ESTRO Course Book

Multidisciplinary Management of Brain Tumours

4 - 6 October, 2015
Turin, Italy

NOTE TO THE PARTICIPANTS

The present slides are provided to you as a basis for taking notes during the course. In as many instances as practically possible, we have tried to indicate from which author these slides have been borrowed to illustrate this course.

It should be realised that the present texts can only be considered as notes for a teaching course and should not in any way be copied or circulated. They are only for personal use. Please be very strict in this, as it is the only condition under which such services can be provided to the participants of the course.

Programme

TIME	TITLE	SPEAKER
DAY 1	**SUNDAY 4-OCT- 2015**	
Introduction		
8:45	Introduction	Michael Brada
9:00	Modern imaging of CNS tumours	Ranj Bhangoo
10:00	What is new in brain tumour classification	Paola Cassoni
10:30	Coffee break / Expo	
11:00	Current surgical approaches	Ranj Bhangoo
Practical radiotherapy		
11:30	Radiotherapy –preparing the patient for treatment	Michael Brada
11:50	Radiotherapy – treatment techniques, wide field irradiation	Cristina Mantovani
12:10	Radiotherapy – treatment techniques, localised treatment	Michael Brada
12:30	Discussion	Michael Brada
13:00	Lunch / Expo	
14:00	Radiation tolerance of of the CNS	Damien Weber
14:30	Systemic therapy issues – current chemotherapy	Patrick Roth
15:00	Systemic therapy issues – novel therapies	Anthony Chalmers
15:30	Coffee break / Expo	
16:00	Debate/cases – proton therapy for CNS tumours	Damien Weber
17:00	Quality of life issues in neuro-oncology	Riccardo Soffietti

DAY 2	**MONDAY 5-OCT- 2015**	
Evidence based management of individual tumour types		
8:30	Management of grade II astrocytic tumours	Anthony Chalmers
9:00	Management of 1p;19q co-deleted tumours (oligodendrogliomas)	Patrick Roth
9:30	Management of grade III & IV astrocytomas	Anthony Chalmers
10:00	Coffee break / Expo	
10:30	Management of ependymoma of the brain and spinal cord	Damien Weber/Ranj Bhangoo
11:00	Management of cranial germ cell tumours	Umberto Ricardi
11:30	Management of CNS lymphoma	Patrick Roth
12:00	debate/cases – management of high grade glioma in the elderly	Anthony Chalmers
13:00	Lunch / Expo	
Evidence based management of individual tumour types – childhood tumours		
14:00	Management of high grade glioma and brain stem tumours	Darren Hargrave/ Umberto Ricardi
14:30	Management of medulloblastoma	Darren Hargrave/ Umberto Ricardi
15:00	Management of low grade gliomas	Darren Hargrave/ Umberto Ricardi
15:30	Coffee break / Expo	
16:00	Radiotherapy outlining / planning exercise	Cristina Mantovani/Michael Brada/Umberto Ricardi

DAY 3	TUESDAY 6-OCT- 2015	
Clinical trials and evidence based management		
8:45	Clinical trials in neuro-oncology	Anthony Chalmers/Darren Hargrave
9:45	Management of skull base tumours	Damien Weber
10:30	Coffee break / Expo	
11:00	Management of other benign intracranial tumours	Michael Brada
11:45	Management of brain metastases	Michael Brada
12:30	Debate	Michael Brada
13:00	Lunch / Expo	
14:00	Medical therapy and care of brain tumour patients	Patrick Roth
14:30	Debate – cranial reirradiation & Systemic therapy for brain metastases	Anthony Chalmers Michael Brada
15:30	Coffee break / Expo	
16:00	Radiotherapy outlining / planning exercise/case discussion	Cristina Mantovani/Michael Brada/Umberto Ricardi

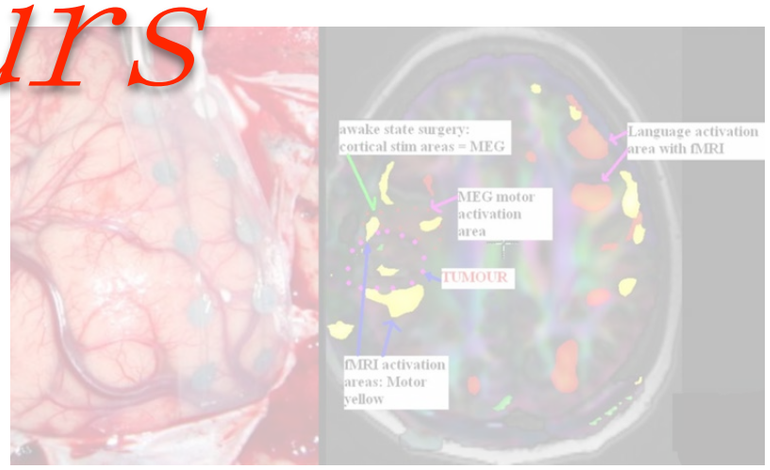
Modern Imaging of Brain Tumours



Ranj Bhangoo, *Christian Brogna*, *Francesco Vergani*

Department of Neurosurgery

King's College Hospital - London

- **CT and routine MRI protocol**
- **Anatomic Imaging**
- **Metabolic Imaging**
- **Physiological Imaging**
- **Functional Imaging**
- **Pros and Cons Imaging followup**

CT

- **CT:** acute symptomatology, first line assessment
  - to exclude: - intracranial hemorrhage
    - brain herniation
    - acute hydrocephalus

→ Urgent Neurosurgical Treatment

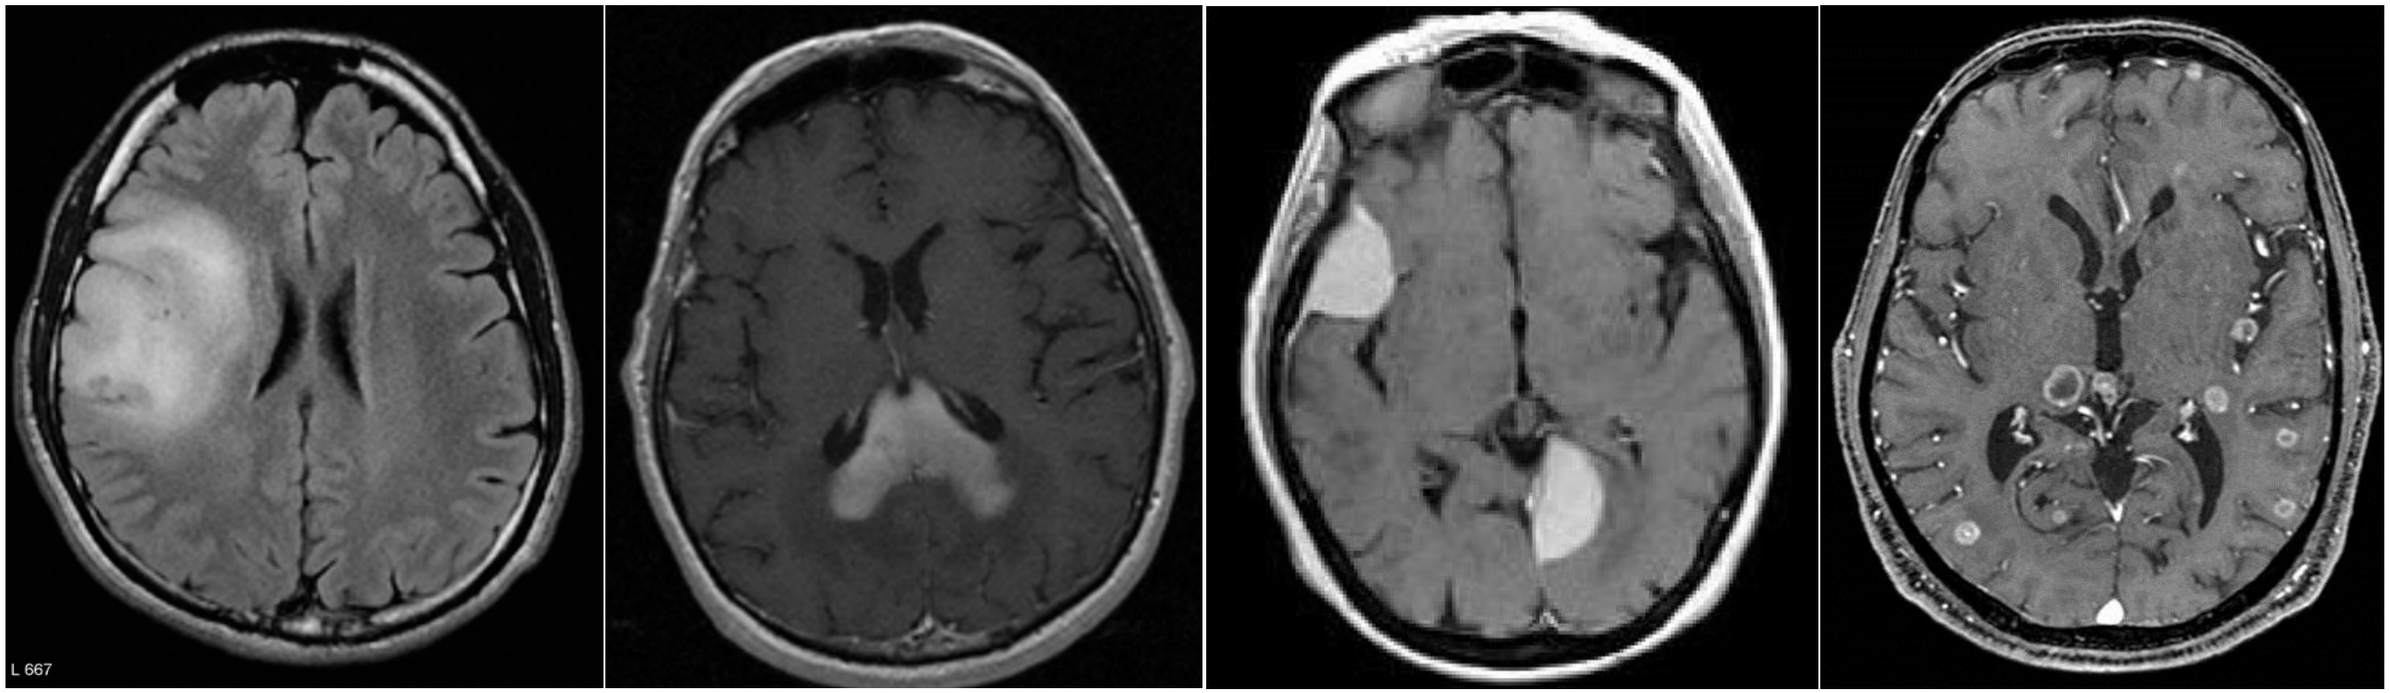
MRI ROUTINE PROTOCOL FOR BRAIN TUMOURS

- **MRI:** routine protocol

  - T1-weighted sequence before IV contrast medium
  - Axial T2 weighted
  - Axial T2 weighted FLAIR sequence (for lesions within the cortex or paraventricular - useful in low grade gliomas)
  - Axial Diffusion Weighted
  - Axial T2*-weighted sequence (sensitive to blood and calcifications)
  - Contrast enhanced T1 weighted sequences

MRI: ANATOMIC IMAGING

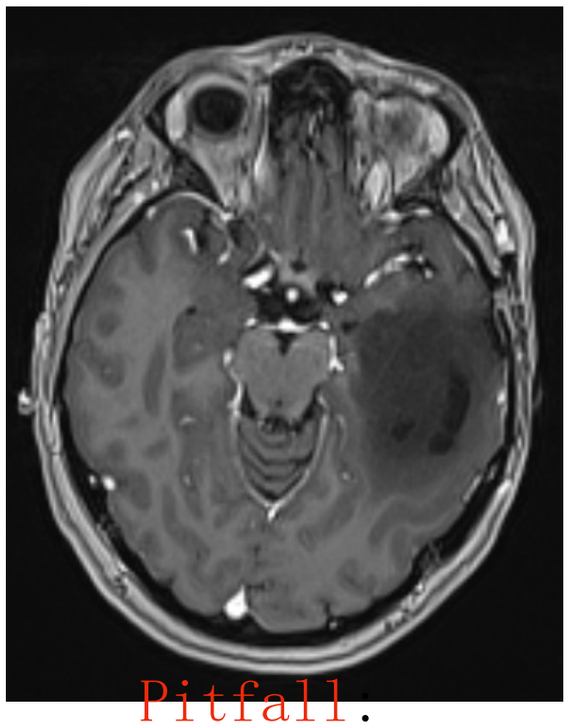
- Intraxial or extra-axial
  - Anatomical location



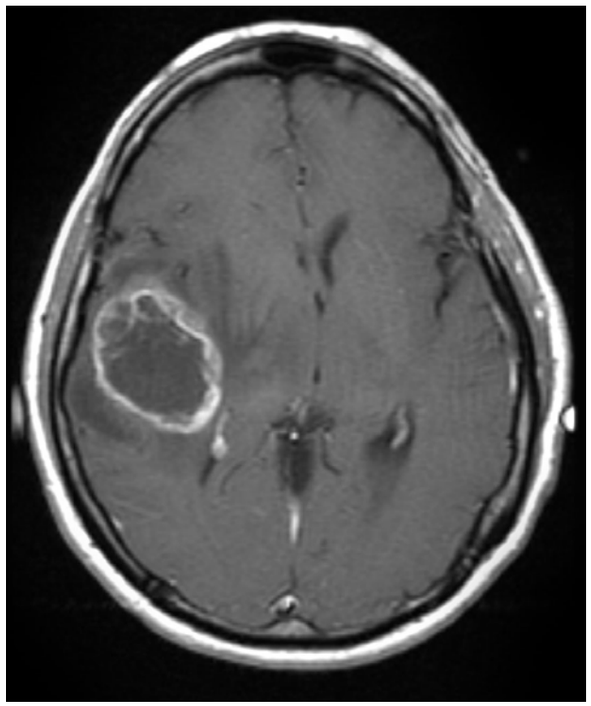
Oligodendroglioma | Lymphoma | Meningiomas | Multiple Mets

MRI: ANATOMIC IMAGING

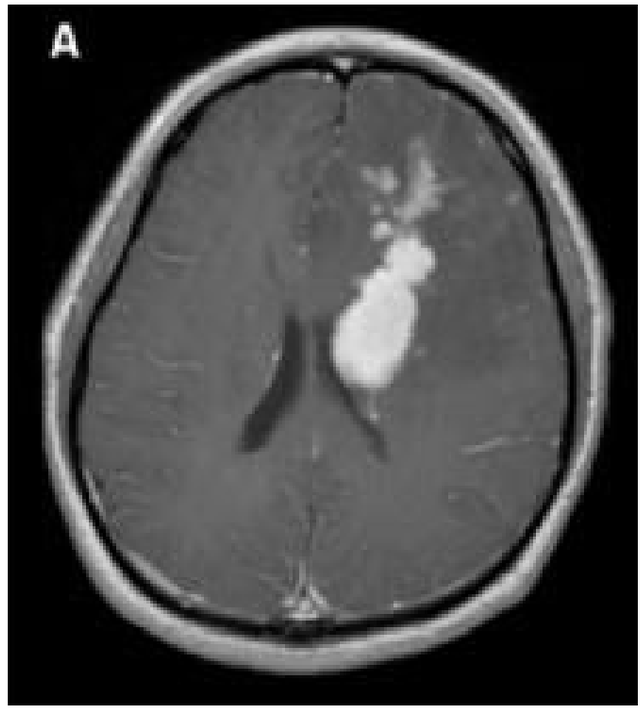
- Pattern of enhancement



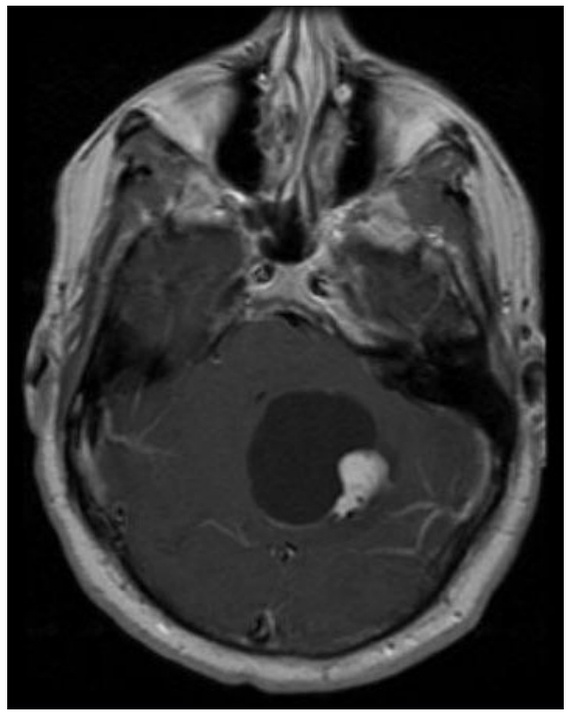
Pitfall:
Non enhancing astrocytoma grade III IDH1 negative, 1p 19q non codeleted



GBM



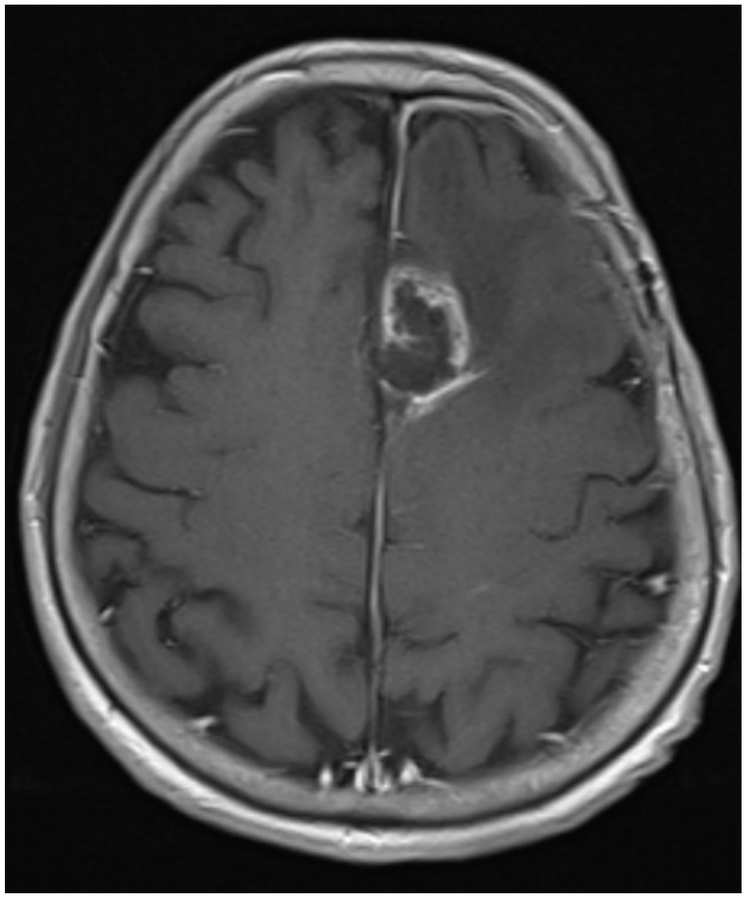
LYMPHOMA

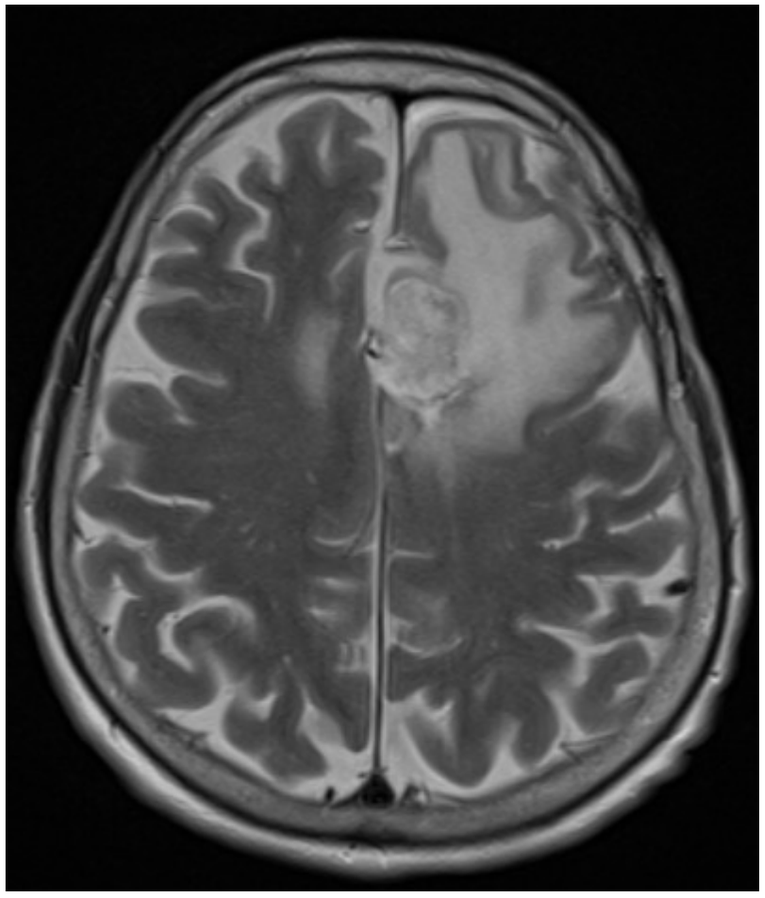


HEMANGIOBLASTOMA

MRI: ANATOMIC IMAGING
TUMOR MARGINS

Pitfall: the non enhancing signal alteration around a high grade brain tumor does not differentiate between brain edema and infiltrating tumor



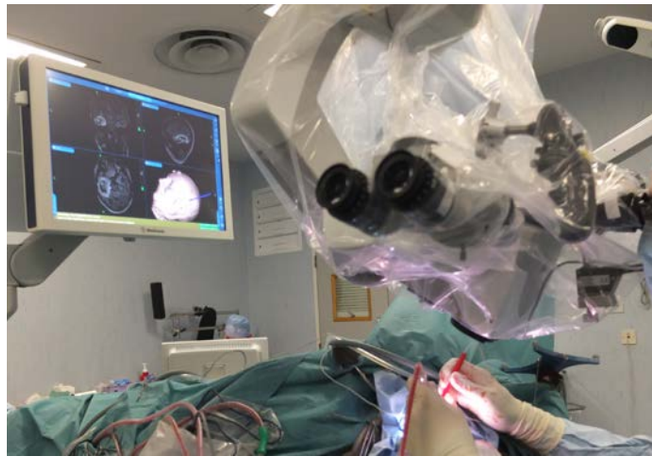


MRI: ANATOMIC IMAGING
TUMOR MIMICS

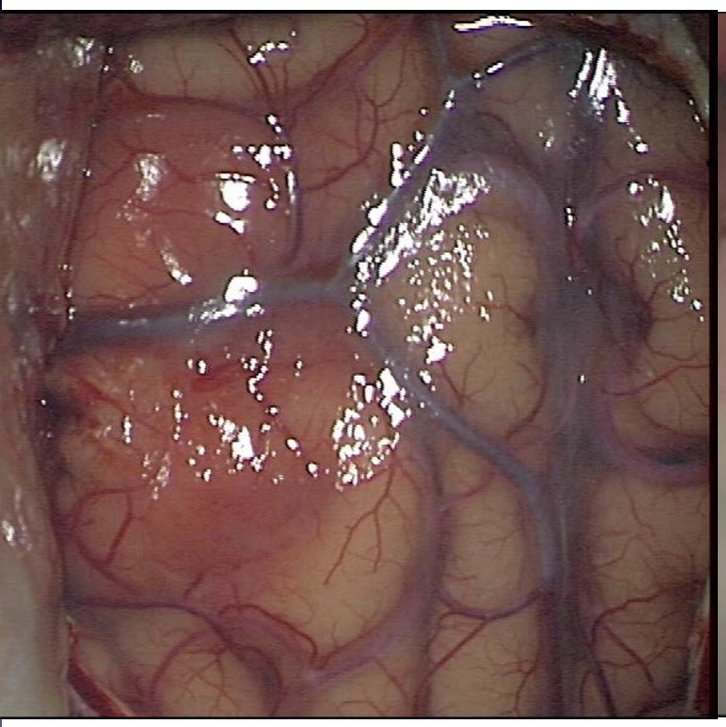
- Bacterial/fungal abscess
- Herpex simplex encephalitis
- Subacute infarction
- Tumefactive demyelination
- Sarcoidosis
- **Radiation Necrosis**

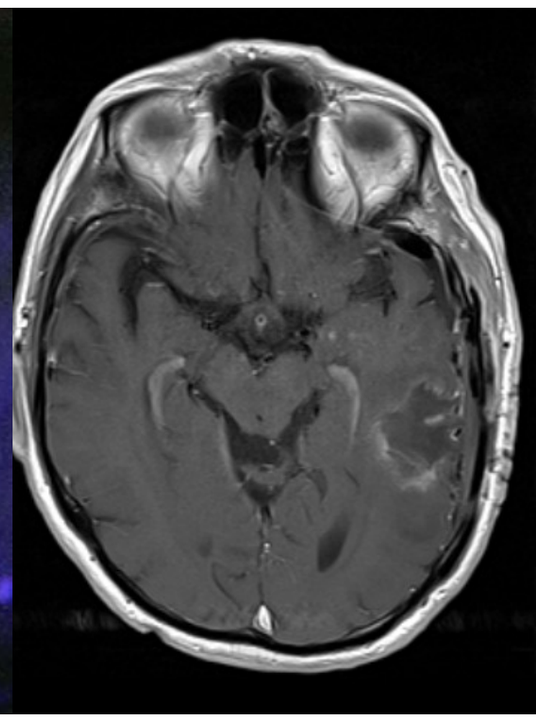
ANATOMIC IMAGING
EARLY POSTOP MRI

Enhancing granulation tissue begins to develop 3 days after surgery, persist for weeks to month, and mimics tutor



Post op imaging should be performed <u>within 48h of surgery</u>, the sooner the better

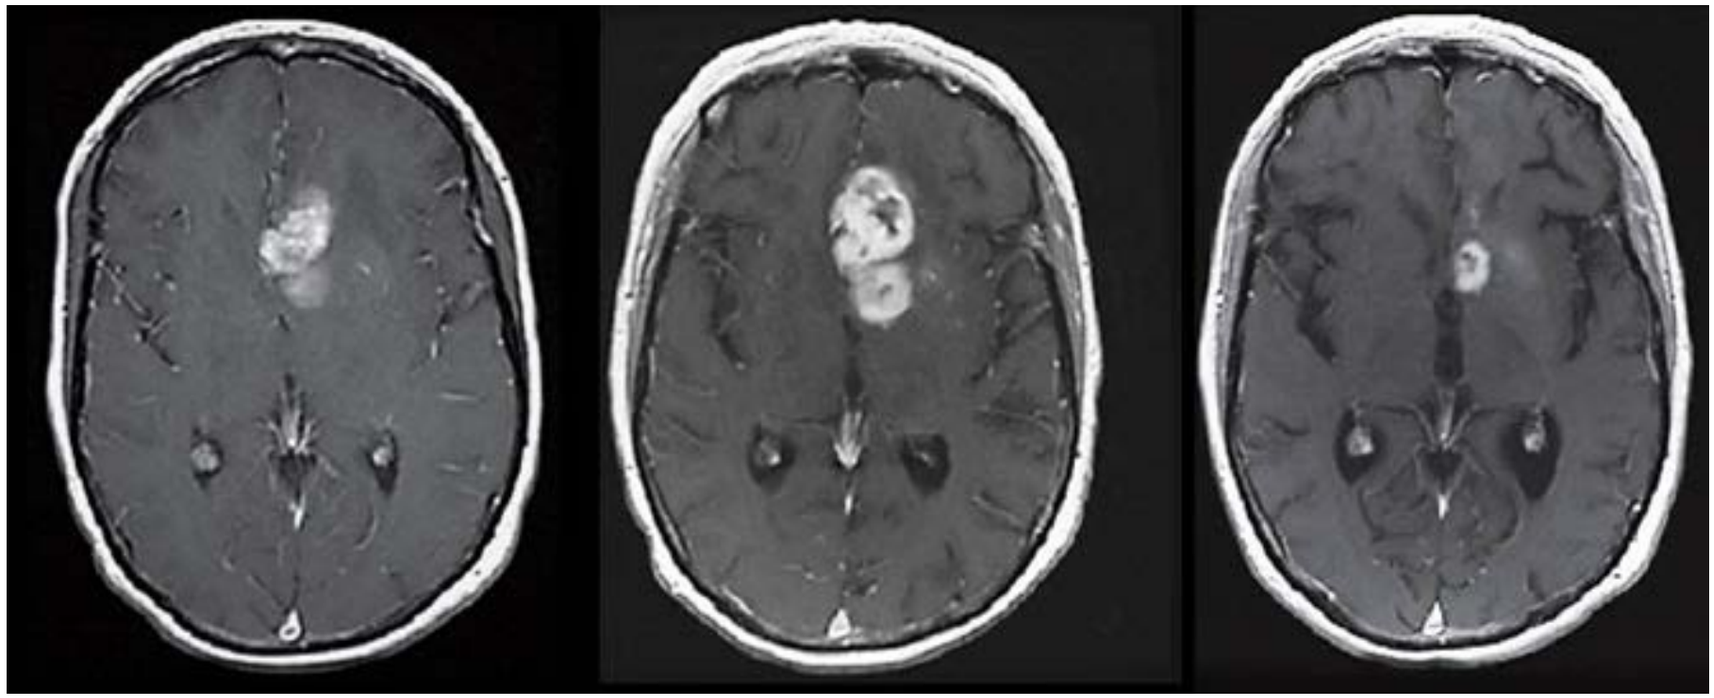




Pitfall: when comparing studies, the size and shape of a tumor can appear substantially different due to differences in the angle of imaging, slic thickness and gaps between slices

MRI: ANATOMIC IMAGING AND PSEUDO-PROGRESSION

PSEUDO-PROGRESSION is a self-limited type of treatment-related tissue injury that is common in the first 3-6 months after TMZ and radiation therapy, and mimics tumor progression, but then stabilises and decreases *(Brandsma D et al. Lancet oncol 2008)*

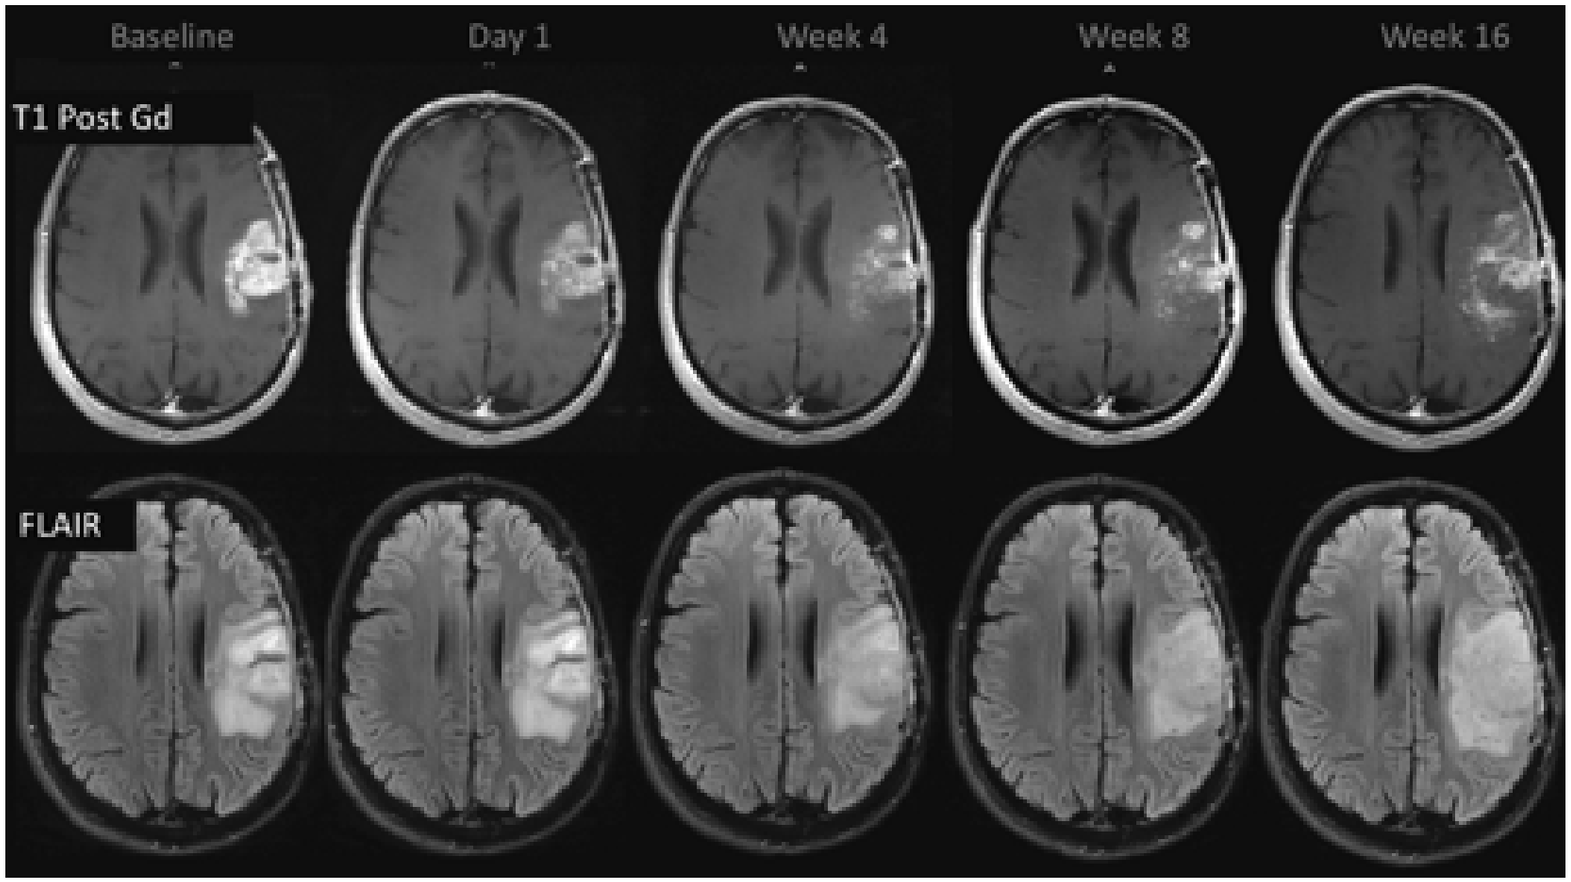


Before RT+TMZ Before adjuvant TMZ After 2 cycles adj TMZ

Differ from classic radiation necrosis, which can also mimics tumour progre
but is typically more severe and delayed in onset.

MRI: ANATOMIC IMAGING AND PSEUDO-RESPONSE

PSEUDO-RESPONSE: Angiogenetic inhibitors can cause a decrease in contrast enhancement due to reduction in blood-brain barrier permeability rather then true reduction in volume (*Clarke JL et al. Curr Neurol Neurosci Rep 2009)*

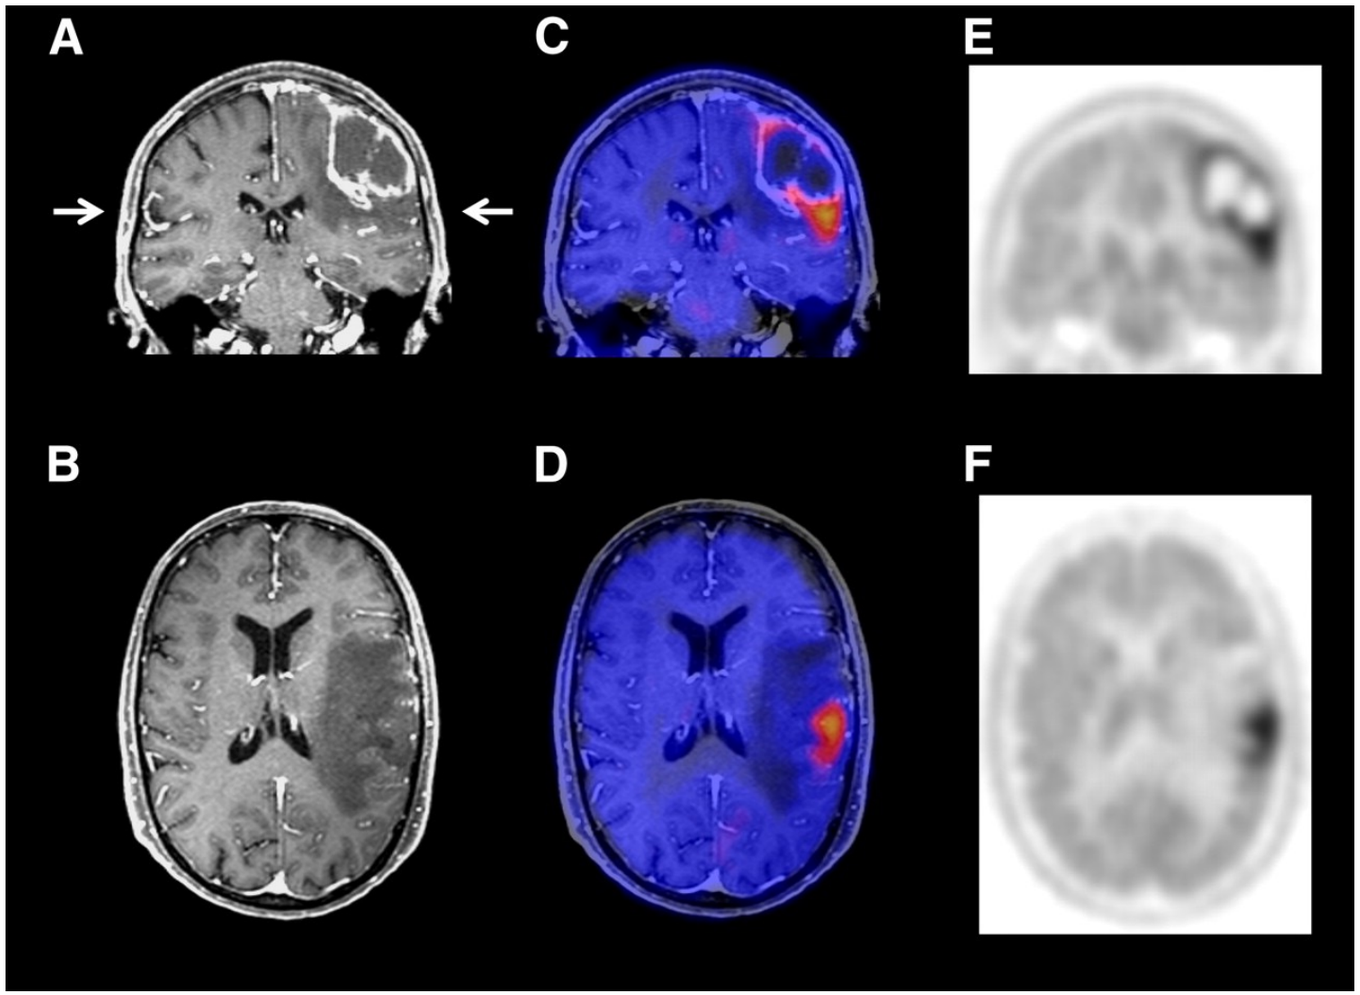


A 47-year-old man with GBM. A reduction of the enhancing portion of the lesion is observed 1 day after initiation of cediranib treatment. Four weeks later, besides a continuing reduction in the enhancing portion, an expansion is observed in the FLAIR images. Expansions in both the enhancing area and abnormal hyperintense areas consistent with tumor progression were observed subsequently (L.C. Hygino da Cruz Jr et al. AJNR 2011)

METABOLIC IMAGING

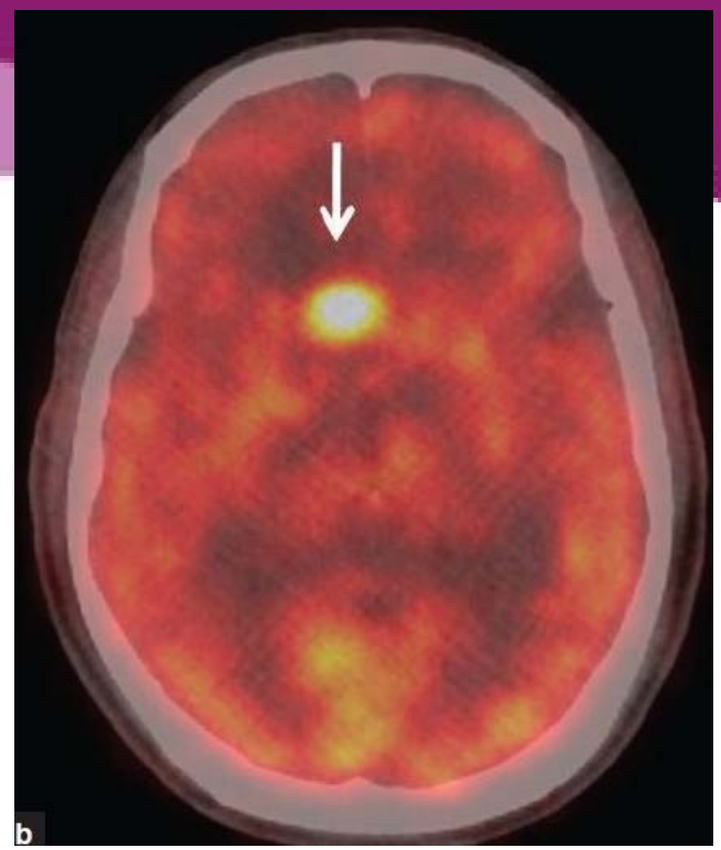
PET provides <u>metabolic in vivo measurement</u> of local tracer activity at a very high sensitivity

(Best if coupled with MRI scan)



- [(18)F]-FDG-PET
- [11C]Methionine (MET)
- [(18)F]-FLT-PET fluorothymidine

[(18)F]-FDG-PET



Pitfalls of [(18)F]-FDG-PET

- **LGG uptake is similar to normal white matter**
- **HGG uptake is similar to normal gray matter**

- **Cannot differentiate tumour vs inflammation vs acute stroke**
- **Radiation necrosis may be indistinguishable from recurrent tumour**

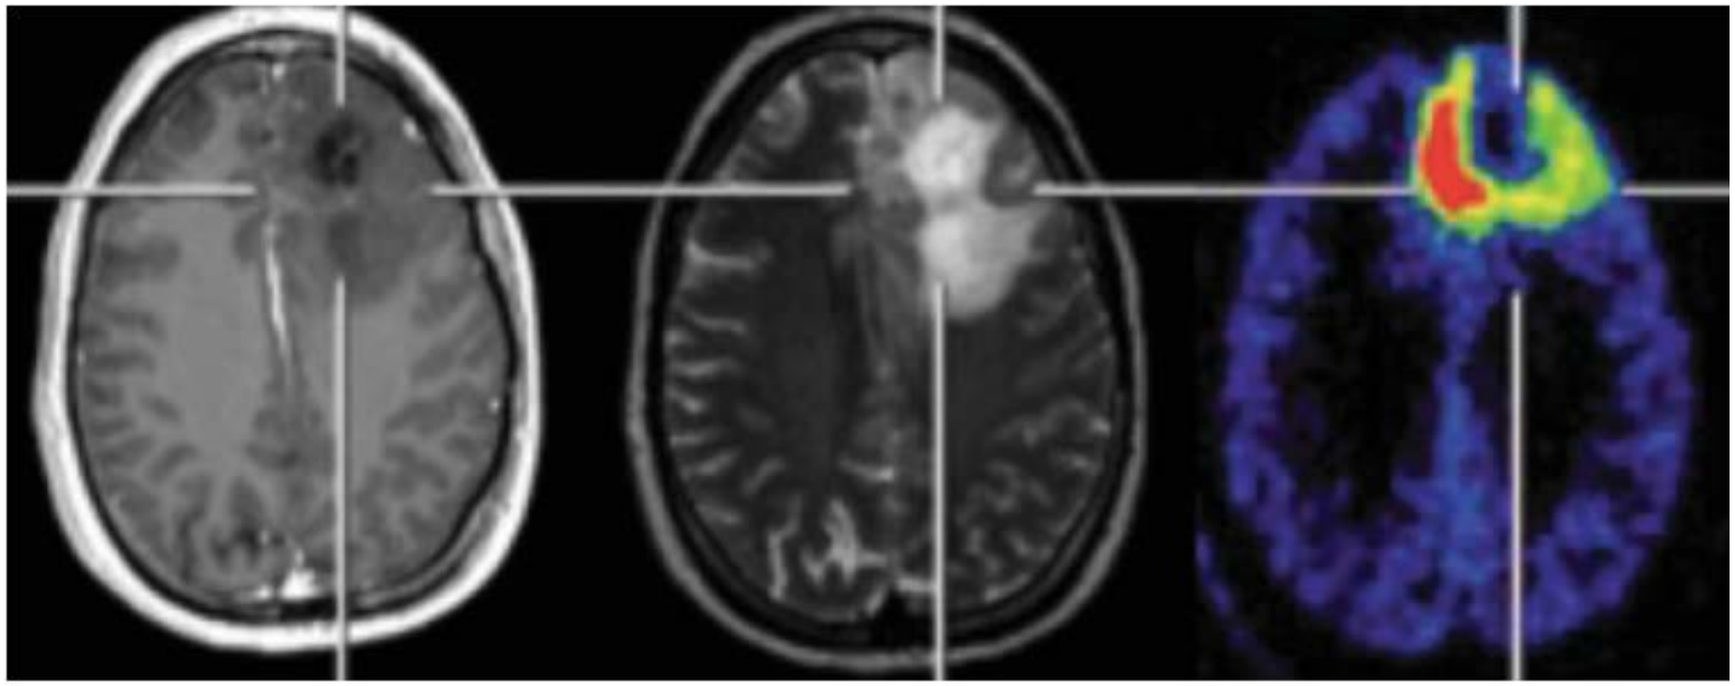
(Due to accumulation of [(18)F]-FDG in macrophages that may infiltrate the sites having received radiation therapy)

High pretreatment glucose metabolic rate is higher in responders to TMZ than non responders in patients with high grade glioma *(Brock CS. Br J Cancer 2000)*

METABOLIC IMAGING
PET [11C]Methionine (MET)

- **Marker for <u>ACTIVE TUMOR PROLIFERATION AND ANGIOGENESIS</u> (Correlates with Ki-67 expression, proliferating cell nuclear antigen expression and micro vessel density)**

- **<u>TRUE TUMOR EXTENSION?</u>** *[11C] MET uptake ratios compared with the background is favourable.*



GBM MARGINS IN PET-MET WELL BEYOND THE ENHANCING COMPONENT

METABOLIC IMAGING
PET [11C]Methionine (MET)

- **The highest uptake is observed in anaplastic oligodendrogliomas WHO grade III**
- **LGG are better detected by aminoacid tracers due to increased uptake in the absence of blood-brain barrier damage**
- **LGG: useful for differentiation from nonntumorous lesions, detection of recurrences, indication of progressing disease**
- **Can differentiate better between <u>Recurrent tumour and Radiation Necrosis</u> with high sensitivity and specificity <u>(~75%)</u>: necrosis and glioses after therapy show a reduction of ammoniated uptake in contrast to recurrent and residual tumour growth.**
- **<u>Deactivation of aminoacid transport is a early sign of response to chemotherapy</u> (Galldicks N et al Mol Imaging 2010). PET responders with a decrease of tumour brain/ratio of >10% had a significant longer TTP and OS than patient with increase tracer uptake after RT and CHT in GBM.**

PET [11C]Methionine (MET)

PITFALLS OF PET-MET

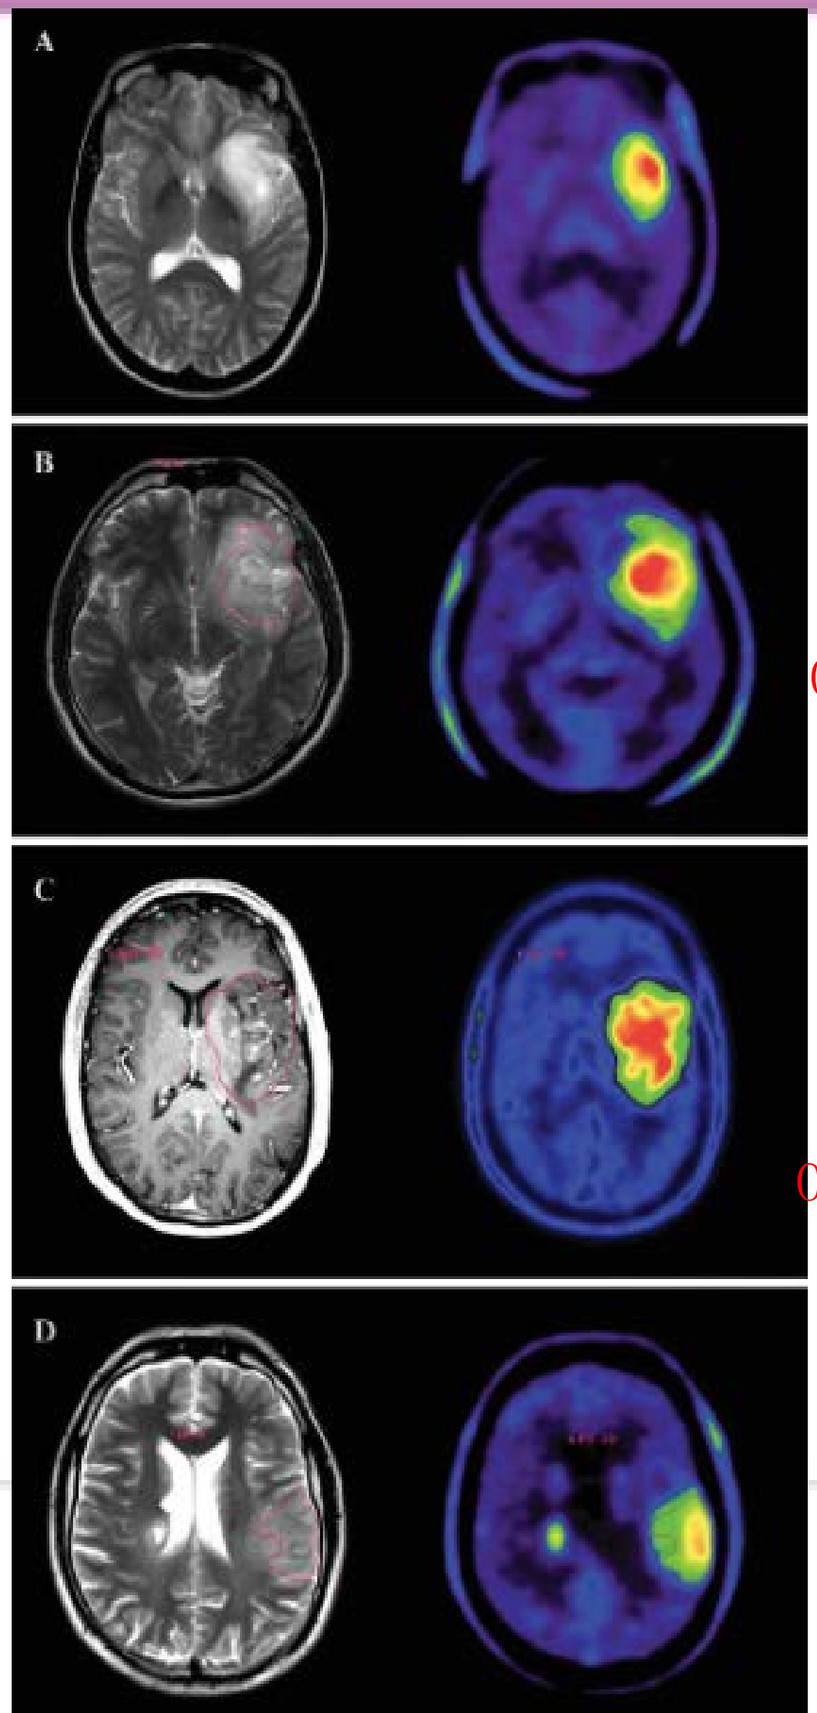
- **some low grade astrocytomas demonstrates only low tracer uptake**
- **acute inflammation or ischemic stroke might present with increased aminoacid uptake**
- **<u>NOT POSSIBLE TO PREDICT HISTOLOGICAL GRADE</u> which is paramount in treatment decision making**

IMAGING TUMOR PROLIFERATION

[(18)F]-FLT-PET *fluorothymidine*

- Uptake of FLT correlates with Thymidine kinase-1 activity expressed during DNA synthesis
- High correlation with Ki-67 expression (Yamamoto J Nucl Med 2012)
- Might be superior to MET for tumour grading
- The kinetics of FLT uptake are closely related to prognosis, early efficacy of treatment and to outcome (Wardak Clin Cancer Research 2011)

- **PITFALLS**:
  - less sensitivity than MET for low grade gliomas
  - **CANNOT PREDICT GRADE**



Astrocytoma Grade II

Oligodendroglioma Grade II

Anaplastic Oligodendroglioma Grade II

GBM Grade IV

PHYSIOLOGICAL IMAGING

- **DWI-MRI**
- **Dynamic Contrast-enhanced Perfusion MRI**
- **Spectroscopy**

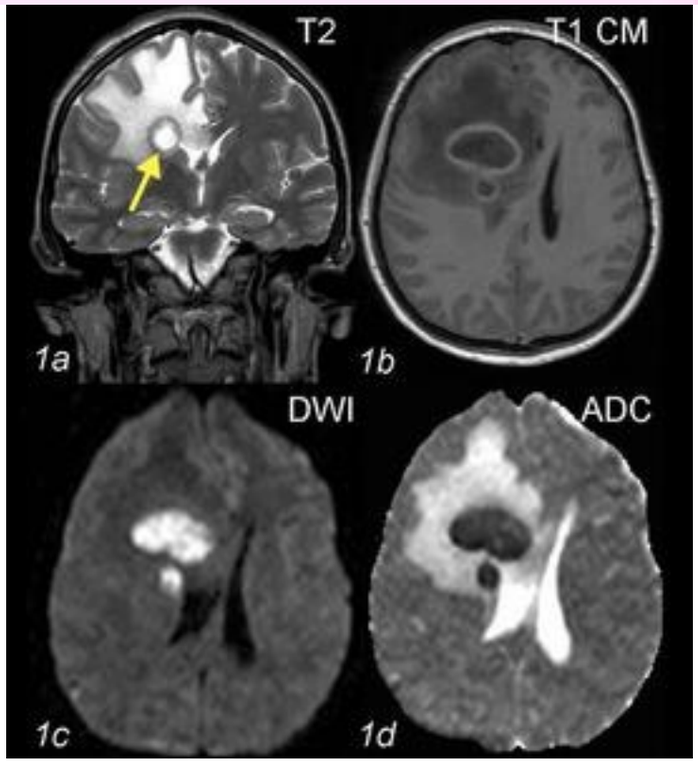
PHYSIOLOGICAL IMAGING
DWI MRI

- Differential diagnosis of cerebral abscess, epidermoid cyst, traumatic shearing injury, toxic and infectious encephalitis, immediate post brain injury

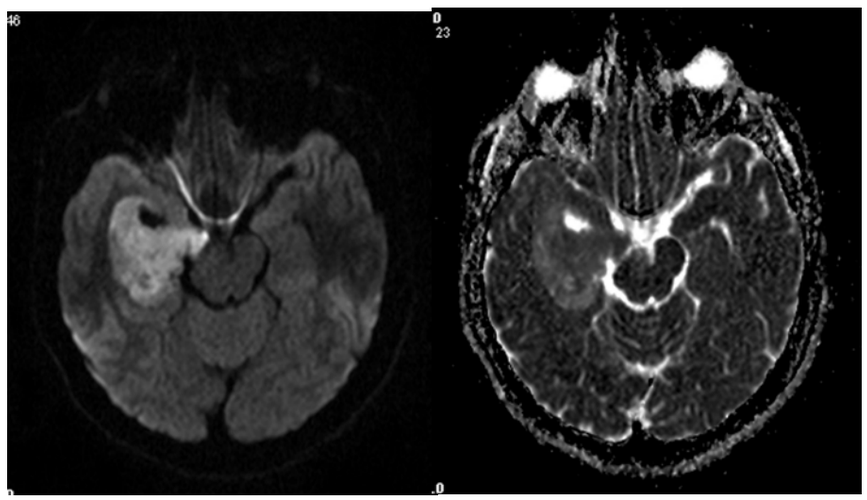
- Postoperative ischemia

- Accurate interpretation of new abnormal contrast enhancement developing soon after tumor resection

PITFALL: Para or ferromagnetic materials such as blood products or calcium within the brain can simulate pathology on DWI as well as perfusion MRI



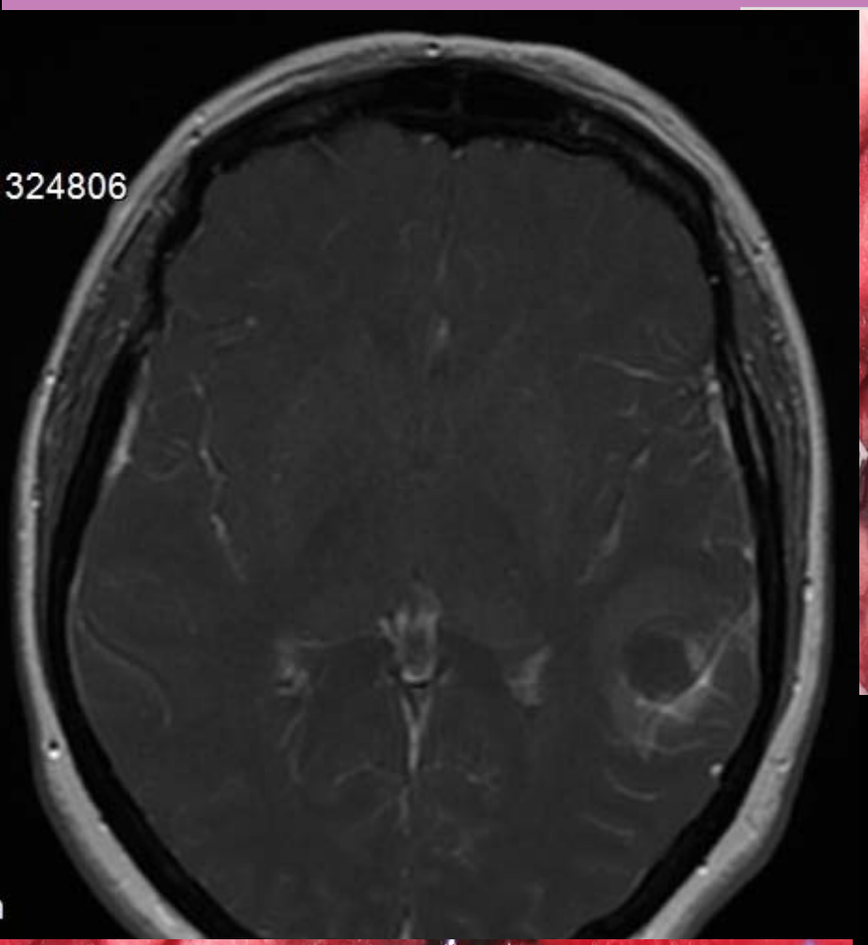
Brain abscess

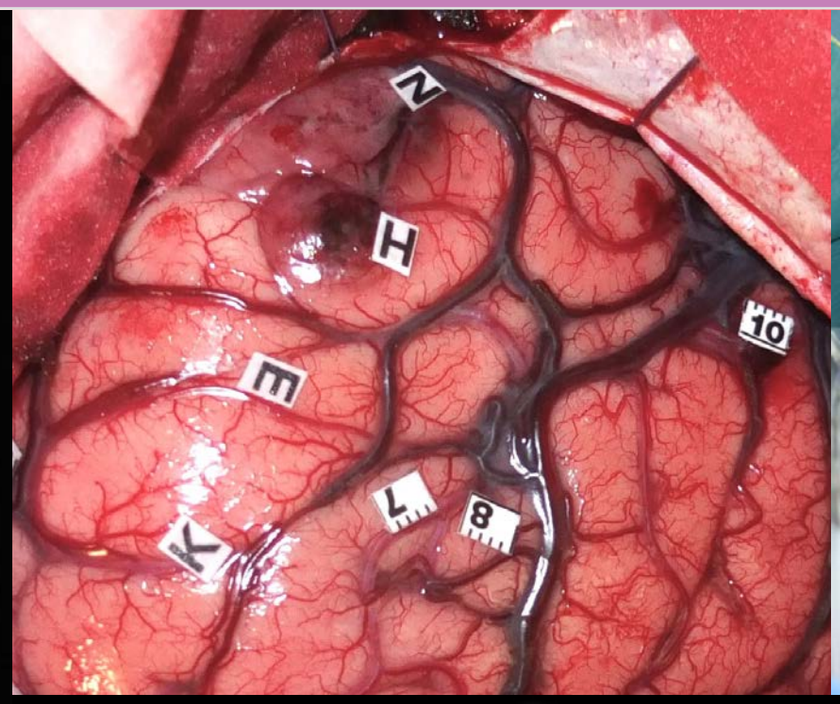


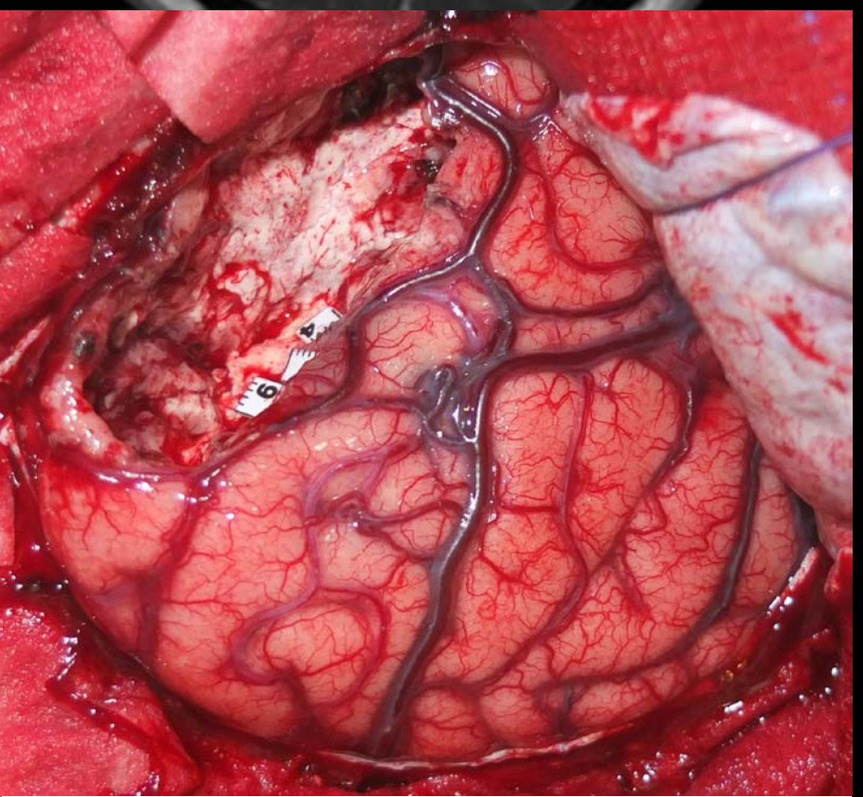
Epidermoid

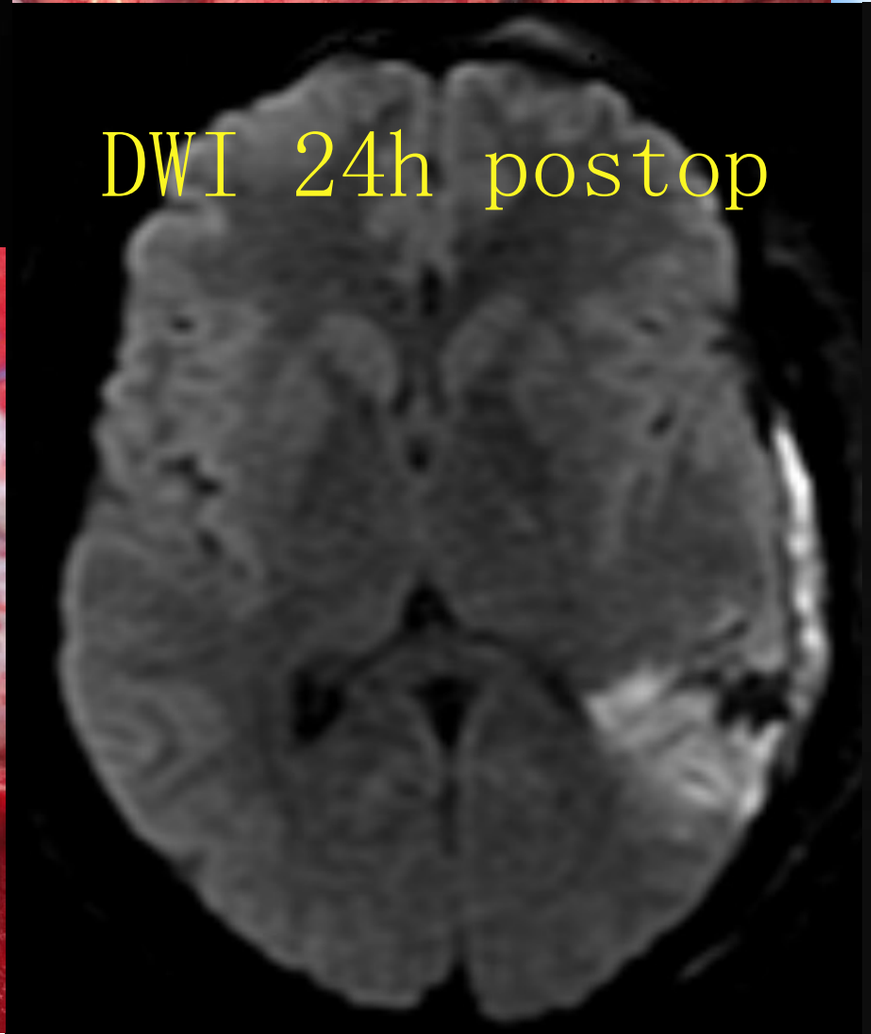
PHYSIOLOGICAL IMAGING

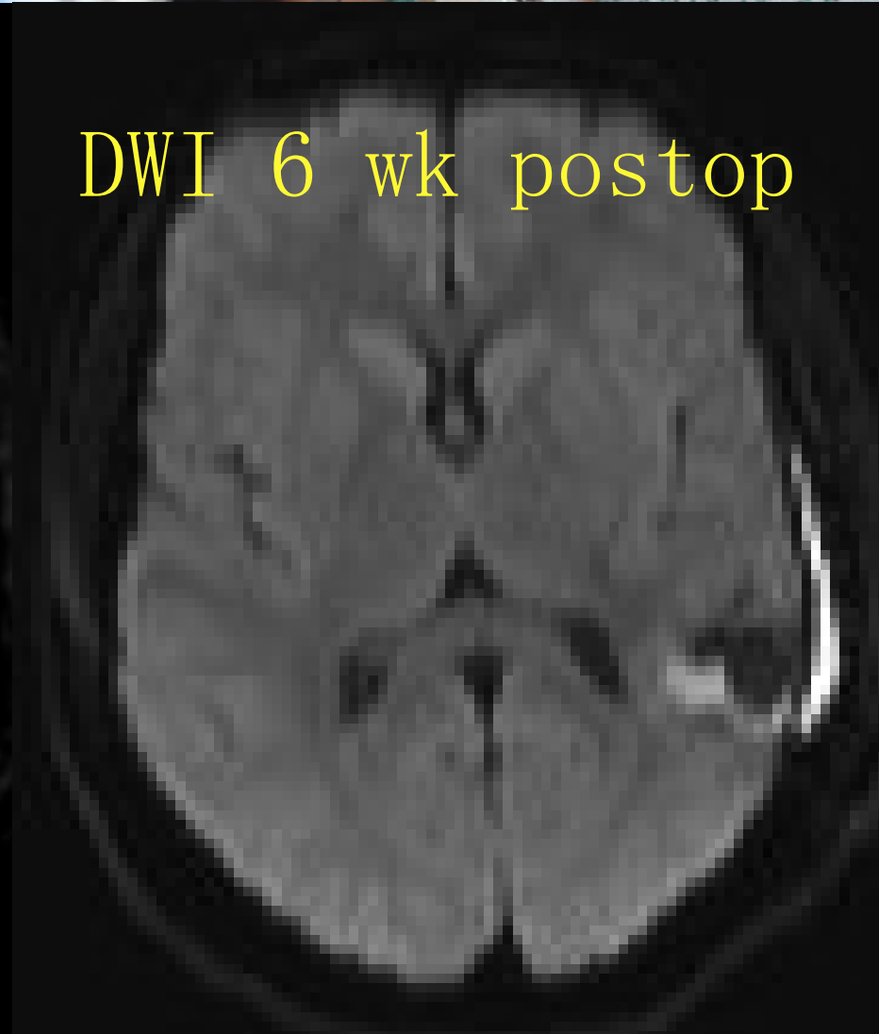
DWI- MRI







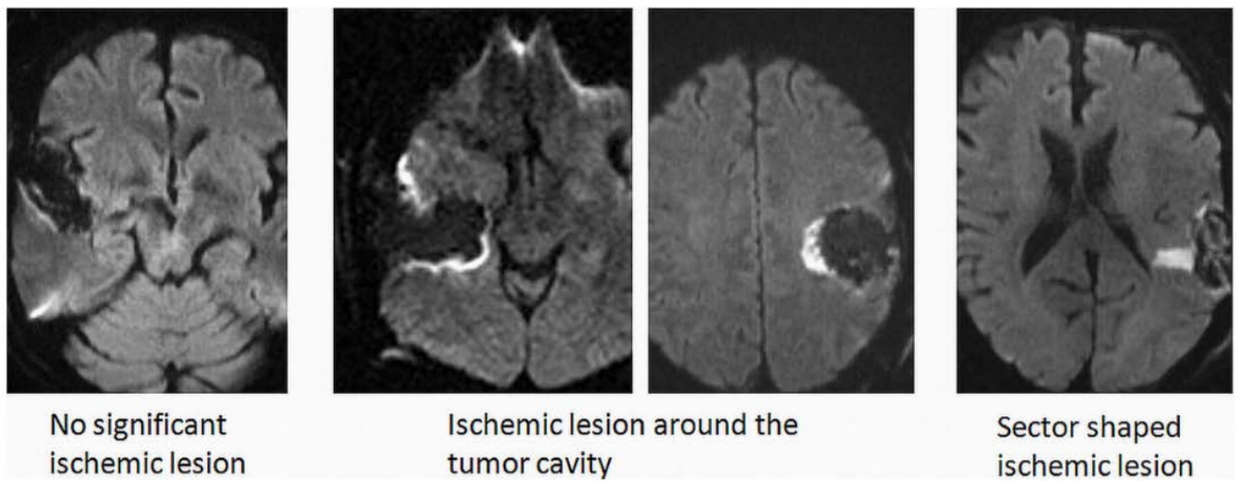




PHYSIOLOGICAL IMAGING
DWI- MRI

Surgically Acquired Deficits and Diffusion Weighted MRI Changes after Glioma Resection - A Matched Case-Control Study with Blinded Neuroradiological Assessment

Asgeir S. Jakola[1,2,3]*, Erik M. Berntsen[4,5], Pål Christensen[4], Sasha Gulati[1], Geirmund Unsgård[1,3,6], Kjell A. Kvistad[4,5], Ole Solheim[1,2,3]



No significant ischemic lesion

Ischemic lesion around the tumor cavity

Sector shaped ischemic lesion

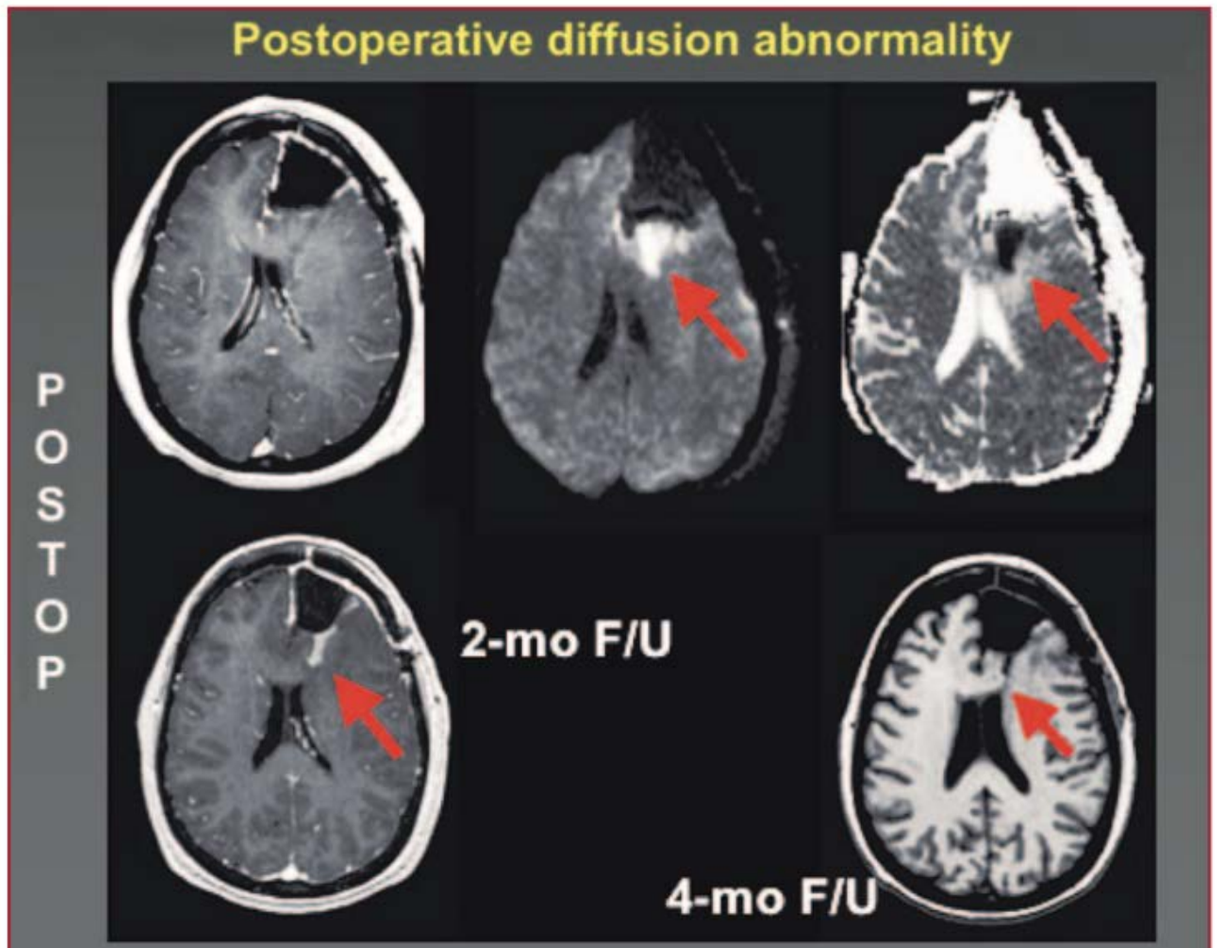


FIGURE 7. *DWI obtained 2 and 4 months postoperatively to identify areas of ischemia (bright signal DWI, dark signal void apparent diffusion coefficient) that enhances briefly postoperatively.*

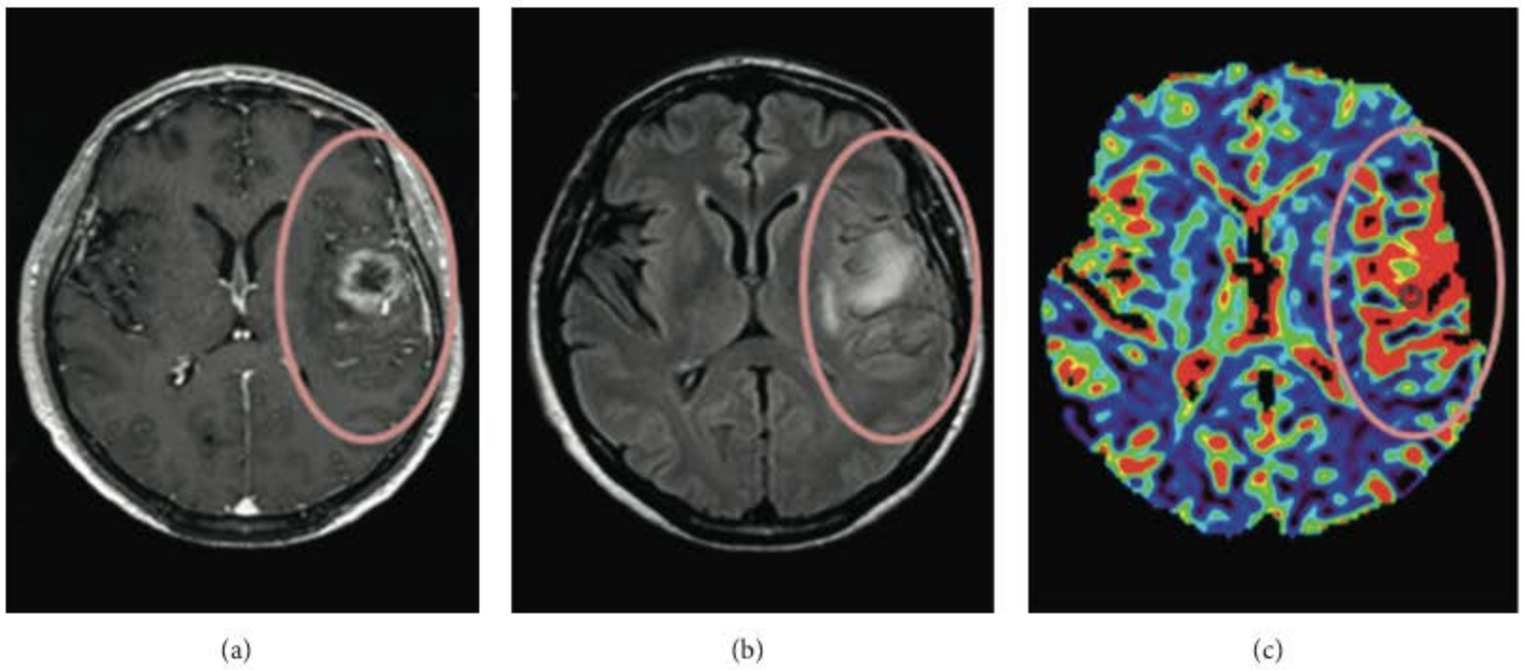
M. Berger et al. Neurosurgery 2000

PHYSIOLOGICAL IMAGING
PERFUSION MRI

- Provides hemodynamic information and estimates the cerebral blood volume that reflect the underlying microvasculature
- Exploit signal changes that accompany the passage of a paramagnetic contrast agent thorugh the cerebrovascular system
- Useful if patients receive antiangiogenetic cancer therapies to monitor its efficacy
- Maps of cerebral blood volume can serve as an additional targets for brain tumour biopsies
- May help in differentiating radiation necrosis and recurrent tumour
- May help differentiating tumor infiltrated edema (high grade gliomas) and vasogenic edema (in case of metastases)

PITFALL:

NO CORRELATION
WITH TUMOR GRADING



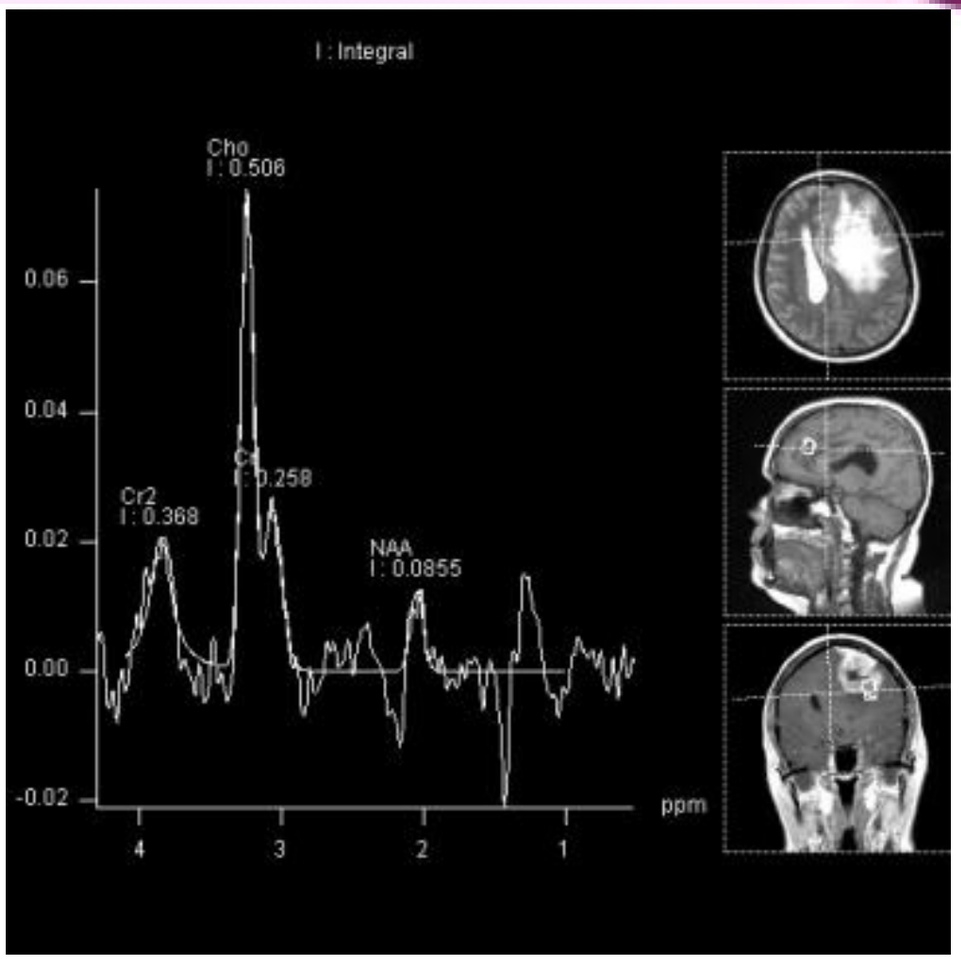
(a) (b) (c)

FIGURE 2: Axial coregistered contrast-enhanced axial T1-weighted image (a), FLAIR image (b), and CBV map (c) from a patient affected by glioma grade IV. In the CBV map (c) warmer colors indicate higher CBV values suggesting higher perfusion and neovascularization. Comparison of CBV map (c) and contrast-enhanced axial T1-weighted image highlights a mismatch area (surrounded by the circle) corresponding to the extension of the high perfusion area outside the contrast-enhancement: this indicates a more extensive neovascularization than that shown by conventional MRI (a, b).

Di Stefano et al. 2014

PHYSIOLOGICAL IMAGING
MRI SPECTROSCOPY

- **NAA**: marker of neural integrity
- **Choline**: membrane turnover
- Creatine: energetic
- **Myoinositol**: astrocytic marker
- **Lipid**: tissue destruction/necrosis marker
- Lactate: hypoxia marker
- Glutamine and Glutamate: excitatory markers

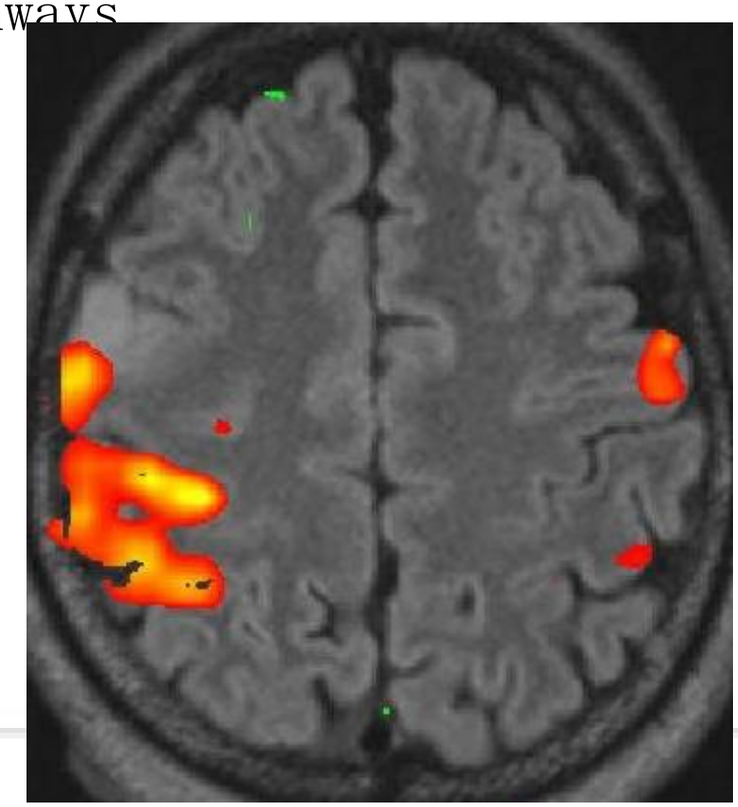


High choline correlate with high tumor proliferative index

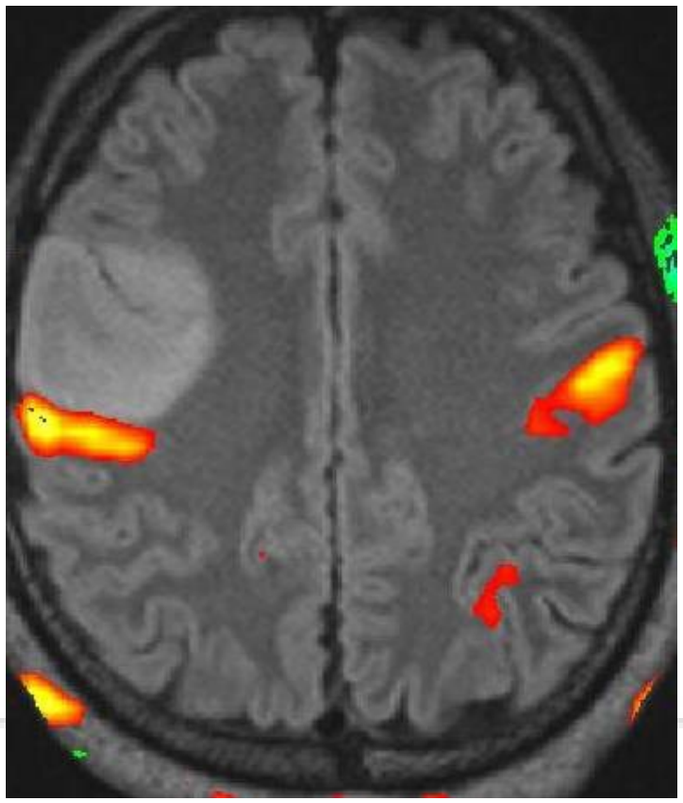
Pitfalls: - min 1 cm3 voxel size
- not suitable for posterior fossa lesions and lesions
- common aspecific spectral findings

PHYSIOLOGICAL IMAGING
FUNCTIONAL IMAGING - fMRI

- **Pitfalls:**
  - Does not monitor the neural response but a “surrogate” hemodynamic response
  - Cannot distinguish essential hubs -> need for intraoperative monitoring
  - Low localisation accuracy
  - **Neurovascular uncoupling** (tumor infiltration zone, neovascularity) with reduced fMRI signal in perilesional cortex
  - More accurate for motor mapping than for speech
  - Not giving any functional information about subcortical white matter pathways



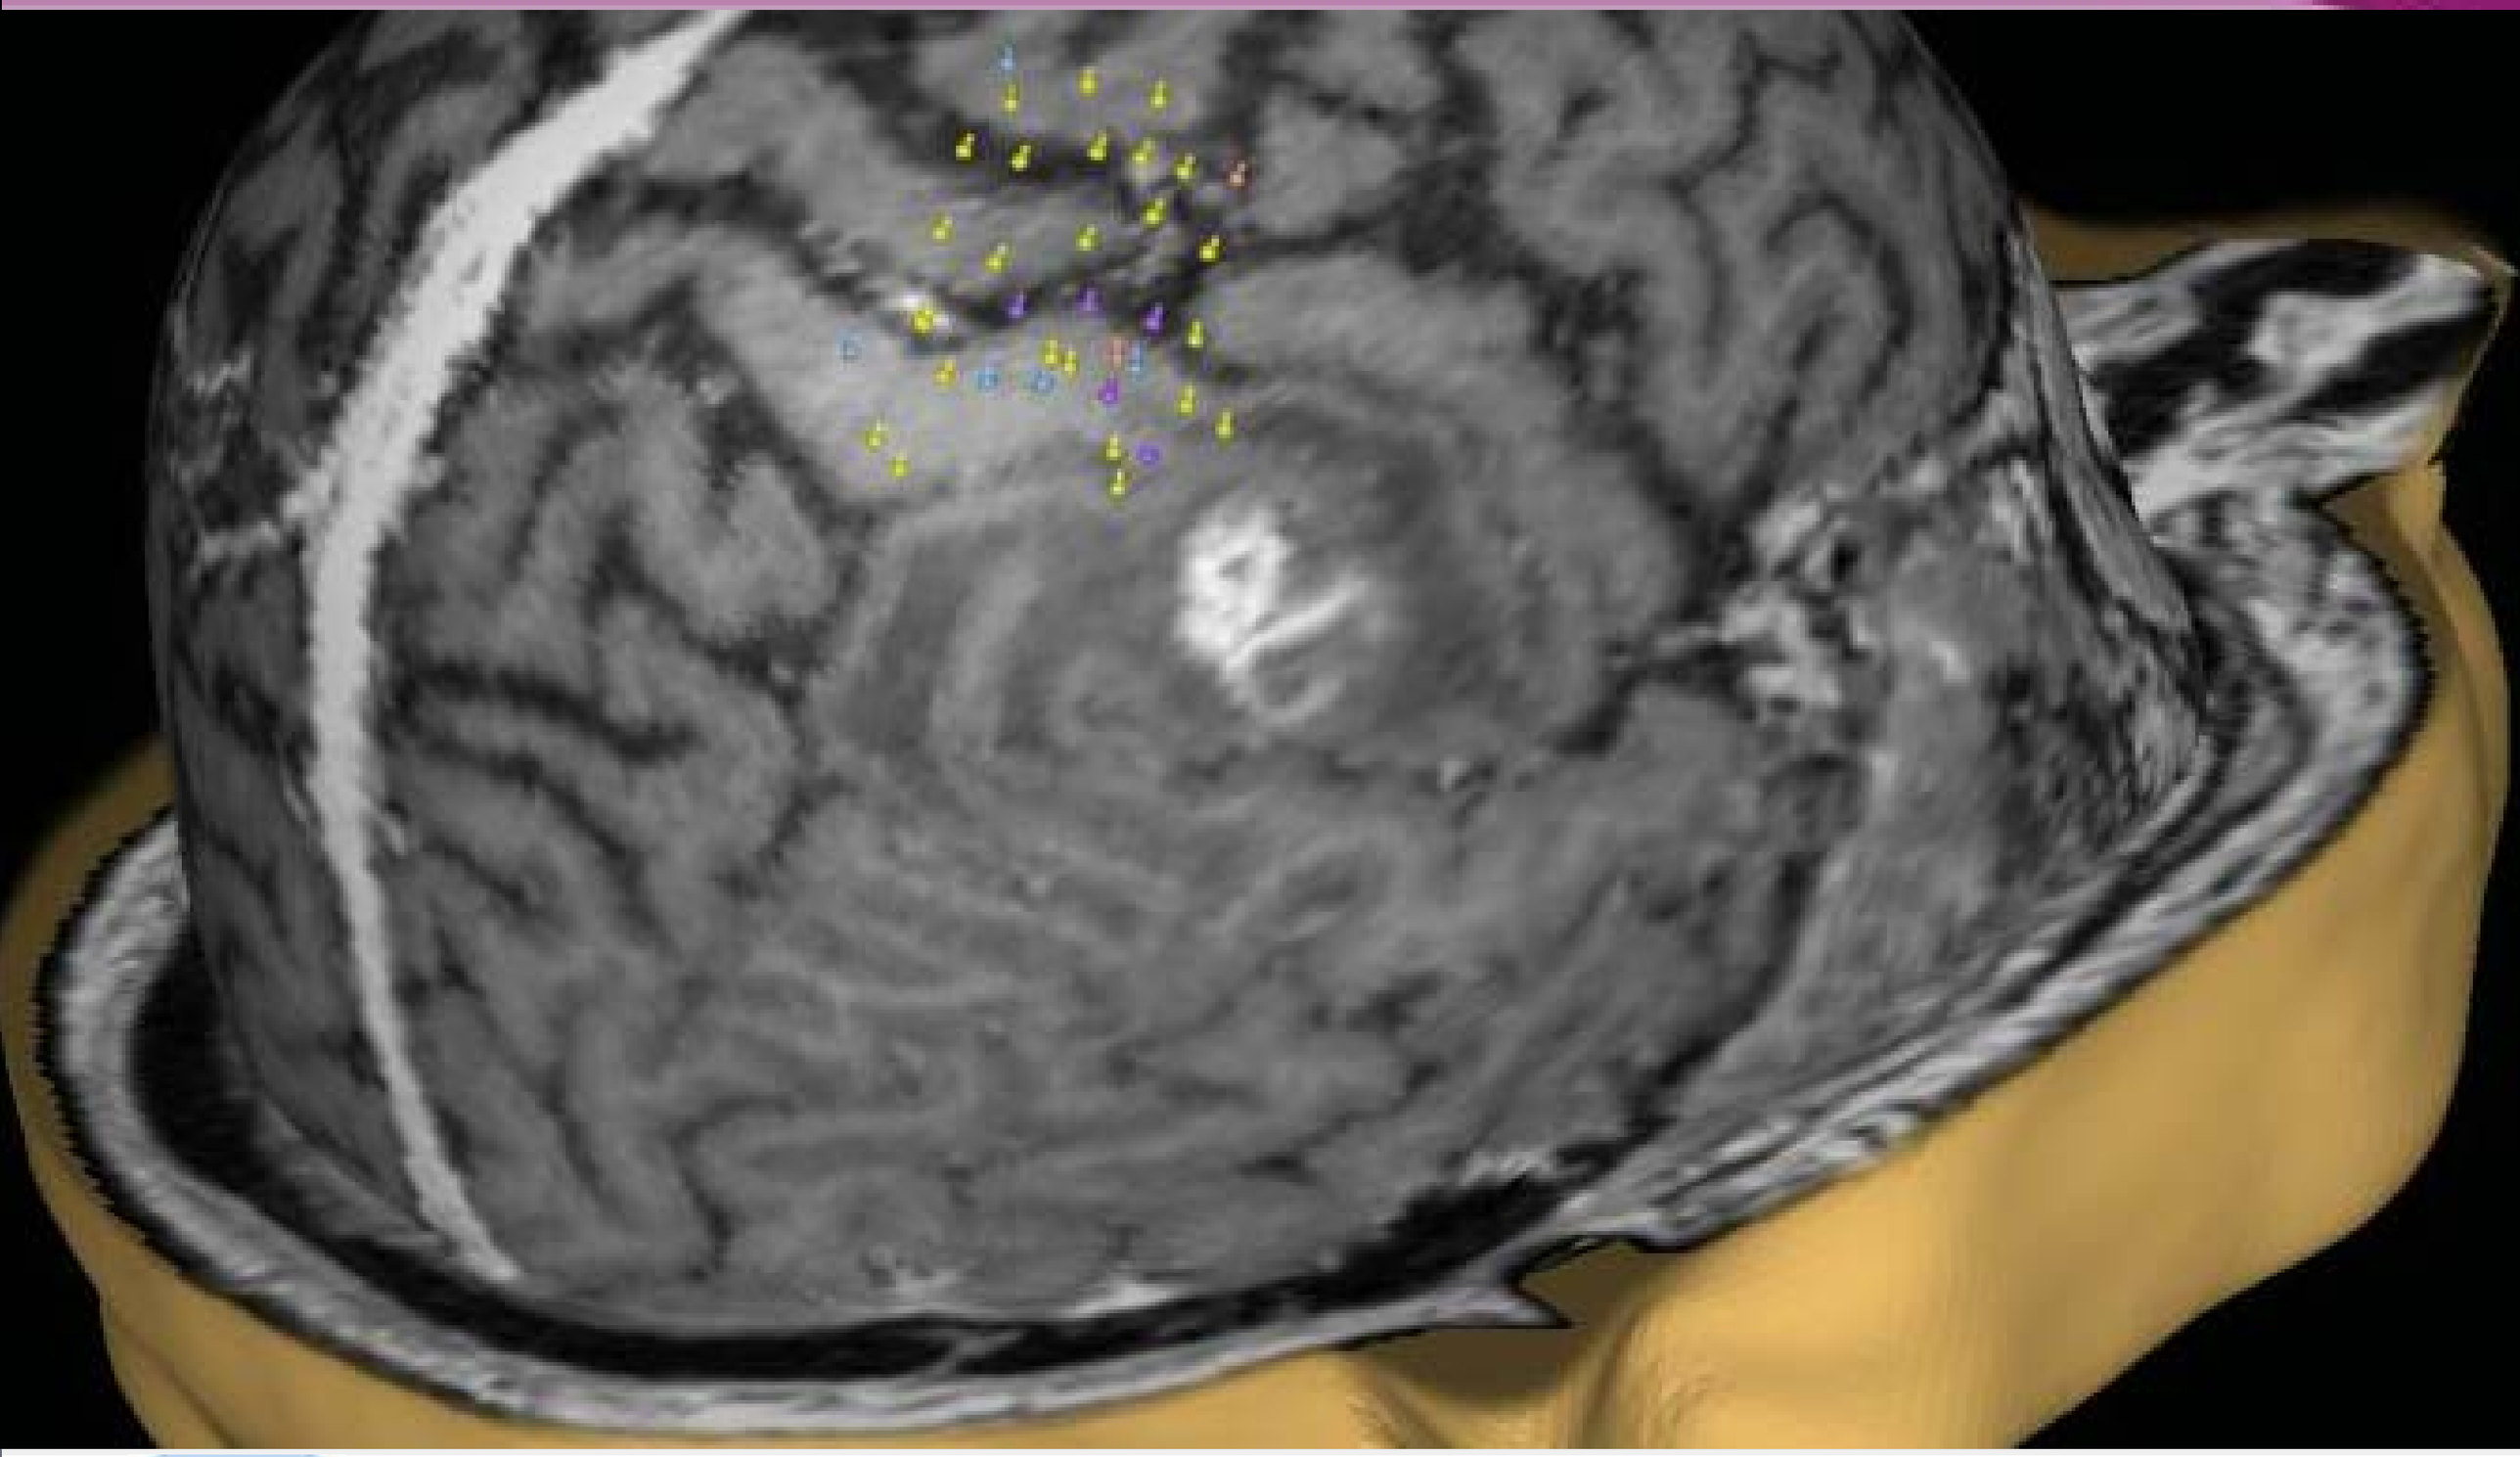
Finger Tapping



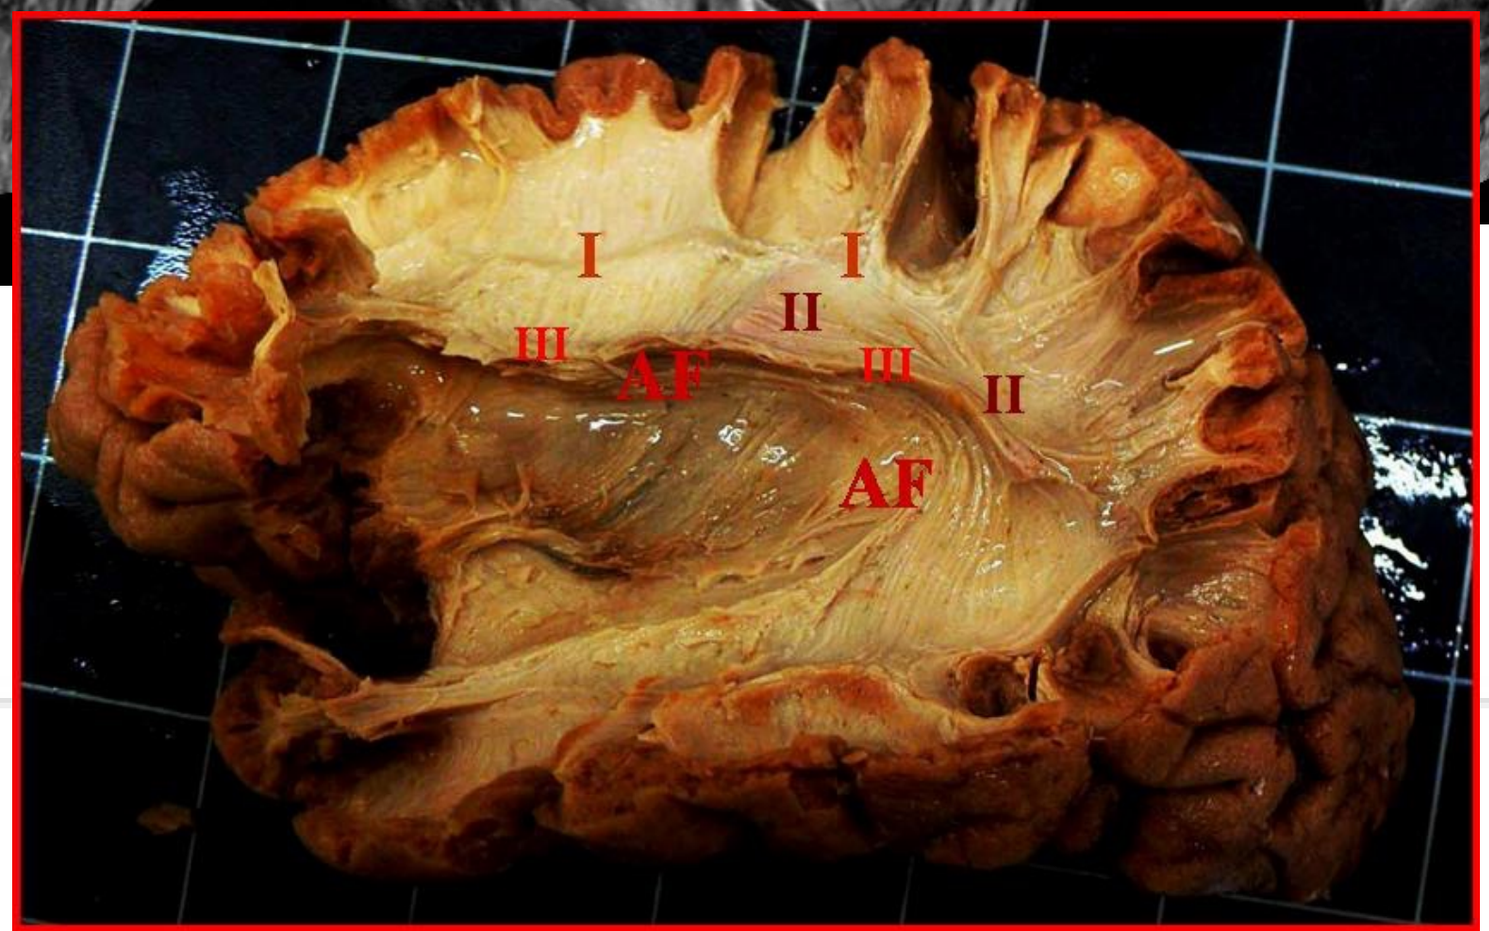
Semantic speech

Trans-Cranial Magnetic Stimulation

Trans-Cranial Magnetic Stimulation



WHITE MATTER TRACTS



WHITE MATTER TRACTS - fMRI+DTI

MODERN IMAGING OF BRAIN TUMOURS
TAKE HOME MESSAGE

- **Modern imaging offers a series of extraordinary complementary tools in diagnosis, treatment and follow up of brain tumours**

- **Unfortunately most of them still need to be validated**

- **Functional imaging and DTI in a clinical setting do not substitute cortical and subcortical intraoperative mapping**

- **<u>Despite advancement in multimodality imaging, definitive diagnosis of brain tumours still requires histopathology and molecular analysis in the vast majority of cases.</u>**

Thank You!

The NEW ENGLAND JOURNAL of MEDICINE

ESTABLISHED IN 1812 JUNE 25, 2015 VOL. 372 NO. 26

Comprehensive, Integrative Genomic Analysis of Diffuse Lower-Grade Gliomas

The Cancer Genome Atlas Research Network*

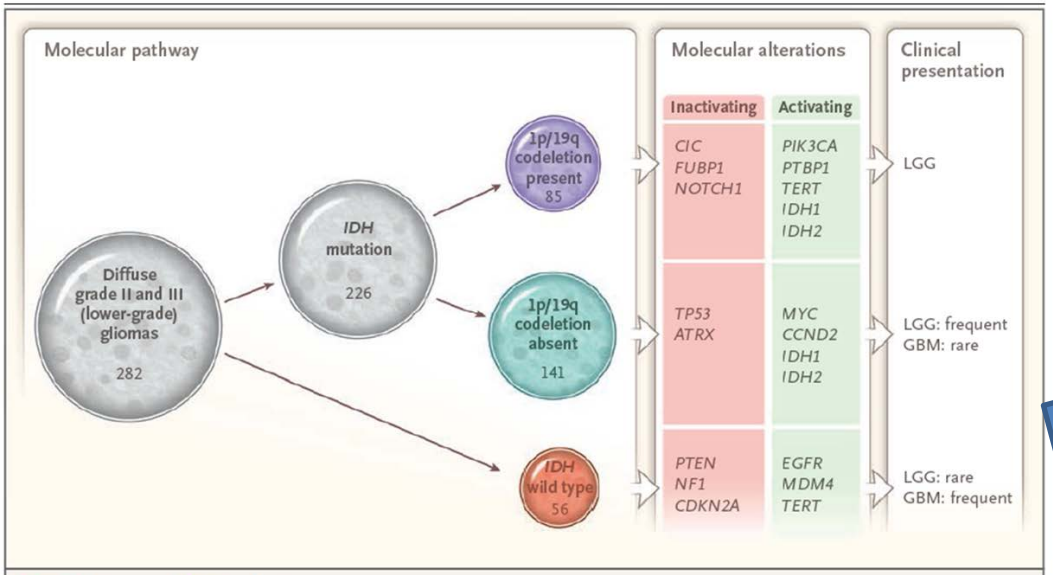

Figure 4. Summary of Major Findings.
Shown is a schematic representation that summarizes the major molecular findings and conclusions of our study: consensus clustering yielded three robust groups that were strongly correlated with *IDH* mutation and 1p/19q codeletion status and had stereotypical and subtype-specific molecular alterations and distinct clinical presentations. GBM denotes glioblastoma, and LGG lower-grade glioma.

