Advanced Brachytherapy Physics A Biennial ESTRO Course since 2014

Imitative started in 2008

Formal Submission of Proposal to ESTRO-ETC November 24, 2009:

- Jack Venselaar
- Dimos Baltas

1st Course in Brussels, Belgium, 18-21 May 2014

Advanced Brachytherapy Physics 07-10 October 2018 | Valencia, Spain

The Faculty of the 3rd Course

Course Director: Teachers:

Dimos Baltas (DE) Luc Beaulieu (CA) Nicole Nesvacil (AT)

Panagiotis Papagiannis (GR) Mark Rivard (USA)

Local Organisers:

Jose Perez-Catalayud Facundo Ballester

Project Manager:

Alessandra Nappa, ESTRO office (BE)

Advanced Brachytherapy Physics 07-10 October 2018 | Valencia, Spain

- Brachytherapy is the pioneer of extreme hypofractionation that has currently become one of the hot topics in radiation oncology.
- Brachytherapy experiences here an ever broader imitation by external beam methods as is especially demonstrated in the radiation therapy of localized prostate cancer.
- There is an emerging role of advance and dedicated 3D imaging modalities, image guidance techniques and navigation technologies for pre-planning of the implant, for the implantation procedure, for the treatment planning and finally for treatment verification.
- The availability of inverse planning and optimization techniques enforces the demand for individualized implant design, dose prescription and accurate 3D dose calculation.
- All above enable adaptive (4D) treatment planning and adaptive (4D) treatment delivery techniques.
- At the same time raises the demand for deep background knowledge and extended expertise for the involved medical physicists.
- There is a central role assigned for clinical medical physicists and researchers for development, validation and implementation of such advance methods and techniques.

Advanced Brachytherapy Physics 07-10 October 2018 | Valencia, Spain

- Brachytherapy remains a lively and interesting field of clinical and research activities.
- It is well worthwhile for young researchers and medical physicists to get involved in this evolving area of radiation oncology with a strong sense of multidisciplinarity and interdisciplinarity.
- We, the faculty and our local organisers, will do our best to demonstrate *"there is really something going on in the Physics and Technology in Brachytherapy".*

Participants 1st Course, Brussels, 2014 N = 62 (33 Countries)

Support from IAEA: 25 travel grants

Participants 2nd Course, Vienna, 2016 N = 39 (15 Countries)

Participants 3rd Course, Valencia, 2018 N = 61 (17 Countries)

Treatment Delivery Technologies in Brachytherapy

Prof. Mark J. Rivard, Ph.D., FAAPM

Advanced Brachytherapy Physics, 29 May – 1 June, 2016

Disclosures

The are no conflicts-of-interest to report.

Opinions herein are solely those of the presenter, and are not meant to be interpreted as societal guidance.

Specific commercial equipment, instruments, and materials are listed to fully describe the necessary procedures. Such identification does not imply endorsement by the presenter, nor that these products are necessarily the best available for these purposes.

Learning Objectives

- 1. Brief history of BT sources and delivery systems
- 2. LDR BT sources and advancements
- 3. HDR BT sources and advancements
- 4. Robotic systems for BT delivery

Manually Delivered LDR BT

[20.4] Radium plaques being applied in the Skin Department, St. Vincent's Hospital, Melbourne, Australia in 1905¹⁹.

Radium Needles and Tubes

[3.17] Although there was a large range of linear radium sources, tubes and needles, in terms of geometrical and active length and linear activity (milligram radium/cm), the basic design from the early 1920s was essentially that shown in the schematic diagram. Evelets were used to suture a needle to the patient's tissue to prevent the possibility of its involuntary removal before the end of treatment, or to attach string threads to a tube to enable removal, such as from the uterus or vagina after gynaecological brachytherapy had been completed. Some designs had removeable screw-on ends so that different radium cells could be placed in the outer container, depending on the required treatment. Union Minière du Haut Katanga, the Belgian company, supplied such sources in the 1920s, but by the 1950s the Radiochemical Centre, Amersham (later Amersham International), who were then the major supplier of radium sources, had no screw-on end designs and certainly did not supply any radium cells which, because of their very thin walls, were of a much greater hazard that the sealed sources illustrated here. These are the well known G-tubes which were 2 cm geometrical length, and available with different milligram radium contents

such as 10 mg, 15 mg, 20 mg and 25 mg. When radium was replaced by artificially produced radionuclides, such G-tubes then contained caesium-137 with an actively specified in terms of milligram radium equivalent [20.12, 20.56].

Sealed Source Configurations

Current LDR Brachytherapy Sources

- Low-energy LDR sources (seeds)
 - ¹²⁵I and ¹⁰³Pd most common with ¹³¹Cs gaining interest
 - about 4.5 mm long and 0.8 mm diameter copsules
 - treatments either temporary or permanent

 $0.4 < D_{Rx} < 2 \text{ Gy/h}$

- High-energy LDR sources (increasingly rarely)
 - ¹³⁷Cs tubes and ¹⁹²Ir ribbons or wire
 - treatments mainly temporary (¹³⁷Cs or ¹⁹²Ir), or permanent (¹⁹²Ir)

Understand the source geometry

Dynamic source orientation influences some dose distributions

(b)

Low-E HDR Brachytherapy Systems

- Low-energy sources for HDR brachytherapy
 - electronic brachytherapy (eBT) can turn on/off
 - similar dose distributions to HDR ¹²⁵I source
 - independence from a radioactive materials license
 - diminished shielding/licensing/security required
 - potential to replace radionuclide-based brachytherapy like linacs replaced ⁶⁰Co
- Vendors for eBT brachytherapy systems
 - Carl Zeiss AG (INTRABEAM)
 - Xoft/iCAD (Axxent)
 - Nucletron/Elekta (esteya)

Medical Physics discussion on eBT

Miniature x-ray tubes will ultimately displace Ir-192 as the radiation sources of choice for high dose rate brachytherapy

Randall W. Holt, Ph.D.

Radiation Oncology Center, Enloe Hospital, Chico, California 95926 (Tel: 530-332-3930, E-mail: randall.holt@enloe.org)

Bruce R. Thomadsen, Ph.D.

Medical Physics, Human Oncology, Engineering Physics and Biomedical Engineering, University of Wisconsin, Madison, Wisconsin 53706 (Tel: 608-263-4183, E-mail: thomadsen@humonc.wisc.edu)

OVERVIEW

Recent advances in the development of miniature x-ray tubes have made electronic brachytherapy a feasible alternative to conventional high dose rate brachytherapy with high activity Ir-192 sources. Because of the obvious radiation safety and security advantages, it is conceivable that the miniature x-ray tube might displace Ir-192 as the source of choice for HDR brachytherapy. This is the proposition debated in this month's Point/Counterpoint.

Arguing for the Proposition is Randall W. Holt, Ph.D. Dr. Holt earned his Ph.D. in Biomedical Engineering at Case Western Reserve University, specializing in 3D-image analysis, after which he received postdoctoral training at the USC Department of Radiation Oncology, specializing in virtual simulation and 3D dosimetry software. Currently Dr. Holt is the Director of

Physics for North Valley Radiation Oncology, which provides a broad range of medical physics services to clinics in Northern California. He is board certified by the ABR in radiation therapy physics.

Arguing against the Proposition is Bruce R. Thomadsen, Ph.D. Dr. Thomadsen earned his M.S. and Ph.D. degrees in Medical Physics at the University of Wisconsin—Madison, where he is currently an Associate Professor in the Department of Medical Physics. He is board certified by the ABR in Radiological Physics, by the ABHP in Comprehensive Health Physics, and by the

ABMP in Radiation Oncology Physics. His major research interests include all aspects of radiation therapy physics but especially brachytherapy. Dr. Thomadsen currently serves on numerous AAPM committees and task groups and chairs the Radiation Safety Subcommittee and the Special Brachytherapy Modalities Working Group, and is a member of the Board of Editors of *Medical Physics*.

FOR THE PROPOSITION: Randall W. Holt, Ph.D

Opening statement

To displace Ir-192, miniature x-ray sources must deliver therapeutic radiation as well as, or potentially better than, Ir-192, under safer conditions, and with favorable economics.

AAPM and GEC-ESTRO guidelines for image-guided robotic brachytherapy: Report of Task Group 192

Tarun K. Podder, Luc Beaulieu, Barrett Caldwell, Robert A. Cormack, Jostin B. Crass, Adam P. Dicker, Aaron Fenster, Gabor Fichtinger, Michael A. Meltsner, Marinus A. Moerland, Ravinder Nath, Mark J. Rivard, Tim Salcudean, Danny Y. Song, Bruce R. Thomadsen, and Yan Yu

This is a joint Task Group with the Groupe Européen de Curiethérapie-European Society for Radiotherapy & Oncology (GEC-ESTRO). All developed and reported robotic brachytherapy systems were reviewed. Commissioning and quality assurance procedures for the safe and consistent use of these systems are also provided. Manual seed placement techniques with a rigid template have an estimated in vivo accuracy of 3–6 mm. In addition to the placement accuracy, factors such as tissue deformation, needle deviation, and edema may result in a delivered dose distribution that differs from the preimplant or intraoperative plan. However, real-time needle tracking and seed identification for dynamic updating of dosimetry may improve the quality of seed implantation. The AAPM and GEC-ESTRO recommend that robotic systems should demonstrate a spatial accuracy of seed placement ≤ 1.0 mm in a phantom. This recommendation is based on the current performance of existing robotic brachytherapy systems and propagation of uncertainties. During clinical commissioning, tests should be conducted to ensure that this level of accuracy is achieved. These tests should mimic the real operating procedure as closely as possible.

Fig. 2. Comparison of the volume of healthy tissue beyond the PTV covered by dose between the 20% and 80% of prescribed dose between (a) HDR BRT and SRS plans and (b) HDR BRT and SBRT plans. There is no significant difference (p = 0.397) between the $V_{20\%}-V_{80\%}$ of SRS and HDR BRT plans. The $V_{20\%}-V_{80\%}$ of SBRT and HDR BRT are significantly different with p = 0.003 in favor of HDR BRT. The $V_{20\%}-V_{80\%}$ parameter of HDR BRT plans increases slower with increase of the PTV compared with that of X-Knife. The $V_{20\%}-V_{80\%}$ is expressed in cm³. PTV = planning target volume; HDR = high-dose-rate; BRT = brachytherapy; SRS = stereotactic radiosurgery; SBRT = stereotactic body radiation therapy.

In contrast to ERT, where the set-up of the real Beams (irradiation) is based on:

- Immobilization of the patient as in planning process (CT)
- (re)Positioning of the patient using the RP and the Machine Coordinate System (Laser Projection of Isocentre)
 RP – Laser-Iso
- → RP = Laser-Iso
- Imaging-based (2D/3D, SIG) verification of Anatomy/Target position
- Fully automatic move: Plan-Isocenter ←→ Machine-Isocenter
- Fully automatic set-up of the beams and MLC-configurations

In contrast to ERT, where the set-up of the real Beams (irradiation) is based on:

Immobilization of the patient as in planning process (CT)

→ RP = Laser-Iso

In contrast to ERT, where the set-up of the real Beams (irradiation) is based on:

- Immobilization of the patient as in planning process (CT)
- (re)Positioning of the patient using the RP and the Machine Coordinate System (Laser Projection of Isocentre)
- → RP = Laser-Iso

In contrast to ERT, where the set-up of the real Beams (irradiation) is based on:

- Immobilization of the patient as in planning process (CT)
- (re)Positioning of the patient using the RP and the Machine Coordinate System (Laser Projection of Isocentre)

➔ RP = Laser-Isocenter

- Fully automatic shift: Plan-Isocenter ←→ Machine-Isocenter
- Imaging-based (2D/3D, SIG) verification of Anatomy/Target position
- Fully automatic set-up of the beams and MLC-configurations

In contrast to ERT

In BRT the "Beams", the implanted Catheters/Applicators, have to be firstly localised (reconstructed; definition of their 3D geometry) and registered to the anatomy based on the available imaging data. Exactly this Co-registration of Anatomy $\leftarrow \rightarrow$ Catheters/Applicators replaces the/corresponds to RP $\leftarrow \rightarrow$ Laser-Iso Positioning of ERT.

The actual aim of the Localisation Process is:

to define the 3D-positions of the sources or of the possible source dwell positions and register these to the relevant anatomy (PTV, OARs).

This presumes:

- Localisation of the implanted Catheters/Needles/ Applicators and
- Knowledge of Afterloader and Catheter/Applicator specific Information/Characteristics.

Knowledge of Afterloader and Catheter/Applicator specific Information/Characteristics

Knowledge of Afterloader and Catheter/Applicator specific Information/Characteristics

In general there are exist two methods for the Localisation of the sources/ possible source dwell positions.

Source Path Method

Here the "*finger-print*" of the individual implanted catheters/ applicators on the acquired images is utilized (interstitial implants, endoluminal and simple endocavitary applicators)

Fig. 7. Position of a library applicator (in the middle) in the transversal (left) and sagittal (right) plane.

3D-Applicator Model Method

Here the 3D Applicator geometry (rigid) is preexisting and stored as a "3D-Object" including all required information for generation of sources/source dwell positions (source paths, all possible source dwell positions and channel length for each path, ...)

GEC-ESTRO Recommendations, Hellebust T., Kirisits, C., Berger, D., et al., Rad Oncol 95, 5, 153-160, 2010.

The actual aim of the Localisation Process is:

to define the 3D-positions of the sources or of the possible source dwell positions and register these to the relevant anatomy (PTV, OARs).

Today's Session on <u>3D Imaging and Localisation</u>

Modern Brachytherapy Treatment Planning Dynamic and Adaptive Implantation Process

- **Define "best-possible" = Inverse Planning**
- It presupposes the availability of:
 - A complete 3D anatomy model Morphology (3D Imaging) VOIs: Target(s), OARs
 - The Desired/Aimed Dose Distribution

Inverse Planning:

The automatic placement of an adequate number of catheters/applicators/needles based on dosimetric objectives and constraints. Consideration of (i) *Medical* (ii) *Anatomical* und (iii) *Technical Implantation* demands/presetting. It is solvable in clinically acceptable time only after *discretisation*

The Inverse Planning of an adequate number of catheters/applicators / needles based on dosimetric objectives and constraints *is solvable in clinically acceptable time* only after *discretisation*

Inverse Planning:

The automatic placement of an adequate number of catheters/applicators/needles based on dosimetric objectives and constraints. Consideration of (i) *Medical* (ii) *Anatomical* und (iii) *Technical Implantation* demands/presetting. It is solvable in clinically acceptable time only after *discretisation*.

Disclosures

• None for this section

Learning Objectives

- Provide an understanding of the challenges of tissue segmentation in brachytherapy
- Present and explain the TG-186 recommendations
- Look at DECT has the next step for tissue segmentation in radiation therapy.

Factor-based TG43

There is no tissue segmentation, only organ contouring

From Åsa Carlsson-Tedgren

Factor-based vs Model-based

FROM: G Landry, Med Phys 2011

On-going Debate

"Results suggest that cells in cancerous and normal soft tissues are generally not radiologically equivalent to either water or the corresponding average bulk tissue"

Thomson, Carlsson, Williamson. PMB 58 (2013)

Procedure: tissue segmentation

	(Density) _i , (Medium) _i	

From F. Verhaegen

Cross section assignments (segmentation)

- MDBCA requires assignment of interaction cross section on a voxel-by-voxel basis
- In EBRT one only needs electron densities ρ_e (e⁻/cm³) from CT scan
- In BT (energy range 10-400 keV) the interaction probabilities depend not only on ρ_e but also strongly on atomic number Z

Cross section assignments

- Accurate tissue segmentation, sources and applicators needed: identification (ρ_e , Z_{eff})
 - ➢ e.g. in breast: adipose and glandular tissue have significantly different ($ρ_e$,Z_{eff}); dose will be different
- If this step is not accurate → incorrect dose
 - > Influences dosimetry and dose outcome studies
 - Influences dose to organs at risk

Large Cavity Theory Cross Section

TG-186 recommendations

- Consensus material definition
- Material assignment method
- CT/CBCT artifact removal

- Extract electron density from CT calibration (see TG53, TG66 ...)
 - Use the density from CT for each voxel
 - Use recommended tissue compositions
 - Organ-based (contoured) assignments
 - Prostate from Woodard et al, BJR 59 (1986) 1209-18
 - All others from ICRU-46 composition
 - From CT calibration: breast, adipose, muscle and bone

	% mass					Mass density

TABLE III. Material definitions. Water is given for comparison.

Consequences:

Uncertainties associated with this process?

- Limited measurements
 - \triangleright e.g. 1930s' data of prostate from a specimen of 14 year old boy ¹
- Considerable tissue composition variability
 - \blacktriangleright e.g. Adipose tissue water content between 23% to 78%²
- Patient-specific distribution of tissue types
 - \blacktriangleright e.g. Breast adipose vs glandular composition: 16% to 68%^{3,4}

- 1) A. H. Neufeld, Canadian Journal of Research 15B, 132-138 (1937).
- 2) B. Brooksby, B. W. et al., PNAS 103 (23), 8828-8833 (2006).
- 3) R. A. Geise and A. Palchevsky, Radiology 198 (2), 347-50 (1996)
- 4) The Myth of the 50-50 breast, MJ Yaffe et al., Med Phys 36 (2009)

Consequences:

Uncertainties associated with this process?

- Human tissues vary from one individual to the other
- Reports (like ICRP 23 or ICRU 44) provides average compositions

Water	11.2			88.8		1.00

- If relevant, artifacts must be removed prior to dose calculations
- Manual override of tissue composition and density is the simplest approach.
- Advanced approaches: if used, must be carefully documented

Sutherland et al, Med. Phys. **38**, 4365 (2012)

- If no CT (US and MRI)
 - Use contoured organs with recommended tissue compositions
 - For ¹⁹²Ir, water is a good approximation <u>for soft tissues</u> <u>only</u>.
 - Air, lung, bone, ... should be assigned correctly
 - Could potentially be generated on MRI (Yu et al., IJROBP, In press; DOI: 10.1016/j.ijrobp.2014.03.028)
 - Use accurate source and applicators geometry <u>and</u> <u>composition</u>

About Pseudo-CT?

IRM: prostate avec proton

Maspero et al, PMB 62(2017)

IRM: prostate avec proton

This study shows that accurate MR-based proton dose calculation for prostate cancer treatment could be performed using a commercial solution originally designed for photon radiotherapy, following adaptation of pseudo-HU values. The correct modelling of internal air cavities was found crucial. For this, a novel method to detect air cavities in an MR-only workflow was pro-Maspero et al, PMB 62(2017)

- Requirements from vendors
 - Accurate geometry (information accessible to users for commissioning)
 - Responsible for providing accurate composition of seeds, applicators and shields.
 - To provide a way for the manufacturers (of the above) or alternatively the end users to input such information into the TPS

> <u>Poke your favorite vendor, this will be critical</u>

Other issues

What is the problem with this figure?

An easier case

Air

Seed/Applicator Model Accuracy Requirements

- Patient CT grids (>1 mm voxel) are <u>probably not</u> adequate for accurate modeling on the spatial scale of brachytherapy sources and applicators.
- MBDCA vendors should use analytic modeling schemes or recursively specify meshes with 1–10 μ m spatial resolution.
- Vendors to disclose their geometry, material assignments, and manufacturing tolerances to both end users and TPS vendors (if responsible for data entry and maintenance)
If TPS Applicator Library provided

- Preferred approach
 - Will ease the verification task.
- Vendor must provide visualization or reporting tools to end user to verify the correctness of each included applicator and source model
 - Ideally against independent design specifications.
- In addition, TPS vendors must disclose sufficient information regarding the model or recursive mesh generation to allow verification of the spatial resolution requirement specified in recommendation (2) in TG-186 Section IV-B

TG-186 Section IV.B: Applicators

• "It is the responsibility of the end-user clinical physicist to confirm that MBDCA dose predictions are based upon sufficiently accurate and spatially resolved applicator and source models, including correct material assignments, to avoid clinically significant dose-delivery error prior to implementing the dose algorithm in the clinic."

Open Issues: Is there a better approach?

- No simple method to extract Z_{eff} from standard imaging modalities
- Dual/Multi energy CT?

Fig. 1. Technical realization of a DSCT system (SOMATOM Definition, Siemens Healthcare, Forchheim, Germany). One detector (A) covers the entire scan field of view with a diameter of 50 cm, while the other detector (B) is restricted to a smaller, central field of view.

M. Bazalova et al., PMB 53 (2008)

Dual-energy x-ray CT material extraction

- CT images are represented by HU = $1000x(\mu/\mu_w-1)$
 - μ and μ_w are the linear attenuation coefficients of a material and of water
- dual-energy material extraction (DECT) is based on
 - Taking CT images at two tube voltages (e.g. 100 kVp and 140 kVp)
 - The farther apart the energy the better!
 - Parameterization of the linear attenuation coefficient results in ρ_e and Z maps

Linear attenuation coefficient

Describes attenuation of a photon beam Torikoshi *et al*: $(7^4 \text{ E} (77^4 \text$

$$\mu(E) = \rho_e \left(Z^4 F(E, Z) + G(E, Z) \right)$$

- $\rho_e = \rho Z / A * N_A$ = electron density
- Z = effective atomic number
- F(E,Z) and G(E,Z) are the photoelectric absorption and scattering terms (Rayleigh and Compton) of μ

For polychromatic x-rays:

$$\mu_j = \rho_e \sum_i \omega_{ji} \left[Z^4 F(E_{ji}, Z) + G(E_{ji}, Z) \right]$$

x-ray spectra represented by weights ω_i at E_i

Torikoshi et al, Phys. Med. Biol. 2003; 48: 673-685. Tsunoo T, et al , NSS Conference Record, IEEE, 2004; 6: 3764-3768

Linear attenuation coefficient

Having the densities the same material measured at two tube voltages, one can solve for Z:

$$\frac{m_{1}}{m_{2}} - \frac{\sum_{i} W_{1i} \left[Z^{4} F(E_{1i}, Z) + G(E_{1i}, Z) \right]}{\sum_{i} W_{2i} \left[Z^{4} F(E_{2i}, Z) + G(E_{2i}, Z) \right]} = 0$$

Or, solve for both Z and density simultanetously

$$Z^{4} - \frac{\frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) + G(E_{2i},Z_{w})\right]\sum_{i}\omega_{i}G(E_{1i},Z) - \frac{\mu_{1}}{\mu_{1w}}\sum_{i}\omega_{i}\left[Z_{w}^{4}F(E_{1i},Z_{w}) + G(E_{1i},Z_{w})\right]\sum_{i}\omega_{2i}G(E_{2i},Z) - \frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) + G(E_{2i},Z_{w})\right]\sum_{i}\omega_{2i}F(E_{2i},Z) - \frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) + G(E_{2i},Z_{w})\right]\sum_{i}\omega_{i}F(E_{1i},Z) - \frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) + G(E_{2i},Z_{w})\right]\sum_{i}\omega_{i}F(E_{1i},Z) - \frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) + G(E_{2i},Z_{w})\right]\sum_{i}\omega_{i}F(E_{1i},Z) - \frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) + G(E_{2i},Z_{w})\right]\sum_{i}\omega_{2i}F(E_{2i},Z) - \frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) + G(E_{2i},Z_{w})\right]\sum_{i}\omega_{2i}F(E_{1i},Z) - \frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) + G(E_{2i},Z_{w})\right]\sum_{i}\omega_{2i}F(E_{2i},Z) - \frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) + G(E_{2i},Z_{w})\right]\sum_{i}\omega_{2i}F(E_{2i},Z_{w}) - \frac{\mu_{2}}{\mu_{2w}}\sum_{i}\omega_{2i}\left[Z_{w}^{4}F(E_{2i},Z_{w}) +$$

M. Bazalova et al., PMB 53 (2008); Bazalova et al Radiother Oncol 86 (2008)

F(E,Z) and G(E,Z) functions

 $\mu = \mu_{photoeffect} + \mu_{Compton+Rayleigh}$

- $(\mu/\rho)_p = Z^5 N_A / A^* F(E,Z) = > \mu_p = \rho_e Z^{4*} F(E,Z)$
- $(\mu/\rho)_{C+R} = ZN_A/A^*G(E,Z) => \mu_{C+R} = \rho_e^*G(E,Z)$

G(E,Z)

F(E,Z)

Improved tissue assignment using dual-energy computed tomography in low-dose rate prostate brachytherapy for Monte Carlo dose calculation

Nicolas Côté Département de Physique, Université de Montréal, Pavillon Roger-Gaudry (D-428), 2900 Boulevard Édouard-Montpetit, Montréal, Québec H3T 1J4, Canada

Stéphane Bedwani Département de Radio-Oncologie, Centre Hospitalier de l'Université de Montréal (CHUM), 1560 Rue Sherbrooke Est, Montréal, Québec H2L 4M1, Canada

Jean-François Carrier^{a)} Département de Physique, Université de Montréal, Pavillon Roger-Gaudry (D-428), 2900 Boulevard Édouard-Montpetit, Montréal, Québec H3T 1J4, Canada and Département de Radio-Oncologie, Centre Hospitalier de l'Université de Montréal (CHUM), 1560 Rue Sherbrooke Est, Montréal, Québec H2L 4M1, Canada

(Received 28 August 2015; revised 9 April 2016; accepted for publication 12 April 2016; published 29 April 2016)

Cote et al, Med Phys 43

Putting these equation to practice

FIG. 3. Raw image at 100 kVp which has been corrected by DECT MAR algorithm. Window level: 461 HU, window width: 1592 HU for both images raw and corrected images. The last image represents the artifact information generated from Eq. (5).

An automatic tissue assignment technique was developed using DECT images. This modality allows for a reduced impact of metallic artifacts, which in turn improves the quality of tissue assignment. Differences in D_{90} were underestimated in the SECT-based approach by up to 2.3% compared with the developed DECT algorithm. Thus, the DECT is a potentially superior method, allowing significant reduction in metallic artifact presentation, and more accurate representation of patient tissue anatomy and density.

Cote et al, Med Phys 43

Lesson learned?

- DECT calculations for low energy sources within 4% of ground truth
 - 7 tissue bins SECT at <9%; 3 tissue bin (like EBRT) failed!</p>
- DECT very sensitive to noise and motion
 - May make DECT difficult for patient imaging (CT dose / mAs settings)
 - Simultaneous imaging
- Still a very active field of research!

Conclusion

- Voxel-by voxel cross section assignment is a critical step
 - > Tissue segmentation; Applicator and source description
 - Follow TG-186 guidelines to ensure centre-to-centre consistency
 - > Poke/Question your favorite TPS/Applicator vendor(s)...
- For ¹⁹²Ir, water is a good representation of soft tissue only
 - Air, bone, metals, ... should be segmented and assigned the right material/densitiy
- Dual-Energy/Multi-Energy-CT should be explored actively
 - > Potential accurate solution to (ρ_e , Z_{eff}) assignments
 - Hot research topics

Learning Objectives

- To identify the various imaging modalities used in brachytherapy planning
- To give key points to be considered in a efficient QA/QC program and some practical considerations
- To provide some examples of recent and in progress topics to improve accuracy

- Contouring + Cath reconstruction + Optimization & calculation
- Most convenient, because of uncertainties, is that all steps on the same image set, avoiding registrations

- Head & Neck
- Skin
- Breast
- Lung
- Esophagus
- Keloid
- Gyn.
- • •
- <u>GENERAL</u>

• Intraoperative prostate HDR & LDR

• Cervix GYN

NON-RIGID REGISTRY

NON-RIGID REGISTRY

Most commonly available imaging modality for treatment planning in radiation oncology Relatively fast Electronic density can be obtained Bone, air, bladder, rectum: OK Excellent resolution in the transverse plane

Resolution limited along the scan axis: needle-cath. tip? Not very good for soft tissue

Distortion evaluation

"A simple method to evaluate MRI distortion in cervical brachytherapy" C. Domingo, J. Richart, A. Otal, V. Carmona, S. Rodriguez, M. Santos, J. Perez-Calatayud ESTRO XIX Congreso SEOR 8-10 June 2017 Santander.

<u>Results</u>: There was no noteworthy difference with measurements done between 1.5T and 3T images, also inter and intra-observer, indicating a substantial agreement. Mean values for statistical analysis were calculated with a 95% confidence interval. There was no significant difference between axial and sagittal measurements. The maximum CT vs MRI deviation mean was 1.6mm \pm 0.39 (SD).

Recent advances on the development of phantoms using 3D printing for imaging with CT, MRI, PET, SPECT, and ultrasound

Valeria Filippou

Institute of Medical and Biological Engineering, Faculty of Mechanical Engineering, University of Leeds, Leeds, LS2 9JT, West Yorkshire, UK

Charalampos Tsoumpasa)

Department of Biomedical Imaging Science, School of Medicine, University of Leeds, Leeds, LS2 9NL, West Yorkshire, UK

Conclusions: The development of this field is rapidly evolving and becoming more refined. There is potential to reach the ultimate goal of using 3D phantoms to get feedback on imaging scanners and reconstruction algorithms more regularly. Although the development of imaging phantoms is evident, there are still some limitations to address: One of which is printing accuracy, due to the printer properties. Another limitation is the materials available to print: There are not enough materials to mimic all the tissue properties. For example, one material can mimic one property—such as the density of real tissue—but not any other property, like speed of sound or attenuation. © 2018 The

Conclusions

- **3D** imaging modalities are **essential** for modern brachytherapy.
- Most convenient: contouring, catheter reconstruction and calculation on the **same image set**. Registration (moreover non-rigid one) must be carefully evaluated.
- **CT** is the most available. Caution: the limited **resolution** along the scan axis. Scout views can help with it.
- **TRUS** is mostly used in intraoperative prostate. Caution: needle **tip** definition. "Free length" can help with it.
- **MRI** T2 has excellent soft tissue definition. Caution: **distortion**. Phantoms and CT patient data can verify it.
- **Society Recommendations** are available to perform QA/QC of all these image modalities.
- TPS applicators libraries and special markers can help in reconstruction to be less sensitive to image resolution and cath. visibility.

perez_jos@gva.es

Regarding QA imaging in brachytherapy, please point the **wrong** statement

- A. Most convenient: contouring, catheter reconstruction and calculation on the same image set.
- B. CT, when used in intraoperative prostate, has the problem that the electronic density can not be obtained.
- C. MRI has excellent soft tissue definition. The distortion must be evaluated.
- D. Society Recommendations are available to perform QA/QC of all these image modalities.

Abstract

An automatic localization method of implanted seeds from a series of post-implant computed tomography (CT) images is described in this paper. Post-implant CT studies were obtained for patients who underwent prostate brachytherapy. Bright areas were segmented using binary thresholding in each CT slice, and geometrical information on these areas was collected. Large areas (possibly containing two connected seeds) were split into smaller ones by geometry-based filtering in each slice. The area connectivity along the longitudinal direction was analysed using a geometry-based connected areas were combined into one object. The weighted centroid of each object was taken as the seed position. This method was tested on a seed-containing prostate phantom as well as using CT studies from patients. Statistical analysis demonstrates that it can achieve above 99% detection rate with reliable localization accuracy and high speed. It is reliable and convenient for localizing implanted seeds on CT and can be used to assist post-implant dosimetry for prostate brachytherapy.

(Received 1 August 2003; revised 11 June 2004; accepted for publication 12 June 2004; published 27 August 2004)

Purpose: The purpose of the work is to describe a new algorithm for the automatic detection of implanted radioactive seeds within the prostate. The algorithm is based on the traditional Hough transform. A method of quality assurance is described as well as a quantitative phantom study to determine the accuracy of the algorithm. Methods and Materials: An algorithm is described which is based on the Hough transform. The Hough transform is a well known transform traditionally used to automatically segment lines and other well defined geometric objects from images. The traditional Hough transform is extended to three-dimensions and applied to CT images of seed implanted prostate glands. A method based on digitally reconstructed radiographs is described to quality assure the determined three-dimensional positions of the detected seeds. Two phantom studies utilizing eight seeds and nine seeds are described. All eight seeds form a contiguous a square while the nine seed phantom describes seeds which are placed side-by-side in groups of two and three. The algorithm is applied to the CT scans of both phantoms and the seed positions determined. Results: The algorithm has been commercially developed and used to perform postsurgical dosimetric assessment on approximately 1000 patients. Using the described quality assurance tool it was determined that the algorithm accurately determined the seed positions in all 1000 patients. The algorithm was also applied to the eight seed phantom. The algorithm successfully found all eight seeds as well as their seed coordinates. The average radial error was determined to be 0.9 mm. For the nine seed phantom, the algorithm correctly identified all nine seeds, with an average radial error of 3 mm. Conclusions: The described algorithm is a robust, accurate, automatic, three-dimensional application for CT based seed determination. © 2004 American Association of *Physicists in Medicine.* [DOI: 10.1118/1.1778837]

ABSTRACT PURPOSE: To compare the uncertainties in CT- and MRI-based seed reconstruction in postimplant evaluation after prostate seed brachytherapy in terms of interobserver variability and quantify the impact of seed detection variability on a selection of dosimetric parameters for three postplan techniques: (1) CT, (2) MRI-T1 weighted fused with MRI-T2 weighted, and (3) CT fused with MRI-T2 weighted.

> **METHODS AND MATERIALS:** Seven physicists reconstructed the seed positions on postimplant CT and MRI-T1 images of three patients. For each patient and imaging modality, the interobserver variability was calculated with respect to a reference seed set. The effect of this variability on dosimetry was calculated for CT and CT + MRI-T2 (CT-based seed reconstruction), as well as for MRI-T1 + MRI-T2 (MRI-T1-based seed reconstruction), using fixed CT and MRI-T2 prostate contours.

> **RESULTS:** Averaged over three patients, the interobserver variability in CT-based seed reconstruction was 1.1 mm (1 SD_{ref}, i.e., standard deviation with respect to the reference value). The D_{90} (dose delivered to 90% of the target) variability was 1.5% and 1.3% (1 SD_{ref}) for CT and CT + MRI-T2, respectively. The mean interobserver variability in MRI-based seed reconstruction was 3.0 mm (1 SD_{ref}), and the impact of this variability on D_{90} was 6.6% for MRI-T1 + MRI-T2. **CONCLUSIONS:** Seed reconstruction on MRI-T1—weighted images was less accurate than on CT. This difference in uncertainties should be weighted against uncertainties due to contouring and image fusion when comparing the overall reliability of postplan techniques. © 2013 American Brachytherapy Society. Cancer Center for the Southern Interior, British Columbia Cancer Agency, Kelowna, BC, Canada

PURPOSE: The use of transrectal ultrasound (TRUS) to both guide and plan high-dose-rate (HDR) brachytherapy (BT) for prostate is increasing. Studies using prostate phantoms have demonstrated the accuracy of ultrasound (US) needle tip reconstruction compared with CT imaging standard. We have assessed the *in vivo* accuracy of needle tip localization by TRUS using cone-beam CT (CBCT) as our reference standard.

METHODS AND MATERIALS: Needle positions from 37 implants have been analyzed. A median of 16 needles (range, 16–18) per implant were inserted, advanced to the prostate base, and their tips identified using live TRUS images and real-time planning BT software. Needle protrusion length from the template was recorded to allow for reverification before capturing images for planning. The needles remained locked in the template, which was fixed to the stepper, while a set of three-dimensional TRUS images was acquired for needle path reconstruction and HDR-BT treatment planning. Following treatment, CBCT images were acquired for subsequent needle reconstruction using a BT Treatment Planning System. The coordinates of each needle tip were recorded from the Treatment Planning System for CT and US and compared.

RESULTS: A total of 574 needle tip positions have been compared between TRUS and CBCT. Of these, 59% agreed within 1 mm, 27% within 1-2 mm, and 11% agreed within 2-3 mm. The discrepancy between tip positions in the two modalities was greater than 3 mm for only 20 needles (3%). **CONCLUSIONS:** The US needle tip identification *in vivo* is at least as accurate as CT identification, while providing all the advantages of a one-step procedure. © 2014 American Brachytherapy Society. Objectives/Outline:

To:

 review the basic principles of the MC method
 outline its implementation for brachy dosimetry (and especially type A and type B uncertainties)

so as to identify:

its potential to provide reference dose distributions
 TG-43 uncertainties
 its potential for clinical implementation

- Let us start from the simplest case (point isotopic monoenergetic photon source in infinite medium of given composition)
 - If I know everything there is to know about the source and the medium, can I calculate dose at a point i ...?

- Let us start from the simplest case (point isotopic monoenergetic photon source in infinite medium of given composition)
 - If I know everything there is to know about the source and the medium, can I calculate dose at a point i ...?

from initial activity i can calculate the radiant energy rate or the radiant energy over t, R_{pr} from R i can calculate energy fluence at any point, $\Psi_{pr_i} = \frac{R_{pr}}{4\pi r_i^2} \exp(-\mu r_i)$ from Ψ_i i can calculate the TERMA at any point, $T_i = (\frac{\mu}{\rho})\Psi_{pr_i}$

i can also calculate the fraction of TERMA that is transferred to kinetic energy of charged particles

= KERMA at any point,
$$K_{pr_i} = (\frac{\mu en}{\rho})\Psi_{pr_i} = (\frac{\mu en}{\mu})T_{pr_i}$$

For brachytherapy photons: • secondary e- ranges are small relative to photon m.f.p.

