Turin, Italy

Radiotherapy & Oncology

Journal of the European Society for
Radiotherapy and Oncology

INFORMATION FOR AUTHORS

ARTICLES should deal with original research or reviews of topics defined in the aims of the journal. Radiotherapy and Oncology publishes original material only. It is therefore understood that the content of the paper has not previously been published in the same or a similar form and that it is not under consideration for publication elsewhere. The act of submitting a manuscript to the journal carries with it the right to publish that paper.

Radiotherapy and Oncology uses an online manuscript submission and peer review process.

Papers and correspondence should be submitted online at <http://www.ees.elsevier.com/ro> and the instructions on the site should be closely followed. Authors may submit manuscripts and track their progress to final decision. Reviewers can download manuscripts and submit their reports to the Editors electronically.

The full contact details for the Editorial Office are shown below:

Professor Jens Overgaard, M.D., Radiotherapy and Oncology Secretariat, Department of Experimental Clinical Oncology, Aarhus University Hospital, Nørrebrogade 44, Building 5, DK-8000 Aarhus C, Denmark (Tel.: +45 78 46 26 29; Fax: +45 86 19 71 09; E-mail: ro@oncology.dk)

TYPES OF PAPERS

1. Full length original papers (max. 3000 words)

Describe original scientific work in the field of radiation oncology or related areas. The content of the paper should be sufficient to reach valid conclusions. Full papers should include a structured abstract and be divided into sections (Introduction; Materials and Methods; Results; Discussion; References; Tables; Figures) and should not normally exceed 6 printed pages, including references and a maximum of 6 tables/figures. Additional material can be submitted as supplementary files.

2. Short communications and Technical notes (max. 2000 words)

Provide a brief but complete account of a particular piece of work, e.g. Phase I or II study, and should in total be no longer than 4 printed pages, normally including a maximum of 2 figures or tables. A summary of not more than 50 words should be included (not a structured abstract), but the manuscript can have fewer subheadings (e.g. short introduction; materials and methods; results and discussion). Authors are advised to see a recent issue of the journal for size and lay-out.

3. Review articles

Rigorous critical assessment of clinical and/or laboratory research in a field of interest to the journal and its subscribers. Reviews are normally solicited by the editors, and it is suggested that authors wishing to contribute a review article contact the editor-in-chief.

4. Editorials and commentaries

Editorials and commentaries relate to articles in the journal or to issues of relevance for the readership. This type of communication is normally solicited by the editors.

5. Letters to the Editor

On topics of current interest or comment upon material previously or simultaneously published in the journal. They should be limited to 500 words and may include 1 table or figure.

6. Announcements

The inclusion of announcements, etc. is at the discretion of the Editors and the Publisher and subject to space availability. Request for inclusion of meeting announcement should be sent to the ESTRO secretariat (see address in journal).

Author inquiries

For inquiries relating to the submission of articles (including electronic submission where available) please visit this journal's homepage at <http://www.elsevier.com/locate/radonc>. For detailed instructions on the preparation of electronic artwork, please visit <http://www.elsevier.com/artworkinstructions>. Contact details for questions arising after acceptance of an article, especially those relating to proofs, will be provided by the publisher. You can track accepted articles at <http://www.elsevier.com/trackarticle>. You can also check our Author FAQs at <http://www.elsevier.com/authorFAQ> and/or contact Customer Support via <http://support.elsevier.com>

Language services. Authors who require information about language editing and copyediting services pre- and post-submission please visit <http://webshop.elsevier.com/languageediting> or our customer support site at <http://support.elsevier.com>.

A full and complete Guide for Authors is available online at

This journal and the individual contributions contained in it are protected under copyright by Elsevier Ireland Ltd., and the following terms and conditions apply to their use:

Photocopying

Single photocopies of single articles may be made for personal use as allowed by national copyright laws. Permission of the Publisher and payment of a fee is required for all other photocopying, including multiple or systematic copying, copying for advertising or promotional purposes, resale, and all forms of document delivery. Special rates are available for educational institutions that wish to make photocopies for non-profit educational classroom use.

For information on how to seek permission visit www.elsevier.com/permissions or call: (+44) 1865 843830 (UK)/(+1) 215 239 3804 (USA).

Derivative Works

Subscribers may reproduce tables of contents or prepare lists of articles including abstracts for internal circulation within their institutions. Permission of the Publisher is required for resale or distribution outside the institution.

Permission of the Publisher is required for all other derivative works, including compilations and translations (please consult www.elsevier.com/permissions).

Electronic Storage or Usage

Permission of the Publisher is required to store or use electronically any material contained in this journal, including any article or part of an article (please consult www.elsevier.com/permissions).

Except as outlined above, no part of this publication may be reproduced, stored in a retrieval system or transmitted in any form or by any means, electronic, mechanical, photocopying, recording or otherwise, without prior written permission of the Publisher.

Notice

No responsibility is assumed by the Publisher for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions or ideas contained in the material herein. Because of rapid advances in the medical sciences, in particular, independent verification of diagnoses and drug dosages should be made.

Although all advertising material is expected to conform to ethical (medical) standards, inclusion in this publication does not constitute a guarantee or endorsement of the quality or value of such product or of the claims made of it by its manufacturer.

ESTRO 35 content

Saturday 30 April 2016

Teaching Lecture

Technology assessment (Abs. 1)

CRISPR/CAS technology: from cells to mice to stem cell therapy (Abs. 2)

Partial Breast Irradiation: who, when and how? (Abs. 3)

New tools to reduce toxicity in pelvic radiation (Abs. 4)

Role of brachytherapy in the management of paediatric tumors (Abs. 5)

Challenges in MR guided radiotherapy (Abs. 6)

Patient specific quality assurance in proton therapy (Abs. 7)

Balancing toxicity and disease control in the evolution of radiotherapy technology (Abs. 8)

Symposium

Selection of patients for proton therapy (Abs. 9-11)

Mitigating normal tissue toxicity (Abs. 12-14)

Regional nodal irradiation for breast cancer (Abs. 15-17)

Assessment and management of rectal morbidity (Abs. 18-20)

Towards user oriented QA procedures for treatment verification (Abs. 21-23)

Robust and accurate functional MRI for radiotherapy (Abs. 24-26)

Joint Symposium

ESTRO-IAEA: Joint ESTRO-IAEA efforts on dosimetry, QA and audit for advanced treatment techniques (Abs. 27-29)

Symposium

Strategies for treatment planning (Abs. 30-32)

Poster Viewing

1: Brachytherapy (Abs. 33-40)

Symposium

Protons or heavy ions? (Abs. 41-43)

Proffered Papers

Radiobiology 1: Radiation effects on normal tissues and the microenvironment (Abs. 44-48)

Clinical 1: Breast (Abs. 49-54)

Clinical 2: Adverse effects in radiotherapy (Abs. 55-60)

Brachytherapy 1: Prostate (Abs. 61-66)

Physics 1: Images and analyses (Abs. 67-72)

Physics 2: Basic dosimetry (Abs. 73-78)

RTT 1: Novelty in treatment planning (Abs. 79-84)

Poster Viewing

2: Clinical: Health economics, urology and brain (Abs. 85-91)

Presidential Symposium

Presidential (Abs. 92)

Award Lecture

E. Van der Schueren Award (Abs. 93)

Symposium with Proffered Papers

Hot topics in SABR: time for randomised clinical trials? (Abs. 94-97)

Symposium

Tumour targeting - considering normal tissue biology (Abs. 98-101)

Debate

This house believes that progress in the treatment of locally advanced NSCLC will come from: (Abs. 102-103)

Symposium

Active surveillance for low risk prostate cancer: to treat or not to treat? (Abs. 104-106)

Achieving excellence in image guided brachytherapy (Abs. 107-109)

Imaging markers for response prediction and assessment (Abs. 110-112)

Debate

There are many existing IGRT options for highly accurate dose delivery. Is there a need for large-scale in-room MR-guidance? (Abs. 113-114)

Symposium

Additional tools for contouring (Abs. 115-117)

Poster Viewing

3: Clinical: Gastrointestinal and gynaecology (Abs. 118-125)

Joint Symposium

ESTRO-ESR: MR-PET (Abs. 126-128)

Proffered Papers

Radiobiology 2: Interplay between cancer stem cells ,hypoxia and the radiation response (Abs. 129-134)

Clinical 3: Lung (Abs. 135-140)

Clinical 4: Late breaking abstracts (Abs. 141-146)

Brachytherapy 2: EYE GI (Abs. 147-152)

Physics 3: Anatomical CT and MR imaging for treatment preparation (Abs. 153-158)

Physics 4: Inter-fraction motion management I (Abs. 159-164)

RTT 2: Improving quality for breast cancer treatments (Abs. 165-170)

Poster Viewing

4: Physics: Treatment planning: applications III (Abs. 171-176)

Honorary Members Lecture

Honorary Members (Abs. 177-179)

Sunday 1 May 2016

Teaching Lecture

Trade off between standardisation and individualisation (Abs. 180)

DNA repair and response for beginners (Abs. 181)

Anal cancer: current guidelines and remaining questions (Abs. 182)

Radiotherapy and immune-therapy, biological basis and potential for future clinical trials (Abs. 183)

Underestimated importance of Intraluminal brachytherapy: bronchus, oesophageal, anorectal and hepatobiliary duct cancer (Abs. 184)

Big data in radiotherapy: technology, challenges and opportunities (Abs. 185)

The role of dosimetry audit in safety, quality and best practice for external beam and brachytherapy (Abs. 186-187)

General introduction to head and neck radiotherapy (Abs. 188)

e-Learning for Professionals in Radiation Oncology: What, Why and How? (Abs. 189)

Symposium with Proffered Papers

Quality beyond accuracy: are we failing to see the forest for the trees? (Abs. 190-193)

Symposium

Targeting DNA repair / DDR pre-clinical evidence (Abs. 194-196)

New approaches in rectal cancer (Abs. 197-199)

Changing paradigm in the management of kidney cancer (Abs. 200-202)

Modern techniques for old indications (Abs. 203-205)

Quantitative imaging to individualise radiotherapy (Abs. 206-208)

Proffered Papers

Physics 5: Intra-fraction motion management I (Abs. 209-215)

Symposium

Head and neck: reduction of margins and side effects (Abs. 216-218)

The future of Radiation Oncology publishing: views through the Red and Green telescopes (Abs. 219-221)

Poster Viewing

5: RTT (Abs. 222-230)

Symposium

QA in clinical trials: processes, impact and future perspectives (Abs. 231-233)

Proffered Papers

Radiobiology 3: Novel targeting approaches in combination with radiation (Abs. 234-238)

Clinical 5: Upper and lower GI (Abs. 239-244)

Clinical 6: Hadron therapy (Abs. 245-250)

Brachytherapy 3: Detectors and dose verification (Abs. 251-256)

Physics 6: Radiobiological modelling (Abs. 257-262)

Physics 7: Treatment planning: optimization algorithms (Abs. 263-268)

RTT 3: Ensuring quality in head and neck treatment (Abs. 269-274)

Poster Viewing

6: Clinical: Lung, palliation, sarcoma, haematology (Abs. 275-281)

Proffered Papers

Donal Hollywood Award (Abs. 282)

Highlights of Proffered Papers (Abs. 283-286)

Symposium

Planning ahead: how to finish your residency / PhD project with a job offer (Abs. 287-290)

Symposium with Proffered Papers

Standardisation in clinical practice (Abs. 291-295)

Symposium

DNA repair inhibition and radiotherapy: moving towards clinic (Abs. 296-298)

Radiotherapy of prostate cancer: technical challenges (Abs. 299-301)

Debate

This house believes that SBRT should become the standard of care for T1 and small T2 NSCLC tumours (Abs. 302-303)

Is brachytherapy the best for partial breast irradiation? (Abs. 304-307)

Symposium

New challenges in modelling dose-volume effects (Abs. 308-310)

Automated treatment plan generation in the clinical routine (Abs. 311-313)

Elderly and radiation therapy (Abs. 314-316)

A Joint session of Young Radiation Oncologists National Societies & YROG (Abs. 317-321)

Poster Viewing

7: Physics: Intra-fraction motion management II (Abs. 322-329)

Symposium with Proffered Papers

Uncovering the gap between optimal and actual utilisation of radiotherapy in Europe (Abs. 330-334)

Debate

Maximising tumour control: crank up the volume or turn off the switches? (Abs. 335-338)

Proffered Papers

Clinical 7: Urology (Abs. 339-344)

Clinical 8: Adult and paediatric CNS malignancies (Abs. 345-350)

Brachytherapy 4: Gynae-Breast (Abs. 351-356)

Physics 8: Dose measurement and dose calculation I (Abs. 357-362)

Physics 9: Adaptive RT for inter-fraction motion management (Abs. 363-368)

RTT 4: How to increase the knowledge for patients and staff (Abs. 369-374)

Poster Viewing

8: Physics: Inter-fraction motion management II (Abs. 375-379)

Award Lecture

Academic award: Jack Fowler University of Wisconsin Award (Abs. 380)

Company Award Lectures (Abs. 381-382)

Monday 2 May 2016

Teaching Lecture

How to bring QUANTEC into the 21st century? (Abs. 383)

Shared decision making (Abs. 384)

The study of therapy resistance in genetically engineered mouse models for BRCA1-mutated breast cancer (Abs. 385)

SBRT/SABR for oligometastatic disease (Abs. 386)

Advanced treatment strategies for head and neck cancer (Abs. 387)

Dose to water vs. dose to tissue in advanced treatment planning: myths, realities and concerns (Abs. 388)

Nanodosimetry: from radiation physics to radiation biology (Abs. 389)

Brachytherapy for the pelvic region: status and perspective for the future (Abs. 390-391)

Symposium with Proffered Papers

Adaptive radiotherapy for coping with anatomical variations: hope or hype? (Abs. 392-395)

Time is not on our side: cardiovascular toxicity after radiotherapy (Abs. 396-400)

Symposium

Emerging biomarkers (Abs. 401-404)

SBRT for oligometastatic disease (Abs. 405-407)

Head and neck: state-of-the-art and directions for future research (Abs. 408-410)

SBRT in lung - choices and their impact on related uncertainties (Abs. 411-413)

Proffered Papers

Physics 10: Functional Imaging I (Abs. 414-420)

Symposium

Adaptive treatments in the pelvic region (Abs. 421-423)

Poster Viewing

9: Radiobiology (Abs. 424-432)

Symposium

Modern ART based on functional / biological imaging (Abs. 433-435)

Secondary cancer after radiotherapy: from cancer registries to clinical implications (Abs. 436-438)

Proffered Papers

Radiobiology 4: Molecular biomarkers for patient selection (Abs. 439-443)

Clinical 9: SBRT and oligometastatic disease (Abs. 444-448)

Clinical 10: Head and neck (Abs. 449-454)

Physics 11: Dose measurement and dose calculation II (Abs. 455-460)

Physics 12: Treatment planning: applications I (Abs. 461-466)

RTT 5: Optimizing treatment planning and delivery in the pelvic region (Abs. 467-472)

Poster Viewing

10: Physics: Functional Imaging II (Abs. 473-478)

Proffered Papers

Selected randomised trials (Abs. 479-481)

Award Lecture

Breur Award Lecture (Abs. 482)

Joint Symposium

ESTRO-ASTRO: In room adaptive imaging with a focus on MRI (Abs. 483-486)

Symposium

Communication with patients (Abs. 487-490)

Imaging biology (Abs. 491-493)

Debate

This house believes that centralised large radiotherapy units will provide the best academia and the best treatment quality (Abs. 494-495)

Joint Symposium

ESTRO-ILROG: Modern radiotherapy in lymphoma (Abs. 496-498)

ESTRO-PTCOG: ART in particle therapy (Abs. 499-503)

Symposium

Small animal irradiation (Abs. 504-506)

Focus on the pelvic region (Abs. 507-509)

Poster Viewing

11: Clinical: Breast, head and neck (Abs. 510-519)

Symposium

Dose painting: those pending issues (Abs. 520-522)

ACROP (Abs. 523-525)

Proffered Papers

Radiobiology 5: Imaging and molecular biomarkers in radiation

oncology (Abs. 526-530)

Clinical 11: Health Economics and patient reported outcomes (Abs. 531-536)

Clinical 12: Rare tumours (Abs. 537-542)

Physics 13: New Technology and QA (Abs. 543-548)

Physics 14: Treatment planning: applications II (Abs. 549-554)

RTT 6: Advanced radiation techniques in prostate cancer (Abs. 555-560)

Poster Viewing

12: Physics: Dose measurement and dose calculation III (Abs. 561-566)

General Assembly

General Assembly

Tuesday 3 May 2016

Teaching Lecture

The new 'Rs' in radiation biology (Abs. 567)

Texture analysis of medical images in radiotherapy (Abs. 568)

Biology of high-energy proton and heavy ion particle therapy versus photon therapy: recent developments (Abs. 569)

Neuroendocrine tumours – personalised diagnosis and treatment using radiolabelled peptides (Abs. 570)

Radiotherapy for paediatric brain tumours (Abs. 571)

Role and validation of deformable image registration in clinical practice (Abs. 572)

VMAT QA: To do and not to do, those are the questions (Abs. 573)

Optimising workflow in a radiotherapy department - an introduction to lean thinking (Abs. 574)

Symposium

New concepts of tumour radioresistance (Abs. 575-577)

Symposium with Proffered Papers

Towards Personalised Radiation Oncology (PRO) (Abs. 578-582)

Symposium

The tumour in 3D: the role of tumour microenvironment (Abs. 583-586)

WBRT for brain metastases- the end of an era? (Abs. 587-589)

Radiotherapy "autovaccination" with systemic immune modulators for modern immunotherapy (Abs. 590-592)

Joint Symposium

ESTRO-AAPM-EFOMP: Functional / biological imaging and radiotherapy physicists: new requests/challenges and the need for better and more specific training (Abs. 593-595)

Symposium

The future of QA lies in automation (Abs. 596-599)

Management and optimisation of the daily workflow (Abs. 600-602)

Combining radiotherapy with molecular targeted agents: learning from successes and failures (Abs. 603-605)

Symposium with Proffered Papers

Radiomics - the future of radiotherapy? (Abs. 606-609)

Symposium

Radiobiology of proton / carbon / heavy ions (Abs. 610-612)

New insights in treating vertebral metastases (Abs. 613-615)

IMRT, the new standard in treatment of gynaecological, lung and breast cancers? (Abs. 616-618)

Symposium with Proffered Papers

Plan of the day (PotD): current status (Abs. 619-621)

Debate

We don't need better dose calculation, it's doing more bad than good (Abs. 622-623)

Are we precisely inaccurate in our adaption? (Abs. 624-625)

Moving away from 2 Gray: are we ready for a paradigm shift? (Abs. 626-629)

Posters

Clinical track: Head and neck (Abs. 630-640)

Clinical track: CNS (Abs. 641-661)

Clinical track: Haematology (Abs. 662-671)

Clinical track: Breast (Abs. 672-677)

Clinical track: Lung (Abs. 678-695)

Clinical track: Upper GI (oesophagus, stomach, pancreas, liver) (Abs. 696-714)

Clinical track: Lower GI (colon, rectum, anus) (Abs. 715-722)

Clinical track: Gynaecological (endometrium, cervix, vagina, vulva) (Abs. 723-735)

Clinical track: Prostate (Abs. 736-758)

Clinical track: Urology-non-prostate (Abs. 759-760)

Clinical track: Skin cancer / malignant melanoma (Abs. 761-763)

Clinical track: Sarcoma (Abs. 764-768)

Clinical track: Paediatric tumours (Abs. 769-771)

Clinical track: Palliation (Abs. 772-779)

Clinical track: Elderly (Abs. 780-782)

Clinical track: Health services research / health economics (Abs. 783-789)

Clinical track: Other (Abs. 790-791)

Physics track: Basic dosimetry and phantom and detector development (Abs. 792-801)

Physics track: Dose measurement and dose calculation (Abs. 802-832)

Physics track: Radiation protection, secondary tumour induction and low dose (incl. imaging) (Abs. 833-836)

Physics track: Treatment plan optimisation: algorithms (Abs. 837-841)

Physics track: Treatment planning: applications (Abs. 842-869)

Physics track: (Radio)biological modelling (Abs. 870-877)

Physics track: Intra-fraction motion management (Abs. 878-893)

Physics track: Inter-fraction motion management (excl. adaptive radiotherapy) (Abs. 894-904)

Physics track: Adaptive radiotherapy for inter-fraction motion management (Abs. 905-911)

Physics track: CT Imaging for treatment preparation (Abs. 912-918)

Physics track: (Quantitative) functional and biological imaging (Abs. 919-931)

Physics track: Images and analyses (Abs. 932-938)

Physics track: Implementation of new technology, techniques, clinical protocols or trials (including QA & audit) (Abs. 939-951)

Physics track: Professional and educational issues (Abs. 952)

Brachytherapy track: Breast (Abs. 953-955)

Brachytherapy track: Gynaecology (Abs. 956-963)

Brachytherapy track: Head and neck (Abs. 964-965)

Brachytherapy track: Physics (Abs. 966-973)

Brachytherapy track: Prostate (Abs. 974-979)

Radiobiology track: Molecular targeted agents and radiotherapy (Abs. 980-985)

Radiobiology track: Tumour biology and microenvironment (Abs. 986-989)

Radiobiology track: Normal tissue effects: pathogenesis and treatment (Abs. 990-992)

Radiobiology track: Biomarkers and biological imaging (Abs. 993-994)

Radiobiology track: Cellular radiation response (Abs. 995-998)

Radiobiology track: Radiobiology of protons and heavy ions (Abs. 999-1000)

RTT track: Strategies for treatment planning (Abs. 1001-1009)

RTT track: Head and neck reduction of margins and side effect (Abs. 1010)

RTT track: Elderly and radiation therapy (Abs. 1011)

RTT track: Adaptive treatments in the pelvic region (Abs. 1012-1014)

RTT track: Other topics for RTTs (Abs. 1015-1022)

RTT track: Position verification (Abs. 1023-1026)

Electronic Posters

Clinical track: Head and neck (Abs. 1027-1110)

Clinical track: CNS (Abs. 1111-1137)

Clinical track: Haematology (Abs. 1138-1143)

Clinical track: Breast (Abs. 1144-1199)

Clinical track: Lung (Abs. 1200-1255)

Clinical track: Upper GI (oesophagus, stomach, pancreas, liver) (Abs. 1256-1279)

Clinical track: Lower GI (colon, rectum, anus) (Abs. 1280-1310)

Clinical track: Gynaecological (endometrium, cervix, vagina, vulva) (Abs. 1311-1332)

Clinical track: Prostate (Abs. 1333-1385)

Clinical track: Urology-non-prostate (Abs. 1386-1390)

Clinical track: Skin cancer / malignant melanoma (Abs. 1391-1397)

Clinical track: Sarcoma (Abs. 1398-1410)

Clinical track: Paediatric tumours (Abs. 1411-1421)

Clinical track: Palliation (Abs. 1422-1440)

Clinical track: Elderly (Abs. 1441-1449)

Clinical track: Health services research / health economics (Abs. 1450-1459)

Clinical track: Communication (Abs. 1460-1462)

Clinical track: Other (Abs. 1463-1481)

Physics track: Basic dosimetry and phantom and detector development (Abs. 1482-1517)

Physics track: Dose measurement and dose calculation (Abs. 1518-1604)

Physics track: Radiation protection, secondary tumour induction and low dose (incl. imaging) (Abs. 1605-1624)

Physics track: Treatment plan optimisation: algorithms (Abs. 1625-1644)

Physics track: Treatment planning: applications (Abs. 1645-1711)

Physics track: (Radio)biological modelling (Abs. 1712-1728)

Physics track: Intra-fraction motion management (Abs. 1729-1774)

Physics track: Inter-fraction motion management (excl. adaptive radiotherapy) (Abs. 1775-1804)

Physics track: Adaptive radiotherapy for inter-fraction motion management (Abs. 1805-1825)

Physics track: CT Imaging for treatment preparation (Abs. 1826-1849)

Physics track: (Quantitative) functional and biological imaging (Abs. 1850-1885)

Physics track: Images and analyses (Abs. 1886-1910)

Teaching Lecture: Technology assessment

SP-0001

Technology assessment

D. Verellen¹

¹Universitair Ziekenhuis Brussel, Radiotherapy, Brussels, Belgium

Radiation therapy is a highly technology driven discipline, and as treatments become more complex and automated, safe implementation and quality assurance become less intuitive. Moreover, the discipline seems to face a dichotomous situation in that on one hand there is a tendency towards truly individualized treatments adapted to patient specific characteristics, short or long term variations in anatomy and delivered dose, that require flexible interventions and optimizations. These individualized treatments call for dedicated QA/QC programs. On the other hand the automatization in delineation and treatment planning in combination with the need to optimize workflows, drive development towards template driven, almost “app-like” solutions. The latter, seems to facilitate workflows and QA/QC procedures in that a strong standardization reduces the need for detailed verification. In fact, commercial solutions are being offered as “plug-and-play” with limited user interaction and QA/QC, almost ignoring the department’s responsibilities towards patient safety and quality. Mix the previous with rapid succession of upgrades and updates, and it becomes clear that the assessment and QA of technology (still) requires constant attention and vigilance. Special care should be given to the workflow and how the individual components are integrated and mutually influence each other in this constantly evolving and increasingly complex situation. The presentation will also focus on the discussion between “one shoe fits all” solutions versus the need for dedicated technology. Are these decisions driven by clinical relevance or a “me-too” argumentation? Finally, some comments will be given comparing mono-vendor and multi-vendor situations.

Teaching Lecture: CRISPR/CAS technology: from cells to mice to stem cell therapy

SP-0002

CRISPR/Cas9 technology: from cells to mice to stem cell therapy

H. Te Riele¹, T. Harmsen¹, H. Van de Vrugt¹, J. Riepsaame¹

¹Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Division of Biological Stress Response, Amsterdam, The Netherlands

Protocols to efficiently generate small genomic sequence alterations in a targeted fashion are of great value to fundamental and clinical applications. We are particularly interested in developing protocols to correct the genetic defects underlying bone marrow failure in Fanconi anemia patients.

The most promising protocols for targeted correction or deletion of small mutations in terms of efficiency and facility make use of site-specific nucleases designed to generate a DNA double-strand break (DSB) in the genomic DNA closely located to the site to be modified. The *Streptococcus pyogenes* derived RNA-guided nuclease Cas9 combines strong and site-specific endonuclease activity with unprecedented design simplicity. By exploiting the endogenous error-free homology-directed repair (HDR) pathway that makes use of sequence homology, repair of the DSB can be accompanied by the introduction of specific base-pair alterations. When a double- or single-stranded DNA template is offered, the HDR reaction copies subtle sequence alterations present in the template sequence effectuating their introduction into the genomic DNA. For introduction of small alterations, short

chemically synthesized single-stranded DNA oligonucleotides comprising 80-120 nucleotides are highly effective. We have optimized the protocol for single base-pair substitution in the genome of mouse embryonic stem (ES) cells by oligonucleotide-templated HDR of a CRISPR/Cas9-generated break, achieving precise introduction of a planned modification in 50% of the recovered cells. Furthermore, we studied the influence of the cell’s DNA mismatch repair system on the efficiency of gene modification.

Fanconi anemia (FA) is a recessive heritable disorder characterized by skeletal abnormalities, progressive anemia and cancer predisposition. The disease is caused by bi-allelic defects in any of 17 genes, designated *FANCA*, *B*, *C*, etc. When a matching donor is available, bone marrow failure can often be treated by hematopoietic stem cell transplantation. Also, bone marrow transplantation from a non-matching donor can be offered, however, this is often associated with severe complications. An alternative strategy to re-establish a functional hematopoietic system may be the functional correction of the FA defect in the patient’s own cells. Ideally, the defect is restored in the patient’s own hematopoietic stem cells (HSC), which can subsequently be used to reconstitute the entire hematopoietic system. For FA patients with insufficient bone marrow cellularity, the FA defect may first be corrected in patient-derived primary fibroblasts. The corrected fibroblasts subsequently need to be reprogrammed into HSCs, most likely requiring the generation of induced pluripotent stem cells (iPSCs). As a first step towards this approach, we demonstrated that CRISPR/Cas9 genome editing can effectively be exploited to repair a deleterious mutation in *Fancc* and restore the FA pathway in cultured mouse ES cells and fibroblasts.

The next step is to use this protocol to correct the *Fancc* mutation in mouse-derived hematopoietic stem cells (HSC) and iPSCs. Gene-edited HSCs will subsequently be transplanted into lethally-irradiated recipient mice to determine their potential to drive long-term hematopoiesis. These preclinical studies are aimed to pave the way for the clinical development of CRISPR/Cas9-mediated gene correction protocols to restore FA gene defects and relieve bone marrow failure in Fanconi anemia patients.

Teaching Lecture: Partial Breast Irradiation: who, when and how?

SP-0003

Partial Breast Irradiation: who, when and how?

C. Coles¹

¹Addenbrooke’s Hospital, Oncology Centre University of Cambridge, Cambridge, United Kingdom

This lecture will explore the rationale for partial breast irradiation and then discuss the results from randomised trials to date. These will include intra-operative radiotherapy, brachytherapy and external beam radiotherapy. There is considerable heterogeneity between these techniques in terms of target volume, dose and fractionation and possible consequences from these differences will be considered. Appropriate patient selection for partial breast irradiation and treatment outside clinical trials will also be discussed.

Teaching Lecture: New tools to reduce toxicity in pelvic radiation

SP-0004

New tools to reduce toxicity in pelvic radiation

I. Joye^{1,2}, K. Haustermans^{1,2}

¹KU Leuven - University of Leuven, Department of Oncology, Leuven, Belgium

²University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium

Radiotherapy plays an important role in the treatment of pelvic tumors. The advances in patients' prognosis come at the expense of radiation-induced late toxicity. Progressive cell depletion and inflammation are the leading mechanisms of acute toxicity which is observed during or shortly after treatment. The pathogenetic pathways of late toxicity, developing 90 days or later after the onset of radiotherapy, are more complex and involve processes such as vascular sclerosis and fibrosis. Since many patients have become long-term survivors, awareness and recognition of radiation-related toxicity has gained in importance and increased efforts are made for its prevention and management.

Technical innovations contribute to a reduction in radiotherapy-associated toxicity. The steep dose gradients of highly-conformal radiotherapy techniques allow for an accurate dose delivery with optimal sparing of the normal tissues. Several studies have demonstrated the dosimetric benefit of intensity-modulated radiotherapy (IMRT) and volumetric modulated arc radiotherapy (VMAT) compared to conventional radiotherapy techniques. It has been shown that the dosimetric benefit of IMRT translated into a clinically significant reduction in lower gastrointestinal toxicity compared with three-field conventional radiotherapy. In the near future MRI-linacs and proton therapy are likely to broaden the therapeutic window further. Prone positioning on a bellyboard reduces small bowel toxicity by pushing away the small bowel loops from the high dose region. Image-guided radiotherapy allows for an accurate definition, localization and monitoring of tumor position, size and shape before and during treatment and may help to reduce set-up margins.

Small randomized controlled trials have shown that the administration of several agents might have a beneficial effect for the prevention of acute (e.g. intrarectal amifostine, oral sulfasalazine and balsalazide) and/or late-onset radiation-induced toxicity (intrarectal beclomethasone and oral probiotics). Once severe toxicity develops, total replacement of the diet with elemental formula may be appropriate. Probiotics influence the bacterial microflora and seem promising in reducing the incidence and severity of radiation-induced diarrhea. Currently there is insufficient evidence for cytoprotective and anti-inflammatory drugs in the management of radiation-induced toxicity. Future challenges lie in the prediction of treatment-related toxicity, which might be a promising step towards an individualized risk-adapted treatment.

Teaching Lecture: Role of brachytherapy in the management of paediatric tumors

SP-0005

Role of brachytherapy in the management of paediatric tumours

⁴Gustave Roussy, Physics Department, Villejuif, France

⁵Gustave Roussy, Pediatric Department, Villejuif, France

As the cure rates for childhood cancers continue to improve with better local control and outcome, the incidence and management of long-term consequences are a constant challenge. Conservative treatments include a combination of chemotherapy, radiotherapy and surgery that may lead to 5 year-survival rates > 90%. The use of brachytherapy, whenever feasible, is an attractive alternative when ionizing radiation is needed for the treatment of paediatric cancers, especially rhabdomyosarcomas (RMS). In genital RMS, brachytherapy represents an alternative to radical surgery: hysterectomy or colpectomy in girls and cysto-prostatectomy in boys. When brachytherapy is properly applied, the probability of late complications remains low with a high

cure-rate. At Gustave Roussy Hospital, since decades, brachytherapy -when possible- has been proposed as an alternative to external irradiation or radical surgery. So far, more than 150 children have been treated with brachytherapy, in the context of multidisciplinary approach, including chemotherapy +/- conservative surgery. The most frequent tumour sites were vagina/uterine cervix, bladder/prostate and nasolabial fold, the most common histopathological type being RMS. In a series of 39 girls treated between 1971 and 2005, interstitial brachytherapy was used for vulval tumors, and endocavitary brachytherapy was used in vaginal tumours with individually tailored moulded vaginal applicators. Among them, 20 patients were treated before 1990, where the initial tumoral extension was included in the brachytherapy volume, while after 1990, only residual disease after initial chemotherapy was treated. The usual prescribed dose was 60-65 Gy delivered in one to three brachytherapy applications, taking into account the doses to organs at risk. With a median follow of 8.4 years, local recurrence was reported in 2 patients (5.1%) in the first year following the treatment, regional relapse in 1 patient (2.6%) and distant recurrences in 7 patients (17.9%). Among the 20 patients treated before 1990, 15 presented long-term sequelae, (vaginal or urethral sclerosis or stenosis) with three requiring surgical treatment. By contrast, among the 19 patients treated after 1990, four patients had vaginal or urethral stenosis, none of them requiring surgery. A recent long-term toxicity analysis confirmed the increase of the total number of G3-4 late effects in patients treated before 1990. From 1991 to 2007, 26 boys with bladder/prostate RMS were treated with brachytherapy as a perioperative procedure. All of them underwent a conservative surgical procedure, with bladder-neck and urethra preservation. Brachytherapy was systematically performed after tumor resection, consisting of two loops encompassing the prostate and the bladder-neck area. A total dose of 60 Gy was delivered with low dose rate. With a median follow-up of 4 years (10 months-14.5 years), only one patient locally relapsed out of the brachytherapy treated area. Among 11 boys older than 6 years, 9 (82%) were normally continent, two had diurnal dribbling treated by bladder education. Recently, sexual and urinary functions, assessed with a quality of life (QoL) questionnaire, were studied in a cohort of 22 long-term survivors. The results showed that the great majority of long terms surviving males (76%) considered themselves as having normal QoL. Between 1971 and 2005, 16 children with RMS of the nasolabial fold were treated with brachytherapy. Ten presented embryonal RMS and six alveolar RMS. In 12 cases, brachytherapy was combined with local excision. The doses ranged from 50 to 70 Gy, depending on chemotherapy response, and surgical margins. With a median follow-up of 4.4 years (1.7-33), 10 patients relapsed: 4 local, 6 regional, and 2 metastatic failures were reported. In this particular context, brachytherapy provided an acceptable local control rate, but with a poor regional control. The ballistic interest of BT has been clearly demonstrated in paediatric RMS, with a very high dose gradient, sparing normal tissue and very high tumor dose. In our experience low dose-rate brachytherapy was used and recently had to move to pulsed dose-rate brachytherapy. Such conservative approach, minimizing late sequelae without detrimental effect on local control, should be offered whenever possible. This treatment is a clear demonstration of the multidisciplinary team approach, including surgeons, pediatricians and radiation oncologists.

Teaching Lecture: Challenges in MR guided radiotherapy

SP-0006

Challenges in MR guided radiotherapy

J. Jonsson¹

¹Umeå University - Norrlands Universitetssjukhus, Department of Radiation Sciences, Umeå, Sweden

Radiotherapy has relied on computed tomography (CT) for both target definition and treatment planning during the last decades. However, the increasing accuracy in radiation

delivery, through highly conformal techniques such as intensity modulated radiotherapy (IMRT) and image guided radiotherapy (IGRT), has highlighted deficiencies in target delineations based on CT. Several studies have shown large variability in target definitions based on CT, for multiple treatment sites. To address this issue, magnetic resonance imaging (MRI) has made its way into the clinical routine at modern radiotherapy departments over the last years. This, however, has presented several new problems that need to be solved.

The traditional method of including MR information in the radiotherapy process is as a complement to the CT. To accomplish this in an integrated and accurate fashion, the images must be placed in a common coordinate system through image registration. This process in itself introduces new uncertainties into the treatment chain, which must be quantified and minimized. Another method of using MR information is to base the entire treatment on MR and exclude the CT altogether. This alleviates uncertainties that stem from the image registration process, but introduces another set of problems. To perform accurate dose calculations, heterogeneity corrections based on CT data have been the clinical standard for many years. MR data does not provide information that can be used for such corrections; however, much research effort has been invested in creating valid photon attenuation maps from MR data over the last years.

Whatever method employed, MR for radiotherapy purposes also imposes practical issues that need to be addressed. The patient needs to be positioned in the same way that will be employed during the radiotherapy itself. This includes a flat table top and immobilization devices such as cast masks and tilted boards, which may not be MR compatible. For example, many radiotherapy fixation devices can contain metal parts such as nuts and bolts, which cannot be used in the MR. Plastic replacements must be used instead. Also, the standard MR coils will often not accommodate the immobilized patient, which forces MR adopters to acquire special coils or coil holders for flexible coils to be able to scan the patient in the radiotherapy treatment position.

MR images do not have the same geometric integrity as CT, which is an issue in the radiotherapy setting. The image distortions can come from the machine itself or from the patient that is in the machine. Machine specific distortions are caused by inhomogeneity in the main magnetic field or gradient non-linearity. Patient specific distortions are mostly caused by susceptibility effects. The machine specific distortions can be measured, modelled and corrected for to a certain extent, while patient specific distortions often need to be handled by choosing imaging parameters wisely.

In the end, the images acquired from the MR scanner must be of sufficient quality to allow physicians to base the radiotherapy treatment on them. MR for radiotherapy has a different set of demands on the images than their diagnostic counterparts, for example slice thickness and gap, as well as other parameters. Also, the vast variety of MR contrasts may be an initial obstacle for radiotherapy oncologists. Many studies have shown differences in target definitions based on CT and MR images, and the effects of these changes in target volumes have not yet been studied in clinical trials.

Teaching Lecture: Patient specific quality assurance in proton therapy

SP-0007

Patient specific quality assurance in proton therapy

R. Amos¹

¹University College London Hospitals NHS Foundation Trust, Department of Radiotherapy Physics, London, United Kingdom

Interest in proton therapy continues to grow worldwide, yet access to proton therapy facilities remains relatively low compared to those offering conventional radiotherapy. As a consequence, pressure exists to maximize patient throughput in each facility. Most facilities operate 24 hours per day, 7 days per week to meet the demands of the clinical load and

to complete machine maintenance, routine quality assurance, and patient specific quality assurance. With the advent of advanced delivery techniques such as pencil beam scanning, the complexity of patient specific quality assurance is increasing. However, there is a need to improve efficiency of these tests whilst maintaining accuracy.

This presentation will summarize contemporary patient specific quality assurance practice for both passive scattering and pencil beam scanning proton therapy, and describe off-line tests that potentially enable improved efficiency.

Teaching Lecture: Balancing toxicity and disease control in the evolution of radiotherapy technology

SP-0008

Balancing toxicity and disease control in the evolution of radiotherapy technology

B. O'Sullivan¹, S. Huang²

¹Princess Margaret Cancer Centre, Toronto, Canada

²Princess Margaret Cancer Centre/University of Toronto, Radiation Oncology, Toronto, Canada

Radiotherapy (RT) is an effective option for treatment of many cancers. It offers organ and functional preservation and enhances surgical outcomes when administered pre-operatively or post-operatively, and for some diseases, such as nasopharyngeal cancer, it is often the only curative option. Disease control is generally of paramount importance to most patients during the urgent point of decision-making following diagnosis. However toxicity will almost certainly emerge as being just as relevant in the aftermath of treatment and in the subsequent follow-up period. In essence, when a patient dies of toxicity or treatment-related complications, it is just as tragic as dying of disease. The long-term result of RTOG 9111 and 9501 suggest that treatment-related deaths are blunting originally observed difference in cancer-related outcome. The recent RTOG 0617 trial was designed to test whether a higher RT dose (74 Gy vs 60 Gy) +/- cetuximab could confer a survival benefit but showed an unexpected therapeutic "disadvantage" with higher RT dose attributable to significant acute and late toxicities. These findings highlight the importance of balancing toxicity and disease control to optimize therapeutic gain. Several strategies have been employed to mitigate toxicities, such as respecting the biology of radiation injury by altered dose fractionation (typically using smaller than conventional fractions), or optimising radiotherapy technical delivery to reduce dose to vulnerable anatomy. Implementing novel RT technologies need to be closely monitored to prove clinical benefit. Historical lessons have shown that putative benefits may not always transfer to real clinical advantages since many unforeseen factors may modify potential anticipated gains. While modern RT technologies, such as IMRT-IGRT, adaptive, and IMPT provide opportunities to reduce RT late toxicity by providing more conformal dose distribution to spatially avoid normal tissue, the steps to achieve this are complex. One needs to appreciate many diverse factors. These include radiobiology of normal tissue (dose/constraints), optimal imaging quality and registration, systematic quality control involving "target" delineation to delivery, and knowledge of a variety of inherent pitfalls in the process (e.g. poor delineation, dose dumping, erratic planning, tumor or normal tissue deformation, and set up uncertainties that may emerge throughout the treatment course). For example, beam path toxicities have been reported due to "dose dumping" from parotid-sparing IMRT in head and neck cancer. Increased local failure has been observed when delivering tight margin carotid-sparing partial organ irradiation for T2 glottic cancer using vertebrae rather than laryngeal soft tissue as the image guidance surrogate. Adaptive radiotherapy appears to be feasible in some situations but the therapeutic advantages are yet to be proven and may be tedious and inefficient under the current technical configurations of many departments. Also, while intensity-modulated proton therapy (IMPT) is an attractive emerging approach that is probably able to spare normal tissue, indications and clinical benefit

are also largely unproven at this time. The path to implementing these approaches will require rigorous attention to the radiotherapy planning and delivery elements, and careful systematic and prospective documentation of tumor and normal tissue outcomes. Even if randomised trials are deemed unsuited to the setting, protocol based approaches in registered phase I/II trials are appropriate to enhance standards and should probably include audit and quality assurance processes, as well as realistic stopping rules to address unexpected or aberrant outcomes.

Symposium: Selection of patients for proton therapy

SP-0009

Patient selection for proton therapy: a clinicians view

A. Mahajan¹

¹MD Anderson Cancer Center, Proton Therapy Center, Houston, USA

Proton therapy is a radiation modality that has become increasingly available world wide over the past decade. It is an attractive radiotherapy intervention because of the charged particles dose deposition profile of characterized by the Bragg peak. By using proton therapy strategically, there is the possibility to deliver effective radiation dose to the target while reducing radiation to the surrounding non-target structures. The goals of any radiotherapy approach is to improve tumor control and/or reduce side effects and proton therapy offers an opportunity to achieve either one or both of these goals. Despite the promise of proton therapy, one must consider its associated risks and benefits, and as with any other radiation approach, to maximize the benefit to the patient. In general concepts that are useful in selecting and predicting a the benefit of proton therapy in individual patients include the following:

- 1) Proton therapy has the same risk of injury within the target area and high dose as other radiation therapies. For infiltrative tumors that require irradiation of a margin of normal tissue (example rhabdomyosarcoma) or those that have normal cells embedded within the tumor (example low grade glioma), the tissues receiving the high dose of radiotherapy will have similar risks of injury as non-proton approaches; therefore, one would not expect a lower risk of injury in the high dose area.
- 2) Since proton therapy is typically associated with a lower risk of late effects Patient who has a very low chance of surviving a long time due to the natural history of the disease, may not benefit from proton therapy, example widely metastatic cancer.
- 3) Patients, for example children, who can derive benefit from normal tissue radiation dose reduction are usually good candidates
- 4) Patients who require high doses of radiation to achieve tumor control, but would otherwise be limited due to normal tissue tolerance, for example patients with skull base chordoma or primary or secondary liver.
- 5) Tumor geometry and surrounding anatomy must be evaluated to estimate the potential benefit of proton therapy. For example, a 2 year old patient requiring flank radiation for Wilms tumor may have not benefit with proton therapy, whereas an 18 year old with a paravertebral Ewing's sarcoma may have significant advantage with proton therapy.
- 6) Patient set up, tissue uncertainties, external devices or implanted need to be evaluated to minimize the risk of uncertainties and disruption in the proton dosimetry.
- 7) Proton therapy may be a good option for re-irradiation in selected patients. In summary, proton therapy can be an excellent option to provide better local control and/or reduced toxicities in selected patients.

Selection of patients for proton therapy: a physicists view

M. Hoogeman¹, T. Arts¹, S. Van de Water¹, S. Van der Voort¹, Z. Perko², D. Lathouwers², S. Breedveld¹, B. Heijmen¹

¹Erasmus Medical Center Rotterdam, Erasmus MC Cancer Center, Rotterdam, The Netherlands

²Delft University of Technology, Radiation Science and Technology, Delft, The Netherlands

Intensity Modulated Proton therapy (IMPT) is a highly promising approach for radiation treatment of cancer patients due to its increased potential to reduce side effects and improve quality of life compared to contemporary radiation therapy techniques, such as IMRT. However, IMPT is associated with high costs and hence limited availability. Ideally, patient selection for IMPT should be based on the highest expected complication reduction compared to IMRT.

For a given patient, it is possible to predict the risk of side effects for proton and photon therapy by applying Normal Tissue Complication Probabilities (NTCP) models to optimized dose distributions. Only patients with clinically relevant reductions in NTCP exceeding minimum pre-defined thresholds will then qualify for proton therapy. While this approach should guarantee effective use of proton therapy, there are several concerns that will be discussed in this presentation:

1. The generation of a radiotherapy treatment plan is a complex procedure and its quality is highly dependent on the planner skills. To enable unbiased comparisons between IMPT and IMRT for each patient, automation of the treatment planning process is imperative.
2. IMPT is highly susceptible to inaccuracies in patient setup, anatomic changes, and to uncertainties in the calculation of the proton range. In IMRT, uncertainties in dose delivery are accounted for in the CTV-to-PTV margin. In IMPT, however, the PTV concept is not applicable. Alternatively, robust treatment planning can be used to take into account patient setup and range uncertainties. However, it is currently unknown which robustness settings need to be used to achieve an adequate target coverage for given population-based distributions of setup and range errors.
3. Image-guidance technology improves the accuracy of radiation therapy delivery, however its impact and current state-of-the-art may vary for proton and photon radiotherapy due to the physical differences between protons and photons and for historical reasons. The applied image-guidance technology will have an impact on the magnitude of NTCP reduction and hence on the selection of patients qualifying for proton therapy.

SP-0011

Future selection practice for proton therapy: selection of patients based on treatment planning comparison and NTCP-modelling

H. Langendijk¹

¹University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

The last decade, many new radiation delivery techniques have been clinically introduced without being subjected to randomized controlled trials. Many of these new techniques have been introduced in order to reduce the dose to the healthy tissues and subsequently to prevent radiation-induced side effects. Due to its superior beam properties, radiotherapy with protons compared to photons enables similar dose administration to the target volume with substantially lower dose to the normal tissue. In the Netherlands, we applied a 4-step model-based approach to select patients for proton therapy and to validate the benefit of protons compared to photons with regard to reducing the risk on radiation-induced side effects.

Step 1 consists of the development and validation of multivariable Normal Tissue Complication Probability (NTCP) models. NTCP models describe the relationship between radiation dose distribution parameters and the probability of a given side effect (NTCP-value). One of the output parameters of this step are the most relevant Dose Volume Histogram (DVH) parameters that can be used to optimize radiation treatment.

Step 2 includes in silico planning comparative studies. In this phase protons are compared with photons with regard to their ability to reduce the most relevant DVH-parameters resulting from step 1 (Δ Dose).

Step 3: Integration step 1 and 2. By integrating the results of the individual in silico planning comparison into the validated

NTCP-models, the differences in dose can be translated into a difference in NTCP-value in each individual patient (Δ NTCP). In the Netherlands, a national consensus has been reached regarding the threshold for (Δ NTCP). Finally, the potential benefits of protons can be clinically validated in step 4, based on external validation of the NTCP-models when patients are treated with protons. The model-based approach is an evidence-based methods for selection and validation of new radiation technologies.

Symposium: Mitigating normal tissue toxicity

SP-0012

The use of ACE inhibitors to attenuate thoracic irradiation-induced cardiopulmonary toxicity.

S.J. Van der Veen¹

¹University Medical Center Groningen UMCG and University of Groningen RUG, Cell Biology and Radiation Oncology, Groningen, The Netherlands

Synopsis:

In thoracic irradiation, the maximum radiation dose is restricted by the risk of radiation-induced cardiopulmonary damage and dysfunction limiting tumor control. Unfortunately, current clinical practice does not include preventative measures to attenuate radiation-induced lung or cardiac toxicity. Inhibition of the renin-angiotensin system (RAS) seems to be an alluring strategy for attenuating radiation-induced cardiopulmonary dysfunction.

Interestingly, angiotensin-converting enzyme inhibitors (ACEi) have been shown to reduce the risk of radiation-induced respiratory dysfunction in preclinical (1) and clinical studies (2). More recently a study in rats showed that ACEi reduces respiratory dysfunction indirectly by reducing acute heart damage (3).

So far, the mechanisms of the protective effect of ACEi on radiation-induced toxicity are not clear. Apart from their hypotensive action, ACEi are known to have other properties such as an anti-inflammatory action. Further, it has been suggested that the sulfhydryl group in the molecular structure of captopril confers in a free radical scavenger activity. All these effects can account in part for its radioprotection. Besides, it might act as an antioxidant to reduce inflammatory reactive oxygen species and thus mitigate radiation-induced toxicity.

To conclude, ACE inhibitors have been shown to mitigate radiation-induced cardio-/pulmonary toxicity in (pre)clinical models. However, the mechanisms of action are not clear. As such the use of ACE inhibitors should be further evaluated as a strategy to reduce cardiopulmonary complications induced by radiotherapy to the thoracic area.

SP-0013

Radiation-induced musculoskeletal late damages: possible clinical cure or simple mitigation?

S. Delanian¹

¹Hôpital Saint-Louis- APHP, Oncologie-Radiothérapie, Paris, France

RI musculo-skeletal sequelae combine opposite tissular aspects of fibrosis and atrophy in a heterogeneous patchwork comprising concomitant active cellular and sclerotic matricial areas. Tissue remodeling follow early, subacute, chronic inflammatory changes, then fibrosis and necrosis, that provides signaling pathways through growth factors and their receptors.

In medicine, clinical cure of a chronic disease is never binary or surgical, if exists, because of the pathologic underground network well-established in the tissues.

Cure for radiation-induced (RI) late damages should be approach by a strategy using a hierarchical control of accurate protagonists. During last decades, each therapeutic intervention has illustrated successively one of the facets of this fibrotic process:

- In seventies, STEROIDS, then non anti-inflammatory drugs, showed able to stop acute RIF progression and are always required today as the first treatment in all sequelae, while anti-collagenic drugs were too toxic.

- In eighties, vascular approach revealed antithrombotic help in some acute aspects (HEPARIN), and interesting role of PENTOXIFYLLINE (speed healing) or HBO.

- In nineties, successful clinical use of superoxide dismutase (SOD) allowed to bring to light reactive oxygen species (ROS) - fibroblasts and their related anti-oxidant strategy, then PENTOXIFYLLINE-VITAMIN E (PE) combination. The fibrotic clinical regression was slow but measurable, followed by convincing "preclinical" studies (histological reversion, in vitro modulation): first cases of fibrotic clinical cure [1,2].

- Then anticytokines (TGF β , CTGF, ...).

- After 2000, adding clodronate, in a PENTOCLO combination, allowed speedier and durable clinical RI responses, highlighting its anti-macrophagic effect on bone necrosis : first cases of osteoradionecrosis clinical cure [3]. However, therapeutic range of these drugs is tight, related to bisphosphonate absence of specificity and the bivalent macrophagic action (M1/M2 populations).

Clinical cure is a difficult art: it should take in account all these several facets. In the future, controlled trials and preclinical studies are necessary to identify best antifibrotic agents (phenotypic reversion of deficient cells), and organ specific targeted drugs and/or stem cell therapy (compensate tissular depletion after cell death), to obtain regular clinical cure if any.

Radiation-induced lung fibrosis is associated with M2 interstitial and hybrid alveolar macrophages

L. Mezzani¹, M. Mondini¹, B. Petit², M.C. Vozenin², E. Deutsch¹

¹Institut Gustave Roussy, INSERM U1030, Villejuif, France

²Centre Hospitalier Universitaire Vaudois, Radio-Oncologie/Radiothérapie, Lausanne, Switzerland

Radiation-induced fibrosis is a delayed complication of radiotherapy often associated with chronic inflammatory process and macrophage infiltration. Nowadays, macrophages are suggested to be important cellular contributors to fibrogenic process, but their implication in the context of RIF is not well known.

To investigate the role of macrophages in RIF we have used a classical experimental model of lung fibrosis developed in C57Bl/6 mice after 16Gy thorax-IR. We then profiled both alveolar macrophages (AM) and interstitial macrophages (IM) during the various steps of the fibrogenic process.

We confirmed the fact that total lung irradiation at 16Gy (IR) induces an interstitial fibrosis associated with delayed recruitment of pulmonary macrophages. We found a transient depletion of AM associated with cytokine secretion during the acute post-IR phase (15 days), followed by an active repopulation and an enhanced number of AM during the late post-IR phase (20 weeks). Interestingly, AM were mostly recruited from the bone marrow and exhibit a hybrid polarization (M1/M2) associated with up-regulation of Th1 and Th2 cytokines. The number of M2-polarized IM significantly increased during the late time points after irradiation and a down-regulation of Th1 cytokine was measured in tissue lysate. These results suggest a differential contribution of hybrid AM vs M2-IM to fibrogenesis. Interestingly, in contrast to activated hybrid AM, activated M2-IM were able to induce fibroblast activation *in vitro* mediated by an enhanced TGF- β 1 expression suggesting a profibrotic role of M2-IM. Specific depletion of hybrid AM using intranasal administration of clodrosome increased radiation-induced fibrosis score and enhanced M2-IM infiltration suggesting a protective role of hybrid AM.

These present study shows a dual and opposite contribution of alveolar *versus* interstitial macrophages in radiation-induced fibrosis and identify M2-IM as a potential therapeutic target to treat radiation-induced fibrosis.

Symposium: Regional nodal irradiation for breast cancer

SP-0015

The axilla- less surgery, more radiotherapy?

M.I. Algara López¹

¹Hospital de la Esperança, Radiation Oncology, Barcelona, Spain

Irradiation of lymph node areas in breast cancer patients, especially in early stages of the disease is a controversial topic. The recommendation to irradiate lymph nodes is

clearly indicated in patients with more than three involved nodes. In these cases, after standard lymphadenectomy, the volumes to irradiate include supraclavicular fossa and axillary level III nodes. Until a few years ago, irradiation of axillary levels I and II, are reserved for cases of very large axillary involvement, or in patients whom lymphadenectomy was insufficient (less than 10 lymph nodes resected). However, when only 1 to 3 nodes are involved, there is no unanimity on the radiotherapy recommendations, despite several studies having show clearly a disease free survival improvement in irradiated patients. The Canadian trial NCIC-CTG MA20, including high risk patients, most of them with 1 to 3 involved nodes, showed that local irradiation with regional lymph node irradiation improved disease-free survival, both loco-regional and distant disease control. The EORTC trial also demonstrates the same findings: regional irradiation in breast cancer patients improve even the overall survival. Therefore the current trend, described in international guidelines, lymph node irradiation is recommended for all patients regardless of the number of positive nodes. Nevertheless, the therapeutic value of axillary lymphadenectomy has been questioned for a long time. The ACOSOG Z0011 study results have caused clinical practice changes since many axillary dissections are being avoided. Even several clinical practice guidelines, including prestigious ones such as those of National Comprehensive Cancer Network, don't recommend lymphadenectomy. The ACOSOG Z0011 does not exactly describe the irradiated nodal volumes exactly. Therefore, the nodal volumes to include in the irradiation treatment of early stages of breast cancer remains under discussion, especially without axillary lymphadenectomy despite involvement of sentinel lymph nodes. In most cases, breast irradiation with tangent fields implies certain "incidental" of axillary level I, and also in some cases the level II. For this reason, some groups have decided to avoid intentional irradiation of these axillary areas, while others advocate to irradiate them intentionally, without clear evidence to do that. The AMAROS trial demonstrated that lymph node radiotherapy obtains the same results as axillary dissection in node-positive patients without primary systemic treatment, with less morbidity. Therefore, it is possible to replace the surgery with radiation. The current situation is that some groups decide to irradiate lymph node in cases with positive sentinel node without lymphadenectomy and other groups in these cases do not treat the lymph node, and accept that some incidental irradiation will arrive by tangential fields. But, we do not know which patients, with positive nodes, do not require lymph node irradiation. It is possible that in patients with low axillary involvement intentional irradiation would not be necessary. In order to demonstrate this hypothesis, we have started the OPTYMAL trial (www.clinicaltrials.gov/ct2/show/NCT02335957?term=osna&rank=7) to investigate the non-inferiority of incidental versus intentional irradiation of axillary nodes in patients with axillary involvement of 250-15000 copies/uL with One Step Nucleic Acid Amplification method (OSNA). We decided to use this method to unify the pathological reports. This international multicenter trial must help us to elucidate the necessity of node area irradiation by combining with reliable information about the tumor load involvement in axillary nodes.

SP-0016

The internal mammary chain - should we treat it in every node-positive patient?

P. Poortmans¹

¹Radboud UMC, Department of Radiation Oncology, Nijmegen, The Netherlands

Locoregional radiation therapy (RT) improves locoregional control and survival for patients treated with breast conserving therapy and for patients after mastectomy with risk factors including involved axillary lymph nodes. In the past, however, this treatment could be linked to an increased risk for late cardiovascular morbidity and mortality as a result of cardiac exposure to radiation. This was especially the case for the treatment of the internal mammary lymph node target volume, for which this was abandoned by many

radiation oncology centers worldwide. We now know that these side effects can most often be attributed to the use of outdated RT techniques. As treatment techniques started to improve, enabling to limit the dose to the organs at risk, prospective trials were initiated to evaluate the contribution of lymph node treatment to overall outcome for early stage breast cancer patients. The results of several studies were presented over the last couple of years. They demonstrate that an increased disease-free survival rate following a decrease of the risk of distant metastases can be obtained in patients with risk factors, including those with involvement of the axillary lymph nodes and those with a centrally or medially located primary tumour. Moreover, a trend towards an improved overall and (statistically significant for some of the studies) breast cancer specific survival was demonstrated. No increase was seen in the other causes of death and, at a median follow-up of around 10 years, no significant or clinically relevant increased toxicity was found, apart from a slight increase in the risk for pulmonary toxicity. The concept of “any recurrences”, introduced by the EBCTCG in 2011, as important endpoint of the evaluation of the effect of all types of treatments (including locoregional ones such as surgery and RT) fits much better to the interpretation of the recently presented results. In this era of earlier diagnosis and more widespread use of adjuvant systemic treatments leading to a 10-year overall survival exceeding 80%, clinically detectable locoregional recurrences as a separate endpoint might indeed be considered as less relevant. Firstly, the patient will be affected heavily by any type of recurrence and secondly because of the complex interaction between the efficacy of systemic treatments with the influence of loco-regional treatments on overall survival. By merely focusing on locoregional control, we risk to neglect that once distant metastases are found no further efforts are undertaken to detect locoregional recurrences. By eliminating microscopically non-detectable cancer cells in the lymph nodes with RT, the risk of secondary metastasizing of those cells and thereby ultimately the overall risk of recurrence of the breast cancer will be reduced. This is in line with the findings of the EORTC trial in which a trend was seen towards more benefit for patients who were treated with both hormonal treatment and chemotherapy and less benefit for the small group of patients with 10 or more involved axillary lymph nodes: patients with a better prognosis (lower risk factors and/or better systemic therapy) experience more benefit from locoregional treatments. With modern RT techniques, the benefits of optimizing locoregional control will likely not be counterbalanced by side effects including late cardiovascular mortality. Moreover, the new ESTRO guidelines for target volume delineation clearly reduce the size of the target volumes while simultaneously considering the regional lymph nodes even more than before as a whole. We also expect that the real benefit of loco-regional RT used to be diluted in the past (including the recently presented trials) by suboptimal dose coverage of the target volumes. Therefore, we expect that with contemporary RT techniques and appropriate target volume delineation, not only a significant reduction of the dose to the organs at risk but also a much better coverage of especially the internal mammary lymph nodes is achievable, which is likely to result in a further improvement of the benefit of locoregional RT for patients with early stage breast cancer that have a risk for bearing microscopical tumor deposits in the regional lymph nodes.

SP-0017

Technical approaches to regional lymph node irradiation for breast cancer

A. Kirby¹

¹The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Radiation Oncology, London, United Kingdom

The quality of radiotherapeutic approaches to treating locoregional lymph nodes in breast cancer is improving. This talk will review the latest evidence pertaining to each aspect of the planning and treatment pathway in order to inform

best practice. Recently published atlases capable of improving consistency in outlining target and non-target volumes will be reviewed. Using data relating outcomes to dosimetry, we will then review the evidence base for target and non-target tissue dose constraints and objectives. Different radiotherapeutic approaches including breath-hold, volumetric-modulated arc therapy, and proton beam therapy will be compared in terms of dosimetry and resource implications. Potential efficiency savings in the treatment pathway will also be discussed together with a review of the possible impact of bluer-sky technologies.

Symposium: Assessment and management of rectal morbidity

SP-0018

Towards a scoring system built on six distinct radiation-induced illnesses producing late gastrointestinal effects

G. Steineck¹, R. Jörnsten², V. Skokic¹, U. Wilderäng¹, G. Dunberger¹

¹Göteborg University, Department of Oncology- Institute of Clinical Sciences, Göteborg, Sweden

²Göteborg University, Chalmers Technical Institute, Göteborg, Sweden

As shown in randomized studies, radiotherapy has a critical role when we cure prostate cancer by using multimodal treatment strategies. We frequently use radiotherapy to cure gynecological cancer. Both Intensity-Modulated Radiation Therapy and Volumetric Modulated Arc Therapy have the potential to drastically increase the ratio between possibilities for cure and risk of late effects. Still, crude measurements of patient-reported outcomes, as well as factors that may modify the how radiation cause late effects, compromise these possibilities. We lack details to provide parameters from dose-volume modelling to utilize the full potential of these new technologies. Concerning bowel health, current scoring systems of radiation-induced late gastrointestinal must be refined. Important socially invalidating symptoms are not scored. An example is unexpected defecation into clothing - not sensing the need to go to the toilet and a sudden defecation into clothing as if one were already on the toilet. We documented this symptom among 11 percent of gynecological-cancer survivors. Another example is frequent and uncontrolled noisy flatulence. Traditional scoring systems have scales that do not distinguish or clearly depict person-incidence (events per individual per time unit), intensity and duration. But, probably most important, as we learn that decreased bowel health depends on several different types of radiation-induced illness, we understand that grouping symptoms from different illnesses together in a score compromises our ability to acquire knowledge for prevention or relief. We cannot disentangle these different radiation-induced illnesses when symptoms from several illnesses are grouped together in the data sets we retrieve. Clearly, new strategies are needed. In my talk, I will propose a scoring system based on the data indicating that the at least 28 radiotherapy-induced atomized late gastrointestinal symptoms derive from six distinct illnesses, that is, six sets of risk organs or mechanisms. We have data from around 1500 survivors supporting this position. As we accumulate data for each of these six illnesses, we can define parameters in dose-volume models built on patient-reported outcomes much better than we previously could. Possibly we can also learn how, by employing probiotics or dietary changes, we can influence the interplay between the gut flora and stem-cell renewal to counteract inflammatory processes that probably are important for several of the six illnesses. Moreover, the knowledge may stimulate development of mouse models in which we can test, for example, how different bacterial species influence radiation-induced inflammation in the rectal wall. In the talk, I will give preliminary results from the establishment of such a model. A simplified nomenclature could label the six illnesses as involving processes resulting in leakage-related symptoms, urgency-related symptoms, constipation-related symptoms, symptoms

related to excessive mucus production, symptoms related excessive gas production and symptoms related excessive blood production. A modern scoring system should have two or more atomized symptoms related to each of the six illnesses and appropriate response scales for frequency, intensity and duration.

SP-0019

Measuring anorectal toxicity and function

D. Vordermark¹

¹Martin Luther University Halle-Wittenberg, Radiation Oncology, Halle / Saale, Germany

Anorectal toxicity is a relevant side effect of pelvic radiotherapy for rectal, anal, gynaecologic and prostate cancer. Toxicity can be scored objectively by the physician according to established systems such as the CTCAE classification. In recent years, patient-reported outcomes (PROs) have received increasing attention when evaluating acute toxicity as well as late effects of cancer treatment. These include information directly obtained from the patient on symptoms and impairment as well as on quality of life. This presentation will focus on validated instruments to measure PROs related to anorectal function, including quality-of-life questionnaires and organ modules, e. g. those developed by the EORTC Quality of Life Group, and symptom questionnaires e. g. to measure continence. Objective measurements to quantify anorectal function such as sphincter manometry and endoscopic scores will be reviewed. The relationship between PROs and objective function assessment with physician-rated toxicity will be addressed. The outcomes for the above endpoints in major trials of pelvic radiotherapy will be presented, with a focus on rectal cancer and the effects of treatment concepts including short-course radiotherapy and long-course chemoradiation. Finally, dose-volume constraints in pelvic radiotherapy treatment planning and potential effects of highly conformal techniques such as IMRT or VMAT on anorectal symptoms, function and quality of life will be examined.

SP-0020

Rectal spacers to minimise morbidity in radiotherapy for prostate cancer

M. Pinkawa¹

¹Uniklinik RWTH Aachen, Radiation Oncology, Aachen, Germany

Radiotherapy is a well recognized curative treatment option for localized prostate cancer. Optimal tumor control rates can only be achieved with high local doses, associated with a considerable risk of rectal toxicity - regarded as dose-limiting toxicity. Apart from already widely adapted technical advances, as intensity-modulated radiation therapy and image-guided radiotherapy techniques, the application of spacers placed between the prostate and anterior rectal wall has been increasingly used in the last years.

Biodegradable spacers, including hydrogel, hyaluronic acid, collagen or an implantable balloon can create the desired effect. They can be injected or inserted in a short procedure under transrectal ultrasound guidance via a transperineal approach. A distance of about 1.0-1.5cm is usually achieved between the prostate and rectum, excluding the rectal wall from the high isodoses. Several studies have shown well tolerated injection procedures and treatments. Apart from considerable reduction of rectal dose compared to radiotherapy without a spacer, clinical toxicity results are favourable. A prospective randomized trial demonstrated a reduction of rectal toxicity after hydrogel injection in men undergoing prostate image-guided intensity-modulated radiation therapy. The results are encouraging for continuing evaluation in dose escalation, hypofractionation, stereotactic radiotherapy or re-irradiation trials in the future.

Symposium: Towards user oriented QA procedures for treatment verification

SP-0021

How to ensure the quality in brachytherapy treatment planning systems?

F.A. Siebert¹

¹University Hospital S-H Campus Kiel, Academic Physics, Kiel, Germany

Treatment planning systems (TPSs) are of high importance in modern brachytherapy. The users rely on the output of these special software; wrong calculations may result in severe patient harm. Thus it is necessary to systematically check these software programs.

Many checks in TPSs are identical for high-dose-rate brachytherapy with afterloaders and low-dose-rate brachytherapy with seeds. But some differences exist, e.g. as checking of afterloader parameters.

After the installation of the software the acceptance test is to be carried out. This test protocol is typically provided by the vendor and should be passed before further checking. In a second step the commissioning is carried out. In this procedure all clinical relevant data and properties of the TPS must be tested and reported. Examples for items to check are:

- Afterloader characteristics (number of channels, min./max. channel lengths, max. allowed dwell time, ...)
- Source characteristics (nuclide, decay, ...)
- TG-43 consensus data/Model-based dose calculation algorithms, commissioning following TG-186 report
- Applicator checks

To ensure the consistency and data integrity of the TPS periodical tests should be performed after the commissioning. Important points are to validate the integrity of base parameters of the TG-43 data and the recalculation of patient treatment plans.

Most TPSs offer inverse planning algorithms. The algorithm itself is often not fully transparent by the user, thus comparison with manual calculations is not practical. Nevertheless, the consistency of such planning technique can be checked by recalculation of a test plan using a constant parameter set. In addition to the tests above end-to-end tests can be performed to check the whole treatment chain, including imaging, TPS, afterloader, and data transfer.

SP-0022

Imaging

T.P. Hellebust¹

¹Oslo University Hospital, Dep. of Medical Physics, Oslo, Norway

In the past decade 3D image guided brachytherapy has been introduced into clinical practice worldwide. This enables conformation of the dose distribution to the target volume and avoidance of high dose to organs at risk (OAR) using CT, MR, and/or ultrasound (US) imaging. In such modern techniques sectional images give the relationship of the shape and the position of the applicator(s)/sources in relation to the anatomy of the patients. This means that the quality assurance (QA) programs also should include specific topics related to image quality additional to traditional procedures checking the source strengths and dose calculation issues. QA for image quality is well established in the area diagnostic and many of these procedures can be used also for brachytherapy. However, the procedures should be modified in order to reflect the conditions of use in brachytherapy compared to a diagnostic session.

To optimise the image quality in diagnostic procedures dedicated phantom is often used. Various image quality parameters are tested by evaluation for example slice thickness, spatial resolution, uniformity and noise. In contrast to diagnostic imaging, the ability to reconstruct several points or a geometric structure with high accuracy is crucial in brachytherapy. Therefore, a procedure to check the geometric accuracy have to be included in a QA program.

A phantom with known geometry should be used, either including markers with known relative coordinates or test objects with known shapes and volumes. The design of the phantom will depend of the modality to be tested.

For ultrasound imaging the AAPM Task Group 128 includes a list with 8 elements of a phantom that allow for all the recommended tests [1]. It is referred to a commercial phantom that include nylon monofilaments in a N-shaped pattern and spherical and non-spherical volume in order to test key imaging parameters such as depth of penetration, axial and lateral resolution, distance, area and volume measurements and geometric consistency.

Roué et al used a commercial PMMA phantom with 25 stainless steel markers with known relative position to check the geometric accuracy of CT and conventional x-ray imaging [2]. A phantom including several inserts with different density can be used to check the volume reconstruction accuracy for CT. Several commercial phantoms are available.

It is well known that geometrical distortions can frequently occur in MR images. The magnitude of the distortions should be investigated by using phantoms with markers or tubes filled with for example Cu²⁺-doped water solution. Additional, the influence of an applicator should also be investigated since for example the presence of a titanium applicator may produce geometric distortion in a high field MR machine.

The slice thickness will also influence the ability to reconstruct the geometry correctly. With too large distance between the slices the partial volume effect will influence the accuracy of the volume reconstruction [3]. On the other hand, de Brabandere et al showed that too small distance between the slices decreased the accuracy of seed detection in a dedicated phantom with agarose gel and 60 iodine seeds with known position using MR imaging [4].

SP-0023

Dose verification

K. Tanderup¹

¹Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

Any radiotherapy delivery is associated with uncertainties and with risk of misadministration/error. Misadministration/error refers to treatment incidents/accidents which can be prevented, while uncertainties can only be controlled to a certain degree and the residual variation must be accounted for through tolerances and treatment margins. Patient safety through prevention of radiation dose misadministration is highly prioritised and several authorities and societies worldwide are focusing on radiation safety and medical events. In 2004, the International Commission of Radiation Protection (ICRP) reported an analysis of 500 radiation events in BT. This investigation and others have shown that a significant share of radiation events are caused by human errors related to the manual procedures of BT. Verification in radiation therapy means the whole process of proof that planned dose is delivered to the patient within a specific level of accuracy. During the last two decades enormous developments and technological innovations in the field of external beam radiotherapy (EBRT) treatment verification have taken place. These developments have focussed on imaging technologies for 2D and 3D (and very actually also 4D) localization and anatomy reconstruction under treatment delivery conditions. Striking innovations have been imaging technologies such as

flat panel detectors, cone beam CT (CBCT), and most recently MRI, which is integrated with the linear accelerators. The combination of 3D-imaging techniques and dose measurements enables the estimation of the daily 3D-dose delivery in the patient anatomy. In contrast, on-board or real-time treatment verification of BT is currently not performed, simply because adequate tools are not available. There is currently a striking unbalance between the availability of treatment verification technology for EBRT and BT, and consequently a different level of safety. Adding even further to this unbalance, BT is related with higher risk of major dose misadministration than EBRT, since BT involves: 1) more manual procedures (e.g. assembly and implantation of applicators, catheter reconstruction, and guide tube connection), 2) mechanical equipment with a higher susceptibility to malfunction (e.g. source cable drive and applicators), 3) more frequent application of hypofractionation schedules, and finally 4) steeper dose gradients. New methodologies for treatment verification are highly warranted. Dose and source geometry are closely linked entities in brachytherapy. Dose calculation with TG43 is the current standard of dose calculation in brachytherapy, and has excellent accuracy in most clinical scenarios. TG43 is based on geometry. Given a direct correspondence between brachytherapy source geometry and dose, a geometric verification is nearly equivalent to a dosimetric verification. There are only few error scenarios where source geometry would be correct, but not dosimetry - e.g. source miscalibration. Therefore several novel "on-board" treatment verification tools are focused on verification of geometry: EM tracking of catheters, flat panel monitoring of source progression, fluoroscopy, and real-time in vivo dosimetry. Given the source geometry is correct, the next important step is to secure that the relation between sources and anatomy is correct. This last step is typically explored with imaging. Combinations between different verification tools may be the way to proceed to reach a higher level of treatment verification in brachytherapy which address geometry, patient anatomy and consequent dose delivery to the patient. The presentation will outline current developments in "on-board" treatment verification tools. The table below shows the current status of treatment verification in EBRT and BT, and indicates visions that can bring brachytherapy treatment verification forward.

Symposium: Robust and accurate functional MRI for radiotherapy

SP-0024

Needs and technical requirements for functional MRI in radiotherapy

U.A. Van der Heide¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Anatomical imaging with T1 and T2-weighted MRI is increasingly used in combination with CT for precise delineation of tumors and normal structures. MRI also offers functional techniques, such as diffusion-weighted MRI (DWI) and dynamic contrast-enhanced MRI (DCE-MRI). These can be applied in radiotherapy for tissue classification, monitoring of treatment response as well as for dose painting. In the diagnostic setting, these sequences are often part of routine scanning protocols. However, as for anatomical MRI sequences, there are some specific issues that need to be considered when applying these techniques in radiotherapy. For image registration with the planning CT, patients need to be scanned in treatment position. If the functional images are used for target delineation, their geometrical fidelity needs to be verified. In particular diffusion-weighted MRI is prone to geometrical distortions. Methods to reduce these distortions will be discussed. The spatial resolution of functional imaging tends to be lower than that of anatomical imaging. Although acquisition with small imaging voxels is feasible, this doesn't mean that the functional quantity (apparent diffusion coefficient for DWI and tracer kinetics parameters for DCE-MRI) can be reliably determined in a

single voxel. Test-retest measurements are a method to determine the smallest volume for which a reliable measurement can be obtained. A key asset of functional imaging is the capacity to measure physical quantities in tissue rather than contrast. In particular for longitudinal studies, monitoring treatment response, or in multi-center studies, this is critical. For radiotherapy dose painting it is necessary to know which threshold should be used to define a subvolume of the target for dose escalation. In the presentation, various quantitative methods and their reliability will be discussed.

SP-0025

Variation in DCE-MRI methodology and its implications for radiotherapy

A. Garpebring¹

¹Umeå University, Department of Radiation Sciences, Umeå, Sweden

Dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) is a technique based on rapid acquisition of a series of images depicting the uptake of a contrast agent (CA) in tissue. Through mathematical modeling of the CA's influence on the MR signal and the distribution of CA in the tissue, physiological parameters can be obtained on a voxel by voxel level.

These parameters, which for instance reflect flow, vessel integrity, cell and vessel density, are highly relevant in cancer treatments such as radiotherapy (RT). Several studies have shown that pretreatment parameter values as well as changes during RT can be correlated with outcome. However, drawing firm conclusions on the practical value of DCE-MRI in RT is currently difficult.

The reason for this difficulty has its roots in the complexity of performing a DCE-MRI study. Obtaining accurate quantitative parameter values reflecting primarily the physiology of a tumor requires advanced imaging as well as complicated post processing. Unfortunately, even though state of the art acquisition and analysis is performed it is likely that influences from the precise acquisition settings and the analysis tools remain in the final result. Hence it is crucial that all variations during a study is minimized to maximize the sensitivity.

Not only is it of great importance to reduce the variability within a study, ideally this should also be the case between studies. But here we have a significant issue. There are a large number of unavoidable trade-offs in DCE-MRI. For instance between spatial and temporal resolution and between accuracy, complexity and robustness of the analysis. Usually each group performing a study make their own decision on where to compromise and what parameters to evaluate. Although this may be optimal in each study it is problematic when drawing conclusions on the overall value of DCE-MRI in RT.

Of this reason several authors are calling for standardization of DCE-MRI acquisition and analysis. One organization that has responded to this call is the Quantitative Imaging Biomarkers Alliance (QIBA) which has published guidelines for standardizing DCE-MRI. In a comparison of methodology in studies employing DCE-MRI in RT the results are mixed. Overall, the technical quality of studies, measured as compliance with QIBA guidelines, is improving with time. However, the spread is also increasing. Hopefully, in the future more people will adhere to the attempts to standardize DCE-MRI and thus enable more homogenous data which can be used for better answering how DCE-MRI can be employed to improve RT.

SP-0026

Importance of b-value selection and geometrical accuracy in DW-MRI for radiotherapy

M. Lambrecht¹

¹University Hospital Gasthuisberg, Department of Radiotherapy and Oncology, Leuven, Belgium

Over the last decade, Diffusion Weighted MRI (DWI) has emerged as a promising imaging technique in the field of radiation oncology.

The ability of DWI to assess a tissue's microstructure makes it potentially very valuable in tumor characterization, delineation, detection of pathological lymph nodes, response prediction and response evaluation.

However, acquisition, analysis and interpretation of the images is far from straightforward. The imaging technique is prone to distortions interfering with the accurate geometrical localisation and quantification of the tissue of interest.

Furthermore quantification is heavily influenced by the choice of machine parameters, making reproducibility an important issue.

Overcoming these problems is of the utmost importance to move DWI out of the realm of research and into daily practice.

In this talk we will identify the important parameters influencing acquisition and quantification of DWI, with emphasis on the choice of b-values and geometrical accuracy. We will discuss the implications when using DWI for extracranial radiotherapy. Finally we will look into possible solutions and provide a framework to ensure maximal exploitation of the imaging technique for the future.

Joint Symposium: ESTRO-IAEA: Joint ESTRO-IAEA efforts on dosimetry, QA and audit for advanced treatment techniques

SP-0027

New IAEA-AAPM Code of Practice for dosimetry of small photon fields used in external beam radiotherapy

H. Palmans^{1,2}

¹National Physical Laboratory, Acoustics and Ionising Radiation, Teddington, United Kingdom

²EBG MedAustron GmbH, Medical Physics, Wiener Neustadt, Austria

Increased use of small photon fields in stereotactic and intensity modulated radiotherapy has raised the need for standardizing the dosimetry of such fields using procedures consistent with those for conventional radiotherapy. While many problems of small field dosimetry have been raised in the past, e.g. in Report 103 of the Institute of Physics and Engineering in Medicine, a vast amount of literature has addressed most of those and solutions have been proposed for specific situations. What has hampered the development of a Code of Practice until recently was the availability of data but in the last few years a considerable number of publications have provided new data and insights that have enhanced our understanding of small field dosimetry.

An international working group, established by the International Atomic Energy Agency (IAEA) in collaboration with the American Association of Physicists in Medicine (AAPM), has finalised a Code of Practice for the dosimetry of small static photon fields. The Code of Practice consists of six chapters and two appendices. The first chapter provides an introduction to situate the distinct role of this Code of Practice as compared to previous recommendations for reference dosimetry in external beam radiotherapy. The second chapter provides a brief discussion of the physics of small photon fields with emphasis on those aspects that are relevant to understanding the concepts of the Code of Practice. Particular issues that are addressed are the definition of field size, the field size dependent response of detectors, volume averaging, fluence perturbation corrections, reference conditions and beam quality in non-conventional reference fields. The third chapter introduces all details of the formalism used, which is based on the IAEA-AAPM formalism published by Alfonso et al. (Med Phys 35:5179-5186, 2008) and is extended to clarify its application to flattening-filter-free beams (FFF beams). The fourth chapter provides a comprehensive overview of suitable dosimeters for reference dosimetry in the conventional 10 cm x 10 cm reference fields, for reference dosimetry in machine-specific reference fields at machines that cannot establish a conventional 10 cm x 10 cm reference field and for the determination of field output factors in small fields. The fifth chapter gives practical recommendations for implementing reference dosimetry in both conventional 10 cm x 10 cm

reference fields and machine-specific reference fields. The sixth chapter provides the practical recommendations for the determination of field output factors in small photon fields. Comprehensive data on beam quality correction factors for ionization chamber types recommended for reference dosimetry are provided in chapter five and a detailed discussion on how they have been derived from the literature as well as a discussion of their uncertainties is given in the first Appendix. For beams with flattening filter (WFF beams) these data are consistent with the ones given in IAEA TRS-398 and the update to AAPM TG-51. For FFF beams additional corrections are taken into account for the difference in water to air stopping power ratios between FFF and WFF beams and for volume averaging due to the non-uniform lateral beam profiles. Comprehensive data on small field correction factors are given in chapter six for a wide range of recommended small field detectors. The second Appendix discusses in detail how these data have been compiled from the literature including both Monte Carlo calculated and experimental data and also provides a thorough evaluation of the uncertainties of those data.

The Code of Practice has been reviewed by referees selected by the AAPM and by the IAEA and is currently submitted for publication by the IAEA. This presentation is given on behalf of the IAEA-AAPM Working Group on small and non-standard field dosimetry.

SP-0028

Which dosimetric uncertainties in small fields are clinically acceptable for IMRT/VMAT?

D. Georg^{1,2}, W. Lechner¹

¹Medizinische Universität Wien Medical University of Vienna, Department of Radiation Oncology, Vienna, Austria

²Christian Doppler Lab for Medical Radiation Research, Department of Radiation Oncology, Vienna, Austria

During the last years small field dosimetry (re-)gained importance. Several working groups highlighted its relevance in the context of high precision radiotherapy techniques. Non-conventional linear accelerators that do not support standard reference geometry and the upcoming unflattened photon beams had an impact on upcoming recommendations in this context as well. However, recent audits revealed large uncertainties in small field dosimetry with deviations up to 10% for 2 x 2 cm² fields, which motivated the present contribution. Clinically used beam models of two TPS (Monaco, ELEKTA and iPlan, BrainLAB) were modified to mimic the large uncertainties in small field output factors. Next IMRT and VMAT treatment plans for prostate and head and neck cancer cases as well as treatment plans for stereotactic brain lesions were generated and calculated with correct and incorrect beam models, respectively. Finally, treatment plans were delivered with an ELEKTA Versa HD linac. Dose calculations were compared with measurements performed with EBT films and a detector array. Effects of uncertainties in small field output factors were less pronounced for IMRT and VMAT plans compared to stereotactic techniques delivered with static fields or dynamic arcs. TPS specific sequencing of IMRT and VMAT had an impact on the final results. The gamma evaluation performed with detector arrays was not able to dissolve uncertainties in small field dosimetry due to the rather large detector. On the other hand single detector signal was sensitive to such uncertainties. Upcoming treatment techniques like dose painting will use small fields more extensively and motivates highest accuracy in small field dosimetry. Published reference data and guidelines including detector correction factors contribute to eliminate gross uncertainties (>5%) in small field dosimetry.

SP-0029

IAEA external audits for advanced radiotherapy - lessons learnt and their relevance for industrialised countries

J. Izewska¹

¹IAEA - International Atomic Energy Agency, Dosimetry and Medical Radiation Physics Section, Vienna, Austria

The postal dose audit programme for radiotherapy dosimetry operated jointly by the International Atomic Energy Agency (IAEA) and the World Health Organization (WHO) has been in existence for over 45 years. To-date the calibration of over 11300 radiotherapy beams in 2200 hospitals in 132 countries has been audited. Several hospitals have improved their dosimetry practices over the years, and the percentage of acceptable results is > 95% at present. The IAEA records suggest that regular participation in audits is associated with higher quality dosimetry than the first participation. It confirms that the dosimetry audit is useful to enhance confidence in radiotherapy dosimetry for both medical physicists and clinicians who need assurance that their patients receive safe and high quality radiation treatment, which is not possible without accurate dosimetry. However, with the increasing complexity of radiotherapy treatments, basic dosimetry audits are no longer sufficient and more complex audit programmes testing different dosimetry parameters and treatment delivery techniques are required. The first IAEA 'end-to-end' audit methodology was developed for 3D conformal radiotherapy. It reviewed dosimetry, imaging, treatment planning and radiotherapy delivery processes following the pathway similar to that of the patient undergoing radiotherapy. The audit was implemented at national levels with the IAEA providing an anthropomorphic thorax phantom (CIRS) and expert advice. National groups conducted the audit at local hospitals through on-site visits. TPS calculated doses were compared with ion chamber measurements for a set of test cases. In Europe, the audit has been carried out in 60 hospitals in 8 countries. About 200 data sets have been collected and reviewed. Discrepancies requiring interventions were discovered in about 10% of datasets. In addition, suboptimal beam modelling in TPSs occurred in several centres. Overall, the audit contributed to better understanding of the performance of TPSs and helped to resolve discrepancies related to imaging, dosimetry and treatment planning.

Recently, a new methodology has been developed for on-site 'end-to-end' audits to review the physics aspects of head and neck IMRT treatments. It uses a dedicated anthropomorphic head and shoulders phantom (CIRS) with a set of contours representing the target volumes and organs at risk. The contours are imported and superimposed on the CT scans of the phantom. The treatment plan is developed and transferred to the treatment machine for the dose delivery. Ion chambers and radiochromic films are used for dose measurements. Comparisons are made between the TPS calculated and measured doses. The audit methodology is currently tested within an international study group.

For >20 years the IAEA has supported the development of audit methodologies for national audit groups using remote audit tools. Current projects focus on remote IMRT audits involving different audit steps, e.g. small beam dosimetry relevant for IMRT. One study compared TPS calculated beam outputs to the published reference data sets. The results showed good agreement (within 1%) between the TPS output and the reference data for field sizes 4x4 cm² and dose overestimation by TPSs by 2%3% for field sizes ≤ 3x3 cm². Auditing methodology was also developed to verify the TPS modelling of small MLC shaped beam profiles using radiochromic film measurements for 2x5 cm² and a 2x2 cm² fields. Relative differences between the profiles at 20%, 50% and 80% dose levels were evaluated. Only 64% beam profiles were within 3 mm agreement between the TPS calculated and film measured doses. This highlights some limitations in TPS modelling of small beam profiles in the direction of MLC leave movements. Such differences can affect patient treatments, especially for stereotactic radiotherapy and IMRT. Another study evaluated MLC performance using picket fence tests and confirmed that most MLCs performed as expected. A comparison of gamma analysis techniques was also conducted through a multicentre analysis of a film irradiated with a complex field arrangement. Differences in gamma agreement occurred that were attributed to the differences in film scanning parameters and gamma calculation algorithms. A newest study on remote 'end-to-end' IMRT audit is on-going. Overall, the results of these studies demonstrate challenges in TPS commissioning for

small fields and challenges in multicentre comparison of gamma analysis for complex dose distributions. Overall, the IAEA supports developments of various audit tools for radiotherapy with the audit scope corresponding to the evolving complexity of radiotherapy technology, in order to verify radiotherapy physics practices and improve the quality of treatments delivered to cancer patients in participating countries.

Symposium: Strategies for treatment planning

SP-0030

Comparisons of treatment planning with photons and protons

M. Enmark¹, I. Kristensen¹, C. Vallhagen Dahlgren²

¹Skåne University Hospital, Department of Radiation Physics, Lund, Sweden

²Skandionkliniken, Uppsala, Sweden

This presentation will focus on the main differences between the radiotherapy treatment planning with photons and protons. An important issue in all treatment planning is the dosimetric uncertainties and margins to account for these. Compared to photons, protons have additional sources of uncertainties that should be analysed and understood. Insufficient quantification of margins can have more serious consequences in proton therapy than is the case for photons.

The main advantage of proton beams is the finite range and sharp distal dose fall off in depth, an advantage that often is a contradiction in the sense that the range uncertainty limits the use of this advantage. A second advantage is the ability to, with every single field, give the target volume a higher dose than the surrounding tissue. The sources of range uncertainties are caused by the patient variations in anatomy and the uncertainties in the conversion of CT numbers to tissues with the correct proton interaction properties. The handling of range uncertainties play a critical role in proton planning and has an impact on the entire treatment planning process that differs from photons.

The generic PTV margin recipes used in photon planning, are not adequate in proton planning. Primarily, this is used to account for lateral beam uncertainties. In proton planning, two margins have to be considered, the lateral and the margin in depth i.e. range uncertainty. In principle, these two margins arises from different physical processes. According to ICRU 78 [1] the PTVs are recommended to be used in proton planning for dose reporting purposes. Additional volumes with beam specific margins, have to be used to account for uncertainties in range. Paganetti has suggested margin recipes that is widely used in proton planning [2].

Consequently, the range uncertainty also has an influence on the selection of beam and their entry angles. In this phase of the treatment planning process, proton planning emphasizes other considerations than photons. Robust planning has the potential of mitigate the impact of range uncertainties, aiming for a robust beam path i.e. heterogeneous geometry along the beam path. Likewise, the robustness should be considered during the optimization as well as during the treatment plan evaluation and the comparison with a photon treatment plan to choose the best treatment plan.

The contents of this presentation are based on experiences from the start-up of the first Scandinavian Proton Centre, Skandionkliniken, where the first patients were treated in late august 2015. Nearly four years before that, in January 2012, we started the Proton School in order to prepare for the clinical start and to train a group of medical physicists, dosimetrists and radiation oncologists in proton planning [3,4]. Thinking protons instead of photons has been the greatest challenge for the group as a whole. *How do we achieve the best plan?* This includes selecting robust beam angles and thinking about what the protons interact with on its way to the target volume. Discussions about target volumes has been frequent, as the use of them. Delineation is a major issue, not only for CTV/PTV but for other structures the protons might interact with in its beam path,

as well as optimisation structures to provide the best treatment plan.

SP-0031

When to re-plan: a practical perspective

B. Bak¹

¹Greater Poland Cancer Centre, Department of Radiotherapy, Poznan, Poland

Anatomical changes are important issue during radiotherapy because they could potentially lead to inadequate dose distribution to target and organs at risk (OAR). Radiation induced complications have a significant adverse impact on health-related quality of life. To minimize the risk adaptive radiotherapy (ART) has become state of art of modern radiotherapy. In clinical practice ART is expressed mostly by Image-Guided Radiation Therapy (IGRT) and re-planning, the last is very individualized but should be more unified. Clear guidelines are therefore needed to determine the timing of re-planning, and an increasing amount of information needs to be acquainted, transferred and stored.

There are several indications that anatomic changes are more pronounced in the first half of treatment, and therefore repeated imaging and replanning should be performed in this first time period. The parotid gland was the most studied OAR and showed the largest volume changes during radiotherapy (26% average volume decrease). The average number of radiation fractions delivered between baseline and re-planning CT scans was 15 (±5) fractions which equals 21 (±8) days. It is also well established in the Head and neck (H&N) area that, because of i.e. weight loss and/or tumor shrinkage especially in more advanced stages of cancer (T3/T4, large N+), re-planning improves relapse-free survival and significantly alleviated the late effects. In many dosimetric studies without replanning during treatment, the doses to normal structures were significantly increased and doses to target volume significantly decreased. According to literature replanning frequency increases also with smaller PTV margins.

To answer the question „When to re-plan?“ we need to know which sites would most benefit. In regard to literature studies it seems that re-plan would be the most beneficial for tumors of the biggest volume or the nearest proximity of the OAR's. Still it does not explain „when“ should we perform it. Despite of the great amount of reports and analysis further research are needed.

SP-0032

Fully automated treatment planning: benefits and potential pitfalls

E. Damen¹, R. De Graaf¹, R. Glorie¹, J. Kneegjens¹, C. Van Vliet-Vroegindewij¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiotherapy Department, Amsterdam, The Netherlands

Purpose/Objective: Labor-intensive procedures, such as adaptive radiotherapy, result in an increased workload in the treatment planning department, which can be reduced by introducing fully automated treatment planning. The benefits of automated planning are many: reduction of workload, increased workflow efficiency, and reduction of plan variability. However, a potential pitfall could be loss of

knowledge and skills among RTTs, leading to less ability to design, judge or adapt treatment plans. The purpose of this work is to show the capabilities of automatic planning and discuss its consequence for a radiation-oncology department.

Material and Methods: At the NKL a project was started to develop single-click treatment planning for techniques based on a class solution. Technically this was accomplished by separating medical planning protocol definition from actual control of the treatment planning system (Pinnacle3, version 9.10, Philips Medical Systems). After target delineation, a single mouse-click initiates the following actions: Pinnacle patient record generation, auto-segmentation of organs at risk (OARs), beam setup, optimization of the dose distribution, and creation of PDF documentation. The plan is then ready for inspection by RTT and physician. This procedure is currently implemented into our clinic for prostate, breast and vertebral metastases. Currently, knowledge and skills among RTTs is primarily maintained by the requirement to perform a certain number of treatment plans per year for a given tumor site. In addition, all treatment plans are checked by a second RTT, and feedback is given on deviations from protocol and/or possibilities to improve the plan. Finally, special cases are discussed with all RTTs on a monthly basis.

Results: A fully automated treatment plan requires 20 minutes for prostate and breast, and 7 minutes for vertebral metastases. Up to now, 185 patients have received a fully automated treatment planning procedure. In about 15% of the cases, the automatically produced plan required manual adjustment, either because of errors in auto-segmentation of OARs, or due to a sub-optimal dose distribution. In general, RTT hands-on time reduced with up to 2 hours per plan, while maintaining plan quality.

To prevent loss of knowledge and skills among RTTs, 10% of the requested plans for a tumor site are randomly assigned for manual treatment planning. In addition, planning challenges are organized in which a number of RTTs makes a treatment plan for the same patient. The results are discussed with all RTTs.

Conclusion: Complete automation of the treatment planning process is feasible for selected tumor sites and results in considerable reduction of hands-on time. By designing new QA methods, loss of skills and knowledge among RTTs can be prevented, thus ensuring that RTTs remain capable of manually designing and/or adapting treatment plans.

Assessing dose contribution to pelvic lymph nodes in intracavitary brachytherapy for cervical cancer
G.W.Y. Chua¹, D.B.H. Tan¹, G.H. Tay¹, Y.W. Foo¹

¹National Cancer Centre - Singapore, Department of Radiation Oncology, Singapore, Singapore

Purpose or Objective: In definitive radiotherapy for cervical cancer, a HDR brachytherapy boost is most commonly used after external beam radiation (EBRT). While brachytherapy doses are chosen such that a cumulative EqD2 of 80 to 90Gy is delivered to the primary tumour after a 45 to 50.4Gy EBRT dose, there is less certainty regarding the brachytherapy dose contribution to pelvic lymph nodes. This poses a challenge as to how high a preceding EBRT dose should be prescribed to gross nodal disease, in order to achieve a cumulative tumoricidal effect.

While the use of MRI guided 3-dimensional brachytherapy is increasing, the point-based Manchester system remains the most widely utilized technique. The objective of this study is to determine the brachytherapy dose contribution to individual pelvic lymph node regions, using CT planning with the Manchester system.

Material and Methods: CT planning datasets from 40 patients who had undergone intracavitary HDR brachytherapy for

stage III or IVA cervical cancer were retrieved. All patients received prior 3D conformal EBRT to a dose of 50.4Gy in 28 fractions, followed by four fractions of CT-based brachytherapy, prescribing to Manchester point A. Half of the patients (n=20) received a brachytherapy dose of 5Gy per fraction, while the other half received 6Gy. Decision on brachytherapy dose was dependent on the ability to meet D2cc constraints for the adjacent organs-at-risk.

Following international consensus guidelines, the right and left external iliac, internal iliac and obturator groups of lymph nodes were separately contoured on the CT dataset (see Figure 1). Applying the initial brachytherapy plan on the Oncentra TPS, mean doses to each nodal group according to laterality (i.e. left and right) were calculated for each patient, and both results combined to obtain the average mean dose to the entire nodal group. All individual patient results were then averaged across the respective study groups (5 and 6 Gy groups) and corresponding EqD2s calculated.

Results: A summary of results is shown in Table 1.

For patients who received a per fraction brachytherapy dose of 5 Gy, average mean absolute dose to the external iliac, internal iliac, and obturator nodal groups was 0.80 Gy, 1.12 Gy and 1.34 Gy respectively. The corresponding EQD2s were 0.72 Gy, 1.05 Gy, and 1.28 Gy respectively.

For patients who received a per fraction brachytherapy dose of 6 Gy, average mean absolute dose to the external iliac, internal iliac, and obturator nodal groups was 1.16 Gy, 1.56 Gy and 1.80 Gy respectively. The corresponding EQD2s were 1.08 Gy, 1.50 Gy and 1.79 Gy respectively.

Table 1: Summary of the per fraction average mean absolute doses and corresponding EqD2 (highlighted in grey) to each lymph node region, classified according to patients who received 5Gy or 6Gy prescribed dose.

Per fraction brachytherapy dose contribution	Average mean doses (Gy)	
	5 Gy/ fraction (n=20)	6 Gy/ fraction (n=20)
EXTERNAL ILIAC		
Absolute dose	0.793	1.156
Corresponding EqD2	0.717	1.083
INTERNAL ILIAC		
Absolute dose	1.124	1.546
Corresponding EqD2	1.048	1.497
OBTURATOR		
Absolute dose	1.343	1.803
Corresponding EqD2	1.276	1.787

Conclusion: Our study demonstrates that the pelvic lymph nodes receive a significant dose contribution from brachytherapy in cervical cancer, when employing the Manchester prescription system. This must be taken into account during external beam radiotherapy planning, and adequate external beam boost doses calculated to achieve cumulative tumoricidal doses to pelvic nodal disease.

HDR BT alone in endometrial cancer: up-date of Piedmont experience in 18 years (71 patients)

S. Gribaudo¹, U. Monetti¹, E. Madon², V. Richetto², M. Tessa³, F. Moretto³, A. Ruggieri³, S. Cosma⁴, S. Danese⁴, A. Urgesi¹

¹A.O.U. "Città della Salute e della Scienza di Torino" P.O. Sant Anna, Radiotherapy, Torino, Italy

²A.O.U. "Città della Salute e della Scienza di Torino" P.O. Sant Anna, Physics, Torino, Italy

³A.S.L. AT P.O. Cardinal Massaia, Radiotherapy, Asti, Italy

⁴A.O.U. "Città della Salute e della Scienza di Torino" P.O. Sant Anna, Gynecology 4, Torino, Italy

Purpose or Objective: Endometrial cancer is the mainly gynaecologic malignancy, 80-85% in stage I at diagnosis. The standard primary treatment remains TAH&BSO, with appropriate surgical staging. The epidemiology of this disease favours elderly, obese women with multiple medical problems (hypertension, diabetes, cardiovascular diseases, coagulation disorders, respiratory disorders) that render some of them medically inoperable. RT alone is the only efficient option for these women. BT is the main component in this cohort of patients (pts).

Material and Methods: September 1997-September 2015: 90 pts RT alone, 71 BT HDR alone. Median age 79 years (range 57-93). Staging: clinical examination, TVUS, MR or CT scan and fractionated curettage. Stage Ia 32 pts, Stage Ib 36 pts, Stage II 3 pts. OS, DSS, LC and late side effects were analysed retrospectively. Follow-up > 10 years (mean 57 months). BT HDR with Rotte "Y" applicator, plus VBT in stage II. Dose prescription at "uterine points" that are two points located 1 cm over the middle of a line drawn between the tips of the two ends of the "Y" applicator and at series of points placed laterally to the tandem according to the pre-treatment imaging data. We treat the entire length of the uterus to ensure coverage of the fund. To maintain the bladder and rectal maximum point doses below 100% of the prescribed dose we optimize with TPS. Until 2002 BT was performed 4-5 times, weekly, mean dose 29.3 Gy (range 18-35 Gy); from 2003 (42 pts) we deliver 30 Gy in five frs, 6 Gy each b.i.d. schedule, 6 hours interval between frs.

Results: 5 years OS, DSS and LC: 52.1%, 85.9%, and 91.2%. Stage Ia: 56.3%, 87.5%, and 90.6%; Stage Ib: 50%, 86.1%, and 94.4%; Stage II: 33.3%, 66.7%, and 66.7%. DSS was not affected by tumour grade or age. One patient had a PD, 6 (10.6%) developed recurrence after a median of 13 months (3 with distant metastases), 2 (3.5%) a lymph node recurrence with distant metastases. One patient have a GE grade III late side effect (1.8%) at 5 years, not related with rectal dose.

Conclusion: HDR BT with "Y" applicator is a very effective treatment modality with good LC rates and suitable DSS for pts who are not fit for surgery. This technique has proven to have a low risk of acute complications and long-term side effects. Longer follow-up will be required to document the incidence of late effects using the b.i.d. schedule. In the short term, it seems that this approach is a feasible way to limit the number of procedural complications and length of hospital stay and bed rest.

⁵Memorial Sloan Kettering Cancer Center, Department of Radiation Oncology, New York, USA

⁶La Fe University and Polytechnic Hospital, Radiotherapy Physics Section- Radiation Oncology Department, Valencia, Spain

⁷La Fe University and Polytechnic Hospital-, Dermatology Department, Valencia, Spain

Purpose or Objective: Basal cell carcinoma (BCC) is a very common cancer in the Caucasian population. Treatment aims to eradicate the tumor with the lowest possible functional and aesthetic impact. Electronic brachytherapy (EBT) is a treatment technique currently emerging. This study aims to show the outcomes of two consecutive prospective pilot clinical trials using different radiation doses of EBT with Esteya® EB system for the treatment of superficial and nodular basal cell carcinoma.

Material and Methods: Two prospective, single-center, non-randomized, pilot studies were conducted. Twenty patients were treated in each study with different doses. The first group (1) was treated with 36.6 Gy in 6 fractions of 6.1 Gy and the second group (2) with 42 Gy in 6 fractions of 7 Gy. In one case the 6.1 Gy/fraction resulting from the theoretical RBE calculation was used, and in the second arm (7 Gy/fraction) the same dose as the Valencia applicator study was used. Cure rate, acute toxicity and late toxicity related to cosmesis were analyzed in the two treatment groups.

Results: In group 1, a complete response in 90% of cases was observed at the 1 year follow-up, whereas in group 2 the complete response was 95%. Tumor persistence or recurrence was suspected clinically and dermoscopically in two patients in the first group at 3 and 6 months respectively and in one patient in the second group at 1 year follow-up. The differences with reference to acute toxicity and the cosmetic results between the two treatment groups were not statistically significant.

Conclusion: Our initial experience with Esteya® EB system to treat superficial and nodular BCC shows that a dose of 36.6 Gy and 42 Gy delivered in 6 fraction of 7 Gy achieves a 90% and 95% clinical cure rate at 1 year respectively. Both groups had a tolerable toxicity and a very good cosmesis.

²European Institute of Oncology, Unit of Medical Physics, Milan, Italy

³University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy

⁴University of Milan, Tecniche di Radiologia Medica per Immagini e Radioterapia, Milan, Italy

Purpose or Objective: Feasibility and dosimetric study of 3D-printed cylindrical and skin mould applicators for High Dose Rate brachytherapy (HDR-BRT) using acrylonitrile butadiene styrene (ABS).

Material and Methods: Three cylindrical applicators (1 as reference and 2 as test) with a single 2.5 mm catheter channel and a 1 mm radial slit for radiochromic film support were 3D printed (HP3DX100, Hamlet, Dublin, IE) using ABS plastic. The reference had the radiochromic slit in contact

with the catheter channel and was printed with 20% infill percentage. The test configurations had the radiochromic slit at 6.3 mm distance from the center of the catheter channel and were printed with 20% (Test 1) and 40% (Test 2) infill percentage. Physical quality of ABS plastic were evaluated by analyzing the depth dose profiles measured by Gafchromic EBT3 films (International Specialty Products, Wayne, NJ) when the ¹⁹²Ir source passing through the catheter channel delivered 2 Gy at 10 mm distance from the axis of the channel (Fig.1a).

Four skin mould applicators with 4 parallel catheter channels of 2.5 mm diameters, 5 mm distance between the axis of the channel and the surface, and 10 mm distance between consecutive channel axes were 3D-printed. Two geometrical shapes were compared to the commercial Freiburg Flap applicator (Nucletron, Stockholm, SE, Fig. 1b): a group of 16 semi-spheres reproducing the actual Freiburg geometry printed at 10% infill percentage (Fig.1c) and a parallelepiped applicator with 10%, 20% and 40% infill printing percentage (Fig.1d). A prescription dose of 2 Gy to the surface at 5 mm distance from the channels axes was delivered using an ¹⁹²Ir source. Surface dose distributions were measured with Gafchromic EBT3 films for both the 3D-printed skin mould applicators and the commercial Freiburg Flap applicator considered as reference. The gamma index method with dose difference (DD) criteria of 3%, distance-to-agreement criteria (DTA) of 3 mm and 10% dose threshold was evaluated.

Results: The radiation attenuation profiles were comparable in all the cylindrical configurations. Dose attenuation were not sensitive to the density of the material (Tab.1a). When comparing 3D-printed skin mould applicators with commercial Freiburg Flap in terms of gamma index analysis, a high pass rates >90% was obtained. Therefore, the isodose overlay and linear dose profiles of film measured using 3D printed applicator and commercial Freiburg were in close agreement (Tab.1b).

(a) Cylindrical Applicator		Profile dose distribution			
		Source distance			
		10 [mm]	15 [mm]	20 [mm]	25 [mm]
Measured Dose [Gy]	Reference configuration	2.0	1.4	1.0	0.8
	Test configuration ABS 20%	1.9	1.2	0.9	0.7
	Test configuration ABS 40%	1.9	1.2	0.9	0.7

(b) Skin mould applicators		Gamma analysis – passing rate –			
		3D printed Freiburg Flap ABS 10%	Parallelepiped ABS 10%	Parallelepiped ABS 20%	Parallelepiped ABS 40%
Commercial Freiburg Flap	97.74%	98.57%	98.03%	91.66%	

Conclusion: ABS3D-printed applicators are a reliable solution for patient-specific HDR-BRT of superficial lesions. Further assessment of 3D printing techniques and materials are required for clinical development.

PV-0037

Application of brachytherapy for residual nasopharyngeal carcinoma after external beam radiotherapy
 G. Cheng¹, H. Zhao¹, M. He¹, J. Wang¹, Z. Zhao¹
¹China-Japan Union Hospital of Jilin University, Department of Radiation Oncology, Changchun, China

Purpose or Objective: Local residual disease occurs in 7-13% after primary treatment for nasopharyngeal carcinoma (NPC). To prevent tumor progression and/or distant metastasis, treatment is indicated. This studies focus on the application of 3D-CT based and endoscopic guided brachytherapy for the treatment of residual lesion in nasopharyngeal cavity of NPC after the radical external beam radiotherapy and to assess the safety and clinical outcome of this technical.

Material and Methods: 26 patients with stage T1-T2b NPC who suffered from locally residual lesion in nasopharyngeal cavity (All the tumors were less than 1 cm below the nasopharyngeal epithelium) after standard radical radiotherapy (70-74 Gy) ± platinum-based chemotherapy were further administrated by the 3D-CT based and endoscopic guided brachytherapy using the Foshan applicator or the standard nasopharyngeal applicator according the tumor location. The prescribed salvage dose of brachytherapy was 3.5 Gy/fraction, twice- daily with an interval of 6 h to a total dose of 7-14 Gy (one week apart) depending on the total dose of external beam radiotherapy. The total dose ranged from 81.8-85.6 Gy when transformed to EQD2 models, and the Pstem D1% < 60 Gy was restricted in planning. The primary endpoint was 1-, 3-year overall survival and secondary endpoints were: local control, distant metastasis and grade 3-4 adverse events.

Results: The whole brachytherapy procedure was well tolerated under local anesthesia. 24 patients (92.3%) get complete response (CR) as confirmed by enhanced CT/MRI after 1-3 month after the brachytherapy. With a median follow-up time of 40 months, no serious complications or late sequelae occurred. The 1-, and 3-year overall survival, locoregional free survival, and distant-metastasis free survival rates were 96.2%, 80.8%, 92.3% and 84.6%, respectively. And the patients with early-T stage at initial diagnosis had 100% local control rate.

Conclusion: Brachytherapy is of benefit to improve the local control of primary lesion of NPC with residual nasopharyngeal cavity involvement. It is a safe and effective approach for patients with poor tumor regression at the end of external beam radiotherapy for boosting the local irradiation dose.

Purpose or Objective: Total salvage Iodine-125 brachytherapy (TS I-125-BT) is a potentially curative treatment strategy for localized prostate cancer (PCa) recurrences after radiotherapy. Prognostic factors influencing PCa-specific and overall mortality (PCaSM & OM) are not known. The objective was therefore to develop a multivariable, internally validated prognostic model for survival after TS I-125-BT.

Material and Methods: Retrospectively, sixty-two TS I-125-BT patients were analyzed. These patients were treated from 1993-2010 in the Netherlands. Multivariable Cox-regression was used to assess the influence of pre-salvage characteristics on PCaSM and OM. Missing data was handled by using multiple imputation (20 imputed sets). Internal validation was done using 500 bootstrap resamples of every imputed set. Discriminatory ability was quantified with the C-statistic. Calibration plots were created to visually assess the

goodness-of-fit of the final model. Optimism-corrected survival proportions were calculated. All analyses were performed according to the TRIPOD statement.

Results: 28 (45%) patients died from PCa after mean (\pm SD) 82 (\pm 36) months. Median total follow-up was 78 months (range 5-139). In total, 36 patients (58%) patients died after mean 84 (\pm 40) months. PSA doubling time (PSADT) remained as a predictive factor for both PCaSM and OM: corrected hazard ratio's (HR's) 0.92 (95%-CI: 0.86-0.98, $p=0.02$) and 0.94 (95%-CI: 0.90-0.99, $p=0.01$), respectively. The adjusted C-statistics were 0.71 and 0.69, respectively. Predictive ability (calibration) was good up to 96 months follow-up. Over 80% of patients can survive 8 years if PSADT >24 months (PCaSM) and >33 months (OM) (Figure 1).

Survival proportion at 8 years

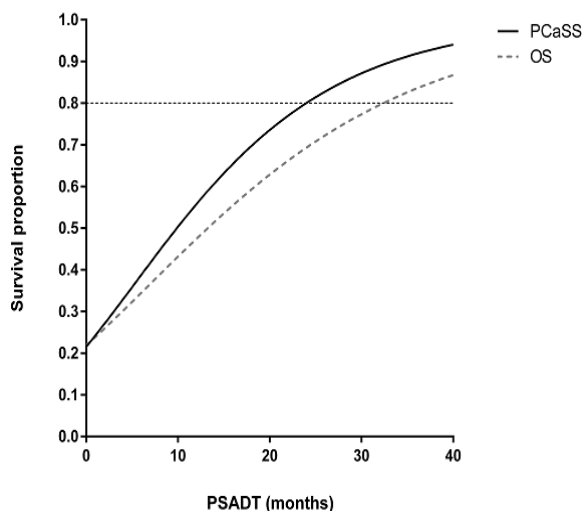

Figure 1: Prostate cancer specific survival (PCaSS) and overall survival (OS) as a function of PSADT.

Conclusion: A PSADT >24 months and >33 months can result in a high probability (>80%) of prostate cancer specific and overall survival 8 years after TS I-125 BT. Larger series and external validation are necessary.

PV-0039

Urinary incontinence rates in salvage high-dose-rate brachytherapy prostate cancer patients
P. Wojcieszek¹, M. Szlag¹, A. Cholewka¹, B. Białas¹, S. Kellas-Slecza¹, M. Fijałkowski¹, A. Andrejczuk¹

¹Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology III Dept, Brachytherapy Department, Gliwice, Poland

Purpose or Objective: Locally recurrent prostate cancer reirradiation may lead to urethral stricture and increase of urinary symptoms including urinary retention. Such patients may undergo urethrectomy or transurethral resection of the prostate (TURP), which may cause urinary incontinence. Our purpose was to evaluate risk of urinary incontinence after salvage high-dose-rate brachytherapy (HDR BT) with or without urological intervention.

Material and Methods: We included in the analysis all salvage HDR BT patients with at least 6 months of follow-up. Urinary retention, urological interventions and urinary incontinence rates were assessed. 5-year adverse event-free survivals were calculated.

Results: One hundred and two men were enrolled in this retrospective analysis. Median age was 71 years (57-81). Median follow-up was 37 months (6-76). Twenty-three men (23%) underwent urological intervention after salvage HDR BT. Fourteen of them suffered from urinary retention, 9 men were treated due to refractory obstructive urinary symptoms. TURP or urethrectomy was performed 15 and 12 times,

respectively. Four patients underwent combination of both. Twelve patients suffered from urinary incontinence with no intervention, twenty men developed it after urological intervention. Five patients needed suprapubic catheter. 5-year urological intervention-free survival was 65%. 5-year urinary incontinence-free survival (UIFS) was 69%. Any urological intervention was linked with higher urinary incontinence probability (4-year UIFS 88% vs 5%, $p=0.0000$; HR-14.05; 95% CI 13.25-14.85).

Conclusion: There is high probability of urinary incontinence in salvage HDR BT prostate cancer patients after urological intervention (TURP/urethrotomy). Therefore patients suffering from refractory obstructive urinary symptoms without urinary retention should be carefully evaluated and counseled before any urological management.

PV-0040

MRI guided focal primary and (secondary) salvage HDR-BT in prostate cancer patients seems safe

M. Maenhout¹, M.A. Moerland¹, K.M. Van Vliet-van den Ende¹, R.I. Schokker¹, M. Borot de Battisti¹, M. Peters¹, M. Van Vulpen¹, J.R.N. Van der Voort van Zyp¹
¹UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

Purpose or Objective: To evaluate the technical feasibility and safety of focal MRI guided HDR brachytherapy as a primary, salvage or secondary salvage treatment in 37 patient with a localized (recurrent) prostate cancer.

Material and Methods: From May 2013 until October 2015, 37 patients were treated with focal MRI guided HDR brachytherapy. 26 patients received MRI guided primary focal HDR brachytherapy, 8 patients salvage treatment and 3 patient secondary salvage treatment. The prescribed dose to the PTV was 19 Gy, with strict limitations to the organs at risk. Patients with a (recurrent) PA proven prostate cancer were included in this evaluation. Before treatment, a diagnostic multiparametric MR was performed to define the tumor region. In patients with recurrent disease, a choline PET scan or PSMA scan was performed to exclude patients with early distant metastasis. The treatment was performed through MR guidance, in a combined MR/HDR facility (Figure 1).

After ultrasound guided insertion of the catheters, an MRI of the prostate was performed for the reconstruction of the inserted catheters. Consequently, a per-operative treatment plan was performed prior to dose delivery. Toxicity was measured using the CTCAE version 4.

Results: For all patients, the treatment was tolerated well. In some patients, a lower dose to the PTV was given in order to protect the organs at risk. This was especially the case in patients that received a second salvage treatment. No patients developed a new grade 3 (or more) toxicity. One patient developed an acute urinary retention after primary focal HDR brachytherapy. Other grade 2 toxicity was uncommon in patients that received HDR brachytherapy as a primary treatment. In patients with a salvage treatment, grade 2 toxicity such as urinary infections and incontinence occurred in 3 of 8 patients. The 3 patients that received a second salvage treatment had not developed severe toxicity. However, follow up of these patients is very short (1-6 months).

Conclusion: Focal HDR brachytherapy as focal, salvage and secondary salvage treatment seems clinically feasible and safe. It could be a promising treatment modality to reduce severe side effect in patients with primary prostate cancer. Furthermore, it could postpone hormonal treatment in patients with recurrent or secondary recurrent prostate cancer.

Symposium: Protons or heavy ions?

SP-0041

Physical advantages of particles: protons vs. heavy ions, what is certain what is not?

O. Jäkel^{1,2}

¹German Cancer Research Center, Medical Physics in Radiation Oncology, Heidelberg, Germany

²Heidelberg Ion Beam Therapy Center, Medical Physics, Heidelberg, Germany

In this contribution the physical properties of protons and other ions will be outlined and the differences between different ions will be highlighted. The relevance of these properties with respect to radiotherapy will be discussed. In detail the physical properties to be discussed are the depth dose distribution, lateral scattering and energy loss straggling. These quantities will mainly affect the dose conformation potential of the various ion beams through the distal and lateral penumbra and the dose in the entrance region. The most important difference here arises through the multiple small angle scattering of particles which is strongly depend on the mass of the ions: for heavier ions, the lateral penumbra will be significantly smaller than for protons.

Another very important physical parameter is the stopping power of the particles, as this quantity will influence the radiobiological properties of the different ions. The stopping power describes the energy loss of a particle per pathlength and be accurately calculated using the Bethe formalism. More important for the radiobiological effects is the linear energy transfer (LET), which is often used synonymously to stopping power. LET describes the energy transferred into a narrow region around the primary ion track and can also be calculated using the Bethe formalism. While the LET of a pure beam of ions with a fixed energy is well defined, the LET of a mixed radiation field is more complex. The reason for that is, that in a mixed radiation field, LET has to be averaged over the different ions contributing. This is often done by using the so-called "dose averaged LET", where the LET of each particle is weighted according to the dose it is contributing. Another way of defining an average LET is by averaging over the fluence (or alternatively over the track length). Both average LET definitions are being used for various biological applications and will be presented. When discussing the relative biological effectiveness (RBE) of ion beams, one has to be aware of this difference.

Finally the nuclear fragmentation of ions may lead to strong differences in the spectrum, or mixture of ions of different kind at different points in depth. The relevance of these nuclear fragments becomes clear, when comparing the dose just behind the Bragg peak of a primary carbon ion beam (which is completely due to light fragments) and a proton beam (which is completely due to protons). An overview of

the characteristics of the fragmentation spectra of ions will therefore also be given.

SP-0042

Radiobiological benefits of protons and heavy ions - advantages and disadvantages

C.P. Karger¹

¹German Cancer Research Center DKFZ, Department of Medical Physics, Heidelberg, Germany

Both, carbon ions and protons show an inverted depth dose profile (Bragg-peak) and allow for highly conformal irradiations of tumors in the neighborhood of radiosensitive normal tissues. Heavier ions such as carbon ions additionally show an increased linear energy transfer (LET) towards the distal edge of the Bragg-peak leading to an increased relative biological effectiveness (RBE) with respect to photon irradiations [1]. While the RBE for clinical proton beams is currently fixed to 1.1, the RBE of carbon ion varies significantly within the treatment field and has to be calculated by RBE-models. The RBE-models, however, introduce additional uncertainties, which have to be considered in treatment planning and especially in clinical dose prescription.

As protons and carbon ions exhibit almost comparable geometrical accuracy, the clinical question whether protons or carbon will be more beneficial for the patient mainly addresses the independent role of the high-LET effect in radiotherapy. The answer to this question is related to the following subquestions: (i) How accurate is the applied RBE-model? (ii) Is a fixed proton RBE of 1.1 accurate enough for all field configurations? (iii) Which tumor types are best suited for heavy ions? (iv) Can high-LET irradiations overcome radioresistance of hypoxic tumors?

While questions (i) and (ii) refer to normal tissue reactions, (iii) and (iv) address the impact of tumor-specific resistance factors on the radiation response. An additional benefit of heavy ions will strongly depend on the differential response between tumor and normal tissue. Although the final prove or disprove of advantages has to be provided by prospectively randomized clinical trials, ongoing preclinical experiments can help to study the subquestions (i)-(iv) separately, i.e. to benchmark RBE-models (e.g. LEM I vs IV), to select suitable tumor entities, to setup clinical trials and to generally improve the understanding of normal and tumor tissue response after high- vs. low-LET irradiation.

The presentation will give an introduction on the concepts describing the response to high-LET irradiations and will give an overview on the available in vivo data with focus on the current answers to the above questions.

How strong is the current clinical evidence for protons and heavy ions ?

P. Fossati^{1,2}

¹Fondazione CNAO Centro Nazionale Adroterapia Oncologica, Clinical Department, Pavia, Italy

²European Institute of Oncology, Radiotherapy Division, Milano, Italy

Particle therapy has been available in hospital setting since 1991. About 100.000 Patients have been treated worldwide with protontherapy and more than 10.000 patients have been treated with carbon ion radiotherapy. After almost 15 years in which this modality was available only in few centres in the last ten years the number of new particle facilities has steeply increased in the US and in Asia and more recently several facilities have been planned in Europe. Protontherapy has traditionally been used because of its strong preclinical rationale based on its favourable physical properties that allow a substantial reduction in integral dose and exposure of non-target tissues. Carbon ion radiotherapy has mainly been used for its radiobiological property that may offer an advantage in the treatment of macroscopic tumours made of

an heterogeneous cell population with a radio-resistant compartment. Evidence to support the use of particle therapy evolved in the past 25 years from level III (preclinical rationale) to level II (prospective non randomized trials). A hot debate has been on-going in the scientific community about the need of prospective RCT testing head to head particles versus modern X-ray radiotherapy. Those against the need of RCT argued that dose distribution was such a strong surrogate endpoint that RCT were not needed and that dose distribution had always guided the evolution of radiotherapy without the need of RCT. Those in favour argued that the only relevant endpoints were clinical outcome and measurable toxicity and that dose distributions of protontherapy despite its unquestionable advantage in terms of integral dose may be in some case less favourable than advanced x-ray dose distribution because of lateral scattering and shallower dose gradients in the high dose region. Historically only a single RCT of particle versus photons has been conducted, namely the UCSF-LBNL trial comparing helium ions radiotherapy versus Iodine-125 plaque brachytherapy for choroidal and ciliary body melanoma. Long terms result of the trial showed a clear advantage of charged particles over brachytherapy in terms of local control. However this result did not definitively solve the issue as helium is no longer used in clinical practice and extrapolation of this trial to protontherapy is maybe not straightforward; moreover the trial was criticized because of a supposed suboptimal technique in the brachytherapy arm. With the increased availability of proton facilities the amount of non-randomized evidence is rapidly increasing and several prospective non-randomized trial are being conducted. At present particle therapy has found its way in several guidelines. As an example in the last version of ESMO guidelines for bone sarcoma particle therapy is considered the first option for chordoma both in the post operative setting and for inoperable disease. In this framework also RCT are at present being conducted. A prospective phase II RCT in stage II-III NSCLC patients (NCT00915005) randomized to either photons or protons adaptive IGRT with two levels of dose (66 Gy [RBE] + vs. 74 Gy [RBE]) with primary endpoints local control and toxicity ≥ 3 has completed its accrual. Two other trials are testing protontherapy vs photons X-Ray in locally advanced NSCLC (RTOG 1308) or in centrally located stage I NSCLC (NCT01511081) and are expected to complete accrual in 2020 and 2016. Another prospective phase III RCT ongoing at MGH testing IMRT vs protontherapy for prostate cancer (NCT01617161) is expected to complete accrual in 2016. A prospective phase II/III RCT for stage III and IV oropharyngeal SCC (NCT01893307) is comparing 70 Gy [RBE] delivered with either IMRT or intensity modulated protontherapy. And is expected to complete accrual by 2023. Another trial is testing protons vs photons in GBM (NCT01854554) and should complete accrual by 2017. A RCT is recruiting patient with oesophageal cancer to test chemo radiation with photons vs. chemo radiation with protons (NCT01512589) and should be completed within 2018. Other RCT are ongoing comparing protons versus carbon ions in sacral chordoma (ISAC trial NCT01811394) in skull base chordoma (NCT01182779) and in skull base chondrosarcoma (NCT01182753). RCT are recruiting patient to test protontherapy vs RF ablation in HCC (NCT01963429) or protontherapy + sorafenib vs. sorafenib alone in HCC (NCT01141478). A RCT of particle therapy vs surgery for sacral chordoma (SACRO) is in its final design stage in Europe. Another phase III RCT of carbon ion radiotherapy versus photons or protons radiotherapy for head and neck soft tissue sarcoma and adenoid cystic carcinoma (PHRC ETOILE-ULICE) is going to start recruitment in the next year. In conclusion the present day clinical evidence for particle therapy is of level II (with the only exception of eye melanoma). A large effort to produce level I evidence is ongoing worldwide.