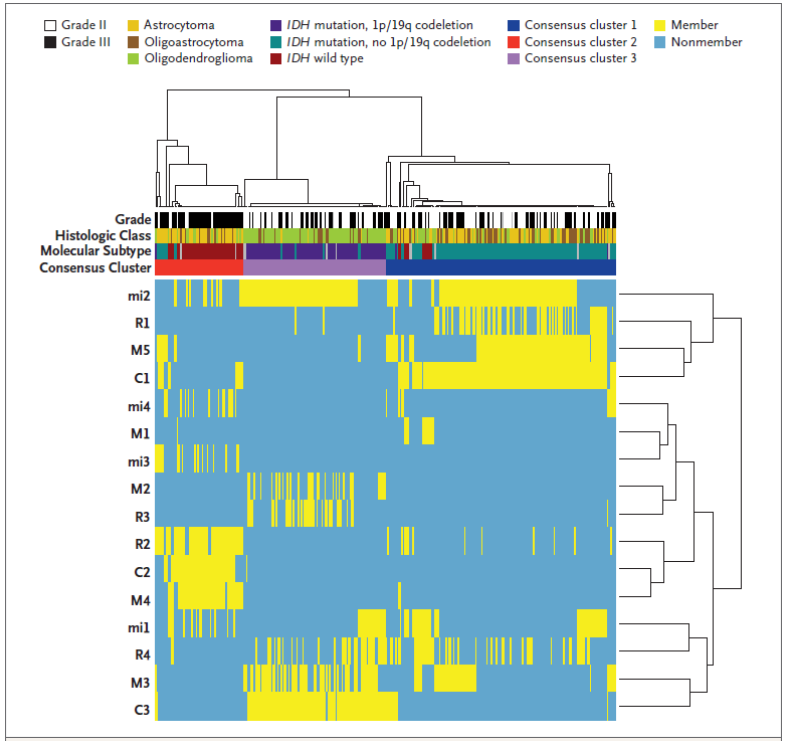

Figure 1. Cluster of Clusters (CoC) Analysis.
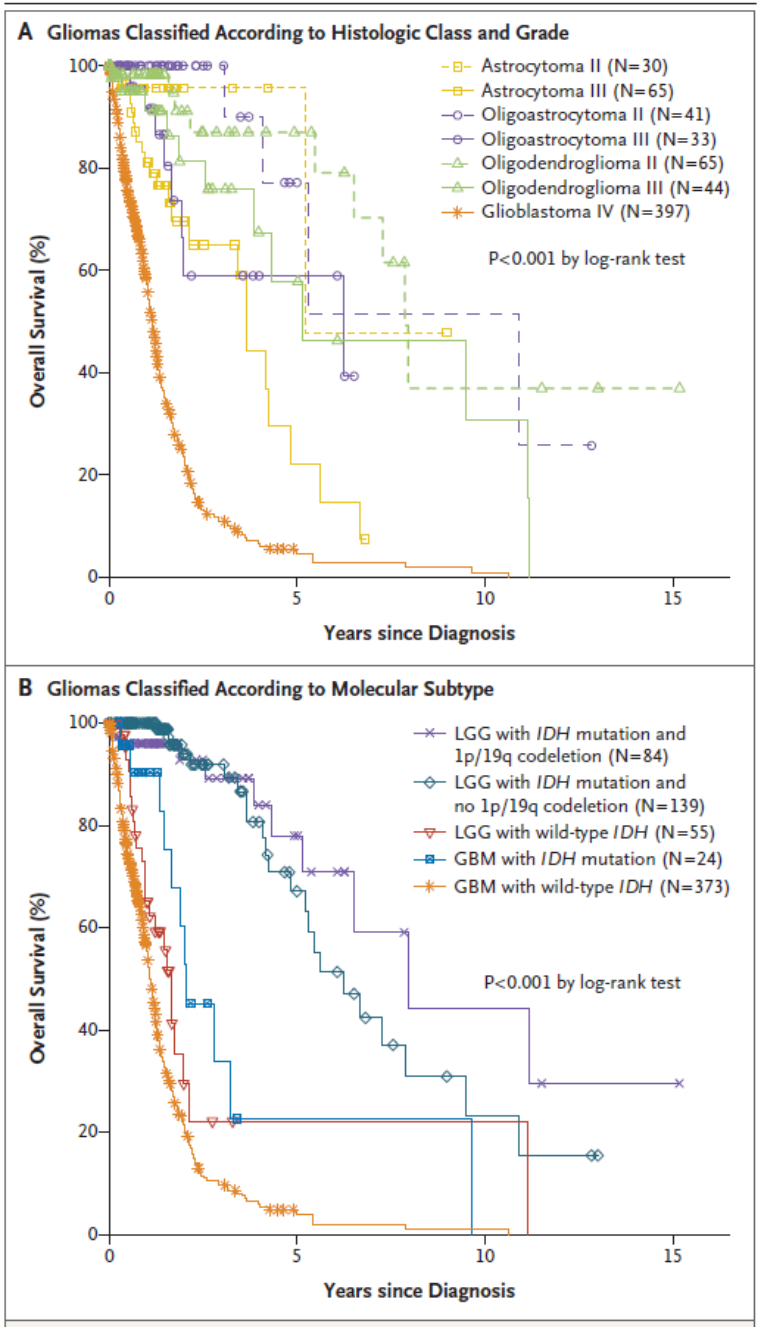
The results of multiplatform analyses point to biologic subtypes defined by *IDH* mutation and 1p/19q codeletion status. CoC analysis uses the cluster assignments derived from individual molecular platforms to stratify tumors, thereby integrating data from analysis of messenger RNA (mRNA) (designated by R on the y axis), microRNA (mi), DNA methylation (M), and copy number (C). For each sample, membership in a particular cluster is indicated by a yellow tick, and nonmembership is indicated by a blue tick. CoC analysis resulted in a strong three-class solution, and a comparison of tracks for CoC consensus cluster with tracks for histologic and molecular class shows a stronger correlation with molecular class.



Lower-grade gliomas with an **IDH mutation and 1p/19q codeletion** were of the **oligodendroglioma** histologic class and were associated with **favorable outcomes**.

Tumors with **wild-type IDH** were **molecularly and clinically distinct from subtypes with mutated IDH**, with most showing a striking resemblance to **primary glioblastoma** on all analytic platforms

It may transpire that **distinct therapeutic strategies** are required for effective disease control in molecular subtypes of lower-grade glioma.

Telomere maintenance and the etiology of adult glioma

Kyle M. Walsh, John K. Wiencke, Daniel H. Lachance, Joseph L. Wiemels, Annette M. Molinaro, Jeanette E. Eckel-Passow, Robert B. Jenkins, and Margaret R. Wrensch

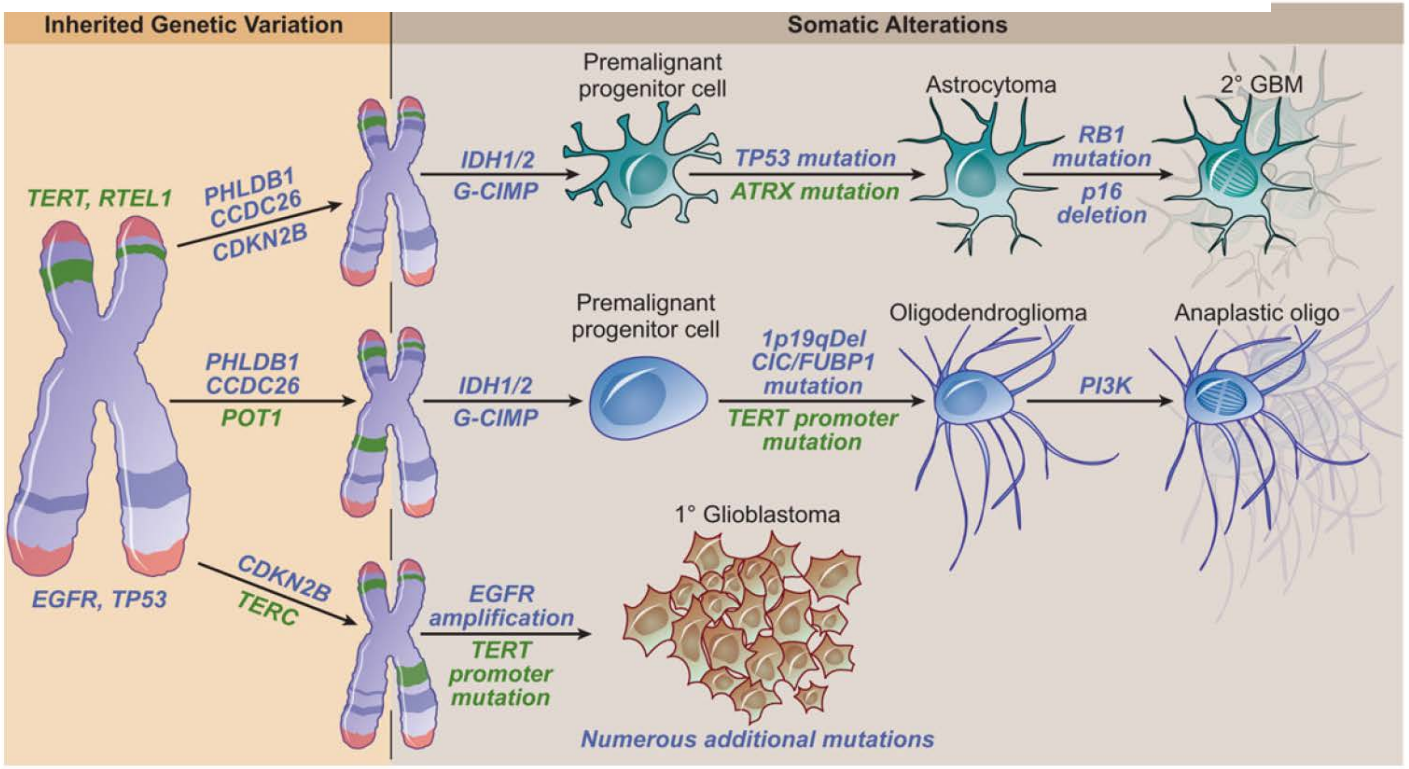

Fig. 1. Hypothesized pathways of glioma development, highlighting heritable and somatic genetic variants. From left to right: gene regions that contribute inherited risk for all histopathologic classifications of glioma. Gene regions that contribute inherited risk for specific histopathologic classifications of glioma. Somatic (ie, acquired) genetic changes that are believed to be early events in the development of glioma. Additional somatic events important for malignant progression. Gene names appearing in green font harbor glioma risk alleles associated with telomere lengthening. (Figure created with assistance from Xavier Studio.)

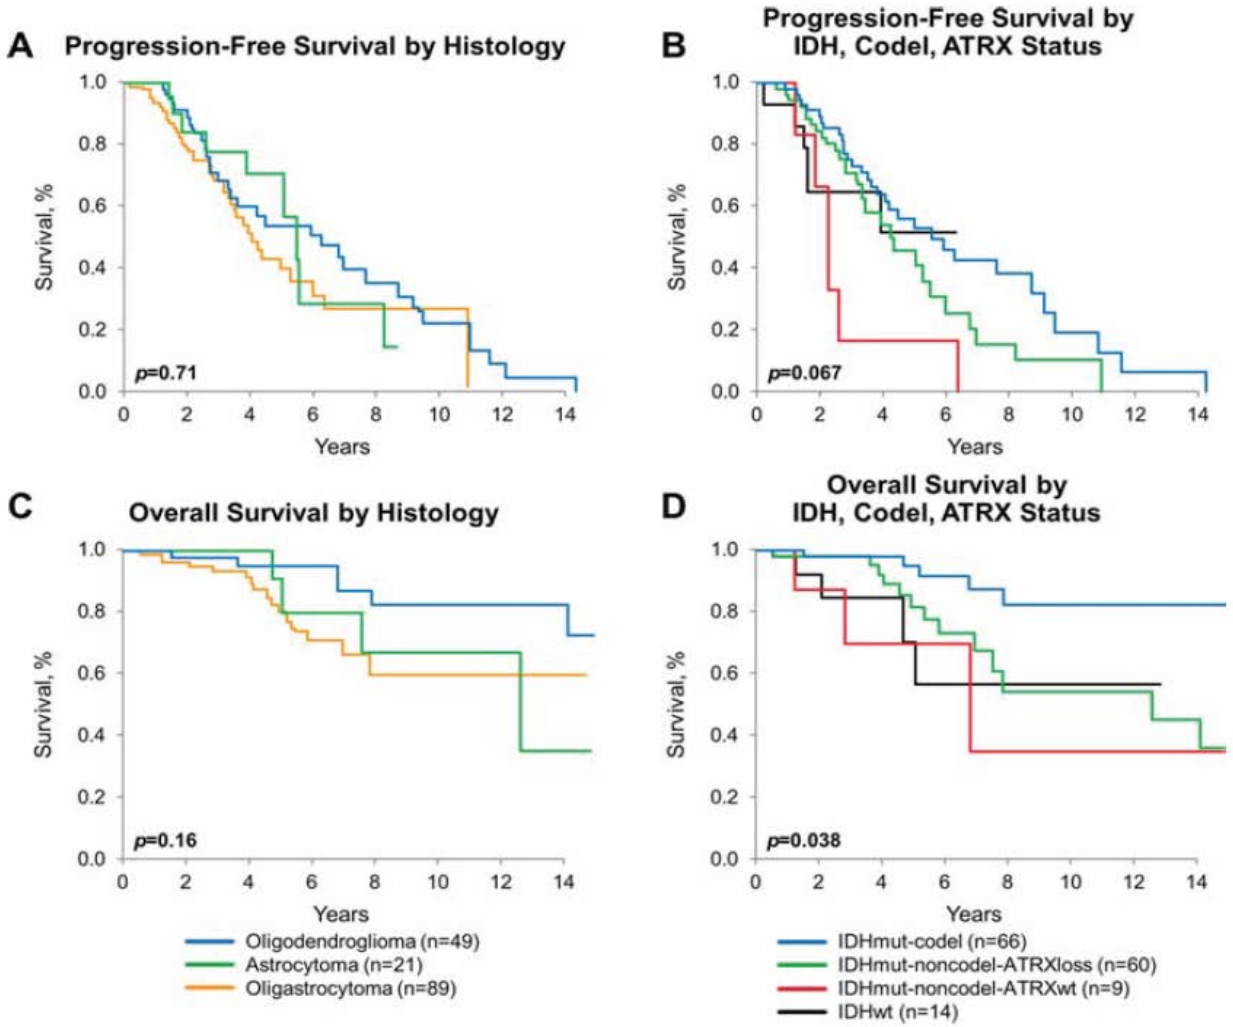

Conclusions: For WHO grade II diffuse glioma, molecular classification using 1p/19qcodel, IDHmut, and ATRX loss more accurately predicts outcome and should be incorporated in the neuropathologic evaluation.

Brain tumor diagnosis: a challenge step by step

- Histology and beyond
- The molecular background

- Constructing an integrated diagnostic report

International Society of Neuropathology-Haarlem Consensus Guidelines for Nervous System Tumor Classification and Grading

David N. Louis[1]; Arie Perry[2]; Peter Burger[3]; David W. Ellison[4]; Guido Reifenberger[5,6]; Andreas von Deimling[6,7]; Kenneth Aldape[8]; Daniel Brat[9]; V. Peter Collins[10]; Charles Eberhart[3]; Dominique Figarella-Branger[11]; Gregory N. Fuller[12]; Felice Giangaspero[13,14]; Caterina Giannini[15]; Cynthia Hawkins[16]; Paul Kleihues[17]; Andrey Korshunov[6,18]; Johan M. Kros[19]; M. Beatriz Lopes[20]; Ho-Keung Ng[21]; Hiroko Ohgaki[22]; Werner Paulus[23]; Torsten Pietsch[24]; Marc Rosenblum[25]; Elisabeth Rushing[26]; Figen Soylemezoglu[27]; Otmar Wiestler[28]; Pieter Wesseling[29,30]

Table 5. Example: integrated diagnoses for WHO grade II adult diffuse gliomas.[#]

Molecular information	Histologic classification: Diffuse astrocytoma	Oligodendroglioma	"Oligoastrocytoma" or ambiguous histology
IDH-mut, 1p/19q-nondel, ATRX loss	*Diffuse astrocytoma, ATRX loss of expression*	*Diffuse glioma* (oligodendroglioma phenotype), 1p/19q non-deleted, ATRX loss of expression*	*Diffuse astrocytoma, ATRX loss of expression*
IDH-mut, 1p/19q-codel, ATRX intact	*Diffuse glioma (astrocytoma phenotype), 1p/19q-codeleted*	*Oligodendroglioma, 1p/19q-codeleted*	*Oligodendroglioma, 1p/19q-codeleted*
IDH wild type	*Diffuse astrocytoma, IDH wild type**	*Diffuse glioma* (oligodendroglioma phenotype), IDH wild type**	*Diffuse astrocytoma, IDH wild type**
Testing not performed	*Diffuse astrocytoma, NOS*	*Oligodendroglioma, NOS*	*"Diffuse glioma, NOS"*

This example shows how the integrated diagnostic terms for adult WHO grade II diffuse gliomas (names in italics in boxes) could involve a combination of histological and molecular data, although an NOS (not otherwise specified) diagnosis would be made in the absence of molecular information (bottom row). Highlighted in light gray are the common, narrowly histologically and molecularly defined, "classic" diffuse astrocytoma and oligodendroglioma. Note that in this suggested scheme, the term "oligoastrocytoma" does not appear in a diagnostic box, with the last column showing the alternative diagnoses for what has been inconsistently termed "oligoastrocytoma."

[#]A similar classification scheme would apply for WHO grade III, anaplastic gliomas.

doi:10.1

LETTER TO THE EDITOR

Letter in Response to David N. Louis *et al*, International Society of Neuropathology-Haarlem Consensus Guidelines for Nervous System Tumor Classification and Grading, Brain Pathology, doi: 10.1111/bpa.12171

Johannes Hainfellner

- The recommendation that tumor entities shall be defined as precisely and objectively as possible in order to optimize

- The recommendation that all tissue-based information (histological, molecular) shall be elements of an integrated

- The recommendation that molecular information should be incorporated in the definition of some diagnostic entities is relevant and is supported by already existing proof of concept

- The statement that the World Health Organization (WHO) grade reflects the natural history of a given tumor after surgery alone rather than the expected patient prognosis following current therapies is a plausible and pragmatic concept. It is good to have such a clarifying statement as contemporary reference in the literature.

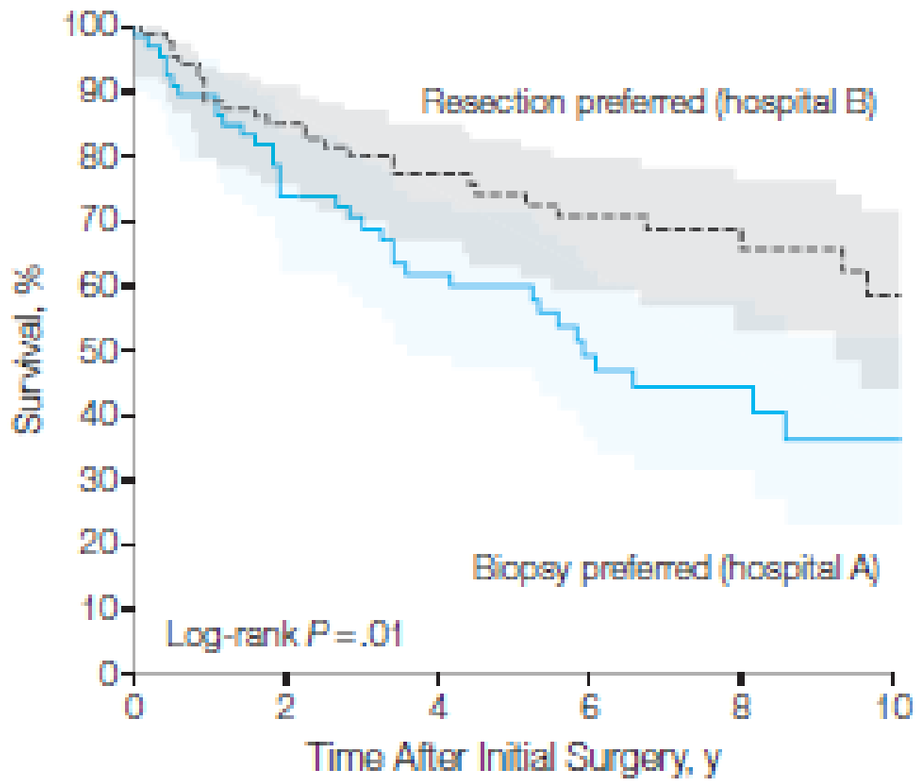
Comparison of a Strategy Favoring Early Surgical Resection vs a Strategy Favoring Watchful Waiting in Low-Grade Gliomas

Survival Analysis Comparing Favored Surgical Strategies for Low-Grade Gliomas

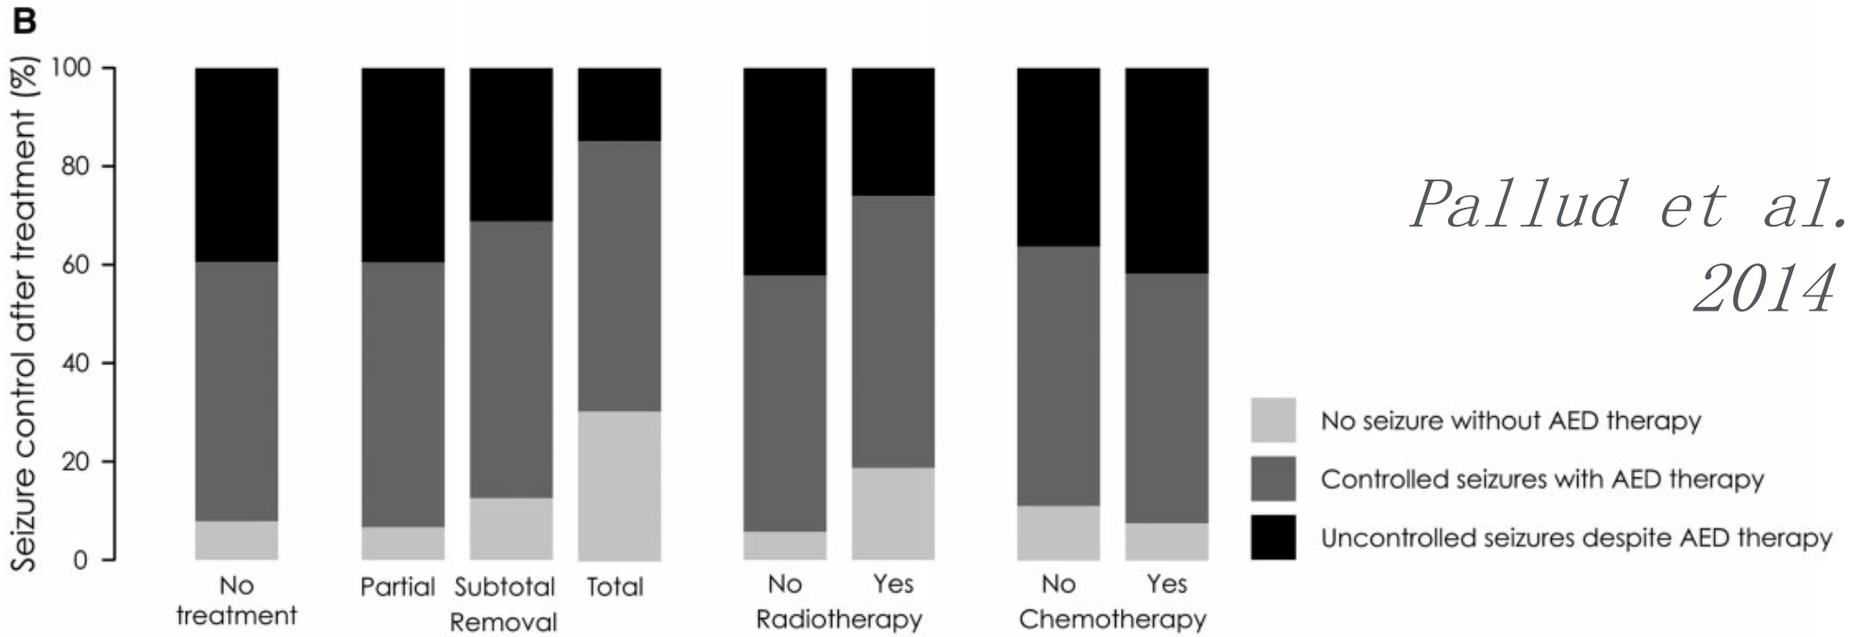


Jakola et al. JAMA, 2012

Low grade gliomas

BRAIN
A JOURNAL OF NEUROLOGY

Epileptic seizures in diffuse low-grade gliomas in adults



Pallud et al. Brain, 2014

Patient age (P≤ 0.001), subtotal (P = 0.007) and total (P≤ 0.001) resections were independent predictors of total epileptic seizure control after oncological treatment. Patients diagnosed with epileptic seizures andthose with complete and early surgical resections have better oncological outcomes.

Early and maximal surgical resection is thus required for diffuse low-grade gliomas, both for oncological and epileptological purposes.

Brain metastases

TABLE II Randomized trials of surgery plus radiation therapy as compared with radiation therapy alone

Brain metastases

AUTHORS' CONCLUSIONS

Implications for practice

It is difficult to advise either patients or colleagues on the basis of evidence from such small studies. It is important to note that these results were obtained in a highly selected group of patients - under close follow-up and receiving further active therapy in many cases - who are not necessarily representative of the majority of those with single brain metastasis. In this group, the surgical approach did not improve OS. Surgery may reduce the number of deaths due to neurological cause, while one trial has suggested an increase in the duration of a patients FIS. Adverse events were similar in each group whilst QoL was not directly examined. Those most likely to benefit from surgery are of young age, have good neurological function, and controlled primary disease (Noordijk 1994). Careful attention to prognostic factors will see only those who have the most to gain from surgery, while those who are less well will avoid unnecessary risks and morbidity. It must not be forgotten that the overall outlook for patients at two years is dismally poor with either intervention and death is commonly due to systemic disease. Currently, the management for the majority of those with single brain metastasis will be WBRT alone, due to active systemic disease and other co-morbidity. Decisions of the most appropriate treatment for an individual patient should be made at an MDT meeting in line with NICE guidance (NICE 2006).

THE COCHRANE COLLABORATION®

Difficult to draw conclusions from small trials

OS no different in pooled analysis – possible improvement in FIS and reduction of neurological deaths

Pts likely to benefit: young age, good neurological function and controlled primary disease

Decision should be made in MDT

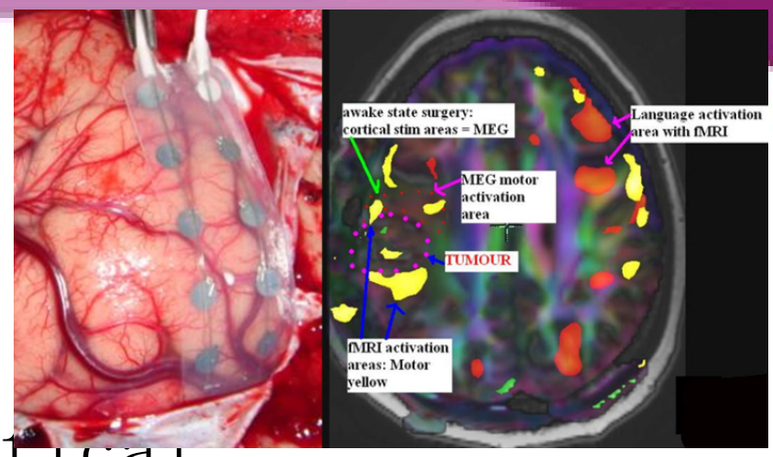
Cortical and subcortical motor mapping

Carrabba G, Fava E, Giussani C, et al. Cortical and subcortical motor mapping in rolandic and perirolandic glioma surgery: impact on postoperative morbidity and extent of resection. J Neurosurg Sci 2007; 51:45 – 51



- Stimulation mapping of cortical and subcortical motor pathways enables the surgeon to identify descending motor pathways during tumour removal.

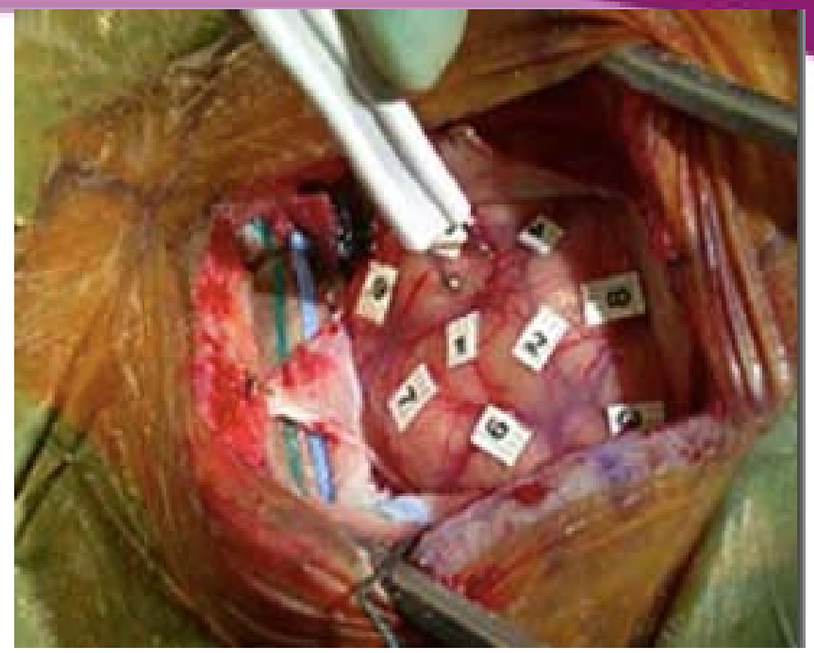
- New immediate postoperative motor deficits documented in 59.3% of patients in whom a subcortical motor tract was identified intra-operatively and in 10.9% of those in whom sub-cortical tracts were not observed.

- Permanent deficits observed in 6.5 and 3.5%, respectively

Language mapping

- Bipolar stimulation
- Cortical mapping started at low stimulus (1 mA)
- Constant-current generator delivers biphasic square wave pulses in 4-s trains at 60 Hz across 1 -mm bipolar electrodes separated by 5 mm
- Stimulation sites marked with sterile numbered tickets
- Throughout motor and language mapping, continuous ECoG used to monitor after discharge potentials

Language mapping



Counting task – “speech arrest”

Denomination task :

- anomias
- semantic paraphasias
- phonological paraphasias

Spontaneous speech

Active dendritic cell immunotherapy for glioblastoma: Current status and challenges

Stavros Polyzoidis[1], Juel Tuazon[2], Lucy Brazil[3], Ronald Beaney[3], Safa Taha Al-Sarraj[4], Lawrence Doey[4], Jamie Logan[5], Victoria Hurwitz[5], Jozef Jarosz[6], Ranjeev Bhangoo[1], Richard Gullan[1], Aleksandar Mijovic[7], Mark Richardson[8], Farzin Farzaneh[9] & Keyoumars Ashkan[1]

Median overall survival ranged between 16.0 and 38.4 months for ND-GBM and between 9.6 and 35.9 months for Rec-GBM.

Vaccine-related side effects were in general mild (grade I and II), with serious adverse events (grade III, IV and V) reported only rarely.

DC immunotherapy appears to have the potential to increase the overall survival in patients with HGG, with an acceptable side effect profile. The findings will require confirmation by the ongoing and future phase III trials.

Comprehensive, Integrative Genomic Analysis of Diffuse Lower-Grade Gliomas

The Cancer Genome Atlas Research Network*

CONCLUSIONS

The integration of genomewide data from multiple platforms delineated three molecular classes of lower-grade gliomas that were more concordant with *IDH*, 1p/19q, and *TP53* status than with histologic class. Lower-grade gliomas with an *IDH* mutation either had 1p/19q codeletion or carried a *TP53* mutation. Most lower-grade gliomas without an *IDH* mutation were molecularly and clinically similar to glioblastoma. (Funded by the National Institutes of Health.)

ORIGINAL ARTICLE

Glioma Groups Based on 1p/19q, *IDH*, and *TERT* Promoter Mutations in Tumors

Gliomas were classified into five principal groups on the basis of three tumor markers. The groups had different ages at onset, survival, and associations with germline variants, which implies that they are characterized by distinct mechanisms of pathogenesis.

Eckel-Passow et al. NEJM, 2015

Take-home Message

- Neurosurgical intervention remains the first step in effective glioma management.
- With intraoperative mapping techniques, aggressive microsurgical resection can be safely pursued even when tumours occupy essential functional pathways.
- With the development of tumour-specific fluorophores, such as 5- aminolevulinic acid, real-time microscopic visualization of tumour infiltration can be surgically targeted prior to adjuvant therapy.

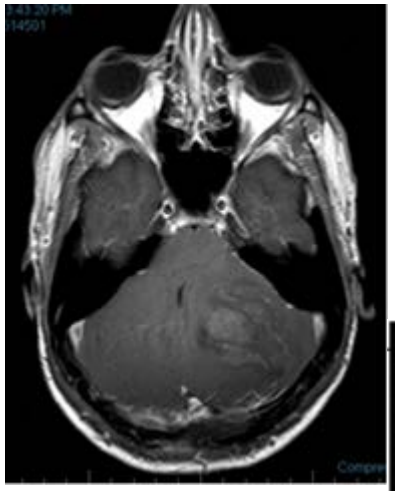
Cranio-spinal irradiation (CSI)

"Irradiation of the entire CSF compartment from the top the skull to the end of the thecal sac in primary CNS tumours that have a propensity to spread via the CSF pathway"



ESTRO School

Radiotherapy technique

- Cranio-spinal irradiation

  - ✓ Clinical target volume = whole brain + spinal cord with overlying meninges

A complex technique….

- Carrie M-SFOP 98 1998-2001
  - 14/48 patients found on pre-RT review to have major targeting errors
    - 9 for eye blocks
    - 5 for spinal field width
    - (Carrie, Int J Rad Onc Biol Phys 2005)
- Packer A9961 1996-2000
  - 421 eligible patients
  - 21% with RT deviations
    - (Packer, JCO 2006)
- QARC ACNS0331 April 2004-August 2005
  - Modifications requested in 40% of the first 53 cases

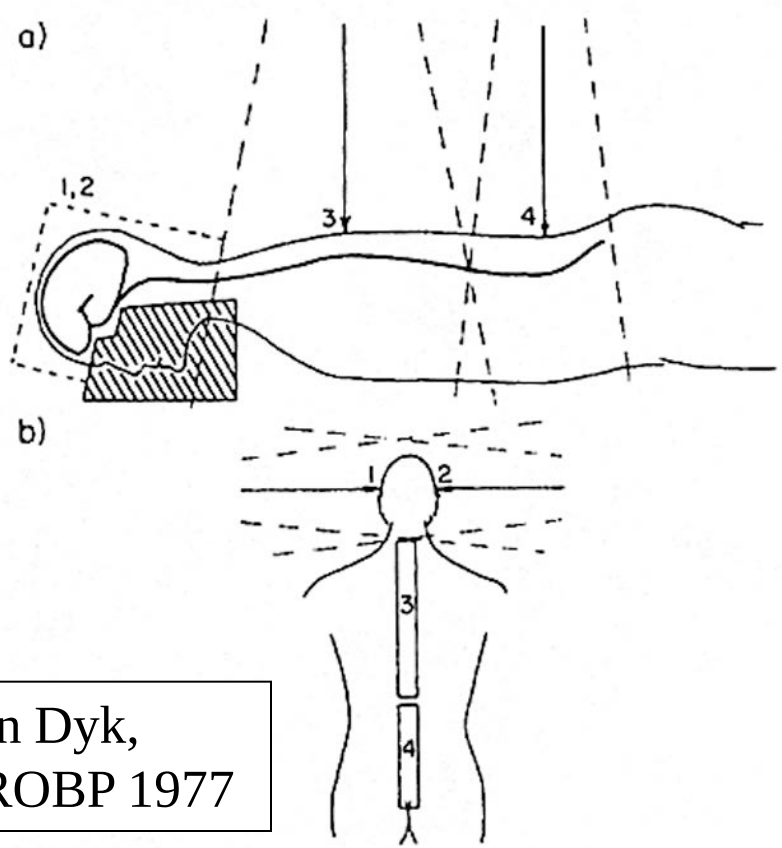
That has to be done properly….

- Targeting deviations correlate with outcome

  (Hardy 1978, Jereb 1982... Carrie 1992, Miralbell 1997, Taylor 2004, Oyharcabal-Bourden 2005)

- Dose reductions to 23.4 and 18 Gy make optimal coverage even more critical

A standard CSI technique



Van Dyk, IJROBP 1977

Patient prone in a head rest with neck extended

Junction of non-coplanar fields over the cervical spine

Extended SSD or second posterior field to cover whole length of spine/second junction over the spinal cord

CSI in 2015: new/improved tools

- Better imaging for target volume definition
  - CT simulation
  - MRI and CT-MRI co-registration
- CT-based treatment planning
- Improved delivery techniques

CSI

- Target volume definition

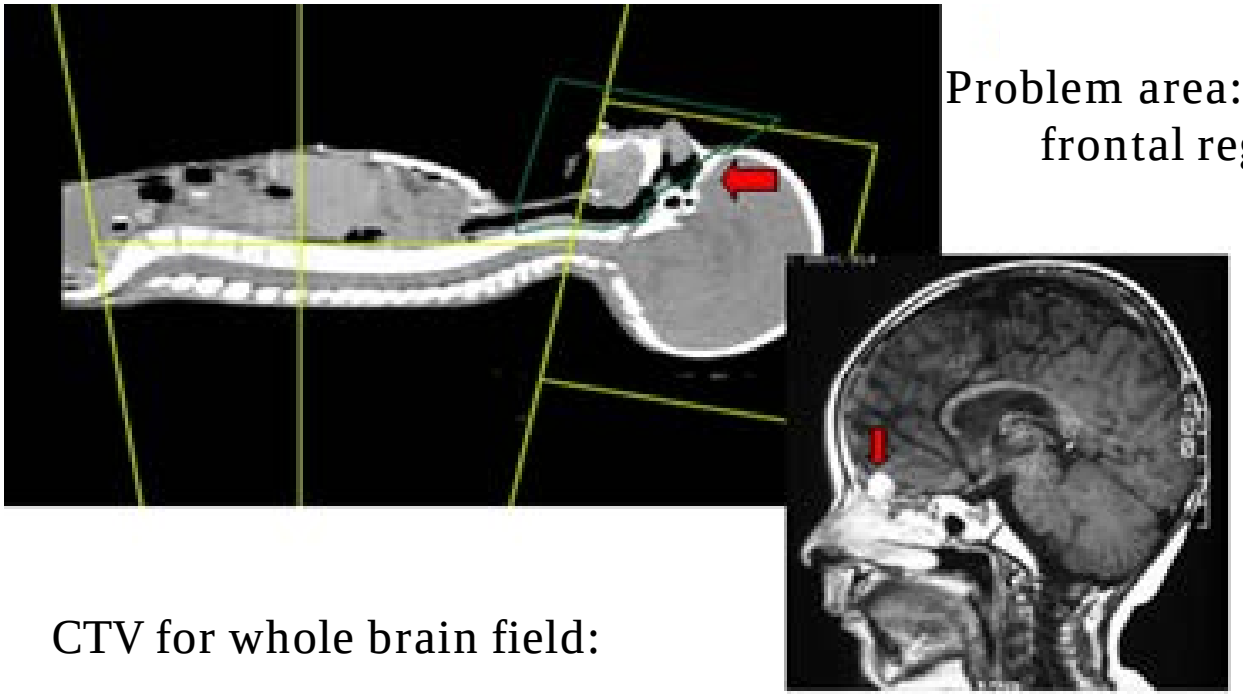
Target volume definition

Target definition: is necessary to outline the cranio-spinal axis → whole brain, spinal cord and thecal sac

The whole brain should include the entire frontal lobe and cribriform plate region

Target volume definition

Frontal region/cribriform plate

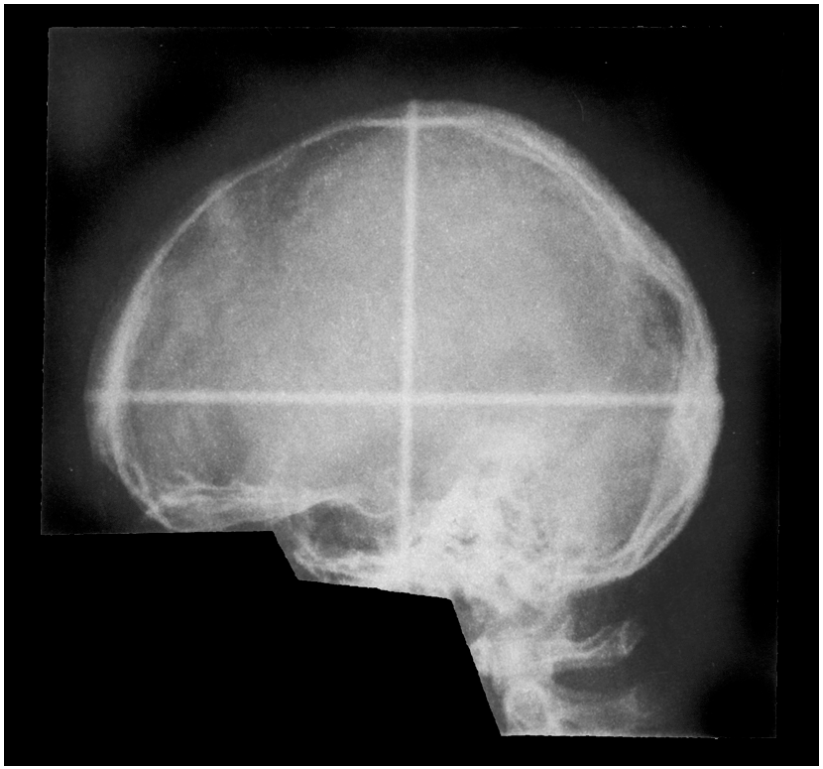


Problem area:
frontal region/cribriform plate

CTV for whole brain field:

« ...shall extend anteriorly to include the entire frontal region and cribriform plate region. The volume shall cover the superior orbital tissue (but not the posterior globe as in leukemia protocols)»

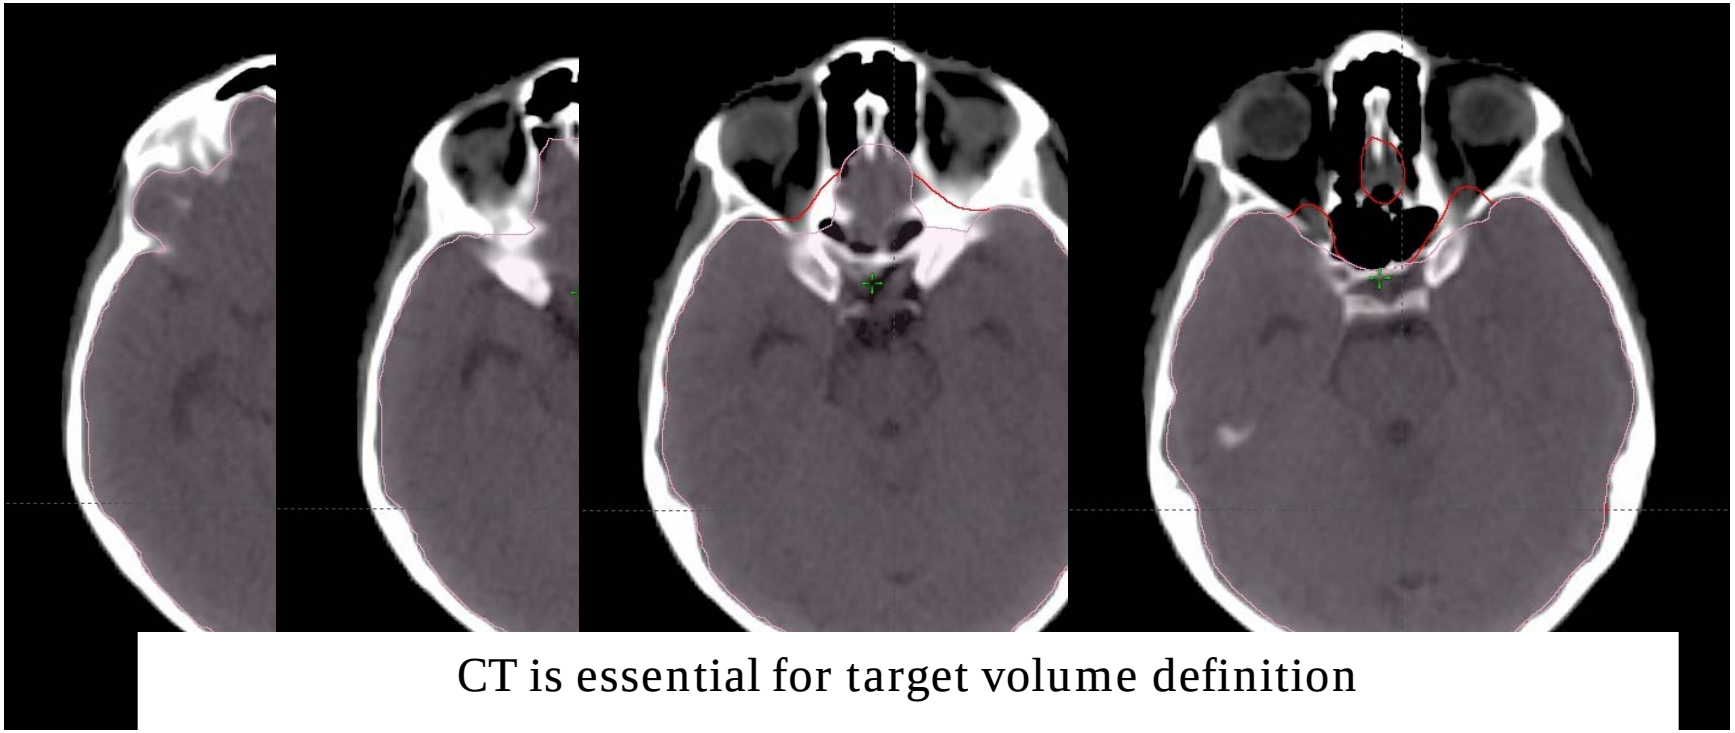
Coverage of the target volume: cribriform plate



- Lateral radiographs are not adequate for target volume delineation
- 5 radiologists and 5 radiation oncologists:
  - Correct within 2mm in only 39% of cases
  - Mislocations
    - 2-5mm in 34%
    - 5-10mm in 20%
    - >10mm in 7%

Gripp IJROBP 2004

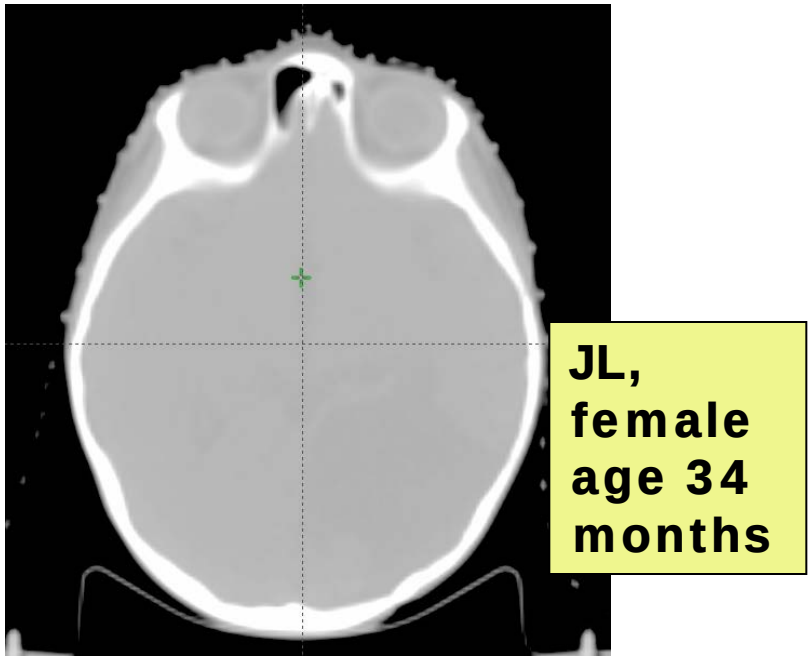
Coverage of the target volume: cribriform plate



CT is essential for target volume definition

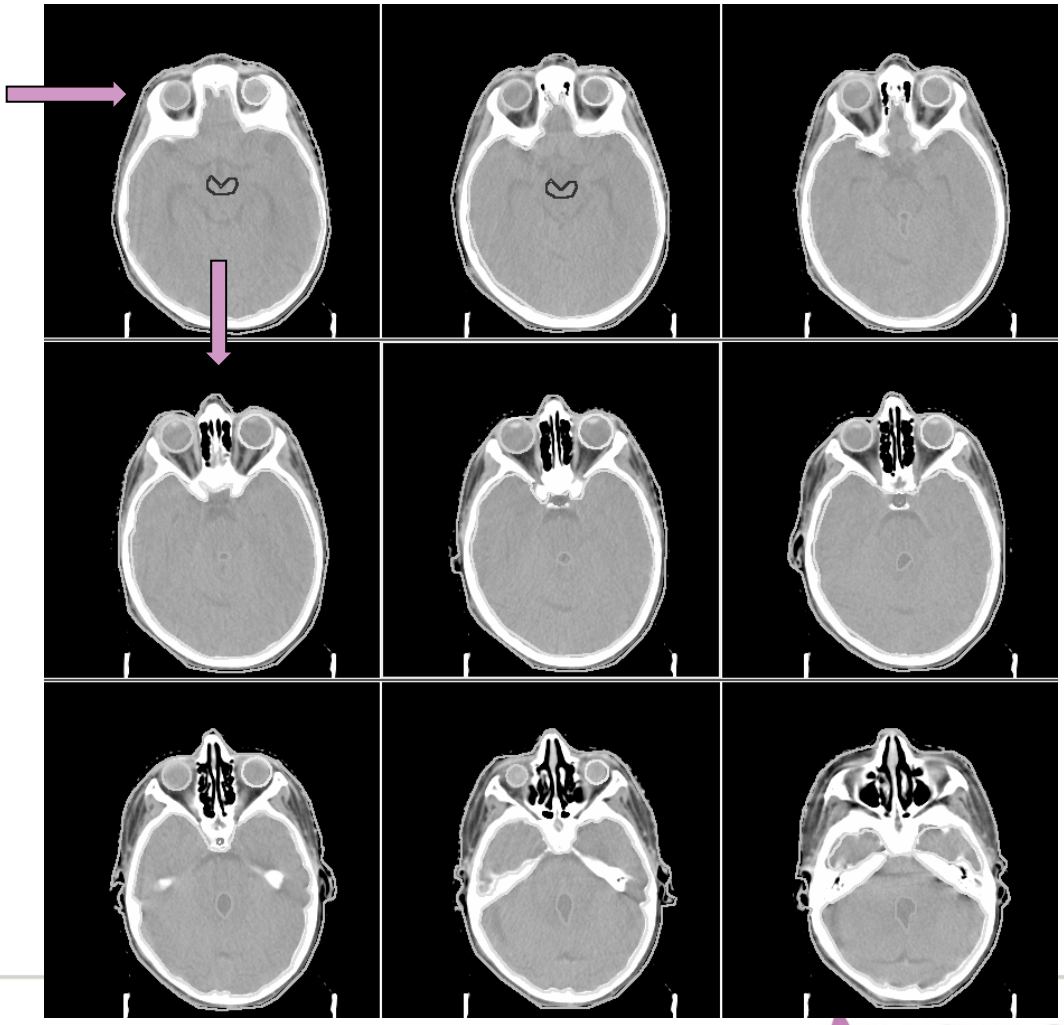
In most children, it is impossible to shield the eyes **and** cover the target volume

Especially in very young children....



Coverage of the target volume: cribriform plate

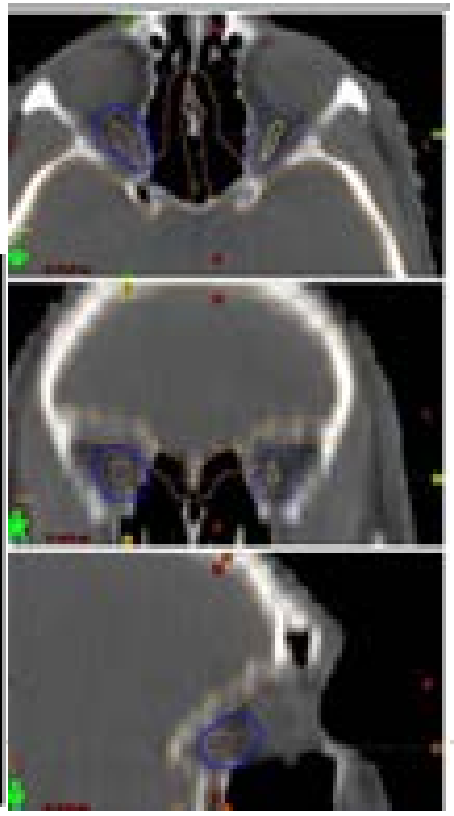
- To include the cribriform fossa in the CTV and allowing an additional appropriate margin to the PTV, the PTV frequently includes the lenses.
- We consider it necessary to frequently deliver a higher dose to the lens (accepting an increased probability of later cataract development) than not adequately cover the cribriform plate.
- SFOP group suggested that the edge of the shielding block/ MLCs is **at least 5 mm below the cribriform fossa** as this field edge definition is not associated with an increase risk of frontal recurrence



ESTRO School

A new problem: the optic nerves

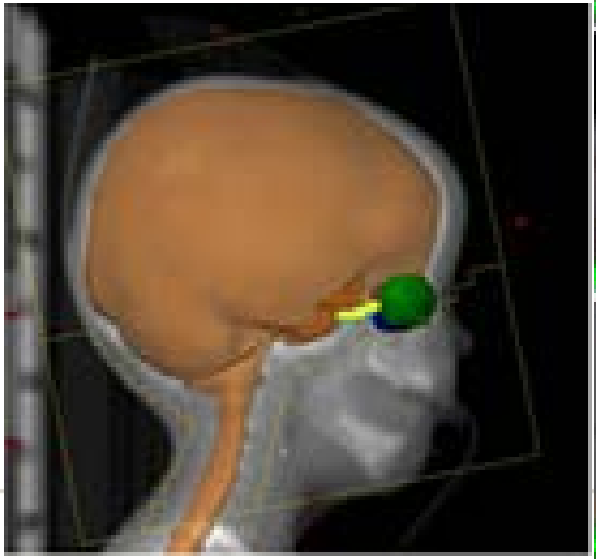
Subarachnoid space ends at the lamina cribrosa



Dose to optic nerve PTV (V95%):

-3DCRT 99% (95%-100%)

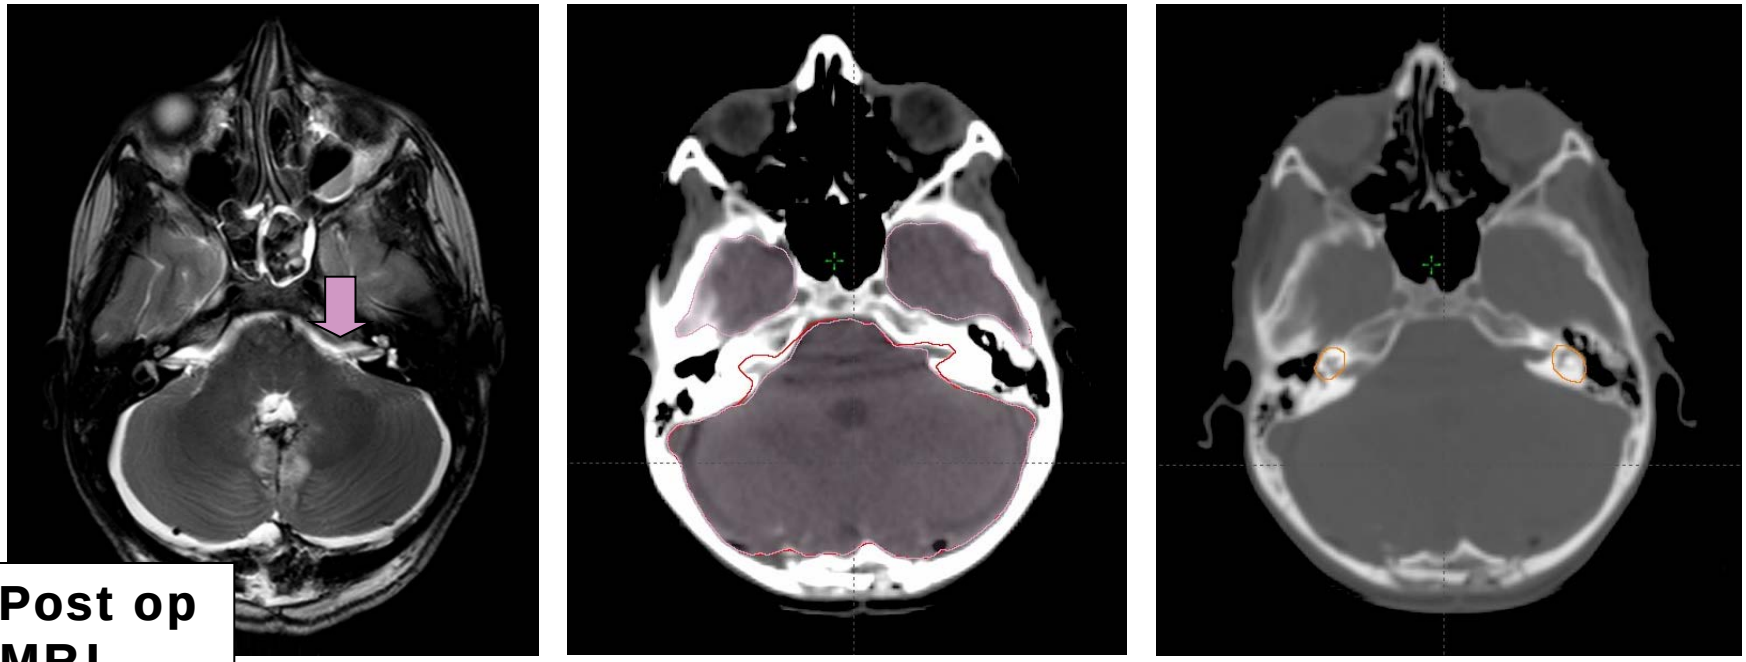
-Tomotherapy 81% (49.9%-96%)



Optic nerves need to be contoured

ESTRO School

Another new problem… extension of subarachnoid space around cranial nerves

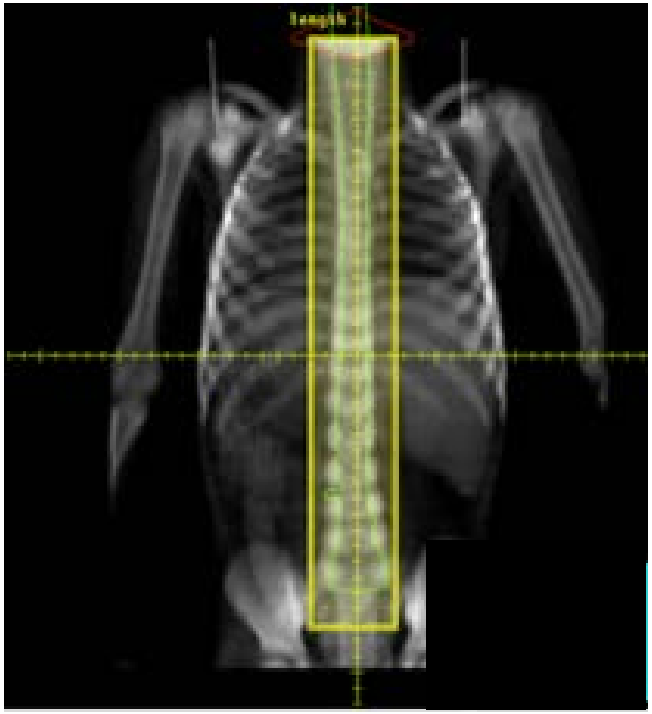


Use T2-weighted MRI for contouring

Difficult or impossible to spare cochlea

The lower cranial nerves too…

Coverage of the target volume: the spine



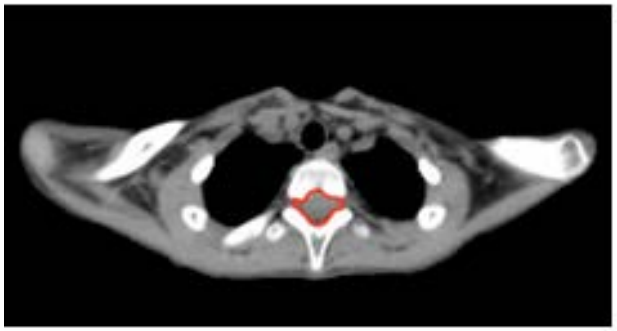
ACNS0331:
«...laterally on both sides to cover the recesses of the entire vertebral bodies, with at least 1 cm margin on either side

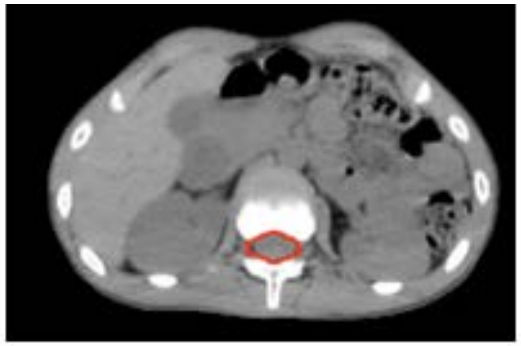
Lower limit: 2 cm below the termination of the subdural space..... At least to the inferior border of the 2° sacral segment (S2-S3 interspace)

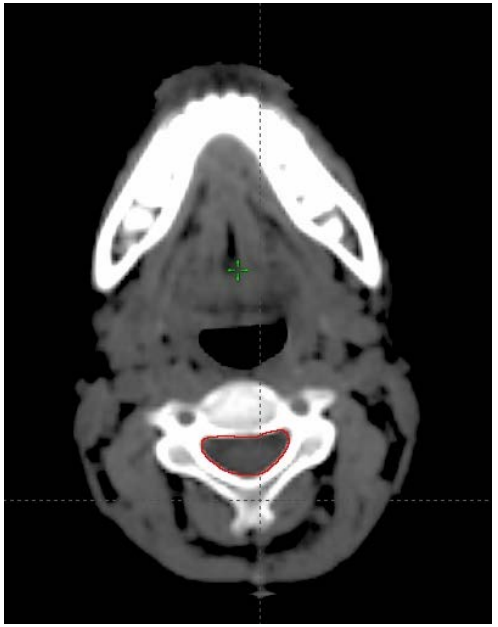
ESTRO School

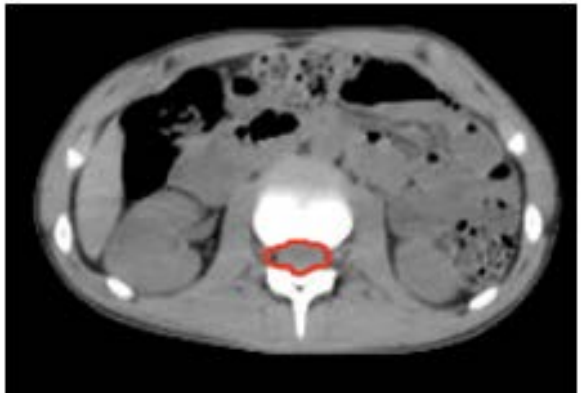
Coverage of the target volume: the spine

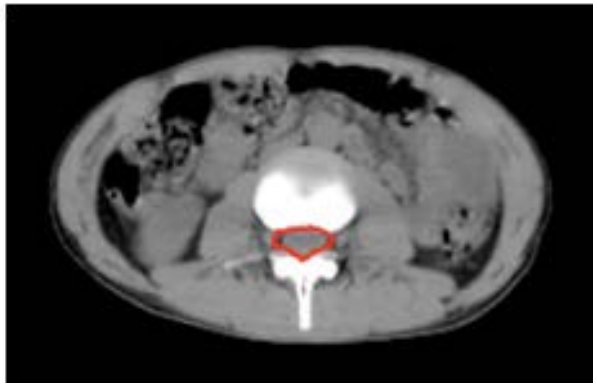
Now spine is contoured slice by slice





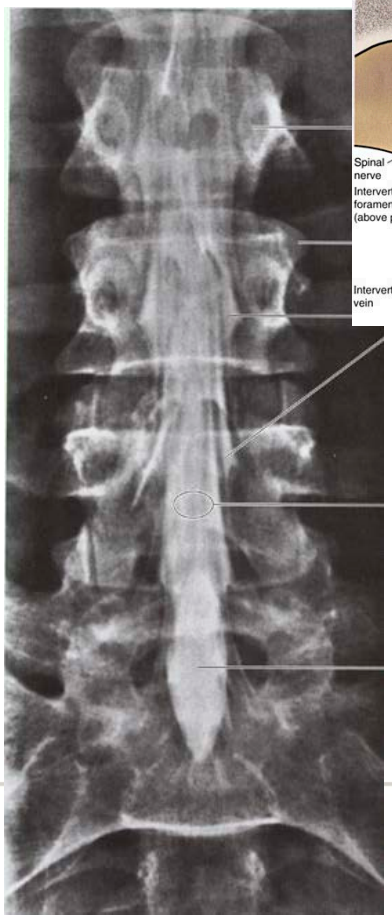


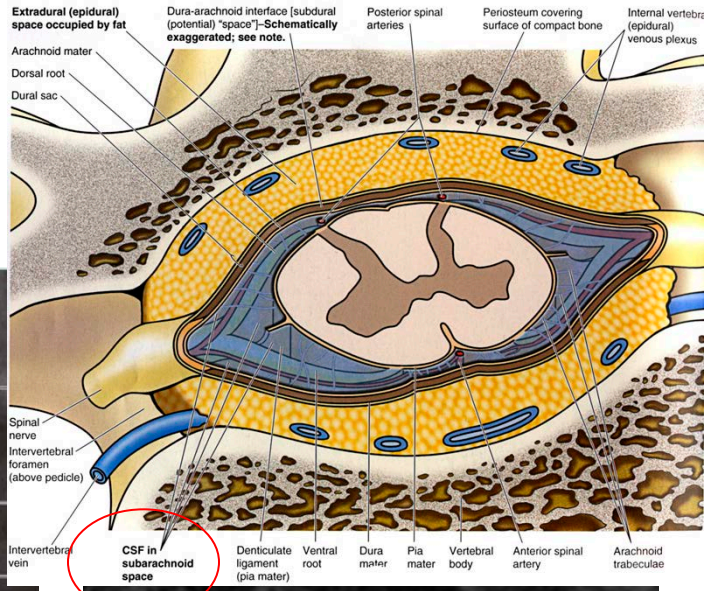




Coverage of the spine: lateral borders

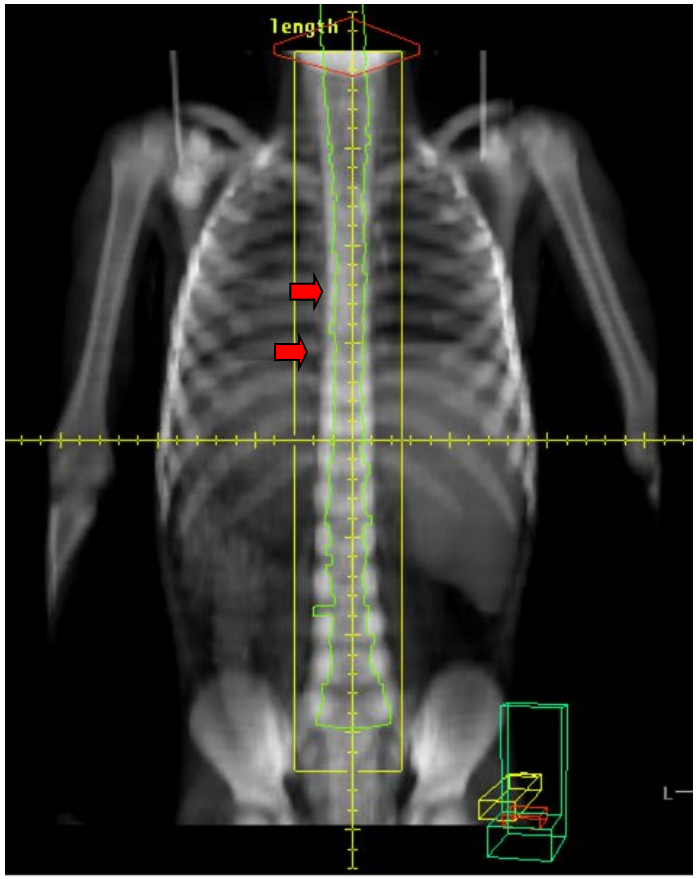
- Dural root sleeves extend to envelop the spinal ganglia
- Lateral aspect of the spinal ganglia have been related to the pedicles as seen on conventional radiographs/ simulation films
- Lateral limit well seen on axial T2- weighted images



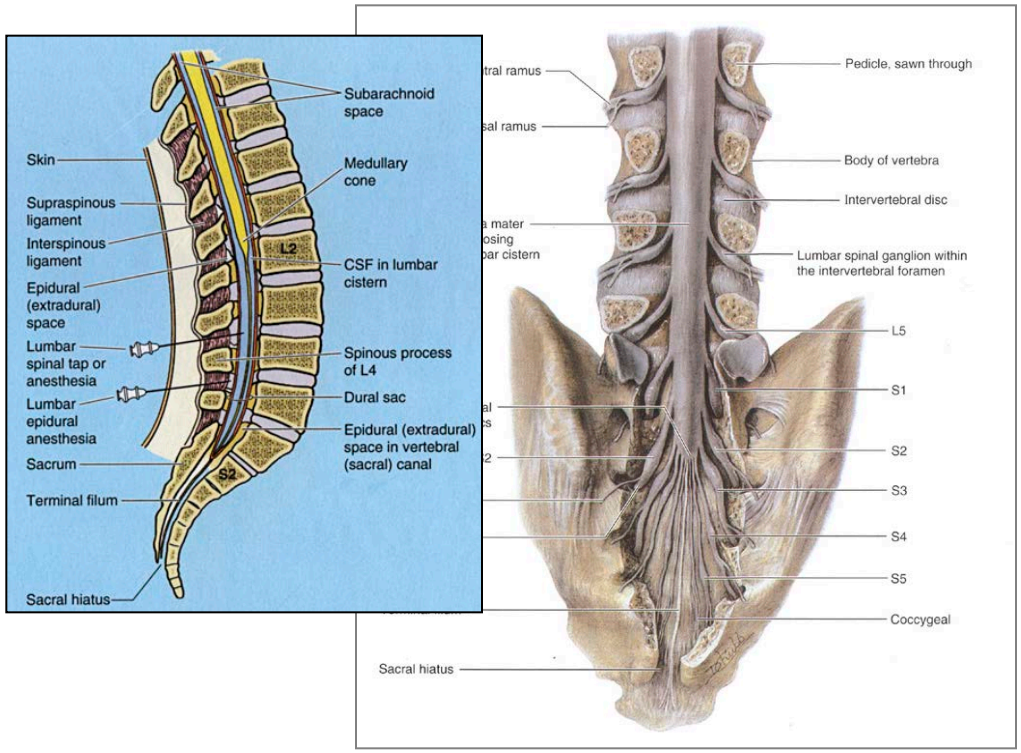


Why is this important?

- Use of optimal imaging/CT simulation/ 3D planning/field shaping allows ↓ width of the spine field
  - Reduces dose to the heart and lungs, other OARs
  - Reduces integral dose



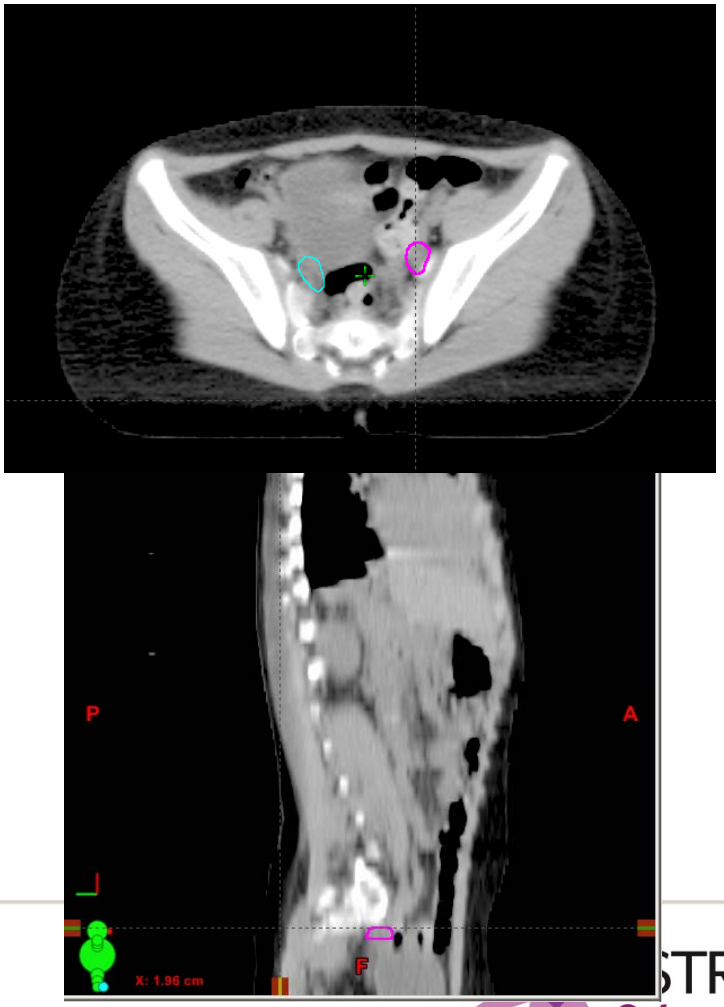
Coverage of the spine: caudal extent of thecal sac



- Dural sac "generally" ends at S1/2
- But:
  - ~50% by bottom S1
  - >90% by bottom S2
  - <10% above L5/S1

Why is this important?

- Accurate determination of the caudal limit of the thecal sac
  - Reduces risk of geographic miss/ recurrence
  - Minimizes dose to OARs, especially the ovaries

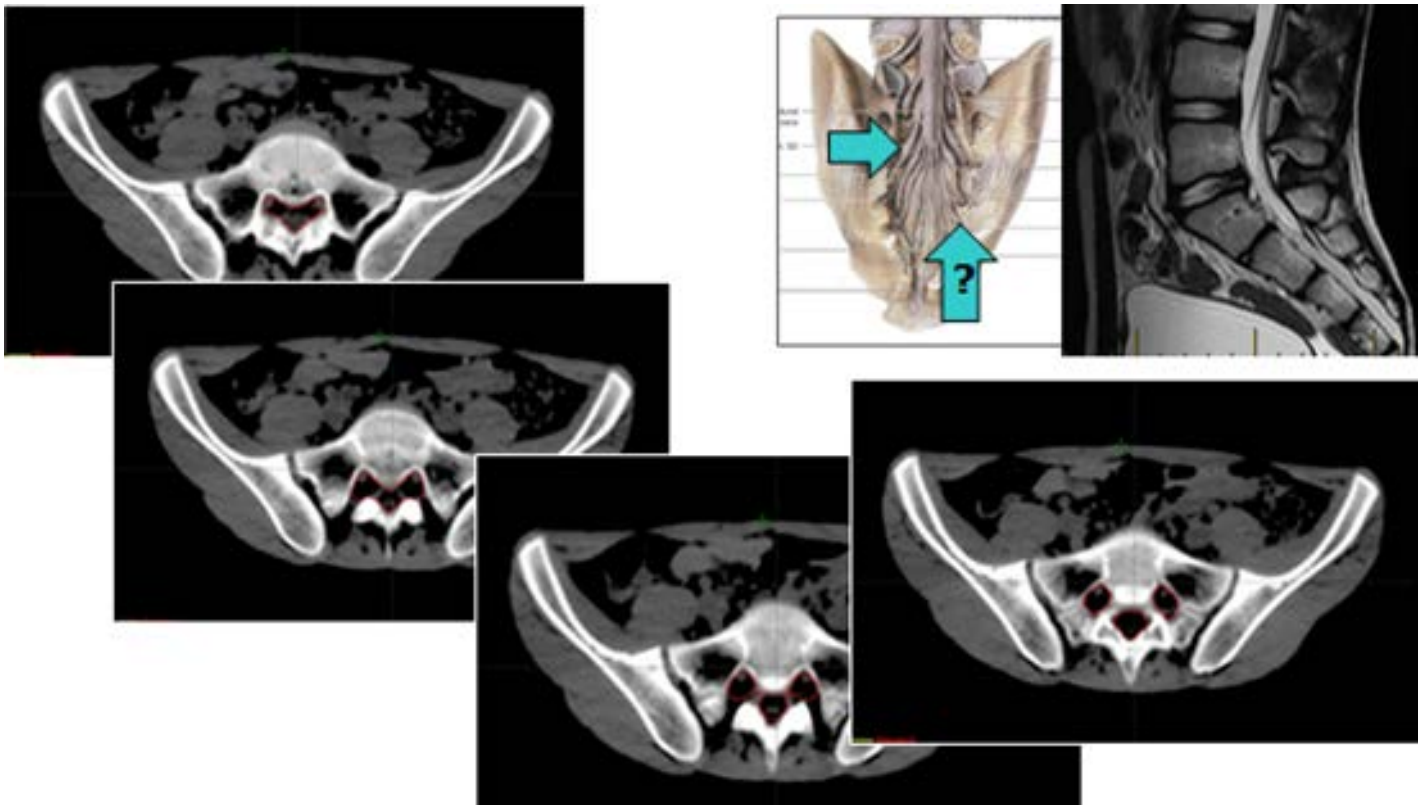


Coverage of the spine: caudal extent of thecal sac

Mid-sagittal T2-weighted MRI

oMRI is **essential** for accurate determination of the caudal extent of the thecal sac

Contouring the distal thecal sac



Bottom line…

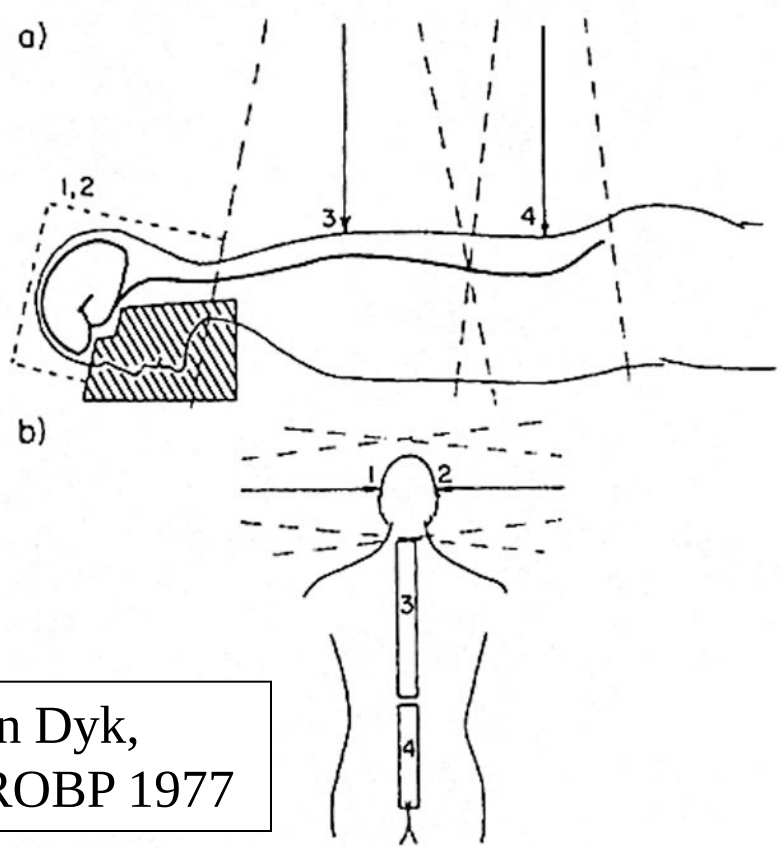
- Contouring for CSI is time consuming but absolutely critical
    - Optimal definition of target volumes
    - Maximum sparing of normal tissues

- Context of new techniques, lower doses

Radiotherapy technique: CSI

CSI: technical issues

A standard CSI technique



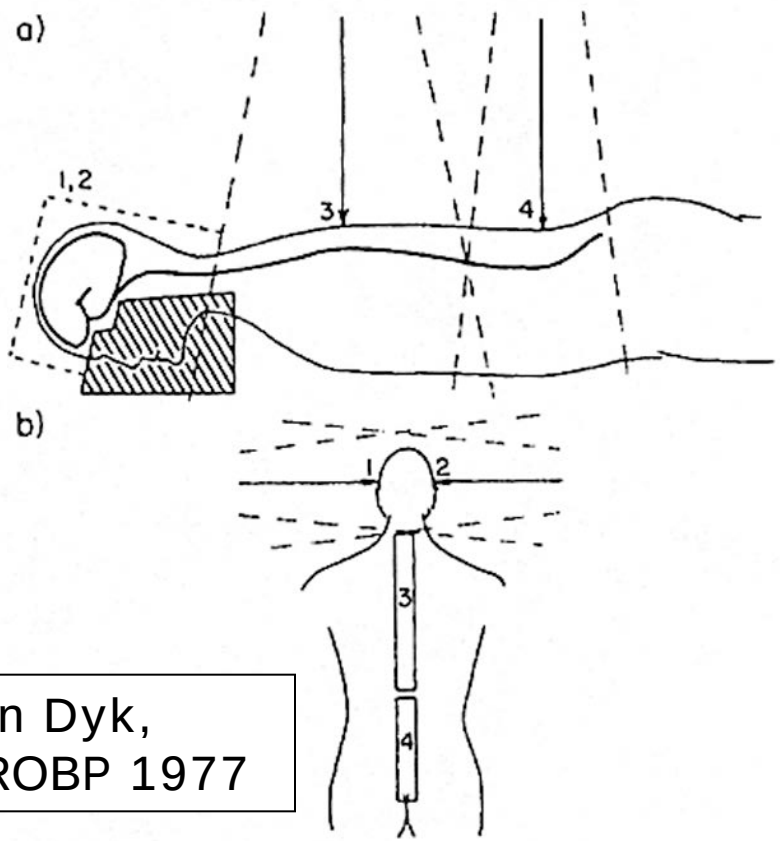
Van Dyk, IJROBP 1977

Patient prone in a head rest with neck extended

Junction of non-coplanar fields over the cervical spine

Extended SSD or second posterior field to cover whole length of spine/second junction over the spinal cord

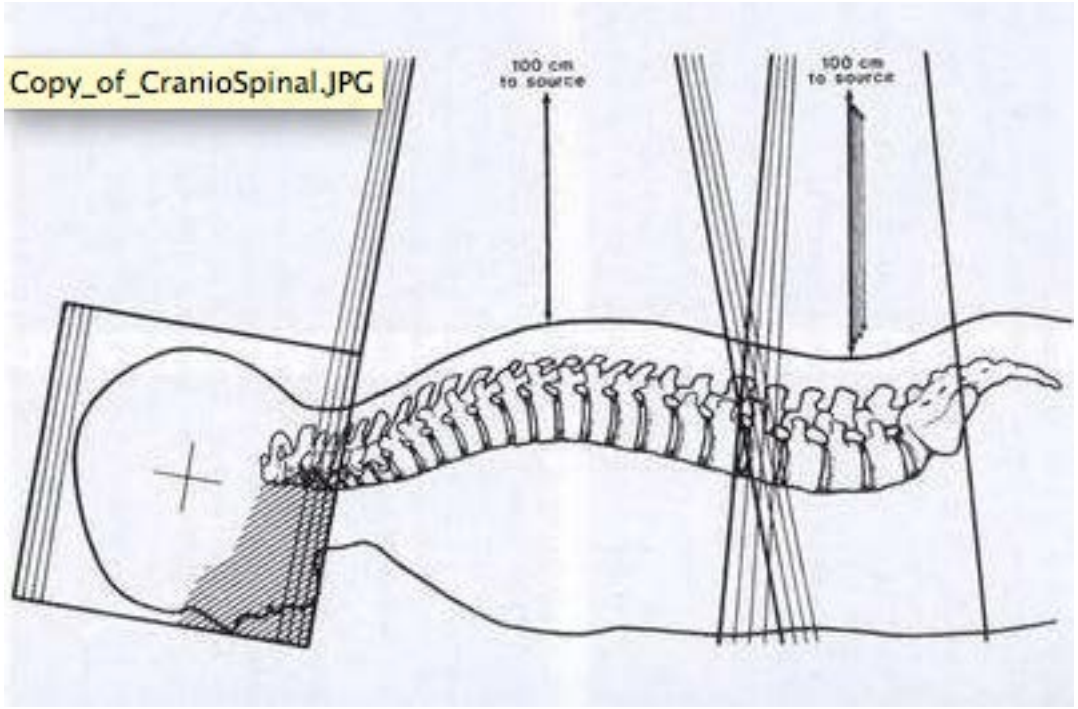
Conventional technique



Van Dyk, IJROBP 1977

- Reproducibility of positioning/margins required to account for set-up errors
- Safety of anaesthesia for infants treated in the prone position
- Time taken for simulation and for each daily treatment
- Dose inhomogeneities in the target volume, especially at the junctions and along the length of the spinal axis

Just some of the issues…



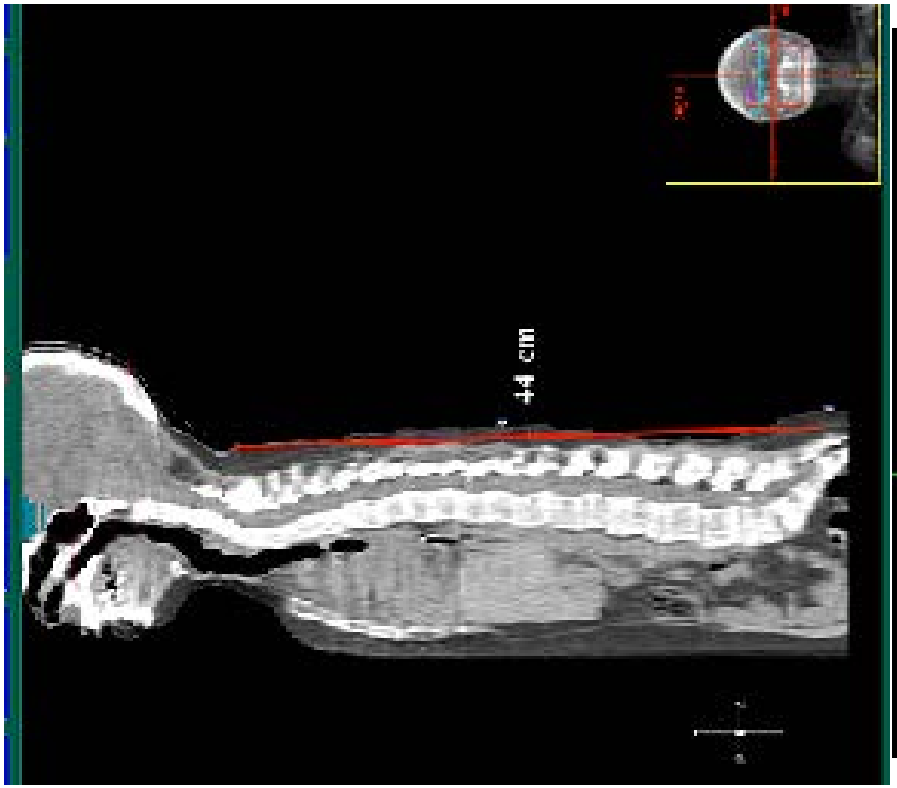
Just some of the issues…

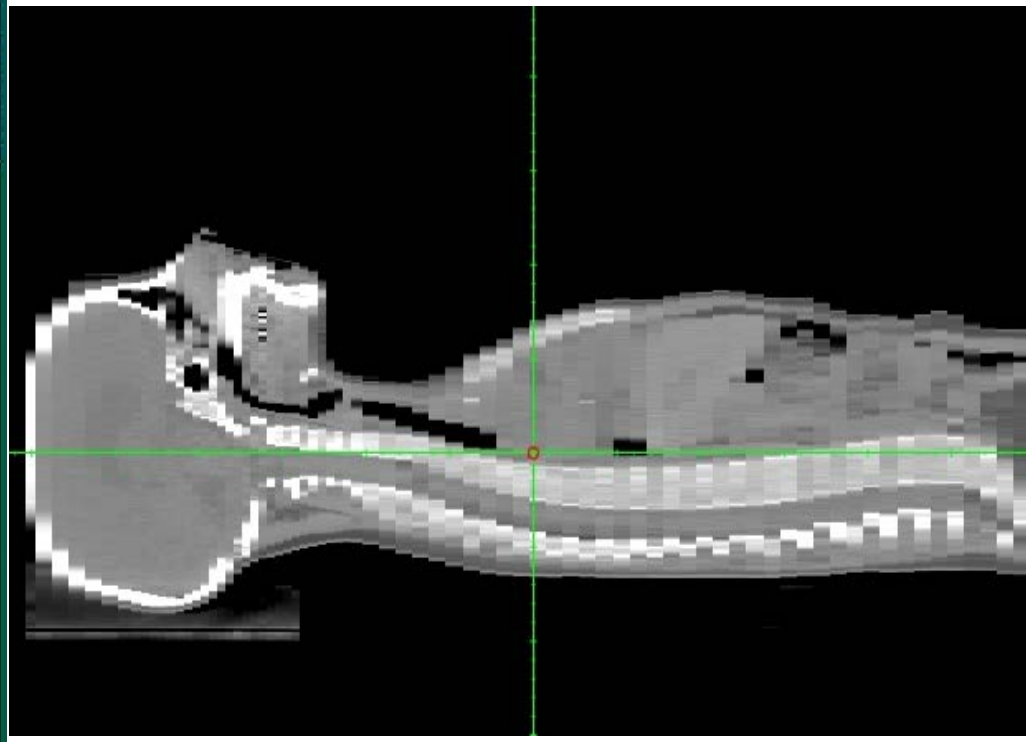
- Placement of centre of brain fields
- Posterior angulation of lateral fields to spare contralateral lens
- MLC *vs* custom blocks for shielding
- High *vs* low junction in the cervical region
- Use of couch rotation or match line wedge for junction in the cervical region
- Use of a gap/feathering of junction in the cervical region
- Second field *vs* extended SSD for spinal axis

Evolution of CSI technique

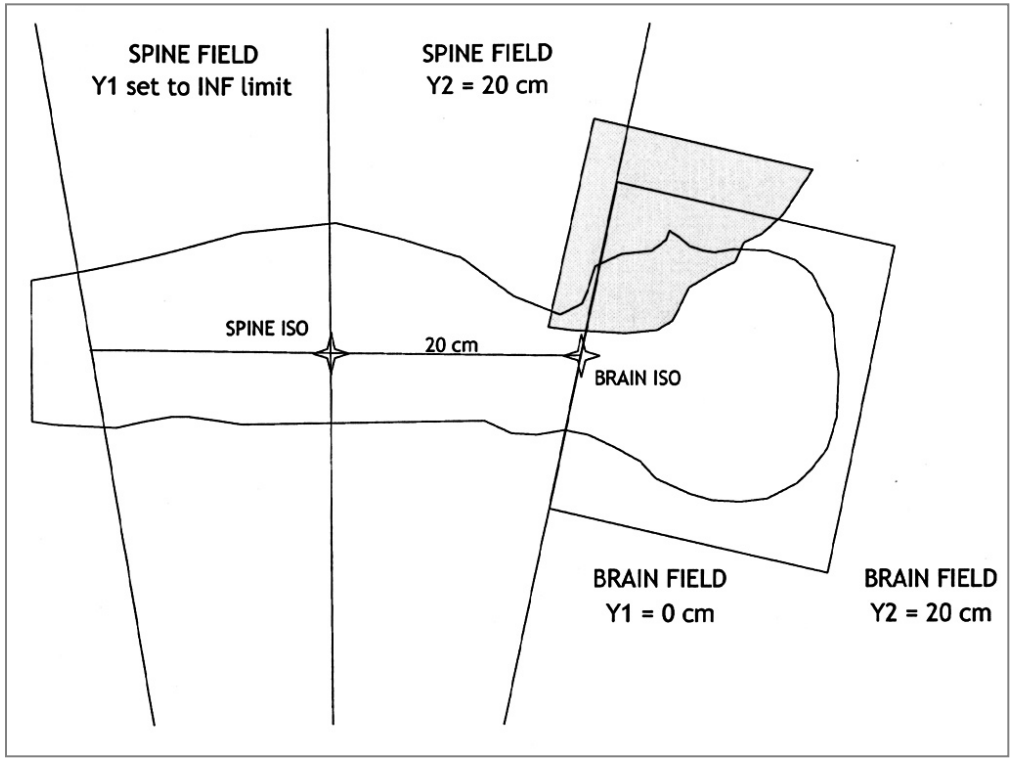
- Supine position
- CT simulation
- Simplification of beam geometry
- Better junction planning
- New delivery options (e.g., Tomotherapy, VMAT)

From prone to supine….





McGill technique

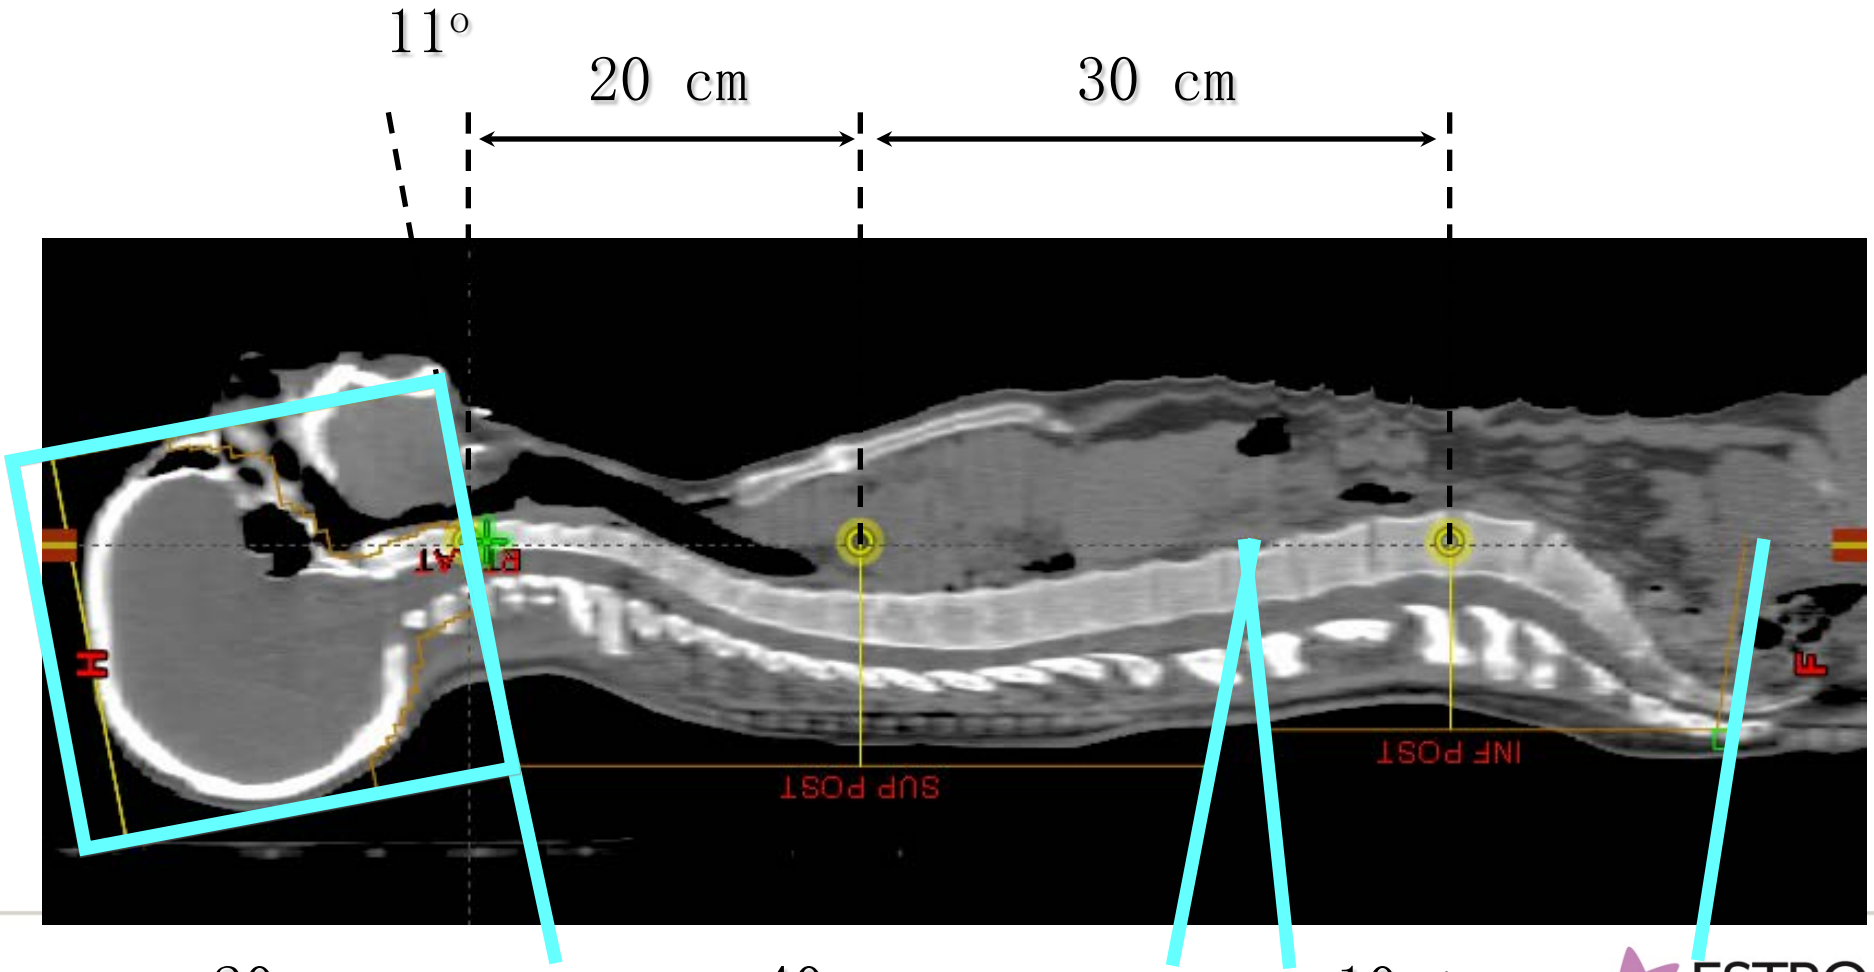


- Supine position, neck extended
- Isocentre of brain fields at junction with spine field
- Isocentre of (upper) spine field at fixed distance from centre of brain field/fixed collimator angle of 11° for brain fields

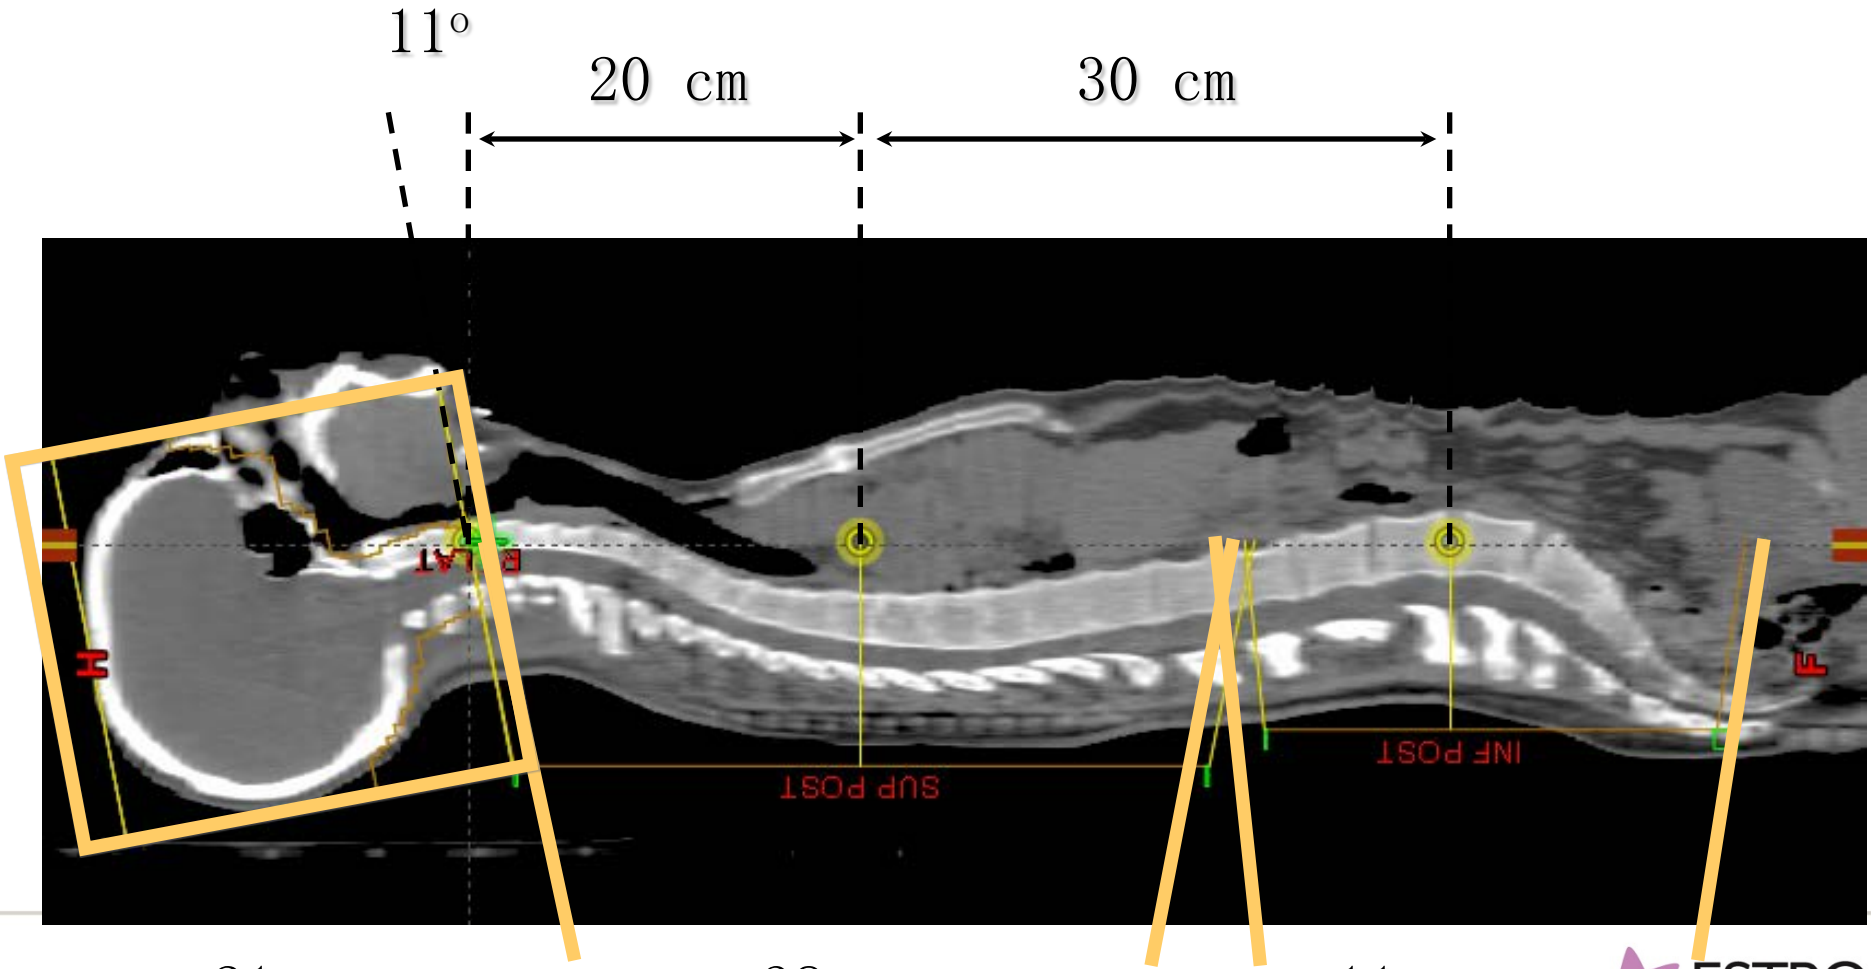
Parker and Freeman, Radiotherapy and Oncology 2006; 78:217-222

ESTRO School

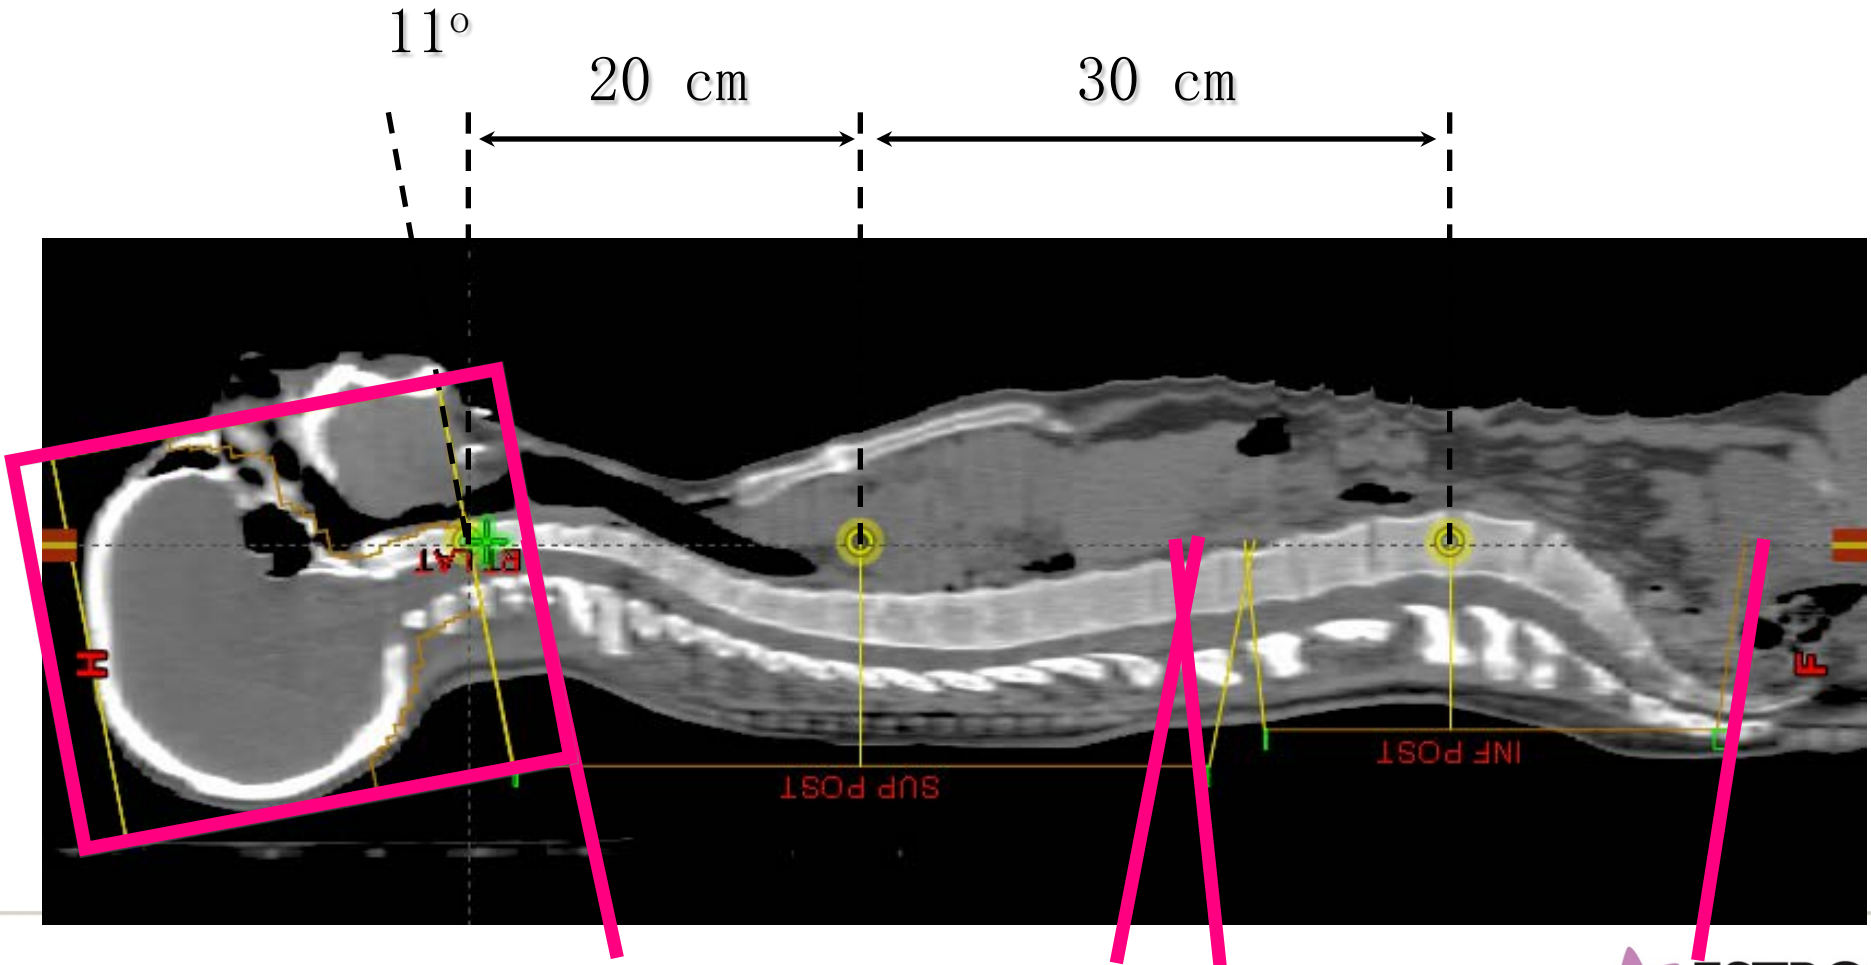
McGill technique: junctions



McGill technique: junctions



McGill technique: junctions



ESTRO School

Comparison with other CT-based techniques

- Advantages of McGill technique
  - **Supine position** → greater comfort, reproducibility, safety if anaesthesia required
  - Clean junction/**no couch rotation**
  - **Fixed distance longitudinal couch movements** only
  - MLC compensation for spinal axis, **automated delivery**
- Fulfills requirement for a technique "as simple and practical as possible" (Van Dyk, 1978)!