•e- radiative energy loss is negligible
• CPE can be assumed to exist at all points (except close to a source or high Z materials)

Energy	CSDA-range	1
[keV]	electrons [g/cm ²]	μ [cm]
30	1.8E-03	2.5
100	1.2E-02	5.6
350	1.1E-01	8.9
1000	4.4E-01	14

Dose to a point can be approximated by collision KERMA throughout a geometry of mm sized voxel elements

In short, to know the dose distribution one needs to know the energy distribution of fluence, Φ_E , at all points of a geometry:

$$D(\mathbf{r}) = K(\mathbf{r}) = \int_{E} E\Phi_{E}(\mathbf{r}) \left[\frac{\mu_{en}(E)}{\rho}\right] dE$$

Table from: Venselaar, Baltas, Meigooni, Hoskin (Eds), Comprehensive Brachytehrapy: physical and clinical aspects. CRC Press, Taylor & Francis, © 2013

- Let us start from the simplest case (point isotopic monoenergetic photon source in infinite medium of given composition)
 - If I know everything there is to know about the source and the medium, can I calculate dose at a point i ...?

under CPE :
$$D_{pr_i} = K_{pr_i} = (\frac{\mu_{en}}{\rho})\Psi_{pr_i}$$

• BUT WHAT ABOUT SCATTER DOSE ...?

- Point isotopic monoenergetic photon source in infinite medium of given composition
- If I know everything there is to know about the source and the medium, can I calculate dose at a point i ...?

$$D_{pr_i} \equiv K_{pr_i} = (\frac{\mu_{en}}{\rho})\Psi_{pr_i}$$

For D_{scat} at point i need $\Psi_{E_{sci}}$ the depends on: the probability of a primary photon interacting in one of a number of possible interaction types **at every point of the geometry**,

the probability distribution determining the new direction of a photon and its energy degradation,

the probability this process is repeated due to multiple scattering at every point of the geometry

 D_{scat} at point i, CANNOT be analytically calculated NOT because of its stochastic nature, but due to the complexity of the calculation

How important is D_{scat} in brachy ...?

The problem ...

How important is D_{scat} in brachy ...?

It associates the dose distribution with the entire calculation geometry (ρ , Z, dimensions) rather than just the path from a source to a point.

E.g. for dimensions:

Figures from: Papagiannis, Pantelis, Karaiskos, Br J Radiol (2014) 87: 20140163

The problem ...

How important is D_{scat} in brachy ...?

It associates the dose distribution with the entire calculation geometry (ρ , Z, dimensions) rather than just the path from a source to a point.

E.g. for materials:

Since we know the Physics underlying radiation transport through matter (probabilities for interaction: site, type and associated energy/direction distributions), can't we reproduce (simulate) all possible photon tracks?

Could I then calculate any related quantity at all points...?

The Central Limit Theorem: the sum of a **large** number of identical, independent random variables is approximately **normally** distributed.

So, if I want to calculate an unknown quantity, m, and k is a random variable of expectation value E(k)=m and variance Var(k)=b². If k₁, k₂, ..., k_N are N <u>RANDOMLY</u> selected values of k,

then: $\sum_{i=1}^{N} k_i$ is normally distributed with E($\sum_{i=1}^{N} k_i$)=Nm and V ($\sum_{i=1}^{N} k_i$)=Nb² or equivalently: $P(Nm - 3b\sqrt{N} < \sum_{i=1}^{N} k_i < Nm + 3b\sqrt{N}) \approx 0.997$ or: $P(-\frac{3b}{\sqrt{N}} < \frac{1}{N} \sum_{i=1}^{N} k_i - m < \frac{3b}{\sqrt{N}}) \approx 0.997$

So, if I want to estimate the photon fluence (or any related quantity) at point r, I can average the contribution of N photon tracks <u>RANDOMLY</u> sampled from the probability distribution of all possible tracks

Do I know the probability distribution of possible tracks? A photon "moves" from phase space element to phase space element. A photon track is composed of the sequential phase space elements or photon states, $\mathbf{S}_{j}(\mathbf{r}_{j}, \mathbf{E}_{j}, \mathbf{\Omega}_{j})$ just before each interaction j.

The probability of occurrence of each photon state j only depends on the probability of occurrence of state j-1.

Or in other words: the probability that the photon interacts at r_{j-1} , the probability that a specific kind of interaction occurs and the probability that during this interaction the photon is scattered in direction Ω_j with energy E_j given Ω_{j-1} and E_{j-1} .

These probability distributions are known in Physics....!

Hence, the only component missing is a method to <u>RANDOMLY</u> sample from the above, known, probability distributions.

How do I sample <u>RANDOMLY</u> from a known probability distribution? There are numerous mathematical methods. In example:

Inversion theorem

Let x be a <u>continuous</u> random variable distributed over the interval [a, b] with a probability density function f(x) and a cumulative probability distribution function F(x) that is invertible. Given a random number, r, in the interval [0, 1], a value x^{*} of x can be randomly selected according to:

$$F = F(x^*) = \int_{-\infty}^{x} f(x) dx$$

Let x be a <u>discrete</u> random variable taking N values, x_i of probability, P_i so that: $\sum_{i=1}^{N} P_i = 1$

Given a random number, r, in the interval [0, 1], a value x^{*} of x can be randomly selected according to:

$$x^* = x_j$$
 where $j = \min\{ : r < \sum_{i=1}^{J} P_i \}$

Simple examples:

Choosing emission direction for a mono-energetic point source.

The emission is isotropic and the probability of emission into a solid angle element $d\Omega$ equals the fraction of this solid angle in the 4π geometry so that:

0.1

20

40

60

80

100

 θ (degrees)

120

140

0.1

180

Figure from: Venselaar, Baltas, Meigooni, Hoskin (Eds), Comprehensive Brachytehrapy: physical and clinical aspects. CRC Press, Taylor & Francis, © 2013

Choosing interaction site.

The probability that a photon interacts within dx after travelling a distance x is $\mu exp(-\mu x)$ so that:

$$r = P(x) = \int_{0}^{x^{*}} \mu \exp(-\mu x) dx \Longrightarrow r = -\exp(-\mu x^{*}) + 1 \Longrightarrow x^{*} = -\frac{1}{\mu} \ln(1-r) = -\frac{1}{\mu} \ln(r)$$

Choosing interaction type.

Interaction type is a discrete random variable of i values so that

 $P_i = \mu_i / \mu_{total}$.

So given r, I choose interaction j so that:

$$j = \min\{ j: r < \sum_{i=1}^{j} P_i \}$$

f(x) 0.9 0.9 P(x)0.8 0.8 random r = 0.73 0.7 0.7 e-µx $f(x) = \mu \cdot e^{-\mu x}$ 0.6 0.6 0.5 0.5 П (X) selected x = 1.3 0.4 0.4 0.3 0.3 0.2 0.2 0.1 0.1 2 3 5 x (mfp's for $\mu = 1$ used in this graph)

Figure from: Venselaar, Baltas, Meigooni, Hoskin (Eds), Comprehensive Brachytehrapy: physical and clinical aspects. CRC Press, Taylor & Francis, © 2013

- Similar procedures (available in the literature from the 50's) are used for sampling randomly from the probability distributions for every process involved in photon transport.
- > MC is a statistical method to approximate dose at all points of a geometry
- ➤ The method inherently accounts for real sources, inhomogeneities, and phantom dimensions according to input data.
- ➤ The collision KERMA can be calculated within voxels by scoring the energy transferred to charged particles from interactions within the voxel and weighing by voxel mass (dm=pdV) (analogue MC).
- > Alternatively, photon energy fluence can be scored in each voxel and weighed by $\mu en/\rho$ to obtain collision KERMA (track length estimator).

MC simulations for single source dosimetry are ALWAYS a set of **2 MC** simulations **one** for the distribution of energy absorbed at all points of the geometry per starting particle and **one** for the air kerma of the source per starting particle

In multiple source MC dosimetry (e.g. a clinical case) results from single source positions can be weighed by t_i , summed and multiplied by TRAK ($S_K^*t_{tot}$)

The general outline of a MC code is:

The questions then are:

- 1. What is the accuracy/precision of the method?
- 2. How efficient can the method be?

Type A uncertainty

► Recall that : $P(-\frac{3b}{\sqrt{N}} < \frac{1}{N} \sum_{i=1}^{N} k_i - m < \frac{3b}{\sqrt{N}}) \approx 0.997$

b, the stdev of unknown quantity m is not known but for N>> $\overline{k} = \frac{1}{N} \sum_{i=1}^{N} k_i$ approximates m and the square root of the variance $Var(k) = \frac{1}{N-1} \sum_{i=1}^{N} (k_i - \overline{k})^2 \approx \overline{k^2} - \overline{k}^2$ approximates b.

 $\sqrt{\frac{Var(k)}{N}}$ therefore forms precision confidence interval (k=3) of our tally and it must be as low as possible.

\succ Type A uncertainty decreases $\sim 1/sqrt(N)$

> type A uncertainty decreases as voxel size increases for analogue MC (at the expense of volume averaging)

 \succ the only other way to decrease type A would be to reduce Var(k) which is in essence an efficiency gain and will be discussed later

Type A uncertainty

> TG-43 U1* suggests that enough histories, N, should be used to ensure that dosimetry results have relative uncertainties <2% at r<5 cm

> AAPM/ESTRO^{**} recommendations are MC Type A uncertainties (k=1)<0.1% for distances < 5 cm and Type A uncertainties (k=1)<0.2% for distances <10cm

➤ TG-138 (AAPM/ESTRO)*** suggests MC type A<0.1% when feasible

Type B uncertainty

All other aspects of the simulation contribute to type B uncertainty

Type B uncertainty ... random number generator

Pseudo random number generators are used, e.g. Lehmer type, multiplicativecongruential of the form:

 $r_{n+1} = Br_n mod 2^M$

with B,M and r_0 (the "seed" of the sequence) appropriately selected.

- <u>These generators are generally robust in benchmarked and extensively used</u> <u>codes</u>
- These generators are periodic with a period of 2^M. Exceeding this period might underestimate result variance
- If you are using different simulations to estimate Var(k) make sure the seed is different

Type B uncertainty ... code

>What MC code should I use? / Should I prepare my own?

➤ Codes benchmarked and extensively used in the literature: PTRAN, MCNP, GEANT4, PENELOPE, and EGS.

➤TG-43U1*: Monte Carlo codes not previously used in brachytherapy dosimetry, should be more rigorously tested and documented in the peer-reviewed literature before proposing to use their results clinically.

≻TG-43U1*: "regardless of the transport code chosen and its pedigree, all investigators should assure themselves that they are able to reproduce previously published dose distributions for at least one widely used brachytherapy source model. This exercise should be repeated whenever new features of the code are explored, upon installing a new code version, or as part of orienting a new user."

Code	Operating System	Availability /License	Applications	Significant features
EGSnrc	All major modern operating systems (portions available for a limited set)	Through NRC web (GitHub) / General Public License for research & education, separate NRC license for commercial use	EGSnrc is a set of functions and subroutines for coupled ph/el transport mainly in Medical Physics. For an application, a user code is required (in Mortran, Fortran, C, C++). Major applications are available, including brachytherapy.	 Accurate condensed history technique implementation for charged particle transport. More accurate Physics (rel. to its predecessor). Choice of cross sections tabulation/data. Faster than other codes for charged particle transport. General purpose geometry package + utility classes.

Code	Operating System	Availability /License	Applications	Significant features
GEANT4	Linux variants, Windows and Mac OS X (verified and supported on specific configurati ons)	Through CERN web subject to the open- source conditions of the Geant4 license (cannot be included in whole or in part in patented applications)	General purpose simulation of particle transport primarily for high-energy and medical physics Comprehensive geometry and physics modeling capabilities are embedded in a flexible structure base using object- oriented technology and C++ A large number of specialized applications based on GEANT4 are available including one for brachytherapy.	 Users can choose existing components, tailor and adapt them, or create their own. A choice of physics models is offered for many physics processes with different trade- offs between accuracy and CPU cost. Tools for optimization of configurations of geometry and physics are also provided. Combinations of Physical processes for typical applications are recommended in Physics lists. Powerful geometry module. Range of visualization options.

Code	Operating System	Availability/License	Applications	Significant features
MCNP6	Supported on most operating systems (32/64-bit) including Windows, Mac OS X, Linux, and UNIX-like.	US: through the Radiation Safety Information Computational Center (RSICC) Europe: to members of the Nuclear Energy Agency (NEA) Data Bank Japan: through the Research Organization for Information Science and Technology (RIST). Limited license and export control regulations restrict the distribution of Fortran source code.	General purpose simulation of particle transport primarily for nuclear applications and medical physics.	 Extensive geometry, source definition, and tallying capabilities. Built in variance reduction techniques. Straightforward generation of structured input files for specific applications.

Code	Operating System	Availability/License	Applications	Significant features				
Penelope	Written in FORTRAN and can be run on any computer with FORTRAN 77 (or higher) compiler. Geometry viewers run under Windows.	Through the Nuclear Energy Agency (NEA) Data Bank and the Radiation Safety Information Computational Center (RSICC) as open software.	Simulation of coupled electron- photon transport in material structures consisting of homogeneous bodies limited by quadratic surfaces. Structured as a set of subroutine packages. User should write a steering main program or build upon the generic one provided.	 Particularly well adapted to simulations of electron transport at low and intermediate energies 				

Type B uncertainty ... scoring

CPE can be assumed and only photons need be simulated
 Photon-only simulation introduces errors >2% @ distances at or below 1.6, 3, and 7mm for Ir-192, Cs-137, and Co-60 sources, respectively (Perez-Calatayud et al. 2012) but this is source specific and clinically irrelevant in most cases.

➤ Scoring cell dimensions are important! See Taylor et al. (2007) for details and Rivard et al. (2004) and Perez-Calatayud et al. (2012) for recommendations

➢ For analogue MC increasing voxel size will reduce type A but increase volume averaging

➢ For track length estimators reducing voxel thickness while preserving surface will reduce volume averaging without affecting type A

Type B uncertainty ... cross sections

Probability distributions are in the form of a cross section data base.
 Total partial and differential photon cross sections are required including atomic form factors F(x, Z) and incoherent scatter factors S(x, Z)
 These cross sections must be: complete (in terms of E, Z) self-consistent and up to date/accurate.

Self-consistency is also required with mass energy absorption data used for kerma calculation from energy fluence

>Up to date cross sections are used in all current versions of benchmarked MC codes: EPDL97 (LLNL) in the ENDL or ENDF/B-VI formats or the DLC-146 format (ORNL) or XCOM (NIST) database. Mass energy-absorption coefficients for water by Seltzer and Hubbell (available on line at NIST).

Data readily available online through NIST (<u>http://www.nist.gov/pml/data/xraycoef/</u>)

> TG-138 (AAPM/ESTRO) cites ~1% cross section type B that contributes to dosimetric uncertainty at r=5 cm about 0.76 % (low E) and 0.12% (high E)

Type B uncertainty ... input

Source geometry

>Information is required on geometry, materials, density, elemental composition, and dimensions.

The uncertainty of this information is more crucial for low energy sources
 For reference dosimetry of new sources geometry and dimensions should be verified experimentally in a sample of sources.

>If the source includes parts of non-negligible mobility, MC should be performed for different configurations and results averaged.

seed cut out view

e microscopy (6711)

(3631 A/M) Pics from: Rogers & Cygler (Eds), Clinical dosimetry measurements in radiotherapy (2009 AAPM Summer School), Monograph No. 34, Medical Physics Publishing 2011

Type B uncertainty ... input

Source geometry

≻Besides verified, the uncertainty in construction details (tolerances) must be included in the uncertainty budget. In example: uncertainty map for an I-125 seed

MC dose rate distr.

% uncert.: geo. + type A

Pantelis et al, J Contemp Brachytherapy 5(4), 240 (2013)

Type B uncertainty ... input

Phantom geometry (for single source dosimetry)
 Remember dose from scatter depends on geometry dimensions...!
 or patient segmentation and source/applicator position (for patient dosimetry)

> Geometry in simulation for S_K (for single source dosimetry)

In order to comply with the definition of S_K :

- Air (point) detector at large distance from the source in vacuo
- Photon emissions of energy lower than δ =5 keV (i.e. characteristic x-rays of Ti encapsulation following photoelectric absorption of 125I photons) must be suppressed.

Geometry for actual measurement of S_{κ}

For low energy sources, simulations must also account for the WAFAC - 7.6° half angle.

• Due to polar angle averaging, S_K increases for sources with radioactivity distributed over cyl. ends, leading to Λ_{WAFAC} lower than Λ_{point} results.

• This effect depends on the ratio of marker diameter to marker length.

• Differences between Λ_{WAFAC} and Λ_{point} range from non-detectable to 3.5%.

How efficient can MC be ...?

Traditionally, MC was said to be too slow for clinical use and therefore reserved for high quality single source dosimetry in reference conditions that was then partitioned to TG-43 quantities and used in TPS for treatment planning purposes.

How efficient can MC be ...?

Traditionally, MC was said to be too slow for clinical use and therefore reserved for high quality single source dosimetry in reference conditions that was then partitioned to TG-43 quantities and used in TPS for treatment planning purposes.

≻ Total t_{CALC} scales with N, which is determined by the level of desired type A uncertainty which is proportional to $\sqrt{Var(k)/N}$

➤ MC for Brachy enjoys t_{CALC}/N reduction from photon only tracking (20%-70%)

> In brachy however, t_{CALC}/N is large when multiple scattering occurs

How efficient can MC be ...?

 t_{CALC} scales with N, type A uncertainty scales with $\sqrt{\frac{Var(k)}{N}}$

 \succ The only means to decrease t_{CALC} for a given level of type A uncertainty is variance reduction.

 \succ Variance reduction:

• Simple techniques: geom. truncation, E cut off, phase space files*, analytical primary scatter separation (PSS), ...

(* Pantelis et al. On source models for 192Ir HDR brachytherapy dosimetry using model based algorithms Phys. Med. Biol. 61, 2016)

• Elaborate techniques**: techniques to bias the sampling distributions while using correction factors to eliminate the biasing effect in the sample mean of the quantity of interest

(** see Sheikh-Bagheri, D., Kawrakow, I., Walters, B., and Rogers, D.W.O. 2006. Monte Carlo simulations: Efficiency improvement techniques and statistical considerations. Integrated New Technologies into the Clinic: Monte Carlo and Image-Guided Radiation Therapy—Proceedings of the 2006 AAPM Summer School)

t_{CALC} reductions from: photon only tracking (20%-70%), track length scoring (20-30), pre-calculated source phase space (30%-40%), variance reduction (40-60) + (inherent) parallelization and reduction of t_{CALC}/N from availability of multi-core processors have facilitated clinically viable calculation times :

Monte Carlo for TPS?

✓ RapidBrachyMCTPS (GEANT4): Famulari et al 2018 Phys. Med. Biol. 63 175007

• DICOM-RT image data and structure set imported using VTK

• GUI serves as a viewer for all data parsed from DICOM-RT

 \circ GUI also serves as a front end GEANT4 software tool (no GEANT4 experience required)

o source and applicator libraries available through the GUI

 \circ CT numbers converted to density and material for each voxel via user-specified data. Segmentation can also be performed based on the patients structure set

 \circ patient data is saved using the egsphant file format

 $_{\odot}$ the user can change various simulation settings, physics options, and scoring options via the GUI

 ○ the GUI also incorporates some (basic) treatment planning functionalities (simulated annealing-based optimization with dose constraints)

Monte Carlo: summary

- Monte Carlo based TPS not clinically available for brachytherapy yet!
- MC is the gold standard for single source dosimetry in brachytherapy (TG-43 data)
- Several public domain codes are available that have been extensively benchmarked, and ample literature/experience/recommendations are available
- Type B uncertainties associated with MC results for single source dosimetry are (mainly) user-related
- > MC is <u>inherently</u> associated with a level of type A uncertainty
- ➤ MC is also used:
 - to support source calibration,
 - to correct experimental dosimetry results,
 - to provide input data to other classes of dose calculation algorithms
 - to provide reference dose distributions for the verification of TPS results

Advanced Brachytherapy Physics, 29 May – 1 June, 2016

Disclosures

The are no conflicts-of-interest to report.

Opinions herein are solely those of the presenter, and are not meant to be interpreted as societal guidance.

Specific commercial equipment, instruments, and materials are listed to fully describe the necessary procedures. Such identification does not imply endorsement by the presenter, nor that these products are necessarily the best available for these purposes.

Learning Objectives

- 1. Review need for international BT dosimetry formalism
- 2. Explore the TG-43 BT dosimetry formalism
- 3. Example calculations and TPS source commissioning

Why Follow the TG-43 Dose Calculation Formalism?

- Accurate interpolation of dose distribution is achieved because geometric dependence of dose falloff (as function of r and θ) is accounted for. This allows use of a limited dataset while providing robust dose calculation.
- Analytic, uniform approach to brachytherapy dose calculation is readily available, thereby promoting consistent clinical practice worldwide.

Update of AAPM Task Group No. 43 Report: A revised AAPM protocol for brachytherapy dose calculations

Since publication of the TG-43 protocol in 1995, significant advances have taken place in the field of permanent source implantation and brachytherapy dosimetry. To accommodate these advances, the AAPM deemed it necessary to update this protocol for the following reasons:

(a) eliminate minor inconsistencies and omissions in the original TG-43 formalism and its implementation.

(b) incorporate subsequent AAPM recommendations, addressing requirements for acquisition of dosimetry data as well as clinical implementation. These recommendations, e.g., elimination of A_{app} (see Appendix E) and description of minimum standards for dosimetric characterization of low-energy photon-emitting brachytherapy sources, needed to be consolidated in one convenient document.

(c) critically reassess published brachytherapy dosimetry data for the ¹²⁵I and ¹⁰³Pd source models introduced both prior and subsequent to publication of the TG-43 protocol in 1995, and to recommend consensus datasets where appropriate.

(d) develop guidelines for determination of reference-quality dose distributions by experimental and Monte Carlo methods, and promote consistency in derivation of parameters used in TG-43 formalism.

High-Energy BT Dosimetry Report

Medical Physics

Dose calculation for photon-emitting brachytherapy sources with average energy higher than 50 keV: Report of the AAPM and ESTRO

Purpose: Recommendations of the AAPM and ESTRO on dose calculations for high energy (avg energy > 50 keV) photon-emitting brachytherapy sources are presented, including physical characteristics of specific ¹⁹²Ir, ¹³⁷Cs, and ⁶⁰Co. **Methods**: This report was prepared by the High Energy Brachytherapy Source Dosimetry (HEBD) Working Group, and includes considerations for applying the TG-43U1 formalism to high-E photon-emitting sources with particular attention to phantom size effects, interpolation accuracy dependence on dose calculation grid size, and dosimetry parameter dependence on active length.

Results: Consensus datasets for commercially available sources are provided, along with recommended methods for evaluating these datasets. Recommendations on dosimetry characterization methods, mainly using experimental procedures and Monte Carlo, are established and discussed. Included are methodological recommendations on detector choice, detector energy response characterization and phantom materials, and measurement specification methodology. Uncertainty analyses are discussed and recommendations are given for sources without consensus datasets.

Conclusions: Recommended consensus datasets for high-energy sources are derived for sources that were commercially available as of January 2010. Data are presented according to the AAPM TG-43U1 formalism, with modified interpolation and extrapolation techniques of the AAPM TG-43U1S1 report for the 2D anisotropy function and radial dose function.

2D Anisotropy Function

$$F(r,\theta) = \frac{\dot{D}(r,\theta)}{\dot{D}(r,\theta_0)} \frac{G_X(r,\theta_0)}{G_X(r,\theta)}$$

- $F(r,\theta)$ is always unity for a perfect point source
- $F(r,\theta) = 1$ at θ_0
- $F(r,\theta)$ accounts for dose-rate variation over angles due to differing attenuation by source capsule, internal components, ...
- Must know source orientation use 2D formalism
 - otherwise, use the 1D formalism

Brachytherapy treatment planning commissioning: effect of the election of proper bibliography and finite size of TG-43 input data on standard treatments

Christian N. Valdés,^{1a} Gustavo H. Píriz,² Enrrique Lozano,³ Departamento de Física Médica,¹ Centro Oncológico de Antofagasta, Antofagasta, Chile; Departamento de Física Médica,² Centro de Oncología ONCOSUR, Florida, Uruguay; Departamento de Física Médica,³ Instituto Nacional del Cáncer, Santiago, Chile cvalcort@gmail.com

The aim of this work is to evaluate performance of a commercial BT TPS with vendor TG-43 data, analyze possible discrepancies with respect to a proper reference source and its implications for standard treatments, and judge the effectiveness of certain widespread recommended quality controls to find potential errors related with interpolations of TG-43 tables.

Total dose calculation uncertainty	3.4		
Expanded uncertainty $(k=2)$	6.8		

DeWerd, et al., Med. Phys. 38, 782-801 (2011)

Summary

- BT dosimetry in the clinic generally follows the TG-43 formalism
 - Luc will next show you its limitations and advancements in accuracy
- uniform BT (over time and space) requires standization
 - consistent formalism (and formats)
 - consistent dosimetry parameters
 - consistent reference data
 - consistent TPS approach
- HDR/LDR and HE/LE have different planning approaches
- medical physicist must know the data trail and commission the source(s)

Learning Objectives

- Review the limitations of TG43
- Understand how these limitations translate to clinical tumor sites and brachytherapy procedures (relative to MC)
- Be able to anticipate potential TG43 failures

TG-43: Brachytherapy Dosimetry

Update of AAPM Task Group No. 43 Report: A revised AAPM protocol for brachytherapy dose calculations

© 2004 American Association of Physicists in Medicine

Rivard et al, Med Phys 31, 633-674 (2004)

The good!

- Each source model is specifically taken into account
- S_k (and RAKR) link to a primary standard!
- The values of the various parameters are compiled following a rigorous process
 - Process includes a review and consensus by a group of experts
- Analytical formulation leads to fast dose computation
 - Hundreds of thousands of iterations possible in a few seconds

What's all the fuss about?

TG-43: Brachytherapy Dosimetry

The limitations

- Homogeneous water medium assumed
- Full scatter condition assumed
 - 5 cm beyond the last position of interest for low energy seed (15 cm geometry)
 - 20 cm beyond the last position of interest for E > 50 keV (40 cm radius geometry)
- No electrons (Dose vs Kerma)
 - Dose may not be related to photon fluence close to the source (e.g.⁶⁰Co)
- Full 3D source geometry not taken into account
 - Close to the source
 - ► Extended line sources, ...
 - > Shielded applicators or directional sources

Why should you care?

Significant dose differences expected

\geq 10% or more relative to TG-43

Dose is the fundamental quantity in RT

Factor-based vs Model-based

Air

Dosimetric effects of an air cavity for the SAVI[™] partial breast irradiation applicator

Susan L. Richardson^{a)}

Department of Radiation Oncology, Washington University School of Medicine, St. Louis, Missouri 63110

Ramiro Pino

Department of Radiation Oncology, The Methodist Hospital, Houston, Texas 77030 and Texas Cancer Clinic, San Antonio, Texas 78240

(Received 8 July 2009; revised 3 June 2010; accepted for publication 5 June 2010; published 12 July 2010)

Purpose: To investigate the dosimetric effect of the air inside the SAVITM partial breast irradiation device.

Methods: The authors have investigated how the air inside the SAVITM partial breast irradiation device changes the delivered dose from the homogeneously calculated dose. Measurements were made with the device filled with air and water to allow comparison to a homogenous dose calculation done by the treatment planning system. Measurements were made with an ion chamber, TLDs, and film. Monte Carlo (MC) simulations of the experiment were done using the EGSnrc suite. The MC model was validated by comparing the water-filled calculations to those from a commercial treatment planning system.

Results: The magnitude of the dosimetric effect depends on the size of the cavity, the arrangement of sources, and the relative dwell times. For a simple case using only the central catheter of the largest device, MC results indicate that the dose at the prescription point 1 cm away from the air-water boundary is about 9% higher than the homogeneous calculation. Independent measurements in a water phantom with a similar air cavity gave comparable results. MC simulation of a realistic multidwell position plan showed discrepancies of about 5% on average at the prescription point for the largest device.

Conclusions: The dosimetric effect of the air cavity is in the range of 3%–9%. Unless a heterogeneous dose calculation algorithm is used, users should be aware of the possibility of small treatment planning dose errors for this device and make modifications to the treatment delivery, if necessary. © 2010 American Association of Physicists in Medicine. [DOI: 10.1118/1.3457328]

Richardson, Ramino, Med Phys, 37(8), 3919-3926 (2010)

TABLE II. Comparison between MC doses calculated at selected distances from the edge of the device using different sized devices for single and multidwell position plans with and without air cavity present. The treatment planning benchmark is shown for comparison to the MC in water. The percent difference represents the absolute difference between the MC in water and MC in air calculation.

Six-strut device

Comparison between Two Dose Calculation Methods, Acuros and TG43: Implications for Accelerated Partial Breast Irradiation *Jill P. Heffernan, M.D., Lynn Gilbert, C.M.D., Douglas W. Arthur, M.D., Dorin A. Todor, Ph.D. Radiation Oncology, Virginia Commonwealth University, Richmond, VA.*

- 30 patients evaluated Skinmax, Ribmax, D90, V100, V150, V200
- Variety of applicators including interstitial
- Results for interstitial were within 3% or 3cc
- Balloon based:
 - Skinmax 8% including >10% if only using central lumen/single dwell
 - Ribmax- 5% on average
 - Target coverage less (3.5% 8%)
 - Larger balloons had greater differences in V100, etc.

MAAST RO

(b) Dose ratio: Heterogenous Model Dmm / TG-43 MC

Summary for Breast Brachytherapy

- The experts agree that in using TG43 for ¹⁹²Ir procedures:
 - If you are using high levels of contrast your overall dose is decreased
 - Skin dose is over-estimated (~ 4-10%)
 - > Dose to ribs is under-estimated (~ 5 7%)
 - Dose coverage is probably slightly over-estimated
- If you use seeds or electronic brachytherapy sources
 - Very large effect due to breast composition (adipose and glandular tissues)
 - Very large effect from bones (ribs)

Graham Cancer Center, Newark, Delaware

Summary

This study investigated the use of a grid-based Boltzmann solver (GBBS) for cervical cancer patients treated with unshielded CT/ MR applicators. The GBBS was found to have minimal impact on clinical dosimetric parameters for these patients. **GBBS** differences from standard TG-43 dose estimates were mainly due to source, boundary, and applicator model differences. CTto-material mapping of rectal and balloon contrast did not

impact clinical dosimetry. Rectal dose parameters may be affected by incorrectly mapping packing material. **Purpose:** To investigate the dosimetric impact of the heterogeneity dose calculation Acuros (Transpire Inc., Gig Harbor, WA), a grid-based Boltzmann equation solver (GBBS), for brachytherapy in a cohort of cervical cancer patients.

Methods and Materials: The impact of heterogeneities was retrospectively assessed in treatment plans for 26 patients who had previously received ¹⁹²Ir intracavitary brachytherapy for cervical cancer with computed tomography (CT)/magnetic resonance-compatible tandems and unshielded colpostats. The GBBS models sources, patient boundaries, applicators, and tissue heterogeneities. Multiple GBBS calculations were performed with and without solid model applicator, with and without overriding the patient contour to 1 g/cm³ muscle, and with and without overriding contrast materials to muscle or 2.25 g/cm³ bone. Impact of source and boundary modeling, applicator, tissue heterogeneities, and sensitivity of CT-to-material mapping of contrast were derived from the multiple calculations. American Association of Physicists in Medicine Task Group 43 (TG-43) guidelines and the GBBS were compared for the following clinical dosimetric parameters: Manchester points A and B, International Commission on Radiation Units and Measurements (ICRU) report 38 rectal and bladder points, three and nine o'clock, and p2cm³ to the bladder, rectum, and sigmoid.

Results: Points A and B, $D_2 \text{ cm}^3$ bladder, ICRU bladder, and three and nine o'clock were within 5% of TG-43 for all GBBS calculations. The source and boundary and applicator account for most of the differences between the GBBS and TG-43 guidelines. The $D_{2\text{cm}^3}$ rectum

(n = 3), D_{2cm3} sigmoid (n = 1), and ICRU rectum (n = 6) had differences of >5% from TG-43 for the worst case incorrect mapping of contrast to bone. Clinical dosimetric parameters were within 5% of TG-43 when rectal and balloon contrast were mapped to bone and radiopaque packing was not overridden.

Conclusions: The GBBS has minimal impact on clinical parameters for this cohort of patients with unshielded applicators. The incorrect mapping of rectal and balloon contrast does not have a significant impact on clinical parameters. Rectal parameters may be sensitive to the mapping of radiopaque packing. © 2012 Elsevier Inc.

WG Shielded Applicator Test Case

Summary for GYN Brachytherapy

- The new brachy dose calculation algorithms provide more accurate dose distributions for GYN brachytherapy than the standard TG-43.
- Unshielded GYN CT/MR applicators impact is within +/-5%
- Shielded Applicator can significantly reduces dose to OARs

Monte Carlo (MCFF) / TG-43

over/under dose compensation between adjacent spheres

Vijande et al, J Contemp Brachy 4, 34-44 (2012)courtesy J. Perez-Calatayud

Summary for Skin Brachytherapy

- Challenges due to irregular surface
 - Interplay between scatter and shielding effects
- Departure from TG43 calculated dose depends on shielding and/or presence of air gaps
 - Small for PTV with unshielded geometry
 - Need further dose recalculation studies of (large) patient cohorts

Geometry

Tooth filling

- Bone and air cavity
- Scatter condition

TG43 vs MC

Poon et al, Med Phys 36 (2009)

MC = solid lines; TG43= dashed lines

TG43 vs MC

- Target dose unaffected
 - Dominated by primary
- D_{TG43} > D_{MC} brain stem
 ➤ Screening by bones
- $D_{TG43} > D_{MC}$ close to skin

Poon et al, Med Phys 36 (2009)

AcurosBV vs TG43

Siebert et al, J Contemp Brachytherapy 2013

- 49 consecutive patients, 2001-2009
 - floor of mouth carcinoma
 - larynx carcinoma
 - parotid carcinoma
- 2.5 Gy/Fx
- BV 8.8 and Acuros 1.3.1

Fig. 1. Transversal CT slice of a patient with mandibular cancer with infiltration of the floor-of-mouth and tongue using a single prescription dose of 2.5 Gy. Dotted isodose lines represent doses of TG-43 formalism, whereas straight lines show isodose lines of computations of the GBBS algorithm

AcurosBV vs TG43

Siebert et al, J Contemp Brachytherapy 2013

Fig. 2. Dose differences in percent between TG-43 formalism and the GBBS (TG-43 minus GBBS) for D_{90} , V_{100} , and V_{150} of the CTV versus volume of the CTV. A positive dose difference means that TG-43 result was larger than the GBBS results

D_{TG43} > D_{MC} by ≈ 3%
 CTV D90 and V100

- Larger volumes lead to larger differences
 - Primary vs scatter
 contributions to total dose
 important

MC vs TG43: Study from 22 patients

V Peppa et al., Radiother Oncol (2016), In Press

Summary for H&N Brachytherapy

- Differences small <u>on average</u> for CTV/PTV
 - Over and under dosage is patient specific(!)
 - Effects greater at distance from CTV
- OARs
 - Indices statistically different for mandible, parotid, skin, spinal cord.
 - But absolute difference small in most cases.

How Important in the clinic?

Site / Application	Importance
Shielded Applicators	Huge
Eye plaque	-10 to -30% (TG129)
Breast Brachy	-5% to -40%
Prostate Brachy	-2 to -15% on D90
GYN	Depends on applicators
H&N	-4% to +7%

Back to Physics!

Importance of the Physics: Scatter Conditions

Perez-Calatayud et al, Med Phys 2004

Primary vs. Scatter

Primary dominate total dose for the first 6 cm

Source: http://www.physics.carleton.ca/clrp

Importance of the Physics: Water vs Tissues

Importance of the Physics: Attenuation by Metals

From NIST website

Rule of thumb

Energy Range	Effect
¹⁹² r	Scatter condition
	Shielding (applicator related)
¹⁰³ Pd/ ¹²⁵ l/eBx	Absorbed dose (µ _{en} /p)
	Attenuation (μ/ρ)
	Shielding (applicator, source)

Rivard, Venselaar, Beaulieu, Med Phys 36, 2136-2153 (2009)

Good to know!

- MBDCA are commercially available (for ¹⁹²Ir and ⁶⁰Co) Varian and Elekta
- Starting with the latest release of Varian Brachy TPS, AcurosBV can be used to optimize the dose:

PHYSICS CONTRIBUTION

PATIENT-SPECIFIC MONTE CARLO-BASED DOSE-KERNEL APPROACH FOR INVERSE PLANNING IN AFTERLOADING BRACHYTHERAPY

MICHEL D'AMOURS, M.Sc.,^{*†} JEAN POULIOT, PH.D.,[‡] ANNE DAGNAULT, MD.,^{*} FRANK VERHAEGEN, PH.D.,^{§¶} AND LUC BEAULIEU, PH.D.^{*†}

Remember

- TG-43 is still the recommended STD for:
 - Prescription dose levels
 - Dose planning/optimization
- Beyond TG43
 - Follow TG-186 recommendations
 - For tissue assignments
 - For dose reporting
 - ATTN to physics!

Conclusion

- TG43 presents limitation for many clinical sites
 - ➢ From a few % to many tens of % for shielded geometries
- Algorithms desperately needed for low energy brachytherapy: seeds or eBx
 - Much larger effects expected
- New approaches depend on going beyond TG43
 - Shielded and directional applicators
 - Directional sources
 - ➢ eBx and low energy brachytherapy.

✓ Ahnesjö A, van Veelen B & Tedgren ÅC 2017 Comput. Meth Prog Biomed 139: 17

and implemented for ¹⁹²Ir dosimetry in Oncentra Brachy:

 \checkmark user manuals

 \checkmark white paper by Elekta: ACE Advanced Collapsed cone Engine

Objectives/Outline:

To:

review the basic principles of the method outline its implementation

so as to identify:

- strengths and weaknesses
- analogies and differences between (current/future) commercially available MBDCAs

> potential improvements over TG-43

> potential shortcomings relative to reference dose distributions

• Let us start again from the simplest case (point isotopic monoenergetic photon source in infinite medium of given composition)

• at any point I know more than D_{prim} :

• If I know the spectrum of the source I know the amount of energy per unit mass scattered in first interactions of primary photons, S_{1sc}

• I know S_{1sc} at each point

$$S_{1sc_i} = T_i - K_i = (\frac{\mu - \mu_{en}}{\rho})\Psi_i = (1 - \frac{\mu_{en}}{\mu})T_i = (\frac{\mu}{\mu_{en}} - 1)D_{prim_i}$$

• I need a way to distribute this energy to all other points ...