Fingolimod mitigates radiation-induced cognitive deficits by restoring dentate gyrus neurogenesis

A. Stessin¹, M. Banu², V. Blaho³, S. Ryu¹

¹Stony Brook University Hospital, Department of Radiation Oncology, Stony Brook, USA

²Columbia University, Department of Neurological Surgery, New York, USA

³Weill Cornell Medical College, Department of Pharmacology, New York, USA

Purpose or Objective: This study evaluates FTY720/Fingolimod as a potential mitigator of radiation-induced neurocognitive dysfunction.

Material and Methods: The effects of radiation and FTY720 on neural progenitor cells (NPCs) and brain tumor stem cells (BTSCs) were tested *in vitro*. To study radiation-induced neurocognitive deficits, 6 week-old C57/BL/6J mice received 0 or 7 Gy cranial irradiation and were treated with intraperitoneal FTY720 or vehicle for seven weeks. Fear conditioning and the Morris water maze were then employed to test learning and memory. Immunohistochemical staining for NPCs and mature neurons was used to assess changes in neurogenesis. To test effects on tumor growth, mice harboring BTSC xenografts were treated with intraperitoneal FTY720 or vehicle for six weeks.

Results: In NPCs, FTY720 induced ERK1/2 phosphorylation in the presence of radiation. In glioma cells, ERK1/2 phosphorylation was detected at baseline, and FTY720 did not elicit any further increase. Correspondingly, FTY720 increased the viability of NSCs but not glioma cells after radiation. Inhibiting S1P1/MAPK signaling in NPCs abolished the protective effects of FTY720. In irradiated mice, learning deficits were manifested by significantly longer latency times compared to non-irradiated controls ($p = 0.001$). The deficits were fully restored by FTY720. In irradiated brains, FTY720 maintained a viable NPC pool and restored the cytoarchitecture of the DG granular cell layer. In mice harboring BTSC xenografts FTY720 delayed tumor growth and improved survival ($p=0.012$).

Conclusion: FTY720 mitigates radiation-induced learning dysfunction by partially restoring DG neurogenesis. Furthermore, FTY720 appears to delay tumor growth and improve survival in a xenograft glioma mouse model.

Dual pathway inhibition attenuates radiation-induced pulmonary inflammation and fibrosis

N.H. Nicolay^{1,2}, M. Dadrich^{2,3}, R. Lopez Perez², U. Wirkner², P. Peschke², J. Debus^{1,2}, P.E. Huber^{1,2}

¹Heidelberg University Hospital, Radiation Oncology, Heidelberg, Germany

²German Cancer Research Center, Radiation Oncology, Heidelberg, Germany

³Frankfurt University Hospital, Radiology, Heidelberg, Germany

Purpose or Objective: Radiation therapy is a mainstay for lung cancer therapy, but the effective dose is commonly limited by the onset of radiation-induced lung damage. Single pathway inhibitors against transforming growth factor β (TGF β), platelet-derived growth factor (PDGF) and others have been shown in experimental models to attenuate radiation-induced pulmonary injury. However, the effects of multiple pathway inhibition regarding the development of these diseases remain unknown.

Material and Methods: C57BL/6 mice were treated with a single dose of up to 20 Gy photons to their thorax to induce radiation induced lung toxicity. After Irradiation, small molecule kinase inhibitors against PDGF, VEGF and TGF β

receptors were administered orally either as single agents or in combination approaches. Survival and treatment-related side effects were followed up for more than 6 months. Lung density and septal fibroses were measured at various time points by HR-CT and MRI, and the molecular changes of irradiated lung tissue were analyzed using immunohistochemistry and gene expression analyses.

Results: Treatment with individual inhibitors attenuated radiation-induced pulmonary inflammation, and reduced radiological and histological signs of pulmonary injury and fibrosis. Multi-pathway inhibition resulted in a significant additional attenuation of radiation-induced pulmonary damage and increased overall survival of treated mice compared to single-agent inhibition. Irradiation induced gene expression changes in lung tissue of downstream genes in particular for PDGF and TGF β pathways; kinase inhibitors altered the expression of downstream proteins suggesting significant crosstalk between pathways during the development of radiation-induced lung injury. The expression of osteopontin as an established biomarker for pulmonary fibrosis was significantly upregulated by irradiation both on mRNA and protein levels; multi pathway inhibition completely normalized its overexpression when administered after radiation therapy.

Conclusion: Multi-pathway signaling inhibition for PDGF, VEGF and TGF β was shown to be an effective treatment for radiation-induced pulmonary damage and correlated well with reduced immune cell influx and expression of the pulmonary fibrosis biomarker osteopontin. Microarray-based gene expression analysis suggested extensive crosstalk between pathways upon thoracic irradiation, warranting a combined Treatment approach. Multi-pathway inhibition suggests a novel treatment approach for the therapy of fibrotic lung diseases.

Radiation induced carcinogenesis of cells with stem cell potential from breast and thyroid gland
 M. Zwar¹, N. Hosper², K. Manda¹, D. Buttler¹, U. Giesen³, R. Nolte³, R. Coppes², G. Hildebrandt¹
¹Radiol. Univ. Klinik Rostock, Department of Radiotherapy and Radiation Oncology, Rostock, Germany
²University Medical Center Groningen, Departments of Cell Biology and Radiation Oncology, Groningen, The Netherlands
³Physikalisch-Technische Bundesanstalt, PTB, Braunschweig, Germany

Purpose or Objective: During treatment of cancer patients using proton therapy, neutrons are generated as unwanted by-products. This out-of-field neutron exposure may affect the whole body of the patients and has been suggested to lead to enhanced formation of secondary cancer, especially in young patients. In recent years, indications for the involvement of stem cells in carcinogenesis have been increasing. Due to their long life span, stem cells may have an increased propensity to accumulate genetic damage relative to differentiated cells. Against this background, the intention of this study is to estimate the risks from neutrons compared to photons. Therefore, the investigation of damage induction on healthy adult stem cells from breast and thyroid tissue as an evidence of relative carcinogenic effectiveness following low and intermediate doses from neutrons compared to photons is performed.

Material and Methods: Human breast cells with stem cell potential as well as murine thyroid stem cells are exposed to x-rays or neutrons (monoenergetic 0.56 MeV and 1.2 MeV neutron fields, neutron field with a broad energy distribution and a mean energy of 5 MeV) at various dose rates. In order to detect early indicators of carcinogenic modifications various *in vitro* analyses are utilised. By means of xenograft mouse models, tumour transformation for both cell types is analysed *in vivo*.

Results: Previous results for cells originated from breast tissue show significant differences in survival, DNA repair and

in the expression of stem cell marker MUC-1 and genes commonly associated with cancer following neutron exposure. The influence of radiation quality on the ability for self-renewal could be demonstrated by the use of a spheres formation assay. By analysing residual double strand breaks via the γ H2AX assay, an effect on DNA repair could be observed, particularly after irradiation with neutrons with a low energy of 0.56 MeV. Furthermore the expression of the proteins p53, p27 and RB1 is modified considerably due to neutron irradiation. Similarly, exposure of thymosphere derived cells showed differences in stem cell survival and remaining γ H2AX foci after 24 hours. Long term passaging revealed changes in growth speed, stem cell marker expression and cancer associates genes changed in individual samples.

Conclusion: Summing up, the study of stem cell behaviour may be a valuable tool in the investigation of carcinogenesis induced by ionizing radiation. The evaluation of the Relative Biological Effectiveness (RBE) of different types and energies of radiation may have a strong impact on our knowledge about the role of stem cells in carcinogenesis and will provide great benefit on the understanding of long-term risks of secondary cancers following low-dose exposure to neutrons during proton therapy.

PD-L1/PD-L2 gene expression differs in tumor vs. lung tissue in non-small cell lung cancer patients

K. Revnders^{1,2}, E. Wauters^{3,4}, J. Vansteenkiste⁴, H. Decaluwé⁵, P. De Leyn⁵, K. Nackaerts⁴, S. Peeters², C. Dooms⁴, W. Janssens⁶, D. Lambrechts³, D. De Ruyscher²

¹KU Leuven, Experimental Radiation Oncology, Leuven, Belgium

²University Hospitals Gasthuisberg, Radiation Oncology, Leuven, Belgium

³KU Leuven, Laboratory of Translational Genetics Vesalius Research Center, Leuven, Belgium

⁴University Hospitals Gasthuisberg, Respiratory Oncology Pneumology, Leuven, Belgium

⁵University Hospitals Gasthuisberg, Thoracic Surgery, Leuven, Belgium

⁶University Hospitals Gasthuisberg, Pneumology, Leuven, Belgium

Purpose or Objective: Targeted therapies like immune checkpoint inhibitors are rapidly turning out to be important assets in the treatment of non-small cell lung cancer (NSCLC). The expression of these genes in both tumor and the surrounding non-malignant lung tissue might play an important role in determining their therapeutic window. This project aims to identify different expression patterns of these target genes. We therefore performed transcriptome analysis and investigated correlations with histology, gender, age, CRP level and smoking status in primary resected NSCLC and the surrounding non-malignant lung of the same patient. Additionally, differentially methylated gene sites were checked for impact on gene regulation.

Material and Methods: Tissue of primary tumor as well as distant lung tissue was collected from 25 untreated, primary resected NSCLC patients. Illumina HiSeq 2000 was used to determine the differential gene expression between different conditions for 14 different target genes. DeSeq was chosen as the definitive method for statistical analysis. Differential methylation status was analyzed on an Infinium HumanMethylation 450K BeadChip. Differential gene expression and methylation status of the 14 chosen target genes were compared for 11 different conditions; results with P-values <0.05 after Benjamini-Hochberg correction were considered significant. For each differentially expressed gene, the locations of differentially methylated sites were checked in the UCSC Genome Browser. Histone markers H3K4Me1, H3K4Me3 and H3K27Ac as well as presence of CpG

islands were used to identify methylated regulatory elements.

Results: Nineteen men and 6 women, with a median age of 69 years, were included. Ten were current smokers, 14 ex-smokers (stopped more than 4 weeks before surgery) and 1 non-smoker. Fourteen patients had adenocarcinoma, eleven patients had squamous cell carcinoma. When compared to distant lung tissue, gene expression of PD-L2, HGF, VEGFR2 and VEGFR3 were downregulated in tumor tissue. PD-L1 expression was also downregulated in tumor tissue, but only in active smokers. For PD-L2, HGF, VEGFR2 and VEGFR3, methylation data shows a clear hypermethylation pattern in the promoter and enhancer regions of tumor tissue, which is conform the results of the transcriptome sequencing. Qualitative results of the expression and methylation data are depicted in figure 1.

Figure 1. Qualitative gene expression and methylation results. Methylation status was not determined when no differential expression was found.

Conclusion: Our results show a lower expression of PD-L1 in tumors of active smokers. PD-L2, VEGFR2 and VEGFR3 and HGF have a lower expression in tumors overall. Methylation data confirms these findings. The therapeutic ratio with targeted treatment might be narrow as a result of this higher expression in distant lung tissue and in the case of immune checkpoint inhibitors, increase the chance of pneumonitis.

OC-0048

Tumor microenvironment response and bone marrow cell migration after pulsed radiotherapy

J.L. Kane¹, S.A. Krueger¹, A. Hanna¹, T.R. Raffel², G.D. Wilson¹, G.J. Madlambayan², B. Marples¹

¹Beaumont Health, Radiation Oncology, Royal Oak MI, USA

²Oakland University, Biology, Rochester, USA

Purpose or Objective: Recent studies have shown that alterations in the pattern of radiation delivery, such as pulsed radiotherapy (PRT), can produce significant changes to the tumor microenvironment. Given the positive effects of PRT on maintaining tumor vasculature, we hypothesized that PRT treatment would allow tumor microenvironments to remain more oxygenated and result in better overall tumor killing compared with SRT. We further postulated that this effect would be associated with decreased tumor hypoxia, leading to lower vascular endothelial growth factor (VEGF) and stromal derived factor-1 alpha (SDF-1α) production and subsequently lower recruitment of bone marrow derived cells (BMDCs) in PRT-irradiated tumors.

Material and Methods: Subcutaneous Lewis lung carcinoma (LLC) tumors were established in C57BL/6 mice. Tumors were allowed to grow to 100-200mm³ before irradiation with a 160 kVp Faxitron cabinet (HVL: 0.77 mm Cu) using a dose rate of 0.69 Gy/min. SRT or PRT was given to 20 Gy at 2 Gy/day using a 5 day-on, 2 day-off schedule to mimic clinical delivery. Tumors were harvested 2-3 days post treatment. Radiation-induced changes in the tumor microenvironment were examined using flow cytometry and antibody-specific histopathology. Normal tissue effects were determined using

non-invasive 18F-FDG PET/CT and MR imaging after naïve animals were given whole-lung irradiation to 40 Gy using the same 2 Gy/day regimens.

Results: PRT was more effective than SRT at reducing tumor growth rate (0.24±0.02mm³/day and 0.67±0.06mm³/day respectively; p<0.0001). Histopathology analysis showed a significant reduction in the levels of Ki-67 (13±8%), hypoxia (8±1%), VEGF (3.5±1%) and SDF-1α (4.2±1.5%) as well as a concomitant decrease in CD45+ BMDC migration (7.8±2.2%) after PRT when compared to SRT. Higher vessel density was also observed in PRT irradiated tumors. No short-term differences were observed in normal lung tissue after PRT or SRT although all irradiated animals demonstrated higher levels of inflammation than controls.

Conclusion: Using a rapidly proliferating LLC allograft model, we have found evidence for improved tumor killing with PRT relative to SRT due to vascular maintenance. PRT irradiated tumors exhibited slower growth rate and reduced hypoxia coincident with loss of supportive mechanisms utilized by tumors in low oxygen microenvironments, such as angiogenesis and recruitment of BMDCs. This study demonstrates the efficacy of PRT and highlights the importance of microenvironment responses during tumor radiotherapy. We conclude that PRT represents an improved treatment strategy that may result in better overall patient outcomes with little alteration in normal tissue toxicity.

Trends in the use of postoperative radiotherapy following mastectomy: a population-based study

S. Corradini¹, J. Engel², C. Belka¹, M. Niyazi¹

¹University of Munich, Radiation Oncology, Munich, Germany

²University of Munich, Munich Cancer Registry MCR of the Munich Tumour Center TZM at the Department of Medical Informatics- Biometry and Epidemiology IBE, Munich, Germany

Purpose or Objective: The objective of this population-based study was to provide an overview on trends and changing patterns in the adoption of postmastectomy radiotherapy (PMRT) over a 25-year period, and to validate the effectiveness of postoperative radiotherapy. Focused attention was given to disparities and barriers related to the use of postoperative radiotherapy in nodal positive disease and elderly patients.

Material and Methods: The study included epidemiological data of 16,675 patients diagnosed with invasive breast cancer from 1988 to 2012, within the catchment area of the Munich Cancer Registry. Use of PMRT, local recurrence free survival (LRF5), cumulative incidence (CI) of time to local recurrence, relative survival and conditional overall survival (cOS), were analysed for different time periods (1988-1997 and 1998-2012). Factors predicting the use of postoperative radiotherapy were analysed using multivariate logistic regression.

Results: Use of PMRT was associated with significant improvements in local control, with a 10-year LRF5 of 88.9% with PMRT vs. 84.1% following mastectomy alone (p<0.001). After adjusting for age, tumour characteristics and other therapies, the Cox-regression analysis for LRF5 identified PMRT as an independent predictor for improved local control (hazard ratio [HR]: 2.145; 95% CI: 1.787-2.574, p<0.001). Patients with 1-3 involved lymph nodes had a 10-year CI of time to local recurrence of 13.7% following mastectomy alone, compared to 6.5% following PMRT (p=0.001). Comparable findings were obtained for the subgroup of patients presenting with 4 positive lymph nodes - presenting with 17.8% 10-year CI of time to local recurrence in the mastectomy only group, compared to 8.2% in the PMRT group (p<0.001). All effects were smaller or extinct in elderly patients aged ≥ 70 years. On multivariate analysis for cOS, no

advantage for PMRT was detected (HR: 1.084; 95% CI:0.986-1.191, $p=0.095$). Variables favouring the use of postoperative radiotherapy on multivariate logistic regression analysis included young age ($p<0.001$), large tumour size (pT3/4) ($p<0.001$), positive resection margin ($p<0.001$), and positive nodal status ($p<0.001$). High-risk patients with ≥ 4 positive lymph nodes who underwent mastectomy in 1998-2012 had a significant increased likelihood of receiving PMRT (OR 6.245) as compared to patients treated in the early period of analysis, from 1988-1997 (OR 2.837).

Conclusion: The present study was useful in providing a window on the adoption of PMRT in a large population-based cohort, and to determine trends over time, as well as to characterize and quantify the outcome in clinical practice. A significant shift in indications for PMRT was registered, especially for high-risk patients with ≥ 4 positive lymph nodes. Moreover, the present findings track a substantial variation and apparent underuse of PMRT within the vulnerable population of elderly patients aged ≥ 80 years.

OC-0050

Variations in use of hypofractionation for early, node-negative breast cancer in NSW 2007-2012

G. Delaney¹, S. Gandhidasan², F. Terlich³, D. Baker³, R. Walton³, D. Currow³

¹Liverpool Hospital, Area Cancer Services, Liverpool, Australia

²Peter MacCallum Cancer Institute, Radiation Oncology, Melbourne, Australia

³Cancer Institute NSW, Ministry of Health, Sydney, Australia

Purpose or Objective: Phase III randomised controlled trials and subsequent evidence-based treatment guidelines suggest that breast hypofractionation has low toxicity and similar cancer outcomes compared to patients undergoing standard fractionation. However, uptake of hypofractionation has not been universal. The aim of this study was to investigate the uptake of hypofractionation regimens in all public radiation oncology facilities in NSW.

Material and Methods: Data from the NSW Clinical Cancer Registry were extracted, cleaned and verified. The inclusion criteria included those patients that are node negative breast cancer (TNM stage I or IIA), year of diagnosis between 2007 to 2012, year of treatment between 2008 and 2012 and received external beam radiotherapy in a public radiotherapy facility. Data extracted included dose and fractionation type, patient age at first fraction, distance from treatment facility, year of diagnosis, year of treatment, laterality of treatment and department of treatment. In this analysis, standard fractionation was defined as dose per fraction of between 1.8 - 2.4 Gy per fraction and hypofractionation as above 2.4 Gy per fraction. Univariate and multivariate analyses were performed to assess which factors predict for hypofractionation use.

Results: Of the 6066 early breast cancer patients fulfilling the study criteria, 3947 patients (65%) had standard fractionation and 2119 patients (35%) received hypofractionation in 14 public radiotherapy centres in NSW. There was a wide spread of fractionation used across departments ranging from 6% to 92%. Hypofractionation use exceeded 50% in only 4 departments. Statistically significant factors to predict for hypofractionation use were increasing patient age, right sided breast cancer, further distance from home to the treating facility, more recent treatment, facility and clinician treating.

Conclusion: While hypofractionation has become more common across NSW, there remains a substantial proportion of patients for whom hypofractionation would be considered appropriate who are not receiving hypofractionation. This has also been found to be the case in US studies, although we believe we are the first to identify laterality as an indicator. Understanding factors that may predict standard fractionation use might assist in developing strategies to address the issue. Hypofractionation for early breast cancer

being adopted more widely would lead to greater patient convenience, better resource efficiencies in radiation oncology departments and perhaps even increase the use of post-lumpectomy radiotherapy, as some patients might currently forego radiotherapy due to the perceived inconvenience of standardly fractionated radiotherapy.

OC-0051

Variability in lymph node delineation for breast cancer radiotherapy: an AIRO multicenter study

D. Ciardo¹, R. Ricotti¹, B.A. Jereczek-Fossa^{1,2}, A.I.R.O. Breast Cancer Working Group³

¹European Institute of Oncology, Department of Radiation Oncology, Milan, Italy

²University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy

³Associazione Italiana di Radioterapia Oncologica, AIRO, Milan, Italy

Purpose or Objective: To investigate inter-operator and inter-center variability in lymph node (LN) volume delineations in breast cancer (BC) nodal irradiation.

Material and Methods: The study was conducted by the Italian Society of Radiation Oncologists (AIRO) - Breast Cancer Working Group. For each center, 3 radiation oncologists (ROs) with different expertise were involved: 1 junior (J), 1 senior (S) not dedicated to BC, and 1 senior (E) expert in BC. The CT series of 3 patients at different levels of complexity were selected: 1 with simple anatomy (P1), 1 obese (P2) and 1 with impaired arm mobility (P3). ROs were asked to contour axillary nodes, as follows: I level (L1), II level (L2) and III level, the latter was further divided into infra (L3) and supraclavicular (L4) nodes on CT images by applying guidelines on breast contouring released by AIRO. The inter-category and the inter-center variability were investigated, by evaluating the variability in volume size, structure overlap (measured as Dice similarity coefficient, DSC), and average Hausdorff distance (AHD) between contours.

Results: Thirty-nine ROs from 14 centres participated and 468 contours were obtained. Firstly, the analysis was focused on volume size. By comparing the operators, E-ROs contoured slightly larger volumes than S-ROs and J-ROs, with no statistically significant differences. Conversely, statistically significant differences were found in volume size when stratifying for patients (larger volumes were obtained for P2) and for LN levels (in order of size: L1, L4, L2, L3 - L1 being the largest and L3 the smallest). Secondly, descriptive and statistical intra-group analysis showed that all the 3 principal factors (different expertise, LN level and patient) contributed to inter-operator variability. When analysing DSC, poor agreement was found among ROs stratified for expertise (Fig. 1a) and the differences between S-ROs and the other groups were statistically significant. Considering the LN levels (Fig. 1b), the highest concordance was found in the contouring of L1 and L4 levels and the lowest for L3 ($p<0.05$). Moreover, inter-operator consistency dramatically decreased as patient complexity increased (Fig. 1c). Consistent results were found in the analysis of AHD. Finally, considering the inter-center variability, statistically significant differences were found in 38.5% of comparisons when considering intra-center median DSC (Fig. 1d) and in 33% of comparisons when considering intra-center median AHD.

		L1		L2		L3		L4	
		mean	st.dev.	mean	st.dev.	mean	st.dev.	mean	st.dev.
J	P1	62.8	15.7	20.1	4.7	9.1	3.1	30.3	8.7
	P2	89.6	34.8	31.4	12.3	17.0	6.5	37.7	9.8
	P3	39.3	16.6	24.0	9.5	12.2	6.6	22.2	10.3
S	P1	65.1	28.4	18.0	3.0	12.4	5.6	35.3	16.8
	P2	87.1	49.1	30.7	12.2	21.8	8.2	42.9	21.7
	P3	41.4	22.8	26.4	11.6	16.1	10.5	23.8	12.6
E	P1	70.4	35.8	17.7	5.3	11.5	7.0	32.4	6.8
	P2	116.2	67.3	32.6	10.6	22.5	11.5	39.0	9.0
	P3	48.6	21.2	22.2	5.8	16.3	12.6	23.0	7.7

Conclusion: Guidelines for regional LN did not significantly improve the consistency of contouring among ROs. The J-ROs were the most accurate in contouring according to AIRO guidelines and showed the highest level of homogeneity, while the S-ROs followed the guidelines to a lesser extent, probably because of higher self-confidence.

Re-irradiation for locally recurrent breast cancer

E. Bräutigam¹, C. Trackl¹, M. Geier¹, H. Geinitz¹

¹Krankenhaus der Barmherzigen Schwestern - Linz, Radiation Oncology, Linz, Austria

Purpose or Objective: To report an analysis of treatment outcomes and toxicity of a cohort of patients re-irradiated after a second breast conserving surgery or no further surgery.

Material and Methods: Between 11/05 and 10/15, 32 women were re-irradiated with 50- 60 Gy for locally recurrent breast cancer. The first RT course included postoperative radiotherapy with a total dose of 50 Gy in 25 or 50,4Gy in 28 fractions followed by a boost dose to the tumor bed

according to risk factors in 81.3%. In 18.7% supraclavicular nodes were treated with 50Gy. The median age at first diagnosis was 53.3 years (range 36- 69.7). 78.1% of the women were postmenopausal. 81.25% of the tumors were pathologically classified as T1, 12.5% as T2 and 6.25% as ductal carcinomas in situ. Axillary lymph node involvement was seen in 34.3%. Most of the tumors were estrogen positive (68.75%) and progesterone positive (65.6%). A systemic therapy was given in 81.25% of the patients. After second breast conserving therapy or no surgery re- RT was given to the involved quadrant using external- beam ports (electrons or photons) with doses of 50-60Gy in 2Gy per fraction. The median age at local relapse was 65.8 years. A second breast conserving therapy was performed in 90.7% of the women, 9.3% had no surgery and were re-irradiated to a dose of 60Gy. A systemic therapy was given in 84.3%. Survival and local control were calculated by the Kaplan-Meier actuarial method.

Results: A total of 32 patients were retrospectively analyzed. The median follow up of survivors was 181 months from first diagnosis and 33 month from second RT. At the time of analysis 4 patients had died. The median time between first and second RT was 9.9 years (range 1.8- 20.3). Fifteen years after first diagnosis 86% of the patients were still alive. Four women died, 3 on cancer. After second RT only one acute G2 toxicity of the skin was reported (desquamation). Late toxicity was scored using the LENT- SOMA Score Criteria. Lymphedema (G1) of the ipsilateral arm was observed in 3.1%, 3.1% reported on intermittent pain in the breast and 9.3% presented with an asymptomatic breast edema. The highest rate of late toxicity was G2 fibrosis in 18.7%. No G3 or G4 toxicity was observed.

Conclusion: Carefully planned re-RT of the involved breast quadrant is a safe alternative therapy for those women who did not give their consent to the recommended mastectomy. No second local relapse was detected after re-RT. Acute side effects were low. In 18.7% of the women fibrosis G2 was detected.

OC-0054

Reirradiation+hyperthermia for recurrent breast cancer-en-cuirasse in previously irradiated area

S. Oldenburg¹, J. Crezee¹, Y. Kusumanto¹, R.M. Van Os¹, S.B. Oei², J.L.M. Venselaar², P.J. Zum Vörde Sive Vörding¹, C.R.N. Rasch¹, G. Van Tienhoven¹

¹Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands

²Institute Verbeeten, Radiation Oncology, Tilburg, The Netherlands

Purpose or Objective: Cancer en cuirasse is a severe locoregional manifestation of breast cancer, usually occurring after a number of treatment failures. Treatment options are limited. One hundred and sixty-nine patients were treated with re-irradiation and hyperthermia (reRT+HT) from 1982 till 2006. Response and toxicity rates as well as the locoregional progression free interval were determined to assess the palliative value of this treatment.

Material and Methods: All patients had received extensive previous treatments, including surgery, irradiation (median dose 50Gy with or without boost) and systemic treatments.. Seventy-five percent of patients had 1-7 previous locoregional recurrence episodes; 68% were treated with systemic therapies and 27% underwent salvage surgery.

At start of re-RT+HT the tumor area comprised > 3/4 ipsilateral chest wall in 54% of patients. Fifty-two percent had areas of ulcerating tumor. Distant metastases were present in 45% of patients. reRT consisted typically of 8x4Gy, twice a week or 12x3Gy, four times a week. Superficial hyperthermia was applied once or twice a week using 434MHz Contact Flexible Microstrip Applicators (CMFA), heating the tumor area to 41-43°C for one hour.

Results: The treatment was well tolerated; 154 patients completed treatment, only 15 patients did not, due to

disease progression in 12, toxicity in 2 and refusal in 1 patient. Overall clinical response rate was 72% (30% CR; 42% PR), while only 6% showed PD. Median follow-up time was 7 months. The 1-year progression-free-interval was 24% with a 1-year survival rate of 36%. Acute \geq grade 3 toxicity occurred in 33% of patients and consisted mostly of ulceration and dermatitis. The occurrence of radiation ulcers was significantly related to the presence of ulcerating tumor before the start of the reRT-HT ($P=0.004$, HR = 4.4).

Conclusion: The combination of re-irradiation and hyperthermia is well tolerated and results in high response rates despite extensive disease and resistance to previous treatments. ReRT+HT is a worthwhile palliative treatment option for this patient group who suffer from extensive locoregional tumor growth and have a very poor prognosis.

OC-0055

Pseudo-progression after stereotactic radiotherapy of brain metastases is serious radiation toxicity

R. Wiggendaad¹, M. Mast¹, J.H. Franssen², A. Verbeek-de Kanter¹, H. Struikmans¹

¹Radiotherapy Centre West, Radiotherapy, The Hague, The Netherlands

²Haga Hospital, Radiotherapy, The Hague, The Netherlands

Purpose or Objective: Stereotactic radiotherapy (SRT) of brain metastases results in regression of most treated metastases, but subsequent lesion growth may occur and is caused by either tumor progression or pseudo-progression, which is probably a radiation effect on surrounding normal brain tissue. It is unknown if active treatment is indicated in symptomatic patients, or if it is better to wait for spontaneous recovery. The purpose of this study is to describe the clinical course of brain metastasis patients developing pseudo-progression after SRT to improve clinical decision-making.

Material and Methods: Follow-up MRI scans of all patients who received SRT of brain metastases from 2009 through 2012 were reviewed for post SRT lesion growth. Depending on the volume of the metastasis, the patients had received one fraction of 21Gy, 18Gy, or 15Gy, or three fractions of 8Gy or 8.5Gy. The GTV-PTV margin was 2mm. Pseudo-progression was considered to be the cause of this lesion growth if a histological diagnosis of necrosis had become available, if the lesion had shown subsequent regression or if two neuro-radiologists agreed upon this diagnosis based on a review of the follow-up perfusion MRI scans. The clinical course of the patients with these pseudo-progressive lesions was retrospectively studied.

Results: In a total of 237 treated patients we identified 37 patients with 50 pseudo-progressive lesions. The median follow-up of all patients still alive was 40.7 months. The main clinical symptoms that were attributed to this lesion growth were neurologic deficits, headache and seizures in 19 (51%), 3 (8%) and 4 (11%) patients respectively (unknown in one). Ten patients (27%) had no symptoms attributed to the lesion growth and remained asymptomatic afterwards. Of the 19 patients with neurologic deficits one improved after spontaneous regression of the lesion, one improved after surgery and 17 did not improve. Two out of the four patients with seizures improved with ant-epileptic drugs (AED's), one improved after surgery and one did not improve. Only one of the three patients with headache improved with steroids. Spontaneous regression of an initially pseudo-progressive lesion was observed in 18 patients. Twelve of these 18 patients had symptomatic pseudo-progression, but only one of these 12 patients experienced neurologic improvement without treatment. In 6 patients their deaths were related to the pseudo-progressive lesion.

Conclusion: Patients with an asymptomatic pseudo-progressive lesion frequently remain asymptomatic. Patients with a symptomatic pseudo-progressive lesion only rarely recover spontaneously. Active treatment, such as surgery, should be considered for these patients. Therefore, symptomatic pseudo-progression after SRT of brain metastases needs to be considered as a serious radiation induced toxicity. Reduction of the high dose volume of normal brain tissue may prevent this toxicity.

FLAME: Influence of dose escalation to 95Gy for prostate cancer on urethra-related toxicity and QoL

J. Van Loon¹, M. Van Vulpen¹, F. Pos², K. Haustermans³, R. Smeenk⁴, L. Van den Bergh³, S. Isebaert³, G. McColl⁴, M. Kunze-Busch⁴, B. Doodeman², J. Noteboom¹, E. Monnikhof⁵, U.A. Van der Heide²

¹UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands

²The Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

³University Hospital Leuven, Radiation Oncology, Leuven, Belgium

⁴University Medical Center Radboud, Radiation Oncology, Nijmegen, The Netherlands

⁵UMC Utrecht, Julius Center for methodology, Utrecht, The Netherlands

Purpose or Objective: Following EBRT for prostate cancer, patients can develop aggravation of urinary symptoms mostly due to urethral dose. With dose-escalated EBRT it is suggested that genitourinary toxicity increases with increasing dose. In the experimental arm of the FLAME-trial (284 patients) a dose of 77Gy to the entire prostate gland in 35 fractions was administered, with an integrated boost up to 95Gy to the macroscopic lesions. No dose constraints for the urethra were set during the trial. The objective of this study is to evaluate urethral dose parameters, urethra-related toxicity and prostate-specific QoL scores for patients treated with and without dose-escalated EBRT.

Material and Methods: Between 2009 and 2015, 571 intermediate and high risk prostate cancer patients were enrolled in the FLAME trial, a phase 3, single blind, multi-center randomized controlled trial (NCT01168479). The control arm (287 patients) received a dose of 77Gy to the entire prostate gland in 35 fractions. The experimental arm (284 patients) received the same dose, but with an integrated boost up to 95Gy to the multi-parametric MRI-based intraprostatic lesion. For this study, the urethra was delineated retrospectively on T2 weighted MRI, using a circle shape with a diameter of 3 mm, to obtain dose parameters. These dose parameters, the Genitourinary Toxicity scores (CTCAE v3.0) and the urinary symptoms scale of the EORTC QLQ-PR25, were compared for both treatment arms. The physician in attendance scored toxicity at baseline, weekly during treatment, 4 weeks after treatment and every 6 months up to 10 years. QoL was filled out 1 week before treatment and the next questionnaires were sent to the patient every 6 months up to 10 years. Mean differences between groups at 1 year of follow-up were calculated using an independent samples t-test (dosimetry and QoL), Chi-square test or Fisher's exact test (toxicity). Statistical significance was considered $P < 0.01$.

Results: Results after analysis of 100 patients (50 patients in each treatment arm) with a median follow-up of 22 months show for the control arm an average Dmean (mean dose to the urethra) of 77.3 ± 0.5 Gy (range 75.9-78.0 Gy), with an average Dmax (maximum dose to the urethra) of 79.6 ± 0.8 Gy (range 78.0-81.3). In the experimental arm, average Dmean was 82.0 ± 2.8 Gy (range 77.4-89.0 Gy) and average Dmax was 89.7 ± 0.6 Gy (range 80.7-97.7 Gy). For both Dmean and Dmax the difference between treatment arms was significant ($p=0.000$). Grade 3 GU toxicity did not occur, grade 2 GU toxicity occurred in a subset of patients, although no significant difference was found between both treatment arms for the separate GU items (table 1). Urinary symptoms-

related QOL was not significantly different across treatment arms.

Time of follow-up	1 year		Difference
	77Gy	95Gy	
Urinary frequency/urgency - \geq grade 2 toxicity	15 (30%)	14 (28%)	0.83 (Chi-Square)
Urinary retention - \geq grade 2 toxicity	4 (8%)	2 (4%)	0.68 (Fisher's exact)
Bladder spasms - \geq grade 2 toxicity	0 (0%)	0 (0%)	-
Incontinence, urinary - \geq grade 2 toxicity	3 (6%)	2 (4%)	1.0 (Fisher's exact)
Hemorrhage - \geq grade 2 toxicity	0 (0%)	1 (2%)	1.0 (Fisher's exact)
Dysuria - \geq grade 2 toxicity	5 (10%)	5 (10%)	1.0 (Fisher's exact)

Table 1. Incidence of GU toxicity at 1 year after radiation treatment.

Conclusion: Results showed a significant difference in urethral dose, but no significant differences in toxicity or quality of life when comparing both treatment arms of the FLAME trial.

OC-0057

Cardiotoxicity and cardiac substructure dosimetry in dose-escalated lung radiotherapy

S. Vivekanandan¹, N. Counsell², A. Khwanda³, S. Rosen³, E. Parsons⁴, Y. Ngai², L. Farrelly², L. Hughes², M. Hawkins¹, D. Landau⁵, J. Fenwick¹

¹University of Oxford, Oncology, Oxford, United Kingdom

²University College London Clinical Trials Unit, Clinical Trials Unit, London, United Kingdom

³Imperial College London, Cardiology, London, United Kingdom

⁴RTQA, Mount Vernon, London, United Kingdom

⁵Guy's and St Thomas' Hospital, Oncology, London, United Kingdom

Purpose or Objective: Radiotherapy of lung cancer delivers quite high doses of radiation to the heart. We explored associations between overall survival (OS) and radiation dose to heart and its substructures and electrocardiographic (ECG) changes.

Material and Methods: We analysed data from 79 patients in IDEAL CRT, a phase I/II trial of isotoxic radiotherapy (RT) dose escalation trial, sponsored by University College London (C13530/A10424). Mean and maximum prescribed doses were 69 and 75.6Gy calculated as 2Gy fractionation equivalents (EQD2, $\alpha/\beta=10$ Gy). Whole heart, left ventricle (LV), right ventricle (RV), right atrium (RA), left atrium (LA) and AV node (AVN) were outlined on RT planning scans and differential dose volume histograms (DVHs) extracted, converting physical DVHs to EQD2s ($\alpha/\beta=3$). Patient-to-patient DVH variability was represented using a small number of Varimax-rotated principal components (PCs) explaining 95% of total variance. ECGs were analysed at baseline, 6 and 12 months (mo) after treatment, and changes in heart rate (HR) recorded, with patients dichotomised according to presence or absence of 'any ECG rhythm change' (conduction abnormalities or ischaemia). OS was modelled using Cox regression from the start of treatment. Univariate analysis (UVA) and multivariate analysis (MVA) of clinical factors included 'any rhythm ECG change' at 6 and 12 months, change in HR at 6 or 12 months, planning target volume (PTV), and prescribed dose (PD). MVA of whole heart dosimetric factors included all 7 Heart PCs, PTV, and PD. MVA of heart substructures included heart substructure PCs with p

< 0.2 on UVA having similar dosimetric distributions to significant Heart PCs, PTV and PD.

Results: ECGs at baseline and 6 mo were available for 54 patients, and at baseline and 12 mo for 49 patients. At 6 mo and 12 mo, 10 and 6 patients had ischemic changes and 12 and 15 patients had conduction abnormalities (AF or sinus tachycardia). Median PTV was 403.4cm³ (Range 138.7-1262.1). Larger PTV and 'any ECG rhythm change' at 6 mo were associated with worse OS (HR = 1.005, 95% CI: 1 - 1.01 p 0.04; HR = 7.9843, 95% CI: 1.293 - 47.583 p 0.03 respectively) on MVA. Increasing values of Heart PC2, Heart PC3 and Heart PC7 (characterizing heart volume (vol) receiving 10-30Gy plus 70-80Gy, 65-75Gy and 1-5Gy respectively) were associated with worse OS (HR = 0.844, 95% CI: 0.715 - 0.995 p 0.04; HR = 1.238, 95% CI: 1.051 - 1.457 p 0.01; HR = 1.725, 95% CI: 1.006 - 2.958, p 0.05 respectively) on MVA. Increasing values of LA PC4 (LA vol receiving 65-75Gy) was associated with worse OS on MVA (HR = 1.129, 95% CI: 1.033 - 1.235 p <0.01).

Figure shows on Cox regression patients with 'Any ECG rhythm change' at 6 months were associated with worse OS compared to those with no ECG rhythm change at 6 months

Conclusion: We found evidence of a possible association between lower OS in IDEAL-CRT patients and high PTV, ischaemic or conduction change on ECG at 6 mo, and relatively high heart volume receiving doses <5Gy, 10-30Gy, 65-75Gy and 70-80Gy with the 65-75Gy localising to LA. Further prospective studies are required to improve understanding of cardiac irradiation in NSCLC.

⁴University of Utrecht, Radiotherapy, Utrecht, The Netherlands

⁵Universiteits Medisch Centrum Utrecht, Radiology, Utrecht, The Netherlands

⁶Universiteits Medisch Centrum Utrecht, Epidemiology, Utrecht, The Netherlands

⁷Erasmus Medical Centre, Radiation Oncology, Rotterdam, The Netherlands

Purpose or Objective: Breast cancer patients with cardiovascular risk factors are at increased risk of radiation- and chemotherapy- induced cardiovascular complications. Presence of coronary artery calcifications (CAC) is a major independent risk factor for cardiovascular disease (CVD). This study investigates the prevalence of CAC in breast cancer patients on radiotherapy (RT) planning CT scans, and its association with cardiovascular risk factors.

Material and Methods: This study was conducted within the Utrecht cohort for Multiple BREast cancer interVENTion studies and Long-term evaluation (UMBRELLA), and includes 561 breast cancer patients undergoing planning CT scans at the UMC Utrecht between October 2013-March 2015. CAC was automatically scored using a validated algorithm that

identifies CAC with a supervised pattern and threshold of 130 Hounsfield Units. Patients were categorized according to CAC (Agatston) scores: 0, 1-10, 11-100, 101-400, >400. Cardiovascular risk factors (diabetes, smoking status, hypercholesterolemia, hypertension, history of CVD) were collected for 36 patients with intermediate to high CVD risk (scores >100), and for a random selection of patients with fair to moderate CVD risk ($1 \leq \text{scores} \leq 100$, $n=36$) and low CVD risk (without CAC, i.e. scores of 0, $n=36$). Demographic, disease characteristics, and presence of cardiovascular risk factors were compared between groups using Chi-square analysis and Kruskal-Wallis test for categorical and continuous data respectively.

Results: Median age of the cohort was 58 years (range: 26-85). There were 427 (76%) patients without CAC, 50 (9%) with scores between 1-10, 43 (7%) with scores between 11-100, and 36 (7%) patients with scores >100. Patients with scores >100 had significantly more often diabetes than those without CAC (28% vs. 3%, $p < 0.001$). Patients with scores >100 had more often three to four CVD risk factors compared to patients with scores between 1-100 or without CAC: 30%, 5%, 0% respectively, $p=0.002$. Ten (28%) patients with scores >100

did not have any other CVD risk factor

Conclusion: CAC is present in one in four breast cancer patients. In one third of patients with CAC scores >100, no other CVD risk factors were present, and these patients would not have been identified as high risk using standard CVD risk factors. Since CAC can be automatically detected without additional cost or radiation exposure in breast cancer patients undergoing RT, it represents a simple and useful way to detect those requiring additional cardio protective measures.

OC-0059

A radiation dose-response relationship for risk of heart failure in survivors of Hodgkin lymphoma

⁶Leiden University Medical Center, Clinical Oncology, Leiden, The Netherlands

⁷Oxford University Hospitals NHS Trust, Oxford Cancer Center, Oxford, United Kingdom

Purpose or Objective: Cardiovascular diseases are increasingly recognized as late effects of Hodgkin lymphoma (HL) treatment. Radiation therapy is known to contribute to the risk of heart failure (HF), but a dose-response relationship has yet not been well described. The purpose of this study was to identify risk factors for HF, and to quantify effects of radiation dose to the heart, chemotherapy, and other cardiovascular risk factors.

Material and Methods: We conducted a nested case-control study in a cohort of 2,617 5-year HL survivors, treated between 1965-1995. Cases were patients who developed HF in the form of either symptomatic congestive heart failure or cardiomyopathy (Common Terminology Criteria for Adverse Events version 4.0: grade 2) as their first clinically significant heart disease. Detailed treatment information was collected from medical records of 91 cases and 278 matched controls. Mean heart dose (MHD) was retrospectively estimated by reconstruction of individual treatments on

representative computed tomography datasets. All statistical tests were two-sided.

Results: The median interval between HL and HF was 20.6 years. Fifty-seven percent of the cases had died at the end of follow-up, with a median time from HF to death of 3.6 years (interquartile range: 0.2-5.6 years). Mediastinal radiotherapy was applied through parallel-opposed fields. Average MHD for cases treated with RT was 25 Gy and for controls 22 Gy. Risk of HF increased in a non-linear way, with no increase at a MHD of 10 Gy, a 1.2-fold increased risk at a MHD of 20 Gy, and a 2.5-fold increased risk at a MHD of 30 Gy. Relatively low doses of anthracyclines (10-279 mg/m²) were associated with a 3.2-fold increased risk of developing HF (95%CI: 1.3-7.7) compared with patients who did not receive anthracyclines. High doses of anthracyclines (280-800 mg/m²) were associated with a similarly increased risk (RR: 2.8, 95%CI: 1.6-5.1). For patients who received anthracyclines in combination with mediastinal radiotherapy the risk of HF (RR: 2.90 at a MHD of 25 Gy) was slightly higher than the risk of mediastinal radiotherapy without anthracyclines (RR: 1.8 at a MHD of 25 Gy), although the difference was not statistically significant (p interaction=0.10). Classical risk factors for cardiovascular diseases did not confound or modify the association between treatment-related risk factors and HF risk.

Conclusion: Risk of HF increased non-linearly with mean heart dose in patients treated for HL. Our findings can be used to predict HF risk and may therefore be useful for patients and doctors both before treatment, during radiation treatment planning and in follow-up. Patients who received both anthracyclines and mediastinal radiation need to be followed carefully.

Cardiac risk prediction: Moving beyond a mean heart dose model?

M. Maraldo¹, F. Giusti², I. Vogelius¹, M. Lundemann¹, S. Bentzen³, M. Van der Kaaij⁴, B. Aleman⁵, M. Henry-Amar⁶, P. Meijnders⁷, E. Moser⁸, C. Fortpied², L. Specht¹

⁷GZA/Iridium Cancer Network, Department of Radiation Oncology, Antwerp, Belgium

⁸Champalimaud Cancer Center, Department of Radiation Oncology, Lisbon, Portugal

Purpose or Objective: Among 6039 patients with Hodgkin lymphoma enrolled in nine successive EORTC-GELA randomized trials (1964-2004), the effect of individual radiotherapy and chemotherapy doses on the risk of developing cardiac disease was investigated. We specifically analysed the added value from radiation dose-volume metrics on cardiac risk prediction as well as the impact of relapse treatment.

Material and Methods: For all patients, dose-volume metrics for the heart (mean dose, volume receiving 5 Gy (V5Gy), V10Gy, V20Gy, V30Gy, V40Gy) were retrospectively estimated by reconstructing individual treatments on representative computed tomography datasets. Cumulative doses of anthracyclines and vinca-alkaloids (mg/m²) were also obtained individually. Relapse occurring before a cardiac disease was analysed qualitatively (no, yes). Cardiac disease was reported during follow-up and through a patient-reported questionnaire (LSQ responders, 2009-2010 cross-sectional study). A multivariable Cox proportional hazards

model with backwards selection was applied to test for patient- and treatment-related factors associated with cardiac disease. The resulting model was compared to a "mean heart dose"-model in terms of prognostic discrimination ability.

Results: 599 patients developed at least one cardiac disease event (465 events obtained from the 1919 LSQ responders). Significant predictors of cardiac disease were: cumulative dose of anthracyclines (HR=1.002 per 1 mg/m² increase in cumulative dose; 95% CI, 1.001-1.003, p=0.005); (any) treatment given for a relapse (HR=1.286; 95% CI, 1.001-1.65, p=0.049) and the radiation dose-volume metrics V30Gy (HR=1.007 per 1% increase in dose; 95% CI, 1.003-1.011, p=0.001) and V40Gy (HR=1.018 per 1% increase in dose; 95% CI, 1.008-1.029, p<0.001). The freedom from cardiac disease estimates with the "V30Gy, V40Gy"-model are plotted against a "mean heart dose"-model (= mean heart dose, cumulative dose of anthracyclines, any relapse treatment) in figure 1.

Figure 1: Freedom from cardiac disease estimates with the resulting "V30Gy, V40Gy"-model versus a "mean heart dose"-model.

Conclusion: In patients treated for Hodgkin lymphoma, the radiation dose-volume metrics V30Gy and V40 Gy, the cumulative dose of anthracyclines, and (any) treatment given for a relapse have a significant impact on the risk of subsequent cardiac disease. There seems to be no improved discrimination ability of the prognostic model when using radiation dose-volume metrics compared to the mean heart dose metric.

⁹Sir Charles Gairdner Hospital, Dept Radiation Oncology, Nedlands, Australia

Purpose or Objective: A novel approach to treatment planning for focal brachytherapy is described, utilizing a biologically-based inverse optimization algorithm and biological imaging to target an ablative dose at known regions of significant tumour burden and a lower, therapeutic dose to low-risk regions. We describe our methods for defining target volume and prescription dose.

Material and Methods: To demonstrate how tumour characteristics may be extracted from multi-parametric MRI (mpMRI) to inform the previously validated biological model(1), 21 patients underwent in vivo mpMRI prior to radical prostatectomy. Co-registration of histology and imaging data using rigid and deformable registration was validated by matching feature points and annotated zonal regions. Automated methods for defining tumour location, tumour cell density (TCD) and Gleason Score (GS) in histology were developed to provide high resolution ground truth data(2,3). Similarly, using ground truth histology data, machine learning methods have been developed and tested to predict tumour location in mpMRI. Further developments are underway to predict TCD, GS and hypoxia in mpMRI to build a multi-level voxel map defining tumour location and characteristics to inform the biological treatment planning model.

Results: Co-registration of the in-vivo mpMRI with histology was achieved with an overall mean estimated error of 3.3 mm (Fig 1).

An ensemble-based supervised classification algorithm, trained on textural image features, demonstrates a highly sensitive method for automated tumour delineation in high resolution histology images(2). Colour deconvolution and the use of a radial symmetry transform provides measures of cell density, shown to highly correlate with an expert pathologist markup of tumour location(3). A Gaussian-kernel support vector machine demonstrated a tumour location predictive accuracy of >80% with potential for significant improvement using Bayesian methods to incorporate neighbourhood information. Similar statistical methods have demonstrated potential for mpMRI parameter/pharmacokinetic maps to be correlated with tumour characteristics including TCD, GS and hypoxia. Whilst imaging methods for hypoxia exist, providing reliable, high spatial resolution ground truth data remains challenging.

Conclusion: A novel approach to focal brachytherapy planning has been developed that incorporates mpMRI parameter/pharmacokinetic maps to inform a biological model and an inverse optimisation algorithm to maximise tumour control probability and minimise dose to organs at risk in prostate brachytherapy. The model can be equally applied to low and high dose rate brachytherapy, and

possibly EBRT with high precision treatment delivery techniques. 1) Haworth, A. et al. *Brachytherapy*. 12, 628-36, (2013). 2) DiFranco, D. et al., *Proc. SPIE* 9420 (2015). 3) Reynolds, H. et al.. *Proc. SPIE* 90410S (2014).

High-dose-rate HDR boost for localized prostate cancer decreases long term rectum toxicity

S. Aluwini¹, M. Hoogeman¹, J. Lebesque², C. Bangma³, L. Incrocci¹, W. Heemsbergen²

¹Erasmus MC Cancer Institute, Department of Radiation Oncology, Rotterdam, The Netherlands

²Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

³Erasmus MC Cancer Institute, Department of Urology, Rotterdam, The Netherlands

Purpose or Objective: A High-Dose-Rate Brachytherapy (HDR-BT) boost combined with external beam radiotherapy (EBRT) produced excellent long term outcome and is an alternative for escalated EBRT (>72 Gy) for low and intermediate risk prostate cancer (PC) patients. The question remains whether the use of HDR-BT results in lower complication rates for equal tumour control. The aim of this study was to compare HDR-BT/EBRT combined to EBRT-only in terms of long-term patient-reported toxicity and oncological outcome for low and intermediate risk PC patients.

Material and Methods: Between 2000 and 2007 low and intermediate risk PC patients (n=231) were treated (stage T1b-T2a, G7, iPSA≤17) with a HDR -BT boost (3x6 Gy) combined with EBRT (25x1.8 Gy). Patients with a maximum prostate volume of 120 cc and a PSA, T-stage, and Gleason in the same range were selected (68 Gy: n=83, 78 Gy: n=74) from the Dutch randomized dose-escalation study (1997-2003). At least 1 follow-up questionnaire had to be completed. Genitourinary (GU) and gastrointestinal (GI) toxicity symptoms were prospectively assessed using same questionnaires in the period 1-7y years post-treatment. Prevalence of long term GU and GI symptoms were calculated with intervals of 1 year and compared between treatment groups (chi-square test). Biochemical failure free survival (BFFS) using the Phoenix definition (stratified for Gleason score) was calculated and compared (log-rank test).

Results: Median follow up was 8.8y for both 68 Gy and 78 Gy patients, and 6.8y for HDR-BT/EBRT. Median age was 69y and 68y, respectively. In general, post-treatment GU complaints were comparable between groups (dysuria, nocturia, day frequency, incontinence). Rectal blood loss was significantly lower for HDR-BT compared to 78 Gy, from the first year of follow-up and onwards (p<0.001). Rectal discomfort (pain/cramps) was significantly lower at 3y follow-up (p<0.01). Rectal incontinence showed lower rates as well, but these were not significant (p=0.08). Differences in stool frequency ≥ 4 were small and not significant. BFFS rates at 7y were 79%, 90%, and 96% (68 Gy, 78 Gy, HDR-BT) for Gleason <7 and 43%, 75%, and 91% for Gleason 7. BFFS was significantly higher in both the HDR-BT and 78 Gy group compared to 68 Gy (p<0.001 and p=0.034 respectively), the difference between HDR-BT and 78 Gy was not significant (p=0.11).

Conclusion: HDR-BT/EBRT is associated with significantly lower long-term GI toxicity compared to escalated EBRT-only (78 Gy) with a favorably comparable 7 years tumor control.

OC-0063

Real-time in-vivo dosimetry in HDR prostate brachytherapy

J. Mason¹, B. Al-Qaisieh¹, A. Henry², P. Bownes¹

¹St James Institute of Oncology, Department of Medical Physics, Leeds, United Kingdom

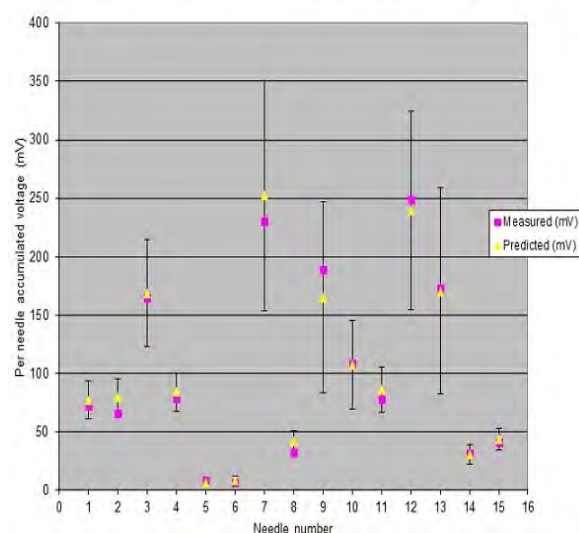

²St James Institute of Oncology, Clinical Oncology, Leeds, United Kingdom

Purpose or Objective: Implement routine in-vivo dosimetry in HDR prostate brachytherapy and develop error detection thresholds for real-time treatment monitoring.

Material and Methods: In vivo dosimetry was performed for 40 HDR prostate brachytherapy patients treated with single fractions of 15Gy (boost) or 19Gy (monotherapy). Treatments were planned using intra-operative trans-rectal ultrasound (TRUS) and for in-vivo dosimetry, an additional needle was inserted centrally in the prostate gland and dose measured using a MOSFET. MOSFET measurements were compared to predicted readings based on exported treatment planning system (TPS) data, per-needle and for total plan dose. To assess impact of needle movement between planning TRUS and treatment, TRUS images were acquired immediately after treatment for 20 patients. To assess impact of heterogeneities (for example steel needles) on the dose at the MOSFET position Monte Carlo (MC) simulations of treatment plans were performed for 10 patients. A retrospective investigation of thresholds for real-time error detection was based on per-needle and total plan uncertainty analysis. Uncertainties included MOSFET calibration/commissioning results, source calibration, TPS, relative source/ MOSFET position and MOSFET reading reproducibility.

Results: The mean measured total plan reading was 6.6% lower than predicted (range +5.1% to -15.2%). Plan reconstruction on post-treatment TRUS showed mean reduction in dose at the MOSFET position of 1.8% due to needle movement. MC simulations showed that heterogeneities caused a mean dose reduction at the MOSFET position of 1.6%. Uncertainty estimates varied between individual treatment plans, for example the uncertainty is higher if the MOSFET is close to a heavily weighted source position. Assuming a source/MOSFET position uncertainty of 1mm, total plan dose uncertainty (k=2) ranged from 10.6% to 17.0% and per needle dose uncertainty (k=2) ranged from 18.2% to 110% (mean 31.0%). Retrospectively applying these uncertainty estimates as error detection thresholds resulted in 1 out of 40 plans and 5% of needles being outside the error detection threshold. The figure shows an example for one patient of predicted versus measured reading for each needle with the k=2 uncertainty illustrated by error bars.

In-vivo Dosimetry - Measured v Predicted MOSFET Readings

Conclusion: In vivo measurements of dose during HDR prostate brachytherapy treatment delivery show good agreement with TPS predictions within measurement uncertainties, providing reassurance in the accuracy of dose delivery. Thresholds for real-time in vivo error detection using this measurement technique should be calculated on an individual plan basis but would still be likely to generate some false errors, with the main limitation of the

measurement technique being that dose is only measured at a single point.

OC-0064

A prediction model for biochemical failure after salvage Iodine-125 prostate brachytherapy

M. Peters¹, J.R.N. Van der Voort van Zyp¹, M.A. Moerland¹, C.J. Hoekstra², S. Van de Pol², H. Westendorp², M. Maenhout¹, R. Kattenvilder², H.M. Verkooijen¹, P.S.N. Van Rossum¹, H.U. Ahmed³, T. Shah³, M. Emberton³, M. Van Vulpen¹

¹UMC Utrecht, Radiation Oncology Department, Utrecht, The Netherlands

²Radiotherapiegroep, Radiation Oncology Department, Deventer, The Netherlands

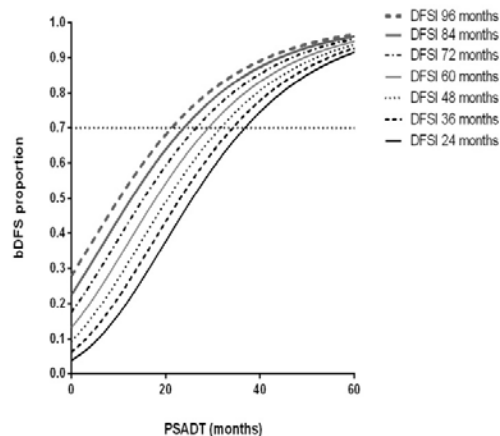

³University College London, Division of Surgery and Interventional Science, London, United Kingdom

Purpose or Objective: Localized recurrent prostate cancer after primary radiotherapy can be curatively treated using salvage, including Iodine-125 brachytherapy (BT). Selection of patients for salvage is hampered by a lack of knowledge on predictive factors for cancer control, particularly in salvage BT. The aim of this study was to develop and internally validate a prediction model for biochemical failure (BF) after salvage I-125-BT using the largest cohort to date in order to aid patient selection in the future.

Material and Methods: Patients with a clinically localized prostate cancer recurrence who were treated with a whole-gland salvage I-125 implantation were retrospectively analyzed. Patients were treated in two centers in the Netherlands. Multivariable Cox-regression was performed to assess the predictive value of clinically relevant tumor-, patient- and biochemical parameters on BF, which was defined according to the Phoenix-definition (PSA-nadir+2 ng/ml). Missing data was handled by multiple imputation (20 datasets). The model's discriminatory ability was assessed with Harrell's C-statistic (concordance index). Internal validation was done using bootstrap resampling (using 2000 resampled datasets). Goodness-of-fit of the final model was evaluated by visual inspection of calibration plots, after which individual survival was calculated for categories of the predictor variables from multivariable analysis. All analyses were performed using the recently published TRIPOD statement.

Results: Sixty-two whole-gland salvage I-125-BT patients were identified. After median follow-up of 25 (range 0-120) months, 43 patients developed BF. In multivariable analysis, disease-free survival interval (DFS_I) after primary therapy and pre-salvage prostate-specific antigen doubling time (PSADT) were predictors of BF; corrected hazard ratio (HR) 0.99 (95% confidence interval [CI]: 0.98-0.997 [p=0.01]) and 0.94 (95%CI: 0.90-0.99 [p=0.01]), respectively. Calibration plots demonstrated accurate predictive ability up to 36 months. The adjusted C-statistic was 0.71. Of patients with a PSADT>30 months and DFS_I>60 months, >70% remained free of recurrence until 3 years. With every 12 months increase in DFS_I, PSADT can decrease with 3 months to obtain the same survival proportion (Figure 1).

bDFS proportions at 3 years

Conclusion: Salvage I-125-BT patients can be selected based on their disease free survival interval after primary therapy and the PSA-doubling time pre-salvage, ensuring sufficient biochemical control of >70% until three years.

OC-0065

Risk of second malignancies after seed prostate brachytherapy as monotherapy in a single institution

A. Fernandez Ots¹, J. Bucci¹, D. Malouf², L. Browne³, Y. Chin¹

¹ST George Hospital, Cancer Care Centre, Sydney, Australia

²ST George Hospital, Urology, Kogarah, Australia

³ST George Hospital, Statistics Cancer Care Centre, Sydney, Australia

Purpose or Objective: To report the incidence of second primary cancer (SPC) after Iodine-125 brachytherapy for early prostate cancer in a single institution with an intense urological surveillance and to compare it with the cancer incidence in the Australian population

Material and Methods: This retrospective, single-institution study included 889 patients treated with Iodine-125 brachytherapy alone. All the patients had a baseline cystoscopy before the implant. Data were collected on all subsequent SPC diagnoses. SPC incidences were retrieved for all type of cancers and for cancers close to the radiation field. Interval since the implant was evaluated for potential association to the treatment. Standardized incidence ratios (SIRs) were calculated for all cancers and for bladder cancers and matched with the general population. The absolute excess risk (AER) was expressed in relation to 10000 person-years in the study. Kaplan-Meier analysis was used to determine the actuarial second malignancy and pelvic malignancy rates and the death from SPC and from any cause

Results: Patients were followed for a median of 4.16 (0-12) years with 370 (42 %) patients having 5 years or more follow up. 62 % patients were older than 60 years. 61 patients (6.8%) subsequently developed a SPC with 12 pelvic malignancies : 8 bladder and 4 rectal cancer. The 5- and 10- year cumulative incidences are 6.9% (95% Confidence Interval 5.0-9.4) and 19% (95% CI 14-26) for any second malignancy, 1.3% (95%CI 0.6-2.7) and 3.9% (95% CI 1.9-7.8) for any pelvic malignancy and 1% (95% CI 0.4-2.4) and 3.2% (1.4-7.1) for bladder cancer, respectively. The SIR was significantly higher for all pelvic malignancies at 2.10 (95% CI 1.09-3.67) and for all bladder cancers at 3.33 (95% CI 1.44-6.57). In the subgroup analysis bladder SPC risk was higher than expected for patients under 60 years (SIR 6.52; 95%CI 1.3-19; AER 13) and within the first 5 years of follow up (SIR 2.9 ; 95% CI 0.97-6.95; AER 10). Rectal cancer SIR were not significant or close in any of the categories. The 5- and 10-year rates of death from SPC were 1.9 % (95% CI 1.0-3.5) and 9.1% (95% CI 5.2-16) and from any cause were 3.2% (95% CI 2-5) and 14.4% (95% CI 9.5-21.6). On multivariable analysis, older age was associated with increased SPC risk (HR 1.05, p=0.021) , all cause mortality (HR 1.13, p<0.001) and mortality due to SPC (HR 1.09, p=0.014). Smoking status was associated with all cause

mortality (HR 2.15, $p=0.026$) and with mortality from second malignancy (HR 2.59, $p=0.045$)

Conclusion: There may be an increased but small risk of second pelvic malignancy after prostate brachytherapy. A tendency towards a higher risk of bladder SPC after brachytherapy was found in the first 5 years of follow-up, probably resulting from screening bias. There was no significant increased rate of rectal cancer in any of the categories. Longer follow up is needed to draw strong conclusions.

OC-0066

Adaptive cone-beam CT planning improves progression-free survival for I-125 prostate brachytherapy

M. Peters¹, D. Smit Duijzenkunst¹, H. Westendorp², S. Van de Pol², R. Kattevilder², A. Schellekens², J. Van der Voort van Zyp¹, M. Moerland¹, M. Van Vulpen¹, C. Hoekstra²

¹University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands

²Radiotherapiegroep Deventer, Radiation Oncology, Deventer, The Netherlands

Purpose or Objective: To determine the independent effect of additional intraoperative adaptive C-arm cone-beam computed tomography (CBCT) planning versus transrectal ultrasound (TRUS)-guided interactive planning alone in primary permanent I-125 brachytherapy for prostate cancer on long term biochemical disease free survival (bDFS).

Material and Methods: All patients with biopsy proven T1/T2-stage prostate cancer treated with I-125 brachytherapy were included in this cohort. Treatments were performed with TRUS-guided primary brachytherapy (+/- neoadjuvant hormonal therapy (NHT)) in a single institution in the period of November 2000 to December 2014. From October 2006 onwards, all patients received additional intraoperative adaptive CBCT planning for dosimetric evaluation and, if indicated, subsequent remedial seed placement in underdosed areas (which was performed in 15% of all patients). These procedures lasted 1-1.5 hours and were performed by a team of 2 radiation oncologists and 2 therapeutic radiographers. Pre-operative characteristics, follow-up PSA and mortality were prospectively registered. Patients were stratified into National Comprehensive Cancer Network (NCCN) risk groups. Kaplan-Meier analysis was used to estimate bDFS (primary outcome), overall survival (OS) and prostate cancer specific survival (PCSS) (secondary outcomes). Cox-proportional hazard regression was used to assess the independent predictive value of CBCT use on biochemical failure (BF) (Phoenix definition) and overall mortality (OM).

Results: 1623 patients were included. Median follow-up was 99 months (interquartile range (IQR) 70-115) for TRUS patients (n=613) and 51 months (IQR 29-70) for CBCT patients (n=1010). BF occurred 203 times and 206 patients died, of which 26 due to prostate cancer. For TRUS and CBCT patients, estimated 7-year bDFS was 87.2% vs. 93.5% (log rank: $p=0.04$) for low risk patients, 75.9% vs. 88.5% ($p<0.001$) for intermediate risk patients and 57.1 vs. 85.0% ($p<0.001$) for high risk patients. For TRUS and CBCT patients with low, intermediate and high risk disease, estimated 7-year OS was respectively 86.5% vs. 90.4% ($p=0.11$), 79.6% vs. 85.1% ($p=0.30$) and 66.4% vs. 84.2% ($p=0.01$). For TRUS and CBCT patients, 7-year PCSS was 96.0% vs. 100% ($p<0.0001$). After Cox regression, CBCT patients had lower rates of BF: HR 0.45 (95%-CI 0.33-0.61; $p<0.0001$). Corrected for age, IPSA, Gleason grade, T-stage, NHT-status and duration of NHT use, year of implantation, activity of the implant and prostate volume, CBCT showed to be an independent predictor of BF: HR 0.54 (95%-CI 0.33-0.89; $p=0.02$). CBCT was not an independent predictor of OM: HR 0.66 (95%-CI 0.40-1.07; $p=0.09$).

Conclusion: Additional intraoperative adaptive C-arm cone-beam CT planning in I-125 prostate brachytherapy leads to a

significant increase in biochemical disease free survival in all NCCN risk groups.

An automated patient-specific and quantitative approach for deformable image registration evaluation

R.G. Kierkels¹, C.L. Brouwer¹, R.J. Steenbakkers¹, H.P. Bijl¹, J.A. Langendijk¹, N.M. Sijtsma¹

¹University of Groningen- University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

Purpose or Objective: In adaptive radiotherapy, deformable image registration (DIR) is used for contour propagation and dose warping. Contour evaluation is visual and qualitative and only accurate in high contrast regions. Dose warping requires fully spatial and quantitative DIR evaluation measures also valid in low contrast regions. While quantitative measures such as the target registration error can be used during commissioning, such measures are not fully spatial and too user intensive in clinical practice. Therefore, we propose a fully automatic and quantitative approach to DIR quality assessment including multiple measures of numerical robustness and biological plausibility.

Material and Methods: Ten head and neck cancer patients who received weekly repeat CT (rCT) scans were included. Per patient, the first rCT was deformable registered (using B-spline DIR algorithm) to the planning CT. The ground-truth deformation error of this registration was derived using the scale invariant feature transform (SIFT), which automatically extracts and matches stable and prominent points between two images. Moreover, complementary quantitative and spatial measures of registration quality were calculated. Numerical robustness was derived from the inverse consistency error (ICE), transitivity error (TE), and distance discordance metric (DDM). For the TE calculations a third CT was used. The DDM was calculated using five CT sets per patient. Biological plausibility was based on the deformation vector field between the planning CT and rCT. Relative deformation threshold values were set based on physical tissue characteristics: 5% for bone and 50% for soft tissues. All measures were evaluated in bone and soft tissue structures and compared against the ground-truth deformation error.

Results: On average, SIFT detected 133 matching points scattered throughout the planning CT, with a mean (max) registration error of 1.6 (8.3) mm. Our combined and fully spatial DIR evaluation approach, including the ICE, TE and DDM, resulted in a mean (max) error of respectively 0.6 (2.0), 0.7 (2.7), and 0.6 (2.7) mm within the external body contour, averaged over all patients. The largest errors were detected in homogeneous regions and near air cavities. Furthermore, 87% of the bone and 2% of the soft tissue voxels were classified as unrealistic deformations. Figure 1 shows the planning CT, DDM, tissue deformation, and error volume histograms of the ICE, TE, and DDM of the body contour of one patient.

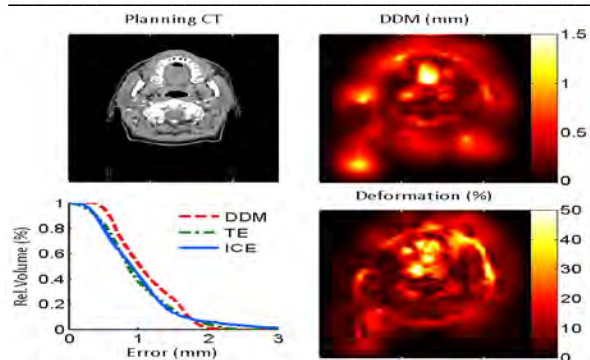

Figure 1. Axial cross section of a planning CT, distance discordance metric (DDM) and tissue deformation of a representative patient. The error volume histograms show the DDM, transitivity error (TE), and inverse consistency error (ICE) of the body contour.

Conclusion: The combination of multiple automatic DIR quality measures highlighted areas of concern within the registration. While current methods on DIR evaluation, such as visual inspection and target registration error are time-consuming, local, and qualitative, this approach provided an automated, fully spatial and quantitative tool for clinical assessment of patient-specific DIR even in image regions with limited contrast.

OC-0068

Can atlas-based auto-contouring ever be perfect?

B.W.K. Schipaanboord¹, J. Van Soest², D. Boukerroui¹, T. Lustberg², W. Van Elmpt², T. Kadir¹, A. Dekker², M.J. Gooding¹

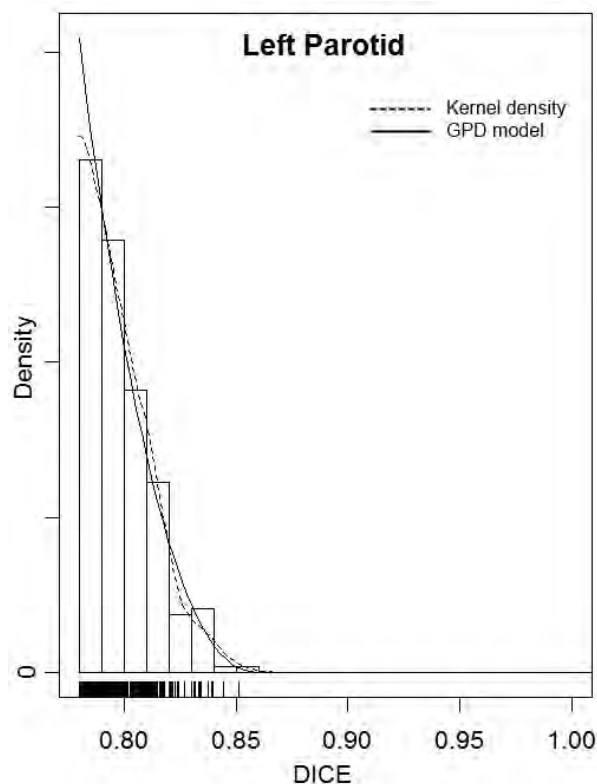

¹Medical Ltd, Science and Medical Technology, Oxford, United Kingdom

²Maastricht University Medical Centre, Department of Radiation Oncology MAASTRO- GROW School for Oncology and Developmental Biology, Maastricht, The Netherlands

Purpose or Objective: Various approaches have been proposed to select the most similar atlases to a patient for atlas-based auto-contouring. While it is known that increasing the size of an atlas database improves the results of auto-contouring for a small number of atlases, such selection assumes the hypothesis that increasing the atlas pool size always increases the chance of finding a good match. The objective of this study is to test this hypothesis, and answer the question; "Given a large enough database of atlases, can single atlas-based auto-contouring ever be perfect?".

Material and Methods: 35 test cases were randomly selected from a dataset of 316 clinically contoured head and neck cases, and were auto-contoured treating each of the remaining cases as potential atlases to be used. Thus, results of contouring were available for approximately 11000 atlas-patient pairs. Dice Similarity Coefficient (DSC), Hausdorff distance (HD), Average Distance (AD) and Root Mean Square Distance (RMSD) were computed between the auto-contours and the clinical contours for each structure and atlas-patient pair. In order to estimate achievable performance under the assumptions of an infinite size atlas database and "perfect" atlas selection, the Extreme Value Theory statistical technique Points over Threshold, used in other domains to perform tasks such as estimating the magnitude of one-in-a-hundred-years flooding, was used to model the distribution of the best scores. Analysis was performed for the ten most commonly contoured structures within the database, with a minimum of 6800 atlas-patient pairs per structure being considered.

Results: The figure shows the distribution of observed extreme values for the left parotid DICE scores, together with the model fit.

For all measures and structures, the model fit indicated a limit on the performance in the extreme. While this is expected since all measures have a limit at perfection, the performance limit in the extreme fell short of a perfect result. Variation was observed between structures, with well-defined structures performing better than more complex ones. This may indicate that the limit on performance reflects the inter-observer variation in delineation. The table shows the best observed score for the experiments performed, together with the expected achievable result predicted by the model assuming an atlas database of 5000 atlases.

Structure	DICE		HD (mm)		AD (mm)		RMSD (mm)	
	Best	Exp	Best	Exp	Best	Exp	Best	Exp
Brain	0.987	0.997	5.98	5.98	0.54	0.52	0.86	0.83
Brainstem	0.886	0.887	4.58	4.50	1.15	1.09	1.43	1.34
Cochlea L	0.909	0.935	0.48	0.47	0.19	0.17	0.22	0.21
Cochlea R	0.909	0.945	0.52	0.47	0.19	0.17	0.23	0.20
Oral Cavity	0.894	0.894	8.07	8.13	1.79	1.75	2.34	2.31
Parotid L	0.852	0.854	6.12	5.68	1.32	1.31	1.70	1.70
Parotid R	0.849	0.853	6.10	6.09	1.41	1.34	1.89	1.83
Spinal cord	0.881	0.881	2.92	3.05	0.65	0.65	0.86	0.82
Submandibular gland L	0.840	0.845	4.88	4.79	1.10	1.05	1.40	1.35
Submandibular gland R	0.841	0.842	4.16	4.04	1.02	1.03	1.34	1.34

Conclusion: Increasing the size of an atlas database within achievable ranges would be insufficient on its own for consistently perfect single atlas auto-contouring, even in the presence of a "perfect" atlas selection method. Thus, improvements in the underlying methods for pre- and post-processing, such as deformable registration or multi-atlas fusion, are necessary to improve the results of atlas-based auto-contouring. Additionally, consistent delineation within an atlas database is required to minimise the effect of inter-observer error on the achievable performance.

OC-0069

Using texture analysis to detect prostate cancer for automated outlining and adaptive radiotherapy

D. Welsh¹, D. Montgomery¹, D.B. McLaren², W.H. Nailon¹

¹Western General Hospital, Oncology Physics, Edinburgh, United Kingdom

²Western General Hospital, Clinical Oncology, Edinburgh, United Kingdom

Purpose or Objective: In radiotherapy, the prostate is one of few anatomical sites where the whole organ is targeted, even in cases of localised cancer. Improvements in outcomes may be achieved by escalating the dose to the dominant intraprostatic lesion (DIL), and thereby reducing the dose to the remainder of the gland. However, reliably identifying the DIL requires considerable clinical experience and is extremely time consuming. Automated outlining would alleviate this problem, and is also desirable for online adaptive radiotherapy. This work investigated the feasibility of automatically detecting the DIL on T2-weighted MR images using image texture analysis methods.

Material and Methods: On the diagnostic T2-weighted MR images from 14 prostate cancer patients previously treated with radiotherapy, the prostate and DIL volumes were defined by a clinician. Two separate projects were carried out using the same data, looking at 2D and 3D texture analysis, respectively. In both cases, a range of texture features were calculated on a sub-volume basis and a machine learning classification scheme was trained to classify individual pixels surrounded by each sub-volume as either healthy prostate or DIL, based on the calculated features, with the clinician defined contours as the ground truth. The classifier was tested on each patient case in turn, with the remaining 13 patients used as the training data in a leave-one out schema. Classification results were assessed in terms of receiver operator characteristic (ROC) and confusion statistics.

		Sensitivity	Specificity	aucROC
2D	Mean	0.43 ± 0.34	0.91 ± 0.09	0.82 ± 0.13
	Min	0.00	0.68	0.54
	Max	0.95	0.99	0.95
3D	Mean	0.43 ± 0.27	0.74 ± 0.12	0.60 ± 0.16
	Min	0.02	0.56	0.26
	Max	0.93	0.94	0.80

Table 1: Summary of classifier performance across the 14 patient cases.

Figure 1: Illustration of classifier results for an example case, with colour map of results shown alongside corresponding MR image slice.

Results: Over the 14 patients, the best performing 2D analysis resulted in a mean area under the ROC curve (aucROC) of 0.82 ± 0.13 , whilst the 3D analysis gave an

aucROC of 0.60 ± 0.16 . A summary of the results is shown in Table 1 and Figure 1 shows a visualisation of the (2D) classification results for an example case. There is wide variation in classifier performance from case to case - performance tended to be poorer on patients with small DILs, giving a low sensitivity but high specificity. The mean value of sensitivity is heavily affected by these low scoring cases. It is expected that the results could be improved with a larger training dataset and morphological post-processing of the detected DIL region.

Conclusion: This work shows that, in principle, texture analysis can be used to identify focal lesions on MR images, facilitating automated delineation for adaptive radiotherapy. 3D analysis does not necessarily lead to improved performance over 2D, although further optimisation of both methods may be possible.

OC-0070

Do radiomics features excel human eye in identifying an irradiated tumor? Rat tumor to patient HNSCC

K. Panth¹, S. Carvalho¹, A. Yaromina¹, R. T.H. Leijenaar¹, S. J. Van Hoof¹, N. G. Lieuwes¹, B. Rianne¹, M. Granzier-Peeters¹, F. Hoebbers¹, D. Eekers¹, M. Berbee¹, L. Dubois¹, P. Lambin¹

¹MAASTRO clinic, Radiation Oncology, Maastricht, The Netherlands

Purpose or Objective: Radiomics hypothesizes that imaging features reflect the underlying gene expression patterns and intratumoral heterogeneities. In this study, we hypothesized that radiation treatment (RT) affects image features and that these radiation-dependent features could distinguish irradiated tumor better than human eye.

Material and Methods: Rhabdomyosarcoma R1 tumors grown on the lateral flank of WAG/Rij rats were irradiated with 12 Gy or 0 Gy (control). Computed tomography (CT) scans were acquired both before and 7 days post RT [2]. These data were used as a training dataset to select RT-related features. For validation, radiomics features were extracted from CT images of head and neck squamous cell carcinoma (HNSCC) patients before and post 10 fractions of radiation. A total of 723 features were extracted and the top 100 robust features were selected for further analysis based on inter-class correlation coefficient (ICC) values obtained from test-retest (TRT) scans. Imaging experts and radiation oncologists were consigned to identify irradiated tumors (IR) vs. non-irradiated (Non-IR) tumors blinded for patient information. Area under the curve of the receiver operating characteristics curve (AUC-ROC) was computed for each individual feature identified in the rat and HNSCC datasets as being both stable and significant for distinguishing IR and non-IR tumors.

Results: 17 significant differentially expressed features were identified between the two imaging time points after TRT feature selection. 8 out of 17 (2 shape and 6 wavelets) significantly ($p < 0.05$) distinguished between pre and post RT scans. AUC-ROC curves demonstrate that out of 8 features, 2 shape and 4 wavelet features had an accuracy of 0.71 and >0.62 respectively in identifying IR tumor from the non-IR ones, whereas imaging experts could only correctly identify 56% (56 ± 5.7) of true cases in rats. 2 (shape) out of 8 features identified in rats also were found to be significantly different between pre and post RT in HNSCC patients (Fig. 1). These two features had an AUC-ROC of 0.85 in identifying a IR tumor while, radiation oncologists were able to solely identify 50% (50 ± 5.6) of true cases in HNSCC patients.

Conclusion: RT radiomics features identified in rats and HNSCC patients were able to distinguish irradiated tumors better than human eye. Thus, in future these features might be used for dosimetric measures and might help in segregating effects of RT from combination treatments that enables to understand the effect of drug or RT alone.

Analysis and reporting patterns of failure in the era of IMRT: head and neck cancer applications

A.S.R. Mohamed¹, D.I. Rosenthal¹, M.J. Awan², A.S. Garden¹, E. Kocak-Uzel³, A.M. Belal⁴, A.G. El-Gowily⁵, J. Phan¹, B.M. Beadle¹, G.B. Gunn¹, C.D. Fuller¹

¹MD Anderson Cancer Center, Radiation Oncology, Houston, USA

²Case Western University, Radiation Oncology, Cleveland, USA

³Şişli Etfal Teaching and Research Hospital, Radiation Oncology, Istanbul, Turkey

⁴Alexandria University, Radiation Oncology, Alexanria, Egypt

⁵Alexandria University, radiation Oncology, Alexandria, Egypt

Purpose or Objective: To develop a methodology to standardize the analysis and reporting of the patterns of loco-regional failure after IMRT of head and neck cancer.

Material and Methods: Patients with evidence of local and/or regional failure following IMRT for head-and-neck cancer at MD Anderson cancer center were retrospectively reviewed under approved IRB protocol. Manually delineated recurrent gross disease (rGTV) on the diagnostic CT documenting recurrence (rCT) was co-registered with the original planning CT (pCT) using both deformable (DIR) and rigid (RIR) image registration software. Subsequently, mapped rGTVs were compared relative to original planning target volumes (TVs) and dose using volume overlap and centroid-based approaches. Failures were then classified into five types based on combined spatial and dosimetric criteria; A (central high dose), B (central elective dose), C (peripheral high dose), D (peripheral elective dose), and E (extraneous dose) as illustrated in figure 1. Paired-samples Wilcoxon signed rank test was used to compare analysis metrics for RIR versus DIR registration techniques.

Results: A total of 21 patients were identified. Patient, disease, and treatment characteristics are summarized in table 1. The registration method independently affected the spatial location of mapped failures (n=26 lesions). Failures mapped using DIR were significantly assigned to more central TVs compared to failures mapped using RIR for both the

centroid-based and the volume overlap methods. 42% of centroids mapped using RIR were located peripheral to the same centroids mapped using DIR (p= 0.0002), and 46% of the rGTVs whole volumes mapped using RIR were located at a rather peripheral TVs compared to the same rGTVs mapped using DIR (p< 0.0001). rGTVs mapped using DIR had significantly higher mean doses when compared to rGTVs mapped rigidly (mean dose 70 vs. 69 Gy, p = 0.03). According to the proposed classification 22 out of 26 failures were of type A as assessed by DIR method compared to 18 out of 26 for the RIR because of the tendency of RIR to assign failures more peripherally.

Table 1. Patient demographics, disease, and treatment characteristics

	n=21	Total (%)
Age (years)		
Median	58

Induction Chemotherapy + Concurrent ChemoRadiation	7	(33)
Radiation dose		
Mean (SD)	69.2	(1.7)
Radiation fractions		
Mean (SD)	33	(2)

Conclusion: DIR-based registration methods showed that the vast majority of failures originated in the high dose target volumes and received full prescribed doses suggesting biological rather than technology-related causes of failure. Validated DIR-based registration is recommended for accurate failure characterization and a novel typology-indicative taxonomy is recommended for failure reporting in the IMRT era.

OC-0072

Respiratory time-resolved 4D MR imaging for RT applications with acquisition times below one minute

C.M. Rank¹, T. Heußer¹, A. Wetscherek¹, A. Pfaffenberger², M. Kachelrieß¹

¹German Cancer Research Center DKFZ, Medical Physics in Radiology, Heidelberg, Germany

²German Cancer Research Center DKFZ, Medical Physics in Radiation Oncology, Heidelberg, Germany

Purpose or Objective: 4D MRI has been proposed to improve respiratory motion estimation in radiotherapy (RT), aiming to achieve a higher treatment accuracy in the thorax and the upper abdomen. In contrast to 4D CT, acquisition time in 4D MRI is not limited by radiation dose, such that multiple breathing cycles can be imaged routinely. However, standard MR reconstruction methods, such as gated gridding, have limitations in either temporal or spatial resolution, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) and artifact level or demand inappropriately long acquisition times. The purpose of this study is to provide high quality 4D MR images from super short acquisitions.

Material and Methods: MR data covering the thorax and upper abdomen of three free-breathing volunteers were acquired at a 1.5 T Siemens Aera system. We applied a gradient echo sequence with radial stack-of-stars sampling and golden angle radial spacing: total acquisition time: 37 s, slice orientation: coronal, field-of-view: 400x400x192 mm³, voxel size: 1.6x1.6x4.0 mm³, TR/TE = 2.48/1.23 ms, 240 spokes per slice, undersampling factor: 16.8, flip angle: 12°. MR data were sorted into 20 overlapping 10% wide motion phase bins employing intrinsic MR gating. Respiratory motion compensated (MoCo) 4D MR images were generated using our

newly developed 4D joint MoCo-HDTV algorithm, which alternates between motion estimation and image reconstruction. With MoCo, each motion phase is reconstructed from 100% of the measured rawdata. In the motion estimation step, the motion vector fields (MVFs) are estimated between adjacent motion phases and regularized by cyclic constraints. Results were compared to the standard reconstruction methods 3D gridding and 4D gated gridding.

Results: 3D gridding reconstructions revealed strong blurring of structures in the lungs, in the diaphragm region and in the liver caused by respiratory motion. 4D gated gridding images were deteriorated by noise and severe streak artifacts, arising from high azimuthal undersampling. These artifacts obscured small anatomical structures. In contrast, 4D joint MoCo-HDTV reconstructions yielded appropriate image quality combining low streak artifact levels and high temporal resolution, SNR, CNR and image sharpness. Thus, the displacement between end-exhale and end-inhale of small liver structures could be determined, which was not possible using 4D gated gridding images due to their limited image quality.

Conclusion: 4D joint MoCo-HDTV facilitates 4D respiratory time-resolved MRI and provides respiratory MVFs at acquisition times below one minute. The method is promising for reliable target delineation in radiation therapy, patient-specific margin or gating window definition, and for adaptive planning based on the provided MVFs. The short acquisition time makes it attractive also for online imaging in an MR-LINAC setting.

Difference in using the TRS-398 code of practice and TG-51 dosimetry protocol for FFF beams

J. Lye¹, D.J. Butler², C.P. Oliver², A. Alves¹, I.W. Williams¹

¹Australian Radiation Protection and Nuclear Safety Agency, Australian Clinical Dosimetry Service, Melbourne- Victoria, Australia

²Australian Radiation Protection and Nuclear Safety Agency, Radiotherapy, Melbourne- Victoria, Australia

Purpose or Objective: The two most commonly used protocols for reference dosimetry in external beam radiotherapy are IAEA TRS-398 and AAPM TG-51. Increasingly flattening filter free (FFF) linacs are in clinical use and published theoretical analysis suggests that a difference of 0.5 % is expected between the two protocols (Xiong 2008).

Material and Methods: The Australian Clinical Dosimetry Service (ACDS) has measured FFF beam dose outputs on 11 linacs using both TRS-398 and TG-51 protocols. The response of an NE2561 chamber was modelled using DOSRZnrc. The model was used to study the difference in kQ in Varian and Elekta linacs when the flattening filter was removed, and when the flattening filter was replaced by a thin metal plate.

Results: Measured differences in dose output derived from TRS-398 and TG-51 protocols were less than 0.1 % for 6 MV FFF beams and less than 0.2 % for 10 MV FFF beams. Figure 1 shows the modelled response from the NE2561 for Elekta and Varian beams with the flattening filter, with the flattening filter removed, and with a thin metal plate replacing the flattening filter. The modelled FFF kQ as a function of TPR_{20,10} is 0.6 % lower than the kQ with flattening filter (WFF). This difference is reduced to 0.3 % when considering kQ as a function of % $dd(10)x$. Thus the measured difference in the TRS-398 and TG-51 protocols should be 0.3% according to the modelled results, however the average measured difference is less than 0.1 %. The commercial realisation of FFF beams includes a thin metal filter in the place of the flattening filter. When a 2-3 mm metal plate was included in the model, the difference between the FFF kQ and the WFF kQ was reduced to approximately 0.1%.

Figure 1 kQ of modelled NE2561 chamber with beams with the flattening filter (closed shapes), beams with the flattening filter removed (open shapes) and beams with thin replacement filter (red shapes). (a) shows the results for Elekta beams and (b) shows the results for Varian beams. The dashed grey line shows the average of kQ from TRS-398 and Muir *et al.*

Conclusion: The average difference between linac outputs measured with TRS-398 and TG-51 protocols was less than 0.2 % for 6 MV FFF and 10 MV FFF. Modelling suggests a 2-3 mm metal plate used in place of the flattening filter offers sufficient filtration for the FFF beam to produce a similar kQ to WFF beams.

A real time in vivo dosimeter integrated in the radiation protection disc for IORT breast treatment

M. Iori¹, A. Montanari², N. Tosi³, E. Cagni¹, A. Botti¹, A. Ciccotelli⁴, G. Felici⁴

¹Arcispedale S. Maria Nuova, Medical Physics Unit, Reggio Emilia, Italy

²Istituto Nazionale di Fisica Nucleare, Sezione di Bologna, Bologna, Italy

³Istituto Nazionale di Fisica Nucleare e Università, Sezione di Bologna, Bologna, Italy

⁴S.I.T. - Sordina IORT Technologies S.p.A., R&D Department, Aprilia, Italy

Purpose or Objective: IORT breast carcinoma treatment clinical practice has evidenced the need of real time monitoring the dose delivery on the target. The actual discussion on the efficacy of the technique is mainly related with the effective coverage degree of the whole PTV. Furthermore the correct positioning of the radiation protection with respect to the applicator is a critical aspect that cannot presently be determined in real time. The commercially available in vivo dosimetry technologies allow either a real time measurement in one point (MOSFET type detectors) or a non real time measurement over a surface (radio chromic films). A cooperation between a clinical hospital, a research institute and an industrial company has led to the conceptual design of a new device capable of satisfying the above mentioned needs. Such device has been

patented. The new dosimeter consists in four leaf shaped plastic scintillators positioned between the two parts of the radiation protection disc, composed by a PTFE and a steel element (see figure). Therefore such device can measure in real time the dose in the four sectors, providing both the integral dose and a measurement of the field symmetry on the target.

Material and Methods: The accelerator employed is a mobile IORT dedicated electron accelerator capable of producing a 4, 6, 8 and 10 MeV electron beam, collimated by means of PMMA applicators. Measurements have been performed with a prototype based on a plastic scintillator tile placed in a PMMA phantom, with the signal processed and integrated by dedicated electronics. The plastic scintillator data has been compared with the standard dose measurements, performed by means of the PTW Roos ionization chamber and the Unidos E electrometer.

Results: The behavior of the plastic scintillator has been tested with the IORT accelerator electron beam. Several tests have been performed, comparing the reading of the system with the reading of the plane parallel ionization chamber in a PMMA phantom. On the basis of the preliminary measurements, the system fully complies with the standards requirements (see figure).

Conclusion: The above described in vivo dosimeter significantly improves the IORT clinical documentation, allowing the real time check of the dose delivery over the whole PTV. Furthermore, since the device sensitivity is high enough to produce a precise dose map with an overall delivery of less than 1 cGy, the correct positioning of the disc with respect to the PTV and the applicator can be checked before delivering the treatment, allowing the surgeon to correct it should the symmetry on the PTV be out of tolerance levels. The system will be engineered in order to meet the standards required for a temporarily implanted medical device too (biocompatibility, sterilizability, etc.) and will undergo the certification process during 2016. It is planned to organize a multicentre study for verifying in the clinical practice the efficacy and safety of the new dosimeter.

OC-0075

Impact of air around an ion chamber: solid water phantoms not suitable for dosimetry on an MR-linac

S. Hackett¹, B. Van Asselen¹, J. Wolthaus¹, J. Kok¹, S. Woodings¹, J. Lagendijk¹, B. Raaymakers¹

¹UMC Utrecht, Department of Radiotherapy, Utrecht, The Netherlands

Purpose or Objective: A protocol for reference dosimetry for the MR-linac is under development. The response of an ion chamber must be corrected for the influence of the 1.5T magnetic field as deflection of electron trajectories by the Lorentz force is greater in the air-filled chamber than the surrounding phantom. Solid water (SW) phantoms are used for dosimetry measurements on the MR-linac, but a small volume of air is present between the chamber wall and

phantom insert. This study aims to determine if this air volume influences ion chamber measurements on the MR-linac. The variation of chamber response as the chambers were rotated about the longitudinal chamber axis was assessed in SW and water to distinguish between the effect of the anisotropic dose distribution in a magnetic field and any intrinsic anisotropy of the chamber response to radiation. The sensitivity of the chamber response to the distribution of air around the chamber was also investigated.

Material and Methods: Measurements were performed on an MR-linac and replicated on an energy-matched Agility linac for five chambers, comprising three different models. The response of three waterproof chambers was measured with air and with water between the chamber and insert to measure the influence of the air volume on the absolute chamber response. Angular dependence of the waterproof chambers and two NE 2571 chambers was measured in an SW phantom, both parallel and perpendicular to the magnetic field, and in water (waterproof chambers only). The influence of the distribution of air around the chambers in the SW phantom was measured by displacing the chamber in the insert using a paper shim, approximately 1 mm thick, positioned in different orientations between the chamber casing and the insert.

Results: The responses of the three waterproof chambers measured on the MR-linac increased by 0.6% to 1.3% when the air volume in the insert was filled with water. The responses of the chambers on the Agility linac changed by less than 0.3%. The angular dependence ranged from 0.9% to 2.2% in solid water on the MR-linac, but was less than 0.5% in water on the MR-linac and less than 0.3% in SW on the Agility linac. An example of the angular dependence of a chamber is shown in Figure 1.

Changing the distribution of air around the chamber induced changes of the chamber response in a magnetic field of up to 1.1%, but the change in chamber response on the Agility was less than 0.3%.

Conclusion: The interaction between the magnetic field and secondary electrons in the air volume around the chamber reduces the charge collected by between 0.6 and 1.3%. The large angular dependence of ion chambers measured in SW in a magnetic field appears to arise from a change of air distribution as the chamber is moved within the insert, rather than an intrinsic isotropy of the chamber sensitivity to radiation. It is therefore recommended that reference dosimetry measurements on the MR-linac be performed only in water, rather than in SW phantoms.

OC-0076

Towards MR-Linac dosimetry: B-field effects on ion chamber measurements in a Co-60 beam

J. Agnew¹, G. Budgell¹, S. Duane², F. O'Grady¹, R. Young¹
¹The Christie NHS Foundation Trust, CMPE, Manchester, United Kingdom
²National Physical Laboratory, Radiation Dosimetry Group, Teddington, United Kingdom

Purpose or Objective: To quantify the effect of small air gaps at known positions on ionisation chamber (IC) measurements in the presence of a strong magnetic (B-)field, and to characterise the response of ICs over a range of B-field strengths in the absence of air gaps.

Material and Methods: The ratio of responses of four commercially available ICs was measured in a Co-60 beam with and without a 1.5T B-field ($M_{1.5T}/M_{0T}$) using a GMW electromagnet unit and a 5cm pole gap. Measurements were made in custom-built Perspex phantoms with the chamber, beam and B-field all orthogonal. The measurements were repeated with the phantoms at each cardinal angle (rotated about the long axis of the ICs). The phantoms were designed to be symmetric under rotation about this axis except for a shallow 90° section next to the sensitive volume of the ICs. The measurements were repeated with the air gap removed by introducing water to the phantom cavity. For the PTW 30013 chamber further measurements were performed after introducing a small (approximately 30 mm³) bubble into the recess when the cavity was otherwise filled with water, which was made possible by the novel phantom design. The measurements in water were repeated with additional build-up material and in multiple phantoms at a single phantom orientation. Measurements were also taken to characterise the ratio of responses for five ICs over a range of B-field strengths (0 - 2T in 0.25T increments).

Results: For all 4 ICs in the rotating setup, the response varied consistently with the position of the recess when the air gap was present, with the lowest value of $M_{1.5T}/M_{0T}$ obtained when the recess was upstream of the IC. The maximum peak-to-peak (PTP) variation was 8.8%, obtained for the PTW 31006 'Pinpoint' IC, and the minimum was 1.1%, obtained for the Exradin A1SL IC. This variation all but disappeared (maximum PTP variation 0.7%, seen for PTW 31010 IC) when the air gap was removed. A large (3.9%) PTP variation was observed for the PTW 30013 when an air bubble was inserted into an otherwise airless setup (0.2% variation without air gap).

	Chamber	$(M_{1.5T}/M_{0T} - 1) \times 100$ averaged over cardinal angles (%)	PTP Variation over cardinal angles (%)
Air Gap	PTW 30013	3.9	2.9
	PTW 30013*	4.7	3.9
	PTW 31006	-1.3	8.8
	PTW 31010	7.1	4.0
	Exradin A1SL	6.4	1.1
Without Air Gap	PTW 30013	5.0	0.2
	PTW 31006	6.3	0.2
	PTW 31010	5.1	0.7
	Exradin A1SL	8.6	0.2

* Bubble air gap

Conclusion: Small air gaps are responsible for large variations in IC response in the presence of a magnetic field. These

variations can be eliminated by introducing water into the cavity, but even small bubbles will cause large variations in the response. Further, IC response in the presence of a 1.5T B-field is insensitive to changes in depth and scatter conditions of the phantoms investigated here. Each IC has different M/M_{0T} response across the range of B-field strength 0 - 2T.

OC-0077

Dual energy CT proton stopping power ratio calibration: Validation with animal tissues

Y. Xie¹, L. Yin¹, C. Ainsley¹, J. McDonough¹, T. Solberg¹, A. Lin¹, B.K. Teo¹
¹University of Pennsylvania, Department of Radiation Oncology, Philadelphia, USA

Purpose or Objective: One main source of uncertainty in proton therapy is the conversion of Hounsfield Unit (HU) to proton stopping power ratio (SPR). In this study, we measured and quantified the accuracy of dual energy CT (DECT) SPR prediction in comparison with single energy CT (SECT) calibration.

Material and Methods: We applied a stoichiometric calibration method for DECT to predict the SPR using CT images acquired sequentially at 80 kVp and 140 kVp. The dual energy index was derived based on the HUs of the paired spectral images and then used to calculate the effective atomic number, electron density, and SPR of the materials. The materials were irradiated with a collimated 2 mm width pristine pencil beam and the water equivalent thickness (WET) and SPRs deduced from the residual proton range measured using a multi-layer ion chamber (MLIC) device. Multiple proton energy (130 to 160 MeV) measurements were made on the tissues to achieve sub mm WET measurement accuracy. Tissue surrogates (lung, adipose, muscle and bone) with known chemical compositions were used for calibration and validated with animal tissues. The animal tissues (veal shanks) were kept in a frozen state during the CT scans and proton range measurements. The results were compared to traditional stoichiometric calibration with SECT at 120 kVp.

Results: The percentage difference of DECT predicted SPR from MLIC measurements were reduced 1) from 3.9% to 0.7% for tissue surrogates; 2) from 1.8% to <0.1% for veal bone (tibia); and 3) from 1.7% to 0.9% for veal muscle compared with SECT calibration. The systematic uncertainties from CT scans were studied by varying the effective phantom size (<1%), surrogate locations (<1%), and repeat CT scans (<0.6%). The choice of the mean ionization values of the chemical elements resulted in a 0.2-0.9% variation in calculated SPRs.

Figure: The percentage difference between SPR prediction and MLIC measurements. Six different materials were used in this study: four tissue substitute surrogates (lung, adipose, muscle and bone) and two animal tissues (veal tibia bone and muscle). The blue diamond symbols represent the predictions from SECT and red squares represent the predictions from DECT. As observed from the figure, SPRs from DECT prediction agree better with MLIC measurements.

Material	SPR		
	MLIC	DECT	SECT
Bone (phantom)	1.107	1.108	1.149
Muscle (phantom)	1.047	1.048	1.028
Adipose (phantom)	0.962	0.955	0.985
Lung (phantom)	0.511	0.514	0.509
Bone (veal)	1.742	1.742	1.773
Muscle (veal)	1.042	1.032	1.024

Table: SPRs from MLIC measurements, DECT prediction, and SECT prediction for the six materials used in this study: four tissue substitute surrogates (lung, adipose, muscle and bone) and two animal tissues (veal tibia bone and muscle).

Conclusion: Our study indicated that DECT is superior to SECT for proton SPR prediction and has the potential to reduce the range uncertainty to less than 2%. DECT may permit the use of tighter distal and proximal range uncertainty margins for treatment thereby increasing the precision of proton therapy.

Monte Carlo calculated beam quality correction factors for proton beams

C. Gomà¹, P. Andreo², J. Sempau³

¹ETH Zürich, Department of Physics, Zürich, Switzerland

²Karolinska University Hospital, Department of Medical Physics, Stockholm, Sweden

³Universitat Politècnica de Catalunya, Institut de Tècniques Energètiques, Barcelona, Spain

Purpose or Objective: To calculate the beam quality correction factors (k_Q) in monoenergetic proton beams using detailed Monte Carlo simulation of ionization chambers. To compare the results with the k_Q factors tabulated in IAEA TRS-398, which assume ionization chamber perturbation correction factors (p_Q) equal to unity.

Material and Methods: Two different Monte Carlo codes were used: (i) Gamos/Geant4 to generate a phase-space file just in front of the ionization chamber and (ii) PENH to simulate the transport of particles in the ionization chamber geometry (or water cavity). Seven ionization chambers (5 plane-parallel and 2 cylindrical) were studied, together with five proton beam energies (from 70 to 250 MeV). k_Q calculations were performed using the electronic stopping powers resulting from the adoption of two different sets of l -values for water and graphite: (i) $l_w = 75$ eV and $l_g = 78$ eV, and (ii) $l_w = 78$ eV and $l_g = 81$ eV.

Results: The k_Q factors calculated using the two different sets of l -values were found to agree within 1.5% or better. The k_Q factors calculated using $l_w = 75$ eV and $l_g = 78$ eV were found to agree within 2.3% or better with the k_Q factors tabulated in IAEA TRS-398; and within 1% or better with experimental values determined with water calorimetry (see figure 1). The agreement with IAEA TRS-398 values was found to be better for plane-parallel chambers than for cylindrical. For cylindrical chambers, our k_Q factors showed a larger variation with the residual range than IAEA TRS-398 values (see figure 1). This is, in part, due to the fact that our k_Q factors take inherently into account the dose gradient effects in unmodulated proton beams.

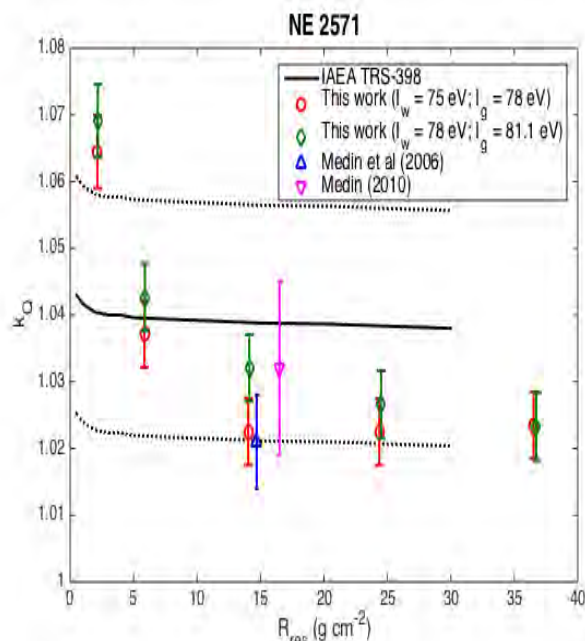

Figure 1: k_Q factor of the NE 2571 cylindrical chamber, as a function of the residual range, (i) tabulated in IAEA TRS-398, (ii) calculated in this work with Monte Carlo simulation and (iii) determined with water calorimetry. The uncertainty bars correspond to one standard uncertainty in the data points. The dashed lines correspond to one standard uncertainty in the IAEA TRS-398 values.

Conclusion: The results of this work seem to indicate that ionization chamber perturbation correction factors in unmodulated proton beams could be significantly different from unity, at least for some of the ionization chamber models studied here. In general, the uncertainty of l_w and l_g seems to have a smaller effect on k_Q factors than the assumption of p_Q equal to unity. Finally, Monte Carlo calculated k_Q factors of plane-parallel ionization chambers seem to be in better agreement with the IAEA TRS-398 values currently in use, than those of cylindrical chambers.

Automated instead of manual planning for lung SBRT? A plan comparison based on dose-volume statistics

B. Vanderstraeten¹, B. Goddeeris¹, C. Derie¹, K. Vandecasteele¹, M. Van Eijkeren¹, L. Paelinck¹, C. De Wagter¹, Y. Lievens¹

¹University Hospital Ghent, Radiotherapie, Ghent, Belgium

Purpose or Objective: Automated planning (AP) aims to simplify the treatment planning process by eliminating user variability. We performed a detailed plan comparison based on clinical objectives and dose-volume histogram (DVH) parameters in a group of stereotactic body radiation therapy (SBRT) lung cancer patients.

Material and Methods: Between March 2012 and May 2015, 55 lung cancer patients were treated with SBRT at our institution. A total dose of 60 Gy in 3 fractions was prescribed to the PTV (D95). For each patient, an IMRT plan was created using in-house developed optimization software by manually tweaking a set of optimization objectives during several iterations. Final dose calculation was performed in Pinnacle 9.8 (Philips Medical Systems Inc, USA). These plans are further referred to as the manual plans (MP).

For each patient, an additional plan was created retrospectively using the Pinnacle 9.10 Auto-Planning software with a template representing the clinical objectives for the following structures: GTV, PTV, lungs minus GTV, spinal cord, esophagus, heart, aorta, trachea, main stem bronchus and chest wall. Using automatic optimization tuning

methods, an automated plan (AP) was created for each patient using the same IMRT beam directions as for the MP. No additional manual tweaking whatsoever was performed. For all of the above-mentioned structures the following DVH parameters were included in our analysis: D99, D98, D95, D90, D50, D5, D2 (in which xx% of the PTV volume receives a dose of at least Dxx) and Dmean. For the organs at risk (OAR) V5, V10 and V20 were also included (in which Vxx is the volume receiving at least xx Gy). The acceptability of each plan was judged against our clinical objectives (result: pass, minor deviation or fail). Additionally, pairwise comparisons of the DVH parameters were performed using paired, two-sided t-tests between the MPs and APs.

Results: Three APs failed in terms of our clinical objectives (1 plan: heart D2, 2 plans: chest wall D2), while 13 plans showed a minor deviation (12 plans: lungs minus GTV V20, 1 plan: chest wall D2). None of the MPs failed our clinical objectives, but 9 also showed a minor deviation (8 plans: lungs minus GTV V20, 1 plan: PTV D99). The graph shows average values over all patients of the dose (in Gy) -volume (in %) parameters for which statistically significant ($p < 0,05$) differences were found between the MPs and APs. Top: GTV and PTV; bottom: clinical OAR objectives. All plans were normalized to PTV D95 = 60 Gy.

Conclusion: Without user intervention, AP resulted in plans that comply with our clinical objectives for almost all patients. Some APs may require slight additional manual tweaking. From a statistical point of view, AP delivers significantly less dose to the OARs, while preserving target coverage. In the near future, all plans will be blindly evaluated by three experienced radiation oncologists to assess the clinical significance of the observed statistical differences.

OC-0080

In-silico implementation of MRI-60Co based RT: a dosimetrical comparison with rectal cancer (SIMBAD)

E. Placidi¹, N. Dinapoli², L. Boldrini², G.C. Mattiucci², L. Azario¹, D. Piccari², S. Teodoli¹, M.A. Gambacorta², S. Chiesa², A. Piermattei¹, V. Valentini²

¹Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Institute of Physics, Rome, Italy

²Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Radiation Oncology Department- Gemelli-ART, Rome, Italy

Purpose or Objective: The ViewRay MRI-Co60 hybrid system (MRIdian) allows MRI based targeting, autosegmentation and direct planning for numerous anatomical districts. Our department is implementing this technology and, up to date, we are comparing planning procedures to our clinical standards in order to define which districts could take advantage from the use of the MRIdian technology. Aim of this investigation was to assess the impact of the MRIdian radiation therapy system through a planning analysis for rectal cancer treatments.

Material and Methods: Ten sets of 3 plans (MRIdian, RapidArc and 5 beams sliding windows IMRT) were calculated for 10

patients affected by locally advanced rectal cancer (cT3-cT4; cN0, cN+). ROIs were contoured on Eclipse TPS. RapidArc (6-15 MV) and 5 beams (6-15 MV) sliding windows IMRT treatment plans were calculated on Eclipse according to our QA protocols. The PTV1 (CTV1+7 mm margin) was represented by tumor+1.5 cm margin craniocaudally and correspondent mesorectum, the PTV2 (CTV2 + 7 mm margin) by mesorectum in toto and pelvic nodes. The body, the bowel bag and the bladder were the OaR considered. The prescribed dose for PTV2 was 45 Gy and 55 Gy for PTV1 through simultaneous integrated boost. The PTV V95 and OaRs QUANTEC dose constraints on the DVHs and Wu's homogeneity indexes (HI) were considered for the QA of the plans. The structure sets were then uploaded on the MRIdian TPS and Co60 step and shoot IMRT plans (7 groups of 3 fields) were calculated. The DVHs and HIs were then compared to the RapidArc and IMRT plans in order to evaluate MRIdian's performances.

Results: MRIdian showed a better HI when compared to the other techniques for PTV1, while this advantage could not be appreciated for PTV2, even if a better PTV2 V100 (45 Gy) was observed. Comparable mean doses for the bladder were registered, while a higher bowel V45 was observed (even if still in the constraints limits). Low dose body V5 was higher for the MRIdian plans. The mean results and the standard deviations are summarized in the table.

Mean	MRIdian	RapidArc	IMRT
V95 PTV1 [%]	99.2	97.8	98.2
V105 PTV1 [%]	0.0	0.0	0.1
V95 PTV2 [%]	98.2	98.4	97.7
V100 PTV2 [%]	62.0	47.3	54.8
V105 PTV2 [%]	14.8	5.0	7.3
V5 Body [cc]	12809	10826	10039
V20 Body [cc]	6871	4559	5901
V45 Bowel Bag [cc]	59.4	10.6	48.7
Mean Dose Bladder [Gy]	35.4	34.0	36.5
Homogeneity Index PTV1	1.3	1.6	1.5
Homogeneity Index PTV2	6.7	3.7	4.4
Standard Deviation	MRIdian	RapidArc	IMRT
V95 PTV1 [%]	0.4	1.1	0.7
V105 PTV1 [%]	<0.1	<0.1	0.4
V95 PTV2 [%]	0.4	1.3	1.6
V100 PTV2 [%]	2.7	6.4	7.1
V105 PTV2 [%]	5.9	2.8	3.3
V5 Body [cc]	1847	1729	1487
V20 Body [cc]	567	730	1071
V45 Bowel Bag [cc]	36.0	23.3	11.6
Mean Dose Bladder [Gy]	3.3	4.5	4.9
Homogeneity Index PTV1	0.2	0.4	0.5
Homogeneity Index PTV2	0.9	1.5	2.2

Conclusion: A comparable PTV dose coverage between the 3 plans was found for rectal cancer, with a HI advantage for the PTV1 for the MRIdian plan. Differences were described for OaRs, especially for low dose areas (V5 Body). MRIdian allowed to reach dosimetrical goals comparable to RapidArc and IMRT gold standards. The evaluation of a possible reduction in PTV margin and a proper target coverage by MRI based gating will be analyzed when the system will become operative at Gemelli ART.

OC-0081

Robust photon versus robust proton therapy planning with a library of plans for cervical cancer

K. Crama¹, A. Van de Schoot¹, J. Visser¹, A. Bel¹

¹Academic Medical Center, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: The cervix-uterus shows large day-to-day variation in position and size, mainly depending on bladder and rectum filling. Image-guided adaptive radiotherapy with a library of plans (LOP) is a strategy to mitigate these large variations, resulting in less dose to organs at risk (OAR) compared to the use of a single plan with a population-based PTV margin. A further reduction of OAR dose can be achieved using proton therapy. However, it is challenging to achieve a target coverage that is robust for range and position uncertainties. The aim of this study is to compare target coverage of robustly optimized photon and

proton therapy plans using a LOP adaptive strategy for cervical cancer.

Material and Methods: Five cervical cancer patients treated with photon therapy were retrospectively included. For each patient a full and empty bladder planning CT and weekly repeat CTs were acquired. Depending on the magnitude of cervix-uterus motion, one to three ITV sub ranges were generated by interpolation of the CTV delineations on full and empty bladder CT. Target and OARs were delineated on all repeat CTs. Robustly optimized photon (VMAT) library plans and proton (IMPT) library plans were generated with a prescribed dose of 46 Gy in 23 fractions to the ITV. For robust optimization, a position uncertainty of 0.8 cm was applied; for protons 3% range uncertainty was included as well. The plans were required to have sufficient target coverage (V95%>99%) for both the nominal scenario and twelve scenarios with different range and position errors. Both for protons and photons the actual delivered dose was simulated. Repeat CTs were registered to the full bladder planning CT using bony anatomy, the best fitting library plan was selected and the dose was recalculated. The DVH for the whole treatment was estimated by adding and scaling DVHs. The target coverage was evaluated for the total CTV as well as the CTVs of the corpus uteri, cervix, vagina and elective lymph nodes.

Results: For the total CTV, on average, the V95% for the whole treatment was 99.9% (range 97.3%-99.8%) for photons and 96.3% (93.5%-98.1%) for protons. The V95% of the corpus uteri was 95.7% (86.3%-99.9%) and 88.7% (68.4%-99.9%) for photons and protons, respectively. Figure 1 shows a repeat CT with insufficient target coverage both for photons and protons. The elective lymph nodes received sufficient dose with photons, on average, V95% was 99.1% (98.1%-99.8%). With protons this volume decreased to 96.2%(94.9%-98.8%). For the cervix and vagina no differences between the use of photons and protons were observed.

Figure 1. Example of a recalculated dose distribution in a sagittal view. The CTV of the corpus uteri is the yellow structure, the GTV the orange structure. The top view shows the photon therapy plan, the bottom view the proton therapy plan. The green line represents the 95% isodose.

Conclusion: The robustly optimized proton therapy plans did not result in an adequate target coverage for all patients for the realistic robustness parameters used. For some cases the used LOP strategy is not sufficient to cope with the large movements of the cervix-uterus for both modalities. The impact of underdosing is larger using protons than using photons.

OC-0082

Validation of MR based dose calculation of prostate cancer treatments

R.L. Christiansen¹, H.R. Jensen¹, D. Georg², C. Brink^{1,3}

¹Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

²Medical University Vienna, Department of Radiation Oncology, Vienna, Austria

³University of Southern Denmark, Institute of Clinical Research, Odense, Denmark

Purpose or Objective: Dose calculation is currently based on the density map provided by CT. However, for delineation of the prostate gland and organs at risk T2-weighted MR imaging is the gold standard. Dose calculation based on MR information would remove the need for a CT scan and avoid the uncertainty related to registration of the images. Pseudo-CT generation from MR scans has recently become available. This study investigates the validity of dose calculation based on pseudo CT created with commercial software (MR for Calculating Attenuation - MRCAT) compared to standard CT based dose calculation.

Material and Methods: Seven high risk prostate cancer patients were MR and CT scanned. The clinical, curatively intended treatment (78 Gy in 39 Fx) using single arc VMAT was based on the conventional CT. From the MR scan pseudo-CT were created using MRCAT (Philips, Helsinki, Finland). To eliminate dose comparison uncertainties related to patient positioning differences between CT and MR rigid CT-MR registration was performed. The VMAT plan was transferred to the pseudo-CT and dose calculation was performed using Pinnacle (V9.10). Pass rate of the Gamma index was used to evaluate the similarity of the dose distributions. The dose acceptance criterion was evaluated as a percentage of the prescribed dose applying 2%/2 mm and 1%/1mm criteria.

Results: MRCAT was generated for six of the seven patients. One patients' pelvic anatomy was not correctly recognized by the software model, which prohibited MRCAT reconstruction. Pass rates for both acceptance criteria are summarized in table 1. For 2%/2 mm, pass rates are high, above 97.6% for all analyzed structures. Even for the 1%/1 mm criterion, pass rates are generally above 97%. In patient 3, lower pass rates in PTV78, seminal vesicles and rectum are observed. For this patient the gamma values above one are located mainly in and around an air cavity in the rectum (see figure 1). MRCAT does not assign air density to air cavities inside the patient, leading to the observed dose differences. However, in the pelvic region it might be at least as good an approximation to treat air cavities as water due to the mobility of the rectal air during the treatment course. As seen in figure 1, gamma values above one are also present close to the surface of the patient, which is caused by differences in definition of the outer contour of the patient.

Figure 1: Corresponding slice on CT and pseudo-CT and gamma analysis of respective dose calculations.

	PTV78	Prostate	Seminal vesicles	Rectum	Small bowel	Bladder	Outer contour
2%/2mm	Patient 1	100	100	100	100	100	99.5
	Patient 2	100	100	100	99	99.2	99.2
	Patient 3	97.6	100	98.5	98.1	100	99.6
	Patient 4	100	100	100	100	100	99.7
	Patient 5	100	100	100	100	100	99.3
	Patient 6	100	100	100	100	99.9	99.6
1%/1mm	Patient 1	99.7	98.9	100	99.9	100	99.0
	Patient 2	100	100	100	96.6	96.9	98.3
	Patient 3	91.5	99.0	84.1	91.7	100	99.9
	Patient 4	100	100	100	100	100	99.0
	Patient 5	100	100	100	100	98.5	98.2
	Patient 6	100	100	100	100	97.8	98.9

Table 1: Pass rates are shown for selected structures. Gamma analysis for penile bulb, left and right femoral heads yielded 100% pass rates for all patients under all criteria.

Conclusion: Overall the pseudo-CT based dose calculations are very similar to the CT based calculation for prostate cancer patients. The MRCAT software classifies internal air cavities as water density leading to dose differences compared directly to CT. In terms of the dose precision observed in this study the MRCAT is able to substitute the standard CT simulation, but a larger cohort of patients is needed to validate this finding. This will also reveal whether bone recognition capability is sufficiently versatile for standard clinical use.

OC-0083

When using gating in left tangential breast irradiation? A planning decision tool

N. Dinapoli¹, D. Piro¹, M. Bianchi¹, S. Teodoli², G.C. Mattiucci¹, L. Azario², A. Martino¹, F. Marazzi¹, G. Mantini¹, V. Valentini¹

¹Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Radiation Oncology Department, Rome, Italy

²Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Physics Institute, Rome, Italy

Purpose or Objective: The use of gating in tangential breast irradiation has shown to reduce the dose delivered to the heart, resulting in the possibility of decreasing heart toxicity in long time surviving patients. The use of gating requires to identify which patients could be addressed to this methodic by comparing planning results of gated and not-gated simulation CT based plans. However, the required double CT scan (with and without gating technology), for patients undergoing to left-breast tangential radiation treatment, can result in working overhead for RTTs executing CTs and for planners that have to produce two opponent plans for allowing final gated, or not-gated treatment decision. In this work a tool for deciding which patients could be selected for gating procedures by using only not gated CT scan is presented.

Material and Methods: Patients addressed to left-breast tangential irradiation without need to irradiate supraclavicular nodes have been retrospectively recruited in this study. Both gated and not-gated simulation CT were available for all of them. Two series of opponent, gated and not-gated, treatment plans have been produced and analyzed using Varian™ Eclipse workstation. DVHs have been extracted from plans and have been analyzed in order to detect which dosimetrical parameters are able to predict the final outcome: mean heart dose in gated treatment plan. Maximum heart distance (MHD) has been also recorded. A multiple linear regression model has been used to predict the final outcome.

Results: 100 patients have been enrolled in this study and 200 plans on 100 gated-CT and 100 not-gated CT have been produced. 10 patients showed mean not-gated CT heart dose (MNGHD) > 5 Gy (institutional threshold for addressing the patient to gating), resulting in a 90% overhead in terms of performed gated-CTs and plans. The final model shows the possibility to predict mean heart dose in gated treatment plan with a p-value < 2.2e-16, adjusted R-squared = 0.5486,

using not gated CT based planning and geometrical parameters summarized as follows:

Coefficients name:	B value	P-val - Pr(> t)
Intercept	0.92151	2.27e-11
V31.5 Gy Lung Basal	-4.20188	0.000299
Mean Basal CT Heart Dose	0.54065	1.29e-13
Basal MHD	-0.44137	0.000748

In order to easily predict which gated-CT mean heart dose would result if patients underwent to this scanning procedure a nomogram has been produced allowing the users to manually calculate this value without scanning the patients with gated CT (figure 1).

Conclusion: The use of gated treatment in left breast tangential radiotherapy can result in high quantity of unrequested CT scans and plans for patients not needing to be addressed to this kind of delivery method. Our decision tool is able to evaluate patients that will benefit from using gating technology without the need to acquire a double CT scan and producing a double treatment plan, so making the whole workflow easier and faster.

OC-0084

Hybrid RapidArc for breast with locoregional lymph node irradiation spares more normal tissue

E. Bucko¹, M. Jeulink¹, P. Meijnen¹, B. Slotman¹, W. Verbakel¹
¹VU University Medical Center, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: The conventional radiotherapy technique for breast cancer with locoregional lymph nodes consists of half beam tangential fields for the breast, junctioning a 3-field AP-PA half beam block for the supraclavicular nodes. The AP-PA fields treat a considerable volume of healthy tissue to high doses, and the lack of slip zone makes it unsuitable for deep inspiration breathhold where some variation of breathhold is expected. Full volumetric modulated arc would lead to an unwanted low-dose spread. We therefore investigated the improvements of a novel hybrid RapidArc (hRA) technique which is now standard in our hospital.

Material and Methods: Previously contoured CT scans from 10 patients with breast tumors including locoregional lymph nodes were used for planning (Eclipse, Varian Medical Systems). Prescription was 16 fractions of 2.67 Gy. Clinically treated hRA plans consisted of 2 tangential open fields with a 2 cm cranial slip zone delivering 85% of breast dose and 3 partial RapidArc arcs of each 80°, delivering the remaining dose to the breast and slipzone and full dose to the cranial lymph nodes. A range of organs at risk (OAR) constraints (from high to low dose) were set on heart, contralateral (CL) breast, ipsilateral (IL) and CL lung, esophagus, thyroid and ring structures. PTV and OAR dosimetry of hRA plans were compared with our old conventional technique hybrid (h)-IMRT). hIMRT plans consisted of 3 APPA half fields, delivering full dose to the cranial lymph nodes, 2 tangential open half fields delivering 85% of breast dose and 2 tangential IMRT fields delivering the remaining dose to the breast and junction. Plans were normalized to deliver similar mean dose. PTV and OAR metrics were compared.

Results: Compared to hIMRT, hRA provided better PTV coverage and OAR sparing (see Table). V107% of PTV reduced from 4.9% to 1.3%. Both the volumes outside the PTV receiving 20Gy and 40Gy were reduced significantly by hRA (from 2014 to 1440cm³ and from 789 to 312 cm³). hRA spared better the esophagus and thyroid gland. Mean lung dose and IL lung receiving 20Gy reduced significantly, at the expense of a non-significant 5% increase of V5Gy to the IL lung.

Table, dosimetric data averaged over 10 patients

Metric	hRA	hIMRT	p-value
PTV volume=1222 cm ³			
PTV V95% (%)	99.0	98.0	0.05
PTV V107% (%)	1.3	4.9	0.001
PTV D _{mean} (%)	101.3	101.3	0.36
PTV D _{max} (%)	111.9	114.9	0.011
PTV D98% (%)	96.2	95.1	0.013
PTV D2% (%)	106.3	108.5	3e-4
IL-Lung D _{mean} (Gy)	12.9	14.3	0.004
IL-Lung V20Gy (%)	26.0	32.2	2e-4
IL-Lung V5Gy (%)	55.1	50.2	0.13
CL-Breast V2Gy (%)	6.2	2.4	0.002
Esophagus V20Gy (%)	2.0	9.0	0.026
Esophagus V30Gy (%)	0.2	3.2	0.12
Thyroid D _{mean} (Gy)	11.7	12.3	0.39
Thyroid V30Gy (%)	14.8	21.8	0.05
Body minus PTV V20Gy (cm ³)	1440	2014	8e-8
Body minus PTV V40Gy (cm ³)	312	789	4e-7

Conclusion: The novel hRA technique had dosimetric advantages for almost all investigated OAR. hRA spared significantly the healthy tissue around the supraclavicular lymph nodes. The 2cm slip zone in the hRA plan, which is not possible to create when using junctioning half beams, makes this technique also suitable for breathhold treatment.