Other options for CSI

Rationale: to reduce long term complications of treatment

Long-term complications of radiotherapy

Due to radiotherapy to the brain
- Neuro-cognitive deficits/effects on social interactions
- Hypopituitarism
- Alopecia
- Cataracts
- Hearing loss

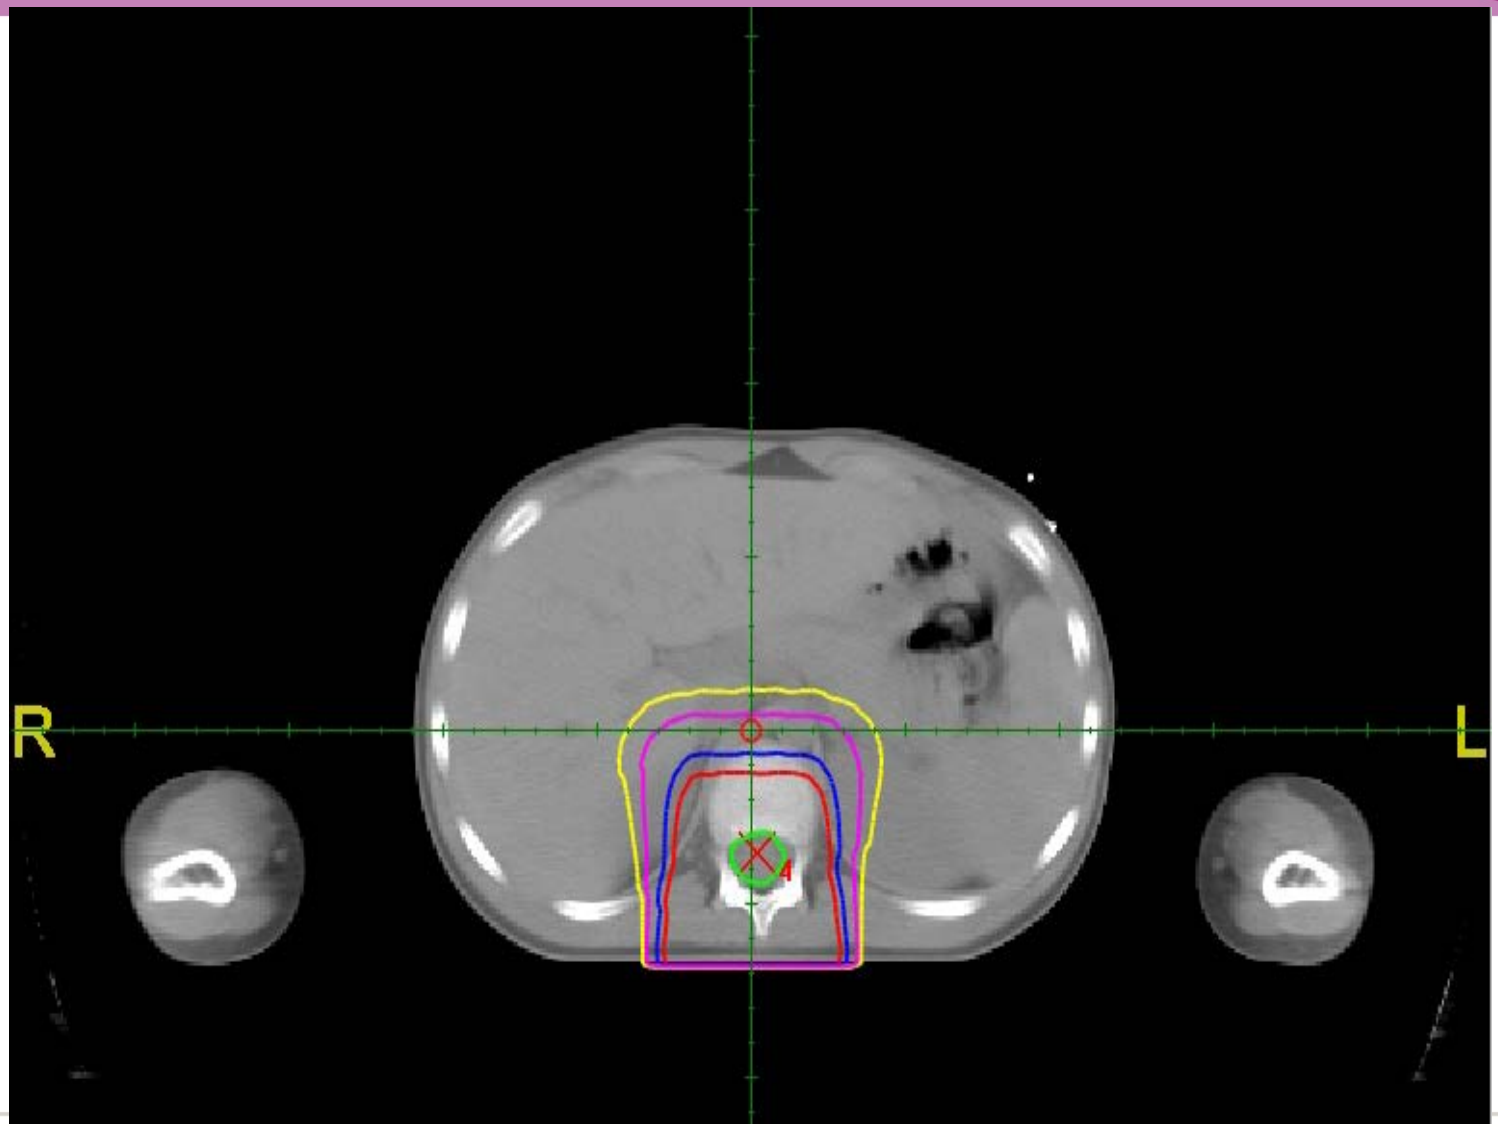
Due to radiotherapy to the spine
- Short stature
- Primary hypothyroidism
- Impaired lung function
- Effects on the heart
- Primary ovarian failure

Both
- Second cancers...

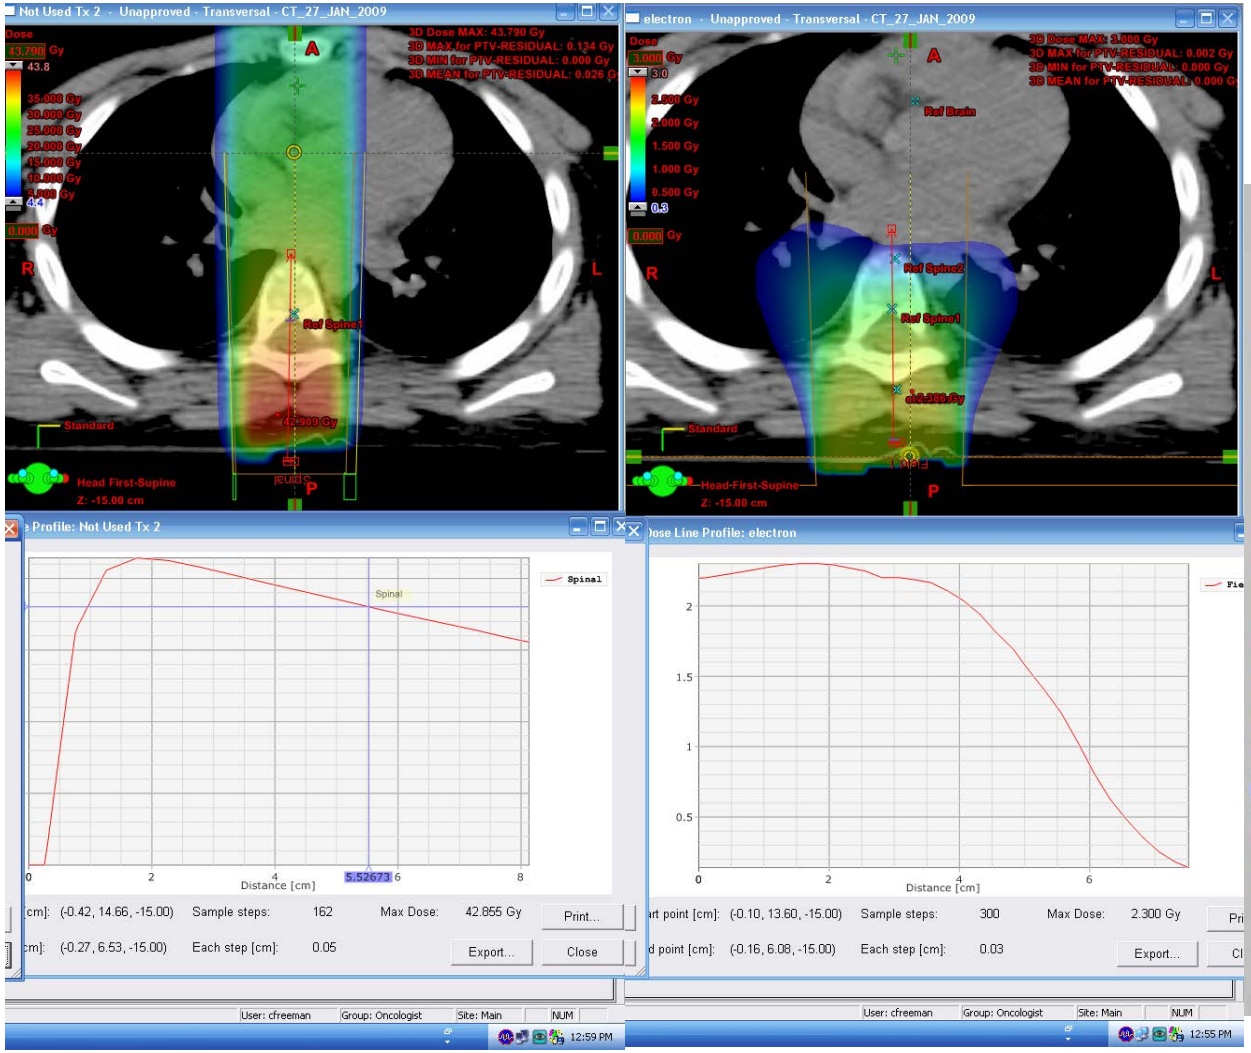
Other options for CSI

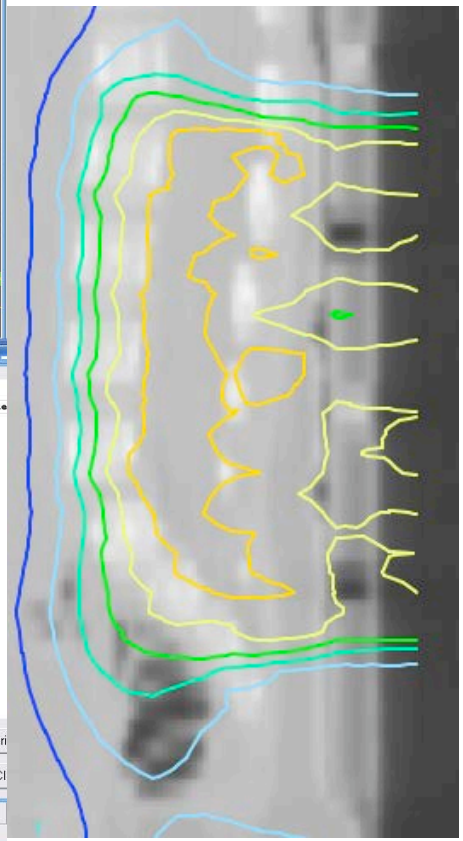
- Electrons for the spinal axis
- IMRT (tomotherapy, VMAT)
- Proton therapy

Electrons for spinal irradiation



Electrons for the spinal axis

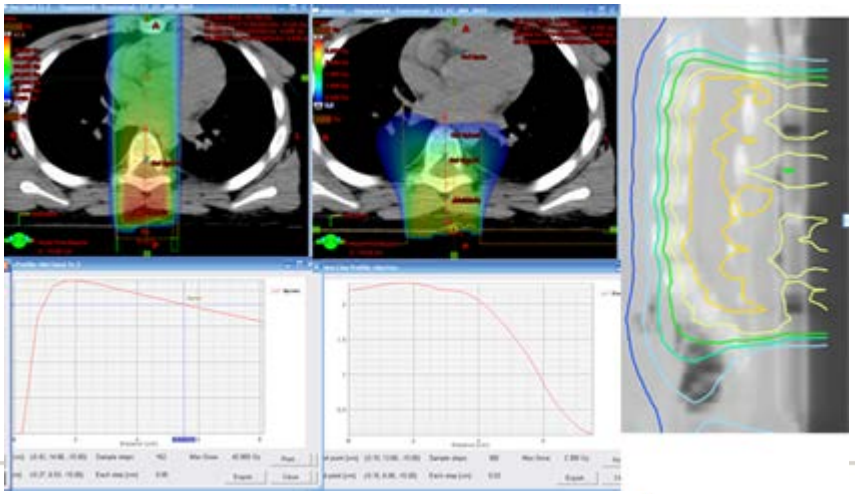




Electrons for the spinal axis

Problems:

- Limitations on length of field (20-25 cm)
- Dosimetry at junctions
- Possible variations in dose to CTV because of attenuation by bone
- Dose gradient in vertebrae
- Increased dose to lungs
- Use of energies < 22 MEV are associated with an excess of failures (Carrie, 1992)
- Use with care !

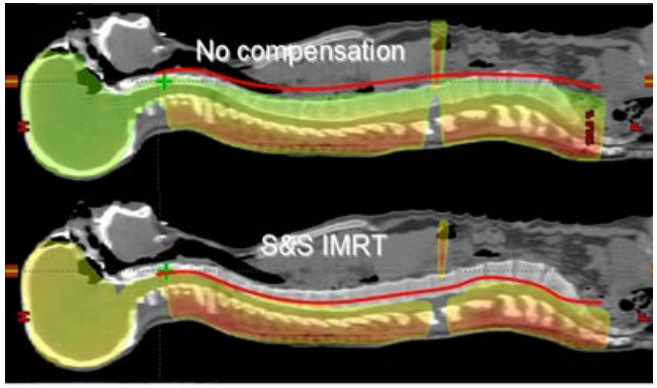


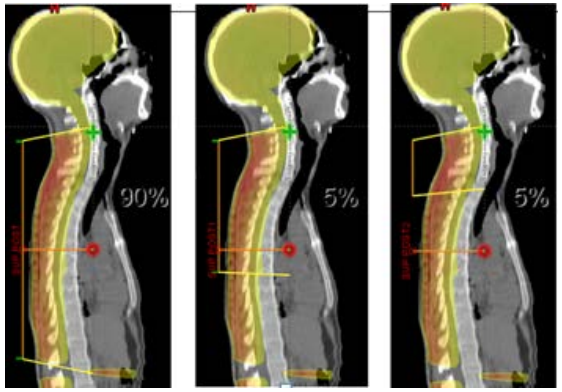
ESTRO School

IMRT for the spinal axis

- IMRT reduces high dose exposure to all OARs: Thyroid,lungs,heart,liver,kidneys,ovaries

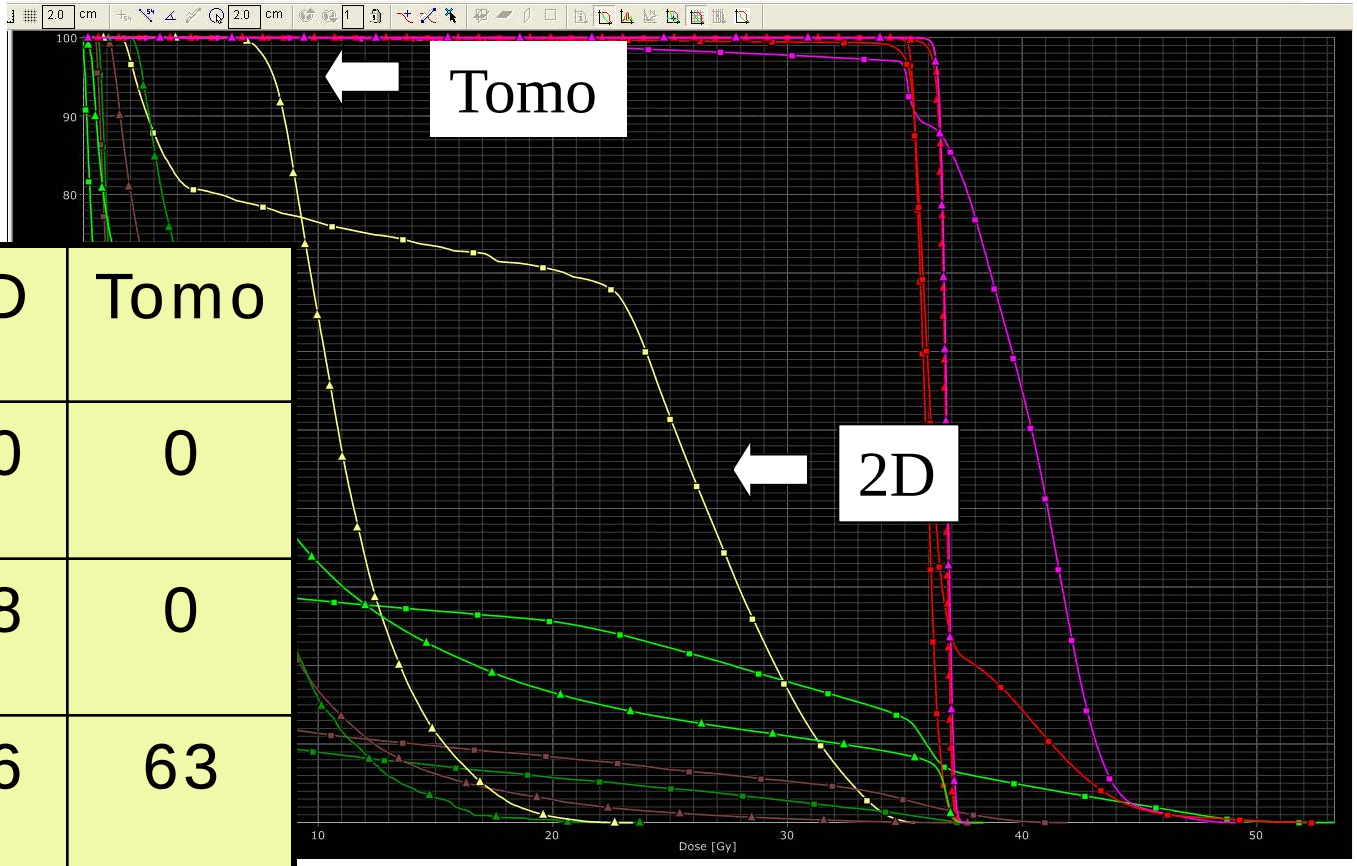
..... At the expense of increased low dose exposure





Dose to the heart

	2D	3D	Tomo
V30Gy	17	10	0
V20Gy	70	58	0
V10Gy	76	66	63
V5Gy	82	73	100

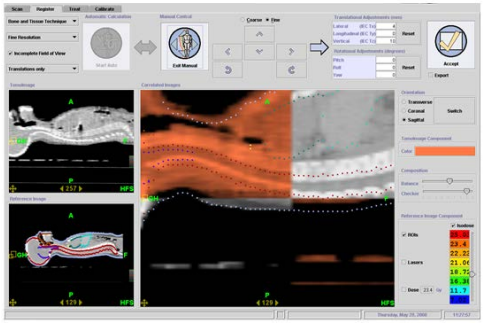


ESTRO School

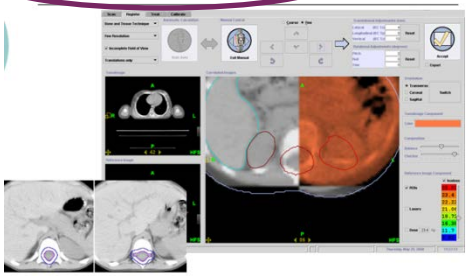
New technical approaches

- Tomotherapy for CSI with IGRT
- VMAT planning using a conventional LINAC with IGRT

Improved reproducibility



Reduced PTV margin



No junctions or field matching

No junctions or field matching

- Less dose posterior to the target
- No overlap/less dose anterior to the target
- Bath dose (?)

A Little to a Lot or a Lot to a Little?

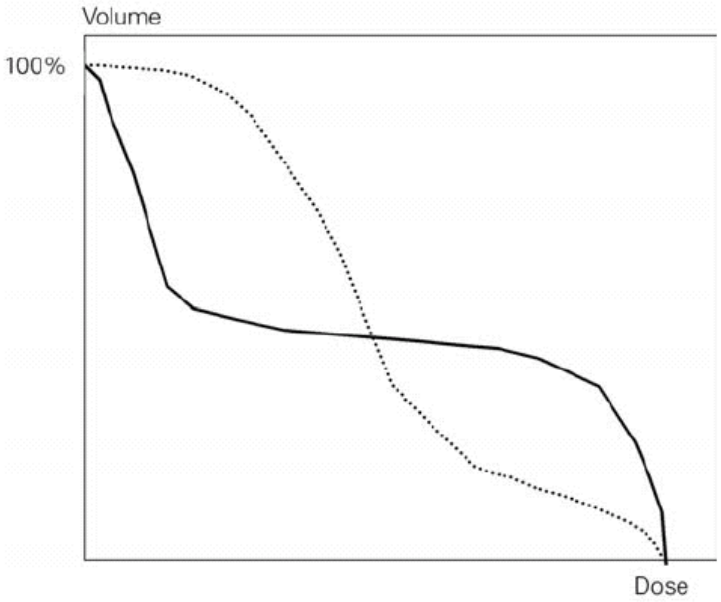


Figure 1. Schematic cumulative dose-volume histogram.

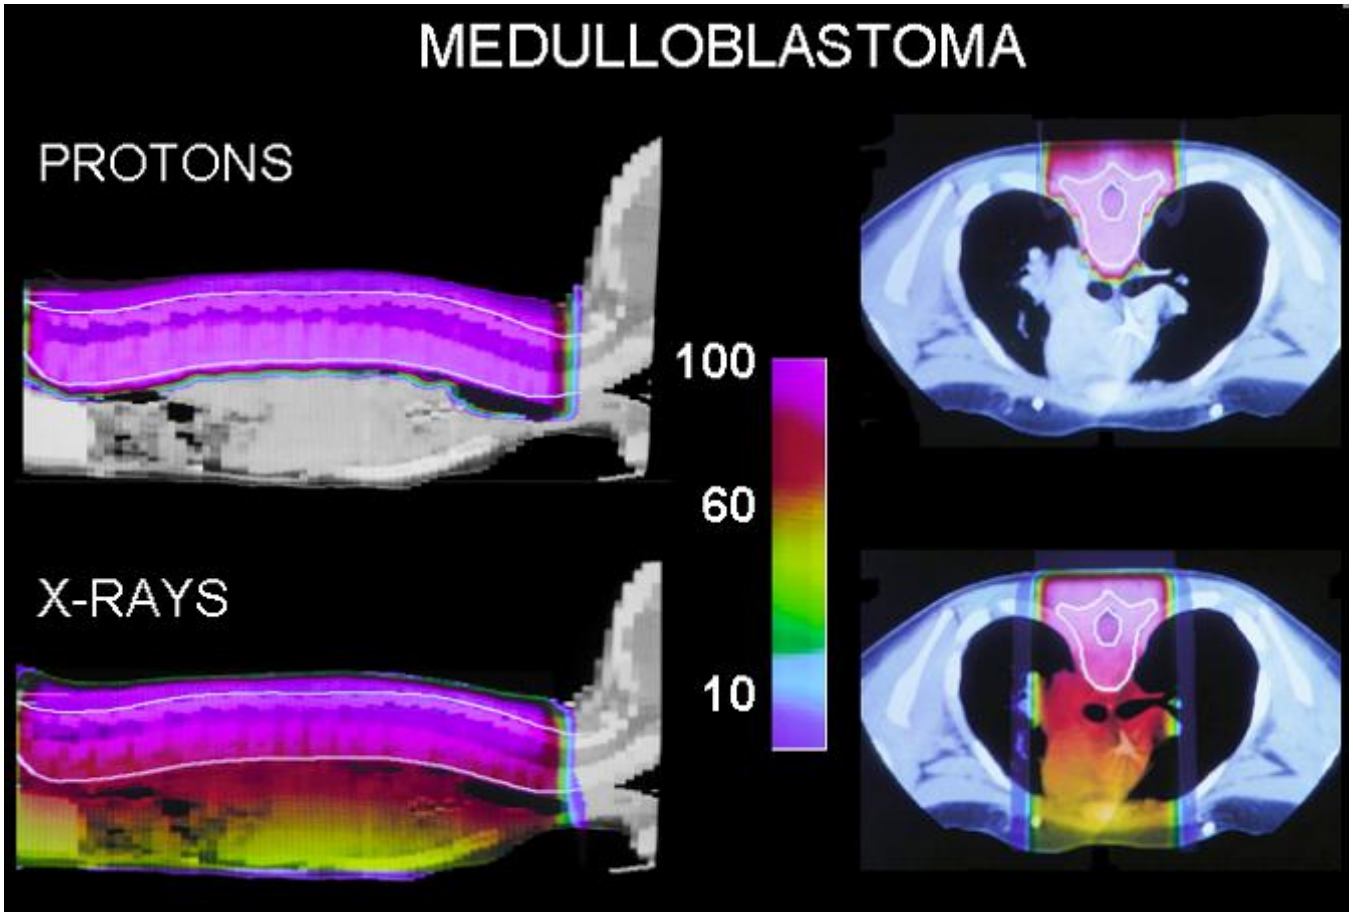
Abbildung 1. Schematische Beschreibung des Problems am Dosis-Volumen-Histogramm.

Protons



Thanks to Nancy Tarbell MD

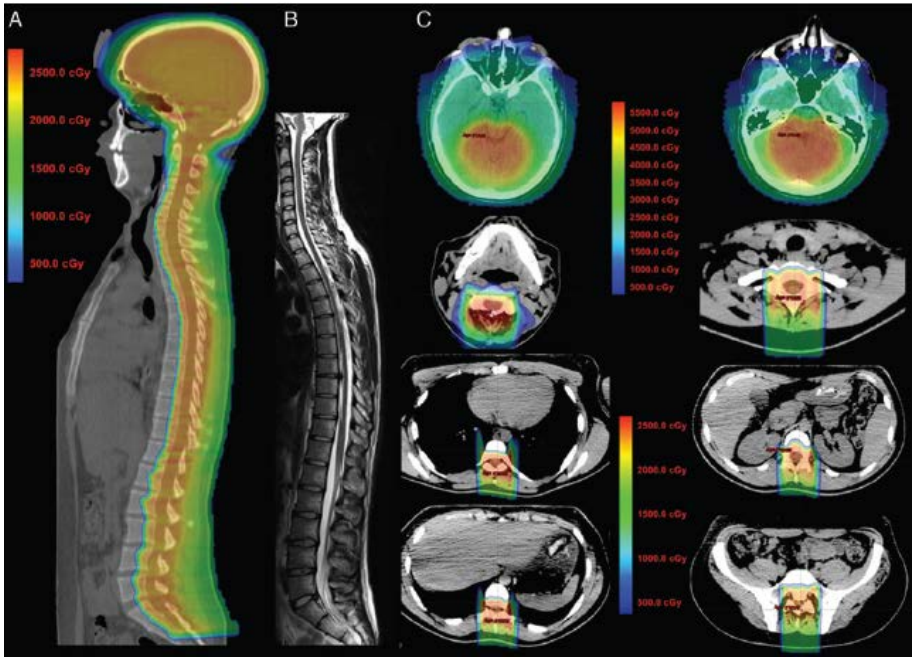
Proton therapy

Attractive for...

•Dose escalation

•Potentially reducing adverse effect of treatment

•Focal treatment and large volumes (i.e. CSI)



Caution for....
-Deviations (organ motion, set-up errors, density changes..)
-Metal implants
-High weighted spots
-Beam arrangements

Barney CL et al., Neuro-oncology, 2014

ESTRO School

CSI: concluding remarks

- CSI is a complex treatment that for optimal results must be done properly, using modern technology including CT simulation with additional information provided by MRI for target volume definition
- Newer techniques address many of the technical issues that were associated with older techniques, as well as being much simpler to plan and treat
- Reduced dose to OARs is possible using IMRT + IGRT
- The future: protons for all?

CSI: concluding remarks

POINT/COUNTERPOINT

Pediatric medulloblastoma: Is proton beam the only ethically appropriate radiation treatment?

Anthony Zietman, MD, FASTRO, *Editor-in Chief IJROBP*

International Journal of Radiation Oncology biology • physics
www.redjournal.org

PRO

- Fewer acute toxicity

- Substantial reduced risk of radiation related secondary neoplasm

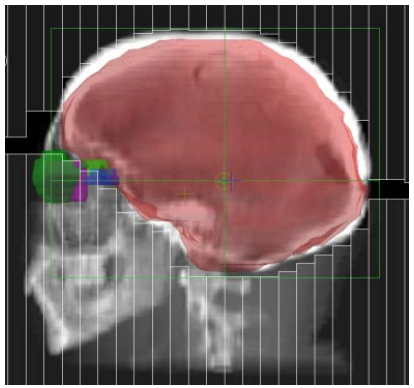
CON

- No sufficient clinical data to argue that proton therapy is the only acceptable treatment

- Future study is required to better characterize the long-term clinical benefit of proton therapy

Radiotherapy: treatment techniques wide field irradiation

Whole Brain Radiation Therapy



ESTRO School

WBI

- WBI: technical aspects

Good RT technique also for palliation

Technical considerations:

PHYSICS CONTRIBUTION

THE ROLE OF CT SIMULATION IN WHOLE-BRAIN IRRADIATION

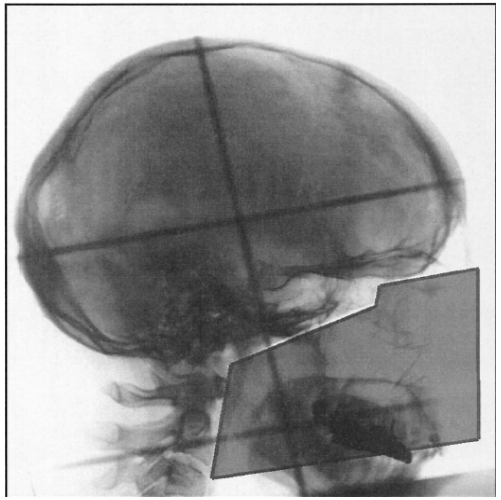
STEPHAN GRIPP, M.D., ROLF DOEKER, M.D., MICHAEL GLAG, M.D., PETRA VOGELSANG, BURCKHARDT BANNACH, M.S., THORSTEN DOLL, M.S., KLAUS MUSKALLA, PH.D., AND GERD SCHMITT, M.D.

Klinik für Strahlentherapie und Radiogische Onkologie, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany

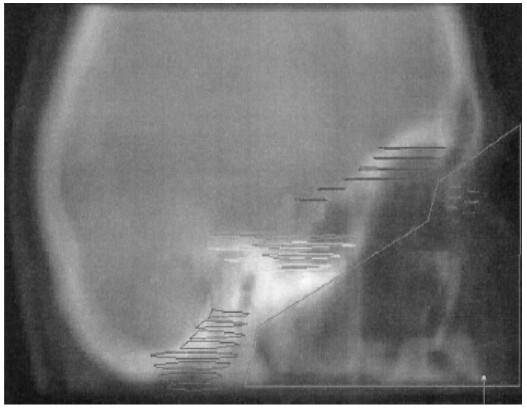
To evaluate the potential benefits of CT simulation in WBI comparing field-shaping based on 3D CT simulation to conventional 2D simulation.

- CT head scans were obtained from 20 patients.
- Conventional 2D planning was obtained by drawing the block contours on digitally reconstructed radiographs (DRR) as in conventional simulation
- 3D-planning was obtained by contouring target volume on the CT slices.

- To assess the adequacy of margins, the minimal distance from the field edge to the contoured organ was measured for both planning situations at six sites (the subfrontal region (midline), both ocular lenses, both temporal lobes, and the medulla)



Portal design in WBI by conventional simulation



3D block shaping in 3D-planning

Klinik für Strahlentherapie und Radiogische Onkologie, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany

RESULTS

In conventional planning using DRR

- major geographic mismatches (>3 mm) occurred in the subfrontal region
- minor mismatches (-3 to 0 mm) predominantly occurred in the contralateral lens (21%), ipsilateral lens (10%), and subfrontal region (9%)
- close margins (0–5 mm) were most frequently noted at the contralateral lens (49%), ipsilateral lens (35%), and the subfrontal region (28%)

In 3D planning

- mismatches were not found
- close margins were inevitable at the ipsilateral lens (5%), subfrontal region (30%), and contralateral lens (70%)

PHYSICS CONTRIBUTION

THE ROLE OF CT SIMULATION IN WHOLE-BRAIN IRRADIATION

STEPHAN GRIPP, M.D., ROLF DOEKER, M.D., MICHAEL GLAG, M.D., PETRA VOGELSANG, BURCKHARDT BANNACH, M.S., THORSTEN DOLL, M.S., KLAUS MUSKALLA, PH.D., AND GERD SCHMITT, M.D.

Klinik für Strahlentherapie und Radiogische Onkologie, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany

CT simulation in WBI is significantly superior to conventional simulation with respect to complete coverage of the target volume and protection of the eye lenses

Neurocognitive effects of WBRT

Dementia after WBI

Risk factors

- Treatment volume
- Fraction size >2 Gy
- Total dose: less important than fraction size
- Concurrent chemotherapy: possible
- Age: elderly patients (> 60 yrs) at higher risk

Neurocognitive effects of WBRT

A European Organisation for Research and Treatment of Cancer Phase III Trial of Adjuvant Whole-Brain Radiotherapy Versus Observation in Patients With One to Three Brain Metastases From Solid Tumors After Surgical Resection or Radiosurgery: Quality-of-Life Results

- HRQOL was assessed at baseline, at 8 weeks, and then every 3 months for 3 years (EORTC Quality of Life Questionnaire C30 and Brain Cancer Module).

- The following six primary HRQOL scales were considered: global health status; physical, cognitive, role, and emotional functioning and fatigue.

- Overall, patients in the observation only arm reported better HRQOL scores than did patients who received WBRT.
- The differences were statistically significant mostly during the early follow-up period (for global health status at 9 months, physical functioning at 8 weeks, cognitive functioning at 12 months and fatigue at 8 weeks).

ESTRO School

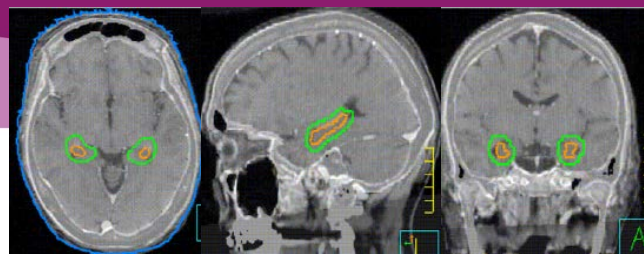
WBI with hippocampal sparing Remarks



- Hippocampus plays a fundamental role in immediate or long-term memory and the spatial learning and is rarely involved by metastasis
- Sparing hippocampi during WBI becomes possible with volumetric modulated arc therapy (VMAT) or with helical tomotherapy
- The delineation of the structures should be performed after co-registration of gadolinium-enhanced T1-weighted MR-images with the planning CT
- The D40 to both hippocampi should not be greater than 7.3 Gy
- Preliminary informations of a possibile neurocognitive sparing effect (delayed recall as assessed by HTVL-R)

Hippocampal avoidance and WBI

Hippocampal avoidance and WBI

Preservation of Memory With Conformal Avoidance of the Hippocampal Neural Stem-Cell Compartment During Whole-Brain Radiotherapy for Brain Metastases (RTOG 0933): A Phase II Multi-Institutional Trial

Vinai Gondi, Stephanie L. Pugh, Wolfgang A. Tome, Chip Caine, Ben Corn, Andrew Kanner, Howard Rowley, Vijayananda Kundapur, Albert DeNittis, Jeffrey N. Greenspoon, Andre A. Konski, Glenn S. Bauman, Sunjay Shah, Wenyin Shi, Merideth Wendland, Lisa Kachnic, and Minesh P. Mehta

- Eligible adult patients with brain metastases received HA-WBRT (30 Gy/10 fr).
- Standardized cognitive function and quality-of-life (QOL) assessments were performed at baseline and 2, 4, and 6 months.
- The primary end point was the Hopkins Verbal Learning Test–Revised Delayed Recall (HVLT-R DR) at 4 months.

- 42/113 pts were analyzable at 4 months. Mean relative decline in HVLT-R DR from baseline to 4 months was 7%, significantly lower in comparison with the historical control ($p < .001$).
- No decline in QOL scores was observed.

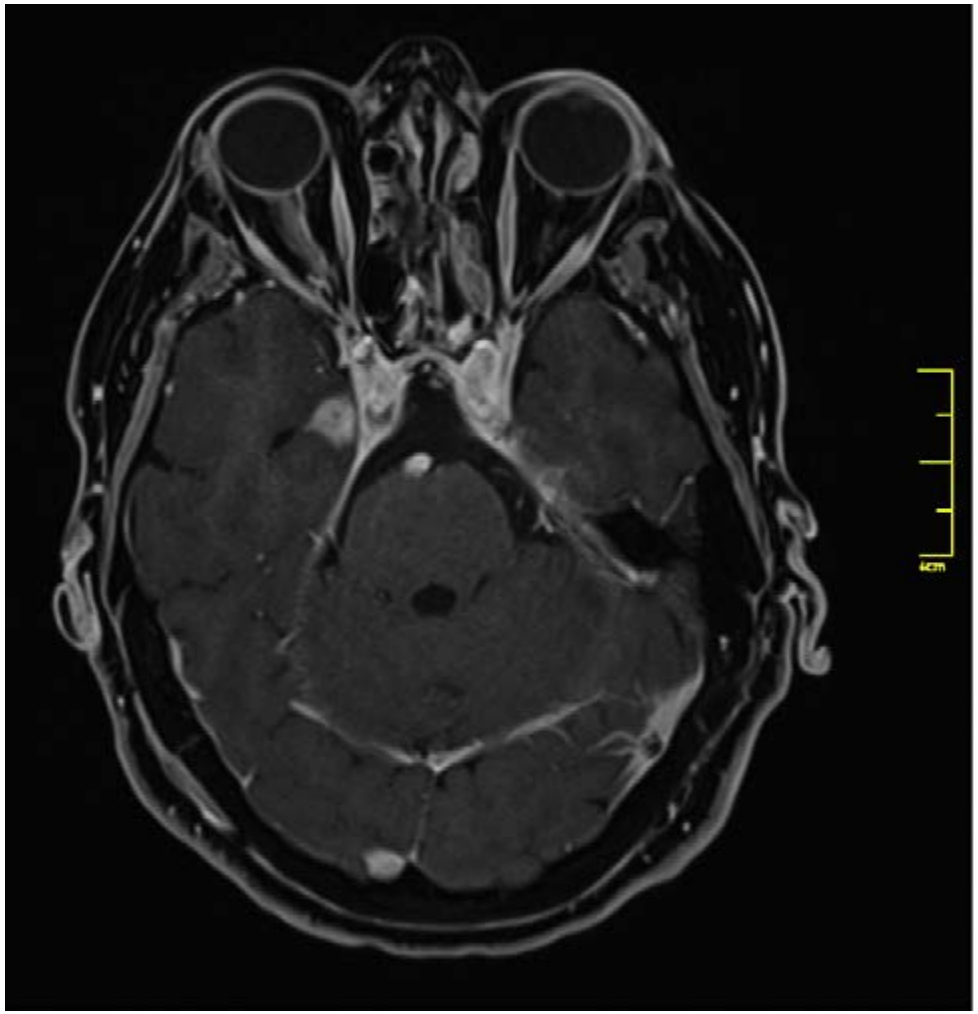
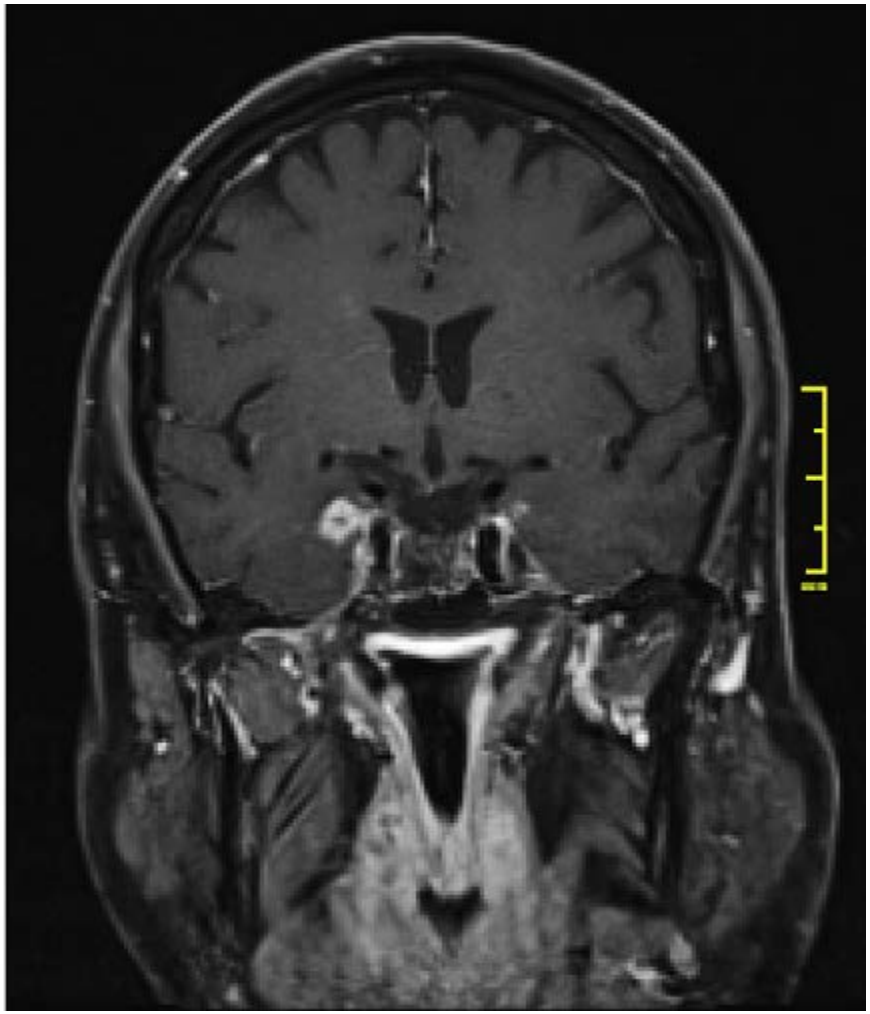
Late toxicity After Radiotherapy….





Type of Late Toxicity (CNS)

- Brain necrosis
- Brainstem damage
- Pituitary dysfunction
- Cochlear toxicity
- Optic apparatus
- Hippocampal toxicity

Factors affecting toxicity (General)

I.	Host	Age Comorbid conditions Host response to radiation Smoking KPS	
II	Organ	Pre-radiation organ condition (Poor PFTs; LFTs; COPD) Regional variation of radiosensitivity with the organ Impact of other organs Hierarchal organization of the organ: Serial: dose effect: spinal cord Parallel: volume effect: lung, liver Both: kidney	
III	Natural history of tumor		
IV	Treatment	A—Radiation Dose (max, min, mean) Fractionation (fractional dose): BED Dose rate Overall treatment time Treatment energy Volume (V dose: absolute or relative)	
IV	Treatment	B—Nonradiation Chemotherapy (drug type, dose, schedule) Radiation modifiers (type, dose, schedule) Surgery (interval)	
V	End points ACUTE	Type: Clinical Radiographical: anatomical, functional Biochemical (blood test, functional test) Degree of severity Degree of frequency Impact on quality of life (QOL)	LATE
VI	Issues on reporting of toxicity		

Reports of Radiotherapy and Oncology

Brain necrosis Introduction

- **Coagulation necrosis**
- **Vascular Thickening**
- **Peri-vascular fibrosis**
- **Infiltartion of chr inflammatory cells**

Therory

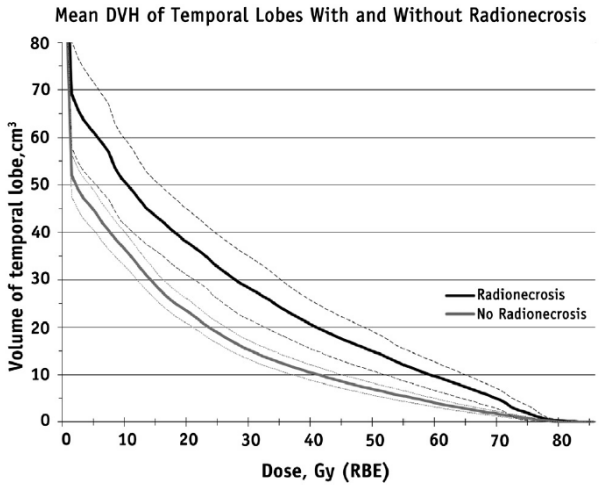
1. **Vascular hypothesis**: lesions of small to medium vessels, necrosis is secondary to ischemia.
2. **Glial hypothesis**: irradiation damage glial cells (oligodendrocytic +++) leading to white matter cavitation and demylenisation
3. **Immunologic hypothesis**: radiation necrosis and vascular change in response to Ag release from damaged glial cells

Brain necrosis (0)

Mental status	Seizures	Motor function
Gr. 1: Mild subjective memory loss or transient alteration of mental status	–	–
Gr. 2: Moderate subjective memory loss or mental disorder status alteration substantially affecting function	Transient seizure	Substantially affects function: <50% decrease of baseline capabilities
Gr. 3: Severe memory loss affecting function <50% of time	Seizure disorder controlled by medical therapy	Substantially affects function: >50% decrease of baseline capabilities
Gr. 4: Coma	Seizure disorder not controlled by medical therapy	Paralysis

Modified RTOG-EORTC late morbidity scoring system.

Brain necrosis (1)



Necrosis @ 3 year	**12.4%**
Necrosis @ 3 year (grade 2 and higher)	5.7%

Dose–Volume Relationships Associated With Temporal Lobe Radiation Necrosis After Skull Base Proton Beam Therapy

Mark W. McDonald, MD,*,† Okechukwu R. Linton, MD, MBA,* and Cynthia S.J. Calley, MA‡

Mean dose–volume information to area of radiation necrosis by grade of radiation necrosis

	Grade 1/asymptomatic	Grade 2 or higher	*P* value
Volume, cm^3	2.15	3.66	.51
Minimum dose	54.0	50.2	.58
Maximum dose	75.0	82.9	<.01
Mean dose	68.6	73.0	.02
Epicenter dose	70.9	76.7	<.01

Dose is given in Gy (relative biological effectiveness).

Dose–volume levels associated with 3-year risk of any-grade temporal lobe radiation necrosis

Risk level	aV40	aV50	aV60	aV70
10%	16.5	9.0	5.1	1.2
15%	16.5	9.6	5.5	1.7
20%	16.6	10.1	5.8	2.0
30%	16.7	10.8	6.3	2.5
40%	16.7	11.4	6.8	3.1
50%	16.8	12.2	7.2	3.9

Abbreviations: aV = absolute volume of temporal lobes exposed to dose in Gy (RBE); RBE = relative biological effectiveness. Volume is expressed in cubic centimeters (cm^3).

Post-PCI brain metastasis	8 (11)*

Risk of Hippocampal Metastases in Small Cell Lung Cancer Patients at Presentation and After Cranial Irradiation: A Safety Profile Study

Conclusions (late toxicity)

1. CNS toxicity is dose dependant and volume dependant
2. Metrics/dose constraints are based on studies with varying parameters (target volume, sample size, radiation modality, brain region, etc...)
3. Brain necrosis after (very) high-dose RT frequent: 10-15% @ 5 years
4. Is usually symptomatic and requires therapy
5. Risk factors: Gender?, DVH metrics
6. Pituitary dysfunction: very common for GHD but not treated in the majority of cases
7. GH replacement for cancer patient: no evidence of tumor recurrence
8. Constraints mean dose to cochlea to < 43-45 Gy
9. Constraint dose to 60 and 55-56 Gy to the ON and OC, respectively.
10. Correlation between hippocampal irradiation and neuro-cognitive toxicity
11. Hippocampal avoidance in young patients with LGG or benigh tumors?

Evaluation of BCNU and/or radiotherapy in the treatment of anaplastic gliomas

A cooperative clinical trial

MICHAEL D. WALKER, M.D., EBEN ALEXANDER, JR., M.D., WILLIAM E. HUNT, M.D., COLLIN S. MACCARTY, M.D., M. STEPHEN MAHALEY, JR., M.D., JOHN MEALEY, JR., M.D., HORACE A. NORRELL, M.D., GUY OWENS, M.D., JOSEPH RANSOHOFF, M.D., CHARLES B. WILSON, M.D., EDMUND A. GEHAN, PH.D., AND THOMAS A. STRIKE, PH.D.

The Brain Tumor Study Group and the National Cancer Institute, National Institutes of Health, Bethesda, Maryland

A controlled, prospective, randomized study evaluated the use of 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU) and/or radiotherapy in the treatment of patients who were operated on and had histological confirmation of anaplastic glioma. A total of 303 patients were randomized into this study, of whom 222 (73%) were within the Valid Study Group (VSG), having met the protocol criteria of neuropathology, corticosteroid control, and therapeutic approach. Patients were divided into four random groups, and received BCNU (80 mg/sq m/day on 3 successive days every 6 to 8 weeks), and/or radiotherapy (5000 to 6000 rads to the whole brain through bilateral opposing ports), or best conventional care but no chemotherapy or radiotherapy. Analysis was performed on all patients who received any amount of therapy (VSG) and on the Adequately Treated Group (ATG), who had received 5000 or more rads radiotherapy, two or more courses of chemotherapy, and had a minimum survival of 8 or more weeks (the interval that would have been required to have received either the radiotherapy or chemotherapy). Median survival of patients in the VSG was, best conventional care: 14 weeks (ATG: 17.0 weeks); BCNU: 18.5 weeks (ATG: 25.0 weeks); radiotherapy: 35 weeks (ATG: 37.5 weeks); and BCNU plus radiotherapy: 34.5 weeks (ATG: 40.5 weeks). All therapeutic modalities showed some statistical superiority compared to best conventional care. There was no significant difference between the four groups in relation to age distribution, sex, location of tumor, diagnosis, tumor characteristics, signs or symptoms, or the amount of corticosteroid used. An analysis of prognostic factors indicates that the initial performance status (Karnofsky rating), age, the use of only a surgical biopsy, parietal location, the presence of seizures, or the involvement of cranial nerves II, III, IV, and VI are all of significance. Toxicity included acceptable, reversible thrombocytopenia and leukopenia.

Mirimanoff, M.D., for the European Organisation for Research and Treatment of Cancer Brain Tumor and Radiotherapy Groups and the National Cancer Institute of Canada Clinical Trials Group*

2005

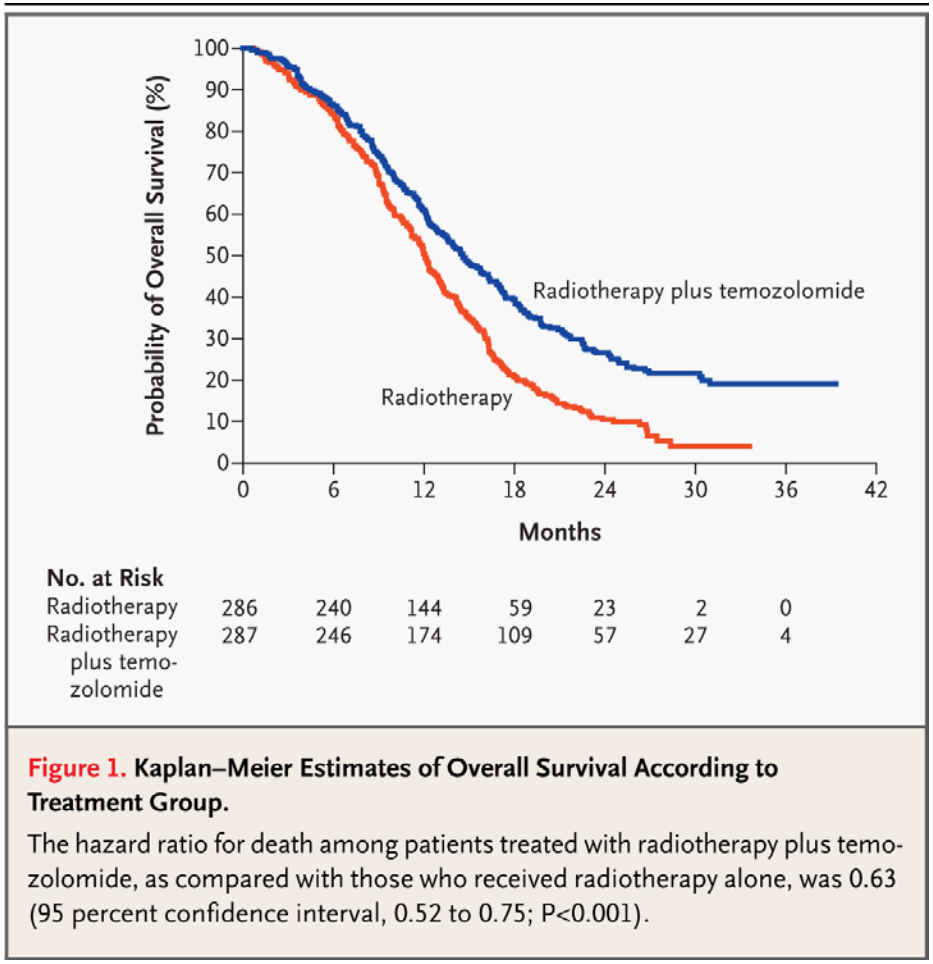

Figure 1. Kaplan–Meier Estimates of Overall Survival According to Treatment Group.

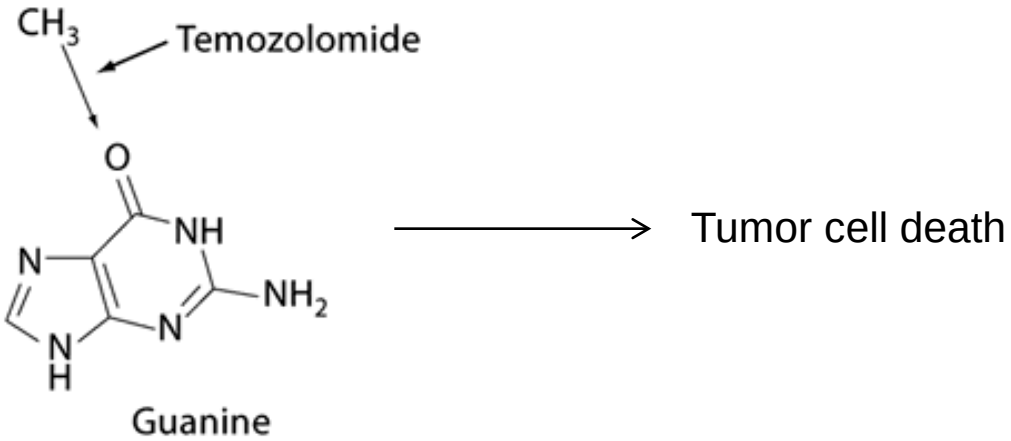
The hazard ratio for death among patients treated with radiotherapy plus temozolomide, as compared with those who received radiotherapy alone, was 0.63 (95 percent confidence interval, 0.52 to 0.75; P<0.001).

ESTRO School

Temozolomide

- Imidazotetrazine derivative of dacarbazine
- Conversion in the systemic circulation at physiological pH to the active compound, 3-methyl-(triazen-1-yl)imidazole-4-carboxamide (MTIC)
- Good BBB penetration
- Oral application (note: there is also an i.v. formulation)
- Methylation of O6 guanine:



Toxicity

Table 4. Grade 3 or 4 Hematologic Toxic Effects in Patients Treated with Temozolomide.

Toxic Effect	Concomitant Temozolomide Therapy (N=284)	Adjuvant Temozolomide Therapy (N=223)	Entire Study Period* (N=284)
	number of patients (percent)		
Leukopenia	7 (2)	11 (5)	20 (7)
Neutropenia	12 (4)	9 (4)	21 (7)
Thrombocytopenia	9 (3)	24 (11)	33 (12)

Anemia	7%	5%
Peripheral neuropathy	2%	8%
Nausea/vomiting	6%	8%
Toxicity leading to treatment stop	38%	20%

Systemic treatment of brain mets

Basic considerations

There is no specific chemotherapy (or any specific medical treatment) for brain mets

Most brain mets derive from chemo-resistant primary tumors

The best chemotherapy for the primary tumor is also the best choice for brain metastases

Brain mets have (probably) no blood-brain barrier (BBB)

Drugs that cross the BBB may be helpful for the prevention of metastasis to the brain and/or for the treatment of „micrometastases“

Good old chemotherapy

Chemotherapeutic drugs used to treat brain mets in NSCLC patients

- **Cisplatin / Carboplatin**
- **Vinorelbine**
- **Paclitaxel / Docetaxel**
- **Gemcitabine**
- **Pemetrexed**

Treatment of brain mets

- **Cerebral response rates of about 40% have been reported for NSCLC patients with BM following treatment with platinum and pemetrexed**
- **These results are not inferior to the local response rates typically seen with WBRT**

Barlesi et al. Ann Oncol 2011
Bailon et al. Neuro Oncol 2012

Chemotherapeutic drugs: BBB crossing

Drug levels in brain metastases and neighboring tissues, measured at time of resection or at autopsy

Drug	Tumor level: necrotic lesion	Tumor level: viable lesion	Neighboring normal brain level
Etoposide (63)	5.9 µg/g	3.4 µg/g	1.4 µg/g adjacent, 0.1 µg/g 2 cm distance
Cisplatin (64)			
20 to 25 mg/m^2	Not reported	1.29 µg/g	0.25 to 0.65 µg/g, 2 to 5 cm
60 to 100 mg/m^2		2.97 µg/g	0.7 to 1.11 µg/g, 2 to 5 cm
Vinorelbine (65)	Not reported	68 ng/g	22 ng/g adjacent, 5 ng/g >4 cm
Mitoxantrone (66)	15 to 322 ng/g	25 to 29 ng/g	Not reported

=> but: drug levels in brain mets lower than in extracranial mets

Deeken and Löscher, Clin Cancer Res 2007

ESTRO School

WBRT + Temozolomide

WBRT +/- temozolomide:

- Patients with NSCLC and ≥ 1 newly diagnosed brain metastasis
- Poor accrual
- WBRT alone: median OS: 5.7 months
- WBRT + temozolomide: median OS 4.4

Daily low-dose temozolomide:

- Patients with advanced NSCLC; many of them with brain mets
- “minimal activity as salvage therapy in patients with advanced NSCLC”

Chua et al. Clin Lung Cancer 2014
Kouroussis et al. Oncology 2009

ESTRO School

Targeted therapy

…the ultimate solution?

Targeted therapy

- **Bevacizumab**

  => probably no need to cross the BBB

- **EGFR inhibitors (erlotinib, gefitinib…)**

  => only in patients with sensitizing EGFR mutation

- **ALK inhibitors (crizotinib, ceritinib…)**

  => only in patients with EML4-ALK translocation

Bevacizumab

- Only low risk for CNS hemorrhage in patients with NSCLC and brain mets who are treated with bevacizumab
- Potentially strong anti-edema activity
- Bevacizumab alone or in combination with chemotherapy in patients with brain mets from NSCLC:
  - Median PFS: 7.8 months
  - Median OS: 14.1 months
- WBRT + bevacizumab in patients with brain mets (REBECA):
  - Safe, but clinical benefit remains unclear

Socinski et al. J Clin Oncol 2009
De Braganca et al. J Neurooncol 2010
Lévy et al. Ann Oncol 2014

EGFR inhibitors

- Activating EGFR mutations particularly commmon in adenocarcinomas of the lung
- EGFR mutations may be overrepresented in brain mets of lung cancer patients
- Clinical activity of EGFR inhibitors in patients with activating EGFR mutations has been shown in several large trials
- Modest BBB penetration of EGFR inhibitors

Lynch et al. N Engl J Med 2004
Paez et al. Science 2004
Matsumoto et al. Int J Cancer 2006
Park et al. Lung Cancer 2012
Maemondo et al. N Engl J Med 2010
Rosell et al. Lancet Oncol 2012

CNS response rates in NSCLC patients treated with EGFR-TKI

Unselected	EGFR-TKI	60%
		43%
		10%
		32%
		33%
		70%
	EGFR-TKI + WBRT	81%
		71%
EGFR mutation	EGFR-TKI	83%
		82%
		89%
		75%
	EGFR-TKI + WBRT	84%

Berger et al. Lung Cancer 2013

ESTRO School

Addition of EGFR inhibitors to WBRT does (probably) not prolong survival

WBRT + gefitinib or temozolomide

- Gefitinib: median OS **6.3** months
- Temozolomide: median OS **4.9** months
- Fatigue as major side effect

WBRT and SRS + erlotinib or temozolomide in patients with ≤ 3 brain mets

- WBRT and SRS: median OS **13.4** months
- Addition of temozolomide: median OS **6.3** months
- Addition of erlotinib: median OS **6.1** months
- Increased toxicity in the gefitinib and temozolomide arm

Pesce et al. Eur J Cancer 2012
Sperduto et al. Int J Radiat Oncol Biol Phys 2013

ALK fusion genes

- Found in around 5% of NSCLC
- Encountered more frequently in never smokers, the adenocarcinoma subtype, and in younger patients
- NSCLC patients with ALK rearrangement have improved OS after radiotherapy for brain metastases compared with EGFR or KRAS mutations

  => Subsequent receipt of targeted therapy is associated with additional improvement in OS
- Crizotinib first approved ALK inhibitor

Shaw et al. J Clin Oncol 2009
Mak et al. Neuro Oncol 2015
Shaw et al. New Engl J Med 2013

Brain mets: a particular challenge?

Cancer Biology & Therapy 13:14, 1376–1383; December 2012; © 2012 Landes Bioscience

Isolated central nervous system progression on Crizotinib

An Achilles heel of non-small cell lung cancer with EML4-ALK translocation?

Stephen G. Chun,* Kevin S. Choe,† Puneeth Iyengar,† John S. Yordy† and Robert D. Timmerman†

=> Crizotinib: very limited CNS penetrance (< 1%)

- Novel ALK inhibitors: ceritinib and alectinib which are both active against ALK-positive NSCLC
- Ceritinib concentration in the CNS may reach approximately 13% of systemic levels in preclinical models

Shaw et al. New Engl J Med 2014
Gadgeel et al. Lancet Oncol 2014
Kim et al. ASCO 2014

ASCEND-1: ceritinib in patients with brain mets

Endpoint[a]	ALKi-pretreated patients with brain metastases n = 98	ALKi-naïve patients with brain metastases n = 26	All NSCLC patients with brain metastases n = 124
ORR, n (%)[95% CI]	49 (50.0)[39.7, 60.3]	18 (69.2)[48.2, 85.7]	67 (54.0)[44.9, 63.0]
DOR, median (months) [95% CI]	6.9[4.8, 8.5]	NE[b][5.5, NE]	7.0[5.5, 9.7]
PFS, median (months) [95% CI]	6.7[4.9, 8.5]	8.3[4.6, NE]	6.9[5.4, 8.4]

=> Promising treatment for patients with brain mets?

Shaw et al. ESMO 2014

ESTRO School

Conclusions

- Systemic therapies can improve outcome in brain tumor patients
- Blood brain barrier can be a limiting factor
- Insufficient understanding of tumor biology as one limiting factor
- Emerging targeted agents with putative activity in brain tumors
- Predictive factors may help to tailor systemic therapies
- Need for more research

Comprehensive genomic characterization defines human glioblastoma genes and core pathways

The Cancer Genome Atlas Research Network*

Human cancer cells typically harbour multiple chromosomal aberrations, nucleotide substitutions and epigenetic modifications that drive malignant transformation. The Cancer Genome Atlas (TCGA) pilot project aims to assess the value of large-scale multi-dimensional analysis of these molecular characteristics in human cancer and to provide the data rapidly to the research community. Here we report the interim integrative analysis of DNA copy number, gene expression and DNA methylation aberrations in 206 glioblastomas—the most common type of primary adult brain cancer—and nucleotide sequence aberrations in 91 of the 206 glioblastomas. This analysis provides new insights into the roles of *ERBB2*, *NF1* and *TP53*, uncovers frequent mutations of the phosphatidylinositol-3-OH kinase regulatory subunit gene *PIK3R1*, and provides a network view of the pathways altered in the development of glioblastoma. Furthermore, integration of mutation, DNA methylation and clinical treatment data reveals a link between *MGMT* promoter methylation and a hypermutator phenotype consequent to mismatch repair deficiency in treated glioblastomas, an observation with potential clinical implications. Together, these findings establish the feasibility and power of TCGA, demonstrating that it can rapidly expand knowledge of the molecular basis of cancer.

CGARN glioblastoma study, Nature 2008

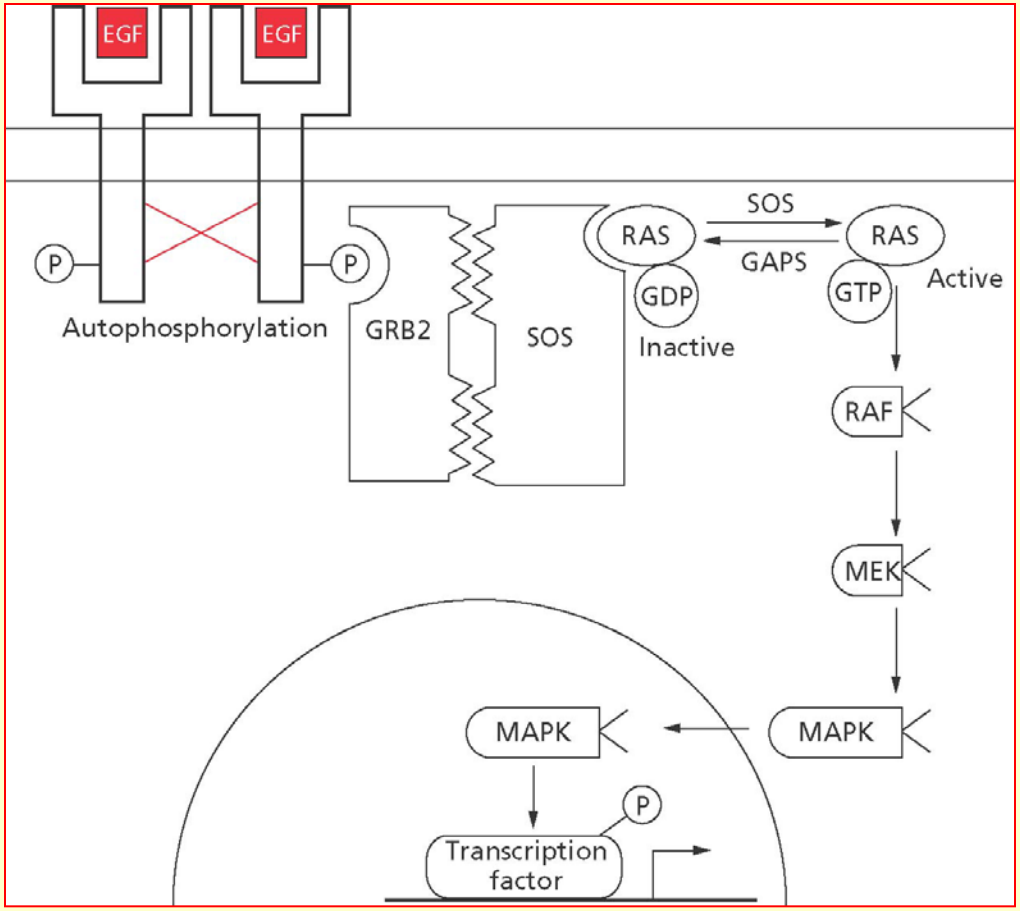
EGFR

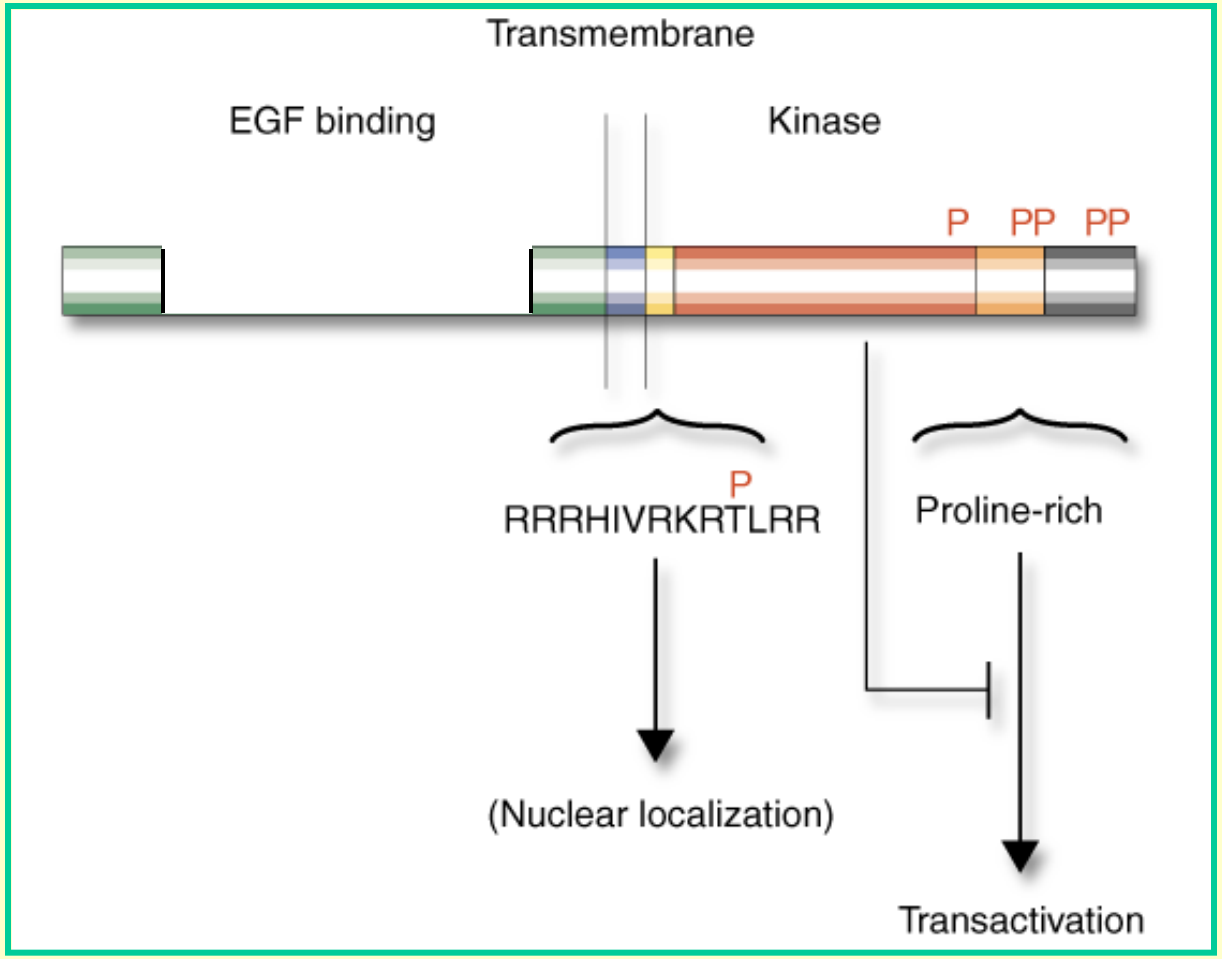
- Growth factor receptor

  erbB encodes the EGFR receptor
- oncogenic mutations generate EGFR that is activated even in the absence of EGF
- amplification of *erbB* gene(s) increases membrane expression of EGFR



Over-activity of RAS - MAPK pathway induces over-expression of genes promoting proliferation and the malignant phenotype

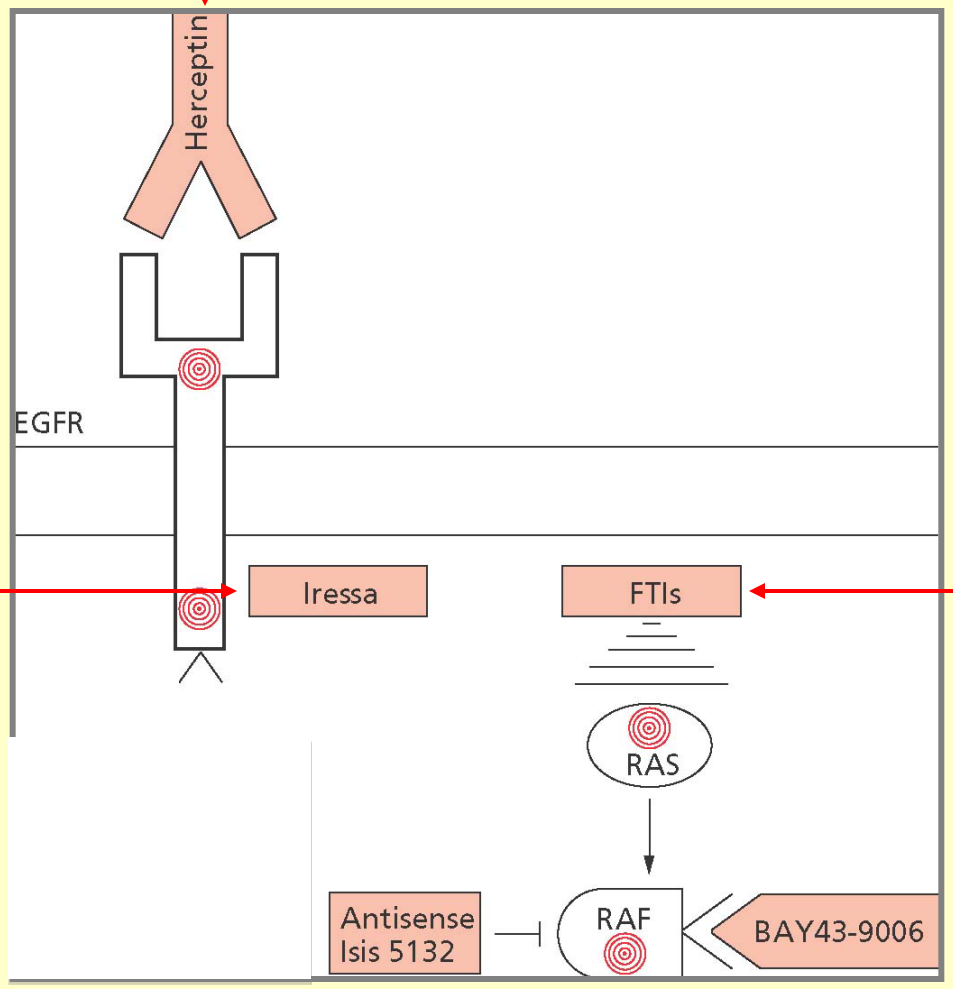
commonest mutation is deletion of exons 2 - 7:



- mutant protein (EGFRvIII) cannot bind ligand but is **constitutively activated**
- common in high grade gliomas (25-30%)

Targeting the EGFR pathway

monoclonal antibodies



tyrosine kinase inhibitors

farnesyl transferase inhibitors

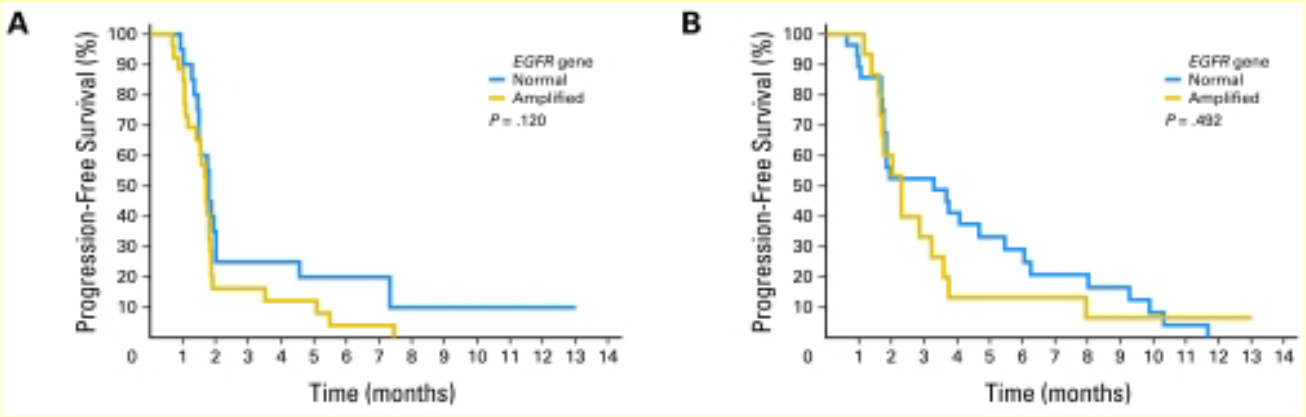
Raf kinase inhibitors

antisense strategies

EGFR inhibitors show efficacy *in vitro* but are ineffective in patients

Erlotinib

TMZ



Randomised phase II study in recurrent GBM:

PFS-6

Erlotinib 11%

TMZ 24%

Van den Bent et. al., J Clin Oncol, 27(8); 2009

Phase II study of erlotinib with radiotherapy and temozolomide in newly diagnosed GBM:

- No improvement in outcome compared to historical controls
- Worse toxicity

Perreboormtet. al., J Neurooncol, 2010

New EGFR targeting strategies showing more promise

Rindopepimut: A Phase 3 Immunotherapy Targeting EGFR*vIII*-expressing Glioblastoma

- Rindopepimut is the only vaccine in development targeting EGFR*vIII* (*v3*)
- EGFR*vIII*
  - Highly tumor specific, expressed only in tumors not normal tissues
  - Target has been validated, gaining importance as a tumor marker
  - Historical poor prognosis for *vIII* patients, historical median survival ~13-15 months, few survive two years
  - ~30% of GB express EGFR*vIII* (~4,000 EGFR*vIII* patients in US and ~8,800 in EU annually)
- Strong proprietary patent position
- Fast track U.S. granted
- Orphan Drug Status in US and EU (7 yrs. & 10 yrs.)

Health-related quality of life in patients with glioblastoma: a randomised controlled trial

Martin J B Taphoorn, Roger Stupp, Corneel Coens, David Osoba, Rolf Kortmann, Martin J van den Bent, Warren Mason, René O Mirimanoff, Brigitta G Baumert, Elizabeth Eisenhauer, Peter Forsyth, Andrew Bottomley, for the European Organisation for Research and Treatment of Cancer (EORTC) Brain Tumour Group, EORTC Radiotherapy Group, and the National Cancer Institute of Canada Clinical Trials Group (NCIC CTG)

Summary

Background A randomised controlled trial of radiotherapy alone versus radiotherapy with concomitant and adjuvant temozolomide for patients with glioblastoma showed that survival was higher for patients assigned combination treatment compared with those assigned standard radiotherapy alone. This paper reports the health-related quality of life (HRQOL) of the patients in this trial.

Methods 573 patients with newly diagnosed glioblastoma were randomly allocated either radiotherapy alone or radiotherapy and temozolomide. The primary endpoint was survival, and HRQOL was a secondary endpoint. We assessed HRQOL at baseline and at every 3 months during treatment until progression using the European Organisation for Research and Treatment of Cancer (EORTC) quality of life questionnaire core-30 (QLQ-C30) and the EORTC brain cancer module (EORTC BN-20). We calculated changes from baseline score for seven predefined HRQOL measures (fatigue, overall health, social function, emotional function, future uncertainty, insomnia, and communication deficit) and differences between groups for these measures at every time point. The significance of, and proportions of patients with, improved HRQOL scores—defined as a change of 10 points or more—were recorded. This trial is registered on the US National Cancer Institute website http://www.cancer.gov/search/NewClinicalTrials, NCT00006353.

Findings Baseline questionnaires were available for 490 (86%) patients. Baseline HRQOL scores did not differ between groups. At first follow-up, groups differed only in social functioning, favouring the radiotherapy-only group (mean score 79·0 [SD 3·2] for patients assigned radiotherapy *vs* 67·4 [2·7] for those assigned radiotherapy and temozolomide; difference between groups 11·6 points [95% CI 3·5–19·7], p=0·0052). Over subsequent assessments, HRQOL was much the same between treatment groups.

Interpretation Addition of temozolomide during and after radiotherapy for patients with newly diagnosed glioblastoma significantly improved survival without a negative effect on HRQOL.

ABSTRACT

Purpose
Radiation Therapy Oncology Group trial 0525 tested whether dose-intensifying temozolomide versus standard chemoradiotherapy improves overall survival (OS) or progression-free survival (PFS) in newly diagnosed glioblastoma. Tests of neurocognitive function (NCF) and symptoms (using the MD Anderson Symptom Inventory–Brain Tumor module; MDASI-BT) and of quality of life (European Organisation for the Research and Treatment of Cancer Quality of Life Questionnaire [EORTC QLQ] –C30/BN20) examined the net clinical benefit (NCB) of therapy.

Patients and Methods
NCF tests (Hopkins Verbal Learning Test–Revised, Trail Making Test, and Controlled Oral Word Association), MDASI-BT, and EORTC QLQ-C30/BN20 were completed in a subset of patients. Multivariate Cox proportional hazard regression modeling determined the prognostic value of baseline and early change from baseline to cycle 1 for OS and PFS. Two-sample proportional test statistic was used to evaluate differences between treatments (dose-dense *v* standard-dose) on NCB measures from baseline to cycle 4 in stable patients.

Results
Overall, 182 patients participated in the study. Baseline NCF tests and the physical functioning quality of life scale were associated with OS and PFS. Baseline to cycle 1 in all NCB components were associated with OS and PFS. There was greater deterioration in the dose-dense arm from baseline to cycle 4 in the Global Health and Motor Function subscales (EORTC QLQ-C30/BN20) as well as in overall symptom burden, overall symptom interference, and activity-related symptom interference subscales (MDASI-BT). There were no between-arm differences in NCF.

Conclusion
Longitudinal collection of NCB measures is feasible in cooperative group studies and provides an added dimension to standard outcome measures. Greater adverse symptom burden and functional interference, as well as decreased global health and motor function were observed in patients randomly assigned to the dose-dense arm. Baseline and early change in NCB measures were associated with decreased rates of survival.

ABSTRACT

Purpose

As glioblastoma progresses, patients experience a decline in health-related quality of life (HRQoL). Delaying this decline is an important treatment goal. In newly diagnosed glioblastoma, progression-free survival was prolonged when bevacizumab was added to radiotherapy plus temozolomide (RT/TMZ) versus placebo plus RT/TMZ (phase III AVAglio study; hazard ratio, 0.64; 95% CI, 0.55 to 0.74; $P < .001$). To ensure that addition of bevacizumab to standard-of-care therapy was not associated with HRQoL detriment, HRQoL assessment was a secondary objective.

Patients and Methods

Patients completed European Organisation for Research and Treatment of Cancer Quality of Life Questionnaires C30 and BN20 at each tumor assessment (Appendix Table A1, online only). Raw scores were converted to a 100-point scale and mean changes from baseline scores were evaluated (stable: < 10-point change; clinically relevant deterioration/improvement: ≥ 10-point change). Deterioration-free survival was the time to deterioration/progression/death; time to deterioration was the time to deterioration/death.

Results

Most evaluable patients who had not progressed (> 74%) completed all HRQoL assessments for at least 1 year of treatment, and almost all completed at least one HRQoL assessment at baseline (98.3% and 97.6%, bevacizumab and placebo arms, respectively). Mean changes from baseline did not reach a clinically relevant difference between arms for most items. HRQoL declined at progression in both arms. The addition of bevacizumab to RT/TMZ resulted in statistically longer ($P < .001$) deterioration-free survival across all items. Time to deterioration was not statistically longer in the placebo plus RT/TMZ arm (*v* bevacizumab) for any HRQoL item.

Conclusion

The addition of bevacizumab to standard-of-care treatment for newly diagnosed glioblastoma had no impact on HRQoL during the progression-free period.

ABSTRACT

Purpose
Patients with low-grade glioma (LGG) often experience long periods of stable disease, emphasizing the importance of maintaining good health-related quality of life (HRQOL). We assessed the changes in HRQOL in long-term survivors of WHO grade I or II astrocytoma, oligodendroglioma, or oligoastrocytoma with clinically and radiologically stable disease.

Patients and Methods
Patients completed self-report measures of generic HRQOL (Short Form-36 [SF-36]) and disease-specific HRQOL (European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire–Brain Cancer Module). Assessments took place at midterm and long-term follow-up, on average 6 and 12 years after histologic diagnosis and initial treatment, respectively. Comparisons between patients with LGG and individually matched healthy controls were made, and change within the patients with LGG was calculated, as was minimal detectable change.

Results
Although no statistically significant differences between patients with LGG and healthy matched controls were found at midterm follow-up, patients with LGG had worse physical role functioning ($P = .004$) and general health perceptions ($P = .004$) than controls at long-term follow-up. Within patients with stable LGG (n = 65), physical HRQOL (the SF-36 physical component summary and the physical functioning subscale) was significantly worse at long-term than at midterm follow-up (both $P < .001$). Although 48% of patients improved or remained stable on all HRQOL scales, 38.5% of patients experienced detectable decline on one or more scales.

Conclusion
Although HRQOL remains mostly preserved in the majority of patients with LGG, a subset of patients experience detectable decline on one or more HRQOL scales despite long-term stable disease. For this subgroup, further research is recommended to better aid patients in dealing with the consequences of LGG.

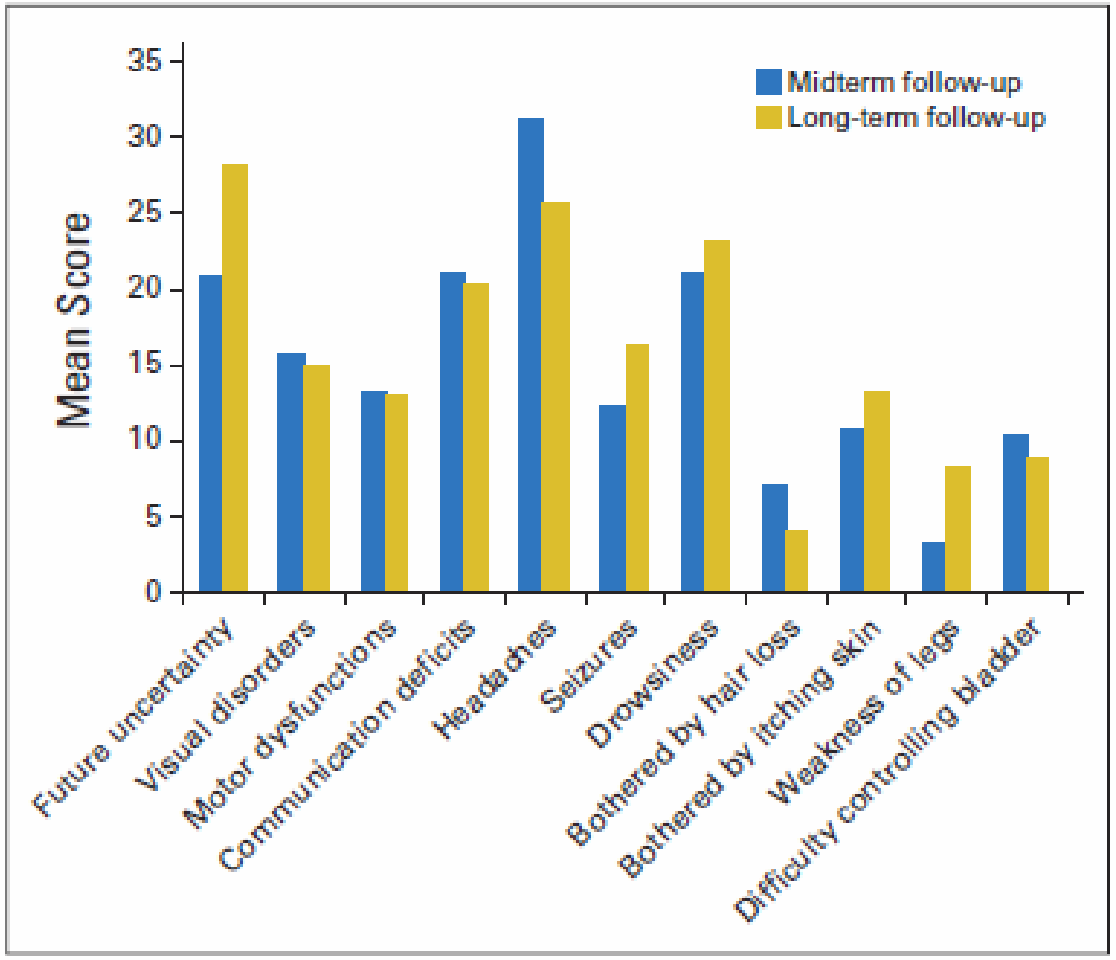

Fig 1. Disease-specific health-related quality of life at first (midterm) and second (long-term) assessment. Higher scores indicate more symptoms being present.

WBRT MAY NEGATIVELY IMPACT HEALTH-RELATED QUALI TY OF LIFE (HRQL) IN BRAIN METASTASIS

- Increasing interest for HRQL as an endpoint for treatment comparisons in many cancer types, especially in advanced stages (*Bottomley et al, Eur J Cancer 2005*)
- After PCI for SCLC significant, but reversible, short-term (3 months) negative impact on selected HRQL scales, such as fatigue, hair loss, or cognitive functioning (*Slotman et al, JCO 2009*).
- After PCI for NSCLC significant decline in memory at 1 year (*Sun et al, JCO 2011*)
- No data available so far regarding the impact of adjuvant WBRT on HRQL of patients with brain metastases.

Summary

Background Our previous study on cognitive functioning among 195 patients with low-grade glioma (LGG) a mean of 6 years after diagnosis suggested that the tumour itself, rather than the radiotherapy used to treat it, has the most deleterious effect on cognitive functioning; only high fraction dose radiotherapy (>2 Gy) resulted in significant added cognitive deterioration. The present study assesses the radiological and cognitive abnormalities in survivors of LGG at a mean of 12 years after first diagnosis.

Methods Patients who have had stable disease since the first assessment were invited for follow-up cognitive assessment (letter–digit substitution test, concept shifting test, Stroop colour–word test, visual verbal learning test, memory comparison test, and categoric word fluency). Compound scores in six cognitive domains (attention, executive functioning, verbal memory, working memory, psychomotor functioning, and information processing speed) were calculated to detect differences between patients who had radiotherapy and patients who did not have radiotherapy. White-matter hyperintensities and global cortical atrophy were rated on MRI scans.

Findings 65 patients completed neuropsychological follow-up at a mean of 12 years (range 6–28 years). 32 (49%) patients had received radiotherapy (three had fraction doses >2 Gy). The patients who had radiotherapy had more deficits that affected attentional functioning at the second follow-up, regardless of fraction dose, than those who did not have radiotherapy (–1·6 [SD 2·4] *vs* –0·1 [1·3], p=0·003; mean difference 1·4, 95% CI 0·5–2·4). The patients who had radiotherapy also did worse in measures of executive functioning (–2·0 [3·7] *vs* –0·5 [1·2], p=0·03; mean difference 1·5, 0·2–2·9) and information processing speed (–2·0 [3·7] *vs* –0·6 [1·5], p=0·05; mean difference 0·8, 0·009–1·6]) between the two assessments. Furthermore, attentional functioning deteriorated significantly between the first and second assessments in patients who had radiotherapy (p=0·25). In total, 17 (53%) patients who had radiotherapy developed cognitive disabilities deficits in at least five of 18 neuropsychological test parameters compared with four (27%) patients who were radiotherapy naive. White-matter hyperintensities and global cortical atrophy were associated with worse cognitive functioning in several domains.

Interpretation Long-term survivors of LGG who did not have radiotherapy had stable radiological and cognitive status. By contrast, patients with low-grade glioma who received radiotherapy showed a progressive decline in attentional functioning, even those who received fraction doses that are regarded as safe (≤2 Gy). These cognitive deficits are associated with radiological abnormalities. Our results suggest that the risk of long-term cognitive and radiological compromise that is associated with radiotherapy should be considered when treatment is planned.

Douw et al, Lancet Neurol 2009

IMPACT OF WBRT ON COGNITIVE FUNCTIONS : GENERAL CONCEPTS IN BRAIN METASTASIS

- A radiation-induced dementia with ataxia and urinary incontinence has been reported in up to 30% of patients by 1 year from receiving unconventional large size fractions of WBRT (6-8.5 Gy) (*De Angelis et al, Neurology, 1989*).

- When using more conventional size fractions (up to 3 or 4 Gy per fraction) the incidence of cognitive deficits in long-term survivors is unknown.

- Long-term survivors frequently develop overtime changes on MRI, such as cortical atrophy, hyperintensity of the white matter in T_2/FLAIR images and hydrocephalus, but the clinical concomitants are poorly known.

WHAT HAVE WE LEARNED FROM CLINICAL TRIALS : EARLY DECLINE AFTER WBRT FOR BRAIN METASTASIS

- Two phase III trials in patients with 1-3 brain metastases comparing SRS + WBRT with SRS alone.
- A significant decline in learning and memory function at 4 months in patients receiving WBRT (*Chang et al, Lancet Oncol 2009*).
- A significant decline at 3 months in immediate recall, delayed recall and verbal fluency (*Brown et al 2015, Irradiance trial, ASCO 2015*).
- Unknown whether this early decline is associated with long-term and/or permanent decline

Purpose: To determine how the omission of whole brain radiotherapy (WBRT) affects the neurocognitive function of patients with one to four brain metastases who have been treated with stereotactic radiosurgery (SRS).

Methods and Materials: In a prospective randomized trial between WBRT+SRS and SRS alone for patients with one to four brain metastases, we assessed the neurocognitive function using the Mini-Mental State Examination (MMSE). Of the 132 enrolled patients, MMSE scores were available for 110.

Results: In the baseline MMSE analyses, statistically significant differences were observed for total tumor volume, extent of tumor edema, age, and Karnofsky performance status. Of the 92 patients who underwent the follow-up MMSE, 39 had a baseline MMSE score of ≤27 (17 in the WBRT+SRS group and 22 in the SRS-alone group). Improvements of ≥3 points in the MMSEs of 9 WBRT+SRS patients and 11 SRS-alone patients ($p = 0.85$) were observed. Of the 82 patients with a baseline MMSE score of ≥27 or whose baseline MMSE score was ≤26 but had improved to ≥27 after the initial brain treatment, the 12-, 24-, and 36-month actuarial free rate of the 3-point drop in the MMSE was 76.1%, 68.5%, and 14.7% in the WBRT+SRS group and 59.3%, 51.9%, and 51.9% in the SRS-alone group, respectively. The average duration until deterioration was 16.5 months in the WBRT+SRS group and 7.6 months in the SRS-alone group ($p = 0.05$).

Conclusion: The results of the present study have revealed that, for most brain metastatic patients, control of the brain tumor is the most important factor for stabilizing neurocognitive function. However, the long-term adverse effects of WBRT on neurocognitive function might not be negligible. © 2007 Elsevier Inc.

ABSTRACT

Purpose
Hippocampal neural stem-cell injury during whole-brain radiotherapy (WBRT) may play a role in memory decline. Intensity-modulated radiotherapy can be used to avoid conformally the hippocampal neural stem-cell compartment during WBRT (HA-WBRT). RTOG 0933 was a single-arm phase II study of HA-WBRT for brain metastases with prespecified comparison with a historical control of patients treated with WBRT without hippocampal avoidance.

Patients and Methods
Eligible adult patients with brain metastases received HA-WBRT to 30 Gy in 10 fractions. Standardized cognitive function and quality-of-life (QOL) assessments were performed at baseline and 2, 4, and 6 months. The primary end point was the Hopkins Verbal Learning Test–Revised Delayed Recall (HVLT-R DR) at 4 months. The historical control demonstrated a 30% mean relative decline in HVLT-R DR from baseline to 4 months. To detect a mean relative decline $\leq$ 15% in HVLT-R DR after HA-WBRT, 51 analyzable patients were required to ensure 80% statistical power with $\alpha = 0.05$.

Results
Of 113 patients accrued from March 2011 through November 2012, 42 patients were analyzable at 4 months. Mean relative decline in HVLT-R DR from baseline to 4 months was 7.0% (95% CI, −4.7% to 18.7%), significantly lower in comparison with the historical control ($P < .001$). No decline in QOL scores was observed. Two grade 3 toxicities and no grade 4 to 5 toxicities were reported. Median survival was 6.8 months.

Conclusion
Conformal avoidance of the hippocampus during WBRT is associated with preservation of memory and QOL as compared with historical series.

ABSTRACT

Purpose
Neurotoxic effects of brain irradiation include cognitive impairment in 50% to 90% of patients. Prior studies have suggested that donepezil, a neurotransmitter modulator, may improve cognitive function.

Patients and Methods
A total of 198 adult brain tumor survivors ≥ 6 months after partial- or whole-brain irradiation were randomly assigned to receive a single daily dose (5 mg for 6 weeks, 10 mg for 18 weeks) of donepezil or placebo. A cognitive test battery assessing memory, attention, language, visuomotor, verbal fluency, and executive functions was administered before random assignment and at 12 and 24 weeks. A cognitive composite score (primary outcome) and individual cognitive domains were evaluated.

Results
Of this mostly middle-age, married, non-Hispanic white sample, 66% had primary brain tumors, 27% had brain metastases, and 8% underwent prophylactic cranial irradiation. After 24 weeks of treatment, the composite scores did not differ significantly between groups ($P = .48$); however, significant differences favoring donepezil were observed for memory (recognition, $P = .027$; discrimination, $P = .007$) and motor speed and dexterity ($P = .016$). Significant interactions between pretreatment cognitive function and treatment were found for cognitive composite ($P = .01$), immediate recall ($P = .05$), delayed recall ($P = .004$), attention ($P = .01$), visuomotor skills ($P = .02$), and motor speed and dexterity ($P < .001$), with the benefits of donepezil greater for those who were more cognitively impaired before study treatment.

Conclusion
Treatment with donepezil did not significantly improve the overall composite score, but it did result in modest improvements in several cognitive functions, especially among patients with greater pretreatment impairments.

J Clin Oncol 33:1653-1659.

NEW APPROACHES TO AVOID COGNITIVE DECLINE FOLLOWING WBRT

- Stereotactic radiosurgery to the resection cavity
- Targeted agents to treat asymptomatic small brain metastases

RISK OF RADIONECROSIS FOLLOWING SRS TO THE RESECTION CAVITY

- The reference value is 2.6% following WBRT (*EORTC study, Kocher et al, JCO 2011*).
- The values following SRS range between 9% and 17.5% in recent papers (*Minniti et al, J Neurooncol 2013; Brennan et al, Cell 2014; Ling et al, Neurosurgery 2015*).
- More often the reported values are based on both biopsy and MRI : thus, the distinction between true radiation necrosis and pseudoprogression is unknown.

RISK OF RADIONECROSIS FOLLOWING SRS TO THE RESECTION CAVITY

- Not always the clinical relevance of the so called “radionecrosis” is detailed.
- Some papers do not mention toxicity or simply state that “no toxicity was observed”.
- The actuarial risk could increase over time: 7% at 1 year ; 16% at 2 years (*Minniti at al, J Neurooncol 2013*).

RISKS OF NEUROLOGICAL COMPLICATIONS OTHER THAN RADIONECROSIS FOLLOWING SRS TO THE RESECTION CAVITY

- Seizures, headache and hemorrhage as acute complications in individual patients (*Minniti et al, J Neurooncol 2013*).
- Increased T2 signal changes on MRI around the resection cavity (radiation-related edema) in 10.8% of patients (*Mathieu et al, Neurosurgery 2008*).
- A steroid dependency can occur, and both frequency and duration have not been recorded.
- Overall, the incidence of both radionecrosis and other neurological complications is underestimated.

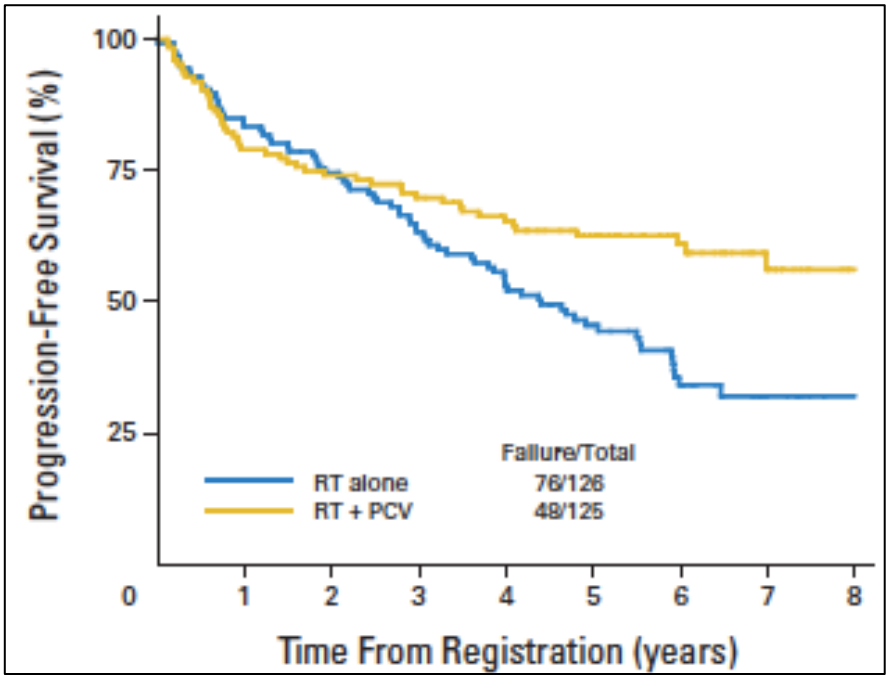
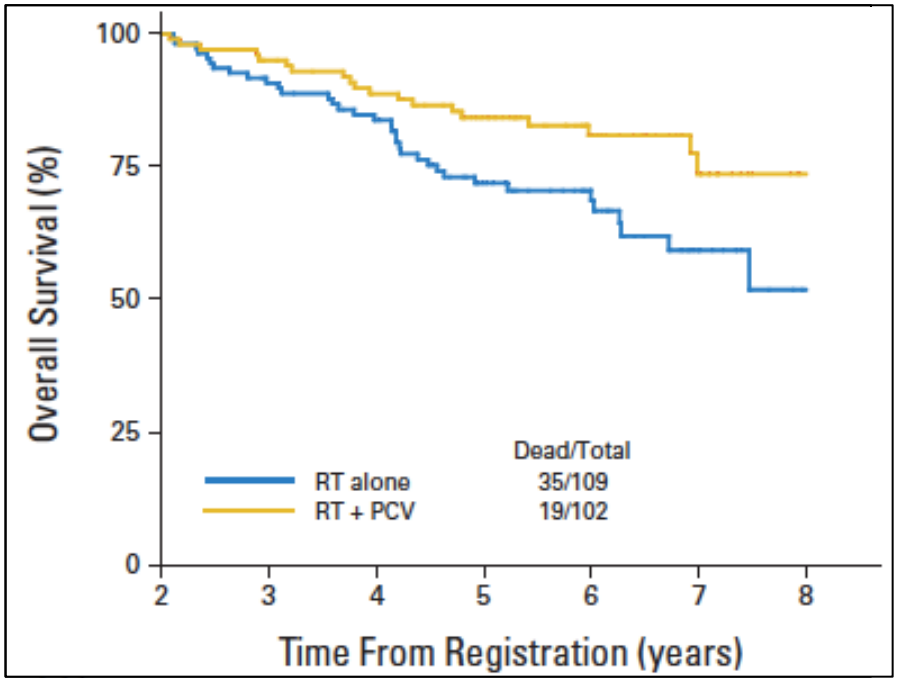
Randomized Trial of Radiation Therapy Plus Procarbazine, Lomustine, and Vincristine Chemotherapy for Supratentorial Adult Low-Grade Glioma: Initial Results of RTOG 9802

Edward G. Shaw, Meihua Wang, Stephen W. Coons, David G. Brachman, Jan C. Buckner, Keith J. Stelzer, Geoffrey R. Barger, Paul D. Brown, Mark R. Gilbert, and Minesh P. Mehta

Table 1. Patient Characteristics

Characteristic	RT Arm No.	RT Arm %	RT + PCV Arm No.	RT + PCV Arm %
Age, years				
Median	40		41	
Range	22-79		18-82	
Median tumor size, cm	5.0		4.7	
KPS 90-100		74		75
Gross total resection		9		11
Histology				
Astrocytoma		23		29
Oligodendroglioma		45		40
Mixed astrocytoma/oligodendroglioma		32		31
Enhancement: yes		60		65





So how should we be treating grade 2 gliomas WITHOUT 1p19q codeletion?

For patients with grade 2 astrocytoma WITHOUT 1p19q codeletion who DO require treatment, I would recommend:

A. Radiotherapy alone
B. Radiotherapy with concomitant TMZ
C. Radiotherapy with concomitant and adjuvant TMZ
D. Radiotherapy with adjuvant PCV
E. PCV followed by radiotherapy

For patients with grade 2 astrocytoma WITHOUT 1p19q codeletion who require radiotherapy, I would recommend:

A. 45 Gy in 25 fractions
B. 50.4 Gy in 28 fractions
C. 54 Gy in 28 fractions
D. 60 Gy in 30 fractions

Cognitive and radiological effects of radiotherapy in patients with low-grade glioma: long-term follow-up

EFNS GUIDELINES/CME ARTICLE

Guidelines on management of low-grade gliomas: report of an EFNS–EANO* Task Force

R. Soffietti[a], B.G. Baumert[b], L. Bello[c], A. von Deimling[d], H. Duffau[e], M. Frénay[f], W. Grisold[g], R. Grant[h], F. Graus[i], K. Hoang-Xuan[j], M. Klein[k], B. Melin[l], J. Rees[m], T. Siegal[n], A. Smits[o], R. Stupp[p] and W. Wick[q]

- For patients with unfavorable prognostic factors (older age, incomplete or no resection, existing neurological symptoms), an adjuvant treatment is indicated at any time (Level B), and this is more commonly RT (good practice point).
- A total RT dose of 50.4–54 Gy in fractions of 1.8 Gy represents the current standard of care (Level A). Modern RT techniques (conformal dose delivery or intensity modulated techniques) should preferably be used (Level B).
- Younger patients (< 40 years of age) with (nearly) complete resection and tumors with an oligodendroglial component have a more favorable prognosis and can be observed after surgery (Level B), but close follow-up is needed (good practice point).

- Chemotherapy is an option for patients with recurrence after surgery and radiation therapy (Level B).
- Chemotherapy is an option as initial treatment for patients with large residual tumors after surgery or unresectable tumors to delay the risk of late neurotoxicity from large-field RT, especially when 1p/19q loss is present (Level B).

Ependymoma (grade II)	30	5.5	45	ND	0	0	0	ND	5.5	0	NA	0	NA	NA
Medulloblastoma (grade IV)	55	7	65	27	0	0	0	ND	7	NA	NA	NA	NA	NA

* Of the indicated tumors, 6 secondary and 60 primary glioblastomas were previously described in Parsons et al.[16] Copy-number changes in *EGFR*, *CDKN2A*, and *CDKN2B* were determined by quantitative real-time polymerase chain reaction. For such assays, copy-number levels of more than 6 or less than 0.3 were considered amplifications or losses, respectively. NA denotes not analyzed, and ND not determined because of limited sample size and status of data censoring.
† Tumors were graded according to histopathological and clinical criteria established by the World Health Organization.
‡ Patient age refers to age at which the study sample was obtained.
§ Alterations included mutations in *TP53* and *PTEN*, loss of heterozygosity in 1p and 19q, amplification in *EGFR*, and deletion in *CDKN2A* or *CDKN2B*.
¶ Secondary glioblastoma designates a tumor that was resected more than 1 year after a previous diagnosis of a lower-grade glioma (grade II or grade III).

