deviation) for target volumes and organs at risk in the nominal plan.

		MFO	MFO Robust	SFO	SFO Robust
Low-risk CTV	D98 / %	99.54 $\pm$ 0.22	97.67 $\pm$ 0.57	99.84 $\pm$ 0.80	98.78 $\pm$ 1.10
	D2 / %	104.53 $\pm$ 0.39	105.49 $\pm$ 0.52	104.26 $\pm$ 0.38	105.05 $\pm$ 0.45
High-risk CTV	D98 / %	99.35 $\pm$ 0.20	98.48 $\pm$ 0.81	99.92 $\pm$ 0.40	99.29 $\pm$ 0.71
	D2 / %	104.53 $\pm$ 0.39	105.49 $\pm$ 0.52	104.26 $\pm$ 0.38	105.05 $\pm$ 0.45
Spinal Cord	D <sub>1cc</sub> / Gy	3.15 $\pm$ 3.36	2.60 $\pm$ 2.22	2.96 $\pm$ 3.87	2.83 $\pm$ 3
Brainstem	D <sub>1cc</sub> / Gy	2.82 $\pm$ 1.96	2.63 $\pm$ 1.77	3.19 $\pm$ 2.34	2.88 $\pm$ 2.07
Parotid Ipsilateral	D <sub>median</sub> / Gy	26.25 $\pm$ 2.37	25.36 $\pm$ 1.57	30.43 $\pm$ 2.21	28.11 $\pm$ 1.71
Larynx	D <sub>mean</sub> / Gy	20.83 $\pm$ 7.35	23.14 $\pm$ 7.48	22.78 $\pm$ 8.65	23.95 $\pm$ 8
Oral Cavity	D <sub>mean</sub> / Gy	12.71 $\pm$ 7.93	12.46 $\pm$ 8.07	13.66 $\pm$ 8.71	13.29 $\pm$ 9

In terms of robustness evaluation, PTV-based MFO showed reduced robustness against both anatomical changes and uncertainties, i.e. wider DVH bands and a disagreement between planned and summed dose, whereas the robust MFO is less influenced. Both SFO approaches resulted in robust plans on the CTVs (Figure 1).

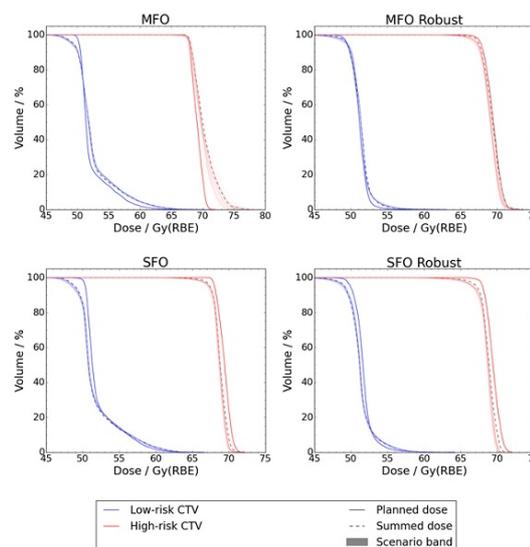

Figure 1. DVH bands, planned and summed doses for the different plans on the target volumes for one patient.

### Conclusion

The PTV-based MFO approach showed less robustness against uncertainties in setup and range, as well as for anatomical changes during the treatment course. Both SFO plans are robust in terms of CTV coverage; however, they present higher doses to the ipsilateral parotid gland. Robust MFO approach presents the lowest doses to the ipsilateral parotid and more robustness against uncertainties.

The dose to more organs at risk and the difference in normal tissue complication probabilities for the 4 planning approaches will be presented as well.

#### Purpose or Objective

To fully automate radiotherapy planning for cervical cancer (4-field box treatments) and head/neck cancer (VMAT/IMRT).

#### Material and Methods

We are using a combination of in-house software, Eclipse Treatment Planning System, and Mobius 3D to create and validate radiotherapy plans. Most planning tasks have been automated using a primary algorithm for the treatment plan, and a secondary independent algorithm to verify the primary algorithm.

The first step is to automatically determine the external body surface and isocenter (based on radiopaque markers in a 3-point setup) using two independent techniques.

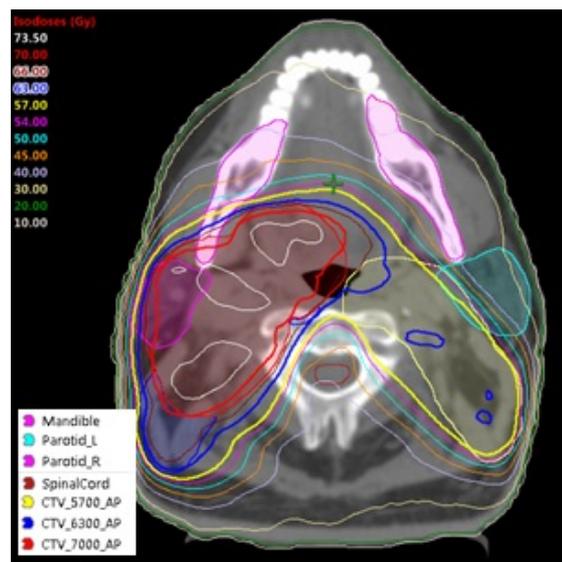

For H/N cases, the radiation oncologist manually delineates the GTV. Normal tissues (parotids, cord, brainstem, lung, eyes, mandible, cochlea, brain), cervical neck nodes (levels II-IV, IB-V or IA-V) and retropharyngeal nodes are automatically delineated using an in-house multi-atlas segmentation tool. The RapidPlan tool (Eclipse) is used to create a VMAT plan.

For 4-field box cervical cancer treatments, the field apertures (jaw and MLC positions) are automatically calculated based on bony anatomy using two techniques: The primary technique uses atlas-based segmentation of bony anatomy, and then calculates apertures based on the projection of these bones to each beam's-eye-view. The secondary technique deformably registers atlas DRRs to the patient's DRR for each beam, then uses the deformation matrix to deform atlas blocks (MLC positions) to the patient's DRR. Relative beam weighting is determined based on a least-squares fit, minimizing heterogeneity in the treatment volume.

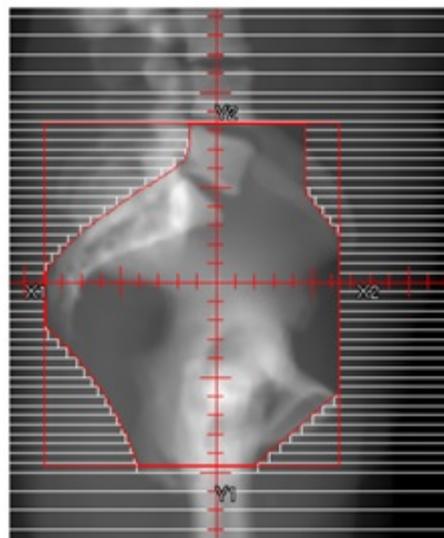

Final dose distributions are automatically sent to Mobius for secondary dose calculation.

#### Results

Primary and secondary techniques for identifying the body surface agreed within 1.0mm/0.99 (mean distance to agreement/average DICE coefficient). Primary and secondary techniques for determining isocenter agreed within 3mm. H/N normal tissue and lymph node segmentation was evaluated by a radiation oncologist (128 patients), and found to be acceptable for all structures, except for esophagus and cochlea and in situations where the head position was non-standard. The figure below shows a fully automated plan including contours and optimized doses.

A radiation oncologist found 96% of cervical cancer beam aperture were clinically acceptable, with all failures caused by a slight error in the position of the superior border. The primary and secondary aperture calculations agreed with average DICE and mean absolute distance of 0.93 and 5.5mm, respectively. An example is shown below. Automated beam weighting reduced hotspots by 1.5% on average.

#### Conclusion

Normal tissue segmentation for head/neck cancer patients and determination of the jaw/MLC for cervical cancer patients are very successful. Both have been introduced into use in our clinic. Next steps include full evaluation of the resulting dose distributions, and assessing the use of these techniques for a prototype linac with flattening-filter-free beam and novel MLC design.

**PO-0821 Automatic re-planning of VMAT plans in prostate and HN patients using constrained optimization**  
L. Künzel<sup>1</sup>, O. Dohm<sup>2</sup>, M. Alber<sup>3</sup>, D. Thorwarth<sup>1</sup>

<sup>1</sup>University Hospital Tübingen Eberhard Karls University Tübingen, Section for Biomedical Physics, Tübingen, Germany

<sup>2</sup>University Hospital Tübingen Eberhard Karls University Tübingen, Radiation Oncology Division of Medical Physics, Tübingen, Germany

<sup>3</sup>University Hospital Heidelberg, Radiation Oncology, Heidelberg, Germany

### Purpose or Objective

To develop and evaluate a new concept for automatic re-planning of VMAT plans as failure concept for solitary treatment machines, e.g. MR-Linac. In contrast to previously published automatic planning approaches which replicate the planned dose distribution, we propose an automatic re-planning concept which uses constrained optimization to generate Pareto-optimal VMAT plans for different treatment machines. The scheme interprets a treatment plan as a point on the corresponding Pareto front, and creates the re-planned one by projecting this point onto the substitute's Pareto front. Thereby, comparable biological effect and hence clinical outcome can be guaranteed.

### Material and Methods

In this automatic re-planning study, n=16 prostate cancer and n=19 head and neck cancer (HNC) cases were included. All patients had previously planned clinical VMAT plans created with in-house TPS Hyperion. Hyperion uses constrained optimization where a Lagrange multiplier  $\lambda_i$  is associated to each cost-function constraint  $C_i$ , rating the effect of each organ-at-risk (OAR) constraint on the target objective.

Automatic re-planning starts from the initially reached optimal constraints  $C_i$  for PTVs and OARs and adapted machine parameters. A full optimization was executed automatically, in order to generate a comparable Pareto-optimal plan. For prostate cases, Elekta BeamModulator plans were re-planned for Elekta Agility, whereas for HNC, Elekta Agility plans were re-planned for Elekta MLCi. For prostate cases we identified rectum and bladder as main OARs and for HNC contralateral parotid gland and spinal cord. For PTV we evaluated variations in EUD,  $D_{\text{Mean}}$ ,  $D_{2\%}$  and  $D_{98\%}$  and for OARs EUD and  $D_{2\%}$ .

### Results

Automatic re-planning using constrained optimization was successful in all cases. Auto-optimized plans never corrupted OAR constraints, in some cases re-planning even improved OAR sparing. The mean deviation (range) in rectum EUD was 0,30% (-1,04 - -0,27%), bladder EUD 0,44% (-1,08 - -0,13%), parotid EUD -0,34% (-14,79 - 8,23%) and spinal cord EUD -0,02% (-0,49 - 0,31%). For the prostate cases the mean EUD deviation in PTV was -0,15% (-0,57 - 0,56%) and for the HNC cases -0,60% for PTV\_60 (-2,58 - -0,08%) and -0,79% (-3,44 - 0,20%) for PTV\_54, respectively. Except of 3 HNC cases, all evaluated parameters for targets showed variations within  $\pm 1\%$ . For 3 HNC cases the target EUD is reduced by up to 3.44%, indicated by  $\lambda > 10 * \lambda_{\text{avg}}$ . Consequently, if all  $\lambda < 10 * \lambda_{\text{avg}}$ , the original and the re-planned plan comply with the given constraints and therefore represent the same optimal point on the Pareto-front, which means they are equal in terms of biological effect for targets and OAR.

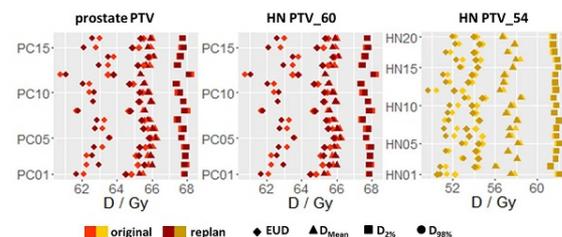

Fig 1: Results of EUD,  $D_{\text{Mean}}$ ,  $D_{2\%}$ ,  $D_{98\%}$  for PTVs of prostate and HN cases.

### Conclusion

This study showed that fully automatic re-planning by taking a prescription list from previously optimized VMAT plans is feasible and successful in terms of equal plan

quality. Furthermore this approach enables the identification of problematic plans beforehand.

### PO-0822 An evolutionary model improvement strategy for knowledge-based planning

Y. Zhang<sup>1</sup>, F. Jiang<sup>1</sup>, H. Yue<sup>1</sup>, S. Li<sup>1</sup>, Q. Hu<sup>1</sup>, M. Wang<sup>2</sup>, H. Wu<sup>1</sup>

<sup>1</sup>Key Laboratory of Carcinogenesis and Translational Research Ministry of Education/Beijing- Department of Radiation Oncology- Peking University Cancer Hospital & Institute, Department of Radiation Oncology, Beijing, China

<sup>2</sup>National Institute for Radiological Protection- China CDC, National Institute for Radiological Protection-, Beijing, China

### Purpose or Objective

It was reported that RapidPlan, a knowledge-based solution, can improve planning efficiency, quality and consistency. Should the performance of RapidPlan be dependent on the quality of the plans training the model, this study hypothesizes that RapidPlan can improve its constituent plans (closed-loop) and improve the model itself by incorporating the better knowledge (evolution). Moreover, the maximum number of iterations to exhaust the full potential was also tested.

### Material and Methods

An initial RapidPlan model ( $M_0$ ) for pre-surgical rectal cancer patients was configured using 81 best-external manual VMAT plans ( $P_0$ ) with SIB (50.6 Gy and 41.8 Gy to 95% PTV<sub>boost</sub> and PTV respectively). For simplification, decreased or increased mean dose to both femoral head (FH) and urinary bladder (UB) were considered as improved ( $P_+$ ) or worsened plans ( $P_-$ ) respectively.  $P_{\pm}$  denoted intertwined plans. The first closed-loop iteration of re-optimizing  $P_0$  using  $M_0$  yielded  $P_+$ : 69  $P_{1+}$ , 12  $P_{1-}$  and 0  $P_{1-}$ . By substituting  $P_{1+}$  for their corresponding  $P_0$ , the library of model  $M_{1+}$  consisted of 12  $P_0$  and 69  $P_{1+}$ . The second closed-loop iteration of re-optimizing  $P_0$  using  $M_{1+}$  produced 35  $P_{2+}$  that were superior to both  $P_0$  and  $P_{1+}$ , hence the knowledge base of  $M_{2+}$  composed 9  $P_0$ , 37  $P_{1+}$  and 35  $P_{2+}$ . As open-loop validation, 30 clinical plans ( $P_v$ ) that were not included in the model were re-optimized using each model. Re-optimization maintained all parameters except the MLC sequences were redesigned using the objectives generated by the models. Renormalizations to target prescriptions were performed to make OAR dose comparable.

### Results

Consistent with literature, knowledge-based solution improved the plan quality in both closed- and open-loop validations than the conventional trial-and-error process. In the first closed-loop evolution, the mean $\pm$ SD of  $D_{\text{mean\_FH}}$  and  $D_{\text{mean\_UB}}$  for 69  $P_{1+}$  were 12.88 $\pm$ 1.38 Gy and 23.06 $\pm$ 3.11 Gy respectively, which were significantly lower by 23.70% and 9.53% than the corresponding values of  $P_0$  ( $P < 0.05$ ). In the second round of closed-loop re-optimization, the  $D_{\text{mean\_FH}}$  of the 35  $P_{2+}$  decreased to 11.12 $\pm$ 1.48 Gy (corresponding  $P_0$ : 17.13 $\pm$ 2.06 Gy;  $P_{1+}$ : 13.08 $\pm$ 1.36 Gy), and  $D_{\text{mean\_UB}}$  decreased to 22.80 $\pm$ 3.72 Gy (corresponding  $P_0$ : 25.79 $\pm$ 3.34 Gy;  $P_{1+}$ : 23.41 $\pm$ 3.59 Gy). Table 1 and figure 1 display the open-loop validation results for various models. The marginal disparities of HI and CI (magnitudes  $\leq 0.04$ ) and largely overlapped DVH lines indicated comparable target dose distribution. In line with the closed-loop test, RapidPlan reduced the dose to OARs massively than clinical plans in the open-loop validation (Fig 1). The first model evolution has greatly and significantly lowered the dose to FH at comparable dose to the UB and targets. The second iteration has made little difference though.

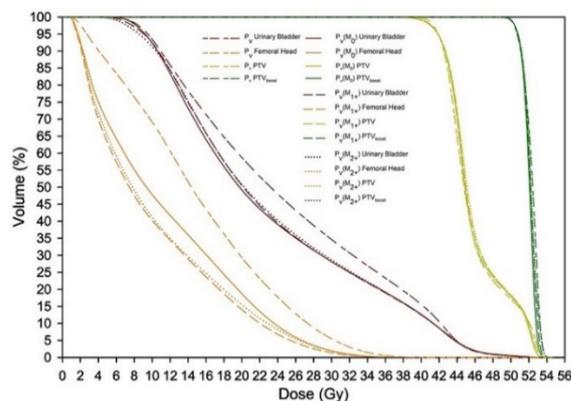

Figure 1. Mean DVHs of 30 validation plans (manual) and the re-optimized results (RapidPlan) using various models

**Conclusion**

RapidPlan model evolves when the sub-optimal constituent training sets were replaced by the improved plans that were re-optimized by the model. One iteration is most cost-effective.

**PO-0823 Hierarchical constrained optimization for automated SBRT paraspinal IMRT planning**

M. Zarepisheh<sup>1</sup>, L. Hong<sup>1</sup>, J.G. Mechalakos<sup>1</sup>, M.A. Hunt<sup>1</sup>, G.S. Mageras<sup>1</sup>, J.O. Deasy<sup>1</sup>

<sup>1</sup>Memorial Sloan Kettering, Medical Physics, New York, United States Minor Outlying Island

**Purpose or Objective**

To develop a fully automated approach to IMRT treatment planning using hierarchical constrained optimization and the Eclipse API for SBRT paraspinal cases.

**Material and Methods**

This study formulates the IMRT treatment planning problem as a hierarchical constrained optimization (HCO) problem (also known as prioritized optimization). HCO prioritizes the clinical goals and optimizes them in ordered steps. In this study, we maximize tumor coverage first and then minimize critical organ doses in the subsequent steps based on their clinical priorities (e.g., (1) maximize tumor coverage, (2) minimize cord or cauda dose, (3) minimize esophagus dose,...). For each organ we define an objective function, based on the gEUD concept, which correlates with the clinical criterion. At each step, we preserve the results obtained in the prior steps by treating them as hard constraints with a slight relaxation or "slip" to provide space for subsequent improvement. Maximum dose criteria to the tumor and other organs is always respected through hard constraints applied at all steps. To solve the resultant large-scale constrained optimization problems, we use two commercial solvers, *knitro* and *AMPL*. The Eclipse API is used to pull patient data needed for optimization (e.g., beam geometries,

influence matrix). After solving the optimization problems, the optimal fluence map is imported back to Eclipse for leaf sequencing and final dose calculation using the Eclipse API. The entire workflow is automated, requiring user interaction solely to prepare the contours and beam arrangement prior to launching the HCO Eclipse API plugin. Optimization requires ~1-3 hours, after which the automated plan including final dose calculation is ready in Eclipse.

**Results**

HCO IMRT automatic planning was tested for 10 patients with spinal lesions who had previously been treated to 24 Gy in a single fraction using either VMAT (8 patients) or multi-field IMRT (2 patients). All automated HCO plans used multi-field IMRT. A typical automated and clinical plan comparison is shown in Figure 1, demonstrating improved PTV coverage, cord and esophagus sparing with the automated plan. As shown in Table 1, on average, the automated plan improved PTV coverage (V95%) by 1%, cord maximum dose by 2%, cord D0.35cc by 12%, cauda maximum dose by 15%, and esophagus V18Gy by 100%. All HCO plans met all clinical planning criteria.

Table-1. Comparison of clinical and HCO automated plans for ten patients. For each criterion, the better score is bolded.

Figure-1. Comparison of the clinical and automated plans for a patient. A1-A3 represent the automated plan and C1-C3 represent the clinical plan.

**Conclusion**

Hierarchical constrained optimization shows promise as a powerful tool to automate IMRT treatment planning. The automated treatment plan meets all clinical criteria and compares favorably in relevant metrics to the plan generated by planners. Using Eclipse API, we developed a plugin which fully automates the workflow and can be implemented into clinical use after thorough testing.

### Purpose or Objective

The goal of this work is to show the technical feasibility and to evaluate the normal tissue complication probability (NTCP) and the tumor control probability (TCP) of the intensity modulated radiation therapy (IMRT) dose painting technique using <sup>68</sup>Ga-HBED-CC PSMA-PET/CT in patients with primary prostate cancer (PCa).

### Material and Methods

We studied 10 RT plans of PCa patients having PSMA-PET/CT scans prior to radical prostatectomy. One contour was semi automatically generated for each patient on the basis of the 30% of SUVmax within the prostate (GTV-PET). For each patient, two IMRT plans were generated: PLAN<sup>77</sup>, which consisted of whole-prostate radiation therapy to 77 Gy in 2.2 Gy per fraction; PLAN<sup>95</sup>, which consisted of whole-prostate RT to 77 Gy in 2.2 Gy per fraction, and a simultaneous integrated boost to the GTV-PET to 95 Gy in 2.71 Gy per fraction. The feasibility of these plans was judged by their ability to reach prescription doses while adhering to the FLAME trial protocol. Comparisons of TCPs based on co-registered histology after prostatectomy (TCP-histo) and normal tissue complication probabilities (NTCP) for rectum and bladder were carried out between the plans.

### Results

Prescription doses were reached for all patients plans while adhering to dose constraints. The mean doses on GTV-histo for [Plan<sup>77</sup> and Plan<sup>95</sup>] were 75.8±0.3 Gy and 96.9±1 Gy, respectively. In addition, TCP-histo values for Plan<sup>77</sup> and Plan<sup>95</sup> were 70±7 %, and 95.7±2 %, respectively. PLAN<sup>95</sup> had significantly higher TCP-histo (p<0.0001) values than PLAN<sup>77</sup>. There were no significant differences in rectal (p=0.563) and bladder (p=0.3) NTCPs between the 2 plans.

### Conclusion

IMRT dose painting for primary PCa using <sup>68</sup>Ga-HBED-CC PSMA-PET/CT was technically feasible. A dose escalation on GTV-PET resulted in significantly higher TCPs without higher NTCPs.

### PO-0825 Multi-scenario sampling in robust proton therapy treatment planning

E. Sterpin<sup>1</sup>, A. Barragan<sup>2</sup>, K. Souris<sup>2</sup>, J. Lee<sup>2</sup>

<sup>1</sup>KU Leuven, Department of Oncology, Leuven, Belgium

<sup>2</sup>Université catholique de Louvain, Molecular imaging-radiotherapy and oncology, Brussels, Belgium

### Purpose or Objective

Beam specific PTVs (BSPTV) or robust optimizers are superior to conventional PTVs for ensuring robustness of proton therapy treatments. In these planning strategies, realizations ('scenarios') of a few types of uncertainties are simulated: errors in patient setup, CT HU conversion to stopping powers, and, more recently, breathing motion. However, baseline shifts of mobile targets should also be taken into account, which complicates the sampling of the space of possible scenarios. We compare

here several sampling strategies. We will also show that current robust optimizers sample scenarios in a statistically inconsistent way.

### Material and Methods

Sampling must optimize the trade-off between clinical optimality and robustness. Both were assessed by computing the volume of the BSPTV and a confidence interval (CI), respectively. The latter is defined as the percentage of all possible ranges and beam positions that the BSPTV encompasses. The findings can then be applied later to robust optimizers.

We have designed a simulation phantom to model uncertainties in lung tumors (Figure 1). Standard deviations of the Gaussian distributions for (systematic) setup errors, baseline shifts, and CT conversion errors were 5 mm, 5 mm, and 2%, respectively. The errors were sampled following three different methods:

1. M1 (conventional approach): sampling of setup errors and baseline shifts within conventional lateral PTV margin for systematic errors (encompassing 90% of possible beam positions). The distal and proximal margins encompass 98% of possible proton ranges scaled by a flat CT conversion error (±3.3% to include 90% of possible CT conversion errors).
2. M2: same as M1 with random sampling of the CT conversion error.
3. M3: all errors are simulated within an is-likelihood hypersurface including 90% of all possible scenarios.

A fixed breathing-induced motion amplitude of 1 cm has been considered for every scenario.

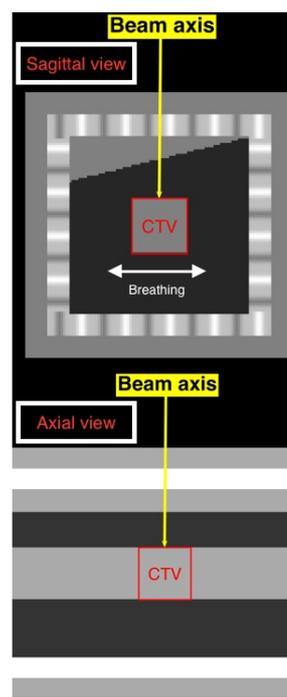

Figure 1: representation of the phantom. Motions and errors simulated are perpendicular to beam axis.

### Results

BSPTVs equaled 430, 420 and 564% of the CTV volume for the three methods, respectively (see figure 2 that illustrates the range margins). M1 does not ensure statistical consistency because of the flat CT conversion error, which overemphasizes unlikely scenarios (large geometrical AND large CT conversion errors) and makes non-trivial the computation of the CI. M3 guarantees at least 90% CI, but with a 34% increase of the irradiated volume. The latter is due to the non-prioritization of

errors and to blindness relative to their potential degeneracies. The CI for M2 equals 88%, but 90% CI can be achieved for M2 by extending slightly the lateral PTV margin to encompass 92% of possible beam positions and 98% of possible ranges, leading to a 425% volume, thus still better than M3.

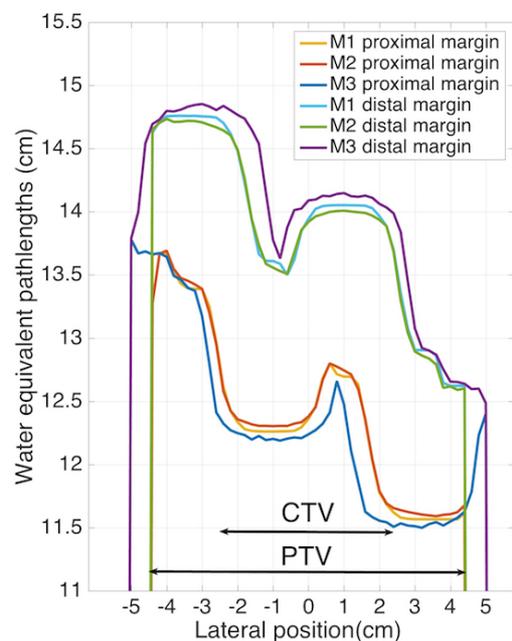

Figure 2: Distal and proximal water equivalent pathlengths (WEPLs) for the various methodologies.

### Conclusion

The best tradeoff between robustness and optimality was achieved through random sampling of all errors limited by the lateral conventional PTV margin and a large margin for the possible proton ranges.

### PO-0826 Evaluation of the new InCise MLC for Cyberknife stereotactic radiotherapy

<sup>2</sup>Centre Eugène Marquis, Radiation Oncology Department, Rennes, France

<sup>3</sup>INSERM, U 1099, Rennes, France

<sup>4</sup>University of Rennes1, LTSI, Rennes, France

### Purpose or Objective

The aim of this study was to evaluate treatment planning performances of the new InCise multileaf collimator (MLC) with reference to the Iris variable circular aperture collimator for intracranial and extracranial Cyberknife stereotactic radiotherapy.

### Material and Methods

The study was performed on a Cyberknife M6 v10.6 (Accuray). A total of 50 cases including 10 brain metastases, 10 acoustic neuromas, 10 liver targets, 10 spinal metastases and 10 prostate cases were investigated. For each case, two treatment plans were generated with TPS Multiplan v5.3 (Accuray): one plan using the InCise MLC v2 associated with the Finite Size Pencil Beam (FSPB) dose calculation algorithm and one plan using the Iris collimator associated with RayTracing (RT) or MonteCarlo (MC) dose calculation algorithm. Dose was prescribed near the 80 % isodose and normalized to obtain the same PTV coverage at  $\pm 0.5$  % for both plans.

The comparison was performed in terms of dose distribution and efficiency by reporting OARs DVH, Baltas' conformal index (COIN), Paddick's gradient index (GI), ICRU homogeneity index (HI), integral dose to normal tissue (NTID), number of monitor units (MU) and treatment time.

For both collimators, accuracy of dose calculation within heterogeneity was evaluated by delivering a typical lung treatment plan on a QUASAR Respiratory phantom (Modus Medical Inc) including a lung target insert. Calculated dose was compared with delivered dose measured by Gafchromic EBT3 films (Ashland) using a gamma index analysis with a local dose criteria of 3 % and a distance-to-agreement criteria of 2 mm.

### Results

Results are summarized in table 1. Compared to Iris plans, MLC plans did not produce significant differences in terms of OARs sparing and dose conformity except for acoustic neuroma for which COIN was degraded by 20 % with MLC. Dose gradient was improved by using the MLC with a GI mean reduction of 18 %. MLC allowed a slight improvement of PTV dose homogeneity for brain metastasis and liver targets and lead to a NTID reduction for extra-cranial treatments. Except for liver targets, MLC plans delivered less MU than Iris plans with a mean reduction of 25 %. MLC plans lead to a treatment time reduction of 28 % in average compared to Iris plans.

The comparison between calculated and measured dose in lung phantom showed a gamma passing rate of 51.6 %, 45.5 % and 98.7 % for FSPB MLC plan, RT Iris plan and MC Iris plan respectively.

Table 1: Comparison of planning parameters (mean value  $\pm$  one standard deviation) for MLC and Iris treatment plans (Ideal value indicated in brackets)

		COIN (1)	GI (lower as possible)	HI (lower as possible)	NTID normalized to volume of normal tissue (Gy) (lower as possible)	Treatment Time (min) (lower as possible)	Delivered MU (lower as possible)
Brain metastases	MLC	1.16 +/- 0.05	2.7 +/- 0.3	0.23 +/- 0.05	91 +/- 57	27 +/- 4	9616 +/- 3454
	IRIS	1.16 +/- 0.07	3.0 +/- 0.4	0.26 +/- 0.05	78 +/- 50	35 +/- 7	15357 +/- 3716
Acoustic neuroma	MLC	1.38 +/- 0.10	3.5 +/- 0.3	0.36 +/- 0.08	21 +/- 7	21 +/- 3	5953 +/- 813
	IRIS	1.15 +/- 0.09	4.2 +/- 0.5	0.28 +/- 0.07	15 +/- 5	31 +/- 5	11437 +/- 2788
Liver targets	MLC	1.09 +/- 0.06	2.7 +/- 0.2	0.24 +/- 0.05	178 +/- 75	39 +/- 5	23304 +/- 5972
	IRIS	1.10 +/- 0.06	3.7 +/- 0.7	0.28 +/- 0.06	254 +/- 91	44 +/- 10	21545 +/- 4464
Spinal metastases	MLC	1.26 +/- 0.12	3.2 +/- 0.3	0.34 +/- 0.11	113 +/- 79	35 +/- 8	22430 +/- 6105
	IRIS	1.22 +/- 0.12	4.2 +/- 0.8	0.33 +/- 0.13	128 +/- 40	46 +/- 8	28480 +/- 7966
Prostate	MLC	1.23 +/- 0.12	3.3 +/- 0.4	0.28 +/- 0.11	132 +/- 76	23 +/- 4	30141 +/- 6782
	IRIS	1.28 +/- 0.15	4.1 +/- 0.6	0.27 +/- 0.10	171 +/- 135	32 +/- 5	38914 +/- 8409

### Conclusion

The use of the InCise MLC for Cyberknife stereotactic radiotherapy allows a significant reduction of MU and treatment time compared to Iris collimator while maintaining a high degree of conformity and a steep dose gradient. However, circular collimators should be still preferred for treatment of small targets like acoustic neuromas due to their smaller field size capability. The use of the InCise MLC for lung targets treatment should not be recommended currently due to the absence of a type B dose calculation algorithm.

### PO-0827 Robustness Evaluation of Head and Neck Treatment with Proton Pencil Beam Scanning Technique

H. Lin<sup>1</sup>, H. Liu<sup>1</sup>, X. Liang<sup>1</sup>, A. Lin<sup>1</sup>, P. Ahn<sup>1</sup>, H. Zhai<sup>1</sup>, M.

Kirk<sup>1</sup>, A. Kassaei<sup>1</sup>, J. McDonough<sup>1</sup>, S. Both<sup>2</sup>

<sup>1</sup>University of Pennsylvania, Radiation Oncology, Philadelphia, USA

<sup>2</sup>Memorial Sloan Kettering Cancer Center, Medical Physics, New York, USA

### Purpose or Objective

To evaluate the treatment robustness of two novel pencil beam scanning proton therapy (PBS PT) beam arrangements relative to volumetric arc therapy (VMAT) for oropharynx head and neck (HN) cancer patients.

## Material and Methods

10 HN oropharynx consecutive patients treated with PBS PT underwent prospective evaluation computer tomography scans (eCTs) during their course of treatment (average 4 eCTs per patient). The robustness of the treatment plans containing two-posterior oblique(PO) PBS fields (2PBS), contingency VMAT plans (2 arcs) and retrospectively generated 3-field PBS plans (3PBS) was evaluated against anatomy changes and residual setup uncertainties via evaluation plans generated on eCTs. 3PBS plan matched two PO fields (same to 2PBS) with an anterior field at thyroid notch level in order to treat the lower neck nodal target. Plan robustness was assessed based on the accumulated dose through deformable image and dose registration between treatment and evaluation plans using VelocityAI. The D98% dosimetric indicator of target coverage and OARs planning constraints were used to evaluate the plan robustness. Changes over 5% in target coverage, excessive cord dose and/or clinical decision triggered proton replan or the use of the VMAT contingency plan.

## Results

The average change of D98% in the accumulated plans for 2PBS, 3PBS and VMAT were:  $4.1\pm 4.8\%$ ,  $-0.1\pm 0.8\%$  and  $-2\pm 3.2\%$  for low risk CTV,  $-1.7\pm 1.8\%$ ,  $-0.5\pm 0.8\%$  and  $-0.73\pm 1.2\%$  for high risk CTV,  $-0.2\pm 0.2\%$ ,  $-0.1\pm 0.1\%$  and  $-0.4\pm 1.3\%$  for gross CTV respectively. The main source of coverage loss at low risk CTV level for 2PBS was found to be due to variable soft tissue deformation of the posterior neck for elderly or short neck patients leading to replanning for 2 out of 10 patients. OARs robustness was maintained within planning constraints.

## Conclusion

2PBS plans were not consistently robust relative to target coverage due to variable folding neck tissue, and therefore it should be cautiously employed for elderly and short neck patients. 3PBS was proved to be consistently robust, similarly with VMAT.

## PO-0828 Stereotactic body radiotherapy (SBRT) for localised prostate cancer on the MR-Linac

A. Pathmanathan<sup>1</sup>, A. Mitchell<sup>2</sup>, K. Thomas<sup>3</sup>, D. Henderson<sup>2</sup>, S. Nill<sup>1</sup>, U. Oelfke<sup>1</sup>, R. Huddart<sup>1</sup>, N. Van As<sup>2</sup>, A. Tree<sup>2</sup>

<sup>1</sup>Institute of Cancer Research, Radiotherapy and Imaging, London, United Kingdom

<sup>2</sup>The Royal Marsden NHS Foundation Trust, Department of Radiotherapy, London, United Kingdom

<sup>3</sup>The Royal Marsden NHS Foundation Trust, Statistics Unit, London, United Kingdom

## Purpose or Objective

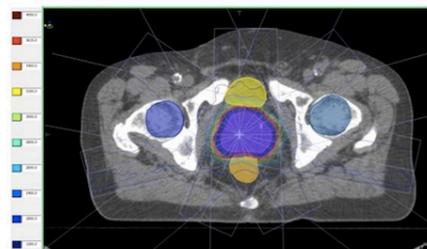

As the estimated alpha-beta ratio for prostate cancer is low (1), moderate hypofractionation has been shown to be isoeffective (2). The MR-Linac (MRL) combines an MR scanner and linac allowing intrafractional tracking of the target (3). However, dose distributions are affected by the magnetic field (4). The first Elekta system MRL (1.5T/7MV) will deliver step-and-shoot intensity modulated radiotherapy (IMRT), a technique rarely used for stereotactic body radiotherapy (SBRT). This planning study assesses whether adequate dose distributions for MRL-based prostate SBRT are possible with comparison to non-MRL based planning techniques: IMRT, volumetric modulated arc therapy (VMAT) and CyberKnife.

## Material and Methods

Using planning CT scans acquired for ten patients with localised prostate cancer, clinical target volume (CTV) was defined as prostate plus proximal 1cm of seminal vesicles. The planning target volume (PTV) was created by addition of a 5mm isotropic margin, except 3mm posteriorly. For the MRL, 5, 7 and 9-field step-and-shoot IMRT plans were created to deliver 36.25Gy in 5 fractions to the PTV with an integrated dose of 40Gy in 5 fractions to the CTV using Monaco 5.19 (research version, Elekta AB,

Stockholm, Sweden). Non-MRL comparison plans included: 7-field 6MV IMRT for a conventional Elekta Agility linac (Elekta AB, Stockholm, Sweden), 6MV FFF single 360° arc VMAT using Pinnacle 9.10 (Philips Radiation Oncology Systems, Fitchburg, WI) for a non-MRL and CyberKnife treatment using Multiplan (Accuray inc, Sunnyvale, CA). Plans were acceptable if the 16 dose constraints of the PACE trial (NCT01584258) were achieved, without a major variation to the protocol.

## Results

**Figure 1:** An example 7-field IMRT plan for prostate SBRT on the MR-Linac. Pink shading- prostate, blue- PTV, orange- rectum, yellow- bladder, red isodose line- 36.25Gy.

**Table 1:** A summary of the number of constraints exceeded and mean values for each plan type.

PLAN TYPE	7-field IMRT MRL	5-field IMRT MRL	9-field IMRT MRL	7-field IMRT Elekta Agility (non-MRL)	CyberKnife	VMAT (non-MRL)
Number of plans optimised	10	9*	10	10	10	10
Constraints exceeded (16 per plan)	23/160	37/144*	21/160	19/160	32/160	22/160
Mean Rectum V36Gy (%) (Dose constraint: V36Gy<1cc)	0.9 (sd 0.5)	1.5 (sd 0.8)	0.8 (sd 0.5)	1.3 (sd 0.5)	1.5 (sd 0.3)	0.9 (sd 0.4)
Mean Bladder V37Gy (%) (Dose constraint: V37Gy<10cc)	6.5 (sd 2.4)	8.5 (sd 2.8)	6.4 (sd 2.4)	7.4 (sd 2.2)	5.9 (sd 2.4)	6.0 (sd 2.3)
Mean Rectum D1cc (Gy) (no trial defined constraint)	35.6 (sd 1.0)	36.4 (sd 1.0)	35.4 (sd 1.2)	36.5 (sd 1.0)	36.5 (sd 0.5)	35.8 (sd 0.5)
Mean Rectum D50 (Gy) (no trial defined constraint)	14.3 (sd 3.2)	14.9 (sd 4.8)	14.1 (sd 3.7)	14.3 (sd 3.4)	11.7 (sd 4.5)	9.5 (sd 4.0)

\*2 of which included a major variation to the PACE protocol constraints.

Clinically acceptable 7-field IMRT MRL plans (see Figure 1) were achieved in all ten patients. Clinically acceptable plans were also achieved for all ten patients using 9-field IMRT, non-MRL 7-field IMRT, non-MRL VMAT and CyberKnife treatment. Clinically acceptable 5-field IMRT MRL plans were only possible in seven patients. Table 1 summarises the number of exceeded constraints, mean rectal doses and mean bladder V37Gy for each plan type. Given the small patient group, exploratory ANOVA analyses were undertaken for the number of constraints missed, the rectum D1cc and the two most challenging constraints to achieve- rectum V36Gy and bladder V37Gy. For the MRL, 5-field IMRT MRL plans performed significantly worse in all these analyses compared to 7-field IMRT. 7-field IMRT MRL plans had significantly lower rectal doses compared to CyberKnife plans. No significant differences were seen between 9-field IMRT MRL plans and non-MRL VMAT plans compared to 7-field IMRT.

## Conclusion

MRL IMRT plans for prostate SBRT achieved the PACE trial constraints in all patients with 9-field appearing similar to 7-field IMRT. 5-field IMRT in this set-up appears inferior for the MRL. All platforms could produce clinically acceptable plans. Further work is needed for dosimetric validation and feasibility of MRL delivery.

## PO-0829 Robustness of IMRT and VMAT for interfraction motion in locoregional breast irradiation

R. Canters<sup>1</sup>, M. Kunze-Busch<sup>1</sup>, P. Van Kollenburg<sup>1</sup>, M. Kusters<sup>1</sup>, P. Poortmans<sup>1</sup>, R. Monshouwer<sup>1</sup>

<sup>1</sup>Radboud University Medical Center, Radiation oncology, Nijmegen, The Netherlands

## Purpose or Objective

Conventional techniques for locoregional breast irradiation using field abutment are challenging, even more in combination with breath-hold irradiation and with hypofractionation, since over- or underdosage may occur more consistently in the abutment region in these circumstances. IMRT and VMAT techniques are likely to

result in more conformal and homogenous irradiation, though robustness for anatomical and posture variations is possibly an issue. Compared to conventional plans, the beams are not fully opposing and fields cannot be opened manually outside the outer contour of the breast and the body. Therefore, in this study we evaluated the robustness of both an IMRT and a VMAT technique for daily variations in patient positioning in comparison to our conventional technique.

#### Material and Methods

20 Patients treated with a dose of 16x2.66 Gy using a conventional technique to the breast and axillary lymph nodes levels I to IV (Figure 1a) were replanned with both an IMRT and a VMAT technique using Pinnacle autoplanning. The IMRT technique consisted of 6 beams with 20° spacing, while the VMAT technique consisted of opposing pairs of 24° arcs (Figure 1). The delivered dose was calculated using the cone beam CT (CBCT) (Elekta XVI) images for each fraction to quantify the influence of patient positioning, both for an online and offline correction protocol. Contours were transferred from planning CT to CBCT by deformable image registration using Mirada RTx. Density overrides were applied to account for imperfections in Hounsfield unit values on the CBCT. IMRT and VMAT techniques were compared to the conventional technique for the V95%, conformity index (CI), mean lung dose and mean heart dose. The CTV-PTV margin used is 7mm. Since the setup error is accounted for when evaluating dose on the CBCT, we used the CTV for the evaluation.

#### Results

Evaluation of the treatment plans for 20 patients showed that V95% coverage of IMRT and VMAT plans was comparable to conventional plans (Table 1). Conformity was significantly higher for IMRT and VMAT. Mean lung dose was approximately 0.7 Gy lower on average, while mean heart dose increased by approximately 0.7 Gy using IMRT or VMAT. Robustness evaluation of the dose on daily CBCT's using an online positioning protocol showed that V95% coverage remained stable for conventional, IMRT and VMAT. Significant conformity improvement was obtained using both IMRT and VMAT, and small differences in mean heart dose (+0.7 Gy) and mean lung dose (-0.8 Gy) were found. Evaluation of an offline positioning protocol showed similar results.

#### Conclusion

Presented IMRT and VMAT techniques show a similar robustness for interfraction motion in locoregional breast irradiation compared to the conventional technique, while conformity of the target volume is increased significantly. An offline positioning protocol would be sufficient for clinically acceptable set-up accuracy.

#### PO-0830 Quantification of density and tissue changes in pencil beam scanning proton treatment.

F. Van den Heuvel<sup>1</sup>, F. Fiorini<sup>1</sup>, B. George<sup>1</sup>  
<sup>1</sup>University of Oxford, CRUK/MRC Oxford Institute for Radiation Oncology, Oxford, United Kingdom

#### Purpose or Objective

Proton pencil beam scanning (PBS) is becoming the methodology of choice to deliver proton therapy in many cases. Several authors have reported discrepancies between the dose distributions generated by commercial planning systems, using analytical models, compared to those using stochastic methods. The differences are greatest in areas with extensive tissue inhomogeneities. In analytically based commercial planning systems, inhomogeneities are taken into account using a water equivalent path length (WEPL) scaling. In this work we quantify and investigate the impact of different densities and tissue on the dose deposition characteristics of a proton pencil beam.

#### Material and Methods

A single pencil beam with nominal energy 226 MeV from an IBA-facility is modeled in homogenous cubic 40x40x40 cm<sup>3</sup> phantom using FLUKA. The pencil beam's dose deposition is uniquely characterised using a stable

distribution parameterisation, yielding three parameters  $\alpha$  (halo or tail describing parameter),  $\gamma$  (scale parameter) and ID (integral dose) as a function of depth in the phantom. Changes of the parameters with changing densities are investigated and the WEPL technique is assessed. In addition, the behaviour of the parameters in a selection of relevant tissues is evaluated.

In addition we investigated different specific media having different atomic properties and show that an effective density representation is can be used for these.

### Results

The parameters  $\alpha$  (Fig 1) describing the scattered radiation and ID (not shown) clearly scale with the density of the material. The scaling parameter  $\gamma$  shows a more complicated behaviour. Indeed, this work shows that an effective density can be calculated which has the form of  $\rho_{\text{eff}} = 1 - (1 - \rho)/2$

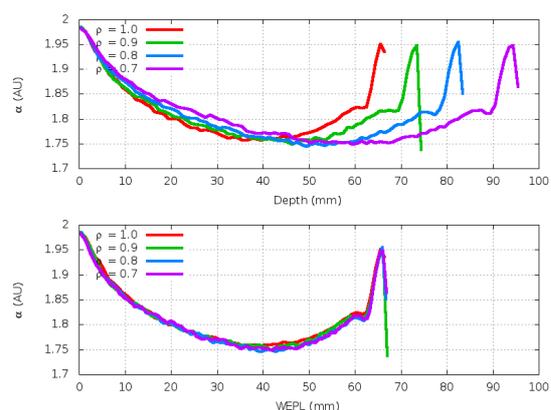

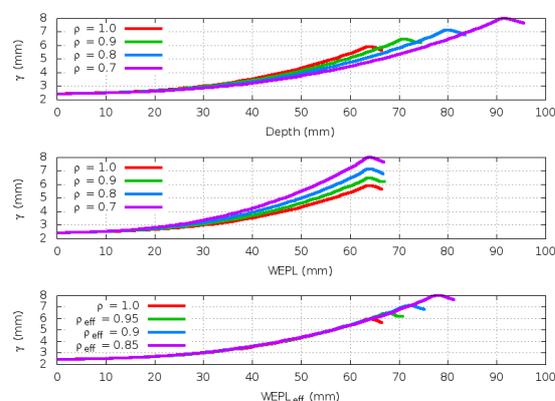

Figure 2 shows the difference between both curves. Note that the maximum of the curves follows the WEPL rule as they are linked to the position of the bragg peak.

### Conclusion

Simple WEPL scaling used in analytical dose calculations may not correctly model the physical properties of a proton pencil beam. A more complex scaling framework that separates the halo and scale parameters could provide a more accurate representation of dose deposition from a proton pencil beam. In further work (not shown) we also show that tissue specific (i.e. stopping power differences) properties can be handled by using effective densities.

### PO-0831 Multi isocentric 4-pi volumetric modulated arc therapy approach for head and neck cancer

S. Subramanian<sup>1</sup>, S. Chilukuri<sup>1</sup>, V. Subramani<sup>2</sup>, M. Kathirvel<sup>1</sup>, G. Arun<sup>1</sup>, S.T. Swamy<sup>1</sup>, K. Subramanian<sup>1</sup>, A. Fogliata<sup>3</sup>, L. Cozzi<sup>3</sup>

<sup>1</sup>Yashoda Super Specialty Hospital, Radiation Oncology, Hyderabad, India

<sup>2</sup>All India Institute of Medical Sciences, Radiation

Oncology, New Delhi, India

<sup>3</sup>Humanitas Research Hospital and Cancer Center, Radiation Oncology, Milan-Rozzano, Italy

### Purpose or Objective

The possibility to deliver intensity modulated plans using most of the 4-pi space, i.e. with extensive use of non-coplanar beams and complex trajectories for the couch-gantry-collimator system, has been explored on stereotactic irradiation in the brain, lungs and prostate and have shown significantly sharper dose gradients. The applicability of 4p techniques to large target volumes with volumetric modulated arc therapy (VMAT) treatments remains unaddressed for head and neck cancer (HNC). The aim of this work is to explore the feasibility and deliverability of multi-isocentric 4-pi VMAT (4pi-VMAT) plans in comparison with coplanar VMAT (CP-VMAT) plans for the irradiation of HNC patients characterized by large targets and the presence of several organs at risk.

### Material and Methods

25 previously treated patients of HNC were planned to achieve the highest dosimetric plan quality with 2 full coplanar VMAT arcs (CP-VMAT) on 6MV from a Clinac-iX (Varian), planned with Eclipse version 13.1, calculated with Acuros. 4pi-VMAT plans were then generated using same priorities and objectives, using 1 full arc and 4-6 non-coplanar arcs on 2-3 isocenters: typically 1 full arc with couch at 0°, 2 partial arcs (length of ±210°) with couch ~±45°, and 2 partial arcs (length of ±250°) with couch ~±15°. Dose was prescribed on three levels: 70, 60/63, and 56 Gy on targets of median volumes of 720, 492, and 94 cm<sup>3</sup>, respectively. The following organs at risk (OAR) were defined and analyzed: parotids, oral cavity, esophagus, trachea, larynx, pharyngeal constrictor muscles, mandible, temporomandibular joint, middle ear, spinal cord and brain stem. Pre-treatment quality assurance was performed to assess deliverability and accuracy of the 4pi-VMAT plans.

### Results

CP-VMAT and 4pi-VMAT plans achieved the same degree of coverage for all target volumes related to near-to-minimum and near-to-maximum doses. 4pi-VMAT plans resulted in an improved sparing of OARs. The average mean dose reduction to the parotids, larynx, oral cavity and pharyngeal muscles were 3Gy, 4Gy, 5Gy and 4.3Gy respectively. The average maximum dose reduction to the brain stem, spinal cord and oral cavity was 6.0Gy, 3.8Gy and 2.4Gy respectively. The average MUs were 525±78 and 548±70 for 4pi-VMAT and CP-VMAT, respectively. The average simulated beam on time for 4pi-VMAT plans (612±77 s) was 3.7 times higher than that of CP-VMAT plans (167±30 s). Pre-treatment QA results showed that plans can be reliably delivered with mean gamma agreement index of 97.0±1.1% with 3% dose difference and 3% distance to agreement criteria.

### Conclusion

4pi-VMAT plans significantly decrease dose-volume metrics for relevant OARs and results are technically feasible and reliable from a dosimetric standpoint. Early clinical experience has begun.

### PO-0832 The impact of variable RBE and breathing control in proton radiotherapy of breast cancer

J. Odén<sup>1,2</sup>, K. Eriksson<sup>2</sup>, A.M. Flejmer<sup>3</sup>, A. Dasu<sup>4</sup>, I. Toma-Dasu<sup>1,5</sup>

<sup>1</sup>Stockholm University, Department of Medical Radiation Physics, Stockholm, Sweden

<sup>2</sup>RaySearch Laboratories, Department of Research, Stockholm, Sweden

<sup>3</sup>Linköping University, Department of Oncology and Department of Clinical and Experimental Medicine, Linköping, Sweden

<sup>4</sup>The Skandion Clinic, Uppsala, Sweden

<sup>5</sup>Karolinska Institutet, Department of Oncology and Pathology, Stockholm, Sweden

### Purpose or Objective

Proton therapy, with or without breathing control techniques, may be used to reduce the cardiopulmonary burden in breast cancer radiotherapy. However, such studies typically assume a constant RBE of 1.1 for protons. This study aims to assess the impact of using a variable RBE in breast proton radiotherapy and to evaluate the sensitivity to respiratory motion when no breathing control is applied.

### Material and Methods

Tangential photon IMRT and 3-fields proton IMPT plans for breast radiotherapy were generated for twelve patients, both on a free-breathing (FB) CT and on a CT using breath-hold-at-inhalation (BHI). 2 Gy(RBE) per fraction in 25 fractions were planned to the whole breast. The physical proton dose was optimized assuming a constant RBE of 1.1. Besides the constant RBE of 1.1, the variable RBE-model by Wedenberg et al. (2013), assuming an  $\alpha/\beta$  of 3.5 Gy for the CTV/PTV and 3 Gy for the OARs, was used for plan evaluation. Subsequently, the FB plans were recalculated on the CT images of the two extreme phases (inhale and exhale) to evaluate the sensitivity of a treatment delivery without breathing control.

### Results

All photon and constant RBE proton plans met the clinical goals with similar target coverage. The target conformity and homogeneity of the proton plans were superior to the photon plans. The plan quality was generally independent on whether the FB or BHI CT-scan was used. However, if the heart was close to the target, the BHI plan lowered the dose to the left anterior descending (LAD) artery in most cases. Applying the variable RBE-model resulted in an average of the mean RBE of 1.18 for the PTV and also increased the heterogeneity. The predicted RBE values in the OARs were also substantially higher than 1.1. However, due to the low physical doses, this is expected to have a minor impact. The dosimetric parameters for the BHI plans are shown in Table 1.

The recalculation of the FB plans on the extreme phases generally resulted in minor differences for the CTV coverage and OAR doses for the proton plans. Small CTV volumes may, however, receive a slightly lower dose for the recalculated photon FB plans. The ranges of dosimetric parameters for the FB plan for one patient are shown in Table 2.

Table 1. Mean values and one standard deviation for dosimetric parameters of the BHI plans for all twelve patients. The variable RBE-model used is the one by Wedenberg et al. (2013), assuming an  $\alpha/\beta$  of 3.5 Gy for the PTV and 3 Gy for the OARs.

NTCP <sup>a</sup> [%]	0.4 (0.5, 0.4)	0.4 (0.5, 0.4)	0.4 (0.6, 0.4)

<sup>a</sup>Grade  $\geq 2$  radiation pneumonitis using the LKB model ( $n=1$ ,  $m=0.37$ ,  $TD_{50}=30.8$  Gy and  $\alpha/\beta=3.0$  Gy from Seppenwoolde et al. 2003) with the total lung volume.

### Conclusion

The use of the variable RBE-model results in substantially higher predicted doses to the CTV compared to the constant 1.1, due to the low  $\alpha/\beta$  associated with breast cancer. Substantially higher RBE values are also predicted for the OARs. This decreases the potential benefit with protons, but could probably be neglected in cases where the physical doses are low. However, if e.g. the LAD is close to the target this could lead to substantially higher predicted doses. The variable RBE could therefore be of importance in certain cases when employing a NTCP model based comparison between proton and photon plans.

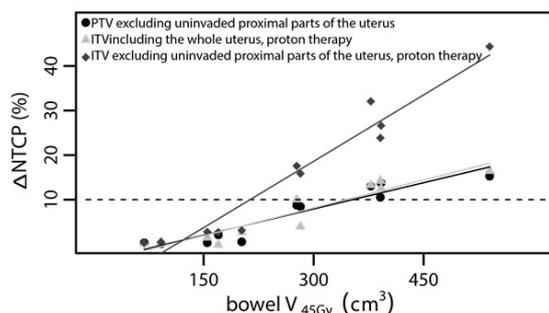

**PO-0833 Reducing small bowel dose for cervical cancer using IMPT and target tailoring in treatment planning**  
 P. De Boer<sup>1</sup>, A.J.A.J. Van de Schoot<sup>1</sup>, H. Westerveld<sup>1</sup>, M. Smit<sup>1</sup>, M.R. Buist<sup>2</sup>, A. Bel<sup>1</sup>, C.R.N. Rasch<sup>1</sup>, L.J.A. Stalpers<sup>1</sup>  
<sup>1</sup>Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands  
<sup>2</sup>Academic Medical Center, Gynaecology and Obstetrics, Amsterdam, The Netherlands

### Purpose or Objective

Current radiotherapy standards for cervical cancer patients lead to irradiation of large bowel volumes and bladder during external beam radiotherapy (EBRT). Highly conformal techniques such as IMRT, arc-rotation therapy and image guided adaptive radiotherapy (IGART) have resulted in considerable reduction in volume to organs at risk (OARs), but there remains room for further improvement. We previously showed that cervical invasion into the uterine corpus assessed by MRI correlates well to pathological invasion [1]. In the present study we wish to investigate the potential clinical benefit from target tailoring by excluding the tumor free proximal part of the uterus during IGART. Furthermore, we compare this benefit with the advantage of an improved dose conformity by intensity-modulated proton therapy (IMPT).

### Material and Methods

Diagnostic MRIs and planning-CTs from eleven patients with locally advanced cervical cancer were used; all previously had photon radiotherapy and a substantial (>4 cm) tumor-free part of the proximal uterus as visualized by MRI. IGART and robustly optimized IMPT plans were generated for both conventional target volumes (including the entire uterus), and MRI-based target tailoring (excluding the non-invaded proximal part of the uterus), which yielded four treatment plans per patient. For each plan, V<sub>15Gy</sub>, V<sub>30Gy</sub>, V<sub>45Gy</sub> and D<sub>mean</sub> for bladder, sigmoid, rectum and bowel bag were compared. The clinical benefit of either and both approaches were estimated by calculating the normal tissue complication probability (NTCP) for at least grade II acute small bowel toxicity.

## Results

Both IMPT or target tailoring by excluding the proximal uterus resulted in significant reductions of  $V_{15Gy}$ ,  $V_{30Gy}$ ,  $V_{45Gy}$  and  $D_{mean}$  for bladder and small bowel. Compared to conventional volumes, target tailoring by excluding the non-invaded uterus resulted in an average reduction of the primary ITV and PTV of 37% and 8%, respectively. IMPT would have reduced the estimated NTCP for small bowel toxicity ( $\geq$  grade 2) from 25% to 18%, and would be additionally reduced to 9% when IMPT were combined with MRI-based target tailoring. Major NTCP reductions of  $>10\%$  were predicted in four patients (36%) by IMPT, and in six patients (55%) when IMPT were combined with MRI-based target tailoring. Patients benefitted most (NTCP reduction  $>10\%$ ) from one of the investigated approaches if the  $V_{45Gy}$  for bowel cavity was  $>275$   $cm^3$  during standard IGART alone; a similar reduction in NTCP from the combined approached would have been obtained in patients with a  $V_{45Gy}$  for bowel cavity  $>200$   $cm^3$ .

## Conclusion

In patients with cervical cancer, both 1) proton therapy and 2) target tailoring by excluding the radiologically uninvolved part of the uterine corpus led to a significant dose reduction to surrounding OARs, which separately would already yield a clinically important decrease in small bowel toxicity, which is cumulative if both approaches would be combined.

## PO-0834 Automated planning to reduce integral dose in robotic radiosurgery for benign tumors

L. Rossi<sup>1</sup>, A. Méndez Romero<sup>1</sup>, M. Milder<sup>1</sup>, E. De Klerck<sup>1</sup>, S. Breedveld<sup>1</sup>, B. Heijmen<sup>1</sup>

<sup>1</sup>Erasmus Medical Center, Radiation Oncology, Rotterdam, The Netherlands

## Purpose or Objective

Highly conformal dose distributions and minimizing integral dose are essential in radiosurgery of benign vestibular schwannoma (VS) tumors to avoid long term side effects. This includes avoidance of secondary tumor induction in these long surviving patients. High delivery accuracy can be obtained with the robotic CyberKnife (CK, Accuray Inc, Sunnyvale, USA) due to real time image-guided tracking, allowing small PTV margins. However, optimal plan quality may be hampered by the current trial-and-error planning approach, as it strongly depends on the planner's experience and available planning time. We have developed a system for fully automated CyberKnife treatment planning. In this study, we have used this system to automatically generate plans for vestibular schwannoma patients (AUTOplan) and we have compared them with plans that were manually generated in clinical routine (MANplan), both with the IRIS collimator.

## Material and Methods

Both MANplans and AUTOplans were generated with the Multiplan TPS (Accuray Inc). For AUTOplanning, a fully automatic pre-optimization was performed with our in-

house multicriterial optimizer to generate input parameters for automated plan generation in Multiplan, including patient-specific parameters to maximally control integral dose. Plan comparisons were made for 15 patients. Both for automatic and manual planning, the goal was to deliver a single fraction of 12 Gy, with planning priorities PTV V100%  $\geq$  98%, Brainstem Dmax  $<$  12.5 Gy, while at the same time keeping the integral dose as small as possible. For un-biased plan quality comparisons, AUTOplans were generated such that the resulting CK treatment time was similar to that for the corresponding MANplan.

## Results

AUTOplans were comparable to manual MANplans in terms of PTV coverage (AUTO:  $99.4 \pm 0.5\%$ , MAN =  $99.1 \pm 0.5\%$ ,  $p=0.1$ ) and treatment time (AUTO =  $39.5 \pm 4.7$  min, MAN =  $38.9 \pm 5.9$  min,  $p=0.3$ ). On average, the brainstem D2%, D1cc and Dmean were very similar, i.e. 9.5 vs. 9.6, 8.6 vs. 8.5, and 2.0 vs. 2.2 Gy for the AUTO- and MANplans, respectively ( $p>0.2$ ). Patient volumes receiving more than 1, 2, 4, and 6 Gy were highly reduced in the AUTOplans for the majority of patients, as visible in figure 1 (upper), with average reductions of 26.0% (SD= 15.4%,  $p < 0.001$ ), 14.7% (SD=10.5%,  $p < 0.001$ ), 9.8% (SD= 10.3%,  $p = 0.002$ ), and 6.3% (SD=10.4%,  $p = 0.010$ ). Conformality was also better in the AUTOplans, and spiky dose leakage away from the target was less frequent and severe, as visible in figure 2. The D2% in ring structures at 1, 2, and 3 cm distance from the PTV were 3.6, 1.9, and 1.3 Gy in AUTOplans vs. 4.7, 2.4, and 1.6 Gy in the MANplans ( $p < 0.001$ ). For almost all patients, ring structures' D2% were lowest in the AUTOplan (see figure 1, lower).

## Conclusion

With automated Cyberknife planning, highly patient-specific parameters for optimal plan generation in Multiplan are automatically established, resulting in substantial reductions in integral dose in treatment of benign vestibular schwannoma tumors, without degrading PTV dose delivery, increasing OAR doses, or enlarging treatment time.

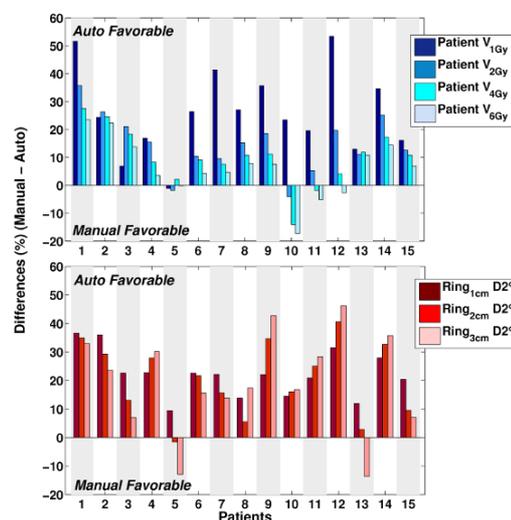

Figure 1: Integral dose reductions with auto planning.

#### PO-0835 PTV margin for pelvic lymph nodes in IGRT guided prostate radiotherapy

H.R. Jensen<sup>1</sup>, C.R. Hansen<sup>1,2</sup>, S.N. Agergaard<sup>1</sup>, E.L. Lorenzen<sup>1,2</sup>, L. Johnsen<sup>1</sup>, S. Hansen<sup>2,3</sup>, L. Dysager<sup>3</sup>, C. Brink<sup>1,2</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

<sup>2</sup>University of Southern Denmark, Faculty of Health Sciences, Odense, Denmark

<sup>3</sup>Odense University Hospital, Department of Oncology, Odense, Denmark

#### Purpose or Objective

In recent years irradiation of the pelvic lymph nodes for high risk prostate cancer has received strong interest, as a potential way to increase locale control probability. However the prostate and the pelvic lymph nodes move independently of each other. The purpose of this study is to calculate the additional PTV margin needed for covering the pelvic lymph node region, when performing a registration and setup on the prostate with implanted gold fiducials.

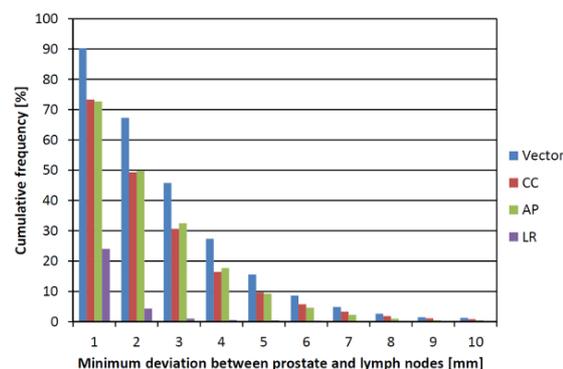

#### Material and Methods

All 40 prostate patients treated at the same accelerator in 2015 were included in the study. The majority of the patients had stage T3 disease. All patients had three gold fiducials implanted into the prostate 2-3 weeks before CT simulation, which were used in the daily online IGRT. A total of 1284 cone beam CT scans were analyzed. An automatic gold seed algorithm (used as a surrogate for the prostate) and bone algorithm covering the upper pelvic and lower spine area (used as a surrogate for the lymph nodes) were performed. The deviation between the two registrations was calculated and the population based random and systematic setup error was calculated. To estimate the PTV margin needed the Van Herk margin formula was used  $M = 2.5 * \Sigma_{\text{systematic}} + 0.7 * \sigma_{\text{random}}$

#### Results

The setup margin needed for the lymph node region of this patient cohort is 2.1, 6.9 and 6.6 mm for the LR, CC, AP directions, respectively (see table). This margin does not incl. any other uncertainties. The minimum deviation between prostate seed and pelvic bone match is shown as a cumulative histogram in the figure for the individual directions. More than 15.4% of the fractions have a deviation of more than 5 mm, and 5% of the fractions have a larger deviation than 7mm. The largest deviations are seen in the CC and AP direction, and a small deviation in the LR direction. The systematic and random errors are shown in the table.

	$\Sigma$ [mm]	$\sigma$ [mm]	PTV margin [mm]
LR	0.7	0.7	2.1
CC	1.8	2.2	6.9
AP	1.8	2.1	6.6

#### Conclusion

Even though the analyzed IGRT protocol focuses entirely on the gold seed of the prostate the needed margins for the lymph nodes are only slightly larger than 5 mm which in many centers are used as a standard PTV margin. Thus, the additional margin needed to include the lymph nodes is actually somewhat modest. However, the optimal balance between dose coverage of tumor and lymph nodes both in regard to local control and toxicity is still unclear, and needs further investigation.

#### PO-0836 Impact of Deep Inspiration Breath Hold on Left Anterior Coronary dose in Left Breast irradiation.

F. Azoury<sup>1</sup>, S. Achkar<sup>1</sup>, N. Farah<sup>1</sup>, D. Nasr<sup>1</sup>, C. El Khoury<sup>1</sup>, N. Khater<sup>1</sup>, J. Barouky<sup>1</sup>, R. Sayah<sup>1</sup>, E. Nasr<sup>1</sup>

<sup>1</sup>Hotel Dieu de France Hospital - Saint Joseph University, Radiation Oncology, Beirut, Lebanon

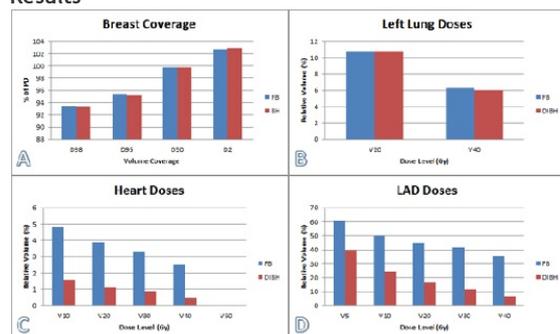

#### Purpose or Objective

Irradiation of Left breast cancer exposes women to higher doses to the heart and LAD coronary. Blocking the heart in the tangent fields will inevitably cause under dosage in proximity to the tumor bed. Here we evaluate the effect of deep inspiration breath hold (DIBH) on the coverage of the whole breast and the reduction of heart and LAD doses.

#### Material and Methods

We performed a dosimetric study on 25 patients treated with DIBH for left breast cancer utilizing RPM (Varian Medical Systems). Treatment plans were generated in Free Breathing (FB) and DIBH. Optimization was done with 3D Field-in-Field technique utilizing two-tangent setup. Care was taken to cover the whole breast volume. Prescription dose was 50Gy in 25 fractions. Planning objectives were: near minimum dose (D98) > 90% (45Gy), near maximum dose (D2) <105% and a median dose of 50Gy. Doses to the heart, LAD and left lung were compiled, left breast coverage was evaluated, and statistical analysis was performed using Student T-test with a 95% Interval of confidence.

## Results

Left breast results: Identical coverage was achieved with a D95 of  $95.2\% \pm 0.4$  (DIBH) vs.  $95.4\% \pm 0.6$  (FB) ( $p=0.27$ ). No statistical difference was found in D98, median and D2 (Figure 1.A). Left lung results: No statistical difference was also found (Figure 1.B). Heart results: Doses were significantly lower with DIBH; Dmean at  $1.5\text{Gy} \pm 0.8$  (DIBH) vs.  $2.9\text{Gy} \pm 1.6$  (FB) ( $p < 0.001$ ) and Dmax at  $36.3\text{Gy} \pm 14.7$  (DIBH) vs.  $46.2\text{Gy} \pm 6.6$  (FB) ( $p=0.004$ ). DVH metrics for V10, V20, V30, and V40 were all significantly better in DIBH (Figure 1.C). LAD coronary results: Doses were significantly lower with DIBH with Dmean at  $9.5\text{Gy} \pm 7.2$  (DIBH) vs.  $21.8\text{Gy} \pm 11.4$  (FB) ( $p < 0.001$ ) and a Dmax at  $29.2\text{Gy} \pm 17$  (DIBH) vs.  $42.3\text{Gy} \pm 12$  (FB) ( $p=0.003$ ). DVH metrics favored the DIBH plans significantly all across the range of doses (Figure 1.D).

### Conclusion

In the treatment left breast cancer, 3D-DIBH showed superior dosimetric advantages in comparison to 3D-FB. Both heart and LAD were significantly spared without compromising left breast coverage. The LAD was spared for doses ranging from the low dose spectrum to the highest dose.

### PO-0837 Dosimetric advantages afforded by Dynamic WaveArc therapy accelerated partial breast irradiation

Y. Ono<sup>1</sup>, M. Yoshimura<sup>1</sup>, K. Hirata<sup>1</sup>, N. Mukumoto<sup>1</sup>, T. Ono<sup>1</sup>, M. Inoue<sup>1</sup>, M. Ogura<sup>1</sup>, T. Mizowaki<sup>1</sup>, M. Hiraoka<sup>2</sup>

<sup>1</sup>Kyoto University- Graduate School of Medicine, Department of Radiation Oncology and Image-applied Therapy, Kyoto, Japan

<sup>2</sup>Japanese Red Cross Wakayama Medical Center, Department of Radiation Oncology, Wakayama, Japan

### Purpose or Objective

We identify dosimetric advantages of the novel volumetric modulated arc therapy (VMAT) featuring continuously varying non-coplanar trajectories. This is the Dynamic WaveArc (DWA) therapy used for accelerated partial breast irradiation (APBI). The dose distribution of DWA therapy was compared to that of non-coplanar three-dimensional conformal radiotherapy (3D-CRT) and coplanar VMAT.

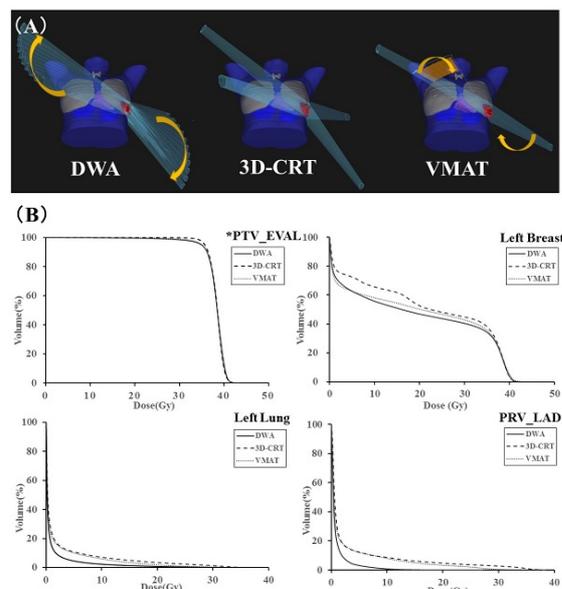

### Material and Methods

We evaluated APBI dose distributions, delivered via DWA, in 24 left-side breast cancer patients via non-coplanar 3D-CRT from November 2011 to April 2016 at our institution. The prescribed dose was 38.5 Gy in 10 fractions. The Vero4DRT enables DWA by continuous gantry rotation and O-ring skewing with moving dynamic multi-leaf collimator (MLC). Thus, the Vero4DRT delivers non-coplanar VMAT without couch rotation, minimizing dose delivery to adjacent organs at risk (OARs). We created two sets of 11 control points (at angles  $315\text{--}35^\circ$  to the O-ring angle, and  $110\text{--}155^\circ$  and  $290\text{--}355^\circ$  to the gantry angle), for two non-coplanar DWA trajectories. DWA, non-coplanar 3D-CRT, and coplanar VMAT treatment plans were created by a clinical treatment planning system, Raystation, using a collapsed cone dose-calculation algorithm (Figure 1-A). The mean DWA doses to the planning target volume (PTV),

the bilateral breasts, the lungs, the heart, the left anterior descending artery (LAD), and the thyroid, were compared to those of non-coplanar 3D-CRT and coplanar VMAT. A  $p$  value  $< 0.05$ , derived using the paired Student's  $t$ -test, was considered to reflect a significant difference.

### Results

Figure 1-B shows the averaged dose-volume histograms for all 24 patients in terms of their PTVs and OARs. The Table summarizes the mean dose volume indices for the targets and OARs, and the MU for each technique. Significant difference was not observed in doses to the PTV. When DWA was employed, the average  $V_{20\text{Gy}}$ ,  $V_{10\text{Gy}}$ , and  $V_{5\text{Gy}}$  to the ipsilateral lung; the average  $V_{10\text{Gy}}$  and  $V_{5\text{Gy}}$  to the heart; the  $D_{2\%}$  for the planning organ at risk volume of the LAD (PRV\_LAD); and the  $V_{50\%}$  of, and the mean dose to the ipsilateral breast, were significantly lower than those of non-coplanar 3D-CRT and coplanar VMAT. The average  $D_{2\%}$  to the contralateral breast and the  $V_{5\text{Gy}}$  to the contralateral lung did not differ significantly among the techniques. Furthermore, the mean prescribed MU for DWA was 486.22 MU, which was only 9.8% higher than that for non-coplanar 3D-CRT (442.67 MU) ( $p < 0.05$ ).

**Figure.** (A) Representative beam arrangement for DWA, non-coplanar 3D-CRT and coplanar VMAT. (B) Averaged dose-volume histograms in 24 patients with each technique for PTV\_EVAL, left breast, left lung and PRV\_LAD.

\*PTV\_EVAL = modified planning target volume  
Abbreviations: DWA = Dynamic WaveArc; 3D-CRT = three-dimensional conformal radiotherapy; VMAT = volumetric modulated arc therapy; SD = standard deviation; PRV = planning organ at risk volume; LAD = left anterior descending artery; MU = monitor unit; D<sub>2%</sub> = lowest dose received by at least 2% of the volume; V<sub>50%</sub> = percentage for the volume receiving 50% Gy or more

## Conclusion

The use of DWA for APBI improved the dose distribution compared to that of non-coplanar 3D-CRT and coplanar VMAT; this may reduce the risk of toxicity without prolonging treatment time.

## PO-0838 Treatment planning for the MR-linac: plan quality compared with current clinical practice

A.J.A.J. Van de Schoot<sup>1</sup>, C. Carbaat<sup>1</sup>, B. Van Triest<sup>1</sup>, T.M. Janssen<sup>1</sup>, J.J. Sonke<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands  
**Purpose or Objective**

Clinical introduction of the MR-linac (MRL) involves treatment planning using Monaco (Elekta AB, Stockholm,

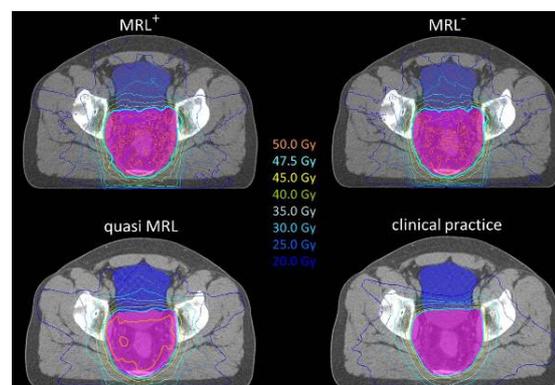

Sweden) for both initial treatment planning and online plan adaptation. Next to the presence of a magnetic field, also several MRL-specific beam and collimator properties need to be taken into account that could influence plan quality. Our aim was to investigate the influence of MRL-specific characteristics on plan quality for rectum cancer and benchmark MRL plans against current clinical practice.

## Material and Methods

Eight rectum cancer patients treated on a conventional CBCT-based linac (25 x 2.0 Gy) were included in this retrospective study. For each patient, the clinically acquired planning CT, delineated structures and treatment plan generated with Pinnacle<sup>3</sup> (dual-arc VMAT, 10MV, collimator 20°, SAD: 100.0 cm) were available. The same CT and structure set were used to create two MRL treatment plans with Monaco: one plan with (MRL<sup>+</sup>) and one plan without (MRL<sup>-</sup>) the presence of a 1.5 T magnetic field. Both MRL plans were created using a 7-beam IMRT technique incorporating MRL-specific properties (7MV, collimator fixed at 90°, FFF, SAD: 143.5 cm). Plan optimization was based on a class solution and objective values were individually optimized. Also, a quasi MRL plan was generated with Pinnacle<sup>3</sup> using a 7-beam IMRT technique and comparable MRL properties (6MV, collimator 90°, FFF, SAD: 143.5 cm). After rescaling (PTV V<sub>95%</sub> = 99.2%), plans were accepted when the clinical acceptance criterion was fulfilled (PTV D<sub>1%</sub> < 107%). Quality differences between MRL<sup>+</sup>, MRL<sup>-</sup> and quasi MRL plans were assessed by calculating PTV D<sub>mean</sub>, PTV D<sub>1%</sub>, bowel D<sub>mean</sub> and bladder D<sub>mean</sub>. Also, D<sub>mean</sub> and D<sub>1%</sub> to the patient excluding PTV<sub>2cm</sub> (i.e. PTV + 2.0 cm) were determined. All MRL plans were benchmarked against the clinically delivered treatment plans and tested for significance (Wilcoxon signed-rank test).

## Results

All MRL plans were clinical acceptable after rescaling. Figure 1 shows an example of dose distributions for the MRL plans and the clinical plan of one patient. The 7-beam IMRT technique used for all MRL plans resulted in a minor decrease in plan homogeneity, indicated by an increased PTV D<sub>mean</sub> (Table 1). Also, all MRL plans showed a significant increase in D<sub>mean</sub> for the bladder, bowel and body compared to clinical practice. However, the clinical relevance of these differences is expected to be limited. Given the similar quality of MRL<sup>+</sup> and quasi MRL plans, differences between MRL<sup>+</sup> plans and clinical practice are mainly induced by the MRL-specific properties. The small difference between MRL<sup>+</sup> and MRL<sup>-</sup> plans indicated limited influence of the magnetic field on plan quality.

**Figure 1.** Example of dose distributions for one patient with an MRL<sup>+</sup> plan, an MRL<sup>-</sup> plan, a quasi MRL plan and the clinically delivered plan. The PTV and bladder are indicated by the magenta color wash and blue color wash, respectively.

**Table 1.** Mean (min – max) differences for dose-volume histogram parameters between the MRL<sup>+</sup> plan, MRL<sup>-</sup> plan and quasi MRL plan compared to the clinically delivered treatment plan as well as dose-volume histogram parameter differences between MRL<sup>+</sup> plans and MRL<sup>-</sup> plans. Positive values indicate higher dose-volume histogram parameter values compared to clinical practice. An asterisk indicates a significant difference between the MRL plans and clinical practice and a dagger indicates a significant difference between the MRL<sup>+</sup> plans and the MRL<sup>-</sup> plans.

Body D <sub>1%</sub> (Gy)	3.30 * (0.10 – 5.50)	3.38 * (-0.50 – 6.20)	1.60 * (-0.50 – 3.30)	-0.08 (-0.80 – 0.60)

Abbreviations: PTV, planning target volume; Gy, gray; MRL, MR-lineac; MF, magnetic field.

**Conclusion**

This study demonstrates the ability of creating high-quality MRL treatment plans for rectum cancer. Given the differences in machine characteristics, some plan quality differences were found between MRL treatment plans and current clinical practice. These results support a well-prepared clinical introduction of the MRL.

**PO-0839 Personalized VMAT optimization for pancreatic SBRT**

I. Mihaylov<sup>1</sup>, L. Portelance<sup>1</sup>

<sup>1</sup>University of Miami, Radiation Oncology, Miami, USA

**Purpose or Objective**

Inverse IMRT planning is a very labor intensive, trial-and-error process, aiming to find a middle ground between the conflicting objectives of adequate tumor coverage and sparing nearby healthy tissues. Even if a plan is clinically acceptable, that plan is unlikely to be the best solution, where the healthy tissue is spared as much as possible. To a large extent the optimization process is user and treatment planning system specific, where more experienced users generate better quality radiotherapy plans. This work introduces a fully automated inverse optimization approach and its application to pancreatic SBRT.

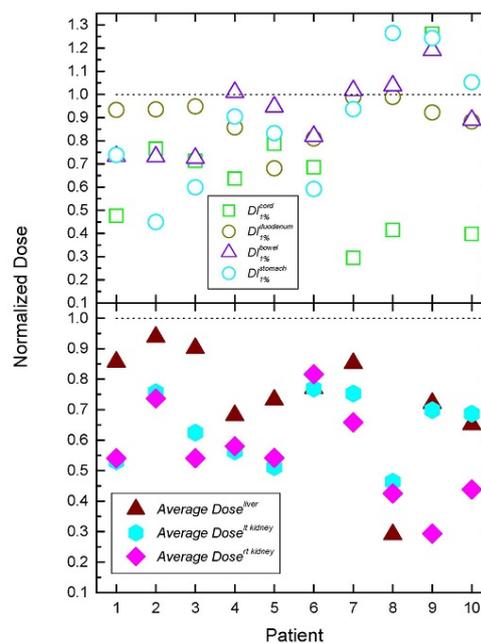

**Material and Methods**

Ten cases, treated breath-hold, were retrospectively studied. The outlined anatomical structures consisted of a PTV, and OARs including duodenum, stomach, bowel, spinal cord, liver, and kidneys. In each case the prescription was set to 35 Gy (to 95% of the PTV) in 5 fractions. The treatment plans were created by experienced dosimetrists, following national and international clinical protocols. Those treatment plans were generated for VMAT delivery. For each case an additional plan was generated with the newly proposed automated inverse optimization. This optimization is based on unattended step-wise reduction of DVHs, where several DVH objectives were specified for each OAR. The automated plans utilized the same number of arcs, with the same parameters as the treatment plans. The treatment and the automated plans (Treatment and Auto hereafter) were compared on commonly used clinical dosimetric parameters. Those parameters included D<sup>PTV</sup><sub>95%</sub> (dose to 95% of the PTV), D<sup>Duodenum</sup><sub>1%</sub>, D<sup>Bowel</sup><sub>1%</sub>, D<sup>Stomach</sup><sub>1%</sub>, D<sup>Cord</sup><sub>1%</sub>, D<sup>Liver</sup><sub>mean</sub>, D<sup>Rt\_kidney</sup><sub>mean</sub>, and D<sup>Lt\_kidney</sup><sub>mean</sub>. The doses to 1% of the volumes of duodenum, bowel, stomach, and spinal cord were used as surrogates for maximum doses. The prescriptions for the Auto plans matched the prescriptions of the Treatment plans.

**Results**

The first row in the table below summarizes the average values of the tallied quantities (over the ten patients) as derived from the treatment plans. The second row outlines the average differences (in per-cent) between the dosimetric endpoints as well as the range of the differences between the Treatment and the Auto-optimized plans. The negative differences indicate that the Auto plans result in lower absolute doses and vice-

versa. The figure outlines the normalized (with respect to the Treatment plans) tallied quantities on patient-by-patient basis. In 8 out of the 40 maximum doses the Treatment plans demonstrated lower absolute doses. For none of the 30 tallied average (or mean) doses the Treatment plans were better than the Auto plans. The average differences over the patient cohort range from -7% to +36%.

	Duodenum D <sub>1%</sub> [cGy]	Bowel D <sub>1%</sub> [cGy]	Stomach D <sub>1%</sub> [cGy]	Cord D <sub>1%</sub> [cGy]	Liver D <sub>mean</sub> [cGy]	Lt Kidney D <sub>mean</sub> [cGy]	Rt Kidney D <sub>mean</sub> [cGy]
Average Value Treatment [cGy]	2878	1960	1843	743	193	250	307
Average Difference (range)	-10.5% (-31.9% to -1.1%)	-9.0% (-27.5% to 18.8%)	-7.2% (-38.7% to 24.3%)	-35.7% (-70.7% to 29.6%)	-26.0% (-71.0% to -4.1%)	-36.0% (-83.7% to -23.7%)	-44.3% (-78.1% to -10.4%)

**Conclusion**

Unattended inverse optimization holds great potential for further personalization and tailoring of radiotherapy to particular patient anatomies. It utilizes minimum user time and it can be used at the very minimum as a good starting point for personalized precision radiotherapy.

**PO-0840 Hypofractionated intensity modulated radiotherapy in patients with immediate breast reconstruction**

### Purpose or Objective

The aim of the study (partially supported by a research grant from Accuray Inc. entitled "Data collection and analysis of Tomotherapy and CyberKnife breast clinical studies, breast physics studies and prostate study") is to assess the dosimetric benefit of intensity-modulated radiotherapy (IMRT) in postmastectomy patients with implant-based immediate breast reconstruction (IBR), candidates to locoregional radiotherapy with hypofractionation.

### Material and Methods

Data of the first 121 consecutive post-mastectomy locoregional patients treated with Helical Tomotherapy between May 2012 and May 2015 with a hypofractionated scheme (2.67Gy/fr, 15 fractions) have been prospectively collected. At the time of surgery, all patients underwent IBR using either temporary tissue expander or permanent prosthesis.

The impact of immediate breast reconstruction on the planning was analyzed. Treatment plans were scored in terms of coverage of the PTVs (chest wall and supraclavicular region) and sparing of organs at risk (heart, lungs and contralateral breast). The coverage of chest wall and supraclavicular region was evaluated according to the amount of volume receiving the 90% of the prescribed dose ( $V_{90\%}$ ) while the sparing of each OAR was evaluated according to the number of satisfied constraints (Tab.1). A plan with optimal coverage of both PTVs had 2 PTV points, while a plan with optimal sparing of all OARs had 4 OARs points. An overall score was assigned to each plan.

Tab. 1. Scoring tool was used to assess the quality of planned dose distribution considering both the coverage of PTVs and the sparing of OARs.  
\* Heart constraints refer to the first 22 patients treated between May 2012 and April 2013.  
\*\* Heart constraints refer to the remaining 99 patients treated from May 2013 to May 2015.

		Optimal	Compromised	
		1 point	0.5 point	0 point
PTVs	Chest wall	$V_{90\%} \geq 95\%$	$90\% \leq V_{90\%} < 95\%$	$V_{90\%} < 90\%$
	Supraclavicular region	$V_{90\%} \geq 90\%$	$85\% \leq V_{90\%} < 90\%$	$V_{90\%} < 85\%$
OARs	Ipsilateral Lung	$D_{15\%} \leq 31$ Gy	All constraints are satisfied	3 out 4 constraints are satisfied
		$D_{20\%} \leq 26.4$ Gy		
		$D_{35\%} \leq 17.6$ Gy		
	Contralateral Lung	$D_{20\%} \leq 13$ Gy	All constraints are satisfied	2 out 3 constraints are satisfied
$D_{35\%} \leq 10.6$ Gy				
$D_{50\%} \leq 9$ Gy				
Heart*	Contralateral Breast	$D_{15\%} \leq 17.6$ Gy	All constraints are satisfied	3 out 4 constraints are satisfied
		$D_{20\%} \leq 9$ Gy		
		$D_{35\%} \leq 6$ Gy		
	Heart*	$D_{15\%} \leq 17.6$ Gy	All constraints are satisfied	—
$D_{20\%} \leq 13$ Gy				
Heart**	Heart**	$D_{15\%} \leq 8$ Gy	All constraints are satisfied	2 out 3 constraints are satisfied
		$D_{20\%} \leq 6$ Gy		
		$D_{mean} \leq 5$ Gy		

### Results

71.1% (86/121) of the 121 post-mastectomy radiotherapy plans had high total scores (total score=6 points) as a result of an optimal coverage of both chest wall and supraclavicular region and optimal sparing of all OARs. The remaining 28.9% (35/121) of plans had a compromised distribution of dose (total score<6 points). In particular, 13.2% (16/121) of plans fully satisfied all the OAR constraint but at a cost of moderate coverage of chest wall (7/121 plans) or supraclavicular region (9/121 plans) target volumes. On the other hand, 13.2% (16/121) of plans fully satisfied coverage of both PTVs compromising the sparing of OARs (heart, ipsilateral lung, or contralateral breast). The residual 2.5% of plans (3/121) had both coverage of PTVs and sparing of OARs compromised.

### Conclusion

In patients having implant-based IBR, IMRT allows optimal treatment plans in more than 2/3 of cases. Superior dosimetric results are even more important when

hypofractionation is used and they are expected to translate into lower late toxicity and improved aesthetic outcome.

**PO-0841 Feasibility of dose decrease in a rectal sub-region predictive of bleeding in prostate radiotherapy**  
C. Lafond<sup>1,2,3</sup>, J. N'Guessan<sup>2</sup>, G. Dréan<sup>1,3</sup>, N. Perichon<sup>2</sup>, N. Delaby<sup>2</sup>, O. Acosta<sup>1,3</sup>, A. Simon<sup>1,3</sup>, R. De Crevoisier<sup>1,3,4</sup>

<sup>1</sup>University Rennes 1, LTSI, Rennes, France

<sup>2</sup>Centre Eugène Marquis, medical physics department, Rennes CEDEX, France

<sup>3</sup>INSERM, U1099, Rennes, France

<sup>4</sup>Centre Eugène Marquis, radiation oncology department, Rennes CEDEX, France

### Purpose or Objective

The inferior-anterior hemi anorectum has been found as highly predictive of rectal bleeding in case of prostate cancer radiotherapy, shown in Figure 1 (Dréan et al., *Radiother Oncol* 2016). The aim of this dosimetric study was to evaluate the feasibility of decreasing the dose in this rectal sub-region (SRR), while keeping a high PTV coverage. Two new and simple strategies were used: identifying the SRR during inverse planning and/or using a recent dosimetric model. This model was used allowing to better define the achievable mean dose to the rectal structures at the inverse planning step of IMRT (Moore et al., *Int. J. Radiation Oncology Biol.* 2011). This model integrates the overlap volume between the OAR and the PTV.

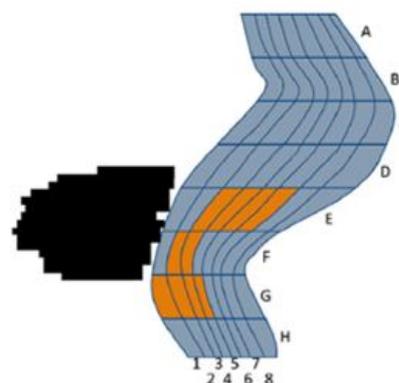

Figure 1: Definition of the rectal sub-region (SRR) (orange) in front of the prostate (black) in a sagittal view

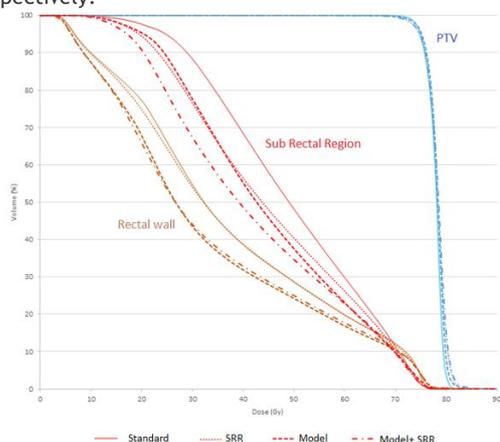

### Material and Methods

60 patients data already treated for prostate cancer to a total dose of 78 Gy were used. For each patient, 4 VMAT plans were generated with Pinnacle v9.10 (Philips): one standard plan corresponding to the current practice ("Standard"), one plan adding specific objectives to the SRR ("SRR"), one plan using the Moore model applied to the rectal wall only ("model") and one plan using the Moore model applied to both the rectal wall and the SRR ("model+SRR"). The plans were compared regarding dose distribution, indexes of conformity and homogeneity, risk of 3-year Grade > 1 RB using the Lyman-Kutcher-Burman NTCP model, and efficiency (Monitor Units and complexity indexes).

### Results

Figure 2 shows the mean DVH of the 60 patients for each of the 4 plans. "Model + SRR" plans showed the most important SRR dose sparing, with mean dose decreases of 4.7 Gy, 5.3 Gy and 7.7 Gy relatively to the "Model", "SRR" and "Standard" plans respectively. Mean NTCP values

were 0.22 for “Standard” plans, 0.19 for “SRR” plans, 0.18 for “Model” plans and 0.17 for “Model + SRR” plans. Plans “Model + SRR” showed slightly less dose homogeneity: mean homogeneity indexes varied from 0.077 for “standard” plans to 0.101 for “Model + SRR” plans. Dose conformity was very similar for all plans: the conformal index varied of 1% in average. “Model + SRR” plans required an increase of 22% in the number of MU compared to the “Standard” plan. The irregularity and modulation indexes increased of 58% and 10%, respectively.

**Figure 2:** Mean DVH for the 60 patients corresponding to the 4 plans: “Standard” plans, plans with inverse constraints to the rectal sub-region (“SRR”), plans using predictive achievable mean dose to the rectal wall only (“Model”) and plans using predictive achievable mean dose to both the rectal wall and the SRR (“Model + SRR”)

**Conclusion**

Compared to standard prostate VMAT plans, applying specific dose constraints to the SRR and rectal wall using the “Moore method” should decrease of around 8 Gy the mean dose to the SRR and decrease relatively of 23% the risk of rectal bleeding.

**PO-0842 Choosing the best heart sparing technique for breast and internal mammary chain radiotherapy**

<sup>5</sup>The Institute of Cancer Research, Physics, London, United Kingdom

<sup>6</sup>The Royal Marsden NHS Trust and The Institute of Cancer Research, Clinical Oncology, London, United Kingdom

**Purpose or Objective**

Published data demonstrate a 4.4% overall survival benefit associated with inclusion of the internal mammary chain (IMC) in the radiotherapy (RT) target volume in patients with breast cancer. Survival gains will be maximised by minimising radiation doses to heart and lungs. This dosimetry study compares the ability of breath-hold techniques in 3D conformal radiotherapy, arc therapy and protons to achieve target volume constraints whilst minimising dose to heart and lungs with a view to defining implementable class solutions for irradiating the IMC.

**Material and Methods**

Breast tissue, level I-IV axillary and IMC lymph nodes were outlined using ESTRO consensus guidelines in 14 patients scanned in both free breathing (FB) and breath hold (BH). Seventy two locoregional RT plans, prescribed to 40Gy/15

fractions were produced using four techniques: 3D-conformal radiotherapy (CRT) wide-tangents (WT), volumetric-modulated arc therapy (VMAT) using a ‘bow-tie’ approach, Tomotherapy (FB only) and proton beam therapy (PBT). PBT planning incorporated a novel approach to robustness optimisation to improve comparability of proton and photon plans. The Wilcoxon-ranked sum (5% significance level) and Friedman tests (2.5% significance level to account for multiple comparisons) were used to compare dose metrics achieved by the different planning solutions.

**Results**

Planning Constraint	WT_BH	WT_FB	VMAT_BH	VMAT_FB	Tomotherapy (FB)	Proton_BH	Proton_FB

**Table 1:** Median (interquartile range) target volume coverage and dose to OAR

**Conclusion**

For most patients heart and lung doses can be minimised using a simple breath hold and wide tangent 3DCRT technique. Arc therapies were more successful in delivering higher dose to a greater proportion of the IMC, especially when combined with breath hold. Proton therapy offers excellent coverage with low OAR dose but is unlikely to be necessary in the majority of patients in whom acceptable plans can be produced using simple photon techniques.

**PO-0843 volumetric-modulated Dynamic WaveArc therapy reduces the doses to the hippocampus**

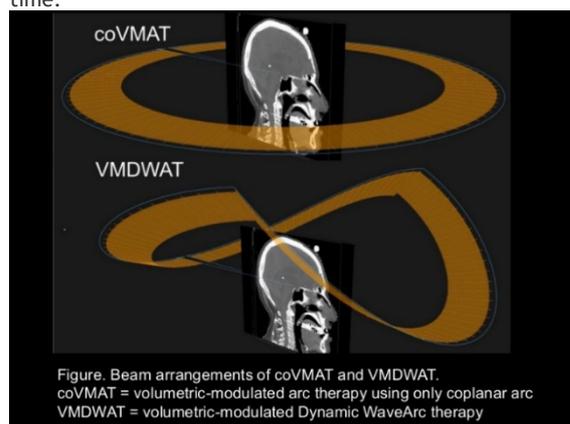

M. Uto<sup>1</sup>, T. Mizowaki<sup>1</sup>, K. Ogura<sup>1</sup>, Y. Miyabe<sup>1</sup>, M. Nakamura<sup>1</sup>, N. Mukumoto<sup>1</sup>, H. Hirashima<sup>1</sup>, M. Hiraoka<sup>1</sup>  
<sup>1</sup>Kyoto University Graduate School of Medicine, Radiation Oncology and Image-Applied Therapy, Kyoto, Japan  
**Purpose or Objective**

Sparing the hippocampus seems to be important for patients with brain tumors to preserve their cognitive function. Vero4DRT (Mitsubishi Heavy Industries, Ltd., Tokyo, Japan, and Brainlab, Feldkirchen, Germany) has a unique design, in which the gantry is mounted in the O-ring structure. The gantry and the O-ring can rotate at the same time, and it allows to use safe sequential noncoplanar volumetric-modulated trajectories, termed as volumetric-modulated Dynamic WaveArc therapy (VMDWAT), without a couch rotation. Since VMDWAT appears to reduce the doses to the hippocampus in patients with pituitary adenomas and craniopharyngiomas, we performed a planning study to compare the dose distribution of volumetric-modulated arc therapy using only a coplanar arc (coVMAT) and VMDWAT.

**Material and Methods**

Thirty patients were included in this study (15/15 patients with pituitary adenoma/craniopharyngioma, respectively). Contouring and treatment planning were performed using the RayStation version 7.4 (RaySearch Laboratories, Stockholm, Sweden). The Collapsed Cone calculation version 3.1 algorithm was employed. All plans were created using one arc. The prescription dose was 52.2 Gy in 29 fractions, and 99% of each PTV was covered by 90% of the prescribed dose. Optimization was performed to maximally reduce the doses to the hippocampus. The two plans were compared in terms of target homogeneity, target conformity, treatment time, the doses to the hippocampus, and the irradiated volume of normal brain. The treatment time was defined as the

beam-on time.

## Results

The mean equivalent doses in 2-Gy fractions to 40% (EQD40%) of the volumes of the bilateral hippocampus were for 9.90/5.31 Gy for coVMAT/VMDWAT, respectively. The EQD40% for VMWAT were < 7.3 Gy, which is the threshold predicting cognitive impairment, as defined by Gondi et al., and were significantly lower than those for coVMAT. The mean equivalent doses in 2-Gy fractions to 2, 10, 20, 30, 50, 80, 98 % (EQD2-98%) of the volumes of the bilateral hippocampus was also significantly lower than those of coVMAT. VMDWAT also significantly reduced the EQD40% and EQD2-98% of the left hippocampus. While the normal brain volume receiving 5 Gy (V5) was significantly larger in VMDWAT, as compared to coVMAT, the normal brain volume receiving 10, 15, 20, 25, 30, 35, 40, 45, and 50 Gy (V10-50) was significantly smaller in VMDWAT. The conformity and homogeneity indices were significantly better in VMDWAT. The mean treatment time of VMDWAT was significantly longer than that of coVMAT (67.1/70.1 seconds in coVMAT/VMDWAT, respectively).

Table. Doses to bilateral hippocampus

Dose (Gy)	coVMAT	VMDWAT	P-value
	(Mean dose±SD)		
EQD2%	25.17±11.34	22.47±12.79	<0.05
EQD10%	19.13±10.45	15.10±11.87	<0.05
EQD20%	15.47±9.67	10.81±10.57	<0.05
EQD30%	12.34±8.05	7.67±8.09	<0.05
EQD40%	9.90±6.13	5.31±4.91	<0.05
EQD50%	8.64±5.13	4.82±5.23	<0.05
EQD80%	6.48±3.70	3.46±3.59	<0.05
EQD98%	4.17±2.62	2.39±2.54	<0.05

coVMAT = volumetric-modulated arc therapy using only coplanar arc

VMDWAT = volumetric-modulated Dynamic WaveArc therapy

EQDX% = equivalent dose in 2-Gy fractions (assuming  $\alpha/\beta=2$ ) to X% of the volume

## Conclusion

VMDWAT significantly reduced the doses to the bilateral and left hippocampus compared to coVMAT. The target conformity and homogeneity were significantly better in VMDWAT. Although the treatment time and V5 of the normal brain was increased in VMDWAT, V10-50 of the normal brain was significantly decreased in VMDWAT. VMDWAT could be a promising treatment technique for pituitary adenomas and craniopharyngiomas.

## PO-0844 Dosimetric Evaluation of MLC and Fixed Cone for Patients in the Prone Position with CyberKnife

S.K. Ahn<sup>1</sup>, J.H. Cho<sup>1</sup>, K.C. Keum<sup>1</sup>

<sup>1</sup>Yonsei Cancer Center- Yonsei University, Department of Radiation Oncology- Yonsei Cancer Center- Yonsei University Health System- Seoul- Korea, Seoul, Korea Republic of

### Purpose or Objective

The constraints of systems using fixed cones have been improved with the recent introduction of the multileaf collimator (MLC) to the CyberKnife® system. This study evaluated the dosimetric impact of the MLC in stereotactic body radiation therapy for spine lesions, with the patient in the prone position.

### Material and Methods

Sixteen patients with spinal tumors, who were treated with CyberKnife® M6™, were placed in a body fixer and scanned with four-dimensional computed tomography (4DCT).

A total of 32 treatment plans were set up with two fixed cones (ray tracing algorithm) and MLC (finite-sized pencil-beam algorithm), using the MultiPlan® System. A total of 24 Gy in four fractions was prescribed to the 78%-83% isodose line, encompassing at least 95% of the planning target volume (PTV).

The XSight® prone tracking method was used for target tracking, and the Synchrony® Respiratory Tracking System was used for motion tracking. For the PTV, the maximum dose, homogeneity index (HI), and conformity index (CI) were analyzed. For the spinal cord and bowel, the maximum dose (D 0.03 cc) was analyzed. The other analyzed parameters included monitor unit, treatment time, beam number, and node number.

### Results

Regardless of the type of collimator, the difference among the maximum dose, HI, and CI values of the PTV was 3.1±2%, while the maximum dose of the spinal cord and bowel was 9.7±4.5%, indicating clinically insignificant differences. For the other parameters, the values of the treatment plan using MLC were lower by 53.8±8.4% for MU, by 39.5±7.5% for treatment time, by 49.3±7.3% for beam number, and by 49.7±7.1% for node number, compared to the use of fixed cones. The differences were larger when the tumors were greater in size.

### Conclusion

There are dosimetric advantages to evaluating patients in the prone position for lesions that are anatomically located in the back, such as spinal tumors. However, MLC, which has fewer treatment nodes and a shorter treatment time, is also useful in the prone position because the maintenance of positional reproducibility is critical.

## PO-0845 Automatic treatment planning of FFF VMAT for breast cancer: fast planning and fast treatment

E.L. Lorenzen<sup>1</sup>, K.L. Gottlieb<sup>1</sup>, C.R. Hansen<sup>1</sup>, H.R.

Jensen<sup>1</sup>, J.D. Jensen<sup>2</sup>, M.H. Nielsen<sup>2</sup>, M. Ewertz<sup>2</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

<sup>2</sup>Odense University Hospital, Department of Oncology, Odense, Denmark

### Purpose or Objective

Forward planned tangential radiotherapy with wedges or few segments is the standard technique in many centres for radiotherapy after breast conserving surgery. Helical techniques such as Tomotherapy and VMAT can be used to increase conformity but may increase the volume receiving low doses and the treatment planning can be time-consuming. In the present study we evaluate FFF VMAT using automated planning by comparison with manually planned tangential radiotherapy on its plan quality as well as its efficiency in both treatment planning and delivery.

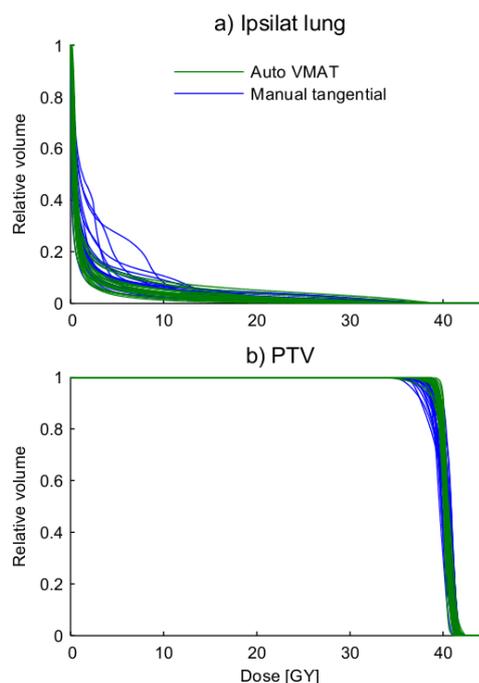

### Material and Methods

Twenty patients, ten right-sided and ten left-sided, were selected by including all patients receiving partial breast radiotherapy between the 1/6-2016 and the 19/9-2016 at our institution. All patients were treated with forward planned tangential step-and-shoot 6MV fields and with 18MV fields used partly for larger breasts. The ten left-sided patients were treated in breath hold using ABC from Elekta. For each patient an additional plan was generated, using two small (30-40 degrees) 6 MV FFF VMAT fields with tangential like beam angles. Dose planning was done in Pinnacle 9.10 and the Auto-Planning module was used for generation of the VMAT plans. Mean doses to target regions and organs at risk were compared using paired t-tests.

### Results

VMAT plans were generated fast with a median time for complete plan generation by Auto-Plan of 10,5 min (range: 9 min - 12 min) with further adjustments needed for 7/20 patients (5 min -15 min additional time). Mean doses to target regions and organs at risk are shown in the table. The doses were similar from both plans except for the dose to the ipsilateral lung being statistically significant lower from the VMAT plans. Dose volume histograms for the ipsilateral lung and the PTV are shown in figure a) and b) respectively. As shown, the dose to ipsilateral lung was lower for all dose levels in the VMAT plans even though the coverage of the PTV was better. The measured delivery time of all VMAT fields were 14,5 s (range: 10 s - 22 s). As a result all VMAT plans could potentially be delivered within two breath holds (our threshold for maximum breath hold duration is 25 s). In comparison the median number of breath holds required for the ten left-sided patients treated in breath hold in the forward planned treatment was 4 (range: 2 - 7).

	Auto (Gy)		Manuel (Gy)		p
	Average	STD	Mean	STD	
PTV	40,3	0,15	40,2	0,32	0,07
CTV	40,4	0,20	40,5	0,35	0,56
Lung_ipsilat	1,7	0,53	2,1	0,66	0,015
Lung_contralat	0,07	0,02	0,07	0,05	1,00
Heart	0,35	0,21	0,40	0,50	0,53
Breast_ipsilat	26,6	2,1	26,3	1,5	0,78
Breast_contralat	0,10	0,05	0,11	0,11	0,62
External	1,6	0,39	1,65	0,42	0,28

### Conclusion

Auto-Plan in Pinnacle allowed fast planning of FFF VMAT plans for partial breast cancer radiotherapy. Compared to forward planned tangential radiotherapy the VMAT plans were better at both sparing of the ipsilateral lung and in covering the PTV. The VMAT plans could be delivered quickly, and as a result patients treated in breath hold could be treated with half the number of breath holds.

### Purpose or Objective

Intestinal toxicity (IT) may affect the quality of life of patients (pts) treated with whole-pelvis intensity-modulated radiotherapy (WPIMRT) for prostate cancer. The aim of this investigation is to identify quantitative bowel dose-volume relationships for acute patient-reported IT.

### Material and Methods

A cohort of pts was enrolled in 6 Institutions within a registered prospective trial. Pts were treated with conventional or moderate hypo-fractionation to prostate/prostatic bed and WPIMRT delivering 51.8 Gy (median dose, range: 50.4-56.1 Gy) to pelvic nodes while sparing the bowel outside PTV as much as possible. Acute IT was evaluated by the Inflammatory Bowel Disease Questionnaire pertaining to the Bowel Domain (IBDQ-B) filled in by pts at baseline and at mid-point/end of RT. IBDQ-B includes 10 items (#item) scored on a 7-point scale (worst symptoms=lower scores).

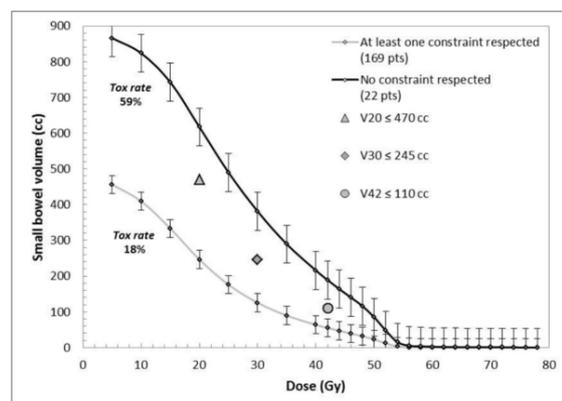

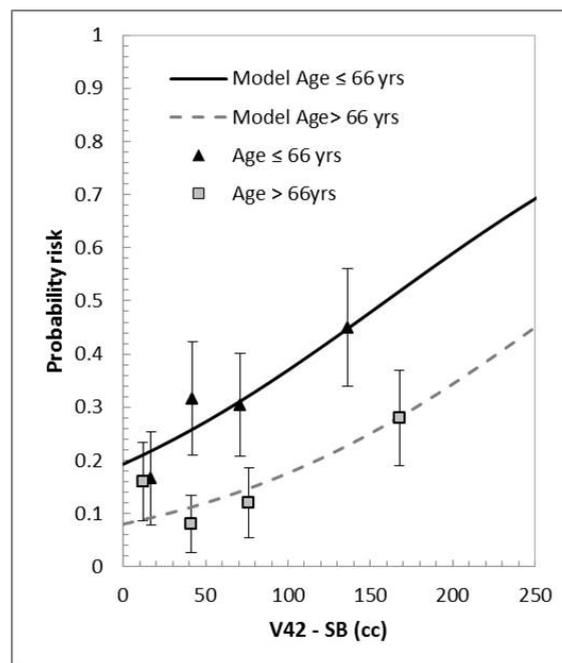

The 25<sup>th</sup> percentiles of the most severe worsening ( $\Delta$ ) between baseline and half/end RT were set as end-points. The correlation between end-points and bowel loops cc/% DVH/DSH (from V5Gy to V60Gy) as well as selected clinical parameters was investigated through multi-variable logistic regression. Goodness of fit was estimated by the Hosmer Lemeshow test (HL) and the Brier score (BS); performances of the model were assessed by the calibration plot. Internal validation was performed by 1000 bootstrap resampling.

### Results

Data of 206 pts (80 radical, 79 adjuvant, 47 salvage RT) were available: 25/109/72 pts were treated with fixed-fields, rotational and Tomotherapy technique respectively. A relatively small but significant  $\Delta$  ( $p < 0.05$ ) was found for all questions: the median  $\Delta$  was 2 points for #1 (bowel movements) and 1 point for #5 (loose stools), #17 (gas passage) and #24 (urgency to defecate with empty intestine);  $\Delta$  was 0 for the remaining 6 items that were then disregarded in current analysis. No DVH/DSH parameters were correlated with  $\Delta$ , except for  $\Delta$ IBDQ5 $\leq$ -3 (25<sup>th</sup> percentile, 43/191).

The resulting model after backward selection of variables ( $R^2=0.89$ , slope:1.037, optimism corrected BS=0.17, Figure 1) included absolute V42Gy and age (protective). Due to the correlation between DVH variables, three values representing 'low' (V20), 'intermediate' (V30) and 'high' (V42) dose levels were also considered to define an overall 'DVH-shape' predictor.

When grouping pts according to best cut-off values assessed by ROC curves (high risk: V20>470cc, V30>245cc, V42>110cc; low risk: the other pts, figure 2), an alternative model including high-risk DVH-shape (OR:9.3) and age (protective, OR:0.94) may be suggested. The model showed very good calibration (slope:1.003,  $R^2=0.92$ ) and accurate prediction even after bootstrap-based internal validation (corrected BS=0.16).

### Conclusion

The DVH shape of bowel loops is highly correlated with the risk of acute patient-reported loose stools due to WPIMRT for prostate cancer. Older age was found to be a protective factor.

### PO-0847 The dose-response curve of post-treatment FDG-uptake in lung tissue of irradiated NSCLC patients

M. La Fontaine<sup>1</sup>, W.V. Vogel<sup>1</sup>, G. Persson<sup>2</sup>, G. Westman<sup>2</sup>, B. Reymen<sup>3</sup>, D. De Ruyscher<sup>3</sup>, J.S. Belderbos<sup>1</sup>, J.J. Sonke<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands

<sup>2</sup>Copenhagen University Hospital- Rigshospitalet, Department of Radiation Oncology, Copenhagen, Denmark

<sup>3</sup>Maastricht University Medical Centre, Department of Radiation Oncology, Maastricht, The Netherlands

### Purpose or Objective

In NSCLC patients undergoing chemoradiotherapy, pneumonitis is a common occurrence. While its exact relationship with radiation dose is unknown, there is evidence that increasing lung dose leads to increased levels of pneumonitis. Using inflammation on post-treatment FDG PET scans as a measure of damage to normal lung tissue, the aim of this study was to investigate the relationship between pneumonitis and planned dose in a radiation dose-escalation trial.

## Material and Methods

42 patients with inoperable, stage II-III NSCLC were treated with (chemo)radiotherapy as part of the (NCT01024829) PET-boost trial. Patients received escalated doses ( $\geq 72$  Gy) in 24 fractions consisting of either a homogenous boost to the PTV, or an inhomogeneous boost to FDG avid ( $\geq 50\%$  SUV<sub>max</sub>) areas. Patients whom could not be boosted received 66 Gy in 24 fractions. All patients received an FDG PET/CT scan 3 months post-treatment, which was registered to the planning CT. The lung contours minus the GTV were compared between the SUV on FDG PET and the planning CT dose. The planning CT dose was adjusted to equivalent doses in 2 Gy fractions, assuming an  $\alpha/\beta = 3$  Gy, and then binned per 5 Gy increments. The SUV was averaged over all patients per dose bin and a dose response sigmoid was fit (SUV vs Gy) to determine upper and lower asymptotes, as well as the EC50. The linear portion of the sigmoid fit (17.6%-82.4% asymptotes difference) was applied to individual patients for linear fitting, yielding the correlation coefficient and the SUV response to an increase in dose (slope). All values were reported as median[interquartile range (IQR)]. All fits were considered significant with an alpha of 0.05.

## Results

A positive relationship was found between SUV and post-treatment dose. A sample patient with post-treatment grade 1 pneumonitis is shown in figure 1. The sigmoidal fit (figure 2) over all patients was significant (chi-squared = 0.01) with an EC50 at 39 Gy, and lower and upper asymptotes at 0.60 SUV and 1.31 SUV, respectively. The linear portion of the sigmoidal fit (15- 60 Gy) was found to be significantly ( $p \leq 0.05$ ), highly linear in individual patients with a median correlation coefficient of 0.93[0.79-0.97]. Four patients did not have significant linear fits (p-values ranging from 0.05 to 0.13). The median SUV response per increase in dose (slope) was heterogeneous with a median of 0.0083[0.005-0.018] SUV/Gy, implying a 55 Gy to 200 Gy increase needed per SUV increase within the IQR.

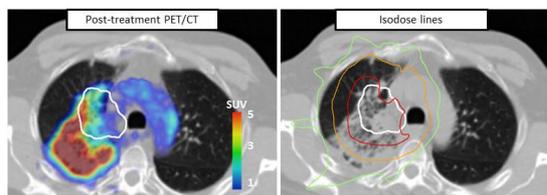

Figure 1. Sample patient. The left image shows an axial slice of a post-treatment FDG PET/CT scan, while the image on the right displays the isodose lines (green = 45 Gy, orange = 60 Gy, red = 75 Gy) on the post-treatment CT scan. The primary tumor (outlined in white) demonstrates marked anatomic and metabolic regression. An area dorsolateral of the tumor shows discernable FDG uptake indicating an inflammatory response to lung tissue damage. The patient clinically had grade I pneumonitis.

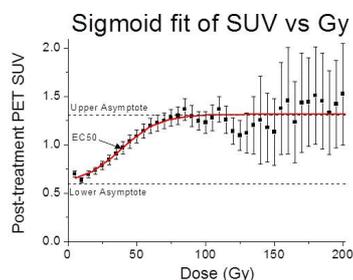

Figure 2. Dosimetric relationship with metabolic activity on FDG-PET SUV. In the graph above, a sigmoid was used (chi-square = 0.01) to describe the relationship between FDG uptake (SUV) and dose (Gy). The upper and lower asymptotes, as well as the EC50 are illustrated in the graph. The error bars represent the standard error of the mean (SEM) with increased uncertainty for higher doses.

## Conclusion

Strong linear and sigmoidal relationships were found between post-treatment SUV and planned dose. These results suggest that increasing dose leads to a highly linear

increase of lung damage up to a certain threshold (60 Gy), before adopting an asymptotic relationship. Patient response in the linear fitting was heterogeneous with a greater than 3 fold difference found in the IQR. These findings may aid in post-treatment response assessment and toxicity modeling in NSCLC patients undergoing escalated dosing regimens.

<sup>8</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milano, Italy

<sup>9</sup>Cliniche Gavazzeni-Humanitas, Radiotherapy, Bergamo, Italy

## Purpose or Objective

To assess clinical and dose factors affecting the incidence of patient-reported urinary incontinence (INC) at three years after radical radiotherapy (RT) for prostate cancer of a large group of patients enrolled in a prospective, multi-centric trial in the period 2010-2014.

## Material and Methods

Enrolled patients were treated in seven Institutions at different prescribed doses with conventional (74-80 Gy at 1.8-2 Gy/fr, CONV) or moderately hypo-fractionated RT (65-75.2 Gy at 2.2-2.7 Gy/fr, HYPO) in 5 fractions/week. Several clinical factors were collected for each patient: comorbidities, drugs, hormone therapies, previous surgeries, smoking, alcohol, age, and body mass index. In addition, the prescribed 2Gy equivalent dose (EQD2) was considered by applying an alpha-beta ratio of 0.8, 3 and 5Gy, according to values recently reported in the literature. INC was evaluated through the International Consultation on Incontinence Modular Questionnaire short form (ICIQ) filled in by the patients at start/end of RT and every 6 months until 5 years of follow up. In the current analysis, patients with ICIQ available at 30 and/or 36 months were considered (n=298); the incidence of INC at 3 years was defined as the occurrence of an ICIQ value >12 at least once between 6 and 36 months. Univariable and backward multivariable logistic analyses were performed to build a predictive model.

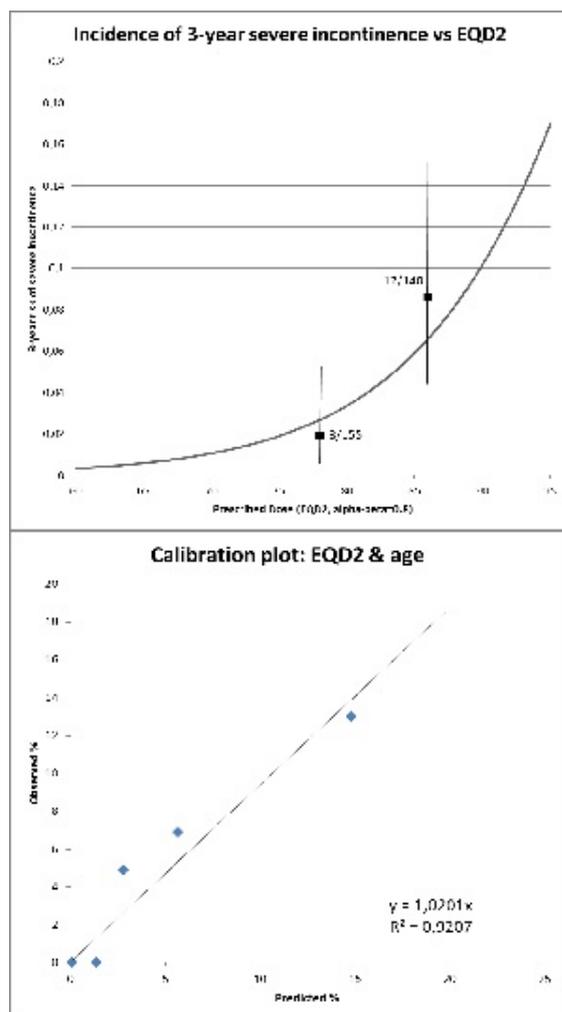

## Results

In total, 298 patients had the required minimum follow-up; patients with baseline ICIQ>12 (n=3) were excluded restricting the analysis to 295 patients (CONV: 149; HYPO: 146, 86% treated with IMRT). The median number per patients of completed questionnaires was 5 (range: 2-6); the incidence of ICIQ>12 was 5.1% (n=15) with a prevalence at 30/36 months equal to 4.1%. Main predictors at univariable analysis were age (p=0.01, OR=1.19), baseline ICIQ>0 (p=0.056, OR=2.9), previous TURP (p=0.04, OR=3.8) and EQD2 (p=0.003-0.02, OR=1.12-1.17 depending on alpha-beta). EQD2 calculated with alpha-beta=0.8Gy showed the best performances in terms of calibration plot and p-value and was included in the multi-variable analysis. Final results suggested a two-variable model including EQD2 (p=0.005, OR=1.13; 95%CI:1.04-1.24) and age (p=0.011, OR=1.19; 95%CI:1.04-1.37); the model showed good performances in terms of goodness of fit

(H&L test,  $p=0.55$ ) and calibration plot (slope:1.02,  $R^2=0.92$ ). In Figure, the risk of 3-year INC vs EQD2 (alpha-beta=0.8Gy) is shown with the calibration plot of the final two-variable model. The validity of the model was confirmed in the HYPO subgroup.

#### Conclusion

The incidence of patient-reported 3-year INC after high-dose RT for prostate cancer dramatically depends on the prescribed dose (EQD2) and, secondarily, on the age of patients. A previously suggested low alpha-beta value (0.8Gy) for late INC resulted in a significantly better calibrated model, consistently with a high sensitivity of late INC to fractionation.

#### PO-0849 Trismus after chemoradiation in head & neck cancer: relation with medial pterygoid and masseter dose

O. Hamming-Vriese<sup>1</sup>, S. Kraaijenga<sup>2</sup>, S. Verheijen<sup>1</sup>, M. Jonker<sup>1</sup>, L. Van der Molen<sup>2</sup>, J. Van de Kamer<sup>1</sup>, M. Van de Brekel<sup>2</sup>, W. Heemsbergen<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

<sup>2</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Head and Neck Surgery, Amsterdam, The Netherlands

#### Purpose or Objective

Reduced maximal mouth opening (MMO) is a serious side effect that can occur after chemoradiation (CRT) in head & neck patients. Recent studies showed dose-effect relationships with both the ipsilateral masseter muscle

(iMM) and the ipsilateral medial pterygoid muscle (iMPM). It is unclear whether these muscles should be regarded as a joined Organ at Risk or separately. The aim of our study was to calculate and compare separate dose-effect relationships between trismus and 1) the dose to the iMM and 2) iMPM dose, taking into account the baseline MMO.

#### Material and Methods

For 83 patients, participating in an exercise program to preserve oral function in the period 2008 - 2014, pre- and post-RT (6 weeks) MMO measurements were available. Treated tumors were mainly located in the oropharynx (40%) and hypopharynx (31%). All patients received concomitant radiotherapy (35x2Gy) via IMRT or VMAT technique with cisplatin 100mg/m<sup>2</sup> at day 1,22 and 43. Pathological MMO (trismus) was set at  $\leq 35$ mm as a functional cut-off. Exclusion criteria were trismus at baseline and gross tumor infiltration of the iMM or iMPM on planning CT. The muscles were retrospectively delineated. A logistic regression with bootstrapping resampling technique (n=2000) was applied to calculate model parameters. Dose-volume parameters (mean-, absolute- and relative dose) were calculated in 5 Gy steps.

#### Results

MMO showed a large range (Fig A) with 14 trismus cases (17%) post-RT. Baseline MMO was a significant predictor for trismus ( $p=0.005$ ) with an optimal cutoff at 45mm. Women more often had a baseline MMO  $\leq 45$  (65%) compared to men (37%,  $p=0.02$ ) and therefore had a higher trismus risk (30% vs 12%,  $p=0.04$ ). Mean doses of the iMPM and iMM correlated significantly (Fig B, Pearson coefficient 0.83,  $p<0.001$ ) with a mean iMPM dose of 53.3Gy versus 30.3Gy for iMM ( $p<0.001$ ). In general, dose parameters of the iMPM showed superior fits (lowest -2 Log Likelihoods, lowest p values, better goodness-of-fit statistics) compared to iMM; differences were not statistically significant. The best fit for the iMPM was with mean dose (odds ratio 1.165,  $p<0.001$ ); for iMM mean dose was most predictive as well (odds ratio 1.070,  $p=0.002$ ). Fig C&D shows the dose-response for iMPM and iMM for the  $\leq 45$ mm and  $>45$ mm subgroups. Best fit for dose volume parameters was for the percentage receiving  $\geq 65$ Gy (iMPM,  $p=0.001$ ) and the percentage receiving  $\geq 40$ Gy (iMM,  $p=0.003$ ).

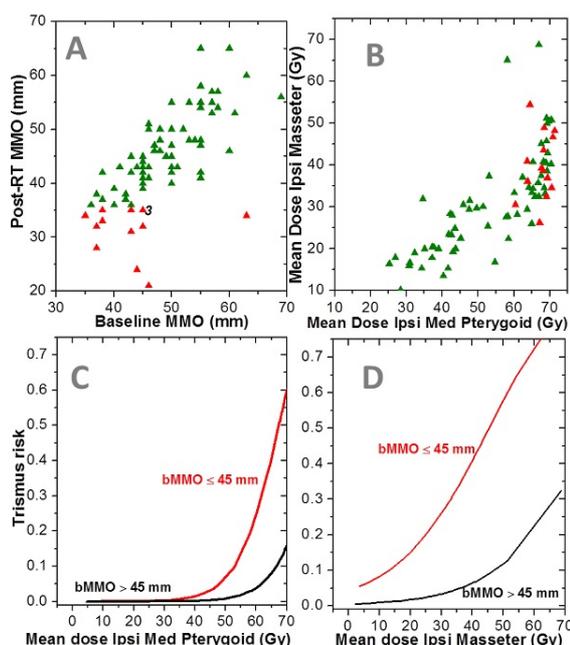

FIG. Scatterplot (A,B) and calculated models of trismus risk as function of dose (C,D).

#### Conclusion

We observed that both the iMPM and the iMM dose are predictive for trismus with a better dose-response fit for

the iMPM. We conclude that the strong correlation between iMPM and IMM is caused by close proximity of the two muscles. However, the different shapes of the dose-response curves of both muscles suggest that they should be regarded as separate OARs and at least the iMPM should be delineated to estimate trismus risks. Furthermore, baseline MMO is highly predictive and is important to take into account in trismus models.

<sup>10</sup>Università degli Studi di Milano, Oncology and Hematology, Milan, Italy

#### Purpose or Objective

To validating a predictive model for late fecal incontinence (FI) on a recent population of prostate cancer patients (pts) treated with radical radiotherapy. NTCP model was derived from literature.

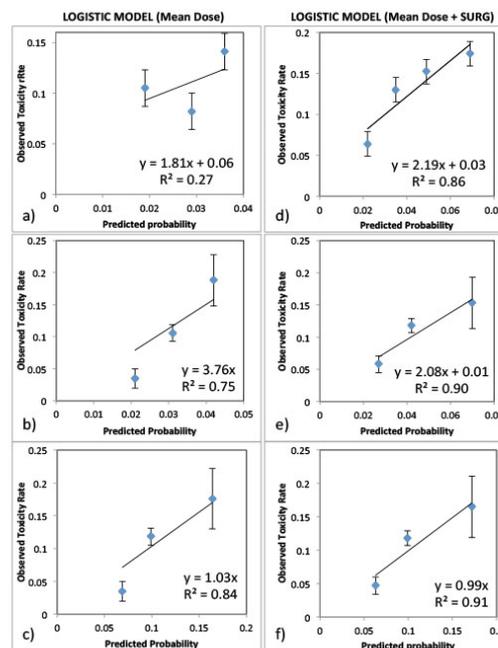

#### Material and Methods

Population included 267 pts treated with Intensity Modulate Radiation Therapy (IMRT) in 2010-2014. Prescribed dose was between 68 and 80 Gy with conventional and hypo-fractionated (HF, from 2.2 to 2.8 Gy) treatment. Rectal toxicity was scored using the LENT/SOMA questionnaire. Follow-up (FU) was considered up to 2 years. The study endpoint was late FI. We chose to validate a model for prediction of chronic fecal incontinence, as evaluated through multiple measures during follow-up. Mean FI was defined as the average score during the FU period after RT. Mean incontinence >1 was the considered endpoint. Pts with at least three out of four FU points in the first 2 years were included (the 2-year point was mandatory). Literature based multivariate model included: mean rectal dose (Dmean), previous diseases of colon and previous abdominal surgery (SURG). Dose distributions were corrected EQD in 2 Gy fractions (alpha/beta=5Gy).

#### Results

256 pts were available. Mean grade>1 FI was scored in 28 patients (10.9%). Univariate logistic analysis confirmed the risk factors reported in literature, with similar Odds Ratios (OR) for Dmean (1.04±0.03 vs 1.05±0.04) and SURG (1.90±1.70 vs 1.50±0.50). As consequence, NTCP models including Dmean and Dmean+SURG were evaluated through calibration plot. The models showed a clear trend (increasing observed toxicity rates with predicted risk), but the observed toxicity rates were underestimated. We guessed this scenario could be due to a hidden effect of HF (OR=2.20, 8.6% vs 17.6%), beyond standard correction using LQ model for late effects. The first approach was to directly evaluate the impact of HF, by including it as a variable into model (keeping coefficients for Dmean and SURG fixed at previously published values). It clearly improved calibrations. A further step was to include the time recovery effect into EQD2 correction

(gamma=0.7Gy/day), thus taking count of a possible consequential effect between acute and late damage. The figure reports calibration plot for all cases.

**Figure 3** Calibration plots for validation of the model including only mean rectal dose (left column) and for validation of the model including mean rectal dose + previous abdominal surgery (right column): a) & d) raw models, b) & e) models with time recovery correction included into calculation of 2Gy/fr equivalent doses, c) & f) models with inclusion of hypo-fractionation as a yes/no variable.

#### Conclusion

The study confirms formerly published results on effect of abdominal surgery and dose to large rectal volumes as potential risk factors for late FI.

Calibrations highlight a possible role of HF beyond linear quadratic correction. Inclusion of time recovery correction improved calibrations, but a further separate effect of HF was still detectable. This might be related to the selected alpha/beta (5Gy), which is currently accepted for late rectal toxicity.

A more suitable value could be found for the longitudinal definition used in these trials (i.e., toxicity starting in acute phase and persisting during follow-up), instead of using the assumption settled in studies focusing on incidence of late peak events (such as rectal bleeding).

**PO-0851 Artificial neural networks for toxicity prediction in RT: a method to validate their "intelligence"**

<sup>7</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy

### Purpose or Objective

Artificial neural networks (ANNs) were used in the last years for the development of models for the prediction of radiation-induced toxicity following RT. In fact, ANNs are powerful tools for pattern classification in light of their ability to model extremely complex functions and huge numbers of data. However, their major counterpoint is that in some specific cases they might not deliver realistic results due to their missing critical capacity. The objective of this study was to develop a method for assessing reliability of ANNs response over the entire range of possible input variables. In particular, in this study the method was applied to the selection of an ANN for the prediction of late faecal incontinence (LFI) following prostate cancer RT.

### Material and Methods

The analysis was carried out on 664 patients (pts) of two multicentre trials. The following information was available for each pt: i) self completed pt reported questionnaire (PRO) for LFI determination, ii) clinical data (co-morbidity, previous abdominal surgery and use of drugs), iii) dosimetric data (DVH and mean dose). Several feed-forward ANNs with a proper balance between complexity and number of training cases were developed, with input variables and hidden neurons ranging between 3 and 5. Once the best ANNs were obtained, a method was developed and applied to verify the reliability of their response over the entire range of possible input variables. The method consists in the development of a virtual library of variables covering all the possible ranges/permutations of continuous/discrete inputs. These are all classified and penalties (pen) are assigned if ANN outputs are not coherent with the real world expectance (i.e., decreasing LFI probability with increasing dose to the rectum).

### Results

More than 1,000,000 different ANN configurations (i.e., architecture and internal weights and thresholds) were developed. For the 200 ANNs showing the best performance, area under the ROC curve (AUC), sensitivity (Se), specificity (Sp) and pen were quantified. The best ANN in terms of classification capability (i.e. AUC=0.79, Se=74%, Sp=72%) was an ANN with 5 inputs (i.e., mean dose, use of antihypertensive, previous presence of haemorrhoids, previous colon disease, hormone therapy) and 5 hidden neurons. However, the application of the method to investigate its coherence with the real life classification expectancy resulted in pen=3, indicating that this wasn't the most "intelligent" ANN to select. The best ANN with pen=0 was a less complex ANN (i.e. 3 inputs, 5 hidden neurons), resulting in AUC=0.67, Se=70%, Sp=57%.

### Conclusion

A new method consisting in the development of a virtual library of cases was established to evaluate ANN reliability after its training process. Application of this method to the development of an ANN for LFI prediction following prostate cancer RT allowed us to select an ANN with the best generalization capability.

<sup>6</sup>Candiolo Cancer Institute -FPO- IRCCS, Medical Physics, Candiolo Torino, Italy

<sup>7</sup>IRCCS San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

### Purpose or Objective

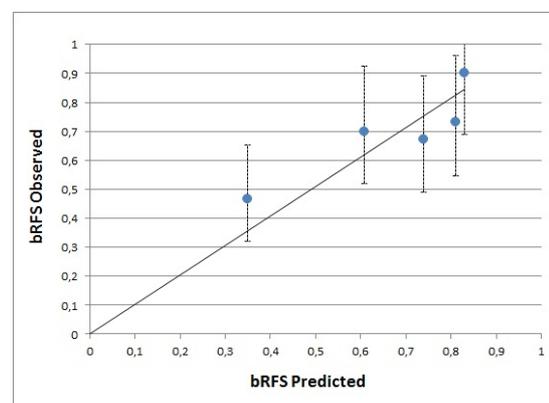

A Poisson-based TCP model of 5-year biochemical recurrence-free survival (bRFS) after post-prostatectomy radiotherapy (RT) was previously introduced: best parameters values were obtained by fitting a large (n=894  $\geq$ pT2, pN0, hormone-naïve patients) multi-centric population including data from five prospective / Institutional series; a satisfactory internal validation was performed. Current investigation dealt with an independent external validation on a large group of patients pooled from two independent Institutional databases with a minimum follow-up of 3 years.

### Material and Methods

Based on the original model, bRFS may be expressed as:  $K \times (1 - \exp(-\text{aeff } D))^{\text{C} \times \text{PSA}}$  where: D is the prescribed dose; aeff is the radiosensitivity factor; C is the number of clonogens for pre-RT PSA=1ng/ml, assuming PSA to be proportional to tumor burden; K (equal to 1-BxPSA) is the fraction of patients who relapse due to clonogens outside the treated volume, depending on pre-RT PSA and Gleason Score (GS). The model works well when grouping patients according to their GS value: best-fit values of aeff (range: 0.23-0.26), C ( $10^7$ ) and B (0.30-0.50) were separately derived for patients with GS<7, GS=7 and GS>7. For current external validation, data of 352  $\geq$ pT2, pN0, hormone-naïve patients treated with conventionally fractionated adjuvant (175) or salvage (177) intent after radical prostatectomy were available from two Institutions not previously involved in the training data set analysis. The predicted risk of 5-year bRFS was calculated for each patient, taking into account the slope and off-set of the model, as derived from the original calibration plot. Five-year bRFS data were compared against the predicted values in terms of overall performance, calibration and discriminative power.

### Results

The median follow-up time, pre-RT PSA and D were 83 months (range: 36-216 months), 0.28 ng/mL (0.01-9.01 ng/mL) and 70.2Gy (66-80Gy); the GS distribution was: GS<7: 118; GS=7: 185; GS>7: 49. The performances of the model were excellent: the calibration plot showed a satisfactory agreement between predicted and observed rates (slope: 1.02;  $R^2=0.62$ , Figure 1). A moderately high discriminative power (AUC=0.68, 95%CI:0.62-0.73) was found, comparable to the AUC for the original data set (0.69, 95%CI:0.66-0.73). The predicted 5-year bRFS for the whole population assessed as the weighted average of the values referred to the three groups (i.e.: GS<7, =7, >7) was 67%, compared to an observed 5-year bRFS equal to  $68 \pm 5\%$  (95%CI). The agreement was slightly worse in the GS<7 group (70% vs  $79 \pm 7\%$ ) compared to GS=7 (66% vs  $66 \pm 7\%$ ) and GS>7 (62% vs  $51 \pm 14\%$ ).

## Conclusion

A comprehensive, radiobiologically consistent Poisson-based TCP model of the response to post-prostatectomy RT was validated for the first time on a completely independent data set. A more extensive validation on a larger population is actually in progress to further corroborate its generalizability.

## PO-0853 A method for automatic selection of parameters in NTCP modelling

D. Christophides<sup>1</sup>, A.L. Appelt<sup>2</sup>, J. Lilley<sup>3</sup>, D. Sebag-Montefiore<sup>2</sup>

<sup>1</sup>Leeds CRUK Centre and Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, United Kingdom

<sup>2</sup>Leeds Institute of Cancer and Pathology - University of Leeds and Leeds Cancer Centre, St James's University Hospital, Leeds, United Kingdom

<sup>3</sup>Leeds Cancer Centre, St James's University Hospital, Leeds, United Kingdom

## Purpose or Objective

The use of multivariate models in predicting NTCP has the potential of improving predictive accuracy compared to univariate models<sup>1</sup>. However the large numbers of clinical parameters and dose metrics involved can make the selection of the optimal multivariate model inconsistent and time consuming.

In this study a genetic algorithm based method is utilised to automatically generate ordinal logistic regression models; subsequently the quality of the parameter selection process is evaluated by comparison with published results on the same patient cohort<sup>2</sup>.

## Material and Methods

A general method for selecting optimal models for outcome prediction in radiotherapy was developed (Fig.1). The method was tested on data from 345 rectal cancer patients, used in a previously published study<sup>2</sup>, to generate ordinal logistic regression models for the prediction of acute urinary toxicity during chemoradiotherapy. Principal component analysis (PCA) was used to derive principal components (PCs) that summarise the variance in the DVH data. Overall 25 clinical parameters were considered in the analysis including demographics, treatment regime, plan parameters and stage of disease; as well as 8 PCs that explained >95% of the variance in the DVHs.

Urinary toxicity was categorised as grade 0, 1 and 2≥ cystitis, according to the CTCAE v3.0. The method (Fig.1) for optimising the models was implemented in Python and the entire procedure was repeated 100 times, using bootstrap sampling from the whole data set, to evaluate the stability of the parameter selection.

Confidence intervals for the Akaike information criterion (AIC) of the final models selected were estimated using

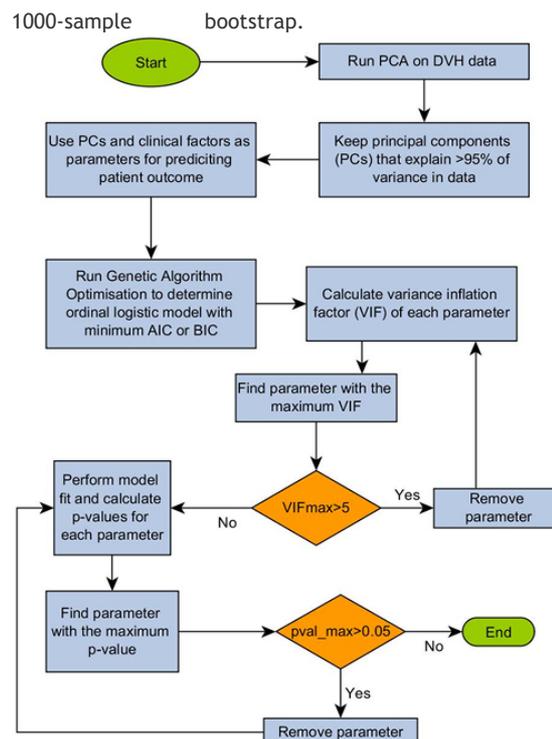

Fig. 1. Flowchart of the method for the automatic generation of ordinal logistic regression models. The variance inflation factor was used to remove collinear parameters following genetic algorithm optimisation; in addition the regression p-values were used to remove non-significant parameters. Two models were produced, one with the genetic algorithm minimising the AIC and another minimising the Bayesian information criterion (BIC).

## Results

The method (Fig.1) used to minimise AIC identified PC1, brachytherapy dose level and gender as the optimal model variables. This agreed well with the model identified by Appelt et al<sup>2</sup> that used the  $V_{35.4Gy}$ , brachytherapy dose and gender; considering that PC1 was found to have a high correlation with the  $V_{35.4Gy}$  ( $R^2=0.96$ ,  $p<0.001$ ). The model determined by minimising the BIC, identified PC1 and brachytherapy treatment status as important predictive variables. The bootstrap analysis identified PC1 and gender as the most stable parameters.

The 95% bootstrap confidence intervals of the AIC for all three models overlapped significantly; with (625.3, 681.5) for the AIC-minimised model, (627.0, 686.2) for BIC-minimised and (624.8, 680.6) for the published model<sup>2</sup>.

The similarity between the models was further demonstrated by plotting the observed and predicted risk with increasing levels of predicted risk (Fig.2).

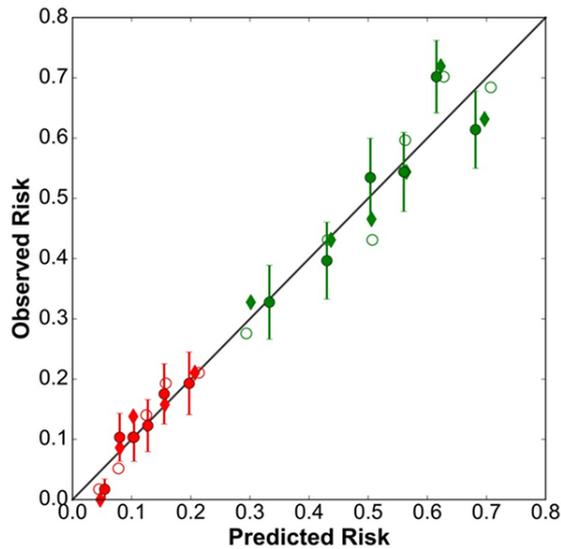

Fig. 2. Scatter plot of predicted vs. observed risk with patients grouped in 6 equally sized bins. Separate predicted risks were calculated, for patients having  $\ge 1$  grade cystitis (green) and  $\ge 2$  grade cystitis (red). No significant differences can be seen between the published model<sup>2</sup> (empty circles), the model derived by using the genetic algorithm to minimise AIC (solid diamonds) and alternatively minimise BIC (solid circles). Error bars indicate 68% confidence intervals.

**Conclusion**

The method proposed can automatically generate ordinal logistic regression models that can have equivalent predictive accuracy as models created manually. Furthermore the method can be used to save time in data analysis, tackle problems with a large number of parameters and standardise variable selection in NCTP modelling.

<sup>3</sup>Institute of Clinical Sciences- the Sahlgrenska Academy at the University of Gothenburg, Department of Otorhinolaryngology- Head and Neck Surgery, Gothenburg, Sweden

<sup>4</sup>University of California San Diego, Department of Radiation Medicine and Applied sciences, La Jolla, USA

**Purpose or Objective**

To investigate temporal radiation-induced etiologies for trismus using dose to five masticatory structures within a thorough internal generalizability approach.

**Material and Methods**

This study included 93 patients previously treated with primary radiotherapy (RT) for head and neck cancer in 2007-2012 to 64.6-68Gy@1.7-2.0 Gy/fraction. All patients had complete dose data, and trismus assessments (maximum interincisial mouth-opening distance, MIO) at baseline, and at 3, 6, and 12 months post-RT. At each follow-up, the mean dose to each of five masticatory structures (bilateral, contralateral and ipsilateral representations) and ten other patient characteristics was included in a univariate linear regression analysis (UVA)

within a 200 times iterated 5-fold cross-validation approach. One additional analysis was performed with the lowest MIO over the three follow-up times as response variable (referred to as “3-12 months”; observed at the 3/6 months follow-ups in 60% of the cases). Candidate predictors from UVA, *i.e.* with a median two-sided  $p$ -value  $\le 0.05$  over all iterations, qualified for multivariate linear regression analysis (MVA) applying the same cross-validation approach. Predictability was assessed using coefficient of determination ( $r^2$ ), and Spearman’s rank correlation coefficient (Rs); both given as the median over all iterations.

**Results**

Of 5-12 variables that presented with  $p \le 0.20$  on UVA (Table), trismus status pre-RT was an independent predictor for post-RT trismus ( $p=0.01-0.02$  for all response variables) as was the mean dose to the ipsilateral masseter ( $p=0.05$  at 3, 6, and 3-12 months). The combination of these two candidate predictors generated MVA models with increased predictability compared to the corresponding UVA models ( $r^2=0.35-0.40$  vs.  $0.20-0.32$ ;  $Rs=0.59-0.63$  vs.  $0.44-0.57$ ), and consequently steeper response curves with 11-13 mm and 15-16 mm MIO difference between the least and the most risky quintile for the UVA and MVA models, respectively (Figure). A tendency of trismus recovery was noted for longer follow-up with a lower pre-RT normalized MIO difference at 12 months compared to that of the two earlier assessments; median (range): 0.14 (-0.67, 0.62) vs. 0.17 (-1.07, 0.66) at 3 months, and 0.16 (-1.33, 0.64) at 6 months.

Figure. The UVA dose-response curves for MIO pre-RT (upper), and  $D_{mean}$  Mass Ipsi (middle), as well as the MVA dose-response curves for them combined (lower) for each investigated response variable. Note: Observed data is given in colored quintiles as the mean (error bars: SD), and predicted as black lines. Abbreviations as in Table.

**Conclusion**

A temporally robust dose-response relationship for radiation-induced trismus, quantified as a millimeter mouth-opening decrease, could be observed within the first year after completed radiotherapy. Our results suggest that the dose-response for trismus within this period relies on the mean dose to the ipsilateral masseter, as well as the underlying pre-treatment mouth-opening ability. Up to ten additional variables presented with  $p$ -values in the interval  $p=0.06-0.19$  and may prove to be of importance if investigated in larger/pooled cohorts with diversified treatment approaches where potential effects can be thoroughly investigated.

**PO-0855 Use of the LKB model to fit urethral strictures for prostate patients treated with HDRB**  
 V. Panettieri<sup>1</sup>, E. Onjukka<sup>2</sup>, T. Rancati<sup>3</sup>, R. Smith<sup>1</sup>, J. Millar<sup>1</sup>

<sup>1</sup>Alfred Hospital, Alfred Health Radiation Oncology, Melbourne, Australia

<sup>2</sup>Karolinska University Hospital, Dept of Hospital Physics, Stockholm, Sweden

<sup>3</sup>Fondazione IRCCS- Istituto Nazionale dei Tumori, Prostate Cancer Program, Milan, Italy

#### Purpose or Objective

High-Dose-Rate brachytherapy (HDRB) is widely used in combination with external beam radiotherapy in the treatment of prostate cancer. Despite providing biochemical control similar to other techniques, due to the variety of fractionation regimes used there is no clear consensus on the dose limits for the organs-at-risk, in particular the urethra.