• I know S_{1sc} at each point

$$S_{1sc_i} = T_i - K_i = (\frac{\mu - \mu_{en}}{\rho})\Psi_i = (1 - \frac{\mu_{en}}{\mu})T_i = (\frac{\mu}{\mu_{en}} - 1)D_{prim_i}$$

• I need a way to distribute this energy to all other points ...

•Suppose
$$h_{1sc, j} \equiv h_{1sc}(r, \theta) = \frac{\varepsilon(r, \theta)}{\overline{R}_{1sc} dV}$$

is the fraction of 1sc energy released at a point (@ the origin) that is absorbed @ (r, θ), per unit of volume

•Can I calculate $h_{1sc}(r,\theta) \dots$?

• From 1st principles:

$$h_{1sc}(r,\theta) = \frac{\varepsilon(r,\theta)}{\overline{R}_{1sc} dV} = \frac{\frac{d\sigma(\theta)}{d\Omega}}{\sigma} \frac{1}{r^2} \exp(-\mu_{1sc,\theta} r) \mu_{en_{1sc,\theta}}$$

• Since I know the spectrum of 1sc photons, I can calculate $h_{1sc}(r, \theta)$

• It is more efficient to use MC to calculate
$$h_{1sc_i}(r,\theta)$$

and fit an analytical expression
 $h_{1sc}(r,\theta) = \frac{\varepsilon(r,\theta)}{\overline{R}_{1sc}dV} = \frac{dR_{1sc}(\theta)}{\overline{R}_{1sc}} \frac{1}{r^2d\Omega} \exp(-\mu_{1sc,\theta}r) \mu_{en_{1sc,\theta}} =$
 $= \frac{dR_{1sc}(\theta)}{E(1-\frac{\mu_{en}}{\mu})} \frac{1}{r^2d\Omega} \exp(-\mu_{1sc,\theta}r) \mu_{en_{1sc,\theta}} =$
 $= \frac{B_{\theta}\exp(-b_{\theta}r)}{r^2}$
where:
 $B_{\theta} = \frac{dR_{1sc}(\theta)}{E(1-\frac{\mu_{en}}{\mu})} \frac{1}{d\Omega} \mu_{en_{1sc,\theta}}$
 $b_{\theta} = \mu_{1sc,\theta}$

• What material should I choose for the calculation of h...?

The method ... is ready!

(and it's convolution/superposition)

• I can calculate D_{1sc} @ any point from any point, e.g.:

$$D_{1sc_{i} \rightarrow j} = \frac{1}{\rho_{j}} R_{1sc,i} h_{j} = \frac{1}{\rho_{j}} S_{1sc,i} \rho_{i} dV h(\vec{r}_{j} - \vec{r}_{i}, \theta) =$$
$$= \frac{\rho_{i}}{\rho_{j}} S_{1sc,i} h(\vec{r}_{j} - \vec{r}_{i}, \theta) dV$$

and the total dose to j would be:

$$D_{1sc_j} = \iiint \frac{\rho_i}{V} S_{1sc,i} h_j dV$$

- I need to be efficient (reduce the # of the N⁶ evaluations required) & work with finite voxels
- 2. I need to account for inhomogeneities
- 3. I need to account for higher order of scatter (D_{2sc}, D_{3sc}, ..., D_{msc})
- 4. I need to work with real sources
- 5. I need to account for finite patient dimensions

• It is inherently beneficial to work in spherical coordinates to lift the kernel singularity since: $dV=dS dr=r^2 d\Omega dr = r^2 \sin\theta d\theta d\phi dr$

$$D_{1sc_{i} \to j} = \iint_{V} \frac{\rho_{i}}{\rho_{j}} S_{1sc,i} h_{j} dV =$$
$$\frac{\rho_{i}}{\rho_{j}} \iint_{r} S_{1sc,i} \frac{B_{\theta} \exp(-b_{\theta} r)}{r^{2}} r^{2} \sin \theta d\theta d\phi dr$$

• Instead of evaluating ALL directions around a scerma generating point, I can DISCRETIZE space using a number M of solid angle elements, $\Delta \Omega_{\rm M}$, defined by $(\theta_0, \phi_0)_M$, and assume scerma does not <u>vary with θ within $\Delta\Omega$ (i.e. on dS for a given r)</u>

$$D_{1sc_{i} \to j} = \iint_{\Delta\Omega} \int_{r}^{\rho_{i}} S_{1sc,i} B_{\theta} \exp(-b_{\theta} r) d\Omega dr = \Delta\Omega \frac{\rho_{i}}{\rho_{j}} S_{1sc,i} B_{\theta_{0}} \int_{r}^{\rho_{i}} \exp(-b_{\theta_{0}} r) dr$$

r

An <u>oversimplified</u> example: one solid angle element per cubic voxel side

M=6, $\Delta\Omega$ =2 $\pi/3$

Our oversimplified example on a plane (one array of voxels or one image):

scerma does not vary with θ within $\Delta \Omega$ → less fitting for B_θ, b_θ

BUT

I still need to evaluate D_{i->j} for all points j at different radial distance

OR

• I could evaluate D_{i-j} only for j at exactly θ_0 , ϕ_0

Hence each **cone** defined by $\Delta\Omega$ is **collapsed** to its main axis and <u>scerma from each point is</u> <u>transported along lines defined by the</u> <u>directions from volume discretization in $\Delta\Omega$ </u> (order of evaluations required~MN⁴)

Figure from: Carlsson & Ahnesjö Med. Phys. 35 (4) 1611 (2008) Can the CC method be both efficient AND accurate...?

 At the limit of fine discretization (M→N³, ΔΩ→dΩ) the collapsed cone method can be exact (but inefficient)

Can the CC method be both efficient AND accurate...?

 I can reduce the number of directions since scerma from voxel A <u>not</u> distributed to voxel B' due to the CC approximation will be <u>compensated</u> by scerma from another point A' along the same transport direction

Figure from: Ahnesjö Med. Phys. 16, 577 (1989)

Can the CC method be both efficient AND accurate...?

YES if I optimize the number of directions

• Optimization criterion...?

Can the CC method be both efficient AND accurate...?

YES if I optimize the number of directions

Optimization criterion...?

• THE SCERMA GRADIENT!!!

Can the CC method be both efficient AND accurate...?

The less scerma varies the more I can reduce the number of directions (increase of efficiency) without a considerable loss of accuracy

Which cases are less/more forgiving...?

Figure from: Carlsson & Ahnesjö Med. Phys. 27, 2320 (2000) Can the CC method be both efficient AND accurate...?

The less scerma varies the more I can reduce the number of directions (increase of efficiency) without a considerable loss of accuracy

The approximation by CC that scerma is transported linearly will only break down at increased distances where $r^2\Delta\Omega=\Delta S>>$ so that the cone opening is greater than voxel cross section

Can the CC method be both efficient AND accurate...?

'he less scerma varies the more I can reduce the number of directions (increase of efficiency) without a considerable loss of accuracy

The approximation by CC that scerma is transported linearly will only break down (ray artefacts) at <u>increased</u> distances where $r^2\Delta\Omega = \Delta S >>$

Discretization artefacts decrease for:

- coarse voxel resolution (voxel cross section ~ Δ S)
- Rapidly decreasing kernels (lower E)

All that is missing then is:

- a method to define a grid of transport lines along the discretization directions and
- a set of recursive equations to calculate stepwise on each transport line and not from point to point

Method to define a grid of transport lines along the discretization directions

Dose **from** points along Δr_1 in voxel 1, **to** a point in voxel 2 : <u>01</u>

$$D_{1sc1 \to 2} = \iint_{\Delta\Omega} \int_{r'}^{PT} \int_{\rho_2}^{PT} S_{1sc,1} B_{\theta} \exp(-b_{\theta} r') \, d\Omega \, dr' =$$

$$\Delta \Omega \frac{\rho 1}{\rho 2} S_{1sc,1} B_{\theta} \int_{r}^{r+\Delta \eta} \exp(-b_{\theta} r') dr' =$$

Equations for the transport of scerma generated at each point along a transport line

Under the collapsed cone approximation:

Scerma does not vary with θ within $\Delta \Omega$ $(B\theta, b\theta \text{ constant along transport line})$ and scerma generated, emitted and absorbed along transport line

and assuming:

$$= \iint_{\Delta\Omega} \int_{r'} \frac{\rho_{1}}{\rho_{2}} S_{1sc,1} B_{\theta} \exp(-b_{\theta} r') d\Omega dr' = \int_{\Delta\Omega} r' \frac{\rho_{1}}{\rho_{2}} S_{1sc,1} B_{\theta} \int_{r} \exp(-b_{\theta} r') dr' = \int_{r} \frac{\Psi_{1sc}}{P_{1sc}} \exp(-b_{\theta} r) [1 - \exp(-b_{\theta} \Delta r_{1})] = \frac{B_{\theta}}{\rho_{2}} \frac{\Delta\Omega S_{1sc,1} \rho_{1}}{b_{\theta}} \exp(-b_{\theta} r) [1 - \exp(-b_{\theta} \Delta r_{1})]$$

 (Bθ, bθ constant along transport line) and scerma generated, emitted and absorbed along transport line

and assuming:

$$\frac{\Delta r_2}{D_{1sc2 \to 2}dr} = \frac{\int_{0}^{\Delta r_2} D_{1sc2 \to 2}dr}{\Delta r_2} = \frac{\int_{0}^{\Delta r_2} [1 - \exp(-b\theta r)]dr}{\Delta r_2} = B_{\theta} \frac{\Delta \Omega S_{1sc,2}}{b_{\theta}} \frac{\{b_{\theta} \Delta r_2 - [1 - \exp(-b\theta \Delta r_2)\}\}}{b_{\theta} \Delta r_2}$$

Overall, exiting voxel 2:

Equations for the transport of scerma generated at each point along a transport line

Under the collapsed cone approximation:

 Scerma does not vary with θ within ΔΩ
 (Bθ, bθ constant along transport line) and scerma generated, emitted and absorbed along transport line

and assuming:

$$\frac{D_{1sc2} = D_{1sc1 \rightarrow 2} + D_{1sc2 \rightarrow 2} =}{\frac{B_{\theta}}{p_2} \frac{\Delta \Omega S_{1sc,1} \rho_1}{b_{\theta}} \frac{[1 - \exp(-b_{\theta} \Delta r_1)][1 - \exp(-b_{\theta} \Delta r_2)]}{b_{\theta} \Delta r_2} + B_{\theta} \frac{\Delta \Omega S_{1sc,2}}{b_{\theta}} \frac{\{b_{\theta} \Delta r_2 - [1 - \exp(-b_{\theta} \Delta r_2)]\}}{b_{\theta} \Delta r_2}}{b_{\theta} \Delta r_2}$$

$$\overline{D_{1sci}} = \sum_{i} \overline{D_{1sci-1} \rightarrow i} + \overline{D_{1sci} \rightarrow i} = \sum_{1}^{i-1} \frac{B_{\theta}}{\rho_{i}} \frac{\Delta \Omega S_{1sc,i-1}\rho_{i-1}}{b_{\theta}} \frac{[1 - \exp(-b_{\theta} \Delta r_{i})][1 - \exp(-b_{\theta} \Delta r_{i})]}{b_{\theta} \Delta r_{i}} + B_{\theta} \frac{\Delta \Omega S_{1sc,i}}{b_{\theta}} \frac{\{b_{\theta} \Delta r_{i} - [1 - \exp(-b_{\theta} \Delta r_{i})]\}}{b_{\theta} \Delta r_{i}}$$

An efficient algorithm for the calculation of dose from 1st scatter:

- Calculate S_{1sc} distr., from D_{prim} distr.
 - Choose $\Delta\Omega$: optimal number of directions
- Construct lattice of transport lines $(B_{\theta}, b_{\theta} \text{ per } \Delta \Omega, \text{ relative to direction of primaries})$
- Ray-trace along each transport line for Δr_i and iteratively calculate D_i
 - Sum D_i from all transport lines

Input:

- D_{prim} distr.
- Source primary spectrum for calculating S_{1sc}
 - 1st scatter kernel
 - Individual voxel density data

Assumptions:

CC:

- S_{1sc} does not vary with θ within $\Delta\Omega$ (B θ , b θ constant along transport line)
 - S_{1sc} generated, emitted and absorbed along transport line and:
 - S_{1sc} generated per unit r is constant within the same voxel (scerma does not vary considerably within voxels)

$$\overline{D_{1sci}} = \sum_{i} \overline{D_{1sci-1 \rightarrow i}} + \overline{D_{1sci \rightarrow i}} = \sum_{1}^{i-1} \frac{B_{\theta}}{\rho_{i}} \frac{\Delta \Omega S_{1sc,i-1}\rho_{i-1}}{b_{\theta}} \frac{[1 - \exp(-b_{\theta} \Delta r_{i-1})][1 - \exp(-b_{\theta} \Delta r_{i})]}{b_{\theta} \Delta r_{i}} + B_{\theta} \frac{\Delta \Omega S_{1sc,i}}{b_{\theta}} \frac{\{b_{\theta} \Delta r_{i} - [1 - \exp(-b_{\theta} \Delta r_{i})]\}}{b_{\theta} \Delta r_{i}}$$

Implementation corrections:

- S_{1sc} does not vary with θ within $\Delta\Omega$ (B θ , b θ constant along transport line)
- → Kernel tilting problem less important as E decreases
 - → b θ evaluated recursively as a moving average of previous and current step
 - S_{1sc} generated per unit r is constant within the same voxel (scerma does not vary considerably within voxels)
 - → Scerma gradient problem more important close to a source
- → in high scerma gradient regions scerma is estimated piecewise from a log-linear interpolation over r

$$D_{1sc j} = \iiint \frac{\rho_i}{\rho_j} S_{1sc,i} h_j dV$$

Medium can be of varying density What changes...?

Our basic equation already accounts for:

- Density @ scatter release voxel
- Density @ energy absorption voxel

$$h_{1sc}(r,\theta) = \frac{\varepsilon(r,\theta)}{\overline{R}_{1sc} dV} = \frac{dR_{1sc}(\theta)}{\overline{R}_{1sc}} \frac{1}{r^2 d\Omega} \exp(-\mu_{1sc,\theta} r) \mu_{en_{1sc,\theta}}$$
$$= \frac{dR_{1sc}(\theta)}{E(1 - \frac{\mu_{en}}{\mu})} \frac{1}{r^2 d\Omega} \exp(-\mu_{1sc,\theta} r) \mu_{en_{1sc,\theta}}$$
$$= \frac{B_{\theta} \exp(-b_{\theta} r)}{r^2}$$
$$B_{\theta} = \frac{dR_{1sc}(\theta)}{E(1 - \frac{\mu_{en}}{\mu})} \frac{1}{d\Omega} \mu_{en_{1sc,\theta}}$$

μ

 $b_{\theta} = \mu_{1sc,\theta}$

The kernel also changes ...!

Medium can be of varying density

So if we also scale all distances with density we solve the problem and our method is in accordance with O'Connor's theorem:

When considering two media of different densities but the same atomic composition exposed to the same beam, the dose at corresponding points in the two media will be the same provided that all geometric distances in the two media are scaled inversely with density

Medium can be of varying density

This affects only the exponential attenuation term in our recursive equation which now has to be:

 $\exp(-b_{\theta}\sum_{1}^{i-1}\rho_{i}\Delta r_{i})$

$$h_{1sc}(r,\theta) = \frac{\varepsilon(r,\theta)}{\overline{R}_{1sc} dV} = \frac{dR_{1sc}(\theta)}{\overline{R}_{1sc}} \frac{1}{r^2 d\Omega} \exp(-\mu_{1sc,\theta} r) \mu_{en_{1sc,\theta}}$$
$$= \frac{dR_{1sc}(\theta)}{E(1-\frac{\mu_{en}}{\mu})} \frac{1}{r^2 d\Omega} \exp(-\mu_{1sc,\theta} r) \mu_{en_{1sc,\theta}}$$
$$= \frac{B_{\theta} \exp(-b_{\theta} r)}{r^2}$$

$$B_{\theta} = \frac{dR_{1sc}(\theta)}{E(1 - \frac{\mu_{en}}{\mu})} \frac{1}{d\Omega} \mu_{en_{1sc},\theta}$$

$$b_{\theta} = \mu_{1sc,\theta}$$

Medium can be of varying material (different elemental composition and Zeff)

This affects cross sections and hence B_{θ}, b_{θ}

Can't we scale the kernel? Yes and different approaches have appeared in the literature.

ACE scales attenuation and absorption voxel-wise according to:

$$b_{\theta m} = b_{\theta} \frac{\rho_m}{\rho_w} \left[\frac{\overline{\mu_{1sc,\theta}}}{\rho} \right]_W^m = b_{\theta} \eta_{1sc}$$
$$B_{\theta m} = B_{\theta} \frac{\rho_m}{\rho_w} \left[\frac{\overline{\mu_{en_{1sc,\theta}}}}{\rho} \right]_W^m = B_{\theta} \chi_{1sc}$$

ACE scales attenuation and absorption voxel-wise according to:

$$b\theta_{m} = b\theta \frac{\rho_{m}}{\rho_{W}} \left[\frac{\overline{\mu_{1sc,\theta}}}{\rho} \right]_{W}^{m} = b\theta \eta_{1sc}$$
$$B\theta_{m} = B\theta \frac{\rho_{m}}{\rho_{W}} \left[\frac{\overline{\mu_{en_{1sc,\theta}}}}{\rho} \right]_{W}^{m} = b\theta \chi_{1sc}$$

Medium can be of varying material (different elemental composition and Zeff)

The same recursive equation applies BUT:

• additional input is required to calculate η_{1sc} , χ_{1sc} : the energy spectrum of 1sc photons generated at each point.

This is taken from calculations in water so:

• the scaling is APPROXIMATE and its accuracy deteriorates as materials yield different 1sc spectrum from water (as Z increases due to coherent & photoelectric phenomena-x ray fluorescence and S(x,Z))

Instead of using h_{1sc} with S_{1sc} obtained from D_{prim} , to obtain D_{1sc} ered couldn't I distribute S_{1sc} due to ALL orders of scattering in a single step using a different kernel, i.e. h_{msc} ...?

I could, but it is NOT a good idea due to:

- h_{msc} reducing less than h_{1sc} with $r \rightarrow$ ray artefacts
- accuracy close to boundaries of finite geometries (discussed in the following)

Figures from: Carlsson & Ahnesjö Phys. Med. Biol. 45 357 (2000)

3. Higher order of scatter

- · Primary photons forced to interact
- Once scattered photons and all subsequent particles transported
- Scoring of dose mediated by - once-scattered photons: h_{1sc}
- all scatter generations : $h_{\rm tsc}$

- · Primary photons forced to interact
- Once scattered photons started but forced to interact without transport
- Twice scattered photons and all subsequent particles transported
- Scoring of dose mediated by multiplyscattered photons: $H_{\rm msc}$

I have to repeat the method 2 times:

$$D_{prim} \rightarrow S_{1sc} \rightarrow CC$$
 with $h_{1sc} \rightarrow D_{1sc}$

$$D_{1sc} \rightarrow S_{2sc} \rightarrow CC \text{ with } H_{msc} \rightarrow D_{msc}$$

Figures from: Carlsson & Ahnesjö Phys. Med. Biol. 45 357 (2000) & Med. Phys. 35 (4) 1611 (2008)

3. Higher order of scatter

- The second step is approximate in that I do not know the orientation of H_{msc} I can assume it is isotropic or align it with h_{1sc}
 - Calculation time increases to $(M_{1sc}+M_{msc})N^3$
 - Required M_{msc} is < M_{1sc} since the gradient of D_{1sc} is considerably less than that of D_{prim}

3. Higher order of scatter

I have to repeat the method 2 times:

 $D_{prim} \rightarrow S_{1sc} \rightarrow CC$ with $h_{1sc} \rightarrow D_{1sc}$

$$D_{1sc} \rightarrow S_{2sc} \rightarrow CC$$
 with $H_{msc} \rightarrow D_{msc}$

An analogous recursive equation applies

with the difference that H_{msc} is better fit by a bi-exponential function

$$H_{msc}(r,\theta) = \frac{C_{\theta} \exp(-c_{\theta} r) + D_{\theta} \exp(-d_{\theta} r)}{r^2}$$

Additional input is required to calculate inhomogeneity corrections: the energy spectrum of msc photons generated at each point

4. real sources

Input must now be source specific:

- Primary dose distribution
- Distribution of primary photon energy spectrum
 - Distribution of 1sc photon energy spectrum
 - Distribution of msc photon energy spectrum

 μ/ρ , $\mu en/\rho$ data for the calculation of scerma, as well as 1sc & msc kernels, must be weighed over the appropriate energy spectra

Implementation detail:

Primary dose distribution is fit by an analytical expression

This allows calculations @ resolution different than that used in the MC simulation to derive the primary dose distribution

5. finite patient dimensions

5. finite patient dimensions

Kernel data are traditionally calculated in full scatter geometries (8mfp)

This overestimates msc dose close to the edges of a bounded geometry

Differences could be lifted if a msc kernel calculated in a phantom of equal dimensions to the geometry was used.

Figure 3. (left): Dose differences between CC and MC as function of the distance from a centrally positioned ¹⁹²Ir source obtained in cubic water phantoms of halfsides 5 cm, 10 cm, 15 cm, 20 cm and 25 cm. A multiple-scatter point kernel that was generated in a water sphere of outer radii 50 cm was used with CC for all the distributions. (right): Dose differences between CC and MC as function of the distance from a centrally positioned ¹⁹²Ir source obtained in cubic water phantoms of halfsides 5 cm, 10 cm, 15 cm, 20 cmm and 25 cm. A multiple-scatter point kernel that was generated in a water sphere of outer radii 10 cm was used with CC for all the distributions.

Important implementation details

Accuracy Level	Voxel size (cm)			
	0.1	0.2	0.5	1.0
Standard	1	8	20	50
High	8	20	35	50
High (single dwell position)	10	20	50	100

	Number of transport directions for first and residual scatter dose calculations			culations	
Accuracy level	1 dwell position	2-50 dwell positions	51-150 dwell positions	151-300 dwell positions	>300 dwell positions
Standard	320 and 180	320 and 180	240 and 128	200 and 80	180 and 72
High	1620 and 240	720 and 240	500 and 200	320 and 180	240 and 128

All calculation settings are preset!

The user only selects between two options denoted as: standard and high accuracy levels.

These options control:

- the extent of each of the 4 regions in the multi-resolution Cartesian calculation grid used
 - the number of directions for 1sc and msc dose calculations.
- Material assignment is ROI based (TG-186 + applicator materials) otherwise water is considered within the patient external contour
- Density can be uniform (ROI based) or HU based (ICRP 44/46 data + method in Knöös et al. Radiother. Oncol. 5, 337, 1986)

Dosimetry using a Grid-Based Boltzmann equation Solver (Acuros)

P. Papagiannis, PhD Medical Physics Laboratory Medical School National & Kapodistrian University of Athens

(no conflict of interest to disclose)

Dosimetry using Dosimetry using a Grid-Based Boltzmann equation Solver (Acuros)

- GBBS algorithms used primarily for neutron transport and shielding problems
- Method evaluated for brachy in the literature as early as 2000
- The first GBBS algorithm incorporated in a commercially available ¹⁹²Ir brachytherapy TPS was Acuros

• Acuros is based on the Attila GBBS developed at Los Alamos National Laboratory, optimized for brachytherapy and later also for external beam therapy (XB) and even CT scatter correction (CTS).

Method can be reviewed in a number of publications:
✓ Daskalov GM et al 2000 Med. Phys. 27(10):2307

[╋]

Objectives/Outline:

To:

review the basic principles of the method outline its implementation

so as to identify:

- strengths and weaknesses
- analogies and differences between (current/future) commercially available MBDCAs

> potential improvements over TG-43

> potential shortcomings relative to reference dose distributions

The basic idea ...

Remember, if I know the energy distribution of fluence, Φ_E , at all points of a geometry, I know the dose distribution!

$$D(\mathbf{r}) = K(\mathbf{r}) = \int_{E} E\Phi_{E}(\mathbf{r}) \left[\frac{\mu_{en}(E)}{\rho}\right] dE$$

Can't I formulate an equation describing Φ_E , at my simple problem (point isotropic source in infinite homogeneous medium) and solve it...?

The basic equation is the LBTE

Let $\Phi_{\Omega,E}(\vec{r}, E, \hat{\Omega})$ be the angular fluence ($d\Phi/d\Omega dE = dN/dAd\Omega dE$) denoting the number of photons in phase space element($\vec{r}, E, \hat{\Omega}$), i.e. passing through a voxel of area dA normal to $\hat{\Omega}$ located at \vec{r} , with $\hat{\Omega}$ within Ω and $\Omega + d\Omega$ and E between E and E+dE.

At any part of this "phase space", conservation of E dictates particle density balance.

The net flow of photons through a phase space cell equals:

photons scattered in it from all others (E', Ω ')

+ photons emitted by a source in it

- photons absorbed or scattered out of it

Ω Ω	$\hat{\Omega} \cdot \nabla \Phi_{\Omega,E}(\vec{r}, E, \hat{\Omega}) =$
	$q_{scat}(\vec{r}, E, \hat{\Omega})$
	$+\frac{q_p(E,\hat{\Omega})}{4\pi}\delta(\vec{r}-\vec{r}_p)$
	$-\mu_t(\vec{r}, E)\Phi_{\Omega, E}(\vec{r}, E, \hat{\Omega})$
	L.B.T.E.
The LBTE

Rearranging the equation, and dropping notation for angular Φ and E distr. of Φ (these can be discerned by the argument):

$$\hat{\Omega} \cdot \vec{\nabla} \Phi(\vec{r}, E, \hat{\Omega}) + \mu_t \Phi(\vec{r}, E, \hat{\Omega}) = q_{scat} + \sum_{p=1}^{P} \frac{q_p}{4\pi} \delta(\vec{r} - \vec{r}_p)$$

Where:

 μ_t is the total linear interaction coefficient

 q_p is the primary photon density due to any of P point sources present at a phase space cell q_{scat} is the scatter photon density

OK...!

Can I solve the LBTE for Φ ...?

The LBTE $\hat{\Omega} \cdot \vec{\nabla} \Phi(\vec{r}, E, \hat{\Omega}) + \mu_t \Phi(\vec{r}, E, \hat{\Omega}) = q_{scat} + \sum_{p=1}^{P} \frac{q_p}{4\pi} \delta(\vec{r} - \vec{r}_p)$

There is no analytical (closed form) solution of the LBTE.

This is because it is an equation of 6 variables which is integro-differential since the scatter source is:

$$q_{scat}(\vec{r}, E, \hat{\Omega}) = \int_{04\pi}^{\infty} \int \mu_s(\vec{r}, E' \to E, \hat{\Omega} \cdot \hat{\Omega}') \Phi(\vec{r}, E', \hat{\Omega}') d\hat{\Omega}' dE'$$

i.e. : I must integrate for the scatter source and this depends on the solution itself at all other (E', Ω ') points of the phase space...!

The only option is to solve the equation numerically (and this is exactly what Acuros and similar algorithms do) by: >> separating variables: $\Phi(\vec{r}, E, \hat{\Omega}) = \Phi(\vec{r}, E)Y(\hat{\Omega}) = \Phi(\vec{r}) f(E)Y(\hat{\Omega})$ >> solve the LBTE iteratively: •make initial guess for $\Phi(\vec{r})$ •approximate integration for the scatter source by summation over discrete E, Ω elements •approximate derivatives by finite differences over discrete space elements

•correct initial guess, and continue until a convergence criterion is met

Let us take a closer look at q_{scat} :

$$q_{scat}(\vec{r}, E, \hat{\Omega}) = \int_{04\pi}^{\infty} \int \mu_s(\vec{r}, E' \to E, \hat{\Omega} \cdot \hat{\Omega}') \Phi(\vec{r}, E', \hat{\Omega}') d\hat{\Omega}' dE'$$

The probability of a photon scattering from Ω ' to Ω (for a given energy) depends only on $\cos\theta \in [-1,1]$, where θ is the scattering angle and

the number of photons scattered in a given direction (for a given energy) depends on the solid angle element around the direction: $sin\theta d\theta d\phi$

or

the area on the unit sphere defined by the solid angle around the direction

Hence, I can expand q_{scat} in an infinite series of spherical harmonics.

It would not strike you as odd that any function in R³ can be expanded as a 3 term series

provided the basis for this expansion is orthogonal, e.g.: $\hat{i} \cdot \hat{j} = \hat{j} \cdot \hat{k} = \hat{k} \cdot \hat{i} = 0$ $\hat{i} \cdot \hat{i} = \hat{j} \cdot \hat{j} = \hat{k} \cdot \hat{k} = 1$

i, j, and k are said to form an orthogonal basis

Many orthogonal bases exist!

Many orthogonal bases exist

In example:

 \succ Legendre polynomials, $P_n(x)$, are a series of functions that exhibit orthogonality

legendre polynomials

for $-1 \le x \le 1$:

$$\int_{-1}^{1} P_m(x) P_n(x) \, dx = \frac{2}{2n+1} \delta_{mn}$$

and therefore they can be used to expand any function defined in [-1,1] in an infinite series:

$$f(x) = \sum_{\substack{n=0 \\ n=0}}^{\infty} w_n P_n(x), \qquad \mu_s(\vec{r}, E' \to E, \hat{\Omega} \cdot \hat{\Omega}') = \sum_{\substack{n=0 \\ n=0}}^{\infty} \frac{2n+1}{4\pi} \mu_{s,n}(\vec{r}, E' \to E) P_n(\hat{\Omega} \cdot \hat{\Omega}'), \mu_{s,n}(\vec{r}, E' \to E) = \frac{1}{2} \int_{-1}^{1} \mu_s(\vec{r}, E' \to E, \hat{\Omega} \cdot \hat{\Omega}') P_n(\hat{\Omega} \cdot \hat{\Omega}') d(\hat{\Omega} \cdot \hat{\Omega}') -1$$

> We can truncate the expansion of μ_s up to N (N=3 is adequate for ¹⁹²Ir anisotropic scattering)

$$\begin{aligned} \mu_{S}(\vec{r}, E' \to E, \hat{\Omega} \cdot \hat{\Omega}') &= \sum_{n=0}^{N=3} \frac{2n+1}{4\pi} \mu_{S,n}(\vec{r}, E' \to E) P_{n}(\hat{\Omega} \cdot \hat{\Omega}'), \\ \mu_{S,n}(\vec{r}, E' \to E) &= 1/2 \int_{-1}^{1} \mu_{S}(\vec{r}, E' \to E, \hat{\Omega} \cdot \hat{\Omega}') P_{n}(\hat{\Omega} \cdot \hat{\Omega}') d(\hat{\Omega} \cdot \hat{\Omega}') \\ &-1 \end{aligned}$$

Note that truncation pertains to the detail in the description of scatter cross section in terms of the scattering angle and that we have NOT discretized in direction

Many orthogonal bases exist

In example:

> Spherical harmonics, $Y_l^m(\theta, \phi)$, are a series of functions defined on the surface of a sphere that exhibit orthogonality:

$$\int_{2\pi \pi} \int Y_{l}^{m}(\theta,\phi) \overline{Y}_{l'}^{m'}(\theta,\phi) \sin \theta \, \mathrm{d}\theta \, \mathrm{d}\phi =$$

 $\int_{2\pi-1}^{1} Y_{l}^{m}(\theta,\phi) \overline{Y}_{l'}^{m'}(\theta,\phi) d(\cos\theta) \, \mathrm{d}\phi = \delta_{\mathrm{mm'}} \, \delta_{\mathrm{ll'}}$

and therefore they can be used to expand any function defined on the surface of a sphere in an infinite series:

$$f(\theta,\phi) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} C_{l,m} Y_l^m(\theta,\phi),$$
$$C_{l,m} = \iint_{\Omega} f(\theta,\phi) Y_l^m(\theta,\phi) d\Omega$$

ŀ

Various types of spherical harmonics are available.

A particular set, of order l=N (orthogonal basis) + the corresponding weights of a function are called a **quadrature set of order N**.

Many orthogonal bases exist

In example:

> Spherical harmonics, $Y_l^m(\theta, \phi)$, are a series of functions defined on the surface of a sphere that exhibit orthogonality:

$$\int_{2\pi \pi} \int Y_{l}^{m}(\theta,\phi) \overline{Y}_{l'}^{m'}(\theta,\phi) \sin \theta \, \mathrm{d}\theta \, \mathrm{d}\phi =$$

1

$$\int_{2\pi-1}^{1} Y_{l}^{m}(\theta,\phi) \overline{Y}_{l'}^{m'}(\theta,\phi) d(\cos\theta) d\phi = \delta_{\text{mm'}} \delta_{ll'}$$

and therefore they can be used to expand any function defined on the surface of a sphere in an infinite series:

$$f(\theta,\phi) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} C_{l,m} Y_{l}^{m}(\theta,\phi),$$
$$C_{l,m} = \iint_{\Omega} f(\theta,\phi) Y_{l}^{m}(\theta,\phi) d\Omega$$

$$\begin{aligned} \Phi(\vec{r}, E', \hat{\Omega}') &= \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \Phi_{l,m}(\vec{r}, E') Y_{l}^{m}(\hat{\Omega}'), \\ \Phi_{l,m}(\vec{r}, E') &= \iint_{l} \Phi(\vec{r}, E', \hat{\Omega}') Y_{l}^{m}(\hat{\Omega}') d\Omega' \\ &\quad 4\pi \end{aligned}$$

Note we have described the energy fluence in spherical coordinates and that we have NOT discretized in direction

OK.

Let us agree that instead of : $q_{scat}(\vec{r}, E, \hat{\Omega}) = \int_{0}^{\infty} \int \mu_{s}(\vec{r}, E' \to E, \hat{\Omega} \cdot \hat{\Omega}') \Phi(\vec{r}, E', \hat{\Omega}') d\hat{\Omega}' dE'$ $q_{scat} \text{ can be written as :}$ $q_{scat}(\vec{r}, E, \hat{\Omega}) = \int_{0}^{\infty} \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \mu_{s,l}(\vec{r}, E' \to E) \Phi_{l,m}(\vec{r}, E') Y_{l}^{m}(\theta, \phi) dE',$ $\mu_{s,l}(\vec{r}, E' \to E) = \frac{1}{2} \int_{-1}^{1} \mu_{s}(\vec{r}, E' \to E, \hat{\Omega} \cdot \hat{\Omega}') P_{l}(\hat{\Omega} \cdot \hat{\Omega}') d(\hat{\Omega} \cdot \hat{\Omega}')$ $\Phi_{l,m}(\vec{r}, E') = \iint_{4\pi} \Phi(\vec{r}, E', \hat{\Omega}') Y_{l}^{m}(\hat{\Omega}') d\Omega'$

is there a benefit?

➢ We have separated r and E, from direction variables and turned integration to summation for direction <u>in the scatter source</u>

$$\hat{\Omega} \cdot \bar{\nabla} \Phi(\vec{r}, E, \hat{\Omega}) + \mu_t \Phi \quad (\vec{r}, E, \hat{\Omega}) = q_{scat} + \sum_{p=1}^{P} \frac{q_p}{4\pi} \delta(\vec{r} - \vec{r}_p) \quad (1)$$

$$q_{scat}(\vec{r}, E, \hat{\Omega}) = \int_{0}^{\infty} \sum_{l=0}^{\infty} \sum_{m=-l}^{P} \mu_{s,l}(\vec{r}, E' \to E) \Phi_{l,m}(\vec{r}, E') Y_l^m(\theta, \varphi) dE' \quad (2)$$

$$\mu_{s,l}(\vec{r}, E' \to E) = 1/2 \int_{-1}^{1} \mu_s(\vec{r}, E' \to E, \hat{\Omega} \cdot \hat{\Omega}') P_l(\hat{\Omega} \cdot \hat{\Omega}') d(\hat{\Omega} \cdot \hat{\Omega}') \quad (3)$$

$$\Phi_{l,m}(\vec{r}, E') = \iint_{4\pi} \Phi(\vec{r}, E', \hat{\Omega}') Y_l^m(\hat{\Omega}') d\Omega' \quad (4)$$

Let us continue with E ...