Yan et al, NEJM 2009

1p/19q deletion and response to chemotherapy

Specific Genetic Predictors of Chemotherapeutic Response and Survival in Patients With Anaplastic Oligodendrogliomas

J. Gregory Cairncross, Keisuke Ueki, Magdelena C. Zlatescu, David K. Lisle, Dianne M. Finkelstein, Robert R. Hammond, Jonathan S. Silver, Paul C. Stark, David R. Macdonald, Yasushi Ino, David A. Ramsay, David N. Louis

Table 2. Univariate genetic predictors of response and risk of death in patients with anaplastic oligodendrogliomas*

	Chemotherapeutic response		Risk of death		
Variable	Response rate, No./total No. (%)	*P*	RR	*P*	95% CI
Chromosome 1p					
Allelic loss	24/24 (100)	**<.001**	0.059	**<.0001**	0.018–0.199
Intact	3/12 (25)				
Chromosome 19q					
Allelic loss	23/28 (82)	.126	0.250	**.0116**	0.085–0.734
Intact	3/6 (50)				
Chromosomes 1p and 19q					
Allelic loss of both	22/22 (100)	**<.001**	0.121	**<.0001**	0.044–0.331
No allelic loss of both	4/13 (31)				
Chromosome 10q					
Allelic loss	5/8 (63)	.126	1.817	.2549	0.650–5.081
Intact	23/26 (88)				
CDKN2A gene					
Deleted	5/8 (63)	.363	4.901	**.0009**	1.924–12.487

1p/19q co-deletion: what is the therapeutic impact?

Two trials – one result:

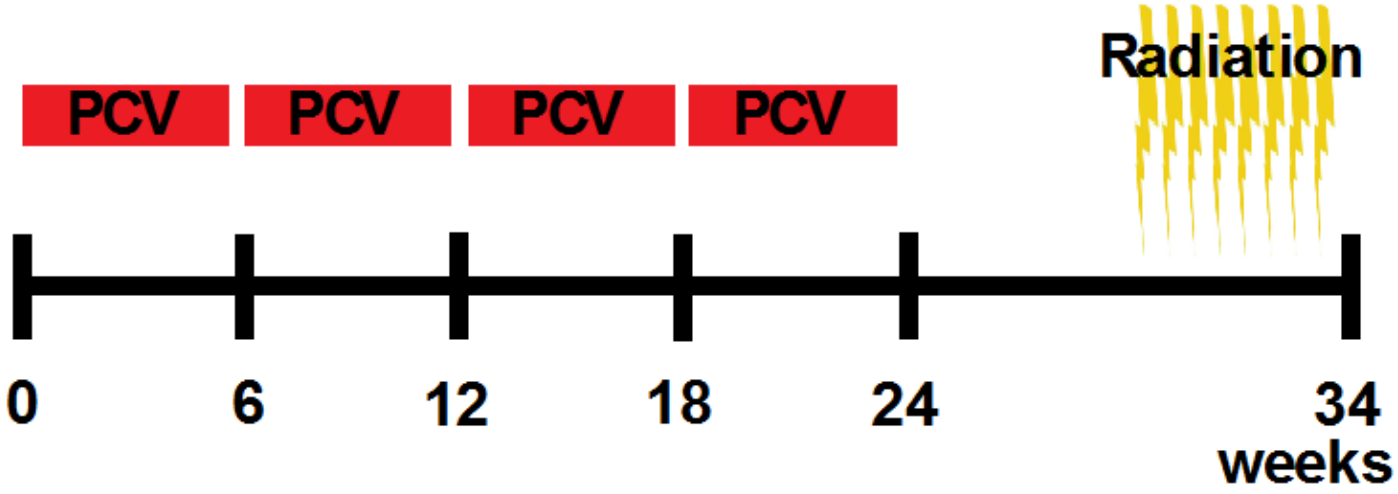
Adjuvant procarbazine, lomustine, and vincristine chemotherapy in newly diagnosed anaplastic oligodendroglioma: long-term follow-up of EORTC Brain Tumor Group Study 26951.

van den Bent et al., J Clin Oncol 2013

Phase III trial of chemoradiotherapy for anaplastic oligodendroglioma: long-term results of RTOG 9402.

Cairncross et al., J Clin Oncol 2013

RTOG 9402



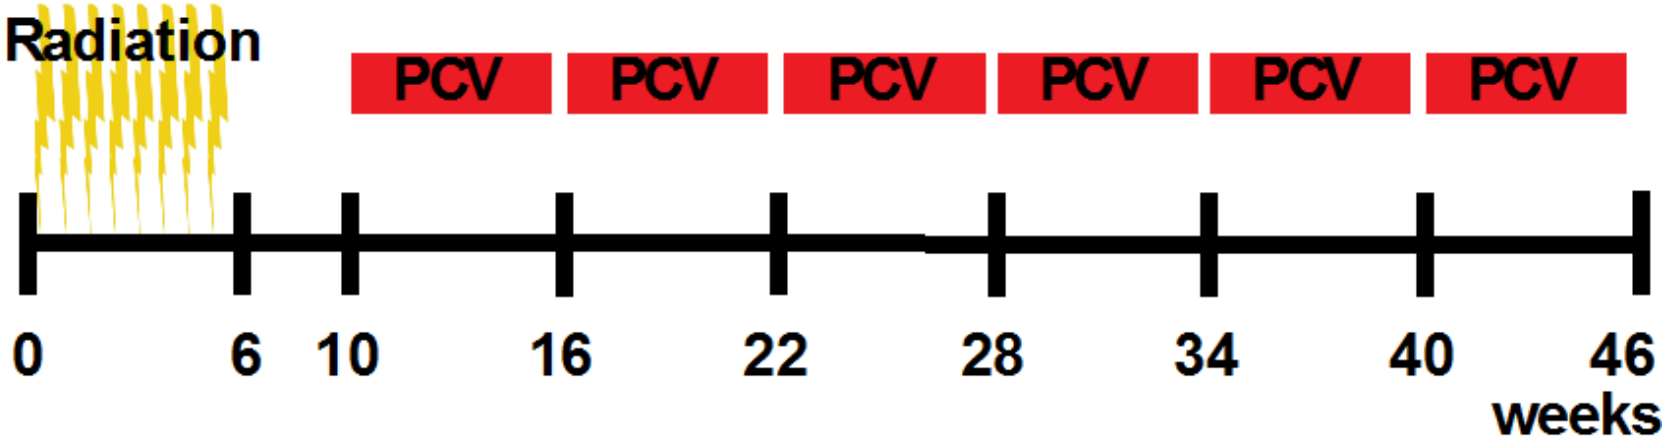
AO or AOA, age >=18, KPS >=60

Intensive PCV followed by immediate involved-field RT (experimental arm) or RT alone (control arm).

RT: 59.4 Gy in 33 fractions (1.8 Gy each), 5 days a week. Patients randomly assigned to PCV plus RT began RT within 6 weeks of the last chemotherapy dose.

Cairncross et al., JCO 2013

EORTC 26951



AO or AOA, age 16-70, ECOG 0-2

RT was to begin within 6 weeks from surgery and consisted of a dose of 45 Gy to be delivered to the planning target volume (PTV-1). Thereafter, a boost of 14.4 Gy (up to a cumulative dose of 59.4 Gy) was delivered to PTV-2

PCV chemotherapy consisted of up to six cycles of standard PCV chemotherapy and had to start within 4 weeks after the end of RT.

Van den Bent et al., JCO 2013

PCV regimens EORTC 26951 vs RTOG 9402

Study Start Date: October 2009

Estimated Primary Completion Date: December 2018

Conclusions: anaplastic gliomas

1p/19q co-deleted tumors:

- The combination of RT and PCV may be regarded as standard of care for newly diagnosed anaplastic oligodendroglial tumors with 1p/19q co-deletion
- RT -> PCV and PCV -> RT are both feasible options
- Temozolomide instead of PCV? => no final answer so far

Non-1p/19q co-deleted tumors:

- RT as current standard for newly diagnosed cases
- Role of temozolomide to be defined in **CATNON** trial

And in patients with low-grade gliomas…?

Feasible options:

- Watch and wait
- Surgery
- Radiotherapy
- Chemotherapy
- Combined radiochemotherapy

And in patients with low-grade gliomas…?

RTOG 9802: Prognostic factors

Cox Proportional Hazards Model for Overall Survival (n=251)

Variable (**Bolded** value has **unfavorable** outcome)	p-value	Hazard Ratio (95%CI)
Assigned treatment (RT+PCV vs. **RT alone**)	0.001	0.56 (0.40, 0.79)
Histology (**Mixed Oligoastrocytoma** vs Oligodendroglioma)	<.001	2.06 (1.38, 3.09)
(**Astrocytoma** vs Oligodendroglioma)	<.001	2.54 (1.66, 3.87)
Gender (**Male** vs. Female)	0.018	1.53 (1.07, 2.17)

Model derived from stepwise selection.

Variable(s) not included in final model: surgery (dropped out during the stepwise selection process)

Buckner, ASCO 2014

Conclusions

- Long-term data from **EORTC 26951** and **RTOG 9402** suggest RT + PCV as standard of care for patients with anaplastic glioma and 1p/19q co-deletion
- **NOA-04** data do not support an attempt to achieve comparable outcomes with monochemotherapy in patients with 1p/19q co-deleted tumors
- **RTOG 9802** long-term data suggest a benefit from RT/PCV compared to RT alone in the entire cohort of grade II tumors
- PFS and OS gain in the RTOG 9802 dataset is most prominent in patients with oligodendroglial (= **1p/19q co-deleted**?) tumors
- Whether **PCV** can be replaced by **temozolomide** remains unclear

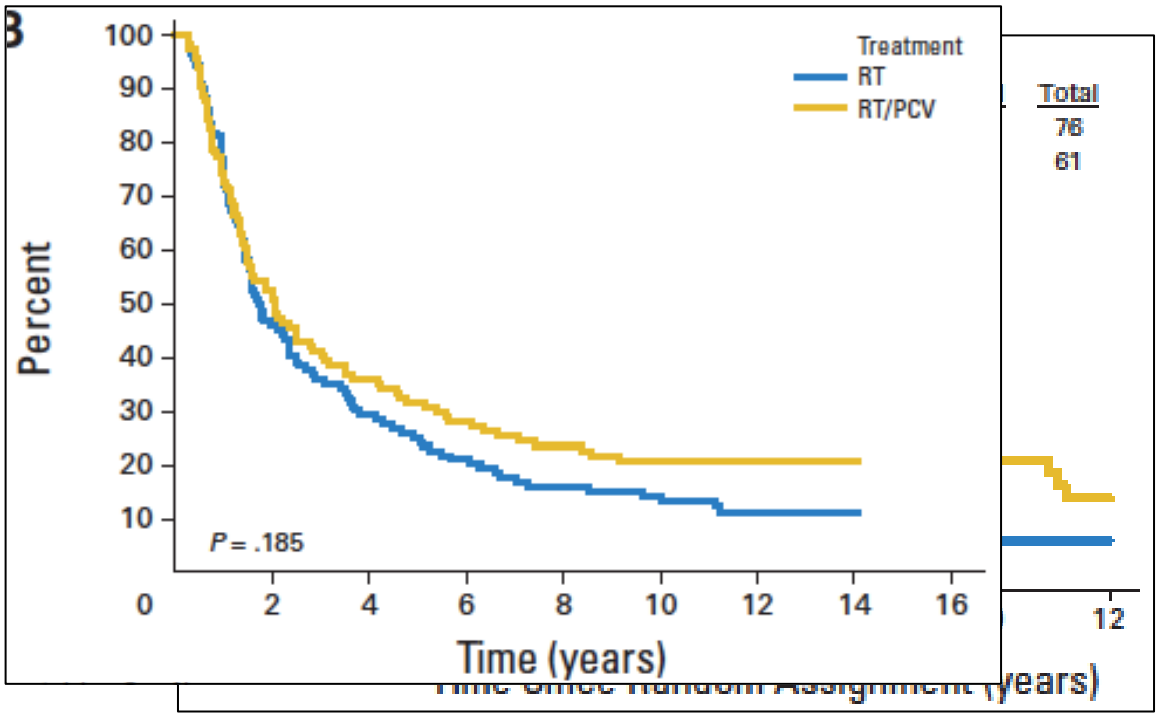
Grade 3 glioma

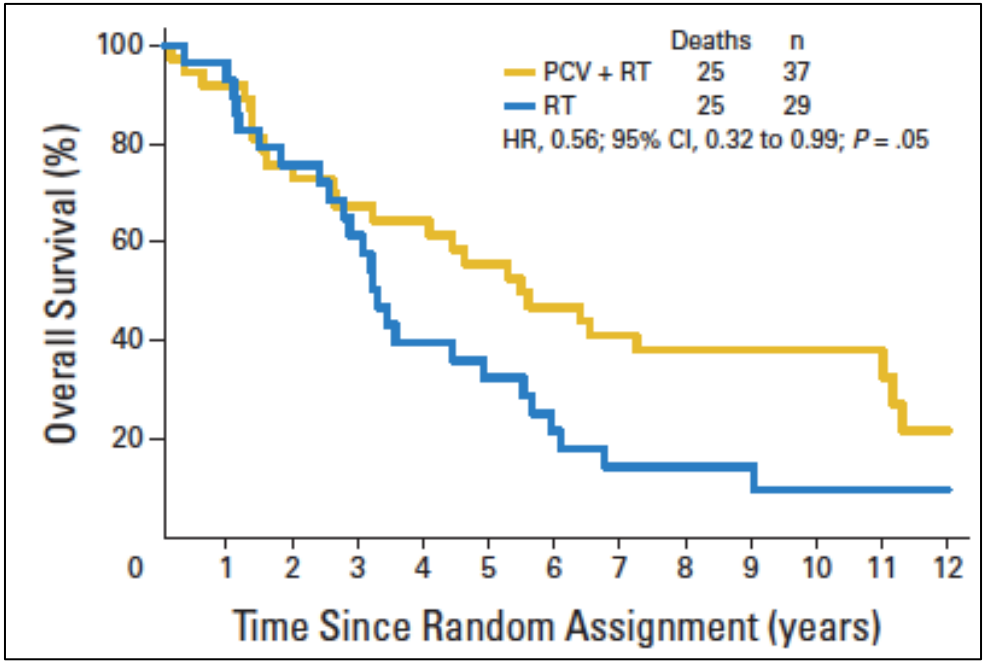
Cairncross, J Clin Onc 2014



All patients without 1p19q codeletion

HR = 0.85
p = 0.39

HR = 0.83
p = 0.185



IDH1 mutated patients without 1p19q codeletion

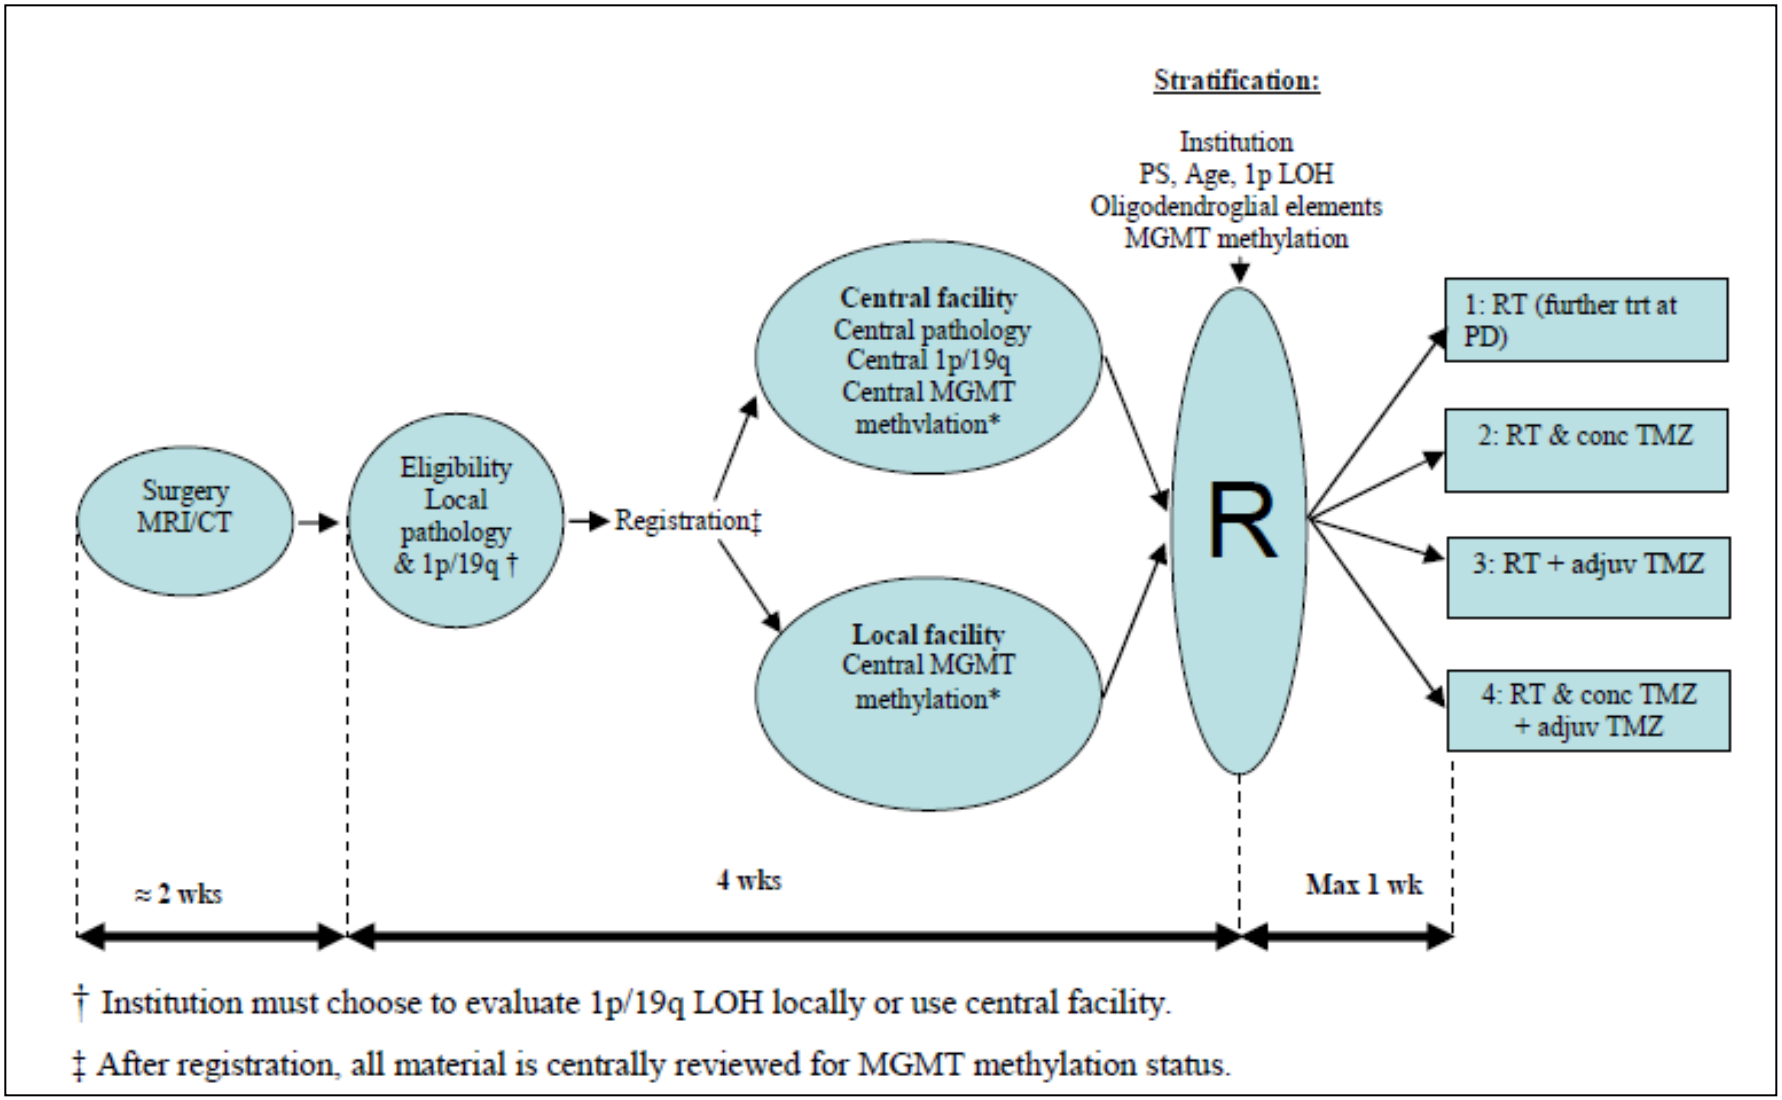
HR = 0.56
p = 0.05

The treatment I would recommend for a patient with grade 3 glioma without 1p19q codeletion is:

A. Radiotherapy alone
B. PCV followed by radiotherapy
C. Radiotherapy followed by PCV
D. Radiotherapy with concomitant TMZ
E. Radiotherapy with concomitant and adjuvant TMZ

CATNON

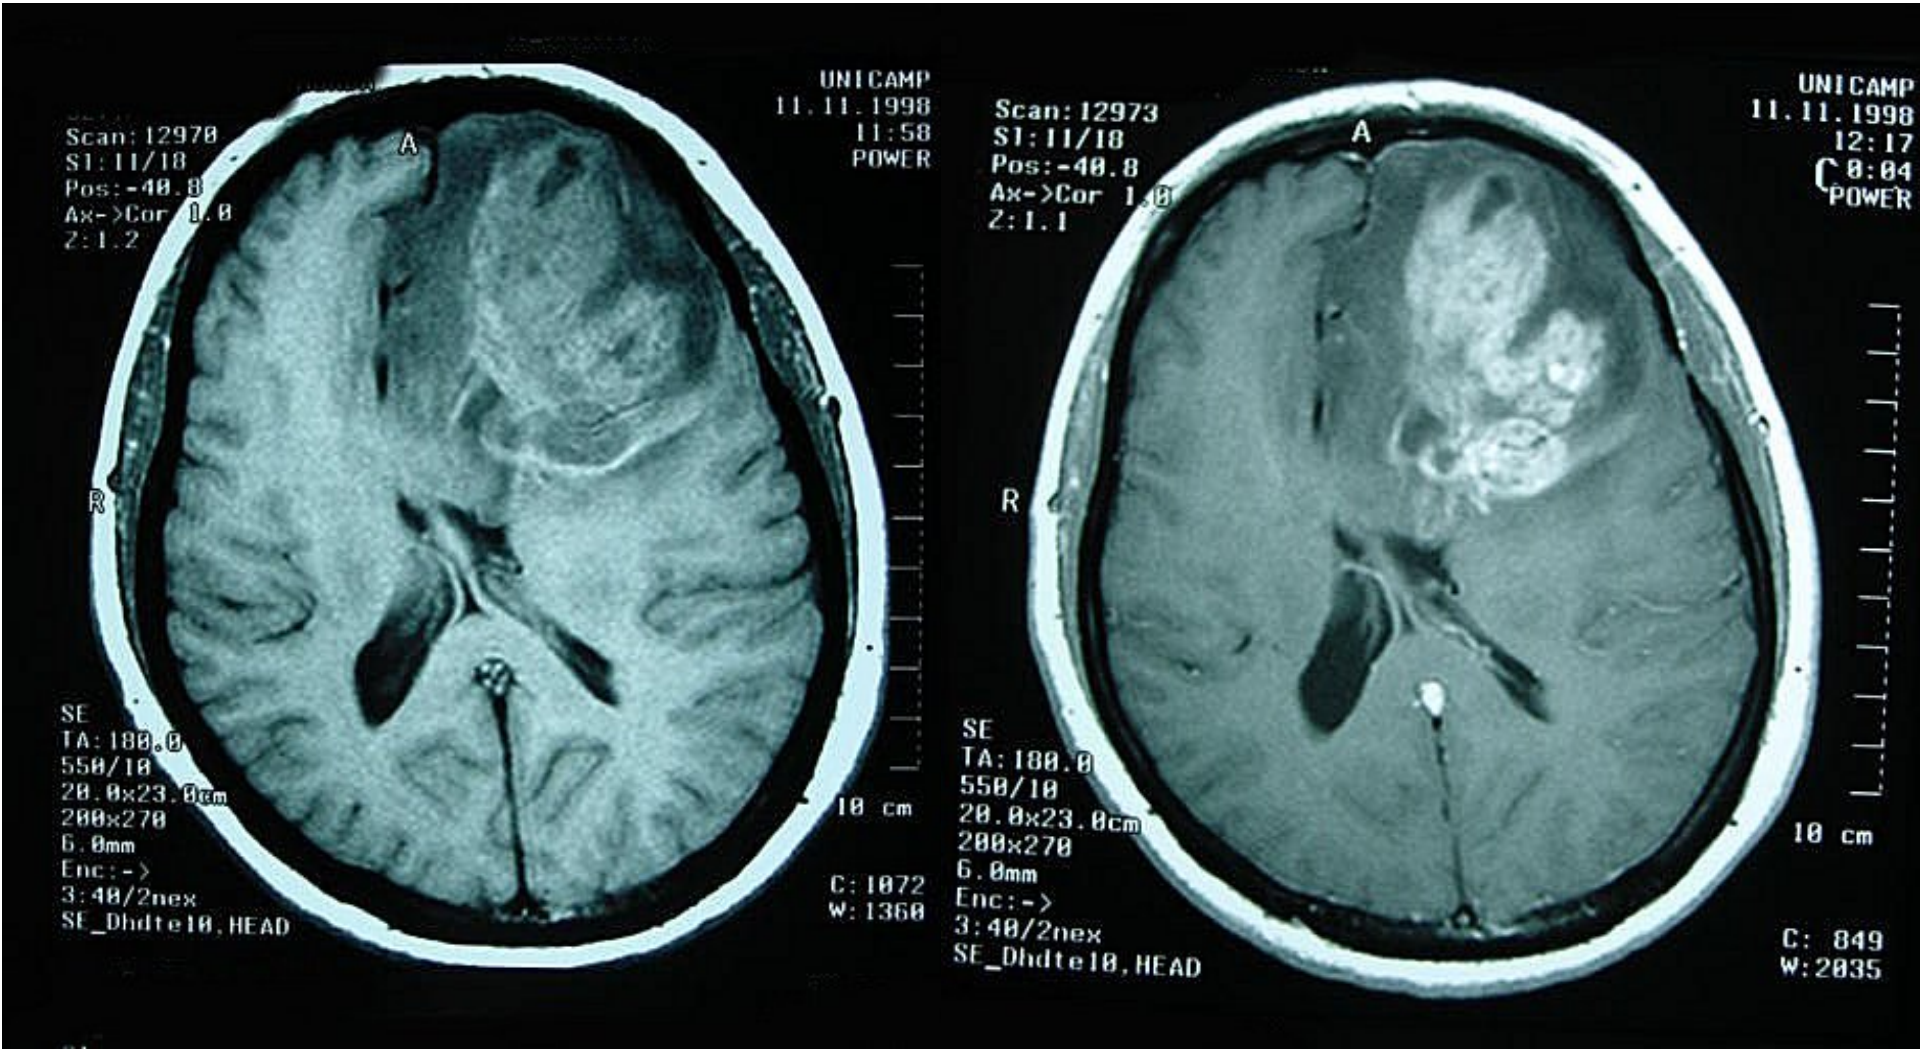
grade 3 gliomas WITHOUT co-deletion of 1p19q

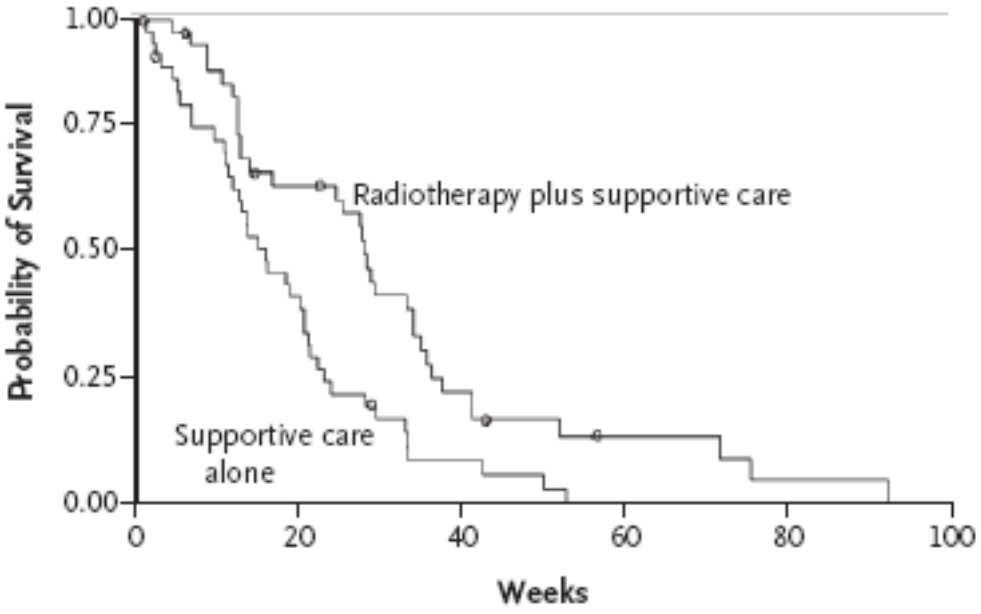


† Institution must choose to evaluate 1p/19q LOH locally or use central facility.

‡ After registration, all material is centrally reviewed for MGMT methylation status.

Glioblastoma





No. at Risk					
Supportive care alone	42	17	3	0	0
Radiotherapy plus supportive care	39	24	8	3	1

Figure 2. Kaplan–Meier Estimates of Overall Survival According to Treatment Group.

The hazard ratio for death among patients who received radiotherapy plus supportive care as compared with those who received supportive care alone was 0.47 (95% CI, 0.29 to 0.76; P=0.002).

Glioblastoma patients aged > 70 yrs

Debate later…

Keime-Guibert NEJM 2007

Survival of GBM patients did not improve between 1978 and 2005....

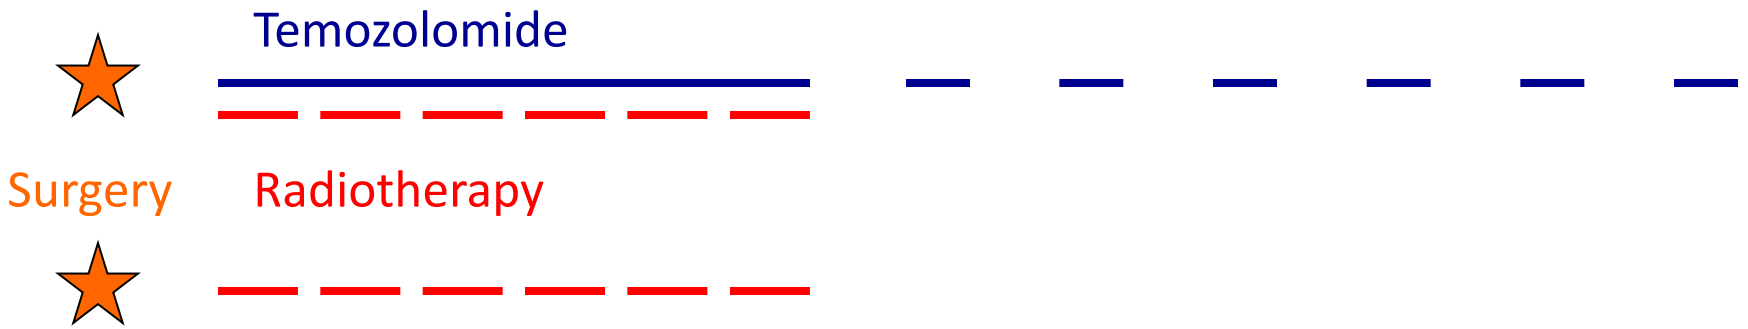
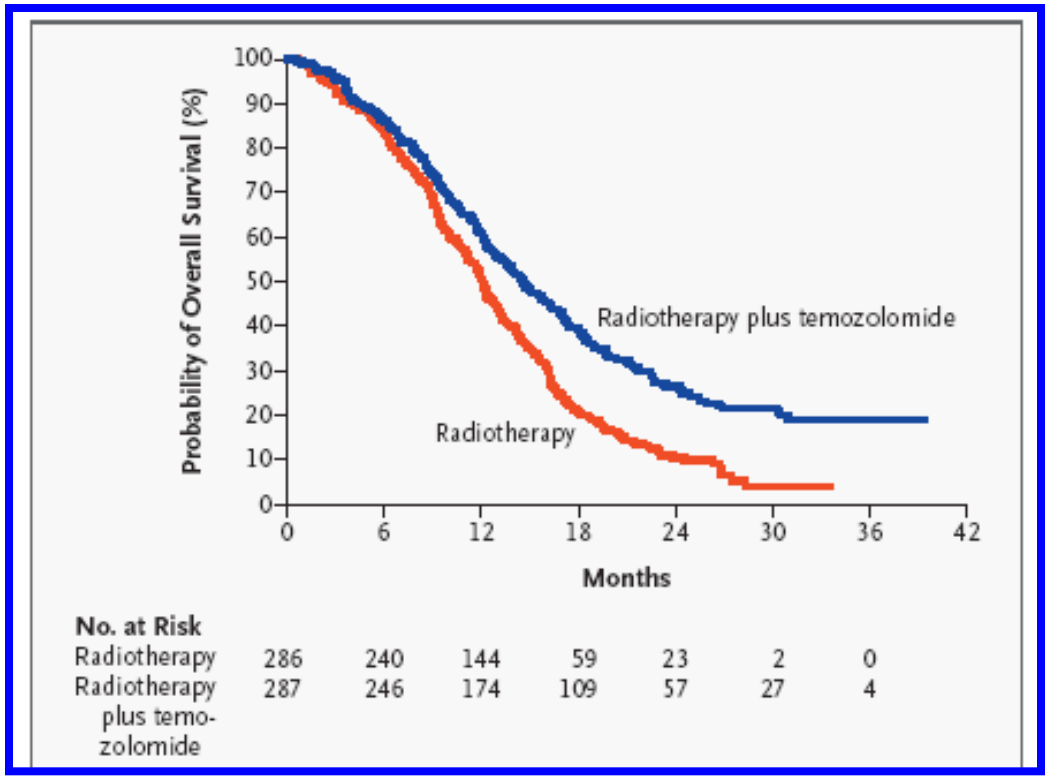
Mirimanoff, M.D., for the European Organisation for Research and Treatment of Cancer Brain Tumor and Radiotherapy Groups and the National Cancer Institute of Canada Clinical Trials Group*





Glioblastoma patients aged < 70 yrs

Stupp NEJM 2005

‘Stupp’ regime

- radiotherapy to enhancing tumour or resection cavity plus 2-3 cm margin
- daily temozolomide 75 mg/m^2 during radiotherapy
- standard radiotherapy dose (60 Gy 30#)
- 6 cycles of adjuvant temozolomide (5/28 days)
  - 1st cycle 150 mg/m^2
  - escalate to 200 mg/m^2 if tolerated
  - about 50% of patients completed 6 cycles

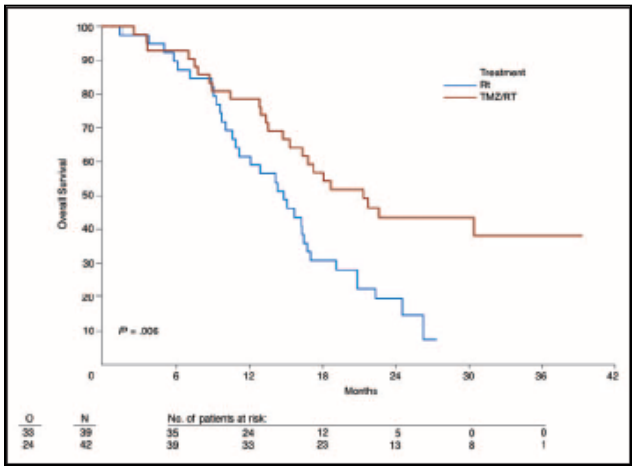
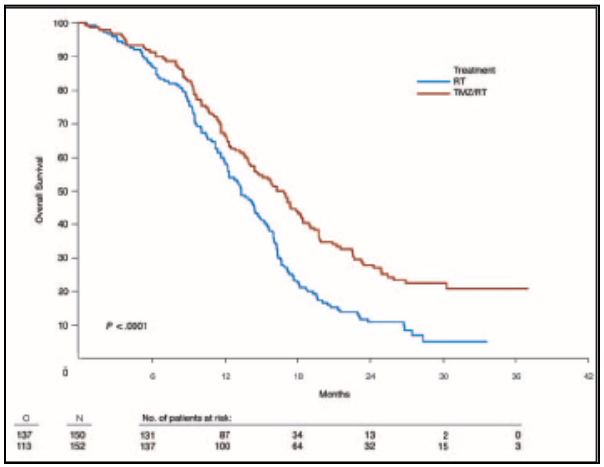
who benefits from TMZ-RT?



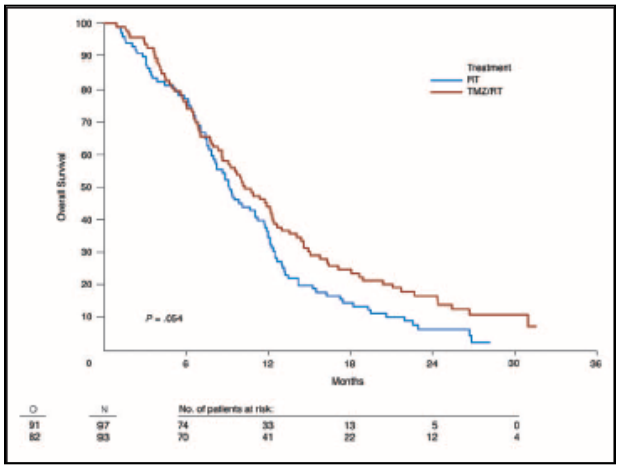
RPA III

p=0.006



RPA IV

p=0.0001



RPA V

p=0.054

48 year old patient with MGMT unmethylated GBM, >90% resection, PS=1 post-op. Completes RT-TMZ. She attends for 1st cycle adjuvant TMZ; PS now 2: fatigue, poor short term memory. Your recommendation is:

A. Commence adjuvant TMZ as protocol

B. Defer adjuvant TMZ until PS = 1 or better

C. Commence adjuvant TMZ but reconsider after cycle 1

D. Decision to proceed with adjuvant TMZ depends on result of MRI scan after RT/TMZ

E. Advise patient no benefit from adjuvant TMZ

61 year old science journalist from Los Angeles. MGMT methylated multifocal GBM, biopsy only. PS=1 post-op. Completes 1st cycle adjuvant TMZ with marked fatigue and ongoing mild cognitive deficit. Patient and wife seek your advice on (a) whether to go ahead with planned 5 week holiday to Italy for 30th wedding anniversary, visiting relatives, and (b) whether to continue with adjuvant TMZ. You advise:

A. Cancel trip to Italy and continue adjuvant TMZ

B. Travel to Italy, continue TMZ while away and on return

C. Travel to Italy, take a break from TMZ, continue on return

D. Decision to proceed with adjuvant TMZ depends on result of MRI scan

E. Advise patient that benefit from adjuvant TMZ is insufficient to justify fatigue and other toxicities

Chemoradiation for GBM

- continuous temozolomide associated with **lymphopenia**
  - exacerbated by prior and concomitant steroid treatment
  - prophylactic co-trimoxazole or pentamidine recommended if lymphocyte count <0.5
- adjuvant temozolomide associated with **neutropenia, thrombocytopenia and fatigue**
- occasional patients experience pancytopenia during concomitant treatment
- no increase in **late neurotoxicity** documented to date
- **'pseudoprogression'** on post-RT imaging
  - may reflect treatment related inflammation or necrosis
  - no validated imaging methods for discriminating progression from pseudoprogression

Post-op, pre-CRT

1 month post-CRT

6 months post-CRT

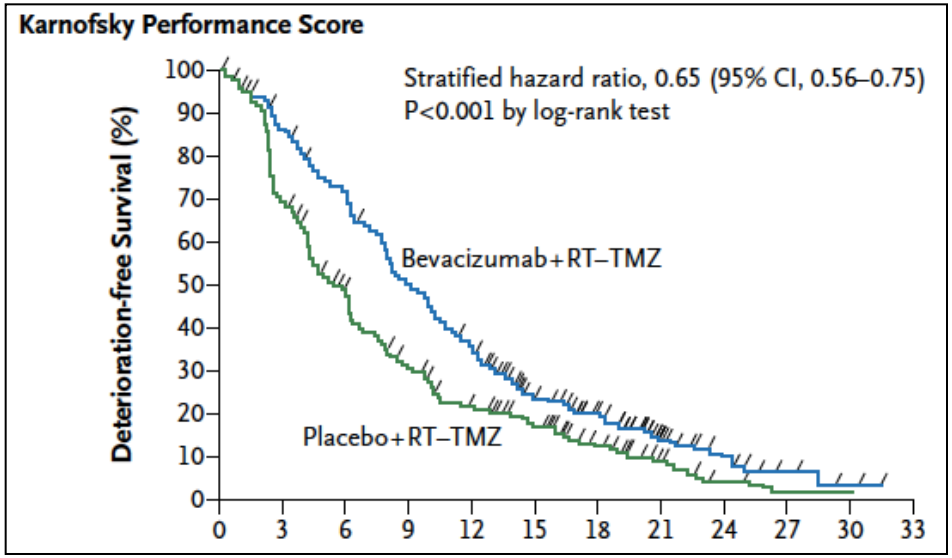
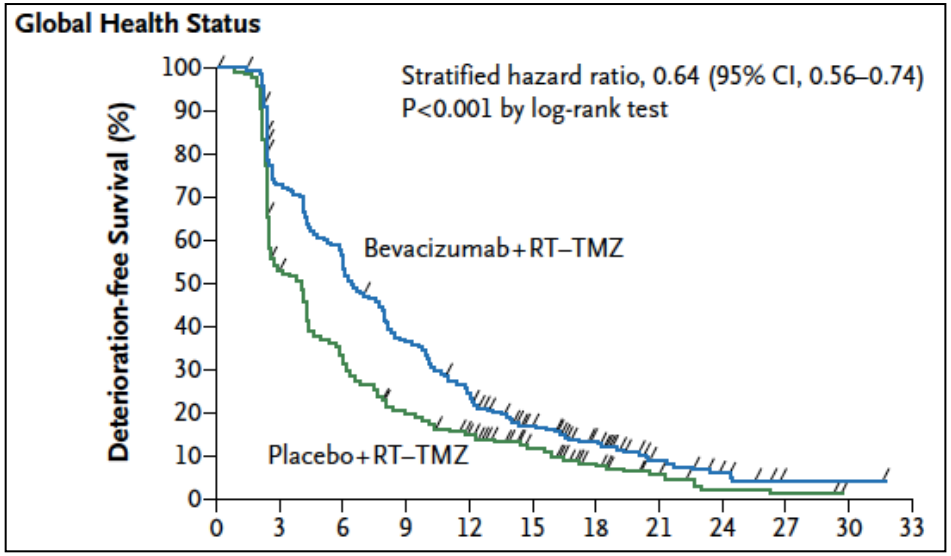
Does bevacizumab maintain QoL?





NET CLINICAL BENEFITS

In the NCB substudy, we found greater deterioration over time in the bevacizumab group than in the placebo group on the basis of the between-group difference in the composite scores on the neurocognitive-function test battery (P=0.05), as well as the scores for the Con-

Longitudinal evaluation also revealed greater deterioration in the bevacizumab group on the basis of the MDASI-BT composite symptom score (P=0.02), composite symptom-interference score (P<0.001), and the scores for activity-related

During the maintenance phase, serious adverse events were more prevalent in the bevacizumab group than in the placebo group, including hypertension (4.2% vs. 0.9%), thromboembolic disease (7.7% vs. 4.7%), wound dehiscence (1.5% vs. 0.9%), fatigue (13.1% vs. 9.0%), visceral perforation (1.2% vs. 0.4%), and serious hemorrhage (1.5% vs. 0.9%).

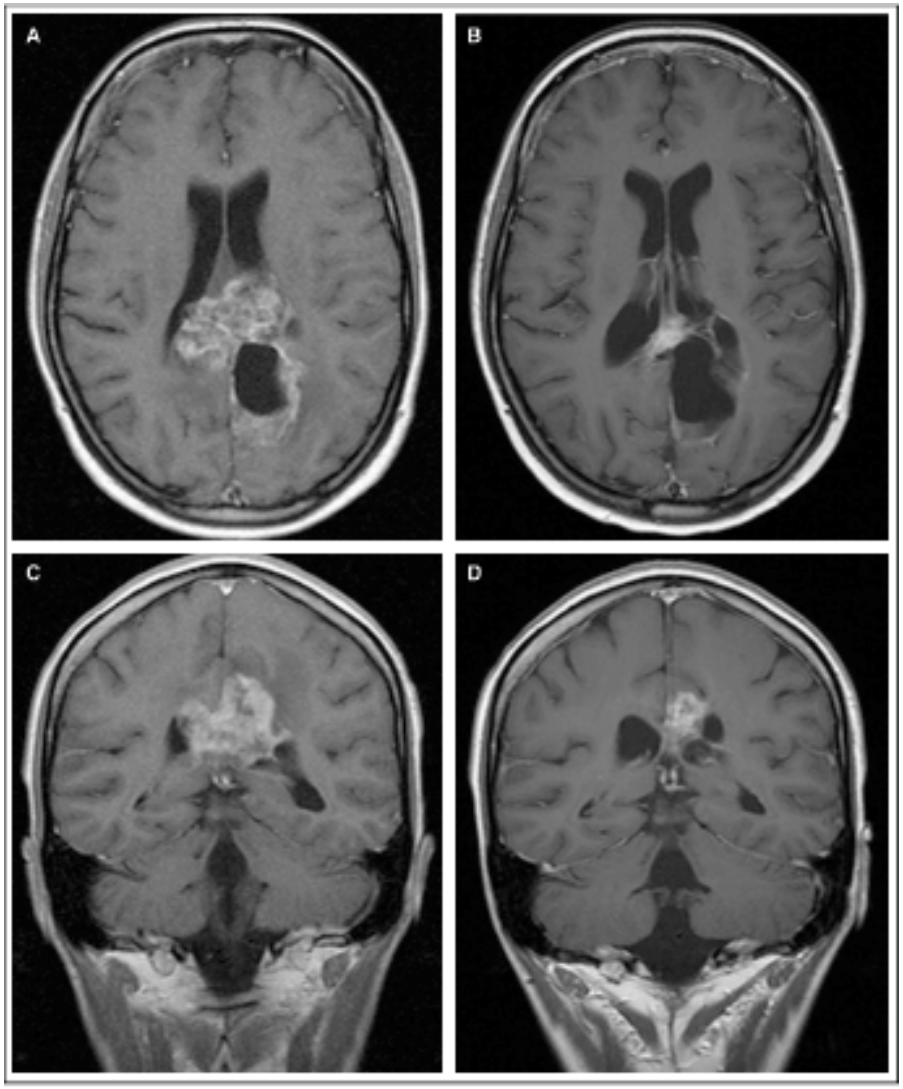
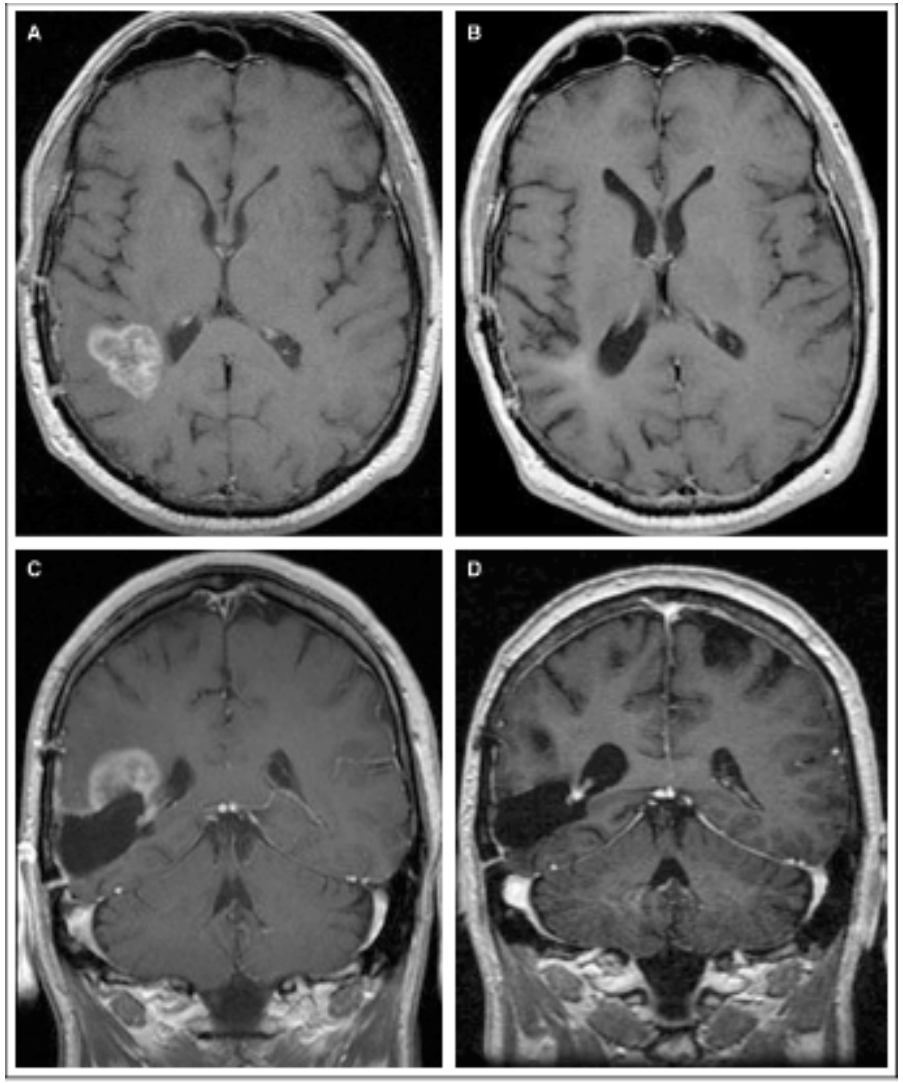
Bevacizumab Plus Irinotecan in Recurrent Glioblastoma Multiforme

James J. Vredenburgh, Annick Desjardins, James E. Herndon II, Jennifer Marcello, David A. Reardon, Jennifer A. Quinn, Jeremy N. Rich, Sith Sathornsumetee, Sridharan Gururangan, John Sampson, Melissa Wagner, Leighann Bailey, Darell D. Bigner, Allan H. Friedman, and Henry S. Friedman

- 35 patients, median 2 progressions
- Median time from diagnosis 14 months
- 57% RR
- 6 month PFS 46%
- 11 patients discontinued because of toxicity





Response v. pseudoresponse?

42 year old patient with MGMT methylated GBM, >90% resection, RT-TMZ. Recurrent, inoperable disease 14 months after completing adjuvant TMZ; PS=1. I would recommend:

A. TMZ rechallenge, 5/28 day schedule
B. TMZ rechallenge, 21/28 day schedule
C. PCV
D. TMZ + bevacizumab
E. Bevacizumab + irinotecan

61 year old patient with MGMT unmethylated GBM, >90% resection, RT-TMZ. Recurrent, inoperable disease 5 months after completing adjuvant TMZ; PS=1. I would recommend:

A. TMZ rechallenge, 5/28 day schedule
B. PCV
C. TMZ + bevacizumab
D. Bevacizumab + irinotecan
E. Best supportive care

Management of ependymoma of the brain and spinal cord

Prof. Damien Charles Weber

Prof. Ranjeev Bhangoo

Intracranial EP

Introduction (1)

- Originate from **ependymal cells** lining the ventricules and central canal
- Classified according to the **WHO** classification (i.e. grade 1*-2-3)
- **30%** of change of grading after centreal review UKCCR/SIOP (50%/50%)
- Can arise anywhere in the CNS but show a preference for the **posterior fossa (Children+++)**
- In older patients, ependymoma often arise within the brain parenchyma

Introduction (2)

Posterior fossa ependymoma

- 69% occur in children
- 3rd most common pediatric brain tumor
- 50% occur before the age of 5 years
- 58% presents in IV ventricule
- 5-6% of all intracranial tumors

Differential diagnosis of ventricule tumors

- **Ependymoma**
- Subependymoma
- MB
- Astrocytoma
- Epidermoid
- Choroid Plexus tumors

Introduction (3)

Treatment

- Goal: Gross total resection
- Recurrence frequent

Aduvant therapy

- RT beneficial
- Chemotherapy: no proven benefit

Outcome

	n	Event-free survival (%)		Overall survival (%)		"Radiotherapy-free" survival

EP and chemotherapy

- Direct evaluation of the response of EP to several chemotherapy agents has **failed** to demonstrate significant chemosensitivity
- However, given the concern of radiation-related neurotoxicity in (very) young children, **several trials of postoperative chemotherapy** have been undertaken
- Response rate to single agents is **11%**, with < **5% complete responses**, **CDDP** being the most active agent in phase II studies

EP and chemotherapy

Table 1 Response rate to single agents in recurrent ependymoma (*CR* complete response, *PR* partial response)

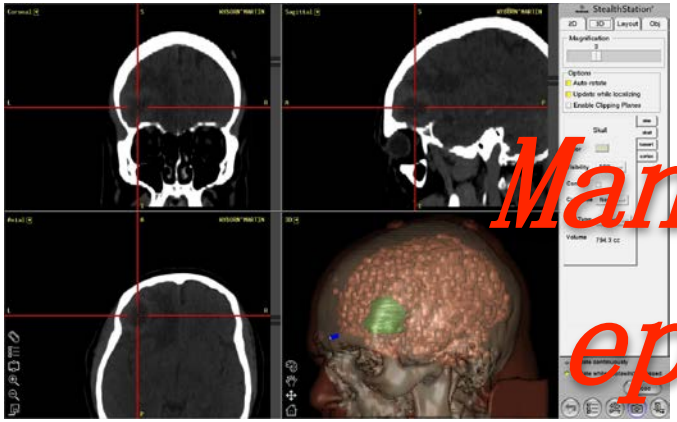
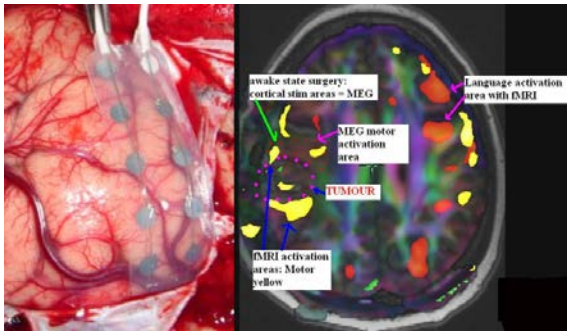
Spinal ependymoma



Management of ependymomas



Ranj Bhangoo, Francesco Vergani, Christian Brogna
Department of Neurosurgery
King's College Hospital - London

Adult intracranial ependymomas

- 2% adult intracranial tumours
- Data often from small series
- Controversy regarding treatment
- Role of chemotherapy/radiotherapy

Myxopapillary

- Commonly occurs in young adults in cauda equina
- Slow growing WHO Grade I
- ? Well Controlled after Surgery

WHO Grade I - Subependymoma

Slow growing noninvasive tumor

Are less cellular masses usually attached to the ventricle wall (cerebrospinal fluid filled cavity in the brain).

More common in adults and older men

Associated with long-term survival

Surgery can be potentially curative

WHO Grade II - Ependymoma (conventional)

Most common brain tumor in young children

Most common type of spinal glioma in adults

Often develop in the ventricles when intracranial

Several variants exist making diagnosis challenging:

- Cellular ependymoma
- Papillary ependymoma
- Clear cell ependymoma
- Tanycytic ependymoma

Can potentially recur as a higher grade tumor even after treatment

WHO Grade III Anaplastic Ependymoma

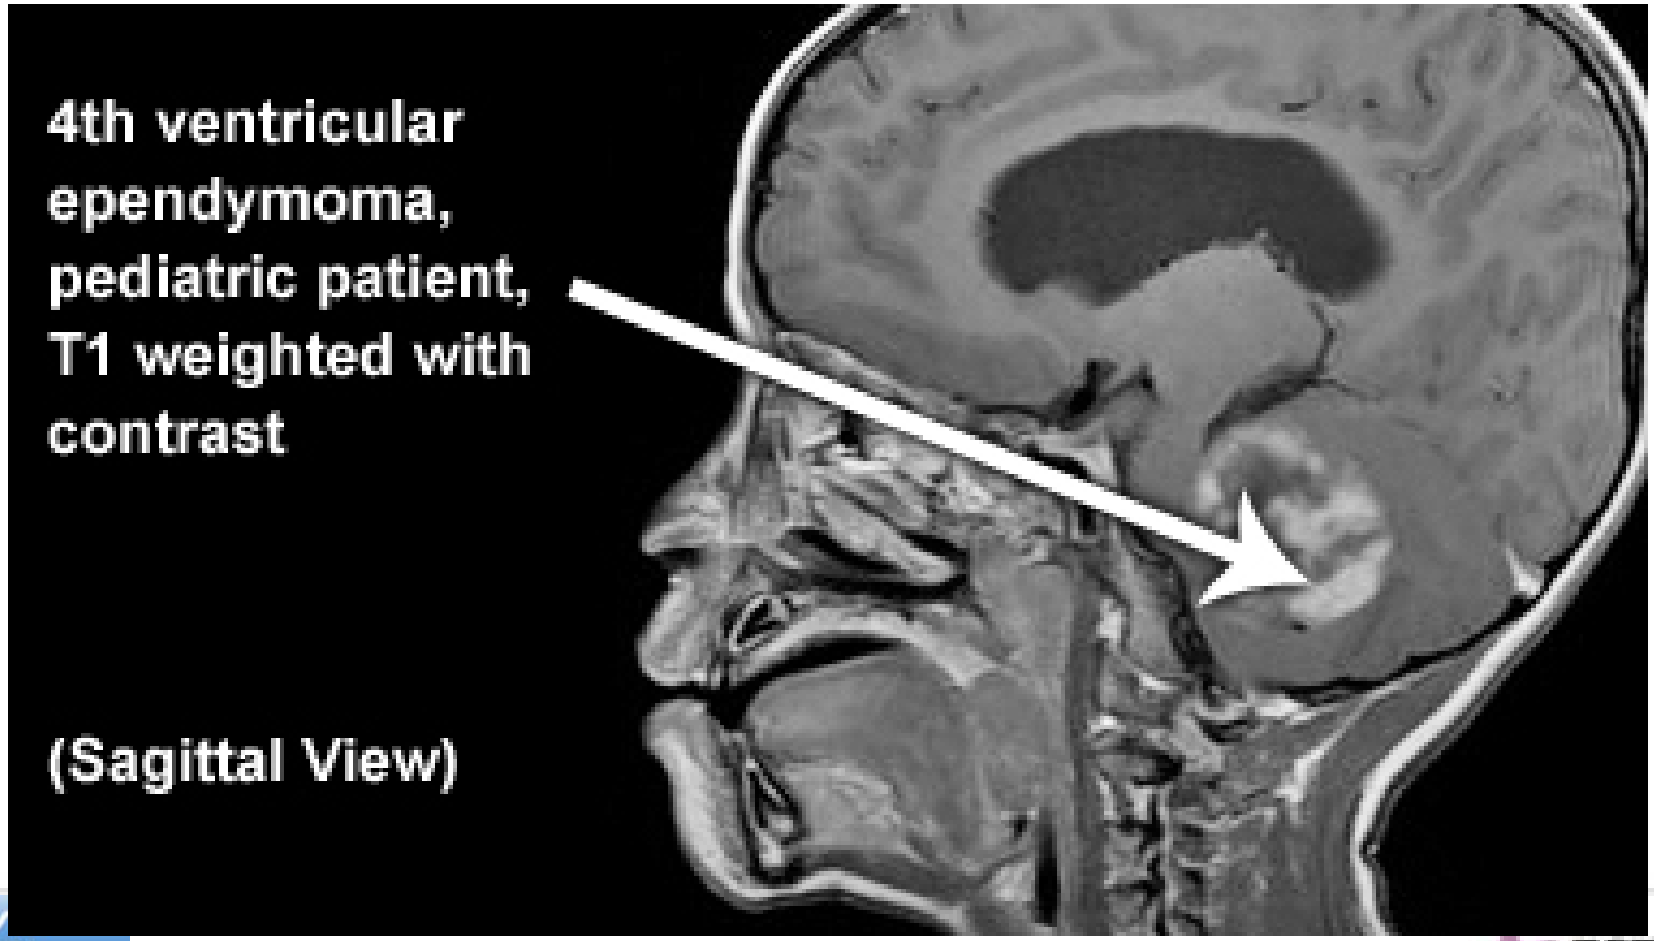
Show evidence of increased tumor cell growth compared to conventional ependymoma

Show evidence of new blood vessel formation to support active growth

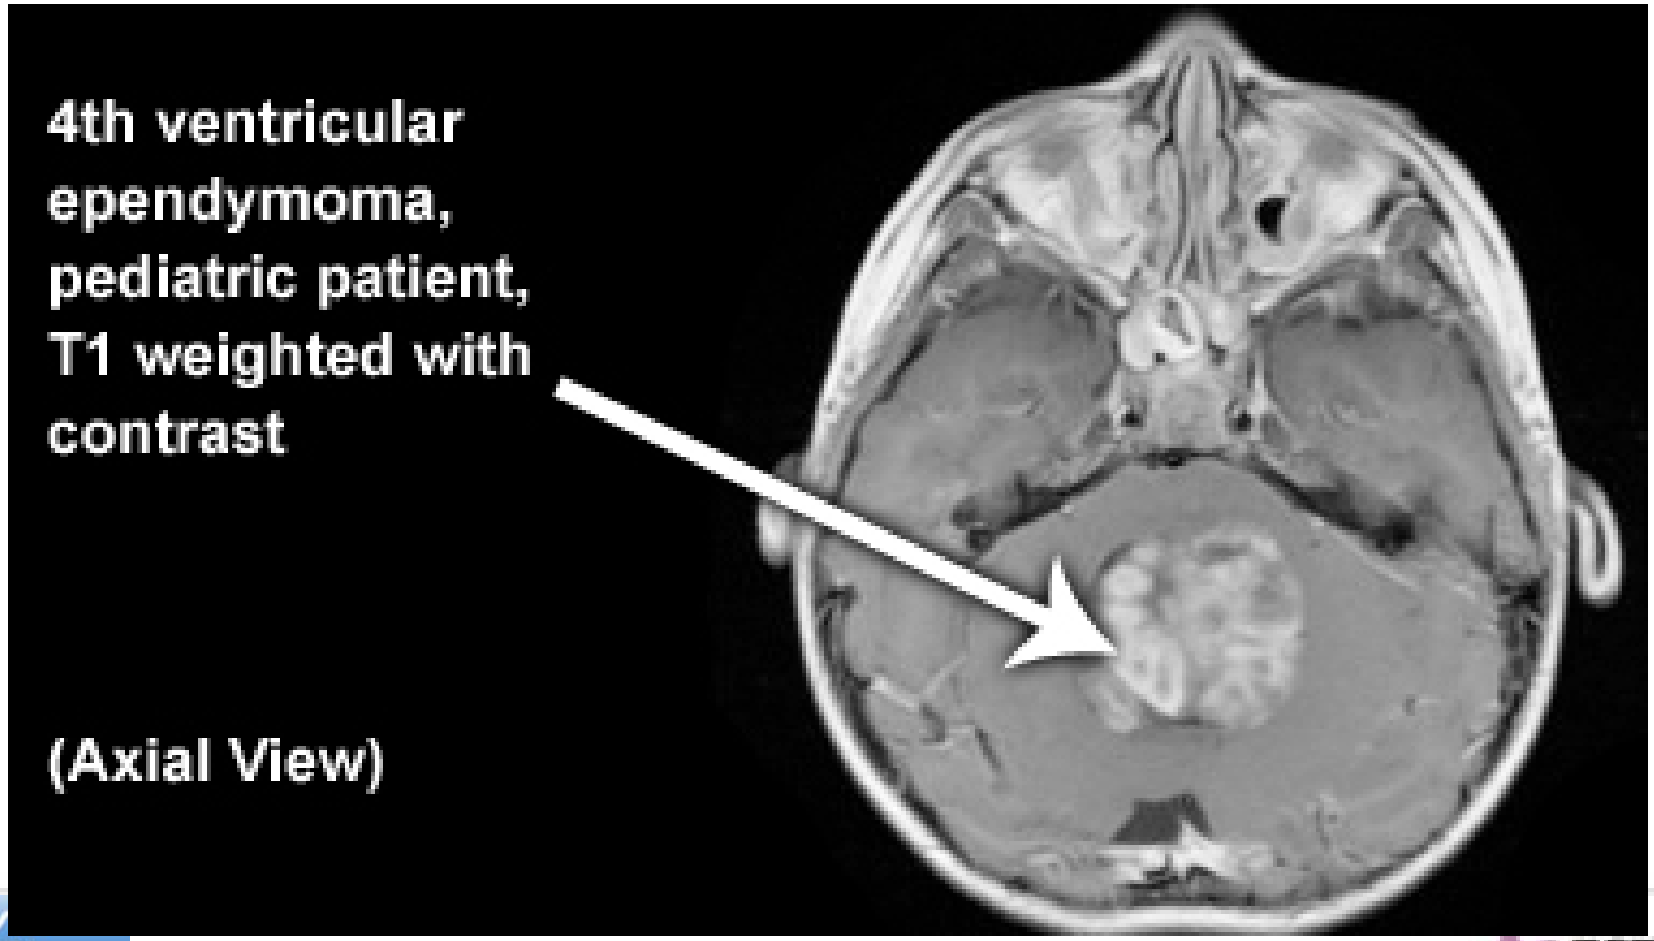
Exhibit more aggressive behavior than low grade ependymomas

Often require additional treatment after surgery and can recur

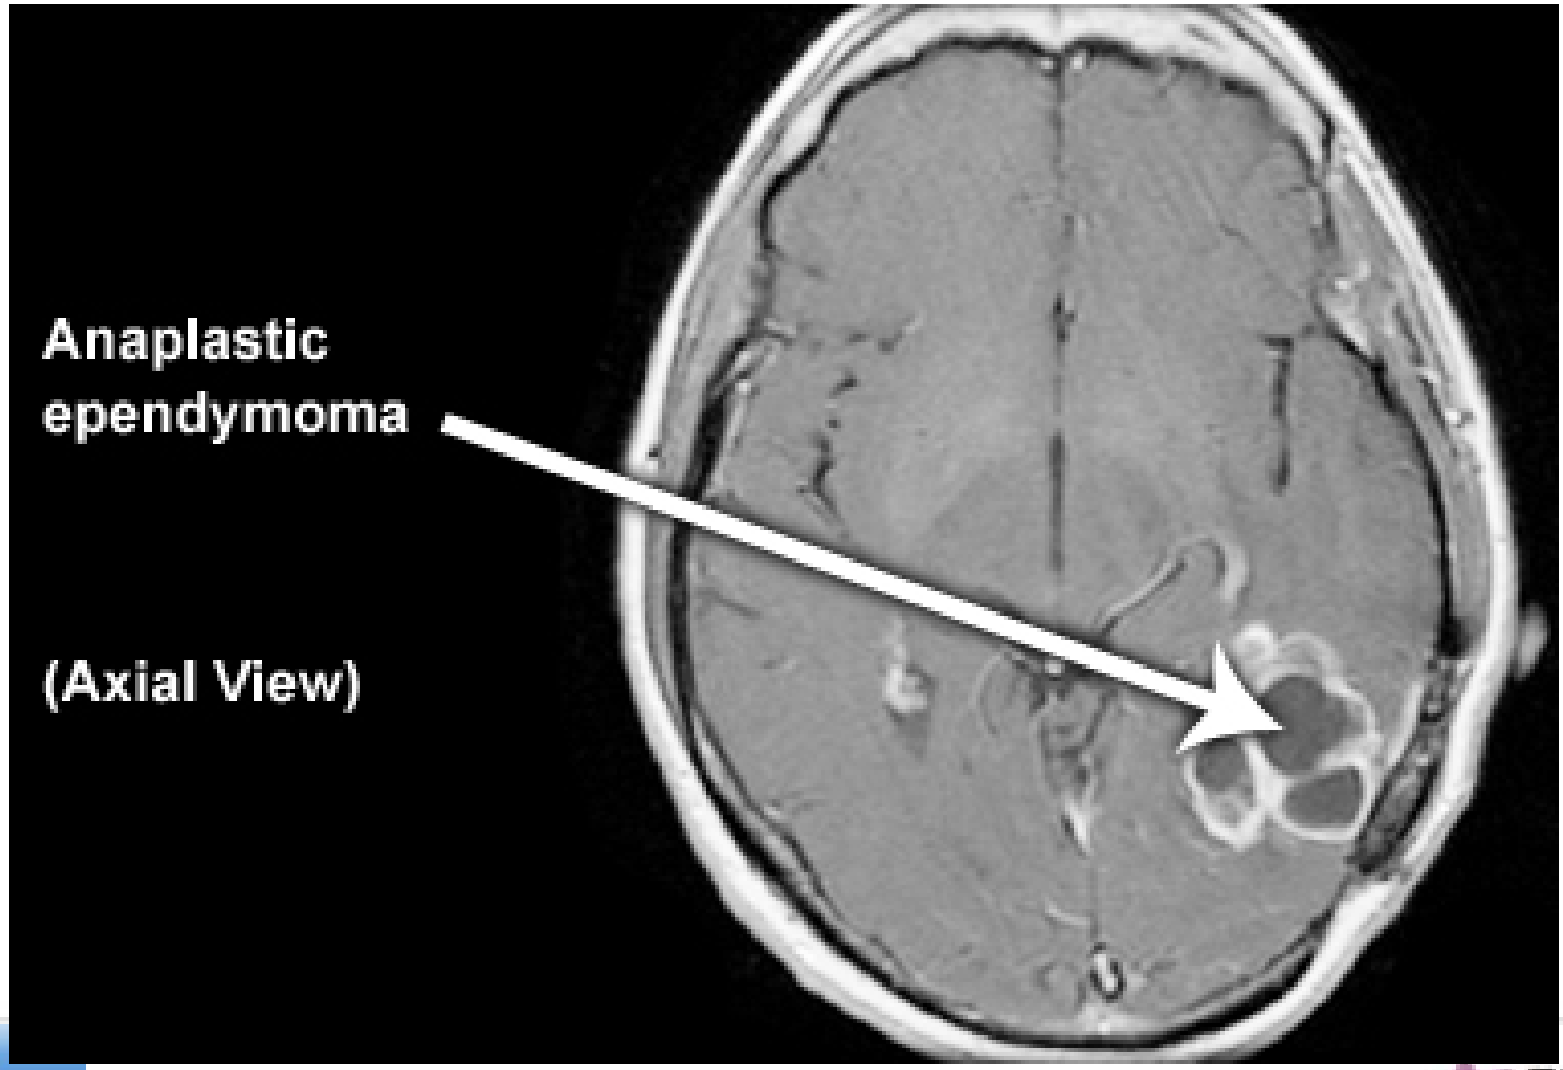
Paediatric Ependymoma



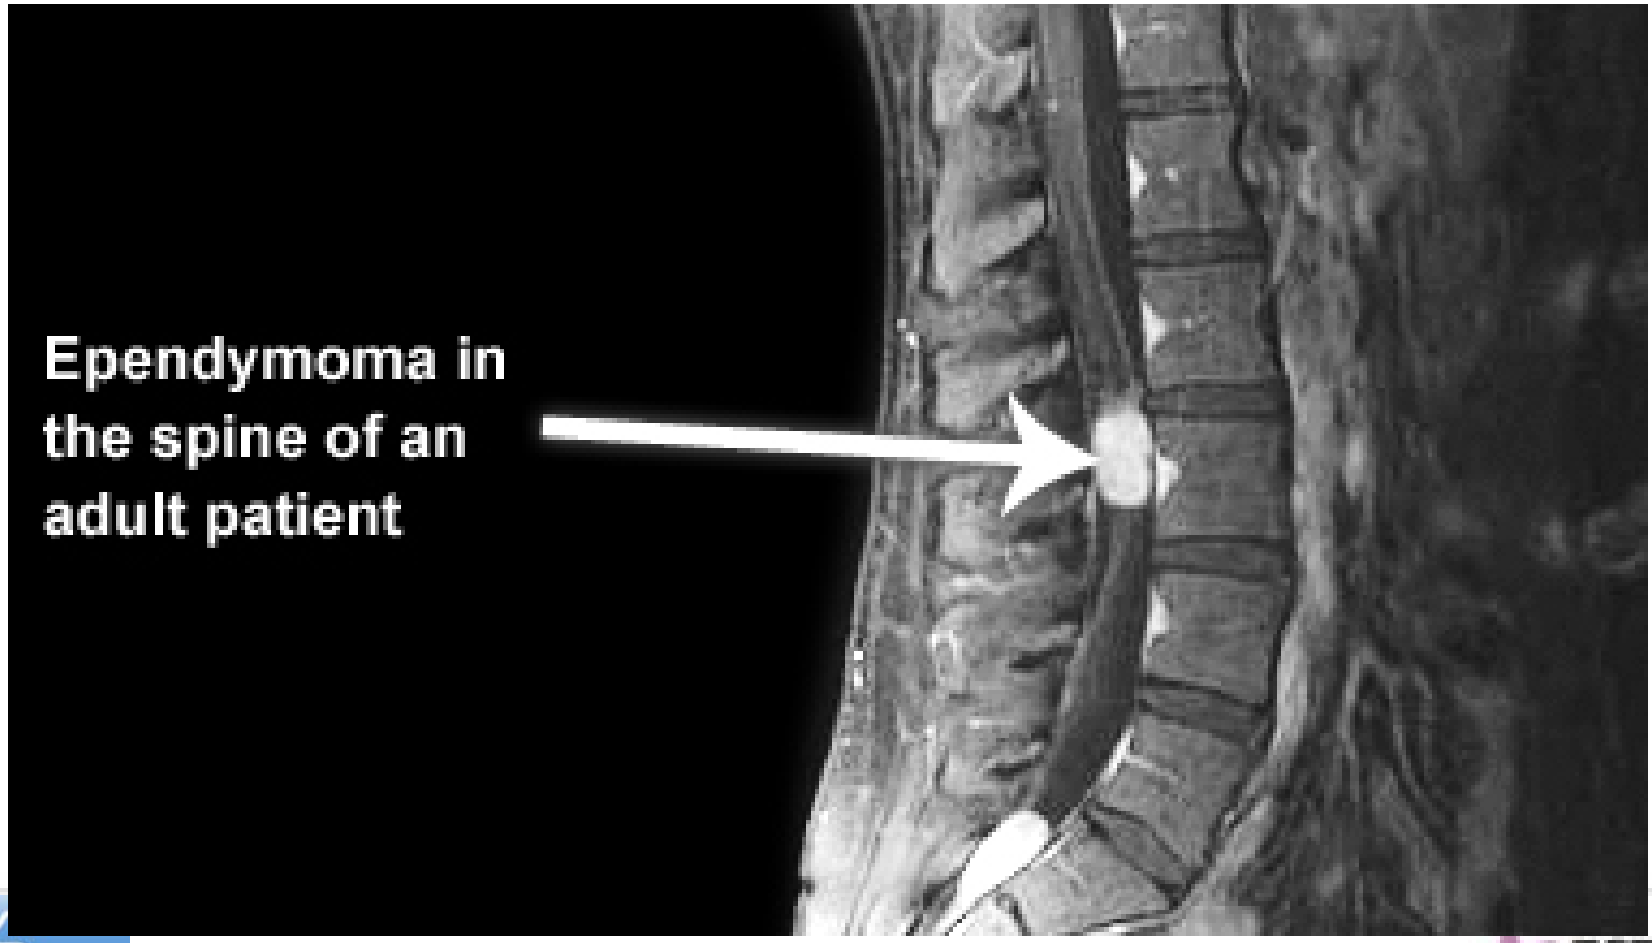
Paediatric Ependymoma



Adult Ependymoma



Drop Mets in Ependymoma



Treatment

- Treat any Hydrocephalus if needed
- Stage with Craniospinal MRI
- Macroscopic Resection if at all possible

Adult intracranial ependymomas

Multicentric French study on adult intracranial ependymomas: prognostic factors analysis and therapeutic considerations from a cohort of 152 patients

If tumour markers are negative or slightly elevated, a histological diagnosis is mandatory

Secreting germ cell tumours

If tumor markers αFP and/or βHCG are elevated (αFP > 25 ng/ml; βHCG > 50 IU/L) and imaging shows a characteristic lesion, a secreting germ cell tumour is diagnosed and treatment should be started with chemotherapy (without histological confirmation)

CNS GCT: Extent of surgery

Germinoma

Which is your proposal in a 14-yo male affected with localized pure germinoma of the pineal region?

1. Chemotherapy only
2. Radiotherapy alone (CSI followed by focal boost)
3. Chemo followed by same RT as above
4. Chemo followed by more limited RT

Germinoma

What do you mean as more limited RT?

1. CSI with lower doses
2. Smaller volumes: whole brain
3. Smaller volumes: WVI
4. Smaller volumes: focal irradiation only

Germinoma

Radiotherapy is the backbone in the treatment of pure intracranial germinoma

Germinoma: Management

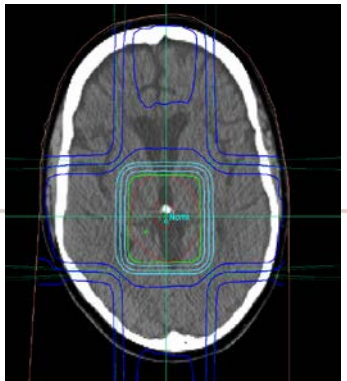
- Standard treatment has been RT alone, with cranio-spinal irradiation plus focal boost, resulting in DFS of 90-95%
  - Microscopic disease:

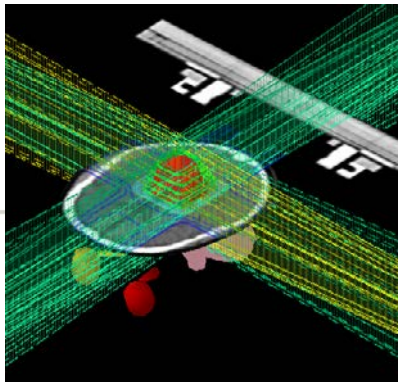
    30-36 Gy
  - Macroscopic disease:

    40-50 Gy

CSA

Boost to tumour site





CSI: risk for late toxicities

Two parallel developments to reduce late effects of CSI:

•evidence that with RT alone:

- ✓ irradiation to limited volumes (<CSI, but WVI/WBI) in well staged pts is equally effective (what is the real risk of spinal seeding?)
- ✓ lower RT doses (MAKEI 40 Gy --> 36 Gy --> 30 Gy) control subclinal disease

• reports of encouraging results using a combination of chemo followed by reduced-volumes RT

Radiotherapy in pure germinoma

Relapsefree survival (CNS) (n=155) (patients - germany)

to macroscopical disease

ESTRO School

Is radiotherapy alone to ventricular system / boost sufficient in non-metastatic disease ?

(no chemotherapy)

Radiotherapy in pure germinoma

Pattern of relapse after radiotherapy alone with respect to target volume (M0) (meta-analysis)

Technique	Pat.	Relapses (total)	Spinal
CSA	287	14 (4.8%)	3 (1%)
Whole brain	91	6 (6.5%)	3 (3.2%)
Ventricular system (boost)	54	3 (5.6%)	1 (1.8%)
Local only	130	31 (23.8%)	13 (10%)

Aoyama et al., 2009

SIOP CNS GCT II

Underlying philosophy:

Convert macroscopic to subclinical disease

by using chemotherapy before RT

Dose reduction from 40 to 24 Gy (primary tumour site)

(Japanese data, : overall tumor-free rate 92.9% (52 of 56 pat.)

Med.f-up, 2.1 years, 1 relapse outside RT area. Matsutani et al., 1998

Dose reduction to non-target brain

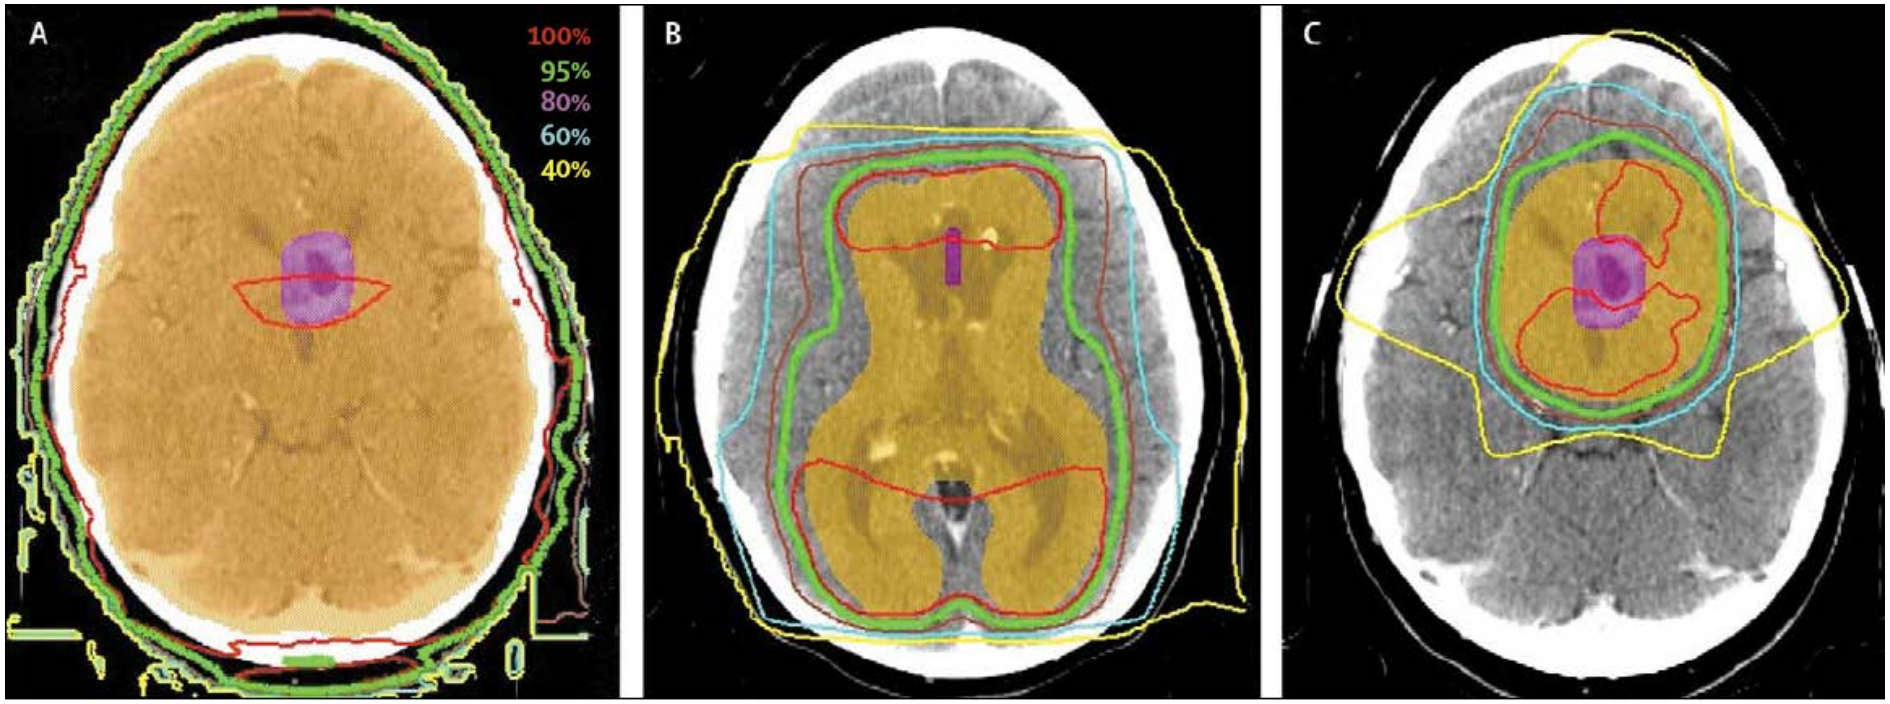
(dose reduction to functionally relevant areas)

⇨ **Reduction of risk for late effects**

Radiotherapy in pure germinoma

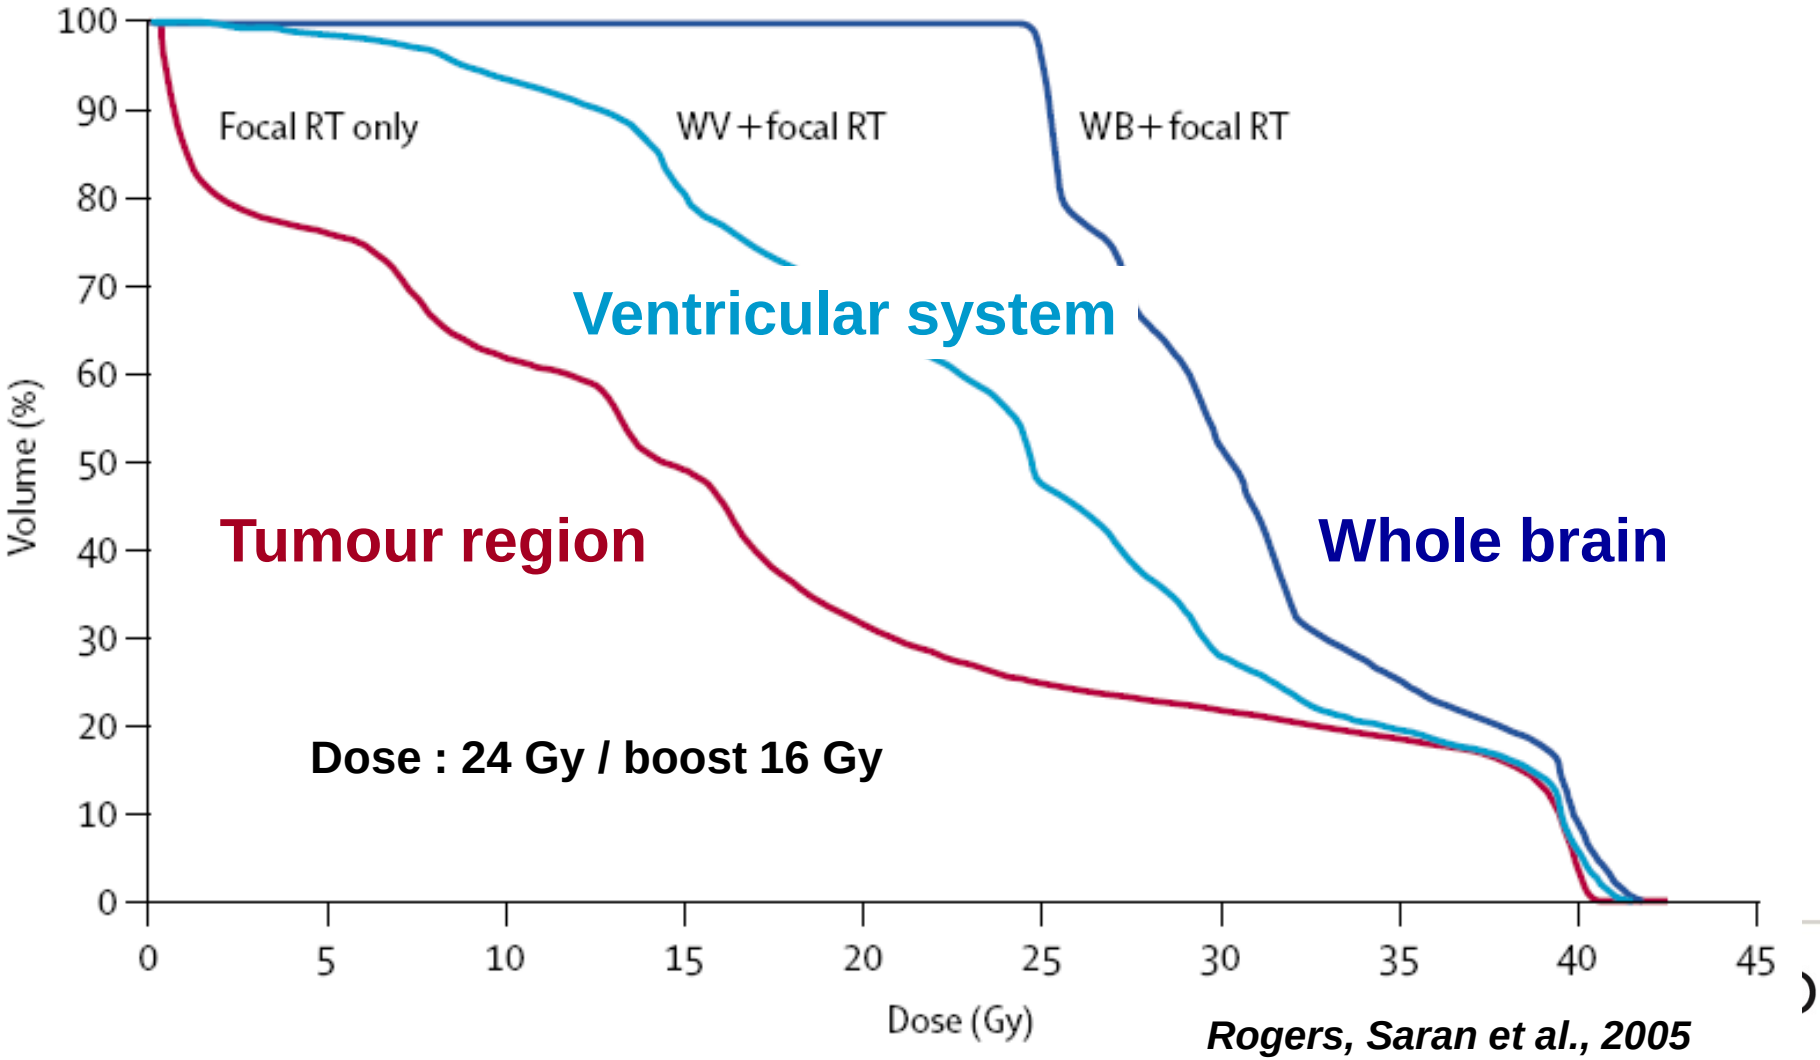
Dose distribution / target volumes

Whole brain **Ventricular system** **Tumour region**



Radiotherapy in pure germinoma

Dose distribution / target volume / DVH‘s (whole brain)



Rogers, Saran et al., 2005

Neurocognitive function
RT CSA versus ventricular RT

Domain	RT- CSA	Ventricular RT
Verbal comprehension	87.30	110.50
Perceptual reasoning	98.56	121.00
Full-scale IQ	91.78	115.17
Reading	85.38	106.17
Receptive vocabulary	85.56	106.20

Problem : total dose and dose distribution unknown
(RT CSA 25 - 30 Gy, boost doses up to 54 Gy ?)

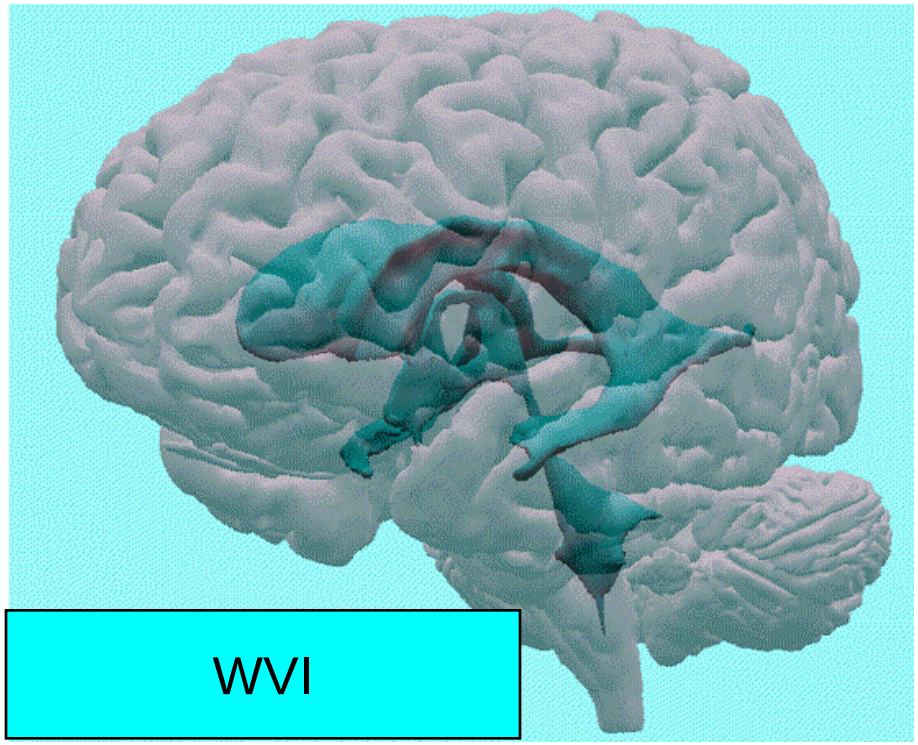
Mabott et al., 2011

WVI: definition

Third ventricle

Lateral ventricles

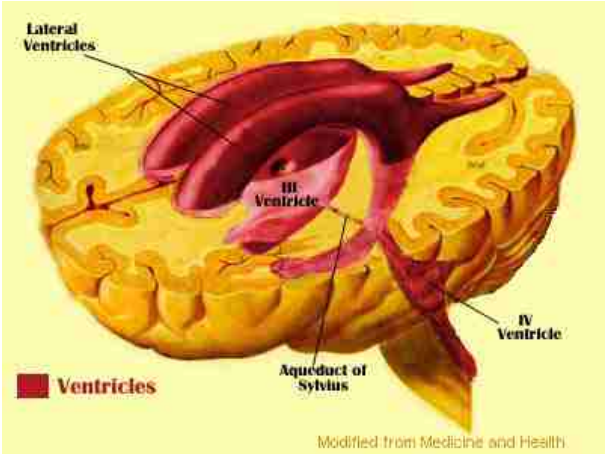
Fourth ventricle (regardless of primary tumor site)



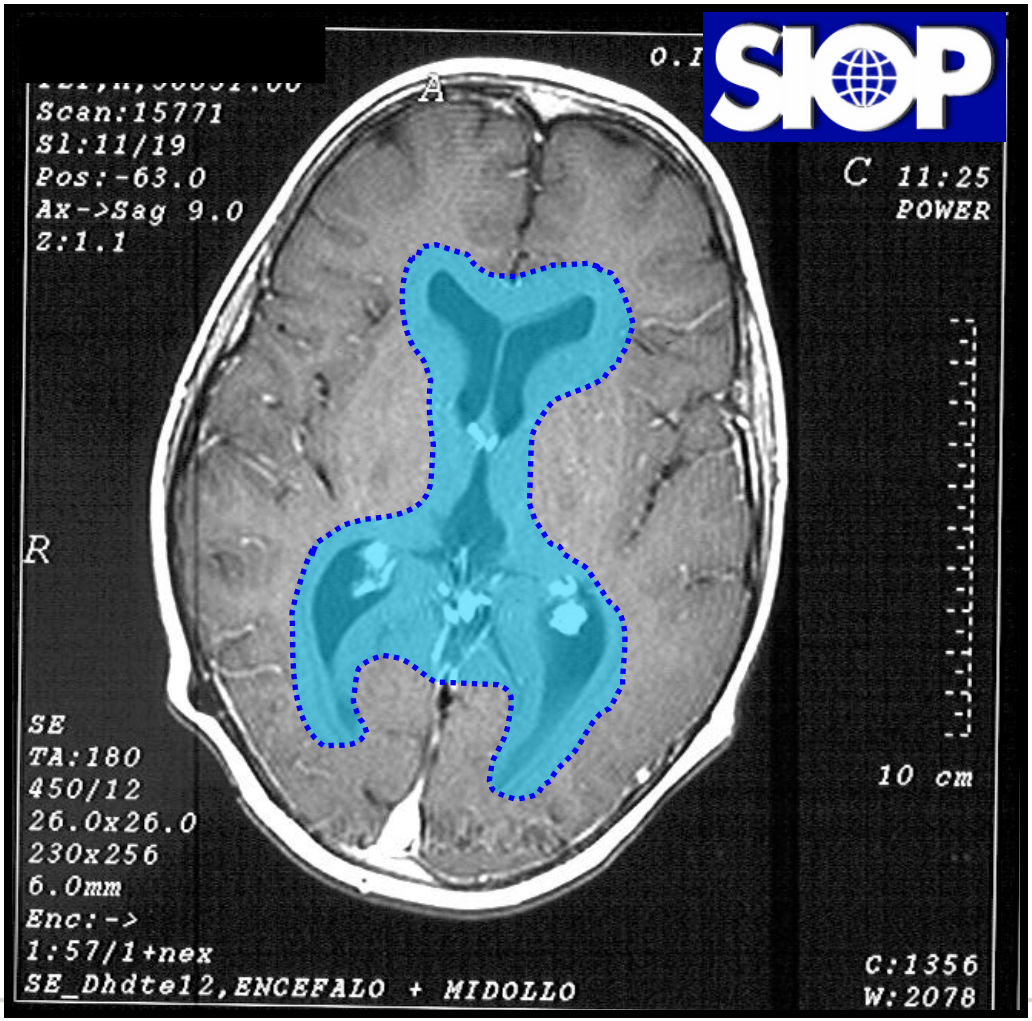
RT techniques for ventricular system irradiation

Very irregular shape of the target volume

New radiation modalities (IMRT) for the best conformity index (target coverage and normal brain sparing)



WVI: concave-shaped target for IMRT



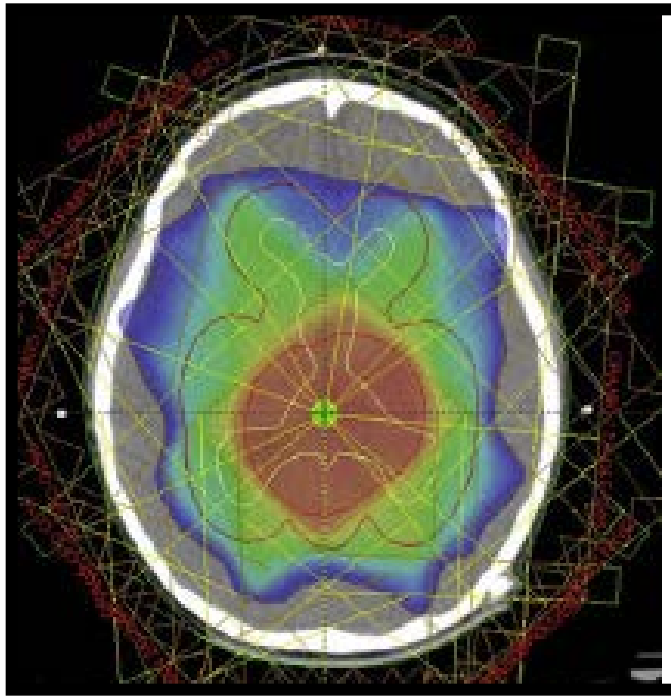
ESTRO School

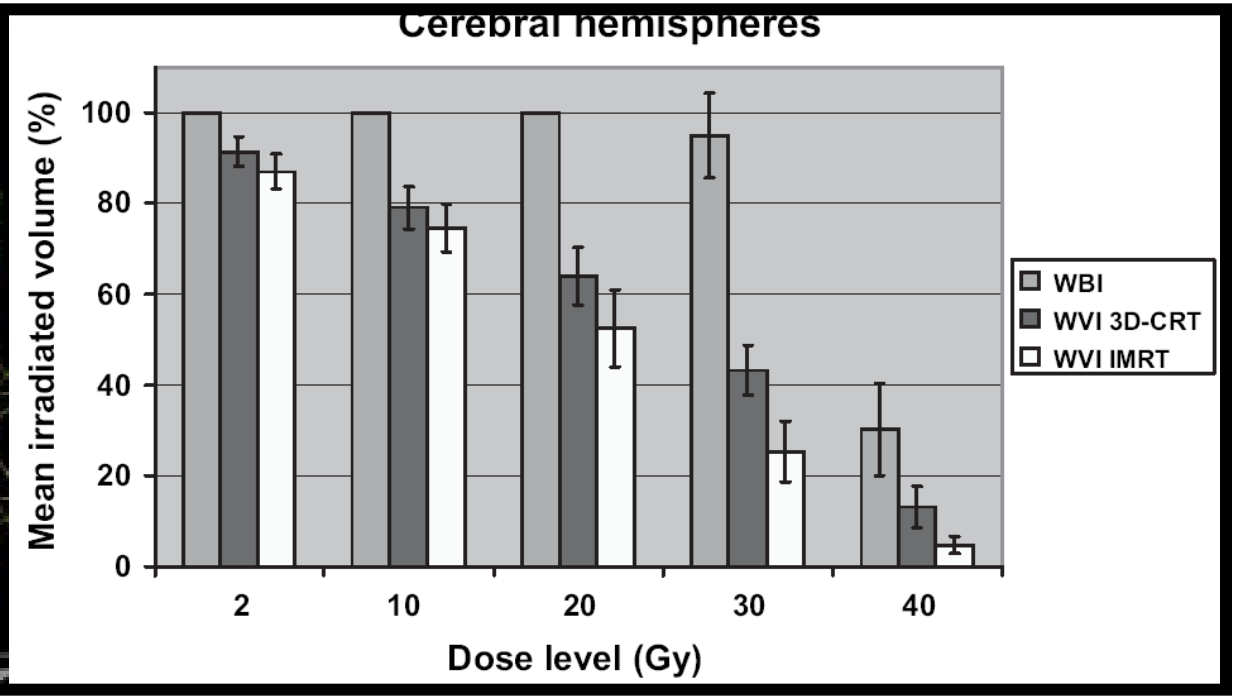
Radiotherapy in pure germinoma

RT ventricular system + boost / IMRT

Reduction of dose to „non-target brain“ / hemisheres

Comparison of plans / 10 patients





Chen et al., 2010

Longitudinal Evaluation of Neurocognitive Function After Treatment for Central Nervous System Germ Cell Tumors in Childhood

Donald J. Mabbott, PhD[1,2,3]; Eric Monsalves, BSc[3]; Brenda J. Spiegler, PhD[1,2,4]; Ute Bartels, MD[2,4]; Laura Janzen, PhD[1,2,4]; Sharon Guger, PhD[1,2]; Normand Laperriere, MD[2,5,6]; Nicole Andrews, PhD[1]; and Eric Bouffet, MD[2,4]

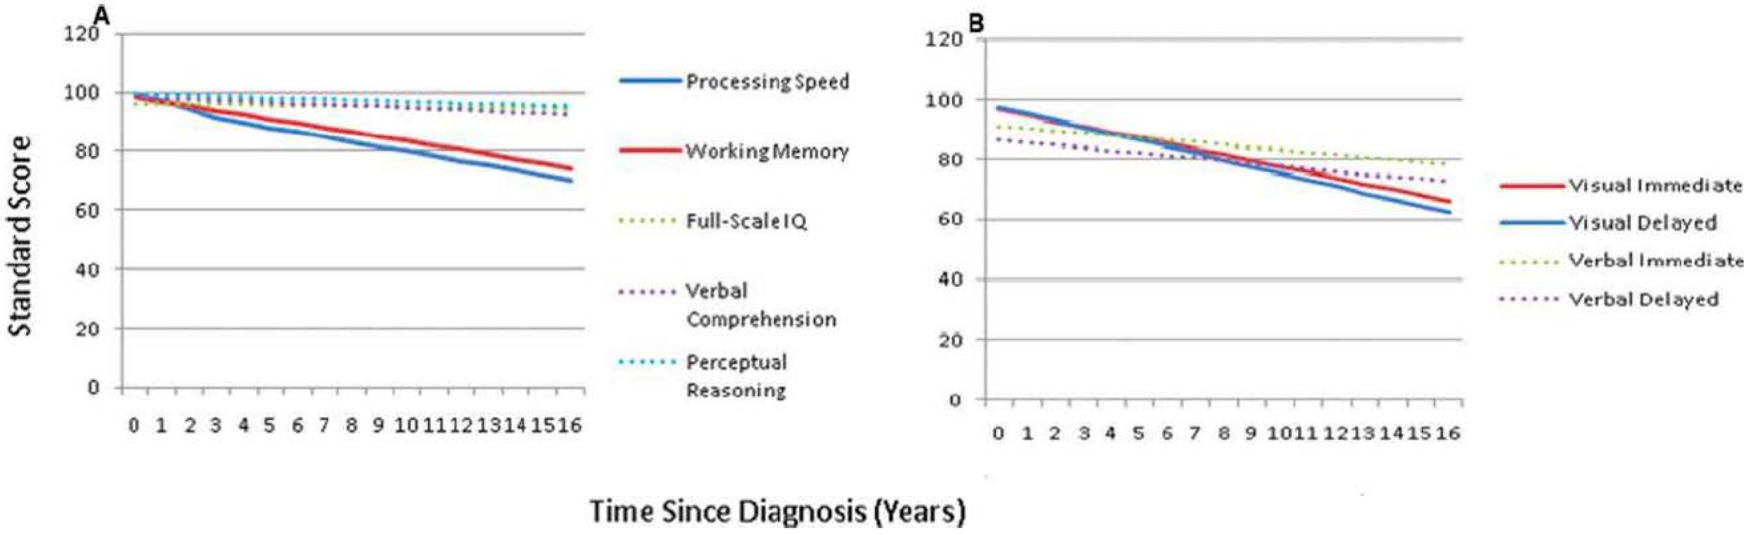


Figure 1. Estimated change over time based on linear models for the entire sample are shown for full-scale IQ, verbal comprehension, perceptual reasoning, working memory, and processing speed indices from the Wechsler Intelligence Scales for Children/ Wechsler Adult Intelligence Scales (A) and visual and verbal memory scores (B).