The level of innovations routinely implemented in Dutch radiotherapy centers: a cross-sectional study

M. Jacobs¹, A. Dekker², L. Boersma², F. Van Merode³, G. Bosmans², L. Linden², P. Simons², S. Moorman², P. Lambin²

¹MAASTRO clinic, Department of Radiation Oncology MAASTRO- CAPHRI School for Public Health and Primary Care- Health Services Research- Maastricht University Medical Centre + MUMC+, Maastricht, The Netherlands

²MAASTRO clinic, Department of Radiation Oncology MAASTRO- GROW School for Oncology and Developmental Biology- Maastricht University Medical Centre + MUMC+, Maastricht, The Netherlands

³MUMC+, Executive Board of Maastricht University Medical Centre + MUMC+, Maastricht, The Netherlands

Purpose or Objective: Radiotherapy centres have the complex task to simultaneously improve patient outcomes (survival and toxicity), safety, service (such as shared decision making) and efficiency. To address this multi headed challenge, centres are forced to innovate. The objective of our study is to investigate how well Dutch Radiotherapy centres have implemented innovation within the care environment. Our two research questions are: 1. What is the annual number of treatment -, technological - and organisational innovations? And 2. Are there differences between the centres?

Material and Methods: A descriptive cross-sectional study was conducted. Two investigators started with semi structured interviews in participating centres, generally with the head of physics and the head of the department. Innovations in the annual policy plans from 2011- 2013 (3

years) were classified into 3 distinct categories based on literature: new or significantly improved 1) treatment, 2) technology, or 3) organisational processes, implemented in clinical routine. Incremental improvements to existing treatments, technologies, or organisational processes were not included in the results below. Centres without annual policy plans were asked to create their own inventory, or to tick listed innovations from other centres. Finally, all participating centres received the listed innovations from other centres with the request to check if their own inventory was complete. The classification was checked independently by two senior investigators.

Results: Out of the 20 centres invited to participate in the study 15 took part in the final study, 8 of which were academic and 7 non-academic. As shown in the table below, the number of innovations in academic centres was higher but not significantly different from non-academic centres. An academic centre implemented on average 17 (range 12-27) innovations per year and a non-academic centre on average of 14 (range 10-18). Treatment innovation (e.g. breath hold mammography, IGRT) was the most frequently implemented innovation (n=102) followed by organisational innovation (e.g. starting a satellite, new Electronic Patient Record)(n=71) and technological innovation (e.g. IMRT, technological new linacs)(n=61). In each innovation category an academic centre is performing the highest number of innovations.

	AC 1	AC 2	AC 3	AC 4	AC 5	AC 6	AC 7	AC 8	sub
treatment innovation	3	7	16	4	3	8	6	11	58
technological innovation	7	8	5	0	4	5	0	6	35
organisational innovation	2	12	5	5	3	3	6	7	43
total	12	27	26	9	10	16	12	24	136

	NAC 1	NAC 2	NAC 3	NAC 4	NAC 5	NAC 6	NAC 7	sub
treatment innovation	7	11	5	6	8	1	6	44
technological innovation	4	6	3	2	2	7	2	26
organisational innovation	3	1	2	8	6	6	2	28
total	14	18	10	16	16	14	10	98

Totals		AC: Academic Centre	NAC: Non-Academic Centre
treatment innovation	102		
technological innovation	61		
organisational innovation	71		
	234		

Conclusion: Radiotherapy centres in the Netherlands implement on average 16 innovations per year in their department; this number is not significantly different for academic or non-academic centres. These numbers confirm that radiotherapy is a very dynamic and innovative discipline. In our next study we will investigate what are the key drivers for innovation.

PV-0086 Clinical implementation of research within a radiotherapy department. A quality indicator?

M. Jacobs¹, L. Boersma², F. Van Merode³, A. Dekker², F. Verhaegen², L. Linden², S. Moorman², P. Lambin²

¹MAASTRO clinic, Department of Radiation Oncology MAASTRO- CAPHRI School for Public Health and Primary Care- Health Services Research- Maastricht University Medical Centre + MUMC+, Maastricht, The Netherlands

²MAASTRO clinic, Department of Radiation Oncology MAASTRO- GROW School for Oncology and Developmental Biology- Maastricht University Medical Centre + MUMC+, Maastricht, The Netherlands

³MUMC+, Executive Board of Maastricht University Medical Centre + MUMC+, Maastricht, The Netherlands

Purpose or Objective: The efficiency in the translation of scientific discoveries into clinical practices in general

healthcare is low. Previous research concluded that approximately 5 % of peer-reviewed papers concern findings which are routinely implemented. We hypothesize that implementation rates in radiotherapy will be higher, in particular in an institution which has an integrated strategy for research, valorisation and patient care, and has a data centre for clinical trials including a software development team. Our aim is to study the efficiency of research implementation in the clinic either in routine or in clinical trials in a large radiotherapy institution over a period of 4 years. The research questions are two-fold: 1) what is the percentage of published findings routinely implemented in clinical practice? And 2) what is the rate of clinical testing of laboratory and technological published findings? Furthermore, we have tried to identify the facilitators and barriers within this process.

Material and Methods: The scientific publications of researchers of our own institute were listed for the period from 2008-2011 (4 years), categorized as shown in the table below. From the literature we listed the facilitators and barriers in the implementation process. We asked clinicians of the tumour expert groups if the published study had yet been implemented into clinical practice or clinical trials, and which facilitators or barriers were applicable. This has been verified by an independent investigator. We calculated implementation rates and the frequency of mentioned facilitators and barriers. Furthermore the head of research scored whether pre-clinical and technological scientific publications had been tested in clinical trials. This was checked independently by two senior investigators.

Results: Internal researchers published 244 papers of which 79 (32%) were clinical (technological) papers. In total, 45/244 papers (18%) were routinely implemented; of the 79 clinical (technological) papers, this percentage was even higher: 33% (26/79). Overall 73/244 (30%) papers (all technical or laboratory papers) were tested in a clinical environment, mostly in the context of a research project (Table). The main facilitator was level of evidence, and the main barriers were workload and high complexity (Figure).

	Number of publications	Implemented in clinical practice	Tested in clinical practice (clinical or non-clinical study)	Tested in prospective clinical trial (RCT) (n=1)
Clinical/Research	82	29		
• Radioactive	51	0		
• Coloni	26	0

• Cost benefit analysis	9	0		
• In Studies	3	0		
TOTAL	244	48 (19.6%)	66 (27.0%)	12 (4.9%)

* IRR Internal Review Board

Conclusion: The efficiency in translation of published research in radiotherapy in reaching the clinic was much higher than in general healthcare. Level of evidence was an important facilitator, whereas high workload and complexity

were important barriers. The next step will be to look at the time needed for implementation and to investigate implementation rate in other centres. We propose that the rate of clinical implementation of published research findings, routinely or in trials, should be a quality indicator of integrated research-patient care organisation such as a comprehensive cancer centre.

PV-0088

Rapid changes in brain metastasis during radiosurgical planning - implications for MRI timing

A.L. Salkeld¹, W. Wang¹, N. Nahar¹, L. Gomes², K. Ng²

¹Crown Princess Mary Cancer Centre Westmead Hospital, Radiation Oncology, Westmead, Australia

²Westmead Hospital, Radiology, Westmead, Australia

Purpose or Objective: The aim of this prospective study was to determine any changes in brain metastases or resection cavity volumes between the planning MRI and radiosurgical (RS) treatment and if these impacted on management or led to an alteration of the RS plan.

Material and Methods: 33 patients with 42 metastases and 12 tumour resection cavities underwent a planning MRI (MRI-1) which was fused to the planning CT. GTV (metastasis) or CTV (cavity) were contoured from the T1 and T2 post-gadolinium MRI. The GTV/CTV had a 2mm circumferential expansion creating a PTV with a plan generated. In addition, a verification MRI (MRI-2) was performed 24-48 hours prior to RS with volumes re-contoured on MRI-2 (verGTV/verPTV). The GTV/CTV and PTV volume changes between MRI-1 and MRI-2 were recorded and the original plan assessed for coverage of the verPTV. A change in plan or management based on MRI-2 was recorded.

Results: Patient and tumour characteristics are shown in Table 1. The median time between MRI-1 and MRI-2 was 7 days with 27 patients (82%) having 14 days or less and 22 patients (66%) with 7 days or less. Changes in GTV/CTV and PTV volumes between MRI-1 and MRI-2 are shown in Figure 1. 19 (58%) patients required a change in management based on changes in lesions on MRI-2 including: re-planning of RS, or a change in treatment to whole-brain radiotherapy (WBRT), surgery or best supportive care (BSC). Per lesion, 30 out of 54 lesions (56%) required re-planning based on MRI-2 including 5 (42%) cavities and 25 (60%) metastases. 2 patients had rapid progression with lepto-meningeal disease diagnosed on MRI-2 and received WBRT. 1 patient (previously received WBRT) had a rapid increase in lesion size and number, with an additional 9 lesions noted on MRI-2 and received BSC. Reasons for re-planning included: increase in volume (27 lesions) with 25 verGTV lying outside the original PTV and 2 touching the original PTV; 2 lesions with a reduction in verGTV/verPTV volumes, and 3 patients with an increase in the number of metastases or leptomenigeal disease on MRI-2.

Conclusion: This study is the first to demonstrate changes in brain metastases volume from planning MRI to RS treatment, where changes often occurred with an interval of 7 days or less. An MRI performed within 24-48 hours of RS led to re-planning or a change in management in more than 50% of patients. Therefore, even a short interval between planning MRI and RS may result in a geographical miss or over treatment, emphasising the need for efficient planning processes.

PV-0089

CyberKnife for prostate cancer patients - early results of 350 patients irradiation

L. Miszczyk¹, A. Namysl-Kaletka¹, A. Napieralska¹, G. Wozniak¹, M. Stapor-Fudzinska², G. Glowacki¹, K. Grabinska¹

¹Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy, Gliwice, Poland

²Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Treatment Planning, Gliwice, Poland

Purpose or Objective: The aim of this study was an evaluation of a toxicity and an early effectiveness of prostate cancer patients CyberKnife based radioablation.

Material and Methods: 350 PC patients (186 Low Risk, 164 Intermediate Risk) aged from 53 to 83 (mean 69) irradiated with CK every other day (fd 7.25Gy, TD 36.25Gy, OTT 9 days). Before the treatment start PSA varied from 0.3 to 19.5 (median 7.5) and T stage from T1c to T2c. Mean prostate dimensions were 42.6x37.2x41.1mm. FU ranged to 48 months (mean 12). Directly after the treatment, 1, 4, 8 months later and the next every 6 months, the percentage of patients with Androgen Deprivation Therapy (ADT), GI (gastro-intestinal) and GU (genito-urinary) toxicity (acute up to the 4th month and the next late) using the EORTC/RTOG scale and PSA concentration were checked.

Results: The percentage of patients without ADT increased from 42.6% to 100% 32 months later. The maximal percentage of acute G3 adverse effects was 0.5% for GI, 0.6% for GU and G2 - 1.9% for GI and 6.0% for GU. No G3 late toxicity was observed. The maximal percentage of late G2 toxicity was 0.5% for GI and 3.0% for GU. PSA median decreased from 2.2 to 0.2 ng/ml during FU. One patient relapsed (18 months after RT- next treated with salvage BT) and one developed metastasis in lymphatic node (treated next with salvage CK). The detailed results are presented in the Table.

	RT end	1 month	4 months	8 months	14 months	20 months	26 months	32 months	38 months
N of observed patients	350	214	255	212	146	91	53	22	7
No ADT [%]	42.6	64.8	72.7	78.1	85.7	84.4	96.2	100	100
GI 0 [%]	90.3	91.0	93.9	93.3	97.8	96.1	100	100	100
GI 1 [%]	9.1	6.6	4.9	6.2	2.2	3.9	-	-	-
GI 2 [%]	0.6	1.9	0.8	0.5	-	-	-	-	-
GI 3 [%]	-	0.5	0.4	-	-	-	-	-	-
GU 0 [%]	77.1	70.8	89.4	95.9	87.3	97.4	98.1	95.2	100
GU 1 [%]	16.3	25.0	8.2	3.6	9.7	2.6	1.9	4.8	-
GU 2 [%]	6.0	3.8	2.4	0.5	3.0	-	-	-	-
GU 3 [%]	0.6	0.4	-	-	-	-	-	-	-
PSA range [ng/ml]	0.008-20.4	0.003-16.3	0.002-8.2	0.0-6.4	0.002-3.5	0.04-2.2	0.0-3.3	0.02-3.8	0.003-0.6
PSA mean	3.7	1.9	1.1	0.7	0.5	0.4	0.4	0.5	0.3
PSA median	2.2	1.0	0.3	0.3	0.2	0.2	0.2	0.1	0.2

Conclusion: The results obtained permit us to form the conclusion that CK based radioablation of low and intermediate risk PC patients is an effective treatment modality enabling OTT shrinkage and giving a very low percentage of adverse effects.

PV-0090

Stereotactic body radiotherapy for localized prostate cancer: a 7-year experience

Y.W. Lin¹, K.L. Lin², L.C. Lin¹

¹Chi Mei Medical Center, Department of Radiation Oncology, Tainan City, Taiwan

²Chi Mei Medical Center, Department of Radiation Oncology, Tainan City, Taiwan

Purpose or Objective: Recent understanding of radiobiology for prostate cancer suggested hypofractionation might achieve a higher therapeutic benefit. Stereotactic body radiation therapy (SBRT) is able to delivery high dose per fraction precisely. SBRT for prostate cancer might escalate biological effective doses while without increasing toxicity. Here, we reported our 7-year experience of SBRT for localized prostate cancer.

Material and Methods: Between November 2008 and Sep 2013, a total of 135 patients with clinically localized prostate were enrolled for analysis. Patients were low-risk (19%), intermediate-risk (37%), and high-risk (44%). Low- and intermediate-risk patients were treated with SBRT alone (37.5Gy in 5 fractions). High-risk patients were treated with whole pelvic irradiation (45Gy in 25 fractions) and SBRT boost (21Gy in 3 fractions). All of intermediate- and high-risk patients received hormone therapy with different duration. The toxicities of gastrointestinal (GI) and genitourinary (GU) tracts were scored by Common Toxicity Criteria Adverse Effect (CTCAE v3.0). Biochemical failure was defined as Phoenix definition.

Results: With a median follow-up of 52 months, there were seven patients with biochemical failure (one low-risk patient; one intermediate patient; five high-risk patients). The estimated 50-month biochemical failure-free survival (BFFS) was 95.8%, 96.4% and 81.5% for low-, intermediate, and high-risk patients, respectively. In the high-risk group, there were two late biochemical failures around 60 months. In the SBRT alone group, acute Grade 3 GU and GI toxicities were seen in 2.8% and 1.4% of the low/intermediate-risk patients, respectively; the incidence rate of late Grade 3 GU and GI toxicity were 3.5% and 0%. In the whole pelvic irradiation with SBRT boost group, acute Grade 2 GU and GI toxicity occurred in 31% and 21% of the high-risk patients, respectively; there was no grade 3 or higher late toxicity of GU and only one patient experienced grade 3 GI tract. Most of acute toxicity effects in the both groups resolved within three to six months of treatment completion.

Conclusion: SBRT with or without whole pelvic irradiation for localized prostate cancer is feasible with minimal toxicity and encouraging biochemical failure-free survival but should be aware of late failure in the high-risk group. Use of whole pelvic irradiation for high-risk patients was not associated with higher GU or GI toxicity. Continued accrual and follow-up would be necessary to confirm the biochemical control rate and the toxicity profiles.

PV-0091

Early salvage RT for PSA recurrence postprostatectomy improves biochemical progression free survival

A.B. Hopper¹, A.P.S. Sandhu¹, J.P. Einck¹

¹University of California San Diego, Radiation Medicine and Applied Sciences, San Diego, USA

Purpose or Objective: The definition of biochemical recurrence following radical prostatectomy for prostate cancer remains controversial in the era of ultrasensitive PSA. The AUA definition of PSA > 0.2 ng/mL may not be valid when PSA can be detected as low as 0.01 ng/mL. Randomized trials have shown a benefit in terms of biochemical progression-free survival (bPFS) and metastasis free survival with adjuvant radiation compared to salvage but many patients enrolled as adjuvant actually had detectable PSA values. We compared patient outcomes with salvage radiotherapy based on pretreatment PSA in order to identify whether early salvage radiotherapy is more effective than treating later.

Material and Methods: We performed an institutional review board-approved retrospective analysis of patients treated at our institution with post-prostatectomy image guided radiotherapy from 2005 to 2013. Patients with positive lymph nodes, those with an undetectable PSA and those with metastatic disease were excluded from our analysis. Data were abstracted from each patient's electronic medical record including age, pathologic stage, Gleason score, margin

status, androgen deprivation therapy, treatment to the pelvis, dose and PSA values. Patients were either treated with intensity modulated radiotherapy (IMRT) or volumetric arc therapy (VMAT) using daily image guidance. The use of ADT and the treatment of nodes was at the discretion of the treating physician. Radiation dose ranged from 6200-7400 cGy. Post-salvage bRFS was defined as PSA < 0.4 ng/mL. Kaplan-Meier survival analysis was used to compare patients with a pre-RT PSA value \leq 0.2 ng/mL to those with a value > 0.2 ng/mL. Multivariate Cox regression analysis was used to evaluate significance of covariates on bPFS.

Results: 196 patients staged N0 or Nx were treated with salvage RT after prostatectomy during the study period. Median pre-treatment PSA was 0.29 ng/mL; 117 patients had a PSA > 0.2 ng/mL and 79 \leq 0.2 ng/mL. Median follow up time was 36 months, determined by the reverse Kaplan-Meier method. Overall comparison of the two groups showed that patients treated with a PSA < 0.2 ng/mL had significantly improved bPFS ($p=0.003$) and increased 36 month bPFS (76% vs 56%, $p=0.0074$) compared to those treated with higher PSA values (Figure 1). In multivariate analysis a pre-RT PSA > 0.2 and increasing T stage and Gleason score were all significantly associated with worsening bPFS while positive margins were significant for improved bPFS (Table 1). Other covariates including treatment of nodes and use of ADT did not significantly influence bPFS following salvage.

Figure 1: Kaplan-Meier plot of biochemical progression free survival in post-prostatectomy patients stratified by pre-treatment PSA

Table 1: Multivariate Cox regression analysis for predictors of PFS

Covariate	Hazard Ratio	95% CI	p-value
T stage [†]	1.580	1.176-2.123	0.002
Positive Margins	0.592	0.356-0.985	0.043
Gleason Score [°]	1.368	1.054-1.774	0.018
Neoadjuvant ADT	0.780	0.399-1.527	0.469
Whole Pelvis	0.662	0.367-1.195	0.171
Age	0.989	0.957-1.023	0.527
PSA > 0.2 ng/mL	2.358	1.350-4.119	0.003

[†] HR for T stage represents each increase in stage with T2a/b as the reference

[°] HR for GS represents each increase in GS with 6 as the reference up to 10

Conclusion: Early post-prostatectomy salvage radiation before the PSA reaches 0.2 ng/mL results in superior bPFS compared to those treated later. This strongly suggests that a new definition of post-prostatectomy progression is needed.

Patient centric approach: myth or fact?

P. Poortmans¹

¹UMC St Radboud, Radiation Oncology, Nijmegen, The Netherlands

Award Lecture: E. Van der Schueren Award

SP-0093

Did I do it right? What was the result? Process and outcomes in radiotherapy

A. Barrett¹

¹University of East Anglia, Radiation Oncology, Norwich, United Kingdom

I am honoured to have been invited to give this memorial lecture for which there are three main criteria: it is firstly to honour Emmanuel van der Scheuren, one of the fathers of our society. Secondly it aims to recognise scientific work within the field of radiation oncology and thirdly a contribution to education through the ESTRO programmes, in which I have been privileged to participate for the last 30 years or so.

The first ESTRO annual conference was held in London in 1982 and was memorable with the preparations being agreed between Emmanuel and Mike Peckham, my boss at the Royal Marsden Hospital at the time. I also want to acknowledge how dependent we were on many others for support, particularly among others for Lea, of whom we are thinking with gratitude especially at this time.

Scientific breakthroughs usually build on work that others have done and there are many examples from within the field of radiation oncology which I have experienced particularly in my area of research into whole-body irradiation. We work with the unchanging laws of physics but technology advances all the time and new biological understanding and new agents impact on the way in which we practice oncology.

I will discuss some of the ways in which progress in radiotherapy may occur and consider the factors which determine the impact of clinical trials, with particular reference to the START trials run by John Yarnold and his team. Consensus guidance, such as that contained in the ICRU report 50, has changed practice but there is still much evaluation work to be done in some areas. In our activity currently, process sometimes seems to take precedence over everything else, without the evaluation which would validate it.

ESTRO's contribution to education has been enormous and it has been exciting to be involved in the teaching courses and publications of ESTRO with its ever-changing and innovative approaches. It is good to note that a new era is starting for the School. Amongst all the changes in current practice the needs of individual patients must remain our priority

Symposium with Proffered Papers: Hot topics in SABR: time for randomised clinical trials?

SP-0094

Do we need randomised clinical data to justify the use of SABR for primary and oligometastatic cancer?

To be confirmed

SP-0095

Pre-clinical and clinical data on the radiobiological mechanism for the efficacy of SABR

M. Brown¹

¹Stanford University School of Medicine, Department of Radiation Oncology, Stanford, USA

Because the results obtained with stereotactic radiosurgery (SRS) and stereotactic ablative radiotherapy (SABR) have been impressive they have raised the question of whether classic radiobiological modeling are appropriate for large doses per fraction. In addition to objections to the LQ model, the possibility of additional biological effects resulting from endothelial cell damage and/or enhanced tumor immunity, have been raised to account for the success of SRS and SABR. However, the preclinical data demonstrate the following:

1) Quantitative *in vivo* endpoints, including late responding damage to the rat spinal cord, acute damage to mouse skin and early and late damage to the murine small intestine, are consistent with the LQ model over a wide range of doses per fraction, including the data for single fractions of up to 20 Gy.

2) Data on the response of tumors to high single doses are consistent with cell killing at low doses. Thus the dose to control 50% of mouse tumors (the TCD50) can be predicted from cell survival curves at low doses and the number of clonogenic cells in the tumors.

Further the clinical data show:

3) The high local control of NSCLC and of brain metastases by SABR and SRS is the result of high radiation doses leading the high BED. In other words the high curability is predicted by current radiobiological modeling.

4) Because high doses are required in SABR it is not possible to use it in all circumstances (e.g. for tumors close to critical normal structures). But because these high doses are needed because of tumor hypoxia there is a major opportunity to improve SABR by the use of hypoxic cell radiosensitizers.

SP-0096

Technical developments in high precision radiotherapy: a new era for clinical SABR trials?

M. Aznar¹

¹Rigshospitalet, Section for Radiotherapy Department of Oncology 3993, Copenhagen, Denmark

The technological developments in radiotherapy have had a considerable impact on the way stereotactic radiotherapy is delivered. Increased confidence, provided for example, by the wide availability of image guidance, has permitted more and more institutions to offer SABR as a treatment option. However, some characteristics of SABR plans such as heterogeneous dose prescription, can make the comparison between different institutions and different technological approaches very challenging. In this session, we will review the impact of image guidance strategies, dose calculation algorithms, and normalization guidelines on the planned dose distribution. We will also discuss how these technological aspects should influence how we look at clinical trials of the past, and what should be taken into account when designing new multi-centre trials.

⁷Erasmus MC Cancer Institute, Department of Radiation Oncology, Rotterdam, The Netherlands

⁸University of North Carolina, Department of Radiation Oncology, Chapel Hill, USA

⁹Princess Margaret Cancer Centre, Department of Radiation Oncology, Toronto, Canada

Purpose or Objective: SBRT is highly effective in providing local control in selected patients with hepatic malignancies. However, various dosing and fractionation schemes with a wide range of toxicity end-points have been reported in the literature. The objective of this work was to review the normal tissue dose-volume effects for liver SBRT and derive normal tissue complication probability models.

Material and Methods: A literature review by the AAPM Working Group on SBRT was performed. Twelve studies that contained both dose/volume and toxicity data from 541 patients with hepatocellular carcinoma, intrahepatic cholangiocarcinoma, and/or liver metastases were identified and analyzed. Patients received a median total dose of 40 Gy (range 18-60 Gy) in 1-6 fractions. The 3 end-points that were chosen for pooled dose-response relationships analysis were grade 3+ (G3+) liver enzyme elevation as a function of mean liver dose (MLD), G2+ GI toxicity as a function of prescription (RX) or PTV dose, and G3+ GI toxicities as a function of RX/PTV dose. The RX/PTV doses were chosen because doses to specific OARs were not available in many instances. Dose-response modeling was performed using a probit model with maximum likelihood (ML) parameter fitting. The model used the average reported toxicity rates and corresponding dose metrics reported in each included study. The average toxicity rate was then binned into binary outcomes to facilitate ML parameter fitting. Confidence intervals for dose-response curves were calculated using bootstrap method using random sampling with replacement.

Results: Increased MLD was positively correlated with G3+ enzyme toxicity; however, the probit model fitting did not produce a statistically significant dose-response fit. Possible explanations are the sparsity of data, low incidence of complications, variations in baseline liver function and cancer type, and lack of standardization of definitions used for liver enzyme abnormalities. The analysis relating G2+ GI toxicity to RX/PTV dose showed a statistically significant probit model fit. Model fitting parameters were D50 of 47.7 Gy (95% CI 43.0 - 68.8 Gy) and γ_{50} of 0.79 (95% CI 0.34 - 1.25). The plot relating G3+ GI toxicity to RX/PTV dose demonstrated a dose response with a statistically significant probit model fit. Model fitting parameters were D50 of 90.2 Gy (95% CI 67.2 - 516.4 Gy) and γ_{50} of 1.17 (95% CI 0.68 - 1.69). The large D50 value of 90.2 Gy can be attributed to the low rates of G3+ GI toxicity.

Conclusion: Our analysis shows a mean RX/PTV dose of 50 Gy in 3 to 6 fractions has resulted in G3+ GI toxicity risk of < 10%. The QUANTEC liver report recommends MLD limits of 13 Gy in 3 fractions and 18 Gy in 6 fractions for primary disease and 15 Gy in 3 fractions and 20 Gy in 6 fractions for metastases. Our analysis shows that the QUANTEC recommended MLD limits would likely result in acceptable G3+ liver enzyme toxicity risks of < 20%.

Symposium: Tumour targeting - considering normal tissue biology

SP-0098

Organoids, a disease and patient specific in vitro model system

R. Vries¹¹Hubrecht Institute, Developmental Biology and Stem Cell Research, Utrecht, The Netherlands

The group of Hans Clevers at the Hubrecht Institute discovered a unique marker (LGR5) for epithelial stem cells of the intestine (Barker et al., Nature 2007). Since then, LGR5 has been shown to be a marker of adult stem cells of multiple other tissues such as liver, pancreas, breast, and lung (eg: Huch et al., Nature 2013; Boj et al., Cell 2014; Karthaus et al., Cell 2014). With the identification of these stem cells and the tools to isolate them, we were able to develop a culture system that allowed for the virtually unlimited, genetically and phenotypically stable expansion of the cells from several animal models including human (Sato et al., Nature 2009, 2011; Gastroenterology 2011; Gao et al., Cell 2014; Boj et al., Cell 2015; Huch et al., Cell 2015; van de Wetering et al., in press Cell). The organoids faithfully represent the in vivo cells also after prolonged expansion in vitro. Hubrecht Organoid Technology (HUB), an entity founded to implement the organoid technology of the Clevers group, in collaboration with the Hubrecht institute, has generated a large collection of patient organoids from a variety of organs and diseases. The intestinal organoids have been shown to be a very powerful tool for the study of Cancer, Cystic Fibrosis and Inflammatory Bowel Disease (Dekkers, Nat Med 2013; van de Wetering, Cell in press). The models represent previously unavailable in vitro models and patient specific samples for drug development, patient stratification and diagnostics. In addition, we recently showed the organoids are amendable to genetic corrections by novel and conventional biochemical techniques such as Crispr/Cas9 (Drost et al., Nature 2015; Schwank et al., Cell Stem Cell 2013). Finally, the in vitro stability of the organoid was demonstrated by the integration after transplantation of human liver cells into recipient mice. This makes the organoid a unique new platform for drug development, for precision medication for patients in the clinic, and a possible new source for cell therapy.

SP-0099

The role of ATM and p53 in normal tissue radiation response

D. Kirsch¹¹Kirsch Lab, Durham, USA

Following ionizing radiation exposure, double strand DNA breaks activate the ataxia telangiectasia mutated (ATM) kinase, which then phosphorylates a large number of target proteins to orchestrate the DNA damage response. One of the key proteins that is activated by ionizing radiation in an ATM-dependent manner is the tumor suppressor protein p53. Our laboratory has utilized the Cre-loxP system to delete ATM, p53 or both genes in different cell types in mice. We have also employed reversible in vivo shRNA to temporarily inhibit p53 during radiation exposure. We find that the roles of ATM and p53 in normal tissue radiation response are cell type specific. In bone marrow exposed to radiation, p53 acts to kill stem and progenitor hematopoietic cells, which increases acute hematological toxicity and promotes radiation-induced lymphomas. In gastrointestinal epithelial cells, p53 prevents the radiation-induced gastrointestinal syndrome. In endothelial cells, p53 prevents radiation-induced heart disease. Although deletion of ATM in endothelial cells does not sensitize mice to radiation-induced cardiac injury, in the setting of p53 deletion, ATM further sensitizes mice to radiation-induced heart disease. Taken together, these studies define cell type specific roles for ATM and p53 in mediating normal tissue response to ionizing radiation and suggest opportunities for combining radiotherapy with inhibitors of the ATM-p53 pathway to improve the

therapeutic ratio when treating cancers at specific anatomic sites.

Radiation sensitivity of human skin stem cells : dissecting epigenetic effects of radiation

M. Martin¹, N. Fortunel², P. Soularue²¹Laboratoire de Génomique et Radiobiologie du Kérat, Evry, France²Laboratoire de Génomique et Radiobiologie du Kérat, CEA, Evry, France

Due to its anatomical localization and high turnover, epidermis is a major target for carcinogens, and skin carcinoma is one of the most frequent human cancers. Ionizing radiation (IR) can induce carcinoma in skin, but the respective roles of keratinocyte stem cells and their progeny in the carcinogenic process is unclear. We characterized cell intrinsic radiosensitivity of keratinocyte stem cells (KSC) to gamma rays. Primary KSC were found radioresistant to high radiation doses (Rachidi, 2007), as well as to low doses. They repair rapidly all types of DNA damage (Harfouche, 2010), both after ionizing radiation and UVB exposure (Marie, submitted), without going to apoptosis. Activated repair was notably due to increased levels of DNA repair proteins and activation of nuclear FGF2 signaling. To evaluate the potential impact of irradiation on the epigenetic status of keratinocyte precursor cells, the Illumina 450K array was used, which measures the methylation level of 480,000 methylation sites (or CpG islands). More than 36 million of GpCs have been identified in the human genome, most of them located directly in gene sequences or in gene promoters. In the present study, analysis of the lists of the modified genes obtained by normalized graph-cut DNA-ranking allowed the definition of: 1) a specific signature of long-term alterations after 2 Gy: hundred genes presented methylation changes over 3 weeks in culture, with 18 genes exhibiting the most discriminant methylation changes at 16 and 23 days after exposure. Six genes were members of the super-family of protocadherins of the alpha type, pointing to alterations of cell-cell interactions. 2) a specific signature of long-term alterations after 10 mGy: 15 specific genes had methylation changes that were discriminant after 16 and 23 days. From their functions, it appears that the major cell responses after 10 mGy were localized at the cell membrane, for processes involved in calcium-related cell adhesion, signaling, energy status and carcinoma development. As a major function of methylation changes is to inhibit transcription, these signatures have been validated by characterizing the expression of the genes found in the signatures. In summary, high and low-dose exposures of immature keratinocytes from human epidermis result in epigenetic changes, part of them being specific to the dose. Methylation changes appear to regulate notably cell functions related to cell-cell interactions, cell adhesion and energy status.

Background: One of the main aims of radiotherapy alone or combined with chemo-, immuno- or biologically targeted therapy is the maximisation of tumour tissue eradication whilst preserving the surrounding normal tissue. This requires a deep understanding of the molecular mechanisms of radiation sensitivity in order to identify its key players and potential therapeutic targets. Currently, a paradigm shift is taking place from pure frequentistic association analysis to the rather holistic systems biology approach that seeks to mathematically model the system to be investigated and to allow the prediction of an altered phenotype as the function of one single or a signature of biomarkers.

Methods: In the current study cell culture models of radiation-resistant tumour cells and normal radiation-sensitive cells were investigated by multi-level (genome, transcriptome, miRNA) omics profiling over time and the resulting multi-layer radiation interactome was reconstructed. Validation of key network elements in biopsy-derived multi-omics data from radiotherapy treated HNSCC patients was performed and tested for association with clinical outcome.

Results: Molecular frameworks including signalling pathways senescence, cell cycle, immune system and PI3K/Akt have been identified and are therefore likely to drive radiation response in tumour and normal cells. Moreover, the identified networks could be used to identify molecular key players and potential targets for the simultaneous modulation of radiation sensitivity. A subset of these candidate molecules could be validated having an impact in clinical outcome of radiation therapy treated HNSCC patients.

Conclusion: Our study demonstrates that multi-level radiation systems biology allows gaining deeper insights into chief mechanisms of radiation sensitivity, thereby paving the way for targeted individualised therapy approaches in radiation oncology.

Debate: This house believes that progress in the treatment of locally advanced NSCLC will come from:

SP-0102 Radiation treatment intensification

J. Belderbos¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

A large proportion of non-small cell lung cancer (NSCLC) patients are diagnosed with locally advanced (stage III) disease. For this patient group the treatment of choice is definitive concurrent chemoradiation (CCRT). CCRT results in an improved overall survival (OS) compared to sequential chemoradiotherapy or radiotherapy alone because of improved locoregional control. However 2-year OS rates of 30-35% are still poor because many patients develop locoregional failures (about 30%) and distant metastases (about 40%)¹. Currently locally advanced NSCLC patients selected for CCRT have FDG-PET scanning and imaging of the brain (MRI or CT scan). Despite this brain imaging with the present chemotherapy regimens used we are faced with the problem of brain metastases in about 10% of the patients within 1 year after chemoradiation.

In several chemoradiation studies it was reported that the Gross Tumor Volume is correlated with OS. This is rational since the tumor volume represents the number of clonogenic tumor cells that needs to be eradicated. To improve locoregional control the dose prescription could be escalated taking into account the individual Gross Tumor Volumes and tolerances using image guided adaptive Intensity Modulated Radiotherapy (IMRT). However there are radiation oncologists who challenge the usefulness of RT dose escalation and intensification in patients with stage III NSCLC. The outcome of a randomized phase III trial, RTOG 06171, revealed that NSCLC patients within the 74 Gy arm given in 7.5 weeks had worse local control and significantly worse overall survival as compared to the patients treated to 60 Gy arm in 6 weeks².

Patients in all study arms received two additional cycles of consolidation chemotherapy ± cetuximab. So the obvious question is: How do we continue?

Dose escalation with prolonged overall treatment time in NSCLC has previously been proven disappointing because of accelerated repopulation³. In an individual patient data meta-analysis in patients with non-metastatic lung cancer, which included trials comparing modified radiotherapy with conventional radiotherapy, a significant OS benefit from accelerated or hyperfractionated radiotherapy was reported⁴. Another issue is the use of consolidation chemotherapy after concurrent chemoradiation. In the RTOG 0617 trial the increase in mortality started < 3 months after randomization during the period of consolidation paclitaxel-carboplatin chemotherapy. Generally taxanes given after RT increases toxicity and the combination of high dose to the heart and consolidation taxane-based chemotherapy might have caused toxic deaths and biased the outcome. RT dose intensification while using modern image guided adaptive IMRT and accelerated schemes is an important area of ongoing clinical research and should not be discontinued.

In Stereotactic Ablative Body Radiotherapy (SABR) much higher biologically equivalent doses are delivered compared to conventionally fractionated RT (typically EQD2 of 70-85 Gy), and has generated outstanding tumor control in early stage NSCLC. For SABR a significant dose-response relationship was observed for prescription EQD2 of 105 Gy or more (2-year LC 96%) or of less than 105 Gy (2-year LC 85%)⁵. Tumor size and overall treatment time were also important factors influencing outcome.

The tumor control probability of SBRT (small tumor volume) and conventionally fractionated chemoradiation (large tumor volume) were successfully described in a single model⁶ suggesting that a dose-response relation in NSCLC does exist. Recently there is a growing interest in genetic profiles that predict a patient's response to radiotherapy, because severe toxicity in a minority of patients limits the doses that can be safely given to the majority. Recent progress in genotyping raises the possibility of genome-wide studies. If we know the normal tissue reactions to radiotherapy by genotype we will really be able to tailor the individual radiation dose.

In conclusion: Besides the unsolved problem of the occurrence of distant metastases there is room for improvement of locoregional control in locally advanced NSCLC patients treated with chemoradiation. In the era of personalized treatment, radiotherapy dose intensification using image guided adaptive IMRT could be directed towards individual tumor volumes and tolerances. RT dose intensification while using accelerated schemes is an important area of ongoing clinical research

Better systemic therapy

J. Van Meerbeeck¹

¹University Hospital Antwerp, Department of Thoracic Oncology-MOCA, Edegem, Belgium

About one third of patients with non-small cell lung cancer (NSCLC) present with locoregional disease extension in either the mediastinum (T4) or the mediastinal lymph nodes (N2/3). Apart from a fraction in which resection after induction therapy is sometimes considered, selected patients with stage 3 are candidate for a so-called definitive radiochemotherapy, administered either sequentially or concomitantly. Despite staging with PET-CT scan and endosonographic mapping of mediastinal lymph nodes and notwithstanding a patient selection for this radical treatment, the outcome in stage 3 is nevertheless moderate with a median survival of 2 years [1]. Progression occurs after a median of 10 months and is due to local relapse or distant metastasis in 30 and 45% of cases, respectively. Any advance in the outcome in stage 3 NSCLC will hence depend on improvements in systemic therapy directed at distant metastasis. The past 10 years have seen important changes in the paradigm of treatment in selected patients with advanced NSCLC, in whom platinum-based doublet chemotherapy used to be the standard of care. The discovery of drugable genomic alterations has introduced precision medicine in oncology. Patients whose NSCLC harbour either an activating EGFR mutation, EML-ALK translocation or ROS1 amplification are now routinely treated with oral small molecule kinase inhibitors of the 1st, 2nd and 3rd generation instead of chemotherapy, with a significant improvement in outcome and a substantial impact on quality of life. Similar, although less pronounced effects have been observed when adding monoclonal antibodies directed at targets associated with angiogenesis or cell growth to the chemotherapy backbone. Unfortunately, the incorporation of these 'targeted' agents in current radiochemotherapy, either given concomitantly or as consolidation, was not successful with even detrimental results due to an increased toxicity and mortality. A lack of adequate patient selection based on the presence of the target biomarker may have contributed to these failures, as subgroup analyses suggest a benefit in target expressing patients. Trials are ongoing specifically addressing patients with stage 3 NSCLC and either an activating EGFR mutation or EML-ALK translocation. 2015 has seen the rapid implementation of immunotherapy in NSCLC treatment, with several monoclonal antibodies inhibiting checkpoint molecules showing superior outcome over 2nd line docetaxel. These agents will now advance in earlier stages and phase 3 trials with a consolidation strategy are ongoing. Controversial issues remain patient selection based on predictive biomarker expression, the combination of different checkpoint inhibitors and the risk of synergistic late pulmonary toxicity, when added to definitive thoracic radiotherapy. Although it is tempting to early implement promising new drugs in stage 3 treatment, caution should guide its sequencing within the radiochemotherapy backbone. Window of opportunity trials with induction treatment in biomarker selected patients will allow to explore the single agent activity and minimize the risk of additional toxicity.

Symposium: Active surveillance for low risk prostate cancer: to treat or not to treat?

SP-0104

Does (very) low risk prostate cancer really exist?

F. Algaba¹

¹Fundacio Puigvert, Barcelona, Spain

Prostate cancer could be considered as insignificant or indolent (IPCa) when its presence does not bring about any risk for the life of the patient. If we start with this idea it is easy to understand that this situation is very difficult to predict since it depends on many variables of each patient, among which the life expectancy of the patient is one of the most important; therefore, it would seem to be a more theoretical question than practical, if it were not because it reflects an emerged reality by finding that up to 31% of the prostate carcinomas detected by high PSA serum levels, through study of the prostatectomy specimen, there were

only small nodules of carcinoma that could have remained totally localized (latent) during the entire life of the patient, therefore they could have been treated with watchful waiting. It is clear that all of this supposition is a speculative exercise and only comes from indirect suppositions of the probable biology of a carcinoma node by its pathological characteristics. This fact explains that there are diverse definitions of IPCa in the radical prostatectomy specimens, although all coincide in requiring a small volume of tumor (< 5cc, although there is an author that accepts < 1cc), absence of aggressive Gleason patterns (no 4 or 5 patterns or Gleason score <7) and the majority also require, for a tumor to be accepted as indolent, to be a confined organ tumour with negative margins. In accordance with these criteria, the prevalence of IPCa varies between 2.3% and 31%, with an average of 18.3%. However, this uniformity of criteria is not the same at the time of determining the pre-operative model to predict IPCa, possibly because all the studies that try to correlate the extension of the prostate cancer in the biopsy with the volume in the prostatectomy specimen show that this correlation is very weak; and therefore, although all the needle biopsy criteria for defining an IPCa require the absence of an aggressive Gleason pattern (pattern 4 and 5 or Gleason score ≤ 7) would vary as regards the extension of the tumor in the cores (< 3 core with no core >50% of the surface, only one positive core < 3mm, 1% of all the cores, no core > 10% of the surface) and the inclusion between the criteria of the PSAD (PSA density). With all this variability the presumption of a possible IPCa in the radical prostatectomy specimen of the different authors has a sensitivity of 23% to 83.9% (average 53.2%) and a specificity of 61.9% to 99% (average 89.1%). Maybe it will help us to better identification of very low aggressive P.Ca patients the recent redefinition of Gleason patterns and the proposed grouping of prognostic grades. A new International Society Urogenital Pathology revision in November 2014 defined the current criteria with a precise definition of Gleason pattern 3 as small glands with variation in size and shape infiltrating amongst non neoplastic glands and Gleason pattern 4 according four different aspects as all cribriform growth (some of them previously considered as pattern 3), fused glands, ill defined glands and glomeruloid glands. But with the intention to improve the correlation with the clinical parameters a new grading system was. This new system follows the accepted the new Gleason patterns grouping them in five prognostic groups: Group 1 (Gleason 3+3), Group 2 (Gleason 3+4), Group 3 (Gleason 4+3), Group 4 (Gleason 4+4) and Group 5 (score Gleason 9 and 10). According this new arrangement an excellent correlation with the risk of biochemical recurrence we can obtain in needle biopsy and radical prostatectomy specimens.

Prostate cancer is considered insignificant (IPCa) when its presence does not bring any vital risk. IPCa in the radical prostatectomy is a small (< 5cc, No Gleason 4 or 5, organ confined, negative margins. The average prevalence is 18.3%. The pre-operative model to predict IPCa is difficult. In the IPCa identification can help the new ISUP Gleason revision, pattern 3 small glands with variation in size and shape and Gleason pattern 4 according four different aspects as all cribriform growth, fused, ill defined and glomeruloid glands. A new system was accepted grouping them in five prognostic groups: 1 (3+3), 2 (3+4), 3 (4+3), 4 (Gs8) 5 (Gs9,10), with excellent clinical correlation .

SP-0105

The role of MRI in active surveillance

G. Villeirs¹

¹Ghent University Hospital, Genitourinary Radiology, Ghent, Belgium

T2-weighted MRI (T2w) typically shows a prostate cancer as a low signal-intensity area among the high signal-intensity normal peripheral zone tissue background. In the transition zone, prostate cancer has an equally low signal-intensity, although contrasting less well with the surrounding heterogeneous signal-intensity of glandular and stromal hypertrophy. It has been shown that the observed signal intensity inversely correlates to some extent with the aggressiveness of the cancer (lowest signal intensities in

higher grade cancers). The sensitivity of T2w imaging for prostate cancer (of any Gleason grade) is quite high (up to 85%), but with a low specificity (about 55%) due to many false positive calls. Therefore, functional imaging tools are required to improve the overall diagnostic accuracy.

Diffusion-weighted MRI (DWI) is currently the most important functional technique in addition to T2w MRI. Its mechanism is based on the inhibition of spontaneous water diffusion in tumor areas, due to both increased cellularity (more hydrophobic cell membranes inhibiting water diffusion) and destruction of fluid-rich acini and ductules. Prostate cancers can hence be detected as areas of decreased signal-intensity on apparent diffusion coefficient (ADC) maps or as increased signal-intensity on high b-value images. It is more than noteworthy that a quite robust inverse correlation exists between ADC-values and tumor aggressiveness (lowest ADC-value in higher grade cancers).

Dynamic contrast-enhanced MRI (DCE) measures the amount and characteristics of tumoral neoangiogenesis. After an intravenous bolus injection of gadolinium-containing contrast media, prostate cancers tend to enhance earlier, more rapidly and with a more pronounced de-enhancement (wash-out) than benign or normal tissue. DCE greatly helps detecting cancers in the peripheral zone, but suffers from false positive calls in the transition zone due to similar enhancement characteristics in glandular hypertrophy.

Magnetic resonance spectroscopic imaging (MRSI) is a more advanced tool that currently is mainly performed in expert centers and in clinical trials. It is based on measurement of the relative concentrations of citrate and choline, markers of benign and malignant tissue, respectively. MRSI adds specificity to T2w MRI (reduction of false-positive findings), but its main value lies in its direct correlation between the choline-to-citrate ratio and tumor aggressiveness.

mpMRI currently more and more consists of T2w MRI combined with DWI. DCE is additionally performed in all cases by some institutions, or only in doubtful cases by others. Meanwhile, it remains very important that all mpMRI studies are performed according to uniform quality and reporting standards, as pointed out by the European Society of Urogenital Radiology Guidelines and the recently revised Prostate Imaging Reporting and Data System (PI-RADS version 2). The latter consists of a diagnostic probability scale, in which PI-RADS 1 and 2 signify "clinically significant disease (highly) unlikely", PI-RADS 3 "clinically significant disease is equivocal", and PI-RADS 4 and 5 signify "clinically significant disease (highly) likely". These scales are largely based on the unique ability of mpMRI to more easily detect high-grade and larger (i.e. clinically significant) tumors than small lower-grade lesions. This holds promise in the assessment of patients suspected of having prostate cancer. In patients who are candidates for active surveillance on the basis of clinical parameters, a PI-RADS 1 or 2 scale can corroborate this choice owing to a negative predictive value for excluding high-grade disease up to 98%, while in patients with a PI-RADS 4 or 5 a targeted biopsy can be performed in the suspicious area, including areas that are more difficult to reach with standard biopsy (e.g. anteriorly located tumors). PI-RADS 3, on the other hand, requires a biopsy in selected cases, taking into account clinical parameters such as PSA-density, PSA-kinetics, patient age and potential comorbidity. Hence, the performance for correctly assigning patients to active surveillance can be increased and mpMRI is currently recommended at enrolment in active surveillance by the UK National Institute for Health and Care Excellence (NICE).

SP-0106

Active surveillance: challenges and perspectives. The clinician point of view

R. Valdagni¹

¹Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Prostate cancer (PCa) is the most common male malignancy. The number of diagnoses has increased since the introduction of the PSA in the early '90ies. Up to 50% of the new PCa detected can be considered clinically insignificant or indolent: this relatively new concept in oncology means that these very well localized, small and non aggressive tumors

(GPS=3+3), which are generally diagnosed with a biopsy following PSA rises, would not cause symptoms and/or death during one's life. Despite this non aggressive behavior, most of these tumors are still treated with curative standard therapies (prostatectomy, external radiotherapy and brachytherapy), which, although equally effective treatment options, are burdened by potentially severe side effects.

As a matter of fact, there is no way to entirely distinguish upfront, before as well as after the biopsy, non aggressive, clinically insignificant, indolent tumors from aggressive, potentially lethal cancers that need to be treated immediately. To deal with the problem of overdiagnosis and overtreatment, active surveillance (AS) is being proposed in alternative to radical treatment to very selected men with favourable disease characteristics. AS is widely accepted in uro-oncologic communities and included in several guidelines, even if its routine application in the clinic is still suboptimal.

Understanding the natural history of clinically insignificant PCa is of primary importance to obtain reliable tools to select and follow-up AS patients. AS inclusion criteria are presently based on: T2a at DRE, PSA/PSA density, number and percentage of positive biopsy cores and GPS. Originally, the approach was more restrictive (i.e. selection of very low risk PCa patients). Nowadays, considering that feasibility and safety of these more strict protocols were assessed, more inclusive protocols are enrolling patients (e.g. including selected GPS=3+4).

One of the main issues AS is currently facing is the chance of "inadequate" diagnoses from biopsies, known to result in upgrading and upstaging at prostatectomy, especially for low-grade PCa. PSA/PSA density or the number of positive cores at diagnostic biopsy do not appear to be associated with the probability of upgrading patients initially fit for AS. This is the main reason to consider a confirmatory biopsy (time varying between 3 and 12 months) in most AS protocols, which can help identify patients ineligible for AS as a result of disease upgrading. The rate of "reclassification" at confirmatory biopsy varies between 16 and 30%, very similar to the one after prostatectomy.

Due to its great potential, MRI is increasingly used, being able to identify lesions that might be missed by standard biopsy. A positive MRI is associated to higher upgrading rates after prostatectomy and also after confirmatory biopsy. At present, in men on AS, MRI is used as an aid to detect clinically significant disease and help target suspicious lesions; however, there is still no solid evidence to endorse MRI in place of repeated biopsies.

Investigation on genetic/biomolecular/biochemical signatures is urgently needed to better classify our patients, trying to take benefit from non-invasive indicators of progression or reclassification. Research is currently focused on finding genetic signatures of both positive biopsy and adjacent normal tissue/stroma and on studying biomolecular markers possibly present in urine and blood (liquid biopsy). Recently, tests based on high expression of selected genes in biopsy specimens were found to be associated with higher risk of disease progression, but the possible true impact on AS is still to be determined.

AS follow-up plays a crucial role, since it enables to monitor the tumor behavior and potentially detect the more aggressive forms, which may benefit from treatment. In most protocols, follow up is based on clinical data (DRE, PSA and repeat biopsies), some protocols recently including mpMRI. Biomarkers (e.g. PCA3 or -2proPSA) are not routinely used in AS protocols, due to confusing results coming from the literature.

In conclusion, the results of AS programs should be primarily assessed on their ability to avoid overtreatment, while guaranteeing the same curability window of upfront radical treatments. The percentage of patients who remain treatment free is one of these measures, with current estimates being ~40% at 20 years from diagnosis. Evaluation of oncological outcomes such as OS and CSS rates is also important, being in the Canadian AS cohort 62% and 94% at 15 yrs, respectively. Secondary objectives should include quality-of-life and comparison of AS vs radical therapies costs. The variety of inclusion criteria and follow-up

protocols makes the evaluation difficult. However, to date, the published outcomes are similar to those in patients receiving immediate curative treatment.

Symposium: Achieving excellence in image guided brachytherapy

SP-0107

Physician training in contouring

P. Petric¹

¹*National Center for Cancer Care & Research A member of Hamad Medical Corporation, Doha, Qatar*

In the past 2-3 decades we have witnessed major advances of radiotherapy planning. These developments were based on implementation of sectional imaging, computerized treatment planning and high precision treatment technologies in the radiotherapy process. When compared with the conventional radiography based method, modern 3-4 dimensional approaches require accurate and reproducible delineation of the target volume and organs at risk on the sectional images of various modalities, including computed tomography, magnetic resonance imaging, positron emission tomography and ultrasound. Contouring variation represents one of the most important contributors to the overall uncertainties in radiotherapy. The dosimetric and clinical benefits of modern high precision radiotherapy can be compromised by inaccurate delineation [Njeh CF. *Med Phys* 2008]. Assurance of consistent and accurate contouring of the regions of interest is one of the main preconditions for safe treatment delivery, optimal clinical outcome and meaningful reporting and comparison of treatments.

In addition to high quality imaging and contouring guidelines, solid knowledge of radiological anatomy is a precondition to achieve best contouring standards. While this subject is recognized as one of the key competencies in the radiation oncology core curricula and training programmes [Eriksen JG, et al. *Radiother Oncol* 2012, www.acgme-i.org], there is limited published data regarding the actual impact of the teaching interventions on contouring skills and the characteristics of the learning curve [Jaswal JK, et al. *IJROBP* 2014, Cabrera AR, et al. *J Am Coll Radiol* 2011, Bekelman JE, et al. *IJROBP* 2009, D'Souza L, et al. *BMC* 2014]. Furthermore, published national surveys among radiation oncology residents and residency program directors indicate that there is room for improvement of training and evaluation of contouring competencies during residency [Jani AB, et al. *Pract Rad Onc* 2015, 12Jaswal JK, et al. *IJROBP* 2013].

Contouring training should not be viewed as a process limited to the residency and fellowship programs and core-curriculums. In a study evaluating the impact of prospective contouring rounds in a high volume academic centre, 36 % of cases required modification of contouring or written directives prior to treatment planning [Cox BW, et al. *Pract Rad Onc* 2015]. In a study of stereotactic body radiotherapy for lung cancer, the institutional peer-reviewers recommended major and minor changes of delineations in 23 % and 37 % of 472 contoured structures, respectively [Lo AC, et al. *J Thor Onc* 2014]. In view of the rapid developments of imaging and radiotherapy delivery, accompanied by constant evolution and development of new contouring recommendations, the importance of continuous education of the experienced practitioners, mentors and trainers cannot be overemphasized.

Research focusing on site-specific volumetric, topographic and qualitative aspects of contouring variation informs the educational activities in this field. The growing number of published inter-observer studies offers valuable resource to guide the training process. Limiting the learning to didactic and case-based instructions has improved knowledge scores and resident satisfaction in one study. However, this was not translated into improved contouring accuracy [D'Souza L, et al. *BMC* 2014]. In our experience, site-specific curriculum based on intensive sequence of didactic presentations, system-based instructions and hands-on contouring workshops represents an optimal strategy to achieve good learning

results [Segedin B, et al. Submitted to *Radiol Oncol* 2016]. Feasibility and effectiveness of similar intensive educational interventions has been confirmed by others [Jaswal J, et al. *IJROBP* 2014].

These favourable early outcomes of teaching cannot be extrapolated on the long-term scale. Further evidence-based characterization of the learning curve is required to quantify the needs for continuous education and identify strategies for long term knowledge consolidation. Relative impact of the individual educational modules and qualifications of trainers on the learning outcome needs to be quantified, taking the tumour-site specific challenges into account. Development of training tools, including e-learning platforms and tools for objective assessment of contouring represent some of the main pre-requisites for future improvements in this field.

SP-0108

Physicist training in 3D dose planning

P. Bownes¹

¹*St James Institute of Oncology, Department of Medical Physics and Engineering, Leeds, United Kingdom*

New physicists entering in to the speciality of brachytherapy normally undertake a formal training scheme in Medical Physics. Within the specialised field of brachytherapy the depth and breadth of training received can be dependent on the training scheme undertaken, training hospital's expertise in brachytherapy, length of time dedicated to brachytherapy training and the assessment process.

This presentation will summarise the key components of knowledge and experience a physicist should be expected to receive during their brachytherapy training and cross reference this to example training schemes. Several key questions need to be addressed when reviewing the training needs for image guided brachytherapy: Is additional training still required after completion of the formal training scheme? Are they appropriately focussed on image guided brachytherapy?

It is important that any training gaps are identified and that measures are put in place to ensure that physicists have an understanding across all the components of image guided brachytherapy, have a full appreciation of the uncertainties and limitations within the brachytherapy pathway and of the systems used.

Additional training resources will likely have to be explored to complement the core training schemes. Examples of available training resources will be presented and how they can potentially help facilitate the training and professional development of brachytherapy physicists.

It is important that we ensure that opportunities for physicist training is not restricted and that physicists are allowed to develop their knowledge, understanding and skill set required for the modern image guided brachytherapy era. Training schemes need to continue to evolve and new training resources explored to complement formal training schemes and work based learning.

SP-0109

New avenues for training with e-learning

L.T. Tan¹

¹*Addenbrooke's Hospital - Oncology Centre University of Cambridge, Cambridge, United Kingdom*

E-learning has the potential to deliver educational content to large numbers of learners world-wide. In 2008, Cook *et al* from the Mayo Clinic conducted a meta-analysis of 201 studies of e-learning in the health professions. They found that internet-based instruction for medical professionals is associated with favorable outcomes across a wide variety of learners, learning contexts, clinical topics, and learning outcomes. Internet-based instruction appears to have a large effect compared with no intervention and appears to have an effectiveness similar to traditional methods. In a separate review in 2010, they identified that interactivity, practice exercises, repetition, and feedback improved learning outcomes.

This talk discusses the potential of e-learning for teaching competency in target volume delineation (TVD). A crucial

component of such a programme is automated assessment of contours with individualised feedback. The talk will compare conventional and novel methods for creating reference contours for TVD assessment, and conventional and novel metrics for automated assessment of TVD competency in individuals and groups of learners. The talk will also discuss the potential to investigate the impact of different instructional designs (e.g. live lectures, podcasts, annotated clinical cases, interactive demos) on TVD competency using quasi-experimental methodology.

Symposium: Imaging markers for response prediction and assessment

SP-0110

Imaging markers for response prediction: the clinical need

V. Goh¹

¹Guys and St Thomas NHS Foundation Trust, Department of Radiology, London, United Kingdom

A variety of therapeutic options are now available to cancer patients. It is recognised that significant biologic heterogeneity exists that may affect a patient's likelihood of response to particular therapies and development of resistance on therapy. To be able to predict whether a patient will respond or not respond to a specific therapy is advantageous in streamlining patient management and minimising the costs of continuing therapy that is not working as well as minimising unwanted side-effects of such therapy. Imaging currently play an important role in routine clinical care and clinical trials in triaging patients to appropriate management and in monitoring patients on therapy. In terms of treatment assessment it is essential for imaging markers to be consistent, reproducible and validated. Standardized response assessment based on morphological change, such as RECIST 1.1 is well established in the clinical trial setting although its limitations for therapies beyond standard chemotherapy are recognised e.g. immunotherapy, and for which alternative response criteria have been proposed. Computed tomography (CT) remains that most commonly performed imaging modality due to its high spatial resolution and its cost-effectiveness, but positron emission tomography (PET) and magnetic resonance imaging (MRI) have advantages in their capability to image beyond morphology.

Measurement of glucose metabolism, cell proliferation, hypoxia, and vascularisation is now possible in clinical practice as well as quantification of their spatial variation, providing an imaging phenotype that is likely to be more beneficial than simple biomarkers e.g. size in predicting individual patient response to therapy. These imaging methods can also be integrated with genomic and pathological data allowing a comprehensive approach to address the clinical need towards individualisation of therapy in the future.

SP-0111

Response prediction in rectal cancer using PET Radiomics

R.T.H. Leijenaar¹, P. Lambin¹

¹MAASTRO clinic, GROW - School for Oncology and Developmental Biology- Maastricht University Medical Centre, Department of Radiation Oncology, Maastricht, The Netherlands

In personalized medicine, early prediction of pathologic complete response for locally advanced rectal cancer (LARC) patients is essential to tailor treatment. The standard treatment for LARC patients consists of preoperative chemoradiotherapy (CRT) followed by surgery, with a complete response being observed in 15-30% of the patients after the neo-adjuvant treatment. Overtreatment of complete responders could be avoided if an accurate prediction of pCR is available, by selecting a wait-and-see policy instead of surgery after CRT, and thereby reducing treatment related complications. Further treatment strategies based on the prediction of pCR include a radiotherapy boost after CRT for patients with good response to achieve a higher complete response rate, and additional

chemotherapy after initial CRT for the worst responding patients.

In recent years, [18F] fluoro-2-deoxy-D-glucose positron emission tomography (FDG-PET) imaging has been increasingly used for decision support, treatment planning and response monitoring during radiotherapy. Radiomics (www.radiomics.org; animation: <http://youtu.be/Tq980GEVPOY>) is a high throughput approach to extract and mine a large number of quantitative features from medical images, characterizing tumor image intensity, shape and texture. The core hypothesis of radiomics is that it can provide valuable diagnostic, prognostic or predictive information. FDG-PET radiomics may therefore facilitate early and accurate prediction of tumor response to treatment to identify LARC patients eligible for a wait and see or organ preserving approach, or patients who may benefit from treatment intensification.

This presentation will focus on the methodology of, and technical challenges in, the development and validation of a predictive PET radiomic model for pCR in LARC patients, illustrated with recent data.

⁷Martinos Center for Biomedical Imaging, Department of Radiology, Boston, USA

In vivo treatment verification is highly desirable, especially but not only in particle therapy where uncertainties in the particle range can compromise the physical advantage of this treatment modality. Existing measurement techniques for range measurements exploit physical effects, in particular secondary radiation that is produced by the proton beam, for example through activation of positron emitters, or prompt gamma radiation. Also biological effects caused by the irradiation can be used for *in vivo* treatment verification, if a functional imaging method is available to visualize the effect.

One prominent example for biology-driven range verification is an irradiation-induced change in contrast-enhanced MRI of the liver. A strong systematic decrease in uptake of the hepatobiliary-directed contrast agent Gd-EOB-DTPA has been shown in irradiated healthy liver tissue 6-9 weeks after irradiation [1-3] using different treatment modalities (brachytherapy, stereotactic body radiation therapy with photons and protons). The underlying mechanism seems to be based on a pro-inflammatory reaction of the irradiated liver tissue resulting in a downregulation of the Gd-EOB-DTPA uptake transporters and an upregulation of the respective excretion transporters [4].

In a prospective clinical study, carried out at Massachusetts General Hospital in Boston (USA), we investigated whether MRI of the liver can be used for *in vivo* dosimetric verification already during the course of hypo-fractionated proton therapy of liver metastases (5 fractions within 2 weeks). In contrast to the previously found late changes weeks after the end of treatment that were seen in all patients, for the early Gd-EOB-DTPA enhanced MR imaging large inter-patient variations were found. For 10 patients, strong or moderate signal changes were detected for 2 and 3 patients,

respectively. For 5 patients no dose-correlated early signal change was found at all. This qualitative scoring was consistent with a quantitative voxelwise dose to signal change correlation. The analysis of additional parameters that could potentially explain inter-patient variations (e.g. dose delivered at time of MRI scans, several timing parameters, liver function parameters and circulating biomarkers of inflammation determined from blood samples taken before and during treatment) revealed no clear correlation or trend with the strength of the signal decrease. Hence, irradiation-induced effects in the liver can be detected with Gd-EOB-DTPA enhanced MRI within a few days after proton irradiation in a subgroup of patients. As all patients possessed a signal decrease in late follow up scans, only the early dynamics of the liver response is influenced by these inter-patient variations. The reason for these large variations in early response is not yet fully understood and needs further investigation.

This presentation will cover a brief overview of biological effects used for treatment verification and will then focus on the irradiation-induced signal change in Gd-EOB-DTPA enhanced MRI of the liver. The hypothesis for the biological mechanism, the available data for late and early MRI signal changes will be presented and open questions will be discussed.

Debate: There are many existing IGRT options for highly accurate dose delivery. Is there a need for large-scale in-room MR-guidance?

SP-0113

For the motion

F. Lohr¹

¹University Medical Center Mannheim, Department of Radiation Oncology, Mannheim, Germany

The statements that will be made highlighting the strong position we are already in when using all currently available advanced image-guidance strategies are used are the following:

- If there is a necessity for on line MR-guidance, there is a general necessity for broad use of advanced image guidance strategies, particularly as successful screening programs such as those for lung cancer and potentially even pancreatic cancer are established, as this potentially leads to more localized disease being treated.

- Several such strategies are now available but are underutilized, typically for lack of funding or perceived complexity. Recent developments such as FFF-delivery and fast collimators have, however, shortened a lot of treatments and thus rendered advanced imaging strategies more feasible. Considerable expertise is needed, as it is mandatory also for MR-guidance.

- MR-guidance can be and has already been more easily applied to brachytherapy, a highly effective form of local therapy where technically applicable.

- Continuous 2D-tracking based on fiducials placed in minimally invasive procedures has entered the clinical routine for the ablation of small lesions without complex interference of OARs.

- 3D-imaging with CBCT, particularly in conjunction with breathhold strategies, still has considerable potential. Accuracies in the range of 3mm can be consistently achieved across treatment targets, in deep inspiration breathhold typically with very favorable dose distributions and straightforward dose accumulation. 4D-approaches are available, ultrafast "snapshot" volume imaging is ready to be deployed clinically.

- Ultrasound, where applicable, allows not only for positioning but for tracking in 2D and 3D.

- Surface scanning may simultaneously provide patient surveillance and gating signals during a therapy session.

- Noncoplanar treatment strategies and high-LET radiation may have further potential to improve clinical results

independent of imaging strategy and are currently not possible in conjunction with in-room MR-guidance.

The statements suggesting that in-room MRI guidance will add significantly to the current armamentarium comprise the following:

- Cancer is primarily a soft tissue disease. MRI offers unparalleled soft tissue contrast imaging across a wide range of cancer types and locations. In-room MRI guidance for cancer radiotherapy combines exquisite soft tissue imaging of the cancer and surrounding healthy structures with precision radiotherapy to optimally target the cancer and spare healthy tissues, affecting quality of life, cancer outcomes and reducing the health and economic burden of managing treatment-related side effects.

- This ability to simultaneously image and target the cancer with radiotherapy is intuitive to patients and the treatment team alike. Indeed, the image quality of MRI-guidance is so high that a commercial online adaptive radiotherapy solution is only available with these systems.

- Cancer physiology is heterogeneous and changes with time. MRI is the only in-room physiological targeting system for cancer radiotherapy. An example, tumor hypoxia, is a strong negative prognostic indicator of survival across a wide range of cancer sites, and the tumor hypoxic status changes over the time period of a single treatment. The ability to selectively image and target the most aggressive and resistant parts of the cancer opens up a new window to dramatically change cancer outcomes.

- In addition to in-room MRI-guidance offering an improved treatment across a range of cancer sites, this new device also opens up the opportunity to explore the treatment of non-oncologic diseases. An example is atrial fibrillation, a disease suffered by 6 million Europeans, with many of these patients treated in an invasive, long, expensive procedure. MRI-guided radiotherapy offers a non-invasive, short and cost-effective treatment of atrial fibrillation. This treatment is enabled by using MRI to solve the challenging problem of imaging and targeting small volumes affected by both respiratory and cardiac motion, a problem too difficult for other in-room imaging systems.

- The improved outcomes and applications observed from in-room MRI-guided radiotherapy will affect patient referral patterns and policy guidelines to increase the global radiotherapy need, benefiting the radiation oncology and global communities.

Functional and molecular imaging techniques and personalised radiotherapy

M. Niyazi¹

¹Klinik und Poliklinik für Strahlentherapie und Radioonkologie, Department of Radiation Oncology, München, Germany

Advances in radiotherapy delivery have been due to improved technique and image guidance. In contrary to the "one size fits it all" paradigm, personalized medicine tries to incorporate all available imaging information in order to optimally delineate the target volume. It will be highlighted, in how far molecular imaging such as PET has become a cornerstone for certain types of cancer and how PET information may be integrated into target delineation. Furthermore, it will be discussed in how far there is a role for a biological target volume (BTV) and how appropriate margins can be chosen; new tracers beyond FDG are discussed. The meaning of MRI and its applications as well as

available pitfalls will be presented employing an example of a brain tumor treatment.

SP-0116

General recontouring with deformal registration

X. Geets¹, E. Sterpin², J. Lee²

¹UCL Cliniques Univ. St.Luc - MIRO Lab - IREC, Radiation Oncology, Brussels, Belgium

²UCL - MIRO Lab - IREC, Radiation Oncology, Brussels, Belgium

Significant patient anatomy changes may occur during the course of radiotherapy, more particularly for head and neck, pelvic and lung tumours. These modifications may degrade the plan quality over time, and hence require treatment adaptation based on the anatomy depicted from images of the treatment day.

Any comprehensive adaptive solution will necessarily require automatic tools that, first, depict patients who actually need adaptation (dose recomputation on daily image and clinical indicators of plan quality), and then assist the radiation oncologist/therapist in the labour-intensive task of target volumes and organs at risk recontouring. Ultimately, this approach should allow treatment plan re-optimization if required, without unmanageable additional workload in real-life clinical routine.

In this framework, deformable image registration allows the alignment of datasets in a non-linear way, providing a voxel-to-voxel mapping between the initial planning scan and the treatment scan. Therefore, deformation maps can be applied to propagate contours from planning CT to daily images, but also to compute dose distribution from the deformed images for dose accumulation purpose.

In this presentation, we will describe the general framework of deformable image registration, and will cover the main class-solutions for registration-based recontouring according to the tumor location and the available imaging modality, i.e. kV- or MV/CB-CT. Typical adaptive workflows based on deformable registration will be presented, as well as their advantages and potential limitations. Last, we will emphasize the essential role of the operator for accuracy and consistency check of the deformed contours, any inaccuracy in this step necessarily introducing systematic errors in the planning process.

SP-0117

Clinical application of atlas-based autosegmentation for contouring of multiple treatment sites

M. Ten Kleij¹, J.J. Penninkhof¹, M. Stoevelaar¹, S. Quint¹, B.J.M. Heijmen¹, M. Hoogeman¹

¹Erasmus Medical Center Rotterdam Daniel den Hoed Cancer Center, Department of Radiotherapy, Rotterdam, The Netherlands

In the Erasmus MC radiotherapy department, atlas-based auto-segmentation of both clinical target volumes and organs at risk (OARs) is an important time-saving tool in daily clinical routine to assist both physicians and technicians. The accuracy of delineations has become increasingly important due to enhanced conformality of dose distributions as realized by IMRT and VMAT, and the use of reduced PTV margins in combination with image guidance. Clinical validation of atlas-based auto-segmentation for head-and-neck patients showed a reduction of hands-on time for delineation from 180 to 66 minutes, where structures were evaluated as 'minor-deviations, editable' or better (D. Teguh; Int. J. Radiation Oncology Biol. Phys., Vol. 81, No. 4, pp. 950-957, 2011). The influence of geometric differences between autocontours and manual delineations by different observers on the dosimetric impact can differ for CTV and for OAR (Voet PW, Radiother. Oncol. 2011 Mar;98(3):373-7). We clinically implemented Admire (Elekta AB, Sweden) as part of our workflow in 2010. In this workflow, critical review and editing of the autocontours is still relevant.

For several target sites, a database was created containing fully contoured reference CT data sets (atlases). Depending on the tumor site, one or more atlases are used as an input for the generation of the patient-specific delineation (using

the staple algorithm). The strategy of a single atlas can particularly be useful in case of adaptive treatments, resulting in a quick and more accurate autocontouring using the original delineated patient CT as the only atlas. An overview of the clinical implementation of Admire with regard to several tumor sites and the relation to treatment techniques such as breath-hold will be presented.

Purpose or Objective: Preoperative level of CA 19-9 (prCA19.9) predicts survival of patients (pts) undergoing surgery for pancreatic adenocarcinoma (PAC). Actually, there is no evidence of using prCA19.9 as a marker customizing and modulating effectiveness of adjuvant treatment or predicting pattern of failure. Therefore, the purpose of this pooled analysis was to determine whether prCA19.9 could predict overall survival (OS), local control (LC), disease metastasis free survival (DMFS) and evaluate effectiveness of adjuvant therapies in a broad population.

Material and Methods: We performed a multicenter retrospective analysis of 1122 patients (pts) who underwent surgical resection +/- adjuvant treatment [chemotherapy (aCT), radiotherapy +/- concomitant CT (RCT)] for PAC between 2000 and 2014 from 8 different institutions. Among 700 pts with prCA19.9 value we applied the Kaplan-Meier method and the log-rank test to investigate differences in OS, LC, DMFS between defined groups based on: clinical and pathological factors, 4 prCA19.9 cutoff (5, 37, 100, 353) and 5 relative prCA19.9 classes (0.0-5.0, 5.1-37.0, 37.1-100, 100.1-353.0, >353.1). We fitted Weibull regression model with shared frailty on institution to identify independent predictors of OS using data from 404 pts with complete information. We applied a backward stepwise strategy to select the covariates, forcing CRT and RT in the final model.

Results: Median follow-up (FU) was 27 months (2-225). At univariate analysis there was a strong impact of prCA19.9 classes (0.0-5.0, 5.1-37.0, 37.1-100, 100.1-353.0, >353.1) on 5-years OS (5.7% vs 37.9 vs 27.1 vs 17.4 vs 10.9, p< 0.001, Figure 1), 5-years LC (47.2% vs 63.3% vs 59.4% vs 43.4% vs 50.2%, p= 0.008), 5-years DMFS (17.0% vs 46.0% vs 39.0% vs 26.7 vs 23.4, p<0.001), respectively. Only in pts with prCA 19.9 > 353.1 U/ml aCT had positive impact on 5-year OS

(47.4% in pts treated with aCT vs 30.2% in pts not treated with aCT, $p = 0.006$). At multivariable model, sub-analysis of 404 pts showed (Table 1): worse OS for grading 3 tumor (HR: 1.85 95%CI 1.26-2.70, $p = 0.002$) tumor diameter > 30 mm (HR: 1.85, 95%CI: 1.35-2.53, $p < 0.001$), and better OS for pts treated with RCT doses > 50 Gy (HR: 0.38, 95%CI: 0.23-0.63, $p < 0.001$). Median OS worsened in pts with prCA19.9 >100 and <353 (HR: 1.77, 95%CI: 1.23-2.56, $p = 0.002$) and in pts with prCA19.9 ≥ 353.1 (HR: 1.92, 95%CI: 1.34-2.76, $p < 0.001$).

	>353.1	18	1.92	(1.34-2.76)	<0.001	PH	22	22	1.00	(Ref.)	<0.001

Abbreviations: CI, confidence interval; HR, hazard ratio; Head: Head; DP, distal pancreatectomy; OS, overall survival; PH, parameter; R², coefficient of determination; RCT, radiotherapy; RT, radiotherapy; Ref., reference category; RT, radiotherapy.

Conclusion: PrCA19.9 was a marker predicting OS and pattern of failure. ACT had positive impact on 5-year OS in pts with prCA19.9 > 353.1 U/ml. Our results suggest that prCA19.9 should be included in predictive models in order to customize treatments basing on prognostic factors of individual pts. Innovative treatments should be tested especially in pts with high prCA19.9 value.

PV-0119

Pattern of regional recurrence in adenocarcinoma of GEJ: implication for target delineation

J. Zhang¹, J. Jin¹, X. Wang¹

¹Cancer Hospital- CAMS, Radiation Oncology, Beijing, China

Purpose or Objective: To investigate the frequency and location of regional recurrence of locally advanced adenocarcinoma of GEJ patients after curative resection and refine the clinical target volume (CTV) delineation of radiotherapy.

Material and Methods: From 2009 to 2013, we retrospectively reviewed 1140 esophagogastric cancer patients treated in our institute. Patients who had curative resection, and were histopathologically diagnosed with locally advanced adenocarcinoma of GEJ (T3/4 or any N+) and confirmed of regional recurrence in follow-up CT images were selected into the analysis. First regional recurrence was recorded and one diagnostic radiologist with specialty of gastrointestinal tract investigated. The frequency and location of regional failure at each node station were analyzed according to Siewert types. Reference CT images was obtained from a healthy volunteer. We then delineated the epicenters of recurrence sites at the equivalent location,

based on the same vessels of reference CT images compared with the recurrence CT images on Pinnacle treatment planning system. The combined contour of all recurrence sites was presented on a digitally reconstructed radiograph (DRR) image.

Results: Regional recurrence was identified in 78 patients. The majority of recurrence occurred within 2 years of follow-up (Median, 10.9 months). Of all, 35 (44.9%) patients were regional nodular failure (NF) only, 24 (38%) experienced regional NF simultaneous with distant failure, 11 (14.1%) were locoregional, and 8 (10.3%) had concurrent distant and locoregional failure. The most common recurrent lymph nodes station were No.16 (62.8%), No. 9 (32.1%), No. 11 (24.4%), No. 8 (17.9%), No. 7 (16.7%), No. 112 (12.8%), No. 4 (12.8%) and No. 12 (10.3%), respectively. 11 patients (14.1%) had recurrence at mediastinal lymph nodes. There was significant difference of NF in No. 9 (42.2% vs 18.2%, $P = 0.027$) between Siewert type II and III AEG, but no difference was observed in the other node stations. Different frequency and location of regional recurrence were shown by CT and digitally reconstructed radiograph (DRR) images. A three-dimensional (3D) atlas based on vessel delineation and distribution of regional recurrence was established.

Conclusion: The most prevalent nodal recurrence in patients with adenocarcinoma of GEJ after curative resection was along the abdominal aorta, celiac artery and splenic artery. Our findings suggest a modified elective lymphatic nodal target volume for IMRT contours in those patients.

Gastric fundus irradiation increases risk of postoperative anastomotic leakage in esophageal cancer

L. Goense¹, P.S.N. Van Rossum¹, J.P. Ruurda², M. Van Vulpen³, G.J. Meijer³, R. Van Hillebersberg²

¹UMC Utrecht, Department of Radiotherapy and Department of Surgery, Utrecht, The Netherlands

²UMC Utrecht, Department of Surgery, Utrecht, The Netherlands

³UMC Utrecht, Department of Radiotherapy, Utrecht, The Netherlands

Purpose or Objective: Concerns have been raised regarding the toxicity of neoadjuvant chemoradiotherapy (nCRT) for esophageal cancer that could contribute to an increased risk of complications after subsequent esophagectomy such as anastomotic leakage. In this respect, radiation dose to the gastric fundus is of interest as this part of the stomach is used for the esophagogastric anastomosis after esophagectomy. The aim of this study was to determine the influence of neoadjuvant radiation dose to the gastric fundus on the risk of postoperative anastomotic leakage in patients with esophageal cancer undergoing nCRT followed by transthoracic esophagectomy.

Material and Methods: Between 2012 and 2015, 97 consecutive patients with esophageal cancer who underwent nCRT followed by transthoracic esophagectomy with cervical anastomosis were analyzed. The nCRT regimen consisted of a total radiation dose of 41.4 Gy in 23 fractions of 1.8 Gy in 5 weeks combined with weekly intravenous administration of carboplatin and paclitaxel. The gastric fundus was retrospectively contoured on the pre-treatment planning CT. Within this contour, dose-volume histogram parameters were calculated and univariable and multivariable logistic regression analyses were used to determine their influence on the risk of anastomotic leakage.

Results: In 25 patients (26%) anastomotic leakage occurred. The mean radiation dose to the gastric fundus was significantly higher in patients with versus without anastomotic leakage (median [interquartile range]: 35.6 Gy [20.2-39.9] versus 24.9 Gy [11.9-35.1], respectively; $p = 0.047$, Table 1). A mean dose above versus below 31.4 Gy was associated with leakage rates of 43% versus 15%, respectively. Two typical examples of dose distributions in relation to the gastric fundus in patients with and without

anastomotic leakage are depicted in *Figure 1*. Adjusted for potential confounders including tumor location, clinical T-stage and radiation modality, the mean radiation dose to the gastric fundus remained significantly and independently associated with an increased risk of anastomotic leakage in multivariable analysis (adjusted odds ratio 1.05 per 1 Gy increase, 95% confidence interval: 1.003-1.10, $p=0.035$). Also, in patients with anastomotic leakage the minimum radiation dose, V25, V30, and V35 to the gastric fundus were significantly higher (*Table 1*).

Figure 1. Examples of pre-treatment planning CT scans with dose distributions in (A) a patient who developed postoperative anastomotic leakage after receiving a mean dose to the gastric fundus of 41.2 Gy, and in (B) a patient who did not experience postoperative anastomotic leakage after receiving a mean dose to the gastric fundus of 11.8 Gy. The areas within the yellow, light blue, dark blue and purple lines received at least 40, 30, 20, and 10 Gy, respectively.

Table 1. Univariable logistic regression analysis of gastric fundus dose characteristics among patients with versus without anastomotic leakage.

[†]Significant difference between patients with versus without anastomotic leakage ($p < 0.05$).
[‡]Odds ratio per 10% increase in volume-percentage.
 OR: odds ratio; CI: confidence interval.

Conclusion: Neoadjuvant radiation dose to the gastric fundus has a significant influence on the risk of postoperative anastomotic leakage in patients with esophageal cancer treated with nCRT followed by transthoracic esophagectomy and cervical anastomosis. This finding is important for clinical practice because it suggests that efforts should be made to minimize the radiation dose to the gastric fundus when planning neoadjuvant radiation treatment for esophageal cancer.

PV-0121

Falcon based Clinical Target Volume Delineation to support Inter-Society Rectal Cancer Guidelines.

M. Gambacorta¹, G. Chiloiri¹, P. Das², K. Haustermans³, I. Joye³, L. Kachnic⁴, P. Maingon⁵, C. Marijnen⁶, S. Ngan⁷, V. Valentini¹

¹Università Cattolica del Sacro Cuore, Radiation Oncology Department, Rome, Italy

²University of Texas MD Anderson Cancer Center, Department of Radiation Oncology, Houston, USA

³University Hospitals Leuven, Department of Oncology, Leuven, Belgium

⁴Boston Medical Center, Department of Radiation Oncology, Boston- Massachusetts, USA

⁵Centre Georges-François Leclerc, Department of Radiation Oncology, Dijon, France

⁶Leiden University Medical Center, Department of Radiation Oncology, Leiden, The Netherlands

⁷Peter MacCallum Cancer Centre, Division of Radiation Oncology and Cancer Imaging, Melbourne, Australia

Purpose or Objective: The delineation of clinical target volume (CTV) is a crucial step in radiation therapy procedure. Uncertainties are related to the availability of several contouring guidelines suggesting different subvolumes and anatomical limits in rectal cancer. Furthermore, individual training creates large inter-operator variability in delineation. An international consensus among expert radiation oncologists might significantly reduce this variability. The definition of the procedures needed to produce consensus guidelines for rectal cancer through

Falcon, the educational web-based multifunctional platform for delineation endorsed by ESTRO, was the primary aim of this study

Material and Methods: Seven skilled radiation oncologists, delegated from ESTRO, ASTRO, TROG, EORTC, defined the steps to produce consensus rectal cancer guidelines on elective nodal level delineation during a preliminary meeting held in August 2014. Step 1: six rectal cancer cases with different clinical stage were chosen and the related CT scans were shared and unanimously approved. Step 2: the experts firstly delineated online the selected CT scan slices following each his own approved guidelines. Step 3: Meeting on person to discuss the first delineation outcome, with also surgeon and radiologist ad hoc invited. Step 4: all the experts had to delineate online the same CT scan slices, based on the new table of boundaries. Step 5: Peer review meeting to evaluate the final outcome and to define the publication plan. The degree of agreement was evaluated through the EduCause™ STAPLE algorithm (ECSa). Step 6: preparation of the cases in Falcon to allow a free consultation after the publication of the guidelines

Results: Falcon platform allowed to succeed in any steps: selection and upload of the proper CT scans proposed among the experts leaving different countries; optimal compliant of all expert their delineation exercise; the possibility to review and share the online delineation, to support the discussion by telephone conference. Some Falcon's features were considered significant to compare concurrently all the experts' delineations, allowing to identify critical nodal boundaries as areas of disagreement. Furthermore the ECSa, has allowed to evaluate during the validation step the degree of agreement where the shared voxels between experts' delineations are graphically represented through an area with different levels of confidence (from 85% to 100%) for each structure set.

Conclusion: The ESTRO's Falcon platform of delineation showed to be a valuable tool in the definition of consensus guidelines for rectal cancer. These procedures might be reproduced to support the validation, discussion and comparison of delineations among skilled radiation oncologists to converge to consensus guidelines also for other scenarios.

PV-0122

Clinical factors as a selection tool for organ-preserving treatment strategies in rectal cancer

I. Joye¹, A. Debucquoy², S. Fieuws³, A. Wolthuis⁴, A. D'Hoore⁴, K. Haustermans¹¹KU Leuven/University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium²KU Leuven, Department of Oncology, Leuven, Belgium³KU Leuven/Hasselt University, I-Biostat, Leuven, Belgium⁴University Hospitals Leuven, Department of Abdominal Surgery, Leuven, Belgium

Purpose or Objective: The standard treatment for locally advanced rectal cancer is radio(chemo)therapy (RCT) followed by total mesorectal excision (TME) surgery. Patients who achieve a good response to RCT may be offered less invasive surgery such as local excision or even no surgery at all. Before such a policy could be safely implemented, precise selection of the eligible patients is mandatory. This study identifies the pretreatment clinical factors that are associated with pathological complete response (pCR) and ypT0-1N0 and evaluates their performance as a tool to select patient for organ-preserving treatment strategies.

Material and Methods: Patients with histologically confirmed rectal adenocarcinoma who were treated with preoperative RCT and TME between January 2000 and December 2014 were retrospectively included. Patients who received no preoperative RCT, patients treated with postoperative RCT and those treated for a local recurrence were excluded. Following pretreatment clinical characteristics were extracted from the medical files: age, gender, body mass index, ASA score, cT-stage, cN-stage, tumor distance from the anal verge, pretreatment CEA, pretreatment hemoglobin and distance from the mesorectal fascia. Univariable and multivariable binary logistic regression models were used to predict pCR and ypT0-1N0. A multivariable prediction model was obtained by combining all predictors and by applying a backward selection procedure with 0.157 as critical level for the p-value. The discriminative ability of the prediction models was evaluated by receiver operating characteristic analysis. To avoid that the same data were used to develop and to validate the model, the area under the curve (AUC) was based on a leave-one out cross-validation.

Results: A total of 620 patients were included of whom 120 patients experienced a pCR (19%) and 170 patients achieved a ypT0-1N0 response (27%). A low pretreatment CEA, a high pretreatment hemoglobin and a high cN-stage were associated with pCR in multivariable analysis (Table). A low pretreatment CEA, a low cT-stage and a high cN-stage were associated with ypT0-1N0. After cross-validation, the AUC of the pCR and ypT0-1N0 prediction model equaled 0.609 and 0.632, respectively.

Table: Multivariable logistic regression models to predict pCR and ypT0-1N0

		pCR		ypT0-1N0	
		OR (95% CI)	p-value	OR (95% CI)	p-value
Gender	Female	1.62 (0.99-2.66)	0.0557	1.15 (0.74-1.79)	0.5282
	Male	#		#	
Age at surgery		1.02 (0.99-1.04)	0.0624	1.01 (0.99-1.03)	0.3110
BMI		0.98 (0.93-1.03)	0.3626	0.97 (0.92-1.01)	0.1464
ASA			0.6832		0.7203
	ASA=2	0.98 (0.56-1.72)	0.9504	1.23 (0.74-2.05)	0.4308
	ASA=3	1.30(0.59-2.86)	0.5087	1.12 (0.54-2.35)	0.7614
	ASA=1	#		#	
cT-stage/MRF			0.1860		0.0009
	cT=3/MRF-	0.86 (0.44-1.66)	0.6458	0.44 (0.24-0.78)	0.0054
	cT=3/MRF+	0.53 (0.26-1.08)	0.0798	0.28 (0.15-0.52)	<0.0001
	cT=4	1.00 (0.40-2.48)	0.9966	0.47 (0.21-1.06)	0.0674
	cT=1-2	#		#	
cN-stage			0.0453		0.0176
	cN=1	3.42 (1.03-11.32)	0.0444	2.96 (1.17-7.52)	0.0226
	cN=2	4.52 (1.32-15.55)	0.0167	3.96 (1.50-10.43)	0.0054
	cN=0	#		#	
Distance to anal verge		1.00 (0.95-1.05)	0.9015	0.98 (0.94-1.03)	0.4714
	Initial CEA	0.86 (0.74-1.00)	0.0490	0.79 (0.68-0.90)	0.0006
	Initial Hb	1.30 (1.10-1.53)	0.0023	1.15 (1.00-1.32)	0.0526

Abbreviations: BMI = body mass index; CEA = carcinoembryonic antigen; Hb = hemoglobin; MRF = mesorectal fascia; OR = odds ratio; pCR = pathological complete response.

Conclusion: Despite their statistical significance, the value of pretreatment clinical variables in the prediction of pCR and ypT0-1N0 is very limited. To safely select rectal cancer patients for organ-preservation, other strategies using functional imaging or molecular markers need to be explored.

PV-0123

Gender and secondary malignancies in rectal cancer patients with and without radiation therapy

R. Warschkow¹, U. Güller², T. Cerny², B.M. Schmied¹, L. Plasswilm³, P.M. Putora⁴¹Kantonsspital St. Gallen, Department of Surgery, St. Gallen, Switzerland²Kantonsspital St. Gallen, Department of Medical Oncology and Hematology, St. Gallen, Switzerland³Kantonsspital St. Gallen, Department of Radiation Oncology, St. Gallen, Switzerland⁴Kantonsspital St. Gallen, Radiation Oncology, St. Gallen, Switzerland

Purpose or Objective: The relationship between radiation therapy for rectal cancer and secondary malignancies is debated. The present study is the first population-based analysis using conventional multivariable analyses as well as propensity score matching to assess this relationship.

Material and Methods: Overall, 87,956 patients after resection of localized or locally advanced rectal adenocarcinoma diagnosed between 1973 and 2012 were identified in the Surveillance, Epidemiology, and End Results (SEER) registry. The occurrence of secondary malignancies diagnosed at least 1 year after diagnosis of rectal cancer was compared in patients who did and did not undergo radiation using adjusted and propensity score matched Cox regression analysis.

Results: Of 77,484 patients, 34,114 underwent radiation and 43,370 did not. Overall, radiation therapy was not associated with secondary malignancies (hazard ratio [HR] = 0.97 (95%CI: 0.92-1.02, P=0.269). In female patients (HR = 1.11, 95%CI:1.02-1.21, P=0.021) the risk for secondary malignancies was increased after radiation therapy, while a decrease of secondary malignancies was found in male patients (HR = 0.90, 95%CI:0.85-0.96, P=0.002). The risk for prostate cancer was significantly decreased (HR=0.44, 95%CI:0.38-0.51, P<0.001) whereas the risk for endometrial cancer was increased (HR=2.07, 95%CI:1.56-2.75, P<0.001). The risks for lung cancer (HR=1.20, 95%CI:1.08-1.34, P<0.001), bladder cancer (HR=1.50, 95%CI:1.26-1.78, P<0.001), and lymphoma (HR=1.29, 95%CI:1.02-1.62, P=0.032) were increased after radiation in the overall population.

Conclusion: The present analysis provides compelling evidence regarding gender-specific differences in the occurrence of secondary malignancies after pelvic radiation. Indeed, radiation for rectal cancer is associated with a significantly decreased risk of prostate cancer, however, an increased risk of endometrial, lung, and bladder cancer as well as lymphoma. Patients undergoing radiation for rectal cancer must be informed regarding the potentially increased risk of secondary malignancies.

PV-0124

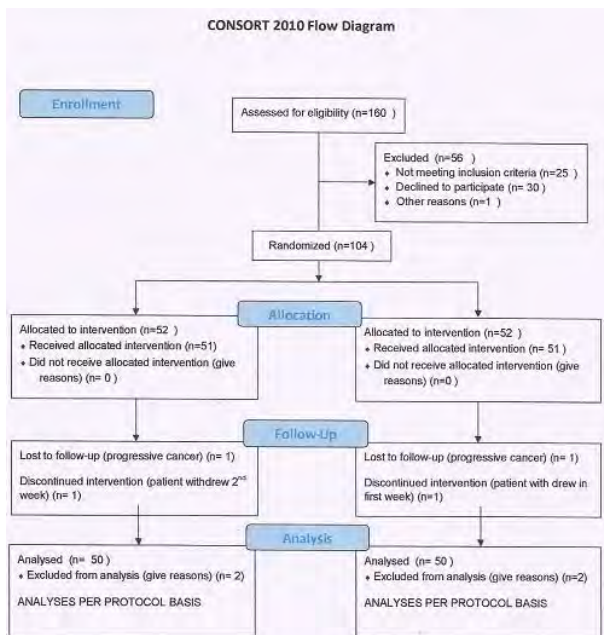

Does daily intake of resistant starch reduce the acute bowel symptoms in pelvic radiotherapy? RCT

B.K. Sasidharan¹, P.N. Viswanathan¹, S. Prasanna², B. Ramadass³, S. Pugazhendhi⁴, B.S. Ramakrishna⁵¹Christian Medical College Hospital, Radiation Oncology, Vellore, India²Christian Medical College Hospital, Biostatistics, Vellore, India³Christian Medical College Hospital, Wellcome Research-Microbiology, Vellore, India⁴Christian Medical College Hospital, Wellcome Research-Biochemistry, Vellore, India

⁵Christian Medical College Hospital, Gastroenterology, Vellore, India

Purpose or Objective: The purpose of the study is to look at the benefit of administration of an oral prebiotic starch in reducing the incidence of acute radiation proctitis, a distressing symptom in patients receiving radiation therapy for cancer of the cervix.

Material and Methods: The study was conducted between 2011 and 2014 in 104 patients receiving radical chemoradiotherapy for carcinoma cervix. Patients were randomized to two arms receiving 30 gm of resistant starch or digestible starch on a daily basis through out the course of the external radiotherapy. All patients received standard 4-field box radiation portals, 50 Gy in 25 fractions with 4 cycles of weekly concurrent Cisplatin. All of them underwent LDR brachytherapy of 30 Gy at completion of external beam radiotherapy. The study was double blinded and allocation was concealed from the investigators. The investigator recorded the radiotherapy related toxicity of the patients according to CTC V 3.0. The incidence and severity of grade 2-4 diarrhoea and proctitis were documented on a weekly basis and compared across the two randomized groups and analysed. Stool short chain fatty acid concentrations were measured at baseline at 2nd and 4th week and after 6 weeks of completion of radiotherapy in both study arm and placebo arm and reported. 2 patients progressed during therapy and were not included in analyses and two patients discontinued the intervention. A per protocol analyses was done.

Results: At analysis there were 50 patients in each arm. The severity of clinical proctitis was found to be similar in both groups of patients with 12.2 % of patients experiencing toxicity of grade 2 and above in digestible starch group versus 14.6% in the resistant starch group. Functional proctitis was similarly graded and it was found that 16.3 % patients in digestible starch group experienced toxicity against 10.2 % patients in the amylase resistant starch group. This difference was seen at 4th week and continued in the subsequent weeks till the end of radiation. Both groups had similar reported toxicity at 6 weeks post intervention. Both groups were also found to have similar incidence of grade 2 and above diarrhea. The non-digestible starch group was found to have 8% incidence as compared to 2% in the other group at the 5th and 6th week. The short chain fatty acid concentrations were found to be not significantly different in the groups at any point.

Variables	n	Digestible		n	Non-Digestible		
		Mean(SD)	Median(min,max)		Mean(SD)	Median(min,max)	
Acetate	Time 1	49	66.41(19.2)	64.07(22.4,120.3)	49	69.74(27.9)	65.99(17.2,141.6)
	Time 2	48	66.7(33.9)	66.26(23.4,181.1)	44	71.82(30.8)	70.57(23.9,158.1)
	Time 3	46	62.41(27.78)	51.68(24.3,134.3)	43	73.02(36.4)	67.72(18.2,151.7)
	Time 4	39	69.49(25.6)	64.04(25.9,129.7)	36	69.74(33.8)	59.68(17.1,169.3)
Propionate	Time 1	48	10.9(5.9)	10.29(1.5,21.2)	48	10.64(6.3)	8.64(2.4,30.5)
	Time 2	45	11.09(8.5)	8.34(0.28,39)	43	9.91(7.6)	8.74(1.2,37.2)
	Time 3	42	9.48(6.9)	6.88(0.03,28.8)	42	9.38(8.0)	7.76(0.1,40.8)
	Time 4	39	12.76(7.7)	10.72(2.3,34.3)	35	11.81(7.2)	10.76(1.5,30.1)
Butyrate	Time 1	48	19.48(13.8)	14.73(1.3,60.23)	49	16.85(11.9)	13.48(0.8,60.23)
	Time 2	47	14.99(10.6)	12.45(0.5,6.4)	44	14.31(7.3)	13.82(2.6,30.9)
	Time 3	45	15.79(11.2)	16.3(0.3,48.1)	43	16.5(15.5)	10.82(0.5,82.9)
	Time 4	39	18.51(13.6)	12.76(1.3,36.3)	36	19.61(15.1)	15.82(2.3,85.0)

Conclusion: The study failed to demonstrate a benefit in administration of resistant starch in excess of normal diet to patients receiving pelvic radiotherapy. This may be postulated to be due to concurrent use of chemotherapy and decrease in intestinal probiotics.

⁵S. Orsola-Malpighi Hospital- University of Bologna, Department of Medical and Surgical Sciences DIMEC, Bologna, Italy

⁶Bellaria Hospital, Radiotherapy Department, Bologna, Italy

⁷Policlinico Universitario "A. Gemelli"- Catholic University of Sacred Heart, Department of Gynecologic Oncology, Roma, Italy

Purpose or Objective: To compare treatment outcomes in locally advanced cervical carcinoma (LACC) patients treated with neoadjuvant chemoradiation followed by radical surgery (surgery group: SG) versus radical chemoradiation plus brachytherapy boost (control group: CG). Results in terms of local control (LC), metastases-free survival (MFS), disease free survival (DFS) and overall survival (OS) were compared.

Material and Methods: Seventy-six patients with LACC (SG) were matched to 76 patients (CG) with respect to age, histology and stage. Matching was performed without knowledge of outcomes. Patients characteristics are summarized in Table 1. The median FU was 35 months (range: 2-107) for SG and 29 months (range: 1-125) for CG, respectively.

Table 1: Patient Characteristics

	Surgery group	Control group	P-value
Age			
Median	64	66	0.001
Range	51-87	50-99	
Stage			
IIb	47 (61.8)	42 (55.3)	0.214
IIa	4 (5.3)	1 (1.3)	0.101
IIIb	8 (10.5)	8 (10.5)	0.992
IVa	3 (3.9)	3 (3.9)	0.992
IVb	3 (3.9)	1 (1.3)	0.100
Histology			
Squamous	67 (88.1)	67 (88.1)	1.000
Adenosarcoma	3 (3.9)	3 (3.9)	0.992
Other	3 (3.9)	3 (3.9)	0.992

Results: At univariate analysis no significant differences between the two groups were recorded. Two-year and 5-year LC were 77.6% and 71.0% for SG and 76.1% and 70.3% for CG

($p=0.8$), respectively. Two-year and 5-year MFS were 79.3% and 70.8% for SG and 78.8% and 78.8% for CG ($p=0.6$), respectively. Two-year and 5-year DFS were 71.9% and 61.6% for SG and 66.1% and 61.0% for CG ($p=0.8$), respectively. Two-year and 5-year OS were 90.9% and 84.4% for SG and 90.3% and 69.9% for CG ($p=0.4$), respectively.

Conclusion: The two treatment approaches achieved comparable outcomes in patients with locally advanced cervical carcinoma. Further analyses are needed to compare the toxicity profile of these two treatment strategies.

Joint Symposium: ESTRO-ESR: MR-PET

SP-0126

MR-PET for radiation oncology: the imaging perspective

K. Riklund¹

¹Umeå University- Umeå University Hospital, Department of Diagnostic Radiology, Umeå, Sweden

MR-PET is an advanced hybrid imaging method giving both structural, functional, molecular and biochemical information simultaneously or almost simultaneously. There are still challenges, not only with the attenuation correction, but also with performance of the examination and timing of the MR and PET acquisition.

It is well known that MR data contains detailed information with high tissue contrast and that PET imaging gives molecular/biochemical information with high molecular sensitivity but what is the added value? A major goal with treatment planning is to delineate the tumor volume, which can be done with both MR and PET, but since the both modalities show different characteristics of the tumor the volume might differ between them. Challenges from the imaging point of view will be discussed. The availability to PET/CT is much higher and the challenges with this method are fewer. Some comparison of the two hybrid modalities will be done. The majority of PET studies are done with the tracer fluorodeoxyglucose, FDG, but beyond FDG a large number of tracers are available, all giving information about different biochemical properties of the tumor. A few of these tracers will be presented and discussed.

SP-0127

MR-PET for radiation oncology: the sub-volume opportunities

D. Thorwarth¹

¹University Hospital Tübingen Eberhard Karls University Tübingen, Tübingen, Germany

Purpose: To investigate the value of combined PET/MR imaging for biologically individualized radiotherapy (RT) planning.

Methods: Hybrid PET/MR imaging offers the possibility to combine molecular information from PET with high resolution anatomical MR imaging. Consequently, a combination of the two different imaging data sets seems promising for improved automatic target volume delineation (TVD). An automatic co-segmentation algorithm has been developed in our institution which derives probabilities of tumor presence by combining PET and MR data. Finally, the PET/MR-based probability maps are segmented to generate RT target volumes. Automatically segmented target volumes were compared to manual delineations from three experienced radiation oncologists. Furthermore, combined PET/MR imaging allows to assess PET and functional MR data at the same time. In the context of a clinical study, diffusion weighted (DW) as well as dynamic contrast enhanced (DCE) MRI were acquired in addition to anatomical images as well as FMISO and FDG PET images. Pairwise correlations of the different functional parameters were calculated in order to analyze for redundancy or complementarity respectively.

Results: Automatic co-segmentation of tumor volumes based on combined FDG PET/MR imaging in head and neck cancer

revealed robust and reproducible contours. The comparison of automatic and manual target volumes showed good agreement in terms of volume overlap. Deviation of the automatic compared to the manual contours was in the same order of magnitude as inter-observer variation. Compared to PET-based TVD, additional information from high resolution MR data improves automatic segmentation.

A pairwise correlation analysis of parameters derived from FMISO PET, FDG PET, DW- and DCE-MRI on a voxel-level did only show moderate to low correlation coefficients hinting at a complementarity of the different investigated imaging methods. However, large inter-patient variations in terms of pairwise parameter correlations were observed.

Conclusion: Functional and molecular imaging with combined PET/MR has the potential to improve TVD. At the same time, PET/MR allows to assess different levels of biological information which may in the future be important to derive individualized measures of radiation sensitivity. As a consequence, PET/MR imaging opens new doors for personalized RT planning and delivery in the near future.

SP-0128

MR-PET for radiation oncology: the implementation issues

T. Nyholm¹

¹Uppsala University, Immunology- Genetics and Pathology, Uppsala, Sweden

Imaging is fundamentally important in modern radiotherapy. For several of the most common diagnoses both PET and MR provide important information in the clinical decision making at the radiotherapy department. The combination of PET and MR in integrated PET/MR scanners could be the most efficient imaging modality for these patients. PET/MR has however primarily been designed for diagnostics and adjustments are needed to enable effective use in radiotherapy. This includes for example the ability to image the patient in treatment position, the ability to account for immobilization devices in the attenuation correction, and the development of adequate quality assurance methods.

Nitroglycerin decreases the hypoxic fraction of non-small cell lung cancer lesions

B. Reymen¹, C.M.L. Zegers¹, W. Van Elmpt¹, F. Mottaghy², A. Windhorst³, A. Van Baardwijk¹, S. Wanders¹, J. Van Loon¹, D. De Ruyscher¹, P. Lambin¹

¹MAASTRO clinic, Radiotherapy, Maastricht, The Netherlands

²Maastricht University Medical Centre, Nuclear Medicine, Maastricht, The Netherlands

³VU University Medical Centre, Nuclear Medicine, Amsterdam, The Netherlands

Purpose or Objective: Nitroglycerin is a nitric oxide donor being investigated because of its potential to increase tumour oxygenation. In phase II trial NCT01210378 nitroglycerin is added to radical radiotherapy in patients with NSCLC stage IB-IV. Using a dedicated hypoxia PET tracer ([¹⁸F]HX4; ref: Dubois et al, Proc Natl Acad Sci USA.2011) we investigate the effect of nitroglycerin on tumour hypoxia. Here, we report the results of the first 14 patients that completed the hypoxia scanning program.

Material and Methods: A baseline [¹⁸F]HX4 PET scan (4h p.i.) was performed to measure hypoxia in the primary tumour and nodes. At least 48 hours later, a second [¹⁸F]HX4 PET scan was taken after application of a nitroglycerin patch (Transderm nitro 5 mg). Between the two scans, patients did not receive any treatment. The primary tumour and involved nodes were defined on the planning FDG-PET-CT scan and fused with the HX-4 scan for analysis. The tumour-to-blood ratio (TBR) of [¹⁸F]HX4 and the Hypoxic Fraction (HF; the fraction of the volume with a TBR >1.4) were calculated for

all lesions. The Wilcoxon signed rank test was used to evaluate differences between scan time points.

Results: In 14 patients, the median interval between the scans was 4.5 +/-2.1 days (range: 2-7days). Seven patients (50%) exhibited hypoxia (HX-4 TBR>1.4) in the primary tumour and 4 of 10 patients (40%) had nodal disease with an HX4 TBR>1.4 in the lymph nodes. In total 9/14 patients (64%) showed hypoxia at baseline in the primary tumour and/or the lymph nodes. The effect of nitroglycerin on HX-4 uptake in hypoxic lesions was as follows: in 8/11 volumes (72%) and in 6/9 patients (66%) nitroglycerin administration resulted in a decrease of the TBR of HX-4. Also, the median HF decreased from 12.9% to 1.2% (p=0.029), corresponding to a decrease in the median hypoxic volume of 5.4 cc to 0.5 cc (p=0.033). In the 7 non-hypoxic tumours and 6 non-hypoxic nodal volumes present at baseline, nitroglycerin caused a decrease of the TBR of HX-4 in 5, an increase in 5 and no effect in 3 lesions. None of the non-hypoxic lesions became hypoxic (TBR >1.4) after administration of nitroglycerin.

Figure 1: Example of HX-4 uptake in lung tumour before and after nitroglycerin.

Conclusion: Nitroglycerin causes a significant decrease in the hypoxic fraction and hypoxic volume of a majority of hypoxic non-small cell lung cancer tumours and metastatic lymph nodes. This promising result encourages further investigation of nitroglycerin as a sensitizing agent in a selected population. CT-based perfusion studies and lab experiments (data not shown) suggest this effect is mediated by an inhibition of mitochondrial respiration rather than a vascular effect.

OC-0130

Biomarker-based hypoxia-adapted radiochemotherapy: preclinical study in HPV+/- H&N cancer xenografts
L. Koi¹, L. Moebius¹, C. Weise¹, C. Erdmann¹, C. Valentini¹, M. Schmidt¹, M. Krause¹, M. Baumann¹
¹Universitaet Klinikum Carl Gustav Carus- Onco Ray, Radiation Oncology, Dresden, Germany

Purpose or Objective: Previous *in vivo* experiments demonstrated that hypoxia and perfusion determined during fractionated RT are associated with local tumour control (LC) in human head and neck squamous cell carcinoma (hNSCC). In a randomized clinical trial Nimorazole improved LC and survival of patients with HNSCC treated with RT. Biomarker studies using tumour material from this trial indicate that hypoxic tumours predominantly benefit from nimorazole, supporting a predictive value for hypoxia assessment. However, this has not been prospectively evaluated for radiochemotherapy (RCTx) which represents the current standard of care in locally advanced head and neck cancer. The hypothesis of the ongoing study is that the microenvironmental parameters are also predictive for response to hypoxic cell sensitizing with nimorazole in combination with RCTx.

Material and Methods: We studied 8 different human HPV-negative and -positive HNSCC in a nude mice xenograft model. Irradiation was performed with 30 fractions (fx) in six weeks combined with weekly cisplatin (3 mg/kg i. p.). Nimorazole (0.3 mg/g i. p.) was applied before each irradiation and was started with the first fx or after 10 fx. Effect of nimorazole was quantified as LC 120/180 days after irradiation. For histological evaluation tumours were excised unirradiated or after 10 fx with and without nimorazole.

Using quantitative image analysis, microenvironmental parameter such pimonidazole hypoxic volume (pHV), relative vascular area (RVA) and perfused fraction of vessels (PF) were determined.

Results: The data of the cell lines show pronounced heterogeneity in the effect of nimorazole on local tumour control after fractionated radiochemotherapy. Nimorazole significantly improved local tumour control in four of the eight tumours. In the two responder models FaDu and SAS, nimorazole was equally effective when given from start of radiochemotherapy or after 10 fx. The treatment with both, RCTx and the application of nimorazole and cisplatin were well tolerated by the animals. Furthermore, pHV was significantly reduced after 10 fx RCT with and without nimorazole in all four responder models in contrast to the non-responders.

Conclusion: Apparently, the decrease of pHV after the first fractions of RCTx has potential as a predictive biomarker for LC for combination of RCTx with nimorazole and should therefore be further evaluated in experimental FMISO analysis and also in clinical trials using hypoxic cell radiosensitisation during RCTx.

miR-875-5p enhances radiation response of prostate cancer cells via EGFR suppression
R. El Bezaawy¹, D. Cominetti¹, P. Gandellini¹, R. Valdagni², N. Zaffaroni¹

¹Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Experimental Oncology and Molecular Medicine, Milan, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Radiation Oncology, Milan, Italy

Purpose or Objective: There is increasing interest in defining a functional association between miRNAs, endogenous small non-coding RNA molecules that negatively regulate gene expression, and tumor radiation response, with the aim of rationally designing miRNA-based strategies to increase patient radiosensitivity. In this study, we investigated for the first time the ability of *miR-875-5p*, a miRNA the role of which in human cancer has not been so far investigated, to enhance the radiation response of prostate cancer (PCa) cells.

Material and Methods: The search for *miR-875-5p* targets relevant to radiation response was carried out by prediction algorithms and confirmed by the luciferase assay. *miR-875-5p* reconstitution by miRNA mimics in PCa cell lines (DU145 and PC-3) was used to elucidate its biological role. Radiation response in miRNA-reconstituted and control cells was assessed by clonogenic assay, immunofluorescence-based detection of nuclear γ -H2AX foci and single-cell electrophoresis comet assay.

Results: EGFR was predicted by 6 different algorithms and confirmed by luciferase assay as a direct target of *miR-875-5p*. Given the role of EGFR in determining tumor cell resistance to ionizing radiation by promoting epithelial-to-mesenchymal transition (EMT) and enhancing DNA-dependent protein kinase activity and DNA damage repair, we assessed whether *miR-875-5p* reconstitution in PCa cells was able to counteract EGFR-mediated radio-resistance. Indeed, miRNA ectopic expression significantly increased the sensitivity of both DU145 and PC-3 cell lines to radiation, as indicated by the reduced clonogenic cell survival. Consistently, the kinetics of accumulation and repair of γ -H2AX nuclear foci showed that the resolution of foci was significantly slower in *miR-875-5p* reconstituted cells compared to control cells. In addition, when a more direct assessment of radiation-induced DNA damage and repair at the single cell level was performed by the comet assay, DNA comet tail moments were found to be significantly extended in *miR-875-5p* reconstituted cells compared to control cells, confirming the ability of the miRNA to impair DNA repair processes. Ectopic expression of *miR-875-5p* in PCa cells was also able to counteract EMT as

indicated by changes in cell morphology, marked cytoskeleton architecture rearrangements, reduced migration ability and increased mRNA and protein levels of E-cadherin and β -catenin, the two most important molecular players in the EMT process.

Conclusion: Overall, results from this study support the clinical interest in developing a novel therapeutic approach for PCa based on *miR-875-5p* reconstitution to increase response to radiotherapy.

FoxO proteins and non-functional p53 determine stemness and radiosensitivity of GBM-stem cells

E. Firat¹, G. Niedermann¹

¹Uniklinik Freiburg, Dept. of Radiation Oncology, Freiburg, Germany

Purpose or Objective: Dual inhibitors of PI3K and mTOR do not efficiently radiosensitize glioblastoma multiforme stem cells (GBM-SCs). However, p53-proficient GBM-SCs are more responsive than p53-deficient GBM-SCs. Here we found that either forkhead box O (FoxO) proteins or non-functional p53 maintain stemness and survival of primary GBM-SCs after combination treatment with gamma-IR and dual PI3K/mTOR inhibitors.

Material and Methods: Patient-derived GBM-SCs were cultured under stem cell culture conditions. Western blot was used for protein expression analyses. Sphere formation served as a surrogate assay for self-renewal and cell death was assessed flow cytometrically. Lentiviral RNA-knockdowns or overexpression of p53 and FoxO proteins were employed for molecular studies. ChiP assay was used to assess binding of FoxO transcription factors to the regulatory region of the *sox2* gene.

Results: p53-proficient GBM-SCs lost stem cell markers and self-renewal ability and underwent differentiation a few days after the combination treatment with γ IR and a PI3K/mTOR inhibitor (PI-103 or NVP-BEZ235); expression of FoxO proteins was also lost. In contrast, stem cell markers and FoxO proteins were not lost anymore upon p53 shRNA knockdown or in p53-deficient GBM-SCs. FoxO1/3 knockdown also caused reduced sphere formation and cell survival after the combination treatment in p53-proficient but not in p53-deficient GBM-SCs. Furthermore, FoxO1 and FoxO3 were found to bind to the *sox2* regulatory region in GBM-SCs, and combined FoxO1/3 deletion abolished Sox2 expression which was confirmed with a novel synthetic FoxO1 inhibitor. Finally, FoxO overexpression prevented GBM-SC differentiation upon combination treatment with gamma-IR and dual PI3K/mTOR inhibitors.

Conclusion: Our results suggest that FoxO proteins are crucial for functional stemness and survival in p53-proficient GBM-SCs and that non-functional p53 can maintain these functions instead.

Radioreistance of glioblastoma stem-like cells is associated with replication stress

R. Carruthers¹, S. Ahmed², D. Biasoli³, K. Strathdee⁴, E. Hammond³, A. Chalmers²

¹Beatson West of Scotland Cancer Centre, Clinical Oncology, Glasgow, United Kingdom

²University of Glasgow, Institute of Cancer Sciences, Glasgow, United Kingdom

³University of Oxford, Oxford Institute of Radiation Oncology, Oxford, United Kingdom

⁴University of Glasgow, Institute of Cancer Sciences, Glasgow, United Kingdom

Purpose or Objective: Tumour recurrence in glioblastoma (GBM) patients is inevitable despite multi-modality treatment with surgery, radiotherapy and chemotherapy. Tumour recurrence is thought to be driven by a small population of glioblastoma stem-like cells (GSCs) that are resistant to conventional therapies. DNA damage response (DDR)

signalling has been shown to be up-regulated in GSCs and implicated in radioresistance and treatment failure. However the cause of enhanced DDR signalling in GSCs and its contribution to radiation resistance and tumour recurrence is not well understood. The objectives of this study were to investigate the underlying cause of DDR upregulation and treatment resistance in GSCs and to identify novel therapeutic targets.

Material and Methods: A panel of primary GBM cell lines cultured under conditions to enrich for or deplete the tumour stem cell population (GSC vs bulk respectively) were utilised to investigate enhanced GSC DDR under basal conditions and after ionising radiation. Confirmatory studies were performed in cells sorted for the putative GSC marker CD133. The effects of a panel of small molecule DDR inhibitors on cell survival in GSC and bulk cells were explored.

Results: GSCs exhibited higher levels of total and activated DDR targets ATR, CHK1, ATM and PARP1 under basal conditions and were radioresistant compared to paired bulk populations. Augmented DDR in GSCs has been linked to increased reactive oxygen species levels by other authors, however we were unable to demonstrate this in our GSC cultures. Instead, we show that RPA is significantly higher in replicating GSCs and confirm by DNA fibre assays that GSCs and CD133+ cells have increased numbers of stalled replication forks, fewer new origins and slower DNA replication compared to bulk or CD133- populations, suggesting that replication stress may be important to constitutive DDR activation seen in GSCs. Importantly, inhibition of ATR or CHK1 was cytotoxic to GSCs and when combined with PARP inhibition caused DNA double strand breaks and reduced neurosphere formation.

Conclusion: This study demonstrates that replication stress is a hallmark of GSCs. We implicate replication stress in GSCs as the driver of enhanced DDR and radioresistance in GSCs and therefore a cause of tumour recurrence in GBM. This suggests that replication stress is a GSC specific therapeutic target, and we are able to demonstrate the effectiveness of inhibitors of replication stress response in targeting this treatment resistant tumour subpopulation.

Irradiation-induced plasticity of the cancer stem cell population in prostate cancer

C. Peitzsch¹, M. Cojoc¹, L. Hein¹, M. Baumann^{1,2,3}, A. Dubrovskaja^{1,3}

¹OncoRay - Center for Radiation Research in Oncology, Medical Faculty Carl Gustav Carus- Technische Universität Dresden, Dresden, Germany

²Medical Faculty and University Hospital Carl Gustav Carus- Technische Universität Dresden, Department of Radiation Oncology, Dresden, Germany

³German Cancer Consortium DKTK, German Cancer Research Center DKFZ, Heidelberg, Germany

Purpose or Objective: Although prostate cancer is the most common malignancy in men, the cellular and molecular mechanisms underlying tumor progression and therapy resistance remain poorly understood. Within this study we discovered cancer stem cell (CSC)-related properties, CSC plasticity and tumor heterogeneity as a source for radiotherapy resistance. Therefore, analysis of CSC-based biomarkers might be an important predictive tool for individualized radiotherapy and treatment.

Material and Methods: Global gene expression and membrane proteomic profiling of radioresistant sublines from established prostate cancer cell lines identified novel biomarker for prostate cancer radioresistance, which were validated in NMRI nu/nu mice *in vivo*, with immunohistochemical analysis of tumor sections and in short-term *ex vivo* cultures of primary prostate cancer tissue.

Results: Within this study we found that the aldehyde dehydrogenase (ALDH) activity is a predictive marker of a

radioresistant prostate cancer progenitor population with enhanced DNA repair capacity and activation of epithelial-mesenchymal transition (EMT). The activation of the WNT/ β -catenin signaling pathway was identified as a key molecular mechanism, which link CSC-related properties to radioresistance. We found that the β -catenin/TCF transcriptional complex is directly activating the *ALDH1A1* gene transcription, and molecular targeting of the WNT pathway with XAV939 leads to radiosensitization. Moreover, our study revealed that irradiation causes long-term up-regulation of stem cell markers and induces tumor cell reprogramming. This phenotypic plasticity is associated with genetic and epigenetic changes induced by irradiation, such as the histone H3 methylation within the promoter sequence of the *ALDH1A1* gene. The inhibition of histone methylation by DZNep triggered radiosensitization by apoptosis induction *in vitro* and *in vivo*.

Conclusion: Our findings suggest that ALDH-positive CSCs contribute to tumor radioresistance, but these radioresistant properties are dynamic in nature. Therapeutic agents inhibiting tumor cell reprogramming may have the potential to increase the effectiveness of radiotherapy. Moreover, monitoring of CSC-related biomarker before and during the course of radiotherapy may be able to predict therapy response and clinical outcome.

⁴University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland

⁵University of Toronto, Princess Margaret Hospital, Toronto, Canada

⁶Thomas Jefferson University Hospital, Department of Radiation Oncology, Philadelphia, USA

Purpose or Objective: This study analyzed whether short-term death of patients with peripheral stage I NSCLC can be predicted reliably to select a sub-group of patients, which will not have a benefit from SBRT and which can be referred to wait and see.

Material and Methods: 802 patients with early stage NSCLC treated with SBRT in 5 institutes for whom information on overall survival within the first six months after treatment was available were included in this analysis. The probability of dying within six months after treatment was modeled by multivariate logistic regression; this interval was chosen because death of early stage NSCLC is a rare event within six months after diagnosis. Model fitting was performed using the LASSO method which simultaneously serves to select the features most closely related to the outcome. The performance of the model that would be achieved on an independent dataset was estimated using double 10-fold cross validation (CV). Because with CV the estimation of test performance depends somewhat on the splitting of the data sets, double 10-fold CV was repeated 100 times, resulting in 1000 models from which the variance in the performance measure could be obtained. The variables age, gender, ECOG status, operability, FEV1 and Charlson comorbidity index (CCI) were considered for model building.

Results: Using different variable combinations for model building resulted in different sample sizes and model performances (Table 1). Common among all models was the identification of the CCI as the most frequently selected and

thus most important variable predicting six-months death, with increasing values predicting higher probability of death. Gender was consistently the second-most frequently selected variable. Regressing on the individual components of the CCI with the LASSO method showed that presence of a second solid tumor was the most important predictor, followed by various forms of heart disease (Figure 1). Replacing the CCI by these individual components in model building confirmed the strong relation between the presence of a second tumor and early death, but led to a worse model performance than with the full CCI (Table 1). Overall the accuracy of all models predicting six-months death was poor with maximum AUC=0.62.

Figure 1: Results of variable selection by the LASSO method when using the individual components of the CCI for predicting death within six months after treatment. 10-fold CV was repeated 1000 times, resulting in a total of 1000 individual models. Shown is the frequency with which a variable was selected into a model.

Variables	(Age, Gender, ECOG, Operability, FEV1, CCI)	(Age, Gender, CCI)	(Age, Gender, MI, PVD, CVD, second tumor)
Sample size	655	801	801
Number of events	48	66	66
AUC	0.619±0.002	0.552±0.002	0.537±0.002
Accuracy [%]	61.0±0.1	56.5±0.2	56.1±0.1
Sensitivity [%]	66.7±1.1	57.5±1.4	57.3±1.0
Specificity [%]	55.2±1.1	55.4±1.4	54.9±0.8
Variables selected into more than 20% of models	CCI: 99.9%	CCI: 99.4% Gender: 69.1%	Secondary tumor: 99.8% PVD: 49.4% CVD: 34.7% Gender: 34.3% MI: 30.5%

Table 1: Results of the model fitting procedure applied to three sub-samples of the data. MI: Myocardial infarct; PVD: Peripheral vascular disease; CVD: Cardiovascular disease.

Conclusion: General patient characteristics together with comorbidity data, especially the history of a previous malignancy, can predict early death, however, prediction accuracy is insufficient to select patients to wait and see instead of offering SBRT as a curative treatment.

Purpose or Objective: NRG/RTOG 0813 is a phase I/II study designed to determine the maximal tolerated dose (MTD) and efficacy of SBRT for NSCLC with centrally located tumors. We hereby report the primary endpoint of the phase I portion of the study.

Material and Methods: Medically inoperable pts with biopsy proven, PET staged T1-2 (<5cm)N0M0 NSCLC and centrally located tumors (within or touching the zone of the proximal bronchial tree or adjacent to mediastinal or pericardial pleura) were successively accrued onto a dose-escalating 5 fraction SBRT schedule ranging from 10-12 Gy/fraction delivered over 1.5-2 weeks. Dose-limiting toxicity (DLT) was defined as any grade 3 or worse toxicity (per CTCAE v.4) occurring within first year, possibly, probably, or definitely related to treatment from a pre-specified list of cardiac, esophageal, respiratory or neurological toxicities. Any potential DLT within the initial year post-SBRT could have led to dose reduction for subsequent patients accrued, using TITE-CRM (time-to-event continual reassessment method) statistical design. MTD was defined as SBRT dose associated with a 20% probability of DLT.

Results: 120 pts were accrued Feb 2009 to Sept 2013 from 43 participating centers. Numbers (n) accrued into each cohort, n eligible for analysis (20 pts were excluded as they did not receive protocol treatment (12) or were ineligible (8)), and n evaluable for DLT analyses (11 not evaluable, 10 of whom died in the first year without a DLT) are shown in the table. Pts were elderly (median age 72), slightly more females (57%), majority had performance status 0-1 (84%). Most cancers were T1 (65%) and squamous cell (45%). Median follow up was 26.6 months. There were 5 events that met the definition of DLTs; Table details the protocol pre-specified DLTs and the worst treatment-related AEs (ie occurring at any time). MTD is 12.0 Gy/fr; Bayesian-based probability of DLT on this arm was 7.2% (95% CI 2.8 -14.4%). The grade 5 AEs occurred at a mean 13 mo postSBRT (range 5.5-14mo).

Dose Level	Pts Accrued (n)	Pts Eligible (n)	Pts Evaluable for DLT (n)	Number and type of DLT	Worst Treatment-Related AE at Any Time		
					Grade 3 (n)	Grade 4 (n)	Grade 5 (n)
10 Gy/fr	8	8	8	0	0	0	0
10.5 Gy/fr	8	7	8	1 (death)	0	0	1
11.0 Gy/fr	18	14	13	1 (neutropenia)	1	0	0
11.5 Gy/fr	43	38	32	2 (thrombocytopenia)	4	0	2
12.0 Gy/fr	43	38	36	1 (neutropenia)	2	1	1

Conclusion: The rates of toxicity pre-specified as DLT were relatively low. The highest dose level allowed by the protocol was reached, and associated with 7.2% rate of DLT. This phase I/II trial of SBRT provides data to inform patients of the potential toxicities with a 5 fraction SBRT schedule for centrally located NSCLC, but data on efficacy are still awaited.