> Up to now, our set of equations is EXACT but we need to separate r from E to solve it iteratively

$$\hat{\Omega} \cdot \vec{\nabla} \Phi_g(\vec{r}, \hat{\Omega}) + \mu_{t,g} \Phi_g(\vec{r}, \hat{\Omega}) = q_{scat,g} + \sum_{p=1}^{P} \frac{q_{p,g}}{4\pi} \delta(\vec{r} - \vec{r}_p)$$
(1)

$$q_{scat,g}(\vec{r},\hat{\Omega}) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \sum_{g'=1}^{G} \mu_{s,l,g'->g}(\vec{r}) \Phi_{l,m,g'}(\vec{r}) Y_{l}^{m}(\theta,\phi)$$
(2)

$$\begin{array}{c} E_{g'-1}E_{g-1} \\ \int & \int \mu_{s,l}(\vec{r},E' \to E)\Phi(\vec{r},E')\,dE'\,dE \\ \hline \mu_{s,l,g'-}g(\vec{r}) = & E_{g'} & E_{g} \\ \end{array}$$

$$\begin{array}{c} E_{g-1} \\ \int & \Phi(\vec{r},E)\,dE \\ E_{g} \end{array}$$

$$(3)$$

$$\Phi_{l,m,g}(\vec{r}) = \int_{E_g}^{E_{g-1}} \Phi_{l,m}(\vec{r},E)dE = \int_{E_g}^{E_{g-1}} \iint_{E_g} \Phi(\vec{r},E',\hat{\Omega}')Y_l^m(\hat{\Omega}')d\Omega'dE$$
(4)
$$E_g^{-1} \mu_t(\vec{r},E)\Phi(\vec{r},E')dE' = E_g^{-1} \int_{E_g}^{E_{g-1}} \mu_t(\vec{r},E)\Phi(\vec{r},E')dE + E_g^{-1} \int_{E_g}^{E_{g-1}} \Phi(\vec{r},E)dE$$
(5)

→ if we define a spectral weighting factor: f(E) so that: $\Phi(\vec{r}, E) = \Phi(\vec{r}) f(E)$, $\int f(E) dE = 1$

$$\hat{\Omega} \cdot \vec{\nabla} \Phi_g(\vec{r}, \hat{\Omega}) + \mu_{t,g} \Phi_g(\vec{r}, \hat{\Omega}) = q_{scat,g} + \sum_{p=1}^P \frac{q_{p,g}}{4\pi} \delta(\vec{r} - \vec{r}_p) \tag{1}$$

 \boldsymbol{E}

$$q_{scat,g}(\vec{r},\hat{\Omega}) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \sum_{g'=1}^{G} \mu_{s,l,g'->g}(\vec{r}) \Phi_{l,m,g'}(\vec{r}) Y_{l}^{m}(\theta,\phi)$$
(2)

Our equations become:

$$\mu_{s,l,g' \to g}(\vec{r}) = \int_{E_g}^{E_{g'-1}E_{g-1}} \int_{E_{g'}}^{\mu_{s,l}(\vec{r},E'\to E)f(E')dEdE'}$$
(3)

$$\Phi_{l,m,g}(\vec{r}) = \int_{E_g}^{E_{g-1}} \Phi_{l,m}(\vec{r})f(E)dE = \int_{E_g}^{E_{g-1}} \int_{E_g}^{(\Phi(\vec{r},\hat{\Omega}'))f(E)Y_l^m(\hat{\Omega}')d\Omega'dE}$$
(4)

$$\mu_{t,g}(\vec{r}) = \int_{E_g}^{E_{g-1}} \mu_t(\vec{r},E)f(E)dE$$
(5)

> All that is left then is to discretize direction and space and solve iteratively!

 $\Phi(\vec{r}, E) = \Phi(\vec{r}) f(E), \quad \int f(E) dE = 1$ E

The importance of f(E):

The spectral weighting factor connects photon fluence to energy fluence at any point of a geometry and hence depends on the actual geometry and its physical properties.

However, as G increases, and ΔE_G become narrow, the energy group cross sections $\mu_{t,g}$, $\mu_{s,g}$, become constant approximations of the continuous $\mu_t(E)$, $\mu_s(E)$ and do not depend heavily on f(E).

This means that generic multi group cross sections (of $\Delta E_G <<$) are used with analytic or semi-analytic f(E) appropriate for the problem at hand.

Let us make the final step:

We ask our equations to hold for a number of directions M determined by a **quadrature set S**_N of order N (Discrete Ordinates Method-DOM) (M is linked to N in a different way for different quadrature sets)

$$\hat{\Omega} \cdot \vec{\nabla} \Phi_{g,n}(\vec{r}) + \mu_{t,g} \Phi_{g,n}(\vec{r}) = q_{scat,g,n} + \sum_{p=1}^{P} \frac{q_{p,g,n}}{4\pi} \delta(\vec{r} - \vec{r}_{p}), \qquad \Phi_{g,n}(\vec{r}) = \Phi_{g}(\vec{r}, \hat{\Omega}_{n})$$

$$q_{scat,g,n}(\vec{r}, \hat{\Omega}) = \sum_{l=0}^{\infty} \sum_{m=-l}^{L} \sum_{g'=1}^{G} \mu_{s,l,g'->g}(\vec{r}) \Phi_{l,m,g'}(\vec{r}) Y_{l}^{m}(\theta, \phi)$$

$$\mu_{s,l,g'->g}(\vec{r}) = \int_{g'}^{E} \int_{g'} \int_{g} \mu_{s,l}(\vec{r}, E' \to E) f(E') dEdE'$$

$$(3)$$

$$\Phi_{l,m,g}(\vec{r}) = \int_{E_g}^{E_{g-1}} \Phi_{l,m}(\vec{r}) f(E) dE = \int_{E_g}^{E_{g-1}} \iint_{A_{\pi}} \Phi(\vec{r}, \hat{\Omega}') f(E) Y_l^m(\hat{\Omega}') d\Omega' dE = \int_{E_g}^{E_{g-1}} \int_{n=1}^{N} \Phi_{g,n}(\vec{r}) f(E) Y_l^m(\hat{\Omega}_n) w_n dE \qquad (4)$$

$$\mu_{t,g}(\vec{r}) = \int_{E_g}^{E_{g-1}} \mu_t(\vec{r}, E) f(E) dE \qquad (5)$$

The method ... is ready

I have GxM equations of the form (1) @ each voxel (GxMxN_{vox} in total)
• begin with E1 (highest energy group)

• make an initial guess for $\Phi_{1,n}(\vec{r})_{iter=0}$

 \rightarrow • calculate cross sections from (3) & (5)

- calculate the expansion from (4)
- use these in (2) to calculate $q_{scat,1,n}$
 - solve (1) for $\Phi_{1,n}(\vec{r})_{iter=1}$

-• if convergence criterion not met, re-iterate

• if convergence criterion met, proceed with g=2

BUT...:

- I need to be efficient (t~ GxMxN_{vox}x#iters.x order of legendre exp.) & work with finite voxels
- 2. I need to account for inhomogeneities
- 3. I need to work with real sources
- 4. I need to account for finite patient dimensions

$$\hat{\Omega} \cdot \vec{\nabla} \Phi_{g,n}(\vec{r}) + \mu_{t,g} \Phi_{g,n}(\vec{r}) = q_{scat,g,n} + \sum_{p=1}^{P} \frac{q_{p,g,n}}{4\pi} \delta(\vec{r} - \vec{r}_p) \tag{1}$$

$$q_{scat,g,n}(\vec{r},\hat{\Omega}) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \sum_{g'=1}^{G} \mu_{s,l,g'->g}(\vec{r}) \Phi_{l,m,g'}(\vec{r}) Y_{l}^{m}(\theta,\phi)$$
(2)

$$\mu_{s,l,g' \to g}(\vec{r}) = \int_{E_{g'}}^{E_{g'-1}E_{g-1}} \mu_{s,l}(\vec{r}, E' \to E)f(E')dEdE'$$
(3)

$$\Phi_{l,m,g}\left(\vec{r}\right) = \int_{E_g}^{E_g-1} \sum_{n=1}^{N} \Phi_{g,n}(\vec{r}) f(E) Y_l^m(\hat{\Omega}_n) w_n \, dE \tag{4}$$

$$\mu_{t,g}(\vec{r}) = \int_{E_g}^{E_{g-1}} \mu_t(\vec{r}, E) f(E) dE$$
(5)

1. I need to be efficient

The iterations are needed because I do not know q_{scat} within the energy group i.e. scattering events with minimal energy transfer

When do I expect delays in convergence?

1. I need to be efficient

The iterations are needed because I do not know q_{scat} within the energy group i.e. scattering events with minimal energy transfer

When do I expect delays in convergence?

1. I need to be efficient

The multigroup (G), DOM (S_N), cross section expansion (P_N) method converges to an analytic solution of the LBTE for G, N \rightarrow infinity

and

no volume averaging is expected for fine spatial discretization ($N_{vox} \rightarrow infinity$)

BUT

I need to be efficient

and since t~ G x M x N_{vox} (x #iters. x order of legendre exp.),

even if I have the perfect finite differencing algorithm for solving the system of equations,

I need to reduce G, M, N_{vox} !!!

Guess what happens when I reduce M (order of S_N) ...

RAY EFFECTS...!

Figure from: Venselaar, Baltas, Meigooni, Hoskin (Eds), Comprehensive Brachytehrapy: physical and clinical aspects. CRC Press, Taylor & Francis, © 2013

 discretization artifacts or "rays": an artificial buildup of particle fluence along the finite number of directions used

with high gradients of scatter fluence, at points where primary dose is small with N_{directions} & voxel size at the expense of calculation time and potential volume

Figure from: Venselaar, Baltas, Meigooni, Hoskin (Eds), Comprehensive Brachytehrapy: physical and clinical aspects. CRC Press, Taylor & Francis, ©

How can I relax the demand on S_N without ray effects?

The LBTE is linear so assuming:

$$\Phi_{g}(\vec{r},\hat{\Omega}) = \sum_{p=1}^{P} \Phi_{p,g}^{unc}(\vec{r},\hat{\Omega}) + \Phi_{g}^{coll}(\vec{r},\hat{\Omega})$$

For any direction, we can split our system of equations in two:

$$\hat{\Omega} \cdot \vec{\nabla} \Phi_{g}^{unc} + \sigma_{t,g} \Phi_{g}^{unc} = \sum_{p=1}^{P} \frac{q_{p,g}}{4\pi} \delta(\vec{r} - \vec{r}_{p}) \qquad (1)$$
$$\hat{\Omega} \cdot \vec{\nabla} \Phi_{g}^{coll} + \sigma_{t,g} \Phi_{g}^{coll} = q_{g}^{scat,coll} + \sum_{p=1}^{P} q_{p,g}^{scat,unc} \qquad (2)$$

Equation (1) for the primary (uncolided) part of the fluence can be analytically solved!!!

I can ray-trace the solution for the spectrum of primary photons through the geometry and arrive at very quick and accurate: initial guess $\Phi_{1,n}(\vec{r})_{iter=0}$ and $q_{\text{scat},1,n}$

Then I proceed to solve the system of equations (2) for the collided fluence to refine my solution with the higher orders of scatter

This is known as the 1st scatter source method

• Acuros uses the first scatter source method so the photon spectrum exiting a source needs to be known

•Acuros uses Triangular-Chebyshev quadrature sets for angular discretization and the integration for the generation of the scattering source

• The angular discretization scheme is <u>adaptive</u> with S_N order

ranging from N=4 (24 discrete directions) to 30 (960 discrete directions) varying both within an energy group $(g \rightarrow g)$ and between energy groups $(g \rightarrow g')$

Guess which energies are given larger N ...!

Remember: Energy discretization is realistic if cross sections do not vary considerably within each group and appropriate f(E) is very important

Acuros (for ¹⁹²Ir) uses an adaptive G=37 group cross section set. For the uncollided component all 37 groups are used, with $f(E) = 1/\Delta E_g$ For the collided (scattered) component, this group is collapsed applying an appropriate (proprietary) energy weighting function f(E).

Acuros uses cross section generated by CEPXS, a multigroup-Legendre cross-section generating code.

CEPXS does not include coherent scattering and uses the Klein-Nishina incoherent scattering cross sections.

1. I need to be efficient, spatial discretization

For spatial discretization, Acuros partitions the computational volume (the CT image series) into <u>variable</u> sized Cartesian elements.

Computational element size varies based on material properties and the gradient of the scatter photon fluence.

The spatial derivatives in the LBTEs are replaced by finite differences at multiple points within each computational element

Supplementary equations are used to describe fluence variation between these points and preserve particle balance (DFEM - linear discontinuous Galerkin finite-element method)

Hence the angular fluence is known everywhere in each element, not only at the points where spatial derivatives are evaluated

BUT

spatial discretization errors can ensue at points in high fluence gradients

$$\frac{\partial \Phi_{m,g}(\mathbf{x}_{i})}{\partial x} = \frac{\Phi_{m,g}(\mathbf{x}_{i+1}) - \Phi_{m,g}(\mathbf{x}_{i-1})}{\Delta \mathbf{x}_{i}}$$

2. inhomogeneities

The method inherently accounts for inhomogeneities assuming material properties are constant within each computational element (!!! restriction on computational element size !!!) through:

• $\mu_{t,g}$, $\mu_{s,l,g}$

- primary fluence ray tracing
 - dose calculation

$$D(\vec{r}) = \frac{1}{\rho(\vec{r})} \sum_{g=1}^{G} \mu_{en,g}(\vec{r}) \left\{ \sum_{p=1}^{P} \Phi_{p,g}^{unc}(\vec{r}) + \Phi_{g}^{coll}(\vec{r}) \right\} \qquad D(\vec{r}) = \frac{1}{\rho_{water}} \sum_{g=1}^{G} \mu_{en,g}^{water}(\vec{r}) \left\{ \sum_{p=1}^{P} \Phi_{p,g}^{unc}(\vec{r}) + \Phi_{g}^{coll}(\vec{r}) \right\}$$

(note that D is calculated as a post processing operation)

3. real sources

Input must now be source specific:

• Energy distribution of primary fluence (in essence the source phase space file)

Acuros uses effective sources: pre-calculated source specific phase space file

+

a number of points within the source volume for ray tracing the primary fluence in the geometry

Brachy sources are small BUT the number of point sources used for ray tracing can be important

Figure from: L. Petrokokkinos et al. Med. Phys. 38 1981 (2011)

4. finite patient dimensions

Inherently taken into account

(there is no geometry specific input to the method apart from f(E) and the method accounts for geometry specific scatter conditions)

Important implementation details

All calculation settings are preset!

- user specifies D output grid (affects t) and resolution (affects t & accuracy)
- D calculation grid is automatically defined as the D output grid +10 cm in all directions, unless CT image boundary is reached
 - > Density is HU based through a user editable calibration
 - Material assignment is based on a density lookup table and data from ICRP 23 (1975)

In short:

	ACE (Oncentra Brachy)	Acuros (BrachyVision)
Long heritage		\checkmark
Angular discretization	adaptive ("accuracy" selection & # sources)	adaptive (24 to 960 auto. varying within/between energy groups)
Spatial discretization	adaptive multi-resolution Cartesian grid ("accuracy" selection)	adaptive multi-resolution Cartesian grid (auto. based on scatter fluence gradient)
Pre-calculated data as input	Primary dose for source model, energy spectra, kernels	Phase space file for source model
Energy discretization	_	37 groups (adaptive for the scatter fluence using an appropriate energy weighting function f(E))
Primary scatter separation		
Ray-tracing for primary		
Successive scattering	Prim. dose →1 st scatter SCERMA → multiple scatter SCERMA	Prim. fluence →1 st scatter source

In short:

(Received 7 May 2012; revised 26 July 2012; accepted for publication 2 August 2012; published 25 September 2012)

The charge of Task Group 186 (TG-186) is to provide guidance for early adopters of model-based dose calculation algorithms (MBDCAs) for brachytherapy (BT) dose calculations to ensure practice uniformity. Contrary to external beam radiotherapy, heterogeneity correction algorithms have only recently been made available to the BT community. Yet, BT dose calculation accuracy is highly dependent on scatter conditions and photoelectric effect cross-sections relative to water. In specific situations, differences between the current water-based BT dose calculation formalism (TG-43) and MBDCAs can lead to differences in calculated doses exceeding a factor of 10. MBDCAs raise three major issues that are not addressed by current guidance documents: (1) MBDCA calculated doses are sensitive to the dose specification medium, resulting in energy-dependent differences between dose calculated to water in a homogeneous water geometry (TG-43), dose calculated to the local medium in the heterogeneous medium, and the intermediate scenario of dose calculated to a small volume of water in the heterogeneous medium. (2) MBDCA doses are sensitive to voxel-by-voxel interaction cross sections. Neither conventional single-energy CT nor ICRU/ICRP tissue composition compilations provide useful guidance for the task of assigning interaction cross sections to each voxel. (3) Since each patient-source-applicator combination is unique, having reference data for each possible combination to benchmark MBDCAs is an impractical strategy. Hence, a new commissioning process is required. TG-186 addresses in detail the above issues through the literature review

Report of the Task Group 186 on model-based dose calculation methods in brachytherapy beyond the TG-43 formalism: Current status and recommendations for clinical implementation

- 1. recommendations to MBDCA early-adopters to evaluate:
 - phantom size effect
 - inter-seed attenuation
 - material heterogeneities within the body
 - interface and shielded applicators
- 2. commissioning process to maintain inter-institutional consistency
- 3. patient-related input data
- 4. research is needed on:
 - tissue composition standards
 - segmentation methods
 - CT artifact removal Beaulieu, et al., *Med. Phys.* 39, 6209-6236 (2012)

V. NEEDED INFRASTRUCTURE

While MBDCAs are expected to produce more accurate dosimetric results than the current TG-43 formalism, the authors feel that the medical community should not immediately replace the current approach without careful consideration for widespread integration. Assessment of the current infrastructure is needed before assigning new resources, with opportunity for further cooperation of national and international professional societies.

V.A. Centralized dataset management

Societal recommendations and reference data do the clinical physicist no good if they cannot be readily implemented. Having quantitative data available beyond the scientific, peer-reviewed literature may be accomplished through expansion of the joint AAPM/RPC Brachytherapy Source Registry. An independent repository such as the Registry to house the reference data would facilitate this process– especially with international accessibility.

WG Charges

- Develop a limited number (approximately 5) of well-defined test case plans and perform MBDCA dose calculations and comparisons.
- Identify the best venue for housing the reference plans/data, and put in place in collaboration with identified partners of the Registry.
- Propose to the community well-defined prerequisites for test case plans to be submitted to the Registry.
- Develop a review process for evaluation as new reference data meeting the prerequisites.
- Engage the vendors to promote uniformity of practice.

Enabling clinical use of advanced dose calculation algorithms

Level 1 Dosimetry Benchmark

Medical Physics

A generic high-dose-rate ¹⁹²Ir brachytherapy source for evaluation of model-based dose calculations beyond the TG-43 formalism Ballester, Carlsson Tedgren, Granero, Haworth, Mourtada, Paiva Fonseca, Zourari, Papagiannis, Rivard, Siebert, Sloboda, Smith, Thomson, Verhaegen, Vijande, Ma, and Beaulieu

Conclusions: A hypothetical, generic HDR ¹⁹²Ir source was designed and implemented in two commercially available TPSs employing different MBDCAs. Reference dose distributions for this source were benchmarked and used for evaluation of MBDCA calculations employing a virtual, cubic water phantom in the form of a CT DICOM image series. Implementation of a generic source of identical design in all TPSs using MBDCAs is an important step toward supporting univocal commissioning procedures and direct comparisons between TPSs.

Close up (Day 2)

P. Papagiannis, PhD Medical Physics Laboratory Medical School National & Kapodistrian University of Athens

(no conflict of interest to disclose)

The essence of MBDCA commissioning and your practical session

In short, the commissioning procedure involves the following steps:

(0. go through the corresponding literature)

1.download test case(s) from the official test case registry

2.import test case files

3. recalculate (local) MBDCA dose for the test case plan

4.compare MBDCA, local MBDCA and reference dose for the test case plan

• Comparison between MBDCA and reference dose data establishes a reference pattern of differences, which is also useful to educate users in the principles and settings of the MBDCA.

•Comparison between local MBDCA and reference data should yield the same pattern of differences.

•If the user TPS version is later than the one used for preparing the test case (v.4.5 for Oncentra and v. 13 for BrachyVision) agreement should be equal or improved. Let us take another look at the test cases you worked with from the perspective of local % dose difference...

(using BrachyGuide distributed freely via: www.rdl.gr)

Test case breast Acuros vs MC

•MBDCAs do present differences from MC dose calculations for a breast case resembling a clinical scenario.

•The cause of these differences should be clear from the corresponding discussion on MBDCAs.

•So maybe it is better to stick with TG-43 ...?

Test case breast TG-43 vs MC (color map: $\pm 20\%$)

TG-43 presents higher differences from MC but these do not appear to be clinically relevant

breast TG-43 vs MC (color map: ±20%)

All cases are NOT the same ... All treatment sites are NOT the same ...
1. MBDCAs were NOT developed for single source dosimetry.

2. Such tests are there to introduce you to MBDCA mechanics and serve as a sanity check (correct source, changes with TPS version change, etc).

3. You can review test case results as: local D diff. (to highlight diffs) global D dif. (to factor in their relative importance) plan metrics such as DVH and associated indices (to review their clinical significance)

4. MBDCAs do improve dosimetric accuracy relative to TG-43

5. Potential clinical benefit is treatment site- and patient- specific.

Disclosures

- We are users of Elekta equipment (HDR Ir-192 and LDR I-125)
- Commercial products included in this presentation just for illustrative purposes

Acknowledgments

Christian KirisitsFrançoise LlisoVicente CarmonaJosé GimenoRafael GarcíaNúria CarrascoJosé Richart

Learning Objectives

- To identify the different aspects to be considered when a brachy dose distribution is evaluated
- To understand the required cautions
- To present the current TPS limitations in biology evaluation

Aspects to be considered for plan evaluation

- Dose points
- Dose distribution
- Dose Volume Histograms
- Global indexes
- Biology (EQD2)

- Points derived from traditional Brachy Systems
- Target points at CTV periphery used for polynomial optimization
- New ICRU 89 points
- Some examples and cautions

- Traditional Brachy Systems:
 - Manchester (Gyn cervix).
 - A points (*ICRU38*) H Points (*ABS 2000*)
 - A "universal" cervix approach to unify prescription criteria and to control the overdose volumes

Overdose volume

- Traditional Brachy Systems:
 - Paris "System": a set of rules to obtain suitable dose distributions.
 - For different regular source patterns, basal points are defined in regions of dose plateau or minimum
 - In HDR it evolved to Steeping Source Dosimetry System (SSDS) (*Van der Laarse 1997*)
 - Adopted by *ICRU 58*

- SSDS basal dose or Mean Central Dose ICRU58
- Reference dose **90%** basal dose

- Optimization using basal points
- Example: breast normalized 90%

- Optimization using basal points
- Example: breast normalized 90%

- Optimization using basal points
- Example: H&N normalized 90% plus graphical optimization

- Optimization using basal points
- Example: Vagina normalized 90% plus graphical optimization

• Dose points at the CTV periphery to be used in HDR polynomial optimization

• Caution: Overdose volume (ie. V200%)

• Caution: Overdose volume (ie. V200%)

• Caution: Overdose volumen (ie. V200%)

• Caution: Overdose volumen (ie. V200%)

• Example: bronchus with prescription to a given distance

Volume sampling and bar width

ABS 2012

For treatment planning systems that use sample dose points, a minimum of 5,000–10,000 sample points should be used for the calculation of each cumulative dose–volume histogram. The planner must ensure that

Indexes

- Dose-Non-Uniformity Ratio
- Independent of CTV-OAR
- Lower DNR more homogeneous is
- Also <u>Dose-Homogeneity-Index</u>

DHI =
$$\frac{V_{PD} - V_{1.5PD}}{V_{PD}} = 1 - DNR$$

- <u>Overdose-Volume-Index</u>
- Characterize the dose homogeneity

- <u>Conformity-Index</u>
- Characterize the dose homogeneity

- <u>Conformity-Index</u>
- Most conformal when the COIN is maximal and is as close to 1 as possible

Biology

- Cervix Gyn recommended doses CTV-OARs are specified in EQD2 (*Rec GEC-ESTRO* and *ICRU 89*)
- Combining ERT with BT (typically 46-50 Gy ERT plus 2 app with 2 fx/app 7 Gy nominal)
- EQD2 CTV-OAR optimization is not included in current versions of TPSs
- In clinical practice, it is evaluated with an external spreadsheet
- Brief illustration of the Cervix GYN clinical procedure (H La Fe)

"Using IPSA algorithm in dose planning for cervix HDR Brachytherapy with the Utrecht applicators. First phase results" D. Krishnamurthy, AJ. Cunha, IC. Hsu, J. Pouliot, J. Perez-Calatayud, A. Tormo, V. Carmona, F. Eliso, ESTRO-GEC-ESTRO. 2011. Radiotheraphy and Oncology Vol 99 Supl 1 May 2011 S278 • Cervix GYN

Typically ERT \rightarrow VMAT with different volumes & doses OAR D2cc can result very different from the low dose prescription volume

Conclusions

- Brachy plan must be evaluated using **point doses** (in some cases), **DVH** parameters, **dose distribution** and global **indexes**.
- Overdose volumes due to "target points" based optimization must be carefully evaluated (more convenient "basal points").
- Resulting **under-over dose** volumes must be evaluated looking in detail at the **3D** dose distribution.
- For small volumes whole OAR volume subrogates well to the wall.
- Sampling and histogram bar with must be selected with high resolution.
- EQD2 evaluation in cervix GYN needs an adequate implementation on TPSs future versions by manufacturers in order to improve efficiency.

Thank you

APPENDIX – EXAMPLES, SPREADSHEETS, DRAWINGS

Target definition

Advanced disease, significant remission after EBRT:

Change of GTV/CTV with time (4D RT) (FIGO IIB)

Tumor Extension before EBT

Target Volume of BT Based on dimensions and Topography at time of BT

Various patterns of tumor response adapted CTV

Chapter 5

OAR concept and related volumes

Chapter 6

Radiobiology: Time-dose pattern

General principles for assessment and reporting of physical and equieffective EBRT and BT dose (all reporting levels)

Physical dose and number of fractions is assessed for target, OARs, dose points:BTEBRT

Total equieffective dose (EQD2) is calculated according to the linear quadratic model through the following steps:

•BT EQD2 for each fraction

- •Total BT EQD2
- •Total EBRT EQD2

•Accumulated total EBRT+BT EQD2*

*Based on current assumptions outlined in chapter 9

Reporting of radiobiological parameters: α/β values for tumour and OARs* In addition T_{1/2} and recovery model for LDR and PDR treatments* *At present: $\alpha/\beta=3$ Gy for late effects in OAR and 10 Gy for tumour, and T_{1/2}=1.5h Chapter 7

Radiotherapy & Oncology Volume 105, Issue 2, Pages 266-268, November 2012

Bioeffect modeling and equieffective dose concepts in radiation oncology – Terminology, quantities and units

FROM PLANNING AIMS TO PRESCRIPTION

Traditional concepts:

"when prescribing to a target, the prescription dose is the planned dose to cover this target as completely as

possible."

or

prescription to a 100% isodose which is "to cover"

the target volume"

Need for common terminology according to ICRU reports on proton treatment and IMRT

Planning aim dose

Set of dose and dose/volume constraints for a treatment

Prescribed dose

Finally accepted treatment plan (which is assumed to be delivered to an individual patient)

Delivered dose

Actually delivered dose to the individual patient

Need for common terminology according to ICRU reports on proton treatment and IMRT

Example:

Previously: 4x7 Gy ~ 84 Gy EQD2 prescribed, mean D90 was 93 Gy

Planning aim was to deliver 4 x 7 Gy ~ 84 Gy, D_{2cm^3} for rectum, sigmoid < 70 Gy EQD2, bladder < 90 Gy EQD2

Prescribed dose was mean 93 Gy \pm 13 Gy (1SD) EQD2 to D₉₀ CTV_{HR}

Delivered dose ? Depending on variations and uncertainties – on average no systematic deviation from prescribed dose

Level 1 - Minimum standard for reporting

Source and dose calculation: Radionuclide and source model

Source strength

Dose calculation algorithm

Level 1 - Minimum standard for reporting

- Comprehensive clinical gynecologic examination
- Volumetric imaging (MRI, CT, US, PET CT) at time of diagnosis and BT FIGO/TNM stage
- Baseline morbidity and QoL assessment
- Schematic 3D documentation on a clinical diagram indicating dimensions and volumes for:
 - GTV_{init} (GTV at diagnosis)
 - GTV_{res} (GTV at brachytherapy)
 - CTV_{HR} (GTV_{res} (plus residual pathologic tissue plus whole cervix)
 - (CTV_{IR}: GTV_{init} and CTV_{HR} plus safefy margin if used for prescription)

Level 1 - Minimum standard for reporting

Dose reporting:

TRAK Point A dose Recto-vaginal reference point dose (=ICRU point) D_{0.1cm³},D_{2cm³} for bladder, rectum or Bladder reference point for radiographs

Level 2 - Advanced standard for reporting All that is reported in level 1 plus:

3D delineation of volumes (on volumetric images with applicator and on clinical diagrams):

 $\mathrm{GTV}_{\mathrm{res}}$

CTV_{HR}

(CTV $_{IR}$ if used for prescription)

With maximum width, height, thickness and with volume

Level 2 - Advanced standard for reporting All that is reported in level 1 plus:

Dose reporting for defined volumes: D_{98} , D_{90} , D_{50} for CTV_{HR} (D_{98} , D_{90} for CTV_{IR} if used for prescription) D_{98} for GTV_{res} D_{98} for pathological Lymph nodes

DVH for target volumes

ESTRO School 22

Level 2 - Advanced standard for reporting All that is reported in level 1 plus:

Dose reporting OARs:

Bladder reference point dose

 $D_{0.1 \text{cm}^3}$, $D_{2 \text{cm}^3}$ for sigmoid*

D_{2cm³} bowel (if fixed)*

EBRT: Intermediate and low dose parameters in bladder, rectum, sigmoid, bowel (e.g. V_{25Gy}, V_{35Gy}, V_{45Gy} or D_{98%}, D_{50%}, D_{2%})
Vaginal point doses at level of sources (lateral at 5 mm)**
Lower and mid vagina doses (PIBS, PIBS ±2cm)**

DVH for OAR

Chapter 8

Vaginal Reference Points

Chapter 8

Dose-response for local control

Commonly reported parameters

Table 1

The most common dose-volume parameters used for reporting in interstitial breast brachytherapy.

Parameter	Definition/calculation
Implant related	
V _{PD}	Absolute volume irradiated by
	the prescribed dose
V _{1.5xPD}	Absolute volume irradiated by
DND data and solitantic setia	1.5 x the prescribed dose
DNR – dose non-uniformity ratio	V1.5xPD/VPD
DHI – dose nomogeneity index	$(V_{PD} - V_{1.5xPD})/V_{PD}$
Target related	
V _{PTV}	Volume of the PTV
V _{xx}	Percentage of PTV receiving xx%
	of the PD
OI – overdose volume index	V _{2xPD} /V _{PTV}
CI – coverage index	V ₁₀₀ /100
COIN – conformal index	$PTV_{PD}/V_{PTV} \times PTV_{PD}/V_{PD}$
D _{xxx}	Percentage dose that covers xx%
	of the PTV
OAR related	
D _{mean}	Mean dose in organ
V _{xGy}	Relative volume receiving \times Gy
V _{xx}	Percentage of organ receiving xx%
	of the PD
D _{xcm3}	Relative dose given to most
	exposed × cm ³ of organ

PD: prescribed dose, PTVPD: volume in PTV received at least the PD.

Dose planning and reporting for 3D image based APBI (GEC-ESTRO trial)

Major et al. 2007, Radiother Oncol 90(1):48-55

Results for 28	pts. ((mean a	ind ranges):

volume PTV	- - •	63.1cm ³	(17.2-124cm ³)
D ₉₀ PTV:		102 %	(99-107 %)
D ₁₀₀ PTV::		69 %	(90-96 %)
DNR:		0.33	(0.25-0.41)
skin D _{max} :		53 %	(18-75 %)
ipsilateral lu	ng D _{max} :	42 %	(7-75 %)
	V5Gy:	42.6 cm	3 (0-160 cm ³)
	V10Gy:	4.8 cm ³	(0-39.5 cm ³)
	V15Gy:	0.5 cm ³	(0-7.9 cm ³)
heart D _{max} :		21 %	(4-40 %)
	V5Gy:	8 cm ³	(0-33.5 cm ³)
	V10Gy:	0.1 cm ³	(0-0.3 cm ³)

planning aim: PD = 30.1Gy (7x 4.3Gy), $V_{100} = 90\%$, DNR <0.35, implant-rib distance $\geq 5mm$

Recommended parameters for reporting

- nuclide, technique (HDR/PDR)
- # catheters, # planes

- method of dose optimization (manual, geometric, graphical, inverse) and normalization
- method of dose prescription: isodose line, volumetric, dose per Fx, total dose, time dose pattern
- implant-related volume parameters: VPD, DNR
- source strength, TRAK

Recommended parameters for reporting

- target-related volume parameters: V_{100} , V_{150} ; V_{200} ; D_{90}
- optional OAR-related parameters:

ipsilateral non-target breast: V_{90} , V_{50} skin: D_{1cm^3} , $D_{0.2cm^3}$ ipsilageral lung: MLD (mean lung dose), $D_{0.1cm^3}$ contralateral breast: D_{1cm^3} contralateral lung: D_{1cm^3}

Recommended values for prescription

Based on experience from GEC-ESTRO randomized multicenter trial (Strnad et al. Lancet, 2016)

Table 3

Recommended dose-volume limits for OAR-s

Table 2 Recommended dose-volume limits for implant and PTV.		Organ	Constraints
		Ipsilateral non-target breast	V ₉₀ < 10% V ₅₀ < 40%
	Constraints	Skin	D _{1cm3} < 90% D _{0.2cm3} < 100%
Implant	$V_{PD} \le 300 \text{ cm}^3$ DNR ≤ 0.35	Rib	D _{0.1cm3} < 90% D _{1cm3} < 80%
PTV	$V_{100} \ge 90\%$ $V_{150} < 65 \text{ cm}^3$	Heart	MHD < 8% D _{0.1cm3} < 50%
	$V_{200} < 15 \text{ cm}^2$ COIN ≥ 0.65	Ipsilateral lung	MLD < 8% D _{0.1cm3} < 60%

Skin volume is defined as a 5 mm shell below the body contour.

" Left sided lesion only, MHD: mean heart dose, MLD: mean lung dose

Need for common terminology

Planning aim dose

- Set of dose and dose/volume constraints for a treatment
 - 4 x 7 Gy to D₉₀ to achieve 84 Gy EQD2 to D₉₀ for HR CTV in cervix (EBRT+BT)
 - 145 Gy to D₉₀ for prostate LDR
 - 8 x 4 Gy to D₉₀ for breast APBI

Prescribed dose

Finally accepted treatment plan (which is assumed to be delivered to an individual patient)

Delivered dose

Actually delivered dose to the individual patient

From ICRU 89

LQ Model

Biological effect E of dose D:

$$E = \alpha \cdot D + \beta \cdot D^2$$

Total dose :

 $D = n \cdot d$ n... Nr. of fractions, d... fraction dose

$$E = n \cdot (\alpha d + \beta d^{2}) = nd(\alpha + \beta d) =$$
$$= \alpha nd(1 + \frac{d}{\alpha / \beta})$$

 $=> E = \alpha x$ total dose x relative dose effectiveness

Biologically effective dose:

BED = total dose x relative dose effectiveness = E / α

Effective dose in EQD_{2Gy} (normalized to
2Gy fx)

$$EQD_{2Gy} = \frac{D_{(xGy)} \cdot (x + \alpha/\beta)}{(2 + \alpha/\beta)}$$

$$\alpha/\beta = 10(tumour)$$

$$\alpha/\beta = 3(OAR)$$
EBRT: $d = 1.8Gy$
 $n = 25$
tumour $EQD_{2Gy} = \frac{45_{(1.8Gy)} \cdot (1.8 + 10)}{(2 + 10)} = 44.3Gy$
OAR $EQD_{2Gy} = \frac{45_{(1.8Gy)} \cdot (1.8 + 3)}{(2 + 3)} = 43.2Gy$

Example for cervix cancer
Brachytherapy

$$EQD_{2Gy} = \frac{D_{(xGy)} \cdot (x + \alpha / \beta)}{(2 + \alpha / \beta)}$$

$$\alpha / \beta = 10(tumour)$$

$$\alpha / \beta = 3(OAR)$$
Brachy:

$$d = 7Gy(tumour)$$

$$d = 4.4Gy(rectum, sigmoid)$$

$$n = 4$$
tumour

$$EQD_{2Gy} = \frac{28_{(7Gy)} \cdot (7 + 10)}{(2 + 10)} = 39.7Gy$$
OAR

$$EQD_{2Gy} = \frac{17.6_{(4.4Gy)} \cdot (4.4 + 3)}{(2 + 3)} = 26Gy$$

Conclusion

Concepts and terminology for prescribing recording and reporting

Radioactive Single Source-based Brachytherapy

General Concept: The Mapping process or The Dose Kernel

From Source/ Energy Fluence Ψ

To Dose Distribution D

A is the energy absorption per unit mass (dose) and unit energy fluence or the *Dose Kernel*

 $\boldsymbol{\Psi}$ is the Source/Energy Fluence Function

The Dose Kernel A

Dose rate from a single source at a point in water-filled space <u>per Unit Source Strength</u> (in Gy min⁻¹ U⁻¹ or cGy min⁻¹ U⁻¹ or cGy h⁻¹U⁻¹) dose to water in water

Characteristic for every Source Type

General Concept: The Mapping process or The Dose Kernel

$$\{\Psi\} \rightarrow \{D\}: D = \Psi . A$$

 Ψ is the Source/Energy Fluence Function

 Ψ is for a single stepping source delivery system (afterloader) the Source Propagation Function

General Concept: The Mapping process or The Dose Kernel

$$\{\Psi\} \rightarrow \{D\}: D = \Psi \cdot A$$

- A is the energy absorption per unit mass (dose) and unit energy fluence or the *Dose Kernel*
- Ψ is for a single stepping source delivery system (afterloader) the Source Propagation Function

With N_{ASDPs} the total number of source dwell positions (steps) at positions r_i and dwell times t_i .

General Concept: The Mapping process or The Dose Kernel

 $\{\Psi\} \rightarrow \{D\}$:

$$D(\vec{r}) = \sum_{i=1}^{N_{ASDPs}} S_{K,i} \cdot t_i \cdot A(\vec{r} - \vec{r}_i)$$

$$D(\vec{r}) = \int_{-\infty}^{+\infty} \Psi\left(\vec{r'}\right) A(\vec{r} - \vec{r'}) \, dv$$

Example for the 1D simplification

The Mapping process or the Dose Kernel:

A dose distribution *D* is *achievable*, if there exist a source/ energy fluence function Ψ that is able to generate it!