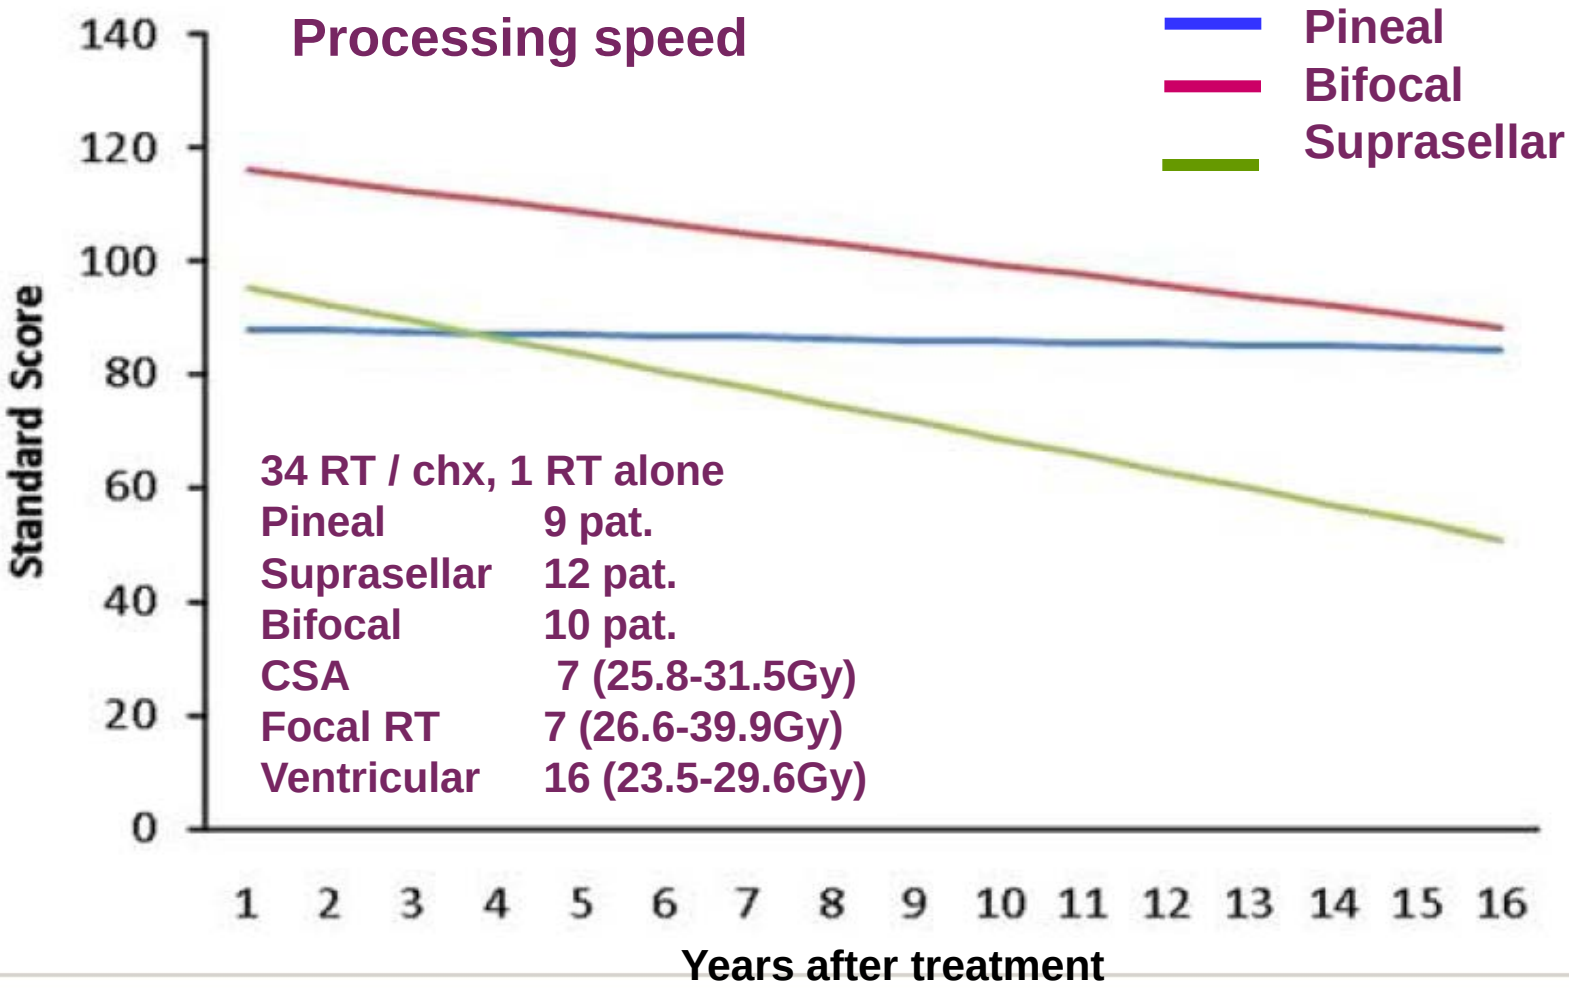
CONCLUSIONS: Although general cognitive abilities appeared stable and intact after treatment for most children with CNS GCT, a significant decline over time in working memory, processing speed, and visual memory was evident. Tumor location appeared to be important in understanding the trajectory of stability and decline in CNS GCT patients, as did radiation field. ***Cancer* 2011;117:5402–11.** © *2011 American Cancer Society.*

Intracranial germ cell tumours (GCT)

Neurocognitive function (29 germinoma, 7 non-germinoma)



Mabott et al., 2011

Intracranial germinoma - Conclusions

- ⇨ High cure rates
- ⇨ RT indispensable (Chx alone : app 50% relapse rate, high toxicity)
- ⇨ Chemotherapy is an effective strategy to avoid spinal RT and to reduce dose of RT
- ⇨ M + : RT CSA / boost alone (no chemotherapy)

Primary CNS lymphoma

ESTRO teaching course
Management of brain tumours

Patrick Roth

Department of Neurology and Brain Tumor Center
University Hospital Zurich

Primary CNS lymphoma

- Lymphoma with exclusive manifestation in the CNS
- Median age: ~ 60 years
- Incidence: approximately 0.5/100.000

  => increasing for unkown reasons
- Particular situation: HIV-associated CNS lymphomas

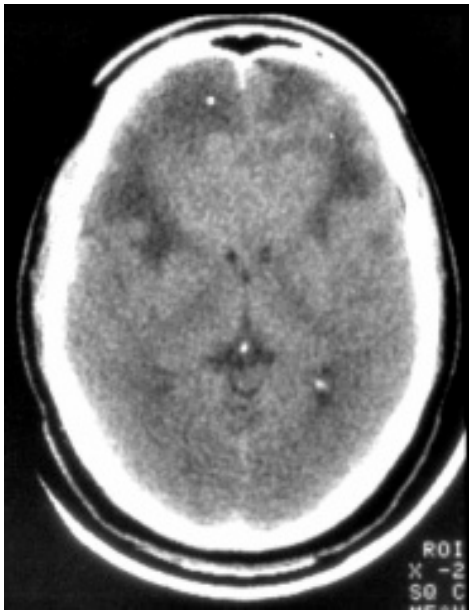
  => incidence decreasing since introduction of HAART
- Unclear pathogenesis => specific CNS tropism?

Clincal presentation

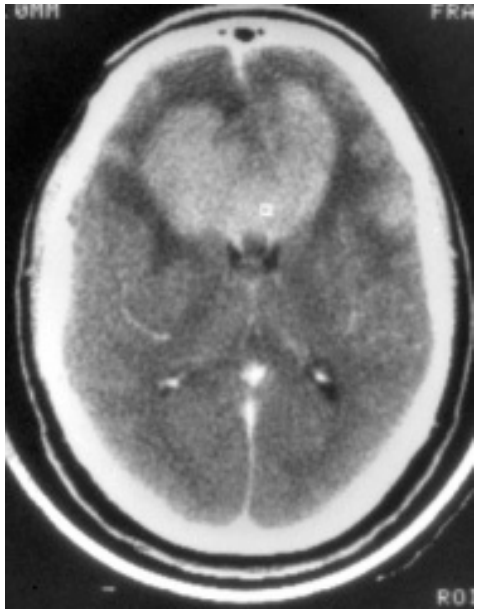
- Personality changes
- Symptoms associated with increased intracranial pressure
- Motor and sensory deficits
- Cranial nerve palsies
- Seizures (rare)
- Cerebellar symptoms

Imaging: CT

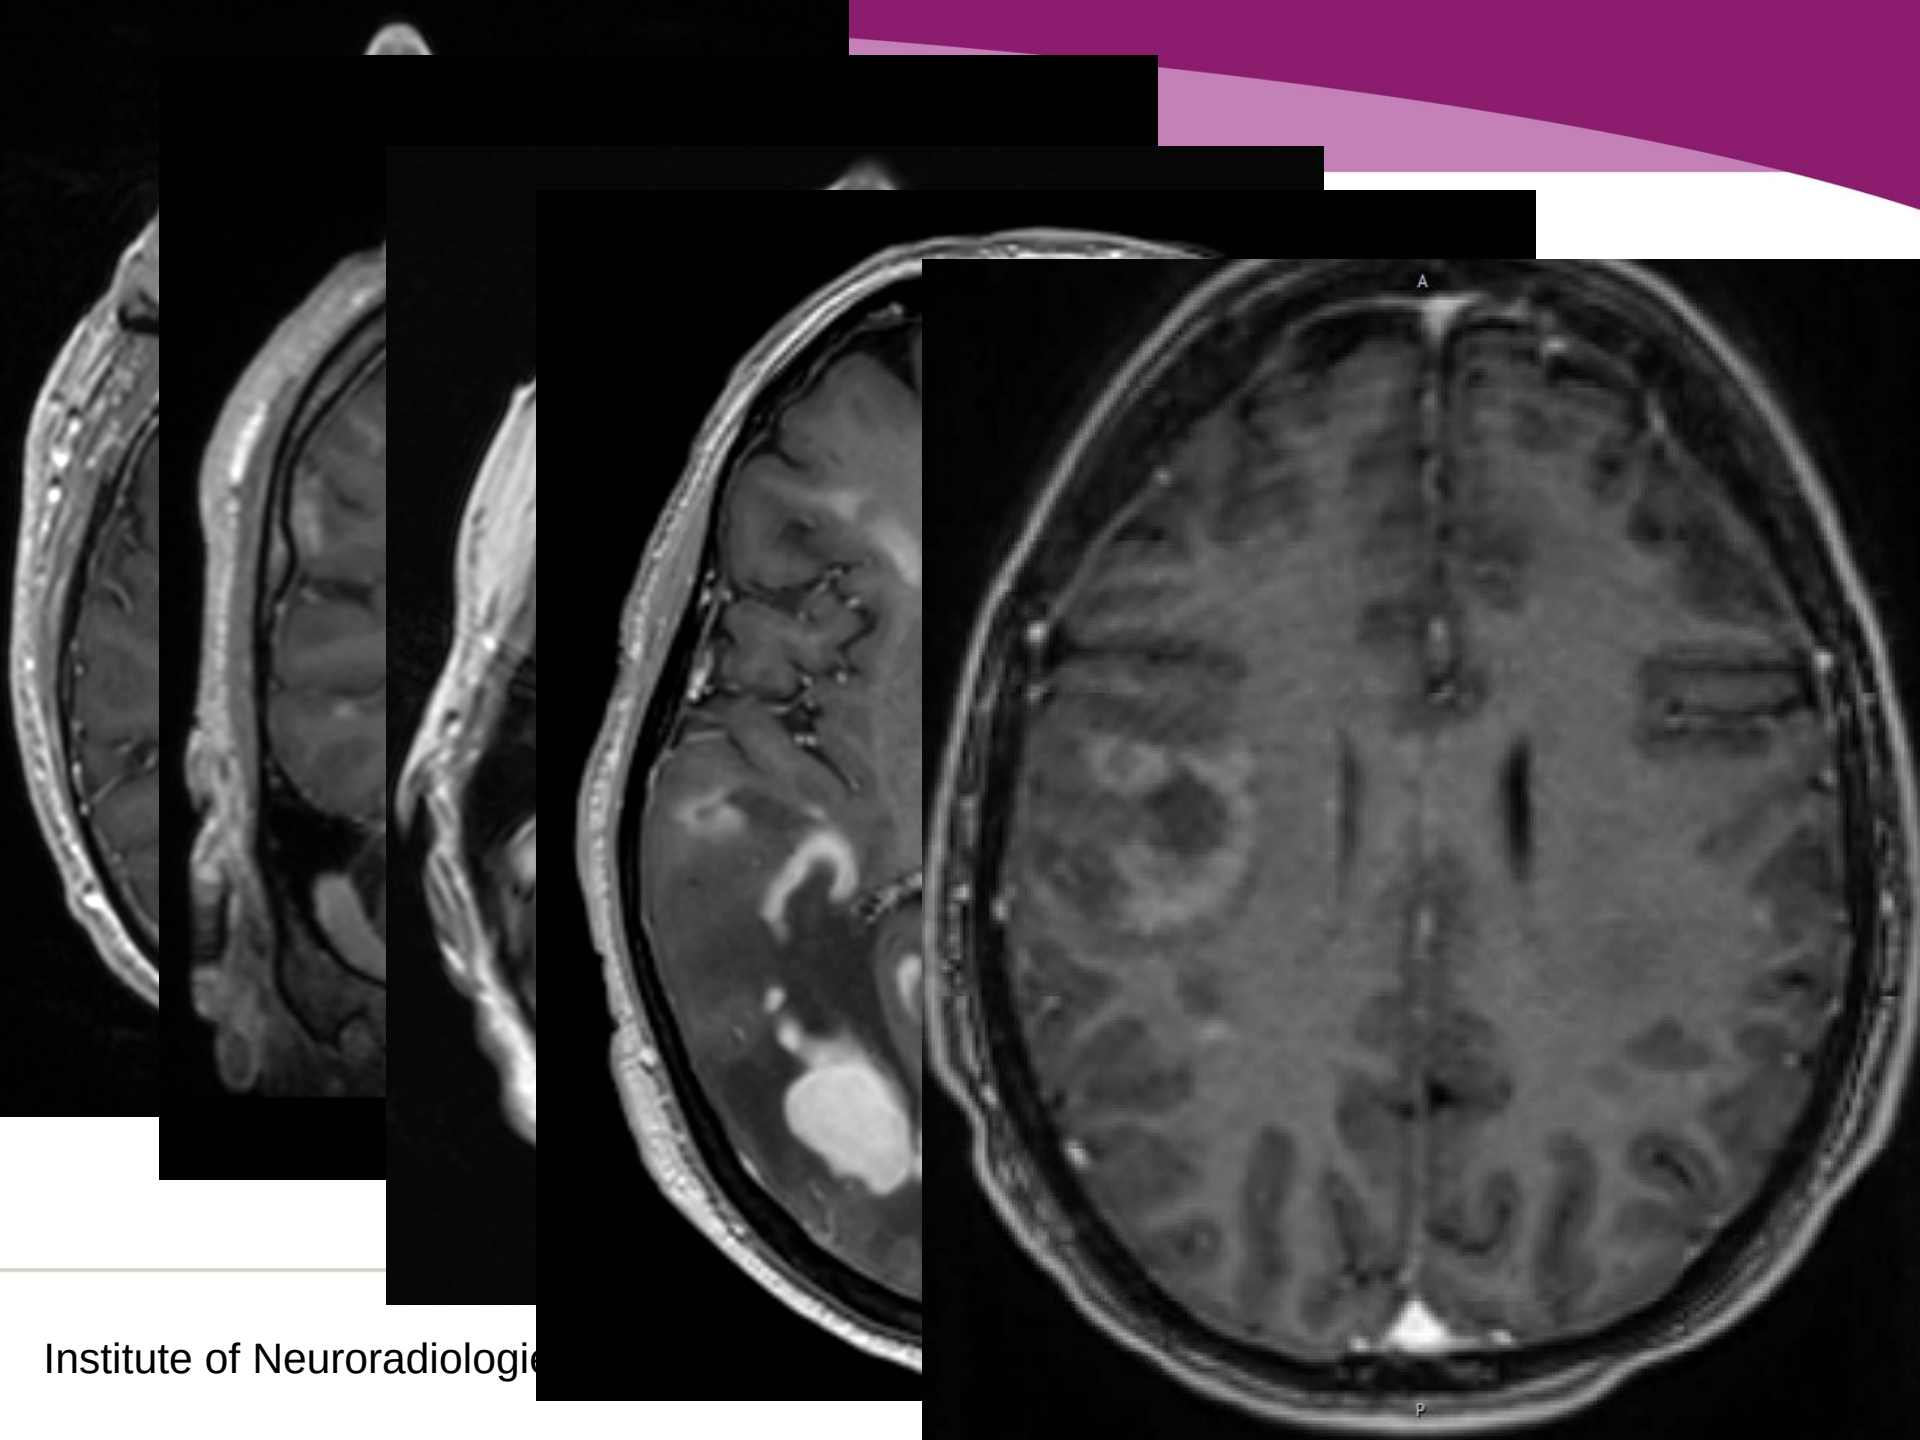
- Iso- or hyperdense mass
- Multiple lesions in about 30-40% of all patients



native



contrast



A
P

How to confirm the diagnosis

- Lumbar puncture: dissemination in the CSF in 20-30% of the patients with newly diagnosed PCNSL

  => Confirmation of a malignant B cell clone (FACS) or clonal IgH rearrangement using PCR

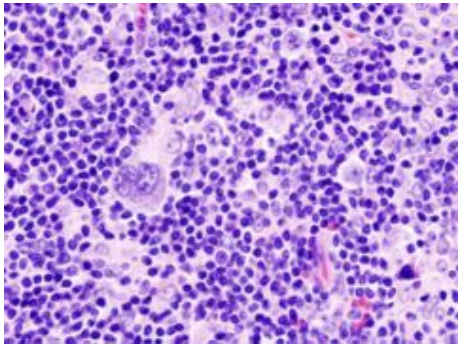
- Stereotactic biopsy: do not administer steroids before!
- Tumor resection does not affect survival – really…?

Staging:

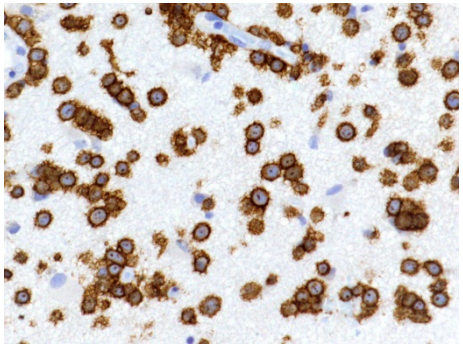
- Slit lamp examination (ocular involvement in 10-15%)
- CT scan chest and abdomen, bone marrow biopsy
- HIV testing

Histology

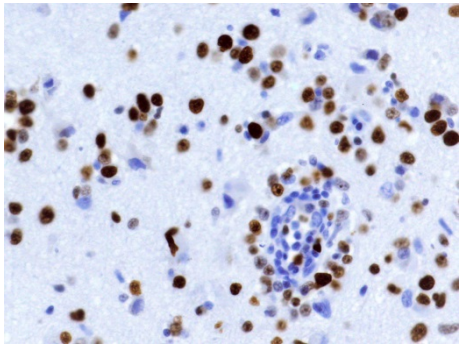
- Diffuse large B cell lymphoma (98%)



- $CD20^{+}$

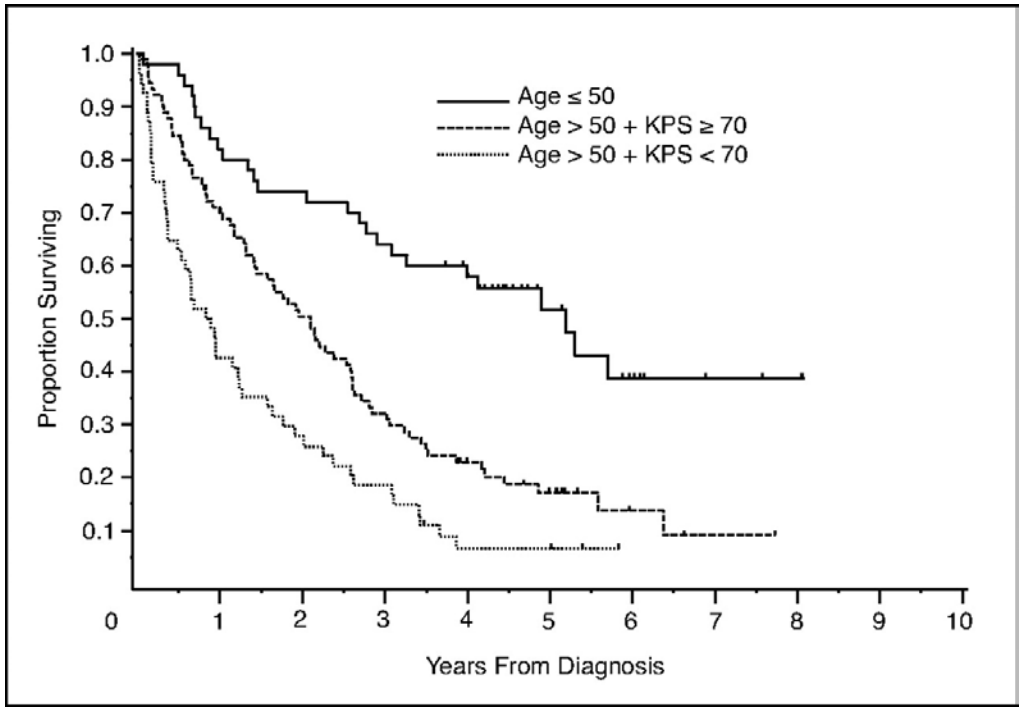


- High proliferation index (>50% $Ki\text{-}67^{+}$)



Prognosis

- Survival without treatment: weeks / few months
- Age and performance status are the most important prognostic factors



Abrey et al. J Clin Oncol 2006

- Histological subtype is **not** a prognostic factor

ESTRO School

Treatment of PCNSL

How would you treat a patient with newly diagnosed PCNSL?

1. Radiotherapy (WBRT)
2. Chemotherapy
3. Radio- and chemotherapy
4. Well, it depends…

Treatment of PCNSL: what do we know?

- WBRT (>40 Gy)

  Median OS 12 months, <5% 5-year survival (Nelson et al., 1992)

- High-dose methotrexate (HD-MTX): most active drug

  Median survival approximately 25 months

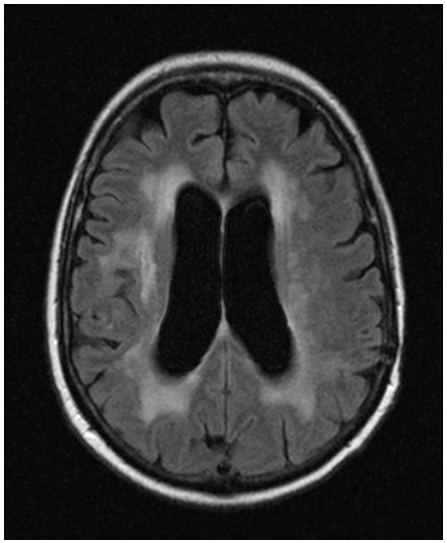
  ~25% surviving 5 years or more (Herrlinger et al., 2005)

- HD-MTX + intrathecal MTX + WBRT

  Median OS 42 months, 25% 5year survival (Abrey et al., 1998, DeAngelis et al., 2002)

  BUT: up to 60% of all patients (and virtually ALL elderly patients) suffer from severe **neurotoxicity** (Abrey et al., 1998; Herrlinger et al., 2001; Harder et al., 2004)

=> no longer appropriate



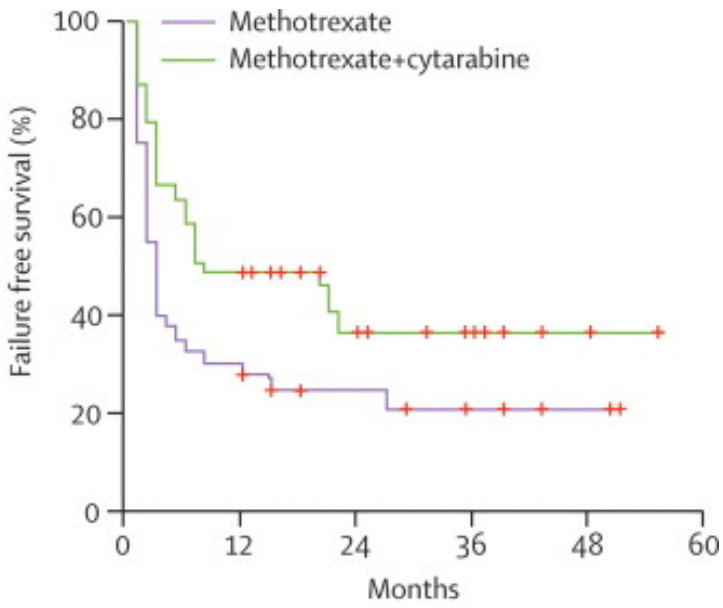
IELSG-20: MTX vs. MTX/Ara-C

- Randomized phase II trial, 24 centers, 6 countries
- 79 patients, age 18-75 Jahre
- 4 cycles of MTX, 3.5 g/m^2 alone **OR** MTX plus 4x Ara-C, 2 g/m^2 d2+3, every 3 weeks, followed by WBRT
- CR rate after MTX-based therapy:
  18% (MTX) versus 46% (MTX + Ara-C)
- Hematological toxicity more frequent and severe with combination

Ferreri et al., Lancet 2009

IELSG-20: MTX vs. MTX/Ara-C

PFS



Number at risk				
Methotrexate	11	7	4	2
Methotrexate+cytarabine	19	9	6	2

No role for resection – for 4 decades

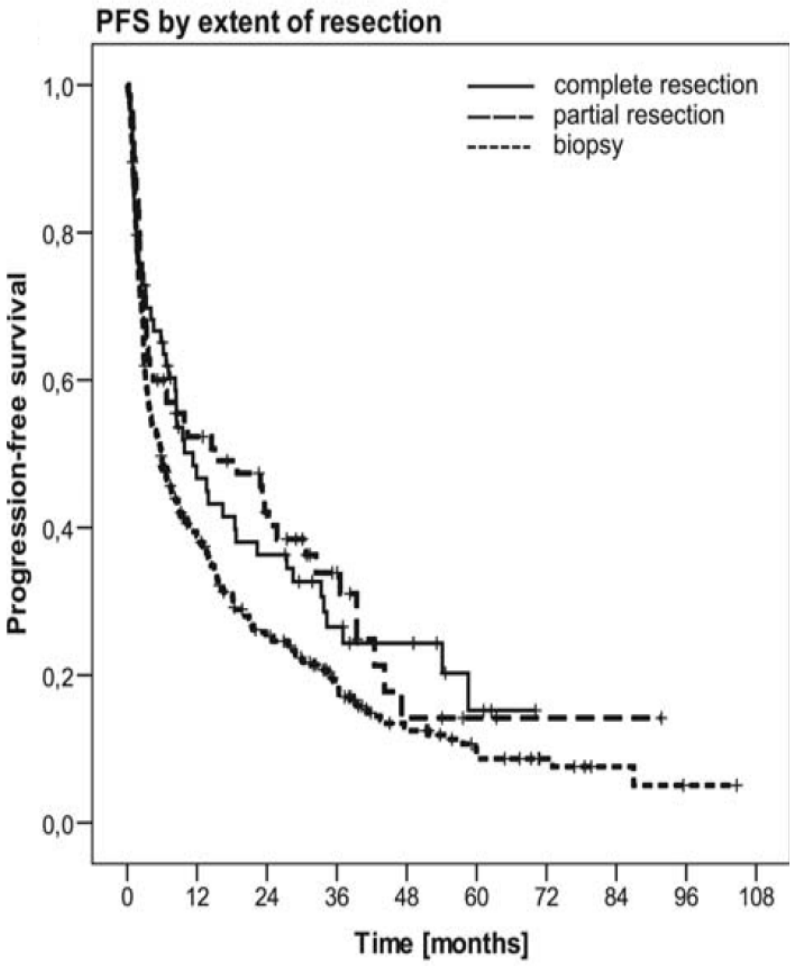
PRIMARY MALIGNANT LYMPHOMAS OF THE CENTRAL NERVOUS SYSTEM

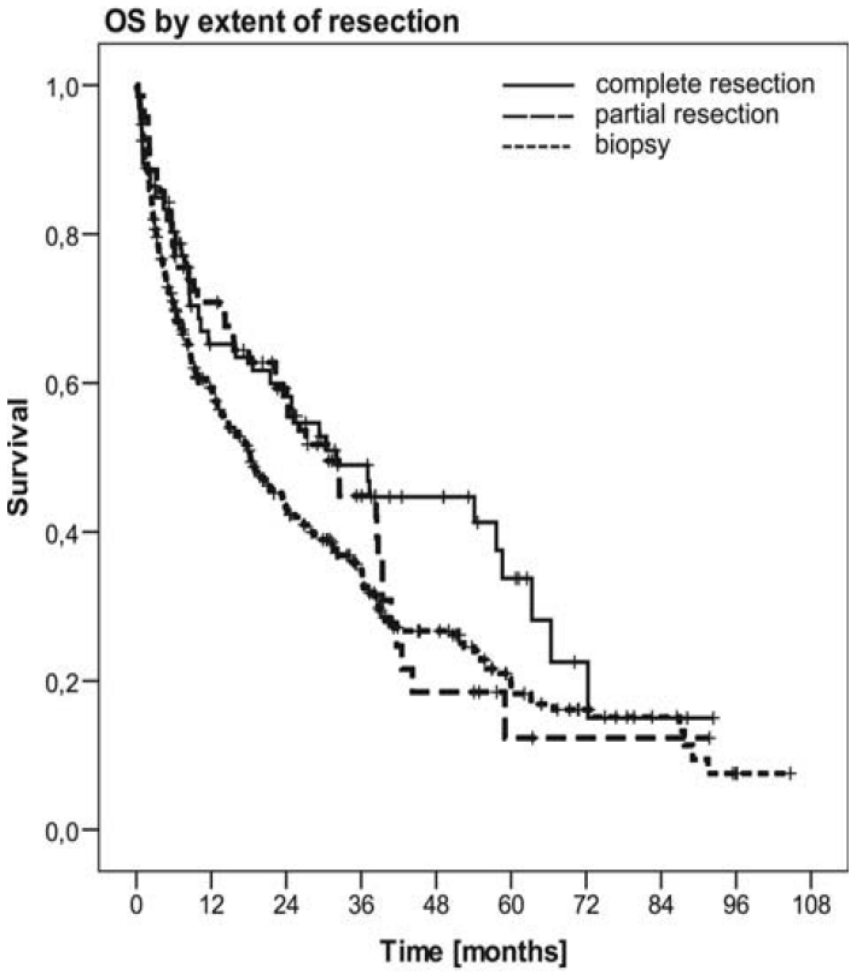
JAMES M. HENRY, MAJ, MC, USA, REID R. HEFFNER, JR, MD,
SAMUEL H. DILLARD, MAJ, MC, USA, KENNETH M. EARLE, MD,*
AND RICHARD L. DAVIS, MD†

Eighty-three cases of primary malignant lymphomas of the central nervous system (CNS) from the files of the AFIP were studied according to various clinical and pathologic parameters. The histologic patterns observed are analogous to those seen in the spectrum of malignant lymphomas arising in the reticuloendothelial system of other organs. The authors favor the diagnosis of primary malignant lymphoma of the CNS rather than that of "reticulum cell sarcoma" or "microgliomatosis" used in the past. Lesions are frequently multifocal, and surgery, other than for diagnostic biopsy, is not usually beneficial. The clinical course can be significantly prolonged by radiation therapy.

***Cancer* 34:1293–1302, 1974.**

Resection – may be considered…





Weller et al., Neuro Oncol 2012

			MTX, TMZ	45%	20%	6.1	14

ESTRO School

Conclusions

- Cure is probably restricted to younger patients

  => cure might even be achieved when the tumor recurs

- Standard of care is only poorly defined

  => further trials are urgently needed

- Whenever possible, HD-MTX should be administered
- Avoid WBRT when possible
- Open questions:
  - Role for rituximab?
  - Optimal treatment for elderly/frail patients?

65–74	1.02 (0.95–1.10)	0.20 (0.17–0.24)	13.27 (13.01–13.54)	0.64 (0.58–0.70)
75–84	1.06 (0.97–1.16)	0.16 (0.13–0.20)	14.49 (14.15–14.82)	1.31 (1.21–1.41)
≥85	0.39 (0.31–0.49)	NR	8.3 (7.91–8.71)	1.48 (1.31–1.66)

*Data derived from Central Brain Tumor Registry of the United States Statistical Report 2011: the CDC National Program of Cancer Registries and the US National Cancer Institute Surveillance, Epidemiology and End Results program, 2004–2007, age-adjusted to the 2000 US standard population. ‡Fewer than 16 cases were reported. Abbreviations: NOS, not otherwise specified; NR, not reported.

Clinical Presentation- non-brainstem HGG

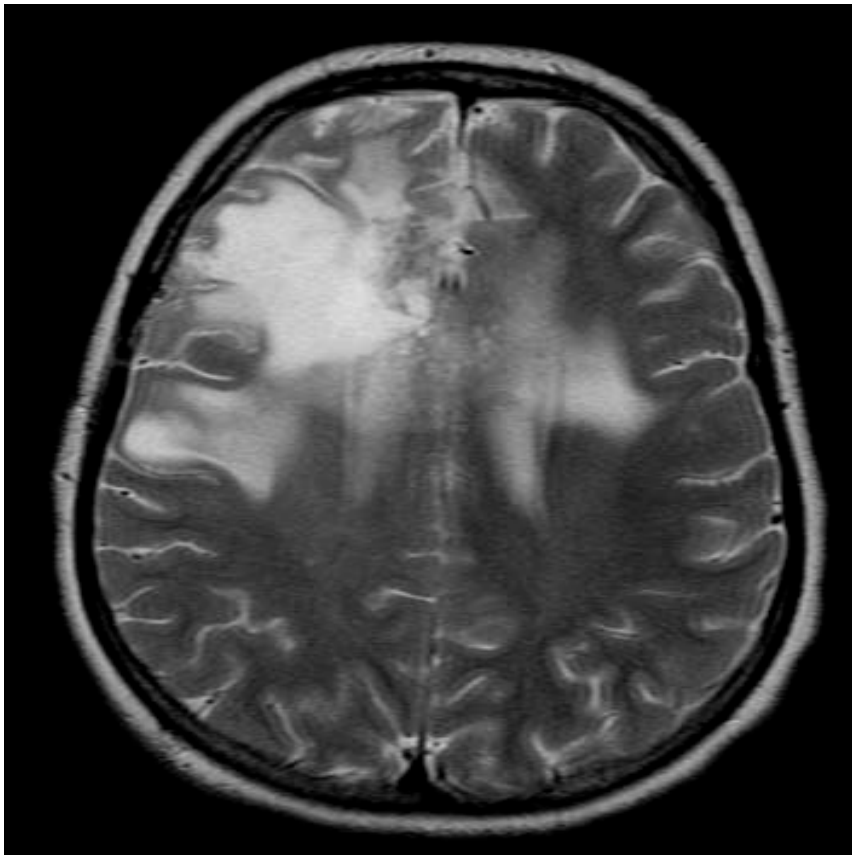
Raised ICP	Focal Signs	Focal Signs
	Post. Fossa	Hemispheric
Headache	Ataxia	Seizures
Vomiting	Nystagmus	Spasticity
Behavioural	Diplopia	Memory deficits
Conscious level	Brainstem	Behaviour
Papilloedema	Facial weakness	Mid-line
VI N palsy	Dysphagia	Growth deficits
Reduced Vision	Ocular palsies	Visual deficits
Head tilt	Spasticity	Appetite
Infant irritability	Behavioural	Endocrine
Head circumference	Ataxia	School performance

Diagnosis: HGG

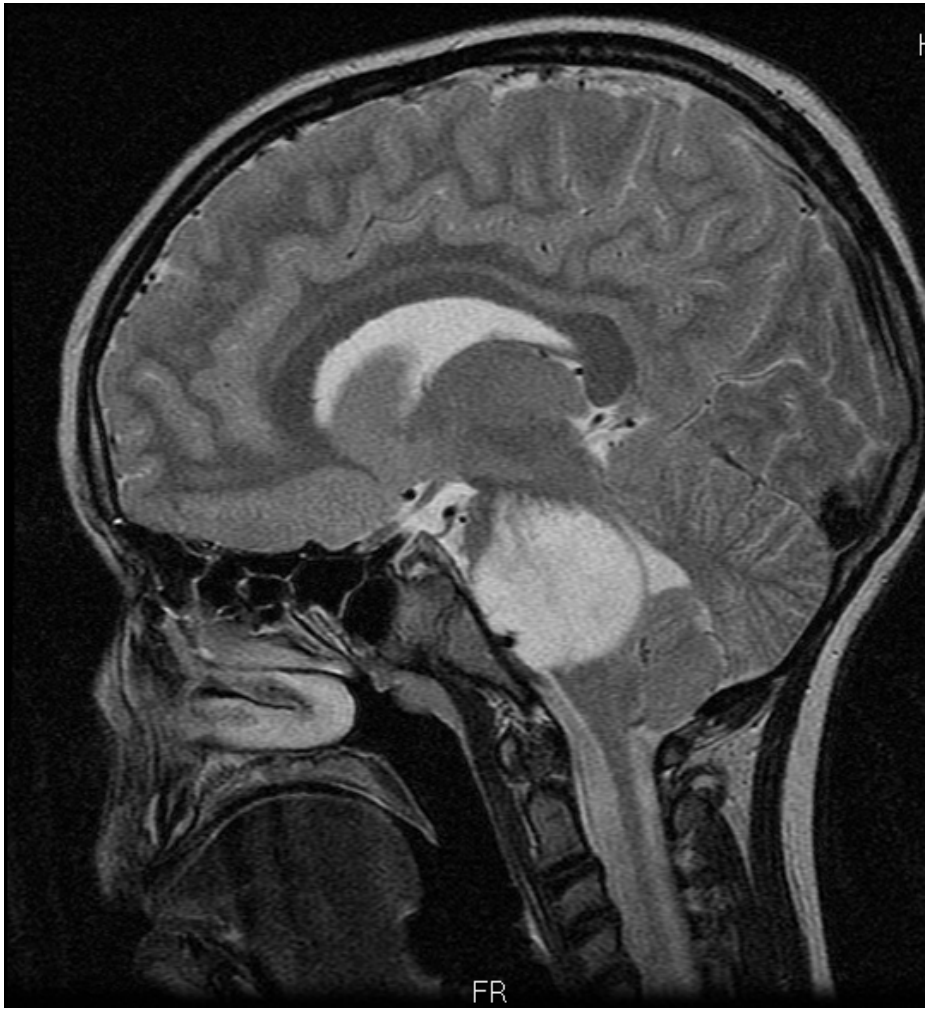
Clinical findings raise a diagnostic concern

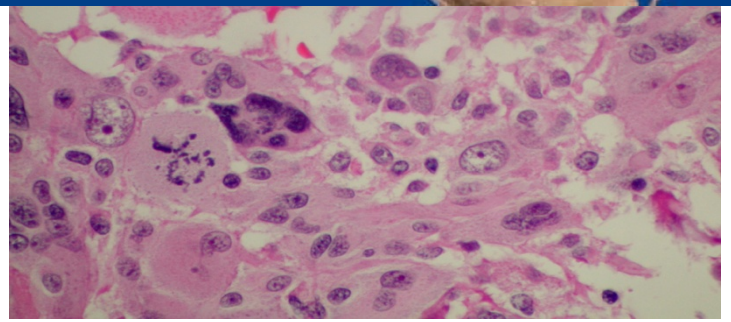
Diagnosis is corroborated by MRI

Surgery/biopsy is performed in majority of cases



Brainstem Glioma in Children





Brainstem tumors

1) Diffuse intrinsic (75-85%)

2) Focal (5-10%)

3) Dorsal exophytic (10-20%)

4) Cervicomedullary (5-10%)

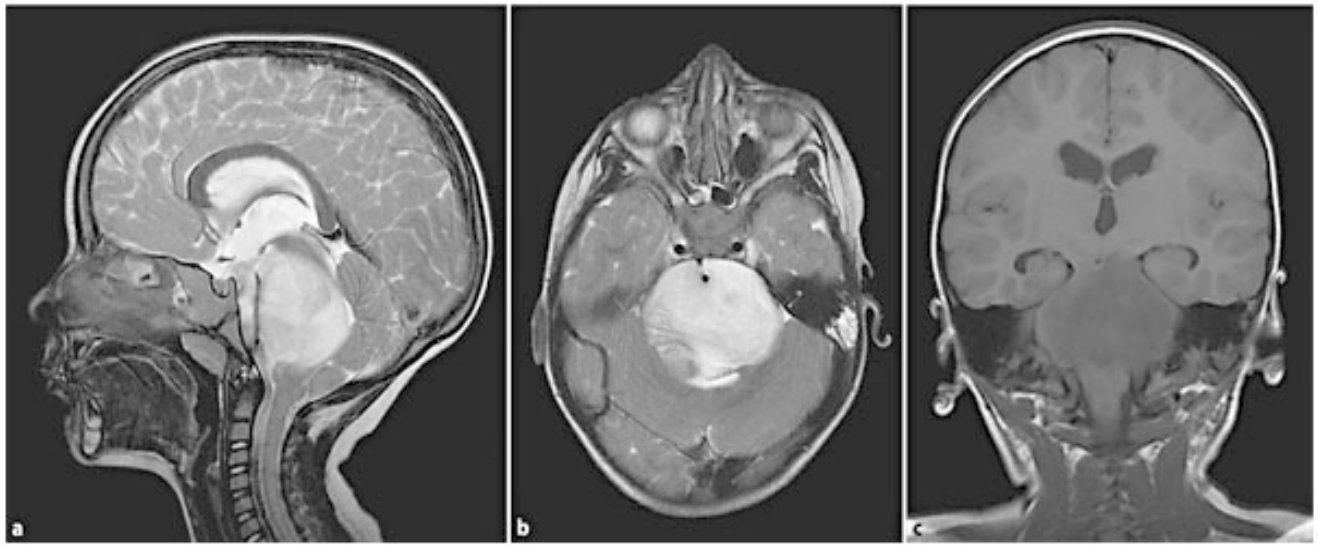
ESTRO School

Diffuse Intrinsic Pontine glioma (DIPG)

Comprise 10-15% of childhood CNS tumours

- Incidence USA ~ 125 cases/year, UK ~ 25/year.
- Median age at presentation is 6-7 years

70% are diffusely infiltrating and involves the pons



ESTRO School

Focal or exophitic Brainstem glioma

- Symptoms often been present for months
- Typical histology is a low grade
- 5 years survival 50-60%
- Radiotherapy and chemotherapy can improve survival

DIPG: Clinical Presentation

- Short duration of symptoms (median 1-3 month)
- Hydrocephalus is not common
- Common triad
  - Cranial nerve palsies
  - Pyramidal tract signs
  - Cerebellar signs

DIPG: Clinical Presentation

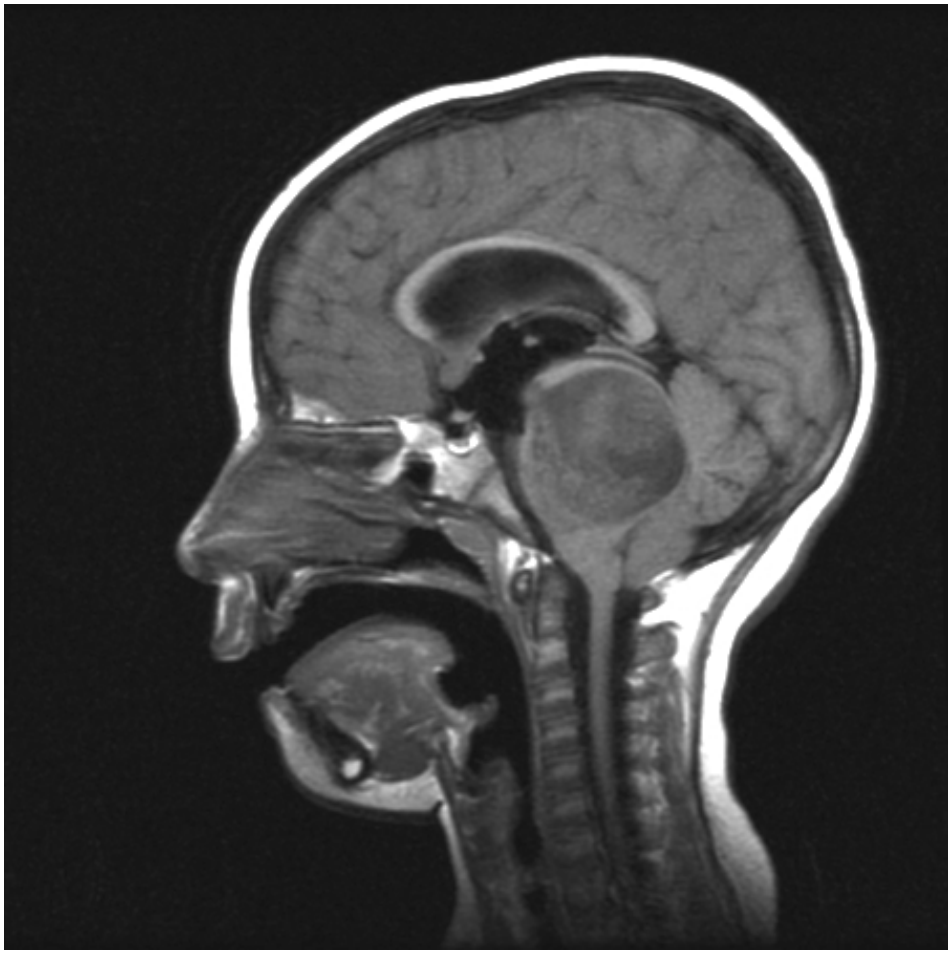
- A fluctuating course is not rare
- Changes in mood and behavior can precede obvious neurological features
  - pathological laughter
- Other presentation symptoms
  - Unexplained vomiting
  - Urinary problems
  - Respiratory insufficiency

Diagnosis: DIPG

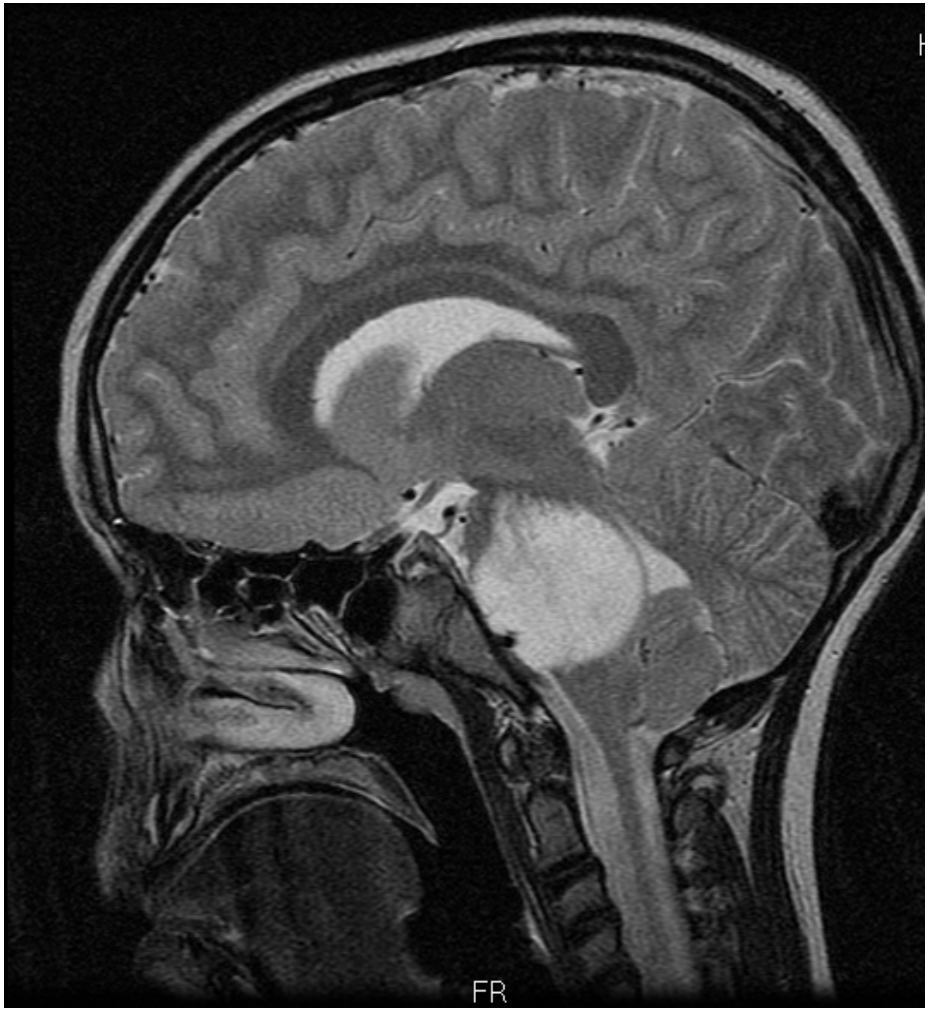
Clinical findings raise a diagnostic concern

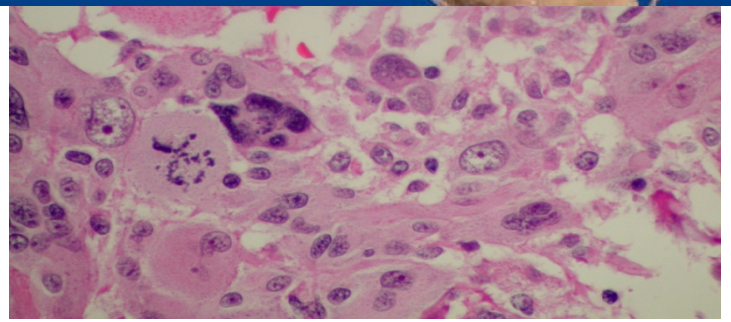
Diagnosis is corroborated by MRI

Biopsy is only performed if tumor has atypical radiological features



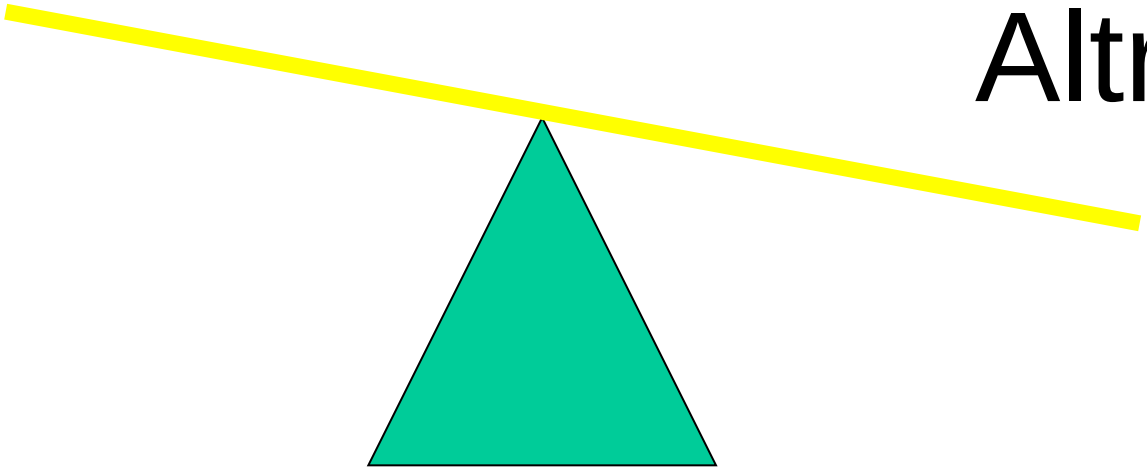
DIPG: To biopsy or not to biopsy?





Ethics of Biopsy?

Individual benefit/ safety



Altruism

ESTRO School

Brainstem glioma

Radiotherapy

Initial studies utilizing hyperfractionated radiation therapy with total doses up to 72 Gy (1 Gy twice day) suggested a modest improvement in survival of children with brainstem gliomas compared to radiation alone, and compared to radiation with neoadjuvant or adjuvant chemotherapy

Packer et al. 1993

However, subsequent trials using radiation doses up to 78 Gy did not confirm this finding

Packer et al. 1994

HFRT for DIPG

Toxicity included intralesional necrosis and steroid dependency at the intermediate and highest dose levels, as well as vascular events in a small # of pts treated at the highest dose levels

Doses as high as 78 Gy did not result in any significant improvement in time to progression, MST, or survival at 1 and 2 yrs

Drug	Target (s)
MK2206	Akt1,2,3
Pazopanib	VEGFRs, c-KIT, PDGFR beta
Temsirolimus (sirolimus prodrug & a	mTOR
Vandetanib	VEGFR-2, EGFR, RET
5-Aza-2 deoxycytidine (Decitabine)	DNA-methyl transferase
Bortezomib	Proteasome
Dasatinib	C-Kit, PDGFR, SFK, Bcr-Abl
OSI-906	Igf1r
ABT-888	PARP-1 and PARP-2
GDC-0449	Smoothened (Hedgehog pathway)
Panobinostat	HDAC
BMS-387032	CDK2, CDK7, CDK9
Imelelstat (GRN 163L)	Telomerase inhibitor
Lapatinib	Egfr, ErbB2
SAHA (Vorinostat)	HDAC
Sorafenib	VEGFR, PDGFR, RAF
AZD6244 (Selumetinib)	MEK1/2 inhibitor
AZD1152-HQPA (Barasertib)	Aurora kinase B
R115777 (tipifarnib, Zarnestra)	Enzyme(Farnesyl transferase - Enzyme)
CC-5013 (lenalidomide, Revlimid)	2, IL-6, IL-10, IL-12, IL-1beta, TNF-alpha, IFN-gamma -
Cediranib	VEGFR
RO4929097	Notch (gamma secretase)
EKB-569	Egfr, ErbB2
Obatoclax mesylate (GX15-070MS)	BCL2, BH3
BMS-754807	Igf1r
SCH-727965	CDK2, CDK5, CDK1, and CDK9
4-hydroxy-tamoxifen	estrogen receptor
Saracatinib (AZD0530)	Src Family Kinases
Flavopiridol (alvocidib)	Cycle(Cyclin-dependent kinases - Protein)
Sodium butyrate	HDAC

Sodium butyrate	HDAC
AP24534 (Ponatinib)	BCR-ABL, VEGFR2, FGFR1, PDGFRα
GANT61	Hedgehog (Gli1)
ATRA	differentiating agent
RO5045337	MDM2
MLN8237	Aurora kinase A
Crizotinib	C-Met, ALK
Carfilzomib	Proteasome
Quinacrine	autophagy pathway
SJ-172550	MDMX
SP600125	JNK 1,2 and 3
Cilengitide	αvβ3 and αvβ5 integrins
INCB018424(Ruxolitinib)	Jak1, Jak2
SB-431542	TGF beta
Enzastaurin	Protein Kinase Cβ
Trichostatin A	HDAC
ZD4054	Endothelin A receptor
Fenretinide	retinoid receptor
Fostamatinib (R788)	SYK kinase
BIX-01294	Histone-lysine methyltransferase
Nilotinib	PDGF-R, c-Kit, BCR-ABL
N-acetyl cysteine	Reactive oxygen species
VX-680	Aurora kinases
Entinostat	HDAC 1,2
PF-04554878	FAK inhibitor
BEZ 235	PI3K, mTOR
vemurafenib	BRAF
AP26113	ALK, EGFR
XL-184	EGFR, c-Met
AUY922	Hsp90
VER-155008	Hsp90, Hsp70

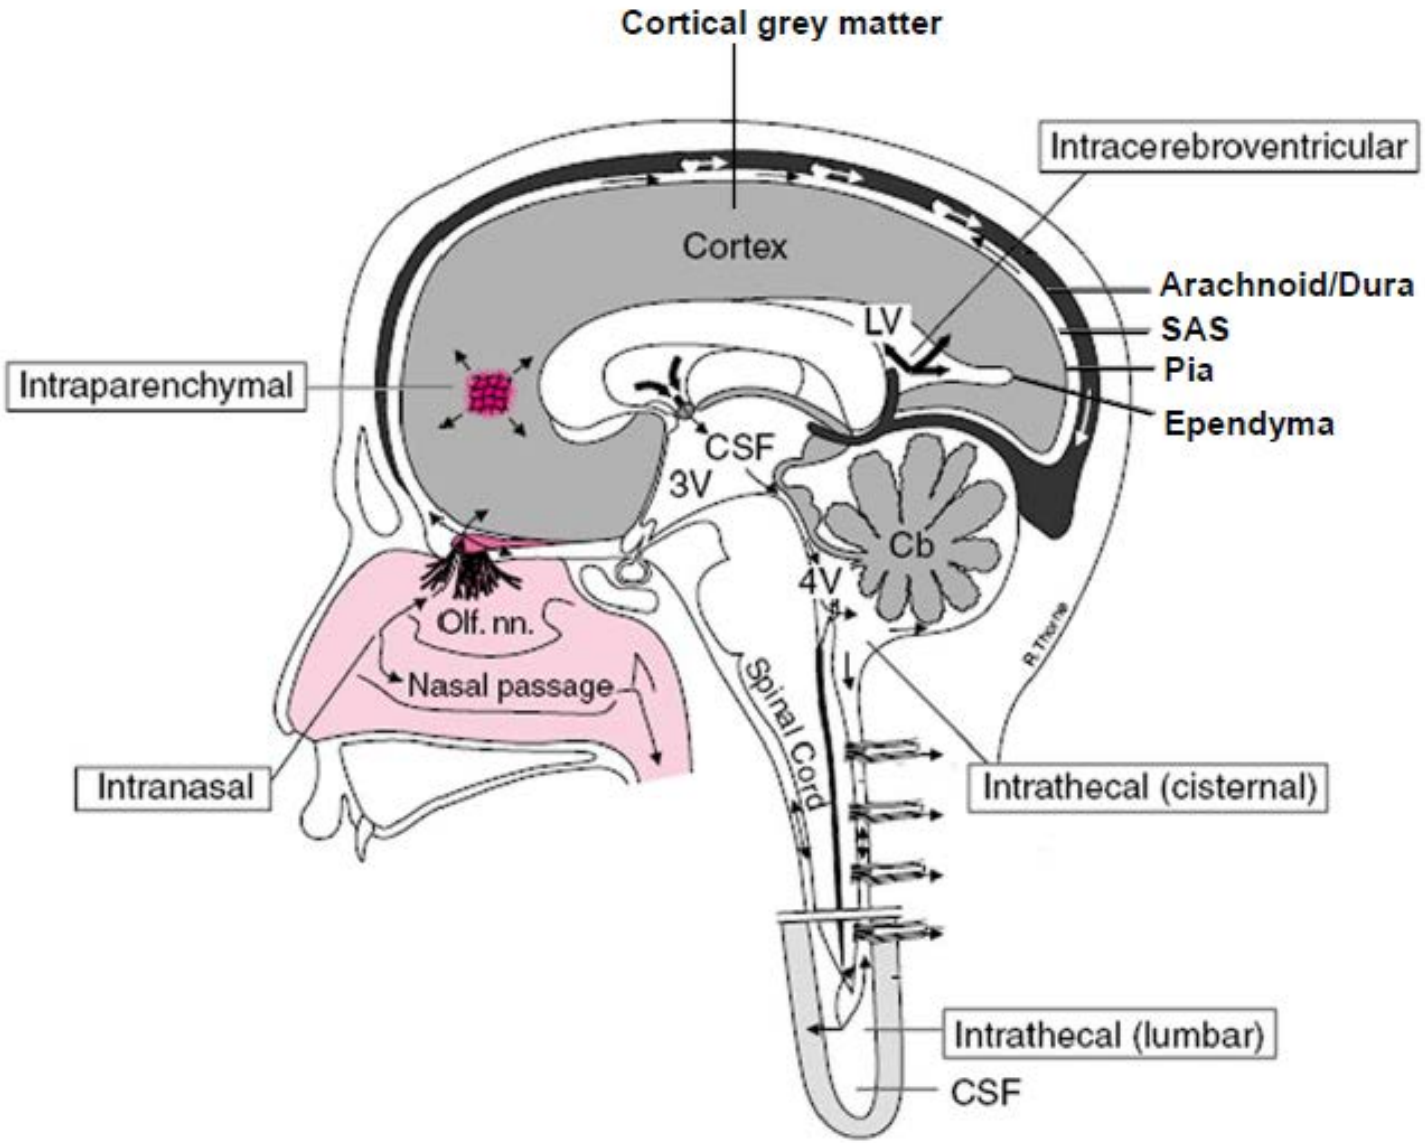
Intranasal Delivery

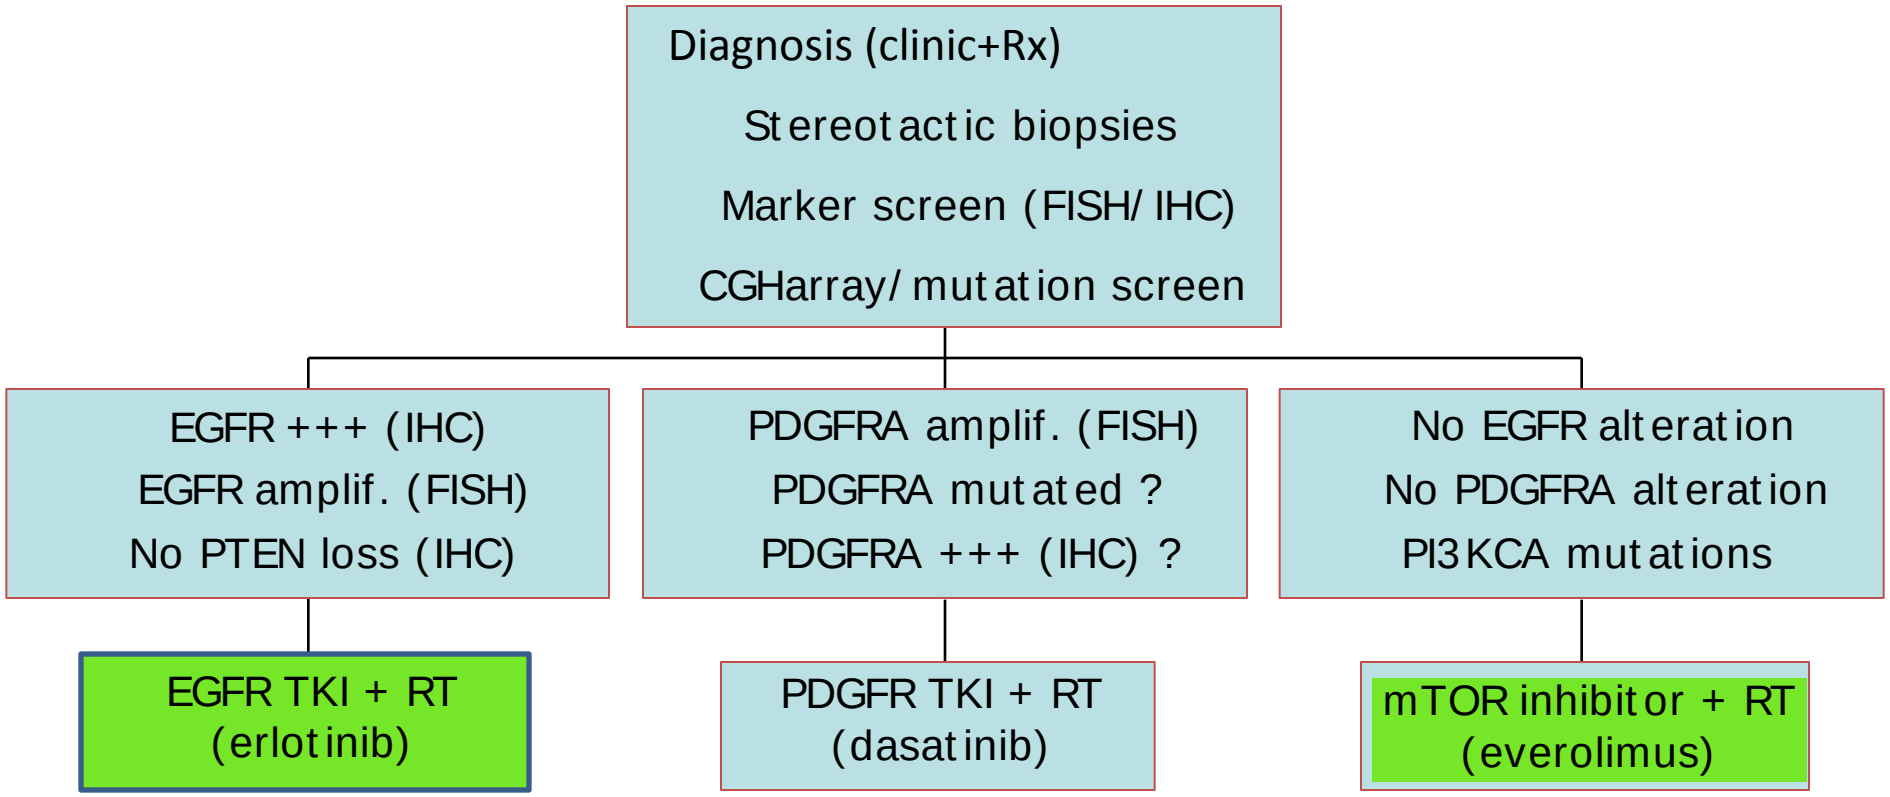


Biopsy directed therapies

- **Molecularly Determined Treatment of Diffuse Intrinsic Pontine Gliomas (DIPG).** NCT01182350
  - up-front stereotactic biopsy of classic DIPG used to stratify patients to different therapies based on the MGMT (temozolomide) and EGFR (erlotinib) expression in combination with focal radiation therapy and bevacizumab

- **BIOMEDE- Biologically-driven phase I/II study in children and adolescent with DIPG**

BIOMEDE Study

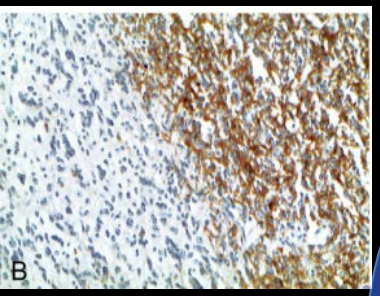


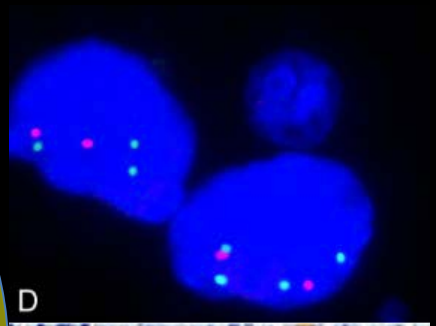
Three major targets selected

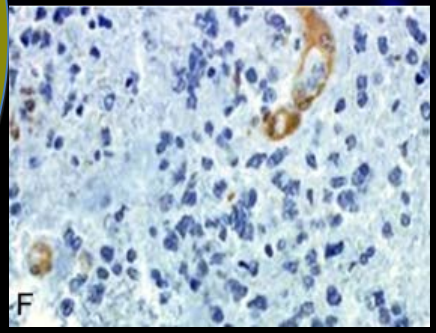
- **EGFR**
  - Rarely amp/mut, frequently overexpressed
- **mTOR pathway**
  - Activated by genomic alteration in ½ of DIPG (Taylor et al, Nat Genet in press).
  - PTEN loss in 80% of DIPG.
- **PDGFRA pathway**
  - PDGFRAamp/mut in 20% of DIPG

EGFR POS

PTEN LOSS







1%

30%

30%

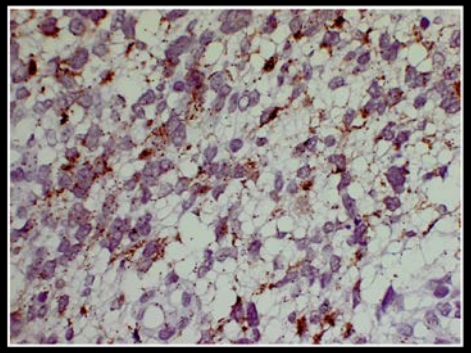
10%

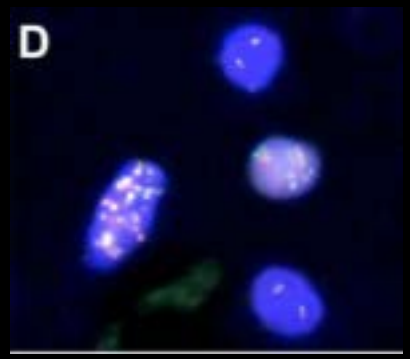
3%

10%

3%

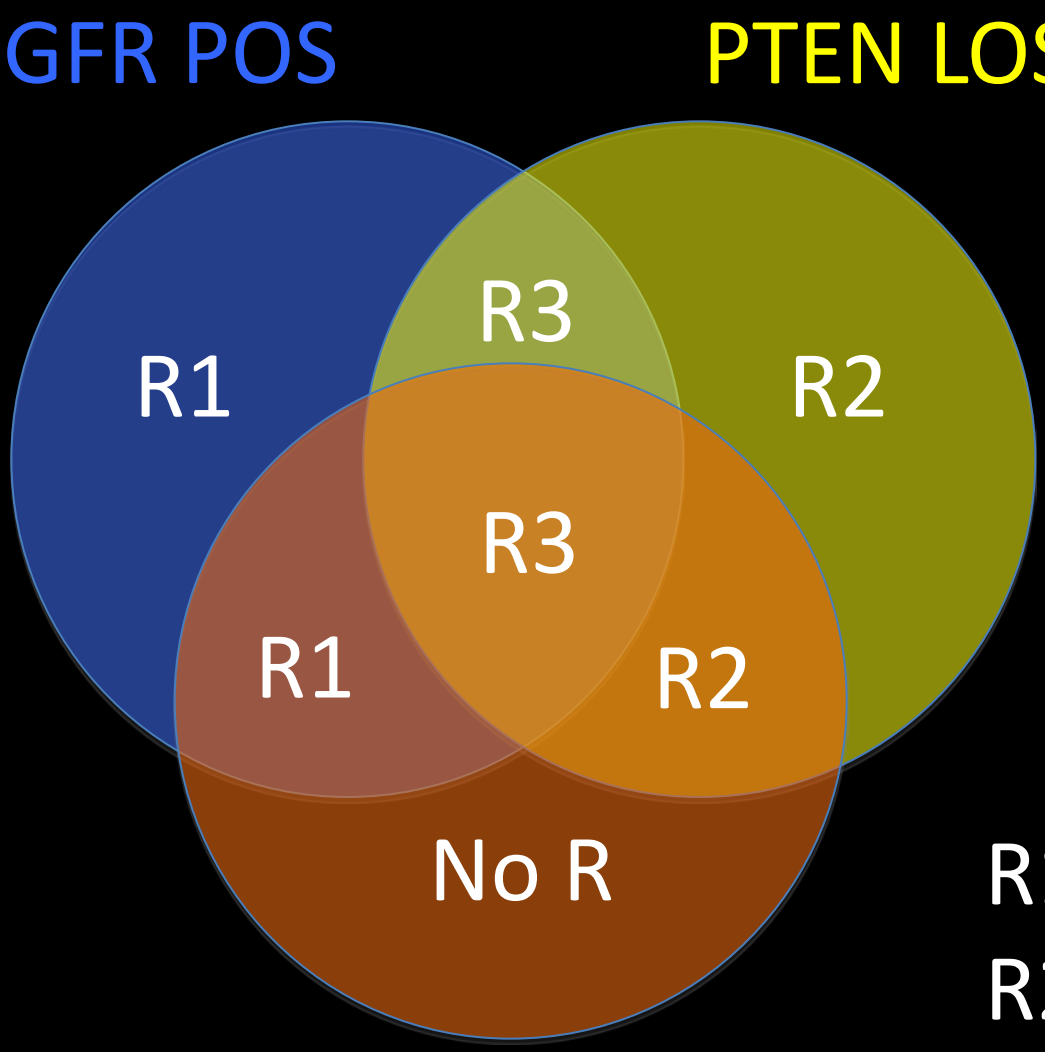
PDGFRA AMP



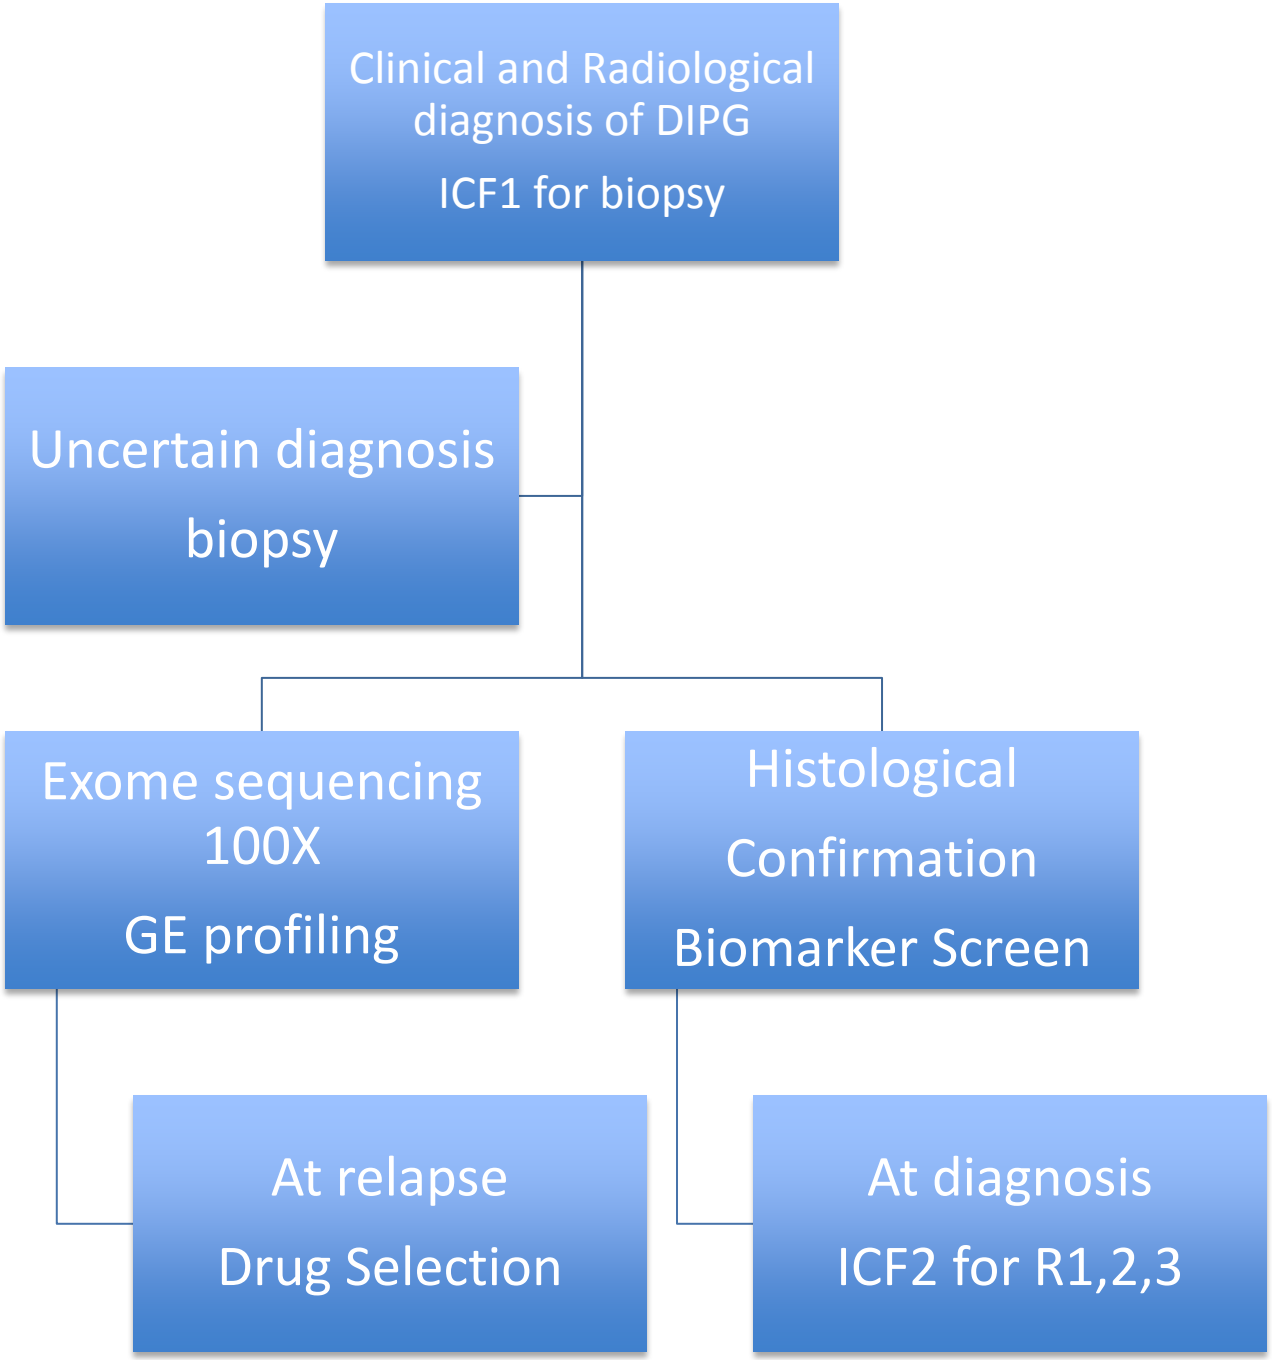


Three drugs selected

- ERLOTINIB to target EGFR
  - Geoerger N0 2010 and others.
- EVEROLIMUS to target mTOR pathway
  - Geoerger EJC 2011 in recurrent DIPG.
- DASATINIB to target PDGFRA pathway
  - Broniscer CCR 2013 in combo with vandetanib together with RT in newly diagnosed pts.
  - Dasatinib is also targeting other TKI.



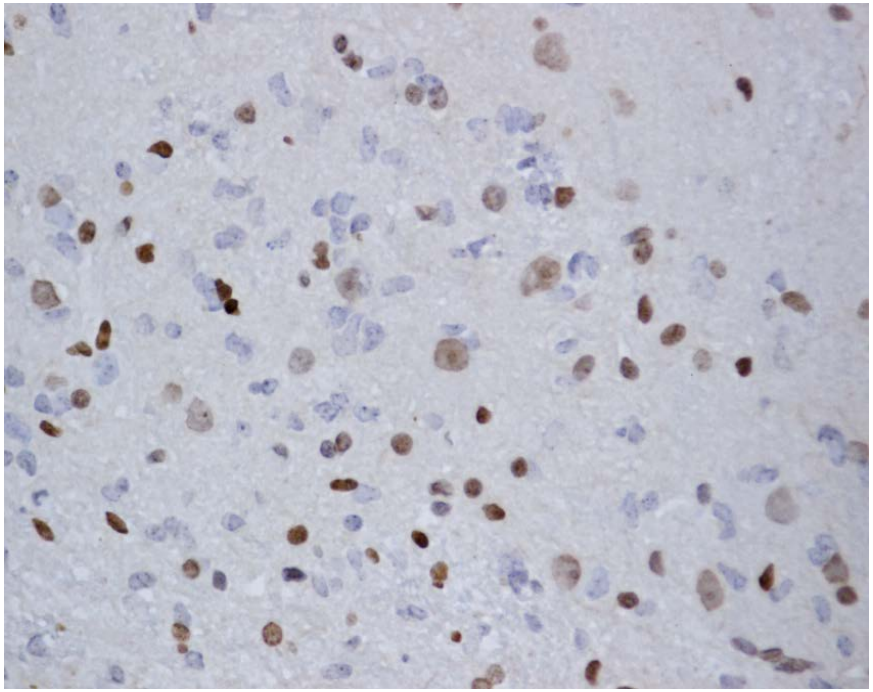
R1=Erlo/Dasa
R2=Ever/Dasa
R3=All three



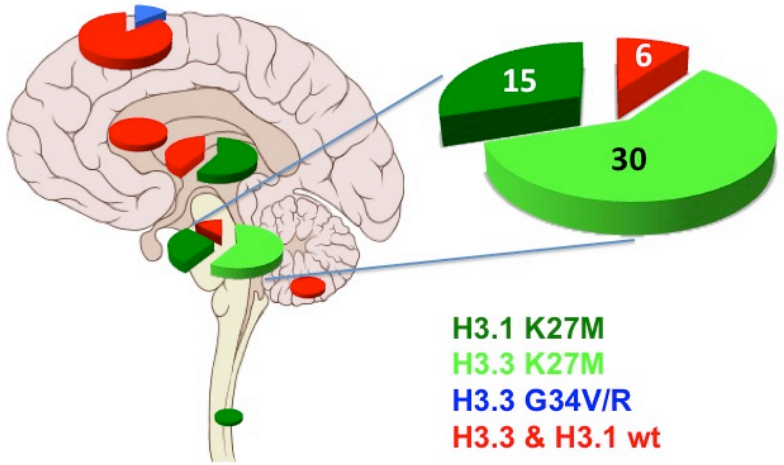
Clinical and Radiological diagnosis of DIPG
ICF1 for biopsy
Uncertain diagnosis biopsy
Exome sequencing 100X
GE profiling
Histological Confirmation
Biomarker Screen
At relapse
Drug Selection
At diagnosis
ICF2 for R1,2,3

Diagnostic workout

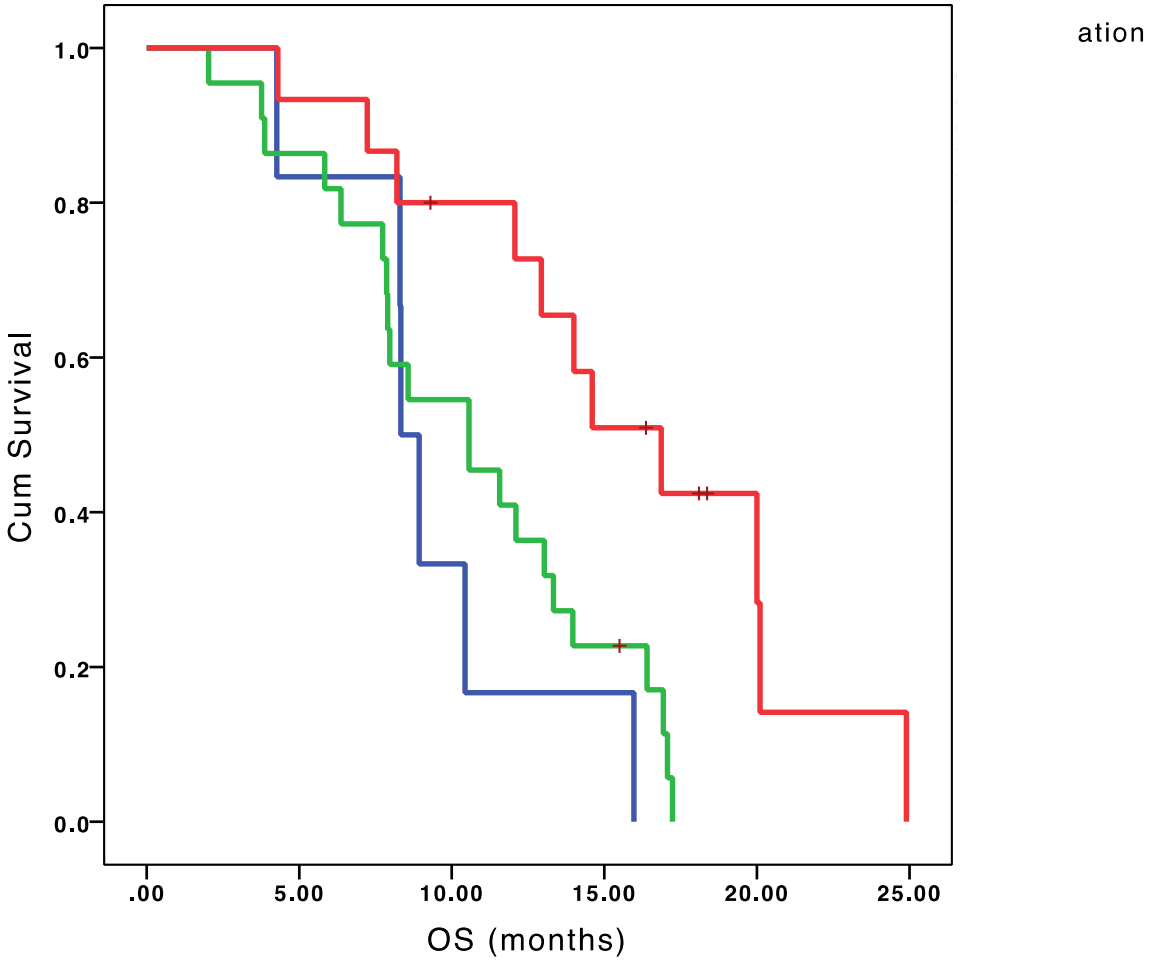
Loss of H3K27trimethylation mark



Histone H3 variant mutations

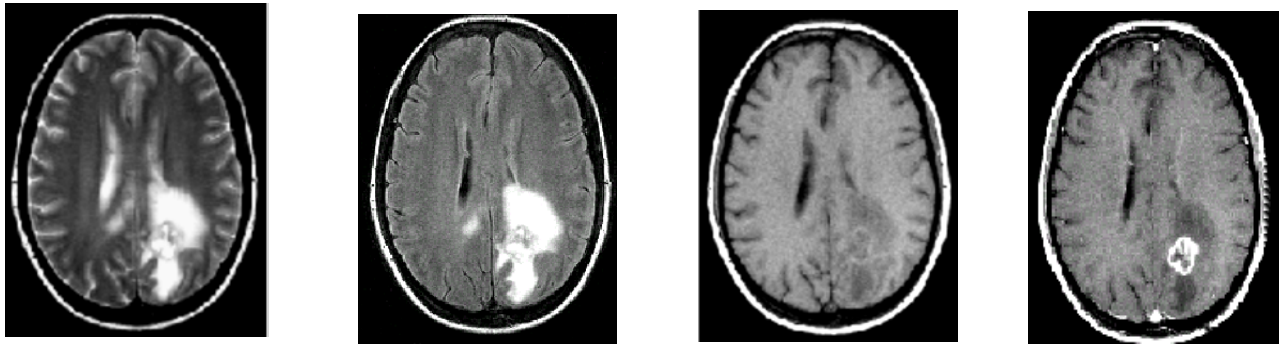


Prognostic impact of histone mutations

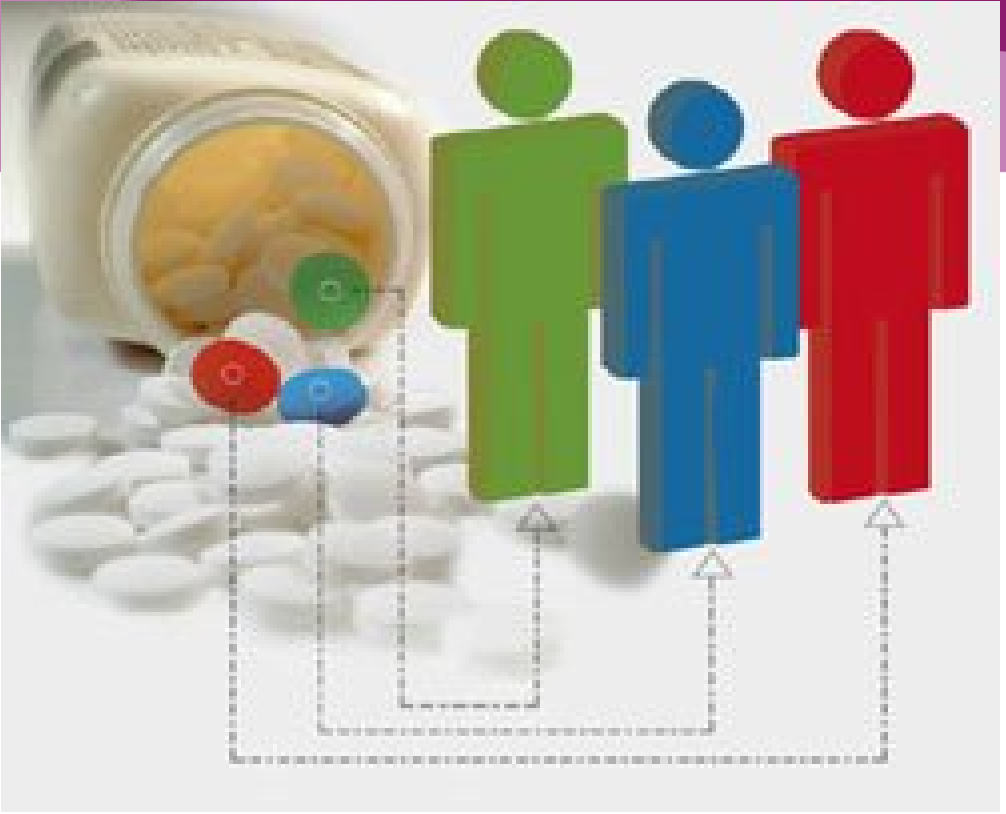


High grade glioma

Prognostic factors



- Extent of resection
- Histological grade (Grade III vs IV)
- Gender (female favourable)
- Radiation Dose > 54 Gy
- Proliferation index
- p53 overexpression (less favourable)
- Tumor location: with the poorest outcomes associated with pontine & thalamic locations



Current standard treatments & outcomes for pHGG

Surgery

The goal of the surgery is:

- obtain tissue for pathological analysis

-achieve an “uncomplicated” gross tumour resection (GTR)

-control possible neurological symptoms associated with mass effect

GTR (over 90% resection) is associated with a longer PFS

Surgery

Children's Cancer Group 945

131 patients with a diagnosis of AA or GBM

- **Surgery biopsy (<10% resection)**
- **Partial resection (10-50%)**
- **Subtotal resection (50-90%)**
- **Radical (90%)**

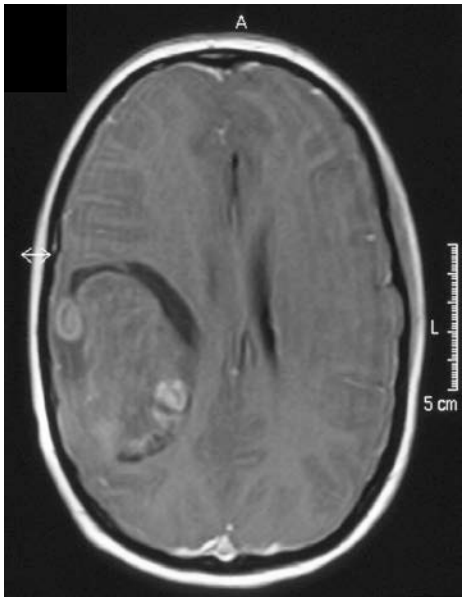
PFS at 5 years rate of 35% in radical resection compared with 17% in subtotal resection (p= 0.006)

AAs PFS at 5 years 44% in radical vs. 22% in subtotal (p= 0.055)

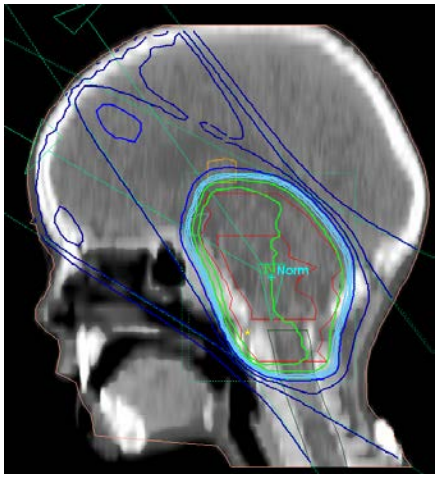
GMB PFS at 5 years rate of 26% in radical vs. 4% in subtotal (p= 0.046)

Wisoff et al. J Neurosurg 1998

High grade glioma + brainstem glioma



Aims of radiotherapy



- **Improvement of local tumour control**
- **Using the advantages of modern treatment techniques**
- **Combination with chx. / „radiosensitizers“**

ESTRO School

High grade glioma

Criteria for treatment planning

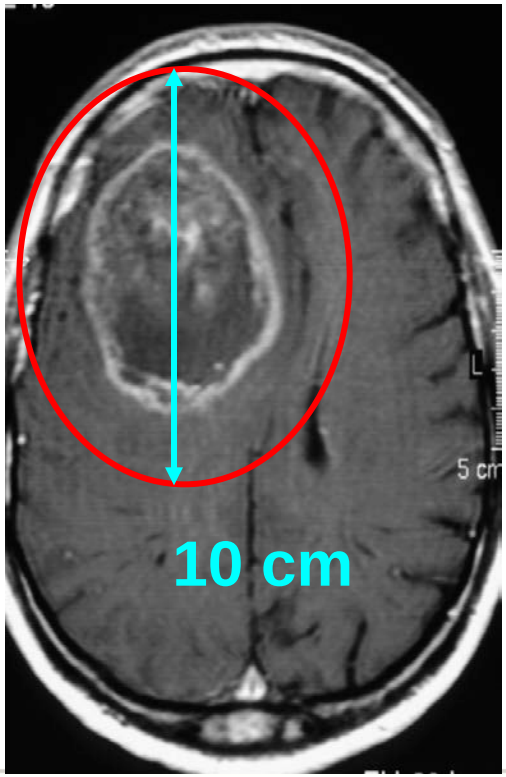
- ⇨ **Location**
- ⇨ **Shape**
- ⇨ **Tendency to infiltration**
- ⇨ **Imaging**

⇨ **Targeting**
Definition of GTV, CTV, PTV

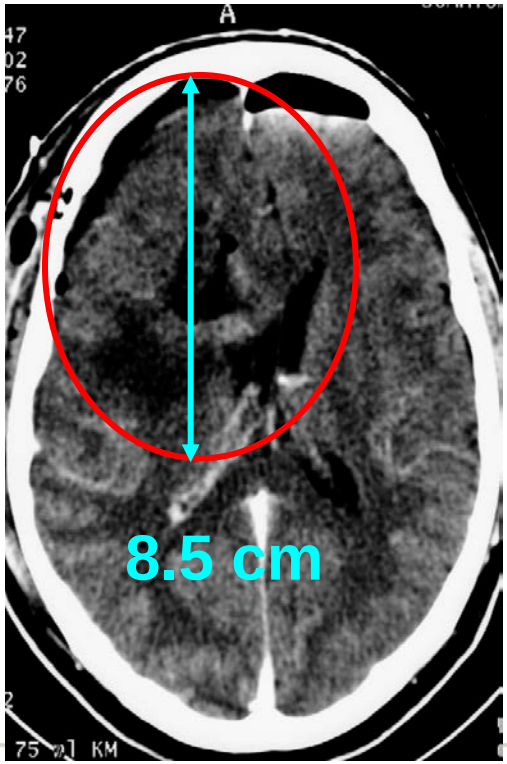
High grade glioma

⇨ Pre- or postoperative definition of CTV ?

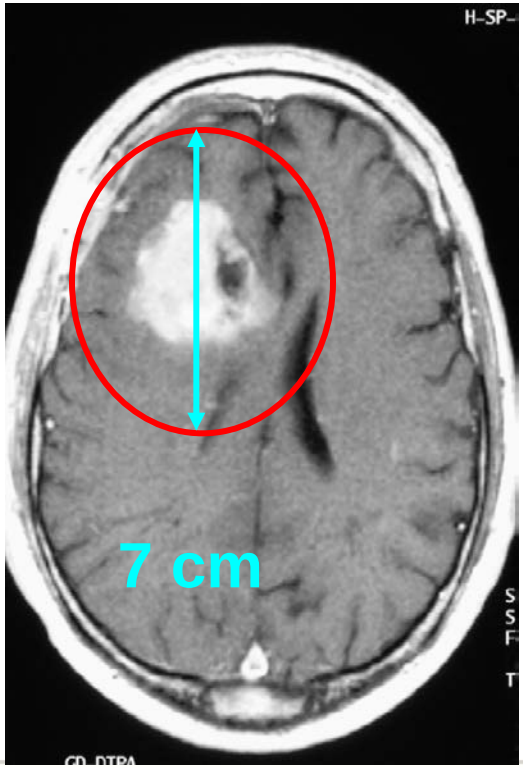
⇨ Technique / timing of imaging ?



MR pre-op.



CT 1 day postop.

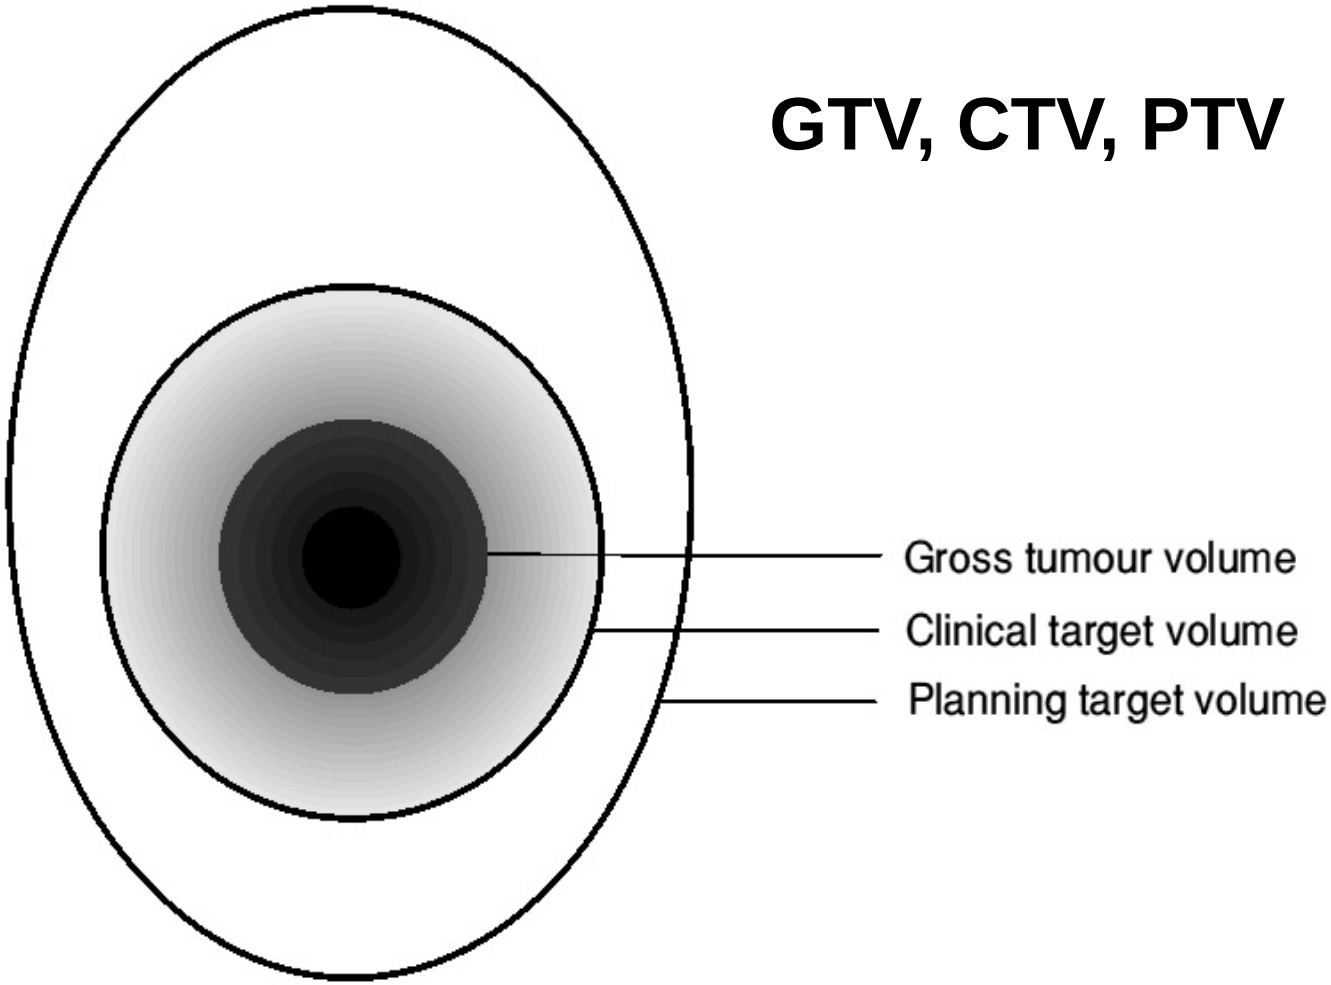


MR 2 weeks post-op.

Target volumes

ICRU 50 target volumes

The PTV can be eccentric



Chemotherapy in childhood HGG

Rationale

⇨ **Rationale for chx. before RT**
Open blood brain barrier (surgery)
lesser toxicity of agents, greater selection of protocols, reduction of tumour burden

⇨ **Rationale for chx. during RT**
Radiosensitization

⇨ **Rationale for chx. after RT**
Elimination of persistent tumour cells
Maintenance approach to prevent early relapse

High grade glioma

Phase III studies

Study	Pat.	survival	Signif.

High grade glioma

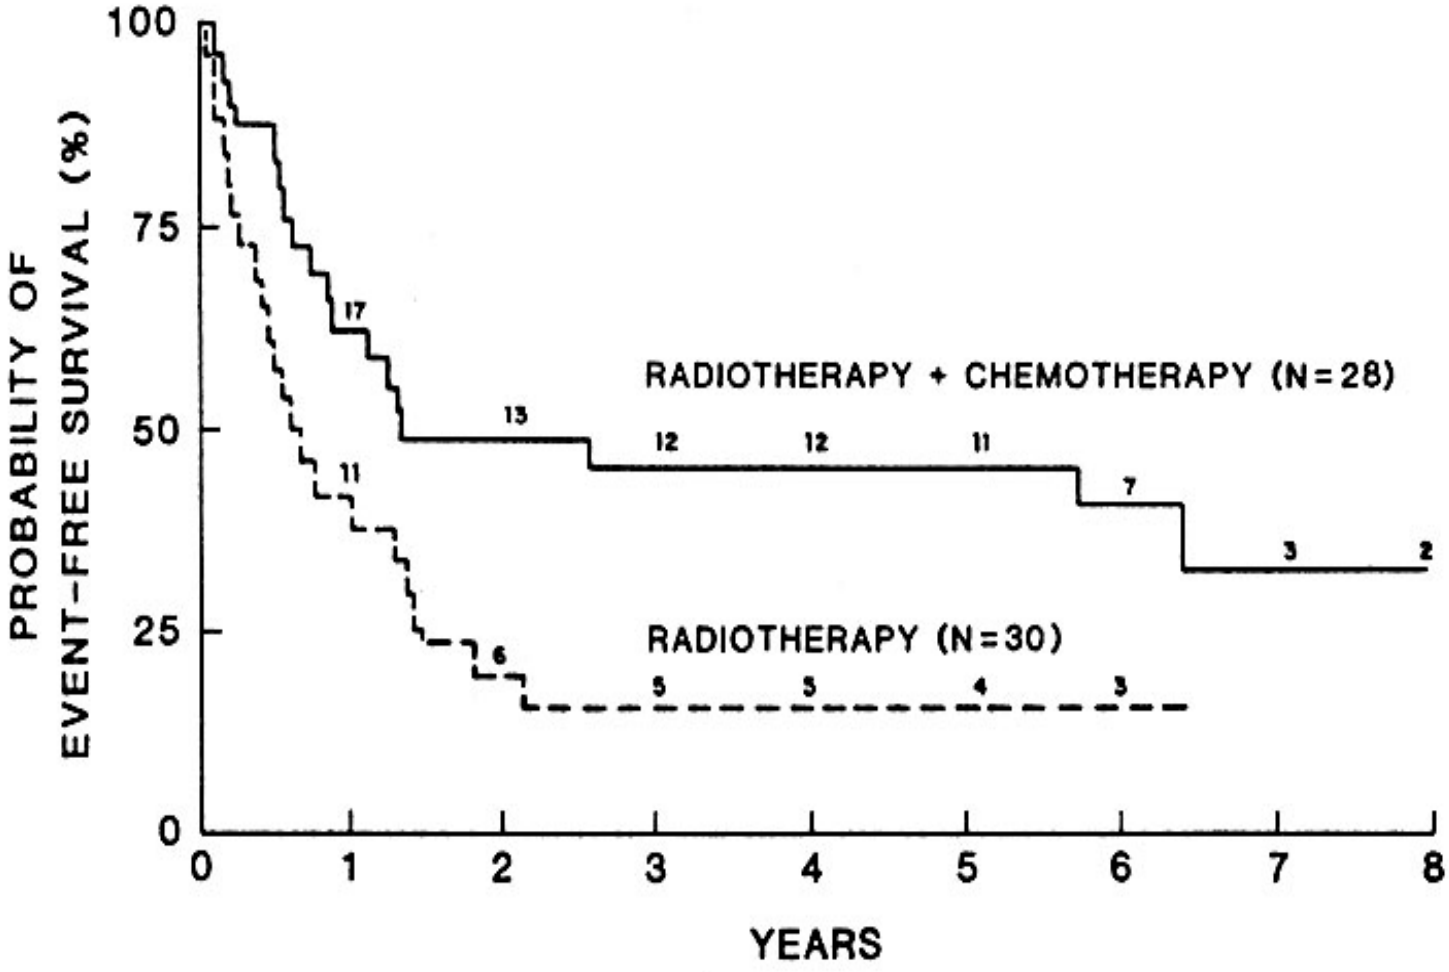
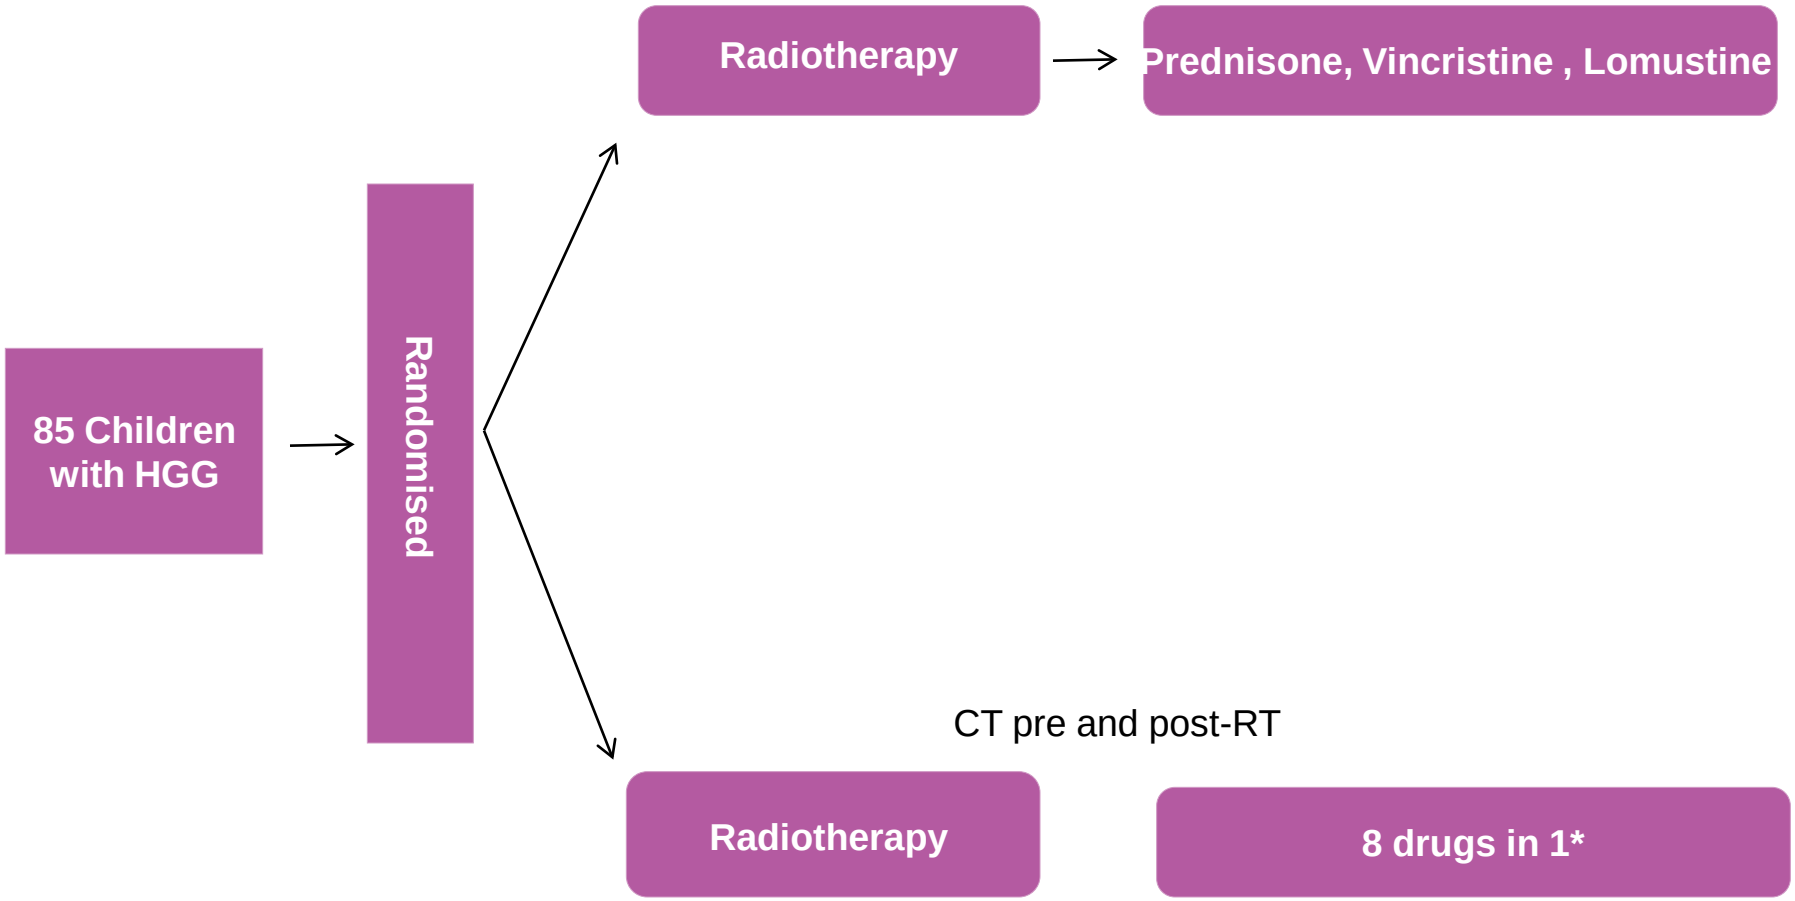
Phase III study CCG943
RT + CCNU, Vincristine, Prednisone versus RT alone



High grade glioma

CCG 945 clinical trial



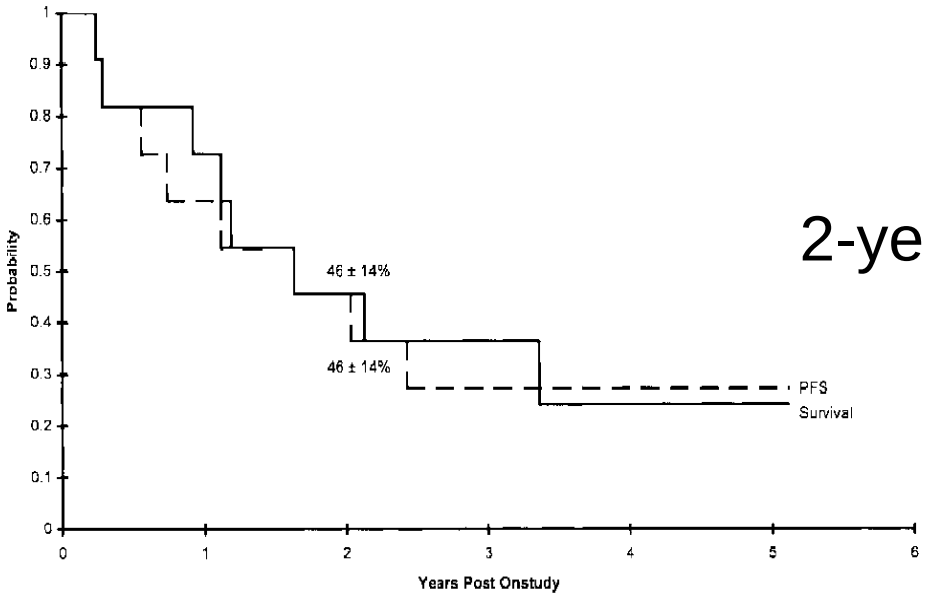
*vincristine, CCNU, procarbazine, hydroxyurea, cisplatin, mannitol, cytarabine, dacarbazine, methylprednisolone

Finlay JL et al. JCO 1995

Chemotherapy and autologous stem cell rescue

***Focal RT** daily — Total dose 54 Gy

11 Children with HGG → **Thiotepa, BCNU, and etoposide** → **ASCR** → **Focal RT***



2-year PFS rate of 46%

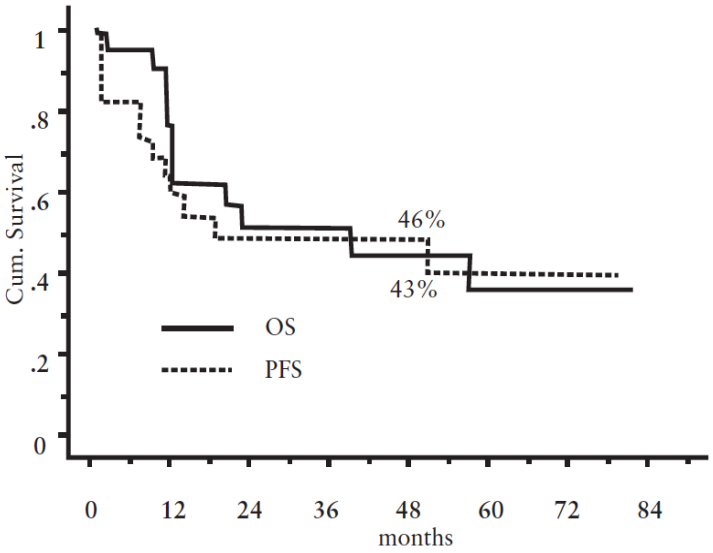
This study was closed early after 5 of the 11 treated. Patients developed significant pulmonary complications

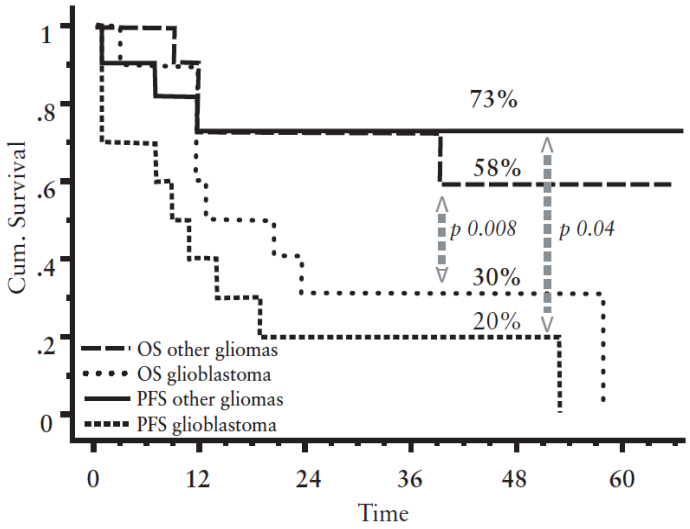
Grovas AC et al. Med Pediatr Oncol 1999

Chemotherapy and autologous stem cell rescue

***Focal RT** daily — Total dose 50-60 Gy

21 Children with HGG → **Cisplatin, etoposide, vincristine ,cyclophosphamide high-dose methotrexate, high-dose thiotepa** → **ASCR** → **Focal RT***





Chemotherapy and autologous stem cell rescue

The most appropriate candidates for ASCR are those with complete or near-complete resection before myeloablative therapy

The use of high-dose chemotherapy with ASCR may contribute to long-term disease control

But…

- At the expense of significant morbidity and mortality as a consequence of the regimens themselves.
- The associated side effects and resultant poor quality of life have led many investigators to question the benefit of high-dose chemotherapy with ASCR despite the potential for better disease control.