The aim of the work has been to fit the Lyman-Kutcher-Burman (LKB) Normal Tissue Complication Probability model to clinical outcome on urethral strictures data collected at a single institution.

#### Material and Methods

Dose-volume histograms and clinical records of 262 patients were retrospectively analysed. The patients had follow-up 6, 12, 18, 24 months and then every year until 10 years after the treatment. Clinical and toxicity data were collected prospectively. The end-point was the time of the first urethrotomy, a follow-up cut-off time of 4 years was chosen and the average stricture rate was about 12.6%. The LKB NTCP model was fitted using the maximum likelihood method and used simulated annealing to find a stable solution. Since the patients were treated with 3 different fractionation regimes (18 Gy in 3, 19 Gy in 2 and 18 Gy in 2 fractions) doses were converted into EQD2 with  $\alpha/\beta = 5$  Gy.

#### Results

For this cohort of patients the risk of urethral stricture could be modelled by means of a smooth function of EUD (see Fig 1). Using the LKB model the risk of complication could be represented by a TD50 of 220 Gy, a steepness parameter  $m$  of 0.55 and a volume-effect parameter  $n$  of 2.7. The fitted model showed good correlation with the observed toxicity rates with the largest deviation shown at higher doses. The large value of  $n$  could suggest a parallel behaviour of the urethra, however further validation is required with an independent dataset.

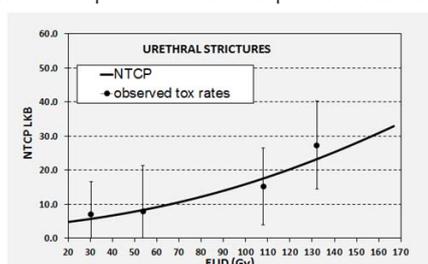

Fig1. Dose-volume response curve obtained with the best estimated parameters for the LKB model for urethral stricture. Solid circles represent the observed toxicity rates.

#### Conclusion

In this work we have fitted the LKB model to clinical outcome on urethral strictures data for patients treated with HDRB collected at a single institution. The results show that the fitted model provides a good representation of the observed data, however further analysis and independent validation are necessary to confirm its behaviour and parameters.

<sup>3</sup>Aarhus University Hospital, Department of Pulmonology, Aarhus C, Denmark

#### Purpose or Objective

Internal target motion results in geometrical uncertainties in lung cancer radiotherapy. The lymph node (LN) targets in the mediastinum are difficult to visualize in cone-beam computed tomography (CBCT) scans for image-guided radiotherapy, but implanted fiducial markers enable visualization on CBCT projections and fluoroscopic kV images. In this study, we determined the intrafraction motion of mediastinal LN targets in both the setup CBCT and fluoroscopic kV images acquired during treatment delivery, and investigated the baseline shifts and treatment accuracy of LNs for ten lung cancer patients.

#### Material and Methods

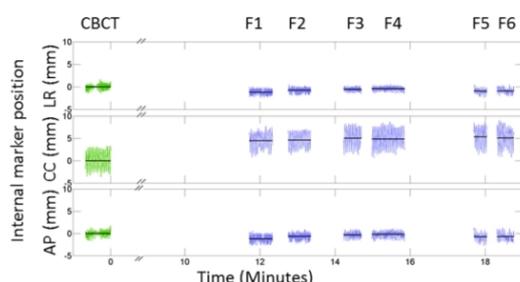

Ten lung cancer patients had 2-4 fiducial markers implanted in LN targets by EBUS bronchoscope. A total of 26 markers were evaluated. The patient received IMRT with daily setup CBCT for online soft tissue match on the primary tumor. During treatment delivery, 5 Hz fluoroscopic kV images were acquired orthogonal to the MV treatment beam. Offline, the marker positions were segmented in each CBCT projection and fluoroscopic kV image. From the segmented marker positions, the 3D marker trajectories were estimated from the segmentations with sample rate of 11 Hz during CBCT acquisition and 5 Hz during treatment delivery.

The 3D motion amplitude and mean position of each LN marker as well as the intrafraction baseline shifts between setup CBCT and treatment delivery were calculated.

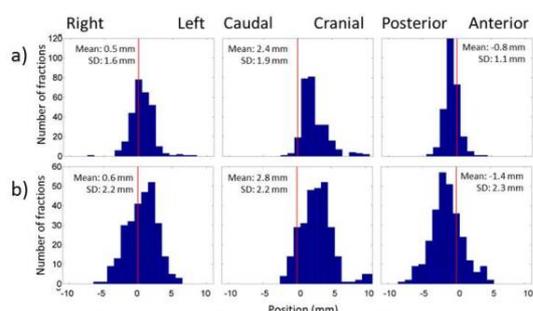

#### Results

Figure 1 shows the internal motion of one marker at one fraction. The motion is shown relative to the mean position during the CBCT scan and corrected for the couch shift between CBCT and treatment. For this marker, the baseline shift was 4.8 mm cranially, 0.6 mm posteriorly, and 0.7 mm towards right. Figure 2a shows the distribution of intrafraction baseline shifts for all patients and LNs at all fractions. Systematic LN baseline shifts occurred between CBCT and treatment delivery in the cranial direction (mean 2.4 mm (SD 1.9 mm)) and posterior direction (0.8 mm (1.1 mm)). The frequency of cranial baseline shifts exceeding 4 mm and 6 mm were 15 % and 4 %. The baseline shifts resulted in systematic mean geometrical errors during treatment delivery of 2.8 mm (cranial) and 1.4 mm (posterior)(Figure 2b) for the LNs. These errors were substantially larger than the sub-millimeter mean errors expected from the setup CBCT based soft tissue tumor match when correcting for the applied couch shifts.

In general, the largest LN motion amplitude was observed in the cranio-caudal direction both during CBCT and treatment delivery. The mean motion amplitudes during CBCT and treatment delivery agreed within 0.2 mm in all three directions.

**Figure 1:** Example of intrafraction marker motion during CBCT and six treatment fields for a lymph node marker in one patient at one fraction. Horizontal lines show the mean position during each field. Markers positions are shown relative to the mean position during the CBCT, i.e. the CBCT mean is always zero.

**Figure 2:** Distributions of **a)** internal baseline shifts between CBCT and treatment delivery measured, and **b)** actual mean geometrical error measured during treatment delivery.

## Conclusion

Systematic cranial and posterior intrafraction baseline shifts between setup CBCT and treatment delivery occurred for mediastinal LN targets in lung cancer patients and reduced the treatment accuracy. Intrafraction motion amplitudes were stable throughout each treatment fraction, as well as the treatment course.

## PO-0857 Analysis of Intrafraction Motion in Image-Guided Stereotactic Radiosurgery of Spinal metastases J.G. Svestad<sup>1</sup>

<sup>1</sup>Oslo University Hospital The Norwegian Radium Hospital, Department of Medical Physics, Oslo, Norway

### Purpose or Objective

Stereotactic radiosurgery of spinal metastases include tight margins and steep dose gradients to the surrounding organs at risk (OAR). The proximity of the target to the adjacent spinal cord and the aim of keeping the dose to the spinal cord within tolerance require a high degree of precision in dose delivery. This study aimed to evaluate intrafractional motion using cone beam computed tomography (CBCT) image guidance, for immobilized spinal stereotactic radiosurgery patients, with correction in all six degrees of freedom.

### Material and Methods

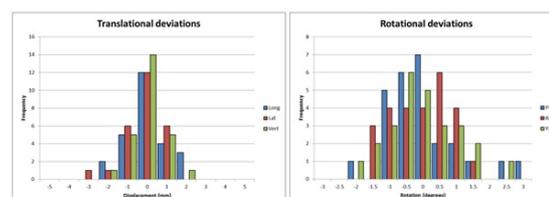

Intrafractional motion during spine radiosurgery treatment in 16 patients (26 fractions) was retrospectively analyzed. All patients were immobilized in the BlueBAG BodyFIX (Elekta, Stockholm, Sweden) that uses a vacuum pump to create a precise mold of the patient's position. Radiation treatment was performed using a Varian Truebeam STx linear accelerator equipped with a PerfectPitch 6 degrees of freedom couch (Varian Medical Systems, Inc., Palo Alto, USA).

Following initial setup, a CBCT was acquired for patient alignment and patient position was corrected in all six degrees of freedom. Patients were reset manually, and the process was reinitiated if the  $\pm 3^\circ$  rotational couch tolerance was exceeded. A post treatment CBCT was

acquired and analyzed using the offline image review workspace in Mosaic (v1.60, Elekta, Stockholm, Sweden) to determine intrafractional patient movements. From each CBCT, 3 translational and 3 rotational coordinates were obtained.

## Results

The average time between the patient setup CBCT and the post treatment CBCT was 9 minutes (range, 6-14). The average absolute translational variations ( $\pm 1$  SD) obtained from the post-treatment CBCT was  $0.7 \pm 0.7$ ,  $0.7 \pm 0.8$  and  $0.5 \pm 0.6$  mm in the lateral, longitudinal and vertical directions, respectively. The average absolute rotational angles were  $0.8 \pm 0.7$ ,  $0.7 \pm 0.4$  and  $0.8 \pm 0.6^\circ$  along pitch, roll and yaw, respectively. Histograms of translational and rotational deviations for all patients are shown in figure 1.

**Figure 1:** Frequency of translational and rotational deviations for all patients.

## Conclusion

Near-rigid body immobilization, CBCT image guidance and six degrees of freedom correction yields minimal intrafractional motion and safe stereotactic spine radiosurgery delivery. It is not easy to determine the effect of rotational deviations. However, for treatment plans with the isocenter placed in the center of the target volume, which is the case for these patients, small rotations would not result in large deviations in dose to the target volume or adjacent OARs. There are different approaches that could result in less patient motion and increased precision in dose delivery. The combination of a polyethylene sheet with a vacuum cushion would presumably result in a more rigid immobilization. Intrafractional imaging during treatment is another alternative that could increase precision in dose delivery.

## PO-0858 Intra-fraction motion quantification of head-and-neck tumors using dynamic MRI

T. Bruijnen<sup>1</sup>, R.H.N. Tijssen<sup>1</sup>, M.E.P. Philippsen<sup>1</sup>, C.H.J. Terhaard<sup>1</sup>, T. Schakel<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, C.P.J. Raaijmakers<sup>1</sup>, B. Stemkens<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

Previous research primarily focused on the effect of deglutition on the accumulated tumor dose. However, resting-state movements, such as respiratory-induced tumor motion, has been largely overlooked. Nonetheless, this may play an important role in the size of the treatment volume of head-and-neck cancer. Here, we investigate head-and-neck resting-state tumor motion in a radiotherapy treatment position in order to provide guidance for adequate internal target volume (ITV) determination.

### Material and Methods

Acquisition: 46 patients with head-and-neck cancer (6 nasopharyngeal/ 25 oropharyngeal/ 15 laryngeal) underwent pretreatment clinical MRI scanning in a radiotherapy treatment setup, including a custom-fit immobilization mask. Two 2D sagittal dynamic acquisitions (RF- and gradient-spoiled gradient echo; TE/TR=1.5/3ms; voxel size=1.42x1.42x10 mm<sup>3</sup>; 158 ms temporal resolution), separated 10 minutes apart, localized to intersect the tumor were acquired on a 3.0T scanner. GTV delineations, as performed by a radiation oncologist, were obtained from the treatment plans.

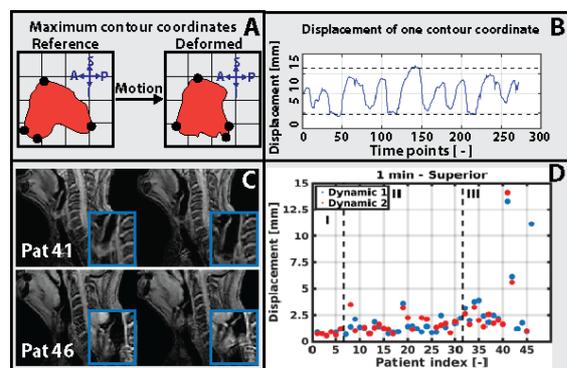

**Image analysis:** The two dynamic MR series were analyzed separately to quantify typical one minute tumor displacements along two orthogonal directions; superior (S), inferior (I), anterior (A) and posterior (P). All time-points affected by non-respiratory associated tongue motion or deglutition were manually discarded from the analysis. One time-point was selected as the reference and all other points were non-rigidly registered to the reference using a validated optical flow algorithm [1]. Motion fields were computed for all the pixels inside the tumor and combined into a single distance metric by assessing the maximum contour coordinates (FIG1-A+B). Typical 10-minutes displacements were investigated by computing the difference

### Results

Mean maximum 1-minute tumor displacements amounted to 2.08 (SD 2.34) mm in (S), 2.26 (SD 1.48) mm in (I) and 1.66 (SD 0.93) mm in (A); 1.65 (SD 1.23) mm in (P) (FIG1-D). However, there was strong inter-subject variability within the laryngeal and oropharyngeal subgroups, with laryngeal tumors exhibiting periodic displacements up to 14 mm in (S) (FIG1-C). The typical 10 minute shifts were smaller than 2 mm for all patients (not shown in figure), with means values of 0.62 (SD 0.44) mm in (S) ; 0.64 (SD 0.58) mm in (I); 0.49 (SD 0.51) mm in (A); 0.41 (SD 0.36) mm in (P).

### Conclusion

Although tumor displacements were small, there were three subjects that exhibited resting-state displacements larger than 5 mm. This suggests individualized ITVs for the laryngeal tumors and oropharyngeal tumors, instead of applying 5 mm margins in both I and S directions for laryngeal tumors. The 10-minutes intrafraction shift was smaller than 2 mm across all the patients and directions and did not show any outliers.

**FIG1:** (A) For every time-point the maximum contour coordinates in all four directions were determined (black dot) and these were compared with the maximum contour coordinates of the reference. (B) Time profile of the maximum superior contour coordinates for all the time-points relative to the reference time-point. The final displacement metric is the distance between the maximum and minimum on the profile (distance dashed line). (C) Two examples of patients that demonstrated the largest displacements. The two images show the extreme tumor positions within the time-series. (D) Maximum 1-minute tumor displacement for all patients in the superior direction, tumors arranged according to their anatomy (I=nasopharynx, II=oropharynx, III=larynx).

### PO-0859 Impact of 4DCBCT reconstruction algorithm and surrogate on motion representation

E. Steiner<sup>1</sup>, C.C. Shieh<sup>1</sup>, V. Cailliet<sup>2</sup>, N. Hardcastle<sup>2</sup>, C. Haddad<sup>2</sup>, T. Eade<sup>2</sup>, J. Booth<sup>2</sup>, P. Keall<sup>1</sup>

<sup>1</sup>University of Sydney, Radiation Physics Laboratory-Sydney Medical School, Camperdown, Australia

<sup>2</sup>Northern Sydney Cancer Centre- Royal North Shore Hospital, Radiotherapy Department, St Leonards, Australia

### Purpose or Objective

Lung tumour motion exceeding the observed motion from planning 4D computed tomography (4DCT) is of concern in stereotactic ablative body radiation therapy (SABR). 4D cone-beam CT (4DCBCT) facilitates verification of tumour trajectories before each treatment fraction and an accurate patient setup. This work aims to assess the impact of the selection of the reconstruction algorithm and surrogate for binning on the motion representation in

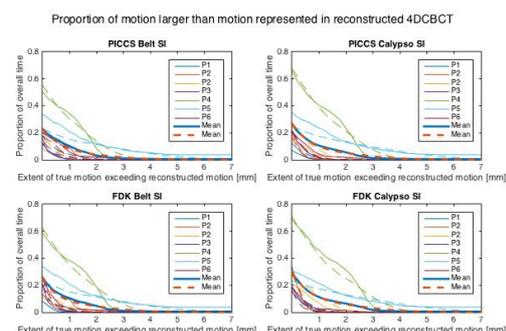

the 4DCBCTs using implanted Calypso beacons in the lung as ground truth.

### Material and Methods

4DCBCTs were reconstructed from projections for treatment setup CBCT for 1-2 fractions of 6 patients using the prior image constrained compressed sensing (PICCS) method and the FDK (Feldkamp-Davis-Kress) method. For both methods reconstructions were performed based on the internal Calypso motion trajectories (three beacons per patient) or an external respiratory signal (Philips Bellows belt). The Calypso beacons were segmented for all 10 bins of the 4DCBCTs and the beacon centroid motion compared to the motion range from the images. Paired t-tests were performed on the mean size of excess beacon motion and the proportion of scanning time with motion larger than represented in 4DCBCT in order to identify a superior reconstruction method.

### Results

All methods for 4DCBCT reconstruction failed to capture sudden motion peaks during scanning and underestimated the actual beacon centroid motion (see Fig. 1), which is a result of phase-based binning and averaging the images in a bin. For the SI direction in general, reconstructions using the belt signal, led to a representation of a larger motion range (PICCS:  $4.88 \pm 3.30$ mm, FDK:  $4.81 \pm 3.35$ mm) than the Calypso-based reconstruction (PICCS:  $4.71 \pm 3.22$ mm, FDK:  $4.76 \pm 3.29$ mm). However, the difference was not significant, as for none of the other directions. For comparison also the Calypso motion during the treatment exceeding the 4DCBCT motion range is shown in Figure 1.

**Figure 1.** Proportion of intra-CBCT (solid lines) and intra-treatment (dashed lines) motion in SI direction larger than the motion represented in the reconstructed 4DCBCT for reconstruction with a) PICCS Belt, b) PICCS Calypso, c) FDK Belt and d) FDK Calypso.

### Conclusion

All 4DCBCT reconstruction methods failed to represent the full tumour motion range, but performed similar. Thus, the belt as an external surrogate is sufficient for 4DCBCT reconstruction. For a safe treatment in spite of motion exceeding the motion range from the images, adequate ITV-to-PTV margins or a real-time treatment adaptation directly tackling motion peaks and unpredictable motion need to be chosen. While the 4DCBCT is not able to capture and predict the whole motion range of a treatment fraction, it serves as a valuable tool for accurate patient setup.

### PO-0860 Characterization of a novel liquid fiducial marker for organ motion monitoring in prostate SBRT

R. De Roover<sup>1</sup>, W. Crijns<sup>2</sup>, K. Poels<sup>2</sup>, R. Peeters<sup>3</sup>, K. Haustermans<sup>1,2</sup>, T. Depuydt<sup>1,2</sup>

<sup>1</sup>KU Leuven - University of Leuven, Department of Oncology, Leuven, Belgium

<sup>2</sup>University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium

<sup>3</sup>University Hospitals Leuven, Department of Radiology, Leuven, Belgium

### Purpose or Objective

Stereotactic body radiotherapy (SBRT) for prostate is a cost-effective treatment option with improved patient comfort and maintained excellent clinical outcomes. However, to ensure low levels of toxicity very accurate delivery is imperative, especially when combined with integrated focal boosts as in the Hypo-FLAME clinical trial methodology. Within this context, intra-fraction organ motion management becomes even more relevant. The novel BioXmark® (Nanovi A/S) biodegradable radio-opaque liquid fiducial marker was studied as alternative for current markers used in prostate motion management. The marker can be injected with very thin needles (down to 25G) and the injection procedure allows to vary the marker-size by altering the injected volume. In this study the automatic detectability of BioXmark® in 2D kV X-ray imaging was determined. Additionally, as Hypo-FLAME involves a multi-modality delineation of the boost foci, visibility/artefacts in different types of volumetric imaging was investigated.

### Material and Methods

BioXmark® consists of sucrose acetate isobutyrate (SAIB), iodinated-SAIB and ethanol solution. Upon injection, ethanol diffusion out of the solution causes a viscosity increase and formation of a gel-like marker. A total of 8 markers (size 5-300  $\mu$ L) organized in a rectangular grid were injected into a gelatin phantom.

X-ray projection images using the Varian TrueBeam STx OBI were obtained by putting the gelatin phantom on top of an anthropomorphic pelvic phantom. A total of 120 images of each marker were acquired varying the positions of the marker relative to pelvic bony structures and using 24 clinically relevant X-ray kVp/mAs settings. Volumetric imaging was performed with CT, CBCT and MRI using a CIRS pelvic phantom.

Automated marker detection was based on the normalized cross-correlation (NCC) of the projection image with a marker template retrieved from the CT image. Prior to detection, single markers were artificially isolated to minimize interference between detection of the different markers. Reference marker positions were manually determined on the image with highest exposure settings. A detection was successful if the optimal NCC value lied within a 1 mm (3 pixels) tolerance of the reference position. The tolerance was extended to 4 pixels to deal with the uncertainty of manual delineation.

### Results

Detection success rates augmented with increasing marker-size obtaining a maximum for intermediate size (25-75  $\mu$ L) markers (Figure 1). Larger marker sizes (>75  $\mu$ L) had decreased detection success rates due to higher susceptibility for interference with the bony structure edges. Volumetric image artefacts were minimal whilst the markers itself were clearly visible (Figure 2).

### Conclusion

Intermediate size (25-75  $\mu$ L) BioXmark® liquid fiducial markers showed high detectability and minimal image artefacts making them a patient friendly alternative (thin needles) for the current markers used in fiducial-marker-based intra-fraction organ motion monitoring in prostate SBRT.

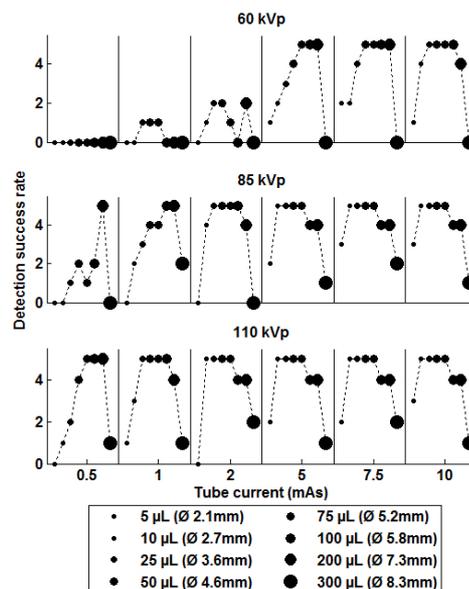

Figure 1: detection success rate (range 0 – 5) of the different marker sizes ordered in terms of ascending volume for the different kVp/mAs image settings. One can clearly observe an increase in detection success rate with increasing marker-size until a maximum value is reached for markers of intermediate size (25-75  $\mu$ L). Larger markers (>75 $\mu$ L) were more prone to interference with bony structure edges resulting in lower detection success rates. The results for 15 mAs and 20 mAs have been excluded as they were identical to the results for 10 mAs and offered no new information.

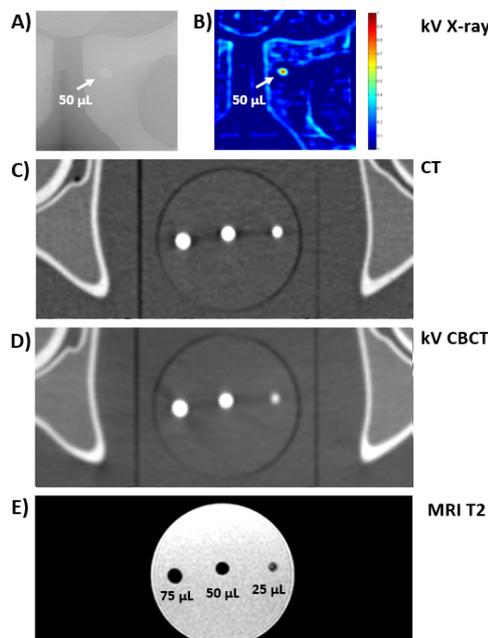

Figure 2: overview of the visibility of intermediate size (25-75  $\mu$ L) liquid fiducial markers for the different imaging modalities employed in this study. A: shows a 2D kV X-ray image (110 kVp, 10 mAs) and B: the corresponding NCC plot for a 50  $\mu$ L marker. C to E: show transversal slices of CT (120 kVp, AEC), CBCT (125 kVp, 1080 mAs) and MRI (1.5 T, T2-weighted) for the 75  $\mu$ L, 50  $\mu$ L and 25  $\mu$ L markers respectively. The markers were clearly visible on the volumetric images and caused minimal image artefacts.

### PO-0861 Geometric validation of a 4D-MRI guided correction strategy on the MR-Linac

T. Van de Lindt<sup>1</sup>, R. Koopman<sup>1</sup>, A. Van de Schoot<sup>1</sup>, I. Torres-Xirau<sup>1</sup>, U. Van der Heide<sup>1</sup>, J.J. Sonke<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

Currently in radiotherapy, respiratory motion correction strategies are performed by the use of 4D-(CB)CT. However, moving targets in for example the upper abdomen are not (clearly) visible on these images because of low soft-tissue contrast. The introduction of an integrated MRI and linear accelerator (MR-Linac) will allow for daily MRI-guidance of the tumor. Therefore, the aim of

this study was to develop and validate a 4D-MRI guided mid-position (midP) correction strategy on an MR-Linac.

#### Material and Methods

Experiments were performed on an MR-Linac (ATL1, Elekta AB, Sweden), using the CIRS MRI-LINAC Dynamic Phantom (CIRS Inc., USA). The moving cylinder was filled with anisotropic MRI contrasts and a Perspex spherical target. Motion was performed in CC direction using a Lujan 4 motion pattern with a 20mm amplitude and 4s period. First, a T2-weighted MRI scan was acquired in midP. The cylinder and target were segmented and the target was expanded with a non-uniform margin (LR, AP:10mm; CC:20mm). A density overwrite of 1 was assigned to the structures and a treatment plan consisting of a single anterior beam shaped around the PTV was created in Monaco (Version 5.19.01 Research). Then, baseline shifts in CC direction of 5, 10, 15 and 20mm were applied to the phantom motion. For every shift, a retrospective self-sorted 4D-MRI was acquired (axial single-shot TSE,  $2 \times 2 \times 5 \text{ mm}^3$ , TE/TR=60/400ms, 30dyn) and each phase was registered to the midP reference image to calculate the time average displacement. The plan was adapted accordingly, performing a virtual couch shift (simple dose shift) using aperture morphing in Monaco. All plans were delivered while electronic portal imaging device (EPID) cine images were acquired. The time average displacement of the target was calculated from the EPID images and geometric accuracy of the workflow was quantified as the distance of the average position of the target to the field edges in the EPID images.

#### Results

In Figure 1, MRI and EPID images of the midP and a shifted inhale and exhale position are shown. Table 1 shows the time average displacement of the target in the 4D-MRI and the EPID images with respect to the reference as well as the distance of the average target position to the field edges.

The geometric accuracy of the 4D-MRI guided workflow was  $0.3 \pm 0.4 \text{ mm}$  in CC, which includes the 4D-MRI registration accuracy.

Table 1. Time average displacement of the target with respect to the reference in 4D-MRI and EPID images and distance of the average position of the target to the field edges in EPID

Baseline shift phantom (mm)	0.0	5.0	10.0	15.0	20.0	Accuracy	
						Mean	SD
<b>Target to reference</b>							
4D-MRI	-0.2	4.5	10.5	15.4	20.2	-0.1	0.4
EPID	0.6	5.3	10.0	14.8	19.7	-0.1	0.4
<b>Target to field edges</b>							
EPID	0.2	0.3	-0.4	0.8	0.6	0.3	0.4

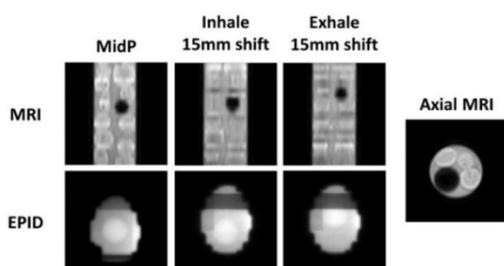

Figure 1. Left: Coronal MRI (target=black) and EPID image (target=white) in midP and in inhale and exhale position with baseline shift 15mm. Right: Axial MRI.

#### Conclusion

4D-MRI guidance on an MR-Linac was shown to be feasible and had sub-millimeter accuracy. Such a correction strategy has great potential for moving targets that are difficult to visualize on alternative image guidance modalities.

#### PO-0862 Correlation of Liver and Pancreas Tumor motion with Normal Anatomical Structures

R. Kaderka<sup>1</sup>, A. Paravati<sup>1</sup>, R. Sar kar<sup>1</sup>, J. Tran<sup>1</sup>, K. Fero<sup>1</sup>, N. Panjwani<sup>1</sup>, D. Simpson<sup>1</sup>, J. Murphy<sup>1</sup>, T. Atwood<sup>1</sup>  
<sup>1</sup>University of California San Diego, Department of Radiation Medicine and Applied Sciences, San Diego, USA

#### Purpose or Objective

Target motion caused by respiration remains the central challenge to delivering SBRT in the abdomen. For targets in the pancreas and liver, SBRT oftentimes necessitates placement of metal fiducials to determine tumor position with fluoroscopy, due to difficulty in visualizing tumors on non-contrast imaging. Metal fiducials have limitations in that they represent an invasive procedure which can introduce treatment delays. Furthermore, fiducials can migrate from their intended position, and the metal can introduce imaging artifacts which make tumor delineation a challenge. We hypothesized that upper abdominal tumor motion would correlate with the motion of nearby organs and could thereby serve as a fiducial-less proxy for tumor motion.

#### Material and Methods

Fifteen patients (12 with pancreas and 3 with liver tumors) underwent a 4-dimensional (4D) CT simulation prior to treatment with SBRT. 4D CT images were divided into 10 phases and normal tissues were contoured on a single 4D-CT phase and propagated to the other phases using deformable image registration. As a means of quality control for image registration and contour propagation the liver was manually contoured on all phases for 5 patients by physicians and compared to the automated contour propagation using a Dice coefficient. Motion was defined from the center-of-mass of each structure, and a patient-specific linear tumor position prediction model based on liver position was developed.

#### Results

We found a strong overlap of manually entered contours and the automatically segmented contours with a mean Dice-coefficient of 0.95 (standard deviation 0.01). The linear models accurately predicted tumor motion with a mean absolute error of 0.5 mm and no error greater than 3.0 mm. Mean absolute and maximum errors by direction and tumor type are listed in the table below.

	Left-right direction	Anterior-posterior direction	Superior-inferior direction
Pancreas tumors mean absolute error (mm)	0.3	0.4	0.5
Pancreas tumors maximum error (mm)	1.0	1.7	2.6
Liver tumors mean absolute error (mm)	0.3	0.4	0.8
Liver tumors maximum error (mm)	1.4	2.7	3.0

#### Conclusion

This study demonstrates that normal organ motion could serve as a fiducial-less proxy for tumor motion with SBRT in the upper abdomen when on-site real-time 4D volumetric imaging becomes available during treatment. Deformable image registration has been demonstrated to be a reliable and fast tool for segmentation of normal organs. Moving this motion management approach into clinic requires additional research to optimize 4D image quality and understand inter-fraction reproducibility.

#### PO-0863 Suggestion of optimal planning target volume margins for stereotactic body radiotherapy of the spine

S.H. Jeon<sup>1</sup>, S.Y. Park<sup>1</sup>, J.H. Kim<sup>1</sup>, J.I. Kim<sup>1</sup>, J.M. Park<sup>1</sup>  
<sup>1</sup>Seoul National University Hospital, Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

To suggest an optimal planning target volume (PTV) margin in stereotactic body radiotherapy (SBRT) of the spine.

### Material and Methods

From December 2014 to July 2016, 40 patients received 42 fractions of SBRT for spinal tumors to thoracic or lumbosacral spines using a volumetric modulated arc therapy technique and patient immobilization. Before treatment, kilovoltage cone-beam CT (CBCT) images were obtained for a 4 degrees of freedom (DoF) correction of patients alignment (translation + yaw). After corrections were made, additional CBCT was acquired just before treatment delivery (pretreatment CBCT). Immediately following SBRT, CBCT was acquired again (posttreatment CBCT). Residual setup errors for pretreatment CBCT was determined by a 6 DoF manual matching. Intrafraction motions were calculated as differences in errors between pretreatment and posttreatment CBCT. Three clinical target volumes (CTVs) were generated by translating and rotating original CTV by residual setup errors alone (CTV\_R), intrafraction motions alone (CTV\_I), and residual setup errors and intrafraction motions combined (CTV\_R+I), respectively. Adding various uniform margins to original CTV generated PTVs. The impact of PTV margins on CTV coverage was evaluated. A provisional criterion of adequate CTV coverage was that PTV encompasses at least 97% of CTV.

### Results

Time interval between pre-treatment and post-treatment CBCTs was  $6.8 \pm 2.5$  min (mean  $\pm$  2SD). The 2SD values of lateral, vertical, longitudinal translations and pitch, roll, and yaw were 0.7mm, 0.8mm, 1.1mm,  $1.7^\circ$ ,  $1.1^\circ$ , and  $1.6^\circ$  for residual setup errors and 1.0mm, 0.9mm, 0.9mm,  $1.1^\circ$ ,  $0.8^\circ$ , and  $1.1^\circ$  for intrafraction motions, respectively. Without margins, PTV showed adequate coverage for CTV\_R, CTV\_I, and CTV\_R+I in 48% (20/42), 71% (30/42), and 48% (20/42) of fractions, respectively. With 1-mm uniform margins, PTV was adequate for 95% (40/42), 98% (41/42), and 100% (42/42) of fractions, respectively. 2-mm uniform margin was adequate in all fractions for all three CTVs.

### Conclusion

With appropriate immobilizations and 4DoF corrections, a uniform 1-mm PTV margin may ensure an adequate CTV coverage in most treatment sessions of spine SBRT. Combined with a shortened treatment time, the small extent of intrafraction motions may obviate the need of treatment interruption for additional intra-session image guidance. Despite perfect 6 DoF patient alignment, 1-mm PTV margin is still needed to address intrafraction motions.

### PO-0864 Accuracy of fiducial based correction of target motion in prostate SBRT treatments

T. Viren<sup>1</sup>, M. Korhonen<sup>2</sup>, J. Seppälä<sup>1</sup>

<sup>1</sup>Kuopio University Hospital, Cancer Center, Kuopio, Finland

<sup>2</sup>University of Eastern Finland, Department of Applied Physics, Kuopio, Finland

### Purpose or Objective

Robotic stereotactic body radiotherapy (SBRT) incorporating a fiducial based motion tracing system has enabled almost real-time correction of intra-fraction motion of a prostate during SBRT treatments of prostate cancer. However, the effect of number and positioning of the fiducials and the amount of prostate movements on the accuracy of the treatment has not been reported. The aim of the present study was to investigate the accuracy of the fiducial based correction of target motion in

prostate SBRT treatments and to evaluate the effect of fiducial number and positioning to the accuracy of the fiducial tracking.

### Material and Methods

CT image was acquired from custom-made phantom incorporating different fiducial configurations (Fig 1). Subsequently, typical prostate SBRT treatment plan (5x7.25Gy) was calculated in the phantom using treatment planning software (Ray Tracing algorithm, Multiplan, Accuray, USA). To measure the dose distribution within the phantom calibrated Gafchromic films (4 x 4 inch, Gafchromic EBT<sup>3</sup>, RPD Inc., USA) were placed inside the phantom. A prostate treatment was irradiated in three different phantom positions: no movement, typical clinical prostate movements, and maximum movements allowed by the automatic fiducial tracing system (Fig 1). The phantom movements were conducted using RoboCouch (Accuray, USA). To mimic the suboptimal positioning of the fiducials the measurements were repeated with four different seed configurations (optimal, typical clinical case, clinical case with three fiducials, clinical case with two fiducially). Measurements were conducted in coronal and sagittal planes. Finally, the films were scanned (Perfection V700, Epson, USA) 72 hours after the irradiation and the measured and calculated dose distributions were compared using gamma-analysis (5%/2mm threshold).

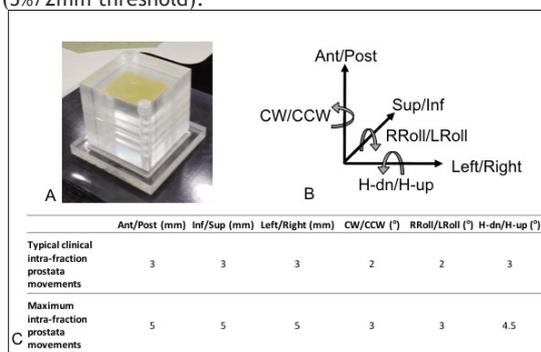

Figure 1. A) Custom made phantom used to measure prostate SBRT treatment plans. B) The directions of the prostate movements and rotations. C) Typical clinical and maximum intra-fraction prostate movements used in the present study

### Results

The accuracy of the automatic correction of intra-fraction motion of the target was clinically acceptable when three or four seed configuration was used in the motion tracking (Table 1). No significant changes in gamma pass rates were detected when the amount of phantom movement was increased. Clinically unacceptable gamma pass rates were detected only when two fiducials where used in tracking.

Table 1. Gamma pass rates of measured and calculated treatment plan comparisons for different fiducial configurations and phantom movements.

Fid. Config/ Movements	no mov.	clinical	maximal
Coronal	Optimal	98.5 %	99.3 %
	Clinical	97.4 %	98.7 %
	3 fiducials	98.2 %	98.2 %
	2 fiducials	91.6 %	81.2 %
Sagittal	Optimal	96.0 %	97.2 %
	Clinical	96.3 %	94.3 %
	3 fiducials	92.2 %	98.8 %
	2 fiducials	96.5 %	71.2 %

### Conclusion

Automatic correction of the target movement was reasonably accurate for clinical use when three or four

fiducials were used. Optimal positioning of the fiducials did not improve the accuracy of the treatment when compared to the accuracy achieved with typical clinical fiducial positions or with three fiducials. Usage of only two fiducials in the target tracking resulted clinically unacceptable accuracy.

#### PO-0865 Commissioning and clinical implementation of intra-fractional 4D-CBCT imaging for lung SBRT

R. Sims<sup>1</sup>

<sup>1</sup>ARO - Auckland Radiation Oncology, Radiotherapy Physics, Auckland, New Zealand

##### Purpose or Objective

Geometric verification of the tumour for free-breathing lung SBRT patients is challenging due to limitations of CBCT imaging at the treatment unit. This can be overcome by using novel acquisition and reconstruction tools to produce a 4D-CBCT dataset that can be acquired both before (inter-fraction) and during (intra-fraction) beam delivery. The commissioning and clinical experience of such a system for lung SBRT will be presented.

##### Material and Methods

An anthropomorphic phantom was used to investigate system efficacy for identifying changes in reconstructed motion with different acquisition settings for a variety of clinical situations. The sensitivity of the system to detect changes to programmed motion was investigated and compared to baseline 4DCT imaging with changes to image quality and kV absorbed dose being quantified using additional phantoms. The use of the system during MV treatment for VMAT deliveries was investigated and compared to baseline 4D-CBCT imaging with overall system performance being assessed in terms of image quality and image registration accuracy at the treatment console.

##### Results

For inter-fraction imaging, the system successfully identifies changes in amplitude motion to within  $\pm 2$ mm and is sensitive to image distortion/artefacts with different/irregular respiratory cycles and number of image projections. The absorbed dose for standard scan settings is  $23.0 \pm 1.6$ mGy with registration accuracy of  $\pm 0.4$ mm and  $\pm 0.3$ degrees. When used intra-fraction there is a reduction in image quality owing to the dependence on VMAT delivery and MV scatter. This can be seen in Figure 1 as a function of VMAT arc length, with the quicker arcs resulting in poorer image quality (for a given BPM of the phantom). Measuring this in terms of contrast-to-noise ratio (between the tumour and surrounding lung tissue) demonstrates that as the arc length and breathing rate increases, the contrast-to-noise ratio approaches that of the inter-fraction 4D-CBCT (see Figure 2). The automatic 4D matching algorithm was found to be influenced by image noise, causing a reduction in the measured amplitude of tumour motion, however despite this the accuracy of automatic registration was excellent varying by  $\pm 0.9$ mm (2SD) for compared to inter-fraction imaging baselines.

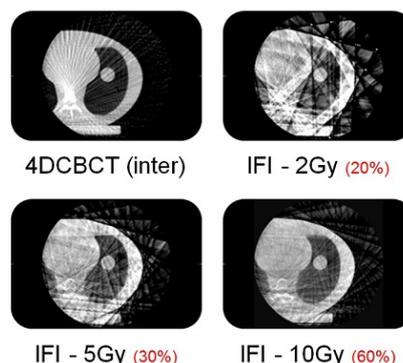

Figure 1 – illustration of the different image artefacts that are apparent when using 4DCBCT in inter- and intra-fractional imaging (IFI) modes. The IFI results for 2Gy, 5Gy and 10Gy arcs are shown, with the red text demonstrating the percentage of data that has been used in the reconstruction (i.e. 20y arc contains only 20% of image frames compared to inter-fractional imaging).

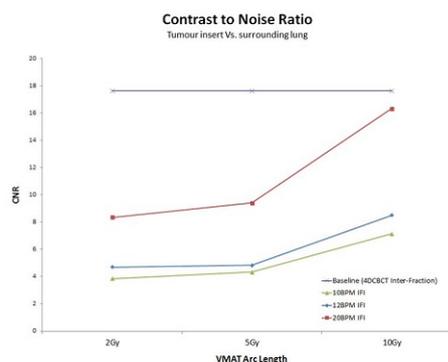

Figure 2 – Contrast to noise results for the tumour insert and surrounding lung for the same phantom as shown in Figure 1. The baseline is inter-fractional 4DCBCT imaging with the increasing CNR results apparent as the BPM of the phantom increases, and the arc length increases, as the sampling (degree/projections) increases. Note that although the number of projections for the 10Gy 20BPM data point exceeds the baseline, the CNR is lower. This is related to limitations of the MV scatter correction algorithm.

##### Conclusion

Intra-fractional 4D-CBCT imaging has been implemented successfully and is now mandated for all lung SBRT patients at our clinic. The system has also been implemented for 3D spinal SBRT imaging although limitations of the MV scatter correction algorithm have resulted in our centre limiting the MU/Arc for VMAT delivery for these cases. Future studies will investigate different acquisition methods for existing conventionally-fractionated treatments to improve the workflow and improve image quality.

#### PO-0866 Visibility, image artifacts and proton dose perturbation of fiducial markers

V.C. Hamming<sup>1</sup>, C.L. Brouwer<sup>1</sup>, M.J. Van Goethem<sup>1</sup>, R.I. Jolck<sup>2</sup>, C. Van Leijssen<sup>1</sup>, A.C.M. Van den Bergh<sup>1</sup>

<sup>1</sup>UMCG University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands

<sup>2</sup>NANOVI radiotherapy, DTU scion, Lyngby, Denmark

##### Purpose or Objective

Fiducial markers (FMs) are necessary for an accurate photon and proton radiation treatment for prostate-cancer. However, conventional FMs may cause problems with dose calculations and perturbations in proton therapy. Therefore, specific proton-treatment FMs are available having smaller dimensions and different material compositions. The goal of this research was to survey the visibility, CT artifacts and proton dose perturbations of available FMs to choose the optimal FM for proton therapy.

**Material and Methods**

The FMs used in this research were: BioXmark (NANOVI, 300, 100, 50, 25 and 10µL (liquid)), BiomarC (Carbon Medical Technologies, Enhanced (1x5mm), Pro (0.9x5mm) and Standard (1x5mm)), Visicoil (IBA, 0.75x5mm, 0.5x5mm), GoldAnchor (Naslund Medical, 0.28x10mm (open and folded)) and the fiducial gold marker (1x5mm, 0.4x5mm). All these FMs were positioned in a gelatin phantom. The above mentioned FMs were rated for the marker visibility on CT (with and without image metal artifact reduction (IMAR)), MRI, 3D-CBCT (low ( $\pm 36.6$ mA) and high ( $\pm 234.9$ mA) dose) and MV imaging by means of the contrast to noise ratio (CNR). A  $CNR \leq 1$  was considered not visible whereas a  $CNR \geq 5$  was considered as visible. For the CT image the streak index (SI) was determined as well and was normalized to the fiducial gold marker (1x5mm). A normalized SI of 0 was considered to have no artifact, whereas a normalized SI of 1 was considered to have the largest artifact amongst the FM.

Proton perturbation film measurements in a solid water phantom (SWP) were done at four different depths (5.4, 5.6, 6.1, 7.1cm) for a selection of the FMs: fiducial gold marker 1x5mm, 0.4x5mm and the GoldAnchor 0.28x10mm folded. A circular (50mm diameter) proton beam of 190 MeV was used to irradiate a dose of 7Gy in the Bragg peak. The Bragg peak was calculated to be at a depth of 7.1cm within the SWP.

Needle sizes were also taken into account with regard to the necessity to temporarily stop anticoagulants. **Results** All FMs were visible on CT (Figure 1). Most of the FMs were visible on MRI except for the GoldAnchor (open), BiomarC (standard) and the visicoils. On 3D-CBCT all FMs were visible. In MV imaging for photon radiation treatment the fiducial gold marker (1x5mm) and visicoil (0,75x5mm) were visible. The SI was maximal for the FM with gold and minimal for the BioXmark FM (Table 1).

The fiducial gold marker (1x5mm) had the maximal proton dose perturbation measured which resulted in 10% underdosage at a depth of 7.1cm. For the other selected FMs no dose perturbation could be detected.

BioXmark and GoldAnchor can be placed with the small 25G needle.

**Conclusion**

The FM BioXmark 25 µL resulted in high visibility, low streak artifacts and smallest needle size.

BioXmark is expected to have a smaller dose perturbation than was researched, because it has a lower atomic number and density than gold based FMs. In case larger volumes are needed a perturbation may become noticeable.

**PO-0867 Magnitude and robustness of motion mitigation in stereotactic body radiation therapy of the liver**

C. Heinz<sup>1</sup>, S. Gerum<sup>1</sup>, F. Kamp<sup>1</sup>, M. Reiner<sup>1</sup>, F. Roeder<sup>1</sup>  
<sup>1</sup>LMU Munich, Department of Radiation Oncology, Munich, Germany

**Purpose or Objective**

SBRT has been established as an effective treatment method of lesions located in the liver. However, respiratory induced motion has to be taken into account for tumor delineation and without proper motion mitigation techniques motion will result in undesirable increased treatment volumes. Abdominal compression has been described as an effective way to limit respiratory induced motion and thereby decrease treatment volumes. However, the whole workflow of motion estimation (4DCT), motion mitigation (abdominal compression), motion incorporation into planning (ITV delineation) and motion evaluation at each fraction (CBCT) depends strongly on the available equipment and is thereby specific to each department. Hence the achievable results in motion management are specific to a department and should be assessed. In this retrospective study the magnitude and robustness of abdominal compression was compared to a free breathing workflow using the specific equipment in our clinic.

**Material and Methods**

A total of 26 patients (abdominal compression n=11; free breathing n=15) that were treated with SBRT of the liver during 2011-2016 were analysed. Prior to the initial imaging fiducial markers were implanted next to each treatment target. Each patient received a 4DCT (Toshiba Medical Systems Corporation, Tokyo, Japan) from which a mean intensity projection CT (Mean CT) was generated (iPlan, Brainlab AG, Munich, Germany). Pre-treatment imaging included a conventional 3D-CBCT (Elekta AB, Stockholm, Sweden). Abdominal compression was realised using the BodyFIX system (Elekta AB, Stockholm, Sweden). Overall 74 fiducial markers (abdominal compression n=28; free breathing n=46) were analysed with regard to respiratory induced motion in the mean intensity projection CT as well as in all available 3D-CBCTs using an in-house developed software tool. The software provided a semi-automatic marker segmentation of the blurred markers and a motion estimation of the segmented markers using a principal component analysis. The estimated motion from the initial imaging was compared to the motion estimated from the pre-treatment imaging in all major axes and 3D distance in magnitude (mean value) and robustness (standard deviation).

**Results**

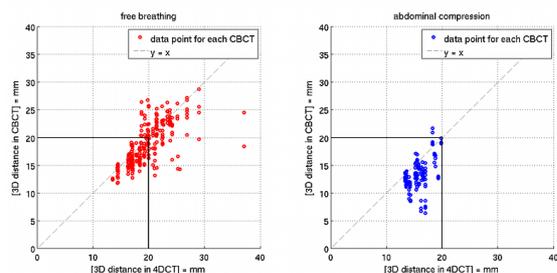

Under free breathing patient data showed a mean marker movement (3D) of 19.8 mm in the Mean CT and 18.7 mm in the CBCT. By using the abdominal compression tool the mean marker movement was reduced to 15.7 mm in the Mean CT and 13.2 mm in the CBCT. Also the standard deviation of the 3D marker movement was reduced from 3.6 mm to 1.7 mm in the Mean CT data and from 3.8 mm to 2.7 mm in the CBCT data (see figure 1).

	0.4x5mm	39.61	42.49	11.91	3.07	5.91	1.86	2.09	-	1.41	0.92	0.93	18G	18G	Gold	

Table 1. Overview of the different FMs regarding the contrast to noise ratio, streak artifact index, needle size and material composition. Red values are considered to have low visibility (<2.5 CNR). \*\* 25G needles have an outer diameter of 0.53mm whereas a 18G needle has an outer diameter of 1.23mm

### Conclusion

The implemented clinical protocol for abdominal compression is able to reduce the mean marker motion by roughly 5 mm in the initial imaging as well as in the pre-treatment imaging. Although the standard deviation in both imaging modalities was reduced by the abdominal compression setup, the reproducibility of the abdominal compression reflected by the decreased standard deviation in the pre-treatment imaging could only be improved slightly.

### PO-0868 Evaluation of Watchdog response to anatomical changes during head and neck IMRT treatment

T. Fuangrod<sup>1</sup>, J. Simpson<sup>1,2</sup>, S. Bhatia<sup>1</sup>, S. Lim<sup>3</sup>, M. Lovelock<sup>3</sup>, P. Greer<sup>1,2</sup>

<sup>1</sup>Calvary Mater Newcastle, Radiation Oncology, Waratah-NSW, Australia

<sup>2</sup>University of Newcastle, School of Mathematical and Physical Sciences, Newcastle-NSW, Australia

<sup>3</sup>Memorial Sloan-Kettering Cancer Center, Radiation Oncology, New York, USA

### Purpose or Objective

Watchdog is a real-time patient treatment verification system using EPID, which has been clinically implemented as an advanced patient safety tool. However, the use of Watchdog requires an understanding of its dosimetric response to clinically significant errors. The objective of this study is to evaluate the Watchdog dosimetric response to patient anatomical changes during the treatment course in head and neck (HN) IMRT.

### Material and Methods

Watchdog utilises a comprehensive physics-based model to generate a series of predicted transit cine EPID image as a reference data set, and compares these to measured cine-EPID images acquired during treatment. The agreement between the predicted and measured transit images is quantified using c-comparison (4%, 4mm) on a cumulative frame basis. The 71.3% c pass-rate error detection threshold in HN IMRT has been determined from our pilot study of 37 HN IMRT patients using the statistical process control (SPC) technique (1). The major source of errors was inter-fractional anatomy changes due to weight loss and/or tumour shrinkage.

To evaluate the Watchdog dosimetric response to HN IMRT anatomical changes, the patient CT data was modified and used for calculating the predicted EPID images. First, soft-tissue patient thickness reduction or weight loss was progressively simulated with a range of 0%, 1%, 2.5%, 5%, 7.5%, 10%, and 12.5% based on real patient deformations using in-house software. Second, Watchdog dosimetric response was determined for four HN patients with observed weight loss during treatment who had a second CT during treatment for replanning purposes. Watchdog dosimetry was calculated using the second CT compared to the original CT. The SPC-based threshold was applied to determine the Watchdog performance for HN IMRT anatomical change detection. These simulations provide the decision rule for HN IMRT replanning based on Watchdog assessment.

(1) Fuangrod (2016). Radiation Oncology, 11(1), 106

### Results

From the simulation of patient weight loss (thickness reduction), Watchdog has less sensitivity to small patient thickness reduction. From figure 1 left, it can imply that dropping by 25% c pass-rate refers to 10% patient thickness reduction or approximately 1.5 cm shrinkage. In clinical case validation, Watchdog was able to detect the significant patient anatomical changes that lead to the decision to replan all four HN IMRT patients (see figure 1 right). Based on this study, we found that Watchdog system can detect the clinically significant anatomical change in HN IMRT based on 1) at least 3 out of 7 fields of the fraction are below the SPC-based threshold, 2) the lowest c pass-rate is less than 30%, and 3) a 25% c pass-rate drop equates to approximately a 1.5 cm (-10.0%) patient thickness reduction.

### Conclusion

The Watchdog dosimetric response to HN patient anatomical changes has been evaluated based on the simulation of patient thickness reduction/weight loss and clinical cases of HN IMRT replan. Using the SPC-based threshold, Watchdog is able to detect clinically significant anatomical changes in HN IMRT treatment.

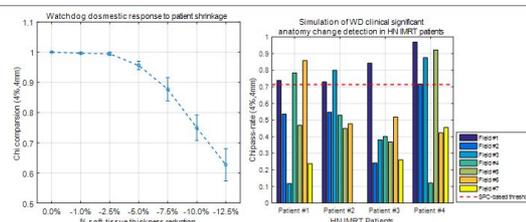

Figure 1. Watchdog dosimetric response in HN IMRT to (left) patient thickness reduction and (right) clinical replanned cases

### PO-0869 A population-based estimate of proton beam specific range uncertainties in the thorax

Y.Z. Szeto<sup>1</sup>, M.G. Witte<sup>1</sup>, M. Van Herk<sup>2</sup>, J. Sonke<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiotherapy department, Amsterdam, The Netherlands

<sup>2</sup>Institute of Cancer Sciences- University of Manchester, Molecular and Clinical Cancer Sciences, Manchester, United Kingdom

### Purpose or Objective

Proton therapy has great potential for locally advanced lung cancer patients because of considerable reduction of intermediate and low dose to the healthy tissues. However, due to their finite beam range, proton dose distributions are more susceptible to anatomical variations. The purpose of this study was to derive a population-based map of beam specific range uncertainties due to anatomical variations.

### Material and Methods

The planning CT (pCT) of 100 NSCLC patients treated between 2010 and 2013 with (chemo-)radiotherapy were included. To simulate realistic anatomical variations, we used a previously developed statistical model, based on principal component analysis for systematic variations in the thorax. This model generates deformation vector fields that deform the planning CT to induce systematic differences between the anatomy of planning and delivery. For each patient, we synthesized 1000 CTs (sCT) representing plausible variations in treatment anatomy. Subsequently, the water-equivalent path length differences ( $\Delta R$ ) between the pCT and sCTs was calculated at the beam's distal and proximal edge of the GTV for 13 equally spaced angles of 15° through the ipsilateral lung. Undershoot and overshoot at the distal edge results in an under-coverage of the target and higher dose in normal tissues respectively, and vice versa at the proximal edge. To summarize the results, first for each scan and angle, the 95th percentile  $\Delta R$  in undershoot ( $\Delta R_u$ ) and overshoot

( $\Delta R_o$ ) was determined at the distal and proximal edge of the tumor respectively. Secondly, for each angle and patient, the 90th percentile of  $\Delta R_u$  and  $\Delta R_o$  were calculated. Finally, median and inter-quartile ranges for these beam-specific range uncertainties were evaluated.

### Results

Figure 1 shows the median and inter-quartile range of  $\Delta R_u$  and  $\Delta R_o$  for the 13 different angles. For both  $\Delta R_u$  and  $\Delta R_o$ , the range errors of the lateral beams (around 90°) are significantly lower (paired T-test,  $p < 0.05$ ) than the anterior and posterior beams. Moreover, there is considerable inter-patient differences in range uncertainties.

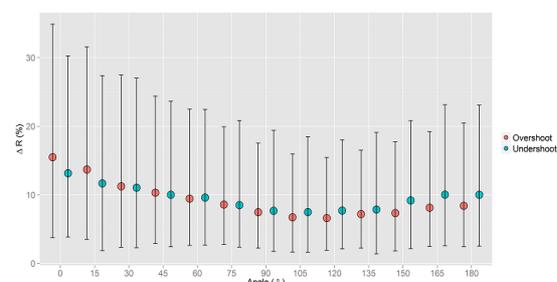

Figure 1. Median and inter-quartile range of the range error  $\Delta R$  in overshoot and undershoot at the beam's proximal and distal edge of the tumor respectively. The angle of 90° is the lateral beam to the ipsilateral lung.

### Conclusion

Variation in anatomy during the course of irradiation causes variation in range, possibly leading to tumor under-coverage and high dose in normal tissue. These range uncertainties depend on patient and beam angle, and are smaller for the lateral beams. Taking these beam-specific range uncertainties into account, could improve the robustness of proton treatment plan against anatomical variations.

**PO-0870 DIBH produces a meaningful reduction in lung dose for some women with right-sided breast cancer**  
J.L. Conway<sup>1</sup>, L. Conroy<sup>1</sup>, L. Harper<sup>1</sup>, M. Scheifele<sup>1</sup>, W. Smith<sup>1</sup>, T. Graham<sup>1</sup>, T. Phan<sup>1</sup>, H. Li<sup>1</sup>, I.A. Olivetto<sup>1</sup>  
<sup>1</sup>Tom Baker Cancer Centre, Radiation Oncology, Calgary-Alberta, Canada

### Purpose or Objective

To determine whether deep inspiration breath hold (DIBH) produced a clinically meaningful reduction in pulmonary dose in comparison to free breathing (FB) during adjuvant loco-regional radiation (RT) for right-sided breast cancer. Subsequently, to prospectively evaluate DIBH in right-sided breast cancer cases with a FB V20Gy  $\geq 30\%$ .

### Material and Methods

Thirty consecutive women with breast cancer treated with tangent pair RT following breast conserving surgery were included. ESTRO guidelines were used to contour right-sided IMC nodes on DIBH and FB scans, with care taken to ensure comparability between scans. A four-field, modified-wide tangent plan was developed on each scan to include the right breast and full regional nodes with a minimum dose of 80% to the IMC CTV. The junction between the supraclavicular and tangent fields was at the inferior extent of the ossified medial clavicle. Treatment plans were calculated in Eclipse using Acuros algorithm version 11. FB and DIBH plan metrics were compared using Wilcoxon-signed rank testing. Commencing in March 2016, as per a new institutional policy based on the above results, all right-sided breast cancer patients with a FB ipsilateral lung V20  $\geq 30\%$  had a DIBH treatment plan developed prior to compromising on IMC coverage. If the absolute difference in lung V20 was  $\geq 5\%$  between plans, the DIBH plan was used. The junction was moved superiorly in only one case.

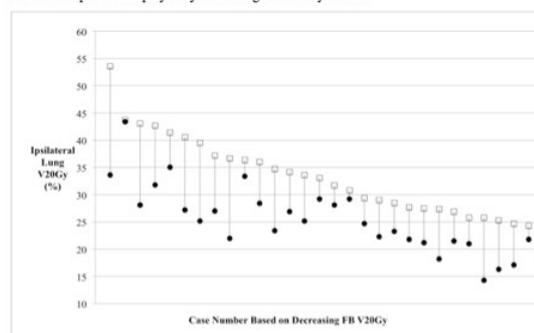

### Results

IMC coverage was equivalent between DIBH and FB plans (Table 1). Twenty-one patients (70%) had  $\geq 5\%$  reduction in ipsilateral lung V20 with DIBH (Figure 1). A reduction in lung metrics was observed with an absolute reduction in mean ipsilateral lung V20 by 7.8% (range: 0.0-20.0%; Table 1). There was a mean reduction of 42.3cc (range: 0-178.9) in the volume of liver receiving 50% of the prescription dose. The differences in cardiac doses were statistically significant, but unlikely clinically significant (Table 1). Seven patients with stages IA-IIIC right-sided breast cancer treated between April to October 2016 received a DIBH scan as a result of a FB V20Gy  $\geq 30\%$ , treatment volumes included IMCs in all cases. In this cohort a  $\geq 5\%$  difference between plans was observed for all patients with a mean FB V20 of 34.8% (range: 30.0-43.4%), which was reduced by an absolute value of 11.8% (range: 5.4-19.1%) with DIBH.

Table 1: DIBH and FB Plan Metrics.

Mean Lung Values:				
	DIBH	FB	Difference (DIBH - FB)	p-value
V20Gy (%)	25.3	33.1	-7.8	<0.001
V5Gy (%)	46.8	51.7	-4.9	<0.001
Mean Lung Dose (Gy)	12.7	16.0	-3.4	<0.001
Lung Volume (cc)	2370.4	1445.0	925.4	<0.001
Mean Liver Value:				
Liver 25Gy (cc)	7.3	49.6	-42.3	<0.001
Mean Heart Value:				
V5Gy (%)	0.18	0.63	-0.45	<0.001
V25Gy (%)	0.00	0.03	-0.03	0.10
Mean Heart Dose (Gy)	0.88	1.00	-0.12	<0.001
Mean IMC Values:				
IMC CTV V80% (%)	100	100	0.00	0.14
IMC CTV D100 (Gy)	39.2	39.5	-0.29	0.28

Figure 1: Percent ipsilateral lung V20Gy for FB (square) and DIBH (circle) scans for 30 consecutive patients displayed by decreasing FB V20Gy values.

### Conclusion

DIBH reduced mean ipsilateral lung V20 by 7.8% and mean lung dose by 3.4Gy. For some patients, the volume of liver receiving  $\geq 25\text{Gy}$  can also be reduced with DIBH. DIBH should be available as a treatment strategy to reduce right lung V20 without compromising on IMC coverage for patients with right-sided breast cancer during loco-regional RT. This strategy can be advantageous when the ipsilateral FB V20  $\geq 30\%$ , a value that prompts many radiation oncologists to exclude IMCs. Within a small prospectively evaluated cohort reflective of a change in institutional policy, we have observed an absolute reduction in mean ipsilateral lung V20 by 11.8% with DIBH.

**PO-0871 Study of the effect of heterogeneous setup random errors in treatment margins**

D. Sevillano<sup>1</sup>, A.B. Capuz Suárez<sup>1</sup>, R. Colmenares Fernández<sup>1</sup>, R. Moris Pablos<sup>1</sup>, M.J. Bejar Navarro<sup>1</sup>, D. Prieto Moran<sup>1</sup>, F. García-Vicente<sup>1</sup>  
<sup>1</sup>Hospital Ramón y Cajal, Medical Physics, Madrid, Spain

### Purpose or Objective

To analyze the effects of considering the real distribution of random errors ( $\sigma$ ) within our patient population in the outcome of setup correction protocols. Results are compared to those predicted by Van Herk's margin formula (VHMF) considering constant random errors.

### Material and Methods

Displacement data from 31 prostate and 31 head and neck (HN) treatments were employed in this study, based on 640 and 540 CBCT images respectively. Values of  $\sigma$  at each direction were calculated by obtaining the standard deviation of the corrections during the treatment of each patient. The proposed distribution for the modelling of heterogeneous  $\sigma^2$  is an IG distribution (eq. 1). This kind of distribution has been demonstrated to be suitable for modelling random errors (Herschtal et al, Phys Med Biol 2012;57:2743-2755). Parameters  $\alpha$  and  $\beta$  of the IG distribution can be obtained from the mean value and standard deviation of the measured  $\sigma^2$  distribution.

Treatment margins proposed by VHMF for a No Action Level using the first 5 fractions for setup correction (NAL 5) protocol were obtained by considering a constant  $\sigma$  for all the patients.

Given the margins proposed, the patient coverage for the real  $\sigma$  distribution was obtained by weighting the dose coverages for each combination of  $\sigma$  values at each direction with the probability that a patient has those values of  $\sigma$ , based on the fitted IG distributions.

$$f(\sigma^2; \alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)} (\sigma^2)^{-\alpha-1} e^{-\frac{\beta}{\sigma^2}}$$

### Results

Results are shown in Table 1. It can be seen that, if heterogeneities in random error distribution are taken into account, the coverage probability yields values smaller than those predicted by VHMF when homogenous  $\sigma$  is considered. After this results were obtained, calculations for different sets of margin were done. It was found that in the HN case, margins had to be increased 1 mm at each direction to obtain coverages of a 92 %, while in the prostate case, margins had to be increased 1.4 mm in all directions in order to achieve a coverage of the 90%. These results suggest that the effects of heterogeneous random errors depend on the characteristics of the random error distribution of the patient population.

	Prostate			Head and Neck		
	SI	LR	AP	SI	LR	AP
Mean $\sigma$ (mm)	2.7	2.7	3.1	1.6	1.8	1.7
std deviation ( $\sigma$ ) (mm)	0.94	0.78	1.07	0.61	0.67	0.65
$\alpha$	2.90	3.75	3.01	2.5	2.6	2.5
$\beta$ (mm <sup>2</sup> )	14.0	19.6	19.9	3.6	5.1	4.4
VHMF margin (mm) (NAL 5)	4.6	4.6	5.6	2.3	2.7	2.6
Coverage with VHMF and heterogeneous $\sigma$	75.5 %			78.8 %		

### Conclusion

The effect of heterogeneous random errors should be taken into account when applying treatment margins, its effects depend on the characteristics of the patient population and should be analyzed for each treatment location at each institution.

### PO-0872 Respiration motion management strategy for sparing of risk organs in esophagus cancer radiotherapy

### Purpose or Objective

Esophagus and the organs at risk (OAR) nearby move with respiration. The purpose of this study was to determine if respiratory gating or deep inspiration breath hold (DIBH) facilitate dose reduction to OAR.

### Material and Methods

CT image sets from ten patients were analysed. Esophagus and OAR were delineated on end expiration (EE) and end inspiration (EI) phases of the 4DCT and on DIBH CT. 5 cm long mock GTVs were delineated in the proximal (P), medial (M) and distal (D) part of the esophagus. CTVs were defined by expanding the GTVs according to our clinical practice. CTV to PTV margin was 7 mm. Relative position of OARs and target were evaluated with cumulative distance volume histograms (DiVHs) [Wu et al. Med Phys 2009], calculated for the part of the OAR located in the beam path. The most and least optimal phase for treatment was selected by comparing the percent of the OAR volume located within the distance intervals A (below 2.5 cm), B (2.5-5.0 cm) and C (5.0-7.5 cm) from the PTV. The organ sparing achieved or lost, by changing treatment from FB to a specific breathing phase, was estimated by assuming that FB can be simulated with 50% EE and 50% EI.

### Results

Esophagus elongation during 4DCT was median 11mm (range 2-20mm) and from EE to DIBH 23mm (10-42mm). Lung volume increased 13.3% (6.9-24.9%) from EE to EI and 63.5% (34.1-120.8%) from EE to DIBH. Absolute volume of lung in the beam path either increased or remained largely constant upon inspiration in all patients. In seven P, four M and four D targets, the absolute volume of lung located within 5 cm of the PTV increased; however, increase in the total lung volume still resulted in either a reduction or a largely unchanged percent lung volume located within 5 cm of the PTV. Results extracted from DiVHs are presented in Table 1.

	PTVP	PTVM	PTVD
Change in percent lung volume located within 5 cm of PTV (pp)			
End Expiration to End Inspiration	-1.0 (-3.5 ; -0.4)	-3.1 (-7.0 ; -1.4)	-1.8 (-3.3 ; 0.3)
End Inspiration to DIBH	-2.4 (-5.9 ; -1.4)	-6.0 (-11.1 ; -3.2)	-1.0 (-2.3 ; 1.2)
Free Breathing to optimal phase	-2.8 (-7.0 ; -2.2)	-7.8 (-14.6 ; -4.3)	-1.8 (-4.0 ; -0.4)
Free Breathing to least optimal phase	0.5 (0.2 ; 1.7)	0.6 (0.2 ; 1.2)	0.9 (-0.1 ; 1.7)
Lung volume located within 5 cm of PTV (%)			
Free Breathing	14.6 (8.9 ; 18.6)	31.2 (19.8 ; 44.9)	16.6 (10.5 ; 22.9)
DIBH	11.3 (6.3 ; 14.9)	21.5 (15.5 ; 30.5)	14.1 (10.3 ; 14.1)
Change in percent lung volume located within the beam path (pp)			
End Expiration to End Inspiration	-1.4 (-4.7 ; 0.5)	-3.4 (-7.2 ; -1.9)	-4.8 (-10.1 ; 0.9)
End Inspiration to DIBH	-2.5 (-6.8 ; -1.2)	-8.7 (-15.8 ; 0.4)	1.6 (-4.0 ; 4.7)
Free Breathing to DIBH	-3.6 (-8.1 ; -1.5)	-10.4 (-19.2 ; -2.5)	-0.4 (-8.1 ; 4.2)

Table 1. Changes in percent lung volume located within 5 cm of the PTV between different breathing phases, percent lung volume located within 5 cm of the PTV in FB and DIBH, and changes in percent lung volume located within the beam path presented as median(range).

DIBH was the optimal treatment phase for all P and M targets and 8/10 D targets. For all targets EE was the least optimal phase.

Heart displacement was  $\leq 12$ mm on 4DCT and  $\leq 26$ mm from EE to DIBH. Relative heart volume DiVH's are shown in Figure 1 for 3 patients. The same respiration phase is clearly not optimal for all patients, neither for M nor for D targets. EE was most optimal for heart sparing in two M and three D, EI in four M and three D and DIBH in four M and four D targets. EE was least optimal in four M and two D, EI in two M and three D and DIBH in four M and five D targets.

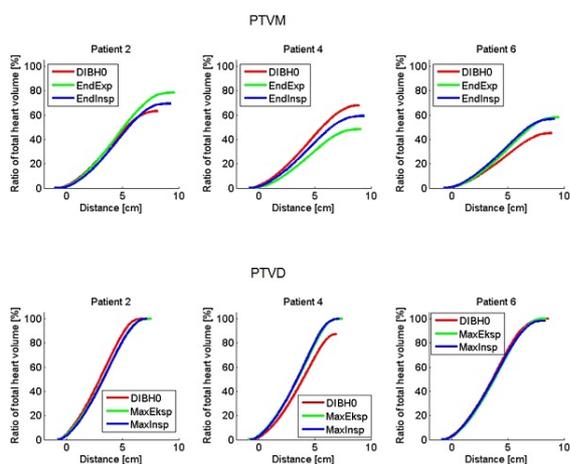

Figure 1. Three examples of percentual heart volume DVHs demonstrating the variation between patients are presented for PTVM and PTVD. No data is shown for PTVP as no heart volume was located within the beam path.

Liver had median displacement of 12mm on 4DCT and 43mm from EE to DIBH. It was only in the beam path for D targets. Even though volume in the beam path decreased with median 1.1% (EI) and 2.6% (DIBH) compared to EE, EE was still optimal in 2 and DIBH only optimal in 5 patients.

#### Conclusion

Lung sparing can be achieved in DIBH for proximal, medial and most distal esophagus targets. For some medial and distal targets heart sparing can be achieved. As the optimal phase is not always DIBH, lung vs. heart sparing must be prioritized. No general conclusions can be drawn for liver. Further investigations are warranted.

#### PO-0873 Inter- and intra-fraction motion of the tumor bed and organs at risk during IGRT for Wilms' tumor

F. Guerreiro<sup>1</sup>, E. Seravalli<sup>1</sup>, G. Jansses<sup>1,2</sup>, M. Heuvel-Eibrink<sup>2</sup>, B. Raaymakers<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiotherapy and Imaging Division, Utrecht, The Netherlands

<sup>2</sup>Princess Máxima Center, Pediatric

Oncology/Hematology, Utrecht, The Netherlands

#### Purpose or Objective

Radiotherapy planning for Wilms' tumor (WT) is currently done according to the SIOP-2001 protocol. The planning target volume (PTV) is defined as the clinical target volume (CTV) plus a margin of 10-mm while no planning risk volume (PRV) margins are recommended. The aim of this study is to assess inter- and intra-fraction motion of the tumor bed and organs at risk (OARs) as well as patient positioning uncertainty to estimate PTV and PRV margins for flank irradiation in WT.

#### Material and Methods

Computed tomography (CT), 4D-CT and daily cone-beam CTs (CBCTs), acquired during planning and treatment of 10 pediatric patients (mean  $3.9 \pm 2.1$  years) were used. OARs (kidney, liver and spleen) were delineated without accounting for any motion in all image sets. OARs motion was quantified in terms of absolute displacements of the center of mass (CoM) in all orthogonal directions. Tumor bed motion estimation was assessed using a quadratic sum of the CoM displacements of 4 clips positioned at the superior, lateral, medial, and inferior border of the tumor during surgical resection. Intra-fraction motion was estimated by calculating the CoM displacements between the maximum inspiration and expiration phases of the 4D-CT. For inter-fraction motion assessment, CoM displacements were calculated using the planning-CT as reference and daily pre-treatment CBCTs.

For intra-fraction patient positioning uncertainty, translational and rotational bone off-sets between the

planning-CT and post-treatment CBCTs were recorded. Inter-fraction patient positioning uncertainty was null as online patient position correction was always performed. Margins were determined by combining systematic ( $\Sigma$ ) and random ( $\sigma$ ) errors. Van Herk ( $2.5\Sigma + 1.7\sigma$ ) and McKenzie ( $1.3\Sigma \pm 0.5\sigma$ ) analytic solutions were used for PTV and PRV margin expansions, respectively.

#### Results

Tumor bed and OARs mean CoM displacements were less than 3-mm for all directions for both inter- and intra-fraction motion. Largest displacements were seen in the cranio-caudal (CC) direction (Figure 1). Inter-fraction motion was larger than intra-fraction motion (Figure 1). Mean intra-fraction patient positioning uncertainty was considered negligible (translation  $<1$ -mm; rotation  $<1^\circ$ ).  $\Sigma$  and  $\sigma$  errors differed less than 2.5-mm for organ motion and 0.5-mm for patient positioning uncertainty. The calculated PTV and PRV margins (Table 1) were up to a maximum of 6/5-mm in the CC direction, respectively.

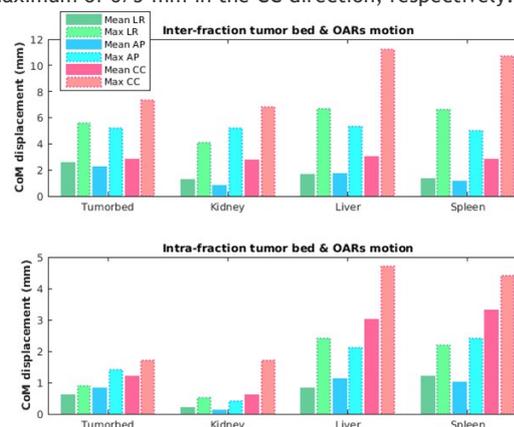

Figure 1- Inter- and intra-fraction tumor bed and OARs motion. LR stands for left-right, AP for posterior-anterior and CC for cranio-caudal directions.

Table 1- Margin expansion (mm) for PTV and margin expansion ranges (mm) for PRVs. Range was presented for PRVs to account for the minus and plus sign in McKenzie's margin recipe. LR stands for left-right, AP for anterior-posterior and CC for cranio-caudal directions.

	Margin (mm)		
	LR	AP	CC
PTV	5	5	6
PRV: Kidney	[1-2]	[0-1]	[1-3]
PRV: Liver	[1-2]	[1-2]	[2-5]
PRV: Spleen	[1-2]	[0-2]	[2-5]

#### Conclusion

Imaging data collected before and during radiotherapy demonstrated limited motion of the tumor bed and OARs and reduced patient positioning uncertainty. By combining 4D-CT and daily CBCTs information, PTV margins can be reduced to 6-mm in the CC direction compared with the existing protocol. The use of PRV margins for OARs protection is also advised. In addition, margins should be applied anisotropically and individualized for each patient.

#### PO-0874 The impact of rectal filling on rectal tumor position

J.J.E. Kleijnen<sup>1</sup>, M. Intven<sup>1</sup>, B. Van Asselen<sup>1</sup>, A.M. Couwenberg<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, B.W. Raaymakers<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy department, Utrecht, The Netherlands

#### Purpose or Objective

In 15% of rectal cancer patients, a pathological complete response (pCR) is observed after neo-adjuvant chemoradiotherapy. To increase this pCR rate, many studies are being performed, in which the GTV dose is escalated. To avoid an increase in toxicity and potential surgical complications, PTV margins must be minimized and geometrical miss has to be avoided. However, rectal filling can change from day-to-day as can be observed in daily practice (see figure 1, A & B), which might alter the

GTV position. Purpose of this study is to investigate the impact of a varying rectum filling on tumor position and quantify potential tumor shifts.

#### Material and Methods

For the analysis, nine patients were included who were scanned twice on MRI in supine position. First on a 1.5 T MRI for diagnostic purposes and next on a 3T MRI for treatment planning. For the diagnostic MRI, the rectum was filled using an ultra sound transducer gel (MRI<sub>full</sub>), and for the planning MRI no rectal preparation was performed (MRI<sub>standard</sub>). On both MRIs the tumor was delineated.

To evaluate tumor displacement, for both MRI<sub>standard</sub> and MRI<sub>full</sub>, three distances in cranial-caudal (CC) direction were determined between the bony anatomy; i.e. the sacrum promontory and the tumor cranial border, the tumor caudal border and the center of mass (COM), (figure 1, C & D). For each distance measure, displacements were then determined by taking the difference in distance between both MRI scans.

#### Results

In all patients a shift in tumor COM in CC direction was observed, ranging between 6.9 and 28.3 mm. Mean tumor displacements between MRI<sub>standard</sub> and MRI<sub>full</sub> were found to be 16.7 mm, 16.5 mm and 17.7 mm for the cranial and caudal tumor border and the COM, respectively (figure 1 C & D). Displacements were all found to be significantly different from zero ( $p < 0.002$  for all distance measures). Displacement was larger for tumors situated higher up in the rectum (figure 2).

#### Conclusion

In all patients, tumor position changes considerably under influence of rectal filling. The found mean displacements are larger than the typical PTV-margins for rectal GTV (Brierley et. al 2011). The higher situated rectal tumors show the largest displacements under influence of rectal filling. To avoid geometrical miss of the tumor, rectal volume preparation prior to boost radiotherapy or adaptive RT with online tumor visualization using MRI (Lagendijk et al. 2008) seems beneficial. Especially for tumors located high in the rectum.

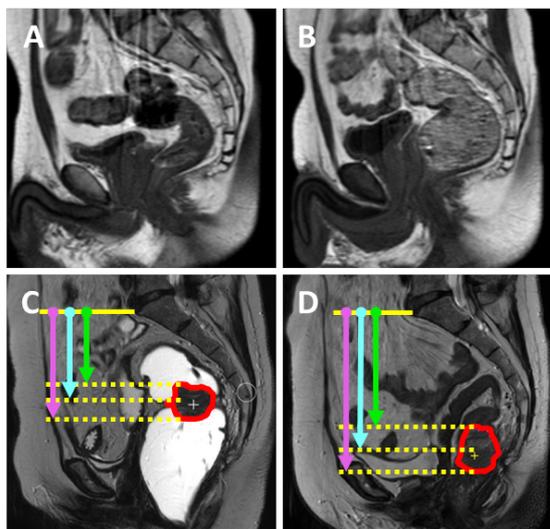

Figure 1, A & B): Clinical example of varying day-to-day rectal filling. Sagittal T1w MRIs of same patient recorded prior to a RT fraction on day 1 and day 3 of treatment.

C & D): Sagittal T2w MRIs of the same patient. On the left the MRI<sub>full</sub> and on the right the MRI<sub>standard</sub> situation. The tumor is delineated in red. Note that the tumor in the MRI<sub>full</sub> is displaced by the rectum filling. The distances from the sacrum promontory to the cranial border, the COM and the caudal border of the tumor is indicated by respectively the green, cyan and purple arrow.

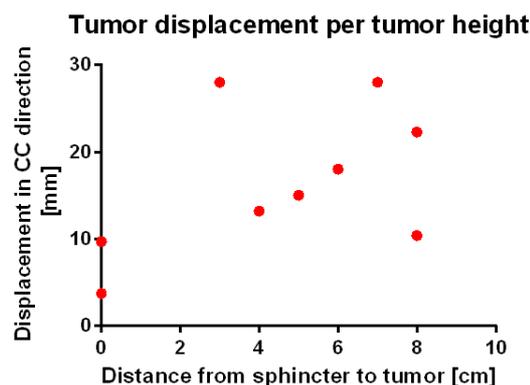

Figure 2: Scatter plot of caudal tumor border displacement as function of the distance from the sphincter to the caudal tumor border.

#### PO-0875 Dosimetric effects of anatomical changes in proton therapy of head and neck (H&N) cancer

G. Miori<sup>1,2</sup>, L. Widesott<sup>1</sup>, F. Fracchiolla<sup>1</sup>, S. Lorentini<sup>1</sup>, P. Farace<sup>1</sup>, R. Righetto<sup>1</sup>, C. Algranati<sup>1</sup>, M. Schwarz<sup>1,3</sup>

<sup>1</sup>Trento Hospital, Protontherapy, Trento, Italy

<sup>2</sup>University of Rome Tor Vergata, Postgraduate School of Medical Physics, Rome, Italy

<sup>3</sup>INFN, TIFPA, Trento, Italy

#### Purpose or Objective

Anatomical changes in H&N patients can affect dose distributions especially in proton therapy. A retrospective analysis of H&N patients undergoing repeat CTs and treated at our Proton Therapy Center was done to evaluate dose changes and to identify a dosimetric index for the need of replanning. Furthermore, TCP analysis was performed to evaluate the magnitude of changes with radiobiological parameters. Finally, non-adapted and adapted plans were compared.

#### Material and Methods

All H&N patients treated in our center between October 2014 and September 2016 with at least one repeat CT (eCT) were considered. 21 patients were identified: 18 patients had at least one eCT (1 to 6 eCTs), but did not need replanning, and 3 patients needed replanning at some stage of the treatment. The original plan was recalculated on each eCT. Differences were calculated for each treatment fraction, considering a stepwedge interpolation on fractions where the eCT was missing. D1 variations ( $\Delta D1$ ) for cord, brainstem, optic chiasm and optic nerves, and Dmax differences ( $\Delta Dmax$ ) for lenses were considered. Target coverage analysis was based on differences in CTV V95 ( $\Delta V95$ ).  $\Delta V95$  values were included in *Non-replanned (controls)* if they came from non-replanned patients or from replanned patient calculations on CT preceding the replanning CT (rCT). On the contrary,  $\Delta V95$  were included in *Replanned (cases)* if they came from replanned patients on the rCT and the following CTs. The choice was made to consider the trend in target coverage after the point identified for replanning. A cut-off  $\Delta V95$  for the need of replanning was identified by the maximum Youden's index on the ROC analysis between *control* and *cases*. Next, TCP differences with respect to the planning TCP ( $\Delta TCP$ ) were calculated.  $\Delta TCP$  values were divided in *Non-replanned* and *Replanned* as for DV95 analysis. Finally, a comparison between adapted and non-adapted plans for the 3 replanned patients was done. All statistics were made by t-Student tests.

**Results**

Patients show no significant variations in OARs doses during the treatment (Table 1).

Table 1. Summary of dose variations in OARs, target coverage and TCP;

	$\Delta V95$ [%]				$\Delta TCP$ [%]			
	Non-replanned		Replanned		Non-replanned		Replanned	
Mean	-0.3		-7.8		-0.1		-5.4	
Median	0.0		-6.8		0.0		-2.8	
1 <sup>st</sup> and 3 <sup>rd</sup> quartile	-0.6	0.0	-11.8	-5.2	-0.5	0.6	-9.7	-2.0
Min & max	-4.8	3.5	-15.3	-1.3	-2.5	1.4	-12.5	-2.0

	$\Delta D1$ Cord	$\Delta D1$ Brainstem	$\Delta D1$ Optic Chiasm	$\Delta D1$ Optic Nerves	$\Delta Dmax$ Lenses					
	[cGyRBE]	[cGyRBE]	[cGyRBE]	[cGyRBE]	[cGyRBE]					
	p<0.001	p=0.003	p=0.004	p<0.001	p<0.001					
Mean	-121.4	-20.8	-20.6	-97.8	-84.7					
Median	-35.0	-20.0	0.0	0.0	0.0					
1 <sup>st</sup> and 3 <sup>rd</sup> quartile	-170.0	0.0	-60.0	10.0	-55.0	60.0	-172.0	36.0	-131.0	16.0
Min & max	-848.0	352.0	-314.0	370.0	-385.0	160.0	-978.0	650.0	-535.0	393.0

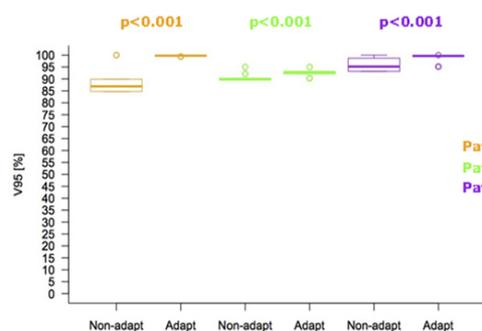

Figure 1. Comparison of V95 between non-adapted and adapted plans in the 3 replanned patients;

Target coverage analysis shows large differences between *Replanned* and *Non-replanned* ( $p < 0.001$ ). The maximum Youden's index identifies CTV  $\Delta V95 = -5\%$  as an optimized threshold level for replanning (sensitivity=87.5%; specificity=100%). TCP analysis shows large variations between *Replanned* and *Non-replanned* ( $p < 0.001$ ).  $\Delta V95$  and  $\Delta TCP$  results are summarized in Table 1.  $\Delta V95$  comparison between non-adapted and adapted plans shows significant CTV coverage improvements (Figure 1).

**Conclusion**

OARs doses were not affected by anatomical changes in all H&N patients studied. On the contrary, there was a significant difference in the effect of anatomical changes for replanned and non-replanned patients, confirmed by radiobiological changes. Therefore, ART reveal great benefits in target coverage for patients that need replanning which can be identified by a threshold dosimetric index.

**PO-0876 Treatment adaptation is mandatory for intensity modulated proton therapy of advanced lung cancer**

L. Hoffmann<sup>1</sup>, M. Alber<sup>2</sup>, M. Jensen<sup>3</sup>, M. Holt<sup>3</sup>, D. Møller<sup>1</sup>  
<sup>1</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark  
<sup>2</sup>Heidelberg University Hospital, Department of Radiation Oncology, Heidelberg, Germany  
<sup>3</sup>Aarhus University Hospital, Department of Radiation Oncology, Aarhus, Denmark

**Purpose or Objective**

Large anatomical changes during radiotherapy are seen for a large proportion of lung cancer patients. Precise delivery of proton therapy is highly sensitive to these changes

which may result in under-dosage of target. We investigated the applicability of a decision support system developed for photon therapy in a proton therapy setting.

**Material and Methods**

Twenty-three consecutive NSCLC patients stage 1B to IV treated with adaptive photon therapy were retrospectively planned using intensity modulated proton therapy. The adaptive protocol was based on geometrical measures of target positioning and large anatomical changes as e.g. atelectasis, as observed on daily CBCT scans. Two surveillance CT-scans were acquired during the treatment course. The consequences of anatomical changes were evaluated by recalculation of the proton plans on the surveillance scans. The CTV receiving 95% of the prescribed dose was analyzed. Proton treatment plans were scaled to prescribed doses of 70, 74 or 78Gy, to investigate if full CTV coverage at 95% of 66Gy = 62.7Gy could be maintained by increasing the prescribed dose.

**Results**

Fourteen (61%) patients needed adaptations when treated with protons, given that 95% of the CTV must be covered by 95% of the dose. In comparison, no patients needed adaptation when treated with photons using this criterion. Figure 1 shows CTV coverage for all patients. For proton therapy, the adaptive protocol was found to identify patients with large target under-dosage (six patients, group A). Additionally, under-dosage was observed for another eight patients (group B) with non-rigid changes up to 15mm in the positioning of the bones. The median decrease in coverage for all patients was 92.8% [48.1-100%]. Robust optimization reduces the decrease in target coverage, but does not eliminate the under-dosage, see Fig.2. All patients in group B would be treated sufficiently when prescribing 74Gy with all CTVs receiving 95% of 66Gy. For patients in group A, only two patients would be treated sufficiently with a 78Gy prescription. A geometric decision support protocol as the present is thus mandatory in order to maintain target coverage of the patients in group A. When increasing the prescribed dose, the maximum dose to important normal tissue such as the oesophagus, trachea, bronchi, and heart increases and may thus be the dose limiting factor.

**Conclusion**

Large anatomical changes can be corrected for by an adaptive protocol. Non-rigid positioning errors are not identified by the geometrical criteria used for photons but can be compensated by an increase in the prescribed dose keeping in mind that this requires additional attention to organs at risk. Robust optimisation reduces, but does not eliminate the risk of under-dosage. Daily imaging and treatment adaptation for a high fraction of patients is mandatory in proton therapy for loco-regional lung cancer.

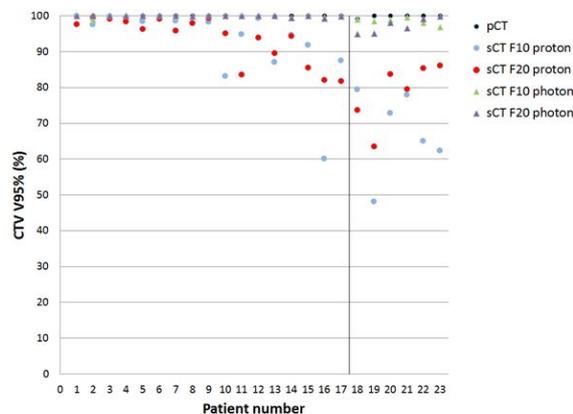

Fig1: Coverage of CTV on planning -T, and surveillance-CT at fraction 10 and 20 for all the patients. Patients to the right of the vertical black line (group A) were treated with adaptive therapy during the photon treatment. Patients in group B had no adaptations during treatment.

### PO-0877 Proton therapy of oesophageal cancer is more robust against anatomical changes than photons

D.S. Møller<sup>1</sup>, M. Alber<sup>2</sup>, T.B. Nyeng<sup>1</sup>, M. Nordmark<sup>3</sup>, L. Hoffmann<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark

<sup>2</sup>Heidelberg University Hospital, Department of Radiation Oncology, Heidelberg, Germany

<sup>3</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

#### Purpose or Objective

Anatomical changes such as changes in the mediastinum and the diaphragm position are seen in oesophageal cancer patients during the course of radiotherapy. Field entrance through areas with a high risk of changes is often unavoidable with intensity modulated photon radiotherapy (IMRT) if target conformity and reduction of dose to especially lungs and heart is pursued. Delivery of proton therapy is highly sensitive to anatomical changes, but using only one posterior field may avoid high risk entrances. We investigate the sparing of normal tissue and the potential gain in robustness towards anatomical changes using intensity modulated proton therapy (IMPT) instead of IMRT.

#### Material and Methods

Twenty-six consecutive patients with medial or lower oesophageal or gastroesophageal junction (GEJ) cancer treated with IMRT (5-8 fields) were retrospectively planned with IMPT using one posterior beam. The fractionation schedules were either 41.4 Gy/23fx (pre-operative regime, 22 patients) or 50Gy/27fx (definitive regime, 4 patients). To ensure dose coverage of the CTV for photon plans, a PTV (5 mm AP, 5mm LR, 8 mm CC) was used to account for uncertainties in planning and delivery. For protons, three different strategies were pursued. Robust optimization of the CTV (IMPT<sub>CR</sub>), robust optimization of the CTV and full coverage of the PTV (IMPT<sub>PR</sub>) and no robust optimization, but full coverage of the PTV (IMPT<sub>P</sub>). Robust optimization was performed accounting for 3mm isocenter shifts and 3% density uncertainty.

IMRT and IMPT plans were compared in terms of dose to lungs and heart. For all patients, an additional surveillance CT-scan was obtained at fraction 10 and used for recalculation of both IMRT and IMPT plans, analysing the percentage of CTV receiving 95% of the prescribed dose.

#### Results

Using IMPT instead of IMRT reduced the lung and heart dose significantly regardless of the IMPT strategy ( $p < 0.001$  using a Wilcoxon signed rank test). The mean lung and heart doses decreased from sample median = 8.7Gy [1.6;16.3] and 17.1Gy [1.1;24.1] using IMRT to 2.2 Gy [0.5;8.5] and 9.1 Gy [0;15.5], using IMPT<sub>PR</sub>.

Recalculation on the surveillance scans demonstrated that 7/26 (27%) IMRT plans showed CTV coverage < 99%. For

protons, IMPT<sub>PR</sub> plans were the most robust and only 4/26 (15%) decreased in coverage to below 99%. The CTV coverage for all patients and plans are shown in Fig 1. The most common anatomical changes are lateral target deformations, enlargement of mediastinum and changes in diaphragm position. The posterior proton plans are sensitive to target deformations, while the multiple photon fields are sensitive to all three types of changes (see Fig. 2).

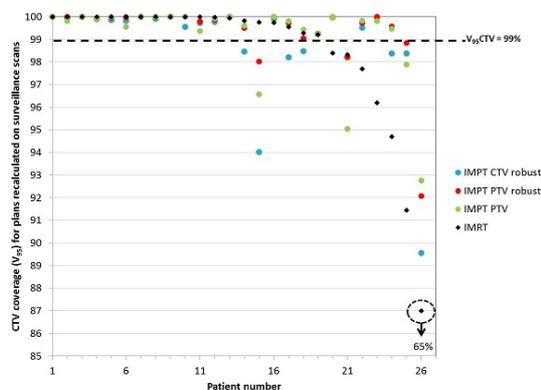

FIG 1: CTV coverage at surveillance scan at fraction 10 for all IMRT and IMPT plans for each patient. The dotted line indicates 99% coverage of the CTV.

#### Conclusion

Treating oesophageal cancer with protons has the advantage of decreasing dose to organs at risk and at the same time it improves the robustness towards common anatomical changes. Frequent imaging is still needed to identify patients with target deformations requiring adaptive treatment planning.

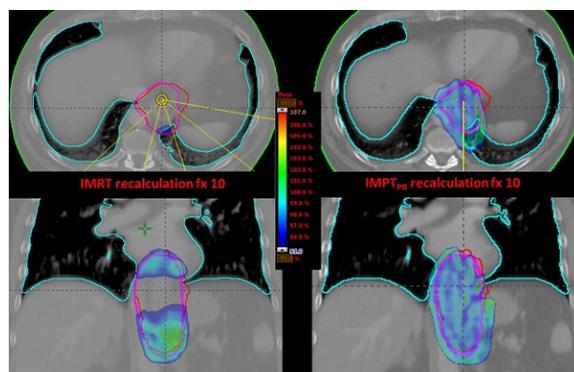

Fig 2: Recalculation on fraction 10 for IMRT (left) and IMPT (right). Underdosage on the IMPT plan is caused by deformation of the CTV. To illustrate this two CTV contours are shown. The red contour is the CTV re-delineated on the surveillance CT, while the pink is rigid transfer of the planning CTV. The diaphragm position on the surveillance scan is more cranial than on planning CT, deforming and broadening the CTV in the lateral direction while compressing the CTV in the longitudinal direction. The large underdosage on the IMRT plan is mainly due to the diaphragm shadowing the photon fields.

### PO-0878 Plan adaptation on the MR-Linac: first dosimetric validation of a simple dose shift

R. Koopman<sup>1</sup>, A.J.A.J. Van de Schoot<sup>1</sup>, J. Kaas<sup>1</sup>, T. Perik<sup>1</sup>, T.M. Janssen<sup>1</sup>, U.A. Van der Heide<sup>1</sup>, J.J. Sonke<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

Patient positioning on the MR-Linac (MRL; Elekta AB, Stockholm) requires online plan adaptations to correct for setup errors due to the fixed couch position. The aim of our study was to validate the size and direction of such plan adaptations (simple dose shifts) and evaluate dosimetric differences for rectum cancer patients.

### Material and Methods

The planning CT and delineated structures of four rectum cancer patients were selected. For each patient, a MRL treatment plan was generated with Monaco using a 7-beam IMRT technique (25 x 2.0 Gy) including all MRL-specific properties (7MV, 1.5 T magnetic field, collimator 90°, FFF, SAD: 143.5 cm). Patient setup errors of 1.0 cm and 2.0 cm in the CC and LR directions were simulated by shifting the planning CT with respect to the isocenter position. For each setup error, the initial plan was adapted by first adjusting the leaves of each segment to approximate the shift and second re-optimize the weight of each segment. Also, a reference plan was generated by adapting the initial plan with a 0.0 cm shift, as the second phase of plan adaptation was observed to introduce dose changes even for a 0.0 cm shift. All plans were rescaled (PTV  $V_{95\%} = 99\%$ ). The reference and adapted plans were irradiated on the MRL on a slab phantom with a 2D detector array (PTW Octavius 1500<sup>MR</sup>) inserted parallel to the couch at the center position of the PTV. For each plan, the phantom position was changed according to the introduced shift. Patient setup errors in the AP direction cannot be evaluated using this measurement setup. The measured 2D dose distribution of the reference plan was rigidly registered to the measured 2D dose distribution of the adapted plans in order to assess the positional accuracy of the simple dose shift. After alignment, the similarity between the 2D dose distributions of the reference plan and the adapted plans was evaluated using a 3%/3mm  $\gamma$  analysis (local dose, 20% low dose threshold).

### Results

For all adapted plans, the measured positional accuracy was within 0.1 cm. The  $\gamma$  analysis between the dose distributions of the reference plan and the adapted plans resulted in an average pass rate ( $\gamma \leq 1$ ) of 96.2% (range: 83.3% - 99.9%). Smaller values of  $\gamma_{\text{mean}}$  were observed for dose shifts in the CC direction compared to the LR direction as well as for 1.0 cm dose shifts compared to 2.0 cm dose shifts (Table 1). Figure 1 shows an example of a 2D  $\gamma$  distribution. High  $\gamma$  values are measured in the low dose area mainly. A simple dose shift to correct for a 1.0 cm setup error in the CC direction resulted in limited dose differences. Various  $\gamma$  hotspots were observed for the 2.0 cm setup error in the LR direction.

Setup error	$\gamma_{\text{mean}}$	$\gamma \leq 1$ (%)
CC 1.0 cm	$0.21 \pm 0.02$	$99.3 \pm 1.1$
CC 2.0 cm	$0.32 \pm 0.03$	$97.7 \pm 2.2$
LR 1.0 cm	$0.34 \pm 0.01$	$96.6 \pm 1.0$
LR 2.0 cm	$0.45 \pm 0.09$	$91.0 \pm 5.3$

Table 1: Dosimetric differences between the adapted plans and the reference are evaluated by a  $\gamma$  analysis. Results are averaged over four patients.

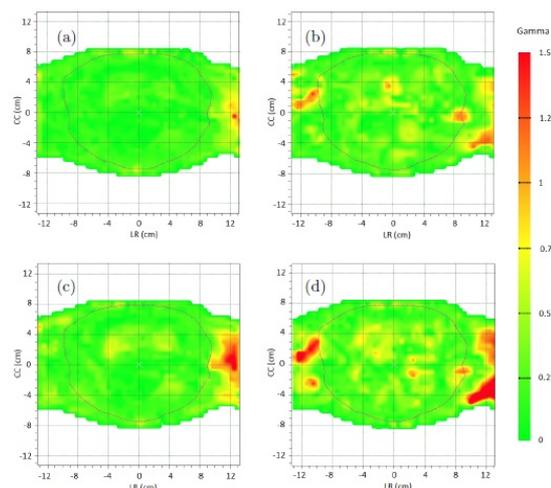

Figure 1: Example of 2D  $\gamma$  distributions for a 1.0 cm shift in (a) the CC and (b) the LR direction and for a 2.0 shift in (c) the CC and (d) the LR direction for one patient. The high dose area is indicated with the 50% isodose line.

### Conclusion

The use of plan adaptations to correct patient setup errors was experimentally validated on the MRL for the first time. The reference dose distribution was reproduced at the shifted location for rectum cancer patients. In addition, high gamma pass rates were measured.

<sup>4</sup>Addenbrooke's Hospital - Oncology Centre University of Cambridge, Medical Physics, Cambridge, United Kingdom

### Purpose or Objective

Adaptive radiotherapy (ART) for head and neck cancer remains resource intensive, and there is little consensus on which patients will benefit most from having it done. Concerns regarding maximum spinal cord dose sometimes trigger re-planning at our centre, and we sought to compute and model differences between planned and delivered maximum dose to the spinal cord in patients undergoing IMRT with daily image-guidance (IG) on the TomoTherapy system.

### Material and Methods

We drew planning kVCT, IG MVCT and planned dose datasets from archive for 33 patients who were treated for head & neck cancer (HNC) on TomoTherapy units at our centre. All patients underwent daily IG, with matching to high dose PTV (close to the spinal cord), or cervical spine vertebrae. To automatically contour the spinal cord, we developed an intensity based deformable image registration (DIR) algorithm using the open source Elastix toolkit to propagate manual contours from the planning CT. Using 'gold standard' contours of an expert observer, the algorithm was optimised on 30 MVCT datasets (567 slices) and validated on a further 90 (2203). Conformity was measured with Jaccard conformity index (JCI) and distance between centres (DBC), and compared with results from intra- and inter-observer studies.

Using in-house dose recalculation software (CheckTomo), TomoTherapy sinograms, MVCT datasets and algorithm

transformation parameters, we created 'voxel histories' for the spinal cord relative to the planning CT, and calculated delivered dose. Maximum planned and delivered spinal cord dose ( $D_{2\%}$ ) were then compared.

### Results

A summary of auto-contouring algorithm performance is shown in Table 1. Auto-contouring performance appeared comparable to manual segmentation, and we proceeded to calculate delivered dose. These results are shown in Figure 1 (A-C). Fig. 1A shows a waterfall plot of planned  $D_{2\%}$  minus delivered  $D_{2\%}$  for each patient. Mean spinal cord  $D_{2\%}$  was 35.96Gy (planned) and 36.01Gy (delivered), and the mean absolute difference between planned and delivered dose was 1.1Gy (3% of mean planned  $D_{2\%}$ ). Differences between planned and delivered dose were plotted as a histogram, which appears to be normally distributed around the mean difference (Fig 1B). The mean difference ( $\mu$ , -0.05) and standard deviation ( $\sigma$ , 1.448) were used to approximate a normal distribution to this data - as shown in Fig.1C. Using this model, a z statistic can be calculated for a chosen difference (e.g. Prob. of delivered  $D_{2\%}$  being 4Gy higher than planned is 2.5%).

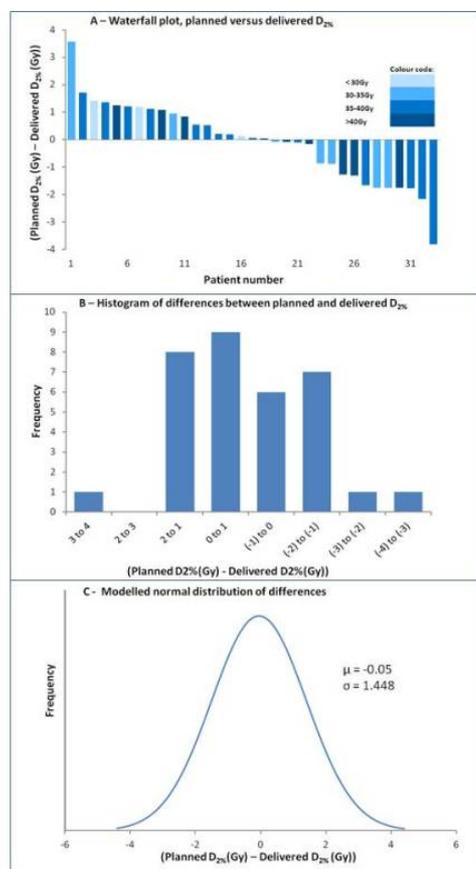

Figure 1: Differences between planned and delivered dose

	Inter-Obs	Intra-Obs	Auto
Median JCI	0.73	0.82	0.78
Mean JCI	0.73	0.81	0.77
Median DBC (mm)	0.95	0.64	0.70
Mean DBC (mm)	1.01	0.69	0.77

Table 1: Auto-contouring performance, intra- and inter-observer variability results.

### Conclusion

Differences between planned and delivered  $D_{2\%}$  to the spinal cord in patients receiving daily IG are small in HNC patients treated with daily IG on TomoTherapy. Our model

permits computation of clinically meaningful differences in context, but differences in spinal cord dose mandating ART should be a rare event.

### PO-0880 Using accumulated delivered dose to predict rectal toxicity in prostate radiotherapy

<sup>5</sup>Cambridge University Hospitals NHS Foundation Trust, Cambridge Clinical Trials Unit, Cambridge, United Kingdom

<sup>6</sup>University of Cambridge, Department of Physics-Cavendish Laboratory, Cambridge, United Kingdom

### Purpose or Objective

Dose-volume tolerances for organs at risk (OARs) adopted during radiotherapy planning have been historically derived from normal tissue complication probability (NTCP) models linking toxicity with planned dose.

On-treatment image guidance facilitates daily tumour localisation ensuring target coverage. However, the positional variation of neighbouring OARs is often disregarded. Anatomical deviations from the pre-treatment CT due to interfraction motion can introduce discrepancies between the planned and delivered dose.

One objective of the VoxTox research programme is to test the hypothesis that delivered radiation dose can be a stronger predictor of toxicity than planned dose.

### Material and Methods

For 109 prostate cancer patients treated with TomoTherapy® (74Gy/37#), daily megavoltage CT scans were acquired. An in-house autocontouring algorithm determines the rectal position, incorporating the effect of displacement and deformation, and an independent dose calculation is performed. Processing is fully automated within the VoxTox study. Dose surface maps (DSMs) of the rectal wall were generated following the virtual cutting and unfolding method of Buettner et al [*Phys. Med. Biol.*, 54, 21 (2009)], allowing conservation of spatial dose information (Figure 1). Daily delivered DSMs were summated to produce an accumulated DSM (Figure 1b) over the whole treatment. Planned and accumulated DSMs were parametrised by calculating 1) the equivalent uniform dose (EUD) and 2) the 'DSM dose-width', the lateral extent of an ellipse fitted to the largest isodose cluster, for 7 discrete dose levels between 30 and 75 Gy.

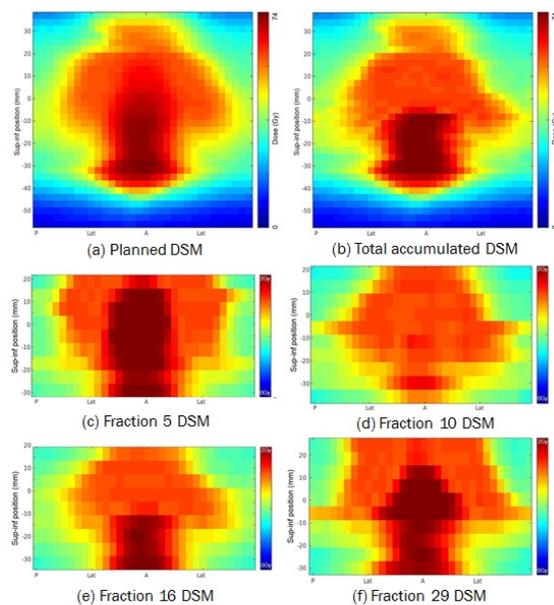

Figure 1: Dose surface maps (DSMs) of virtually unfolded rectal walls calculated using (a) manual contours outlined on the planning CT scan, (b) accumulation of 37 daily DSMs, (c)-(f) daily MVCT scans, each autocontoured with independent dose calculation

Receiver-operator characteristic curves were plotted, linking the extracted dose parameters with six patient-reported clinical endpoints: rectal bleeding, proctitis, sphincter control, rectal pain, and “How big a problem are bowels?” ( $\geq$ Grade 1,  $\geq$ Grade 2). Statistical correlations between planned and accumulated DSMs were compared using the calculated area under the curve (AUC) presented on High-Low plots.

### Results

For rectal bleeding, the 30, 40, and 60 Gy accumulated DSM dose-widths were significant predictors (AUC 0.629, 0.621 and 0.643 respectively), where planned dose was not (Figure 2a). For DSM dose-widths up to 70 Gy, AUC was greater for accumulated dose than planned dose. EUD was the strongest predictor of rectal bleeding from both accumulated (AUC 0.682) and planned (AUC 0.673) DSMs. The only significant predictor of proctitis was EUD of the accumulated DSM (AUC 0.673) (Figure 2b). Neither planned nor accumulated doses were predictive of the other endpoints

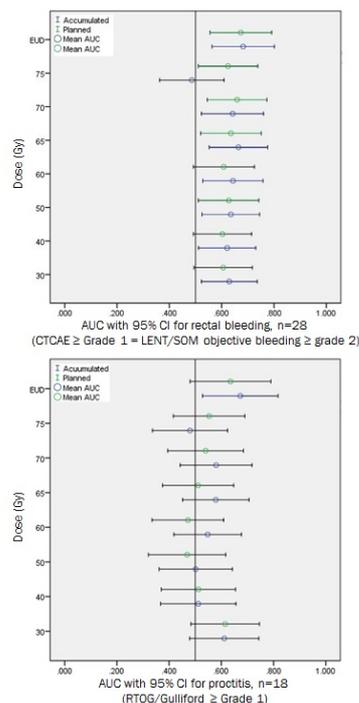

Figure 2: High-Low plots of the area under the receiver operator characteristic curve (AUC) and associated 95% confidence intervals showing correlation significance between planned and accumulated DSM dose widths and equivalent uniform dose, with (a) rectal bleeding and (b) proctitis

### Conclusion

For the first time, it has been possible to quantitatively demonstrate that accumulated delivered dose to the rectal wall is more strongly correlated with rectal bleeding and proctitis in prostate radiotherapy than planned dose. The results support the hypothesis that incorporating delivered dose into multi-variable predictive models could improve toxicity outcomes.

PO-0881 4DMRI for RT planning; novel precise amplitude binning in the presence of irregular breathing  
I. Bones<sup>1</sup>, O.J. Gurney-Champion<sup>2</sup>, A. Van der Horst<sup>1</sup>, A. Bel<sup>1</sup>, T. Alderliesten<sup>1</sup>, G. Van Tienhoven<sup>1</sup>, K. Ziemons<sup>3</sup>, Z. Van Kesteren<sup>1</sup>

<sup>1</sup>Academic Medical Centre, Radiotherapy, Amsterdam, The Netherlands

<sup>2</sup>Academic Medical Centre, Radiotherapy and Radiology, Amsterdam, The Netherlands

<sup>3</sup>FH Aachen University of Applied Sciences, Medical Physics, Jülich, Germany

### Purpose or Objective

Irregular breathing, often the case in clinical practice, introduces the need for proper outlier handling for 4DMRI reconstruction. Discarding outliers may lead to underestimation of the respiratory-induced organ motion. Our study aimed to develop and evaluate an amplitude binning strategy that reduces reconstruction artefacts while improving precision in the presence of irregular breathing.

### Material and Methods

Twelve volunteers and 2 abdominal cancer patients were scanned with our 4DMRI sequence. In this 6 minute scan, 11 2D coronal slices were acquired repetitively (60 times) during free breathing, using a T2W TSE sequence (resolution: 1.3x1.6x5.0 mm<sup>3</sup>). Prior to each slice acquisition, the position of the diaphragm was assessed using a 1D acquisition.

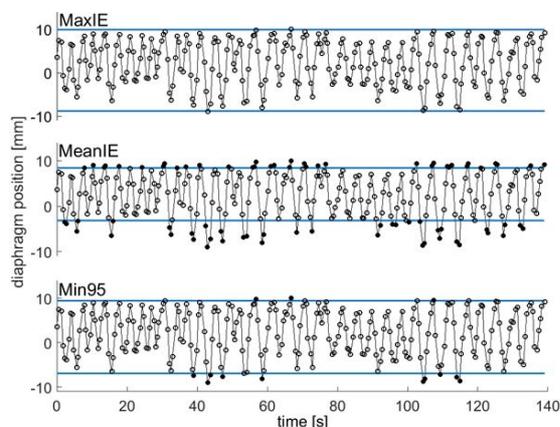

Subsequently, the 2D slices were binned in 10 equidistant bins according to the 1D diaphragm position (amplitude binning). To account for outliers, we developed a strategy that sets the inclusion range such that 95% of the diaphragm positions are included, while the peak-to-peak range is minimized (denoted Min95). We compared this with two frequently used strategies (Fig.1): one that selects the maximum inhale and exhale position as range (MaxIE), not discarding outliers, and one that selects the mean inhale and exhale position as inclusion range (MeanIE).

The strategies were evaluated based on the following parameters:

- \* Data included (DI); the fraction of data used for reconstruction after exclusion of outliers.
- \* Reconstruction completeness (RC); the fraction of the 110 (11 slices x 10 bins) bin/slice combinations in the 4D data set that are filled.
- \* Intra-bin variation (IBV); the standard error of the mean diaphragm position inside a bin/slice combination.
- \* Peak-to-peak range (PP);
- \* Image smoothness (S); assessed by quantifying how well a parabola fits the diaphragm shape in a sagittal plane of the reconstructed 4DMRI, per bin ( $S = R^2_{adj}$  averaged over all bins). S ranges from 0 (discontinuous diaphragm shape; artefacts) to 1 (smooth shape; no artefacts).

A low DI indicates underestimation of motion amplitude. A low IBV indicates high binning precision. Low RC, low S and high IBV result in image artefacts, e.g. discontinuities between reconstructed slices.

A paired Wilcoxon's signed rank test was used to test differences in parameters between binning strategies.

**Figure 1:** Example of the 3 amplitude binning strategies for a section of a typical volunteer breathing pattern. Open circles: diaphragm positions for which the image was included in the reconstruction; filled circles: discarded images.

## Results

Excluding only 5% of images during amplitude binning, the developed Min95 strategy outperformed the MaxIE strategy with a 9.5% higher mean RC, 5.6 mm lower mean PP and virtually the same mean IBV and S (all significant, Table 1).

The MeanIE strategy with a mean DI of 76.4%, severely underestimated the motion amplitude even though it had a higher S, higher RC and lower IBV compared to MaxIE. The Min95 strategy outperformed the MeanIE strategy with an 18.6% higher mean DI.

**Table 1:** Mean (standard deviation) values calculated including 12 healthy volunteers and 2 patients as well as differences in quality parameters for the three strategies.

	Quality parameters			Differences		
	MaxIE	MeanIE	Min95	Min95 - MaxIE	Min95 - MeanIE	MeanIE - MaxIE
DI [%]	100 (0.0)	76.4 (3.4)	95.0 (0.0)	<b>-5.0</b>	<b>18.6</b>	<b>-23.6</b>
RC [%]	85.9 (7.0)	95.2 (2.3)	95.5 (2.3)	<b>9.5</b>	0.3	<b>9.3</b>
IBV [mm]	0.45 (0.17)	0.36 (0.08)	0.39 (0.10)	<b>-0.07</b>	0.03	<b>-0.10</b>
PP [mm]	20 (7.9)	11.1 (3.4)	14.4 (4.5)	<b>-5.6</b>	<b>3.3</b>	<b>-8.9</b>
S	0.78 (0.11)	0.94 (0.06)	0.92 (0.08)	<b>0.14</b>	<b>-0.02</b>	<b>0.16</b>

Data inclusion (DI), reconstruction completeness (RC), intra-bin variation (IBV), peak-to-peak range (PP) and image smoothness (S). Statistically significant differences (2-sided Wilcoxon's signed-rank test,  $\alpha=0.05$ ) are in **bold**.

## Conclusion

Our novel binning strategy for 4DMRI outperformed the classical strategies, resulting in a 4DMRI with high precision and fewer artefacts in the presence of irregular breathing.

## PO-0882 Proxy-free slow-pitch helical 4DCT reconstruction

R. Werner<sup>1</sup>, C. Hofmann<sup>2</sup>, T. Gauer<sup>3</sup>

<sup>1</sup>University Medical Center Hamburg-Eppendorf, Department of Computational Neuroscience, Hamburg, Germany

<sup>2</sup>Siemens Healthcare, Imaging & Therapy Systems, Forchheim, Germany

<sup>3</sup>University Medical Center Hamburg-Eppendorf, Department of Radiotherapy and Radio-Oncology, Hamburg, Germany

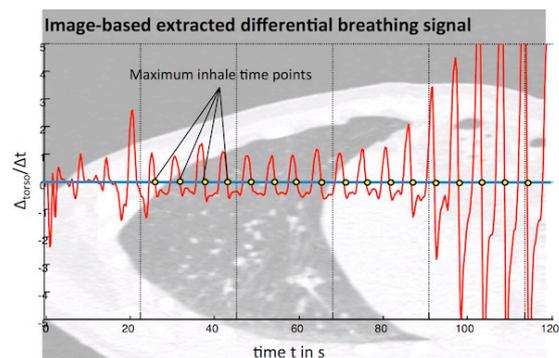

## Purpose or Objective

Standard 4DCT protocols correlate external breathing signals (exploiting e.g. surface tracking devices or abdominal belts) to raw or reconstructed image data to allow for reconstruction of a series of CT volumes at different breathing phases. From a radiotherapy (RT) workflow perspective, dealing with external devices for breathing signal recording is cumbersome. Moreover, if the respiratory signal is corrupted, 4DCT reconstruction is not possible at all. At this, proxy-free reconstruction - i.e. 4DCT reconstruction without using an external breathing signal - could improve RT workflows. We present a novel approach for slow-pitch helical 4DCT reconstruction and illustrate its feasibility.

## Material and Methods

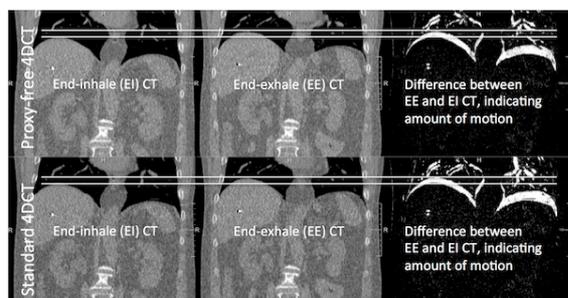

Similar to standard external breathing signal-driven slow-pitch helical CT we assume a sufficiently low pitch and gantry rotation time to be given to ensure existence of appropriate raw data for reconstruction of image data at each z position and desired breathing phase. We then pursue a three-step process: (1) image-based derivation of a differential breathing signal; (2) correlation of the extracted breathing signal to raw data; and (3) integration and minimization of an artifact-metric into the final (here: phase-based) reconstruction process. For the crucial step (1), we initially reconstruct slices at a series of z-positions and points in time and determine (slice wise, averaged over a specific region of interest) the change  $\Delta_{\text{torso}}/\Delta t$  in chest wall height. As  $\Delta_{\text{torso}}/\Delta t$  can be considered as derivation of the desired breathing signal (figure 1); its zero-crossings represent the end-inspiration (and the end-expiration) breathing phases to be correlated to the raw data.

Feasibility of the afore-mentioned approach is investigated using routinely acquired 4DCT lung and liver data sets. A detailed analysis of motion dynamics and image artifacts is performed in proxy-free reconstructed 4DCT data sets of three patients and resulting numbers are compared to corresponding standard external breathing curve-driven phase-based (PB) reconstructions based on the same 4DCT raw data plus RPM breathing signal.

## Results

Figure 2 illustrates that proxy-free and common external breathing signal-driven PB-reconstructed 4DCT data are comparable both in terms of image quality and represented motion amount. In detail, the considered proxy-free datasets contained approximately 5% more artifacts than the PB data sets. Differences of represented tumor mass center motion as well as the amount of e.g. diaphragm motion between end-inhalation and -exhalation were negligible (max. 1 voxel).

## Conclusion

We presented a novel approach for proxy-free slow-pitch helical 4DCT reconstruction and illustrated its feasibility. Although the proxy-free reconstructed images contain slightly more motion artifacts, we consider the approach to be helpful especially in the case of corrupted breathing signals recordings (no need for re-scanning the patient).

## PO-0883 Clinical Implementation Model-Based CT to Replace 4DCT for Lung Cancer Treatment Planning

D. Low<sup>1</sup>, D. O'Connell<sup>1</sup>, L. Yang<sup>1</sup>, J. Lewis<sup>1</sup>, P. Lee<sup>1</sup>  
<sup>1</sup>UCLA Medical Center, Department of Medical Physics, Los Angeles, USA

### Purpose or Objective

To implement motion-model based CT into clinical practice, replacing 4DCT for breathing motion management treatment planning.

### Material and Methods

A breathing motion model that employs a mathematical motion equation, two real-time breathing surrogates, breathing amplitude and breathing rate, and employing multiple fast helical, low-dose CT scanning has been introduced into clinical practice. The imaging process uses a bellows-based system to monitor the breathing cycle, which is defined as the amplitude and rate of the bellows signal. The fast helical CT scans are registered to determine the lung tissue positions, correlated to the breathing amplitude and rate on a slice-by-slice basis. A published motion equation is employed to characterize the motion for each voxel. The motion model is employed to reconstruct the original fast helical CT scans and the original and reconstructed scans compared to determine the overall model motion prediction accuracy. Eight amplitude-based CT images are constructed and sent to

the treatment planning system, along with a three-dimensional motion model accuracy (defined as the 75th percentile motion error in each voxel) map. The patients still undergo a commercial 4DCT protocol to provide a comparison between the current standard of care and the model-based process. Comparisons between the commercial and model-based approaches have been conducted on 19 patients to evaluate the magnitude of sorting artifacts in each process on a scale of 1-4, 1 having no artifacts and 4 having severe artifacts. The average CT noise for both protocols was described by examining a region of interest in the liver.

### Results

Mean tumor displacement was 11.5 +/- 6.9 mm and the mean motion model error was 1.77 +/- 0.79 mm. The mean artifact severity ratings for the 4DCT and model-based CT approaches were 2.2 and 1.2, respectively. There were three instances of grade 4 artifacts and no instances of grade 3 or worse artifacts for the 4D and model-based approaches, respectively. The average CT noise was reduced from 57.7 HU to 11.6 HU.

### Conclusion

The model-based approach provides the clinic with motion artifact free images that have lower noise and whose geometry accurately reflects the tumor and other lung tissues during the CT scanning session. We are still limited by the treatment planning system's input requirements for a series of breathing-phase defined images. Work is ongoing to develop treatment planning protocols that better match the data resulting from the model-based approach.

## PO-0884 Availability of MRI improves interobserver variation in CT-based pancreatic tumor delineation

<sup>5</sup>MAASTRO Clinic, Department of Radiation Oncology, Maastricht, The Netherlands

<sup>6</sup>Academic Medical Center, Department of Radiology, Amsterdam, The Netherlands

<sup>7</sup>University of Manchester and Christie NHS trust, Faculty of Biology- Medicine & Health- Division of Molecular & Clinical Cancer Sciences, Manchester, United Kingdom

<sup>8</sup>Academic Medical Center, Department of Medical Oncology, Amsterdam, The Netherlands

### Purpose or Objective

To assess whether the availability of magnetic resonance images (MRIs) alongside the planning CT scan for target volume delineation in pancreatic cancer patients decreases interobserver variation.

### Material and Methods

Eight observers (radiation oncologists) from six institutions delineated gross tumor volume (GTV) on contrast-enhanced (CE) 3DCT and internal GTV (iGTV) on 4DCT for four pancreatic cancer patients. At least six weeks after submitting these delineations, the observers were asked to repeat the delineations, now with MRIs available in a separate window (3DCT+MRI and 4DCT+MRI). The MRI included plain and CE T1-weighted gradient echo, T2-weighted turbo spin echo, and diffusion-weighted imaging. Interobserver variation in volumes of (i)GTVs was analyzed. Also, the generalized conformity index ( $CI_{gen}$ ), a

measure of overlap of the delineated volumes (1=full overlap, 0=no overlap), was calculated. Furthermore, the local observer variation was calculated for approx. 32,000 points on the median delineated surface (i.e. the surface of the volume that  $\geq 50\%$  of the observers included in their delineation). Local observer variation was defined as the standard deviation (SD) over the perpendicular distances between delineated surfaces at that point and is also known as local SD. The overall observer variation was defined as the root-mean-square of all local SDs. These parameters were compared between CT-only and CT+MRI delineations, for 3DCT and 4DCT (Wilcoxon signed-rank test; significance level  $\alpha=0.05$ ).

### Results

Delineations differed substantially between observers in both CT and CT+MRI, as illustrated for the GTV in the figure. For both GTV and iGTV, the mean volume on CT+MRI was 32% smaller than on CT only ( $p<0.0005$ ) (Table). Although smaller volumes were delineated on CT+MRI, the  $CI_{gen}$  was similar in both studies (CT+MRI: 0.33, CT: 0.32). Furthermore, CT+MRI showed smaller overall observer variations (average  $SD=5.9$  mm) in six out of eight delineated structures compared to CT only (average  $SD=7.2$  mm). The median volumes from the (i)GTV on CT+MRI were included for 97% and 92% in the median volumes from GTV and iGTV on CT, respectively. Finally, iGTV delineation on 4DCT increased uncertainty with and without MRI, compared to GTV delineation on 3DCT.

Both CT and CT+MRI delineations had regions of large local observer variation ( $SD>0.8$ ) close to biliary stents and enlarged lymph nodes. This was largely due to ambiguous instructions (near stents) and poor protocol compliance (near lymph nodes).

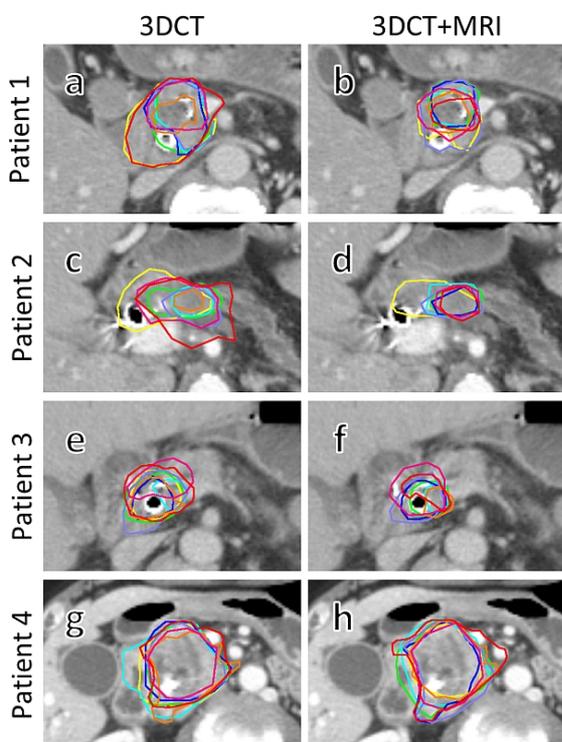

Figure: GTV delineations by the eight observers (each a different color) for 3DCT+MRI and 3DCT.

Table: Mean parameter values (and range) over the patients for delineated volume,  $CI_{gen}$  and overall observer variation (overall SD).

	3DCT	3DCT+MRI	4DCT	4DCT+MRI
Volume (cm <sup>3</sup> )	30 (10–52)	20 (6–53)	40 (21–66)	27 (11–60)
$CI_{gen}$	0.37 (0.22–0.59)	0.36 (0.23–0.56)	0.27 (0.16–0.45)	0.31 (0.17–0.61)
Overall SD (mm)	6.3 (4.3–8.4)	4.1 (4.0–4.3)	8.0 (6.8–9.0)	7.3 (3.9–11.1)
SD CT+MRI < SD CT	-	3 / 4	-	3 / 4

Abbreviations: SD = standard deviation;  $CI_{gen}$  = generalized conformity index. The range is indicated in brackets. The final column indicates how often the overall observer variation from CT+MRI was smaller than the overall observer variation from CT.

### Conclusion

The availability of MRI images during target delineation of pancreatic cancer on 3DCT and 4DCT improved the interobserver variation. Furthermore, delineated volumes are smaller on CT+MRI than on CT only. An approach of 3DCT GTV delineation with margins may be preferable to 4DCT iGTV delineation since the latter increases uncertainty.

#### PO-0885 Assess Tumor Voxel Dose Response (SF2) Using Multiple FDG PET Images

D. Yan<sup>1</sup>, S. Chen<sup>2</sup>, D. Krauss<sup>2</sup>, P. Chen<sup>2</sup>, G. Wilson<sup>2</sup>

<sup>1</sup>Beaumont Health System, Radiation Oncology, Royal Oak MI, USA

<sup>2</sup>Beaumont Health system, Radiation Oncology, Royal Oak- MI, USA

#### Purpose or Objective

To determine human tumor voxel dose response with using bio-marker (SF2) derived from multiple FDG PET images and evaluate the pattern of tumor local radioresistance and failure.

#### Material and Methods

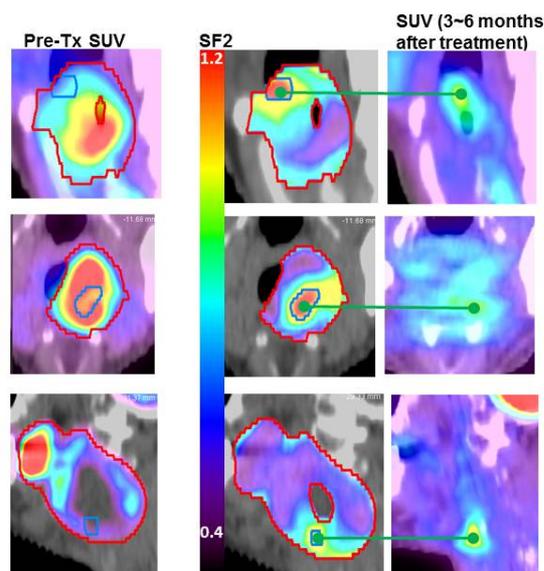

Multiple FDG PET/CT images obtained at the pre- and weekly during the treatment (35x2Gy) for 15 HN cancer patients were used for the study. from 0 to 70Gy, for each tumor voxel,  $v$ , such that  $TMR(v, d) = SUV(v, d)/SUV(v, 0)$ . TMR of each patient was constructed following voxel-by-voxel deformable PET/CT image registration. Assuming  $\ln(TMR(v, d)) = k \cdot \ln(SF(v, d))$ , the optimal linear regression with unknown break-points was used to determine the tumor voxel survival fraction, SF at different treatment dose levels. Therefore,  $SF2(v, d)$ , the tumor voxel survival fraction after 2Gy, was obtained and used as the tumor voxel dose response marker. Tumor voxel SF2 distribution at different treatment dose level was analyzed to evaluate the pattern of tumor voxel dose response, specifically the tumor local radioresistant pattern; meanwhile the effects of tumor voxel reoxygenation and proliferation with respect to tumor local failure were also evaluated. The tumor volumes with different SF2 cutoffs were also correlated to treatment outcome.

#### Results

Human tumor has significant inter- and intra-tumor variations in their voxel dose response (Table). Tumor voxels with the mean  $SF2 > 0.7$  shows significant prediction power ( $p < 0.01$ ) after the treatment dose of 20-40Gy on tumor local failure. Tumor local recurrence showed strong correlation to the tumor local radioresistance determined using SF2 (Figure). Two of 3 failures showed a clear reoxygenation effect after 20Gy, therefore could be potentially controlled by escalating dose to destroy the local radioresistant niches. One failure had a small ( $< 1cc$ ) local radioresistant sub-volume and showed the minimal reoxygenation, therefore it may need a local ablation.

**Table. Tumor voxel SF2 (Mean and SD of each controlled (C#) and recurrent (F#) tumors**

<b>C10</b>	22.06	0.68	0.13
<b>C11</b>	33.81	0.66	0.12
<b>C12</b>	96.84	0.67	0.1

**Figure. SF2 map and pre/post-tx SUV for the 3 failures****Conclusion**

Tumor voxel metabolic ratio determined using multiple FDG PET images can be used to assess tumor voxel dose response, SF2, which shows an excellent predictive value for tumor local radioresistance and failure. Our results demonstrate that a heterogeneous dose distribution in tumor should be prescribed to optimize cancer radiotherapy. Tumor voxel TMR determined at the early treatment will be good bio-parametric matrix to determine a new tumor dose prescription function at the voxel level for the treatment of adaptive dose-painting-by-number.

**PO-0886 Early changes of FDG-PET markers predict the outcome after chemo-radiotherapy for pancreatic cancer**

S. Broggi<sup>1</sup>, P. Passoni<sup>2</sup>, E.G. Vanoli<sup>3</sup>, C. Fiorino<sup>1</sup>, G.M. Cattaneo<sup>1</sup>, C. Gumina<sup>2</sup>, P. Mapelli<sup>3</sup>, E. Incerti<sup>3</sup>, L. Gianolli<sup>3</sup>, N. Slim<sup>2</sup>, M. Picchio<sup>3</sup>, R. Calandrino<sup>1</sup>, N.G. Di Muzio<sup>2</sup>

<sup>1</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy

<sup>2</sup>San Raffaele Scientific Institute, Radiotherapy, Milan, Italy

<sup>3</sup>San Raffaele Scientific Institute, Nuclear Medicine, Milan, Italy

**Purpose or Objective**

To investigate the predictive role of early changes of <sup>18</sup>F-fluorodeoxyglucose (FDG) positron emission tomography (FDG-PET) based biomarkers in locally advanced pancreatic carcinoma (LAPC) patients (pts) treated with induction and concomitant chemo-radiotherapy (CRT) on overall survival (OS), local relapse free survival (LRFS), distant relapse free survival (DRFS) and progression free survival (PFS).

**Material and Methods**

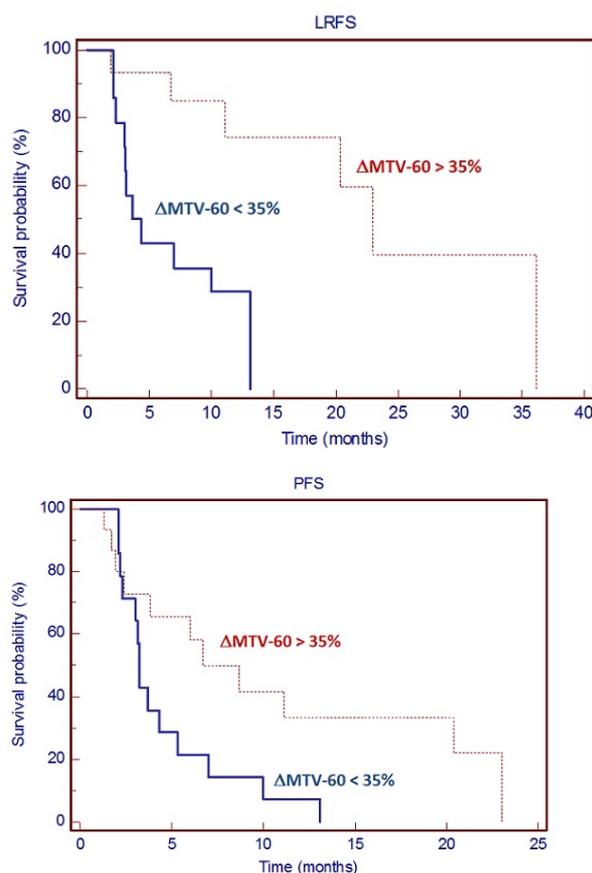

Data of 39 pts included in an Institutional trial were considered. Most pts (92%) received neoadjuvant chemotherapy, followed by CRT. Pts received 44.25Gy in 15 fractions to the tumor: a simultaneous integrated boost (SIB) to the sub-volume infiltrating the great abdominal vessels up to 48-58Gy was delivered in 17/39 pts. FDG-PET-CT was performed in all pts before (PET\_pre) and after CRT (PET\_post), at a median time of 3-months after the end of CRT. The predictive value of the % difference of FDG-PET parameters between PET\_post and PET\_pre was investigated, including maximum standard uptake value ( $\Delta$ SUVmax), metabolic tumor volume ( $\Delta$ MTV) and total lesion glycolysis ( $\Delta$ TLG), these last two estimated considering different uptake thresholds (40-50-60%) of SUVmax. The % difference between gastrointestinal cancer-associated antigen (GICA) levels measured at roughly the same timing of PET scan (pre and post) was also considered. For each parameter, median  $\Delta$  values were used to categorize the pts in high vs low risk groups: logrank tests and univariable Cox regression analyses were performed to assess the prognostic value of the considered parameters on OS, LRFS, DRFS and PFS.

**Results**

The median follow-up was 11 months (range: 3.7-106); the median age was 63 years (35-84). Median OS, LRFS, DRFS and PFS after the start of CRT were 22, 10, 4.3, 5.3 months, respectively. No uptake was present at PET\_pre in 9 pts: a longer median time to progression for PET negative pts (9.0 vs 3.7 months,  $p=0.06$ ) was found compared to pts with positive PET\_pre. Focusing on the 30/39 pts with positive PET-pre,  $\Delta$ MTV-60 was the most significant predictor of LRFS ( $p=0.007$ ; RR=0.16) and PFS ( $p=0.04$ ; RR=0.41). Median LRFS were 4.3 and 23 months for pts with  $\Delta$ MTV-60 < 35% and pts with  $\Delta$ MTV-60 > 35%, respectively ( $p=0.002$ ; RR=3.8, Figure1); the corresponding median PFS were 3.2 vs 6.7 months ( $p=0.03$ ; RR=2.2, Figure2).  $\Delta$ TLG-50 and  $\Delta$ TLG-60 showed borderline significance in predicting OS ( $p=0.05$ ; RR=0.33). No correlation was found between the % variation of PET parameters and DRFS while the % change of GICA levels was a significant predictor ( $p=0.03$ ; RR=0.28).

**Conclusion**

The early assessment of FDG-PET biomarkers response predicts clinical outcome in LAPC pts, except DRFS. The early variation of GICA values predicts DRFS suggesting that the integration of the information concerning early changes of PET biomarkers and GICA may be useful in identifying patients at higher risk of early local and/or distant relapse and to discriminate the pattern of relapse.

#### PO-0887 Experimental validation of a 3D model to simulate FMISO spatial retention in HNSCC tumor xenografts

<sup>2</sup>University Hospital Tübingen, Department of Radiation Oncology, Tübingen, Germany

<sup>3</sup>University Hospital Tübingen, Department of Pathology and Neuropathology, Tübingen, Germany

<sup>4</sup>Preclinical Imaging and Radiopharmacy, Werner Siemens Imaging Center, Tübingen, Germany

#### Purpose or Objective

Tumor hypoxia is prognostic for poor outcome after radiotherapy (RT). A method for non-invasive assessment of hypoxia is PET using hypoxia radiotracers such as FMISO. For this study, we evaluated a tool to simulate 2D and 3D FMISO accumulation on realistic vessel architectures, which can be compared against experimental pimonidazole (pimo) stainings of the same tumor.

#### Material and Methods

Dynamic PET/MR imaging was performed in FaDu tumors (human HNSCC) grown in the right hind leg of nude mice for about 5 weeks, using an injected FMISO activity of ~12MBq. Pimo and hoechst 33342 were injected 1h and 1min prior to tumor excision, respectively, to allow staining for tumor hypoxia and perfusion status of blood vessels. After excision, two tumors were snap frozen and the central part was cut into 120 consecutive sections of 10µm. Immunofluorescence staining was performed for pimo and endothelial marker CD31. Sections were subsequently scanned on a Zeiss Axiovert fluorescence microscope to detect pimo, CD31 and hoechst. The fluorescence images were rigidly registered, manually

adjusted and thresholded to create a binary 3D vessel map (VM). Hoechst-negative vessels were excluded from the VM. These VMs were used to simulate 3D oxygen distributions based on a Michaelis-Menten relation. An average input function (AIF) was determined by fitting activities in the left ventricles over 4 mice to derive mean parameters. Based on oxygen distribution and AIF, FMISO retention was simulated on the same VMs. FMISO-positive regions of 3x3mm<sup>2</sup> in the tumor center in 5 random sections were compared against manually contoured pimo-positive regions to validate the simulation by determining hypoxic fraction (HF) and overlap ratio. Necrosis was excluded based on H/E staining on the same sections. To compare 3D and 2D simulations, the simulations and analysis were repeated in 2D. Parameters for all simulations were set to commonly used values (Mönnich et al., 2011).

	Pimonidazole	2D simulation	3D simulation
Tumor 1			
Hypoxic fraction	0.38 ± 0.06	0.35 ± 0.05	0.33 ± 0.12
True-positive rate		0.47 ± 0.05	0.62 ± 0.03
True negative rate		0.66 ± 0.09	0.72 ± 0.06
False-positive rate		0.52 ± 0.05	0.37 ± 0.03
False-negative rate		0.34 ± 0.09	0.28 ± 0.06
Tumor 2			
Hypoxic fraction	0.30 ± 0.02	0.25 ± 0.04	0.28 ± 0.03
True-positive rate		0.27 ± 0.03	0.50 ± 0.05
True negative rate		0.69 ± 0.02	0.78 ± 0.02
False-positive rate		0.73 ± 0.03	0.50 ± 0.05
False-negative rate		0.31 ± 0.02	0.22 ± 0.02

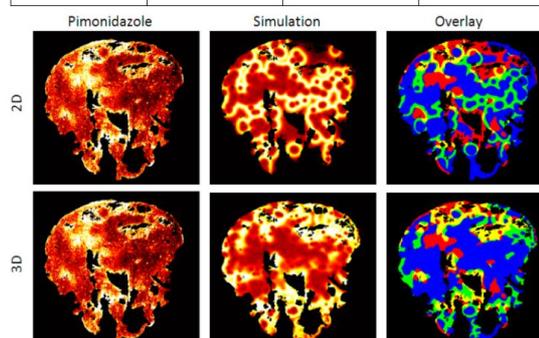

Figure: Comparison of experimental pimonidazole stainings, simulated FMISO accumulation and resulting overlay: normoxic (blue), pimonidazole-positive (staining, red), FMISO-positive (simulation, green), and hypoxic in simulation and staining (yellow)

#### Results

Differences in experimental and 3D-simulated hypoxic fractions (HF) were not significant, while differences between experimental and 2D-simulated HF was significantly different for Tumor 2 ( $p=0.02$ , cf. Table). 3D simulations matched much better with pimo distribution than 2D simulations only. The true-positive rate was increased about 0.2 for both tumors, the true-negative rate by about 0.08 for 3D simulations when compared to 2D. 56% of 3D-simulated FMISO-positive voxels were located within pimo-positive areas, while another 14% were located within 50µm distance, as to 37% and 8% for 2D, respectively (cf Table, Figure).

#### Conclusion

When performing hypoxia tracer simulations on actual VMs, 3D models accounting for out-of-plane diffusion must be used to obtain realistic results. In a 3D vascular model, spatial tracer distributions similar to those observed *in vivo* can be simulated. Hence, 3D FMISO simulation on

realistic VMs can help to optimize clinical imaging protocols and image analysis tools.

#### PO-0888 Response monitoring by <sup>18</sup>FDG-PET in locally advanced NSCLC treated with concurrent chemoradiotherapy

J.N.A. Van Diessen<sup>1</sup>, M. La Fontaine<sup>2</sup>, M. Van den Heuvel<sup>3</sup>, W. Vogel<sup>4</sup>, J.S.A. Belderbos<sup>1</sup>, J.J. Sonke<sup>2</sup>

<sup>2</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Academic Physics, Amsterdam, The Netherlands

<sup>3</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Pulmonology, Amsterdam, The Netherlands

<sup>4</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Nuclear Medicine, Amsterdam, The Netherlands

#### Purpose or Objective

The randomized phase 2 Reditux-trial (NTR2230) in locally advanced non-small cell lung cancer (NSCLC), investigating the additional benefit of Cetuximab to concurrent chemoradiotherapy (CCRT) did not show improved survival but revealed a remarkable 5-year overall survival (OS) of 37.3% [1]. Patients were staged with <sup>18</sup>FDG-PET-scans before and 4 weeks after CCRT. The purpose of this study was to investigate whether PET metrics have prognostic value in relation to local, regional, and distant failure.

#### Material and Methods

In the Reditux-trial, 102 stage IIIA-B NSCLC patients were included. CCRT consisted of 66 Gy in 24 fractions (using IMRT) combined with daily low dose Cisplatin. A subgroup of the patients had a repeat <sup>18</sup>FDG-PET-scan for response evaluation of the primary tumor and lymph nodes after a median of 4.2 weeks (range, 1.6-10.1). Twenty patients underwent additional surgery and were excluded. Ten patients were excluded due to technical reasons. The pre- and post-treatment <sup>18</sup>FDG-PET-scans from the remaining 42 patients were anatomically registered with the planning CT-scan. The following pre- and post-treatment PET metrics were calculated of the primary tumor (PT) as well as the combined lymph nodes (LNs): SUV<sub>max</sub>, total lesion glycolysis (TLG) and metabolic tumor volume (MTV). The response ratio between the pre- and post-treatment values was also calculated. These parameters were tested as prognostic factors using the Kaplan-Meier method and Cox regression analysis for univariate and multivariate analyses.

#### Results

Forty-two patients were evaluated for the prognostic value of the PET metrics. The median follow-up and OS was 32 and 33 months, respectively. Median GTV of the PT and the LNs was 80 cc (range, 2-439) and 27 cc (range, 2-195). The SUV<sub>max</sub> of both PT and LNs decreased significantly as well as TLG of the PT and MTV of the LNs (p≤0.001). The post-treatment and the response ratio of the SUV<sub>max</sub> of the LNs was correlated significantly with regional failure (p=0.009; p=0.009) (Table 1). The response ratio of the SUV<sub>max</sub> of the LNs was also significantly correlated with OS (p=0.014). No parameters corresponded with local and distant failure.

Table 1

The P-values and HR of the PET metrics of the primary tumor (PT) related to local failure and combined lymph nodes (LNs) related to regional failure of the pre- and post-treatment <sup>18</sup>FDG-PET-scan as well as the response ratio.

	Pre-treatment		Post-treatment		Response	
	PT	LNs	PT	LNs	PT	LNs
SUV <sub>max</sub>	P=0.544 HR 0.969	P=0.146 HR 0.852	P=0.496 HR 1.078	P=0.009 HR 3.181	P=0.305 HR 1.01	P=0.006 HR 1.024
TLG	P=0.415 HR 0.999	P=0.317 HR 0.990	P=0.888 HR 1.078	P=0.376 HR 0.991	P=0.859 HR 1.00	P=0.908 HR 1.00
MTV	P=0.609 HR 0.995	P=0.983 HR 1.000	P=0.824 HR 0.998	P=0.329 HR 0.974	P=0.332 HR 0.998	P=0.249 HR 0.998

#### Conclusion

The post-treatment and response SUV<sub>max</sub> of the LNs were found to be significant prognostic factors for regional failure and OS in patients with locally advanced NSCLC treated with hypofractionated CCRT. These parameters might be useful in the selection of patients for additional therapy.

#### PO-0889 FLT PET kinetic analysis biomarkers of resistance to radiotherapy for nasal tumours in canines U. Simoncic<sup>1</sup>, T.J. Bradshaw<sup>2</sup>, L. Kubicek<sup>3</sup>, L.J. Forrest<sup>4</sup>, R. Jeraj<sup>5</sup>

<sup>1</sup>Jozef Stefan Institute, F-8, Ljubljana, Slovenia

<sup>2</sup>University of Wisconsin, Department of Radiology, Madison, USA

<sup>3</sup>Angell Animal Medical Center, Angell Animal Medical Center, Boston, USA

<sup>4</sup>University of Wisconsin, Department of Surgical Sciences- School of Veterinary Medicine, Madison, USA

<sup>5</sup>University of Wisconsin, Department of Medical Physics, Madison, USA

#### Purpose or Objective

Imaging biomarkers of resistance to radiotherapy are prerequisite for precise treatment. Multiple imaging biomarkers are typically provided by a separate multi-tracer or multimodal imaging. This study assessed kinetic analysis as a means to create multiple imaging biomarkers of resistance to radiotherapy from a dynamic 3'-(<sup>18</sup>F)fluoro-3'-deoxy-L-thymidine (FLT) positron emission tomography (PET) scan.

#### Material and Methods

Sixteen canine cancer patients with spontaneous nasal tumours were imaged dynamically with FLT PET before and during the radiotherapy. Images were analysed for kinetics on a voxel basis using a two tissue, four rate-constant compartmental model. Overall parameter values (mean and median over the region of interest (ROI)) and heterogeneity measures (coefficient of variation (COV), ratio of interquartile range to median (IQR/median)) were evaluated over the tumour gross target volume for the transport ( $K_1=K_1k_3/(k_2+k_3)$ ), perfusion/permeability ( $K_1$ ) and vascular fraction ( $V_b$ ) parametric images. Response biomarkers were evaluated as a ratio of mid-therapy to pre-therapy regional values, (i.e. mean, median, COV, IQR/median). Alternative, spatial responses were evaluated as a mean, median, COV or IQR/median taken on a ratio of mid-therapy to pre-therapy parametric images. The time to progression after radiotherapy (TTP) was estimated by assessing the therapy response according to the RECIST. Kaplan-Meier analysis and univariate Cox proportional hazards (PH) regression were used to assess the impact of each imaging biomarker on the TTP.