- The dose space {D} defines the space of all physically achievable dose distributions
- The source/energy fluence space {Ψ} defines the space of all *physically possible* source/energy fluence functions

While the determination of D from Ψ , the solution of the so-called forward problem, is always possible, the inverse problem, i.e. determination of Ψ for a specified D is not always possible.

The forward problem is the *dose calculation* problem for which a unique solution exists.

Figure 1. Forward and inverse problem in radiotherapy: The sets $\{\Psi^*\}$ and $\{D^*\}$ are all possible fluence and dose distributions respectively which include the corresponding physical possible distributions $\{\Psi\}$ and $\{D\}$. The determination of a fluence distribution from a desired optimal dose distribution D_{opt} is not always possible, such as for the two physical possible dose distributions D_1 and D_2 because the corresponding fluence distribution Ψ_{opt} may not be an element of $\{\Psi\}$

List of Content

- Introduction on Dose Optimisation
- Forward Planning
- Inverse Optimisation and Planning

General Concept: The Inverse Problem

$$\{D\} \xrightarrow{} \{\Psi\}: \qquad D = \Psi . A$$

- A is the energy absorption per unit mass (dose) and unit energy fluence or the *Dose Kernel*
- Ψ is for a single stepping source delivery system (afterloader) the Source Propagation Function

With N_{ASDPs} the total number of source dwell positions (steps) at <u>which</u> positions r_i and with <u>what</u> dwell times t_i ?

Inverse Optimisation and **Planning** Preconditions:

- Complete 3D anatomy model: Targets (GTVs), CTV/PTV, OARs
- Implantation rules (anatomical constraints)
- Implantation methods, instruments, ...
- Desired dose distribution $D(\vec{r})$

Inverse Optimisation and Planning Preconditions:

- Complete 3D anatomy model: Targets (GTVs), CTV/PTV, OARs
- Implanted catheters/applicators
- Rules/selection of source dwell positions
- Desired dose distribution $D(\vec{r})$

$$\Psi(\vec{r}) = \Psi(\{\vec{r}\},\{t\}) = \sum_{i=1}^{N_{ASDPs}} S_{K,i} \cdot t_i \cdot \delta(\vec{r} - \vec{r}_i) = ?$$

Desired/Aimed Dose Distribution:

Even if the "ideal" dose distribution can be easily decided:

due to the "*nature*" of the dosimetric Kernel A(r), $D \in \{D^*\}$ as defined here <u>does not belong</u> to the *Physically* achievable dose distributions $D \notin \{D\}$.

Desired Dose Distribution:

"Desired" Dose Distribution

$$D(\vec{r}) = \begin{cases} D_{prescription} & \forall \ \vec{r} \in \text{PTV} \\ 0 & \forall \ \vec{r} \notin \text{PTV} \end{cases}$$

Objectives and Objective Functions:

- The selected and defined Dose-Volume parameters, usually D_V , for the inverse optimisation process determine the *Objectives* of the optimisation.
- The measure of how well these values are achieved defines the "*Metrics*" the *Objective Functions* of the optimisation methodology (algorithm).
- A natural measure quantifying the similarity of a dose distribution at N sampling points with dose values d_i to the corresponding desired dose values d_i^* is a distance measure. A common measure is the L_p norm:

$$L_{\rm p} = \left\{ \sum_{i=1}^{N} \left(d_{\rm i} - d_{i}^{*} \right)^{p} \right\}^{1/p}$$

For p = 2, i.e. L_2 we have the Euclidean distance.

Desired Dose Distribution:

"Desired" Dose Distribution Define Dose Window for Target(s), NT & OAR(s) Objectives Objectives Functions

General Form of an Objective Function and DVH

Dose window

Transition Function Θ : $\Theta(y) = \begin{pmatrix} 0, & \forall y < 0 \\ 1, & \forall y \ge 0 \end{pmatrix}$

Low dose Objective for PTV/GTVs $D_L = D_V$ for $V_{100\%}$

$$f_i = \frac{1}{N_i} \sum_{j=1}^{N_i} \left[\Theta \left(D_L^i - d_j^i(\boldsymbol{x}) \right) \left[D_L^i - d_j^i(\boldsymbol{x}) \right]^p \right]$$

High dose Objective for PTV/GTVs $D_{H} = D_{V}$ for $V_{0\%}$

$$f_i = \frac{1}{N_i} \sum_{j=1}^{N_i} \left[\Theta \left(d_j^i(\boldsymbol{x}) - D_H^i \right) \left[d_j^i(\boldsymbol{x}) - D_H^i \right]^p \right]$$

The Norm Factor p0 : Volume counting1 : Linear penalty2 : Quadratic penalty

Inverse Optimisation and Planning Objectives & Objective Functions

Optimising the values of the *Objective Functions* results to *Optimisation of the 3D Dose Distribution*.

Due to the fact that in general *Objective Functions* are defined as overdosages (High-Objective) or under-dosage(s) (Low-Objective), *Optimisation of an Objective Function means Minimization of its value (ideally 0) by adjusting the independent parameter values such as catheter positions, active source dwell positions and source dwell times.*

Objectives & Objective Functions

Define Dose Window for Target(s), NT & OAR(s)

$$\begin{aligned} & \text{Low-Objective} \\ & \textbf{D}_{L} \text{ for } \textbf{V}_{Low} \end{aligned} \qquad f_{i} = \frac{1}{N_{i}} \sum_{j=1}^{N_{i}} \left[\Theta \left(D_{L}^{i} - d_{j}^{i}(x) \right) \left[D_{L}^{i} - d_{j}^{i}(x) \right]^{p} \right] \end{aligned}$$

$$\begin{aligned} & \text{High-Objective} \\ & \textbf{D}_{H} \text{ for } \textbf{V}_{High} \end{aligned} \qquad f_{i} = \frac{1}{N_{i}} \sum_{j=1}^{N_{i}} \left[\Theta \left(d_{j}^{i}(x) - D_{H}^{i} \right) \left[d_{j}^{i}(x) - D_{H}^{i} \right]^{p} \right] \end{aligned}$$

 d_{i}^{i} is the Dose at the Sampling Point *j* for Objective Function *i*:

Inverse Optimisation and Planning **Objectives & Objective Functions**

 d_{j}^{i} is the dose at the *j*th-sampling point for the *i*th-objective function:

• $x_{lk}^2 = t_{lk}$ to avoid negative (non-physical) dwell time values t_{lk}

• \tilde{d}_{jkl}^{i} , can (should) be calculated in a pre-processing step and are then available in a sense of <u>a Look-Up-Table</u> for the optimisation process. Implementations in this way make optimiser independent of the dose calculation engine considered (TG 43, MC, BS, CC, other Engines)

Facts

Inverse Optimisation and Planning for brachytherapy has to consider several *Objectives* and is thus a *Multiobjective* (*MO*) problem.

We have *competing Objectives*. Increasing the dose in the Target will increase the dose outside it.

A trade-off between the Objectives exist and we never have a situation in which all the Objectives can be in the best possible way satisfied <u>simultaneously</u>.

$$\begin{bmatrix} \mathbf{GTVs} \\ \mathbf{CTV/PTV} \\ \mathbf{OARs} \\ \mathbf{NT} \end{bmatrix} \begin{bmatrix} f_i = \frac{1}{N_i} \sum_{j=1}^{N_i} \left[\Theta \left(D_L^i - d_j^i(\mathbf{x}) \right) \left[D_L^i - d_j^i(\mathbf{x}) \right]^p \right] \text{ (low)} \\ f_i = \frac{1}{N_i} \sum_{j=1}^{N_i} \left[\Theta \left(d_j^i(\mathbf{x}) - D_H^i \right) \left[d_j^i(\mathbf{x}) - D_H^i \right]^p \right] \text{ (high)} \end{bmatrix}$$

Dominance & Pareto Front

A plan/solution x_1 dominates a plan/solution x_2 *if and only if* the two following conditions are true:

- x_1 is no worse than x_2 in all objectives, *i.e.* $f_i(x_1) \le f_i(x_2) \forall j=1,...,M$.
- x_1 is strictly better than x_2 in at least one objective, i.e. $f_j(x_1) < f_j(x_2)$ for at least one $j \in \{1,...,M\}$.

Among a set of solutions *P*, the *non-dominated set of solutions P'* are those that *are not dominated* by any other member of the set *P*: *The Pareto Optimal Set P'*. For the case that the set *P* is the entire feasible search space then the set *P'* is called *the global Pareto Optimal Set*.

The image *f(x)* of the Pareto Optimal Set is called the Pareto Front (PF). The Pareto Optimal Set is defined in the Parameter Space, while the Pareto Front is defined in the Objective Space.

Example of **a bi-objective space** (f_1 , f_2). We assume as mentioned already the minimization problem.

The *Pareto Front* is the boundary between the points P_1 and P_2 of the *feasible set F*. Solutions 1 and 3 are *non-dominated Pareto optimal solutions*. Solution 2 is *not Pareto Optimal* as solution 1 has simultaneously smaller values for both objectives. <u>There is no reason why solution 2 should be accepted rather than solution 1.</u> <u>Therefore the aim of MO optimisation is to obtain a representative set of non-</u>

dominated solutions.

The *Multiobjective Optimisation (MO)* consists of two main Steps:

- Estimation/Localisation of the Pareto Front (<u>Optimisation</u>)
- 2. Selection of the *most appropriate Plan* (<u>Decision</u>)

Some issues:

- Computationally intensive (time)
- Decision Tools (expertise)

Examples of a Pareto Front

Left: there is a strong trade-off between the objectives/ objective functions f_1 and f_2 . The smaller the f_1 value is that we want the larger is the corresponding f_2 value. The "*ideal point/plan" I* lies far away form the front. There is a high dependence on the selection of the f_1 value.

Right: there is *a weak trade-off* between the objectives/ objective functions f_1 and f_2 . It is possible to optimise (minimise) the f_1 significant and close to the *"ideal point/plan" I.* Only very close to *I* we observe a rapid increase of f_2 . This is a case where for a set of parameters we can obtain <u>simultaneously almost individual optimal values for f_1 and f_2 </u>

Example:

Bi-Objective Pareto Fronts obtained for **22 prostate implants**. The variety shows that a single objective optimization does not give always a good result. In general a strong trade-off is observed. *

Example of a Pareto Front: there is a strong trade-off between the objectives/ objective functions f_1 and f_2 . The smaller the f_1 value is that we want the larger is the corresponding f_2 value. The "ideal point/plan" I lies far away form the front. There is a high dependence on the selection of the f_1 value.

*Lahanas, Milickovic, Baltas, Zamboglou: "Application of Multiobjective Evolutionary Algorithms for Dose Optimization Problems in Brachytherapy", EMO 2001, LNCS 1993, 574-587, 2001.

Inverse Optimisation and Planning: <u>A Multi-Objective (MO) Problem</u>

Trade-off between three objectives (objective functions) for a prostate implant:

 f_1 : *PTV coverage*, f_2 : *urethra overdose* and f_3 : *rectum overdose*.

There resulting *three two-dimensional projections* are shown. These show the *trade-off* between two objectives in each case.

While for two objectives a solution very close to the optimal can be found, this becomes more difficult as more objectives are considered. The complexity of the *Pareto Front* increases rapidly with the number of objectives / objective functions.

Inverse Optimisation and Planning Objectives & Objective Functions (several: GTVs, OARs, NT,..)

Create a single Objective Function via weighted Aggregation

The M objective functions f_m are combined into a single objective function f, by using a weighted sum (aggregation) of all objectives:

 w_m : the relative Importance Factors (IFs) for the individual Objective Functions f_m or Penalties for the penalisation of the violation of the individual objectives.

These are considered as a measure of the significance of each of the *objectives/objective functions* in the optimisation process.

The optimisation process equals then the minimisation of the < Aggregated Objective Function f.

Inverse Optimisation and Planning

Create a single Objective Function via weighted Aggregation

The minimisation of the Aggregated Objective Function f can be interpreted as finding the value f for which the line with slope $-w_1/w_2$ just touches the boundary of F as it proceeds outwards from the origin.

w1 f1 + w2 f2 ???

The plan/solution which is obtained in the *Weighted Aggregation* approach depends on the shape of the *Pareto Front* and the *importance factors/penalties* used.

Planner is not aware if there exist a better "choice" on the *Pareto Front* just next door!

Empirically estimated penalisation schemes, found to result to "good" dose distributions are ussually saved as *presets / protocols / class solutions* and can be used as starting points for the individual patient plan optimisation process.

Summary – Inverse Optimisation

A single Objective Function via weighted Aggregation

Minimise

$$e \quad f = \sum_{m=1}^{M} w_m f_m = f(\{\vec{r}\}, \{t\}, \{w\})$$

$$f_{i} = \frac{1}{N_{i}} \sum_{j=1}^{N_{i}} \left[\Theta \left(d_{j}^{i}(\boldsymbol{x}) - D_{H}^{i} \right) \left[d_{j}^{i}(\boldsymbol{x}) - D_{H}^{i} \right]^{p} \right] \qquad \textbf{Over-dosage (high)}$$

<u>with</u>

$$d_{j}^{i}(\mathbf{x}) = \sum_{k=1}^{N_{cath}} \sum_{l=1}^{N_{ASDP}^{k}} x_{lk}^{2} S_{K,lk} \tilde{d}_{jkl}^{i}$$
 parameter values

Summary – Inverse Optimisation

Diversity of Solutions regarding objective function minimisation:

- Exact Solver
 - Linear Programming (LP) (e.g. Simplex)
- **Deterministic**
 - Gradient based (e.g. Broyden-Fletcher-Goldfarb-Shanno-BFGS, L-BFGS→ HIPO, Fletcher-Reeves-Polak-Ribiere-FRPR)
 - Gradient-free (e.g. Nelder-Mead Simplex Algorithm, ...)
- Stochastic/Probabilistic
 - Simulating Annealing (SA) → IPSA
 - Genetic/Evolutionary Algorithms (GA)

Diversity of techniques of dose analysis (sampling points, where values of the objective functions are analysed)

Inverse Optimisation and **Planning** Preconditions:

- Complete 3D anatomy model: Targets (GTVs), CTV/PTV, OARs
- Implantation rules (anatomical constraints)
- Implantation methods, instruments, ...
- Desired dose distribution $D(\vec{r})$

Dosimetric

 $\Psi(\vec{r}) = \Psi(\{\vec{r}\}, \{t\}) = \sum_{i=1}^{N_{ASDPs}} S_{K,i} \cdot t_i \cdot \delta(\vec{r} - \vec{r}_i) = ?$

Inverse Optimisation and **Planning**

Objectives & Objective Functions

- Define Dose Window for Target(s), NT & OAR(s)
 - Low-Objective D_L for V_{Low}
 - High-Objective D_H for V_{High}

$$f_{i} = \frac{1}{N_{i}} \sum_{j=1}^{N_{i}} \left[\Theta \left(D_{L}^{i} - d_{j}^{i}(\boldsymbol{x}) \right) \left[D_{L}^{i} - d_{j}^{i}(\boldsymbol{x}) \right]^{p} \right]$$

$$f_{i} = \frac{1}{N_{i}} \sum_{j=1}^{N_{i}} \left[\Theta \left(d_{j}^{i}(\boldsymbol{x}) - D_{H}^{i} \right) \left[d_{j}^{i}(\boldsymbol{x}) - D_{H}^{i} \right]^{p} \right]$$

Objectives

Objective Functions

 d_{j}^{i} is the Dose at the Sampling Point *j* for *Objective Function i*:

Inverse Optimisation and **Planning Objectives & Objective Functions**

 d_{j}^{i} is the dose at the *j*th-sampling point for the *i*th-objective function:

• $x_{lk}^2 = t_{lk}$ to avoid negative (non-physical) dwell time values t_{lk}

• \tilde{d}_{jkl}^{i} , can (should) be calculated in a pre-processing step and are then available in a sense of <u>a Look-Up-Table</u> for the optimisation process. Implementations in this way make optimiser independent of the dose calculation engine considered (TG 43, MC, BS, CC, other Engines)

Inverse Optimisation and **Planning**

The Inverse Planning of an adequate number of catheters/applicators / needles based on dosimetric objectives and constraints <u>is solvable in clinically acceptable time</u> only after discretisation $\{b_k\}$:

Inverse Optimisation and **Planning**

Objectives & Objective Functions

Grid-based discretisation -> Set of Feasible Catheters/Needles

Summary – Inverse Planning

A single Objective Function via weighted Aggregation

<u>Minimise</u>

$$f = \sum_{m=1}^{M} w_m f_m = f(\{\vec{r}\}, \{t\}, \{w\})$$

$$f_{i} = \frac{1}{N_{i}} \sum_{j=1}^{N_{i}} \left[\Theta \left(d_{j}^{i}(\boldsymbol{x}) - D_{H}^{i} \right) \left[d_{j}^{i}(\boldsymbol{x}) - D_{H}^{i} \right]^{p} \right] \qquad \qquad \textbf{Over-dosage (hig)}$$

<u>with</u>

$$d_j^i(\mathbf{x}) = \sum_{k=1}^{N_{feasible}} \sum_{l=1}^{N_{ASDP}^k} \boldsymbol{b}_k \boldsymbol{x}_{lk}^2 \boldsymbol{S}_{K,lk} \boldsymbol{\tilde{d}}_{jkl}^i$$

parameter values

Summary – Inverse Planning

- b ∈ {0, 1} & x ∈ R single stepping source HDR-afterloader z.B.¹⁹²Ir
- *b* ∈ {0, 1} & *x* ∈ {0, 1} seeds implants permanent z.B. ¹²⁵I

Inverse Optimisation and Planning Topography based (TOP)

- TOP: Additional not morphology (VOIs, DVHs) based Features, and/or local History:
 - Dwell Time Modulation Restriction (MR) (Smoothness of Source Movement)

Inverse Optimisation and Planning Topography based (TOP)

Independently of the used Inverse Optimization Algorithm it is not an uncommon result for HDR implants that there exist a few very dominating Dwell positions where the largest part of the total dwell time is spent.

This leads obviously to a *selective extension of high dose volumes* around such dwell positions. If there is *no information available* about its necessity (e.g. location of a GTV/IDL), then it is reasonable to investigate whether this can be avoided.

Inverse Optimisation and Planning Topography based (TOP)

Dwell Time *Modulation Restriction (MR) - Smoothness of Source Movement* - can be achieved by considering Dwell Time (Modulation) related *Objective Functions*:

- Smoothness of Dwell Time Modulation within Catheters
- Pseudo: Restricting the maximal possible Dwell Time per Source Dwell Position
- Overall Dwell Time

Source Strength Determinations in Brachytherapy

Prof. Mark J. Rivard, Ph.D., FAAPM

Advanced Brachytherapy Physics, 29 May – 1 June, 2016

Disclosures

The are no conflicts-of-interest to report.

Opinions herein are solely those of the presenter, and are not meant to be interpreted as societal guidance.

Specific commercial equipment, instruments, and materials are listed to fully describe the necessary procedures. Such identification does not imply endorsement by the presenter, nor that these products are necessarily the best available for these purposes.

Learning Objectives

- 1. Accepted standard units for brachytherapy source strength
- 2. Source calibration traceability and standards labs
- 3. Calibration methods and techniques
- 4. Calibration uncertainties
- 5. Future calibrations

Photon Sources Examined

2004 AAPM TG-43U1 Brachytherapy Dosimetry Formalism

RAKR nearly identical to air-kerma strength S_{K} (distance specification)

$$\dot{D}(r,\theta) = S_K \cdot A \cdot \frac{G_L(r,\theta)}{G_L(r_0,\theta_0)} \cdot g_L(r) \cdot F(r,\theta)$$

$$\dot{D}(r,\theta) \text{ dose rate to water in water at point } P(r,\theta)$$

$$S_K \text{ air-kerma strength}$$

- *∧* dose-rate constant
- $g_{\rm L}(r)$ radial dose function
- $G_{L}(r, \theta)$ geometry function (line-source approximation)
- $F(r, \theta)$ 2D anisotropy function

Brachytherapy Source Strength

Only the reference air kerma rate (RAKR) K_R is a quantity that is traceable to a standards laboratory (i.e., NMI or PSDL)

RAKR defined as kerma rate to air @ 1 meter *in vacuo*, corrected for attenuation/scatter

RAKR defined on the source transverse-plane for photons with E > δ threshold is dependent on source calibration protocol

RAKR has units Gy/s, also Gy/h or µGy/s (unit conversion - convenience)

mg Ra, mgRaEq, mCi (apparent activity), Bq are not traceable quantities

Obsolete units: mg Ra, mgRaEq, mCi (apparent activity), Bq

Uncertainty is a Quantitative Measure of Quality

AAPM + ESTRO TG-138 Report

Medical Physics

A dosimetric uncertainty analysis for photon-emitting brachytherapy sources: Report of AAPM Task Group No. 138 and GEC-ESTRO

This report addresses uncertainties pertaining to brachytherapy single-source dosimetry preceding clinical use. The International Organization for Standardization (ISO) Guide to the Expression of Uncertainty in Measurement (GUM) and the National Institute of Standards and Technology (NIST) Technical Note 1297 are taken as reference standards for uncertainty formalism. Uncertainties in using detectors to measure or utilizing Monte Carlo methods to estimate brachytherapy dose distributions are provided with discussion of the components intrinsic to the overall dosimetric assessment. Uncertainties provided are based on published observations and cited when available. The uncertainty propagation from the primary calibration standard through transfer to the clinic for air-kerma strength is covered first. Uncertainties in each of the brachytherapy dosimetry parameters of the TG-43 formalism are then explored, ending with transfer to the clinic and recommended approaches. Dosimetric uncertainties during treatment delivery are considered briefly but are not included in the detailed analysis. For low- and high-energy brachytherapy sources of low dose rate and high dose rate, a combined dosimetric uncertainty <5% (k=1) is estimated, which is consistent with prior literature estimates. Recommendations are provided for clinical medical physicists, dosimetry investigators, and source and treatment planning system manufacturers. These recommendations include the use of the GUM and NIST reports, a requirement of constancy of manufacturer source design, dosimetry investigator guidelines, provision of the lowest uncertainty for patient treatment dosimetry, and the establishment of an action level based on dosimetric uncertainty. These recommendations reflect the guidance of the American Association of Physicists in Medicine (AAPM) and the Groupe Européen de Curiethérapie-European Society for Therapeutic Radiology and Oncology (GEC-ESTRO) for their members and may also be used as guidance to manufacturers and regulatory agencies in developing good manufacturing practices for sources used in routine clinical treatments.

Methodology for Uncertainty Estimation

Guide to Expression of Uncertainty in Measurement ISO GUM (2010) precision \neq accuracy

Type A (statistical: standard deviation of results)

Type B (non-Type A uncertainties)

Law of Propagation of Uncertainty (no covariations)

TG-138 applies principles for expressing brachytherapy dosimetric uncertainties

expanded uncertainty, k = 2 (95.45% confidence, 21/22)
special case for large # DOF
k = t-factor otherwise with covariations

Low-Energy Calibration Uncertainty

Table I Propagation of best practice uncertainties (k = 1 unless stated otherwise) associated with the transfer of air-kerma strength from NIST through the ADCL to the clinic for LDR low-energy brachytherapy sources.

Row	Measurement description	Quantity (units)	Relative propagated
			uncertainty (%)
1	NIST WAFAC calibration	$S_{K,NIST}$ (U)	0.8
2	ADCL well ion chamber calibration	$S_{K,NIST}$ / I_{ADCL} (U / A)	0.9
3	ADCL calibration of source from manufacturer	$S_{K,ADCL}$ (U)	1.1
4	ADCL calibration of clinic well ion chamber	$S_{K,ADCL}$ / I_{CLINIC} (U / A)	1.2
5	Clinic measures source air-kerma strength	$S_{ extsf{K,CLINIC}}\left(extsf{U} ight)$	1.3
	Expanded uncertainty $(k = 2)$	$S_{ extsf{K,CLINIC}}$ (U)	2.6

Table II Propagation of best practice uncertainties (k = 1 unless stated otherwise) associated with the transfer of the air-kerma strength standard from NIST to the manufacturer for LDR low-energy brachytherapy sources.

Row	Measurement description	Quantity (units)	Relative propagated
			uncertainty (%)
1	NIST WAFAC calibration	$S_{K,NIST}$ (U)	0.8
2	Manufacturer well ion chamber calibration	$S_{K,NIST}$ / I_M (U / A)	0.9
3	Manufacturer calibration of QA source	$S_{K,M}(\mathbf{U})$	1.1
4	Manufacturer instrument calibration for assay	$S_{K\!,\!M}$ / I_M (U / A)	1.2
5	Manufacturer assays production sources	$S_{K,M}(\mathbf{U})$	1.3
6	Manufacturer places sources in 2% or 7% bins	$S_{K,Mbin}$ (U)	1.4 or 2.4
	Expanded uncertainty ($k = 2$)	$S_{K,Mbin}$ (U)	2.8 or 4.8

High-Energy Calibration Uncertainty

Table III Propagation of "best practice" uncertainties associated with the transfer of air-kerma strength from NIST through the ADCL to the clinic for LDR high-energy brachytherapy sources. Well chamber measurement uncertainty is estimated to be 0.5 %.

Step	Measurement description	Quantity (units)	Relative propagated
			uncertainty (%)
1	NIST calibration	$S_{K,NIST}(\mathbf{U})$	1.0
2	ADCL well ion chamber calibration	$S_{K,NIST}$ / I_{ADCL} (U / A)	1.1
3	ADCL calibration of source from manufacturer	$S_{K,ADCL}$ (U)	1.2
4	ADCL calibration of clinic well ion chamber	$S_{K,ADCL}$ / I_{CLINIC} (U / A)	1.3
5	Clinic measures source air-kerma strength	$S_{K,CLINIC}$ (U)	1.4
	Expanded uncertainty $(k = 2)$	$S_{K,CLINIC}(\mathbf{U})$	2.8

Table IV Propagation of "best practice" uncertainties associated with the transfer of air-kerma strength from a traceable NIST coefficient from the ADCL to the clinic for **HDR high-energy** brachytherapy sources.

Step	Measurement description	Quantity (units)	Relative propagated
			uncertainty (%)
1	ADCL calibration	$S_{K,NIST}(\mathbf{U})$	1.1
2	ADCL well ion chamber calibration	$S_{K,NIST}$ / I_{ADCL} (U / A)	1.2
3	ADCL calibration of source from manufacturer	$S_{K,ADCL}$ (U)	1.3
4	ADCL calibration of clinic well ion chamber	$S_{K,ADCL}$ / I_{CLINIC} (U / A)	1.4
5	Clinic measures source air-kerma strength	$S_{K,CLINIC}(\mathbf{U})$	1.5
	Expanded uncertainty $(k = 2)$	$S_{K,CLINIC}$ (U)	2.9

Summary of TG-138 Report

- AAPM + ESTRO recommend GUM methods for expressing dosimetric uncertainties
- precision \neq accuracy
- Type A (statistical: standard deviation of results)
 Type B (non-Type A uncertainties)
- low-E (8.7%, *k*=2) high-E (6.8%, *k*=2)
- expanded uncertainty, k=2 (95% confidence 21/22)
- pre-Tx recommendations: S_{K} , exp, MC, vendors
- clinical practice uncertainties are larger

AAPM Calibration Recommendations

Medical Physics

Third-party brachytherapy source calibrations and physicist responsibilities: Report of the AAPM Low Energy Brachytherapy Source Calibration Working Group

Compiling and clarifying recommendations established by previous AAPM

Task Groups 40, 56, and 64 were among the working group's charges, which also included the role of third-party handlers to perform loading and assay of sources. This document presents working group findings on the responsibilities of the institutional medical physicist and a clarification of the existing AAPM recommendations in the assay of brachytherapy sources. The AAPM leaves it to the discretion of the institutional medical physicist whether the manufacturer's or institutional physicist's measured value should be used in performing dosimetry calculations.

Butler, et al, Med. Phys. 35, 3860-3865 (2008)

AAPM Calibration Recommendations

TABLE I. Quantities of brachytherapy sources to be assayed by the end-user physicist.

Source form	number to be assayed
All loose sources, nonsterile Nonsterile cartridges	$\geq 10\%$ of total or 10 seeds, whichever is larger. $\geq 10\%$ of total via whole cartridge assay or via single
Mixture of nonsterile loose sources and sterile assemblies	sources. Loose sources amounting to $\geq 10\%$ of the total order or ten seeds, whichever is larger.
Sterile source assemblies	$\geq 10\%$ of assemblies via sterile well chamber inserts or quantitative image analysis.
	Alternatively, order and assay nonsterile loose seeds equal to 5% of the total or five seeds, whichever is fewer.
Strands	≥10% of total or two strands, whichever is larger, using single-seed calibration coefficient (see Ref. 15). Alternatively, order and assay
	nonstranded loose seeds equal to 5% of the total or five seeds, whichever is fewer.

^aEach source-strength grouping in an order should be sampled. If the number of sources in a strength group is <10, the entire group should be assayed.

Butler, et al, Med. Phys. 35, 3860-3865 (2008)

AAPM Calibration Recommendations

TABLE II. Actions to be taken by the physicist at the end-using institution based on the sample size assayed and the relative difference, ΔS_K , found between the manufacturer's source strength certificate and the assay by the physicist at the using institution.^a

Sample size for assay of sources by end-user medical physicist	ΔS_K	action by medical physicist
Individual source as part of an	$\Delta S_K \leq 6\%$	Nothing further.
order of ≥ 10 sources	$\Delta S_K > 6\%$	Consult with the radiation oncologist regarding use of the outlier source: Dependent on the radionuclide, intended target, source packaging, and the availability of extra sources.
$\geq 10\%$ but $< 100\%$ of order, or	$\Delta S_K \leq 3\%$	Nothing further.
batch measurements of individual sterile strands, cartridges or	$5\% \ge \Delta S_K > 3\%$	Investigate source of discrepancy or increase the sample size.
preloaded needles	$\Delta S_K > 5\%$	Consult with manufacturer to resolve differences or increase the sample size. For assays performed in the operating room, consult with the radiation oncologist regarding whether to use the measured source strength or to average with the manufacturer's value.
100% of order, or batch	$\Delta S_K \leq 3\%$	Nothing further.
measurements of each and every	$5\% \ge \Delta S_K > 3\%$	Investigate source of discrepancy.
individual sterile strand, cartridge or preloaded needle	$\Delta S_K > 5\%$	Consult with manufacturer to resolve differences. For assays performed in the operating room, consult with the radiation oncologist regarding the consequences of proceeding with the implant using the measured source strength.

^aAssay results obtained at sites other than the end-user institution should not replace the source strength value on the manufacturer's certificate. The source strength value to be used in planning may be either that stated on the manufacturer's certificate or the value determined by institutional medical physicist when the difference is $\geq 5\%$.

^bFor orders consisting of < ten sources, the action threshold is $\Delta S_K > 5\%$ for individual sources.

Butler, et al, Med. Phys. 35, 3860-3865 (2008)

Calibration of Low-Energy Photon Brachytherapy Sources

Summary:

Small radioactive "seed" sources used in prostate brachytherapy, containing the radionuclide 103 Pd, 125 I, or 131 Cs, are calibrated in terms of air-kerma strength using the NIST Wide-Angle Free-Air Chamber (WAFAC). The WAFAC is an automated, free-air ionization chamber with a variable volume, allowing corrections to be made for passage of the beam through non-air-equivalent electrodes.

Description:

Since 1999, over 1,000 seeds of more than 40 different designs from 18 manufacturers have been calibrated using the WAFAC. On-site characterization at seed manufacturing plants for quality control, as well as at therapy clinics for treatment planning, relies on well-ionization chamber measurements. Following the primary standard measurement of air-kerma strength, the responses of several well-ionization chambers to the various seed sources are determined. The ratio of air-kerma strength to well-chamber response yields a calibration coefficient for the well-ionization chamber for a given seed type. Such calibration coefficients enable well-ionization chambers to be employed at therapy clinics for verification of seed air-kerma strength, which is used to calculate dose rates to ensure effective treatment planning. To understand the relationship between well-ionization chamber response and WAFAC-measured air-kerma strength for prostate brachytherapy seeds, emergent x-ray spectra are measured with a high-purity germanium (HPGe) spectrometer.

NIST: Electronic Brachytherapy

NIST Home > PML > Radiation Physics Division > Dosimetry Group > Calibrations of a Miniature X-ray Source Used for Electronic Brachytherapy

Calibrations of a Miniature X-ray Source Used for Electronic Brachytherapy

Summary:

A new laboratory dedicated to establishing a national primary air-kerma rate standard for Xoft's AXXENT[™] miniature x-ray source has been fabricated. The Xoft source was designed to provide low-energy xrays (< 50 keV) for use in brachytherapy.

Description:

The Xoft source was designed to provide low-energy x-rays (< 50 keV) for use in brachytherapy. The air-kerma rate is being directly realized through use of the Lamperti free-air chamber, which was compared with another national x-ray standard with these sources. A high-purity germanium (HPGe) x-ray spectrometer is used to monitor the energy spectrum of the beam in real time, as well as provide necessary input data for Monte Carlo calculations of correction factors for the free-air chamber. To account for spatial anisotropy of emissions, the free-air chamber and spectrometer are rotated about the long axis of the x-ray tube during measurements. The response of well-ionization chambers to the x-ray sources is being studied in preparation for the development of a measurement assurance program for the dissemination of the new NIST standard to Accredited Dosimetry Calibration Laboratories (ADCLs). The ADCLs are accredited by the American Association of Physicists in Medicine (AAPM), and calibrate radiation measuring instruments for use in therapy clinics.

HDR and LDR brachytherapy

Calibration Service for ¹⁹²Ir High Dose Rate (HDR) Brachytherapy Dosemeters

NPL's ¹⁹²Ir HDR brachytherapy calibration service is for ionisation chambers used as secondary standards or instruments required for measurement of the greatest accuracy. Calibration of either an ionisation chamber alone or of a complete system including an electrometer is available.

Service Features

- · Calibration directly against the NPL air kerma primary standard
- Reference air kerma rate (RAKR) of the ¹⁹²Ir source up to 50. mGv/h

Specification and Availability

- · Calibration of well-type (re-entrant) chambers suitable for HDR sources
- Calibration of thimble chambers with customer provided calibration iid
- Electrometer calibration (charge or current calibration)
- · Calibrations are normally carried out in spring, and are undertaken using a microSelectron ¹⁹²Ir HDR source
- Calibration conforms to IPEM Code of Practice (2010)

For more information, please contact Thorsten Sander or our Radiation Dosimetry Team

Calibration Service for Low Dose Rate (LDR) Brachytherapy Sources

NPL's LDR brachytherapy service includes the calibration of ¹²⁵I seeds and ¹⁹²Ir wires and pins. The sources are calibrated with the Fidelis secondary standard radionuclide calibrator.

Service Features

 Source calibration traceable to the NPL air kerma primary standard

Specification and availability

- Source calibrations in terms of µGy/h at 1 m or MBq
- Calibration of ¹²⁵I seeds and ¹⁹²Ir wires and pins, including ¹²⁵I seeds (e.g. IMC 6711 OncoSeedTM, IMC 7000 RAPIDStrandTM)and ¹⁹²Ir wires and pins (e.g. Amersham ICW-series)
- Calibrations of other source types/configurations possible
- · Calibrations are available by arrangement throughout the year

Fidelis secondary standard radionuclide calibrator

IAEA TECHDOC 1274

Calibration of photon and beta ray sources used in brachytherapy

Guidelines on standardized procedures at Secondary Standards Dosimetry Laboratories (SSDLs) and hospitals

INTERNATIONAL ATOMIC ENERGY AGENCY

March 2002

Chapter 5: Calibration at the SSDL and Hospital Level

5.1. Establishment of standards for photon and intravascular sources

5.1.1. Traceability in calibrations at SSDLs

The recommended detector is an appropriately calibrated well type chamber. The preferred traceability method is to have the well type chamber calibrated against the primary standard at the PSDL. Calibrations at an ADCL or the IAEA Dosimetry Laboratory can serve as an alternative. This calibration should be carried out for each radionuclide and source type to be used.

5.1.2. Traceability in calibrations at hospitals

It is recommended that for brachytherapy sources be calibrated with an appropriately calibrated well type chamber. For traceability, the well type chamber should be calibrated at the SSDL (or ADCL).

Chapter 5: Calibration at the SSDL and Hospital Level

5.2. Maintenance of standards for photon sources and intravascular sources Well type chambers should be recalibrated regularly. SSDL recalibrations at ¹³⁷Cs quality can be made at a PSDL or the IAEA Dosimetry Laboratory.

5.3. Maintenance of standards for ¹⁹²Ir quality

Upon calibrating well type chambers every 2 years with HDR ¹⁹²Ir sources, some chamber types have shown calibration factor constancy to within 0.5%, and chamber-to-chamber variation of the ratio of HDR ¹⁹²Ir source calibration to ¹³⁷Cs and ⁶⁰Co also within 0.5%. Thus, a practical solution for checking a well chamber HDR ¹⁹²Ir source calibration factor is for the physicist to monitor chamber response throughout its lifetime by bracketing the ¹⁹²Ir average energy of 397 keV with ¹³⁷Cs and ²⁴¹Am sources.

INTERNATIONAL ATOMIC ENERGY AGENCY

Chapter 5: Calibration at the SSDL and Hospital Level

5.5. Guidance on constancy limits for well type chambers

Chamber output stability should be checked at least 4 times per year. If the calibration factor from ¹³⁷Cs re-calibrations, and periodic constancy checks, remain the same within 1% for high-energy photon sources, or within 1.5% for low-energy photon sources, it can reasonably be assumed that the calibration factor for other sources has not changed. Recalibration is recommended if it is observed that response changes by more than the limits given above.

5.6. Electrometer to be used

IEC 60731 describes desired characteristics of electrometers. They also shall be capable of measuring up to 0.2 μ A for HDR sources and have a signal resolution of 0.1%. For LDR sources, signal resolution should be \leq 10 fA or less; this may be achieved by charge resolution of 0.2 pC when used in charge integration mode. It may be necessary to have two electrometers to cover the full range of brachytherapy sources to be calibrated.