OC-0137

Tumour size but not location determines survival and control of lung stereotactic body radiotherapy

M. Roach¹, S. Rehman¹, T. DeWees¹, J. Bradley¹, C. Robinson¹

¹Siteman Cancer Center, Radiation Oncology, Saint Louis, USA

Purpose or Objective: Patients with early stage non-small lung carcinoma (NSCLC) located centrally within the thorax present a therapeutic challenge with stereotactic body radiation therapy (SBRT). We compared outcomes of early stage NSCLC located in central and peripheral locations.

Material and Methods: A total of 472 patients with early stage NSCLC were identified from a prospective IRB-approved thoracic SBRT registry. Tumors were classified as central if they were within 2 cm of the proximal bronchial tree or immediately adjacent to the mediastinal or pericardial pleura. Peripheral tumors were treated to 54 Gy in 3 fractions, and central tumors to 50 or 55 Gy in 5 fractions. Patients were reviewed for overall survival (OS) calculated from completion of therapy and local failure (LF). The log-rank test and Cox regression were used to identify factors predictive of OS and LF.

Results: 127 patients had central tumors and 345 had peripheral tumors. Median follow-up was 30 months for living patients. For the entire cohort at 2 years, OS was 57% and LF was 10%. OS at 2 years was 50% for patients with central tumors and 60% for those with peripheral tumors (p=0.11). LF at 2 years was 19% for central lesions and 8% for peripheral lesions (p=0.08). On multivariate analysis, increasing tumor size (HR 1.21 per cm, 95% CI: 1.10-1.33, p<0.0001), increasing age-adjusted Charlson comorbidity score (HR 1.15 per point, 95% CI: 1.09-1.20, p<0.0001), and worse KPS (HR 10.1 per 10% loss, 95% CI: 10.1-10.2, p=0.0003), but not location predicted for worse OS. Only increasing tumor size (HR 1.37/cm, 95% CI: 1.06-1.78, p=0.02) predicted for LF on multivariate analysis.

Conclusion: The use of five SBRT fractions of 10-11 Gy for central early stage NSCLC results in similar outcomes as peripheral early stage NSCLC treated in three SBRT fractions of 18 Gy. Larger tumors result in worse outcomes suggesting the need for additional treatment strategies.

Apnea-like suppression of respiratory motion: first clinical evaluation

N. Peguret¹, M. Ozsahin¹, C. Beigelman², M. Zeverino³, A. Durham¹, F. Duclos¹, K. Grant⁴, B. Belmondo⁴, J. Simons⁴, O. Long¹, R. Moeckli³, J. Prior³, R. Meuli², J. Bourhis¹

¹Centre Hospitalier Universitaire Vaudois, Department of Radiation Oncology, Lausanne Vaud, Switzerland

²Centre Hospitalier Universitaire Vaudois, Department of Radiology, Lausanne Vaud, Switzerland

³Centre Hospitalier Universitaire Vaudois, Institute of Radiation Physics, Lausanne Vaud, Switzerland

⁴Centre Hospitalier Universitaire Vaudois, Department of Physiotherapy, Lausanne Vaud, Switzerland

⁵Centre Hospitalier Universitaire Vaudois, Department of Nuclear Medicine, Lausanne Vaud, Switzerland

Purpose or Objective: Pulmonary tumours are subject to respiratory motion which induces PET/MRI artefacts and imposes to use specific additional margins when treated by radiotherapy (RT). Gating techniques can solve these issues by stabilizing lung targets, and sustaining breath-holds in maximal inspiration (MI). However, these are limited by the patient's capacity to hold his breath. The purpose of this work was to implement a new non-invasive respiratory assistance using high frequency percussive ventilation (HFPV - Percussionaire®; Idaho, USA), and to report its first clinical use in maintaining breath holds long enough during chest imaging and complex RT treatments.

Material and Methods: ethical committee approval was obtained to conduct a clinical study, after evaluating its feasibility and tolerability in a cohort of volunteers. HFPV was applied in patients eligible for breast 3DRT, lung stereotactic RT, locally-advanced lung RT. Durations of breath hold obtained under HFPV for each clinical situation were reported. Dosimetric parameters in free breathing (FB), MI gating, or HFPV conditions were compared. The HFPV was also adapted and tested for thoracic MRI and PET.

Results: For volunteers, HFPV offered a mean duration time for apnea like breath hold of 10.6 minutes. Transferred in patients, this percussion assisted radiotherapy (PART) was applied with good tolerance in the first 3 patients without treatment breaks during the overall fractionated RT. All together, 50 RT fractions have been delivered under PART, and the mean duration of apnea-like breath hold necessary for "beam on" was 7.61 minutes (SD 2.3). HFPV offered a favorable dosimetric profile when compared to MI or FB for these 3 clinical RT situations (table). In addition, the HFPV markedly improved both PET and MRI image quality in detecting small pulmonary lesions (figure).

Conclusion: the HFPV allowed prolonged apnea-like breath hold that could be used both for fractionated RT and chest imaging. These preliminary results were very promising and prompt to develop larger studies to evaluate its reproducibility and potential clinical benefits both for radiotherapy and for lung PET/MRI imaging.

Expert knowledge vs. data-driven algorithms: Bayesian prediction models for post-radiotherapy dyspnea

T.M. Deist¹, A. Jochems¹, C. Oberije¹, B. Reymen¹, K. Vandecasteele², Y. Lievens², R. Wanders¹, K. Lindberg³, D. De Ruyscher⁴, W. Van Elmpt¹, S. Vinod⁵, A. Dekker¹, P. Lambin¹

¹MAASTRO Clinic, Department of Radiation Oncology MAASTRO Clinic- GROW - School for Oncology and Developmental Biology- Maastricht University Medical Centre, Maastricht, The Netherlands

²Ghent University Hospital, Department of Radiation Oncology, Ghent, Belgium

³Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden

⁴KU Leuven, Universitaire Ziekenhuizen Leuven, Leuven, Belgium

⁵University of New South Wales, South Western Sydney Clinical School, Liverpool, Australia

Purpose or Objective: Moving away from guideline-based treatment to a more personalized approach requires accurate outcome prediction. Yet, physicians' predictions of survival and toxicity after lung radiotherapy are as good as flipping a coin (Oberije et al., Radiother. Oncol. 2014). We hypothesize that the physicians' knowledge of complex interactions between clinical variables and treatment outcomes is a valuable resource for prediction modelling. Therefore, we created and compared expert-based and data-driven prediction models. The predicted endpoints are severe dyspnea (CTCAE dyspnea score ≥ 2) and increases in the CTCAE dyspnea score after radiotherapy (RT). Severe dyspnea occurs in approximately 15% of all patients treated with lung

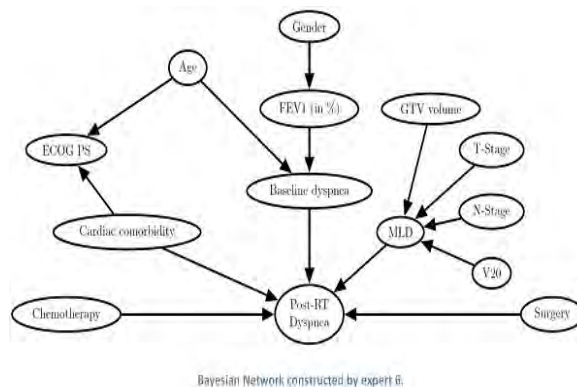

radiotherapy and has a possibly severe impact on patients' quality of life.

Material and Methods: Data from 1152 lung cancer patients treated in clinical routine (2006-2015, partially incomplete data) were used. Seven experts selected causal links between 19 variables (patient, disease, treatment, and dose-related variables) and post-RT dyspnea to construct Bayesian Networks (BNs). Their individual choices, the consensus choices, and a data-driven algorithm were used to build BNs for both endpoints. 80% of the data were used for model building. Validation was performed for all models in terms of discrimination (Area under the Curve) in the remaining 20% of the data, isolated before modelling.

Results: Expert-based networks were more complex than algorithmically-constructed networks (range: 7-30 vs. 3-6 arcs) but their predictions for severe dyspnea in non-dyspneic patients were not significantly better (see 95% confidence intervals in table). Furthermore, all models besides expert model 6 were not different from chance as AUC confidence intervals include 0.5. Models predicting increases in CTCAE dyspnea scores performed better (all models' AUCs > 0.6) and different from 0.5 with 97.5% confidence. Among those, the data-driven approach performed significantly better than 3 of the 7 expert models. Consensus networks between experts did not improve the predictive performance.

	Predicting Severe Dyspnea (CTCAE dyspnea scores ≥2)				Predicting Dyspnea Score Increase				Number of Arcs
	AUC		(AUC - AUC _{Alg})		AUC		(AUC - AUC _{Alg})		
	95% CI	95% CI	95% CI	95% CI	95% CI	95% CI	95% CI

AUC and Brier scores in validation. CI based on 1000 bootstraps.

Conclusion: The results suggest that reliable predictions of post-RT dyspnea scores ≥ 2 in non-dyspneic patients are not achievable with any of the presented models. Clinical routine appears to still miss appropriate biomarkers. In contrast, prediction modelling for post-RT increases in dyspnea is feasible with expert knowledge as well as data-driven algorithms. The comparison between expert- and data-driven modelling indicates that data-driven modelling can yield simpler models with similar performance as expert-driven modelling.

⁷Institute of Cancer Sciences, Manchester University, Manchester, United Kingdom

Purpose or Objective: The role of thoracic radiotherapy (TRT) in extensive stage small-cell lung cancer (ES-SCLC) has been evaluated in a recent phase 3 randomised control trial. The results of the Chest Radiotherapy Extensive stage Small cell lung cancer Trial (CREST) were published in the Lancet (2015,385,36-42). This study showed that TRT did not significantly improve 1-year overall survival, which was the primary endpoint. However there was a significant improvement in 2-year overall survival, suggesting TRT should be considered for all patients with ES-SCLC who respond to chemotherapy. An additional analysis showed that in patients with a response but residual disease after chemotherapy, the difference in 1-year survival was significantly better after TRT (Lancet 2015,385,1292-3). We carried out a European survey to determine the impact of the publication on clinical practice.

Material and Methods: In May 2015 an electronic questionnaire of 34 items was composed using Select Survey software designed for running online surveys. Questions covered the use of TRT before and after the CREST study, evaluated the current practice of prophylactic cranial irradiation (PCI), including dose and fractionation, and asked whether practice was restricted based on performance status (PS) and age. The survey was distributed by email to one thoracic clinical/radiation oncologist per centre in 7 European countries. A reminder was sent to non-responders.

Results: This European-wide survey received 95 complete responses (UK n=42, Belgium n=23, Netherlands n=14, France n=8, Switzerland n=5, Germany n=2, Poland n=1). A response rate of 74% was achieved within the UK. Before the publication of the CREST study only 25% of centres were giving TRT routinely to patients who had responded to chemotherapy, compared to the current practice of 81%. Currently the preferred dose and fractionation of TRT is 30 Gy in 10 fractions in 70% of centres, however a wide variety of fractionations were used before the CREST publication. An upper limit of PS ECOG 2 is commonly applied to TRT (83%). In the 18 centres (19%) not implementing TRT there were a wide variety of explanations with no single reason standing out. Regarding the practice of PCI in ES-SCLC, 96% of centres give PCI routinely if patients have responded to chemotherapy. Of these, 52% deliver 25Gy in 10 fractions and 44% deliver 20Gy in 5 fractions. An upper age limit was applied in 76% of all centres, the most common age limit being 75 (60%). An upper limit for PS was applied in 88% of all centres, most commonly ECOG 2.

Conclusion: Following the publication of the CREST study there has been a dramatic increase in the use of TRT in patients with ES-SCLC who have responded to chemotherapy. The dose and fractionation schedule used in the study has widely been adopted as standard practice across Europe. There is also evidence of high consistency in European practice in the use of PCI in patients with ES-SCLC.

Does an integrated boost increase acute toxicity in prone hypofractionated breast irradiation?

L. Paelinck¹, A. Gulyban², F. Lakosi², T. Vercauteren¹, W. De Gerssem¹, B. Speleers¹, C. Monten¹, T. Mulliez¹, P. Berkovic², A. Van Greveling¹, P. Coucke², W. De Neve¹, L. Veldeman¹

¹University Hospital Ghent, Department of Radiation Oncology, Ghent, Belgium

²University Hospital Liège, Department of Radiation Oncology, Liège, Belgium

Purpose or Objective: To compare acute skin toxicity between prone whole-breast irradiation (WBI) with a sequential boost (SeqB) and a simultaneous integrated boost (SIB).

Materials and Methods: 167 patients were randomized between WBI with a SeqB or a SIB. 150 patients were treated at Ghent University Hospital (UZ Gent) and 17 at Liège University Hospital. All patients were treated in prone position to 40.05 Gy in 15 fractions to the whole breast. In the SeqB arm a median dose of 10 Gy in 4 fractions (negative surgical margins) or 14.88 Gy in 6 fractions (transsection) was prescribed to the PTV_boost (CTV to PTV margin of 5 mm). In the SIB arm a median dose of 46.8 or 49.95 Gy (negative and positive surgical margins, respectively) was prescribed to the CTV_boost with dose decay to 40.05 Gy in the first 2 cm around the CTV_boost. In the SeqB arm dose parameters were calculated on the summed plan (WBI + boost). For comparison, a PTV_optim was created including the PTV for WBI more than 2 cm away from the CTV_boost as illustrated in Figure 1.

Dermatitis was scored using the Common Toxicity Criteria for Adverse Events (CTCAE). Desquamation was scored as: none, dry or moist; pruritus as absent or present.

Results: The analysis of dose parameters was done on 146 patients treated at UZ Gent. Reasons for excluding patients were electron boost (2), 3 different plans on 3 different CTs (1) and changed treatment arm due to machine breakdown (1). This latter patient was excluded from the toxicity analysis as well. Patient age was the only significantly different parameter between treatment arms (mean age 59.6 ± 11.0 vs 55.7 ± 10.4 years, p=0.0210). Dose coverage of the CTV_boost was slightly better in the control arm (D95 of 98 ± 1% vs 97 ± 2%, p<0.01). The volume of the PTV_optim and the skin receiving more than 105% of the prescription dose were significantly higher in the SeqB-arm than in the SIB-arm (27 ± 20% vs 9 ± 6% for the PTV_optim and 394 ± 216cc vs 201 ± 125cc for the skin, both p<0.01). In both arms, 6/83 patients developed moist desquamation (primary endpoint). Grade 2/3 dermatitis was significantly more frequent in the SeqB arm (38/83 vs 24/83 patients, p=0.037). In the SIB and SeqB arm, respectively, 36 and 51 patients developed pruritus (p=0.015). The incidence of edema was lower in the SIB arm (59 vs 68 patients), but not statistically significant (p=0.071).

Conclusion: Acute toxicity is not increased using a SIB in prone hypofractionated WBI. In contrast, grade 2/3 dermatitis and pruritus are significantly less frequent. With

our SIB-technique, high dose regions outside the boost region are smaller than with a SeqB.

OC-0142

Hypo- vs normofractionated radiation of early breast cancer in the randomised DBCG HYPO trial

B.V. Offersten¹, E.H. Jacobsen², M.H. Nielsen³, M. Krause⁴, L. Stenbygaard⁵, I. Mjaaland⁶, A. Schreiber⁷, U.M. Kasti⁸, M.B. Jensen⁹, J. Overgaard¹⁰

⁹Copenhagen University Hospital, DBCG- Rigshospitalet, Copenhagen, Denmark

¹⁰Aarhus University Hospital, Dept Experimental Clinical Oncology, Aarhus C, Denmark

Purpose or Objective: Based on poor results using hypofractionated adjuvant radiotherapy (RT) of early breast cancer (BC) 50 Gy/25 fr. has been Danish Breast Cancer Group (DBCG) standard since 1982. Results from the UK and Canada stimulated a renewed interest in hypofractionation, and the non-inferiority DBCG HYPO trial was initiated. The hypothesis was that 40 Gy/15 fr (2.67 Gy/fr, 3 weeks) does not result in more grade 2-3 breast induration than 50 Gy/25 fr (2.0 Gy/fr, 5 weeks) 3 years post RT.

Materials and Methods: From 2009-2014 1868 patients >40 years operated with breast conservation for early pT1-2 pN0-1(mic) BC (n=1617) or DCIS (n=251) were enrolled irrespective of breast size, systemic therapy and boost, and randomized 50 Gy/25 fr vs. 40Gy/15 fr. Strata were institution, breast size (≤ 600 ml vs. > 600 ml), systemic therapy and boost. The primary endpoint was grade 2-3 induration 3 years post RT, secondary endpoints were other normal tissue responses, genetic risk profile for RT-induced fibrosis and recurrences. ClinicalTrial NCT00909818.

Results: 942 pts (50.4%) were assigned to the 50 Gy group and 926 (49.6%) to the 40 Gy group. Median age was 59 years (range 39-83). Median follow up was 3 years. The analysis was by intention to treat. Results are actuarial 3 year rates using morbidity in 1801 pts 1 yr post RT as baseline. 1086 pts (60%) had 3 year scores of morbidity and the rate of grade 2-3 induration was 12.2% \pm 1%. Grade 2-3 induration was seen in the 50 Gy group in 119 out of 904 pts with the rate 14.2% \pm 1.4%, and in the 40 Gy group in 97 out of 897 pts, the rate being 10.1% \pm 1%, representing a HR 1.27 (95% CI 0.97-1.66), p=0.08. 859 pts (48%) had small breasts with a rate of grade 2-3 induration of 9.8% \pm 1% compared to 14.3% \pm 1% among 942 pts with large breasts, HR 1.56, (95% CI 1.18-2.05), p=0.001. Among the 653 pts (36%) treated with chemotherapy (CT) the rate of grade 2-3 induration was 12.4% \pm 1%, whilst in the 1148 pts with no CT the rate was 11.8% \pm 2%, HR 0.98 (95% CI 0.74-1.30), p=0.90. In 423 pts (23%) treated with sequential boost (10-16 Gy/5-8 fr) the rate of grade 2-3 induration was 12.4% \pm 1% compared to 12.1% \pm 1% among 1378 pts with no boost, HR 0.93 (95% CI 0.67-1.29), p=0.65. Multivariate analysis using grade 2-3 induration at 3 yr as endpoint and including hypofractionation, breast size, chemotherapy and boost identified large breast size as the only independent risk factor. Overall the 3 yr risk of loco-regional recurrence was 0.3% \pm 0.1%. In the 50Gy / 40 Gy group loco-regional recurrence was reported in 2 pts / 4 pts, distant failure 4 pts / 3 pts, new contralateral cancer or DCIS 2 pts / 3 pts.

Conclusion: Moderately hypofractionated whole breast irradiation in early node-negative BC or DCIS does not result in more grade 2-3 induration compared to normofractionated therapy. Large breast size is an independent risk factor for developing induration. The 3 yr loco-regional recurrence risk is very low.

A Bayesian randomisation trial of IMRT vs. PSPT for locally advanced non-small cell lung carcinoma

Z. Liao¹, J. Lee², R. Komaki¹, D. Gomez¹, M. O'Reilly¹, P. Allen¹, F. Fossella³, J. Heymach³, N. Choi⁴, T. Delaney⁴, S. Hahn¹, C. Lu³, J. Cox¹, R. Mohan⁵

¹The University of Texas MD Anderson Cancer Center, Radiation Oncology, Houston- TX, USA

²The University of Texas MD Anderson Cancer Center, Biostatistics, Houston- TX, USA

³The University of Texas MD Anderson Cancer Center, Thoracic Medical Oncology, Houston- TX, USA

⁴Masachusetts General Hospital- Harvard University School of Medicine, Radiation Oncology, Boston, USA

⁵The University of Texas MD Anderson Cancer Center, Radiation Oncology Physics, Houston- TX, USA

Purpose or Objective: We report preliminary results from a Bayesian randomized trial of IMRT vs. PSPT, both given with concurrent chemotherapy, for locally advanced (stage II-IIIb) NSCLC. The purpose of the trial was to assess and compare the incidence and time to development of treatment failure defined as (1) grade 3 pneumonitis or (2) local failure, whichever occurred first in 12 month.

Materials and Methods: The sample size for this trial (n=150) was based on the assumption that incidence would be log-normally distributed and that IMRT would produce event rates of 30% at 6 mo and 40% at 12 mo, and PSPT would reduce the event rate by 10%. The Bayesian design was chosen so that more patients will be randomly allocated to the more effective of the two treatments. All patients must have been candidates for concurrent chemoradiation, and all underwent 4D CT-based treatment planning. An IMRT and a PSPT plan were created for each patient. Patients were eligible for randomization only if both plans satisfied normal tissue constraints at the same prescription dose (74 Gy (RBE) if achievable, otherwise 66 Gy (RBE), where RBE is 1 for photons and 1.1 for protons)

Results: Total 147 patients who were randomized to IMRT (n=90) or PSPT (n=57) and treated according to randomization were included for this analysis. Demographic characteristics were well balanced between the two arms. The GTV and PTV volumes were bigger in the PSPT arm though the difference was not statistically significant. More patients in PSPT arm received higher tumor dose. Patients in PSPT arm had larger volume of the lung receiving ≥ 30 -80 Gy (RBE) compared with IMRT patients, presumably due to the larger target volume and 3D nature of PSPT. The incidence of protocol failure at 12 month were 20.7%, 15.6%, and 24.6% in all, in IMRT, and in PSPT patients, respectively. The median failure free survival times were 67.6, 67.6, and 69.8 months in all, in IMRT, and in PSPT patients, respectively. Total of 12 patients developed grade ≥ 3 or higher RP, 6 in each arm. Two of the 6 patients had grade 5 RP in IMRT arm. The incidences of grade 3 RP were 8.7%, 7.2%, and 11.0% in all, in IMRT, and in PSPT patients, respectively.

Conclusion: Considerably fewer events occurred in the evaluable randomized patients than were expected from historical experience. No statistical differences were found between IMRT vs. PSPT in the incidence of treatment failure, grade ≥ 3 pneumonitis, or local failure. Future analyses will involve comparing data from CT and PET images, blood samples and symptoms and their correlations with dose distributions to clarify factors affecting outcomes and to determine how physical and biological uncertainties affect proton dose distributions. *Supported in part by NCI grants P01 CA021230 and U19 CA021239.

Maximum response and PCI are important prognostic factors in LD SCLC patients staged with cMRI

C. Eze¹, O. Roengvoraphoj¹, M. Niyazi¹, S. Gerum¹, G. Hildebrandt², R. Fietkau³, C. Belka¹, F. Manapov¹

¹Ludwig-Maximilian University Munich, Department of Radiation Oncology, Munich, Germany

²University of Rostock, Department of Radiation Oncology, Rostock, Germany

³Friedrich-Alexander University Erlangen-Nuernberg, Department of Radiation Oncology, Erlangen, Germany

Purpose or Objective: The role of prophylactic cranial irradiation (PCI) in limited disease (LD) small-cell lung cancer (SCLC) has proven to significantly decrease the incidence of brain metastases (BMs) with only modest improvement of overall survival.

Materials and Methods: To evaluate the impact of PCI on survival we reviewed 179 LD SCLC patients treated with definitive chemoradiotherapy (CRT) in the concurrent or sequential setting. PCI was applied in the partial and complete responders exclusively provided contrast-enhanced cranial magnetic resonance imaging (cMRI) before and after primary treatment showed no signs of occult BMs. Correlation between PCI and time to progression (TTP) as well as overall survival (OS) was analysed. Kaplan-Meier analysis, uni- and multivariate Cox regression were used to describe survival within subgroups defined by treatment response and application of PCI.

Results: Concurrent and sequential chemoradiotherapy CRT was applied in 71 (40%) and 108 (60%) patients, respectively. In 58 (32%) patients metachronous BMs were detected. PCI was applied in 71 (39%) patients. 15 patients developed BMs after PCI. Median TTP and OS in responders treated with PCI were 812 and 801 compared to 355 (range: 284 - 456) ($p < 0.0001$, log-rank test) and 385 (range: 318 - 452) ($p < 0.0001$, log-rank test) days in the rest of the patient cohort. In multivariate analysis, application of PCI in treatment responders comprehensively staged with cMRI was a variable that significantly correlated with TTP (HR 2.16 CI HR 1.37-3.42, $p < 0.001$) and OS (HR 1.89 CI HR 1.37-2.63, $p < 0.0001$) after adjustment of other patient- and treatment-related factors.

Conclusion: In this LD SCLC patient cohort comprehensively staged with cMRI, achievement of maximum treatment response and application of PCI significantly affects time to progression and overall survival.

⁵IRCCS San Martino-IST Genoa, Department of Radiation Oncology, Genoa, Italy

⁶National Cancer Institute, Department of Radiotherapy, Vilnius, Lithuania

⁷Institut de Cancérologie de l'Ouest, Department of Radiotherapy, Nantes, France

Purpose or Objective: Preoperative chemoradiotherapy (CRT) has been established as the standard treatment for T3-4 rectal cancers. In a phase II trial, we reported limited toxicity and excellent local control using image-guided and intensity-modulated RT (IG-IMRT) with a simultaneous integrated boost (RTSIB) instead of concomitant chemotherapy. The present multicentric randomized trial

compares this strategy to CRT. In addition, the neutrophil-to-lymphocyte ratio (NLR) and C-reactive protein (CRP) were examined as a prognostic immunoscore in a subset of patients.

Materials and Methods: cT3-4 rectal cancer patients were randomly assigned to receive either preoperative IG-IMRT 46Gy/23 fractions plus capecitabine 825 mg/m² twice daily (CRT-arm) or IG-IMRT 46Gy/23 fractions with a SIB to the rectal tumor up to a total dose of 55.2 Gy (RTSIB-arm). Metabolic tumor activity reduction, by measuring the percentage of SUVmax difference (Response Index = RI) on sequential 18-fluorodeoxyglucose positron emission tomography (FDG-PET), was the primary endpoint. We assessed whether RTSIB was non-inferior to CRT with a non-inferiority margin of -10% for RI.

Results: A total of 174 patients were randomly assigned to the CRT-arm (n=89) or RTSIB-arm (n=85). A consort flow diagram is presented in Figure 1. The RI difference between RTSIB and CRT was -2.9% (95% CI, -10.1% to 4.3%). The ypCR rate was 24% with CRT compared to 14% with RTSIB ($p=0.13$). There was no significant difference in sphincter preservation (75% vs 68%, $p=0.29$). The R0 resection rate was 98% in the CRT-arm and 97% in the RTSIB-arm. Acute grade 3 toxicity was 6% and 4% in the CRT- and RTSIB-arm, respectively. A detailed analyses of early adverse events is shown in Table 1. The highest quartiles of NLR and CRP identified high-risk patients in terms of disease free and overall survival.

Table 1. Early Adverse Events

Grade	CRT (n=86)		RTSIB (n=82)		p-value
	No. of Patients (%)	No. of Patients (%)	No. of Patients (%)	No. of Patients (%)	
Gastrointestinal					
Diarrhea	36 (42)	1 (1)	35 (43)	2 (2)	.91 (.53)
Enteritis (abdominal pain)	17 (20)	0	17 (21)	1 (1)	.85 (.30)
Proctitis	18 (21)	0	10 (12)	0	.13
Urinary	13 (15)	1 (1)	18 (22)	1 (1)	.25 (.97)
Dysuria	7 (8)	0	11 (13)	0	.27
Urinary frequency	4 (5)	0	10 (12)	0	.08
Haemathology	5 (6)	0	4 (5)	0	.79
Anemia	3 (3)	1 (1)	2 (2)	0	.69 (.33)
Leucopenia	0	1 (1)	1 (1)	0	.30 (.33)
Thrombopenia	3 (3)	1 (1)	0	0	.09 (.33)
Other	0	0	1 (1)	0	(.30)
Hand-foot syndrome*	0	0	0	0	
Radiation dermatitis	14 (16)	2 (2)	10 (12)	1 (1)	.45 (.59)
Vaginal mucositis	2 (2)	2 (2)	1 (1)	0	.59 (.16)
Overall toxicity score	43 (50)	5 (6)	46 (56)	3 (4)	.43 (.51)

* 5 patients (6%) in the CRT-arm experienced grade 1 hand-foot syndrome
 p-value from test grade 2 (grade 3)

Conclusion: Preoperative CRT is well tolerated when IG-IMRT is used. RTSIB represents an attractive alternative to CRT for patients with a contra-indication for chemotherapy. The immunological landscape of colorectal cancer shapes novel possibilities for risk assessment.

Purpose or Objective: PROS-IT is a national, multicenter, observational prospective cohort study on prostate cancer (PCa) coordinated by the Italian National Research Council, aiming at a comprehensive evaluation of the impact of PCa and its treatment in an unselected aging population. Present analysis evaluates the frequencies of the different comorbidities and medications in the study population at diagnosis.

Materials and Methods: 1684 patients (pts) consecutively enrolled 9/2014 to 7/2015 in 96 Institutions were submitted to a structured interview to record comorbidities and drugs assumption. The severity of comorbidities was measured with the Cumulative Illness Rating Scale (CIRS). Quality of life (QoL) was assessed by the SF-12 questionnaire (PCS = Physical and MCS = Mental Component Summary) and through the Italian UCLA P Ca Index (Function/Bother: UF,UB=Urinary, SF,SB=Sexual, BF,BB=Bowel). Differences between pts enrolled by Urology [URO] and Radiation Oncology Centers [RO] were assessed with logistic regression and/or general linear models.

Results: 996/1684 (59.1%) and 688/1684 (40.9%) pts were respectively enrolled by URO and RO Centers; CIRS data were available for 1637 pts. RO pts were older (average 71.9 yrs vs 66.4, $p < 0.0001$), with more advanced T category (T1 cases: 38% vs 54.6%, $p < 0.0001$). 445/1684 (27.2%) pts suffered from vascular, lymphatic or hematopoietic moderate, severe or very severe (MSVS) diseases; 304/1684 (18.6%) from heart MSVS disease; 231/1684 (14.2%) had gastro-intestinal problems; 163/1684 (10%) neurological diseases. The presence of ≥ 3 MSVS comorbidities had a significant negative impact on PCS, MCS, UB, BF and BB, SF if compared to 0-2 MSVS comorbidities ($p < 0.001$). Diabetes was more frequent in RO pts than in URO ones (18.4% vs. 11.4%, $p = 0.0082$); MSVS gastrointestinal disease (18.8% vs. 7.5%), abdominal hernia (5.7% vs. 4.8%), and neurological disease (11.4% vs. 7.9%) in URO pts. 74.3% of the pts use drugs for vascular disease, 36.7% antithrombotic agents, 34.2% digestive drugs, 14.4% hypoglycemic drugs, 31.6% drugs for low urinary tract symptoms. A significant difference between URO and RO populations in the use of antithrombotic agents was evident: 32.5% URO vs. 44% RO ($p = 0.0377$).

Conclusion: This study shows that number and severity of comorbidities had a negative impact on QoL at the time of diagnosis of PCa. Moreover, men enrolled in URO and RO Centers present a different pattern of associated diseases/medications.

Organ preservation in T2 T3 NX M0 rectal. French results using the new Papillon 50TM machine

J.P. Gérard¹, A. Frin², J. Doyen¹, N. Barbet³, R. Coquard⁴, K. Benezery¹, S. Marcié⁵

¹Centre Antoine Lacassagne, Radiotherapy, Nice, France

²CHU Nice, Gastroenterology, Nice, France

³Centre Radiotherapie, Radiotherapy, Macon, France

⁴Centre Bayard, Radiotherapy, Lyon-Villeurbanne, France

⁵Centre Antoine Lacassagne, RadioPhysic, Nice, France

Purpose or Objective: Contact X Ray Brachytherapy (CXB) was pioneered in France for conservative treatment of rectal cancer using the Philips RT 50TM machine. Since 2009 the new Papillon 50TM was manufactured. It delivers high dose rate (20 Gy/ mn) well targeted dose (30 Gy) into the rectal tumor using an endoscopic approach. For T2 T3 CXB is always combined with external beam Radiotherapy (EBRT) or with chemoradiotherapy (CRT). Three centers have been treating patients in France with such regimen in Lyon-Villeurbanne, Mâcon and Nice.

Material and Methods: All patients presented adenocarcinoma of the distal or middle rectum. Staging used Digital examination, endoscopy, MRI and or Endorectal ultrasound. CXB dose was 90Gy in 3 fractions (Day 1- 14 -28) and EBRT delivered 50 Gy/25 fr/5 weeks usually with concurrent capecitabine (800 mg/m² BID). After clinical complete response (cCR) either watch and Wait (W&W) or Local excision (LE) was proposed.

Results: Between 2009 and 2014, 44 patients were treated. All these patients were either high surgical risk, refusal of surgery or referred after MDT approval for such a conservative approach Results are shown in Table .

Centre	N° pts	T2	T3	cCR	Loc. Rec.	Organ Preserv	Surv. 3 years
Mâcon	14	6	8	10	3	9	75%
Nice	22	13	9	20	2	21	70%
Villeurbanne	8	6	2	8	1	7	87%
Total	44	25	19	89% (38)	13% (6)	83% (37)	77%

Conclusion: The present early results achieved with the Papillon 50 machine are at least equivalent to the previous one using Philips RT 50. CXB technique is validated in France for rectal cancer since 2008 (HAS) and recently in UK (NICE). Organ preservation using CXB in frail, elderly patients is a well admitted treatment and the ongoing OPERA trial is aiming at showing its benefit in operable patients. Gerard JP et al. Acta Oncol. 2015 Apr;54(4):545-51.

⁵Verbeeten Institute, Department of Radiotherapy, Tilburg, The Netherlands

Purpose or Objective: TME surgery, with or without pre-operative (chemo-)radiotherapy is the standard of care in patients with resectable rectal cancer. In patients unfit for surgery, radiotherapy alone is often used with palliative intent. However, complete response can be achieved when high doses are administered. In this study we examined the feasibility of external beam radiotherapy (EBRT) followed by an endorectal brachytherapy boost in elderly patients, unfit for surgery. Primary results, presented at ESTRO 2014, are now complemented with response assessment and long-term FU at 3 years.

Material and Methods: A dose finding feasibility study was performed from 2007 to 2013 in two hospitals in inoperable rectal cancer patients. Treatment consisted of EBRT (13x3 Gy) followed by 3 weekly applications of intraluminal high dose rate brachytherapy (HDRBT) starting 6 weeks after EBRT. The starting dose level was 3x5 Gy with escalation of 1 Gy per fraction if acute toxicity was acceptable. Toxicity was acceptable if <2/6 patients or <3/9 patients exhibited dose limiting toxicity (DLT), defined as grade 3 proctitis (CTCAE v 3.0), within 6 weeks after HDRBT. Secondary endpoints were severe treatment-related late toxicity, clinical tumor response and progression free survival (PFS). Clinical tumor response was evaluated based on all available endoscopy pictures and defined as complete clinical response (CR), partial response (PR), stable disease (SD) or progression (PD).

Results: Thirty-eight patients with a mean age of 81 years, entered the study of whom 36 received HDRBT. Two patients died directly after HDRBT and 3 patients refused follow-up endoscopies, leaving 31 patients for response evaluation. At time of current analyses 13 patients were still alive, with a median FU of 30 months. Primary endpoint was reached at the 8 Gy dose-level with 3/9 patients showing a DLT. Response was observed in 25 patients (80.6%); of the 18 patients achieving a CR, 6 developed progressive disease later on. Of the 7 patients with PR, 4 showed progression, whereas this occurred in 5/6 patients with SD. Median time to progression was 6.3 months. PFS at 1,2 and 3 years was 65.6%, 46.4% and 22.1% respectively. Late treatment related grade 3/4 toxicity occurred in 13 patients, of those 9 patients also showed progressive disease. Outcomes related to doselevel are displayed in table 1.

Table 1. Outcomes

Dose level	5Gy	6Gy	7Gy	8Gy
Dose limiting toxicity	1/6	0/5	0/11	3/9
Late toxicity grade 3/4	2/6	1/5	5/13	5/9
Complete response	2/7	1/4	9/12	7/9
Progression	4/7	2/4	5/12	4/9

[‡] due to missing data number of patients per evaluation group could vary.

Conclusion: A combination of EBRT and HDRBT is feasible in inoperable elderly patients with acceptable acute toxicity and a promising overall response rate of 80.6%. However, given the observed toxicity, a randomized trial comparing EBRT with or without HDRBT boost is necessary. In this trial the clinical relevance of the added tumor control in light of additional toxicity from HDRBT will be evaluated in this fragile population.

OC-0149

Patterns of relapse in rectal cancer patients following pre-operative high dose rate brachytherapy

T. Vuong¹, F. Desjardins², V. Pelsner³, T. Niazi¹, A. Robillard², M. Leventhal³

¹Jewish General Hospital, Radiation Oncology, Montreal, Canada

²Centre Hospitalier Pierre-Boucher, Radiology, Longueuil, Canada

³Jewish General Hospital, Radiology, Montreal, Canada

Purpose or Objective: Radiation therapy is an established neoadjuvant modality for patients with advanced rectal cancer. As the quality of surgery improved with Total Mesorectal Excision surgery (TME), radiation is now being challenged, as the number of patients needed to treat remains high when facing long-term normal tissue toxicity in the pelvis. High dose rate endorectal brachytherapy is a highly targeted form of radiation based on quality imaging with magnetic resonant imaging and was introduced in our institution along with TME. Unlike external beam radiation therapy, the clinical target volume is aiming mostly at the tumor bed. We are reporting the patterns of relapse of our patients after 15 years experience.

Material and Methods: Patients with operable rectal cancer based on pelvic MRI staging, are considered at risk for local recurrence were included; for physical reasons, those with obstructive tumors and positive extramesorectal nodes were excluded. Patients received treatment with 26 Gy in 4 fractions using a remote afterloader with an endoluminal cylindrical multichannel applicator and an Iridium 192 source. The CTV is defined as the gross tumor volume observed on the diagnostic MRI with no attempt to cover the perirectal nodes. 667 patients treated from 1999-2015, most of which were T3 tumors (84%), low T2 (13%) and early T4 (3%); 36 % of the patients had positive nodes on pre-operative imaging. The local failure in our patient population is 4.7 % with a median follow up time of 65 months for 608 patients (range 6-165 months). Twenty-eight patients had pelvic recurrence, of which 25 were documented with MRI and 3 were found with CT scan. The Imaging was reviewed by two radiologists.

Results: The location of recurrence were identified as: iliac or lateral nodes in 11 patients, anastomotic in 10 patients, inguinal nodes in 3 patients, anterior compartment in 4 patients and pre-sacral space in one patient (one patient had more than 2 sites). In the patients with nodal pelvic relapses, the relapse was isolated for 3 patients and in the other 8 patients there were associated systemic relapses, and these patients were asymptomatic and did not require pelvic radiation while the former 3 patients underwent successful salvage radiation with IMRT (1) /SBRT for 2 patients. Another 9 patients with isolated pelvic relapses received pre-operative pelvic radiation with salvage surgery.

Conclusion: In patients with rectal cancer treated with pre-operative HDRBT, pelvic nodal relapse was the most common site of recurrence and was often associated with asymptomatic systemic relapse. Those patients with isolated nodal relapse are salvageable with either IMRT of SBRT. For patients with localized recurrence, pre-operative pelvic radiation was possible with salvage surgery. Pre sacral recurrence is a rare event, with a single patient observed.

Intraluminal brachytherapy in unresectable biliary carcinoma with malignant biliary obstruction

N. Rastogi¹, V.A. Saraswat², S.S. Baijal³

¹Sanjay Gandhi Postgraduate Institute of Medical Sciences, Radiotherapy, Lucknow UP, India

²Sanjay Gandhi Postgraduate Institute of Medical Sciences, Gastroenterology, Lucknow UP, India

³Medanta Medicity, Radiodiagnosis, Gurgaon, India

Purpose or Objective: Locally advanced unresectable biliary carcinoma often present as extrahepatic malignant biliary obstruction with jaundice. The aim of treatment is to relieve jaundice and pruritus either by endoscopic biliary drainage (EBD) or percutaneous transhepatic biliary drainage (PTBD) followed by stenting. Stent is frequently blocked due to either tumour ingrowth or overgrowth. Intraluminal brachytherapy (ILBT) allows high dose to of radiation to local tumor area and delays the stent block. The purpose of this study is to assess the safety and efficacy of ILBT and impact of external beam radiotherapy(EBRT) on stent patency and survival.

Material and Methods: From 1998-2008, 172 unresectable, locally advanced biliary cancers (pancreas-12, gallbladder-140, cholangiocarcinoma-20), presenting with malignant extrahepatic biliary obstruction were prospectively treated with PTBD and stenting followed by ILBT with or without EBRT. The 110/172(64%) patients received ILBT alone (ILBT group) while 62/172(36%) received ILBT followed by EBRT(EBRT group). Endoscopic retrograde cholangiopancreatography (ERCP) and/or percutaneous cholangiogram (PC) was done in all. Biliary drainage was done by standard ultrasound and fluoroscopy guided percutaneous transhepatic puncture. The stricture was dilated by balloon catheter over the guide wire. The biliary tract was dilated repeatedly and upsized till 12 French Malecot catheter. High dose rate brachytherapy with Ir192 source used to deliver 10 Gy/1fr at 1 cm radius from the center of source. PTBD tube was replaced by 10 mm, non sheathed self expandable metallic modified Giantruco Z stent. In EBRT group, stenting, followed by EBRT(dose of 45Gy/25fr/ 5 weeks) by conformal technique to primary tumour and stent area. All the patients were given single agent 5-Fluorouracil chemotherapy 370 mg/m² Day1-5 at 4 weekly for 6 cycles.

Results: Palliation of jaundice and pruritus was achieved in all. The median overall survival in ILBT and EBRT group was 8 and 9 months with the stent patency 7 and 8 months and overall survival at 1 year was 21% and 23%. Gastric outlet obstruction was 29% in ILBT group and 19% in EBRT group(p=ns), while distant failure rate were 60 % & 55%. No ILBT related morbidity was observed.

Conclusion: PTBD is safe, well tolerated and effective in palliation of Jaundice. Intraluminal Brachytherapy (ILBT) appears to prolong stent patency The addition of EBRT to ILBT does not show any advantage in terms of stent patency and overall survival.

OC-0151

Radiation induced toxicity and tumour control in pts treated for uveal melanoma with ru-106 plaques
C.A. Espensen¹, L.S. Fog², M.C. Aznar², L. Specht², J.F. Kiilgaard³

¹Rigshospitalet, Department of Radiation Therapy 3994- the Oncology Clinic, Copenhagen, Denmark

²Rigshospitalet, Department of Radiation Therapy 3994- the Oncology Clinic, Copenhagen, Denmark

³Rigshospitalet, Ophthalmology Department, Copenhagen, Denmark

Purpose or Objective: In a retrospective study of 100 consecutive patients treated with Ru-106 eye plaques for uveal melanoma from 2005 to 2008 at our clinic, we aimed to investigate the correlation between the dose to the optic nerve and optic nerve damage; the dose to the macula and macular damage; and the minimum dose to the tumour and tumour control.

Material and Methods: Pre-treatment fundus images were imported into Plaque Simulator TM and the tumour was retrospectively contoured by an ophthalmologist. The plaque position was determined from the radiation scar on post-treatment images. 3D dosimetric data was calculated. The point doses to the optic nerve and macula and minimum dose to the tumour were estimated. TCP, and damage to the optic nerve and macula, were determined from the patients' notes. The correlations between optic nerve damage, macular damage and TCP with dose, dose rate, gender, and plaque type was investigated using univariate and multivariate analyses.

Results: 16 % of the patients developed optic nerve damage. Only optic nerve dose was correlated with damage to the optic nerve (p=0,000063) in univariate analysis.

51% of the patients had macular damage. Only macular dose was correlated with damage (p=0,00049) in univariate analysis.

32 % of the patients did not achieve tumour control. TCP was correlated with minimum tumour dose and gender in

univariate analysis. Patients with minimum doses > 80 Gy had 100% TCP. For 80% of the patients with tumour recurrence, the plaque did not geometrically overlap the tumour.

Dose response curves were drawn for optic nerve damage, macular damage and TCP. Such curves could not be found in the literature so no comparison was possible. Previously published values for TCP are similar to, or higher than, the one found in the present material. However, the papers citing higher values have selected patients with smaller tumours, which tend to have higher values of TCP. We emphasise that the number of patients is quite small and that a study of a large patient cohort is planned.

Conclusion: Tumour control only failed in patients who received less than the prescription dose. The use of image guided planning software (such as Plaque Simulator TM) may aid in optimizing tumour control in the future. The present analysis presents the first reported dose response curves for damage to the optic nerve and macula. This information may be useful in delivering the optimal treatments in future.

OC-0152

Novel software modules for treatment planning of 106Ru eye plaque brachytherapy

G. Heilemann¹, L. Fetty¹, I. Birlescu¹, M. Blaickner², N. Nesvacil³, D. Georg³

¹Medical University of Vienna, Department of Radiation Oncology, Wien, Austria

²Austrian Institute of Technology GmbH, Health and Environment Department Biomedical Systems, Vienna, Austria

³Medical University of Vienna/ Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Department of Radiation Oncology, Vienna, Austria

Purpose or Objective: Treatment of uveal melanoma by means of brachytherapy using 106Ru eye plaques achieves very good tumor control while keeping morbidity at an acceptable level. However, a deeper understanding of the underlying dose-response relationship is still missing not least because of the lack of appropriate software packages for 3D treatment planning and volumetric dose assessment. This motivated the in-house development of software modules to calculate the dose distributions in critical, ophthalmologic structures as well as tumor for an eye model.

Material and Methods: A resizable 3D model of an eye was created in Sidefx Houdini, consisting of lens, ciliary body and optic nerve as well as macula, retina and sclera. A dome-shaped tumor model can be added with apex height and basal diameter as adjustable parameters. The position of the tumor model can be fixed by reference to the distance between tumor and macula and tumor and optical nerve. Alternatively fundus images can be incorporated into the 3D model in order to account for the individual tumor shape. A specially designed algorithm projects the images onto the virtual eye model and converts them to volumetric data. Different types of BEBIG eye plaques (CCA, CCB and COB) can be positioned within the computer model. Corresponding dosimetric lookup tables were generated from MC simulations using MCNP6. Superposition onto the 3D eye model enables the calculation of doses and dose volume parameters for the tumor and adjacent healthy tissue. Finally, dosimetric safety margins have been obtained by performing film measurements and can be included in order to determine dosimetric uncertainties.

Results: The software modules can calculate full 3D dose distributions with a cubic dose grid of 200 µm in < 5 s (and < 1 s with GPU). The 3D eye model can be adjusted on the basis of simple geometric measures such as the measured size of the eye as well the distances between tumor, macula and optic nerve and thereby be used for individual treatment planning, i.e. the selection and positioning of the type of plaque. The registered fundus projection can be used to guide the tumor delineation. Dose-volume metrics can be generated for all structures of the individualized model which in turn can be used for assessing dose-response relationships

for the target volume and organs-at-risk. The dosimetric uncertainty assessment provides information on safety margins. Local agreement between MC and film was better than 6 % for the first 7 mm.

Conclusion: In this study we presented novel software modules for treatment planning in ¹⁰⁶Ru eye plaque brachytherapy of uveal melanomas. It is aimed to be used in daily treatment planning as well as for performing pro- and retrospective studies to provide further information on dose-response relationships and prognostic values for treatment morbidity and local control. Future works involves the registration of pre- and/or post-application MR images as well as a quantitative evaluation on the basis of retrospective data.

Dual energy CT and iterative metal artefact reduction for accurate tumour delineation

D. Kovacs¹, L. Rechner¹, J. Bangsgaard¹, A. Berthelsen¹, J. Costa¹, J. Friberg¹, G. Persson¹, L. Specht¹, I. Vogelius¹, M. Aznar¹

¹Rigshospitalet, Oncology, Copenhagen, Denmark

Purpose or Objective: To compare the accuracy of tumor delineation on a standard CT scan and on CT scans with two metal artifact reduction methods in an oral cavity phantom with a known tumor surrogate.

Material and Methods: A set of teeth containing an amalgam-filled removable tooth and an artificial polycaprolactone tumour was placed in water and CT scanned (Siemens Somatom Definition AS) at 120 kVp, 80 kVp, and 140 kVp. The two latter scans were used to reconstruct virtual monochromatic (VM) images. All image sets were additionally reconstructed with metal artefact reduction (MAR) software (iMAR, Siemens Healthcare). The following 4 MAR reconstructions were studied: 1) 130 keV VM 2) 70 keV VM with MAR, 3) 120 kVp with MAR, 4) 130 keV VM with MAR. A conventional 120 kVp CT was also taken and a 120 kVp image where the metal tooth was removed was used as control. 3 oncologists and 2 radiologists contoured the tumour volume on all 6 image sets while blinded to the image reconstruction type. A 7th high-quality image of only the artificial tumour was contoured to obtain the true shape of the tumour. Maximal Hausdorff distances and DICE coefficients of the 5 delineated contours compared to the true contour were used to quantify delineation accuracy in all 6 image sets. Statistically, a Friedman-test was used for primary comparisons and a Neményi-test is performed for pairwise post hoc analysis.

Results: In all cases, MAR reconstructions clearly improved tumour delineation precision and accuracy (see Figure 1 and Table 1). The highest level of DICE similarity between observers was found based on 120 kVp iMAR reconstructions (DICE = 0,87 [0,86 - 0,88]), while the highest level of accuracy was found in the 130 keV iMAR reconstructions (Hausdorff max = 4,0 mm [2,9 - 8,1]). A statistical analysis comparing DICE coefficients and Hausdorff distances between modalities showed that contouring accuracy on the 120 kVp standard and 130 keV VM images were significantly degraded from the control image ($p < 0,05$ for both), whereas we found no significant differences between the control and the 70 keV VM iMAR, the 120 kVp iMAR and the 130 keV VM iMAR reconstructions. Verifying the model used for this study, a high level of precision and accuracy was observed (Hausdorff max = 2,9 mm [2,0 - 3,3] and DICE = 0,9 [0,89 - 0,92]) when no metal was present during the scan.

		Standard	Reconstruction Modality				Control
		120 kVp	130 keV	70 keV + iMAR	120 kVp + iMAR	130 keV + iMAR	120 kVp no metal
Hausdorff max	Median [Range]	10,7 [6,3 - 14,5]*	9,8 [5,6 - 11,5]**	7,7 [4,1 - 9,2]	5,1 [3,9 - 6,6]	4,0 [2,9 - 6,1]	2,93 [2,0 - 3,3]
	[mm]						
DICE	Median [Range]	0,75 [0,72 - 0,81]*	0,78 [0,75 - 0,80]*	0,84 [0,80 - 0,85]	0,87 [0,86 - 0,88]	0,88 [0,83 - 0,89]	0,9 [0,89 - 0,92]

Table 1 showing the median and range of maximal Hausdorff distances and DICE coefficients when comparing to the true contour. Statistical significance after a pairwise post-hoc Neményi test is shown as * ($p < 0,01$) or ** ($p < 0,05$)

Conclusion: MAR reconstructions resulted in a clear improvement in contouring accuracy compared to conventional CT and DECT VM images, where a significant degradation of tumour delineation accuracy was found in comparison to the control image. The highest level of similarity between observers was found in MAR reconstructions of 120 kVp, while 130 keV VM images showed potential to further improve accuracy when reconstructed with MAR software.

Clinical use of dual-energy CT for proton treatment planning to reduce CT-based range uncertainties

P. Wohlfahrt^{1,2}, C. Möhler^{3,4}, A. Jakobi¹, M. Baumann^{1,2,3,5,6}, W. Enghardt^{1,2,3,5,6}, M. Krause^{1,2,3,5,6}, S. Grelich^{3,4}, C. Richter^{1,2,3,5,6}

¹OncoRay - National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden- Helmholtz-Zentrum Dresden - Rossendorf, Dresden, Germany

²Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology, Dresden, Germany

³German Cancer Research Center DKFZ, Heidelberg, Germany

⁴Heidelberg Institute for Radiation Oncology HIRO, National Center for Radiation Research in Oncology, Heidelberg, Germany

⁵Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Department of Radiation Oncology, Dresden, Germany

⁶German Cancer Consortium DKTK, Dresden, Germany

Purpose or Objective: To improve CT-based particle treatment planning the additional tissue information

provided by dual-energy CT (DECT) compared to single-energy CT (SECT) can be clinically used to reduce CT-based range uncertainties and to analyze intra- and interpatient tissue variations. First, a DECT scan protocol was optimized and clinically introduced. Second, in a first analysis patient DECT scans were evaluated concerning CT number variability.

Material and Methods: After an experimental analysis of several CT scan settings concerning beam hardening, image quality and planned dose distribution using tissue surrogates, head and body phantoms and real tissues, an optimized and standardized DECT protocol (voltages: 80/140 kVp, kernel: D34) is clinically applied for patients treated with protons. 45 planning and 360 control DECT scans of overall 70 patients were acquired with a single-source DECT scanner (Siemens SOMATOM Definition AS) until October 2015. Contouring and treatment planning are performed on pseudo-monoenergetic CT scans (MonoCT) derived by a weighted sum of both CT datasets. 25 patients with different tumor sites (head, head & neck, prostate, pelvis) and overall 200 DECT scans were initially investigated to evaluate intra- and interpatient tissue variabilities. Based on the frequency distribution of voxelwise 80/140kVp CT number pairs, a linear correlation of low-density, soft and bony tissues can be determined, respectively.

Results: A DECT-based MonoCT of 79 keV is found optimal for proton treatment planning. Assuming identical CT dose to a SECT scan, the MonoCT shows a signal-to-noise ratio increased by 8% and a CT number constancy raised by 23% on average and up to 69% for bones. Consequently, the current uncertainties of a heuristic conversion of CT numbers into stopping power ratios (SPR) using a look-up table are reduced.

Evaluation of patient variability revealed that 80/140kVp CT number pairs of human tissues are on average well described by linear correlations with a slope ($\pm \sigma$) of (1.023 ± 0.006) for low-density, (0.825 ± 0.008) for soft and (0.696 ± 0.006) for bony tissues. The slope variation between different patients, independent from tumor site and patient size, is comparable to the variability between different control DECT scans of one patient (σ of about 1-3%). However, a band of CT number pairs deviating from the mean linear correlation, e.g. caused by image noise and partial volume effects, reveals potential insuperable uncertainties of a voxel-based heuristic CT number-to-SPR conversion.

Figure 3. Normalized logarithmic frequency distribution of voxelwise 80/140kVp CT number pairs using planning DECT scans of 17 patients with different tumor sites in head and head & neck (a) as well as 12 control DECT scans of one head-and-neck patient (b). Linear correlations determined for low-density, soft and bony tissues (red lines) based on the logarithmic frequency distribution describe tissue surrogates (blue dots) and tabulated human tissues (green triangles) quite well. Non-tissue surrogates differ from these relations and can thus be separated.

Conclusion: The clinical application of DECT-based MonoCT can contribute to a more precise range prediction. Further improvements are expected from a direct, non-heuristic SPR calculation, which is not yet clinically available. The further growing DECT patient database enables not only a detailed analysis of intra- and interpatient variations, but also a robustness analysis for different direct SPR prediction approaches.

OC-0155

MR-guided multi-atlas based synthetic CT for MR-only radiotherapy of head and neck cancer patients

R. Farjam¹, N. Tyagi¹, H. Veeraraghavan¹, A. Apte¹, K. Zakian¹, M. Hunt¹, J. Deasy¹

¹Memorial Sloan-Kettering Cancer Center, Medical Physics, New York- NY, USA

Purpose or Objective: To develop an image analysis approach for generation of the synthetic CT for MR-only radiotherapy of head and neck (H&N) cancer patients.

Material and Methods: Eleven sets of CT and MRI (in-phase, Philips mDixon sequence) scans were randomly selected from a pool of H&N cancer patients. A bias field correction algorithm was primarily applied to each MRI scan to eliminate the intensity variation due to B0 and B1 field inhomogeneity and tissue susceptibility effect. A landmark-based MRI standardization technique was then used to standardize the MR intensity histograms wherein each landmark, total of 4, corresponds to a different histogram extremum. Using a rigid + deformable registration, CT scan from each patient was registered to the standardized MRI to construct an atlas of CT-MRI. To improve the performance of the registration, bone intensity in the CT image was suppressed to assimilate CT and MRI scans. CT image is initially clustered into classes of air, bone and soft tissue. The cluster center of the bone class is then transformed to the air class to suppress the bone signal. To synthesize CT for a new patient, using the displacement fields achieved by registering each MRI in the atlas to the new patient MRI, all CTs from the atlas were also deformed onto the new patient. A generalized registration error (GRE) metric was then calculated as a measure of goodness of local registration between each pair of MRIs. GRE is the Euclidean distance of the mean normalized local mean, variance and entropy of the difference map between the two registered standard MRIs. The synthetic CT value at each point would be the average of GRE weighted CTs from all CT scans in the atlas. To evaluate our proposed method, the mean absolute error (MAE) between the synthetic CT and the original CT was computed over the entire CT and air and bone regions in a leave-one-out scheme. The efficiency of our proposed registration scheme was also compared with commercial software. Comparison of the dose plan between the original and synthetic CT is also ongoing.

Figure 1. Example of the synthetic CT generated by our proposed atlas-based approach: (left panel) Original CT, (middle panel) MRI: in phase, (right panel) Synthetic CT

Results: MAE between the original and the synthetic CT was 67 ± 9 , 114 ± 22 , and 116 ± 9 HU for the entire image, air and bone regions, respectively. We found that our proposed registration strategy and GRE metric each could lower up to 30% and 15% of the MAE over the entire CT and up to 50% and 40% in the MAE of the bone regions. Our primary dose

calculation revealed highly consistent results between the original and the synthetic CT.

Table 1. Example of dose calculation for a head and neck cancer patient using original and synthetic CT generated by our proposed multi-atlas based algorithm. Numbers are in cGy.

Table 1.	PTV70	PTV66	PTD54	PTV50	Parotid		SMG		Mandible	Brachial Plexus		Larynx
					R	L	R	L		R	L	
Original CT	Min	5526	5657	2920	4026							
	Max	6585	6613	6526	5702				6300	5991	5270	5914
	Mean	6306	6352	5823	5206	1550	2386	5791	3983			
	D95	6113	6142	5482	5061							
Synthetic CT	Min	5479	5621	3114	4180							
	Max	6590	6685	6538	5689				6319	5993	5280	5933
	Mean	6307	6370	5829	5211	1597	2366	5811	4078			
	D95	6110	6144	5488	5064							

Conclusion: A multi-atlas based approach was presented in this work for generation of the synthetic CT for MR only radiotherapy of the head & neck cancer patients. While the registration scheme presented in this work enhances the performance of the atlas propagation, generalized registration error (GRE) helps to construct a better synthetic CT using a locally more similar atlas.

OC-0156

MRI only prostate radiotherapy using synthetic CT images

E. Persson¹, F. Nordström^{1,2,3}, C. Siversson^{3,4}, C. Ceberg²

¹Skåne University Hospital, Medical Radiation Physics, Lund, Sweden
²Lund University, Medical Radiation Physics, Lund, Sweden
³Spectronic Medical AB, Medical, Helsingborg, Sweden
⁴Lund University, Medical Radiation Physics, Malmö, Sweden

Purpose or Objective: Introducing an MRI-only workflow into the radiotherapy clinic, requires that MR-images can be used both for treatment planning calculations and for patient positioning. The two-fold aim of this study was to evaluate the use of MR-images with respect to 1) the accuracy of treatment planning dose calculations, and 2) the reliability of fiducial marker identification for patient positioning.

Material and Methods: Synthetic CT images (sCT) were generated using the Statistical Decomposition Algorithm (SDA, MriPlanner, Spectronic Medical AB, Sweden). The algorithm uses a T2-weighted MRI for sCT generation, based on a multi-template assisted classification method. In order to exclude the effect of geometrical distortions and patient deformation owing to reposition between imaging sessions, a registered CT (rCT) was constructed by deformable registration with the MR using the Elastix toolbox.

Five-field IMRT plans (both 6 and 10 MV) were created for six patients, using the Eclipse treatment planning system (Varian Medical Systems, Palo Alto, CA). Final dose calculations were made using the anisotropic analytical algorithm (AAA). The rCT was used for the initial treatment planning and the plan was recalculated on the sCT. Thus, the two treatment plans created for each patient had the same number of monitor

units for each field. The resulting dose distributions from the rCT- and sCT-treatment plans were compared based on a set of dose volume histogram criteria according, and by using gamma evaluation.

The reliability of the MRI-based fiducial marker identification was evaluated by an observer study. For this part of the study, the position of gold fiducial markers were determined by six independent observers using an MRI sequence dedicated for marker identification (LAVA-flex). Each marker position, three for each patient, were compared between the observers. The observers graded (one to five, where five represents the highest level of confidence) their confidence by which the markers for each patient were identified.

Results: The mean dose differences to PTV between plans based on sCT and rCT were $-0.1\pm 0.3\%$ (1 s.d) (6MV) and $-0.2\pm 0.2\%$ (1 s.d) (10 MV). Gamma analysis showed pass rates ranging between 98% and 100% for both energies, with gamma criteria of 1%/2mm (local dose deviation). The mean standard deviation of the marker position, as determined by the observers, was 0.6 mm in all directions (x, y and z). One marker identification result was excluded due to an incorrect identification by one observer. The confidence grading ranged between 2 and 5.

Conclusion: This work demonstrates that SDA can provide sufficient dosimetric accuracy for an MRI only workflow for prostate cancer patients. However, gold fiducials cannot be identified using LAVA-flex with high enough confidence and further work is needed to develop methods for marker identification in an MRI only workflow.

OC-0157

Prostate fiducial markers detection with the use of multiparametric-MRI

C.D. Fernandes¹, C. Dinh¹, L.C. Ter Beek², M. Steggerda¹, M. Smolic¹, L.D. Van Buuren¹, P.J. Van Houdt¹, U.A. Van der Heide¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

²The Netherlands Cancer Institute, Department of Radiology, Amsterdam, The Netherlands

Purpose or Objective: Prostate cancer patients scheduled for EBRT are often implanted with fiducial markers for position verification. A precondition for an MR-only workflow is the possibility to identify them on MRI. The markers present as signal voids in most images and their apparent position depends on their shape and orientation relative to the magnetic field. Rather than acquiring a sequence for this single purpose, we propose to use a model for the automatic detection of fiducial markers combining information from the entire multiparametric (mp) MRI protocol used for target delineation.

Material and Methods: Thirty prostate cancer patients scheduled for EBRT were implanted with 2-3 gold fiducial markers (0.9x3mm). A mp-MRI (T1w, T2w, B0-mapping and mDIXON) was performed using a 3T MRI (Achieva, Philips) and a CT with a 24-slice CT scanner (Somatom-Sensation-Open, Siemens). The reference position of the markers was based on the segmented CT images. The MRI was registered to the CT and resampled to the grid of 0.9x0.9x3mm³. A logistic regression model was developed to estimate the location of the markers based on the following MRI features: signal intensity, mean, median, min, max and standard deviation values in a kernel of 3x3x3vox and a multi-scale blobness filter [1] of the prostate region. The model was cross-validated using a leave-one-out method. Performance was assessed using features from each separate imaging sequence and by combining the features from all sequences. Voxels detected as markers by the model were grouped into clusters. We defined the probability of each cluster candidate as the highest probability value of all voxels within it. Results were further post-processed by selecting the n(i) highest probability clusters, where n(i) is the number of markers implanted in patient i. Results were classified as a false positive (FP) if the distance between the reference

centroid coordinates and the detected location was larger than 2.7mm in plane and 3mm in slice direction.

Results: Table1 shows the average AUC values for the model results of all patients using a single sequence and when combined. The combined model (AUC=0.94) performs significantly better than the best imaging sequence alone (T1-THRIVE AUC=0.84). Without post-processing the model correctly identifies 80/86 markers but with a total of 98 FP. After post-processing, we reduced the FP to a total of 20 but the true positives (TP) were also reduced to 66. Figure 1 shows the model pipeline. Deviations between the reference and the correctly identified marker location are < 1mm.

Conclusion: The standard mp-MRI provides valuable information to detect fiducial markers. The combination of different sequences is more accurate than the use of a single sequence. The number of TP after processing needs to be further addressed but the overall findings support the feasibility of automatic marker detection in an MR-only workflow.

[1] Lindeberg et al, IJCV 1998

Total number of markers present in 30 patients: 86

	Average AUC	Total TP	Total FP	Average Distance (mm)		
				x	y	z
T1-THRIVE	0.84	21	65	0.66	1.07	0.97
T2 TSE	0.69	6	80	1.15	1.95	1.31
B0 mag	0.80	29	57	0.96	1.44	0.78
mDIXON IP	0.82	12	74	0.75	1.21	1.14
Combined	0.94	66	20	0.74	0.97	0.97

Table 1 - Number of markers detected by the model when using sequences individually and when combining them together. The results presented above are obtained after post-processing. The distance was calculated between the centroid coordinates of the reference and the detected location. The distribution of AUC values over all patients is significantly different (p<0.05) between any of the single sequences and the combined model using a Wilcoxon signed-rank test. AUC: Area under the curve; TP: True positives; FP: False positives. The use of "mag" in B0 mag refers to the amplitude of the signal.

Figure 1 - Model pipeline and outcome for a representative patient. The CT image (a) is used as a reference to generate the reference position of the markers. The MRI was used for prostate delineation. The combination of prostate delineations and reference marker position is used as the labeling for our data (f). The imaging features are extracted from the MR sequences (b),(c), (d) and (e). In figure (g) one can see the final result after post-processing and reconstruction of a cylindrical structure with the dimensions of the marker based on the identified clusters' centroid coordinates.

OC-0158

Impact of breathing guidance and prospective gating on 4DCT image quality: a digital phantom study

S. Pollock¹, J. Kipritidis¹, D. Lee¹, K. Bernatowicz², P. Keall¹
¹University of Sydney, Sydney Medical School - Central, Sydney, Australia
²Paul Scherrer Institute, Center for Proton Therapy, Villigen, Switzerland

Purpose or Objective: Irregular breathing motion has a deleterious impact on thoracic and abdominal four-dimensional computed tomography (4DCT) image quality. Two pathways to overcome this problem are: (i) improving the regularity of breathing motion using the audiovisual biofeedback (AVB) breathing guidance system, and (ii) prospectively respiratory gating the 4DCT scan based on real-time respiratory motion. Until now, the effects of these technologies on 4DCT imaging have not been directly compared. The purpose of this study was to compare the impact of AVB and respiratory gating on thoracic 4DCT image quality and acquisition time using a deformable digital phantom driven by lung cancer patient breathing patterns

Material and Methods: We obtained simultaneous measurements of chest, abdominal, diaphragm, and tumor motion for 6 lung cancer patients with tumor motion > 5 mm. Breathing signals were acquired under two breathing conditions: (1) AVB, and (2) free breathing. For each breathing condition, we used the 4D eXtended Cardiac Torso

(XCAT) to simulate 4DCT acquisitions in the cine and respiratory gated mode. For each combination of breathing condition and acquisition mode, 4DCT image quality was quantified in terms of Dice similarity coefficient between reconstructed and ground truth lung and tumor volumes (DSC(lung) and DSC(tumor), respectively), in addition to an automated method of artefact detection (utilizing normalized cross coefficient (NCC)). 4DCT acquisition times were also compared for each breathing condition and acquisition mode

Results: In cine mode, AVB improved DSC(lung) and DSC(tumor) by 0.3% (p = 0.005) and 0.3% (p < 0.001), respectively, and improved NCC by 11% (p = 0.002). In respiratory-gated mode, AVB did not have a significant impact on image quality. AVB increased the acquisition length of cine mode 4DCT by an average of 4 seconds, but reduced the length of respiratory gated acquisitions by 10 seconds. Respiratory gating improved image quality over cine mode irrespective of the breathing condition. Utilizing both AVB and respiratory gating together garners the greatest improvement in DSC(lung), DSC(tumor), and NCC values over conventional free breathing in cine mode by 0.9% (p < 0.001), 1.5% (p = 0.25), and 18.5% (p < 0.001), respectively

Conclusion: This was the first study to directly compare the impact of breathing guidance and respiratory gating on 4DCT acquisition. We observed that AVB significantly improves the quality of 4DCT images in cine mode over free breathing, but can also reduce the amount of time needed to acquire a respiratory gated 4DCT scan. The results presented here demonstrate that AVB and respiratory-gating can both be beneficial pathways to improve 4DCT simulation for cancer radiation therapy, but the biggest gains are achieved when using these technologies simultaneously

X-ray tube current modulation with dynamic blade collimation for CBCT guidance

D. Parsons¹, J. Robar¹
¹QEII Health Sciences Centre - Dickson Building, Medical Physics, Halifax- Nova Scotia, Canada

Purpose or Objective: The focus of this work is the development of a novel blade collimation system enabling volume-of-interest (VOI) CBCT using the kV source on a TrueBeam linear accelerator. Advantages of the system are assessed, particularly with regard to reduction and localization of dose, as well as improvement of image quality.

Material and Methods: A four-blade dynamic KV collimator was developed to track a VOI during CBCT acquisition. The system is controlled using a Raspberry Pi computer placed within the linac gantry. The current prototype is capable of tracking an arbitrary volume defined by the treatment planner for subsequent CBCT guidance. During gantry rotation, the collimator tracks the VOI with adjustment of position and dimension. CBCT image quality was investigated as a function of collimator dimension, while maintaining the same dose to the VOI, for a 20 cm diameter cylindrical water phantom with a 9 mm diameter bone insert centered on isocenter. Dose distributions for various anatomical sites were modeled using a dynamic BEAMnrc library and DOSXYZnrc. The resulting VOI dose distributions were compared to full-field distributions to quantify dose reduction and localization to the target volume. X-ray tube current modulation was investigated in combination with the VOI approach, using digitally reconstructed radiographs to estimate tube pulse width for each CBCT projection. The technique was evaluated in Developer Mode on the linear accelerator.

Results: Measurements show contrast increase by a factor of 1.3 and noise reduction by a factor of 1.7, for VOI CBCT, and thus an increase in contrast-to-noise ratio (CNR) by a factor of approximately 2.2. Depending upon the anatomical site, dose was reduced to 15%-80% of the full field value along the central axis plane and down to less than 1% along the axial planes. The use of tube current modulation allowed for specification of a desired signal-to-noise ratio within projection data. For approximately the same dose to the VOI, CNR was increased by a factor of 1.2 for tube current-modulated compared to unmodulated VOI CBCT.

Conclusion: The VOI CBCT approach allows imaging of a planner-defined volume, offering both image quality improvement and reduction of imaging dose for the patient.

Growth and oedema related shifts of brain metastasis treated with stereotactic radiosurgery

K. De Vries¹, M. Beerendonk¹, L. Dewit¹, W. Boogerd², D. Brandsma², A. Van Mourik¹, G. Borst¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands

²Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Neuro-oncology, Amsterdam, The Netherlands

Purpose or Objective: Stereotactic Radiosurgery (SRS) has emerged as a treatment of choice for many cancer patients

with brain metastasis. Most institutes use linac-based irradiations with multiple days between imaging and irradiation and a subset of patients is treated with fractionated SRS. So far, the geometrical uncertainties induced by such time intervals have not yet been quantified. Therefore, we investigated the growth rates of different tumour entities, the effect of oedema and the use of steroids on possible tumour shifts to estimate the effect on the tumour dose.

Material and Methods: Thirty-six patients were included, equally divided over lung-, breast- and melanoma cancer patients. Patients receiving systemic cytotoxic treatment 3 months prior to the diagnostic MRI were excluded, except for breast cancer patients on hormonal therapy that started more than 6 months prior to the diagnostic MRI. All patients had undergone a diagnostic and a radiotherapy planning MRI of which the T1w+contrast sequences were registered with the planning CT scan for target definition on both scans. Consensus was reached for all delineations by two radiation oncologists. The median time between the two MRI scans was 18 days (range 6-54). For all tumour delineations, the volume, radius (assuming spherical tumours) and Centre of Mass (CoM) were calculated. Growth rates were determined from volumetric or radial increase per day between the MRI scans. CoM differences between scans served as a measure for tumour shifts that can be caused by oedema (-clearance) and/ or anisotropic growth. Oedema was scored only if an experienced radiologist diagnosed peritumoural oedema on the diagnostic MRI.

Image 1: Delineations on diagnostic (left) and planning MRI (right), both registered on planning CT.

Results: Table 1 shows the results for tumour growth and tumour shifts. The highest growth rate in radial increase is seen in large melanoma tumours (0.07 mm/day (SD 0.02), $p < 0.01$). Large heterogeneities in growth rate are seen in tumours of both small and large brain metastasis of lung cancer patients (small: mean=7%/day, SD=10%, range=0%-26%, large: mean=3%/day, SD=6%, range=-1%-15%). In this lung group, three patients showed shrinkage; all three started steroids after diagnostic MRI. Large tumour shifts (mean=1.7 mm) and variability (SD=1.0 mm) were observed in the patient group with oedema receiving steroids (whereby the growth rate of tumours in these patients was not different).

Table 1. Growth rates and shifts of brain metastasis

Tumour	Small n=6			Large n=6		
	Volume planning MRI (cc)	Growth rate % volume/day (SD)	Growth rate mm/day (SD)	Volume planning MRI (cc)	Growth rate % volume/day (SD)	Growth rate mm/day (SD)
Melanoma (n=12)	0.21-1.29	5 (2)	0.05 (0.02)	1.32-8.41	3 (1)	0.07 (0.02)
Breast (n=12)	0.57-1.69	5 (1)	0.05 (0.01)	2.05-5.75	2 (1)	0.03 (0.04)
Lung (n=12)	0.11-1.97	7 (10)	0.04 (0.03)	2.68-8.29	3 (6)	0.03 (0.09)

Shift factors	CoM shift (mm) (SD)	p*	Growth rate (mm/day) (SD)	p*	CoM shift+growth rate (mm/day) (SD)	p*
	Oedema and steroids (n=17**)	1.73 (1.02)	p<0.001	0.04 (0.04)	NS	0.15 (0.09)
No oedema and/or no steroids (n=18)	0.53 (0.34)		0.04 (0.02)		0.07 (0.02)	

*Unpaired parametric t-test
**1 patient was excluded because the shift was mainly caused by intratumoural bleeding

Conclusion: Within the limitations of a retrospective study, our results show that the growth and shift of brain metastasis over time can be significant and may vary over patient groups. Given the typical steep dose gradient in SRS treatments (>10%/mm), tumour growths and shifts may have a significant impact on the tumour dose. Therefore, this phenomenon must be considered if the workup and treatment of SRS for brain metastasis is encompassing multiple days.

OC-0161

Renal and diaphragmatic interfractional motion in children and adults: is there a difference?

I.W.E.M. Van Dijk¹, S.C. Huijskens¹, M.A.J. De Jong¹, J. Visser¹, R. Dávila Fajardo¹, C.R.N. Rasch¹, T. Alderliesten¹, A. Bel¹

¹Academic Medical Center, Department of Radiation Therapy, Amsterdam, The Netherlands

Purpose or Objective: One of the factors determining the size of planning target volume (PTV) margins is organ motion. Organ motion is comprehensively studied in adults and paediatric PTV margins are generally based on these data. We hypothesize that adult-based PTV margins are too large for paediatric patients because children and adults differ in body composition. Our aim was to compare renal and diaphragmatic interfractional motion in children with that in adults and to investigate the correlation with age and height.

Material and Methods: This single-centre retrospective study consisted of 35 children and 35 adults who received thoracic/abdominal irradiation between October 2009 and December 2014. The mean age of children and adults was 10.3 years (range 3.1-17.8 years) and 59.9 years (range 34.1-94.0 years) respectively. Mean height in children and adults was 140 cm (range 92-184 cm) and 175 cm (160-203 cm) respectively. According to protocol, abdominal and/or thoracic Cone Beam CT (CBCT) images were acquired for setup verification before radiation delivery. A total of 70 reference CT (refCT) scans, 350 paediatric CBCTs (mean 10; range 5-30) and 476 adult CBCTs (mean 14; range 5-27) were available for registration using Elekta XVI software. In order to assess renal and diaphragmatic motion, each CBCT was registered to its refCT in 2 steps; registration of: 1) the bony anatomy (i.e., the vertebral column), and 2) the left kidney, right kidney and diaphragm separately. For each individual, we assessed organ motion in the left-right (LR), cranio-caudal (CC), and anterior-posterior (AP) directions for the left and right kidney. Diaphragmatic motion was measured in the CC direction only as a surrogate for upper abdominal organ motion. Subsequently, for all organs the mean and standard deviation of the measurements in all directions were calculated and analysed to estimate the group systematic error (Σ) and the group random error (σ). The correlations

between organ motion and age and height were investigated using a univariate regression analysis.

Results: Interfractional organ motion in children and adults was different; displacements in children were notably smaller than in adults. Consequently, the estimated group systematic (Σ) and random errors (σ) for the two groups were different (Table 1). Within each group, no correlation was found between organ motion and age or height. Overall, in the CC direction, weak correlations were found between the patient random error, and age and height (Figure 1).

Table 1. The estimated group systematic (Σ) and random error (σ) for children and adults.

	Systematic error Σ (mm)						
	Right kidney			Left kidney			Diaphragm
	LR	CC	AP	LR	CC	AP	CC
Children	1.3	3.6	1.8	1.4	3.1	4.0	3.8
Adults	1.9	6.6	3.2	2.1	6.5	2.2	9.9

	Random error σ (mm)						
	Right kidney			Left kidney			Diaphragm
	LR	CC	AP	LR	CC	AP	CC
Children	1.0	2.9	1.5	1.5	2.9	2.3	3.7
Adults	1.5	5.0	2.9	1.5	5.0	2.1	4.8

Abbreviations: AP anterior-posterior, CC cranio-caudal, LR left-right

Figure 1. The correlation between the patient random error (mm), and age (years) and height (cm) in children (black dots) and adults (open circles) in the cranio-caudal direction.

Conclusion: Our results show that renal and diaphragmatic interfractional motion in children tend to be smaller than in adults, suggesting that abdominal PTV margins in children could be reduced. The difference in organ motion in the two groups could not completely be explained by age or height, indicating that further research is needed to understand the underlying mechanisms.

⁴Gentofte University Hospital, Department of Pulmonary Medicine, Copenhagen, Denmark

⁵Rigshospitalet, Centre for Clinical Education, Copenhagen, Denmark

⁶DTU Nanotech, Department of Micro-and Nanotechnology, Lyngby, Denmark

⁷Nanovi, Nanovi Radiotherapy A/S, Lyngby, Denmark

Purpose or Objective: We developed a new liquid fiducial marker (BioXmark®) for use in image-guided radiotherapy (IGRT). The liquid solidifies into a three dimensional (3D) structure after injection into tissue. A good level of marker's

visibility in a lung phantom using 2D and 3D x-ray imaging was previously shown. We report results and experiences from the study examining the performance (structural - and geometrical stability) of the liquid marker during radiotherapy of patients with non-small cell lung cancer (NSCLC) in free breathing (FB) or deep inspiration breath hold (DIBH).

Material and Methods: Fifteen patients had markers implanted into the primary tumour and/or involved lymph nodes. Cone-beam computed tomography (CBCT) images were acquired daily during the course of radiotherapy (66 Gy / 33 fractions). The fiducial markers were contoured automatically on all the daily acquired images, using a 400 Hounsfield Units (HU) level as threshold, in the treatment planning system Eclipse (v. 13.0), the data was retrieved and analysed using Eclipse scripting API and Matlab v2014b, respectively. The stability of the marker inside the tumour and the lymph nodes was evaluated visually. The structural stability of the marker regarding volume and radio-opacity was evaluated as physical measured volume and mean HU, analysed over time. Furthermore the positional stability of all markers was analysed by weekly measurements of the change of the distance between marker centre position and carina, as a surrogate for inter-fractional variation in position of the tumours and the lymph nodes.

Results: Two patients did not receive radiotherapy and thus 13 patients with 29 markers were analysed (9 injected into tumours and 20 injected into lymph nodes). Ten patients were treated in DIBH and three in FB. All injected markers stayed in the injected site between planning and end of treatment. The variation in global mean HU was larger for all primary tumour markers (937 ± 227 HU, mean \pm SD) compared to lymph nodes markers (921 ± 153 HU). This might be because tumours have a larger anatomical change/shrinkage compared to lymph nodes, which in turn affects the liquid marker. The measured sizes of the markers showed good stability during treatment (See Figure)

In terms of IGRT, the markers were visible on CBCT throughout the treatment; DIBH related artefacts in the markers (elongated markers due to inter-breath hold variation) were observed on a few patients. Three patients (two DIBH and one FB) showed > 5 mm inter-fraction variation in marker position relative to carina, possibly due to

tumour/lymph node shrinkage or anatomical changes. They were all rescanned for treatment adaptation.

Conclusion: The liquid fiducial markers remained stable throughout the treatment course regarding position inside the target, physical volume and radio-opacity on CBCT. The BioXmark® liquid marker offers an interesting alternative to solid markers.

OC-0163

Robustness of proton RT with different beam angles towards inter-fractional motion in the pelvis

A. Andersen¹, O. Casares-Magaz¹, J. Petersen¹, J. Toftegaard¹, L. Bentzen², S. Thörnqvist³, L. Muren¹

¹Aarhus University Hospital, Medical Physics, Aarhus, Denmark

²Aarhus University Hospital, Radiation Oncology, Aarhus, Denmark

³Haukeland University Hospital, Medical Physics, Bergen, Norway

Purpose or Objective: The benefit of proton therapy may be jeopardized by dose deterioration caused by water equivalent path length (WEPL) variations e.g. due to inter-fractional motion. The aim of this study was to explore patient- and population-specific patterns in the robustness towards inter-fractional motion for pelvic lymph node (LN) irradiation of prostate cancer patients using proton beams from different directions.

Material and Methods: Image data sets of 18 patients consisting of a planning computed tomography (pCT) and multiple repeat CT (rCT) scans with target volumes and organs at risk (ORs) outlined in all scans were used. Ray path WEPLs were computed by averaging over beams eye view WEPL maps at all possible beam angle configurations (for both gantry and couch in 5° angle intervals) considering left and right LNs separately. For 0° couch angle the mean and the standard deviation of the WEPL differences between all rCTs and the pCT WEPL map were extracted for the entire population. Finally, single beam spot scanning proton plans were optimized for all gantry angles (couch angle 0°) over the planning target volume (PTV) generated from the clinical target volume (CTV) using isotropic margin configurations (3 and 5 mm). The optimized fluence maps for the pCT for each beam angle were applied onto all rCTs and the dose distributions re-calculated, and dose differences were extracted.

Results: The WEPL analysis for the left and right section of the lymph nodes showed a general pattern of least variation around couch angle = 0°. Furthermore it showed three minima across the mean of the patient WEPL maps at couch angle = 0° for gantry angles of 0-25°, 125-140° and 170-180° for the left section, as well as gantry angles of 180-220° and 330-355° for the right section, which also appeared to be the angles of lowest variations among patients (Fig.1). The clustering analysis of the WEPL maps at couch angle = 0° against the angles showed for the left section of the lymph nodes that the patients split into three groups from which one group of two patients showed a clearly different pattern of lower variation in the lateral and posterior angles. The other fourteen patients were closer correlated and showed highest variation for the lateral angles (Fig.1). For the right section of the lymph nodes the patients were split into two groups of nine and seven patients, where the seven had a visibly higher variation in the posterior angles as the main difference. The dose calculation results showed similar results as for the WEPL variation, e.g. for the left LNs angles around 25-35°, 100-110° and 160-170° were consistently preferable for the bowel, bladder and rectum as well as LN dose deterioration.

Conclusion: We have found that WEPL maps show population-specific patterns and that there were consistent patterns in which angles are most robust. Similar 'robust' angles were also found in the dose/volume analysis.

Fig. 1: Standard deviation of all rCT WEPL maps from the respective pCT at couch angle = 0° with mean and standard deviation, for the left section of the L3 for 16 patients. Fig. 2: Pearson k-nearest neighbor clustering of patients against angles with respect to the WEPL deviation, where a lower "value" means less variation. Gantry angle given as 0, 1 for ipsilateral side, n/10 for anterior/lateral/posterior followed by the angle.

Integrate range shifting in immobilisation for proton therapy: 3D printed materials characterisation

S. Michiels¹, N. Lammens², A. D'Hollander³, K. Poels⁴, W. Crijns⁴, G. Defraene¹, S. Nuyts¹, K. Haustermans¹, T. Debuydt¹

¹KU Leuven, University of Leuven, Department of Oncology
²Ghent University, Department of Materials Science and Engineering, Ghent, Belgium
³Materialise NV, Department of BioMedical Engineering, Leuven, Belgium
⁴University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium

Purpose or Objective: 3D printing technology is investigated for the purpose of patient immobilization during proton therapy. It potentially enables a merge of patient immobilization, bolus range shifting/compensator and other functions into one single patient-specific structure. Beside minimizing the lateral spread of the proton beam due to the removal of the air gap it also ensures the correct range shifting is present for each beam portal. Compared to a movable nozzle snout this reduces the risk of collision and treatment time, hence can increase cost-effectiveness of proton therapy. In a first step, a set of 3D printed materials is characterized, in terms of structural and radiological properties, elemental composition, directional dependence and structural changes induced by radiation damage. These data will serve as input for the design of 3D printed immobilization structure prototypes.

Material and Methods: In total 9 materials used in 4 different 3D printing production techniques were subjected to testing. Samples with a nominal dimension of 20x20x80mm were 3D printed. The actual dimensions of each printed test object were measured with a calliper. The samples were compression tested according to a standardized method (ASTM D695). The composition in terms of effective atomic number (Z_{eff}) and relative electron density (RED) to water was derived from dual-energy CT (DE-CT) data (80kVp,Sn140kVp), allowing estimation of the stopping power ratio (SPR) to water. Range shifting and directional dependence in 3D printed materials were investigated in a 62 MeV proton beam, using radiochromic film in a Plastic Water phantom.

Results: The data of the different experiments are compiled in Table 1. Young's moduli as low as 1 MPa and as high as 2582 MPa were seen. These experiments will be repeated after extensive radiation exposure to verify radiation hardness of the structural properties. The DE-CT decomposition yielded relative electron densities ranging

from 0.62 to 1.20, and Z_{eff} from 6.06 up to 9.35. The calculated SPR ranged from 0.69 up to 1.21. The differences in range shifts of the obtained Bragg peaks were results of differences in SPR, and of deviations from the nominal 20 mm thickness due to printing technique geometrical tolerances. For 4 out of the 9 materials, a different orientation of the sample with respect to the beam incidence resulted in more than 5% difference in the obtained range shift. Measurements using a Bragg-peak ionization chamber will be included allowing a water equivalent thickness measurement validation of the material decomposition method with DE-CT.

Table 1: Overview of the different 3D printed materials in terms of their mechanical, radiological and range shifting capabilities.

Material	3D-printing Production method	Thickness in orthogonal directions [mm]	ASTM D695 compression test		DE-CT derived properties (*)		62 MeV Proton beam measurements	
			Young's-modulus [MPa]	RED [#cc]	Z _{eff} [-]	SPR [-]	Residual range (d90%) [mm]	Directional residual range difference [%]
ABS	Fused Deposition Modeling (FDM)	20/20.3	618	0.62	9.35	0.62	14.45	31.36
Tusk XC2700T	Stereolithography	20/20	1953	1.14	9.07	1.15	6.6	6.06

Plastic Water (baseline)		20/20	/	1.00	9.24	1.00	8.85	0
True water		/	/	1.00	7.41	1.00	/	/

(*) Method used from Hünemohr N. et al., "Experimental verification of ion stopping power prediction from dual energy CT data", Phys. Med. Biol. 59, 83-96 (2014)

Conclusion: 3D printed materials exhibit a wide variation in structural and radiological properties. The quantification of these characteristics can be used for optimal material selection for the design of a 3D printed immobilization structure for proton therapy with integrated range shifting.

Proffered Papers: RTT 2: Improving quality for breast cancer treatments

Deep inspiration breath hold - can it be detrimental to the heart?

B. Done¹, A. Michalski¹, A. Windsor^{1,2}

¹Central Coast Cancer Centre, Radiation Oncology, Gosford, Australia

²University of New South Wales, Faculty of Medicine, Randwick, Australia

Purpose or Objective: Deep inspiration breath hold (DIBH) is widely used internationally as a standard treatment for left sided breast cancer patients. Preliminary results from our institution suggest that there is a cohort of patients who have an increase in cardiac dose with DIBH compared to free breathing (FB). To our knowledge, there are no published studies assessing if DIBH can be a detriment in selected patients. Our primary objective was to identify patient cohorts based on the potential detriment to heart dose constraints. The secondary objective was to evaluate predictive criteria which would define the degree of benefit of DIBH.

Material and Methods: All patients who had left breast or chest wall radiotherapy and had both a FB and DIBH CT simulation scans at a single institution were selected for this study. Planning target volumes (PTV), lung, heart and left anterior descending (LAD) artery were contoured on both FB and DIBH CT data sets. Both data sets were planned using parallel opposed tangents and dynamic wedges. Plans were prescribed either 50Gy in 25 fractions or 42.4Gy in 16 fractions. DIBH plans were considered acceptable for treatment delivery where the heart dose constraints were reduced, without exceeding lung dose tolerances. Given the lack of guidelines on LAD contouring and acceptable dose constraints, LAD was contoured and doses recorded for

research purposes, but not used for clinical decision making. Doses to the PTV, lung, heart and LAD were recorded. Four patient groups were identified for comparison: those who had at least one heart parameter worse with DIBH, minimal benefit arbitrarily defined as less than 20%, moderate benefit defined as between 20%-70% and a major benefit defined as greater than 70%.

Results: Data was collected for a total of 70 patients. Overall, using DIBH, lung volume increased on average by 68% (range: 18.5% - 124.3%) while the heart volume in the treatment field was reduced by an average 69.5%. The LAD volume within the treatment field was reduced by 53%. The degree of benefit for heart and LAD doses is outlined in table 1. 10% had at least one heart parameter worse with DIBH. Where the mean heart dose was higher all other heart constraints were worse. Five patients had an increase in the heart volume and maximum heart distance in the treatment field.

Table 1: Number of patients (n) and the detriment or degree of benefit to the heart and LAD doses compared to the range of lung volume increase (%) using DIBH versus free breathing

n (% of lung volume increase)	Dose Increase	Minimal Dose Reduction (<20%)	Moderate Dose Reduction (20-70%)	Maximum Dose Reduction (>70%)
Heart mean	4 (18.5-86.1)	11 (27.4-98.9)	48 (24.9-124.3)	7 (54.6-108.4)
Heart max (D2%)	7 (18.5-98.9)	8 (33.2-94.4)	24 (24.9-103.3)	31 (47.9-124.3)
Heart V25Gy	4 (23.73-86.1)	5 (27.4-98.9)	16 (32.57-98)	36 (24.86-124.3)
LAD mean*	9 (27.4-98.9)	10 (23.7-103.6)	26 (33.2-103.3)	18 (24.9-124.3)
LAD max (D2%)*	10 (18.5-98.9)	20 (23.7-103.6)	17 (32.6-108.4)	16 (24.9-124.3)
LAD V20Gy*	6 (18.5-98.9)	10 (32.9-103.6)	17 (23.7-93.2)	30 (24.9-124.3)

*Only 63 patients had LAD contours completed

Conclusion: Patients where DIBH was detrimental to heart dose constraints, no clear correlation could be drawn to identify this cohort of patients. Lung volume or percentage increase did not necessarily lead to more favourable outcomes, thus could not be used as a criteria for patient selection for DIBH. We aim to establish further predictive criteria in the second phase of this study. Until such time dual planning remains essential to identify patients who should not be offered DIBH.

The influence of tumour location in the breast on boost modality selection.

E. Reilly¹, C. Baker², M. Flynn³, H.M.O. Mayles², A.J. Reilly⁴
¹Altnagelvin Area Hospital, Radiotherapy, Londonderry, United Kingdom
²Clatterbridge Cancer Centre, Radiotherapy Physics Department, Wirral, United Kingdom
³University of Liverpool, School of Health Sciences, Liverpool, United Kingdom
⁴Altnagelvin Area Hospital, Radiotherapy Physics Department, Londonderry, United Kingdom

Purpose or Objective: To establish whether photon or electron beams provide better dose coverage to tumour bed sites in different regions of the breast.

Material and Methods: 10 patient data sets were selected from a trial cohort, 2 patients each with tumour beds in one of 5 regions within the breast - Superior Lateral Quadrant (SLQ), Superior Medial Quadrant (SMQ), Inferior Lateral Quadrant (ILQ), Inferior Medial Quadrant (IMQ) and the Central Quadrant. The dose to the whole breast treatment of 50Gy in 25 fractions was combined with a boost plan to the tumour bed of either photons or electrons with a dose of 16Gy in 8 fractions. Dose to the PTV, lung, heart and breast tissues outside the tumour bed were assessed by using DVHs.

Results: Tumours in the SLQ received better dose coverage by the photon boost plans. In all other areas of the breast the tumour bed coverage objectives were met with either photons or electrons. The target coverage in the combined plans was at least the same as or better than electrons with photon beams in all cases (Figure 1). Electron beam coverage is dependent on surface contour regularity and tumour geometric shape, particularly if the PTV is not perpendicular to the skin surface and so requiring higher electron energies for PTV coverage at the deep margin. Lung had consistently lower doses with photon boost plans as the higher electron energies selected for target coverage in some plans increased lung dose (Figure 2). The breast outside the tumour bed received lower doses with photon boosts. The heart doses were not consistently lower with either modality.

Conclusion: Electrons were a less favourable modality for SLQ tumours, but either photons or electrons could be suitable for treating tumours in other regions of the breast in terms of target coverage and organ sparing. As photon boosts provided the same as or better coverage than electrons in combined plans, it would be feasible to use photons for all boosts. However, individualised planning is necessary to account for tumour position in relation to normal anatomy, surface contour and geometrical shaping of the tumour bed to optimise PTV coverage and organ sparing. If using electrons particular attention must be paid to the use of bolus for beams planned on irregular surface contours.

OC-0167

Advanced left-side breast cancer: does VMAT allow doses of organs at risk to be reduced?

P.C. Yu¹, H.H. Nien¹, C.J. Wu¹, Y.L. Tsai¹
¹Cathay General Hospital, Radiation Oncology, Taipei, Taiwan

Purpose or Objective: This study was to quantify the reduced dose of right lung and right breast tissue by modified volumetric modulated arc therapy (VMAT) for advanced left-side breast cancer including lymph node irradiation.

Material and Methods: For all cases, the clinical target volume (CTV) consisted of the left breast, axillary lymph nodes, internal mammary chain lymph nodes, infraclavicular lymph nodes, and supraclavicular lymph nodes. 7 patients of VMAT and 5 patients of volumetric modulated arc therapy (VMAT) were generated with the Eclipse Version 11 treatment planning system. VMAT plans were generated using a five full rotation without avoidance sector. VMAT plans were generated using a five partial rotation with avoidance sector. Two half arcs were for supraclavicular lymph nodes. Gantry angle started at 179 degree, stopped at 335 degree, and the 60-120 degree was set to be avoidance sector.

Gantry angle started at 181 degree, stopped at 35 degree, and the 240-300 degree was set to be avoidance sector. Two half arcs were for left-side breast and axillary nodes. Gantry angle started at 153 degree, stopped at 282 degree, and the 0-90 angle was set to be avoidance sector. Gantry angle started at 282 degree, stopped at 161 degree, and the 0-90 angle was set to be avoidance sector. One quarter arc was for internal mammary node. Gantry angle started at 179 degree, stopped at 270 degree, and the 60-120 angle was set to be avoidance sector. The dose-volume-histogram were evaluated the target homogeneity and conformity and normal tissue tolerance dose.

Results: MVMAT has significantly (p-value = 0.031) decreased right-side breast dose (V5Gy (%) = 39.9 ± 7.6), and has significantly (p-value = 0.005) decreased right lung dose (V5Gy (%) = 23.6 ± 7.3). Slightly less heart and left lung dose are found for MVMAT (heart V10Gy (%) = 45.7 ± 17.4, left lung V10Gy (%) = 48.6 ± 3.4) than in VMAT (heart V10Gy(%)=55.7 ± 19.9, left lung V10Gy(%)=53.4 ± 5.1). MVMAT for advanced left-side breast cancer retains target homogeneity and coverage when compared to VMAT.

	V5(%) 62.4	17.3	39.9	7.6	0.031*

Conclusion: MVMAT is suitable for advanced left-side breast cancer treatment. It retains target homogeneity and coverage and decreases the dose of right breast and right lung.

OC-0168

A simple visual test is adequate for testing vmDIBH reproducibility in locoregional breast cancer

L.A. Den Otter¹, T.T. Nuver¹, M. Boerhof¹, H.H. Kolkman-Nijland¹, W.J. Schoevers¹, K. Muller¹, A.W.H. Minken¹
¹Radiotherapiegroep, Radiotherapy, Deventer, The Netherlands

Purpose or Objective: Voluntary moderately deep inspiration breath hold (vmDIBH) reduces the heart dose for radiotherapy of left-sided breast cancer patients. For locoregional breast cancer patients, the application of vmDIBH requires high reproducibility to assure the absence of gap or overlay between tangential breast fields and supraclavicular irradiation fields.

In this study we present a simple and fast visual method to quantify movement around the junction of the tangential and supraclavicular fields. The simple method is evaluated by testing the target volume reproducibility using two consecutive CT-scans during vmDIBH. Heart position reproducibility is assessed as well, with the resulting dosimetric consequences.

Material and Methods: For 80 consecutive breast cancer patients cranial-caudal (CC) displacement around the clavicle was quantified between five vmDIBHs. This was done in the CT room, before obtaining the planning CT scan. Intersecting CT laser lines were marked on tape and the maximum displacement was measured. This tape was positioned midclavicularly, with the horizontal laser lines on the junction line.

For 19 patients who would be irradiated locoregionally, a second CT scan was additionally acquired. The CC displacement of the left clavicle between the two breath holds was quantified by contouring the clavicle in both CT scans, and rigid registration of the two volumes in ProSoma (v.3.3.266, Medcom, Darmstadt, Germany) virtual simulation software.

The heart was delineated in both CT scans, excluding the great vessels. The two volumes were registered in ProSoma to measure CC, left-right (LR) and anterior-posterior (AP) displacements. Influence of the heart displacement on dosimetry was measured by superimposing the contoured heart volume of the second CT scan onto the treatment planning CT scan and calculating mean heart dose.

Results: Results of the tape test show a mean CC displacement of 3.3 mm (range 0.5-8.0 mm) for the midclavicular region. For the two breath hold CT scans mean CC clavicle displacement was 1.1 mm (range 0.1 - 2.8 mm). The measured CC displacements of the tape test were for all 19 locoregional patients larger than measured with CT. Mean difference in contoured heart volume was 3.7% (range 0.5 - 11.2%). Mean heart dose differed on average 0.12 Gy (range 0.01 - 0.38 Gy), where planned mean heart dose varied between 0.59 and 3.58 Gy. Mean heart displacement was 1.7 mm (range 0-4.7 mm) CC, 1.5 mm (range 0.1-4.2 mm) AP and 1.9 mm (range 0.1-6.9 mm) LR.

Conclusion: A simple visual test is a good surrogate for CT scans in analyzing vmDIBH reproducibility. We showed that vmDIBH is reproducible with minimal gap or overlay between

the tangential and supraclavicular fields, allowing for implementation of vmDIBH in locoregionally irradiated patients. Heart position variation is limited to 2 mm and dose variation to 0.4 Gy, between sequential breath holds for most patients.

OC-0169

Patient information through group sessions to improve knowledge regarding breast cancer radiotherapy

M.T.A. Tinggaard Axelsen¹, M.J. Jensen¹, B.H. Haislund², H.M.N. Melgaard Nielsen³

¹Aarhus University Hospital, Department of Oncology, Herning, Denmark

²Aarhus University Hospital, Department of Oncology-, Herning, Denmark

³Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

Purpose or Objective: To inform early breast cancer patients about postlumpectomy radiotherapy (RT) in group session, and to evaluate their knowledge regarding side-effects and precautions compared with patients informed by doctors.

Material and Methods: From April 2015 to June 2015, patients referred for RT at a single institution were informed about RT during one hour group sessions (pilot group). These were held twice a month with up to six patients and their relatives. The patients and relatives were informed about RT preparation procedures, structure of the linac and beams effect, side effects, precautions and lifestyle recommendations during and after RT, by radiation therapists, using power-point presentations. After these group sessions, the patients had a 30 min individual consultation including an examination by a doctor. The patient's knowledge regarding side-effects and precautions were evaluated using a questionnaire that they anonymously were asked to answer in connection with the following planning CT scan. The same questionnaire was filled in by patients before April 2015 (control group), thereby being able to compare knowledge of side-effects and precautions during RT among patients informed during group sessions compared with patients informed by doctors. The two groups were compared using chi-square statistics.

Results: 33 patients filled in the questionnaire after conventional information and 25 patients after group sessions. The following subjects were more often correctly answered by patients informed during group sessions: Acute toxicity ($p < 0.001$), sequence of acute events ($p = 0.16$), precautions during RT ($p = 0.006$), late toxicity ($p = 0.07$), reasons for recommendation of non smoking ($p = 0.03$) and use of skin care cream (0.002). The group sessions were timesaving for both the radiation therapists and the doctors and especially for left sided patients, information about respiratory gated RT resulted in reduced scheduled time for information. The patients were generally satisfied e.g. one said "I wish I was informed that way the last time I was given RT". Participating patients were able to create personal relations to other participating patients. The radiation therapists were in general content and satisfied by the challenge of being responsible for RT information to these patients.

Conclusion: Patient's contentment and level of knowledge before initiating RT can be improved by educating and preparing the patients for RT during group sessions. These group sessions are now implemented as standard information procedure for all breast cancer patients, and it is considered to expand these sessions to other groups of cancer patients.

OC-0170

Detection of setup errors with body surface laser scanning system for whole breast irradiation

P. Jiang¹, Z. Liu¹, J. Wang¹, S. Zhou¹, J. Li¹, H. Sun¹, S. Jiang¹

¹Peking University Third Hospital, Radiation Oncology department, Beijing, China

Purpose or Objective: To investigate the clinical application of a technique for patient set-up verification in whole breast irradiation after conservative surgery based on a surface laser scanning registration system

Material and Methods: Displacements from concurrent Sentinel™ (Sentinel®, C-Rad Positioning AB, Sweden) surface imaging and Elekta Axesse accelerator cone beam CT (CBCT) registrations were compared for 10 patients with breast cancer after conservative surgery for a total of 130 set-ups. As comparison, the patient outline extracted from the planning CT system (Oncentra®, nucletron/Elekta, Sweden) was used as Sentinel™ reference (C_{ref}) and also was used as a reference for the CBCT method. Patients were first scanned both with surface laser scanning and CBCT, shifted to the optimal isocenter position according to CBCT verification. And then another optical scan was performed to verify the matching in relation to CBCT. Position detection by both surface scan and CBCT acquired for the first five fractions of radiotherapy and then twice weekly. The data collected by both systems were statistical analyzed by paired t-test using SPSS 13.0.

(A) extracted from the planning CT system was used as Sentinel™ reference C_{ref}. (B) optical scan area range from the supraclavicular region to submammary sulcus. (C) images of surface registration: green is the reference contour surface, and blue is new contour surface obtained by laser scan.

Results: The absolute translational setup errors (mean \pm SD) in X (Lateral), Y (Longitudinal), Z (Vertical) axes detected by CBCT prior radiation were 0.21 ± 0.21 cm, 0.29 ± 0.26 cm and 0.42 ± 0.22 cm respectively; rotational setup errors (mean \pm SD) in Rx (Pitch), Ry (Roll), Rz (Yaw) axes were $0.83^\circ \pm 0.7$, $1.12^\circ \pm 0.79$ and $1.07^\circ \pm 0.81$. The absolute translational setup errors (mean \pm SD) in six directions detected by Sentinel™ prior radiation were 0.14 ± 0.18 cm, 0.15 ± 0.14 , 0.13 ± 0.13 , $0.77^\circ \pm 0.54$, $0.76^\circ \pm 0.61$ and $1.23^\circ \pm 0.95$. The system accuracy was better than 1.5 mm and 1.1° when a Sentinel image was used as reference. Paired setup errors from Sentinel™ and CBCT showed no significant difference in five directions: X ($t = -1.827$, $P = 0.07$), Y ($t = 0.125$, $P = 0.9$), Z ($t = 1.595$, $P = 0.112$), Ry ($t = -1.717$, $P = 0.09$) and Rz ($t = 2.382$, $P = 0.6$) axes, and significant difference in one direction of Rx ($t = -3.409$, $P = 0.03$) axes.

	Absolute set up errors of 6D directions (Mean \pm SD)					
	Lat (mm)	Lng (mm)	Vir (mm)	Pitch Rx ($^\circ$)	Roll Ry ($^\circ$)	Yaw Rz ($^\circ$)
CBCT (n=130)	0.21 ± 0.21	0.29 ± 0.26	0.42 ± 0.22	0.83 ± 0.7	1.12 ± 0.79	1.07 ± 0.81
Sentinel™ (n=130)	0.14 ± 0.18	0.15 ± 0.14	0.13 ± 0.13	0.77 ± 0.54	0.76 ± 0.61	1.23 ± 0.95

Conclusion: The Sentinel™ surface imaging device is a reproducible and consistent system able to detect misalignments with accuracy. This study shows good agreement between the surface scanner and CBCT in patient positioning. The Sentinel™ surface imaging system is a good supplement to the CBCT system for accurate set-up for fractions for whole breast irradiation after conservative surgery.

Can protons reduce bone marrow toxicity in definitive chemoradiotherapy for oesophageal tumours?

S. Warren¹, C. Hurt², T. Crosby³, M. Partridge¹, M. Hawkins¹

¹CRUK/MRC Oxford Institute for Radiation Oncology, Department of Oncology, Oxford, United Kingdom

²Wales Cancer Trials Unit, School of Medicine, Cardiff, United Kingdom

³Velindre Hospital, Velindre Cancer Centre, Cardiff, United Kingdom

Purpose or Objective: Radiotherapy dose escalation using a simultaneous integrated boost (SIB) is predicted to improve local tumour control in oesophageal cancer patients (Warren IJROBP 2014), yet any increase in acute bone marrow toxicity could reduce treatment intensity, and limit any predicted improvement in patient outcome. In the SCOPE oesophageal trial, 28% of patients treated with concurrent cisplatin/capecitabine and 50 Gy in 25 fractions experienced grade ≥ 3 haematological toxicity (HT3+) (Crosby Lancet Oncol 2013). Proton therapy has been shown to significantly reduce haematological toxicity in lung cancer patients receiving concurrent chemotherapy (Komaki Radiother Oncol 2011); we investigate the potential of bone marrow sparing with protons compared to photons, in radiotherapy dose escalation for oesophageal tumours.

Material and Methods: 21 mid-oesophageal cancer patients with their original conformal plan (3D50) (chosen to be a representative subset of the SCOPE trial) were used to study the bone marrow dose delivered. A surrogate for bone marrow was created by outlining the thoracic vertebrae, sternum, scapulae, ribs and clavicles using the automatic thresholding tool in Eclipse (Varian). Additional plans were created retrospectively: a volumetric modulated arctherapy plan (VMAT50) with the same dose as 3D50. SIB plans with a dose prescription of 62.5 Gy to the high risk sub-region within the planning treatment volume were created using VMAT (VMAT62.5) and proton therapy plan (IMPT62.5). Bone V20 Gy and V10 Gy dose-metrics were recorded and compared across all plans using the Wilcoxon test and Holm Bonferroni correction for multiple testing. Parameters from gynaecological cancers (Bazan IJROBP 2012) were used to predict normal tissue complication probability (NTCP) of HT3+.

Results: 3D50 plans show the highest NTCP and V20 values for each patient. There is no significant difference between the VMAT50 and VMAT62.5 plans, although VMAT plans may cause a larger bone volume to be irradiated below 10 Gy than 3D50. IMPT62.5 showed significant sparing for both V10 and V20 and much reduced NTCP

Comparing V_{10Gy} (top) and V_{20Gy} (bottom) for the four different plans. Plots show median (horizontal bar), interquartile range (box) and maximum and minimum (capped lines) values across all patients, with statistically significant differences between plans marked *.

Conclusion: Proton therapy plans show significant dose sparing for bone marrow in the 10-20 Gy dose region thought to be correlated with toxicity. These plans are predicted to reduce the risk of HT3+ by ~50% compared to photon techniques, and could therefore improve treatment efficacy of concurrent chemoradiotherapy for oesophageal cancers.

PV-0172

Selecting patients with lung cancer for proton therapy should be based on multivariable NTCP models.

M.C.A. Kramer¹, A.G.H. Niezink¹, E.W. Korevaar¹, R.G.J. Kierkels¹, H.P. Van der Laan¹, A. Van der Schaaf¹, V.C. Hamming¹, P. Kalk¹, J.A. Langendijk¹, J. Widder¹

¹UMC Groningen, Radiotherapy Oncology Department, Groningen, The Netherlands

Purpose or Objective: The aim of the study was to evaluate how the dosimetric benefit of intensity-modulated proton therapy (IMPT) translates into estimated toxicity risk reduction in patients with locally advanced non-small cell lung cancer (NSCLC). In addition, the potential to spare the heart with protons and photons was explored.

Material and Methods: Five patients with NSCLC were treated with concurrent chemoradiation, using standard lung-sparing photon volumetric-modulated arc therapy (L-VMAT) to 60 Gy in 25 fractions. Three additional treatment plans were created for each patient: heart-sparing VMAT (H-VMAT), worst-case robust heart-sparing IMPT (H-IMPT), and worst-case robust lung-sparing IMPT (L-IMPT). Doses to the organs at risk (heart, lung) were evaluated. Resulting normal tissue complication probability (NTCP) values for radiation pneumonitis were estimated using the dose-only QUANTEC model and the adjusted QUANTEC model including clinical risk factors 1.

Results: With IMPT, both H-IMPT and L-IMPT, DVH parameters including the mean lung dose (MLD), the lung volume receiving ≥ 20 Gy (V20L), the mean heart dose (MHD), and the volume of the heart receiving ≥ 30 Gy (V30 H) were all between 32 - 80% lower compared with L-VMAT (Tab 1). Furthermore, at these considerably lower dose levels with protons vs photons, the amount of dose redistributed to the lungs when the heart was particularly spared was still lower with protons (H-IMPT vs L-IMPT: 65% decrease MHD, 11% increase MLD), compared with photons (H-VMAT vs L-VMAT: 62% decrease MHD, 28% increase MLD). Using the dose-only QUANTEC model, comparing L-VMAT with L-IMPT, the lung-dose reductions translated into a reduction in the risk of symptomatic radiation pneumonitis between 4.5% to 9.2% (average, 5.8%). However, the QUANTEC model adjusted for a priori clinical risk factors showed a reduction of symptomatic radiation pneumonitis risk in patients without clinical risk factors by 2.5% to 5.4% (average, 3.3%) in contrast to 14.2% to 26.7% (average, 18.2%) risk reduction in patients with the highest a priori risk (Fig 1). For identical DVH reductions, and assuming a threshold risk reduction of $\geq 10\%$ for G2-toxicity required for indicating proton therapy, an

actual indication for protons thus heavily rests on individual clinical and patient dependent a priori risk factors.

Table 1.

Dosimetric parameters for lung and heart for the different techniques and corresponding NTCP for symptomatic radiation pneumonitis (values in Gy or %).

	H-VMAT	L-VMAT (reference)	H-IMPT	L-IMPT
MeanLungDose	18.3±2.6	14.3±1.9	8.9±2.1	8.0±2.3
V20 Lung	34.7±4.2	25.0±2.7	17.0±4.0	14.8±4.4
MeanHeartDose	9.9±3.1	15.9±2.9	3.7±1.1	4.9±1.1
V30 Heart	10.1±5.9	19.1±2.9	4.3±2.0	7.1±2.1
Risk of radiation pneumonitis				
QUANTEC_dose only	17.7±4.5	11.4±2.4	6.2±1.7	5.6±1.6
QUANTEC_low clinical risk ¹	10.1±1.4	6.0±1.5	3.0±0.9	2.6±0.9
QUANTEC_high clinical risk ¹	54.8±6.1	41.2±6.2	25.3±5.7	23.0±5.8

Figure 1.

Estimated NTCP value reductions (arrows) for symptomatic radiation pneumonitis for low (red line) and high (green line) a priori risk patients and patients irrespective of a priori risk factors (blue lines). Marked are the estimated risk reductions of symptomatic radiation pneumonitis for lung-sparing IMPT (grey lines) versus lung-sparing VMAT (black lines).

Conclusion: These results demonstrate that the potential of proton therapy to reduce the risk of radiation pneumonitis requires considerable reduction in lung dose, but translation into clinical significance is heavily driven by patient and clinical a priori risk factors. Therefore, multivariable NTCP models should play a major role in identifying patients eligible for proton therapy.

PV-0173

Dosimetric assessment of three-source Co-60 and Linac-based lung SBRT for feasibility of MR-IGRT

N. Dogan¹, N. Lamichhane¹, A. Ishkanian¹

¹University of Miami- Sylvester Comprehensive Cancer Center, Department of Radiation Oncology, Miami- Florida, USA

Purpose or Objective: The purpose of this study is to provide a dosimetric assessment for the feasibility of delivering lung SBRT using an integrated three-source Co60 and Magnetic Resonance Imaging (MRI) Guided Radiation Therapy (MR-IGRT) System.

Material and Methods: Ten lung patients who were previously treated with Linac-based SBRT were included. For each patient, GTV, PTV, cord, lungs, heart, esophagus, and ribs were delineated. All Linac-based SBRT plans were generated using VMAT and consist of 2-10 6MV Rapid Arcs. Patients received prescription doses of 48 Gy/4fx to 50 Gy/5fx. The Linac-based plans were imported into the View Ray MR-IGRT system for planning. Three-source Co60 plans were generated using step-and-shoot IMRT and utilized Monte Carlo dose calculation including the magnetic field correction of 0.35T. The PTV coverage for both Linac-based three-source Co60 SBRT plans were such that 95% of the PTV received 100% the prescription dose. Finally, Linac- and three source Co60 - based plans were evaluated using dose-volume constraints for critical structures and target conformity index (CI), homogeneity index (HI) for the PTV.

Results: The differences between PTV HI for Linac- and three-source Co60 -based SBRT plans were not statistically significant, ranging from 1.05 to 1.15. Three patients with the CIs >1.2 had target volumes <20cc although the location of the target did not have much influence on meeting the criteria for the target conformity. For all patients, the critical structure doses, such as maximum cord dose (<26 Gy), dose to <15 cc of the heart (28Gy<15cc), and <5cc of the esophagus (18.8 Gy<5cc) were satisfactory with both techniques. For lung, although both the dose to <1500cc (11.6 Gy<1500cc) and <1000cc (13.6Gy<1000cc) criteria were met with both techniques, on average, the lung volumes receiving the 11.6Gy and 13.6Gy were 59.5% and 61.28% higher with three-source Co60 as compared the Linac-based SBRT plans respectively (P<0.05). As expected, low dose portion of the DVH for all critical structures generally covered much higher percentage of the critical structure volumes with three-source Co60 SBRT plans as compared to the Linac-based SBRT plans.

Figure 1. Dose distributions in axial, sagittal and coronal slices obtained with (a) three-source Co⁶⁰ MR-IGRT system (View Ray, Inc) and (b) 3 Rapid Arcs (Varian Eclipse) for one of the lung SBRT cases included in this study (Prescription Dose: 50 Gy/5 fx, green isodose line).

Conclusion: Overall, a three-source Co60 integrated MR-IGRT system produced comparable dose distributions to the ones obtained with the Linac-based lung SBRT. Further studies are needed to evaluate benefits of this novel MR-IGRT system for lung SBRT, especially its ability to image and plan in real time and online adaptive treatment delivery.

PV-0174

Experimental verification of 4D Monte Carlo calculations of dose delivered to a moving anatomy

J. Cygler¹, S. Gholampourkashi², J. Belec¹, M. Vujicic¹, E. Heath²

¹The Ottawa Hospital Regional Cancer Centre, Medical Physics, Ottawa, Canada

²Carleton University, Physics, Ottawa, Canada

Purpose or Objective: To experimentally validate a 4D Monte Carlo (MC) simulation method to calculate the dose

delivered by an Elekta Agility linear accelerator to a moving anatomy.

Material and Methods: A Quasar respiratory motion programmable phantom (Modus Medical) with a lung insert containing a 3 cm diameter tumour was used for dose measurements. Measurements were performed on an Elekta Agility linac with the phantom in static and moving (sinusoidal motion, 1.8 cm respiratory amplitude) states. Dose to the centre of the tumor was measured using calibrated EBT3 film and the RADPOS 4D dosimetry system. The RADPOS position tracker recorded the phantom motion with time steps of 100 ms. Static and 4DCT scans of the Quasar phantom were acquired using a helical CT scanner (Brilliance CT Big Bore). A single 6 MV 4x4 cm² square field covering the tumour was planned on the static CT scans using the Elekta XiO V.4.7 treatment planning system. A previously validated BEAMnrc model of our Elekta Agility linac was used for all simulations. The DOSXYZnrc and defDOSXYZnrc user codes were used, respectively, for static and moving anatomy dose simulations with 500,000,000 histories to achieve a statistical uncertainty of 0.4%. The defDOSXYZnrc code was modified to sample a new geometry for each incident particle, thereby simulating the continuous phantom motion. The treatment plan was exported from XiO as DICOM format and a Python script was used to extract the data and generate input files for MC simulations. An egsphant file with 0.1250 x 0.1250 x 0.1 cm³ resolution was generated from static CT scans for all simulations. The multipass deformable image registration algorithm in Velocity (Varian Medical Systems) V.3.0.1 was used to register the CT image of the phantom in end-of-exhale state to the static CT image. For 4D simulations, deformation vectors from Velocity were input to the defDOSXYZnrc code as well as the phantom motion trace measured with RADPOS. To examine the impact of deformable registration accuracy, 4D simulations were also performed using manually generated deformation vectors that exactly modelled the rigid translation of the lung insert.

Results: Table 1 shows the calculated and measured tumor doses and their uncertainties. Calculated dose for the moving anatomy using vectors generated by Velocity was 75.9 cGy±0.4% that is 0.5% lower than the similar calculation using manually generated vectors.

Table 1. Calculated and measured tumor doses and their uncertainties

Phantom	Dose (cGy)				%Ratio					
	TPS	MC	Measured		MC/TPS	Film/TPS	RADPOS/TPS	MC/Film	MC/RADPOS	Film/RADPOS
			Film	RADPOS						
Static	80.5±0.8%	79.9±0.4%	79.2±2.3%	79.0±1.4%	-0.75%	-1.61%	-1.86%	0.88%	1.13%	0.25%
Moving (manual vectors)	-	76.3±0.4%	76.0±2.3%	77.3±1.4%	-	-	-	0.39%	-1.31%	-1.71%

Figure 1 shows the calculated and measured tumor profiles

Fig1. Comparison of simulated (MC with manually generated vectors) and measured (Film) dose profiles for static (left) and moving (right) states.

Conclusion: The level of agreement between MC Simulation results and measurements is within 2%. This makes our 4D Monte Carlo simulations using the defDOSXYZnrc code an accurate and reliable method to calculate dose delivered to a moving anatomy.

PV-0175

Knowledge-based DVH predictions for automated individualised treatment plan quality assurance

J. Tol¹, M. Dahele¹, A. Delaney¹, B. Slotman¹, W. Verbakel¹
¹VU University Medical Center, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: Determining whether individual treatment plans are near optimal is important for routine clinical care and clinical studies. However, plan quality assurance (QA) is difficult, time consuming and operator dependent. Furthermore, applying checklists of generic QA parameters to all patients cannot accurately gauge the quality of individual patient plans. RapidPlan (Varian Medical Systems, Palo Alto, USA), a commercial knowledge-based planning solution, could automate individualized plan QA by benchmarking the plan against predicted patient-specific organ-at-risk (OAR) doses derived from a library of plans that consists of various OAR-planning target volume (PTV) geometries and associated dose distributions. Using RapidPlan for this purpose requires that the predicted doses are achievable when RapidPlan is subsequently used to generate a plan. This was investigated for locally advanced head and neck cancer.

Material and Methods: A RapidPlan model consisting of 90 plans, generated using previously created automatically optimized plans, was used to predict achievable OAR dose-volume histograms (DVHs) for the parotid glands, submandibular glands, individual swallowing muscles and oral cavities of 20 HNC patients. Differences between the achieved and predicted DVH-lines were analyzed for all OARs. To illustrate the possible gains that individualized plan QA could realize, the RapidPlan predictions were used to evaluate achieved OAR sparing of an evaluation group (EG) of 20 manually interactively optimized plans.

Results: The Figure shows strong linear correlations (solid lines, R²=0.94-0.99) found between the predicted and achieved mean doses for all OARs, demonstrating the accuracy of the RapidPlan DVH predictions. The dashed lines have a slope of 1 and run through the origin, meaning that for OARs on this line, the mean dose predicted by RapidPlan was exactly achieved. More detailed analysis of the predicted and achieved DVHs showed that at higher dose regions (OAR volumes <30%), the amount of achievable sparing is underestimated for OARs with mean doses <20Gy while it is progressively overestimated for OARs with higher mean doses. Using the predicted OAR DVHs identified that for 10 plans in the EG, sparing of the composite (volume weighted) salivary glands, oral cavity or composite swallowing muscles could be improved by at least 3Gy, 5Gy or 7Gy, respectively. These predicted gains were confirmed by replanning the identified patients using RapidPlan.

Conclusion: Strong correlations between predicted and achieved mean OAR doses indicates that RapidPlan could accurately predict achievable mean doses, showing the feasibility of using RapidPlan DVH predictions alone for automated individualized HNC plan QA. Since this QA approach does not require the creation of additional plans, these findings indicate that automated individualized plan QA is now a realistic proposition for individual centers and clinical trials.

PV-0176

Evaluation of biologically effective dose in stereotactic radiotherapy for prostate cancer

T. Viren¹, T. Lahtinen², J. Hopewell³, J. Seppälä¹

¹Kuopio University Hospital, Cancer Center, KYS, Finland

²Delfin Technologies Ltd, Kuopio, Finland

³University of Oxford, Green Templeton College, Oxford, United Kingdom

Purpose or Objective: Image guided robotic stereotactic radiotherapy (SRT) is becoming increasingly commonly used in the treatment of prostate cancer. As SRT treatment may consist of 100-300 small beams, the dose-rate (DR) and thus the biologically effective dose (BED) can vary significantly within the target volume, despite the creation of a very uniform total physical dose distribution (1). However, the significance of the spatial variations in DR on BED in robotic SRT treatments remains unknown.

The aim of the present study is to measure the DR distribution, with treatment progression, in a representative robotic SRT treatment for prostate cancer and to investigate the effect of these spatial and time related variations in the measured DR on the calculated BED.

Material and Methods: A representative robotic SRT treatment plan for prostate cancer (5 x 7.25 Gy, 222 beams, treatment time 28 min) was created with the Multiplan treatment planning software (v 4.6.0., Accuray, USA). Based on this plan a quality assurance plan was calculated for a MultiCube phantom incorporating a MatriXX Detector (32 x 32 matrix of ionization chambers) spatial resolution 7.6 mm, time resolution 0.5 s (IBA Dosimetry, Germany). The DR distributions were measured in four different coronal planes (separated by 1cm) covering the volume of the target structure to create a 3D DR distribution. Then BED values, calculated using bi-exponential repair (repair half times 0.2 h and 2.5 h, $\alpha/\beta = 1.5\text{Gy}$) were calculated for each voxel based on the measured DR (BED_M), average dose-rate (measured dose divided by the overall treatment time, BED_A) and physical dose (measured dose without the repair component, BED_P) distributions.

Results: Compared to the BED_P, where no repair was allowed for, both BED_M and BED_A values, within the target volume, were significantly lower (Fig 1). Furthermore, BED_M values were found to be systematically higher than BED_A values. Significant variation was observed in BED_M values corresponding to the same BED_P value (Fig 1). This effect was not observed with BED_A values (Fig 1).

Figure 1. A: Representative SRT plan, B: corresponding BED_P values, C: Frequency distributions of BED_P, BED_M and BED_A values within the target volume, D: Range of BED_M or BED_A values corresponding uniform BED_P value.

Conclusion: The simple use of the average DR in the determination of BED does not take into account the variations in the spatial DR, and this leads to an underestimation of BED values. Furthermore, significant variations were observed in BED_M values when compared to uniform BED_P values, an observation also consistent with comparable Gamma Knife treatments (1). Thus, the actual and not the average DR should be used in the calculation of BED when the efficacy of the SRT treatments is evaluated or different treatment modalities are compared.

Evidence-based education: Radiation Oncology's forgotten foundation?