#### Results

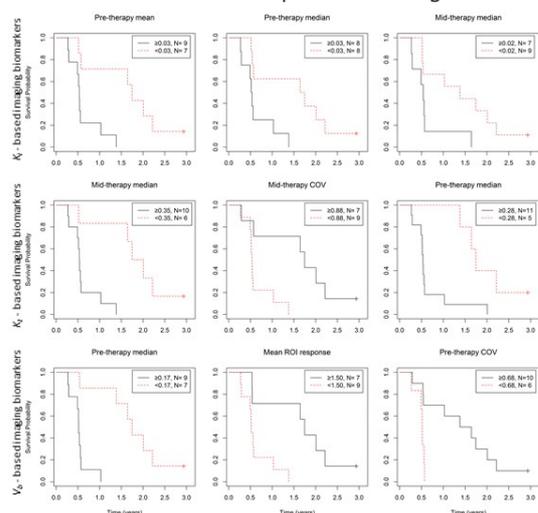

Pre- or mid-therapy overall  $K_1$  parameters were significant predictors of TTP after the radiotherapy. However, many imaging biomarkers based on  $K_1$  and  $V_b$  parameters had higher predictive power for the radiation therapy response. Table shows results of univariate Cox proportional hazard regression for imaging biomarkers derived from FLT PET parametric images. Hazard is significantly increased for higher pre- or mid-therapy overall  $K_1$  parameter values, higher or increasing pre- or mid-therapy overall  $K_1$  parameter value, lower or

decreasing pre- or mid-therapy  $K_1$  spatial heterogeneity, higher but decreasing pre- or mid-therapy overall  $V_b$  parameter value, and lower pre-therapy  $V_b$  spatial heterogeneity.

Results of univariate Cox proportional hazard regression for imaging biomarkers derived from FLT PET parametric images.

		Mean			Median			COV			IQR median

$V_b$	Pre-therapy	4.07	1.21	13.65	17.37	2.11	143.29	0.16	0.04	0.67	0.16	0.04	0.67
	Mid-therapy	2.58	0.78	8.56	3.78	1.01	14.10	0.35	0.12	1.05	0.51	0.18	1.46
	ROI response	0.14	0.03	0.67	0.14	0.03	0.67	3.26	0.87	12.26	3.20	0.91	11.23
	Spatial response	0.13	0.03	0.54	0.15	0.03	0.74	0.35	0.12	1.07	0.35	0.12	1.07

Figure shows selected results of Kaplan-Meier analyses that illustrates prognostic power of some imaging biomarkers based on FLT PET parametric images.

## Conclusion

Worse outcome after radiotherapy was significantly associated with higher pre- or mid-therapy overall  $K_1$ . Additionally, we found that various imaging biomarkers derived from vascular parameters or their change through the therapy, contains even stronger prognostic information than the FLT transport parameter, which justify use of kinetic analysis.

## PO-0890 PET-based radiobiological modeling of changes in tumor hypoxia during chemoradiotherapy

M. Crispin Ortuzar<sup>1</sup>, M. Grkovski<sup>1</sup>, B.J. Beattie<sup>1</sup>, N.Y. Lee<sup>2</sup>, N. Riiaz<sup>2</sup>, J.L. Humm<sup>1</sup>, J. Jeong<sup>1</sup>, A. Fontanella<sup>1</sup>, J.O. Deasy<sup>1</sup>

<sup>1</sup>Memorial Sloan Kettering Cancer Center, Medical Physics, New York, USA

<sup>2</sup>Memorial Sloan Kettering Cancer Center, Radiation Oncology, New York, USA

## Purpose or Objective

To develop a mechanistic radiobiological model of tumor control probability (TCP) for predicting changes in tumor hypoxia during chemoradiotherapy, based on pre-treatment imaging of perfusion and hypoxia with <sup>18</sup>F-Fluoromisonidazole (FMISO) dynamic PET and of glucose metabolism with <sup>18</sup>F-Fluorodeoxyglucose (FDG) PET.

## Material and Methods

The mechanistic prediction is based on a radiobiological TCP model describing the interplay between tumor cell proliferation and hypoxia (Jeong et al., PMB 2013). The study presented here (see Sup. Figure 1) focuses on a cohort of 35 head and neck cancer patients treated with chemoradiotherapy which received baseline FDG PET and FMISO dynamic PET, and intra-treatment FMISO dynamic PET scans, and which excluded subjects having a significant increase in hypoxia during treatment. The model is used to predict the radiobiological evolution of each tumor voxel of the baseline image up until the intra-treatment scan (9.2±3.4 days). The main inputs to the model are the initial fractions of proliferative and hypoxic tumor cells in each voxel, obtained from an approximate solution to a system of linear equations relating cell fractions to voxel-level FDG uptake, perfusion (FMISO  $K_1$ ) and hypoxia (FMISO  $k_3$ ). For each lesion, the predicted levels of intra-treatment hypoxia are compared to the measured  $k_3$  from the intra-treatment scan. A single global parameter (the average fraction of extremely hypoxic cells that take up FMISO) is determined from a training subset of 29 lesions by minimizing the average discrepancy between each lesion's measured and predicted intra-treatment  $k_3$  histograms (Cramér-von Mises criterion). A validation subset of 10 lesions is held out to test the resulting model.

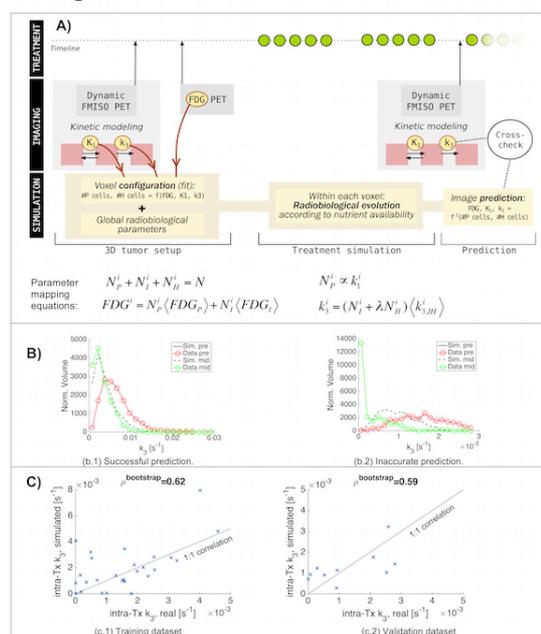

Figure 1. (a) Schematic of the methodology, including the radiotherapy treatment timeline, image analysis, and treatment simulation using the multiscale radiobiological model. P, I and H refer to the three categories of cells considered in the model, namely proliferative, intermediately hypoxic and extremely hypoxic. FDG PET is used for lesion segmentation. The kinetic modeling is based on an irreversible 2-compartment model. Dynamic FMISO PET scans consist of 30 min of initial dynamic scan followed by two 10-minute static scans at approximately 90 and 150 minutes post-injection. (b) Examples of intra-treatment  $k_3$  (hypoxia) predictions for two lesions from the validation cohort. (c) Correlation between measured and simulated median  $k_3$  in the training and validation datasets.  $\rho^{bootstrapped}$  refers to the mean Pearson's correlation coefficient obtained from bootstrapping.

## Results

The average fraction of extremely hypoxic cells that take up FMISO is 0.15 (95% CI 0.05 - 0.30 on bootstrap). In the training subset, the model predicts the mean, median and standard deviation of each lesion's intra-treatment  $k_3$  histograms (Pearson's linear correlation coefficients between predicted and measured values of  $\rho=0.62$ , 0.60 and 0.69 respectively, all with positive 95% CI on bootstrap - see Sup. Table 1). In the validation subset, only the predictions of the intra-treatment mean and median  $k_3$  of each lesion are significant ( $\rho=0.59$  and 0.60 respectively).

**Table 1.** Pearson's linear correlation coefficients of the predicted vs. measured values of various hypoxia statistics, obtained from the training and validation subsets.

	Training subset		Validation subset	
	Linear correlation coef.		Linear correlation coef.	
	Nominal	95% CI	Nominal	95% CI
median( $k_s$ )	0.62	(0.27, 0.83)	0.59	(0.26, 0.84)
mean( $k_s$ )	0.60	(0.27, 0.81)	0.60	(0.31, 0.87)
SD( $k_s$ )	0.69	(0.42, 0.88)	0.42	(-0.23, 0.86)
skewness( $k_s$ )	0.24	(-0.03, 0.52)	-0.10	(-0.75, 0.47)
kurtosis( $k_s$ )	0.06	(-0.17, 0.31)	-0.31	(-0.78, 0.21)

## Conclusion

This work presents a methodology to estimate the parameters of a mechanistic, radiobiological TCP model based on pre-treatment FMISO and FDG PET scans. The method is able to predict mean and median values of intra-treatment hypoxia for each of the lesions in a validation dataset held out from the analysis. This could potentially be used in the future to, for example, select patients for a de-escalation protocol based on their expected response. More patients will be added to the analysis in order to refine the prediction, find the defining characteristics of the outliers, and consolidate the results.

## Purpose or Objective

Skagen Trial 1 is a multicenter, non-inferiority trial randomising early breast cancer patients to loco-regional irradiation with 50 Gy/25 fractions vs 40 Gy/15fractions. Primary endpoint is arm lymphedema.

The protocol has pre-specified criteria for target volume delineation and dose planning, and quality assessment of this is reported. Inter-observer variability in delineation and its impact on dose parameters were assessed. Automated atlas-based segmentation was used in order to streamline assessment procedure.

## Material and Methods

Treatment CT scans from up to 8 randomly selected patients included in the trial had target volumes auto delineated with MIM Maestro™ software version 6.5 (MIM Software Inc., Cleveland, OH) and manually edited according to ESTRO target volume delineation guidelines. Post editing of contours were verified by an observer (BVO), and considered as a gold standard reference (GS). Dice similarity coefficient (DSC) between original delineation (OD) and GS was calculated. Protocol compliance and dose distribution of delineated volumes (Dmin, Dmax, D2%, D95%, D98% and Homogeneity index (HI) for breast and nodal target volumes) were assessed in OD. HI and D95% were compared between OD and GS delineation of primary (CTVp), CTVn\_L2-4- interpectoral (CTVn), internal mammary CTV (CTVn\_IMN) and CTVn\_L1.

**Fig.1** example of dosimetric comparison between gold standard (A) and Original delineation (B)

## Results

88 treatment plans from 12 centres in 4 countries were assessed. Delineation of all target volumes and organs at risk was complete in 99% and 96% of the patients, respectively. DSC showed high agreement in contouring, with average values of 0,9 for CTVp and 0,77 for nodal volumes. Complete dosimetric assessment was available in all patients for CTVp, but 1 patient with missing target volume delineation required integration with data extrapolated from GS. No deviations for target dose distribution were found in 76% of the patients, and 82% and 95% of the patients had successful target coverage of CTVp and CTVn, with 95% of volume covered by >95% and >90% of prescribed dose, respectively. Dose comparison for CTVp was performed in all patients, but 17 patients were excluded from CTVn comparison due to incomplete target delineation or exclusion of one or more nodal levels from target volume according to institutional policy. No differences were found for CTVp HI and D95% between OD and GS. CTVn, CTVn\_L1 and CTVn\_IMN were successfully covered (D95>90% of prescribed dose) in both delineations. Minimal differences were found in D95% and HI for CTVn (p<0,001 for both), CTVn\_IMN (p=0,001 for D95%) and CTVn\_L1 (p=0,02 for HI and p=0,03 for D95%).

D2%: Percentage of dose covering 2% of volume; D99%: Percentage dose covering 99% of volume; D98%: Percentage dose covering 98% of volume; D95%: Percentage of dose covering 95% of volume; CTVp: Breast/chest wall clinical target volume; CTVn: clinical target volume of the Levels 2,3,4 and interpectoral; OD: original delineation; GS: gold standard delineation; HI= Homogeneity Index; IQR= inter-quartile range; Δ: difference between OD and GS

## Conclusion

There was low interobserver variability across all centres. Low rates of protocol deviations ensured high compliance of the participating centres. Targets were adequately and homogeneously covered in the majority of patients. Dose parameters were comparable between OD and GS and confirmed that interobserver variability did not influence treatment outcomes.

### PO-0892 Automatic quality assurance of rectal contours on image guidance scans

M. Romanchikova<sup>1</sup>, D.I. Johnston<sup>1</sup>, M.P.F. Sutcliffe<sup>2</sup>, K. Harrison<sup>3</sup>, S.J. Thomas<sup>1</sup>, J.E. Scaife<sup>4</sup>, N.G. Burnet<sup>4</sup>

<sup>1</sup>Cambridge University Hospitals, Medical Physics and Clinical Engineering, Cambridge, United Kingdom

<sup>2</sup>University of Cambridge, Engineering, Cambridge, United Kingdom

<sup>3</sup>University of Cambridge, Physics, Cambridge, United Kingdom

<sup>4</sup>University of Cambridge, Oncology, Cambridge, United Kingdom

#### Purpose or Objective

Assessment of the quality of contours produced by automatic methods is labour-intensive and inherently dependant on the skills of the evaluator. The utilisation of these contours in radiotherapy requires objective quality metrics and efficient tools for contour quality assurance. We present a method to determine the quality of automated rectum contours on daily image guidance scans (IG).

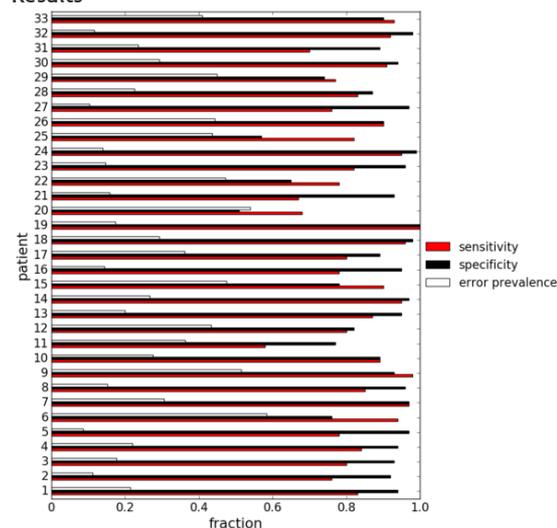

#### Material and Methods

We analysed 11519 automatically produced rectum contours on 1062 pelvic IG scans of 33 prostate cancer patients. Each contour was evaluated by 1) a trained clinician and 2) an automated classification software that applied a set of binary and numeric metrics to each contour. The metrics included 1) centre-to-centre contour distances, 2) differences in contour areas between

adjacent contours, 3) conformity index (CI) between adjacent contours, 4) presence of air or bone across the line of the contour, 5) presence of air or bone within 5 mm outside of the contour boundary, and 6) presence of spacing > 20 mm between adjacent contour points.

The threshold values for the metrics 1-3 were calculated from the rectum contours drawn by oncology experts on 315 pelvic KVCT scans, where we used 6 mm superior-inferior contour spacing to match the slice spacing of the IG scans. The settings for metrics 4-6 were determined empirically. Our software developed in Python 2.7 analysed the DICOM RTSTRUCT and IG scan data, applied the metrics and recorded the evaluation results in a spreadsheet. A contour was marked as "error" if any of the thresholds defined in the metrics was triggered.

## Results

The automatic evaluation of 11519 contours for 33 patients took 6 minutes on a computer with 8 GB RAM and 1.6 GHz Intel Xeon CPU. The evaluation results were compared to the errors recorded by a human observer, and confusion matrices were calculated. The mean error prevalence in the observer evaluation was  $0.29 \pm 0.1$ . Our algorithm achieved a mean sensitivity of  $0.84 \pm 0.1$  (range [0.58 - 1.0]) and a mean specificity of  $0.88 \pm 0.1$  (range [0.51 - 1.0]). One patient data set totalling 339 slices was evaluated with a sensitivity and specificity of 1.0.

## Conclusion

Metric-based evaluation of rectum contours is a feasible alternative to evaluation of contours by a human observer. It provides an unbiased contour classification and detects over 80% of typical errors in the contours. The method can be used to assess the performance of automated contouring tools and to aid the development of improved contouring software.

### PO-0893 Improving CBCT image quality for daily image guidance of patients with head/neck and prostate cancer

I. Chetty<sup>1</sup>, P. Paysan<sup>2</sup>, F. Siddiqui<sup>1</sup>, M. Weihua<sup>1</sup>, M. Brehm<sup>2</sup>, P. Messmer<sup>2</sup>, A. Maslowski<sup>3</sup>, A. Wang<sup>3</sup>, D. Seghers<sup>2</sup>, P. Munro<sup>2</sup>

<sup>1</sup>Henry Ford Health System, Radiation Oncology, Detroit, USA

<sup>2</sup>Varian Medical Systems Imaging Laboratory GmbH, Image Enhancement and Reconstruction, Baden-Daettwil, Switzerland

<sup>3</sup>Varian Medical Systems- Inc., Oncology Systems, Palo Alto, USA

#### Purpose or Objective

Image quality of on-board CBCT imaging in radiation therapy generally falls short of diagnostic CT in particular

in terms of low contrast visibility. This limits the application of CBCT mainly to patient setup based on high contrast structures. We address these limitations by applying advanced preprocessing and reconstruction algorithms to improve patient setup and facilitate advanced applications like adaptive radiotherapy.

#### Material and Methods

The commercially available TrueBeam CBCT reconstruction pipeline removes scatter using a kernel-based correction followed by filtered back-projection-based reconstruction (FDK). These reconstruction pipeline steps are replaced by a physics-based scatter correction (pelvis only) and an iterative reconstruction. We use statistical reconstruction that takes the Poisson distribution of quantum noise into account, and applies an edge preserving image regularization. The advanced scatter correction is based on a finite-element solver (AcurosCTS) to model the behavior of photons as they pass (and scatter) through the object. Both algorithms have been implemented on a GPU cluster platform, and algorithmic acceleration techniques are utilized to achieve clinically acceptable reconstruction times. The image quality improvements have been analyzed on TrueBeam kV imaging system phantom scans, as well as on daily CBCT scans of head/neck and prostate cancer patients acquired for image-guided localization.

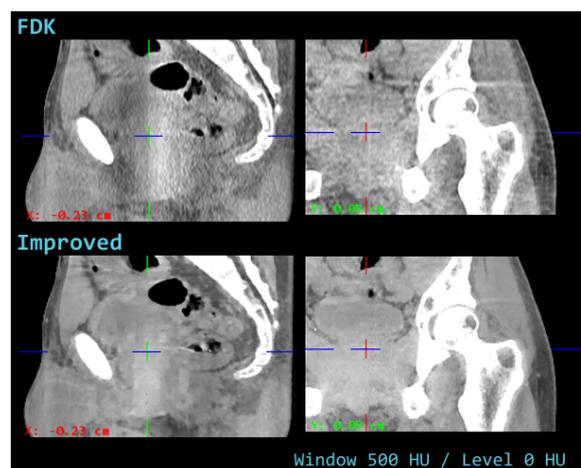

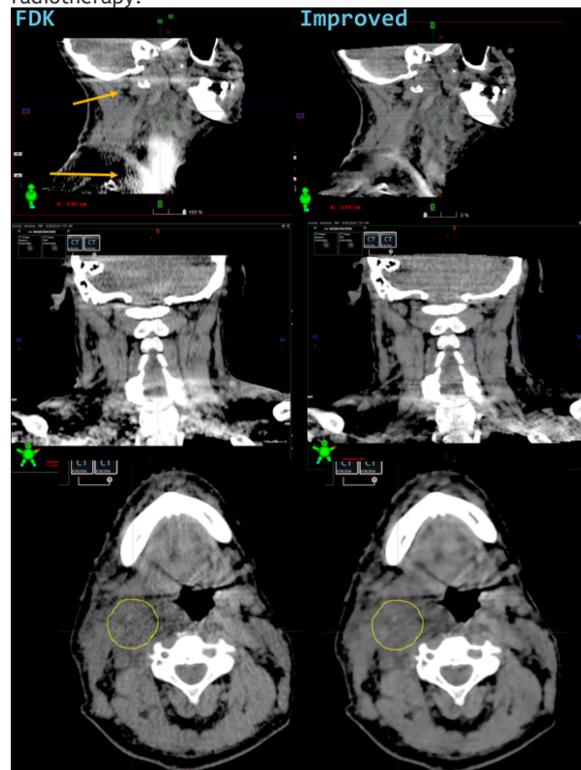

#### Results

Artifacts in head/neck FDK reconstructions (Fig. 1) e.g. resulting from photon starvation in the shoulder region or cone-beam are highly reduced in the iterative reconstructions. The iterative reconstructions show enhanced soft tissue definition providing better clarity for boundary definition (see the level 2 lymph node located in the contoured region of the axial view, Fig. 1). The advanced scatter correction applied for pelvis scans removes residual scatter artifacts, increasing the mean homogeneity from  $78.2 \text{ HU} \pm 18.0 \text{ HU}$  to  $20.9 \text{ HU} \pm 10.9 \text{ HU}$  within the bladder region of 9 daily CBCT scans of typical prostate patients. Iterative reconstruction provides further benefit by reducing image noise as well as eliminating streak and cone-beam artifacts, thereby significantly improving soft-tissue visualization, as noted in the clinical pelvis CBCT scan (Fig. 2). The noise level was reduced to 45% of the original value.

#### Conclusion

Statistical reconstruction in combination with advanced scatter correction substantially improves CBCT image quality by enabling removal of artifacts caused by remaining scatter, projection noise, photon starvation, and cone-beam angle. These artifact reductions improve soft tissue definition that is necessary for accurate visualization, contouring, dose calculation, and deformable image registration in clinical practice. The presented improvements are expected to facilitate soft tissue-based patient setup. Promise has been demonstrated for new applications, such as adaptive

radiotherapy.

#### PO-0894 Comparing the spatial integrity of 7T and 3T MR images for image-guided radiotherapy of brain tumors

<sup>4</sup>University Hospital RWTH Aachen University, Department of Nuclear Medicine, Aachen, Germany

<sup>5</sup>University Hospital Carl Gustav Carus at the Technische Universität Dresden, Department of Radiotherapy, Dresden, Germany

<sup>6</sup>OncoRay, National Center for Radiation Research in

Oncology, Dresden, Germany

<sup>7</sup>Institute of Radiooncology, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

### Purpose or Objective

In neuro-oncology, 3 Tesla (3T) MRI is the current clinical standard for tumor localization, radiotherapy volume delineation and stereotactic (radio)surgery, sometimes complemented by amino acid PET imaging. With superior SNR and image resolution, anatomical 7T MRI can visualize micro-vascularization in glioblastomas potentially allowing improved target volume delineation. However, concerns about geometrical distortion (GD) with increasing field strength ( $B_0$ ) are detrimental for applications of 7T MR in image-guided interventions. For high-precision treatment strategies, the spatial integrity of anatomical images needs to be warranted within  $\pm 1$ mm. The aim of the study was to evaluate  $B_0$ - and sequence-related GD in clinically relevant 7T sequences and compare it to equivalent 3T sequences and CT images

### Material and Methods

To quantify  $B_0$ - and sequence-related GD in T1-GRE, T1-TFE, T2-TSE, T2-TSE FLAIR on 7T and 3T sequences, a dedicated anthropomorphic head-phantom (CIRS Model 603A) was used. The phantom is composed of bone-/soft-tissue equivalent materials and contains a 3D grid (3mm rods spaced 15mm apart). System-based distortion correction methods were applied to restore the gradient uniformity of 3T and 7T. For all CT and MR images, 436 points of interests (POIs) were defined by manual reconstruction of the 3D grid points in the respective images. GD was assessed in 3 ways. Firstly, global GD was estimated by the mean absolute difference ( $MAD_{global}$ ) between the measured and the true Euclidian distances of all unique combinations of POIs, independent of location within the phantom. Secondly, local GD was assessed by  $MAD_{local}$  between the measured and the true Euclidian distances of all POIs relative to the magnetic field isocenter. Thirdly, a distortion map was created by evaluating 3D displacement vectors for each individual grid point

### Results

$MAD_{global}$  in 3T and 7T images ranged from 0.19–0.75mm and 0.27–1.91mm, respectively, and was more pronounced than in CT images. CT was not entirely free of GD with  $MAD_{global}$  ranging from 0.14–0.64mm.  $B_0$ -related GD was larger in 7T than in 3T MRI with  $MAD_{local}$  ranging from 0.21–1.81mm and 0.11–0.73mm, respectively ( $p < 0.05$ ).  $MAD_{local}$  increased with increasing distance from the magnetic isocenter and largest GDs were noted at the level of the skull (Fig. 1).  $MAD_{local}$  was  $< 1$ mm for all sequences up to 68.7mm from the isocenter. Sequence-related GD at 7T was prominent in T1-TFE and significantly differed from other 7T sequences ( $p < 0.001$ ). Figure 2 shows an anisotropic distribution of GD in T1-TFE with increasing GD along the frequency-encoding direction

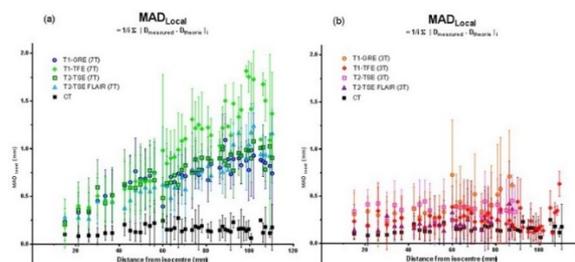

Figure 1:  $MAD_{local}$  values ( $\pm SD$ ) relative to the distance from the magnetic isocenter at 7T (a) and 3T (b), both relative to CT

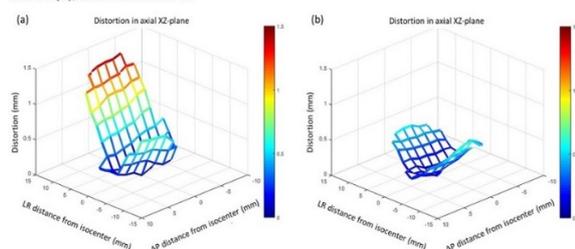

Figure 2: Distortion maps of a T1-TFE sequence at 7T (a) and at 3T (b) measured in the axial XZ-plane nearest the magnetic isocenter ( $Z=0$ )

### Conclusion

System-related GD was present in all 3T and 7T MR images but remained within the 2mm tolerance limit. Near the magnetic isocenter, 7T anatomical images showed no difference in geometric reliability to 3T MR images. Careful selection of 7T sequences and judicious use of GD correction methods can warrant the geometrical quality required for incorporation of 7T MR into image-guided interventions

### PO-0895 MRI-based analysis of volumetric changes of healthy brain tissue in glioma patients after photon RT

A. Gommlich<sup>1,2,3</sup>, H. Wahl<sup>4</sup>, F. Raschke<sup>2</sup>, M. Baumann<sup>1,2,3,5,6</sup>, M. Krause<sup>1,2,3,5,6</sup>, E.G.C. Troost<sup>1,2,3,5,6</sup>

<sup>3</sup>NCT - National Center for Tumor Diseases- partnersite Dresden- Germany, partnersite, Dresden, Germany

<sup>4</sup>Institute of Neuroradiology- University Hospital Carl Gustav Carus, Institute of Neuroradiology, Dresden, Germany

<sup>5</sup>University Hospital Carl Gustav Carus, Department of Radiotherapy and Radiation Oncology, Dresden, Germany

<sup>6</sup>DKTK - German Cancer Consortium, Partnersite, Dresden, Germany

### Purpose or Objective

State-of-the-art Linac-based photon beam irradiation achieves highly conformal target volume coverage in glioma patients, but is also known to cause side-effects to surrounding tissues and organs. Apart from subjective measures (e.g., questionnaires, function tests) objective means to quantify tissue damage, e.g., anatomical or functional magnetic resonance imaging (MRI) are urgently needed to compare different treatment techniques and beam qualities (e.g., protons vs. photons) and to develop predictive measures for optimal sparing of normal brain tissue. As initial part of our program for dose-dependent spatial mapping of structural and functional radiation induced brain damage, we assessed here a retrospectively collected MRI-dataset in order to potentially detect volumetric changes of the healthy brain tissue (gray and white matter) in the non-affected hemisphere of glioma patients treated with photon irradiation.

## Material and Methods

Structural MRI-scans (T1-weighted) from 18 glioma patients (grade II and III), who underwent high dose radio(chemo)therapy (54-60 Gy) with curative intent have been analyzed. MRIs were acquired before treatment and at several time intervals thereafter. Because of the individual characteristics of these data e.g., voxel size (0.5...6 mm<sup>3</sup>) and the field strength (1...3 T) a standardized image processing approach was developed. For bias field correction, registration with atlas data, resampling, and segmentation of different tissue types, image processing methods from the ANTs-, FSL- and SPM-toolbox were used, respectively. Based on these images the volumes of white matter and gray matter have been longitudinally analyzed.

## Results

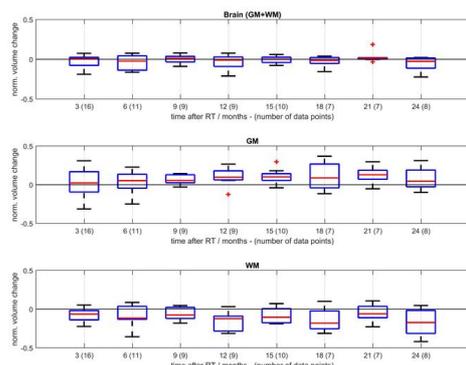

Figure 1 shows the changes of brain tissue volume depicted as box plots with the median values highlighted in red. While the entire brain volume on average remains constant over two years after therapy, in the same time period the volume of gray matter and white matter varies conversely in a wide range. Noteworthy, this work points out the difficulties of retrospectively analyzing clinically acquired data due to differences in acquisition parameters and in investigation intervals.

## Conclusion

The observed changes over time underpin the importance of exact follow-up protocols in quantitative evaluation of structural brain changes after radiotherapy. Together with the data on interpatient heterogeneity, our findings allowed to design a prospective study in a larger cohort of patients treated by photons vs. protons for assessing the dependence of MRI-detected volumetric changes with delivered dose.

**PO-0896 Quantitative MRI-based characterization of obturator muscles after prostate cancer radiotherapy**

<sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milano, Italy

<sup>4</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiology, Milano, Italy

<sup>5</sup>Università di Milano, Department of Oncology and Hemato-oncology, Milano, Italy

## Purpose or Objective

To investigate radiation-induced alterations in periprostatic muscles, such as internal obturators, in prostate cancer patients treated with external-beam radiotherapy (RT). These tissues are usually included in the high dose radiation field and can be involved in genitourinary toxicity. In this work, a texture analysis for

quantitative image-based structural tissue characterization was performed.

## Material and Methods

T2-weighted and T1-weighted MRI after contrast agent (CA) injection at 1.5T were acquired in thirteen patients before RT (MRI1) and at about 12 months of follow-up (MRI2). In order to reduce possible errors due to non-quantitative values of signal intensity, a normalization step was performed between MRI1 and MRI2 of each patient, using a histogram matching method.

Right and left internal obturator muscle contours were manually delineated upon T2w MRI1 by an expert and then automatically propagated on MRI2 by an elastic registration method.

The following textural features were extracted in each volume: histogram-based indices (mean intensity, variance, 95<sup>th</sup> percentile, entropy, skewness, kurtosis), GLCM (Grey-Level Co-occurrence Matrix)-based indices (energy, correlation, homogeneity, entropy, contrast, dissimilarity), NGTDM (Neighborhood Grey-Tone Different Matrix)-based indices (coarseness, contrast, busyness, complexity, strength) and fractal dimension.

To assess changes in internal obturator muscles, a comparison of the parameters extracted on MRI1 and MRI2 was carried out by Wilcoxon test, with significant p-value < 0.05.

## Results

Exemplificative T1w MRI1 and MRI2 with relative muscles histograms were shown in Figure 1. From a qualitative assessment, a homogenous higher enhanced area (red circle in Figure 1) was localized in MRI2 in a region near the prostate.

Quantitatively, significant increase in mean, variance and 95<sup>th</sup> percentile values on both T1w MRI and T2w MRI2 was also found, as well as variation of indices describing histogram shape as visible by the histograms reported in Figure 1.

Moreover, changes of GLCM and NGTDM-based indices confirmed that the spatial distribution of this intensity enhancement was concentrated in a homogeneous local area, as suggested by increased homogeneity and correlation indices and decreased complexity and fractal dimension (Table 1).

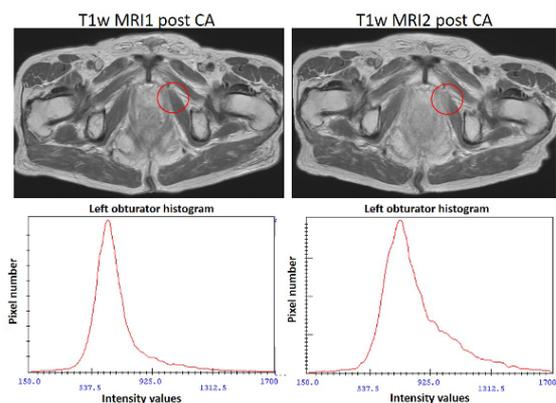

Figure 1. T1w-MRI before and after RT with the correspondent histograms of the left obturator muscles

\*\*  $p < 0.001$  – Wilcoxon test for paired samples

## Conclusion

In patients who underwent RT for prostate cancer treatment, an increase in signal intensity of the internal obturator muscles was observed. Specifically, this enhancement was concentrated in the area near the prostate, likely to be included in high dose regions. This evidence was present both in T2w and T1w post CA injection MRI and can be compatible with an inflammatory status that normally follows RT. This inhomogeneous structural variation may be explained by the spatial dose distribution. Moreover, correlations with toxicity scores should be investigated, considering the involvement of the pelvic floor muscles in the urinary dysfunctions.

## PO-0897 Atlas-based auto-segmentation of heart structures in breast cancer patients

R. Kaderka<sup>1</sup>, R. Mundt<sup>1</sup>, A. Bryant<sup>1</sup>, E. Gillespie<sup>1</sup>, B. Eastman<sup>1</sup>, T. Atwood<sup>1</sup>, J. Murphy<sup>1</sup>

<sup>1</sup>University of California San Diego, Department of 858-822-4842, San Diego, USA

## Purpose or Objective

Radiation therapy deposited in the heart increases the risk of ischemic heart disease, and sudden cardiac death. Reproducible contouring of the heart on CT imaging represents a critical component of treatment planning, though the literature demonstrates substantial variability in contouring among providers. In this study we assess the accuracy of an atlas-based auto-segmentation approach of the whole heart and the left anterior descending artery (LAD).

## Material and Methods

We randomly selected a cohort of 38 breast cancer radiotherapy patients treated between 2014 and 2016. For all patients the whole heart and LAD were manually contoured according to guidelines published by Feng et al. (2011). The patients were divided into a training dataset (N=18), and a test dataset (N=20). We used the training dataset to create a contouring atlas using commercially

available imaging software (MIM Vista, Cleveland OH). On the test dataset the agreement between the manually drawn gold standard contours and atlas-based auto-segmented contours was measured with a Dice-coefficient. To determine the impact of auto-segmented contours on dosimetry calculations we determined the mean radiation dose for the manual contours and the auto-segmented contours for left-sided breast cancer patients. Differences in dose between the two contours were expressed with mean absolute errors.

## Results

Within the test dataset the atlas-based auto-segmentation approach accurately delineated the heart with a Dice-coefficient of  $0.87 \pm 0.06$  (mean  $\pm$  standard deviation). Auto-segmentation was much less accurate for the LAD with a Dice-coefficient of  $0.05 \pm 0.06$ . Among left-sided breast cancer patients the mean heart dose was  $1.2 \pm 0.9$  Gy for the manually contoured heart, and  $2.7 \pm 0.9$  Gy for the manually contoured LAD. The auto-segmented mean heart dose was similar to the manually contoured mean heart dose, with a mean absolute error of  $0.1 \pm 0.2$  Gy (range 0.0 - 0.7 Gy). The auto-segmented mean LAD dose differed moderately from the manual contoured mean LAD dose, with a mean absolute error of  $1.0 \pm 1.2$  Gy (range 0.0 - 1.7 Gy). There were no statistically significant differences between the manual contours and the automated-contours for either the whole heart ( $p=0.78$  by Wilcoxon-rank sum test), or the LAD ( $p=0.85$ ).

## Conclusion

This study demonstrates that atlas-based auto-segmentation accurately delineates the whole heart, though less accurately captures the LAD. The high concordance in mean heart dose between the manual contours and automated contours suggests that atlas-based auto-segmented contours could play a role in radiation treatment planning.

**Purpose or Objective**

To internally and externally validate an atlas based automated segmentation (ABAS) tool for loco-regional radiation therapy of early breast cancer based on the ESTRO consensus guideline for target volume delineation.

**Material and Methods**

Structures of 60 patients manually delineated according to the ESTRO consensus guideline were included in four categorized multi-atlas libraries (based on laterality and surgery) using MIM Maestro™ software. These libraries were used for automated segmentation of primary and nodal target volumes and organs at risk. Internal Validation of ABAS was done by comparing ABAS before and after correction against a gold standard manual segmentation (MS) in 50 patients from the local institution using Dice Similarity Coefficient (DSC), Average Hausdorff Distance (AHD), difference in volume (ΔV) and time. External validation was done by comparing ABAS without correction against MS in 40 patients from other institutions using DSC and AHD. In the internal validation phase MS and correction of ABAS was performed by only one observer, while in the external validation phase MS was performed by multiple observers from 10 different institutions.

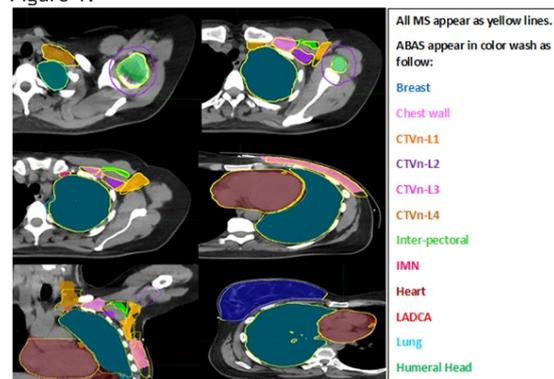

**Results**

ABAS reduced the time of MS before and after correction by 93% and 32%, respectively. In the internal validation phase, ABAS showed high agreement with MS for lung, heart, breast and humeral head, moderate agreement for chest wall and axillary nodal levels and poor agreement for inter-pectoral, internal mammary nodal regions and left anterior descending coronary artery (Figure 1). Correcting ABAS significantly improved all the parameters defined as increased DSC and decreased AHD and ΔV. Applying ABAS in an external group of patients with different arm positions, immobilization techniques and respiratory gating status showed comparable results (Table 1).

Figure 1.

**Conclusion**

ABAS is a clinically useful tool for segmenting structures in breast cancer loco-regional radiation therapy in a multi-institutional setting. The introduction of ABAS in daily clinical practice will significantly reduce the workload especially in departments where the radiation therapy technologists (RTTs) are responsible for target volume delineation and treatment planning. Manual correction of some structures is important before clinical use. Moreover, applying ABAS may be a reasonable alternative for consistent segmentation and easy quality assurance testing in multi-institutional trials. Careful selection and stratification of atlas subjects seems to be the most influencing factor in the outcome of the ABAS. Further investigation to find out the best stratification factors is encouraged. Based on these results, ABAS is now made available for Danish patients.

**PO-0899 Tumor volume delineation using non-EPI diffusion weighted MRI and FDG-PET in head-and-neck patients.**

B. Peltenburg<sup>1</sup>, T. Schakel<sup>1</sup>, J.W. Dankbaar<sup>2</sup>, M. Aristophanous<sup>3</sup>, C.H.J. Terhaard<sup>1</sup>, J.M. Hoogduin<sup>2</sup>, M.E.P. Philippens<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands  
<sup>2</sup>UMC Utrecht, Radiology, Utrecht, The Netherlands  
<sup>3</sup>MD Anderson Cancer Center, Radiation Physics, Houston, USA

**Purpose or Objective**

Diffusion weighted (DW) MRI shows high contrast between tumor and the surrounding tissue, which makes it a candidate to facilitate target volume delineation in head-and-neck (HN) radiotherapy treatment planning. In this study we assess the performance of geometrically undistorted DW MRI for target delineation in terms of interobserver agreement and spatial concordance with automatic delineation on <sup>18</sup>F-fluorodeoxyglucose (FDG) positron emission tomography (PET).

**Material and Methods**

Fifteen head-and-neck cancer patients underwent both standard echo-planar imaging based (EPI) and undistorted fast spin-echo based (SPLICE) DW MRI in addition to FDG-PET for RT treatment planning. Target delineation on DW MRI was performed by 3 observers, while for PET a semi-automatic segmentation was performed using a Gaussian mixture model. Volumes, overlap metrics, defined as dice similarity coefficient and generalized conformity index, and hausdorff distances were calculated from the delineations.

**Results**

The median volumes delineated by the 3 observers on DW MRI were 10.8, 10.5 and 9.0 mL respectively. The median conformity index over all patients was 0.73 (range 0.38 - 0.80). On PET, a significantly smaller median volume of 8.0 mL was found. Compared with PET, the delineations

by the 3 observers showed a median dice similarity coefficient of 0.71, 0.69 and 0.72 respectively. For all 3 observers the mean hausdorff distance was small with median (range) distances between PET and DW of 2.3 (1.5 - 6.8), 2.5 (1.6 - 6.9) and 2.0 (1.35 - 7.6) mm respectively. Over all patients, the median 95<sup>th</sup> percentile distances were 6.0 (3.0 - 13.4), 6.6 (4.0 - 24.0) and 5.3 (3.4 - 26.0) mm.

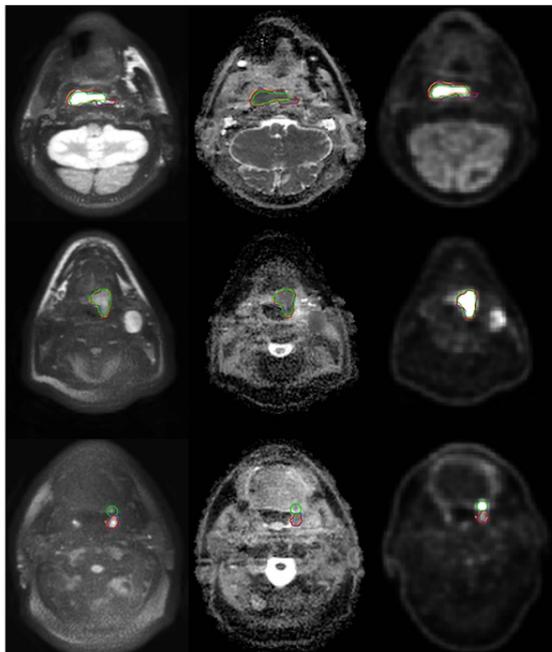

Figure 1: Patient examples showing the correspondence of the delineated target volumes. Each row of images is from a single patient and shows transverse slices with, from left to right: DW b800; ADC map; FDG-PET. The delineations from FDG-PET (green) and the three observers (red, blue, orange) are shown on all imaging.

### Conclusion

Diffusion weighted imaging optimized for geometric accuracy resulted in target volume delineation with good interobserver agreement and a large similarity with PET.

### PO-0900 Quantifying the Effect of MRI Geometrical Distortions on Radiotherapy Treatment Planning Doses.

M. Adjeiwaah<sup>1</sup>, M. Bylund<sup>1</sup>, J. Lundman<sup>1</sup>, J. Jonsson<sup>1</sup>, T. Nyholm<sup>1</sup>

<sup>1</sup>Umeå University, Radiation Sciences, Umeå, Sweden

### Purpose or Objective

The use of MRI for Radiotherapy Treatment Planning (RTP) is increasing and the proposed MR-only workflow could be beneficial. One worry of an MR-only RTP is geometrical distortions. There are at present few studies focusing on the effect of MR geometrical distortions on planned doses in an MR-only treatment planning and to our knowledge, none fully takes into account both gradient non-linearities and Patient-induced Susceptibility effects. This study focused on quantifying the effect of gradient non-linearities and Patient-induced Susceptibility effects on dose distributions for Prostate Cancers.

### Material and Methods

The deformation field was generated by adding measured machine-specific and simulated patient-induced susceptibility effect deformation fields for a 3T scanner as shown in Fig. 1. Different bandwidths and simulated gradient readouts in the anterior/posterior (A/P) and right/left (R/L) directions were used. To isolate the effect of the distortions, the deformation fields were applied to 17 Prostate Patient CT images and their corresponding clinically delineated structures, giving a distorted CT (dCT). VMAT optimized plans were generated for all distorted cases and recalculated on the undistorted CT

images. Plans optimized on the realistically distorted data and undistorted data were compared based on their DVH and the two one-sided equivalence test (TOST).

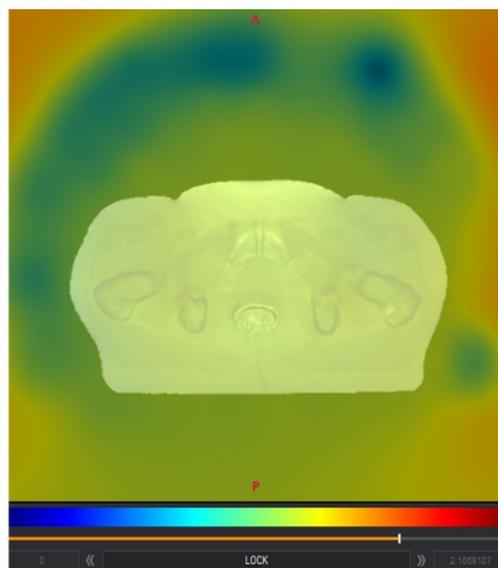

Fig.1 Combined Deformation field from gradient non-linearities and patient Susceptibilities

### Results

Increasing the bandwidth reduced the distortions. Moving from 122 to 244 Hz/Pixel decreased the maximum distortions by 43% and reduced the absolute difference in doses to the PTV between dCT and CT plans from  $0.417 \pm 0.241$  Gy to  $0.129 \pm 0.286$  Gy in the R/L gradient readout direction. However, this increase in bandwidth did not significantly affect the difference in doses in the A/P readout direction:  $0.347 \pm 0.150$  Gy and  $0.362 \pm 0.240$  Gy respectively. We found a difference of 1.2% and 1.9% between dCT and undistorted plans for gradient readout in R/L and A/P directions for the rectal volume receiving more than 69 Gy. The equivalence test on the two plans showed the 90% Confidence Interval all lied within the equivalence intervals (-0.6, 0.6) Gy for difference in PTV mean doses and (-1, 1) % for difference in the relative volume of the PTV and Rectum with a 0.05 significance.

### Conclusion

By combining measured Machine-specific and simulating Patient-induced Susceptibility effects we have successfully investigated their combined effect on dose distributions for Prostate cancer treatment plans. Our results showed that dose errors due to disturbed Patient outline and shifts due to Patient-induced Susceptibility effects at Prostate/Rectum interfaces caused by gas in the Rectum were small. The smallest effect was found for high bandwidth and readout in the R/L direction. Equivalence tests showed equivalence within our investigated equivalence intervals at 0.05 alpha level for all studied dose distribution quality indicators.

### PO-0901 Is MRI in immobilization mask necessary for brain metastasis patients?

A. Van Lier<sup>1</sup>, A. De Boer<sup>1</sup>, M. Kramer<sup>1</sup>, G. Fa netti<sup>2</sup>, W. Eppinga<sup>1</sup>, J.J.C. Verhoeff<sup>1</sup>, M. Philippens<sup>1</sup>, E. Seravalli<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

<sup>2</sup>European Institute of Oncology, Department of Radiation Oncology, Milan, Italy

### Purpose or Objective

To investigate the necessity of performing MRI in treatment position (ie. with immobilization mask) for brain metastasis patients.

**Material and Methods**

Ten patients who were referred for brain metastasis radiosurgery were analysed in this study. A planning CT (1 mm slice thickness), a contrast-enhanced T1 3D MRI scan (1.5T, 1 mm isotropic voxel size, surface coils) with patient immobilized in a 3-point thermoplastic shell (mask-MR) and a contrast-enhanced T1 3D MRI scan (1.5T, 1 mm isotropic voxel size, multi-channel head coil) without immobilization mask (no mask-MR) were acquired. First, a clinician stated which of the MRI scans had superior quality, to assure that the no-mask MR had at least the same image quality compared to the clinically used mask-MR. Then, the two MRIs were registered independently to the planning CT by a normalized mutual information algorithm which was restricted to rigid registration. The GTV was delineated by 3 clinicians on 1) mask-MR and 2) no mask-MR. The brain stem, chiasm and right eye were delineated by one clinician. Furthermore, 8 well-defined landmarks were marked by an observer in both scans. Residual registration errors were estimated for both MRIs by measuring the absolute coordinate differences in the three orthogonal directions between the set of landmarks on both imaging series after registration. Moreover, the absolute differences in the centres-of-gravity coordinates of GTV (median of 3 observers), brain stem, chiasm and right eye on mask-MR and no mask-MR were compared.

**Results**

The no mask-MR image quality was found to be superior in 9 of the 10 patients. The average coordinate difference between mask-MR and no mask-MR for all landmarks along the three orthogonal directions were within 0.5 mm (table 1). Similar results were found for the coordinates of the centre-of-gravity of all delineated OARs and GTV. Deviations in OAR registration > 1mm could be attributed to variations in delineation (figure 1). Only in one case, a registration error was observed. All GTV deviations were within 1mm.

Distance between mask-MR and no-mask MR after registration

	Landmarks coordinates				Centre-of-gravity OAR's				Centre-of-gravity GTV			
	x	y	z	vector	x	y	z	vector	x	y	z	vector
	mm	mm	mm	mm	mm	mm	mm	mm	mm	mm	mm	mm
average	0.5	0.3	0.3	0.9	0.2	0.3	0.4	0.6	0.3	0.3	0.4	0.6
st. dev.	0.5	0.4	0.6	0.7	0.2	0.3	0.5	0.5	0.3	0.2	0.2	0.6
minimum	0.0	0.0	0.0	0.8	0.0	0.0	0.0	0.1	0.0	0.1	0.1	0.2
maximum	1.6	1.6	2.0	2.5	0.9	1.4	2.6	2.7	0.8	0.5	0.7	1.1

**Conclusion**

The registration of MRIs obtained with or without immobilization mask to a planning-CT generally differs less than the MRI resolution (1 mm isotropic). Therefore, immobilization of the head during MRI for patients undergoing radiotherapy of brain metastasis is not necessary.

However, to guarantee high accuracy of image registration when omitting an immobilization device during MRI, more attention should be paid to the quality of MR-CT fusion. Furthermore, consecutive MR images should be matched separately to CT, to correct for intra-scan motion.

We foresee two benefits of scanning without mask. Firstly, the patient comfort during the MRI scan sessions will be improved. Secondly, omission of the immobilization mask permits the use of a multi-channel head coil which results in higher image quality. Moreover, using a head coil allows for introduction of MRI techniques which require high signal-to-noise ratios or acceleration (e.g. DWI and FLAIR).

**PO-0902 Identifying the dominant prostate cancer focal lesion using 3D image texture analysis**

D. Montgomery<sup>1</sup>, K. Cheng<sup>1</sup>, Y. Feng<sup>1</sup>, D.B. McLaren<sup>2</sup>, S. McLaughlin<sup>3</sup>, W. Nailon<sup>1</sup>

<sup>1</sup>Edinburgh Cancer Centre Western General Hospital, Department of Oncology Physics, Edinburgh, United Kingdom

<sup>2</sup>Edinburgh Cancer Centre Western General Hospital, Department of Clinical Oncology, Edinburgh, United Kingdom

<sup>3</sup>Heriot Watt University, School of Engineering and Physical Sciences, Edinburgh, United Kingdom

**Purpose or Objective**

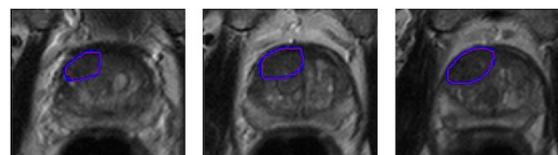

Prostate cancer is one of the few solid organs where radiotherapy is applied to the whole organ. This is because accurately identifying the dominant cancer foci on magnetic resonance (MR) images, which can then be mapped onto computerised tomography (CT) images for radiotherapy planning, is difficult. The aim of this study was to investigate the use of three-dimensional (3D) texture analysis for automatically identifying the dominant cancer foci on MR images acquired for diagnosis and prior to the administration of androgen deprivation therapy, which may shrink the tumour foci.

**Material and Methods**

On 14 patients with confirmed prostate cancer, 3D image texture analysis was carried out on T2-weighted MR images acquired for diagnosis on a Symphony 1.5T scanner (Siemens, Erlangen, Germany). The prostate, bladder, rectum and the location of the main cancer foci were outlined on all images. In 5x5x5 pixel<sup>3</sup> volumes within the prostate 446 3D texture analysis features were calculated. These features were used to train an AdaBoost model, which was used to predict the class of each 5x5x5 region as either 'prostate' or 'focal lesion.' Morphological filtering was applied to each region to remove invalid elements and to clean the final outline. The Dice similarity coefficient was used to assess the agreement between the clinical and predicted contours.

**Results**

Figure 1 shows an example of a contour produced by the algorithm where the Dice similarity coefficient was 0.98. Table 1 shows the Dice coefficients calculated between the clinical contours and the contours predicted by 3D image analysis. 11 of the 14 cases had a Dice score greater than 0.65 and 8 of the 14 cases had a score greater than 0.9, indicating good agreement between the clinical and predicted contours. In 3 cases the image analysis technique failed to identify the focal lesion.

**Figure 1:** Clinical contour in blue and predicted contour generated by 3D texture analysis shown in red on three T2-weighted MR images from the same patient (Patient 6).

Patient ID	1	2	4	5	6	8	9	10	11	12	14	15	16	18
Dice	0.80	0.96	0.99	0.98	0.98	0.76	0.98	0	0	0	0.96	0.68	0.96	0.95

**Table 1:** Dice coefficient between the clinical contours and the contours predicted by image analysis.

**Conclusion**

The 3D image analysis results presented are encouraging and demonstrate the potential of this approach for automatically identifying focal disease on T2-weighted MR images. However, further investigation is required to establish why the approach fails in certain circumstances

and to establish the performance of the approach on a much larger patient cohort.

#### PO-0903 Patient-induced susceptibility effects simulation in magnetic resonance imaging

J.A. Lundman<sup>1</sup>, M. Bylund<sup>1</sup>, A. Garpebring<sup>1</sup>, C. Thellenberg Karlsson<sup>1</sup>, T. Nyholm<sup>1</sup>  
<sup>1</sup>Umeå University, Department of Radiation Sciences, Umeå, Sweden

##### Purpose or Objective

The role of MRI is increasing in radiotherapy. A fundamental requirement for safe use of MRI in radiotherapy is geometrical accuracy. One factor that can introduce geometrical distortion is patient-induced susceptibility effects. This work aims at developing a method for simulating these distortions. The specific goal being to objectively identify a balanced acquisition bandwidth, keeping these distortions within acceptable limits for radiotherapy.

##### Material and Methods

A simulation algorithm based on Maxwell's equations and calculations of shift in the local B-field was implemented as a dedicated node in Medical Interactive Creative Environment (MICE), which is available as a free download. The algorithm was validated by comparison between the simulations and analytical solutions on digital phantoms. Simulations were then performed for four body regions using CT images for eight prostate cancer patients. For these patient images, CT Hounsfield units were converted into magnetic susceptibility values for the corresponding tissues, and run through the algorithm.

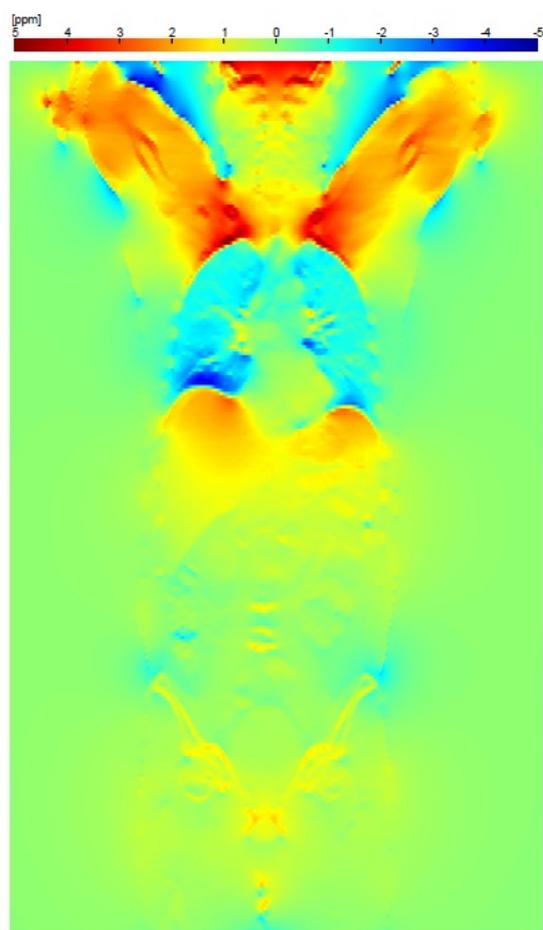

Figure 1: Simulated normalized local B-field for one of the patients [ppm].

##### Results

The digital phantom simulations showed good agreement with analytical solutions, with only small discrepancies due to pixelation of the phantoms. For a bandwidth of 440 Hz at 3 T, the calculated distortions in the patient-based images showed maximal 95th percentile distortions of 0.39, 0.32, 0.28, and 0.25 pixels for the neck, lungs, thorax with the lungs excluded, and pelvic region, respectively. In order to accommodate other field strengths and bandwidths, normalized displacement values were also simulated for these body regions.

Table 1: Simulated displacement values normalized to field strength and bandwidth [pixels \* BW / B0]

Area	Median	95 <sup>th</sup> %-ile	Max
Pelvis	6.7 - 10.5	18.9 - 37.1	101.1 - 124.8
Thorax excl. lungs	8.4 - 16.9	24.4 - 41.5	114.4 - 186.2
Lungs	3.0 - 19.2	11.2 - 46.6	31.9 - 165.6
Neck	12.6 - 25.7	37.1 - 57.7	114.1 - 167.5

##### Conclusion

The 95th percentile of the patient-induced susceptibility distortions can be kept below 0.5 pixels for a 3 T system and 440 Hz bandwidth. With the provided normalized data, distortions for other field strengths and bandwidths can be calculated. The developed simulation software can also be used to quickly and easily estimate the susceptibility-based distortions from a given series of patient CT images that are converted into susceptibility values, or directly from a susceptibility map.

#### PO-0904 Development of an MRI-protocol for radiotherapy treatment guidance in gastric cancer

V.W.J. Van Pelt<sup>1</sup>, M.F. Kruis<sup>1</sup>, T. Van de Lindt<sup>1</sup>, L.C. Ter Beek<sup>2</sup>, M. Verheij<sup>1</sup>, U.A. Van der Heide<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

<sup>2</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiology, Amsterdam, The Netherlands

##### Purpose or Objective

Because of the superior soft-tissue contrast of MRI, integration of MRI in pre-operative radiotherapy (RT) for gastric cancer, is expected to improve the identification of shape and position of the target volume. MRI of the stomach is technically challenging due to respiratory, cardiac and bowel motion. In this study we therefore developed a scan protocol consisting of anatomical and functional sequences for staging and target delineation (TD), for treatment planning (TP) including motion modeling and for intra-fraction motion monitoring (MM).

##### Material and Methods

For staging and TD we compared high resolution (HR) T2-weighted (T2w) turbo spin echo (TSE) MRI, applying either navigator or respiratory sensor triggering during the exhale position of the diaphragm to reduce motion artifacts. For TP, the feasibility of a fast 3D HR mDixon with a large Field of View (FoV) within one exhale breath-hold (BH) was evaluated. For motion modeling, a 4D T2w MRI with retrospective self-sorting reconstruction was tested for robustness [1]. For intra-fraction MM, 2D T1w dynamic turbo field echo (TFE), fast field echo (FFE) and TSE Cine-MRI with a refocusing pulse were compared. For staging and treatment response monitoring, a single-shot echo planar Diffusion Weighted Imaging (DWI) was tested using b-values of 0, 200 and 800 s/mm<sup>2</sup>, applying either free-breathing (FB), BH, navigator or respiratory triggering. For Dynamic contrast enhanced (DCE) MRI, FB T1w spoiled gradient echo, 4D mDixon and 4D THRIVE with keyhole technique were compared. Subtraction images

were reconstructed to show the uptake of intravenous contrast agent.

The sequences were tested on healthy volunteers and one patient using a 3T MR system (Ingenia; Philips Healthcare, The Netherlands) and reviewed by two MR-experts and one radiologist. Pineapple juice was given orally to distend the stomach and suppress signal from the stomach filling. Gadolinium was used as intravenous contrast agent for the patient only. **Results**

Visual inspection showed that for TD and staging, T2w exhale respiratory navigator triggered, rather than a respiratory sensor, provides excellent contrast with limited motion artifacts. For TP, mDixon with a large FoV, a high signal to noise ratio (SNR) and HR in one BH is feasible. For motion modeling, 4D T2w MRI resulted in a good slice ordering, high SNR and HR. For MM, TSE Cine-MRI gave a good SNR and HR without artifacts. For staging and treatment response monitoring, FB DWI with an increased number of averages gave the best result, only limited motion and susceptibility artifacts were visible. FB 4D THRIVE DCE resulted in a good temporal resolution and limited motion artifacts. (Figure 1)

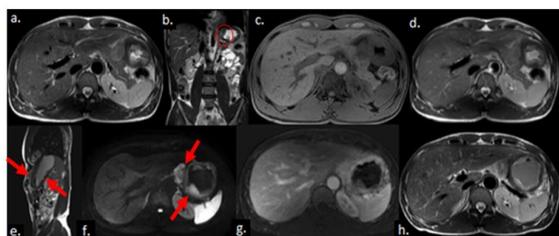

Figure 1. Patient data. The red arrows and circle indicate the tumor, all images are presented in the same slice.

a. Axial T2w TSE navigator triggered in exhale b. Coronal T2-weighted TSE navigator triggered in exhale c. 3D mDixon BH in exhale d. Axial 4D T2w TSE e. Sagittal Cine MRI f. Axial FB DWI b 800 s/mm<sup>2</sup> g. Axial 4D THRIVE DCE subtracted 1.25 min post-injection and base line h. Axial T2w TSE navigator triggered in exhale. Figure 1 e-h are with pineapple juice.

## Conclusion

We developed a comprehensive imaging protocol for the entire RT guidance treatment chain. The complex motion artifacts were reduced by applying either navigator triggering or BH techniques. The new gastric cancer protocol looks therefore very promising and will be used for MR-based delineation for RT.

[1] van de Lindt T, et al. ESTRO 35 2016 Abstract-book:PV-0325; 171-172

## PO-0905 (Semi-)Automatic contouring strategies for rectal boost treatment on the MR-Linac

C.N. Nomden<sup>1</sup>, M.P.W. Intven<sup>1</sup>, A.N.T.J. Kotte<sup>1</sup>, I.H. Kiekebosch<sup>1</sup>, S. Mook<sup>1</sup>, I.M. Jürgenliemk-Schulz<sup>1</sup>, G.G. Sikkes<sup>1</sup>, L.T.C. Meijers<sup>1</sup>, E.N. De Groot<sup>1</sup>, G.H. Bol<sup>1</sup>, B. Van Asselen<sup>1</sup>, L.G.W. Kerkmeijer<sup>1</sup>, B.W. Raaymakers<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands

### Purpose or Objective

The MR-Linac enables online treatment adaptations in response to changes in anatomy. This stresses the need for fast contouring strategies for target and OARs. Unfortunately, manual delineation in an online workflow is time consuming and therefore suboptimal. The purpose of this study was to investigate whether automatic and semi-automatic contouring strategies result in clinical acceptable contours for an online workflow on the MR-Linac.

### Material and Methods

Fifteen patients with early staged rectal cancer were scanned at an 1.5T MRI for five consecutive days. The scan consisted of a T2 weighted MRI; voxel size 0.63x0.63mm, slice thickness 4 mm and a total number of 30 slices. For each scan the following contours were delineated by an experienced radiation oncologist (manual contours): GTV, mesorectum, bladder, rectum, sphincter, gynecological

volume (in one contour: vagina, cervix and uterus), left and right femur. The manual contours of the first day were used as input for the automatic/semi-automatic contouring strategies. Automatic contouring software (ADMIRE research v1.13.5 Elekta AB, Stockholm, Sweden) was used for MR based deformable registration and contour propagation. For the automatic contouring strategy the daily propagated contours were based on an intra-patient atlas consisting of the manual contours of the first day and propagated contours of other previous days. The semi-automatic contouring strategy included additional manual adjustments made by a technologist after each daily automatic contour propagation serving as input for the following days. All automatic and semi-automatic contours were compared with the manual contours of the corresponding day by calculating dice coefficients, mean and Hausdorff distances. Timing measurements were done for both strategies.

### Results

Higher median dice coefficients with smaller ranges were found for the semi-automatic strategy compared to the automatic strategy (figure 1). However, large variations after manual adjustments were still found for the GTV. Outliers found in the mean and Hausdorff distances of the automatic strategy were not seen in the semi-automatic strategy (figure 2).

The contours were automatically propagated for day 2, 3, 4 and 5 in respectively 18, 38, 54 seconds and 1:13 minutes on average. The propagated contours of the semi-automatic strategy were manual adjusted with an average time of 14:49 minutes (in comparison with approximately 45 minutes for full manual contouring). Manual adjustments of the cranial and caudal slices of the contours were most time consuming.

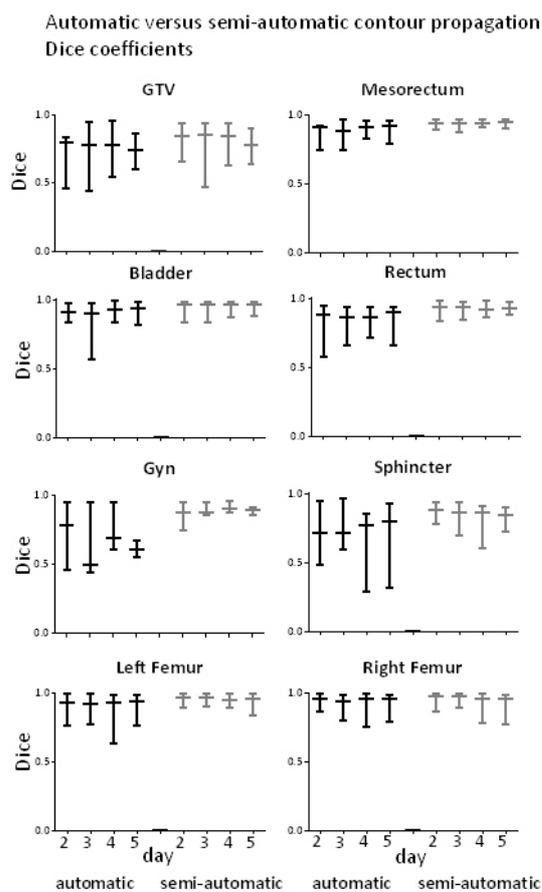

Figure 1 Dice coefficients (median and range) between automatic/semi-automatic contours and manual contours calculated for each day for target and OARs.

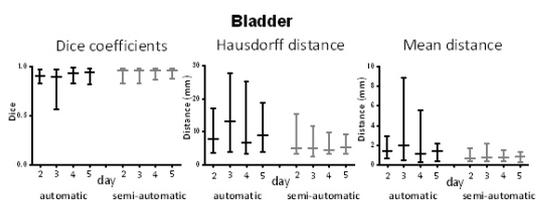

Figure 2 Dice coefficients, Hausdorff and mean distances (median and ranges) between automatic/semi-automatic contours and manual contours of the bladder. Bladder chosen as example to visualise large variation found in automatic contours compared with smaller variations in the semi-automatic contours.

**Conclusion**

Automatic propagated contours for target and OARs need manual adjustments for clinical acceptance. Mesorectum and OARs adjustments can be made by an experienced technologist and are not clinically relevant different from the manual contours of an experienced radiation oncologist. This semi-automatic contouring strategy can be used in an online workflow for rectal boost treatment, however further speed-optimisation is desirable.

**PO-0906 Textural analysis of MR images to improve the characterisation of recurrent prostate cancer**  
 J. Stirling<sup>1</sup>, R. Alonzi<sup>2</sup>, P.J. Hoskin<sup>2</sup>, N.J. Taylor<sup>1</sup>, W.L. Wong<sup>1</sup>, A.R. Padhani<sup>1</sup>, B. Sanghera<sup>1</sup>  
<sup>1</sup>Paul Strickland Scanner Centre, Research, Northwood, United Kingdom  
<sup>2</sup>Mount Vernon Hospital, Academic Oncology Unit, Northwood, United Kingdom

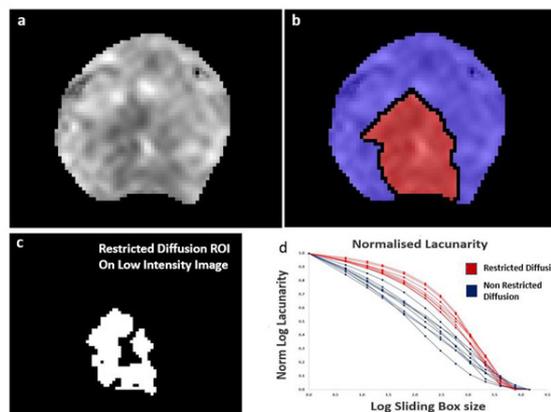

**Purpose or Objective**

MR has the ability to assess numerous physiological and biochemical tumour characteristics. Fractal analysis may provide a better insight into the biology and behaviour of prostate tumour than simplistic comparisons of multiparametric data. In this pilot study, we aim to determine whether fractal and lacunarity analysis can characterize the properties of radio-recurrent prostate cancer, using Apparent Diffusion Coefficient (ADC) MR Images.

**Material and Methods**

Retrospective analysis of eight patients with recurrent prostate cancer after previous radical radiotherapy (mean age: 71.25 years), underwent MRI examination for re-staging prior to consideration of salvage therapy. ADC images of the prostate were manually segmented from surrounding tissue and a region of interest (ROI) drawn to distinguish between restrictive diffusion and non-restrictive tissue (figure 1b). Low, medium and high ADC value maps were generated by intensity thresholding the respective restrictive and non-restrictive ROIs. These were processed and converted to 8-bit black and white images (figure 1c, low intensity in restrictive diffusion) for application to in-house textural analysis software (image 1d) to estimate (a) fractal dimension (b) fractal abundance and (c) lacunarity<sup>Curve1</sup>

Figure 1: (a) an ADC image of the prostate gland (b) an ADC image showing areas of restricted diffusion (red) and non-restricted diffusion (blue) (c) shows a binary image used for fractal and lacunarity analysis (d) lacunarity curves from restricted areas (red) and non-restricted areas (blue)

**Results**

The average fractal characteristics are summarised in table 1 with the fractal dimension between areas of restricted diffusion and non-restrictive diffusion of the low and medium intensity images being of significant difference (p=0.0014 and 0.0023 respectively). The fractal abundance of the medium intensity image between the restricted diffusion and non-restrictive diffusion was also significant (p=0.0012).

Table 1: The average patient for fractal Dimension and Abundance for the Low and Medium Intensity Images.

Patient	Low Intensity Image				Medium Intensity Image			
	Fractal Dimension		Fractal Abundance		Fractal Dimension		Fractal Abundance	
	Restricted Diffusion	Non Restricted Diffusion	Restricted Diffusion	Non Restricted Diffusion	Restricted Diffusion	Non Restricted Diffusion	Restricted Diffusion	Non Restricted Diffusion
Pt 1	1.551	1.046	5.477	4.638	1.146	1.557	4.189	6.372
Pt 2	1.391	1.063	3.799	3.812	0.145	1.532	0.327	6.036
Pt 3	1.291	0.791	3.868	2.99	0.831	1.521	2.707	6.347
Pt 4	1.426	0.507	5.082	2.562	0.757	1.172	2.305	4.347
Pt 5	1.512	0.581	4.997	2.597	1.296	1.530	4.078	6.170
Pt 6	0.985	0.595	3.036	2.365	0.574	1.659	1.718	6.819
Pt 7	1.266	0.95	3.696	4.239	1.282	1.536	4.383	6.021
Pt 8	0.940	1.245	3.422	5.319	1.513	1.563	5.618	6.773
P Value	0.0014		0.0661		0.0023		0.0012	

## Conclusion

These preliminary data show that fractal and lacunarity analysis may be able to characterise areas of restricted diffusion and non-restrictive diffusion on ADC images. Restrictive diffusion often indicates areas of aggressive prostate tumour. This method could be used in future studies to investigate other MR sequence images where the visual difference between prostate tumour and normal tissue is not so obvious to the naked eye, or where simple analysis of multiparametric data fails to adequately characterise tumour biology.

**Poster: Physics track: Implementation of new technology, techniques, clinical protocols or trials (including QA & audit)**

### PO-0907 Remote auditing of IMRT/VMAT deliveries

N. Miri<sup>1</sup>, K. Legge<sup>2</sup>, J. Lehmann<sup>3</sup>, P. Vial<sup>4</sup>, B. Zwan<sup>5</sup>, P. Greer<sup>6</sup>

<sup>1</sup>University of Newcastle, School of Mathematical and Physical Sciences, Newcastle- NSW, Australia

<sup>2</sup>University of Newcastle, School of Mathematical and Physical Sciences, Newcastle, Australia

<sup>3</sup>Calvary Mater Newcastle Hospital, Radiation and Oncology, Newcastle, Australia

<sup>4</sup>Liverpool and Macarthur Cancer Therapy Centres, Department of Medical Physics, Sydney, Australia

<sup>5</sup>Gosford Hospital, Central Coast Cancer Centre, Gosford, Australia

<sup>6</sup>Calvary Mater Newcastle Hospital, Radiation and Oncology departement, Newcastle, Australia

## Purpose or Objective

**Purpose:** To perform a novel study on remote auditing of dose deliveries of VMAT/IMRT clinical trials of different radiotherapy centres. The assessment is undertaken using EPID images from the centres and a local 'signal to dose' conversion model.

## Material and Methods

**Methods:** The assessment included IMRT deliveries from 12 centres and VMAT deliveries from 6 centres. The centres downloaded benchmarking CT data sets and instructions to produce IMRT/VMAT trial plans, a head and neck (H&N) and post-prostatectomy (P-P) plan. Two virtual phantom data sets were provided for a flat and a cylindrical phantom. Trial plans were transferred to the phantoms; individual field/arcs at gantry zero on the flat phantom and the trial plan at actual gantry angles to the cylindrical phantom. EPID images acquired from a calibration plan were used to align and calibrate the EPID systems and model/correct EPID-linac sag. Integrated images were acquired for IMRT fields and cine images for VMAT arcs each cine image encompassing approximately 5 degrees. For 2D and 3D analysis, the images were converted to dose inside respectively the virtual flat and cylindrical phantom. The dose conversion was performed using an established model. To assess the delivered doses, the modelled dose was compared with corresponding TPS dose using the gamma function with all doses greater than 10% of the global maximum dose assessed.

## Results

At 3%/3mm, 2D analysis of the H&N plan resulted in 99.6% (SD: 0.1) and 99.1% (SD: 0.1) mean pass rates for respectively IMRT and VMAT deliveries. Similarly, the P-P plan analysis resulted in 99.7% (SD: 0.2) and 99.6% (SD: 0.3) mean pass rates for corresponding deliveries over the centres. 3D analysis, on the other hand, resulted in slightly lower pass rates. H&N deliveries resulted in 98.3% (SD: 0.2) and 96.4% (SD: 2.6) mean pass rates. The P-P plan assessment resulted in 98.3% (SD: 1.5) and 97.2% (SD: 1.3) mean pass rates. Using a more stringent criteria, 3%/2mm, the H&N analysis resulted in 92.2% (SD:1.9) and 93.3% (SD:5.4) mean pass rates and the P-P plan resulted in 94.0% (SD:4.3) and 95.6% (SD: 1.8) mean pass rates for

respectively IMRT and VMAT deliveries. For VMAT deliveries, slightly higher standard deviation was observed than IMRT.

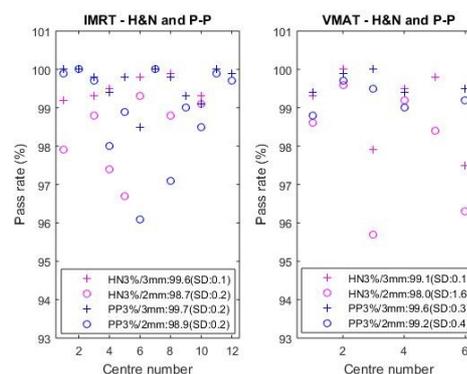

Figure 1- Planar dose assessment of the centres for head and neck and post-prostatectomy plans: a) IMRT delivery, b) VMAT delivery

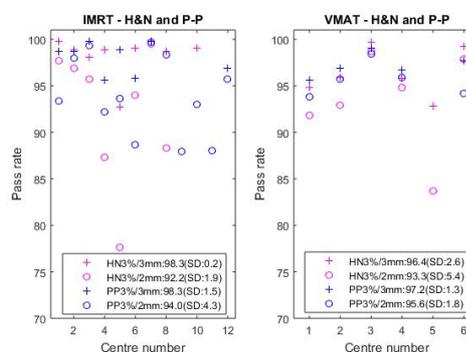

Figure 2- 3D dose assessment of the centres for head and neck and post-prostatectomy plans and: a) IMRT delivery, b) VMAT delivery

## Conclusion

All linacs were equipped with EPIDs so a consistent detection system was used by the centres. The method was significantly less expensive and faster than conventional audits due to its remote nature and use of virtual phantoms. All measured data were analysable with relatively high pass rates. Interactive communications with centres was often necessary to ensure quality data were provided.

### PO-0908 Application of Failure Mode and Effects

Analysis to linac quality controls: advantages and limits

F. Bonfantini<sup>1</sup>, T. Giandini<sup>1</sup>, S. Meroni<sup>1</sup>, C. Stucchi<sup>1</sup>, M.

Carrara<sup>1</sup>, V. Mongioj<sup>1</sup>, I. Veronese<sup>2</sup>, E. Pignoli<sup>1</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical

Physics, Milan, Italy

<sup>2</sup>Università degli studi, Physics, Milan, Italy

## Purpose or Objective

The increased complexity of the modern linac-based radiotherapy requires more thorough quality assurance programs to reduce the risk of errors and ensure patient safety. However, these demands are cumbersome and the efforts should be optimized in order to take maximum advantage of the available resources. In this context, prospective methods for risk analysis, such as Failure Mode and Effects Analysis (FMEA), can be a useful tool. Aim of this work was to evaluate advantages and limits of the application of FMEA for the optimization of linac quality controls (QCs).

## Material and Methods

Each parameter tested by the QC was considered as a potential failure mode (FM) and a Risk Priority Number

(RPN) was calculated from the product of three indexes: likelihood of occurrence (O), severity of effect (S) and lack of detectability (D). Forty tests were examined just above the expected tolerance levels and indexes O, S, and D were scored from 1 (lowest risk) to 10 (highest risk) using two methods:

- 1) A survey was submitted to each of the medical physicists of our institute involved in the linac QC
- 2) The QC data over a period of three years were analyzed and some FMs were simulated with the treatment planning system.

The average RPN for each test was obtained taking into account both the methods. For each linac, the tests were then sorted by their frequency (daily, monthly or annual) and RPN value. Two different Varian linacs (DBX, Unique) were considered, the first used only for conformal therapy and the second one used essentially with volumetric modulated arc therapy (VMAT) technique.

**Results**

A high variability was found in the O-D-S scores of the survey, as shown in the box plots of figure 1 for the dosimetric tests of the Unique linac. Nevertheless, a lower variability was obtained for RPNs, highlighting at the same time the more relevant tests.

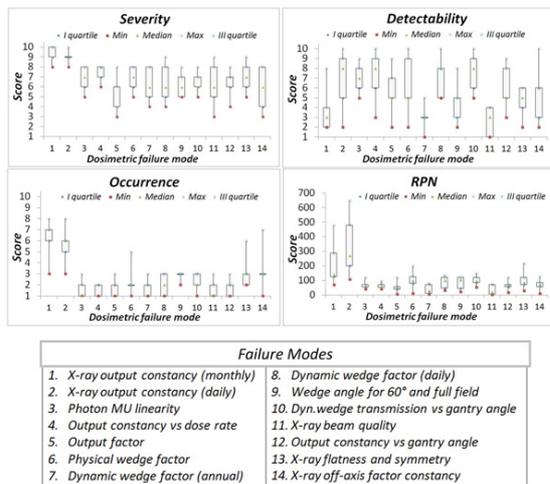

Figure 1: Box-plots example of survey results for FMEA score (Occurrence, detectability, severity and RPN) for 14 failure modes (dosimetric tests) for Varian Unique linac.

Both the FM simulations and the analysis of the QC trend allowed to reduce the subjectivity of the FMEA score. Integration of both evaluations provided the RPN-based ranking of tests: an example is shown in figure 2 for monthly tests for DBX and Unique linacs.

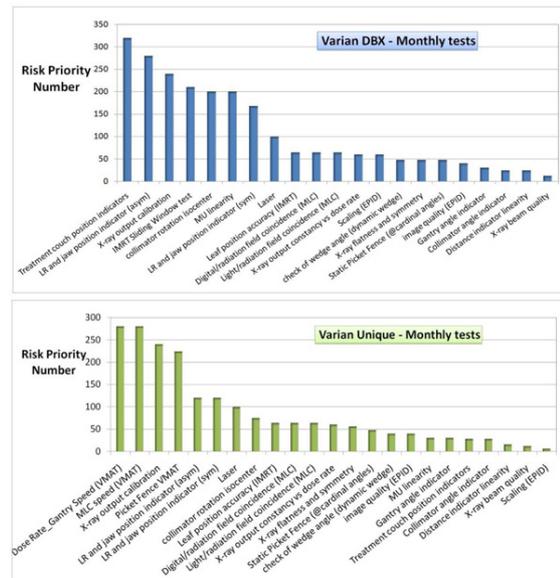

Figure 2: Classification of priority monthly tests, based on RPN score, for Varian DBX and Unique linacs

To note that, except for output constancy, the differences in ranking order in the first positions are due to the treatment techniques implemented on the two linacs: VMAT for Unique, requiring accurate tests on dose modulation and multi leaf collimator speed; treatment with multiple isocenters and/or junctions between adjacent fields for DBX, requiring accurate tests on couch and jaw position indicators.

**Conclusion**

FMEA is a useful tool to optimize and prioritize the linac QCs. It allowed to identify the more relevant tests for patient safety by taking into account the specific equipment, treatment modalities and clinical practice. The variability and subjectivity of the FMEA scoring, mostly caused by individual differences in risk perception and professional experience of the involved physicists, can be limited by a semi-quantitative analysis of each failure mode and of the QC trend.

**PO-0909 QA test of MLC speed using a fluorescent screen-CCD based dosimetry system**

B. Yang<sup>1</sup>, T.L. Chiu<sup>1</sup>, C.W. Cheung<sup>1</sup>, H. Geng<sup>1</sup>, W.W. Lam<sup>1</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Happy Valley, Hong Kong SAR China

**Purpose or Objective**

The purpose of this study is to demonstrate quality assurance (QA) test on the speed accuracy of multileaf collimator (MLC) which is crucial for intensity modulated radiotherapy treatment (IMRT) modality, using a fluorescent screen-CCD based dosimetry system.

**Material and Methods**

Our fluorescent screen-CCD based dosimetry system consisted of a fluorescent screen sandwiched by two transparent PMMA blocks and a low dark noise CCD camera. The fluorescent screen was aligned perpendicularly to the radiation beam line and the fluorescent light was directed to the CCD camera by a 45° mirror underneath. All components were assembled in an L-shape light-tight box. The median filter was applied to remove the radiation induced spike noise. Test delivery plans with fixed 1cm MLC gap and constant movement speed for both carriage A and B sliding from one side to another were created for QA of MLC speed. During the delivery of these plans, the CCD camera captured the images continuously with a fixed exposure time 0.1s at its

maximum frame per second (fps) under different settings of pixel binning. The maximum fps of our current system is limited to 0.98, 1.61 and 3.11 under 1×1, 2×2 and 4×4 pixel binning setting which corresponds to a spatial resolution of 0.259, 0.518 and 1.036 mm/pixel respectively. By tracking the movement of the edge of leaves, the speed could be calculated. Further the machine trajectory log files were also analyzed for comparison and t-test was performed to evaluate the statistical significance between our measured speeds and those calculated from log file.

### Results

The calculated speed of leaf #30 for both carriage A and B is listed in Table 1. By analyzing the machine log file, the speed of the same leaf was calculated to be 25.00±0.10, 15.05±0.12 and 4.99±0.12mm/s for carriage B; 25.00±0.12, 15.05±0.11 and 4.99±0.13mm/s for carriage A under nominal speed 25, 15 and 5mm/s respectively. Our measured MLC speed for 1×1 pixel binning setting and that extracted from log data are also plotted in figure 1. T-test results show that the p values are all larger than 0.3, which suggest the measured results are not statistically distinguishable from log data and our measurement is accurate compared with log data. Similar results were also obtained for other leaves.

Table 1. Measured speed of leaf #30 for both carriage A and B under different settings of pixel binning.

Pixel Binning	Nominal Speed	Carriage B: Leaf #30			Carriage A: Leaf #30		
		Mean	SD	P value	Mean	SD	P value
1x1	25mm/s	24.96	0.17	0.37	25.00	0.18	0.92
	15mm/s	15.08	0.14	0.36	15.08	0.16	0.47
	5mm/s	5.01	0.09	0.50	5.01	0.10	0.35
2x2	25mm/s	25.02	0.20	0.73	24.99	0.21	0.77
	15mm/s	15.04	0.17	0.81	15.03	0.20	0.56
	5mm/s	4.98	0.16	0.72	4.96	0.17	0.47
4x4	25mm/s	25.00	0.45	0.99	24.97	0.46	0.77
	15mm/s	15.04	0.43	0.90	15.00	0.41	0.60
	5mm/s	5.00	0.38	0.88	5.01	0.35	0.83

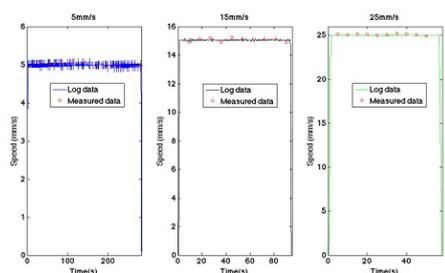

Figure 1. MLC speed vs time curves for leaf #30 calculated from log data and measured images under 1×1 pixel binning setting.

### Conclusion

The fluorescent screen-CCD based dosimetry system can serve as an independent and reliable tool for QA of MLC speed, whose temporal resolution as a motion monitor can be further improved by using the camera with higher fps.

### PO-0910 Is Linac-Based Total Body Irradiation (TBI) on the coach by VMAT Feasible?

B. Tas<sup>1</sup>, I.F. Durmus<sup>1</sup>, A. Okumus<sup>1</sup>, O.E. Uzel<sup>1</sup>

<sup>1</sup>Yeni Yuzyil University Gaziosmanpasa Hospital, Radiation Oncology, Istanbul, Turkey

### Purpose or Objective

In our study, we investigate the use of Linac-Based TBI by VMAT technique at nominal SAD on the coach. Eight TBI patient's treatment planning were performed using Monaco5.1<sup>®</sup> treatment planning system with dual arc VMAT techniques for each patient.

### Material and Methods

For treating patients, Versa HD<sup>®</sup> (Crawley, Elekta) linear accelerator with 6 MV, equipped with Agility<sup>®</sup> collimator system, XVI 5.0 cone beam CT was used as a Image Guided Radiation Therapy (IGRT) method for VMAT delivery.

Agility<sup>®</sup> collimator system included 160 MLC, minimum leaf width was 5 mm. MLC effective speed was 6.5 cm/sec and leaf travel was 15cm over the central axis. VMAT plans were generated on Monaco 5.1<sup>®</sup> (Crawley, Elekta) treatment planning system with Monte Carlo algorithm. All calculation parameters were grid spacing 0.3 cm, minimum segment width 1.0 cm, Max. 180 of control Points Per Arc, Fluence smoothing medium, Statistical Uncertainty 1% per plan, increment of gantry 30° and dose to medium.

The VMAT-TBI technique consisted of three isocentres and three dual overlapping arcs from top of head to the bottom of pelvis region. The prescribed dose was 90% of target volume receiving dose of 12Gy. Mean dose to lung and kidney were restricted less than 10Gy and maximum dose to lens were restricted less than 6Gy. The plans were verified using 2D array IBA Matrixx<sup>®</sup> and CC13 ion chamber. The comparison between calculation and measurement were made by  $\gamma$ -index (3%-3mm) analysis and absolute dose measurement at the isocentre.

### Results

An average total delivery time was determined 923±34 seconds and an average monitor unit (MU)s was determined 2614±231MUs for dual arc VMAT technique. When we evaluated organ at risk(OAR)s, mean dose to lungs was 9.7±0.2Gy, mean dose to kidneys was 8.8±0.3Gy, maximum dose to lens was 5.5±0.3Gy and maximum point dose was 14.6±0.3Gy, HI of PTV was 1.13±0.2, mean dose to PTV was 12.6±0.15Gy and mean  $\gamma$ -index (%3-3mm) pass rate was %97.1±1.9. Absolute doses were measured by CC13 ion chamber and we determined %2.0±0.6 dose difference between measurement and treatment planning system's (TPS) calculation at the isocentre.

### Conclusion

The results show that dose coverage of target and OAR's doses are feasible for TBI using VMAT technique on the coach. A benefit could be demonstrated with regard to dose distribution and homogeneity and dose-reduction to organs at risk. Additionally, we determined highly precise dose delivery by patient QA and point dose measurement at the isocentre. Based on the dose distributions we have decided to plan TBI in our clinic with dual arc VMAT technique on the treatment coach.

### PO-0911 Can the therapeutic benefits of microbeam radiation therapy be achieved using a clinical linac?

N. Suchowerska<sup>1</sup>, V. Peng<sup>1</sup>, L. Rogers<sup>1</sup>, E. Claridge-Mackonis<sup>1</sup>, D.R. McKenzie<sup>2</sup>

<sup>1</sup>Chris O'Brien Lifefhouse, Radiation Oncology, Camperdown- Sydney, Australia

<sup>2</sup>University of Sydney, School of Physics, Sydney, Australia

### Purpose or Objective

The increasing availability of high definition multileaf collimators (HDMLCs) with 2.5mm leaves provides an opportunity for 'grid' therapy to more closely approach the clinical outcomes of Microbeam Radiation Therapy (MRT). However, periodic spatial modulation of the dose in the target volume runs counter to current clinical practice. To optimize the modulation, a better understanding of cell dose responses to such treatments is needed. The aim of this study is to determine if some of the therapeutic benefits of MRT can be achieved using a clinical linac with HDMLCs and if so, to develop a predictive model to optimize the benefits of such treatments.

### Material and Methods

Varian Novalis Tx<sup>TM</sup> HD120-MLCs were used to generate grid patterns of 2.5mm and 5.0mm spacing, which were dosimetrically characterized using Gafchromic<sup>TM</sup> EBT3 film [Figure 1]. Clonogenic survival of normal (HUVEC) and cancer (lung NCI-H460, breast HCC-1954, melanoma MM576) cell lines were compared in vitro for the same

average dose, following irradiation with periodically modulated and open 6MV photon fields.

#### Results

Survival of normal cells in a 2.5mm striped field was the same as for an open field, but the survival of the cancer cells was significantly lower. However for cancer cell lines in the 5.0mm modulated fields, the response compared to an open field was no longer statistically significant. A mathematical model was developed to incorporate the dose gradients of the spatial modulation into the standard linear quadratic model. Our new extended bystander LQ model assumes spatial gradients drive the diffusion of soluble factors that influence survival through bystander effects. The model successfully predicts the experimental results that show an increased therapeutic benefit.

#### Conclusion

We have confirmed that HDMLCs can create spatially modulated fields that increase the therapeutic advantage between normal and cancer cells. Our results challenge conventional radiotherapy practice and propose that additional gain can be realized by prescribing spatially modulated treatments to harness the bystander effect.

#### PO-0912 Short- and long term stability of the isocenter of a three-source Co60 MR guided radiotherapy device

D. Hoffmans<sup>1</sup>, M.A. Palacios<sup>1</sup>, J.P. Cuijpers<sup>1</sup>

<sup>1</sup>VU University Medical Center, Radiotherapy, Amsterdam, The Netherlands

#### Purpose or Objective

Recently a 0.35T Co<sup>60</sup> MRIdian system (Viewray Inc., Cleveland) is implemented at our institution. In a similar way as for other image guided radiotherapy techniques, the coincidence of the radiation therapy (RT) and imaging isocenter is of major importance. The purpose of this study is to present a method for daily QA of MR-RT isocenter coincidence and to assess its short- and long term stability using daily film-based isocenter QA.

#### Material and Methods

Two pieces of radiochromic film (GafChromic EBT3) are taped to square inlays on the top and the side of a cubic water-filled phantom. The phantom is aligned to the MRI isocenter using MR guided setup relying on three internal cylindrical markers.

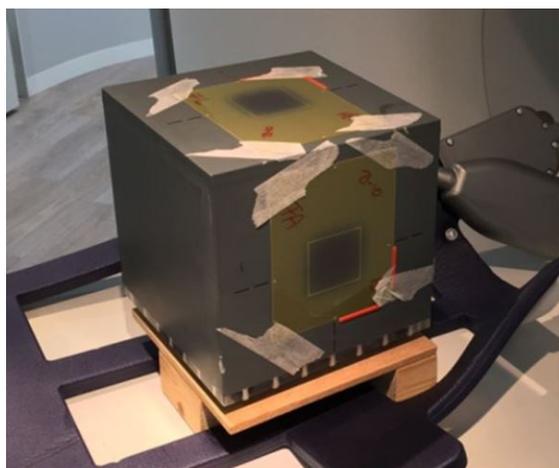

Figure 1: Daily QA phantom with two pieces of film

A treatment plan, consisting of an AP and a lateral square field is delivered. The direction of the lateral field is altered daily between 90° and 270° in order to monitor all 3 treatment heads (Head 1 and 2 for the lateral fields respectively, head 3 for the AP field). The films are digitized and the positions of the square fields with respect to the phantom are determined. These data provide a daily measurement of the coincidence of the RT- and MR- isocenters in 3 dimensions. The AP field provides

information about the alignment along the lateral (X) and the longitudinal (Y) axis. The lateral fields provide the shift in the vertical (Z), and the Y directions. Data were collected daily over a period of 4 months. A linear regression is performed in order to determine any trends in time. Furthermore, the correlation between the two daily values for the shift along the Y-axis is assessed.

#### Results

The average 3D vector of the daily shift is found to be 0.8mm (P95 = 1.3 mm). The average misalignments as determined by the individual heads are shown in Table 1.

Table 1: Average misalignments determined by individual heads.

	Head 1 N = 41	Head 2 N = 29	Head 3 N = 70	Average
Lateral avg [mm]			0,0	0,0
Lateral std [mm]			0,4	0,4
Longitudinal avg [mm]	0,3	0,1	-0,3	0,0
Longitudinal std [mm]	0,6	0,4	0,4	0,6
Vertical avg [mm]	0,4	0,0		0,2
Vertical std [mm]	0,6	0,5		0,6

The systematic shift in 3D is zero in X and Y direction and 0.2 mm in the Z direction, which is caused by the vertical shift measured with head 1. No time trend in the shift is observed in any direction as the regression coefficients were not statistically significant different from zero: p=0.39, 0.64 and 0.50 for the X, Y and Z axes respectively. The Pearson correlation coefficient between the Y-shift determined using the two perpendicular fields was very weak and found to be 0.24.

#### Conclusion

A method is developed for daily assessment of the coincidence of the MV- and MR-isocenter for an integrated MR-RT unit. The alignment of the MR- to the RT-isocenter is found to be stable during a time period of 4 months. A small systematic shift in vertical direction was found, a star shot measurement confirmed that this was caused by a slight misalignment of Head 1. This misalignment can be compensated by realignment of the MLC leaf positions. The weak correlation in the pair of Y-measurements suggests that the daily misalignment is dominated by random measurement inaccuracies such as the placing markers on the film and rotational setup misalignments of the phantom.

#### PO-0913 A national review of equipment, techniques and PTV margins used for SRS

R. Patel<sup>1</sup>, J. Lee<sup>1</sup>, C. Walker<sup>2</sup>, D.J. Eaton<sup>1</sup>

<sup>1</sup>Mount Vernon Hospital, Radiotherapy RTTQA, Northwood Middlesex, United Kingdom

<sup>2</sup>Northern Centre for Cancer Care, Radiotherapy, Newcastle, United Kingdom

#### Purpose or Objective

As part of a national commissioning programme, treatment providers were required to complete a SRS quality assurance review in order to benchmark current practice. The process was designed to ensure providers were able to deliver a service in line with parameters developed by a multidisciplinary expert advisory group (EAG).

The long term aim of this programme was to progress a system of standardisation and quality improvement of service by promoting consistency and the development of services over time. The short term goals were to highlight any significant variation in practice in order to identify centres that may require further support or mentoring in order to meet nationally agreed parameters.

#### Material and Methods

A questionnaire was circulated to 20 centres to establish the equipment, treatment techniques and PTV expansions used to deliver SRS. Centres reported on their current

practice without any guidance. Responses were evaluated by the EAG and used to inform on best practice and identify centres where additional support was required. Results are given here for PTV margins used for metastatic disease. PTV margins are particularly important when treating multiple mets as they can increase the volume of normal brain irradiated and the commissioning criteria requires the total treated volume to be below 20cc, so the choice of PTV margins can impact patient eligibility for treatment.

## Results

All 20 centres responded to the questionnaire with one centre excluded as they were in process of changing equipment. Responses are summarized in Table 1.

Equipment	No.	Techniques
Cyberknife	3	Multiple Non-Coplanar Beams
Gammaknife	7	Multiple Non-Coplanar Beams
Novalis	3	Static conformal, circular collimators, dynamic conformal arcs
Tomotherapy	1	Helical Arcs
Elekta Agility/Versa HD	3	Static conformal, dynamic conformal arcs, VMAT
Varian Truebeam STx	2	Dynamic conformal arcs, VMAT
Varian Clinac with cones	1	Non coplanar arcs with cones

Table 1 List of Centres and equipment and treatment techniques

The most common platform used was the Elekta Gammaknife system. A variety of linacs were used, the majority of those used for the commissioning were specialised units (e.g. Novalis, Truebeam STx) or had been adapted (e.g. fixed cones) for SRS treatments. Centres used a 0, 1 or 2mm margin for brain mets. All Gammaknife centres used a 0mm margin, but other platforms varied depending on the centre as seen in Figure 1. Only four centres used a 2mm expansion for treating brain mets, three of these were non specialised linacs.

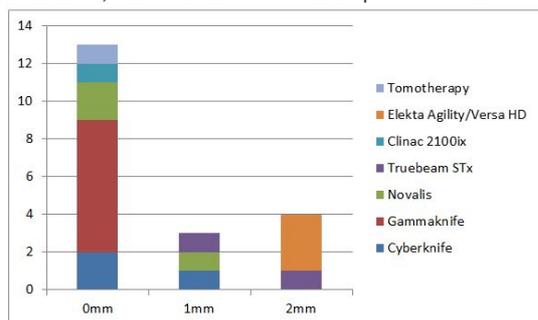

Figure 1 PTV margins used by participating centres

## Conclusion

There is significant variation in the equipment used to treat SRS nationally. A 0mm PTV expansion was the most common for SRS treatment regardless of platform. Gammaknife centres were consistent with their PTV margins, which is based on historical practice but other platforms varied depending on the centre. No system has an end to end accuracy of 0mm, however many centres are choosing to use, which may lead to under-coverage of the target.

Following feedback, centres using non-specialised equipment are planning to acquire either stereotactic linacs or upgrades such as the Apex head, with some frameless users acquiring Exactrac systems to reduce uncertainty in patient positioning. These will facilitate margin reduction at centres using 2mm PTV expansions, in line with the  $\leq 1$ mm recommended by the EAG.

## PO-0914 Helium Beam Radiography System based on pixelized semiconductor detectors

T. Gehrke<sup>1</sup>, G. Arico<sup>1</sup>, S. Berke<sup>2</sup>, J. Jakubek<sup>3</sup>, M. Martisikova<sup>4</sup>

<sup>1</sup>Heidelberg University Hospital, Radiation Oncology and Radiation Therapy, Heidelberg, Germany

<sup>2</sup>German Cancer Research Center, Medical Physics in Radiation Therapy, Heidelberg, Germany

<sup>3</sup>Czech Technical University in Prague, Institute of Experimental and Applied Physics, Prague, Czech Republic

<sup>4</sup>German Cancer Research Center DKFZ, Department of Medical Physics, Heidelberg, Germany

## Purpose or Objective

(1) Purpose: In highly conformal radiotherapy, like ion beam radiotherapy, inter- and intrafractional monitoring of the target is desirable. Due to the steepness of the rising part of the Bragg curve, ion beam radiography can in principle provide high resolution of the traversed tissue thickness. Ion beam radiography is furthermore attractive due to its potential to measure the stopping power of the tissue directly. However, currently there is no detection system for clinical imaging of patients. Helium ions as the imaging modality provide the advantages of decreased multiple scattering in comparison to protons and lower biological effectiveness than the carbon ions.

## Material and Methods

(2) Methods: Plastic phantoms containing 1mm deep step-like inhomogeneities were imaged with helium ion beams at the Heidelberg Ion Beam Therapy facility in Germany. To register the radiation, a system of 5 parallel layers, based on the semiconductor pixelized detector Timepix, which was developed by the Medipix Collaboration at CERN, was used. Two layers in front of the phantom enabled us to measure the position and direction of incoming helium ions. Another pair of detection layers, located behind the phantom, registered the outgoing particles and an additional layer was used to measure their energy loss and to identify the ion type. Synchronization of all the five detector layers enabled us to associate the outgoing particles to the incoming ones. To build the image of the phantom, we used the measured information about the transversal position of the incoming and outgoing particle, their direction and type (He or H).

## Results

(3) Results: With this system we imaged a 1 mm step in a 160 mm thick PMMA phantom. Spatial resolution below 2 mm was reached when the inhomogeneity was located in the phantom, while resolution below 1 mm was achieved in the cases where the step was located at the front or at the end of the phantom. Hereby we have shown that the information about flight direction of the incoming and outgoing ion, together with the capability to identify them and thus select solely helium ions, enables to improve the spatial resolution by a factor of more than three.

## Conclusion

(4) Conclusion: We have shown experimentally that helium beam radiography reaches in simple phantoms spatial resolution in the region which is attractive for highly conformal radiotherapy. In the presentation the results obtained with helium beams as the imaging modality will be compared to proton-based imaging.

## PO-0915 Performance study of a prototype straight-through linac delivery system with an EPID assembly

R. Scheuermann<sup>1</sup>, C. Kennedy<sup>1</sup>, D. Mihailidis<sup>1</sup>, J. Metz<sup>1</sup>

<sup>1</sup>University of Pennsylvania, Radiation Oncology, Philadelphia, USA

## Purpose or Objective

To study and expand the use of the Machine Performance Check (MPC) tool in monitoring the continuous operational performance of a prototype delivery system composed of a straight-through-linac and an in-line MV portal imaging panel (Proof-of-Concept).

## Material and Methods

The MPC, as implemented in TrueBeam (TB), is an integrated self-check tool that assures that critical machine performance are within specifications, e.g. mechanical accuracy and radiation output. As adapted to the prototype straight-through linac delivering 6X-FFF (filter-free) beam, the automated tests are based on its

in-line MV EPID. The MPC acquires a series of MV images of an IsoCal phantom, capturing beam properties and mechanical data such as MLC and gantry accuracies. A new MPC test monitors output stability in terms of percent deviation from the baseline data of the actual measured beam. All measured data are automatically processed, analyzed, and displayed for evaluation, thus providing a reliable and fast method for routine machine performance assessment. Independent tests such as star-shots, Winston-Lutz, MLC picket fence patterns and output measurements on a daily basis were employed to benchmark the MPC test results for the prototype system.

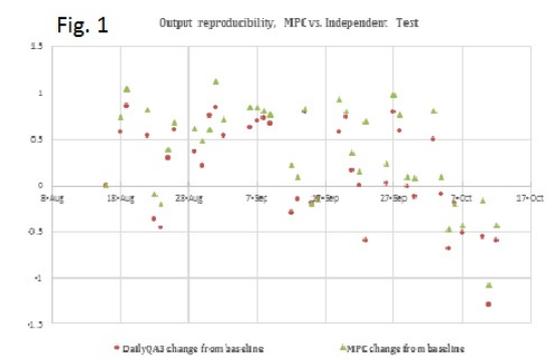

**Results**

MPC results were collected daily for six months on both the prototype and a TB. The independent tests on the prototype system were repeated weekly to validate the MPC results. A sample comparison of the MPC results for the prototype against independent tests are shown in Table 1. The output stability of the prototype system, as measured with the MPC and a DailyQA™3 device, is comparable (Fig. 1), and within 0.5% of independent output measurement for the period shown. All tests performed were within the tolerances allowed by the MPC and agreed in most cases with the result of the independent tests. The prototype system performs as well as the TB system. A summary of MPC test results and comparisons with independent measurements will be shown alongside with the TB MPC results.

**Table 1**

Test	MPC Result	Independent measurement method/result
Isocenter Size	0.54 mm	Starshot analysis: • Gantry rotation plane: 0.406 mm • G-T plane: 0.303 mm • Collimator: 0.361 mm
MV imager offset	0.14 mm	BB cube/starshot: < 0.2mm
Output change	0.5%	Daily QA3: <0.5% difference
Uniformity change	0.24%	Daily QA3: <0.5% difference
MLC position	0.16 mm max	Picket fence: <0.5 mm
MLC reproducibility	0.4 mm max	Radiographic measurement: <0.2mm
Y field edge offset	<0.2 mm	Radiographic measurement: <0.2mm
Rotation offset	<0.2 mm	Radiographic measurement: <0.2mm
Gantry absolute/relative	<0.2 deg	Bubble level line marked on radiochromic film starshot: < 0.5 deg
Couch readouts	<0.2 mm	Ruler: <0.5 mm

**Figure 1**

**Conclusion**

The performance of a straight-through linac delivering 6X-FFF (filter-free) beam with an EPID panel was investigated with the MPC testing tool and that method was validated against independent tests for proof of concept. MPC is a complete, reliable and quick test suite that monitors the performance of a treatment unit on routine basis.

**PO-0916 Feasibility and potential for treating locally advanced non-small cell lung cancer with a MR-linac**  
M.J. Menten<sup>1</sup>, H. Bainbridge<sup>2</sup>, M.F. Fast<sup>1</sup>, S. Nill<sup>1</sup>, F. McDonald<sup>2</sup>, U. Oelfke<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Physics, Sutton, United Kingdom  
<sup>2</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Lung Unit, Sutton, United Kingdom

**Purpose or Objective**

Treatment plans for MRI-guided radiotherapy delivered with an MR-linac vary from those designed for conventional linacs due to differing technical specifications of dose delivering systems and the presence of a static magnetic field. This study investigated this issue for radiotherapy of locally advanced non-small cell lung cancer (LA NSCLC) by comparing treatment plans for a conventional Versa HD linac (Elekta AB, Stockholm, Sweden) and the Elekta 1.5 T MR-linac. Furthermore, the effect of reducing planning target volume (PTV) margins on the MR-linac was examined.

**Material and Methods**

Ten patients with LA NSCLC were retrospectively re-planned six times using the Monaco treatment planning system, research version 5.19.00. Three plans were designed according to our institution's protocol for conventionally fractionated treatment (55 Gy/ 20 fractions) and three plans following guidelines for isotoxic dose escalation up to 79.2 Gy/ 44 fractions (NCT01836692). In each case, two plans were designed for the MR-linac, using IMRT with nine equidistant, coplanar beams, either with standard (7 mm) or reduced (3 mm) PTV margins, while one plan was created for a conventional linac using VMAT with standard margins. Treatment plan optimization and dose calculation were conducted under consideration of magnetic field effects. Potential to escalate tumour dose was quantified for the isotoxic plans, and differences in dose-volume metrics were analysed for conventionally fractionated treatment plans. Statistical significance was evaluated using a paired t-test after confirming normal distribution and correcting for multiple endpoints.

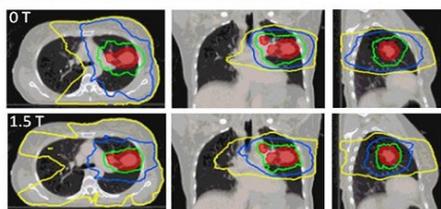

**Results**

All generated treatment plans fulfilled their respective planning constraints and would have been clinically acceptable. With the conventionally fractionated schedule small differences in dose-volume metrics could be identified with statistical significance (see table). Mean lung doses were similar between conventional and MR-linac plans, whereas high lung doses were reduced and low lung doses increased on the MR-linac (graphically illustrated in the figure). In terms of dose-escalation, the mean achievable doses were 75.4, 74.0, and 76.9 Gy for Versa HD, MR-linac (standard margins) and MR-linac (reduced margins) respectively, with inferiority of the standard margin MR-linac plans versus the Versa HD plans (p=0.003).

Table 1: Differences in the investigated dose-volume metrics between the plans designed for the MR-linac with either standard or reduced PTV margins, and the conventional linac when planned to a dose of 55 Gy in 20 fractions. Values are averaged over the 10 patient cohort. Statistically significant values are marked in *italics* with changes in the five primary endpoints (top of table) evaluated at a significance level of p = 0.01. Exploratory endpoints of statistical significance are shown below and were evaluated at p = 0.05. No statistical significance was seen in oesophagus D<sub>mean</sub> (Gy), heart D<sub>mean</sub> (Gy), brachial plexus D<sub>1cc</sub> (Gy) or GTV D<sub>95</sub> (Gy). Distal lung tissue is defined as any healthy lung tissue more than 5 cm from the ITV.

Dose volume metric	MR-linac – Versa HD with:			
	MR-linac standard margins		MR-linac reduced margins	
	Difference	p-value	Difference	p-value
Lung D <sub>mean</sub> (Gy)	+ 0.28 ± 0.72	0.26	-0.43 ± 0.66	0.07
Lungs V <sub>17</sub> (%)	+ 1.8 ± 2.17	0.03	+ 0.95 ± 1.73	0.12
Oesophagus V <sub>45</sub> (%)	+ 1.56 ± 3.13	0.15	-1.51 ± 4.51	0.32
Heart V <sub>15</sub> (%)	+ 2.32 ± 5.43	0.21	-1.65 ± 8.08	0.54
Skin D <sub>2</sub> (Gy)	-1.65 ± 1.83	0.019	-4.90 ± 1.47	<0.001
Distal lungs D <sub>mean</sub> (Gy)	+ 1.12 ± 0.83	0.002	+ 1.18 ± 0.80	0.001
Distal Lungs D <sub>2</sub> (Gy)	-3.16 ± 2.84	0.007	-4.39 ± 2.54	<0.001
Skin D <sub>mean</sub> (Gy)	+ 0.59 ± 0.44	0.002	+ 0.14 ± 0.38	0.26
Spinal Canal D <sub>1cc</sub> (Gy)	-1.62 ± 3.34	0.16	-3.86 ± 3.65	0.01

Figure 1: Dose distribution of the conventionally fractionated treatment plans (55 Gy in 20 fractions) for a single patient displayed over an axial (left), coronal (central) and sagittal (right) slice of the average phase of 4DCT scan. Plans were created either for a conventional linac with standard ITV-PTV margins (top row) or the MR-linac with reduced margins (bottom row) and were normalized to 100% of the ITV dose. Marked are the ITV (red), 95% (green), 50% (blue) and 20% (yellow) isodose contours.

## Conclusion

It is feasible to generate conventionally fractionated treatment plans for LA NSCLC patients on a 1.5 T MR-linac with minor differences in dose-volume metrics, which are unlikely to be clinically meaningful. When using standard PTV margins, isotoxic dose escalation was limited on the MR-linac. However, reducing margins alleviates these observed effects. This study only represents an early indicator of the treatment implications of MRI-guided radiotherapy. It is conceivable that the availability of MRI-guidance will result in further benefits through inter- and intrafractional treatment adaptation.

## PO-0917 Nationwide audit of small fields output calculations in Poland

W. Bulski<sup>1</sup>, K. Chelminski<sup>1</sup>

<sup>1</sup>The Maria Skłodowska-Curie Memorial Cancer Center, Medical Physics Department, Warsaw, Poland

### Purpose or Objective

The delivery of accurate intensity-modulated radiation therapy (IMRT) or stereotactic radiotherapy depends on a multitude of steps in the treatment delivery process. Within the treatment planning system's (TPS) dose calculation algorithm, various unique small field dosimetry parameters are essential, such as multileaf collimator modeling and field size dependence of the output. One of the most considerable challenges in this process is to determine accurate small field size output factors. Modern radiotherapy routinely involves the use of small radiation fields as components of IMRT. Because of the difficulties in commissioning small field data, a set of field size dependent output factors could prove to be an invaluable tool to confirm the validity of an individual institution's dosimetry parameters. Such a set of data has been prepared by the Radiological Physics Center (RPC), M. D. Anderson Cancer Center, Houston. The RPC has gathered multiple small field size output factor datasets for X-ray beam qualities, ranging from 6 to 18 MV, from Varian, Siemens and Elekta linear accelerators. These datasets were measured at 10 cm depth and ranged from 10×10 cm<sup>2</sup> to 2×2 cm<sup>2</sup>. Within the framework of the IAEA CRP E2.40.16 project "Development of Quality Audits for Radiotherapy Dosimetry for Complex Treatment Techniques, a methodology of the audit of small field output performance was established.

### Material and Methods

The participants had to calculate the output factors for the beams formed by the multi-leaf collimator (MLC). The results of their calculations were compared with the reference RPC data. 32 Polish radiotherapy departments took part in the audit. In total, 65 beams were audited. The participants of the audit were asked to calculate the number of monitor units (MU) for the delivery of a prescribed dose to water with square fields of different sizes. A dose of 10 Gy was prescribed to a reference point at 10 cm depth on the central axis, at 100 cm source-to-phantom distance (SFD). The output factors for five field sizes, 10×10, 6×6, 4×4, 3×3 and 2×2 cm<sup>2</sup>, shaped by a multileaf collimator (MLC), were calculated.

### Results

For Elekta accelerators, all the calculation results show a deviation from the reference values lower than 3%. For Siemens and Varian accelerators, the resulting calculations for fields larger than 2×2 cm<sup>2</sup> differ less than 4%. For 2×2 cm<sup>2</sup> large fields formed by Siemens and Varian MLC, the differences between the calculated and measured output factors often exceed 5%, but still are below 10%.

### Conclusion

The RPC measured values provide a consistent dataset for small field output factors that can be used as a redundant QA check of a treatment planning system dosimetry data for small-field treatments. The results of the audit are very useful for the participants who should carefully investigate any detected discrepancies between the standard dataset and calculated values, with attention to the specific beam model.

## PO-0918 Radiotherapy and Her2 targeting agents: synergism and antagonism in clonogenic and confluence assays

N. Suchowerska<sup>1</sup>, J. Toohey<sup>2</sup>, S. Carroll<sup>2</sup>, L. Rogers<sup>2</sup>, G. Lyons<sup>3</sup>, J. Beith<sup>4</sup>, A. Dos Santos Esteves<sup>2</sup>, D.R. McKenzie<sup>5</sup>

<sup>3</sup>Royal Prince Alfred Hospital, Dermatology Cancer, Sydney, Australia

<sup>4</sup>Chris O'Brien Lifecare, Medical Oncology, Camperdown Sydney, Australia

<sup>5</sup>University of Sydney, School of Physics, Sydney, Australia

### Purpose or Objective

Her2 amplified cancers, comprising 15-20% of patients presenting with breast cancer, are now routinely prescribed Trastuzumab (Herceptin), a monoclonal antibody targeting Her2 receptors, leading to a significant improvement in outcomes in this previously high risk breast cancer subtype. Such targeting agents are rapidly being introduced into the clinic, based on trials showing a survival advantage. Now combination therapies with drug conjugates have emerged. The biological interactions of combined targeting agents, when given concurrently with radiation, are not well described. Our aim is to identify whether there is a synergistic or antagonistic interaction between targeting agents and ionising radiation for two distinct Her2+ subtypes.

### Material and Methods

Two molecular subtypes of HER2+ breast cancer cell lines were used: HCC-1954, which is ER and PR hormone negative and BT-474, a luminal B which is ER negative and PR positive. Both cell lines were treated to Her2 targeting agents (Trastuzumab and T-DM1) and radiation (6MV photons, 0 to 4Gy), individually and in combination to identify whether the response was synergistic, additive or antagonistic. The alpha/beta ratio was experimentally determined for each cell line. Synergy (S) is defined as the fractional difference between the observed (S<sub>o</sub>) and the predicted survival for each treatment given alone (S<sub>1</sub> x S<sub>2</sub>):

$$S = \frac{S_o - S_1 \times S_2}{S_o}$$

The observed response was determined using two assays: the clonogenic assay and the confluence assay.

### Results

The alpha/beta ratio for HCC-1954 (ER-/PR-/Her2+) and BT474 (Luminal B ER-/PR+/Her2+) are found to be 35 Gy and 5 Gy respectively, highlighting a heterogeneous treatment response. The survival of HCC-1954 was not affected by Trastuzumab alone, but when combined with radiation, a synergistic interaction was observed. BT-474

showed a 20% decrease in survival when exposed to Trastuzumab alone, but a combined treatment with radiation did not yield the expected decrease in survival, indicating an antagonistic interaction.

#### Conclusion

Our results show that before starting clinical trials, the combination of radiation therapy and combined targeting agents needs to be closely examined for each sub-type under consideration. The assumption that a combination of treatments will result in a synergistic response is clearly not always true.

#### PO-0919 Stereotactic radiotherapy for brain

metastases : Cyberknife versus VersaHD / ExacTrac  
M. Perdreux<sup>1</sup>, M. Celeste<sup>1</sup>, I. Lecouillard<sup>1</sup>, E. Nouhaud<sup>1</sup>,  
C. Blay<sup>1</sup>, F. Jouyaux<sup>1</sup>, N. Delaby<sup>1</sup>, J. Bellec<sup>1</sup>, C. Lafond<sup>1</sup>  
<sup>1</sup>Centre Eugène Marquis, Radiotherapy, Rennes CEDEX,  
France

#### Purpose or Objective

The aim of this study was to compare dosimetric and geometric performances of the CyberKnife (Accuray) and VersaHD (Elekta) with the ExacTrac system (BrainLab) in stereotactic radiotherapy for brain metastases.

#### Material and Methods

This study was conducted on 10 patients for Cyberknife M6 v10.6 with Iris collimator and VersaHD equipped with ExacTrac v6.1 and the Frameless system (BrainLab). The prescribed dose was 27 Gy in 3 fractions with 1mm margin between CTV and PTV for both modalities. The dosimetric study was also conducted with 2 mm margin for VersaHD plans in accordance to our clinical practices.

Plans have been computed for CyberKnife with non-isocentric non-coplanar beams generated by inverse optimization on Multiplan v5.3 (Accuray) with the RayTracing dose calculation algorithm. For VersaHD, 4 non-coplanar arcs (VMAT) have been generated by inverse optimization on Pinnacle v9.10 (Philips) with the Adaptive Convolution algorithm. For each case, plans were normalized to obtain the same PTV coverage at +/- 0.2 %.

The comparison was based on the brain volume outside PTV receiving 23.1 Gy. The volume of isodoses 6 Gy, 2.7 Gy and 1 Gy have been reported as well as the Paddick's Gradient Index to characterize the dose gradient around PTV and the spread of low doses.

Quality controls have been performed with Gafchromic EBT3 films (Ashland) and with an ionization chamber (Pinpoint 31014 /PTW) in an anthropomorphic phantom (STEEV/CIRS). The measured dose with film has been compared to the calculated dose according to the gamma index method with a 3% (local) / 2 mm criteria (analytical threshold : 30% of the maximum dose). The geometric shift between the measured and calculated dose distribution has been also reported.

#### Results

Table 1 shows that dosimetric criteria for plan validation were reached for both modalities and both margins. Compared to VersaHD, dose gradients obtained with Cyberknife were greater and lower volumes of healthy tissue received doses below 6 Gy.

Ionization chamber measurements showed mean differences with the calculated dose of 2.53% and 0.03% for Cyberknife and VersaHD respectively. The mean value of the gamma index was 0.42 for the Cyberknife and 0.38 for the VersaHD. The mean geometric shifts between the measured and calculated dose distributions were 0.87 mm and 0.84 mm for Cyberknife and VersaHD respectively.

	Cyberknife	VersaHD		Criteria
	1 mm	1 mm	2 mm	
CTV → PTV margins	1 mm	1 mm	2 mm	
PTV : V 27 Gy (%)	97.5	97.5	97.5	> 95
BRAIN OUTSIDE PTV : V 23.1 Gy (cm <sup>3</sup> )	3.1	3.3	3.5	< 7
Gradient Index	3.1	4.2	3.4	Ideal : 1
V 6 Gy (cm <sup>3</sup> )	58.8	78.2	93.6	lower as possible
V 2.7 Gy (cm <sup>3</sup> )	238.5	235.0	253.6	lower as possible
V 1 Gy (cm <sup>3</sup> )	841.2	926.4	994.6	lower as possible

**Tab. 1 :** Dosimetric comparison for 10 patients between Cyberknife and VersaHD with ExacTrac for stereotactic radiotherapy of brain metastases (mean values)

#### Conclusion

For brain metastases stereotactic radiotherapy, Cyberknife with Iris collimator and VersaHD with ExacTrac both allowed compliance to dosimetric criteria. Cyberknife provided higher dose gradients than VersaHD and limited low dose irradiation of healthy tissues. The agreement between calculated dose and measured dose was acceptable for both modalities with mean gamma values lower than 0.5. An investigation will be performed to evaluate the use of low margins (1 mm) with the VersaHD / ExacTrac due to the very low geometric deviations.

#### PO-0920 Utilizing monte carlo for log file-based delivery QA

C. Stanhope<sup>1</sup>, D. Drake<sup>1</sup>, M. Alber<sup>2</sup>, M. Sohn<sup>2</sup>, J. Liang<sup>1</sup>, C. Habib<sup>1</sup>, D. Yan<sup>1</sup>

<sup>1</sup>Beaumont Health System, Radiation Oncology, Royal Oak MI, USA

<sup>2</sup>Scientific RT, Munich, Germany

#### Purpose or Objective

The purpose of this study is to (1) investigate the feasibility of using Elekta's R3.2 Log File (LF) Converter as a standalone technique for patient-specific QA, and (2) assess Scientific RT's SciMoCa monte carlo (MC) algorithm for use in said system.

#### Material and Methods

Eleven clinical, dual-arc VMAT patients [9 H&N, 2 low dose rate brain (35MU/min)] previously planned in Pinnacle and calculated using Adaptive Convolution (CS) were selected for this study. Arcs were delivered on Sun Nuclear's ArcCHECK (AC) phantom and LF recorded. LF were converted into dicom plan files and calculated using CS and MC. For MC, all LF samples were reconstructed with no increase in calculation time. For CS, plans were reconstructed using 1° control point spacing to decrease computational cost. Original (Plan), LF, and AC doses were compared; statistical distributions (mean ± σ) of percent diode dose error, as well as 1%/1mm gamma pass rates, were calculated and compared for the five comparisons C1 to C5 shown in Table 1. A standard 10% threshold was utilized for both statistical and gamma analyses. Dosimetric degradation due to increased control point spacing (1/2/3/4°) was assessed for CS using 1%/1mm gamma criteria for 4 H&N and 1 brain patient. Delivering a 25x25 arc at various dose rates (35 to 570 MU/min) diode sensitivity dependence on dose rate was quantified.

#### Results

In-field diodes under-responded by 1.5±0.4% at 35 MU/min compared to 570 MU/min. Consequently, the four brain fields yielded lower Plan-MC pass rates (44±8%). These arcs were excluded from subsequent gamma analysis. Pass rates and diode dose errors are shown in Table 1. Comparing C2 to C1, MC and CS are compared. MC resulted in decreased σ values for 17/22 arcs (-3.7 ± 6.5%) and increased passing rates for 10/18

beams ( $0.4 \pm 3.2\%$ ). Comparing C4 to C2, log file accuracy is analyzed for MC. LF resulted in lower  $\sigma$  values for 20/22 arcs ( $-5.4 \pm 3.4\%$ ) and improved pass rates for 14/18 arcs ( $1.1 \pm 1.4\%$ ). Comparing C5 to C2, LF and AC QA techniques are compared. The LF technique yielded decreased  $\sigma$  values for 22/22 arcs ( $-51 \pm 7\%$ ) and improved pass rates for 18/18 fields ( $9.9 \pm 3.8\%$ ). The LF technique also eliminated systematic AC errors; mean dose errors decreased from 3.2% to 0.1%. For  $1/2/3/4^\circ$  LF-CS control point spacing, 1%/1mm pass rates were  $80.0 \pm 5.0\%$ ,  $78.0 \pm 4.2\%$ ,  $74.0 \pm 5.1\%$ , and  $68.8 \pm 5.3\%$ . Plan-CS pass rates were  $80.2 \pm 4.0\%$ . Figure 2 plots difference in pass rates [(LF-CS vs. AC) minus (Plan-CS vs. AC)] as a function of control point spacing for each arc. Calculation times for CS and MC were 12s per control point and 3 minutes per VMAT arc respectively.

Table 1 Gamma pass rates as well as percent differences in diode dose (mean  $\pm$  std) are calculated for five dose-pairs. \* Gamma pass rates exclude the four low dose rate cases.

	1%/1mm Pass Rate*	Percent Diode Dose Error (Mean $\pm$ StDev)
(C1) Plan-CS vs. AC	$81.6 \pm 6.5\%$	$2.6 \pm 6.5\%$
(C2) Plan-MC vs. AC	$82.0 \pm 4.9\%$	$3.2 \pm 6.2\%$
(C3) LF-CS vs. AC	$79.2 \pm 8.1\%$	$3.4 \pm 6.5\%$
(C4) LF-MC vs. AC	$83.1 \pm 5.0\%$	$3.3 \pm 5.8\%$
(C5) LF-MC vs. Plan-MC	$91.0 \pm 2.7\%$	$0.1 \pm 3.1\%$

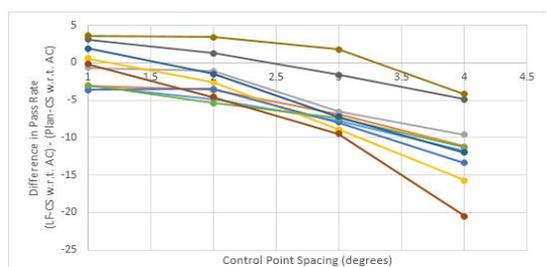

Figure 1 Difference in pass rate [(LF-CS vs. AC) minus (Plan-CS vs. AC)] is plotted as a function of control point spacing for each arc.

**Conclusion**

MC doses proved more accurate than CS when compared to AC measurement. LF-MC plans yielded superior accuracy and shorter calculation times than LF-CS plans. By cutting out the phantom and comparing LF dose to that of the original plan, systematic error was eliminated and random error greatly reduced.

**PO-0921 Dose considerations of IGRT using MV projection and MV CBCT on a prototype linear accelerator**

P. Balter<sup>1</sup>, T. Netherton<sup>1</sup>, Y. Li<sup>1</sup>, P. Nitsch<sup>1</sup>, S. Gao<sup>1</sup>, M. Muruganandham<sup>1</sup>, S. Shaitelman<sup>1</sup>, S. Frank<sup>1</sup>, S. Hahn<sup>1</sup>, A. Klopp<sup>1</sup>, L. Court<sup>1</sup>

<sup>1</sup>UT MD Anderson Cancer Center Radiation Physics, Radiation Physics, Houston- TX, USA

**Purpose or Objective**

The use of the mega-voltage treatment beam for image-guided patient setup has some potential advantages over kV imaging, especially reduced equipment and QA requirements. One of the challenges that MV imaging introduces is the increase in daily imaging dose. Here we investigate (1) whether the MV imaging dose can be correctly calculated and incorporated into the treatment plan, and (2) the impact of MV imaging dose on the dose to normal tissues such as the lung and heart.

**Material and Methods**

MV imaging dose to the lung, heart and other soft tissue was measured using an ion chamber in anthropomorphic thorax phantom (CIRS), and compared with dose calculated in the TPS (Eclipse) for orthogonal MV-MV imaging fields and MV CBCT images using a prototype linear accelerator, each with a low-dose and high-quality mode (total 4 modes). The impact of the imaging

technique (orthogonal vs. CBCT and high vs. low quality) on the doses to normal tissue was evaluated using Eclipse, where the imaging doses were used as based plans in the treatment planning process. For breast plans, doses to the heart and lung were evaluated. For head/neck plans, doses to all the normal tissues were compared.

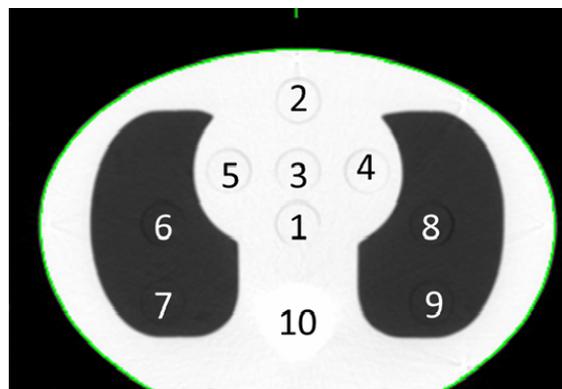

Figure 1. Anthropomorphic phantom (CIRS) with dose measurement points identified.

**Results**

Average imaging dose was measured as 1.3, 2.5, 3.7, and 7.6cGy for daily low dose MV pairs, high quality MV pairs, low dose CBCT and high quality CBCT, respectively. Over a 30 fraction treatment with daily IGRT, this equates to 38 - 227cGy. The average agreement between measured and calculated tissue doses due to imaging was  $0.4 \pm 0.4$ cGy. The largest difference was 1.3cGy, found in the lung for high quality CBCT imaging ( $-39$ cGy over a 30 fraction treatment).

With imaging dose incorporated into the treatment planning process, it was possible to create clinically acceptable treatment plans for a range of treatment sites, including breast, head and neck and prostate. The imaging technique did, however, increase the heart and lung dose for breast plans. For an example left breast treatment, the mean heart dose in our original, clinically delivered plan was 60cGy. With daily MV imaging included, this increased to 140, 150, 190 and 260cGy for daily low dose MV pairs, high quality MV pairs, low dose CBCT and high quality CBCT, respectively. The corresponding values for mean lung dose were 360cGy (original clinical) and 470, 490, 510 and 570cGy.

Position	Tissue doses (cGy)							
	High quality CBCT		Low dose CBCT		High quality MV pair		Low dose MV pair	
	M	C	M	C	M	C	M	C
1	7.5	8.4	3.7	4.2	3.2	3.3	1.6	1.7
2	9.0	9.4	4.5	4.7	2.8	2.7	1.4	1.4
3	8.2	8.8	4.1	4.4	3.4	3.5	1.7	1.7
4	8.2	8.9	4.0	4.5	2.9	3.0	1.5	1.5
5	8.1	8.9	4.0	4.5	3.6	3.8	1.8	1.9
6	7.5	8.8	3.7	4.4	2.4	2.6	1.2	1.3
7	6.6	7.8	3.3	3.9	2.3	2.5	1.2	1.2
8	7.6	8.8	3.8	4.4	1.2	1.4	0.6	0.7
9	6.6	7.9	3.3	3.9	1.2	1.4	0.6	0.7
10	6.3	7.0	3.1	3.5	2.5	2.6	1.2	1.3

Table 1: Tissue doses(cGy/fraction) at different points in the anthropomorphic phantom. M: Measured. C: Calculated

**Conclusion**

Image-guided radiation therapy using MV imaging can be incorporated into the treatment plan to give clinically acceptable dose distributions. Dose to normal tissues is increased, however, and depends on the imaging technique, it is important to select the technique which minimizes normal tissue dose while providing sufficient image quality for patient setup.

<sup>4</sup>Clinic for Plastic Surgery, University of Luebeck/UKSH-CL- Germany, Lübeck, Germany

<sup>5</sup>Institute for Oncology and Radiology IORS, Radiation Oncology Department, Belgrad, Serbia

#### Purpose or Objective

Accelerated partial breast irradiation (APBI) has become a valid option in treating patients with early stage breast cancer following breast conservation surgery (BCS). This work reports on the late toxicity and the cosmetic outcome following APBI using interstitial multicatheter HDR intensity modulated brachytherapy (HDR-IMBT).

#### Material and Methods

Between 2006 and 2014, 114 patients received adjuvant APBI using interstitial multicatheter HDR-IMBT. Late toxicities were reported according to both the RTOG/EORTC score and the LENT/SOMA score. Cosmetic changes were documented by taking digital photographs before the APBI and during each follow-up visit. For each patient, we assessed two photographs, the first was taken after surgery and before APBI (baseline image), and the second at the last available follow-up visit. The cosmesis was assessed through a multidisciplinary team using the Harvard breast cosmesis scale. The clinical and the dosimetric parameters were investigated for any potential correlations with the cosmetic results.

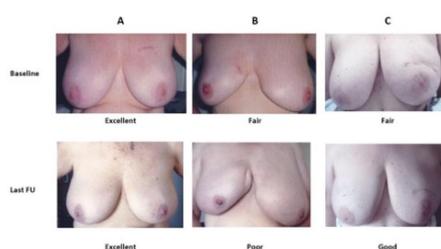

Figure Representative photographs of different cosmetic results.

Representative photographs of three patients (A, B, and C), for each patient two photographs were assessed, baseline (upper), and last FU (lower). Ratings shown represent cosmetic outcome assessments by The MDT (below each image). Notice the change in the cosmesis score.

#### Results

The median follow-up period was 3.5 years (range 0.6 - 8.5). Late skin/soft tissue toxicities at the last follow-up visit are listed in Table 1. Ten patients had grade-3 toxicity (8.8%) and no patients showed grade-4 toxicity. The most common toxicities were fibrosis (56.2% by LENT/SOMA score, and 47.4% by RTOG/EORTC score) followed by pain (42.1%).

The final cosmetic scores were 81.5% excellent/good and 18.5% fair/poor. Comparing both the baseline and the last follow-up cosmetic scores, 59.6% of the patients had the

same score, 36% had a better final score, and 4.4% had a worse final score. Patient age, tumor location, tumor size, number of catheters, V100 (volume receiving 100% of the prescription dose), V150 (volume receiving 150% of the prescription dose), DNR (dose non-uniformity ratio), and skin  $D_{max}$  (maximum skin dose) were correlated with the final cosmetic scores and with the change in cosmetic scores between both photographs. Only lower DNR values (0.3 vs 0.26;  $p=0.009$ ) were significantly associated with improved cosmetic outcome vs same/worse cosmetic outcome.

Table-1. Late toxicity reported during follow-up.

Toxicity	G1	G2	G3	G4	Total
Skin (RTOG/EORTC)	17 (14.9%)	2 (1.8%)	2 (1.8%)	-	21 (18.5%)
Subcutaneous (RTOG/EORTC)	48 (42.1%)	4 (3.5%)	2 (1.8%)	-	54 (47.4%)
Pain (LENT/SOMA)	43 (37.7%)	4 (3.5%)	1 (0.9%)	-	48 (42.1%)
Fibrosis (LENT/SOMA)	54 (47.4%)	9 (7.9%)	1 (0.9%)	-	64 (56.2%)
Pigmentation (LENT/SOMA)	6 (5.3%)	6 (5.3%)	2 (1.8%)	-	14 (12.4%)
Telangiectasia (LENT/SOMA)	1 (0.9%)	2 (1.8%)	2 (1.8%)	-	5 (4.4%)
Lymphedema (LENT/SOMA)	-	-	-	-	-
Fat necrosis (LENT/SOMA)	1 (0.9%)	1 (0.9%)	-	-	2 (1.8%)

RTOG/EORTC: Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer, LENT/SOMA: Late Effects Normal Tissue Task Force subjective, objective, management, and analytic scores.

#### Conclusion

APBI using interstitial multicatheter HDR-IMBT adjuvant to BCS results in acceptable rates of late toxicity and cosmetic outcome. Deterioration in the breast cosmetic scores occurs in less than 5% of the patients. The final breast cosmetic outcome seems to be mainly influenced by the cosmetic result of the surgery. Lower DNR value is significantly associated with better cosmetic outcome.

#### PO-0923 Does catheter entry-exit dosimetry correlate with grade of skin marks after breast brachytherapy?

T. Wadasadawala<sup>1</sup>, R. Krishnamurthy<sup>1</sup>, U. Gayake<sup>1</sup>, R. Phurailatpam<sup>1</sup>, S. Paul<sup>1</sup>, R. Sarin<sup>1</sup>

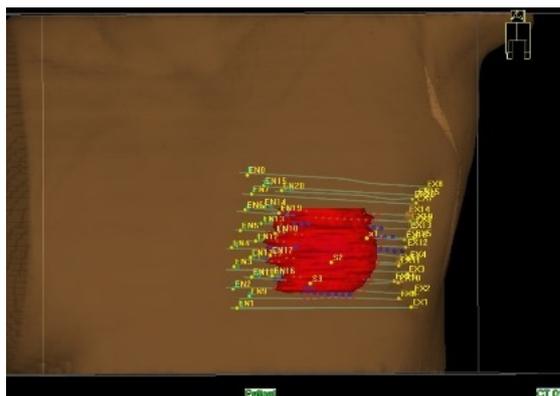

<sup>1</sup>Actrec-Tata Memorial Centre, Radiation Oncology, Navi Mumbai, India

#### Purpose or Objective

Grade of post-implant skin marks after multi-catheter interstitial brachytherapy (MIB) is an important factor in determining cosmesis. This study intends to establish the correlation if any between catheter entry-exit (E-E) dosimetry and grade of skin marks at the E-E sites.

#### Material and Methods

Visibility of the post implant E-E catheter marks was noted plane-wise for 25 patients (173 planes) with minimum 18 months follow-up post implant. All patients were treated with 34 Gy in 10 fractions, twice a day at minimum 6 hours apart. These were graded as 'not visible', 'faint', 'clear' and 'prominent'. Dose received by the skin at the E-E sites was calculated from the treated plans which were retrieved from the Oncentra treatment planning system (Figure 1). Dose maximum ( $D_{max}$ ) for each plane was determined meticulously. Closest distance of each E-E point in each plane from the respective first or last dwell position, clinical target volume (CTV) and the reference isodose (85%) was measured. Statistical analysis was done in IBM SPSS version 21. Correlation between quality of implant marks and dosimetric parameters was analyzed using Spearman's co-efficient (single tailed). Chi square test was done between the quality of marks and plane  $D_{max}$  as well as closest distances each from CTV, prescription isodose and first or last dwell position. ROC curve was used to determine dose constraints.

## Results

The median plane Dmax dose was 1.33 Gy (40% of 3.4Gy, range 0.24-3.74 Gy) and showed moderate correlation with grade of skin marks (0.505, p value 0.000). Similarly, the closest distance of the CTV, prescription isodose (Figure 2) and first-last dwell position was 1.74 (range 0.32-6.58), 1.09 (range 0.02-5.71) and 1.55 (range 0.25-4.58) cm respectively all of which also showed moderate correlation (-0.444, -0.471 and -0.495 respectively, p value 0.000 for each). 70.1% (61/85) planes with Dmax <40% of prescribed dose showed invisible or faint marks and 72.1% (62/88) planes with Dmax >40% of prescribed dose showed clear or prominent marks (p = 0.001). 86.4% (19/22) planes with closest distance from CTV <0.7 cm and 91.4% (32/35) planes with closest distance from 85% isodose < 0.5 cm showed clear or prominent marks (p = 0.001). There was very high correlation between closest distance from CTV 0.7 cm and closest distance from isodose 0.5 cm (0.715). Taking 1.33 Gy (40% of prescription dose per fraction) as a cut-off value for plane Dmax resulting in clear-prominent implant marks on ROC curve resulted in sensitivity 65% and specificity 60%.

## Conclusion

This study highlights the need for minimization of dose to the skin E-E site for reducing the risk of clear or prominent skin marks which affect cosmesis. Wherever possible it is advisable to edit the CTV to maintain a safe distance between the prescription isodose from the skin E-E points. However, larger sample size needs to be studied to increase sensitivity and specificity of the E-E dose constraint.

## PO-0924 HDR boost in CT3 breast carcinoma with neoadjuvant chemotherapy and conserving therapy

F. Romero<sup>1</sup>, J. Guinot<sup>1</sup>, M. Santos<sup>1</sup>, M. Tortajada<sup>1</sup>, P. Santamaría<sup>1</sup>, L. Oliver<sup>1</sup>, V. Campo<sup>1</sup>, L. Arribas<sup>1</sup>

<sup>1</sup>Fundación Instituto Valenciano de Oncología, Radiation Oncology, Valencia, Spain

## Purpose or Objective

Locally advanced tumors with conservative surgery have a higher relapse rate than early tumors. We analyze the clinical outcome of HDR brachytherapy boost in patients at high risk for tumor size, in terms of local control, adverse effects and cosmetic results.

## Material and Methods

Between February 1999 and October 2011, forty two patients with 43 tumours, consecutively diagnosed with cT3 infiltrative breast carcinoma were treated with neoadjuvant systemic treatment, conservative surgery and Whole Breast Irradiation (WBI) (50 Gy) followed by High Dose Rate (HDR) interstitial brachytherapy boost (3 x 4.4 Gy at 85% isodose) in two days, with rigid needles. Survival rates were calculated using the Kaplan-Meier method, and the Cox proportional hazards model to demonstrate the influence of tumor response to neoadjuvant chemotherapy.

## Results

Median age was 48 years (30-77). Median follow-up was 95 months (8-201). The average lesion size was 56.7 mm (50-100) before receiving any treatment. Local Control (LC) at 5 and 10 years was 87.1%. Overall Survival (OS) at 5 and 10 years was 85.7% and 72.4% respectively. Cancer-Specific Survival (CSS) to 5 and 10 years was 85.7% and 75.8%. Disease-Free Survival (DFS) was 74.4% and 62.7% at 5 and 10 respectively. Twenty-five tumor lesions (58%) had a complete response after neoadjuvance. There were no significant differences in terms of local control depending on the tumor response to neoadjuvant chemotherapy (p = 0.66). Nor concerning overall survival (p = 0.52) or cancer-specific survival (p = 0.74). Grade 1 early toxicity was 38.5% and Grade 2 was 12.8%. There were no early Grade 3-4 toxicity. For late toxicity, 7/43 (16.3%) of patients had fibrosis. Some of the patients reported induration from surgery. There were no trophic skin changes. Good or excellent cosmesis was recorded in 95.3% of patients.

## Conclusion

Adding HDR brachytherapy boost to conserving therapy allows preservation of breast in 87% of locally advanced breast tumors (cT3) at 10 years, with good cosmetic outcome. This technique is effective and well tolerated.

## PO-0925 Timing of post-implant analysis in permanent breast seed implant: results from a serial CT study

E. Watt<sup>1</sup>, M. Peacock<sup>2</sup>, L. Conroy<sup>1</sup>, S. Husain<sup>3</sup>, A. Frederick<sup>1</sup>, M. Roumeliotis<sup>3</sup>, T. Meyer<sup>3</sup>

<sup>1</sup>University of Calgary, Department of Physics & Astronomy, Calgary- Alberta, Canada

<sup>2</sup>University of British Columbia, Division of Radiation Oncology, Vancouver- British Columbia, Canada

<sup>3</sup>University of Calgary, Department of Oncology, Calgary- Alberta, Canada

## Purpose or Objective

Permanent breast seed implant (PBSI) is a novel, one-day procedure for the treatment of early-stage breast cancer. In this technique, stranded <sup>103</sup>Pd seeds are permanently implanted in a volume surrounding the post-lumpectomy seroma. Post-implant dosimetry is used to assess implant quality, but the timing for this analysis is performed inconsistently across cancer centres. The use of different time points for analysis limits the ability to combine results for long-term outcome studies. The purpose of this study is to determine the most appropriate timing for post-implant dosimetry.

## Material and Methods

Ten patients underwent CT scans at 0 (immediately after), 15, 30, and 60 days post-implant. Each post-implant CT scan was deformably registered to the planning scan to obtain the seroma contour (clinical target volume, CTV) using MIM Maestro™ (MIM Software, Inc., Cleveland OH). This contour was reviewed and adjusted as necessary by a radiation oncologist. Using the TG-43 dose calculation formalism, a postplan was generated for each scan. For

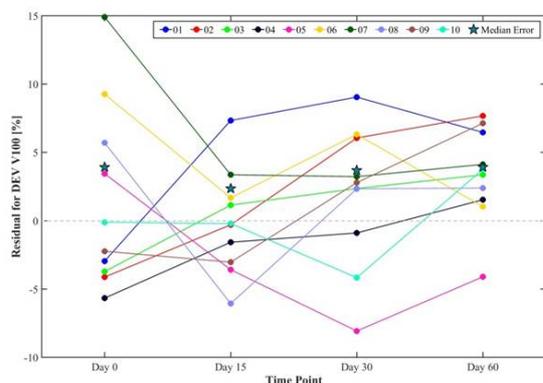

comparison, a model of the total accumulated dose to the target was calculated by summing the dose contributions from each time point. This was accomplished by deformably registering each post-implant CT scan and associated dose to the day 0 CT scan, scaling the dose contribution according to the seed activity at the time of the scan. A dose evaluation volume (DEV) was defined on all scans as a 5 mm isotropic expansion of the CTV trimmed to skin and chest wall muscle. Dosimetric indices for the CTV (V100) and DEV (V90, V100, and V200) were compared between each individual postplan and the accumulated dose using either a paired t-test or a Wilcoxon signed rank test, whichever carried more power given the distribution of the data. Residuals were also calculated, defined as the difference in dosimetric indices for a given time point and the accumulated dose model. As either a positive or a negative residual represents a deviation from the model, the median of the errors (where each error is the absolute value of the residual) was also calculated for each time point.

### Results

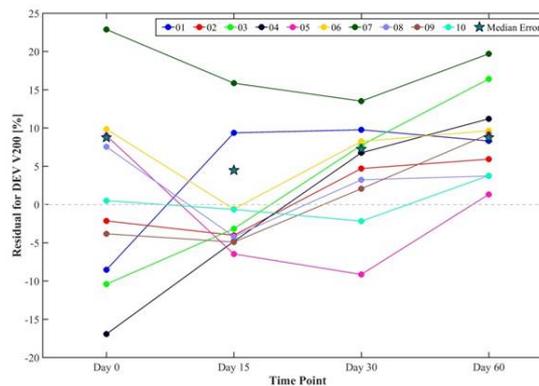

The residuals for the DEV V100 and V200 for all 10 patients at each time point are shown in Figures 1 and 2, respectively. A statistically significant difference was observed between the day 60 scan and the accumulated dose for the DEV V90, V100, and V200 (paired t-test); no other significant differences were found. The smallest median (range) error occurred for the day 15 CT scan (as demonstrated in Figures 1 and 2); 2.4% (0.2-7.3%) and 4.5% (0.6-15.9%) for the DEV V100 and V200, respectively.

### Conclusion

The results of this study indicate that the day 15 scan is the most representative of the accumulated dose delivered to target volumes in PBSI. For a 10-patient cohort, the median error was found to be at a minimum for the DEV V100 and V200 for the day 15 time point when compared to the day 0, 30, and 60 scans.

**Figure 1:** Residuals for all 10 patients for the DEV V100. Each residual is the difference between the DEV V100 for the given time point and that calculated for the accumulated dose. The median error is also shown.

**Figure 2:** Residuals for all 10 patients for the DEV V200. Each residual is the difference between the DEV V200 for the given time point and that calculated for the accumulated dose. The median error is also shown.

## Poster: Brachytherapy: Prostate

### PO-0926 Interstitial HDR prostate brachytherapy: comparison of pre- and post-implant dose distribution. S. Novikov<sup>1</sup>, S. Kanaev<sup>1</sup>, N. Ilin<sup>1</sup>, R. Novikov<sup>1</sup>, M. Girshovich<sup>1</sup>

<sup>1</sup>Prof. N.N. Petrov Research Institute of Oncology, Radiation Oncology, St. Petersburg, Russian Federation

#### Purpose or Objective

Prospective planning of interstitial high dose rate brachytherapy (HDRBT) for prostate cancer permit high accuracy of dose delivery to the tumour and/or prostate with excellent sparing of normal organs. On line correction of post-implant changes of prostate and normal tissues volumes is the key factor of precious dose delivery. The aim of the study was to evaluate possible uncertainties in dose distribution in cases when brachytherapy procedure is based only on pre-implant planning with dose distribution after HDRB with post-implant correction of dose distribution.