Chapter 6: Calibration Using Free In-air Measurements

6.1. General

The free in-air measurement technique cannot be used for low-energy sources due to air-kerma calibration factor uncertainties, low air-kerma rates, and uncertainties due to air humidity. For long-lived radionuclides, e.g., ¹³⁷Cs, a source can be a working standard.

$$K_{R} = N_{K} \cdot (M_{u}/t) \cdot k_{air} \cdot k_{scatt} \cdot k_{n} (d/d_{ref})^{2}$$

6.2. Formalism for reference air kerma rate

- $K_{\rm R}$ reference air kerma rate
- $N_{\rm K}$ chamber air kerma calibration factor at desired photon energy
- $M_{\rm U}$ measured charge, corrected for T, P, recombination, transit error
- *t* time for collecting charge
- $k_{\rm scat}$ correction for room scatter
- k_n correction factor for non-uniform electron fluence within the cavity
- *d* measurement distance from source center to chamber center
- d_{ref} reference measurement distance (i.e., 1 meter)

INTERNATIONAL ATOMIC ENERGY AGENCY

Chapter 6: Calibration Using Free In-air Measurements

6.3. Ionization chambers to be used

For HDR sources, chambers volumes > 0.5 cm^3 can be used (e.g. Baldwin-Farmer 0.6 cm^3 chamber). For LDR sources, chamber volumes up to 1,000 cm³ may be used for sufficient signal, but have large non-uniformity correction factor uncertainties. For ¹⁹²Ir, chambers should have air-kerma calibration factors vary less than 5% between ⁶⁰Co and 60 keV.

6.4. Air kerma calibration of ionization chambers

6.5. Correction factors for free in-air measurements

6.6. Uncertainty of free in-air calibration

etc., etc.

INTERNATIONAL ATOMIC ENERGY AGENCY

Chapter 7: Calibrations Using Well Type Chambers 7.1. General guidance

7.2. Calibration of SSDL reference sources

7.3. Calibration of hospital's well type chamber

The hospital's well chamber system is calibrated at the SSDL using the SSDL reference source. The response curve, spacer and insert, ion recombination, atmospheric communication, and air kerma calibration are checked.

7.4. Calibration of hospital's non-standard ¹³⁷Cs sources

7.5. Guidance for some special cases

7.6. Calibration of source trains

7.7. Traceability of ¹³⁷Cs source calibrations

etc., etc.

A PRACTICAL GUIDE TO QUALITY CONTROL OF BRACHYTHERAPY EQUIPMENT

Chapter 3: Calibration of Brachytherapy Sources

3.3 In-air measurement technique

3.4 Calibration using well type chambers

3.5 Calibration using solid phantoms

Measurements in solid phantoms are not suitable for low-energy sources.

3.6 Relative measurements

Readings of consecutive source deliveries can be compared and deviations larger than 3% or 5% should be investigated. Serious incidents may be identified before treatment.

Chapter 9.2 on TPS Commissioning

9.2.6 Influence of shields, missing tissue, and inhomogeneities (abridged)

Presently, only simple correction algorithms are applied in some TPS. The effect of these algorithms must be verified and documented.

Published shielding or tissue inhomogeneity data are based on MC. yes

Validation of these MC data should be done by comparing with measured data, such as those obtained using TLD or small ionisation chambers.

Algorithms are under development to account for scatter conditions and tissue inhomogeneities.

Validation of these algorithms should be done in a similar way to the method used for checking the shielding algorithms. **ouch!**

Comparison of RAKR Measurement Methods

Adequate measurement precision (within 0.5%) using well chambers and Farmer chambers in-air or in-plastic phantoms.

Baltas, et al., Intl J Radiat Oncol, Biol, Phys 43, 653-661 (1999)

UK IPEM Code of Practice for HDR ¹⁹²Ir RAKR

Figure 1. The graph shows the calibration history of a Standard Imaging 1000 Plus well chamber over 7 years. Calibrations were carried out with 11 different Nucletron microSelectron-v1 (classic) HDR ¹⁹²Ir brachytherapy sources. The maximum variation of all calibration coefficients, $N_{\text{KR},i}$, determined between 2002 and 2009 was found to be $\pm 0.4\%$ of the running mean, \bar{N}_{KR} .

Figure B1. Reference air kerma rate (RAKR) comparison between a Standard Imaging 1000 Plus well chamber, calibrated using the new COP, and a Farmer chamber, calibrated at 280 kVp according to the old 1992 BIR/IPSM recommendations.

This COP aims to eliminate systematic differences between users, and reduce uncertainties by recommending the well chamber method of source calibration over the previously recommended (Aird *et al.*, 1993) Farmer method.

Bidmead, et al., Phys Med Biol 55, 3145-3159 (2010)

Implementation of UK IPEM Code of Practice

Improved measurement precision using well chambers instead of Farmer chambers.

Fourie and Crabtree, A technique for calibrating a high dose rate ¹⁹²Ir brachytherapy source. *Australas Phys Eng Sci Med* 35, 85-92 (2012).

Kaulich, et al., Direct reference air-kerma rate calibration of ¹⁹²Ir for a thimble-type ionization chamber in a cylindrical solid phantom. *Metrologia* 49, S241-S245 (2012).

etc., etc.

Take Home Message

1. Independent assay of RAKR from the manufacturer is required.

2. Calibration methods are established for all brachytherapy sources.

3. Calibration infrastructure (i.e., SSDL availability) is variable.

4. Future improvements forthcoming in calibration methods and infrastructure.

Experimental dosimetry in brachytherapy

P. Papagiannis, PhD Medical Physics Laboratory Medical School National & Kapodistrian University of Athens

(no conflict of interest to disclose)

Objectives:

After this lecture the attendants should:

➢ have a clear understanding of:

- dosimeter selection criteria & brachytherapy dosimetry challenges
 be familiar with:
- a general terminology introduced to describe dosimeter characteristics
 - a general formalism for absorbed dose measurement
 - the key properties & operational features of utilized dosimeters (mainly TLD and radiochromic Film)
 - ➤ be informed of:
 - current trends
 - relevant literature
 - sources for further reading

Experimental dosimetry in brachytherapy WHY...?

"theory is an interpolation of experiment" (J.H. Hubbell in: X-Ray Spectrom. 28(4), 215–223, 1999)

Experimental dosimetry is needed for: • establishing source reference dose rate distributions (for clinical TG43-based TP) • commissioning and QA testing of TPS (planned dose is accurate) • dose verification in phantom or "in-vivo" (planned dose is accurately delivered)

Experimental dosimetry:

Use of a detector (dosimeter) providing a <u>measurable signal</u> that is of a <u>known relationship</u> with the absorbed dose in its volume

- The relationship between signal and dose is known for <u>absolute dosimeters</u> (calorimeters, ion chambers & Fricke gels)
- All other dosimeters must be **calibrated** <u>relative</u> to an absolute one in a beam quality Q_o, to obtain the **absorbed dose sensitivity**:

$$S_{AD,W}(Q_0) = \frac{M(Q_0)}{D_W(Q_0)}$$

or equivalently the **calibration coefficient**:

$$N_{AD,W}(Q_0) = \frac{D_W(Q_0)}{M(Q_0)}$$

- Dose to a medium in the absence of the detector (water) is of interest
 - The calibration must be traceable to international standards

* The terminology used in this lecture is that introduced in:

Rogers & Cygler (Eds), Clinical dosimetry measurements in radiotherapy (2009 AAPM Summer School), Monograph No. 34, Medical Physics Publishing 2011

Dosimeter characteristics/requirements :

- (1) **Sensitivity**: must be high enough for low dose rate measurements. If the sensitivity is too high, it may cause rapid saturation at high dose rate
- (2) Adequate **dose range** and (preferably) **linearity of the response** as a function of accumulated dose
- (3) Insensitivity of response to influence quantities (dose rate, temperature, pressure, directional effect, accumulated dose, etc.): response should be independent, or variation should be known or measurable in order to perform adequate correction
- (4) Energy response: preferably independence of response as a function of energy
- (5) **Repeatability**: stability for repeated measurements over a short period of time
- & **Reproducibility**: stability of material, construction, etc. over a long period of time
- **(6)** Accuracy/precision: the derivation of the dose from the dosimeter response must be possible with minimum uncertainty, but the requirements may differ for different applications

Quoted from: Mayles, Nahum, Rosenwald (Eds): Handbook of radiotherapy physics: theory and practice, © 2007 by Taylor & Francis Group LLC

Dose range / linearity / saturation:

$$D_{\text{det}}(D) = k_l(M(D)) \alpha M(D)$$

where: k_l is the **intrinsic linearity** (normalized to 1 @ some D_o) and α relates D_o to $M(D_o)$

- Detector response is linear if k₁ is 1 for any D, M(D)
- !!!This is not always the case!!!

Figure from: Rogers & Cygler (Eds), Clinical dosimetry measurements in radiotherapy (2009 AAPM Summer School), Monograph No. 34, Medical Physics Publishing 2011

Influence quantities:

A series of correction factors must be applied (if appropriate) to correct the dosimeter reading for any measurement condition affecting it In example:

•environmental conditions

background correction:

 $k_{bkgd} = (1 - \frac{M_{bkgd}}{M})$ •dose rate dependence:

 $\dot{M'(D)} = k_{dr}(M(D))M(D)$

Sensitivity, calibration & energy response:

Our calibration coeff. (inverse of dosimeter A.D. sensitivity) actually comprises 2 parts:

$$N_{AD,W}(Q) = \frac{D_{W}(Q)}{M(Q)} = \frac{D_{W}(Q)}{D_{\det}(Q)} \frac{D_{\det}(Q)}{M(Q)} = f(Q)k_{bq}(Q)$$

• we define the **absorbed dose energy dependence** of the detector as the ratio of dose to water per unit dose to the detector at a given beam quality,

$$f(Q) = \frac{D_{W}(Q)}{D_{\det}(Q)}$$

• We define the **intrinsic energy dependence** of the detector as the ratio of dose required to be absorbed to produce a unit signal

$$k_{bq}(Q) = \frac{D_{\det}(Q)}{M(Q)}$$

Sensitivity, calibration & energy response:

Our calibration coeff. (inverse of dosimeter A.D. sensitivity) actually comprises 2 parts:

$$N_{AD,W}(Q) = \frac{D_{W}(Q)}{M(Q)} = \frac{D_{W}(Q)}{D_{\det}(Q)} \frac{D_{\det}(Q)}{M(Q)} = f(Q)k_{bq}(Q)$$

• we define the **absorbed dose energy dependence** of the detector as the ratio of dose to water per unit dose to the detector at a given beam quality,

$$f(Q) = \frac{D_{W}(Q)}{D_{\det}(Q)}$$

This depends on physical properties and radiation quality (cross sections) and detector geometry. It can be calculated via MC!

• We define the **intrinsic energy dependence** of the detector as the ratio of dose required to be absorbed to produce a unit signal

$$k_{bq}(Q) = \frac{D_{det}(Q)}{M(Q)}$$

This depends mainly on the physical process underlying the conversion of dose to the measured signal (and hence LET). It can only be measured!

Practical significance of f(Q), $k_{bq}(Q)$

- ➤ Using a detector at the same quality as calibration (Q_0) is straightforward: $D_W(Q_0) = M(Q_0) * \prod (corr.factor)_i N_{AD,W}(Q_0)$
- > Using a detector at a quality Q different than calibration (Q_0) :

$$\begin{split} D_{W}(Q) &= M(Q_{0}) * \prod_{i} (corr.factor)_{i} N_{AD,w}(Q_{0}) \frac{N_{AD,w}(Q)}{N_{AD,w}(Q_{0})} = \\ &= M(Q_{0}) * \prod_{i} (corr.factor)_{i} N_{AD,w}(Q_{0}) \frac{f(Q)}{f(Q_{0})} \frac{k_{bq}(Q)}{k_{bq}(Q_{0})} = \\ &= M(Q_{0}) * \prod_{i} (corr.factor)_{i} N_{AD,w}(Q_{0}) f^{rel}(Q,Q_{0}) k_{bq}^{rel}(Q,Q_{0}) \end{split}$$

 f^{rel}, k_{bq}^{rel} cannot be generally assumed energy independent f^{rel} must be calculated k_{bq}^{rel} must be measured

or taken from the literature for **matching** exp. conditions (Q, Q_0 , detector make, size, set up, ...)

f^{rel} or k^{rel} >1 => detector under-responds ...! f^{rel} or k^{rel} <1 => detector over-responds ...!

Dosimeter characteristics/requirements :

- (1) **Sensitivity**: must be high enough for low dose rate measurements. If the sensitivity is too high, it may cause rapid saturation at high dose rate
- (2) Adequate **dose range** and (preferably) **linearity of the response** as a function of accumulated dose
- (3) Insensitivity of response to influence quantities (dose rate, temperature, pressure, directional effect, accumulated dose, etc.): response should be independent, or variation should be known or measurable in order to perform adequate correction
- (4) Energy response: preferably independence of response as a function of energy
- (5) **Repeatability**: stability for repeated measurements over a short period of time
- & **Reproducibility**: stability of material, construction, etc. over a long period of time
- **(6)** Accuracy/precision: the derivation of the dose from the dosimeter response must be possible with minimum uncertainty, but the requirements may differ for different applications

Quoted from: Mayles, Nahum, Rosenwald (Eds): Handbook of radiotherapy physics: theory and practice, © 2007 by Taylor & Francis Group LLC

Brachy dosimetry is challenging ...

Dose rate varies from ~20 Gy/s @ $(0.5\text{cm},90^\circ)$ from an Ir-192 HDR source to ~2 μ Gy/s @ $(5\text{cm},90^\circ)$ from an I-125 LDR source

Sensitivity high for low uncertainty, dose range high, (preferably) with $k_l=k_{dr}=1$

Spatial dose gradient is high (i.e. ~25%/mm in the radial direction @ (0.5cm,90°) from an Ir-192 HDR source)

Volume must be small, positional accuracy is very important

(1% rel. uncert. in D(1cm,90°) requires 0.05mm uncertainty in r, assuming $1/r^2$ dose dependence since: $\frac{\sigma_D}{D} = 2\frac{\sigma_r}{r}$) If solid phantoms are used to increase positional accuracy a correction is required from D_{w,phant} to D_{w,w} at each meas. position

Brachytherapy Q is source/position dependent...

 f^{rel}, k_{bq}^{rel} may be considerable (especially for low E) BUT

- They are source dependent (source materials)
- and position dependent (source spectra vary with distance, angle)

especially for high Z detectors

Figure from: Papagiannis, Pantelis, Karaiskos, Br J Radiol (2014) 87: 20140163

Calibration:

!!! Calibration uncertainty will be propagated as a type B unc. component to experimental results **!!!**

Absorbed dose sensitivity calibration

 $S_{AD,w}(Q_0) = \frac{M(Q_0)}{D_w(Q_0)} = \frac{1}{N_{AD,w}(Q_0)}$

is usually performed using a Linac where:

 $M(Q_o)$ is the dosimeter reading $D_w(Q_o)$ is dose to water at the point of measurement in the absence of the detector obtained using an established reference dosimetry protocol (e.g. TRS398) and an ion chamber with a dose to water calibration traceable to international standards

Let us do single source dosimetry (TG-43 characterization of a source) using TLD as is traditionally done in the literature.

Figures from: Rogers & Cygler (Eds), Clinical dosimetry measurements in radiotherapy (2009 AAPM Summer School), Monograph No. 34, Medical Physics Publishing 2011

TLD: basic principles

- In imperfect crystals (i.e. TLD100: LiF doped with Mg and Ti in trace amounts) part of the energy absorbed by ionising radiation is stored and re-emitted upon heating in the form of light. Light is detected and correlated to the absorbed dose.
- Stored energy is in the form of the fraction of e⁻ freed by irradiation, that is trapped in a metastable energy state.
- When the crystal is heated, part of these erecombine with holes trapped in luminescence centers and emit light (thermoluminescence, TL)
- The curve of TL output versus temperature (glow curve) shows peaks characteristic of trap energy depths in the crystal
 - Besides TL crystal, glow curve shape varies with heating rate & max temperature

TLD is effective in terms of interacting with photons in the brachytherapy E range

- The TL mechanism however is inefficient
- About 0.04% of TLD absorbed dose is emitted as TL energy per unit mass
- <u>Individual TLD calibration</u> is required as well as meticulous care in <u>reproducible conditions</u> of use to ensure precision/accuracy
- TLD dynamic dose range is wide. It comprises a linear D region followed by a region of supralinearity and, eventually, saturation
- <u>Linearity cannot be assumed</u> and has to be measured by irradiating TLD groups in graded doses in the region of interest

Table from: Mayles, Nahum, Rosenwald (Eds): Handbook of radiotherapy physics: theory and practice,© 2007by Taylor & Francis Group LLC

TLD: influence factors

• TLD response is <u>not significantly affected from environmental conditions</u> (normal room temperatures, moderate exposure to light).

BUT

Traps are not stable @ room temperatures and annealing @ 400 °C for 1 h is required to ensure trap stability.

Fading can affect low T peaks. This can be mitigated by eliminating corresponding traps (annealing @ 80 °C for 24 h pre-irradiation) or emptying them before readout (annealing @ 100 °C for 2 h pre-irradiation and 10 min post-irradiation)

- <u>background correction</u> is necessary for PM dark current and TL non-related to D (the latter is reduced with N₂ gas purging during readout)
 - TLD response is <u>dose rate independent</u>

General formalism

$$\frac{\frac{\Phi_{W,W}(Q)}{S_{K}}}{=} \frac{M(Q) * k_{bkgd} * k_{l} * g(t)}{S_{K}} * N_{AD,W}(Q_{0}) \frac{N_{AD,W}(Q)}{N_{AD,W}(Q_{0})} * p_{phant} = \frac{M(Q) * k_{bkgd} * k_{l} * g(t)}{S_{K}} * N_{AD,W}(Q_{0}) * k_{bq}^{rel} * f^{rel} * p_{phant}$$

Where:
$$g(t) = \frac{\lambda}{\exp[-\lambda(t_{start} - t_{cal})][1 - \exp(-\lambda\Delta t_{exp})]}$$

and
$$p_{phant} = \frac{D_{w,w}(Q)}{D_{w,phant}(Q)}$$
 can be calculated using MC

I need to measure: $M, N_{AD,w}(Q_0)$, corrections k_I , and k_{bq} , calculate: $g(t), f, p_{phant}$, and know: S_K ,

with as low an uncertainty as possible!

Uncertainty requirements for single source dosimetry

In their methodological recommendations for measuring dosimetry parameters:

> TG-43U1^{*} advises on using a dosimeter system with sufficient precision and accuracy to permit dose-rate estimations with combined 1 σ Type A uncertainty <5% and 1 σ Type B uncertainty <7% for a total 1 σ uncertainty <9% for LE sources

> Joint AAPM-ESTRO report^{**} advises on using a dosimeter system with sufficient precision and accuracy to permit dose-rate estimations with k=1 Type A (statistical) uncertainties 3% and k=1 Type B uncertainties 6%

* Rivard et al., 2004. Update of AAPM Task Group No. 43 Report: A revised AAPM protocol for brachytherapy dose calculations. Med. Phys. 31(3), p.633.

** Perez-Calatayud et al., 2012. Dose calculation for photon-emitting brachytherapy sources with average energy higher than 50 keV: report of the AAPM and ESTRO. Med. Phys. 39(5), p.2904
TLD: absorbed dose energy dependence

- <u>TLD dose changes more than water at Q<<Q_o</u> <u>due to higher Z than water, so f^{rel}<1</u>
 - Assuming TLD is a large cavity (dimensions large compared to max. e⁻ range & small compared to photon m.f.p.):

$$f^{rel}(Q,Q_0) = \frac{(\mu_{en}/\rho)_{TLD}^{W}(Q)}{(\mu_{en}/\rho)_{TLD}^{W}(Q_0)} \approx 0.7$$

for LDR sources relative to Co-60.

This is only an approximation.

MC is used to account for:

- photon spectra @ each point in Q, Q_o
- TLD attenuation,
- v. averaging
- cavity corrections, ... etc.

See: Rodriguez and Rogers, Med. Phys. 41(11) p. 114301 (2014) for an excellent review...!

Figure from: Rogers & Cygler (Eds), Clinical dosimetry measurements in radiotherapy (2009 AAPM Summer School), Monograph No. 34, Medical Physics Publishing 2011

$$f^{rel}(Q,Q_0) = \frac{D_W(Q)/D_{TLD}(Q)}{D_W(Q_0)/D_{TLD}(Q_0)}$$

TLD: absorbed dose energy dependence

Best practice example for I-125 dosimetry with 6 MV linac calibration:

- f^{rel} is close to 0.7 but varies with point around the source
- Uncertainties: Type A=0.56%, type B=1%

<u>Neglecting f^{rel} would introduce a type B uncertainty</u> (dose overestimation) of 40%...!

Moutsatsos et al. Experimental determination of the Task Group-43 dosimetric parameters of the new I25.S17plus (125)I brachytherapy source, Brachytherapy, 13(6), 618 (2014).

GmbH & Co

It was well known that dose to TLD to produce a unit signal <u>decreases</u> as energy decreases and LET increases

i.e.: $k_{ba}^{rel} < 1$ @ the brachy energies equivalently: TLD over-responds or (more signal per unit dose) at lower energies due to LET increase

 $k_{bq}^{rel}(Q,Q_0) = \frac{D_{TLD}(Q)/M(Q)}{D_{TLD}(Q_0)/M(Q_0)}$

In the light of studies indicating $k_{ba}^{rel} = 1$ within experimental uncertainties (i.e. Das et al disregarded by 1996) k_{ba} was most experimentalists

• Until Davis et al (2003) measured TLD100 over-response at low E due to LET increase and the race to determine k_{bq} was on ...!

 $k_{bq}^{rel}(Q,Q_0) = \frac{D_{TLD}(Q)/M(Q)}{D_{TLD}(Q_0)/M(Q_0)}$

- Davis et al. k_{bq}^{rel} down to 0.9 (0.6 % Type A uncertainty, k=1, x-ray beams, LiF:Mg,Ti).
- Nunn et al. k_{bq}^{rel} down to 0.885 (3.5% combined standard uncertainty, k=1, x-ray beams, LiF:Mg,Ti).
- Carlsson Tedgren et al. k_{bq} down to 0.935 (1.9% combined standard uncertaintiy, k=1, x-ray beams, LiF:Mg,Ti). They also discussed potential differences due to TLD handling and formulation, and expressed concern regarding the applicability of determinations obtained using x-ray beams to other photon fields.
- Reed et al. $k_{bq}^{rel} = 0.883 \pm 0.011$ (I-125), 0.870 ± 0.012 (I-125 w. Ag), 0.871 ± 0.013 (Pd-103) (combined standard uncertainties, k=1 LiF:Mg,Ti).
- Rodriquez and Rogers minimized the difference between Λ measurements in the literature and MC calculations and arrived at $k_{bq}^{rel} = 0.931 \pm 0.013$ (I-125) and 0.922 ± 0.022 (Pd-103).

Figure from: Carlsson Tedgren et al, Med. Phys. 38(10) 3839 (2011)

 $k_{bq}^{rel}(Q,Q_0) = \frac{D_{TLD}(Q)/M(Q)}{D_{TLD}(Q_0)/M(Q_0)}$

- k_{bq}^{rel} is in the order of 0.90±0.05 to 0.935±0.03 for I-125 and Pd-103
- This correction appears to be protocol and TLD make specific.
- A correction might be needed for HE sources as well (Joint AAPM-ESTRO report suggests $k_{bq}^{rel} = 1$) but for Ir-192 Carlsson et al. (Med. Phys. 39(2), 1133. 2012) suggests $k_{bq}^{rel} = 0.95$ but with increased uncertainties (3.5%, k=1).

Phantom correction

• Plastics fabricated for water equivalence in MV beams used as phantom material (solid water 457-Gamex, white water RW3-PTW, plastic water CIRS)

 $=\frac{D_{W,W}(Q)}{D_{W,phant}(Q)}$

 $p_{phant} = -$

• Williamson (1991) first noted the need for a p_{phant} correction

Atomic species	Water	РММА	WT1	RW -1
н	11.2	8.0	8.1	13.2
С		60.0	67.2	79.4
Ν			2.4	•••
0	88.8	32.0	19.9	3.8
Ca	•••	<i></i>	2.3	2.7
Mg	•••		•••	0.9
CĨ	•••		0.1	•••
Density (g cm $^{-3}$)	1.00	1.17	1.015 ^b	0.97

TABLE II. Percent atomic composition (by weight) and densities of phantoms.^a

Table from: Luxton, Med. Phys. 21(5), 631 (1994)

Phantom correction

• p_{phant} increases with distance due to increased density and increased attenuation from %Ca content

 $D_{w,w}(Q)$

 p_{phant}

• There might also be a minor θ dependence

Atomic species	Water	PMMA	WT1	RW- 1
н	11.2	8.0	8.1	13.2
С		60.0	67.2	79.4
Ν	•••		2.4	•••
0	88.8	32.0	19.9	3.8
Ca	•••	<i>.</i>	2.3	2.7
Mg	•••		•••	0.9
CI	•••		0.1	•••
Density (g cm $^{-3}$)	1.00	1.17	1.015 ^b	0.97

TABLE II. Percent atomic composition (by weight) and densities of phantoms.^a

$$p_{phant} = \frac{D_{w,w}(Q)}{D_{w,phant}(Q)}$$

Phantom correction

• Phantom material MUST be checked for density variation and composition (Ca or other high Z content variation that can be up to 30%) to minimize type B uncertainty.

Figure from: Luxton, Med. Phys. 21(5), 631 (1994)

High purity plastics (PMMA, polystyrene) might be preferable since p_{phant} deviation from unity is greater for LE source dosimetry BUT type B uncertainty of the correction will be lower.

TLD: uncertainty budget

Table 1

Analysis of the uncertainty associated with TLD results for the dose-rate constant of the I25.S17plus brachytherapy source

Component	Type A (%)	Type B (%)
Average of repetitive measurements	3.22 ^a	_
TLD dose calibration	0.48	1.21
Relative intrinsic energy dependence, k_{ba}^{rel}		2.50
Phantom material correction factor, P_{phant}	0.14	2.46
Relative absorbed dose energy dependence, $f^{\rm rel}$	0.56	1.0
TLD-source relative positioning		0.6
Source strength, S_K		0.78^{b}
Quadratic sum	3.31	3.97
Combined total uncertainty $(k = 1)$	5.16 [°]	

TLD = thermoluminescent dosimeter.

Random or statistical effects are described with type A uncertainties, whereas type B uncertainties account for nonstatistical discrepancies. The tabulated values correspond to the National Institute of Standards and Technology–calibrated seed.

^a 3.20%, 5.90%, and 3.44% for seed 1, 2, and 3, respectively.

^b 1% for seed 1, 2, and 3.

^c 5.19%, 7.18%, and 5.34% for seed 1, 2, and 3, respectively.

In summary:

- TLD remains the standard method for single source exp. dosimetry (both LE,HE)
- Methodological recommendations are included in TG43U1 (Rivard et al. 2004), Joint AAPM-ESTRO report (Perez-Calatayud et al, 2012) and refs therein
- At minimum calculate your f^{rel} correction using MC and including TLD att./volume and p_{phant} as a function of (r, θ). These are significant for LE and less for HE.
- What you don't know (phantom composition, density, etc) goes in your uncertainty budget!
- Overall uncertainty for LE is high mainly due to k_{bq}^{rel} uncertainty. Dose rate constants measured are on average ~5% higher than MC and hence the recommendation for equally averaged, consensus values in TG43U1 (Rivard et al. 2004)
- A dosimeter with reduced uncertainty would be welcome!

Alternatives to TLD

Systems used for single source dosimetry and especially QA: ion chambers, alanine, OSLDs, PSDs, film, i.e:

- ➢ Due to spatial measurement resolution, other limitations, and mainly level of development, TLD remains the method of choice for single source dosimetry.
- ➢ OSLDs, PSDs and alanines are also used for in-vivo and will be reviewed in the next lecture.
- ▶ What about 2D dosimetry using radiochromic films ...?

Radiochromic films

- Self-developing films based on diacetylenes researched since the 1960s as high dose radiations dosimeters
- A more sensitive film, known as GAFchromicTM, was introduced by the mid-1980s by International Specialty Products (ISP) Technology, a division of GAF Chemical Corporation (General Aniline & Film Corporation)
- ISP was acquired by Ashland Inc in 2011
- for commercial information on radiochromic films see: <u>http://www.gafchromic.com/index.asp</u>

RADIOTHERAPY FILMS

Ashland's Gafchromic self-developing dosimetry film has been created specifically for applications in radiotherapy at the processorless environment of the modern medical center. It supports all major technologies with convenience and cost-savings, complimented by our FilmQA PRO software. The product line includes:

- EBT3 Patient dosimetry for IMRT plan verification. Dose Range: 0.2 10 Gy.
- EBT-XD Ideally suited for patient dosimetry for SRS and SBRT. Dose Range: 0.4 40 Gy
- RTQA2 Film for routine machine QA, such as radiation field/ light field testing/HDR
- MD-V3 Films for measuring medium to high dose of patient dosimetry. Dose Range: 1 Gy 100Gy
- HD-V2 film for ultra high dose dosimetry needs. Dose Range: 10 Gy 1000 Gy

Radiochromic films: basic principles

- Diacetylene molecules in a w. sol. polymer matrix coated on a polyester substrate
- Radiation induces polymerization of diacetylene molecules to form polydiacetylene dye polymers (self-developing)
- These are blue in color and cause light absorbance (mainly) in the other parts of the visible spectrum
- The change in net OD is measured using flat-bed scanners employing broad band visible light sources, and correlated to dose
- OD=log(1/T)=log(I_o/I_T)

Radiochromic films: influence factors

- There is <u>post-irradiation signal growth</u> that depends on t (log, 5% per decade) and T. A k_{t,T}(t,T,D) correction must be applied OR films are kept @ stable T (store exposed and unexposed films at ambient temperature ~22 C or less) for (at least 8h) 24h before scanning.
- <u>Background signal</u> from an un-irradiated control film of the same batch and size, handled in the same way as the exp. films must be subtracted pixel-by-pixel to account for base OD and absorbance changes due to environmental conditions (T, visible light, humidity, scanning light, etc.) and obtain net OD change
 - <u>Film non-uniformity</u> correction, $k_{nu}(x,y)$, is important. A double exposure technique with pixel-by-pixel subtraction must be employed.
 - Alternatively, a triple channel technique has been developed (Micke et al, Multichannel film dosimetry with nonuniformity correction, *Med. Phys. 38(5)* 2523, 2011) and commercially available (FilmQA Pro software, Ashland-former ISP).
- There is also <u>reader non-uniformity</u> and films should always be read at the same scanner bed location to avoid application of a $k_{pos(x,y)}$ correction
 - Film response is <u>dose rate independent</u>!
 - <u>Films can be used in water (~1mm/h water penetration)</u>!

EBT films: sensitivity/linearity

- Sensitivity is film, scanner, protocol, and dose dependent
- It is non-linear and different or all RGB channels can be used
- A variety of fitting functions has been used in literature. Popular choices are power fits and rational functions:

$$\Delta OD = -\log \frac{a+bD}{c+D} / \Delta OD = \frac{a+b}{D-c} / D = a+b\Delta OD + c\Delta OD^{n}$$

- Separate calibration recommended for each lot
- Calibration quality criterion is (of course) uncertainty

Figures from: Devic, Physica Medica 27(3) 122 (2011)

Radiochromic films: rel. E response

 $f^{rel}(Q,Q_0) = \frac{D_W(Q)/D_{TLD}(Q)}{D_W(Q_0)/D_{TLD}(Q_0)} \qquad k_{bq}^{rel}(Q,Q_0) = \frac{D_{TLD}(Q)/M(Q)}{D_{TLD}(Q_0)/M(Q_0)}$

- Investigators reported inconsistent results of rel. E response.
- E.g.: for EBT3 Brown et al (2012) used synchrotron mono-chromatic x-rays and found up to 3% dose over-response ($f^{rel}k_{bq}^{rel} = 0.97$) at low E (25-35 keV) while Massillon-JL et al (2012) reported under-response up to 13% for 50kVp beams.
- It became apparent that manufacturing and compositional changes do take place, that are not always accompanied by updates to the film model or label (!!!)

Radiochromic films: rel. E response

 $f^{rel}(Q,Q_0) = \frac{D_W(Q)/D_{TLD}(Q)}{D_W(Q_0)/D_{TLD}(Q_0)} \qquad k_{bq}^{rel}(Q,Q_0) = \frac{D_{TLD}(Q)/M(Q)}{D_{TLD}(Q_0)/M(Q_0)}$

- Bekerat et al (2014) indicate different marketed versions of EBT3 and report:
 - no relative energy dependence of the latest EBT3 between Ir-192 and Co-60 (albeit for 3cm film-source distance in a parallel-opposed Ir-192 HDR irradiation setup)
 - an under response ($f^{rel}k_{ba}^{rel} > 1$) at all energies <100 keV, varying from 20% ± 4% • at 20 keV to \pm 4% at 40 keV.

Figure from: Bekerat et al, Medical Physics 41(2) 022101 (2014)

Radiochromic films: rel. E response

 $f^{rel}(Q,Q_0) = \frac{D_w(Q)/D_{TLD}(Q)}{D_w(Q_0)/D_{TLD}(Q_0)} \qquad k_{bq}^{rel}(Q,Q_0) = \frac{D_{TLD}(Q)/M(Q)}{D_{TLD}(Q_0)/M(Q_0)}$

- Hammer et al (2018) further elaborated on the **three versions of EBT3 marketed without notice** and yield results in agreement with Bekerat et al (2014) for the latest version
- EBT3-V1 was released in early 2011 and discontinued in October 2011 when EBT3-V2 was initially released.
- EBT3-V3 was initially released in August 2013, when EBT3-V2 was discontinued.
- EBT3-V3 is the currently available version of EBT3.

	Н	Li	С	Ν	0	Na	S	Cl	Br	Al	$Z_{\rm eff}$	Density (g/cm ³)

EBT3-V1	9.7	0.9	58.4	0.1	28.4	0.4	0.2	1.1	0.8	-	9.38	1.2
EBT3-V2	8.9	1.0	61.3	0.1	23.5	0.5	0.01	4.5	-	0.1	7.99	1.2
EBT3-V3	8.8	0.6	51.1	-	32.8	-	-	-	-	6.7	7.26	1.2

TABLE I. The material compositions of EBT2 and EBT3 film listed in mass percent (%). EBT3 film has undergone three chemical compositions (the first, second, and third versions of EBT3 are denoted here as V1, V2, and V3, respectively), with each iteration becoming more water equivalent.^{12,23}

Radiochromic films: rel. E response $f^{rel}(Q,Q_0) = \frac{D_W(Q)/D_{TLD}(Q)}{D_W(Q_0)/D_{TLD}(Q_0)} \qquad k_{bq}^{rel}(Q,Q_0) = \frac{D_{TLD}(Q)/M(Q)}{D_{TLD}(Q_0)/M(Q_0)}$

- Hammer et al (2018) further elaborate on the **three versions of EBT3 marketed without notice** and yield results in agreement with Bekerat et al (2014) for the latest version
- EBT3-V3 is the currently available version of EBT3.

Figures from : Hammer et al, Medical Physics 45 (1) 448 (2018)

Radiochromic films: precision/accuracy

- Ignoring intrinsic E dependence, Dempsey et al. (Med. Phys. 27(10) 2462 2000) reported 1.5-4% agreement of Gafchromic MD-55-2 results around a single Ir-192 source with MC
- Chiu-Tsao et al. (Med. Phys. 35, 3787 2008) reported 6.8% (k=1) uncertainty for I-125 dose rate constant determination using EBT1 calibrated using a I-125 seed
- Ignoring intrinsic E dependence, Sarfehnia et al. (Med. Phys. 37(4) 1924 2010) reported 1.78% (k=1) uncertainty for dose rate to water determination around a single Ir-192 source using EBT-1

In summary:

• Radiochromic films mature for brachytherapy dosimetry

BUT

- (some) work still required for their accurate relative energy response characterization in brachytherapy
- Due to calibration uncertainty (rel. high and dose dependent) and influence factors they are reserved mainly for relative dosimetry in QA and D verification

3D dosimeters...?

• radiation-induced chemical change in a gel matrix can be mapped in 3D using MRI or optical CT

Figure from: Baltas, Sakelliou, Zamboglou (Eds), The Physics of modern brachytherapy for oncology, Taylor & Francis Books Inc, 2006

Figure from: Rogers & Cygler (Eds), Clinical dosimetry measurements in radiotherapy (2009 AAPM Summer School), Monograph No. 34, Medical Physics Publishing 2011

- <u>polymer gels</u>: Custom made with organic co-monomers
- <u>PRESAGE</u> (Heuris Inc.): color forming leucodye (LMG) + initiator within a polyurethane matrix (not a gel)
- <u>Radiochromic gels: FXG, tetrazolium salt</u>, or leucodye based (e.g. <u>Truview/Clearview</u> gels by Modus Medical devices Inc.)

3D dosimeters

Advantages

- Dosimeter is the phantom (negligible to small p_{phant} depending on type)
- 3D character facilitates concurrent measurements and processing for minimizing positional and type A uncertainty
- negligible to small f^{rel} (depending on type)
- No dose rate dependence (except for methacrylic acid based gels-MAGIC & PRESAGE at very low dose rates)

Disadvantages

- Sensitivity varies with type and batch
- k^{rel}_{bq} can be significant for some dosimeters @ low E
- 3D character augments influences and problems similar to that of films increasing type B uncertainty

Example PRESAGE

relative response variation with dose rates encountered outside the PTV in HDR brachy, measured with PRESAGE cuvvettes

Figure 5. Normalized dose sensitivity as a function of dose rate, measured using PRESAGE cuvette samples from the same batch as the experimental and calibration PRESAGE dosimeters of this work. Data presented for each dose rate correspond to the average relative signal from the 2 cuvettes. Uncertainty bars correspond to the total combined uncertainty at k = 1. The gray and black dashed lines correspond to the maximum average dose rate in the experimental PRESAGE irradiation (0.12 Gy min⁻¹) and the minimum dose rate considered from the calibration PRESAGE irradiation (range of 0.34–13.79 Gy min⁻¹), respectively.