Infant HGG (< 3 years)
can be spared from radiation therapy with a good outcome

In children < 3 years:

French study BB-SFOP
(Dufour *et al.*, Eur J Oncol 2006)

Single arm phase II study of **radiation-sparing approach** in young children with newly diagnosed HGG

neurosurgery + carboplatin/procarbazine, cisplatin/etoposide and vincristine/ cyclophosphamide over a 16-month period

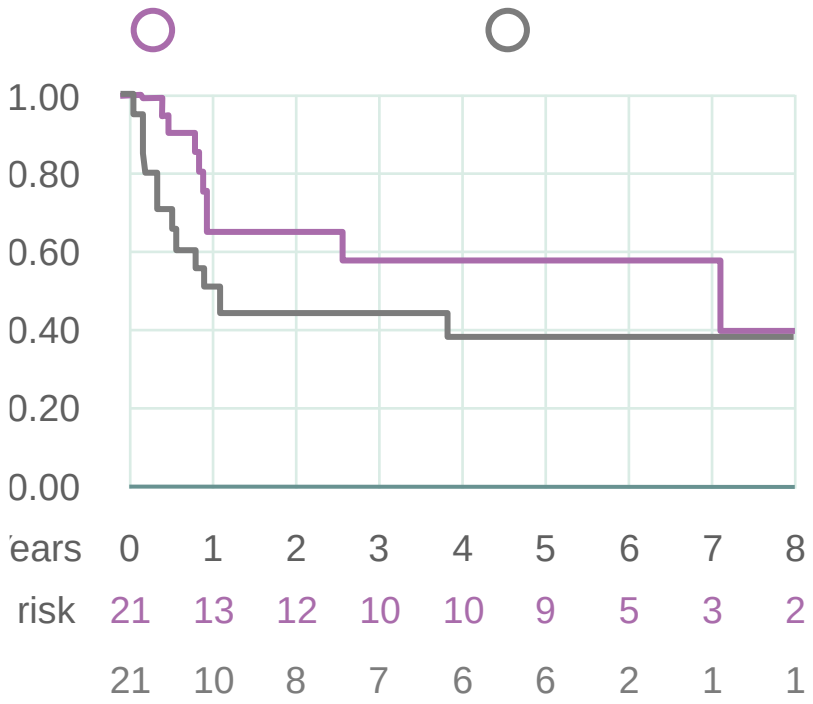
XRT only in case of recurrence or progression

Medium age = 23 months

5-year OS = 59%

5-year PFS = 35%

Median f/u = 5.2 years



Last f/u: 12/12 children alive (10 without XRT)

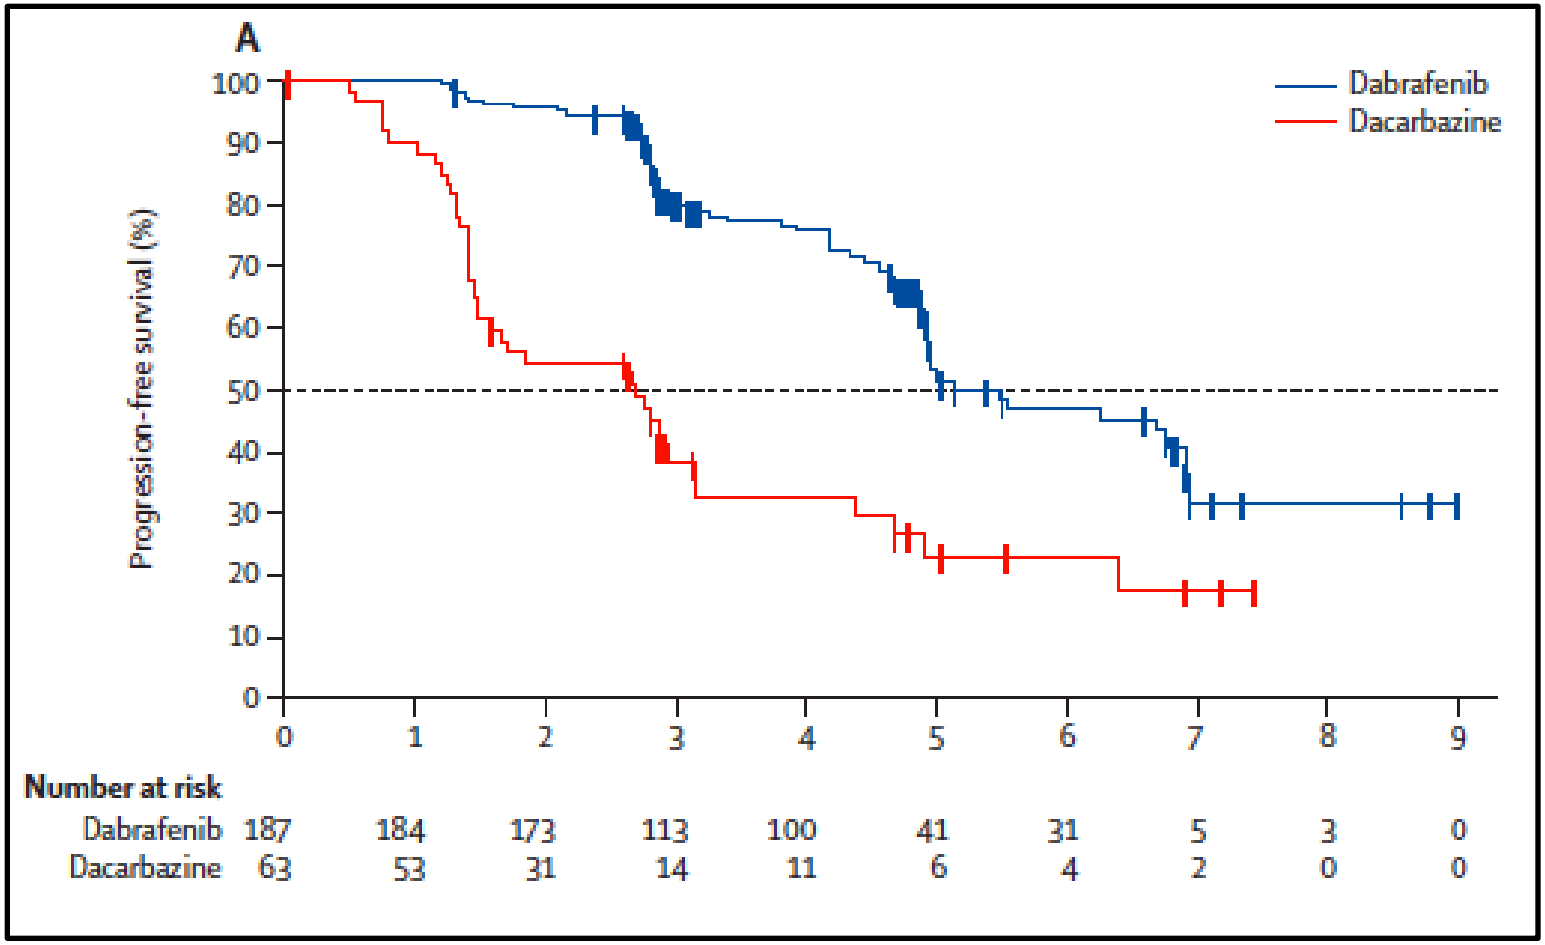
Dabrafenib in *BRAF*-mutated metastatic melanoma: a multicentre, open-label, phase 3 randomised controlled trial

Axel Hauschild, Jean-Jacques Grob, Lev V Demidov, Thomas Jouary, Ralf Gutzmer, Michael Millward, Piotr Rutkowski, Christian U Blank, Wilson H Miller Jr, Eckhart Kaempgen, Salvador Martín-Algarra, Boguslawa Karaszewska, Cornelia Mauch, Vanna Chiarion-Sileni, Anne-Marie Martin, Suzanne Swann, Patricia Haney, Beloo Mirakhur, Mary E Guckert, Vicki Goodman, Paul B Chapman

Lancet 2012; 380: 358–65



BRAFV600 Mutations –pHGG Target?

- **Good Target?**
- **PROs**
  - Established oncogene with known mechanism
  - Established clinical drugs & validated biomarkers
  - Proof of mechanism and concept proven in melanoma
- **CONs**
  - Low prevalence in pHGG (6-8%)
  - Target can be heterogenous in tumours
  - Resistance can be inherent or acquired

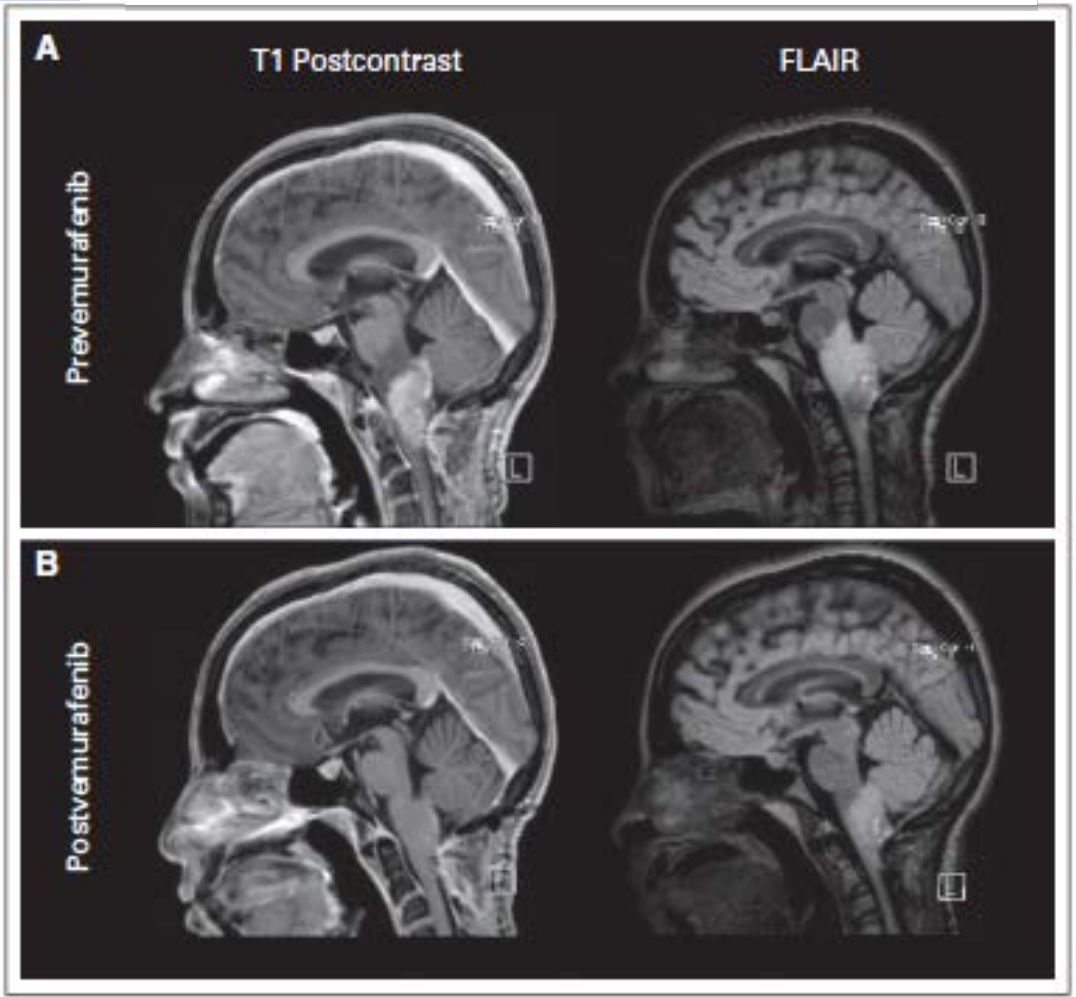
DIAGNOSIS IN ONCOLOGY

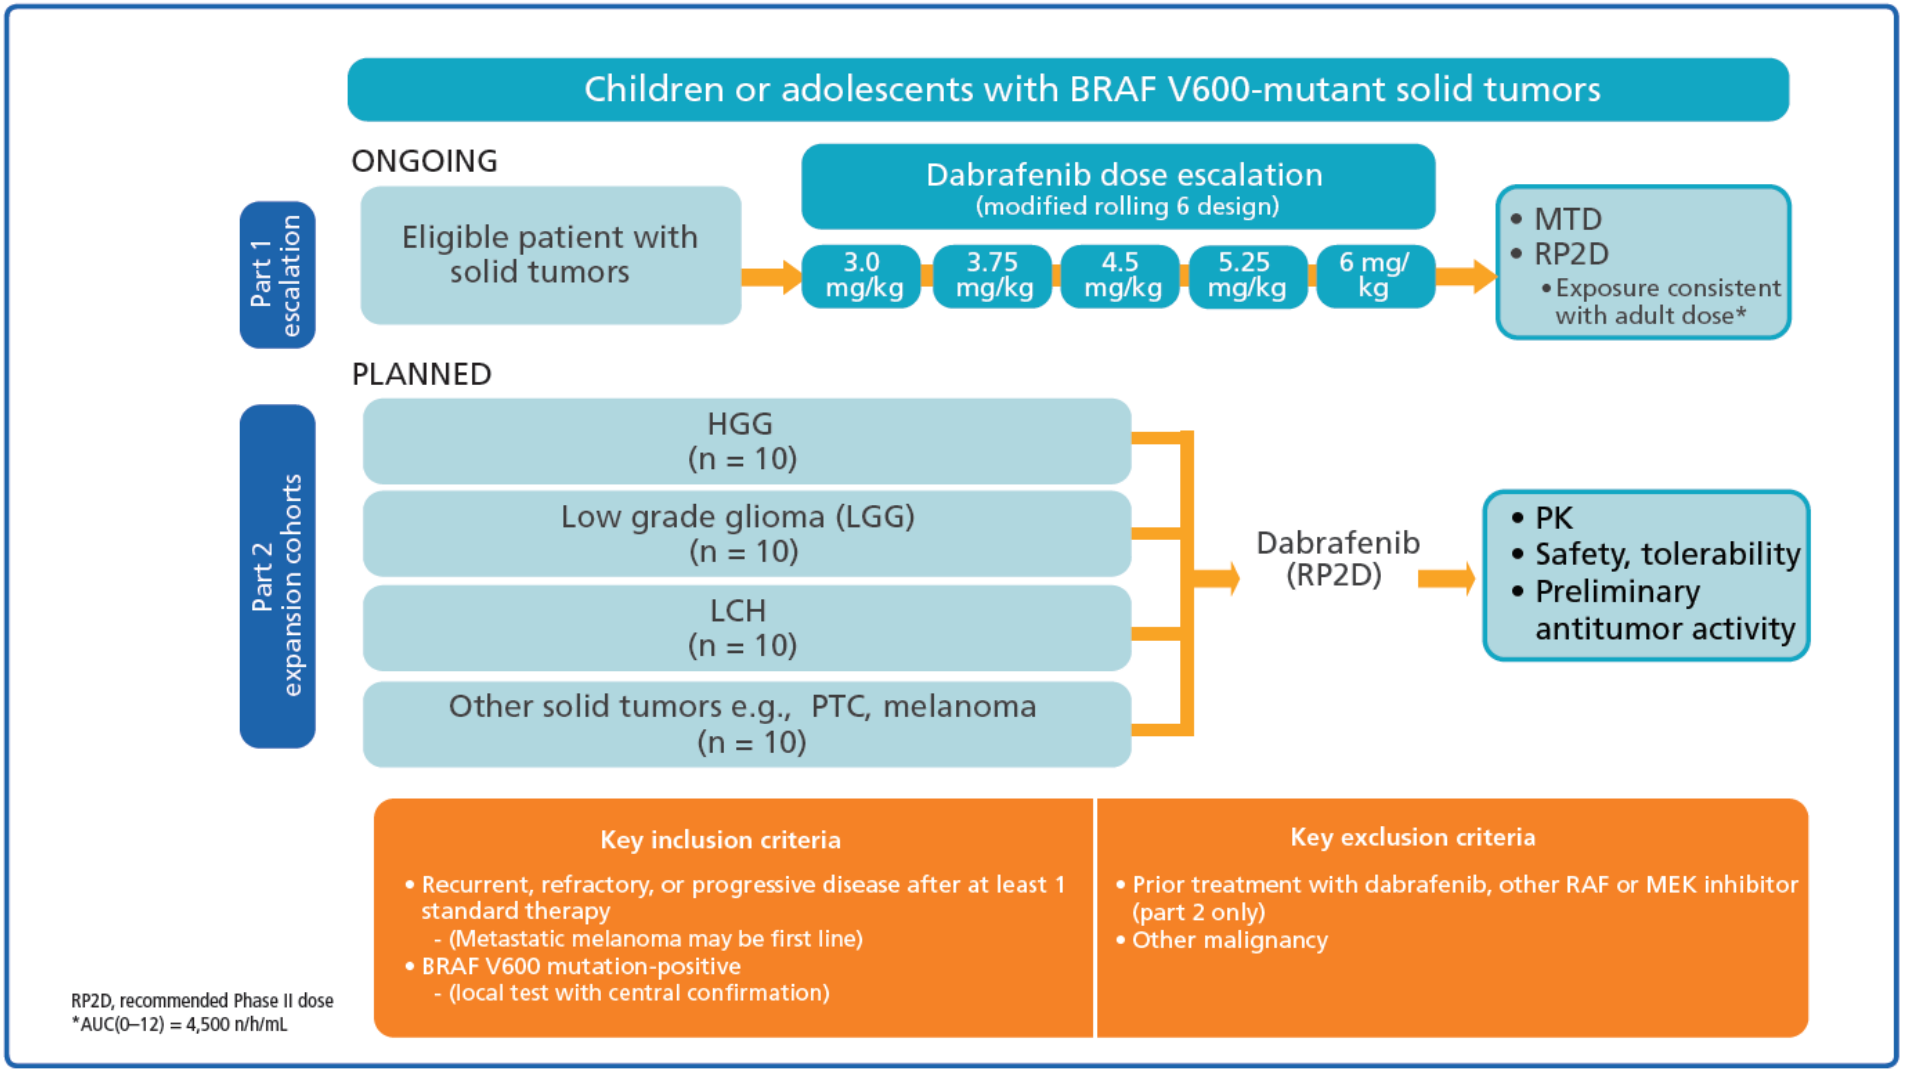
Brainstem Ganglioglioma Successfully Treated With Vemurafenib



Complete Radiographic Responses in Pediatric Patients with BRAF V600–Positive Tumors Including High Grade Gliomas: Preliminary Results of an Ongoing Phase I/IIa Safety and Pharmacokinetics (PK) Study of Dabrafenib

Mark W. Kieran[1], Kenneth J. Cohen[2], Francois Doz[3], Ira J. Dunkel[4], Darren R. Hargrave[5], Trent Ryan Hummel[6], Irene Jimenez[3], Sarah Leary[7], Andrew D.J. Pearson[8], Christine A. Pratilas[4], James Whitlock[9], Michael Durante[10], Diana M. Gibson[11], Patricia Haney[10], Mark W. Russo[10], A. Benjamin Suttle[11], Birgit Geoerger[12]

Figure 1. Study Design



RP2D, recommended Phase II dose
*AUC(0–12) = 4,500 n/h/mL

Figure 2. Preliminary Treatment Duration and Best Response

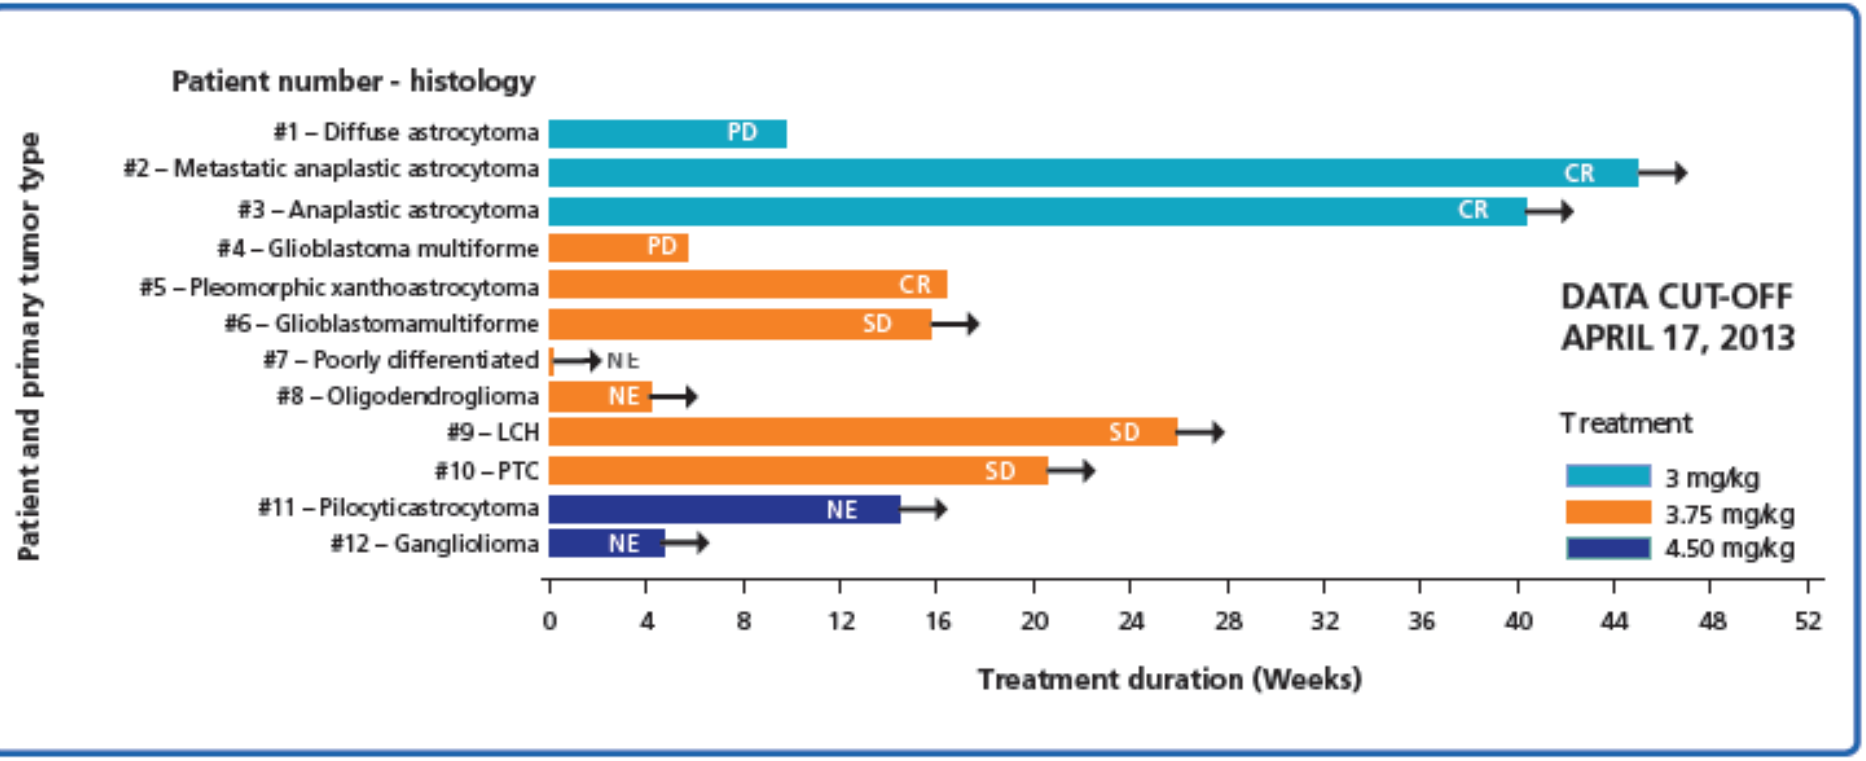


Figure 3. Radiologic Response, Patient 3

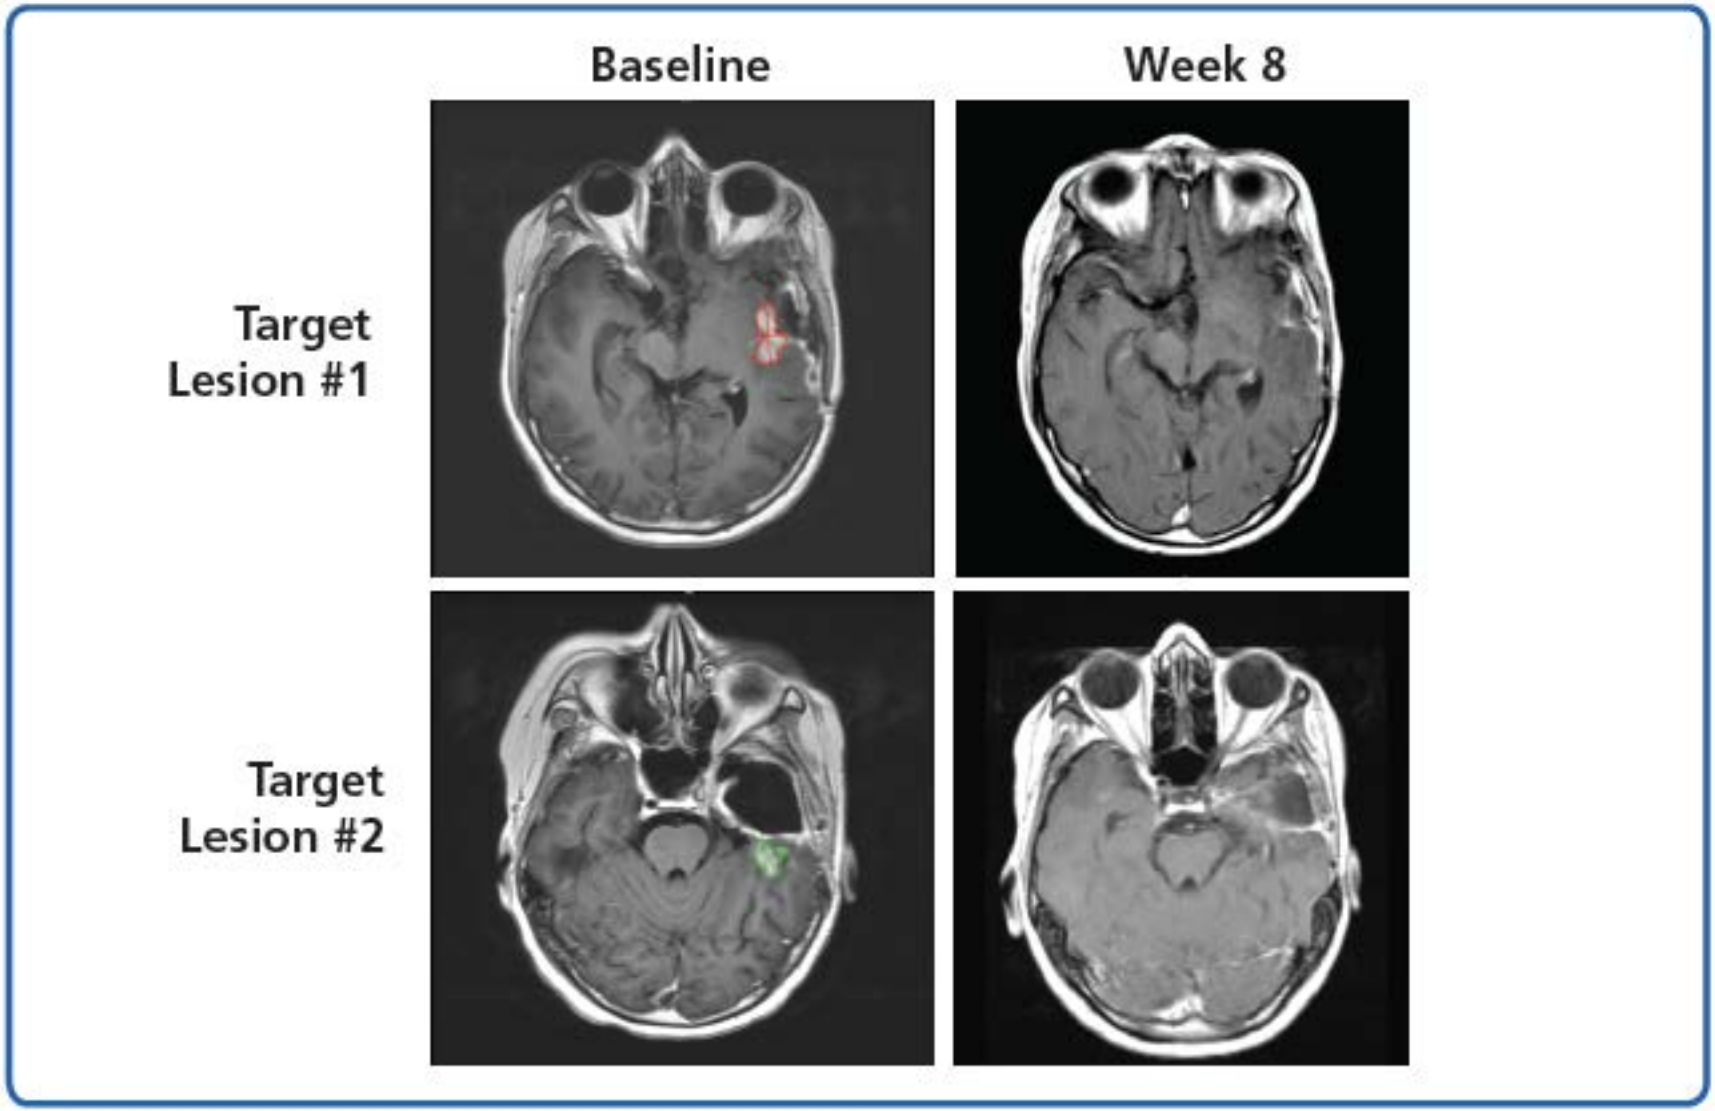


CONCLUSIONS

- Very encouraging preliminary activity seen in patients with relapsed/refractory V600 mutant glioma
  - CR or PR seen in 5/10 patients
    - Investigator-assessed best response
    - Follow-up confirmatory scans pending in 2 of the 5 patients with initial response
  - Trial is ongoing and includes expansion cohorts with plans to enroll additional patients with V600 mutant gliomas to confirm these preliminary findings
- Dose escalation continues
  - PK at 3.75 mg/kg does not satisfy pre-specified systemic exposure target
- Safety profile in children is similar to adults
  - 1 DLT event: maculopapular rash (onset day 1)

PAEDIATRIC HIGH GRADE GLIOMA:
CONCLUSIONS

Conclusions

In order to make progress in pHGG, DIPG or aHGG

- Biologically targeted therapies are needed
- Biomarkers are required for patient selection
- Accurate preclinical models needed

Extrapolation of data/ studies only possible for

- Shared targets and defined molecular groups
- Needs to be confirmed if these targets are relevant in different tumour entities

e.g. DIPG> pHGG > aHGG

Conclusions

Need to develop and validate new response criteria e.g. RANO & RAPNO

Must consider drug delivery as a vital component of neuro-oncology trials & possible reason for an active agent failing!

Efficient, adaptive and flexible clinical trial designs

- allow study of multiple arms
- combination targeted therapies
- parallel and sequentially

ESTRO School

Management of medulloblastoma in children

Umberto Ricardi

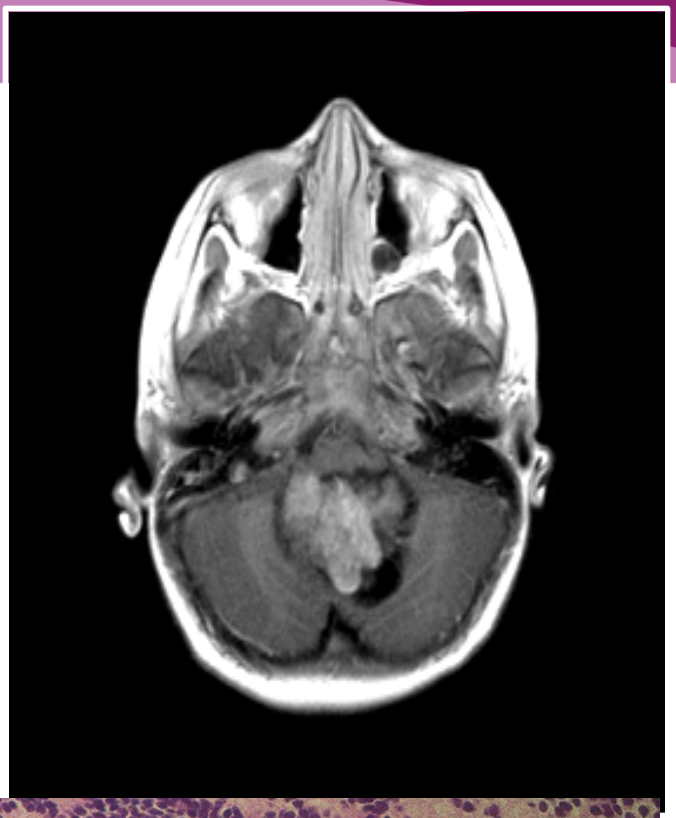
DEPARTMENT OF
ONCOLOGY
UNIVERSITY OF TURIN

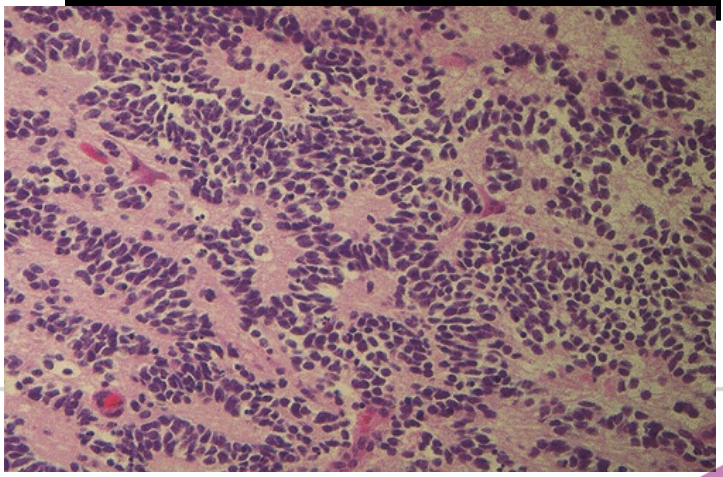
Medulloblastoma

- Most common malignant CNS tumour in children

- Tremendous progress over last 20 years
  - Treatment
  - Biology >>> several distinct subtypes

Medulloblastoma





Posterior fossa PNET

Small round blue cells tumor

ESTRO School

Medulloblastoma

- 15-20% of all CNS tumors in children

- Bimodal peak incidences at ages 3-4 and 8-9 years

- 10/15% in infancy

- 70% <16 years

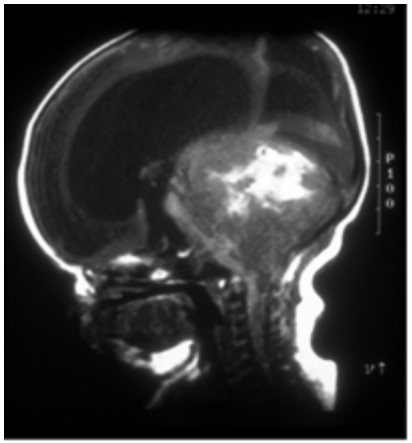
- Very rare after age 40

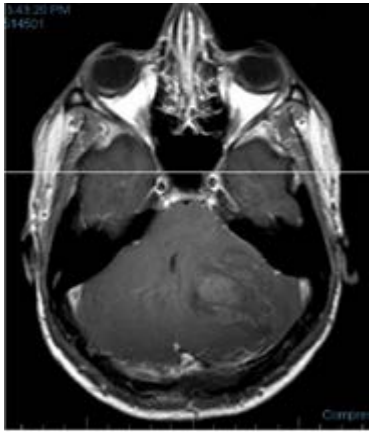
- Rate M:F 1.4 : 1

Medulloblastoma - Clinical presentation

- Typical midline location, arising in the vermis, causing IVth ventricle compression (symptoms and signs of raised intracranial pressure)

- Hemispheric location more common in very young children and adults

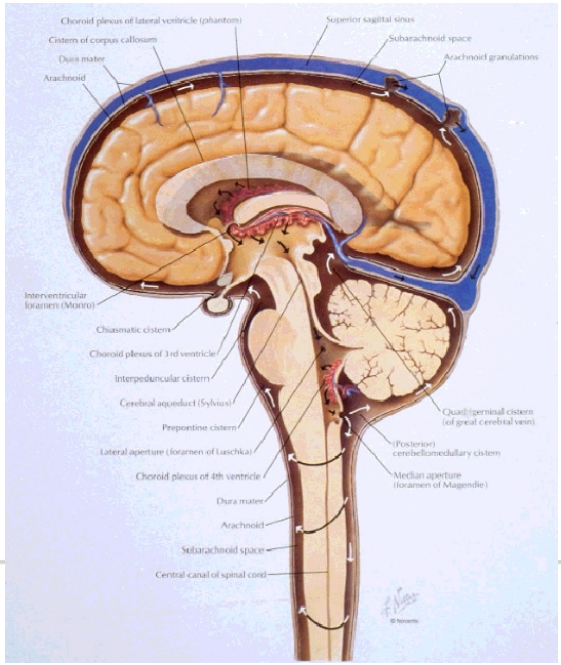


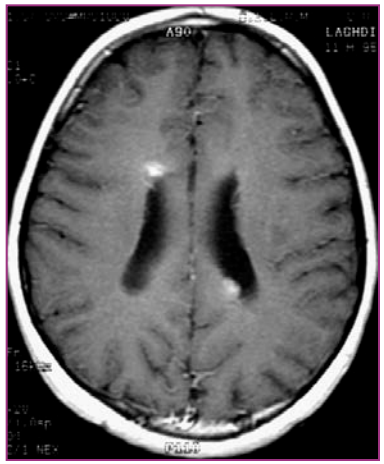


Medulloblastoma: pattern of spread

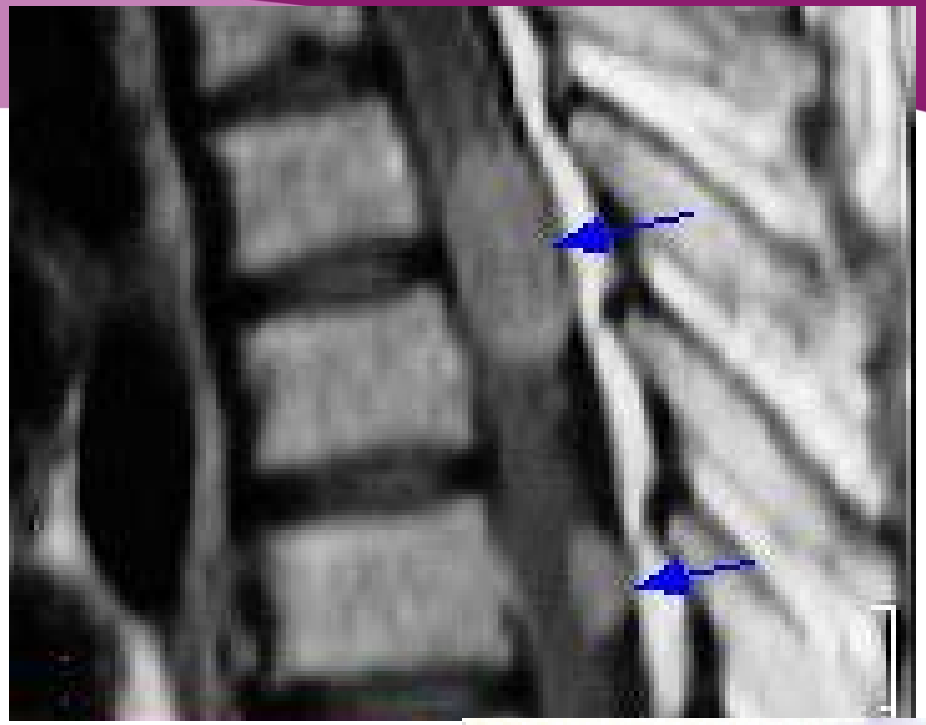
- Frequency of leptomeningeal seeding at diagnosis 30-35%

- Extra CNS metastases very uncommon (<5%) [lymph nodes, bone, bone marrow]



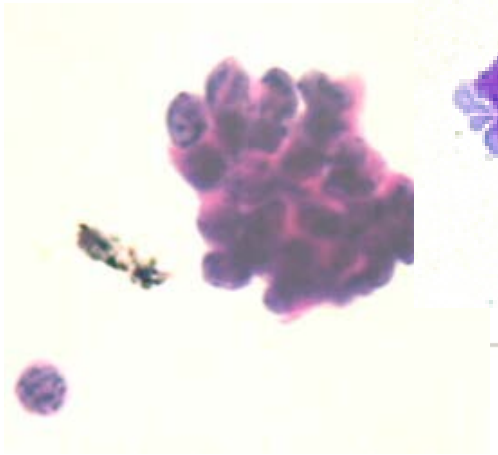


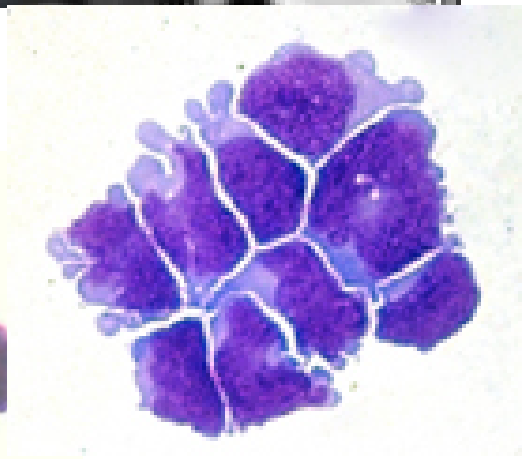
ESTRO School



Chang staging system for metastases

- M0: no metastases
- M1: CSF cytology +ve
- M2: macroscopic seeding in subarachnoid space, IIIrd or lateral ventricles
- M3: macroscopic seeding along spinal axis
- M4: extra-CNS spread





ESTRO School

Medulloblastoma - Work-up

- Pre-op craniospinal MR imaging
- Post-op cranial MR (24-48 hours after surgery)
- Lumbar CSF cytology > 14 d post-op

Chang staging system for metastases

- M0: no metastases
- M1: CSF cytology +ve
- M2: macroscopic seeding in subarachnoid space, IIIrd or lateral ventricles
- M3: macroscopic seeding along spinal axis
- M4: extra-CNS spread

Medulloblastoma - Prognosis

Prognosis depends on…

- Extent of primary tumour/ completeness of surgical resection
- Presence or absence of leptomeningeal seeding

Also...

- Pathologic/molecular subtype

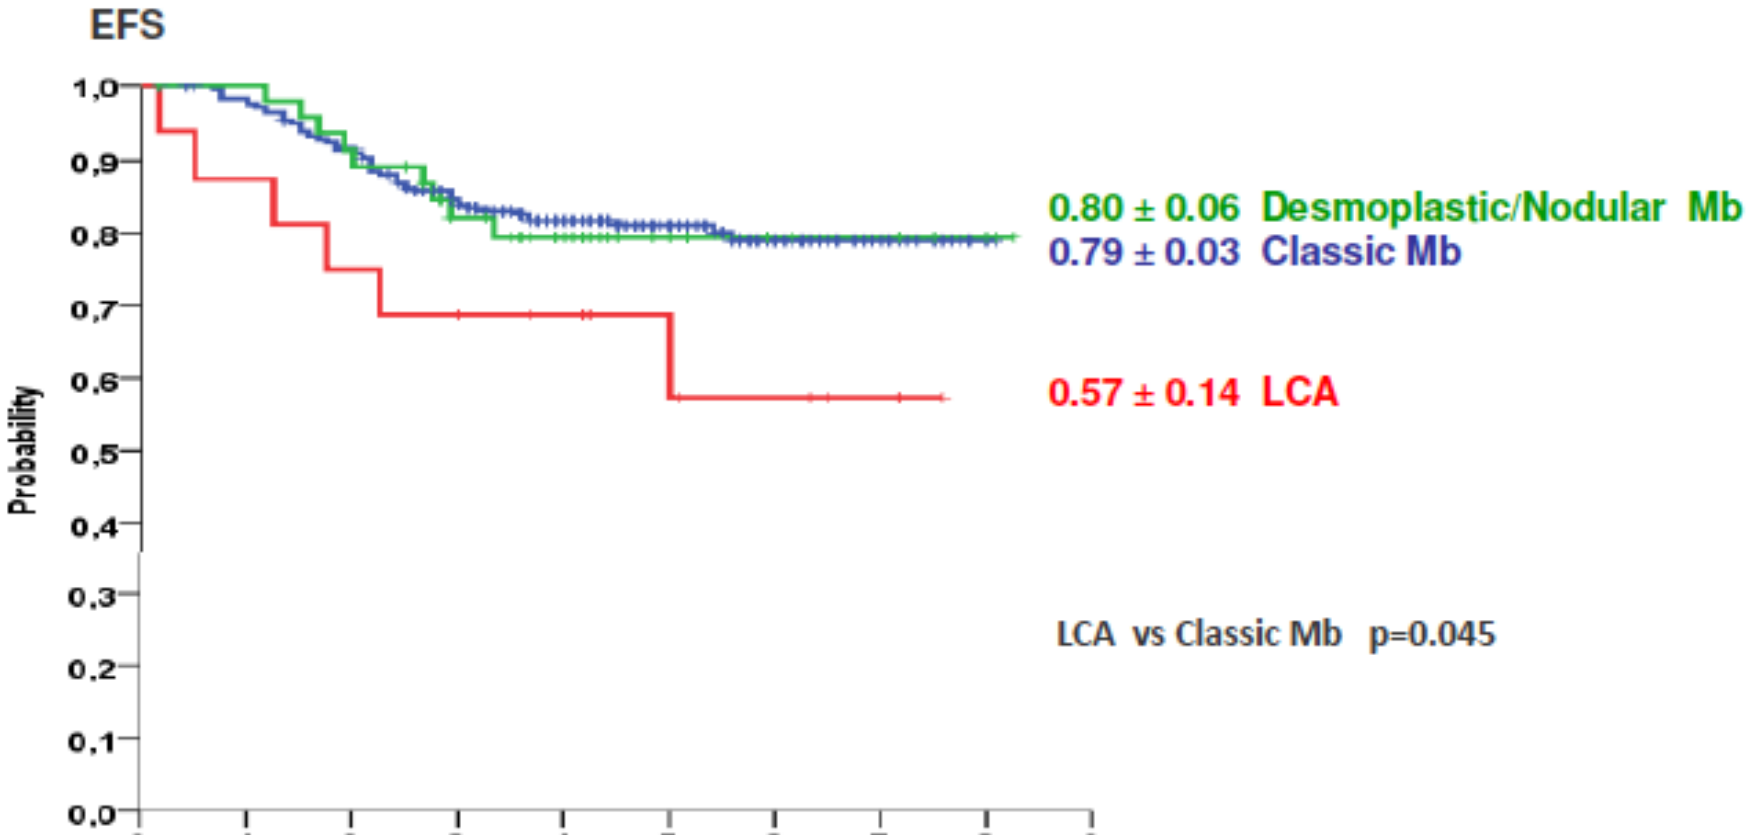
Medulloblastoma - Prognosis

Risk groups for management

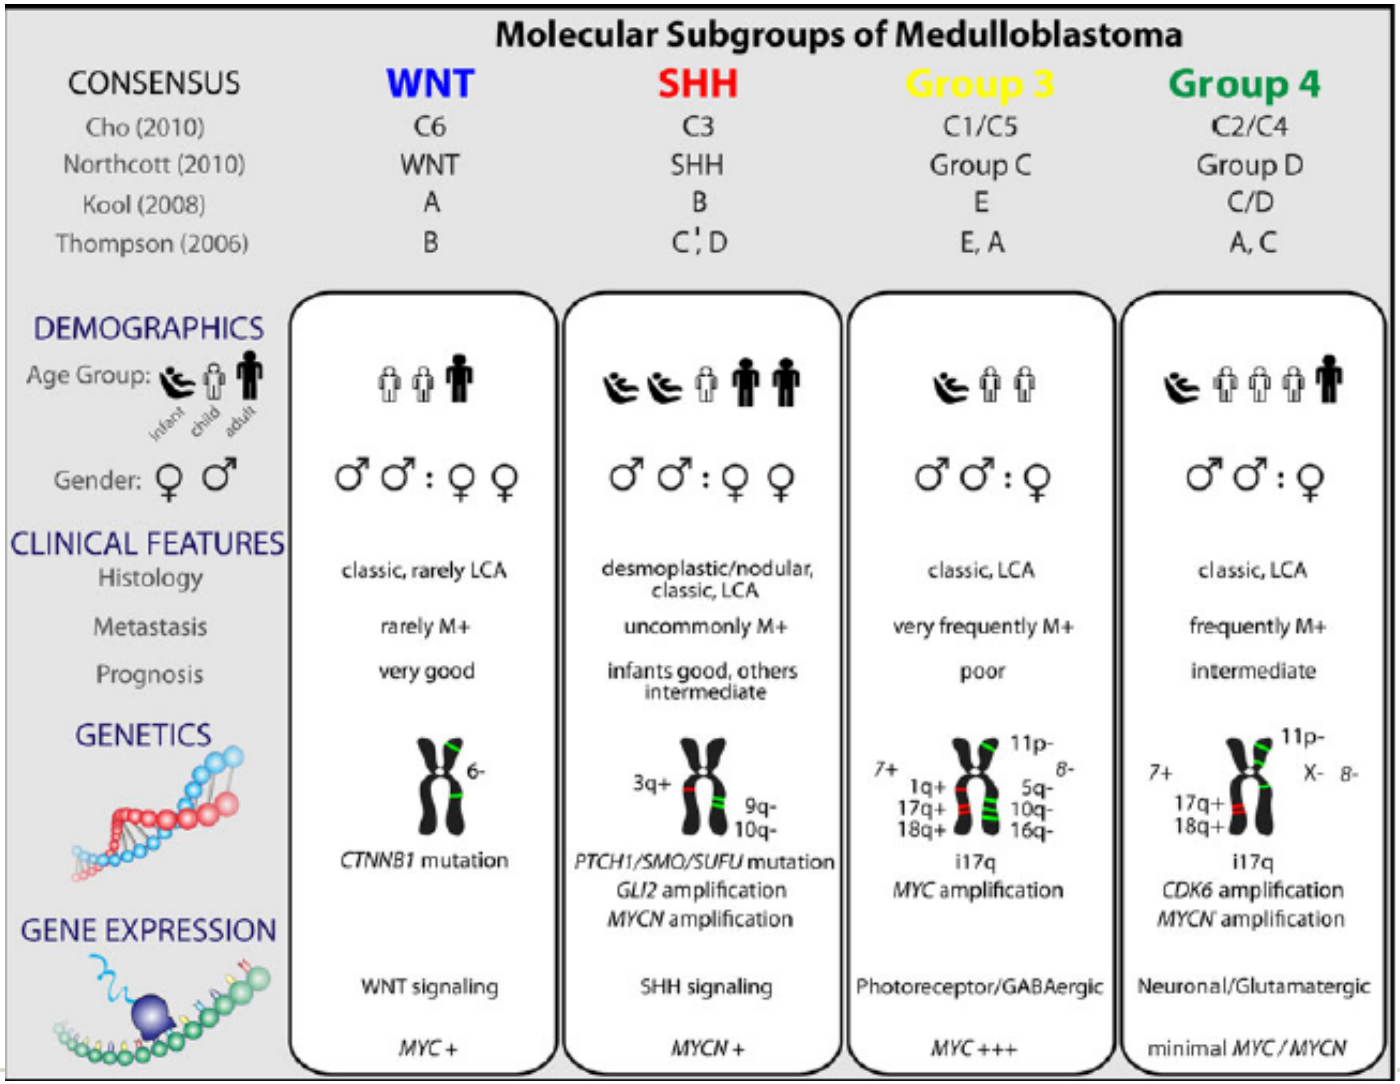
- Standard risk
  - GTR/residual tumour <1.5 cm^2 on post-op MRI
  - No leptomeningeal seeding by MRI of the spine or lumbar CSF cytology (M0)
- High risk
  - All others (1/3 to 1/2 all)
- Infants and very young children

SIOP PNET 4 : survival by histologic subtypes

Central Pathology Review



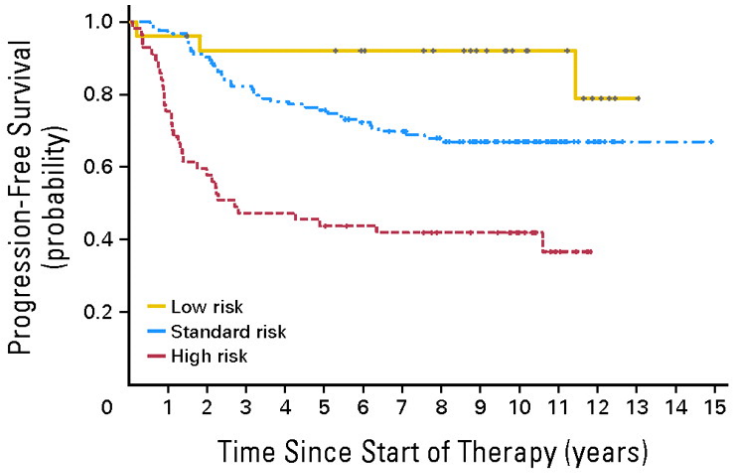
Comparison of the various subgroups of medulloblastoma including their affiliations with previously published papers on medulloblastoma molecular subgrouping



ESTRO School

Histology + molecular variables

- 3 risk categories
  - Low (13%)
    - β-catenin+, M0, not large cell/anaplastic, no MYC amplification
  - High (28%)
    - M+ or
    - LC/A or
    - MYC amplification
  - Standard (59%)
    - All others



No. at risk														
Low risk	26	25	23	23	23	23	21	20	18	15	11	8	4	1
Standard risk	124	120	112	101	96	92	85	81	72	60	45	23	8	1	1
High risk	57	43	33	27	27	24	23	22	19	17	12	5			

Ellison JCO 2011

Medulloblastoma: the (near) future

- Patients will be stratified for treatment on the basis of biological markers
  - Low risk: reduce therapy → reduce risks associated with treatment
  - High risk: intensify treatment/use novel treatment approaches
- Possibility of developing agents that would target specific molecular aberrations

New risk groups

Risk Group	Definition of Risk Group	5 y EFS
1. Low "PNET5"	Nuclear ß-catenin +, no myc gene amplification, residual tumor ≤1.5 cm^2, no LC- or anapl. histology	91 %
2. Intermediate "PNET6"	Nuclear ß-catenin -, no myc gene amplification, residual tumor ≤1.5 cm^2, no LC- or anapl. histology	81 %
3. High "PNET-HR"	myc gene amplification, or residual tumor >1.5 cm^2, or LC- or anapl. histology	67 %

Medulloblastoma: the management

- **Standard risk Medulloblastoma**

- Standard risk
  - GTR/residual tumour <1.5 cm^2 on post-op MRI
  - No leptomeningeal seeding by MRI of the spine or lumbar CSF cytology (M0)

Post-operative treatments

- Craniospinal irradiation

  - ✓ Clinical target volume = whole brain + spinal cord with overlying meninges
  - ✓ CSI: 36 Gy, followed by local boost to 55 Gy
  - ✓ Cure rates: 60-80%

- ± Chemotherapy

Late toxicity related to CSI

- Due to radiotherapy to the brain
  - Neuro-cognitive deficits/effects on social interactions
  - Hypopituitarism
  - Alopecia
  - Cataracts
  - Hearing loss
- Due to radiotherapy to the spine
  - Short stature
  - Primary hypothyroidism
  - Impaired lung function
  - Effects on the heart
  - Primary ovarian failure
- Both
  - Second cancers…

How can we reduce the risks associated with CSI?

- Risk reduction
  - Reduce CSI dose
  - Use hyperfractionated RT?

Medulloblastoma

History of Chemotherapy Clinical Trials:

- 1970s-1980s:
- Adjuvant chemotherapy
- SIOP I,CCSG 942

Chemo better for high-risk subgroups
Standard dose RT (35-36 Gy established)

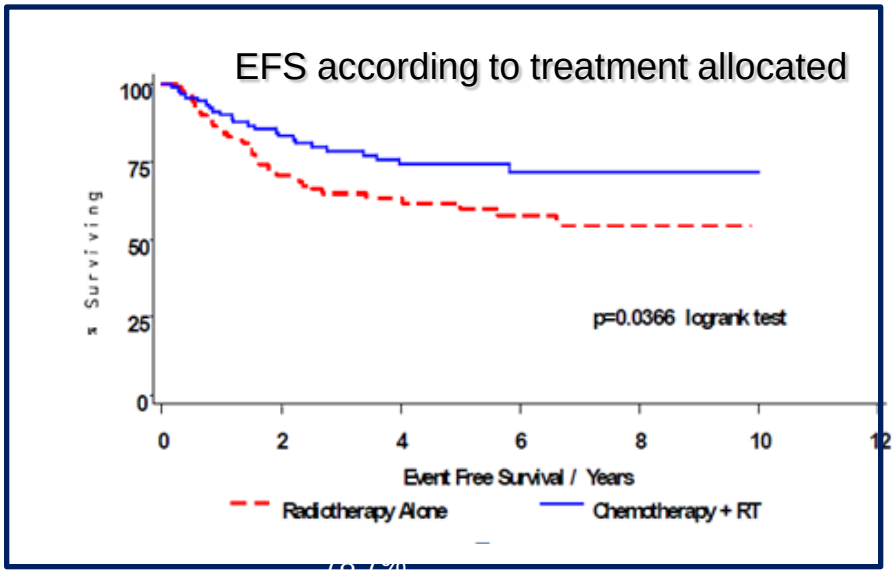
- 1980s-1990s:
- Pre-RT (Sandwich CT)
- SIOP II, SIOP/UKCCSG PNET 3
- Pre vs post RT chemotherapy : HIT 91,CCG 921
- CCG 9862 adjuvant chemotherapy (CVP)

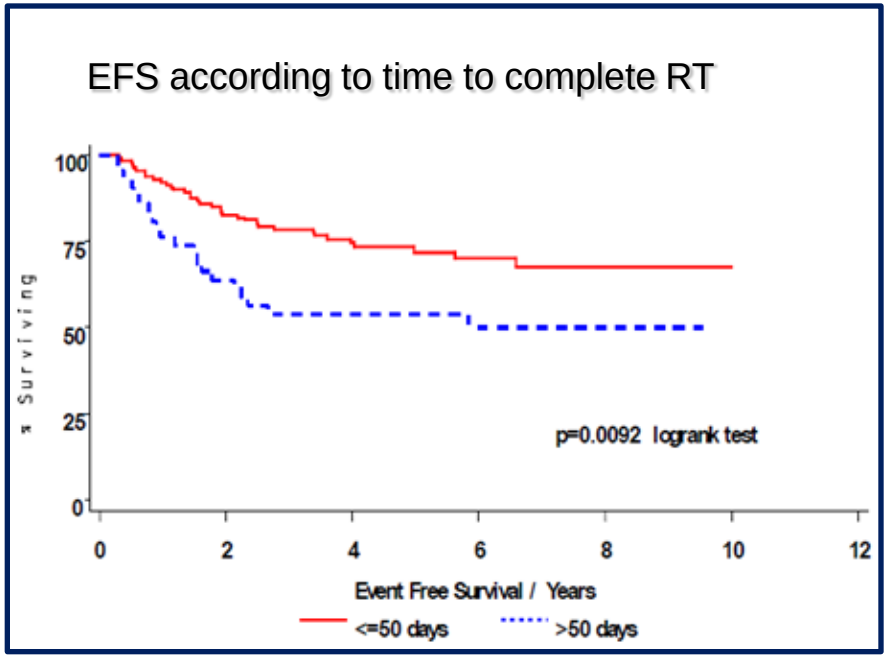
Intensive sandwich CT better than RT alone (PNET 3)
Immediate RT better than delayed

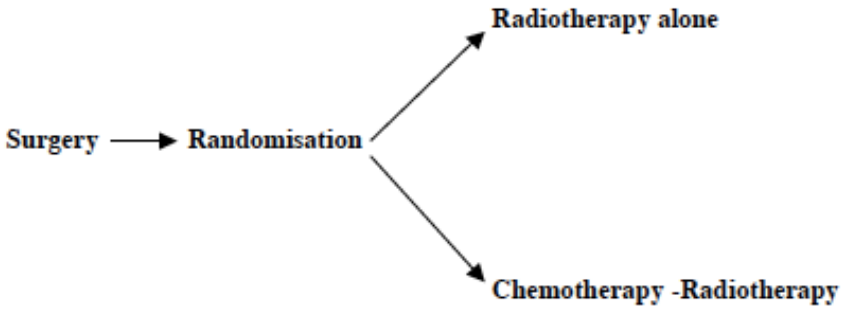
Cisplatin, VCR,CCNU chemo standard and reduced dose RT (23.4 Gy) established

ESTRO School

UKCCSG/SIOP PNET III



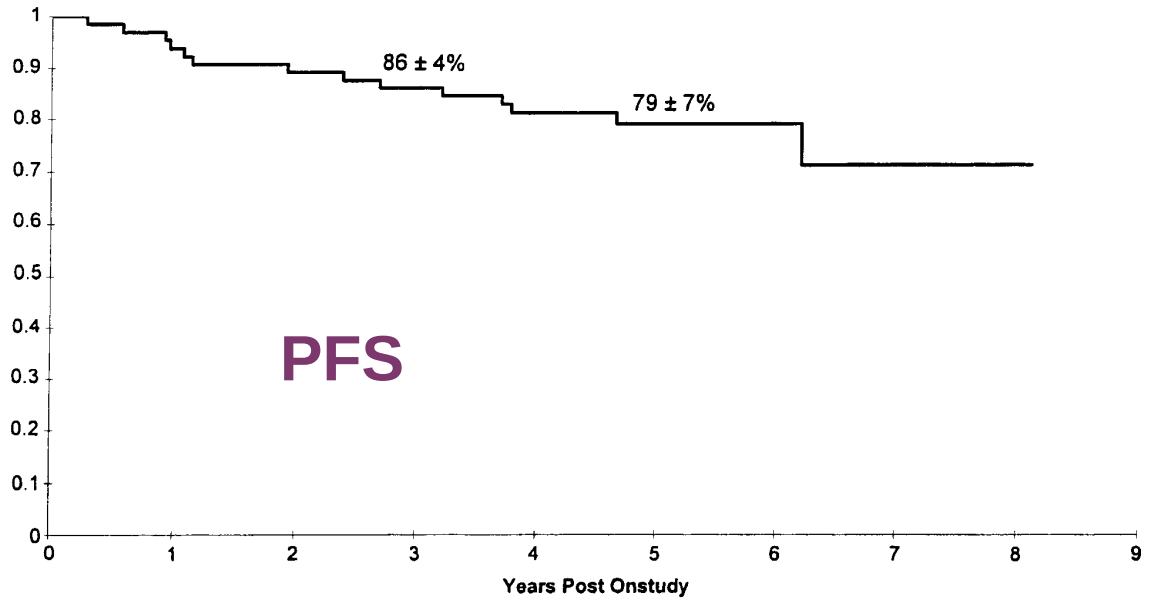




Combined CT-RT and completing RT within 50 days had a significant impact on EFS in multivariate analysis

ESTRO School

Reduced dose Cranio Spinal Irradiation with CT



- 65 “Standard-Risk” patients:
- RT doses
  Craniospinal: 23.4 Gy
  Posterior fossa: 55.2 Gy
- Concomitant CT:
  weekly Vincristine
- Adjuvant CT:
  Vincristine
  CCNU
  Cisplatin

“These overall survival rates compare favorably to those obtained in studies using full-dose radiation therapy alone”

Packer, J Clin Oncol 1999; 17:2127-36

Medulloblastoma- Randomised studies of CSI RT dose

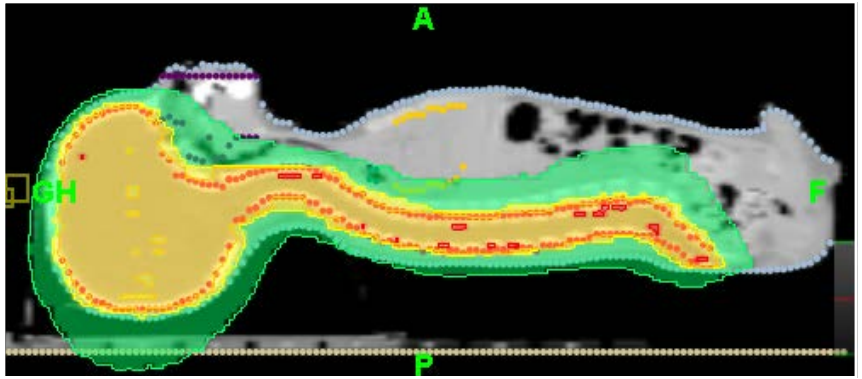
POG 8631/CCG 932 (1986-1990)

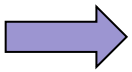
- 23.4 Gy – 52 % 5 year EFS
- 36 Gy – 67 % 5 year EFS
- p 0,08 (trial stopped for an increased risk of isolated neuraxis failure)

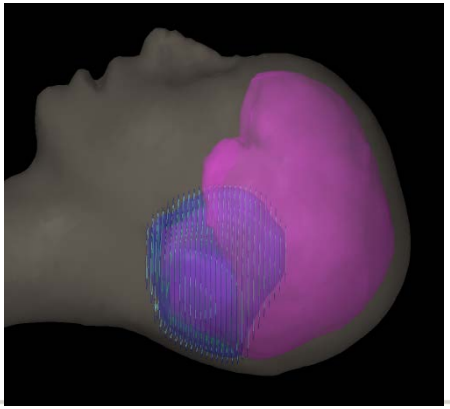
- 23.4 Gy – 52 % 8 year EFS
- 36 Gy – 60 % 8 year EFS
- p 0,141

Standard risk childhood MB

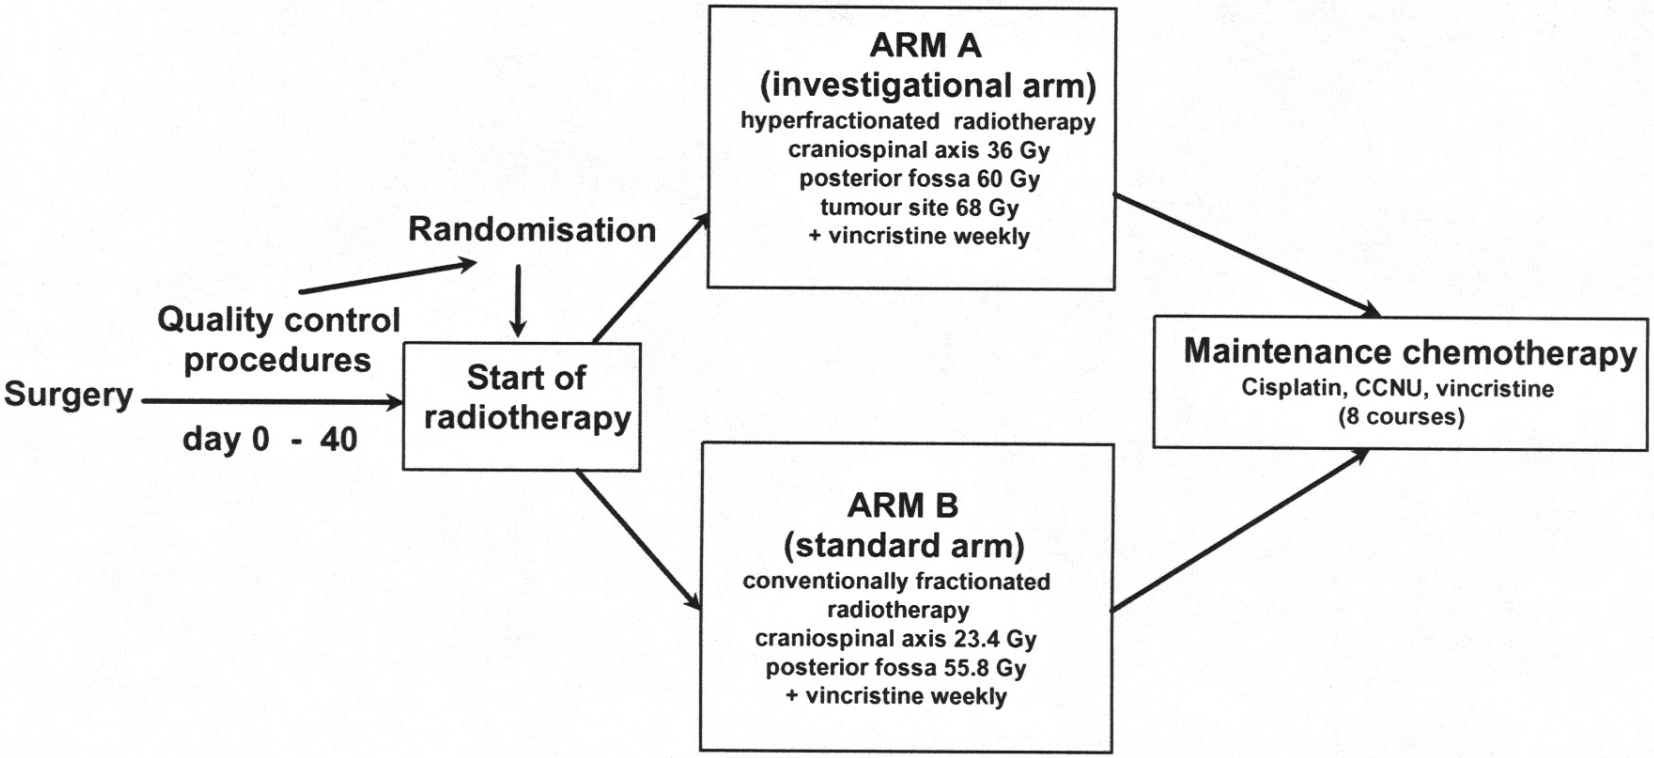
- CSI
  - Standard risk
    - 23.4Gy/13 daily fractions of 1.8 Gy
- Primary site
    - Total dose 54-55.8Gy
- Plus chemotherapy



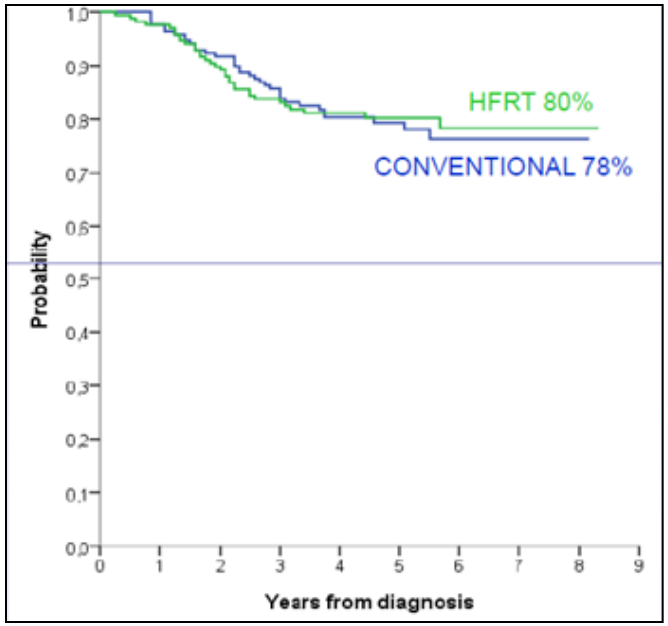




A prospective randomised controlled trial of hyperfractionated versus conventionally fractionated radiotherapy in standard risk medulloblastoma: SIOP Trial PNET 4



HIT2000/SIOP PNET-4 study for M0 medulloblastoma



Event Free Survival

- Pts with post-op residual tumor > 1.5 cc had a significantly inferior prognosis compared to pts without residual tumor (5 yrs-EFS 64% vs 82%, p<0,01)

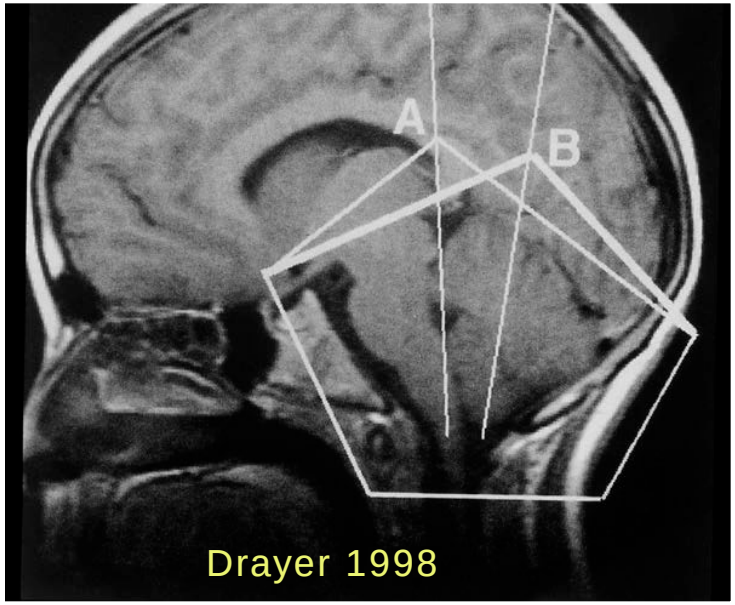
- Pts with RT starting < 49 days after surgery had a 5 year EFS of 81% compared with 67% for pts who commenced RT > 49 days after surgery (p=0.04)

The posterior fossa boost

- Whole posterior fossa
- Limited volume/tumour bed

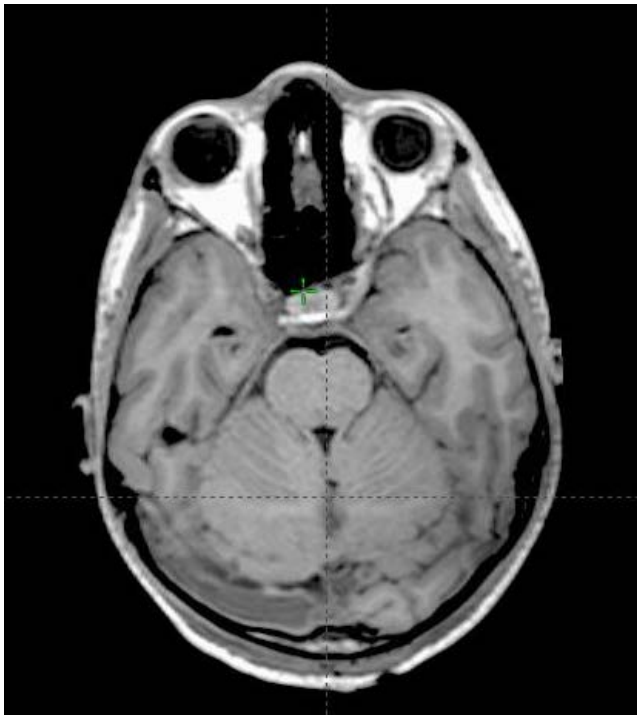
CTV for the posterior fossa boost

- Inferiorly
  - Bottom of C1
- Laterally
  - Bony walls of the occiput and temporal bones
- Superiorly
  - Tentorium cerebelli



The posterior fossa boost

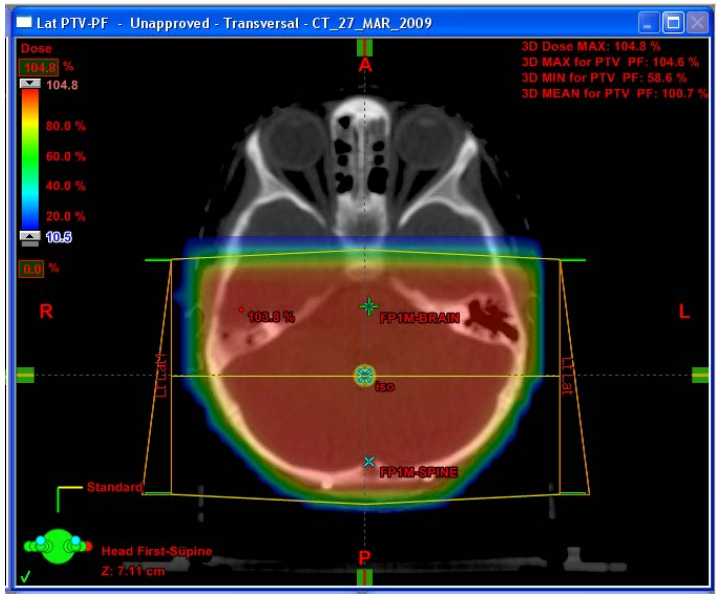
- Whole posterior fossa

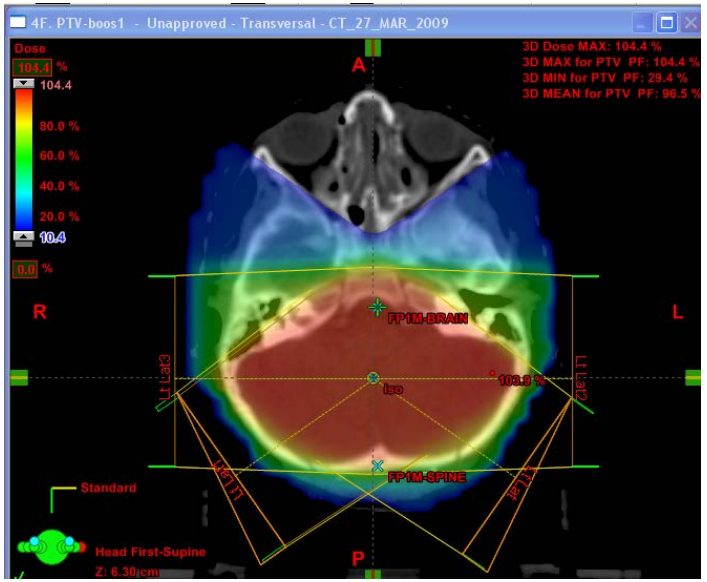


Radiotherapy technique

- Options include
  - Lateral opposed
  - Posterior obliques
  - 3D CRT
  - IMRT
- Principal consideration
  - Least dose to OARs

Whole PF: Lateral opposed → 3D CRT





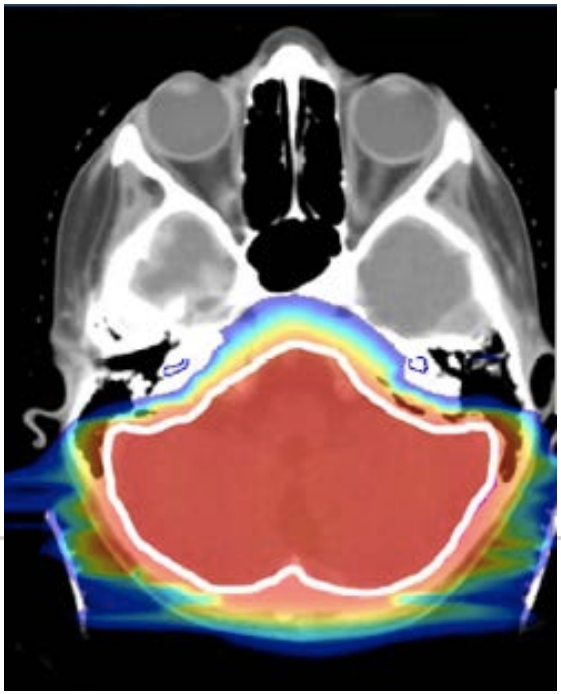
- No sparing of cochlea
- Increased dose to hypothalamus/pituitary, optic chiasma, temporal lobes

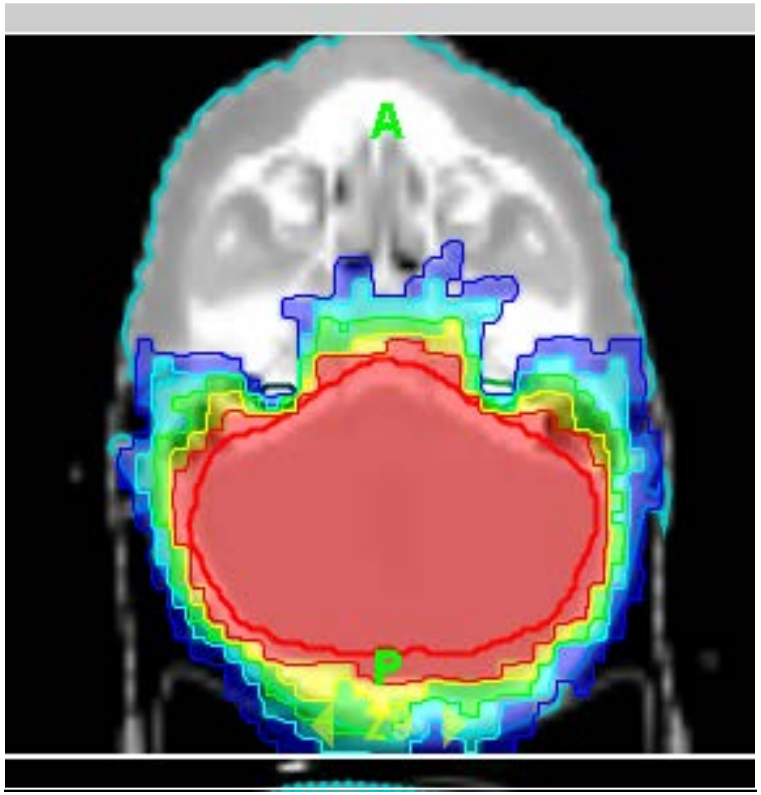
ESTRO School

Whole PF: Lateral opposed → IMRT

Better sparing of cochlea

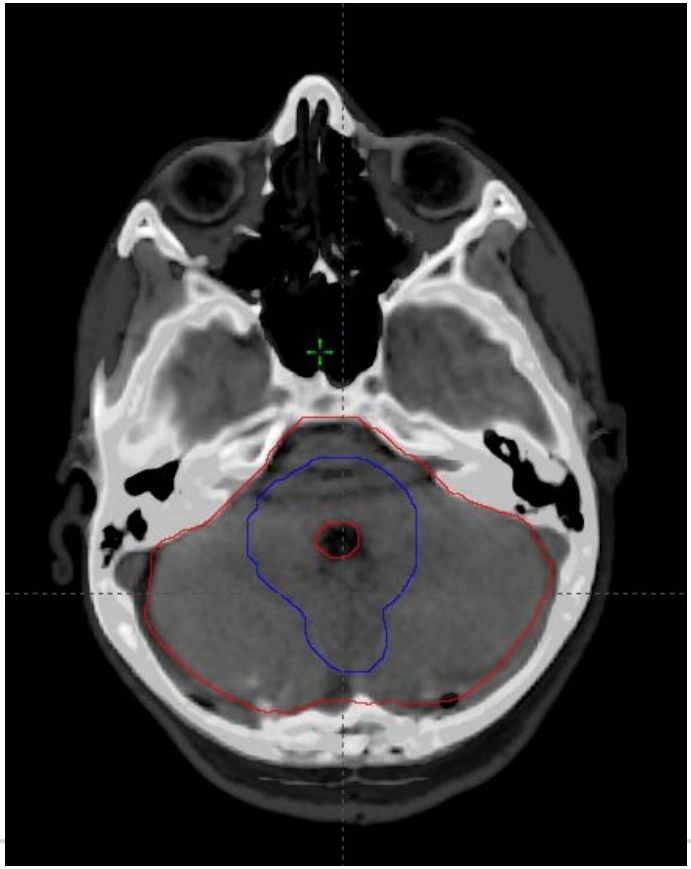
Reduced volume of supratentorial brain receiving high dose

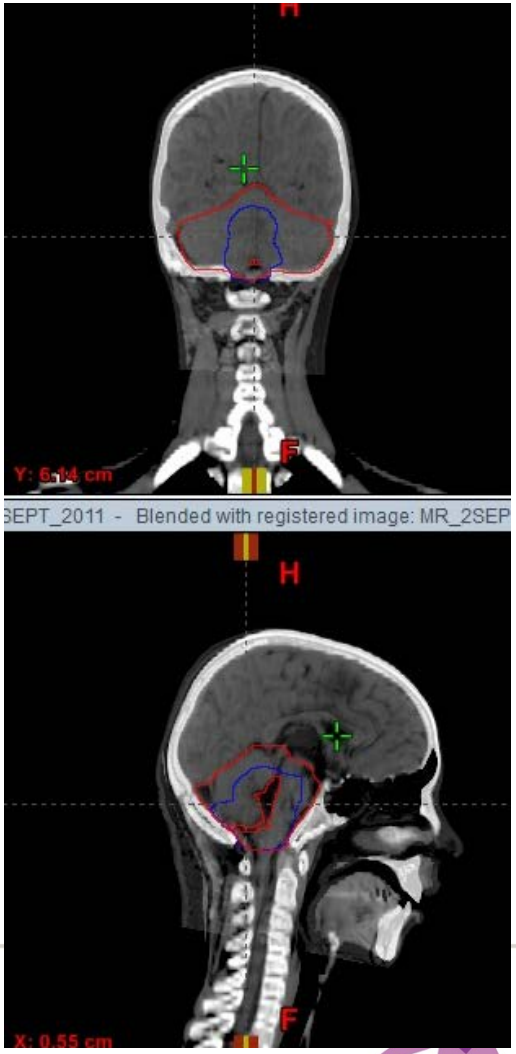




Whole PF vs tumour bed boost: ongoing trials

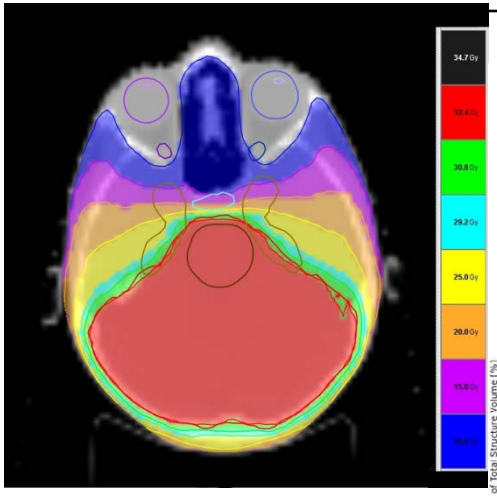
Benefit: less dose to surrounding healthy tissues

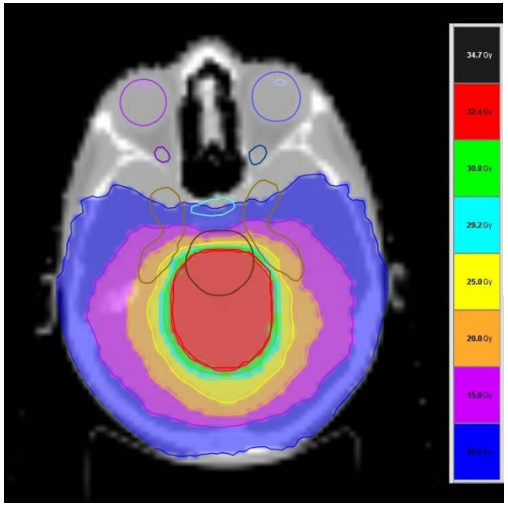


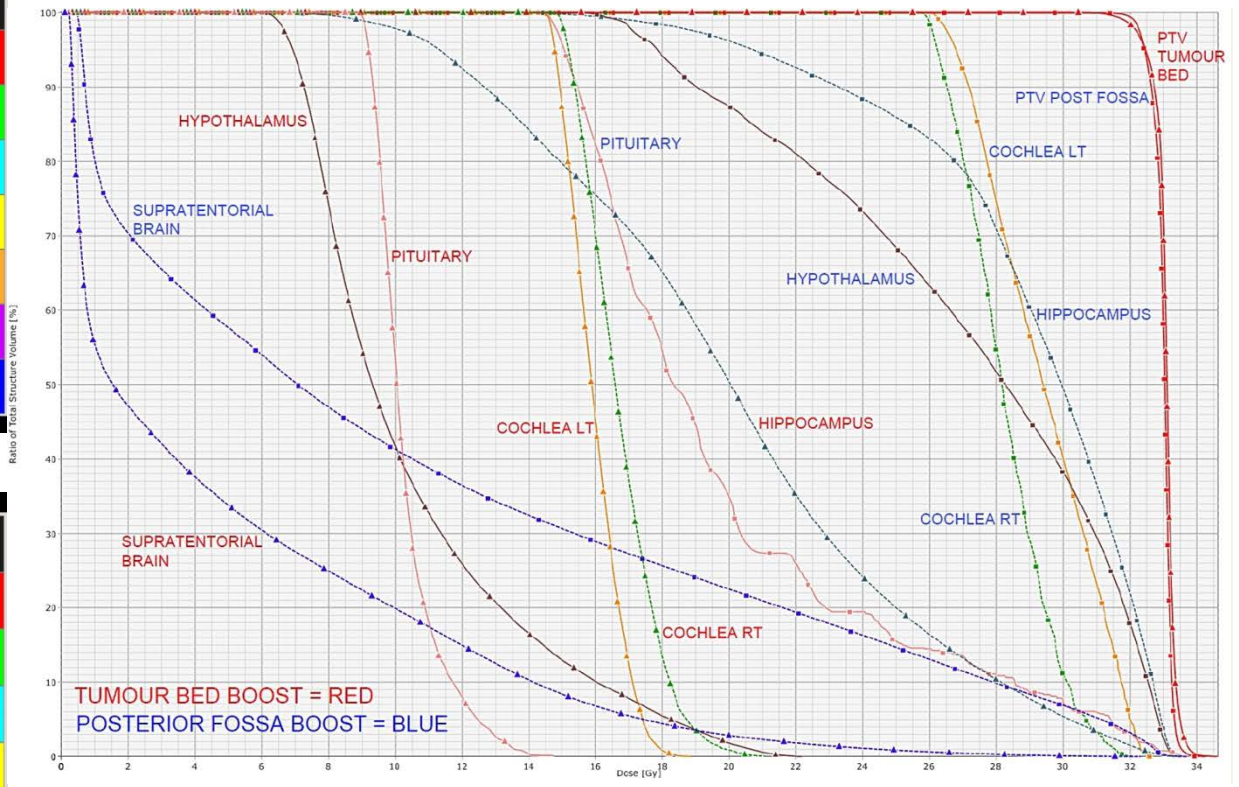


ESTRO School

Whole PF vs tumour bed







+ med dose of 15.4Gy to cochlea

+ med dose of 6.4Gy to hypothalamus

+ med dose of 18.4Gy to R hippocampus

+ med dose of 2.4Gy to R supratentorial brain

Reduced volume tumour bed boost

	Years of study	Number of patients	CSI/ whole PF dose	Treatment volume for tumour bed boost	Isolated failures in PF outside boost volume
Merchant 1999	1994-1996	10	0-36Gy	TB + 1-2 cm + 0.5 cm	0
Wolden 2003	1994-2002	32	23.4-36Gy	TB + 1-2 cm + 0.5 cm	1 (@ 84 mo)
Douglas 2004	1994-2001	33	23.4Gy	TB + 2 cm to block edge	0
Carrie 2005	1998-2001	48	36Gy/36 fx (HFRT)	TB + 1.5 cm	0
Merchant 2008	1996-2003	86	23.4Gy/36 Gy	TB + 2 cm + 0.5 cm	max 3

Limit volume boost (ACNS0331)

- 3D planning mandatory using CT-MRI co-registration
- GTV based on pre-op extent of disease, taking account of shifts that have taken place since surgery i.e., any macroscopic residual + wall of surgical cavity
- Margin for CTV of 1.5 cm

Medulloblastoma: the management

- **High risk medulloblastoma**

Medulloblastoma

- High risk: intensify treatment/use novel treatment approaches

Historic outcome for conventional RT and chemotherapy for M2-M3 MB

Study	Entry Period	Outcome at 3 years
SIOP 2	1984-1989	43% EFS
HIT-91	1991-1997	30% PFS
PNET-3	1992-2000	39.7% EFS

Milan HART Study

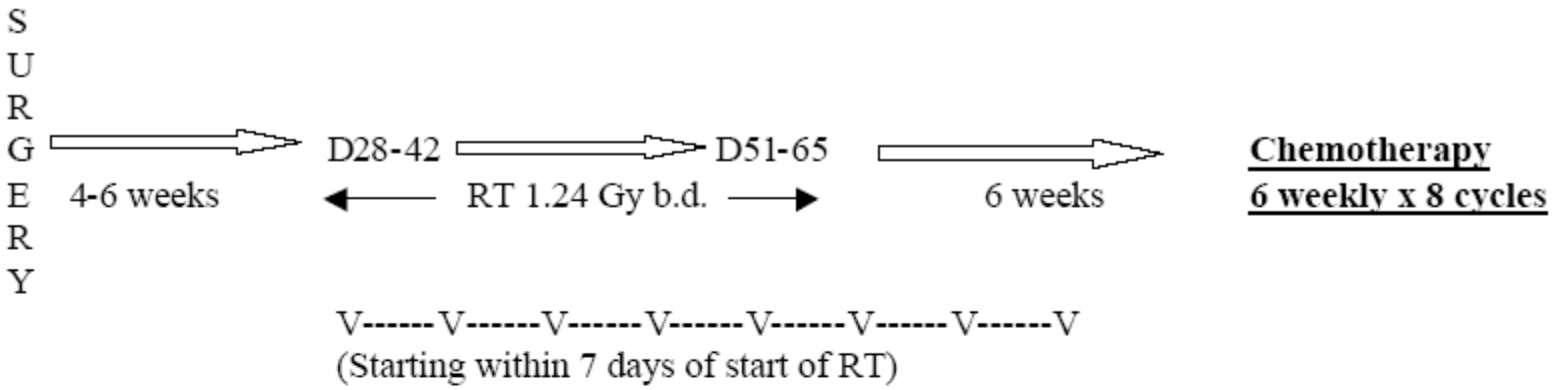
- 1998-2007
- 33 pts (M1 9, M2 6, M3 17, M4 1)
- High dose chemotherapy approach
- HART: CSI 39 Gy; 1.3 Gy bid
  posterior fossa boost up to 60 Gy; 1.5 Gy bid

- 7 pts aged < 10 yrs who achieved CT after chemo received a lower dose to the neuraxis (31.2 Gy)

- Median 82 months follow-up

- 5 yr EFS 70%
- 5 yr PFS 72%
- 5 yr OS 73%

UK HART: High Risk



***Radiotherapy (RT)**

Brain – 39.68 Gy in 32 fractions of 1.24 Gy over 16 treatment days
Spine - 39.68 Gy in 32 fractions of 1.24 Gy over 16 treatment days
Primary tumour boost – 22.32 Gy in 18 fractions of 1.24 Gy over 9 treatment days
Total dose to primary – 62.00 Gy in 50 fractions of 1.24 Gy
Boost to metastases – 9.92 Gy in 8 fractions of 1.24 Gy over 4 treatment days

Chemotherapy

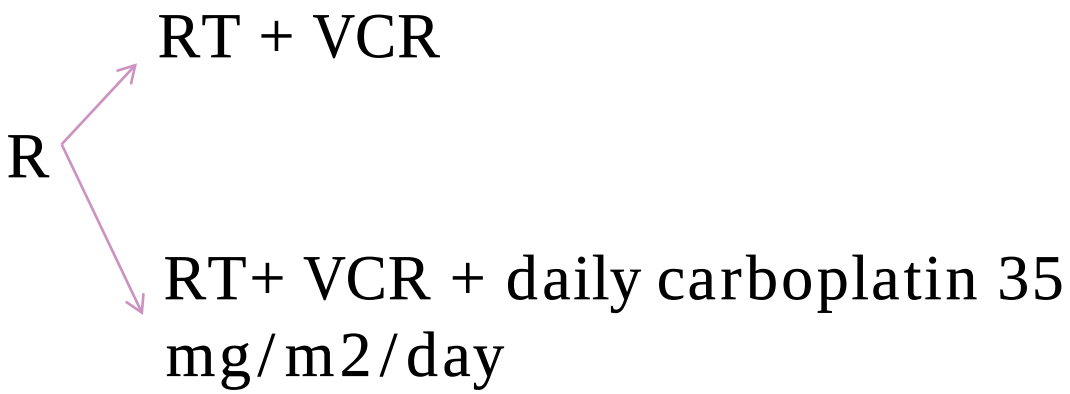
V – Vincristine 1.5 mg/m^2 (maximum 2 mg)
C – Lomustine (CCNU) 75 mg/m^2
P - Cisplatin 70 mg/m^2

Weeks					
1	2	3	4	5	6
V------	V------	V------	------	------	------
C					
P					

ESTRO School

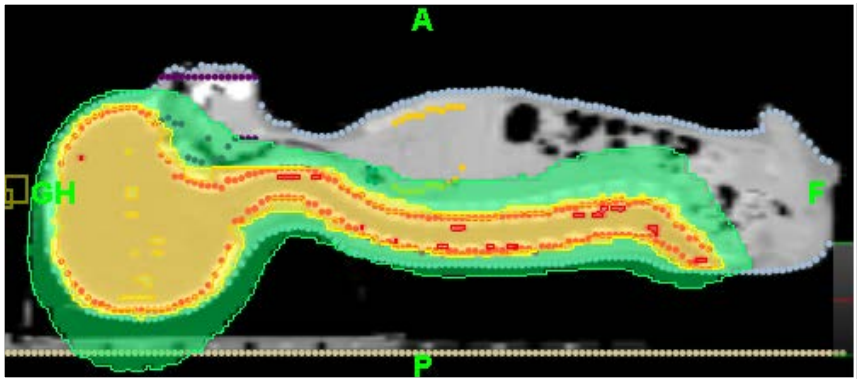
COG ANS0332 - Radiosensitisation study

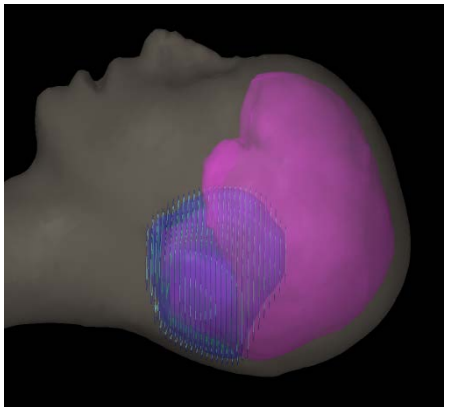
- Opened March 2007
- Planned recruitment 300
- RT: CSRT 36 Gy, post fossa 55.8 Gy
- Maintenance chemo cisplatin/VCR/Cy



Radiotherapy dose

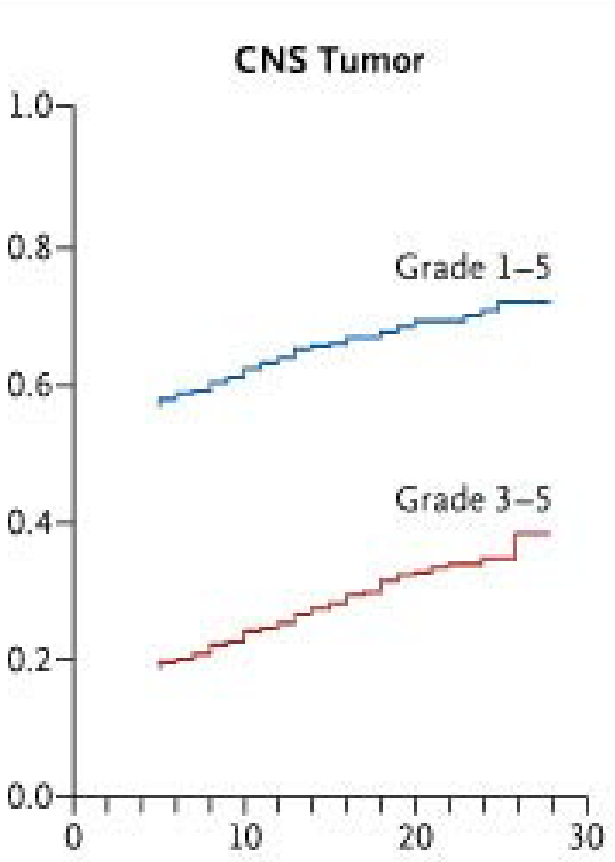
- CSI
  - High risk
    - 36(-39.4)Gy/20(-23) daily fractions of 1.8Gy
- Primary site
    - Total dose 54-55.8Gy





Long-term complications of treatment

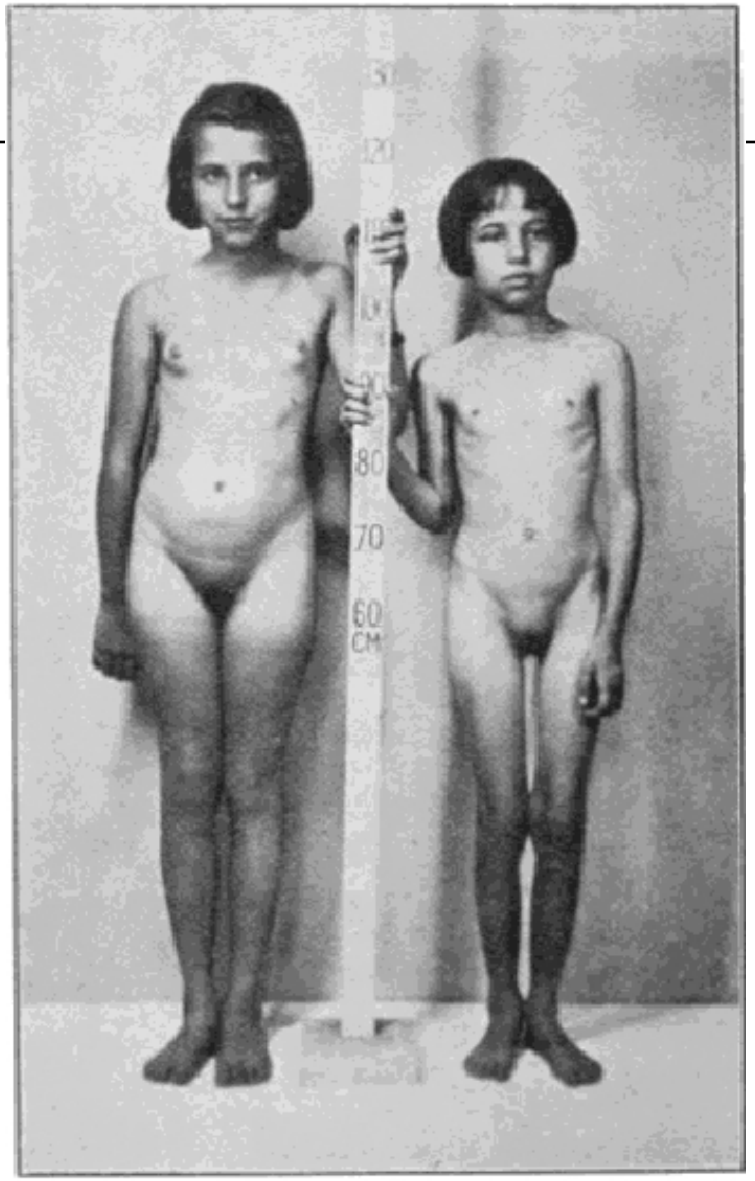
- Overall 62.3% of survivors of childhood cancer have at least one chronic health problem and 27.5% have a severe/life-threatening one
- Survivors of CNS tumours most likely to be functionally impaired



Oeffinger, N Engl J Med 2006

- MB poorest overall health of all CNS tumours
- Multiple health problems
  - Very frequent
  - Some related to tumour, surgery
  - Worse with chemo-RT than with RT alone

Late effects of CSI



Late toxicity related to CSI

- Due to radiotherapy to the brain
  - Neuro-cognitive deficits/effects on social interactions
  - Hypopituitarism
  - Alopecia
  - Cataracts
  - Hearing loss
- Due to radiotherapy to the spine
  - Short stature
  - Primary hypothyroidism
  - Impaired lung function
  - Effects on the heart
  - Primary ovarian failure
- Both
  - Second cancers…

How can we reduce the risks associated with CSI?