#### Material and Methods

In 70 primary patients with prostate cancer we analyzed dosimetric plans that were obtained during the first session of HDRBT. Pretreatment planning was performed according to standard procedure with calculation of the following dosimetric parameters: V100, D90 - for prostate, D2cc - for rectum and D10 - for urethra. According to standard HDRBT procedure after the end of needle insertion we performed final US 3D-scanning with post implant correction of prostate, urethra, bladder and rectal volumes and subsequent post-implant optimization of treatment plan.

During the study we also performed fusion of pre-implant and post-implant images. Fusion was based on needle and base-plan topography. After that we calculated dose distribution according to the model when pre-implant plan was used in patients with post-implant prostate and normal organs volumes.

#### Results

Analysis of treatment plans with post-implantation correction of the contours demonstrated high precision and excellent dosimetric parameters: mean V100 - 94.1% (V100 more than 90% in 97.2% cases), mean D90 - 104.3% (D90 more than 100% in 95.7% observations). On the contrary, after fusion of non-corrected plans and post-implant volumes we mentioned high discrepancies between preplanned and real dose distribution: V100 was below 80% in 38.6% observations; D90 was below 80% in

24.3% cases. Only in 24.3% observations D90 was above 100% (table 1). In addition, in 18% of these cases D10 for urethra was between 116% and 189%.

**Table 1.** Prostate D90 obtained on brachytherapy plans performed with and without post-implantation correction of the volumes.

Plan without volume correction		Plan with volume correction after needle implantation	
D90*	Number of patients (%)	D90*	Number of patients (%)
less than 80%	17 (24,3%)	less than 80%	-
from 80% to 90%	22 (31,4%)	from 80% to 90%	-
from 90% to 100%	17 (24,3%)	from 90% to 100%	3(4,3%)
more than 100%	14 (20,0%)	more than 100%	67 (95,7%)

### Conclusion

post-implantation correction of prostate, urethra, bladder and rectum volumes with subsequent postimplantation planning of dose distribution must be considered as obligatory part of safe and accurate prostate brachytherapy.

### PO-0927 Plug-free needles provide dosimetric advantages over plugged needles in I-125 prostate brachytherapy

A.B. Mohamed Yoosuf<sup>1</sup>, L. Sarri<sup>1</sup>, M. Byrne<sup>1</sup>, G. Workman<sup>1</sup>, D. Mitchell<sup>2</sup>, S. Jain<sup>2</sup>

<sup>1</sup>Northern Ireland Cancer Centre, Radiotherapy Medical Physics Service, Belfast, United Kingdom

<sup>2</sup>Northern Ireland Cancer Centre, Department of Clinical Oncology, Belfast, United Kingdom

### Purpose or Objective

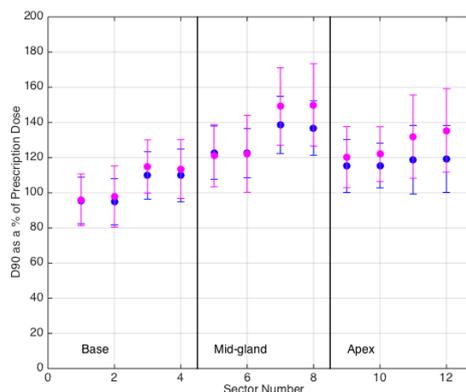

To compare the dosimetric outcome of plugged and plug-free implant needles in permanent prostate brachytherapy (PPB) using global and multi-sector post implant dosimetric analysis.

### Material and Methods

70 consecutive men treated with I-125 PPB using either plugged (group 1, n=35) or plug-free (Group 2, n=35) had their post implant (CT) dosimetry compared. For global analysis, dosimetric quality indicators evaluated between two groups included: prostate volume (CT), number of needles per unit volume, the minimum dose delivered to 90% of prostate volume (D<sub>90</sub>) and dose to 0.1 cm<sup>3</sup> of the rectum (D<sub>0.1cc</sub>). Twelve sectors of the post-implant CT was analysed for each case by dividing the prostate base, mid gland and apex into four sectors each and D<sub>90</sub> was compared for both groups.

### Results

The mean prostate volume for Group 2 (40.38 cc ± 8.0 cc) was significantly larger (p < 0.05) than Group 1 (36.45 cc ± 8.5 cc) but fewer needles were required per unit volume (Group 2 - 0.59 ± 0.12 cm<sup>3</sup> vs Group 1 - 0.72 ± 0.18 cm<sup>3</sup>; p < 0.001). Global dosimetry was similar for both groups however seed loss was significantly reduced in Group 2 (p < 0.05). Sector analysis, for Group 2, indicated increased D<sub>90</sub> in the posterior mid-gland and apex regions (p < 0.05) and a trend towards increased dose in the base sector as shown in Figure 1. The mean rectal D<sub>0.1cc</sub> was higher in Group 2 than Group 1 (124.73% ± 12.2% vs 122.54% ± 10.3%; p = 0.4) which reflected the increased dose in the posterior mid-gland. However, these remained within recommended tolerances.

**Figure 1:** Difference in D90 (%) between plugged (blue) and plug-free (pink) needles in each sector.

### Conclusion

Our study suggests that plug-free needles have the potential to improve implant quality via better spatial dose distribution within the prostate using fewer numbers of needles and reduced seed loss. Further, it provides added freedom to use any number of special loaded strands without increasing needle numbers.

### PO-0928 Androgen deprivation therapy influences PSA bounce rate after brachytherapy

W. Burchardt<sup>1</sup>, M. Kanikowski<sup>1</sup>, J. Skowronek<sup>1</sup>

<sup>1</sup>Greater Poland Cancer Centre, Brachytherapy, Poznan, Poland

### Purpose or Objective

To evaluate predictive clinical and dosimetric factor for PSA bounce (PB) after HDR and LDR brachytherapy with or without androgen deprivation therapy (ADT). PB can imitate biochemical failure and causes introduction of unnecessary diagnostics and patients' treatment.

### Material and Methods

We analysed data of 101 patients (age 50-81 years) with clinical localized prostate cancer (T1-T2cN0) treated with brachytherapy from June 2008 to December 2010 at Greater Poland Cancer Centre in Poznan, Poland. Neoadjuvant or adjuvant androgen deprivation therapy was applied in 33 cases. All patients underwent LDR (LDR n=41) or HDR (HDR n=53) brachytherapy with curative intent. The total doses (TD) for LDR was 145 Gy and for HDR brachytherapy 3 x 10,5 - 15 Gy.

### Results

A total of 94 patients were followed up at our Cancer Centre. Median follow-up was 3,0 years. Average initial PSA (iPSA) value was 7,8 ng/ml +/-3,1 (SD). In the follow up the median PSA nadir 0,1 ng/ml was achieved after median 21 months. In 58 cases PSA decreased gradually without any event. In 23 cases PB was observed using 0,2 ng/ml definition. In 10 cases (11%) biochemical failure (BF) was diagnosed using nadir + 2 ng/ml definition. In 24% of patients PB was observed. Patients treated with ADT experienced fewer PB than hormone naïve patients (90 % vs. 62%, p=0,016). Patients with PB achieved later and higher PSA nadir (time to nadir 30 vs. 18 months and PSA nadir 0,3 vs. 0,1 ng/ml). Clinical stage, Gleason scale, iPSA and risk groups were not different between PB and No PB groups.

### Conclusion

Patients after brachytherapy for low and intermediate risk prostate cancer had PB in 24 % of cases. ADT decreased the PB rate after brachytherapy what could have protected the patients from unnecessary interventions. Patients with PB had later and higher level of PSA nadir. Other clinical and dosimetric factors were not predictive for PB.

### PO-0929 Needle Migration in HDR Brachytherapy for Prostate Cancer evaluated by Serial MRI and Photos

S. Buus<sup>1</sup>, M. Lizondo<sup>2</sup>, S. Hokland<sup>3</sup>, S. Rylander<sup>3</sup>, E.

Pedersen<sup>4</sup>, L. Bentzen<sup>1</sup>, K. Tanderup<sup>3</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

<sup>2</sup>Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain

<sup>3</sup>Aarhus University Hospital, Department of Medical physics, Aarhus C, Denmark

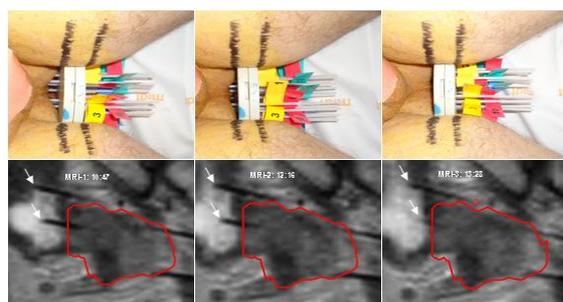

<sup>4</sup>Aarhus University Hospital, Department of Radiology, Aarhus C, Denmark

#### Purpose or Objective

Needle migration in high dose rate brachytherapy (HDR-BT) for prostate cancer may lead to insufficient target coverage and increased dose to organs at risk. The aim of this study was to assess the magnitude of needle migration in HDR-BT with serial MRI and photos.

#### Material and Methods

12 patients with high risk prostate cancer treated with EBRT and two separate boosts of HDR-BT were included in the study. In order to fixate the needles, a thin silicone pad was placed within the template, which was fixated to perineum with 4 sutures. Following US guided needle implant, patients were placed in supine position on an MRI couch on trolley for the rest of the procedure. Three MRIs were performed; one for planning (MRI1), one immediately before HDR-BT (MRI2), and one after HDR-BT (MRI3). All MRIs were a transversal T2-weighted turbo spin-echo with 2 mm slice thickness and 1.2 x 1.49 mm resolution. The position of the template was marked with indian ink on the thighs of patients, and photos of the perineum were taken after each MRI. MRI2 and MRI3 were co-registered to MRI1 to match the prostate. Coordinates of each needle tip defined on all three MRIs were used to calculate the migration for each needle. An average needle migration of  $\leq 3$  mm was considered "acceptable". On photos, movement of the template relative to the ink markings was regarded as needle migration, which was scored as either "acceptable" or "considerable" from MRI1 to MRI2 and from MRI1 to MRI3. Scoring of needle migration with MRI and photos was compared. An analysis was performed to examine whether posterior needles were more prone to migrate compared with anterior needles.

Time corresponding serial photos and sagittal MRIs showing the needle implant. Needle tips are marked with arrows and prostate is outlined in red. Note the developing oedema of the perineum

#### Results

A median of 16 needles (14 - 21) were used for each HDR-BT procedure. Serial photos were taken in 19/24 procedures. MRI2 was performed in 24/24 procedures and MRI3 in 22/24 procedures. MRI evaluated needle migration was median 2.2 mm per needle (-0.8 - 4.4) from MRI1 to MRI2, median 2.6 mm per needle (0 - 10) from MRI2 to MRI3, and median 3.9 mm per needle (0.3 - 9.8) from MRI1 to MRI3. Needle migration evaluated by MRI was found "acceptable" in 23/24 procedures from MRI1 to MRI2, and in 7/22 procedures measured from MRI1 to MRI3. Needle migration evaluated by photo was found "acceptable" in

17/19 procedures from MRI1 to MRI2 and in 13/18 procedures from MRI1 to MRI3. Concordance between scoring by photo and MRI was found in 24/37 procedures. Average needle migration was  $2.9 \pm 1.6$  mm for anterior needles and  $3.6 \pm 1.5$  mm for posterior needles (students t-test,  $p=0.08$ )

#### Conclusion

Needle migration was of acceptable magnitude measured from MRI1 to MRI2, but of considerable magnitude from MRI1 to MRI3. Insufficient concordance between scoring by photo and MRI indicates that visual inspection is inadequate for evaluating implant stability. A likely explanation for the lack of concordance between photos and MRI is the developing oedema following needle insertion.

### PO-0930 CT to TRUS based Prostate HDR: what is the optimal dosimetric margin to use?

F. Lacroix<sup>1</sup>, M. Lavallée<sup>1</sup>, E. Vigneault<sup>1</sup>, W. Foster<sup>1</sup>, A.G. Martin<sup>1</sup>

<sup>1</sup>Centre Hospitalier Universitaire de Québec- L'Hôtel-Dieu de Québec, Department of radio-oncology, Quebec, Canada

#### Purpose or Objective

The contouring volume variability resulting from delineating the target with Computed Tomography (CT) or Transrectal Ultrasound (TRUS) results in a 30 to 50% increase in volume when contouring a prostate on CT versus TRUS due to the poor soft tissue contrast of CT. This may have a significant dosimetric impact when moving from a CT to a TRUS based prostate high-dose rate (HDR) brachytherapy planning as the treated volumes are susceptible to differ significantly. This study aims at determining the proper dosimetric margin to apply when going from CT to TRUS based planning in order to compensate for this volume difference. By doing so, we aim to treat the same volume of prostatic tissue in CT or TRUS and insure a constancy in quality of care for prostate cancer patients treated with HDR.

#### Material and Methods

Twenty-seven prostate cancer patients were given a 15Gy HDR boost using a TRUS-based catheter insertion and planning approach. A 2 mm isotropic dosimetric margin was used for the TRUS planning. An average of 17 catheters were implanted. Without moving patients still under general anesthesia, a CT on rails located inside the operating room was used to image the pelvis. Three experienced radiation oncologists specialized in brachytherapy delineated the prostate on the resulting CT images and an offline, independent CT based planning was performed. A 1 mm isotropic dosimetric margin was used in CT planning. The prostate volume, 15Gy volume and V100 of the prostate were then collected and compared for the US and CT based plans.

#### Results

The average prostate, 15Gy volumes and V100 are presented in table 1.

Table 1: Average prostate volume, 15Gy volume and V100 for TRUS and CT based planning

Modality	Average prostate volume (CC)	Average 15 Gy volume (CC)	V100 (100%)
TRUS	38.0	50.2	96.3
CT	44.3	54.2	96.0

The average TRUS volume is 16.5% smaller than the average CT volume. When using a 2 mm dosimetric margin, the volume receiving 15Gy is smaller by 8% in TRUS compared to CT based planning. The V100 are almost identical with both modalities. The standard deviation on the TRUS prostate volume is slightly lower (10.6) than on CT (11.2).

## Conclusion

Our study shows an average systematic 16% smaller prostate volume on TRUS compared to CT. This differs from the 30 to 50% smaller volumes on TRUS reported in the literature. This discrepancy is probably due to the presence of catheters implanted under TRUS guidance in CT based planning which means that catheters are inserted under TRUS guidance in both planning modalities. These catheters act as fiducial markers to delimit the prostate capsule transversely on CT. The residual 16% volume variation is largely due to the uncertainty in identifying the prostate apex. A 2.8 mm isotropic dosimetric margin should be used in order to treat comparable volumes in TRUS compared to CT based planning.

## PO-0931 Clinical outcome and quality of life after MRI-guided HDR boost for prostate cancer.

F. Lakosi<sup>1</sup>, A. Miovicz<sup>1</sup>, G. Antal<sup>1</sup>, J. Pall<sup>2</sup>, D. Nagy<sup>3</sup>, M. Csima<sup>4</sup>, J. Hadjiev<sup>1</sup>, I. Repa<sup>1</sup>, G. Toller<sup>1</sup>

<sup>1</sup>Kaposvar University, Radiotherapy, Kaposva r, Hungary

<sup>2</sup>Csolnoky Ferenc Hospital, Radiotherapy, Veszprem, Hungary

<sup>3</sup>Kaposi Mor Teaching Hospital, Urology, Kaposvar, Hungary

<sup>4</sup>Kaposvar University, Faculty of Pedagogy, Kaposvar, Hungary

## Purpose or Objective

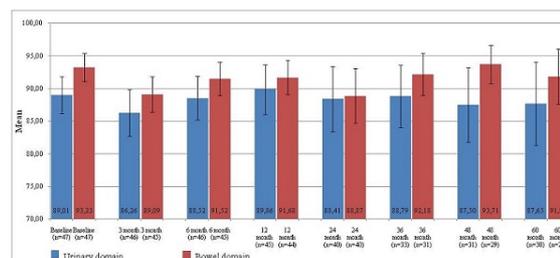

To analyze 5-year clinical outcome and quality of life (QoL) after MR-guided high-dose-rate brachytherapy (HDR-BT) combined with 3D conformal external beam radiotherapy (3D-EBRT).

## Material and Methods

Fifty-two patients with intermediate (IR) (n=22) to high-risk (HR) (n=30, 18 T3 diseases) localized prostate cancer were treated with 46-60 Gy of 3D EBRT preceded and/or followed by a single dose of 8-10 Gy MR-guided HDR-BT. Template reconstruction, trajectory planning, image guidance, contouring and treatment planning were exclusively based on MR images. Ninety-six percent of the patients received androgen deprivation. Biochemical relapse-free survival (bRFS, Phoenix definition), local relapse-free survival (LRFS), distant metastasis-free survival (DMFS), cancer-specific survival (CCS) and overall survival (OS) were analyzed actuarially. Morbidity were scored using CTCAEv4.0, while patients self-reported urinary and bowel QoL was measured with the Expanded Prostate Cancer Index Composite (EPIC) instrument and International Prostate Symptom Score (IPSS) at baseline and at regular intervals up to 6 years.

## Results

Median follow-up time was 73 (range:13-103) months. The crude/5-year actuarial rates of bRFS, LRFS, DMFS, CSS and OS were 94/97.4 %, 98/100 %, 96/97 %, 100/100 % and 92/91 %, respectively. Two distant failures occurred in HR group, while one local recurrence in IR group. The main urinary toxicity was dysuria, which were Gr. 2 in 24/52 cases, including 9 patients with alfa blocker use at baseline. There were 3 urinary strictures including one Gr. 3 event. Late GI morbidity was mild, representing Gr. 1 diarrhea (10/51), Gr. 1 urgency (9/51), Gr. 2 proctitis (1/52) and Gr. 2 fecal incontinence (1/52), respectively. A significant decline in urinary domain was observed within the first 3 months, which mostly recovered by 6 months, thereafter declined progressively (p>0.05) and remained stable from 4th years follow up (p>0.05) (Figure). A similar trend was seen for bowel QoL, where a significant decline occurred within the first 3 months that subsequently returned to nearly baseline level within 6 months, however, in contrast to urinary functions remained stable over time (p>0.05). The evolution of IPSS scores showed the same pattern as EPIC urinary scores.

## Conclusion

Five-year clinical outcome of MR-guided HDR-BT boost is encouraging, providing excellent disease control and lack of serious late side effects. A slight decline in long-term urinary QoL was observed.

## PO-0932 Prostate-specific Antigen bounce in patients treated with 125I prostate brachytherapy: Keep calm

A. Pires<sup>1</sup>, D. Moreira<sup>1</sup>, C. Castro<sup>1</sup>, A. Oliveira<sup>1</sup>, J. Oliveira<sup>2</sup>, L. Trigo<sup>3</sup>

<sup>1</sup>Instituto Português de Oncologia do Porto Francisco Gentil- EPE, Radioncology, Porto, Portugal

<sup>2</sup>Instituto Português de Oncologia do Porto Francisco Gentil- EPE, Urology, Porto, Portugal

<sup>3</sup>Instituto Português de Oncologia do Porto Francisco Gentil- EPE, Brachytherapy, Porto, Portugal

## Purpose or Objective

Permanent low-dose-rate brachytherapy (BT) with <sup>125</sup>I is an established curative modality for the treatment of localized prostate cancer. After treatment, prostate-specific antigen (PSA) level may fluctuate and temporarily increase without a clear reason. This phenomenon is called "PSA bounce" (PSAb) and often causes anxiety in patient and physician. Our aim was to analyse the kinetics of PSA in our patients and the association between PSA bounce and the long term disease outcome after prostate BT with <sup>125</sup>I.

## Material and Methods

We analysed 134 patients treated with <sup>125</sup>I implantation monotherapy between 2004 and 2006 in a single institution. All patients had tumour stage T1-T2cN0M0, Gleason score ≤ 7 and follow-up time was ≥ 9 years. Patients who received neo-adjuvant hormone therapy were excluded. PSAb was defined as a rise beyond 0.2 ng/ml the initial PSA nadir with a subsequent decline to or below the initial nadir without treatment. Biochemical failure (BF) was determined using the Phoenix definition (nadir +2 ng/mL). Associations between PSAb and the various pre and post-treatment factors were assessed with logistic regression analysis, the association between a PSAb and BF was examined with the *log-rank* test and the *Mann-Whitney U* test was applied to test for difference in the time to a PSA rise between PSAb and BF patients.

## Results

PSAb occurred in 53 (39,8%) patients with a median time to bounce of 18,8 months. Only 7 (13,2%) patients with PSAb developed BF, in contrast to 12 (15%) patients without previous bounce (p = 0,084). Among the pre and post-treatment factors, only younger age predicted a PSAb on a multivariate analysis (p = 0.049). PSA levels during the bounce reached levels as high as 8,85 ng/mL in this cohort. BF occurred in 19 patients (14,4%). The 9-year overall survival rate was 83,6%, the 9-year disease-specific survival was 95,8% and the rate of survival at 9-year freedom from BF was higher than 90%.

## Conclusion

PSAb is a common finding in our population and is associated with a lower rate of subsequent BF. Patients should be advised for the eventual PSAb after permanent <sup>125</sup>I prostate BT. Those who experience a PSAb are more likely to be younger. The physicians involved in patients follow-up after prostate BT should also be aware

of this phenomenon, encouraging them to adhere to appropriate PSA surveillance and avoiding unnecessary and repetitive PSA measurements, biopsies and premature or inappropriate initiation of salvage therapy during PSAB.

#### Poster: Brachytherapy: Gynaecology

##### PO-0933 Urethral dose in cervical image guided brachytherapy

K. MacLennan<sup>1</sup>, M. Zahra<sup>2</sup>, W. Keough<sup>2</sup>

<sup>1</sup>NHS Lothian, ST6, Edinburgh, United Kingdom

<sup>2</sup>NHS Lothian, Edinburgh Cancer Centre, Edinburgh, United Kingdom

##### Purpose or Objective

Urethral dose is not currently included in the recommendations for the dose constraints for organs at risk (OARs). However, combined external beam and HDR cervical brachytherapy can result in significant urinary toxicity. We investigated the urethral dosimetry for patients treated with HDR brachytherapy.

##### Material and Methods

Retrospective audit of 117 patients undergoing cervical brachytherapy for cervical cancer in the Edinburgh Cancer Centre between 2010-2015. Patients were treated with 45Gy/25 fractions EBRT followed by 3 fractions of CT-guided HDR brachytherapy with a ring and tandem aiming for D90 between 80-85Gy. The urethra and peri-urethral tissues were retrospectively contoured 1cm inferiorly from bladder neck or to the axial slice corresponding to the metal connector of ring and tandem device (whichever most inferior). Dose volume histograms were used to determine the urethral D2cc and expressed as 2Gy equivalent (EQD2) using an a/b ratio of 3. A combined EQD2 dose for external beam and HDR treatment was calculated. Data was also collected on the length and angle of the tandem applicator and a paired T-test with 0.05 significance level was used to assess the effect of the angle or tandem length on the urethral dose.

##### Results

117 patients aged 21-84. A 30° applicator angle was used in 12% cases, 45° in 67%, 60° in 21% patients. A 6 cm applicator was used in 68% patients; 4cm in 32% patients. 7 patients had a single fraction of HDR brachytherapy and converted to a CT planned phase 2 with external beam radiotherapy. Excluding the phase 2 patients, median combined dose to HRCTV was 84.03 Gy and to the urethral d2cc was 50.7Gy (range: 44.8- 173.9Gy) Comparing the maximum EQD2 to 2cm<sup>3</sup> urethra from the fractionated treatment by applicator angle and length;

Applicator Angle	30° Tandem	45° Tandem	60° Tandem
Maximum EQD2 per fraction to 2cm <sup>3</sup> urethra	Median 1.52 Gy (range 0.94-4.90)	Median 3.63 Gy (range 0.70-60.98)	Median 3.262 Gy (range 0.76-23.67)
Total EQD2 2cm <sup>3</sup> urethra 3 fractions HDR BT	Median 3.59 Gy (range 1.59-12.30)	Median 8.07 Gy (range 1.82-130.75)	Median 6.89 Gy (range 2.14-52.81)

T test for angle (30° vs 45°, 45° vs 60° and 60° vs 45°) suggested a difference in urethral dose using a 30° applicator, with a tendency for lower urethral D2cc with a 30° angle. (30 vs 45 p = 0.002 and 30 vs 60 p = 0.04).

There was no difference in urethral dose per HDR fraction according to applicator length (t-test, p = 0.54).

##### Conclusion

There is little existing data guiding urethral dose constraint but study in peri-urethral cancer has demonstrated a higher risk of urethral toxicity in patients with a urethral EQD2 of >85Gy. Our median EQD2 was below this level but with a wide range, indicating the degree of adaptation using image guidance. Given the poor correlation of applicator angle and length with dose to OARs choice of applicator should remain dictated by the patients' anatomy.

##### PO-0934 Brachytherapy as part of the conservative treatment for primary and recurrent vulvar carcinoma

C. Chargari<sup>1,2</sup>, P. Castelnau-Marchand<sup>1</sup>, A. Escande<sup>1</sup>, I.

Dumas<sup>1</sup>, R. Mazon<sup>1</sup>, P. Maroun<sup>1</sup>, E. Bentivegna<sup>3</sup>, S.

Gouy<sup>3</sup>, A. Cavalcanti<sup>3</sup>, P. Morice<sup>3</sup>, C. Haie-Meder<sup>1</sup>

<sup>1</sup>Gustave Roussy Cancer Campus, Brachytherapy unit- Radiation oncology, Villejuif, France

<sup>2</sup>French Military Health Services Academy, French

Military Health Services Academy, Paris, France

<sup>3</sup>Gustave Roussy Cancer Campus, Department of Surgery, Villejuif, France

##### Purpose or Objective

There are only scarce data on the place of brachytherapy (BT) for treatment of vulvar carcinoma. Our institutional experience of interstitial BT for vulvar carcinoma patients is reported.

##### Material and Methods

Clinical records of patients receiving low-dose rate (LDR) or pulsed-dose rate (PDR) BT as part of the primary treatment for primary/recurrent vulvar squamous cell carcinoma or as part of adjuvant treatment between 2000 and 2015 were included. Patients, tumors and treatments characteristics as well as clinical outcome were examined.

##### Results

A total of 26 patients treated with BT were identified. BT was delivered as part of primary intent treatment for locally advanced/recurrent cancer in 11 patients, and as part of adjuvant treatment in 15 patients. Median age at time of BT was 63 years (range: 41 - 88 years). PDR and LDR were used in 15 patients and 11 patients, respectively. BT was performed as a boost to the tumour bed following EBRT (n=13) or as only irradiation modality (n=13). Total median dose at the level of primary tumor was 60 GyEQD2 (range: 55 - 60 GyEQD2). With mean follow-up of 41 months (range: 5 months - 11.3 years), 11 patients experienced tumour relapse. Ten patients experienced local relapse as first event, associated with synchronous extra-vulvar events in 8/10 patients. Three-year estimated disease-free survival and overall survival rates were 57% (95%CI: 45-69%) and 81% (95%CI: 72-90%). All toxicities were grade 2 or less.

##### Conclusion

Interstitial BT used as part of the primary or adjuvant treatment of vulvar carcinoma is feasible with a satisfactory toxicity profile. Prognosis remains however, dismal, with a high frequency of local and distant failures in patients with locally advanced tumors.

##### PO-0935 Modeling to compensate for intra-fractional bladder dose variations in gynecological brachytherapy

Z. Siavashpour<sup>1</sup>, R. Jaber<sup>2</sup>, M.R. Aghamiri<sup>1</sup>, C. Kirisits<sup>3</sup>

<sup>1</sup>Shahid Beheshti University, Medical Radiation

Engineering, Tehran, Iran Islamic Republic of

<sup>2</sup>Tehran University of Medical Sciences, Radiotherapy, Tehran, Iran Islamic Republic of

<sup>3</sup>Comprehensive Cancer Center- Medical University of Vienna, Department of Radiotherapy and Oncology, Vienna, Austria

##### Purpose or Objective

Proposing a model to compensate for intra-fractional bladder dose variations during gynecological (GYN) brachytherapy.

### Material and Methods

Thirty advanced cervical cancer patients treated with HDR ( $^{192}\text{Ir}$  source) intracavitary brachytherapy were selected. Rotterdam applicators (tandem-ovoids) were used for them. Patients pelvic CT scans were done twice; pre- and post-treatment (about 30 min after dose delivery), with applicator in situ. Flexiplan<sup>®</sup> (version 2.6, Isodose control, the Netherlands) as a 3D treatment planning software was used. Applicator reconstruction and organs delineation were done by the same physicist /physician on both image sets. Totally identical plans (dwell times/positions) were applied to both image sets and DVH parameters were recorded; planning aims: 80-90 Gy (EQD2) for  $D_{90}$  of  $\text{CTV}_{\text{HR}}$  and less than 85, 75, and 75 Gy for  $D_{2\text{cm}^3}$  of bladder, rectum, and sigmoid, respectively.

RT-Structure files (in DICOM format) of the patients for whom intra-fractional dose ( $D_{2\text{cm}^3}$ ) variations were higher than 5% were exported from planning system. Applicator-organs distances along the active length of three applicators were extracted by some in-house MATLAB written codes. Source dwell times were extracted from treatment planning report files (in xps format). A model was design to propose new source dwell times to compensate for the bladder wall to applicators walls distances intra-fractional variations, considering the TG43 algorithm and inverse square law. Some dwell times acceptance criteria were considered during modeling such as:  $D_{90}$  of  $\text{CTV}_{\text{HR}}$  and  $\text{CTV}_{\text{IR}}$  have not changed to be less than 85 Gy 70 Gy, respectively. New dwell times were applied to the plans to test their influences on DVH parameters. Also, the model was further optimized to reduce the executing time by searching for the most impressive part of the applicators lengths on bladder dose.

### Results

For one third of the considered patients bladder dose changes were higher than 5%. Mean  $\pm$  SD of  $D_{2\text{cm}^3}$  intra-fractional relative changes ( $(D_{2\text{cm}^3(\text{before})} - D_{2\text{cm}^3(\text{after})}) / D_{2\text{cm}^3(\text{before})} \times 100$ ) of these ten cases were  $19.3 \pm 18.0$  %. After correcting the plans these variations became  $10.5 \pm 14.5$ . More bladder dose correction would lead to a significant decrease in dose to  $\text{CTV}_{\text{HR}}$  and was unjustifiable. Model runtime was about 3 minutes (Intel corei7 laptop, RAM = 8 GB, CPU = 2 GHz).

### Conclusion

A model was developed to correct the bladder dose to be as similar as possible to the pre-treatment plan one. It is a semi-online model that can be used in the routine clinical workflow to reduce the GYN image-guided adaptive brachytherapy uncertainties. The model can be generalized to other organs at risk.

### PO-0936 Dose effects of draining rectal gas in image-guided brachytherapy for gynecological cancer

H. Takase<sup>1</sup>, N. Ii<sup>2</sup>, Y. Yamao<sup>1</sup>, T. Kawamura<sup>2</sup>, M. Naito<sup>1</sup>, Y. Watanabe<sup>2,3</sup>, Y. Toyomasu<sup>2</sup>, A. Takada<sup>2</sup>, H. Tanaka<sup>2</sup>, T. Yamada<sup>1</sup>, H. Maki<sup>1</sup>, H. Sakuma<sup>4</sup>, Y. Nomoto<sup>5</sup>

<sup>1</sup>Mie University Hospital, Department of Radiology, Tsu, Japan

<sup>2</sup>Mie University Hospital, Department of Radiation Oncology, Tsu, Japan

<sup>3</sup>Matsusaka central hospital, Department of Radiation Oncology, Matsusaka, Japan

<sup>4</sup>Mie University Graduate School of Medicine, Department of Radiology, Tsu, Japan

<sup>5</sup>Mie University Graduate School of Medicine, Department of Radiation Oncology, Tsu, Japan

### Purpose or Objective

To verify the usefulness of draining rectal gas in image-guided high-dose-rate brachytherapy for gynecological cancer, we quantified the dose delivered to the rectum and urinary bladder with and without draining rectal gas.

### Material and Methods

From October 2013 to July 2014, 116 brachytherapy fractions from 34 patients were performed in our

department for gynecological cancer. After the applicators were inserted, cone beam computed tomography (CT) images were obtained. Rectal gas was observed in 11 brachytherapy fractions from 8 patients. After draining rectal gas with a Nelaton catheter, cone beam CT images were obtained again. Brachytherapy was prescribed to point A using standard two-dimensional dosimetry and planning. To quantify the dose delivered to the rectum and urinary bladder, three-dimensional dose distributions were calculated using the images from before and after draining rectal gas. The dose to the rectum and urinary bladder was evaluated based on dose-volume histograms. The influence of the volume of discharging rectal gas (pre-draining rectal volume - post-draining rectal volume) on the rectal dose was investigated. The minimum doses to the maximum exposed 0.1, 1 and 2 cc ( $D_{0.1\text{cc}}$ ,  $D_{1\text{cc}}$  and  $D_{2\text{cc}}$ ) volumes were evaluated using the dose from point A. Statistical analyses were conducted using the paired t-test and a linear regression model.

### Results

The mean rectal dose after draining rectal gas was significantly lower than that before draining. The rectal doses ( $D_{0.1\text{cc}}$ ,  $D_{1\text{cc}}$  and  $D_{2\text{cc}}$ ) relative to point A at post-draining vs. pre-draining were as follows: 106.9% vs. 121.2%, 88.3% vs. 98.6% and 81.5% vs. 90.9%, respectively ( $p < 0.05$ ). The mean urinary bladder dose was not significantly different after draining rectal gas from before. The urinary bladder doses ( $D_{0.1\text{cc}}$ ,  $D_{1\text{cc}}$  and  $D_{2\text{cc}}$ ) relative to point A at post-draining vs. pre-draining were as follows: 136.0% vs. 133.2%, 112.3% vs. 111.8% and 103.3% vs. 102.4%, respectively. The volume of discharging rectal gas slightly correlated with the rectal dose at  $D_{0.1\text{cc}}$  ( $R^2=0.45$ ); however, no significant correlation was found for  $D_{1\text{cc}}$  or  $D_{2\text{cc}}$  ( $R^2=0.10$  and  $-0.01$ , respectively).

### Conclusion

Our data suggested that draining rectal gas is useful for reducing the rectal dose in high-dose-rate brachytherapy for gynecological cancer.

### PO-0937 HDR image-guided interstitial brachytherapy for postoperative local recurrent uterine cancer

K. Yoshida<sup>1</sup>, H. Yamazaki<sup>2</sup>, T. Takenaka<sup>2</sup>, T. Kotsuma<sup>3</sup>, K. Masui<sup>2</sup>, T. Komori<sup>1</sup>, T. Shimbo<sup>1</sup>, N. Yoshikawa<sup>1</sup>, H. Narumi<sup>1</sup>

<sup>1</sup>Osaka Medical College, Radiology, Takatsuki, Japan

<sup>2</sup>Kyoto Prefectural University of Medicine, Radiology, Kyoto, Japan

<sup>3</sup>National Hospital Organization Osaka National Hospital, Radiation Oncology, Osaka, Japan

<sup>4</sup>Kansai University of Welfare Sciences, Rehabilitation Sciences, Kashiwara, Japan

### Purpose or Objective

In order to evaluate the usefulness of high-dose-rate (HDR) image-guided interstitial brachytherapy (ISBT) for postoperative local recurrent uterine cancer, we analyzed our clinical experience.

### Material and Methods

We investigated 48 patients treated with HDR-ISBT at National Hospital Organization Osaka National Hospital and Osaka Medical College between May 2003 and January 2014. All patients received radical surgery and 10 patients also received post-operative radiotherapy as previous treatments. Histologic finding was squamous cell carcinoma (SCC), endometrioid adenocarcinoma (AD), mucinous adenocarcinoma (MAD) and the others (serous/adenosquamous/endocrine/undifferentiated) for 20, 17, 5 and 6 patients. The median maximum tumor diameter was 25 mm (range; 5-79 mm). In 38 patients who had non-irradiation history, 23 patients also received external beam radiotherapy (EBRT). The median ISBT

doses were 54 Gy in 9 fractions as monotherapy and 30 Gy in 5 fractions as combination of EBRT. In 10 patients who had irradiation history, lower doses (36 to 48 Gy in 6 to 8 fractions) were selected. We implanted 7-16 (median, 13) applicators under transrectal ultrasonography guidance. We used free-hand implantation with ambulatory technique for later 42 patients. Magnetic resonance imaging (MRI)-assisted image-based treatment planning was also performed. Clinical target volumes (CTV) were the gross tumor volume with or without 10 mm of vaginal margin for patients with or without non-irradiation history.

#### Results

The median follow-up time was 41 months (range; 4-115 months). The median  $D_{90}(CTV)$ s were 91.3 Gy and 75.6 Gy for patients with or without non-irradiation history. The 4-year local control and overall survival rates were 78% and 67% for all patients. The 4-year local control rates were 83% and 60% for patients with or without non-irradiation history ( $p=0.02$ ). Tumor diameter, primary site and histology were not significant prognostic factors of local control. The 4-year overall survival rates were 73, 65, 100 and 20% for SCC, AD, MAD and the others ( $P=0.06$ ). The  $D_{90}(CTV)$ s were  $93.5\pm 24.3$  Gy and  $81.4\pm 9.2$  Gy for local control and failure patients ( $p=0.1$ ). Grade  $\geq 3$  late complications occurred in 11 patients (23%). Ileus was only observed for patients receiving EBRT.

#### Conclusion

Our treatment result of image-guided HDR-ISBT showed good local control result. However, previous irradiation history was a worse prognostic factor of local control. Dose-volume histogram seems to be useful for dose prescription.

#### PO-0938 Should we use point A dose for image-guided adaptive brachytherapy reporting in cervix cancer?

R. Mazon<sup>1</sup>, I. Dumas<sup>2</sup>, A. Escande<sup>1</sup>, W. Bacorro<sup>1</sup>, R. Sun<sup>1</sup>, C. Haie-Meder<sup>1</sup>, C. Chargari<sup>1</sup>

<sup>1</sup>Institut Gustave Roussy, Radiation Oncology, Villejuif, France

<sup>2</sup>Institut Gustave Roussy, Medical Physics, Villejuif, France

#### Purpose or Objective

The recent ICRU report 89 recommends continuing the reporting of point A dose in the era of Image-guided adaptive brachytherapy (IGABT). The study aim was to evaluate the interest of such recommendation by testing the value of point A as a surrogate of volumetric dosimetric parameters and as a predicting factor of local control.

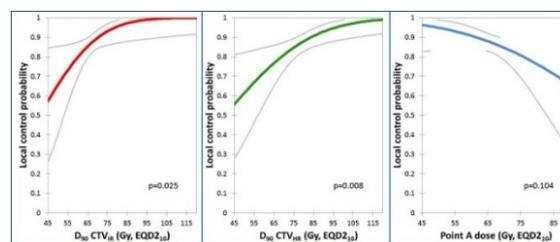

#### Material and Methods

The dosimetric data from patients treated with a combination of chemoradiation and intracavitary image-guided adaptive brachytherapy were confronted to their outcomes. Prescribing followed the GEC-ESTRO recommendations. Point A was used for reporting, without specific planning aim. All doses were converted in 2-Gy equivalent, summing brachytherapy and EBRT doses. The relationships between the  $D_{90}CTV_{HR}$  and  $CTV_{IR}$  and point A doses were studied. Dose-effect relationships based on the probit model and log-rank tests were assessed using the different dosimetric parameters.

#### Results

Two hundred and twelve patients were included with a median follow-up of 53.0 months. MRI guidance was used in 89.6% of the cases. A total of 28 local relapses were reported resulting in a local control rate of 86.6% at 3 years. Mean  $D_{90}CTV_{HR}$ ,  $D_{90}CTV_{IR}$  and point A doses were respectively:  $79.7\pm 10.4$  Gy,  $67.4\pm 5.8$  Gy and  $66.4\pm 5.6$  Gy. The mean  $D_{90}CTV_{HR}$  and  $CTV_{IR}$  were significantly different from the mean point A dose ( $p=p<0.0001$ , and 0.022 respectively). Both  $D_{90}CTV$  were independent from point A doses, even in bulky (width  $>5$ cm) tumors at diagnosis or in large  $CTV_{HR}$  lesions ( $\geq 30\text{cm}^3$ ) Whereas significant

relationships between the probability of achieving local control and the  $D_{90}CTV_{HR}$  and  $CTV_{IR}$  ( $p=0.08$  and 0.025 respectively) were observed, no significant relationship between point A dose and local control probability could have been established (Figure). Moreover, a trend towards an inverse relation was observed. After sorting patients according to 3 levels of doses, highest local control rates were reported in patients with  $D_{90}CTV_{HR} \geq 85$  Gy, whereas the patients with point A doses  $\geq 70$  Gy had the worst outcomes.

#### Conclusion

In patients treated with IGABT, point A dose is not predictive of local control, and nor correlated to  $D_{90}$ . It tends to be inversely related to  $D_{90}$  and therefore to be a surrogate of the irradiated volume. The pertinence of reporting point A dose should be questioned.

#### PO-0939 Comparison of brachytherapy sources of endometrial cancer: Electronic brachytherapy source and 192Ir

S. Lozares<sup>1</sup>, J.A. Font Gómez<sup>1</sup>, A. Gandía Martínez<sup>1</sup>, A. Miranda Burgos<sup>2</sup>, A. Méndez Villamón<sup>2</sup>

<sup>1</sup>Hospital Universitario Miguel Servet, Medical Physics and Radiation Protection Department, Zaragoza, Spain

<sup>2</sup>Hospital Universitario Miguel Servet, Oncologic Radiotherapy Department, Zaragoza, Spain

#### Purpose or Objective

To compare 29 endometrial cancer patients treated in our center with cylindrical applicators and Axxent (Xoft Inc.) electronic brachytherapy with an equivalent planning made for Ir-192 source.

#### Material and Methods

29 patients previously treated with Axxent (50 kV source) have been replanned with Ir-192 source. The calculation for both types of sources were performed on BrachyVision (Varian Inc.) treatment planning system. The prescription was 5 Gy per fraction applied in 3 fractions or 5 fractions depending on previous radiotherapy treatment.

The planning parameters of the planning target volume (PTV) counted from the cylinder surface to 5 mm along the active length were evaluated. V150 and V200 data for PTV and D2cc, V50% and V35% for organs at risk (OAR) were evaluated, the percentage of the volume receiving 35% and 50% of the prescription dose, respectively, and D2cc, highest dose to a 2 cubic centimetre volume of an OAR. Results for bladder, rectum and sigmoid are showed.

## Results

Table 1				
n=29	Axxent 50kV	SD	Ir-192	SD
<b>PTV</b>	<b>%</b>	<b>%</b>	<b>%</b>	<b>%</b>
V150	20,5	5,9	8,6	4,9
V200	1,5	1,7	0,1	0,2
<b>Bladder</b>				
D2cm <sup>3</sup> (%PD)	66,4	17,1	71,6	13,9
V50%	7,2	6,9	11,9	9,5
V35%	14,8	12,3	26,6	17,9
<b>Rectum</b>				
D2cm <sup>3</sup> (%PD)	68,4	17,9	73,5	16,3
V50%	9,9	6,6	16,7	11
V35%	19,9	11,3	36,0	18,8
<b>Sigmoid</b>				
D2cm <sup>3</sup> (%PD)	51,4	29	59,8	24,6
V50%	12,9	15,6	21,3	22
V35%	28,8	28,6	41,5	28,2

PD:prescribed dose

We may observe a reduction in dose at V35% and V50% in all OAR and also a reduction in D2cm<sup>3</sup> occurs (Table 1). PTV parameters increase in the case of Axxent, as reported previously, but very few cases of vaginal mucositis have been reported in our center as is showed in another clinical abstract. All patients were treated between 2015 and early 2016, enough time to develop early problems.

#### Conclusion

Preliminary results are very optimistic about the adequacy of Xofig equipment for treatment of endometrial cancer with a clear reduction of the physical dose in organs at risk and very few development of acute mucositis despite the considerable increase V150 in the treatment volume. Further studies will be necessary to take into account the RBE in treatments with such sources.

#### PO-0940 3D mapping for precise definition of GTV, CTV and their correlation in cervix cancer BT (EMBRACE)

#### Purpose or Objective

Image Guided adaptive Brachytherapy (BT) for cervix cancer is based on MRI and gynaecologic examination (GE) at diagnosis (D) and at BT to define the HR CTV. For documentation of disease at D and at BT schematic mapping diagrams (SMD) are used indicating values for maximum dimensions of GTV at D and at BT. For comprehensive assessment of available volumetric information through MRI at D and at BT an advanced schematic 3D mapping diagram (3DMD) was developed to provide precise reproducible topographic and quantitative information (Fig1). This was used to evaluate the topographic and quantitative relation between GTVD, HR CTV and IR CTV.

#### Material and Methods

42 proven cervical cancer FIGO IIB-IIIB patients from Vienna and Mumbai were selected, mean age was 52 years. All were enrolled in the EMBRACE study and completed the planned treatment with MRI at D and at BT. SMDs from GE with individual tumour contours and dimensions as prescribed for EMBRACE were available. A 3DMD in axial, coronal and sagittal orientation was used with a scale (grid with 10 mm distance) for the precise

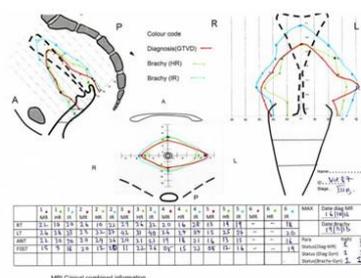

documentation of available volumetric information through MRI at D and at BT. This 3DMD had been developed by the authors to provide precise reproducible topographic and quantitative information in one comprehensive overview (Fig1).

Dimensions of GTV<sub>D</sub>, HR-CTV and IR-CTV for width, thickness and maximum height (GEC-ESTRO Recommendations) as assessed on MRI D/BT (SE T2 weighted sequences) was drawn at all grid levels and in all 3 dimensions as requested in the 3DMD. The cervical canal was taken as the central axis and the external os (surrogate for flange) as reference for the various dimensions.

A qualitative observation was done based on the drawings of all 42 cases on individual maps. A quantitative analysis was done with SPSS v20. The dimensions (height, width and thickness) and volumes were compared and correlated (n= 42). Thereafter another quantitative analysis of the widths of GTVD, HRCTV and IRCTV at 0, 1, 2 and 3 cm and at NMD (Near Maximum distance from the central tandem/central canal) was done (n=84).

Figure 1: advanced schematic mapping diagram (3DMD) in axial, coronal and sagittal orientation with a measurement scale (grid with 10 mm distance). A table indicates tumor/target (bilateral) dimensions at various levels at the time of diagnosis and brachytherapy. The schematic diagram combines maximum information from the MRI images and gynaecological examination. A typical case (stage IIB) is mapped to illustrate the qualitative final results that were available for evaluation.

Fig1

Abbreviations used in the Figure: MR: GTV at diagnostic MRI (GTV<sub>D</sub>); HR: HRCTV; IR: IRCTV; Date of diag MR: Date of MRI done before any treatment; Date of Brachy: Date of 1<sup>st</sup> Brachytherapy; Para: Parametrium; Status (Diag MR): Status of parametrium on MRI finding at diagnosis; Status (Diag Gyn): Status of Parametrium from Gynaecological Exam; Status (Brachy gyn): Status of parametrium from Gynaecological Exam during first Brachytherapy. The Values 1, 2 and 3 indicates status of parametrium as per EMBRACE study; MR clinical combined information: The schematic diagram combines maximum information from the MRI images and also the status of parametrium from the Gynaecological examination.

#### Results

The dimensions of the HRCTV followed closely that of GTVD, with some variations and exceptions. The IRCTV volumes were closely overlapping the HRCTV volumes. In most of the cases the HRCTV and IRCTV were encompassing the GTVD volumes.

For the detailed quantitative results see table 1.

TABLE 1	Mean $\pm$ SD	Mean $\pm$ SD	Mean $\pm$ SD	Mean $\pm$ SD	Mean $\pm$ SD
	(Median; range)	(Median; range)	(Median; range)	(Median; range)	(Median; range)
	[Correlation( $\rho$ value)]	[Correlation( $\rho$ value)]	[Correlation( $\rho$ value)]		
Volume in cm <sup>3</sup>	75.7+/50.8 (64.8, 9.7-227)	55.3+/36.3 (44.3, 12.3-163) [0.66(0.00)]	98.6+/51.1 (87.1, 23-231) [0.64(0.00)]	1.7+/1.6 (1.3, 0.34-9.89)	0.9(+/-0.6) (0.7, 0.16-4.0)
Height in mm	47.5+/13.1 (46.5, 22-75)	45.3+/10.8 (44.5, 30-70) [0.65(0.00)]	54.8+/11.3 (53.5, 39-80) [0.56(0.00)]	1.1+/0.2 (1.0, 0.6-1.8)	0.9(+/-0.2) (0.9, 0.5-1.4)
Width in mm	60.95+/11.98 (62, 41-90)	55.09+/11.57 54.5, 35-83 [0.45(0.003)]	69.45+/12.95 (68.5, 44-94) [0.48(0.001)]	1.1+/0.3 (1.1, 0.8-2.6)	0.89+/0.2 (0.8, 0.6-1.9)
Thickness in mm	46.2+/13.4 (42, 20-92)	39.3+/10.8 (39, 19-62) [0.47(0.002)]	48.07+/10.96 (47, 25-71) [0.49(0.001)]	1.2+/0.4 (1.2, 0.5-2.7)	1.0(+/-0.3) (0.9, 0.5-1.7)

**Table 1** Describes quantitatively the volumes and dimensions of GTVD, HR-CTV and IR-CTV at first brachytherapy. The Pearson's correlation values of volumes of HRCTV and IRCTV with GTVD are 0.66 and 0.64, respectively, with each value significant ( $P=0.00$ ). The Pearson's correlation coefficient ( $r$ ) for height, width and thickness between initial dimensions of disease and HRCTV at first brachytherapy was significant with values of 0.66(0.00), 0.45(0.003) and 0.47(0.002) respectively. The correlation among similar dimensions between GTVD and IRCTV were similar with values of 0.56(0.00), 0.48(0.001) and 0.49(0.001) and, respectively. The correlation between HRCTV and IRCTV approaches one in all the three dimensions of height, thickness and width. The correlations of the maximum width of HRCTV and IRCTV with that of GTVD (NMD) were 0.41(0.00) and 0.4(0.00) respectively.

## Conclusion

The advanced schematic 3D mapping diagram provides precise topographic and quantitative 3D information on extent of disease and for CTV for BT, using repetitive MRI. There is a significant correlation of GTVD with HRCTV and IRCTV in regard to volumes and dimensions. This new tool may also be used for BT CTV definition based on GE and CT/US.

**PO-0941 Verifying the treatment planning system in individualized HDR brachytherapy of cervical cancer**  
M. Van den Bosch<sup>1</sup>, B. Vanneste<sup>1</sup>, R. Voncken<sup>1</sup>, L. Lutgens<sup>1</sup>  
<sup>1</sup>MAASTRO Clinic, Department of Radiation Oncology, Maastricht, The Netherlands

## Purpose or Objective

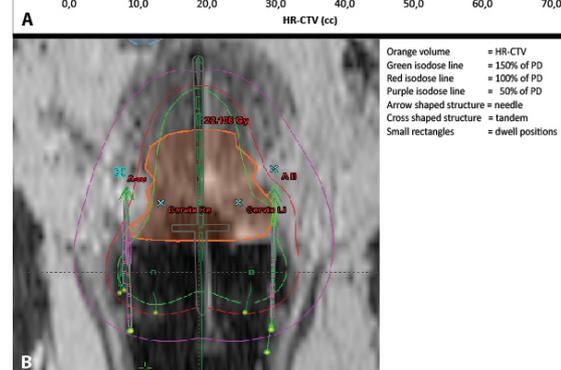

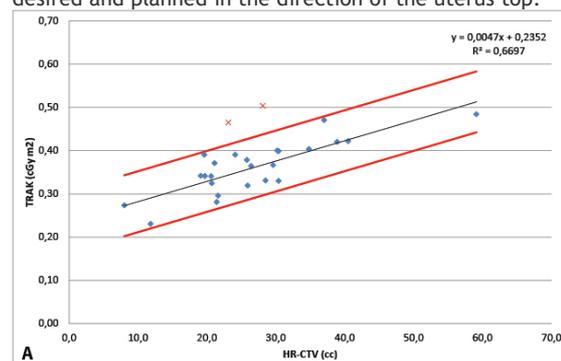

In state of the art high-dose-rate (HDR) brachytherapy of the cervical cancer interstitial needles are regularly placed in addition to the standard applicators to increase the possibility for dose optimization, i.e. higher tumour coverage and/or sparing of OAR's. The use of these needles enables more individualized treatment plans. Consequently dose distributions and dose plans have become highly individualized. As a result, the main output parameter of the planning system, the total reference air kerma (TRAK), is more difficult to verify. In this study, it is investigated whether the high risk clinical target volume (HR-CTV) can be used to predict the TRAK.

## Material and Methods

26 treatment plans of 10 cervical cancer patients were included in this study. In all patients the titanium Varian Fletcher applicator was inserted. The number of interstitial PEEK Varian needles was determined by the radiation oncologist at the time of the application. T2-weighted MR scans were acquired in treatment position and used for delineation of the HR-CTV, intermediate risk-CTV (IR-CTV) and organs at risk (OARs). Contouring was done by the responsible radiation oncologist whereas a treatment plan was made by the radiation therapist using BrachyVision (algorithm: TG-43). The calculated TRAK values of each plan were rescaled to a source strength of 10 Ci and to a fraction dose of 7 Gy (prescribed to the HR-CTV).

## Results

The number of needles varied from 0 to 8 (average 3.8 needles per application). The rescaled TRAK and mean volume of the HR-CTV was 0.37 cGy m<sup>2</sup> (range: 0.23-0.50 cGy m<sup>2</sup>) and 26.8 cc (range: 8.0-59.1 cc), respectively. In general, the TRAK value increased with volume. In figure 1a the TRAK values are plotted against the HR-CTV. The relation between these parameters can be described by a linear equation (see figure 1b). When setting an upper and lower limit of two standard deviations a 95% confidence interval can be derived and outliers can be identified. The higher TRAK value of these outliers suggest the volume that received the prescribed dose is much larger than the HR-CTV. This was true for these plans: due to excessive reduction of the HR-CTV, a higher dose in the IR-CTV was desired and planned in the direction of the uterus top.

**Figure 1.** (A) HR-CTV vs. TRAK. Black line represents the linear fit. The red lines encompass the 95% confidence interval. Blue dots are plans with "normal" TRAK values. Red crosses indicate outliers. (B) Dose distribution of outlier

## Conclusion

The HR-CTV can be used to predict the TRAK value. Outliers may indicate abnormalities in treatment planning and further inspection of their dose distributions is required. In this study, the deviations in the dose distributions of the outliers were accepted, since they resulted in an improved individualized treatment plan. Using this relationship, the quality assurance of the treatment plan can be improved.

**PO-0942 Real time in vivo dosimetry for cervix HDR brachytherapy - feasibility study using a MOSFET**  
J. Mason<sup>1</sup>, P. Bownes<sup>1</sup>  
<sup>1</sup>Leeds Cancer Centre, Medical Physics & Engineering, Leeds, United Kingdom

## Purpose or Objective

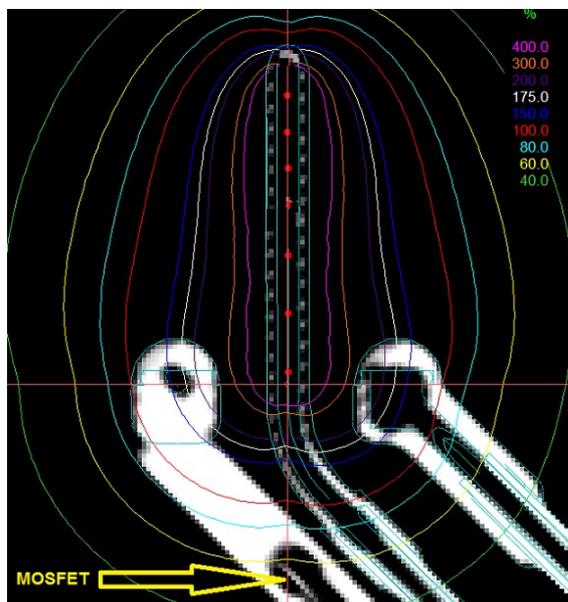

Implementation of in vivo dosimetry (IVD) in brachytherapy is partly limited by lack of commercially available devices that support IVD. In this study a modified rectal retractor and MOSFET were used to investigate the feasibility of real time IVD for cervix brachytherapy with simulated treatment plans delivered in a water phantom.

### Material and Methods

A decommissioned rectal retractor was modified by drilling a small hole to allow a microMOSFET to be inserted. The MOSFET was commissioned measuring energy dependence and angular dependence of response for the range of source-MOSFET positions expected in cervix brachytherapy treatments. Standard and conformal cervix plans covering the range of applicator sizes and geometries used in clinical treatments were delivered in a water phantom. The MOSFET was monitored during treatment delivery and measured doses compared to treatment planning system (TPS) calculated doses for the total plan and for ring and inter-uterine tube (IUT) individually.

### Results

Corrections were applied for energy dependence response (6% variation between 1 and 8 cm source-MOSFET positions) and angular dependence of response (up to 8% under response for the largest polar angle of 170°). Total plan measurements agreed with TPS calculated doses within 3.1% - 7.8% for 30° and 60° applicators but measured 16% -24% high for 45° applicators (k=2 uncertainty was estimated as 14% for total plan measurements). Separate analysis of ring and IUT measurements similarly showed good agreement for all cases except the 45° IUT for which measurements were on average 55.3% higher than expected. For the 45° IUT the MOSFET position is directly in line with the source cable and longitudinal source axis based on the source positions assumed by the TPS (see figure). A combination of a small rotation of the source relative to the IUT axis and deviation of the actual source position from the centre of the IUT could explain the measurement difference. To verify this, treatments for the 45° applicator were re-measured with the MOSFET taped to the outside of the rectal retractor in a position that was not aligned to the IUT and measured doses agreed within 8%.

### Conclusion

In vivo dosimetry for cervix brachytherapy would be feasible if commercial rectal retractors were designed to allow a dosimeter to be inserted. However it is important to avoid dosimeter positions aligned with the source longitudinal axis as this is a region of high dose uncertainty.

**PO-0943 Evaluation of a recent in vivo dosimetry methodology for HDR prostate BT using MOSFET detectors**

R. Fabregat Borrás<sup>1</sup>, S. Ruiz-Arrebola<sup>1</sup>, E. Rodriguez Serafín<sup>1</sup>, M. Fernández Montes<sup>1</sup>, A. García Blanco<sup>2</sup>, J. Cardenal Carro<sup>2</sup>, J.T. <sup>1</sup>Hospital Universitario Marqués de Valdecilla, Radiophysics, Santander, Spain

<sup>2</sup>Hospital Universitario Marqués de Valdecilla, Radiation Oncology, Santander, Spain

<sup>3</sup>Hospital Universitario San Cecilio, Radiophysics, Granada, Spain

### Purpose or Objective

In vivo dosimetry (IVD) applied to HDR BT treatments allows to monitor real dose delivered to clinically relevant areas. MOSFET detectors are the most suitable devices for this task because of their tiny dimensions, which enables their introduction into identical needles to those used in treatments. However, these type of detectors show responses depending on source-to-detector angle and distance. Mathematical models describing these dependences can be obtained from a correct detector characterization. Applying these models on the measurements should minimize the impact of those dependences, improving precision and accuracy. The purpose of this study was to evaluate clinical data of IVD applied to HDR prostate BT using MOSFET TN-502RDM from Best Medical Canada with the Ir-192 Vr2 source contained in Flexitron aferloader (Nucletron-Elekta) and mathematical models describing those dependences obtained in a previous characterization work.

### Material and Methods

Clinical data were taken from five patients suffering from prostate cancer. One to three measuring points were taken for each patient, where the MOSFET were positioned. Anatomical areas measured were neurovascular bundles, bulbourethral area and periurethral area. Nine measuring points were taken and evaluated.

Real time ultrasound image guided technique was used to implant the treatment needles. An additional needle was needed for each measuring point. Oncentra Prostate 4.2.2.4. was used to calculate the treatment planning following a standard procedure. Subsequently, coordinates of measuring points and dwell positions were taken as well as dose contribution of each dwell position to each measuring point.

After irradiation, mathematical models were applied on measured dose. Table 1 shows the three models considered, their parameters and the goodness of fit. TPS dose, direct MOSFET measured dose and calculated dose after applying the mathematical models on direct MOSFET dose were evaluated.

**Table 1. Mathematical models.**

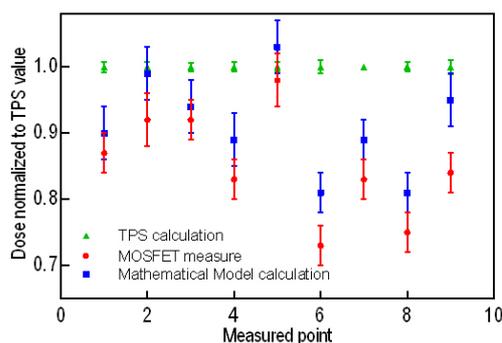

$Y=b_0+b_1 \cdot X+b_2 \cdot X^2$	$b_0$	$b_1$ [rad <sup>-1</sup> ]	$b_2$ [rad <sup>-2</sup> ]	$\chi^2/\nu$
Polar	1.099(6)	-6.5e-2(5)	1.03e-2(7)	1.567
Azimuthal	6.7e-1(4)	1.23e-1(18)	-1.15e-2(17)	2.374
$Y=b_0+b_1 \cdot X$	$b_0$	$b_1$ [m <sup>-1</sup> ]	$R^2$	
Distance	9.53e-1(6)	1.53(13)	0.9617	

The number between parentheses indicates the uncertainty (k=1) in the last significant digit, that is -0.093(10) = -0.093 ± 0.010.

### Results

Figure 1 shows the results normalized to TPS dose. All measurements suffer an approach to TP S dose after applying the mathematical models. The average value of percentage difference between TPS dose and direct measured dose was 15% while the average percentage difference decreases to 9% without any point exceeding 20%. Estimated global uncertainty associated to these corrected measurements were into the range 3.7-4.3%.

Figure 1.

Error bars show the  $k=1$  uncertainty for each dose value.

### Conclusion

The application of mathematical models describing the significant dependences of MOSFET TN-502RDM on their measurements results in an accuracy increase besides an improvement in precision. However, IVD implementation in HDR prostate BT treatments as a possibility of real-time decision making related to an error detection needs a retrospective evaluation of a larger sample data to define correctly these error detection thresholds.

### PO-0944 Dosimetric influence produced by the presence of an air gap between the skin and the freiburg flap

Sierrasesumaga Martín<sup>2</sup>, D. Guirado llorente<sup>3</sup>, I. Bernat Piña<sup>4</sup>, P.J. Prada Gómez<sup>2</sup>

<sup>1</sup>Hospital Universitario Marqués de Valdecilla, RADIOPHYSICS, Santander, Spain

<sup>2</sup>Hospital Universitario Marqués de Valdecilla, Radiation ONCOLOGY, Santander, Spain

<sup>3</sup>Hospital Universitario San Cecilio, Radiophysics, Granada, Spain

<sup>4</sup>Hospital Universitario Marqués de Valdecilla, Medical Oncology, Santander, Spain

### Purpose or Objective

Surface applicators were proposed as a way to treat superficial lesions with HDR brachytherapy. The Freiburg Flap (FF) is an applicator used in this type of treatment that has limited flexibility, so that in certain situations it is not perfectly adapted to the surface treatment. The purpose of this study is to quantify the discrepancy in the TPS dose calculation produced by unsuitable positioning of the applicator, as opposed to the ideal situation, when the applicator is perfectly adapted to the patient's skin leaving no air gap.

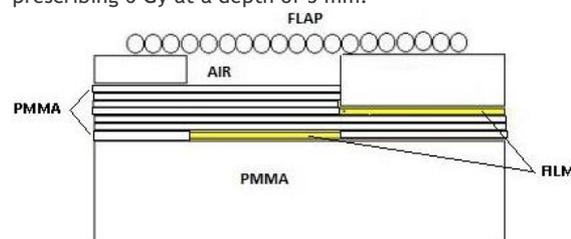

### Material and Methods

Nucletron FF, is an applicator comprising of silicone spheres attached to each other, 1 cm in diameter, arranged in parallel rows, capable of adapting to the surface to be treated.

The TPS Brachy Nucletron Oncentra (Elekta, v-4.5.2) was used for dose calculation using an <sup>192</sup>Ir radiation source and radiochromic film (Gafchromic EBT3) have been used for dose measures which were subsequently analyzed with ImageJ

To quantify the discrepancy between the TPS dose calculation and the real administrated dose when adaptation to the surface is not suitable, the experimental setup designed shown in figure 1 was made, where we can

distinguish two regions between flap and film. In one region, the film is at a distance of 5 mm from the applicator, and in the other region at a distance of 7 and 9 mm (5mm of PMMA plus 2 or 4mm air gap respectively). Two different treatment plans have been designed, in the first one the source stops in the center of the spheres and in the other one at the edge, to compare the difference between dwell positions. The dwell times are set to get the dose distribution as uniform as possible, prescribing 6 Gy at a depth of 5 mm.

### Results

Results obtained are shown in table 1. Underdosage is observed, produced by air layers, ranging from 4.8% to 10.8% when dwell positions are at the center of the spheres, and from 6.2% to 11.8% when dwell positions are at the edge of the spheres, with 2 and 4 mm air gap respectively.

Table 1

		Difference regarding the absence of air (%)	
		2 mm gap	4 mm gap
Dwell position	Centre	-4.8 (3)	-10.8 (4)
	Extreme	-6.2 (4)	-11.8 (4)

The number between parentheses indicates the uncertainty ( $k=1$ ) in the last significant digit, that is  $0.093 (10) = 0.093 \pm 0.010$  (Uncertainties are type A)

### Conclusion

In view of the results obtained, it can be concluded that several layers of air between the applicator flap and the skin can lead to considerable variation in dosimetry, which may involve the loss of effectiveness of treatments with this type of applicators. Thus, utmost care is required during the placement of the flap to minimize the error due to the air gap, therefore avoiding an underdosage in the volume to be treated.

### PO-0945 Pretreatment verification for brachytherapy

G. Fonseca<sup>1</sup>, M. Podesta<sup>1</sup>, M. Bellezzo<sup>1</sup>, B. Reniers<sup>2</sup>, F. Verhaegen<sup>1</sup>

<sup>1</sup>Maastric Clinic, Physics, Maastricht, The Netherlands

<sup>2</sup>University of Hasselt, NuTeC, Hasselt, Belgium

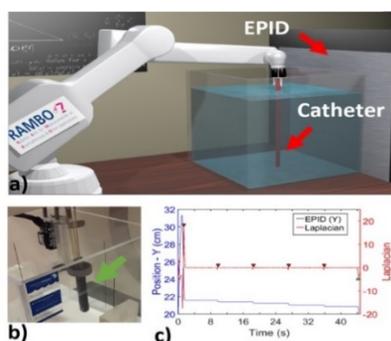

### Purpose or Objective

Individual plan QA is not performed in brachytherapy mostly due to the large uncertainty associated with dose measurements. Traditional setups require precise and accurate positioning, and therefore usually laborious procedures to detect anything other than large discrepancies with an unclear distinction between source or detector mispositioning. This study evaluates the use of an Electronic Portal Imaging (EPID) to verify the treatment plan.

### Material and Methods

The EPID panel response was characterized with an High Dose Rate (HDR) Ir-192 source. A robotic arm was employed for positioning within a water tank (Figure 1a) assuring 0.2 mm accuracy during the calibration, which covered a clinically relevant range for the distance between the source and the panel (from 6 up to 25 cm). Experiments were performed with an acquisition rate of 6.7 fps for a single catheter and for a gynecological

cylinder applicator (Figure 1b) with 5 catheters. Inter-dwell distances of 2 and 5 mm were employed and the experiments performed for source activities between 5 and 10 Ci. The EPID response is proportional to the source activity so it is possible to obtain the activity by sending the source to pre-defined dwell position.

**Figure 1.** a) representation of the experimental setup illustrating the robotic arm, EPID panel and catheter; b) gynecological applicator (green arrow) employed to mimic a treatment plan with 5 catheters; c) source position along Y axis for an irradiation with 5 dwell positions 2 mm apart from each other. The Laplacian was employed to define the dwell positions by identifying high gradient regions (arrows within the figure) that are related with movement of the source. |

## Results

3D Cartesian coordinates can be obtained with 0.2 mm accuracy using a single EPID panel. The panel can clearly identify dwell positions 2 mm apart even with the catheter at 24 cm distance (Figure 1c) from the panel. Absolute coordinates can be obtained by adding reference points (representing the corners of the water phantom) in the treatment plan that can be related with the position of the water phantom over the panel during the experiments. An *in-house* developed software compares all dwell positions/times against the treatment plan. The software can also monitor the sequence of the treatment identifying the afterloader channel connected to each catheter. Therefore, it is possible to detect catheter misplacements, swapped transfer tube connections, wrong dwell times and/or positions and also verify the source activity.

## Conclusion

This work describes an experimental system that can be implemented in the clinic providing experimental pre-treatment verification that is not currently available. This method provides several advantages when compared against other dosimeters such as films or MOSFETs as it combines a 2D dosimeter, which has an online response. Our system can detect several problems that would be unnoticed during the treatment if only traditional QA is performed.

### PO-0946 Entropic model for real-time dose calculation: I-125 prostate brachytherapy application.

G. Birindelli<sup>1</sup>, J.L. Feugeas<sup>1</sup>, B. Dubroca<sup>1</sup>, J. Caron<sup>1,2</sup>, J. Page<sup>1</sup>, T. Pichard<sup>1</sup>, V. Tikhonchuk<sup>1</sup>, P. Nicolai<sup>1</sup>

<sup>1</sup>Centre Lasers Intenses et Applications, Interaction-Fusion par Confinement Inertiel- Astrophysique, Talence, France

<sup>2</sup>Institut Bergonié Comprehensive Cancer Center, Department of radiotherapy, Bordeaux, France

## Purpose or Objective

This work proposes a completely new Grid Based Boltzmann Solver (GBBS) conceived for the description of the transport and energy deposition by energetic particles for brachytherapy purposes. Its entropic closure and mathematical formulation allow our code ( $M_1$ ) to calculate the delivered dose with an accuracy comparable to the Monte Carlo (MC) codes with a computational time that is reduced to the order of few seconds without any special processing power requirement.

## Material and Methods

The kinetic  $M_1$  model, is based on the spherical harmonic expansion of the distribution function, solution of the linear Boltzmann equation. The first two angular moments equations, combined with the Continuous Slowing Down Approximation, are closed using the Boltzmann's principle of entropy maximization. The algorithm computes at the same time all primary and secondary particles created by the interactions of the beam with the medium. Thanks to the implementation of the interaction cross sections for electrons and photons in the energy range from 1keV up to 100 MeV, the algorithm can simulate different treatment techniques such as the external radiotherapy, brachytherapy or intra-operative radiation therapy.

As a first validation step, a large number of heterogeneity shapes has been defined for various complex numerical phantoms both for electron and photon monoenergetic sources. Dose profiles at different positions have been measured in water phantoms including inhomogeneity of bone ( $\rho = 1.85 \text{ g/cm}^3$ ), lung ( $\rho = 0.3 \text{ g/cm}^3$ ) and air ( $\rho = 10^{-3} \text{ g/cm}^3$ ). Secondly, taking as reference the Carleton Laboratory for Radiotherapy Physics Database, different radioactive seeds have been implemented in the code. Moreover, several simulations based on CT scan of prostate cancer have been performed. The  $M_1$  model is validated with a comparison with a standard, accurate but time consuming, statistical simulation tools as PENELOPE.

## Results

The  $M_1$  code is capable of calculating 3D dose distribution with  $1\text{mm}^3$  voxels without statistical uncertainties in few seconds instead of several minutes as PENELOPE. Thanks to its capability to take into account the presence of inhomogeneities and strong density gradients, the dose distributions significantly differ from those calculated with the TG-43 approximations. More in detail: inter-seed attenuation is treated, the real chemical composition of the different tissues can be taken into account and the effects of patient dimensions are considered.

## Conclusion

In the comparison with the MC results the excellent accuracy of the  $M_1$  model is demonstrated. In general,  $M_1$ , as the MC codes, overcomes the approximations that are formalised in TG-43 in order to decrease the complexity of the calculations. Thanks to its reduced computational time and its accuracy  $M_1$  is a promising candidate to become a real-time decision support tool for brachytherapists.

### PO-0947 Image-guided brachytherapy with <sup>106</sup>Ru eye plaques for uveal melanomas using post implantation MRI

G. Heilemann<sup>1</sup>, N. Nesvacil<sup>2</sup>, M. Blaickner<sup>3</sup>, L. Fetty<sup>1</sup>, R. Dunavoelgyi<sup>4</sup>, D. Georg<sup>2</sup>

<sup>1</sup>Medical University of Vienna/ AKH Vienna, Department for Radiotherapy, Vienna, Austria

<sup>2</sup>Medical University of Vienna/ AKH Vienna, Department for Radiotherapy/ Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

<sup>3</sup>Austrian Institute of Technology GmbH, Health and Environment Department Biomedical Systems, Vienna, Austria

<sup>4</sup>Medical University of Vienna/ AKH Vienna, Department for Ophthalmology and Optometry, Vienna, Austria

## Purpose or Objective

In radiation oncology magnetic-resonance imaging (MRI) is an important modality for tissue characterization, target delineation and allows image-guidance due to its high soft tissue contrast as a tool for better cancer treatment. In <sup>106</sup>Ru-brachytherapy of uveal melanomas MRI is mainly used for pre-treatment planning scans to assess tumor size and location. However, post-implantation MR scans yield additional information on the plaque position in relation to the target volume and critical structures. Together with

funduscopy images MRI can be used to better assess the delivered doses to the target and the organs-at-risk (OAR). The main goal of this feasibility study is to demonstrate that fundus mapping and post implantation MR imaging can be incorporated into the treatment planning workflow of  $^{106}\text{Ru}$  plaque brachytherapy.

#### Material and Methods

Patients were scanned in a 0.35 T MR scanner (Magnetom C! Siemens, Germany) after  $^{106}\text{Ru}$  eye plaque implantation. To achieve a good normal tissue contrast for tumor delineation and organ-at-risk (OAR) segmentation a fast low angle shot (FLASH) T1 weighted sequence was utilized (TR = 15 ms, flip-angles =  $25^\circ$ ). A second FLASH MRI scan with lower repetition times (TR = 11.2 ms) and flip-angles ( $20^\circ$ ) was applied in order to display the plaque as a well-defined void with minimal distortion artifacts at the cost of lower signal to noise ratio and less soft tissue contrast. Based on the MRI the resizable 3D eye model of a newly developed treatment planning software (described in detail in [1]) was adapted to the individual patient anatomy in terms of size and plaque position. Furthermore, the funduscopy image was projected onto the retina of the digital 3D eye model.

#### Results

The presented method using two MR sequences yielded 3D image sets that allowed segmenting both the anatomical structures and the  $^{106}\text{Ru}$  plaque. The funduscopy image on the other hand is the optimal modality for tumor segmentation. By combination the 3D eye model can be adapted to match the individual patient and thus allow for individual treatment planning and dose calculation (based on MR anatomy) where the post-implantation imaging accounts for the actual position of the plaque with respect to the target and critical structures. This way irradiation times can be calculated which guarantee full tumor coverage. Moreover, the workflow can be applied for treatment plan optimization strategies where plaques are shifted in order to reduce doses to OARs.

#### Conclusion

In this feasibility study it was shown that MRI in combination with funduscopy can be used to optimize brachytherapy with  $^{106}\text{Ru}$  plaques. The additional spatial information on plaque position relative to critical structures, tumor geometry as well as position can be used for more precise dose calculations and therefore improved treatment planning.

##### PO-0948 Role of HDR Intraluminal Brachytherapy in carcinoma Esophagus: An institutional experience.

P.B. Kainthaje<sup>1</sup>, P. Gaur<sup>1</sup>, A. Malavat<sup>1</sup>, R. Paliwal<sup>1</sup>, V. Sehra<sup>1</sup>

<sup>1</sup>Dr. Sampurnanand Medical College, Department of Radiotherapy, Jodhpur, India

#### Purpose or Objective

To study the profile of patients of Carcinoma Esophagus treated with Intraluminal Brachytherapy (ILBT), the outcome of the treatment in terms of response assessment, toxicity and survival.

#### Material and Methods

The study period was between January 2014 and June 2015, with 25 patients of carcinoma esophagus middle third, treated with ILBT either as part of definitive Radiotherapy or as part of palliative Radiotherapy. The patients with unifocal disease  $\leq 10\text{cm}$  in length and with no recorded intra-abdominal or distant metastases received definitive Radiotherapy with 44Gy/22Fr through EBRT with

concurrent Cisplatin and 5-Fluorouracil followed by, 10Gy/2Fr of ILBT boost once weekly. The patients with local advanced disease for palliation received 36Gy/12Fr through EBRT followed by, 10Gy/2Fr of ILBT once weekly. The outcome of treatment was assessed in terms of dysphagia score, dysphagia free survival, toxicities and overall survival.

#### Results

Median age of patients was 55 years. Histopathologically 96 % has Squamous cell carcinoma. 16 (64%) of patients were treated with definitive radiotherapy while the rest, 9 (36%) with palliative intent. At a median follow up of 9 months, 13 patients were dysphagia free and there were 5 deaths. One month after completion of treatment, 18 patients were dysphagia free while, 2 patients had partial relief and 5 patients did not notice any relief in dysphagia. 2 patients died within 6 months of completion while, 2 patients developed trachea-esophageal fistula during follow-up.

Group	Number of patients	Relief of dysphagia (1 months post ILBT)	Relief of dysphagia (1 year)	Local control (1 year)	Overall survival (1 year)
Definitive group	16	14 (87.5%)	7 (43.75%)	8 (50%)	10 (62.5%)
Palliative group	9	4 (44.44%)	0 (0%)	0 (0%)	0 (0%)

Figure A: Response to ILBT

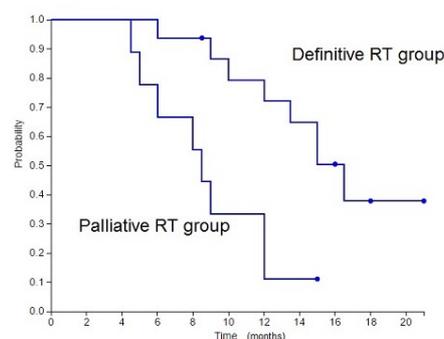

Figure B: Kaplan Meier survival curve

#### Conclusion

ILBT is a safe modality for boost in treatment of carcinoma esophagus provided, the patients are selected with caution.

##### PO-0949 Evaluation of role of Interstitial Brachytherapy in Soft Tissue Sarcoma: Single institute experience

V. Pareek<sup>1</sup>

<sup>1</sup>Jupiter Hospital- Thane, Radiation Oncology, Mumbai, India

#### Purpose or Objective

Soft tissue Sarcomas are rare group of solid tumors comprising of 1% of all solid tumors. The management of soft tissue sarcomas have evolved due to advancements in imaging, histopathology, cytogenetics, and the use of multimodality treatment. The treatment strategies emphasizes on the control of disease locally, sparing of limb function and improvement in the quality of life. High dose brachytherapy has formed a part of the management and has the advantage of providing concentrated dose to tumors and sparing of surrounding normal tissues. In this study we examined the clinical outcome of High dose Brachytherapy for STS at our Hospital through retrospective analysis of the prospective database maintained.

**Objectives:** To review the clinical outcome and quality of life in patients with Soft Tissue Sarcoma treated at our center through High dose rate interstitial brachytherapy.

### Material and Methods

Twenty patients with different sites and grades of Soft Tissue Sarcoma underwent surgery and Intraoperative catheter implantations in single plane in biopsy proven Soft tissue sarcoma cases. These patients then underwent High Dose Brachytherapy with Iridium - 192. The patients received average dose of 3.5Gy per Fraction (Two fractions per day 6 hours apart) with total dose of 35 Gy/10 Fr/5 Days and after completion of treatment were followed up at 1 month and later every 3 months for 2 years; Followed by 6 monthly interval.

### Results

The Patients were followed up for range of 6 - 42 months (Median 25 months) and overall control rate was 72.72%. The Local recurrence was noted in only one patient (9.09%) and two patients developed distant metastases (18.18%). The dosimetric outcomes were assessed and results analyzed related to the dose to the surrounding organs at risk. The quality of life parameters were also assessed prior to treatment and later during follow up and results showed better quality of life parameters.

### Conclusion

The results in our study suggested the importance of HDR Brachytherapy in management of Soft Tissue Sarcoma. The local control rate was 72.72 %. The dose of 35Gy over 10 fractions over 5 Days was found to be effective in local control and limb salvage in case of Soft Tissue Sarcoma as practiced at our Centre.

### PO-0950 High-dose-rate brachytherapy treatment in T1-T2 stage non-melanoma skin cancer patients.

M.A. González Ruiz<sup>1</sup>, J. Quirós Rivero<sup>1</sup>, M.F. Ropero Carmona<sup>1</sup>, A. Ruiz Herrero<sup>1</sup>, M.C. Cruz Muñoz<sup>1</sup>, P. Simón Silva<sup>1</sup>, J.J. Cabrera Rodríguez<sup>1</sup>, J.L. Muñoz García<sup>1</sup>, Y. Ríos Kavadoy<sup>1</sup>, F. García Urra<sup>1</sup>, P. Almendras Manzano<sup>2</sup>  
<sup>1</sup>Infanta Cristina Hospital, Radiation Oncology, Badajoz, Spain

<sup>2</sup>Infanta Cristina Hospital, Radiophysics, Badajoz, Spain

### Purpose or Objective

To analyze the results in terms of overall survival (OS), cancer specific survival (CSS), local control (LC), cosmesis and toxicity in patients (pts) with non-melanoma skin cancer (NMSC) treated with high-dose-rate brachytherapy (HDR-BT) treatment, plesiotherapy modality; with radical or adjuvant intention in our hospital.

### Material and Methods

Retrospective study of 50 pts with 63 NMSC lesions, T1 (74%) and T2 (26%) stage treated from May 2015 to May 2016. HDR-BT treatment (6 Gy/fraction; total dose 42 Gy) was used in 48 pts with an equivalent 2 Gy dose (EQD2) of 56 Gy. Median total dose of HDR-BT was 42.6 Gy (range 36-50). All the lesions for the selected cases were limited 3-4 mm depth. Treatment intention was radical in 86% pts and adjuvant in 14% pts. The median age of the pts was 76 years-old (range 52-94); 64% males. Basal-cell carcinoma (84%) and face (92,4%) were the most frequent histological type and location respectively. The 34% of the lesions were treated with Valencia applicators and 66% with custom-made moulds. Kaplan-Meier curves have been used for the statistical analysis of survival. Treatment-related toxicity was assessed using RTOG and the NCI-Common Terminology Criteria for Adverse Events guidelines.

### Results

The median follow-up was 18 months (range 7-45). The OS, CSS and LC was 96%, 100% and 96% respectively. The majority of pts had acute skin toxicity grade 1-2. Conjunctival toxicity appeared in 10% of the pts. Cosmetic results were considered as excellent/good in all patients.

### Conclusion

In patients with NMSC T1 and T2 stage HDR-BT treatment, plesiotherapy modality is a good alternative treatment for non-surgical patients. Plesiotherapy treatment provides

excellent results for local control and cosmesis which is a safe and attractive treatment option.

### PO-0951 Episcleral Brachytherapy for Uveal Melanoma

A. Ponte<sup>1</sup>, T. Teixeira<sup>1</sup>, I. Nobre-Góis<sup>1</sup>, J. Casalta-Lopes<sup>1</sup>, P.C. Simões<sup>1</sup>, A. Cavaco<sup>1</sup>, J. Veríssimo<sup>2</sup>, R. Proença<sup>2</sup>, M. Borrego<sup>1</sup>

<sup>1</sup>Hospitais da Universidade de Coimbra, Serviço de Radioterapia, Coimbra, Portugal

<sup>2</sup>Hospitais da Universidade de Coimbra, Serviço de Oftalmologia, Coimbra, Portugal

### Purpose or Objective

Uveal melanoma is the most common intraocular tumor in the adult age, and the second most common after skin melanoma, with an annual incidence rate of 4-10 per million people. Until November 2013 portuguese patients with uveal melanoma were sent abroad for treatment. Different therapeutic approaches include enucleation, proton therapy, episcleral brachytherapy (EBT), with similar outcomes.

The purpose of this work was to evaluate treatment response in patients with uveal melanoma submitted to EBT.

### Material and Methods

Included all patients with uveal melanoma treated in our institution by the Radiation Oncology Department in cooperation with the Ophthalmology Department, between November 2013 and September 2016. Plaques with low energy photon seeds (<sup>125</sup>I) were used. Dose prescription was 85 Gy to the tumor apex. Response was evaluated by ophthalmic ultrasound with serial lesion measurements and treatment side effects were recorded. A type I error of 0.05 was considered for inferential statistics.

### Results

50 EBT procedures were done in 50 patients, with a median age of 64 years, female gender (58,0%) and right eye (62,0%) predominance. Initial median diameter and thickness were 12,23 mm (5,92 to 18,70 mm) and 6,73 mm (2,60 to 12,67 mm), respectively. No distant metastatic disease was present at the time of diagnosis. Staging was as follows: Stage IIB 50,0%, Stage IIA 44,0% and Stage IA 4,0%.

The median treatment time was 140,7 hours, with a median prescribed dose of 85,90 Gy. A notched eye plaque (ROPES15n) was used in 26,0% of cases. No complications during implant procedure or treatment period were registered.

The median follow-up was 10,5 months (1 to 33 months). During this period, a significant reduction in thickness (median difference of 2,035 mm, p<0,001) and diameter (median difference of 2,43 mm, p<0,001) was recorded. Radiation retinopathy was observed in 20,0% of patients, treated by intra-ocular anti-VEGF injection in all cases. Tumor relapse occurred in 2 patients (4,0%) and distant spread in one of these. No cancer related death was registered.

### Conclusion

EBT is an effective and well tolerated eye sparing method to treat patients with uveal melanomas. A progressive significant reduction in tumors dimension was observed. No severe late side effects was registered, although follow-up time is still limited.

**PO-0952 Integral heart dose and lymphocytopenia in lung cancer patients treated with radical radiotherapy**  
 N. Joseph<sup>1</sup>, A. McWilliam<sup>2</sup>, K. Haslett<sup>2</sup>, J. Kennedy<sup>2</sup>, C. Faivre-Finn<sup>2</sup>, A. Choudhury<sup>2</sup>
<sup>1</sup>General Hospital Polonnaruwa, Clinical Oncology, Polonnaruwa, Sri Lanka

<sup>2</sup>The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom

**Purpose or Objective**

Optimal radiation dose delivery in lung cancer patients is limited by the risk of toxicity to adjacent organs especially the heart, lung and spinal cord. Post-treatment lymphocytopenia is a recognised complication in patients undergoing thoracic radiotherapy and if severe, can lead to opportunistic infections. We hypothesised that a higher integral heart dose is associated with post-treatment lymphocytopenia in patients with small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC) treated with radical radiotherapy.

**Material and Methods**

138 patients (103 NSCLC and 32 SCLC) treated with radical radiotherapy were included in this study. Concurrent chemotherapy was administered in 85/135 patients. Prescribed dose to planning target volume ranged from 41.4 to 72 Gy with a median of 66 Gy. Lymphocyte counts prior to treatment and up to 100 days post-treatment were obtained. The integral heart dose was derived by using the product of mean dose and volume. A linear mixed effects model, incorporating the following variables: integral heart dose, integral heart dose per fraction, baseline lymphocyte count, time from start of treatment and use of concurrent chemotherapy was used to analyse the effect on post-treatment lymphocyte counts

**Results**

The median integral heart dose in the cohort was 14.5 Litres-Gy (range 4-35.6). Integral heart dose ( $p=0.03$ ) and time from start of therapy ( $p < 0.001$ ) were negatively correlated with post-treatment lymphocyte counts while integral heart dose per fraction ( $p=0.05$ ) and baseline lymphocyte count ( $p<0.001$ ) were positively correlated. Use of concurrent chemotherapy was not statistically significant in the model.

**Conclusion**

Total integral heart dose predicts a lower post-treatment lymphocyte count in lung cancer patients treated with radical radiotherapy. The positive correlation with higher integral heart dose per fraction suggests that fractionation has an adverse effect on post-radiotherapy lymphocyte counts.

<sup>2</sup>University of Freiburg, Department of Molecular Medicine and Cell Research, Freiburg, Germany

<sup>3</sup>University of Luebeck, Department of Radiation Oncology, Luebeck, Germany

<sup>4</sup>German Cancer Consortiumion DKTK and German Cancer Research Center DKFZ, Department of Pathology, Heidelberg, Germany

<sup>5</sup>University of Luebeck, Department of Visceral Surgery, Luebeck, Germany

<sup>6</sup>German Cancer Consortiumion DKTK and German Cancer Research Center DKFZ, Institute of Molecular Medicine and Cell Research- Freiburg, Heidelberg, Germany

**Purpose or Objective**

Complete surgical resection remains the only curative option in patients with pancreatic ductal adenocarcinoma (PDAC). Microscopically incomplete resection (R1) is often associated with early local recurrence (LR) and, therefore, represents a negative prognostic factor. The aim of this study was to analyze the total PDAC proteome of patients who received radiochemotherapy (RCT) following incomplete resection in order to identify proteins associated with post-RCT LR.

**Material and Methods**

Three patients with early LR (median 6 months after resection, range 5 to 10 months) and three patients with late LR (median 18 months after resection, range 13 to 27 months) were identified from our clinical database. Formalin fixed paraffin-embedded tissue obtained from surgical PDAC specimens was used for proteome analysis. After micro-dissection, tissue was de-paraffinized and rehydrated, followed by protein extraction and trypsin digestion. The samples were analyzed by tandem mass spectrometry. To identify significantly up- or down-regulated proteins, linear models for microarray data (LIMMA) were applied; the p-value was set to 0.01.

**Results**

Patients received a median RT total dose of 50.4Gy and concurrent chemotherapy with two courses of 5-FU. Overall survival was reduced in patients with early LR as compared to patients with late LR (7 vs. 30 months,  $p=0.0001$ ). A total of 1,878 proteins were quantified in both cohorts with 1,656 proteins quantified in the early LR group and 1,769 quantified in the late LR group. LIMMA method identified 18 proteins significantly up- or down-regulated. 7 proteins were up-regulated in the early LR group such as MAOA, ALDH1A1, creatine kinase B and mucin-5AC being involved in tumorigenesis. 11 proteins were up-regulated in the late LR group including fascin, integrin beta-4, histidine rich glycoprotein and CDC42. Further analysis demonstrated the early LR group to exhibit an exocrine-like phenotype including expression of pancreatic proteins absent in the late LR group. 13 exocrine-related proteins were identified such as carboxypeptidase B and chymotrypsin-C.

**Conclusion**

Analyzing proteomic data of PDAC patients undergoing post-operative RCT after R1-resection, proteomic expression profiles associated with early vs. late post-RCT LR were identified. These proteomic biomarkers may serve to stratify patients according to prognosis in future trials and to assess a potential benefit of post-operative RCT.

**PO-0954 A model to study long-term impact of radiation towards the colorectal area**  
 F. Sjöberg<sup>1</sup>, D. Malipatlolla<sup>1</sup>, G. Steineck<sup>1</sup>, C. Bull<sup>1</sup>
<sup>1</sup>The Division of Clinical Cancer Epidemiology, Department of Oncology- University of Gothenburg, Gothenburg, Sweden

**Purpose or Objective**

A deeper understanding of the radiophysiology following radiotherapy is imperative. With a few exceptions, rodent models of high-dose gastrointestinal radiation injury typically cause lethality within 5-8 days, limiting the possibility to study the progression of injury over time. We have developed a model that allows for delivering radiation in fractions at high doses, while maintaining excellent survival.

### Material and Methods

Adult male C57/BL6 mice placed in a silicone mold were exposed to rectal irradiation using a linear accelerator (Varian Clinac 600 CD), the field limited to 1,5 cm of the distal part of the colon. Each mouse received 6 or 8 Gy, twice daily in 12 hours intervals, in 2, 3 or 4 fractions total. Acute cell apoptosis was examined, and histological changes at six weeks post-irradiation.

### Results

Irradiation caused apoptosis at 4.5 hours, mainly limited to the distal colon. At six weeks post-irradiation, crypts displayed overt signs of radiation-induced degeneration, as has been described in human irradiated intestinal tissue. The number of degenerated crypts was heavily increased at the fourth fraction, regardless of dose. The number of macrophages, indicating inflammation, was likewise apparent after the fourth fraction. Crypt damage was restricted to individual crypts, nearby crypts were unaffected with regards to cell production and survival. Angiogenesis was induced, likely as a compensatory mechanism for hypoxia.

### Conclusion

Our model is suitable to study late gastrointestinal injury induced by high-dose fractionated radiation. The placement of the radiation field makes the model especially convenient for testing interventions that can be delivered rectally.

### PO-0955 Co-treatment of MSC and vascular permeability inhibitor reduces radiation side effects on the colon

V. Monceau<sup>1</sup>, C. Demarquay<sup>1</sup>, A. Accarie<sup>1</sup>, L. Moussa<sup>1</sup>, B. Doix<sup>1</sup>, M. Benderitter<sup>1</sup>, A. Sémont<sup>1</sup>, N. Mathieu<sup>1</sup>

<sup>1</sup>Institut de Radioprotection et de Sûreté Nucléaire IRSN, PRP-HOM- SRBE- LR2I, Fontenay aux roses, France

### Purpose or Objective

The efficacy of radiotherapy requires an optimal compromise between tumor control and normal tissue injury. Non-neoplastic tissues around abdomino-pelvic tumor can be damaged by ionizing radiation leading to acute and/or chronic gastrointestinal complications which affect quality of life with substantial morbidity and mortality. There is no unified approach to the assessment and the treatment of radiotherapy delayed side effects, characterized mainly by uncontrolled inflammation and tissue fibrosis. We previously demonstrated that mesenchymal stromal cells (MSC) treatment improves colonic regeneration and reduces partially the ulcer size by the margins (Sémont, 2013). Moreover, studies showed that the vascular compartment is improved after MSC treatment and could play a key role in the inflammatory process and the epithelial regeneration. However, these aspects have not yet been investigated after irradiation. In this study, we investigate the effect of MSC treatment on vascular compartment. We analyze the angiogenesis process, progenitor's recruitment in blood and associated chemoattractant molecules secretion as well as vascular permeability. The aim of this study is to determine a new way to improve MSC treatment.

### Material and Methods

We generated, in SD rat, colonic radiation-induced lesions similar of those seen in patients suffering of late side effects after pelvic radiotherapy (29Gy). Three weeks after irradiation (established damages)  $5.10^6$  of MSC from fat tissue were injected intravenously (IV).

### Results

The first results showed that MSC treatment increase the amount of blood vessels. This process is associated with an increase of the growth factor VEGF, but also a recruitment of endothelial progenitor cells, two events necessary for the neo-vascularization. We also demonstrated that MSC treatment ameliorates the quality of blood vessels (the number of fully muscularized capillaries was reduced in ulcer and border areas).

However, MSC treatment has no effect on the vascular permeability nor the number of inflammatory cells. Therefore, we realized MSC injections concomitantly with an inhibitor of vascular permeability which was iteratively infused intravenously. We demonstrated that the co-treatment reduces considerably the size of the ulcer comparatively with only MSC treatment suggesting that the beneficial effects of MSC were potentiated with an inhibitor of vascular permeability.

### Conclusion

Results of this study constitute a first approach to demonstrate the therapeutic benefit of MSC infusion on vascular compartment in a model of severe colonic damages induced by radiations. We also characterized the molecular mechanisms involved in regenerative capacities of MSC and determined that the limitation of the vascular permeability could be a way of therapeutic improvement. This cell and pharmacologic co-treatment could be used for compassionate applications to reduce colorectal damages induced by pelvic radiotherapy.

### PO-0956 Prediction of irradiated cells fate: the necessity to revisit RBE by multi-parametric investigations

V. Paget<sup>1</sup>, M. Ben Kacem<sup>1</sup>, M. Dos Dantos<sup>2</sup>, F. Soysouvanh<sup>1</sup>, M. Benadjaoud<sup>2</sup>, A. Francois<sup>1</sup>, O. Guipaud<sup>1</sup>, F. Milliat<sup>1</sup>

<sup>1</sup>Institute for Radiological Protection and Nuclear Safety IRSN, Department of Radiobiology and Epidemiology SRBE / Research on Radiobiology and Radiopathology Laboratory L3R, Fontenay-aux-Roses- Paris, France

<sup>2</sup>Institute for Radiological Protection and Nuclear Safety IRSN, Department of Radiobiology and Epidemiology SRBE, Fontenay-aux-Roses- Paris, France

### Purpose or Objective

The evaluation of radiosensitivity is historically linked to the survival fraction measured by the clonogenic assay, which is until now the gold standard in such evaluation. The representation of the survival fraction as a function of the dose leads to survival curves which are modelled by the linear-quadratic model (LQ-model). The Relative Biological Effectiveness (RBE) is defined as the ratio of the doses required by two types of ionizing radiations to cause the same biological effect (for instance the survival fraction). The RBE is an empirical value that varies depending on the type of particle, the Linear Energy Transfer (LET), the dose rate and the dose fractionation, and can be easily used to predict biological outcome in different situations. Nevertheless, the clonogenic assay is a quite restrictive method which does not take into account cell-cell interactions and the phenotype of surviving cells as well. Thus, the aim of this study is to demonstrate, by a proof of concept, the limits of the clonogenic assay to predict the cellular fate and in a lesser extend its unsuitability to predict accurately on healthy tissues the risk associated to the use of ionizing radiations.

### Material and Methods

Radiation-induced damage to the vascular endothelium is potentially involved in the initiation and the development of normal tissue injury. Thus, in this study we compared the biological effects on HUVECs (Human Umbilical Vein Endothelial Cells) exposed to low energy x-rays (generated at 220 kV on a SARRP) and high energy x-rays (generated at 4 MV on a LINAC). Cell survival fractions were measured/calculated by using clonogenic assay while morphological changes, cell viability/mortality, cell cycle analysis and  $\beta$ -galactosidase activity were evaluated by flow cytometry. Finally molecular footprinting of 44 genes

involved in senescence process were measured by RT-qPCR.

#### Results

While the clonogenic assay showed very similar survival fraction curves for both conditions, we found highly significant differences between the two conditions of irradiation, when considering other biological outputs when cell were irradiated at confluence. Cell number and survival, morphological changes, cell cycle analysis, molecular footprinting and  $\beta$ -galactosidase activity were measured for doses up to 20 Gy. For all the assays, we observed and demonstrated stronger effects on HUVECs irradiated with the LINAC (4 MV) compared to the same irradiation performed with the SARRP (220 kV).

#### Conclusion

All together these results strongly support the fact that the clonogenic assay is not sufficient alone and that we need to implement new models with multi-parametric biological outputs to estimate a RBE that accurately predicts the biological cellular fate. Such approach could be useful for radiation protection but also for conditions such as stereotactic body radiation therapy where the LQ-model is inappropriate.

#### PO-0957 Radiobiological studies in *in vitro* reconstituted squamous epithelia

G. Zemora<sup>1</sup>, W. Dörr<sup>1</sup>

<sup>1</sup>Medical University of Vienna, Department of Radiotherapy- ATRAB - Applied and Translational Radiobiology, Vienna, Austria

#### Purpose or Objective

Preclinical *in vivo* models are indispensable for radiobiological investigations. However, their application needs to follow the basic guidelines of animal studies (reduction, refinement, replacement) and such research should thus be supplemented by exploitation of suitable alternatives, e.g. *in vitro* model systems. Three-dimensional (3D) organotypic culture systems have been shown to more accurately reflect the *in vivo* cell situation as compared to standard 2D monolayer cell cultures. The present study was initiated to generate and characterize *in vitro* reconstituted human normal and malignant squamous epithelia. These will then be applied for analyses of the response to photon and ion irradiation, as a basis for the design of subsequent *in vivo* studies. Relevant damage processing pathways (including their dependence on radiation quality) will be identified, and biological targeting strategies will be screened. Also, dedicated RBE studies at different positions in the ion beam track for various endpoints will be performed.

#### Material and Methods

The 3D organotypic squamous epithelial tissues consist of epithelial cells cultured on top of "dermal matrices", i.e. collagen gels formed from a collagen I solution populated by metabolically active fibroblasts. Epithelial cells are then seeded on top and cultured submerged. After 4 days of submerged culture the gels are lifted so that the epithelial cell monolayer is placed at the air-medium interface and further cultured for 10 days until stratification is complete. To reproduce skin equivalents, HaCaT cells were seeded onto human skin fibroblasts gels as mentioned above. To reconstruct normal and malignant oral epithelia we will use immortalized normal oral and FaDu squamous carcinoma cells, respectively. In radiobiological studies, endpoints to be compared to the *in vivo* situation will include morphology, differentiation, DNA damage/repair (e.g.  $\gamma$ H2AX, micronuclei) and various radiation response-related signaling pathways, e.g. of inflammation through IL-6, TGF- $\beta$  and pro-MMP1. Single dose as well as, importantly, daily fractionated irradiation protocols will be applied for both photons and ions.

#### Results

Our preliminary efforts to reconstruct squamous epithelia using HaCaT cells indicate the formation of a stratified

epithelium on top of a fibroblast-populated matrix. Our results show positive IHC staining for the proliferating cells expressing Ki67 located at the stratum basale, as well as for the late differentiation proteins (involucrin and loricrin). The experiments for the reconstruction of 3D oral mucosa are ongoing.

#### Conclusion

*In vitro* reconstituted squamous epithelia are suitability models, with intermediate complexity between 2D cell cultures and tissues *in vivo*, for *in vitro* radiobiological studies. Prospectively, macrophages will be integrated in the 3D reconstructs to study radiation effects on the immune system.

#### PO-0958 Radiogenomics: role of non-coding RNA genes in increased radiotherapy sensitivity

<sup>4</sup>Hospital de la Santa Creu i Sant Pau, Medical Oncology Department, Barcelona, Spain

<sup>5</sup>Vall d'Hebron University Hospital, Area of Clinical and Molecular Genetics, Barcelona, Spain

#### Purpose or Objective

Breast cancer (BC) is the first cause of cancer-related mortality of Spanish women and most common cancer in women worldwide. It is frequently treated with radiotherapy (RT), which can cause early and late side-effects that impact negatively on quality-of-life of cancer survivors. MicroRNAs and long non-coding RNAs (lncRNAs) modulate key cellular pathways in response to radiation. Single nucleotide polymorphisms (SNPs) in these two types of non-coding RNAs can alter their function and consequently modify the expression of genes that regulate, affecting the respective biological activities. As part of a long-term ongoing study, our aims were to test genetic association of SNPs in microRNAs and lncRNAs with late radiotherapy-induced toxicity and to characterize the expression of lncRNAs in blood cells of BC treated patients. Our final goal is to discover new genetic endpoints to predict individuals with increased susceptibility to radiotherapy side effects.

#### Material and Methods

DNA samples and clinical data were collected from 198 prospectively and 72 retrospectively recruited BC patients treated with RT in two hospitals. All patients were followed at least between two and six years after RT. 34 SNPs in microRNAs and lncRNA genes related to radiation response were genotyped using iPLEX® Gold with MassArray Agena Bioscience (Sequenom). RNA was obtained from blood before and after radiotherapy of 19 BC patients from the prospective cohort. Eight lncRNAs (FAS-AS1, MALAT1, TP53TG1, HOTAIR, PANDA, MEG3, ANRIL and LINC00467) involved in radiation cell response were assessed by RT-PCR, agarose gels and direct sequencing. A semiquantitative capillary electrophoresis of fluorescent amplicons was performed to estimate the proportion of total transcripts.

#### Results

The first analysis showed an association of overall long term toxicity after radiotherapy with rs4559081 A/A genotype of LINC00336 (OR=3.91 95%CI = 1.34-11.37), and grade  $\geq 2$  late radiation skin toxicity (fibrosis or telangiectasias) with rs17762938 A/C or CC of PCAT1 (OR=2.63 95% CI=1.00-6.86) and rs2910164 C/G of miR-146a (OR=0.27 95%CI = 0.008-0.94). The expression and presence of different isoforms of all lncRNAs evaluated, except ANRIL and HOTAIR, were observed in blood cells.

After radiotherapy the level of MEG3 and PANDA expression increased.

#### Conclusion

The potential genetic association of the lncRNAs LINC00336 and PCAT1, and microRNA miR-146a with radiotherapy-induced late toxicity needs to be confirmed in larger breast cancer cohorts. The expression of lncRNAs can be a biomarker of radiotherapy response measurable in blood.

**Funding:** This research was supported by a grant [FIS 05/2181] from "Fondo de Investigación Sanitaria, Instituto de Salud Carlos III, Ministerio Español de Economía y Competitividad".

#### Purpose or Objective

Recently the first replicated genetic associations for radiotherapy-induced adverse reactions were reported. The European Union funded REQUITE consortium aims to validate known predictors of adverse reactions to develop clinically useful tools. One such predictor is low levels of radiation induced lymphocyte apoptosis which has previously been found in patients experiencing increased rates of late radiation induced toxicity.

#### Material and Methods

REQUITE is a multi-centre, observational study. Enrolment was open for two and a half years in nine centres (eight in Europe and one in the United States), with another two years of follow-up still ongoing. The primary endpoints are change in breast appearance at two years (breast), rectal bleeding at two years (prostate) and breathlessness at 12 months (lung). Work Package 4 involves validation of biomarkers. This includes genetic polymorphisms and the radiation induced lymphocyte apoptosis assay (RILA). The RILA was carried out in three of the European centres using a standardised protocol which had been verified with inter lab testing; it assesses percentage radiation induced apoptosis in lymphocytes, detected by flow cytometry, 48 hours after ex-vivo irradiation of whole blood.

#### Results

More than 4300 patients have been enrolled in REQUITE. 1322 samples have been analysed using the apoptosis

assay. The levels of apoptosis 48 hours after ex-vivo irradiation increase over baseline in a range from 2.4% to 62.4%, confirming large inter-patient variability. In the Leicester cohort mean RILA is higher in the prostate patients compared to the breast patients (24.9% vs 20.3%; p=0.004). Analysis of predictive value for acute toxicity is being carried out.

#### Conclusion

Variation in percentage of lymphocyte apoptosis is in keeping with previous studies. This large scale prospective observational study will be the largest to date to assess the use of predictive biomarkers for assessing radiotherapy related toxicity.

#### PO-0960 Radiobiological effectiveness and its role in modelling secondary cancer risk for proton therapy

A. Madkhali<sup>1,2</sup>, C. Timlin<sup>1</sup>, M. Partridge<sup>1</sup>

<sup>1</sup>University of Oxford, Oncology, Oxford, United Kingdom  
<sup>2</sup>King Saud University, Medicine, Riyadh, Saudi Arabia

#### Purpose or Objective

In proton therapy, a radiobiological effectiveness ratio (RBE) of 1.1 (RBE<sub>1,1</sub>) is often used. In reality, RBE depends on dose, linear energy transfer (LET), biological end point, and tissue type. Using a value of RBE that may be not accurate may affect dose calculation and hence, outcome.

#### Material and Methods

We used an in-house built code for modelling malignant induction probability (MIP) from voxel-by-voxel dose map (Timlin 2014) and implement a published model to calculate structure-specific RBE, recalculate dose and MIP, and compare the outcomes with initial calculations using RBE<sub>1,1</sub>. MIP was calculated using linear quadratic (LQ), linear (LIN), and linear-no-threshold (LNT) models for proton therapy plans for an adult and a teenage patient diagnosed with medulloblastoma (MB). The MIP was then re-calculated using the RBE model by Dale and Jones which is a function of dose (d),  $\alpha$  and  $\beta$  and RBE<sub>min</sub> and RBE<sub>max</sub>:

$$RBE = \frac{-\alpha + \sqrt{\alpha^2 + 4\beta d(RBE_{max}\alpha + RBE_{min}^2\beta d)}}{2\beta d}$$

#### Results

Results are shown in Table 1. The difference in MIP by using RBE<sub>1,1</sub> and RBE<sub>minMax</sub> is ~2-3%. The effect on mean dose varies between different organs and is between 6% and 8%. Clinical implications due to difference in RBE depend on beam characteristics, dose, structures concerned, and the volume irradiated.

Medulloblastoma - Adult			
Model	RBE <sub>1.1</sub>	RBE <sub>MinMax</sub>	RBE <sub>1.1</sub> :RBE <sub>MinMax</sub>
LQ	0.099	0.097	1.03
LIN	0.078	0.076	1.03
LNT	0.643	0.655	0.98

(a)

Medulloblastoma - Teen			
Model	RBE <sub>1.1</sub>	RBE <sub>MinMax</sub>	RBE <sub>1.1</sub> :RBE <sub>MinMax</sub>
LQ	0.068	0.066	1.02
LIN	0.057	0.056	1.02
LNT	0.554	0.567	0.98

(b)

Mean Dose (Gy) - Adult			
Name	RBE <sub>1.1</sub>	RBE <sub>MinMax</sub>	RBE <sub>1.1</sub> :RBE <sub>MinMax</sub>
Right lung	1.41	1.50	0.94
Left lung	1.36	1.45	0.94
Nasopharynx	4.16	4.48	0.93
Right kidney	0.54	0.58	0.94
Left kidney	1.10	1.16	0.94
Left parotid	4.44	4.75	0.94
Right parotid	2.15	2.30	0.93
Thyroid	0.19	0.20	0.92
Oral cavity	0.04	0.04	0.92

(c)

Table 1: Values of whole body MIP using RBE of 1.1 (RBE<sub>1.1</sub>) and RBE using the described model (RBE<sub>MinMax</sub>) and the relationship between them for the adult (a) and the teenage patient (b).

(c) Mean dose for selected structures from the adult patient's plan using RBE<sub>1.1</sub> and RBE<sub>MinMax</sub> and the relation between them.

#### Conclusion

Using RBE<sub>1.1</sub> makes proton therapy dose and dose-dependent predictions less accurate. Our results using a RBE calculation model show that decreased accuracy may have clinical implications, which agrees with published literature (Jones 2012; Jones, 2014), and may affect secondary cancer risk and normal tissue complication probability calculations as well.

**PO-0961 DNA damage and repair influence tumor sensitivity to diffusing alpha emitters radiation therapy**  
 Y. Keisari<sup>1</sup>, R. Etzyoni<sup>1</sup>, H. Bittan<sup>2</sup>, E. Lazarov<sup>2</sup>, M. Efrati<sup>1</sup>, M. Schmidt<sup>2</sup>, T. Cooks<sup>1</sup>, L. Arazi<sup>2</sup>, I. Kelson<sup>2</sup>  
<sup>1</sup>Tel-Aviv University / Faculty of Medicine, Clinical Microbiology and Immunology, Tel-Aviv, Israel  
<sup>2</sup>Tel Aviv University, School of Physics and Astronomy-Sackler Faculty of Exact sciences, Tel Aviv, Israel

#### Purpose or Objective

We developed an alpha radiation based brachytherapy, which provides efficient ablation of solid tumors by alpha radiation. This treatment termed, *Diffusing Alpha emitters Radiation Therapy* (DaRT) utilizes radium-224 loaded wires, which when inserted into the tumor release by recoil short-lived alpha-emitting atoms. These atoms disperse in the tumor, and spray it with highly destructive alpha radiation.

DaRT achieved substantial tumor growth retardation, extended survival, and reduced lung metastases in mice bearing various mouse and human derived tumors. Better tumor control was achieved when DaRT was applied with chemotherapy. Furthermore, tumor ablation by DaRT boosted anti-tumor immune responses.

In the present study we examined the relative sensitivity of various tumor cells in vivo and in vitro to alpha radiation and the role of DNA damage control in this effect.

#### Material and Methods

Implanted murine tumors were treated with a single <sup>224</sup>Ra-loaded source, and tumor progression and survival were recorded. Intratumoral alpha particle distribution was measured by the spread of <sup>212</sup>Pb. The sensitivity of the various cancer cells was determined by their ability to form colonies after irradiation in vitro with alpha particles. The formation and disappearance of gamma-H2AX foci (DSBs indicators), and activation of non-homologous end joining following recruitment of Ku70 into the nucleus, served to evaluate DNA damage control and repair.

#### Results

- DaRT caused significant damage in vivo to squamous cell tumors (SQ2) but not to pancreatic (Panc02) and breast adenocarcinoma (4T1).

- Tissue necrosis and tumor growth retardation were in correlation with the intratumoral distribution of released alpha emitting isotopes.

- SQ2 cells were the most radiosensitive to alpha particles (mean lethal dose required to reduce cell viability to 37%; D<sub>0</sub>=0.57) while the pancreatic (D<sub>0</sub>=1.1) and breast cancer cells (D<sub>0</sub>=1.05) were less radiosensitive.

- The three cell lines exhibited different damage accumulation and repair kinetics. The radio-resistant cell line 4T1 had the lowest number of double strand breaks (DSBs) and a fast recruitment of nuclear Ku70, indicating a quick and efficient repair process. The relatively radio-resistant Panc02 cells, had an intermediate number of DSBs, and fast damage repair. SQ2 cells exhibited high DNA damage and a low and very slow Ku70 nuclear recruitment, indicating a slow and not efficient repair process that consequently resulted in cell death.

#### Conclusion

The radiosensitivity of tumors to alpha radiation was in correlation with their ability to avoid or repair double strand breaks. Identifying the mechanism(s) responsible for the resistance of various tumor cells to alpha radiation may open the possibility to block this mechanism(s) and render the cells more susceptible to alpha particles. This may have practical implications for the treatment of solid tumors by DaRT.

#### PO-0962 Proton minibeam irradiation leads to reduced acute side effects in an in-vivo mouse ear model

E. Zahnbrecher<sup>1</sup>, M. Sammer<sup>2</sup>, J. Reindl<sup>2</sup>, C. Greubel<sup>2</sup>, B. Schwarz<sup>2</sup>, C. Siebenwirth<sup>1,2</sup>, D.W.M. Walsh<sup>1,2</sup>, K. Illic<sup>1</sup>, J.J. Wilkens<sup>1,3</sup>, S.E. Combs<sup>1,3</sup>, G. Dollinger<sup>2</sup>, T.E. Schmid<sup>1,3</sup>

<sup>1</sup>Klinikum rechts der Isar, Technische Universität München, Munich, Germany

<sup>2</sup>Institut für angewandte Physik und Messtechnik, Universität der Bundeswehr München, Neubiberg, Germany

<sup>3</sup>Institute of Innovative Radiotherapy, Helmholtz Zentrum München, Neuherberg, Germany

#### Purpose or Objective

In Radiation Oncology, the maximum dose which can be delivered to a certain tumor is often limited by the radiation induced damage in normal tissue surrounding the actual tumor. Proton minibeam radiotherapy aims to minimize normal tissue damage, especially in the entrance channel. Due to beam widening with increasing track length, it leads to a homogeneous dose distribution in the tumor area, which permits tumor control as in conventional proton therapy. Acute side effects of proton minibeam irradiation were examined in an in-vivo mouse ear model to account for immune system, vasculature and higher complexity. In this study, the effect of partially widened proton minibeam was investigated as occurring

at different depths on their way through the irradiated volume.

#### Material and Methods

A total of six different minibeam sizes were applied to the ear of Balb/c mice using 20 MeV protons. The average dose of 60 Gy was distributed in 4x4 minibeam sizes with beam sizes of  $\sigma = 0.09, 0.2, 0.31, 0.45, 0.56$  and  $0.9$  mm and a beam-to-beam distance of 1.8 mm. Inflammatory response, i.e. ear swelling and skin reactions, were observed for 90 days after irradiation.

#### Results

The results show a link between the applied beam sizes and the dimension of acute side effects after irradiation. The largest beam sizes lead to significant inflammatory reactions such as ear swelling, erythema and desquamation within 3-4 weeks after irradiation. The maximum skin reactions were reduced with decreasing beam sizes until almost no ear swelling or other visible skin reactions to the irradiation could be detected.

#### Conclusion

Our results show that the tissue sparing effect of proton minibeam sizes is highest for the smallest beam sizes as occurring in the superficial layers of an irradiated volume. The positive effect decreases with increasing beam size and is therefore smallest for the biggest beam size which is equivalent to a homogeneous dose as desired in the target volume. However, since all minibeam sizes have significantly reduced acute side effects compared to broad beam irradiation, proton minibeam radiotherapy may offer various possibilities for new approaches in clinical proton radiotherapy.

Supported by the DFG Cluster of Excellence: Munich-Centre for Advanced Photonics.

#### PO-0963 RBE variations along the Bragg curve of a 200 MeV proton beam

C. Vandevoorde<sup>1</sup>, A. Baeyens<sup>2</sup>, A. Vral<sup>2</sup>, J. Slabbert<sup>3</sup>  
<sup>1</sup>iThemba LABS, Radiation Biophysics, Cape Town, South Africa

<sup>2</sup>Ghent University, Basic Medical Sciences, Ghent, Belgium

<sup>3</sup>iThemba LABS, Medical Directorate, Cape Town, South Africa

#### Purpose or Objective

A lack of strong radiobiological datasets has resulted in the clinical adoption of a fixed, generic relative biological effectiveness (RBE) of 1.1 in current proton therapy (PT). However, in the distal area of the spread-out Bragg peak (SOBP), the RBE is certainly higher than 1.1 due to the rapid decrease in proton energy, resulting in an increased linear energy transfer (LET). Therefore, the RBE was quantified at different positions of the depth-dose profile for the 200 MeV clinical proton beam at iThemba LABS.

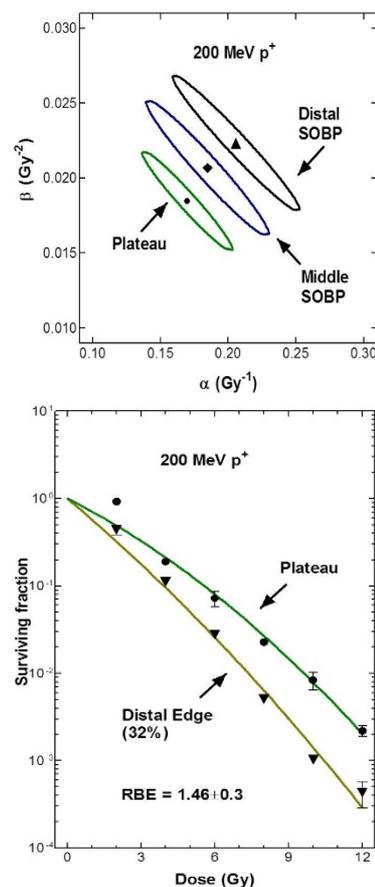

#### Material and Methods

V-79 fibroblasts were irradiated as monolayers at the plateau, proximal, middle and distal positions, as well as in the distal edge (32% of the maximum dose) of a 7 cm SOBP. At the same time, V-79 cells were also irradiated with <sup>60</sup>Co  $\gamma$ -rays as reference radiation.  $\alpha$  and  $\beta$  values were determined from the cell survival curves and the 95% confidence ellipses of these covariant parameters were compared in the analysis. Mean inactivation dose (MID) values were calculated and used for the RBE calculations.

#### Results

A large overlap in the 95% confidence ellipses was observed for proton plateau and <sup>60</sup>Co  $\gamma$ -rays, so there is no statistical significant difference in radiation quality. The MID decreases with depth from 3.65 Gy at the entrance plateau, to 3.52 Gy, 3.40 Gy and 3.15 Gy for the proximal, middle and distal position along the SOBP respectively. Since the entrance plateau results were not significantly different from <sup>60</sup>Co  $\gamma$ -rays, RBE was calculated based on the plateau MID as a reference. This resulted in RBE values of 1.04, 1.07 and 1.16 for the proximal, middle and distal positions respectively. Furthermore, a clear separation

was observed between the 95% confidence ellipses for the three positions in the SOBP (see Fig 1). An RBE increase up to 1.46 was determined for the distal fall-off position (see Fig 2).

#### Conclusion

The results obtained in the current study with V-79 fibroblast cells confirm the expected increase in RBE along the proton Bragg curve.

#### PO-0964 Biomarkers in wound drainage fluids affect response to radiations of head and neck cancer cells

M. Mangoni<sup>1</sup>, M. Sottili<sup>1</sup>, T. Gualtieri<sup>2</sup>, A. Javarone<sup>2</sup>, M. Loi<sup>1</sup>, I. Meattini<sup>1</sup>, P. Bonomo<sup>1</sup>, I. Desideri<sup>1</sup>, A. Deganello<sup>2</sup>, L. Livi<sup>1</sup>

<sup>1</sup>University of Florence, Experimental and Clinical Biomedical Sciences, Firenze, Italy

<sup>2</sup>University of Florence, Academic Clinic of Otorhinolaryngology and Head and Neck Surgery, Firenze, Italy

#### Purpose or Objective

In recent years in head and neck oncology many efforts have been made in order to characterize molecular biomarkers with potential prognostic and therapeutic value. The detection of significant features in the early perioperative setting could possibly lead to a refinement of current adjuvant treatments in high-risk patients. The purpose of our study is to report the feasibility and preliminary results of a pilot prospective study on wound drainage fluids (WDF) analysis in head and neck squamous cells carcinoma (HNSCC) and to evaluate effect of WDF microenvironment on HNSCC response to radiation.

### Material and Methods

19 consecutive surgically resected HNSCCs were studied. WDF were collected 1 day and 3 days after surgery from the cancer operative bed. EGF, VEGF, SDF-1 and osteopontin levels were measured in WDF using enzyme-linked immunosorbent assay (ELISA) kits. Clonogenic assays were performed using Cal27 HNSCC cells irradiated with 1 to 6 Gy in presence or not of WDF and pretreated or not with cetuximab 6 hours before irradiation.

### Results

The correlations between molecular levels and pathological cancer features showed that CXCL-12 expression was significantly increased in WDF in presence of lymph node metastasis ( $p < 0,05$ ), lymph node density ( $p < 0,05$ ) and extra capsular spread (ECS) ( $P < 0,05$ ). Osteopontin expression was significantly increased in presence of ECS ( $p < 0,05$ ). TGF- $\beta$  expression was significantly reduced in presence of ECS ( $P < 0,0000001$ ) and for patients treated for a cancer relapse ( $p < 0,001$ ). Clonogenic assays evidenced that WDF reduced efficacy of irradiation on Cal27 cells with an increase of clonogenic survival compared to control (that is irradiated cells without WDF). Pretreatment of cells with cetuximab reduced surviving fraction to values comparable to control.

### Conclusion

Preliminary data from pilot study evidenced that microenvironment in WDF favors residual tumor cell proliferation and affects response to radiation. Early treatment with biological therapies can increase radio sensitivity and improve outcome.

### PO-0965 Imaging of the hypoxia related marker Carbonic Anhydrase IX in human head and neck cancer xenografts

F.J. Huizing<sup>1</sup>, B.A.W. Hoeben<sup>1</sup>, O.C. Boerman<sup>2</sup>, J. Bussink<sup>1</sup>

<sup>1</sup>Radboudumc, Radiation oncology, Nijmegen, The Netherlands

<sup>2</sup>Radboudumc, Nuclear medicine, Nijmegen, The Netherlands

### Purpose or Objective

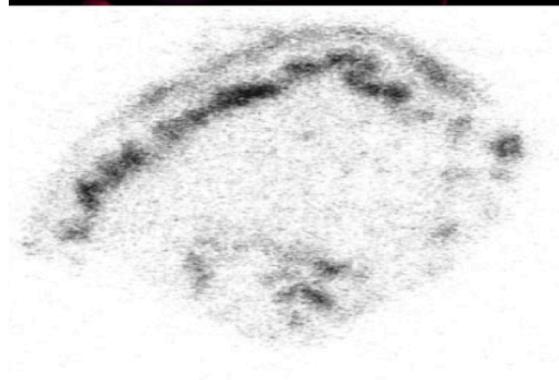

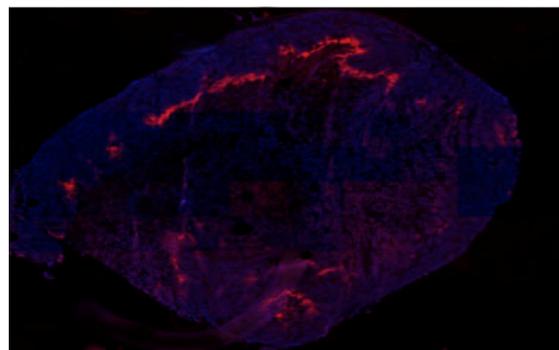

Tumor hypoxia forms a major factor in radio- and chemoresistance in head and neck cancer and other solid tumors. Assessment of tumor hypoxia may allow patient selection for hypoxia or CAIX targeting treatment combined with radiotherapy. Recently, the radioactive tracer <sup>111</sup>In-girentuximab-F(ab')<sub>2</sub> was designed to target the endogenous hypoxia related marker carbonic anhydrase IX (CAIX), in combination with a SPECT scan this tracer can be used for imaging. The purpose of this study was to characterize <sup>111</sup>In-girentuximab-F(ab')<sub>2</sub> in a preclinical setting.

### Material and Methods

First the affinity and internalization kinetics of <sup>111</sup>In-girentuximab-F(ab')<sub>2</sub> were determined in vitro with the use of SK-RC-52 cells. The optimal timing and optimal protein dose for imaging were determined in athymic nude mice with a subcutaneous xenografted human head and neck carcinoma. Tracer uptake was measured using the U-SPECT, by analyzing ex vivo activity counting and by autoradiography of tumor sections. Immunohistochemical staining was used to validate the tracer uptake to the CAIX expression.

### Results

In vitro 26% of the tracers internalized into the SK-RC-52 cells after 24 hours. The half maximal inhibitory concentration was  $0.69 \pm 0.08$  nM. As optimal time between tracer injection and imaging we found 24 hours to be optimal. The protein dose of 10 microgram will result in the highest tumor to blood ratio after 24 hours. Immunohistochemical images show a distinct spatial correlation to autoradiography images (Fig. 1).

### Conclusion

<sup>111</sup>In-girentuximab-F(ab')<sub>2</sub> has a high affinity to CAIX. For optimal imaging of CAIX expression in human xenografts, a tracer protein dose of 10 microgram should be administered 24 hours before scanning. These results suggest that <sup>111</sup>In-girentuximab-F(ab')<sub>2</sub> is a promising tracer, in ongoing studies we will assess the tracer's applicability for treatment selection and monitoring.

### PO-0966 Prognostic value of tissue necrosis, CD34 MVD and CA-IX in head and neck cancer patients

D. Ou<sup>1,2</sup>, I. Garberis<sup>3</sup>, J. Adam<sup>3</sup>, P. Blanchard<sup>1</sup>, F. Nguyen<sup>1</sup>, A. Levy<sup>1</sup>, O. Casiraghi<sup>3</sup>, P. Gorphe<sup>4</sup>, I. Breuskin<sup>4</sup>, F. Janot<sup>4</sup>, S. Temam<sup>4</sup>, J. Scoazec<sup>3</sup>, E. Deutsch<sup>1</sup>, Y. Tao<sup>1</sup>

<sup>1</sup>Institut Gustave Roussy, Department of Radiation Oncology, Villejuif, France

<sup>2</sup>Fudan University Shanghai Cancer Center, Department of Radiation Oncology, Shanghai, China

<sup>3</sup>Institut Gustave Roussy, Department of Pathology, Villejuif, France

<sup>4</sup>Institut Gustave Roussy, Department of Head and Neck Oncology, Villejuif, France

### Purpose or Objective

Tumor hypoxia is adversely correlated to patient prognosis. The aim of the present study was to investigate the role of three hypoxia-related biomarkers in patients with locally advanced head and neck squamous cell carcinoma (HNSCC) treated with concurrent chemoradiotherapy or bioradiotherapy.

### Material and Methods

In tumor tissue material from 100 patients with known HPV status, we evaluated the extent of tumor necrosis, the expression level of CA-IX and the microvascular density (MVD) measured as the density of CD34+ vascular structures. The Kaplan-Meier method, univariate and multivariate analyses, were used to analyze the correlations between biomarker status and clinicopathological characteristics and treatment outcomes.

### Results

We found a significant correlation between MVD and overall stage ( $p = 0.02$ ) and T classification ( $p = 0.05$ ). CA-

IX was significantly correlated with overall stage ( $p=0.03$ ) and N classification ( $p=0.04$ ). There was a significant inverse correlation between MVD and CA-IX expression ( $r=-0.22$ ,  $p=0.03$ ). Multivariate analysis showed that low MVD combined with high CA IX-expression was a significant independent prognostic factor for worse loco-regional control (HR=2.6, 95%CI 1.1-5.0,  $p=0.02$ ) in the whole population. However, in the p16-positive subgroup, the difference was not significant (85.7% vs. 89.7%,  $p=0.73$ ). Patients treated with CRT had a better LRC than those with BRT independent of MVD or CA-IX expression.

#### Conclusion

The combination of MVD and CA-IX status might give additional prognostic information in HNSCC patients with known HPV status.

#### PO-0967 Analysis of tumour microenvironment using multi-parametric PET/MR imaging in HNSCC xenograft models

S. Boeke<sup>1</sup>, R. Winter<sup>2</sup>, A. Menegakis<sup>1</sup>, P. Mena-Romano<sup>2,3</sup>, M. Krueger<sup>4</sup>, E.C. Sezgin<sup>1</sup>, G. Reischl<sup>4</sup>, B. Pichler<sup>4</sup>, D. Zips<sup>1</sup>, D. Thorwarth<sup>2</sup>

<sup>1</sup>University Hospital Tübingen, University Department of Radiation Oncology, Tübingen, Germany

<sup>2</sup>University Hospital Tübingen, University Department of Radiation Oncology - Section for Biomedical Physics, Tübingen, Germany

<sup>3</sup>Pontificia Universidad Católica de Chile, Institute of Physics, Santiago, Chile

<sup>4</sup>Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, Tübingen, Germany

#### Purpose or Objective

Hypoxia is a major determinant of outcome in radiotherapy (RT) especially in head and neck squamous cell carcinoma (HNSCC). Non-invasive imaging of tumour microenvironment with multi-parametric PET/MRI, using e.g. hypoxia specific tracers, is a potentially powerful technology for personalisation of RT. The aim of this study is to investigate simultaneously fMRI and hypoxia PET in HNSCC xenografts during the course of fractionated RT.

#### Material and Methods

FaDu tumours ( $n=7$ ) were xenografted on the right hind leg of immunodeficient nude mice. After a growth period of 4-6 weeks multi-parametric FMISO-PET/MRI (7T, Bruker) was performed before and after RT (10 x 2 Gy in two weeks, small animal image guided RT platform, SAIGRT, Dresden, Germany). Following the second imaging, tumours were excised after injection of Pimonidazole and Hoechst for further histological analysis. The imaging protocol included a 80-90 min dynamic FMISO-PET acquisition, anatomical T2w and diffusion-weighted MRI (DWI, 9 b-values from 0 to 800 s/mm<sup>2</sup>) as well as DCE MRI. T2w anatomical MRI data was used for precise manual segmentation of the actual tumour region of interest (ROI). Within each tumour ROI, mean and maximum tumour-to-muscle ratios (TMR, TMR<sub>max</sub>) as well as mean ADC values were analysed prior and post fractionated RT treatment.

#### Results

Two animals presented with very small tumor volume (< 10 mm<sup>3</sup>) which did not allow for ROI-based analysis before ( $n=1$ ) or after ( $n=1$ ) RT, respectively. The mean (SD) volume was 479.3 (651.7) and 808.0 mm<sup>3</sup> (1146.3), mean ADC was 760.0 (138.3) and 950.0 10<sup>-3</sup>mm<sup>2</sup>/sec (176.9), mean TMR at 80 min post injection (pi) was 1.42 (0.27) and 0.98 (0.17) and mean TMR<sub>max</sub> at 80 min pi was 2.47 (0.18) and 1.75 (0.75) before and after 2 weeks of RT respectively (cf. figure 1). Mean changes (SD) during the two weeks of irradiation were 25.0% (71.64%), 19.7% (24.0%), -31.7% (10.5%), -21.5 % (86.9%) for tumour volume, ADC, TMR and TMR<sub>max</sub>, respectively.

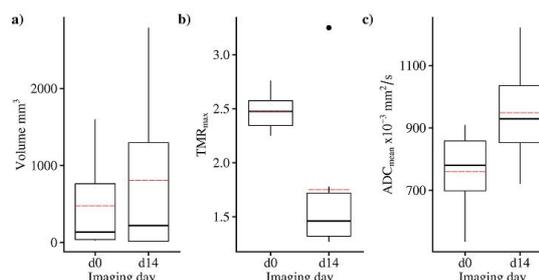

Fig. 1: Tumour volume, TMR<sub>max</sub> and mean ADC before and after 10 fractions of RT. Red dashed-line depicts the mean, black the median, lower and upper hinges the 25 and 75 percentile, respectively.

#### Conclusion

Intra- and intertumoural heterogeneity in hypoxia distribution and fMRI parameters were observed. FMISO uptake after irradiation decreased and ADC-value increased during radiotherapy as a surrogate for reoxygenation and lower cell density or increasing necrotic areas, respectively. Our data will be extended with various tumour models and will form the preclinical data base for the development of an integrated multiparametric prediction model for personalised RT in HNSCC.

#### PO-0968 The Role of epithelial to mesenchymal transition (EMT) as Biomarker for Radioresistance in HNSCC

I. Kurth<sup>1,2</sup>, D. Digomann<sup>2</sup>, L. Hein<sup>2</sup>, A. Linge<sup>1,2,3,4</sup>, L. Koi<sup>5</sup>, S. Loeck<sup>2</sup>, K. Maebert<sup>2</sup>, H. Stephan<sup>2</sup>, C. Peitzsch<sup>1</sup>, M. Krause<sup>1,2,3,4,5</sup>, M. Baumann<sup>2,3,4,5,6</sup>, A. Dubrovskaya<sup>2,5</sup>

<sup>1</sup>NCT Partnerstandort Dresden, Translationale Onkologie, Dresden, Germany

<sup>2</sup>OncoRay-National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus, Dresden, Germany

<sup>3</sup>Department of Radiation Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus, Dresden, Germany

<sup>4</sup>German Cancer Consortium DKTK Dresden, German Cancer Research Center DKFZ, Dresden, Germany

<sup>5</sup>Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiation Oncology, Dresden, Germany

<sup>6</sup>Deutsches Krebsforschungszentrum DKFZ, Heidelberg, Germany

#### Purpose or Objective

It is described that epithelial-to-mesenchymal transition (EMT) plays an important role in head and neck squamous carcinomas (HNSCC) progression and resistance to therapy [1]. Recent studies suggest that for instance the expression of EMT related microRNAs may cause intrinsic radioresistance in HNSCC [2]. During the process of EMT epithelial cancer cells obtain a more mesenchymal-like motile and invasive phenotype, which has been argued to sustain survival and therapy resistance of those tumor cells and facilitate cancer progression. Radiotherapy is one of the main approaches to treat HNSCC. However, tumor radioresistance often impedes the success of radiotherapy and has been found to drive tumor aggressiveness and expansion. In this study we asked the question, if radioresistant HNSCC populations display EMT features on a molecular as well as on a functional level and whether we can correlate those characteristics to treatment outcome.

#### Material and Methods

We used multiple irradiated HNSCC lines (IR) as an established model to investigate the traits of radioresistance [3]. Global gene expression, protein

analysis *in vitro* and on xenograft models and functional radiobiological analysis was applied.

#### Results

Interestingly, global gene expression analysis revealed a negative correlation of genes associated with cell motility and migration in the IR derivatives of two HNSCC cell lines, namely Cal33, FaDu. We functionally validated those findings and screened for known EMT marks from literature by functional migration assays and EMT-related protein expression in several HNSCC model cell lines and established xenografts as well as in their IR-derivatives in order to correlate the acquired findings to radiotherapy outcome. The only positive correlation was found for the initial-before therapy protein expression *in vitro* and *in vivo* for Slug, a zinc-finger protein encoded by the *SNAI2* gene and c-Met, a receptor tyrosine kinase encoded by the *MET* gene. Functional knockdown of Slug or c-Met expression led to radiosensitization in 3-D clonogenic survival assays of several HNSCC cell lines.

#### Conclusion

Currently the expression of these molecules is scored for clinical outcome to better understand the context of EMT biomarkers for HNSCC progression and the development of a potential well-directed combinational radiochemotherapy.

#### PO-0969 Accelerated fractionation should start early for laryngeal/ hypopharyngeal cancer.

C. Terhaard<sup>1</sup>, N. Kasperts<sup>1</sup>, H. Dehnad<sup>1</sup>, E. Smid<sup>1</sup>, L. Janssen<sup>2</sup>, R. Wigggenraad<sup>3</sup>, C. Raaijmakers<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiation Oncology Department, Utrecht, The Netherlands

<sup>2</sup>UMC Utrecht, Head and neck surgical oncology, Utrecht, The Netherlands

<sup>3</sup>RCWEST- Medisch Centrum Haaglanden, radiotherapy, Den Haag, The Netherlands

#### Purpose or Objective

Accelerated repopulation during radiotherapy is a main cause of local recurrence after conventional radiotherapy for H&N cancer. Based on meta-analysis accelerated fractionation (AF) is superior to conventional fractionation. In most studies around 70 Gy is given in 6 weeks. The objective of this study is to analyze 3 AC schedules with three start points of acceleration: at week 3, 4 and 5, looking for the optimum.

#### Material and Methods

Since 1995 we treat T2-3 larynx (including bulky T2 glottic) and hypopharynx cancer with AF. Three schedules have been used. AF started in week 4 for the hyperfractionated AF (HAS, n=28), in week 3 for the ASO schedule (n=283), and in week 5 in the ARCON study (n=86). Since local control was equal<sup>2</sup>, results of both arms were combined. Mean follow-up was 75 months. Age ranged from 32-87 years, 25% ≥ 70 years. WHO performance was 0-1 in 95%. T2, T3, T4, was 57%, 35%, and 8%; 27% was N+. Distribution between the schedules was equal for gender, stage, WHO p., and age. Tumor location was glottis, supraglottis and hypopharynx, in 44% 45% and 11%, respectively.

#### Results

Treatment delay was only seen in 5%, independent of the schedule. Actuarial local control rates and disease free survival rates differed significantly between the schedules (table 1). In univariate analysis actuarial local control was significantly correlated with T stage (T2, n=228, 82%, T3, n=135 79%, T4 45%), sex (female fared better), stage, and marginally significant years of treatment. Local control was equal for patients < age 70 and above (80%). In multivariate analysis the only independent prognostic factors for local control were stage, sex and treatment schedule. Independent factors for disease free survival were stage and, marginally, treatment schedule.

Tube feeding during treatment was given in 24%, for HAS, ASO and ARCON 32%, 25% and 17% (p=ns). Severe late laryngeal was equal for the schedules (table 1).

	Hyperfractionated Fractionation (HAS) <sup>1</sup> n=28	Accelerated fractionation only (ASO) <sup>1</sup> ; n=283	ARCON study <sup>2</sup>	n=86 <sup>P</sup>
n (fractions); d (Gy); T (overall treatment time in days) Total Dose:	50; 1.2/1.7; 33 Wk 1-3: 30 x 1.2 Gy, BID Wk 4-5: 20 x 1.7 Gy, BID 70 Gy	40; 2/1.8/1.5; 33 Wk 1-2: 10 x 2 Gy Wk 3-5: 15 x 1.8/1.5 Gy, BID 69.5 Gy	4; 2; 37 Wk 1-4: 20 x 2 Gy Wk >5, 14 x 2 Gy, BID 68 Gy	
ERD (a=0.3, a/ B=10, Tpot=5)	67.7	66.5	64.5	
ETD (a/ B=10)	103.7	116.9	113	
5 yr local control	56%	83%	75%	0.004
5 yr disease free	50%	76%	65%	0.02
Serious late toxicity (larynx)	12%	10%	12%	ns

#### Conclusion

In this large group of patients treated for intermediate size laryngeal/ hypopharyngeal cancer superior local control and disease free survival was seen when the accelerated fractionation started in week three. The rate of serious toxicity was equal for all three schedules. Also, age ≥ 70 was not a negative prognostic factor for local control, disease free survival and risk of complications. For patients ≥ 70, with a WHO performance 0-1 excellent outcome is shown.

#### PO-0970 Prostate brachytherapy; DNA damage biomarker (gH2AX) induction rate correlates with late toxicity

S. Osman<sup>1</sup>, S. Horn<sup>1</sup>, D. Brady<sup>1</sup>, S.J. McMahon<sup>1</sup>, A.B. Mohamed Yoosuf<sup>2</sup>, D. Mitchell<sup>3</sup>, K. Crowther<sup>2</sup>, C.A. Lyons<sup>1</sup>, A.R. Hounsell<sup>2</sup>, K.M. Prise<sup>1</sup>, C.K. McGarry<sup>2</sup>, S. Jain<sup>1</sup>, J.M. O'Sullivan<sup>1</sup>

<sup>1</sup>Queen's University Belfast, Centre for Cancer Research & Cell Biology, Belfast, United Kingdom

<sup>2</sup>Northern Ireland Cancer Centre- Belfast Health and Social Care Trust, Radiotherapy Physics, Belfast, United Kingdom

<sup>3</sup>Northern Ireland Cancer Centre- Belfast Health and Social Care Trust, Clinical Oncology, Belfast, United Kingdom

#### Purpose or Objective

Low-dose-rate permanent prostate brachytherapy (PPB) is an attractive treatment option and offers excellent outcomes for patients with localised prostate cancer. As standard CT-based post-implant dosimetry often correlates poorly with late treatment toxicity, a study was conducted to investigate correlations between radiations induced DNA damage biomarker levels, bowel, urinary, and sexual toxicity

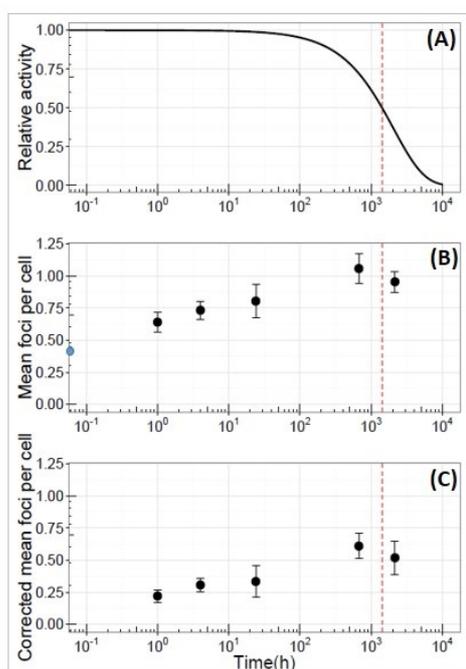

#### Material and Methods

Twelve prostate cancer patients treated with <sup>125</sup>I PPB monotherapy (145Gy) were included in this prospective study. Post-implant CT based dosimetry assessed the minimum dose encompassing 90% (D<sub>90%</sub>) of the whole prostate volume (global), sub-regions of the prostate (12 sectors) and the near maximum doses (D<sub>0.1cc</sub>, D<sub>2cc</sub>) for the

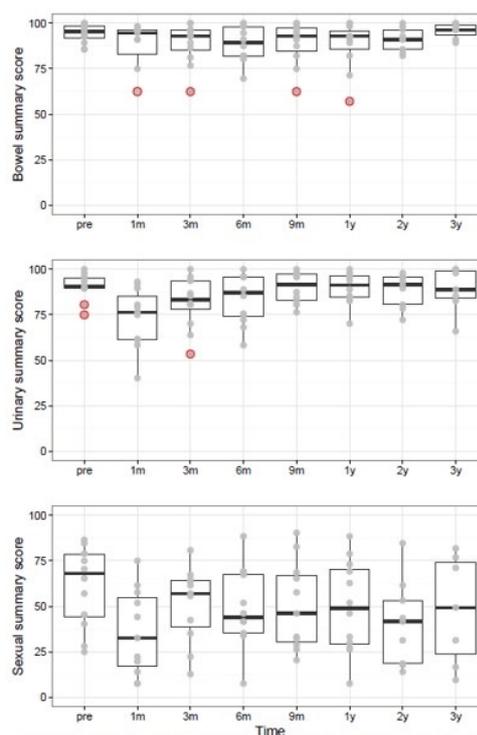

rectum and bladder. Six blood samples were collected from each patient; pre-treatment, 1 hour (h) post implant, 4h, 24h, 4weeks (w) and at 3 months (m). DNA double strand breaks were stained using the  $\gamma$ H2AX and 53BP1 proteins. Patient self-scored quality of life from the Expanded Prostate Cancer Index Composite (EPIC) were obtained at baseline, 1 m, 3m, 6m, 9m, 1 year (y), 2y and 3y post treatment. Spearman's correlation coefficients were used to evaluate correlations between temporal changes in  $\gamma$ H2AX, dose and toxicity

### Results

The minimum follow-up was 2 years. Population mean prostate  $D_{90\%}$  was  $144.6 \pm 12.1$  Gy. Rectal near maximum dose  $D_{0.1cc} = 153.0 \pm 30.8$  Gy and  $D_{2cc} = 62.7 \pm 12.1$  Gy and bladder  $D_{0.1cc} = 123.1 \pm 27.0$  Gy and  $D_{2cc} = 70.9 \pm 11.9$  Gy. Pre-treatment, mean ( $\pm$ SD) background foci (co-localising  $\gamma$ H2AX and 53BP1) was  $0.42 \pm 0.20$  foci per cell (Figure 1B). A Shapiro-Wilk test confirmed the data was normally distributed ( $w=0.943$ ,  $p=0.540$ ). Post seed implantation,  $\gamma$ H2AX/53BP1 foci numbers were significantly elevated as early as 1 hour post implantation and remained so at 4 and 24 hours, 4 weeks and 3 months post implantation (Figure 1B). The  $\gamma$ H2AX/53BP1 foci numbers continued to rise at 4 weeks (672 h) even after reduction in seeds activity due to natural decay (Figure 2A) before dropping at 3 months. EPIC summary scores for bowel, urinary, and sexual domains are presented in Figure 2. Changes in EPIC scores from baseline showed high positive correlation between acute toxicity and late toxicity for both urinary and bowel symptoms, EPIC 1y ( $r = 0.67$ ,  $p = 0.035$ ), EPIC 2y ( $r = 0.86$ ,  $p = 0.001$ ). Overall, no correlations were observed between dose metrics (prostate global or sector doses) and  $\gamma$ H2AX foci counts.

**Figure 1** A) Relative activity of  $^{125}\text{I}$  as a function of time post seed-implantation. B) Mean foci number per cell in patients' peripheral blood lymphocytes (blue circle indicates mean background counts) and corrected for background (C). The error bars represent the standard error and the red dashed line represents the  $^{125}\text{I}$  half-life of 1426.3 hours (59.43 days).

**Figure 2** Changes in quality-of-life scores over time for each domain studied on the Expanded Prostate Cancer Index Composite (EPIC) questionnaire. EPIC scores range from 0 to 100, with higher values representing a more favourable health-related quality of life. In the figure median with inter-quartile range IQR (boxes), and  $\pm 1.5 \times \text{IQR}$  (whiskers) are presented. Dots are different data points and red dots are outliers.

### Conclusion

Our results show that a prompt increase in  $\gamma$ H2AX foci at 24 hours post-implant relative to baseline may be a useful measure to assess elevated risk of late RT related toxicities for PPB patients. A subsequent investigation recruiting a larger cohort of patients is warranted to verify our findings.

### PO-0971 Estimating second malignancy risk in IMRT and VMAT in radiotherapy for carcinoma of left breast

J. Selvaraj<sup>1</sup>, V. Sakthivel<sup>2</sup>

<sup>1</sup>The Canberra Hospital, Medical Physics and Radiation Engineering, Canberra, Australia

<sup>2</sup>Advanced Medical Physics, Medical Physics, Houston-Texas, USA

### Purpose or Objective

IMRT and VMAT produce dose distributions with superior target dose uniformity and normal tissue sparing. However, this increases amount of volume receiving very low doses substantially compared to conventional techniques. This increases the risk of radiation-induced second malignancy (SCR) as reported in the literature. The aim of this study is to use a mechanistic radiobiological model which is more accurate in predicting the dose-response at low as well as high dose levels to estimate SCR. Studies have shown patient age at exposure is important in estimating SCR, thus patients' age is also accounted for in the SCR estimation. Moreover, the mechanistic model also takes cell proliferation and dose fractionation into account.