S. Turner¹

¹Westmead Hospital, Radiation Oncology, Sydney, Australia
Learning Objectives

At the end of this talk you will have a better awareness of:

1. reasons why educational 'science' may be overlooked
2. how principles of adult learning might apply to radiation oncology
3. potential benefits of applying an evidence-based approach to educational activities

Radiation Oncology is a discipline with a history firmly founded on the sciences of radiobiology, radiation physics, anatomy, pathology and clinical medicine that remain as relevant as ever to its exciting future. An evidence-based approach to practice and progress in our field is seen as core to our identity as radiation oncology professionals.

So how can it be that the 'science' of teaching the next generation of practitioners, as well as the current one (ourselves), especially in such a rapidly changing arena, is often left to chance? Why is so little focus placed on the

health education literature and scholarship in this area? And why do we accept that random and variable acquisition of knowledge and skills, irrespective of the evidence for pedagogical best-practice, is good enough for our specialty and for our patients?

This talk will deal with possible reasons that we may be blinkered to important aspects of learning in radiation oncology. It will outline the knowledge that we *do* have to guide us, and the benefits of working more cooperatively in education across professions and jurisdictions. By paying attention to the 'forgotten foundation', that of high quality teaching and training, we dramatically enhance our chances of achieving the goals in quality, safety, effectiveness and leadership in cancer patient management, for which we strive.

SP-0178

The future of surgical oncology

R. Audisio¹

¹University of Liverpool - St Helens Teaching Hospital, St Helens, United Kingdom

The role of cancer surgery has been consolidated over the years but drastic changes are taking place and Surgical Oncologists need to be prepared for substantial changes. Traditionally, cancer treatment rested on tissue diagnosis: a sample of the affected area is taken, analyzed and classified according to its morphology. "Tissue diagnosis" results into "tissue-based treatment". As times are rapidly changing and we are becoming accustomed to "molecular diagnosis", leading to "genetically informed treatment plans", surgical oncologists should be up to date with newly described diagnostic and therapeutic options. Genetic counseling is also reshaping: low prevalence (but high penetrance) genes have been associated to the risk of developing breast cancer; more interestingly, several other genetic markers (high prevalence but low penetrance) are being identified. Improved understanding of their specific role will twist the way family clinics are run. Advanced diagnostic tools are being developed and their availability will also modify the way we treat patients: digital tomography will probably reconfigure breast cancer screening; liquid biopsy is slowly but steadily being introduced into clinical practice, in view of optimizing neoadjuvant treatment as well as palliative treatment, the whole practice of follow-up and other steps of clinical practice. A multidisciplinary approach is mandatory - it is a *condition sine qua non* for the surgical oncologist to understand issues and problems from the point of view of medical and radiation oncologists, radiologists and pathologists, without dismissing nurses and social workers, psycho-oncologists, geneticists, and others. Complex and inter-specialty treatment options are becoming routine (e.g. intra-operative radiotherapy). The success of new treatment plans will necessarily open new, previously unthinkable, therapeutic options. Patients' advocacy and a sympathetic approach is extremely rewarding, beside science and research. Patients are at the center of our practice and social mandate. It is therefore to keep in mind the complexity of issues affecting cancer patients, cancer survivors and their relatives in their every day's life. Education is significantly modified, with remote-learning and training labs becoming available; virtual education is becoming popular and relatively inexpensive and young generations are rather accustomed to such new educational tools. The ongoing attempt in homogenizing education with other international societies aims to allowing exchanges, improving knowledge and boosting cross-fertilization. The political role of cancer surgeons should be kept in mind at all times, with surgeons firmly determined to play a substantial part within the multidisciplinary oncology team.

SP-0179

Imaging in lung cancer radiotherapy: beyond the "pictures"

L. Bonomo¹

¹Institute of Radiology - Catholic University, Diagnostic Imaging, Roma, Italy

Lung cancer is still today the leading cause of death worldwide despite the availability of a variety of treatments. In particular Radiation Oncology is widely involved in lung cancer management, both as a neo or adjuvant therapy as well as a definitive one.

As the suffix "Radio-" suggests, the Radiologist and the Radiotherapist have been "step-brothers" since their origins, as co-actors in the main steps of treatment: staging / treatment planning and follow-up.

An accurate staging is essential in treatment planning in order to include macro- and micro-scopic cancer and to avoid unwanted toxicities. Lung injury is common in patients treated with Radiotherapy. The knowledge of radiological patterns of lung abnormalities after non surgical treatments is critical to accurately assess the overall effectiveness of these therapies and to differentiate normal appearances from incomplete treatments and/or local recurrences. Nowadays, a new multidisciplinary challenge for our disciplines is required: the "individualized medicine". The idea is to "design" a patient personalized therapy by identifying and integrating multimodal prognostic factors in models of treatment outcomes and also in clinical-decision support systems. Clinical imaging is particularly involved in this new field, the so-called "Radiomics" process, which offers a comprehensive and non-invasive "photograph" of patients and cancer heterogeneity.

Indeed in recent years we have witnessed a continual evolution of both Radiology and the Radiologist. Diagnostic Imaging has moved from focusing on image quality to a molecular level, from pictures to data. An important contribution has been provided by nuclear medicine, not only in identifying pathological sites, but also in outlining more active components. The "anatomical" evolution has offered the Radiotherapist the capability to better define the target and the "functional" evolution the capability to select the right one. The Radiologist, similarly, has evolved from a photographer to an interpreter and, in the future, will become a decision maker.

The aim of this lecture is to make a "journey" through the evolving role of the doctor as an "image artist" of lung cancer Radiotherapy.

Teaching Lecture: DNA repair and response for beginners

SP-0181

DNA repair and response for beginners

K. Borgmann¹

¹University Medical Center Hamburg - Eppendorf UKE, Hamburg, Germany

Dysregulation of the DNA damage response (DDR) is associated with a predisposition to cancer and affects responses to DNA-damaging anticancer therapies. Dysregulation of a certain DNA repair pathway may be

compensated by another, functionally overlapping DDR pathway whose activity may be increased, causing resistance to DNA-damaging radiotherapy and chemotherapy. Therefore, the DDR response makes an ideal target for therapeutic intervention by preventing or reversing therapy resistance or by using a synthetic lethality approach to specifically kill cancer cells that are dependent on a compensatory DNA repair pathway for survival in the context of cancer-associated oxidative and replicative stress. However, in the context of DNA replication several DNA repair pathways are gathered with overlapping functions, as demonstrated by the synthetic lethal interaction between the DNA double strand repair pathway homologous recombination (HR) and the base excision repair pathway (BER) as well as between checkpoint signaling (ATR/CHK1) and the Fanconi anaemia pathway. As the number of inhibitors that target components of these pathways expands the potential for using these synthetic lethal interactions increases, provided that the exploitable defects in the tumour can be identified with suitable biomarkers. These hypotheses are currently being tested in the laboratory and translated into clinical studies.

Teaching Lecture: Anal cancer: current guidelines and remaining questions

SP-0182

Anal cancer: current guidelines and remaining questions

D. Sebag-Montefiore¹

¹*St James Institute of Oncology, Department of Radiation Oncology, Leeds, United Kingdom*

Introduction - Anal cancer is a rare disease but its incidence is rising rapidly. The majority of tumours are squamous cell carcinoma or its histological variants. Despite its rarity phase III clinical trials have been successfully performed. The “first generation” of phase III trials tested the benefit of concurrent chemotherapy when added to radiotherapy. This led to Mitomycin C 5Fluorouracil and radiotherapy (CRT) becoming the standard of care. The shift from radical surgery with permanent stoma to non-surgical combined modality treatment was achieved through these clinical trials and recent published evidence confirms the impact on population based practice. The “second generation” of phase III did not change the standard of care. They demonstrated no benefit from the addition of neoadjuvant or maintenance chemotherapy to CRT and no improvement in outcome from the use of cisplatin based CRT. The ESMO-ESSO-ESTRO and NCCN guidelines provide evidence based recommendations for the management of anal cancer and aspects of the guidelines will be reviewed during this teach lecture.

Staging - Whilst it is important to identify the relatively small minority of patients who present with synchronous metastatic disease, the main role of imaging is to determine the extent of disease in the pelvis prior to CRT. Although pelvic MR is not mandated in the guidelines it provides superior anatomical images of the primary tumour which is very helpful for conventional CT planning and delineation of the gross tumour volume. CT-PET is also not mandated but is shown to upstage a minority of patients from a “N0” category to “N+.” Examples of this will be presented and discussed.

Radiotherapy dose fractionation - there is wide variation in the prescribed radiotherapy dose to both gross tumour volume and clinical target volumes. Many centres will use higher doses of 60Gy or greater to more advanced tumours. However, to date randomized clinical trials have not demonstrated any clear benefit for dose escalation. There is also a paucity of late toxicity and patient reported outcome data to determine the impact of such an approach.

Radiotherapy technique and target volume definition - The use of IMRT has significantly increased in the treatment of anal cancer and its use is supported by the RTOG 0529 phase II trial. Although IMRT may be preferred and will reduce acute genital toxicity, careful target volume definition and delineation of organs at risk and high quality QA are required to ensure accurate treatment delivery. The AGITG contouring atlas has been very helpful to clinicians. The UK approach to introducing IMRT will be discussed.

Response assessment - Clinical and radiological assessment is required to both identify early local treatment failures and to establish whether complete response had been achieved. The European guidelines recommend assessment at 11, 18 and 26 weeks from the start of CRT. Recent published data will be reviewed. The optimal timing and imaging is the subject for further research.

Follow up - Most centres will review patients at least three monthly in the first two years, with approximately 80% of pelvic recurrences occurring during this period. The duration of follow up and the intensity of imaging varies widely.

Late toxicity - Although it is assumed that most patients will experience improved quality of life with CRT rather than radical surgery there is limited data on the impact of late radiotherapy effects on patients. New data is required particularly with the use of IMRT to understand this in more detail. An anal cancer specific module quality of life module is in development through the EORTC.

Treatment of metastatic disease - Approximately 10-20% of patients will develop metastatic disease. There is no consensus on the best first or second line chemotherapy regimens and reports of the outcomes following surgical or non surgical treatment of oligometastatic disease are sparse. The InterAACT trial is an international randomized phase II study comparing cisplatin 5FU with Carboplatin and Paclitaxel and will be discussed

Future research - Future clinical trials will provide more information on outcome and late toxicity with the use of IMRT. The UK led PLATO trial consortium are conducting a “platform” type trial with the ACT3 ACT4 and ACT5 trials addressing specific research questions. ACT3 evaluates a selective use of reduced dose CRT for patients with T1N0 anal margin tumours; ACT 4 will compare standard versus lower dose CRT for early stage disease; ACT5 will test two IMRT SIB dose escalation CRT schedules against standard dose CRT.

Teaching Lecture: Radiotherapy and immune-therapy, biological basis and potential for future clinical trials

SP-0183

Radiotherapy and immune-therapy, biological basis and potential for future clinical trials

E. Deutsch¹

¹*Institut Gustave Roussy, Villejuif, France*

The immunosuppressive effects of radiation therapy have long been the only one considered. Dying cancer cell may release signals which activate the surrounding immune cells, namely through the immunological cell death process. Irradiation can also increase the diversity of tumor neo antigens which are crucial to the induction of adaptive antitumor immunity. It has recently been shown that the inhibition of immune inhibitory checkpoints synergizes with ionizing radiation in preclinical models. Hypoxia is one of the key factors influencing clinical outcome after radiotherapy responsible for reduced local control that will influence overall survival, as may the hypoxic conditions by increasing malignant progression. For decades, hypoxia was thought to act primarily on tumor cells resistance, namely the number of clonogenic cancer stem cells surviving after radiation treatment. Increased cellular turnover and hypoxia promote the production and release of large amounts of immunosuppressive adenosine into the local microenvironment. Hypoxia can induce HIF-1a-dependent expression of arginase-1 and M2 polarization of macrophages. Recent data suggest that the immune contexture of tumors might be correlated with outcome after irradiation. The purpose of tumor immunotherapy is based on the principle that reversal of tolerance to immunogenic tumors would be able to activate an immune response against tumor cells. The importance of the immune component into the process of tumor response to radiation offers novel opportunities for therapeutic interventions.

Teaching Lecture: Underestimated importance of Intraluminal brachytherapy: bronchus, oesophageal, anorectal and hepatobiliary duct cancer

SP-0184

Underestimated importance of Intraluminal brachytherapy: bronchus, oesophageal, anorectal and hepatobiliary duct cancer

J. Skowronek¹

¹Greater Poland Cancer Centre, Poznan, Poland

Intraluminal brachytherapy is still an important part of brachytherapy procedures done especially in palliative patients. But large differences between countries over the world are observed. It is not clear how the future of intraluminal brachytherapy will look like. Brachytherapy is one of the most efficient methods in overcoming difficulties in breathing that is caused by endobronchial obstruction in palliative treatment of bronchus cancer. Depending on the location of the lesion in some cases brachytherapy is a treatment of choice. Because of uncontrolled local or recurrent disease, patients may have significant symptoms such as: cough, dyspnea, haemoptysis, obstructive pneumonia or atelectasis. Efforts to relieve this obstructive process are worthwhile, because patients may experience improved quality of their life. Brachytherapy plays a limited but specific role in definitive treatment with curative intent in selected cases of early endobronchial disease as well as in the postoperative treatment of small residual peribronchial disease. Various methods of palliation have been used in an attempt to improve patients' quality of life and to provide near normal, if not normal, swallowing until death occurs because of progressive esophageal cancer. Endoesophageal brachytherapy makes it possible to use high doses of radiation to the tumor itself with concurrent protection of adjoining healthy tissues due to the rapid fall in the dose with the square of the distance from the center of the dose. The above treatment also leads to a smaller proportion of late radiation complications. The aim of palliative brachytherapy is to reduce dysphagia, diminish pain and bleeding, and to improve the patient's well-being. Palliative treatment options for bile duct cancer or pancreas cancer remain limited due to the large number of patients with advanced disease at the time of diagnosis. Radical surgery is possible in less than 10-15% of these cases. Unrespectable bile duct or pancreas cancers are very difficult to treat with external beam therapy alone due to the proximity of adjacent normal organs and the high doses required to effectively irradiating these neoplasms. Although the results available in the literature are somewhat contradictory as regards the possible use of intraluminal brachytherapy in a curative setting, some evidence indicates that intraluminal brachytherapy can add something to the treatment of unresectable extrahepatic bile duct and pancreatic cancers if a proper subset of patients is identified and a rational and aggressive scheme of multimodality treatment is designed. High rate of advanced cases affects the enrollment of brachytherapy (BT) into treatment of bile duct cancers. Indications for brachytherapy include all malignant strictures of the bile duct which can be cannulated. Intraluminal brachytherapy (ILBT) is an important component in the multimodality approach to bile duct cancers. The objective of this treatment is to deliver a high local dose of radiation to the tumor while sparing surrounding healthy tissues. The treatment can be safely adapted for right and left hepatic duct as well as for common bile duct lesions. The standard of care in rectal cancer is still surgery. For limited size rectal cancer (T1, small T2), brachytherapy alone offers an alternative to radical surgery and leads to excellent results without major morbidity. In advanced rectal cancer, a proportion of patients can achieve complete clinical response after external beam chemoradiotherapy (EBCRT) that can be demonstrated on MRI after neoadjuvant treatment. Chosen summarized indications, treatment schedules, results and complications are discussed in the following presentation.

Teaching Lecture: Big data in radiotherapy: technology, challenges and opportunities

SP-0185

Big data in radiotherapy: technology, challenges and opportunities

A. Dekker¹

¹Maastricht Radiation Oncology MAASTRO GROW - School for Oncology and Development, Maastricht, The Netherlands

Big data is a buzzword. But what is Big Data? And what can we do with Big Data in radiotherapy?

In this teaching lecture we will discuss what Big Data is and what kind of data a modern radiotherapy center produces. Innovative technology to extract, store and process these Big Data are becoming available and will be discussed.

Big Data is often seen as tremendously promising and is predicted to change health care radically, but at this point in time is mostly a challenge as we keep accumulating data without a clear path to clinical applications while privacy concerns are on the rise. Methods and examples how we go from data to making a difference in lives of cancer patients will be presented. As will the methods to do this in a way that preserves the privacy of patients.

Finally the future of Big Data is drawn and the case will be made that more data is not always the answer if we do not have a Big Machine ready to learn from these data.

Teaching Lecture: The role of dosimetry audit in safety, quality and best practice for external beam and brachytherapy

SP-0186

The role of dosimetry audit in safety, quality and best practice for external beam and brachytherapy

C. Clark¹

¹National Physical Laboratory, Medical Radiation Physics, Teddington, United Kingdom

Joint abstract submitted

SP-0187

The role of dosimetry audit in safety, quality and best practice for external beam and brachytherapy

A.L. Palmer¹, C.H. Clark²

¹Portsmouth Hospital NHS Trust, Medical Physics Department, Portsmouth Hampshire, United Kingdom

²Royal Surrey County Hospital, Department of Medical Physics, Guildford, United Kingdom

Independent dosimetry audit is an essential component of best practice radiotherapy. However the value and concepts are not always fully understood. This lecture will review the methods and approaches of dosimetry audit and discuss its clinical importance. Examples will be given from a range of previously completed audits as well as considering what is needed in the role of audit in the implementation of new technologies.

Drawing on experience from both external beam and brachytherapy dosimetry audits worldwide, we will review the key elements of audit design, implementation and analysis, including: choice of phantoms and detectors, remote or on-site visits, efficiency and efficacy of the audit methodology, and reporting and feedback considerations.

The learning outcomes of this teaching lecture are:

- to understand why audit can improve safety, quality and best practice radiotherapy;
- to know how to choose appropriate methodology for audit and understand the outcomes;
- to appreciate the scientific, philosophical and legal reasoning for dosimetry audit.

Teaching Lecture: e-Learning for Professionals in Radiation Oncology: What, Why and How?

SP-0189

e-Learning for Professionals in Radiation Oncology: What, Why and How?

A. Berlanga Flores¹

¹*MAASTRO clinic, GROW School for Oncology and Developmental Biology- Maastricht University Medical Centre, Maastricht, The Netherlands*

Radiation Oncology is a dynamic and evolving field. Professionals need to find efficient and effective ways to stay informed of the latest developments, to collaborate and exchange knowledge with others, and to update or acquire new skills and competences.

E-Learning is an excellent way to achieve this. E-Learning is defined as the use of information and communication technologies to enable learning and performance. It has the potential to help radiation oncologists around the world to develop their competences whenever they want, at any time; allowing them to tailor their learning experiences to their goals, preferences, and needs.

This lecture will introduce the concept of e-Learning and its role for professional development in Radiation Oncology. It will present practical examples and strategies for young scientist to stay updated with recent findings and guidelines in the field, to develop their competences, and to find peers and opportunities for collaboration.

Symposium with Proffered Papers: Quality beyond accuracy: are we failing to see the forest for the trees?

SP-0190

Has higher accuracy in treatment delivery translated into noticeable improvements in clinical outcomes

N. Burnet¹

¹*Cambridge University Hospitals, Department of Oncology, Cambridge, United Kingdom*

We will define 'accuracy' as delivering the desired radiation dose to the target whilst minimising as much dose as possible to the surrounding normal tissues, thus embracing the classical balance which must be achieved with all radiotherapy.

The process begins with identifying the target, and therefore includes improving imaging for target volume delineation. Nevertheless, considerable uncertainties still exist especially in the personalisation of the Clinical Target Volume (CTV). Better conformation of dose to target shape has been a long term objective, beginning even in the ortho-voltage era. The biggest step, a revolutionary change, was the introduction of 3D conformal RT. IMRT represents 'ultra-conformal' treatment. Use of proton and carbon ion beams represents further steps along this path.

Improving accuracy also includes ensuring that today's highly conformal treatment plans are actually delivered to the target, without missing, and not to surrounding normal tissues. This brings us to image guidance, which appears to be vital, especially with steep dose gradient IMRT plans, but which is difficult (perhaps impossible) to test using the conventional trial paradigms.

A further concept is that the planned dose may differ from the accumulated delivered dose (DA), as the result of patient

or tumour changes. Computational developments mean that individual patient DA can be estimated in a research setting using daily image guidance scans, so that clinical implementation will need to be addressed.

An additional development is the use of real time imaging during the exposure to monitor patient or organ movement, using X-ray or MRI approaches.

In terms of clinical outcomes, good evidence exists that better imaging improves outcomes. The introduction of 3D CRT, perhaps the most important step of all, has a strong evidence base. IMRT is also supported by strong clinical evidence. There is highly suggestive evidence that charged particle beams have a valuable role. Sadly, there is also good evidence that bad quality in plan preparation and delivery leads to worse local control and survival (TROG). Image guidance is a more challenging component of the radiotherapy chain for which to provide hard trial evidence, although it has a clear rationale.

Overall, there is a definitive evidence base that better accuracy improves outcomes for both tumour control and normal tissue sparing using current technologies. Additional opportunities are also developing, making this is a truly exciting time to be working in radiation oncology.

SP-0191

The patient: an active partner in quality and safety process in radiotherapy

S. Cucchiaro¹

¹*C.H.U. - Sart Tilman, Radiotherapy Department, Liège, Belgium*

Beyond the technological advances to improve radiation therapy, the patient can also actively participate in its care process and contribute to ameliorate its management. The patient is a key player in security and improvement care processes. The patient's needs and expectations can be harvested through satisfaction surveys, adverse event declarations, records of complaints and patient committee.

An important place in our Radiotherapy Department is given to harvesting and processing patient's opinions to add value for it. In order to know the views of patients on the quality of our services and help us to improve it, we have developed a survey covering 6 themes. Figure 1 shows the surveys' results of the last three years for the 6 themes, which are close or greater than the institutional goal.

Figure 1 : Patients satisfaction surveys results

A patient committee is under construction. This committee, including former treated patients, will meet to discuss the satisfaction rates and improvement actions.

We also collect complaints and unexpected events. These are declared on adverse event reports. These reports are investigated during Experience feedback committee (EFBC). Through these different channels the patient is actively involved in the quality processes of the Radiotherapy

Department. Thus, the patient becomes a key actor in the quality and safety of its own treatment.

In conclusions: empowerment of the patient is essential for two reasons, on one hand at the individual level by strengthening its capacity to act on health determinants and on the other hand at the organizational level with continuous improvement of the Radiotherapy Department. Our goal is to strengthen the quality and safety of treatments, adjust them to the life project of the patient and promote a participative approach focused on the patient's needs and expectations.

SP-0192

Beyond accuracy: how can medical physics help improve treatment quality?

H. Nyström¹

¹The Skandion Clinic, Uppsala, Sweden

It has often been claimed and acknowledged that Radiotherapy (RT) as a modality to combat cancer has been technology driven, or even physicist driven. Higher energies, better accuracy, computerised delivery systems, improvements in imaging are all examples of this. Together with increased knowledge of how to combine RT with e.g. systemic treatments, RT has remained one of the most important tools in cancer therapy. The continuous improvements of RT has often involved complex technology, less intuitive to its nature than earlier technologies. It has been one of the most pronounced duties of the medical physicist to ensure that the clinical introduction of such new technologies has been done with the highest possible safety standards and that any risk associated with the new technology could be brought to an absolute minimum. As a result RT, in particular advanced RT, is a very safe modality compared to almost any other hospital activities. In their quest for the highest possible level of safety, the medical physicist is often left alone with high demands, ambitions but with limited means and lack of understanding from the hospital management of the recourses needed. As a consequence the clinical introduction of new, superior treatment options are delayed, months, years and sometimes even decades, and the patients have to be content with older methods, e.g. less conformal RT. This dilemma can be boiled down to the search for the optimal balance between quality (e.g. modern high precision treatments) and safety (reliable, well proven and understood methods). The priority often tends to go towards safety rather than quality since the focus from the general public as well as regulatory authorities always favours the latter at the expense of the former. As medical physicists, however tempting it might be to focus on safety only, must take a patient oriented approach and in all considerations include the aspect of what will be the most beneficial way from a patient's perspective. Just as a high quality cannot be justified to apply is the safety issues are not properly handled, safety without quality is of limited value. In the search for the ultimate balance between quality and safety, the medical physicist is in a key position since no other profession has a better understanding of the technology, the physics and the interactions between different complex systems. A more patient-centred approach to accuracy, safety and quality can, however only result from a multidisciplinary strategy where different profession work together towards the common goal to offer the best possible treatment to all patients in need thereof.

Evaluation of models for plan QA using fully automated Pareto-optimal plans for prostate patients

Y. Wang¹, S. Breedveld¹, B. Heijmen¹, S.F. Petit¹

¹Erasmus Medical Center Rotterdam Daniel den Hoed Cancer Center, Radiation Oncology, Rotterdam, The Netherlands

Purpose or Objective: Current IMRT treatment planning with commercial treatment planning systems is a trial-and-error process, based on a series of subjective human decisions. So the quality of the IMRT treatment plans may not be consistent among patients, planners or institutions with different experience. Different plan quality assurance (QA) tools have been proposed recently, that could flag

suboptimal plans that may benefit from an additional treatment planning effort. However, since conventional treatment planning was used to validate these models, the inherent accuracy of the existing treatment planning QA models is unknown. Therefore we fully automatically generated a dataset of Pareto-optimal prostate IMRT plans using Erasmus - iCycle, an in-house TPS for fully automated, multi-criterial plan generation. This dataset was used to assess the prediction accuracy of an overlap volume histogram (OVH) based plan QA tool.

Material and Methods: 115 prostate plans were fully automatically generated using Erasmus-iCycle. These plans were based on a fixed 'wish-list' which contains hard constraints and objectives in a predefined order of priority. An existing OVH model was modified and used to predict DVHs for these patients. First, the entire DVH of the rectum, bladder and anus of a validation cohort (N=57) were predicted, using the plans of an independent training cohort (N=58). To investigate the impact on prediction accuracy of an enlarged training cohort, the DVHs were also predicted by a leave-one-out method. The predicted rectum Dmean, V65, and V75, and Dmean of the anus and bladder were compared with the achieved values to validate the OVH QA tool.

Results: For rectum, the prediction errors (predicted-achieved) were small: -0.2 ± 0.9 Gy (mean ± 1 SD) for Dmean, $-1.0 \pm 1.6\%$ for V65, and $-0.4 \pm 1.1\%$ for V75. 72% and 96% of the predicted rectum Dmean had prediction errors within 1 Gy and 2 Gy, respectively. For Dmean of anus the prediction error was only 0.1 ± 1.6 Gy, whereas for the bladder it was much larger: and 4.8 ± 4.1 Gy (see also Fig 1). Increasing the training cohort to 114 patients (using leave-one-out) led to minor improvement.

Conclusion: A dataset of consistently prioritized Pareto-optimal prostate IMRT plans was generated. This dataset can be used to validate any planning QA model and will be made publicly available at the Treatment Planning QA Section of http://www.erasmusmc.nl/radiotherapie/research/radiationoncologymedicalphysicsandimaging/research_projects. It was applied here to assess the accuracy of the OVH model. The OVH model was highly accurate in predicting rectum and anus DVHs. For the bladder large prediction errors were observed, which indicates that the OVH has difficulty in capturing the interdependence of sparing different OARs. We are currently

investigating how the OVH model should be modified to be suitable as a plan QA tool for prostate patients.

Symposium: Targeting DNA repair / DDR pre-clinical evidence

SP-0194

Tumour-specific radiosensitisation by ATR inhibitors

T. Brunner¹

¹Universitätsklinik Freiburg, Department of Oncology, Freiburg, Germany

The human ataxia telangiectasia and Rad3-related protein (ATR) kinase is activated by DNA damage and replication stress as a central transducer of a checkpoint signaling pathway. Subsequent to activation, ATR phosphorylates many substrates, including the kinase Chk1, which regulates cell-cycle progression, replication fork stability, and DNA repair. All of the three mentioned events promote cell survival during replication stress and in cells with DNA damage. It was hypothesized that ATR inhibitors would be therapeutically useful, with a predicted specificity for tumors sparing normal cells. Since the introduction of potent ATR inhibitors a hand full of studies in conjunction with radiotherapy has been published including our own work where we showed sensitization of pancreatic cancer in vitro and in vivo to radiotherapy in conjunction with VE-822 (=VX-970), an ATR inhibitor. The drug decreased maintenance of cell-cycle checkpoints, increased persistent DNA damage and decreased homologous recombination in irradiated cancer cells. Furthermore, we observed decreased survival of pancreatic cancer cells but not normal cells in response to XRT or gemcitabine. VE-822 markedly prolonged growth delay of pancreatic cancer xenografts after XRT and gemcitabine-based chemoradiation without augmenting normal cell or tissue toxicity. Others have shown that different tumours such as head and neck squamous cell carcinoma or promyelocytic leukaemia were also sensitized to radiation by co-treatment with an ATR inhibitor. Additionally, human tumor cells were also sensitized to high LET radiation. The first clinical early phase trials combining ATR inhibitors with radiotherapy or chemotherapy are underway to generate important insights into the effects of ATR inhibition in humans and the potential role of inhibiting this kinase in the treatment of human malignancies.

⁴Johns Hopkins University School of Medicine, Department of Radiation Oncology, Baltimore, USA

ATR and ATM are protein kinases activated at stalled and collapsed replication forks and DNA double-strand breaks (DSBs), respectively, where they function to maintain genome integrity by mediating cell cycle checkpoints and DNA repair. ATM has been widely studied since ataxia telangiectasia individuals who express no ATM protein are the most radiosensitive humans identified. It has therefore been postulated that ATM kinase inhibitors (ATMi's) will increase the efficacy of radiotherapy. ATR has also been widely studied, but advances have been complicated by the finding that ATR is an essential protein in mice and mammalian cells. Nevertheless, pharmacologic ATR and ATM kinase inhibitors have been identified and these sensitize cancer cells to ionizing radiation (IR) in tissue culture. ATR kinase inhibitors (ATRi's) also synergize with cisplatin to induce cell death in tissue culture. Since concurrent cisplatin and radiation is used as standard of care for locally advanced and metastatic

NSCLC patients, ATR kinase inhibition may significantly improve the efficacy of first line treatment in tens of thousands of patients in the USA every year. Until recently, however, *in vivo* studies have been limited by the absence of bioavailable ATR and ATM kinase inhibitors.

Here we describe orally active and bioavailable ATR and ATM kinase inhibitors and show that, in contrast to expectations, ATRi is surprisingly well tolerated. We show that cisplatin-ATRi induces a complete response in ATM-deficient lung cancer xenografts and potentiates the effect of cisplatin in p16^{INK4A}-deficient lung cancer xenografts. We also show that conformal radiation-ATRi and radiation-ATMi induce profound responses in an autochthonous Kras^{G12D}/Twist1 mouse model of lung adenocarcinoma, and that the efficacy of radiation-ATRi for the treatment of lung cancer appears to be better than that of radiation-ATMi due to lower toxicity.

SP-0196

Realising the full potential of DNA damage response inhibition in the treatment of cancer

S. Galbraith¹

¹AstraZeneca, Oncology Innovative Medicines, Cambridge, United Kingdom

An underlying hallmark of cancers is their genomic instability, which is associated with a greater propensity to accumulate DNA damage. Historical treatment of cancer by radiotherapy and DNA-damaging chemotherapy is based on this principle, yet it is accompanied the significant risk of collateral damage to normal tissue and unwanted side effects. Targeted therapy based on inhibiting the DNA damage response (DDR) in cancers, either alone or in combination, offers the potential for a greater therapeutic window by tailoring treatment to patients with tumours lacking specific DDR functions. The recent approval of olaparib (Lynparza), the poly (ADP-ribose) polymerase (PARP) inhibitor for treating tumours harbouring BRCA1 or BRCA2 mutations, represents the first medicine based on this principle, exploiting an underlying cause of tumour formation that also represents an Achilles' heel. Different forms of DNA damage evoke responses by different repair mechanisms and signalling pathways and the choice of pathway will also be influenced by the phase of the cell cycle in which the damage occurs. DDR represents a good source of anticancer drug targets as there are at least three key aspects of DDR that are different in cancers compared with normal cells. These are a) the loss of one or more DDR capability b) the increased levels of replication stress and c) the higher levels of endogenous DNA damage in cancer cells compared to normal cells.

This talk will focus on examples of how each of these concepts is currently being exploited to treat cancer. As an example of the exploitation of the first concept, the use of PARP inhibitors to treat cancers deficient in *BRCA1* and *BRCA2* gene function, as well as other homologous recombination repair deficiencies, will be presented. The second concept - the exploitation of high levels of replication stress in cancers, will be exemplified through data presented resulting from the use of inhibitors of ATR and WEE1. As part of the discussion on how best to exploit the higher levels of endogenous DNA damage in cancers, the focus will be on the challenges associated with expanding the therapeutic window for the use of DDR inhibitors in combination with DNA damaging agents such as radiation and chemotherapy. Finally, the ambition of how best to realise the full potential of DNA damage response-based therapy will be discussed including the use of different synergistic combinations in a personalized healthcare approach.

Consequences of bowel cancer screening programmes

M. Van Leerdam¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, The Netherlands

Colorectal cancer (CRC) is the third most common type of cancer among men and the second among women in the European region. CRC is the second most common cause of cancer related death in Europe. Several trials have shown a mortality reduction of screening by either faecal occult blood test or flexible sigmoidoscopy. Next to mortality reduction, there also is a reduction of the CRC incidence by CRC screening. Furthermore, different CRC screening modalities have been proven to be cost-effective and maybe even cost-saving. Most countries of the European Union do have a type of CRC screening, but still many countries do have opportunistic programs without an explicit policy, defined target population and without a dedicated organisation responsible for the roll out of the program. Preferable, CRC screening should be a population based program, using an up to date IT system/ data warehouse and with close monitoring and evaluation of the whole program and the outcome measures. Quality assurance is of utmost importance and can only be established in an organised program. Part of the results of the Netherlands CRC screening program will be presented as example.

SP-0199

How to delineate the CTV for rectal cancer? An international consensus

V. Valentini¹

¹Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Gemelli ART, Rome, Italy

Purpose: The delineation of clinical target volume is a critical step in radiation therapy procedure. Several contouring guidelines suggest different subvolumes and anatomical limits in rectal cancer, supporting a variability in delineation that largely depends on inter-operator discordance in delineation. An international agreement among expert radiation oncologists might significantly reduce this variability, converging on a consensus rectal cancer contouring guideline through Falcon, the educational web-based multifunctional platform for delineation endorsed by ESTRO.

Material and Method: Seven skilled radiation oncologists, delegated from ESTRO, ASTRO, TROG and EORTC, defined the steps to produce consensus rectal cancer guidelines on elective nodal levels delineation. Six rectal cancer cases with different clinical stage were selected and the related CT scans were shared and uploaded on Falcon platform. The experts firstly delineated online the selected CT scan slices following each his personal guidelines. The first delineation outcome was then discussed in a face-to-face meeting with the contribution of surgeons and radiologist and a table of boundaries was compiled. All the experts had then to delineate online the same CT scan slices, considering the new table of boundaries. In a peer review meeting the final outcome was obtained and the publication plan defined.

Results: Falcon allowed a comparison of the experts' delineations, identifying critical nodal boundaries as areas of disagreement. The ontology of structure sets was defined and a new table of boundaries was generated. The major modifications to the previously published guidelines were about lateral lymph nodes (LLN) and ischio-rectal fossa (IRF). One of the discussed issues was the level of the cranial and anterior border of LLN according to clinical rectal cancer stage. The delineation of the entire IRF was recommended only when there was an infiltration of the external anal sphincter or the IRF and new limits were defined (Table).

Subsite	Limits	Definition	Recommendation
Lateral lymph nodes	Anterior	When the external iliac vessels leave the pelvis, the anterior border should be limited to a virtual line at the level of the anterior wall of the ureters.	In case of: - positive nodes in the posterior lateral lymph nodes (internal iliac); - cT4; - numerous mesorectal nodes; the anterior limit is the anterior surface of obturator artery.
	Cranial	Bifurcation of common iliac artery into internal and external iliac arteries	In case of: - cT3N0; - MRF-; the cranial limit may be lowered at the level of the bifurcation of the IMA in SA and SRA (corresponding to the cranial limit of the mesorectum).
Ischio-rectal fossa	Cranial	Where the inferior pudendal artery leaves the pelvis	Include both when there is an infiltration of the external anal sphincter or the ischio-rectal fossa
	Caudal	1 cm below the inferior rectal artery (which travel horizontally in the IRF)	

Conclusion: The definition of consensus guidelines for rectal cancer delineation endorsed by skilled radiation oncologists may support in reducing contouring variability. The structure sets of the six cases used will be available online as consultation atlases on the Falcon platform for individual test and a paper describing the agreed guidelines will be soon published.

Symposium: Changing paradigm in the management of kidney cancer

SP-0200

Partial nephrectomy: indication and results

P. Gontero¹

¹University of Studies of Torino Molinette Hospital, Department of Surgical Sciences, Torino, Italy

Historically, the standard treatment modality used for the vast majority of small renal masses (< 4 cm) was radical nephrectomy (RN). Partial nephrectomy (PN) was conceived to preserve renal parenchyma and function. It was pioneered in patients who would require renal replacement after RN (imperative indications). Based on the "belief" that PN is "better" than RN, utilization of PN has increased worldwide in the last few years. This has been supported by extensive literature of retrospective studies demonstrating renal functional outcomes and "overall survival" benefits of PN over RN. For T1 renal cancer (up to 7 cm lesion according to current TNM), > 95% 5 years disease specific survival rates have been reported. The probability of a positive surgical margin (PSM) on the resection bed has been shown to be below 5%. The impact of a PSM on disease recurrence remains controversial with some series suggesting no additional risk compared to a negative margin. A tumour resection technique conducted at the edge of the tumour (enucleation) has been advocated as a mean to preserve more renal parenchyma and oncologically "non-inferior" to the standard "enucleoresection" technique where a margin of up to 1 cm of healthy parenchyma is left on the resected mass. Besides, a significant reduction in the risk of developing chronic kidney disease (CKD) has been reported with PN as compared

to RN. This has also translated into a reduced risk of all cause mortality in large population series receiving PN as compared to RN, as a result of a lower rate of cardiovascular events potentially driven by CKD. Backed by these data, current guidelines (NCCN 2015, EAU 2014 and AUA 2009) make strong recommendations for PN in all T1a (up to 4 cm) and whenever feasible in T1b (4-7 cm) kidney cancers. The recommendation becomes imperative in patients with baseline CKD, bilateral tumours or tumour in a solitary kidney. Surprisingly, the only level I evidence available from a European RCT could not prove equivalence between PN and RN. While the trial did not meet accrual goals (541 out of 1300 patients required), overall survival (the primary study end point) at 9.3 years of follow up was eventually better in the RN arm in spite of a better preserved renal function in the PN arm. Notably more cardiovascular events were observed in the PN group! All these observations taken together suggest that the survival advantage of PN over RN observed in large retrospective series or meta-analyses is likely the effect of unaccountable selection biases in favour of PN (healthier patients more likely to be treated with PN). The beneficial effect of PN on kidney function is out of question, yet its clinical relevancy (= reduced risk of non cancer related morbidity) is restricted to patients with baseline CKD. Up to 30% of patients with SRM have some degree of baseline CKD and hence would require a PN that must be performed with surgical skill in order to optimize both oncological efficacy (negative surgical margin) and kidney function preservation (keep ischemia time < 25 minutes or even lower). The currently available surgical techniques (open, laparoscopic and robotic assisted) have all proved effective to accomplish a PN matching the criteria for both oncological and functional efficacy.

SP-0201

Stereotactic radiotherapy for renal cell carcinoma: the hidden treasure or the forbidden kingdom

G. De Meerleer¹

¹University Hospital Ghent, Department of Radiotherapy and Experimental Cancer Research, Ghent, Belgium

Normal 0 21 false false false FR-BE X-NONE X-NONE

Renal-cell carcinoma (RCC) is considered to be a radioresistant tumour, but this dogma is wrong and based on traditional radiation schedules. If given in a few (even single) fractions, but at a high fraction dose (stereotactic body radiotherapy or SBRT), RCC becomes highly radiosensitive. Both in the primary setting and in treatment of oligometastatic disease, local control rates >90% are achieved. There is an established biological rationale for the radiosensitivity of renal-cell carcinoma to SBRT which is based on the ceramide pathway, which is activated only when a high dose per fraction is given. This pathway does not involve damage at the DNA level (nucleus) but at the level of the cell membrane. The ultimate target of this pathway is the tumour vasculature, similar to lots of targeted drugs.

Apart from the direct effect of SBRT on renal-cell carcinoma, stereotactic body radiotherapy can also induce an abscopal effect. This effect, caused by immunological processes and involving dendritic cells, might be enhanced when targeted drugs and stereotactic body radiotherapy are combined. Therefore, rigorous, prospective randomized trials involving a multidisciplinary scientific panel are needed urgently. The presence of a radiation oncologist in such panels is vital.

This oral presentation will focus on:

1. Radiobiology of SBRT in RCC (ceramide pathway).
2. Rationale for the abscopal effect.
3. Local control rates of SBRT in RCC.
4. Interaction between targeted drugs and SBRT.
5. Increasing visibility of radiation oncology in this setting.

SP-0202

Ablative treatment for renal cancer

H. Baumert¹

¹Groupe Hospitalier Paris Saint-Joseph, Department of Uro-oncology, Paris, France

There has been an increase in incidence of small renal masses over the last two decades. There is evidence that nephron sparing surgery offers equivalent long-term oncological results compared to radical nephrectomy. More recent evidence suggests that radical nephrectomy is associated with greater chronic renal insufficiency, which is in turn associated with increased risk of cardiovascular death, in patients with localised T1 renal mass. It is for these reasons that nephron sparing surgery is recommended, when technically feasible, for the management of renal tumour smaller than 7 cm.

Partial nephrectomy is the gold standard treatment for small renal masses, however it is associated with a significant morbidity.

Ablative treatments are alternative options that cause necrosis of the renal tumour without removing it. This can be achieved by heating tumour up to 80°C, with radiofrequency, or by freezing it below -40°C with cryosurgery. These percutaneous ablative treatments are performed under CT scan guidance or by laparoscopic approach. The percutaneous approach can be performed under local anaesthesia, which is particularly useful in fragile patients. These two minimally invasive ablative treatments allow, on average, to halve the postoperative morbidity when compared to partial nephrectomy. On the other hand, the risk of local recurrence is higher compared to partial nephrectomy.

Cancer specific survival rate on literature review is quoted around 90 to 95% for T1a (<4 cm) tumours. The 5 years overall survival or metastatic free survival, don't seem to be different from partial nephrectomy, if salvage treatments are proposed in case of local recurrence. To achieve these oncological results, appropriate patient selection along with adequate follow up is required.

According to the various urological guidelines, renal biopsy must be performed prior to these ablative treatments. When a malignant tumour is confirmed histologically, these treatments are recommended for cortical tumours, smaller than 4 cm, ideally in elderly patients or patients with multiple comorbidities who have a reasonable life expectancy. Patients with bilateral synchronous tumours, genetic diseases leading to multiple bilateral recurrences, renal insufficiency or presence of solitary kidney, are also ideal candidates for ablative treatments. Patients with shorter life expectancy, tumours in the hilum or in close proximity to the collecting system and proximal ureter are contraindications. Cryosurgery appears to treat central tumours with less morbidity compared to radiofrequency ablation. Close radiological follow up is required. Renal CT scan or MRI is usually performed at regular intervals looking for any possible enhancement of recurrent/residual tumour.

Conclusion: Partial nephrectomy remains the gold standard treatment for management of small renal tumours. Ablative treatment is a validated option associated with a favourable risk benefit balance, especially for fragile patients.

Symposium: Modern techniques for old indications

SP-0203

Robotic surgery and brachytherapy

B. Pieters¹

¹Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands

The practice of brachytherapy nowadays has been developed decades ago. In the course of years modifications are introduced by the use of different isotopes, the development of afterloading techniques, the introduction of image-guided techniques, and many more. Robotics technologies are on a wide scale increasingly being used in the treatment of patients. Also in brachytherapy this emerging technology has been adopted and is still in development. A robot is a

reprogrammable multifunctional manipulator designed to move materials, parts, tools, or specialized devices through variable programmed motions for the performance of a variety of tasks defined by The Robotics Institute of America. Dependent on the degree of automation and autonomy different classes can be recognized. Examples where robotic systems are used in brachytherapy are e.g. in prostate and bladder implantations.

Several commercial and non-commercial systems exist to plan and place needles into the prostate. These systems can be automated for radioactive seed delivery and HDR treatments. Clinical study show robotic implantations to be feasible, although still manual corrections are done.

In bladder brachytherapy a laparoscopic robotic system is available for catheter placement without the need to open the bladder (cystotomy). As with the traditional way of implanting, the catheters can be placed parallel and equidistantly. The major advantage is reduction of treatment morbidity with this technique, although also misplacements have been observed preventing adequate brachytherapy.

Development of new technologies, such as robotic-aided brachytherapy implantations is welcomed to increase the precision and reproducibility of treatments and reduce morbidity. On the other side it should be appreciated that also for these techniques a learning curve exist. Clinical results in comparison to the traditional techniques should be awaited and carefully discussed before widespread adaptation of these new techniques.

SP-0204

New techniques in brachytherapy for head and neck

G. Kovács¹

¹University of Lübeck - UKSH CL, Interdisciplinary Brachytherapy Unit, Lübeck, Germany

Interventional radiotherapy (brachytherapy) was the first medical application in the treatment of cancer after discovering radium. User experience was growing over the time and useful rules of meaningful application were developed. For many decades this experience based rules regulated the indication as well the performance of brachytherapy applications. After introducing milestone developments in the technical performance (stepping source technology and modern treatment planning software packages) as well in target definition modalities (multiparametric imaging, real-time imaging) and in quality assurance issues (medical & physical QA) biological planning and intensity modulation potential become available. Furthermore, interdisciplinary networking and education in the field lead to a higher level of cure rates with low toxicity and better Quality of Life of the patients. Economical comparison with other methods proved the necessity of involving interventional radiotherapy in to modern function preservative interdisciplinary treatments.

Head & Neck cancer represents a special need for interdisciplinary cooperation because:

1. Most of the recurrences following modern external beam radiotherapy (with or without complementary systemic treatment) are in-field recurrences. This indicates the need for higher local dose and interventional radiotherapy offers the highest possible dose in a small volume accompanied by very low radiation dose on surrounding normal tissues or organs at risk.
2. Aggressive surgery cause functional or cosmetic damages on the head & neck. The combination of surgery and perioperative interventional radiotherapy results in higher rates of function preservation or in better cosmetic results.
3. Modern multiparametric imaging techniques including hypoxia imaging has the potential to guide necessary very high dose areas to the right but very small volumes within the target.

Regarding healthcare economy issues: preliminary analyses of healthcare professionals stated the advantage of involving interventional radiotherapy in to the treatment of head & neck cancers.

SP-0205

Image guided brachytherapy in vaginal cancer

L.U. Fokdal¹, R. Nout²

¹Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

²Leiden University Medical Center, Department of Radiotherapy, Leiden, The Netherlands

Vaginal cancer is a rare disease, accounting for only 2-3% of all gynaecological cancers. The majority (85%) of the tumours are squamous cell carcinomas and associated with a previous HPV infection.

The FIGO classification is used for clinical staging and is an important prognostic factor. Approximately 25% of patients present with FIGO stage I, limited to the vaginal wall with a 5-year survival rate of approximately 80%, compared to 20% for FIGO stage IV tumours that invade other pelvic organs or extend beyond the true pelvis (10-15% of patients). Other known prognostic factors are site, size and histologic subtype.

The treatment of vaginal cancer may include surgery in limited stage I disease, in the upper third of the vagina. However, surgery is often extensive especially if tumors extend to the lower two thirds of the vagina and it is often difficult to achieve negative margins in tumors larger than 2-3 cm. Because of these difficulties, radiotherapy is generally recommended as the standard treatment for all vaginal cancers irrespectively of the stage.

In general, radiotherapy is very similar to that for cervical cancer and includes a combination of 45-50 Gy external beam radiotherapy (EBRT) with concomitant weekly cisplatinum followed by brachytherapy boost to a total dose of 70 Gy to 80 Gy. With regard to the brachytherapy technique small residual tumors ($\leq 5\text{mm}$ thick) can be treated with intracavitary technique alone while combined intracavitary and interstitial technique should be considered for larger tumours.

Published data on the results of radiotherapy are mainly based on small retrospective studies and can be categorised in two groups. The first group includes studies where patients mainly were treated with 2-dimensional (x-ray based) radiotherapy. The second small group includes studies where patients have been treated using image guided (CT or MRI) adaptive treatment planning. Any direct comparison between the two groups of studies is difficult because of the retrospective nature of the data, limited number of patients and short follow-up. However, it seems that image guided brachytherapy is associated an increased local control rate from 75% (44-87%) for the radiograph based studies to 85% (75-94%) for the studies using an image guided approach, together with a decrease in moderate to severe treatment related morbidity. In 2005 the GEC-ESTRO GYN group successfully introduced an image guided adaptive target concept for brachytherapy in locally advanced cervical cancer. This concept takes the initial tumour extent at time of diagnosis as well as tumour regression during EBRT into account. Several studies have shown a therapeutic benefit with improvements in local control and reductions in moderate to severe morbidity using this concept.

Based on these results, a task group within GEC ESTRO GYN was formed with the aim to introduce image guided adaptive target concept in the treatment of vaginal cancer. This initiative started in the beginning of 2014 comparing the different target concepts from each of the 5 involved centres. In a next step each centre contoured 5 different cases with their own target concept in mind. During this work many similarities were found in the target concepts and between the contours of each centre. Therefore the group proceeded to investigate the differences and similarities in dose and treatment planning. In this project each centre performed treatment planning for the 5 contoured cases using both their own target contours and on a set of contours that were provided.

Importantly, radiotherapy for vaginal cancer is based on a combination of clinical findings as well as imaging. Especially for the clinical findings the precise documentation can be challenging. In order to increase the uniform reporting a clinical drawing for this documentation has been developed.

This practical tool is now at the stage that it will be evaluated clinically in each centre. By now several centres have experience with image guided adaptive brachytherapy in limited numbers of patients with vaginal cancer. To gain more knowledge from this already existing experience a retrospective database has been established with inclusion of approximately 90 patients that have been treated with CT or MRI guided brachytherapy. Although different target concepts have been used, this cohort will allow for analysis of disease control, prognostic factors and descriptive analysis of the radiotherapy related parameters in a more contemporary series. A future goal will be establishment of a prospective multicentre database with inclusion of patients treated with a common target concept. During this presentation existing results for radiotherapy in vaginal cancer will be reviewed, followed by an overview of the work that has been performed to introduce image guided adaptive brachytherapy in primary vaginal cancer within the GEC ESTRO GYN group.

Symposium: Quantitative imaging to individualise radiotherapy

Tissue characterisation using quantitative radiomics

W. Van Elmpt¹

¹Maastricht University Medical Centre, Department of Radiation Oncology MAASTRO, Maastricht, The Netherlands

In this presentation the possibilities for image quantification for tissue characterization will be discussed that go beyond quantification of Hounsfield Units for CT or SUV for PET imaging. Standardization aspects of advanced imaging techniques are important for reliable and robust quantification. Besides the image acquisition, an equally important part is validation of the used image analysis techniques. Especially for textural feature calculations (e.g. radiomics) this is not a trivial task and may require some more detailed guidelines for acquisition, segmentation, analysis and reporting of results. The entire pipeline from image acquisition to analysis should be designed to allow interchangeable and robust results between e.g. institutes, software packages and imaging equipment. This presentation will illustrate the possibilities of advanced image quantification, concepts and techniques with clinical examples: Radiomics of tumours are currently investigated to predict local control, metastasis patterns or survival of patients, whereas advanced image quantification of normal tissues may allow better prediction of patients prone to toxicity.

SP-0207

Image-based radiobiological tumour control probability modelling

E. Malinen¹

¹DNR - Norwegian Radium Hospital, Oslo, Norway

Solid tumors may be heterogeneous with respect to radiosensitivity, and a homogeneous tumor dose is thus not always optimal. Thus, medical images of radiobiological relevance may be used to guide focal irradiation of tumors. Tumor control probability (TCP) modeling may be useful for optimizing dose painting treatment plans and for estimating the effect of such therapeutic strategies.

Both magnetic resonance imaging and positron emission tomography may provide voxel-by-voxel maps potentially reflecting tumor aggressiveness and radioresistance. The talk will elaborate on the biological relevance of these imaging approaches and their pros and cons in terms of radiotherapy planning. Then, from the voxelwise mapping of tumor radiosensitivity, proposed frameworks for the tumor control probability modelling will be presented. Both data-driven and model-driven approaches are discussed. Furthermore, the potential use of TCP modelling in dose painting will be elaborated. Also, the concept of 'LET' painting in particle therapy will be highlighted.

In concluding, the current and future role of image based TCP modelling will be discussed, seen together with both advances in biologic imaging and in radiotherapy delivery and guidance techniques.

²Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Pathology Department, Amsterdam, The Netherlands

³Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Urology Department, Amsterdam, The Netherlands

⁴Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Division of Biological Stress Response, Amsterdam, The Netherlands

In this era, image-guided radiotherapy provides the technology to modulate dose based on the variation in radiation sensitivity within cancer of the prostate. This raises the question what to irradiate and to which dose. Here, functional imaging techniques play an essential role. Multi-parametric (mp) MRI, consisting of T2-weighted, diffusion-weighted and dynamic contrast-enhanced MRI is a key element in the detection of prostate cancer, and is increasingly used for delineation of tumors inside the prostate gland. Validation with histopathology however shows that tumor detection and particularly tumor delineation is challenging. Prostate cancer is often multifocal and small lesions (<0.5cm³) are often missed. Tumor sub-volumes with low cell and microvessel density that resemble healthy tissue are also difficult to find with mp-MRI. The most aggressive parts of the tumors, containing high cell and microvessel density and a higher Gleason score, are more likely to be detected. The heterogeneity in the histopathology of prostate cancer together with the limitations of mpMRI in detecting small satellites has implications for dose prescriptions in radiotherapy. We therefore evaluated the potential impact of dose differentiation on the tumor control probability (TCP) in prostate radiotherapy using histopathological properties of prostate tumors. We defined GTV and CTV based on tumor volumes on H&E stained slices from prostatectomy specimen of 25 patients. Each patients' TCP was simulated taking into account differences in the cell numbers (NO) and Gleason Scores (GS). We further evaluated the assumption that these tumors all have the same radiosensitivity, or that radiosensitivity decreases with increasing Gleason grade. Our results demonstrate feasible dose differentiations between GTV and CTV based on the heterogeneity in the histopathology of prostate tumors and the impact on the TCP of the patient population. We will further discuss the different GTV-CTV dose differentiations considering heterogeneity only in the number of tumor cells or also in the radiosensitivity, based on Gleason grade. Further studies in carefully designed clinical trials are needed to determine the effect of heterogeneous radiosensitivity on the response of individual patients to different regimes of radiotherapy.

Real-time liver motion monitoring on conventional linac by external surrogate and sparse kV imaging

J. Bertholet¹, E. Worm¹, R. Hansen¹, M. Høyer¹, P. Poulsen¹

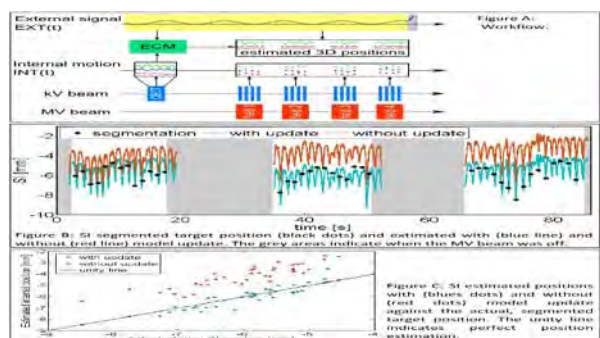

¹Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

Purpose or Objective: Intrafraction motion is a challenge for accurate delivery of stereotactic body radiation therapy (SBRT) in the liver. Real-time treatment adaptation (gating,

tracking) may mitigate the detrimental effects of motion, but requires reliable target motion monitoring. On a conventional linac, monitoring can be obtained by intrafraction kilovoltage monitoring (KIM) using continuous imaging of implanted fiducials with a standard gantry-mounted x-ray imager. However, KIM adds imaging dose, is incompatible with large couch rotation, and KIM images suffer from MV scatter onto the kV imager. This study investigates the use of external monitoring combined with sparse kV imaging during beam pauses to overcome KIM limitations.

Material and Methods: Six patients with 2-3 implanted gold markers received three fraction liver SBRT on a conventional linac. A setup CBCT was acquired with simultaneous recording of the motion of an external marker block on the abdomen (Fig. A). The 3D marker motion during the CBCT was estimated at 15Hz from the 2D motion in the CBCT projections and used to establish an external correlation model (ECM) of the internal marker motion INT(t) in each direction (RL, SI, AP) as a function of the external marker block motion EXT(t): $INT(t) = A \cdot EXT(t) + B \cdot EXT(t-\tau) + C$, where A, B, C are coefficients and τ is a time constant. During treatment delivery, INT(t) was estimated from the external motion at 20Hz, while MV-scatter-free kV images were acquired every 3s during beam pauses. INT(t) was estimated from the ECM of the CBCT without any model update and with updates of the coefficient C/SI by use of the first image of each treatment field. Post-treatment, the 3D marker positions were estimated for each intra-treatment kV image and used as ground truth to quantify the root mean square error (rmse) of the INT(t) estimations.

Results: Figs. B-C compare the estimated INT(t) with and without model updates with the ground truth positions in intra-treatment kV images at one fraction. Table 1 shows the mean rmse for all fractions. ECM updates more than halved the SI rmse. Substantial internal cranial baseline drift up to 7 mm (mean 1.4 mm) occurred between the setup CBCT and the last field without a similar drift for the external surrogate, illustrating the need for intra-treatment ECM updates.

	Pre-treat	Intra-treatment kV images	
RMSE [mm]	CBCT	With update	Without update
RL	0.19	1.15	1.15
SI	0.61	1.09	2.55
AP	0.31	1.13	1.13
3D	0.73	2.12	3.14

Table 1 : Mean rmse of the ECM for all fractions. The first column describes the fit-performance of the ECM to motion during the CBCT. Note that model-update (second column) was only performed in the SI direction.

Conclusion: A correlation model between external surrogate motion and internal liver motion was established on a conventional linac from pre-treatment CBCT projections and used to estimate the intra-treatment target positions with and without model update. A simple update based on only one kV image per field substantially improved the localization accuracy. Real-time update of the model in all 3 motion directions is currently being developed and is expected to further improve the localization accuracy. The proposed method increases the versatility and reduces the imaging dose compared to current clinical KIM implementations.

OC-0210
Motion management for partial arc VMAT treatments using intra-fractional 2D/3D registration

H. Furtado¹, Y. Seppenwoolde², E. Steiner², M. Bsteh³, W. Birkfellner⁴, D. Georg²

¹Medical University of Vienna, Center for Medical Physics and Biomedical Engineering / Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

²Medical University of Vienna, Department of Radiation Oncology / Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

³Medical University of Vienna, Department of Radiation Oncology, Vienna, Austria

⁴Medical University of Vienna, Center for Medical Physics and Biomedical Engineering, Vienna, Austria

Purpose or Objective: Rotational radiotherapy IMRT (VMAT) has shown superior delivery efficiency with similar overall treatment plan quality compared to conventional IMRT. For lung treatments intra-fractional tumor motion is a major source of uncertainty in dose application leading to the enlargement of the PTV margins and possibly to increased dose delivery to OARs. Motion management by tracking the tumor using intra-fractional kV planar images has the potential to reduce position uncertainty and reduce the PTV margins. The challenge for rotational treatments is the poor tumor visibility at certain gantry angles. In this work we investigate the feasibility of delivering VMAT treatments using only partial arcs where the tumor is well visible and therefore tracking is feasible.

Material and Methods: For our study we used the x-ray images acquired for CBCT reconstruction from five patients with NSCLC undergoing hypo-fractionated SBRT treatment (3 fractions of 13.5Gy prescribed to the 65% isodose). These x-rays are comparable to kV fluoroscopy images acquired during a VMAT treatment. For each patient the evaluation consisted of two steps: first real-time 2D/3D registration was used to track the tumor location on each of the x-rays from the CBCT acquisition. We determined the gantry angle intervals for which it was possible to track the tumor by comparing registration results with manually annotated diaphragm motion. Second, VMAT plans were created for partial arcs chosen depending on the anatomy and tumor location (U=unlimited) for a PTV based on an ITV approach (ITV plus 4mm margin) and for the limited partial arcs where the tumor tracking worked (L=limited) for a PTV based on the midventilation CTV (5mm margin). The L partial arc plans were evaluated using the U plans as benchmark.

Results: For all cases it was possible to track the tumor in two arcs of about 90 degrees, typically with imaging around anterior-posterior (AP) or posterior-anterior (PA) projections. For patient 5 it was possible to track the tumor in all projections. In terms of plan quality, a target coverage of at least 99% to the 65% isodose was aimed for and could be achieved for all the U plans and for all the L plans except for one, where the available angle range led to an unfavorable dose distribution, which would be clinically not acceptable. Therefore this patient was omitted for further data evaluation. Table 1 summarizes the tracking angles and the DVH parameters. Figure 1 shows example tracking results and obtained plans for one patient.

Patient	Tracking angles (deg)				Used arc ranges (deg)		PTV volume (cc)		DVH parameters					
	AP	PA	U	L	U	L	U	L	U	L	U	L	U	L
1	136	25	32	155	285	185	19.7	15.4	5.08	5.94	5.70	5.50	3.00	11.30
2	160	65	20	108	NA	NA	NA	NA	NA	NA	NA	NA	NA	NA
3	141	48	52	149	160	93	27.4	23.7	5.94	7.00	3.70	20.40	5.50	9.70
4	135	51	66	127	160	84	13.2	11.4	8.40	10.00	14.90	5.70	23.30	10.90
5	180	0	0	180	245	245	33.2	32.9	17.07	16.23	2.00	2.80	12.20	8.30

Conclusion: The results indicate the feasibility of VMAT treatments under tumor tracking for selected patients. The arcs available for planning influence the quality of treatment. The L partial arc plans had clinically acceptable quality in four patients. Treatments with reduced margins could be safely delivered by gating the treatment beam if the tumor motion exceeds the margins. Also, a great advantage is that the dose delivered to the tumor could be exactly monitored.

Real-time MRI-guided Radiotherapy for pancreatic cancer
 S.A. Rosenberg¹, A. Wojcieszynski¹, C. Hullett¹, M. Geurts¹, S.J. Lubner², N.K. LoConte², D.A. Deming², D.L. Mulkerin², C.S. Cho³, S.M. Weber³, E. Winslow³, K.A. Bradley¹, J. Bayouth¹, P.M. Harari¹, M.F. Bassetti¹

¹University of Wisconsin, Department of Human Oncology, Madison, USA

²University of Wisconsin, Division of Hematology and Oncology-Department of Medicine, Madison, USA

³University of Wisconsin, Division of Surgical Oncology-Department of Surgery, Madison, USA

Purpose or Objective: Pancreatic cancer with vascular involvement has a poor prognosis regardless of treatment. The toxicity of chemoradiation to adjacent normal organs can contribute to treatment discontinuation and adverse outcomes in some patients. We hypothesized that real-time MRI guided radiotherapy for borderline or locally advanced pancreatic carcinoma would enable safer treatment delivery with tight margins and diminished normal tissue toxicity than conventional treatment approaches.

Material and Methods: Patients with borderline or locally advanced pancreatic cancer were eligible for evaluation for MRI-guided radiotherapy. Patients underwent complete staging, including baseline CA19-9 and triple phase CT imaging. Patients underwent simulation with an inhale breath hold 3D and cine scans on a MRI Guided Treatment Planning

system. Locoregional lymph node coverage was incorporated at the discretion of the Radiation Oncologist. The mean CTV to PTV expansion was 3 mm (range 2-5 mm). The primary GTV was tracked in real-time throughout treatment and the PTV or similar structure was used as a boundary for triggering treatment. A patient initiated repeated breath hold strategy was used to increase the reproducibility and duty cycle of radiotherapy.

Results: We have completed treatment for our first 5 patients with borderline or locally advanced pancreatic adenocarcinoma. The population was 4:1 Male:Female with a mean age of 61.8 years (range 52-67). All patients had an elevated CA19-9 at presentation, with a mean of 714 U/mL (range 62 - 2350 U/mL). Locoregional lymphatics were treated in 4/5 patients. The mean PTV was 222.7 cc (range 40.3-346.4 cc). The PTV was treated to 50.4 Gy at 1.8 Gy per a fraction with concurrent chemotherapy for all patients. With a median follow-up of 166 days (range 50 - 278 days), an average 66% reduction in CA19-9 1-2 months following chemoradiation was observed. The OS is 60% at time of follow up. One grade 4 toxicity was observed with duodenal ulceration during radiotherapy requiring hospitalization. The number of patients, overall survival, local control, progression free survival, and changes in CA19-9 levels will be updated at the time of presentation.

Conclusion: Real-time MRI-guided radiotherapy enables the design and delivery of highly conformal treatment for patients with borderline or locally advanced pancreatic carcinoma. A significant reduction in CA19-9 levels after treatment was observed. Real time MR imaging throughout treatment enables high precision tracking to minimize treatment margins and normal tissue dose exposure. MRI-guided radiotherapy may provide opportunities for normal organ toxicity reduction and future dose escalation strategies.

OC-0212

Liver motion tracking using optical flow cine-MRI registration

M. Seregni¹, C. Paganelli¹, P. Summers², M. Bellomi², G. Baroni¹, M. Riboldi¹

¹Politecnico di Milano, Dipartimento di Elettronica-Informazione e Bioingegneria, Milano, Italy

²Istituto Europeo di Oncologia, Department of Radiology, Milano, Italy

Purpose or Objective: The development of radiotherapy treatment units with integrated MRI scanners is stimulating interest in fully MRI-guided treatment protocols. Cine-MRI sequences capable of acquiring 5-6 2D images per second are already available, thus providing a potential means of non-invasive, online motion monitoring with high soft-tissue contrast. This work investigates the feasibility of liver motion tracking using optical flow registration of Cine-MR images series.

Material and Methods: Liver cine-MRI series (balanced steady-state free precession, 256x256 pixel, 1.28x1.28mm spacing, f = 3.3Hz) providing 220 images over a 70s scan were acquired in 25 patients and 5 healthy volunteers after informed consent. Ground-truth liver motion consisted in the trajectories of numerous sparse features (P_{SIFT}) extracted using a previously tested algorithm based on the Scale Invariant Feature Transform (SIFT) [1]. For each subject, optical flow (OF) registration, as proposed in [2], was applied between the first image of the series and each subsequent frame, thus obtaining time-resolved dense motion fields [Fig. 1]. Trajectories based on OF (P_{OF}) were then derived by applying these motion fields to the positions of the SIFT features detected in the first image. To assess the accuracy of the motion fields, the 2D frame-by-frame distances ($D_{SIFT-OF}$) between P_{SIFT} and P_{OF} were calculated for every trajectory and, for each subject, their distributions were described with median, inter-quartile range, 5th and 95th percentiles. Linear correlation coefficients ($r_{SIFT-OF}$) between

P_{SIFT} and P_{OF} were also calculated. Finally, the computation time required for OF registration was measured.

Figure 1. Panel A: overlay between reference (cine-MRI first frame) and full inhale image before optical flow registration. Panels B and C: overlay and absolute difference between reference and full inhale after registration, respectively. Panels D and E: motion field magnitude and direction at full inhale and full exhale, colour-coded as in Panel F.

Results: A total of 1345 trajectories were extracted (from 5 up to 99 per subject). Table I reports the motion fields accuracy results. The median value of $D_{SIFT-OF}$ was within the pixel size (1.28 mm) in 27 out of 30 subjects. The median $r_{SIFT-OF}$ was 0.92 ± 0.08 (mean \pm SD among all subjects) with just 18/1345 trajectories reporting not statistically significant correlations (t-test p -value $\geq 1\%$) to SIFT. The computation time for a single registration was 49.2 ± 2.4 ms (mean \pm SD, 3.20GHz processor, 64GB RAM).

Table I. Minimum, Mean \pm Standard Deviation and Maximum values among 30 subjects of the $D_{SIFT-OF}$ distributions parameters

$D_{SIFT-OF}$ [mm]	Minimum	Mean \pm SD	Maximum
5 th Percentile	0.21	0.26 ± 0.03	0.33
Median	0.85	1.04 ± 0.16	1.45
IQR	0.72	1.09 ± 0.29	1.89
95 th Percentile	2.20	4.10 ± 1.17	8.34

Conclusion: Liver motion trajectories obtained through OF registration were comparable to those measured using robust feature matching. Moreover, the OF method calculates a dense motion field that can be used to simultaneously track multiple internal structures (e.g. tumour and OAR contours) during irradiation. Finally, OF registration appears well suited to online motion monitoring, as it is fully automated and its low computational cost allows tracking within current cine-MRI acquisition periods.

Towards on-line sub-mm and sub-second positional verification during stereotactic spine radiotherapy
C. Hazelaar¹, M. Dahele¹, B. Slotman¹, W. Verbakel¹
¹VU University Medical Center, Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Spine SBRT requires high positioning accuracy to avoid target miss and excessive OAR dose. However, conventional linacs do not allow high resolution spine position monitoring during irradiation. We analyzed kilo-voltage (kV) images routinely acquired by the gantry-mounted imager during spine SBRT using markerless template matching + triangulation. The aims were to determine whether this method would be suitable for sub-mm, sub-

second on-line verification of spine position, and to determine spine stability.

Material and Methods: kV images, continuously acquired at 7 or 11 frames/s during FFF VMAT spine SBRT of 18 patients, comprising 89 fluoroscopy datasets (1 dataset/arc), were analyzed off-line. Four patients were immobilized in a head/neck mask, 14 had no rigid immobilization. 2D reference templates of the planning CT (1 template/ $^{\circ}$) were created in the form of filtered DRRs. The 360 templates consisted of the contoured vertebra + 2 mm. kV projection images were pre-filtered with a band-pass filter. Normalized cross correlation was used to find the 2D template position resulting in the best match between template and kV image. Multiple registrations were triangulated to determine 3D position. Average position and SD were calculated for each resulting motion trajectory. These SDs include spine stability and precision of the template matching + triangulation. To verify the accuracy and precision, mean and SD of two stationary phantom datasets with different baseline shifts were measured.

Results: Template matching + triangulation was performed within 0.1s/image. For the phantom, SDs were 0.21-0.23 mm for left-right (LR), 0.20-0.18 mm for superior-inferior (SI) and 0.24-0.23 mm for the anterior-posterior (AP) direction. The maximum difference in average detected and applied shift was 0.15 (LR), 0.37 (SI) and 0.03 (AP) mm. The table summarizes the SDs and percentages of tracked images for the clinical datasets. The template matching software performed less well for datasets in which the kV projection images contained overlying structures (e.g. clavicle, ribs, heart, diaphragm). Maximum spine position offsets were: -1.43-2.20 (LR), -3.48-0.68 (SI) and -1.14-1.52 (AP) mm. Average positional deviation was ≤ 1 mm in all directions in 90% of the arcs. 91% of all tracked points (total combined x, y and z points=81327) deviated by <1 mm from the planned position, 97.4% by <1.5 mm, and 98.8% by <2 mm.

SD (mm)		LR	SI	AP	% Tracked
Cervical (n=16)	Average	0.30	0.21	0.38	75.8
	SD	0.07	0.04	0.10	16.1
	Min	0.21	0.14	0.24	53.8
	Max	0.42	0.28	0.63	95.6
Thoracic (n=36)	Average	0.59	0.29	0.61	50.4
	SD	0.25	0.09	0.25	18.3
	Min	0.20	0.17	0.20	31.8
	Max	1.28	0.59	1.22	93.8
Lumbar (n=37)	Average	0.28	0.24	0.33	78.9
	SD	0.07	0.05	0.12	13.1
	Min	0.16	0.15	0.19	36.8
	Max	0.43	0.37	0.77	95.3

Conclusion: Template matching + triangulation using kV images acquired during irradiation allows markerless spine position detection with sub-mm accuracy at sub-second intervals, without the need for supplementary hardware. This method is fast enough to be applied to near real-time on-line positional verification. Further technical improvements, such as increase of tracking rate, are anticipated. Although most patients were not immobilized they were stable at the sub-mm level for the majority of tracking observations.

OC-0214

Hybrid MLC and couch tracking

J. Toftegaard¹, R. Hansen¹, K. Macek², P.R. Poulsen¹¹Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark²Varian Medical Systems, Imaging Laboratory, Baden, Switzerland

Purpose or Objective: MLC and couch tracking are promising techniques for intrafractional tumor motion management. However, both techniques have their limitations that result in residual dosimetric errors: MLC tracking perpendicular to the MLC leaves is limited by the finite MLC leaf width, while couch tracking has slower dynamics than the MLC and might be uncomfortable for the patient. Here, we suggest a range of potential hybrid MLC-couch tracking strategies and test the performance of each strategy with extensive tracking simulations.

Material and Methods: Three hybrid MLC-couch tracking strategies were investigated and compared with pure MLC tracking and pure couch tracking. Dividing the target motion into motion parallel and perpendicular to the MLC leaves in beam's eye view, the investigated tracking strategies were as follows (in order of increasing MLC tracking fraction). 1) Pure couch tracking; 2) Couch for all perpendicular target motion and MLC for parallel motion; 3) Couch for perpendicular motion below one leaf width and MLC for the remaining motion; 4) Same as 3) except that the couch only adapts to stable perpendicular shifts with standard deviation below 0.5mm during the last second; 5) Pure MLC tracking.

The current developer release of TrueBeam tracking system does not allow for hybrid MLC-couch tracking, but our in-house built tracking simulator allowed investigation of the hybrid strategies. The simulator was experimentally validated to mimic the TrueBeam MLC and couch tracking system. Tracking treatments with each tracking strategy were simulated for 160 lung tumor and 695 prostate trajectories. A high and a low modulated VMAT treatment (1 arc) with MLC motion in the superior-inferior direction were simulated for each trajectory.

The tracking performance of each simulated treatment was quantified as the mean MLC exposure error in beam's eye view. The MLC exposure error is the sum of under-exposed areas Au (MLC shielded areas that should ideally be exposed) and over-exposed areas Ao (MLC exposed areas that should ideally be shielded). Au+Ao has previously been shown to be a good surrogate for dosimetric errors in tracking treatments.

Results: The figure shows the cumulative distribution of mean MLC exposure errors for all trajectories and for trajectories with large motion (>3mm for prostate, >5mm for lung). The table shows the median reduction in the exposure error relative to pure MLC tracking as well as the mean 3D couch speed for all tracking strategies.

Figure 1: Cumulative plot for Mean over- and under-exposed areas for each site. Upper figure are all traces and lower are only traces with motion more than 5mm (Lung) and 3mm (Prostate). Numbers in legend refer to numbers in methods.

		Prostate		Lung	
		all	>3mm	all	>5mm
Exposure error	(1) Couch	42.31%	80.92%	42.31%	37.69%
	(2)	48.78%	81.67%	48.78%	45.90%
	(3)	42.78%	73.98%	42.78%	36.35%
	(4)	33.94%	68.57%	33.94%	29.05%
	(5) MLC	0.00%	0.00%	0.00%	0.00%
Motion	(1) Couch	0.827 mm	0.882 mm	2.52 mm	3 mm
	(2)	0.741 mm	0.86 mm	1.84 mm	2.34 mm
	(3)	0.766 mm	1.03 mm	1.84 mm	2.35 mm
	(4)	0.67 mm	0.809 mm	1.07 mm	1.17 mm
	(5) MLC	0 mm	0 mm	0 mm	0 mm

Table 1: Upper part: Median reduction in percent of mean exposure error relative to pure MLC tracking. Lower part: Average couch speed.

Conclusion: Hybrid MLC-couch tracking offers a continuum of trade-offs between tracking accuracy and couch motion. A modest degree of couch tracking (strategy 4) largely improved MLC tracking, especially for prostate motion exceeding 3mm. Couch tracking perpendicular to the MLC leaves and MLC tracking parallel to the leaves (strategy 2) gave the most accurate tracking and a large couch motion reduction compared to pure couch tracking.

OC-0215

Mapping of breathing and cardiac induced motion of lymph node targets in lung cancer patients

M.L. Schmidt¹, L. Hoffmann², M. Knap¹, T.R. Rasmussen³, B.H. Folkersen³, J. Toftegaard¹, D.S. Møller², P.R. Poulsen¹¹Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark²Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark³Aarhus University Hospital, Department of Pulmonology, Aarhus C, Denmark

Purpose or Objective: Malignant mediastinal lymph nodes (LNs) are often included in the planning target volume for lung cancer patients (pts), but LN motion is not well investigated and this may potentially undermine the locoregional control. LNs in the mediastinum are difficult to visualize in cone-beam CT (CBCT) scans. In this study, the position of implanted fiducial markers obtained from daily CBCT projections was used to map the 3D intrafraction and interfraction motion of LN targets throughout the treatment course for ten lung cancer pts.

Material and Methods: Ten lung cancer pts with Visicoil fiducial markers implanted in LN targets by EBUS bronchoscope received intensity modulated radiotherapy (RT) treatment in 30-33 fractions. A total of 26 LN targets with Visicoils were analyzed. A pre-treatment setup CBCT scan with ~675 projections was used for daily online soft tissue match on the primary tumor (GTV-T). The Visicoil positions were segmented offline in each projection using a semi-automatic template-based algorithm. From the segmented Visicoil positions the 3D Visicoil trajectories were estimated with 11Hz sample rate by a probability-based estimation method. By frequency analysis, the 3D trajectories were separated into a cardiac and a breathing component. The motion ranges of the Visicoils were extracted in the left-right (LR), cranial-caudal (CC) and anterior-posterior (AP) direction for the total motion, as well as the separated cardiac and breathing induced motions. Also, the daily mean setup error of the Visicoils after the GTV-T soft-tissue match was extracted and used to calculate motion margins required for interfraction baseline shifts of the LN targets (using the formula $2.5\sigma + 0.7\sigma^*$).

Results: The 2-98 percentile motion ranges, for the patient group were in mean (with standard deviation) 2.1mm (0.5mm)(LR), 7.3mm (2.6mm)(CC), 3.3 mm (1.3mm)(AP). The cardiac induced mean motion ranges were 1.3mm (0.7mm)(LR), 1.3mm (0.6mm)(CC), 2.3mm (1.5mm)(AP). The figure shows the averaged waveform in the coronal plane of the cardiac and breathing motion components of each Visicoil at the first RT fraction. The waveforms were obtained by averaging over a number of breathing/cardiac cycles.

Breathing motion was largest in the CC direction and more prominent for more caudal LNs. Cardiac induced motion was often (77%) largest in the AP direction (not shown) and tended to be largest for more cranial LNs, occasionally (44 %) being the dominant motion component. The daily baseline shifts from all fractions resulted in interfraction motion margins of 4.9mm(LR), 4.7mm(CC), and 6.4mm(AP).

Figure 1: Bronchie-map showing the breathing (blue) and cardiac (red) component of the Visicoil lymph node motion during the first setup CBCT scan. The LN stations, trachea, aorta and heart are marked for clarity. The trajectories are displayed at the approximate Visicoil position in the planning 4DCT scan

Conclusion: The motion of Visicoils in projection images of daily CBCTs was used to map and analyze intrafraction and interfraction motion of mediastinal LNs. While the motion was governed by breathing induced motion, the most cranial LNs had substantial cardiac induced motion.

SP-0216

Contouring of normal tissues in head and neck radiotherapy

S. Hol¹

¹Dr. Bernard Verbeeten Instituut, Tilburg, The Netherlands

In the head and neck region, there are a lot of organs at risk (OAR) to take into account when making a treatment plan. The radiation fields are often very large and can go up to the brain and down to the lungs. The OAR in this region are responsible for a lot of body functions, like walking, talking, swallowing and taste. Some of the OAR are parallel organs, so they will be able to compensate the loss of part of the organ and others are serial organs, which implies that the dose to the entire organ has to be below a threshold value in order to maintain the functionality.

In recent years most hospitals have started delineating more OAR in the head and neck region, but for some, there is no consensus on the constraints that have to be applied. Recently, consensus guidelines for head and neck OAR delineation were defined by Brouwer et al (1) To make sure that in the future we will be able to define constraints for these OAR we need a lot of data. This can only be obtained if there is consensus among institutes on delineation and reporting in the same manner.

In this presentation the different OAR will be discussed and a short summary of recently published guidelines will be provided.

(1) CT-based delineation of organs at risk in the head and neck region: DAHANCA, EORTC, GORTEC, HKNPCSG, NCIC CTG, NCRI, NRG Oncology and TROG consensus guidelines. Brouwer, C. et al. Radiother. Oncol. 2015; 117: 83-90.

SP-0217

The ESTRO perspective - a guideline for positioning of head and neck patients

M. Mast¹, M. Leech², M. Coffey², F. Moura³, A. Ostavics⁴, D. Pasini⁵, A. Vaandering⁶

¹Haaglanden Medical Centre Location Westeinde Hospi, Den Haag, The Netherlands

²Trinity College Dublin, University of Dublin, Dublin, Ireland Republic of

³Hospital Cuf Descobertas, Radiotherapy, Lisbon, Portugal

⁴General Hospital Vienna AKH Wien, Radiotherapy, Vienna, Austria

⁵Policlinico Universitario Agostino Gemelli, Radiotherapy, Rome, Italy

⁶UCL Cliniques Univ. St.Luc, Radiotherapy, Brussels, Belgium

Purpose: These guidelines have been developed to assist Radiation Therapists (RTTs) in positioning, immobilisation, position verification and treatment for head and neck cancer (HNC) patients presenting for radiation therapy.

Methods and materials: A critical review of the literature was undertaken by the authors, searching relevant databases including PubMed, Embase and Google Scholar. Search terms used included combinations of and Boolean operations of 'head and neck cancer', 'radiation therapy', 'radiotherapy', 'positioning', 'immobilisation', 'verification', 'cone beam CT', and 'electronic portal imaging'. Studies in English, French, Portuguese, Italian and German were included. Based on the literature review, a survey was developed to ascertain the current positioning, immobilisation and position verification methods for head and neck radiation therapy across Europe. The survey consisted of 40 questions, divided into 5 sections. The sections contained both open and closed questions on: Demographics, Patient Positioning, Immobilisation devices, CT/Simulation Practice, Position Verification as well as elements of quality assurance (QA) in relation to positioning and immobilisation. Data analysis was performed using SPSS Statistics version 20.0 (IBM SPSS Statistics for Windows. Armonk, NY: IBM Corp.). Descriptive statistics were calculated and appropriate figures and tables constructed. Cross tabulations were performed where appropriate to maximise data analysis.

Results: Results from the European-wide survey indicated that a wide variety of treatment practices and treatment verification protocols are in operation for head and neck cancer patients across Europe currently. These ranged from 3DCRT to VMAT and from daily online CBCT imaging to offline correction protocols using kV EPIs or in some cases, MV portal imaging. In terms of immobilisation, the majority of respondents use thermoplastic masks in their immobilisation of head and neck patients, with some variance in how shoulder position is maintained. The full results from this survey are available in the complete guideline document, available on the ESTRO website. Guidelines were given for: Positioning prior to thermoplastic mask construction Construction of thermoplastic mask The CT procedure Treatment Verification and delivery Match Structures for Image Verification.

Conclusion: The preparation of this guideline document has demonstrated that although there have been substantial changes in the set up, positioning, immobilisation and verification of head and neck cancer patients over the last number of years across Europe, significant variations still exist. These variations can be attributed to differences in resource type and quality, institutional protocols as well as considerable differences in education level of radiation therapy professionals across Europe. RTTs must be aware of the potential dosimetric impact of poor positioning and immobilisation and/or position verification procedures as well as their influence on required margins for HNC radiation therapy. These guidelines have been developed to provide RTTs with guidance on positioning, immobilisation and position verification of HNC patients. The guidelines will also provide RTTs with the means to critically reflect on their own daily clinical practice with this patient group.

SP-0218

Late effects in patients treated for head and neck cancer
K. Henneberg¹, K. Jensen¹, H. Primdal¹, P.R. Olsen¹, M.W.H. Nielsen¹

¹Aarhus University Hospital, Department of Radiation Oncology, Aarhus C, Denmark

Introduction and purpose: Patients with head and neck cancer are treated with surgery, radiotherapy and chemotherapy either alone or in combination. The treatment has serious consequences for the patients, because of frequent and severe late side effects that often affects the patient's everyday life. The aim of the study was to investigate the unmet needs of the head and neck cancer survivors and to manage the late effect of the treatment. We wanted to investigate which health care efforts the patient needed in order to improve their quality of life.

Method/material: This mixed methods study included 204 patients, that were seen once during the first two years after the end of treatment. Patients were recruited from our follow up clinic and invited by letter. Patients completed three different questionnaires: EORTC QLQ C30, -H&N35 and HADS. The patients were thereafter interviewed, using focused questions dealing with 14 predefined topics and, analyzed by content analysis.

Result: In general the patients were doing well, but with large individual differences. Common side effects were dysphagia (60%) and, dry mouth (75%). The derived consequences of these side effects were - amongst others - difficulties with social interaction, speech, eating with others, fatigue, sexual problems, sleeplessness and memory problems. The frequency of side effects declined with time but some of the patients struggled years after treatment. The patients use at least three coping strategies; "avoid", "accept" and "action". In our study the patients were largely incapable of finding help to handle the late effects of the treatment. The questionnaires were not a sufficient screening tool for unmet individual needs that were commonly only identified during the interview.

Conclusion: The late effects, after treatment for head and neck cancer, have multidimensional consequences for the experienced health related quality of life. The patients need support and counseling to cope with the late effects and a specialized rehabilitation service with a multidisciplinary approach should be offered. It is important to screen and talk with head and neck patients systematically because there are large individual differences in how they deal with the long term consequences of treatment.

Symposium: The future of Radiation Oncology publishing: views through the Red and Green telescopes

Green Journal

J. Overgaard¹

¹Aarhus University Hospital, Radiation Oncology, Aarhus C, Denmark

Abstract not received

SP-0220

Publishing the science of radiation oncology: the perspective of the Red Journal's editor

A. Zietman¹

¹Massachusetts Gen. Hosp. RT, Department of Radiation Oncology, Boston MA, USA

Most published medical science ultimately proves to have little value as the results are founded on weak methodology and prove unrepeatable. In addition a "publish or perish" approach to academic medicine has placed pressures on investigators that weaken the ethical fabric of journal publication. This reality has become increasingly apparent in recent years, and many now feel that the traditional

concepts of peer-review and static print journals are a thing of the past. This talk will address issues around the quixotic peer-review process and efforts made by the Red Journal to get around them including: double-blind review, prospective review, and editorial review of the reviewers. Three additional concepts, made possible in an electronic age, promise to upend the old order changing the way science is placed into the public arena and critiqued. These include: unselective open access publication based on methodology alone, "as-you-go" publication of original data and results in open source databases, and "crowd sourced" review. These concepts are starting to gain considerable traction in the basic science world but have yet to change the way clinical science is presented. The Red and Green Journals will have to react to this changing environment and it is likely that within 10 years the current format will have changed beyond recognition.

SP-0221

How to do a good manuscript review

L.P. Muren¹

¹Aarhus University Hospital, Department for Medical Physics, Aarhus C, Denmark

Peer review is an important basis for scientific activities and progression. Peer review is the cornerstone for evaluation of scientific work, including applications for research grants and positions as well as scientific reports and publications in scientific journals. This presentation will focus on the role of peer review of manuscripts submitted for consideration for publication in journals. Initially, the presentation will address the importance of peer review as the main method for scientific evaluation; alternatives to the conventional peer review process will also be mentioned. Subsequently the presentation will go through the major steps in reviewing a manuscript. This also includes the issues to consider when receiving the invitation from the journal. Key questions to address when evaluating the various parts of the manuscript (Introduction, Materials & methods, Results and Discussion) will be covered.

PV-0222

Enhancing safety and quality of the radiotherapy process using a multidisciplinary end-to-end review

M. Albers¹, J. Stam¹, T. Janssen¹, A. Van Mourik¹, A. Van Giersbergen¹, C. Van Vliet-Vroegindeweij¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: In radiotherapy (RT) extensive quality assurance (QA) protocols exist to guarantee the safety and quality of treatments. Generally, the QA consist of performance, consistency and/or stability checks of individual items such as CT acquisition, treatment planning or treatment device. Besides QA of individual items, the coherence of all items constituting the entire chain is crucial for the overall treatment quality. Therefore, in 2013, we started with the "Analysis of Process Quality" (APQ); an analysis of the RT process from CT to RT. The purpose of this retrospective analysis of the APQ results is to investigate whether the APQ improves and optimizes the RT process.

Material and Methods: The APQ is performed monthly for four randomly chosen patients for a specific tumor site. For each patient, a physicist and a radiation technologist (RTT)

review every step in the RT process. They check whether the used protocol is applicable, if the choices made in the RT process are logical and whether the workflow was correct. Afterwards, the reviews are discussed plenary by the four physicist-RTT couples and a radiation oncologist (RTO) specialized in the tumor site. In this meeting, actions to optimize the RT process are defined. For the retrospective analysis, the items on the action lists are categorized either as: protocol checks (incomplete/incorrect protocol), procedure checks (difference in interpretation of protocols) and abnormalities in human actions (misunderstanding/human error) or techniques (technical shortcoming).

Results: In three years the APQ resulted in a total of 76 actions. The results are displayed in Table 1. Examples of some typical actions include: adjusting the dose volume histogram reports in showing more relevant information, unifying the workflow around peer review of delineations, securing consistency of patient setup information.

Table 1. Percentage categories per process step

Percentage (%)	Imaging preparation	Treatment planning	Radiation treatment
Protocol	7%	14%	5%
Procedure	8%	13%	7%
Abnormality (human)	5%	8%	3%
Abnormality (technique)	5%	7%	18%

Only small abnormalities were found, which didn't influence the radiation treatment or caused any injury. In addition, the APQ turns out to be a good tool to enhance collaboration between multidisciplinary professionals like physics, RTT's and physicians.

Conclusion: From our results, it follows that the APQ detects several types of (small) abnormalities in the total RT process. It is known that large errors typically result from a combination of small abnormalities through the process chain. Therefore we believe that by finding and correcting these small abnormalities, the APQ inherently improves the quality and safety of our treatment. In discussing the quality of our treatment in this multidisciplinary setting, we increase commitment and mutual understanding. In short, the APQ is a unique and effective process audit to enhance the quality and safety of the entire RT process.

PV-0223

Accuracy of 2D angiogram to 3D MRI registration for frameless stereotactic targeting of brain AVM

I.T. Kuijper¹, O. Hertgers¹, J.P. Cuijpers¹, F.J. Lagerwaard¹
¹VU University Medical Center, Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Stereotactic Radiosurgery (SRS) is an established treatment option for arteriovenous malformations in the brain (bAVM). Two dimensional (2D) digital subtraction angiography (DSA) is used for accurate delineation of the AVM because of its high temporal resolution. In current practice, an invasive head frame and localizer box are used to indirectly register 2D DSA with 3D magnetic resonance angiography (MRA) datasets. The new registration method, which is commercially available, segments a vessel tree from the 3D MRA, and matches this unique vessel projection with the vessel projection in the 2D DSA images. This study aimed to measure the accuracy and feasibility of this new registration method and compare it to the traditional image localization technique.

Material and Methods: 69 image-registrations from 52 bAVM patients were analyzed. Patients with more than one AVM feeder artery had two registrations. In the traditional technique the 3D CT and 2D DSA datasets were indirectly registered using the localizer box. The CT was fused to the 3D MRA establishing a registration between DSA- and MRA-datasets. In the new technique the vessel tree segmentation from the 3D MRA was directly fused to the vessel tree from

the frontal and lateral 2D DSA images of each patient (figure 1). Two observers independently performed registrations and the accuracy was compared to the traditional one. The mean rotational and translational differences and outliers were calculated for the frontal and lateral DSA images. In addition, feasibility was analyzed for different factors e.g. vertebral or carotid artery registrations, prior embolization/hemorrhage and MRA/DSA image quality.

Results: The mean difference of the new compared to the traditional registration technique was 1.1 mm and 1.3 ° for translations and rotations, and 2/69 (3%) exceeded 3 mm. The 3D vector had a mean (SD) of 1.5 ± 0.71 mm (range 0.1-4.7 mm). The mean (± 1 SD) results for 69 registrations of each DSA image are shown in figure 1. No difference >0.5 mm was seen between registrations with the DSA of either the carotid- or vertebral artery. Furthermore, no significant differences were found in patients with prior hemorrhage and/or embolization (p>0.05). The mean inter-observer disagreement between the two observers was 0.3 mm with maximum differences of 2.6 mm. Good image quality, the correct orientation of the DSA image sets together with whole brain MRA scans for optimal vessel segmentation are important criteria for accurate registration using the new method.

Conclusion: The new software based DSA-MRA registration using vessel tree segmentation is a feasible and accurate approach and agrees to within a mean of 1.1 mm and 1.3 ° with the traditional method using a frame and localization box. The new registration method allows the application of frameless (fractionated) radio surgery and could facilitate the import of external diagnostic DSA images for treatment planning.

PV-0224

To be greeted as a human being - A meta-synthesis of cancer patients' experiences of radiotherapy

S. Petri¹
¹Copenhagen University Hospital - Rigshospitalet, Department of Oncology- Section for Radiotherapy, Copenhagen, Denmark

Purpose or Objective: Around 35,000 Danish people are diagnosed with cancer each year, and approximately 16,000 people receive one or several radiotherapy fractions. In Denmark radiotherapy is delivered by special educated oncology nurses and radiographers, in the following referred to as radiation therapists (RTTs). Results from existing research suggest that the RTTs play an important role in relation to how the radiotherapy treatment is experienced by the patients. In addition, patients feel tied down and as slaves of the time due to the daily treatments. Furthermore the high-tech context in a radiotherapy department may seem intimidating to the patients and consequently create insecurity and uncertainty in an already vulnerable situation. However, in order to establish a culture of patient-centered care and communication in clinical practice more knowledge on how patients experience radiotherapy treatment is warranted. The purpose of the study was therefore to explore how adult cancer patients experience radiotherapy based on existing qualitative research.

Material and Methods: Based on qualitative meta-synthesis as described by Sandelowski and Barroso four research articles were systematically identified and included in the study. Only studies conducted in the Scandinavian countries were included to ensure a similar cultural context and organization of the health care system. The meta-synthesis was conducted in a hermeneutic perspective, and consisted of five phases; *search phase, appraisal phase, classification phase, analysis phase and synthesis phase*. The synthesis phase was complemented by the approach *imported concepts* to expand comprehension and integrate the findings.

Results: The results suggest that the experience of radiotherapy is described by the main theme: *The importance of being greeted as a human being* and six sub-themes; *The role and competence of the RTT; Continuity and relationships; Isolation; High-tech environment; Active participation and Knowledge and guidance*. The main theme and sub-themes are illustrated in Figure 1.

Figure 1

The results are integrated with notions on care by Kari Martinsen with reference to the Danish philosopher Loegstrup, suggesting that the RTTs must be very aware of their role in the encounter with the individual; including being responsible for building trust and protecting the continuity in the relationship. The results suggest that structural issues in the health care system, such as efficacy and task prioritization, can jeopardize the relationship and communication between the RTT and the patient.

Conclusion: The results of the study provide evidence to work more actively with ensuring continuity during the radiotherapy trajectory to provide a higher level of care and communication with the individual patient. In addition, the study introduces an increased awareness amongst RTTs regarding their specific role in the patients' experiences of a radiotherapy trajectory.

PV-0225

Investigating optimal modality for boost treatment of left breast with deep inspiration breath hold

A. Sen¹, A. Michalski¹, B. Done¹, A. Windsor^{1,2}

¹Central Coast Cancer Centre, Radiation Oncology, Gosford, Australia

²University of New South Wales, Faculty of Medicine, Randwick, Australia

Purpose or Objective: Deep inspiration breath hold (DIBH) for breast boost requires photons due to the limitations of the Varian RPM DIBH monitoring equipment, precluding the use of electrons. Traditionally, an electron boost was felt to be superior compared to photons due to their rapid dose fall off and resultant low dose to the heart and short treatment

time. If an electron boost was deemed superior, this would need to be delivered with the patient free breathing (FB) due to aforementioned limitations. The primary aim of this study is to compare photons at DIBH to electron boost at FB with regards to plan quality and organ at risk (OAR) constraints to the heart and lungs in left sided breast patients. The secondary aim was to assess if the dosimetric detriment of the inferior modality would detract from the benefits gained in Phase 1, whole breast DIBH treatment.

Material and Methods: Twenty consecutive patients undergoing radiotherapy to the left breast with DIBH were identified. All patients underwent dual CT scans at DIBH and FB as per the standard departmental protocol. A boost treatment was retrospectively planned with electrons on the FB scan and photons on a DIBH scan to a prescription on 10Gy in 5 fractions. PTV coverage, mean and maximum, doses to the heart and left anterior descending artery (LAD) and mean doses to the lungs were compared. The results were further analysed by the location of the boost volume as defined by breast quadrants.

Results: Doses to the planning target volume (PTV) and mean heart doses were comparable between photons and electrons. Maximum heart doses reduced by 60% while maximum and mean LAD doses reduced by 54% and 51.2% respectively using photons, while mean left lung dose reduced by 43%. These reductions were seen across all four breast quadrants.

When combined with the reductions in doses seen using DIBH for Phase 1, whole breast treatment, electrons would result in an overall treatment dose increase of 11% for the heart maximum, 7.3% and 14% for LAD mean and maximum respectively and 70% for lung mean.

Conclusion: Dosimetrically photons was a superior modality when compared to electrons in phase 2 Left breast treatment maintaining benefits to the heart and lung gained through DIBH without compromising PTV coverage. The results were applicable regardless of the location of the boost volume. The increase in mean lung, maximum heart and maximum and mean LAD doses would negatively impact on the dosimetric benefit seen during DIBH for Phase 1 of left breast treatment.

PV-0226

Pattern of relapse of glioblastoma treated with Stupp protocol: could a margin reduction be proposed?

S. Pedretti¹, M. Buglione², P. Borghetti¹, L. Costa¹, L. Triggiani², L. Pegurri¹, P. Ghirardelli², F. Foscarini², S. Pandini², L. Spiazzi³, G. Tesini³, C. Uccelli³, F. Saiani³, S. Magrini²

¹Spedali Civili di Brescia, Radiation Oncology, Brescia, Italy

²Brescia University, Radiation Oncology, Brescia, Italy

³Spedali Civili di Brescia, Medical Physics, Brescia, Italy

Purpose or Objective: To analyse the pattern of recurrence and acute and late toxicity of 105 patients treated with Stupp protocol in relation to both radiotherapy technique (3D, IMRT and helical IMRT) and treatment volumes; to compare in silico plans with reduced GTV-CTV margin (1 cm) with the original ones (2 cm). The CTV-PTV margin (5 mm) was maintained.

Material and Methods: Relapse was considered as in field, marginal and distant if more than 80%, 20-80% or <20% of the relapse volume was included respectively in the 95% isodose. In silico plans with reduced margin were retrospectively recalculated using exactly the same technique, the same fields angles and, if possible, the same TPS of the original plans. Statistical analysis was performed with SPSS® software.

Results: Eighty-five patients had local recurrence: 3 were excluded because underwent follow-up MRI in other hospitals; 14 because the original treatment plans were not recoverable. The analysis was therefore executed on 68 patients. They were in field, marginal and distant respectively in 88%, 10% and 2% of the cases. This pattern of

relapse was similar (pt student= ns) when the analysis was done on the in silico plans. The margins reduction appears to avoid the inclusion in the high dose volume of about 100 cc of healthy brain (p=0.02) (Table 1). The target coverage was significantly worse in original than in the in silico plans (pt student <0.001) (Table 1), especially if the tumour was close to organs at risk (px2 <0.001). PTV coverage of original plans was significantly better with IMRT and helical-IMRT when compared with 3D ones (pAnova test=0.038). This difference was no more statistically significant with in silico planning (pAnova test= n.s.). Higher incidence of asthenia and leuko-encephalopathy was observed in patients with greater percentage of healthy brain included in the 57 Gy isodose (pAnova test=0.038 and 0.034).

Table 1:
Comparison between really delivered plans (GTV-CTV margin=2cm) and in silico plans (GTV-CTV margin =1cm)

		GTV-CTV 2cm	GTV-CTV 1cm	p
Pattern of recurrence	In field	60 (88%)	55 (81%)	ns.
	Marginal	7 (10%)	10 (15%)	
	Distant	1 (2%)	3 (4%)	
Organ at risk	Brain - PTV percentage	Median (range)	Median (range)	0.023
		80% (50%-97%)	88% (69%-98%)	
	cc	1080 cc (580-1446cc)	1175 cc (850-1547 cc)	
	Brain - isodose 95% (57 Gy)	Median (range)	Median (range)	<0.001
percentage		75% (35%-95%)	83% (53%-98%)	
cc	1004 cc (407-1364 cc)	1105 cc (605-1487 cc)		

Conclusion: No differences in the pattern of recurrence according to the extent of margins have been found. The incidence of asthenia and leuko-encephalopathy varies with the percentage of healthy brain included in the high dose volume. The margin reduction allows significant sparing of healthy cerebral tissue and could possibly reduce the incidence of late toxicity. Margin reduction is compatible with appropriate target coverage, thereby limiting the need for more sophisticated and costly techniques to selected cases.

PV-0227

Radiotherapy in elderly patients with lung cancer. Performance status and fractionation analysis

J.L. Monroy Anton¹, V. Sanz Ballester², R. Gironés Sarrió³, C. Gaspar Martínez⁴, M. Soler Tortosa¹, A. Navarro Bergada¹, M. Estornell Gualde¹

¹Hospital Universitario De La Ribera, Radiation Oncology, Alzira, Spain

²Universidad Católica De Valencia, School Of Nursing, Alzira, Spain

³Hospital Lluys Alcanyis, Medical Oncology, Xativa, Spain

⁴Hospital Universitario De La Ribera, Medical Oncology, Alzira, Spain

Purpose or Objective: Elderly patients with lung cancer are often referred to treatment with radiotherapy. Tolerance to treatment and survival may be determined by their age and performance status. Different fractionation schedules in these patients can also influence the results.

Our objective was to analyze survival in patients ≥ 70 years, depending on age groups, Karnofsky Status (KPS) and fractionation schemes.

Material and Methods: We analyzed 70 patients, aged 70 years, with diagnostic of lung tumors (T1-4; N1-3), with no previous surgery treatments, referred for external radiotherapy.

Total Dose range: 20-64Gy; fractionation schedules: 1.8-2Gy (considered standard, std), >2 Gy (hypofractionation/stereotactic SBRT) Karnofsky Performance Status (KPS), was the tool to evaluate functional status the first day of treatment, and analysis was performed with two KPS groups: <70 vs ≥ 70

Results: Global survival: mean 9months (m); median 8 m.

12m survival: 22patients (31,4%)

18m survival: 8pts (11,4%)

>23 m survival: 4pts (5,7%)

AGE:

70-79y: mean 9m; median 8 m

≥ 80 y: mean: 9,2m; median: 8 m

KARNOFSKY PERFORMANCE STATUS (KPS)

Survival:

KPS <70 : mean: 9,2m; median: 8

KPS ≥ 70 : mean: 9m; median: 8

FRACTIONATION SCHEDULE:

standard fx: 29 pts mean:9.2m; median: 8

hypofractionation: 34pts mean: 8m; median: 7 m

only SBRT: 7pts mean: 9.7m; median: 8.5m

fractionation survival:

≥ 6 months: std: 20 pts (67%) hypofx: 19 (56%)

≥ 12 m: std: 11pts (38%) hypofx: 9pts (26.4%)

≥ 18 m: std: 5 pts (17.2%) hypofx: 2 pts (0,6%)

Conclusion: In elderly patients the most advanced age (> 80 years) does not determine differences in survival after radiotherapy treatment.

There are no differences in survival of elderly patients according to the KPS (<70 vs ≥ 70)

Survival is very similar regardless of the fractionation scheme used (mean 9.2 vs 8 months). However, 6, 12 and 18 months survival is greater in patients with standard fractionation We can conclude that in elderly patients, the variables age, KPS or fractionation scheme does not determine significant differences in survival.

Hypofractionation techniques or SBRT should be considered as an alternative in frail elderly patients to avoid prolonged treatment in time. The analysis of other parameters such as tumor stage or additional chemotherapy could also discriminate populations with different prognostic.

PV-0228

Size and impact of intra-fractional changes in baseline shift during lung SBRT

M. Kamphuis¹, M.A.J. De Jong², E.M. Dieleman², A. Bel², N. Van Wieringen²

¹Academic Medical Center, Academic Physics, Amsterdam, The Netherlands

²Academic Medical Center, Department of Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: A baseline shift can be defined as a shift of the target volume relative to its surrounding organs at risk (OAR). The baseline shift varies from day to day and can potentially lead to an overdosage of the OARs. In our clinic, the magnitude of the baseline shift is measured at the start of treatment in patients treated for solitary lung cancer. In case an OAR moves towards the target and the baseline shift exceeds the PRV margin, treatment is prevented. Limited data is available about the intra-fractional change of the baseline shift. The aim of this study is to determine if an intra-fractional change of the baseline shift necessitates multiple measurements to ensure safe delivery of SBRT.

Material and Methods: In this study a retrospective analysis was performed using the data of 87 patients, treated for lung cancer with SBRT in the period January 2010 to February 2014. Patients were treated according to one of three protocols: 3x18Gy (n=19), 5x11Gy (n=47), or 8x7.5Gy (n=21). Treatment delivery was performed using multiple (> 9) non-coplanar conformal beams or VMAT using 2 arcs. A planning risk volume (PRV) margin of 10mm was used standard around OARs (e.g. the heart and spinal cord). Smaller PRV margins, with a minimum of 3mm, were used in case prescriptions/constraints could not be met during planning. Conebeam-CT scans were performed at the beginning, halfway, and at the end of each treatment fraction. Grey-value registrations of Conebeam-CT scans with Planning-CT scan were performed for both the target and the patient specific most critical OAR. The difference between the registrations is the baseline shift. The number of times the vector length of the baseline shift exceeded the PRV margin

during treatment was scored. In these cases, it was investigated whether or not this would result in overdose for the OAR.

Furthermore, the change in baseline shift was calculated for the first and second half of each fraction as well as for the fraction as a whole. The average vector length and standard deviation of the change in baseline shift were determined per patient and for the population as a whole. Data were stratified according to the applied protocol.

Results: Figure 1 shows the results of change in baseline shift during treatment. Slightly larger changes in baseline shift were seen in the 3x18Gy and 5x11Gy protocol. In 11 out of 460 treatment fractions, the baseline shift exceeded the PRV margin at the end of the treatment fraction. In none of the patients this exceeding led to overdosage.

Figure 1: Intra-fractional changes in baseline shift

	Average vector (SD) Protocol 3x18Gy	Average vector (SD) Protocol 5x11Gy	Average vector (SD) Protocol 8x7.5Gy
Start - Halfway RT	0.19 cm (0.20)	0.18 cm (0.14)	0.13 cm (0.10)
Halfway RT - End	0.19 cm (0.16)	0.18 cm (0.14)	0.12 cm (0.08)
Start - End	0.27 cm (0.24)	0.24 cm (0.19)	0.18 cm (0.13)

Conclusion: Intra-fractional baseline shift can vary substantially during treatment, especially in patients treated with a 3x18Gy or 5x11Gy protocol. However, clinical impact of changes in baseline shift during treatment were not found in this study. A single assessment of the baseline shift at the start of treatment ensures a safe treatment delivery.

PV-0229

IGRT for pediatric patients: How much can we reduce the dose?

L. Johansen¹, T.H. Larsen¹, M. Aznar¹, B. Smulders¹

¹Rigshospitalet - Copenhagen University Hospital, Department of Oncology - Section of Radiotherapy, Copenhagen, Denmark

Purpose or Objective: In our institution, orthogonal kV X-rays is at present the preferred imaging method for children as imaging dose is a concern. In this study, we varied the CBCT acquisition parameters and investigated how much we can reduce dose, and still be able to perform a secure bone match in clinical practice.

Material and Methods: An Alderson phantom equivalent to an adult was CT scanned. Due to the absence of a real child size phantom only the head and neck was used. On our Varian Novalis Tx accelerator, we performed 12 full-fan 200° CBCT scans with different parameter settings. The number of projections, mA and ms were systematically decreased, while kV was constantly at 100. After each scan an automatic bone match was performed to investigate the ability to perform this kind of match, since this is our procedure in clinical practice. The image quality of the scans was visually inspected for noise and artefacts. Six of the scans were chosen for dose measurements relative to the standard preset for these types of scans. The relative dose measurements were performed using the RTI Barracuda system, consisting of a DCT10-pencil ion chamber positioned in the centre of the CTDI 16 cm diameter cylindrical phantom. The parameters from the scan comprising the largest dose reduction and with the ability to match were

used for a new CBCT preset. The phantom was CBCT scanned with the old and the new preset. Additionally the phantom was four times repositioned slightly different and re-scanned. Four RTT's independently matched these CBCT scans with the original CT scan offline in order to validate the new preset.

Results: A dose reduction of up to a factor of 14 could be achieved by changing the full-fan CBCT scan parameters from 20 mA and 20 ms (standard preset) to 10 mA and 2 ms. Reducing the number of projections from 650 to 360 added no further dose reduction. The new imaging preset results in a total dose of only 0.39 mGy compared to 0.14 mGy for 2 orthogonal X-ray imaging. Table 1 shows the average match difference between the different presets. The maximum deviations are +/-0,5 mm and 0.6°. Figure 1a+b show the difference in image quality between the standard and the new preset.

Table 1 Average match difference between scans obtained with standard preset and new.

Avg. Dev (cm)	Position 1	Position 2	Position 3	Position 4	Position 5
VRT	0.00	0.03	0.00	0.03	0.00
LNG	0.00	0.03	0.05	0.03	0.05
LAT	0.03	0.00	0.03	0.03	0.00
RTN(°)	0.03	0.18	0.03	0.63	0.03

Figure 1a Scan obtained with std preset. Figure 1b Scan obtained with new preset.

Conclusion: It is possible for RTT's to use low dose daily CBCT scans in paediatric radiation therapy and still perform a reliable automatic bone match.

Risk assessment of solid secondary malignancies in childhood Hodgkin Lymphoma after radiotherapy

G. Zanella^{1,2}, M. Mascarini¹, A. Drigo³, A. Pusiolo², E.C. Fuga⁴, F.M. Giugliano¹, A. Rosolen⁵, M.G. Trovò⁴

³Centro di Riferimento Oncologico, Fisica Sanitaria, Aviano PN, Italy

⁴Centro di Riferimento Oncologico, Radioterapia, Aviano PN, Italy

⁵Azienda Ospedaliero Universitaria, Clinica Pediatrica, Udine, Italy

Purpose or Objective: This work develops risk assessments of solid secondary malignancies (SMN) after radiotherapy (RT) in survivors of childhood and adolescent Hodgkin Lymphoma (HL) patients (pts) using the Schneider's dose-response model for solid cancers induction (Theoretical Biology and Medical Modelling 2011), comparing conventional technique (3D-CRT) with IMRT delivered with Helical Tomotherapy (HT).

Material and Methods: Our cohort includes 15 pts (6 girls, 9 boys) treated with RT for HL, in age 6-25 years (median 17)

at the RT, from 2008 to 2013. The 15 pts are representative of different RT target volumes (e.g. bilateral neck, ipsilateral neck, mediastinum, mantel-field, lombo-aortic and spleen, inverted Y, inguinal field, or a combination of them). We calculated the excess absolute of risk (EAR) and the cumulative risk of "all solid" and "single organ" SMN: mouth and pharynx, parotids glands, thyroid, lung, stomach, small intestine, colon, liver, cervix, bladder, brain and spinal cord, skin, female breast, bone and soft tissue. Every HT plan has been compared with 3D-CRT plan, both for EAR, cumulative risk and target coverage.

$$EAR^{org} = \frac{1}{V_T} \sum_i V(D_i) \beta_{EAR} RED(D_i) \mu(age_x, age_a)$$

Results: The risk of SMN solids is high, for both techniques, for breast, lung, thyroid, skin and colon. Some HT treatments may lead to increased risk of SMN solid than 3D-CRT plans, depending on the patient's age at exposure, on the specific organ volume or target volume and on the dose-response of each site. All the HT plans have the best conformation to the target and the greatest homogeneity of the dose to it delivered (best conformation number and homogeneity index).

bone	HT	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02
	3D-CRT	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02
	HT/3D-CRT	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00
soft tissue	HT	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02
	3D-CRT	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02	0.02
	HT/3D-CRT	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00

In this table: EAR (/10000 pts-year) at agea 60 in HT and 3D-CRT for all pts (1-15: pink=girl, cyan=boy); DT=target dose in cGy, age_x= age at pt's radiation treatment, n= number of RT fractions. Green=max value for each line. Red= statistically significant EAR ratio with EAR HT>EAR 3D-CRT; blue= statistically significant EAR ratio with EAR 3D-CRT> EAR HT

Conclusion: Even if HT increases the target coverage in all pts, it could increase the incidence of SMN compared with 3D-CRT for long-term survivors, depending on single specific target, target volume and pts age. However, EAR estimates are affected by large uncertainties and more works should be performed to better understand the risk of SMN with modern RT techniques after a childhood cancer.

Symposium: QA in clinical trials: processes, impact and future perspectives

SP-0231
How effective is current clinical trial QA?
E. Miles¹
¹Mount Vernon Hospital, Academic Physics, Northwood Middlesex, United Kingdom

A central independent quality assurance (QA) process is acknowledged as an essential component of current

radiotherapy clinical trials. QA processes are implemented both pre accrual and during accrual. The former ensures centres have the equipment, expertise and ability to comply with trial protocol requirements and that they are able to deliver treatment accurately and consistently. During accrual processes assure continued compliance and consistency of treatment delivery both within individual centres and across all recruiting centres throughout the trial. The key process areas in QA activity are:

- Target volume and organ at risk outlining
- Treatment planning and optimisation
- Treatment delivery and verification
- Dosimetry Audit

This talk will focus on the following main themes expanding on the processes involved and providing evidence and examples from individual trial QA programmes.

The implementation of clinical trial QA: Appropriate QA tasks to include questionnaires, process documents through review of example patient cases to dosimetry audit site visits, are assigned on an individual trial basis. The level of QA required will vary according to the complexity and novelty of the radiotherapy technique.

Defining standards: It is well recognised that target volume and OAR delineation and treatment planning and optimisation may be variable and open to individual interpretation. Through multi professional trial workshops, provision of delineation guidelines and setting of dose-volume constraints, consensus benchmark standards can be defined.

Assessment against a benchmark: Conformity metrics and pre-defined mandatory and optimal dose constraints can be used to review against consensus standards to highlight potential protocol variations. Historically this review has been retrospective; however increasing use of prospective evaluation with constructive feedback can allow correction of protocol variations before treatment is delivered.

Verification of treatment delivery: Dosimetry audit in the form of a postal or site visit serves to provide an independent assessment of dose delivered and directly compares individual centres. Recently, resulting from advances in image guidance, adaptive radiotherapy has been introduced in the clinical trial setting, introducing new challenges in assessment of plan selection competency and compliance.

As more advanced technology is introduced in the clinical trial setting, QA activities must continually evolve to provide a safe framework for implementation of technical radiotherapy. Increased participation in clinical trials demands a streamlined approach to QA to reduce workload, improve efficiency and facilitate opening centres for recruitment earlier. Participation in a comprehensive QA programme not only accredits the centre for recruitment but also benefits the general standard of RT delivered.

SP-0232 How does QA impact on clinical outcomes?
D.C. Weber¹
¹Paul Scherrer Institute PSI- Center for Proton Therapy- ETH Domain, Radiation Oncology, Villigen PSI, Switzerland

Radiotherapy (RT) planning and delivery for cancer management has substantially evolved over the last three decades with lately the introduction of intensity modulated RT, image-guided RT and stereotactic ablative RT to name a few techniques. The evaluation of these high precision delivery techniques in routine care and in clinical trials alike are error prone. They thus do require optimal RT quality (RTQA) assurance programs which aim at defining the range of acceptable variations and importantly developing mechanisms of action for correction and prevention of potential variations. RTQA outside a clinical trial is defined by all processes that ensure consistency of the dose prescription and the safe delivery of that prescription with regard to dose to the target and critical structures, minimization of the exposure of the RT personnel. In the framework of clinical trials assessing the efficacy of RT with or without a combined modality, RTQA is also necessary to avoid the corruption of the study-endpoint, as RT variations from study protocol decrease the therapeutic effectiveness and/or increase the likelihood of radiation-induced toxicities. Prospective trials have shown that RTQA variations have a

significant impact on the primary study end-point and could bias the analysis of the trial results[6]. A large prospective phase III (i.e. TROG 02.02) trial showed indisputably that poor radiotherapy resulted in suboptimal patient's outcomes. Moreover, the impact of poor quality radiotherapy delivery exceeded greatly the benefit of chemotherapy, thus biasing the primary end-point of this study. This large Australian trial provided a contemporary benchmark that future studies will need to exceed. Other specific consideration for RTQA in trials includes, but is not limited to, education of the accruing sites in RT-trial guidelines, promotion of consistency between centers and estimation of inter-patient and inter-institutional variations. Additionally, global cooperation is essential in the environment of common and rare cancers alike, in order to be able to create sufficiently large patient data sets within a reasonable recruitment period. This cooperation is not without issues and recently the need to have harmonized RTQA procedures has been strongly advocated by the Global Harmonisation Group. Ensuring RT compliance with protocol guidelines involves however gradually more resources-intensive procedures which are also labor intensive and are not cost-neutral. This will consequentially have a significant impact on the overall study budget. There are suggestion that QA programs are however cost-effective. This financial investment is of paramount importance, as non-adherence to protocol-specified RT requirements in prospective trials is very frequent. The European Organisation for the Research and Treatment of Cancer (EORTC) Radiation Oncology Group started to implement RTQA strategies in the 1980s, including on how to write a protocol for RT trials, defining RTQA procedures (such as benchmark case, dummy run and complex treatment dosimetry checks), assuring prospective individual case review feasibility and implementing an electronic data-exchange platform.

Keywords: Quality assurance, RTQA, prospective trial, patient's outcome, toxicity

SP-0233

What will we need for future RTQA in clinical trials?

C. Hurkmans¹

¹Catharina Ziekenhuis, Eindhoven, The Netherlands

A trial protocol with clearly established delineation guidelines and dose-volume parameters is key to all RTQA. Acceptable and unacceptable variations thereof should be defined before the trial starts as these are the standards to which all RTQA data collected will be compared. The experience so far has been addressed by the previous two speakers. Dr. Miles presented the RTQA procedures in clinical trials, differentiating between pre-accrual and during accrual tasks. Thereafter, Dr. Weber clearly showed that non adherence to protocol-specified RT requirements is associated with reduced survival, local control and potentially increased toxicity. Thus, it can be concluded that clinical trial groups have established RTQA procedures and conformance to these procedures strengthen the trial results. In this talk the remaining issues that need to be solved will be addressed. These issues can be separated in:

1. How can we further optimising the current RTQA
2. How should we include new imaging and treatment modalities in our RTQA program?

The first part of the talk will address several initiatives to further optimise current RTQA procedures. As we have learned from past RTQA experience, currently the individual case reviews (ICRs) are the most common source of variations from trial protocols. ICR variation is also the most important RTQA factor affecting trial outcome. Thus, a transition is needed from retrospective ICRs to timely, full prospective ICRs. Also, with the further advancement of tailored treatments for small subgroups of patients there is a growing need for intergroup trials to increase the accrual rates when conducting trials for such patient groups. These changes place new requirements on multiple parts in the RTQA procedure:

- Standardisation of RTQA across various trial groups. The Global Harmonisation Group initiative.

- Standardisation of protocol requirements with clear definitions of acceptable and unacceptable variations.
- Standardisation of OAR and target naming conventions.
- Automated upload of RTQA data from institutions to the RTQA review organisation, including anonymisation software, use of Dicom standards.
- Metrics and software tools to automatically evaluate image quality, delineations and treatment plans.

The second part of the talk will address the ideas of including new diagnostic, treatment and evaluation modalities and techniques in RTQA programs. Examples will be shown of RTQA trial procedures for breathing correlated 4D-CT, 4D PET-CT, MRI and CBCT currently in use or under development.

Enhancing stereotactic radiation schedules using the vascular disrupting agent OXi4503

M.R. Horsman¹, T.R. Wittenborn¹

¹Aarhus University Hospital, Department of Experimental Clinical Oncology, Aarhus C, Denmark

Purpose or Objective: The novel combretastatin analogue, OXi4503, is a vascular disrupting agent (VDA) that has recently been shown to significantly enhance a stereotactic radiation treatment. This was achieved using an OXi4503 dose of 10 mg/kg combined with a stereotactic treatment of 3 x 15 Gy. The current study was undertaken to determine the OXi4503 dose dependency when using different stereotactic radiation dose schedules.

Material and Methods: A C3H mammary carcinoma grown in the right rear foot of female CDF1 mice was used in all experiments. Treatments were performed in restrained non-anaesthetised animals when tumours had reached 200 cubic mm in size. Tumours were locally irradiated (230 kV x-rays) with 3 fractions of radiation varying from 5-20 Gy (each fraction given with an interval of 2-3 days over a one week period). OXi4503 was dissolved in saline prior to each experiment; once prepared it was kept cold and protected from light. Various doses (5-25 mg/kg) were intraperitoneally injected into mice 1-hour after each irradiation treatment. Three days after the final irradiation the tumours were subjected to a clamped top-up dose which involved giving graded radiation doses with the tumour bearing leg clamped for 5 minutes before and during irradiation. The percentage of mice in each treatment group showing local tumour control 90 days after irradiating was then recorded. Following logit analysis of the clamped top-up radiation dose response curves, the TCD50 values (radiation dose to control 50% of tumours) were estimated. A Chi-squared test ($p < 0.05$) was used to determine significant differences between the TCD50 values.

Results: The clamped top-up TCD50 values (with 95% confidence intervals) obtained following irradiation with 3 treatments of 10, 15 or 20 Gy were found to be 42 Gy (38-

47), 30 Gy (23-39), and 0.8 Gy (0.3-2.3), respectively. A plot of the TCD50 values against the stereotactic doses gave rise to a linear response (slope = -4.1; correlation coefficient = 0.97). OXi4503 significantly decreased the clamped radiation top-up TDC50 values and this affect appeared to be independent of both the ambient radiation dose applied with each of the 3 fractions and the VDA dose; the curve showing the TCD50 values against stereotactic radiation dose was similar to that for radiation alone (slope = -4.3; correlation coefficient = 0.94), but the radiation + OXi4503 curve was some 15 Gy lower than the radiation only curve.

Conclusion: OXi4503 is an effective agent for enhancing a stereotactic radiation treatment. But, the enhanced response appeared to be a simple additive effect independent of both the radiation dose applied with each fraction and the VDA dose used.

²University of Auckland, Auckland Cancer Society Research Centre, Auckland, New Zealand

³Victoria University of Wellington, School of Biological Sciences, Wellington, New Zealand

Purpose or Objective: Hypoxia is a common feature of solid tumors. Conventional treatments such as chemo- and radiotherapy (RT) are less effective against hypoxic tumor cells. Hypoxia-activated prodrugs (HAPs) are specifically activated in hypoxia to target hypoxic cells as well as adjacent oxygenated tumor cells via their bystander effect. DTP-006 is a newly synthesized nitroaromatic HAP with highly favorable properties: 1) activation under hypoxia, 2) high bystander effect, 3) excellent aqueous solubility, 4) murine oral bioavailability and 5) no off-mechanism activation by human aerobic reductases NQO1 and AKR1C3. Here we show the effects of DTP-006 on tumor cell viability, spheroid growth and radiation resistant tumor cells *in vivo*, and assess its pharmacokinetics and oral bioavailability in mice.

Material and Methods: The one-electron reduction potential (E1) of DTP-006 was determined by pulse and steady state radiolysis. IC50 viability ratios were assessed in 2D cell culture exposed to normoxic or anoxic (0% O2) conditions. H460 multicellular layers (MCLs) under aerobic (5% CO2, 95% O2) or anoxic (5% CO2, 95% N2) conditions were incubated with DTP-006 for 5 h after which cells were plated for clonogenic survival. H460 spheroids were incubated with DTP-006 upon confirmation of a hypoxic core. NIH-III mice bearing H460 tumors received a single i.p. dose of DTP-006 (781 mg/kg) after irradiation (10 Gy) of tumors. 18 h later tumors were excised and single cell suspensions were generated and plated for clonogenic survival. Tumor-free female NIH-III mice received a single i.v. or oral dose of DTP-006 (383 mg/kg). Terminal blood samples collected at time points via cardiocentesis were analyzed by LC/MS/MS. Plasma half-life (T1/2) and absolute oral bioavailability (Fabs) were calculated.