- Second cancers
  - Patients with MB at highest risk of a 2nd malignancy of all CNS tumours
    - Actuarial risk at 20-30 years 4-10%
  - Especially
    - 2nd CNS tumour (glioma, meningioma)
    - Soft tissue sarcoma incl desmoid
    - Thyroid
    - Skin cancers
- Risk reduction
  - Reduce dose outside the target
    - New techniques

IMRT for the spine field

- IMRT reduces high dose exposure to all organs at risk:
  - Thyroid
  - Lungs
  - Heart
  - Liver
  - Kidneys
  - Ovaries

- ... at the expense of increased low dose exposure

Concluding remarks

- Radiotherapy is an indispensable component in medulloblastoma treatment
- CSI is a complex treatment that for optimal results must be done properly
- Reduced dose to OARs is possible using new techniques
- Tremendous progress in medulloblastoma treatment over the last 20 years

Management of low grade glioma in children

Darren Hargrave

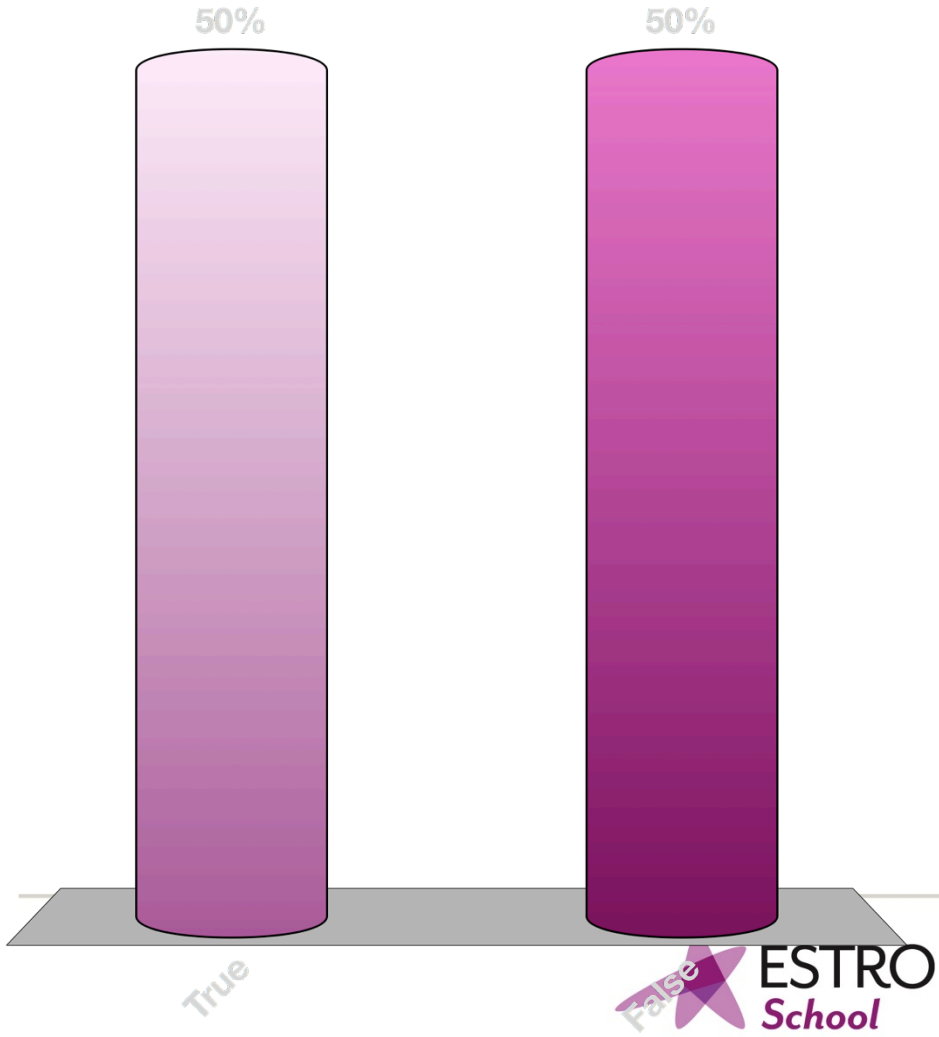
Consultant Paediatric Oncologist,

Neuro-oncology & Experimental Therapeutics

Great Ormond Street Hospital. London, UK.

Pathology of LGG in adults and children is usually the same!

A. True
B. False

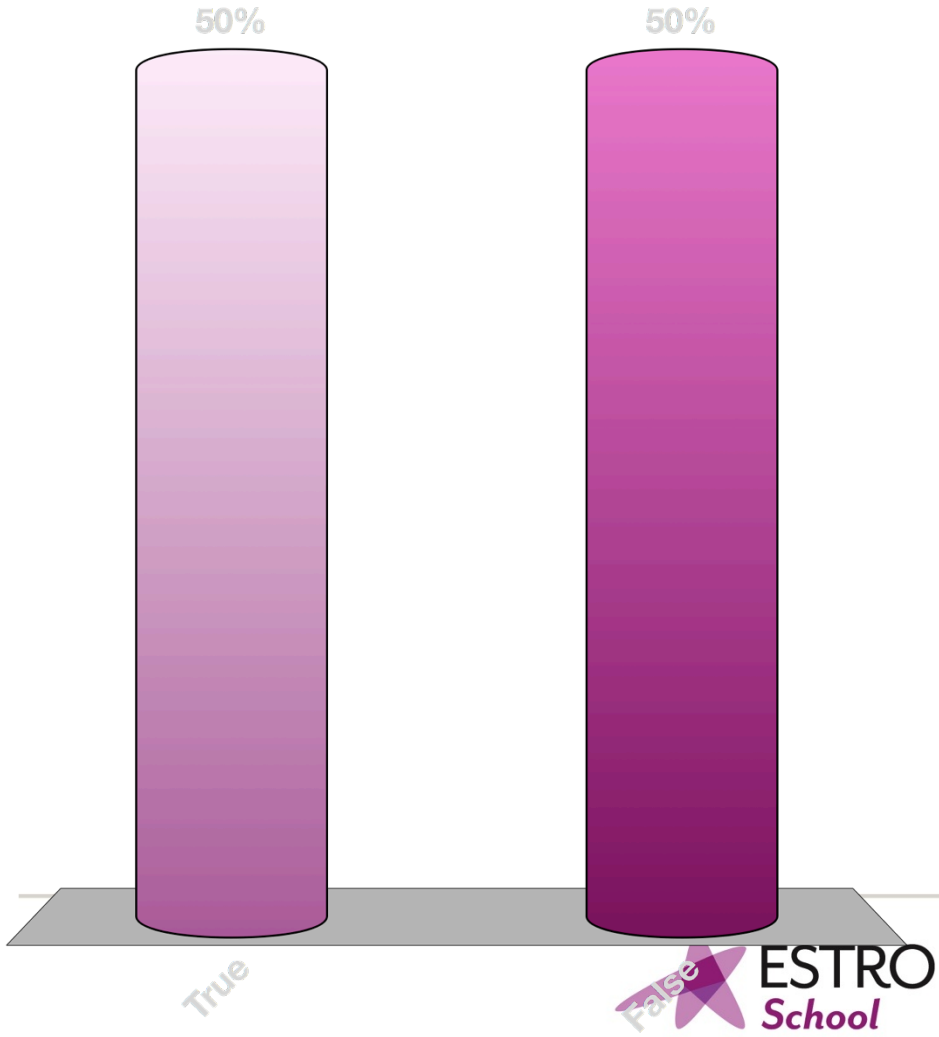


ESTRO School

Most common location for childhood LGG is cerebral hemisphere

A. True

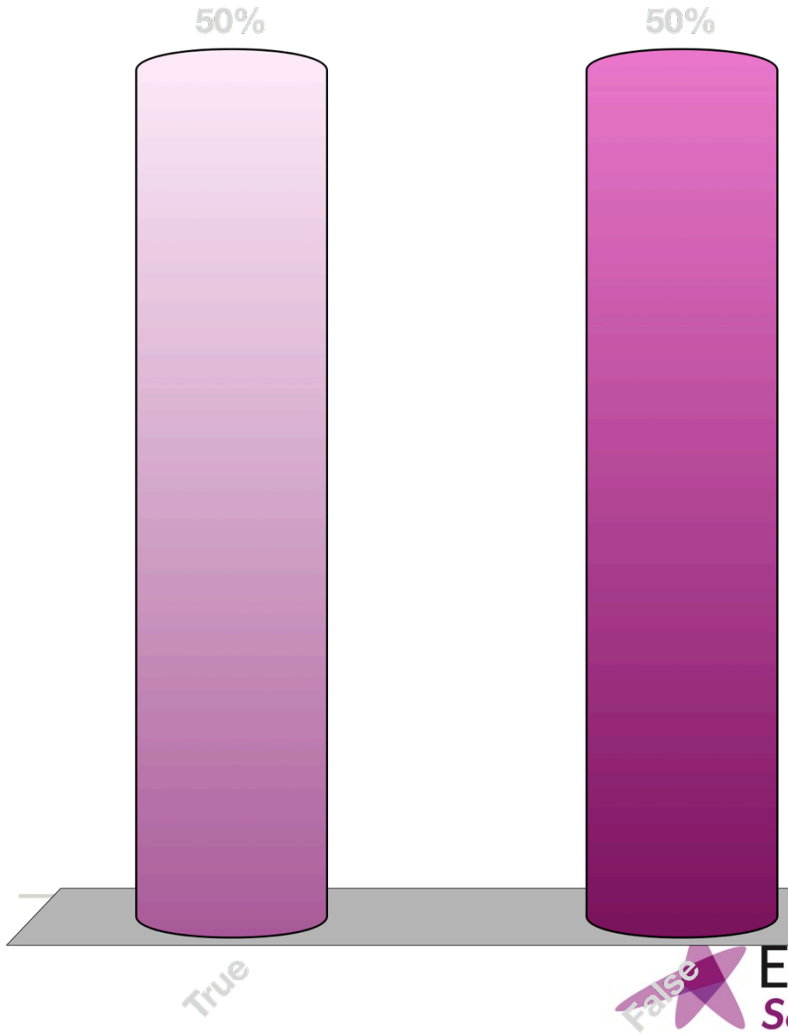
B. False



ESTRO School

LGG in children <1 year has a better prognosis!

A. True
B. False



ESTRO School

Malignant transformation rate in childhood LGG is ~30%.

A. True

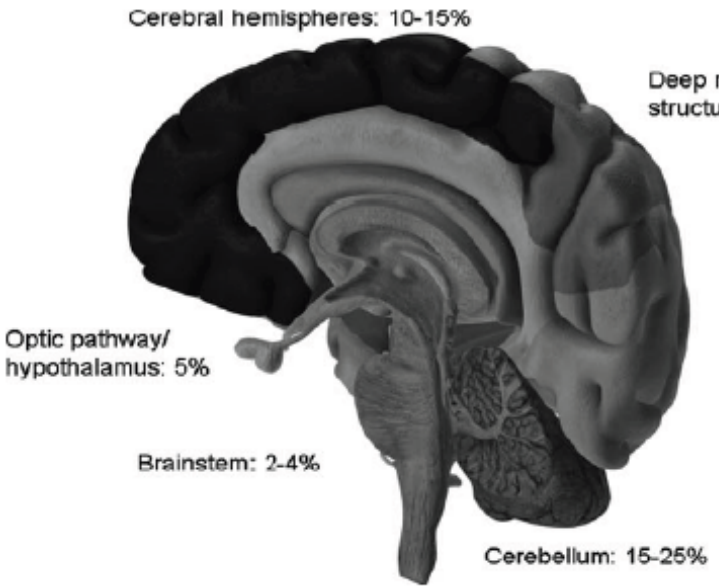
ESTRO School

Low Grade Glioma in Children

- Heterogeneous set of tumors characterised by an indolent clinical course

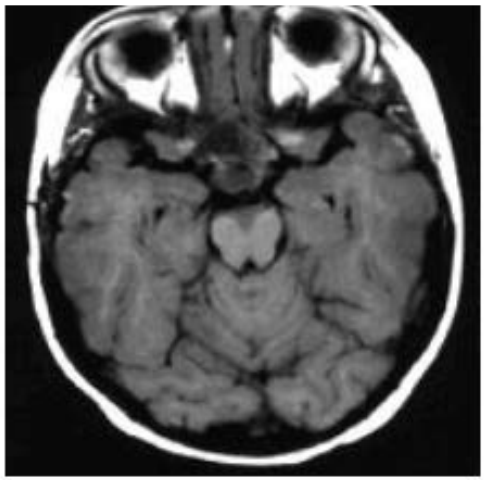
- They account for one third of all CNS tumours in the pediatric age group

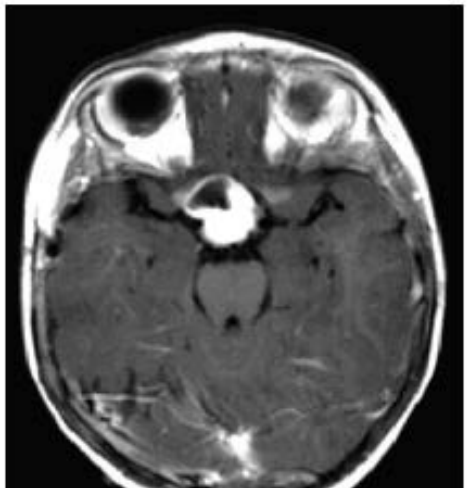
- The 2 most common low-grade glioma histologies in children are the pilocytic (WHO grade 1) and diffuse fibrillary astrocytoma (WHO grade 2)

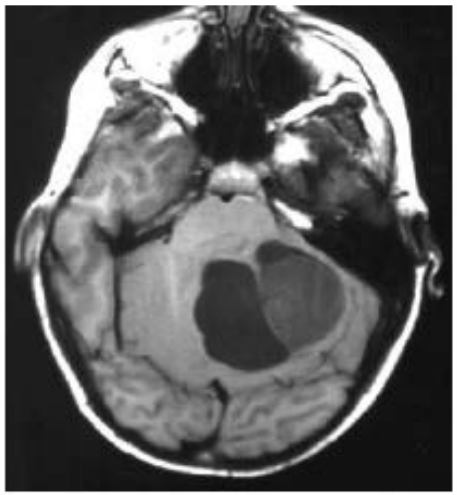


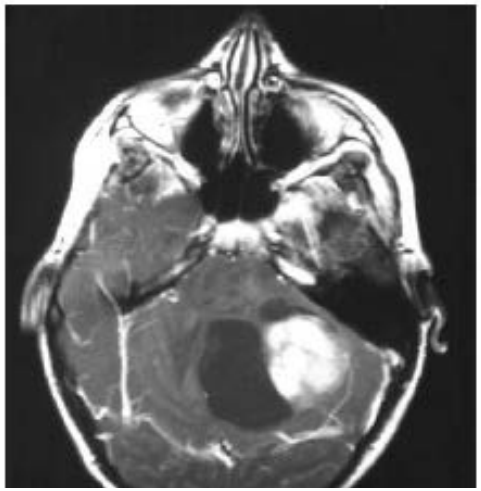
Distribution by location of LGGs

Low Grade Glioma in Children





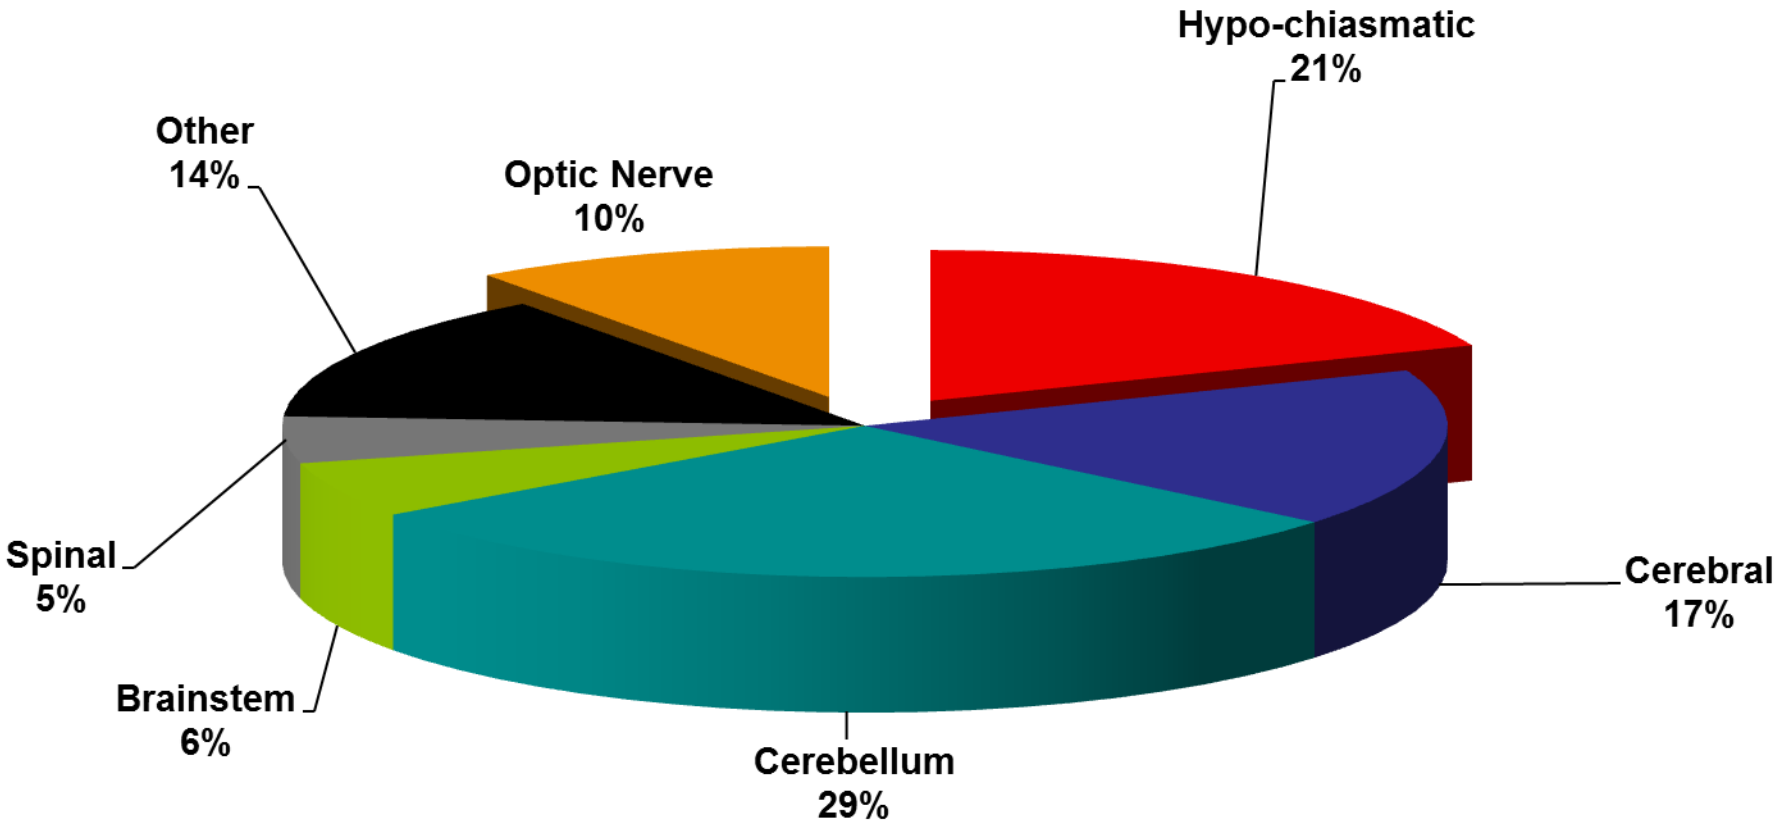




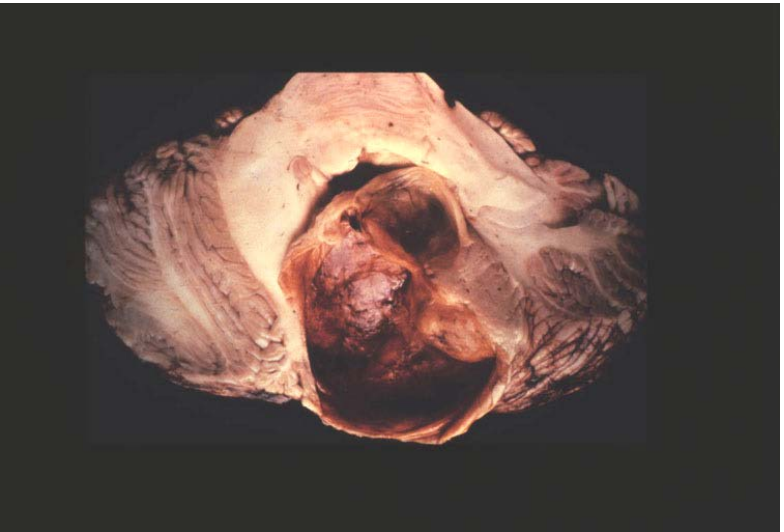
Childhood LGG

30-40% of CNS tumors

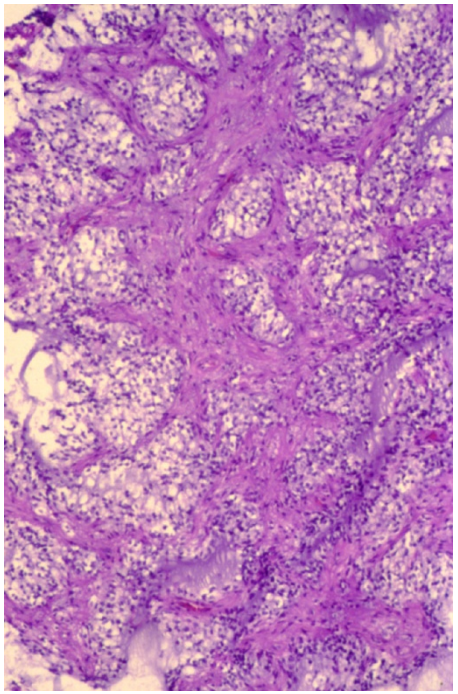
Primary Site of Low Grade Glioma

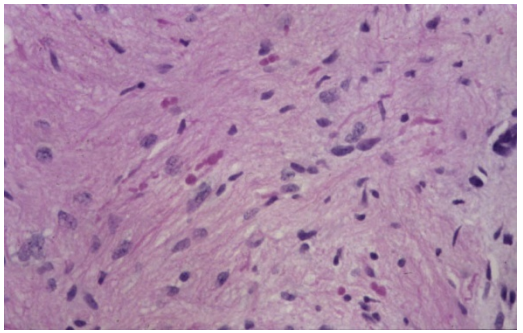


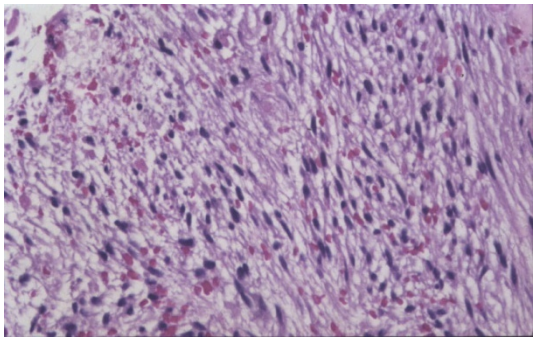
Low Grade Glioma



Pilocytic astrocytomas





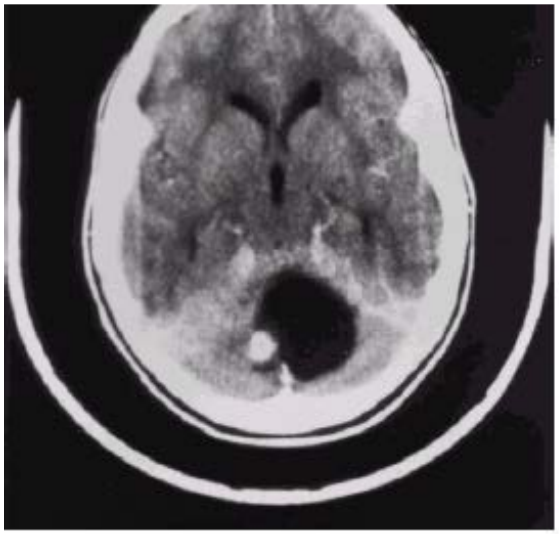


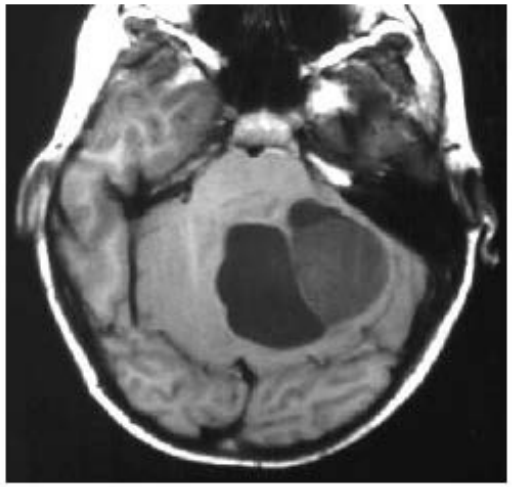
Tumor of cerebellum, often with cyst, biphasic, Rosenthal fibers, piloid cells

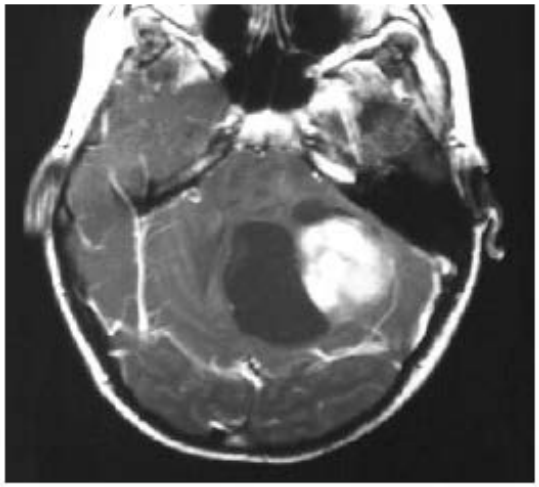
Juvenile Pilocytic Astrocytoma

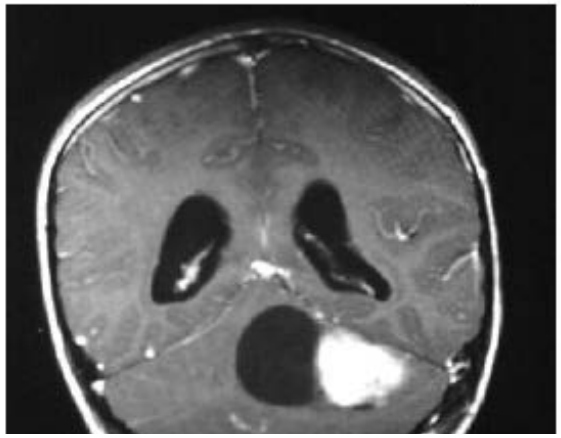
- Most common type in children
- Seen predominantly in younger children (median ~ 4 years)
- Usually well circumscribed, often partially cystic, with little oedema, no mass effect
- Enhance brightly and uniformly with contrast material
- Gross total resection often possible

Low Grade Glioma in Children

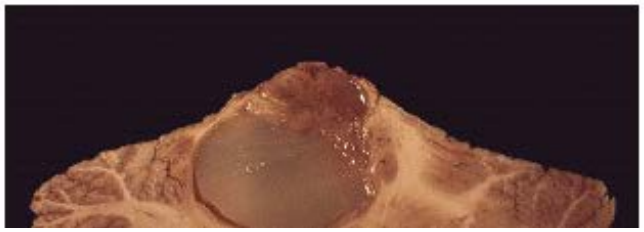


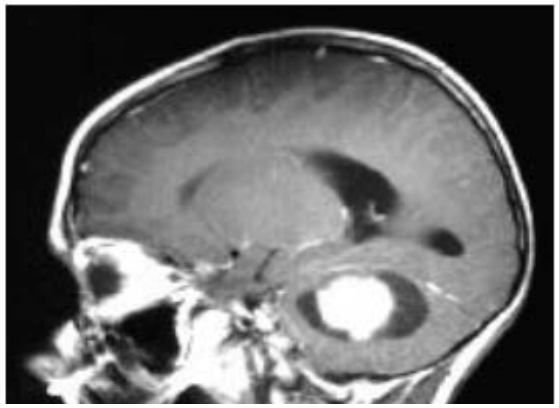






JPA

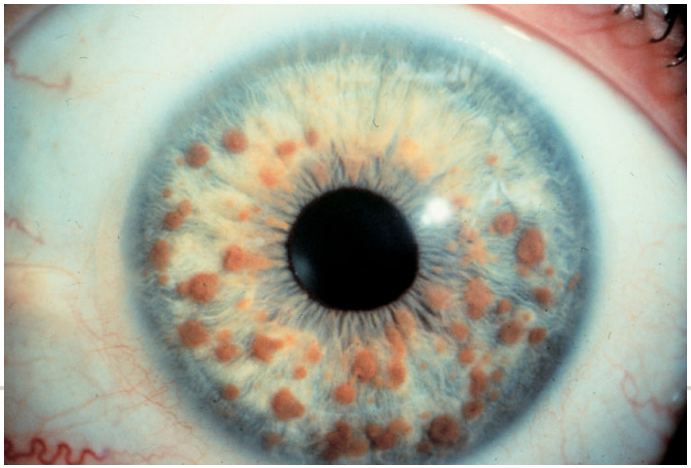




Low Grade Glioma in Children

- 30-40% of paediatric brain tumours
- Heterogeneous pathologically, anatomically, clinically and biologically
- < 5% present with leptomeningeal metastases
- Frequently protracted clinical course
- Balance between anti-tumour effects and long-term morbidity of therapy

Aetiology of Childhood LGG



NF-1

Recurrent somatic alterations of *FGFR1* and *NTRK2* in pilocytic astrocytoma

David T W Jones[1,39], Barbara Hutter[2,39], Natalie Jäger[2,39], Andrey Korshunov[3,4], Marcel Kool[1],

NATURE GENETICS VOLUME 45 | NUMBER 8 | AUGUST 2013

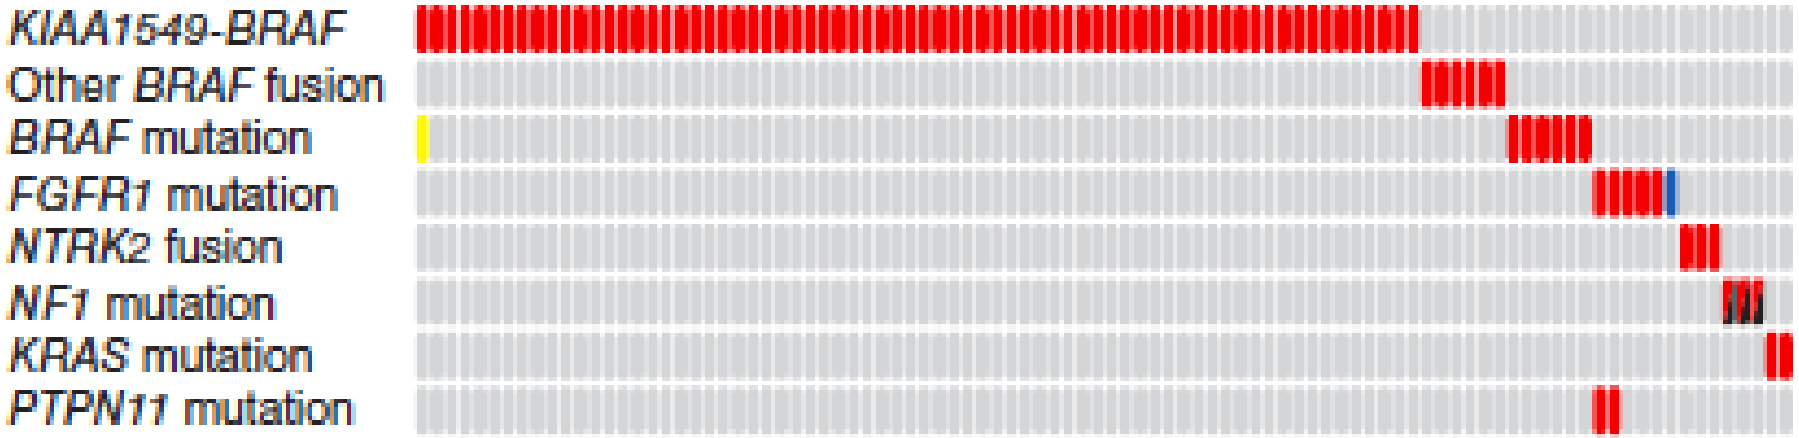

Figure 4 Summary of MAPK pathway alterations in pilocytic astrocytoma.

Surgery in LGA

- Surgery is the mainstay of treatment
- Advances in neurosurgical techniques including computer-assisted resections have resulted in much higher rates of complete resection than in the past, even for tumours in locations previously considered inaccessible (thalamus, brain stem)
- EFS and OS after complete resection 90-100%

Pylocitic astrocytoma- Management

- Surgery remains the mainstay of therapy and GTR is the most consistent prognostic factor for prolonged PFS and OS

- Adjuvant treatment? (CT/RT)

- In case of GTR → no further therapy (10-year OS rates of 90% or greater and rare tumor recurrences)

- In case of PTR → a «wait and see policy» with follow-up brain MRI at 3-6-month intervals and adjuvant treatment postponed until there is either measurable progression by neuroimaging or clinical symptoms

- In case of biopsy/no surgical approach → observation until radiographic progression if there are minimal clinical symptoms

Low grade glioma in children

- Importance of recognizing behaviour specific to particular tumor type
- Timing of intervention
- Role of adjuvant therapy following incomplete resection
- Choice of modality (Chemo/RT) for adjuvant therapy
- Issues specific to RT (target volume, treatment technique and dose)

Criteria for non-intervention in LGA

- Asymptomatic and non-progressive lesions in patients with neurofibromatosis

- Lesions in the tectal region

Eras of LGG Management
SIOP Studies

- [Pre-LGG1]
- LGG1
- LGG2
- Current/Future

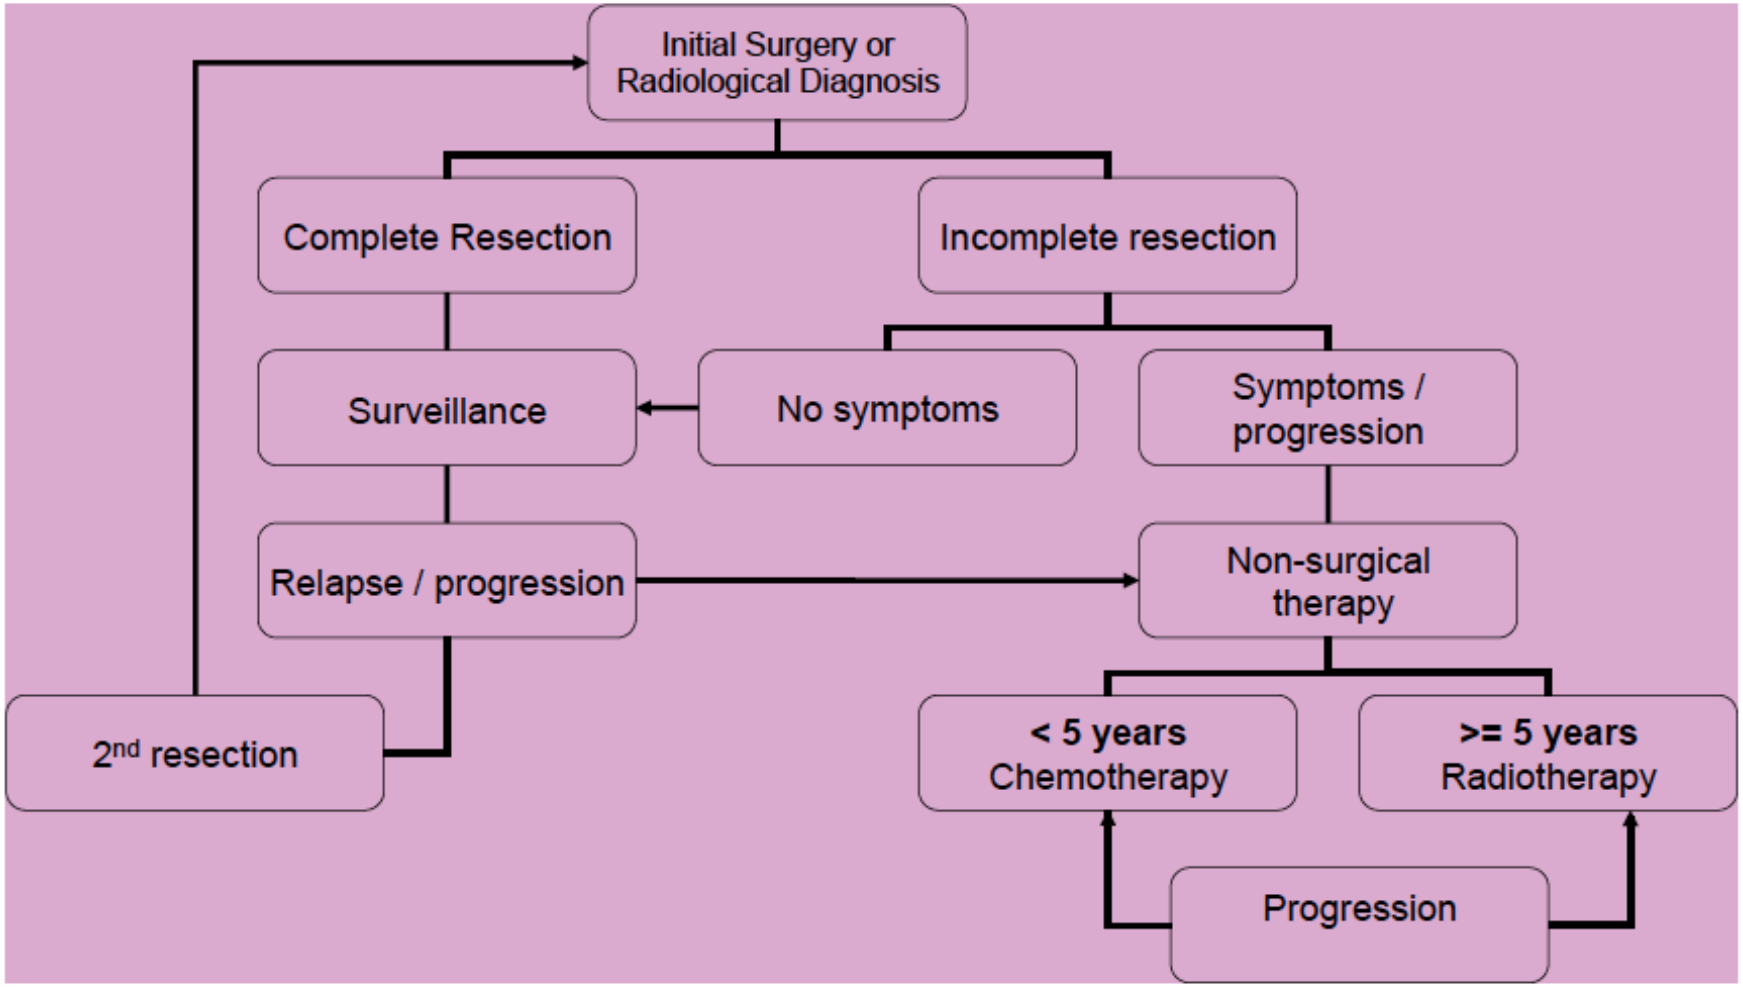
LGG1

October 1996 – March 2004

LGG1

- 1996 – 2004
- International Consortium
  - Germany, Italy, UK
- New paradigm in LGG management
- Standardised schema:
- Initial period of observation after surgery or radiological diagnosis (based on typical appearances of optic pathway glioma)
- Standardised RT and chemotherapy protocols

LGG1 Schema

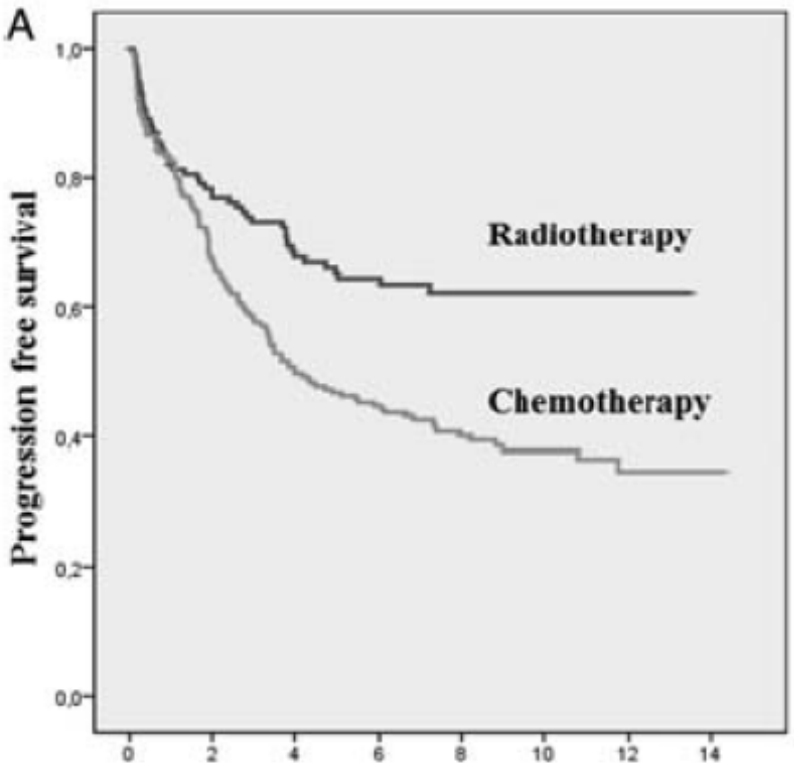


ESTRO School

LGG1 - RT

- MR imaging – T2
- 1 cm margin for CTV (2 cm if only CT scan used)
- Intracranial primaries: 54 Gy in 30 fractions of 1.8 Gy
- Spinal primaries: 50.4 Gy
- Children aged <5: 50 Gy in 30 fractions of 1.67 Gy

LGG1 German Cohort



- Ten-year PFS 62% following RT and 44% following chemotherapy
- 61 of 216 chemotherapy patients received RT 0.3–8.7 years after initial diagnosis
- Approximately 75% of surviving chemotherapy patients had not received RT at time of analysis

ESTRO School

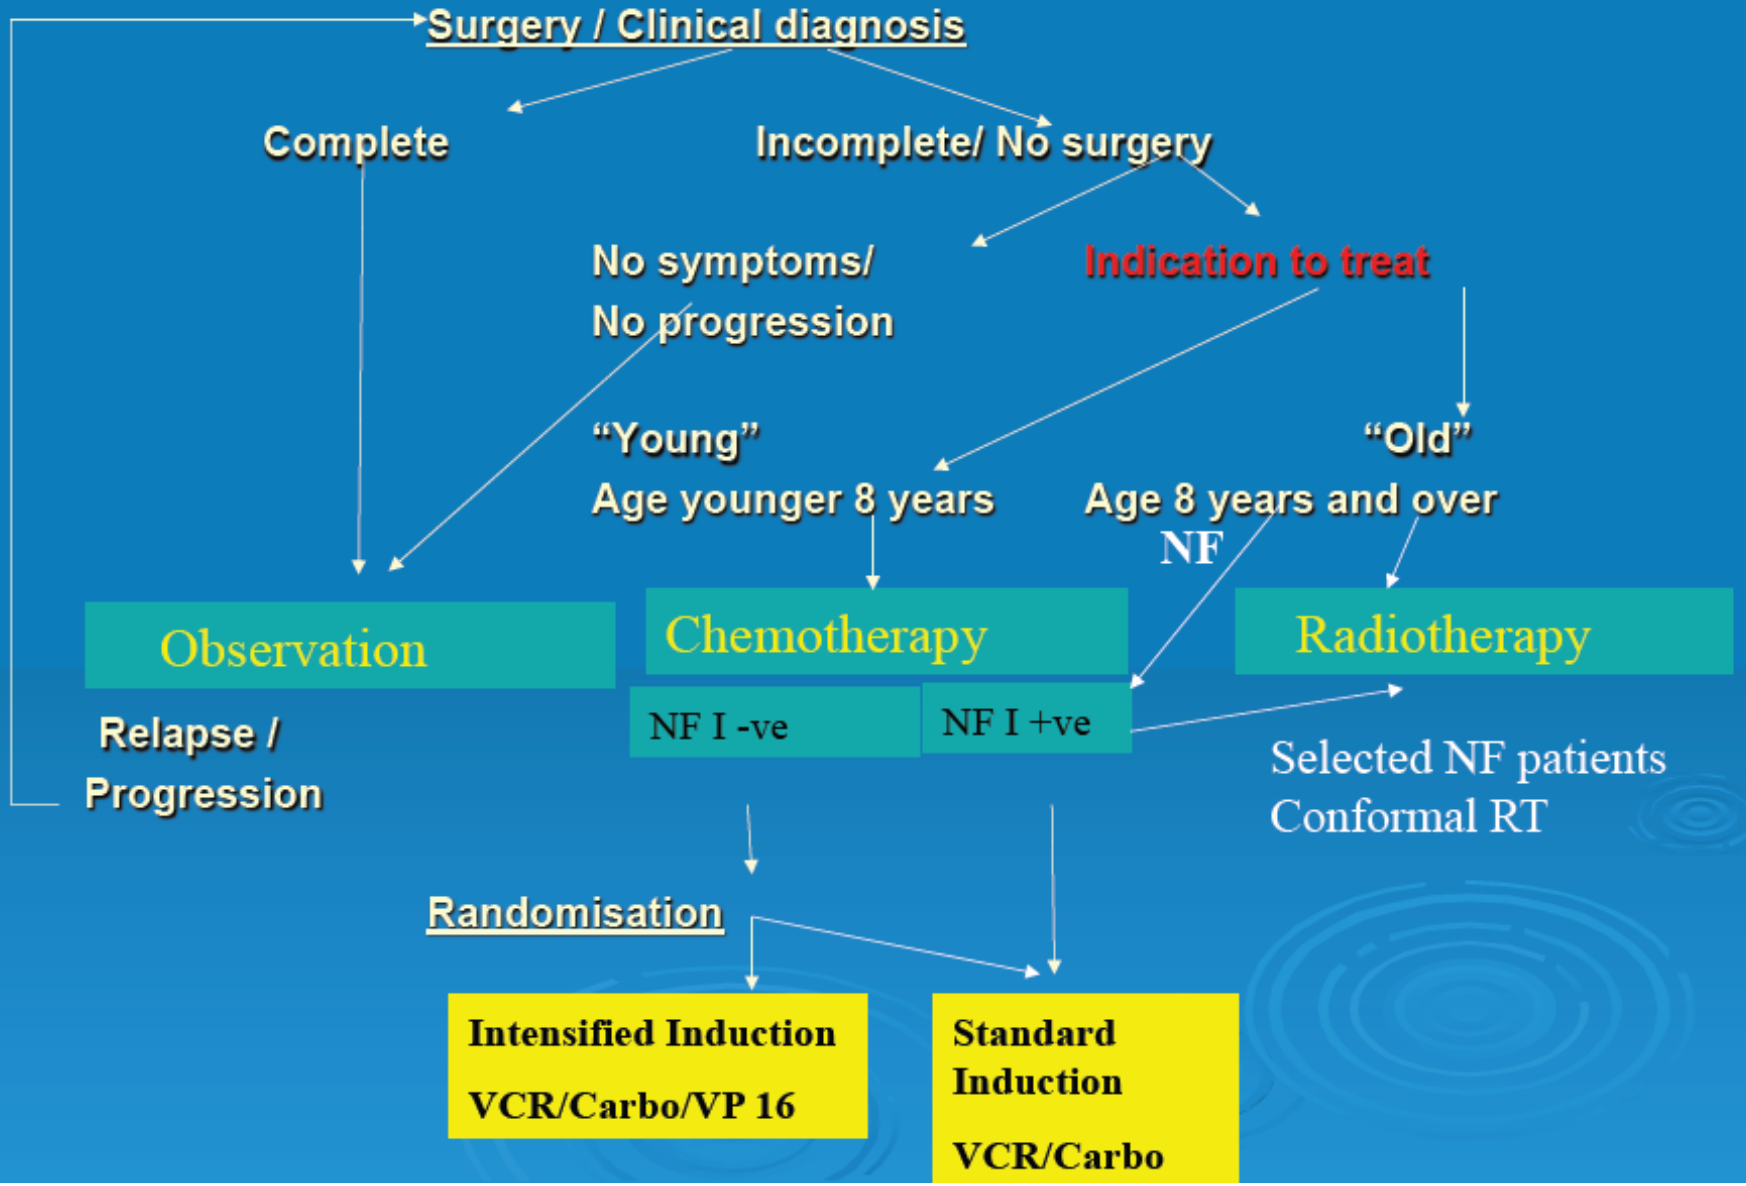
LGG1 German Cohort

- Analysis of clinical factors for progression and survival
- LGG1 patients recruited October 1996 – March 2004
- Main tumour location: supratentorial midline (40.4%)
- Main histology: pilocytic astrocytoma (67.9%)
- Following a median observation of 9.3 years, 10-year OS was 94% and 10-year EFS was 47%
- Infants with or without diencephalic syndrome and dissemination bear the highest risk for death and progression following diagnosis or treatment

LGG2 Study Aims

- Opened 2004
- Closed 2012
- Built upon achievements of LGG1
- Standardised approach for LGG
- Initial observation policy
- Non-surgical treatment for radiological progression or severe symptoms (RT age > 8)
- **Chemotherapy Study:**
- Randomisation between Carboplatin +/- Etoposide with the aim of increasing PFS

Overview of SIOP LGG 2003 treatment strategy



LGG2 RT Protocol Aims

- To utilize modern treatment techniques to reduce the integral radiation dose to normal tissue
- To record the integral dose to tumor and normal tissue as a basis for future assessment of QoL of long-term survivors
- To assess response of tumour and clinical symptoms to radiotherapy with respect to primary treatment or after chemo failure
- To assess the pattern of relapse, when using modern treatment techniques
- To assess the efficacy of CSRT for metastatic disease

ORIGINAL REPORT

Phase II Trial of Conformal Radiation Therapy for Pediatric Low-Grade Glioma

Thomas E. Merchant, Larry E. Kun, Shengjie Wu, Xiaoping Xiong, Robert A. Sanford, and Frederick A. Boop

Materials and Methods

Between August 1997 and August 2006, 78 pediatric patients with LGG and a median age of 8.9 years (range, 2.2 to 19.8 years) received 54 Gy CRT by using a 10-mm CTV and by targeting with systematic magnetic resonance imaging (MRI) registration. Tumor locations were diencephalon (n = 58), cerebral hemisphere (n = 3), and cerebellum (n = 17). Sixty-seven patients had documented or presumed WHO grade 1 tumors, 25 patients had prior chemotherapy, and 13 patients had neurofibromatosis type 1.

Conclusion

This large, prospective series of irradiated children with LGG demonstrates that CRT with a 10-mm CTV does not compromise disease control. The results suggest that CRT should be delayed in young patients to reduce the risk of vasculopathy.

Socialization	57	98.7889	−0.0559	95.4349	
Visual auditory learning	30	92.2834	0.1768	102.8914	< .0001

NOTE. Instruments for each evaluation are as follows: IQ, Bayley second edition; Wechsler Preschool and Primary Scale of Intelligence revised; Wechsler Intelligence Test for Children third edition or Wechsler Adult Intelligence Scale revised, as appropriate for age; math, reading, and spelling: Wechsler Individual Achievement Test; memory: California Verbal Learning Test: Child Version; behavior problems, externalizing, internalizing, activities, school, socialization: Child Behavior Checklist; communication composite, daily living, socialization: Vineland Adaptive Behavior Scale; and visual auditory learning: Woodcock Johnson revised, visual auditory learning subtest.

Abbreviations: CRT, conformal radiation therapy; IQ, intelligence quotient.

*Score = baseline + ([change per month] × time).

†*P* value for change per month.

‡Increasing scores represent worsening performance.

Five years after CRT, only the decline in spelling scores was clinically significant

Influencing factors

RT related

- Dose: Total tumour dose, but dose to critical structures more important
- Fraction size: Hypo-fractionation or hyper-fractionation
- **Volume**: Whole brain Vs CSI Vs Partial brain
- Technique: Conformal, margins, accuracy of execution
- Energy: Photons Vs particle beam…..Telecobalt
- Planning: Dose constraint models to minimise cognitive impairment

Proton Therapy

Advantages

⇒ **reduction of integral dose to organs at risk (highly conformal even to irregular tumour shapes)**

⇒ **reduction of late effects is expected (neurocog., endocrin., hearing, sec. malignancies..)**

Disadvantages

⇒ **limited information regarding tumour control rates and reduction of late effects**

⇒ **limited access (will change in future)**

Prospective, european wide studies necessary

Case Report/Case Series

Marked Recovery of Vision in Children With Optic Pathway Gliomas Treated With Bevacizumab

Robert A. Avery, DO, MSCE; Eugene I. Hwang, MD; Regina I. Jakacki, MD; Roger J. Packer, MD

IMPORTANCE Children with optic pathway gliomas (OPGs) frequently experience vision loss from their tumors. Standard front-line treatment using carboplatin-based chemotherapy typically produces only a modest benefit (eg, stabilization or 0.2 logMAR improvement) in visual acuity (VA). Bevacizumab is a monoclonal antibody that targets vascular endothelial growth factor and acts primarily as an anti-angiogenic agent. Recent reports suggest a qualitative improvement in vision after bevacizumab-based treatment in children with OPGs.

OBSERVATIONS We report 4 cases of pediatric OPGs (2 neurofibromatosis type 1–related and 2 sporadic cases) that received treatment with bevacizumab due to progressive VA or visual field (VF) loss despite prior treatment with chemotherapy or proton-beam radiation. All 4 subjects demonstrated a marked improvement in their VA, VF, or both while receiving bevacizumab-based therapy. Three patients had complete resolution of their VA or VF loss in at least 1 eye—2 of whom had previously received bevacizumab therapy.

CONCLUSIONS AND RELEVANCE Given that most patients with OPG-related visual impairment will show modest or no visual improvement with standard treatment, the incorporation of bevacizumab in these cases may greatly improve visual outcomes and should be considered in appropriate clinical situations.

FUTURE MANAGEMENT OF LGG

LO GIC

EUROPE

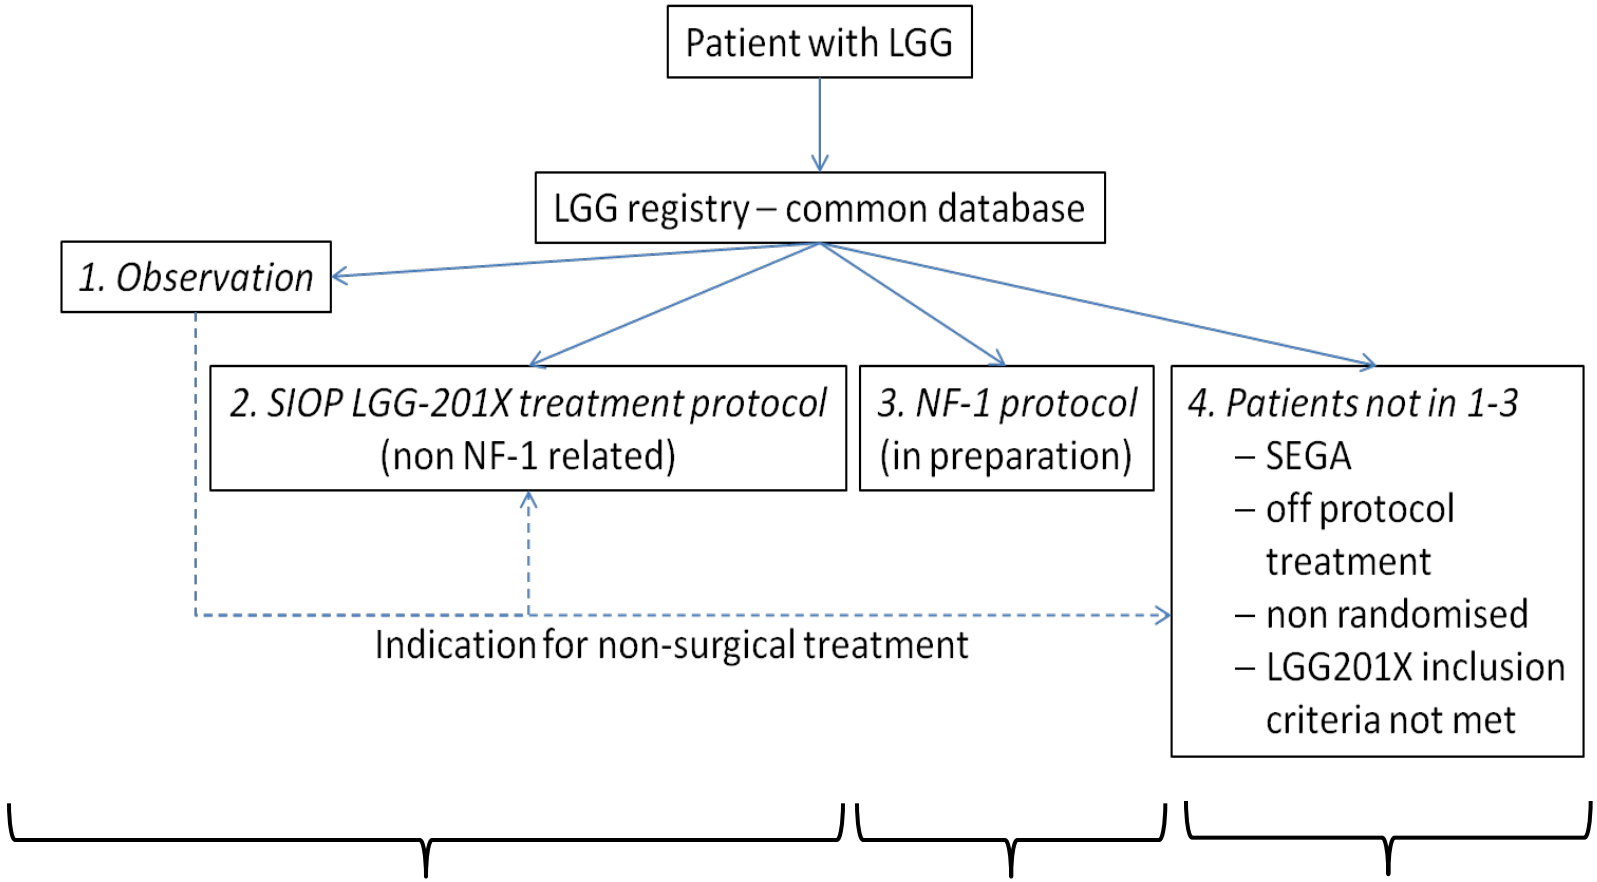
... because function & biology matters

Update
LOGGIC Europe trial

Olaf Witt & Netteke Schouten van Meeteren
on behalf of the SIOP LGG Trial Protocol Working Group

We Care for **all** LGG Patients ….

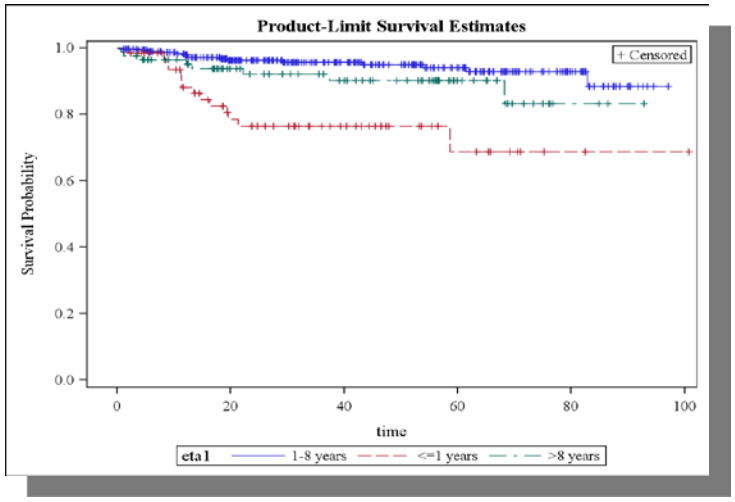
LO GIC
EUROPE

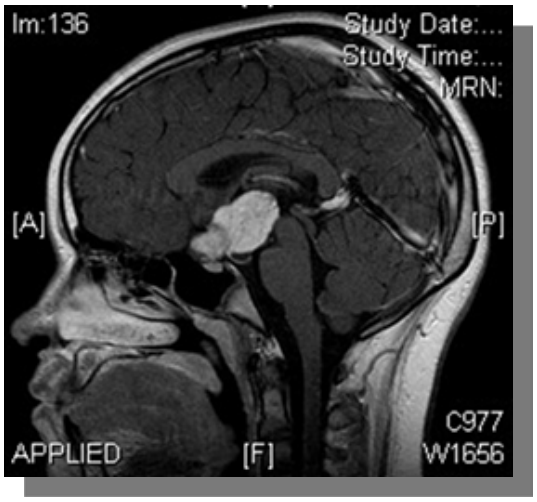


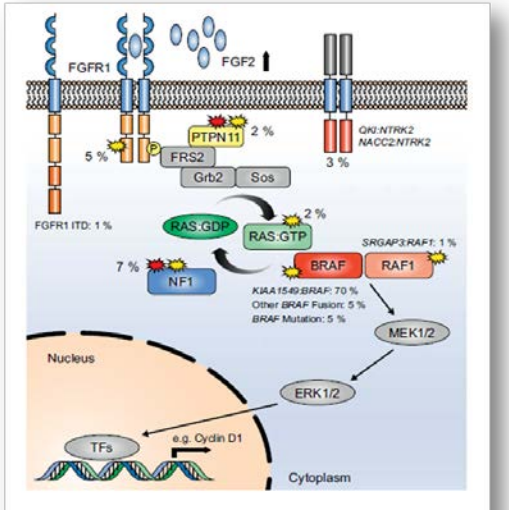
LGG principles….

LO GIC
EUROPE

1. Chronic disease
2. Brain function matters
3. Biology is key







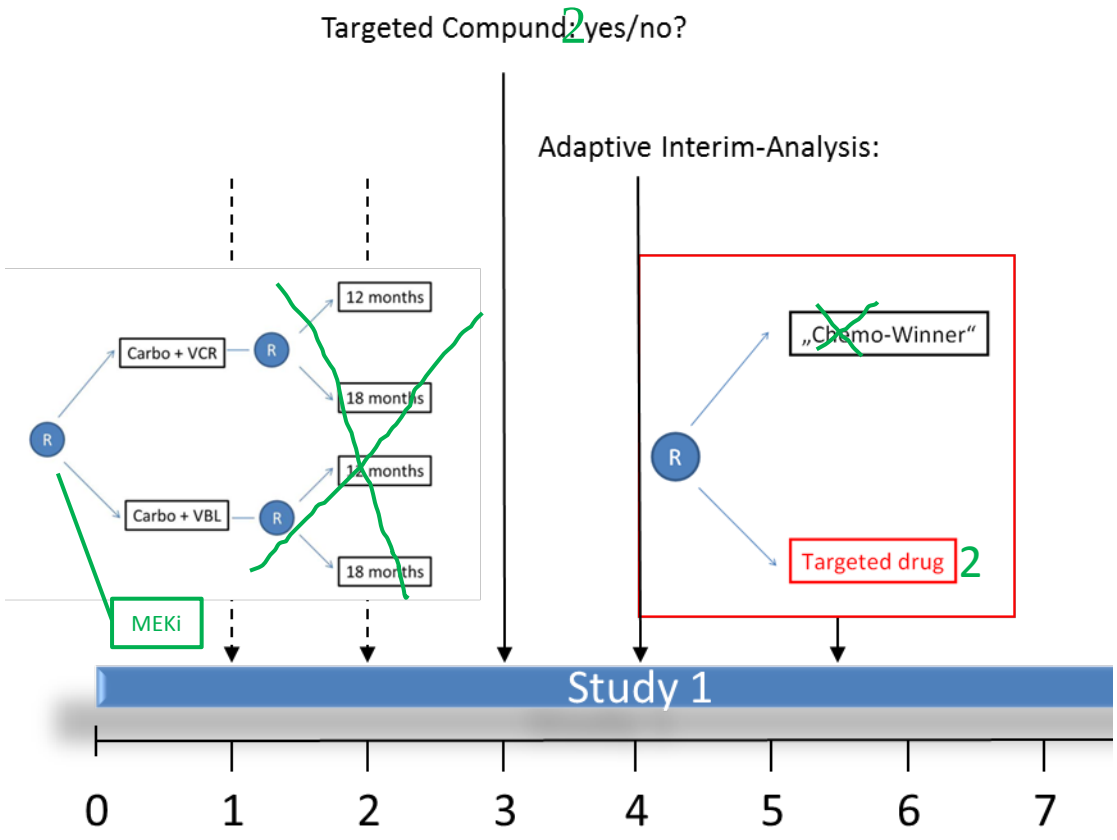
Aims of the Trial

LO GIC
EUROPE

- Reduction of neurotoxicity
- Introduce **combined primary endpoint**:
  + PFS (MRI)
  + neurological function (VABS II)
  + visual function (VA, LogMAR)
- **Biology:** biomarker for prediction of natural course of LGG, prediction response to chemotherapy/targeted therapy
- Introduction of **targeted compounds** asap after promising phase II data

Trial design

LO GIC
EUROPE



Primary objectives:

=> PFS & CNS & visual function

=> biomarker driven prediction of overall course of disease

Secondary objectives:

=> PA, DG2, infants, other LGGs

=> outcome in molecular subgroups

=> neuro-psychology, endocrinology, diencephalic syndrome, neurotox+pharmacogenomics

under discussion:

- Introduce MEKi now
- skip 12 vs 18 months randomization
- keep adaptive design

Key inclusion criteria

LO GIC
EUROPE

- age: 0 -20.99 years
- histologically verified LGG
- collection of **fresh frozen tumor tissue** for biomarker determination **mandatory**.

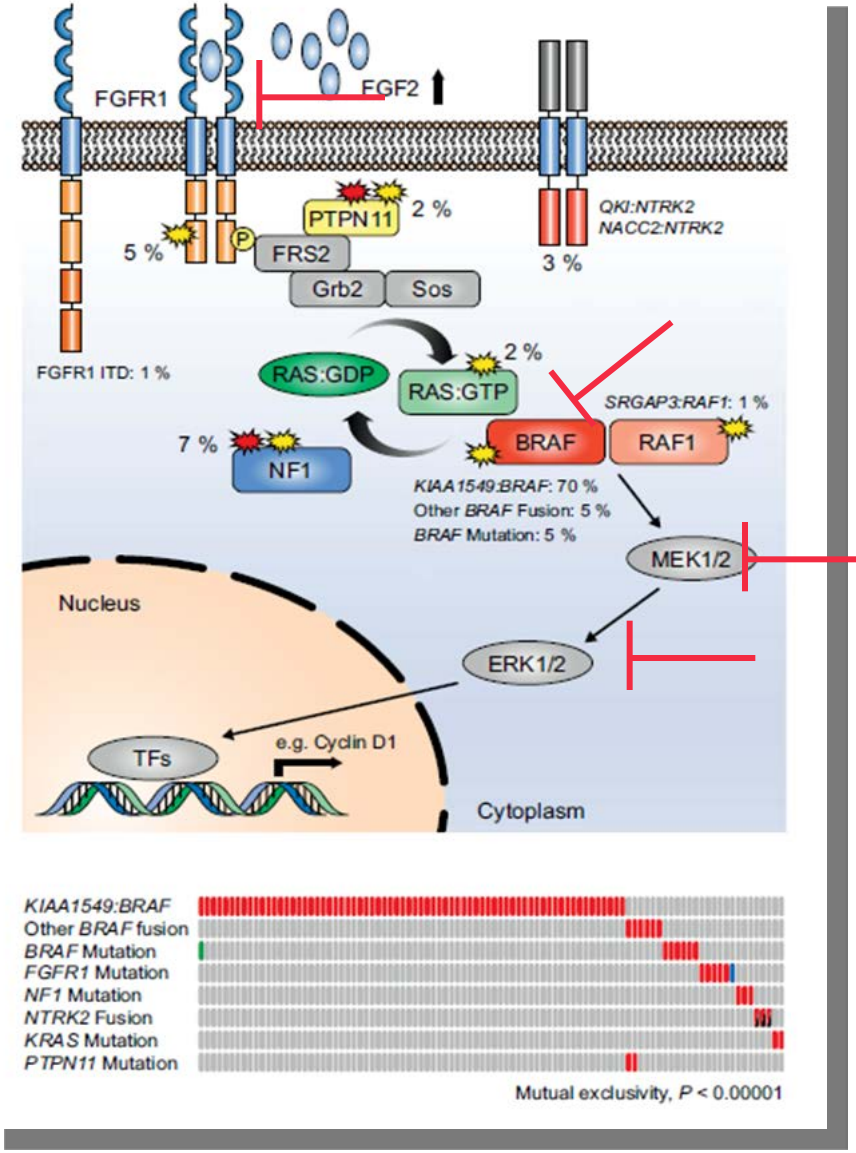
Exception: single cases of stereotactic biopsy in which larger biopsy would impose unacceptable risk to patient

- Indication to start chemotherapy: progressive disease on MRI, neurological function, visual function,
- all infants **< 1 year**

no default first line radiation therapy

Why biomarkers mandatory?

LO GIC
EUROPE



=> Primary endpoint:
multistate model
=> Response prediction
=> Target available at relapse
=> Planning targeted trials
=> No increased risk

Why Vinblastine?

LO GIC
EUROPE

- Single agent activity
  Bouffet et al., JCO 2012, Phase II, n=51, 5 year PFS 42%
- Low neurotoxicity
  => OPG/Thalamic tumors
- Anti-angiogenic activity at low doses
  Klement et al., JCI 2000; Vacca et al., Blood 2004
- Phase I Carbo+VBL
  Jakacki et al., 2011, Carbo +VBL at 400mg/m2/d + VBL 4mg/m2/d
  1 PR=>CR, 6 OR (1PR), 11 SD, 3 PD (total 21)
  7/9 OPG: improvement of vision

Visual acuity (VA) as the primary measure

- Aim to "*measure the **best possible corrected** VA under the **best possible conditions** at every time point using an **age-appropriate** test*"
- Use a quantitative **continuous scal**e (logMAR based)
- In case of poor cooperation and/or suspected visual decline "*it is mandatory to **retest the child*****"** (within 1-2 weeks)
- it is crucial to "***exclude** refractive error, amblyopia, or other non-OPG-related causes*"
- A **national reference ophthalmologist** necessary

Visual indications to treatment

Additional criteria only for OPG subgroup

(other criteria may influence treatment indication i.e. infant age, radio progression, neurologic symptoms…)

At diagnosis

- Presence of visual-related "severe symptoms"

During observation

- Visual decline (0.2 logMAR or more) in one or both eyes)

Vision-related severe symptoms (WHO def)

Named Ranges of Vision Loss (ICO, 1978 and ICD-9-CM)		Numbered ranges (WHO, ICD-9)		Visual Acuity: Decimal notation	Visual Acuity: U.S. notation	Visual Acuity: 6 m notation	Linear scales: Letter count	Linear scales: Log MAR

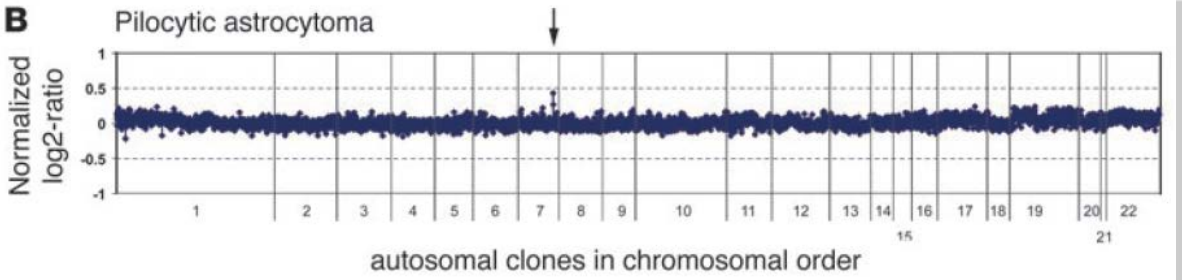
Low vision (> 0.5 logMAR) in the worse eye (threat to vision)

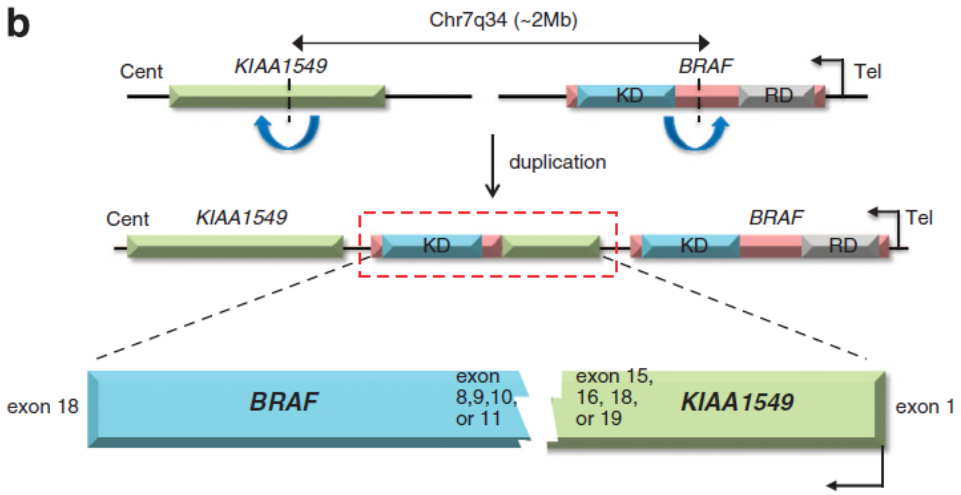
Targeting BRAF and MEK pathway in LGG

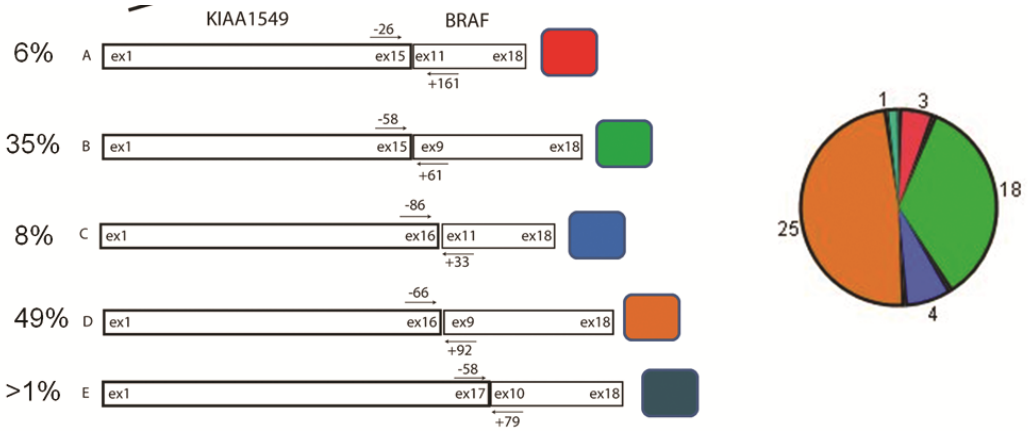
Outline

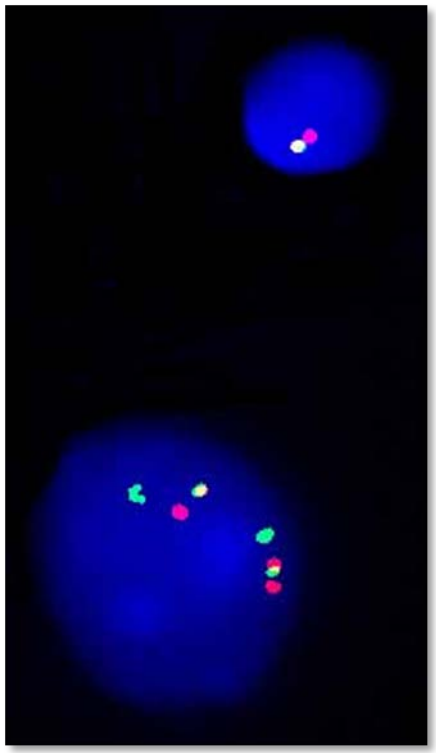
- Biology of Low Grade Glioma
- Sorafenib (NYU and collaborating Institutions)
- Sunitinib (PBTC – NCI Sponsored Trial)
- Dabrafenib (Company Sponsored – GSK; Transatlantic accrual)

BRAF abnormalities – hallmark signature for PA





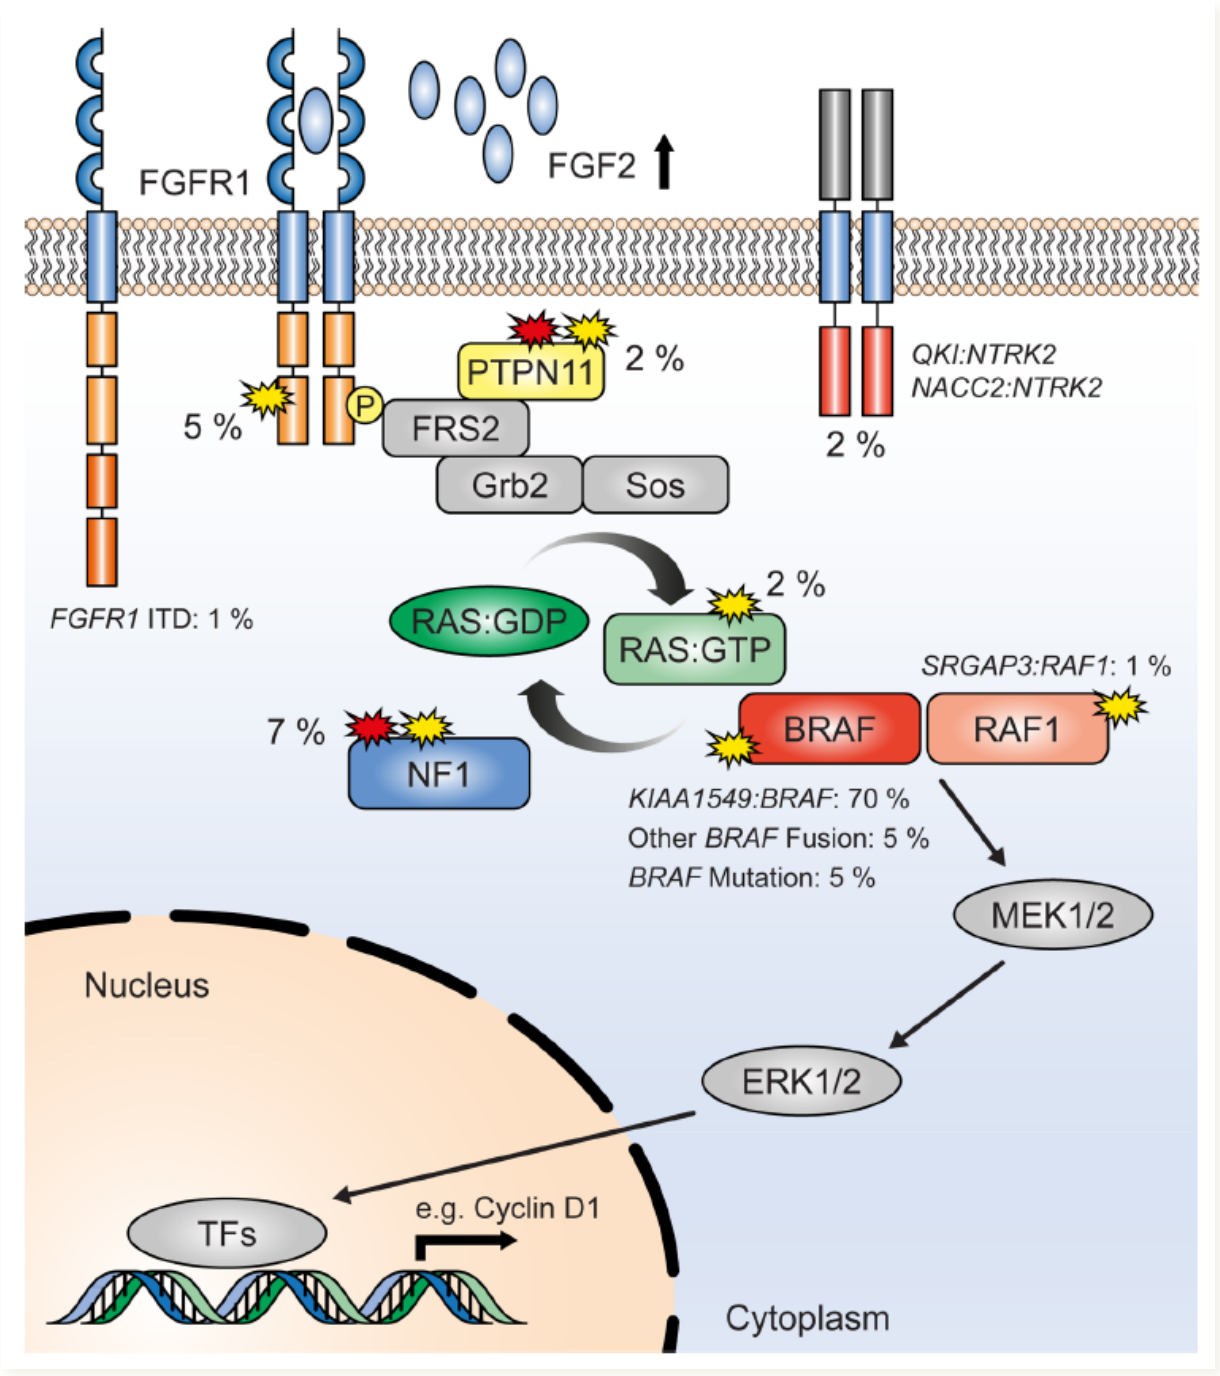




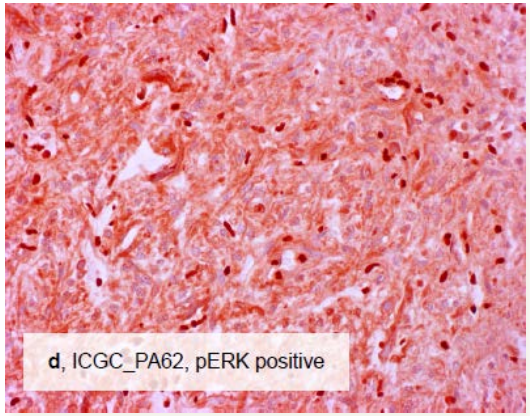
Pfister *et al.*, JCI 2008

Chen and Guttmann, Oncogene 2013

Lin *et al.*, J Neuropathol Exp Neurol 71, 2012



Germline and Somatic mutations in PA

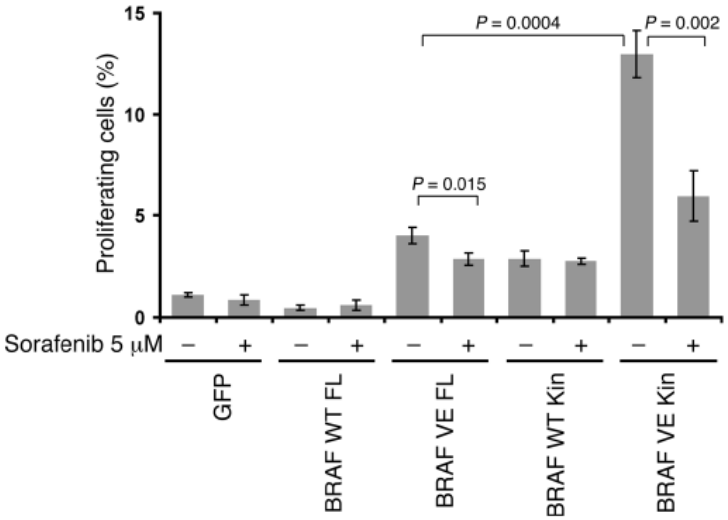


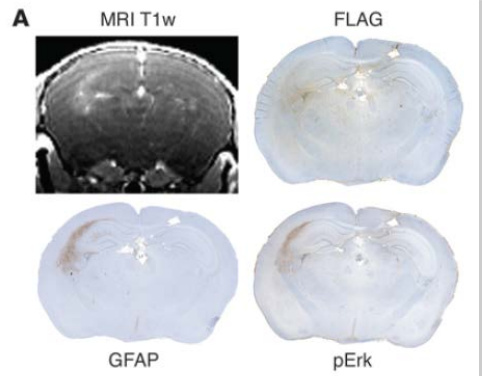
BRAF driven mouse model of PA

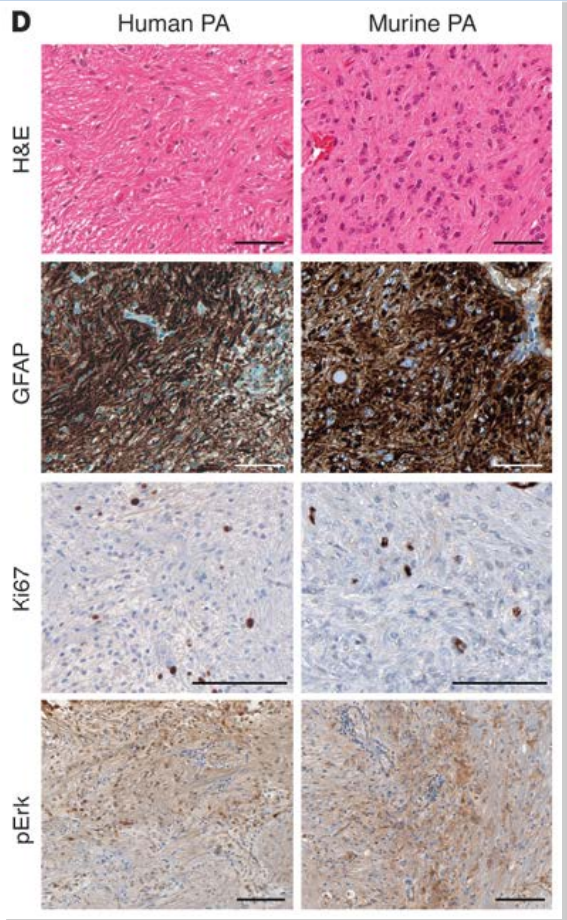
Brief report

An activated mutant BRAF kinase domain is sufficient to induce pilocytic astrocytoma in mice

Jan Gronych,[1] Andrey Korshunov,[2] Josephine Bageritz,[1] Till Milde,[3,4] Manfred Jugold,[5] Dolores Hambardzumyan,[6] Marc Remke,[1,4] Christian Hartmann,[2] Hendrik Witt,[1,4] David T.W. Jones,[1] Olaf Witt,[3,4] Sabine Heiland,[7] Martin Bendszus,[7] Eric C. Holland,[6] Stefan Pfister,[1,4] and Peter Lichter[1]

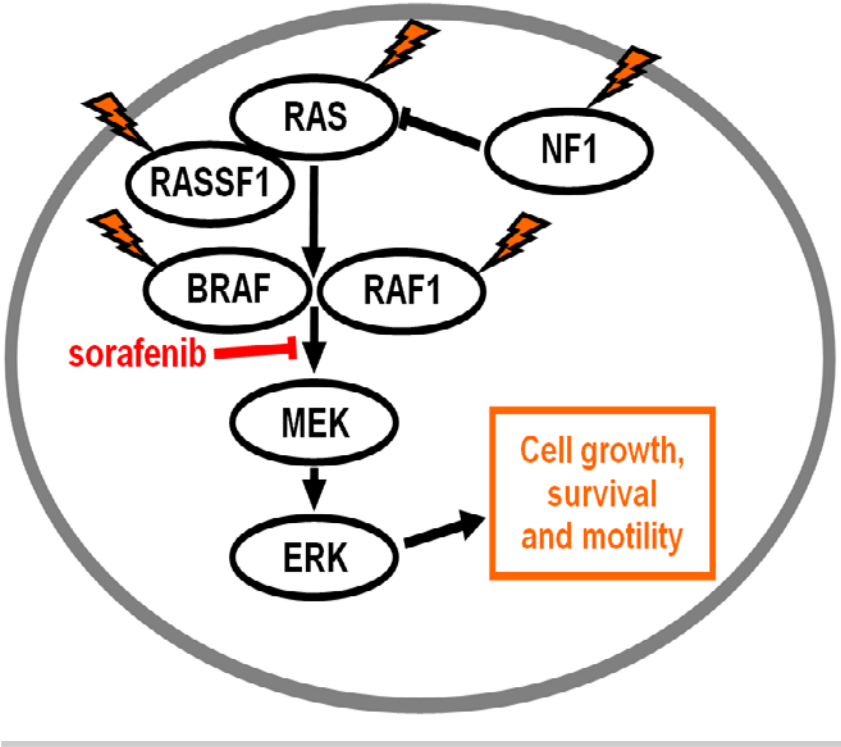


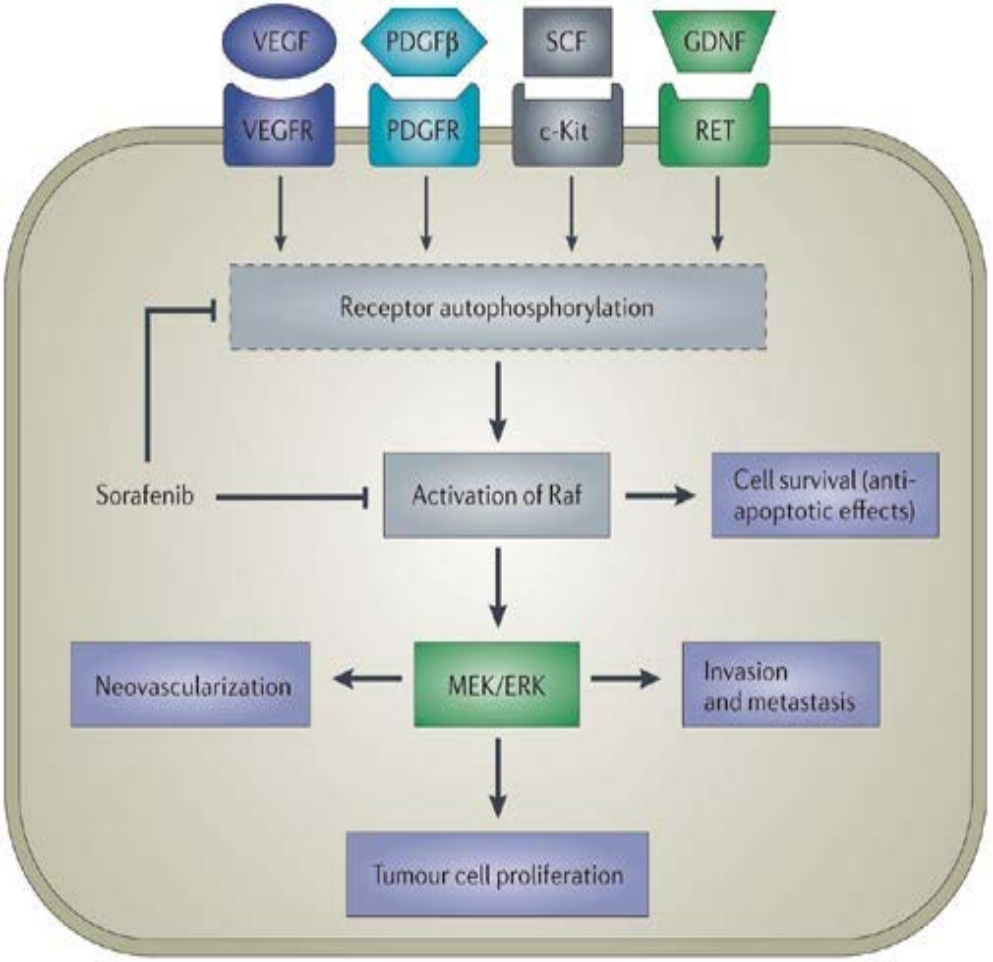




Construct	Incidence	Histology
BRAF WT FL	0/10 (0%)	–
BRAF VE FL	0/10 (0%)	–
BRAF WT kin	0/10 (0%)	–
BRAF VE kin	21/23 (91%)	Pilocytic astrocytoma

Sorafenib as a MEK inhibitor





Sorafenib

- Developed as a selective ATP-competitive RAF inhibitor
- Inhibits CRAF (RAF-1) and BRAF , including BRAF ^{v600E} at low nanomolar concentrations
- Also targets VEGF2/3, PDGFR, FGFR-1, FLT3 and c-KIT
- Preclinical data suggest good CNS bioavailability (10% of systemic exposure)
- Most advanced RAF inhibitor in clinical space
- FDA approved for treatment of renal cell carcinoma and hepatocellular carcinoma
- Pediatric MTD determined and safety data established in Phase I trials

Sorafenib – in vitro inhibitory concentrations

Table 2: *in vitro* inhibitory profile of sorafenib (from: Voliotis and Dumas in: Tumor Angiogenesis, Springer 2007, 655-671)

Kinase target (biochemical kinase assay)	***In vitro* IC_{50} value (nM)**	***Kinase target (cellular kinase assay)***	***In vitro* IC_{50} value (nM)**
RAF1 (CRAF)	6	MEK phosphorylation in MDA MB 231 cells	40

A Phase 1 Study of AZD6244 in Children with Recurrent or Refractory Low Grade Gliomas: A Pediatric Brain Tumor Consortium Report.

Anuradha Banerjee, Regina Jakacki, Arzu Onar-Thomas, Shengjie Wu, Theodore Nicolaides, David C. Turner, Stacye Richardson, Tina Young-Poussaint, Joanna Phillips, Michael Prados, Roger Packer, Ibrahim Qaddoumi, Sridharan Gururangan, Stewart Goldman, Ian Pollack, Austin Doyle, Clinton F. Stewart, James Boyett, Larry Kun, Maryam Fouladi

- Age > 3 and < 21 years with recurrent or refractory low grade glioma that has failed prior chemo or radiotherapy
- Drug administered by mouth, daily, BID continuously
- One course=28 days, up to 26 courses of treatment allowed
- Dose limiting toxicity (DLT) observation period is end of 1st 28 day cycle
- 3 dosage levels (DL) investigated
  - DL0, 25 mg/m2/dose, BID
  - DL1, 33 mg/m2/dose, BID
  - DL2, 43 mg/m2/dose, BID

A Phase 1 Study of AZD6244 in Children with Recurrent or Refractory Low Grade Gliomas: A Pediatric Brain Tumor Consortium Report.

Subject characteristics

- 38 eligible subjects
- Pilocytic astrocytoma most common diagnosis (22/38)
- Median age 13.3 years

AGE at Registration (Years): Median (Min, Max)	13.3 (5.6, 20.8)	
	Number	***Percentage***
SEX		
Males	19	50.0
Females	19	50.0
ETHNICITY

Oligodendroglioma, Nos	1	2.6
Pleomorphic Xanthoastrocytoma	1	2.6

A Phase 1 Study of AZD6244 in Children with Recurrent or Refractory Low Grade Gliomas: A Pediatric Brain Tumor Consortium Report.

Toxicity

- Dose limiting toxicities were headache, rash, mucositis, and elevation of amylase and lipase
- Maximum tolerated dosage = 25 mg/m2/dose
- At dose levels above 25mg/m2/dose, toxicities resulted in treatment discontinuation rate of 36%

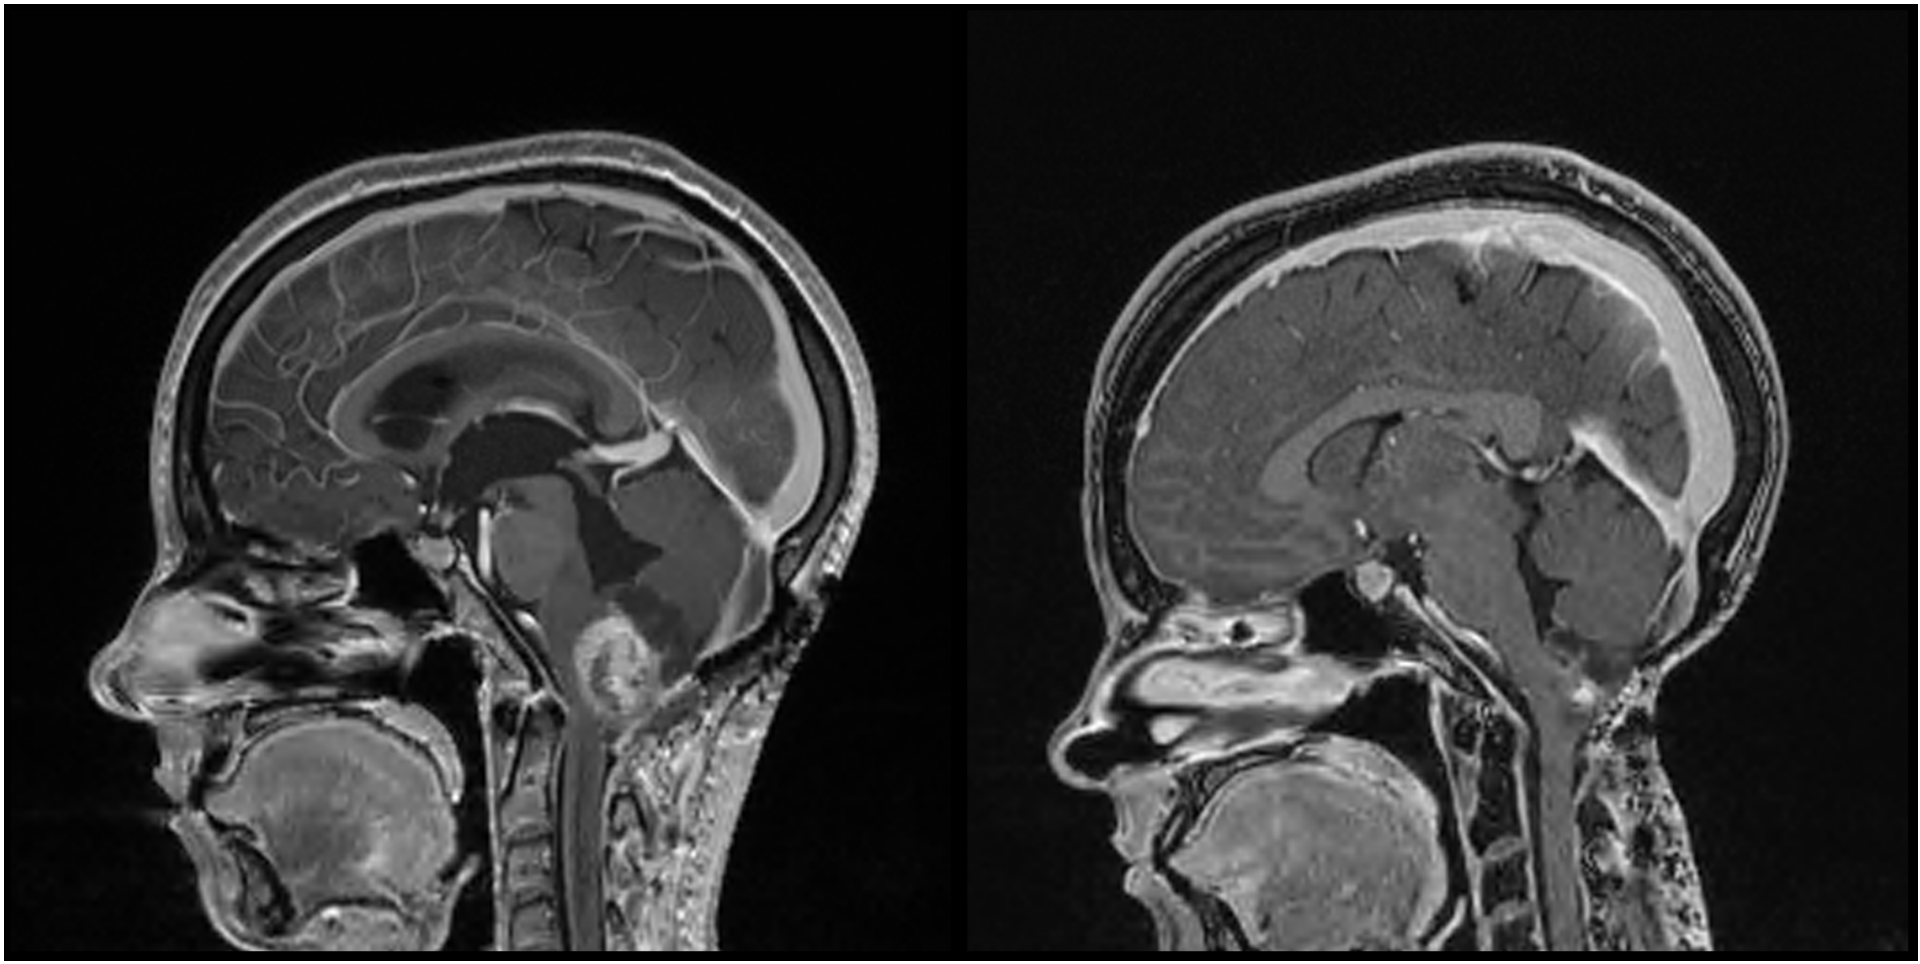
Stratum I				
Dose level (mg/m^2/dose BID)	*Number of eligible patients*	*Number of evaluable Patients*	*Number of patients with DLTs*	*Description of DLTs*
25	25	24	3	Grade 3 Elevation of Amylase\ Lipase (n=1) Grade 3 Rash (n=1) Grade 3 Mucositis (n=1)
33	10	10	4	Grade 3 Headache (n=1) Grade 2 Rash (n=1) Grade 3 Rash (n=2)
43	3	3	2	Grade 3 Rash (n=2) Grade 3 Mucositis (n=1)

A Phase 1 Study of AZD6244 in Children with Recurrent or Refractory Low Grade Gliomas: A Pediatric Brain Tumor Consortium Report

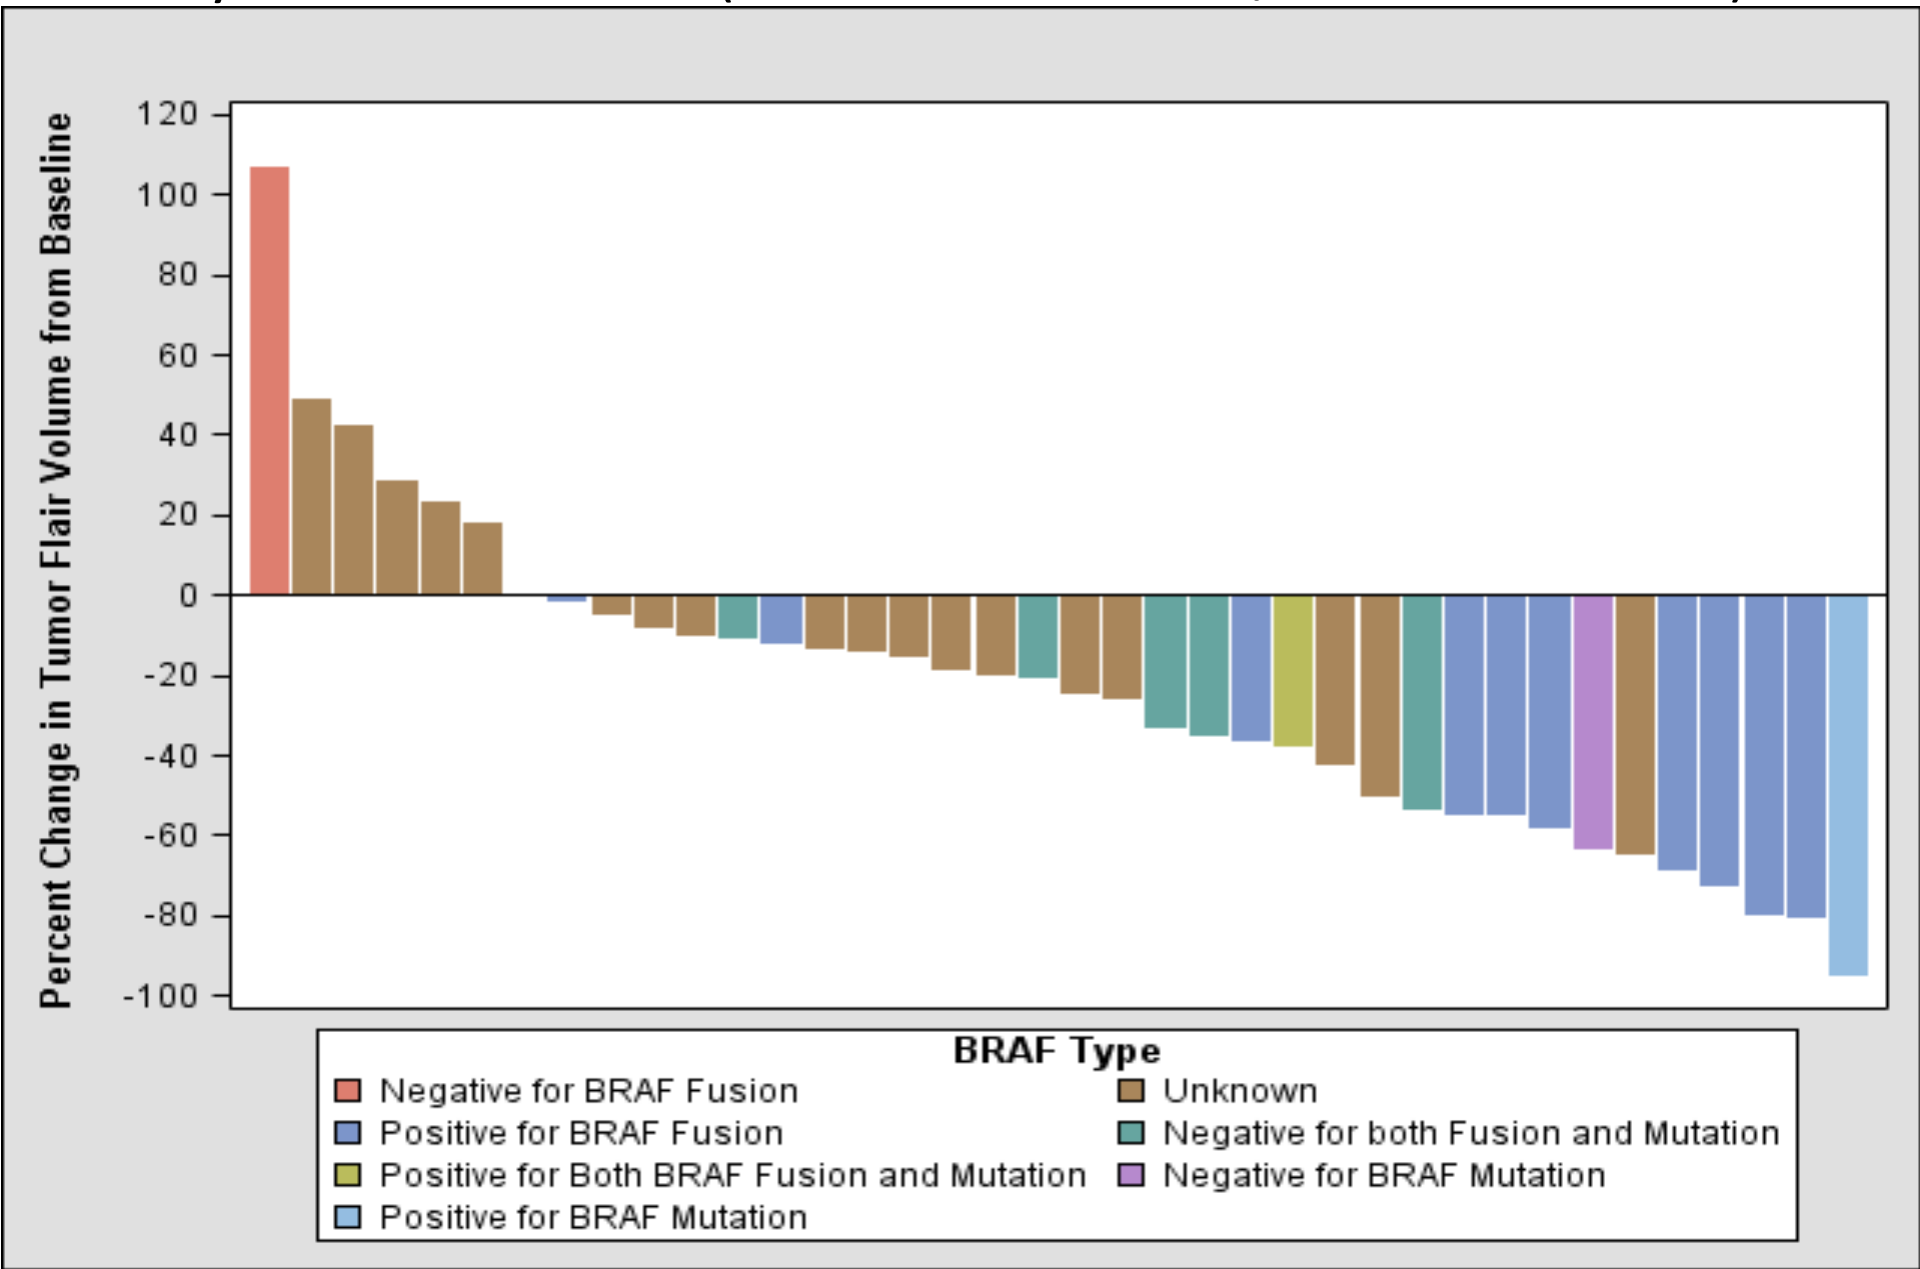
Responses

- 8 subjects with radiographic partial response
- 6 of 8 PRs observed in subjects treated at MTD (**25** mg/m2/dose)
- **Objective response rate at MTD = 6/24 (25%)**
- 5 of 8 subjects with PR had sufficient tissue for BRAF studies; 4 of these 5 had a BRAF mutation (n=1) or fusion (n=3)

AZD 6244 - RESPONSE



Largest Percentage Reduction in Tumor Volume from Baseline by BRAF Aberration (Min Tumor Volume/Baseline Volume)



A Phase 1 Study of AZD6244 in Children with Recurrent or Refractory Low Grade Gliomas: A Pediatric Brain Tumor Consortium Report

Conclusions

- The maximum tolerated dosage of AZD6244 in children and adolescents is 25 mg/m2/dose
- Pharmacokinetic analysis shows that this dosage results in plasma exposures similar to those known to inhibit phospho-ERK in peripheral blood cells
- Radiographic responses observed in this cohort demonstrates that therapeutic targeting of pediatric low grade glioma with the MEK inhibitor AZD6244 has promise as a novel treatment

Pediatric Brain Tumor Consortium

PBTC29 – Phase II study

Stratum 1	Stratum 2	Stratum 3	Stratum 4	Stratum 5	Stratum 6
Patients with non NF-1 associated progressive, recurrent or refractory pilocytic astrocytoma **with** pre-trial tumor material available and **with** a BRAF aberration, excluding patients with optic pathway glioma NON NF1 With BRAF aberration	Patients with non NF-1 associated progressive, recurrent or refractory pilocytic astrocytoma **with** pre-trial tumor material available and **without** BRAF aberration, excluding patients with optic pathway glioma NON NF1 without BRAF aberration	Patients with NF-1 associated progressive, recurrent or refractory low grade glioma (WHO I or II), **with or without** tissue NFI with or without Tissue – non OPG	Patients with non NF-1 associated progressive, recurrent or refractory optic pathway glioma (OPG) **with or without** tissue available for BRAF evaluation. NFI with or without tissue - OPG	Patients with non NF-1 associated progressive, recurrent or refractory low grade glioma (other than pilocytic astrocytoma or optic pathway glioma). These patients‟ tumors must have BRAF aberrations which will be determined by screening prior to enrollment on the treatment protocol. Non NF-1; Non PA Must have BRAF aberrations	Patients with non NF-1 associated progressive, recurrent or refractory low grade glioma (other than OPG) with tissue available for BRAF analyses who cannot be classified into Stratum 1, 2 or 5 due to inadequate tissue quality, assay failure, etc Non NF-1; Must have BRAF Aberrations Does not qualify for Stratum 1,2,5

Phase 1 study of dabrafenib in pediatric patients with relapsed or refractory BRAFV600-mutant high-grade gliomas, low-grade gliomas, histiocytosis, and other solid tumors

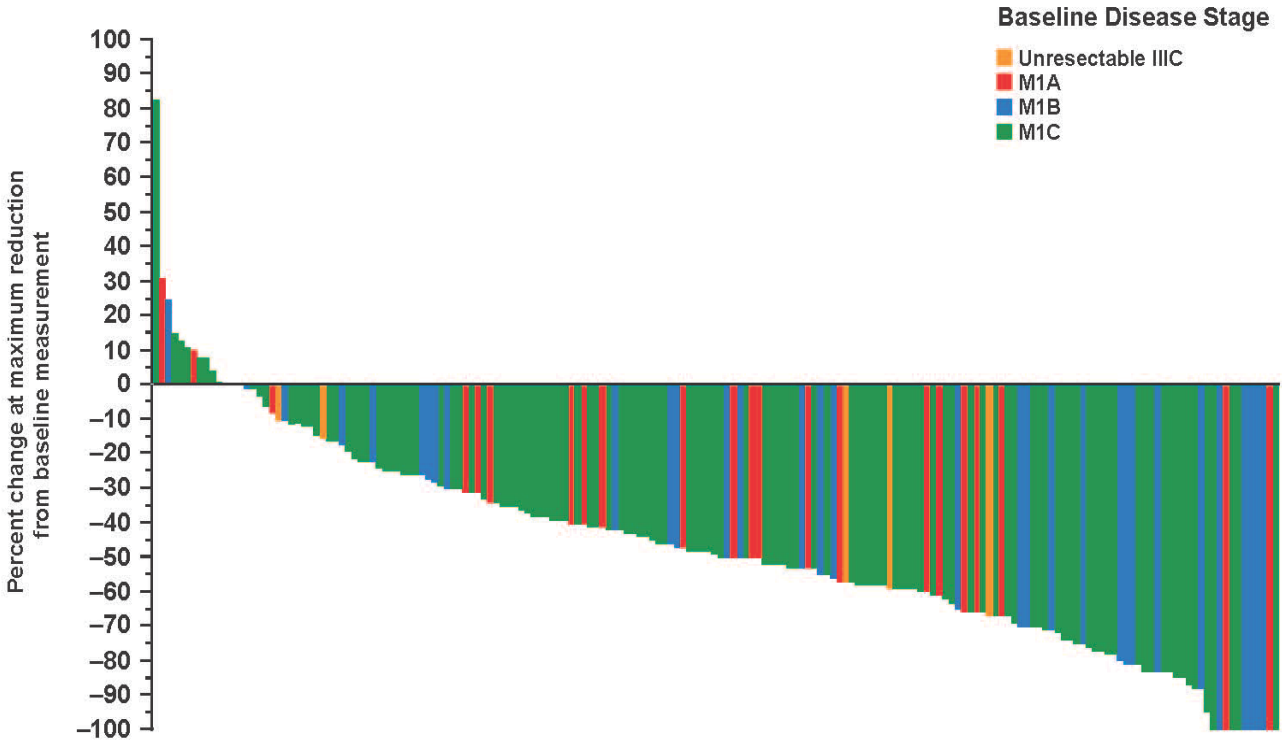
Dabrafenib Activity in Adults With *BRAF*V600-mutant Melanoma

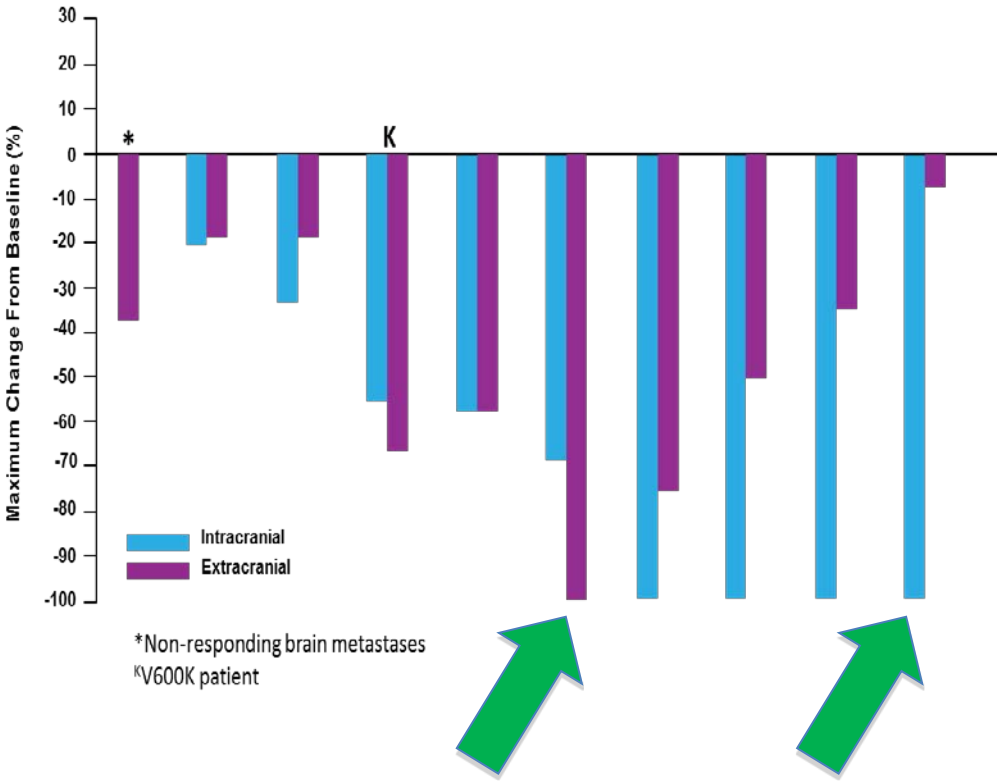


- Best tumor response from baseline in adult patients with melanoma treated with dabrafenib

Hauschild A, et al., *Lancet* 2012;380:358-365.