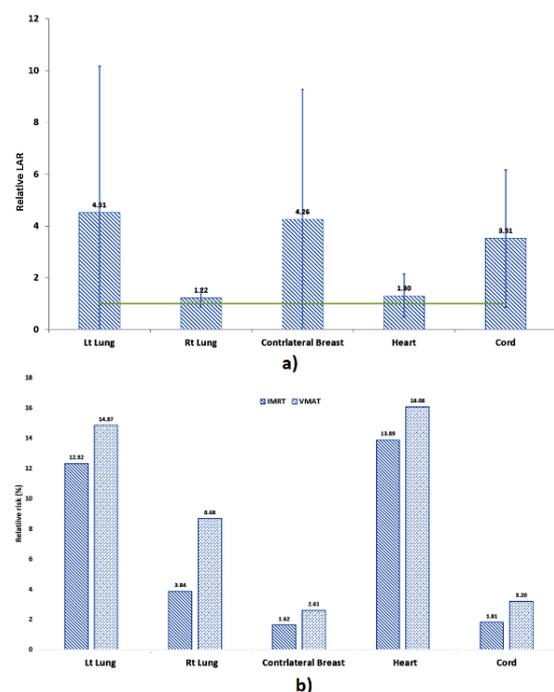

### Material and Methods

Fifty IMRT and VMAT plans with similar dose-volume objectives were selected for the study. The prescription

dose was 50 Gy in 25 fractions to the PTV. Monte Carlo based dose calculation engine was the preferred choice as it is more accurate at low dose levels which is more relevant for estimating SCR. Appropriate model parameters were taken from the literature for the mechanistic model to calculate excess absolute risk (EAR), lifetime attributable risk (LAR), integral dose and relative risk (RR) for both lungs, contralateral breast, heart and spinal cord.

### Results

The mean MU in IMRT and VMAT plans were  $751.1 \pm 133.3$  and  $1004.8 \pm 180$  respectively for IMRT and VMAT. The mean EAR values per 10,000 person years (PY) estimated for IMRT and VMAT treatments including gender-specific correction with and without age correction factor are shown in figure 3. The mean EAR values with one standard deviation without age correction were  $42.4 \pm 11.3$ ,  $10.6 \pm 6.0$ ,  $12.3 \pm 6.7$ ,  $1.9 \pm 0.7$  and  $0.6 \pm 0.3$  for left lung, right lung, contralateral breast, heart and spinal cord respectively for the IMRT plans. These values were  $51.9 \pm 19.7$ ,  $28.7 \pm 11.4$ ,  $31.9 \pm 13.4$ ,  $2.3 \pm 0.8$  and  $1.5 \pm 0.8$  for the VMAT plans. However the values were reduced with age correction, especially for the contralateral breast. The values obtained with age correction were  $44.6 \pm 11.9$ ,  $11.2 \pm 6.4$ ,  $5.4 \pm 4.0$ ,  $1.4 \pm 0.5$  and  $0.3 \pm 0.2$  for left lung, right lung, contralateral breast, heart and spinal cord respectively for the IMRT treatments and  $54.6 \pm 20.6$ ,  $30.2 \pm 12.0$ ,  $13.8 \pm 8.6$ ,  $1.6 \pm 0.6$  and  $0.9 \pm 0.5$  for the VMAT treatments.

### Conclusion

Results showed VMAT plans had a higher risk of developing second malignancy in lung, contralateral breast, heart and cord compared to IMRT plans. However, the increase in risk was found to be marginal. The increase in risk was greater in both IMRT and VMAT for left lung and contralateral breast compared to other organs included in the study. Incorporating the age correction factor decreased the risk of contralateral breast SCR. No strong correlation was found between EAR and MU.

### PO-0972 Breast cancer cell survival using flattening filter-free beam compared to a standard flattened beam

M. Boccia<sup>1</sup>, L. Manti<sup>2</sup>, S. Clemente<sup>3</sup>, C. Oliviero<sup>3</sup>, F. Perozziello<sup>2</sup>, R. Liuzzi<sup>4</sup>, M. Conson<sup>1</sup>, L. Cella<sup>4</sup>, R. Pacelli<sup>1</sup>  
<sup>1</sup>Federico II University School of Medicine, Department of Advanced Biomedical Sciences, Napoli, Italy

<sup>2</sup>University of Naples Federico II, Department of Physics, Napoli, Italy

<sup>3</sup>Azienda Ospedaliera Universitaria Federico II, Radiation Oncology Department, Napoli, Italy

<sup>4</sup>National Council of Research CNR, Institute of Biostructures and Bioimaging, Napoli, Italy

### Purpose or Objective

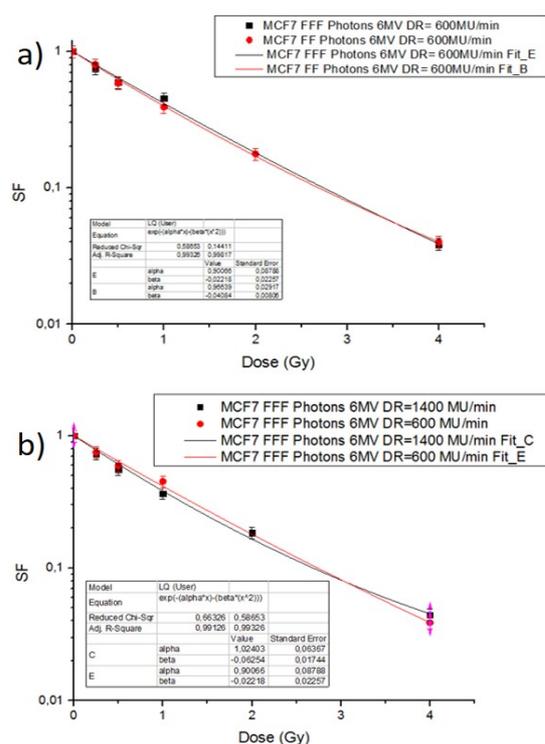

The innovative radiotherapy techniques such as Intensity-Modulated Radiation Therapy (IMRT) and Volumetric-Modulated Arc Therapy (VMAT) allow for more conformity of dose to the tumor target and sparing of healthy tissues. However, these techniques require an increase of monitor units (MUs) and therefore an increase of treatment/delivery times for each fraction. In addition, a higher dose outside the field caused by photons scattering in the flattening filter (FF) is expected. Flattening Filter-Free (FFF) photon beams can deliver higher dose rates and reduce the treatment time by about a factor 4 compared to conventional photon beams. Additional benefits also include reduced head scatter, a lower peripheral dose and neutron contamination. Purpose of the present study is to compare the radiobiological effects of FFF versus FF photon beams in mammary epithelial tumor cells (MCF7).

### Material and Methods

MCF7 cells were irradiated with conventional and FFF 6MV photon beams using a TrueBeamSTx (Varian Medical Systems). Different dose rate values were considered (600 MU/min and 1400 MU/min). The cells were exposed to 0.25, 0.5, 1.0, 2.0 and 4.0 Gy doses. The number of monitor units required to deliver the desired doses to the cells was calculated using Pinnacle<sup>3</sup> (Philips) Treatment Planning System (TPS). Irradiations were performed with the flasks placed on 5 cm of equivalent water phantom (RW3) slabs and gantry angle at 180° to deliver homogeneous dose to the cell layer. A check of the actual dose delivered to cells was done exposing 9 thermoluminescent dosimeters (LiF:Mg,Ti TLD-100) placed on the bottom of one of the irradiated flask. Clonogenic cell survival of MCF7 cells was determined. Cell survival data were fitted to linear-quadratic model.

### Results

In the investigated dose range (0-4Gy), no statistically significant differences on breast cancer cell survival curves was observed a) with or without flattening filter (600 MU/min vs. 600 FFF MU/min) and b) at different dose rates (600 FFF MU/min vs 1400 FFF MU/min). Cell survival curves are reported in figure 1.

### Conclusion

Our preliminary results suggest that the use of FFF beams does not influence cancer cell survival rate when compared with standard flattened beams. The effects of higher dose per fraction have to be further investigated.

### PO-0973 Dimensionality reduction of clonogenic survival data to identify candidates for radiosensitization

N. Brix<sup>1</sup>, R. Hennen<sup>1</sup>, C. Belka<sup>1</sup>, K. Lauber<sup>1</sup>

<sup>1</sup>LMU University Hospital Grosshadern, Department of Radiation Oncology, Munich, Germany

### Purpose or Objective

With approximately 70,000 new cases per year in Germany, breast cancer is the most common malignancy in women. Together with surgery and chemotherapy, the majority of patients is undergoing radiotherapy. While stratification by clinicopathological parameters - such as hormone receptor and Her2 expression - is part of the clinical routine, biomarkers for tumor radioresistance and targets for radiosensitization are currently not available. The colony formation assay represents a versatile tool to analyze cellular radiosensitivity *in vitro* making it indispensable for the identification of factors involved in tumor cell radioresistance. As an alternative to the linear-quadratic model, we propose a novel approach of dimensionality reduction to fully exploit the information obtained from clonogenic survival assays which allows, for instance, correlation with gene expression data.

### Material and Methods

Clonogenic survival of 13 breast cancer cell lines and normal human mammary epithelial cells upon irradiation with 0-8 Gy was analyzed in colony formation assays. The data derived thereof were subjected to linear-quadratic fitting and principal component analysis (PCA) to extract scores of radioresistance for each cell line.

Next, mRNA expression levels of more than 40 DNA damage response (DDR) regulators were measured by qRT-PCR. In order to identify predictors of radioresistance and potential targets for radiosensitization, mRNA expression levels were correlated with the PCA-derived radioresistance scores.

### Results

Among the 14 cell lines analyzed, strong differences in clonogenic survival were observed. Using the linear-quadratic model, very high goodness-of-fit levels were obtained ( $R^2 \geq 0.98$ ). However, obvious differences in radiosensitivity between several cell lines were not revealed by the respective  $\alpha/\beta$  values which failed to reflect the overall steepness of survival curves.

Data reduction by PCA allowed the extraction of radioresistance scores. Notably, more than 70% of the variance in the dataset was covered by the first PC. Correlation of radioresistance scores with mRNA expression levels of DDR regulators identified potential predictors of radioresistance. Target validation using RNA interference and selection of suitable pharmacological inhibitors are ongoing.

### Conclusion

Dimensionality reduction by PCA is a suitable method to extract scores of radioresistance from clonogenic survival datasets which can be correlated with other types of data, such as mRNA expression levels. This approach facilitates the identification of DDR regulators which may be further validated as potential biomarkers of radioresistance and/or targets for radiosensitization.

### PO-0974 Biomarkers of radiosensitivity for patient stratification and personalized radiotherapy treatment

E. Palumbo<sup>1</sup>, C. Piotto<sup>1</sup>, L. Baggio<sup>1</sup>, E. Groff<sup>1</sup>, E. Calura<sup>2</sup>, F. Busato<sup>1</sup>, B. El Khouzai<sup>1</sup>, E. Fasanaro<sup>1</sup>, M. Rigo<sup>1</sup>, L. Loreggian<sup>1</sup>, C. Romualdi<sup>2</sup>, A. Russo<sup>3</sup>, M. Mognato<sup>2</sup>, D. Zafiroopoulos<sup>4</sup>, L. Corti<sup>1</sup>

<sup>1</sup>Istituto Oncologico Veneto IOV-IRCCS, UOC of Radiotherapy, Padua, Italy

<sup>2</sup>University of Padua, Department of Biology, Padova, Italy

<sup>3</sup>University of Padua, Department of Molecular Medicine, Padova, Italy

<sup>4</sup>National Laboratories of Legnaro- Italian Institute of Nuclear Physics, LNL-INFN, Padua, Italy

### Purpose or Objective

The personalization of radiotherapy (RT) represents the goal of future clinical radiation trials. A screening tool able to classify each patient according to his/her own sensitivity to ionizing radiation (IR) before the administration of RT would be essential to set personalized dosing schedules, effective in improving RT outcomes and in reducing side effects. Genetic variation is a likely source for the normal tissue radiosensitivity variation observed among individuals. Mutations in key genes of the DNA-Damage Response (DDR) pathway, or the individual modulation of DDR gene expression after IR-exposure, may underlie these differences. This study aims at defining a genetic signature useful to discriminate patients undergoing RT as radiosensitive, normal and radioresistant and to predict the likelihood of a late IR-toxicity. In this frame, gene expression data concerning DDR pathway, obtained from blood samples of breast and head-neck cancer patients, are overlaid with the individual *in vitro* radiosensitivity index and the *in vivo* tissue radiosensitivity detected during the follow-up. We expect to identify a 5-10 gene network determining the individual radiophenotype.

### Material and Methods

1. Criteria for patient enrolling: breast or head-neck cancer diagnosis; exclusion of congenital syndromes predisposing to radiosensitivity; patients not previously treated with chemo-radiotherapy; age > 18 years; patient agreement to undergo follow-up; informed consent. 2. G2-assay for the prediction of radiosensitivity: an individual radiosensitivity index (IRS) is calculated according to the G2-chromosomal radiosensitivity and the G2 checkpoint efficiency. Details of the protocol are in <sup>1</sup>. 3. Gene expression analysis: Gene expression analysis is performed by quantitative real-time PCR (qRT-PCR) on total RNA

isolated from blood draws harvested before the administration of the first fractionated dose of RT and 24 h later. 4. Statistical analysis: Anova test is performed to analyse the differential expression across IRS classes and a Spearman analysis is performed to assess correlation between expression and IRS index.

#### Results

The expression of *DDB2*, *GADD45A*, *CDKN1A*, and *ATM* genes following irradiation<sup>2,3</sup> has been correlated with the *in vitro* IRS evaluated by the G2-chromosomal assay; at present, a positive correlation between *ATM* expression and IRS could be inferred despite the unavoidable inter-individual variability. The analyses on other DDR genes are in progress.

#### Conclusion

The innovation of this study is the use of a molecular biology approach to assess patient radiosensitivity before RT, in the frame of an integrated approach between clinicians and biologists.

#### PO-0975 Clinical utilization of the radiation-hypoxia-induced abscopal/bystander effect in lung cancer

S. Tubin<sup>1,2</sup>, S. Gupta<sup>3</sup>, A.M. Mansoor<sup>4</sup>

<sup>1</sup>KABEG Klinikum Klagenfurt, Radioonkologie, Klagenfurt, Austria

<sup>2</sup>Sylvester Comprehensive Cancer Center- University of Miami Leonard Miller School of Medicine, Department of Radiation Oncology, Miami, USA

<sup>3</sup>Georgia Cancer Center- Augusta University- Augusta-GA- USA, Health Sciences, Augusta, USA

<sup>4</sup>National Cancer Institute- National Institutes of Health, Radiotherapy Development Branch- Radiation Research Program- Division of Cancer Treatment and Diagnosis, Rockville, USA

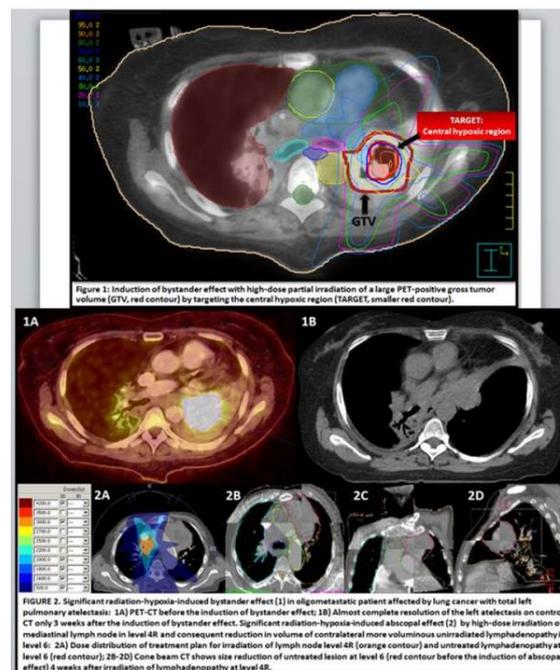

#### Purpose or Objective

To report on initial results in a small series of consecutive patients treated with high-dose hypofractionated radiotherapy (1-3 fractions) in the treatment of oligometastatic patients with large tumor masses focusing on application of results previously obtained by *in vitro* studies on radiation-induced abscopal/bystander effect. Our previous study (unpublished data) focused on targeting tumor hypoxia that induced a strong abscopal/bystander effect. We provide data that support the contention that high-dose radiation to the part of a large gross tumor volume (GTV) has the potency to induce a robust bystander effect, as well as abscopal (distant) effects.

#### Material and Methods

In the *in vitro* studies conditioned medium-transfer experiments with A-549, H-460 lung cancer cells, as well as their hypoxic clones (A-549HR, H-460HR), were performed. All the cells were irradiated in normoxic or hypoxic conditions with 10Gy single dose and cell growth and survival were monitored by real time cell electronic sensing (RTCES) System and colony forming assay, respectively. In the clinical study, 5 consecutive oligometastatic patients with large hypoxic cancers of lung (3), neck (1) and mediastinum (1) were treated with high dose radiotherapy using high-energy photons. All lesions were irradiated partially by targeting the central hypoxic region (Figure 1), which corresponded to 30% of total GTV (Mean GTV volume 181 cc, mean diameter 6, 8

cm) with 10Gy single fraction prescribed to the 70% isodose line (Dmax 14 Gy). No patient got chemotherapy/immune therapy.

#### Results

10Gy- *in vitro* induced abscopal effect in hypoxic conditions was very effective in inducing growth delay of both, unirradiated normoxic and hypoxic lung cancer cells (Table 1), so we moved forward with clinical application of bystander/abscopal effect. In all the treated patients, a significant bystander effect after mean time of 3 weeks and in 1 of the patients significant abscopal effect was also observed (Figure 2). Overall response rates for symptom relief and mass response were 100% (1 complete and 4 good partial response). No patient experienced acute or late toxicity of any grade.

Treatments:	Strongest Abscopal effect reached in:			
	A549	A549HR (hypoxia-resistant clone)	H460 (hypoxia-resistant clone)	H460HR (hypoxia-resistant clone)
N-RCM (2Gy) vs. H-RCM (2Gy)	H-RCM ↓ (80%) (pR1-1, pR2)	N-RCM ↓ (20%) (VEGF, bFGF)	N-RCM ↓ (25%) (bFGF)	H-RCM ↓ (20%) (VEGF)
N-RCM (10Gy) vs. H-RCM (10Gy)	H-RCM ↓ (80%) (pR1-1, pR2)	N-RCM ↓ (5%) (VEGF, bFGF)	H-RCM ↓ (5%) (pR1-1)	H-RCM ↓ (50%) (pR2, VEGF)
N-RCM (2Gy)+2Gy vs. H-RCM (2Gy)+2Gy	H-RCM ↓ (70%)	H-RCM ↓ (20%)	N-RCM ↓ (20%)	H-RCM ↓ (80%)
N-RCM (10Gy)+2Gy vs. H-RCM (10Gy)+2Gy	H-RCM ↓ (80%)	H-RCM ↓ (7%)	No difference	H-RCM ↓ (100%)

Table 1: Comparison of radiation-induced abscopal effects in normoxic and hypoxic conditions on proliferation of A549, A549HR (hypoxic clone), H460, and H460HR (hypoxic clone) cells: "↓" arrow-reduction of cells proliferation by certain percentage induced by abscopal effect. The table represents various medium-transfer "treatments" of the unirradiated cells with different types of 2Gy and 10Gy radiation-conditioned media (RCM) in normoxic (N) or hypoxic (H) conditions as well as a stronger abscopal effect (red fields) induced in hypoxic conditions. A549 and H460 cells were grown in either normoxia or hypoxia. Once about 80% confluent, media was changed and cells were either left untreated or irradiated (2Gy or 10Gy in single fraction). Cells were again incubated for 24h in the respective microenvironment after which media was collected (N-RCM(2Gy), N-RCM(10Gy), H-RCM(2Gy) and H-RCM(10Gy)). 2000 of A549, A549HR, H460 and H460HR cells per well were plated in 6-16 plates and exposed to all types of previously collected conditioned media(CM). In addition to the indirect effects of radiation (media transfer), effects of combination of direct and indirect radiation were also studied by exposing one set of cells to direct irradiation of 2Gy after first 24h (N-RCM(2Gy)+2Gy, H-RCM(2Gy)+2Gy, N-RCM(10Gy)+2Gy and H-RCM(10Gy)+2Gy) and cell growth was then followed dynamically using RTCES system. After overnight plating, cells were treated by incubating in N-RCM (2Gy), H-RCM (2Gy), H-RCM (10Gy) and left for colony formation. After incubation for 8-10 days, colonies were stained with crystal violet and the colonies containing more than 50 cells were counted. The surviving fraction was calculated as a ratio between the number of colonies formed and the product of the number of cells plated and the plating efficiency. Levels of bFGF, pR2, pR1-1 and VEGFR-1, and VEGF were determined in each sample of CM and RCM by electrochemiluminescence detection using a MULTI-SPOT 96-well 4 Spot Human Growth Factor 1 Plate assay kit according to the manufacturer's instructions in A549 cells and H460 cells.

#### Conclusion

Considering the clinical benefit/toxicity ratio, the clinical exploitation of biological properties of bystander/abscopal effect induced by partial irradiation of large tumor masses, and almost any dose distribution to the normal tissue outside the irradiated tumor, could make bystander/abscopal effect at least more effective than conventional radiation therapy for treatment of advanced cancers and the perfect treatment option for symptomatic patient. Further, by inducing the distal responses, like in the case of one of the patients,

'radiation/hypoxia induced abscopal effects' offer one more possibility for the oligometastatic population also to get cured. We continue to investigate this hypothesis in the laboratory and clinical setting.

**PO-0976 Mechanisms of normal tissue toxicity from SAHA, an HDAC inhibitor and radiosensitizer**

I.S. Barua<sup>1,2</sup>, A.H. Ree<sup>1,2</sup>, L. Sønstevoid<sup>1</sup>, K.R. Redalen<sup>1</sup>, E. Kalanxhi<sup>1</sup>

<sup>1</sup>Akershus University Hospital- Norway, Department of Oncology, Oslo, Norway

<sup>2</sup>Institute of Clinical Medicine- University of Oslo, Campus AHUS, Oslo, Norway

**Purpose or Objective**

Histone deacetylase inhibitors (HDACi) are therapeutic agents, which through epigenetic alterations can cause tumor cell death and have shown radiosensitizing properties in preclinical models. HDACi have been largely regarded as tumor-specific, while their effects on normal tissues remain poorly investigated. The latter is important as an increase in therapeutic efficacy resulting from combining such agents with radiotherapy may come at the expense of patient tolerance, undesired treatment interruptions and dose limitations. In the phase I Pelvic Radiation and Vorinostat (PRAVO) study, we investigated mechanisms of adverse effects to the HDACi vorinostat (suberoylanilide hydroxamic acid; SAHA) when given as potential radiosensitizer. Vorinostat-induced transcriptional responses in patients' peripheral blood mononuclear cells implicated cell death pathways as a possible mechanism of toxicity. In experimental models we showed that apoptosis in epithelial cells of the intestinal mucosa may account for the gastrointestinal-related adverse effects commonly associated with the use of HDACi (Kalanxhi E, et al. Cancer Res Treat, 2016). In the current work we further investigate HDACi-induced apoptosis and the possible interplay with autophagy in experimental normal and colorectal cancer (CRC) models.

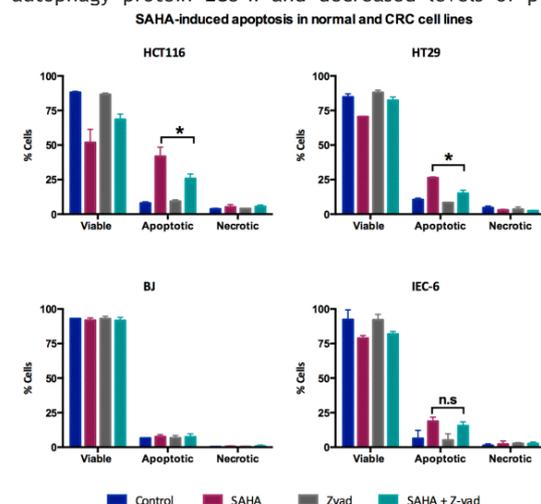

**Material and Methods**

Two normal cell lines (rat IEC-6 intestinal epithelial cells, human BJ fibroblasts) and two CRC cell lines (HCT116, HT29) were exposed to a therapeutically relevant concentration of SAHA alone, or in combination with the caspase inhibitor ZVAD-fmk and the autophagy inhibitor bafilomycin A1 for 24 hours. Induction of apoptosis and autophagy were analyzed with flow cytometry (Annexin V/PI staining) and western blot analysis (LC3 I/II and p62 expression).

**Results**

SAHA induced apoptosis in the CRC cell lines with 42% and 26% of the HCT116 and HT29 cell populations respectively, showing Annexin V/PI staining indicative of early and late phases of apoptosis (Figure 1). Normal BJ fibroblasts remained unaffected, whereas intriguingly, intestinal epithelial IEC-6 cells responded similarly as the cancer cells, although apoptosis was induced at a lesser extent (18% of cells). Addition of ZVAD-fmk halved the number of apoptotic cells in CRC cells, whereas the same number of IEC-6 cells (16%) displayed apoptotic phenotypes. We further looked into induction of autophagy and found that SAHA induced autophagy both in the CRC cell lines and the IEC-6 cells, as reflected by increased levels of the

autophagy protein LC3-II and decreased levels of p62.

**Figure 1.** CRC (HCT116 and HT29) and normal cell lines (BJ and IEC-6), were treated with SAHA (2.5  $\mu$ M for 24 hours) in the presence or absence of the apoptosis inhibitor Zvad, and the percentage of apoptotic and necrotic cell populations was quantified with flow cytometry and Annexin V/PI staining. Values represent the average of three experiments and error bars indicate the SD.

**Conclusion**

Treatment with the HDACi SAHA resulted in induction of apoptosis and autophagy in both CRC cells and at a lesser extent in a relevant normal tissue model. Firstly, our results may contribute to explain adverse effects of SAHA on normal intestinal epithelial cells, and secondly, identify a therapeutic window where tumor radiosensitization can be achieved by SAHA.

**PO-0977 Plasma lipidomics for predictive biomarker analysis in rectal cancer.**

P. Bulens<sup>1,2</sup>, A. Debucquoy<sup>2</sup>, K. Bloch<sup>2</sup>, S. Fieuws<sup>2</sup>, J. Swinnen<sup>2</sup>, K. Haustermans<sup>1,2</sup>

<sup>1</sup>University Hospital Leuven, Radiation Oncology, Leuven, Belgium

<sup>2</sup>KU Leuven - University of Leuven, Oncology, Leuven, Belgium

**Purpose or Objective**

Selection of patients with locally advanced rectal cancer, eligible for individualized treatment strategies, is hampered by the lack of reliable predictors of response. Plasma markers based on liquid biopsies would allow minimally invasive patient stratification. Most liquid biopsy approaches are based on the detection of free circulating DNA or tumor cells. Since the development and progression of cancer is associated with dramatic changes in lipid metabolism, we propose a radically different approach based on alterations in circulating lipids.

**Material and Methods**

From prospectively collected plasma samples of 85 rectal cancer patients at 3 time points (before chemoradiation (CRT), 2 weeks into CRT, end of CRT), lipids were extracted using a modified Bligh-Dyer protocol. Samples were subjected to mass spectrometry-based lipid profiling on a fully operational lipidomics platform. This approach allowed us to assess the concentration of approximately 200 different lipid species including phosphatidylcholine (PC), phosphatidylethanolamines (PE), phosphatidylinositol (PI), phosphatidylserine (PS) and ceramides (Cer). Based on the assessment of these species, discriminative lipid profiles of patients achieving a pathologic complete response (pCR) and patients lacking such response will be delineated using biostatistical approaches including PCA analysis followed by LDA and correction for false discovery due to multiple testing.

**Results**

13 out of 85 patients achieved a pCR (15,3%). Preliminary analyses showed slightly less lipogenic profiles for patients

with pCR. This effect was most pronounced for the PC lipid species (Fig. 1). Furthermore, preliminary results identified changes in plasma lipid species during CRT. A steeper increase in lipogenicity (PC, PE, Cer) was observed during CRT (time point 1 to 3) for patients achieving pCR in comparison to patients without pCR. Statistical analyses on the complete patient group are ongoing in order to validate our findings and to develop a discriminative marker panel with the most promising lipid markers.

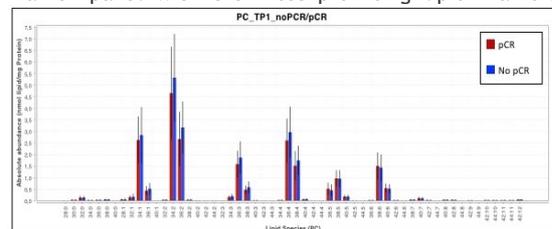

Fig. 1. Comparison of plasma lipid profiles (PC) at diagnosis of patients with and without pCR.

### Conclusion

Plasma lipidomics is a novel field for biomarker development. Preliminary analyses show the potential of lipid profiling to discriminate rectal cancer patients with heterogeneous responses, treated with standard CRT. Further work will lead to the development of a predictive lipid plasma marker panel. Such a predictive panel might be used to stratify patients for an individualized treatment, thereby improving the quality of life for these patients.

### PO-0978 Potential predictive biomarkers to chemoradiotherapy response in rectal cancer: a lipidomic study.

F. Perrotti<sup>1</sup>, P. Del Boccio<sup>2</sup>, D. Pieragostino<sup>2</sup>, L. Caravatta<sup>1</sup>, M. Di Tommaso<sup>1</sup>, C. Rosa<sup>1</sup>, M. Di Perna<sup>1</sup>, P. Sacchetta<sup>2</sup>, D. Genovesi<sup>1</sup>

<sup>1</sup>SS Annunziata Hospital, Radiotherapy, Chieti, Italy

<sup>2</sup>G. D'Annunzio University, Medical Oral and Biotechnological Sciences, Chieti, Italy

### Purpose or Objective

To highlight the lipid signature able to predict the tumor response to chemoradiotherapy (CRT), in patients with advanced rectal cancer (LARC), by using a Lipidomics approach.

### Material and Methods

Between March 2013 and September 2014, 18 patients with LARC were treated with preoperative CRT at the Radiation Oncology Unit of SS Annunziata Hospital in Chieti - Italy. Sera were prospectively collected during routine chemistry tests before treatment (T0) and at day 14° (T14) and 28° (T28) of CRT. An open Liquid Chromatography tandem Mass Spectrometry (LC-MS/MS) analysis was performed to characterize lipid expression at T0. Differential lipids were validated by an independent targeted approach and studied during treatment.

### Results

Sixty-five lipids significantly differentiated responder (RP) vs no-responder (NRP) patients; five lipids were validated as predictive of response to CRT: Sphingomyelin (SM, d18:2/18:1), Lysophosphatidylcholine (LPC, 16:0/0:0), Lysophosphatidylcholine (LPC, 15:1(9z)/0:0), Lysophosphatidylethanolamine (LPE, 22:5/0:0) and Phosphatidylcholine (PC, 40:2). Receiver Operator Characteristic curve (ROC curve), generated combining the pattern of the 5 validated lipids, showed an AUC of 0.95.

### Conclusion

The prediction of response to neoadjuvant CRT in LARC allows to personalize treatments and to improve response rate and survival outcomes. In this study we focused on serum lipids to define a differential profile able to predict response. Our results showed a pattern of 5 lipids that differentiated RP and NRP before treatment. The ongoing confirmation of these results could provide a new insight

on lipid metabolism in modulation of CRT response in LARC, in effort to personalize treatments.

### PO-0979 Differential response of glioma cell lines to microbeam versus conventional radiotherapy

L. Smyth<sup>1,2</sup>, P. Rogers<sup>1</sup>, J. Crosbie<sup>3</sup>, J. Donoghue<sup>1,4</sup>

<sup>1</sup>The University of Melbourne, Department of Obstetrics & Gynaecology, Parkville, Australia

<sup>2</sup>Epworth HealthCare, Radiation Oncology, East Melbourne, Australia

<sup>3</sup>MIT University, School of Science, Melbourne, Australia

<sup>4</sup>Hudson Institute of Medical Research, Centre for Cancer Research, Clayton, Australia

### Purpose or Objective

Synchrotron microbeam radiotherapy (MRT) has been proposed as an alternative treatment for Diffuse Intrinsic Pontine Glioma (DIPG). The aim of this study was to compare the cellular response of two human DIPG cell lines to MRT and conventional broad-beam radiotherapy (CRT). We hypothesised that MRT would elicit a different cellular response to CRT, and that different DIPG cell lines would have different intrinsic radio-sensitivities.

### Material and Methods

Two human DIPG cell lines, SF7761 and JHH-1, were exposed to MRT (112 to 560 Gy) or CRT (2 to 8 Gy) in vitro to produce clonogenic cell-survival curves which were fit to the linear-quadratic model. Equivalent CRT doses were interpolated for each MRT dose. Apoptosis induction and cell-cycle response assays were performed five days after irradiation via flow cytometry to assess differences in cellular response between the cell lines and radiotherapy modalities at equivalent doses.

### Results

Equivalent CRT and MRT doses for each cell line are summarised in Table 1. The SF7761 cell line, which originated from a six year old female patient with no prior history of radiation treatment, was significantly more radiosensitive to both CRT and MRT compared to the JHH-1 cell line, which originated from a six year old male who had previously undergone combined chemotherapy and radiotherapy (Figure 1). JHH-1 formed polyploid cells and exhibited delayed G2/M arrest following both CRT and MRT. Furthermore, apoptosis and cell cycle assays demonstrated that at equivalent doses, MRT induced more unrepaired DNA damage that was detrimental to the cell-cycle and cell viability for both cell lines five days following irradiation.

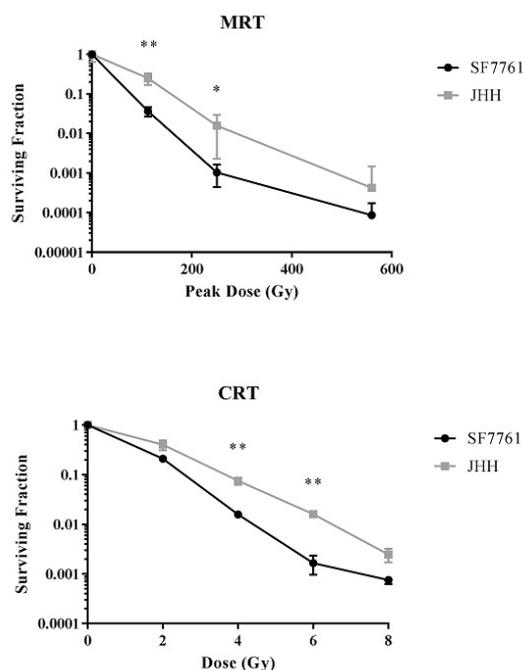

Figure 1. Day fourteen clonogenic cell-survival curves for MRT and CRT. Data are presented as mean  $\pm$  SEM,  $n = 3$ , \* $P < 0.05$ , \*\* $P < 0.01$ .

Table 1. Interpolated equivalent CRT doses for increasing MRT doses

Cell Line	Equivalent CRT doses (Gy) <sup>a</sup>		
	112Gy MRT	250Gy MRT	560Gy MRT
SF7761	3.21 $\pm$ 0.25	6.76 $\pm$ 0.43	9.07 <sup>b</sup>
JHH	2.46 $\pm$ 0.11	6.05 $\pm$ 0.21	9.25 $\pm$ 0.31

<sup>a</sup> Interpolated from linear quadratic dose-response curves fitted to the clonogenic survival data.  
<sup>b</sup> Interpolation possible for only one sample

### Conclusion

This is the first study to compare the response of DIPG cell lines to MRT and CRT. Although MRT caused more DNA damage that was detrimental to the cell cycle compared to CRT, the JHH-1 cell demonstrated radio-resistance regardless of the radiation modality used. The findings of this study support the use of MRT as a potential alternative to CRT for patients with radiosensitive tumours and also contribute to our understanding of the differential response of cancer cells to MRT and CRT.

### PO-0980 MEK/ERK pathway sustains radioresistance of embryonal rhabdomyosarcoma stem-like cell population.

F. Marampon<sup>1</sup>, G. Gravina<sup>1</sup>, C. Festuccia<sup>1</sup>, C. Ciccarelli<sup>1</sup>, F. De Felice<sup>2</sup>, D. Musio<sup>2</sup>, V. Tombolini<sup>2</sup>

<sup>1</sup>University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy

<sup>2</sup>University of Rome "Sapienza", Department of Radiotherapy, Rome, Italy

### Purpose or Objective

The identification of signaling pathways that affect the cancer stem-like phenotype may provide insights into therapeutic targets for combating embryonal rhabdomyosarcoma. The aim of this study was to investigate the role of the MEK/ERK pathway in controlling the cancer stem-like phenotype using a model of

rhabdospheres derived from the embryonal rhabdomyosarcoma cell lines.

### Material and Methods

Rhabdospheres enriched in cancer stem like cells were obtained growing ERMS cells in non adherent condition in stem cell medium. Stem cell markers were evaluated by FACS analysis and immunoblotting. ERK1/2, myogenic markers, proteins of DNA repair and bone marrow X-linked kinase (BMX) expression were evaluated by immunoblotting analysis. Radiation was delivered using an x-6 MV photon linear accelerator. Xenografts were obtained in NOD/SCID mice by subcutaneously injection of rhabdosphere cells or cells pretreated with U0126 in stem cell medium.

### Results

MEK/ERK inhibitor U0126 dramatically prevented rhabdosphere formation and down-regulated stem cell markers CD133, CXCR4 and Nanog expression, but enhanced ALDH, MAPK phospho-active p38 and differentiative myogenic markers. By contrast, MAPK p38 inhibition accelerated rhabdosphere formation and enhanced phospho-active ERK1/2 and Nanog expression. ERMS cells, chronically treated with U0126 and then xenotransplanted in NOD/SCID mice, delayed tumor development and reduced tumor mass when compared with tumor induced by rhabdosphere cells. U0126 intraperitoneal administration to mice bearing rhabdosphere-derived tumors inhibited tumor growth. The MEK/ERK pathway role in rhabdosphere radiosensitivity was investigated in vitro. Disassembly of rhabdospheres was induced by both radiation or U0126, and further enhanced by combined treatment. In U0126-treated rhabdospheres, the expression of the stem cell markers CD133 and CXCR4 decreased and dropped even more markedly following combined treatment. The expression of BMX, a negative regulator of apoptosis, also decreased following combined treatment, which suggests an increase in radiosensitivity of rhabdosphere cells.

### Conclusion

Our results indicate that the MEK/ERK pathway plays a prominent role in maintaining the stem-like phenotype of ERMS cells, their survival and their innate radioresistance. Thus, therapeutic strategies that target cancer stem cells, which are resistant to traditional cancer therapies, may benefit from MEK/ERK inhibition combined with traditional radiotherapy, thereby providing a promising therapy for embryonal rhabdomyosarcoma.

### PO-0981 Disturbance of redox status enhances radiosensitivity of hepatocellular carcinoma

H. Zhang<sup>1</sup>, C. Sun<sup>1</sup>

<sup>1</sup>Institute of Modern Physics- Chinese Academy of Sciences, Department of Heavy Ion Radiation Biology and Medicine, Lanzhou, China

### Purpose or Objective

High constitutive expression of Nrf2 has been found in many types of cancers, and this high level of Nrf2 also favors resistance to drugs and radiation. Here we investigate how isoliquritigenin (ISL), a natural antioxidant, inhibits the Nrf2-dependent antioxidant pathway and enhances the radiosensitivity of HepG2 cells and HepG2 xenografts.

### Material and Methods

Treatment of HepG2 cells with ISL for 6 h, Keap1 and ubiquitination of Nrf2 were measured by RT-PCR and Western blot. Pretreatment with ISL for 6 h followed by X-ray irradiation, confocal microscopy was used to visualize Nrf2 translocation to the nucleus and  $\gamma$ -H2AX foci. To investigate the radiosensitization effect of ISL, apoptosis, clonogenic potential and HepG2 xenografts were examined.

### Results

Treatment of HepG2 cells with ISL for 6 h selectively enhanced transcription and expression of Keap1. Keap1

effectively induced ubiquitination and degradation of Nrf2, and inhibited translocation of Nrf2 to the nucleus. Consequently, expression of Nrf2 downstream genes was reduced, and the Nrf2-dependent antioxidant system was suppressed. Endogenous ROS was higher than before ISL treatment, causing redox imbalance and oxidative stress in HepG2 cells. Moreover, pretreatment with ISL for 6 h followed by X-ray irradiation significantly increased  $\gamma$ -H2AX foci and cell apoptosis, and reduced clonogenic potential compared with cells irradiated with X-rays alone. In addition, HepG2 xenografts, ISL, and X-ray cotreatments induced greater apoptosis and tumor growth inhibition, when compared with X-ray treatments alone. Additionally, HepG2 xenografts, in which Nrf2 was expressed at very low levels due to ectopic expression of Keap1, showed that ISL-mediated radiosensitization was Keap1 dependent.

#### Conclusion

ISL inhibited the Nrf2-antioxidant pathway by increasing the levels of Keap1 and ultimately inducing oxidative stress via disturbance of the redox status. The antioxidant ISL possessed pro-oxidative properties, and enhanced the radiosensitivity of liver cancer cells, both *in vivo* and *in vitro*. Taken together, these results demonstrated the effectiveness of using ISL to decrease radioresistance, suggesting that ISL could be developed as an adjuvant radiosensitization drug. Disturbance of redox status could be a potential target for radiosensitization.

#### PO-0982 Fused Toes Homolog (FTS) is a potential target for Notch-mediated radioresistance in cervical cancer

W.Y. Park<sup>1</sup>, P.D. Subramania<sup>1</sup>, J.R. Yu<sup>2</sup>

<sup>1</sup>Chungbuk National University Hospital, Dept of Radiation Oncology, Cheongju, Korea Republic of

<sup>2</sup>Konkuk University, Department of Environmental and Tropical Medicine, Chungju, Korea Republic of

#### Purpose or Objective

Radiation therapy is one of the major treatment modalities for cervical cancer. Increasing evidences suggest that cancer stem cells (CSC) in tumours contribute to radioresistance and recurrence. Notch pathway plays a vital role in maintenance of cancer stemness and its activation leads to disease progression and metastasis. FTS gene was initially identified as one of six genes deleted in a mouse mutant called Fused Toes, due to defects in limb development, and referred as FT1/FTS. However, the function of FTS has not been elucidated well in human. We previously reported that FTS plays an essential role in nuclear phosphorylation of EGFR and repair of DNA damage, and epithelial-mesenchymal transition. In this study, we evaluated the role of FTS in Notch signaling and CSCs.

#### Material and Methods

A human cervical cancer cell line (ME180) was used. Silencing of FTS was obtained using siRNA. Western blot and immunofluorescence was done to analyze the expression and localization of the proteins.

#### Results

Protein expression of Notch 1, cleaved Notch1, Notch 3,  $\gamma$ -secretase complex and its downstream Hes-1 was increased by ionizing radiation and it was reduced by FTS-silencing. Spheroid formation ability and cancer stem cell markers Nanog, Oct-4A, Sox2 were reduced by FTS-silencing. Cell survival was decreased by FTS-silencing.

#### Conclusion

FTS is involved in the regulation of Notch signaling and CSC maintenance. FTS can be a target to overcome Notch-mediated radioresistance in cervical cancer.

#### PO-0983 Antrodia cinnamomea Regulates DNA Repair and Enhances Radiosensitivity of Esophageal Cancer Cells

Y.M. Liu<sup>1</sup>, Y.J. Chen<sup>2</sup>, Y.K. Liu<sup>3</sup>, T.H. Tsai<sup>4</sup>

<sup>1</sup>Taipei Veteran General Hospital, Div. of Radiation Oncology- Dept. of Oncology, Taipei, Taiwan

<sup>2</sup>MacKay Memorial Hospital, Department of Radiation Oncology, New Taipei City, Taiwan

<sup>3</sup>Chang Gung University, Department of Chemical and Material Engineering, Taoyuan City, Taiwan

<sup>4</sup>National Yang Ming University, Institute of Traditional Medicine, Taipei, Taiwan

#### Purpose or Objective

This study investigated the adjunctive effects of *Antrodia cinnamomea* mycelial fermentation broth (AC-MFB), a Taiwanese medicinal fungus, in enhancing the radiosensitivity of esophageal cancer cells. *in vitro* and *in vivo*.

#### Material and Methods

**Materials:** *Antrodia cinnamomea* mycelial fermentation broth, Human CE81T/VGH squamous and BE3 adenocarcinoma esophageal cancer cells, BALB/c mice. **Method:** MTT assay, colony formation assay, DNA histogram study,  $\gamma$ -H2AX immunofluorescence assay, Western blotting assay, BALB/c mice animal model study.

#### Results

A colony formation assay showed that pretreatment with AC-MFB decreased the survival of irradiated esophageal cancer cells, with a maximum sensitizer enhancement ratio of 1.91 and 37% survival. A DNA histogram study showed that AC-MFB pretreatment enhanced cell cycle arrest at the G2/M phase, the most radiosensitive phase. An immunofluorescence assay and a Western blotting assay showed that AC-MFB delayed the abrogation of  $\gamma$ -H2AX, upregulated p21 expression, and attenuated the radiation-induced phosphorylation of ataxia telangiectasia-mutated kinase and checkpoint kinase 2. An *in vivo* validation study showed that AC-MFB treatment tended to have a synergistic effect with radiation on the tumor growth delay of CE81T/VGH cells in BALB/c mice.

#### Conclusion

These data suggest that this edible fungus product could enhance the effect of radiotherapy against esophageal cancer.

#### PO-0984 Checkpoint HLA-G or its ligands ILT2/ILT4 changes radiosensitivity of renal carcinoma cell lines

C. Hennequin<sup>1</sup>, M. Daouya<sup>1</sup>, D. Tronik-Le Roux<sup>1</sup>, J.

LeMaoult<sup>1</sup>, N. Rouas-Freiss<sup>1</sup>, F. Desgrandchamps<sup>1</sup>, E. Carosella<sup>1</sup>

<sup>1</sup>Hôpital Saint-Louis, Research in Immuno-hematology, Paris, France

#### Purpose or Objective

HLA-G is an immune checkpoint physiologically implicated in maternal-foetal tolerance. It is also neoexpressed in many cancers and particularly in more than 50% of renal cancers. Stereotactic radiotherapy efficiency is at least in part mediated by the immune system, and could be modulated by the presence of immune checkpoints; for example the use of antibodies directed against PD1/PDL1 increased radiotherapy efficiency. We investigated the impact of expression of HLA-G or its ligands (ILT2/ILT4) on radiotherapy efficiency at the cellular level on renal carcinoma cell lines (RCCL).

#### Material and Methods

The effect of ionizing radiations (IR: 8 Gy) on the expression of HLA-G, ILT2 and ILT4 was evaluated on RCCL expressing or not HLA-G, ILT2 or ILT4. The impact of HLA-G, ILT or ILT4 expression on radiosensitivity was evaluated by clonogenic assays on transduced RCCL or controls. In order to explain the results obtained, the following mechanisms were investigated by cytofluorimetry: 1/ quantification of double-strand breaks (H2AX) 2/

apoptosis (Annexin V and propidium iodine PI) 3/ Cell cycle modifications (PI)

#### Results

Our results showed that IR on RCCL not expressing HLA-G, ILT2 or ILT4 did not induce these molecules. However, in constitutively expressing HLA-G or ILT4 RCCL, IR decreased significantly HLA-G and ILT4 expression. Furthermore, we found that HLA-G, ILT2 and ILT4 transduction increased radioresistance. This effect was partially aborted by the use of antibodies directed against these molecules. Mechanisms of radio resistance are under investigations and will be presented at the meeting.

#### Conclusion

Ionizing radiation decreases the expression of HLA-G or its receptors in RCCL constitutively expressing these molecules. HLA-G and its ligands increase radioresistance. This finding could have some clinical implications for stereotactic radiotherapy of renal cancer or its metastasis.

#### PO-0985 Tumor metabolic changes after neoadjuvant radiotherapy: consequences for surgery-related metastases

N. Leroi<sup>1</sup>, F. Lallemand<sup>2</sup>, J. Leenders<sup>3</sup>, S. Blacher<sup>4</sup>, P. De Tullio<sup>3</sup>, P. Coucke<sup>5</sup>, A. Noel<sup>4</sup>, P. Martinive<sup>1</sup>

<sup>1</sup>C.H.U. Liège - Université de Liège, Radiotherapy Dept-Laboratoire de Biologie des Tumeurs et du Développement, Liège, Belgium

<sup>2</sup>C.H.U. Liège - Université de Liège, Radiotherapy Dept-Research center of Cyclotron, Liège, Belgium

<sup>3</sup>Université de Liège, CIRM- Chimie Pharmaceutique, Liège, Belgium

<sup>4</sup>Université de Liège, Laboratoire de Biologie des Tumeurs et du Développement, Liège, Belgium

<sup>5</sup>C.H.U. Liège - Université de Liège, Radiotherapy Dept., Liège, Belgium

#### Purpose or Objective

Neoadjuvant radiotherapy (NeoRT) aims at improving tumor local control and patient overall survival. In the case of locally advanced rectal cancer, NeoRT increases significantly local control compared to surgery alone, but patient overall survival is not improved. Currently, predicting tumor response and recurrences represent a major challenge for personalized medicine. Previously, we developed a pre-clinical model of NeoRT and showed that the timing of surgery and NeoRT schedules both influenced metastasis burden (Leroi et al., Oncotarget, 2015). Based on this model, we study the impact of RT schedule on the primary tumor metabolome at the time of surgery to predict local recurrence and metastatic profile.

#### Material and Methods

We locally irradiated primary tumors (MDA-MB231 cells and 4T1 cells), subcutaneously implanted to SCID and BalbC mice, with two NeoRT schedules (5x2Gy and 2x5Gy). We surgically removed tumors 4 or 11 days after the end of RT and kept the mice alive for the metastatic growth. Non-irradiated control tumors were also surgically collected at the same time. For metabolomic study, tumor samples were homogenized in deuterated phosphate buffer and supplemented with maleic acid and TMSP before Nuclear Magnetic Resonance (NMR) analyses. Data were analyzed with powerful statistical tool (supervised and multivariate analyses).

#### Results

Irradiated 4T1 and MDA-MB231 tumors displayed different metabolic profile than non-irradiated tumors, especially 4 days after the end of RT for 4T1 tumors and 11 days after NeoRT for MDA-MB231 tumors. Moreover, we observed a decrease in some metabolite levels (i.e. glutamate, taurine, glycine, myoinositol) in tumors following both NeoRT schedules. We also noticed an increase in general lipid signals in irradiated MDA-MB231 tumors. This was not related to adipocyte infiltration, as we observed, by immunostaining, decreased infiltration of perilipin and

FABP4+ cells in these tumors following NeoRT. Preliminary results with OPLS-DA analyses showed discrimination of primary tumor metabolome according to the propensity to induce loco-regional recurrence (significant for tumors collected 4 days after 5x2Gy). Furthermore, based on the metabolic profile of the primary MDA-MB231 tumors and OPLS linear regression, mathematical models were established in the different groups allowing to predict the metastatic burden ( $r^2=0,80-0,90$ ).

#### Conclusion

In preclinical models, we show profound modifications of the primary tumor metabolome following NeoRT through NMR analyses, offering new opportunities to understand tumor metabolism adaptation following NeoRT. Furthermore, others NMR results appear very relevant when transposed to clinic. Indeed, with mathematical models, local recurrence and metastatic profiles were predictable based on the metabolomic profile of the primary tumor at the time of surgery, which could be helpful to adapt adjuvant therapies in order to prevent relapse.

#### PO-0986 Downregulation of the oncoprotein SET enhances RT-induced apoptosis in hepatocellular carcinoma

C.Y. Huang<sup>1</sup>, M.H. Hung<sup>2</sup>, C.W. Kuo<sup>3</sup>, C.T. Shih<sup>4</sup>, M.H. Chen<sup>4</sup>, K.F. Chen<sup>5</sup>

<sup>1</sup>National Taiwan university hospital, Division of Radiation Oncology- Department of Oncology, Taipei, Taiwan

<sup>2</sup>Taipei Veterans General Hospital, Division of Medical Oncology- Department of Oncology, Taipei, Taiwan

<sup>3</sup>Yuanpei University of Medical Technology, Department of Medical Imaging and Radiological Technology, Hsinchu, Taiwan

<sup>4</sup>National Yang-Ming University, Institute of Biopharmaceutical Sciences, Taipei, Taiwan

<sup>5</sup>National Taiwan university hospital, Department of Medical Research, Taipei, Taiwan

#### Purpose or Objective

Hepatocellular carcinoma (HCC) is among the most lethal human malignancies worldwide. Radiotherapy (RT) is not commonly used to treat HCC with regard to both suboptimal treatment efficacy and toxicity. The current project aimed to characterize the role of a novel oncoprotein SET/ I2PP2A (Inhibitor-2 of protein phosphatase 2A) in mediating the radio-resistance of HCC cell and explore the potential on antagonizing SET to improve the anti-HCC effects of RT.

#### Material and Methods

The effects of RT in HCC cells with different expression of SET were assessed by colony formation and sphere formation assay. We generated a novel SET antagonist, EMQA (N<sup>4</sup>-(3-ethynylphenyl)-6,7-dimethoxy-N<sup>2</sup>-(4-phenoxyphenyl) quinazoline-2,4-diamine), to validate the therapeutic potential of targeting SET. The combination effects of EMQA and RT were tested in vitro using four different HCC cell lines, Hep3B, PLC5, HA22T and HA59T, and a subcutaneous PLC5 xenografted model in vivo. HCC cells were exposed to 1 fraction of 4-Gy radiation using a cobalt 60 unit (at a dose rate of 0.5 Gy/min) with the source-axis-distance set at 80 cm to the bottom of the dish. After 48 hours, the cells were treated with or without EMQA.

#### Results

To explore the roles of SET in affecting the radio-sensitivity in HCC, we first generated PLC5 and Hep3B cells with different SET activity, and assessed the effects of RT on these cells by colony formation and tumor sphere assay. Comparing to mock-treated cells, HCC cells transfected with shRNA against SET were shown with significant reduced viability under the same RT treatment. Oppositely, cells with ectopic expression of SET were more resistant to RT. Next, we used EMQA to test whether

antagonizing SET could enhance the effects of RT against HCC. Using sub-G1 analysis, we showed that adding EMQA significantly increased RT-induced apoptosis of HCC cells. The number of tumor colony was also significantly decreased in HCC cells exposing to EMQA plus RT than either of the treatment alone. Lastly, using the PLC5 xenografted tumor model, the synergistic effects of SET antagonist combining RT were also observed.

#### Conclusion

SET is a novel oncoprotein that affects the radiosensitivity of HCC cells. A combination therapy with RT and the SET antagonist, such as EMQA, enhanced RT-induced apoptosis of HCC cells in vitro and in vivo.

**PO-0987 Gemcitabine-based chemoradiotherapy gets improved with PARP inhibitor in pancreatic cancer cells**  
W. Waissi<sup>1</sup>, H. Burckel<sup>1</sup>, E. Magisson<sup>1</sup>, G. Larderet<sup>1</sup>, G. Noel<sup>1</sup>

<sup>1</sup>CLCC Paul STRAUSS, EA3430- Laboratoire de Radiobiologie, Strasbourg, France

#### Purpose or Objective

Pancreatic ductal adenocarcinoma (PDAC) is a devastating disease with a cumulative 5-year overall survival of less than 5% for all stages. Thirty percent of patients diagnosed with pancreatic adenocarcinoma present with a locally advanced disease and could benefit from chemoradiotherapy with gemcitabine, which is effective but toxic. Over the past few years, studies have focused on the development of targeted radiosensitizer such as poly(ADP-ribose) polymerase (PARP) inhibitor. We conducted this in vitro study to determine whether PARP inhibition enhances radiation-induced cytotoxicity of pancreatic adenocarcinoma.

#### Material and Methods

Pancreatic carcinoma cells, MIA PaCa-2 (BRCA1/2 wild-type), were treated with olaparib and/or gemcitabine and/or irradiation (2,5 and 10 Gy). In vitro cell viability, clonogenic assay, cell cycle distribution,  $\gamma$ -H2AX quantification, apoptosis and autophagy were assessed.

#### Results

In vitro, treatment with olaparib alone at 1  $\mu$ M was not cytotoxic but highly radiosensitized cells (standard enhancement ratio =1.23 $\pm$ 0.02) and particularly at high dose per fraction (10 Gy). After 24 hours, the number of remaining  $\gamma$ -H2AX stained cells was higher when cells were treated with a combination of 10 Gy irradiation and olaparib compared to irradiation or olaparib alone. Furthermore, combination of olaparib and irradiation induced a G2/M arrest. In contrast, a non-cytotoxic concentration of gemcitabine could also radiosensitize cells, but clearly less than olaparib (SER=1.11 $\pm$ 0.04). Radiosensitization by gemcitabine was associated with percentage of cells blocked in early S-phase just before irradiation. Finally, cell death quantification after 24 hours showed that none of the treatments induced apoptosis, whereas gemcitabine or 10 Gy irradiation alone induced autophagy.

#### Conclusion

Our results showed that MIA PaCa-2 cells could be radiosensitized with low dose of olaparib, through an increase of unrepaired double-strand breaks and a block in G2 phase. The radiosensitization was higher with high dose radiation. This may be translated into an enhancement of local control in vivo and better disease free survival. Investigations in three other pancreatic cells lines are in progress.

**PO-0988 Following tumour microenvironment after Neoadjuvant radiotherapy with IVIM perfusion analysis**  
F. Lallemand<sup>1</sup>, N. Leroi<sup>2</sup>, M. Bahri<sup>3</sup>, E. Balteau<sup>3</sup>, A. Noël<sup>2</sup>, P. Coucke<sup>1</sup>, A. Plenevaux<sup>3</sup>, P. Martinive<sup>1</sup>

<sup>1</sup>C.H.U. - Sart Tilman, Radiothérapie, Liège, Belgium  
<sup>2</sup>ULg, Laboratory of Tumor and Development Biology,

Liège, Belgium

<sup>3</sup>ULg, Cyclotron Research Center, Liège, Belgium

#### Purpose or Objective

Neoadjuvant radiotherapy (NeoRT) improves tumor local control and facilitates tumor resection in many cancers. The timing between the end of the NeoRT and surgery is driven by the occurrence of side effects or the tumor downsizing. Some clinical studies demonstrated that the timing of surgery and the RT schedule influence tumor dissemination and subsequently patient overall survival. Previously, we developed a pre-clinical model demonstrating an impact of NeoRT schedule and the timing of surgery on metastatic spreading (Leroi et al. Oncotarget 2015). Here, we evaluate the impact of NeoRT on the tumor microenvironment by functional MRI (fMRI). We aim to identify non-invasive markers allowing to determine the best timing to perform surgery and avoiding tumor spreading.

#### Material and Methods

Based on our NeoRT model, MDA-MB 231 and 4T1 cells were implanted in the flank of SCID and BalbC mice, respectively. We locally irradiated tumors with 2x5Gy and then surgically removed at different time points after RT. Diffusion Weighted (DW) -MRI was performed every 2 days between RT and surgery. For each tumors we acquired 8 slices of 1 mm thickness and 0.5 mm gap with an "in plane voxel resolution" of 0.5 mm. For DW-MRI, we performed FSEMS (Fast Spin Echo MultiSlice) sequences, with 9 different B-value (from 40 to 1000) and B0, in the 3 main directions. We performed IVIM (IntraVoxel Incoherent Motion) analysis to obtain information on intravascular diffusion, related to perfusion (F: perfusion factor) and subsequently tumor vessels perfusion.

#### Results

With the MDA-MB 231, we observed a significant peak of F at day 6 after irradiation, this increasing is about 60% of the basal value (n=6, p<0,05). Moreover, D\* parameters (also related to perfusion) increase at the same time. The other parameters of the DW-MRI, ADC and D presented no modification. We observed similar results with 4T1 cells, where F increased at day 3 (about 55%, n=10, p<0,05) then returned to initial level. The difference in timing for the peak of F (day 6 vs day 3) could be related to the difference in tumor growth according to the cell line (four weeks for MDA-MB 231 cells vs one week for 4T1cells). We performed surgery at the time of the F parameter peak in the MDA-MB 231 and we observed a decrease of the metastatic burden compared to surgery performed at day 4 or day 11 (absolute number of metastasis 23 VS 1 VS 8 with n=4).

#### Conclusion

For the first time, we demonstrate the feasibility of repetitive fMRI imaging in preclinical models after NeoRT. With these models, we show a significant difference in perfusion-related parameters (D\* and F) at a specific time point depending of the tumor cells. These modifications are correlated to a decrease of metastasis spreading related to the surgery procedure. These results open new perspectives in the personalized medicine and MRI guided surgery timing after NeoRT.

**PO-0989 Sub-lethal radiation allows an efficient antitumor therapy with engineered T-cells in RIP-Tag2 mice**

F. Maione<sup>1</sup>, E. Garibaldi<sup>2</sup>, X. Zhuang<sup>3</sup>, J. Robinson<sup>3</sup>, R. Bicknell<sup>3</sup>, E. Delmastro<sup>2</sup>, A. Miranti<sup>4</sup>, S.P. Lee<sup>3</sup>, P. Gabriele<sup>2</sup>, E. Giraudo<sup>1</sup>

<sup>1</sup>Candiolo Cancer Institute- Torino- Italy, Department of Science and Drug Technology, Candiolo TO, Italy

<sup>2</sup>Candiolo Cancer Institute- Torino- Italy, Radiotherapy Unit, Candiolo TO, Italy

<sup>3</sup>University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom

<sup>4</sup>Candiolo Cancer Institute- Torino- Italy, Medical Physics Unit, Candiolo TO, Italy

### Purpose or Objective

The important goal of tumor immunotherapy is to identify strategies to modulate *in vivo* the anti-tumor immunity in order to achieve clinical efficacy. In the last decade great progresses have been made in the field of tumor immunology and an increasing number of tumor antigens have been identified. In particular, several different engineering T-cells were designed to express receptors specific for antigens expressed in the tumor compartment. Herein, in order to block tumor progression, we employed Chimeric Antigen Receptors (CARs) technology to target the tumor vasculature. To this aim we used a spontaneous mouse tumor model of pancreatic neuroendocrine insulinoma, RIP-Tag2. Despite its low frequency in cancer patients, we chose this model, since develops invasive tumors through well-characterized and synchronous pre-malignant stages, sustained by active angiogenesis. Little is known about the effects of ionizing radiation on tumor burden of RIP-Tag2 mice and the impact of whole-body irradiation on the overall survival.

### Material and Methods

In the current study tumor-bearing RIP-Tag2 mice were irradiated with two different sub-lethal dosages (5 and 6 Gy respectively), by means of 6MV x rays of Tomotherapy; a treatment plan was performed and evaluated for each cage pie . We hypothesized that sub-lethal radiation might be more effective than a lethal dose radiation and clinically acceptable in promoting anti-tumor immunity. The day after the irradiation mice were injected with engineered T-cells (20 million cells).

### Results

Firstly, we observed that irradiation *per se* did not affect tumor growth and all the mice survived until the end of treatment. Furthermore, by means of this approach, we found statistically significant inhibition of tumor growth in mice treated with anti-vascular CAR-T-cells compared with controls. Interestingly, we noticed a strong reduction in tumor vessel area and a decrease of blood vessel permeability.

### Conclusion

These data suggest that the tumor vasculature can be efficiently targeted by specific CAR-T-cells, causing a significant reduction in the tumor burden of RIP-Tag2 mice and potentially in other tumor types.

### PO-0990 Combining radiotherapy and notch inhibition in melanoma

K. Thippu Jayaprakash<sup>1,2</sup>, M. Hussein<sup>3</sup>, A. Nisbet<sup>3,4</sup>, R. Shaffer<sup>2</sup>, M. Ajaz<sup>1,2</sup>

<sup>1</sup>University of Surrey, Department of Clinical and Experimental Medicine, Guildford, United Kingdom

<sup>2</sup>St Luke's Cancer Centre- Royal Surrey County Hospital, Department of Oncology, Guildford, United Kingdom

<sup>3</sup>St Luke's Cancer Centre- Royal Surrey County Hospital, Department of Medical Physics, Guildford, United Kingdom

<sup>4</sup>University of Surrey, Department of Physics, Guildford, United Kingdom

### Purpose or Objective

Melanoma is classically viewed as a radioresistant tumour. Phenotypic plasticity, specifically the emergence of a cancer stem cell (CSC) population, may be one reason for this. The notch signalling pathway plays a crucial role in maintenance of the CSC phenotype, and also in cell migration. This pathway is frequently aberrant in melanoma and is therefore a potential mechanism for the observed radioresistance. The aims of this project were (1) to investigate whether notch inhibition with the  $\gamma$  - secretase inhibitor, RO4929097 that targets  $\gamma$  - secretase cleavage and thereby inhibiting the notch signalling pathway, improves the radiation sensitivity of melanoma

cell lines; (2) to investigate the effects of notch inhibition and radiotherapy on melanoma cell migration.

### Material and Methods

Two melanoma cell lines, A375 and SKMEL28 were irradiated with 250 kV x-rays to 1, 2, 4, 6, 8 and 16 Gy in combination with 1, 3, 10, 30 and 100  $\mu$ m of RO4929097 in 96-well plates. Cells were permitted to grow for a further 5 - 7 days and viability was assessed with the MTS assay. Loewe's combination index (CI) was used ( $CI = (C_{A, X}/IC_{X, A}) + (C_{B, X}/IC_{X, B})$ ) to evaluate the interaction between radiation and RO4929097. For cell migration experiments, A375 and SKMEL28 cells were treated with 10 and 100  $\mu$ m of RO4929097, alone and in combination with radiation (2 and 8 Gy) in 6-well plates. A scratch was performed and daily light field microscope photographs were taken. In all experiments, radiation was delivered one hour after cells were treated with RO4929097.

### Results

Loewe's CI of < 1 and > 1 are taken to indicate synergism and antagonism respectively. The Loewe's combination index analysis reproducibly showed strong synergy in A375 melanoma cells when radiation doses of 1, 2, 4, 6 and 8 Gy were combined with 100  $\mu$ m of RO4929097 and a trend towards mild synergy was observed with lower doses of radiation and higher doses of RO4929097 (Figure 1). This may be due to a reduction in the number of CSCs by RO4929097 that renders lower radiation doses more effective. Similar patterns of interaction were observed for SKMEL28 cells.

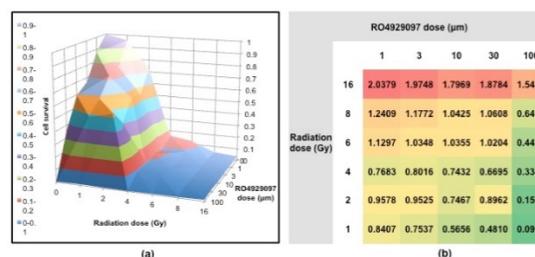

Figure 1. A375 melanoma cell line  
(a) Radiation and RO4929097 3D dose response map  
A dose response was seen with both radiation and RO4929097. Radiation  $IC_{50} = 2.5$  Gy and RO4929097  $IC_{50} = 10.8$   $\mu$ m.  
(b) 3D surface map of Loewe's Combination Index (CI) values  
Strong synergy with radiation doses of 1, 2, 4, 6 and 8 Gy and 100  $\mu$ m RO4929097 (CI values of 0.1, 0.2, 0.3, 0.4 and 0.6 respectively). A low synergy (CI 0.5 - 1) at lower doses of radiation with higher doses of RO4929097. Antagonistic effect with 16 Gy and RO4929097 (CI values of 2, 2, 1.8, 1.9 and 1.5 with 1, 3, 10, 30 and 100  $\mu$ m of RO4929097 respectively).

Cell migration assays showed that cell migration was inhibited in both cell lines following treatment with 10 and 100  $\mu$ m of RO4929097 and this was more pronounced at 100  $\mu$ m, and similar effects were seen when radiation was combined with RO4929097. 8 Gy alone failed to control cellular migration but this was abrogated by the addition of RO4929097 (Figure 2).

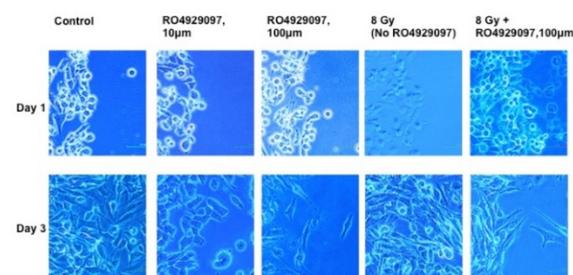

Figure 2 - Cell migration assay (SKMEL28 melanoma cell line)  
Light field microscopy pictures (20x magnification) showing inhibition of cell migration at 10 and 100  $\mu$ m of RO4929097, more pronounced with 100  $\mu$ m. No inhibition of cell migration with radiation alone but cell migration inhibited with the addition of RO4929097.

### Conclusion

Inhibition of the notch signalling pathway increases the radiosensitivity of melanoma cells. We hypothesise this is

due to impairing of the phenotypic plasticity that causes cells to adopt stem cell and pro-migratory characteristics. Further mechanistic studies are focusing on alterations to stem cell subpopulations after radiation and superadded notch inhibition.

**PO-0991 Chromosomal radiosensitivity and genomic instability of Fanconi anaemia patients in South Africa**  
F.Z. Francies<sup>1</sup>, R. Wainwright<sup>2</sup>, J. Poole<sup>2</sup>, J. Slabbert<sup>3</sup>, A. Baeyens<sup>4</sup>

<sup>1</sup>Univ. of Witwatersrand, Radiation Sciences, Johannesburg, South Africa

<sup>2</sup>Univ. of Witwatersrand, Paediatrics, Johannesburg, South Africa

<sup>3</sup>iThemba LABS, Radiation Biophysics, Cape Town, South Africa

<sup>4</sup>Ghent University, Basic Medical Sciences, Ghent, Belgium

**Purpose or Objective**

Fanconi anaemia (FA) is an autosomal recessive disorder characterised by defects in DNA repair associated with chromosomal instability. FA cells exhibit cellular hypersensitivity to DNA cross-linking agents such as mitomycin C (MMC). The clinical manifestations include congenital and developmental abnormalities and haematological defects. It has previously been shown that FA patients undergoing radiotherapy display increased clinical radiosensitivity by exhibiting adverse normal tissues side-effects. Evidence suggests that FA patients are chromosomally radiosensitive to ionising radiation, however, with very limited data.

The aim of this study is to investigate chromosomal radiosensitivity and genomic instability of homozygous and heterozygous carriers of FA mutations compared to healthy individuals using the micronucleus (MN) assays.

**Material and Methods**

For the G0 MN assay, heparinised blood in culture medium was irradiated at 0Gy (Baseline), 2Gy and 4Gy followed by the immediate stimulation of lymphocytes using phytohaemagglutinin (PHA). Cytochalasin B was added 23 hours later to inhibit cytoplasmic division. Cells were harvested 70 hours post irradiation.

The S/G2 MN assay is a modified version of the G0 MN assay. To initiate the assay, the cultures are stimulated with PHA and then irradiated with the same radiation doses 72 hours after stimulation. To detect DNA damage in the S/G2 phase of the cell cycle, the cells were harvested 8 hours post irradiation.

The third assay is similar to the G0 MN assay except the cell damage is induced using MMC.

Subsequent to harvest, all slides were prepared and stained with acridine orange and micronuclei were scored using a fluorescent microscope.

**Results**

When compared to parents and healthy controls, spontaneously occurring micronuclei are significantly higher in FA patients indicating genomic instability. A similar trend is noticed in the micronuclei frequency of irradiated FA cells signifying chromosomal radiosensitivity. This sensitivity is evidently pronounced in the S/G2 phase. Elevated chromosomal damage was also detected with MMC treatment in the FA patients.

**Conclusion**

Chromosomal radiosensitivity and genomic instability of FA mutation carriers are notably higher when compared to healthy individuals.

**PO-0992 Low-dose whole lung irradiation plus Re-188-liposome eliminates lung metastasis of esophageal cancer**

Y.J. Chen<sup>1</sup>, S.Y. Liu<sup>2</sup>, H.C. Tai<sup>1</sup>, T.W. Lee<sup>3</sup>, C.H. Chang<sup>3</sup>

<sup>1</sup>Mackay Memorial Hospital, Department of Radiation Oncology, Taipei, Taiwan

<sup>2</sup>Mackay Memorial Hospital, Department of Medical

Research, Taipei, Taiwan

<sup>3</sup>Institute of Nuclear Energy Research, Isotope Application Division, Taoyuan, Taiwan

**Purpose or Objective**

External beam radiotherapy (EBRT) treats gross tumors and local microscopic diseases. Radionuclide therapy by isotopes can control tumors systemically. Rhenium 188 (<sup>188</sup>Re)-liposome, a nanoparticle undergoing clinical trials, emits gamma rays for imaging validation and beta rays for therapy with biodistribution profiles preferential to tumors. We designed a unique combinatory treatment and examined its effects on lung metastasis from esophageal cancer, a malignancy with poor prognosis.

**Material and Methods**

Human esophageal cancer BE-3 cells with luciferase gene for optical imaging were injected into tail vein of nude mice to induce lung metastasis. The radiochemical purity of <sup>188</sup>Re-liposome exceeded 95%. Molecular imaging by NanoSPECT/CT (NanoSPECT/CT PLUS, Mediso, Alstatorokvesz, Budapest, Hungary) showed that lung metastatic lesion could uptake the <sup>188</sup>Re-liposome. For biodistribution, the radioactivity of <sup>188</sup>Re-liposome was detected by Auto-Gamma counter (Packard Cobra II, Canberra, Germany), and the uptake of <sup>188</sup>Re-liposome in each organ was expressed as the percentage of injected dose per gram of tissue (% ID/g). Low-dose whole lung EBRT with 3 consecutive daily fractions of 1 Gy was delivered by linear accelerator with 6-MV photon (Clinac iX, Varian Medical Systems, USA) followed by intravenous <sup>188</sup>Re-liposome (250 µCi) administration 2-h after last teletherapy. Flow cytometry was used to estimate the amount of myeloid derived suppressor cells and macrophages.

**Results**

The combination of EBRT and <sup>188</sup>Re-liposome inhibited tumor burden of lung metastasis faster and better than each treatment alone (Figure 1 and 2). Combination treatment did not cause additive adverse effects on white blood cell counts, body weight, or liver and renal functions. EBRT significantly reduced the uptake of <sup>188</sup>Re-liposome in lung, kidney, bone marrow and blood. In spleen, <sup>188</sup>Re-liposome administration declined the amount of myeloid derived suppressor cells and increased the amount of M1 and M2 macrophages.

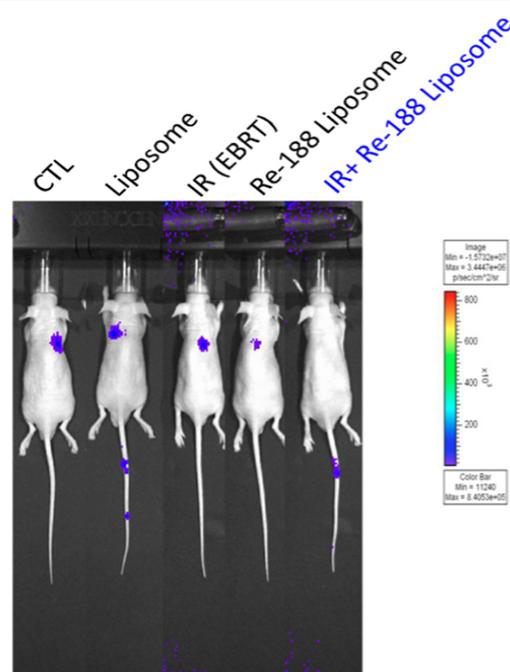

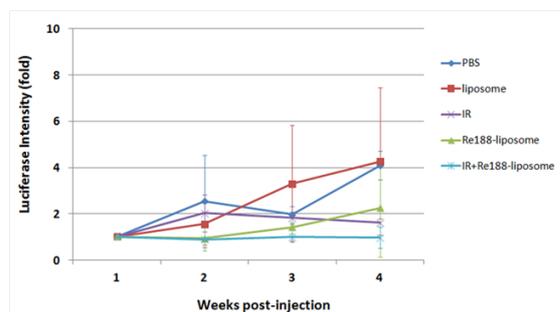

Figure 1. The therapeutic efficacy of <sup>188</sup>Re-liposome

combined with EBRT on lung metastasis from esophageal cancer. The representative optical images show lung metastatic burden detected by D-luciferin assay.

**Figure 2.** The therapeutic efficacy of  $^{188}\text{Re}$ -liposome combined with EBRT on lung metastasis from esophageal cancer. Low-dose whole lung EBRT with 3 consecutive daily fractions of 1 Gy was delivered followed by intravenous  $^{188}\text{Re}$ -liposome (250  $\mu\text{Ci}$ ) administration in combination group. N=3 for each group.

#### Conclusion

The combination of low-dose whole lung EBRT with systemic  $^{188}\text{Re}$ -liposome administration might be a potential treatment modality for lung metastasis from esophageal cancer. Modulation of tumor microenvironment by the combination treatment is warranted in translational research. This proof-of-concept study needs to be validated by clinical investigation.

#### PO-0993 Influence of radiotherapy on differentiation, maturation and functionality of dendritic cells

L. König<sup>1</sup>, A. Gardyan<sup>2</sup>, J. Hörner-Rieber<sup>1</sup>, P. Huber<sup>2</sup>, K. Herfarth<sup>1</sup>, S. Rieken<sup>1</sup>

<sup>1</sup>University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

<sup>2</sup>German Cancer Research Center- Heidelberg, Clinical Cooperation Unit Molecular Radiooncology-, Heidelberg, Germany

#### Purpose or Objective

Primary purpose of radiotherapy (RT) is elimination of cancer cells by inducing DNA-damage that either causes induction of tumor cell death or inhibition of the proliferating capacity of these cells. In addition, considerable evidence emerges that antineoplastic effects extend beyond these mechanisms. These secondary effects can contribute to anti-tumor responses in a local but also systemic manner via activation of the immune system: The role of dendritic cells (DCs) is well described to be essential for priming effective radiation-induced adaptive immunity. Through increased release of tumor-associated antigens (TAA) after RT, DCs are recruited and cross-presentation of TAA leads to activation of B- and T-lymphocytes, therefore playing a pivotal role in adaptive immune response and immunogenic cell death. However, there are still many hypotheses regarding the influence of RT on activation of the immune system. The aim of our experiments is to further characterize the impact of different radiation types and dosages on differentiation and functionality of DCs.

#### Material and Methods

Human CD14-positive monocytes were isolated from peripheral blood mononuclear cell samples of six individuals. In the presence of appropriate cytokine stimulation with Interleukin-4 (IL-4) and granulocyte macrophage colony-stimulating factor (GM-CSF) monocytes were induced into immature DCs (iDCs) and later mature DCs (mDCs). Monocytes were irradiated with different photon radiation doses (1x15Gy, 5x2Gy, 1x0.5Gy) on day 0. Maturation to mDCs was induced on day

7 by adding tumor necrosis factor alpha (TNF $\alpha$ ) to the culture medium. Differentiation and maturation of DCs was assessed on day 2, 9 and 12 by staining of the cell surface molecules CD14, CD83, CD80, CD86 and HLA-DR via flow cytometry. Functional analysis of irradiated DCs was performed through FITC-labelled phagocytosis assay.

#### Results

No major significant changes in the immune profile during differentiation of monocytes (CD14<sup>high</sup>, CD83<sup>low</sup>, CD86<sup>low</sup>, CD80<sup>low</sup>, HLA-DR<sup>high</sup>) into iDCs (CD83<sup>low</sup>, CD86<sup>low</sup>, CD80<sup>medium</sup>, HLA-DR<sup>medium</sup>) and mDCs (CD83<sup>high</sup>, CD86<sup>high</sup>, CD80<sup>high</sup>, HLA-DR<sup>high</sup>) were seen after treatment with different radiation doses (1x15 Gy, 5x2 Gy, 1x0.5 Gy) compared to the untreated control group. Functional analysis showed no difference in the phagocytotic capacity of irradiated iDCs and mDCs compared to the control group.

#### Conclusion

Our experiments reveal that after irradiation with different fractionations and doses maturation of DCs was unchanged compared to the control group. The capability for phagocytosis was unaffected after irradiation of DCs, indicating persistent functionality of the immune system. Additional RT-induced effects on the immunogenic potential of DCs will be investigated by using further functional assays (migration assay, mixed lymphocyte reaction assay). To investigate the effect of particle therapy, DCs will be irradiated with protons and carbon ions (C12) in future experiments.

#### PO-0994 Integrin antagonistic drugs reveal different effectiveness in 2D monolayer vs. 3D spheroid culture

V. Kopatz<sup>1,2</sup>, E. Selzer<sup>1</sup>, W. Dörr<sup>1,2</sup>

<sup>1</sup>Medical University of Vienna, Department for Radiation Oncology, Vienna, Austria

<sup>2</sup>Medical University of Vienna, Christian Doppler Lab for Medical Radiation Research for Radiooncology, Vienna, Austria

#### Purpose or Objective

Preclinical evaluation of novel therapeutic substances, as well as the assessment of radiation effects, is frequently performed under standard 2D cell culture conditions. However, such monolayer cultures may fail with regard to representation of morphological *in vivo* conditions and their (radio)biological consequences. An alternative, in the latter aspect is the use of 3D *in vitro* models - like tumor spheroid culture - which are of intermediate complexity between standard *in vitro* monolayer cultures and *in vivo* tumor models. In spheroid culture, tumor cells grow in 3D aggregates that display greater similarity to *in vivo* tumor architecture and growth conditions, such as the presence of oxygen and nutrient gradients as well as more complex cellular interactions or 'in vivo-like' gene expression profiles. Depending on their size, multicellular spheroids may also display central hypoxic and/or necrotic areas and show quiescent and proliferating compartments. Thus spheroids often depict different behavior and sensitivity towards certain drugs or radiotherapeutic treatment as cells cultured as 2D monolayers. Especially for the study of surface receptors like integrins the 3D structure and environment is a critical aspect as these receptors transduce signals from the extracellular space to the inside, thus influencing different cell signaling pathways like cell survival, proliferation and invasion.

#### Material and Methods

Therefore in addition two standard 2D cell culture, 3D spheroid models were established with 518A2 and other melanoma cell lines for evaluation of their response to two different integrin antagonists, cilengitide and a novel integrin antagonist (NIA), as well as for the characterization of the effects of radiation treatment alone or in combination with the drugs.

## Results

While in 2D cultures of 518A2 melanoma cells, the comparator substance cilengitide showed to be more efficient than our novel compound NIA (IC50 value of 0,65µM), it had no inhibitory effect in 3D spheroid culture up to 50µM. Comparatively NIA revealed to have similar effectiveness in 2D as well as 3D cultures, both in the low micromolar range. During monitoring of spheroid growth, NIA treated spheroids initially depicted a growth retardation, before cells started to disintegrate and die. The radiosensitivity of 518A2 melanoma cells was found to be similar in both culture conditions.

## Conclusion

Similar differences in drug response and efficacy between 2D and 3D cell culture environments have been reported for various anti-cancer substances as well as for some radiation exposure endpoints. However, other endpoints may - in a treatment-related manner - be depending on the culture system used. We thus plan to perform further comparative studies on survival-dependent aspects (apoptosis, intracellular signaling, and others) with integrin antagonists alone as well as in combination with irradiation in 2D cell culture versus 3D spheroids.

## PO-0995 Estimation of radiobiology parameters of infiltrative low-grade gliomas WHO Grade II.

S. Milyukov<sup>1</sup>, Y. Lysak<sup>2</sup>, G. Panshin<sup>2</sup>, N. Kharchenko<sup>1</sup>, Z. Tsallagova<sup>2</sup>, T. Izmailov<sup>2</sup>

<sup>1</sup>Peoples' Friendship University of Russia, Department of oncology and roentgenoradiology, Moscow, Russian Federation

<sup>2</sup>Russian Scientific Center of Roentgenoradiology of Russia, Research department of innovative technologies of radiotherapy and chemoradiation treatment of malignant tumors, Moscow, Russian Federation

## Purpose or Objective

Determine the value of radiobiological parameters of infiltrative low-grade gliomas WHO Grade II

## Material and Methods

In total (the data from) 5 clinical studies: EORTC 22844 (Karim AB et al., 1996.), EORTC 22845 (van den Bent MJ et al., 2005), NCCTG 86-72-51 (Shaw E et al., 2002), the RTOG 9802 (Shaw EG et al., 2012), the study on the hyperfractionated radiotherapy (Jeremic B et al., 1998), and selected data from our database were used for the calculation radiobiological parameters of LGG. In total, our study included 870 patients. All patients received surgery (1-phase treatment) and radiotherapy (2-phase treatment). Following radiobiological parameters of radiotherapy were used for the calculation: dose per fraction, total dose of radiotherapy, total number of treatment days, 5-year progression-free survival.

## Results

Following radiobiological parameters of infiltrative low-grade gliomas WHO Grade II were calculated:  $\alpha$ ,  $\beta$ ,  $\alpha/\beta$ ,  $T_d$ ,  $D$  proliferating,  $T_k$ ,  $N$  clonogens. Following values were calculated (95% CI):  $\alpha$  ( $Gr^{-1}$ ) = 0,096 (0,08-0,11),  $\beta$  ( $Gr^{-2}$ ) = 0,014 (0,012-0,018),  $\alpha/\beta$  ( $Gr$ ) = 6,8 (4,3-9,2),  $T_d$  (days) = 21,3 (18,3-26,4),  $D_{prolif}$  ( $Gr$ ) = 0,27 (0,21-0,35),  $T_k$  (days) = 44 (34-55),  $N_{clonogens}$  =  $2,18 \cdot 10^3$  (1,2-5,3)  $\cdot 10^3$ .

## Conclusion

The calculated values of radiobiological parameters give a better idea of the biological properties of the low-grade gliomas and estimate as accurately as possible of the total dose of radiotherapy using a linear-quadratic model.

## Poster: RTT track: Patient preparation, positioning and immobilisation

## PO-0996 Accuracy of an optical surface monitoring device to reduce daily imaging of breast cancer patients

J. Sharpe<sup>1</sup>, A. Tini<sup>1</sup>, A. Moreira<sup>1</sup>, I. Pytko<sup>1</sup>, C. Winter<sup>1</sup>, M. Guckenberger<sup>1</sup>, C. Linsenmeier<sup>1</sup>

<sup>1</sup>University Hospital of Zurich, Radiation Oncology Clinic, Zurich, Switzerland

## Purpose or Objective

To further test the positioning accuracy of an optical surface monitoring device called Align RT for the treatment of breast cancer patients. The data will then be analyzed to determine if the daily positioning with Align RT is accurate enough to allow for fewer weekly MV imaging of breast radiotherapy patients.

## Material and Methods

16 breast cancer patients were treated using 3D tangential fields. Patients were positioned supine on the breast board using an optical surface detector (Align RT). After positioning, MV imaging and bone match on the chest wall was done to verify the patients position, and corrected accordingly. All shifted values were recorded. The Align RT system consists of 6 cameras, which acquire the patients' position in 2D, and a computer vision algorithm, which reconstructs the image into 3D. The patients' reference surface was imported from the CT scan and the region of interest of the treated area was selected. The patient was positioned by using the Monitoring mode in Align RT and driving couch values until pre-shift Align RT deltas were as close to zero as possible. The Vertical (VRT), Lateral (LAT), Longitudinal (LNG) shift values generated from the MV images equal to or less than 5mm were marked as falling within our accepted tolerance for breast patients. This data was further analyzed to conclude if it would be acceptably accurate enough to reduce daily imaging.

## Results

Out of the 16 patients involved in the study, a total of 213 fractions were treated using Align RT. Of these fractions, 201 (94.4%) had MV shift values, in all directions, within our 5mm tolerance. 209 of 213 fractions (98%) were within a 6mm tolerance or less. The largest shift observed was 9.5mm in the lateral direction, however the most frequent axis that fell out of tolerance were VRT and LNG. The most failed fractions (fractions with shift greater than 5mm) observed from an individual patient was 3 out of her 25 recorded fractions. 9 of the 16 patients were treated with all fractions within tolerance.

## Conclusion

The data was found to be very consistent across all patients, with 9 from 16 patients having all MV shifts equal to or less than 5mm in all directions after using Align RT for positioning and the remaining having minimal fractions outside this tolerance. This data suggests a strong argument for reducing daily imaging with breast patients being positioned with Align RT. Reducing daily imaging to 2-3 times per week in combination with daily positioning using Align RT would then be valuable in reduction of both excess dose to the patient and treatment time on the Linear accelerator.

## PO-0997 Improving shoulder positioning in a 5-points mask.

L. Mesch<sup>1</sup>, S. Hol<sup>1</sup>, G. D'Olieslager<sup>2</sup>, C. Buijs<sup>1</sup>, D. Washington<sup>1</sup>

<sup>1</sup>Dr. Bernard Verbeeten Instituut, Department of Radiation Oncology, Tilburg, The Netherlands

<sup>2</sup>Dr. Bernard Verbeeten Instituut, Department of medical Physics & Engineering, Tilburg, The Netherlands

### Purpose or Objective

Immobilization and positioning are necessary in radiation therapy of head-and-neck patients. A 5-points mask offers stability, although large shifts of the shoulder (>1cm) routinely can occur. A wrong positioned shoulder can cause coverage loss or an increased critical structure dose. The purpose of this study was to decrease the shouldershifts by increasing the awareness of the RTT's.

### Material and Methods

In the period January 2014 till June 2016 head-and-neck patients were immobilized daily with a 5-points mask (2014/2015: CIVCO Medical solutions: Posicast®, 2016: Orfit Industries: Efficast® Push Pin)/Wedges 5° & 7° (Cablon Medical)/Head supports (2014/2015: CIVCO Medical solutions: Posifix® Supine Headrests, 2016 Orfit Industries: Raycast® Head supports regular density with lateral neck flaps).

For each year, 10 patients with head-and-neck cancer were selected randomly.

All patients had daily CBCT imaging (Varian Medical Systems). The position of both shoulders on the CBCT relative to the mask was quantified in inferior direction in Offline Review (Varian Medical Systems). Measurements were performed on the coronal plane, 1.5cm dorsal of the isocenter (Figure 1).

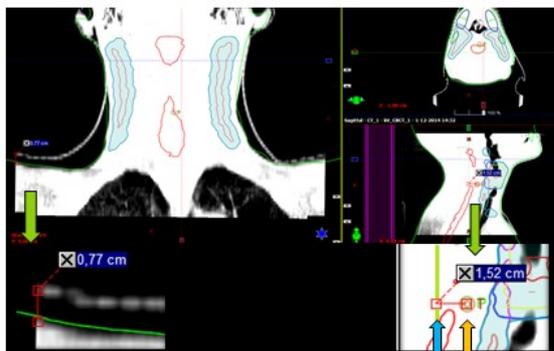

Figure 1: Measurement on the coronal plane (blue arrow), 1.5cm dorsal of the isocenter (orange arrow).

### Results

Three hundred CBCT scans (600 shoulder positions) were examined. Table 1 shows the shoulder shifts in inferior direction. In 2014 23% of the shoulders was positioned  $\geq 15$ mm inferior relative to the mask. At the end of 2014 the results were presented at our institute. Extra awareness of the RTT's resulted in a decrease of the shouldershifts  $\geq 15$ mm (7%). After a second presentation in December 2015, the percentage of shifts  $\geq 15$ mm decreased (3.5% vs. 7%) in 2016. The percentage of shifts  $5\text{mm} \leq x < 10\text{mm}$  increased relative to 2015 (34.5% vs. 24.5%). This might be due to lack of experience with the new type of masks.

Table 1: Shouldershifts in inferior direction (%)

Year		$0 \leq x < 5$ (mm)	$5 \leq x < 10$ (mm)	$10 \leq x < 15$ (mm)	$x \geq 15$ (mm)
2014	CIVCO Medical solutions: Posicast®	33.5	28	15.5	23
2015	CIVCO Medical solutions: Posicast®	58.5	24.5	10	7
2016	Orfit Industries: Efficast®	51	34.5	11	3.5

### Conclusion

A presentation and discussion session is a simple and efficient way to create more awareness. Extra awareness of the RTT's improved the setup of the shoulders in a 5-points mask, but the immobilization of the shoulders demands attention. The reason for the increase in shifts  $5\text{mm} \leq x < 10\text{mm}$  will be further investigated.

### PO-0998 Comparison of the accuracy of different pillow for radiation therapy of head and neck cancer

C.Y. Lin<sup>1</sup>, W.H. Yu<sup>1</sup>, C.Y. Lin<sup>1</sup>, J.T.C. Chang<sup>1</sup>  
<sup>1</sup>Chang Gung Memorial Hospital, Department of Radiation Oncology, Taoyuan, Taiwan

### Purpose or Objective

Random error occurring in daily treatment is always a serious concern in fractionated radiotherapy (RT). Image guided radiotherapy can partially solve some of these problems. However, the curvature of the cervical spine is still a problem. Change of spine curvature can easily result in a deviation of more than 3mm. Therefore, we initiate this study to evaluate the accuracy of different pillow used for radiotherapy and to eliminate the errors caused by curvature change.

### Material and Methods

With the agreement of institutional review board, 71 head and neck patients were enrolled and randomly assigned to use different pillow for either primary or postoperative RT. The three different pillows including conventional pillow (CP, Silverman Headrests, CIVCO, medical solution), customized pillow with alpha cradle (AC, Smithers Medical Products, Inc. ), and Moldcare Head Cushion pillow (MP, Alcar Co, Inc. ). All patients used head and shoulder mask for fixation. Daily on-board image (OBI) was acquired for evaluation and correction of set-up error. Change of curvature was measured by the movement of the vertebral body of first (C1) and 5<sup>th</sup> (C5) cervical spine, comparing to the location on digital reconstructed image from CT simulation.

### Results

Of all patients accrued, 34 patients received surgery and postoperative radiotherapy, and 13, 11, and 10 patients used CP, AC, and MP respectively. Thirty-seven patients received primary radiotherapy without surgery, and 14, 11, and 12 of them used CP, AC, and MP respectively. There were 1633 OBI acquired. In postoperative RT group, the absolute movement of C1 were  $0.07 \pm 0.03$  cm,  $0.07 \pm 0.03$  cm, and  $0.09 \pm 0.03$  cm, when CP, AC, and MP was used, respectively ( $p > 0.05$ ). In RT group, the absolute movements of C1 were  $0.07 \pm 0.03$  cm,  $0.06 \pm 0.02$  cm, and  $0.08 \pm 0.08$  cm, when CP, AC, and MP were used, respectively ( $p > 0.05$ ). In comparison the movement of C5, the absolute movements were  $0.15 \pm 0.04$ ,  $0.21 \pm 0.07$ , and  $0.16 \pm 0.72$ , when CP, AC, and MP was used in postoperative RT group, respectively ( $p > 0.05$ ). In primary RT group, the absolute movements were  $0.23 \pm 0.09$ ,  $0.14 \pm 0.05$ , and  $0.15 \pm 0.03$ , when CP, AC, and MP was used, respectively. The movements of C5 in patients who used AC ( $p = 0.048$ ) or MP ( $p = 0.05$ ) were significant lower than patients who used CP in primary RT group.

### Conclusion

Customized pillow could reduce setup error in patients who received primary radiotherapy but not postoperative radiotherapy.

### PO-0999 Control of rectal volume with Kampo formula during prostate radiotherapy: A prospective study

J. Kobayashi<sup>1</sup>, T. Tahara<sup>2</sup>, Y. Matsuzaki<sup>1</sup>, Y. Ono<sup>1</sup>, J. Matsumoto<sup>1</sup>, H. Sato<sup>1</sup>, K. Onko<sup>1</sup>, Y. Kishimoto<sup>1</sup>, T. Tanino<sup>2</sup>, H. Sakaguchi<sup>2</sup>, N. Uchida<sup>2</sup>

<sup>1</sup>Tottori University Hospital, Radiology, Yonago, Japan

<sup>2</sup>Tottori University Hospital, Radiation Oncology, Yonago, Japan

### Purpose or Objective

During intensity-modulated radiation therapy (IMRT) for prostate cancer, volume and position of the prostatic gland, bladder and rectum should be kept stable to minimize adverse events such as radiation proctitis or rectal bleeding. For this purpose, keeping the rectal volume small is essential. Daikenchuto (DKT) is a traditional Japanese herbal (Kampo) formula used to treat patients with abdominal bloating or constipation and is

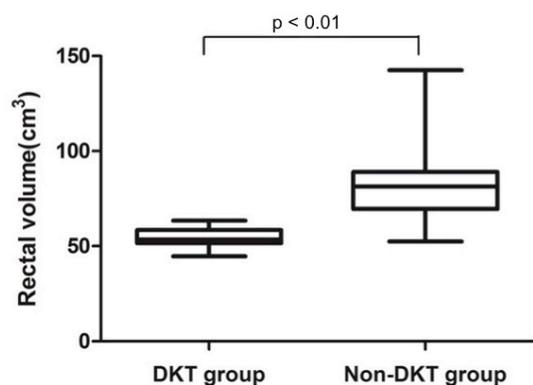

reported to increase intestinal motility. DKT is composed of three medical herbs (ginger, ginseng radix, Japanese pepper) and maltose powder. The purpose of this study was to investigate the effect of DKT on rectal volume during prostate IMRT prospectively.

#### Material and Methods

The institutional review board approved this study and written informed consent was obtained from all patients. We divided consecutive 30 non-metastatic (cT1cN0 to cT3bN0) prostate cancer patients into two groups. 15 patients were orally administered 15 grams of DKT per day from one month before IMRT until the last day of the treatment (DKT group). The remaining 15 were not administered DKT (non-DKT group). The prescribed radiation dose was 78 Gy in 39 fractions for 7.5 weeks to the prostatic gland and proximal one-third or entire seminal vesicle according to their stratified recurrence risk. Kilo-voltage computed tomographic image (KV-CT) by linear accelerator (Trilogy, Varian Co.) was taken for three-dimensional matching set-up before each treatment session. Each KV-CT was sent to a radiation treatment planning workstation (Pinnacle 3, Phillips Medical Systems Co.) and rectal volume of anal-sided 8cm length was then measured. Calculated rectal volumes of the DKT group were compared to those of the non-DKT group. Administration of laxative agent, tubal gas suction or colon irrigation was done depending on residual rectal content before radiation.

#### Results

Total of 1,170 KV-CT were evaluated. Rectal volumes of DKT and non-DKT groups were 48.79-63.46 (mean 54.69 +/- 4.00) cm<sup>3</sup> and 52.41-142.57 (mean 81.37 +/- 16.36) cm<sup>3</sup>, respectively (p < 0.01). Adverse effects associated with DKT use such as appetite loss, liver dysfunction or interstitial pneumonia were not noted.

#### Conclusion

DKT appears to be useful in reducing rectal volume and intra-fractional volume variance which would help prevent radiation proctitis or rectal bleeding in prostate curative radiotherapy. Longer follow-up with a larger patient population is desired.

**PO-1000 Immobilisation systems for brain treatment: are individual head supports needed for stable fixation?**  
S. Meessen<sup>1</sup>, F. De Beer<sup>1</sup>, P. Van Haaren<sup>1</sup>, D. Schuring<sup>1</sup>  
<sup>1</sup>Catharina Hospital Eindhoven, Department of Radiation Oncology, Eindhoven, The Netherlands

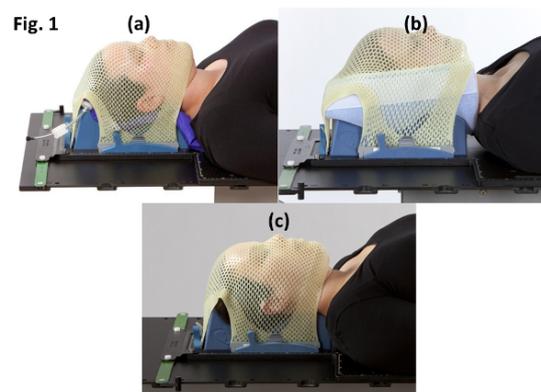

#### Purpose or Objective

For stereotactic treatment of brain metastases, good fixation of the patient is necessary to enable the use of small PTV margins and reduce the volume of healthy brain tissue receiving high doses. These fixations should prevent significant intrafraction movement, and reduce the interfraction rotations. The purpose of this study was to compare three different fixation systems, two with individual head supports and one with standard head

support, and to evaluate which of these systems was best suited for stereotactic brain treatments.

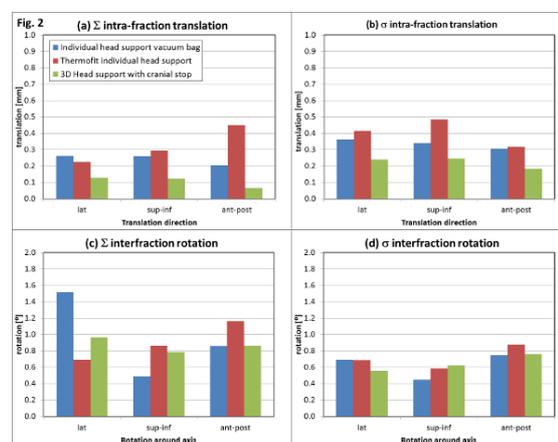

#### Material and Methods

Patients receiving brain RT were treated with either one of three different fixation systems (Orfit Industries, see figure 1): a hybrid mask combined with (a) an individual head support vacuum bag (n=20); (b) a Thermofit individual head support (n=17); (c) a standard 3D head support with cranial stop (n=10). All patients received a correction protocol and were imaged at least 3 times during the treatment course using an Elekta XVI CBCT, both before and at the end of the treatment fraction. All scans were registered on bony anatomy and translations and rotations were recorded and analysed. For the three different fixation systems the mean (M), systematic ( $\Sigma$ ) and random ( $\sigma$ ) errors were determined over the patient population for the intrafraction translations and rotations, and interfraction rotations.

#### Results

Figure 2 shows the systematic and random errors of the intrafraction translations (a,b) and interfraction rotations (c,d) of the three different fixation systems. Intrafraction translations were small for all systems, with maximum deviations generally lower than 1 mm for all fractions, and a systematic and random error both in the order of 0.3 mm. No statistically significant differences were found between the vacuum bag and Thermofit system, while the 3D head support showed a slight improvement for the systematic errors compared to the individually moulded head supports. Intrafraction rotations were typically in the order of 0.2°, and no differences were observed between the three groups. The systematic and random errors of the interfraction rotations were in the order of 1° and 0.6° for all systems, with no significant differences between the three fixation systems, and maximum rotations of up to 4° were observed occasionally.

## Conclusion

Inter- and intrafraction variations were analysed for three different cranial fixation systems. Intrafraction translations were small for all systems, while interfraction rotations could be significant. The addition of an individual head support does not seem to decrease the interfraction rotations, and for intrafraction variations the results seem to even indicate a slight improvement when using a standard head support with a shape that provides good fixation for the head. Individual supports might have added value for patients with a deviating anatomy.

Poster: RTT track: Imaging acquisition and registration, OAR and target definition

### PO-1001 Evaluation of target volume delineation of the regional lymph nodes in breast cancer patients

M. Mast<sup>1</sup>, E. Gagesteijn<sup>1</sup>, T. Stam<sup>1</sup>, N. Knotter<sup>2</sup>, E. Kouwenhoven<sup>1</sup>, A. Petoukhova<sup>1</sup>, E. Coerkamp<sup>3</sup>, J. Van der Steeg<sup>1</sup>, J. Van Egmond<sup>1</sup>, H. Struikmans<sup>1</sup>

<sup>1</sup>Haaglanden Medical Centre Location Antoniusshove, Radiation therapy, Den Haag, The Netherlands

<sup>2</sup>Leiden University Medical Centre, Clinical oncology, Leiden, The Netherlands

<sup>3</sup>Haaglanden Medical Centre Location Westeinde, Radiology, Den Haag, The Netherlands

#### Purpose or Objective

New ESTRO guidelines have been developed for the delineation of the Clinical Target Volumes (CTVs) of the regional lymph nodes of the breast. Until now we used the methods based on the article of 'Dijkema et al.'. In response to these new insights, we decided to develop a tool to implement this new ESTRO guideline. The main question, which will be answered, is: "What are the differences between delineating the regional lymph nodes of breast cancer according to the method 'Dijkema et al.', 'the ESTRO guidelines' and 'the Tool combined with ESTRO guidelines ('Tool')'?"

#### Material and Methods

In ten patients CTVs of the regional lymph nodes of the breast were delineated (in Pinnacle [1]) by three dedicated radiation oncologists, according to the two different guidelines and the 'Tool'. The 'Tool' is a method where the subclavian and the axillary vessels are delineated by a radiation therapist and is expanded in all directions with 5 mm. This volume is then adjusted by the radiation oncologist on the basis of the prescribed anatomical boundaries of 'the ESTRO guidelines'. After that, all CTVs were exported to MATLAB to calculate the Conformity Index generalized (Clgen) [2]. In MATLAB the differences in the various directions on the axial coupes of the treatment planning-Computed Tomography scans were analysed. Also the volumes of the CTVs were calculated in Pinnacle. Finally, the required delineating times per patient, per guideline and per radiation oncologist were compared and analyses were carried out using SPSS [3].

[1]: Pinnacle Treatment Planning System, version 9.10 (Philips Healthcare)

[2]: E. Kouwenhoven, 2009, [Phys Med Biol](#).

[3]: IBM SPSS Statistics for Windows, IBM Corp., Armonk, NY, USA

#### Results

The MATLAB analyses showed that the 'Tool' had the highest Clgen (0.64 and  $\sigma = 0.05$ ) relative to the other two methods ( $p < 0.04$ ) (table 1). Furthermore, the delineating time was shortest (13.6 min and  $\sigma = 2.4$ ) by using the 'Tool'. The use of the ESTRO guideline without the 'Tool' resulted in the smallest average CTV volume (150.6 cm<sup>3</sup> and  $\sigma = 41.0$ ). Furthermore, we saw a clear decrease of the standard deviations in most delineating directions when using the 'Tool', except in the ventral

direction.

Table 1. The differences of the Clgen between the three methods.

	ClgenDijkema et al.	ClgenESTRO	ClgenTool
Average	0,58	0,57	0,64
Standard deviation ( $\sigma$ )	0,05	0,06	0,05

Clgen = Conformity Index generalized

#### Conclusion

Using the 'Tool' we found a significantly higher Clgen and a smaller CTV volume (compared with the method 'Dijkema et al.'). The advice is to use the 'Tool' as delineating method for delineating the CTV of the regional lymph nodes of breast cancer patients due to the increase of the Clgen combined with the shortest delineation time and the smallest standard deviation per delineating direction. We also recommend performing second reading to improve the concordance between radiation oncologists. Finally, further research is required because the Clgen did not reach a level higher than 0.8.

### PO-1002 Comparison of Best Commercial Model and Atlas based segmentation with CT and MR in brain cancer.

J.Y. Woo<sup>1</sup>, T.Y. KIM<sup>2</sup>, J.Y. SEOK<sup>3</sup>, T.M. KIM<sup>1</sup>, Y.W. CHO<sup>1</sup>, S.Y. KIM<sup>1</sup>, J.G. BAEK<sup>1</sup>, J.H. KIM<sup>1</sup>, J.H. CHO<sup>1</sup>

<sup>1</sup>Yonsei Cancer Center, Radiation Oncology, Seoul, Korea Republic of

<sup>2</sup>National Cancer Center, Radiation Oncology, Gyeonggi-do, Korea Republic of

<sup>3</sup>Seoul National University Bundang Hospital, Radiation Oncology, Gyeonggi-do, Korea Republic of

#### Purpose or Objective

It is important to accurately delineate critical organ such as optic chiasm, pituitary gland and brainstem when radiation therapy is delivered in brain cancer. MR images were usually used to delineate critical organ accurately in most brain cases. But manually delineated contours by different users sometimes have different shape and region in the same planning CT. Even if different users delineate contours, we would expect to get more accurate and regular critical organ if using auto contouring method. Recently there are many commercial auto contouring softwares including model based segmentation (MBS) and atlas based segmentation (ABS) softwares even supporting MR images. This study aims to compare auto contouring methods to delineate critical organ accurately and to have certain shape and region.

#### Material and Methods

It is multi-center study. We selected 10 patients. We used three MBS software solutions and ABS software solution (MIM software ver. 6.5.5.) to generate the automatic contouring on the planning CT. All MBS software just made contours without any preparation, and we chose the best result among 3 MBS solutions for comparison. But ABS software should have subjects (who are already registered for ABS to work on auto contouring and also they are not the patients involved in this study). We made two groups of atlas, 60 subjects of CT based and 20 subjects of MR based. We used two matching techniques for MR based ABS, Majority-vote and STAPLE. We analyzed auto contouring with 4 classified groups - best MBS (BM), CT based ABS for 60 subjects (CA), and MR based ABS using Majority-vote (MR\_MV) and MR based ABS using STAPLE (MR\_ST). We gained brain stem, optic chiasm, and pituitary gland contours. Average Dice Similarity Coefficients (DSC) was calculated for each structure to compare against 'gold' standard contours which are manually defined of 4 groups respectively. Values closer to 1 indicate higher accuracy.

## Results

MR\_ST was significantly more accurate than other group according to DSC of  $0.646 \pm 0.094$  compared to  $0.564 \pm 0.102$ ,  $0.298 \pm 0.109$ ,  $0.39 \pm 0.254$  respectively for MR\_MV, CA and BM in optic chiasm. DCS scores in pituitary gland were following,  $0.624 \pm 0.055$  in MR\_ST,  $0.582 \pm 0.052$  in MR\_MV,  $0.514 \pm 0.140$  in CA and  $0.28 \pm 0.24$  in BM respectively. Brainstem was showed similar DSC score as  $0.89 \pm 0.021$ ,  $0.892 \pm 0.017$ ,  $0.842 \pm 0.038$  and  $0.73 \pm 0.156$  respectively for MR\_ST, MR\_MV, CA and BM.

## Conclusion

Most of auto delineated contours was smoothed in advance. Among 4 groups, DSC of MR based was the highest. Even though auto contouring is conducted by different users, it shows certain shape and included similar region when we use same subject's data. ABS software takes more effort and time to use in the first place. However, MR based ABS would have better auto contouring accuracy compared with MBS and CT based ABS in brain cancer. In addition STAPLE has provided better results for smaller volumes based on my study.

### PO-1003 A analysis of safety of whole brain radiotherapy with Hippocampus avoidance in brain metastasis

Y. Han<sup>1</sup>, J. Chen<sup>1</sup>, G. Cai<sup>1</sup>, X. Cheng<sup>1</sup>, Y. Kirova<sup>2</sup>, W. Chai<sup>3</sup>  
<sup>1</sup>Shanghai Jiao Tong university-ruijin hospital, radiation oncology, Shanghai, China

<sup>2</sup>Institute Curie- Paris- France, Department of Radiation Oncology, Paris, France

<sup>3</sup>Shanghai Jiao Tong university-ruijin hospital, Department of Radiology, Shanghai, China

#### Purpose or Objective

**Purpose:** Whole brain radiotherapy (WBRT) remains reference treatment in patients with brain metastasis (BM), especially with multiple lesions. Hippocampus avoidance in WBRT (HA-WBRT) offers the feasibility of less impaired cognitive function than conventional WBRT and better intracranial control than SBRT. Oncological safety is critical in defining the proper role of HA-WBRT. The study aims to investigate the frequency of intracranial substructure involvement based on large series of radiological data and to optimize the margin definition in treatment planning.

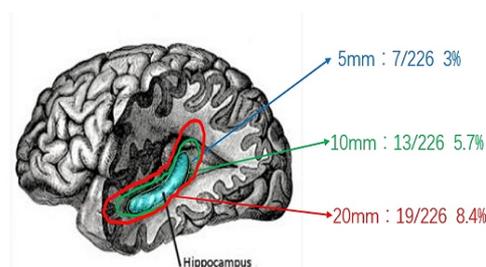

#### Material and Methods

**Methods:** Consecutive patients with diagnosis of BM from enhanced MRI between 03/2011 and 07/2016 diagnosed and treated in RuiJin Hospital were analyzed. Lesions of each patient were confirmed by a senior radiologist and the closest distances from tumor to the hippocampal area were measured and analyzed by radiation oncologist.

#### Results

**Results:** A total of 226 patients (pts) (115 males and 111 females) with 1080 metastatic measurable lesions have been studied. The distribution of the primary tumours was as following: 72.6% lung cancers (LC) (n=164), 19.9% breast cancer (BC) patients (n=45) and 7.5% from other malignancies (n=17). Seventy-one pts were diagnosed with BM before or simultaneously with their primary malignancy. In the case of others 155 pts, the latency of BM appearance was as following: 14 months in LC pts (n=100), 59 months in BC pts (n=42). Totally, 758 (70.2%) lesions were situated beyond the tentorium. The median diameter of the lesions was 10 mm (1.2mm-162mm). The situation of the lesions was as following: 322 (29.8%) in the cerebellum, 268 (24.8%) in the frontal lobe, 168 (15.6%) in the temporal lobe, 128(11.9%) in the parietal lobe, 131 (12.1%)in the occipital lobe, 45 (4.2%)in the thalamus and 18 (1.6%) in the brainstem. After measuring the closest between the lesions and the Hippocampus in every case, the pts with lesions close to this zone (n=45) were classified into 3 categories: 7 (3.1 %) at 5 mm or less, 13 (5.7%) within 10 mm or less and 19 (8.4%) at 20 mm or less (Fig1). 45 patients received WBRT only and 18 of 45

patients who had complete radiological follow-up after WBRT in the same hospital were founded progress of BM. The median follow-up was 11 months. Only one new lesion was observed in area of Hippocampus (less than 5 mm).

Probability of involvement of the hippocampus in different ranges

## Conclusion

**Conclusion:** With complete radiological diagnosis, HA-WBRT can be delivered with oncological safety. Proper margin definition of HA in delineation is to be confirmed with individual technique.

### PO-1004 Machine learning methods for automated OAR segmentation

P. Tegzes<sup>1</sup>, A. Rádics<sup>1</sup>, E. Csernai<sup>1</sup>, L. Ruskó<sup>2</sup>  
<sup>1</sup>General Electric, Healthcare, Budapest, Hungary

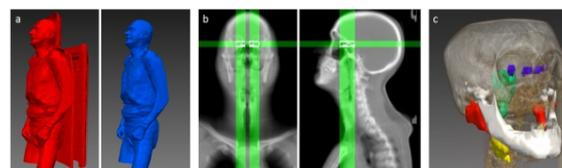

<sup>2</sup>General Electric, Healthcare, Szeged, Hungary

#### Purpose or Objective

Manual contouring of organs at risk can take significant time. The aim of this project is to use machine learning to develop fully automated algorithms to delineate various organs in the head and neck region on CT images.

#### Material and Methods

Machine learning models were built based on 48 CT sequences of the head and neck region with 5 manually contoured organs from the Public Domain Database for Computational Anatomy. Data were randomly separated to 32 train, 8 cross-validation and 8 test sequences. Three different machine learning models were combined to achieve automated segmentation. The first step uses a support vector machine classifier to separate patient anatomy from all other objects (a). The second step applies slice-based deep learning classification to detect the bounding box around the organ of interest (b). The final step achieves voxel-level classification based on a fully connected neural net on the voxel intensities of suitably selected neighboring voxels (c). Very similar model architectures were trained for all the different organs.

## Results

The body contour detection has been previously trained on another dataset containing full-body images and achieved an average accuracy of 96.6%. The mean error of the bounding box edges was 3mm, the corresponding dice scores ranged from 72% to 94% depending on the organ of interest. The first results of the voxel level segmentation gave average dice values of 38% to 77% depending on the investigated organ, and several opportunities for further fine-tuning have been identified.

## Conclusion

Machine learning methods can be competitive with standard image processing algorithms in the field of organ segmentation.

## PO-1005 Automatic segmentation of cardiac sub-structures in the treatment of HL

C. Fiandra<sup>1</sup>, M. Levis<sup>1</sup>, F. Cadoni<sup>1</sup>, V. De Luca<sup>1</sup>, F. Procacci<sup>1</sup>, A. Cannizzaro<sup>1</sup>, R. Ragona<sup>1</sup>, U. Ricardi<sup>1</sup>

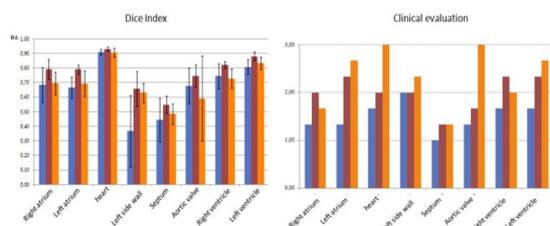

<sup>1</sup>University of Torino, Oncology, Torino, Italy

### Purpose or Objective

to validate, in the context of treatment of Hodgkin Lymphoma, three commercial software solutions for atlas-based segmentation of cardiac sub-structures

### Material and Methods

25 patients were selected and then divided into two groups: 15 patients will make up the personalized atlas and 10 patients on which will be applied atlases created in order to assess its quality. For the selection of patients, the following inclusion criteria were selected: patients with HL presentation of a mediastinal mass at the onset of the disease and the availability of CT imaging with contrast. Two expert physicians have delineated on the diagnostic CT with contrast the selected 15 patients cardiac structures: the heart as a whole, the four chambers of the heart, the coronary artery and valvular structures; which will compose the atlas. We use three commercial solutions (Velocity AI, MIM and RayStation) in order to compare their results; the structures delineated by doctors on the 5 control patients will be compared with those automatically drawn by atlases, through the conformity function (Dice Index (DI)). In addition, the atlases underwent a clinical evaluation of the involved physicians: in particular it was asked to a Radiation Oncologist to analyze contours made by the three software on reference patients to evaluate the goodness of the warp made from atlases than those performed by him. Clinical judgments were recorded on a scale of numerical values: 1 = poor; 2 = medium; 3 = good.

## Results

in terms of statistical analysis, the data obtained from the values of Dice Index were compared structure by structure between the three platforms. The Figure 1 shows only structures with a Dice Index more than 0.5 (right atrium, left atrium, the heart, the left side wall, interventricular septum, aortic valve, left ventricle and right ventricle). The differences between the 3 software were calculated and the structures delineated by MIM have more frequently higher values of Dice Index, compared to those of Velocity and RayStation, with respectively 0.03 to 0.01 p-value. Instead the difference between Velocity and RayStation is not statistically significant (p-value = 0.8). Regarding the evaluation of the Radiation Oncologist as compared to DI, values show that RayStation is the software that realizes contours more applicable in clinical practice, with statistically significant differences from Velocity and MIM, with p-value respectively of 0.038 and 0.046. While the difference between Velocity and MIM is not statistically significant (p-value = 0.083).

## Conclusion

In general we can say that the contours applied by atlases are valid, even if not yet optimal and they may represent a starting point for the step of contouring, useful to speed up this process; based on the values of Dice Index collected in this study, MIM performs better while RayStation appears the most powerful software from a clinical point of view thus obtaining contours more "similar" to those defined by the Radiation Oncologist.

## PO-1006 Evaluation of an auto-segmentation software for definition of organs at risk in radiotherapy

M.D. Herraiz Lablanca<sup>1</sup>, S. Paul<sup>1</sup>, M. Chiesa<sup>1</sup>, K.H. Grosser<sup>1</sup>, W. Harms<sup>1</sup>

<sup>1</sup>St. Claraspital, Radioonkologie, Basel, Switzerland

### Purpose or Objective

The aim of this work is to evaluate the capability of a commercial software performing automatic segmentation of relevant structures for radiotherapy planning, as well as the time saving of its use on a daily Basis.

### Material and Methods

The software Smart Segmentation Knowledge Based Contouring (Version 13.6) from Varian Medical System was evaluated according to segmentation quality and time saving. For that purpose, 5 consecutive prostate and breast patients were contoured manually and automatically using the software, recording the time needed in both, manual and automatic contouring with corrections. This task was performed by the RTTs, since they are responsible of the OARs contouring in our department.

Segmentation quality was qualitatively scored in four levels: 'excellent'(1), 'good'(2), 'acceptable'(3) and 'not acceptable'(4) and quantitatively evaluated calculating five parameters: Relative difference in volume, DICE similarity coefficient, Sensitivity Index, Inclusiveness Index, Mass Center Location.

### Results

Mean values of the qualitative evaluation and acceptance are summarized in Table 1. The acceptance of the structures automatically contoured is higher for breast cancer than for prostate patients, as well as the mean time saving, that is above four minutes for breast and around 1 minute for prostate.

	PROSTATE		BREAST		
	Mean	Acceptance	Mean	Acceptance	
Bladder	2.4	80%	Heart	3	80%
Body	2	75%	Humerus	2.2	80%
Penile bulb	4	0%	Lung li	2	100%
Small bowel	4	0%	Lung re	2	100%
Femoral head right	3.6	20%	Liver	2	100%
Femoral head left	3.4	40%	Mammilla	3.5	25%
Rectum	3.8	20%	Esophagus	4	0%
Rectum wall posterior	4	0%	Spinal Canal	1.25	100%
Rectum wall anterior	4	0%			
Sigma	4	0%			

Good agreement was found between manual and automated segmentation for heart with a mean difference in volume of 7%, DICE of 0.87 and deviation of mass center less than 2mm in all directions and for liver with a mean difference in volume of 11%, DICE of 0.91 and deviation of mass center less than 2mm in all directions. Poor acceptance was found in complex structures as penile bulb, small bowel, sigma and rectum wall anterior and posterior.

### Conclusion

Smart Segmentation software is a useful tool for the delineation of relevant structures for breast although did not generate useful delineation for neither the mammilla nor the esophagus. For relevant structures for prostate as penile bulb, small bowel, sigma and rectum wall anterior and posterior the software was not good enough. Further analysis will be performed including more patients.

Poster: RTT track: Treatment planning and dose calculation / QC and QA

**PO-1007 The effect of VMAT on tumor coverage and organs at risk for head and neck cancer patients**

M. Kertevig<sup>1</sup>

<sup>1</sup>Rigshospitalet, Department of Oncology- Section for Radiotherapy, Copenhagen, Denmark

**Purpose or Objective**

Throughout the course of radiotherapy in head and neck patients tumor shrinkage occurs. This may influence the dose to organs at risk (OAR) around the tumor area, as tumor shrinkage can lead to different dose distribution in the patient than originally calculated. As Volumetric Modulated Arc Therapy (VMAT) technique is frequently used for head and neck patients, it is relevant to study the impact of VMAT treatment on tumor coverage and OAR, during a course of radiotherapy, and the necessity to adaptive plans during the course of treatment.

**Material and Methods**

A retrospective study has been carried out on 13 consecutive patients who have been treated with VMAT for head and neck cancer. The Cone-beam Computed Tomography (CBCT) from the first treatment fraction was compared with the CBCT from the last fraction. Dose and volume comparison was performed for planning target volume (PTV), spinal cord, brainstem and both parotid glands. A paired t-test was used to test for significance and *p*-values <0.05 were considered statistically significant

**Results**

The mean volume of PTV on the CBCT from the first treatment fraction was 283.98 cm<sup>3</sup> compared with the CBCT from the last fraction which was 270.33 cm<sup>3</sup>. The mean volume of the PTV decreased significantly with 5% (*p* = 0.003), due to tumor shrinkage during the course of treatment. The mean D<sub>95</sub> to the PTV decreased by less than 1% from 62.34 Gy to 61.88 Gy. The mean D<sub>max</sub> to the spinal cord increased by 1% from 41.33 Gy to 41.78 Gy and to the brainstem by 3.8% from 32.11 Gy to 33.33 Gy. The mean dose to the left parotid gland decreased with less than 1% from 22.08 Gy to 22.06 Gy. In contrast, the mean dose to the right parotid gland was significantly increased by 6.5% (*p* = 0.033) (table 1). There were no significant differences in the mean dose to either PTV (*p* = 0.12) spinal cord (*p* = 0.27), brainstem (*p* = 0.22) and left parotid gland (*p* = 0.98), which means that treatment with VMAT, had negative effect on dose to spinal cord, brainstem and left parotid gland with a 95% probability for this patient cohort. Even though the dose to the right parotid gland increased significantly, the dose to all OAR remained within the defined constraints. In addition, the tumor coverage remained sufficient throughout the treatment. This need to be studied further with larger sample sizes together with a dose study for all the OAR in the head and neck region to fully determine the necessity to adapt the patients plan, especially since it might be possible to reduce the dose to the parotid glands for patients suffering from xerostomia.

Table 1. Dosimetric comparison of mean values of the CBCT for the first and last treatment fraction

	CBCT first treatment fraction	CBCT last treatment fraction	Mean % change	<i>p</i> value
<b>PTV</b>				
D <sub>95</sub> (Gy)	58.38	56.88	2.57%	0.015
D <sub>5</sub> (Gy)	62.34	61.88	0.74%	0.12
<b>Spinal cord</b>				
D <sub>max</sub> (Gy)	41.33	41.78	1.09%	0.27
<b>Brainstem</b>				
D <sub>max</sub> (Gy)	32.11	33.33	3.79%	0.22
<b>Right parotid gland</b>				
D <sub>mean</sub> (Gy)	19.48	20.74	6.47%	0.033
<b>Left parotid gland</b>				
D <sub>mean</sub> (Gy)	22.08	22.06	0.09%	0.98

**Conclusion**

This study showed that VMAT treatment plans were relatively robust during the treatment course. In this patient cohort small changes in dose to OAR were not significant, despite a reduction in PTV.

**PO-1008 Feasibility of stereotactic ablative radiotherapy for locally-advanced non-small cell lung cancer**

K. Woodford<sup>1</sup>, V. Panettieri<sup>1</sup>, T. Tran Le<sup>1</sup>, S. Senthil<sup>1</sup>

<sup>1</sup>The Alfred Hospital, Alfred Health Radiation Oncology, Melbourne, Australia

**Purpose or Objective**

Stereotactic ablative radiotherapy (SABR) has enabled a curative treatment for elderly patients or those with significant comorbidities diagnosed with early-stage non-small cell lung carcinoma (NSCLC) who would have otherwise gone untreated. As a result population-based survival has improved. If SABR could be utilized in the treatment of locally-advanced NSCLC in the same way, the public health impact would be greater, as twice as many patients are diagnosed with advanced disease. We assessed the feasibility of SABR for locally-advanced NSCLC.

**Material and Methods**

Twenty three patients with N2 and/or N3 locally-advanced lung cancer were retrospectively replanned. Targets and organs-at-risk (OAR) were delineated using 4DCT and replanned with RapidArc delivery (AcurosXB Vn13.6). Three planning approaches were assessed; conventional approach (1.0cm ITV to PTV expansion, prescribed to 100%); SABR approach (0.5cm ITV to PTV expansion, prescribed to 80%) and a hybrid approach (0.5cm ITV to PTV expansion, prescribed to 100%). We assessed the feasibility of three dose regimes, with PTV doses all having a biologic equivalence of 60Gy in 30 fractions (*α/β*=10). The planning aim was to determine the least number of fractions to deliver an acceptable plan. Acceptable was defined as ≥95% target coverage by the prescribed dose whilst maintaining the OAR tolerances below. Marginally acceptable was defined as 90-95% target coverage with lung V20 <30% and other OAR tolerances met. Descriptive statistics were used. We assessed doses to the PRVs (2mm expansion) of each OAR to determine the IGR requirements for each strategy.

**Results**

Fourteen patients had N2 involvement whilst nine had N3 involvement. Mean ITV size was 207.7cc (range 31-706.1cc). The hybrid approach generated acceptable plans in 48% of patients (11/23), while the conventional and SABR approaches achieved 26% (6/23) and 4% (1/23) respectively. If acceptable was defined by >90% target coverage by the required dose and lung V20 was less than 30%, 70% (16/23) of patients had acceptable plans with the hybrid approach. Those that failed the hybrid

approach did so due to poor PTV coverage (n=5) or unacceptable lung dose (n=2). Of the 18 patients who had an acceptable plan generated (regardless of planning approach), one was achieved with the 8-fraction regime, with the remaining needing the 12-fraction regime. OAR PRV max doses were 2-3.5% over the OAR dose for the conventional and hybrid approaches and 6% for the SABR approach, highlighting the need for IGRT.

#### Conclusion

SABR was feasible for approximately half of the locally-advanced NSCLC patients we assessed and for almost all of these cases only a 12-fraction scheme was feasible. If the alternative to SABR is no treatment at all, compromises to tumour coverage or OAR tolerances may be acceptable, increasing feasibility. This data will inform a phase I study testing the safety of SABR for locally advanced NSCLC.

#### PO-1009 Evaluation of setup margins using cone-beam CT for prostate and pelvic nodes irradiation

A. Van Nunen<sup>1</sup>, T. Budiharto<sup>1</sup>, B. De Vocht<sup>1</sup>, D. Schuring<sup>1</sup>  
<sup>1</sup>Catharina Ziekenhuis, Radiotherapie, Eindhoven, The Netherlands

#### Purpose or Objective

In 2014 radiotherapy for prostate and pelvic nodes was introduced in the Catharina hospital. For this tumour site, CBCT is used for position verification. Due to variation in prostate position in relation to lymph nodes, large setup margins are required to deliver the correct target dose to both volumes. A CTV-PTV margin of 1 cm is used for both prostate and lymph nodes. The aim of this study was to evaluate the required setup margins using different correction and registration strategies.

#### Material and Methods

CBCT-scans of 20 patients were included in this study. 220 scans were analysed retrospectively. Patients were treated with an offline SAL correction protocol with an initial action level of 10 mm and a maximum number of 3 measurements. When large day-to-day variations were observed, an online correction protocol was performed. All CBCT-scans were registered automatically using a grey value, seed or bone match algorithm of the XVI software (Elekta, Crawley, UK). For these automatic matches either a clipbox containing bony structures and the entire PTV, a mask consisting of the prostate or a mask consisting of lymph nodes CTV was used (figure 1). Registration of the lymph node area was performed to determine the correlation between bony anatomy and the position of the pelvic lymph nodes. For all these registrations all translations, rotations and table corrections were collected. From these results the random and systematic setup errors were determined. The required setup margins were then calculated using the margin recipe  $M = 2.5\Sigma + 0.7\sigma$  ( $\Sigma$ : systematic error,  $\sigma$ : random error).

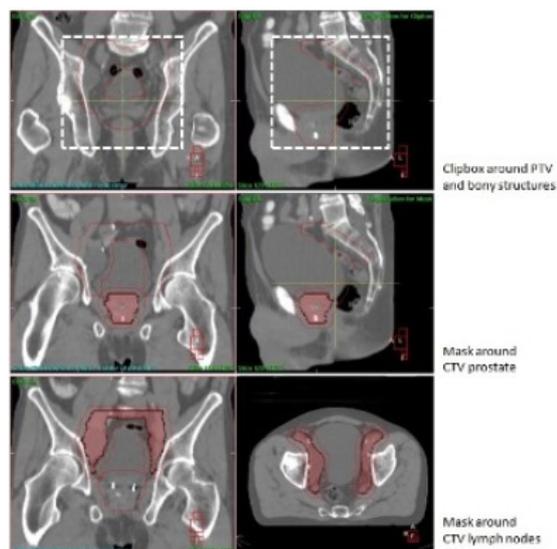

Figure 1. Different registration methods

#### Results

There was a large correlation between bony structures and lymph nodes in all directions (correlation coefficient > 0.82). Correlation between bony structures and the prostate position was large in lateral direction and small in longitudinal and vertical direction due to large variation in rectal filling. This resulted in larger margins in this direction. The required setup margins are summarised in Table 1. In this margin calculation, we did not account for rotations, intrafraction variation, delineation, treatment and match uncertainties.

When applying online position verification on the prostate, setup margins for lymph nodes must be 0.19 cm (lateral), 0.73 cm (longitudinal) and 0.57 cm (vertical). When applying online setup correction on bony structures, setup margins for the prostate must be 0.25 cm, 0.73 cm and 0.73 cm respectively. Offline setup correction on prostate resulted in the largest margins for both volumes.

Table 1. Required setup margins (cm)

	Bone match			Prostate match		
	X	Y	Z	X	Y	Z
<b>Prostate</b>						
Offline	0.58	0.88	0.85	0.56	0.94	0.95
Online	0.25	0.73	0.73	0	0	0
<b>Lymph Nodes</b>						
Offline	0.52	0.49	0.44	0.59	1.19	1.11
Online	0	0	0	0.19	0.73	0.57

#### Conclusion

The required setup margin depends on the applied correction strategy. When applying position verification on bony structures, larger margins are required for CTV prostate. When applying position verification on prostate, larger margins are required for CTV lymph nodes. When applying these margins clinically, additional margins are needed to account for rotations, intrafraction variation, delineation, treatment and match uncertainties.

#### PO-1010 Investigation of reproducibility of bolus position based on kV CBCT imaging

E. Dabrowska<sup>1,2</sup>, P. Czuchraniuk<sup>3</sup>, M. Gruda<sup>1</sup>, P. Kukulowicz<sup>1</sup>, A. Zawadzka<sup>1</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Medical Physics, Warsaw, Poland

<sup>2</sup>Faculty of Physics University of Warsaw, Department of Biomedical Physics, Warsaw, Poland

<sup>3</sup>Maria Skłodowska-Curie Memorial Cancer Center and

Institute of Oncology, Department of Radiotherapy, Warsaw, Poland

#### Purpose or Objective

On-board kilovoltage (kV) Cone Beam Computed Tomography (CBCT) imaging is being used predominantly for patients' positioning to improve the precision and accuracy of treatment delivery. Moreover, volumetric CBCT images can be used to evaluate anatomy changes like tumour shrinking or weight loss as well as changes in organ volume, deformation or position. Also reproducibility of accessories used in radiotherapy (the vacuum bag, bolus position, etc.) can be monitored. Additionally, the CBCT data set can be used for calculation of dose distribution. The aim of our study was to analyze reproducibility of bolus's position based on kV CBCT imaging and compare planned and delivered dose distribution in Clinical Target Volume (CTV).

#### Material and Methods

For 10 post-mastectomy patients, 35 sarcoma patients and 5 patients with vulva cancer the treatment CT based plans with bolus were prepared (Eclipse, Varian). For the post-mastectomy patients the planning CT was acquired with bolus. For the two other groups the planning CT was made without bolus. Bolus was drawn in the treatment planning system. For each patient CBCTs were acquired in the first and mid fraction and also at the end of treatment. CBCTs were co-registered offline (automatic rigid match) to the planning CT. The correctness of boluses positions were evaluated. Also dose distributions were calculated with CBCT images and compared with dose distributions obtained with planning CT. For each patient we took a photo to document the bolus's position. To compare dose distribution calculated on CT and CBCT, a new HU-density calibration curve was measured and introduced into treatment planning system. CatPhan®503 phantom was used.

#### Results

Fusions of CTs and CBCTs showed that there are several different problems with reproducibility of bolus position. First of all, bolus generated in TPS will never adhere to skin like it is presented in TPS, especially when an irregularity of patient surface is high (Fig. 1a). Moreover, usually air gaps occur even when there is a smooth surface of the patients' body (Fig. 1b). Another problem is the compatibility of bolus position relative to a field edge (Fig. 1c) which is difficult to reproduce despite it is accurately described in patient folder. The last two discrepancies appear regardless if bolus was placed on patient's skin during CT scanning or generated in TPS. Preliminary calculations for 10 soft tissue patients treated with 3D-CRT plan show, that there is  $5,9\% \pm 2,0\%$  a discrepancy between D98% calculated on CT and CBCT. More advanced data analysis will be presented for each location separately, for treatment planning techniques and information about taken/not taken photo before CT scanning.

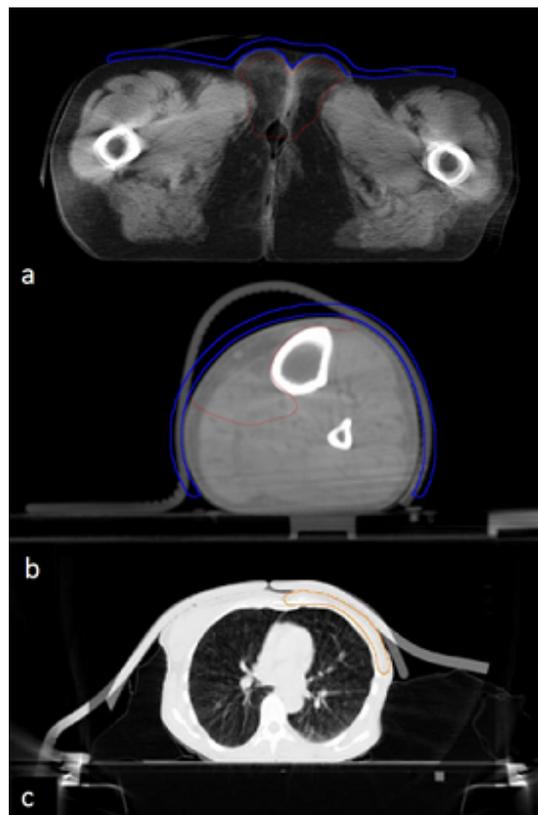

Figure 1. Comparison of bolus position between CT and CBCT images.

#### Conclusion

CBCT is a very useful method for accuracy of treatment planning verification. It allows not only patient position verification but also for evaluation of bolus positioning accuracy. Based on CBCT several mistakes influencing dose deposited to CTV were revealed, what was not noticeable during a routine verification based on two-dimensional orthogonal images.

#### PO-1011 Is it safe to omit a setup correction validation scan for central lung lesions treated with SBRT?

M.M.G. Rossi<sup>1</sup>, H.M.U. Peulen<sup>1</sup>, J.S.A. Belderbos<sup>1</sup>, J.J. Sonke<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

Our standard IGRT protocol for SBRT of pulmonary lesions consists of a pre correction CBCT to determine the couch shift that aligns the tumor, post correction (PCorr) scan for verification and two intra-arc CBCT scans to monitor position stability. The intra-arc scans are acquired simultaneously during VMAT delivery. To limit the number of scans for patients with centrally located lesions treated with 8x7.5 Gy, the pCorr CBCT is omitted and the 1<sup>st</sup> intra-arc CBCT is used as the verification scan. In this study we evaluate the positional accuracy of this protocol for the 8x7.5Gy patient cohort and compare this to a 3x18Gy cohort.

#### Material and Methods

All 16 patients treated since the implementation of a setup protocol in April 2016 without a validation scan for a single centrally located tumor with 8x7.5Gy(Gp1), were included. Fifty patients were randomly selected from our

3x18Gy(Gp2) database. Patient characteristics were compared and intra-fraction tumor position variability in Left/Right(LR), Cranial/Caudal(CC) and Anterior/Superior(AP) was calculated in terms of Group Mean(GM), systematic( $\Sigma$ ) and random( $\sigma$ ) variations for both groups from either the 1<sup>st</sup> intra-arc CBCT or a CBCT taken between the arcs if no intra-arc CBCT was available.

#### Results

No significant difference in patient characteristics between the groups was observed; gender: female 44% vs 48%, male 56% vs 52%, median age 78.5 vs 72.0years and mean GTV 32.2 vs 12.3cc in Gp1 and Gp2 respectively. Intra-fraction tumor position variability in both groups was small in all directions. The GM and random error were not significantly different between the 2 groups whereas the systematic error was significantly smaller for the 8x7.5Gy group in the AP direction (table 1). Twelve (75%) patients completed the new protocol i.e. no validation scan throughout the whole of their treatment. Four (25%) patients started with a no validation protocol but reverted to the standard SBRT IGRT protocol after a varied number of fractions (fraction 2-5) when the threshold of  $\geq 0.3$ cm was exceeded in the 1<sup>st</sup> intra-arc scan. For some patients the intra-arc CBCT was not acquired due to technical issues or intra-arc CBCT image quality and a CBCT between the arcs was used for verification. This occurred in 35% of the fractions. Besides omitting the verification scan some patients (9% fractions) required an intervention between arcs.

Intra-fraction tumor position variability in intra-arc CBCTs or CBCT scans between arcs (cm)			
Group 1 8 x 7.5 Gy			
N=16 (cm)	LR	CC	AP
GM	-0.003	0.035	-0.078
$\Sigma$	0.056	0.082	<b>0.072</b>
$\sigma$	0.074	0.100	0.103
Group 2 3 x 18Gy			
N=50 (cm)	LR	CC	AP
GM	0.015	0.055	-0.087
$\Sigma$	0.106	0.131	<b>0.199</b>
$\sigma$	0.117	0.148	0.135

Table 1 Tumor position variability in Intra-arc CBCTs or CBCT scans between arcs in 16 patients treated for centrally located tumors with 8 x 7.5Gy SBRT and 50 randomly selected patients treated for peripheral tumors with 3 x 18Gy SBRT. The systematic variability (in bold) in the AP direction was significantly different between the groups.

#### Conclusion

The setup correction validation scan could be safely omitted for most patients with central tumors treated with a 8x7.5Gy dose regimen. Nevertheless, careful monitoring is recommended for any SBRT dose regimen to capture patients with larger intra-fraction position variability.

#### PO-1012 Traffic Light Protocol as a guide for optimal registration of LACC complex tumor pathology

E. Bogaert<sup>1</sup>, L. Van den Berghe<sup>1</sup>, A.L. Michiels<sup>1</sup>, C. De Wagter<sup>1</sup>, Y. Lievens<sup>1</sup>, K. Vandecasteele<sup>1</sup>  
<sup>1</sup>Ghent University Hospital, Radiation Oncology, Gent, Belgium

#### Purpose or Objective

Pre-treatment CBCT imaging for locally advanced cervix carcinoma (LACC) is challenging. A Dual Registration (DR) protocol (Mask-based VOI (MVOI) Autoregistration (AR) for the primary PTV + Clipbox-Based (CVOI) AR for lymph node (LN) coverage) had been set up with limits of 3°, 6 mm for CVOI and 3 mm for MVOI AR. However DR optimizes target and LN coverage, it does not provide a decision framework in case anomalies occur. The purpose is to setup a Traffic Light Protocol (TLP) for RTTs, that includes DR and where recommendations for Treat, Reposition or Call Support are clearly outlined and specific actions to take are visualized in green/orange/red.

#### Material and Methods

The recently introduced DR protocol was enrolled on 7 patients, counting for 206 CBCT-planning CT (pCT) registrations. All 3D rotations and translations, together with categorical data were recorded. (e.g. *Did scan lead to treatment?, Did DR algorithms perform well?, Were predefined limits exceeded? Final approval (RTT /MD)? Categories for deviation from pCT: pelvic tilt, bladder filling, tumor shrinkage,...*).

Based on this DR experience, a TLP dedicated for LACC pre-treatment registration was set up in collaboration with an RTT, Physician (MD) and Physicist. The MD and RTT applied the TLP to 30 scans (1 patient) as an initial validation. A 4-scale score reflecting the degree of confidence about the RTTs decision was taken up.

#### Results

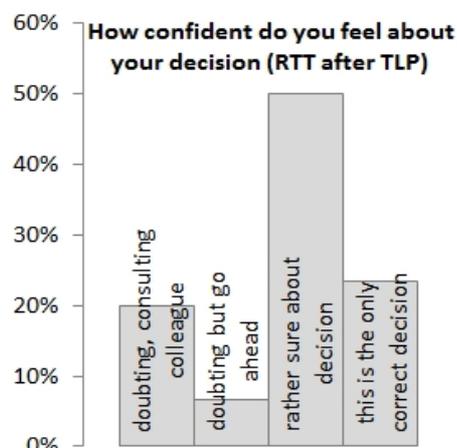

The necessity of the DR protocol, in comparison with a CVOI bony anatomy AR alone, was emphasized by the absolute mean (and maximum) differences of 0.2 (1.5) cm (L/R), 0.3 (2.9) cm (S/I) and 0.3 (1.5) cm (A/P) between the two methods.

In 7.3% of the cases the DR was misled due to high contrast regions in the intestine (alternated gastrografine and air bulbs), requiring manual adjustments. For 19.6 % of the CBCT scans that finally led to treatment and where DR performed well, anatomical deviations had been reported and not entirely corrected for (table 1). Some are: pelvic tilt > 3°, tumor shrinkage, bladder or rectum over- or underfilling, or exceeding of translational DR limits. In 25.2 % of all CBCT scans, MD support for final decision was needed.

The color code of the TLP is green= go ahead, orange = go ahead AND e-mail to attending MD AND copy note into Record & Verify system; red = do not proceed and call support of MD. In this way reporting was standardized, tumor shrinkage is followed more strictly in consideration of re-planning, and DR failure led to clear recommendations for manual registration. The TLP's results were validated to be 'correct'. The confidence level of the RTTs on their final decision, after following the TLP was high (figure 1).

	CBCT image evaluation against planning CT			Total
	NO anatomical deviation	Pelvic Tilt > 3°	Anatomical deviation apparent	
CBCT image has not led to irradiation (rescan)	0	15 (11 RTT, 4 MD)	18 (14 RTT, 4 MD)	33
CBCT image has led to irradiation	127 (103 RTT, 24 MD)	8 (5 RTT, 3 MD)	23 (11 RTT, 12 MD)	158
	127	23	41	191

191 CBCT-pCT image sets where DR performed well, i.e. no manual intervention needed

#### Conclusion

For CBCT pre-treatment imaging of LACC, Clipbox based bony AR alone is less accurate than DR. Even so DR alone is not sufficient. A TLP with DR included was setup to improve the level of correct and fast decision making. In this way, RTTs felt confident about their decision.

Poster: RTT track: Motion management and adaptive strategies

PO-1013 Library of plans and CTV-PTV margins for VMAT irradiation of cervical cancer

P.M. Kager<sup>1</sup>, S. Ali<sup>1</sup>, I. Valkering<sup>1</sup>, M. Bloemers<sup>1</sup>, P. Remeijer<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

**Purpose or Objective**

In December 2012, a library of plans (LoP) methodology for cervical cancer was developed and implemented in our clinic to deal with variations of cervix-uterus position and shape caused by variations in bladder volume. A LoP consists of several VMAT plans corresponding to full bladder volume, empty bladder volume and intermediate bladder volumes. Based on improved motion management due to LoP, it was hypothesized that the clinically used CTV-PTV margin of 1 cm left-right and 2 cm in other directions could be reduced. The aim of this study was to investigate to what extent the CTV-PTV margin with VMAT irradiation of cervical cancer could be reduced with the use of LoP.

**Material and Methods**

Twelve cervical cancer patients, treated with 46 Gy in 23 fractions, were included in this retrospective study. Before planning CT (pCT) simulation, three fiducial markers were placed in the top of the vagina or cervix. For each patient intermediate CTV structures were constructed from manual CTV delineations of the cervix-uterus on a full and empty bladder pCT in combination with an algorithm that utilizes Robust Point Matching for interpolation. Intermediate CTV structures were generated with a maximum distance of 1 cm between CTV structures. The number of CTV structures within the library depends on the maximum distance between the manual CTV delineations of the cervix-uterus on the full and empty bladder pCT (Figure). Two CTV-PTV margins were applied: A) 1 cm left-right and 1.5 cm in other directions, B) 1 cm isotropic. Subsequently, three observers, radiation therapists with plan selection experience, selected the most appropriate CTV out of the library for each CBCT of each patient. The observers verified for each CBCT if the uterus and cervical markers were in- or outside of the PTV corresponding to the selected CTV, for margin A as well as margin B.

Max distance between CTVs full and empty bladder pCT (cm)	# CTVs
≤ 0.5	1
> 0.5 and ≤ 1.5	2
> 1.5 and ≤ 2.5	3
> 2.5 and ≤ 3.5	4
> 3.5 and ≤ 4.5	5
> 4.5 and ≤ 5.5	6
> 5.5 and ≤ 6.5	7
> 6.5 and ≤ 7.5	8
> 7.5 and ≤ 8.5	9

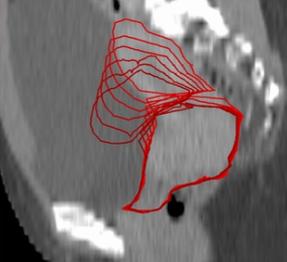

Figure. The number of CTV structures within the library depends on the maximum distance between the manual CTV delineations of the cervix-uterus on the full and empty bladder pCT (table). Intermediate CTV structures were generated with a maximum distance of 1 cm between CTV structures (sagittal view, full bladder pCT).

**Results**

For each patient, 23 pretreatment CBCTs and 7-11 post treatment CBCTs were included. For margin A, in 8% of the pretreatment and 15-17% of the post treatment CBCTs the top of the uterus was outside the PTV. For margin B, in 14-16% of the pretreatment and 25-26% of the post treatment CBCTs the top of the uterus was outside the PTV. For margin A, the cervical markers were always inside the PTV. For margin B, the cervical markers were outside of

the PTV in 1-2% of the pretreatment and 2-3% of the post treatment CBCTs.

**Conclusion**

The clinically used CTV-PTV margin of 1 cm left-right and 2 cm in other directions that is used for VMAT irradiation of cervical cancer could be reduced with the use of LoP, provided that the geometry of cervix-uterus with respect to the PTV is carefully monitored. Concluding, in order to reduce the CTV-PTV margin to a uniform 1 cm, a combination of a LoP strategy and a traffic light protocol to monitor outliers is advised.