Results: DTP-006 has an E1 value of -351 mV, indicating strong oxygen inhibition of nitro radical formation. IC50 were lower in anoxia than normoxia by factors of 203 (MDA-MB-468), 55 (C33A), and 20 (HCT116). In a H460 MCL clonogenic assay, 100 µM DTP-006 caused 99% cell kill under anoxia but exhibited no aerobic cell kill. It caused a concentration-dependent growth delay in spheroids, where 250 µM completely halted growth. A single dose of DTP-006 caused a significant loss of clonogenicity when combined with RT in an

in vivo excision assay (log cell kill 2.35 relative to control). T1/2 after oral administration was 0.82 h and bioavailability was 47%.

Conclusion: DTP-006 kills tumor cells only in severe hypoxic conditions *in vitro*, reduces growth of tumor cell spheroids, and sterilizes radiation resistant tumor cells *in vivo*. It has clinically relevant bioavailability after oral administration. As such, DTP-006 is a promising new HAP with potentially favorable properties for clinical use. Further studies to determine the antitumor effects of DTP-006 as a monotherapy and in combination with RT in several preclinical tumor models are ongoing.

Adding Notch inhibition increases efficacy of standard of care treatment in glioblastoma

⁴Maastricht University, Department of Psychiatry and Neuropsychology, Maastricht, The Netherlands

⁵University of Glasgow Institute of Cancer Sciences, Department of Translational Radiation Biology, Glasgow, United Kingdom

⁶Leeds Institute of Cancer and Pathology, Department Radiation Biology and Therapy, Leeds, United Kingdom

Purpose or Objective: Glioblastoma multiforme (GBM) is the most common malignant brain tumour in adults. The current standard of care includes surgery followed by radiotherapy (RT) and chemotherapy with temozolomide (TMZ). Treatment often fails due to the radiation and TMZ resistance of a small percentage of cells with stem cell-like behavior (CSC). The Notch signaling pathway is expressed and active in human glioblastoma and Notch inhibitors attenuate tumor growth *in vivo* in xenograft models. Here, we investigate the efficacy of a clinically (FDA) approved γ-secretase inhibitor (GSI) RO4929097 in tumor control in combination with standard care of treatment (TMZ+RT) in an orthotopic glioma tumour model.

Material and Methods: Treatment efficacy *in vitro* was tested in 2D cultures using proliferation and clonogenic survival assays. 3D sphere assays were used as a model for pharmacological treatment response with quantification of spheroid growth delay in the different different treatment arms. Flow cytometry was used to detect cells expressing stem cell markers. Luciferase-expressing U87 cells were intracranially injected into the brain of CD-1 mice. Tumor volume was quantified using contrast-enhanced microCT and bioluminescence imaging. Animals received TMZ (ip), RO4929097 (GSI, orally) or radiation (RT, 8Gy) alone or in combination. RT dose was calculated and prescribed using SmART-Plan software with two 5-mm parallel-opposed beams placed at the center of the tumour.

Results: GSI in combination with RT and TMZ attenuated tumour cell proliferation, clonogenic survival as well as glioma spheroid growth. The expression of glioma stem cell markers SOX2 and CD133 was blocked by single or combined treatments with Notch inhibitors *in vitro*. Using our image guided micro-CT and radiotherapy platform *in vivo*, a significant growth delay was observed in GSI-, RT- and TMZ-only treated groups compared to the control group. Standard of care treatment (RT + TMZ) or addition of GSI to either TMZ or RT irradiation resulted in a significant growth delay and prolonged survival. Strikingly, the longest tumour growth delay together with an increase in median survival was observed in mice treated with the triple combination (GSI+RT+TMZ), with 1 out of 4 mice showing tumour cure.

Conclusion: We show in an orthotopic glioblastoma mouse model that adding a clinically approved Notch inhibitor to the TMZ/RT standard of care results in a significant growth delay and increased overall survival. The observed therapeutic benefit is promising for clinical translation in order to increase survival in patients bearing glioblastoma with active Notch signaling.

Akt1 facilitates DNA double-strand breaks repair through a direct physical interaction with DNA-PKcs

M. Toulany¹, J. Maier², U. Rothbauer², H.P. Rodemann¹
¹Division of Radiobiology & Molecular Environmental Research, Department of Radiation Oncology- University of Tuebingen, Tuebingen, Germany

²Natural and Medical Sciences Institute at the University of Tuebingen, Reutlingen, Germany

Purpose or Objective: It is well known that PI3K/Akt pathway is hyperactivated in K-RAS mutated tumor cells and is involved in radioresistance. Exposure to ionizing radiation induces activation of DNA-dependent protein kinase catalytic subunit (DNA-PKcs) as an essential enzyme for repair of DNA double-strand breaks (DSBs) through non-homologous end joining. Radiation-induced DNA-PKcs activity is partially dependent on serine/threonine kinase Akt1. In this study, role of DNA-PKcs in Akt1-mediated DSBs repair and post-irradiation cell survival was investigated. Likewise, a direct physical interaction of Akt1 with DNA-PKcs was studied.

Material and Methods: Non-small cell lung cancer cell line A549 and colorectal cancer cell line HCT116 with point mutations in K-RAS gene were utilized. Complex formation of Akt1 with DNA-PKcs and role of Akt1 in DSBs repair were tested by immunoprecipitation and γ H2AX foci assays, respectively. Localization of Akt1 to DSB site was tested by immunofluorescence staining and confocal microscopy of P-Akt (S473) and γ H2AX following microbeam laser irradiation and after exposure to ionizing radiation. To determine the potential interacting domain of Akt1 with DNA-PKcs; GST, GST-Akt1 full-length, GST-Akt1-N-terminal fragment (1-150 a.a.), and GST-Akt1-C-terminal (151-480 a.a.) proteins were incubated with purified DNA-PKcs and pull-down assay was performed. In order to identify the domain of DNA-PKcs that interacts with Akt1, constructs expressing four distinct fragments of DNA-PKcs (1-426, 427-1400, 2401-3850, 3700-4128 a.a) tagged with EGFP and full length Akt1 tagged with mCherry were produced. Akt1/DNA-PKcs was studied in A549 cells, transiently transfected with the appropriate constructs.

Results: Akt1 formed a complex formation with DNA-PKcs in the nuclear fraction immediately after irradiation. Nuclear Akt1 was co-localized with γ H2AX foci and found to be essential for the efficient repair of ionizing radiation-induced DSBs and post-irradiation cell survival, in a DNA-PKcs dependent manner. A direct physical interaction of DNA-PKcs to the C-terminal domain of Akt1 could be demonstrated. Additionally, Akt1 was found to make physical interaction not only with the C-terminal domain of DNA-PKcs (3700-4188 a.a.) but also with the N-terminal domain (1-426 a.a.).

Conclusion: Akt1, through a direct physical interaction with DNA-PKcs, regulates repair of ionizing radiation-induced DSBs. Thus, due to overexpression of Akt1 in tumor cells and constitutive Akt activity in K-RAS mutated tumors cells, Akt1 can be proposed as a tumor specific target for radiosensitization.

Survival of clinical stage I-III rectal cancer patients: a population-based comparison

I. Joye¹, G. Silversmit², E. Van Eycken², A. Debucquoy³, T. Vandendael², F. Penninckx⁴, K. Haustermans¹

¹KU Leuven/University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium

²Belgian Cancer Registry, Statistics, Brussels, Belgium

³KU Leuven, Department of Oncology, Leuven, Belgium

⁴KU Leuven, Department of Abdominal Surgery, Leuven, Belgium

Purpose or Objective: Total mesorectal excision is the cornerstone of rectal cancer treatment and preoperative (chemo)radiotherapy and adjuvant chemotherapy are often administered. This population-based study compares the survival in clinical stage I-III rectal cancer patients who received either preoperative radiotherapy, preoperative chemoradiotherapy or no preoperative therapy. The effect of type of radical resection and adjuvant chemotherapy on survival was also investigated.

Material and Methods: Patients diagnosed between January 2006 and December 2011 with clinical stage I-III rectal adenocarcinoma were retrieved from the national Cancer Registry database. Only first primary invasive rectal tumors were included and only patients who underwent a radical resection were retained. The observed survival was calculated from the date of surgery until the date of death or until the last known vital status. Conditional survival was defined as the survival conditional on surviving one year after surgery and was calculated in order to avoid the impact of adverse events in the postoperative course.

Multivariable Cox proportional-hazards regression models were applied to evaluate the association of preoperative treatment, type of radical resection and use of adjuvant chemotherapy with survival, adjusting for the baseline characteristics age, gender, WHO score and clinical stage.

Results: A total of 5173 eligible rectal cancer patients were identified from the national database. Preoperative treatment was as follows: none in 1354 (26.2%), radiotherapy in 797 (15.4%) and chemoradiotherapy in 3022 (58.4%) patients. Patients who received no preoperative therapy or preoperative radiotherapy and those who underwent abdominoperineal resection had a lower observed survival as compared with patients receiving preoperative chemoradiotherapy or treated with sphincter-sparing surgery respectively (Table). The patient group receiving adjuvant chemotherapy had a worse observed survival than the group receiving no adjuvant therapy. These effects were age-dependent. Multivariable analysis demonstrated similar findings for the observed survival conditional on surviving the first year after surgery.

Table: Hazard ratios of treatment-related predictors from the multivariable Cox model for observed survival and conditional survival.

	Hazard ratio	95% CI	p-value
Observed survival			
Preoperative treatment			
none vs. CRT, <65 years	1.27	0.96-1.69	0.0991
none vs. CRT, 65-74	1.04	0.78-1.37	0.8094
none vs. CRT, ≥75 years	1.77	1.46-2.14	<0.0001
RT vs. CRT, <65 years	1.38	1.02-1.87	0.0281

⁴Ospedale Molinette University of Turin A.O.U. San Giovanni Battista di Torino, Oncological Centre for Gastrointestinal Neoplasm- Medical Oncology 1- Turin- Italy, Torino, Italy

Purpose or Objective: To model acute hematologic toxicity (HT) and dose to pelvic osseous structures in anal cancer patients treated with definitive chemo-radiation (CT-RT).

Material and Methods: 53 patients receiving CT-RT were analyzed. Pelvic bone marrow (PBM) and corresponding subsites were contoured: ilium (IBM), lower pelvis (LPBM) and lumbosacral spine (LSBM). Dose-volume histograms points and mean doses were collected. Logistic regression was performed to correlate dosimetric parameters and > G2-G3 HT as endpoint. Normal tissue complication probability (NTCP) was evaluated with the Lyman-Kutcher-Burman (LKB) model.

Results: Logistic regression showed a significant correlation between LSBM mean dose and >G2 neutropenia (β coefficient:0.109;p=0.037;95%CI:0.006-0.212) and >G3 leukopenia (β coefficient:0.122; p=0.030;95% CI:0.012-0.233) (Table 1). According to NTCP modeling, the predicted HT probability had the following parameters: TD50:32.6 Gy, γ50:0.89, m:0.449 (>G2 neutropenia) and TD50:37.5 Gy, γ50:1.15, m:0.347 (>G3 leukopenia) (Figure 1). For node positive patients TD50:30.6 Gy, γ50:2.20, m:0.181 (>G2 neutropenia) and TD50:35.2 Gy, γ50:2.27, m:0.176 (>G3 leukopenia) were found (Figure 1)

Table 1.

	> G2 neutropenia					> G2 neutropenia				
	β coeff	Std err	z value	p value	95% CI	β coeff	Std err	z value	p value	95% CI
PBM-mean dose	-0.017	0.063	-0.28	0.781	-0.141-0.106	0.051	0.059	0.87	0.394	-0.064-0.168

LPBM-mean dose	-0.007	0.073	-0.11	0.915	-0.151-0.135	0.071	0.070	1.01	0.312	-0.066-0.208
LSBM-mean dose	0.065	0.053	1.23	0.220	0.490-0.536	0.109	0.052	2.08	0.037	0.006-0.212
	> G3 leukopenia					> G3 leukopenia				
PBM-mean dose	0.042	0.057	0.74	0.461	-0.070-0.153	0.086	0.075	1.15	0.248	-0.060-0.234
IBM-mean dose	0.017	0.043	0.40	0.688	-0.068-0.103	0.013	0.047	0.30	0.768	-0.078-0.106
LPBM-mean dose	0.001	0.069	0.03	0.979	-0.134-0.130	0.062	0.074	0.83	0.405	-0.083-0.208
LSBM-mean dose	0.122	0.056	2.18	0.030	0.012-0.233	0.062	0.051	1.23	0.220	-0.037-0.162

Legend - Coeff: coefficient; Std err: standard error; CI: confidence interval; PBM: pelvic bone marrow; IBM: iliac bone marrow; LPBM: lower pelvis bone marrow; LSBM: lumbosacral bone marrow;

Node positive patients had significantly higher PBM-V15 (Mean:81.1%vs86.7%;p=0.04), -V20 (Mean:72.7%vs79.9%;p=0.01) and V30 (Mean:50.2%vsMean:57.3%;p=0.03). Patients with a mean LSBM dose >32 Gy had a 1.31 (95%CI:0.75-2.35) and 1.81 (95%CI:0.81-4.0) relative risk to develop >G2 neutropenia and >G3 leukopenia. For node positive patients those risks were 1.67 (95%CI:0.76-3.64) and 2.67 (95%CI:0.71-10). To have a <5%, <10%, <20% risk to develop >G2 neutropenia and >G3 leukopenia, LSBM mean dose should be below 6 Gy, 13 Gy and 20 Gy and 14 Gy, 20 Gy and 26 Gy, respectively. For node positive patients these thresholds were below 21 Gy, 23 Gy and 26 Gy (>G2 neutropenia) and 24 Gy, 27 Gy and 30 Gy (>G3 leukopenia). On the whole cohort, within a dose range between 25 and 40 Gy, this probability rises from 30.3% to 69.1% for >G2 neutropenia and from 17.5% to 57.1% for >G3 leukopenia. For node positive patients these ranges were 16.5%-93.7% (>G2 neutropenia) and 6.7%-77.6% (>G3 leukopenia).

Conclusion: LKB modeling seems to suggest that LSBM mean dose should be kept below 32 Gy to minimize > G2-G3 HT in anal cancer patients treated with IMRT and concurrent chemotherapy. The sensitivity of LSBM and its contribution to the development of HT above 25 Gy seems higher in node positive patients.

OC-0241

MR radiomics predicting complete response in radiochemotherapy (RTCT) of rectal cancer (LARC)
 N. Dinapoli¹, B. Barbaro², R. Gatta¹, G. Chiloiro¹, C. Casà¹, C. Masciocchi¹, A. Damiani¹, L. Boldrini¹, M.A. Gambacorta¹, M. Di Matteo², G.C. Mattiucci¹, M. Balducci¹, L. Bonomo², V. Valentini¹

¹Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Radiation Oncology Department, Rome, Italy

²Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Radiology Department, Rome, Italy

Purpose or Objective: RTCT is widely used as treatment in LARC before surgery. A challenging aspect for tailoring radiation dose prescription is prediction of cases that will show a pathological complete response (PCR) after surgery, because they have better expectation in survival outcomes. "Radiomics" refers to the extraction and analysis of large amounts of advanced quantitative imaging features with high throughput from medical images. Up today radiomics findings in LARC have been limited either to small case series and CT or PET scan imaging. Objective of this study is to find a radiomics signature able to distinguish PCR patients using pre-treatment MR.

Material and Methods: Histologically proven LARC patients were recruited retrospectively since May 2008 to December 2014. They were staged by T2 MR, high resolution ($.7 \times .7 \times 3$ mm pixel spacing on x-y-z axes) perpendicular to tumor major axis oblique scans, before RTCT start. Finally they underwent to surgery with definition of pathological response. All patients were addressed to RTCT treatment with 50.4 Gy @ 1.8 Gy/fr prescription dose on GTV+surrounding mesorectum (PTV1) and 45 Gy @ 1.8 Gy/fr on lymphatic drainage (PTV2). For radiomics analysis GTV was delineated on pre treatment MRI by a radiologist and a radiation oncologist experienced in GI. Images were processed by using a home-made software. Before analysis MR images were pre-processed using a normalization procedure and application of Laplacian of Gaussian (LoG) filter on raw data. After pre-processing, GTV volumes were analyzed extracting 1st order features (Kurtosis, Skewness and Entropy). These features were extracted by scanning all possible values of σ in LoG filter from 0.3 to 6 (step 0.01). A total number of 570×3 features were analyzed respect to the PCR in order to detect the most significant ones using AUC and Mann-Whitney test. Tumor clinical (cT, cN) and geometrical features (volume, surface, volume/surface ratio) were finally added for building a multivariate logistic model and predicting PCR. Model performance was evaluated by ROC analysis and internal bootstrapping for detecting calibration error (TRIPOD 1b classification).

Results: 173 patients have been enrolled in this study. 1st order features analysis shows as candidate-to-analysis ones the Skewness ($\sigma=0.69$ - SK069) and Entropy ($\sigma=0.49$ - EN049). Multivariate logistic model shows as significant covariates cT (p-val = 0.003), SK069 (p-val = 0.006) and EN049 (p-val = 0.049). AUC of model is 0.73 and bootstrap based internal calibration shows prediction mean absolute error = 0.017. The model has been summarized in a nomogram.

Conclusion: This is the first radiomics model able to predict PCR in LARC patients only using pre-treatment imaging. Model performance is fair but its limitation is in the availability of internal validation alone. External validation is already planned. Use of such a model could address patients to different treatment pathways according outcome expectation.

⁸Mount Vernon Cancer Centre, Department of Medical Oncology, Northwood, United Kingdom

Purpose or Objective: Predictive and prognostic models in locally advanced rectal cancer have been developed in the last years. Starting with predictions models on pathologic complete response (as intermediate endpoint), afterwards local recurrence (LR), distant metastasis (DM) and overall survival (OS) at different time points (e.g. 5 or 10 years post-treatment) finally resulting in a model for the aggregate outcome, disease free survival (DFS). The current work aimed to reproduce the prediction models for LR, DM and OS, and to investigate the time dependence of these models.

Material and Methods: The dataset characteristics are shown in Table 1. This pooled dataset merged the datasets of the ACCORD, TME, CAO/ARO/AIO '94, Polish, FFCO, Italian (Sainato) and UK (Glynne-Jones) trials. As the current pooled dataset contains different trials, we used 20% of patients (stratified on the trial) as a validation dataset. In accordance to the methods used in previous work, we trained prediction models for the outcomes LR, DM and OS on this larger dataset. Prediction model variables were selected by evaluating the univariate Kaplan Meier curves for every variable at a significance level of $p < 0.05$. Afterwards, a Cox proportional hazards model and logistic regression models (in the latter situation a model for every month) were trained. Furthermore, we analyzed the covariate weights for the regression models. Finally, all the models were validated on discriminative ability using the Area under the Receiver Operating Curve (AUC).

Variable	Distribution / frequency	# missing values
Sex		0 (0%)
Male	323 (60%)	
Female	1696 (34%)	
Age		0 (0%)
< 50	566 (11%)	
50 - 59	1272 (26%)	
60 - 69	1827 (37%)	
≥ 70	1264 (26%)	
Tumor distance from anal verge	6.26 (SD: 3.20)	129 (3%)
Clinical T stage		2364 (48%)
T1	2 (0%)	
T2	82 (2%)	
T3	2248 (46%)	
T4	233 (5%)	
Clinical N stage		2704 (55%)
N0	1235 (25%)	
N1	939 (19%)	
N2	530 (13%)	
Prescribed dose		1088 (22%)
< 45 Gy	1123 (23%)	
45 Gy	1630 (33%)	
> 45 Gy	1092 (22%)

No	8548 (72%)	
Adjuvant chemotherapy		0 (0%)
Yes	2287 (46%)	
No	2579 (52%)	
Surgery procedure		1302 (27%)
LAR	2141 (48%)	
ABR	1486 (30%)	
Pathological T stage		190 (4%)
T0	364 (7%)	
T1	243 (5%)	
T2	1428 (29%)	
T3	2266 (52%)	
T4	128 (3%)	
Pathological N stage		300 (6%)
N0	306 (6%)	
N1	1834 (23%)	
N2	409 (8%)	
Outcomes after 5 years:		
Local Recurrence	394 (13%)	1630 (41%)
Distant Metastasis	978 (35%)	1119 (28%)
Overall survival	1899 (63%)	951 (24%)

Results: The AUC values for the prediction models are shown in figure 1 (blue: previous model, red: current Cox PH model, black: current logistic regression models). In general, the discriminative performance of the logistic regression model is higher in comparison to the newly trained Cox proportional hazards model or the original models, for all three outcomes. The covariates which changed the most over time were adjuvant chemo (LR, DM & OS), neo-adjuvant chemo (LR & OS), prescribed radiotherapy dose (LR) and pathological N-stage (DM).

Conclusion: Based on the current results, analyzed on the current dataset, we have shown that the logistic regression model (separate model for every time point) may perform better than models trying to cover the complete follow-up period. This may be due to the optimization capabilities, when training a new model for every follow-up time point, but might be susceptible for overfitting. From a clinical perspective, this could be plausible as the influence of variables (e.g. (neo-)adjuvant chemotherapy) may vary during the follow-up period and targeted outcome and could show how clinical and/or treatment decisions have influence on the patient outcome over time. Future work also involves handling of missing values, which is a major concern when merging trial datasets.

⁸Ospedale Civile, Dipartimento di Radioterapia, Terni, Italy

⁹Azienda Ospedaliero-Universitaria Ospedali Riuniti-Università Politecnica delle Marche, Dipartimento di Radioterapia, Ancona, Italy

Purpose or Objective: To investigate long term outcome and predictors between two schedules of platin based preoperative radiochemotherapy (RTCT)

Material and Methods: Patients with rectal adenoca, MRI based stage cT3N0-N2, were randomized into two arms:

1) PLAFUR: RT= 50.4 Gy; Concurrent chemotherapy (CT)= CDDP 60 mg m² (days 1-29) + 5FU continuous infusion in 96 h (days 1-4 and 29-32)

2) TOMOX-RT: RT=50.4 Gy; CT= Tomudex 3 mg / m² + oxaliplatin 130 mg / m² (days 1, 19 and 38).

Restaging at 6-8 weeks after the end of RTCT, followed by surgery in 1-2 weeks.

Adjuvant CT was recommended in ypN1-2.

Local control (LC), metastases-free survival (MFS), disease-free survival (DFS) and overall survival (OS) were analyzed.

Predictive endpoints of clinical outcome were tested by univariate and multivariate analysis. The investigated variables were: (i) patients (age, sex), (ii) therapy (RTCT

schedule, adjuvant CT, surgery type, colostomy), (iii) tumor related (cT, cN, ypT, yCN, TRG grade, site of primary T).

Results: From 2002 to 2005, 164 patients were enrolled (M: F = 104: 60); 83 were randomized to PLAFUR and 81 to TOMOX-RT. The median follow-up was 120.2 months (5.8-152.5).

The 10-years rates of the efficacy endpoints, per arm, were as follows: LC: PLAFUR= 89.2% , TOMOX-RT= 96.3% (p=0.0757); MFS: PLAFUR= 81.9% , TOMOX-RT= 81.5% (p=0.987) ; DFS: PLAFUR= 78.3% , TOMOX-RT= 77.8% (p=0.982); OS: PLAFUR =50%, TOMOX-RT= 50% (p=0.918) TOMOX-RT showed a non-significantly higher rate of ypT0 compared to PLAFUR: 35.8% vs 24.1% (p = 0.102), respectively.

Sphincter-saving surgery procedure was applied in: PLAFUR= 87.9%, TOMOX-RT= 86.4%.

Grade 3-4 acute toxicity occurred in: 7.1% in the PLAFUR arm vs 16.4% in the TOMOX-RT arm.

Confirmed predictors of outcome were found:

- For LC: at univariate analysis= ypT; ypN, TRG Grade; at multivariate analysis= TRG Grade (p = 0.0126)
- For MFS: at univariate analysis= age ypT, ypN and TRG Grade; at multivariate analysis= TRG Grade (p = 0.0255)
- For DFS: at univariate analysis= age ypT, ypN and TRG Grade; at multivariate analysis= TRG Grade (p = 0.0224)
- For OS: at univariate analysis= age ypT, ypN and TRG Grade; at multivariate analysis= no predictor was significantly associated.

Conclusion: The TOMOX-RT schedule allowed higher non-significant local control, and comparable clinical outcome to the compared schedule. Moreover the ypT downstaging was significantly improved. Acute toxicity was comparable between arms.

The TRG Grade was a good independent variable predicting LC, MFS and DFS, but not OS.

OC-0244

Similar quality of life after short-course radiation versus chemoradiation in rectal cancer patients

A.M. Couwenberg¹, J.P.M. Burbach¹, M. Van Vulpen¹, M.P.W. Intven¹, O. Reerink², W.M.U. Van Grevenstein³, M. Koopman⁴, H.M. Verkooijen⁵

²Isala, Radiotherapy, Zwolle, The Netherlands

³UMC Utrecht, Surgery, Utrecht, The Netherlands

⁴UMC Utrecht, Oncology, Utrecht, The Netherlands

⁵UMC Utrecht, Imaging, Utrecht, The Netherlands

Purpose or Objective: A majority of patients with rectal cancer is treated with neoadjuvant radiotherapy, with or without chemotherapy. If after chemoradiation (CRT) patients show a good clinical response, organ-preserving strategies are increasingly being offered. To increase the amount of patients with a good clinical response, it has been proposed to replace short-course radiotherapy (SCRT) by CRT. However, intensified treatment may affect patients' quality of life (QoL). This study aims to compare self-reported QoL between routinely treated rectal cancer patients receiving SCRT versus CRT before, during and after treatment.

Material and Methods: This multicenter prospective cohort study includes rectal cancer patients of all stages referred for radiotherapy between February 2013 and May 2015. QoL was assessed by EORTC-C30 and -CR29 questionnaires at baseline, 3, 6 and 12 months. For each patient, a propensity score (PS) for receiving CRT was calculated and used for restriction and adjustment. Changes in QoL over time were analyzed by mixed models between patients receiving CRT and SCRT, and additionally compared to a normative age-matched Dutch population.

Results: After PS based restriction, 191 of 208 eligible patients were included, of which 69 underwent SCRT and 122 CRT. Patients undergoing CRT were younger (62.2 vs. 68.0 year), had more mesorectal fascia invasion (66.6% vs. 27.9%),

more T4 (20.5% vs. 11.6%) and less T2 tumors (3.3% vs. 11.6%). Questionnaire return rates were 84% at baseline and 63-80% during follow-up. In both groups, 3 and 6 months QoL scores for global health, physical, emotional, social and role function were lower than at baseline and similar in both groups at all time points. At 12 months, all functional scores in both groups returned to baseline level, except for role function. No significant differences were found on symptom scales (constipation, diarrhea, pain, fatigue, nausea) between SCRT- and CRT-patients. Compared to the Dutch reference population, patients with rectal cancer still had impaired role and social function at 12 months.

Figure 1. EORTC-C30 Quality of life function domains at baseline, 3, 6 and 12 months for patients receiving short-course radiotherapy (blue line), chemoradiation (red line) and the age-matched Dutch population (green line).

Conclusion: Over the course of neoadjuvant rectal cancer treatment, similar drops in QoL are observed for patients receiving SCRT or CRT. After 12 months, most QoL scores return to baseline levels.

Protontherapy for uveal melanomas of temporal superior
S. Lanteri¹, C. Maschi¹, J. Herault², G. Angellier², M. Peyrichon², S. Baillif¹, J. Thariat², J. Caujolle¹

¹Pasteur 2 Hospital- Eye University Clinic, Ophthalmology, Nice, France

²Centre Antoine Lacassagne, Department of Radiation Oncology, Nice, France

Purpose or Objective: Protontherapy is a standard treatment for uveal melanomas. One area of current controversy is the use of protontherapy for uveal melanomas of temporal superior location owing to the presence of the lacrimal gland and the risk of radiation-induced dry eye syndrome (DES). Some teams have been contra-indicating such tumor locations for protontherapy and advocate brachytherapy. We investigated whether temporal superior (TS) melanomas should no longer be treated with proton therapy based on the rate of severe non manageable complications for DES.

Material and Methods: This retrospective study includes consecutive patients treated from 1999 to 2014 with protontherapy at our center. Patients received 52 Gy in four fractions and four days. Conjunctival melanomas were not excluded. Melanoma location was determined using an oriented clockwise goniometer. DES grades were defined as

Group 0 : no sign of dry eye, group 1: discomfort, group 2: keratitis, group 3 (severe): corneal ulcer. Percentages of the lacrimal gland receiving 90% of the prescribed dose, 20% to 50% or $\leq 20\%$ were assessed in the frontal and sagittal planes in Eyeplan blindly by two operators. The spss v12 statistics software was used. Kaplan Meier curves and Log rank tests were used for survival data.

Results: Of 1445 patients in the study, 14.7% and 2.0% had DES and severe DES, respectively. Two and five year DES-free survival rates were 88.9% and 83.6%, respectively. There were 7.6% melanomas of TS location. DES and severe DES correlated with TS location 13.8% vs 24.8% and 1.7% versus 5.8% in case of non-TS and TS ($p < 0.05$). 21/25 of patients with severe DES were in TS or temporal location. No patient had enucleation for DES. On MVA, diameter (hazard ratio HR:1.103, CI95:1.042-1.169, $p = 0.001$), tumor volume (HR:0.0696, CI95:0.486-0.996, $p=0.048$, % of ciliary body in the 90% isodose line (HR:1.014, CI95:1.003-1.026, $p=0.015$), gel compensator (HR:0.717, CI95:0.535-0.960, $p=0.025$) and TS location (HR:2.581, CI95:1.695-3.929, $p<0.001$) were significantly associated with the occurrence of DES.

Conclusion: Although the incidence of DES and severe DES was increased in TS melanomas and this correlated with the dose to the lacrimal gland, their characteristics were less favorable (larger, superior involvement of ciliary body and limbus). Occurrence of severe DES in TS but also temporal locations suggests that involvement of the ciliary arteries may also be responsible for severe DES. The correlation of TS with ciliary involvement suggests that limbus cells may participate in the occurrence of DES. The role of palpebral and corneal irradiation will be further investigated. Since DES is manageable, TS location should not be considered a contraindication for protontherapy.

OC-0246

Visual outcomes of parapapillary uveal melanomas following proton beam therapy

J. Thariat¹, J. Grange², C. Mosci³, L. Rosier⁴, C. Maschi⁵, F. Lanza³, A. Nguyen², F. Jaspard⁶, F. Bacin⁶, M. Bonnin⁶, D. Gaucher⁷, W. Sauerwein⁸, G. Angellier¹, M. Peyrichon¹, J. Herault¹, J. Caujolle⁵

⁵Eye University Clinic Pasteur 2, Ophthalmology, Nice, France

⁶Eye University Clinic Gabriel Montpied, Ophthalmology, Clermont-Ferrand, France

⁷Eye University Clinic - Hôpital Civil, Ophthalmology, Strasbourg, France

⁸NCTeam, Radiation therapy, Essen, Germany

Purpose or Objective: In parapapillary melanoma patients, radiation-induced optic complications are frequent and visual acuity is often compromised. We investigated dose effect relationships for the optic nerve with respect to visual acuity after protontherapy.

Material and Methods: of 5205 patients treated between 1991 and 2014, those treated between 1994 and 2013 (using CT-based planning) to 52 Gy in four fractions, minimal 6 month follow-up and documented initial and last visual acuity, were included. Deterioration of ≥ 0.3 logMAR between initial and last visual acuity was reported.

Results: 865 consecutive patients were included. Median follow-up was 69 months, mean age 61.7 years, tumor abutted the papilla in 64.9% and tumor to fovea distance was ≤ 3 mm in 74.2% of patients. Five-year relapse-free survival rate was 92.7%. Initially, 72.6% of patients had $\geq 20/200$ visual acuity, 47.2% had $\geq 20/200$ at last follow-up. A wedge filter was used in 47.8% of the patients, with a positive

impact on vision and no impact on relapse. Glaucoma, radiation-induced optic neuropathy, maculopathy were reported in 17.9%, 47.5%, and 33.6%, respectively. Patients irradiated to $\geq 80\%$ of their papilla had better visual acuity when limiting the 50% (30 Gy) and 20% (12 Gy) isodoses to ≤ 2 mm and 6 mm of optic nerve length, respectively.

Conclusion: A personalized protontherapy plan can be used efficiently with good oncologic and functional results in parapapillary melanoma patients.

OC-0247

Carbon ion radiotherapy for adenoid cystic carcinomas invading the skull base

A. Hasegawa¹, M. Koto¹, R. Takagi¹, K. Naganawa¹, H. Ikawa¹, H. Tsuji¹, T. Kamada¹

¹National Institute of Radiological Sciences, Research Center Hospital for Charged Particle Therapy, Chiba, Japan

Purpose or Objective: To estimate the toxicity and efficacy of carbon ion radiotherapy for adenoid cystic carcinomas (ACC) invading the skull base.

Material and Methods: Between April 1997 and August 2013, a total of 193 patients with ACC of the head-and-neck were treated with carbon ion radiotherapy. All of these patients had neither regional lymph node nor distant metastasis before carbon ion radiotherapy. The prescribed tumor doses were 57.6 or 64.0 Gy (RBE) in 16 fractions over four weeks. Of the 193 patients, 78 patients with ACC invading the skull base were analyzed. There were 37 males and 41 females. The median age was 52 years (range, 23-75 years). The most common primary site was the paranasal sinus (46%), followed by the nasopharynx (13%), the nasal cavity (10%) and the hard palate (10%). The extent of surgery was biopsy alone in 52 patients (67%), partial resection in 5 patients (6%). Twenty of 78 patients (27%) had recurrence tumors after surgery. Median follow-up time was 52 months (range, 10-177.7 months). Patients were divided into two groups according to intracranial involvement; Group A was made up of 32 patients whose tumors invading the cranial fossa, Group B consisted of 46 patients whose tumors invading the intracranial region or cerebra. Acute and late morbidities were evaluated by the RTOG, the RTOG/ EORTC and the CTCAE (version 4.0).

Results: The 5-year local control and overall survival rates of all patients were 65 % and 60 %, respectively. Median survival time was 74.4 months. In total 45 patients died, the major cause of death was distant metastases (67%). The 5-year local control rates were 71% for Group A and 56% for Group B. The 5-year overall survival rates were 74% for Group A and 49% for Group B. In univariate analysis using log-rank test, there were no significant differences in local control and overall survival rates between the two groups. There was no evidence of any unexpected severe acute (grade ≥ 4) and late (grade ≥ 3) reactions to the skin, the mucosa and other critical organs. In regard to brain toxicity, 5 of 32 patients (16%) in Group A and 9 of 42 patients (21%) in Group B developed grade 2 late reactions, which necessitated steroid administration temporarily. Four patients in Group B who had marginal recurrence received re-irradiation. Therefore, it was difficult to evaluate brain toxicity for these patients.

Conclusion: Our results showed acceptable brain toxicities and excellent therapeutic effectiveness for unresectable adenoid cystic carcinomas invading the skull base.

OC-0248

Proton Beam Therapy in childhood - First 2-years of practice results from the WPE

A.L. Mazhari¹, S. Schulze Schleithoff¹, F. Guntrum², C. Plass², M. Stickan-Verfürth², J. Lambert¹, C. Blase², G. Fleischhack⁴, M. Christiaens², B. Timmermann²

¹West German Proton Therapy Center Essen, University Hospital Essen, Essen, Germany

²West German Proton Therapy Center Essen, Clinic for Particle Therapy / University Hospital Essen, Essen, Germany

³AnästhesieNetz Rhein-Ruhr ARR, West German Proton Therapy Center Essen, Bochum, Germany

⁴Paediatrics III, University Hospital Essen, Essen, Germany

Purpose or Objective: Proton beam therapy (PT) has experienced increasing interest over time especially in pediatric malignancies as PT offers a chance to reduce post-treatment late effects. The West German Proton Therapy Center Essen (WPE) started treatments for pediatric tumors in June 2013. Since September 2013 all children under the age of 18 years were enrolled in the standardized prospective registry study for children ("KiProReg") at WPE. Initial findings are presented.

Material and Methods: Between September 2013 and September 2015, data on 138 children (78 males, 60 females, aged 0.9-17.9 years (median 5.7 years)) were prospectively collected in KiProReg at WPE. Diagnoses were CNS tumours (n=73), sarcomas (n=59), extracranial germ cell tumors (n=3) and others (n=3), respectively. Treatment sites were brain (n=72), head and neck including base of skull (n=38), spine (n=15), or pelvis (n=13). In 73.9% of the patients, macroscopic residual disease was present before PT. The median total dose of PT was 54.0 Gy (range 29.8-74.0 Gy). Only two patients had a mixed beam technique. Due to the very young age, sedation was necessary in 55.1% of children. Concurrent chemotherapy was applied in 54.3% of children. Side-effects were classified according to Common Terminology Criteria for Adverse Events (CTCAE) V4.0 grading system.

Results: Median follow-up (FU) since first diagnosis was 1.2 years (range 0.3-16.3 years). PT was well tolerated. No or only mild to moderate acute side-effects (grade 1 to 2) were documented in the majority of children (n=116). During PT, acute grade 3 side-effects were observed for blood/bone marrow (n=21), gastrointestinal (n=8) or as general disorders (n=3) as well as anorexia (n=1) when compared to baseline. Acute grade 4 side-effects during PT were only seen for blood/bone marrow (n=9). In 77 children, information on toxicity three months after PT is available. Only few patients presented with grade 3 or 4 toxicities, predominantly for blood/bone marrow (grade 3 n=7, grade 4 n=2). Seven of them had received chemotherapy after PT. So far, 17 patients failed due to recurrence or progression (local n=5; systemic n=12). Six of them (4.3%) have died so far, all due to disease.

Conclusion: Initial prospective data from WPE registry suggest good feasibility with only mild or moderate side-effects in the majority of children even when administering high doses at critical sites. Higher-grade side-effects primary for blood and bone marrow are obviously influenced by concurrent chemotherapy. Early local control rates achieved with PT are promising so far. However, longer FU is needed to analyze long-term outcome and late effects.

OC-0249

Five-year clinical outcomes after dose-escalated image-guided proton therapy for prostate cancer

C. Bryant¹, W. Mendenhall¹, B. Hoppe¹, R. Henderson¹, R. Nichols¹, C. Morris¹, C. Williams¹, Z. Su¹, Z. Li¹, N. Mendenhall¹

¹University of Florida Proton Therapy Institute, Radiation Oncology, Jacksonville- Florida, USA

Purpose or Objective: To report clinical outcomes for patients treated with image-guided proton therapy for localized prostate cancer.

Material and Methods: Under institutional review board approval, the medical records of 1,215 men enrolled either on a prospective protocol or an outcomes tracking study treated for localized prostate cancer with proton therapy at our institution between 2006 and 2010 were reviewed. Ninety-eight percent of patients received 78 Gy (RBE) or higher; 15% received androgen deprivation therapy (ADT). Five-year freedom from biochemical progression (FFBP),

distant metastasis-free survival, and cause-specific survival rates are reported for each risk group. Prospectively collected patient-reported quality-of-life data and high-grade toxicities are reported. A multivariate analysis was performed to identify clinical predictors of biochemical failure.

Results: The median follow-up was 5.5 years. The 5-year FFBR rates were 99%, 94%, and 74% in low-, intermediate-, and high-risk patients, respectively. Actuarial 5-year rates of late grade 3 gastrointestinal and genitourinary toxicity were 0.6% and 2.4%, respectively. Median International Prostate Symptom Scores (IPSS) before treatment and at >4 years after treatment were 7 and 7. Median changes in EPIC scores between baseline and 4+ years of follow-up were minimal in the bowel, urinary irritative/obstructive, and urinary incontinence summary domains.

Conclusion: Image-guided proton therapy provided excellent biochemical control rates for patients with localized prostate cancer. Patient-reported quality of life outcomes are favorable and actuarial rates of high-grade toxicity were low following proton therapy.

OC-0250

Hadrontherapy as re-irradiation using active beam delivery at CNAO

E. Ciurlia¹, M. Bonora¹, P. Fossati², V. Vitolo¹, A. Iannalfi¹, M. Fiore¹, B. Vischioni¹, A. Facoetti³, A. Hasegawa⁴, F. Valvo¹, M. Krengli⁵, R. Orecchia²

¹Fondazione CNAO, Area Clinica, Pavia, Italy

²Università di Milano, Radioterapia, Milano, Italy

³Fondazione CNAO, Radiobiologia, Pavia, Italy

⁴NIRS, Radiotherapy, Chiba, Japan

⁵Università del Piemonte Orientale "Amedeo Avogadro", Radioterapia, Novara, Italy

Purpose or Objective: Reirradiation of non resectable local recurrence, after previous full course of radiotherapy, is extremely challenging. Particle therapy may theoretically be the ideal tool for re-irradiation thanks to its complete sparing of large volumes of non target tissues already irradiated to low-medium dose with conformal X-ray based techniques. We report CNAO experience, in terms of acute toxicity and early response to hadrontherapy, in patients with head and neck, skull-base and sacral local relapse, re-irradiated with carbon ions or protons.

Material and Methods: Since February 2013 to February 2015, 70 patients (M/F = 41/29) underwent hadrontherapy in CNAO as re-irradiation. Site of disease was head and neck in 52 patients cancer, sacrum in 12 patients, skull - base in 4 patients and brain in 2 cases. The histologies were: squamous cell carcinoma (21 pts), adenoid cystic carcinoma (18 pts), chordoma (7 pts), other sarcoma (6 pts), adenocarcinoma (7 pts), meningioma (4 pts), others (7 pts). Sixty-two patients had been treated with Carbon Ions, the rest (8 pts) with protons. Average age was 59 (range 31 - 78). Previous radiotherapy doses ranged between 54 to 76 Gy (with conventional fractionation) and 20 to 28 Gy (with hypofractionation). Mean prescription dose was 61.7 Gy [RBE] (32.5 - 64), mean dose per fraction was 2.4 Gy [RBE] (2 - 4.5). Early toxicity was evaluated during, at the end and within 90 days after radiotherapy (RT). Patients were also followed up for late toxicity and radiologic response every three months after RT with magnetic resonance (MRI) and clinical evaluation.

Results: Acute toxicity was mild with no G4 event. At the end of treatment 26 pts (37%) had G0 toxicity; 27 pts (38%) had G1 toxicity; 16 pts (23%) had G2 toxicity and only 1 pts (1%) had G3 mucositis. At three months this favorable profile was maintained; FU average 9 months (range 3 - 24). Only one patient had G4 toxicity detected at 3 months (unilateral blindness due to intentional irradiation of one optic nerve beyond tolerance dose). Only 3 patients had G3 toxicity: skin fistula and osteoradionecrosis, 6 months after RT and cerebral edema (requiring medical treatment) 9 months

after RT. The patient with longest FU (24 months), has late toxicity G1 (hearing impairment). At the time of analysis 11 patients had died of progressing disease (PD), 6 and 9 months progression free survival were 83% and 72% respectively.

Conclusion: Hadrontherapy as reirradiation allows good dose distribution with optimal sparing of already irradiated organs at risk. Due to mild acute toxicity hadrontherapy may be considered safe and well tolerated. Longer follow up is needed to confirm the efficacy and the late side effects.

Electromagnetic tracking for error detection in interstitial brachytherapy

M. Kellermeier¹, D. Elz^{1,2}, V. Strnad^{1,2}, C. Bert^{1,2}

¹University Clinic Erlangen, Radiation Oncology, Erlangen, Germany

²Friedrich-Alexander Universität Erlangen-Nürnberg, Radiation Oncology, Erlangen, Germany

Purpose or Objective: Catheter reconstruction errors, wrong indexer length and misidentified first dwell position are among the most common medical events related to high-dose-rate brachytherapy (HDR-BT) treatment, reported in the United States by the Nuclear Regulatory Commission. The purpose of this study is a feasibility analysis for the detection of such events based on electromagnetic tracking (EMT).

Material and Methods: In a phantom-based experiment series, swap of catheters and displacement ($\Delta l = 0, 1, 2, 3, 4, 5$ and 6 mm) of a single catheter along direction of insertion were simulated. For the detection of errors the measured implant geometry was registered to the nominal one. Then the residual distances between corresponding dwell positions were analyzed.

Within an IRB approved study the breast implants of 18 patients treated with HDR interstitial brachytherapy (HDR-iBT) were measured by EMT after implantation, after CT imaging in imaging position, and as part of each of 9 treatment fractions in treatment position. The data were used to simulate catheter reconstruction errors, wrong indexer length, and swapping of catheters. Based on determining the pairwise difference of all EMT-reconstructed dwell positions and by registering the measured implant geometry with the nominal one established during treatment planning, the feasibility of error detection by EMT was tested.

Results: Swapping of catheters can be detected in phantoms. The shift of individual catheters was detected quantitatively within the determined EMT-accuracy (95th percentile of 0.83 mm). For example, the shift of $\Delta l = 6$ mm resulted in an EMT-determined shift of 6.09 mm compared to measured values of < 0.8 mm for all catheters without an induced shift. First analyses of the data indicate that pairwise differences result into a catheter specific "fingerprint" (see figure 1a for catheters 5-8). This fingerprint stays stable over multiple fractions (figure 1b for DICOM treatment planning, fractions 2, 4) such that, e.g., a swap as simulated in fraction 4 (fig. 1b) can easily be identified.

Figure 1: Histogram of pairwise dwell position distances resulting into a „fingerprint“ characteristic for each catheter. a) Examples of such histograms for different catheters measured by EMT in a single fraction. b) Histogram of catheter #8 extracted from the DICOM data of the treatment plan and measured by EMT in fractions #2, #4, and #6. In fraction #4 an error was induced (swap of catheters #8 and #11) which can be identified by a change in the „fingerprint“/histogram.

Conclusion: EMT is a promising technique for error detection in interstitial brachytherapy. Further analysis of our clinical data will be conducted to determine the sensitivity and specificity of the proposed error detection methods.

BrachyView: A novel technique for seed localisation and real-time quality assurance

S. Alnaghy², M. Petasecca¹, M. Safavi-Naeini¹, J.A. Buccic², D.L. Cutajar¹, J. Jakubek³, S. Pospisil³, M.L.F. Lerch¹, A.B. Rosenfeld¹

¹University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia

²St George Hospital, St George Cancer Care Centre, Kogarah, Australia

³Institute of Experimental and Applied Physics, Czech Technical University of Prague, Prague, Czech Republic

Purpose or Objective: In low dose rate (LDR) brachytherapy, seed misplacement/movement is common and may result in deviation from the planned dose. Current imaging standards for seed position verification are limited in either spatial resolution or ability to provide seed positioning information during treatment. BrachyView (BV) is a novel, in-body imaging system which aims to provide real-time high resolution imaging of LDR seeds within the prostate.

Material and Methods: The BV probe consists of a gamma camera with three single cone pinhole collimators in a 1 mm thick tungsten tube. Three, high resolution, pixelated detectors (Timepix) are placed directly below. Each detector comprises of 256 x 256 pixels, each 55 x 55 μm² in area. The system is designed to reconstruct seed positions by finding the centre of mass of the seed projections on the detector plane. Back projection image reconstruction is adopted for seed localisation.

A thirty seed LDR treatment plan was devised. I-125 seeds were implanted within a CIRS tissue-equivalent ultrasound prostate gel phantom. The prostate volume was imaged with transrectal ultrasound (TRUS). The BV probe was placed in-phantom to image the seeds. A CT scan of the setup was performed. CT data were used as the true location of seed positions, as well as reference when performing the image co-registration between the BV coordinate system and TRUS coordinate system.

An in-house graphical user interface was developed to perform 3D visualisation of the prostate volume with the seeds in-situ. The BV and CT-derived source locations were compared within the prostate volume coordinate system for evaluation of the accuracy of the reconstruction method. A Dose Volume Histogram (DVH) study of the Clinical Target Volume (CTV) was performed using TG-43 calculations, using reconstructed source positions provided by BV system and CT scanner.

Results: Figure 1 (a) shows the reconstructed prostate volume using ultrasound slices. The reconstructed seed positions using BV probe and CT images are merged with the prostate volume (shown in same coordinate system). (b) shows the discrepancy between calculated seed positions using CT and BV datasets. (c) shows the DVH calculated from CT data set and BV probe.

Figure 1:

Conclusion: The reconstructed seed positions measured by the BV probe demonstrate excellent agreement with seed positions calculated using CT data with a maximum discrepancy of 1.78 mm. It was observed that 75% of seed positions were reconstructed within 1 mm of their nominal location. The DVH study was performed to evaluate the effect of reconstructed seed locations on estimated dose delivered. V100 showed a discrepancy of 0.604 cm³ between CT and BV-derived 3D seed distribution. The BV technique has proven to be an effective tool for quality assurance during LDR brachytherapy, providing anatomical and seed positioning information without need for external irradiation for imaging.

OC-0253

A high sensitivity plastic scintillation detector for in vivo dosimetry of LDR brachytherapy

F. Therriault-Proulx¹, L. Beaulieu², S. Beddar¹

¹The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

²CHU de Quebec and Université Laval, Radiation Oncology, Quebec, Canada

Purpose or Objective: There are multiple challenges behind developing an *in vivo* dosimeter for LDR brachytherapy. The dose rates are orders of magnitudes lower than in other therapy modalities, the detectors are known to be energy-dependent, and introducing materials that are not tissue-equivalent may perturb the dose deposition. The goal of this work is to develop a high sensitivity dosimeter based on plastic scintillation detectors (PSDs) that overcomes those challenges and to validate its performance for *in vivo* dosimetry.

Material and Methods: The effect of the energy dependence of PSDs on dosimetry accuracy was studied using GEANT4 Monte Carlo (MC) simulations adapted from the ALGEBRA source code developed for brachytherapy. The photon energy distribution at different positions around a modeled I-125 source was obtained and convoluted to a typical PSD response. The effect of the different materials composing the PSD was also investigated.

To measure dose rates as low as 10 nGy/s, the selection of each single element composing a typical PSD dosimetry system was revisited. A photon-counting photomultiplier tube (PMT) was used in combination with an optical fiber designed to collect more light from the scintillator. A spectral study was performed to determine the best combination of scintillator and optical fiber to use.

Finally, doses up to a distance of 6.5 cm from a single I-125 source of 0.76U (0.6 mCi) held at the center of a water phantom were measured. The PSD was moved at different radial and longitudinal positions from the source using an in-

house computer-controlled device developed for this study and allowing for sub-mm positioning accuracy. The measurements were compared to the expected values from the updated Task-Group 43 formalism.

Results: The change in the energy distribution with position around the I-125 source was shown from MC simulations to have a limited impact on the PSD's accuracy over the clinically relevant range (<1.2%). Therefore, the energy-dependence can be neglected, as long as the PSD is calibrated using the same isotope. The effect of the different materials on the photon energy distribution was also shown to be limited (<0.1%). The different improvements made to the PSD dosimetry system are presented in Table 1. Those led to a 44 times better signal-to-noise ratio than for a typical PSD. Measurements with the PSD around a single I-125 source were shown to be in good agreement with the expected values (see Fig.1). The uncertainty was shown to be a balance between positioning uncertainty near the source and measurement uncertainty as the detector moves farther away from the source.

Improvements	Factor
Cooling PMT (reduction in dark noise)	1.6
Selection of scintillator + Shorter fiber	5.7
Using a Mylar reflector	2
collected light	1.44
NA = 0.6 vs. NA = 0.5	0.996
increase in OPL	0.996
Scintillator length (5 mm vs 3 mm)	1.67
Total	43.75

Table 1. Summary of the different improvements made to the PSD dosimetry system (PMT: Photomultiplier Tube, NA: Numerical aperture, OPL: optical path length).

Figure 1. Measured dose-rate with the PSD as a function of position along the longitudinal axis of the source (z) for different radial distances (r) in comparison to the expected values (TG43). The TG43 values (lines) account for uncertainties in source-to-detector positioning of ± 1 mm along the x-y- and z-axes.

Conclusion: This optimized PSD system was shown to be capable of accurate in-phantom dosimetry around a single LDR brachytherapy seed, which confirms the high sensitivity of the detector as a potential *in vivo* dosimeter for LDR brachytherapy applications.

OC-0254

MR compatibility of fiber optic sensing for real-time needle tracking

M. Borot de Battisti¹, B. Denise de Senneville^{2,3}, M. Maenhout¹, G. Hautvast⁴, D. Binnekamp⁴, J.J.W. Lagendijk¹, M. Van Vulpen¹, M.A. Moerland¹

¹University Medical Center Utrecht, Radiotherapy, Utrecht, The Netherlands

²UMR 5251 CNRS/University of Bordeaux, Mathematics, Bordeaux, France

³University Medical Center Utrecht, Imaging Division, Utrecht, The Netherlands

⁴Philips Group Innovation, Biomedical Systems, Eindhoven, The Netherlands

Purpose or Objective: The development of MR-guided HDR brachytherapy has gained an increasing interest for delivering a high tumor dose safely. However, the update rate of MR-based needle localization is inherently low and the required image interpretation is hampered by signal voids arising from blood vessels or calcifications, which limits the precision of the needle steering.

This study aims to assess the potential of fiber optic sensing for real-time needle tracking during MR-guided intervention. For this, the MR compatibility of a fiber optic tracking system and its accuracy are evaluated.

Material and Methods: *Fiber optic tracking device:* The device consists of a flexible stylet with three optic fibers embedded along its length, a broadband light source, a spectrum analyzer and a PC with Labview application. Along each fiber, Bragg gratings are evenly spaced at 20 mm intervals. To reconstruct the shape of a needle, the stylet is inserted inside the lumen of the needle. This set-up placed in the 1.5T MR-scanner provides real-time measurement of the needle profile, without adverse imaging artefacts since no ferromagnetic material is involved.

MRI-acquisition protocol: 3D MR-images were acquired with a 1.5T MR-scanner, using a 3D Spectral Presaturation with Inversion Recovery (SPIR) sequence (TR=2.9ms, TE=1.44ms, voxel size= 1.2x1.45x1mm³, FOV=60x250x250mm³).

Experimental evaluation: The two following experiments were conducted:

1. A needle was placed inside the MR-bore and its shape was imposed by a specially designed plastic mold with different known paths (see Fig. 1a). For path 1, 2 and 3, the shape of the needle was measured by fiber optic tracking during MR-imaging along 4 orientations (i.e 0°, 90°, 180°, 270°), by rotating the needle along its longitudinal axis.
2. Four plastic catheters were introduced in an agar phantom. The corresponding catheter shapes were measured with fiber optic sensing during simultaneous MR imaging (see Fig. 1d, phantom shifted out of scanner for photograph). The MR-based needle shape stemmed from a segmentation step followed by a polynomial fitting (order 5). A rigid registration of the obtained MR-based needle model and the fiber optic tracking was then performed.

Assessment of the fiber optic tracking: The fiber optic needle tracking accuracy was quantified by calculating the Euclidian distances between: the gold-standard shapes and fiber optic based measurements (Experiment #1); MR- and fiber optic based measurements (Experiment #2).

Results: For all tested needle shapes, the maximum absolute difference between the fiber optic based and the gold-standard values was lower than 0.9mm (Experiment #1, Fig. 1b and 1c). Over the 4 tested catheters, the maximal absolute difference between MR- and fiber optic based measurements was lower than 0.9mm (Experiment #2, Fig. 1e, 1f and 1g).

Conclusion: This study demonstrates that the employed fiber optic tracking device is able to monitor the needle bending during MR-imaging with an accuracy and update rate eligible for MR-guided intervention.

OC-0255

Correction function for MOSkin readings in realtime in vivo dosimetry in HDR prostate brachytherapy

G. Rossi¹, M. Carrara², C. Tenconi², A. Romanyukha³, M. Borroni², G. Gambarini⁴, D. Cutajar³, M. Petasecca³, M. Lerch³, J. Bucci⁵, A. Rosenfeld³, E. Pignoli²

¹University of Milan, Department of Physics, Milan, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Diagnostic Imaging and Radiotherapy Department, Milan, Italy

³University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia

⁴National Institute of Nuclear Physics, Physics, Milan, Italy

⁵St George Hospital, Cancer Care Centre, Kogarah, Australia

Purpose or Objective: MOSkin detectors coupled to a trans-rectal ultrasound (TRUS) probe were used to perform in vivo dosimetry (IVD) on the rectal wall surface during US-based HDR prostate brachytherapy (BT). The system, called dual purpose probe (DPP), has proven to be an accurate tool to measure in vivo the integral dose, however discrepancies between planned and measured doses from each single catheter can be much higher than the overall discrepancies. In this work, three HDR prostate BT sessions were studied to find a possible distance and angle dependence correction function (CF) to be applied in real time to each single catheter, and data with and without the application of the obtained CF were compared.

Material and Methods: The DPP can be sketched as follows: four MOSkin dosimeters are firmly attached to TRUS rectal probe and are connected to a multichannel reader which provides measurements of the voltage shifts (proportional to the dose) in the MOSkin sensitive layer caused by radiation exposure. A dedicated software plots and records the measured dose with each MOSkin as a function of time, allowing the identification of the dose contribution of each single catheter in real time. Based on the treatment plan data (i.e. planned source strength, dwell times and positions) a software was implemented in the Matlab environment to compute the dose contribution to the MOSkin from each catheter based on TG-43 algorithm. The software reports also the weighted average distance of source to MOSkin for each catheter and the resulting weighted polar angles. IVD data were acquired on three patients treated between June and

October 2015 and retrospectively analysed, providing 141 dose measurements for all the MOSkins. Measured and calculated contributions by each single catheter were quantified separately. Discrepancies were plotted depending on weighted average polar angles and distances between MOSkins and source, and a linearly fitting CF was calculated.

Results: A correction function CF linearly depending on the weighted average distance and polar angle of the catheter from the dosimeter was obtained ($R=0.35$, showing a significant correlation). The results showed an increase in sensitivity of MOSkins at higher distances (i.e., due to radiation softening) and at wider polar angles (i.e., due to increased radiation contamination by the presence of the TRUS probe). The percentage dose discrepancy between calculated and measured dose contribution from each single catheter with and without the application of obtained CF resulted in $1.3\pm 13.1\%$ and $1.2\pm 7.7\%$ ($k=1$), respectively (figure 1).

Conclusion: The use of the CF significantly reduces percentage discrepancy between planned and measured dose per single catheter. Implementation of the CF to correct MOSkin readings online is a further step towards accurate and reliable real time IVD in prostate BT performed with the DPP. Based on the real time measured dose discrepancy, the next step will be defining an action protocol to use the acquired information online.

OC-0256

Column generation-based Monte Carlo treatment planning for rotating shield brachytherapy

M.A. Renaud¹, G. Famulari², J. Seuntjens³, S. A. Enger³

¹McGill University, Physics, Montreal, Canada

²McGill University, Medical Physics, Montreal, Canada

³McGill University, Oncology, Montreal, Canada

Purpose or Objective: Rotating shield brachytherapy (RSBT) is an intensity modulated high dose rate (HDR) BT treatment technique, where radiation sources are surrounded by catheters containing rotating shields that direct radiation towards the tumour and away from healthy tissues. RSBT for HDR requires sources with lower energies than Ir-192, such as Gd-153 and Se-75, due to shield thickness constraints. The distinct features of shield angle, catheter material and source isotope require the development of a specific Monte Carlo (MC)-based treatment planning and optimization system.

Material and Methods: An MC based dose calculation engine for RSBT has been developed and coupled with a column-generation optimizer. At every iteration of the optimization loop, the column-generation process solves a pricing problem to determine the best dwell position and shield angle

combination to add to the treatment plan, resulting in the best possible plan with the shortest treatment time.

As a source model, the microSelectron-v2 source geometry was selected and placed inside a cylindrical platinum shield with a diameter of 1.8 mm and 3.0 mm for interstitial and intracavitary cases, respectively. An emission window coinciding with the active core of the source was created by removing half (180°) of the wall of the shield.

For an interstitial prostate case, RSBT plans were generated only using Gd-153 as a source due to the extreme limitations on shield size in interstitial catheters. For the intracavitary GYN case, both Gd-153 and Se-75 plans were generated. All RSBT plans were compared with conventional HDR BT. Only the original dwell positions used in conventional BT were sampled to create the RSBT plans.

Results: RSBT plans resulted in a considerable reduction in both rectum and bladder doses without sacrificing target coverage for the prostate case. With 95% of the PTV volume receiving over 15 Gy, only 40% of the rectum volume received more than 2 Gy for the Gd-153 RSBT case, as opposed to 85% for the unshielded Ir-192 conventional plan.

For the GYN patient, the median rectum dose was 2.4 Gy, 3.2 Gy and 3.45 Gy for Gd-153 RSBT, Se-75 RSBT and unshielded Ir-192, respectively, with an identical target coverage. The Gd-153 case was also able to reduce the dose to the bladder by 41%.

Conclusion: The development of the first MC-based TPS devoted to RSBT has been successfully accomplished. For the prostate case, a significant dosimetric improvement was achieved over conventional BT using Gd-153 with optimized shield angles. For the GYN case, the improvement was diminished by the central position of the conventional BT dwell positions within the target volume. RSBT allows the placement of dwell positions much closer to normal tissue, which will yield superior dose distributions when properly optimized. RSBT will decrease normal tissue toxicity and allow for tailoring treatments to each individual patient by treating all parts of the tumour without over-irradiation of large regions of normal tissues.

A Bayesian network model for acute dysphagia prediction in the clinic for NSCLC patients

A.T.C. Jochems¹, T.M. Deist¹, E. Troost², A. Dekker¹, C. Faivre-Finn³, C. Oberije-Dehing¹, P. Lambin¹

¹MAASTRO clinic, Radiotherapy, Maastricht, The Netherlands

²Helmholtz-Zentrum, Radiooncology, Dresden-Rossendorf, Germany

³The Christie NHS Foundation Trust & University of Manchester, Radiation Oncology, Manchester, United Kingdom

Purpose or Objective: Acute dysphagia is a frequently observed toxicity during concurrent chemo-radiation (CRT) or high-dose radiotherapy (RT) for lung cancer. This toxicity can lead to hospitalizations, treatment interruptions and

consequently reduce chances of survival. Models to predict acute dysphagia are available. However, these models were based on limited amounts of data and the performance of these models needs improvements before implementation into routine practice. Furthermore, Bayesian network models are shown to perform better than conventional modeling techniques on datasets with missing values, which is a common problem in routine clinical care. In this work, we train a Bayesian network model on a large clinical datasets, originating predominantly from routine clinical care, to accurately predict acute dysphagia in NSCLC patients during and shortly after (C)RT.

Material and Methods: Clinical data from 1250 inoperable NSCLC patients, treated with radical CRT, sequential chemotherapy or RT alone were collected. The esophagus was delineated using the external esophageal contour from the cricoid cartilage to the GE junction. A Bayesian network model was developed to predict severe acute dysphagia (Grade 3 according to the CTCAEv3.0 or v4.0). The model utilized age, mean esophageal dose, timing of chemotherapy and N-stage to make predictions. Variable selection and structure learning was done using the PC-algorithm. The model was trained on data from 1250 patients. The model's performance was assessed internally and on an external validation set (N=218) from the United Kingdom. Model discriminative performance was expressed as the Area Under the Curve (AUC) of the Receiver Operating Characteristic (ROC). ROCs were compared using the method proposed by DeLong and colleagues. Model performance was also assessed in terms of calibration. Calibration refers to the agreement between the observed frequencies and the predicted probabilities and is expressed as the coefficient of determination (r^2).

Results: One-hundred forty patients (11,2%) developed acute dysphagia (\geq Grade 3 according to the CTCAEv3.0 or v4.0). The model was first validated internally, by validating on the training cohort (N=1250, AUC = 0.77, 95% CI: 0.7325-0.8086, $r^2 = 0.99$). Subsequently, the model was externally validated on a UK dataset (N = 218, AUC = 0.81, 95% CI: 0.74-0.88, $r^2 = 0.64$). The ROC curves were not significantly different ($p = 0.28$).

Conclusion: The Bayesian network model can make accurate predictions of acute dysphagia (AUC = 0.77, 0.81 in the internal and external validation respectively), making it a powerful tool for clinical decision support.

Linear-quadratic modeling of acute rectum toxicity in a prostate hypo-fractionation trial

M. Witte¹, W. Heemsbergen¹, F. Pos¹, C. Vens², S. Aluwini³, L. Incrocci³

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

²Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology- Division of Biological Stress Response, Amsterdam, The Netherlands

³Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

Purpose or Objective: In the Dutch prostate hypo-fractionation trial (19x3.4Gy versus 39x2Gy) a higher incidence of acute gastro-intestinal toxicity was observed in the experimental arm. We performed model estimations using various alpha/beta ratios to determine whether this difference can be explained according to the linear-quadratic model.

Material and Methods: Patients with localized prostate cancer were randomized between standard fractionation (SF=5x2Gy per week, N=293) and hypo-fractionation (HF=3x3.4Gy per week, N=285). Proctitis (grade 2) was defined as moderate to severe mucous or blood loss, or mild mucous or blood loss combined with at least 2 other complaints: diarrhea, incontinence, tenesmus, cramps, pain. Peak incidences over treatment weeks 4 and 6 were available

from prospectively collected patient reports. Normalized Total Dose (NTD, 2Gy equivalent) was accumulated per week for alpha/beta ratios of 3, 5, 10, and ∞ (=physical dose), and used to derive relative Dose-Surface Histograms (DSHs) of the delineated anorectum for each patient. Maximum likelihood logistic regressions were performed using a DSH point as variable. Univariate (UV) models and multivariate (MV) models with fractionation schedule as factor were constructed.

Results: Acute proctitis incidences were highest for hypofractionation (SF: n=67; 22.9%, HF: n=98; 34.3%, p<0.01). The 7Gy/week DSH point correlated well with proctitis, and was used for subsequent modeling. Figure 1 illustrates the models for the various alpha/beta ratios, and incidences for five (roughly) equal size patient bins. Note that the NTD correction decreases the surface areas that receive <2Gy per day, and increases surfaces receiving >2Gy. The central NTD values of the patient bins therefore lie at higher values for HF than for SF. The MV models have higher likelihood than the UV models, but likelihood for different alpha/beta ratios is similar. All MV models have odds ratios >1.5 (p<0.05) for HF versus SF, i.e. fractionation remains a factor.

Conclusion: Linear-quadratic dose correction cannot explain the observed acute rectum toxicity difference between hypofractionated and standard treatment in patients with prostate cancer. Subsequent modeling will concentrate on alternative mechanisms.

Figure 1 Acute proctitis models (UV solid, MV dashed) for standard (green) and hypo-fractionation (orange)

Spatial rectal dose-response for patient-reported leakage, obstruction, and urgency in prostate RT

O. Casares-Magaz¹, L.P. Muren¹, S.E. Petersen², V. Moiseenko³, M. Høyer², J.O. Deasy⁴, M. Thor⁴

¹Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark

²Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

³University of California San Diego, Radiation- Medicine and Applied Sciences, San Diego, USA

⁴Memorial Sloan Kettering Cancer Center, Department of Medical Physics, New York, USA

Purpose or Objective: To explore whether spatial dose measures explain the occurrence of rectal leakage, obstruction, and urgency after radiotherapy (RT) for localized prostate cancer.

Material and Methods: Spatial dose measures were extracted for 210 patients treated with RT in 2005-2007, and who all completed patient-reported outcomes (PROs) at a median of 3.6 years post-RT. The rectum was digitally unfolded and 2D maps were created for each patient by interpolating across 25 points for 45°-sectors of each contour. The areas and extents (lateral and longitudinal) were calculated for dose thresholds between 35 and 75 Gy in 5 Gy steps over 9 equally distributed segments over the 2D maps (Fig. 1A), and their lateral and longitudinal combinations, resulting in a total of 216 spatial dose metrics. Univariate (UVA) followed by multivariate (MVA) analysis using logistic regression with 50 times iterated 5-fold cross-validation was applied to investigate the relationship between the spatial measures and 'at least a moderate severity' of five symptoms related to defecation urgency, fecal leakage, or obstruction. The prevalence for all investigated symptoms was 3 25%. The UVA and MVA were first conducted in 70% of the data, and the performance of the most frequent MVA model, judged by the area under the receiver-operating characteristics curve (AUC), was investigated in the complete cohort.

Results: On UVA 3-11 metrics (mean±SD: AUC=0.58±0.11) were suggested as potential predictors for the investigated symptoms (Table 1). The AUC of the final MVA models was 0.57-0.62 (Fig. 1B). Defecation urgency was explained by metrics related to high doses (>55 Gy), fecal leakage was governed by medium to high-dose extensions in the anterior part of the rectum, and obstruction by metrics related to the lower part of the rectum, as well as extents of the high dose (>75 Gy).

Figure 1. Left Panel: 2D map extracted from one of the patients; Right Panel: ROC plots for the five studied symptoms suggested by the final MVA models.

DEFECATION URGENCY 1: "Have to defecate before you feel like you can"			OBSTRUCTION 1: "Have to strain to pass stool"			OBSTRUCTION 2: "Strain to defecate"			FECAL LEAKAGE: "No defecation/leakage after defecation"		
Spatial Metric	AUC	SE	Spatial Metric	AUC	SE	Spatial Metric	AUC	SE	Spatial Metric	AUC	SE
Lateral Extent 65 Lower	0.57	0.08	ASH Low*	0.60	0.12	Lateral Extent 55	0.62	0.12	Longitudinal Extent 65 Left Side	0.60	0.12

Spacial Metric	AUC	SE	Longitudinal Extent 65 Right Side	0.57	0.13	Longitudinal Extent 65 Right Side	0.59	0.13	ASH Central Anterior*	0.59	0.09
Lateral Extent 55*	0.51	0.11	Longitudinal Extent 75	0.56	0.12	ASH Low Right Side*	0.60	0.11	Lateral Extent 75 Upper	0.58	0.12
ASH Upper*	0.50	0.10	A70 Lower Right Side	0.56	0.06	A70 Low Right Side	0.59	0.06	ASH Anterior Upper	0.58	0.09
ASH Left Side	0.50	0.10	ASH Low Left Side	0.56	0.11	Longitudinal Extent 65	0.56	0.14	Longitudinal Extent 75	0.58	0.10
			Lateral Extent 55 Upper Part	0.57	0.10	ASH	0.56	0.11	A70 Central Left Side	0.57	0.11
			ASH Left Side	0.55	0.12	Lateral Extent 75*	0.55	0.12	Longitudinal Extent 65 Right Side	0.56	0.12
			Longitudinal Extent 75*	0.56	0.11	ASH Left Side	0.52	0.13	Longitudinal Extent 65 Right Side	0.55	0.13
			A70 Central Left Side	0.54	0.10				Lateral Extent 65	0.54	0.11

Table 1. Proposed metrics as predictors of the different medical endpoints. These metrics were extracted from the UVA performed over the 70% of the data set, and all of them were not suitable (Pearson Coefficient < 0.75, LogP < 0.05) and the highest AUC (> 0.54). Underlined metrics were included in the final predictor model using a MVA. *A70 is the percentage size of the 2D map outlined by the contour of 70 Gy. * is a specific segment, the "Event 0" is the extension of the largest distal segment above 70 Gy for the different segments.

Conclusion: Our analysis suggests that spatial dose metrics explain symptoms of the gastrointestinal tract such as defecation urgency, fecal leakage and obstruction, and that these symptoms present spatial-specific relationships. The robustness of these results will be explored in other available cohorts (N>500) to evaluate whether these findings, and spatial dose metrics in general should be taken into account

in the RT planning and treatment for localized prostate cancer.

¹⁰Cliniche Gavazzeni-Humanitas, Radiotherapy, Bergamo, Italy

Purpose or Objective: To investigate the relationship between patient-reported acute urinary (GU) toxicity (tox) and bladder local dose distribution in patients (pts) treated with radical RT for prostate cancer (PCa) by a pixel-wise method for analysis of bladder surface dose maps (DSMs).

Material and Methods: Analyses were performed on the final cohort of pts of a multi-centric study, consisting of 539 pts with PCa treated with conventionally (CONV: 1.8 - 2Gy/fr) or moderately hypo-fractionated RT (HYPO: 2.2-2.7 Gy/fr) in 5 fx/week. GU tox was evaluated by the International Prostate Symptoms Score (IPSS) given to the pts at the beginning and at the end of RT, comprising 7 questions relating to different symp: feeling of incomplete emptying (EMP), frequency (FRE), intermittency (INT), urgency (URG), weak stream (WST), straining (STR) and nocturia (NOC). We here considered the seven symp separately and moderate/severe tox for each item was selected as endpoint (score at RT end), including only pts who had no disturbs before RT (IPSS at basal < 4). As different fractionation schemes were allowed, DSMs of all pts were corrected into 2Gy-equivalent maps using the LQ model, converting the dose in each pixel with an α/β equal to 10 Gy and a repair factor =0.7 Gy/day. DSMs of all pts were generated by unfolding the bladder: its contour was cut anteriorly at the points intersecting the sagittal plane passing through its centre of mass, normalised in the axial direction and aligned at the bladder base, at the posterior central point, generating a common frame for all pts. For each endpoint average DSMs of pts with/without tox were compared pixel by-pixel by two-sided t-tests, separately analyzing HYPO and CONV pts: the resulting p-value maps were used for identifying the regions better discriminating between pts with/without tox, considering a threshold of $p < 0.01$.

Results: DSMs of 437/539 pts (81%) were available (185 CONV and 252 HYPO). EMP was reported by 28/358 (8%) pts, FRE by 60/361 (17%), INT by 35/366 (10%), URG by 50/357 (14%), WST by 66/341 (19%), STR by 29/377 (8%) and NOC by 63/348 (18%) pts. For HYPO pts, areas significantly correlated with GU tox were found for all endpoints (excepting WST) in the posterior region at 5-17 mm from the base of bladder, consistently with the bladder trigone, with evidence of a threshold effect around 85 Gy (2Gy equivalent). For CONV pts, only 2 endpoints (FRE and URG) showed significantly predictive areas, robustly summarized in the % surface receiving >50-70Gy at 5mm from the base and the vertical extension of 50-70Gy isodoses along the bladder central axis. In the figure, the results concerning FRE and URG are shown.

Conclusion: The method of DSMS analysis allowed to assess new local-dose descriptors that might be better correlated with tox and promises to find important applications in investigating urinary tox. The incorporation of the found local dose predictors into multi-variable models including clinical predictors is currently in progress.

CT Image biomarkers improve the prediction of xerostomia and sticky saliva

N.M. Sijtsema¹, L.V. Van Dijk¹, C.L. Brouwer¹, R.J. Beukinga¹, A. Van der Schaaf¹, H.G.M. Burgerhof², J.A. Langendijk¹, R.J.H.M. Steenbakkers¹

¹University of Groningen- University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

²University of Groningen- University Medical Center Groningen, Epidemiology, Groningen, The Netherlands

Purpose or Objective: Current models for the prediction of xerostomia and sticky saliva after radiotherapy (RT) are based on clinical and dosimetric information. Our hypothesis is that such models can be improved by the addition of patient-specific characteristics, quantified in CT image biomarkers (IBMs). The aim of this study is to improve the performance of prediction models for patient-rated moderate-to-severe xerostomia (Xer12m) and sticky saliva (Stic12m) 12 months after radiotherapy with the addition of these IBMs obtained from CT images before the start of RT.

Material and Methods: Head and neck cancer patients were primarily treated with RT alone or in combination with systemic treatment. The patient rated complications were prospectively collected (EORTC QLQ-H&N35). The potential CT IBMs represent geometric (20), CT intensity (24) and pattern characteristics (88) of the CT-image of the parotid (PG) and submandibular (SG) glands. Furthermore, Xerbaseline, tumour, patient characteristics and mean doses to contra- and ipsi-lateral PG and SG were considered. Variables were preselected by omitting the least prognostic variable if inter-variable correlation was larger than 0.80. Lasso regularisation was used to create multivariable logistic regression models with and without IBMs to predict patient rated moderate-to-severe Xer12m and Stic12m. A repeated 10-fold cross validation was used to determine the optimal regularization term lambda. The final models were internally validated by testing the models on bootstrapped data.

Results: Of the 254 patients with follow-up information at 12 months, 100 (39%) and 62 (24%) had moderate-severe xerostomia and sticky saliva, respectively. Pre-selection of variables resulted in a selection of 26 variables for XER12m and 28 variables for STIC12m. For xerostomia, the lasso regularization selected in addition to mean contra-lateral PG dose and Xerbaseline, the image biomarker "Short Run Emphasis" (SRE). This CT IBM quantifies the occurrence of short lengths of CT intensity repetitions and thereby indicates the homogeneity of the parotid tissue. For sticky saliva, the IBM maximum CT intensity of the submandibular gland was selected in addition to STICbaseline and mean dose

to SGs. The maximum intensity of the SG was related with the intra-vascular contrast in the artery or vein supplying the SG.
 For the prediction of both Xer12m and STIC12m, the addition of the multivariable selected CT-IBMs improved the performance measures significantly compared to the models that were based on dose and baseline complaints only (table 1). The models were stable when internally validated.

Table 1. Model Performance of models prediction Xer_{12m} and Stic_{12m} with and without CT IBMs

	Xerostomia		Sticky saliva	
	No IBM model	IBM model	No IBM model	IBM model
Log-Likelihood-ratio test (p-value)	-	0.02	-	0.006
Discrimination Slope	0.18	0.20	0.13	0.16
AUC	0.74	0.76	0.73	0.75
AUC bootstrapped	0.74	0.76	0.73	0.74

Xerostomia model : (1) mean dose to contra lateral PG (2) Xer_{baseline} (3. IBM) Short Run Emphasis (SRE)
 Sticky saliva model : (1) Stic_{baseline} (2) mean dose to SGs (3. IBM) Maximum CT intensity

Conclusion: Prediction of XER12m and STIC12m could be improved with CT derived IBMs. The IBM associated with XER12m, "short run emphasis", might be a measure of non functional fatty parotid tissue. The STIC12m IBM, maximum intensity was related with the submandibular vascularization. Both predictive IBMs might be independent measures of radiosensitivity of the PG and SG.

³Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Department of Nuclear Medicine, Dresden, Germany

⁴German Cancer Research Center DKFZ Heidelberg and German Cancer Consortium DKTK partner site Dresden, Dresden, Germany

⁵Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology, Dresden, Germany

Purpose or Objective: Radiomics is a new emerging field in which machine-learning algorithms are applied to analyse and mine imaging features with the goal to individualize radiation therapy. The identification of an effective and robust machine-learning method through systematic evaluations is an important step towards stable and clinically relevant radiomic biomarkers. Thus far, only few studies have addressed this question. Therefore, we investigated different machine-learning approaches to develop a radiomic signature and compared those signatures regarding to their predictive power.

Material and Methods: Two datasets of patients with UICC stage III/IV advanced head and neck squamous cell carcinoma (HNSCC) were used for training and validation (N=23 and N=20, respectively, NCT00180180, Zips et al. R&O 105: 21-28, 2012). All patients underwent FMISO- and FDG-PET/CT scans at several time points. We defined 45 radiomic-based image features, which were extracted from the gross tumour volume, delineated in CT0/FDG-PET0 and FMISO-PET0 (baseline; 0 Gy), FMISO-PET20 (end of week 2; 20 Gy) and CT40 (end of week 4; 40 Gy). Furthermore, we computed the delta features CT40/CT0 as well as FMISO-PET20/FMISO-PET0, leading to 315 image features in total. Radiomic signatures were built for the endpoints local tumour control (LC) and overall survival (OS) based on a semi-automatic approach using Cox regression models (SA) and automatic methods using random forests (RF) as well as boosted Cox regression models (CB). All models are applied to continuous survival endpoint data and were trained on the training cohort using a repeated (50 times) 2-fold cross validation. The prognostic performance was evaluated on the validation cohort using the concordance index (CI).

Results: The SA signature achieved the best prognostic performance for local tumour control (CI=0.93). Furthermore, the CB and RF signatures performed well in the validation cohort (CI=0.86 and CI=0.74, respectively). The signature for overall survival built by the RF model achieved the best performance (CI=0.91, compared to CI=0.87 by the CB model and CI=0.77 by the SA method). Figure 1 exemplarily shows Kaplan-Maier curves determined by the SA radiomic signature for both endpoints. The patients could be statistically significantly separated into a low and high risk survival group in the training (LC: p=0.015 and OS: p=0.023) and the validation cohorts (LC: p=0.003 and OS: p=0.001).

Conclusion: Our evaluation reveals that the RF and the CB model yield the highest predictive performance for both endpoints. The obtained signatures and features will be tested for stability using further delineation datasets. The comparison of machine-learning methods within the Radiomics processing chain is one important step to increase the robustness of the results and standardization of methods.

VMAT plus few optimized non-coplanar IMRT beams is equivalent to multi-beam non-coplanar liver SBRT
 A.W.M. Sharfo¹, M.L.P. Dirkx¹, S. Breedveld¹, A.M. Mendez Romero¹, B.J.M. Heijmen¹
¹Erasmus MC Cancer Institute, Radiation Oncology/ Radiotherapy, Rotterdam, The Netherlands

Purpose or Objective: To compare fully non-coplanar liver SBRT with: 1) VMAT and 2) VMAT plus a few computer-optimized non-coplanar beams. Main endpoint was the highest feasible biologically effective dose (BED) to the tumor within hard OAR constraints.

Material and Methods: In our institution, liver metastases are preferentially treated with 3 fractions of 20 Gy. If not feasible for OAR constraints, the total dose of 60Gy is delivered in either 5 or 8 fractions. Assuming a tumor a/b of 10 Gy, the tumor BEDs for 3x20 Gy, 5x12 Gy, and 8x7.5 Gy are 180 Gy, 132 Gy, and 105 Gy, respectively. For fifteen patients with liver metastases we generated (i) plans with 15-25 computer-optimized non-coplanar IMRT beams (fully NC), (ii) VMAT plans, and (iii) plans combining VMAT with a few optimized non-coplanar IMRT beams (VMAT+NC). All plans were generated using our platform for fully automated multi-criterial treatment planning including beam angle optimization, based on the in-house iCycle optimizer and Monaco (Elekta AB, Stockholm, Sweden). For each patient and treatment technique we established the lowest number of feasible treatment fractions, i.e. 3, 5 or 8 to achieve highest possible tumor BED. All generated plans were clinically deliverable at our linear accelerators (Elekta AB, Stockholm, Sweden).

Results: Using 15-25 computer-optimized non-coplanar IMRT beams, 12 of the 15 patients (80%) could be treated with 3 fractions, one patient (7%) with 5 fractions, and two patients (13%) with 8 fractions. With VMAT only, achievable tumor BEDs were considerably lower for 1/3 of the patients, for 5 patients the fraction number needed to be increased to protect OARs: for 4 patients from 3 to 5 and for 1 from 5 to 8 (Table). Otherwise the healthy liver constraint (1 patient), or the constraint for the stomach (2 patients), bowel (1 patient) or oesophagus (1 patient) would be exceeded. With VMAT+NC, for all 5 patients this could be fully restored, resulting in the same low fraction numbers as for fully NC (Table). Contributions of the added NC IMRT beams to the PTV mean dose were relatively high: one patient needed a single IMRT beam with a weight of 14.8%, 1 patient needed 2 IMRT beams with a total weight of 39.9%, 2 patients required 3 IMRT beams with total weights of 45.5% and 47.7%, and 1 patient had 4 IMRT beams with a total weight of 46.1%.

Table. Number of patients planned per technique per fractionation regimen.

	3 fractions (BED = 180 Gy)	5 fractions (BED = 132 Gy)	8 fractions (BED = 105 Gy)
Fully NC	12	1	2
VMAT	8	4	3
VMAT+NC	12	1	2

Abbreviations: Fully NC = plans with 15-25 computer-optimized non-coplanar IMRT beams, VMAT = Volumetric Modulated Arc Therapy, VMAT+NC = plans combining VMAT with few optimized non-coplanar IMRT beams, BED = Biologically Effective Dose.

Conclusion: A novel approach for liver SBRT at a linear accelerator was developed. The basis of the treatment is a fast VMAT plan, supplemented with a few (1-4) computer-optimized non-coplanar IMRT beams. In terms of achievable tumor BED within the clinical OAR constraints, this approach is equivalent to time-consuming, fully non-coplanar treatment. The technique is currently also explored for other treatment sites.

Fast biological RBE modeling for carbon ion therapy using the repair-misrepair-fixation (RMF) model

F. Kamp^{1,2,3}, D. Carlson⁴, J. Wilkens^{1,2}
¹Technische Universität München- Klinikum rechts der Isar, Department of Radiation Oncology, Munich, Germany
²Technische Universität München, Physik-Department, Munich, Germany
³Klinikum der Universität München, Klinik und Poliklinik für Strahlentherapie und Radioonkologie, Munich, Germany
⁴Yale University School of Medicine, Department of Therapeutic Radiology, New Haven, USA

Purpose or Objective: The physical and biological advantages of carbon ion beams over conventional x-rays have not been fully exploited in particle therapy and may result in higher levels of local tumor control and improvements in normal tissue sparing. Treatment planning must account for physical properties of the beam as well as differences in the relative biological effectiveness (RBE) of ions compared to photons. In this work, we present a fast RBE calculation approach, based on the decoupling of physical properties and the $(\alpha/\beta)_x$. The $(\alpha/\beta)_x$ ratio is commonly used to describe the radiosensitivity of irradiated cells or organs. The decoupling is accomplished within the framework of the repair-misrepair-fixation (RMF) model.

Material and Methods: Carbon ion treatment planning was implemented by optimizing the RBE-weighted dose (RWD) distribution. Biological modeling was performed with the RMF and Monte Carlo Damage Simulation (MCDS) models. The RBE predictions are implemented efficiently by a decoupling approach which allows fast arbitrary changes in $(\alpha/\beta)_x$ by introducing two decoupling variables c_1 and c_2 . Dose-weighted radiosensitivity parameters of the ion field are calculated as (Fig 1). This decoupling can be used during and after the optimization.

$$\alpha_D = \alpha_x \cdot c_1 + \beta_x \cdot c_2 \text{ and } \beta_D = \beta_x \cdot c_1^2 \text{ resulting in}$$

$$RBE_{RMF}(c_1, c_2, (\alpha/\beta)_x, d) = \frac{-(\alpha/\beta)_x + \sqrt{(\alpha/\beta)_x^2 + 4d(c_1(\alpha/\beta)_x + c_2 + c_1^2 d)}}{2d}$$

Carbon ion treatment plans were optimized for several patient cases. Predicted trends in RBE are compared to published cell survival data. A comparison of the RMF model predictions with the clinically used Local Effect Model (LEM1 and 4) is performed on patient cases.

Figure 1: Axial CT slice of a treatment plan using the RMF model. The astrocytoma plan with two carbon ion fields was

optimized on 3 Gy(RBE) using a spatially constant $(\alpha/\beta)_x = 2$ Gy ($\alpha_x = 0.1 \text{ Gy}^{-1}$, $\beta_x = 0.05 \text{ Gy}^{-2}$). The PTV is shown in red, along with 3 organs at risk: left optic nerve (green), left eye (orange) and left lens (brown). The panels show A) RWD, B) RBE, C) physical dose d and the beam geometry in D. The two decoupling variables c_1 and c_2 are shown in panels E and F, along with αD and βD in panels G and H.

Results: The presented implementation of the RMF model is very fast, allowing online changes of the $(\alpha/\beta)_x$ including a voxel-wise recalculation of the RBE. For example, a change of the $(\alpha/\beta)_x$ including a complete biological modeling and a recalculation of RBE and RWD for 290000 voxels took 4 ms on a 4 CPU, 3.2 GHz workstation. Changing the $(\alpha/\beta)_x$ of a single structure, e.g. a planning target volume (PTV) of 270 cm^3 (35000 voxels), takes 1 ms in the same computational environment. The RMF model showed reasonable agreement with published data and similar trends as the LEM4.

Conclusion: The RMF model is suitable for radiobiological modeling in carbon ion therapy and was successfully validated against published cell data. The derived decoupling within the RMF model allows extremely fast changes in $(\alpha/\beta)_x$, facilitating online adaptation by the user. This provides new options for radiation oncologists, facilitating online variations of the RBE during treatment plan evaluation.

OC-0265

Efficient implementation of random errors in robust optimization for proton therapy with Monte Carlo
 A.M. Barragán Montero¹, K. Souris¹, E. Sterpin¹, J.A. Lee¹
¹Cliniques Universitaires Saint Luc UCL Bruxelles, Molecular Imaging Radiation Oncology MIRO, Brussels, Belgium

Purpose or Objective: In treatment planning for proton therapy, robust optimizers typically limit their scope to systematic setup and proton range errors. Treatment execution errors (patient and organ motion or breathing) are seldom included. In analytical dose calculation methods as pencil beam algorithms, the only way to simulate motion errors is to sample random shifts from a probability distribution, which increases the computation time for each simulated shift. However, the stochastic nature of Monte Carlo methods allows random errors to be simulated in a single dose calculation.

Material and Methods: An in-house treatment planning system, based on worst-case scenario optimization, was used to create the plans. The optimizer is coupled with a super-fast Monte Carlo (MC) dose calculation engine that enables computing beamlets for optimization, as well as final dose distributions (less than one minute for final dose). Two strategies are presented to account for random errors: 1) Full robust optimization with beamlets that already include the effect of random errors and 2) Mixed robust optimization, where the nominal beamlets are involved but a correction term C modifies the prescription. Starting from $C=0$, the method alternates optimization of the spot weights with the nominal beamlets and updates of C , with $C = D_{\text{random}} - D_{\text{nominal}}$ and where D_{random} results from a regular MC computation (without pre-computed beamlets) that simulates random errors. Updates of C can be triggered as often as necessary by running the MC engine with the last corrected values for the spot weights as input. MC simulates random errors by shifting randomly the starting point of each particle, according to the distribution of random errors. Such strategy assumes a sufficient number of treatment fractions. The method was applied to lung and prostate cases. For both patients the range error was set to 3%, systematic setup error to 5mm and standard deviation for random errors to 5 mm. Comparison between full robust optimization and the mixed strategy (with 3 updates of C) is presented.

Results: Target coverage was far below the clinical constraints ($D_{95} > 95\%$ of the prescribed dose) for plans where random errors were not simulated, especially for lung case. However, by using full robust or mixed optimization strategies, the plans achieved good target coverage (above

clinical constraints) and overdose comparable to the nominal case. Doses to organs at risk were similar for the three plans in both patients.

		CTV _{mean} 74 Gy	CTV _{low} 60 Gy
worst D ₀	Nominal plan	67.1	38.2
	Full robust optimization	73.3	59.8
	Mixed robust optimization	70.2	56.4
worst D ₁	Nominal plan	77.8	62.4
	Full robust optimization	76.9	62.6
	Mixed robust optimization	78.2	69.9

Conclusion: The proposed strategies achieved robust plans in term of target coverage without increasing the dose to the CTV nor to the organs at risk. Full robust optimization gives better results than the mixed strategy, but the latter can be useful in cases where a MC engine is not available or too computationally intensive for beamlets calculation.

OC-0266

Automated treatment plan generation for advanced stage NSCLC patients
 G. Della Gala¹, M.L.P. Dirks¹, N. Hoekstra¹, D. Franssen¹, M. Van de Pol¹, B.J.M. Heijmen¹, S.F. Petit¹
¹Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

Purpose or Objective: The aim of the study was to develop a fully automated treatment planning procedure to generate VMAT plans for stage III/IV non-small cell lung cancer (NSCLC) patients, treated with curative intent, and to compare them with manually generated plans.

Material and Methods: Based on treatment plans of 7 previously treated patients, the clinical protocol, and physician's treatment goals and priorities, our in-house developed system for fully automated, multi-criterial plan generation was configured to generate VMAT plans for advanced stage NSCLC patients without human interaction. For 41 independent patients, treated between January and August 2015, automatic plan generation was then compared with manual plan generation, as performed in clinical routine. Differences in PTV coverage, dose conformity R50 (the ratio between the total volume receiving at least 50% of the prescribed dose and the PTV volume) and sparing of organs at risk were quantified, and their statistical significance was assessed using a Wilcoxon test.

Results: For 35 out of 41 patients (85%), the automatically generated VMAT plans were clinically acceptable as judged by two physicians. Compared to the manually generated plans, they considered the quality of automatically generated plans superior for at least 67% of patients, due to a combination of better PTV coverage, dose conformity and sparing of lungs, heart and oesophagus (positive values in figure). For the other acceptable plans plan quality was considered equivalent. On average, PTV coverage (V95) was improved by 1.1 % ($p < 0.001$), the near-minimum dose in the PTV (D99) by 0.55 Gy ($p = 0.006$) and the R50 by 12.4% ($p < 0.001$). The mean lung dose was reduced by 0.86 Gy (4.6%, $p < 0.001$), and the V20 of the lungs by 1.3 % ($p = 0.001$). For some patients it was possible to improve PTV V95 by 3.8%, D99 by 3.3 Gy, to reduce mean lung dose by 3.0 Gy and

V20 by 6.2%. All plans fulfilled the planning constraints for the spinal cord, heart and plexus.

For the 6 automated VMAT plans that were initially not acceptable, it took a dosimetrist less than 10 minutes hands-on time to manually fine-tune the VMAT plan in our TPS to make it acceptable. In contrast, to generate a VMAT plan from scratch 3-4 hours were required.

For 5 out of 10 patients with a PTV prescription dose of less than 66 Gy in the manual plan, we were able to escalate the tumour dose using automated planning. For two patients dose escalation from 60 Gy to 66 Gy was possible, for other patients from 60.5 Gy to 66 Gy, 45 Gy to 57.75 Gy, and 55 Gy to 60.5 Gy, respectively.

Conclusion: Using our fully automated treatment planning procedure, clinically deliverable, high quality VMAT plans for advanced stage NSCLC patients may be generated without human interaction for the far majority of patients. When manual adjustments were required, they took very little hands-on time only. With automated planning, a higher tumour dose could be achieved for a subgroup of patients. Clinical introduction has been started.

OC-0267

Fully automated planning for non-coplanar CyberKnife prostate SBRT - comparison with automatic VMAT

L. Rossi¹, S. Breedveld¹, S. Aluwini¹, B. Heijmen¹

¹Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

Purpose or Objective: In stereotactic body radiation therapy, high accuracy is required to deliver high fraction doses with steep dose gradients. Non-coplanar beam setups may improve plan quality. This can be realized with a robotic CyberKnife (CK, Accuray Inc, Sunnyvale, USA). Due to its tumor tracking features, CTV-PTV margins may be reduced compared to linac treatment. In previous works we have built and validated a system for fully automated, multi-criterial VMAT plan generation (iCycle/Monaco). Recently, we have extended the system with an option for fully automated plan generation for the CK (iCycle/Multiplan). In this study we have used fully automated plan generation for un-biased comparison of non-coplanar CK with coplanar VMAT at a linac, for prostate SBRT.

Material and Methods: Our in-house iCycle system was first coupled to the Multiplan TPS that comes with the CK treatment unit. The iCycle/Multiplan and iCycle/Monaco systems were then configured for automated prostate SBRT plan generation for CK and linac-VMAT, respectively. Plans were then generated for 10 prostate SBRT patients, delivering 38 Gy in 4 fractions. Three clinically deliverable

plans were automatically generated for each patient, one for CK with 3 mm PTV margin, and two for VMAT with 3 and 5 mm PTV margin, respectively.

Results: With automated planning, high quality CK and VMAT plans could be generated without user dependency and trial-and-error approach. PTV coverage was similar for the 3 approaches, with on average a V100% of 95.2, 95.4%, and 94.1% for CK, VMAT-3mm and VMAT-5mm. However, for some VMAT plans with 5mm margin, coverage > 95% was not feasible. Mean values for rectum D1cc were 26.1, 28.5, and 34.3 Gy, for rectum Dmean 6.3, 7.1, and 10.8 Gy, for bladder D1cc 37.7, 37.3, and 39.4 Gy, and for bladder Dmean 8.7, 7.5, and 9.2 Gy, for CK, VMAT-3mm and VMAT-5mm, respectively. Rectum doses were lower with CK compared to VMAT-3mm ($p = 0.015$ and $p = 0.08$ for rectum D1cc and Dmean) and highly decreased compared to VMAT-5mm ($p = 0.007$ and 0.008). Bladder sparing worsened slightly with CK compared to VMAT-3mm, but this was not statistically significant. No relevant differences were found for other OARs. With CK, the low-medium dose bath was reduced compared to VMAT: V10Gy = 1157.5, 1525.6, 1741.8 cc, V20Gy = 286.3, 325.5, 382.0 cc, for CK, VMAT-3mm and VMAT-5mm, with $p = 0.007$ and $p=0.008$ for CK comparing to VMAT 3 and 5 mm.

Conclusion: The first system for automated generation of clinically deliverable Cyberknife plans was built and used for unbiased plan comparison with VMAT at a linac. Optimized non-coplanar setups showed better rectum sparing compared to VMAT plans. This difference was especially large with the smaller CK CTV-PTV margin, possible with CyberKnife tumor tracking feature.

⁴Medical University Vienna /AKH Wien, Radiation Oncology, Vienna, Austria

⁵St James's Institute of Oncology- St James's Hospital, Radiation Oncology, Leeds, United Kingdom

⁶University Medical Center Mannheim- Heidelberg University, Radiation Oncology, Mannheim, Germany

Purpose or Objective: Recently, iCycle/Monaco, a system for fully automated, multi-criterial plan generation, consisting of the in-house iCycle optimizer and Monaco (Elekta AB, Stockholm, Sweden) has been developed. So far, the system was only validated in a single institution. In this study, iCycle/Monaco was validated in 4 independent centers for prostate cancer VMAT. Hypothesis of the study was that automatically generated plans had similar or superior quality compared to plans generated by manual planning in clinical routine, using the Monaco TPS only.

Material and Methods: For each of the 4 centers, plans of 10 recently treated patients were used to configure iCycle/Monaco. For 20 independent patients, manually generated VMAT plans (MANplan) were then compared with automatically generated VMAT plans (AUTOplan). Plans were compared using dose-volume parameters and by 'blind' scoring by treating physicians. The scoring of the plans by physicians was performed in 2 sessions: A) the in total 40 anonymized plans (20 AUTO, 20 MAN) were evaluated in random order to assess clinical acceptability, B) for each of the 20 patients, the AUTOplan and MANplan were compared to select the most favorable plan. In these comparisons, plans could be scored as i) of higher quality with a clinically

relevant difference, ii) of higher quality but with a low clinical impact, or iii) of similar quality. In one participating center, plan scoring was performed independently by 2 physicians.

Results: A total of 200 separate plan evaluations and 100 plan comparisons were made in this study. In the separate plan evaluations, 100% of MANplans and 98% of AUTOplans were clinically acceptable. The 2 AUTOplans that were not clinically acceptable had too high bowel dose, which was due to the absence of patients with small bowel delineation among the patients used for configuration of iCycle/Monaco in 2 centers. For 38/100 plan comparisons, the AUTOplan was considered superior to the MANplan, with high clinical relevance. Only in 9 comparisons, the MANplan was superior with high relevance for the patient. In all other comparisons, differences were absent or of minor clinical relevance (Figure). With similar PTV coverage, dose delivery to OARs was on average lower for the AUTOplans: -14.8%, -24.6%, and -14.6% for rectum V75, V60, and Dmean ($p=0.001$, $p<0.001$, $p<0.001$), and -5.1% for bladder Dmean ($p=0.009$).

Frequency histogram showing the scores for 100 comparisons of an automatically (AUTO) and a manually (MAN) generated plan.

Conclusion: In an international, multi-institutional setting, automatic planning for prostate cancer has proven to be overall superior to manual planning. Automated planning avoids planning workload and contributes to standardized radiotherapy treatment with high plan quality.

Comparison of dosimetric parameters of two techniques with VMAT for head and neck cancers

M. Miyazaki¹, Y. Ueda¹, S. Ohira¹, K. Tsujii¹, M. Isono¹, A. Masaoka¹, T. Teshima¹

¹Osaka Medical Center for Cancer and Cardiovascular Diseases, Radiation Oncology, Osaka, Japan

Purpose or Objective: Simultaneously integrated boost (SIB) used in many sites, replanning is not made. In SIB of intensity-modulated radiotherapy (IMRT), doses per fraction are often unconventional, because of equal fractions treating multiple targets. We assessed sequential SIB (SEQ-SIB) to resolve the problem. The purpose of this study is to compare dosimetric parameters of SEQ-SIB with those of SIB using deformable imaging registration (DIR) for head and neck cancer patients.

Material and Methods: Subjects were 10 cases HNC treated with IMRT at our institute in 2014. In all cases, high-risk planning target volume (PTVboost) was based on the primary tumor and clinical lymph node metastases, while PTVelective (PTVel) included bilateral cervical nodal areas. The D95 was defined as the prescribed dose. For SIB, doses were 66 and 54 Gy in 30 fractions to PTVboost and PTVel, respectively. For SEQ-SIB, they were 55 Gy to PTVboost and 50 Gy to PTVel in 25 fractions using SIB, followed by 11 Gy in

5 fractions to PTVboost. We chose to maintain the size of the original GTV when contouring the GTV on the anatomy of the second CT scan. SIB created two plans. One is 1st CT / 1st Plan and the other is SIB sum (25 fractions (deformed CT) and 5 fractions (2nd CT)). A deformed CT (dCT) with structures was created by deforming the 1st CT to the 2nd CT. We summed up dose used in 1st Plan and 2nd Plan using a commercial software (MIM Maestro 6.3). The two types of plans were compared with respect to DVHs for other dosimetric parameters of the PTVboost, PTVel, brainstem, spinal cord and parotid gland.

Results: The mean dose for the brainstem, the spinal cord and the parotid was lower for SEQ. The D95 of PTVboost and PTVel were significantly lower for SIB sum than for SIB ($p<0.003$, $p<0.02$). The D95 of PTVboost and PTVel were significantly lower for SIB sum than for SEQ-SIB ($p<0.03$, $p<0.03$). The difference between the CI of PTVboost of SIB sum and that of SEQ-SIB was not significant ($p=0.03$). The CI of PTVel was significantly lower for SIB sum than for SEQ-SIB ($p<0.001$).

Table 1. Dosimetric Parameters (means of 10 cases)

	brainstem max (Gy)	spinalcord max (Gy)	mean parotid dose ipsi (Gy) contra (Gy)	PTVboost D95 (Gy)	PTVel D95 (Gy)	PTVboost CI	PTVel CI
SIB	36.9	36.2	32.5 23.2	66	54.6	1.11	1.1
SIB sum	37.5	36.4	33.6 24.2	64.9	53.7	1.04	1.07
SEQ-SIB	34	34.2	32.4 22.4	65.7	50.8	1.08	1.19

Conclusion: SEQ-SIB is an approach for resolving the fraction size problem posed by SIB. The dosimetric parameters for OARs showed some variation between SIB and SEQ-SIB, especially for the parotid glands. SEQ-SIB is good in the point of coverage of PTV, because of replanning. The mean dose for ipsilateral and contralateral parotid was lower for SEQ-SIB, because of the lower elective dose. The availability of SEQ-SIB using replanning was suggested.

Development of a model to produce reference parotid dose from anatomical parameters in IMRT of NPC

W.S. Leung^{1,2}, V.W.C. Wu², F.H. Tang², A.C.K. Cheng¹

¹Princess Margaret Hospital, Department of Oncology, Kowloon, Hong Kong SAR China

²The Hong Kong Polytechnic University, Department of Health Technology and Informatics, Hong Kong, Hong Kong SAR China

Purpose or Objective: Dose to parotid glands in IMRT depended on the setting of constraints during inverse planning and could be varied by planners' experience. This study aimed to tackle the problem of IMRT plan variability by the development of a multiple regression model to associate parotid dose and anatomical factors. By measuring a few anatomical factors before performing inverse planning, reference parotid dose would be suggested by the model to guide planners to undergo the inverse planning optimization process.

Material and Methods: 25 NPC subjects who previously received radical IMRT (70Gy/60Gy/54Gy in 33-35 fractions) were randomly selected. Optimized IMRT plans produced by a single planner were used for data collection. Multiple regression was performed using parotid gland Dmean, and D50% as the dependent variable, and various anatomical factors as the independent variable. The anatomical factors included (1) gland size, (2) %volume with 1cm gap from PTV60, (3) volume with 1cm gap from PTV60, (4) %volume overlap with PTV60, (5) volume overlap with PTV60, (6) %volume overlap with PTV70, (7) volume overlap with PTV70 (8) max. distance from PTV60 and (9) max. distance from PTV70. Gland size was measured using the "measure volume" function. Volume with 1cm gap was measured by using "crop structure" function and cropping the parotid with 1cm gap from the PTV60. Volume overlap with PTV was measured by using the "Boolean operator" which created the overlapped

volume. Max. distance was measured by the magnitude of expanding the PTV using the "margin for structure" function until the PTV covered the whole parotid gland. Multiple regression was performed using the stepwise method which eliminated independently variables with least effect.

Results: Anatomical factors statistical significantly predicted parotid gland Dmean and D50%. For Dmean, gland size, %volume overlap with PTV60 and %volume with 1cm gap from PTV60 were included in the model. (F(3, 46) = 44.244, p<0.0005, R2 = 0.743). For D50%, volume overlap with PTV60, %volume with 1cm gap from PTV60 and gland size were included in the model. (F(3, 46) = 37.709, p<0.0005, R2 = 0.711).

Conclusion: These models explained over 70% of the dependent variables. Cross validation will be provided to support the accuracy of the model. The predicted parotid dose could be used for a guide to set dose constraints during inverse planning and as the benchmark dose during plan evaluation. Eventually the suggested model could improve the parotid sparing in the IMRT of NPC cases.

Positional accuracy valuation of a three dimensional printed device for head and neck immobilisation

K. Sato¹, K. Takeda¹, S. Dobashi¹, K. Kishi², N. Kadoya³, K. Ito³, M. Chiba³, K. Jingu³

¹Tohoku University Graduate School of Medicine, Department of Radiotherapy- Course of Radiological Technology- Health Sciences, Sendai, Japan

²Tohoku Pharmaceutical University Hospital, Department of Radiation Technology, Sendai, Japan

³Tohoku University School of Medicine, Department of Radiation Oncology, Sendai, Japan

Purpose or Objective: Our aim was to investigate the feasibility of a three-dimensional (3D)-printed head-and-neck (HN) immobilization device by comparing its positional accuracy with that of the conventional thermoplastic mask.

Material and Methods: We prepared a 3D-printed immobilization device (3DID) consisting of a mask and headrest developed from the computed tomography (CT) data obtained by imaging an HN phantom. The CT data was reconstructed to generate the Digital Imaging and Communication in Medicine (DICOM) dataset. Then, the HN-phantom surface was determined by the Otsu segmentation method. After converting the DICOM dataset of the phantom surface to a Surface Tessellation Language (STL) file format, 3D modeling was performed. Next, the STL file was 3D printed using acrylonitrile-butadiene-styrene resin. For comparison of positional accuracy, the conventional immobilization device (CID) composed of a thermoplastic mask and headrest was prepared using the same HN phantom. Subsequently, the simulation CT images were acquired after fixing the HN phantom with 3DID. After positioning the HN phantom by matching surface marks, radiographs were acquired using the ExacTrac X-ray image system. Then, we quantified the positional deviations, including three translations and three rotations, between the coordinate origin in the localization images prepared from kV X-rays and the expected position on the digitally reconstructed radiograph from the simulation CT images. This process was repeated fifteen times to collect data on positional deviations. Afterwards, the same procedure was performed in the same HN phantom fixed with CID for comparison.

Results: The translational displacement (mean [standard deviation, SD]) in the vertical, lengthwise, and lateral directions was -0.28 [0.09], -0.02 [0.08], and 0.31 [0.27] [maximum, 0.81 mm (lateral direction)] for 3DID and 0.29 [0.06], 0.03 [0.14], and 0.84 [0.27] [maximum, 1.23 mm (lateral direction)] for CID, respectively. The rotational shift in the yaw, roll, and pitch directions was 0.62 [0.13], 0.08 [0.74], and -0.31 [0.08] [maximum, -0.41° (pitch direction)] for 3DID and 0.15 [0.17], 0.17 [0.67], and -0.09 [0.06]

[maximum, -1.23° (roll direction)] for CID, respectively. The means of the two devices were almost similar in each direction except the vertical, lateral, and pitch directions (t-test, p < 0.0001), whereas the maximal deviations in the three directions were slight. The SDs were not statistically different in each direction except the lengthwise and roll directions (F-test, p < 0.05), although the SDs were small in the corresponding two directions for CID.

Conclusion: This study suggested that 3DID could show positional accuracy almost similar to that of CID. However, further investigation is needed for use in clinical practice.

OC-0272

A comparison of CTCAE version 3 and 4 in assessing oral mucositis in oral/oropharyngeal carcinoma

M. Hickman¹, J. Good², A. Hartley², P. Sanghera²

¹University Hospital Birmingham, Radiotherapy, Birmingham, United Kingdom

²InHANSE- University of Birmingham, Radiotherapy, Birmingham, United Kingdom

Purpose or Objective: CTCAE version 3 is an observation based grading system for oral mucositis whereas version 4 is based on function and intervention. Although version 4 has been widely adopted in clinical trials there is limited data on its correlation with version 3 from which considerable radiobiological data has been derived. The purpose of this study was to assess the frequency of discrepancy between these two grading systems.

Material and Methods: Oral mucosal reactions of patients undergoing chemoradiation or radiation alone for oral or oropharyngeal cancer were graded by three radiation oncologists in weekly on treatment and post treatment clinics. CTCAE version 3 and 4 mucositis grading and patient factors were recorded prospectively. Differences in the rate of discrepancy were compared by time since the commencement of radiotherapy, synchronous agent and patient age.

Results: 485 measurements were recorded for 64 patients. Grading from version 3 and version 4 were equal in 270 (56 %) measurements. In the 215 (44%) measurements where version 3 and version 4 were not equal, discrepancies were seen in: Week 0-4 = 79/179 (44%); Week 5-8 = 60/163 (37%); > week 8 = 76/143 (53%) (p=0.02); patients receiving platinum agents = 113/316 (36%) or cetuximab = 48/70 (69%) (p<0.01); patients > 70 years = 26/57 (46%) or < 50 years = 21/68 (31%) (p=0.09).

Conclusion: Statistically significant discrepancies were seen when patients receiving platinum agents were compared with those receiving cetuximab and in those measurements performed following treatment completion. These initial results suggest that functional/interventional based grading systems should be used with care in dose escalation studies where the healing of acute mucositis may be related to subsequent late damage.

OC-0273

Including specific symptoms in clinical scoring: predictive modelling and nursing of swallowing pain

D. Nyeng Christiansen¹, K. Olling¹, L. Wee¹

¹Vejle Hospital, Radiotherapy Department, Vejle, Denmark

Purpose or Objective: Acute esophagitis (AE) is a common side-effect of radiotherapy (RT) for lung cancer. Previous predictive modelling studies focussed on clinical criteria (such as CTC) for significant AE (such as G2 or higher). Our clinic uses an integrative patient care approach where Nurse-RTTs routinely monitor symptoms and provide nursing interventions to manage side-effects. Therefore, Nurse-RTTs include with clinical scoring a note of actual symptoms mentioned by the patient during consultations, such as swallowing pain (SP). A retrospective audit of 131 patients was used to examine correlative patterns for SP, and hence to develop predictive models for SP before the start of RT. We propose that a predictive model will facilitate nurse/RTT-

led efforts to reduce the impact of SP on patient comfort, overall QoL and clinical workflow.

Material and Methods: An electronic journal audit was performed for patients commencing curative RT for lung cancer between January 2013 and March 2015. All NSCLC and SCLC patients were included, as well as various dose/fractionation, chemotherapy and medication schedules. Exported treatment plan DVHs were merged with nursing data. The highest score following weekly assessments of AE during radiotherapy was recorded, as was the appearance of SP and the time point at which it was mentioned. Predictive models of SP were developed using multivariable regression and machine learning algorithms.

Results: The most typical patient was treated for NSCLC at 60-66Gy normo-fractionated with concurrent chemotherapy. Acute esophagitis (CTC grade 1 or higher) was observed in 110/131 (84%) and patient-reported SP in 99/131 (76%). Pain medication prior to RT was marginally protective against SP but was not statistically significant in single-parameter analysis (OR 0.58, 95%CI 0.24-1.41, $p=0.21$). A strongly significant dose-volume response exists between SP and radiobiologically-adjusted dose to the hottest 1cc of the esophagus. Predictive models of SP with repeated cross-validation accuracy of 78-84% were developed (sensitivity 88-89%, specificity 48-75%). Trained machine learning models correctly predicted SP 76-84% of the time in an unseen validation cohort of 25 patients (sensitivity 94-100%, specificity 25-62%).

Conclusion: An integrative nursing care approach in the RT clinical workflow has been used to monitor symptoms and intervene for treatment-related pain. The risk of one particular patient-centred symptom, SP, can be sensitively predicted with nursing and treatment planning variables. A future nurse-led interventional study is planned, using predictive modelling for swallow pain, to examine the possible effects of pre-treatment pain-medication or corticosteroids on reducing dependence on additional pain medication.

OC-0274

Analysis of set-up errors in head and neck cancer treated with IMRT technique assessed by CBCT

D. Delishaj¹, S. Ursino¹, E. Lombardo¹, F. Matteucci¹, C. La Liscia¹, A. Sainato¹, F. Pasqualetti¹, B. Manfredi¹, L.R. Fatigante¹, M. Panichi¹, S. Spagnesi¹, M.G. Fabrini¹

¹Azienda Ospedaliero Universitaria Pisana, Radiotherapy, Pisa, Italy

Purpose or Objective: The aim of this study was to investigate systemic set-up errors in head and neck (H&N) cancer treated with intensity modulated radiation therapy (IMRT) by kilovoltage (kV) cone-beam computed tomography (CBCT) evaluation.

Material and Methods: Between September 2014 and August 2015, 360 CBCT in 60 patients (pts) affected by histological confirmed H&N cancer treated with IMRT technique were analyzed. The majority of patients treated 45 (75 %) were male and only 15 (25%) were female; median age was 68 years (range 44-88 years). The type of head and neck cancer treated were, oropharynx, hypopharynx, nasopharynx, larynx, tonsil, oral cavity and parotid cancer. All patients underwent planning Computerized Tomography (CT) simulation on supine position on a GE LightSpeed RT 16 CT Simulator for 2.5 mm slice thicknesses. As immobilization system we utilized a head-shoulder thermoplastic mask (Easy Frame (Candor TM)). The CT data sets were transferred to the Focal and Varian Eclipse treatment planning system through DICOM network. The target delineation was contoured by one Radiation Oncologist and according to (ICRU62) the PTVs volumes were generated by adding a 3-mm margin in all directions to the respective CTVs. The prescribed dose was 66 Gy in 30 fractions delivered to GTVs, 54-63 Gy in 30 fractions to CTVs. The IMRT plans were created on the Varian Eclipse treatment planning system

using coplanar beams with 6 MV photons and the treatment was performed with DHX LINAC, VARIAN System. Pretreatment kV CBCT images were obtained at 1, 2 and 3 day of irradiations set-up corrections were made before treatment if the translational setup error was greater than 3 mm in any direction. Subsequently a weekly kV CBCT was repeated for whole duration of treatment.

Results: A total of 360 CBCT scans were acquired and analyzed. The systemic errors results 1.26 mm (SD \pm 0.177) in RL direction, 1.25 mm (SD \pm 0.187) in SI direction and 1.8 mm (SD \pm 0.255 in AP direction. The range of deviations were 0-9 in RL directions, 0-5 mm in SI direction and 0-10 mm in AP direction. The frequencies of setup errors > 3 mm in RL direction was 3.9 %, in SI 8 % and AP directions 15.5 %, respectively. Analyzing the CBCT before set-up corrections the frequencies of set-up error > 3 mm were 17.8 %, 10.6 % and 5.6 % in AP, SI and RL respectively. After set-up errors corrections (corrections via couch shifts or patient repositioning) these rates were reduced to 13,3%, 7.2 and 2.2 % in PA, SI and RL direction, respectively.

Conclusion: The results of our study confirmed that image guidance with kV CBCT represents an effective tool for measuring set-up accuracy in the treatment of H&N cancer patients. This study suggested that kV CBCT once a week is adequate to overcome the problem of set-up errors in head and neck cancer treated with IMRT technique.

IMRT for non-small cell lung cancer: a decade of experience at the Ghent University Hospital.

P. Desevne¹, Y. Lievens¹, W. De Gersem¹, P. Berkovic², M. Van Eijkeren¹, V. Surmont³, C. Derie¹, B. Goddeeris¹, W. De Neve¹, K. Vandecasteele¹

¹Ghent University Hospital, Radiation Oncology Department, Ghent, Belgium

²CHU Liège, Radiation Oncology Department, Liège, Belgium

³Ghent University Hospital, Thoracic Oncology Department, Ghent, Belgium

Purpose or Objective: In 1998, our institute developed a class-solution for intensity-modulated radiotherapy (IMRT) for lung cancer. Clinical implementation of IMRT gradually started as of 2002. This retrospective study reports on toxicity and overall survival (OS) of non-small cell lung cancer (NSCLC) patients treated with curative intent using the described IMRT set-up.

Material and Methods: Between 2002 and 2013, a total of 434 patients with a thoracic malignancy have been treated with IMRT in the Radiation Oncology department of the Ghent University Hospital. Those with NSCLC and receiving a total dose of \geq 60Gy with fraction size <3Gy, a total 223, were retrospectively reviewed and formed the basis of this analysis. Clinical endpoints of OS and acute and late pulmonary and esophageal toxicity grade \geq 3 were analyzed in relation to chemotherapy (concomitant vs. sequential chemoradiotherapy (CRT) vs. no chemotherapy) and use of standardized dose-volume evaluation criteria. Analysis was performed in SPSS using Kaplan-Meier curves for survival and Chi-square analysis for toxicity.

Results: Median follow-up time is 18 months (range 2-125). The table reports patient, tumor and treatment characteristics. OS was scored for all patients as date of death (N=140) or, if missing, as date of last consultation in our hospital (N=83). Acute and late toxicity data were available for 219 and 95 patients respectively. Median OS for the entire population was 25 months, 5 year OS 24%. OS was significantly better for patients treated with concomitant CRT than for those undergoing the sequential approach (median OS 30 months vs. 23; 5 years OS 32% vs. 12%) ($p<0,05$). Acute grade \geq 3 pulmonary toxicity occurred in 7,8%

of the patients, without significant difference between concurrent and sequential CRT. Acute grade 3 esophageal toxicity occurred in 5,5% of patients overall; and was significantly worse ($p < 0,01$) in patients treated with concomitant CRT compared to sequential CRT: 10,4% vs. 4,3% respectively. Late grade 3 pulmonary and esophageal toxicity was observed in 3,3% and 0% respectively; late grade 2 toxicity in 13,2% and 1,4% of the cases respectively. Although there was a trend towards reduced esophageal toxicity, the use of standardized dose-volume evaluation criteria (N=38) did not influence pulmonary ($p=0.60$) nor esophageal ($p=0.08$) toxicity significantly.

Conclusion: In spite of the low 5-year OS in patients undergoing sequential CRT, the entire NSCLC population treated with IMRT in our institution obtained OS in line with that reported in the literature. IMRT further confirms the potential for reduced toxicity as observed in other single-center experiences. Regardless of the lack of documented significant impact, we are convinced that the use of standardized dose-volume evaluation criteria has contributed to this positive outcome and is a precondition to exploit the full potential of IMRT in NSCLC.

Table: Patient, tumour and treatment characteristics (n = 223)

Adaptive radiotherapy: rate of "marginal" failure after "replanning" in combined treatment of NSCLC

S. Silipigni¹, E. Molfese¹, E. Ippolito¹, M. Fiore¹, B. Floreno¹, P. Matteucci¹, A. Sicilia¹, L. Trodella¹, R. D'Angelillo¹, S. Ramella¹

¹Campus Biomedico University, Radiotherapy, Rome, Italy

Purpose or Objective: Respiratory movement and anatomical changes of the lesion during radiotherapy are the main causes of target missing and/or irradiation of healthy lung tissue. The organ motion control and the correct identification of target volume (TV) contribute to manage these issues; however, the open question is if the adaptation of TV during treatment leads to an increased incidence of recurrences in the area of target reduction. The aim of this study is to evaluate patients' pattern of failure distinguishing "marginal", in field and out of field recurrences.

Material and Methods: In this prospective study, since 2010, locally advanced NSCLC patients treated with radiochemotherapy (RCT) underwent a weekly chest-CT simulation during therapy. In case of tumor's shrinkage, a new TV was delineated and then a new treatment plan outlined ("replanning"). At the end of treatment, patients were sent to follow-up. The patterns of failure were classified as: in field (persistence or recurrence in TV post-"replanning"), "marginal" (recurrence in the area of initial TV excluded from the post-"replanning" TV) and out of field (recurrence outside of initial TV). We also evaluated distant failure.

Results: Two hundred seventeen NSCLC patients were treated in our center. In fifty cases there was a volume reduction, so a "replanning" was outlined. Patients' characteristics were: mean age 69.6 years (range 38-92), squamous histology 56%, 32% adenocarcinoma, other 12%, stage IIIA 58% and IIIB 42%. The median total dose delivered was 65.7 Gy with standard fractionation. Median CTV at CT simulation and at "replanning" was 125.2 cc and 74.7 cc, respectively, with a median reduction of 43.1%. The "replanning" has been performed at a median dose of 45 Gy. At first follow up, 48 patients were evaluated. Response, according to RECIST criteria, was as follow: 2 complete responses (4.1%), 33 partial responses (68.8%) and 13 stable disease (27.1%). Grade 3 toxicities (CTCAE_4.0) were: acute esophageal in 4% of cases, pulmonary 6% (1 case acute and 2 chronic). With a median follow-up of 20.5 months, there have been 15 local (31%) and 22 distant (46%) failures. The observed local failures were: in field in 20.8% of cases, "marginal" in 6.1% and out of field in 4.1%. The median time to local failure, progression free survival and overall survival were 8.5, 8.3 and 30.5 months, respectively. The median onset of "marginal", in field, out of field and distant failures was 12, 9.2, 7.1 and 7.8 months, respectively.

Conclusion: Our results show that "replanning" during RCT has an acceptable local failure rate comparable to literature data; in particular, given the low incidence of "marginal" failures combined with the low rate of acute toxicity, the strategy appears promising, bringing to a method of dose escalation aimed at reducing in field failures.

PV-0277

SBRT with concurrent chemoradiation in stage III NSCLC: first results of the phase I Hybrid trial

H. Peulen¹, J.J. Sonke¹, E. Van der Bijl¹, E. Damen¹, J. Belderbos¹

¹Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: To assess the feasibility and safety of combined stereotactic body radiotherapy (SBRT) of the primary tumor (PT) and concurrent chemoradiation (CCRT) in stage III NSCLC, the Hybrid study (single center phase I: NCT01933568) was initiated. Primary endpoint is the mean lung dose (MLD) associated with 15% chance on radiation pneumonitis (RP) \geq G3 and dyspnea \geq G3. Secondary endpoints are toxicity and disease control. This is the first report of adverse events observed.

Material and Methods: Eligible patients had stage III or inoperable stage II NSCLC with a peripheral PT < 5 cm. Patient received CCRT: 24x2.75 Gy or 24x2.42 on the pathological lymph nodes (LN) with daily low dose cisplatin 6 mg/m² with an overall treatment time of 32 days. SBRT was delivered in 3 fractions of 14-18 Gy in the 2nd week concurrent with CCRT. If the fractionated LN treatment plan contributed to the PT dose, the total SBRT dose was corrected for accordingly. The MLD was escalated with 2 Gy increments using the Time-to-Event Continuous Reassessment Method (TITE-CRM) statistical design driven by dose limiting toxicity (RP or dyspnea \geq G3; CTCAE v4) within 12 months post treatment. The range of acceptable SBRT fraction doses allowed accruing patients in different MLD dose bins.

Results: From March 2013- October 2015 12 patients gave informed consent for the trial. One patient was excluded after the 1st week of treatment due to a baseline shift of the PT towards the mediastinum, causing unacceptable dose to the mediastinal organs at risk (OAR) if treated with SBRT. Median follow up (FU) was 8 months (range 0-26), median age was 63 years (range 61-75), 73% was male, 73% had adenocarcinoma, 18% squamous cell carcinoma, 9% large cell NOS. 73% had T1 tumors, 9% T2, 18% T3 (2 tumors), 18% N1, 73% N2 and 9% N3. Ten patients received CCRT, 1 patient radiotherapy only due to co-morbidities. No locoregional recurrences have been observed. Two patients developed distant metastases, one of which died 12 months post treatment due to leptomeningeal metastases. Median SBRT

dose was 53 Gy (range 43-54 Gy) and median LN dose was 2.75 Gy. Median MLD ($\alpha/\beta=3$ Gy) was 11.9 Gy (range 5.2-18 Gy). In 2 patients SBRT dose was decreased: in 1 patient due to allocation in a lower MLD risk group than the treatment plan MLD, in 1 patient because of normal tissue constraints of the mediastinal OAR. During treatment 4 patient developed dysphagia G2, 2 fatigue G2, 1 thrombocytopenia G2, 1 anorexia G2 and 1 patient hemoptysis G2. Radiation pneumonitis G2 occurred in 1 patient at 2.5 months FU with an MLD of 12.4 Gy. One patient developed chest wall pain G2 due to a rib fracture at 32 months FU. There were no G3-5 toxicities.

Conclusion: A Hybrid treatment of SBRT of the primary tumor combined with concurrent chemoradiation is feasible. This phase I trial is currently accruing and no unexpected toxicity has been observed thus far.