Commissioning/dose verification

• Laborious...!

• No single, ideal, system exists

• Registration of measured and calculated dose distributions comes into play

Still there is a way to verify calculations, albeit, within the experimental uncertainties

Can't we do it like the EBRT colleagues do it...? (active detectors, software support, automation, ...)

Modern Brachytherapy: Treatment Verification – An Example

The planned treatment delivery

CT-Verification

CT-Planning

Needle free length

- measured after implantation and before CT-imaging
- controlled before each fraction

Modern Brachytherapy: Treatment Verification – An Example

Delivered Treatment versus Planned Treatment

Modern Brachytherapy: Treatment Delivery Verification

- Delivered Treatment versus Planned Treatment
- Currently we assume that:
 - The geometry and location of the implanted catheters
 - The connection of **channels** to implanted catheters
 - The length of the channels
 - The source movement patterns (dwell positions and dwell times) within the implanted catheters
 - The patient **anatomy** at the relevant **location**

are during treatment delivery exact as considered and planned in the RTP.

Beam Delivery System in BRT

- **Beam** = Implanted Catheter/Needle/Applicator
- **MLC Settings** = Source moving patterns within implanted Catheter/ Needle/Applicator
- *Monitor Units* = Dwell Times

Thus "beams" become for BRT *patient-dependent parameters*, that requires 3D reconstruction (Localization: Imaging, ...) and registration to anatomy

Verification

We mean the <u>process</u> of proof that we deliver the dose we planned to the tissue (3D) within a specific <u>accuracy and</u> <u>precision</u> level.

• BRT (HDR)

In opposite to EBRT our dose delivery system (stepping source within implanted catheters) <u>depends on the specific patient</u> <u>implant geometry (anatomy)</u>.

This is not the case for EBRT, where the performance of the dose delivery system itself (MLC, Dose Rate, Energy, Gantry Angle, Collimator Angle & Couch Settings) is independent of the specific patient.

Abstract

Review pape

Electromagnetic tracking (EMT) is used in several medical fields to determine the position and orientatio ed sensors, e.g., attached to surgical tools. Recently, EMT has been introduced to brachytherapy for implam tion and error detection. The manuscript briefly summarizes the main issues of EMT and error detection in apy. The potential and complementarity of EMT as treatment verification technology will be discussed is *in vivo* dosimetry and imaging.

Table 1. Errors and variations in brachytherapy along with the potential of detectability by real-time *in vivo* dosimetry (IVD), real-time imaging (each according to [19,22,23]), and real-time electromagnetic tracking (EMT). The probability of error and the potential effect were reported by Kertzscher *et al.* [23], i.e. only the classification of detectability by real-time EMT and the needed EMT coordinate systems is original in this manuscript. The EMT coordinate systems refer to: «E», the intrinsic coordinate system of the EMT device; «F» fiducial markers visible in imaging and EMT reproducibly placed during each treatment fraction; «A» an absolute cross-calibration between EMT and imaging as, e.g., reported by Bharat *et al.* for transrectal ultrasound and EMT [24]. A schematic drawing of the coordinate system options is shown in Figure 2. (\checkmark) refers to partially applicable

	Quality item		Detectability		EMT coordinate	Error probability and effect [23]

3D Dose reconstruction/delivery

A Concept of Verification in BRT: Computational Verification CoVer

Dose Planned = Dose Delivered ? can not completely be answered w/o incorporating <u>in-situ imaging and 3D-localization techniques</u>! If the *performance* of our BRT-MLC, thus the correct stepping with the correct dwell time pattern (fluence) at the correct geometrical configuration (the analogue of Gantry, Collimator, Couch Set-Up) is the appropriate (planned) can be most probably answered by applying *Computational Techniques*.

Computational, since in BRT we have to compute firstly and on the top issues similar to a DRR, an EPID, or a Fluence profile (the Finger-Print ?), which currently are not part of our standard RTP-procedure (as it is the case in ERT-RTP-Process).

In vivo dosimetry (IVD) has been used in brachytherapy (BT) for decades with a number of different detectors and measurement technologies. However, IVD in BT has been subject to certain difficulties and complexities, in particular due to challenges of the high-gradient BT dose distribution and the large range of dose and dose rate. Due to these challenges, the sensitivity and specificity toward error detection has been limited, and IVD has mainly been restricted to detection of gross errors. Given these factors, routine use of IVD is currently limited in many departments. Although the impact of potential errors may be detrimental since treatments are typically administered in large fractions and with high-gradient-dose-distributions, BT is usually delivered without independent verification of the treatment delivery. This Vision 20/20 paper encourages improvements within BT safety by developments of IVD into an effective method of independent treatment verification. © 2013 American Association of Physicists in Medicine. Key words: in vivo dosimetry, brachytherapy, treatment errors, quality assurance

The "finger print" or the measurable fluence of a treatment

Compute time-resolved information (dose-rate, dose, etc..)

CONCLUSION: Time-resolved in vivo dosimetry can be used to provide geometric information about the treatment progression of afterloading brachytherapy. This information may provide a clear indication of errors and uncertainties during a treatment and, therefore, enables real-time treatment monitoring.

A Concept of Verification in BRT: Computational Verification - Cover

The "finger print" or the measurable fluence of a treatment

(1) Compute time-resolved information (dose-rate, dose, etc..)

that can be considered as the *reference* information for an *on-line* (in-vivo) verification process. This could be the *analogon* to DRR or fluence profile in ERT and could be considered as the "Finger-Print" of the treatment delivery (?):

Abstract

Review pape

Electromagnetic tracking (EMT) is used in several medical fields to determine the position and orientatio ed sensors, e.g., attached to surgical tools. Recently, EMT has been introduced to brachytherapy for implant tion and error detection. The manuscript briefly summarizes the main issues of EMT and error detection in apy. The potential and complementarity of EMT as treatment verification technology will be discussed in in vivo dosimetry and imaging.

BRACHYTHERAPY

Brachytherapy 17 (2018) 94-102

Treatment Delivery Verification in Brachytherapy Assessment of the implant geometry in fractionated interstitial HDR breast brachytherapy using an electromagnetic tracking system

Markus Kellermeier, Rainer Fietkau, Vratislav Strnad, Christoph Bert* Department of Radiation Oncology, Universitätsklinikum Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

PURPOSE: During the partial-breast treatment course by interstitial brachytherapy, electromagnetic tracking (EMT) was applied to measure the implant geometry. Implant-geometry variation, choice of reference data, and three registration methods were assessed.

METHODS AND MATERIALS: The implant geometry was measured in 28 patients after catheter implantation (EMT_{bed}), during CT imaging (EMT_{CT}), and in each of up to n = 9 treatment fractions (EMT_{F(k), k = 1, 2,... n}). EMT_{F(k)} were registered to the planned implant reconstruction (CT_{plan}) by using all dwell positions (DPs), the button centers, or three fiducial sensors on the patient's skin. Variation in implant geometry obtained from EMT_{F(k)} was assessed for EMT_{bed}, EMT_{CT}, and CT_{plan}.

RESULTS: EMT was used to measure 3932 catheters. A duration of 6.5 ± 1.7 min was needed for each implant measurement (mean, 17 catheters) plus setup of the EMT system. Data registration based on the DP deviated significantly lower than registration on button centers or fiducial sensors. Within a registration group, there was a <0.5-mm difference in the choice of reference data. Using CT_{plan} as reference for registration, the mean residual distance of DPs on EMT-derived DPs was found at 2.1 ± 1.6 mm (EMT_{bed}), 1.3 ± 0.9 mm (EMT_{CT}), and 2.5 ± 1.5 mm (EMT_{F(k)}).

CONCLUSIONS: EMT can assess the implant geometry in high-dose-rate interstitial brachytherapy breast treatments. EMT_{bed} , EMT_{CT} , and CT_{plan} data can serve as reference for assessment of implant changes. © 2017 American Brachytherapy Society. Published by Elsevier Inc. All rights reserved.

Fig. 2. Patient in treatment position in the HDR treatment room. The 5DoF implant sensor is manually inserted in each catheter of the implant. EMT is performed using the field generator (FG) and the three 6DoF fiducial sensors on the patient's chest to correct for breathing motion. DoF = degree of freedom; EMT = electromagnetic tracking; HDR = high-dose-rate.

Fig. 3. Example data from Patient ID 20. The data indicate the differences of the registration methods that use (a) all dwell positions (R_{DP} , open circles), (b) the centers of the distal buttons (R_{BC} , filled circles), or (c) the three fiducial sensor positions (FS_1 , diamond; FS_2 , star; and $FS_{sternum}$, square) on the skin for the minimization of the distances between reference data set (blue) and a data set (red) for comparison (here: EMT_{bed}). EMT = electromagnetic tracking; FS = fiducial sensor. (For interpretation of the references to color in this figure legend, the reader is referred to the Web version of this article.)

A Concept of Verification in BRT

Dose Planned = Dose Delivered ? can not completely be answered w/o incorporating <u>in-situ imaging and 3D-localization techniques</u>!

If the *performance* of our BRT-MLC, thus the correct stepping with the correct dwell time pattern (fluence) at the correct geometrical configuration (the analogue of Gantry, Collimator, Couch Set-Up) is the appropriate (planned) can be most probably answered by applying *Computational Techniques*.

Computational, since in BRT we have to compute firstly and on the top issues similar to a DRR, an EPID, or a Fluence profile (the Finger-Print ?), which currently are not part of our standard RTP-procedure (as it is the case in ERT-RTP-Process).

In Vivo Dosimetry (IVD)

Prof. Luc Beaulieu, Ph.D., FAAPM, FCOMP

1- Département de physique, de génie physique et d'optique, et Centre de recherche sur le cancer, Université Laval, Canada

2- Département de radio-oncologie et Centre de recherche du CHU de Québec, CHU de Québec, Canada

Valencia, Spain – Oct 7-10 2018

Disclosures

- I am leading a research effort to develop scintillator-based dosimeters
- I hold patents related to scintillation dosimetry
- My institution has a licensing agreement with Standard Imaging

Learning Objectives

- Context surrounding IVD in brachytherapy.
- Overview of the tools available and use for clinical IVD in brachytherapy.
- Know the key challenges associated with IVD in brachytherapy.
 - ✓ and possible solutions and NextGEN tools...
- Provide a "skeleton framework" to set-up an IVD in your clinic → Pointers

In-Vivo Dosimetry

- Dose measurement(s) performed while the Tx. is proceeding
 - > Within catheters
 - > Intracavity
 - Surface
 - ➢ <u>Not necessarily in real-time</u>...

In-Vivo Dosimetry

"In vivo dosimetry (IVD) is in use in external beam radiotherapy (EBRT) to detect major errors, to assess clinically relevant differences between planned and delivered dose, to record dose received by individual patients, and to fulfill legal requirements"

- In vivo dosimetry in external beam radiotherapy. Mijnheer et al, Med. Phys 2013 (Vision 20/20)

In-Vivo Dosimetry

"The initial motivation for performing IVD in BT was mainly to assess doses to organs at risk (OAR) by direct measurements, because precise evaluation of OAR doses was difficult without 3D dose treatment planning."

- In vivo dosimetry in brachytherapy. Tanderup et al, Med. Phys 2013 (Vision 20/20)

- Prevent, rare but major accidents
 - Brachytherapy procedures are performed without the safeguards of Record and Verify systems.
- Human errors are the main cause of inadequate brachytherapy dose delivery, although mechanical failures occur as well. Examples are:
 - exchanged guide tubes;
 - misadjusted applicators;
 - reconstruction errors;
 - \succ mechanical errors.

• About 1/3 of the reported incidents in this IAEA booklet refer to brachytherapy!

- Planned = delivered ?
 - Learning curve
 - Small number of fractions with increasing doses
 - Organ movement or deformation during treatment delivery
 - Organ swelling (LDR/PDR) or relative organ-catheter motion (HDR – multiple fractions)

- Commissioning of new treatment technique "in vivo" in phantom;
- Quality control of patient treatments;
- Confirmation of delivered dose (proof of good Tx);
- Used for inter-comparisons and audit systems.

• Support for the use of in-vivo dosimetry by (inter-) national bodies

• Legal obligation in many countries

Key questions!

• What do we want to know?

• What do we need to measure?

Incidents in brachytherapy

Uncertainties - Position

- 2mm uncertainty accepted for tip of the needle.
- 0.2mm freedom for the source.
- In total $\Delta pos \approx 2mm$.
- GEC ESTRO survey (2005) 15/18 responded they encountered incidents
 - Incorrect guide tube connection (5 clinics) Position
 - Wrong reconstruction of catheter orientation (tip vs. end) Position
 - Swapped reconstruction of ring and intrauterine applicator Position
 - Uncertain catheter reconstruction Position
 - Wrong catheter length Position
 - Wrong source offset in TPS Position
 - Software bug: wrong definition of template position Position
 - New computer: default dose prescription not updated Dose rate
 - Wrong protocol followed Position
 - Shielding in treatment plan no shielding in treatment Dose/dose rate
 - Shifts (small) of vaginal applicator (due to patient transfer) Position
 - Wrong date change \rightarrow source activity 1 month off Dose rate
 - Mis-typed RAKR value in source certificate by vendor Dose rate
 - Wrong patient in fractionated scheme Position

Most incidents are due to wrong positioning!

On uncertainty, detector position and the like...

Source-Detector Distance "problem"

- 1. Displacement of the dosimeter relative to plan position
 - a) Organ-induced displacement
 - b) Manipulation error (digitization, displacement before measurements...)
- 2. Displacement of source position(s) relative to plan position(s)
 - a) Displacement of one or more catheters or an applicator, including rotation for certain applicators.
 - b) Organ-induced displacement
 - c) Manipulation error (wrong transfer tube connection...)
- 3. Combination of the above two i.e. source and sensor displacements
 - a) Perfectly in sync: no effect on dose measured but effect on dose delivered
 - b) Out of sync
- 4. Organ-related change that does not impact the relative distances but organ dosimetry (e.g. swelling, deformation, ...)

Integrated vs Time-Resolved IVD?

Swap of two needles

High SNR IV Dosimeter

Source Tracking

Source Tracking

- 1 IV dosimeter and at least 3 dwell positions
 ➤ Or 3 dosimeters and 1 dwell positions
 ✓ +1 on a separate line removes solution degeneracies
- Knowledge of source channel: catheter(s) / applicator
- Knowledge of expected dose at the dosimeter position from each dwell position
 - High SNR/SBR dosimeter
 - Energy/temperature/angle independent or corrected
- Express any deviation in measured dose as a positional deviation along the channel axis (Δz) and radial distance from it (Δr)

Source tracking with one point dosimeter

 $\Delta r = \Delta z = 0$

- Δz shifts the curve along the x-axis.
- Δr increases maximum and decreases width.

Results from 20 HDR treatments

 $\Delta r vs \Delta z$ (~300 Needles)

Projections and fits to Gaussian:

 Δr : Mean = 0.19 mm 1SD = 1.1 mm

Johansen J.G. et al. Brachy. 17 122-132 (2018)

 Δz : Mean = 0.34 mm 1SD = 2.0 mm

Results from 20 HDR treatments + 2

 $\Delta r vs \Delta z$ (~300 Needles)

Projections and fits to Gaussian:

- All needles in a single treatment shifted ~70 mm
 - Dosimeter drifted 70 mm

 Δz : Mean = 0.34 mm 1SD = 2.0 mm

Some pointers...

To do before usage!

- Get to know your IVD tool(s)
 - > No dosimeters is perfect
 - Expected performance in controlled conditions
 - Establish the uncertainty budget

Limitations

- Explore characteristics (dependence): energy, angular, temperature, ...
- Detection thresholds (dose, dose rate, known displacements)

To do before usage!

- Plan to use imaging think position(s)
 - IV Dosimeters have no direct relation to patient anatomy.

- Take into account TPS limitation
 - ➢ Use MBDCA if available.

Consider the following:

- Use time-resolved measurements whenever possible
 - ➢ Use more than 1 measurement points if possible
 - Nakano T, Suchowerska N, Bilek M M, McKenzie D R, Ng N and Kron T 2003 High dose-rate brachytherapy source localization: positional resolution using a diamond detector. Phys. Med. Biol. 48 2133–46
 - > Track your IV dosimeters in real-time if possible

Back to our key questions...

• Is IVD really the most appropriate tools for the task(s) you are trying to achieve?

Beaulieu et al.

Ouality item	Typical quality test	Appropriate technology
Source calibration	Independent source calibration in the department	Well chamber
Afterloader source positioning and dwell time (nonpatient specific)	Autoradiography, commissioning of applicators, other source stepping and dwell time QA	 Films (position) Well Chamber (time) Flat Panel (possible for both)
Afterloader malfunction	Unpredictable afterloader malfunction is difficult to target with general QA.	 Real-time feedback IVD Flat Panel
Patient identification	Manual check	Not relevant
Correct treatment plan	Manual check	Checksum and similar independent software validation tools is the more efficient
Intra- and interfraction organ/applicator movement	Reimaging performed just before treatment delivery can in some cases be used to assess organ or tumor dose in image-guided BT.	 For organ motion: real-time imaging if possible Applicator motion: real-time tracking of the applicator or 3D source tracking within the applicator (EM, optical, Flat Panel) IVD could be relevant depending on decoupling between applicator and dosimeters
Applicator reconstruction and fusion errors	Manual check	 IVD relevant to catch error during treatment Pre-delivery or real-time imaging Independent applicator/channel reconstruction technology (e.g. EM tracking)
Applicator length/source- indexer length	Manual check	 IVD relevant to catch error during treatment Flat Panel technology EM tracking (if link to the afterloader drive wire)
Source step size (patient specific)	Manual check	 IVD relevant to catch error during treatment Flat Panel technology
Interchanged guide tubes	Manual check	 IVD relevant to catch error during treatment Flat Panel technology EM tracking (if link to the afterloader drive wire)
Recording of dose	General QA related to dose calculation in the TPS	 IVD only direct mean to measure the real delivered dose Flat Panel (dose engine needed, not direct)

ESTRO School

Table 9.3 Table adapted from Tanderup *et al.* (2013) recast in term of potentially appropriate technology for the test to be performed.

Conclusion

- IVD has a role in brachytherapy
 - Remains the only way to measure the <u>delivered dose</u> to OARs and target.
- Execution in a clinical setting requires a high level expertise and background preparation
 - It is more difficult than measuring S_k using you well chamber!
- Commercial implementation of appropriate tools needed
 - > Tracking
 - Better software (Intelligent, variable action level)

Terminology

Planning aim dose

- Set of dose and dose/volume constraints for a treatment
 - 4 x 7 Gy to D90 to achieve 84 Gy EQD2 to D90 for HR CTV in cervix (EBRT+BT)
 - 145 Gy to D90 for prostate LDR
 - 8 x 4 Gy to D90 for breast APBI

Prescribed dose = reported dose (input dose for dose-response analysis)

Finally accepted treatment plan (which is assumed to be delivered to an individual patient)

Delivered dose = dose that produces observable effect (input effect for doseresponse analysis)

Actually delivered dose to the individual patient 89

Example for fractionated brachytherapy

A center performs 4 fractions with the same treatment plan. The mean prescribed D_{90} is 7 Gy per fraction.

What is the uncertainty in dose delivery due to target volume and OAR changes compared to the treatment plan?

Raw data

Prescribed D_{90} values in Gy

	Fraction 1	Fraction 2	Fraction 3	Fraction 4
Patient 1	7,0	7,0	7,0	7,0
Patient 2	6,5	6,5	6,5	6,5
Patient 3	7,9	7,9	7,9	7,9
Patient 4	6,7	6,7	6,7	6,7
Patient 5	6,8	6,8	6,8	6,8
Patient 6	8,1	8,1	8,1	8,1
Patient 7	7,5	7,5	7,5	7,5
Patient 8	6,4	6,4	6,4	6,4
Patient 9	6,2	6,2	6,2	6,2
Patient 10	7,0	7,0	7,0	7,0

School

Results - Study 1 – Total physical dose The mean prescribed D90 is 28 Gy (4 x 7 Gy) The mean delivered D90 is 28.3 Gy

This means on average a 1 % deviation.

Results - Study 2 – Difference per fraction

The mean difference of prescribed dose and delivered dose

per fraction is

0.1 Gy

This means on average a 1 % deviation.

Results – Study 3 – Difference per fraction

The mean difference of prescribed dose to delivered dose per fraction is 0.1 Gy (1%) systematic uncertainty

> One standard deviation 0.9 Gy (13 %) random uncertainty

Results – Study 4 – Difference in total EQD2

The total prescribed dose including 45 Gy EBRT in EQD2

is

84.2 Gy EQD2

The delivered dose is 84.8 Gy EQD2 <u>Mean difference is 0.6 Gy (< 1%)</u>

Results - Study 5 – Difference in total EQD2

The total prescribed dose including 45 Gy EBRT in EQD2

is

84.2 Gy EQD2

The delivered dose is 84.8 Gy EQD2 <u>Mean difference is 0.6 Gy (< 1%)</u> One standard deviation is 3.5 %

"A substantial reduction of uncertainties in clinical brachytherapy should result in improved outcome in terms of increased local control and reduced side effects. Types of uncertainties have to be identified, grouped, and quantified."

- Comprehensive literature review of uncertainty components in Brachytherapy for different clinical sites, and their relative importance to the combined overall dosimetric uncertainty.
- Examples for gyn, prostate, breast BT that can be used as templates for future dose and uncertainty reporting.

Need for common terminology

Errors

- Mainly resulting in systematic deviations
 - Wrong source strength in afterloader unit
 - Wrong offset for applicator tip to first dwell position
 - Wrong catheter connections, etc...

Need for common terminology

Uncertainties

- Type A (statistical)
- Type B (everything else)

Analyze and present systematic effects (target volume shrinkage, edema causing applicator shifts)

Analyze and present normally distributed effects (random catheter shifts, reconstruction with finite slice thickness)

Need for common terminology

Variations

- Known effects which can be predicted.
 - E.g. bladder filling can have an impact on dose to bladder or bowel
 - Prostate swelling influences the D90 if the variations over time are known the delivered dose can be predicted

Systematic set-up uncertainties

- Same error in every fraction
- Examples
 - Incorrect reconstruction procedures (source path commissioning)
 - Systematic misinterpretation of images

Random set-up uncertainties

- Different in every fraction
- Visibility of applicator (dependent on slice thickness)
- Uncertainties of image fusion
- Pronounced in longitudinal direction (perpendicular to slice orientation)

Berger et al. 2009, R&O 93

Hellebust et al 2007, PMB 52

3 + 3

Nesvacil et al. 2013, Radiother Oncol 107

Multicenter Center study of inter-/intrafraction variations for target and OARs in cervix BT

	ΔD_{2cm^3} between 2 acquisitions [%] (fixed plan, variable anatomy)								∆ D ₉₀ [%] (fixed plan, variable anatomy)			
	bladder rectum					sigmoid/bowel			HR CTV			
	Mean	median	SD	mean	median	SD	mean	median	SD	mean	median	SD
total	2.7	1.5	20.3%	4.5	4.1	22.0%	1.6	-0.9	26.8%	-1.1	-1.7	13.1%
Intraaplication	1.3	1.5	17.7	3.8	2.3	20.5	-2.3	-3.7	23.5	-2.5	-4.3	10.8
interapplication	3.9	0.0	22.3	5.8	5.2	23.2	6.8	3.7	30.2	0.4	-0.8	15.1

Random uncertainties (1SD) of physical dose per BT fraction can be

- ~ 10% for HR CTV D90
 - (contouring uncertainty (Petric, Hellebust R&O 2013))
- $\sim 20\%$ for bladder, rectum D_{2cm^3}
- ~ 30% for sigmoid $D_{\rm 2cm^3}$

No correlation with time between images was detected!

<u>Conclusion</u>: As long as there is no direct imaging and dose reporting at the time of irradiation (online imaging, verification), we have to expect 20-30% dosimetric uncertainty for D_{2cm^3} for OARs for each fraction, between prescribed and delivered dose.

"A substantial reduction of uncertainties in clinical brachytherapy should result in improved outcome in terms of increased local control and reduced side effects. Types of uncertainties have to be identified, grouped, and quantified."

- Comprehensive literature review of uncertainty components in Brachytherapy for different clinical sites, and their relative importance to the combined overall dosimetric uncertainty.
- Examples for gyn, prostate, breast BT that can be used as templates for future dose and uncertainty reporting.

Example for HDR intracavitary Cervix brachytherapy – per fraction

Category	Optimum level	Assumptions
Source strength	2%	PSDL traceable calibrations
Treatment planning	3%	Reference data with the appropriate bin width is used
Medium dosimetric corrections	1%	Applicator without shielding and CTV inside pelvis (concerning for scatter)
Dose delivery including registration of applicator geometry to anatomy	4%	Accurate QA concept for commissioning and constancy checks, especially for source positioning and applicator/source path geometry, appropriate imaging techniques, applicator libraries
Interfraction/Intrafraction changes	11%	For one treatment plan per applicator insertion but several subsequent fractions – check for major deviations in subsequent fractions

Total dosimetric uncertainty for one single fraction

Difference on uncertainty per fraction to uncertainty for total dose

For normal distributions the number of subsequent

fractions (observations) results in compensation of

variations

 $1 / \sqrt{N}$

including constant EBRT results in

1 / 2

So 13% per fraction can be 3.5% for total dose

Example for HDR intracavitary Cervix brachytherapy – total dose 4 fractions

Category	Optimum level	Assumptions
Source strength	2%	PSDL traceable calibrations
Treatment planning	3%	Reference data with the appropriate bin width is used
Medium dosimetric corrections	1%	Applicator without shielding and CTV inside pelvis (concerning for scatter)
Dose delivery including registration of applicator geometry to anatomy	$\frac{1 / \sqrt{N}}{2\%}$	Accurate QA concept for commissioning and constancy checks, especially for source positioning and applicator/source path geometry, appropriate imaging techniques, applicator libraries
Interfraction/Intrafraction changes	$\frac{1 / \sqrt{N}}{11\%}$	For one treatment plan per applicator insertion but several subsequent fractions –
Total dosimetric uncertainty for entire BT	7%	

Example for LDR prostate brachytherapy

Category	Optimum level	Assumptions
Source strength	3%	PSDL traceable calibrations
Treatment planning	4%	Reference data with the appropriate bin width is used
Medium dosimetric Corrections	5%	A general prostate tissue is considered, but no consideration is given for calcifications (or their composition) in the patient
Inter-seed attenuation	4%	An advanced dose calculation formalism may indicate source models and orientations cause the largest effects
Treatment delivery imaging	2%	US QA performed according to AAPM TG-128
Anatomy changes between dose delivery and post-implant imaging	7%	Post-implant (day 0) imaging using CT, with a scalar correction factor for edema correction

Total dosimetric uncertainty 11%

Example for US-based HDR prostate brachytherapy

Category	Optimum level	Assumptions
Source strength	2%	PSDL traceable calibrations.
Treatment planning	3%	Reference data with the appropriate bin width.
Medium corrections	1%	Full scatter conditions in the pelvic region and for the prostate location are assumed.
source positioning accuracy	2%	Assuming usage of dedicated catheter reconstruction tools (0.7 mm) and 1.0 mm source positioning accuracy
US-imaging overall effect	2%	US QA performed according to AAPM TG-128 report.
Changes of catheter geometry	y 2%	Assuming that new image acquisition and treatment plan calculation before each fraction.
Total dosimetric uncertainty	5%	For treatment delivery without patient movement and changes in the lithotomic set- up and with the US probe at the position of the acquisition

Example for HDR ¹⁹²Ir BT source for breast balloon applicator

Category	Optimum level	Assumptions
Source strength	2%	PSDL traceable calibrations.
Treatment planning	3%	Reference data with the appropriate bin width.
Medium dosimetric correct	ions 3%	Balloon filled with standard level of contrast agent, no consideration or composition of chestwall, lung, or breast.
Scatter dosimetric correctio	ons 7%	A non-scalar correction for skin dose is needed, and will require an advanced dose calculation formalism to properly account for radiation scatter conditions in the patient.
Dose delivery including reg	gistration	
of applicator geometry to a	natomy 7%	Accurate QA concept for commissioning and constancy checks, especially for source positioning and applicator/ source path geometry, appropriate imaging techniques (either small slice thickness, 3D sequences or combination of different slice orientations), applicator characterization.

Example for HDR ¹⁹²Ir BT source for breast balloon applicator

Category	Optimum level	Assumptions
Interfraction/Intrafraction cha between imaging and dose de	inges livery 7%*	For one treatment plan per applicator insertion and measures to detect major variations for subsequent fractions.
Total dosimetric uncertainty	13%	For treatment delivered with the same BT source.

*Estimated value based on expert discussion

Dosimetric uncertainties and dose-response relationships

Schematic illustration of the effect of dosimetric ucertainties of prescribed vs. delivered dose on response probabilities

Tanderup et al. 2013, Radiother Oncol 107 School

Radiotherapy

estro

Translating random uncertainties to EQD2: single fraction dose

The effect on the total treatment dose depends on the fractionation scheme! The PDR uncertainties per pulse are currently unknown because of low time resolution of observations.

Translating random uncertainties to EQD2:

e.g. n~500 with same prescribed dose and SD 30% / fx: mean of delivered doses $\langle d_{EOD2} \rangle$ from 500 patients \rangle prescribed dose in EQD2

 $\begin{array}{l} d_{abs} \ldots \ldots \ prescribed \ dose \ (Gy) \\ d_{EQD2} \ldots \ldots \ d_{abs} \ converted \ to \ (Gy \ EQD2) \\ \\ \Delta d \ \ldots \ e.g. \ 30\% \ d_{abs} \ (Gy) \\ \\ d_{abs}^{-/+} \ldots \ prescribed \ dose \ -/+ \ \Delta d \ (Gy) = delivered \ dose \ in \ Gy \\ \\ d_{EQD2}^{-/+} \ldots \ d_{abs}^{-/+} \ converted \ to \ Gy \ EQD2 \\ \\ \\ d_{abs} - \ d_{abs}^{-} = \ d_{abs}^{+} - \ d_{abs} \qquad d_{EQD2}^{-} - \ d_{EQD2}^{+} - \ d_{EQD2} \\ \end{array}$

Dose-response relationships (published examples for cervix BT)

urinary bladder G2-4: Georg et al. 2012, IJROBP 82

rectum G2-4: Georg et al. 2012, IJROBP 82

Relationship between EBRT-C+BT dose and local control from retroEMBRACE patients (*Tanderup et al, GEC-ESTRO workshop, Brussels, 2013*)

Other OARs for cervix: sigmoid, vagina, and upcoming dose response curves from EMBRACE study (www.embracestudy.dk)

Clinical outcome reports for prostate: e.g. *Martinez A. et al.* 2011 *IJROBP 79, Ghilezan et al.* 2012, *IJROBP 83, Martinez E. et al.* 2015, *Brachytherapy 14, ...*

Dose response for breast (APBI): e.g. Herskind & Wenz ESTRO Strahlentherapie und Onkologie 186

Effect of uncertainties on observed dose response relationships

Comparison of model dose response curve (based on published curves, see previous slides), and simulated "observed" dose response curves assuming different systematic and random uncertainties.

Example: systematic uncertainties for target

effect of systematic underestimation of target D_{90} on observed dose-response

Systematic 1.5 mm applicator reconstruction uncertainty for MRI- based cervix BT (*Tanderup et al.*, *R&O 2008*):

e.g. $\Delta D90 \le +3\%/fx =>$,,observed" local control @85 Gy <1% higher than model prediction

Systematically larger contours on CT vs. MRI => underestimation of D90 by CT contours (*e.g. Viswanathan et al. 2007, IJROBP 68*):

- e.g. i) $\Delta D_{90} = +10\%/fx => 2\%$ overestimation of local control @ 85 Gy
 - ii) $\Delta D_{90} = +20\%/fx => 3.5\%$ overestimation of local control @ 85 Gy

(model based on preliminary retroEMBRACE data: Tanderup et al, GEC-ESTRO workshop, Brussels, 2013)

Example: random uncertainties for target + OAR

effect of random intra-/interfraction variation on D₉₀, D_{2cm³} and dose-response

Example: 75Gy, random variation of rectum D_{2cm³}:

- $\Delta D_{2cm^3} = \pm 10\%/fx \rightarrow observed NTCP 7.5\%$ (vs 7.3% model prediction)
- ΔD_{2cm³} = ±20%/fx -> observed NTCP 8.9 %
 ΔD_{2cm³} = ±30%/fx -> observed NTCP 10.5 %
 Model predicts 10.5% morbidity NTCP @ 80Gy EQD2!

For target – differences in TCP < 0.5%

Example: influence of the number of BT Fx Random uncertainties and dose response for different fractionation schemes

Example: random uncertainty $\Delta D_{2cm^3} = \pm 20\%/fx$:

- nFx=5 => observed morbidity @75Gy 8.5%
- nFx=4 => observed morbidity @75Gy 8.9%
- $nFx=3 \Rightarrow observed morbidity @75Gy 9.4\%$
- nFx=2 => observed morbidity @75Gy 10.3%
 nFx=1 => observed morbidity @75Gy 12.3%

For target: using 1 fx vs 2-5 fx results in ~0.5% lower response probability than predicted by model

Difference between models and simulated (TCP and NTCP) dose-response

	dose	systematic		random			
	$(Gy EQD2_{\alpha/\beta=10Gy})$	U _s 5%	U _r 10%	U _r 20%			
ΔΤCΡ	75	1.0%	-0.1%	-0.3%			
	90	0.8%	-0.1%	-0.3%			
	$(Gy EQD2_{\alpha/\beta=3Gy})$	U _s 5%	U _r 10%	U _r 20%	U _r 30%		
Δ ΝΤCΡ	65	0.5%	0.1%	1.1%	2.3%		
	75	1.4%	0.2%	1.6%	3.2%		

"Can reduction of uncertainties in cervix cancer brachytherapy potentially improve clinical outcome?" Nesvacil et al. 2016, submitted to R&O

Increasing OAR dose constraints by reducing uncertainties

total dose in Gy EQD2 ($\alpha/\beta=3$ Gy)

If uncertainty can be reduced by 10%, clinicans could think about relaxing their dose constraint.in this case

ESTRO

Nesvacil et al. 2016, R&O

TAKE HOME MESSAGES

- Investigate your uncertainty budgets for your specific clinical workflows and report them
- Clinical impact depends on dose level (EQD2, α/β) and shape of the dose-response curve
- Observed dose-response curves in the literature are subject to (unreported) uncertainties
- Uncertainty reduction can help in individual cases near OAR dose limits and below target planning aims

TAKE HOME MESSAGES

- reducing random uncertainties can change the slope of the dose-response relationship observed in a patient cohort
 - Online image-based treatment delivery verification (reduce time between treatment simulation and treatment)
 - Advanced in vivo treatment dose verification
- reduction of large systematic uncertainties should be a goal for OAR and target structures
 - Contouring uncertainties
 - Large dose calculation uncertainties (see Luc's presentation on clinical outcome vs. dose calculation algorithm)
 - Systematic OAR filling changes during treatment (filling protocols!)

Impact of geometrical uncertainties in extreme hypo with brachytherapy

Intraaplication												
interapplication												

No correlation with <u>time</u> between images was detected! Random inter-intrafraction uncertainties (1SD) of absorbed dose can be

- ~ 10% for HR CTV D90 / fx
- ~ 20% for bladder, rectum D_{2cm^3}/fx
- ~ 30% for sigmoid D_{2cm^3} / fx

Translating random uncertainties to EQD2:

e.g. n~500 with same prescribed dose and SD 30% / fx: mean of delivered doses $\langle d_{EOD2} \rangle$ from 500 patients \rangle prescribed dose in EQD2

 $\begin{array}{l} d_{abs} \ldots \ldots \ prescribed \ dose \ (Gy) \\ d_{EQD2} \ldots \ldots \ d_{abs} \ converted \ to \ (Gy \ EQD2) \\ \\ \Delta d \ \ldots \ e.g. \ 30\% \ d_{abs} \ (Gy) \\ \\ d_{abs}^{-/+} \ldots \ prescribed \ dose \ -/+ \ \Delta d \ (Gy) = delivered \ dose \ in \ Gy \\ \\ d_{EQD2}^{-/+} \ldots \ d_{abs}^{-/+} \ converted \ to \ Gy \ EQD2 \\ \\ \\ d_{abs} - \ d_{abs}^{-} = \ d_{abs}^{+} - \ d_{abs} \qquad d_{EQD2}^{-} - \ d_{EQD2}^{+} - \ d_{EQD2} \\ \end{array}$

Dosimetric uncertainties and dose-response relationships

Schematic illustration of the effect of dosimetric ucertainties of prescribed vs. delivered dose on response probabilities

Tanderup et al. 2013, Radiother Oncol 107 School

Radiotherapy

estro

Dose-response relationships (published examples for cervix BT)

urinary bladder G2-4: Georg et al. 2012, IJROBP 82

rectum G2-4: Georg et al. 2012, IJROBP 82

Relationship between EBRT-C+BT dose and local control from retroEMBRACE patients (*Tanderup et al, GEC-ESTRO workshop, Brussels, 2013*)

Other OARs for cervix: sigmoid, vagina, and upcoming dose response curves from EMBRACE study (www.embracestudy.dk)

Clinical outcome reports for prostate: e.g. *Martinez A. et al.* 2011 *IJROBP 79, Ghilezan et al.* 2012, *IJROBP 83, Martinez E. et al.* 2015, *Brachytherapy 14, ...*

Dose response for breast (APBI): e.g. Herskind & Wenz ESTRO Strahlentherapie und Onkologie 186

Effect of uncertainties on observed dose response relationships

Comparison of model dose response curve (based on published curves, see previous slides), and simulated "observed" dose response curves assuming different systematic and random uncertainties.