PO-1014 Target volume motion during anal cancer IGRT using cone-beam CT

C. Brooks<sup>1</sup>, L. Bernier<sup>2</sup>, V. Hansen<sup>1</sup>, D. Tait<sup>2</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Physics, Sutton, United Kingdom

<sup>2</sup>The Royal Marsden NHS Foundation Trust, Department of Clinical Oncology, Sutton, United Kingdom

**Purpose or Objective**

Image guidance during anal cancer radiotherapy allows visualisation of soft tissue and the potential to reduce the margin applied to generate the PTV. In order to safely reduce planned PTV margins it is essential to understand the internal motion of the target volume to be treated to avoid a geographical miss and thus under dosage to the tumour. There is a paucity of published literature regarding an IGRT protocol and the internal target volume motion for anal cancer radiotherapy. At best there are a handful of studies that have investigated this area within rectal cancer. We prospectively analysed the setup data based on bone match for a cohort of anal cancer patients receiving radical radiotherapy using cone-beam CT (CBCT). Using this data we investigated and report the inter-fractional motion of the anal GTV for the same cohort of patients.

**Material and Methods**

20 patients with stage T1-4 N0-3 anal cancer were prospectively treated with radical radiotherapy using IMRT. All patients received 28 fractions of radiotherapy. CBCTs were acquired for the first 3 fractions and weekly thereafter as a minimum. A total of 196 CBCT images were acquired with 8 CBCTs as the minimum per patient. Each CBCT was exported to the treatment planning system with positional correction and registered with the planning CT. Retrospectively, the GTV of the anal canal tumour was localised again on the planning CT (as defined by the documented digital exam and multi-modality imaging) and all the CBCTs. The GTVs were localised by the same gastrointestinal clinical oncologist. To reduce bias the original planning GTV, CTV and PTV were absent. Similarly the CBCT GTV's were delineated in one session per patient to reduce variation in GTV contours caused by a time lapse. Volume data for all GTVs were collected. To measure CBCT GTV displacement compared to the planning CT all CBCT GTV's were collated into a single GTV contour. The maximum displacement was then measured in the anterior (A), posterior (P), superior (S), inferior (I) and lateral directions (R and L).

**Results**

The anal GTV volume size for the planning CT and the mean CBCT GTV volumes are reported in table 1 for all individual cases and for the whole group. The mean CBCT GTV volume was larger than the planning CT for the whole group analysed together. Large variations in the CBCT GTV were observed for some of the cases. Figure 1 shows the planning CT GTV in yellow and all the CBCT GTVs in orange. The maximum displacement between the planning CT GTV and the CBCT GTV envelope are also reported in table 1 for all individual cases and for the whole group. Some of these displacements were in the order of up to 2 cm.

Case	Planning CT GTV (cm <sup>2</sup> )	Volume size for all CBCT GTVs (cm <sup>2</sup> )		Maximum displacement between planning CT GTV edge and CBCT GTV envelope (cm)					
		Mean	Std Dev	Anterior	Posterior	Superior	Inferior	Right	Left
1	14.1	20.0	2.8	-0.5	1.4	-0.5	-1.0	0.7	-1.0

20	14.7	18.8	2.2	-0.9	0.7	0.8	0.3	0.5	0.0
mean	56.1	58.9	8.7	-0.6	0.6	0.4	-0.4	0.3	-0.3
stdev				0.5	0.6	0.4	0.7	0.5	0.6

### Conclusion

This study shows there are large displacements within the anal canal internal motion and caution should be applied when considering margins applied to the GTV. Further in depth study within this area is required when developing an IGRT protocol based upon soft tissue matching.

### PO-1015 Dosimetric comparison of the breath-hold based and conventional radiation therapy of lung cancer.

A.H. Choi<sup>1</sup>, K.Z. CHUNG<sup>1</sup>, B.S. PARK<sup>1</sup>, J.H. PARK<sup>1</sup>, H.R. PYO<sup>1</sup>, B.K. CHOI<sup>1</sup>

<sup>1</sup>samsung medical center, radiation oncology, Seoul, Korea Republic of

### Purpose or Objective

The breath-hold (BH) based radiation therapy (RT) is one of the motion management options for a moving tumor with a beneficial feature of increased lung volume. This additional feature can reduce the volume of normal lung irradiated by radiation and thus the radiation treatment related toxicities. In this study, we evaluated dosimetric properties of the BH based RT compared to those of the conventional free-breathing (FB) based RT of lung cancer.

### Material and Methods

Five patients with lung cancer received Deep Inspiration Breath-Hold (DIBH) respiratory training and then CT scan. The CT scans in DIBH were acquired following one FB scan and one 4DCT scan in cine-mode. In case the motion of the target volume in 4DCT scan is greater than 1 cm, a series of 6 scans in DIBH was acquired. A three dimensional conformal treatment plan was generated for each CT scan, giving each patient both FB and DIBH plan using the Pinnacle RTP system for photon plan and corresponding proton plans were generated by using RayStation. The

prescription dose for all five patients was 60Gy. The dose-volume characteristics of the total lung volume were compared in order to evaluate the dosimetric benefits, and the conformity index (CI) and homogeneity index (HI) were calculated as a treatment plan quality index.

### Results

In average, the total lung volume was increased by 27.2 % and the CTV volume was decreased by 22.1 % in DIBH. For photon plans, CI was improved by 20 % with DIBH but HI was not significantly different. The dosimetric parameters of lung volume were improved in DIBH: Dmean(Gy)(6 in FB and 4.8 in DIBH), V5(%) (25 in FB and 21 in DIBH), V10(%) (15 in FB and 11 in DIBH) and V20(%) (9 in FB and 7 in DIBH). For proton plans, CI and HI were not significantly different between BH and DIBH. The dosimetric parameters of lung volume were improved in DIBH: Dmean(Gy)( 3.2 in FB and 2.7 in DIBH) , V5(%) (11 in FB and 10 in DIBH), V10(%) (8.6 in FB and 7.4 in DIBH) and V20(%) (6 in FB and 5 in DIBH).

### Conclusion

DIBH provides an advantage to lung sparing by increasing total lung volume and reducing the normal lung volume in high-dose region. Therefore, DIBH could be recommended for the patient with tumor motion of >1cm. In addition, since the dosimetric difference in terms of CI between FB and DIBH in photon plans is larger than that in proton plans, DIBH could be considered in photon radiotherapy.

### PO-1016 Impact of CBCT based IGRT strategies on margins in IMRT of gynecological tumors after hysterectomy

M. Buijs<sup>1</sup>, M. Bloemers<sup>1</sup>, P. Remeijer<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

Several studies have investigated the vagina wall or vaginal cuff movement during post-operative radiotherapy of gynecological tumors, using fiducial markers (FM) to quantify the interfractional vaginal motion and derive proper CTV tot PTV margins. The aim of this study was to assess the accuracy of FM registrations on Cone beam CT and investigate the impact of different IGRT strategies on the margins for the CTV(vagina) and the electively treated lymph nodes(LN).

### Material and Methods

18 patients treated postoperatively for gynecological cancer were selected for this study. On 369 out of 441 (83.7%) CBCT's the interfractional vagina motion was measured by performing two registration methods

1) Soft Tissue (ST) registration using a 3D shaped Region of interest based on the CTV and a grey value registration algorithm.

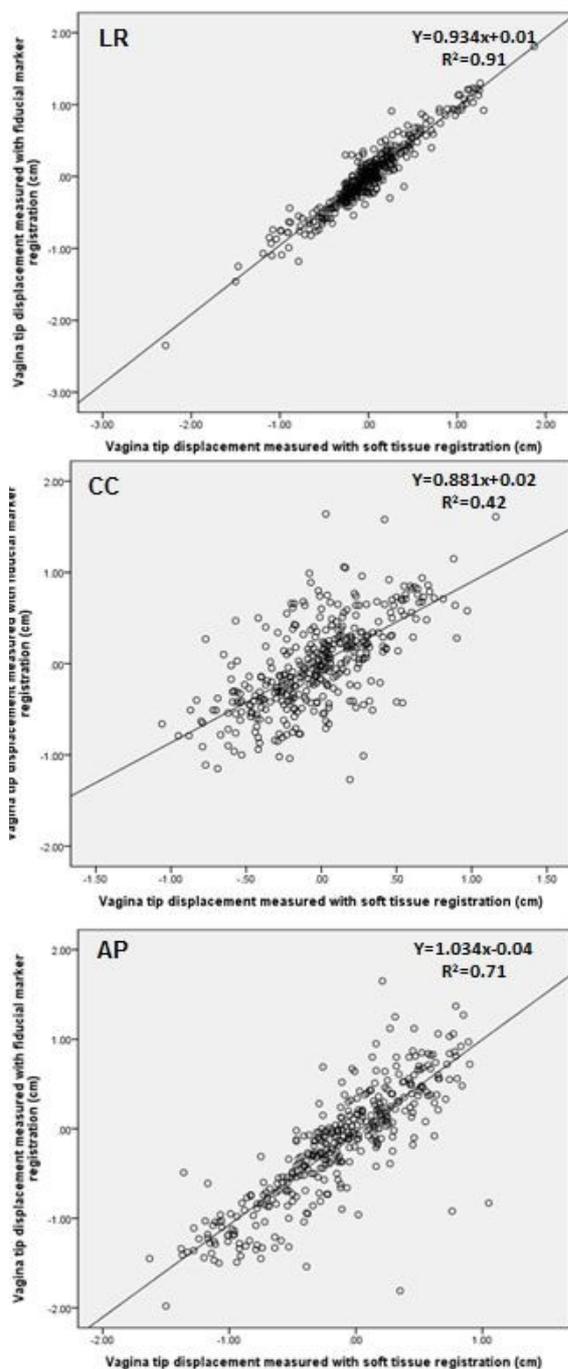

2) Fiducial Marker registration using a 3D shaped region of interest on the CTV and a chamfer match algorithm optimized for fiducial markers.

In 14.3% of the FM registrations and in 11.8% of the ST registrations a manual adaptation was performed to obtain a visual validated accurate registration. If that was not possible due to loss of markers during RT, shape deformation or poor CBCT quality, the results were excluded from analysis (16,3%). The results of both registration methods were compared using linear regression analysis to assess marker registration accuracy. Because ST registration was expected to be more representative for measuring the entire vagina motion than FM (as they are generally placed in the tip of the vagina), ST registration was used as golden standard. Using these motion measurements and online performed bony anatomy (BA) based corrections, the impact of BA and FM based IGRT strategies on the CTV to PTV margins for the CTV(vagina) and the CTV(LN) were evaluated.

### Results

Linear regression analysis shows a good agreement between the two registration methods in measuring the

interfractional vaginal motion in the LR and AP direction and a moderate agreement in the CC direction (see figure 1), which we in all directions significant ( $p < 0.00$ ). Considering only interfractional vagina motion, applying a BA based image guidance strategy requires CTV to PTV margins of 0.3 cm, 0.8 cm and 1.0 cm in the LR, CC and AP direction. When applying a FM or ST registration based imaging strategy the residual LN variability (which move with the BA) will be larger, and needs to be considered in the CTV to PTV margins, leading to LN margins of 0.3, 1.1 and 1.3 cm in the LR, CC and AP direction.

### Conclusion

FM registrations can be applied as an IGRT strategy to measure and correct the vagina motion. However applying FM registration increases the LN interfractional position variability, subsequently increasing the CTV to PTV margins for the LN regions even more in comparison to the margins needed to encompass the interfractional vagina

motion. We are currently investigating an offline adaptive workflow to address this.

### PO-1017 Dose guided adaptive radiotherapy based on cumulated dose in OAR for prostate cancer

M. Nassef<sup>1</sup>, A. Simon<sup>1</sup>, B. Rigaud<sup>1</sup>, L. Duvergé<sup>2</sup>, C. Lafond<sup>2</sup>, J.Y. Giraud<sup>3</sup>, P. Haigron<sup>1</sup>, R. De Crevoisier<sup>2</sup>  
<sup>1</sup>LTSI, INSERM U1099, Rennes, France  
<sup>2</sup>Centre Eugène Marquis, Radiothérapie, Rennes, France  
<sup>3</sup>CHU Grenoble, Radiothérapie, Grenoble, France

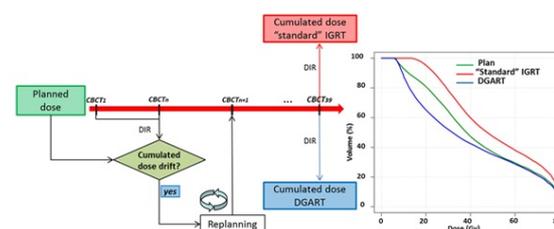

### Purpose or Objective

Large dose differences between planned and delivered doses may be observed in the rectum and in the bladder, resulting from anatomical variation in the course of prostate IMRT. The objective of this study was to compare dosimetrically an original approach of Dose Guided Adaptive Radiotherapy (DGART) to the standard IGRT (CBCT daily repositioning).

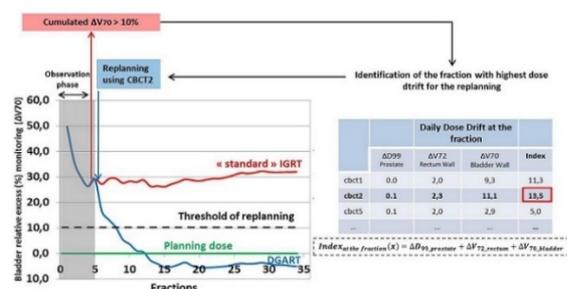

### Material and Methods

Based on a series of 24 patients with daily CBCT, planned and delivered dose were compared in manually delineated structures (prostate, rectum and bladder), using dose accumulation process after estimation of the fraction dose [Nassef et al, Radiother Oncol 2016]. The four patients with the most important overdose in the rectum wall and the bladder wall were selected to estimate the DGART benefit compared to the standard IGRT.

The DGART strategy (Figure 1) was based on replanning(s) triggered by monitoring the cumulated doses to the prostate, the rectum wall and the bladder wall. Thereby, the first step consisted in estimating the relative excess of the cumulated dose compared to the planned dose after every fraction for the prostate  $D_{99}$ , the rectum wall  $V_{72}$  and the bladder wall  $V_{70}$ . After an observation phase of 5 fractions, the adaptation was triggered (i.e. a replanning was performed), if a 2 % underdose of  $D_{99}$  for prostate or an overdose of 10 % on  $V_{72}$  for the rectum wall or  $V_{70}$  for the bladder wall occurred.

If a replanning was triggered at the fraction  $n$ , the CBCT chosen for the replanning corresponded to the anatomy leading to the highest dose drift compared to the planned dose. For that, for every fraction  $x$  ( $x=1..n$ ), an index (see figure 2) was calculated to select the morphology leading to the highest dose drift compared to the planned dose. If the relative excess was compensated by the replanning, no other adaption was needed and the new replanning was used for the rest of the fractions. If the relative excess was not compensated, the replanning process was repeated in case of a new CBCT leading to a higher index value. An example of DGART implementation is provided in Figure 2, showing the benefit of DGART to decrease the dose to the bladder.

## Results

For the four patients, the DGART resulted to only one replanning during the first week of treatment. For the rectum wall V<sub>72</sub>, the overdose was on average reduced of 50% (100% maximum) and the mean dose reduced of 4.5 Gy compared to standard IGRT. For the bladder wall V<sub>70</sub>, the overdose was on average reduced of 19% (37% maximum) and the mean dose reduced of 6.6 Gy compared to standard IGRT. For the prostate, the D<sub>99</sub> was on average 0.5 Gy higher (0.7 Gy maximum) using DGART compared to standard IGRT.

## Conclusion

DGART with only one replanning applied to a selected subgroup of patients may reduce the rectum and bladder overdose in prostate IGRT.

Poster: RTT track: Patient care, side effects and communication

## PO-1018 Improvement of radiation-induced late toxicity after hyperbaric oxygen treatment

R. Roncero<sup>1</sup>, J. Pardo<sup>1</sup>, E. Jimenez-Jimenez<sup>1</sup>, D. Morera<sup>2</sup>, N. Aymar<sup>1</sup>, I. Ortiz<sup>1</sup>, M. Vidal<sup>1</sup>

<sup>1</sup>Hospital Universitari Son Espases, Radiation Oncology, palma de mallorca, Spain

<sup>2</sup>Hospital Universitari Son Espases, Medical Physics, palma de mallorca, Spain

## Purpose or Objective

To assess the efficacy of hyperbaric oxygen therapy (HBOT) in the management of patients with radiation-induced late effects, in which more conservative treatments have failed

## Material and Methods

We retrospectively reviewed the clinical records of 33 patients treated at our Department, from 2012 to 2016, who developed late toxicity (Grade IV CTCAE4.0) and which did not respond to conservative treatment, and recorded the variation, if occurred, in the degree of toxicity after hyperbaric treatment. The average age of the patients was 61 +/- 12 years and the mean dose delivered during the radiotherapy treatment was 52 +/- 12Gy with standard fractionation. Regarding HBOT, they received an average of 61 sessions. The patients presented the following toxicities: enteritis/proctitis in 33%, bone necrosis and sacroileitis in 30%, skin injury 9%, Cystitis 6% and others 9% (neurocognitive impairment, dysphagia and xerostomy).

In order to its evaluation, responses were classified into three groups according the CTCAE4.0 scoring:

**Major Response Group:** Improvement of toxicity from Grade IV to Grade I or 0 (without toxicity, or minor toxicity not requiring medical treatment),

**Minor Response Group:** Improvement from Grade IV to Grade III/II (permanent toxicity controlled with medical treatment) and

**No Response Group.** The statistical study was carried out by using SPSS\_22.

## Results

Ninety-one percent of the patients (30) completed the treatment sessions with hyperbaric chamber scheduled (2

patients didn't start the treatment and 1 patient stopped after 4 sessions). Statistical significant toxicity improvement (p<0.05) was observed after the hyperbaric oxygen treatment. 60% of the patients presented a Major Response, and 18% presented a Minor Response. 9% (3) of our patients were no responders. In our patients, no relationship was founded between the response and the age, the number of sessions of HBOT, or the time elapsed since radiation treatment to the indication of the HBOT. Table 1 presents the patients outcomes according the toxicity.

Table 1. Patients outcomes according the toxicity

INDICATION FOR HBOT	TOTAL PATIENTS TREATED %	CHANGE OF TOXICITY			
		NO RESPONSE	MINOR RESPONSE	MAJOR RESPONSE	LOST
SKIN INJURY	9%	0%	0%	9%	0%
BONE NECROSIS	24%	0%	9%	12%	0%
SACROILEITIS	12%	3%	0%	9%	0%
ENTERITIS	18%	0%	0%	15%	3%
PROCTOCOLITIS	12%	3%	0%	6%	3%
CYSTITIS/HEMATURIA	12%	3%	3%	3%	3%
OTHERS	12%	3%	6%	3%	0%
OVERALL RESPONSE %	100%	0%	18%	58%	9%

## Conclusion

In our patients, there is a significant improvement in late radiation toxicity after HBOT, with the best responses being observed in gastro-intestinal and bone toxicity.

## PO-1019 Mobile Oncology: Survey with Healthcare Professionals about Telemedicine, mHealth and mobile Apps

K. Kessel<sup>1,2</sup>, M. Vogel<sup>1</sup>, F. Schmidt-Graf<sup>3</sup>, S. Combs<sup>2,3</sup>

<sup>1</sup>Technical University Munich TUM, Department of Radiation Oncology, München, Germany

<sup>2</sup>Institute for Innovative Radiotherapy iRT, Department of Radiation Sciences DRS, Neuherberg, Germany

<sup>3</sup>Technical University Munich TUM, Department of Neurology, München, Germany

## Purpose or Objective

Mobile applications (apps) are an evolving trend in the medical field. To date, no native mobile applications for smartphones or tablets in an oncological setting exist, which support patients during therapy and follow-up and allow for data analysis and/or direct feedback about therapy parameters. Moreover, there is an ongoing discussion whether such apps are really valuable, and whether healthcare professionals (HCP) will accept their use in clinical day-to-day life. Hence, we analyzed their attitude about telemedicine, mHealth, and mobile apps.

## Material and Methods

We developed an online survey with 24 questions evaluating HCPs' attitude towards telemedicine and patients using medical mobile apps in general, as well as specified questions on functionality and possible disadvantages of an app. A link to the survey was sent to all HCPs of our hospital via an in-house e-mail distributor and lasted for six weeks.

## Results

A total of 108 HCPs completed the survey. Of all, 88.9% consider telemedicine as useful, 84.3% versus 15.7% support the idea of an oncological app complementing classical treatment. Automatic reminders, timetables, laboratory results, and assessing side effects as well as quality of life during therapy were rated as the most important functions. In contrast, uncertainty regarding medical responsibility (88.2%) and data security (82.3%) were reasons mostly named by critics. The wish for personal contact between HCP and patient (41.2%), missing technical skills (23.5%) and disbelieving in improvements of data documentation (23.5%) are additional reasons. Of all respondents, 77.8% (84/108) believe in a resulting time saving if collected data by an

app are available at aftercare check-ups, while 22.2% (24/108) are not convinced of a benefit of app-based patient documentation. Favorable of an alert function due to data input by patients with the need for further clarification are 64.8% (versus 35.2%), 94.3% are willing to contact the patient after notification. Of all, 93.5% support the idea to use collected data for scientific research and 75.0% believe it could be beneficial for the providing hospital.

#### Conclusion

The present work shows a great approval for telemedicine, mHealth and apps in oncology amongst HCPs. Assessing side effects can lead to quicker response and thus lower inconvenience of patients. Clinical data as life quality and treatment satisfaction could be used to evaluate and improve the therapy workflow. Regular input of patient-reported outcome or side effects can be used to early detect and document the disease progression. Overall, this patient data can be used for scientific evaluations. Eventually, a mobile app would enhance the patient relation to his treating department as he has permanent contact using the mobile app - a trend also evolving in the medical field.

#### PO-1020 Re-irradiation of Head and Neck Sarcomas: initial results of Protontherapy Center of Trento, Italy

I. Giacomelli<sup>1</sup>, D. Scartoni<sup>1</sup>, M. Cianchetti<sup>1</sup>, F. Dionisi<sup>1</sup>, B. Rombi<sup>1</sup>, M. Amichetti<sup>1</sup>

<sup>1</sup>Azienda Provinciale per i Servizi Sanitari APSS Trento, U.O. di Protonterapia, Trento, Italy

#### Purpose or Objective

Radiotherapy for head and neck (H&N) recurrent sarcomas is usually limited by the dose tolerance of critical structures mainly in the skull base. Re-irradiation of such cases is rarely performed in clinical practice. Numerous dosimetric studies have shown that proton therapy (PT) can spare more healthy tissue than conventional X-ray therapy and it can result in fewer side effects. We report the preliminary results in terms of feasibility and tolerance of re-irradiation with PT for recurrent previously irradiated H&N sarcomas.

#### Material and Methods

Between November 2015 and September 2016 four patients (pts) with five recurrent H&N Sarcomas were re-irradiated with PT. Histology of the primary lesions were: pleomorphic sarcoma (1), alveolar rhabdomyosarcoma (2), sclerosing rhabdomyosarcoma (1), radiation-induced spindle cell sarcoma (1). Median age at re-irradiation was 30.0 years (range, 29.0-50.0 years). Karnofsky performance status was 90-100. Median interval time between previous radiotherapy and PT was 55.4 months; the median total dose received at the first radiotherapy course was 54.7 Gy (range, 50.4 - 60.0 Gy). Target definition was based on CT and MR imaging. Median CTV volume was 45.36 cc (range, 10.48-132.2 cc) and median PTV volume was 126.4 cc (range, 35.87-277.8 cc). Patients received a median total dose of 60.0 GyRBE (range, 50.0-60.0 GyRBE), 1.8-2.0 GyRBE per fraction; two pts received also sequential and one concomitant chemotherapy. All pts were treated with active beam scanning PT using 2-3 fields with single field optimization (SFO) technique. Acute and late toxicities were registered according to Common Terminology Criteria for Adverse Events version 4.0. Patients' quality of life was assessed using the EORTCEORTC QLQ-C30 questionnaire.

#### Results

Treatment was well tolerated: all patients completed PT without breaks. Acute Grade 3 cutaneous erythema occurred in four pts. Registered G2 toxicities were fatigue (1) and soft tissue edema (1). Concerning late toxicities, one patient had persistent G1 pain at the site of previous irradiation and in one pt acute G3 skin erythema became G1 chronic dyschromia. At a median follow-up of 7.4

months (range, 1.4-12.7 months), all pts are alive with controlled local and distant disease

#### Conclusion

Our preliminary experience shows that PT re-irradiation of recurrent H&N sarcoma is feasible and safe. Longer follow-up and a larger number of patients are needed to definitively assess efficacy and late toxicity.

#### Poster: RTT track: Risk management / quality management

#### PO-1021 An electronically configurable checklist program for quality control of RT treatment planning

K.H. Grosser<sup>1</sup>, A.C. Schulte<sup>1</sup>, W. Harms<sup>1</sup>  
<sup>1</sup>St. Claraspital, Radiooncology, Basel, Switzerland

#### Purpose or Objective

To assess efficacy of an adaptive checklist program to facilitate plan review for physicists.

#### Material and Methods

Pre-treatment plan review is fundamentally important to patient safety and treatment plan quality. A critical control point in this process is the 'Planning Approval' process. To reduce the error rate we developed an adaptive electronic planning approval checklist as part of our quality assurance. We applied this program to more than 600 treatment plans produced with the Eclipse treatment planning system (VARIAN). Because we wanted to optimize the checklist continuously the program was set up to be adaptive with respect to the plan type and to allow the addition of new checklist items. All evaluated cases were documented in a database. The incidence rates of errors and their types are reported.

#### Results

The checklist program was introduced into clinical routine in October 2012 and was used in this version until the end of 2015.

In total 638 plans were checked. With the help of this checklist program 303 errors in 190 treatment plans were detected. Most errors were classified as minor errors (i.e. incorrect target volume nomenclature). However, 29 dose-related errors have also been found.

13 new checklist items have been gradually added to the existing checklist to account for newly detected error possibilities.

The average time to complete the checklist was approximately 3 minutes. The compliance rate was very high. As expected, the acceptance of the "Do-Confirm" strategy was higher than for the "Read-Do" practice.

#### Conclusion

A planning approval checklist is a valuable tool to reduce the error rate of treatment plan validation to almost zero. An automated or semi-automated checklist tool with direct access to the database of the treatment planning system would be desirable.

#### PO-1022 Implementation of a paperless workflow in radiotherapy; Reducing transcription

O. Shoffren<sup>1</sup>, Y. Tsang<sup>1</sup>, J. Kudhail<sup>1</sup>  
<sup>1</sup>Mount Vernon Cancer Centre, Radiotherapy Department, Borehamwood, United Kingdom

#### Purpose or Objective

It is well recognised that due to the complexities of the radiotherapy pathway transcription errors are common. As such robust processes are in place throughout the treatment pathway to ensure checking processes are fit for purpose.

With the importance on using source data to eliminate this potential for transcription errors to arise, our centre has adopted a paperless workflow allowing access to source data; from referral to the last fraction of radiotherapy.

The aim of the study was to evaluate the effectiveness of the new workflow in terms of reducing errors.

#### Material and Methods

Since April 2016, a paperless workflow has been introduced for each area of the pathway including; referral, data capture at CT, planning information and treatment information up to the last fraction. A focus group was formed to investigate the options available for recording the required information at all stages. These included using an electronic referral and booking form, dynamic documents for recording treatment setup details, electronic journals for recording actions and histories throughout the treatment and toxicity scoring. All checks required on before, during and after treatments were assigned as tasks or checklists and these were made into a standardised automated protocol. All errors at our centre are recorded electronically on a centralised incidence reporting system. The numbers of error occurrences that happened 3 months before and after the introduction of the process were analysed.

#### Results

In total, there were 51 and 49 radiotherapy related incidents recorded before and after the introduction of the paperless workflow respectively. The number of incidents related to transcription errors decreased from 29% (15/51) to 16% (8/49) since the paperless change. It's noted that there was a small rise in reported incidences in other areas of the pathway due to a change in work procedure.

#### Conclusion

It's suggested the number of transcription errors was minimised through the adoption of the paperless workflow. It's also proved to be beneficial to have a centralised electronic incident reporting system to monitor and review incidents in a radiotherapy department, in order to streamline and optimise existing patient pathways.

#### PO-1023 Reducing waiting room times - A 5 year review of an in-house KPI tool

A. Wallis<sup>1</sup>, D. Moretti<sup>1</sup>

<sup>1</sup>Liverpool Hospital, Radiation Oncology, Liverpool, Australia

#### Purpose or Objective

Patient waiting times has a significant impact in a patient's overall satisfaction of their healthcare experience (1). The main contributors to patient waiting times are inadequate appointment duration, staff experience level, patient late arrival and machine breakdowns (1). Literature on radiation oncology productivity is dominated by variation and validation of the basic treatment equivalent (BTE) model (2). However, the technological advancements in imaging and treatment modalities such as intensity modulated radiation therapy (IMRT), image guided radiotherapy (IGRT), volumetric RT (VMAT) and Tomotherapy have changed the landscape of RT and its productivity measures (4).

In 2011, the management team at Liverpool and Macarthur Cancer Therapy Centres (LMCTC) introduced an in-house key performance indicator (KPI) tool to measure the performance of the treatment machines. The catalyst for the design and implementation of the tool was the introduction of the New South Wales (NSW) Performance Measures report of 2010 (3). The main objective of the tool was to capture each individual patient's appointment time to ensure adequate and individualised patient appointment scheduling. It was hypothesised that the introduction of this tool would reduce the waiting room time for patients.

#### Material and Methods

In 2010, Mosaic 2.0X was installed in LMCTC. This version allowed the extraction of time stamps in a reporting tool (Crystal reports version 11). Standardisation of the treatment processes improved the robustness of patient

data and allowed accurate extraction of time stamps in Mosaic. This data were then imported into Microsoft Excel on a weekly basis for visual display of the KPIs. The tool was launched in October of 2010 for a trial period of two months and has been in use in the department since its introduction.

#### Results

During the period of October to December 2010, the department recorded that 56% of patients were treated on time. Since the tool was introduced and actioned in 2011, the department has recorded an average of 71.2% (range 69-76%) of patients treated on time. These results are encouraging considering the number of attendances to the department has increased over the 5 year period (Fig 1). The percentage of patients arriving late to their appointment is 8% (range 7.0-9.1) (Table 1). The average waiting room time for a patient is 3.5 minutes (range 2.3 - 4.5 minutes).

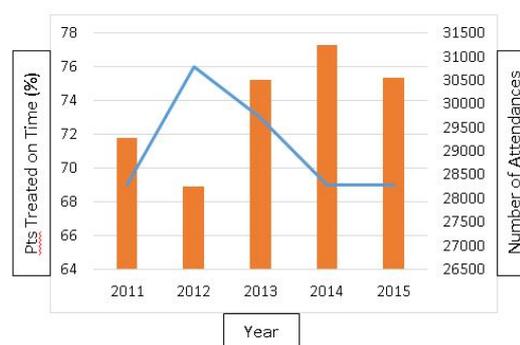

Fig 1: Number of attendances during the period of 2011 to 2015 shown in orange columns. The blue line shows the percentage of patients treated on time per year.

Year	2011	2012	2013	2014	2015
Late arrivals (%)	9.1	8.0	8.2	7.8	7.0

#### Conclusion

The development of an in-house KPI tool has reduced waiting time for patients at LMCTC. Since the introduction of the tool we have increased the number of patients treated on time from 56% to 71.2% over the past 5 years. This is despite the increasing patient attendances and changes in technology and complexity. Interestingly, despite improvements from hospital management to improve parking and access to the departments, 8% of patients do not arrive on time for their appointment.

#### PO-1024 Effectiveness of couch coordinate constraints to reduce error rates in radiation therapy delivery

O. Nairz<sup>1</sup>, N. Breitzkreutz<sup>1</sup>

<sup>1</sup>MVZ InnMed, Strahlentherapie, Oberaudorf, Germany

#### Purpose or Objective

"Movement from reference marks" is one of the most error-prone steps in the radiation therapy process. The use of indexed immobilization devices and constrained absolute, patient specific couch coordinates is generally considered to be an efficient tool to reduce the risk of radiation therapy errors (RTE) during treatment delivery. In the light of implementing a quantitative risk assessment we analyzed table coordinates of patients treated in our department. We investigated the effectiveness of tolerance values to lower the incidence of both wrong movements from reference marks and irradiation of the wrong patient or isocenter.

#### Material and Methods

Actual table values of patients in treatment position during a period of 18 months were extracted from the records of the verification system. Patient setups were

divided into four groups: thermoplastic head masks, patient specific indexed whole body vacuum cushions, doubly indexed non-patient-specific immobilization - i.e. indexed knee/feet rests together with indexed head or head and arm rests - and not indexed at all. For the definition of the tolerance windows we required that at most one in forty setups should provoke an interlock. Furthermore movements between reference marks and target points have to be large enough to violate the tolerances with a high probability if they are not performed. We required this probability to be 99%.

#### Results

For all four subgroups feasible interlock thresholds can be defined. Especially for patient specific immobilization devices they can be set very tightly. For thermoplastic masks the limits are below plus or minus one centimeter in all three directions and for the vacuum cushions the largest tolerance value, which is in the longitudinal direction, amounts to not more than  $\pm 2.5$  cm. But even ample tolerances, as we find for non-indexed immobilizations, should be implemented since they help to decrease the risk of irradiating the wrong patient or isocenter significantly.

Also the obtained minimum shifts from the reference marks are feasible and can easily be adopted in routine setup.

#### Conclusion

Tolerances to table coordinates help to detect shifts which are not applied at all or not in all directions. They also prove to be efficient in discriminating between two different isocenters or patients.

The values presented here are both dependent on the immobilization devices used and on the patient collective. Therefore each department has to examine the applicability of the values in its setting.

Especially if other technical means, e.g. surface scanning or RFID technology, are not available, indexed immobilization devices and couch coordinate tolerances can serve as a simple and effective method to reduce the risk of RTEs in treatment delivery.

#### PO-1025 Development of a in-house KPI tool

A. Wallis<sup>1</sup>, D. Moretti<sup>1</sup>

<sup>1</sup>Liverpool Hospital, Radiation Oncology, Liverpool, Australia

#### Purpose or Objective

Health informatics and data mining have enabled the analysis of operational performance and assist managers in making informed decisions in their departments (1). In 2010 the New South Wales Government in Australia requested that all departments, both public and private, were required to report on the percentage of patients treated within 10 minutes of their scheduled appointment time. At the time, the Liverpool and Macarthur Cancer Therapy Centres (LMCTC) did not have a tool which could measure the patient's waiting time. This was the catalyst for developing an in-house tool to measure the patient's waiting time as well as a number of other key performance indicators (KPIs). The purpose of this abstract is to present how an in-house tool can be developed and established within a department to measure departmental KPIs such as individual patient appointment times, patient waiting time, machine utilisation and the impact of changing techniques and technology.

#### Material and Methods

In 2010, Mosaik 2.0X was installed in LMCTC. This version allowed the extraction of time stamps into a reporting tool (Crystal Reports V11). Definition of a patient's appointment required the standardisation of the treatment processes. This ensured improved robustness of patient data and allowed accurate extraction of time stamps in Mosaik. The data from the reporting tool is imported into Microsoft Excel 2013 on a weekly basis for visual display and actioning on the KPIs.

#### Results

A weekly in-house KPI tool which compares machine utilisation and performance, completion of QA tasks and individual patient appointments has been utilised at LMCTC since 2011. The tool has enabled staff to monitor patient appointment duration on a daily basis and allows direct comparison with the patient's scheduled time. A traffic light system has been developed to allow easy visualisation of patient appointments requiring adjustment (Fig 1). A buffer time which is -12% and + 8% of the scheduled appointment time is applied to allow easy visualisation of appointments requiring action. Based on the results and traffic light display, each patient's appointments are adjusted for the following week, resulting in a machine schedule made up of individualised patient appointments. Queue times are compared with scheduled patient appointments to review the timeliness of patients attending their appointment. The tool was designed and released in October of 2010 for a trial period of two months and has been in use in the department since its introduction.

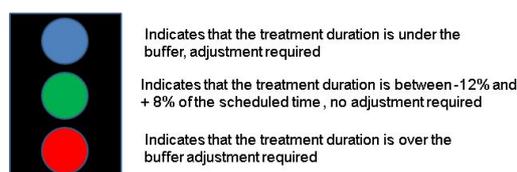

Figure 1: Traffic light system which compared individual appointment duration against the scheduled appointment time.

#### Conclusion

The development of an in-house KPI tool has many advantages for a radiation oncology department. Individual appointment times can be recorded and adjusted to ensure adequate time is allocated for an individual's needs. Ensuring adequate scheduling results in reducing patient waiting times and stress for treatment staff. It also displays machine utilisation and overall performance.

## Electronic Poster: Clinical track: Head and Neck

## EP-1026 Clinical Outcomes of Taiwan cT4b OSCC: Toward the Identification of the Optimal Initial Treatment

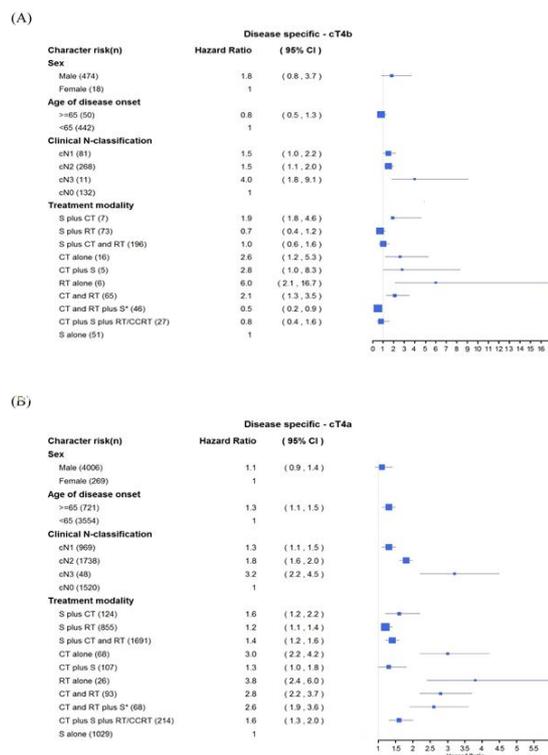

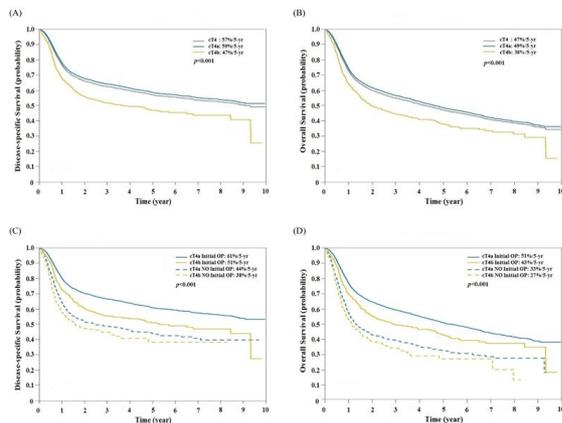

T.C. Yen<sup>1</sup>, C.T. Liao<sup>2</sup>, Y.W. Wen<sup>3</sup>, L.Y. Lee<sup>4</sup>, C.Y. Lin<sup>5</sup>, H.M. Wang<sup>6</sup>, C.H. Lin<sup>7</sup><sup>1</sup>Chang Gung Memorial Hospital, Nuclear Medicine, Taoyuan, Taiwan<sup>2</sup>Chang Gung Memorial Hospital, Otorhinolaryngology-Head and Neck Surgery, Taoyuan, Taiwan<sup>3</sup>Chang Gung University, Clinical Informatics and Medical Statistics Research Center, Taoyuan, Taiwan<sup>4</sup>Chang Gung Memorial Hospital, Pathology, Taoyuan, Taiwan<sup>5</sup>Chang Gung Memorial Hospital, Radiation Oncology, Taoyuan, Taiwan<sup>6</sup>Chang Gung Memorial Hospital, Medical Oncology, Taoyuan, Taiwan<sup>7</sup>Chang Gung Memorial Hospital, Plastic and Reconstructive Surgery, Taoyuan, Taiwan

## Purpose or Objective

The NCCN guidelines recommend that patients with oral cavity squamous cell carcinoma (OSCC) and cT4b disease should be either included in clinical trials or treated with a non-surgical approach. However, surgery may be feasible in selected patients with adequate safety margins. Using the nationwide Taiwanese Cancer Registry Database, we examined the prognosis of cT4b OSCC patients in relation to their treatment approach.

## Material and Methods

Of the 18,910 patients with previously untreated first primary OSCC identified between 2004 and 2010, 492 (2.6%) had cT4b tumors. Of them, 327 (66%) received initial treatment with surgery, whereas 165 (34%) were initially treated with a non-surgical approach. Of the latter group, 78 patients subsequently underwent surgery. A 5-year disease-specific survival (DSS)  $\geq 45\%$  was considered as a favorable outcome.

## Results

Better 5-year DSS and overall survival (OS) rates were observed in cT4b patients initially treated with surgery (versus non-surgery; DSS, 51% versus 38%; OS, 43% versus 27%, respectively,  $p < 0.001$ ). Of the participants initially treated with surgery, patients with cN0-2 disease had better 5-year survival rates (DSS: cN0, 59%; cN1, 53%; cN2, 46%; OS: cN0, 49%; cN1, 50%; cN2, 37%) than those with cN3 disease (DSS: 0%; OS: 0%). Among cT4b patients who initially received a non-surgical treatment, subjects who subsequently underwent surgery showed better outcomes.

## Conclusion

Primary surgery is performed in approximately two-thirds of cT4b OSCC patients, with cN0-2 cases showing a good prognosis. Patients who initially received a non-surgical approach can subsequently be treated with surgery and achieve favorable outcomes.

## EP-1027 Evaluation of induction chemotherapy followed by radiation therapy in advanced oropharyngeal cancers

R.K. Pothamsetty<sup>1</sup>, B.P. THALIATH<sup>1</sup>, R.R. GHOSH<sup>1</sup><sup>1</sup>Kamala Nehru Memorial Hospital, Radiation Oncology, Allahabad, India

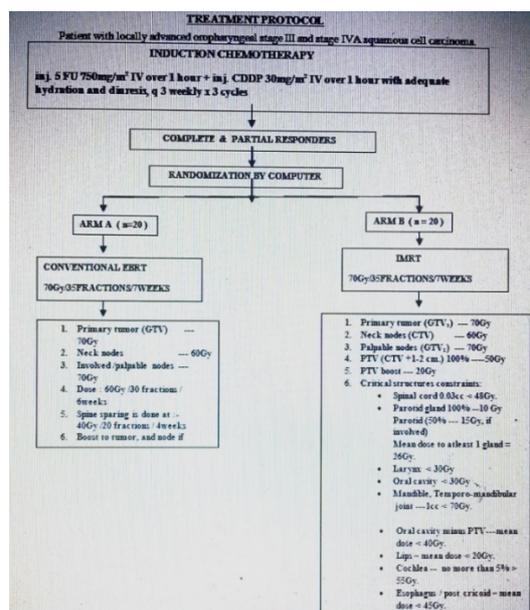

## Purpose or Objective

1. Evaluation of acute and late radiation morbidity using the RTOG criteria in both arms.
2. Evaluation of loco-regional failures, diffuse free survival and overall survival in both arms.

## Material and Methods

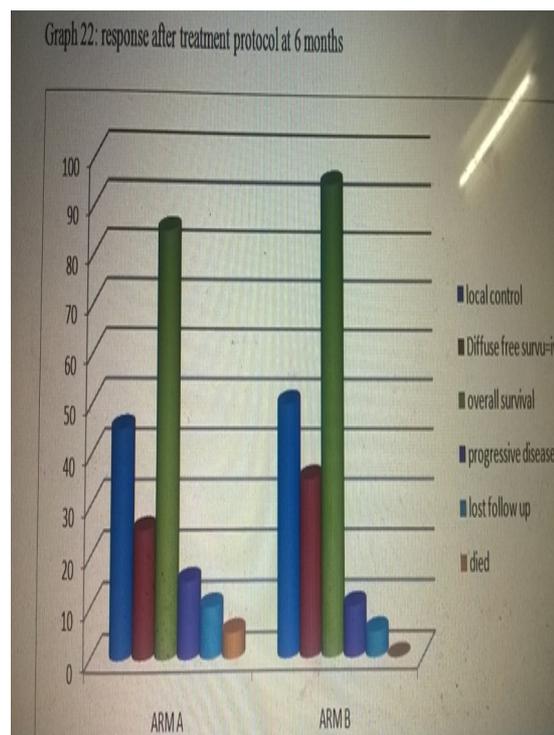

The study design was a prospective, comparative, randomized double arm study involving patients of all age groups of both the sexes, Stage III and Stage IVA oropharyngeal cancer who were biopsy proven squamous cell carcinoma reported to Kamala Nehru Memorial Hospital, Allahabad from February 2014-June 2015. They were subjected to induction chemotherapy as scheduled. Complete and partial responders were randomized into 2 arms: Arm A (Conventional external beam radiotherapy) and Arm B (Intensity modulated radiotherapy). Both the groups

received 70 Gy /35 fractions /7 weeks as per institutional protocol.

## Results

Out of 54 patients only 46 patients (85%) completed NACT. The most common side effect encountered during induction chemotherapy is nausea and vomiting representing 24%, followed by anorexia representing 20%. After completion of induction chemotherapy we had observed radiologically 24%, 63% and 13% as complete, partial and non-responders respectively. Acute toxicities like skin reactions, mucosal reactions, xerostomia, pharyngitis/hoarseness, upper GI side effects, and hematological complications are more in Arm A than Arm B. Patients in arm B has tolerated the local radiation therapy compared to the patients in arm A. The quality of life of patients in arm B compared to arm A was appreciable during the local treatment. At 6<sup>th</sup> month follow up local control, disease free survival, overall survival, found in arm A vs arm B was 45% vs 50%, 25% vs 35%, 85% vs 95% respectively. Progressive disease and lost to follow up was 15% vs 10%, 10% vs 5% respectively. Patients died in arm A vs arm B was 5% vs 0% respectively. Late radiation toxicities were assessed clinically at 6 months as per RTOG criteria and results had found not statistically significant.

## Conclusion

As observed in our study, 40 patients out of 54 has been down staged. Symptoms like swallowing, anorexia, tumor related pain, weight loss has been improved after induction chemotherapy. However, this study definitely showed down staging and better treatment tolerance towards IMRT arm in locally advanced oropharyngeal carcinoma. A long term study for longer follow up required for any statistically significant result. Better response can be expected in early stage disease

**EP-1028 MRI during radiotherapy: tumor geometry and changes in organs at risk for head-and-neck patients**  
C. Grundmann<sup>1</sup>, K.A. Kessel<sup>1,2</sup>, S. Pigorsch<sup>1</sup>, S. Graf<sup>3</sup>, F. Nüsslin<sup>1</sup>, S.E. Combs<sup>1,2</sup>

<sup>1</sup>Technische Universität München TUM, Department of Radiation Oncology, München, Germany

<sup>2</sup>Helmholtz Zentrum München, Institute for Innovative Radiotherapy iRT, Neuherberg, Germany

<sup>3</sup>Technische Universität München TUM, Department of Otorhinolaryngology, München, Germany

## Purpose or Objective

The use of image-guided radiotherapy (IGRT) leads to a protection of OARs and a resulting reduction of side effects for the patient. The aim of this work is to make a statement about the relevance of MRI during radiotherapy (RT) and illustrate the importance for radiation oncology.

## Material and Methods

In a retrospective analysis, for 17 patients with head-and-neck-cancer, the volume of eight OARs relevant for swallowing was examined on MRI. Contouring was performed on MRI before, during and after radiation and the dose applied to the OARs was determined. Five of the 17 patients additionally participated in a voice and swallowing test on average 22.2 months after RT. Three questionnaires (Anderson Dysphagia Inventory (ADI-D), Voice Handicap Index, EORTC QLQ-H&N35) were used to evaluate subjective voice and swallowing disorders and the related quality of life.

Additionally, fiberoptic endoscopic evaluation of swallowing (FEES) and a voice test were performed, including the assessment of the patient's phonation and

the severity of the vocal disorder after the Dysphonia Severity Index (DSI). Rosenbeks 8-points-penetration-aspiration-scale (PAS, Rosenbek 1996) was used to determine the severity. The Functional Oral Intake Scale (FOIS) classified by Crary (Crary et al., 2005) was used to assess the oral food intake of the patients.

#### Results

A paired t-test showed a significant change in volume of five OARs: superior and middle pharyngeal constrictor muscle, cricopharyngeal muscle, proximal esophagus and transglottic larynx ( $p \leq 0.055$ ). There was a significant increase in volume in four OARs and a significant decrease in the proximal esophagus. The linear regression analysis of the volume changes of the respective OARs and the applied dose showed no significant correlation. The binary logistic regression showed a significantly ( $p = 0.015$ ) 1.5 times higher risk to suffer from dysphagia when the dose is increased by steps of 1 Gy. No association could be found for dose-dependent dysphonia. The results of the FEES showed conspicuous PAS levels in all five subjects and the FOIS scale reached grade 3 to grade 6. Also, dysphonia ranged from a mild to a high degree. The evaluation of the ADI-D questionnaire correlated with the degree "rather conspicuous" in the Bauer and Rosanowski Scale. The Voice Handicap Index showed one patient with a moderate and four with no subjective voice disorder. Apart from problems caused by xerostomia only minor discomfort in respect of tumor-specific symptoms was observed based on the EORTC QLQ-H&N35 questionnaire.

#### Conclusion

In this study, a tendency of increase in the volume of OARs under RT with distinct clinical symptoms (dysphagia and dysphonia) was detected, also after more than one year post-RT. MRI use for RT is essential for an optimal protection of the OARs in terms of adaptive radiotherapy (ART) and is expected to improve treatment as MR-guided radiotherapy (MRgRT)

#### EP-1029 Improved interobserver reproducibility in nasopharyngeal tumor delineation using a reference GTV

A. Lapiere<sup>1</sup>, F. Lorchel<sup>1</sup>, P. Boisselier<sup>2</sup>, B. Fleury<sup>3</sup>, F. Craighero<sup>4</sup>, M. Deberne<sup>1</sup>, G. Gascou<sup>5</sup>, M. Rousset<sup>6</sup>, V. Favrel<sup>1</sup>, J.B. Pialat<sup>7</sup>, J.M. Ardiet<sup>1</sup>, P. Céruse<sup>8</sup>, O. Chapet<sup>1</sup>

<sup>2</sup>CRLC Val d'Aurelle, Service de Radiothérapie, Montpellier, France

<sup>3</sup>Centre Marie Curie, Service de Radiothérapie, Valence, France

<sup>4</sup>Centre Hospitalier Universitaire Croix Rousse, Service de Radiologie, Lyon, France

<sup>5</sup>Centre Hospitalier Universitaire Saint Eloi, Service de Radiologie, Montpellier, France

<sup>6</sup>Centre Hospitalier Lyon Sud, Service de Radiologie, Pierre Benite, France

<sup>7</sup>Centre Hospitalier Universitaire Edouard Herriot, Service de Radiologie, Lyon, France

<sup>8</sup>Centre Hospitalier Universitaire Croix Rousse, Service de chirurgie ORL, Lyon, France

#### Purpose or Objective

Standard treatment for nasopharyngeal cancer (NPC) relies on concurrent chemoradiotherapy, using intensity modulated radiotherapy (IMRT). Adequate tumor volume definition is essential for precision radiotherapy such as IMRT. However, tumor volume delineation reproducibility on CT scans has been shown to be variable among radiation oncologists. The main goal of this study was to assess the reproducibility of radiologists in defining nasopharyngeal tumor volumes, and whether a common gross tumor volume (GTV) delineated by specialized radiologists would improve reproducibility between radiation oncologists in

defining high risk tumor clinical target volumes (CTV) in NPC cases.

#### Material and Methods

Ten patients treated at our institution over the last 5 years for nasopharyngeal tumors were selected for the study. In the first part of the study, five experienced radiation oncologists were asked to independently delineate tumor GTV and high risk tumor CTV. Meanwhile, three radiologists independently delineated the tumor GTV on the diagnosis MRI, after which, the radiation oncologist were asked to delineate the high risk tumor CTV again, using the reference GTV delineated by the radiologists.

#### Results

The intraclass correlation coefficient (ICC) for GTV delineation was 0.914 for radiologists, and 0.754 for radiation oncologists. Use of a common GTV increased the generalized conformity index ( $CI_{gen}$ ) from 0.44 to 0.49 for CTV delineation by the radiation oncologists.

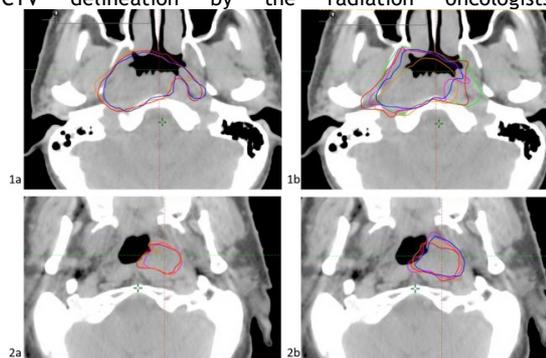

Figure 1: Examples of GTV delineations

1: patient with a T4 tumor. 1a: GTV delineated by the radiologists. 1b: GTV delineated by the radiation oncologists. 2: patient with a T1 tumor. 2a:

GTV delineated by the radiologists. 2b: GTV delineated by the radiation oncologists

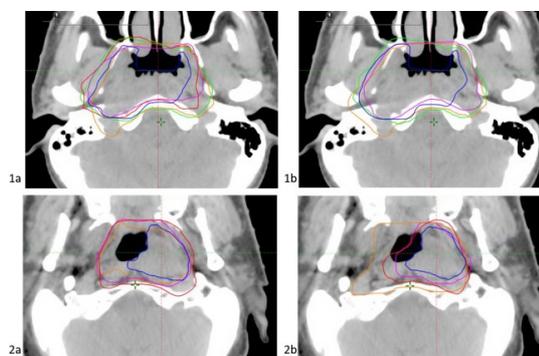

Figure 2: First and second draft high risk tumor CTV delineations

1: patient with a T4 tumor. 1a: first draft CTV. 1b: second draft CTV, using

the reference radiologist GTV. 2: patient with a T1 tumor. 2a: first draft CTV. 2b: second draft CTV

#### Conclusion

Interobserver variations tend to be lower between radiologists than radiation oncologists in the definition of NPC tumor volumes, and that use a single reference GTV improves reproducibility between radiation oncologists.

#### EP-1030 External beam radiation therapy for locoregionally recurrent differentiated thyroid carcinoma

C.Y. Kim<sup>1</sup>, N.K. Lee<sup>1</sup>, K.Y. Jung<sup>2</sup>, S.K. Baek<sup>2</sup>

<sup>1</sup>Korea University Anam Hospital, Radiation Oncology, Seoul, Korea Republic of

<sup>2</sup>Korea University Anam Hospital, Otolaryngology-Head and Neck Surgery, Seoul, Korea Republic of

#### Purpose or Objective

the purpose of this study was to evaluate the treatment outcomes of external beam radiation therapy in patients

with locoregionally recurrent differentiated thyroid carcinoma.

#### Material and Methods

The data of 21 patients with locoregionally recurrent differentiated thyroid papillary carcinoma who underwent external beam radiation therapy between 2001 and 2010 were analyzed retrospectively. External beam radiation therapy was considered for locoregional recurrence that is unresectable or with extranodal extension or involvement of soft tissues. The primary endpoint was the locoregional recurrence-free survival rate.

#### Results

The median follow-up time was 87 months (range, 38 to 173 months). Six (28.6%) patients developed treatment failure: Two (9.5%) patients had locoregional failure and 4 (19.4%) patients had distant failure. The 10- and 14-year locoregional relapse-free survival rates were 89.9% and 89.9%, respectively. The 10- and 14-year distant relapse-free survival rates were 77.3% and 51.6%, respectively. The 10- and 14-year overall survival rates were 95.2% and 71.4%, respectively.

#### Conclusion

External beam radiation therapy can achieve favorable treatment outcomes. External beam radiation therapy should be considered for locoregional recurrence that is unresectable or with extranodal extension or involvement of soft tissues.

#### EP-1031 FDG-PET/CT as a guide for Intensity-Modulated Radiation Treatment of advanced head and neck cancer

F. Ricchetti<sup>1</sup>, R. Mazzola<sup>1</sup>, S. Fersino<sup>1</sup>, N. Gaj-Levra<sup>1</sup>, A. Fiorentino<sup>1</sup>, U. Tebano<sup>1</sup>, D. Aiello<sup>1</sup>, R. Ruggieri<sup>1</sup>, F. Alongi<sup>1</sup>  
<sup>1</sup>Sacro Cuore Don Calabria Cancer Care Center, Radiation Oncology Department, Negrar, Italy

#### Purpose or Objective

To analyze the impact of Fluorodeoxyglucose-PET/CT (PET/CT) in the radiotherapy (RT) planning-strategy in head and neck cancer, focusing on neck-nodes treatment planning and correlating CT-scan and PET/CT performances.

#### Material and Methods

Inclusion criteria of this retrospective analysis were: age > 18 years old, histologically proven squamocellular head and neck cancer, patients candidate to curative Intensity-Modulated Radiation Treatment ± chemotherapy, evaluation of stage of disease by means of PET/TC and CT-scan performed at our Institution.

#### Results

Sixty patients, treated between October 2011 and February 2016, were included in the analysis. Primary tumor site was represented as follow: Nasopharynx in 8 patients (13%), Oropharynx in 25 (42%), Oral Cavity in 19 (32%) and Larynx non-glottic in 8 (13%). Oral cavity tumors revealed to be at particular risk of nodal stage migration, occurring in 21% of cases (5/19). PET/CT findings caused changes in the management of RT volumes in 10% of patients. In one case of nasopharynx cancer, PET/CT allowed to detect the primary tumor previously unknown at CT-scan, in 5 cases of oral cavity tumors neck-nodes PET/CT positive from one side and/or the opposite (not detected at CT-scan) were included in the high-risk volume, and in 2 cases of oropharyngeal cancer RT was avoided because of distant metastases.

#### Conclusion

Present findings show that PET/CT images could be a guide in head and neck cancer in order to individualize the RT curative strategy. Further investigations are advocated to evaluate if this strategy could impact on long-term outcomes in these patients.

#### EP-1032 Optimising head and neck radiotherapy for dental rehabilitation

S. O'Cathail<sup>1</sup>, N. Karir<sup>2</sup>, K. Shah<sup>3</sup>

<sup>1</sup>CRUK/MRC Institute for Radiation Oncology University of Oxford, Oncology, Oxford, United Kingdom

<sup>2</sup>Oxford University NHS Foundation Trust, Department of Dentistry, Oxford, United Kingdom

<sup>3</sup>Oxford University NHS Foundation Trust, Department of Oncology, Oxford, United Kingdom

#### Purpose or Objective

Squamous cell carcinomas (SCC) of the oropharynx are potentially curable cancers with a combination of surgery, radiotherapy or chemoradiotherapy. Osteoradionecrosis (ORN) is a significant late side effect of radiotherapy. Recent data suggests the risk of mandible ORN increases significantly if the mean dose is >37.5Gy. The anterior mandible is an important structure for dental rehabilitation, with implants in this area regarded as the standard of care. Our study had two aims; firstly to accurately describe the dose distribution to defined areas of the mandible and maxilla in a population of oropharyngeal patients receiving radical (chemo)radiation. Secondly, to test *in silico* the hypothesis that it is possible to limit the dose to the anterior mandible to facilitate implant-based rehabilitation.

#### Material and Methods

All radically treated oropharyngeal patients between March 2014 and March 2015 treated at our centre were reviewed. The inclusion criteria were patients over the age of 18, with an oropharyngeal primary (tonsil or tongue base) SCC, who had treatment with primary (chemo)radiotherapy dose of 65Gy in 30 fractions and who required nodal irradiation. Only patients treated using a volumetric arc therapy dose solution were included, and static gantry IMRT was excluded. Treatment records were reviewed for patients' characteristics including age, primary site, tumour size, nodal stage, HPV status, dentate status and use of cisplatin based chemotherapy. A published mandible and maxilla contouring atlas was used to create 6 sextant volumes; 3 in each structure. Plans were selected for replanning if the anterior mandible sextant received a mean dose of >37.5Gy. Ethical approval for the study was obtained by the West Midlands Research Ethics Committee. Radiotherapy planning was performed on Varian Eclipse RapidArc v.11 and calculated using Varian's Analytical Anisotropic Algorithm (AAA) 10.0.28. All replans were approved by a Consultant Clinical Oncologist who specialises in Head and Neck treatment.

#### Results

60 patients were included. Patient characteristics are outlined in Table 1 and dose metrics to each mandible sextant, by primary site, are described in Table 2. Patients who had Level I nodal irradiation received significantly higher doses to the anterior mandible (Wilcoxon rank sum,  $p < 0.0001$ ). 11 patients were included in the planning study as per study protocol. 91% were successfully re-optimised to a Mean Dose < 37.5Gy. Replanned patients had statistically significant increased doses in spinal cord D1cc (Wilcoxon signed rank,  $p = 0.005$ ) and spinal cord PRV D1cc (Wilcoxon signed rank,  $p = 0.002$ ), but remained within absolute tolerances. Other organs at risk received no statistically significant increase in dose.

Table 1: Patient Characteristics

Gender	N (%)

<b>Right Lateral Mandible</b>				
Maximum dose (Gy)	65 (44.5 – 67.8)	54.1 (20.4 – 63.5)	65.95 (32 – 68.7)	< 0.002
Mean Dose (Gy)	41.38 (33.03 – 58.51)	38.09 (14.52 – 50.52)	46.57 (20.2 – 62.49)	< 0.05
V <sub>100</sub> (%)	10.62 (0 – 89.65)	1.335 (0 – 56.4)	36.1 (0 – 97.94)	< 0.02
V <sub>105</sub> (%)	1.87 (0 – 48.47)	0 (0 – 2.29)	3.47 (0 – 82.13)	< 0.002

### Conclusion

Dose to the anterior mandible could be constrained in most patients. Planned use of this technique will further inform pre-treatment dental assessments and allow greater prospective planning of dental rehabilitation to improve head and neck cancer survivorship.

### EP-1033 Survival patterns in elderly head & neck squamous cell carcinoma patients treated with definitive RT

L. Sommers<sup>1</sup>, R. Steenbakkers<sup>1</sup>, H. Bijl<sup>1</sup>, J. Vemer-van den Hoek<sup>1</sup>, J. Roodenburg<sup>2</sup>, S. Oosting<sup>3</sup>, S. De Rooij<sup>4</sup>, J. Langendijk<sup>1</sup>

<sup>1</sup>UMCG University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands

<sup>2</sup>UMCG University Medical Center Groningen, Oral and Maxillofacial Surgery, Groningen, The Netherlands

<sup>3</sup>UMCG University Medical Center Groningen, Medical Oncology, Groningen, The Netherlands

<sup>4</sup>UMCG University Medical Center Groningen, University Center for Geriatric Medicine, Groningen, The Netherlands

### Purpose or Objective

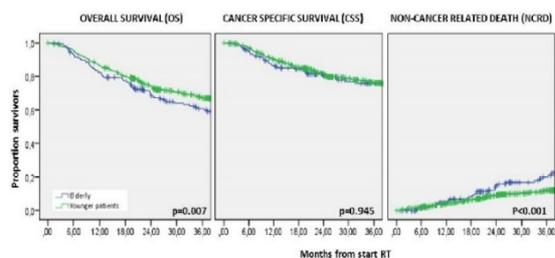

To investigate the effect of age on overall survival (OS), cancer-specific survival (CSS) and non-cancer related death (NCRD) in elderly (i.e. ≥70 years) head and neck squamous cell carcinoma (HNSCC) patients treated with definitive radiotherapy compared to younger patients and determine the most important prognostic factors on these survival endpoints.

### Material and Methods

This was a retrospective analysis of prospectively collated data of all consecutive HNSCC patients treated between April 2007 and December 2014 at our department with primary curative radiotherapy (66-70 Gy). Multivariable association models for age were performed as well as a multivariate analysis to identify potential prognostic factors for these endpoints in only the elderly patients.

### Results

The study population was composed of 674 consecutive patients, including 168 elderly patients (24.9%). Three-year OS and NCRD rates in elderly patients were significantly worse, respectively p=0.007 and p<0.001. In the multivariable association analysis on the relation between age and OS, lymph node involvement and worse WHO performance status were found significant confounders. Multivariable association analysis between age and NCRD only identified UICC stage as a significant confounder. Worse WHO performance status, lymph node involvement and specific tumor site were independent prognostic factors for OS and CSS in the elderly patients. Almost half of the elderly patients died during follow-up, of which 45.0% due to index tumor. In elderly patients, treatment with combined modality (radiotherapy with systemic agent) was significantly associated with adverse NCRD.

Independent prognostic factors	B	P-value	HR	95% CI HR
<b>Overall survival</b>				
WHO-performance baseline		<0.001		
WHO 1 versus WHO 0	0.992	<0.001	2.69	(1.63 - 4.46)
WHO 2/3 versus WHO 0	1.146	0.001	3.14	(1.58 - 6.28)
<b>N-stage</b>				
N-plus versus N0	0.904	0.002	2.47	(1.40 - 4.37)
<b>Primary tumor</b>				
Hypopharynx versus larynx	0.052	0.906	1.05	(0.44 - 2.50)
Oropharynx/nasopharynx versus larynx	0.048	0.883	0.95	(0.50 - 1.81)
Oral cavity versus larynx	1.073	0.003	2.92	(1.45 - 5.89)
<b>Cancer specific survival</b>				
WHO-performance baseline		0.014		
WHO 1 versus WHO 0	1.045	0.008	2.84	(1.31 - 6.17)
WHO 2/3 versus WHO 0	1.215	0.016	3.37	(1.25 - 9.09)
<b>N-stage</b>				
N-plus versus N0	0.988	0.022	2.69	(1.15 - 6.25)
<b>Primary tumor</b>				
Hypopharynx versus larynx	0.269	0.514	1.51	(0.44 - 5.21)
Oropharynx/nasopharynx versus larynx	0.269	0.582	1.31	(0.50 - 3.41)
Oral cavity versus larynx	1.382	0.005	3.98	(1.51 - 10.5)
<b>Non-cancer related death</b>				
WHO-performance baseline		0.001		
WHO 1 versus WHO 0	1.036	0.003	2.82	(1.44 - 5.52)
WHO 2/3 versus WHO 0	1.533	0.001	4.63	(1.87 - 11.5)
<b>Treatment modality</b>				
Accelerated versus conventional fractionation	0.112	0.760	1.12	(0.55 - 2.29)
Combined modality versus conventional fractionation	1.498	0.002	4.47	(1.73 - 11.5)

## Conclusion

Elderly HNSCC patients have worse survival outcomes in relation to younger patients. Age is an independent prognostic factor for OS, mainly due to an increase in non-cancer related mortality and comorbid diseases.

## EP-1034 Significance of mutant p53 and Ki67 as predictive biomarkers post Chemo-RT in locally advanced HNSCC

P. Baskaran Shanmuga<sup>1</sup>, K. Periasamy<sup>1</sup>, S. Sharma<sup>2</sup>, G.K. Singh<sup>1</sup>, K. Pratap<sup>1</sup>, P. Singh<sup>2</sup>, V. Yadav<sup>1</sup>, A.K. Mandal<sup>2</sup>, K.T. Bhowmik<sup>1</sup>

<sup>1</sup>Safdarjung Hospital, Radiotherapy, New Delhi, India

<sup>2</sup>Safdarjung Hospital, Pathology, New Delhi, India

## Purpose or Objective

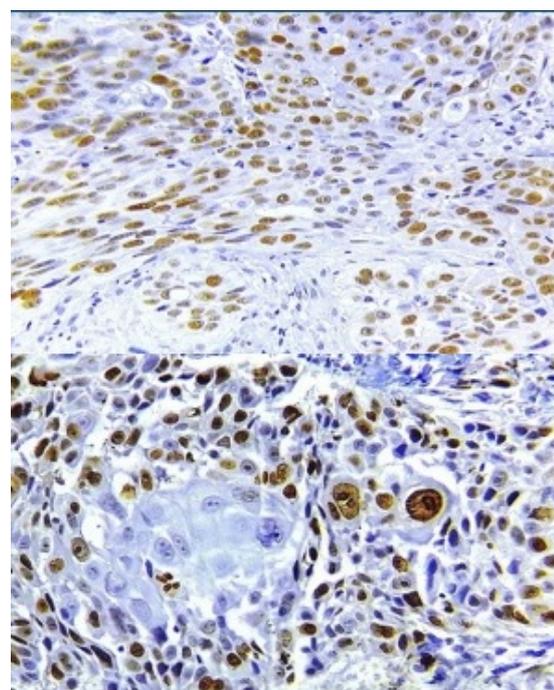

The heterogeneity in outcome following chemoradiation (CRT) in locally advanced HNSCC has drawn the attention of clinical researchers towards molecular markers. Despite almost three decades of research the role of several biomarkers remain uncertain. This study intended to speculate the significance of expression of mutant p53 and Ki67 in treatment response, locoregional control and survival.

## Material and Methods

This prospective observational study included 62 patients with stage III-IV non-nasopharyngeal head and neck squamous cell carcinoma of which 58 patients completed CRT. Immunohistochemistry was done on the pre-treatment biopsy specimens and the expression of mutant p53 and Ki67 in the tumor were graded based on the degree of nuclear staining as negative (0%), low ( $\leq 20\%$ ), medium ( $>20\%$  -  $<40\%$ ) and high ( $\geq 40\%$ ). For statistical analysis, negative and low expressions were categorized

as negative whereas medium and high expressions were categorized as positive. The initial response to CRT was documented at 8 weeks post CRT and patients were followed up for a minimum period of one year for locoregional control and survival.

		Relative Risk	95% confidence interval	Chi-square	p Value		
Relative Risk (RR)	Treatment response at 8 weeks post CRT	p53	7.886	2.058 to 30.211	17.771	<0.001	
		Ki67	3.361	1.334 to 8.467	8.513	0.004	
	Disease status at 1 year post CRT	p53	6.332	2.188 to 18.444	24.602	<0.001	
		Ki67	3.300	1.493 to 7.293	13.047	<0.001	
Logistic regression	Survival at 1 year post CRT	p53	2.629	0.313 to 22.058	0.213	0.644	
		Ki67	2.444	0.292 to 20.491	0.146	0.702	
	Treatment response at 8 weeks post CRT	Variable	Coefficient	Std. Error	Odds ratio	95% CI	P
	Disease status at 1 year post CRT	p53 Absent	3.33153	0.82474	22.9091	4.5496 to 115.3560	0.0001
	p53 Present	1.47266	0.76451	32.2222	7.2009 to 144.1882	<0.0001	
	Survival at 1 year post CRT	N0 & N1 (Early nodal stage)	2.41080	1.16063	11.1425	1.1416 to 108.3796	0.0378

## Results

60% of the patients had p53 expression and 62% had Ki67 positivity.

Positive expression of p53 and Ki67 had a statistically significant relative risk (RR) of 7.88 ( $p<0.001$ ) and 3.36 ( $p=0.004$ ) respectively for treatment failure at 8 weeks post CRT. Similarly, positive expression of p53 and Ki67 had a statistically significant relative risk (RR) of 6.32 ( $p<0.001$ ) and 3.30 ( $p<0.001$ ) respectively for locoregional failure and distant metastases at 1 year post CRT. On multivariate analysis, the absence of p53 was a statistically significant independent predictor for complete response at 8 weeks and locoregional control at 1 year post CRT with an Odds ratio of 22.90 ( $p=0.0001$ ) and 32.22 ( $p<0.0001$ ) respectively. Likewise, the presence of early nodal stage (N0 - N1) was a statistically significant independent predictor for survival with an Odds ratio of 11.14 ( $p=0.0378$ ). Positivity of p53 and Ki67 showed a RR of 2.62 ( $p=0.64$ ) and 2.44 ( $p=0.70$ ) respectively, for mortality, although their values did not reach statistical significance.

## Conclusion

The presence of p53 and Ki67 were associated with significant risk of treatment failure, poor locoregional control and distant metastasis whereas the absence of p53 and early nodal stage favored locoregional control and

survival respectively. These results signify the predictive roles of p53 and Ki67 in treatment of head and neck cancer.

#### EP-1035 Dose-volume analysis of the hypoglossal nerve and its correlation with Dysarthria-Dysphagia Syndrome

F. Chen<sup>1</sup>, R. Rer<sup>2</sup>

<sup>1</sup>Chenzhou No.1 People's hospital, radiation oncology, chenzhou, China

<sup>2</sup>Yee-Ren Hospital, Radiation Oncology, taibei, Chinese Taipei

##### Purpose or Objective

Cranial nerve palsy is a radiotherapy-related late toxicity in nasopharyngeal cancer patients after radiotherapy, and the glossopharyngeal, vagus and hypoglossal nerve are the most commonly damaged, causing speech and swallowing handicap. Damage to the larynx or pharyngeal constrictor muscles have been mentioned as the cause of swallowing disorder in head & neck cancer patients after radiotherapy. We hypothesize that direct radiation damage to the nerve is the etiology of hypoglossal palsy and the subsequent dysarthria-dysphagia syndrome. This study aims to test our hypothesis using dosimetric data.

##### Material and Methods

Twelve Nasopharyngeal Cancer Patients were enrolled in this study, with three patients for each stage. They all received IMRT technique. We gave 70 Gy to the nasopharynx and positive neck lymph node, 60 Gy to the high-risk neck and 50 Gy to the low-risk neck. We contoured the larynx and the constrictor muscles including superior, middle, inferior, cricopharyngeus, and the proximal esophagus. Hypoglossal nerve was also delineated and divided into cisternal, intracanalicular, carotid, horizontal, and lingual part. The Maximal Dose, Minimal Dose, Mean Dose, V50, V55, V60, V65 and V70 were derived using Varian Eclipse planning system, respectively.

##### Results

Of the constrictor muscle, the superior always had the highest dose in all stages. V65 of the superior constrictor muscle was 60%±15%, 100%±20%, 100%±21.6% and 78.4%±14.3% for stage I, II, III & IV, respectively. V60 of the larynx was 2.75%±0.65%, 11.7%±0.3%, 12.3%±0.6%, 15.2%±1.8% for stage I, II, III & IV, respectively. For hypoglossal nerve, the intracanalicular and the carotid segment had the highest dose. V65 of the intracanalicular segment were 43%±12.5%, 42%±6.2%, 48%±22% and 80%±14%, for stage I, II, III, and IV, respectively. It was 53%±12.5%, 81%±2%, 82%±7% and 86%±14%, for the carotid segment.

##### Conclusion

Hypoglossal nerve palsy and the subsequent Dysarthria-Dysphagia Syndrome in nasopharyngeal cancer patients may be related to the high dose of the carotid segment of the hypoglossal nerve. Constrictor muscle and larynx are less likely to be the underlying etiology according to dose-volume data.

#### EP-1036 18F-FDG-PET in Guiding Dose-painting with IMRT in Oropharyngeal Tumours (FiGaRO) - Swallow Results

C. Doughty<sup>1</sup>, J. Dunton<sup>1</sup>, A. Michaelidou<sup>2</sup>, M. Lei<sup>2</sup>, T. Guerrero Urbano<sup>2</sup>

<sup>1</sup>Guy's and St. Thomas' Hospital NHS Foundation Trust, Speech and Language Therapy, LONDON, United Kingdom

<sup>2</sup>Guy's and St. Thomas' Hospital NHS Foundation Trust, Radiotherapy, LONDON, United Kingdom

##### Purpose or Objective

The FiGaRO trial is a Phase 1 multicentre study that aims to determine the feasibility and safety of <sup>18</sup>F-FDG-PET/CT dose-painted IMRT in locally advanced oropharyngeal SCC.

Dose escalation strategies are explored, with target volume definition and toxicity being the main challenges. It is well recognised that swallowing dysfunction is a significant determinant of long term quality of life. We present early swallow outcomes in the first 15 patients.

##### Material and Methods

Patients with ≥T2, HPV-negative or high-risk HPV-positive disease, suitable for radical treatment with neo-adjuvant chemotherapy and chemo-IMRT, are eligible. Swallow measures are taken at 3 time points: at baseline, at 3 and 12 months post treatment. The Performance Status Scale - Normalcy of Diet subset (PSS - NoD) is based on the patient's reported current diet. The Penetration-Aspiration scale (PAS) is scored from presentation on videofluoroscopy (VF).

##### Results

Fifteen patients (14-male, 1-female; mean age-61, range 49-71) were treated April'14-March'16, across two centres (median follow-up 10 months, range 4-26 months).

All patients had a baseline assessment: On the PSS - NoD 73% (n=11) scored 100 (full diet, no restrictions), 27% (n=4) scored 50 (soft chewable foods). On the PAS 60% (n=9) scored 1 (material does not enter the airway), 27% (n=4) scored 2 (material enters the airway, remains above the vocal folds and is ejected from the airway), 13% (n=2) scored 8 (material enters the airway, passes below the vocal folds and no effort is made to eject).

Fourteen patients were assessed at 3 months post-treatment (one declined):

On the PSS - NoD 14% (n=2) scored 100 (full diet, no restrictions), 50% (n=7) scored 50 (soft chewable foods), 21% (n=3) scored 40 (soft foods requiring no chewing), 7% (n=1) scored 30 (pureed foods) and 7% (n=1) scored 20 (warm and cold liquids).

On the PAS 7% (n=1) scored 1 (Material does not enter the airway), 14% (n=2) scored 2 (Material enters the airway, remains above the vocal folds and is ejected from the airway), 7% (n=1) scored 6 (Material enters the airway, passes below the vocal folds and is ejected into the larynx or out of the airway), 7% (n=1) scored 7 (Material enters the airway, passes below the vocal folds and is not ejected from the trachea despite effort) 64% (n=9) scored 8 (Material enters the airway, passes below the vocal folds and no effort is made to eject).

No patient was nil oral at 3 month follow - up and no patient reported a history of chest infections.

##### Conclusion

VF assessment of swallow following PET/CT-guided selective dose escalation demonstrates deterioration of swallow status at 3 months. However, clinical significance is yet to be determined. 12 month post-treatment swallow measures are currently being taken.

#### EP-1037 Chronic radiation-associated dysphagia (RAD) after curative reirradiation in head and neck cancer

L. Gutierrez Bayard<sup>1</sup>, M. Salas Buzón<sup>1</sup>, E. Porras Alonso<sup>2</sup>, S. Garduño Sánchez<sup>1</sup>, M. Macías<sup>1</sup>, L. Ingunza Barón<sup>1</sup>, E. Gonzalez Calvo<sup>1</sup>, I. Villanego Beltran<sup>1</sup>, V. Diaz Diaz<sup>1</sup>

<sup>1</sup>Hospital Universitario Puerta del Mar, Radiation Oncology, Cadiz, Spain

<sup>2</sup>Hospital Universitario Puerto Real, Otorrinolaringology, Puerto Real, Spain

##### Purpose or Objective

Chronic radiation-associated dysphagia (RAD) is a complex toxicity. The Total Dysphagia Risk Score (TDRS) was developed to predict which patients are most at risk to develop grade ≥ 2 dysphagia at 6 months following radiotherapy (RT). The mylo/geniohyoid complex (MHM) V69 ( the volume receiving ≥69 Gy), , and superior constrictor muscle (SPC V70), especially in older patients (>62-years), were associated with chronic-RAD. Acute

during the course of RT are strong prognostic factors for late dysphagia. There is no effective treatment to reverse chronic-RAD in longterm survivors; and intensive and costly therapies are required for incremental gains in functionality.

We have the objective to study the incidence of chronic RAD in these head and neck recurrent tumors, previously irradiated, including patients over 70 years old (y)

#### Material and Methods

We evaluated 69 patients with recurrent disease, between 2005 to 2015. 33 larynx, 7 nasopharynx, 15 oropharynx, 6 hypopharynx and 8 oral cavity. The initial dose received 50- 70 Gy(2-2.2Gy/fraction), 30/69 received radical radiotherapy,21/69 radical chemoradiation; other adjuvant radiotherapy, of which 10/ 69 was combined with chemotherapy. In 29/69 nodal recurrence (N1-N2), local 22/69 (T2-T4), 7/69 local+nodal recurrence, 11/69 seconds tumor, median age 59 year (range 42-79) . Reirradiation with external 3D conformal/IMRT techniques/ and dose: 50-70 Gy bjective to study the incidence of chronic RAD in these head and neck recurrent tumors, previously irradiated, including patients over 70 years old (y)

#### Results

The acute grade 2-4 RTOG dysphagia in week 6 (RTOG G2-4) was 75.4% (G2: 32/69, G3: 20/69). Of 69 patients, 21 (29.8%) had chronic-RAD at 12 months (G2: 17/69, G3: 3/69 G4: 1/69). All of these patients had acute toxicity G2-G3. After calculation of the TDRS, nine patients ( 3 patients <62 years old/ 6p ≥ 62 y (3p ≥ 70 y)), were classified in the low-risk group (TDRS 0-9); 15 patients ( 5 patients <62 years old/ 10 p ≥ 62 y (4p ≥ 70 y)),in the intermediate-risk group (TDRS10-18) and 45 patients ( 16 patients <62 years old/ 29p ≥ 62 y (14p ≥ 70 y)),in the high-risk group (TDRS > 18). MHM V69 was ≥ 79.5% in all patients with chronic-RAD at 12 months, with median age 59, 68% ≥ 62 years (31.5% ≥ 70 years old)

#### Conclusion

Aggressive treatment of this disease recurring, allowing long survival, even in extensive disease is superior to best supportive care.

We have not seen a high incidence of severe damage in healthy tissues. TDRS can be used to predict chronic-RAD at 12 months (Grade ≥2), but also other relevant endpoints such as acute dysphagia during RT and MHM V69. In our series patients older than 70 years did not suffer more chronic toxicity dysphagia type

#### EP-1038 Intraoperative electron beam radiotherapy for locoregionally recurrent head and neck cancer

P. Wald<sup>1</sup>, J. Grecula<sup>1</sup>, A. Bhatt<sup>1</sup>, V. Diavolitsis<sup>1</sup>, T. Teknos<sup>2</sup>, M. Old<sup>2</sup>, J. Rocco<sup>2</sup>, A. Agarwal<sup>2</sup>, E. Ozer<sup>2</sup>, R. Carrau<sup>2</sup>, D. Blakaj<sup>1</sup>

<sup>1</sup>OSU Medical Center -James Cancer Hospital, Radiation Oncology, Columbus, USA

<sup>2</sup>OSU Medical Center -James Cancer Hospital, Otolaryngology, Columbus, USA

#### Purpose or Objective

When feasible, standard of care for locoregionally recurrent head and neck cancer is saly age surgery. However, locoregional control (LRC) is unacceptably low with surgery alone. Adjuvant chemoradiation was shown to improve LRC and progression free survival (PFS) in a randomized controlled trial, but LRC at one year was still only about 60%. The role for intraoperative radiotherapy (IORT) in the salvage setting remains unclear due to limited data and variable patient selection criteria between institutions. We report our institutional outcomes using IORT for recurrent head and neck cancer.

#### Material and Methods

Between 2004 and 2015, 61 patients underwent salvage surgery and IORT for recurrent head and neck cancer at

our institution. IORT was delivered using a mobile electron unit. A single fraction was delivered to a median dose of 12.5 Gy (range, 10 - 17.5 Gy). We retrospectively evaluated LRC, PFS, and overall survival (OS) for the entire group. We then evaluated the squamous cell carcinoma patients alone. Univariate analysis was performed using log-rank tests to correlate clinical outcomes with histology (squamous cell carcinoma vs. others), surgical margin status (positive vs. negative), and adjuvant therapy received. LRC, PFS, and OS curves were generated using the Kaplan-Meier method.

#### Results

Median follow up for surviving patients was 15.9 months (range, 4.9 - 74.4). Forty-one patients (67%) were treated to the primary site and 20 (33%) to a neck recurrence. Forty-five patients (74%) had squamous cell histology (SCC). Fifty-seven patients (93%) had previously received external beam radiotherapy (EBRT) as a component of their definitive therapy (median dose 66 Gy). The median time interval between prior EBRT and IORT was 16.4 months (range, 1 - 227 months). Final surgical margins were positive in 28 patients (46%), negative in 27 patients (44%), and unknown in 6 patients (10%). Twenty-three patients (38%) received a course of post-operative EBRT (median dose 45 Gy, range 25 - 66 Gy) with a median time interval between IORT and completion of post-operative EBRT of 78 days (range, 52 - 131). Nine patients (15%) received post-operative chemotherapy. There was one grade 5 toxicity which resulted from carotid rupture 18 days after surgery/IORT.

	N	Median LRC (months)	1 yr LRC	Median PFS (months)	1 yr PFS	Median OS (months)	1 yr OS	2 yr OS
All histologies	61	16.6	59%	9.8	39%	19.1	62%	42%
Squamous cell	45	14.5	55%	6.2	28%	15.0	60%	32%
Non-squamous cell	16	18.4		18.1		37.7		
		p = 0.30		p = 0.09		p = 0.03		
SCC - Positive margin	18	5.2	42%	4.5	17%	9.6	44%	27%
SCC - Negative margin	21	14.5	60%	7.4	40%	16.1	75%	42%
		p = 0.31		p = 0.09		p = 0.06		
Post-op EBRT	23	16.8		6.5		13.1		
No post-op EBRT	38	15.9		8.9		26.3		
		p = 0.68		p = 0.38		p = 0.26		

#### Conclusion

The use of IORT for recurrent head and neck cancer at our institution has shown effective locoregional control and overall survival, despite only 38% of our patients receiving post-operative EBRT. OS was significantly better for non-SCC histologies compared to SCC. For SCC patients, there is a trend toward improved PFS (p = 0.09) and OS (p = 0.06) associated with negative surgical margins. IORT in the re-irradiation setting has shown acceptably low rates of severe toxicity. We plan to initiate a prospective trial to investigate the safety and efficacy of IORT in combination with post-operative chemoradiation for recurrent head and neck cancer in the near future.

#### EP-1039 CTV growth evaluation for involved site neck lymphoma RT if pre-chemo RT position PET-CT is absent

D. Bird<sup>1</sup>, C. Patel<sup>2</sup>, A. Scarsbrook<sup>2</sup>, V. Cosgrove<sup>1</sup>, E. Thomas<sup>3</sup>, D. Gilson<sup>3</sup>, R. Prestwich<sup>3</sup>

<sup>1</sup>Leeds Teaching Hospitals Trust, Medical Physics and Engineering, Leeds, United Kingdom

<sup>2</sup>Leeds Teaching Hospitals Trust, Radiology and Nuclear Medicine, Leeds, United Kingdom

<sup>3</sup>Leeds Teaching Hospitals Trust, Clinical Oncology, Leeds, United Kingdom

#### Purpose or Objective

A pre-chemotherapy PET-CT acquired in the radiotherapy treatment position has not been widely implemented in the management of lymphoma. An involved site radiotherapy (ISRT) CTV requires an expansion to account for the absence of optimal pre-chemotherapy

imaging. The aim of this prospective imaging study is to determine the size of the expansion required for neck radiotherapy.

#### Material and Methods

10 patients with Hodgkin lymphoma and diffuse large B cell lymphoma were identified from a prospective single centre imaging study who had undergone a pre-chemotherapy PET-CT in both the diagnostic and radiotherapy treatment position with immobilisation devices, and had subsequently received neck radiotherapy following chemotherapy. CTVs were delineated according to the principles of modern ISRT guidelines. A CTV<sub>INRT</sub> (involved node radiotherapy) was delineated following coregistration of the radiotherapy position PET-CT to the planning CT scan. A CTV<sub>diagPET</sub> was delineated by side-by-side assessment of the diagnostic PET-CT; no additional CTV expansion was made to account for uncertainties introduced by the absence of optimal pre-chemotherapy imaging. CTV<sub>INRT</sub> and CTV<sub>diagPET</sub> were compared using multiple positional metrics. Repeat coregistrations and delineations were undertaken for 3 patients to determine the effect of intra-observer variation. Figure 1 shows the variation in CTV when using the diagnostic and radiotherapy position PET-CT data respectively during the delineation process.

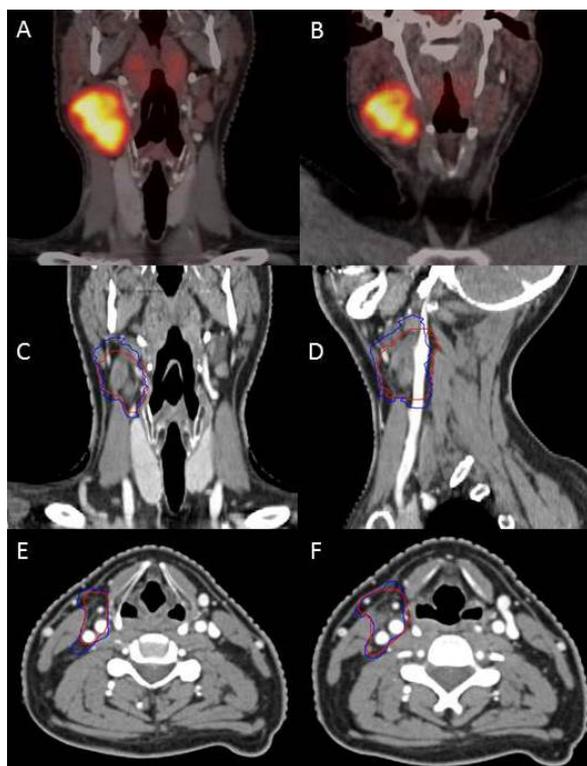

Figure 1: Comparison of CTV<sub>INRT</sub> and CTV<sub>diagPET</sub>. A) represents pre-chemotherapy FDG PET-CT acquired in the radiotherapy treatment-position, B) represents routine diagnostic pre-chemotherapy PET-CT with arms up, C-F) planning CT scan with CTV<sub>INRT</sub> (blue) (contoured using coregistered pre-chemotherapy radiotherapy treatment-position PET-CT) and CTV<sub>diagPET</sub> (red) (contoured using side-by-side assessment of diagnostic PET-CT) in the coronal plane (C), in the sagittal plane (D), in the axial plane at the inferior extent of the CTVs (E), in the axial plane at the superior extent of the CTVs (F).

#### Results

Intra-observer variability was limited, with delineation of CTV<sub>INRT</sub> highly reproducible and slightly lower for CTV<sub>diagPET</sub> (mean DICE 0.88 and 0.8 respectively). Superiorly, CTV<sub>diagPET</sub> varied by -10 to + 15mm from CTV<sub>INRT</sub>, with a

mean difference of +0.5mm. Inferiorly, CTV<sub>diagPET</sub> varied by -18 to +6mm compared with CTV<sub>INRT</sub>, with a mean difference of +3.8mm.

Comparing CTV<sub>INRT</sub> and CTV<sub>diagPET</sub> in the axial plane, the mean DICE was 0.74. Mean sensitivity index was 0.75 (range 0.56-0.91), showing that on average 75% of the CTV<sub>INRT</sub> was encompassed by the CTV<sub>diagPET</sub>. The average and maximum 'mean distance to conformity' (MDT) under-coverage was 2.6mm (range 1-4.8) and 7.4mm (range 1.5-14.3) respectively.

#### Conclusion

In the absence of treatment-position PET-CT, CTV expansion cranially and caudally by 10mm and 18mm respectively, along with generous contouring in the axial plane, was required to encompass pre-chemotherapy disease.

#### EP-1040 Identifying risk factors for L'Hermitte's syndrome after chemo-IMRT for head and neck cancer

H. Laidley<sup>1</sup>, D. Noble<sup>2</sup>, G. Barnett<sup>2</sup>, R. Jena<sup>2</sup>, N. Burnet<sup>2</sup>

<sup>1</sup>Cambridge University Hospitals, School of Clinical Medicine, Cambridge, United Kingdom

<sup>2</sup>Cambridge University Hospitals, Oncology, Cambridge, United Kingdom

#### Purpose or Objective

Studies suggest that L'Hermitte's syndrome (LS) after chemo-radiotherapy for head and neck cancer patients is related to higher spinal cord doses and younger age. IMRT plans limit spinal cord dose, but the incidence of LS remains high. We aimed to identify other risk factors.

#### Material and Methods

128 patients treated with TomoTherapy™ between 2008 and 2015 prospectively completed a side-effect questionnaire 3, 6 and 12 months post-treatment. 45 (35.2%) reported typical LS symptoms (consistent with Grade 1 CTCAE v4.03 myelitis) at least once, and graded severity of tingling/electric shock sensations down their spine. Data on age, diabetes, hypertension, concurrent systemic therapy, and unilateral versus bilateral neck irradiation (UNI vs BNI) were collected. Radiotherapy plans were assessed to compare maximum dose, mean dose, and absolute and partial volumes receiving 10, 20, 30 and 40 Gy to the spinal cord in LS and non-LS patients. Univariate analyses of baseline parameters against LS incidence were assessed with Fisher's exact test and student's t-test. Box and whisker plots were used to inspect dosimetric parameters against LS incidence. Variables reaching or trending towards significance were included in a binary logistic regression model.

#### Results

The only significant variable on univariate analysis was diabetes (p = 0.032). 13 patients in our cohort were diabetic (9 on metformin); only 1 developed LS (OR = 0.13). Concurrent weekly cisplatin did not increase LS risk; 23/61 (38%) patients receiving cisplatin developed LS, compared with 22/67 (33%) who did not (p = 0.58). V<sub>40Gy</sub> was the only dose parameter showing a difference between LS and non-LS patients, so others were excluded from logistic regression to prevent co-linearity.

The binary logistic regression showed that higher absolute volume receiving 40 Gy (V<sub>40Gy</sub>) was significant (p = 0.037, OR = 1.55), despite only 29% of patients with LS, and 28% of patients without LS receiving any dose to the spinal cord over 40 Gy. There was also a trend for LS patients to be slightly younger (mean age 56.3 vs 59.4, p = 0.074), and a protective effect of diabetes was again seen (p = 0.035). Patients receiving UNI (p = 0.015, OR = 2.82) were more likely to develop LS; 42% of LS patients received UNI, compared to 25% of non-LS patients.

Table 1. Results of logistic regression<sup>a,b</sup> with occurrence of LS as dependent variable (n=128)

Independent Variable	Univariate test	Univariate p value	Logistic regression coefficient	Regression p value	Odds Ratio <sup>c</sup> (95% confidence interval)
Age	Student's t test	0.101	-0.036	0.074	0.97 (0.93-1.00)
UNI vs BNI	Fisher's exact	0.072	1.10	0.015	2.82 (1.22-6.50)
Non-diabetic vs diabetic	Fisher's exact	0.032	2.33	0.035	10.3 (1.18-89.56)
V40 [ml]	Mann-Whitney U	0.330	0.44	0.037	1.55 (1.03-2.34)
Constant			-1.23	0.437	0.293

a. Hosmer and Lemeshow test  $\chi^2(8) = 11.042, p = 0.199$

b. pseudo-R<sup>2</sup> = 0.13 to 0.18

c. Odds ratio per unit increase in variable or for unilateral radiation and being non-diabetic

## Conclusion

Despite significance in the logistic regression, proportions of patients receiving over 40Gy to the spinal cord were low, and similar in both patient groups. Cisplatin did not increase risk of LS. Other factors may be important and our results suggest age and unilateral treatment may also be key factors, possibly due to axial dose gradient across the spinal cord. Further work will focus on relationships between dose gradient and LS risk, and whether metformin could be neuroprotective in head and neck cancer patients undergoing radical radiotherapy.

## EP-1041 The Preliminary Report of PG2 in Improving QoL of Pharyngeal Cancer Patients in Chemoradiotherapy

H.M. Wang<sup>1</sup>, J.R. Lin<sup>2</sup>, C.H. Hsieh<sup>1</sup>, C.L. Hsu<sup>1</sup>, C.Y. Lin<sup>3</sup>, J.T.C. Chang<sup>3</sup>

<sup>1</sup>Chang Gung Memorial Hospital, Division of Medical Oncology- Department of Internal Medicine, Taoyuan, Taiwan

<sup>2</sup>Chang Gung University, Clinical Informatics and Medical Statistics Research Center and Graduate Institute of Clinical Medicine, Taoyuan, Taiwan

<sup>3</sup>Chang Gung Memorial Hospital, Department of Radiation Oncology, Taoyuan, Taiwan

## Purpose or Objective

Concurrent chemoradiation (CCRT) is the current standard of care for patients with locally advanced squamous cell carcinoma (SCC) of head and neck. This therapy can interfere the basic functions, including eating and speech, and can have a profound effect on social interactions and psychological state. PG2 (PhytoHealth Corporation, Taiwan, ROC), extracted, isolated and purified from the root of Astragalus (Huang-Chi), is the first FDA NDA-approved botanical new drug for alleviating cancer-related fatigue and for the treatment of low energy level, low WBC counts, deteriorated quality of life, and an impaired immune function among cancer patients undergoing chemotherapy. To investigate the effect of PG2 for the reduction of the toxicities and deteriorated quality of life (QoL) and even increase the compliance of CCRT among advanced pharyngeal or laryngeal SCC patients receiving CCRT, the double-blind, randomized and placebo controlled trial was conducted.

## Material and Methods

Advanced pharyngeal or laryngeal SCC patients were recruited and randomly assigned to receive either CCRT with PUL regimen (cisplatin/tegafur plus uracil/leucovorin) plus 500 mg PG2 t.i.w by IV infusion or CCRT with PUL plus placebo (normal saline) t.i.w by IV infusion.

## Results

The study was early termination after 17 patients completed the study due to the development of new formulation of PG2. Among these patients, a noticeably higher proportion of patients in PG2 group did not exhibit predefined clinical significant deterioration in HN pain, appetite loss, social eating, feel ill, physical functioning,

role functioning, insomnia, swallowing, nausea/vomiting, and pain domains of QoL assessment by EORTC-QLQ-C30 and HN35 compared to the Control group (HN pain: 100% vs. 29%; appetite loss: 60% vs. 0%; social eating: 60% vs. 0%; feel ill: 60% vs. 14%; physical functioning: 100% vs. 57%; role functioning: 80% vs. 43%, insomnia: 80% vs. 43%; swallowing: 60% vs. 29%, nausea/vomiting: 60% vs. 29%, and pain: 60% vs. 29%). No difference in tumor response, CCRT compliance, and adverse events was observed.

## Conclusion

PG2 is safe and has the potential role as a complementary treatment to improve quality of life during CCRT for patients with advanced pharyngeal or laryngeal SCC.

## EP-1042 Olfactory neuroblastoma - 10-year experience with VMAT radiotherapy

H. Ariyaratne<sup>1</sup>, A. Ward<sup>1</sup>, P. Bhudia<sup>1</sup>, V. Lund<sup>2</sup>, D. Carnell<sup>1</sup>

<sup>1</sup>University College London Hospital NHS Trust, Clinical Oncology, London, United Kingdom

<sup>2</sup>Royal National Throat Nose and Ear Hospital, Professorial Unit, London, United Kingdom

## Purpose or Objective

Olfactory neuroblastoma is an unusual head and neck tumour arising from neuroectodermal cells. Localized disease is best managed with combined modality treatment with surgery and radiotherapy. Treatment is challenging due to the location of tumours around the cribriform plate. The majority of previously reported series of patients were treated with conformal radiotherapy. We report our experience in using volumetric modulated arc treatment (VMAT) with concurrent chemotherapy, in the management of this tumour.

## Material and Methods

We retrospectively reviewed the records of patients with olfactory neuroblastoma treated at University College London Hospital between Aug 2006 and June 2016. Patients were treated by a specialist sinonasal surgeon and clinical oncologist, in a tertiary referral centre. Radiotherapy was inverse-planned and delivered using Rapidarc<sup>TM</sup> VMAT. The planning constraints used included DMax 55 Gy for brainstem, and DMax 50 Gy for optic nerves and chiasm. A dose of 60 - 65 Gy in 30 fractions was delivered to the target volume. Induction chemotherapy was used for bulky disease. Concurrent platinum-based chemotherapy was administered to patients during radiotherapy. Acute toxicity was assessed using the CTCAE grading system. Kaplan-Meier survival analysis was used for the whole group.

## Results

17 patients treated with VMAT radiotherapy were included. The median follow-up of patients was 43 months. The median age was 57 years (range 22 - 75 years). 53% were male. The Kadish stage distribution was: 4 patients had stage A, 3 patients had stage B, 7 patients had stage C, and 3 patients stage D disease. 13 patients had endoscopic surgery and 3 patients had open craniofacial resection. One patient had unresectable disease. The majority of patients received concurrent cisplatin chemotherapy. Even with inverse-planned treatment, radiotherapy constraints for the optic apparatus were not met in many patients, due to the proximity of organs at risk. There was no acute grade 3/4 toxicity, and no long-term visual or neurological toxicity during the period of follow-up. 5-year overall survival of patients in this series was 83%.

## Conclusion

VMAT radiotherapy with concurrent chemotherapy for olfactory neuroblastoma is well-tolerated. Overall survival of patients with olfactory neuroblastoma is good after multi-modality treatment.

#### EP-1043 Chemo-reirradiation with simultaneously integrated boost in patients with local recurrence of HNSCC

A. Mikhaylov<sup>1</sup>, N. Vorobyov<sup>1,2,3</sup>, E. Sokolova<sup>4</sup>, G. Andreev<sup>5</sup>, A. Kalesnik<sup>5</sup>, A. Lyubinskiy<sup>5</sup>, M. Rukhlenko<sup>6</sup>, V. Sokurenko<sup>7</sup>

<sup>6</sup>Dr. Berezin Medical Center, Radiology department, Saint-Petersburg, Russian Federation

<sup>7</sup>Russian Scientific Center Of Radiology And Surgical Technologies, Radiation Therapy department, Saint-Petersburg, Russian Federation

#### Purpose or Objective

Locoregional recurrence is a major cause of death in patients with squamous cell carcinoma of the head and neck (HNSCC). At the moment, there are no clear recommendations and standards regarding the timing, total doses and dose tolerance of normal tissues to re-exposure. Based on limited studies on the re-irradiation with high total doses, we evaluated the tolerability and clinical outcomes of high-dose chemo-reirradiation with simultaneous integrated boost.

#### Material and Methods

18 patients with histologically confirmed locoregional recurrence of HNSCC, received chemo-reirradiation. Median time after primary radiotherapy course was 60 months. The treatment volumes and total doses were formed as follows: GTV (primary lesion and involved lymph nodes, delineated on CT, MRI and <sup>18</sup>F-FDG PET-CT) + CTV (0.5-1.0 cm) + PTV (0.3-0.5 cm) was treated to the total dose equivalent to 66-70 Gy of conventional fractionation, the high-risk lymph nodes (if indicated, PTV 0.5 cm) to 60 Gy, the low-risk lymph nodes (if indicated, PTV 0,5 cm) - equivalent to 50 Gy. Single doses to these volumes were 2.14-2.21 Gy, 2.0 Gy and 1.8 Gy, respectively. Radiation treatment was once a day, five days a week, 6 weeks long (30 fractions). Varian Eclipse v.10 was used for treatment planning (IMRT and VMAT); patients were treated on Varian Clinac 2100 and Varian TrueBeam STx. According to the literature, in a year after primary irradiation almost complete recovery of normal tissue tolerances is observed. Tolerances of organs at risk were not exceeded. IGRT was used for patient positioning. Patients received cisplatin every three weeks, 100 mg/m<sup>2</sup>.

#### Results

16 of 18 patients received full course of radiation therapy without a break. Radiation toxicity manifested with grade 2-3 oral and pharyngeal mucositis and grade 2 radiation epidermitis. After one month, almost complete relief of radiation mucositis and dermatitis was observed. One patient took a break of 7 days after 25th fraction due to the development of grade 3 mucositis and grade 3 dysphagia. Late toxicity were grade 2 xerostomia in 1 patient (recurrent tumor, located near the parotid salivary glands), chronic atrophic sinusitis - in 2 patients (recurrence in the ethmoidal labyrinth and maxillary sinus). In 14 patients, who received re-irradiation with a total dose of more than 60 Gy, partial response was observed at the first follow-up examination (MRI) at 1 month after treatment. Two patients showed stabilization. Median follow-up was 11 months (from 2 to 20). One year overall survival was 48%. The cause of death in two patients was disease progression (distant

metastases), two patients died from complications related to the treatment (elderly patients, who developed grade 3 dysphagia and subsequent septic complications).

#### Conclusion

Using technique of SIB with IMRT/VMAT during curative chemo-reirradiation of recurrent HNSCC is available with maintaining satisfactory tolerability. Local control rate is quite encouraging, and late toxicity is at acceptable rates.

#### EP-1044 survival and functional outcome after treatment for primary base of tongue cancer

S. Park<sup>1</sup>, Y. Cho<sup>1</sup>, J. Lee<sup>1</sup>, K.C. Keum<sup>1</sup>, C.G. Lee<sup>1</sup>

<sup>1</sup>Yonsei university college of medicine, Radiation oncology, Seoul, Korea Republic of

#### Purpose or Objective

The preservation of speech and swallowing function in the treatment of base of tongue (BOT) cancer is critical issue. At present, BOT cancer patients treated with either surgery followed by postoperative radiotherapy or definitive RT without consensus of optimal treatment. The purpose of this study is to compare the clinical and functional outcome in patients with primary BOT cancer who received definitive radiotherapy or surgery followed by radiotherapy.

#### Material and Methods

Between January 2002 and June 2016, a total number of 99 patients with stage I-IVB primary BOT squamous cell carcinoma underwent either definitive radiotherapy (RT group, n=43) or surgery followed by radiotherapy (SRT group, n=56). In the RT group, 28 patients (65.1%) were treated with concurrent chemotherapy and 11 patients (25.6%) with induction plus concurrent chemotherapy. In the SRT group, 18 patients (32.1%) received concurrent chemotherapy. Median radiation doses of the RT group and SRT group were 70 Gy (range, 63-76 Gy) and 63 Gy (range, 45-68.4 Gy), respectively. Radiotherapy was performed using both 3-dimensional conformal RT (3D CRT, n=30) and Intensity modulated RT (IMRT, n=69). Among patients in SRT group, 31 patients (55.4%) were treated with wide excision, 18 (32.1%) with partial glossectomy, and 7 (12.5%) with total glossectomy. Expression of p16 was available in 53 patients (53.5%). Among these, 38 patients (71.7%) had p16 positive and 15 patients (28.3%) had p16 negative BOT cancer.

#### Results

The median age of patients was 59 years (range, 36-96). There were more patients that had advanced T stage (T3-4) disease (58.1% vs. 37.5%, p=0.041) and received chemotherapy (90.6% vs. 35.7%, p=0.001) in RT group than those in SRT group. At a median follow up of 36.1 months (range, 0.8-178.4), 5-year overall survival (OS) and disease free survival (DFS) were 74.6% and 69.6%, respectively. Respect to treatment group, 5-year OS and DFS in both RT group and SRT group were 71% vs. 77.2% (p=0.941) and 65% vs. 72.9% (p=0.805), respectively. In univariate analysis, T stage (OS: p=0.041, DFS: p=0.008), RT modality (OS: p=0.004, DFS: p=0.002) and p16 expression (OS: p=0.009, DFS: p=0.009) were observed prognostic factors related to both OS and DFS. In multivariate analysis, OS showed significant difference according to p16 expression (p16 negative vs. p16 positive, HR 0.152, 95% CI 0.028-0.816, p=0.028). Regarding DFS, p16 expression (p16 negative vs. p16 positive, HR 0.261, 95% CI 0.073-0.936, p=0.039) showed significant effect in multivariate analysis. Dysphagia and voice alteration (severe than grade 2) were more frequently observed in SRT group than RT group (19.6% vs. 2.3%, p=0.009).

#### Conclusion

Even with more advanced disease, patients in RT group showed comparable survival outcome with better functional preservation to those in SRT group.

#### EP-1045 L Glutamine in reducing severity of oral mucositis due to chemoradiation in head and neck cancer

V. Pareek<sup>1</sup>, R. Bhalavat<sup>2</sup>, M. Chandra<sup>2</sup>

<sup>1</sup>Jupiter Hospital- Thane, Radiation Oncology, Mumbai, India

<sup>2</sup>Jupiter Hospital, Radiation Oncology, Thane, India

##### Purpose or Objective

The incidence of mucositis in the oral cavity, pharynx and larynx is high among patients with head and neck cancer (HNC) receiving chemo-radiotherapy (CRT), resulting in significant pain and impairment of quality of life. The present study investigated whether L-glutamine (glutamine) decreases the severity of mucositis in the oral cavity, pharynx and larynx induced by CRT

##### Material and Methods

Patients were randomized to orally receive either glutamine or placebo at a dose of 10 g 3 times a day throughout the CRT course. Mucositis was assessed using the National Cancer Institute Common Terminology Criteria for Adverse Events version 3.0. The primary end point was mucositis severity. Seventy biopsy proven patients with head and neck cancer receiving primary or adjuvant radiation therapy were randomized to receive either oral glutamine suspension daily 2h before radiation in the study arm (10 g in 1000 ml of water) ( $n = 35$ ) or placebo before radiation; control arm ( $n = 35$ )

##### Results

Total 30 patients in the glutamine arm and total 33 patients in placebo developed mucositis. Grade 3 mucositis and grade 4 mucositis in the study arm (who received oral glutamine) were significantly less in the glutamine arm. The mean duration of grade 3 or worse mucositis (grade 3 and grade 4) was significantly less in study arm with  $P < 0.001$ . Mean time of onset of mucositis was significantly delayed in patients who took glutamine in comparison to control arm with  $P < 0.001$ . Overall, glutamine was associated with a significant reduction of mucositis, WL, and enteral nutrition.

##### Conclusion

Glutamine delays oral mucositis in the head neck cancer patients. Moreover, it reduces the frequency and duration of grade 3 and grade 4 mucositis. More of the patients not receiving glutamine developed severe malnutrition when compared with those receiving this supplement, but there were no differences in other outcomes such as interruption of RT, hospitalization, use of opioid analgesics, or death during RT. Glutamine may have a protective effect during RT, reducing the risk and severity of OM, preventing weight loss, and reducing the need for nutritional support.

#### EP-1046 Hypofractionated palliative radiotherapy in head and neck cancer

P. Vargas Arrabal<sup>1</sup>, I. Tovar Martin<sup>1</sup>, C. Prieto Prieto<sup>1</sup>, M. Zurita Herrera<sup>1</sup>, R. Guerrero Tejada<sup>1</sup>, J. Exposito Hernandez<sup>1</sup>, R. Del Moral Avila<sup>1</sup>, A. Ruiz Martinez<sup>1</sup>, S. Rodriguez Pavan<sup>1</sup>, R. Ching<sup>1</sup>

<sup>1</sup>Complejo Hospitalario de Granada, Radiation Oncology, Granada, Spain

##### Purpose or Objective

There are few published studies on the choice of the best palliative treatment option for head and neck cancer, as well as high toxicity and its impact on symptom control and quality of life, once ruled treatment with curative intent.

The objective is to evaluate the role of radiotherapy (RT) in the palliation of tumors advanced head and neck: identifying patients optimal candidates, appropriate dose, outcome and duration of palliation and secondary toxicity.

##### Material and Methods

We retrospectively reviewed 31 patients treated between 2006-2015 histological diagnosis of epidermoid head and neck cancer stage IV, not candidates for radical treatment under performance status with advanced locoregional recurrent disease or metastatic. All patients are treated with three-dimensional conformal external beam radiotherapy (3D) with different schemes hypofractionation: dose 30 Gy fractions of 6 Gy (2 x week): 52.4% (16), 30 Gy fractions of 3 Gy (5 x week): 14.3% (5), 20 Gy to 4 Gy fractions (5 x week): 9.5% (3) 23.8% other (7).

##### Results

With a mean follow up of 20 months, 90% of patients completed RT scheme originally planned. The median time to progression of symptoms is 5 months. The objective tumor response is complete response: 23.8% (7), Partial / stabilization: 57.1% (18). The median time to tumor progression 3 months. The median overall survival is 9 months (2-57).

The acute toxicity is recorded after RT oromucositis G2 9.5% (3), G3 57% (18), radiodermatitis G2 9.5% (3), dysphagia G2 71.4% (22).

##### Conclusion

In patients with advanced head and neck cancer and no subsidiary of radical treatment, palliative RT Hypofractionated, provides a satisfactory rate of disease control and symptom control with a secondary tolerable toxicity and better life quality.

#### EP-1047 Comparison of TPF and CF induction chemoradiotherapy for radical treatment of head and neck cancer.

C. Adkin<sup>1</sup>, D. Adjogatse<sup>1</sup>, T. Guerrero Urbano<sup>1</sup>, M. Lei<sup>1</sup>  
<sup>1</sup>Guy's and St.Thomas' Hospital NHS Foundation Trust, Clinical Oncology, London, United Kingdom

##### Purpose or Objective

To compare the impact of induction chemotherapy using the TPF (Docetaxel, Cisplatin and 5-fluorouracil) and standard CF (Cisplatin and 5-fluorouracil) regimens on toxicity and hospital admissions for radical treatment of locally advanced head and neck cancer. The aim was to assess if the TPF regimen increases toxicity during induction and concomitant chemoradiotherapy and if this results in increased burden of hospital admissions and clinic attendance.

##### Material and Methods

Patients undergoing radical chemoradiotherapy for locally advanced head and neck cancer at Guy's hospital during 2015 were selected. Timing, dose and duration of chemoradiotherapy were recorded. All admissions were included up to 3 months after completion of radiotherapy. These admissions were attributed to radical treatment. The number and duration of hospital admissions, both elective and acute were assessed, as well as the number of acute outpatient clinic attendances. The number of episodes of neutropenia was recorded, as well and the need for nasogastric/jejunal or gastrostomy feeding tubes. The cohort was followed up to assess clinical and radiological response to treatment as well as recurrence and survival at 3 and 12 months.

##### Results

44 patients were included (10 TPF, 34 CF). Per patient, the TPF regime was shown to increase the number of acute clinic attendances (4.5 vs 2.7), acute admissions (2.4 vs 1.0), length of stay per admission (4.9 days vs 3.8 days) and total length of stay (13.4 days vs 8.6 days). There was a considerable increase in the number of episodes of neutropenia per patient with TPF (1.2 vs 0.4). There was only a modest increase in elective admissions (0.5 vs 0.4) and the need for feeding tubes (0.7 vs 0.6). There were 4

deaths during the observed period, all amongst the CF group.

#### Conclusion

Within the group of patients selected, the use of TPF induction chemotherapy appears to increase toxicities, including neutropenia, the need for clinic attendance and inpatient admission. The length of stay also appears to be longer, which may act as a surrogate for severity of admission. Overall, the TPF induction regimen carries an increased cost, in terms of morbidity, patient quality of life and a financial burden of hospital admission and clinic attendance. This will need to be weighed up against the potential added benefit over standard CF induction chemotherapy, in terms of efficacy of response, extended time to progression and survival.

#### EP-1048 Phantom Tumour Phenomenon in Nasopharyngeal Carcinoma Patients after Radiotherapy

Y.M. Jen<sup>1</sup>, S. Shi<sup>2</sup>

<sup>1</sup>Yee-Ren Hospital, Department of Radiation Oncology, Nei Hu- Taipei, Taiwan

<sup>2</sup>Chenzhou NO.1 People's Hospital, Radiation Therapy Center, chenzhou, China

#### Purpose or Objective

To report our finding that image-based diagnosis of recurrent nasopharyngeal carcinoma (rNPC) may not be real recurrence, the "phantom tumor" phenomenon.

#### Material and Methods

From January 2010 to July 2016, we collected 16 cases of image-based diagnosis of recurrent nasopharyngeal carcinoma who have been subsequently confirmed to be not genuine recurrence by pathological biopsy or by the absence of EB viral load & long-term follow-up. Analysis was conducted for imaging features and clinical manifestations of these patients with images mimicking recurrence or residual lesion.

#### Results

There are 2 types of image patterns of this "phantom tumor" phenomenon. The most common one is characterized by extensive skull base lesions (11/16), and the other one is persistent or residual primary lesion (5/16). 13 cases were confirmed by pathological diagnosis (13/16), with histological findings of necrosis, inflammation, or granulation tissue. 3 cases had no pathological proof (3/16) and were judged to have no real recurrence/residual tumour by negative EBV DNA copy number as well as physical & fiberoptic results. EBV viral load is 0 in 93.8% (15/16) of patients, and one did not have EBV viral load test. Nasopharyngeal necrosis by nasopharyngoscopy was noted in 56.3% (9/16) of patients, and cranial nerve palsy by physical examination in 43.8% (7/16) of patients.

#### Conclusion

Image-based diagnosis of recurrent nasopharyngeal carcinoma, especially images showing extensive skull base involvement, is unreliable, especially in T4 NPC patients. Some of these lesions are not real recurrence but benign pathological changes of the skull base including necrosis, inflammation or granulation tissue. Images showing persistent or residual primary lesions may also be misleading. Biopsy must be conducted with every effort to confirm recurrence or residual tumor. Without a pathological confirmation, the possibility of a "phantom tumor" is likely, and the final diagnosis must be made taking into account of endoscopic findings & EBV viral load. A second irradiation of a patient with a phantom tumor must be avoided which is certain to bring some irreparable damages or death to the patients.

#### EP-1049 Intensity-Modulated Radiotherapy(IMRT) could provide better outcomes for nasopharyngeal carcinoma.

P. Pattaranutaporn<sup>1</sup>, N. Ngamphaiboon<sup>2</sup>, T. Chureemas<sup>2</sup>, J. Juengsamarn<sup>2</sup>, S. Lukerak<sup>2</sup>, R. Sophonsakulchot<sup>2</sup>, C. Jiarpinitnun<sup>1</sup>

<sup>1</sup>Faculty of Medicine Ramathibodi Hospital- Mahidol University, Division of Radiation Oncology- Department of Radiology, Bangkok, Thailand

<sup>2</sup>Faculty of Medicine Ramathibodi Hospital- Mahidol University, Division of Medical Oncology- Department of Medicine, Bangkok, Thailand

#### Purpose or Objective

Intensity-Modulated Radiotherapy(IMRT) has shown significant benefits for nasopharyngeal carcinoma in term of normal tissues sparing especially for the salivary glands. However, its benefit on treatment outcomes was controversy. This study was aimed to determine the treatment outcome benefits of IMRT over conventional radiotherapy in nasopharyngeal carcinoma.

#### Material and Methods

Stage I-IVb Nasopharyngeal carcinoma patients who treated with definitive radiation or chemoradiation at our hospital between 2007 and 2014 were identified through the cancer registry database. Patient characteristics, radiotherapy, chemotherapy and medical records were retrospectively reviewed. Locoregional failure, distant failure and survival were analyzed in overall population and by radiation technique (Conventional vs IMRT).

#### Results

From 2007 to 2014, a total of 187 stage I-IVb nasopharyngeal carcinoma patients were treated with definite radiation or chemoradiation at our hospital. Of these, 107 and 80 patients were treated with conventional radiotherapy and IMRT, respectively. Conventional radiotherapy was mostly 3D conformal radiotherapy with 20 patients (18.69%) were 2D radiotherapy. Patient's characteristics and tumor stage were generally similar in both groups except patients with conventional radiotherapy had earlier year of treatment. Median follow-up time for survival were 64.7 and 37.8 months for conventional and IMRT groups. Radiation therapy was delivered in 180-200cGy per fraction for conventional radiotherapy. IMRT was usually delivered with Simultaneous Integrated Boost (SIB) technique with radiation dose per fraction ranged between 163-220cGy per fraction. Median total radiation dose were 7020cGy for conventional group and 6996cGy for IMRT group. 94.12% of patients received concurrent chemoradiation. 3-year locoregional failure (LRF) were 11.34% and 5.91% for conventional and IMRT group, respectively (p=0.2082). Disease-free survival (DFS) was marginal significant difference between conventional and IMRT group, 3-year DFS were 71.46% and 80.96% (p=0.0762). However, 3-year overall survival (OS) was not significant difference between conventional and IMRT group at 76.13% and 81.83%, respectively (p=0.2856).

#### Conclusion

In our experience, IMRT showed marginal significant DFS benefit and trended to have better locoregional control and overall survival.

#### EP-1050 Prognostic factors analysis in advanced SCCHN treated by induction chemotherapy/local therapy

C. Wu<sup>1</sup>, H.Y. Hsieh<sup>2</sup>, Y.C. Liu<sup>2</sup>, W.Y. Wang<sup>3</sup>, J.C. Lin<sup>2</sup>

<sup>1</sup>Changhua Show-Chwan Memorial Hospital, Radiation Oncology department, Changhua, Taiwan

<sup>2</sup>Taichung Veterans General Hospital, Radiation Oncology, Taichung, Taiwan

<sup>3</sup>Hung Kuang University, Nursing, Taichung, Taiwan

### Purpose or Objective

To investigate the prognostic factors in patients with advanced squamous cell carcinoma of the head and neck (SCCHN) who received a novel weekly induction chemotherapy (IndCT) followed by local therapy (surgery/radiotherapy).

### Material and Methods

Fifty patients with stage III/IV SCCHN were enrolled. Outpatient IndCT consisted of a uniform 4-drug regimens (cisplatin 60 mg/m<sup>2</sup>, day 1; docetaxel 50 mg/m<sup>2</sup>, day 8; 5-fluorouracil 2500 mg/m<sup>2</sup> + leucovorin 250 mg/m<sup>2</sup>, day 15; epirubicin 30 mg/m<sup>2</sup> + methotrexate 30 mg/m<sup>2</sup>, day 22; repeated every 4 weeks for 3-4 cycles). After finishing IndCT, local therapy including surgery, radiotherapy, concurrent chemoradiotherapy, or bio-radiotherapy was administered. Univariate and multivariate Cox proportional hazard model were used to identify significant prognostic factors. Analyzed variables included patient's characteristics (age, gender, performance status), tumor factors (primary site, pathological differentiation, T-stage, N-stage), treatment factors (chemotherapy, surgery, radiotherapy) and pre-treatment FDG PET scan parameters (SUVmax of primary tumor, metabolic tumor volume [MTV], total lesion glycolysis [TLG]).

### Results

After a median follow-up of 25 months, 13 patients experienced locoregional recurrence, 1 distant metastasis, and 1 both locoregional recurrence and distant metastasis. Kaplan-Meier survival analysis revealed TLG (> vs. < 520), MTV (> vs. < 70), SUVmax (> vs. < 14.0) of primary tumor, and chemotherapy duration affected overall survival significantly (P=0.0004, P=0.0059, P=0.0209, and P=0.0039, respectively). Only TLG (P=0.0102) and MTV (P=0.0164) were significant factors for locoregional failure-free survival. In univariate analysis, chemotherapy duration (P=0.0101), SUVmax of the primary tumor (P=0.0279), MTV (P=0.0094), and TLG (P=0.0011) were significant predictors for death; MTV (P=0.0236) and TLG (P=0.0159) were significant factors in predicting locoregional recurrence. In multivariate analysis, both TLG and MTV revealed as an independent predictor for death (P=0.0057 and P=0.0156) and locoregional recurrence (P=0.0157 and P=0.0225). nuage:EN-US; total lesion glycolysis [TLG]).

### Conclusion

TLG and MTV were the most important prognostic factors in predicting mortality and locoregional recurrence in patients with advanced SCCHN treated by IndCT followed by surgery/radiotherapy.

### EP-1051 Characteristics and Impact of HPV to Head and Neck Squamous Cell Carcinoma in Thai Patients

C. Jiarpinitnun<sup>1</sup>, P. Pattaranutaporn<sup>1</sup>, N. Larbcharoensub<sup>2</sup>, T. Chureemas<sup>3</sup>, J. Juengsamarn<sup>3</sup>, N. Trachu<sup>4</sup>, S. Lukerak<sup>3</sup>, P. Chansriwong<sup>3</sup>, N. Ngamphaiboon<sup>3</sup>  
<sup>1</sup>Ramathibodi Hospital, Radiology, Bangkok, Thailand  
<sup>2</sup>Ramathibodi Hospital, Pathology, Bangkok, Thailand  
<sup>3</sup>Ramathibodi Hospital, Medicine, Bangkok, Thailand  
<sup>4</sup>Ramathibodi Hospital, Research center, Bangkok, Thailand

### Purpose or Objective

Head and Neck Squamous Cell Carcinomas (HNSCC) is the one of common malignancies in Asia. Smoking, alcohol consumption and betel nut chewing are well-known major risk factors. Association between human papilloma virus (HPV) and HNSCC, especially oropharyngeal sites, have been reported. However, most data reported were from the Western countries. This study evaluated the prevalence, the characteristics and the impact of HPV on the clinical outcomes of treatment in Thai HNSCC patient

### Material and Methods

Non-nasopharyngeal HNSCC patients treated at our hospital between 2007 and 2013 were identified through the cancer registry database. Baseline patient characteristics, treatment data and survivals were retrospectively reviewed. The formalin-fixed paraffin-embedded tissue sections were retrieved for p16 analysis. The HPV status was determined by p16 immunohistochemistry, defined by tumor cells demonstrated nuclear and cytoplasmic staining  $\geq 70\%$ . To identify the impact of HPV as prognostic factor, the survival outcomes were analyzed in cases which p16 status were confirmed.

### Results

Total of 205 available FFPE tissues of HNSCC patients was evaluated for p16 expression. The p16 status was positive in 24 of 205 cases (11.7%); the positive p16 were found in men more than women with calculated ratio of 4:1 (20:4 cases). The oropharynx was the most common site found in p16 positive (34.4%), followed by larynx (11.4%), hypopharynx (11.1%) and oral cavity (3.2%). The p16 positive was shown in patients who were ever smokers (77.3%) more than non-smokers (22.7%). Clinical AJCC stage III-IV was presented in 17 (70.8%) of 24 HNSCC patients with p16 positive. Baseline patient characteristics and treatment characteristics were not statistically different between p16 positive and negative groups except the site of primary tumor (p<0.001). The 3-year overall survival was not statistically different but trended toward p16 positive group (62% vs. 41%, p=0.09). However, p16 positive HNSCC was significant superior in 3-year disease-free survival (3-yrs DFS 93% vs. 57%, p=0.01) and in 3-year locoregional free survival (3-yrs LRFS 100% vs. 54%, p=0.007) when compared with p16 negative HNSCC patients.

### Conclusion

In our study, the prevalence of HPV-related HNSCC in Thai patients was found to be less and the difference in some characteristics were observed when compared to the results reported from the Western countries. Nevertheless, DFS and LRFS were better in p16 status positive. The trend toward improved overall survival was also seen. The analyses suggested that p16 status is still a strong prognostic marker for HNSCC patient in Thailand.

### EP-1052 Hypofractionated vs. conventional radiotherapy for early glottic cancer: a propensity score analysis

W. Takahashi<sup>1</sup>, H. Yamashita<sup>1</sup>, M. Sakuramachi<sup>1</sup>, T. Imae<sup>1</sup>, K. Okuma<sup>1</sup>, K. Nawa<sup>1</sup>, K. Nakagawa<sup>1</sup>  
<sup>1</sup>University of Tokyo, Radiology, Tokyo, Japan

### Purpose or Objective

The purpose of this study was to compare the treatment results and toxicity of hypofractionated radiotherapy (HRT) with conventionally fractionated radiotherapy (CRT) for early stage glottic squamous cell carcinoma (ESGC).

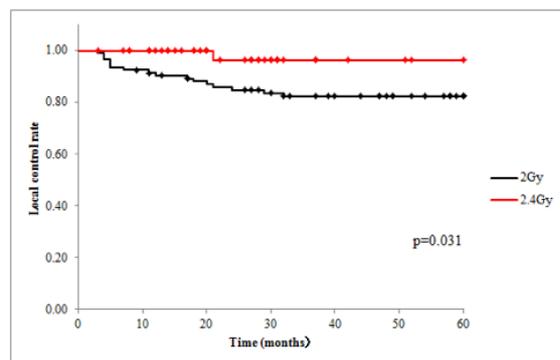

### Material and Methods

A single-institutional retrospective study was conducted to review ESGC patterns of care and treatment outcome. From February 1998 to January 2016, 204 consecutive patients with T1-2N0 GSCC were treated in our institution. Forty-seven patients received HRT and 157 CRT. Using 4 MV photon beam, a median dose of 66 Gy (range, 60-70 Gy) was delivered with daily doses of 2.0 Gy/fraction (CRT) or 2.4Gy/fraction (HRT). None of the patients received prophylactic nodal RT. Patients in both treatment groups were matched using the propensity score matching method (1:2 ratio). Treatment outcome was analyzed in terms of local control rate (LCR), distant failure-free survival (DFFS), progression-free survival

(PFS), overall survival (OS), and treatment-related adverse events (AE).

#### Results

The matched cohort consisted of 47 HRT and 94 CRT patients with the median follow-up of 27 and 62 months, respectively. Significant higher 5-year LCR and PFS were observed in the HRT group (96% vs. 82% and 96% vs. 76%,  $p=0.031$  and  $0.015$ , respectively). No significant differences in DFFS and OS were observed between groups. Most acute AE included grade 1-2 mucositis, dermatitis, dysphagia and/or hoarseness. Except for one patient who had grade 3 dysphagia in the CRT group, there was no grade 3 or greater chronic AE.

#### Conclusion

This large, single-institutional experience of definitive radiotherapy for ESGC using HRT vs. CRT demonstrates that HRT achieved high rates of LCR and PFS with minimal long-term toxicity. Although these results must be confirmed by randomized controlled study, HRT should be considered for the treatment of ESGC.

#### EP-1053 Analysis of outcomes of Adenoid cystic Carcinoma of Head and Neck region: Single Institution Study

M. Rafi<sup>1</sup>, M. Anjanappa<sup>1</sup>, C. Kainickal<sup>1</sup>, P. George<sup>2</sup>, R. Kumar<sup>1</sup>, R. Kunnambath<sup>1</sup>

<sup>1</sup>Regional Cancer Centre, Radiation Oncology, Trivandrum, India

<sup>2</sup>Regional Cancer Centre, Epidemiology and biostatistics, Trivandrum, India

#### Purpose or Objective

To study the treatment outcomes of Adenoid cystic carcinoma of the head and neck region.

#### Material and Methods

The case records of patients who were diagnosed and treated for adenoid cystic carcinoma of head and neck region in a tertiary care hospital in India between 2004 and 2011 were retrospectively reviewed. Demographic data, clinico-pathological details and treatment outcomes were captured using a structured proforma, for survival analysis and identification of prognostic factors.

#### Results

A total of 164 patients reported to the institution with biopsy proven adenoid cystic carcinoma of the head and neck region during this period. Out of this, 142 patients were included in the analysis after excluding the patients who did not undergo any treatment at this centre.

Out of the 142 patients analyzed, 57.7% were females. The mean age of presentation was 46.5yrs (Range 16-84 yrs). The most common site of presentation was oral cavity (28.2%) followed by paranasal sinus and nasal cavity (22.5%), and parotid gland (15.5%). A total of 44.4% of patients had stage I /II disease. Node positivity was seen in 16 patients (11.2%) and three patients had metastatic disease at presentation.

Surgery was the primary modality of management in 120 patients(84.5%).Among them 67 patients (47.2%) had margin positive resection. Most of these were either unplanned excisions or were paranasal sinus lesions. Radiotherapy was delivered to 120 patients (84.5%) as a part of their treatment, with majority being given adjuvant radiotherapy (100 patients). Curative radiotherapy was used in 18 patients. Radiotherapy dose ranged from 60-70 Gy in two Gy equivalent.

Recurrence was recorded in 47 patients (33%); 21 patients had isolated recurrence in the primary site, 20 had systemic failure, 5 patients had nodal failure and 1 patient had systemic and local failure. The mean time for development of failure was 32 months (Range 1-99months) for systemic and 44.5 months (Range 5-105months) for loco-regional site. Of the 18 patients who were given radical RT, 14 had complete response (77.7%) and among them eight patients had disease recurrence.

Radiotherapy was given to 13 patients with recurrence, eight patients underwent surgery, three patients had chemotherapy and 11 patients were just kept on follow-up.

The disease free survival at 5 years was 76.9%.

#### Conclusion

Adenoid cystic carcinomas are relatively rare neoplasms of salivary glands. A good proportion of these tumours occur in minor salivary glands as reflected in this analysis. Surgery remains the preferred primary treatment modality with a large proportion of patients also getting RT as a part of their treatment. Along with loco-regional failure, these tumours also have a propensity for distant metastasis.

#### EP-1054 Disease Outcomes following Post-operative IMRT for Oral Cavity Cancer: A Single Institution Analysis

A. Michaelidou<sup>1</sup>, M. Lei<sup>1</sup>, T. Guerrero Urbano<sup>1</sup>

<sup>1</sup>Guy's & St Thomas' NHS Foundation Trust, Oncology- 4th Floor Bermondsey Wing, London, United Kingdom

#### Purpose or Objective

The purpose of this study is to analyse survival outcomes in patients with oral cavity squamous cell carcinoma (OCSCC) treated with radical surgery and post-operative IMRT (POIMRT), +/- chemotherapy, at our institution.

#### Material and Methods

A retrospective analysis was performed of all patients with OCSCC who received IMRT with radical intent between March 2010 and March 2016. Data were extracted from electronic case records, reviewed only by members of the responsible clinical team. Statistical analysis was done using IBM SPSS and Microsoft Excel. Estimates of overall survival (OS), disease-free survival (DFS) and disease specific survival (DSS) were done using life tables and the Kaplan-Meier method.

#### Results

138 patients with OCSCC received IMRT in total. 127 (73-male, 54-female; mean age-62, range 26-86) were included in the survival analysis. 9 patients unsuitable for surgery that had primary IMRT alone, and one patient who died of aspiration during treatment were excluded. Of the 127 patients analysed, 7 did not complete the prescribed course of POIMRT (patient choice in 3, clinician decision because of toxicity in 4).

Most patients had advanced disease on pathological staging: AJCC stage IV - 77.2%, n=98; stage III - 15.7%, n=20; Stage II - 2.4%, n=3; Stage I - 4.7%, n=6. Smoking history was recorded in 124 patients: 64.5%, n=80 reported a significant smoking history (smoking at diagnosis or ex-smokers with >10 pack years).

Standard POIMRT doses were 60Gy in 30# (64.6%, n=82) and 65-70Gy in 30-33# (24.4%, n=31) for those with involved margins. Doses of 50-55Gy in 20# were used in

those with significant co-morbidities or a poor performance status (11.0%, n=14). Concurrent chemotherapy with cisplatin 100mg/m<sup>2</sup> or carboplatin AUC5 (when cisplatin contra-indicated), 3-4weekly, was considered in patients with extracapsular spread and/or involved margin (49.6% n=63) and given to those with no contra-indications (31.5%, n=40).

Median follow up from the end of treatment was 20.7 months (range 0.9-76.8 months) in all patients. Median follow in survivors was 30.9 months (range 7.3-76.8 months). At the time of analysis 39 patients had a confirmed relapse and 52 patients had died (35 disease related). Mean survival rates were: OS 45.9 months (95% CI 39.8-52.1); DFS 43.5 months (95%CI 37.5-49.5); DSS 55.4 months (95% CI 49.4-61.3).

One-year survival rates were: OS 74% (95%CI - 66.2 - 81.8); DFS 74% (95%CI - 66.2 - 81.8); DSS 79% (95%CI - 71.2 - 86.8). Three-year survival rates were: OS 54% (95%CI - 44.2 - 63.8); DFS 51% (95%CI - 41.2 - 60.8); DSS 66% (95%CI - 56.2 - 75.8).

#### Conclusion

Our results are consistent with nationally reported survival data. Ongoing work is carried out to report treatment related toxicities and identify histopathological factors that may influence prognosis.

#### EP-1055 A Novel Postoperative Chemoradiotherapy Protocol versus Conventional CCRT for High-risk SCCHN

Y.T. Shih<sup>1</sup>, W.Y. Wang<sup>2</sup>, C.T. Wu<sup>3</sup>, J.C. Lin<sup>4</sup>

<sup>1</sup>St. Martin De Porres Hospital, Radiation Oncology Department, Chiayi, Taiwan

<sup>2</sup>Hung Kuang University, Department of Nursing, Taichung, Taiwan

<sup>3</sup>Changhua Show Chwan Memorial Hospital, Department of Radiation Oncology-, Changhua, Taiwan

<sup>4</sup>Taichung Veterans General Hospital, Department of Radiation Oncology-, Taichung, Taiwan

#### Purpose or Objective

Postoperative concurrent chemoradiotherapy (CCRT) is superior to RT alone for squamous cell carcinoma of the head and neck (SCCHN) with high-risk factors (such as extracapsular invasion, positive resection margin) by both RTOG 9501 and EORTC 22931 trials. We developed a new protocol of intensive chemotherapy followed by IMRT (IntCT+RT) and compared the toxicity and efficacy with CCRT for patients with SCCHN and poor prognostic factors after surgery.

#### Material and Methods

Ninety-two SCCHN patients who received curative resection first and with at least one of the following characteristics, resection margin involvement or close to the tumor, extracapsular invasion, perineural invasion, angiolymphatic invasion, pathological stage T4, and multiple neck nodes metastasis were eligible for this study. Postoperative multi-drugs combination chemotherapy (Methotrexate 30 mg/m<sup>2</sup> d1, Epirubicin 30 mg/m<sup>2</sup> d1, alternating with Mitomycin-C 4 mg/m<sup>2</sup> d8, Oncovin 1 mg/m<sup>2</sup> d8, Cisplatin 25 mg/m<sup>2</sup> d8, Leucovorin 120 mg/m<sup>2</sup> d8, 5-fluoroUracil 1000 mg/m<sup>2</sup> d8, and Bleomycin 10 mg/m<sup>2</sup> d8) for 10-12 weeks were administered followed by IMRT in the IntCT+RT groups. Patient in the CCRT group received similar RT and concurrent chemotherapy of either tri-weekly cisplatin 100mg/m<sup>2</sup> alone or tri-weekly cisplatin 50mg/m<sup>2</sup> plus oral tegafur-uracil 2# bid for 7 weeks.

#### Results

The IntCT+RT group (n=37) had less regional (8.1% vs. 12.7%) and distant (2.7% vs. 7.3%) failures, compared with the CCRT group (n=55). The Kaplan-Meier survival analyses revealed that patients treated by IntCT+RT had better regional failure-free survival (3-year rate, 94.5% vs. 72.4%, P=0.0294) and overall survival (75.9% vs. 61.8%, P=0.1343)

than those who received CCRT. Grade 3/4 acute toxicity of IntCT phase included leucopenia (51.4%), anemia (27.0%), vomiting (5.4%), alopecia (5.4%) and mucositis (2.7%) but patients could tolerate it well. During RT period, patients in the CCRT group had significantly higher grade 3/4 mucositis (76.4% vs. 57.7%, P=0.0356) and vomiting (27.3% vs. 0%, P<0.0001) than those in the IntCT-RT group.

#### Conclusion

IntCT+RT in postoperative setting for high-risk SCCHN patients is feasible. We observe a significant better regional control, favorable overall survival and less grade 3 or 4 mucositis and vomiting in the IntCT-RT group compared with the CCRT. This novel approach deserves to be studied in a phase III randomized trial.

#### EP-1056 Radiation and concurrent superselective intra-arterial cisplatin for maxillary sinus cancer

T. Ebara<sup>1</sup>, K. Ando<sup>1</sup>, M. Kawahara<sup>1</sup>, M. Suzuki<sup>2</sup>, H. Horikoshi<sup>3</sup>, Y. Tamaki<sup>4</sup>

<sup>1</sup>Gunma Prefectural Cancer Center, Division of Radiation Oncology, Ota, Japan

<sup>2</sup>Gunma Prefectural Cancer Center, Division of Head and Neck Surgery, Ota, Japan

<sup>3</sup>Gunma Prefectural Cancer Center, Division of Radiology, Ota, Japan

<sup>4</sup>Tsukuba University Hospital, Department of Radiation Oncology, Tsukuba, Japan

#### Purpose or Objective

This study aimed to evaluate the efficacy of radiation and concomitant superselective high-dose intra-arterial cisplatin (RADPLAT) for maxillary sinus squamous carcinoma (MS-SCC).

#### Material and Methods

We conducted a retrospective chart review of MS-SCC patients treated with RADPLAT between 2008 and June 2016.

#### Results

Thirty-four MS-SCC patients were received RADPLAT. There were 9 patients (26%) diagnosed with T3, 14 (41%) with T4a, and 11 (32%) with T4b disease. Lymph-node involvement was present in 6 patients. Cisplatin with median 150 mg was administered using the superselective intra-arterial infusion method bi-weekly. Of them, 29, 3, 1 and 1 patients were received 4, 3, 2 and 1 times cisplatin infusions, respectively. Radiation, ranged with 50-74 Gy with median 60 Gy was administered by 2 Gy fraction in 5 times a week. The median follow-up was 24.6 months, ranged with 4.1-92.4 months. Complete responses in the primary site were obtained in 11 (32%) patients and partial responses in 19 (56%) patients. The 2 and 5-year overall survival rates (OS) were 66 and 45%, respectively. The 2 and 5-year primary-site recurrence free survival rates (PRFS) were 49 and 40%, respectively. The 2 and 5-year disease-free survival rates (DFS) were 45 and 37%, respectively. The patients with T3 showed significantly better OS (p=0.03). The patients with 4 time infusions showed significantly better OS, PRFS, and DFS (p<0.05). There was no life-threatening toxicity.

#### Conclusion

In RADPLAT for MS-SCC, 4 times cisplatin infusions could improve the prognosis.

#### EP-1057 Predictive and prognostic value of pretreatment [18F] FDG-PET parameters in head-and-neck cancer

L. Deantonio<sup>1</sup>, M. Paolini<sup>1</sup>, E. Puta<sup>2</sup>, L. Vigna<sup>3</sup>, R. Matheoud<sup>3</sup>, L. Masini<sup>1</sup>, G. Sacchetti<sup>2</sup>, M. Brambilla<sup>3</sup>, M. Krengli<sup>1</sup>

<sup>1</sup>University Hospital Maggiore della Carità, Radiotherapy, Novara, Italy

<sup>2</sup>University Hospital Maggiore della Carità, Nuclear Medicine, Novara, Italy

<sup>3</sup>University Hospital Maggiore della Carità, Medical Physics, Novara, Italy

#### Purpose or Objective

To evaluate the predictive and prognostic value of [F18] FDG-PET parameters performed prior to radiotherapy in head-and-neck cancer patients.

#### Material and Methods

Thirty-eight patients with newly diagnosed head-and-neck cancer treated with concomitant chemoradiotherapy underwent [F18] FDG-PET before the treatment course. The maximum and the mean standardized uptake value (SUVmax, SUVmean), the metabolic tumor volume (MTV), and total lesion glycolysis (TLG) were analysed. Multiple threshold levels were tested in order to define the most suitable threshold value for the metabolic activity of each patient's tumour: the fixed threshold of the 41% and 50% of the maximum uptake value (SUV41%, SUV50%) and an adaptive threshold algorithm (ATA) implemented on the iTART workstation (Tecnologie Avanzate, Italy). We evaluated the relationship of mean values of SUVmax, SUVmean, MTV, and TLG with tumour characteristics, treatment response, local recurrence, distant metastasis and disease-related death. Receiver-operating characteristic (ROC) curve analysis was done to obtain optimal predictive cut-off values for PET parameters. Disease-free (DFS) and overall survival (OS) disease-related were examined according to these cut-offs.

#### Results

The mean value and range of each parameters were calculated (Table1).

Higher SUVmean<sub>ATA</sub> was associated to higher primary tumour staging (p= 0.04).

Thirty-two/38 patients (84.2%) had a complete response, 4/38 (10.5%) a partial response, and 2/38 (5.2%) a no response 8 weeks after the completion of treatment. SUV parameters resulted not predictive of tumour response.

After a median follow-up of 22 months, 6/38 (15.8%) patients developed local recurrence and 6/38 (15.8%) distant relapse. Eight patients (21.1%) died of tumour progression.

The TLG<sub>ATA</sub> was predictive of local recurrence (p = 0.04). ROC curves analysis revealed a cut-off value of 19.6 for SUVmax, and 13.7 for SUVmean<sub>ATA</sub> (AUC 0.72, p=0.03 and AUC 0.72 p=0.03, respectively). The 2-year DFS rate was significantly lower in patients with a SUVmax >19.6 (p= 0.001) and with a SUVmean<sub>ATA</sub> >13.7 (p= 0.02).

ROC curves analysis revealed a cut-off value of 19.6 for SUVmax, 8.6 for SUVmean<sub>ATA</sub> and 49.1 for TLG<sub>ATA</sub> (AUC 0.8, p=0.03; AUC 0.9 p=0.007, and AUC 0.8 p= 0.01 respectively). The 2-year OS rate was significantly lower in patients with a SUVmax >19.6 (p= 0.004), with a SUVmean<sub>ATA</sub> >8.6 (p= 0.03) and TLG<sub>ATA</sub> >49.1 (p= 0.004).

Table 1. [18F] FDG-PET parameters based on multiple threshold levels.

Parameters	SUVmax	SUVmean	MTV (cc)	TLG
Adaptive threshold algorithm (ATA)	16.37 (4.41 - 34.53)	9.15 (2.8 - 19.71)	17.21 (1.5 - 61.53)	149.89 (5.3 - 877.85)
SUV41%	16.37 (4.41 - 34.53)	10.50 (2.94 - 21.78)	10.30 (1.02 - 58)	130.90 (3 - 850.86)
SUV50%	16.37 (4.41 - 34.53)	11.45 (3.33 - 23.73)	7.79 (0.45 - 47.11)	107.77 (2.10 - 736.33)

#### Conclusion

Adaptive threshold-based SUVmean, MTV, and TLG and SUVmax could have a role in predicting local control and survival in head and neck cancer patients treated with chemoradiotherapy.

#### EP-1058 A multicenter study of carbon-ion RT for locally advanced olfactory neuroblastomas (J-CROS1402HN)

H. Suefujii<sup>1</sup>, M. Koto<sup>2</sup>, Y. Demizu<sup>3</sup>, J. Saitoh<sup>4</sup>, Y. Shioyama<sup>1</sup>, H. Tsuji<sup>2</sup>, T. Okimoto<sup>3</sup>, T. Ohno<sup>4</sup>, K. Nemoto<sup>5</sup>, T. Nakano<sup>4</sup>, T. Kamada<sup>2</sup>

<sup>1</sup>Ion Beam Therapy Center- SAGA-HIMAT Foundation, radiation oncology, tosu, Japan

<sup>2</sup>National Institute of Radiological Science Hospital-National Institutes for Quantum and Radiological Sciences and Technology, radiation oncology, chiba, Japan

<sup>3</sup>Hyogo Ion Beam Medical Center, radiology, tatsuno, Japan

<sup>4</sup>Gunma University Heavy Ion Medical Center, radiology, maebashi, Japan

<sup>5</sup>Yamagata University Faculty of Medicine, radiation oncology, yamagata, Japan

#### Purpose or Objective

The combination with surgery and postoperative radiotherapy is the most common therapy for locally advanced olfactory neuroblastomas (ONB), but has a high incidence of local recurrence. We analyzed the ONB patients treated by carbon-ion radiotherapy (C-ion RT) in the Japan Carbon Ion Radiotherapy Study Group study. In this study, we evaluated the efficacy and safety of C-ion RT for locally advanced ONBs in Japan.

#### Material and Methods

Patients with T4N0-1M0 ONBs who were treated with C-ion RT at 4 institutions in Japan between November 2003 and December 2014 were analyzed retrospectively. A total of twenty-one patients (16 male and 5 female; median age, 53 years) with locally advanced ONBs were enrolled in this study.

#### Results

Main tumor sites included the nasal cavity in 11 patients and sphenoid sinuses in 10, respectively. Seven patients had T4a and 14 had T4b tumors. All 21 patients enrolled in this study did not have cervical node metastases. The median total dose and number of fractions were 60.8 Gy (RBE) and 16 fractions, respectively. Four patients received neo-adjuvant chemotherapy. The median follow-up period was 39 months (range, 5-111 months). The 3 year overall survival and local control rates were 88.4% and 83.0%, respectively. Grade 4 late toxicity was observed in 3 patients. Of the three patients, 2 developed ipsilateral optic nerve disorder and 1 ipsilateral retinopathy. With respect to these patients whose adverse events could not be avoided, the GTV was over 34cc and the tumors were in close proximity to the orbit. Except eye disorder, grade ≥4 late toxicities did not occurred.

#### Conclusion

C-ion RT is an effective treatment modality for locally advanced ONB.

#### EP-1059 A [18F] FDG-PET adaptive thresholding algorithm for delineation of RT volumes of head&neck cancer.

M. Paolini<sup>1</sup>, L. Deantonio<sup>1</sup>, L. Vigna<sup>2</sup>, R. Matheoud<sup>2</sup>, G. Loi<sup>2</sup>, G. Sacchetti<sup>3</sup>, M. Brambilla<sup>2</sup>, M. Krengli<sup>1</sup>

<sup>1</sup>University Hospital Maggiore della Carità, Radiotherapy, Novara, Italy

<sup>2</sup>University Hospital Maggiore della Carità, Medical Physics, Novara, Italy

<sup>3</sup>University Hospital Maggiore della Carità, Nuclear Medicine, Novara, Italy

### Purpose or Objective

A standardized way of converting PET signals into target volume is not yet available. The aim of this study was to evaluate a [18F] FDG-PET adaptive thresholding algorithm for the delineation of the biological tumour volume for the radiotherapy (RT) treatment planning of head and neck cancer patients.