PV-0278

Volume concepts in routine radiotherapy for localized Hodgkin lymphoma: results of a national survey

R. Mazon¹, L. Gonzague-Casabianca², K. Peignaux³, V. Remouchamps⁴, C. Chira⁵, P. Moisan⁶, J. Lazarovici⁷, V. Edeline⁸

⁸Institut Curie, Nuclear Medicine, Saint-Cloud, France

Purpose or Objective: Background The definition of target volumes in radiotherapy for Hodgkin lymphoma quickly evolved during the last decades, with the comings of Involved-field radiotherapy (IF), then the Involved Node (IN)¹, and more recently the concept of Involved-site (IS)². The latter two concepts are based on the observation that recurrences mainly concern the adenopathies present at diagnosis when radiotherapy is not performed and on the need to reduce the irradiated volumes to limit the radiation-induced late morbidity. If the H103 and RAPID4 trials confirmed the interest of radiotherapy in localized disease, the standard technique is still debated. The studies currently led by the LYSA illustrate this confusion since one (BREACH) made IN its standard technique, while the other (BRAPP2) requires IF-radiotherapy.

To assess routine radiotherapy practices in the treatment of localized Hodgkin lymphoma.

Material and Methods: At the initiative of multicentric and multidisciplinary working group involving radiation oncologists, hematologists, and nuclear medicine physicians,

so called "PET-RT-Hodgkin", a survey focusing on the target volumes concepts (IN, IF and IS) and the use PET-CT in treatment position was sent to 35 French academic centers (university hospitals and cancer centers) through the SFRO (French Society for Radiation Oncology).

Results: Returns were obtained from 28 of the 35 centers contacted (80%). Of them, 10.7% were treating less than 5 patients per year, 28.6% from 5 to 10, 46.4% from 10 to 20, and 14.3% more than 20. The radiation therapists in charge were 19.0 ± 9.8 years of experience, including 14.9 ± 10.1 in the treatment of Hodgkin lymphoma. 86% of practitioners said that they were comfortable with the 3 concepts of target volume. Fifteen (53.6%) stated that IN was a standard and routinely use it; 8 answered that they were applying IS (28.6%). Five responded that IF was their standard of care, off-study (17.9%). If all used PET scans to define the target volumes; 19 centers offered the opportunity to perform it in treatment position (67.9%). Three radiotherapists admitted having difficulties in accessing it (10.7%) and six reported no access at all (21.4%). In 5 centers, patients were referred after chemotherapy and therefore with no possibility to perform this examination (17.9%). While most declared having a collaboration with a nuclear medicine physician, 53.6% of the radiotherapists were interested in implementing an expert PET images review network.

Conclusion: In routine, the definition of target volumes and access to the PET-CT in treatment position remain heterogeneous. The PET-RT-Hodgkin group aims to harmonize the conditions of realization of PET and justify the means to implement

⁴Ospedale San Luigi, Department of Internal Medicine and Hematology, Orbassano- Torino, Italy

⁵Ospedale Mauriziano, Department of Hematology, Torino, Italy

Purpose or Objective: High-dose chemotherapy (HDCT) followed by autologous stem cell transplantation (ASCT) is the standard of care for relapsed or primary refractory Hodgkin's lymphoma (HL) after first line treatment. The role of involved-field radiotherapy (IFRT) is controversial in this setting. Aim of this retrospective study was to investigate for a possible role for IFRT by comparing patients who received IFRT (prior or after ASCT) and patients who received salvage chemotherapy (CT) alone.

Material and Methods: We enrolled 73 consecutive HL patients treated with ASCT between 2003 and 2013. Twenty-one patients (28.8%) received pre (7 patients) or post (14 patients) ASCT radiotherapy. A Cox regression analysis was performed to evaluate the prognostic role of any risk factor. OS and PFS were calculated from the first day of HDCT. Response to HDCT and ASCT were evaluated with PET scan and defined according to Cheson's criteria.

Results: Median follow up was 47 months (range 1-145) for the entire population. Population characteristics by treatment modality are summarized in Table 1.

Factors	CT-RT N=21 (%)	CT alone N=52 (%)	p-value

Median Follow up (time from relapse)	47 months	48 months	

PFS and OS in the overall population were respectively 61.4% and 68.1% at 5 years. At the univariate analysis, advanced stage at relapse (HR 2.65, $p = 0.026$), persistent disease prior to ASCT (HR 2.53, $p = 0.05$) and IPS score ≥ 2 (HR 2.49, $p = 0.04$) affected OS, while advanced stage at relapse (HR 2.77, $p = 0.007$) and persistent disease prior to ASCT (HR 2.85, $p = 0.01$) were related to worse PFS. The Cox regression confirmed persistent disease prior to ASCT (HR 3.65, $p = 0.013$) and stage III-IV at relapse (HR 3.65, $p = 0.013$) as associated to an increased risk of death. OS at 3 and 5 years was slightly better in patients receiving RT (86.5% and 78.7% respectively) compared to patients treated with CT alone (76.8% and 65.9%), even without reaching statistical significance ($p = 0.42$). A similar faint benefit was also observed in term of PFS ($p = 0.39$). We then performed a subgroup analysis in patients with progressive or relapsed stage I-II disease ($N = 26$) who failed induction CT prior to ASCT: 14 received IFRT (pre or post ASCT) and 12 CT alone. OS rates at 3 and 5 years were higher for the IFRT group (92.3% and 79.1% respectively) compared to CT alone group (61.9% and 51.6% respectively), even if this difference was not significant at the log-rank test ($p = 0.13$), probably due to the small numbers (Figure 1). Similarly, PFS was higher in patients receiving IFRT (69.6% vs 50% at 3 years), again without reaching a statistical significance ($p = 0.22$).

Conclusion: In our cohort, IFRT did not result to be associated to a PFS or OS benefit vs CT alone in the overall population. IFRT seemed to provide a survival benefit at 3 and 5 years compared to CT alone (92.3% vs 61.9% and 79.1% vs 51.6%) in patients with stage I-II disease at relapse and with persistent disease prior to ASCT. A larger sample size is needed to further explore the effect of IFRT in this particular setting.

⁸Institut Paoli-Calmette, Radiotherapy, Marseille, France

⁹Universitary Hospital Bordeaux, Radiotherapy, Bordeaux, France

¹⁰Leon-Berard Center, Radiotherapy, Lyon, France

Purpose or Objective: Desmoplastic small round cell tumor (DSRCT) is a rare peritoneal tumor affecting predominantly children and young adult Caucasian males with a high rate of local failure after surgery. We performed a multicentric retrospective study to identify the prognostic impact of adjuvant abdominal radiotherapy.

Material and Methods: All patients treated for primary abdominal DSRCT in 8 French centers from 1991 to 2014 were included. Patients were retrospectively staged into 3 groups: group A treated with adjuvant radiotherapy (RT) after cytoreductive surgery, group B without RT after cytoreductive surgery and group C by exclusive chemotherapy. Peritoneal progression-free survival (PPFS), progression-free survival (PFS) and overall survival (OS) were evaluated. We also performed a direct comparison between group A and B to evaluate RT after cytoreductive surgery. RT was also evaluated according to completeness of surgery: complete cytoreductive surgery (CCS) or incomplete cytoreductive surgery (ICS).

Results: Thirty-seven (35.9%), thirty-six (34.9%) and thirty (28.0%) patients were included in group A, B and C, respectively. Three-year OS was 61.2% (41.0-76.0), 37.6% (22.0-53.1), and 17.3% (6.3-32.8) for group A, B and C, respectively. OS, PPFS and PFS differed significantly between the 3 groups ($p < 0.001$; $p < 0.001$ and $p < 0.001$, respectively). OS and PPFS were higher in group A (RT group) compared to group B (no RT group) ($p = 0.045$ and $p = 0.006$, respectively). Three-year PPFS was 23.8% (10.3-40.4) for group A and 12.51% (4.0-26.2) for group B. After CCS, RT improved PPFS ($p = 0.024$) but differences in OS and PFS were not significant ($p = 0.40$ and $p = 0.30$, respectively). After ICS, RT improved OS ($p = 0.044$). A trend of PPFS and PFS increase was observed but the difference was not statistically significant ($p = 0.073$ and $p = 0.076$).

Conclusion: Adjuvant radiotherapy as part of multimodal treatment seems to confer oncological benefits for patients treated for abdominal DSRCT after cytoreductive surgery and perioperative chemotherapy. This study is the largest series evaluating DSRCT treatment and the first of its kind comparing patients who received RT after cytoreductive surgery with patients who did not.

⁸St Luke's Radiation Oncology Network, Operational Services, Dublin, Ireland Republic of

⁹St Luke's Radiation Oncology Network, Radiology, Dublin, Ireland Republic of

Purpose or Objective: To compare Quality of Life (QoL) outcomes in patients (pts) with Malignant Spinal Cord Compression (MSCC) not proceeding with surgical decompression and treated by External Beam Radiation Therapy (EBRT) with one of two Fractionation Schedules (FS).

Material and Methods: ICORG 05-03 was an ICH-GCP compliant prospective (1.1) randomised non-inferiority phase III trial comparing two FS: arm 1 (control): 20Gy/5 Fractions (#) vs. arm 2 (experimental): 10Gy/1#, with 80% power, 5% significant level and 0.4 non-inferiority margin. While the primary end point of this trial (previously presented (ASTRO 2014)) was change in mobility at 5 weeks (wks), the current focus is on a secondary endpoint, QoL (EORTC QLQ-C30 questionnaire).

Results: From 2006 to 2014, 5 institutions accrued 115 eligible pts (2 non-eligible pts, no treatment allocation violation). 70 pts with QoL data at 5 wks were evaluable. Baseline characteristics were balanced between arms [\bar{x}/σ : 30/40, median age: 69 (range: 30-87)]. Analysis showed a statistically significant benefit of radiotherapy (RT) for 'Pain interfered with daily activities' but not for Overall QoL. There was no statistically significant benefit between arms for either: 1. Overall QoL (mean change from pre-treatment .52 in arm 1 vs. .21 in arm 2; 95% CI: -0.84 - 1.45, $p = 0.596$); 2. Pain interfered with daily activities (mean change: .84 in arm 1 vs. 1.00 in arm 2; 95% CI: -0.66 - .98, $p = 0.698$). A non-planned exploratory regression analysis checked for independent prognostic factors for less pain at 5 wks. Multiple regression analysis revealed baseline pain as the strongest unique and statistically significant contributor to explaining less pain at 5-wks ($\beta = -0.63$; $p = 0.002$).

Exploratory analyses were also conducted to characterise pts dying at <5 wks, who might not benefit from RT. Primary malignancy (Chi-square test: $X^2(3, n=106) = 15.6$, $p = 0.001$, $\phi = 0.38$) and initial mobility status (Chi-square test, $X^2(2, n=106) = 11.0$, $p = 0.004$, $\phi = 0.32$.) were found to be associated with a life expectancy <5 wks. 67% of lung and 13% of breast cancer pts died before 5 wks, as did 49% of bed-bound and 15% of pts who could walk unaided.

Conclusion: With respect to QoL, primary RT significantly improves the pain related variables used in the trial, with 10Gy/1# FS being at least equivalent to 20Gy/5#. Baseline pain is the most significant independent prognostic factor for less pain at 5 wks. Tumour site and mobility should be considered when offering RT treatment to similar pts.

²AvL/NKI, Radiation Oncology, Amsterdam, The Netherlands

³UZ Leuven, Radiation Oncology, Leuven, Belgium

⁴Radboud UMC, Radiation Oncology, Nijmegen, The Netherlands

⁵UMC Utrecht, Julius Center for methodology, Utrecht, The Netherlands

Purpose or Objective: The aim of this study was to compare treatment related side-effects and quality of life of an MRI-based 95Gy boost to the multi-parametric MRI visible tumor with 77Gy whole prostate external beam radiotherapy in patients with intermediate or high risk localized prostate cancer.

Material and Methods: FLAME (NCT01168479) was a phase 3, single blind, multi-center randomized controlled trial. Patients with biopsy proven intermediate and high risk prostate cancer (D'Amico risk classification) were randomly assigned and stratified per center. Analysis was done by intention to treat. The control group received a dose to the entire prostate of 77Gy in 35 fractions. The experimental arm received an additional integrated boost up to 95 Gy to the mp-MRI-visible lesions. Treatment related toxicity was measured by the Common Toxicity Criteria for adverse events version 3.0 (CTCAE). Quality of Life (QoL) was measured by SF-36, EORTC QLQ-C30 and EORTC QLQ-PR25. All items and scale scores were linearly transformed to a 0-100 scale, with higher scores reflecting either more symptoms or higher levels of functioning. Clinical relevance was considered a difference of more than 10 points between arms. Mean differences between groups were calculated using a linear mixed model with adjustment for baseline values. Statistical significance was considered $P < 0.01$.

Results: Between 2009 and 2015 287 patients were assigned to the control group and 284 to the dose-escalated (FLAME) arm. Mean follow up was 22 months. In both arms, 84% of patients had high risk disease. Regarding GU toxicity, 134 patients (47.2%) in the FLAME arm and 147 patients (51.4%) in the control arm experienced any grade 2 or higher toxicity. Grade 3 GU toxicity occurred in 15 patients (5.3%) in the FLAME arm and 12 patients (4.2%) in the control arm. Regarding GI toxicity, 60 patients (21.1%) in the FLAME arm and 47 patients (16.4%) in the control arm experienced grade 2 or higher toxicity. Grade 3 toxicity occurred in 2 patients (0.7%) in the FLAME arm and in 5 patients (1.7%) in the control arm. None of these differences were statistically significant. For all quality of life measures no statistically significant or clinically relevant differences were observed.

Conclusion: Up to a median follow-up of 22 months no differences in toxicity and quality of life were observed between the FLAME arm and the standard arm. Therefore, dose escalated 95Gy MRI-based lesion boost in prostate cancer external beam radiotherapy seems safe.

Proffered Papers: Highlights of Proffered Papers

OC-0283

Dose escalation with contact x-ray brachytherapy to improve organ preservation in rectal cancer

A. Sun Myint¹, F. Smith², K. Whitmarsh¹

¹The Clatterbridge Cancer Centre - Wirral NHS Foundation Trust, Papillon Suite, Bebington- Wirral, United Kingdom

²The Royal Liverpool & Broadgreen University Hospital, Colorectal Surgery, Liverpool, United Kingdom

Purpose or Objective: 'Watch and Wait' policy for complete clinical responders (cCR) following CRT is gaining acceptance as this avoids extirpative surgery and a stoma. However, up to 30% required major surgery for recurrences and organ preservation achieved reduced to 40% for the whole group. We report our experience with dose escalation using Contact X-ray brachytherapy [Papillon] (CXB) boost which reduce recurrences and improve the chance of organ preservation.

Material and Methods: We review 573 patients with rectal cancer treated at Clatterbridge Cancer centre from 2003 - 2012 and report on 200 patients treated radically to cure by non-surgical approach. There were 134(67%) males with median age 74 years (range 32-94). Histological diagnosis confirmed in all patients. Staging include CT in all and MRI except in 30(15%) with pace maker. Radiological stages were 21(10.5%) T1, 89(44.5%) T2, 87(43.5%) T3 and 3(1.5%) T4. EBCRT with 45 Gy /25#/35 days and capecitabine 825 mg/m² or 5 FU infusion 1G /m² X 4 days week 1+5 was given to 127 (63%)patients, except EBRT alone in unfit 57(28%) who had 25 Gy/5#/5 days. Papillon boost of 80-110 Gy in 3-4 fraction was given to 92% of patients who had EBCRT or EBRT. Papillon alone (80-110 Gy /3-4 #/ 6 weeks) was used in 16 (8%) of elderly patients with mainly cT1 cancers.

Results: Initial complete clinical response [cCR] (no residual tumor visible, palpable or on radiology) was achieved in

136(68%) and residual abnormality either clinical or radiological were seen in 64(32%). Immediate salvage surgery was carried out in 38(60%) patients with progressive residual disease who were fit. Eight (21%) had no pathological residual disease (ypT0). Surgery was withheld in further 8 (4%) out of 64 without progression of residual abnormality. Those with cCR 116(85%) maintained complete response. Sixteen (11.7%) developed local relapse after cCR. Early staged tumors respond better with less local and total relapse. At median follow up of 2.49 months following completion of treatment; complete remission was achieved in 160 (80%) patients, 12(6%) had asymptomatic static disease and 28 (14%) had progressive residual disease but not fit for salvage surgery due to age or medical co-morbidity. The main toxicity was bleeding occurring in 30% of cases and 10% needed argon beam. Organ preservation for the whole group was achieved in 158 (79%). Overall Survival (94% vs. 76%) [p=0.02] was better for responders (cCR +SD) at 2 years.

Conclusion: CXB (Papillon) boost reduced local recurrence to 11.7% after achieving cCR compared to 30-40% in those who had EBCRT alone. Organ preservation of 79% for the whole group is much higher than any 'watch and wait' studies with 40% published so far. A randomised trial OPERA has been set up to evaluate this further. Papillon has acceptable toxicity and is now recommended by NICE for patients not suitable for surgery. Papillon should be considered as a treatment option for elderly patients with early rectal cancer.

OC-0284

PD-L1 inhibition improves response of pancreatic cancer to radiotherapy

A. Azad¹, Z. D'Costa¹, S.Y. Lim¹, O. Sansom², W.G. McKenna¹, R. Muschel¹, E. Fokas¹

¹CRUK/MRC Institute for Radiation Oncology University of Oxford, Department of Oncology, Oxford, United Kingdom

²Cancer Research UK Beatson Institute-, Glasgow- Institute of Cancer Sciences- University of Glasgow, Glasgow, United Kingdom

Purpose or Objective: The programmed death ligand 1 (PD-L1) plays a key role in tumour progression and metastasis of pancreatic ductal adenocarcinoma (PDAC). Although recent preclinical studies have explored the radiosensitising potential of PD-1/PD-L1 inhibitors, the effect of PD-L1 blockade on the response of PDAC to radiotherapy remains unexplored.

Material and Methods: Herein, we investigated the influence of an anti-PD-L1 mAb on the tumour response to single dose and fractionated radiotherapy, and chemotherapy with gemcitabine and capecitabine.

Results: In-vitro, radiation and chemotherapy resulted in PD-L1 upregulation in both human (PSN-1) and murine (KPC-derived, Pan02) PDAC cells, although variability was observed. Exposure to conditioned media from pre-treated cells did not alter PD-L1 expression. In-vivo, PD-L1 was also upregulated in the tumour microenvironment after radiation and chemotherapy in the KPC-derived and Pan02 syngeneic mouse models. Similarly, chemotherapy induced PD-L1 upregulation in the KPC (Pdx1Cre, KRASG12D/+, P53R172H/+), a genetically-engineered mouse model of pancreatic cancer. In-vitro, PD-L1 blockade failed to radio- or chemosensitise PDAC cells. The anti-PD-L1 mAb significantly improved tumour response after irradiation in the KPC and Pan02 syngeneic mouse models. This effect was mediated by a cytotoxic T cell-dependent mechanism, whereas blockade of CD8+ cells attenuated the radiosensitising potential of anti-PD-L1. The effect of scheduling of anti-PD-L1 mAb with radiotherapy (concomitant vs sequential) was also investigated. Finally, we assessed the intratumoural and systemic expression of several immune markers (CD45+: CD8, CD4, CD19, NK1.1, CD11b Gr1, Ly6G, CXCR2, FOXP3, IFN-γ) after the different treatments.

Conclusion: Altogether, our findings support PD-L1 inhibition in combination with radiation as a promising approach in the treatment of PDAC.

OC-0285

Experimental benchmarking of a probe-format calorimeter for use as an absolute clinical dosimeter

J. Renaud¹, A. Sarfehnia¹, J. Seuntjens¹

¹McGill University, Medical Physics Unit, Montreal, Canada

Purpose or Objective: In this work, the design, fabrication, and operation of a small-scale graphite calorimeter probe (GPC) developed for use as a practical clinical dosimeter, is described. Similar in size and shape to a Farmer-type cylindrical ionization chamber, the GPC represents the first translation of calorimetry from the primary standards dosimetry laboratory to the radiotherapy clinic. Providing a measure of absolute dose, its purpose is to help meet the clinical need for accurate reference dosimetry in non-standard fields without the need for calibration.

Material and Methods: Based on a numerically-optimized design obtained in previous work, a functioning prototype capable of two independent modes of operation (constant-power & constant-temperature) was constructed in-house. In constant-power mode, the radiation-induced temperature rise, ΔT , is measured in the sensitive volume (*i.e.* the core) while the outermost portion of the device is thermally stabilized by a software-based temperature controller. In constant-temperature mode, the entire device is subject to active thermal control and the quantity of interest is the electrical power, ΔP , necessary to maintain a stable temperature while irradiated.

Absorbed dose to water measurements were performed in a water phantom, under standard conditions, using both GPC operation modes in a 6 MV photon beam and subsequently compared to dose to water measurements derived using a reference-class ionization chamber (Exradin A12). Linearity, dose rate, and field size dependence were evaluated by varying the irradiation period, the linac repetition rate, and primary collimating jaw settings, respectively.

Results: Compared to the chamber-derived dose to water of 0.765 cGy/MU, the average GPC-measured doses were 0.765 ± 0.005 ($n = 25$) and 0.769 ± 0.005 ($n = 32$) cGy/MU for the constant-power and constant-temperature modes, respectively.

The linearity of the detector response was characterized by an adjusted R^2 value of 0.9996 ($n = 40$), and no statistically-significant dose rate dependence for rates greater than 1.8 Gy/min was observed. For lower dose rates, an over response of 1.7% was attributed to the resolution of

the current-driven temperature controller. No field size dependence was observed down to $2 \times 2 \text{ cm}^2$.

Table 1. Estimated uncertainty budget for the GPC's constant-power and constant-temperature modes of operation in high-energy photon absolute dose to water measurements.

Quantity	Constant-power mode		Constant-temperature mode	
	Type A (%)	Type B (%)	Type A (%)	Type B (%)
Heat transfer	--	0.3	--	0.1
Reproducibility	0.6	--	0.6	--
Bridge calibration	--	0.1	--	--
Thermistor calibration	--	0.2	--	--
Electrical power	--	--	--	0.2
Specific heat capacity	--	0.8	--	--
Mass	--	--	--	0.5
Positioning	0.2	--	0.2	--
Perturbation-dose conversion	--	0.4	--	0.4
Other not considered	--	0.3	--	0.3
Quadratic summation	0.6	1.0	0.6	0.7
Combined uncertainty	1.2		1.0	

Conclusion: This work demonstrates the feasibility of using an ion chamber-sized calorimeter as a practical means of measuring absolute dose to water in the radiotherapy clinic. The potential introduction of calorimetry into the clinical setting is significant as this fundamental technique has formed the basis of absorbed dose standards in many countries for decades. Considered as the most direct means of measuring dose, a "calorimeter for the people" could play an important role in solving the major challenges of contemporary dosimetry. In particular, investigations into the use of the GPC for MR-linac dosimetry are currently underway.

²Radboud University Medical Center, Dermatology, Nijmegen, The Netherlands

Purpose or Objective: Build-up material is commonly used in electron beam radiation therapy to overcome the skin sparing effect and to homogenise the dose distribution in case of irregular skin surfaces. Often, an individualised bolus is necessary. This process is complex and highly labour-intensive, while adaptation of the bolus is time consuming. We implemented a new clinical workflow in which the bolus is designed on the CT scan in the treatment planning system (TPS). Subsequently a cast with the bolus shape is 3D-printed and filled with silicone rubber to create the bolus itself [1].

Material and Methods: In the new workflow (figure 1), a patient-specific bolus is designed in the TPS. A 2 mm expansion is used to create a cast around the bolus. Subsequently, this cast is smoothed to remove CT scan resolution effects. After conversion to a stereolithography file, the cast is printed in polylactic acid (PLA) with a filament printer and filled with silicone rubber. After removal of the PLA cast, the bolus is ready for clinical use.

Before clinical implementation we performed a planning study with 11 patients to evaluate the difference in tumour coverage with a 3D-print bolus in comparison to the clinically delivered plan with a manually created bolus.

During clinical implementation of the 3D-print workflow, for 7 patients a second CT-scan with the 3D-print bolus in position was made to assess its geometrical accuracy and the resulting dose distribution.

Results: The planning study showed at least equal coverage of GTV and CTV: V95% of the GTV was on average 97% (3D-print) vs 84% (conventional). V85% of the CTV was on average 97% (3D-print) vs 88% (conventional).

Geometric comparison of the 3D-print bolus to the originally contoured bolus showed a high similarity (mean dice similarity coefficient of 0.87 (range 0.81 to 0.95)).

Comparison of the dose distributions at the planning CT scan to dose distributions at the second CT scan with the 3D print bolus in position showed only small differences (median difference in V95% GTV and V85% CTV of 0% (interquartile range: -12% to 0%) and -1.6% (interquartile range: -3.8 to 0.5%), respectively).

Time efficiency of the 3D-print workflow is likely to increase in comparison to the conventional workflow, with one less patient visit, and up to 3 hours less mould room time.

Conclusion: The implemented workflow is feasible, patient friendly, safe, and results in high quality dose distributions. This new technique increases time efficiency and logistically aligns electron with photon external beam treatments.

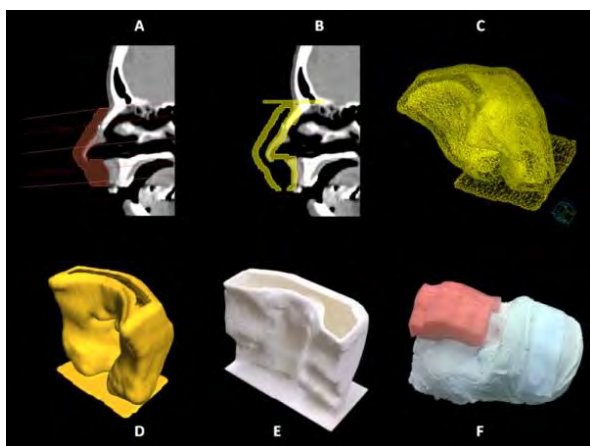

Figure 1: Illustration of the clinically implemented 3D-print workflow with designed bolus(A) and cast around the bolus(B) at the planning CT scan, smoothed cast (C), 3D model of the cast (D), printed cast (E) and silicone rubber final bolus (F).

Symposium: Planning ahead: how to finish your residency / PhD project with a job offer

SP-0287

How to finish your residency / PhD project with a job offer as a radiation oncologist

S. Rivera¹

¹Institut Gustave Roussy, Villejuif, France

Radiation oncology is a rapidly evolving profession requiring continuous learning on the top of all routine activities. Residency is a unique period in a professional life where the main objective is to learn. Residency is full of research and educational opportunities for young radiation oncologists to gain know-how and expertise in clinical practice, patient care, fundamental, translational and/or clinical research and innovative technologies in the various aspects of our specialty. Through local, national and international programs, trainees gain valuable clinical and research experience and skills during and rapidly get the opportunity to disseminate information and update colleagues in their home institution. Playing a proactive role in the training will not only give access to the best training opportunities but will motivate as well supervisors in supporting trainee's career development.

In a competitive world with limited resources, building up good curriculum vitae with a number of publications and presentations is a major advantage that should be

considered and kept in mind early and during the whole residency. This will not only be of value when applying for a job but will open a number of collaborations as well introducing the trainee in a virtuous circle which will tremendously facilitate future projects, recognition, satisfaction and professional pleasure.

International exchanges and mobility are of utmost importance. From personal initiatives directly contacting a department head abroad via email or at a meeting to local/national or scientific societies programs there are many opportunities to gain such an enriching experience. ESTRO for instance supports short terms (few weeks) educational visits called mobility grants twice a year which allow for learning a specific technique in the context of a project propose by the candidate through a motivation letter which can be an excellent way to get some connections to look for longer term mobility. Entering a PhD program is another excellent opportunity to access the kind of international exchange and mobility that together with the scientific production and publication resulting from it will serve a career when looking for a position in a high level academic center. Indeed, having an international professional experience and a strong scientific background will be highly considered when applying for a job offer in a university hospital or a cancer center. This will even be almost mandatory when aiming at a research/teaching position.

Mentorship can be very helpful throughout a career. Benefiting from privileged dialogue, support and guidance from a more experienced person in the field considered as a mentor can enhance the effectiveness of any talent, help avoiding painful mistakes and optimizing choices that will have a major career impact and sometimes even an impact on the balance between professional and personal life which is often a fragile point in a demanding profession. Many countries across Europe are lacking of mentorship programs but in many institutions even without a dedicated program various types of mentoring are in place. Most of more experienced people are happy to share their experience and give some advices so one should not hesitate to ask for this helpful interaction. With or without a mentor here are key questions that are essential to guide one's choices:

Who am I?

Where do I want to go?

What type of professional activity will I enjoy?

Which life will make me happy?

To conclude, the best advice would be to always wonder how to get the most out of one's training period. In that aspect, ESTRO offers young professionals in the field of radiation oncology a wealth of opportunities from networking, grants, educational courses, fellowships, mentorships and workshops aiming at refining skills and gaining access to the latest developments in the field that will be of value finishing your residency not only with a job offer but with the job you want.

SP-0288

How to finish your residency / PhD project with a job offer as a radiobiologist

M.C. Vozenin¹

¹Centre Hospitalier Universitaire Vaudois, Department of Radiation Oncology, Lausanne Vaud, Switzerland

PhD training/residency is a long-term and enriching experience, it requires time and commitment for scientific achievement; in addition, the future of a young scientist needs to be planned ahead. Therefore, having a clear view of your career's perspectives at least 18 months before your defense is the way to professional success. Early during your training discuss your career aspirations and important issues in your professional development with your mentor, he/she will be able to provide you with career information and guidance. But ultimately you will be the one to define if you are seeking for an academic career, job in the industry or other professional options. In any case your mentor will introduce you to colleagues, potential employers, and other professionals who might help to advance your career. You also need to be highly proactive and present your research and creative work as often as possible in multiple forums

including your department/university but also at professional conferences/meeting. You will need to apply for fellowships, awards, teaching opportunities and service committees in the scientific community. The aim is to create a strong network that will serve as the base for your job research and will provide you with multiple opportunities.

Guideline-based contouring and clinical audit systems

C. Weltens¹

¹*University Hospital Leuven- KU Leuven, Radiotherapy-Oncology, Leuven, Belgium*

Modern radiotherapy techniques focus on the precise irradiation of the target volume while minimizing the dose to adjacent normal tissues. Technical advances at all levels of the complex radiotherapy preparation and delivery process allowed reductions of safety margins and conformation of the high dose volume to the target volume. The introduction of these technical innovations has been supported by extended quality assurance procedures. A small part of the radiotherapy preparation process however has for a long time remained unaddressed: the quality of the target delineation is still a weak link in the radiotherapy chain. Accurate, unambiguous and precise target delineation is mandatory in high conformal radiotherapy, since the treatment plan and subsequently treatment delivery are based on the delineated target volumes. Errors in target delineation will on the one hand lead to systematic errors in treatment delivery and possibly to geographical misses in clinical practice. The projected outcome will be undermined both with respect to the chances of tumor control and the risks of side effects. On the other hand, inconsistencies in target volume contouring compromise the validity of the results of clinical trials. To improve the quality of the delineations, guidelines were made for nearly all tumor sites as well as for the normal tissues. Notwithstanding these published guidelines, important inter- and intra-observer variation in target delineation have been demonstrated. Several solutions have been proposed to improve the quality of target delineation: (1) for nearly all tumor sites delineation guidelines with complementary atlases have been published, (2) the registration of CT scans in treatment position with a combination of different imaging modalities has been tested and introduced, (3) automated and semi-automated delineation software has been developed, and (4) education through hands-on workshops at radiotherapy meetings and online tutoring sessions (e.g. FALCON) is available. Studies also show that peer review can improve delineation quality. The quality of target delineation was measured in Belgium through clinical audits for rectal and breast cancer patients. We have evaluated the role of a central review platform in improving uniformity of clinical target volume delineations within a national Belgian project. All 25 Belgian radiation oncology departments were invited to participate in this QA project. CTV delineation guidelines and atlases were discussed and distributed at a national meeting. After this education of the radiation oncologists, a review process was set up. Departments were asked to delineate the clinical target volumes and to upload it to a secured server. For

rectal cancer, the clinical target volume was delineated and for breast cancer, the regional nodal areas (internal mammary, level I to IV axillary and Rotter space) were contoured. A trained radiation technologist then reviewed all cases according to the guidelines and feedback was given within 24 hours. Twenty-four departments participated to the study and in total more than 2200 contours were reviewed: over 1200 rectal cancer patients and over 1000 breast cancer patients. Evaluation of the contours showed that 74 % of rectal cancer cases were modified. These high numbers indicate that the interpretation of guidelines is not always straightforward. More important however is the learning curve that was achieved. The rectal overlap and volumetric parameters significantly increased between the first ten patients per center and others. The study of the contouring of the locoregional nodal delineation in breast cancer is still ongoing and first results will be presented at presented at the ESTRO 35. For both breast and rectal cancer, some deficiencies in the description of the guidelines were demonstrated, making the interpretation ambiguous, and the guidelines will be adapted accordingly. Within a national QA project, we have shown that clinical audit of target delineation improves the quality of the contouring: the inter-observer variability and the major deviations from the guidelines are substantially reduced. Variability in anatomical contouring contributes to uncertainty in treatment planning and compromises the quality of the treatment plan and delivered treatment. The standardization of tumor and target volume contouring is therefore highly desirable and can be positively influenced by consensus guidelines, education and clinical audits.

SP-0292

Standardisation and treatment planning

B. Heijmen¹, A. Henry², S. Breedveld¹

¹*Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands*

²*St James's Institute of Oncology- St James's Hospital, Radiation Oncology, Leeds, United Kingdom*

Current plan generation is an iterative trial-and-error procedure in which the planner tries to steer the treatment planning system (TPS) towards an acceptable plan by tweaking of parameters, such as beam angles, goal functions or weights. A plan is generally considered acceptable if it fulfills minimum requirements for tumour and OARs, while significant further improvement of the dose distribution is considered infeasible (within the allotted time). On top of the high workload, the current planning approach leads to suboptimal plan quality: the quality is strongly dependent on the skills and experience of the planner (operator dependence), plan quality is dependent on allotted time, and quality is dependent on subjective preferences and priorities of the planner and the treating physician. Can this variability be reduced? Can treatment planning be standardised? Can we guarantee that each patient will be treated with an individualised, clinically highly favourable (best) treatment plan when generated in an efficient manner? In this presentation, data will be provided demonstrating difficulties that clinicians encounter in evaluating treatment plans. Furthermore, the concept of automated treatment plan generation will be discussed as a procedure that may be used to standardise treatment planning. Examples of the positive impact on plan quality will be presented and consequences for involved personnel and plan quality assurance will be discussed.

SP-0293

Potentials and challenges of automated contouring in treatment planning

S. Pallotta¹

¹*University of Florence, Department of Medical Physics, Florence, Italy*

Delineation of targets and normal tissues, typically performed on CT and/or MR images, is still one of the largest sources of variability in radiation therapy treatment plans. In fact, despite well-described guidelines for manual

contouring, substantial intra and inter-observer variations exist. Moreover manual contouring is a time consuming process that, depending on the number and complexity of contours to be delineated, can hinder the implementation of adaptive radiotherapy approach. Current perspectives on contouring procedure suggest that an automated approach could reduce both the contouring time and inter-observer variations. Studies evaluating automated contouring in multiple disease sites have in fact demonstrated the potential to improve efficiency and variability associated with manual segmentation. In practice, automated contour are carried out using atlas-based, model-based or hybrid approaches. In atlas-based segmentation the CT scan of a new patient is segmented using segmented scans of one (single-patient) or more (multi-patient) previously treated patients, called atlases. Methods based on classical deformable models use local image features and automatically adapts the model shape to fit patient's organ. Various implementations of these two principal methods are described in the literature and are available in commercial contouring software. Prior their clinical use automated contouring methods need an accurate validation. This is a challenging task as medical image segmentation lacks a known gold standard in its real world application. Phantoms as well as synthetic images provide an easily identifiable ground truth but are an unrealistic surrogate for patient imaging. Moreover, evaluation methods have also lacked consensus as to comparison metrics. A number of different methods have been utilized for comparing segmentation results. The common metrics used fall into one of two categories: volume based or distance based. Each of the comparison metrics has limitations and thus it is desirable to use multiple metrics where possible. This presentation will discuss the advantage in standardization deriving from the use of automatic contouring and the different approach followed in the implementation and validation of automated segmentation tools in different anatomical districts.

SP-0294

Implementation of new standards in your department: a RTT perspective

A. Baker¹, Y. Tsang¹

¹Mount Vernon Cancer Centre, Department of Radiotherapy, Middlesex, United Kingdom

Standardisation of clinical practice is essential for the delivery of safe, accurate radiotherapy treatments. Implementation of new standards can be at both local and national levels and examples of these approaches, from an RTT perspective, will be discussed. New standards should be developed and implemented within a multi-professional team setting. Each profession has a role to play and bring different perspectives to the development and implementation process.

Development of training and competency assessments for the use of new delivery techniques are an essential aspect of implementing any new standards. These assessments can be established locally using national guidelines. For example the UK National Radiotherapy Implementation Group IGRT recommendations¹ which was written by a multi-profession team to assist centres in utilising IGRT equipment and details content for IGRT training and competency assessment programmes. This recommendation document has been instrumental in the UK with ensure appropriate utilisation of IGRT for each anatomical site and ensuring quality IGRT is delivered to patients. RTTs are also involved in the preparation of national SABR guidelines, as part of the UK SABR consortium, particularly focusing on the treatment delivery and IGRT sections.

Clinical trials provide a controlled environment where new standards can be developed in a quality assured way. A UK prostate radiotherapy clinical trial utilised both IMRT and IGRT within the context of a study evaluating a number of fractionation schedules. This assisted the centres involved to develop IMRT and IGRT standards within their departments within a quality assured clinical trial. RTTs were able to use IGRT processes clearly defined within the protocol and the support of the QA team for the trial were available for advice

and support. This same method is currently being adopted in the UK for a number of adaptive radiotherapy trials and this will assist in establishing new evidence for adaptive radiotherapy and the community will be prepared for routine implementation if the results favour an adaptive approach. It is important to consider the role of QA together with audit programmes both during the implementation phase and also on a routine basis following the implementation of the new evidence based standards. RTTs are a key component of this process within the multi-professional team.

Conclusion

Utilisation of national recommendations or clinical trial processes ensure that new standards are developed and implemented safely and accurately. There is sometimes a tendency to slowly adopt new technologies and evidenced based practice into routine practice but by having national protocols, quality assurance and multi-centre clinical trials, new standards can be implemented timely, appropriately and safely.

Purpose or Objective: Very recently, the DAHANCA, EORTC, GORTEC, HKNPCSG, NCIC CTG, NCRI, NRG Oncology and TROG consensus guidelines for delineating organs at risk (OARs) in the head and neck region have been published (1). The purpose of this study was to investigate whether these international consensus guidelines improved delineation quality among observers.

Material and Methods: Ten radiation oncologists, considered experts in the field, were asked to delineate 20 different OARs on CT images (2 mm slice thickness) in two delineation sessions. The first session was performed in 2013 without the use of any predefined guidelines. The second session was performed in 2015 just after publication of the consensus guidelines. The observer variation was measured in 3D by measuring the distance between the median delineated OAR and each individual delineated OAR (2). The variation in distance of each OAR was expressed as a standard deviation (SD). Furthermore, to assess the overlap between observers the concordance index (CI) was calculated. The CI has values

ranging from 0 for no overlap to 1 for perfect agreement between all observers (3).

Results: Seven observers delineated most of the contours in the first and second session. Five observers delineated 14 OARs in both delineation sessions. For fair comparison between first and second delineation session, observer variability was only calculated among the five observers who delineated all 14 OARs in both sessions. The average 3D variation in distance for the first and second session was 3.0 mm and 2.1 mm (1 SD), respectively (Table 1).

Table 1. The observer variation for delineation session 1 (without consensus guidelines) and delineation session 2 (with delineation guidelines) expressed in 3-D variation in distance and conformity index for 14 OARs.

OAR	3-D variation (mm) (1 SD)			Conformity index (CI)		
	Without guidelines	With guidelines	Difference	Without guidelines	With guidelines	Difference
	(Session 1)	(Session 2)		(Session 1)	(Session 2)	
Anterior part Eye L	3.5	1.3	2.2	0.06	0.17	0.11
Anterior part Eye R	3.2	1.2	2.0	0.08	0.16	0.08
Posterior part Eye L	2.4	1.4	1.0	0.26	0.52	0.26
Posterior part Eye R	2.5	1.4	1.1	0.26	0.55	0.29
Parotid gland L	2.2	1.4	0.8	0.47	0.57	0.10
Parotid gland R	2.0	1.5	0.5	0.45	0.48	0.03
Submand. gland L	3.5	4.5	-1.0	0.32	0.27	-0.05
Submand. gland R	3.2	3.5	-0.3	0.41	0.36	-0.05
Oral Cavity	5.8	2.1	3.7	0.36	0.67	0.31
Mandible	1.7	1.2	0.5	0.55	0.67	0.12
Pharyngeal constrictor muscles	6.7	4.2	2.5	0.05	0.09	0.04
Thyroid gland	1.6	1.3	0.3	0.58	0.62	0.04
Pituitary	1.9	1.6	0.3	0.17	0.42	0.25
Chiasm	2.1	2.3	-0.2	0.10	0.01	-0.09
Mean	3.0	2.1	1.0	0.29	0.40	0.10

Out of 14 OARs, 11 OARs showed reduced 3D variation (reduction range 0.3-3.7 mm) using the consensus guidelines. The largest reduction of 3.7 mm was seen for the oral cavity, from 5.8 mm to 2.1 mm (Figure 1).

Figure 1. Contours delineated on CT (left) and the 3-D variation (right) of the oral cavity without and with consensus guidelines.

For 3 OARs (i.e. both submandibular glands and the chiasm) the 3D variation was larger using the guidelines (range 0.2-1.0 mm). For the first and second session, the average CI was 0.29 and 0.40, respectively (Table 1). For 11 OARs an improvement of the CI was seen (improvement range 0.03 - 0.31). The largest improvement was again seen for the oral cavity from 0.36 to 0.67. For 3 OARs the CI became worse. For the submandibular glands the differences were however small; 0.05.

Conclusion: The use of the consensus guidelines for head and neck OARs reduced observer variation for most OARs investigated. This stresses the importance to use uniform internationally accepted guidelines in daily clinical practice,

to support consistent reporting of dose-volume data and NTCP-models. However, further improvement of delineation quality can be achieved by training and education, and a more consistent use of these guidelines. References: 1. Symposium: DNA repair inhibition and radiotherapy: moving towards clinic

SP-0296

Challenges in combining radiation and chemo-radiation with PARP inhibitors

J. Schellens¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Molecular Pathology, Amsterdam, The Netherlands

Locally advanced NSCLC is a heterogeneous disease both with regard of the staging and the tumor behavior. In order to improve outcome, combinations of radiation (RT) with cytotoxic drugs to modulate RT-induced cytotoxicity were introduced and are now standard of care. Also in many other malignancies combined modality has shown to improve outcome and has become standard of care. These treatment options are in particular of benefit in patients that can tolerate such treatment regimens. Improvements have been made both in chemotherapy and the radiotherapy. However, co-morbidities and the observed increased normal tissue toxicity limit the use of potent chemoradiotherapy approaches. In order to enhance the therapeutic window, tumor targeted strategies are needed to allow tumor radiosensitization while not affecting normal tissue. This warrants the evaluation of the potential of novel targeted radiosensitizers with tumor targeted properties. The main mechanism by which both radiation and cisplatin kill tumor cells is by an accumulation of un- or misrepaired DNA damage. PARP inhibitors increase radiation and chemotherapy (cisplatin) response in preclinical studies including lung cancer models. PARP inhibitors have been shown to specifically kill homologous recombination deficient tumor cells as single agent. ATM mutations are expected to affect DSB repair and homologous recombination status therefore amplifying damage induced by the combined PARP inhibitor radiation treatment. Thus tumor targeted treatment and radio-chemosensitization in lung cancer could be achieved in the presence of frequently observed ATM gene mutations in lung cancer. Olaparib exhibits low systemic toxicity profiles when given as monotherapy. When combined with cisplatin and RT enhanced toxicity is anticipated, necessitating careful dose- and schedule-finding and development and validation of supporting pharmacodynamic markers. Such approach could also serve as a template for other promising radiosensitizers, for example DNA-PK, ATM and ATR inhibitors of kinases that are key mediators of the so-called DNA damage response (DDR).

³Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Head and Neck Surgery, Amsterdam, The Netherlands

⁴Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Biological Stress Response, Amsterdam, The Netherlands

Increased understanding of the molecular mechanisms underlying tumour and normal cell radiosensitivity has led to

the identification of a variety of potential targets for rational intervention. These are based on the “hallmarks of cancer”, eight biological capabilities acquired during the multistep development of human tumours. Among these, targeting the DNA damage response represents an attractive strategy, especially in tumours that contain mutations in specific components of the DNA repair pathway, such as BRCA1 and BRCA2. In addition to their use as single agents, inhibitors of the DNA damage response, when combined with radiation could increase tumour response while sparing the normal tissue.

Poly(ADP-ribose) polymerase (PARP) inhibitors affect DNA repair and thus are good candidates for combined use with DNA damaging agents. Indeed, PARP inhibitors increase radiation and chemotherapy responses in preclinical studies. As a single agent they have been shown to specifically kill homologous recombination (HR) deficient tumour cells. A large variety of tumour-specific mutations, such as in BRCA or ATM, affect double strand break repair and HR status and therefore amplify the damage induced by the combined PARP inhibitor radiation treatment. We found that the PARP inhibitor olaparib induced radiosensitisation in mouse breast cancer cells and in a panel of human head and neck cancer cell lines at much lower doses than those required for its single agent activity. Importantly, at these low doses olaparib prevented PAR induction by radiation. Also, the extent of radiosensitisation by olaparib depended on the integrity of the HR pathway, as witnessed by the difference in olaparib dose required to induce radiosensitisation in BRCA2-deficient versus BRCA2-complemented cells.

We have designed 3 phase I-II studies evaluating the safety and tolerability of olaparib, in combination with radiotherapy in locally advanced breast cancer, non-small cell lung cancer and head and neck cancer. Dose-escalation according to the TITE-CRM design allows the evaluation of late toxicity and ensures continuous patient accrual. In support of these trials, biomarkers for the radiosensitisation efficacy of PARP inhibitors have been developed and are evaluated. Tumour and normal tissue samples are collected from all patients to measure PARP inhibition and γ H2AX foci formation. These measurements will help to guide the dose-escalation strategy used in these trials.

SP-0298

Phase I Results of PARPi (Olaparib) + RT + Cetuximab in LAHNSCC

D. Raben¹, D. Bowles¹, T. Waxweiler², S. Karam², A. Jimeno¹

¹University of Colorado Health, Medical Oncology, Aurora, USA

²University of Colorado Health, Radiation Oncology, Aurora, USA

DNA repair within cancers contributes to radioresistance and is a concept across all histology's. Cancer cells employ rapid and efficient methods for repairing damaged single and double strand DNA breaks from radiation and chemotherapy. Can we take advantage of this survival mechanism? One strategy incorporates the use of poly(ADP-ribose) polymerase (PARP) inhibitors. What do we know about PARP? PARP inhibition sparked interest in oncology based in part on the concept of “synthetic lethality” in which cancer cells with pre-existing deficiencies in homologous-recombination pathways (e.g. BRCA mutations) exhibit highly selective cytotoxicity to single agent PARP inhibitors in contrast to normal cells - a differentiation that radiation oncologists find attractive and might provide an opportunity with radiation based studies for locally advanced cancers. Building upon the synthetic lethality story, PARP inhibitors show promise as radiosensitizers by directly preventing cancer cells from repairing stress induced DNA damage. In the preclinical setting, our data suggested enhanced sensitivity to PARP(I) monotherapy as well as when combined with radiation across a variety of HNSCC lines known to be HPV negative many groups have shown the ability of PARP inhibitors to sensitize a variety of histology's, both p53 wild type and null, to radiation in both in vitro and in vivo settings. The data seems to suggest that the levels of PARP inhibition required to enhance radiation may be significantly lower than when used

as a monotherapy. Remarkable activity has been observed in patients with BRCA1/2 mutations using Olaparib (AZD2281), an orally bioavailable PARP inhibitor, recently approved for refractory ovarian cancer with BRCA1/2 mutations. Toxicity with monotherapy has been remarkably low. Is the BRCA mutation story the only predictor of PARP inhibition (I) sensitivity? Perhaps other homologous and non-homologous repair defects may also contribute to PARP(I) sensitivity. Fanconi anemia phenotypes may also relate to sensitivity as well as pathways related to the SMAD family. We assessed the safety, toxicity and early response when combining escalating doses of Olaparib with fixed dose cetuximab and RT in heavy smoker HNSCC patients. We chose this group of patients due to their high local-regional failure rates and hypothesized amplified rates of HR defects that would lend itself to Olaparib sensitivity. We used a TITE-CRM model with a starting Olaparib dose of 50 mg po BID. The TITE-CRM algorithm uses both the length of observation and whether or not a DLT has occurred in each previous patient enrolled on the trial to estimate the probability of a DLT for each dose level, thereby optimizing subsequent dose assignment. We enrolled 13 patients to date. Among these patients, with a median follow-up of ~14 months, two failed distantly and one failed locally. Patients who experienced local/regional failures continued to smoke during treatment. Toxicity was primarily related to grade 3 dermatitis and acneiform rash. Skin toxicities resolved in all patients after treatment concluded; long-term follow up has revealed development of grade 2 fibrosis in the neck areas where dermatitis was most severe in four patients. The optimal timing of PARP inhibitors and radiation remains unknown and with dose enhancement factors seen pre-clinically, might it be possible to investigate radiation de-intensification or perhaps consider novel combinations with checkpoint inhibitors. This discussion will include a review of some of the pertinent pre-clinical studies with radiation, a review of toxicities and cautions as it relates to combinations with radiation and what are the possibilities for future approaches with DNA repair in locally advanced disease.

Symposium: Radiotherapy of prostate cancer: technical challenges

⁶Kalmar Hospital, Department of Oncology, Kalmar, Sweden

The α -B ratio for prostate cancer (PCa) is postulated to be low; < 3 Gy, i.e. even lower than for late normal tissue reactions. Hence hypofractionated radiotherapy (RT) is hypothesized to be advantageous for treatment of localized PCa. Literature data indicating that this is the case for a moderately hypofractionated regimen was first reported from Italy by Arcangeli. This study was however quite small. At ECC 2015 Dearnaley presented the results from the UK three-armed CHHiP-trial comprising 3,200 patients. This three-armed trial showed non-inferiority between the 74 Gy conventional arm (37 fr; 2 Gy/fr) and the 60 Gy moderately hypofractionated arms (20 fr; 3 Gy/fr) while the experimental arm given 57 Gy arm (19 fr; 3Gy/fr.) had lower efficacy. Patients had predominately intermediate risk tumours and most patients received 6 month of neoadjuvant and concomitant castration treatment. Previously published toxicity data from the trial showed similar results for the trial arms. Results from other moderately hypofractionated

schedules have also been reported recently. RTOG 0415 with only low-risk patients, showed that 70 Gy in 28 fr over 5.6 weeks is non-inferior to 73.8 Gy in 41 fr over 8.2 weeks for low risk PCa patients. The Dutch randomised phase III HYPRO trial with 804 evaluable patients with intermediate/high-risk PCa, comparing moderately hypofractionated RT (19 fr; 3.4 Gy/fr.) with conventional RT (39 fr; 2 Gy/fr), showed non-inferiority with comparable toxicity.

Some prospective results of Stereotactic Body RadioTherapy (SBRT) with 5 fractions and 7-8 Gy/fr suggest equal clinical outcome compared to conventional RT and with acceptable toxicity. The Scandinavian multicentre phase III trial "HYPO-RT-PC" was recently closed, with 1200 patients recruited during 2005-2015. All patients had intermediate risk PCa (PSA \leq 20; one or two of the risk factors; T3, Gleason \geq 7, PSA 10-20). No hormones were used. Patients were randomized to either conventionally fractionated RT (39 fr; 2.0 Gy/fr) over 7 weeks, or to a schedule with extreme hypofractionation (7 fr; 6.1 Gy/ fr) in 2.5 weeks (always including two weekends). The two treatment arms are designed to be equieffective for late normal tissue complications assuming $\alpha/\beta=3$ Gy. Primary endpoint will be mature within 2 years, and toxicity data will be reported by late this year.

Brachytherapy as a boost: the way to go?

P. Hoskin¹

¹Mount Vernon Hospital, Northwood Middlesex, United Kingdom

Brachytherapy has always represented the most focal means on delivering radiation having the advantages of the inverse square law around the radiation source which ensures delivery of an intense high dose within the implant and a rapid fall dose outside. These characteristics mean that brachytherapy can deliver very high doses to the prostate gland within the tolerance doses of bladder and rectum and that the characteristics of dose distribution within the implant mean that the volume receiving 150% and 200% prescribed peripheral dose (the 150 and the 200) are considerably greater than can be achieved with any external beam technique.

Brachytherapy as a boost can be used in two distinct ways. First is as a boost to the whole gland following external beam radiotherapy. There is now grade a level I evidence from randomised controlled trials that both low dose rate and high dose rate brachytherapy achieve effective dose escalation and consequently better biochemical relapse free survival.

There is also increasing interest in the use of brachytherapy to deliver a focal boost to dominant lesions defined on multi-parametric MR scanning and mapping template biopsies. Thus within a whole gland brachytherapy volume sub volumes can be defined within which the dose can be further escalated. Planning studies have confirmed the feasibility of this approach with both low dose rate and high dose rate brachytherapy and the requirements for catheter or seed placement to achieve these endpoints has been described. The clinical application of this approach is still in its infancy although early results confirm its feasibility.

Summary: both low dose rate and high dose rate brachytherapy offer optimal means of focal dose delivery within the prostate gland. The use of this modality for whole gland treatment is now well established sound evidence base. Emerging application sub volume posts to dominant tumour volumes is under investigation.

Debate: This house believes that SBRT should become the standard of care for T1 and small T2 NSCLC tumours

SP-0302

For the motion

K. Franks¹

¹St James Institute of Oncology, Clinical Oncology, Leeds, United Kingdom

The current standard of care for T1 and small T2 early-stage non-small cell lung cancer (NSCLC) is surgical resection with lobectomy and nodal sampling/resection. There is randomized evidence that wedge resection is an inferior operation to lobectomy [1] but no large series randomized evidence of surgery versus any other curative intervention for early stage lung cancer. In addition, for patients over 71 years there may be no benefit of lobectomy over limited resection[2]. Stereotactic body radiotherapy (SBRT) is not a new treatment and has been used in medically inoperable stage I NSCLC for 20 years[3]. Given the very high rates of local control ~90% at 3-5 years[4], the low rates of acute toxicity and little detriment to quality of life post treatment[5] SBRT is now a standard of care for medically inoperable peripherally located T1 and T2 tumours up to 5cm in diameter. For medically operable patients where the risks of surgery are low, surgery does offer a theoretical advantage over local ablative treatment such as SBRT. Optimum surgery with removal of the tumour and surrounding lobe may remove occult cancer cells outside the treated volume that may not be included in the SBRT treatment volume. In addition, nodal resection may convey an additional survival benefit and for those patients with occult N1/2 disease those patients could further benefit with the addition of adjuvant chemotherapy.

However, the average age at the time of diagnosis of lung cancer is 70, often in patient's with significant medical comorbidity that precludes lobectomy and reduces the chance of them receiving adjuvant chemotherapy[6]. Surgical mortality at both 30 and 90 days increases with age further reducing the potential benefit from lobectomy and nodal sampling/resection[7]. In addition, with PET/CT staging and minimally invasive techniques (EBUS) for pathologically sampling the mediastinum now routine practice, the chance of missing occult N1/N2 nodal disease is small being <9% in one series[8].

Propensity analysis of patients receiving surgery versus SBRT have been performed on retrospective series with some reports suggesting no difference in survival between the two match groups and others suggesting a benefit with surgery. Randomized controlled trials (RCT) of surgery versus SBRT (STARS/ROSEL) have been attempted but have been closed prematurely due to poor accrual. A recent pooled analysis of the STARS and ROSEL studies showed no significant difference between SBRT and surgery, though a trend for improved survival with SABR but this was based on 58 patients[9]. Given the limited data from STARS/ROSEL and conflicting results from propensity matched analysis there is a need for successful randomized trials of surgery versus SBRT to prove whether SBRT should be the standard of care. Hopefully, the open SABRtooth (UK) and STABLE-MATES (USA) trial combined with other planned trials of SBRT versus surgery will recruit and provide the answer to this key question.

SP-0303

Against the motion

P. Van Schil¹¹University Hospital Antwerp, Department of Thoracic and Vascular Surgery, Edegem, Belgium

For early-stage non-small cell lung cancer (NSCLC) surgical resection remains the treatment of choice providing excellent long-term results (1). Recently, stereotactic body radiotherapy (SBRT) has become an alternative treatment for localized NSCLC (2). SBRT has mainly been applied for functionally in operable patients with severe cardiopulmonary morbidity. Currently, there is an ongoing debate whether SBRT is also a valid oncological treatment for low-risk patients who are operable from a technical and functional perspective. No large randomized studies are available directly comparing SBRT and surgical resection with systematic lymph node dissection. Several trials closed prematurely due to poor accrual.

From a thoracic surgical point of view several concerns emerge when applying SBRT to operable early-stage NSCLC: precise pathology is not obtained in all cases, information on locoregional lymph node involvement is not always available making it difficult to recommend adjuvant chemotherapy in specific cases, and rather troublesome, different criteria are used when comparing results of surgery and SBRT, mainly in relation to local recurrence (3,4). Moreover, thoracic surgeons are more and more dealing with "salvage surgery" after previous radiotherapy when no other therapeutic options are available (5). Technically, these resections may be very challenging due to technical difficulties during dissection of the hilar region not encountered during primary intervention. These procedures should be performed in dedicated thoracic centres with a large experience.

Due to the lack of clear evidence, different opinions are expressed in present-day literature.

In a pooled analysis of two randomised trials comparing SBRT with lobectomy for stage I NSCLC that closed prematurely due to poor accrual, the authors concluded that SBRT can be considered a valid treatment option for operable stage I NSCLC (6). However, because of small patient sample size and short follow-up time, they indicate that further randomized studies should be performed before more definite recommendations can be made (6).

A different conclusion was reached in a recent propensity score analysis matching 41 patients who underwent video-assisted (VATS) lobectomy with 41 patients treated with SBRT for stage I NSCLC (7). Significant differences were found in overall survival, cause-specific survival, recurrence-free survival, local and distant control favouring VATS lobectomy. Conclusion of this study was that VATS lobectomy may offer a significantly better long-term outcome than SBRT in potentially operable patients with biopsy-proven clinical stage I NSCLC.

Another propensity score analysis compared SBRT with sublobar resection for stage I NSCLC in patients at high risk for lobectomy (8). In 53 matched pairs the difference in overall survival was not significant and the cumulative incidence of cause-specific death was comparable between both groups. Conclusion of this study was that SBRT can be an alternative treatment option to sublobar resection for patients with severe comorbidity who cannot tolerate alobectomy due to functional impairment (8).

In June 2015 the "Comité del'Evolution des Pratiques en Oncologie (CEPO) from Québec, Canada published recommendations regarding the use of SBRT (9). For medically operable patients with T1-2N0M0 NSCLC surgery remains the standard treatment due to the lack of high-level evidence and valid comparative data. For medically inoperable patients with T1-2N0M0 NSCLC or medically operable patients who refuse surgery, SBRT should be preferred to external beam radiotherapy. In the latter cases a biological equivalent dose (BED) of at least 100 Gy should be administered. The choice of using SBRT should be discussed within a multidisciplinary tumor board. Radiotherapy should not be considered for patients whose life expectancy is very limited because of comorbidities.

In summary, main points are:

- surgical resection remains the treatment of choice for operable early-stage NSCLC
- SBRT may be considered for functionally compromised patients who cannot tolerate lobectomy.
- further high-level evidence is needed which requires close cooperation between radiation oncologists and thoracic surgeons to design comparative trials with clear inclusion criteria and unequivocal definitions of endpoints.

Debate: Is brachytherapy the best for partial breast irradiation?

SP-0304

Multicatheter brachytherapy is the best for APBI

V. Strnad¹¹University Hospital Erlangen, Dept. of Radiation Oncology, Erlangen, Germany

Accelerated Partial Breast Irradiation (APBI) using multicatheter brachytherapy is an attractive treatment approach not only to shorten the course of radiation therapy from 3-6 weeks to 2-5 days but also to reduce significantly the radiation exposure to the breasts, the skin, the lung and particularly to the heart very effectively.

Over the last 20 years different modalities of APBI have been introduced into clinical practice -multicatheter brachytherapy, single catheter brachytherapy, IORT techniques, different techniques of External Beam Radiation Therapy (EBRT). Unfortunately fact is that the results of APBI trials with IORT using intraoperative electrons or 50 kV photons have been negative. As well Vaidya et al. (TARGIT trial) as Veronesi et al. (ELIOT trial) reported high 5-year recurrence rate after IORT, namely 3.3%-4.4% in IORT groups versus statistically significant lower recurrence rates in control groups 0.4%-1.3%. Possibility of APBI using EBRT is of course very attractive, since this technique is broadly available and easy to perform. Unfortunately, hitherto reported results of phase 3 APBI trials using EBRT are either disappointing (RAPID trial) or with low statistical power (Olivetto et al., Livi et al.). On the contrary, during the last decade number of modern phase 2 and phase 3 APBI trials, using multicatheter interstitial brachytherapy for the delivery of APBI, have demonstrated favorable long-term local control

rates and cosmetic outcomes, comparable to the results of whole breast irradiation (WBI). In the largest phase 3 randomized non-inferiority GEC-ESTRO trial with sufficient statistical power (~1200 pts.), importantly using for APBI solely multicatheter interstitial brachytherapy in 5 days, after median follow-up of 6.6 years the 5-year local recurrence rates were 1.4% in the APBI arm, and 0.9% in the WBI arm ($p=0.4$), and 5-year disease-free and overall survival were 96-97% in the WBI group versus 97% in the APBI group - all events are without any statistical and clinical significance. The equivalence of local recurrence rates was evident in all age groups, in all histological subgroups and also independent of the type of systemic therapy. Thus it's the first phase 3 study proving non-inferiority of APBI in comparison to whole breast irradiation for selected early stage breast cancer patients. Undoubtedly is, that in the light of the landmark UK and Canadian trials comparing 5 versus 3 weeks of WBI the difference in total treatment time between WBI and APBI using multicatheter brachytherapy (4-5 days) has been partially diminished. However the difference between 3 weeks of WBI versus 4-5 days of APBI still remains clinically and socio-economically relevant. Moreover, due to the extreme steep fall-off of dose of Iridium-192, the significant dose reduction of irradiated normal tissues (including the heart and skin) is a unique advantage of interstitial multicatheter brachytherapy, which is hardly ever achievable by other APBI techniques. The remaining, hitherto unreported ongoing APBI trials unfortunately use for APBI only different techniques of EBRT. The results of these trials will therefore particularly contribute to further fine-tuning of selection criteria and to precise requirements for quality assurance of EBRT-based APBI.

In summary: At the present time only the long-term results of APBI using sole multicatheter brachytherapy for appropriate selected patients demonstrate impressive low local recurrence rates - similar as WBI, accompanying with excellent radiation protection of surrounding organs - better as WBI. Consequently "APBI used multicatheter brachytherapy is today a proven and valid alternative treatment option after breast conserving surgery, and can be offered for all low risk breast cancer patients in clinical routine".

SP-0305

IORT is the best for PBI

R. Orecchia¹

¹European Institute of Oncology, Milan, Italy

Over the past ten years the results of several clinical trials have been published, detailing various approaches of PBI. Among the different techniques used, IORT has increased rapidly in popularity, mainly in Europe, and up to date many thousands of women have been treated in clinical setting. IORT allows to realize a radiation dose to the index quadrant, eliminating the treatment to the tissue remote from the tumour bed, and using only one very high dose (20 Gy or more) in a single session. When single doses above certain thresholds of 10 Gy are given, some additional biological effects on tumor cell killing and from the surrounding microenvironment can be expected. IORT also represents the possibility of overcoming some constraints such as the accessibility to the centres of radiotherapy, the socio-economic impact on the working life and on the personal habits of the patient. Another important advantage is the avoidance of the interactions with the systemic therapy, that may determine delays in the initiation or in the carrying out of the adjuvant treatment. These potential benefits must be balanced with the potential higher risk of recurrence within the untreated gland tissue in the same breast as well as the still unknown long-term results on survival and cosmesis. Two prospective randomized clinical studies establishing the role of IORT in clinical practice have been published up to now. A single-center study, named ELIOT, was performed at the European Institute for Oncology (EIO) in Milan, Italy. Patients with limited size tumor (2.5 cm) and age of 48 years or more were either randomized to a single dose of 21 Gy of IORT with electrons or to standard WBI. The local recurrence rate (LRR) at 5-years was higher in the experimental arm (4.4%

versus 0.4%), and just fell within the pre-defined non-inferiority margin of 4.5%. However, in patients with low risk factors like suggested by the ESTRO or ASTRO consensus' criteria, there were not statistically different LLRs in both arms, and also in patients with luminal A molecular subtype the LLR was very low in the IORT arm, about 1%. It was also found that there was no significant difference in the 5-year overall survival rate in two arms, that is, 96.8% in the ELIOT arm and 96.9% in the EBRT arm. For patients with higher risk factors, a new strategy has been now developed, which include a hypofractionated WBI to be given after surgery and ELIOT. The TARGIT-A trial was a multicentric trial. The inclusion criteria were stricter than in the ELIOT trial. It included patients with unifocal small breast cancer with non-lobular histology and tested the concept of risk-adapted single-dose IORT, which was followed by external-beam WBI in patients with additional unfavorable risk factors. The latest published results from the TARGIT-A trial, with a median follow-up of 2 years and 4 months, reported a LRR with IORT of 3.3% and with EBRT of 1.3, meeting the non-inferiority margin of 2.5%, set at the outset. Overall, breast cancer mortality in the IORT arm was 2.6% versus 1.9% in the WBI arm. In addition, non-breast cancer deaths were found to be significantly reduced in the IORT arm: 1.4% versus 3.5%, with $p = 0.0086$. Toxicity and cosmesis were assessed by different methods in the studies, but in any case a favorable outcome has been shown. The comparison between the current standard or alternative PBI approaches for early stage breast cancer with data coming IORT techniques poses a dilemma as to when preliminary results are sufficiently mature to be allow practitioners and patients to consider a new treatment approach as safe. We know that most data from studies of breast conservation therapy have demonstrated the importance of long-term data (up to 20 years) in determining the ultimate efficacy of a treatment. The level 1 randomized evidence produced by the IORT trials show that this technique is very convenient for the patient, effective and has few side effects, rather than any postoperative treatment or procedures. Patients have every right to be offered an informed choice.

SP-0306

IMRT is the best for PBI

B. Offersen¹

¹Aarhus University Hospital, Dept Oncology, Aarhus C, Denmark

Several clinically controlled randomized trials on accelerated partial breast irradiation (APBI) are currently being conducted and some of these have now published results. The trials have used different strategies, for example different patient selection criteria, doses and number of fractions, overall treatment time, treated volume and radiation techniques. Many trials have compared the APBI treatment to whole breast irradiation (WBI) 50 Gy/25 fr followed by a boost. External beam APBI is an attractive strategy, because every radiation department will be able to do the dose planning. The demand for technical skills is in principle not higher than for conventional dose planning. Few randomized trials have reported data, but unfortunately the largest one has not been promising.

In the phase III randomized RAPID trial significantly worse cosmetic outcome was reported with median follow up 36 months in 2135 patients randomized 1:1 to APBI based on 3D-CRT with 38.5 Gy/10 fractions, 5 days, versus WBI based on 42.5Gy/16 fr or 50Gy/25 fr +/-boost. Adverse cosmesis was higher in APBI-treated patients compared with WBI patients as assessed by trained nurses (29% vs 17%; $p=0.001$) and by patients (26% vs 18%; $p=0.02$). Grade 3 adverse events were seen in 1.4% of APBI patients, and not in WBI patients. With median 5 years follow up data from another phase III trial involving 520 patients randomized to APBI with IMRT using 30 Gy/5 fr versus WBI using 50 Gy/25 fr + boost has been reported by Livi and coworkers. Significantly better results were seen in APBI patients regarding acute ($p=0.0001$), late ($p=0.004$) and cosmetic morbidity ($p=0.045$). Local recurrence was seen in 1.5% of the patients. Thus data from large phase III trials supporting routine use of external beam

APBI at the present time are not available. However, it is to be expected that the UK IMPORT LOW Trial will be able to report data from >2000 patients with median 5 years follow up at the Early Breast Cancer Conference (EBCC) March 2016. In that trial the strategy is based on 40 Gy/15 fr in all 3 arms, where arm 1 is WBI, arm 2 is partial breast irradiation, and arm 3 has a gradual dose using 40 Gy/15 fr to partial volume and 36 Gy/15 fr to residual breast. At EBCC, data on morbidity will also be reported from the DBCG PBI trial, which has included >800 patients and randomized them to APBI versus WBI using 40 Gy/15 fr in both arms. Data from these 2 trials will be presented and discussed at ESTRO 35. If the results from the IMPORT LOW Trial show that PBI using 40 Gy/15 fr is safe, and these data are supported by results from the DBCG PBI trial using the same treatment, then there is support for the statement that *IMRT is the best for PBI*. However, we are also awaiting results from the ongoing NSABP B-39/RTOG 0413 trial, which has accrued >4000 patients, who were randomized to APBI versus WBI. The majority of patients in the APBI arm have been treated with 3D-CRT. Many of the APBI trials were designed and initiated a decade ago, where the local recurrence risk was higher than we see today. Therefore some of these trials are underpowered to support the statement they are investigating. It is to be expected that results from several trials investigating external APBI will be published in the near future, and hopefully results from the trials will be included in meta-analyses to achieve enough statistical power to identify subgroups of patients where APBI is safe and other subgroups where WBI is to be preferred.

SP-0307

Dosimetric pros and cons of available PBI techniques

T. Major¹

¹National Institute of Oncology, Budapest, Hungary

Partial breast irradiation (PBI) can be performed with various techniques including both brachytherapy (BT) and external beam radiotherapy (EBRT). These methods differ from each other regarding technical skill and dosimetric characteristics. Recent developments in imaging, dose calculation algorithms and beam delivery techniques have made all methods clinically feasible, but in most institutions the applied method mostly depends on the physician's preference and the technical availability.

Among all techniques the longest experience exists with multicatheter interstitial BT which can provide highly conformal dose distribution, large dose gradient at target edge, but it is quite complex and requires certain manual skilfulness. The possible geometric miss can result in significant under dosage of the target.

Technically, the intracavitary applicators are easier to be used and with balloon-type applicators no geometric miss can occur, but proper tissue conformance is not always guaranteed. In dosimetric point of view drawbacks of the Mammosite applicator are the spherical dose distribution, the symmetric margin and the potential high dose to skin, lungs and ribs. In some anatomical situation the balloon can be asymmetric resulting in asymmetric target coverage. The multichannel applicators are more flexible regarding shaping the dose distribution and reducing dose to critical structures without compromising the target volume coverage. With these applicators asymmetric margins can be used to a small degree.

In intraoperative electronic BT using spherical applicators the dose distribution is also spherical and a large dose inhomogeneity develops due to the sharp dose fall-off of the low energy X-ray beam. The margin is always symmetric, but the geometric accuracy is always ensured.

At intraoperative irradiation with electron beams there is no 3D-defined target volume, modulation possibilities to shape the dose distribution are very limited and conformal radiotherapy cannot be performed.

Linear accelerator based EBRT techniques expose relatively large volumes of non-target breast to high dose mainly due to the extended target volume created from CTV. In three-dimensional conformal radiotherapy (3D-CRT) dose to contralateral breast, lung or heart can be reduced with

proper selection of beam orientations. With intensity modulated radiotherapy (IMRT) highly conformal dose distribution can be achieved, but volumes irradiated by low doses can be larger than with 3D-CRT. Regarding the dose to OARs, with multicatheter BT the critical structures can be better spared than with 3D-CRT/IMRT except for the heart whose dose in BT is strongly dependent on the location of the PTV. With image guidance in EBRT the dose to OARs can be significantly reduced. At left sided lesion the dose to heart can be considerably decreased with deep inspiration breath-hold technique.

With special EBRT equipments such as Cyberknife or Tomotherapy which are equipped with image guidance smaller CTV-PTV margin can be applied which reduces the dose to OARs while maintaining proper target coverage. Real-time tracking with Cyberknife can provide better target volume coverage and spare nearby critical organs, but the treatment time is too long.

Proton beam irradiation, due to the more favourable dose characteristics of proton beam, can provide the less dose to organs at risk, but the availability of the technique is sparse.

Symposium: New challenges in modelling dose-volume effects

SP-0308

Evaluating the impact of clinical uncertainties on TCP/NTCP models in brachytherapy

N. Nesvacil¹, K. Tanderup², C. Kirisits¹

¹Medical University of Vienna, Department of Radiotherapy-Comprehensive Cancer Center- and CDL for Medical Radiation Research, Vienna, Austria

²Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

During the past decade many investigations have been performed to investigate and minimize clinical uncertainties that could lead to significant deviations between the planned and the delivered doses in radiotherapy. Among the sources of uncertainties patient setup plays an important role in EBRT. Analogously, in brachytherapy the geometric uncertainties caused by movement or reconstruction uncertainties of the implant position in relation to the CTV and/or normal tissue can lead to systematic or random variations between prescribed and delivered dose. At the same time interfraction or intrafraction variations of the anatomy, e.g. caused by variations of position, shape and filling status of OARs, during the course of a treatment pose an additional challenge to all types of radiotherapy.

Recent investigations of different types of uncertainties for a variety of treatment sites, including gynaecological, prostate, head and neck, or breast BT, have led to numerous reports on accuracy of image guided brachytherapy. These have triggered the development of the recommendations for reporting uncertainties in terms of their dosimetric impact (GEC-ESTRO / AAPM guidelines, Kirisits et al. 2014, Radiother Oncol 110). Following these guidelines for uncertainty analysis, individual BT workflows can be analysed in order to identify those components of the overall uncertainty budget which will have the largest impact on the total delivered treatment dose. Once identified, strategies for reducing these uncertainties can be taken into consideration, such as repetitive/near treatment imaging, advanced online dose verification tools, etc.

In order to assess the clinical benefit of such uncertainty reduction measures, it is important to understand the interplay between different types of uncertainties and their combined effect on clinical outcome, in terms of TCP and NTCP. In the past, dose-response relationships have been derived from clinical data, which could not take into account the accuracy of the reported dose. For some treatment sites, e.g. for cervical cancer, uncertainty budgets and dose-response relations have been described in the literature in sufficient detail that now allows us to simulate what impact specific clinical uncertainties would have on TCP/NTCP modelling. In addition to that, one can simulate how TCP or

NTCP models would change, if systematic and random dosimetric uncertainties could be reduced.

In this presentation a few such simulation examples will be shown to illustrate the clinical impact of uncertainties for source calibration, applicator reconstruction, interobserver variations and anatomical interfraction variations. Strategies for reducing clinical uncertainties will be discussed.

Finally, we will come one step closer to answering the questions whether reducing our clinical uncertainties is possible and meaningful, and if so, which strategies would have the largest clinical impact. In the future dose prescription may be affected by technological improvements that lead to a reduction of dosimetric uncertainties and a subsequent widening of the therapeutic window. These developments would benefit from a common effort in the BT community to investigate dose-response relationships for various treatment sites, and to simultaneously report uncertainty budgets for the underlying workflows applied for image guided brachytherapy, in our current clinical practice.

SP-0309

Incorporation of imaging-based features into predictive models of toxicity

C. Brink^{1,2}

¹*Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark*

²*University of Southern Denmark, Institute of Clinical Research, Odense C, Denmark*

The probability of local tumor control is limited by the amount of dose deliverable to the tumor, which is limited by the amount of radiation induced toxicity. There is a large, and currently unpredictable, interpatient variation in the amount of observed toxicity. Since the expected patient specific toxicity is not known, the prescribed dose is restricted such that, within the patient population, the number of patients with major or even fatale toxicity is limited. Due to the interpatient variation in toxicity the population based dose limits lead to undertreatment of patients with low normal tissue irradiation sensitivity. This issue could be addressed if, on a patient specific level, it would be possible to classify the patients according to expected toxicity prior to or early during the treatment course - which calls for predictive models of toxicity.

Many clinical factors such as performance status, patient age, and other co-morbidity are associated with observed toxicity, and models based on such factors are today available (e.g. <http://www.predictcancer.org/>). The models can be a useful tool to optimize the treatment on the population level, but in order to be used on a patient specific level, input of more patient specific information is needed. During planning and delivery of radiotherapy a large number of patient images are acquired. The information content in the images is often reduced to a few figures (e.g. volume of tumor or measurement of patient positioning). The different types of images (CT/SPECT/PET/MR/CBCT) are available for free, and it is tempting to believe that these images could provide more patient specific information, if extracted in a proper way. Also as part of the response evaluation it is likely that imaging could be used to quantify the degree of toxicity. At the end of the day, the overall toxicity level can only be assessed by the patient, who should cope with the toxicity on a daily basis. However, in terms of biological tissue response to the radiation, patient (or oncologist) reported toxicity is likely to underestimate the "true" amount of toxicity since the toxicity effects might be overshadowed by treatment related gains e.g. re-ventilation of obstructed airways due to tumor regression in lung cancer patients, or because the toxicity is assumed to be related to co-morbidity. Disentanglement of such effects is desirable during creation of predictive models of toxicity; which might be feasible by evaluation of follow-up images.

The most used imaging-based feature to predict toxicity is obviously measurement of dose to individual risk organs (e.g. dose to heart or lung). These values are routinely used clinically and typical not regarded as image-based features. More advanced imaging-based features such as homogeneity, texture, or time changes of signals/images has been proposed

and showed to be associated with toxicity. It is important to remember that such features, to some extent, might be confounded by more simple factors (e.g. tumor volume or volume of irradiated region). Nevertheless, image based features appears in a number of studies to add independent toxicity information; but it is likely that no single image-based feature (or no single feature at all) will be able to make a perfect patient specific toxicity prediction for the entire population. In many studies the correlation between a specific image-based feature and observed toxicity is relative weak. However, if predictive toxicity models simply are able to identify a subset of patients who are likely to have modest toxicity that would be very beneficial, since this group of patients could then be offered a more aggressive treatment, which hopeful would result in improved local control. Predictive toxicity models should thus not only be evaluated on their overall prediction performance for the entire population, but also on their ability to identify a significant subgroup of patients who are candidates for intensified treatment.

The current lecture will present examples of image-based features and point to their potential clinical impact; but will also focus on the potential use of patient specific toxicity models to select subgroups of patients as described above. Moreover comments on image quality will be made, since high images quality is the foundation for imaged-based features used in predictive models for toxicity.

SP-0310

Growing importance of data-mining methods to select dosimetric/clinical variables in predictive models of toxicity

T. Rancati¹

¹*Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milan, Italy*

In the field of toxicity modeling it is common practice to build statistical models starting from analysis of clinical data which are prospectively collected in the frame of observational trials. Modern prospective observational studies devoted to modelling of radioinduced toxicity are often accumulating a large amount of dosimetric and patient-related information, this requires particular attention when normal tissue complication probability modelling is approached. A core issues is related to selection of features, which then influences overfitting, discrimination, personalization and generalizability.

These risks are particularly high in clinical research datasets, which are often characterized by low cardinality - i.e. the number of cases is overall low - and are often strongly imbalanced in the endpoint categories - i.e. the number of positive cases (e.g. toxicity events or loss of disease control) is small, or even very small, with respect to the negative ones. This is obviously positive for patients, it is however a disadvantage for model building.

In this context a possible methods using in-silico experiment approach for toxicity modelling will be discussed together with some applications.

This method aimed at identifying the best predictors of a binary endpoint, with the purpose of detecting the leading robust variables and minimizing the noise due to the particular dataset, thus trying to avoid both under- and overfitting. It followed, with adjustments, a procedure firstly introduced by El Naqa [IJROBP2006]: the treatment response curve was approximated by the logistic function, while the bootstrap resamplings were performed to explore the recurrence of the selected variables in order to check their stability. A further bootstrap resampling was introduced for the evaluation of the odds ratios of the selected variables.

The in-silico experiment was implemented using the KNIME software (KNIME GmbH, Germany) and consisted in the following processing steps:

- 1) 1000 bootstrap samplings of the original dataset are created, as suggested by El Naqa [IJROBP2006];
- 2) backward feature selection based on minimization of residuals is performed on each bootstrap sample;
- 3) the rate of occurrences and the placement of each variable (selected by the backward feature selection) in the

1000 bootstrapped datasets are used to classify the most robust predictors. A synthetic index, called normalized area, is defined for ranking each predictor: it corresponds to the area under the histogram representing the number of occurrences of each variable (x-axis) at a given importance level in each re-sampled dataset;

4) a basket analysis of the 1000 sets of predictors is used to identify the predictors that appears together with higher probability;

5) the best set of predictors is chosen, with its maximum size determined by the rule of thumb "one tenth of the number of toxicity events";

6) the distribution of odds ratios are determined through 1000 bootstrap re-samplings of the original dataset including the set of predictors selected in the previous step;

7) a logistic model with the best set of predictors and the median odds ratios, calculated from the distributions obtained in the previous step, is defined.

In this approach, logistic regression is enhanced with upstream and downstream data processing to find stable predictors.

The method was tested with satisfactory results on different datasets aimed at modelling radio-induced toxicity after high-dose prostate cancer radiotherapy.

Symposium: Automated treatment plan generation in the clinical routine

Automated treatment plan generation - the Zurich experience

J. Kravenbuehl¹, M. Zamburlini¹, I. Norton², S. Graydon¹, G. Studer¹, S. Kloeck¹, M. Guckenberger¹

¹University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

²Philips, Philips Radiation Oncology Systems, Fitchburg, USA

Intensity modulated radiotherapy and volumetric modulated radiotherapy (VMAT) involves multiple manual steps, which might influence the plan quality and consistency, for example planning objectives and constraints need to be manually adapted to the patients individual anatomy, tumor location, size and shape [1]. Additional help structures are frequently defined on an individual basis to further optimize the treatment plan, resulting in an iterative process. This manual method of optimization is time consuming and the plan quality is strongly dependent on planner experience. This is especially true for complex cases such as head and neck (HN) carcinoma and stereotactic treatment.

In order to improve the overall plan quality and consistency, and to decrease the time required for planning, automated planning algorithms have been developed [2,3]. In this pilot study, we compared two commercially available automatic planning systems for HN cancer patients. A VMAT model was created with a knowledge based treatment system, Auto-Planning V9.10 (Pinnacle, Philips Radiation Oncology Systems, Fitchburg, WI) [4] and for a model based optimization system, RapidPlan V13.6 (Eclipse, Varian Medical System, Palo Alto, CA) [2]. These two models were used to optimize ten HN plans. Since the aim was to achieve plans of comparable quality to the manually optimized plans in a shorter time, only a single cycle of plan optimization was done for both automated treatment planning systems (TPS). Auto-Planning was additionally used to evaluate the treatment of lung and brain metastases stereotactic treatments.

The results from the planning comparison for HN cancer patients showed a better target coverage with AutoPlanning in comparison to Rapidplan and manually optimized plans ($p < 0.05$). RapidPlan achieved better dose conformity in comparison to AutoPlanning ($p < 0.05$). No significant differences were observed for the OARs, except for the swallowing muscles where RapidPlan and the manually optimized plans were better than AutoPlanning and for the mandibular bones were AutoPlanning performed better than the two other systems. The working time needed to generate

clinical accepted plans for both automated TPS was drastically reduced to less than ten minutes.

For the two stereotactic sites evaluated, target coverage and OARs doses differences were not clinically relevant between Auto-Planning and manually optimized plans.

The encouraging results of automatic planning shows that highly consistent treatment plans for complex cases can be achieved with an automated planning process.

SP-0312

Automated treatment plan generation - the Milan experience

A. Fogliata¹

¹Humanitas Research Hospital, Department of Radiation Oncology, Rozzano-Milan, Italy

A knowledge based planning process, named RapidPlan, has been recently implemented into the Varian Eclipse treatment planning system. The goal of the engine is to generate patient tailored and personalized objectives to input in the optimization process for IMRT or VMAT inverse planning. Data from previously generated high quality plans are used to estimate DVH ranges where the specific DVH of a structure will most likely land according to the prior plans knowledge. Estimate-based optimisation objectives are hence generated. A complete pre-clinical preparation have been established before the clinical implementation of RapidPlan and the configured specific models. The anatomical sites and pathologies chosen for the first models generation in Milan were Head and Neck, and Breast. For the first site the choice was driven by the complexity of the planning phase due to the anatomy and critical structures; the breast was chosen since, beside of its planning complexity, almost one third of our patient population presents breast cancer. For each of the two chosen sites the process of the model generation included different phases. Initially a set of about 100 patients per site, having quite spread anatomical characteristics (as, for example, the breast size) while excluding extreme anatomies, was selected. The selected plans were all clinical plans of high quality, for VMAT (RapidArc) delivery. Those plans were used to train the model for the extraction of the parameters, based on principal component analysis methods and regression models, needed to estimate the DVH for any new patient. The training results were analysed to evaluate possible outliers and their eventual exclusion from the model. Finally the validation process was followed on another group of patients to assess the model reliability and usability. From this last phase improvements in the plan quality when using RapidPlan was assessed. Once the two models were evaluated, a number of head and neck and breast cases were selected for the pre-clinical trial. The planners used to plan without RapidPlan were asked to produce plans using the knowledge based planning models. Two kind of evaluations were felt interesting: on one side the plan quality, for which the same cases were asked to be planned without RapidPlan by the same planner, and on the other side the time required to obtain such plans. The results were very promising, both on the plan quality, and especially on planning time. We are ready to move to the clinical daily use of the automated treatment plan generation.

SP-0313

Fully automated treatment plan generation using Erasmus-iCycle - the Rotterdam experience

M.L.P. Dirkx¹, A.W. Sharfo¹, P.W.J. Voet², G. Della Gala¹, L. Rossi¹, D. Fransen¹, J.J. Penninkhof¹, M.S. Hoogeman¹, S.F. Petit¹, A.M. Mendez-Romero¹, J.W. Mens¹, L. Incrocci¹, N. Hoekstra¹, M. Van de Pol¹, S. Aluwini¹, S. Breedveld¹, B.J.M. Heijmen¹

¹Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

²Elekta AB, Physics Research, Uppsala, Sweden

Aim: Treatment plan generation in radiotherapy is commonly a trial-and-error procedure in which a dosimetrist tries to steer the treatment planning system (TPS) towards an acceptable patient dose distribution. For a single patient, this process may take up to several days of workload. The

quality of the final treatment plan is dependent on the skills and experience of the dosimetrist, and on allotted time. In addition, for the treating physician it is extremely difficult to assess whether the generated plan is indeed optimal considering the unique anatomy of the individual patient. At Erasmus MC, systems for fully automated plan generation have been developed to obtain plans of consistent high quality, with a minimum of workload. This presentation will focus on their clinical implementation and applications.

Materials and methods: An IMRT or VMAT plan is generated fully automatically (i.e., without human interface) by the clinical TPS (Monaco, Elekta AB), based on a *patient-specific* template. The patient-specific template is automatically extracted from a plan generated with Erasmus-iCycle, our in-house developed pre-optimizer for lexicographic multi-criterial plan generation (Med Phys. 2012; 39: 951-963). For individual patients of a treatment site (e.g., prostate), automatic plan generation in Erasmus-iCycle is based on a *fixed* 'wishlist' with hard constraints and treatment objectives with assigned priorities. The higher the priority of an objective, the higher the chance that the planning aim will be achieved, or even superseded. All plans generated with Erasmus-iCycle are Pareto optimal. In case of IMRT, the system can be used for integrated beam profile optimization and (non-coplanar) beam angle selection. *Site-specific wishlists* are a priori generated in an iterative procedure with updates of the wishlist in every iteration step, based on physicians' feedback on the quality of plans generated with the current wishlist version. Also for patients treated at a Cyberknife, either with the variable aperture collimator (Iris) or MLC, the clinical TPS (Multiplan, Accuray Inc.) can be used to automatically generate a deliverable plan, based on a pre-optimization with Erasmus-iCycle.

Results: Currently, automatic treatment planning is clinically used for more than 30% of patients that are treated in our department with curative intent. It is routinely applied for prostate, head and neck, lung and cervical cancer patients treated at a linac. In a prospective clinical study for head and neck cancer patients, treating radiation oncologists selected the Erasmus-iCycle/Monaco plan in 97% of cases rather than the plan generated with Monaco by trial-and-error (IJROBP 2013; 85: 866-72). For a group of 41 lung cancer patients, clinically acceptable VMAT plans could be generated fully automatically in 85% of cases; in all those cases plan quality was superior compared to manually generated Monaco plans, due to a better PTV coverage, dose conformality, and/or sparing of lungs, heart and oesophagus. For plans that were initially not clinically acceptable, it took a dosimetrist little hands-on time (<10 minutes) to modify them to a clinically acceptable plan. In 44 dual-arc VMAT Erasmus-iCycle/Monaco plans for cervical cancer treatment small bowel V45Gy was reduced by on average 20% ($p < 0.001$) when compared to the plans that were manually generated by an expert Monaco user, spending 3 hours on average. Differences in bladder, rectal and sigmoid doses were insignificant. For 30 prostate cancer patients, differences between Erasmus-iCycle/Monaco VMAT plans and VMAT plans manually generated by an expert planner with up to 4 hours planning hands-on time, were statistically insignificant (IJROBP 2014; 88(5): 1175-9). Attempts to use acceptable, automatically generated plans as a starting point for manual generation of further improved plans have been unsuccessful. For prostate SBRT, clinically deliverable Cyberknife plans that were automatically generated with Erasmus-iCycle/Multiplan showed a better rectum sparing and a reduced low-medium dose bath compared to automatically generated VMAT plans with the same CTV-PTV margin.

Conclusion: In our department, automatic plan generation based on Erasmus-iCycle is currently widely used, showing a consistent high plan quality and a vast reduction in planning workload. Extension to new target sites (breast, liver, lymphoma, spine, vestibular schwannoma) is being investigated. In addition, the use of automated planning for intensity modulated proton therapy is being explored, making objective plan comparison with other modalities possible.

Symposium: Elderly and radiation therapy

SP-0314

Geriatric assessment is a requirement to effectively provide a quality radiotherapy service to the older person
A. O'Donovan¹, M. Leech¹

¹Trinity Centre for Health Sciences, Discipline of Radiation Therapy, Dublin 8, Ireland Republic of

Most European countries are currently faced by a major demographic shift that will see increasing numbers of older patients. This represents a corresponding increase in the number of older patients presenting for radiation therapy. It is recognised that this will require "age attuning" of our cancer treatment services to provide a more holistic approach to the care of older patients. Comprehensive Geriatric Assessment (CGA) or Geriatric Assessment (GA) as used in the oncology literature, can identify risk factors for adverse outcomes in older cancer patients. CGA was designed to more accurately detect frailty in older patients, and both the National Comprehensive Cancer Network (NCCN) and International Society of Geriatric Oncology (SIOG) recommend its use in Oncology. CGA includes a compilation of reliable and valid tools to assess geriatric domains such as comorbidity, functional status, physical performance, cognitive status, psychological status, nutritional status, medication review, and social support. The benefits of CGA include greater diagnostic accuracy, reduced hospitalisation and improved survival and quality of life. Benefits for cancer patients include predicting complications of treatment, estimating survival and detection of problems not found using standard oncology performance measures, such as performance status. Cancer treatment is a physiologic stressor, and its impact on older patients is poorly defined in relation to baseline reserve capacity. GA provides a means of quantifying known heterogeneity in older patients, and may identify problems that could potentially be reversed, or better managed, in order to improve outcomes. Despite the evidence demonstrating the benefits of GA in improving the health status of older patients, its adoption in (radiation) oncology has not been widespread. The published literature lacks a standardised approach to GA in Oncology, making interpretation of the current evidence difficult. Exacerbating this issue is the traditional exclusion of older patients from clinical trials. GA has the potential to predict toxicity, survival and quality of life in older patients, and further research is needed to clarify its role. GA is known to be time and resource intensive, and recent studies have sought to develop shorter screening tools specifically for oncology patients, such as the G8. However, none of these approaches have been validated to date, with one obvious drawback being the lack of comparison in the form of a "gold standard" comprehensive approach. One potential solution to resource and time issues is the sharing of responsibility among the multidisciplinary team, with radiation therapists having a valuable role to play as front line staff. Recent focus in policy documents on measures to improve the quality of healthcare for older patients has resulted in a need to adequately prepare qualified health professionals to work together in a more collaborative manner. Many international models of Geriatric Oncology exist, however implementation is institution-specific and must take account of existing resources and infrastructure. In addition, there is currently no formal Geriatric Oncology fellowship scheme in most countries (apart from the US) or education programme in place for oncology professionals on how to best implement geriatric assessment. Many healthcare professionals, do not receive any training in the fundamental principles of geriatric medicine and how they may apply to their profession. The aim of this presentation is to present a critical overview of the current literature on GA in radiation oncology, and previous research by the authors in this field. It will also incorporate aspects of feasibility and requirements for a geriatric oncology service. The latter will include educational aspects and the need for adapted curricula in radiation

oncology to incorporate aspects of aging, optimal treatment and attitudes towards aging.

Treatment choices in the elderly: focus on breast cancer

N. De Glas¹

¹Leiden University Medical Center LUMC, Department of Surgery, Leiden, The Netherlands

- The evidence for treatment of older patients with breast cancer is scarce due to lack of clinical trials and selective inclusion of patients
- Older patients are less willing to trade quality of life for absolute survival gain, but data that can provide patients with information concerning these outcomes are lacking
- The recently performed "FOCUS onChoice" study has shown that older patients choose a mastectomy more frequently than younger patients
- Recent trials suggest that radiotherapy can be omitted in older patients with low-risk tumours

Symposium: A Joint session of Young Radiation Oncologists National Societies & YROG

SP-0317

What is the Young ESTRO Committee and what can it do for young radiation oncology professionals?

J.E. Bibault¹

¹Hôpital Européen Georges Pompidou, Radiation Oncology Department, Paris, France

The Young Task Force

The first YTF was formed in 2011 at the Anniversary congress based on the decision of the ESTRO Steering Committee of 16 June 2009. At the beginning, members of the YTF were appointed by the Board each year. In 2012, at the Agorá meeting, YTF members' term was changed to three years, renewable once. This meeting allowed for "strategic discussions", bringing young, promising RT scientists / professionals together with the core ESTRO leadership. The Agorá meeting provided valuable input for the YTF. Several projects realised by the YTF were based on the results of the Agorá meeting.

The first chair of the YTF, Daniel Zips, thought that the aim of the YTF, from the start, was to become a committee and be an integral part of ESTRO governance contributing to activities and supporting the young members. The Young task force (YTF) is a key structure in securing the long-term future of ESTRO. The 3rd YTF succeeded in initiating several projects (e.g. revision of YTF structure, involvement in ESTRO committees, improvement of online communication, etc.). To carry on these essential activities, the YTF was changed to become a full ESTRO Committee in 2015.

Composition of the Young Committee

The Young Committee reflects the diversity and multidisciplinary nature of ESTRO with members from clinical radiation oncology, radiobiology, physics and RTTs. Each member also acts as an observer in one of the other standing committees of ESTRO:

- Jean-Emmanuel Bibault (Paris, France): National Societies Committee
- Gerben Borst (Amsterdam, The Netherlands) : Clinical Committee
- Laura Mullaney (Dublin, Ireland): RTT Committee
- Kasper Rouschop (Maastricht, The Netherlands): Radiobiology Committee
- Maximilian Schmid (Vienna, Austria): GEC-ESTRO Brachytherapy Committee

- Mateusz Spalek (Warsaw, Poland): ACROP Committee
- Daniela Thorwarth (Tübingen, Germany): Physics Committee
- Wouter van Elmpt (Maastricht, The Netherlands): Physics Committee

Future vision: carry on the activities initiated by the previous task Forces and work on new perspectives

Standing committee involvement

Young Committee members' positions as observers allow us to represent the interests of the young ESTRO members and to evaluate the contribution and participation of the young members in other standing committees' activities.

Young scientist session at ESTRO Forum and Young scientist track at numbered ESTRO congresses

The Young Committee is responsible for the organisation, contribution and promotion of the young scientist session / track at all ESTRO congresses. Each year, a young track is held with symposia and teaching lectures aimed at the young radiation oncology professionals, with subjects such as "how to build a career", "how to write a good article/abstract". We also organize a young reception at the end of the track, which is always a nice moment to meet other young Europeans and network with each other.

Online services (Facebook, videos, FALCON, DOVE, scientific networking)

The 3rd YTF started several projects regarding online services. The main task will be to maintain, promote and communicate these activities. The Young Committee will also contribute to ESTRO online services like FALCON, DOVE, etc.

ESTRO Fellow

In regard of the heterogeneous training in the field of radiation oncology within Europe, the "ESTRO Fellow" was created to achieve a high level of education as well as reflect a high dedication towards ESTRO. It has become a prestigious mark of distinction.

The next ESTRO fellow exam will take place on April, 29th 2016 at ESTRO35 in Turin. The Application deadline is set for March, 29th 2016.

The future

The Young Committee is currently involved in the setup of the 3rd Agora Meeting which should take place late 2015 or early 2016. This meeting will bring together motivated young ESTRO members to discuss and exchange our vision for our field. A call for applications will be sent in that perspective.

SP-0318

The Young Radiation Oncology Group of EORTC -ROG

O. Kaidar-Person¹

¹Rambam Health Care Campus- Faculty of Medicine- Technion, Oncology Institute, Haifa, Israel

The Young Radiation Oncologists Group (YROG) is a working party of the European Organization for Research and Treatment of Cancer (EORTC) -Radiation Oncology Group (ROG). Its members are the "young members" of the ROG.

The YROG was initiated in 2012 with an aim to incorporate radiation oncologists in early phases of their career within the EORTC- ROG activities. This was done to have a new generation of radiation oncologists actively involved in research.

Joining the YROG is an opportunity to present your research and new study proposals and to take part in the discussions held at the different ROG working parties. By being a part of the EORTC-ROG you will learn about designing clinical trials and have a chance to work side by side with world-leaders in oncology.

If you are at the early stages of your career in radiation oncology and are looking for an opportunity to be involved in key research, come to hear about the YROG.

SP-0319

The French Society of Young Radiation Oncologists

T. Leroy¹

¹Centre Oscar Lambret, Lille, France

Since 2003, the SFjRO (French Society of young Radiation Oncologist) promote radiation oncology teaching in France.

The goals of our society are to promote and ease the teaching of radiation oncology by developing relationships between residents and professors. By creating specific tools, giving access to scientific journals and organizing each year two theoretical courses, the SFJRO aims to give access to a better understanding of current practices in Radiation Oncology. Nowadays our society has more than 200 members. Each year French residents attend one national radiation therapy courses covering each fundamental field of radiation oncology : radioanatomy, radiobiology, radiophysics and brachytherapy and a summer school dedicated to a specific organ. All these courses are available freely on our website which has now a database of more than 300 radiation oncology courses. The SFJRO works with SFRO (French Society of Radiation Oncologists) and organize a young session during the National meeting of Radiation oncology. We also represent resident in front of national organisation such as National cancer Institute (Inca) and National Board of Oncology Teachers (CNEC). Another goal of SFJRO is to promote research among residents and we have published several studies about delineation variability, burnout or mobile technology and social media use by young radiation oncologists. In the future we hope to strengthen our cooperation with European young radiation oncologist societies, and to take part in young sessions such as the YROG sessions.

SP-0320

The Young AIRO (Italian Association of Radiation Oncology) Group

D. Greto¹

¹University of Florence- Azienda Ospedaliera Universitaria Careggi, Sperimental and Clinica Biomedical Sciences, Firenze, Italy

The Young AIRO group (yAIRO) is a part of the Italian Association of radiation oncology composed by members below 40 years old. The increasing participation of the young member to the AIRO scientific activities resulted in the foundation of the Young group in 2007. The main purpose of the yAIRO was to create a network connections between junior physicians working in different institutions throughout the country, to promote the collaboration with junior groups of other national scientific societies in the field of oncology. Nowadays the Young group has approximately 350 members. Every years there is an annual scientific national event dedicated to young members, a scientific session dedicated to the young members takes place during the AIRO national meeting. One of the main project of the yAIRO is to create collaboration programs with other young specialists involved in the oncology field. In the last years, relationships were created with the young group of the Italian medical oncology association (AIOM), young urologists (SIURO) and young medical radiologists (SIRM). The yAIRO published some collaborative research projects: the INTER-ROMA Project (2011), the BUONGIORNO Project (2013), the PROCAINA part I and II Project (2013), the STYRO Project (2013), the PEDRO project (2015). A project about the history and development of Italian radiation oncology residency programs and one about the pacemaker and implanted cardioverter defibrillator management in radiation therapy are in progress. The fundamental role of young members in the Italian radiation oncology society will induce yAIRO to improve young specialists' participation, involvement and commitment into education, research and clinical care.

Target displacement evaluation for fluoroscopic and four-dimensional cone-beam computed tomography

H. Iramina¹, M. Nakamura², Y. Iizuka², Y. Matsuo², T. Mizowaki², M. Hiraoka², I. Kanno¹

¹Kyoto University, Nuclear Engineering, Kyoto, Japan

²Kyoto University, Radiation Oncology and Image-Applied Therapy, Kyoto, Japan

Purpose or Objective: Four-dimensional cone-beam computed tomography (4D-CBCT) has great capability to provide volumetric and respiratory motion information with one gantry rotation. It is necessary to quantitatively assess, how difference of tumor displacement between actual and 4D-CBCT image exists. In this study, we evaluated the displacement of implanted fiducial markers assumed as tumor on fluoroscopic projection images and reconstructed 4D-CBCT images with different sorting methods.

Material and Methods: We have developed 4D-CBCT utilizing dual source kV X-ray imaging subsystems. Five lung cancer patients with two to four implanted fiducial markers were enrolled in the institutional review board-approved trial. Each patient underwent three consecutive 4D-CBCT imaging. For at least two scans out of three, the imaging parameters were 110 kV, 160 mA and 5 ms, the rotational speed of the gantry was 1.5°/s, rotation time was 70 s, the image acquisition interval was 0.3°, and the rotational angle of 105°. A marker that located the most nearest to the lung tumor was used for surrogate respiratory signal. The marker motion in superior-inferior (SI) direction was used as surrogate respiratory signal for 4D-CBCT image reconstruction. Surrogate respiratory signal were converted eight phase bins with retrospective amplitude- or phase-based sorting. On reconstructed 4D-CBCT images, the marker was contoured on all phases to detect its 3D positions. Meanwhile, the marker positions on two fluoroscopic images obtained simultaneously were converted to 3D position. Evaluation was employed among the displacement on fluoroscopic image (*d*fluoro), that on amplitude-based sorting 4D-CBCT (*da*-4DCBCT) and that on phase-based sorting 4D-CBCT (*dp*-4DCBCT) in left-right (LR), anterior-posterior (AP), and SI direction. Difference between *da*-4DCBCT and *d*fluoro (*Da*-f), and difference between *dp*-4DCBCT and *d*fluoro (*Dp*-f) were obtained for all patients.

Results: Depending on the sorting methods, the positional difference was up to 2 mm on 4D-CBCT images. Overall mean ± standard deviation of *Da*-f and *Dp*-f in LR, AP, and SI direction were -1.5±1.2, -2.9±1.2, -5.1±1.6 mm and -1.4±1.1, -2.3±0.9, -5.2±1.2 mm, respectively (Table 1). 4D-CBCT underestimated displacement of marker by 5 mm on average in SI direction.

Table 1. Means and standard deviations of D_{a-f} and D_{p-f} for LR, AP, and SI direction.

Note: For Patient 3 to 5, 4D-CBCT images at 2nd session was taken for different purpose with different imaging conditions from others.

Conclusion: We performed displacement evaluation of fiducial markers on 4D-CBCT with two sorting methods. Since 4D-CBCT requires convolution of marker motion in eight bins, underestimation of 5 mm on average was observed in SI direction.

PV-0323

Prospective evaluation of markerless tumour tracking using 4D/3D registration and dual energy imaging

J. Dhont¹, D. Verellen¹, K. Poels², M. Burgelea¹, K. Tournel¹, T. Gevaert¹, B. Engels¹, C. Collen¹, R. Van Den Begin¹, G. Storme¹, M. De Ridder¹

¹Universitair Ziekenhuis Brussel, Radiotherapy, Brussels, Belgium

²Universitair Ziekenhuis Leuven, Radiotherapy, Leuven, Belgium

Purpose or Objective: Image registration of Digitally Reconstructed Radiographs (DRRs) and real-time kV images is the only clinically implemented solution to markerless tumor tracking. However, registration still suffers from poor soft tissue visibility, restricting the workflow to only a certain size and density of tumors. The purpose of this study is to evaluate the feasibility of markerless tumor tracking on a clinical system through 4D/3D registration and the use of dual-energy (DE) imaging.

Material and Methods: For 3 patients treated for NSCLC with dynamic tracking on the Vero SBRT system, on average 90 soft-tissue enhanced DE images were created from sequential low- (LE) and high-energy (HE) orthogonal fluoroscopy. All DE images were binned in either inhale, exhale, maximum inhale or maximum exhale, using the amplitude of the synchronous external breathing signal.

For each respective breathing phase, DRR templates were created from the 4D planning CT using the open-source Insight Toolkit (itk).

As such, the localization problem was reduced to 2D/2D registration of 2 orthogonal kV images and 2 DRRs.

Before registration, the currently implanted marker was removed on all images so to not bias the results.

Intensity-based 2D/2D registration was carried out between each DE image and the respective DRR. The same was done with all HE images to evaluate the benefit of using DE imaging.

The implanted marker was recovered and used as a benchmark to quantify the accuracy of the tumor localization. The mean Euclidean distance between the center of the marker in the DE and HE images, and the center of the marker in the matched DRR template was defined as the tracking error (TE).

Results: Table 1 summarizes the localization results for each patient and imaging angle. All TEs remain below 2.5 mm and results between DRR-HE and DRR-DE are similar. However, a significant difference in TE is present for 1 imaging angle. From a qualitative analysis, see Figure 1, it can be observed that for those imaging angles where the tumor is mainly obscured by bony anatomy, tumor localization through intensity based registration is more accurate when dual-energy images are applied.

Figure 1 High-energy (left) and dual-energy (right) images from patient 1. Note that the tumour, indicated by the implanted marker, is obscured by soft tissue only for imager 1 (above), while for imaging angle 2 the tumour is mostly obscured by the ribs.

Table 1 Root-mean square (RMS) tracking errors, defined based on the implanted marker distance, from 2D/2D registration between DRR and dual-energy images, and DRR and high-energy images.

	RMS tracking error		t-test
	DRR - DE	DRR - HE	
patient 1 Im. 1 - 10°	1.7 ± 0.8	2.2 ± 0.8	p = 0.08
patient 1 Im. 2 - 100°	1.2 ± 0.6	1.3 ± 0.5	p = 0.83
patient 2 Im. 1 - 70°	1.8 ± 0.7	3.1 ± 1.1	p < 0.01
patient 2 Im. 2 - 340°	1.4 ± 0.5	1.6 ± 0.8	p = 0.78
patient 3 Im. 1 - 250°	1.3 ± 0.4	1.2 ± 0.4	p = 0.85
patient 3 Im. 2 - 160°	1.3 ± 0.4	2.1 ± 0.5	p = 0.06

Conclusion: The results of this prospective evaluation indicate that for markerless localization of lung tumors through 4D/3D intensity-based registration, using DE images is more accurate than using regular kV images for certain imaging angles. Removing overlying bony anatomy and enhancing tumor visualization prior to registration makes the workflow more robust.

PV-0324

Intra-fraction motion characterisation of head-and-neck tumors using cine-MRI

T. Bruijnen¹, B. Stemkens¹, M.E.P. Philippens¹, L.P.W. Canjels¹, R.H.N. Tijssen¹, T. Schakel¹, C.H.J. Terhaard¹, J.J.W. Lagendijk¹, C.P.J. Raaijmakers¹

¹University Medical Center Utrecht, Radiotherapy, Utrecht, The Netherlands

Purpose or Objective: Intensity modulated radiotherapy and the recent introduction of the MR-linac emphasize the need for detailed tumor motion characterization for adequate motion management in radiotherapy planning and online MRI-guidance. Hitherto, intra-fraction head-and-neck (H&N) tumor motion has been assessed as the displacement of local

landmarks in cone beam CT or X-ray. The superior soft-tissue contrast of MRI enables characterization of the actual tumor displacement. Here, we investigate the intra-fraction tumor displacement on a sub-second and 10-minute time scale, using cine-MRI.

Material and Methods: Thirteen patients with H&N squamous cell carcinoma underwent pretreatment clinical MR imaging in a radiotherapy immobilization mask. Two 2D sagittal cine-MR scans (balanced steady state free precession; TE/TR = 1.2/2.5 ms; 1.42x1.42mm², slice thickness 10 mm, 500 dynamics), positioned through the tumor were acquired with 8 frames per second and an interval of 10-15 min on a 3.0T MR scanner. Tumor GTVs were delineated by a radiation oncologist.

Image analysis: Tumor motion was estimated by non-rigid image registration over the 1 minute dynamic MRI data using an optical flow algorithm (Fig. 1a). The displacement vectors on the GTV border were combined into a 95th percentile distance (dist95%) for every image. 95% of the range of dist95% over time was used as a measure of tumor displacement. The standard deviation of the GTV border displacement vectors was calculated and averaged over the time series as a measure of tumor deformation. Tumor displacement over 10 minutes was estimated by computing the difference in the average tumor position between the two dynamic series with an equivalent non-rigid registration.

Results: Results of the image registration (Fig. 1c) showed respiratory-induced tumor motion, which was confirmed by a peak at the principle respiratory frequency in a power spectrum analysis. Displacements were relatively small in both directions with a median displacement of 0.60 ± 0.13 mm (range: 0.18-1.44 mm) (AP) and 0.59 ± 0.11 mm (range: 0.32-2.69 mm) (CC) (Fig. 1b), which agreed with visual inspection. For two patients standard deviations within the border pixels were > 0.20 mm, which might imply a deformation of the tumor. The average tumor position differences over 10 minutes were smaller than the tumor displacement in the 1-minute data for both directions, with means of 0.28 mm (range: 0.08-0.99 mm) (AP) and 0.34 mm (range: 0.07-0.99 mm) (CC).

Figure 1. (A) Displacement vectors of a pharynx GTV between two frames of the 2D sagittal cine-MR data. (B) P95 displacement values for the surface pixels of delineated GTVs. red and green markers show the average AP/CC displacement of the tumor during respiration. Blue markers show the difference in average tumor position over 10 minutes. (C) Tumor displacement in CC direction over a single dynamic MRScan.

Conclusion: Tumor displacements on both time scales were relatively small, but varied considerably between patients.

PV-0325

Retrospective self-sorted 4D-MRI for the liver

T. Van de Lindt¹, U. Van der Heide¹, J. Sonke¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: There is an increasing interest in 4D-MRI for MR-guided radiotherapy. 4D-MRI methods are typically based on either an external respiratory surrogate with possible deviations from internal motion or an internal navigator channel which can disturb the image acquisition.

Experimental methods, using self-gated strategies based on the center of k-space, lack a quantitative signal and have extensive scan times. To overcome these limitations, a new self-sorted 4D-MRI method was developed for treatment planning and MR-guided radiotherapy of the liver.

Material and Methods: For 3 volunteers, a 2D multi-slice MRI of the upper-abdomen was acquired 30 times (single-shot TSE, slices=25, voxel size=2x2x5mm³, TR=383ms, TE=80ms, dynamics=30) and resulted in a total of 750 axial slices (scan time 4:50min) in an unknown respiratory state. For comparison, a navigator was acquired, outside the FOV, prior to every slice acquisition.

To extract the respiratory signal from the data, first a 3D exhale reference dataset was constructed. As the anatomy predominantly moves in the SI-direction, the average position of every slice is located below the exhale position. Therefore, for each slice, the dynamic with the highest mean correlation with all dynamics of the slice below was selected for the exhale reference set. The exhale data was then interpolated to slices of 1mm. Then all slices of all dynamics were registered to the exhale reference frame in SI-direction, using correlation as an objective function, resulting in a displacement relative to exhale. To obtain a 4D-MRI reconstruction, the resulting respiratory signal was processed to identify inhale positions and sort the data according to phase. This was compared to the navigator signal and associated sorting.

Results: The self-sorting signal (SsS) and the navigator signal (NavS) correlate very well (mean r=0.86). For all volunteers, the SsS and NavS identified the same number of inhale positions with an average mean absolute difference (MD) of 268ms. This is in good agreement with the slice acquisition time. The 10 phase 4D-MRI was on average under-sampled 7% (NavS) and 14% (SsS) and missing slices were linearly interpolated. After reconstruction, the average MD of the LR, SI and AP motion obtained by local rigid registration were 0.3, 0.6 and 0.3mm, respectively. Reconstruction time was ~20s on a 8 Core Intel CPU, 3.4GzH, 16GB RAM PC.

Volunteers	A	B	C
Respiratory signal			
r = corr(NavS,SsS)	0.96	0.74	0.89
Inhale positions			
MD(NavS, SsS) (ms)	273	284	249
4D reconstruction			
Under-sampling NavS (%)	2	5	14
Under-sampling SsS (%)	7	14	15
Motion			
LR: MD(NavS, SsS) (mm)	0.1	0.3	0.6
SI: MD(NavS, SsS) (mm)	0.4	0.5	1.0
AP: MD(NavS, SsS) (mm)	0.2	0.2	0.5

Table1: Comparison between navigator (NavS) and self-sorting signal (SsS) for 3 volunteers

Figure1 (top): Navigator (blue) and self-sorting signal (red). Blue circles at the bottom represent minima derived from the NavS and red dots represent minima derived from SsS.
Figure2 (bottom): Axial, coronal and sagittal slice from reconstructed 4D-MRI. FOV was lowered for minimal interaction with the navigator channel.

Conclusion: A 4D-MRI dataset could be acquired in ~5min and reconstructed by retrospective sorting using a self-sorting signal. The signal correlated very well with an additionally acquired navigator signal. Differences in motion between the reconstructed data using the self-sorting signal and the navigator were minimal. Before clinical implementation, acquisition and reconstruction parameters should be optimized and the method should be verified in more volunteers as well as in patients.

Respiratory gating guided by internal electromagnetic motion monitoring during liver SBRT

P. Poulsen¹, E. Worm², R. Hansen², L. Larsen³, C. Grau¹, M. Høyer¹

¹Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

²Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark

³Aarhus University Hospital, Department of Radiology, Aarhus, Denmark

Purpose or Objective: Accurate dose delivery is crucial for stereotactic body radiation therapy (SBRT), but the accuracy is challenged by intrafraction motion, which can be several centimeters for the liver. Respiratory gating can improve the treatment delivery, but may be inaccurate if based on external surrogates. This study reports on the geometric and dosimetric accuracy of our first four liver SBRT patients treated with respiratory gating using internal electromagnetic motion monitoring. We expect to include 10-15 patients in this gating protocol with three new patients being recruited at the time of writing.

Material and Methods: Four patients with liver metastases were treated in three fractions with respiratory gated SBRT guided by the position signal of three implanted electromagnetic transponders (Calypso). The CTV was defined in the end exhale phase of a CT scan and extended by 5 mm (LR/AP) and 7-10 mm (CC) to form the PTV. 7-field conformal or IMRT plans were designed to give a mean CTV dose of 18.75Gy or 20.60Gy per fraction (=100% dose level) and minimum target doses of 95% (CTV) and 67% (PTV). The treatment was delivered in free respiration with beam-on in end-exhale when the centroid of the three transponders deviated less than 3mm (LR/AP) and 4mm (CC) from the planned position. The couch was adjusted remotely if intrafraction baseline drift caused the end exhale position to

deviate more than -2 mm from the gating window center. Log files provided the transponder motion during beam-on in the actual gated treatments and in simulated non-gated treatments with CBCT-guided patient setup. This motion was used to reconstruct the actually delivered CTV dose distribution with gating and the would-be dose distribution without gating. The minimum dose to 95% of the CTV (D95) for each fraction and each course was compared with the planned CTV D95.

Results: Fig. A shows the internal tumor motion at a fraction with large baseline drift of 3mm (LR), 9mm (CC), and 6mm (AP) relative to the pre-treatment CBCT. Fig. B shows the same motion with four drift compensating couch adjustments applied as marked with red lines. The width of the green areas indicates the time of beam delivery. The height indicates the allowed positions for beam-on without (Fig. A) and with (Fig. B) gating. The course mean geometrical error was <1.2mm for all gated treatments, but would have ranged from -2.8mm to 1.2mm (LR), from 0.7mm to 7.1mm (CC), and from -2.6mm to 0.1mm (AP) without gating due to baseline drift. Fig. C shows the CTV D95 reduction relative to the planned D95 versus the 3D mean error for each fraction and course. The mean reduction in D95 for the 12 fractions was 1.1% [range: 0.1-2.1%] with gating and 10.8% [0.9-35%] without gating. The mean duty cycle was 59% [54-70%].

Conclusion: Respiratory gating based on internal electromagnetic monitoring was performed for four liver SBRT patients. The gating added robustness to the dose delivery and ensured a high CTV dose even in the presence of large intrafraction motion.

PV-0327

Patient-specific motion management and adaptive respiratory gating in Pancreatic SBRT

B.L. Jones¹, W. Campbell¹, P. Stumpf¹, A. Amini¹, T. Scheffer¹, B. Kavanagh¹, K. Goodman¹, M. Miften¹

¹University of Colorado School of Medicine, Radiation Oncology, Aurora, USA

Purpose or Objective: Ablative radiotherapy is rapidly emerging as an effective treatment for locally advanced pancreatic adenocarcinoma. However, the pancreas undergoes erratic and unstable respiratory-induced motion, which decreases coverage of the tumor and increases dose to the duodenum. The purpose of this study was to develop and optimize motion management protocols which allow for safe delivery of pancreatic SBRT.

Material and Methods: We analyzed 4DCT and CBCT data from 35 patients who received pancreatic SBRT; the majority were locally advanced tumors receiving 30 Gy in 5 fractions.

In total, the data from 175 treated fractions was analyzed. For each fraction, the daily trajectory of the tumor was reconstructed by calculating a Gaussian probability density function using the location of gold fiducial markers in the CBCT projections. These trajectories represented over 600 samples of the position of the tumor during the course of CBCT acquisition. Using the calculated trajectories, we investigated the dosimetric impact of several respiratory motion management strategies, including gating based on instantaneous kV imaging of implanted fiducial markers.

Results: 4DCT was a poor predictor of pancreatic motion, as the amplitude of daily motion exceeded the predictions of pre-treatment 4DCT by an average of 3.5 mm in the SI direction. In a Fourier-based analysis, these uncertainties were correlated with an increase in low-frequency motion (potentially due to peristalsis of the duodenum). Abdominal compression increased the consistency of motion and reduced the amplitude by 2.7 ± 2.8 mm. On average, respiratory gating decreased the apparent motion even further, with attainable effective motion amplitudes of 2 mm. However, gating based on external surrogates (either phase- or amplitude-based) is greatly hindered in some patients by the inconsistency of pancreatic motion. In these cases, internal gating surrogates are warranted. In a simulated clinical scenario, fiducial-based internal gating using a 2 mm SI window greatly outperformed conventional gating using external surrogates ($p < 0.001$), with a mean target D95 of $99 \pm 2\%$, 95% CI 93-100% (conventional gating - D95 $97 \pm 7\%$, 95% CI 68-100%). Additionally, we analyzed the dosimetry of motion by convolving the dose distribution with phase-specific motion information. Using these data, we developed a metric that predicts patient-specific consistency, and in a simulated adaptive protocol which adjusted margins based on this metric, there were significant increases in mean target D95 and minimum dose.

Conclusion: Motion management is essential in reducing the size of target volumes and minimizing dose/side effects to the small bowel. Motion uncertainties and patient-specific differences warrant an adaptive approach to respiratory management. Our data shows that using real-time kV imaging of implanted fiducial markers to adapt the gating protocol based on the instantaneous position of the tumor outperforms conventional approaches.

Figure 1: Axial and sagittal MRI slice showing Points of Interest (white dots)

prostate cancer. The objective of this sub-study is to evaluate infraction motion, using cine MRI, and the dosimetric impact when using a rectal immobilisation device (RID).

Material and Methods: The initial 10 patients recruited underwent planning CT and MRI, with and without a RID. Cine MRI images were captured using an interleaved T2 HASTE sequence in sagittal and axial planes with a temporal resolution of 5.4 seconds acquired over 4 minutes, the average time for a single SBRT VMAT fraction. Points of interest (POI) were outlined by a single investigator and a validated tracking algorithm measured displacement of these points over the 4 minutes in the anterior - posterior, superior - inferior and left - right directions (Figure 1).

Planning CT and MRI scans were fused and contoured by a single investigator. They were planned using a VMAT technique to 19Gy in 2 fractions by a single investigator. The planning priority set for the non - RID plan was to match the coverage achieved in the RID plan. Dose Volume Histogram results of both plans were analysed.

Results: There was an overall trend for increasing POI displacement in all directions as time progressed when no RID was insitu. POI remained comparatively stable with the RID. In the sagittal plane, the RID resulted in statistically significant improvement in the range of anterior - posterior displacement over the entire 4 minutes of the inferior anterior and posterior rectal wall (both $p < 0.001$), mid anterior and posterior rectal wall (both $p = 0.007$), anterior prostate ($p = 0.019$), prostate apex ($p = 0.003$) and prostate base ($p = 0.011$).

The RID also resulted in improvement in range of superior - inferior displacement of the inferior posterior rectal wall ($p = 0.002$), mid anterior rectal wall ($p = 0.043$) and posterior rectal wall ($p = 0.023$).

In the axial plane, the RID resulted in statistically significant improvement in the range of anterior - posterior displacement of the anterior rectal wall ($p = 0.008$) and posterior prostate ($p = 0.011$).

For all these points, the RID approximately halved the range of displacements, with some points moving over 2mm when no RID was insitu.

Dosimetrically, the use of a RID significantly reduced rectal V16 (0.27cc vs 1.71cc; $p < 0.001$), V14 (1.12cc vs 2.32cc; $p = 0.02$) and Dmax (15.72Gy vs 18.90Gy; $p < 0.001$), as well as percentage of posterior rectal wall receiving 8.5Gy (7.38% vs 12.20%; $p = 0.003$). There was no statistically significant difference between bladder or urethral Dmax, CTV D98 or conformity index between both plans.

Conclusion: The rectal immobilisation device used in stereotactic prostate radiotherapy leads to reduced infraction motion of the prostate and rectum, with increasing improvement with time. It also results in significant improvement in rectal wall dosimetry.

³Hospital Clinic de Barcelona, Radiation Oncology Department, Barcelona, Spain

⁴Edinburgh Cancer Centre, Department of Oncology Physics, Edinburgh, United Kingdom

⁵Universitat Politècnica de Catalunya, Institut de Tecniques Energetiques, Barcelona, Spain

Purpose or Objective: The purpose of this study was to analyze the modulation indexes proposed in the literature for predicting interplay effects in lung SABR treatments

Material and Methods: 23 SABR plans (4 arcs of 200°-220° for 6MV and 2 arcs for 10 MV FFF) calculated on Eclipse V10.1 (Varian) were analyzed with the Quasar respiratory phantom (Modus Medical Devices) by comparing dose distributions on EBT3 radiochromic film. Static and dynamic irradiation at 0.5 cm amplitude (1 cm peak-to-peak) and 12 breaths per minute (BPM) was used. 18 plans were irradiated in a Silhouette LINAC with 6 MV and 5 on a TrueBeam (Varian) LINAC with 6 MV FFF. The acceptance criteria was set to be < 5% of points with $\gamma(3\%,3\text{mm}) > 1$ on the comparison between static and dynamic dose distributions. A threshold of 90% was fixed since the aim was to study the influence of the modulation on the ITV. The modulation indexes analyzed were: The Modulation Complexity Score (MCS)-McNiven 2010; the Modulation Index Total (MI_T)- Park 2014 which introduces speed and MLC acceleration and finally the Aperture Irregularity (AI) -Du 2014 which analyzes the non-circularity of the MLC apertures. A Matlab (Mathworks) program was developed to calculate them. Finally, the PUMA method, which is based on splitting arcs in the TPS and modeling movements by changing their isocenter positions, was also used. Possible linear correlation between these indexes and radiochromic films was analyzed and a statistical analysis performed.