Dabrafenib Activity in Brain Metastases

- Dabrafenib, at the recommended phase 2 dose, has activity against brain metastases in adult patients with melanoma[1]
  - Nine of ten (90%) melanoma patients with untreated brain metastases showed reduction in brain lesion size



1. Falchook GS, *et al*. *Lancet* 2012;379:1893–1901.

BRAFV600 Mutations in Pediatric Tumors

- ~60% papillary thyroid carcinoma[1]
- ~60% Langerhans cell histiocytosis[2]
- ~50% melanoma[3,4]
- ~10% Low grade gliomas
  - ~10% fibrillary astrocytoma, pilocytic astrocytoma[5]
  - ~60% pleomorphic xanthoastrocytoma[6]
  - ~60% gangliogliomas[7]
- ~10% malignant astrocytomas[8]

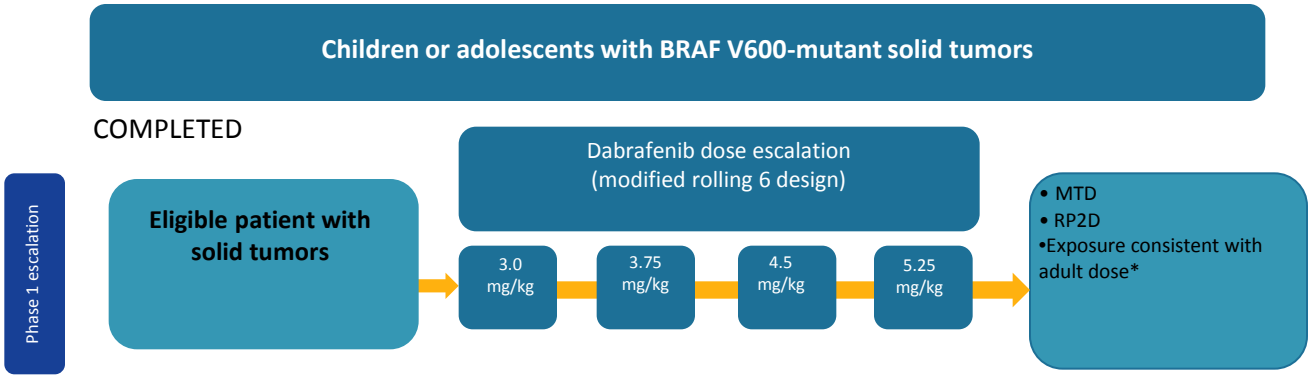
Study Objectives

- Determine the recommended pediatric phase 2 dose (<18 years)
  - Maximum tolerated dose, or if not seen
  - Similar steady-state systemic exposure to adults (AUC, 4000–5500 ng•h/mL)
- Assess dabrafenib safety and efficacy in pediatric population



Key inclusion criteria

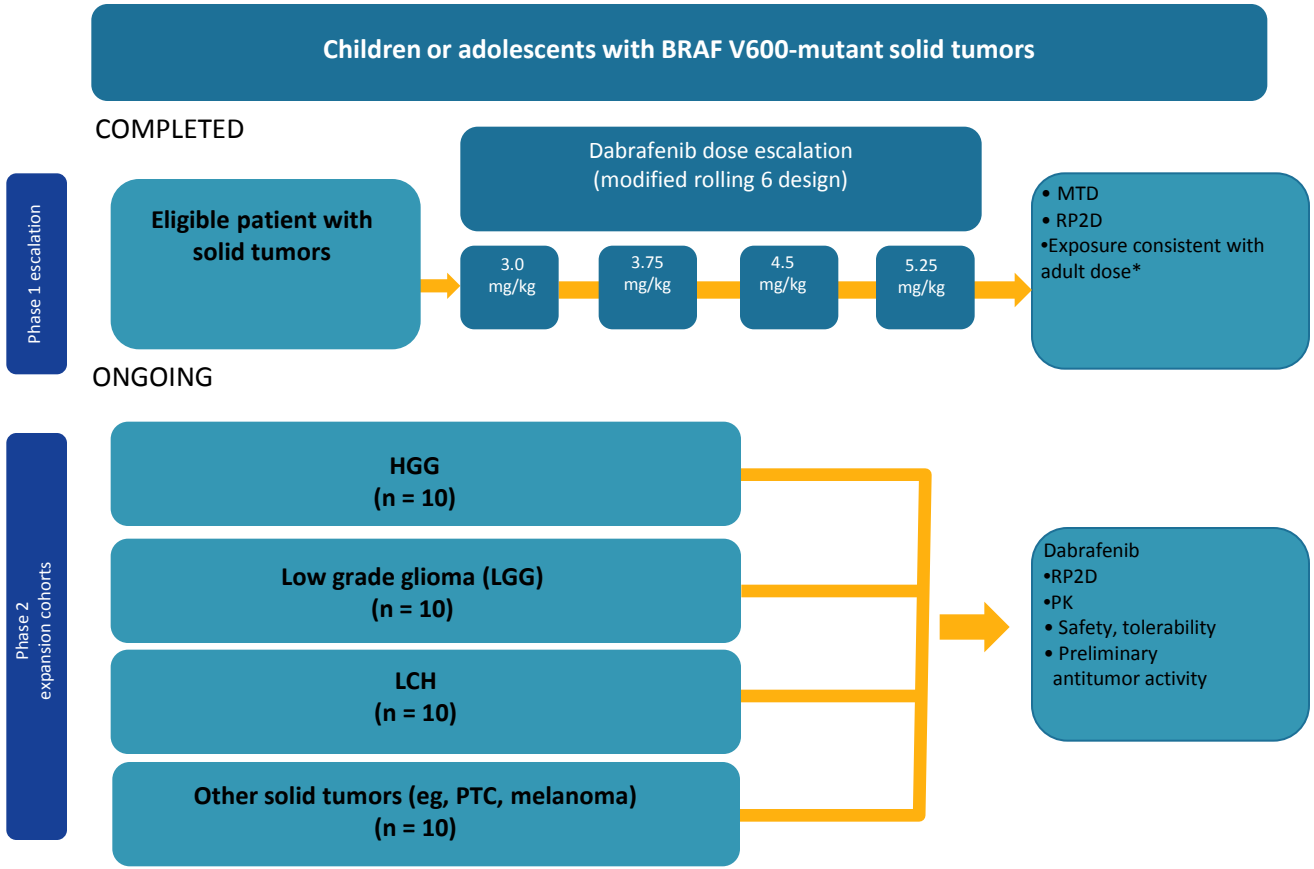
- Recurrent, refractory, or progressive disease after at least 1 standard therapy
  - (metastatic melanoma may be first line)
- BRAF V600 mutation positive
  - (local test with central confirmation)

Key exclusion criteria

- Prior treatment with dabrafenib, other RAF or MEK inhibitor (part 2 only)
- Other malignancy

RP2D, recommended phase 2 dose.
*$AUC_{(0\text{-}12)}$ = 4,000-5,500 ng•h/mL.

Registered at clinicaltrials.gov as NCT01677741



Key inclusion criteria

- Recurrent, refractory, or progressive disease after at least 1 standard therapy
  - (metastatic melanoma may be first line)
- BRAF V600 mutation positive
  - (local test with central confirmation)

Key exclusion criteria

- Prior treatment with dabrafenib, other RAF or MEK inhibitor (part 2 only)
- Other malignancy

RP2D, recommended phase 2 dose.
*$AUC_{(0\text{-}12)}$ = 4,000-5,500 ng•h/mL.

Registered at clinicaltrials.gov as NCT01677741

Methods

- V600 mutation status established locally; central confirmation available
- Dabrafenib given orally twice daily, starting dose of 3.0 mg/kg/day
  - Formulations HPMC capsules (10, 25, 50, 75 mg strengths) and powder for suspension in water
- Toxicity, pharmacokinetics, and response assessed at each dose level for patients aged ≥12 months to ≤12 years and >12 years
- During assessment of filled dose level, enrollment allowed into lower tolerable dose levels (backfill)
- Therapy to continue as long as patient is benefitting
- Intrapatient dose escalation permitted

Baseline Patient Characteristics

	Dose cohort				
	3 mg/kg (n = 3)	3.75 mg/kg (n = 10)	4.50 mg/kg (n = 8)	5.25 mg/kg (n = 6)	Total (N = 27)

Results

- Phase 1 portion completed
  - N = 27 patients
  - May 2013 to November 2014
- Clinical data cut 7 March 2015
- Duration on study from 9 weeks to 23 months (ongoing)
- 20 of 27 patients remain on dabrafenib

Adverse Events

- Most common AE class
  - Skin and subcutaneous tissue disorders 25 (93%) patients
- Most common AE terms
  - Pyrexia 14 (52%) patients
  - Fatigue 12 (44%) patients
  - Vomiting 12 (44%) patients
  - Headache 11 (41%) patients
- Dose-limiting toxicity (1 event)
  - Grade 3 transient maculopapular rash at 4.5 mg/kg/day dose
    - Patient remains on study at reduced dose (3.75 mg/kg/day)

Investigator-assessed Best Confirmed Response[a] by Tumor Type

Tumor type	High-grade glioma n = 8	Low-grade glioma n = 15	LCH n = 2	Other solid tumor n = 2	Total N = 27

AA, anaplastic astrocytoma; **AG**, anaplastic glioma; **AGG**, anaplastic ganglioglioma; **APXA**, anaplastic pleomorphic xanthoastrocytoma ; **GBM**, gliobastoma multiforme; **GG**, ganglioglioma; **LGG**, low grade glioma; **NB**, neuroblastoma; **PA**, pilocytic astorcytoma; **PMA**, pilomyxoid astrocytoma; **PTC**, papillary thyroid carcinoma; **PXA**, pleomorphic xanthoastrocytoma.

Summary

- Dabrafenib was well tolerated in pediatric patients
- Phase 2 recommended doses were identified and different in children ≤12 years and children >12 years based on PK parameters
- Radiographic responses (44%) and prolonged stable disease (19%) were seen across a number of tumor types driven by BRAFV600 mutations
- The multistrata phase 2 component of trial is open and accruing around the world

Conclusions

- MEK inhibitors are exciting new agents for low grade gliomas.
- Imaging responses can be documented after prolonged exposure to therapy (4-6 months)
- BRAF V600E specific inhibitors being tested in low-grade and high-grade gliomas; responses have been observed in patients with progressive disease
- Phase I/II studies ongoing with mTOR inhibitors, BRAF V600E inhibitors; MEK inhibitors and combination of BRAF inhibitors and MEK inhibitors
- New paradigm for treatment of LGG that uses tumor biology to direct therapy

Conclusions

Low grade gliomas have a good prognosis (especially with NF1)

Aim is to preserve function at least cost.

Possible targeted therapies in the future.

Adult Medulloblastoma

Darren Hargrave

Consultant Paediatric Oncologist,

Neuro-oncology & Experimental Therapeutics

Great Ormond Street Hospital. London, UK.

Have you ever treated an adult MB patient?

A. True

B. False

Clinical Study

The incidence of medulloblastomas and primitive neurectodermal tumours in adults and children

Nicolas R. Smoll [a,*], Katharine J. Drummond [b,c]

SEER database from 1973 to 2007: 369 adult MBs
Approx 11/year (children 10 x more likely to have MB)

Risk Groups

- Use same risk group as children
  - i.e. Chang staging metastatic disease
  - Pathology- LCA
  - Biology MYC amplified
  - Residual disease >1.5cm2
- 33% adult MB High Risk

What would be your standard Rx for adult SR-MB

A. CSI only 36Gy (54Gy PF).

B. CSI only 23.4Gy (54Gy PF).

C. CSI 36Gy (54Gy PF) + ChemoRx.

D. CSI 23.4Gy (54Gy PF)+ ChemoRx.

Treatment protocol

Low-risk patients. In low-risk patients, radiation therapy alone was planned and started within 28 days of surgery. For patients receiving craniospinal radiation therapy, the radiation dose was 36 Gy in 20 fractions of 1.8 Gy/5 fractions per week, followed by a boost of 18.8 Gy in 10 fractions to the posterior fossa, including the entire tentorium, with the anterior aspect of the field extending to the posterior clinoid process (up to a total dose of 54.8 Gy).

Table 1. Cisplatin-based chemotherapy: Dose levels

	Level −2	Level −1	Level 0	Level +1
Cyclophosphamide (mg/m^2/ on Day 4)	600	750	1000	1000
Etoposide (mg/m^2 on Days 1 to 4)	26	32	40	50
Cisplatin (mg/m^2 on Days 1 to 4)	20	25	25	25

Outcomes?

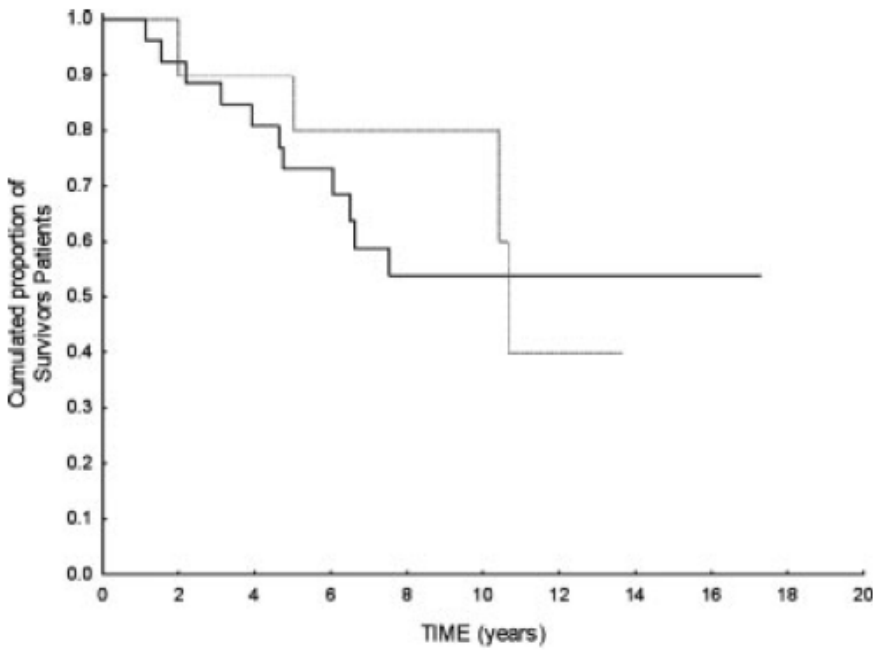

FIGURE 2. These overall survival curves were calculated according to the risk-assessment method described in Chang et al., 1969[4] (black line, high-risk group; gray line, low-risk group).

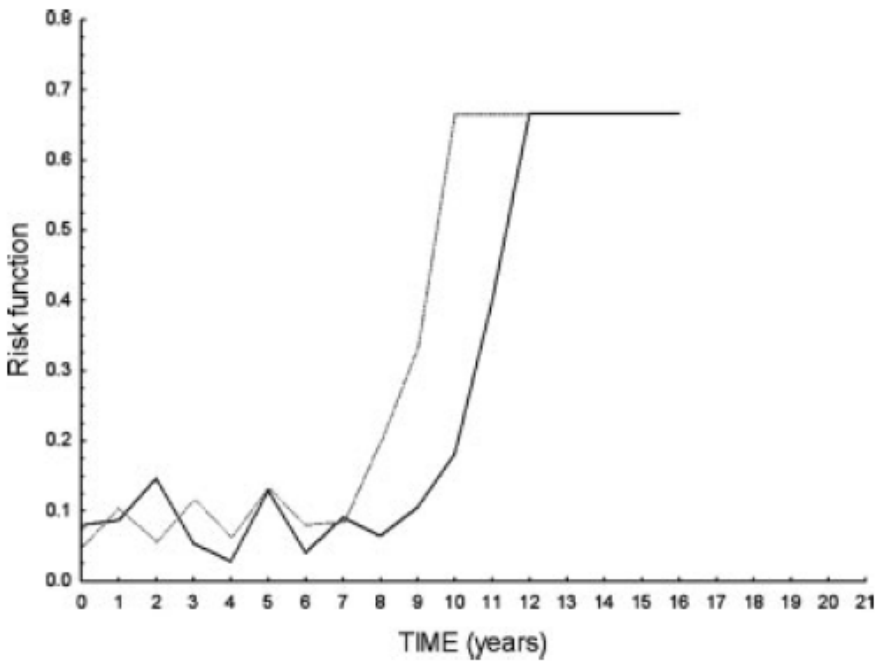

FIGURE 3. These curves illustrate the risk of recurrence according to the risk-assessment method described in Chang et al., 1969[4] (black line, high-risk group; gray line, low-risk group).

Outcomes?

TABLE 3
Largest Adjuvant Adult Medulloblastoma Chemotherapy Trials in the Literature

Study	No.	Chemotherapy	Outcome
Carrie et al., 1994[11]	156	75 Patients, 8 in 1 CT: SIOP protocol; IFO/CDDP/VCR	5-Y PFS rate: 58% in M0 group vs 51% in M+ group; 59% in R0 group vs 64% in R+ group
Prados et al., 1995[12]	47	32 Patients	5-Y PFS 5 rate: 54% in LR group vs 38% in HR group
Chan et al., 2000[13]	32	24 Patients: 3-5 cycles of CT	5-Y PFS rate: 59% in M0 group vs 47% in M+ group; 86% in R0 group vs 27% in R+ group
Louis et al., 2002 (unpublished results)	51	24 SR patients, no CT; 27 HR patients, CT with CARBO/VP-16	5-Y PFS rate: 60% in SR group vs 63% in HR group
Abacioglu et al., 2002[1]	30	10 Patients	5-Y PFS rate: 69% in CT-treated patients; 60% in untreated patients
Greenberg et al., 2001[14]	17	17 Patients: Packer regimen or POG protocol	PFS, 48 mo

CT indicates chemotherapy; SIOP, International Society of Pediatric Oncology; IFO, ifosfamide; CDDP, cisplatin, VCR, vincristine; PFS, progression-free survival; M0, negative for metastasis; M+, positive for metastasis; R0, curative resection; R+, noncurative resection; LR, low risk; HR, high risk; SR, standard risk; CARBO, carboplatin; VP-16, etoposide; POG, Pediatric Oncology Group.

Update on molecular and genetic alterations in adult medulloblastoma

Marcel Kool, Andrey Korshunov, Stefan M. Pfister

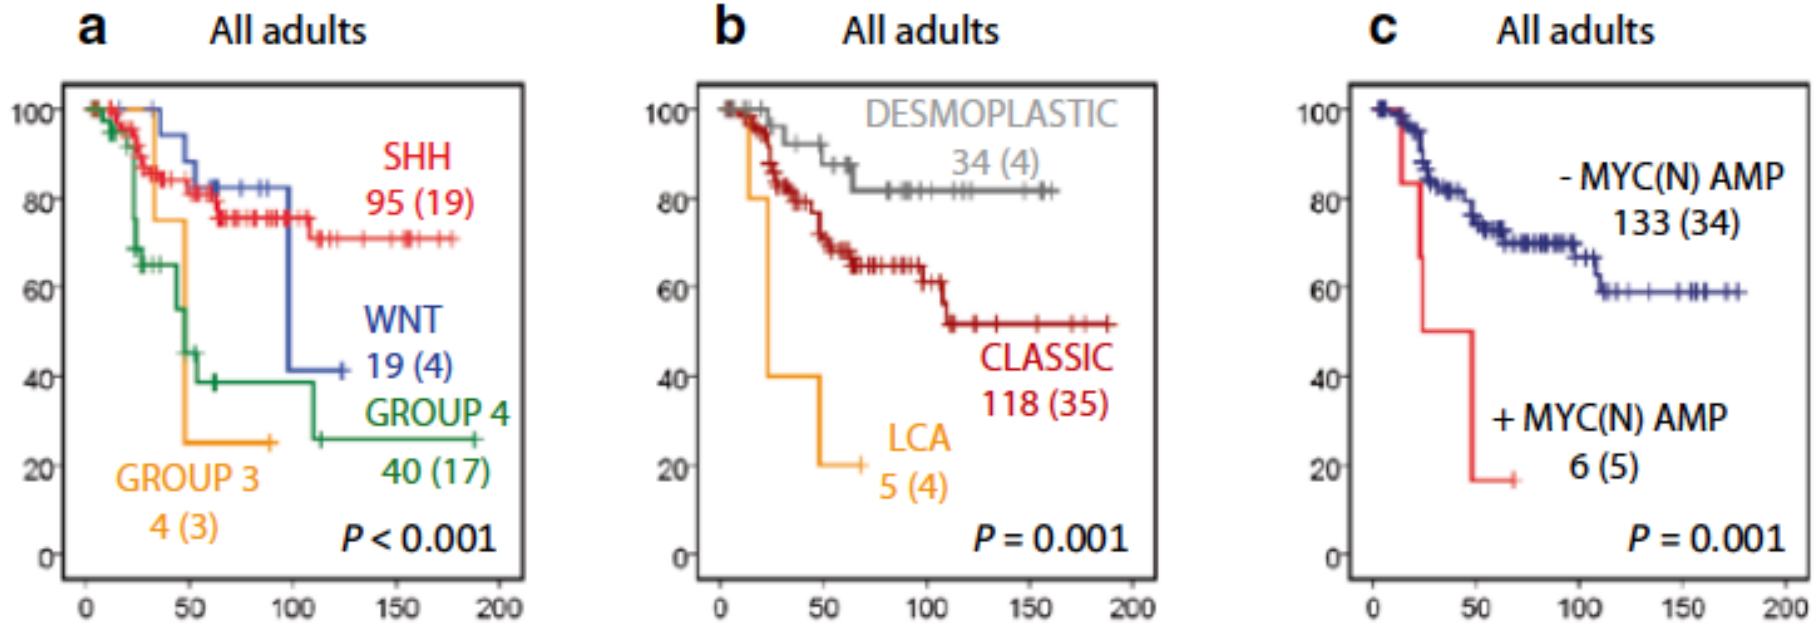

Table 1 verview of medulloblastoma molecular subgroup distribution, histological subgroup distribution, and metastatic groups in infants (age <4 years), children (age 4–16), and adults (age >16)

	Infants		Children		Adults	
	Percentage[a]	OS[b]	Percentage[a]	OS[b]	Percentage[a]	OS[b]
Molecular subgroups						
WNT	1	NA	12	96	13	82
SHH	57	77	18	81	57	81
Group 3	34	29	26	55	2	25
Group 4	8	57	44	78	28	39
Histological subgroups	Percentage[a]	OS[b]	Percentage[a]	OS[b]	Percentage[a]	OS[b]
Classic	43	49	80	79	79	68
Desmoplastic	43	88	8	86	18	88
Large cell/Anaplastic	15	26	12	48	3	20
Metastatic stage	Percentage[a]	OS[b]	Percentage[a]	OS[b]	Percentage[a]	OS[b]
M0	68	66	68	81	93	71
M+	32	50	32	65	7	52

Data are from meta-analyses performed on published datasets of medulloblastomas analyzed and categorized into subgroups either by gene expression profiling or immunohistochemistry [6]

OS overall survival

[a]Numbers indicate the frequency each subgroup occurs within that age category

[b]For each subgroup the percentage of patients is shown that is still alive 5 years after medulloblastoma diagnosis as determined by Kaplan Meier analysis

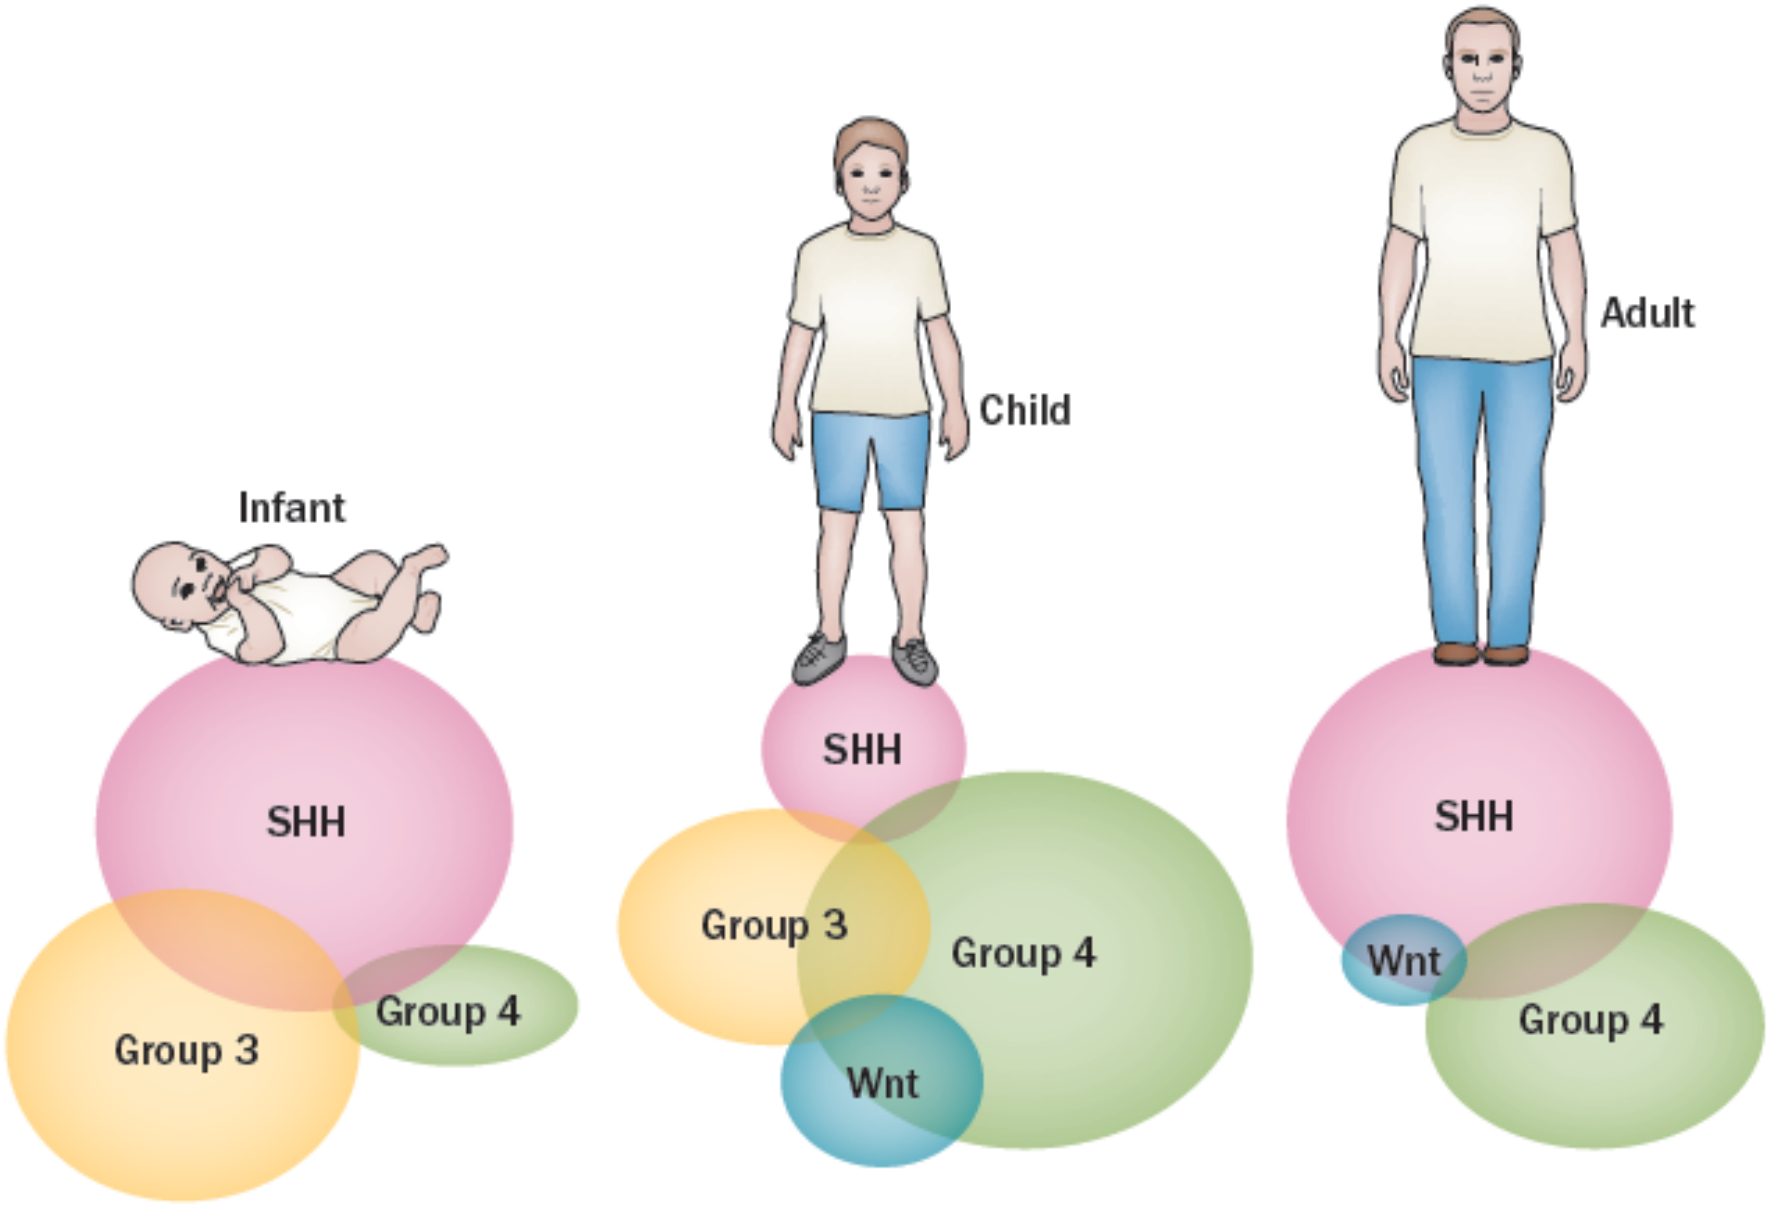

Figure 2 | Schematic distribution of the prevalence of the molecular medulloblastoma subtypes among different age groups. The approximate frequency

Rare cancer syndromes identify genes commonly mutated in sporadic medulloblastoma

Syndrome	Gene	Locus	Tumour susceptibilities
Turcot's syndrome	*APC*	5q21-q22	Medulloblastoma Multiple colorectal adenomas
Naevoid basal cell carcinoma syndrome (NBCCS) / Gorlin syndrome	*PTCH*	9q22.3	Medulloblastoma Basal cell carcinoma
Li-Fraumeni syndrome	*TP53*	17p13.1	Medulloblastoma Multiple primary neoplasms, including: Soft tissue sarcomas Osteosarcoma Breast carcinoma Brain tumours Leukaemias Adenocortical carcinoma

APC in 5% of cases

PTCH in 10% of cases

TP53 in 10% of cases

Cancer Cell. **6:** 229-240, 2004.

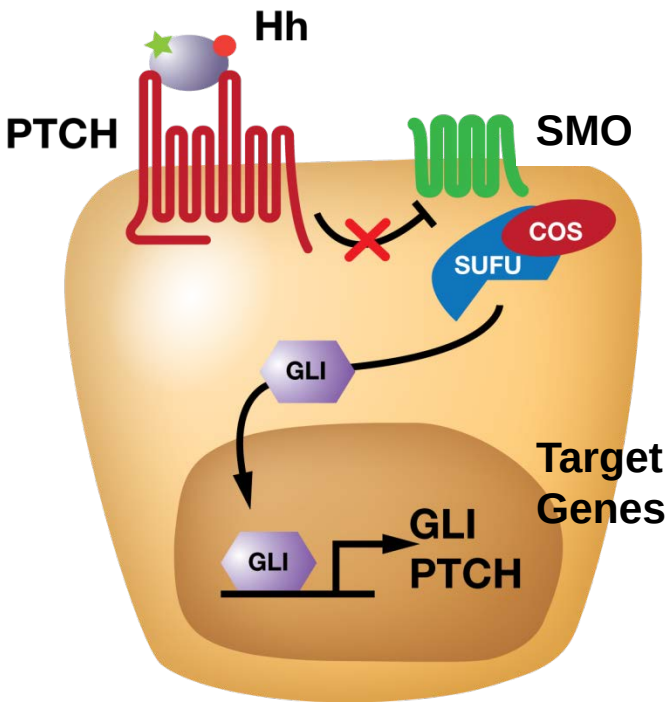
The Hedgehog (Hh) Pathway



- Hh signaling pathway is essential in mammalian embryonic development and adult tissue homeostasis[1]
- Mechanism:[2,3]
  - PTCH inhibits SMO
  - Hh ligand binding to PTCH relieves inhibition of SMO
  - SMO signaling, via SUFU, activates GLI transcription factors
- Constitutive activation can result from mutations (*PTCH*, *SMO* or *SUFU*) or overexpression of the ligands[4–8]
  - Hypermethylation of *PTCH* and the negative regulator HIP1 can lead to pathway activation[9,10]

COS, conserved ortholog set; GLI, glioma-associated oncogene; Hh, hedgehog; HIP1, hedgehog interating protein 1; PTCH, patched; SMO, smoothened; SUFU, suppressor of fused

BRIEF REPORT

Treatment of Medulloblastoma with Hedgehog Pathway Inhibitor GDC-0449

Charles M. Rudin, M.D., Ph.D., Christine L. Hann, M.D., Ph.D., John Laterra, M.D., Ph.D., Robert L. Yauch, Ph.D., Christopher A. Callahan, M.D., Ph.D., Ling Fu, M.D., Thomas Holcomb, M.S., Jeremy Stinson, B.S., Stephen E. Gould, Ph.D., Barbara Coleman, R.N., C.C.R.P., Patricia M. LoRusso, D.O., Daniel D. Von Hoff, M.D., Frederic J. de Sauvage, Ph.D., and Jennifer A. Low, M.D., Ph.D.

This article (10.1056/NEJMoa0902903) was published on September 2, 2009, at NEJM.org.

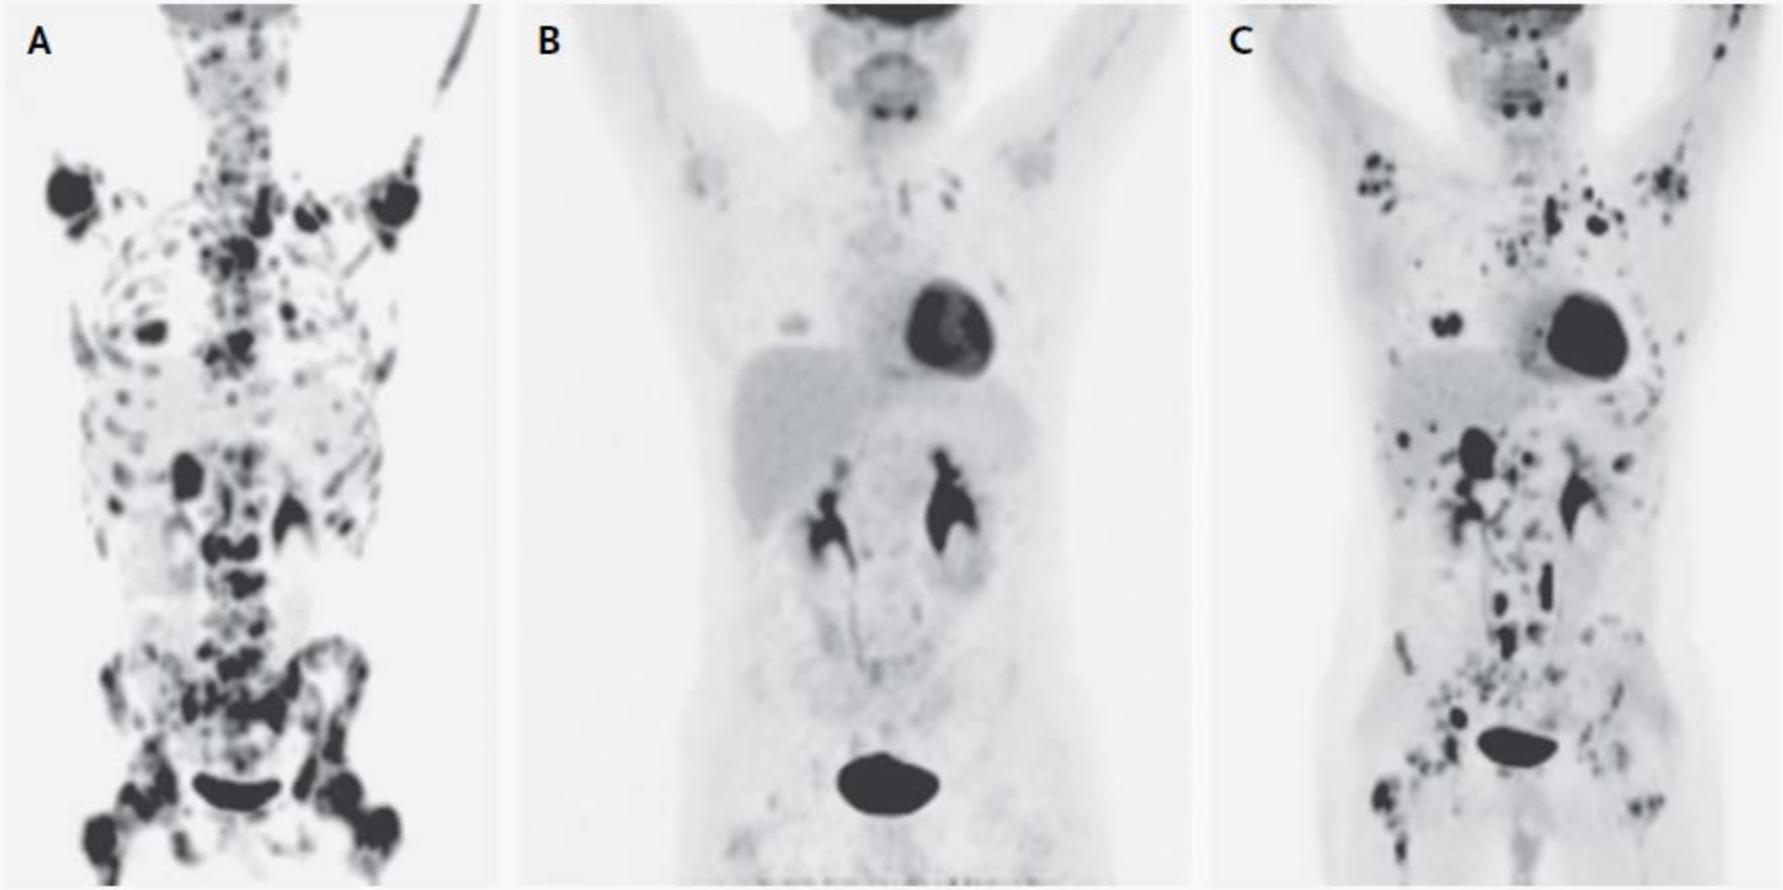

Figure 1. Tumor Response on Positron-Emission Tomographic (PET) Scanning.

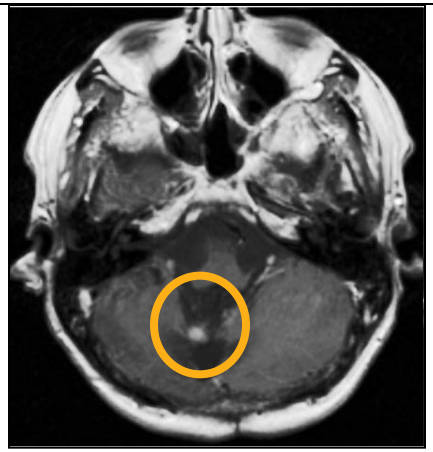
Whole-body projections from ^{18}F-fluorodeoxyglucose (FDG)–PET scans are shown. Panel A shows the pretreatment scan; Panel B, the repeat scan after 2 months of therapy with the hedgehog pathway inhibitor GDC-0449; and Panel C, the repeat scan after 3 months of therapy.

LDE225: responses in medulloblastoma

Patient A (200 mg QD)

- Prior surgery, radiation, 4 chemotherapy regimens and autologous BMT
- Partial response maintained for 4 months

Pre-treatment



Cycle 2

Patient B (1500 mg QD)

- Prior surgery, radiation, 4 chemotherapy regimens and autologous BMT
- Partial response by PET scan maintained more than 7months

Pre-treatment

Cycle 2

Phase I/II: Study Design

Phase I→ Pediatric patients with recurrent/refractory MB, rhabdomyosarcoma, neuroblastoma, hepatoblastoma, high-grade glioma, or osteosarcoma

Dose escalation

Oral, once-daily LDE225 in 28-day cycle
Starting dose = 372 mg/m^2

Bayesian logistic regression model using overdose control*
DLT evaluation at 6 weeks

MB enrichment
Enrollment to previously tested lower dose levels

→ **Declaration of MTD** →

Safety expansion (n = 12)

Once-daily LDE225 at declared MTD

Primary endpoint – MTD, DLTs
Secondary endpoints – Safety, PK, ORR, PD/biomarkers (validation of Hh gene expression signature)

Phase II→ Pediatric patients with recurrent or refractory MB

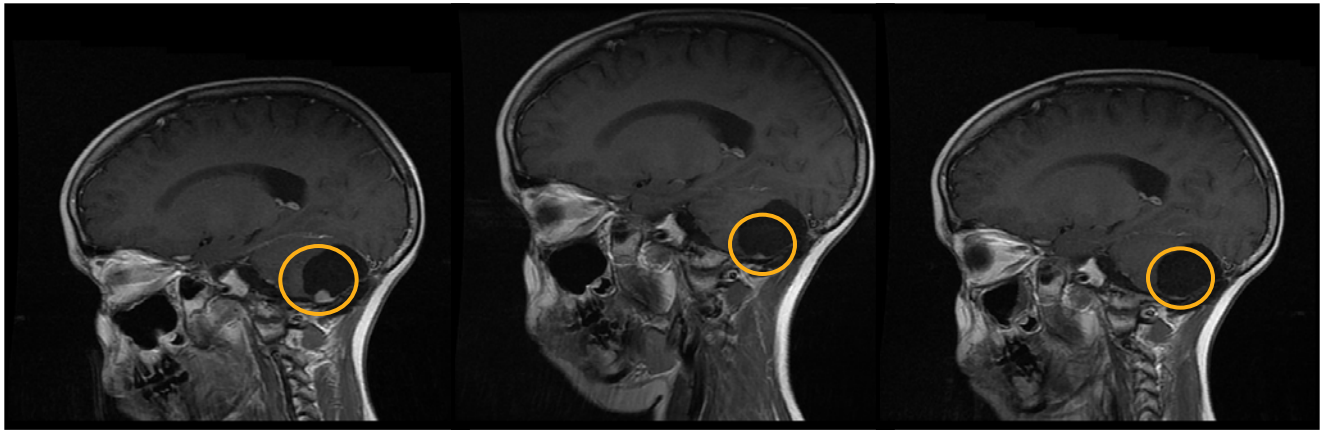
Recommended Dose LDE225
Pediatric MB patients (n = 30)

Primary endpoint – ORR (regardless of Hh pathway status)
Secondary endpoints – ORR and duration of response as a function of Hh pathway status, safety, PK

DLT, dose-limiting toxicity; Hh, hedgehog; MB, medulloblastoma; MTD, maximum tolerated dose; ORR, overall response rate; PD, pharmacodynamics; PK, pharmacokinetics; PR, partial response

NOVARTIS

Phase I: Complete Tumor Responses in MB



Baseline | Cycle 2 | Cycle 3

11-year-old with recurrent desmoplastic MB

372 mg/m^2

Treatment duration: 254 days

Baseline | Cycle 2 | Cycle 5

4-year-old with recurrent desmoplastic MB

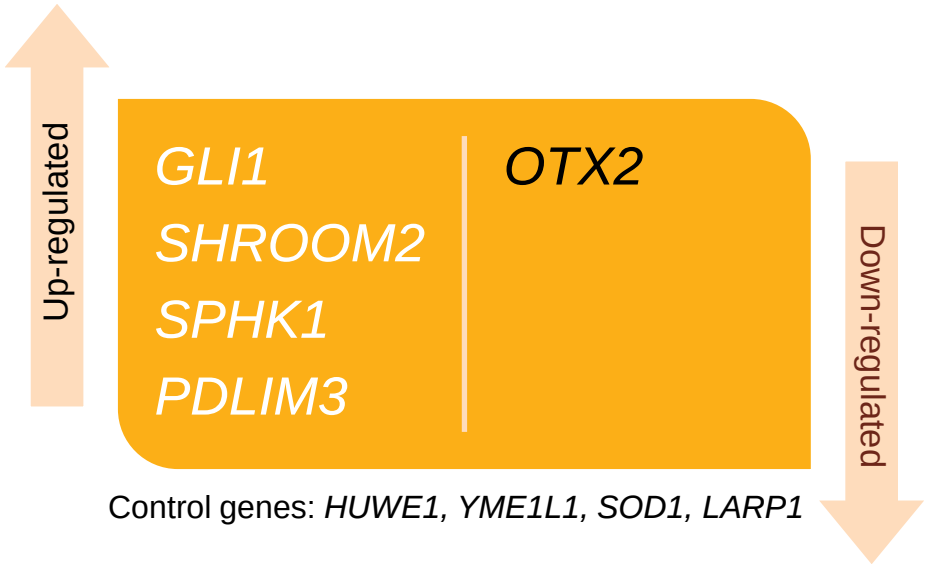
425 mg/m^2

Treatment duration: 280 days

NOVARTIS

The 5-Gene Hh Signature

- The 5-gene Hh signature can robustly identify Hh-pathway activation in FFPE tumor samples by standard RT-PCR
- Hh activation status determined by the 5-gene Hh signature is in 100% agreement with the Hh status determined by Affymetrix
- A robust patient pre-selection tool for LDE225 treatment



Control genes: *HUWE1, YME1L1, SOD1, LARP1*

GLI1, glioma-associated oncogene homolog 1; HUWE1, HECT, UBA and WWE domain containing 1; LARP1, la ribonucleoprotein domain family, member 1;OTX2, orthodenticle homeobox 2; SHROOM2, shroom family member 2; SOD1, superoxide dismutase 1, soluble; PDLIM3, PDZ and LIM domain 3; SPHK1, sphingosine kinase 1; YME1L1, YME1-like 1; ZP2, zone pellucida sperm-binding protein 2.

Amakye D, et al. AACR 2012. Abstract #4818.

NOVARTIS

Phase I: Best Overall Tumor Response and Correlation With 5-Gene Hh Signature in MB

	Responders/Hh-activated	Responders/Hh-non-activated
Adults	3/3 (3 PR)	0/4
Children	2/2 (2 CR)	0/12
Total	**5/5**	**0/16**

CR, complete response; Hh, hedgehog; MB, medulloblastoma; PR, partial response
Amakye D, et al. AACR 2012. Abstract #4818.

NOVARTIS

Clinical Trial Design Options?

- Newly diagnosed versus relapse?
- Randomised versus single arm?
- Biomarker selected versus all comers?
- Age groups?

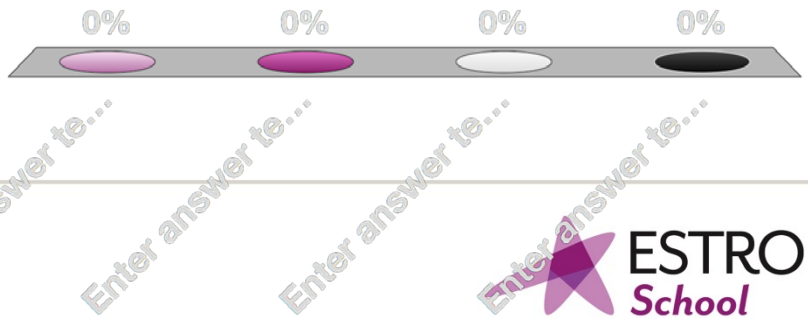
Which of the following trials do you prefer?

A. Upfront randomised study?

B. Upfront single arm study?

C. Relapse randomised study?

D. Relapse single arm study?



ESTRO School

Discussion on which trial is best/ feasible?

Dr Darren Hargrave

Consultant Paediatric Oncologist

Neuro-oncology & Experimental Therapeutics

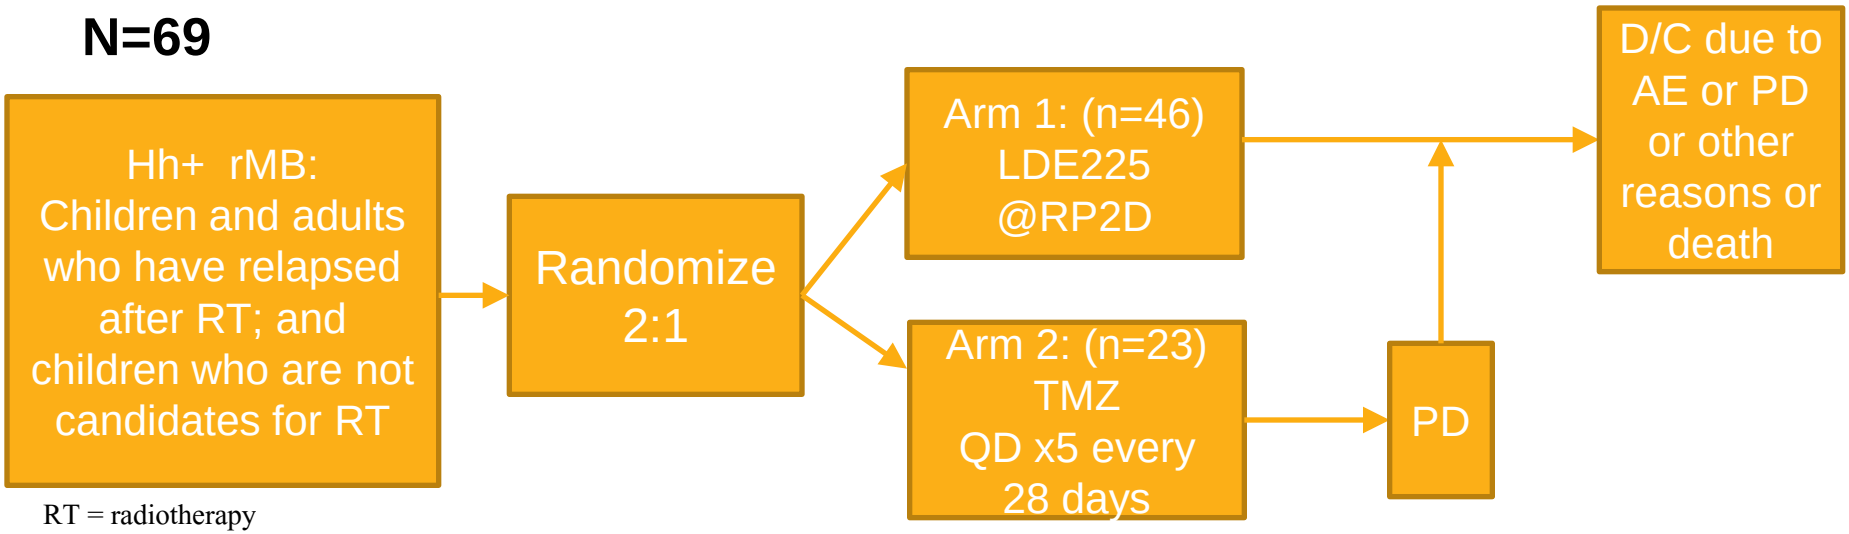
Great Ormond Street Hospital for Children, London

NOVARTIS

Randomized Phase II C2201 Study Design

Hh-pathway activated relapsed MB in children and adults

N=69



RT = radiotherapy

Primary endpoints: ORR

Secondary endpoints: DoR, PFS, safety, OS, QoL

Randomization stratified by age (adults/children)
Patients on TMZ may cross-over to LDE225 at progression. Patients not previously treated with RT will be analyzed as a separate subgroup. Safety data will be analyzed by age (children/adults)

Conclusions

Population –problems with rarity how to overcome

Right target- patients selection

Right drug(s)-

Chordoma and Chondrosarcoma

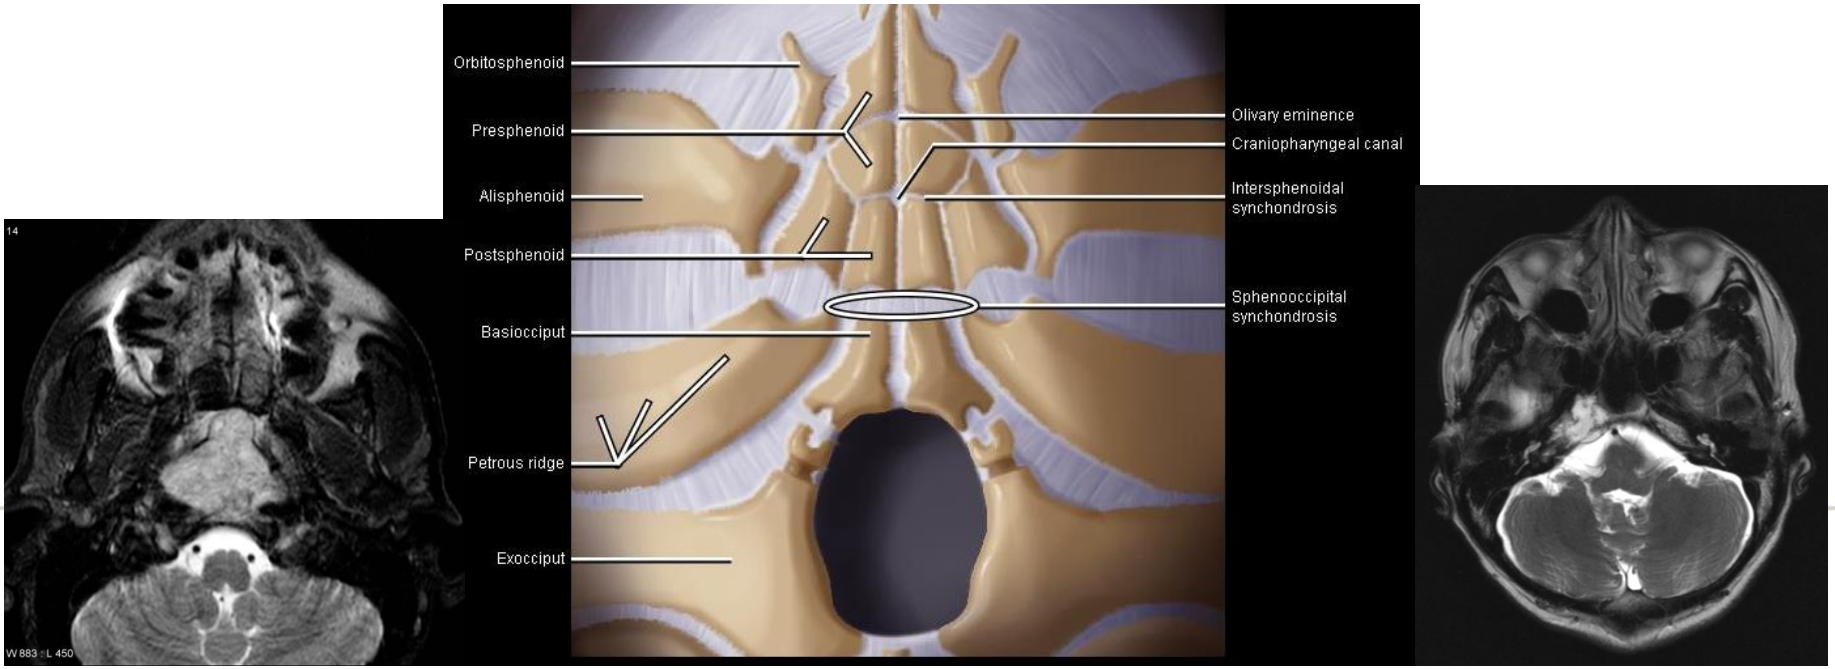
CHORDOMA

Presumed to arise from remnants of primitive notochord, an embryonic precursor replaced by mesodermal elements to form vertebrae and skull base

Typically midline

CHONDROSARCOMA

- Arise from embryonal rests of cartilaginous matrix that escape reabsorption during endochondral ossification
- Off-midline and originate within the temporal bone and petroclival fissure



Chordoma Chondrosarcoma

EPIDEMIOLOGY

CHORDOMA

0.84 per 1'000'000 (M>F)*

Median age 58 (3 - 95)

Intracranial chordomas invariably involve the clivus

Those arising from :

(a) the most rostral notochordal extension in the dorsum sellae present as sellar/parasellar tumors

(b) the most ventral part of the clivus present as nasopharyngeal tumors

(c) those associated with body and dorsal aspect of clivus manifest as spheno-occipital or petrosal lesions

(d) those related to the lower clivus will present at the ventral portion of the foramen magnum

Direct dural invasion responsible for extension to posterior fossa

CHONDROSARCOMA

- 5 per 1'000'000 (M>F)
- Median age 51 (1 – 102)
- Appendicular > axial > soft tissue

*Incidence and relative survival of chordomas: the standardized mortality ratio and the impact of chordomas on a population.

NR, Gautschi OP, Radovanovic I, Schaller K, **Weber DC**. Cancer. 2013 Jun 1;119(11):2029-37. doi: 10.1002/cncr.28032. Epub 2013 Mar 15

Chordoma Chondrosarcoma

CHORDOMA - Pathology

Macroscopically:

Chordomas are soft, gelatinous, lobulated neoplasms

Microscopically:

Vacuolated, bubble-containing cytoplasm: **physaliphorous cells**

Express S-100, EMA and cytokeratin

Notochordal developmental transcription factor, **BRACHYURY** *(when combined with cytokeratin staining, sensitivity of 98% and specificity of 100% for chordoma)*

Chondroid Chordoma:

Favorable prognosis (UNRESOLVED ISSUE)

About 20% were later found to be chondrosarcomas

Mayo clinicopath study revealed no difference in survival (attributed to occurrence in younger pts)

Chordoma Chondrosarcoma

NATURAL HISTORY

CHORDOMA

5 yr and 10 yr DFS 70% and 45%

Exhibit locally destructive growth

Recurrences may be noted many years after treatment

Distant metastasis extremely rare (6% - 22%)

Metastasis higher in the presence of recurrent disease

After recurrence, 3-yr and 5-yr OS about 43% and 7%

CHONDROSARCOMA

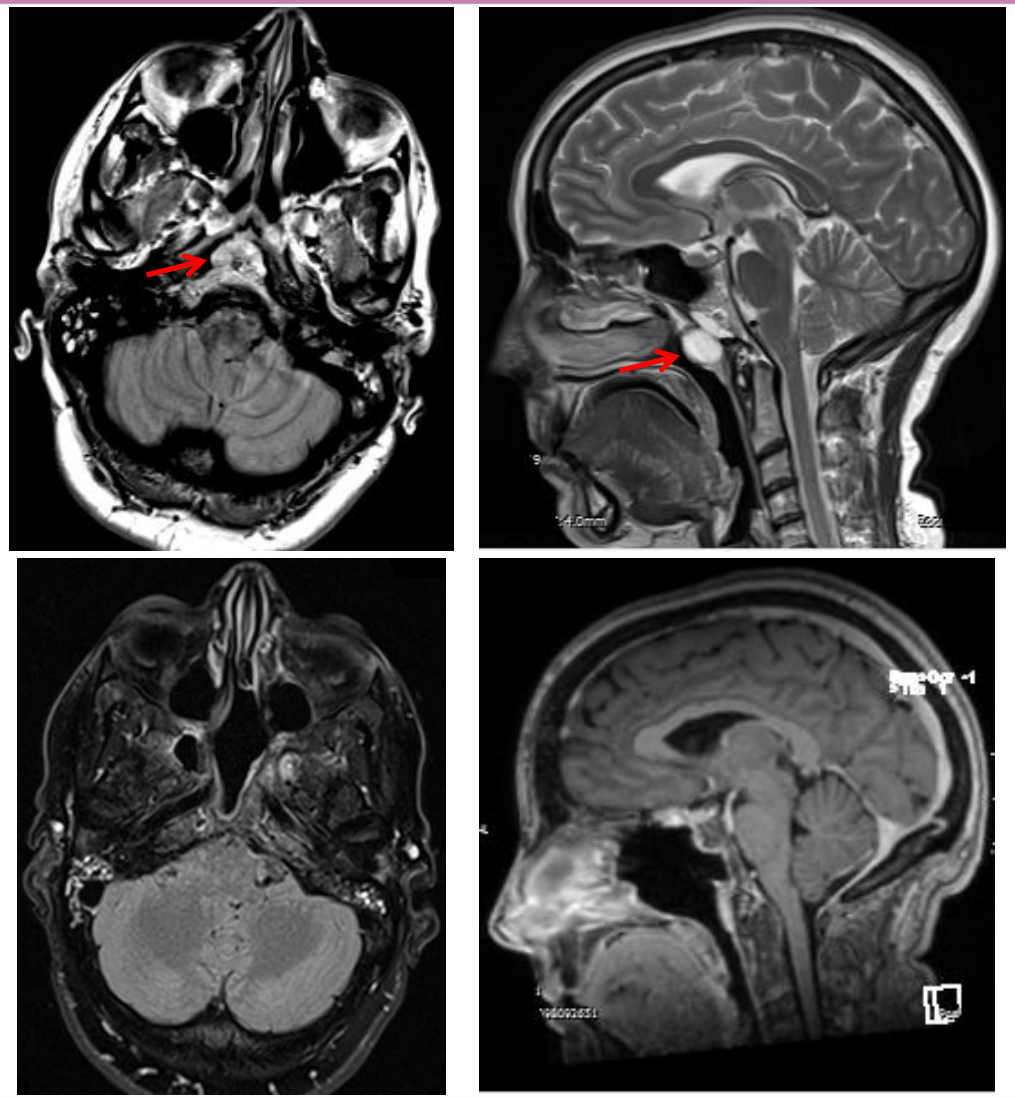
- More **indolent** and associate with much more favorable prognosis
- 10-yr local control and disease-specific survival 98-99%
- No relationship between histological subtype and grade

Treatment - Surgery

- Goal is to remove as much of the tumor while minimizing complications
- Whenever brainstem compression present, decompress
- Fat graft as spacer to increase distance between clivus and contiguous brainstem to facilitate safe delivery of radiation

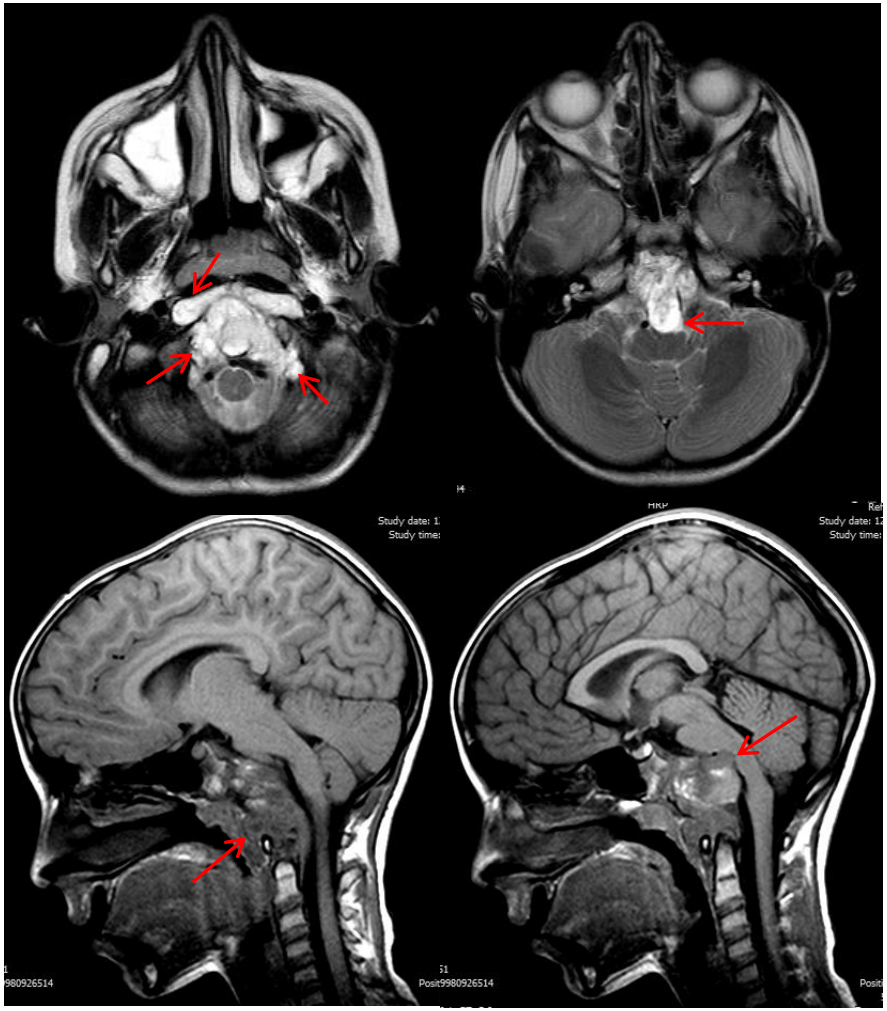
Chordoma Chondrosarcoma

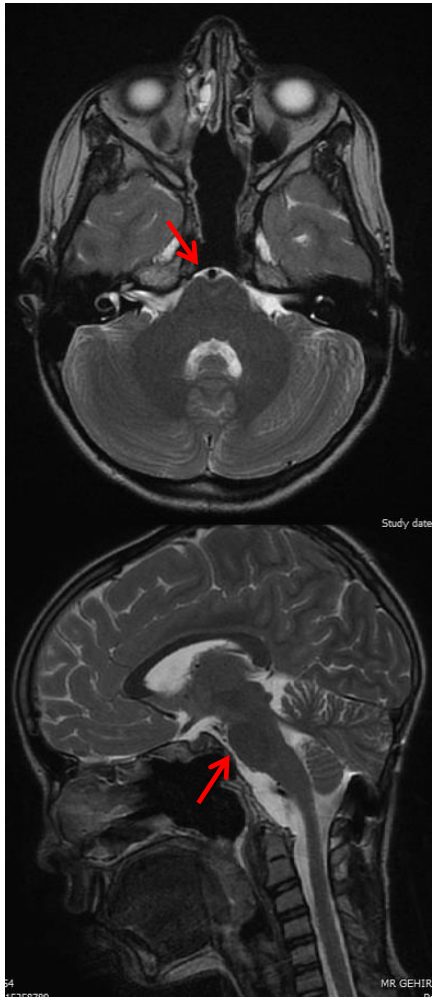
Goal of Surgery - Chordoma



Chordoma Chondrosarcoma

Goal of Surgery - Chordoma





Goal of Surgery - Chondrosarcoma

2007

2015

Planning CT

Chordoma - Surgery

	Radical Resection (No tumor)	Subtotal Resection (>90% resected)	Partial Resection (<90% resected)	Biopsy
Al-Mefty	43%	48%	9%	
Watkins		89%		11%
Gay	47% (total) 20% (near total)	23%	10%	

-Multiple retrospective studies have suggested **improved local control and survival in those patients with optimal surgical debulking**

- Tzortzidis reported that in patients with chordomas who underwent surgery aimed at performing a complete resection, GTR could be accomplished in only 72%.
- The 10-year recurrence-free survival was 31% indicating that **even after GTR, the likelihood of tumor control is low with surgery alone**

Chordoma: Surgery + Radiation

Tai et al, Cancer, 1995:
159 patients with cranial chordomas treated by various regimens:

- Subtotal resection followed by adjuvant radiation had a significantly improved survival over surgery alone (p=0.011)

- No difference when compared to radiation alone (p=0.271)

- The survival curves for the combined treatment separate with follow up and suggest a benefit to include surgery in the management

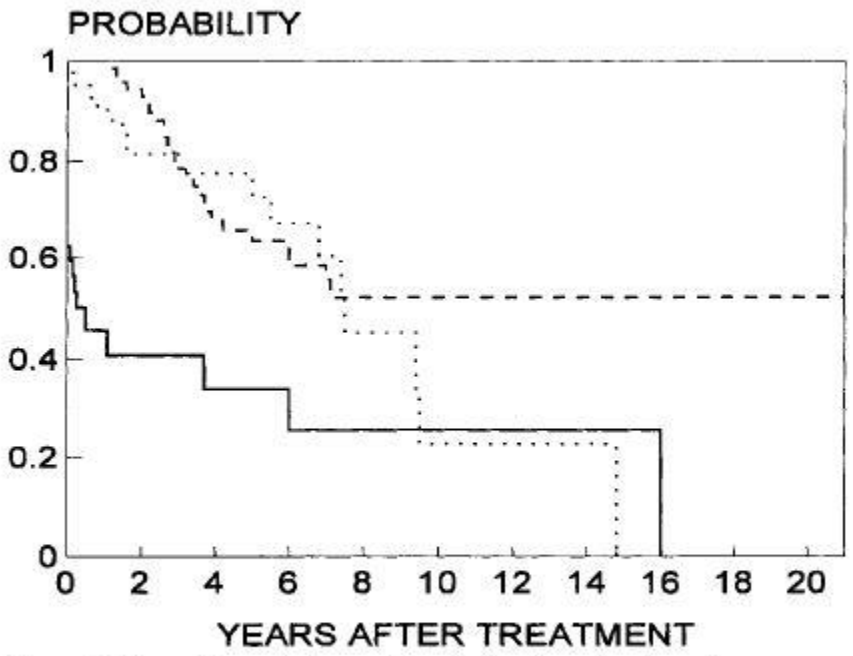


Figure 3. Overall survival according to the three treatments: ——, surgery alone, · · · ·, radiation alone; and – – – –, combined surgery and postoperative radiation.

Chordoma: Radiation

- The primary role of radiation therapy following maximal surgical resection is to improve local control
- There have been no randomized studies investigating optimal dose
- Initial results in the 1960s and 1970s suggest an improvement in symptomatic response and local control with increasing dose
- Used antiquated techniques and often included multiple sites in their reports
- In 1970 Pearlman and Friedman: Decrease in local failure with ↑ dose

Dose	Rates of Failure
<40 Gy (n=47)	85%
40 – 60 Gy (n=18)	60%
60-80 Gy (n=8)	43%
>80 Gy (n=2)	0%

Abbreviations: Ch, Chordoma; CS, Chondrosarcoma; SRS, Stereotactic radiosurgery.

- Response correlated to only small volumes
- Increased marginal failures
- Increased morbidity: cranial nerve dysfunction, brain necrosis

Chordoma - Small Tumor Volume

In contrast to SRS, even in small tumors treated with protons, consistently a CTV and a PTV are created

Chordoma Chondrosarcoma

Target definition

- GTV (gross tumor volume)= gross residual tumor (and high-risk area in immediate proximity)
  - MRI (T1, T1GD, T2)
  - CT (bone window)
- CTV (clinical target volume) = postop. tumor bed (taking in account pre-op. extension), modifying for anatomical boundaries and compartments.

Prescription dose to targets

- PTV1 (CTV): 54 Gy(RBE) at 2 Gy/fr
- PTV2 (GTV): 74 Gy(RBE) Chordoma / 70 Gy(RBE) Chondrosarcoma at 2 Gy/fr

Skull Base Chordoma and Chondrosarcoma

OAR Constraints:

Optic chiasm and nerves: max 60 Gy(RBE)
Brainstem surface: max 64 Gy(RBE)
Brainstem center: max 54 Gy(RBE)
Cochlea: max 36 Gy(RBE), mean 30 Gy(RBE)
Temporal Lobe (outside PTV): ≤ 20 Gy(RBE)
Spinal cord surface: max 60 Gy(RBE)(generally ≤54 Gy(RBE)
Spinal cord center: ≤50.4 Gy(RBE)
Hippocampus: V_{40} = <7.3 Gy(RBE

Chordoma Chondrosarcoma

Ares *et al*. IJROBP 2009;75(4):1111-8

Prognostic Factors Significant for Local Control in CHORODMA

- Residual tumor volume >25 c.c.
- Brainstem compression

Radiation-induced Late Toxicity

- Asymptomatic MRI white matter changes (G1) = 5 patients

- High grade late toxicity = 4 patients (all diagnosed with chordoma)
  - optic pathway: G4 (1 patient) – unilateral blindness
    G3 (1 patient) – unilateral visual deficit, steroid dependent
  - neurologic: G3 (2 patients) – **symptomatic brain necrosis**

Actuarial 5-year freedom from high-grade toxicity: 94%

Chordoma Chondrosarcoma

Protons: Improved Local Control for “Smaller Size Tumors”

LLUMC: < 25 c.c. vs. > 25 c.c. (100% vs. 56%)

- **CPO: <29 c.c. vs. > 29 c.c.**
- **PSI: > 25 c.c. vs. > 25 c.c. (90% vs. 74%)**
- **MGH: < 70 c.c. vs. > 70 c.c. (disease-free survival)**

Chordoma Chondrosarcoma

Risk of severe (>Grade 3) following high-dose proton therapy

- **Tumor size**
- **Compression of: chiasm, optic N, brainstem, brain**
- **Number of surgeries**
- **Diabetes, HTN, smoking**
- **KPS**

Summary of Prognostic Factors

- (+++) Skull base: Chondrosarcomas versus Chordomas
- (+++) Tumor Size
- (++) Skull Base versus Spine
- (+) Primary versus recurrent disease
- (+) Chondroid versus Non-Chondroid Pathology
- (?) Gender
- (+) Age
- (+) Pediatric versus Adult
- (+++) Ability versus Inability to deliver dose: Optimal / suboptimal dose distribution by involvement or abutment of critical structures
- (+++) Radiation Dose
- (+++) Protons versus Photons

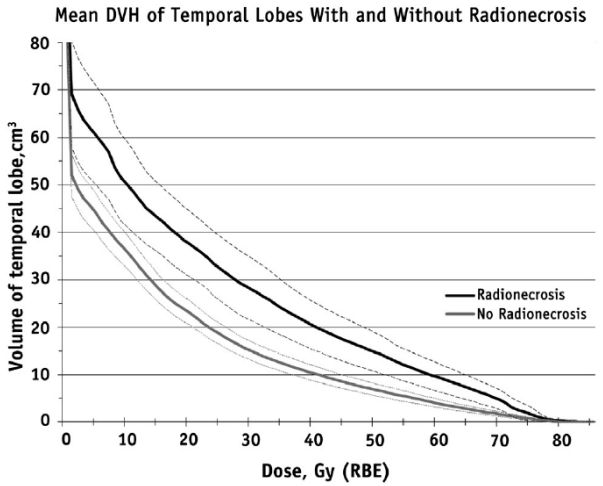
Occurrence = 6%

Chordoma Chondrosarcoma



Necrosis @ 3 year	12.4%
Necrosis @ 3 year (grade 2 and higher)	5.7%

Dose–Volume Relationships Associated With Temporal Lobe Radiation Necrosis After Skull Base Proton Beam Therapy

Mark W. McDonald, MD,*,† Okechukwu R. Linton, MD, MBA,* and Cynthia S.J. Calley, MA‡

Mean dose–volume information to area of radiation necrosis by grade of radiation necrosis

	Grade 1/asymptomatic	Grade 2 or higher	*P* value
Volume, cm^3	2.15	3.66	.51
Minimum dose	54.0	50.2	.58
Maximum dose	75.0	82.9	<.01
Mean dose	68.6	73.0	.02
Epicenter dose	70.9	76.7	<.01

Dose is given in Gy (relative biological effectiveness).

Dose–volume levels associated with 3-year risk of any-grade temporal lobe radiation necrosis

Risk level	aV40	aV50	aV60	aV70
10%	16.5	9.0	5.1	1.2
15%	16.5	9.6	5.5	1.7
20%	16.6	10.1	5.8	2.0
30%	16.7	10.8	6.3	2.5
40%	16.7	11.4	6.8	3.1
50%	16.8	12.2	7.2	3.9

Abbreviations: aV = absolute volume of temporal lobes exposed to dose in Gy (RBE); RBE = relative biological effectiveness. Volume is expressed in cubic centimeters (cm^3).

Int J Radiation Oncol Biol Phys, Vol. 91, No. 2, pp. 261–267, 2015

ESTRO School

Summary

1. Excellent tumor control with for SBM with various radiotherapeutic modalities
2. SBM: Increase tumor response with radio-surgery
3. SBM: Increase radiation-induced toxicity with SRS
4. QoL in meningioma patients ill-assessed
5. High-dose radiation therapy necessary to control Chordomas
6. No PRT (level I evidence)
7. Prognostic factors: Chordoma, volume, tumor size, compression of BS, photons
8. Main toxicity of PT is brain necrosis

Management of benign brain tumours

Radiotherapy in patients with non-functioning pituitary adenoma

1. prolongs survival
2. should be given soon after incomplete resection
3. should avoid hypothalamus
4. all of these
5. none of these

Radiotherapy in patients with secreting pituitary adenoma

1. is the primary treatment for persistent elevation of GH after surgery for acromegaly
2. higher total dose leads to faster hormone decline
3. radiosurgery compared to fractionated treatment leads to faster hormone decline
4. all of these
5. none of these

focal radiotherapy (SRT) & radiosurgery (SRS)

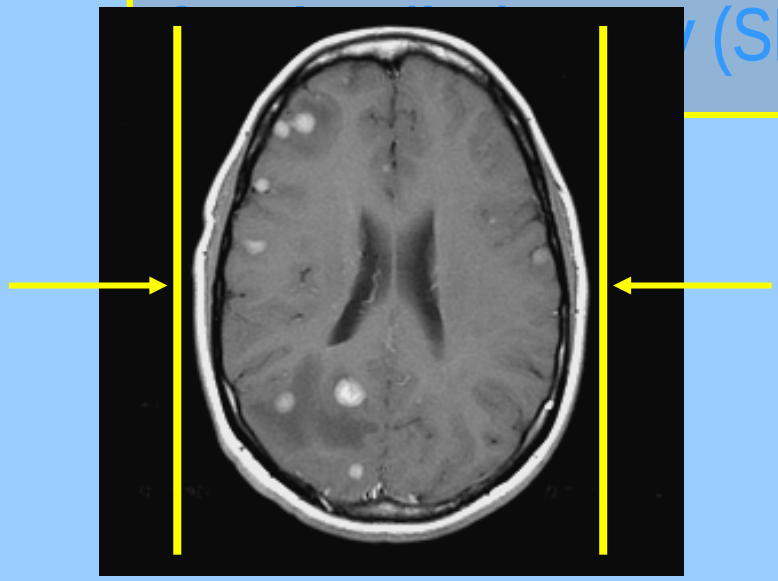
Radiotherapy options

Extent of irradiation

whole brain radiotherapy (WBRT)

partial brain radiotherapy (PBRT)

(SRT) & radiosurgery (SRS)



Radiotherapy options

Whole brain radiotherapy for multiple brain metastases

1. higher dose achieves better tumour control
2. 30Gy in 10 fractions is the best regimen
3. more protracted fractionation is less toxic
4. causes somnolence and fatigue
5. all of these
6. none of these

Supportive care of brain tumor patients

ESTRO teaching course
Management of brain tumours

Patrick Roth

Department of Neurology and Brain Tumor Center
University Hospital Zurich

Overview

- Management of pain
- Antiemesis
- Treatment of seizures
- Steroids for the treatment of tumor-associated edema

Seizures in brain tumor patients

Background

- Incidence of brain tumor-associated epilepsy
- Tumor-mediated epileptogenesis

Medical treatment

- Available drugs
- Treatment recommendations
    - Interaction with other drugs / tumor-specific treatment
    - Appropriate antiepileptic drugs
- Duration of treatment

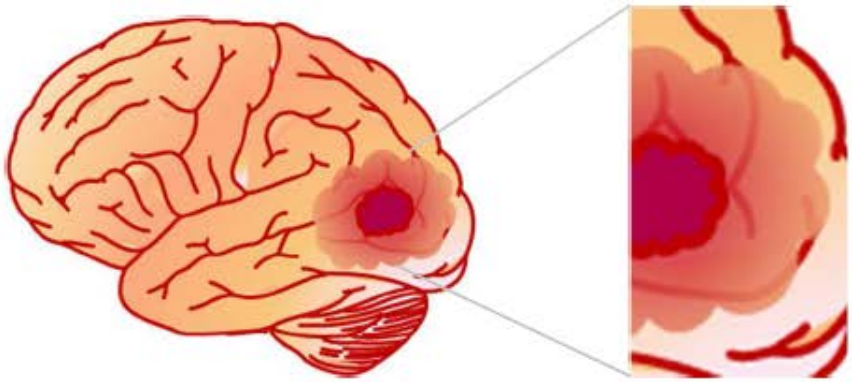
Epilepsy in brain tumor patients

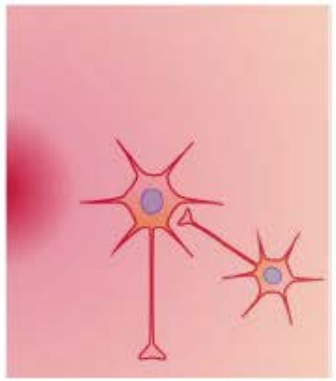
- Approx. 30-50% of all brain tumor patients are affected by seizures
  => frequently first clinical manifestation of a brain tumor

- Seizures are particularly common in slowly growing tumors and tumors of glial origin

• **DNET**	**100%**
• **Ganglioglioma**	**80-90%**
• **Low-grade glioma**	**70-80%**
• **Meningeoma**	**30-60%**
• **Glioblastoma**	**30-50%**
• **Metastases**	**20-35%**
• **CNS lymphoma**	**10-15%**

Brain tumors & epileptogenesis





- Blood-brain barrier
- Edema
- Intracranial pressure
- Hemosiderin

- Alkalinization
- Deafferentiation
- Glial excitability ↑

- Glutamate ↑
- GABA-mediated inhibition ↓
- Adenosine ↓

ESTRO School

Impact of tumor-specifc therapy on epilepsy

- **Radiotherapy: may increase edema, necrotic areas may also enhance the excitability**

- **Chemotherapy: increased risk of infections => fever => may trigger seizures**

- **Concomitant medication:**

  Steroids may alter glucose and electrolyte levels

  Neuroleptics may trigger seizures

Which antiepileptic drugs (AED) are appropriate?

Basic considerations

- Antiepileptic activity
- Side effects
- Interaction with other drugs
- Approval for monotherapy

Specifically for brain tumors

- Interaction with tumor-specific treatment
- Direct effects on the tumor
- i.v. administration

Numerous AED are available

Drug	Trade name (CH)	Dose (mg)	costs/day (CHF)
Phenobarbital	Luminal®	50-300	0.1-0.5
Phenytoin	Phenhydan®	200-350	0.15-0.5
Carbamazepine	Tegretol®	600-2000	0.7-2.5
Valproic acid	Orfiril®	1200-2400	1-2
Lamotrigine	Lamictal®	100-300	3-7
Gabapentin	Neurontin®	900-2400	2-5
Topiramate	Topamax®	50-200	2-5
Levetiracetam	Keppra®	1000-3000	4-13
Lacosamide	Vimpat®	100-400	4-13
Zonisamide	Zonegran®	300-500	5-12

ESTRO School

Which AED do you choose?

45 yo patient with a low-grade glioma has 2 generalized tonic-clonic seizures.

Which drug will you prescribe?

1. **Phenytoin**
2. **Valproic acid**
3. **Levetiracetam**
4. **Any other AED**
5. **The neurologist should tell me**

AED in brain tumor patients: where is the evidence?

THE COCHRANE COLLABORATION®

Antiepileptic drugs for treating seizures in adults with brain tumours (Review)

Kerrigan S, Grant R

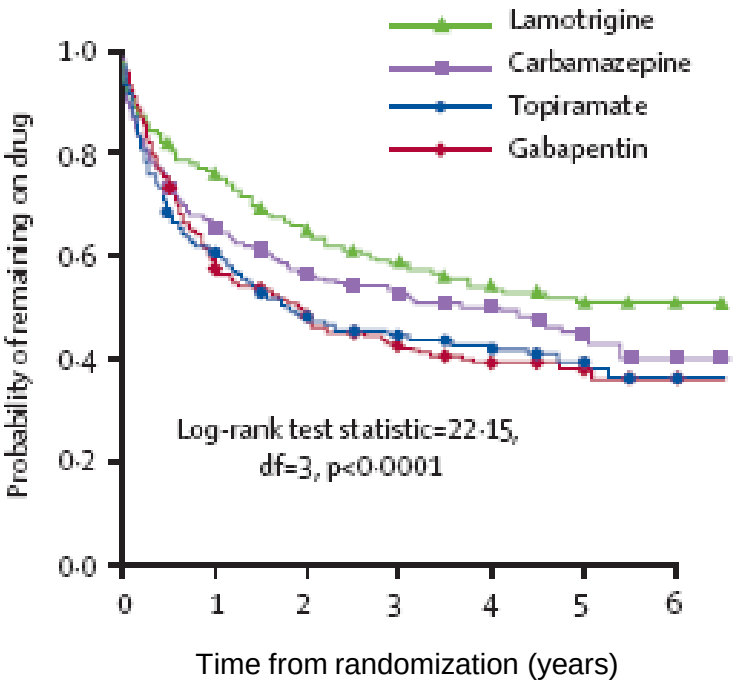
Cochrane Database Syst Rev 2011

"There is a lack of robust, randomised, controlled evidence to support the choice of antiepileptic drug for the treatment of seizures in adults with brain tumors"

"There is a need for further large randomised, controlled trials in this area"

ESTRO School

How to choose the best AED



„time to treatment failure“:
LTG > CBZ, GBP und TPM

Marson et al., Lancet 2007

„seizure control“
LEV = CBZ

Brodie et al., Neurology 2007

1.	Carbamazepine	CBZ
2.	Gabapentin	GBP
3.	Lacosamide	LAC
4.	Lamotrigine	LTG
5.	Levetiracetam	LEV
6.	Oxcarbazepine	OXC
7.	Perampanel	PER
8.	Phenobarbital	Pb
9.	Primidon	PRM
10.	Phenytoin	PHT
11.	Pregabalin	PGB
12.	Topiramate	TPM
13.	Valproic acid	VPA
14.	Zonisamide	ZON

Old AED: pros and cons

Phenobarbital	Sedation, allergic reactions Enzyme induction (cytochrome P450)
Phenytoin	Vertigo, allergic reactions, liver enzymes ↑, gingival hyperplasia, cerebellar degeneration Enzyme induction (cytochrome P450)
Carbamazepine	Vertigo, Nausea, Ataxia, low blood sodium, nystagmus, allergic reactions, Enzyme induction (cytochrome P450)
Valproic acid	Tremor, gain of weight, coagulation disorders, thrombopenia, teratogenicity Enzyme inhibition

New(er) AED: pros and cons

Lamotrigine	Skin reactions, tremor, sedation
Gabapentin	Fatigue, vertigo
Pregabalin	Vertigo
Levetiracetam	Fatigue, psychiatric disorders
Topiramate	Fatigue, loss of appetite, cognitive impairment
Lacosamide	Vertigo

Further considerations

- Enzym-inducing drugs may reduce the activity of chemotherapeutic drugs and steroids
- VPA (enzyme inhibition): impact is unclear
- Probably no interaction of lamotrigine, gabapentin, pregabalin, levetiracetam, topiramate or lacosamide with chemotherapeutic agents

1.	Carbamazepine	CBZ
2.	Gabapentin	GBP
3.	Lacosamide	LAC
4.	Lamotrigine	LTG
5.	Levetiracetam	LEV
6.	Oxcarbazepine	OXC
7.	Perampanel	PER
8.	Phenobarbital	Pb
9.	Primidon	PRM
10.	Phenytoin	PHT
11.	Pregabalin	PGB
12.	Topiramate	TPM
13.	Valproic acid	VPA
14.	Zonisamide	ZON

Which drugs are approved for monotherapy?

Monotherapy (CH):

CBZ, GBP, LTG, LEV, OXC, Pb, PHT, PRM, TPM, VPA, ZON

i.v. administration:

LAC, LEV, Pb, PHT, VPA

1.	Carbamazepine	CBZ
2.	Gabapentin	GBP
3.	Lacosamide	LAC
4.	Lamotrigine	LTG
5.	Levetiracetam	LEV
6.	Oxcarbazepine	OXC
7.	Perampanel	PER
8.	Phenobarbital	Pb
9.	Primidon	PRM
10.	Phenytoin	PHT
11.	Pregabalin	PGB
12.	Topiramate	TPM
13.	Valproic acid	VPA
14.	Zonisamide	ZON

Who to treat and for how long?

- **Shall all brain tumor patients be treated with an AED?**
  No
- **Prophylaxis in all patient who undergo surgery?**
  No – or only transiently
- **Treatment following a seizure?**
  Yes
- **How long shall patients be treated with an AED?**
  Depends on histology, overall prognosis, tolerance…

Conclusions: brain tumors and epilepsy

- Hardly any data from randomized trials
- **Levetiracetam**: may be overall well tolerated and have good activity against seizures in brain tumor patients
- **Lamotrigine**: no comprehensive testing in brain tumor patients; overall good antiepileptic activity, well tolerated
- **Pregabalin**: may be considered as an alternative drug, probably not approved as monotherapy in most countries
- **Valproic acid**: active, moderate tolerability, may have anti-tumor properties (?)

Overview

- Management of pain
- Antiemesis
- Treatment of seizures
- **Steroids for the treatment of tumor-associated edema**

Steroids in neurooncology: history

CORTISONE AND ACTH AS AN ADJUNCT TO THE SURGERY OF CRANIOPHARYNGIOMAS*

FRANC D. INGRAHAM, M.D.,† DONALD D. MATSON, M.D.,‡ AND ROBERT L. MCLAURIN, M.D.§

BOSTON

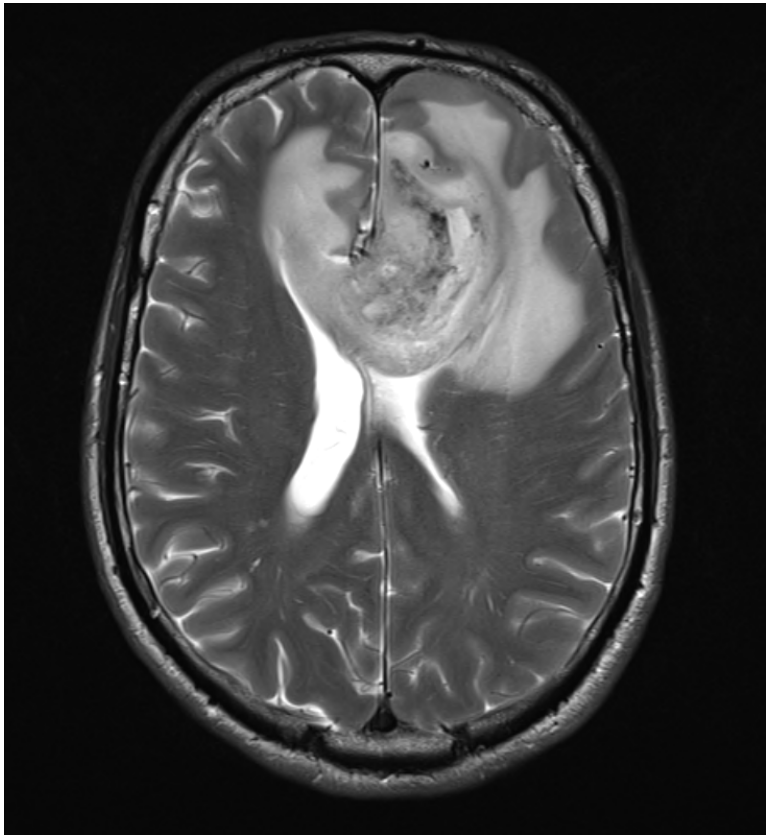
THE surgical management of craniopharyngiomas, whether radical or conservative, has always been hazardous. Gordy, Peet and Kahn[1] reported a series of 51 cases in which the operative mortality was 41 per cent, due principally to severe hypothalamic reactions incident to the surgical manipulation. Grant,[2] in summarizing the results of 40 operations on 30 patients, found a case mor-

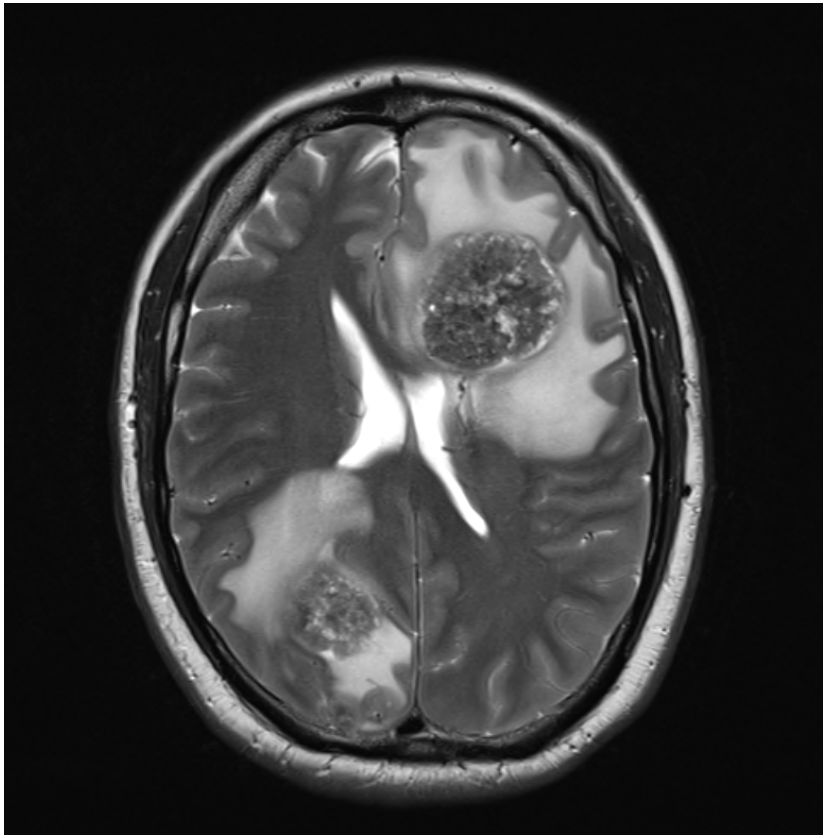
pacity of the pituitary adrenal system were, of course, not employed.

It is apparent that most of the operative complications in the treatment of craniopharyngioma result from the proximity of the lesion to the pituitary gland and the hypothalamus. Manipulation in this region is perilous at all times, but the danger is accentuated in the majority of these cases because

Treatment of edema

Primary or secondary brain tumors with surrounding edema





Which steroid and which dose?

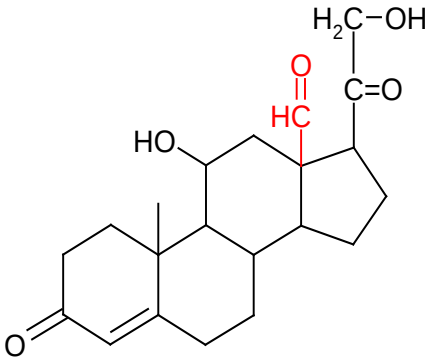
57 yo patient with a recurrent glioblastoma and pronounced edema requires treatment with steroid because of increasing hemiparesis on the right side.

What will you do?

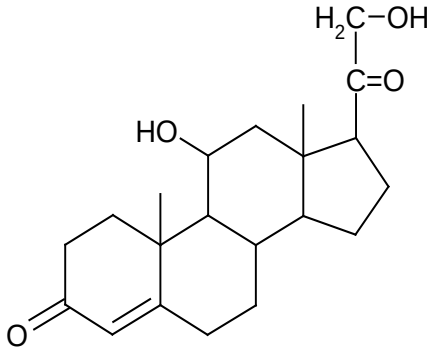
1. **Hydrocortisone 30 mg/d**
2. **Prednisone 100 mg/d**
3. **Dexamethasone 4 x 4 mg**
4. **Dexamethasone 16 mg**

Physiological steroid hormones

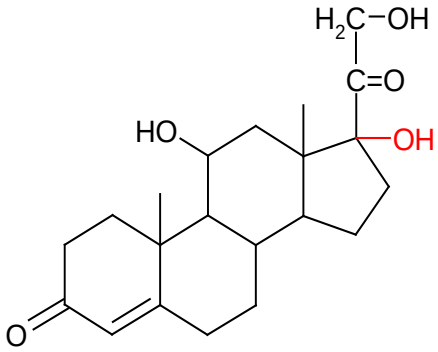
glucocorticoid activity



aldosterone



corticosterone



cortisol/hydrocortisone

mineralocorticoid activity

Steroids: which compound?

	Glucocorticoid Potency	Plasma half-life (h)	Biological half-life (h)	Mineralo-corticoid effects
Hydrocortisone	1		8-12	1
Prednisone	5	3-4	12-36	0.8
Methylprednisolone	4	1.5-3	12-36	0.5
Dexamethasone	~ 30	2-5	36-54	0

Advantages of dexamethasone:

- Least amount of mineralocorticoid activity
  => Low rate of fluid retention
- Long biological half-life
  => frequent dosing not required

Dexamethasone dosing

Dose-effect relationship of dexamethasone on Karnofsky performance in metastatic brain tumors:

A randomized study of doses of 4, 8, and 16 mg per day

Ch.J. Vecht, MD, PhD; A. Hovestadt, MD, PhD; H.B.C. Verbiest, MD; J.J. van Vliet; and W.L.J. van Putten, MSc

Neurology®

- 96 patients; 2 randomized, double-blind trials
- Dexamethasone: 4 vs. 16 mg/d
  8 vs. 16 mg/d
- Primary endpoint: KPS => no difference
- Side effects: more frequent in patients taking 16 mg/d

Vecht et al., Neurology 1994

Steroids: side effects

- **Hyperglycemia ("steroid diabetes": > 50% of all patients)**

VOLUME 27 · NUMBER 7 · MARCH 1 2009

JOURNAL OF CLINICAL ONCOLOGY

ORIGINAL REPORT

Association Between Hyperglycemia and Survival in Patients With Newly Diagnosed Glioblastoma

Rachel L. Derr, Xiaobu Ye, Melissa U. Islas, Serena Desideri, Christopher D. Saudek, and Stuart A. Grossman

Cushing's syndrom:

- **Central obesity**
- **"moon face"**
- **Arterial hypertension**

Osteoporosis & myopathy

Osteoporosis:

- **Development of osteoporosis is particularly high in patients taking other osteoporosis-inducing drugs (e.g. loop diuretics, thyroxine)**

- **Prophylaxis: Calcium, vitamine D, biphosphonates**

Myopathy:

- **Weakness of the proximal muscles of the upper and lower limbs**
- **No data supporting the hypothesis that myopathy occurs more frequently when „fluorinated“ steroids are used**
- **Prophylaxis: physiotherapy**

Side effects: many more…

- Gastrointestinal symptoms (peptic ulcers)
- Steroid cataract
- Psychiatric side effects (depression, psychosis, insomnia)
- Increased risk for infections (e.g. Pneumocystis jirovecii) (particularly in patients who receive radio- and/or chemotherapy)

=> Steroid toxicity may reduce the benefit from other treatment modalities, e.g. radio- and chemotherapy

Guidelines for the use of steroids

- **Regular check of blood pressure and glucose levels**
- **Proton pump inhibitor and thrombosis prophylaxis should be considered**
- **PJP prophylaxis, particularly in patients on radio-/chemotherapy**
  - **Trimethoprim/sulfamethoxazole (Co-trimoxazole)**
  - **Pentamidine inhalation**
- **Check interaction(s) with other drugs**

Steroid tapering

- **Tapering should be persued as soon as clinically possible**
- **Short treatment => rapid tapering**
- **Long duration of therapy => slow tapering**

  => Watch for signs of hypocortisolism!

  - **Nausea, vomiting, headaches**
  - **Myalgia, hypotension**

- **Manifest hypocortisolism: substitution with hydrocortisone**

  => average daily dose: 20-30 mg

Can we avoid/replace steroids?

- **H15 (Boswellia serrata): limited activity**

Boswellia serrata Acts on Cerebral Edema in Patients Irradiated for Brain Tumors

A Prospective, Randomized, Placebo-Controlled, Double-Blind Pilot Trial