### Material and Methods

Thirty-eight patients, who underwent exclusive intensity modulated RT with simultaneous integrated boost (IMRT-SIB) for head-and-neck squamous cell carcinoma (3 oral cavity, 9 nasopharynx, 19 oropharynx, 6 hypopharynx, and 1 larynx cancer) were included in the present study. Thirty-five/38 patients presented a locally advanced disease (92.1%), and 30/38 patients (78.9%) received a concomitant chemoradiotherapy. For all patients, [18F] FDG-PET/CT was performed in treatment position with the customized thermoplastic mask. Two radiation oncologists defined the primary biologic tumour volumes (BTV) using the adaptive thresholding algorithm implemented on the iTART workstation (Tecnologie Avanzate, Italy). The algorithm used specific calibration curves that depended on the lesion-to-background ratio (LB ratio) and on the amplitude of reconstruction smoothing filter (FWH).

The evaluation of reproducibility of adaptive thresholding algorithm for volume estimation was determined by the volume overlap of multiple segmentation of the same lesion by two radiation oncologists. Each primary tumour volume was segmented by the adaptive thresholding algorithm (BTV<sub>ATA</sub>). The target volumes for the primary tumours previously delineated on the planning computed tomography (CT) scan using anatomic imaging (CT and MRI) (gross tumour volume standard GTV<sub>ST</sub>) and a fixed image intensity threshold method (40% of maximum intensity) of [18F] FDG-PET standardized uptake value (GTV<sub>40%SU<sub>V</sub></sub>) were used to perform a volumetric comparison.

### Results

The algorithm generated a tumour volume in all but two patients. The mean values with standard deviation (SD) of volumes based on the three different methods were reported in Table 1.

The BTV<sub>ATA</sub> was significantly smaller than the GTV<sub>ST</sub> (17 vs. 21 cc,  $p = 0.04$ ); the conformity index (CI) was 0.46, and the similarity coefficient (DICE) was 0.7 (Sensitivity 66%, specificity 85%). BTV<sub>ATA</sub> is a part of the GTV<sub>ST</sub>.

The BTV<sub>ATA</sub> was bigger than the GTV<sub>40%SU<sub>V</sub></sub> (17 vs. 15 cc) but the difference was not statistically different ( $p > 0.05$ ), the CI was 0.8 and the DICE was 0.2.

**Table 1. Tumour Volumes defined by the three different methods.**

GTV	Mean Volume (cc)	Volume Ranges	Standard Deviation
GTV <sub>ST</sub>	21.4	4.5 - 66.3	±16.0
GTV <sub>40%SU<sub>V</sub></sub>	14.7	1.3 - 58.5	±13.7
GTV <sub>T<sub>ATA</sub></sub>	17.2	1.5 - 61.5	± 12.8

### Conclusion

The proposed adaptive thresholding algorithm resulted robust and reproducible in the clinical context of head and neck tumours. The tumour volumes obtained by the algorithm were a part of the GTV<sub>ST</sub> and were similar to GTV<sub>40%SU<sub>V</sub></sub>. This tumour volume could allow the delineation of a BTV for dose escalation in head and neck cancer treated with IMRT-SIB.

### EP-1060 Analysis of failure patterns and prognostic factors after postoperative IMRT for buccal cancer

Y.W. Lin<sup>1</sup>, L.C. Lin<sup>1</sup>

<sup>1</sup>Chi Mei Medical Center, Department of Radiation Oncology, Tainan, Taiwan

### Purpose or Objective

Squamous cell carcinoma (SCC) of buccal mucosa has a high incidence of locoregional failure. Its aggressive behavior and the change of lymphatic and vascular drainage after surgery make the design of radiotherapy difficult. The aim of this study is to analyze failure patterns and prognostic factors in patients with locally advanced buccal cancer after postoperative intensity modulated radiotherapy (IMRT).

### Material and Methods

Between January 2007 to October 2012, 84 patients with histological confirmed SCC of buccal mucosa underwent surgery followed by postoperative IMRT were retrospectively analyzed. All patients were stage III/IV buccal cancer. The high-risk clinical target volume (CTV) covered the surgical tumor bed and ipsilateral or bilateral upper neck. The median dose to high-risk CTV was 60Gy. Analyzed end-points were overall survival (OS), local recurrence-free survival, loco-regional recurrence-free survival, supra-mandibular notch recurrence-free survival, distant metastasis-free survival, prognostic factors and patterns of failure.

### Results

The median follow up was 51 months (range, 2-112 months). The first recurrent sites were local tumor bed (17 patients) with or without regional/distant recurrence. The median time from treatment completion to first locoregional recurrence was 7.3 months. Of the 17 patients with local recurrence, 11 exhibited the supra-mandibular notch recurrence; most were classified as marginal failure. The estimated 4-year local failure-free, locoregional failure-free, distant metastasis-free and overall survival rates were 72%, 63.3%, 85.9% and 68.8%. In multivariate analysis, lymphovascular invasion ( $P = 0.002$ ), N2 disease ( $P = 0.003$ ), and ratio of tumor thickness to tumor size larger than 1/3 ( $P = 0.014$ ) were independent prognostic factors for overall survival. Patients received tumor excision with maxillectomy was a predictive factor for the development of supra-mandibular notch recurrence.

### Conclusion

SCC of buccal mucosa is a highly aggressive form of oral cavity cancer with a high locoregional failure rate and most locoregional recurrences led to lethal events. Design of postoperative IMRT for buccal cancer, especially CTV delineation, based on failure patterns and clinicopathological prognostic factors might transfer into better disease control.

### EP-1061 Towards a validated Decision Aid Tool for advanced larynx cancer patients

A.J. Berlanga<sup>1</sup>, M. Petersen<sup>2</sup>, F. Hoebels<sup>1</sup>, S. Delbressine<sup>1</sup>, M. Van den Breke<sup>2,3,4</sup>, P. Lambin<sup>1</sup>

<sup>1</sup>Maastricht Clinic, GROW School for Oncology and Developmental Biology- Maastricht University Medical Centre, Maastricht, The Netherlands

<sup>2</sup>The Netherlands Cancer Institute, Department of Head and Neck Surgery and Oncology, Amsterdam, The Netherlands

<sup>3</sup>Academic Medical Center, Department of Oral and Maxillofacial Surgery, Amsterdam, The Netherlands

<sup>4</sup>University of Amsterdam, Institute of Phonetic Sciences, Amsterdam, The Netherlands

### Purpose or Objective

Advanced larynx cancer patients may be eligible for more than one treatment: laryngectomy, radiotherapy, chemoradiation, or combinations thereof. These treatments have a distinct impact on quality of life (e.g. disfigurement, speech, swallowing problems), and outcomes depending on TNM-classification.

To empower these patients to participate in shared-decision making, we are creating a web-based Patient

Decision Aid Tool (PDA, [www.treatmentchoice.info](http://www.treatmentchoice.info)). The goal is help patients to understand treatment options and support clinicians to gain perspective of patients' preferences.

#### Material and Methods

The PDA was validated following the International Patient Decision Aid Standards (IPDAS). First, a prototype was created considering literature and input from an interdisciplinary group. A mixed-method (interview, 5-Likert questionnaire) was used to identify patients' decisional needs, and to evaluate if the tool was clear and perceived as useful for shared-decision making. Clinicians (N=8) and patients (N= 12) from two hospitals were included.

#### Results

Patients and clinicians agreed on patient's difficulty to recall spoken information and understand risk probabilities. They mentioned the need of information about treatment options, side effects, and effectiveness. Patients asked for information about procedures before and after treatment.

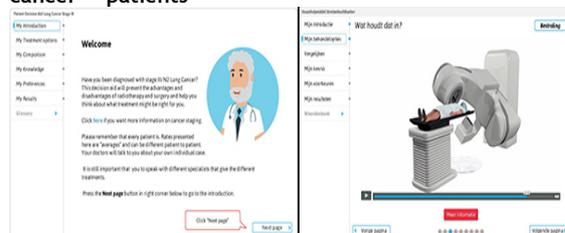

Patients preferred information that is simple, visual, and in small chunks. Clinicians preferred information adapted to patient's psychosocial level.

Patients were positive about the PDA. All criteria (satisfaction, effectiveness, clarity, usability, usefulness, intention use) had a median (IQR) of 4 ('agree'). Patients asked for simpler terms, information on psychological effects and the 'no treatment option'.

Considering these results, a new version was created (Fig.1). It is a visual tool, containing video interviews with clinicians and animations to explain the treatments.

This version will be validated by clinicians and patients for comprehensibility and usability. Results will be considered to create a final version. Thereafter, we will evaluate its impact on shared decision-making in a multi-center setting.

**Fig. 1: Web-based decision aid tool for advanced larynx cancer patients**

#### Conclusion

A systematic validation process, as IPDAS, makes it possible to understand the characteristics and decisional needs of patients and clinicians, which are specific and differ among diseases and contexts. This is essential for implementation of PDAs in the clinical practice.

#### EP-1062 Hypofractionated vs standard radical radiotherapy in early (T1-T2) glottic cancer patients.

M.A. González Ruiz<sup>1</sup>, J.J. Cabrera Rodríguez<sup>1</sup>, A. Ruiz Herrero<sup>1</sup>, M.C. Cruz Muñoz<sup>1</sup>, P. Simón Silva<sup>1</sup>, J. Quirós Rivero<sup>1</sup>, J.L. Muñoz García<sup>1</sup>, Y. Ríos Kavadoy<sup>1</sup>, M.F. Ropero Carmona<sup>1</sup>, F. García Urra<sup>1</sup>

<sup>1</sup>Infanta Cristina Hospital, Radiation Oncology, Badajoz, Spain

#### Purpose or Objective

To analyze the results [(disease free survival (DFS) and overall survival (OS)] of patients (pts) with glottic cancer (GC) treated with hypofractionated radiation therapy versus standard radiotherapy treatment with radical intention.

#### Material and Methods

Retrospective comparative study of 125 pts with GC T1 or T0is stage (119 pts) and T2 stage (6 pts) treated with radical intention with radiation therapy in our hospital from June 1995 to June 2015. Hypofractionated treatment (2,25 Gy/fraction; total dose 63 Gy) was used in 42 pts and standard treatment (2 Gy/fraction; total dose 70 Gy) was used in 83 pts. Baseline characteristic were similar in both groups. Median total dose of radiotherapy was 66 Gy (range 63-70). Kaplan-Meier curves have been used for the statistical analysis of survival and the log-rank test for the comparison of the survivals. Treatment-related toxicity was assessed using RTOG and the NCI-Common Terminology Criteria for Adverse Events guidelines.

#### Results

The median follow-up was 215 months. The DFS and OS in hypofractionated group were 97,6% and 93% respectively and in standard radiotherapy group were 93% and 95,2% respectively without statistically significant differences. When we analyzed OS by stage subgroups, we can see that in T1 or T0is group the results are better (95,8%) than in T2 group 66,7% (p 0,001) without differences because of the treatment regimen used. In the analysis according to the age of the pts, we had the following results in terms of OS: < 70 years-old pts treated with hypofractionated treatment (28 pts) were 96,4 % and >70 years-old pts (14 pts) were 100%. The OS in < 70 years-old pts treated with standard treatment (43 pts) was 93% and in >70 years-old pts (40 pts) was 92,5% without statistically significant differences. When we analyze OS according to the anterior commissure involvement, we haven't found statistically significant differences. In both groups the majority of pts had acute skin and mucosa toxicity grade 1-2 without statistically significant differences regardless the regimen of treatment used.

#### Conclusion

Hypofractionated treatment supposed better local disease control than standard treatment but in terms of OS there weren't any differences. When we analyzed our pts by subgroups stage, we found that T2 stage group had worse results than T1 or T0is stage group in terms of OS (p 0,001) regardless of treatment used. There weren't no differences in terms of toxicity nor local control between elderly pts and young pts regardless of treatment used either.

#### EP-1063 Epidemiology and clinical outcome of HPV in different head and neck cancer a subgroup analysis

E. Boelke<sup>1</sup>, B. Gössler<sup>1</sup>, B. Tamaskovic<sup>1</sup>, W. Budach<sup>1</sup>, C. Matuschek<sup>1</sup>

<sup>1</sup>University Hospital Düsseldorf Heinrich Heine University Düsseldorf, Radiation Oncology, Düsseldorf, Germany

#### Purpose or Objective

Human papillomavirus (HPV)-associated squamous cell carcinoma of the oropharynx is a well-defined disease typically affecting young to middle-aged male non-smokers. The incidence of HPV-associated oropharyngeal cancers is rapidly increasing in most Western countries, but detailed epidemiological data are not available for the Dusseldorf population. Moreover, among other head and neck regions, a less significant proportion of oral high-grade dysplasia and cancers appears to depend on HPV infection, whereas its role in laryngeal cancer is recognized as less significant. The aim of this study was to find out the incidence and clinical outcome of HPV infection in different head neck cancer patients in a German population.

#### Material and Methods

In this retrospective study, the tumour tissue from 164 patients (110 men, 54 women, 62.8 years + 12.7) with head neck cancer (oropharynx = 65 nasopharynx = 10, larynx = 13, hypopharynx = 15, oral cavity = 33 CUP = 5,

Other = 23) were tested for HPV infection. Furthermore, the clinical outcome for all tumor sides was examined with uni and multivariate analysis. We analyzed p16 in all tumor tissues as a surrogate marker for HPV infection with immunohistochemistry. Moreover, risk factors such as nicotine, alcohol abuse, location of the tumour, resection margin of the tumour tissue, histology, lymph nodes involvement, extracapsular spread, tumour stage, and the treatment of the tumour (surgery, chemo and radiation therapy) were examined for local tumour control and overall survival for all patients.

#### Results

The prevalence of HPV infection in oropharynx-carcinoma patients in Dusseldorf was 33%. Patients with HPV-positive oropharyngeal carcinomas showed a tendency towards longer survival time, ( $p = 0.76$ , HR: 2.42, 95% CI 0.91 - 6.44) compared to HPV-negative tumours. This association was independent from alcohol and nicotine abuse. Other tumour locations like larynx or hypopharynx carcinoma showed no association between HPV infection and clinical outcome. As expected the tumour stage in all tumour locations was significant in the uni and multivariate analysis for local control and overall survival.

#### Conclusion

The HPV infection in Dusseldorf was lower than anticipated. Furthermore, in our study it seems that p 16 positive oropharyngeal carcinoma patients have a better clinical outcome than p 16 negative patients. In this patient group p 16 can be used as a prognostic biomarker. This was independent from alcohol and nicotine abuse. But for other tumor localizations we could not find a better clinical outcome.

#### EP-1064 Does parotid sparing adaptive radiotherapy (PSART) benefit patients? Interim results of PARITY study

M. Arunsingh<sup>1</sup>, C. Nallathambi<sup>1</sup>, S. Prasath<sup>1</sup>, A. Balakrishnan<sup>1</sup>, R.K. Shrimali<sup>1</sup>, R. Achari<sup>1</sup>, I. Mallick<sup>1</sup>, S. Chatterjee<sup>1</sup>

<sup>1</sup>Tata Medical Center, Department of Radiation Oncology, Kolkata, India

#### Purpose or Objective

Intensity Modulated Radiotherapy (IMRT) to the head and neck cancer has been proven to reduce the incidence of long-term xerostomia and thereby improve quality of life (QOL) of survivors. However, it is also well known that there are ongoing changes in the dose intended to the parotids during radiotherapy often resulting in higher parotid doses. Parotid sparing adaptive radiotherapy (PSART) provides dosimetric corrections for such unintended higher doses. Our study evaluates the clinical benefits of PSART and also calculates the resource intensiveness.

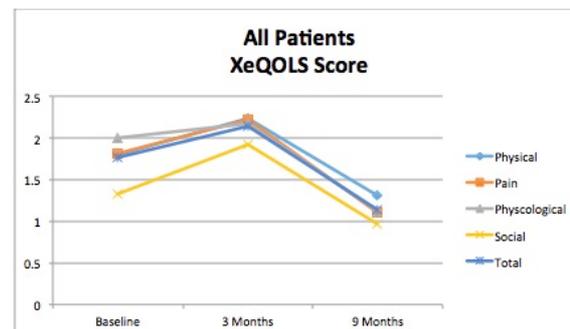

#### Material and Methods

Thirty-nine of the planned 90 patients of head and neck cancer were screened if to at least one or both parotid (index parotid/s) were receiving a mean dose (MD) of between 25 to 30Gy and were recruited. The index parotid was delineated on the verification images acquired on 14<sup>th</sup> and 19<sup>th</sup> day and the MD was determined by overlaying the fused verification image on the planned CT. Dosimetric comparison was done using adaptive planning. If the MD had increased by 2% of the initial intended dose, an adaptive plan (AP) was attempted with an aim to reduce MD by 2% without compromising PTV coverage; this plan was then used to deliver the remaining treatment. The time required and number of personnel involved during each step was recorded and person hours (PH) were calculated using the formula: (Minutes x Personnel involved)/60. Xerostomia was assessed by a questionnaire (XeQOLS) at baseline, at 3 and 9 months after completion of treatment.

#### Results

Eighteen patients underwent radical radiotherapy with remaining receiving adjuvant treatment. Thirty were treated on Tomotherapy whilst others were treated on Novalis Tx. The median increase in parotid dose was 1.1Gy corresponding to a median reduction in the parotid volume of 1.1cc. Twenty-three patients required an AP with fifteen requiring it after the 14<sup>th</sup> day. An acceptable adaptive plan, which met the criteria as described above, was achieved for 19 of these 23 patients. A median of 7.5 fractions were delivered with the adaptive plans. Median PH required for normal RT of a patient was 26PH while an additional 14.34PH was required in those undergoing PSART. All components of the XeQOLS (physical, pain, social and personal) were worse at 3 months compared to baseline and improved over time at 9 months in all patients irrespective of whether they underwent PSART or not (Figure 1). However, early data does not reveal any significant difference in QOL for those who underwent PSART. (Table 1)

XeQOLS Score at 9 months	No PSART Patients (Median Score)	PSART Patients (Median Score)	Significance, p (Mann-Whitney)
Physical Domain	1.00	2.00	0.64
Pain Domain	1.00	2.00	0.64
Physiological Domain	1.00	2.13	0.92
Social Domain	0.67	2.17	0.64
Total Score	0.93	2.07	0.77

#### Conclusion

The results confirm that PSART, which is resource intensive procedure, definitely reduces dose to the parotid. However, it is still unclear if such plans improve clinical QOL parameters further to the planned IMRT plans. Completion of this study could give us further confirmation on the clinical benefits of PSART.

#### EP-1065 Prediction of Dysphagia and Xerostomia based on CT imaging features of HNSCC Patients

K. Pilz<sup>1,2</sup>, S. Leger<sup>1</sup>, A. Zwanenburg<sup>1</sup>, C. Richter<sup>1,2,3,4</sup>, M. Krause<sup>1,2,3,4,5</sup>, M. Baumann<sup>1,2,3,4,5</sup>, S. Löck<sup>1,2,4</sup>, E.G.C. Troost<sup>1,2,3,4,5</sup>

<sup>4</sup>Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology, Dresden, Germany

<sup>5</sup>National Center for Tumor Diseases partner site  
Dresden, Dresden, Germany

### Purpose or Objective

Radiochemotherapy (RCT) for patients with head and neck squamous cell carcinoma (HNSCC) frequently causes xerostomia and dysphagia, which may be alleviated by treatment adaption, e.g., modulation of dose distribution to the salivary glands. Current clinical models, which are based on dosimetric parameters, mostly achieve moderate prediction accuracy. Therefore, we aimed to improve the prediction of xerostomia and dysphagia by using additional imaging biomarkers based on computed tomography (CT) scans.

### Material and Methods

In this study 46 patients with UICC stage III/IV advanced head and neck squamous cell carcinoma (HNSCC) were considered (NCT00180180, [1]). All patients received primary RCT and underwent a pre-treatment CT scan without intravenous contrast agent. Patient-reported xerostomia and dysphagia were evaluated at baseline, every week during RCT, four weeks after treatment and three months thereafter. 5040 imaging features were extracted from the parotid and submandibular glands. Feature reproducibility tests based on the RIDER re-test data set [2] were performed leading to 1513 imaging features in total. The most informative features were selected by a univariate logistic regression analysis. The developed radiomic signature was used to train and validate multivariate logistic regression and random forest models using repeated 5-fold cross validation. The prediction accuracy was assessed by the area under the curve (AUC).

### Results

The logistic regression and the random forest model achieved similar performance in predicting xerostomia (AUC=0.71). The developed signature consisted of one dosimetric parameter and one imaging feature. For the prediction of dysphagia both models achieved only a moderate prediction accuracy (AUC=0.55).

### Conclusion

For prediction of xerostomia, a signature was developed and showed a good performance. For dysphagia only moderately performing models could be obtained in this cohort. Based on our results, subgroups of patients at a high risk of xerostomia may be identified and offered treatment adaption. However, further investigations are currently ongoing, i.e., externally validating the developed signature, which is an important step in developing clinically relevant prediction models.

### EP-1066 Hypofractionated accelerated SIB-VMAT radiotherapy for H&N cancer: brachial plexus constraint

<sup>6</sup>Policlinico Universitario "A. Gemelli"- Universta  
Cattolica del Sacro Cuore, Department of Radiotherapy,  
Rome, Italy

### Purpose or Objective

To perform a dosimetric evaluation of the brachial plexus (BP) dose in locally advanced H&N cancer patients undergoing moderate hypofractionated-accelerated chemoradiation performed by a SIB-VMAT technique.

### Material and Methods

Patients with locally advanced H&N cancer receiving induction chemotherapy (ICT) and subsequent platinum based concurrent radiotherapy were included in this retrospective analysis. Toxicity and outcomes data were recorded during the routine follow-up. In all patients, right (RBP) and left (LBP) BP were delineated according to RTOG guidelines by the same radiation oncologist. RBP and LBP mean doses, V50, V55 and V60 were recorded and correlated with late neurological toxicity.

### Results

From July 2010 to January 2015, 50 patients [M/F: 40/10; median age: 57y, range 30-77; stage III: 11 (22%), stage IV: 39 (78%)] were treated and represent the object of the analysis. ORL subsites were as follows: oropharynx (22; 44%), epipharynx (8;16%), oral cavity (9; 18%), larynx (4; 8%) and hypopharynx (7; 14%). Cisplatin plus 5-fluorouracil chemotherapy schedule was administered as ICT in 72% of cases, while 22% of patients received a 3-drugs protocol (cisplatin, 5-fluorouracil and docetaxel). A moderate accelerated hypofractionation was delivered by using a 2 arc SIB-VMAT technique. Doses to macroscopic disease (T and N) ranged from 67.5/2.25 Gy (8 patients; 16%) to 70.5/2.35 Gy (42 patients; 84%), while the high and low risk nodal areas received 60/2 Gy/die and 55.5/1.85 Gy in 30 fractions, respectively. As per DVH analysis, LBP and RBP mean dose were 48.4 Gy and 48 Gy, V50 were 68.5% and 68.9%, V55 were 56.1% and 58.9%, V60 were 28% and 32.6%, respectively. In 44% of cases part of the LBP was included within the high dose PTV (67.5Gy in 12% and 70.5 Gy in 32% of patients). Conversely, in 46% of cases part of the RBP was included within the high dose PTV (67.5Gy in 8% and 70.5 Gy in 38% of patients). With a median follow-up of 19 months (range 3-53) no symptoms of brachial plexopathy were reported, although in 87% of cases doses to BP exceeded the suggested literature constraint of 60 Gy.

### Conclusion

A SIB-VMAT moderate accelerated hypofractionation at the doses reported in this analysis seems to be tolerable and safe, without cases of neurological toxicity. Longer follow-up and further prospective studies in larger series are warranted to confirm these findings.

### EP-1067 is adenoid cystic carcinoma (ACC) radioresistant?: the effect of radiotherapy for ACC of head and neck

I. Jung<sup>1</sup>, J. Kim<sup>1</sup>, S. Ahn<sup>1</sup>, S. Song<sup>1</sup>, S. Yoon<sup>1</sup>, S. Kim<sup>1</sup>, J. Park<sup>1</sup>, E. Choi<sup>1</sup>, S. Lee<sup>1</sup>

<sup>1</sup>Asan Medical Center- Univ of Ulsan, Radiation oncology,  
Seoul, Korea Republic of

### Purpose or Objective

The adenoid cystic carcinoma (ACC) of head and neck showed insidious onset and usually advanced at initial presentation. Because of limitation of anatomy of head and neck, in some cases, wide excision may not be possible. And even further, in other cases surgical excision may not be possible.

Therefore we evaluated efficacy and safety of definitive radiation therapy in head and neck ACC. Also, we analyzed prognostic factors in adjuvant radiation therapy of it.

### Material and Methods

From January 1995 to December 2013, 94 patients received radiotherapy for head and neck adenoid cystic carcinoma in Asan medical center. Fourteen patients were excluded because of systemic metastasis (n=7), other primary cancer (n=3), incomplete RT (n=2), and previous

RT history (n=2). We retrospectively reviewed records of 80 patients about clinical stage, pathologic characteristics, performing surgery or chemotherapy, aim of radiotherapy, radiation dose and technique, and clinical outcomes such as local recurrence, overall survival according to radiation groups. We analyzed prognostic factors of adjuvant RT such as stage, extent of surgery, resection margin, radiation dose, and chemotherapy. We also reviewed treatment related complication using CTCAE criteria version 4.0. All analyses were performed using SPSS, version 22.

#### Results

Median age at diagnosis was 51 years (21-82 years). Most common sites were salivary glands (n=35, 43.8%), oral cavity (n=14, 17.5%), and paranasal sinuses (n=12, 15.0%). Half of patients (n=41, 51.3%) had a locally advanced tumor at diagnosis (T3 : n=11, 13.8%), T4 : n=30, 37.5%). Sixty-nine patients underwent surgery. Detailed patient's characteristics according to RT aim were in table. Sixty-nine (86.2%) patients underwent adjuvant radiotherapy and 11 patients (13.8%) underwent definitive radiotherapy. Radiation dose were 50.4 - 76 Gy per 24-42 fx (median 64.8 Gy). With median follow-up of 114.3 months (9.7 - 236.3 months), local tumor progression was found in 21 patients (26.3%). 5 year overall survival (OS) rate was 82.4-91.4% in adjuvant arm and 72.7% in definitive arm. 5 year local recurrence free survival (LRFS) rate was 74.1-97.1 % in adjuvant arm, and 48.5% in definitive arm. Survival curves following treatment arms and stage were in graph. All patients tolerated the radiotherapy well.

#### Conclusion

Adjuvant radiotherapy to head and neck ACC seemed better clinical outcomes compared with definitive radiotherapy. However, in this report, all patients who received definitive radiation therapy were advanced stage (stage III :1, stage IV :10). Considering stage, 72.7% of 5YOS rate and 48.5% of 5YLRFS rate in definitive radiotherapy arm were not inferior results. Therefore definitive radiotherapy may be considered alternative treatment modality in patients with inoperable adenoid cystic carcinoma of head and neck.

#### EP-1068 Hypoxic imaging obtained at 2-h postinjection in FMISO-PET

M. Kawamura<sup>1</sup>, M. Yoshimura<sup>1</sup>, T. Katagiri<sup>1</sup>, T. Mitsuyoshi<sup>1</sup>, H. Inokuchi<sup>2</sup>, T. Ishimori<sup>3</sup>, Y. Nakamoto<sup>3</sup>, T. Mizowaki<sup>1</sup>, M. Hiraoka<sup>2</sup>

<sup>1</sup>Kyoto University- Graduate School of Medicine, Radiation Oncology and Image-Applied Therapy, Kyoto, Japan

<sup>2</sup>Japanese Red Cross Wakayama Medical Center, Radiation Oncology, Wakayama, Japan

<sup>3</sup>Kyoto University- Graduate School of Medicine, Diagnostic Imaging and Nuclear Medicine, Kyoto, Japan

#### Purpose or Objective

Positron emission tomography (PET) / computed tomography (CT) using 18F-fluoromisonidazole (FMISO) has been used as an imaging tool for tumor hypoxia. It has been reported that several quantitative values in FMISO-PET at 4-h postinjection were reproducible. However, it is controversial whether they are reproducible when scanning is performed in earlier time, e.g. 2-h postinjection. If quantitative values at 2-h postinjection are equivalent with those at 4-h postinjection, the total examination time in FMISO-PET can be shortened. The purpose of this study was to investigate the difference of quantitative values in FMISO-PET at 2-h and 4-h postinjection in patients with head and neck cancer.

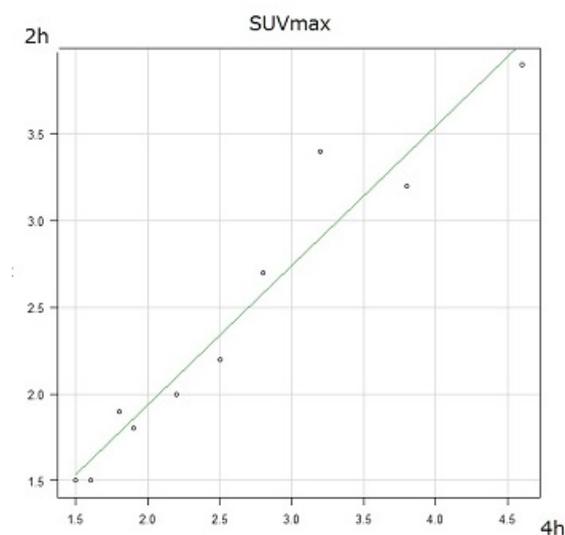

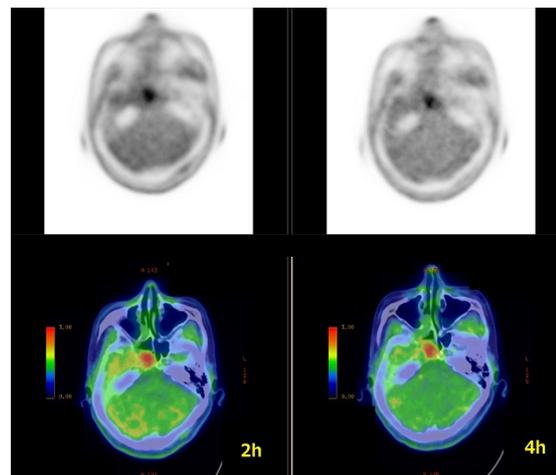

#### Material and Methods

A total of 10 patients with untreated locally-advanced head and neck cancer who underwent FMISO-PET/CT scan

from August 2015 to October 2016 in our institute were analyzed. Image acquisition was performed twice, 2-h and 4-h after administration of FMISO using a combined PET/CT scanner (Discovery IQ, GE Healthcare). After taking a region of interest in a primary tumor, the maximum standardized uptake value (SUVmax), SUVmean, SUVpeak, tumor-to-blood ratio (TBR), tumor-to-muscle ratio (TMR), metabolic tumor volume (MTV) and total lesion hypoxia (TLH) were measured. We evaluated the Spearman's rank correlation coefficients of these quantitative values, and also calculated the percent difference defined as difference between the two values divided by average of two values.

#### Results

SUVmax (mean±SD) at 2-h and at 4-h were 2.4±0.8, and 2.6±1.0, respectively, in this population. The Spearman's rank correlation coefficients of SUVmax, SUVmean, SUVpeak, TBR, TMR, MTV, and TLH were 0.97, 0.97, 0.97, 0.93, 0.93, 0.95, and 0.95, respectively. The percent differences (mean±SD) of these values were 8.3±5.6%, 6.8±6.3%, 4.1±5.1%, 16.8±12.5%, 17.1±9.1%, 42.7±52.7%, and 41.7±58.1%, respectively. Quantitative values were highly correlated between the two scans; however, there were two cases in which %differences of MTV and TLH exceeded 50%, i.e. 62.1% and 166.7% in MTV and 57.1% and 180.0% in TLH.

#### Conclusion

Our preliminary data demonstrate that quantitative values at 2-h and 4-h were highly reproducible. In a few patients, volumetric parameters had moderate percent difference,

so it needs careful evaluation to measure hypoxic tumor volume at 2-h after administration of FMISO.

#### EP-1069 Survival-weight health profile in nasopharyngeal cancer patients

C.H. Lai<sup>1</sup>, W.C. Chen<sup>1</sup>, M.F. Chen<sup>1</sup>

<sup>1</sup>Chang-Gung Memorial Hospital- Chiayi branch, Radiation Oncology, Chiayi Conuty, Taiwan

#### Purpose or Objective

This

study was designed to estimate the life expectancy (LE), quality-adjusted life expectancy (QALE) and survival-weight psychometric scores (SWPS) in nasopharyngeal cancer (NPC) patients.

#### Material and Methods

A sample of 875 non-metastatic NPC patients diagnosed between January 1, 2009 and June 30, 2013 was collected from the cancer registry database in four branch hospitals of our hospital system for estimation of lifetime survival function. All 875 patients were followed up until death or censored on December 31, 2015. To obtain the utility and psychometric score for estimation of LE, QALE and SWPS, eighty-seven patients were measured with the Taiwanese version of the EuroQol instrument (EQ-5D) and the Taiwan Chinese versions of the European Organization for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire (QLQ)-C30 and QLQ-H&N35 between October 1, 2013 and March 31, 2016. The LE of NPC patients was obtained using linear extrapolation of a logit-transformed curve and was adjusted by the corresponding QOL function to calculate the QALE and SWPS.

#### Results

The mean age at diagnosis of the 875 non-metastatic NPC patients was 50.7 years. The median duration from the beginning of radiotherapy to the date of completing questionnaires was 6.5 months (range, 0-154.9 months). The average LE and QALE were estimated to be 15.7 years and 14.5 quality-adjusted life years (QALYs) for NPC patients and 29.5 years and 29.5 QALYs for the reference population, respectively. On average, the lifelong duration of pain and painkiller use were 5.7 years and 1.8 years. The lifelong duration of any impairment of swallowing, smell and taste were 14.6 years, 8.5 years and 6.9 years, respectively. The life long duration of dry mouth was 13.3 years. Furthermore, the lifelong duration of tube-feeding was only 1.5 months.

#### Conclusion

This study offers more understandable information than the 5 year survival outcomes when communicating with patients or the general population regarding cancer risk and the impact of treatments on the quality of life. In the future, evaluating the robustness of comparative assessments for the outcome of NPC patients undergoing different treatment protocols will be possible.

#### EP-1070 Concurrent chemoradiation versus upfront surgery for clinical T3-4 hypopharynx and larynx cancer

G.S. Yoo<sup>1</sup>, D. Oh<sup>1</sup>, J.M. Noh<sup>1</sup>, Y.C. Ahn<sup>1</sup>, C.H. Baek<sup>2</sup>, Y.I. Son<sup>2</sup>, H.S. Jeong<sup>2</sup>, J.M. Sun<sup>3</sup>, M.J. Ahn<sup>3</sup>, K. Park<sup>3</sup>

<sup>1</sup>Samsung Medical Center, Department of Radiation Oncology, Seoul, Korea Republic of

<sup>2</sup>Samsung Medical Center, Department of Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea Republic of

<sup>3</sup>Samsung Medical Center, Department of Medicine-Division of Hematology-Oncology, Seoul, Korea Republic of

#### Purpose or Objective

The optimal treatment regimen for advanced T stage hypopharynx and larynx cancer is controversial. In this

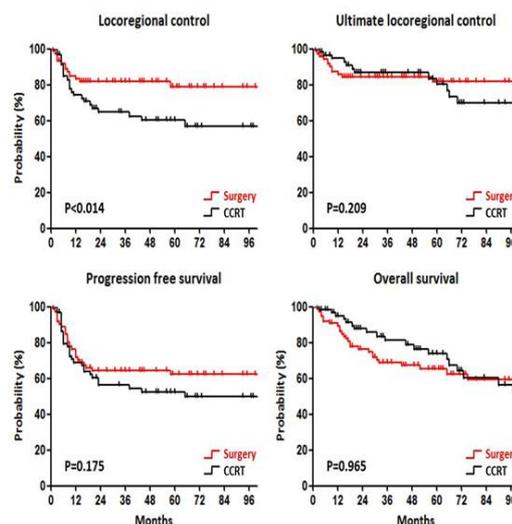

study, we aimed to compare the oncologic outcomes and functional larynx-preservation (FLP) rates for advanced clinical T stage (T3-4) hypopharynx and larynx cancer between definitive concurrent chemoradiotherapy (CCRT) and upfront surgery with or without adjuvant therapy.

#### Material and Methods

We reviewed the medical records of 148 patients with clinical T3-4 hypopharynx or larynx cancer who were treated between January 2005 and May 2013. Primary treatment was determined in the multidisciplinary team. In the CCRT group (N=63), 7 (11.1%) patients received induction chemotherapy, followed by definitive CCRT. Fifty-five (87.3%) patients were treated with 3-dimensional conformal radiation therapy (RT), and 8 (12.7%) patients with intensity-modulated RT. The median RT dose in the CCRT group was 70 Gy (range, 15.4 to 72 Gy). In the surgery group (N=76), TL was performed in 47 patients (61.8%), partial laryngectomy in 28 patients (36.8%), and partial pharyngectomy only in 1 (1.3%). Fifty-nine (77.6%) patients received adjuvant RT and 5 (6.6%) patients received adjuvant CCRT. Median RT dose in the surgery group was 60 Gy (range, 52 to 70 Gy).

#### Results

Median follow-up duration was 46 months (range, 0 to 172 months). In total cohort, the 5-year locoregional control (LRC), progression-free survival (PFS), and overall survival (OS) rates were 68.7%, 56.5%, and 64.1%, respectively. Between the CCRT and surgery group, there was significant difference in LRC rate (CCRT vs. surgery, 57.5% vs. 78.9% at 5 years,  $p=0.014$ ). The ultimate LRC rate including salvage treatment, however, was not different significantly between the groups (73.2 vs. 81.7% at 5 years,  $p=0.209$ ). There was no significant difference in PFS ( $p=0.175$ ), and OS rates ( $p=0.965$ ) between the groups. On the multivariate analysis, treatment modality was not independent factor for oncologic outcomes.

The 5-year FLP rate was higher significantly in CCRT group (75.4% vs. 35.5%,  $p<0.001$ ). The laryngoesophageal dysfunction-free survival rate in CCRT group was 56.9%. On the multivariate analysis, treatment modality was independent factor in FLP with hazard ratio of CCRT group as 0.261 (95% confidential interval with 0.139-0.488,  $p<0.001$ ).

#### Conclusion

Under the multidisciplinary approach, there were no significant differences in oncologic outcomes between the CCRT and surgery groups, while CCRT gave more opportunity to preserve the laryngeal function.

**EP-1071 Organ-sparing SBRT in reirradiation of head and neck cancer: efficacy, toxicity, and quality of life**  
 I. Zhang<sup>1</sup>, G. Gill<sup>1</sup>, M. Marrero<sup>1</sup>, A. Sharma<sup>1</sup>, A. Riegel<sup>1</sup>, D. Paul<sup>2</sup>, J. Knisely<sup>1</sup>, S. Teckie<sup>1</sup>, M. Ghaly<sup>1</sup>

<sup>1</sup>North Shore LIJ Health System, Radiation Medicine, New Hyde Park, USA

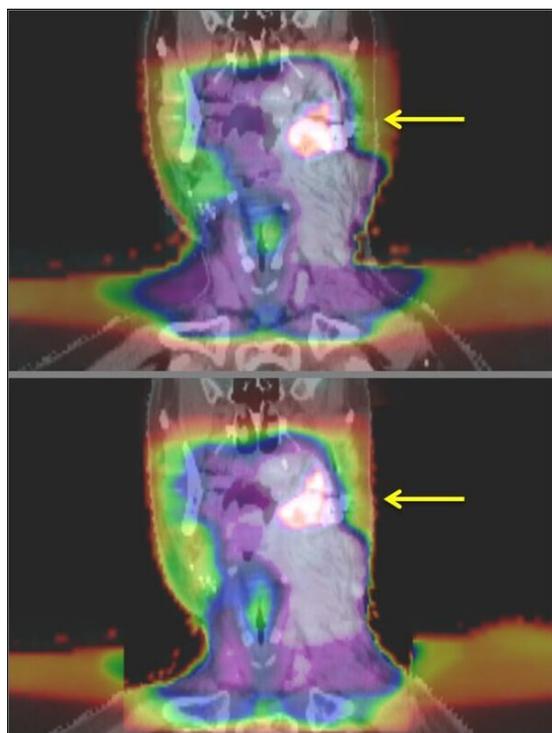

<sup>2</sup>North Shore LIJ Health System, Medical Oncology, New Hyde Park, USA

**Purpose or Objective**

To present a retrospective analysis of the efficacy, toxicity, and quality of life (QOL) of patients treated with organ-at-risk (OAR)-sparing salvage stereotactic body radiotherapy (SBRT) in previously-irradiated head and neck cancer.

**Material and Methods**

From November 2012 to July 2015, 60 patients with in-field recurrence of head and neck cancer underwent reirradiation with OAR-sparing SBRT at our institution. OARs were defined as critical structures that had approached their radiation tolerances after prior irradiation and had a high potential to impair QOL if damaged with re-irradiation. Intact tumors were prescribed 40 Gy while 35 Gy was prescribed for post-operative treatments. Doses previously received by the OARs were estimated by deformably registering the prior treatment plan onto the new simulation CT to more accurately delineate dose distributions (Figure 1: Prior plan overlying the new planning CT without (top) and with (bottom) deformable registration). Dose constraints for SBRT were calculated with a biological equivalent dose (BED) using an alpha/beta ratio of 3 to reduce the risk of late toxicities. Treatments were delivered twice a week for a total of 5 fractions via image-guided volumetric arc therapy with the OAR as the fusion surrogate. Quality of life (QOL) data was collected at consultation and follow up using the MD Anderson Dysphagia Inventory (MDADI), Symptom Inventory - Head and Neck Module (MDASI-HN), and Xerostomia Questionnaire. Local control and overall survival were estimated using the Kaplan-Meier method.

**Results**

Sixty patients were treated to 69 sites (9 for a second metachronous failure). Thirty two patients underwent surgical salvage prior to SBRT. Retreatment sites included the aerodigestive tract (43%), lateral neck (22%), and skull base (35%). The median prior radiotherapy dose was 63.6 Gy and the median reirradiation planning target volume (PTV) was 61.0 cm<sup>3</sup> (range 16.8 to 349 cm<sup>3</sup>). Despite prioritizing OAR-sparing over PTV coverage, the median V90 was 98.4% and D90 was 99.0%. The 1- and 2- year rates of local control were both 54%. Median survival was 18.5 months after SBRT. Late grade 3 toxicities occurred in 3% of the aerodigestive tract group, 1% of the skull base group, and none treated to the lateral neck. No grade 4 or 5 toxicities were observed. Compared to baseline, patients with skull base reirradiation maintained a stable QOL, while patients treated to the aerodigestive tract demonstrated decreased QOL associated with worsening dysphagia. All groups experienced increased xerostomia.

**Conclusion**

OAR-sparing SBRT is able to achieve excellent tumor coverage while protecting the organs at highest risk of reirradiation-related complications. Compared to conventional fractionation, the potential for lowered toxicity and maintained QOL makes SBRT a promising salvage option for recurrent head and neck cancer. Further, prioritizing OARs preserves a treatment option for repeat reirradiation in patients who develop a second in-field tumor recurrence.

**EP-1072 Early nutritional support in head and neck: survey of Italian radiation oncologists/otolaryngologists.**

M. Trignani<sup>1</sup>, A. Allajbej<sup>1</sup>, A. Di Pilla<sup>1</sup>, M. Nuzzo<sup>1</sup>, S. Di Biase<sup>1</sup>, M. Di Perna<sup>1</sup>, A. Croce<sup>2</sup>, M. Di Nicola<sup>3</sup>, I. Porfilio<sup>3</sup>, D. Genovesi<sup>1</sup>

<sup>1</sup>Ospedale Clinicizzato S.S. Annunziata, Radiotherapy, Chieti, Italy

<sup>2</sup>Otolaryngology, Otolaryngology, Chieti, Italy

<sup>3</sup>Preventive Medicine and Hygiene, Biomedical Science, Chieti, Italy

**Purpose or Objective**

The aim of this study was to evaluate the most common approaches among Italian radiation oncologists (RO) and otolaryngologists (OL) in early nutritional management of head and neck (H&N) cancer patients. Type of nutritional supplements prophylactically used, timing and criteria of percutaneous endoscopic gastrostomy placement (PEG) and role of nutritional counseling were investigated.

**Material and Methods**

A questionnaire, focused on different points of nutritional management in H&N cancer patients, was created and approved by a multidisciplinary team (MDT) including RO, OL and nutritionists. The survey, containing 10 multiple-choice questions, was prepared on SurveyMonkey online interface and emailed to 106 Italian centers of radiation oncology and 100 centers of otolaryngology. Responses were collected over a 2-month period. Descriptive analyses in terms of frequencies and percentages was automatically elaborated by SurveyMonkey. Chi-square test was performed to establish any significant difference between interviewed.

**Results**

A total of 67/106 and 27/100 questionnaires sent to Italian centers of Radiation Oncology and Otorhinolaryngology were filled in, corresponding to a response rate of 63.2% and of 27% respectively. Respondents answered all questions, so all were included in the analysis. Regarding nutritional counseling before starting treatment, 53.7% of RO claimed to make it rarely, while 26.9% always; 33.3% of OL affirmed to practice a preventive nutritional counseling rarely, 29.6% always and 22.2% almost always.

53.7% of RO affirmed they did not employ any nutritional supplement before starting treatment, while 20.9% declared to use PEG. Among OL, 37.0% affirmed the use of other nutritional supplements in a prophylactic phase, while 29.6% did not use any nutritional supplement ( $p=0.05$ ). Considering selection criteria for PEG placement, tumor stage (locally advanced) and tumor site (oropharynx) were the most important criteria for both RO (73.1%) and OL (85.2%). To the question 'when you use PEG?', 26.9% of RO and 11.1% of OL replied to place PEG in a prophylactic phase ( $p=0.166$ ). PEG is positioned in reactive phase in 73.1% of cases by RO and in 88.9% of case by OL. RO (82.1%) and OL (92.6%) stated that the placement of the PEG before starting treatment should not be a standard procedure ( $p=0.330$ ); they also respectively stated (85.2% and 88.1%) that the assessment of medical nutritionist before starting a treatment should represent a standard procedure ( $p=0.971$ ). Finally, 86.6% of RO and 92.6% of OL stated to evaluate H&N cancer patients in MTD.

#### Conclusion

Management of early nutritional supplementation in H&N cancer is still controversy. It seems necessary to improve nutritional evaluation among the Italian MDTs of H&N cancer care, because this appear lacking. Participation to surveys should be encouraged in order to better use the information that this precious, fast and cheap tool can provide.

#### EP-1073 Volumetric changes in parotid volume during radiation therapy in head and neck cancer

M.R. Tonse<sup>1</sup>

<sup>1</sup>Tata Memorial Centre, Radiation Oncology- Neuro Oncology, Mumbai, India

#### Purpose or Objective

Many patients receiving fractionated radiotherapy (RT) for head-and-neck cancer have marked anatomic changes during their course of treatment. We conducted a study to quantify the magnitude of these anatomic changes with systematic CT re-scans done after 1st week and 4th week of treatment.

#### Material and Methods

A total of 30 patients with head and neck cancer treated with Intensity modulated radiotherapy are enrolled in the study. All patients underwent re-scans after 1st week and 4th week of radiation. Volumetric changes were analyzed for Right parotid and Left parotid.

#### Results

Thirty patients were analyzed. Mean volumes of right parotid at initial, after 5# and after 20# was 21.62, 17.55 and 14.53 cc. Mean reduction volume after 5# and 20# was 4.07 and 7.09 cc. Mean volumes of left parotid at initial, after 5# and after 20# were 22.70, 17.86 and 14.13cc. Mean reduction volume after 5# and 20# is 4.83 and 8.57cc.

#### Conclusion

Measurable anatomic changes occurred throughout fractionated external beam RT for head-and neck cancers. The data may, therefore, be useful in the development of an adaptive RT strategy that takes into account such treatment-related anatomic changes. Such a strategy would maximize the therapeutic ratio of RT

#### EP-1074 Dose impact using standard head and neck immobilization system in brain tumours

M. Rincon<sup>1</sup>, J. Olivera<sup>1</sup>, J. Penedo<sup>1</sup>, I. Prieto<sup>1</sup>, S. Gomez<sup>1</sup>, M. Garcia<sup>1</sup>, J. Luna<sup>1</sup>, D. Esteban<sup>1</sup>, A. Ilundain<sup>1</sup>, J. Vara<sup>1</sup>

<sup>1</sup>Fundación Jimenez Diaz, Radiotherapy, MADRID, Spain

#### Purpose or Objective

To evaluate the dosimetric impact using the standard head and neck immobilization system during the radiotherapy course in patients with brain tumours.

#### Material and Methods

10 cases of glioblastomas patients were analyzed

In our department, the standard immobilization system for brain tumours consists of a flat carbon fiber headboard, an acrylic head support and an IMRT reinforced thermoplastic mask.

CT in 3-mm slice thickness was obtained. The image fusion of CT/MRI allowed a more correct delineation of the planning target volume (PTV) and the organs at risk (brainstem, chiasm, optic nerves and crystalline lens). Three fiducial marks were placed on the mask: two lateral marks and one on midline. The isocenter was located in the center of the three markers.

In all patients two plans were considered: with and without the immobilization system contoured.

The treatment planning was performed using Monaco planning system (version 3.30.01) based on the Monte Carlo algorithm. Six MV photon beams generated from Elekta Synergy Beam Modulator linac equipped with 40 pairs of opposing leaves (4mm thickness at isocenter) were utilized.

A double-arc volumetric modulated arc therapy (VMAT) technique was used: one arc from 50° to 180° and another from 180° to 310°, both in the clockwise, avoiding eyes. The target prescription dose was 60 Gy to tumoral bed.

The maximum dose in organs at risk brainstem and chiasm, the dose at the isocenter and D95 and Dmean of PTV were compared. The difference errors were analyzed.

#### Results

D95 and Dmean with and without the immobilization system contoured showed differences of 0.7% and 0.6% respectively. The maximum dose in brainstem and chiasm were lower by 0.9% and 0.4%. The dose at the isocenter decreased by 0.5 %

#### Conclusion

The dose impact using standard head and neck immobilization system in brain tumours was not significant, less than 1 %, even in the worst case where this accessory directly interfered with the treatment beam. With other immobilization systems this attenuation should be measured and implemented into the treatment planning process to diminish it when it was necessary.

#### EP-1075 Role of Diffusion Weighted Imaging in Laryngeal & Hypopharyngeal Cancers treated with Radiotherapy

S. Pavamani<sup>1</sup>, S. Thomas<sup>1</sup>, P. Surya<sup>2</sup>, R. Michael<sup>3</sup>, G.

Mathew<sup>3</sup>, S. Mathews<sup>2</sup>, S. Balukrishna<sup>1</sup>, M. Sunithi<sup>2</sup>

<sup>1</sup>Christian Medical College Hospital, Radiation Oncology, Vellore, India

<sup>2</sup>Christian Medical College Hospital, Radiology, Vellore, India

<sup>3</sup>Christian Medical College Hospital, Otorhinolaryngology, Vellore, India

#### Purpose or Objective

Locally Advanced Squamous Cell Carcinoma of the Larynx & Hypopharynx can be treated with an Organ Preserving approach utilising Concurrent Chemoradiotherapy (CRT), Radical Radiotherapy (RT) or targeted therapy. Due to various reasons, some patients may not respond to this treatment & will eventually need salvage surgery. However, if the outcome of the treatment can be predicted beforehand, this can prevent unnecessary side effects & toxicity. The patient can then be offered surgery upfront. Diffusion Weighted MRI (dWMRI) is an imaging modality wherein an increase in the Apparent Diffusion Coefficient (ADC) in the tumour indicates an increase in the movement of water molecules. This in turn indicates

a decrease in the cellularity in the tumour & tumour response. Thus, a rising ADC value during treatment versus Pretreatment ADC values may be used to predict outcomes.

The aim of this study was to investigate the role of diffusion weighted MRI derived parameters like ADC, as an imaging biomarker, to predict response to RT in locally advanced squamous cell carcinoma of the larynx and hypopharynx.

#### Material and Methods

From May 2014 to August 2015, 19 patients with locally advanced laryngeal & hypopharyngeal malignancies, treated with organ preservation intent with concurrent radiotherapy with Cisplatin (n=14), radiotherapy with Nimotuzumab (n=2) and radical radiotherapy (n=3) were recruited. The patients were all male with predominantly T3 stage. They were assessed for treatment response with dWMRI at baseline, first week, fourth week during RT and at the time of first response assessment at 6 to 8 weeks after RT. The ADC values were compared at different time points and correlated with the treatment response.

#### Results

All the 19 patients in the study showed an increasing trend in the ADC values over the chosen 4 different time points. It was observed that an abrupt rise from the pretreatment ADC to the first week ADC was characteristic of complete response while a gradual rise of ADC over the different points suggested a partial treatment response. The patients who responded to chemoradiation therapy had a higher pretreatment ADC than patients with partial response. At the last follow up, 12 patients were disease free, while 5 patients developed recurrence. Four patients with recurrence had shown a partial response while only one had exhibited a complete response during RT. One patient died during treatment of aspiration pneumonia while undergoing CRT & another did not follow up after completion of treatment.

#### Conclusion

This study suggests that an abrupt rise in the ADC value in the tumour after one week of treatment may predict complete response & long term tumour control. However this finding needs to be investigated in a larger cohort of patients over a longer follow up before dWMRI can be utilised in clinical practice.

#### EP-1076 toxicity of concomitant chemotherapy and IMRT in locally advanced OPSCC: sequential vs SIB technique

G. Abate<sup>1</sup>, F. De Felice<sup>1</sup>, A. Galdieri<sup>1</sup>, G. Gravina<sup>2</sup>, F. Marampon<sup>3</sup>, D. Musio<sup>1</sup>, V. Tombolini<sup>1</sup>

<sup>1</sup>Policlinico Umberto I- "Sapienza" University of Rome, radiotherapy, Roma, Italy

<sup>2</sup>University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences- Laboratory of Radiobiology, L'Aquila, Italy

<sup>3</sup>University of L'Aquila-, Department of Biotechnological and Applied Clinical Sciences- Laboratory of Radiobiology, L'Aquila, Italy

#### Purpose or Objective

Concurrent radiochemotherapy is the standard of care for locally advanced oropharyngeal squamous cell carcinoma (OPSCC) patients. Due to a substantial locoregional recurrence rate especially in human papilloma virus (HPV) negative disease, an improvement in treatment outcome is desirable.

Treatment intensification with radiation dose escalation could represent a valid option by applying accelerated radiotherapy with higher dose for fraction and non-uniform dose distribution with simultaneous integrated boost (SIB). Even if radiobiological and clinical data suggest that accelerated fractionation with higher dose per fraction given in GTV may produce better locoregional

control, a higher toxicity is expected especially with concomitant platinum 100 mg/mq based chemotherapy.

A comparison between sequential IMRT (S-IMRT) and SIB-IMRT was planned. The aim was to evaluate the tolerability and safety of SIB regimen in HPV negative patients with locally advanced OPSCC

#### Material and Methods

Patients with histologically proven HPV negative OPSCC, staged T3-4 with or without involved lymph nodes at diagnosis, who received primary CRT, were included. S-IMRT was defined as radiotherapy equivalent to 70 Gy (2 Gy/fraction). SIB-IMRT was administered to a total dose of 67.5 Gy (2.25 Gy/fraction) to high dose volume and 60 (2 Gy/fraction) and 54 Gy (1.8 Gy/fraction) to high risk and low risk volumes respectively..

Fusion CT-MR imaging with a deformable registration software was performed to accurately localize target volumes and organs at risk.

Concomitant cisplatin (100mg/m2 on day 1 and day 22 day of treatment) was used.

#### Results

A total of 46 patients (31 males, 15 females) with a median age of 64 years (range 41-75) were examined between February 2009 and March 2016. All patients completed the programmed CRT treatment. No patients suspended planned chemotherapy and all patients received the IMRT prescribed total dose. No severe life risking complications occurred and no significant differences between S-IMRT and SIB-IMRT were observed in term of major acute toxicities. Details are shown in table 1

Table 1: number of patients with G3 acute toxicity in the two groups

	IMRT-SIB	Conventional IMRT	P value
<i>G3 acute toxicity</i>			
Mucositis	5 (25%)	10 (38%)	0,63
Oral pain	5 (25%)	2 (8%)	0,25
Dysphagia	3 (15%)	5 (20%)	0,96
Feeding tube	7 (35%)	8 (30%)	0,99

#### Conclusion

Our data shows that IMRT-SIB with 2.25 Gy/fraction with concurrent platinum-100- based chemotherapy is a safe treatment approach without increasing toxicities. This regimen is therefore acceptable for the therapy of locally advanced oropharyngeal cancer and patients with poor prognosis as HPV negative OPSCC could benefit from it. A longer follow up is needed to fully evaluate late toxicity and survival.

#### EP-1077 Predictive modeling for radiation-induced acute dysphagia in head and neck cancer patients.

D. Alterio<sup>1</sup>, M. Gerardi<sup>1</sup>, L. Cella<sup>2</sup>, V. D'Avino<sup>2</sup>, G. Palma<sup>2</sup>, D. Ciardo<sup>1</sup>, E. Rondi<sup>3</sup>, A. Ferrari<sup>1</sup>, M. <sup>6</sup>European Institute of Oncology - University of Milan, Medical Imaging and Radiation Sciences - Oncology and Hemato-oncology, Milan, Italy

<sup>7</sup>European Institute of Oncology - University of Milan,

Radiation Oncology - Oncology and Hemato-oncology, Milan, Italy

### Purpose or Objective

To explore dosimetric predictors of acute dysphagia in head and neck (H&N) cancer patients (pts) treated with definitive radiotherapy (RT). We prospectively examined correlation between doses to swallowing-associated structures and acute radiation-related side effects, in terms of dysphagia and percutaneous endoscopic gastrostomy tube (PEG) requirement.

### Material and Methods

We analyzed all consecutive not previously treated pts with H&N cancer who underwent RT at our Department between May 2010 and March 2011. Exclusion criteria were: baseline dysphagia (functional dysphagia or enteral nutrition) and previous surgery in the H&N region. A nutritional standardized step-wedge protocol was applied. Dysphagia (grade  $\geq 3$  according to CTCAE v4.0) and indication to PEG insertion were classified as acute toxicity events. Ten swallowing-related structures were considered for the analysis: pharyngeal axis, base of tongue, constrictor muscles (superior, middle and inferior), cricopharyngeal muscle, soft palate, cervical esophagus, oral cavity and supraglottic larynx. Dosimetric parameters included mean dose (Dmean), near maximum dose (D2%) and the percentage volume exceeding X Gy (Vx) evaluated in 5-Gy steps. The correlation of clinical information along with swallowing-related structure dose parameters related to acute toxicity events was analyzed by means of Spearman's rank correlation coefficient (Rs). Multivariate logistic regression method using resampling methods (bootstrapping) was applied to select model order and parameters for normal tissue complication probability (NTCP) modeling. Model performance was evaluated through the area under the curve (AUC) of the receiver operating characteristic (ROC) analysis.

### Results

Patient and treatment characteristics are summarized in Table 1. Two pts required PEG, 3 pts had grade 3 dysphagia and 4 pts had both PEG and grade 3 dysphagia. A strong multiple correlation between dosimetric parameters was found. Intra-organ dosimetric parameters were strongly correlated as well as inter-organ dosimetric parameters. Accordingly, the highly correlated variables ( $R_s > 0.75$ ) were not included in the multivariate analysis. A two-variable model was suggested as the optimal order by bootstrap method. The optimal model ( $R_s = 0.452$ ,  $p < 0.001$ ) includes V45 of the cervical esophagus (OR=1.016) and Dmean of the cricopharyngeal muscle (OR=1.057). The model AUC (Fig1a) was 0.82 (95% CI 0.69-0.95). The comparison of the predicted incidence of acute radiation-related toxicity and the actuarial incidence in the population is shown in Figure 1b.

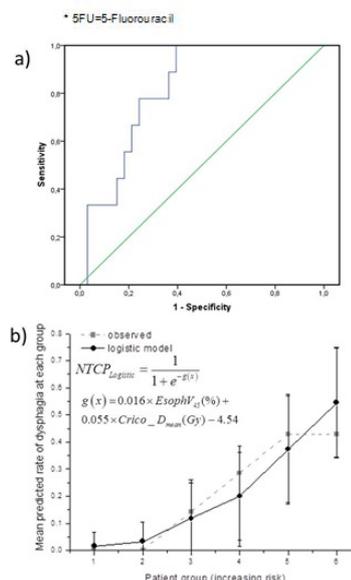

Figure 1 a) ROC curve analysis for acute radiation-induced dysphagia NTCP; b) Mean predicted rates of acute toxicity vs. observed rates for patients binned by predicted risk. The patients are binned according to the 2-variable models with equal patients number in each bin.

### Conclusion

We propose a 2-variable predictive NTCP model including both cervical esophagus and cricopharyngeal muscle dosimetric parameters with a good prediction performance for acute radiation-related toxicity in H&N cancer pts

EP-1078 Transient xerostomia in head and neck cancers with significant parotid inclusion in target volume

A. Datta<sup>1</sup>, A. Mukherji<sup>1</sup>, E. Thiraviyam<sup>1</sup>

<sup>1</sup>Jawaharlal institute of post graduate medical education and research, radiation oncology, Puducherry, India

### Purpose or Objective

To assess xerostomia patterns in patients requiring significant parotid inclusion in target volumes for treatment of locally advanced head and neck cancers.

### Material and Methods

30 patients (male = 20, female = 10) with head and neck cancers (oral cavity = 6, oropharynx = 8, nasopharynx = 3, larynx = 7) of AJCC stage II = 4, III = 12, and IV = 14 who were treated with radical chemo radiation from August 2013 - September 2015 and received significant parotid dose (more than 22 Gy Dmean) were analyzed retrospectively at 3, 6 and 12 months post completion of treatment. They received an external radiotherapy dose of 69.34 Gy EQD2 (to HR-CTV, mean HI - 0.13, mean CI - 0.99) using SIB-IMRT by VMAT technique. Their xerostomia patterns were recorded based on subjective complaints (Grade 1 = slight dryness, Grade 2 = moderate dryness, Grade 3 = complete dryness, Grade 4 = fibrosis).

### Results

1 patient died during treatment due to aspiration and 1 patient developed a second primary in lung at 10 months. The mean of Dmean to right parotid was 43.95 Gy (23-51.2) to a mean volume of 16.71 cc (9-30.2) while for the left parotid it was 43.6 Gy (23.1-58.2) to a mean volume of 16.9 cc (7.7-26.3). The mean spared right parotid (outside PTV) Dmean was 23.1 Gy (30.2-69.2% of whole parotid volume, mean volume 42.5%) while for the left parotid it was 26.3 Gy (22-65% of whole parotid volume, mean volume 48.7%). At 3 months of completion of treatment Grade 2 and 3 xerostomia were seen in 2 (6.9%) and 27 (93.1%) patients respectively. At 6 months Grade 2 and 3 xerostomia were seen in 12 (41.3%) and 17 (58.7%) patients respectively. While at 12 months Grade 1, 2 and 3 xerostomia were seen in 7 (24.1%), 16 (55.2%) and 6 (20.7%) respectively. 1 patient had a stable residual disease.

### Conclusion

Significant parotid inclusion in target volumes for locally advanced cases had a reversible loss of parotid function at 12 months of completion of treatment. However, loss of function was irreversible when the Dmean was greater than or equal to 50 Gy.

### EP-1079 Carotid blowout syndrome after reirradiation with particle therapy in the head and neck region

J.E. Dale<sup>1</sup>, S. Molinelli<sup>2</sup>, E. Ciurlia<sup>2</sup>, O. Dahl<sup>1,3</sup>, P. Fossati<sup>2,4</sup>

<sup>1</sup>Haukeland University Hospital, Department of oncology, Bergen, Norway

<sup>2</sup>CNAO Foundation, Pavia, Italy

<sup>3</sup>University of Bergen, Department of clinical science, Bergen, Norway

<sup>4</sup>European Institute of Oncology IEO, Milano, Italy

### Purpose or Objective

Carotid blowout syndrome (CBS) is a serious complication to treatment of neoplasms in the head and neck (H&N) region. Surgery, infection, necrosis and tumor properties are the most significant risk factors, but the rate of CBS is also affected by properties of radiotherapy (RT). Rates seem to increase in hypofractionated or accelerated hyperfractionated regimens. We here investigate the cumulative doses received by the carotid artery (CA) and CBS-rate in a cohort of patients reirradiated with particle therapy in the H&N region.

### Material and Methods

Dosimetric information, medical records and tumor characteristics of 49 patients were collected. CT, structure set and dose files were available for 32 patients, making it possible to perform deformable image and dose registration to allow plan summation and extract precise cumulative dose statistics for the CA. For the remaining 17 patients a reliable approximation of the cumulative

dose to the CAs was made by comparing printed CT-slices with isodose curves from the previous RT courses with the dose distribution from the reirradiation. Corresponding EQD2 was calculated with an  $\alpha/\beta$ -ratio=3.

### Results

Forty-four patients had received 1 prior RT course, while 5 had received 2 prior RT courses. Ten patients received reirradiation with proton RT and 39 with carbon ion RT (CIRT). In the 49 patients a total of 74 CAs had been reirradiated to a median cumulative Dmax<sub>EQD2</sub> of 106 Gy (RBE) (range: 25-167 Gy (RBE)). Details are presented in TABLE 1 and FIGURE 1. Median time between 1<sup>st</sup> and final RT was 29 months (range: 3-205 months). Median time of follow-up was 10 months (range: 1-41 months). Two patients (4%) experienced profuse oronasal bleeding at 6 and 8 months after reirradiation, both fatal. Cumulative Dmax<sub>EQD2</sub> for these patients CAs were 130 and 107 Gy (RBE), respectively. Both had recurrent tumors completely surrounding the CA. The first patient had undergone surgery close to the CA prior to the reirradiation. At the time of bleeding he performed a CT-angiography revealing a pseudoaneurysm on the CA, making the diagnosis of CBS highly probable. The second patient had a recurrent tumor at the site of bleeding. Autopsy was refused, making it impossible to ascertain if the bleeding was due to CBS or from pathological tumor vessels. If we attribute both cases to CBS, the CBS-rate for reirradiated CAs was 2.7% (95% CI 1.0-6.4%).

TABLE 1

PATIENTS, n=49		
<b>Prior RT courses</b>		
Radiation quality	Photon	No. 51
	Cobalt-60	1
	Carbon	3

intracranial		4 (5.4)
<b>Tumor involvement</b>		
		No. (%)
No involvement of CA		27 (36.5)
< 1/3 of CA circumference		11 (14.9)
≥ 1/3 < 2/3 of circumference		3 (4.1)
≥ 2/3 < 3/3 of circumference		3 (4.1)
3/3 of circumference		30 (40.5)

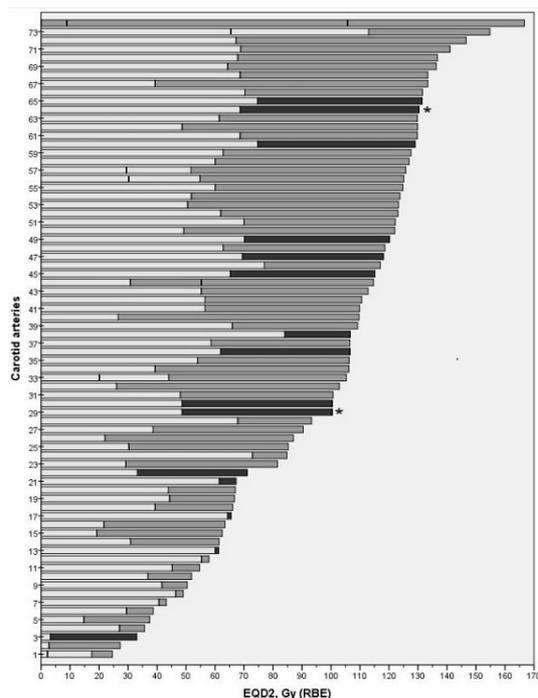

Figure 1: Cumulative Dmax (EQD2) for all 74 CAs, displaying contribution from photon RT (light grey), carbon RT (dark grey) and proton RT (black). \* = CAs of the 2 patients who developed oronasal hemorrhage.

## Conclusion

Reirradiation in the H&N region with particle therapy gives CBS-rates comparable to normo- or hyperfractionated photon RT, and does not seem to increase in hypofractionated schedules typically used in CIRT, in contrast to what is reported in hypofractionated SBRT with photons. The low number of events does not make it possible to define significant risk factors or tolerance doses for the CA.

## EP-1080 Psychological distress in patients with head and neck cancer during radiotherapy

M. Massaccesi<sup>1</sup>, L. Dinapoli<sup>1</sup>, A. Pesce<sup>1</sup>, R. Autorino<sup>1</sup>, A. Tenore<sup>1</sup>, M. Balducci<sup>1</sup>, D. Smaniotto<sup>1</sup>, G. Chiloiro<sup>1</sup>, M. Rigante<sup>2</sup>, G. Cadoni<sup>2</sup>, G. Paludetti<sup>2</sup>, V. Valentini<sup>1</sup>, F. Micciché<sup>1</sup>

<sup>1</sup>Università Cattolica del Sacro Cuore -Fondazione Policlinico A. Gemelli, Radiation Oncology Department- Gemelli ART, Rome, Italy

<sup>2</sup>Università Cattolica del Sacro Cuore -Fondazione Policlinico A. Gemelli, Institute of Otorhinolaryngology, Rome, Italy

## Purpose or Objective

The treatment of patients with head and neck (H&N) cancer is usually complex and burdensome. Radical radiotherapy (RT), which may follow surgery and be combined with chemotherapy, usually lasts 6 to 7 weeks and more than half patients can experience relevant acute toxicity. Therefore the experience of receiving RT can be both stressful and anxiety provoking. Aim of this study was to evaluate the psychological distress of patients with H&N cancer during RT.

## Material and Methods

Consecutive patients with H&N cancer who underwent RT with radical intent between January and September 2016 were included in this analysis. Psychological support was available for all patients and Distress Thermometer (DT) and Hospital Anxiety and Depression Scale (HADS) were administered to evaluate emotional distress and mood, respectively at the beginning (T0), after three-four weeks

(T1), and at the end (T2) of the RT course. Toxicity was evaluated weekly by CTCAE version 4.0 criteria.

## Results

Fifty patients (36 male and 14 female, mean age 61, range 14-82 years) were included. RT was post-operative in 22 patients (44.0%) and 25 (50.0%) patients received concurrent CT.

At T0 evaluation, 32/50 patients (64.0%) were emotionally distressed (cut off value DT score $\geq$ 4) and 12/50 patients (24%) showed anxiety/depression (cut off value HADS score $\geq$ 14). No difference was observed according to previous surgery.

During RT, patients who were distressed (32/50) or anxious and depressed (12/50) at the beginning of treatment did not show any significant variation of their DT score, while HADS score significantly improved at T2 evaluation (median HADS score 19 and 15, at T0 and T2 respectively, p=0.03). Patients who were not distressed (18/50) or anxious and depressed (38/50) at baseline, showed a worsening of DT score at both T1 (p=0.02) and T2 (p=0.01) as compared to baseline; HADS score remained substantially stable at T1 while worsened at T2 (p=0.03).

At T1, 9/40 (22.5%) evaluable patients had G $\geq$ 3 acute toxicity. Twenty seven/40 (67.5%) patients had significant emotional distress and 9/40 (22.5%) patients had significant anxiety and depression. Emotional distress was more frequently observed among patients who were also experiencing severe toxicity (77.7 versus 22.5% respectively, p<0.01). These patients were also more frequently anxious and depressed (55.5 versus 24.0% respectively, p=0.08).

At T2, 10/34 (29.4%) evaluable patients had G $\geq$ 3 acute toxicity. Twenty five/34 (73.5%) patients had significant emotional distress and 12/34 (35.3%) patients had significant anxiety and depression. No significant difference was observed according to severe toxicity occurrence.

## Conclusion

Patients with H&N cancer frequently experience emotional distress and side effects of radiotherapy are stressful and anxiety provoking events. Beside adequate medical support, these patients also require focused psychological interventions.

## EP-1081 Tumor response after palliative radiotherapy in head and neck cancer and its influence on survival

M. Cruz<sup>1</sup>, C. Sousa<sup>1</sup>, D. Branco<sup>1</sup>, L. Khouri<sup>1</sup>, J. Brandão<sup>1</sup>, G. Melo<sup>1</sup>

<sup>1</sup>Instituto Português de Oncologia de Coimbra, Radiation Oncology, Coimbra, Portugal

## Purpose or Objective

The aim of this study is to evaluate tumor response in Head and Neck (H&N) cancer patients who underwent different fractionation schemes of palliative radiotherapy (RT) and its influence on overall survival.

## Material and Methods

This is a retrospective unicentre study including patients diagnosed with H&N cancer not suitable for curative treatment. Those patients completed palliative radiotherapy to primary local-regional sites in our department between January 2013 and December 2015. Radiation therapy was delivered using a mega-voltage linear accelerator with 6 MV photons. Target volumes generally included the gross tumor volume with 1 to 2 cm margins. Tumor response patterns were evaluated following a cervical and chest Computed Tomography (CT) performed 4-6 weeks after RT.

## Results

53 patients were included in this study (73.4% male). Mean age was 71.3 years ( $\pm$ 1.2). Primary tumor was localized in oropharynx in 34% of the patients, oral cavity in 20.7% and larynx in 18.9% of the patients. 92.4% of the tumors were

histologically classified as squamous cells carcinoma. At the time of the diagnosis, 86.8% of the patients had stage IV disease.

Mean Karnofsky Performance Status (KPS) was 68%.

RT palliative schemes chosen were 50Gy delivered in 20 fractions during 4 weeks (50Gy/20fr/4w) in 35% of our patients, 30Gy/10fr/2w in 32%, 37.5Gy/15fr/3w in 18.9% and 40Gy/20fr/4w in 13.2% of our patients.

After the analysis of cervical and chest CT, 61.2% of the patients had partial response while 10.2% had complete imagiologic response, 18.4% had imagiologic progression and 8.2% had stabilised disease.

After a mean follow-up period of 27.2 months ( $\pm 8,3$ ), overall survival was 9.55 months ( $\pm 9,3$ ). The group with better tumor response on CT was the group that underwent for the 50Gy/20fr/4w scheme (in which 89.4% had partial/complete response) with no need for interruption of the treatment due to toxicity. The group with longer overall survival was the group that underwent for the 30Gy/10fr/2w (11.8 months) and the shortest overall survival was verified after the 37.5Gy/15fr/3w scheme (5.2 months). Despite these results, there were no statistically significant differences between the four RT schemes delivered to our patients and overall survival ( $p=0.41$ ).

Patients who had better tumor response on CT (partial or complete response) had longer overall survival comparing to patients who had stabilised disease or progression (11.6 months vs. 6.65 months;  $p=0,011$ ).

Fractionation	Finished planned RT (n)	Motive for interruption	Imagiologic response n (%)	Mean survival (months)	ANOVA
50Gy/20fr	19/19	-	17/19 (89,4%)	10	$p=0,41$
30Gy/10fr	15/17	Death Fistula	9/15 (60%)	11,8	
37,5Gy/15fr	9/10	Death	5/9 (55,5%)	5,2	
40Gy/20fr	6/7	Grade 3 toxicity	4/6 (66,7%)	8,2	

Tumor response	Number of patients	Mean survival (months)	Chi square test
Complete response	5	11,2	$p=0,011$
Partial response	30	12	
Stabilised disease	4	10,6	
Progression	10	2,7	

## Conclusion

There is no consensus regarding the choice of the optimal RT fractionation scheme used in palliative care of H&N cancer patients and careful patient selection. Patients with advanced incurable H&N cancer have a poor prognosis but the addition of palliative RT provides better local-regional control of the disease with the possibility of longer survival rates. More studies should be carried out in order to evaluate predictive factors of tumor response as a mean of improving patient's outcomes and quality of life.

## EP-1082 Primary surgery vs. radiotherapy in early-stage oropharyngeal cancer: a single centre experience

<sup>2</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil- EPE, Oncology Department, Lisboa, Portugal

<sup>3</sup>NOVA Medical School UNL, Radiation Oncology, Lisboa, Portugal

<sup>4</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil- EPE, Otorhinolaryngology Department, Lisboa, Portugal

<sup>5</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil- EPE, Clinical Research Unit, Lisboa, Portugal

## Purpose or Objective

To review the outcomes of early-stage oropharyngeal squamous cell carcinoma (OSCC) submitted to primary surgery or primary radiotherapy (RT).

## Material and Methods

Retrospective study of patients diagnosed with OSCC between January 2009 and December 2014, clinically staged cT1 to cT2 cN0/cN1, who underwent primary surgery or primary RT. Cases surgically upstaged were excluded. We analyzed patient charts, imaging and clinical data regarding primary therapy, adjuvant treatment and side effects. Toxicity was graded according to Common Terminology Criteria for Adverse Events (v4.0). Overall survival (OS) and progression-free survival (PFS) were analyzed using the Kaplan-Meier method and log-rank test for group comparison. Time-to-event endpoints were calculated from the date of first treatment.

## Results

We found 61 patients with cT1 to cT2 cN0/cN1 OSCC treated with primary surgery or primary RT. Ten were excluded after surgical upstage. From the remaining 51, 45 were male, with a median age of 56 years. The majority was treated with surgical resection (n=35), followed by RT (n=30) with or without (n=21) chemotherapy (high-dose cisplatin), due to positive (n=9), close (<5mm, n=20) or non-evaluable (n=3) margins. Sixteen were submitted to primary RT, with or without (n=13) concomitant chemotherapy. Disease was in stage I in 10 patients, stage II in 24 and stage III in 17. Patients were treated with IMRT using simultaneous integrated boost (n=33) or 3D-CRT. Prescribed dose was 60-70Gy to the high-risk PTV and 50-54Gy to the low/intermediate-risk PTV.

Median follow-up time in patients alive was 5 years. Three patients had tumor persistence, 4 had local failure and no one developed distant metastasis. In both groups, median OS and PFS were not reached. In the primary surgery group, 3-year and 5-year OS were 80% and 62%, and 3-year and 5-year PFS were 74% and 50%, respectively. In the primary RT group, both 3-year and 5-year OS were 81%, and 3-year and 5-year PFS were 81% and 70%, respectively. There was no significant difference in the two groups (OS  $p$  value = 0,4; PFS  $p$  value = 0,3). Acute grade 3 toxicity was reported by 15 patients (mucositis, dysphagia, dermatitis, xerostomia). Late side effects were grade 1 xerostomia (n=10) and mandibular osteoradionecrosis (ORN, n=6). ORN occurred in patients submitted to primary (n=3) or adjuvant RT, who had been given 66-70Gy with 3D-CRT (n=4) or concomitant cisplatin (n=2). Fourteen died due to disease progression (n=3), treatment complications (sepsis, n=1) or other unrelated causes.

## Conclusion

In our study, there was no significant difference in the OS and PFS between primary surgery vs. primary RT. Although surgery was the most frequent primary approach, almost all patients required adjuvant treatment due to close margins. Our toxicity profile reminds us that careful patient selection is necessary as well as further surgical margins studies are warranted to identify subgroups where treatments can be safely avoided.

## EP-1083 HPV as an etiological and prognostic factor for the Polish patients with HNC.

<sup>5</sup>maria sklodowska-curie memorial cancer center and institute of oncology iii dept., department of epidemiology and silesia cancer registry, gliwice, poland

#### Purpose or Objective

Despite of confirmed prognostic importance of human papilloma virus (HPV) for patients with head and neck cancer (HNC) such data based on Polish population is scarce. The aim of the study was to estimate the ratio of HPV related tumors in patients with HNC and to evaluate the prognostic role of HPV in patients with pharynx or larynx cancer treated with radiotherapy alone (RT) or in combination with chemotherapy (CHRT) in the Cancer Center-Institute in Gliwice, Poland between 2012 and 2014.

#### Material and Methods

322 consecutive patients with HNC (nasopharyngeal cancer (NPC) 25 (7.8%), oropharyngeal cancer (OPC) 125 (38.8%), hypopharyngeal cancer (HPC) 36 (11.2%), laryngeal cancer (LXC) 132 (41%), cancer of unknown primary (FPI) 4 (1.2%) treated radically with RT (121/38%) or CHRT (201/62%) have been included. HPV etiology has been confirmed basing on tissue material and/or circulating-free DNA HPV. The ratio of HPV-related tumor has been estimated in all group and in OPC patients. Patients with OPC HPV-related (HPV+) and HPV-not related (HPV-) were compared acc. to other prognostic factors. Three-years local (LC), nodal (NC) control survival rates and disease-free (DFS), distant metastases-free (DMFS) and overall survival (OS) rates were compared for patients with OPC (HPV+) and OPC (HPV-).

#### Results

Median follow up was 36 months. HPV-related tumors have been confirmed in 72 (23%) patients, in 3 (4.2%), 58 (80.5%), 1 (1.4%), 9 (12.5%), 1 (1.4%) of patients with NPC, OPC, HPC, LXC and FPI respectively. In OPC patients these with HPV+ and HPV- did not differ by sex and the age. OPC (HPV-) were smokers more often ( $p=0,0007$ ). T stage in both groups was similar, but N stage was significantly higher in (HPV+) ( $p=0.03$ ). Patients with OPC (HPV+) had significantly higher 3-year LC (91% v 72%,  $p=0,006$ ), NC (90% v 70%,  $p=0,008$ ), DFS (85% v 63%,  $p=0,008$ ) and OS (78% vs 66%,  $p=0,17$ ). 3-year DMFS was the same in both groups (93% v 94%,  $p=0.6$ ). In multivariate analysis HPV appeared to be an independent factor influencing OS ratio.

#### Conclusion

HPV-related tumors in Polish patients with HNC could be found in a similar percentage like in other countries, reaching almost half of patients with OPC. Polish patients with OPC (HPV+) are not so young but do not smoke and present higher advanced nodal stage. Our findings confirm that HPV is a strong, independent and beneficial prognostic factor in Polish patients with OPC.

#### EP-1084 Laryngeal preservation using chemo-radiotherapy, single institution experience from Egypt.

A. Al Nagmy<sup>1</sup>, T. Shouman<sup>1</sup>, A. Hassouna<sup>1</sup>, M. Gaber<sup>2</sup>  
<sup>1</sup>Cairo University- National Cancer Institute, Radiation

Oncology Department, Cairo, Egypt

<sup>2</sup>Cairo University- Faculty of medicine, Clinical Oncology Department, Cairo, Egypt

#### Purpose or Objective

to evaluate organ preservation by radical radiotherapy ± chemotherapy (CT) in locally advanced laryngeal cancer

#### Material and Methods

we reviewed medical records of 71 patients with locally advanced laryngeal cancer (T3-4 or N+) treated at the Radiation Oncology Department, National Cancer Institute, Cairo University, Egypt, during the period from 2007 to 2013 inclusively. Prognostic factors, treatment modalities, and their effect on loco-regional control (LRC) and overall survival (OS) were studied.

#### Results

mean age was 61 years. Smoking history was present in 94% of patients. Squamous cell carcinoma was the most common pathological type (98%). Glottic carcinoma represent 31%, supraglottic carcinoma represent 60.5%, while transglottic carcinomas represent 8.5% of patients. Prescribed radiotherapy dose was 70Gy/35 fractions/7 weeks. Combined chemoradiotherapy was used in 72%, while radiotherapy alone was used in 28% of patients. Concurrent chemotherapy regimens used were weekly Cisplatin (93%), weekly Carboplatin (5%), and Cisplatin D1,22,43 (2%). Twenty five patients received induction chemotherapy (IC); mostly Docetaxel/Cisplatin/5-FU (TPF) protocol (17 patients). The majority of patients (64%) achieved complete remission (CR). Locoregional failure was reported in 4 patients, and salvage surgery was done for those patients. The 3-year LRC and OS rates were 73% and 46.3% respectively. The only adverse prognostic factor affecting OS was poorly differentiated tumors ( $P=0.05$ ). Other factors which did not significantly affect LRC or OS were pretreatment Hemoglobin ( $P=0.14$ ), T stage ( $P=0.52$ ), nodal stage ( $P=0.10$ ), radiotherapy machine used ( $P=0.09$ ), received dose of RT ( $P=0.14$ ), dose per fraction ( $P=0.68$ ), gaps during RT ( $P=0.10$ ), use of IC ( $P=0.32$ ), and time interval between IC and RT ( $P=0.47$ ). Laryngectomy free survival (LFS) rate at 2 and 3 year were 42% and 34% respectively.

#### Conclusion

Concomitant chemoradiotherapy is an effective modality for organ preservation in advanced laryngeal cancer with LFS 42% which can be further improved by better selection of patients. The poorly differentiated tumors significantly affect OS.

#### EP-1085 Comparative study of outcomes and toxicities in conventional 2DRT vs IMRT in locally advanced HNSCC

K. Periasamy<sup>1</sup>, P. Baskaran Shanmuga<sup>2</sup>, S. Sambasivam<sup>1</sup>, T.P. Soni<sup>1</sup>, N. Patni<sup>1</sup>, G.K. Singh<sup>2</sup>, J. Kaur<sup>2</sup>, A. Gupta<sup>2</sup>, K.T. Bhowmik<sup>2</sup>

<sup>1</sup>Bhagwan Mahavir Cancer Hospital and Research Center, Radiation Oncology, Jaipur, India

<sup>2</sup>Safdarjung Hospital, Radiation Oncology, New Delhi, India

#### Purpose or Objective

To compare conventional 2DRT with intensity modulated radiation therapy (IMRT) in locally advanced head-neck squamous cell carcinoma (HNSCC) patients treated with curative-intent chemoradiation (CRT) with respect to treatment outcome and toxicities.

#### Material and Methods

This bi-institutional study is a retrospective comparative analysis of patients with biopsy-proven locally advanced HNSCC (stage III-IV) who were treated either with conventional 2DRT or IMRT to a radiation dose of 66-70 Gy with concurrent chemotherapy. In this study the treatment response to CRT, treatment related acute and

chronic toxicities, disease status and overall survival at 2 years were compared between conventional 2DRT and IMRT. Treatment related toxicities were reported using physician rated RTOG acute and late toxicity criteria.

### Results

58 patients who were treated with conventional 2DRT and 56 patients who were treated with IMRT for locally advanced HNSCC between 2012 and 2014 were chosen for comparative analysis. The 2DRT arm consisted of 45% of stage III and 55% of stage IV patients whereas the IMRT arm had 27% and 73% of them respectively. In the 2DRT arm 53% and 47% had grade 2 and 3 acute mucositis whereas in the IMRT arm it was 80% and 5% respectively. This difference reached statistical significance ( $p < 0.001$ ). But, acute skin toxicity was only marginally higher in the 2DRT arm than the IMRT arm.

In the 2DRT arm 84% had grade 2 and 3 acute xerostomia while in the IMRT arm it was 45% and this difference reached statistical significance ( $p = 0.004$ ). Likewise, the difference remained statistically significant ( $p = 0.01$ ) with chronic xerostomia evaluated at 1 year post treatment with an incidence of 76% in the 2DRT arm and 38% in the IMRT arm.

It was observed that the treatment break due to acute radiation reactions were more in the 2DRT arm (16%) than in the IMRT arm (9%), however this did not reach statistical significance. However, these two modalities showed no significant differences in response to CRT and locoregional control or survival at 2 years.

		2DRT		IMRT		Total	
		Number	Percentage (%)	Number	Percentage (%)	Number	Percentage (%)

	Grade 2,3	49	84.48	25	44.64	74	64.91
Chronic xerostomia	Grade 0,1	14	24.14	35	62.50	49	42.98
	Grade 2,3	44	75.86	21	37.50	65	57.02

		2DRT		IMRT		Total	
		Number	Percentage (%)	Number	Percentage (%)	Number	Percentage (%)
Treatment response post CRT	CR	41	70.69	42	75.00	83	72.81
	PR	17	29.31	14	25.00	31	27.19
Disease status at 2 years	DM	6	10.34	3	5.36	9	7.89
	LR	28	48.28	34	60.71	62	54.39
	LR+DM	19	32.76	13	23.21	32	28.07
	LR+DM	5	8.62	6	10.72	11	9.65
Survival at 2 years	No	7	12.07	6	10.71	13	11.40
	Yes	49	84.48	48	85.71	97	85.09
Locoregional control at 2 years	No	22	37.93	17	30.36	39	34.21
	Yes	36	62.07	39	69.64	75	65.79

### Conclusion

IMRT significantly reduces the incidence and severity of acute mucositis and acute and chronic xerostomia when compared with conventional 2DRT in the treatment of locally advanced HNSCC. However, IMRT did not show

superiority over 2DRT with respect to response to CRT, locoregional control and survival at 2 years.

### EP-1086 Health status and physical activity in head and neck cancer survivors

A. Matias-Pérez<sup>1</sup>, G. Gallego-Herreros<sup>1</sup>, B. G. Díaz de Tudanca<sup>1</sup>, P. Soria-Carreras<sup>1</sup>, A. Nieto-Palacios<sup>1</sup>, A. Rodríguez-Gutiérrez<sup>1</sup>, L.A. Pérez-Romasanta<sup>1</sup>

<sup>1</sup>Hospital Universitario de Salamanca, Radiation Oncology Department, Salamanca, Spain

### Purpose or Objective

Head and Neck (H&N) cancer survivors are an increasingly population, due to the improvement in diagnosis and treatment. The aim of this study is to analyse the health status and physical activity in H&N cancer survivors in a single institution.

### Material and Methods

The population was composed of a series of 50 H&N cancer patients survivors (>3 years post-diagnosis) treated in our institution from 2006 to 2013, having no signs of cancer recurrence to the date. They were reviewed based on personal interviews and specific questionnaires. The health status items measured were: nutritional assessment (with the Body Mass Index (BMI), the Malnutrition Universal Screening Tool (MUST) and the Subjective Global Assessment (SGA)), cardiovascular risk (with the HeartScore® tool), toxic habits (tobacco and alcohol by the Alcohol Use Disorders Identification Test (AUDIT)) and physical activity (with the Global Physical Activity Questionnaire (GPAQ)).

### Results

The mean age was 64 years (range, 43-84 years) and 46 patients (92%) were male. The most frequent site of the primary tumour was larynx (48%) and the main histology squamous cell carcinoma (76%). 72% of patients had advanced cancers (stages III and IV), whereas 26% had stages I and II. All patients received radiotherapy, of which 31 patients (62%) were given 3DRT technique and 19 patients (38%) IMRT technique. Surgery was performed in 17 patients (34%), and 20 patients (40%) underwent neck dissection. The most part of our population had overweight (BMI 27 ± 3). The MUST score showed that 7 patients (14%) were at high risk of malnutrition, and regarding SGA, 12 patients (24%) were suspected of malnutrition. Cardiovascular risk was high or very high in 12 (24%) and 19 (19%) patients, respectively. Taking into account toxic habits, 6 patients (12%) were active smokers, while 38 (76%) were ex-smokers. AUDIT score showed that 3 (6%) were risk drinkers and 3 (6%) had problems related with alcohol abused. 86% of the patients accomplished WHO recommendations of physical exercise.

### Conclusion

Our study indicates that head and neck cancer survivors could have clinical issues regarding health status, and efforts should be done to identify these patients, especially those with risk of malnutrition, high cardiovascular risk or toxic habits, in order to offer the best clinical care.

### EP-1087 Real-world Cetuximab toxicity in curative and recurrent/metastatic setting in HNSCC patients.

I. Desideri<sup>1</sup>, C. Muntoni<sup>1</sup>, C. Ciabatti<sup>1</sup>, M. Lo Russo<sup>1</sup>, P. Bonomo<sup>1</sup>, M. Loi<sup>1</sup>, D. Greto<sup>1</sup>, I. Meattini<sup>1</sup>, L. Livi<sup>1</sup>

<sup>1</sup>University of Florence, Radiotherapy, Firenze, Italy

### Purpose or Objective

Observational monocentric study to assess, in patients affected by head and neck squamous cell carcinomas (HNSCC), the acute toxicity of Cetuximab (CTX) administered concurrently with radiotherapy (RT) in the curative setting, or as a chemotherapy (CT) in patients with recurrent/metastatic disease.

## Material and Methods

A total of 110 HNSCC patients undergoing chemotherapy with Cetuximab were retrospectively analyzed. Patients were treated in our Institution between February 2007 and May 2016. Performance Status (PS) evaluated with the Eastern Cooperative Oncology Group (ECOG) scale. Relevant comorbidity were evaluated with the Charlson Comorbidity Index (CCI). Skin toxicity was evaluated according to Common Terminology Criteria for Adverse Events (CTCAE) version 4.03.

## Results

The median age was 67 years (range 32-84 years); 83 (75.5%) patients were male. Ninety (82%) were smokers, most of them had a smoking history > 20 pack/years. PS was scored  $\leq 1$  in 100 (90.9%) patients. The median CCI was 6 (range 1- 13). The most represented head and neck subsites in the study were the oropharynx (27%) and the larynx (32%). Forty-three (39.1%) patients underwent a curative treatment with a concomitant CTX-RT treatment, while 67 (60.9%) received a CTX-containing chemotherapy regimen. In patients undergoing a curative treatment, the median number of CTX cycles administered amounted to 6 (range 2-8) ; median RT dose was 67Gy (range 66-70). Acute mucositis G $\leq 2$  and G3 was observed in 24 (55,8%) and 18 (41,9%) patients respectively. Actinic dermatitis G $\leq 2$  was observed in 25 (58,1%) patients, while G3 and G4 dermatitis was present in 17 (39,5%) and in 1 (2.3%) patient, respectively. In the advanced disease subgroup, CTX was administered as first-line CT in 39 cases (53.6%) as a triplet combination (cis/carboplatin, 5-FU, CTX), and in 21 (26.8%) as a 2-drugs regimen (carboplatin / CTX); 7 patients (19.6%) received CTX monotherapy. Incidence of acneiform rash G1-G2 was 37.3%, while G3 was 3.0%(25 and 2 patients, respectively); incidence of hypomagnesemia G1-G2 was 4.5% (3 patients), no G3 toxicity was reported. Infusion reactions G2 was reported in 2 (3.0%) patients.

## Conclusion

Cetuximab is a mainstay in the radical and palliative treatment in HNSCC patients but its toxicity in our serie is not negligible, though in line with data from literature. Accurate patients selections and toxicity management during treatment are mandatory to ensure safety and clinical benefit.

## EP-1088 EGFR as blood biomarker improves prognostic value of nomogram for survival in laryngeal carcinoma

F.W.R. Wesseling<sup>1</sup>, G. Feliciani<sup>1</sup>, C. Oberije<sup>1</sup>, M.P. Van de Waarenburg<sup>2</sup>, C.G. Schalkwijk<sup>2</sup>, P. Lambin<sup>1</sup>, F.J. Hoebers<sup>1</sup>  
<sup>1</sup>Maastricht Radiation Oncology MAASTRO clinic- GROW - School for Oncology and Developmental Biology- Maastricht University Medical Centre, Department of Radiation Oncology, Maastricht, The Netherlands  
<sup>2</sup>Laboratory for Metabolism and Vascular Medicine- Maastricht University, Department of Internal Medicine, Maastricht, The Netherlands

## Purpose or Objective

To improve the prognostic value of a previously validated nomogram for laryngeal carcinoma derived from clinical parameters<sup>1</sup> by adding blood biomarker results for hypoxia, inflammation, tumor load and cell growth.

## Material and Methods

For 50 patients treated for laryngeal carcinoma at our clinic by radiotherapy with curative intent, blood samples were stored in a blood biobank (ClinicalTrials.gov: NCT01084785) before start of treatment. Eight biomarkers representing hypoxia, inflammation, tumor load and cell growth were selected and measured with commercially available kits: IL6, IL8, CEA, c-kit, E-cad, EGFR, MMP-9 and osteopontin. Primary outcome was overall survival (OS). Blood biomarker results and a

prognostic score, based on our previously developed nomogram were entered in a Cox regression analysis using least absolute shrinkage and selection operator (LASSO) variable selection procedure with 10-fold cross validation. Significant biomarkers were added to the nomogram score to investigate whether the prognostic value would be improved. Concordance index (C-index) was used to evaluate the performance of the model.

## Results

Clinical staging was: St. I: 18%, St. II: 20%, St. III: 34% and St. IV: 28%. Most patients were treated with accelerated locoregional radiotherapy (68%) or local radiotherapy (16%). After a median follow up of 56 months, 2 and 5 year OS was 75% and 58%. LASSO procedure selected EGFR and the nomogram score as variables significantly associated with OS. Spearman  $\rho$  coefficient and visual inspection showed no correlation between EGFR and nomogram score ( $\rho=0.29$ ). After validating the existing nomogram with this new cohort, its performance was comparable to the published data<sup>1</sup> (C-index = 0.68). By performing multivariate Cox regression, the addition of EGFR to the nomogram improved its concordance index to 0.73 as shown in table 1. Interestingly we found that high-risk patients had lower EGFR levels in blood samples compared to low-risk patients. This is opposite to results obtained from tissue samples as reported in literature.<sup>2</sup>

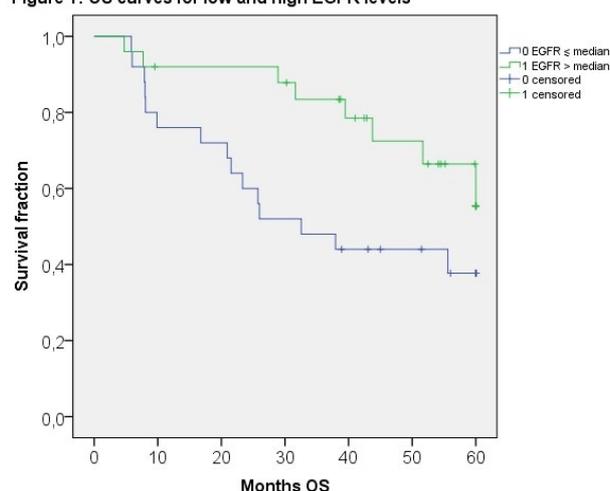

Table 1: Results of Cox regression analyses

	Univariate Cox Regression					
	B	HR	95.0% CI for HR		P-value	C-Index
			Lower	Upper		
Nomogram score	0.63	1.878	1.192	2.956	0.007	0.68
Multivariate Cox Regression						
Nomogram score	0.526	1.692	1.054	2.716	0.029	
EGFR	-0.062	0.94	0.882	1.001	0.054	0.73

## Conclusion

EGFR as blood biomarker is an independent predictor for OS of patients with laryngeal carcinoma. OS curves for patients in high vs low EGFR group are visible in figure 1. Based on this small cohort the prognostic value of our existing nomogram was improved, but an independent cohort would be needed for external validation. Further research is needed to correlate EGFR blood values with EGFR expression in tumor samples.

Figure 1: OS curves for low and high EGFR levels

**EP-1089 Prospective study of body composition changes during IMRT for H&N cancer as assessed by DXA scans**

J. Johansen<sup>1</sup>, A. Hermann<sup>2</sup>, S. Lønbro<sup>3</sup>

<sup>1</sup>Odense University Hospital, Oncology, Odense, Denmark

<sup>2</sup>Odense University Hospital, Dept. of Endocrinology, Odense, Denmark

<sup>3</sup>Aarhus University, Dept. of Public Health- Section for Sport Science, Aarhus, Denmark

**Purpose or Objective**

Weight loss is common after radiation treatment of head and neck cancer (H&N) as assessed by only pre/post measurements. Thus, only scarce data exists regarding body changes during overall treatment time. This study investigated changes in weight and body composition of H&N patients during radical radiation treatment, and correlated the findings to individual tests of muscle strength.

**Material and Methods**

Prospective study of 30 H&N patients undergoing IMRT (60-68 Gy) during a 16 month period. Patients were followed weekly during treatment, and all had individualized nutritional counseling. At baseline, and with 2-week intervals during IMRT and 2 weeks after, patients underwent whole-body dual-energy X-ray absorptiometry (DXA) scans, as well as weight measurements and pre/post treatment maximal muscle strength tests (n=21)(one-repetition maximum chest press, leg press, and knee extension). Changes over time were analyzed by linear regression, and pre/post data were compared by Student's paired t-tests.

**Results**

A total of 131 DXA scans were obtained. Mean age was 58.2, and the patients were predominantly stage II-IV (77%). Two-thirds received concomitant chemotherapy. Baseline BMI was 27.4 (± 4.8). Significant overall declines (p<0.001) were observed in weight (-8.2%; range +2.0 to -18.4), fat mass (10.3%; range +2.4 to -29.1), and lean body mass (10.7%; range +0.8 to -23.9). All changes were mutually correlated in regression analysis, e.g., R<sup>2</sup>=0.74 (p<0.001) for weight loss versus lean body mass. The decline in lean body mass was correlated with loss of muscle strength as assessed by chest press (R<sup>2</sup>=0.61; p<0.001) and knee extension (R<sup>2</sup>=0.25; p=0.03), but not with leg press (p=.08). Concomitant chemoradiation was associated with a 10% decline in lean body mass in univariate analysis, however, no independent predictors were discerned in multivariate regression.

**Conclusion**

The overall weight loss during IMRT for H&N was 8.2%. Weight loss correlated proportionally with the percentage decline in both fat mass and lean body mass. Loss of lean body mass correlated well with loss of muscle strength during treatment. The proportional loss of fat and lean body mass indicates that physical exercise during radiotherapy may be required to favor muscle/fat distribution.

**EP-1090 Particle therapy and IMRT for patients with esthesioneuroblastoma: a single-institution experience**

J. Liermann<sup>1</sup>, M. Syed<sup>1</sup>, D. Bernhardt<sup>1</sup>, N. Bougatf<sup>2</sup>, S.B. Harrabi<sup>1</sup>, A. Paul<sup>1</sup>, T. Sprave<sup>1</sup>, S. Rieken<sup>1</sup>, T. Haberer<sup>2</sup>, K. Herfarth<sup>1</sup>, J. Debus<sup>1</sup>, H. Hauswald<sup>1</sup>, S. Adeberg<sup>1</sup>

<sup>1</sup>University Hospital of Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

<sup>2</sup>University Hospital of Heidelberg, Heidelberg Ion-Beam Therapy Center HIT, Heidelberg, Germany

**Purpose or Objective**

Esthesioneuroblastoma or olfactory neuroblastoma is a rare tumor entity originating from the olfactory neuroepithelium. There is only few data about the efficacy of different treatment strategies so far. Several approaches have been made and a combination of radiation and surgery is thought to be effective. Most tumors are situated in the nasal cavity and thus applied radiation therapy (RT) should be very precise. Intensity modulated radiotherapy (IMRT) and carbon ion radiotherapy (CIRT) are highly precise techniques with advanced dose conformity and improved sparing of organs at risk which might translate into improved local control and moderate radiation induced toxicity.

**Material and Methods**

The retrospective analysis contained 17 patients with esthesioneuroblastoma (Kadish stage ≥ C: 88%; n=15). 4 patients initially presented with cervical lymph node metastasis and 4 patients already underwent a previous RT. The treatment consisted of either IMRT (n=5) or CIRT (n=4) or a combination of both techniques (n=8). Applied median doses were 60 Gy in 30 fractions (IMRT only), 51 Gy (RBE) in 17 fractions (CIRT only) and 52 Gy in 26 fractions as well as 21 Gy (RBE) in 7 fractions (bimodal RT). Overall survival and local control rates were determined after a median follow-up of 8 months (range: 2-72 months). Acute toxicity was evaluated up to three months after completion of the radiotherapy according to CTCAE criteria (Version 4.03).

**Results**

Local recurrence-free survival and overall survival rates were 90% after a follow-up of 6 months (n=9/10) and 86% after a follow-up of 12 months (n=6/7). One patient died 5 months after the treatment. Local recurrence occurred in another patient after 36 months who died 26 months later. Both of these patients belonged to the group who underwent a previous RT before. 15 of 17 patients (88%) are still alive and recurrence-free so far. Grade I toxicity (100%; n=17) and grade II toxicity (65%; n=11) were frequently observed. The most common toxicities were nasal and/or oral mucositis (76%; n=13) and radiation dermatitis (82%; n=14). Only one patient (6%; n=1) developed a grade III toxicity (hyposmia).

**Conclusion**

Considering the advanced tumor stage of the cohort the results showed good local control and overall survival rates in short term follow-ups. Our results show that IMRT, CIRT or a combined approach seem to be a feasible and effective treatment in esthesioneuroblastoma without leading to severe acute treatment-related side effects. Further follow-up will be needed to investigate the benefit of CIRT.

**EP-1091 Low dose fractionated RT in association to TPF as induction therapy in advanced head and neck cancer**

Bussu<sup>4</sup>, J. Galli<sup>4</sup>, S. Chiesa<sup>1</sup>, G. Paludetti<sup>4</sup>, V. Valentini<sup>1</sup>, F. Micciche<sup>1</sup>

<sup>1</sup>Polyclinic University A. Gemelli- Catholic University, Institute of Radiotherapy, Rome, Italy

<sup>2</sup>Polyclinic University A. Gemelli- Catholic University, Institute of Radiology, Rome, Italy

<sup>3</sup>Polyclinic University A. Gemelli- Catholic University, Institute of Nuclear Medicine, Rome, Italy

<sup>4</sup>Polyclinic University A. Gemelli- Catholic University, Institute of Otorhinolaryngology, Rome, Italy

**Purpose or Objective**

To analyze the efficacy and the feasibility of induction chemotherapy (ICT) with low-dose radiotherapy (LDR) compared to ICT alone prior to chemoradiation (CRT) in locally advanced head and neck squamous cell carcinoma.

### Material and Methods

Between September 2008 and May 2012, 59 patients, with locally advanced stage III and IV squamous cell carcinoma of head & neck cancer, received three courses of induction chemotherapy with docetaxel (75 mg/mq), cisplatin (75 mg/mq) and 5-fluoruracil (750 mg/mq/day on days 1-5) followed by radiotherapy plus two or three cycles of concurrent cisplatin 100 mg/mq (Group A). Twenty-nine of this patients received low dose radiotherapy concomitantly to induction chemotherapy (Group B). Treatment courses, hematological data and other parameters were also investigated.

### Results

Three cycles of ICT were administered in all patients: only one (Group B) received two cycle because of high hematological toxicity. After neoadjuvant therapy completion, clinical tumor response was observed in 49 patients (83%); patients undergone low dose radiotherapy showed better complete remission ( $p=0.08$ ). Grade > 3 toxicity with dose reduction occurred in 5 patients (8%). Median time from the final cycle of TPF to starting radiotherapy was 21 days. All patients received radical radiotherapy; one, two and three cycles of concurrent cisplatin was delivered in 0 (0.0%), 17 (58.6%), 10 (41.4%) patients of Group A and 1 (3.5%), 28 (96.5%), 0 (0.0%) patients of Group B, respectively. With a median follow-up of 28 months (range 2-58), one-year local control was 66% and 81% for Group A and Group B, respectively ( $p=0.05$ ). No difference was observed in terms of overall survival and disease free-survival between the two groups ( $p=0.9$  and  $0.8$ ). Toxicity during chemo-radiation was acceptable in both groups without difference, specially, in terms of hematological toxicity ( $p=0.76$ ). But we found a correlation between hematological toxicity > G3 and local control ( $p=0.03$ ).

### Conclusion

Low dose radiotherapy in association with ICT prior to CRT, even if it is not the standard, could be considered tolerable, with encouraging efficacy in terms of response and local control, in locally advanced head and neck squamous cell carcinoma. Further investigation is warranted to confirm these data.

### EP-1092 Perioperative high dose rate brachytherapy in previously irradiated head and neck cancer: Results

M.I. Martínez Fernandez<sup>1</sup>, M. Cambeiro<sup>1</sup>, J. Alcalde<sup>2</sup>, R. Martínez-Monge<sup>1</sup>

<sup>1</sup>*Clinica Universitaria de Navarra, Department of Oncology, Pamplona, Spain*

<sup>2</sup>*Clinica Universitaria de Navarra, Department of Otolaryngology, Pamplona, Spain*

### Purpose or Objective

This study was undertaken to determine the feasibility of salvage surgery and perioperative high dose rate brachytherapy (PHDRB) in patients with previously irradiated, recurrent head and neck cancer or second primary tumors arising in a previously irradiated field.

### Material and Methods

Sixty-three patients were treated with surgical resection and perioperative high dose rate brachytherapy (PHDRB). The PHDRB dose was 4 Gy b.i.d. x 8 (32 Gy) for R0 resections (surgical margins equal to or greater than 10 mm) and 4 Gy b.i.d x 10 (40 Gy) for R1 resections (close or microscopically positive surgical margins, or the presence of extra- capsular nodal extension), respectively. Further external beam radiotherapy or chemotherapy was not given.

### Results

Resections were categorized as R0 in 7 patients (11.1%) and R1 in 56 patients (88.9%). Thirty-four patients with R1 resections (54.0%) had microscopically positive margins, and 22 patients (34.9%) had close margins. Thirty-two

patients (50.8%) developed RTOG grade 3 or greater adverse events including 3 fatal events. After a median follow-up of 6.8 years, the 5-year locoregional control rate and 5-year overall survival rates were 55.0% and 35.6%, respectively.

### Conclusion

Surgical resection and PHDRB is a successful treatment strategy in selected patients with previously irradiated head and neck cancer. Long-term locoregional control can be achieved in a substantial number of cases despite a high rate of inadequate surgical resections although at the expense of substantial toxicity.

### EP-1093 Hypofractionated robotic stereotactic radiotherapy of Head and neck Paragangliomas

F. Meniai-Merzouki<sup>1</sup>, B. Coche-Dequeant<sup>1</sup>, E. Bogart<sup>2</sup>, T. Lacornerie<sup>3</sup>, X. Mirabel<sup>1</sup>, E. Lartigau<sup>1,4</sup>, D. Pasquier<sup>1,5</sup>

<sup>1</sup>*Centre Oscar Lambret, Radiation oncology, Lille, France*

<sup>2</sup>*Centre Oscar Lambret, Biostatistics departement, Lille, France*

<sup>3</sup>*Centre Oscar Lambret, Medical Physics, Lille, France*

<sup>4</sup>*Cristal Cnrs, Umr 9181, Villeneuve D'ascq, France*

<sup>5</sup>*Cristal Cnrs, UMR 9181, Villeneuve d'Ascq, France*

### Purpose or Objective

The aim of this study was to evaluate the outcomes of hypofractionated robotic stereotactic radiotherapy for paraganglioma (PGL) of the head and neck region

### Material and Methods

We retrospectively studied 10 patients with benign head and neck PGL(s), treated with robotic hRST using Cyberknife at Oscar Lambert center between December 2008 and November 2012. Three of these patients were diagnosed with recurrent tumors after surgery. The median time to recurrence after surgery was 42 months. None of them was embolised before radiotherapy. The median follow-up was 49,2 months (range: 3-80,4 months).

### Results

Eight patients presented with jugular-bulb PGL, 1 patient with jugular-carotid body PGL and 1 patient with cerebral posterior fossa PGL. The female/male ratio was 4/1. The median tumor volume was 12,91 cm<sup>3</sup> (range: 0,89-141,51). The median dose was 36 Gy (range: 21-40). The median number of fractions was 9 (range: 3-10). The tumor growth and clinical outcome were evaluated every 6 months in the 2 years and then annually. The 1 and 3 year freedom from disease progression was 100% and 88% respectively. PGLs were stable in 8 patients, and partial response was observed in 2 patients. No toxicity was observed.

### Conclusion

According to our early experience, robotic stereotactic radiotherapy with Cyberknife seems to be successful treatment option in management of head and neck PGL

### EP-1094 Transoral Laser Microsurgery associated to Radiotherapy in advanced laryngeal carcinomas.

I. Nieto Regueira<sup>1</sup>, V. Ochagavia<sup>2</sup>, A. Nuñez<sup>2</sup>, C. Ponte<sup>2</sup>, V. Muñoz<sup>2</sup>

<sup>1</sup>*Hospital do Meixoeiro. Complejo Hospitalario Universitario de Vigo, Radiation Oncology, Vigo, Spain*

<sup>2</sup>*Hospital do Meixoeiro. CHUVI, Radiation Oncology, Vigo, Spain*

### Purpose or Objective

Transoral Laser Microsurgery is a surgical option treatment that seems to have similar results to radiotherapy with or without chemotherapy and offers similar outcomes in local control and survival compared with open surgery, preserving the larynx and its function.

### Material and Methods

We analyzed the incidence of local side-effects during adjuvant radiotherapy treatment in 24 locally advanced laryngeal cancer patients who underwent laser microsurgery.

In terms of TNM classification 14 patients were T3 stage and 10 patients T4a stage.

In 20 patients chemotherapy was associated to radiation (83%)

The incidence of acute local side-effects during Radiotherapy treatment were analyzed according to the following factors: Laryngeal mucositis grade (RTOG scale); Swallowing dysfunction measured by Visual Analogue Pain Scale; Radiation treatment duration and early discontinuation of Radiation treatment.

All patients were treated with IMRT technique

### Results

We observed an increased acute toxicity in this group of patients compared to those who underwent chemoradiation alone or associated to laryngectomy.

Ten patients presented grade 3 or 4 mucositis during the treatment (41%)

The grade of swallowing dysfunction were up to 5 in all patients and up to 8 in 6 (20%) measured in a 1 to 10 pain scale.

The median treatment duration were 45 days, that reveals an increase compared to conventional cohort (48%)

Five patients required definitive early suspension of treatment (20%).

Eight patients underwent percutaneous gastrostomy when the weight-loss was above 15%.

Three patients underwent tracheotomy due to severe glottic stenosis produced by edema (12%).

### Conclusion

In our experience Transoral Laser Microsurgery with adjuvant Radiotherapy in advanced laryngeal cancer patients has increased side-effects.

We do not recommend this association

### EP-1095 Combined induction chemotherapy and radiotherapy in locally advanced nasopharyngeal carcinoma.

A. Gevorgov<sup>1</sup>, A. Boyko<sup>1</sup>, L. Bolotina<sup>2</sup>, A. Kornietskaya<sup>2</sup>, T. Deshkina<sup>2</sup>

<sup>1</sup>Moscow Research Gerzen Oncology Institut, Radiation oncology, Moscow, Russian Federation

<sup>2</sup>Moscow Research Gerzen Oncology Institut, Chemotherapy, Moscow, Russian Federation

### Purpose or Objective

This prospective trial was conducted to evaluate the efficacy and toxicity in previously untreated patients with stage III-IV nasopharyngeal carcinoma who received an induction chemotherapy followed by radiotherapy.

### Material and Methods

From January 2004 to December 2010, 50 patients with T2-4N2-3M0 squamous cell carcinoma of the nasopharynx were treated with three or six cycles of docetaxel 75 mg/m<sup>2</sup> (1-st day), cisplatin 75 mg/m<sup>2</sup> (1-st day), doxorubicin 45 mg/m<sup>2</sup> (1-st day) (50 patients) followed by radiotherapy using the conventional time/dose schedule.

### Results

The response rate to chemotherapy was 88% (48% complete response [CR]; 40% partial response [PR]), and the overall CR rate after radiotherapy was 92%. With a median follow-up period of 90 months, the 3-year survival rate was 63,6% and 3-year loco-regional control was 45,8%. The 5-year survival rate was 58% and 5-year loco-regional control was 42%. Treatment was tolerated, but with significant acute or chronic toxic effects and radiotherapy treatment gaps.

### Conclusion

The results of this study demonstrate that docetaxel, cisplatin and doxorubicin followed by radiotherapy can induce a durable remission in a high proportion of patients with poor-prognosis stage III-IV nasopharyngeal carcinoma. Treatment may be associated with severe toxicity and unplanned irradiation delays.

### EP-1096 Using DIR to study patterns of loco-regional failure in patients with head and neck cancer

Y. Zheng<sup>1</sup>, D.J. Noble<sup>2</sup>, R. Jena<sup>2</sup>, N. Burnet<sup>2</sup>

<sup>1</sup>Addenbrooke's Hospital- Cambridge University Hospitals NHS Foundation Trust, School of Clinical Medicine, Cambridge, United Kingdom

<sup>2</sup>Addenbrooke's Hospital- Cambridge University Hospitals NHS Foundation Trust, Department of Oncology- Cancer Research UK VoxTox Research Group, Cambridge, United Kingdom

### Purpose or Objective

Using deformable image registration (DIR), we examined patterns of loco-regional failure in patients who had undergone IMRT with daily image guidance for head and neck squamous cell carcinoma (HNSCC).

### Material and Methods

A database of HNSCC patients recruited to the Cancer Research UK VoxTox study between March 2013 and January 2016 was reviewed. All patients had been treated on TomoTherapy units, according to local protocol. Inclusion criteria for this sub-study were: full details of treatment protocol (RT and chemo) available, adequate follow-up, confirmed residual or loco-regionally relapsed disease, and diagnostic quality imaging of this disease (including MRI, PET/CT, CT) available for review. This gave a final cohort of 12.

Imaging confirming relapse or residual disease was uploaded to virtual simulation software (Prosoma 3.3), where an in-built DIR package was used to fuse these images with the planning CT and treatment dose-cube. Residual/relapsed disease was contoured on the relapse imaging, named rGTV, and the volume of this structure recorded. Contours describing the 95% isodose of 65Gy, 60Gy, 55Gy and 54Gy where relevant were generated. For each case, the proportion of rGTV covered by these isodoses and the treatment PTV and CTVs were recorded (labelled 'V'). Relapses were classified according to the 95% isodose of prescription dose contour: 'in-field' V > 75%, 'marginal' V - 25-75%, 'out of field' V < 25%. **Results**

Diagnosis/primary site	Staging	Prescription dose (Gy)	SACT	Relapse site	Time to relapse (weeks)
<b>Ipsilateral relapse</b>					
1 Oral cavity (RMT)	T4a/N2b	60/30	Ctx	Local soft tissue (discharging sinus)	24
2 Oral cavity (let. tongue)	T2N1	65/30	Cap	Neck (ulcerating node, level II/III)	39
3 Oropharynx (BoT)	T4N2b	65/30	Cap	FoM, BoT and neck (level II)	10
4 Oropharynx (BoT)	T4a/N2b	65/30	Ctx	Oral cavity & BoT	9
5 Hypopharynx	T2N0	65/30	None	Hypopharynx	19
6 Oropharynx (tonsil)	T3N2b	65/30	Cap	Tonsil, neck (level Ib/II) and nasopharynx	18
7 Larynx (supraglottis)	T2N1	65/30	Cap	Neck (level II)	14
8 Oropharynx (post-pharyngeal wall)	T2N0	55/20	None	Oropharynx	19
9 Oral cavity (let. tongue)	T1 N0	65/30	Cap	Neck (level IA, IB)	14
10 Oral cavity (let. tongue)	T3N2b	60/30	Cap	Post. pharyngeal wall & hypopharynx	16
<b>Contralateral relapse</b>					
11 Oral cavity (let. tongue)	T2N0M0	60/30	None	Neck (level III)	20
12 Oral cavity (let. tongue)	T2N2b	65/30	Cap	Neck (level V)	8

BoT – Base of tongue  
FoM – Floor of mouth  
RMT – Retro-molar trigone

Cap – Cisplatin  
Ctx – Cetuximab

Table 1: Case details

Case details are given in Table 1. Oral cavity primary disease accounted for 15% of cases in the original cohort available for review (prior to exclusions), but half of patients who relapsed loco-regionally. Mean time to relapse was 18 weeks (Std. error +/- 2.4 weeks). 10 of 12 patients (83%) had residual or relapsed disease ipsilateral to the primary site. 2 (both lateral tongue SCCs who underwent primary surgery followed by RT +/- chemo to the primary site and ipsilateral neck) relapsed early (8 and 20 weeks respectively) in the contralateral, un-irradiated neck.

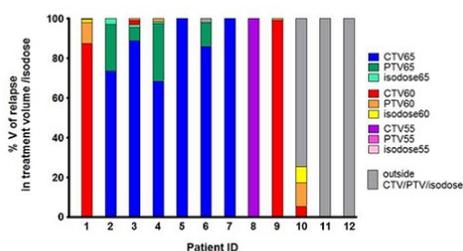

Figure 1: Stacked bar chart showing proportional volume of relapse covered by treatment plan volumes and dose.

Figure 1 describes the volume of rGTV covered by pertinent isodose contours and target CTV/PTVs. According to our criteria, 9 of 12 relapses were in-field (75%), 1 (8.3%) was marginal and 2 (16.7%) were in deliberately un-irradiated contralateral neck nodes as described. **Conclusion**

Oral cavity tumours appeared at highest risk of relapse in our cohort. Using DIR to map disease relapse to treatment volumes and dose, we found most relapsed HNSCC (75%) occurred within the high dose volume, in keeping with previous studies, and suggesting that unfavourable biology rather than inadequate RT is the predominant reason for loco-regional HNSCC relapse. Our results will be used to inform review of our neck irradiation policy, particularly for SCCs of the oral cavity.

### EP-1097 P16 expression: a predictive marker for treatment-related outcomes in oropharyngeal cancer patients?

A. Modesto<sup>1</sup>, T. Galissier<sup>2</sup>, A. Lusque<sup>3</sup>, E. Uro-Coste<sup>2</sup>, J. Delord<sup>4</sup>, A. Laprie<sup>1</sup>, J. Sarini<sup>5</sup>, P. Graff<sup>1</sup>, P. Vergez<sup>5</sup>, M. Rives<sup>1</sup>

<sup>1</sup>Institut Universitaire du Cancer, radiation therapy, Toulouse, France

<sup>2</sup>Institut Universitaire du Cancer, Pathology, Toulouse, France

<sup>3</sup>Institut Universitaire du Cancer, Biostatistics, Toulouse, France

<sup>4</sup>Institut Universitaire du Cancer, Medical Oncology, Toulouse, France

<sup>5</sup>Institut Universitaire du Cancer, Head and Neck Surgery, Toulouse, France

#### Purpose or Objective

Treatment strategies in oropharyngeal squamous cell carcinomas (OSCC) consist in either surgery followed by adjuvant radio(chemo)therapy or definitive radio(chemo)therapy. P16 overexpression (p16+) is considered as a surrogate marker for HPV-induced tumors that are associated with improved outcome whichever treatment modality is considered in comparison with p16 negative (p16-) OSCC. To date no predictive factors are known to guide treatment decision.

#### Material and Methods

All consecutive patients treated for an OSCC with a curative intent at a single tertiary cancer center between 2009 and 2013 were eligible to this study. P16 status was determined by immunohistochemistry and centrally reviewed. Late toxicities incidence ie: dysphagia, xerostomia, painful shoulder, osteoradionecrosis or nerve palsy were registered and graded according to CTCAE v4 in patients alive without loco-regional evolution at least 6 months after treatment completion. Three-year disease free survival (DFS) and late severe toxicity occurrence were compared according to p16 expression and treatment modality: initial surgical treatment or definitive radio(chemo)therapy.

#### Results

Among the 167 patients included in this study, 77 (44%) presented a tumoral p16 overexpression (p16+). Initial surgery was performed in 51 (66%) and 48 (53%) cases and definitive radiochemotherapy was performed in 26 (34%) and 42 (47%) cases among p16 + and p16 - patients respectively (p=0.05). 99 patients (60%) underwent initial surgery followed by adjuvant radio (chemo) therapy in 51 cases (91%). After a 51-month of median follow-up [47-54 months], the 3-year DFS was 82% and 42% among overall p16 + and p16 - patients respectively (p=0.01). Among p16 - patients, the 3-year DFS after initial surgery or definitive radiochemotherapy was 62% and 32% respectively (p=0.003). Among p16 + patients, the 3-year DFS was 85% and 77% (p=0.16) whereas severe delayed toxicity occurred in 42% vs. 18% after initial surgery or definitive radiochemotherapy respectively (p=0.05).

#### Conclusion

Whereas p16- OSCC are at high risk of loco-regional failure and highly benefited from aggressive multimodal treatment including surgery and adjuvant radio(chemo)therapy, p16+ OSCC didn't harbour the same benefit from the combinative approach that was associated with a significant increase of delayed severe toxicity. The benefit of initial surgery or definitive radio(chemo) therapy seemed not equivalent among OSCC patients according to p16 status that might be a useful tool to guide initial treatment decision.

### EP-1098 Survival predictors in patients with head and neck cancer treated with surgical resection

R.C.D.O. Franco<sup>1</sup>, L.L. De Matos<sup>2</sup>, G. De Castro Junior<sup>3</sup>, M.A.V. Kulcsar<sup>2</sup>, G.N. Marta<sup>1,4</sup>

<sup>1</sup>Instituto do Câncer do Estado de São Paulo ICESP - Faculdade de Medicina da Universidade de São Paulo, Radiation Oncology, Sao Paulo, Brazil

<sup>2</sup>Instituto do Câncer do Estado de São Paulo ICESP - Faculdade de Medicina da Universidade de São Paulo, Division of Head and Neck Surgery, Sao Paulo, Brazil

<sup>3</sup>Instituto do Câncer do Estado de São Paulo ICESP - Faculdade de Medicina da Universidade de São Paulo, Clinical Oncology, Sao Paulo, Brazil

<sup>4</sup>Hospital Sirio-Libanês, Radiation Oncology, São Paulo, Brazil

#### Purpose or Objective

This study aims to identify clinical factors that impact on overall survival of head and neck squamous cell carcinoma (HNSCC) patients who received surgery and post-operative radiation therapy (RT), with or without adjuvant chemotherapy.

#### Material and Methods

Between 2009 and 2013, patients diagnosed with HNSCC who underwent surgical resection with curative intent, followed by post-operative RT, with or without concurrent cisplatin-based adjuvant chemotherapy were assessed. Cox regression analyses were performed to evaluate the clinical and pathological features that could influence overall survival rates.

#### Results

170 patients were included (75.3% male). Oral cavity, larynx and oropharynx cancer were represented by 57.4%, 30.8% and 11.8% of all patients. Most patients (90.6%) had locally advanced disease (stage III or IV). Perineural and lymphovascular involvement were found in 70% and 31%, respectively. Free surgical margins were observed in 84% of cases and 66% had positive lymph nodes, 57% with extracapsular extension. 92.0% of patients received at least 60 Gy to the tumor bed. 45.0% of patients received concurrent chemotherapy. After a 23-month median follow-up, the overall survival rate was 60.7%. At univariate analysis, perineural invasion ( $p = 0.025$ ), positive lymph nodes ( $p = 0.011$ ), extracapsular extension ( $p = 0.005$ ), radiation dose less than 60 Gy to tumor bed ( $p=0.000$ ) and stage IV (versus stage III) [ $p=0.007$ ] negatively impacted on the overall survival. Multivariate analysis demonstrated that presence of extracapsular extension ( $p=0.005$ ) and stage IV ( $p=0.01$ ) were independent predictors of a lower overall survival rate.

#### Conclusion

The main factors that negatively affected overall survival rates in HNSCC patients treated with surgery with curative intent and post-operative radiation therapy with or without concurrent cisplatin-based adjuvant chemotherapy were the presence of extracapsular extension and stage IV disease.

### EP-1099 Evaluation of laryngeal preservation & outcomes following RT for locally advanced laryngeal SCC

A.M. Glynn<sup>1</sup>, J. O Shea<sup>1</sup>, R. McDermott<sup>1</sup>, S. Brennan<sup>1</sup>

<sup>1</sup>St Lukes Radiation Oncology Network, Radiation Oncology, Dublin, Ireland

#### Purpose or Objective

To assess failure rates and to evaluate functional outcomes in patients treated with radical radiotherapy for locally advanced laryngeal cancer based on cartilage invasion status

#### Material and Methods

A retrospective analysis of sixty-four patients who received radiotherapy (70Gy) with or without platinum-

based chemotherapy for locally advanced SCC of the larynx from January 2010 to December 2015 at St Luke's Radiation Oncology Network, Dublin, Ireland. Patients were categorised according to the degree of cartilage invasion based on radiological staging as having no cartilage invasion (T2/T3), minimal cartilage invasion (T3+) or gross cartilage invasion (T4)

#### Results

Sixty-four patients all receiving 70Gy using intensity-modulated radiation therapy techniques (IMRT) were analysed. Median age was 62.7 years. Eighty percent were males and 20% females. Thirty eight (59%) were smokers at the time of diagnosis and 89% ( $n=34$ ) continued to smoke during their treatment. Ninety two percent underwent PET-CT and 52% had MRI staging prior to commencing radiotherapy. Thirteen percent ( $n=8$ ) were staged as T2, 54.7% ( $n=35$ ) were T3, 20.3% ( $n=13$ ) were T3+ and 12.5% ( $n=8$ ) were T4. Median time from biopsy date to radiotherapy start date was 7.2 weeks. Two thirds ( $n=42$ ) had chemotherapy.

Median follow-up time was 6.5 months. Median survival was 23.6 months. Forty seven percent ( $n=30$ ) documented failures were identified and median time to failure was 4.5 months. Of those who failed 53% ( $n=16$ ) failed locally, 27% ( $n=8$ ) failed regionally, 7% ( $n=2$ ) failed loco-regionally and 13% ( $n=4$ ) failed distantly. Furthermore seven percent of those who failed had T2 disease ( $n=2$ ), 50% had T3 ( $n=15$ ), 23% had T3+ ( $n=7$ ) and 20% had T4 ( $n=6$ ). Thirty nine percent ( $n=26$ ) had PEG tubes inserted, of which 20 had them inserted pre-RT. Based on last follow-up appointment our overall PEG dependence rate was 27%. Thirty-four percent ( $n=21$ ) had tracheostomy tubes, of which 15 had them inserted pre-RT. Our overall tracheostomy dependence rate was 23%

#### Conclusion

Traditionally cartilage invasion is considered an indication for surgical management of laryngeal cancer. With the reclassification of minor thyroid cartilage invasion as T3, it is more difficult to decide which patients should be treated with radiotherapy as part of a laryngeal preservation approach. Our evaluation did not show a significant difference in failure rates in terms of cartilage invasion status. Our results show comparable outcomes with recent up-to-date literature in terms of PEG and tracheostomy rates

### EP-1100 Nodal Response During Radiotherapy for Head and Neck Cancer Correlates with Outcome

K. Latifi<sup>1</sup>, A. Rishi<sup>1</sup>, J. Caudell<sup>1</sup>

<sup>1</sup>H. Lee Moffitt Cancer Center, Radiation Oncology, Tampa, USA

#### Purpose or Objective

We hypothesized that the nodal response at the midpoint of radiotherapy for squamous cell carcinoma of the head and neck would correlate with outcome.

#### Material and Methods

After IRB approval, 37 patients with non-metastatic squamous cell carcinomas of the head and neck treated with definitive radiotherapy (RT) with cone beam computed tomography (CBCT) or CT on rails during treatment were identified. Nodal volumes were contoured on CT simulation films as well as weekly CBCT or CT on rails. Volume change between the first week of treatment and fourth week of treatment were calculated. Outcomes, including locoregional control (LRC) and disease free survival (DFS) were calculated from the end of RT and estimated via Kaplan-Meier method, with comparisons made via log-rank test.

#### Results

Median follow-up of all patients was 12 months. Primary sites included oropharynx ( $n=34$ ) and oral cavity ( $n=3$ ). Median dose was 70 Gy (range 54 - 70 Gy). Systemic

therapy was used in 78.4% of patients (n = 29). Median response was 32% (range -39.3% - 78%) comparing week 4 and week 1 nodal volumes. Patients with a response greater than 32% at week 4 had a 1 year locoregional control rate of 100% compared with 75.6% for patients with a  $\leq 32\%$  response (p = 0.03). Similarly, patients with a nodal response  $> 32\%$  had a 1 year DFS rate of 100% vs. 67.1% for  $\leq 32\%$  (p = 0.01).

#### Conclusion

Nodal response at four weeks may be associated with ultimate outcome of patients with squamous cell carcinoma of the head and neck treated with definitive radiotherapy. While further work is needed, monitoring of nodal response may allow for both volume and dose adaptation of therapy.

#### EP-1101 Leptomeningeal spread after stereotactic radiation for brain metastases from breast cancer

O. Kaidar-Person<sup>1</sup>, A. Deal<sup>2</sup>, C. Anders<sup>3</sup>, M. Ewend<sup>4</sup>, L. Carey<sup>3</sup>, E. Dees<sup>3</sup>, J. Camporeale<sup>1</sup>, J. Ramirez<sup>5</sup>, J. Benbow<sup>3</sup>, L. Marks<sup>1</sup>, T. Zagar<sup>1</sup>

<sup>1</sup>University of North Carolina- Chapel Hill- North Carolina- USA-, Department of Radiation Oncology, Chapel Hill, USA

<sup>2</sup>UNC Lineberger Comprehensive Cancer Center- Chapel Hill- NC, Statistics, Chapel Hill, USA

<sup>3</sup>University of North Carolina- Chapel Hill- North Carolina- USA-, Medicine, Chapel Hill, USA

<sup>4</sup>University of North Carolina- Chapel Hill- North Carolina- USA-, Neurosurgery, Chapel Hill, USA

<sup>5</sup>University of North Carolina- Chapel Hill- North Carolina- USA-, UNC Lineberger Comprehensive Cancer Center- Chapel Hill- NC, Chapel Hill, USA

#### Purpose or Objective

Our objective was to explore the incidence and predictive factors for subsequent development of leptomeningeal disease in women with breast cancer who received stereotactic radiation (SRT, 1 to 5 fractions) for brain metastases.

#### Material and Methods

We conducted a retrospective analysis from a prospective collected metastatic breast cancer database of all patients with brain metastases seen between 2012 to 2016.

#### Results

A total of 98 patients with breast cancer brain metastases were included. Twenty-one (21%) patients developed leptomeningeal spread (initial enhancement on MRI, with/without symptoms). The median time to development of leptomeningeal spread from the diagnosis of primary breast cancer was 3.7 years (95% CI 1.3 to 15.3) and the median time to development of leptomeningeal spread from the diagnosis of brain metastases was 1.3 years (95% CI 7 days to 4.3 years). All 21 patients developed symptoms due to leptomeningeal disease. Age, primary tumor receptor status, Karnofsky performance status, craniotomy prior to SRT, whole brain irradiation (WBRT), prior to SRT were not associated with increased or reduced risk of leptomeningeal spread (all p > 0.05). Median overall survival from initial diagnosis of leptomeningeal spread was 2.7 years (95% CI 1.4 to 3.7), with 2 patients surviving 5 years (5 and 5.3 years).

#### Conclusion

In this study, we did not identify clinically significant factors that were associated with an increased risk of leptomeningeal dissemination. The relatively long overall survival for breast cancer patients with brain metastases suggests that brain SRT remains a valid option for breast

cancer brain metastases. Several exceptional responders with brain metastases and leptomeningeal disease were identified. A better understanding of this unique population of patients is needed.

#### EP-1102 Primary and secondary gliosarcomas: clinical, molecular, and survival characteristics

H.J. Kim<sup>1</sup>, S.H. Kim<sup>2</sup>, J.H. Chang<sup>3</sup>, I.J. Lee<sup>1</sup>, C.O. Suh<sup>1</sup>, J. Cho<sup>1</sup>

<sup>1</sup>Yonsei University, Radiation Oncology, SEOUL, Korea Republic of

<sup>2</sup>Yonsei University, Pathology, SEOUL, Korea Republic of

<sup>3</sup>Yonsei University, Neurosurgery, SEOUL, Korea Republic of

#### Purpose or Objective

Gliosarcoma is an extremely rare disease, which is a variant of glioblastoma exhibiting a biphasic histologic characteristic of both glial and mesenchymal components. We investigated to identify prognostic or therapeutic factors impacting on survival outcomes in patients with gliosarcoma treated in a single institution.

#### Material and Methods

Patients who had been treated with a pathology-confirmed diagnosis of gliosarcoma at Yonsei University Medical Center between 1991 and 2015 were retrospectively analyzed. Patients who were <20 years old at diagnosis or have not been followed up after treatment were excluded. Primary gliosarcoma (PGS) was defined as a tumor developed de novo, whereas those diagnosed subsequent to glioblastoma that have been treated with surgery and adjuvant radiotherapy were termed secondary gliosarcoma (SGS). Molecular analysis performed on 9 patients including IDH1, TP53, Ki-67 and EGFR.

#### Results

A total of 19 patients were identified, including 17 PGS and 2 SGS patients. All patients received surgery followed by adjuvant radiotherapy with a median dose of 60 Gy. Gross total resection was performed in 6 patients, while subtotal resection was performed in 13 patients. The concurrent chemotherapy with temozolomide was performed in 10 patients. The Median overall survival (OS) for all patients was 12.9 months from the diagnosis of gliosarcoma, with a progression free survival (PFS) of 5.5 months. The median OSs were 12.9 and 5.2 months for PGS and SGS, respectively (P = 0.035) and the median PFSs were 6.1 and 0.8 months (P = 0.048). In the two cases of SGS, SGS developed 10 and 18 months after the diagnosis of GBM for each. The univariate analysis revealed that good performance status (KPS  $\geq 80$ ), PGS and salvage treatment after recurrence were significant prognostic factors related to better OS. All these factors were also remained as independent prognostic factors for OS in the multivariate analysis. Molecular analysis revealed a high incidence of P53 expressions and, rarely, EGFR and IDH1 mutations.

#### Conclusion

Primary and secondary gliosarcoma had an even poorer survival, compared with primary and recurrent glioblastoma, respectively. Further molecular marker study should be done to explain the dismal prognosis of gliosarcoma. And multi-institutional collaborative study is needed to characterize prognostic factors and design optimal treatment.

#### EP-1103 Are hippocampi considered organs at risks during stereotactic radiotherapy for brain metastases?

U. Tebano<sup>1</sup>, A. Fiorentino<sup>1</sup>, G. Sicignano<sup>1</sup>, N. Giaj-Levra<sup>1</sup>, S. Fersino<sup>1</sup>, R. Mazzola<sup>1</sup>, F. Ricchetti<sup>1</sup>, S. Naccarato<sup>1</sup>, R. Ruggieri<sup>1</sup>, F. Alongi<sup>1</sup>

<sup>1</sup>Sacro Cuore Don Calabria Cancer Care Center, Radiation Oncology Division, Negrar, Italy

### Purpose or Objective

Hippocampal-dependent neurocognitive functions, including learning, memory and spatial information processing, could be affected by brain radiotherapy. Aim of the present study is to evaluate the dose to the ipsilateral and contralateral hippocampus (O-H, C-H, respectively) during Stereotactic Radiotherapy (SRT) or Radiosurgery (SRS) for brain metastases (BM).

### Material and Methods

Patients eligible for SRS/SRT treatment had a number of BM <5, with a size  $\leq 30$ mm, Karnofsky Performance Status (KPS)  $\geq 80$  and a life expectancy over 3 months. Gross Tumour Volume (GTV) was delineated by the fusion between Magnetic Resonance Imaging and Computed Tomography. A Planning Target Volume (PTV) was obtained from GTV by adding a 2mm isotropic margin. The total dose ranged between 18-27 Gy in 1-3 fractions. For each BM, a Volumetric modulated arc therapy plan was generated with one or two arcs and hippocampus sparing was not considered during optimization phase. For the dosimetric evaluation of O-H and C-H, the  $D_{median}$ ,  $D_{mean}$ ,  $D_{0.1cc}$  and the  $V_{1Gy}$ ,  $V_{2Gy}$ ,  $V_{5Gy}$  and  $V_{10Gy}$  were analyzed.

### Results

From April 2014 to December 2015, 81 BM in 41 patients were treated with SRS/SRT and selected for the present analysis. The average value of PTV dimension and hippocampus volumes were (5.8 + 9.5) cc and (1.1 + 0.3) cc, respectively.

For the O-H, the average values of  $D_{median}$ ,  $D_{mean}$  and  $D_{0.1cc}$  were (1.5 + 3.65) Gy, (1.54 + 3.6) Gy, (2.2 + 4.7) Gy, respectively, while the  $V_{1Gy}$ ,  $V_{2Gy}$ ,  $V_{5Gy}$  and  $V_{10Gy}$  values were (25 + 40) %, (18.9 + 35) %, (8.9 + 25.3) % and (2.1 + 11.8) %, respectively. For the C-H, the average  $D_{median}$ ,  $D_{mean}$  and  $D_{0.1cc}$  were (0.7 + 1.5) Gy, (0.7 + 1.4) Gy, (0.9 + 1.8) Gy, respectively, while the average values of  $V_{1Gy}$ ,  $V_{2Gy}$ ,  $V_{5Gy}$  and  $V_{10Gy}$  were (18 + 35) %, (10.2 + 27.7) %, (2.8 + 15.4) % and (1.4 + 11.6) %, respectively. The differences between O-H and C-H, in terms of received dose, was statistically significant ( $p=0.03$ ). Moreover, the PTV dimension (>5cc or >6cc) did not influence the dose of hippocampus ( $p=0.06$ ; 0.2, respectively).

### Conclusion

During SRT/SRS treatments for BM, hippocampus received a very low dose and its clinical significance seems to be negligible, even if it is still under investigation. However, considering the increasing use of SRS/SRT for multiple BM, including also patients with up to 10 BM, the dose to hippocampus need to be seriously evaluated in the treatment planning.

### EP-1104 SABR for brain metastases with VMAT and FFF: feasibility and early clinical results

N. Gajj Levrá<sup>1</sup>, A. Fiorentino<sup>1</sup>, G. Sicignano<sup>1</sup>, U. Tebano<sup>1</sup>, S. Fersino<sup>1</sup>, R. Mazzola<sup>1</sup>, F. Ricchetti<sup>1</sup>, D. Aiello<sup>1</sup>, S. Naccarato<sup>1</sup>, R. Ruggieri<sup>1</sup>, F. Alongi<sup>1</sup>

<sup>1</sup>Sacro Cuore Don Calabria Cancer Care Center Hospital, Radiation Oncology, Negrar-Verona, Italy

### Purpose or Objective

For selected patients with brain metastases (BMs), the role of stereotactic radiosurgery (SRS) or stereotactic fractionated radiotherapy (SFRT) is well recognized. The recent introduction of Flattening-Filter-Free (FFF) delivery during linac-based SRS or SFRT allows shorter beam-on-time, improving patients' comfort and facility workflow. Aim of the present study was to analyze SRS/SFRT linac-based FFF-delivery for BMs in terms of dosimetric and early clinical results.

### Material and Methods

Patients with life expectancy > 3 months, number of BMs < 5, diameter < 3cm and controlled or synchronous primary

tumor, received SRS/SRT. The prescribed total dose and fractionation, based on BMs size and proximity to organs at risk, ranged from 15Gy in 1 fraction to 30Gy in 5 fractions. A FFF-Volumetric Modulated Arc Therapy (VMAT) plan was generated with one or two coplanar partial arcs. Toxicity was assessed according to CTCAE v4.0.

### Results

From April 2014 to February 2016, 45 patients (89 BMs) were treated with SRS/SFRT linac-based FFF-delivery. The mean beam-on-time was 140 seconds for each lesion (range 90-290 seconds) and the average brain Dmean was 1Gy (range 0.1 - 4.8 Gy). With a median follow-up time of 12 months (range 1-27 months), the median overall survival was 14 months and the 6-month overall survival was 77% and. At the time of analysis local control was reported in 83 BMs (93.2%) and 6-month actuarial rates was estimated in 76.4%. Finally, the median intracranial disease control was 11 months. Acute and late toxicities were acceptable without severe events (no adverse events  $\geq$  G2 were recorded).

### Conclusion

These preliminary results confirmed the feasibility and safety of linac-based SRS/SFRT with FFF delivery for BMs patients. A longer follow-up is necessary to assess the definitive efficacy and tolerability of SRS/SFRT with FFF in BM patients.

### EP-1105 Treatment Outcomes and Prognostic Factors of Atypical Meningioma: A Single-Institution Experience

H.J. Kang<sup>1</sup>, B.O. Choi<sup>1</sup>

<sup>1</sup>The Catholic University of Korea- Seoul St. Mary's Hospital, Radiation oncology, SEOUL, Korea Republic of

### Purpose or Objective

We aimed to evaluate the treatment outcomes and prognostic factors in patients with atypical meningioma.

### Material and Methods

From 2001 to 2016, 131 patients were retrospectively reviewed in this study. All patients were treated with surgical resection and histologically confirmed as atypical meningioma. The histology grading was defined by the 2000/2007 WHO classification. Ninety-five patients (75.5%) underwent gross-total resection (GTR) and 36 patients (27.5%) underwent subtotal resection (STR). Of the 36 patients treated with STR, 20 (15.7%) received adjuvant radiation therapy (ART).

### Results

The median follow-up time was 36 months (range, 6-152 months). The 3- and 5-year progression-free survival (PFS) rates were 81.8% and 74.6%, respectively, and the 3- and 5-year overall survival rates were 93% and 86.5%, respectively. Only the surgical resection status was significantly associated with disease progression ( $p=0.002$ ). In the STR subgroup, ART was also significantly associated with progression ( $p=0.003$ ). When stratified into 3 groups according to the surgical resection status and ART, the patients treated with STR alone showed significantly lower PFS, while those treated with GTR and STR plus ART did not (3-year PFS, 30.8% vs 91% vs 83.6%;  $p=0.013$ ).

### Conclusion

Although the most important prognostic factor related to progression was the surgical resection status, ART in patients with STR improved PFS, which is similar to those with GTR. Routine use of ART after STR is recommended.

### EP-1106 Local control and overall survival after frameless radiosurgery

A. Bilger<sup>1</sup>, F. Frenzel<sup>1</sup>, O. Oehlke<sup>1</sup>, R. Wiehle<sup>1</sup>, D. Milanovic<sup>1</sup>, V. Prokic<sup>2</sup>, C. Nieder<sup>3</sup>, A.L. Grosu<sup>1</sup>

<sup>1</sup>University Medical Center Freiburg, Department of

*Radiation Oncology, Freiburg, Germany*

<sup>2</sup>*University of Applied Sciences Koblenz, Department of Radiation Oncology and Medical Technology, Koblenz, Germany*

<sup>3</sup>*Institute of Clinical Medicine, Faculty of Health Sciences- University of Tromsø, Tromsø, Norway*

#### **Purpose or Objective**

Stereotactic radiosurgery (SRS) has been increasingly advocated for 1-3 small brain metastases. Goal of this study was to evaluate the clinical results in patients with brain metastases treated with SRS using a thermoplastic mask non-invasive fixation system and image-guided treatment.

#### **Material and Methods**

In this single-institution study 48 patients with 77 brain metastases were treated between February 2012 and January 2014. The head fixation was realized using a BrainLAB thermoplastic mask. The prescribed dose was 20 Gy or 18 Gy as a single dose. The SRS were performed with a True Beam STX Novalis Radiosurgery LINAC (Varian Medical Systems). The verification of positioning was done using the BrainLAB ExacTrac® X-ray 6D system and cone-beam CT.

#### **Results**

In 69 of 77 (89.6%) treated brain metastases the follow-up was documented on MR imaging performed every 3 months. In 7/69 (10.1%) brain metastases local failure was diagnosed with a mean follow-up time of 10.7 months (range 1-43 months). Estimated 1-year local control was 83.1%. Median progression free survival (PFS) was 3.7 months, largely due to distant brain relapse. Breast cancer was significantly associated with a worse progression free survival. A GTV of  $\leq 2.0$  cm<sup>3</sup> was significantly associated with a better PFS than a GTV > 2.0 cm<sup>3</sup>. We observed 2 cases of radiation necrosis diagnosed by histology after surgical resection. No other cases of severe side effects (CTACE $\geq$ 3) were observed.

#### **Conclusion**

In our experience local control after frameless (ringless) LINAC based SRS with mean follow-up of 10.7 months is 89.9%. Without the invasive head fixation radiotherapy is more comfortable for the patients

#### **EP-1107 Treatment Strategies for local and distant recurrence after HFSRT of the Resection Cavity**

A. Bilger<sup>1</sup>, E. Bretzinger<sup>1</sup>, H. Lorenz<sup>1</sup>, O. Oehlke<sup>1</sup>, A.L. Grosu<sup>1</sup>, S.E. Combs<sup>2</sup>, H.M. Specht<sup>2</sup>

<sup>1</sup>*University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, Germany*

<sup>2</sup>*Klinikum rechts der Isar- Technical University of Munich, Department of Radiation Oncology, München, Germany*

#### **Purpose or Objective**

In patients undergoing surgical resection of brain metastases the risk of local recurrence remains high (50-60%). Adjuvant Whole Brain Radiation Therapy (WBRT) can reduce the risk of local relapse but fails to improve overall survival.

At the Departments of Radiation Oncology, University Medical Center Freiburg and Department of Radiation Oncology, Technical University Munich, a retrospective multicenter study was performed to evaluate the role of hypofractionated stereotactic radiotherapy (HFSRT) in patients with brain metastases after surgical resection. After a median follow up of 12.6 months (range 0.3 - 80.2 months) the crude rate for local control was 80.5% (Manuscript in preparation). In this analysis we evaluated the treatment strategies after intracranial local (LF) and locoregional (LRF) failure.