Example: systematic uncertainties for target

effect of systematic underestimation of target D_{90} on observed dose-response

Systematic 1.5 mm applicator reconstruction uncertainty for MRI- based cervix BT (*Tanderup et al.*, *R&O 2008*):

 $\Delta D90 ≤ +3\%/fx =>$,,observed" local control @85 Gy <1% higher than model prediction

Systematically larger contours on CT vs. MRI => underestimation of D90 by CT contours (*e.g. Viswanathan et al. 2007, IJROBP 68*):

- e.g. i) $\Delta D_{90} = +10\%/fx => 2\%$ overestimation of local control @ 85 Gy
 - ii) $\Delta D_{90} = +20\%/fx => 3.5\%$ overestimation of local control @ 85 Gy

(model based on preliminary retroEMBRACE data: Tanderup et al, GEC-ESTRO workshop, Brussels, 2013)

Example: random uncertainties for target + OAR

effect of random intra-/interfraction variation on D₉₀, D_{2cm³} and dose-response

Example: 75Gy, random variation of rectum D_{2cm³}:

- $\Delta D_{2cm^3} = \pm 10\%/fx \rightarrow observed NTCP 7.5\%$ (vs 7.3% model prediction)
- ΔD_{2cm³} = ±20%/fx -> observed NTCP 8.9 %
 ΔD_{2cm³} = ±30%/fx -> observed NTCP 10.5 %
 Model predicts 10.5% morbidity NTCP @ 80Gy EQD2!

For target – differences in TCP < 0.5%

Example: influence of the number of BT Fx Random uncertainties and dose response for different fractionation schemes

Example: random uncertainty $\Delta D_{2cm^3} = \pm 20\%/fx$:

- nFx=5 => observed morbidity @75Gy 8.5%
- nFx=4 => observed morbidity @75Gy 8.9%
- $nFx=3 \Rightarrow observed morbidity @75Gy 9.4\%$
- nFx=2 => observed morbidity @75Gy 10.3%
 nFx=1 => observed morbidity @75Gy 12.3%

For target: using 1 fx vs 2-5 fx results in ~0.5% lower response probability than predicted by model

Strategies to reduce uncertainties for brachytherapy planning and treatment

- Organ filling protocols
- Optimize target contouring (MRI, US, ...)
- Adaptive planning to reduce large systematic/random variations between fractions (online planning, plan of the day)
- Advanced in vivo dosimetry (dose rate time profiles)
- Online imaging in treatment room (comparable to CBCT in EBRT) limited by infrastructure of the BT suite (imaging in treatment room)
 - CBCT, in-room MRI/CT, 3D ultrasound, ...

Conclusions

- Extreme hypo with BT bears large dosimetric uncertainties, and benefits from high target dose per fraction: flat part of dose response curve is less sensitive to uncertainties in dose
- Future development of BT fractionation schemes should take into account
 - Existing/missing knowledge about dose response relationships
 - For target and OARs!
 - Existing/missing knowledge about uncertainty budget of the specific treatment technique and workflow
 - All these combined will help to improve safety of predicting the optimal therapeutic window

Elements for a Quality Management Program in Brachytherapy

Prof. Mark J. Rivard, Ph.D., FAAPM

Advanced Brachytherapy Physics, 29 May – 1 June, 2016

Disclosures

The are no conflicts-of-interest to report.

Opinions herein are solely those of the presenter, and are not meant to be interpreted as societal guidance.

Specific commercial equipment, instruments, and materials are listed to fully describe the necessary procedures. Such identification does not imply endorsement by the presenter, nor that these products are necessarily the best available for these purposes.

Special thanks is extended to Bruce Thomadsen as the source for many of the slides in this presentation.

Learning Objectives

- 1. Definitions, terminology, and accepted nomenclature
- 2. Pre-purchase preparations and installation
- 3. Acceptance testing requires formalization
- 4. Commissioning a brachytherapy program
- 5. Example forms for clinical practice

QMP Schema

QMP Presentation Focus

QMP Philosophy

• Devise the QMP mission

patients will be treated safely, accurately, and efficiently as defined by Rx, regulations, and societal standards

equipment + patient + staff + culture = success

Shewhart: Father of Statistical Quality Control

Walter Andrew Shewhart (1891–1967)

1917: Ph.D. in Physics, University of California, Berkeley

- 1918: Joined Western Electric Company (supplier to AT&T)
- 1924: Invented the Control Diagram

1924-1932: Initiated study on sensitivity of worker productivity to light Improvements were later attributed to management attention

Deming: Father of PDSA

William Edwards Deming (1900–1996)

1926: Ph.D. in Mathematical Physics, Yale University

1927: Employed by USDA and met Walter Shewhart Applied statistics to industrial production methods

A system must be managed. It will not manage itself.

1943: Deming Cycle
Plan or design an experiment
Do the experiment by performing the steps
Study the results by analyzing the information
Act on decisions based upon the analyzed results

Fault Tree Analysis

Developed in 1961 at Bell Laboratories by H. A. Watson

Launch Control Safety Study for Intercontinental Ballistic Missile

Translation of system failure behavior into visual diagram and logic model

Visual model portrays system relationships and root cause pathways

Logic model provides qualitative & quantitative system evaluation

Utilizes Boolean algebra and probability theory

FTA popularized by US tragedies: Apollo 1 fire (1967), Three Mile Island nuclear meltdown (1979), Space Shuttle Challenger (1986)

FTA provides top-down risk assessment, FMEA is a bottom-up approach

First Known Paper on Brachytherapy Risk Analysis

Intl. J. Radiation Oncology, Biology, Physics

Analysis of treatment delivery errors in brachytherapy using formal risk analysis techniques

Purpose: To identify hazardous situations in treatments, analyze the nature of errors committed, and assess the value of several analysis techniques.

Methods and Materials: The study applied several risk analysis techniques to brachytherapy events (misadministrations) reported to the U.S. Nuclear Regulatory Commission and the International Atomic Energy Agency.

Results:

- (1) Events usually have multiple causes.
- (2) Failure to consider human performance in the design of equipment led to a large fraction of the events.
- (3) Verification procedures often were ineffectual.

(4) Many events followed the failure of persons involved to detect that the situation was abnormal, often even though many indications pointed to that fact. Once the event was identified, the response often included actions appropriate for normal conditions, but inappropriate for the conditions of the event.

- (5) Events tended to happen most with actions having the least time available.
- (6) Lack of training and procedures covering unusual conditions frequently contributed to events.
- (7) New procedures or new persons joining a case in the middle present increased hazards.

Conclusion: Risk analysis tools common in industry provide useful information for error reduction in medical settings, although not as effectively, and modification of such techniques could improve their efficacy.

Thomadsen, et al, Intl. J. Radiat. Oncol., Biol., Phys. 57, 1492-1508 (2003)

Numerous Opportunities for Errors

Table 3. Summary of the branches of the fault tree for high-dose-rate brachytherapy misadministrations, tracing backward to the initiating errors, with the frequency of errors along each branch indicated

Result of error	Major process	General category	Subcategory	Type of initial error
Wrong dose distribution or site 0.98 (43/44)	Treatment planning error 0.30 (13/44)	Localization 0.07 (3/44)		Improper simulation: >Marker misinterpretation 0.05 (2/44) Digitization error: >Entry error: Localization 0.07 (3/44) ≫Digitization not follow protocol 0.02 (1/44) Calculation error: >Wrong input data 0.02 (1/44)
		Dosimetry error 0.23 (10/44)	Source strength 0.07 (3/44)	Erroneous source strength data: >Failure to enter or alter data 0.07 (3/44)
			Dose calculation 0.16 (7/44)	Incorrect data entry (or (r)) Incorrect data entry for calculation 0.02 (1/44) Wrong dose: >Incorrect dose entry 0.05 (2/44) Wrong position of dose distribution: >Inaccurate source position entry 0.05 (2/44) Dose specified to the wrong point 0.05 (2/44)
	Treatment implementation 0.68 (30/44)	Applicator shifted in patient 0.07 (3/44)	Applicator shifts >Patient movement ≫Failure of securing mechanism 0.07 (3/44)	Poor techniques 0.05 (2/44) Equipment failure 0.02 (1/44)
		Applicator connection 0.05 (2/44)	Incorrect guide tubes 0.02 (1/44) Wrong channel 0.02 (1/44)	Applicator connected to through the wrong transfer tube type 0.02 (1/44) Applicator connected incorrectly 0.02 (1/44)
		Treatment programming error 0.48 (21/44)	Manual programming error 0.48 (21/44)	Transcription error $0.41(17/44)$
		Treatment delivery error: >Source fails to progress	Drive mechanism fails 0.05 (2/44)	Interpretation error 0.07 (3/44) Mechanical malfunction 0.02 (1/44) Kink in catheter 0.02 (1/44)
0.10 (4/44) Wrong patient treated 0.02 (1/44)		Source disconnect 0.05 (2/44)

Recent Paper on Brachytherapy FMEA

Failure modes and effects analysis applied to high-dose-rate brachytherapy treatment planning

D. Allan Wilkinson*, Matthew D. Kolar

Department of Radiation Oncology, Cleveland Clinic, Cleveland, OH

PURPOSE: To apply failure modes and effects analysis to high-dose-rate treatment planning to identify the most likely and significant sources of error in the process.

METHODS: We have made a list of 25 failure modes grouped into six categories (imaging, catheter reconstruction, dwell position activity, dose points/normalization, optimization/dose, and evaluation). Each mode was rated on a one to five scale for severity, likelihood of occurrence, and probability of escaping detection. An overall ranking was formed from the product of the three scores. The authors assigned scores independently and the resulting rankings were averaged. We also analyzed 44 reported medical events related to high-dose-rate treatment planning listed on the Nuclear Regulatory Commission Web site and compared them with our own rankings.

RESULTS: Failure modes associated with image sets, catheter reconstruction, indexer length, and incorrect dose points had the highest ranking in our analysis (scores higher than 20). The most often cited failure modes in the Nuclear Regulatory Commission reports examined were indexer length (20/44) and incorrect dose points (6/44). Several of our high-ranking modes are not associated with reported events.

CONCLUSION: It is a useful exercise to identify failure modes locally and analyze the efficacy of the local quality assurance program. Comparison with nationally reported failures can help direct the local analysis, but the absence or small number of reports for failure modes with a high score may be owing to low detectability. Such modes obviously cannot be ignored. © 2013 American Brachytherapy Society. Published by Elsevier Inc. All rights reserved.

Key Concepts

- Quality Management Program (QMP)
 - ALL activities designed to contribute to process quality
- Quality Assurance (QA) non-patient tests
 - activities that **measure the quality level** of a process
- Quality Control (QC) patient treatment checks
 - activities that force specific qualities onto a process

Quality Controls vs. Quality Assurance

ISO 900X and Quality Management

ISO 9000

A series of standards that define, establish, and maintain an effective QA system for manufacturing and service industries.

ISO 9001

Requirements for organizations wishing to meet the ISO 9000 standard

Reported benefits

- 1. Improve efficiencies and effective operations
- 2. Increases customer satisfaction and retention
- 3. Reduces audits
- 4. Enhances marketing
- 5. Improves employee motivation, awareness, and morale
- 6. Promotes international trade
- 7. Increases profit
- 8. Reduces waste and increases productivity
- 9. Common tool for standardization

Appropriate for large scale industries, not individual clinics

Learning Objectives

1. Definitions, terminology, and accepted nomenclature

2. Pre-purchase preparations and installation

- 3. Acceptance testing requires formalization
- 4. Commissioning a brachytherapy program
- 5. Example forms for clinical practice

Pre-Installation Preparations

- Assist administrators to create a realistic business plan
 - prepare for reimbursement fluctuations
 - include QA equipment and dummy markers
 - budget for regular training for new staff and facility upkeep
- Plan disease site(s): GYN, breast, prostate, skin, etc.
 - consider future potential for treating additional disease sites
 - balance desires for growth with a dash of realism
- Review potential manufacturer system specifications, installation requirements, and clinical integration
- RAU-to-R&V connectivity is available with newer systems

Pre-Installation Preparations

- Physical layout
 - location of electrical/telephone/network connections, interconnectivity with linac interlocks, special gases, closed loop AV system
 - consider imaging proximity and position RAU near imaging (dept CT, US, MRI?) or OR, maybe not in RadOnc center proper
- Regulatory aspects
 - vault design (primary/scatter/maze/door) ala NCRP 147/151/155, acceptable exposure levels, workflow
 - enhanced security measures, source controls, staff bkgnd checks
 - approval for *n* sources and max individual/total Ci (not RAKR)
 - broadscope license need not name individuals
- Visit established centers, contact colleagues, phone a friend

Learning Objectives

- 1. Definitions, terminology, and accepted nomenclature
- 2. Pre-purchase preparations and installation
- 3. Acceptance testing requires formalization
- 4. Commissioning a brachytherapy program
- 5. Example forms for clinical practice

Acceptance Testing: General

- Acceptance testing results set baseline for clinical use
- Usually no formal ATP form as for linacs
- Performance evaluation of system within manu. specs
- Re-perform annually to ensure system stability

Acceptance Testing: Applicators & Source

- Make electronic inventory of all hardware and disposables
- Applicators
 - confirm dimensions and serial numbers
 - confirm applicator shielding magnitude and shape
 - check connecting tubes and other ancillary equipment
- Source
 - validate source-to-dummy marker coincidence
 - superposition: transmission radiograph & autoradiograph
 - use electronic imaging tools if no radiochromic film
- Determine source strength (covered on Day 3)

Acceptance Testing: TPS

- AAPM TG-53 and TG-43 reports are good resources
- Verify functionality of dose, dwell time, and Tx time calculations
- High-level check of single-source isodose distributions
- Understanding of plan rotation matrix and coordinate recon

Acceptance Testing: TPS

- Accuracy of electronic data transfer to TCS/RAU
- Evaluate optimization software
 - develop reference dataset for accuracy & constancy
- DVH and implant figures of merit
- End-to-end testing
 - general functionality of entire system
 - identify QMP weaknesses by using items incorrectly

ideas courtesy of Bruce Thomadsen

Acceptance Testing: General

- Field service engineer provides system familiarization
- Test all components and features the time is now
- Ignore pressure to hurry and sign form
- Technical understanding of equipment is your responsibility

Learning Objectives

- 1. Definitions, terminology, and accepted nomenclature
- 2. Pre-purchase preparations and installation
- 3. Acceptance testing requires formalization
- 4. Commissioning a brachytherapy program
- 5. Example forms for clinical practice

References for Brachytherapy Commissioning

- Consider AAPM Task Group Reports and Guidance
 - TG-41 Remote Afterloading Technology (1993)
 - TG-43 Brachytherapy Dosimetry Formalism (1995)
 - TG-56 Code of Practice for Brachytherapy (1997)
 - TG-59 High Dose Rate Tx Delivery (1998)
 - AAPM/ESTRO HEBD Report #229 (2012)
- Consider AAPM Summer School texts
 - 1994 Chapters 28, 30, 31, 32
 - 2005 Chapters 6, 7, 11, 22, 32, 48
- Consider Bruce Thomadsen's 1999 text
 "Achieving Quality in Brachytherapy"

Commissioning: General

- Medical Event notification plan and action levels
- Patient/personnel radiation safety plan
- Patient positioning standards and contingencies
- Use of dummy markers, contrast agents, and imaging system settings to visualize disease/applicator/markers
- Form creation
 - WD (disease-site specific)
 - daily QA (performed by therapist under physicist supervision)
 - Tx runsheet QC
 - new source QA (TPS backup, TCS backup)
 - annual QA, rigorously check applicators and TPS data

Commissioning: General

- Establish disease-specific clinical standards to minimize "medical arts" and to follow ABS/ESTRO guidelines
- Create policies-and-procedures, have staff read, provide feedback, and document understanding (annually)
- Establish workflow for all processes: identify tasks, frequency, needed resources, responsible party(s)
- Develop safety standards and clinic-specific FMEAs, share results with all stakeholders
- Staff training on HDR system (RAU, applicators, and TPS) usage, emergency procedures, and common expectations

Commissioning: RAU

- Master all aspects of TCS functionality
- Document logic chain of RAU safety interlocks
- Determine timer linearity
- Understand emergency buttons, warnings, and error codes
- Demonstrate well chamber stability

Commissioning: Source

- Absorbed dose measurements not performed in the clinic
 - detector response sensitive to photon spectrum
 - dose falloff sensitive to medium composition
 - influence of positioning, attenuation, and scatter
 - no AAPM protocol for absorbed dose measurements
- Source form, inventory, wipe test documentation
- Understand eBT output variations for same source model

Commissioning: Source

- Validate source/dummy marker coincidence
- Source positional accuracy
- eBT source output stability
 - overall / global
 - spatial dependence (spectral changes)
- Demonstrate well chamber stability

Source Strength Measurements

- All HDR ¹⁹²Ir sources can have RAKR measured by physicist
- Using PSDL traceably-calibrated equipment for RAKR measurement
- For the eBT sources, only the Axxent has direct traceability to PSDL
- INTRABEAM and esteya sources do not yet have direct traceability
 - physicist may use AAPM TG-61 calibration method if they know the electron scatter/absorber thickness and the HVL for their device

Commissioning: Applicators

- Inventory all applicators
- Document sterilization procedures/responsibilities
- Determine intra-applicator source positioning
- Determine source/marker congruence in applicator

Commissioning: Applicators

- Validate dimensions (c.f., TPS applicator library info)
- Applicator performance evaluation (e.g., T&R)
- Confirm applicator/marker compatibility
- Establish standard imaging protocols (Day 2)

Commissioning: TPS

- Establish dose calc methods
 - imaging slice thickness, dummy marker usage, step size, optimization type and parameter ranges
- Compare TPS TG-43 dosimetry parameters to reference dataset or publication(s)
- Compare TPS dose calcs to TG-43 hand calcs
 - devise independent (secondary) dose calculation method
 - MBDCA covered on Day 1
- Commission source over required radii and polar angles

Commissioning: TPS

- AAPM TG-53 and TG-43 reports are good resources
- Evaluate data transfer between TPS and TCS/RAU
- Compare system performance range with TPS data
- Recommission TPS following all upgrades
- For advanced dose calculation modules, read carefully the TG-186 report for specific commissioning tasks (Day 1)

Commissioning: TPS

eBT Commissioning Specifics

- Consider AAPM Task Group Reports and Guidance TG-43 Brachytherapy Dosimetry Formalism TG-56 Code of Practice for Brachytherapy TG-59 High Dose Rate Tx Delivery TG-182 Recommendations on eBT Quality Management 2008 AAPM (Butler *et al.*) Low-energy Source Calibrations 2008 ASTRO Emerging Technology Cmte: Electronic Brachytherapy
- Need comparisons of measured and calculated dose distributions, and consensus datasets
- HDR breast commissioning by Hiatt et al. JACMP (2008)

Learning Objectives

- 1. Definitions, terminology, and accepted nomenclature
- 2. Pre-purchase preparations and installation
- 3. Acceptance testing requires formalization
- 4. Commissioning a brachytherapy program
- 5. Example forms for clinical practice

Philosophy on Forms

- Forms should be dynamic, constant improvements
- Use electronic forms, minimize paper usage (scan the paper!)
- Use mathematical tools (e.g., Excel) for non-patient data
- Data mining permits analysis across broad timescales
- Consider action levels beyond societal guidance
- Take high-level perspective on why to perform QA tasks

Example Daily HDR ¹⁹²Ir QA Form (upper)

Nucletron V2 MicroSelectron Remote Afterloader, Model # 105.088-03 Serial # 31743 Source is manufactured by QSA Global, model 105.002.

On each treatment day, the treating therapist will test the following system components and initial at the right indicating that the test was performed and that the result was within normal ranges. Any deviations must be promptly reported to a physicist.

1. Are the TV monitors at the control console operational (focus/zoom/pan)?

2. Is the intercom operational (2-way communications)?

3. Does the radiation survey meter function (battery check)?

4. Is the emergency basket stocked and the emergency storage container in place? [forceps/tongs, scissors, suture removal kit, and "CAUTION RADIATION AREA" tape]

5. Are the source guide tubes free of kinks, etc?

6. Did control console pass self-diagnostic checks when key switch is first turned?

7. Is the emergency STOP button in the treatment room (near emergency basket) operational? [verify illumination of the red "*Reset*" light, lower left of console]

8. Is the emergency STOP button on the HDR unit operational? [verify illumination of the red "*Reset*" light, lower left of console]

Attach source position check ruler to channel 2 (**incorrect channel**). Turn on ceiling light and adjust TV camera so that check ruler is clearly visible. Run: Daily QA, DQA patient to set the dummy source end to 1435 mm, and active source end to 1330 and 1430 mm. On the left side of the screen will be depicted a pre-Treatment Record

9. Are the date and time correct (within 5 minutes compared to local PC)?

10. Is the source strength on the printout within 0.020 cGy m2/h of the logbook activity?

Example Daily HDR ¹⁹²Ir QA Form (lower)

11. Confirm program and dwell times, press START to initiate treatment, and verify that Error Code 14 appears on the screen and that the source is not extended out of the safe.

Attach the source position check ruler to channel 1 (correct channel). Press START to initiate treatment. 12. Does the distal end of the dummy source goto 1435 ± 1 mm, and active source end goto 1330 ± 1 mm (dwell position 35) and $1430 \pm 1 \text{ mm}$ (dwell position 15)?

While the source is dwelling at dwell position 15 (nominally 1430 mm), check the door light, door interlock, interrupt button, and console emergency stop button. The source end should return to dwell position 15 after each restart.

13. Is the "HDR IN USE" door light on, and does the radiation area monitor function (red light)?

14. Is the door interlock operational?

15. Does the interrupt button on the console function properly?

16. Does the emergency STOP button on the treatment console promptly retract the source and emit an audible alarm and display the status on the screen?

[verify illumination of the red "*Reset*" light, lower left of console]

Example Manufacturer Calibration Form: HDR¹⁹²Ir

Certificate For Sealed Sources					
Issue Date:	2012-01-16 (1)				
Product Code: Serial Number: Production Code:	REF 105002 SN D36E-0374 LOT HDR011312				
Serial no. Transport Container: Serial no. Check Cable: Certificate Number:	2392C6 N/A FUwNz U0J0r v3V6G ad2vp 60				
Source Specification					
Reference Air Kerma Rate:	43.84 mGy h ⁻¹ +/- 5% at 1m (2)				
Measurement Reference Date:	2012-01-17 18:00 CET (1)				
Apparent Activity:	398 GBq (10.8 Ci) at measurement reference date. $\ _{\scriptscriptstyle (3,4)}$				
Source Type: Capsule dimensions: Source pellet dimensions: Source pellet form: Radionuclide: Encapsulation: Capsule material: ISO Classification:	MICROSELECTRON-HDR 0.9 mm diameter, 4.5 mm length 0.6 mm diameter, 3.5 mm length Solid Iridium Ir-192 single stainless steel, AISI 316L ISO/99/C63211				
Special form certificate number:	D/0070/S-96				
Quality Control Laser Weld Visual Check: Source Capsule Integrity (15 N pull test): Leakage Test: Surface Contamination test:	Passed Passed Passed ⁽⁵⁾ < 185 Bq (5 nCi) ⁽⁶⁾				
The undersigned, authorized officer of QSA Global, Inc. certifies hat this source complies with the requirements of ISO2919 and that a nformation given in this certificate is true and correct.	II of the				
Quality Assurance	m IM				
(1) Date Format yyyy-mm-dd.					

(2) Confidence level of 99.7%.

(3) The apparent activity is determined by applying a conversion factor (0.110 mGy $m^2 h^{-1} GBq^{-1}$) to the measured gamma radiation output of the

sealed source determined with a calibrated instrument. The instrument is traceable to the National Institute of Standards & Technology. (NIST) (4) The apparent activity is the Iridium-192 activity; other radionuclides not detectable.

(5) Leakage test method according to ISO9978 method Liquid nitrogen bubble test (6.2.4).

(6) Surface contamination test according to ISO9978 method Wet wipe test (5.3.1).

(7) The quality assurance system of QSA Global Inc. is certified by Lloyd's

Register Quality Assurance (LRQA) according to ISO 9001 and ISO 13485.

40 North Avenue Burlington, MA 01803 1(781) 272-2000

Quality Assurance

(1) Date Format yyyy-mm-dd.

(2) Confidence level of 99.7%. $\mathbf{k} = \mathbf{3}$

(3) The apparent activity is determined by applying a conversion factor (0.110 mGy $m^2 h^{-1} GBq^{-1}$) to the measured gamma radiation output of the sealed source determined with a calibrated instrument. The instrument is traceable to the National Institute of Standards & Technology. (NIST)

Take Home Message

- QMP is a complex, systems concept
- QMP contains many familiar items coordination is key
- Many societal guidelines available for brachytherapy QMP elements
- QMP should be specific to equipment and department – no "template" QMP, only guidance
 - regular, independent departmental review is desirable
- Forms help formalize QMP goals and make tasks consistent
- e-forms provide robust documentation, but can be altered
- Balance tension of form constancy and form advancements
- TG-100 and international error databases may alter current QMP focus

Future Perspectives I: Tracking Technologies in Brachytherapy

Prof. Luc Beaulieu, Ph.D., FAAPM, FCOMP

1- Département de physique, de génie physique et d'optique, et Centre de recherche sur le cancer, Université Laval, Canada

2- Département de radio-oncologie et Centre de recherche du CHU de Québec, CHU de Québec, Canada

Valencia, Spain – Oct 7-10 2018

Disclosures

- I am actively involved in the development of tracking systems for brachytherapy
- I hold research contracts and grants with:
 - Canada's NSERC Industrial Research Chair
 - ≻ Elekta
 - Philips

Learning Objectives

- Tracking technologies for brachytherapy
 - What are they?
 - How they work?
- Provide examples of use
- Discuss other potential applications

Tracking in Brachytherapy?

- Position of needle, catheter or applicator in real-time
 - Angulation/rotation
 - > On the fly decision -> replanning
- Automated, fast and accurate channel reconstruction
 - Wrong connection between transfer tube and afterloader
- Potentially tracking organ motion/deformation
- Enabling new brachytherapy and interventional procedures

Potential Technologies

• Image-based tracking: CT, MR or US

Accuracy of Catheter Reconstruction?

See e.g. F.-A. Siebert et al, Med Phys 36 (2009) 3406-3412.

Potential Technologies

- Image-based tracking: CT, MR or US
- Real-time tracking
 - > Optical IR tracking
 - Camera-based (Xbox style!)
 - Passive EM tracking
 - Active EM tracking
 - Optical Fiber Shape Sensing (Bragg Grating)

IR/Optical Tracking

Limited to line of sight

Same for white light camera

Overview of the technologies

Potential Technologies

Table 6 Performance accuracy of EM catheter mapping system in the OR environment

		In-plane discrepancy (mm)			Out-of-plane discrepancy (mm)		
EM vs. TRUS (in OR)	Mean	Standard deviation	Maximum	Mean	Standard deviation	Maximum	
Calibrating and testing in a "low distortion" environment	0.4	0.2	1	0.8	0.4	1.7	
Calibrating in a "low distortion" environment and testing in distorting environment	1	0.2	1.5	1.1	0.8	1.9	
Calibrating in a "low distortion" environment and testing in distorting environment, after updating the calibration in the distorting environment	0.3	0.2	1.1	1.1	0.8	1.9	
Calibrating and testing in distorting environment	0.6	0.3	1.5	0.4	0.2	0.6	

EM = electromagnetic; OR = operating room; TRUS = transrectal ultrasound.

In the OR, a "low distortion" environment refers to the absence of clinical equipment other than the treatment table and the ultrasound system near the testing area. A distorting environment refers to an environment that includes the presence of other clinically used brachytherapy equipment, such as leg stirrups, stepper holder, treatment planning computer, treatment afterloader, instrument table, and others, in their typical positions.

Interim Summary

- Needs to be used within the first 30 cm of the field generator
- Needle parallel to the field generator yield better angular accuracy
- Field generator generate heat: <u>not under the</u> <u>patient</u>
- Interference seen only for CRT monitor and bulky metalic arms (not shown)
 - Insensitive to US probe and needles/catheters

What can you do with this?

- Follow needles, catheters or an applicators in space (up to 6 DOF) in real-time (40 Hz)
 - Insertion guidance
 - Automatically reconstruct catheter/ applicator channels
 - Error detection
 - Workflow optimization
 - Direct link to real-time imaging
 - Direct link to a optimization engine (background replanning)

(Received 8 May 2014; revised 9 January 2015; accepted for publication 26 January 2015; published 18 February 2015)

Purpose: In high dose rate brachytherapy (HDR-B), current catheter reconstruction protocols are relatively slow and error prone. The purpose of this technical note is to evaluate the accuracy and the robustness of an electromagnetic (EM) tracking system for automated and real-time catheter reconstruction.

Methods: For this preclinical study, a total of ten catheters were inserted in gelatin phantoms with different trajectories. Catheters were reconstructed using a 18G biopsy needle, used as an EM stylet and equipped with a miniaturized sensor, and the second generation Aurora[®] Planar Field Generator from Northern Digital Inc. The Aurora EM system provides position and orientation value with precisions of 0.7 mm and 0.2°, respectively. Phantoms were also scanned using a μ CT (GE Healthcare) and Philips Big Bore clinical computed tomography (CT) system with a spatial resolution of 89 μ m and 2 mm, respectively. Reconstructions using the EM stylet were compared to μ CT and CT. To assess the robustness of the EM reconstruction, five catheters were reconstructed twice and compared.

Results: Reconstruction time for one catheter was 10 s, leading to a total reconstruction time inferior to 3 min for a typical 17-catheter implant. When compared to the μ CT, the mean EM tip identification error was 0.69 ± 0.29 mm while the CT error was 1.08 ± 0.67 mm. The mean 3D distance error was found to be 0.66 ± 0.33 mm and 1.08 ± 0.72 mm for the EM and CT, respectively. EM 3D catheter trajectories were found to be more accurate. A maximum difference of less than 0.6 mm was found between successive EM reconstructions.

Conclusions: The EM reconstruction was found to be more accurate and precise than the conventional methods used for catheter reconstruction in HDR-B. This approach can be applied to any type of catheters and applicators. © 2015 American Association of Physicists in Medicine. [http://dx.doi.org/10.1118/1.4908011]

Medical Physics 2015;42(3):1227-32.

- EM reconstructions at 40 Hz
- μCT reconstruction (GE) at 89 μm (<u>reference</u>)
- CT reconstructions (Philips BigBore) at 2 mm
- Reconstructions using the EM stylet were compared to μCT and CT (<u>3D distances used; tips as</u> reference).

Real-Time Active MR-Tracking of Metallic Stylets in MR-Guided Radiation Therapy

Wei Wang,^{1,2}* Charles L. Dumoulin,³ Akila N. Viswanathan,² Zion T.H. Tse.⁴ Alireza Mehrtash.¹ Wolfgang Loew,³ Isaiah Norton,¹ Junichi Tokuda,¹ Ravi T. Seethamraju,⁵ Tina Kapur,¹ Antonio L. Damato,² Robert A. Cormack.² and Ehud I. Schmidt¹

Purpose: To develop an active MR-tracking system to guide placement of metallic devices for radiation therapy.

Methods: An actively tracked metallic stylet for brachytherapy was constructed by adding printed-circuit micro-coils to a commercial stylet. The coll design was optimized by electromagnetic simulation, and has a radio-frequency lobe pattern extending ~5 mm beyond the strong Bo inhomogeneity region near the metal surface. An MR-tracking sequence with phase-field dithering was used to overcome residual effects of B₀ and B₁ inhomodeneities caused by the metal, as well as from inductive coupling to surrounding metallic stylets. The tracking system was integrated with a graphical workstation for real-time visualization. The 3 Tesla MRI catheter-insertion procedures were tested in phantoms and ex vivo animal tissue, and then performed in three patients during interstitial brachytherapy.

Results: The tracking system provided high-resolution (0.6 × 0.6 × 0.6 mm³) and rapid (16 to 40 frames per second, with three to one phase-field dithering directions) catheter localization in phantoms, animals, and three ovnecologic cancer patients.

Conclusion: This is the first demonstration of active tracking of the shaft of metallic stylet in MR-guided brachytherapy. It holds the promise of assisting physicians to achieve better targeting and improving outcomes in interstitial brachytherapy. Magn Reson Med 73:1803-1811, 2015. © 2014 Wiley Periodicals, Inc.

Key words: active MR-tracking; metallic device; radiation therapy; phase-field dithering

INTRODUCTION

Gynecologic malignancies (endometrial, ovarian, cervical, and vagina/vulva cancers) accounted for over 91,000 new cancer cases and approximately 28,000 deaths in 2013 in the United States (1). Brachytherapy places radi-

oactive sources directly into the tumor-bearing tissues to achieve high doses of radiation to the tumor, while minimizing the dose to surrounding normal tissue. Brachytherapy is considered standard-of-care for many gynecologic cancer patients and improves survival (2). MRI is often used in gynecologic brachytherapy, due to its higher accuracy in evaluating the extent of disease in the primary tumor, as well as adjacent tissue spread. Its capacity to detect the morphology of the tumor can also be beneficial for interventional brachytherapy procedures, assisting in the navigation and targeting the lesion. Recently, real-time rather than postinsertion MRI has been integrated into radiation treatment planning to aid the insertion of interstitial implants and treatment planning (3). The initial study demonstrated that realtime MRI guidance during insertion of interstitial catheters, followed by three-dimensional (3D) planning, maximized opportunities for tumor targeting as well as the sparing of normal tissues (4).

In MRI-guided brachytherapy, multiple (10-30) catheters are typically placed into the tumor (Fig. 1). Each catheter consists of a hollow tip-sealed plastic tube into which radioactive sources are later temporarily loaded, and a metallic needle ("stylet") constructed from tungsten alloy to provide the mechanical strength needed to drive the catheter to its desired position. As a result, reliable tracking of a metallic device is crucial to the success of interventional brachytherapy procedures. Currently, MRI-guided brachytherapy is conducted by passively visualizing the magnetic susceptibility image artifact created by the metallic stylet (5). Metal itself does not generate MR signals and the presence of metal can result in severe distortion to the static magnetic field (Bo) around it because of the large susceptibility differences with surrounding tissues. The signal voids created by the metal in MR images are used as a negative contrast to identify the device, but the accurate location and size of the device is difficult to determine because the susceptibility artifact on MR images depends on the shape and material properties, the device's orientation relative to Bo, and pulse sequence parameters (6), Highresolution image-based passive tracking methods are typically time-consuming (0.5-2 tracking frames per minute) and may also compromise the contrast-to-noise ratio of anatomic images. Furthermore, this approach becomes more difficult in MR-guided brachytherapy, where the individual paths of multiple catheters need to be tracked, because catheters are close to each other (<10 mm apart) or cross paths during insertion. Various

Description of prototype

- Length: 195mm, diameter: 1.15mm
- 3 optic fibers separated by an angle of 120 degree
- 9 sets of FBGs embedded separated by intervals of 20mm

Description of prototype (2)

- Broadband LED Source, Reflected wavelength measured by spectrum analyzer
- Determination of strain along the stylet

When the stylet is inserted into the needle

Measurement of the 3D needle's deflection

Result experiment #2: Comparison with MR-based measurement

• Typical example

Euclidean distance between MR- and FBG-based measurements

Overall catheters:

Average error: 0.42mm

Key Issue: Calibration to a Relevant Reference Frame

- Sensor to needle/stylet tip or relevant applicator ref. position
- Template (if used) to EM coordinate system
- Clinical images (target+OARs) to EM coordinate system
 US and/or CT to EM

Each of the above will have an impact on the overall accuracy of the clinical system

Joint AAPM-ESTRO TG

Real-time Tracking Technologies

They already in hospitals being use clinically

They are coming to brachytherapy

- Real-time position/angulation of needle, catheter or applicator
- Fast and accurate HDR channel reconst. and tips

Could be incorporated in specific workflows

- Automated imaging plane display
- Real-time continuous dosimetry and replanning (Seed)
- QA of channel (reconstr., swapped, ...)

Perspective on Future Progress for Brachytherapy Physics and Technological Advancements: Radionuclides and Novel Applicators

Prof. Mark J. Rivard, Ph.D., FAAPM

Advanced Brachytherapy Physics, 29 May – 1 June, 2016

Disclosures

Dr. Rivard serves as a consultant to CivaTech Oncology and a minor shareholder to Advanced Radiation Therapy, LLC

Opinions herein are solely those of the presenter, and are not meant to be interpreted as societal guidance.

Specific commercial equipment, instruments, and materials are listed to fully describe the necessary procedures. Such identification does not imply endorsement by the presenter, nor that these products are necessarily the best available for these purposes.

Learning Objectives

- 1. Examine radiological properties of current and potential radionuclides. Consider if these differences will be clinically meaningful.
- 2. Learn about current novel BT sources and applicators and possibilities. Consider if these differences will be clinically meaningful.

New BT Radionuclides: Mean Photon Energy

• How sensitive is dosimetry for novel radionuclides and eBT to material heterogeneities (and general differences with TG-43)?

What Would Olaf Do?

Summary

- new sources (radionuclides and eBT) fall in the energy range sensitive to scatter, requiring advanced BT dose calculations
- new sources and applicators have significant shielding, not compatible with current TPS based on simple TG-43
- commercially available (Acuros BV and Oncentra ACE) for ¹⁹²Ir (and academic-based TPS) can accurately calculate BT dose
- current and ongoing societal guidance for advanced BT dose calcs