#### **Material and Methods**

183 patients were treated with HFSRT of the surgical cavity after resection of brain metastases. In addition to the assessment of local control, distant intracranial control, overall survival and progression-free survival (manuscript in preparation), in this analysis we focused on the evaluation of individual patient histories and treatment strategies after intracranial recurrence.

#### **Results**

Imaging follow-up (cMRI) for the evaluation of LF and LRF was available in 160/183 (87%) patients. 100/183 (63%) patients showed intracranial progression after HFSRT.

At the first time of recurrence 81/100 (81%) patients received salvage therapy. Median time to the first recurrence was 5 months (6LF, 73LRF, 21LF+LRF). 14/81 patients underwent another surgery, 78/81 patients received radiation therapy as a salvage treatment (53% WBRT). Patients with single or few metastases distant from the initial site or WBRT in the past were re-treated by HFSRT (14%) or stereotactic radiosurgery (SRS, 33%). In case of second failure 32/48 patients received further salvage therapy (10WBRT, 18SRS, 4HFSRT). Median time to second recurrence was 10 months (5LF, 38LRF, 5 LF+LRF). Twelve patients developed a third failure (2LF, 8LRF, 2LF+LRF) after a median time of 14 months and 6 of them had a reirradiation (1WBRT, 4SRS, 1HFSRT). After a median time of 23 months 5 patients had a fourth recurrence (3LRF, 2LF+LRF) and 3 had another salvage treatment (2WBRT, 1SRS).

Seven (3.8%) patients experienced radionecrosis. No other severe side effects (CTCAE $\geq$ 3) were observed.

**Conclusion**  
In our first analysis we have shown that postoperative HFSRT to the resection cavity is a highly effective concept leading to long-term local control after surgery (crude rate for local control was 80.5%). In this analysis we focused on salvage therapy in case of intracranial progression. 100/183 patients developed intracranial failure and 81 received a first salvage therapy. Thirty-two of 48 patients with a second recurrence, 6/12 patients with a third recurrence and 3/5 patients with a fourth recurrence received salvage treatment without severe side effects. Local failures are rare and distant intracranial failures can be effectively salvaged by further radiotherapy.

#### **EP-1108 CyberKnife® stereotactic radiation therapy for re-irradiation of recurrent high grade gliomas.**

H. Grzbiela<sup>1</sup>, M. Stąpór-Fudzińska<sup>2</sup>, E. Nowicka<sup>1</sup>, M. Gawkowska<sup>1</sup>, R. Tarnawski<sup>1</sup>

<sup>1</sup>*Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, III Radiotherapy and Chemotherapy Clinic, Gliwice, Poland*

<sup>2</sup>*Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Planning Department, Gliwice, Poland*

#### **Purpose or Objective**

Patients suffering from brain tumors, especially high grade gliomas (HGG), often have to face a recurrence of the tumor, after the primary treatment. Stereotactic radiotherapy with CyberKnife® seem to offer a valuable treatment option.

#### **Material and Methods**

33 patients diagnosed with HGG, aged 25-71 (median 57), were re-irradiated due to tumor progression between 2011 and 2014. All patients underwent neurosurgery at the time of primary diagnosis (2008-2012). Pathology was: anaplastic astrocytoma G3 in 2 patients, and glioblastoma G4 in 31 patients. The surgery was followed by concurrent radiochemotherapy with temozolomide. All patients completed the treatment receiving 60 Gy. During follow-up gadolinium-enhanced MRI was performed every 3 months. Recurrence was found in MRI scans 3-54 months

after completion of treatment (median time to recurrence was 9 months). In 8 patients partial tumor resection was performed (pathology was confirmed as glioblastoma G4 in this group). All patients were planned for re-irradiation. CyberKnife® stereotactic radiation therapy was used. Total dose and dose per fraction delivered to tumor depended mainly on tumor volume and time interval after the first course of radiation therapy. The irradiated tumor volume ranged from 9.4 to 75.7 cm<sup>3</sup>. 4 patients received 18 Gy in 3 fractions, 14 patients - 16 Gy in 2 fractions, 11 patients - 12 Gy in 2 fractions, and 4 patients - 8 Gy in a single fraction.

#### Results

All patients completed the stereotactic radiation therapy. 82% of patients reported mild or moderate headache (CTCAE grade 1 or 2). No grade 3 or 4 acute toxicity was observed. Follow-up time after re-irradiation was 3 - 48 months (median 12 months). Progression-free survival was 3 - 39 months (median 6 months). The early results were assessed with MRI scans performed 3 months after the stereotactic radiation therapy. Stable disease was observed in 5 patients (15.2%). Partial tumor regression was observed in 6 patients (18.2%).

#### Conclusion

In our experience, CyberKnife® stereotactic radiation therapy can be considered as a valuable treatment option, which can slow down the inevitable progression of high grade gliomas in about 30% of patients. It also seems to be a safe method of re-irradiation, provided that the total dose and dose per fraction are chosen carefully and individually.

#### EP-1109 measurement of hippocampus atrophy after whole brain irradiation using voxel based morphometry

T. Ito<sup>1</sup>, M. Nishihara<sup>2</sup>, S. Takaki<sup>2</sup>, Y. Tani<sup>2</sup>

<sup>1</sup>Japanese Redcross society nagaoka hospital, radiation therapy, Nagaoka, Japan

<sup>2</sup>Japanese Redcross society nagaoka hospital, radiology, Nagaoka, Japan

#### Purpose or Objective

To estimate the adverse effect of whole brain radiation therapy (WBRT), especially cognitive disorder, we measured retrospectively about mesial temporal lobe size after WBRT using voxel based morphometry in cancer patients.

#### Material and Methods

From 2013 to 2015, 11 cancer patients with multiple brain metastasis (7 men and 4 women, average age was 59 years) were examined by gadolinium enhanced MRI before and after WBRT. The sequence was followed; T1-weighted 3D-variable flip angle sagittal image in 1mm slice thickness, using 1.5T MRI scanner, and it is routine sequence in our hospital for cancer patient's examination. And this image set was analysed by voxel based morphometry from the view point of the ratio of the mesial temporal lobe to the whole brain. Voxel based morphometry software was VSRAD advanced 2, and this program was generally used for Alzheimer's disease evaluation.

Images were obtained before WBRT, and after several months in variable periods. (longest case was 14 months)

#### Results

33 MRI images were analysed and calculated by VSRAD advanced 2. The examinations with severe brain edema or huge metastasis were excluded. 2 patients were alive and 9 patients were dead by original disease (include caused by brain metastasis). In only one patient, mental disturbance was occurred clinically, but other patients were not reported mental disorder by clinician. No patient

was examined mini-mental state examination. Temporary increase tendency of hippocampus atrophy compared to whole brain were observed in the period of about 4 months after WBRT. But reliability was low statistically.

#### Conclusion

A minimal change of hippocampus size was observed, but it might be a measurement error. Further investigation is needed, especially more number of cases. Furthermore, from the perspective of with or without of chemotherapy, or comparison to after stereotactic radiosurgery alone are required.

#### EP-1110 Evaluation of [18F]FET-PET and MRI assessed recurrence pattern in patients with high-grade glioma

J. Hesse<sup>1,2</sup>, K. Kessel<sup>1</sup>, H. Specht<sup>1</sup>, M. Schwaiger<sup>3</sup>, T. Pyka<sup>3</sup>, C. Zimmer<sup>4</sup>, S. Combs<sup>1,2</sup>

<sup>1</sup>Technical University Munich TUM, Department of Radiation Oncology, München, Germany

<sup>2</sup>Institute of Innovative Radiotherapy iRT, Department of Radiation Sciences DRS, Neuherberg, Germany

<sup>3</sup>Technical University Munich TUM, Nuclear Medicine, München, Germany

<sup>4</sup>Technical University Munich TUM, Department of Neuroradiology, München, Germany

#### Purpose or Objective

Despite multidisciplinary therapy concepts the prognosis of high-grade glioma (HGG) remains poor and recurrence is frequent. In this analysis, we evaluated the recurrence pattern and gross tumor volume (GTV) comparing two different imaging techniques: MRI and [18F]FET-PET. Our aim was to identify high-risk areas for recurrence in order to optimize concepts of radiotherapy-planning.

#### Material and Methods

We analyzed 14 patients with HGG (WHO III: n=6, WHO IV: n=8) treated in our department. All patients were incompletely resected received adjuvant radiotherapy. GTV and tumor volume at recurrence (RecTV) definition was based on MRI (GTV<sub>MRI</sub>, RecTV<sub>MRI</sub>) and FET-PET (GTV<sub>PET</sub>, RecTV<sub>PET</sub>). In order to evaluate the recurrence pattern, the percentage of RecTV<sub>PET</sub> and RecTV<sub>MRI</sub> residing within the planning target volume (PTV) was determined. We classified RecTV as 'in-field' if more than 90% of RecTV was detected inside PTV, as 'field-border' if 30-90% and as 'out-field' if less than 30% was located within PTV. We compared the volumes and calculated various intersection (IV) and conjunction volumes (CV) as well as the conformity index (CI=IV/CV). CI takes not only volumetric size into account, but also the extend of overlap. For image fusion and target definition iPlan RT® (BrainLab, Munich, Germany) and Eclipse® (Varian, Palo Alto, US) were used.

#### Results

Median PTV was 192.9 ml (range 10.1-490.8 ml). RecTV<sub>PET</sub> and RecTV<sub>MRI</sub> showed no major differences concerning recurrence localization: In-field recurrence was detected in 64% (9/14), field-border in 29% (4/14) and out-field 7% (1/14). We were not able to evaluate the RecTV<sub>MRI</sub> of one

patient because the MRI showed no enhancement. Since FET-PET enables differentiation between vital tumor and therapeutic associated changes, we compared RecTV<sub>PET</sub> to GTV<sub>MRI</sub> and GTV<sub>PET</sub>. Median IV of GTV<sub>PET</sub>/RecTV<sub>PET</sub> (4.1 ml, range: 0-20.8 ml) was larger than GTV<sub>MRI</sub>/RecTV<sub>PET</sub> (2.8 ml, range: 0-18.1 ml). Accordingly, the median CI showed higher conformity with 0.19 (range: 0-0.63) and 0.07 (range: 0-0.48), respectively. We calculated median ratio of IV GTV<sub>PET</sub>/RecTV<sub>PET</sub> to GTV<sub>PET</sub> (44.8%, range: 0-100%) and the median ratio of IV GTV<sub>MRI</sub>/RecTV<sub>PET</sub> to GTV<sub>MRI</sub> (32.2%, range: 0-96.6%) to show that the proportion of GTV<sub>PET</sub> developing tumor recurrence tended to be higher than the proportion of GTV<sub>MRI</sub>.

#### Conclusion

The patterns of recurrence were similar in MRI and FET-PET concerning localization related to PTV. Only one patient showed out-field recurrence, all others developed in-field/field-border recurrence. Therefore, it is indicated that current margin concepts are a safe way to define PTV. However, the GTV<sub>PET</sub> displays remaining tumor more reliable, and it seems to offer a better prediction of the localization of later tumor growth than the GTV<sub>MRI</sub>. This leads to the assumption that dose escalation in the GTV<sub>PET</sub> area might be a worthy subject for future trials.

#### EP-1111 Cyber knife for Idiopathic Trigeminal Neuralgia - Novel technique to reduce brainstem dose

P.S. Sridhar<sup>1</sup>, N. Madhusudhan<sup>1</sup>, K. Roopesh<sup>1</sup>, H. Madhusudhan<sup>2</sup>, R. Satish<sup>3</sup>, G. Swaroop<sup>3</sup>, A. Jerrin<sup>1</sup>, A. <sup>3</sup>Sakra hospital, Neurosurgery, Bangalore, India

<sup>4</sup>Health Care Global Enterprises Ltd, Radiology, Bangalore, India

<sup>5</sup>Health Care Global Enterprises Ltd, Aneesthesia, Bangalore, India

#### Purpose or Objective

Idiopathic trigeminal neuralgia is a functional disorder and most painful condition known to mankind. Diagnosis is always clinical, no radiological and functional scans will be helpful. Medical management and Microvascular decompression of aberrant vessel, Radiofrequency ablation, alcohol injection are used extensively with minimal response. Stereotactic radiosurgery is becoming popular with good results. Most commonly used is targeting the trigeminal nerve at its root entry zone. Dose schedule varies from 66-86Gy single fraction. Brainstem dose is still a concern which is not addressed

Primary objective is to assess the safety and efficacy of treating Idiopathic Trigeminal Neuralgia by Stereotactic Robotic Radiosurgery in Meckels cave area to reduce brain stem dose.

#### Material and Methods

12 patents of Idiopathic Trigeminal Neuralgia treated with Stereotactic Robotic Radiosurgery (Cyberknife) between Jan 2010 to Dec 2015.6 were female,6 male. Age range 34-75,mean age 46 .6 were on right side,6 left side. Duration of symptoms before the treatment range from 2 to 25 years. All patients had one or other form of standard treatment with unsatisfactory response. All patent undergo MRI based Cyberknife planning. The affected side trigeminal nerve is identified ,The part of nerve in Meckels cave and 3 branches are marked ,brain stem and other critical structures are contoured .

GTV ranged 260-824mm<sup>3</sup>,mean 500mm<sup>3</sup>, Dose prescription ranged from 70-80% mean 76% and peripheral dose ranged from 56Gy-70Gy,maximum dose 70Gy to 80Gy

mean 75.4Gy.Brain stem maximum dose ranged between 7.6Gy to 18.3Gy mean 12.7Gy.

#### Results

All 12 patients had complete response at 6 weeks,2 patent had recurrence of pain at 8 and 10 months ,10 patents has altered sensation on treated trigeminal area in the form of loss of sensation,hyperesthesia.None of them had brainstem symptoms.

#### Conclusion

Stereotactic Robotic Radiosurgery (Cyberknife) is 76Gy single fraction is safe and effective in Idiopathic Trigeminal Neuralgia .Treating trigeminal nerve in Meckels cave area and 3 branches will give good pain control with less dose to brainstem.

#### EP-1112 Dosimetric evaluation in tri-cobalt60 viewray system for hypofractionated imrt in brain metastases

M. Ferro<sup>1</sup>, E. Placidi<sup>2</sup>, S. Chiesa<sup>1</sup>, F. Cellini<sup>1</sup>, M. Massaccesi<sup>1</sup>, G.C. Mattiucci<sup>1</sup>, V. Frascino<sup>1</sup>, R. Cannà<sup>3</sup>, C. Masciocchi<sup>4</sup>, L. Azario<sup>5</sup>, V. Valentini<sup>6</sup>, M. Balducci<sup>6</sup>

<sup>5</sup>Università Cattolica del Sacro Cuore, Institute of Physics- UOC Fisica Sanitaria- Gemelli ART - Radiation Oncology, Rome, Italy

<sup>6</sup>Università Cattolica del Sacro Cuore, Gemelli ART - Radiation Oncology, Rome, Italy

#### Purpose or Objective

Meridian is a system equipped with 3 rotating 60Co sources for IMRT and magnetic resonance imaging (MRI) for real-time vision of target volume (TV). The aim of this in silico study was to evaluate the dosimetric impact of this technology when hypofractionated IMRT is used to treat brain metastases (BM).

#### Material and Methods

Treatment plans were performed with a monoisocentric IMRT technique using different number of beams. Margin to PTV was 3 millimeters as normally used for LINAC plans. Total dose prescribed according to ICRU 83 was 25.5 Gy in 3 fractions.

TV coverage, Paddick dose conformity (CI), homogeneity (HI), dose to organ at risk (OAR) and to normal brain were analyzed for all plans.

**Results**  
Sixteen brain metastases were evaluated and 80 plans were analyzed. No significative statistical difference was observed in HI when beams number was increased (p > 0.5). The CI did not change between different beams arrangements. No significant statistical difference was observed when beam's number was correlated with TV or sparing normal tissues.

#### Conclusion

IMRT plans using the tri-60Co ViewRay System are feasible according to ICRU 83. The real-time vision of target volume by MR could allow to reduce the PTV margin saving the normal tissue. An ongoing study is comparing ViewRay plans with 3 millimeters to PTV with plans in which no margin is added and PTV is the equal to GTV.

#### P-1113 Helical Tomotherapy and altered fractionation in the treatment of Glioblastoma

C. Caruso<sup>1</sup>, R. Barbara<sup>1</sup>, S. Gomellini<sup>1</sup>, A.D. Andrulli<sup>1</sup>, A. Caccavari<sup>2</sup>, M. Moreschi<sup>3</sup>, U. De Paula<sup>1</sup>

<sup>1</sup>Complesso Ospedaliero San Giovanni Addolorata, Radioterapia, Roma, Italy

<sup>2</sup>Complesso Ospedaliero San Giovanni Addolorata, Fisica Sanitaria, Roma, Italy

<sup>3</sup>Complesso Ospedaliero San Giovanni Addolorata, Oncologia Medica, Roma, Italy

#### Purpose or Objective

New technologies, as IMRT, VMAT and Helical Tomotherapy (HT) is one of the most emerging aspect of radiation therapy, especially regarding brain tumors management; glioblastoma (GBM), for its radio-resistance and high rate of local recurrence, is a challenging field of application of new technologies. In this retrospective study we evaluated the impact of altered fractionation, administered with HT, associated with temozolomide (TMZ) in the treatment of GBM.

#### Material and Methods

From 2010 to 2014, 23 patients with primary diagnosis of GBM were treated at our Institution. Median age was 57 (range 26-75) and all patients had histologically proven diagnosis of GBM; 15 patients (65%) had a radiological proven residual disease after surgery. Bio-molecular markers profiling was not routinely analyzed; molecular genetic profile, using FISH test, was assessed in 11 (48%) of the 23 patients; evaluation of MGMT promoter was performed in 10 patients: 7 presented an unmethylated profile, and 3 a methylated status. In 6 patients mutations of IDH1 were tested and only in 2 patients they are present. Considering extent of the disease and its location, patients were treated with two different radiation therapy schedules. In 16 patients (70%) two different volumes were identified: PTV1, encompassing surgical bed and/or residual disease (GTV1) with a margin of 0.5 cm, treated with a total dose of 59.8 Gy in 23 fractions of 2.6 Gy, and PTV2, obtained expanding the PTV1 of 1 cm all around, treated with a total dose of 46 Gy in 23 fractions of 2 Gy (Simultaneous Integrated Boost SIB technique). In the remaining 7 patients (30%) it was possible treated a single volume (PTV1) with a total dose of 59.8 Gy in 23 fractions of 2.6 Gy. According to the EORTC regimen, concomitant daily TMZ dose of 75 mg/mg was administered for the entire period of radiation therapy followed by adjuvant schedule at a dose of 150-200 mg/mq daily for 5 consecutive days every 4 weeks.

#### Results

All patients completed the combined therapy without grade  $\geq 3$  acute toxicity. Complete blood count every 2 weeks, and contrast-enhancement brain MR every 3 months were performed during follow up. At the time of the present study, 12 patients (52%) were died, 2 patients (9%) had disease progression, two patients (9%) had a radiological evidence of stable disease (SD) and 7 (30%) were free from disease. The average follow-up was 12 months (range 2-46) and median overall survival (OS) was 12 months with a progression free survival (PFS) average time of 7.6 months.

#### Conclusion

Our results, in terms of OS and PFS, are similar to the literature ones; but it is remarkable that about 65% of patients had a subtotal resection and therefore a poor prognosis and poor expected outcome as well documented in large previous studies. Altered fractionation that we used achieved similar results of standard schedule of treatment of 60 Gy in 30 fractions, without increasing acute and late toxicity, and reducing total time of about 25%.

#### EP-1114 A prospective multicenter feasibility trial of Spine Stereotactic Body Radiation Therapy

T. Hiroshi<sup>1</sup>, T. Furuya<sup>1</sup>, K. Nihei<sup>1</sup>, Y. Kumazaki<sup>2</sup>, K. Miyaura<sup>2</sup>, H. Mayahara<sup>3</sup>, H. Nishimura<sup>3</sup>, M. Nakayama<sup>3</sup>, Y. Nomto<sup>4</sup>, N. Shikama<sup>2</sup>, K. Karasawa<sup>1</sup>

<sup>1</sup>Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Radiation Oncology, Tokyo, Japan

<sup>2</sup>Saitama Medical University International Medical Center, Radiation Oncology, Hidaka, Japan

<sup>3</sup>Kobe Minimally Invasive Cancer Center, Radiation Oncology, Kobe, Japan

<sup>4</sup>Mie University Hospital, Radiation Oncology, Tsu, Japan

#### Purpose or Objective

Spine Stereotactic Body Radiotherapy (Spine SBRT) is rapidly being accepted in the clinic especially in North America without high quality evidence. In Japan, this treatment, however, has not been accepted widely. Since several toxicities such as 10% to 39% of vertebral compression fractures (VCF), high-grade toxicity of esophagus and radiation myelopathy have been reported, we decide to perform a small multi-center feasibility trial to validate the safety and feasibility of Spine SBRT to accept it in our clinic.

#### Material and Methods

In this prospective multi-center single arm trial, patients from 3 centers in Japan were allocated to receive Spine SBRT to their one or two continuous vertebral bone metastases. Patients were eligible if ECOG performance status 0, 1 or 2, group 1 or 2 in Recursive Partitioning Analysis (RPA) Index, stable in Spinal Instability Neoplastic Score, grade I or II in Bilsky grade and aged 20 to 75 years. Rate of treatment related grade 3 or worse toxicities during 6 months after treatment was the primary endpoint and toxicities were evaluated with Common Terminology Criteria for Adverse Events version 4.0 by intent-to-treat until patients' death or at least 6 months. Severity of pain was scored 0 to 10 on the Brief Pain Inventory (BPI) before and after treatment. Amounts of opioid analgesic intakes were also recorded before and after treatment. Pain response was evaluated according to Inter national consensus on palliative radiotherapy endpoints. This study is registered with University hospital Medical Information Network, number UMIN000013428.

#### Results

Between March 2014 to October 2015, 20 patients are assigned to this trial with median follow up of 330 days. The locations of bone metastases were follows; cervical vertebra 2 patients (10%), thoracic vertebra 7 patients (35%), lumbar vertebra 10 patients (50%), sacrum vertebra 1 patients (5%). Patient's reported pain scores before treatment were follows; Median over all survival time from treatment was 330 days (ranged 35-736). Twelve patients were group 1 and eight patients were group 2 in RPA index. No treatment related grade 3 or worse toxicity was observed entire the trial (0%). Rate of grade 1 or 2 toxicities were follows; grade 1 esophagitis 15%, grade 1 dermatitis 10%, grade 1 mucositis 5%, grade 1 pain flair 5% and grade 1 dizziness 5%. Pain response rate 1 month after treatment and 6 months after treatment was as follows, respectively: Complete Response (CR) 15% and 12%, Partial Response (PR) 5% and 0%, Indeterminate Response (IR) 65% and 82%, and Pain progression (PP) 15% and 5% (Figure). Grade 2 VCF was observed in 1 patient (5%) entire this trial.

#### Conclusion

No grade 3 or worse toxicities were observed. This study validated the safety and feasibility of Spine SBRT.

#### EP-1115 Linac vs viewray in brain metastases: a dosimetric comparison of hypofractionated IMRT and VMAT

F. Cellini<sup>1</sup>, M. Ferro<sup>1</sup>, E. Placidi<sup>2</sup>, S. Chiesa<sup>3</sup>, B. Diletto<sup>1</sup>, M. Massaccesi<sup>1</sup>, C. Votta<sup>4</sup>, C. Masciocchi<sup>5</sup>, V. Frascino<sup>1</sup>, G.C. Mattiucci<sup>6</sup>, L. Azario<sup>7</sup>, V. Valentini<sup>6</sup>, M. Balducci<sup>6</sup>  
<sup>1</sup>Fondazione Policlinico A. Gemelli, Gemelli ART - Radiation Oncology, Rome, Italy

<sup>2</sup>Fondazione Policlinico A. Gemelli, UOC Fisica Sanitaria - Gemelli ART - Radiation Oncology, Rome, Italy

<sup>3</sup>Fondazione Policlinico A. Gemelli, Rome, Italy

<sup>4</sup>Fondazione Policlinico A. Gemelli, TSRM - Gemelli ART - Radiation Oncology, Rome, Italy

<sup>5</sup>Fondazione Policlinico A. Gemelli, KBO Labs - Gemelli ART - Radiation Oncology, Rome, Italy

<sup>6</sup>Università Cattolica del Sacro Cuore, Gemelli ART - Radiation Oncology, Rome, Italy

<sup>7</sup>Università Cattolica del Sacro Cuore, Rome, Italy

#### Purpose or Objective

To evaluate the feasibility of planning hypofractionated intensity-modulated radiotherapy (IMRT) for brain metastases (BM) with a tri-cobalt-60 (tri-60Co) system equipped with real-time magnetic resonance imaging (MRI) guidance, as compared to linear accelerator (LINAC) based IMRT and Volumetric Modulated Arc Therapy (VMAT).

#### Material and Methods

Patients treated with LINAC-based IMRT and VMAT were replanned using a tri-60Co system. Radiotherapy plans were structured with a mono-isocentric IMRT technique using 21 beams. Dose prescription followed ICRU 83 indications; 25.5 Gy in 3 fractions. Both LINAC and ViewRay plans were considered acceptable when median absorbed dose of Planning Target Volume (PTV), D50%, was equal to prescription dose, D98% was  $\geq 95\%$ , and D2% to optic chiasm and optic nerves, brainstem and normal brain were  $<19.5\text{Gy}$ ,  $<23\text{Gy}$  and  $<21\text{Gy}$ , respectively. D50% of normal brain and to hippocampus were set as low as possible. The plans were evaluated for target volume (TV) coverage, Paddick dose conformity (CI), homogeneity (HI), dose to organ at risk (OAR) and to normal brain. Plan comparisons were performed.

#### Results

In all, 16 brain metastases were evaluated. The median PTV was 4.0 cc (range 1.7-13.6cc). Slightly higher median value of HI and lower median value of PCI were observed when tri-60Co was compared to LINAC plans (0.07 vs 0.03;  $p=0.59$  and 0.50 vs 0.54;  $p=0.73$ ).

For the OAR, no statistically significant differences were registered in D2% of brainstem, optic chiasm, optic nerves, hippocampus and normal brain even if higher doses were noted in tri-60Co vs LINAC plans (1.04 Gy vs 0.26 Gy,  $p=0.6$ ; 0.58 Gy vs 0.18 Gy,  $p=0.58$ ; 0.54 Gy vs 0.12 Gy,  $p=0.56$ ; 1.66 Gy vs 0.41 Gy,  $p=0.64$ ; 17.37 Gy vs 11.73 Gy,  $p=0.61$ ; respectively). Similarly, D50% and V21Gy of normal brain were higher in tri-60Co plans (3.17 Gy vs 0.18 Gy,  $p=0.62$  and 14.20cc vs 6.15cc,  $p=0.57$ ).

There were statistically significant differences in V100% between tri-60Co and VMAT plans (2.01cc vs 1.67cc,  $p=0.005$ ) whilst non statistical significant difference was observed between tri-60Co and LINAC-based IMRT plans (2.01 cc vs 1.72 cc,  $p=0.56$ ).

V50% was marginally statistically lower in LINAC than in tri-60Co plans (30.79 cc vs 90.05 cc,  $p=0.49$ ).

#### Conclusion

All ViewRay plans were deemed acceptable for clinical delivery. It should be noted that every dose-volume criteria studied in this article was lower in the LINAC plans than in the tri-60Co SBRT plans, with statistical significance noted only for the 100%- and 50%-isodose volume without a statistically significant impact on OAR or TV coverage. The MRI may afford the opportunity to both reduce PTV margins and improve critical organ sparing, so a new study about LINAC and tri-60Co with reduced PTV margins is ongoing.

#### EP-1116 Reirradiation and concurrent bevacizumab high-grade recurrent gliomas: experience and perspectives.

A. Schernberg<sup>1</sup>, F. Dhermain<sup>1</sup>, S. Dumont<sup>2</sup>, A. Patrikidou<sup>2</sup>, J. Domont<sup>2</sup>, J. Pallud<sup>2</sup>, E. Deutsch<sup>1</sup>, G. Louvel<sup>1</sup>

<sup>1</sup>Gustave Roussy, Radiotherapy, Villejuif, France

<sup>2</sup>Gustave Roussy, Oncology, Villejuif, France

<sup>3</sup>Saint Anne, Neurosurgery, Paris, France

#### Purpose or Objective

Analyze feasibility and prognostic factors of concurrent re-irradiation and bevacizumab (BVZ) for recurrent high-grade gliomas.

#### Material and Methods

Between 2009 and 2015, 35 patients (median age 57 years, 21 men and 14 women) with WHO grade-3 (n=11) or grade-4 gliomas (n=24) were included in this retrospective single-center study. All patients received BVZ (median number of treatments = 12) concomitant with re-irradiation (median dose = 45Gy, median number of fractions = 18) experiencing recurrence after a first irradiation (median = 22 months, median dose = 60Gy).

#### Results

Median follow-up was 9.2 months. Median overall survival (OS) was 10.5 months (95%CI: 4.9 - 16.1) and progression-free survival 6.7 months (95%CI: 2.9 - 10.5) from re-irradiation. Median OS from initial diagnosis was 44.6 months (95% CI 32 to 57.1). No grade  $\geq 3$  toxicities were reported. Prognostic factors in univariate analysis significantly correlated with better OS were: age  $\leq 55$  ( $p=0.024$ ), initial surgery ( $p=0.003$ ), and equivalent 2Gy dose (EQD2)  $\geq 50$  Gy at reirradiation ( $p=0.046$ ). Naïve BVZ patients at time of re-irradiation had significantly increased OS from reirradiation compared to patients treated with re-irradiation after BVZ failure (15.1 vs. 5.4 months,  $p<0.001$ ) as well as OS from initial diagnosis (58.9 vs. 33.5 months,  $p=0.006$ ). This outcome was similar in patients with initial glioblastomas ( $p=0.018$ ) or anaplastic gliomas ( $p=0.021$ ). There was no correlation between OS and GTV or PTV volume, frontal localization, or number of salvage therapies before reirradiation ( $p=0.05$ ).

#### Conclusion

Concomitant re-irradiation with BVZ in high grade recurrent gliomas shows encouraging results in terms of survival and toxicities. Our data suggests that re-irradiation should be favored at initiation of BVZ, with  $\geq 50\text{Gy}$  EQD2.

#### EP-1117 Sequential Proton Boost after Standard Chemoradiation for High-Grade Glioma

S. Adeberg<sup>1</sup>, D. Bernhardt<sup>1</sup>, S. Harrabi<sup>1</sup>, M. Uhl<sup>1</sup>, A. Paul<sup>1</sup>, N. Bougatf<sup>1</sup>, V. Verma<sup>2</sup>, T. Haberer<sup>3</sup>, S. Combs<sup>4</sup>, K. Herfarth<sup>1</sup>, J. Debus<sup>1</sup>, S. Rieken<sup>1</sup>

<sup>1</sup>University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

<sup>2</sup>University of Nebraska Medical Center, Department of Radiation Oncology, Omaha, USA

<sup>3</sup>Heidelberg Ion-Beam Therapy Center HIT, Heidelberg, Germany

<sup>4</sup>Technische Universität München, Department of Radiation Oncology, Munich, Germany

#### Purpose or Objective

To retrospectively assess the feasibility and safety of a sequential proton boost following conventional chemoradiation in high-grade glioma (HGG).

#### Material and Methods

Sixty-six consecutive patients with HGG were treated at the Department of Radiation Oncology, University Hospital Heidelberg, Germany with 50.0 Gy photons (range: 50.0 - 50.4 Gy) in 2.0 Gy (range: 1.8 - 2.0 Gy) fractions (median

PTV volume: 394.6ccm), followed by a proton boost with 10 Gy equivalent (Gy(RBE)) in 2.0 Gy(RBE) fractions (median PTV volume: 134.7ccm). The target volume definition for the proton boost volume was initially defined by the prospective CLEOPATRA protocol (GTV + 5mm) and transferred into clinical routine. Patients were matched one to one with 66 patients with HGG undergoing conventional radiation therapy (RT) with 60.0 Gy photons (range: 59.4 - 60.0 Gy) in 2.0 Gy fractions (range: 1.8 - 2.0 Gy)(median PTV volume: 369.4ccm). Matching criteria were age, WHO grade, Karnofsky performance status, PTV size, temozolomide therapy (each  $p > 0.1$ ). The majority of all patients in both groups received concomitant and adjuvant temozolomide. The study assessed overall survival (OS) using the log-rank test, treatment-related toxicity using the CTCAE classification (version 4.03) and pseudoprogression according to the Response Assessment in Neuro-Oncology (RANO) criteria for the complete study cohort (n = 132).

#### Results

Median overall survival was similar in both treatment groups (bimodality RT, 19.1 months [4 to 41 months]; photon-only RT, 20.4 months [3 to 53 months];  $p = 0.306$ ). The median PTV volume of the proton boost was significantly smaller compared to the median PTV volume of the photon plans (each  $p < 0.001$ ). Acute toxicity was mild in both treatment groups. Toxicity  $\geq$  grade II was observed in 6 patients (9.1%) receiving bimodality RT and 9 patients (13.6%) receiving photon-only RT. Two types of severe adverse events (CTCAE grade III) occurred solely in the photon-only group: severe increase in intracranial pressure (3 cases; 4.5%); and generalized seizures (2 cases; 3.0%). Median PTV of these patients was 384.4ccm. The intensity of all symptoms decreased after corticosteroid therapy or anticonvulsant therapy. Pseudoprogression was rare, occurring on average 6 weeks after radiotherapy, and was balanced in both treatment groups (n = 4 each; 7.6%).

#### Conclusion

Using a sequential proton boost in HGG is safe and feasible. Delivering a proton boost to significantly smaller target volumes when compared to photon-only plans, yielded comparable survival rates at lower CTCAE  $\geq$  III toxicity rates. Pseudoprogression occurred rarely and evenly distributed in both treatment groups. Thus, bimodality RT was at least equivalent regarding outcome and potentially superior with respect to toxicity in patients with HGG.

#### EP-1118 Radiotherapy-related endocrine dysfunction in patients treated for craniopharyngioma

N. Taku<sup>1,2</sup>, A. Powlson<sup>3</sup>, M. Gurnell<sup>3</sup>, N. Burnet<sup>1</sup>

<sup>1</sup>University of Cambridge Department of Oncology, Addenbrooke's Hospital, Cambridge, United Kingdom

<sup>2</sup>Perelman School of Medicine, University of Pennsylvania, Philadelphia, USA

<sup>3</sup>Metabolic Research Laboratories- Wellcome Trust-MRC Institute of Metabolic Science- University of Cambridge and National Institute for Health Research Cambridge Biomedical Research Centre, Addenbrooke's Hospital, Cambridge, United Kingdom

#### Purpose or Objective

Craniopharyngioma is a rare, histopathologically benign intracranial tumor originating in the sellar region. Neurosurgery (NS) remains the primary management strategy. However, radiotherapy (RT) is an important adjuvant and salvage treatment. The probability of improved disease control with RT must always be weighed against the risk of RT-related morbidity, including damage to the hypothalamic-pituitary axis (HPA). Many patients will require lifelong treatment with hormone replacement therapies (HRTs).

Thus, the objective of minimizing RT-related HPA dysfunction is primarily to reduce the number of required HRTs. The current study evaluates a historical cohort of adult patients treated with NS and RT for craniopharyngioma and seeks to examine the development of RT-related endocrine dysfunction using HRT as a proxy for clinical hypopituitarism.

#### Material and Methods

The clinical records of 20 adult patients diagnosed with pathologically-confirmed craniopharyngioma and treated with both NS and RT at Addenbrooke's Hospital (Cambridge, United Kingdom) from 2001 to 2013 were reviewed. All patients received either subtotal or gross total neurosurgical resection of their craniopharyngioma. Post-operative RT was 50 Gy in 30 fractions, in either the adjuvant or salvage setting. Patients were assessed for evidence of HPA dysfunction throughout the course of diagnosis, treatment, and follow-up. Those found to have hypopituitarism were prescribed estradiol (women), testosterone (men), hydrocortisone, thyroxine, growth hormone (GH), or desmopressin in accordance with the deficient axis, and as clinically indicated. Clinical records were reviewed for HRT both before and after radiotherapy.

#### Results

Patients included 10 males and 10 females with a median age at diagnosis of 44 years (range, 18-76 years). The mean and median lengths of endocrine follow-up were 5.2 and 5.0 years, respectively (range, 0.5 - 9.6 years). Pre-RT HRT data were available for 15 of the 20 patients. Unlike other hormone axes, testing for GH deficiency was not routinely performed prior to the delivery of RT. When hormone supplementation excluding GH was considered, all but one patient were taking some form of HRT prior to RT. Before RT 53% of patients were receiving at least 3 HRT medications, compared to 73% of patients after RT (Figure 1). The post-RT increase in the mean and median HRT for all patients were 0.7 and 1 additional medications, respectively (Figure 2). Eight patients (53%) required no change in HRT following RT, and only 2 patients required an increase of more than 1 HRT from pre- to post-RT treatment.

#### Conclusion

While radiotherapy may cause or exacerbate HPA dysfunction, the actual requirement for additional hormone replacement therapies in routine clinical practice appears to be relatively modest, especially in those patients with pre-existing hormone deficits. Accordingly, the probability of increased tumor control with adjuvant or salvage radiotherapy outweighs the risk of increased HPA morbidity.

#### EP-1119 Radiosurgery for meningioma: Evaluation of radiological outcome and factors of recurrence

S. Hassas yeganeh<sup>1</sup>, M. Tabatabaiefar<sup>1</sup>, R. Sarghampour<sup>1</sup>  
<sup>1</sup>Imam Hussain Hospital-, clinical oncology, tehran, Iran Islamic Republic of

#### Purpose or Objective

Meningioma is one of the most common benign brain tumors with various clinical manifestations. Since the most common prevalence age of meningioma is forth to fifth decades which are the active population, the attention to optimal treatment and contributing factors for recurrence would result in health improvement by reduction in mortality. In this study the therapeutic outcomes and contributing factors for recurrence were evaluated among patients with treated meningioma by radiosurgery.

#### Material and Methods

In this retrospective study 1082 consecutive meningioma patients treated in Gamma-Knife Center since 2003 to 2011 were enrolled and the required data were collected

form existing medical documents including the therapeutic outcomes.

#### Results

Totally 1082 cases including 1164 lesions were included. The mean age was 52 years (7 to 88 years). 293 patients (27.1%) were male and 789 subjects (72.9%) were female. The mean follow-up time was 39.4 ± 24.9 months. In 403 cases, the follow-up was not complete and in remaining cases, the size of lesion was reduced in 338 lesions (44%), not changed in 377 cases (49%), and was increased in 46 lesions (7%). Hence, totally 93% of cases were controlled by treatment. Also 80 patients (6.8%) had recurrence.

#### Conclusion

Totally according to the obtained results it may be concluded that Gamma-knife surgery is effective in more than ninety percent of cases with cranial meningioma leading to low recurrence rate. However further studies should be carried out to determine the other contributing factors for recurrence and also comparison of the results of Gamma-knife therapy with other conventional methods.

#### EP-1120 Fractionated stereotactic radiotherapy in adult craniopharyngiomas : outcomes and complications

R. Benlloch Rodríguez<sup>1</sup>, R. Magallón Sebastián<sup>1</sup>, D. Rincón Cruz<sup>1</sup>, M.I. García Berrocal<sup>1</sup>, P. Ruiz García<sup>2</sup>, J. Romero Fernández<sup>1</sup>, I. Zapata Paz<sup>1</sup>, M.J. Expósito Casas<sup>1</sup>, B. Vaquero Barrón<sup>1</sup>, A. De la Torre Tomas<sup>1</sup>

<sup>1</sup>Hospital Universitario Puerta de Hierro, Radiation Oncology, Majadahonda - Madrid, Spain

<sup>2</sup>Hospital Universitario Puerta de Hierro, Radiology, Majadahonda - Madrid, Spain

#### Purpose or Objective

To evaluate treatment-related complications and long term outcomes in adult craniopharyngioma patients treated with surgery and Fractionated Stereotactic Radiotherapy (FSRT).

#### Material and Methods

Between 2002 and 2015, 30 patients (p.) with histologic diagnosis of craniopharyngioma were treated with FSRT. Median age: 42 years; Sex: 17 males, 13 females. FSRT was indicated for progressive disease after surgery or postoperatively after partial resection. FSRT was delivered to a median dose of 50.4Gy (1.8Gy/fraction).

To evaluate tumour and treatment-related complications and quality of life, "Craniopharyngioma Clinical Status Scale" and "Functional Classification scale" were used. These questionnaires were completed before and after surgery and after FSRT. Median follow-up was 87 months. Follow-up included neurologic, ophthalmologic, endocrinology evaluations and MRI every 3 to 6 months. Statistics: Kaplan-Meier method and long-rank test.

#### Results

Five and 10-year actuarial local control and overall survival were 97% and 89% and 89% and 80% respectively. Seven patients presented enlargement of cystic component and 2 required drainage. Two patients died due to tumour progression.

At initial diagnosis, 69% had visual field loss or decreased of visual acuity and 6% presented others neurological deficits Eight p. (27%) and 4 p. (13%) had partial or complete endocrinopathy, respectively; and hypothalamic function was deteriorated in 9 p. (31%). All p. presented good cognitive status at initial presentation.

After surgery patients suffered a significant impairment of their neurologic ( $p=0.004$ ), endocrinologic ( $p<0,0001$ ) and hypothalamic ( $p=0.004$ ) functions. Visual status worsened in 9 p. (31%), 5 of whom presented severe deficit or complete blindness. Other neurologic deficits were seen in 6 p. (20%). Twenty p. (68%) had panhypopituitarism and diabetes insipidus and 10 p. (34%) presented severe

hypothalamic dysfunction. Cognitive function worsened in 6 p.

No patient presented decrease of vision or hypothalamic dysfunction after FSRT and only 1(3%) had neurologic and endocrinologic deficits. Cognitive status worsened in 1 p. after FSRT.

Improvement of visual, neurologic and hypothalamic deficits were observed in 6 p. (20%), 3 p. (10%) and 6 p. (20%) respectively after FSRT.

A total of 8 p. (27%) presented some grade of loss of independence in activities of daily living after both surgery and FSRT.

#### Conclusion

A high incidence of treatment-related side effects is reported mainly after surgery. Neurologic, endocrinologic and hypothalamic impairments after surgery were statistically significant compared with initial presentation. In our series FSRT is effective, well tolerated and in some cases even improves deficits.

Further studies are needed to establish if a less aggressive surgery combined with postoperative FSRT provides same tumor control while diminishes complications.

#### EP-1121 Newly diagnoses grade III glioma patients: evaluation of factors conditioning outcome.

P. Navarra<sup>1</sup>, F. Pessina<sup>2</sup>, S. Tomatis<sup>1</sup>, L. Cozzi<sup>1</sup>, G.R. D'Agostino<sup>1</sup>, A.M. Ascolese<sup>1</sup>, M. Simonelli<sup>3</sup>, A. Santoro<sup>3</sup>, E. Clerici<sup>1</sup>, C. Franzese<sup>1</sup>, L. Bello<sup>2</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

<sup>2</sup>Istituto Clinico Humanitas, Neurosurgery Oncology Department, Rozzano Milan, Italy

<sup>3</sup>Istituto Clinico Humanitas, Oncology and Hematology Department, Rozzano Milan, Italy

#### Purpose or Objective

Current treatments in WHO grade III gliomas include surgery, radiation therapy (RT) and chemotherapy (CHT), but so far a standard of care is still lacking. The aim of this study was to analyze the outcome of patients with newly diagnosed WHO grade III gliomas treated with a multimodal approach. The adjuvant treatment, after surgery, has been chosen in relation to extent of resection (EOR), histological subtype and molecular profile.

#### Material and Methods

The present retrospective study includes patients with newly diagnosed WHO grade III gliomas treated at our institution. All patients underwent surgery followed by adjuvant treatment, chemotherapy only or radiation therapy with concurrent and adjuvant chemotherapy (TMZ) in relation to the extent of surgical resection (EOR), histological subtype, and molecular profile. Patients with oligodendroglial features (anaplastic oligodendroglioma or anaplastic oligodendroglioma), complete resection (CR), 1p/19q codeletion, IDH1 mutated, and MGMT methylated status underwent adjuvant chemotherapy alone; all the others underwent to concomitant and adjuvant CHT. CHT consisted of TMZ. The total RT dose prescribed was 60 Gy in 30 fractions. Clinical outcome was evaluated by neurological examination and brain MRI performed, one month after RT and then every 3 months. Response was recorded using the Response Assessment in Neuro-Oncology (RANO) criteria. The tumor progression was described as local, if it occurred in/or within 2 cm from primary site, and distant for new and non-contiguous enhancing or non-enhancing lesions. Hematologic and non-hematologic toxicities were graded according to Common Terminology Criteria for Adverse Events version 4.0.

#### Results

From January 2008 to May 2014, 123 consecutive patients were treated. Thirty-three (26.8%) patients had diagnosed of anaplastic astrocytoma, 36 (29.3%) patients anaplastic

oligoastrocytoma and 54 (43.9%) anaplastic oligodendroglioma. Fifty-one (41.5%) underwent surgery plus adjuvant chemotherapy and 72 (58.5%) surgery plus concomitant and adjuvant chemo-radiotherapy. The median, 1-2-3- and 5-year PFS was 27 months, 85.4%, 65.5%, 21.2% and 21.2% respectively and the 1-2-3- and 5-year OS was 97.65%, 89.7%, 83.0%, and 58.4%, respectively. On univariate and multivariate analysis the EOR, IDH1 mutation and 1p19q codeletion influenced PFS while KPS, histological subtype, and IDH1 mutation influenced OS.

#### Conclusion

The presence of oligodendroglial features and IDH 1 mutation in patients underwent complete surgical resection allowed to identify a subgroup with better outcome in which radiation therapy can be delayed at disease progression.

#### EP-1122 TSPO PET imaging RT treatment planning in malignant glioma

D.F. Fleischmann<sup>1,3</sup>, N.L. Albert<sup>2</sup>, M. Unterrainer<sup>2</sup>, P. Bartenstein<sup>2</sup>, C. Belka<sup>1,3</sup>, M. Niyazi<sup>1,3</sup>

<sup>1</sup>LMU Munich, Radiation Oncology, Munich, Germany

<sup>2</sup>LMU Munich, Nuclear Medicine, Munich, Germany

<sup>3</sup>German Cancer Consortium (DKTK) German Cancer Research Center (DKFZ) Heidelberg, Germany,

#### Purpose or Objective

TSPO PET imaging has been recently hypothesized to accurately display biologically active tumor in high-grade glioma patients and is of major interest for radiotherapy (RT) treatment planning. Biological tumor volumes (BTVs) with different thresholds were analyzed retrospectively for their concordance with MRI-based gross tumor volumes (GTVs).

#### Material and Methods

TSPO PET images of 12 patients were retrospectively analyzed. Eleven GBM patients and one patient with anaplastic astrocytoma (IDH wt) were included into the analyses. Five patients underwent primary definitive radiochemotherapy (RCx) with temozolomide, three patients hypofractionated RT and four patients re-irradiation at HGG recurrence. Median dose was 2 to 60 Gy for primary RCx, 2.67 to 40.05 Gy for hypofractionated RT and 2.4/2 Gy to 43.2/36 Gy (three patients) with SIB or 2 to 36 Gy (one patient due to a very large recurrence) at re-irradiation with concomitant bevacizumab.

#### Results

Different BTV thresholds were tested, BTV1.6, BTV1.8 or BTV2.0. As per definition, BTV1.6 was largest (86.5 cc > 72.3 cc > 59.3 cc). Median PTV volume was 341.8 cc (primary RCx) or 82.2 cc (PTV36) and 34.9 cc (PTV43.2). The Sorensen-DICE coefficient of BTVs vs. GTV (solely MRI-based) was 0.48 (BTV1.6), 0.54 (BTV1.8) or 0.58 (BTV2.0). Volumetric comparisons revealed significantly larger BTVs in comparison to the median GTV volume of 29.4 cc (respectively p=0.002/0.003/0.008, paired Wilcoxon tests). It was tested whether the BTV volume was included within the PTV (60 Gy) or PTV36/43.2. For this purpose, the amount of BTV included within the PTV was calculated as  $(BTV \cap PTV) / BTV$ . For a threshold of 1.6, the amount was median 0.99 in primary GBM and median 0.70 for PTV36 (four patients) and 0.43 for PTV43.2 (three patients). At a threshold of 1.8, the corresponding values were 0.996, 0.80 and 0.60, and at a threshold of 2.0, the values were 0.997, 0.88 and 0.71.

#### Conclusion

TSPO PET imaging seems to be a very interesting approach for GBM delineation at primary RT and re-RT. GTV and BTV concordance was poor, but almost the whole BTV content was included within the primary PTV (60 Gy). TSPO might have a high relevance for re-irradiation as margins are far tighter than for primary GBM (8 mm added to the GTV for

PTV36, 3 mm for the PTV43.2 as SIB). Future studies on recurrence patterns are warranted to analyze the initial tumor coverage of the boost volume.

#### EP-1123 To contour or not contour hippocampus in stereotactic brain radiotherapy? A dosimetric study.

C. Di Carlo<sup>1</sup>, S. Di Biase<sup>1</sup>, L. Caravatta<sup>1</sup>, G. Caponigro<sup>1</sup>, C. Rosa<sup>1</sup>, M. Di Biase<sup>1</sup>, F. Perrotti<sup>1</sup>, M. Trignani<sup>1</sup>, A. Vinciguerra<sup>1</sup>, A. Augurio<sup>1</sup>, S. Giancaterino<sup>1</sup>, A. De Nicola<sup>1</sup>, M.D. Falco<sup>1</sup>, D. Genovesi<sup>1</sup>

<sup>1</sup>Ospedale Clinicizzato S.S. Annunziata, Radiotherapy, Chieti, Italy

#### Purpose or Objective

To evaluate hippocampal irradiation in patients treated with fractionated stereotactic brain radiotherapy (FSRT).

#### Material and Methods

We performed a dosimetric analysis on 22 patients with 1-4 brain metastases treated with 24 Gy/3 fractions or 20 Gy/4 fractions using volumetric intensity-modulated arc therapy (VMAT). Original plans did not include hippocampus as a structure to avoid in optimization criteria. All cases were then retrospectively replanned for the VMAT planning hippocampus-spared study. Hippocampus was delineated on diagnostic T1-weighted Magnetic Resonance images (MRI) co-registered with planning computed tomography (CT) images. A planning risk volume (PRV) for hippocampus sparing was generated adding an isotropic 5 mm margin. Hippocampus was defined both as a single (Hu) and as pair organ (Hdx, Hsn). Delineation was performed using RTOG atlas as reference than revised by neuroradiologist. Assuming an  $\alpha/\beta$  ratio of 2 Gy, biologically equivalent dose in 2 Gy fractions (EQD2) was calculated. Constraints analyzed were: Dmax<16 Gy, D40%<7.3 Gy, D100%=Dmin<9 Gy. In addition, neurological status (NS) was investigated at baseline and during follow-up and memory or other neurologic deficit were evaluated by CTACE 4.0 scale.

#### Results

Among constraints analyzed, Dmax and D40% have been exceeded in 10/22 cases (20 Gy in 6 cases, 24 Gy in 4), whereas D100% was respected in all cases. Hu Dmax ranged between 17-58.9 Gy, with a mean of 31.1 Gy. D40% ranged between 8.9-13.7 Gy and mean D40% was 11.4 Gy. PRV Hu showed a mean Dmax of 33.2 Gy (range 21.5-60.5 Gy) and a mean D40% of 10.8 Gy (7.7-13.7 Gy). When considered as pair organ, Hdx and Hsn respectively, mean Dmax was 33.2 Gy (range 17-58.9 Gy) and 18.4 Gy (range 16.5-20.9 Gy), while mean D40% was 17.5 Gy (7.6-44.2 Gy) and 10.7 Gy (range 8.2-14.3 Gy). PRV Hdx received a mean Dmax of 35.5 Gy (range 23.4-60.5 Gy) and mean D40% was 15.9 Gy (7.5-36.4 Gy); PRV Hsn received a mean Dmax of 22.6 Gy (range 16-28.7 Gy) and a mean D40% of 9.9 Gy (8.7-12.4 Gy). At 3-months follow-up, at least, 14/22 patients were clinically evaluable; NS was investigated in 9/14 patients while missed in 5/14. Neurological deficits occurred in 4/9 patients and 3 of these presented Dmax and D40% exceeding limit.

#### Conclusion

Our data showed that hippocampus might be often over-irradiated if not considered in the optimization of the treatment plan in brain FSRT. Hippocampal delineation should be performed especially in case of good life expectation where its saving could be reasonable avoiding relevant damage.

#### EP-1124 PET-MRI prior to re-irradiation of high-grade glioma patients - a planning study

D.F. Fleischmann<sup>1,3</sup>, M. Unterrainer<sup>2</sup>, S. Corradini<sup>1</sup>, M. Rottler<sup>1</sup>, P. Bartenstein<sup>2</sup>, C. Belka<sup>1,3</sup>, N.L. Albert<sup>2</sup>, M. Niyazi<sup>1,3</sup>

<sup>1</sup>LMU Munich, Radiation Oncology, Munich, Germany

<sup>2</sup>LMU Munich, Nuclear Medicine, Munich, Germany

<sup>3</sup>German Cancer Consortium (DKTK) German Cancer Research Center (DKFZ) Heidelberg, Germany,

#### Purpose or Objective

Imaging of positron emission tomography (PET) combined with MRI was conducted prior to re-irradiation for 7 high-grade glioma patients. MRI-based treatment planning of three independent raters was compared with biological tumor volumes (BTVs) automatically generated from PET-MRI data in this prospective phase I clinical trial (NCT01579253).

#### Material and Methods

MRI-based treatment plans for 7 high-grade glioma patients with PET-MR imaging preceding re-irradiation were created by three independent raters including all contrast-enhancing regions. Inter-rater reliability was evaluated by the intraclass correlation coefficient (ICC). BTVs with a threshold of 1.6 and a union of these BTVs with the consensus MRI-based GTVs were compared to the consensus GTVs only. OTP-Masterplan<sup>®</sup> was used for treatment planning. Dice coefficients and conformity indices were used for comparing the consensus GTVs and BTVs and for the union of consensus GTV plus BTV with the original planning target volume (PTV).

#### Results

PET-MR imaging conducted prior to re-irradiation of 7 high-grade glioma patients (2 WHO grade III, 5 WHO grade IV) was used for this planning study with three independent raters. Median follow-up from initial diagnosis was 52 months and median post-recurrence survival 13 months. Median age at the beginning of re-irradiation was 54 years and median KPS 80. Median post-recurrence progression-free survival from the beginning of re-irradiation was 8 months. Six patients received bevacizumab concomitantly to re-irradiation and 1 patient temozolomide. Median GTV volume ranged from 35 to 40.5 cc, median consensus GTV volume of all three raters was 41.8 cc, median BTV 36.6 cc and the union of consensus GTV and BTV in median 59.3 cc. The ICC between the raters was on average measures 0.96, 0.96 and 0.97. The dice coefficient between the consensus GTV and the BTV was in median 0.61 and the conformity index 0.44. The dice coefficient between the union of consensus GTV and BTV with a margin of 8 mm and the original PTV was median 0.84 and the conformity index in median 0.73.

#### Conclusion

PET-MRI derived BTVs may help to adjust the margin at treatment planning of recurrent high-grade glioma re-irradiation and reduce inter-rater variability. The most prominent advantage of this imaging modality is the „one-stop-shop“ including two coregistered imaging modalities of high quality.

#### EP-1125 Concomitant temozolomide therapy improves survival outcome of patients with multifocal glioblastoma

M. Syed<sup>1</sup>, J. Liermann<sup>1</sup>, T. Sprave<sup>1</sup>, V. Verma<sup>2</sup>, J. Rieber<sup>1</sup>, S.B. Harrabi<sup>1</sup>, N. Bougatf<sup>3</sup>, D. Bernhardt<sup>1</sup>, A. Mohr<sup>1</sup>, S. Rieken<sup>1</sup>, J. Debus<sup>1</sup>, S. Adeberg<sup>1</sup>

<sup>1</sup>Universitätsklinik Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

<sup>2</sup>University of Nebraska Medical Center, Department of Radiation Oncology, Omaha, USA

<sup>3</sup>University Hospital Heidelberg, Heidelberg Ion-Beam Therapy Center HIT, Heidelberg, Germany

#### Purpose or Objective

Concomitant temozolomide (TMZ) therapy has been established as first line treatment of malignant gliomas after several studies had shown better survival outcomes. These studies have largely been performed with patients with unifocal lesions. Our study aims to investigate the role of temozolomide therapy in multifocal glioblastoma

(GBM) along with radiotherapy by comparing differences in survival rates of patients with unifocal GBM (uGBM) and multifocal GBM (mGBM).

#### Material and Methods

We retrospectively analyzed 265 patients with primary GBM undergoing radiation therapy at the Department of Radiation Oncology, Heidelberg University Hospital between 2004 and 2013. Of these, 202 (76%) were uGBMs and 63 (24%) were mGBMs. 133 (65%) with uGBM and 43 (68%) with mGBM received concomitant treatment with TMZ. First, progression-free survival (PFS) and overall survival (OS) between groups were compared using the Kaplan-Meier method. Second, univariate and multivariate Cox proportional hazards regression was applied to discern prognostic factors including TMZ with PFS and OS in the cohorts.

#### Results

Hundred ninety-five patients (73%) experienced tumor progression on follow-up MRI scans performed after radiation therapy. Patients with mGBM experienced significantly worse OS of 11.5 months (range 1.6 - 25 months) as compared to patients with uGBM with an OS of 14.8 months (range 1 - 55.9 months) ( $p=0.032$ ), with similar patient characteristics in both Groups. There were no significant differences in PFS between the respective groups (6.5 versus 6.6 months,  $p=0.750$ ).

Concomitant TMZ therapy was associated with significantly better OS in mGBM (8.3 vs 14.2 months,  $p=0.006$ ) and uGBM (11.7 vs 17.0 months,  $p<0.001$ ). Univariate and multivariate analyses for OS revealed a negative prognostic effect for multifocal disease ( $p<0.001$ ) and a positive prognostic effect for concomitant TMZ treatment in mGBM ( $p=0.008$ ) and uGBM ( $p<0.001$ ).

#### Conclusion

Patients with mGBM generally experienced significantly worse overall survival than patients with uGBM after radiation therapy. Concomitant TMZ treatment improved OS of patients with mGBM and uGBM by approximately five months.

#### EP-1126 Whole brain radiotherapy of breast cancer brain metastases: intracranial progression and prognosis.

D. Qu<sup>1</sup>, L. Cao<sup>1</sup>, C. Xu<sup>1</sup>, J. Chen<sup>1</sup>

<sup>1</sup>Ruijin Hospital- Shanghai Jiaotong University School of Medicine, Radiation Oncology, Shanghai, China

#### Purpose or Objective

Despite the increasing systemic treatment for breast cancer (BC), CNS metastases represent one of most aggressive conditions of metastatic disease. The prognosis became very diverse with regard to molecular subtypes of the primary disease. The current study aims to assess the survival benefit and pattern of intracranial progress of BC patients with brain metastasis (BM) after whole-brain radiotherapy (WBRT).

#### Material and Methods

A total of 79 consecutive BCBM, who were diagnosed and treated with WBRT between Jan 2010 and Mar 2016 were studied. All of them were diagnosed with primary invasive ductal carcinoma. Molecular subtypes were defined in 77 patients, as following: Luminal A-like (n=14), Luminal B-like (n=26), HER-2 positive non-luminal (n=13) and Triple Negative (TN) (n=24).

#### Results

The median patient age at the diagnosis of BM was 49 years (range 22-77 years) and the median KPS at BM was 80. The median time to BM (TTBM) was 36 months (range 0-232 months). Sixty-five patients received upfront WBRT and 14 received WBRT subsequent to SBRT. Systemic treatment were administered to 50 patients after WBRT, including endocrine therapy in 10 patients, chemotherapy in 42 patients, anti-HER2 therapy in 14 patients.

The time to BM in patients with HER-2 positive was shorter than Luminal-A like (20.5 vs. 89.0 months,  $p < 0.001$ ). Median overall survival (OS) after BM was significantly associated with Breast-GPA 0-1, 1.5-2, 2.5-3 and 3.5-4 were 4.3, 14.0, 14.8 and 18.2 months, respectively ( $p = 0.012$ , fig A). Univariate analysis found that KPS at the diagnosis of BM, infra-tentorial metastases, total doses and systemic therapy after WBRT were significantly associated with OS after BM ( $p < 0.05$ ). The multivariate analysis showed infra-tentorial metastases, total doses and systemic therapy after WBRT were independent prognostic factors for OS after BM ( $p < 0.05$ ). The median OS was significantly improved in HER-2 + patients receiving anti-HER2 therapy after WBRT (25.4 vs. 5.6 months,  $p = 0.040$ ). Also, the median OS was significantly improved in GPA 1.0-2.0 patients who received upfront WBRT (14 vs. 7.9 months,  $p = 0.012$ ). The proportion of occurrence of intracranial progress for hormone receptor (HR) negative patients was higher than HR positive (51.4 % vs. 27.5 %,  $p = 0.018$ ).

#### Conclusion

The breast cancer molecular subtype is an important prognostic factor in BCBM. The patients with infra-tentorial metastases, radiation dose of less than 40Gy or no systemic treatment after WBRT are associated with worse OS. Patients with HR negative disease were more likely to develop intracranial progress. Those with less favorable prognosis according to Breast-GPA may benefit from the upfront WBRT.

#### EP-1127 Dose to hippocampus in brain metastases radiosurgery: need for an hippocampal sparing approach

S. Scoccianti<sup>1</sup>, D. Greto<sup>1</sup>, S. Calusi<sup>2</sup>, L. Poggesi<sup>1</sup>, C. Arilli<sup>2</sup>, M. Casati<sup>2</sup>, A. Compagnucci<sup>2</sup>, C. Bono<sup>3</sup>, S. Pallotta<sup>2</sup>, L. Livi<sup>1</sup>

<sup>1</sup>Azienda Ospedaliera Universitaria Careggi, Radiotherapy Unit, Florence, Italy

<sup>2</sup>Azienda Ospedaliera Universitaria Careggi, Medical Physics Unit, Florence, Italy

<sup>3</sup>Azienda Ospedaliera Universitaria Careggi, Neurosurgery Unit, Florence, Italy

#### Purpose or Objective

In recent years, on the basis of experimental and clinical evidence, some authors have suggested that neural stem cells in the gyrus dentatus of the hippocampus may be implicated as the main site of treatment-related cognitive deficits. Learning and memory impairment may be proportional to the volume of irradiated tissue in this location. Gondi et al (JROBP 2013) suggested using very low dose constraints for the bilateral hippocampi volume (BHp) when patients are treated in conventional fractionation [dose to 40% of the BHp volume ( $D_{BHp40\%}$ ) < 7.3 Gy]. To date, dose constraints for hippocampus to be used in a single session are unknown. As far as they will be established, minimizing the dose is the only choice we can make. The aim of this study was to evaluate the dose received by hippocampus during Gammaknife Radiosurgery (GKRS) treatment for multiple brain metastases (BM) and to evaluate whether an Hippocampal Sparing approach could be useful.

#### Material and Methods

From 2013 to July 2015, 148 patients with BM were treated using GKRS. 20 plans of patients with  $\geq 5$  brain metastases were selected. In the 'real' plans for these patients, no attempt was made to spare the hippocampus. The plans were reviewed and, after contouring of BHp according to RTOG atlas, dose volume histograms for BHp were generated. Data regarding maximum, mean and  $D_{BHp40\%}$  were collected. Brain volume receiving 12 Gy ( $V12_{brain}$ ) was registered. All plans were replanned

('theoretical plans') in order to minimize dose to BHp while maintaining equal target coverage.

#### Results

Median BHp was 3,95 cc.  $V12_{brain}$  was <10cc in all plans. Distance from the hippocampus of each single lesion was the most important factor related to BHp dose. When this distance is >2 cm  $D_{BHp40\%}$  is negligible (<1.5 Gy). The size of lesions also affected the dose to BHp. Number of lesions do not have an impact on the BHp dose. Dosimetric parameters both for 'real' and 'theoretical' plans are listed in table 1.

We observed a significant reduction of dose to BHp in optimized plans (i.e. 33% reduction in average  $D_{BHp40\%}$ ).

	Real Plan (Gy)	Theoretical Plan (Gy)
Max D BHp	5,57 (0,1-24,3)	3,12 (0,1-18,2)
Min D BHp	0,6 (0-2,3)	0,41 (0-1,3)
Mean D BHp	1,5 (0-5)	0,99 (0-3,4)
$D_{BHp40\%}$	1,53 (0,03-5,1)	1,02 (0,03-3,7)

#### Conclusion

Dose to BHp may be quite high during radiosurgery for brain metastases, especially in patients with lesions within 2 cm from the hippocampus. Since the hippocampus has been shown to be very radiosensitive also during a conventionally fractionated treatment, it is reasonable avoiding high single dose to this structure during a radiosurgical treatment. Thus, hippocampus needs to be included among the organs at risk during the planning process of radiosurgery, in order to be spared and to further minimize the risk of treatment-related neurocognitive impairment. Currently, in our institution, we are prospectively evaluating the neurocognitive impairment in patients treated with radiosurgery in order to find a relationship between dose and neurocognitive deficits.

#### EP-1128 Stereotactic radiotherapy or whole brain with simultaneous integrated boost in brain metastases?

<sup>1</sup>Policlinico A.Gemelli, Radiation oncology department-Gemelli ART, Roma, Italy

#### Purpose or Objective

Brain metastasis (BMs) are frequently observed during oncological history. Treatment options include surgery, whole-brain radiotherapy (WBRT), stereotactic radiotherapy (SRT) or some combination of these. Despite multimodal treatment, prognosis remains severe. In this analysis we compared the SRT with WBRT plus simultaneous integrated boost (WBRT-SIB) in oligometastatic brain patients.

#### Material and Methods

From our database we selected oligometastatic patients affected by less than 3 brain metastases, with a primary tumor control, who underwent to SRT or WBRT-SIB. The SRT group received 850 cGy/die for 3 fractions, while the WBRT-SIB group received 300 cGy/die to the whole brain with a simultaneous integrated boost of 500 cGy/die to the BMs for 10 fractions. The two groups were matched for the following potential prognostic factors: age, gender, tumor type, number of brain metastasis and recursive partitioning analysis class (RPA). Local control (LC), overall survival (OS) and toxicity were evaluated.

#### Results

From 538 patients submitted consecutively to radiotherapy for brain metastases, 45 patients were eligible for this analysis. The groups were comparable in terms of sex, age, number of metastasis and RPA class. Median age was 63 years (range 38 - 87), 27 male and 18

female. Twenty-six patients (57.7%) underwent to SRT, nineteen (42.3%) to WBRT-SIB. The median number of brain metastases was 1 (range, 1-3). Acute toxicity (headache, hearing problems, nausea and vomiting), did not occur in treated patients. With a median follow-up of 20 months (range, 1.7 - 56 months), the median LC was not reached. The 1 year LC was 77% in all patients. The median and 1 year OS was 16 months 71%, respectively. No significant impact of treatment option on clinical outcomes was observed. Local control and OS data for each group are reported in table 1.

OUTCOMES	WB-SIB	SRT	p-value
<b>Local Control</b>			
median	Not reached	Not reached	0.3
1 yrs (%)	83.5	72	
2 yrs (%)	83.5	58.8	
3 yrs (%)	63.5	58.8	
<b>Overall Survival</b>			
median	26	16	0.53
1 yrs (%)	75.2	67.8	
2 yrs (%)	50.1	22.6	
3 yrs (%)	14.3	22.5	

### Conclusion

Our study shows that SRT and WBRT-SIB offer a good LC and OS, without significant differences. Probably these data maybe due to the baseline patients selection and size simple therefore we are analyzing QoL and neurocognitive function of survivor patients to understand the global impact of these two modalities of treatments.

### EP-1129 Fractionated stereotactic radiotherapy for the treatment of cavernous sinus meningiomas

I. Tovar Martin<sup>1</sup>, P. Vargas<sup>1</sup>, M. Zurita<sup>1</sup>, R. Guerrero<sup>1</sup>, E. Saura<sup>1</sup>, J.L. Osorio<sup>2</sup>, A. Horcajadas<sup>3</sup>, J. Busquier<sup>4</sup>, C. Prieto<sup>1</sup>, S. Rodríguez<sup>1</sup>, A. Ruiz<sup>1</sup>, R. Ching<sup>1</sup>, J. Expósito<sup>1</sup>, R. Del Moral<sup>1</sup>

<sup>1</sup>Virgen de las Nieves University Hospital, Radiation Oncology, Granada, Spain

<sup>2</sup>Virgen de las Nieves University Hospital, Physics, Granada, Spain

<sup>3</sup>Virgen de las Nieves University Hospital, Neurosurgery, Granada, Spain

<sup>4</sup>Virgen de las Nieves University Hospital, Neuroradiology, Granada, Spain

### Purpose or Objective

The aim of this retrospective study is to report the results obtained with this technique at our institution in terms of local control, toxicity and clinical situation at the end of the study

### Material and Methods

From April 2005 to December 2014, 54 patients with cavernous sinus meningiomas have been treated. 53,5% of meningiomas were located in the right cavernous sinus, 41,9% in the left cavernous sinus, and 4,7% were bilateral. The median age was 60 years (interquartile range (IQR): 50-66), 76,7% women and 23,3% men. 23,3% of patients were operated before the treatment. The mean dose of radiation was 50 Gy in 25 fractions of 2 Gy per day, given five days per week over 5 weeks. Most cases were treated using a LINAC accelerator with 1 isocenter (97,6%) and 8 arcs of treatment (32,6%).

### Results

The mean of follow-up was 29 months (range: 3-92). At the end of the study 69,8% of the patients presented disease stabilization and 23,3% decrease of the tumor size. Only 2,3% of the patients had disease progression. Related to clinical situation, 60,5% of the patients related the same symptom as before the treatment, 9,3% had no symptom and 18,6% had improvement of their quality of live. Only 4,7% of the patients had worsening of their symptoms. No acute toxicity was reported in 65,1% of the patients. The most frequent one was headache and mainly

grade 1. In the 79,1% not late toxicity was reported, the remainder presented toxicity grade 1-2 that was easily controlled by medication.

### Conclusion

Fractionated Stereotactic Radiotherapy is a modality of treatment good tolerated and with excellent local control for this kind of meningiomas that have traditionally posed a major challenge for neurosurgeons and neuro-oncologists.

### EP-1130 Hippocampus Dosimetry in patients treated with Stereotactic Radiosurgery for Brain Metastases

N.S. Iqbal<sup>1</sup>, J.R. Powell<sup>1</sup>, D.W.O. Tilsley<sup>1</sup>, A. Bryant<sup>2</sup>, A.E. Millin<sup>2</sup>, D. Lewis<sup>2</sup>, J.N. Staffurth<sup>1</sup>

<sup>1</sup>Velindre Cancer Centre, Department of Clinical Oncology, Cardiff, United Kingdom

<sup>2</sup>Velindre Cancer Centre, Department of Physics, Cardiff, United Kingdom

### Purpose or Objective

Brain metastases occur in 20-40% of patients with cancer and common primary sites include lung, breast, kidney and melanoma. Traditionally, whole brain radiotherapy (WBRT) has been the mainstay of treatment. Stereotactic radiosurgery (SRS) has demonstrated improved survival, better quality of life and neurocognitive function (NCF) for patients with 1-3 brain metastases and high functionality. Despite the precision of SRS, a significant proportion of patient experience decline in NCF after the treatment: 63.5% of patients undergoing SRS alone had neurocognitive decline at 3 months (Brown et al., 2016). The hippocampus (HC) has been implicated in NCF impairment following radiation as well as other disease processes such as dementia. The tolerance dose of the HC is unclear for single fraction SRS treatment. In a study of fractionated radiotherapy, a dose of more than 7.3 Gy delivered to >40% of the bilateral HC is associated with significantly higher NCF impairment (Gondi et al., 2011). In animal studies, doses as low as 2 Gy have shown evidence of increased cell apoptosis in HC (Acharya et al., 2010).

### Material and Methods

At Velindre Cancer Centre, Cardiff patients with 1-3 brain metastases with WHO performance status 0-2 are treated with SRS. A retrospective review of all patients treated with SRS without WBRT was performed over 1 year (January 2015 - January 2016). Patients were identified using electronic database. We studied dose delivered to hippocampi in our patient population. Bilateral hippocampi were outlined manually according to RTOG 0933 atlas (Gondi et al., 2010) and dose volume histograms were recreated using iPlan RT Dose 4.5, a BrainLab software.

### Results

30 patients were treated with SRS without WBRT in 1 year. Mean age was 61. The most common primary site was lung (12) followed by kidney (7) and melanoma (4). 19 patients had a single metastasis. 70% (n.21) patients were alive for more than 6 months after SRS; median survival was not reached. Dmax (dose to 0.1cc of the HC) was >5Gy in 8 and 2-4.9 Gy in 12patients. 6 patients received >5 Gy and 8 patients received 2 - 4.9 Gy to 50% of the HC. A major factor influencing high HC dose was the location of the tumour. Metastases located in the temporal and medial parietal lobes and cerebellum were associated with Dmax >5Gy. Objective neurocognitive assessment was not attempted in this study due to the challenges of collecting such data retrospectively and the known confounding factors including steroid and systemic anti-cancer therapy use.

### Conclusion

We have identified a considerable proportion of patients receiving significant radiation dose to the HC. Overall survival of patients is in line with previously published studies. Prospective studies measuring NCF with SRS treatment should also investigate doses to HC in order to determine dose effect relationship and establish dose tolerance for HC in SRS.

### EP-1131 Evaluation of overall survival following SRS for non-small cell lung cancer brain metastases

A. Keller<sup>1</sup>, S. All<sup>1</sup>, H. Patel<sup>1</sup>, C. Sherrill<sup>1</sup>, B. Dumas<sup>1</sup>, M. Mejia<sup>1</sup>, N. Ramakrishna<sup>2</sup>

<sup>1</sup>University of Central Florida, College of Medicine, Orlando, USA

<sup>2</sup>UF Health Cancer Center-Orlando Health, Radiation Oncology, Orlando, USA

### Purpose or Objective

We examined the impact of patient and tumor-specific factors on overall survival in patients with brain metastases from non-small cell lung cancer (NSCLC) treated with stereotactic radiosurgery (SRS).

### Material and Methods

We undertook an institutional review board-approved retrospective analysis of patients treated with LINAC-based SRS for brain metastases from non-small cell lung cancer between November 2008 and July 2016 at our institution. We identified 418 metastatic brain lesions treated in 136 non-small cell lung cancer (NSCLC) patients. Out of the 418 treated brain metastases, 376 had at least one follow up study. Patients were followed with serial brain MRIs with contrast to assess for local progression and recurrence every 2-3 months. Patient characteristics collected included: extracranial disease (ECD) status, Karnofsky performance status (KPS), tumor histology, history of whole brain radiation therapy, history of IMRT, history of craniotomy, date of death or last clinical contact, and age at initial SRS treatment. Treatment characteristics were obtained from the treatment plans, including tumor volume, prescription dose, prescription isodose, and maximum dose. Actuarial patient survival was defined as the time in months from initial SRS treatment to date of death or date of last clinical contact. The overall survival was calculated from date of first SRS treatment session to date of death or progression via the Kaplan-Meier method. At the time of initial treatment, 14% of patients were categorized as RPA class I, 71% as RPA class II, and 15% as RPA class III. Five patients were ALK positive, 43 were ALK-negative. Nineteen patients were EGFR positive and 44 were EGFR negative.

### Results

The median overall survival was 13.2 months. The Kaplan-Meier overall survival estimates at 6 and 12 months were 81.4% and 52.8%, respectively. There was a significant difference in survival between adenocarcinoma vs. squamous histology, 14.3 months vs. 8.1 months (p-value = 0.013). Patient pre-treatment RPA class was predictive of survival (p-value = 0.047). The median survival was 39.8 months for RPA class I, 12.8 months for RPA class II, and 7.5 months for RPA class III. The median survival for inactive ECD was 15.3 months and 11.5 months for inactive ECD (p-value = 0.034). Concurrent or prior WBRT, age, ALK mutation status, EGFR status, and KPS did not have a significant impact on survival following SRS.

### Conclusion

SRS is an important modality in the management of discrete brain metastatic disease. Survival following SRS for NSCLC brain metastases varies widely, and the prognosis may depend on a broad range of tumor and patient parameters. Among our patient group, those with adenocarcinoma versus squamous histology, inactive

extracranial disease status, and favorable RPA class had the longest overall survival. Prior or concurrent WBRT, age, ALK mutation status, EGFR status, and KPS were not predictive of survival.

### EP-1132 Hypofractionated Stereotactic Reirradiation for Recurrent High-grade Glioma

L. Hynkova<sup>1</sup>, P. Slampa<sup>1</sup>, T. Kazda<sup>1</sup>, J. Garcic<sup>1</sup>, M. Vrzal<sup>1</sup>, P. Fadrus<sup>2</sup>, R. Belanova<sup>3</sup>, I. Sikova<sup>4</sup>, D. Dvorak<sup>1</sup>, H. Dolezelova<sup>1</sup>, P. Pospisil<sup>1</sup>

<sup>1</sup>Masaryk Memorial Cancer Institute, Clinic of Radiation Oncology, Brno, Czech Republic

<sup>2</sup>The University Hospital Brno, Department of Neurosurgery, Brno, Czech Republic

<sup>3</sup>Masaryk Memorial Cancer Institute, Department of Radiology, Brno, Czech Republic

<sup>4</sup>Masaryk Memorial Cancer Institute, Department of Neurology, Brno, Czech Republic

### Purpose or Objective

The treatment for recurrent high-grade glioma is diversified. In this retrospective analysis, we evaluated outcomes of stereotactic hypofractionated radiotherapy (SRT) in patients re-treated for recurrent high-grade glioma.

### Material and Methods

From July 2004 to April 2013, 27 patients were treated. At the initial diagnosis, all patients underwent open-surgery resections to remove maximum of their tumors. SRT was performed with multileaf microcollimator systems (BrainLab) for linear accelerator. The dose given ranged from 16-25 Gy in a median five fractions (range, 1-5 fractions). The median volume of the tumor was 5,1 cm<sup>3</sup> (range, 0,03-33,7 cm<sup>3</sup>). All the patients were treated with radiotherapy previously (range dose 50-60 Gy). Only patients with Karnofsky performance Status (KPS) > 60 were re-irradiated. The median age was 46 years (21-58). 9 patients (33 %) had a glioblastoma diagnosis and 18 patients (67 %) were affected by grade III glioma (anaplastic astrocytoma/anaplastic oligoastrocytoma). After reirradiation 18 patients (67 %) received chemotherapy and 8 patients (30 %) received study of dendritic cells.

### Results

The median overall survival from the date of salvage stereotactic radiotherapy was 13,9 months (95% CI 7,7-20,5 months) with the range of follow-up from 2,9 to 128,9 months and the median overall survival following initial treatment was 46,8 months (95% CI 32-121,4). The survival was significantly shorter in the subgroup of patients with grade IV gliomas (p < 0,0036, HR 7,45, 95% CI: 1,62-34,31). From the date of stereotactic radiotherapy, the 1-year, 3-year and 5-year overall survival was 50,2 % (95% CI 33,7-77,4%), 20,9 % (95% CI 9,6-45,6 %) and 12,5 % (95% CI 4,4-36,1 %), respectively. The patients who underwent resection of subsequent post-stereotactic radiotherapy recurrence had better survival (p < 0,0142, HR 4,377, 95% CI: 1,23-15,55). The increased survival was also observed in patients with longer intervals between initial treatment and stereotactic reirradiation (p < 0,0205, HR 0,984 95% CI: 0,07-1,0). The radiological response to reirradiation evaluated by MRI has not been a predictor of survival. No severe toxicity was recorded (any case of radionecrosis).

### Conclusion

In our experience, hypofractionated stereotactic radiation therapy could be a safe and feasible option for recurrent high grade glioma.

### EP-1133 Multifraction Radiosurgery for Large Brain Metastasis: Initial Results from Brazilian Experience.

A. Borges<sup>1</sup>, L. Ercolin<sup>1</sup>, M. De Mattos<sup>1</sup>, J. Alexandre<sup>1</sup>, M. Giglioli<sup>1</sup>, A. Camargo<sup>1</sup>, D. Marconi<sup>1</sup>, D. Fonseca<sup>1</sup>, T. Kaprelian<sup>2</sup>

<sup>1</sup>Barretos Cancer Hospital, Radiation Oncology, Barretos, Brazil

<sup>2</sup>UCLA, Radiation Oncology, Los Angeles, USA

#### Purpose or Objective

To evaluate the clinical outcomes with linear accelerator-based multifraction stereotactic radiosurgery (mSRS), 3 fractions, to treatment of the large Brain Metastasis in Brazilian Population.

#### Material and Methods

Patients with brain metastases were included with 30 days or more of the end of the mSRS, between May 2015 to August 2016.

The primary endpoint was acute toxicity and the secondary endpoints were overall survival, local control (in field) and Regional recurrence free survival. Prognostic factors were analyzed, as Ds-GPA, RPA, the number of treated lesions, the major lesion, time between the last chemotherapy and procedure, fractionation (7, 8 or 9 Gy / fraction). The acute toxicity scale used was the RTOG / EORTC. For the survival curve calculations were used Kaplan- Mayer and Log-Rank test. To compare different categories of the same variable was used chi-square test. The significance level was 0.05.

#### Results

Were treated 51 patients, corresponding 110 lesions, 49% patients had one lesion. The study showed median follow-up of 8.00 months (2.42- 13.57). The overall survival (OS) estimated at 6 and 12 months were 58% and 43% respectively, with 84% non-neurologic deaths at 12 months. The primary sites were lung (39.2%), breast (29.4%) and colon/rectum (15.7%). The 9 Gy/fractions was the most used in 84.3% patients, 5.9% were treated with 8 Gy/fraction and 9.8% with 7 Gy/fraction. The median KPS was 80% (50-100%). Of the DS-GPA found, 31.9% had 0 - 1, 38.3% was 1.5 - 2.5 and 3 - 4 in 29.8%. The most of the RPA was 2 (45.1%). There were influence of the RPA and Ds-GPA in overall survival. The local control estimated at 12 months was 81%. There wasn't statistical significance between local control with fraction, GTV and PTV volume, WBRT and Primary tumor. Toxicity Grade 2 was 31 % (most common was seizure, 16%). The regional recurrence free survival were 69.2% and 43% in 6 and 12 months. There were 3 patients with acute grade 3 CNS toxicity. Radionecrosis was observed in 6% of patients until this moment, and we had 2 "radiation Recall" episodes, after FOLFOX chemotherapy. There weren't relation between toxicity and Radionecrosis with dosimetric and clinical variables, as Conformity Index, Brain Volume receiving 24 Gy, number of lesions, fractionation, etc.

#### Conclusion

Until this moment, our trial showed that mSRS is safe and feasibility, with excellent local control rates and low toxicity. Despite the most patients showed regional failure, out of field, death by neurologic causes was very low, just 15%. More patients included and longer follow-up must be help in improve and confirm the efficiency of this strategy.

#### Electronic Poster: Clinical track: Haematology

##### EP-1134 Head and neck DLBCL in HIV-positive patients: long-term results in the HAART era

F. De Felice<sup>1</sup>, L. Grapulin<sup>1</sup>, A. Di Mino<sup>1</sup>, J. Dognini<sup>1</sup>, D. Musio<sup>1</sup>, V. Tombolini<sup>1</sup>

<sup>1</sup>Polclinico Umberto I- Sapienza Università Roma, Radiotherapy, Rome, Italy

#### Purpose or Objective

To report long-term outcomes and toxicity rates after chemotherapy (CHT) followed by radiotherapy (RT) in the

highly active antiretroviral therapy (HAART) era in human immunodeficiency virus (HIV) positive patients with head and neck diffuse large B-cell lymphomas (HN-DLBCL).

#### Material and Methods

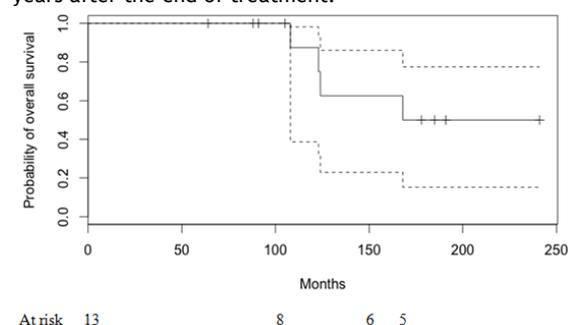

Clinical data concerning consecutive HIV patients treated for DLBCL located in head and neck region with CHT and RT between January 1995 and August 2010 were retrospectively reviewed. Systemic treatment consisted of combination CHT agents given with concomitant HAART and regimen was left to oncologists' discretion. Involved field RT was delivered with a 3D-conformational technique at a total dose of 30/36 Gy (2 Gy per fraction). Survival rates were estimated using the Kaplan-Meier method. Toxicity was evaluated using National Cancer Institute's Common Terminology Criteria for Adverse Events.

#### Results

Overall, 13 patients were included. There were no missing data. Seven patients had limited disease (stage I = 3; stage II = 4) and 6 patients had stage IV disease. Primary tumour location was sinus (n = 4), oral cavity (n = 7), nasopharynx (n = 1) and larynx (n = 1). All patients completed the programmed treatment.

Overall, 4 patients had died. No treatment-related deaths were recorded. The 10-year, 15-year and 20-year overall survival (OS) rates were 87.5% (95% confidence interval [CI] 0.387 - 0.981), 62.5% (95% CI 0.229 - 0.861) and 50% (95% CI 0.152 - 0.775), respectively. Median OS was 168 months. Details are shown in Figure 1. In total, only 1 patient had local relapse, 10 years after the end of RT. The patient received CHT and is still alive without evidence of disease. No patients had developed distant metastasis.

Globally, there were no RT-related late complications. One patient had a second cancer arising from cervix, 5 years after the end of treatment.

#### Conclusion

This data analysis suggested that CHT followed by RT can be safely proposed in the management of patients with HIV-related HN-DLBCL in the HAART era. Combined modality therapy reduced local recurrence rates and achieved a high response rate, without chronic toxicity.

##### EP-1135 Radiotherapy in primary CNS lymphoma

R. Muni<sup>1</sup>, G. Gritti<sup>2</sup>, L. Feltre<sup>1</sup>, F. Filippone<sup>1</sup>, E. Iannacone<sup>1</sup>, M. Kalli<sup>1</sup>, L. Maffioletti<sup>1</sup>, F. Piccoli<sup>1</sup>, S. Takanen<sup>1</sup>, L. Cazzaniga<sup>1</sup>

<sup>1</sup>ASST Papa Giovanni XXIII, Radiation Oncology, Bergamo, Italy

<sup>2</sup>ASST Papa Giovanni XXIII, Haematology, Bergamo, Italy

#### Purpose or Objective

Primary CNS lymphoma(PCNSL) is a rare and aggressive brain tumor with poor prognosis. Patients are primarily treated with high dose chemotherapy while radiotherapy plays a role as consolidation after chemotherapy. Total dose and fractionation are not well established.

In patients older than 60 years the incidence is higher with a worse outcome. The management of these patients is

critical because a standard is lacking and treatments are associated with a higher toxicity.

We evaluated efficacy and tolerance in patients with PCNSL treated with whole brain radiotherapy because unfit for chemotherapy or with recurrence/ no response after chemotherapy treatment.

#### Material and Methods

From April 2010 to December 2014, fifteen consecutive patients with histologically proven PCNSL underwent whole brain 3-dimensional conformal radiotherapy at our institution. One patient was excluded because lost to follow-up. Mean age was 59.7 and median age was 70(range 30-77). Median KPS was 60(range 50-90).

Two patients had a recurrence after a complete response to upfront chemotherapy. The other 12 patients were unfit for chemotherapy or had chemotherapy suspended for toxicity or underwent chemotherapy with no response. Median radiotherapy dose was 38,5 Gy(range 24-45), median fraction dose was 2 (range 1,8-3 Gy) and median number of fractions was 19(range 10-23).

Data were retrospectively analyzed. Survival was calculated from the diagnosis to the death date or last follow-up.

#### Results

Median follow-up was 28.5 months(range 23-76) . Eleven patients (79%) completed radiotherapy without breaks. One patient died during radiotherapy, one stops the treatment because of neurological deterioration and one for lack of compliance.

Median survival from first diagnosis was 8.5 months (range 1-70). Median survival from the end of radiotherapy was 4 months(range 1-34).

In patients older than 60 years (64%) median survival from diagnosis was 14 months and in patients younger than 60 years(36%) was 4 months. One of these patients, HIV-positive, died one month after the completion of radiotherapy.

One-year survival rates from diagnosis was 46%, 2 years survival rate was 30% and 5 years survival rate was 7%.

Fifty percent of patients had a radiologic or clinical progression. In 5 patients radiologic response was not assessed because of poor clinical conditions. Five/9 patients (55%) who underwent imaging evaluation had a response (33% complete and 22% partial).

In 25% of patients an early improvement of neurological status during radiotherapy was reported.

#### Conclusion

Despite limitations due to the small number of patients, radiotherapy may represent a feasible option in patients with diagnosis of PCNSL that are unfit for chemotherapy or had recurrence or no response, with a quite good tolerance and survival in same cases. We have not observed worse tolerance or survival in older patients.

#### EP-1136 Technical results of total skin irradiation using helical TomoTherapy.

K. Okuma<sup>1</sup>, A. Haga<sup>1</sup>, Y. Imae<sup>1</sup>, W. Takahashi<sup>1</sup>, K. Nakagawa<sup>1</sup>

<sup>1</sup>University of Tokyo Hospital, Radiology, Tokyo, Japan

#### Purpose or Objective

The purpose of this study was to report results of dose distributions of total skin irradiation (TSI) for cutaneous T-cell lymphoma using helical TomoTherapy (Accuray, Sunnyvale, CA).

#### Material and Methods

In our institution, six patients with refractory T-cell lymphoma were tried to treat of TSI using TomoTherapy. Treatments were delivered to three parts of the body (legs, head and neck, and trunk). Patients were received a prescription dose of 10-20 Gy in 10 fractions over 14 days in each part.

#### Results

Five out of six patients, TomoTherapy technique was able to achieve good coverage of the planning target volume (PTV) and good sparing of organ at risk. In one patient who was a 25-year-old big man diagnosed mycosis fungoides, dose distribution of trunk, especially abdominal skin, were not able to achieve good coverage of PTV. The body mass index (BMI) of the patient was 30.6 while the mean BMI of other patients were 22 (18-25). However, a trial planning using another big patients' CT (BMI=38) showed good dose distribution.

#### Conclusion

Using helical TomoTherapy was a good new treatment technique for TSI. It was not able to get good coverage of PTV for all patients. This treatment method will be needed further research to get good dose distribution for all patients.

#### EP-1137 Meningeal localisation in Sezary Syndrome patient treated with VMAT craniospinal irradiation

R. Munil<sup>1</sup>, M. Fortunato<sup>2</sup>, L. Feltre<sup>1</sup>, F. Filippone<sup>1</sup>, E. Iannacone<sup>1</sup>, M. Kalli<sup>1</sup>, L. Maffioletti<sup>1</sup>, F. Piccoli<sup>1</sup>, S. Takanen<sup>1</sup>, L. Cazzaniga<sup>1</sup>

<sup>1</sup>ASST Papa Giovanni XXIII, Radiation Oncology, Bergamo, Italy

<sup>2</sup>ASST Papa Giovanni XXIII, Medical Physics, Bergamo, Italy

#### Purpose or Objective

Sezary syndrome(SS) is a rare erythrodermic and leukemic variant of cutaneous T cell lymphomas(CTCL) that belongs to extranodal non-Hodgkin's lymphomas. SS together with mycosis fungoides (MF) are the most common forms of CTCL.SS has an aggressive behavior with a median survival of 1-5 years.In CTCL nervous system involvement has been reported in 1.6% of patients. Most patients had a MF with malignant transformation and usually it is associated with late stage disease and very poor prognosis. Individual case reports of patients with large cell transformation of MF but not of SS, were described.We report a case of histologically proven meningeal involvement in a patient with early stage SS treated with craniospinal irradiation with Volumetric Modulated Arc Therapy(VMAT) technique with long term radiologic complete response, alive 5 years after diagnosis.

#### Material and Methods

Case report. A 67-year-old woman with a Sezary Syndrome diagnosed 3 years before, with a 3 months history of headache, underwent a cranial magnetic resonance imaging (MRI) showing diffuse meningeal contrast enhancement with thickening, especially in frontal meninx. A biopsy was performed with diagnosis of meningeal localisation of T cell lymphoma.She underwent intrathecal chemotherapy with radiologic stable disease, so a craniospinal irradiation with VMAT technique was performed. Prescription dose was 18 Gy on entire neuraxis in 10 fractions (1.8 Gy per fraction) and a 6 Gy sequential boost in 3 fractions on the brain(total dose 24 Gy). Treatment was performed in supine position with a head long mask and a vacuum pillow including body till pelvis. PTV length was 70 cm. Three isocenters were used. Distance between cranial and thoracic isocenters and between thoracic and abdominal isocenters was 23 cm. Plan was optimised defining an overlapping region between arcs of different isocenters so that no field matching was necessary. Set-up position verification by daily CBCT was performed.

#### Results

Headache resolution was observed before the end of radiation treatment. No toxicity was reported.The first MRI performed 1 month after the completion of radiotherapy showed a partial response and after 6 months, a complete radiologic response was achieved. At

present, with a 17 months follow-up, she is still in clinical and radiological complete remission with good performance status and quality of life.

#### Conclusion

This is the first reported case of meningeal metastasis in SS patients. In contrast with previous reports, our patient didn't present with advanced or aggressive disease. Our report reinforces the hypothesis of a possible neurotropism of malignant cells in MF and SS. CNS involvement could be evaluated in patients with unexplained neurologic symptoms or neuropathic pain, that are not unusual. Although a poor outcome is expected in these patients, we reported a long term complete response with impact on quality of life and survival with VMAT craniospinal irradiation.

#### EP-1138 Dosimetric accuracy of linac based Total marrow Irradiation

B. Aydogan<sup>1</sup>

<sup>1</sup>Univ. of Chicago Medical Center, Radiation and Cellular Oncology, Chicago, USA

#### Purpose or Objective

We are currently investigating the feasibility of adding linac based total marrow irradiation (TMI) with myeloablative chemotherapy prior to stem cell transplant. Here we report our initial clinical experience regarding patient setup error and its dosimetric consequences.

#### Material and Methods

7 patients with advanced hematological malignancies were treated according to our institutional phase I clinical trial designed to evaluate the feasibility of IMTMI in addition to preconditioning chemotherapy regimen. Patients were immobilized using a customized whole body mold. The bones are contoured and a 3 mm margin is added to obtain PTV. Three separate treatment plans, for the head and neck, chest, and pelvic were generated. Plans were optimized for 95% PTV coverage with the 95% of prescription dose. Positioning and alignment of all three isocenters were confirmed prior to each treatment with megavoltage orthogonal port films. Residual setup errors of each patient and each fraction were retrospectively analyzed by co-registering port films and digitally reconstructed radiographs. Dosimetric consequences of setup errors were evaluated by shifting the isocenters based on the determined setup errors. We applied previously determined actual isocenter shifts for each session and recalculated dose distributions to determine delivered dose distributions. Simulated dose distributions were then compared with the planned dose distributions.

#### Results

Setup errors were less than 5 mm, more specifically, they were, on average,  $3.1 \pm 0.7$  mm,  $2.3 \pm 0.8$  mm,  $3.2 \pm 0.8$  mm in vertical, longitudinal, and lateral directions, respectively. Maximum vectorial displacement was 4.6 mm. When the determined isocenter shifts were applied and the new dose distributions were calculated, the bone marrow volume that received the 95% of the prescription dose ( $V_{95}$ ) was reduced from 99.4% ( $\pm 0.7\%$ ) to 96.8% ( $\pm 1.3\%$ ), on average. The mean lung dose and the mean PTV dose changed less than 5%. The change in the maximum dose ranged between 6% and 19%.

#### Conclusion

Linac-based IMTMI is clinically feasible affording significant OAR sparing in a combined chemo-RT treatment. Based on our clinical experience with the first 7 patients in this study, we found a 3 mm bone to PTV expansion was adequate to accurately target bone marrow in IM-TMI treatments.

<sup>1</sup>Azienda Socio-Sanitaria Territoriale Papa Giovanni XXIII, Radiation Oncology, Bergamo, Italy

<sup>2</sup>Azienda Socio-Sanitaria Territoriale Papa Giovanni XXIII, Breast Cancer Surgery, Bergamo, Italy

<sup>3</sup>Azienda Socio-Sanitaria Territoriale Papa Giovanni XXIII, Medical Physics, Bergamo, Italy

#### Purpose or Objective

We report preliminary results from a clinical trial aimed to evaluate the incidence of in-breast tumour recurrence (IBR) and the acute and late toxicity in patients affected by early breast cancer (BC), undergoing conservative surgery and electron intraoperative radiation (ELIOT) boost, followed by hypofractionated external beam radiotherapy (EBRT).

#### Material and Methods

From February 2012 to January 2016, 83 early BC patients underwent conservative surgery and ELIOT boost, followed by EBRT at Papa Giovanni XXIII Hospital in Bergamo (Italy). Patients inclusion criteria are: infiltrating carcinoma histology (T1-2, N0-1, M0), unifocality or multifocality (maximum distance between two lesions  $\leq 2$  cm), PS (ECOG)  $\leq 2$ , age  $> 18$ , premenopausal status. ELIOT boost was delivered for all patients at the level of tumour bed by a dedicated linear accelerator NOVAC 7 HITESYS (NRT, Italy), using 9 MeV electron beam, a single dose of 12 Gy at 90%.

EBRT was given at the whole breast in 13 daily fractions of 2.85 Gy.

Fifteen patients underwent adjuvant chemotherapy and 74 patients underwent hormone therapy. IBR is any local relapse within the treated breast. Acute and late toxicity were assessed using RTOG toxicity scale.

#### Results

Forty-seven patients (56.6%) started EBRT boost in 28 days after ELIOT boost procedure.

Current median follow up was 23 months and is too short to evidence any IBR.

After ELIOT, 2 patients underwent mastectomy, after the identification of another breast metachronous nodule and BRCA1 mutation respectively. Four patients underwent conventional scheduled EBRT: 3 for the presence of unfavourable prognostic disease factors as discovered on the surgical specimen and 1 for severe post-surgical side effects.

Most patients had slight local post-surgical oedema: 1 patient had necrosis of the scar area. After EBRT, slight skin erythema (G1) was evidenced in all patients. Considering late toxicity, slight scar fibrosis (G1) was assessed in most patients: 1 patient showed scar retraction and 1 dehiscence of surgical scar.

#### Conclusion

The advantages of the ELIOT-boost followed by hypofractionated EBRT in early BC are the reduction of treatment duration and skin toxicity with better cosmetic results, the delineation of tumour bed under direct visual and palpable evaluation, no adjuvant chemotherapy delay and the immediate inhibition of cells repopulation. With these preliminary results, it seems to be manageable with acceptable acute toxicity. A longer follow up is needed in order to show IBR and late effects rate.

### EP-1140 Dosimetric comparison between Helical Tomotherapy and IMRT for Bilateral Breast Cancer

M.H. Wang<sup>1</sup>

<sup>1</sup>Shuang Ho Hospital, Department of Radiation Oncology, Taipei, Taiwan

#### Purpose or Objective

This study aimed to compare treatment between Tomotherapy and IMRT for bilateral breast cancer.

#### Material and Methods

We selected 10 patients of breast cancer who were performed partial mastectomy for study. All patient were early stage breast cancer pT1-T2. A total dose of 5040cGy was delivered for definitive breast irradiation of IMRT and Tomotherapy for each patient in treatment planning system. In this study, we analyzed comparable treatment of IMRT vs Tomotherapy for bilateral breast. Bilateral whole breast dose coverage, Conformity index, Homogeneity index and dose volume constraints of normal tissue (Right and Left lung, Heart) were analyzed.

#### Results

Tomotherapy was better than IMRT for significant improvements in reducing the volume of normal tissue. In volume of heart in V20 (Tomo: 1.543% versus IMRT: 2.955%;  $p=0.023$ ) and in lung volume achieving lower mean lung dose (MLD) (Rt lung mean dose: Tomo: 6.388 Gy versus IMRT: 8.828Gy;  $p = 0.017$ ; Lt lung mean dose Tomo: 6.24 Gy versus IMRT: 7.71Gy;  $p = 0.013$ ). The conformity indices ( $V_{95\%}/V_{PTV}$ ) of right and left breast were (1.08 +/- 0.01) & (1.07 +/- 0.02) in Tomo and (1.07 +/-0.02) & (1.08 +/- 0.01) in IMRT. For homogeneity indices, Tomo were (1.36 +/- 0.08) & (1.53 +/- 0.46) and IMRT was (1.65 +/- 0.44) & (1.51 +/- 0.26) in right and left breast.

#### Conclusion

Tomotherapy provided significant reduction in heart's dose volume and mean lung dose.

### EP-1141 Acute and late toxicity of IORT during BCS followed by whole breast radiotherapy (WBI).

B. Urbanski<sup>1</sup>, A. Roszak Andrzej<sup>1</sup>, K. Bratos<sup>1</sup>, P. Milecki<sup>2</sup>, A. Karczewska-Dzionk<sup>3</sup>, M. Litoborski<sup>4</sup>, S. Adamczyk<sup>5</sup>

<sup>1</sup>Greater Poland Cancer Centre, Radiotherapy and Gynecological Oncology, Poznan, Poland

<sup>2</sup>Greater Poland Cancer Centre, Radiotherapy Ward I, Poznan, Poland

<sup>4</sup>Candela, Candela, Warsaw, Poland

<sup>5</sup>Intra Op, Intra Op, Sunnysvale, USA

#### Purpose/Objective:

The aim of the study was to report acute and late toxicity of intraoperative radiotherapy (IORT) given as a boost during breast conserving surgery (BCS) followed by adjuvant whole breast radiotherapy (WBRT).

#### Material and Methods

Between 2008 and 2011 in 150 breast cancers patients treated in Greater Poland Cancer Centre. Intraoperative radiotherapy as a tumor bed boost was applied using mobile electron accelerator Mobetron 1000 (IntraOp Medical, Inc.). IORT boost (10 Gy) was followed by 50 Gy whole-breast external beam radiotherapy (EBRT). Chemotherapy, if indicated, was given before EBRT. The observation period was 1,5-5,5 years.

The data was assessed by CTCAE ver. 3.0 scale 1 month and 6 months after RT. The statistical analysis was performed with Maentel-Haenszel test. Late toxicity was analyzed with LENT-SOMA scale 1 year after RT.

## Results

Tab 1. Acute toxicity data set.

	Month after radiotherapy		6 months after radiotherapy	
	Grade I	Grade II	Grade I	Grade II
Radiation induced dermatitis	21	10	6	3
Skin pain in breast	35	18	14	7

There was only grade I and II acute toxicity reactions. There was no statistical significance differences between (Mantel-Haenszel test) percentage of patients with acute reaction in 1 month and 6 months after RT.

Tab 2. Late toxicity data set.

	Grade I	Grade II	Grade III
Retraction	5	29	5
Fibrosis	20	40	0
Teleangiectasia	9	16	0
Oedema	8	14	0

The late toxicity occurred in 82 patients (55%). The main side effect of treatment was fibrosis, which has occurred in 60 patients (73.1%) from 82 in general with late radiation induced reactions. There was grade I and II predominance. Grade III occurred in 5 patients (skin retraction).

#### Conclusion

Intraoperative radiotherapy is proved to be safe, well tolerable and perspective treatment procedure in breast cancer treatment.

### EP-1142 EORTC QLQ C-30 scores evolution in stage I-III breast cancer patients during sequential treatment

A. Vila<sup>1</sup>, J. Perez de Olaguer<sup>1</sup>, P. Gallego<sup>1</sup>, G. Carrera<sup>1</sup>, A. Pedro<sup>1</sup>

<sup>1</sup>Platón Hospital, Oncology and Radiation therapy, Barcelona, Spain

#### Purpose or Objective

To analyse the quality of life in stage I-III breast cancer patients under systemic treatment versus in adjuvant radiotherapy respect a control group, to observe and to assess priorities regarding quality of life

#### Material and Methods

Between May and July of 2014, n: 90 EORTC QLQ C-30 global tests were retrospectively observed in 48 women divided in 3 groups: A) Sixteen breast cancer patients under systemic treatment (following adjuvant chemotherapy or hormonal treatment). B) Sixteen breast cancer patients following radiotherapy were scored at the beginning, during radiotherapy and when radiotherapy courses just ended. C) Sixteen women, hospital workers, without cancer control group, which two were finally refused because they had symptoms of chronic fatigue

#### Results

Women mean ages were 63.5 years old (A), 60.5 years old (B) and 41 years old in group C, respectively.

Among those 32 breast cancer patient (n: 76 tests), 6 (19%) were submitted to mastectomy and 26 (81%) to conservative surgery, with 5 of them that had been treated with neo - adjuvant chemotherapy. Breast cancer (TNM) stage was I, II or III in 50%, 37.5% and 12.5%, respectively.

Asthenia was the main symptom in all cases being low in control group. However, asthenia was considerable or severe in the 56% of cases in the systemic treatment group and 27.5% in radiotherapy group. Asthenia increases a 6%

just after radiotherapy. Apart of asthenia, by groups; A) they showed weakness (87.5%) and anorexia (70%) in relation with cytotoxic effects, and 50% in this group of patients showed considerable to severe depression feeling. B) Pain (50%), generally caused by the set-up position and the skin effects of radiotherapy, and 31% of this group of patients showed considerable to severe depression feeling. C) Low degrees of Insomnia, constipation and mild depression were also present in this group.

It was found relationship between high degrees of fatigue and females older than 45 years old, tumour poor differentiation, advanced II-III stage, and hormonal treatment when they were tested. In second term PS, several skeleton bone or articular diseases. The presence of mastectomy and thyroidal diseases were frequent in the worst answer tests. Also depression status is determinant in prognosis, but none common profile or clear relationship between high degrees of fatigue and biological factors as ki67, P-53, hormonal receptors, perineural affection, C-her2neu/FISH, tumoral markers as CA 15.3 were found

**Conclusion**  
1. Quality of live and treatment toxicities differed among patients under systemic treatment or radiotherapy, since the toxicity is cumulative. 2. Asthenia is the main symptom in all cases. 3. The data of high depression redraw the need of psychological and social cares. 4. International organisms recommend applying probate quality of life tests in every oncology department, if possible

#### EP-1143 Hypofractionated vs conventionally fractionated breast radiotherapy: Economic consequences.

A.C. Ciafre<sup>1</sup>, J.M. Torices<sup>1</sup>, E. Jordá<sup>1</sup>, D. Dualde<sup>1</sup>, R. García<sup>1</sup>, E. Ferrer<sup>1</sup>

<sup>1</sup>Hospital Clínico Universitario, Oncología Radioterápica, Valencia, Spain

#### Purpose or Objective

Hypofractionated radiotherapy for post-operative breast cancer has consolidated as the standard treatment for breast cancer due to similar results compared with mastectomy in terms of local relapse, disease recurrence and survival rates. On clinical trials, Multiples fractionated schemes have been tested in the past years, demonstrating that hypofractionated whole-breast irradiation was not inferior to standard radiation treatment in women who had undergone breast-conserving surgery for invasive breast cancer with clear surgical margins and negative axillary nodes. The purpose of this study was to compare the economic outcomes in our institution resulting from an hypofractionated treatment in selected patients.

#### Material and Methods

A retrospective review from January 1<sup>o</sup> 2010 to December 31<sup>o</sup> 2015 of hypofractionated whole-breast irradiation was performed. Inclusion criteria was: Early breast cancer (I, II) Breast-conserving surgery, Age >18 years and absence of previous RT treatment at the same area. Pregnancy, breastfeeding and axillary nodes involvement were excluded. 3D conformal radiotherapy was delivered with 6-15 MV photons: 40 Gy in 15 fractions, 5 fractions per week. Additionally, boost doses to the tumor bed in patients <50 years, close margins of IDC or positive margins on DCIS with an equivalent dose in 2Gy fractions (EQD2) of 10-20 Gy. The estimated cost by treatment was obtained multiplying the number of sessions received by the stipulated cost of each session according to the law in force. Additionally we calculated an estimated cost of the treatment as if it has been performed with conventionally fractionated schedule, comparing the total amount between treatments.

#### Results

361 patients who fitted the inclusion criteria were treated in our institution using hypofractionated schemes. The cost by session was estimated in 285,53€ according with the law in force provided by the Economic department of our institution. 75,6% (n273) of patients received 15 fractions with an estimated cost by treatment of 1.169.245,35€ and the remain 24,4% of patients (n88) received 18 fractions with an estimated cost of 452.279,52€. Comparing a standard irradiation in 25 fractions with hypofractionated irradiation in 15 fractions, a total saving estimated on 779.496,9€ was obtained. Likewise in patients who underwent boost doses to the tumor bed receiving 18 fractions, a total saving of 301.519,68€ was calculated compared to a conventional treatment of 30 fractions.

#### Conclusion

The increasing demand of treatments in health care institutions makes necessary the implementation of cost-efficacy strategies, in attendance of each patients needs without letting a side the importance of optimization of health resources. Hypofractionated schedules reduces the total time of treatments which translates in a reduction of sanitary personnel costs, time machine, waiting lists, transportation and patient discomfort among others.

#### EP-1144 Old age impact on radiotherapy omission in breast cancer patients

S. Cima<sup>1</sup>, B. Muoio<sup>1</sup>, P. Fanti<sup>1</sup>, A. Richetti<sup>1</sup>, C. Azinwi<sup>1</sup>, F. Martucci<sup>1</sup>, K. Yordanov<sup>1</sup>, G. Pesce<sup>1</sup>, M. Valli<sup>1</sup>

<sup>1</sup>Istituto Oncologico della Svizzera Italiana, Radiation Oncology, Bellinzona, Switzerland

#### Purpose or Objective

Increasing life expectancy and overall aging in the western countries will improve the impact of breast cancer treatment in old women. The aim of this study was to analyse the impact of age on post-operative radiotherapy (RT) omission in breast cancer patients, older than 69 years.

#### Material and Methods

We analysed retrospectively 384 women, treated from January 2007 to June 2015, dividing them into three subgroups: 70 to 79 years, 80 to 89 years and 90 years and older.

#### Results

A total of 280 patients (72.9%) were treated with conservative surgery. The adjuvant RT was given to 135 patients (71.4%) aged 70-79 years, 27 patients (34.2%) aged 80-89 years and 3 patients (25%) older than 90 years. RT was omitted in 115 (41.1%) cases. A significant correlation was observed between age and RT omission, comparing younger subgroup to the others ( $p < 0.001$  and  $p = 0.002$ ), with a smaller number of older patients treated with RT. The 2 and 5 year DFS of patients treated with conservative surgery was 94.5% and 82.7% without significant difference between age subgroups ( $p = 0.36$ ). No significant difference in 2 and 5 years DFS was detected ( $p = 0.12$ ) between patients treated with adjuvant RT and conservative surgery alone ( $p = 0.12$ ). The 5 year OS was 81% in patients aged 70-79 years; 71% in patients aged 80-89 years and 65% in patients older than 90 years, with a significant difference ( $p = 0.009$ ). The 5 year OS in patients treated with adjuvant RT was 79% while it was 75% in patients treated with conservative surgery alone, without significant difference ( $p = 0.11$ ). Mastectomy was performed in 124 patients: 17 patients (13.7%) received RT while 107 (86.3%) no further RT, with omission in 22 patients (17.7%). The adjuvant RT was given to 13 patients (16.7%) aged between 70-79 years, 4 patients (10.3%) aged between 80 and 89 years, while no patients older than 90 years was treated with post-mastectomy RT. No statistically significant difference in term of RT omission

was observed between age subgroups, comparing younger subgroup to the others ( $p=0.40$  and  $p=0.60$ ). The 2 and 5 year DFS of patients treated with mastectomy was 90% and 81.7% without significant difference between age subgroups ( $p=0.51$ ). The 2 year DFS in patients treated with adjuvant RT was 91% and 89% in patients treated with mastectomy alone. The 5 year DFS in patients treated with adjuvant RT was 86% and 65% in patients treated with mastectomy alone. No significant difference was detected ( $p=0.26$ ). The 5 year OS was 70% in patients aged 70-79 years; 55% in patients aged 80-89 years and 14% in patients older than 90 years, with a significant difference ( $p<0.001$ ). The 5 year OS was 64% and 52% in patients treated with or without adjuvant RT respectively, without significant difference ( $p=0.12$ ).

#### Conclusion

An higher percentage of patients aged between 70-79 years received RT after conservative surgery if compared with the older subgroups. No difference was detected in RT omission after mastectomy.

#### EP-1145 Troponin I for the detection of cardiac

toxicity in adjuvant breast cancer radiotherapy  
K. Boudaoud<sup>1</sup>, H. Allioueche<sup>2</sup>, O. Haderbeche<sup>2</sup>, K. Sifi<sup>3</sup>, S. Taleb<sup>4</sup>, C. Kourtelis<sup>5</sup>, K. Benmebarek<sup>3</sup>, M. Setta<sup>6</sup>, S. Serradj<sup>6</sup>, T. Filali<sup>7</sup>, A. Djemaa<sup>4</sup>, N. Abadi<sup>3</sup>

<sup>1</sup>Scientific research laboratory of molecular biology and genetics- Faculty of Medicine- UC3, Radiation oncology, Constantine, Algeria

<sup>2</sup>CHUC, Radiation oncology, Constantine, Algeria

<sup>3</sup>Scientific research laboratory of molecular biology and genetics- Faculty of Medicine- UC3, Laboratory of biochemistry, Constantine, Algeria

<sup>4</sup>Faculty of medicine- UC3, Radiation oncology, Constantine, Algeria

<sup>5</sup>University Constantine 1, Radiation oncology, Constantine, Algeria

<sup>6</sup>Faculty of Natural and Life Sciences- UC1, Department of animal biology, Constantine, Algeria

<sup>7</sup>Scientific research laboratory of molecular biology and genetics- Faculty of Medicine- UC3, Medical oncology, Constantine, Algeria

#### Purpose or Objective

Chemotherapy, targeted agents, hormone therapy and radiation therapy improve survival for women with locally advanced breast cancer but increases the risk for heart failure and cardiomyopathy. Radiation induced heart disease generally occurs with a latent period of 5-10 years. Cardiac troponin I (cTnI) is highly sensitive and specific biomarker of cardiac damage. Our aim was to evaluate the early effect of breast cancer radiotherapy on serum high sensitivity troponin I levels.

#### Material and Methods

A total of 28 patients with breast cancer who received adjuvant 3D conformal radiation therapy (RT) were included in a prospective, study. High sensitivity cardiac troponin I ( $\mu\text{g/ml}$ ) was analyzed from serum samples taken before, during and after two or three radiation therapy weeks. According to cTnI value ( $\leq 0.009$  or  $> 0.009$   $\mu\text{g/ml}$ ), patients were allocated into two groups; group A ( $> 0.009$   $\mu\text{g/ml}$ ) and group B ( $\leq 0.009$   $\mu\text{g/ml}$ ) All patients underwent left ventricular ejection fraction (LVEF, Echo) examination before and after radiation therapy. Dose-volume-histograms (DVH) for the heart were also calculated.

#### Results

In the whole study population, cTnI was detectable ( $> 0.009$   $\mu\text{g/ml}$ ) in 6 (21.42 %) patients before RT, in 5 (17.85 %) during RT and in 6 (21.42 %) patients after RT. Patients with increased cTnI values (group A, N = 6) had higher radiation doses for the heart (5.14 vs, 4.06 Gy). This increase in the cTnI level was more marked in patients

with high blood pressure (33% vs, 4.54%), left-sided breast cancer (66.66% vs, 50%), and those who had received lymph nodes RT; (internal mammary chain (50 vs, 27.27%), supra clavicular and infraclavicular lymph nodes (83.33 vs, 22.72%).

#### Conclusion

In spite of the limited patient number, our study shows that circulating cTnI confirms subclinical myocardial damage during and after breast cancer radiation therapy. The role of cTnI as biomarker in predicting future cardiovascular events in patients undergoing adjuvant radiation therapy remains to be determined in large studies and could become a useful research tool.

#### EP-1146 Acute toxicity of hypofractionation with SIB in the radiation therapy for breast cancer

J. Fernandez-Ibiza<sup>1</sup>, J. Calvo<sup>1</sup>, O. Coronil<sup>1</sup>, S. San José<sup>1</sup>, E. Puertas<sup>1</sup>, R. Robaina<sup>1</sup>, J. Casals<sup>1</sup>

<sup>1</sup>Hospital Quiron Barcelona, Radiation Oncology, Barcelona, Spain

#### Purpose or Objective

The aim of our study is to evaluate the tolerance and acute/immediate toxicity of a 'mild' hypofractionation with simultaneous integrated boost in the radiation therapy after breast conserving surgery in women with diagnosis of early breast cancer.

#### Material and Methods

Between January 2015 to October 2016, 100 women with breast cancer diagnosis (Tis-T2, N0-1) were treated with a hypofractionated simultaneous integrated boost (SIB) after breast-conserving surgery, using IMRT, field-in-field technique (FIF) or a mixed technique. Dose prescribed was 45,57 Gy (2, 17 Gy/fr.) in 21 fractions to the breast (+ supraclavicular fossa in 25p), and a simultaneous integrated boost to the surgical bed to achieve 55, 86 Gy (2, 66 Gy/fr.). All patients were treated with chemotherapy (27, 9% were neoadjuvant), except 6 cases of intraductal carcinoma. We registered the acute toxicity at the end of the treatment, one week after and 6 weeks after, prospectively, using the NCI-CTCAE v4.0 scale.

#### Results

The acute toxicity at the end of the treatment was grade 1 in 62% of patients, grade 2 in 38% of patients, and grade 3 in 1 patient. One week after the treatment, we observed grade 0 in 2 patients, grade 1 in 54 patients, and grade 2 in 44%. Hence, we detected an increase of gradation toxicity, only in 10 patients (10%), when the toxicity was registered a week later. Finally, 6 weeks after the radiation therapy; 67 % of the patients had recovered their skin's normal appearance, and 33 % of them persisted with faint erythema (G1) or pigmentation. We collect other parameters of acute toxicity as desquamation, observing no desquamation in 51 % of the patients, dry desquamation in 43% and moist desquamation in 6%.

#### Conclusion

This scheme of 'mild' hypofractionation with SIB, in the postoperative radiation treatment of early breast cancer after conserving-surgery, showed to be well tolerated and feasible, and is associated with acceptable immediate/acute skin toxicity. Longer follow up is needed to demonstrate acceptable subacute and late toxicity.

#### EP-1147 Radiation induced oesophagitis in breast cancer patients

K. West<sup>1</sup>, N. Coburn<sup>1</sup>, R. Beldham-Collins<sup>1,2</sup>, K. Tiver<sup>1</sup>, K. Stuart<sup>2</sup>, V. GebSKI<sup>2</sup>

<sup>1</sup>Nepean Cancer Care Centre, Nepean Hospital, Penrith, Australia

<sup>2</sup>Crown Princess Mary Cancer Centre, Westmead Hospital, Westmead, Australia

### Purpose or Objective

To investigate if a relationship exists between the dose volume parameters leading to moderate oesophagitis in early breast cancer patients receiving radiotherapy to both the breast and supraclavicular nodes (SCF). Oesophagitis has been widely reported in treatment sites such as lung and head and neck, however there is limited data for breast cancer patients.

### Material and Methods

Seventy-seven breast cancer patients receiving radiotherapy to their breast and SCF were recruited for the study. Patients were prescribed 50Gy to the breast or chest wall and SCF +/- a simultaneous integrated boost to the tumour bed of 57Gy. Analysis of the dose volume histogram (DVH) data of the irradiated volume of the oesophagus was performed. Patients were graded twice weekly with a modified RTOG oesophagitis scale to determine the onset, duration and severity of reported oesophagitis. Patients who experienced a grade 1B or worse by the end of their treatment were followed up twice weekly until the symptoms of oesophagitis had resolved.

### Results

From the 77 patients analysed, 2 patients had no reaction, 22 patients reached a grade 1A reaction, 30 patients reached grade 1B, 16 patients reached grade 2A and 7 patients reached grade 2B. The onset of each grade reached throughout the treatment showed those who reached a maximum grade of 1B, did so at an average of 13 fractions. Patients that reached a maximum grade of 2A, reached grade 1B at 10 fractions and 2A at 18 fractions. Patients that reached a maximum grade of 2B reached the 1B grade at just 8.3 fractions, the 2A at 14 fractions and the 2B at 21.7 fractions suggesting the faster the onset, the worse the outcome for the patient. The average mean dose to the oesophagus for patients that had a maximum grade of 0-1A was 31.95Gy, 1B was 32.46Gy, 2A was 34.22Gy and 2B was 34.64Gy. The average maximum doses recorded for 0-1A was 49.86Gy, 1B 50.44Gy, 2A 50.36Gy and 2B 51.26Gy; maximum doses did not seem to have an impact on the incidence of oesophagitis, however the mean dose showed a steady increase from grade 0-1A up to 2B. Also recorded was the mean dose delivered at each grade, based on when the patient reported the changes.

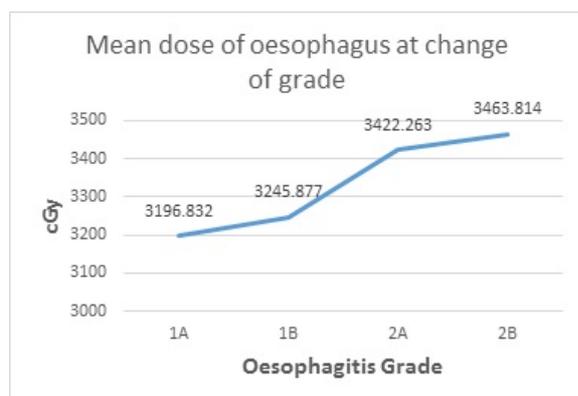

Figure 1 Difference in the average mean dose between grades 1 and 2

The graph (Figure 1) shows between grades 1A-1B there is almost a plateau and similarly between grade 2A-2B, however there is a sharp increase between grade 1B-2A, suggesting a potential limiting mean dose of 32Gy.

### Conclusion

Moderate oesophagitis is prevalent in breast cancer patients receiving radiotherapy to the SCF. Limiting the

mean oesophageal dose to 32Gy could decrease the severity of oesophagitis in these patients.

### EP-1148 Distress and self-awareness of disease severity in early breast cancer: two Institutions comparison

I. Meattini<sup>1</sup>, T. Zagar<sup>2</sup>, G. Francolini<sup>1</sup>, A. Deal<sup>2</sup>, G. Carta<sup>1</sup>, J. Camporeale<sup>2</sup>, L. Terzo<sup>2</sup>, L. Livi<sup>1</sup>, O. Kaidar-Person<sup>2</sup>  
<sup>1</sup>Azienda Ospedaliero Universitaria Careggi - University of Florence, Radiation Oncology Unit - Oncology Department, Florence, Italy  
<sup>2</sup>University of North Carolina, Department of Radiation Oncology, Chapel Hill, USA

### Purpose or Objective

Coping with cancer, even in the curative setting, may lead to emotional and psychological distress. However, resilience is dependent on many factors including social support and ethnic/cultural coping strategies. The aim of this multicenter retrospective study is to evaluate the distress among curative breast cancer (BC) patients in two different continents: USA and Europe.

### Material and Methods

We collected data from medical records of early BC patients treated with curative intent at the Florence University Hospital (FUH; Italy) and at the University of North Carolina (UNC; USA) seen between November 2014 and December 2015. Data included demographics, stage, BC subtype, treatment received, referral to supportive services (SP), and use of mood/anxiety lytic and sleep medications (meds). Patients with inoperable or metastatic disease, known psychiatric disorder, or recurrent/synchronous cancer were excluded from this study. The use of SP and meds were compared between the two cohorts using Wilcoxon, Fisher's exact, and Jonckheere-Terpstra tests. Adjusted relative risks (RR) were estimated using Poisson regression.

### Results

In patients treated at FUH (n=110), rate of SP referral and use of meds was not significantly influenced by adjuvant or primary systemic therapy (PST), type of surgery (mastectomy versus conservative surgery), regional nodal irradiation (RNI) or use of boost, T or N stage. Patients treated at UNC (n=121) who received mastectomy had higher rates of SP vs BCT (62% vs 35%) p=0.02). The use of meds was significantly higher in patients who received adjuvant chemotherapy and RNI. Both SP referral and use of meds were significantly associated with increasing T stage (p=0.03 and p=0.003, respectively) and N stage (p=0.03 and p=0.0004, respectively). Younger UNC patients (age <60 years) had a significantly higher rate of meds use (55% vs 33%, p=0.02). UNC patients had a significantly higher rate of SP referral (41% vs 29%, p=0.003), meds (44% vs 18%, p<0.0001), PST (p=0.03), mastectomy (p=0.002), RNI (<0.0001), and tumor bed boost administration (p=0.03) compared to FUH. After adjusting for age, subtype, T stage, surgery, and PST: UNC patients remained significantly more likely to refer to SP (RR=1.7) and to receive meds (RR=2.4).

	UNC n=121 (%)	FUH n=110 (%)	p-value
Mean age	59 (20-82)	61(60-86)	0.42
Patients younger than 60	58 (48%)	55 (50%)	0.8
Preoperative chemotherapy	23 (19%)	10 (9%)	0.03
Mastectomy	21 (17%)	5 (4.5%)	0.002
Postoperative chemotherapy	52 (43%)	33 (30%)	0.14
Regional nodal irradiation	43 (35.5%)	7 (6%)	<0.0001
Radiation therapy boost	113 (93%)	93 (84.5%)	0.03
SP referral	49 (40.5%)	24 (22%)	0.002
Psychotropic medications	53 (44%)	20 (18%)	<0.0001

**Conclusion**

The rate of SP referral and the use of meds were higher in USA cohort versus the cohort from south of Europe. The reasons for these differences might be related to social and cultural differences, rather than availability of medications.

**EP-1149 Omission of completion axillary lymph node dissection in patients underrepresented in ACOSOG Z11**

B. Gebhardt<sup>1</sup>, Z. Horne<sup>1</sup>, G. Ahrendt<sup>2</sup>, E. Diego<sup>2</sup>, S. Berwal<sup>1</sup>

<sup>1</sup>University of Pittsburgh Cancer Institute, Radiation Oncology, Pittsburgh, USA

<sup>2</sup>University of Pittsburgh Cancer Institute, Surgical Oncology, Pittsburgh, USA

**Purpose or Objective**

ACOSOG Z0011 demonstrated that axillary lymph node dissection (ALND) can be omitted in patients (pts) managed with breast conserving surgery (BCS) and 1-2 positive sentinel nodes (SLN) without adverse effects on loco-regional control (LRC) or survival. Adjuvant radiotherapy (RT) fields in this trial were heterogeneous and included high tangents in half of pts and a 3<sup>rd</sup> nodal-directed field in one-third of pts. Most pts enrolled in Z11 were post-menopausal with hormone receptor positive breast cancer and axillary micrometastases. We investigated breast cancer pts with clinicopathologic features underrepresented Z11 and analyzed RT patterns and clinical outcomes.

**Material and Methods**

We retrospectively reviewed the records of pts who underwent BCS with positive SLNs but not undergoing ALND and who completed adjuvant RT. Eligible patients had T3 tumors, >2 positive SLNs, invasive lobular carcinoma, triple negative receptor status, extracapsular extension (ECE), positive surgical margins, Nottingham Grade 3, or age <50 years. Binary logistic regression was used to examine association of pt characteristics with delivered RT fields. Disease-free survival (DFS) and LRC were assessed using the Kaplan-Meier method and log-rank test for association with risk factors.

**Results**

We identified 106 pts treated from July 2011 to July 2016. The median follow-up among living pts was 28 (range, 1-62) months. Nineteen (17.9%) pts were treated with whole-breast irradiation only, and 87 (82.1%) were treated with modified tangential fields covering axillary level I/II. Thirty-four (32.1%) pts received comprehensive nodal RT including a 3<sup>rd</sup> supraclavicular (SCV) field. Fifty-two (49.1%) pts received adjuvant chemotherapy. There were 43 (41%) pts with ECE and 43 (41%) with Grade 3 disease. Complete patient characteristics are included in Table 1. There were trends toward significance with use of a 3<sup>rd</sup> SCV field and pN1a disease (p=0.062), increased tumor size (p=0.062), and positive ECE (p=0.077). The overall rates of 2-year DFS and LRC were 95.1% and 98.9%, respectively. One patient experienced an internal mammary nodal recurrence, 1 contralateral breast tumor, and 2 distant metastases. There were no axillary or ipsilateral breast tumor recurrences. Factors associated with decreased DFS on univariate analysis include Grade 3 disease (p=0.021) and use of a SCV field (p=0.008).

96	96	96.0	99	99	99.0
97	97	97.0	100	100	100.0

**Conclusion**

This retrospective analysis of pts undergoing BCS and SLN biopsy with positive SLNs included pts who were underrepresented or excluded from the Z11 trial yet demonstrated comparable rates of LRC and DFS. Nottingham Grade 3 disease and use of a 3<sup>rd</sup> SCV field were associated with decreased DFS, though the apparent detrimental effect of SCV treatment was likely due to greater adverse risk factors causing pts to be selected for more intensive treatment. The high rates of LRC and DFS suggest that completion ALND may be safely omitted in this patient population, though prospective data is needed to confirm this finding.

**EP-1150 Preliminary results of Intra-Operative RadioTherapy in old women with good prognostic features**

S. Guillermin<sup>1</sup>, E. Boursstyn<sup>2</sup>, R. Itti<sup>1</sup>, I. Fumagalli<sup>1</sup>, V. Martin<sup>1</sup>, L. Cahen-Doidy<sup>2</sup>, L. Quero<sup>1</sup>, S. Giacchetti<sup>2</sup>, C. Cuvier<sup>2</sup>, M. Espié<sup>2</sup>, C. Hennequin<sup>1</sup>

<sup>1</sup>Hôpital Saint-Louis, Department of Radiation Oncology, Paris, France

<sup>2</sup>Hôpital Saint-Louis, Breast Cancer Unit, Paris, France

**Purpose or Objective**

In women > 65 yrs with good prognostic features (Isolated tumour <3 cm, infiltrative ductal carcinoma (IDC), presence of Estrogen Receptors ER+, pN0), adjuvant RT increases the local control but do not improve overall survival<sup>1</sup>. One possible alternative is to perform RT during surgery to minimize patient's travels and cost.

<sup>1</sup> Hughes, JCO 2013; 31:2382-2387; Kunkler, Lancet Oncol 2015; 16: 266-73

**Material and Methods**

we reviewed our experience with Intra-Operative RadioTherapy (IORT) for this population. All patients had histologically confirmed breast cancer before surgery and were judged eligible for IORT (Isolated IDC less than 3 cm, ER+). Surgery consisted in sentinel lymph node dissection (SNLD) with intraoperative touch imprint cytology and lumpectomy. IORT was performed only in case of negative SLND. It consisted in a radiation dose of 20 Gy delivered with 50 kV photons (Intrabeam®, Zeiss).

**Results**

Between October 2012 and February 2015, 76 pts with pre-operative good prognostic features were planned to have IORT. Seven pts did not have it (positive SNLD: 4pts; multifocality: 3pts). For the remaining 69 pts, characteristics were: mean age: 78yrs [67-96]; mean pT size: 15 mm [3-30]; OMS performance status 0-1: 65pts (94%); Charlson Age-Comorbidity Index: Mean: 4.5 [2-9]. Mean duration of hospitalization was 2.5 days [0-6]. Grade 2 post-operative complications occurred in 19 pts (27%): Abscess: 3pts; Hematoma: 3pts; Seroma: 2pts; Radiation epithelitis: 10pts. Delay in healing was observed in 6 pts. Adjuvant external beam RT after IORT was performed in 3 pts (SNLD+: 2pts; positive margins: 1pt). Hormonal treatment was prescribed in 53 pts (77%). Minimal and mean follow-up were 1 yr and 2 yr, respectively. No local relapse occurred. Two pts died of intercurrent disease. Cosmetic result was assessed in 60pts: excellent: 30pts; good: 28pts; poor: 2pts. Cytosteatonecrosis and cutaneous pigmentation were observed in 7 and 6 pts, respectively.

**Conclusion**

IORT in old women is feasible without increasing the rate of post-operative complications. Preliminary results are excellent in terms of local control and cosmesis.

### EP-1151 Hypofractionated Radiotherapy in breast cancer treatment: A comparison between 3-DCRT and IMRT

A. Fiorentino<sup>1</sup>, R. Mazzola<sup>1</sup>, N. Gij Levra<sup>1</sup>, G. Sicignano<sup>1</sup>, G. Di Paola<sup>1</sup>, S. Naccarato<sup>1</sup>, S. Fersino<sup>1</sup>, U. Tebano<sup>1</sup>, F. Ricchetti<sup>1</sup>, R. Ruggieri<sup>1</sup>, F. Alongi<sup>1</sup>

<sup>1</sup>Sacro Cuore Don Calabria Hospital, Radiation Oncology Department, Negrar, Italy

#### Purpose or Objective

to compare 3-Dimensional Conformal RadioTherapy (3D-CRT) and 4-fields Intensity Modulated RadiationTherapy (IMRT) treatment plans, in terms of target dose coverage, integral dose and dose to Organs at risk (OARs) in early breast cancer (BC) hypofractionated RT.

#### Material and Methods

Twenty consecutive patients with early BC, after lumpectomy, were selected for the present analysis. A total dose of 40.5Gy in 15 fractions was prescribed to Planning Target Volume (PTV<sub>breast</sub>) of the whole breast, while a simultaneous total dose of 48Gy was prescribed to the PTV of the surgical bed (PTV<sub>boost</sub>). For each patient both a 3D-CRT plan with two couples of tangential-fields, and a 4-fields sliding-window IMRT plan were generated. Conformity and homogeneity indexes (CI, HI) were calculated for PTVs. For evaluation of OARs and normal tissue (NT), V<sub>5Gy</sub>, V<sub>10Gy</sub> and various organ specific V<sub>xGy</sub> values were analyzed.

#### Results

In terms of HI, IMRT (0.18 ± 0.02) was superior to 3D-CRT (0.23 ± 0.02) for the PTV<sub>breast</sub> (p<0.0001). Both techniques achieved the required dose for the PTV<sub>boost</sub> coverage, but a significant difference for CI was observed in favour of IMRT (0.9 ± 0.4) compared to 3D-CRT (3.7 ± 4.3) (p<0.0001). With regards to the heart, IMRT improved both mean and near-maximum doses. The inter-patients average of the heart D<sub>mean</sub> was (1.9 ± 1) Gy for 3D-CRT, and (1 ± 0.8) Gy for IMRT (p < 0.0001). For the analysis of left BC, the inter-patients average of the heart D<sub>mean</sub> was (2.9 ± 0.8) Gy for 3D-CRT, and (1.7 ± 0.6) Gy for IMRT (p = 0.0005). For the ipsilateral lung, the average of D<sub>mean</sub> for overall patients was 6.3 ± 1.4 Gy with 3D-CRT, and 4.8 ± 1.3 Gy with IMRT (p<0.0001). The V<sub>25Gy</sub> value of the ipsilateral lung was also lower with the use of IMRT (p<0.0001). For the contralateral lung, the inter-patients median of D<sub>mean</sub> to the contralateral lung was 0.4Gy for 3D-CRT and 0.08Gy for IMRT (p<0.0001). For the contralateral breast, both D<sub>mean</sub> and D<sub>2%</sub> were improved by the use of an IMRT planning technique. The inter-patients average of D<sub>mean</sub> was (0.3 ± 0.3) Gy for IMRT, while (1 ± 0.5) Gy for 3D-CRT (p < 0.0001). For NT, all DVH parameters are in favor of IMRT, except the V<sub>5Gy</sub> for which the difference was not statistically significant. The mean value of D<sub>mean</sub> was 2.2 ± 0.6 for 3D-CRT and 1.5 ± 0.4 for IMRT (p < 0.0001).

#### Conclusion

IMRT technique significantly reduced the dose to OARs and NT, with a better target coverage compared to 3D-CRT. Clinical evaluations are advocated.

<sup>5</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Radiotherapy Unit, Campobasso, Italy

<sup>6</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Medical Physics Unit, Campobasso, Italy

#### Purpose or Objective

Single-dose intraoperative radiotherapy (IORT) is an alternative treatment for selected cases of early stage breast cancer. The purpose of this study is to present preliminary results of patients treated with IORT at Bellaria Hospital, Bologna, Italy

#### Material and Methods

We analysed data of 108 women who underwent lumpectomy and IORT with primary intent. IORT treatment was performed with a dedicated mobile electron accelerator (21 Gy were prescribed at 90% isodose). Data collected were histopathology, adjuvant treatment, clinical tolerability, local recurrences and outcomes.

#### Results

From December 2011 to December 2015, 108 women (median age 72 years) were treated with IORT. 75% of patients were treated with adjuvant ormonotherapy and 11.1% with combined chemotherapy plus hormonotherapy. The median follow-up was 26 months (range 2-52). 82.4% of patients had disease that was <2 cm in size, 65.7% of patients had an infiltrative duct carcinoma. At the end of follow-up 89.9% had a G0-G2 grade of late parenchymal fibrosis and 69.4% of patients a good cosmetic result. One patient underwent a mastectomy after five months because of chronic fistula in the irradiated area. One patient had a local relapse in a different quadrant and one patient had an axillary lymph node recurrence. Only one patient developed systemic metastasis. One patient died from breast progressive disease.

#### Conclusion

IORT represents a safe and effective alternative treatment option in selected patients with early breast cancer. Low complication rate with good clinical and cosmetic outcomes support IORT as a treatment option for selected women.

### EP-1153 Post-Mastectomy Hypofractionated Radiotherapy for Breast Cancer Treatment

C.S. Ortiz Arce<sup>1</sup>, A. Chagoya González<sup>2</sup>, E.N. Barrientos Luna<sup>2</sup>

<sup>1</sup>Hospital Regional de Alta Especialidad Bajío, Radiotherapy, León, Mexico

<sup>2</sup>Centro Médico Nacional Siglo XXI- IMSS, Radiotherapy, Mexico City, Mexico

#### Purpose or Objective

Radiotherapy (RT) for Breast Cancer improves local control and provides benefit in overall survival; this is given mainly in daily fractions (Fx) over a period of 5-6 weeks.

Hypofractionated schedules reduce the number of sessions, shortening the treatment time. Many studies reported local recurrence in patients treated with breast-conserving surgery (BCS) with less than 5% in a lapse of 5 years.

However, the indication of a hypofractionated scheme after a Modified Radical Mastectomy (MRM) is not clearly established, since there is only one study with a 7-year follow-up which reported 3 patients with local recurrence. Due to the high number of patients requiring RT, we initiated this transversal and comparative study, at the Centro Médico Nacional Siglo XXI, IMSS. We compared hypofractionated and conventional schedules in order to evaluate acute toxicity and local

control, including patients treated with BCS and MRM, between November 2012 and March 2016.

#### Material and Methods

We included 560 patients: 394 were treated with MRM and 166 with BCS.

According to the radiotherapy schedule received, they were divided in 3 groups: 40Gy/15Fx, 42Gy/16Fx, and 50Gy/25Fx.

#### Results

At the end of the treatment, acute skin morbidity grade 1 was found in 57, 72 and 32% of the cases; grade 2 in 42, 27 and 64% for treatments with 40, 42 and 50 Gy, respectively, and grade 3 in 3% for a dose of 50 Gy in patients treated with MRM.

Regarding BCS, skin morbidity grade 1 was found in 48, 66 and 23% of the cases, while grade 2 in 51, 33 and 73% for treatments with 40, 42 and 50 Gy, respectively, and grade 3 in 3% of patients treated with 50 Gy (Figure 1). After the first month, morbidity was reported in 489 patients (341 MRM and 148 BCS); mainly xerosis and hyperpigmentation; subacute morbidity (at third month) was reported in 346 patients (247 of MRM group and 99 of BCS group), mainly xerosis (Table 1). In follow-up studies, radiation pneumonitis was found in seven patients treated with MRM (2.8% of the total), regardless of the schedule received; they were still asymptomatic in the last follow-up. So far, we have an average 6-month follow-up after ending RT treatment with 226 patients (136 of them were treated with MRM, and 90 with BCS), with a maximum 3-year follow-up.

In total, nine locoregional recurrences (LR) are reported, either on the chest wall, breast or the lymph node regions, while we found 14 systemic recurrences which are reported in one or more sites. Most LR were observed among patients treated with MRM, which may be associated with the patients undergoing radical treatments that generally have a more advanced clinical stage.

#### Conclusion

With these results we can conclude that it is safe to use hypofractionated treatments for patients with breast cancer treated either with MRM, with acute and subacute morbidity similar to that found in patients treated with conventional schedules, at least with a similar local control between the different schedules. It is required, however, to complete the long-term monitoring.

#### EP-1154 Changes in skin microcirculation during radiation therapy for breast cancer

E. Tesselaaar<sup>1</sup>, A.M. Flejmer<sup>2</sup>, S. Farnebo<sup>3</sup>, A. Dasu<sup>4</sup>

<sup>1</sup>Linköping University, Department of Radiation Physics and Department of Medical and Health Sciences, Linköping, Sweden

<sup>2</sup>Linköping University, Department of Oncology and Department of Clinical and Experimental Medicine, Linköping, Sweden

<sup>3</sup>Linköping University, Department of Hand and Plastic Surgery and Burns and Department of Clinical and Experimental Medicine, Linköping, Sweden

<sup>4</sup>Skandionkliniken, ---, Uppsala, Sweden

#### Purpose or Objective

The majority of breast cancer patients who receive radiation treatment are affected by acute radiation-induced skin changes that are usually assessed by subjective methods, like Radiation Therapy Oncology Group (RTOG) scoring. These methods complicate the comparison between treatments or patient groups and therefore objective and robust methods are needed to assess acute skin reactions. This study investigates the feasibility of new camera-based methods for monitoring

skin microcirculation to objectively assess and quantify acute skin reactions during radiation treatment.

#### Material and Methods

Fifteen patients undergoing adjuvant radiation therapy for breast cancer were included in the study. The patients received 42.56 Gy in 16 fractions using three dimensional conformal radiotherapy with tangential photon irradiation. Radiation-induced changes in microvascular perfusion and red blood cell (RBC) concentration in the skin of the patients were quantified with laser Doppler flowmetry, laser speckle contrast imaging and polarized light spectroscopy imaging. Measurements were made before treatment, once a week during treatment and directly after the last fraction. Changes in measured values were analysed with two-way analyses of variance with Dunnett's correction for multiple comparisons.

#### Results

Perfusion (Figure 1) and RBC concentration (Figure 2) were increased in the treated breast after 1-5 fractions, with largest effects in the areola and the medial area. No changes in perfusion and RBC concentration were seen in the untreated breast. In contrast, RTOG scores were increased above 0.5 only after two weeks of treatment. Correlations have also been found between perfusion ( $r=0.52$ ) and RBC concentration ( $r=0.59$ ) measurements performed during current week and the RTOG score in the following week. Furthermore, a good correlation has been found between perfusion, as measured with LSCI, and relative RBC concentration ( $r=0.64$ ). Clinically, the results indicate that optical techniques could be used for early assessment of skin changes, with RBC concentration the better predictor.

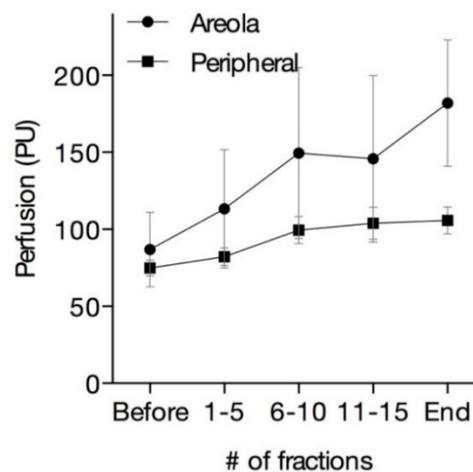

Figure 1. Variation of capillary perfusion in irradiated skin of breast cancer patients

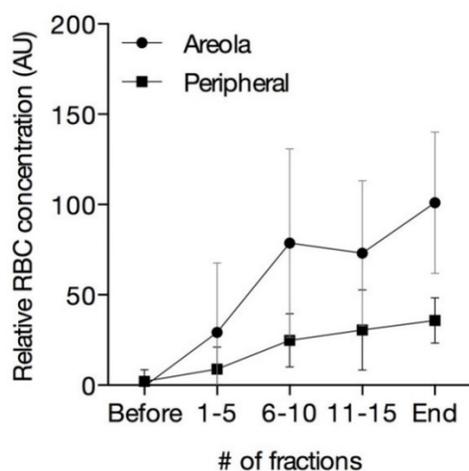

Figure 2. Variation of red blood cell concentration in irradiated skin of breast cancer patients

#### Conclusion

The results showed that radiation-induced microvascular changes in the skin can be objectively measured using novel camera-based techniques before visual changes in the skin are apparent. Also, the proposed methods may be valuable in the comparison of skin reactions between different radiation treatments.

#### EP-1155 Outcomes of breast cancer patients older than 80 years treated with adjuvant radiotherapy

#### Purpose or Objective

The main purpose was to estimate survival of patients older than 80 years, diagnosed by Stage I-III breast cancer that were treated by surgery and adjuvant radiotherapy with curative intent. Breast cancer specific survival different clinical and pathologic factors that influence survival were estimated.

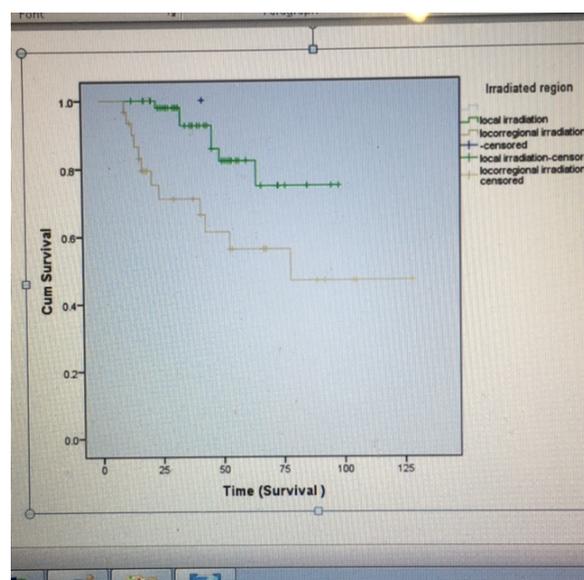

#### Material and Methods

We analyzed 85 breast cancer patients older than 80 years old that received surgery and adjuvant radiotherapy with curative intent. Overall survival was defined as the time from the date histopathological diagnosis until the last date of follow-up (official death certificate). Survival was performed by Kaplan Meier method. A log rank test was used to compare survival of different clinical and pathologic factors. Significance level was determined by (p-value <0.05).

#### Results

The median age at the time of diagnosis was 82.7 (range 77 to 88). The median follow up was 42 months. Overall survival was 70% at 5 years. Breast cancer specific survival (BCSS) was 94% at 5 years. Four patients (4.2%) died of cardiovascular disease. Fifty five patients (65%) received partial mastectomy, while 30 patients (35%) received total mastectomy (MT). Fifty four patients (63%) received whole breast or chest wall irradiation, while 31 patients (37%) received locoregional irradiation. Five patients presented cutaneous toxicity grade  $\geq 3$ . In the univariate analysis clinical preoperative nodes, clinical tumor, locoregional irradiation and pathologic tumor stage were significant for overall survival. No other examined factor was significant.

	Number of patients	Percentage(%)	Number of events	5-year survival	Log rank test (p-value)
Clinical tumor stage					
cT1	8	9	1	80	0.001
cT2	8	9	4	90	
cT3	36	42	6	68	
cT4a	28	33	4	NR	
cT4d	5	7	2	NR	
Overall	85	100	19		
Clinical Nodes					
positive	56	66	11	80	0.006
negative	29	34	8	75	
Overall	85	100	19		
Regional lymph node irradiation					
Local irradiation	53	62	7	74	0.02
Locoregional irradiation	32	38	12	56	
Overall	84	100	19		
pathologic tumor stage					
pT1	40	48	7	77	0.003
pT2	31	37	5	76	
pT3	8	9	4	38	
pT4a	2	2	2	NR	
pT4d	3	3	1	NR	
Overall	83	98	19		

#### Conclusion

Patients older than 80 treated by Stage I-III breast cancer have long survival after treatment. OS and BCSS is high at five years. Patients with locally advanced preoperative disease, pathologic tumor size and locoregional irradiation contributed negatively to survival.