Results: Modulation indexes are shown in Table 1. A statistical analysis of the goodness of fit was done; which found only significant linear correlation ($p < 0.0001$) between film-PUMA, film-MI_T and also between PUMA-MI_T. A positive plan is considered to be a plan suitable for treatment when evaluating the interplay effect. A value of 0.6 for the MI_T index is proposed as the upper limit. This value was selected in order to minimize the number of false negative plans. MI_T and PUMA have the same specificity (100%) since both detected all of the failing plans. However, PUMA has a greater sensitivity (95% vs 85%).

	Plan	Rad. film (%)	PUMA	MCS	MI _T	AI
	1	4.3	4.9	0.19	0.83	5.75
	2	7.1	9.2	0.20	0.72	5.31
	3	3.7	11.7	0.24	0.66	6.68
	4	3.6	2.1	0.18	0.70	8.33
	5	3.3	1.2	0.24	0.49	4.28
	6	8.1	17.8	0.60	1.04	1.69
	7	2	0.0	0.45	0.33	1.86
	8	2.5	3.2	0.28	0.45	3.49
	9	0.2	0.4	0.31	0.54	4.69
	10	1.4	0.0	0.41	0.37	3.50
	11	0.0	0.0	0.31	0.44	3.08
	12	0.0	4.5	0.32	0.44	2.81
	13	0.3	0.0	0.42	0.38	2.24
	14	3.0	2.0	0.43	0.55	5.11
	15	0.2	0.0	0.45	0.38	3.68
	16	2.9	0.5	0.34	0.60	3.80
	17	2.5	0.5	0.30	0.52	4.21
	18	1.6	0.0	0.48	0.37	3.29
	19	1.5	0.0	0.43	0.41	2.02
	20	15.1	9.0	0.24	0.79	4.31
	21	1.7	0.8	0.29	0.48	3.54
	22	0.0	0.0	0.41	0.42	2.22
	23	3.2	0.0	0.35	0.43	2.76

Table 1. Calculated indexes for the 23 plans.

Conclusion: Most of the modulation indexes proposed in the literature are related to the robustness and modulation of a plan. However, none of them has been conceived to appropriately predict the interplay effect in lung SABR. MI_T has been found to be the only published index capable of detecting failing plans. MI_T and PUMA have the same specificity since both detected all of the failing plans. However, PUMA has a greater accuracy and sensitivity.

Modelled effects of hypofractionation on radiotherapy demand in England

T. Mee¹, N.F. Kirkby¹, K.J. Kirkby¹, R. Jena²

¹University of Manchester, Institute of Cancer Sciences, Manchester, United Kingdom

²University of Cambridge, Department of Oncology, Cambridge, United Kingdom

Purpose or Objective: Current clinical trials and studies are identifying hypofractionation as a viable treatment option when compared with current fractionation regimens. Our work estimates the reduction in the number of fractions prescribed and the potential effect on the overall demand for radiotherapy across the whole of England. With the evidence based estimates of demand for radiotherapy currently outstripping the supply capacity in England, this potential reduction in fraction demand needs to be calculated to assess the potential effects for radiotherapy service and infrastructure planning.

Material and Methods: The Malthus Program, a tool for modelling radiotherapy demand, was used to calculate the potential effect of three hypofractionation studies/trials for the population of England. Well-published and potential clinical indications for hypofractionation have been modelled for prostate cancer, non-small cell lung cancer (NSCLC) and breast cancer. The hypofractionation indications for radiotherapy were mapped into the original Malthus clinical decision trees and simulations completed to study the effects of hypofractionation on demand.

Results: If the CHHiP prostate trial achieves universal uptake throughout England then it has the potential to reduce radiotherapy demand by 3,500 fractions per million population (#pmp). SBRT for medically inoperable (or refusal of surgery) for stage 1 and stage 2 NSCLC has the potential to reduce the demand by a further 700 #pmp. The FAST-Forward trial, using 5# instead of 15# for T1-3 N0-1 M0 breast cancer has the potential to reduce demand by 4,600 #pmp. A potential reduction in modelled demand of 8,800 #pmp arises from these three studies alone. Across the total population of England, this translates to approximately 479,600 fractions per year.

Conclusion: The current clinical indications and trials for hypofractionation have the potential to reduce the evidence-based estimates of demand of radiotherapy sufficiently to be achievable with a modest increase of the current levels of equipment in England. While the presented calculations are for England as a whole, the Malthus program offers the facility to calculate the changes in modelled demand at a regional level within England, enabling a more precise calculation for treatment centres and their local catchment.

Evaluation of radiotherapy utilisation in Belgium: patterns and possible causes of suboptimal use

E. Van Eycken¹, H. De Schutter¹, K. Stellamans², M. Rosskamp¹, Y. Lievens³

¹Belgian Cancer Registry, Brussels, Belgium

²General Hospital Groeninge, Radiation Oncology, Kortrijk, Belgium

³Ghent University Hospital, Radiation Oncology, Ghent, Belgium

Using the evidence-based decision analytic model developed by the Collaboration for Cancer Outcomes, Research and Evaluation (CCORE) (1), the ESTRO-HERO project (2,3) calculated that 53.2% of incident cancer patients in Belgium would require external beam radiotherapy during the course of their disease. In order to find out what is the actual utilization of radiotherapy in Belgium and how it compares

with this calculated optimal utilization proportion (OUP), a population consisting of 112,235 patients with a unique invasive cancer diagnosis in the years 2009 and 2010 was evaluated. Tumour categories were defined according to the CCORE methodology. For each cancer, the data set consisted of the incidence date, topography, histology, TNM stage and the treatment recommendations formulated during the multidisciplinary team meetings (MDT), the latter giving an indication on the pattern of radiotherapy prescription in Belgium. Data on reimbursement for external beam radiotherapy, obtained through linkage with the administrative database from the Health Insurance Companies and covering a time period up till 3 years after the year of incidence, provided insight in the actual utilization. Besides overall analyses at the Belgian population level, variability of actual and optimal utilization amongst cancer types was assessed.

For the Belgian cancer population diagnosed in 2009-2010, the actual use of radiotherapy was 35.1%. About 3 in 4 of these patients received radiotherapy within the first 9 months after diagnosis, providing an estimate of those irradiated in the context of the primary treatment strategy. The global result was in line with the percentage of prescribed or recommended radiotherapy series (35.0%) during the MDT.

Radiotherapy uptake varied with primary tumour site. Most of the cancers in Belgium have a lower actual utilization than predicted with the exception of leukaemia, ovarian, thyroid, testicular, colon and liver cancer. Most pronounced differences between optimal and actual utilization were found in less typical radiotherapy indications such as in bladder, brain, lymphoma, myeloma, pancreas and stomach cancer. For more common radiotherapy indications such as breast, head and neck and rectal cancer, the underutilization is about 10-15% while in lung, oesophagus and prostate cancer, the underuse was more pronounced resulting in only about 55-60% of the patients requiring radiotherapy being actually treated.

These data, derived at the unique patient-level, illustrate that even in a country that is well-resourced in terms of radiotherapy staffing and infrastructure, a clear discrepancy can be observed between the optimal and actual radiotherapy delivery. Potential reasons for this may include physician and patient preferences favouring non-radiotherapy regimens in case of competing treatment modalities (e.g. in prostate cancer), deviation from guidelines (e.g. due to comorbidity or low performance status), an overestimation of the real needs by the evidence-based OUP-model and an underestimation of the actual utilisation due to available nomenclature data being limited to 3 years after incidence. These reasons all deserve further evaluation and they must be carefully taken into account when forecasting and planning radiotherapy staffing and infrastructure.

Cancer plans in Europe and radiotherapy needs assessment: can we dance a tango?

T. Albreht¹

¹National Institute of Public Health NIJZ, Ljubljana, Slovenia

European countries have a several decade long history of planning for cancer services and cancer care. The World Health Organization (WHO), whose focus was on middle-income countries, had launched the original initiative. WHO at that time at the beginning of the 1980s also proposed the first comprehensive definition of National Cancer Control Programmes (NCCP): "A national cancer control programme is a public health programme designed to reduce the number of cancer cases and deaths and improve quality of life of cancer patients, through the systematic and equitable implementation of evidence-based strategies for prevention, early detection, diagnosis, treatment, and palliation, making the best use of available resources." Cancer control programmes bear different names - cancer plans, cancer control programmes, cancer strategies, etc. They may be national or regional, but in either case they are closely related with the decision-making authorities. They depend on the appropriate allocation of resources and on the legal enactment of regulation of cancer care delivery and all of its services and activities. The rapid growth in cancer incidence coupled with exorbitantly rising costs brought the reflection on the planning of cancer care and its services to the European Union's table. As a result of the conclusions of the Slovenia's Presidency to the Council of the European Union, an initiative called European Partnership for Action Against Cancer (EPAAC) was born and launched by Commissioner Dalli in September 2009. At the same time the European Commission called upon Member States (MS) to develop and adopt national cancer plans (NCPs) or strategies by 2013. In the Joint Action (JA) EPAAC, which acted as the practical implementation of the partnership, the status of the national cancer plan development was revised through a comprehensive survey in all MSs, Norway and Iceland. What should be practical consequences of an NCP? In principle they should be the following: Mapping all the processes belonging to the comprehensive control and management of cancer. Identifying priorities in cancer care. Defining clear patient pathways and assuring the necessary resources for them. Securing sufficient financial resources through the implementation of both guidelines and patient pathways. Introducing new programmes - therapeutic and screening, treatment approaches and new concepts, such as survivorship. Raising awareness of the different elements in cancer care and management. From the point of view of radiotherapy all of the above are relevant and pertinent. The changing epidemiology, treatment patterns and improved survival rates all raise the importance of comprehensive approaches. Radiotherapy has not seen appropriate attention in terms of economic evaluation since a lot of attention lies with the medical, i.e. pharmacological treatment. Contrary to the analyses on the innovative therapies and new lines of cancer drugs, radiotherapy does not attract that many health technology assessments. There are at least the following reasons why it should: The greater and rising use of radiotherapy treatments in cancer care. The high cost of initial investment and maintenance - the latter being equally important as the former. The need for more flexibility in its availability and use. The inherent multi- and interdisciplinarity needed to successfully carry out the radiotherapeutic care. For policy makers often the immediate needs and problems are more relevant than rather remote projections. Nevertheless, the need to plan is even more pertinent to the investments needed for radiotherapy than for other types of care. This makes it benefit better from the planning process but also raises the need to better balance the different therapeutic elements in cancer care when adopting and changing guidelines and patient pathways. Consequently, plans may better reflect the future need for investment and for the planning and development of human resources. In that sense and through its dependence on technology, radiotherapy should be even more interested in supporting and contributing to the idea of the national cancer plans. There have been recent challenges for many countries lately. Austerity measures have cut into health care budgets similarly as into other public expenditures. Careful epidemiological analyses that can evaluate the contribution of the different elements of care to patient survival and

quality of life are extremely important and may very often offset the costs of complex treatments. Radiotherapy is a vital element of comprehensive cancer care. Given its needs for careful planning, equipment purchases and development of human resources in combination with a rising need for radiotherapy, there is a definite need for clear identification of radiotherapy in national cancer plans. Only through such transparency it is possible to secure all the conditions for further development of cancer radiotherapy.

Debate: Maximising tumour control: crank up the volume or turn off the switches?

More acute proctitis symptoms with hypofractionation (3.4 Gy) than 2 Gy fractions

W. Heemsbergen¹, L. Incrocci², C. Vens³, M. Witte¹, S. Aluwini², F. Pos¹

¹Netherlands Cancer Institute, Dept of Radiation Oncology, Amsterdam, The Netherlands

²Erasmus MC Cancer Institute, Dept of Radiation Oncology, Rotterdam, The Netherlands

³Netherlands Cancer Institute, Division of Biological Stress Response, Amsterdam, The Netherlands

Purpose or Objective: Several clinical studies investigated hypofractionation schedules with fractions ≥ 3 Gy in prostate cancer. Recovery from rectal radiation damage has been reported to depend on weekly dose rates, implying that acute rectal toxicity is regarded as little fractionation sensitive. A phase 3 randomized trial, with dose delivery of ≈ 10 Gy/week in both arms, recently reported a significantly higher peak incidence of RTOG grade ≥ 2 gastrointestinal (GI) toxicity in the 3.4 Gy vs the 2 Gy fractions arm. Here, we further analyzed the acute proctitis symptoms of the two schedules with 3.4 Gy or 2 Gy fractions delivered with image-guided (IG)-IMRT, and compared it with the incidence of patients receiving 2 Gy fractions delivered with a 3D conformal technique (3DCRT).

Material and Methods: We selected patients treated with IG-IMRT (planning margins 5-8 mm) from a randomized trial for localized prostate cancer, with patients in the Hypofractionation arm (HF, n=303) receiving 3 fractions per week of 3.4 Gy with 48h intervals, during 6.5 weeks. Patients in the standard arm (SF, n=298) received 5 fractions of 2 Gy per week with 24h intervals, for 8 weeks. A third historical group (3DCRT) contained patients from a previous

trial (n=522) treated with 2 Gy/fraction (7-8 weeks), planning margins of 10 mm, and a three-field 3D-conformal technique. Prospectively collected patient-reported symptoms were available for week 4 and week 6. Peak incidences (maximum week 4 & 6) were compared between the groups (chisquare test).

Results: We found a significantly increased risk for acute rectal bleeding in the HF group (15.1% versus 7.6% for SF, Table 1, Figure 1), which implies a relative risk of 2.0. Increased risks for HF vs SF ($p < 0.05$) were also found for mucus loss, loose stools, and increased stool frequency. Figure 1 shows the incidences for bleeding and mucus loss (with 1 SE). The increased risks for bleeding in the HF schedule were comparable with the observed risks in the historical 3DCRT cohort. Risks for other toxicities with HF were somewhat lower than for 3DCRT, with no significant differences except for stools ≥ 4 (HF 34.7% vs 3DCRT 42.9%, $p = 0.02$). Incidence of diarrhea exceeded that of the 3DCRT schedule, but not significantly ($p = 0.1$).

Conclusion: We observed significantly more acute proctitis symptoms in the HF group. These data might point to an underestimated fractionation sensitivity of acute rectal tissue. Our findings suggest that the repair capacity between two fractions was less effective when 3.4 Gy was delivered every other day, compared to daily 2 Gy fractions. The increased damage by hypofractionation is in the same order as the reduction in damage previously achieved with the introduction of IG-IMRT.

Table 1. Acute gastrointestinal symptoms with p for hypofractionation (HF, 3.4 Gy) vs standard fractionation (SF, 2 Gy).

GI symptom	Peak incidence W4 - W6 (%)			
	HF N=303	SF N=298	p	3DCRT N=522
Blood loss	15.1	7.6	0.004	15.6
Mucus loss	50.8	38.2	0.002	57.9
Pain/cramps	46.0	39.4	0.110	51.9

Effect of dose and image guided radiotherapy (IGRT) on erectile potency (EP) in prostate radiotherapy
J. Murray¹, J. Dean², H. Mossop³, E. Hall³, D. Dearnaley¹, S. Gulliford²

¹The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Radiotherapy and Imaging, London, United Kingdom

²The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, Sutton, United Kingdom

³The Institute of Cancer Research, Clinical Trials and Statistics Unit, London, United Kingdom

Purpose or Objective: IGRT enables accurate target volume localisation, potentially permitting reduced treatment margins, which may decrease normal tissue toxicity.

Erectile dysfunction is a common toxicity of prostate RT and the penile bulb (PB) is suggested as a surrogate for undetermined structures critical for erectile function. However, PB dose-volume effects are not well established.

We aim to determine dose-response characteristics of the PB in prostate cancer patients treated using IGRT with standard and reduced margins.

Material and Methods: Men with previously untreated localised prostate cancer were randomised within the multicentre CHHiP (Conventional or Hypofractionated High dose Intensity Modulated Radiotherapy for Prostate Cancer) IGRT sub-study (CRUK/06/16). Men were randomised to receive 2Gy or 3Gy per fraction, delivered either with or without daily online image-guidance, with standard or reduced CTV-PTV margins. Short course hormone therapy (HT) was allowed and details were recorded.

EP was assessed at baseline, pre-RT and at 6 monthly intervals to 2 years, then annually to 5 years post-RT. EP was physician graded as normal erection (G0), decreased (G1), absent (G2) and unknown. Analysis included the subset of men treated with IGRT within the sub-study with an EP assessment at 2 years.

Planning CT scans and reference dose distributions were imported into analysis software (Vodca, MSS GmbH). The PB was retrospectively contoured using established anatomical boundaries (1) and published guidelines (2,3) by one clinician. In-house software was used to convert the hypofractionated plans into equivalent dose in 2Gy per fraction using the Withers formula ($\alpha/\beta = 3\text{Gy}$). PB dose-volume (DVH) parameters were evaluated against EP at 2 years using atlases of complication incidence (ACI) (Matlab, Mathworks, Natick, MA) for G2 EP. Dose-volume constraints were derived using ROC analysis (Youden index) and assessed against the no information rate.

Results: Between June 2010 and June 2011, 293 men entered the study. Complete dose-EP data sets were available for 129 men treated with IGRT. 14/129 men had G2 EP at baseline and were excluded. At 2 years, 27/52 (52%) men treated with standard margins (IGRTS) and 25/63 (40%) men treated with reduced margins (IGRTR) had G2 EP. HT characteristics between the two groups were similar. The PB volume was $7.1(\pm 2.8)\text{cm}^3$ in IGRTS group and $6.5(\pm 2.5)\text{cm}^3$ in IGRTR group. The reduced margins resulted in a reduction in dose to the PB and statistically significant dose-volume constraints for G2 EP were derived for 45, 50, 55, 60 and 65Gy (Table 1). The ACI is presented in Figure 1 and demonstrates a dose-volume response.

		% Penile bulb volume receiving dose										Mean dose	Max dose
		20Gy	30Gy	40Gy	45Gy	50Gy	55Gy	60Gy	65Gy	70Gy			
IGRTS (n=52)	Median	40.8	34.0	24.4	18.0	17.5	10.3	1.6	0	0	20.7Gy	60.0Gy	
	IQR	14.9-77.5	9.7-87.5	0-55.8	0-49.0	0-42.1	0-29.7	0-26.7	0-14.3	0-0.03	8.8-41.6Gy	37.9-69.0Gy	
IGTRT (n=63)	Median	15.5	6.0	0	0	0	0	0	0	0	9.1Gy	33.6Gy	
	IQR	0-39.3	0-26.2	0-24.0	0-12.0	0-11.2	0-0.1	0	0	0	4.5-18.8Gy	16.3-55.9Gy	
Dose volume constraints					45	28	25	18	9				
AUC (95%CI)					0.61 (0.51-0.71)	0.61 (0.51-0.71)	0.62 (0.52-0.71)	0.59 (0.50-0.68)	0.58 (0.50-0.66)				
Predictive accuracy (%)					66	67	65	63	63				
p value *					0.009	0.005	0.01	0.04	0.04				

Table 1: Penile bulb dose-volume characteristics in patients treated using IGRT with standard and reduced margins and calculated statistically significant dose-volume constraints with associated parameters

IGRTS: IGRT with standard margins; IGTRT: IGRT with reduced margins; AUC: area under the curve; CI: confidence interval; IQR: interquartile range; *compared to the no information rate

Figure 1: Atlas of complication incidence for grade 2 erectile potency (G2 EP). Each box within the atlas describes dose (EQD2) and percentage volume of penile bulb. The numeric fraction presents the patients whose dose volume histogram (DVH) falls within the box (denominator) and the number of patients whose DVH falls within the range who experienced G2 EP (numerator). The fractional incidence (intervals of 10%) of G2 EP was used to generate a colour for each box (scale: blue (low incidence) to red (high incidence)).

Conclusion: There is evidence to suggest a dose volume effect between the PB and EP. Discriminatory PB dose-volume constraints were found to predict G2 EP. Further analysis is in progress to include patient reported outcomes related to EP.

Anal dose reduction for radiotherapy of prostate cancer does not lead to less rectal incontinence

E. Pos¹, L. Incrocci², R. Wortel², U. Van der Heide¹, J. Lebesque¹, S. Aluwini², M. Witte¹, W. Heemsbergen¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands

²Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

Purpose or Objective: Radiation-induced rectal incontinence has a negative impact on Quality of Life in patients irradiated for prostate cancer. Several studies identified dose-effect relationships for the anal canal and lower rectum and hence, dose constraints for treatment planning have been implemented. We studied patient-reported rectal incontinence in a population treated with Image-guided intensity modulated radiotherapy (IG-IMRT) and planned with a dose constraint for the anal canal, and compared it with a reference population treated with 3D-conformal radiotherapy (3D-CRT) with no dose constraint for the anal canal. For that purpose we analyzed data from two large prospective cohorts

Material and Methods: We selected patients treated to 78Gy (39x2Gy) from two trials (CKTO 96-10 and CKTO 2006-08), who completed at least 2 follow-up questionnaires which

included questions on pad use and fecal incontinence (IGIMRT group n=242, 3DCRT group n=189). In the IG-IMRT group, mean dose to the anal canal was restricted to 58 Gy per protocol (more strict constraints depended on local planning guidelines). Grade ≥ 2 ($G \geq 2$) incontinence was defined as use of pads for uncontrolled loss of feces or mucus, **Gratle** ($G \geq 1$) incontinence was defined as any reported fecal incontinence regardless use of pads. Prevalence and cumulative incidences of ≥ 2 and $G \geq 1$ incontinence were calculated. Cox regression was used to calculate Relative Risks (RR)

Results: Planned mean dose to the anal canal was on average 44.6 Gy (range 17-65) for 3D-CRT and 23.6 Gy (range 3-50) for IG-IMRT ($p < 0.001$). Median follow-up was 60 months. The 5y cumulative incidence of ≥ 2 incontinence was 15.2% for IG-IMRT vs 14.9% for 3D-CRT (RR=1.02, $p=0.9$). Prevalence of $G \geq 1$ incontinence was $\approx 5\%$ at baseline and in the range of 30% - 40% in the years after treatment, with no significant differences between the groups (Figure 1). Within the 3D-CRT group, previous abdominal surgery was predictive for ≥ 2 G incontinence (RR=2.1, $p=0.05$), whereas age >70 years at start RT (RR=2.9, $p < 0.01$), diabetes mellitus (RR=2.4, $p=0.04$), and seminal vesicle dose 70 Gy vs 0 Gy (RR=9.2, $p=0.03$) were predictive in the IG-IMRT group. At multivariate analysis, adjusting for the significant baseline factors, RR of mean anal canal dose was 1.00 ($p=0.9$) for IG-IMRT patients and 1.05 (for each increase of 1 Gy) for 3D-CRT ($p=0.04$). Acute toxicity $G \geq 2$ (mainly proctitis) was predictive ($p < 0.01$) in both groups with a RR of 3.1 (IG-IMRT) and 4.1 (3D-CRT). $G \geq 1$ incontinence at any time during follow-up was significantly associated with abdominal surgery in the 3D-CRT group, and with age >70 years, and diabetes mellitus in the IG-IMRT group

Conclusion: IG-IMRT with anal canal dose constraints did not reduce long-term incidence of rectal incontinence in prostate cancer patients, despite significantly reduced dose levels to the anal canal region. Further investigations are needed to understand the mechanisms of radiation damage causing rectal incontinence

¹³Hospital Universitari Vall d'Hebron, Medical Oncology, Barcelona, Spain

Purpose or Objective: To assess the toxicity and feasibility of concomitant radiotherapy with low doses of docetaxel plus

standard hormonal treatment in patients with high risk localized prostate cancer.

Material and Methods: Patients were randomly assigned to either arm A (LH-RH analogs every 3 months for 3 years and radiotherapy 74 Gy [2Gy x 37 fractions]) or arm B (LH-RH analogs every 3 months for 3 years, radiotherapy 73.8 Gy [1.8 Gy x 41 fractions] and concurrent weekly docetaxel at 20 mg/m² for 9 weeks). Chemotherapy was started one week before of radiotherapy. Primary endpoint was PSA relapse according to the Phoenix definition. The planned number of patients was 130 to detect a 15% difference with a power of 80% and an alpha of 0.05 (two-sided).

Results: From 12/2008 to 9/2012, 130 pts were accrued (Arm A: 64, Arm B: 66). Median age was 68 years (61-73). Patients had T3-T4 (82.6%), Gleason Score 8 (76.3%), PSA > 20 ng/mL (26.9%) and pN+ (18.9%). All characteristics were well-balanced between arms. Median dose of radiotherapy was 74 Gy (72-74.8) in arm A, and 73.8 Gy (72-75.6) in arm B. 75.7% of patients received the planned 9 treatments of docetaxel and median number of cycles delivered per patient was 9. After a median follow-up of 29.6 months (9.6-40.2), most common grade 1/2 toxicities (arm A and arm B) were: cystitis (12.5% vs 8.3%), diarrhea (35.9% vs 70%), proctitis (12.5% vs 13.3%), rectal tenesmus (3.1% vs 23.3%), asthenia (23.4% vs 61.6%) and dysuria (28.1% vs 30.0%). Toxicity grade 3/4, diarrhea was reported in 8.3% of patients in arm B and 0% in arm A. Grade 3/4 lymphopenia occurred less often in arm A than in arm B (3.1% vs 23.3%). There was no toxicity-related death.

Conclusion: The QRT SOGUG phase IIb trial shows that standard doses of radiotherapy and concurrent weekly docetaxel can be administered without increasing toxicity profile.

OC-0343

Pattern of intraprostatic recurrence on multiparametric MRI after radiotherapy for prostate cancer

H. Ariyaratne¹, D. Kopcke², A. Padhani², R. Alonzi¹

¹Mount Vernon Cancer Centre, Clinical Oncology, Northwood, United Kingdom

²Paul Strickland Scanner Centre, Radiology, Northwood, United Kingdom

Purpose or Objective: The majority of intraprostatic recurrences after radical prostate radiotherapy occur at the site of initial tumour, in previous reported series. However, there is no published data directly comparing recurrence patterns after different modalities of radiotherapy. The aim of this study was to investigate differences in spatial pattern of intra-prostatic recurrences on multiparametric MRI, after external beam radiotherapy or brachytherapy.

Material and Methods: We identified 382 consecutive patients referred for multiparametric MRI after previous prostate cancer treatment. Patients with post-radiotherapy biochemical recurrence and intraprostatic recurrence on MRI were included in the study. Scans were independently reviewed by two radiologists. The location of recurrence was mapped to prostate sectors based on European consensus guidelines. The chi-square test was used to analyse differences in site of recurrence between modalities of radiotherapy.

Results: 66 patients who had radical radiotherapy between 1997 and 2013 had intraprostatic recurrence on MRI. The D'Amico risk stratification at initial diagnosis was 14% low-risk, 34% intermediate-risk and 52% high-risk. The series consisted of 34 patients after external beam radiotherapy (EBRT), 20 patients after low-dose rate brachytherapy (LDR) and 12 after high-dose rate brachytherapy monotherapy (HDR mono). 68% of the EBRT recurrences had received a dose-fractionation schedule with an EQD2 less than 74 Gy. The mean time between the end of radiotherapy and imaging recurrence was 77 months (95% CI 68 - 85 months) with no significant differences between treatment groups. 80% of

patients did not have any associated pelvic bony metastasis or nodal disease. 88% of patients had a contiguous intraprostatic recurrence. The median recurrence size detected on MRI was 2.0 cm (range 0.6 - 4.2 cm). Recurrences after EBRT were more likely to involve multiple sectors of the prostate. 71% of EBRT recurrences involved the apex compared to 30% after LDR and 25% after HDR mono (p = 0.003). In the LDR group, recurrences involved the base of the gland in 60% of cases, compared to 41% after EBRT and 8% after HDR mono (p = 0.016). 21% of patients underwent salvage treatment with cryotherapy, HDR brachytherapy or prostatectomy.

Conclusion: Apical recurrences predominated in patients following EBRT. This highlights the need for MR-fusion during EBRT target definition because the apex is difficult to visualise on CT. Basal recurrences were associated with LDR brachytherapy, which may reflect a tendency of radioactive seed migration away from the base. The use of multiparametric MRI facilitates identification of patients for focal salvage treatment.

OC-0344

Risk of second primary cancers after radiotherapy for prostate cancer

N.S. Hegemann¹, U. Ganswindt¹, J. Engel², C. Belka¹

¹Klinikum der Universität München, Department of Radiation Oncology, Munich, Germany

²Klinikum der Universität München, Munich Cancer Registry of the Munich Tumour Centre- Department of Medical Informatics- Biometry and Epidemiology IBE, Munich, Germany

Purpose or Objective: The average 5-year survival rate of men diagnosed with prostate cancer (PCa) is 93%. The long life expectancy exposes them to a greater risk of developing second primary cancers. To quantify the risk of radiation induced second primary cancer, we analysed data of PCa patients based on our Cancer Registry.

Material and Methods: We analysed 19.538 patients treated for PCa from 1988 until 2008. They were either treated with surgery (RPE only) or received radiation therapy as primary (RT only) or as postoperative treatment (RT after RPE). Statistical analysis was performed using a stratified Cox proportional hazard model and a chi-square test.

Results: Patients who received RT only were 5 years older (median) than patients who underwent RPE only or RT after RPE. Second primary cancers were observed with 13.1% and 13.6% in the RPE only and in the RT after RPE group and 16.4% in the RT only group (p= 0.0001), respectively. Colon carcinoma was seen in the RPE only and RT only group in roughly 10 percent, whereas in the RT after RPE group in 14.6% (p= 0.2140). Bronchial cancer surpassed 10% in the RT only group (12.5%) vs. 9.7% and 7.8% in the RPE only and the RT after RPE group (p= 0.0552). Bladder cancer was observed with roughly 10% in the RPE only (10.2%) and RT after RPE (10.4%) group versus 15.5% in the RT only group (p= 0.0007). Rectal cancer after treatment of PCa was diagnosed in 5.7%, 7% and 3.1% in the RPE only, RT only and RT after RPE group (p= 0.1037). Within the first 10 - 15 years the cumulative hazard curves for second primary cancers gave no hint to an increased tumor risk due to prior treatment. After 15 years there are hardly any cases left and the occurring events can no longer be reasonably interpreted. Cox proportional hazard ratio revealed that patients with a higher age have a significantly higher risk of developing second primary cancer (Hazard Ratio 1.279 in 60 - <65 year old patients vs. 2.169 in ≥75 year old patients, p <0.0001).

Conclusion: Based on this population with PCa from the PSA era the incidences of second primary cancers did not differ significantly between the three arms apart from bladder and lung cancer that came close to being significantly different. However, these differences cannot reliably be ascribed to radiation, but to other factors such as older age, lifestyle habits like smoking and the well known fact that cancer

survivors generally have an increased risk of new tumor formation.

Purpose or Objective: The aim of this study was to investigate the patterns of failure after radiotherapy for pediatric intracranial ependymoma and their correlation to dose parameters.

Material and Methods: Between 2000 and 2013, 206 patients with intracranial ependymoma were treated in the 13 french reference pediatric radiotherapy centers. The magnetic resonance imaging obtained at recurrence were registered with the original planning CT for topographic analysis of the patterns failure. Clinical target volume (CTV) and planning target volume (PTV) margins were extracted; several dosimetric quality indices were derived from Dose Volume Histogram (DVH) to compare relapse with no-relapse patient.

Results: With a median follow-up of 44.81 months (95% CI [36.80; 56.51]), 85 (41.3%) patients presented with recurrence. The topographic analysis of patterns of failure showed 50 (58.8%) patients with local recurrence in the radiation field (LF), 6 (4.1%) in the edge of field (EFG), 6 (7.1%) were loco-regional outside the field (LRF), 8 (9.4%) in spine (SF), 5 supratentorial (SUF) and 10 (11.8%) local and distant (LDF). The median prescription dose was respectively: 55.8 Gy [50.4; 60] in LF, 54 Gy [48.6; 59.4] in EF, 56.7 Gy [50.4; 60] in LRF, 54 Gy [50.4; 59.4] in LDF, 59.4 Gy [48.6-59.4] in SUF and 56.7Gy [54; 60] in SF. The median PTV margins was 0.5 mm [0.3; 1]. The median Coverage index and The Target Coverage index of the PTV were both lower in the relapse group as they were respectively 0.97 and 94.8% in the relapse group compared with 0.98 and 95.99% in the no-relapse group. The median Homogeneity index was 0.097 in the relapse group versus 0.091 in the no-relapse group. The median volume of relapse was 1.29 cc [0.11; 27] in the LF group, with a median dose of 58.81 Gy [50.86; 61.38].

Conclusion: In patients with intracranial ependymoma, local failure in the tumor bed was the major pattern of failure. The preliminary results showed that all dosimetric indices on the PTV were worse in the relapse group. Improving the coverage of target volume may be an effective way to reduce the local failures. Thus a complementary correlation of

relapse patterns with dose parameters to PTV and organs at risks and the irradiation techniques is under statistical analysis and final results will be presented at the meeting.

OC-0346

Pediatric diffuse intrinsic pontine glioma re-irradiation: better survival and better time

L. Gandola¹, E. Pecori¹, V. Biassoni², B. Diletto¹, E. Schiavello², S. Meroni³, F. Spreafico², E. Pignoli³, M. Massimino²

¹Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology- Pediatric Radiotherapy Unit, Milan, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Pediatric Oncology, Milan, Italy

³Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy

Purpose or Objective: Since 2009 we launched a strategy for children with centrally reviewed MRI diagnosis of diffuse intrinsic pontine glioma (DIPG) implying the intravenous administration of vinorelbine with nimotuzumab -an anti-EGFR monoclonal antibody- weekly, for a total of 12 weeks, during radiotherapy delivery of 54 Gy, 1.8 Gy/fraction daily. After radiotherapy completion, vinorelbine and nimotuzumab were administered any other week until tumor progression or for a total of two years. In the attempt to improve survival and quality of life of our children, a protocol amendment in July 2011 introduced re-irradiation at relapse/progression.

Material and Methods: Local re-irradiation consisted of 19.8 Gy, fractionated over 11 days. A 3DCRT with 5-6 coplanar beams was adopted with a beam geometry possibly not overlapping that of the first line irradiation; the most demanding planning issue of re-irradiation was to meet optic chiasm dose constraints. Three additional children were re-irradiated to distant sites of relapse, spine (2) or ventricular system at doses of 36 Gy or 54 Gy respectively.

Results: Of the 39 patients treated from 8/2009, 28 had local (23) or disseminated (5) progression and 18 were given local (15) or distant (3) relapse re-irradiation at a median of 8 months after first radiotherapy (2.5-19 months). Reasons for not re-irradiating the other 10 children were: progression before July 2011 (4), parents refusal (4), too poor Lansky status (2); median PFS and progression site were not different in the two subgroups. Survival after re-irradiation lasted between two weeks and 14 months, median 6 months, and determined a statistically difference in median OS between the two groups of re-irradiated or not children, being 16 and 12 months, respectively (P=0.004). In 16 radiologically evaluated patients, re-irradiation induced: reduction of tumor volume in 8, stable volume in 3 while 5 had progression; 13 had symptom amelioration and 12 steroid suspension. Volume reductions were obtained in 7/8 children that have shown the same response after first line irradiation while one was obtained after stable disease in first line treatment. No adverse event was reported and all children were re-irradiated as outpatients.

Conclusion: Re-irradiation after relapse/progression represented a significant benefit for both OS and quality of life of children with DIPG with symptom amelioration in 13/18. This option is worth to be offered also in case of disseminated progression.

Purpose or Objective: For the treatment of adult patients newly diagnosed with medulloblastoma, there is no standard to guide multimodality therapy. With a multi-institutional cohort, we investigated and reported the multidisciplinary approach, clinical outcome, and prognostic factors of medulloblastoma in adult patients treated with postoperative radiotherapy (RT).

Material and Methods: Thirteen (13) institutions from the RCN study group among Europe and United States enrolled 206 adult medulloblastoma patients who underwent postoperative RT between 1976 and 2014. All hospitals received their respective Institutional Review Board approval, and extracted data were sent to one investigator (B.A.) for data analyses. Log-rank univariate and Cox-modeled multivariate analyses were performed.

Results: There were 118 men and 88 women, and median age was 29 (range, 16-67). The median follow-up was 31 months. Tumor resection was performed in all patients, and surgery was complete in 140 (68%) of the patients. For those patients with reported residual volume, 83 (66%) achieved <1.5 cm² after resection. Histological subtype was classic (61%) predominantly. Postoperative RT was given in 202 (98%) patients, and 93% of them received craniospinal irradiation (CSI) to a median dose of 36 Gy, with a median RT boost of 18 Gy to the posterior fossa. Ninety-eight (48%) patients had chemotherapy before, after, or concomitant with RT; the most common chemotherapy regimens were cisplatin and vincristine-based. At 5 and 10 years' marks, the overall survival (OS) rates were 63 and 51%; local control (LC) rates were 60 and 46%; and disease-free survival (DFS) rates were 52 and 38% for all patients, respectively. On univariate analyses, Karnofsky performance status (KPS) 80%, time between surgery and RT \leq 47 days, negative CSF, total RT dose \geq 54 Gy, CSI completion, use of boost field, and chemotherapy were associated with better LC, DFS, and OS. Additionally, complete surgery, <1.5 cm² residual volume, desmoplastic pathology, and age \geq 29 were significant favorable prognostic factors for DFS and OS. In multivariate analyses, KPS \geq 80% (P=0.001) and CSI (P=0.0002) were the remaining significantly favorable prognostic factors for DFS and OS; presence of chemotherapy (P=0.0002) and KPS \geq 80% (p=0.03) correlated with better LC rates.

Conclusion: We retrospectively reported the largest clinical series for the treatment of adult medulloblastoma and elucidated prognostic factors for tumor control and also survival outcomes. For patients with high KPS who also

received CSI, their DFS and OS were better. The use of chemotherapy may associate with better local control, possibly due to improved radio-sensitization. This information should serve as the benchmark and provide the basis for future prospective clinical trials in further improving the outcome for this group of adult patients with rare medulloblastoma.

Figure: A. Overall survival of the entire cohort (N=206 patients); B. Disease-free survival, 206 pts; C. Local control rate, also 206 pts; D. Local control as stratified by the use of any adjuvant chemotherapy, P=0.0273, Log-Rank testing

Purpose or Objective: A multicenter randomized trial evaluated neurological status (including neurological deaths) and cognitive function of patients with resected single brain metastasis (BM) after stereotactic radiotherapy of the tumor bed (SRT-TB) in comparison with adjuvant whole-brain radiotherapy (WBRT). This study reports a preliminary comparison of pattern of failure and neurological deaths in this trial.

Material and Methods: A planned number of 60 patients was randomly assigned into SRT-TB (30) and WBRT (30) arms. Inclusion criteria were: total or subtotal resection of BM, single BM in the MRI before craniotomy, KPS \geq 70, KRAS expectancy >6 months. Patients in the SRT-TB arm received linac-radiosurgery of 15 Gy/1 fraction, or 5 x 5Gy if large cavity or proximity of critical structures. WBRT consisted of 30 Gy in 10 fractions. Evaluation at baseline (before RT), eight weeks after RT, and next every three months consisted of EORTC QLQ-C30 - BN-20, MiniMental test, KPS, neurologic status, and MRI of the brain. Neurological death was defined as every death from progression in the brain, toxicity of treatment of BM, and from undetermined cause. Crude rates of neurological deaths and relapses in the brain were compared according to the treatment actually received analysis with chi2 test. Overall survival (OS) and interval free from neurological death (IFFND) rates were compared with log-rank test.

Results: In the SRT-TB arm, six patients were ineligible (new BM detected during RT planning [5], withdrawal of consent [1]), one received WBRT by error, two had rapid extracranial progression (one had no BM treatment, one received WBRT), thus finally 21 (72%) patients received the assigned treatment in this group. In the WBRT arm, 29 (97%) received the assigned treatment. With median follow-up of 12 months (range: 1-36) for 26 living patients, one-year OS rates (intention-to-treat) were 48% (95% CI: 36-60%) and 61% (95% CI: 43-79%) for SRT-TB and WBRT arm, respectively, $p=.14$. In the intention-to-treat analysis, one-year IFFND rates were 59% (95% CI: 35-84%) and 74% (95% CI: 56-93%) for SRT-TB and WBRT arm, respectively, $p=.10$. In the treatment actually received analysis, one-year IFFND rates were 62% (95% CI: 37-88%) and 72% (95% CI: 53-90%) for SRT-TB and WBRT arm, respectively, $p=.26$. There were 9 (41%) and 9 (30%) neurological deaths, in the patients receiving SRT-TB and WBRT, respectively, $p=.10$.

Ten (45%) of 22 patients treated with SRT-TB had relapse in the brain including 5 (23%) relapses in the tumor bed; 9 (31%) of 30 patients treated with WBRT had relapse in the brain including 7 (24%) relapses in the tumor bed, $p=.29$.

Conclusion: Our results showed high rate of neurological deaths with omission of WBRT, thus such treatment might not be safe. Planned analysis of the results from our study that will compare neurological and cognitive functions following two treatments will be also helpful in decision making process.

OC-0349

Hippocampal dosimetry predicts the change in neurocognitive functions after whole brain radiotherapy
S.Y. Lin¹, C.C. Yang², C.C. Chuang³, P.C. Pai¹, P.F. Tsai¹, D.L. Tsan¹, C.K. Tseng¹

¹Chang Gung Memorial Hospital, Department of Radiation Oncology, Taoyuan, Taiwan

²Chang Gung University, Division of Clinical Psychology-Master of Behavioral Sciences- Department of Occupational Therapy, Taoyuan, Taiwan

³Chang Gung Memorial Hospital, Department of Neurosurgery, Taoyuan, Taiwan

Purpose or Objective: Whole brain radiotherapy (WBRT) has been the treatment of choice for patients with brain metastases. However, change/decline of neurocognitive functions (NCFs) resulting from impaired hippocampal neurogenesis might occur after WBRT. It is reported that hippocampal sparing would provide the preservation of NCFs. Our study aims to investigate the correlations between hippocampal dosimetry and neurocognitive outcomes in patients receiving hippocampal sparing during WBRT (HS-WBRT).

Material and Methods: Fifty prospectively recruited cancer patients underwent HS-WBRT for therapeutic or prophylactic purposes. Before receiving HS-WBRT, all participants received a battery of baseline neurocognitive assessment, including memory, executive functions and psychomotor speed. The follow-up neurocognitive assessment at 4 months after HS-WBRT was also performed. To deliver HS-WBRT, Volumetric Modulated Arc Therapy (VMAT) with two full arcs and two non-coplanar partial arcs was employed. For each treatment planning, dose volume histograms were generated for left hippocampus, right hippocampus, and the composite hippocampal structure respectively. Biologically equivalent doses in 2-Gy fractions (EQD2) assuming an alpha/beta ratio of 2 Gy were computed. To perform analyses addressing the correlation between hippocampal dosimetry and the change in NCF scores, pre- and post-HS-WBRT neurocognitive assessments were available in 32 patients.

Results: NCF scores were quite stable before and after HS-WBRT regarding hippocampus-dependent memory. For verbal memory, the corresponding EQD2 values of 0%, 10%, 50%, 80% irradiating the composite hippocampal structure with <12.60Gy, <8.81Gy, <7.45Gy and <5.83Gy respectively were

significantly associated with neurocognitive preservation indicated by the immediate recall of Word List Test of Wechsler Memory Scale-III. According to logistic regression analyses, it showed that dosimetric parameters specific to left hippocampus exerted an influence on immediate recall of verbal memory (adjusted odds ratio, 4.08; p -value, 0.042, predicting patients' neurocognitive decline after HS-WBRT).

Conclusion: Functional preservation by hippocampal sparing during WBRT is indeed achieved in our study. Providing that modern VMAT techniques can reduce the dose irradiating bilateral hippocampi below dosimetric threshold, patients should be recruited in prospective trials of hippocampal sparing during cranial irradiation to accomplish neurocognitive preservation while maintaining intracranial control.

OC-0350

Post-radiation neuronal depletion in hippocampus measured by in-vivo magnetic resonance spectroscopy

P. Pospisil¹, T. Kazda¹, R. Jancalek², P. Stampal¹

¹Masaryk Memorial Cancer Institute, Radiation Oncology, Brno, Czech Republic

²St. Anne's University Hospital Brno, Department of Neurosurgery, Brno, Czech Republic

Purpose or Objective: Ongoing clinical trials are evaluating advantage of hippocampal avoiding whole brain radiotherapy (WBRT), however, further basic research focusing on in-vivo description of radiation injury processes is still needed. Using magnetic resonance spectroscopy (MRS), it is possible to measure specific metabolite concentrations in any region of interest in the brain. N-acetylaspartate (NAA) represents a marker of viable neurons. To describe hypothesized post-WBRT neuronal depletion in hippocampus, we prospectively measured changes in NAA concentrations 4 months after WBRT.

Material and Methods: Patients referred for WBRT with favorable prognosis estimated by graded prognostic assessment and without MRI hippocampal pathology were eligible for study enrollment. Before standard WBRT (two-dimensional planning, 2 laterolateral 6 megavoltage fields, dose 10x3.0 Gy delivered by linear accelerator), hippocampal spectroscopy was performed using GE Medical Systems Discovery MR 750 3T. Region of interest was placed through the whole temporal lobe with the voxel layer position adjusted based on the localization of hippocampi. Specialized software was utilized for measurement of absolute NAA concentration in voxels within right, left and both hippocampi. The control MRS with the same setup parameters was performed 4 months after the end of course of WBRT. Wilcoxon's signed rank test was employed for calculation of NAA concentration changes.

Results: Thirty-five patients (68% mens, mean age 59.5) were enrolled and underwent baseline MRS while only 18 (51%) of them finished the whole protocol with control measurement (15 died before and 2 refused). The most common primary cancer was lung (44%), kidney (20%) and breast (15%). On average, 9 voxels were analyzed per right and left hippocampus. The mean NAA concentration pre- and post-WBRT was 8.47 [mM] and 7.43 [mM] for the right and 8.80 [mM] and 8.04 [mM] for the left hippocampus, respectively. The statistically significant decrease was observed in the right (-11.4%; 95% confidence interval -6.9 to -15.9; $p=0.0003$) as well as in the left (-8.5%; 95% confidence interval -2.9 to -14.0; $p=0.0034$) hippocampus.

Conclusion: Hippocampal MR spectroscopy is feasible and sensitive method for non-invasive measurement of brain radio injury. In our study, we observed correlation between left hippocampal N-acetylaspartate concentration and verbal memory decline with smaller effect of right hippocampus. Robust analysis of pre-irradiation imaging studies may provide valuable predictive biomarkers for decision making for the best radiotherapy approach in the treatment of brain metastases.

MRI-guided brachytherapy in cervical cancer: high doses to small bowel don't predict late morbidity

C. Petit¹, R. Mazon¹, C. Chargari¹, I. Dumas¹, P. Maroun¹, P. Annedé¹, T. Seisen¹, C. Haie Meder¹

¹Gustave Roussy, Radiation Oncology, Villejuif, France

Purpose or Objective: To establish dose-volume effect correlations for late small bowel toxicities in patients treated for locally advanced cervical cancer with concomitant chemoradiation followed by MRI-guided adaptive brachytherapy.

Material and Methods: In a cohort of patients treated in curative intent and followed prospectively, those who had completed the treatment one year before were retained for this study. The small bowel loops were delineated during the planning process, but no specific dose constraint was applied. The dosimetric data, converted in 2 Gy equivalent ($\alpha/\beta=3$) were confronted to the occurrence of small bowel events: diarrhea, pain, flatulence, bleeding, obstruction, and fistula. Patients were followed every 3 months for the first year then every 6 months, for 3 years, then annually. Late morbidity was defined over the threshold of 90 days from treatment initiation and assessed using the CTC-AE 3.0. Patients who experienced recurrences were censored from the date of their relapse. Dose-effect relationships were assessed using mean dose comparisons (T-pair and Kruskal-Wallis tests), log rank tests on event-free survivals, and probit analyses. The highest graded event, or in cases of similar grade the earliest, was considered for analyses.

Results: One hundred and fifteen patients were eligible. Of them, 94.8% received concomitant chemoradiotherapy; 12.2% extended-field radiotherapy, and 32.2% nodal sequential boost. Their mean age was 47.5 years. The median follow-up was 35.5 months. A total of 522 events was reported. Focusing on the highest grade per patient: 17 had grade 0, 75, grade 1, 20, grade 2 and 3, grade 3. The prevalence of grade 1 events appeared stable during the study period, ranging between 31.2 and 50%. The one of grade 2 events tended to worsen: 2.2% at 6 months, 4.5% at 1 year, 6.9% at 2 years, and 7.0% at 3 years. Incidences of grade 2-4 events were 0.9% at 6 months, 6.6%, 19.0%, and 27.2% at 1, 2, 3 years respectively. The mean D2cm3 and D0.1cm3 were respectively 68.7 ± 13.6 Gy and 85.8 ± 33.1 Gy and did not differ according to grade ($p=0.47$ and $p=0.52$). Comparisons of mean D2cm3 and D0.1cm3 according to grade 0-1 versus 2-4 were not significant (68.0 ± 12.4 vs 71.4 ± 17.7 Gy, $p=0.38$ and 83.7 ± 26.4 vs 94.5 ± 51.9 Gy, $p=0.33$ respectively). Log rank tests were performed after splitting patients into 4 groups according to D2cm3 levels: > 80 Gy, 70 to 79 Gy, 60 to 70 Gy and < 60 Gy. No difference was observed for grade 1-4 ($p=0.52$), grade 2-4 ($p=0.52$) or grade 3-4 ($p=0.21$). Probit analyses showed no correlation between both dosimetric parameters and the probability of small bowel events grade 1-4, 2-4, or 3-4 (p ranging from 0.19 to 0.48).

Conclusion: No significant dose-volume effect relationships were demonstrated between the D2cm3 and D0.1cm3 and the probability of late small bowel morbidity. These two parameters should not limit the optimization process.

OC-0352

The high doses employed in brachytherapy of cervical cancer counteract hypoxia - a modelling study

E. Lindblom¹, A. Dasu², I. Toma-Dasu³

¹Stockholm University, Medical Radiation Physics, Stockholm, Sweden

²Linköping University, Department of Radiation Physics and Department of Medical and Health Sciences, Linköping, Sweden

³Stockholm University and Karolinska Institutet, Medical Radiation Physics, Stockholm, Sweden

Purpose or Objective: Brachytherapy is a well-established radiotherapy treatment modality that has been employed in treatments of several cancer types for more than a century. One of the most common treatment strategies for cervical cancer today is a combination of external beam radiotherapy, chemotherapy and brachytherapy. Similar to other forms of radiation therapy, pre-treatment imaging of hypoxia is rarely done for cervical cancer. Nevertheless, the clinical outcome is highly positive, despite the fact that hypoxia has been repeatedly confirmed in cervical tumours. It was therefore the purpose of this study to investigate whether the success of brachytherapy in these tumours, seemingly regardless of oxygenation status, could be explained by the characteristics of the brachytherapy dose distributions in comparison to external beam radiotherapy.

Material and Methods: A previously used *in silico* model of tumour oxygenation and radiation response was further developed to simulate the treatment of cervical cancer employing the combination of external beam radiotherapy and intracavitary brachytherapy. Based on the local clinical protocol and using a clinically derived brachytherapy dose distribution and assuming a homogeneous dose delivered by external radiotherapy, survival was assessed on voxel level taking into account the dose-modifying effect of the oxygenation as well as the effects of repair and repopulation of tumour cells during treatment. Two scenarios were considered for brachytherapy: one in which the high dose region was highly conformal to the hypoxic region in the target and one in which they were displaced relative to each other. Overall-response was assessed as Poisson-based tumour control probability (TCP). The interplay between tumour oxygenation and the heterogeneous high-dose distribution was also studied by simulating different spatial and temporal patterns of hypoxia. The results were compared to the case when irradiation was performed only with external beams delivering a homogeneous dose to the target.

Results: Predicted values of D50 with respect to the external treatment and assuming reoxygenation were in agreement with the clinically observed high cure rates. Assuming fast reoxygenation, the D50 was similar for the different cases of overlap between the brachytherapy dose distribution and the tumour, regardless if the hypoxic fraction was 10% or 25% (Table 1). To achieve 50% control with external RT only, a total dose of more than 70 Gy in 25 fractions would be required for both cases of hypoxic fraction assuming reoxygenation (Figure 1).

Figure 1. TCP curves for external RT given in 25 fractions for various scenarios for the brachytherapy (BT) dose distribution: highly conformal or shifted relative to the hypoxia area and the corresponding curves for the external RT (XT) only, for a simulated tumour with 10% hypoxia in (a) and 25% hypoxia in (b).

Hypoxic fraction	Oxygenation pattern	D_{50} (Gy)		
		BT highly conformal	BT shifted	XT only
10%	No reoxygenation	77.9	100.3	124.1
	Fast reoxygenation	40.4	60.6	73.4
25%	No reoxygenation	95.1	118.7	129.9
	Fast reoxygenation	44.3	65.4	76.2

Table 1. Values of D_{50} for external RT given in 25 fractions for various scenarios for the brachytherapy (BT) dose distribution: highly conformal or shifted relative to the hypoxia area and the corresponding values for the external RT (XT) only.

Conclusion: Assuming fast reoxygenation, the dependence on the degree and extent of hypoxia has little impact on the outcome and therefore the high doses delivered in brachytherapy could counteract the negative impact of hypoxia.

OC-0353

EBRT and interstitial brachytherapy for recurrent vault carcinomas: Factors influencing the outcomes

R. Engineer¹, S. Chopra², U. Mahantshetty², A. Maheshwari¹, R. Kerkar¹, R. Phurailatpam², J. Swamidas², S.K. Shrivastava²
¹Tata Memorial Centre, Surgical Oncology, Mumbai, India
²Tata Memorial Centre, Radiation Oncology, Mumbai, India

Purpose or Objective: Post hysterectomy vaginal vault recurrences have poor outcomes with pelvic control rates ranging from 50-60%. We conducted this prospective study at our centre with an aim to determine the factors influencing the outcomes of these patients treated with external beam radiotherapy (EBRT) and interstitial brachytherapy.

Material and Methods: Ninety patients were accrued between October 2008 and May 2014. All the patients underwent prior hysterectomy and were diagnosed to have recurrent vault cancers with squamous cell carcinomas. Only patients with minimum gap of 6 months between the hysterectomy and recurrence were accrued in the study. All underwent EBRT of 50Gy (2Gy/fraction) to pelvis and simultaneous boost to the pelvic nodes of (10 Gy/5 fraction) if present, using Intensity Modulated Radiotherapy with concurrent chemotherapy of weekly cisplatin (40mg/mt2) followed by HDR Interstitial brachytherapy boost of 20Gy (4Gy/fraction b.i.d).

Results: Eighty (88%) patients were post simple hysterectomy and 20(22%) had Wertheim's hysterectomy, 16 (18%) had pelvic nodes and 46(51%) had parametrial extension upto the pelvic side walls. All the patients completed EBRT and concurrent chemotherapy and 28 (31%) patients had gross residual disease at the time of interstitial brachytherapy. Post brachytherapy 5 patients continued to have persistent disease, 6 had local relapse, 2 had local + distant relapse and 9 patients had only distant relapse. At the median follow up of 42 months for the surviving patients the local control rate was 86% and the 5-year actuarial disease-free survival (DFS) and overall survival (OAS) was 75%, 71%. In univariate analysis OAS was influenced by tumor involving the pelvic side wall (55% vs 84% p=0.004) and large pelvic nodes >1cm (44% VS.73% P=0.01) at presentation and partial vs. complete tumor response to EBRT at the time of brachytherapy (40% vs. 83% p=0.001). On multivariate analysis pelvic nodes at presentation and the tumor response to EBRT were significant factors affecting DFS and OAS. Other factors such as age, disease volume, and vaginal extension did not impact the survivals. Grade III/IV rectal toxicity was seen in 5 (5%) patients, bladder toxicity in 3 (3%) patients, whereas none of the patients developed Grade III small bowel toxicity.

Conclusion: Using EBRT with concurrent chemotherapy and interstitial brachytherapy a majority of the recurrences can

be salvaged. An excellent local control and survival is achievable using this technique and 28 (31%) patients had gross residual disease at the time of interstitial brachytherapy.

OC-0354

Artificial neural network for bladder dose interfractional variation prediction in GYN brachytherapy

Z. Siavashpour¹, M.R. Aghamiri¹, R. Jaber², R. Ghaderi¹, C. Kirisits³

¹Shahid Beheshti University, Medical Radiation Engineering, Tehran, Iran Islamic Republic of

²Tehran University of Medical Science, Radiotherapy, Tehran, Iran Islamic Republic of

³Comprehensive Cancer Center- Medical University of Vienna, Radiotherapy and Oncology, Vienna, Austria

Purpose or Objective: Introducing a fast technique to estimate bladder dose due to interfractional variations.

Material and Methods: 30 cervical cancer patients treated with HDR intracavitary brachytherapy were selected. After applicator insertion all cases pelvic CT scans were performed twice; pre- and post-treatment (15-30 min after dose delivery), with applicator in situ and identical bladder filling protocol. A 3D treatment planning software (TPS) (Flexiplan®, version 2.6, Isodose control, the Netherlands) was used. Applicator (Rotterdam tandem-ovoid) reconstruction and organs contouring were done by the same physicist and physician on both image series. Planning was performed on the pre-treatment CT. Fractional prescription dose was calculated for each patient based on the EQD2 and defined planning aims: 80-90 Gy for D90 of the high-risk clinical target volume and D2cm³ of bladder, rectum, and sigmoid less than 85, 75, and 75, respectively. DVH parameters (D2cm³, D0.1cm³, D10, D30, and D50) were recorded after each planning. 192r dwell times were copied manually to the post-treatment CT in the TPS. The recalculations of the DVH parameters showed the interfractional OAR dose variations. Images and structures of each pre- and post-treatment plan were exported in DICOM format to an in-house MATLAB written code. An artificial neural network (ANN) based on the 'back-propagation algorithm' was developed to predict the OARs dose variations. ANN input data was based on the changes of OAR wall distance-to-dwell positions along the applicators, that were extracted from two images series of each case. 25 cases were randomly selected as the training and model validation set (20 cases for training and 5 for validation), and the last 5 one for the resulted ANN model testing. Testing was performed by comparing the interfractional dose variations obtained from TPS calculated DVH and that obtained from ANN-based computing. The performance of the ANN was analyzed by root mean square error (RMSE).

Results: RMSE of the designed ANN was 0.28. RMSE of the testing cases was 0.72. TPS-based interfractional variations for D2cm³ were -2.9 % ± 18.7 %. As an example of the model performance, relative differences of TPS-calculated and ANN-based interfractional variations for D2cm³ of the training + validation cases (just the first 25 ones) are presented schematically in the Figure 1. It can be seen that these relative differences are almost less than 3%.

Figure 1: Relative difference of D_{2cm} , interfractional variations of ANN model-based and TPS-based data.

Conclusion: An ANN-based model was introduced which can give a fast prediction of bladder interfractional dose variations during cervical cancer intracavitary brachytherapy independent from TPS based dose calculations. This can serve as a basis for online verification tools in brachytherapy dose delivery.

OC-0355

Long term analysis of electron vs. HDR boost in breast conservation - an Indian experience

S. Saha¹, S. Sarkar², A. Mitra³, A. Ghosh Dastidar⁴, S. Chattopadhyay⁵, S. Gupta⁶

¹Apollo Gleanegles Cancer Hospital, Department of Radiation Oncology, Kolkata, India

²Calcutta Medical Research Institute, Oncology, Kolkata, India

³Vivekananda Institute of Medical Science, Paediatrics, Kolkata, India

⁴IPGMER, Radiotherapy, Kolkata, India

⁵Medical College Hospital, Radiotherapy, Kolkata, India

⁶Apollo Gleanegles Cancer Hospital, Department of Surgical Oncology, Kolkata, India

Purpose or Objective: Last decade has witnessed a revolution in breast conservation (BCS) in India as a consequence of sustained awareness campaigns and detection of early cases. But success of BCS demands not only local control but cosmetic excellence as well. Radiotherapy plays a major role in this treatment and selected high risk cases require boost also. This retrospective analysis aims to explore impact of modality of boost radiotherapy (electron vs. HDR interstitial brachytherapy) on long term cosmesis.

Material and Methods: 194 early breast cancer patients (T1N0, T2N0, T1N1) underwent BCS (Lumpectomy =125, Quadrantectomy = 69) + N3 nodal dissection in our unit between July 2004 and March 2010 after metastatic work up. Clips (4 or 5) were placed in all for subsequent delineation of radiotherapy target. Receptor status (including Her 2 neu) was detected for all. All patients received post BCS adjuvant chemotherapy - FEC for 'low risk' cases and EC X 4 then taxane X 4 for 'intermediate' and 'high risk' cases. Whole breast radiotherapy was given to all (50 Gy/ 25 fractions with CT-based planning). 145/194 patients also received boost - either 15 Gy/ 6 fractions electron or 10 Gy/ single fraction HDR interstitial implant (2 or 3-planes) with individualized CT-based planning and geometrical optimization. DVH was analyzed in each for D90, Coverage index, Dose received by skin, DNR and COIN. Cosmetic outcome was analyzed in each follow up visit using 4-point scale (excellent, good, fair, poor).

Results: Out of evaluable 173/ 194 patients (4 died of metastasis, 17 lost to follow up) with minimum duration of follow up of 36 months, 86 did receive electron boost and 38 received HDR. Local recurrence was in none so far. The PTV differed significantly - median 38 cc with HDR vs. median 90

cc with electron. Cosmetic outcome was significantly different - only 48/86 patients receiving electron boost have 'excellent and good' cosmesis compared to 31/38 receiving HDR brachytherapy (P = 0.008). Grade 1-2 fibrosis was seen in 39/86 (46%) with electron and 6/38 with brachytherapy (P= 0.002). Grade 1-2 telangiectasia was also significantly lower with HDR brachy 3/38 vs 29/86 with electron (P= 0.0019). Arm oedema was negligible in all patients - only 2.8%.

Conclusion: For best cosmetic outcome after BCS, HDR brachytherapy (with CT-based 3D planning) for patients requiring boost radiotherapy appears to be much better option compared to electron unless the tumour is very superficial.

OC-0356

Long terms results of permanent breast seed implants (PBSI) as partial breast irradiation

J.P. Pignol¹, J. Caudrelier², C. McCann³, S. Doggett⁴, J. Crook⁵

¹Erasmus Medical Center Rotterdam Daniel den Hoed Cancer Center, Radiation Oncology, Rotterdam, The Netherlands

²The Ottawa Hospital Cancer Centre, Radiation Oncology, Ottawa, Canada

³Sunnybrook Health Sciences Centre, Radiation Oncology, Toronto, Canada

⁴Tustin Radiation Clinic, Radiotherapy, Tustin, USA

⁵BCCA Centre for the Southern Interior, Radiation Oncology, Kelowna, Canada

Purpose or Objective: Since 2004 breast cancer patients have been prospectively included in three clinical trials using post-operative permanent breast seed implant (PBSI) brachytherapy. We report the long term efficacy results of the technique on patients with low risk, small (less than 3 cm) and node negative tumors.

Material and Methods: The first trial was a Phase I/II accruing patient with low risk infiltrating ductal carcinoma (IDC), the second trial was a Phase II trial DCIS patients, and the third trial was a Multicentre Registry. All patients received PBSI delivering a dose of 90 Gy after CT-simulation and planning. Stranded ¹⁰³Pd seeds were implanted using light sedation, ultra-sound guidance, fiducial needle localization, and using template. Patients were followed-up annually for 10 years. Overall survival, disease free survival, local recurrence and ipsilateral recurrence at 5 years were compared to theoretical ones calculated using the DCTUFT University IBTR and DCIS Memorial Sloan Kettering Cancer Center nomograms.

Results: From April 2004 to May 2014, a total of 134 patients have been accrued. The median FU of the entire series is 58.6 months [range 1.3 to 121.8 months]. The median age at surgery was 61.9 years old [41 to 84.5], 91% of patients had an invasive tumor and the remaining were DCIS. All patients were T1-2 N0, grade 1 or 2 but one was found node positive on pathology review. At time of evaluation 119 patients were without any evidence of disease. The local recurrence free survival at 5 years was 98.8% (SD ± 1.20%), which was not statistically significantly different to the theoretical rate of 98.6% for patients receiving whole breast radiotherapy (p=0.23). But this rate was significantly better than the 95.4% theoretical risk of local recurrence with surgery alone (RR=0.27, p<0.001). The 5 year overall survival was 97.4% (SD ± 1.91%) and the disease free survival was 96.4% (SD ± 2.07%). In terms of tolerance, 22% of patients had telangiectasia almost exclusively grade I at 2 years. This rate decreases over time to 16% at 8 years. Of note 40% of the patients developed a palpable and asymptomatic induration in the surgical scar.

Conclusion: Long-term results suggest that PBSI is a well-tolerated treatment, with an efficacy similar to whole breast radiotherapy for well-selected early stage breast patients. This treatment represents a good treatment option for patients having difficulties attending prolonged radiotherapy protocols.

⁶Helsinki University Central Hospital, Department of Oncology, Helsinki, Finland

⁷CHU André Vésale, Radiation Oncology Department, Charleroi, Belgium

Purpose or Objective: The new methodology for end-to-end remote dosimetric quality audit for IMRT and VMAT treatments for national dosimetry audit networks has been developed within a co-ordinated research project (CRP). The purpose of this audit is to verify the entire radiotherapy chain including imaging, treatment planning and dose delivery for a clinical IMRT treatment executed with either a static or rotating gantry. Overall 16 research groups from 13 countries participate in this CRP. Results of a pilot study involving 6 CRP participants are presented.

Material and Methods: A polystyrene phantom (see Fig. 1) was designed for this exercise with the solid water structures representing PTV and OAR. Each participant received a phantom preloaded with a custom cut EBT3 film and 4 TLDs (2 in PTV and 2 in OAR), extra TLDs for imaging and a set of instructions and datasheets. Participants were asked to scan the phantom, contour the structures, create the treatment plan and irradiate the phantom. The plan was generated as for a patient to deliver 4 Gy to PTV in 2 fractions and limit the dose to OAR to 2.8 Gy (additional target objectives were provided).

Fig. 1 IMRT phantom with an insert loaded with film and TLDs.

Upon receipt of the irradiated phantom by the CRP organiser, TLDs and film were evaluated. Comparison was performed between the calculated and the film measured dose distributions using a gamma analysis tool (FilmQA ProTM, Ashland). The gamma acceptance criterion of 3%/3 mm over all pixel values exceeding 20% of the maximum dose was adopted. TLD results were presented as ratios of the TLD measured dose and the participant stated dose, $D(\text{TLD})/D(\text{stat})$.

Results: The results were obtained for 6 participants using 6 different accelerator models, 4 MLC models, 3 TPS models and 5 dose calculation algorithms. All participants created treatment plans which fulfilled the dose constraints provided. The results of gamma evaluation were between 93.5% and 100%. TLD results for PTV showed good agreement with the average $D(\text{TLD})/D(\text{stat}) = 0.995$ and 1.2 % standard deviation (SD), whereas for OAR the average $D(\text{TLD})/D(\text{stat})$ was 1.041 and the SD = 4.6%. As OAR was located in a high dose gradient region, even a 1 mm positional shift could cause significant TLD dose difference.

Conclusion: The methodology of this audit, examined through a pilot study, proved to work well. The instructions and datasheets appeared to be clear and straightforward to follow. The results showed good agreement for TLDs in PTV and also between the planned and the film measured dose distributions. However, TLD measurements in the OAR were challenging because of the high dose gradient in this region. The results of the pilot study were used to assess the measurement uncertainties and will help in establishing the acceptance limits for audit results. The study continues with 10 additional research groups involved in the CRP.

OC-0358

Surface doses with FFF VMAT dose delivery for breast cancer

J. Seppälä¹, A. Voutilainen², J. Heikkilä¹, T. Koivumäki¹, T. Viren¹, M. Vauhkonen²

¹Kuopio University Hospital, Cancer Center / Radiotherapy dept. 4251, Kuopio, Finland

²University of Eastern Finland, Faculty of Science and Forestry, Kuopio, Finland

Purpose or Objective: Flattening filter free (FFF) beams have the potential to speed up breast cancer radiotherapy (RT) treatments and reduce whole body dose of a patient by reducing treatment head leakage. However, the near surface dose data of modulated FFF beams is lacking. In this work the surface doses were studied with various treatment plans for breast cancer RT with both FFF and flattening filter (FF) beams.

Material and Methods: This study was executed with EBT3 films irradiated in a cylindrical phantom (CIRS, $\phi 16\text{cm}$). The phantom was imaged with CT scanner (slice width 1 mm). PTV and critical organs were contoured to the 3D images (Fig.1). Four clinical treatment plans (photon energy 6 MV, fractional dose 2 Gy) were created for Elekta Infinity accelerator with Agility MLC: 1) tangential open field, 2) tangential IMRT with dynamic MLC (DMLC), 3) tangential VMAT (tVMAT) and 4) continuous VMAT (cVMAT) (Fig.1). Doses were calculated to water with X-ray Voxel Monte Carlo algorithm (XVMC, Monaco v5.00.04, Elekta) with a resolution of 1 mm and STD of 0.5%. Treatment plans were normalized to mean dose of PTV. All irradiations were repeated three times and the calibrated films were scanned in RGB mode. Red channel data was used in analysis with OmniProlMRT software (v1.7, IBA, Germany).

Results: Calculated and measured surface dose distributions were compared and are presented for FFF in Fig.1. The overall accuracy of XVMC calculation was good with the largest point dose difference of -11% recorded with FFF DMLC. Line dose analysis was performed in lateral and central parts of the phantom to evaluate surface doses with

respect to beam directions (shown in Fig.1). Compared with measured dose the calculated doses were on average 3% larger at the depths of 0-2 mm (relevant depth for RT induced skin reactions). At 2-5 mm depths the dose deviation was on average 0% (Table 1). Central part surface doses at 0-2 mm were on average 27% higher with open fields than with both VMAT techniques which was also well predicted by the TPS (max error 4%). Within the lateral parts the average surface doses between the techniques deviated less than 8% (range 45% - 48%). An important finding was also that on average the lowest values of surface doses were measured with open fields (lateral parts). No significant differences in surface doses were detected between FFF and FF techniques.

Fig.1: Calculated dose distributions of (A) open field, (B) tVMAT and (C) cVMAT treatment plans with FFF and the corresponding differences against the measured dose distributions (meas-calc) in D, E and F, respectively. Table 1: Measured and calculated surface doses of FFF and FF (depths of 0-2mm and 2-5mm).

	Open field		DMLC		tVMAT		cVMAT	
FFF	Meas.	Calc.	Meas.	Calc.	Meas.	Calc.	Meas.	Calc.
Lateral 0-2 mm	45 %	50 %	45 %	44 %	46 %	47 %	48 %	52 %
2-5 mm	66 %	73 %	59 %	55 %	62 %	70 %	68 %	76 %
Central 0-2 mm	69 %	66 %	55 %	62 %	55 %	56 %	50 %	52 %
2-5 mm	98 %	94 %	87 %	84 %	89 %	89 %	90 %	84 %
FF	Meas.	Calc.	Meas.	Calc.	Meas.	Calc.	Meas.	Calc.
Lateral 0-2 mm	46 %	50 %	45 %	48 %	44 %	42 %	50 %	48 %
2-5 mm	69 %	66 %	66 %	69 %	63 %	63 %	74 %	75 %
Central 0-2 mm	62 %	71 %	64 %	62 %	62 %	59 %	48 %	49 %
2-5 mm	92 %	88 %	94 %	91 %	96 %	92 %	80 %	82 %

Conclusion: The accuracy of surface dose calculation was acceptable in Monaco TPS. There was no significant difference in surface doses between FFF and FF beams. Based on our results the VMAT techniques produce more homogeneous surface doses when compared to tangential open fields.

OC-0359

Superficial dose verification of four dose calculation algorithms

Y. Cao¹, Z. Yang¹, X. Yang¹, X. Qiu²

¹Xiangya Hospital Central-South University, Oncology Department, Changsha- Hunan, China

²University Of South China, School of Nuclear Science and Technology, Hengyang-Hunan, China

Purpose or Objective: The aim of this study is to verify superficial dose calculation accuracy of four commonly used algorithms in commercial available treatment planning systems (TPS) by Monte Carlo (MC) simulation and film measurements.

Material and Methods: EGSnrc (BEAMnrc\DOSXYZnrc) code was performed to simulate the central axis dose distribution of Varian Trilogy accelerator, combined with measurements of superficial dose distribution via extrapolation method of multilayer radiochromic films, to verify the dose calculation accuracy of four algorithms of AXB (Acuros XB), AAA (Analytical Anisotropic Algorithm), CCC (Collapsed Cone Convolution) and PBC (Pencil Beam Convolution) in the superficial region which was described in detail by ICRU and ICRP, under the conditions of source to surface distance (SSD) of 100cm, field size (FS) of 10cm×10 cm, solid water size of 30cm×30cm×30cm and the incident angles of 0°, 30° and 60°.

Results: In superficial region, good agreement was achieved between MC simulation and film extrapolation method, with the mean differences respectively less than 1%, 2% and 4%, and the relative skin dose difference were 0.84%, 1.88% and 3.90% for 0°, 30° and 60°; the mean dose errors (0°, 30° and 60°) between four algorithms and MC simulation were AXB (2.41±1.55%, 3.11±2.40%, 1.53±1.05%), CCC (3.09±3.0%, 3.10±3.01%, 3.77±3.59%), AAA (3.16±1.5%, 8.7±2.84%, 18.2±4.1%) and PBC (14.45±4.66%, 10.74±4.54%, 3.34±3.26%).

Table 1. Skin dose difference of film measurements and different algorithm calculations(%)

Incident angle	Method				
	Film	AXB	AAA	CCC	PBC
0°	0.84	-0.05	4.07	11.37	22.15
30°	1.88	-0.71	0.15	12.17	20.00
60°	3.94	0.74	-9.51	14.11	11.74

Fig. 1. Superficial dose distributions of film measurements and algorithm calculations with incident angle of 0° (a), 30° (b) and 60° (c) compared with those of MC simulations within the initial 2 mm depth.

Conclusion: Monte Carlo simulation validated the feasibility of the superficial dose measurement via multilayer Gafchromic film detectors. And the rank of superficial dose calculation accuracy of four algorithms was AXB>CCC>AAA>PBC. AAA and PBC algorithms were not applicable for superficial dose calculation.

OC-0360

TomoTherapy tangential breast treatment position uncertainty via exit detector fluence

N. Corradini¹, P. Urso¹, C. Vite¹

¹Clinica Luganese, Radiotherapy Center, Lugano, Switzerland

Purpose or Objective: To analyze the exit detector fluences from tangential breast treatments in estimation of the breast

position uncertainty of daily IGRT on the TomoTherapy system.

Material and Methods: Twenty patients who received tangential breast radiotherapy on the TomoTherapy system were selected randomly. All patients were aligned daily to the planning-kVCT using MVCT prior to treatment. For each detector measurement, the treatment projection containing the fluence passing through the midpoint of the breast was extracted for analysis in MATLAB. The high fluence gradient indicating the interface between the breast surface and tangential beam flash was easily observed and used for analysis (Fig 1). Each CT detector channel has a nominal width of ~ 0.76 mm projected at treatment isocenter, therefore absolute position of the projected breast surface was calculated. Separately, a study was performed using the TomoTherapy Cheese phantom simulating breast patient. A radiotherapy plan mimicking that of the breast patients was created. The plan was delivered onto the phantom in the correct treatment position, as well as with known phantom displacements in increments of 1-mm along the x- and z-axes. The analysis described above was subsequently performed on the phantom detector data to correlate the known displacements to those measured from the detector fluence. The correlation fit obtained from the phantom measurements was applied to the patients in estimation of breast surface position.

Figure 1. Above shows a schematic of the breast treatments illustrating how the CT detector records the exit fluence profile at one treatment projection. Below is an example of one patient's full dataset, i.e. 25 fluence profiles from one treatment projection, and detailed explanations are added to help interpret the measurement profiles.

Results: The phantom study showed that phantom position was linearly correlated with the exit detector measurements resulting in an $r > 0.99$. The standard deviation in the measured breast surface position, σ , was 2.28 mm for the 453 analyzed detector fluences ($\sigma_{\min} = 1.39$ mm, $\sigma_{\max} = 4.33$ mm). The uncertainty in the detector measurements was estimated to be under one detector channel's width.

Conclusion: The σ results of this study should be an indicator of the overall positioning uncertainty in our IGRT process for these treatments, i.e. kVCT-MVCT image registration, patient movement, and respiratory motion. Even if only one projection of the treatment data was used in the estimation, our results compare very well with similar studies' (von Tienhoven et al (1991), Smith et al (2005), Wang et al (2013)) findings on breast displacement due to respiratory motion. Furthermore, the novelty of this study is its evaluation of the breast position was performed on exit detector fluence of intensity-modulated fields, which we believe to be a first.

OC-0361

Simulation of clinical relevance errors detected by real-time EPID-based patient verification system

T. Fuangrod¹, J. Simpson^{2,3}, R. Middleton¹, P. Greer^{2,3}

¹University of Newcastle, School of Electrical Engineering and Computer Science, Newcastle- NSW, Australia

²Calvary Mater Newcastle, Radiation Oncology, Newcastle- NSW, Australia

³University of Newcastle, School of Mathematical and Physical Sciences, Newcastle- NSW, Australia

Purpose or Objective: A real-time patient treatment verification system using EPID (Watchdog) for clinical implementation was developed as an advanced patient safety tool. However to use Watchdog for treatment intervention we need to understand its response to clinically significant errors. The purpose of this study is to investigate the performance of Watchdog under controlled error conditions.

Material and Methods: The real-time verification system (Watchdog) utilises a comprehensive physics-based model to generate a series of predicted transit cine EPID image as a reference data set, and compares these to measured cine-EPID images acquired during treatment. The agreement between the predicted and measured transit images is quantified using chi-comparison on a cumulative frame basis. To determine the ability of Watchdog to detect clinically significant errors during treatment delivery we used real patient data and simulated dosimetric and patient positional errors. Four study cases were used; dosimetric error in Prostate IMRT, HN patient weight loss, prostate displacement and lung SBRT displacement errors. These errors were introduced by modifying the planning CT scan data and recalculating the predicted EPID data set. The error embedded predicted EPID data sets were compared to the measured EPID data acquired during patient treatment.

Results: The average % cumulative chi pass-rate across four case studies were 84.0% and 94.5% for 3%, 3mm and 4%, 4mm respectively. In the figures, the cumulative chi pass-rate results based on error simulation are shown. The difference ratio of chi comparison criteria between 3%, 3mm and 4%, 4mm was approximately 13%. As a result, the threshold level should determine based on the criteria and clinical acceptant limit.

Conclusion: We have evaluated our proposed real-time EPID-based treatment verification system using clinical relevant error simulation in prostate, HN and lung cases. Using either a 3%, 3mm or 4%, 4mm criteria, the real-time EPID-based patient verification system successfully detected simulated errors introduced into patient plan deliveries; including 5% dosimetric errors on prostate IMRT, 5mm prostate IMRT displacement, 5% HN patient weight loss, and 5mm Lung SBRT displacement.

⁵CFO, U.O. Fisica Medica, Firenze, Italy

⁶Azienda Ospedaliero-Universitaria, UOC Fisica Sanitaria, Parma, Italy

⁷Ospedale S. Camillo de Lellis, UOC Radioterapia, Rieti, Italy

⁸OC S.S. Annunziata, UOC Radioterapia, Chieti, Italy

Purpose or Objective: The increasing complexity of modern radiation therapy requires major quality control (QC) to ensure safety and reliability of patients' treatments. The large number of QCs requires a considerable amount of work that sometime is responsible of missing controls that may lead to dosimetric errors. In this frame the in vivo dosimetry (IVD) by EPID images has an important role to detect eventual dosimetric discrepancies between planned and delivered doses. The present work reports the results of 7500 IVD tests obtained in the last 2 years in 7 Italian Centers.

Material and Methods: SOFTDISO is an IVD-program distributed by the Best Medical Italy for 3D-CRT, IMRT and VMAT treatments, and it is based on correlation functions between EPID signals and doses in patient. The software is easy to implement for Varian, Elekta and Siemens linacs, and it is connected with the Record and Verify system of the Center, supplying the results in a few seconds. The method supplies two tests (i) the ratio $R = (\text{Diso}/\text{Diso}, \text{TPS})$ between the reconstructed and computed isocentre dose, with pass criteria of $\pm 5\%$ and (ii) a 2D γ -analysis between EPID images with the following pass criteria: the percentage of the points $P_{\gamma < 1}$ should be higher than 90% for 3DCRT and 95% for IMRT and VMAT; the γ -mean should be less than 0.5 and 0.3 for 3DCRT and IMRT-VMAT respectively.

Results: The percentage of the off-tolerance tests ranged between 10% and 17%, depending on the type of treatment checked. The causes of dosimetric discrepancies, in order of frequency were: set-up variations, attenuators left in the field, morphological changes, TPS implementation and linac output factor. All the causes of the off-tolerance tests were justified and, once removed, the mean R values of all patients were within 5% and the γ -analysis indexes satisfied the specific pass criteria. The discrepancies due to patient morphological changes triggered new TC or CBCT scans to verify the need of an adaptive plane. Some of these cases have been discussed by radiotherapists and physicists.

Conclusion: The multicenter result proved: (i) the great utility to obtain IVD tests in quasi real time, (ii) the positive role of the physicists during the dose-delivery step, (iii) SOFTDISO allows to understand the causes of dose discrepancies triggering adequate QC, and once the causes of errors were removed all the pass criteria were respected (iv) the role of IVD to intercept patient morphological changes to examine for eventual adaptive radiotherapy strategy.

Dose escalation in lung cancer patients, the dosimetric implications of inter-fractional change

L. Hoffmann¹, M. Knap², A. Khalil², D. Möller¹

¹Aarhus University Hospital, Medical physics, Aarhus, Denmark

²Aarhus University Hospital, Oncology, Aarhus, Denmark

Purpose or Objective: To date no satisfactory treatment options exist for locally advanced lung cancer. Based on promising phase II studies, dose escalation gave hope for better local control. However, the phase III RTOG 0617 [1] dose escalation trial showed that treatment related deaths can increase. Strict normal tissue constraints, as well as focus on the actual delivered dose, are essential when aiming for safe dose escalation. For standard doses, adaptive radiotherapy (ART) has mainly been concerned with ensuring target coverage, but with escalated doses anatomical changes during treatment can result in critical over dosage of organs at risk (OARs). Furthermore, it is important to monitor doses to known OARs such as the heart, and other structures as connective tissue and chest wall, where we don't know the risk for high dose RT. The present study investigates the impact of anatomical changes during RT on the escalated dose distribution used in the Danish NARLAL2 dose escalation trial.

Material and Methods: Fifteen patients (pts) with a standard treatment plan and an experimental dose escalation plan were analysed. The standard plan delivered a homogeneous dose of 66 Gy/ 33 fractions (fx) while the experimental plan delivered a heterogeneous escalated dose distribution. The dose escalation was driven by the most FDG-PET active region of the tumour and lymph nodes, with mean doses up to 95 Gy/ 33 fx and 74Gy/ 33 fx, respectively. The dose distribution was limited by constraints to the OARs (Table 1). All pts had a surveillance scan (sCT) at fx 10 and ten pts also at fx 20. The original treatment plans were recalculated on the sCTs to evaluate the impact of inter-fractional changes during the RT course. For most OARs, a maximum dose constraint was set, allowing higher doses for $< 1\text{cm}^3$ of the OAR. The number of pts with OARs reaching the maximum dose for the escalation plan, was determined. For some pts, the volume receiving doses above the maximum constraint, increased on the sCT. Volume increments $\Delta V > 1\text{cm}^3$ were made up.

Organ at risk OAR	Constraint, escalation plan	D > x Gy, pCT #patients	$\Delta V > 1\text{cm}^3$, sCT #patients
Lung	MLD < 20Gy		
Lung	$V_{20\text{Gy}} < 35\%$		
Heart	$V_{50\text{Gy}} < 20\%$		
Heart	$D_{1\text{cm}^3} < 74\text{Gy}$	2	0
Oesophagus	$D_{1\text{cm}^3} < 70\text{Gy}$	5	1
Trachea	$D_{1\text{cm}^3} < 74\text{Gy}$	0	0
Bronchi	$D_{1\text{cm}^3} < 74\text{Gy}$	3	0
Aorta	$D_{1\text{cm}^3} < 74\text{Gy}$	3	1
Connective tissue	$D_{1\text{cm}^3} < 74\text{Gy}$	14	7
Chest wall	$D_{1\text{cm}^3} < 74\text{Gy}$	12	5
Spinal cord	$D < 45\text{Gy}$	0	0

x=20 Gy for mean lung dose (MLD), 45 Gy for spinal cord, 70 Gy for oesophagus and 74 Gy for all other OARs. Connective tissue: All tissue between the lungs, exclusive the gross tumour volume (GTV) and all OARs delineated.

Results: At least one OAR reached maximum dose constraint on planning CT (pCT) for all pts. Of these, 9 pts showed doses to OARs increasing above maximum dose on sCT, see Table. Heart doses ($V_{50\text{Gy}}$) increased more than 1cm^3 (up to 19cm^3) in eight pts and in one pt the oesophagus was over dosed on the sCT. For connective tissue and chest wall, the volume receiving $> 74\text{Gy}$ increased more than 1cm^3 on the sCT in 7 and 5 pts, respectively. The anatomical changes leading to higher OAR doses were tumour shrinkage (5 pt), body contour changes (3 pt) and resolving atelectasis (1 pt). The mean dose to the PET-GTVT was $92 \pm 3\text{Gy}$. In six pts, the mean dose decreased more than 1% (up to 10%) on the sCT.

The caudal part of the heart (pink) moves into the high dose region. V_{50Gy} (turquoise) increases from 2.4% to 5.4% and mean heart dose increases from 14Gy to 18 Gy.

Conclusion: Anatomical changes during RT may result in increased doses to OAR. Introduction of dose escalation therefore requires frequent evaluation of treatment plans and ART should be used in order to avoid over dosage of OARs.

OC-0364

Adaptive radiotherapy for advanced lung cancer ensures target coverage and decreases lung dose

D.S. Moeller¹, M.I. Holt², M. Alber¹, M.M. Knap², A.A. Khalil², L. Hoffmann¹

¹Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark

²Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

Purpose or Objective: Effective treatment options are needed for locally advanced lung cancer. Increased treatment precision and decreased treatment volumes are mandatory for more aggressive radiotherapy. Adaptive radiotherapy (ART) was implemented to adjust the treatment plan to positional or volumetric changes of the tumour, and to normal tissue changes like atelectasis. Recently, ART was shown to improve local control without increasing radiation pneumonitis [1]. The present study investigates the dosimetric consequences of ART for 235 patients.

Material and Methods: ART intervention rules were implemented for lung cancer patients treated with definitive chemo-radiotherapy, in concordance with smaller PTV margins and daily online soft-tissue matching. Intervention rules derived from geometrical criteria for normal tissue and tumour changes. Violation of these for three consecutive fractions triggered an evaluation. If the observed change was suspected to lead to an underdosage of tumour/lymph nodes or an overdosage of normal tissue, a CT rescan and a replan were made. The original plan was recalculated on the rescan to evaluate the consequence of replanning for patients receiving a plan adaptation in a cohort of 235 consecutive patients treated with ART. For the first 50 patients, in order to assess the efficacy of the intervention rules, two additional surveillance CT scans were acquired during the RT course and the treatment plans were recalculated on these scans. The change in lung dose due to the implementation of

ART was found comparing the treatment plans of the first 50 ART-patients with 50 pre-ART-patients.

Results: Due to ART, the PTV decreased from 569 cm³ to 398 cm³, and consequentially the mean lung dose decreased from 14.1 Gy (SE 0.6) to 12.6 (SE 0.6) Gy. The criterion for the need of adaptation was a decrease in target coverage of CTV>1% or PTV>3%. The cohort of patients with two surveillance scans showed coverage above this in 94% of the cases not replanned. Sixty-one (26%) patients treated with ART had at least one replan. In total 77 adaptations were made. Fifty three adaptations corrected for a decrease in overall target coverage. Figure 1 shows the extent of decrease and designates the reason for replanning. In five patients with several separate targets under dosage of one of the targets were seen. One patient was replanned in order to avoid overdosage of spinal cord. Three patients were replanned due to changes in atelectasis making match evaluation impossible. In 15 patients, target shrinkage or less conformal dose distributions counterbalanced the geometric shifts that triggered adaptation.

Conclusion: The implementation of soft-tissue match and ART secured high treatment precision and allowed safe margin reduction in terms of persistent target coverage. The reduced margins reduced the mean dose to the lung.

OC-0365

The need for anatomical landmarks in adaptive rectal cancer boost radiotherapy

J.J.E. Kleijnen¹, B. Van Asselen¹, M. Intven¹, J.J.W. Legendijk¹, B.W. Raaymakers¹

¹UMC Utrecht, Radiotherapy Department, Utrecht, The Netherlands

Purpose or Objective: In rectal cancer 15% of the patients show a pathological complete response (pCR) after neo-adjuvant chemo-radiotherapy and these patients show better overall survival. To increase this pCR rate, in several studies a boost dose is given to the tumor. To safely deliver this boost, insight in the tumor position is needed. Currently, online imaging techniques provide no contrast of the tumor. However, since tumors are situated in the rectal wall, which is visible on online imaging like CBCT, the rectal wall position may be used as a surrogate for the tumor position. We therefore investigate the feasibility of tracking a part of the rectal wall close to the initial tumor as a motion surrogate for the tumor, to be used in online adaptive boost radiotherapy in rectal cancer.

Material and Methods: We scanned 16 patients daily on a 1.5T MRI scanner during a one-week short course of radiotherapy (5 times 5Gy). Rectum and tumor were delineated on the T2 weighted scan of each day. All scans were registered on bony anatomy, mimicking daily patient set-up. For both tumor and rectum separately, displacements

from the first day to every other day were determined, by calculating per voxel the shortest distance to each delineation.

To find out how proximate to the tumor we have to define our rectum motion surrogate, we selected that part of the rectum that lies within 1, 3, 5, 7 and 10 mm of the initial tumor (ProximateRectum). For each point on these ProximateRectums, we determined the nearest point of the tumor as corresponding point. Between all the corresponding points of ProximateRectum and tumor, the displacements to every day were correlated to each other. We also determined how much of the variance in tumor motion was explained by each ProximateRectum. These analysis were done for the 1, 3, 5, 7 and 10 mm ProximateRectum separately.

Results: Different motion patterns were found for tumor and ProximateRectums, especially when movement of the tumor is in cranial-caudal direction, since no anatomical landmarks are available (see figure 1). We found correlations of $\rho = 0.66, 0.64, 0.55, 0.53$ and 0.45 ($\text{all } \leq p < 0.001$) for ProximateRectum of respectively 1, 3, 5, 7 and 10 mm. This results in only 44%, 40%, 31%, 28% and 20% of the variance of tumor motion being explained by local rectum motion for respectively ProximateRectums of 1, 3, 5, 7 and 10 mm.

Conclusion: Even when the rectal motion surrogate is defined within 1 mm of the tumor, tracking this part of the rectal wall will not result in an accurate tumor positions since only 44% of the variance in tumor motion is explained by tracking the rectal wall. The lack of anatomical landmarks prevents finding the true rectum deformation and thus an accurate tumor position. Especially for motion in cranial-caudal direction, there is poor correlation between tumor and local rectal motion. Therefore, anatomical landmarks are needed for positioning the tumor e.g. direct imaging of the tumor using MRI or indirect imaging of the tumor using implanted markers.

Figure1: Rectum (yellow) and tumor (purple) delineations overlaid on sagittal MRI scan. The dashed delineations are from a different day. Note the difference in motion direction and extent between rectum and tumor (cyan arrows).

OC-0366

Dosimetric benefit of adaptive proton therapy compared to adaptive photon therapy in cervical cancer

A.J.A.J. Van de Schoot¹, P. De Boer¹, K.F. Crama¹, J. Visser¹, L.J.A. Stalpers¹, C.R.N. Rasch¹, A. Bel¹

¹Academic Medical Center, Department of Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: In cervical cancer, adaptive radiation therapy (ART) can be applied to compensate for interfraction target motion. However, organs at risk (OAR) still receive substantial dose when photon-based ART is applied. Adaptive proton therapy (APT) holds the promise to further limit OAR dose while maintaining adequate target coverage. Our aim was to investigate the potential dosimetric advantages of image-guided APT (IGAPT) compared with photon-based image-guided ART (IGART).

Material and Methods: Twelve cervical cancer patients treated with photon therapy were included in this retrospective study. Besides the clinically acquired full bladder planning CT, additional empty bladder planning CT and weekly repeat CTs were acquired for study purposes. Planning CTs were registered based on bony anatomy and multiple interpolated cervix-uterus structures were derived using a point-based non-rigid registration method. For each interpolated structure, a photon (VMAT) and a proton (IMPT) plan was created to build patient-specific plan libraries. All plans were robustly optimized with a prescribed physical CTV dose of 46 Gy-equivalent (GyE) (23×2 GyE) for pelvic irradiation or 50.4 GyE (28×1.8 GyE) for para-aortic irradiation. For each patient, repeat CTs were registered to the full bladder planning CT based on bony anatomy and IGART and IGAPT treatments were simulated by selecting library plans and recalculating the dose. For each simulated fraction, CTV coverage ($V95\% > 98\%$) was assessed and differences in Dmean and D2cc fraction dose and fractionated substitutes of V15Gy, V30Gy and V45Gy parameters (i.e. dose levels divided by the number of fractions) for bladder, bowel and rectum were evaluated and tested for significance (Wilcoxon signed-rank test). Also, fraction dose distributions were accumulated and differences in the overall rectum toxicity related DVH parameter (V30Gy) and normal tissue complication probability (NTCP) for grade 2 acute gastrointestinal toxicity were determined.

Results: In 6 fractions (10.7%), the cervix-uterus structure deviated substantially from the pre-treatment derived structures. Adequate CTV coverage was obtained in 92% (96%) of the remaining fractions for IGAPT (IGART) which resulted in adequate CTV coverage on average per patient. All DVH parameters for bladder, bowel and rectum, except for the fractionated substitute of rectum V45Gy, were improved using IGAPT (Figure). Also, the mean dose to bowel, bladder and rectum was reduced significantly ($p < 0.01$). Compared to IGART, IGAPT indicated a mean reduction of 7% for rectum V30Gy and a mean decrease from 0.33 to 0.18 in bowel NTCP.

Figure: Boxplots of fraction parameter substitutes over all simulated fractions for Bladder (upper), rectum (middle) and bowel cavity (lower). Boxes represent the median value and upper and lower quartiles, whiskers give the lowest and highest data point within 1.5x inter quartile range and the dots show the outliers. Horizontal lines indicate significant differences: * $P < 0.01$.

Conclusion: This study demonstrates the feasibility of IGAPT in cervical cancer using a plan library based adaptive strategy

to compensate for interfraction target motion. Compared to photon-based IGART, IGAPT maintains adequate target coverage while a significant dose reduction in bladder, bowel and rectum can be achieved.

⁹Az.Osp.Ospedali Riuniti Marche Nord, Medical Physics, Pesaro, Italy

Purpose or Objective: The retrospective analysis of anonymous data investigates the benefit of predictive analysis to assess anatomical and dosimetric variations for Adaptive Radiation Therapy (ART) purpose. Within a multicenter research network, clinical outcome were evaluated to determinate eligible patients for re-planning; a time series analysis allows scheduling re-planning during RT. We highlighted advantage and challenges due to the combination of IGRT (MVCT and CBCT), deformable image registration (DIR) and different set-up protocols comparing the multicenter data.

Material and Methods: The retrospective study enrolled 40 head and neck (H&N) anonymous patients from Center-A (MVCT), 20 from Center-B (CBCT), 8 from Center-C (CBCT), 8 from Center-D (CBCT). We have post-processed more than 2100 CT studies obtained by the imaging on board (>200000 slices). We analyzed parotid gland (PG) such as organs most affected by warping during the weeks of therapy. Volume and dose were normalized to the first day of treatment in order to remove bias related to machine/images variability and anatomical dimension. Structures were re-contoured automatically and the doses deformation was performed by RayStation® within an automated ART workflow supported by IronPython® scripting. Using DIR algorithms and GPU fast computing, the daily setup images were analyzed and compared. To support the data-mining; a Neural Network (NN) tool was developed and implemented in MATLAB® to evaluate abnormal clinical cases and re-planning strategies during fractions.

Results: A weekly analysis was carried out to follow and predict variations. After 6 weeks of therapy, PG showed a mean volume decrease of 23.7±8.8%: 25.1±9.2% in Center-A, 23.8±6.6% in Center-B, 21.2±10.3% in Center-C, 24.4±9.8% in Center-D. The NN analysis showed that, during the first 3 weeks, almost the patients' cohort followed a similar trend. Mean PG morphing can be predictable in 86.3% of the center cases: 89.6% A, 92.7% B, 76.0% C, 87.0% D. From the 4th week some challenges appeared. The patients that benefit from a review of the initial plan increased during treatment, highlighting the need of re-planning. Based on PG shrinkage, 53.5% of patients would need a re-planning with an inter-centers variability of 19.7%. An amount of 17.0% of cases is affected by bias due to algorithm and set-up error: 11.5% and 5.5% respectively.

Figure 1: PG outcome predicted by NN during 6 weeks of therapy. Cases are divided into 4 outcomes: 1) patients with normal trend (no re-plan needed); 2) patients with abnormal morpho-dosimetric variations (re-plan suggested); 3) software bias; 4) possible set-up error

Center	Output	Week					
		1	2	3	4	5	6
A	1 (no re-plan)	92%	92%	85%	41%	19%	21%
	2 (re-plan)	8%	8%	15%	59%	69%	77%
	3 (bias)	0%	0%	0%	0%	8%	2%
	4 (set-up error)	0%	0%	0%	0%	4%	0%
B	1 (no re-plan)	100%	89%	89%	56%	18%	23%
	2 (re-plan)	0%	11%	11%	44%	38%	27%
	3 (bias)	0%	0%	0%	0%	33%	38%
	4 (set-up error)	0%	0%	0%	0%	11%	13%
C	1 (no re-plan)	76%	75%	77%	66%	20%	20%
	2 (re-plan)	10%	10%	23%	34%	72%	77%
	3 (bias)	14%	15%	0%	0%	2%	3%
	4 (set-up error)	0%	0%	0%	0%	6%	0%
D	1 (no re-plan)	100%	100%	61%	52%	29%	66%
	2 (re-plan)	0%	0%	39%	48%	66%	25%
	3 (bias)	0%	0%	0%	0%	0%	4%
	4 (set-up error)	0%	0%	0%	0%	5%	5%

Table 1 Outcome of patients' percentage during 6 weeks of therapy. Data are analyzed by Center (A, B, C, D) and NN output (1, 2, 3, 4)

Conclusion: IGRT and ART techniques ensure a personalization of patients' treatment. A predictive NN tool was implemented and trained in order to detect criticalities in a multi-centric study supporting the feasibility of national data-mining for ART purpose. Based on PG warping and data prediction, a mid-course re-planning could be scheduled in the 4th week to ensure an adequate dose distribution during the treatment course.

OC-0368

Accurate CBCT based dose calculations

R.S. Thing^{1,2}, U. Bernchou^{1,2}, O. Hansen^{1,3}, C. Brink^{1,2}

¹Institute of Clinical Research, University of Southern Denmark, Odense, Denmark

²Laboratory of Radiation Physics, Odense University Hospital, Odense, Denmark

³Department of Oncology, Odense University Hospital, Odense, Denmark

Purpose or Objective: Cone beam CT (CBCT) based dose calculations are inaccurate due to the image quality of CBCT images acquired for image guided radiation therapy (IGRT). This study demonstrates that a post-processing of the raw projection data can improve the CBCT image quality such that the accuracy of CBCT based dose calculations can be recovered.

Material and Methods: 5 lung cancer patients were selected for analysis, all of whom had a re-simulation CT (rCT) scan performed on the same day as a CBCT scan during their radiotherapy treatment. For each patient, two CBCT reconstructions were computed and used for dose calculation. The first CBCT was a clinical 3D reconstruction of the CBCT images as acquired for IGRT by the Elekta XVI R4.5 system (denoted cCBCT). The second CBCT used the clinical projection images, but was corrected for image lag, detector scatter, body scatter, beam hardening, and truncation artefacts prior to reconstruction using the open-source Reconstruction Toolkit. This second reconstruction is denoted iCBCT.

Although the rCT and CBCT images were acquired on the same day, setup errors and anatomical differences such as

diaphragm and chest wall position were evident when the CBCT images were compared with the rCT. Therefore, deformable image registration was performed with elastix, to eliminate dose differences due to anatomical differences between the scans. Missing anatomy in the CBCT images due to the limited field of view was copied from the rCT image after deformable registration of the CBCT images.

The original treatment plan was recalculated on the rCT, cCBCT, and iCBCT image sets using Pinnacle ver. 9.10. The resulting dose matrices were compared using a 2%/2mm and 1%/1mm gamma analysis with the rCT dose as reference dose. The dose criterion was evaluated as 2% (1%) of the prescribed dose of 66 Gy. A low dose threshold of 10% of the prescription dose was used, and the gamma analysis was only performed in the CBCT volume.

Results: High gamma pass rates were achieved. The cCBCT-based doses resulted in 2%/2mm gamma pass rates between 89.4 and 96.4%, while the iCBCT-based doses resulted in gamma pass rates between 98.4 and 100%. The 1%/1mm gamma analysis yielded pass rates between 77.5 and 80.3% for the cCBCT images, while the iCBCT images provided pass rates between 90.7 and 98.7%. For all patients, the iCBCT images provided superior pass rates compared to the cCBCT images. The table below shows all gamma pass rates for the 5 patients.

γ -criterion	Image	Pt 1	Pt 2	Pt 3	Pt 4	Pt 5
2%/2 mm	cCBCT	89.4%	96.4%	95.8%	94.7%	93.1%
	iCBCT	100%	98.4%	99.9%	100%	100%
1%/1 mm	cCBCT	77.5%	80.3%	77.6%	79.9%	79.5%
	iCBCT	98.7%	90.7%	98.6%	98.6%	95.1%

Conclusion: CBCT images can recover the image quality necessary for accurate dose calculations through comprehensive artefact corrections. While the iCBCT doses are accurate, further studies are required to determine how this result can be translated into clinical practice where the accurate dose calculation has potentials within adaptive radiotherapy and CBCT-based online planning. The present study is an important step towards the routine use of CBCT images for adaptive radiotherapy.

Proffered Papers: RTT 4: How to increase the knowledge for patients and staff

OC-0369

Video glasses to reduce claustrophobic anxiety in radiotherapy treatment

V. Althof¹, H. Althof¹, E. Dahmen², P. Bouma¹

¹Radiotherapiegroep, Deventer, Deventer, The Netherlands

²Brainspa, Institute for Biofeedback, Zutphen, The Netherlands

Purpose or Objective: To investigate whether video glasses can reduce the anxiety level in claustrophobic patients in radiotherapeutic treatment. Claustrophobic patients experience a high level of stress and discomfort which can hamper therapeutic procedures and possibly lead to non optimal treatment. The influence of video glasses (Luna5, Cedexis Inc.) on stress level during radiotherapy was measured using the Beck Anxiety Inventory (BAI) and biometrical parameters.

Material and Methods: In radiotherapy, systems may be equipped with a tight bore (CT, Tomotherapy) and the patients are immobilized on the treatment couch. A mild to moderate level of anxiety due to claustrophobia occurs at 10% of the population, a more severe level occurs at 4%. The common method to deal with a claustrophobic patient is to spend time with the patient to simulate treatment or to prescribe a tranquillizer. The idea of the video glasses is to focus patient attention to a movie using images and sounds from nature ('Beter door Beeld' Inc.). Volunteers (n=15) underwent a simulation of a radiotherapy treatment on the Tomotherapy system. Each volunteer filled in the BAI form in advance, which estimates the severity of their anxiety, based

on a past individual claustrophobic experience. Severe level of anxiety was present in 11 volunteers, moderate level was found in 4 volunteers. Each volunteer was exposed to 3 runs: one without glasses, one with and the third without to measure a possible effect on habituation. The glasses were placed when the volunteer was on the couch (no immobilization). The volunteer was positioned in the bore of the Tomotherapy system and left alone during 2 minutes. After each run the volunteer filled in the BAI form with reference to the anxiety felt during the last run. Moreover, the volunteer was monitored continuously during each run using the Nexus-10 biofeedback system (MindMedia Inc.) to access the experienced level of anxiety more objectively. Results shown here are based on the detection of the high beta EEG wave.

Results: Reduced level of anxiety (based on the BAI score) was indicated by 13 out of 15 volunteers when using video glasses (see figure 1). This was confirmed by the observed trend in the 'high beta' brain wave amplitude. This brain signal is associated with stress level. The difference in mean amplitude of this wave between the run with and without video glasses is depicted in figure 2.

Conclusion: Using video glasses with an especially composed movie using images and sounds from nature during radiotherapy treatment, clearly lowers the level of anxiety of claustrophobic volunteers both subjectively based on the questionnaire as objectively by biometric measurements. Feedback of the volunteers overwhelmingly expressed a preference to undergo treatment with video glasses: "it was much easier to relax, never without glasses!"

OC-0370

The influence of virtual training on pelvic radiotherapy education for the multidisciplinary team

A. Williams¹, U. Shah¹, G. Fury¹, L. Codd¹, M. Brown¹, Y. Tsang¹

¹Mount Vernon Cancer Centre, Radiotherapy, Middlesex, United Kingdom

Purpose or Objective: Radiotherapy accelerates rapidly and ongoing training is essential to maintain and develop knowledge. A virtual reality environment is one way to provide training.

This study aims to demonstrate how a training package for advanced prostate and cervix radiotherapy can be

implemented effectively in a multi-disciplinary setting using a virtual reality environment.

Material and Methods: The training package consists of a virtual reality training tool (visual demonstration) and workbooks (self filled questions). Each training tutorial is delivered by a senior radiographer and includes identification of pelvic anatomy, review of different radiotherapy treatment planning and delivery techniques (conformal, static field intensity modulated radiotherapy and volumetric modulated radiotherapy), image guided treatment scenarios and radiotherapy related side effects.

The trainees were asked to complete pre and post tutorial questionnaires by grading their knowledge from 1 not confident at all, to 10 being exceptionally confident. These were devised to assess the effectiveness of the training package in terms of the trainees' knowledge and decision-making skills in advanced prostate and cervix radiotherapy. An evaluation of the session was also completed.

Results: The session was presented to 20 attendees comprising of 14 radiographers, 4 physicists and 2 clinical oncologists. In general, all attendees found the session useful and appropriate for their level of experience. All would recommend the training package to their peers.

The results of the pre and post tutorial questionnaires were summarised in table 1 below. Using Wilcoxon signed rank test, significant improvements in scoring were found in all questions ($p < 0.05$)

Question	Pre-tutorial score	Post-tutorial score	P value
How confident are you at identifying pelvic anatomy on CT	Median= 7 Range= 3 to 9	Median= 8 Range= 6 to 9	<0.05
How confident are you to decide if a patient is suitable to treat with image matching decision making for prostate and cervix patients using images, DVH and organ at risk tolerance dose information	Median= 6 Range= 1 to 10	Median= 8 Range = 5 to 10	<0.05
Please rate your knowledge of planning for prostate and cervix patients when looking at rapid ARC, IMRT and conventional plans.	Median= 5 Range= 1 to 9	Median= 8 Range= 3 to 9	<0.05

Conclusion: Our analysis of the data suggests the virtual reality teaching tool can enhance learning, influence decision making, improve knowledge and understanding of cervix and prostate radiotherapy for radiographers, physicists and clinicians. To this effect, further training sessions will be held and evaluated with the multidisciplinary team.

OC-0371

Introduction of a consultant radiographer to stereotactic radiotherapy service

Y. Tsang¹, P. Ostler², N. Shah², J. Kudhail¹, P. Hoskin²

¹Mount Vernon Cancer Centre, Radiotherapy Department, Northwood Middlesex, United Kingdom

²Mount Vernon Cancer Centre, Clinical Oncology, Northwood Middlesex, United Kingdom

Purpose or Objective: The role of a radiotherapy consultant radiographer has been proposed by the government in the United Kingdom with the aim to take advantage of the competencies of radiographers in driving forward the implementation of protocol-based care. With the increasing demand for Stereotactic Radiosurgery and Radiotherapy (SRS/SRT), our institution has appointed a consultant radiographer to lead the service since 2014. This study aims to investigate the impact of a consultant radiographer on the SRS/SRT service.

Material and Methods: A consultant radiographer is defined as someone with the appropriate education and training who is able to provide clinical leadership within a specialism, bringing strategic direction, innovation and influence through practice, research and education to the post. It is

acknowledged that the role of a consultant radiographer was introduced to enhance our SRS/SRT service delivery and hence improve patient outcomes by increasing capacity and patient throughput. This helps the service to meet national and cancer targets.

A retrospective review of SRS/SRT patients who were treated in 2013, 2014 and 2015 at our institution was carried out to determine the interval between decision to treat and treatment start dates (INT). Kruskai-Wallis ANOVA was performed to test for any significant difference in INT across the three years.

Results: Between January 2013 and September 2015, 229 patients were included in the study and the descriptive statistics were summarised in the table below.

Year	2013 (Jan - Sept)	2014 (Jan - Sept)	2015 (Jan - Sept)
Number of patients treated	66	74	89
Mean INT (days)	39.4	28.6	22.0
95% Confidence Intervals for Mean INT (days)	32.2-46.7	24.2-32.9	18.9-25.0

A significant difference ($p < 0.05$) was found in INT between 2013, 2014 and 2015. The mean INT in 2015 is shortened to nearly half of that in 2013.

Conclusion: This analysis suggests that intervals between decision to treat and treatment start dates of our SRS/SRT patients have been shortened since the consultant radiographer was appointed. The post holder has streamlined the patient pathways that still deliver high quality services but in more resourceful and innovative ways including radiographer led target volume delineations and consent.

Changes in student attitudes following a pre-registration interprofessional learning experience

K. Coleman¹, B. Darlow², E. McKinlay², P. Gallagher³, M. Perry⁴, L. Beckingsale⁵, B. Gray⁶, H. Nesar¹, S. Donovan², J. Stanley⁷, S. Pullon²

¹University of Otago- Wellington, Department of Radiotherapy, Wellington, New Zealand

²University of Otago- Wellington, Department of Primary Health Care and General Practice, Wellington, New Zealand

³University of Otago- Wellington, Medical Education Unit, Wellington, New Zealand

⁴University of Otago- Wellington, School of Physiotherapy, Wellington, New Zealand

⁵University of Otago- Wellington, Department of Human Nutrition, Wellington, New Zealand

⁶University of Otago- Wellington, Department of Primary Health Care and General Practice, Wellington, New Zealand

⁷University of Otago- Wellington, Biostatistical Group- Dean's Department, Wellington, New Zealand

Purpose or Objective: Interprofessional Education (IPE) aims to improve collaborative practice by bringing together health professionals from different disciplines who learn about, from and with each other. This study evaluated whether an IPE program changed health professional students' attitudes to interprofessional teams and learning, students' self-reported effectiveness as team members, and students' perceived ability to manage long-term conditions.

Material and Methods: A prospective controlled trial evaluated an eleven-hour IPE program delivered over a four-week period by an interdisciplinary teaching team. The program included an initial three-hour interactive workshop, a home visit in interdisciplinary groups to a person living in the community with long-term conditions, and a peer presentation with facilitated group discussion. Pre-registration students from the disciplines of dietetics ($n = 9$), medicine ($n = 36$), physiotherapy ($n = 12$) and radiation therapy ($n = 26$) were allocated to either an intervention group ($n = 41$) who received the IPE program or a control group ($n = 42$) who continued with their usual discipline

specific curriculum. Attitudes were measured pre- and post-intervention using the Attitudes Toward Health Care Teams Scale (ATHCTS), Readiness for Interprofessional Learning Scale (RIPLS), the Team Skills Scale (TSS), and the Long-Term Condition Management Scale (LTCMS).

Results: Mean post-intervention attitude scale scores adjusted for baseline variation (all on a five-point scale), were significantly higher in the intervention group than the control group for all scales. The mean difference for the ATHCTS was 0.17 (95%CI 0.05 to 0.30; $p=0.006$), for the RIPLS was 0.30 (0.16 to 0.43; $p<0.001$), for the TSS was 0.71 (0.49 to 0.92; $p<0.001$), and for the LTCMS was 0.75 (0.56 to 0.94; $p<0.001$).

Conclusion: This trial found significant improvement in students' attitudes towards both interprofessional teams and learning as a result of receiving the IPE intervention. It also found significant improvements in intervention group students' self-reported effectiveness as team members and self-perceived confidence, knowledge, and ability to manage long-term conditions. This study indicates that a brief, modular, multifaceted IPE intervention using purpose-developed resources can have immediate positive effects and contribute to the development of health professionals who are ready to collaborate with others to improve patient outcomes.

IGRTonline: development and evaluation of a free online course on Image Guided Radiation Therapy

I. Mallick¹, R. Achari¹, S. Chatterjee¹, R. Shrimali¹, S. Prasath¹, B. Arun¹, A. Mahata¹

¹Tata Medical Center, Department of radiation Oncology, Kolkata, India

Purpose or Objective: Despite the rapid increase in use and availability of highly conformal treatment techniques and image guided treatment delivery, there is a lack of availability of focussed training in Image Guided Radiation Therapy (IGRT) for users in most countries. Online education has the potential to reach a wide audience across geographical regions, and offer flexibility of access. The aim was to develop a free, online, self-paced, interactive course on IGRT catering to the non-expert end-users of IGRT, primarily radiation oncologists and radiation therapists (RTT).

Material and Methods: An online platform for IGRT courses was developed (www.igrtonline.com) on a learning management platform called Moodle. The first course, called 'IGRT: Principles and Practice', was an introductory level online course was developed by radiation oncologists and medical physicists in our center, a tertiary care cancer hospital in India. The teaching material was created in the form of Flash and HTML5 interactive content, compliant with SCORM 1.2 standards. Interactive elements like triggered animation, inline quizzes were used. Nineteen modules were prepared in 3 sections covering the (a) principles of uncertainty, margins and correction protocols, (b) image guidance technology; and (c) clinical application in different anatomical sites. Self-assessment quizzes were prepared for every module with a question bank of > 200 questions, including optional preliminary and final assessment quizzes. Capabilities for downloading course modules to mobile devices was added. At the end of 6 months, course enrolment and participation was audited. A short online feedback survey was conducted.

Results: Course development took 16 months. The course was launched in April 2015. Between 15 April to 10 October 2015, 717 participants (from 44 countries across 5 continents) registered into the learning platform. The 5 most common countries of origin were India 409, USA 75, Brazil 37, UK 19 and Canada 10. The distribution of registrants according to

job description consisted of radiation oncologists (49.4%), radiographer/therapists (31.4%) and medical physicists (19.2%). Of the registered students 553 enrolled themselves into the course in question. The number of students who completed > 5 modules was 337 (60.9%). Of the 48 students who completed both the preliminary and final quizzes, the score improved from a mean of 68.25% to 82.75% ($p=0.002$). A total of 103 responded to the online feedback survey. Results are shown in Table 1.

Table 1. Survey of users of IGRTonline (total respondents = 103)

	Rad Onc	RTT	Dosimetrist	Physicist	
Job description	53 (51.4%)	15 (14.6%)	3 (2.9%)	32 (31.1%)	
	New	0-2 years	3-5 years	> 5 years	
IGRT Experience	45 (43.7%)	18 (17.5%)	19 (18.4%)	21 (20.4%)	
	Strongly agree	Agree	Neither agree or disagree	Disagree	Strongly disagree
Were important topics covered?	53 (51.5%)	48 (46.6%)	2 (1.9%)	0	0
Were you able to understand the content?	62 (60.2%)	41 (39.8%)	0	0	0
Was the course a valuable addition to your knowledge and understanding of IGRT?	64 (62.1%)	39 (37.9%)	0	0	0
	Excellent	Good	Average	Poor	Very Poor
Rate Course Design	65 (63.1%)	38 (36.9%)	0	0	0
Rate Overall quality of content	60 (58.3%)	40 (38.8%)	3 (2.9%)	0	0
	Yes	Maybe	No		
Interested in more online courses on this platform?	102 (99.0%)	1 (1%)	0		

Conclusion: Online education platforms have the capacity to reach a wide audience across geographical boundaries. Quiz results suggest that the online course was successful in improving the student's knowledge and understanding of IGRT. User perception of the course was good and the majority of participants were keen on more online education opportunities.

OC-0374

Use of IV contrast media in pre-treatment radiotherapy planning CT scans: A UK study

K. Williams¹, H. Probst²

¹Clatterbridge Cancer Centre, Radiotherapy, Bebington, United Kingdom

²Sheffield Hallam University, Faculty of Health and Wellbeing, Sheffield, United Kingdom

Purpose or Objective: The primary aim analysed adherence to current UK Royal College of Radiologists (RCR) 2004 and 2015 guidelines. The secondary aim identified if current guidelines are adequate for optimum enhancement and image quality or should be redefined to reflect new evidence based practice.

Material and Methods: Questionnaires were sent to 80 UK cancer centres; 34 questions covered a wide range of topics including RCR compliance, contrast timings, cannulation protocols and administration in conjunction with advanced techniques to ensure comprehensive analysis could be performed.

Results: Eighty three percent of centres responded; 22% were excluded from analysis due to incomplete responses or duplication where one questionnaire applied to multiple satellite centres resulting in 52 responses.

Ninety eight percent of centres administer IV contrast to at least one tumour site. However, only 6% of centres administer to all 8 of the RCR 2004 recommended tumour sites (pharynx, neck nodes, lung, oesophagus, stomach, pancreas, cholangiocarcinoma, liver) with 40% of centres administering to 5 sites or less. Sixty two percent of centres routinely administer IV contrast to at least three tumour sites

not supported by RCR 2004; most commonly para-nasal sinus (73%) prostate (62%) and brain (60%).

RCR 2015 compliance was also poor with the most common response to which eGFR formula used was stated as unknown, although 88% of centres do check eGFR for every patient. Fifteen percent of centres did not have an extravasation policy although centres with policies had a wide range of procedures with no standardised requirements.

Only 35% of centres use IV contrast in conjunction with 4DCT, of the centres that don't use IV contrast with 4DCT most patients are dual scanned i.e. IV contrast 3D scan followed by non contrast 4DCT.

Sixty five percent of centres agreed or strongly agreed updated guidelines would be useful.

Conclusion: The results suggest adherence to RCR guidelines is poor. Very little current evidence exists relating to optimal IV contrast protocols both in the UK and internationally. No standardised guidelines exist in relation to 4DCT IV contrast protocols and timings which in some centres is resulting in patients being dual scanned. There are many areas such as flow rates, timings and administration in conjunction with advanced techniques which require further research to enable updated standardised guidelines to be identified. The need for updated guidelines is supported by 65% of respondents of this study.

Comparison of carina- versus bony anatomy-based registration for IGRT in esophageal cancer.

M. Machiels¹, P. Jin¹, C.H.M. Van Gorp¹, J.E. Van Hooft¹, T. Alderliesten¹, M.C.C.M. Hulshof¹
¹Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: In image-guided radiotherapy (IGRT) for esophageal cancer, it is common to use bony anatomy-based registration (BR) for setup verification. A recent study, in which we investigated fiducial marker-based registration relative to BR, indicated marker-based registration to be infeasible due to tissue deformation. In the present study, we investigated the feasibility and geometric accuracy of carina-based registration (CR) for CBCT-guided setup verification in esophageal cancer IGRT.

Material and Methods: Retrospectively, 24 esophageal cancer patients with 65 implanted fiducial markers, visible on planning CTs and follow-up CBCTs, were included in this study. Fiducial markers were considered as standard for tumor position. All available CBCT scans (n=236) were independently rigidly registered to the reference CT with respect to either the bony anatomy or to the carina using XVI software (Elekta Ltd. Crawley) to determine the individual marker displacement relative to the bony anatomy and to the carina, respectively. Automatic registrations were visually checked and manually adjusted when necessary. Subsequently, we assessed and compared per individual marker the mean marker displacement over the treatment course (systematic position error, SE) associated with either BR or CR. Markers were classified into four subgroups based on their locations in the esophagus (proximal, mid-esophagus, distal, cardia) and analysis was similarly as mentioned above performed per subgroup. Comparison between both registration methods was done using a paired Wilcoxon signed-rank test.

Results: The distributions of the absolute mean systematic position error of the individual markers relative to the bony anatomy and the carina are given in Figure 1.A. Overall, a large SE is associated with the use of both bony anatomy and carina, especially in the CC direction. Figure 1.B, illustrates the slightly favorable use of the BR for proximal located markers. Markers located in the mid-esophagus show a smaller SE in CC and AP direction when using the CR,

however this difference was not significant. For markers located in the distal esophagus and cardia, the BR is favorable in AP direction ($p < 0.001$). Furthermore, the majority of the CRs were more challenging given the low contrast resolution in comparison with the BRs.

Figure 1.A Distributions of the absolute mean systematic position errors (SE) of the individual markers relative to the carina (upper) and the bony anatomy (lower). The distribution of absolute mean SE is given for each marker subgroup separately as well as for all markers together (Overall). Results are given in the left-right (LR), cranio-caudal (CC), and anterior-posterior (AP) direction as well as in the 3D vector distance (3D).

Figure 1.B Scatterplots of the absolute systematic position errors (SE) of the individual markers relative to the bony anatomy versus the carina. Results are given in 3 directions for all 4 subgroups. Above blue line = preference for bony anatomy-based registration. Underneath blue line = preference for carina-based registration. The red dot indicates the mean absolute systematic error.

Conclusion: The mean marker displacement (SE), residual tumor position error, over the treatment course remains large and is in most directions even slightly larger when using CR compared with BR. Only for tumors located in the mid-esophagus the CR can be slightly favorable. However, esophageal tumors typically extend across regions and the majority of tumors are located distally. Therefore, our data endorse the use of BR over CR for setup verification.

PV-0376

Contrast-enhanced respiration managed cone-beam CT for image-guided intrahepatic radiotherapy

M. Lock¹, N. Jensen², R. Kozak³, J. Chen⁴, T. Lee⁵, E. Wong⁶
¹London Regional Cancer Centre - Victoria Hospital, Department of Radiation Oncology, London- Ontario, Canada
²Næstved sygehus, Department of Oncology, Næstved, Denmark
³University of Western Ontario, Medical Imaging, London, Canada
⁴University of Western Ontario, Radiation Oncology, London, Canada

⁵University of Western Ontario, Lawson Imaging, London, Canada

⁶University of Western Ontario, Physics and Astronomy, London, Canada

Purpose or Objective: Contrast enhancement and respiration management are widely used during image acquisition for radiotherapy treatment planning of liver tumors along with respiration management at the treatment unit. However, neither respiration management nor intravenous contrast is commonly used during cone-beam CT (CBCT) image acquisition for alignment prior to radiotherapy. In this study, the authors investigate the potential gains of injecting an iodinated contrast agent in combination with respiration management during CBCT acquisition for liver tumor radiotherapy.

Material and Methods: Five rabbits with implanted liver tumors were subjected to CBCT with and without motion management and contrast injection. The acquired CBCT images were registered to the planning CT to determine alignment accuracy and dosimetric impact. We developed a simulation tool for simulating contrast-enhanced CBCT images from dynamic contrast enhanced CT imaging (DCE-CT) to determine optimal contrast injection protocols. The tool was validated against contrast-enhanced CBCT of the rabbit subjects and was used for five human patients diagnosed with hepatocellular carcinoma.

Results: In the rabbit experiment, when neither motion management nor contrast was used, tumor centroid misalignment between planning image and CBCT was 9.2 mm. This was reduced to 2.8 mm when both techniques were employed. Tumors were not visualized in clinical CBCT images of human subjects. Simulated contrast-enhanced CBCT was found to improve tumor contrast in all subjects. Different patients were found to require different contrast injection protocols to maximize tumor contrast.

Conclusion: Localization of the tumor during treatment is the weak link in IGRT for liver. Respiration managed contrast enhanced CBCT provides a possible solution. Simulation tools for optimal contrast injection, recommended margins for interfraction motion and additional benefits from patient specific tracer kinetics determined from DCE-CT are presented.

PV-0377

Inter-fraction bladder variations in RT of prostate cancer: impact on dose surface maps

A. Botti¹, F. Palorini², V. Carillo², I. Improta², S. Gianolini³, C. Iotti⁴, T. Rancati⁵, C. Cozzarini⁶, C. Fiorino²

¹Arcispedale S. Maria Nuova, Medical Physics, Reggio Emilia, Italy

²San Raffaele Scientific Institute, Medical Physics, Milan, Italy

³Medical Software Solutions GmbH, Medical Physics, Hagendorn, Switzerland

⁴Arcispedale S. Maria Nuova, Radiation Oncology Unit, Reggio Emilia, Italy

⁵Istituto Nazionale dei Tumori IRCCS, Prostate Cancer Program, Milan, Italy

⁶San Raffaele Scientific Institute, Radiotherapy, Milan, Italy

Purpose or Objective: Bladder is a hollow and flexible organ exposed to high doses in RT for prostate cancer. Its absorbed dose can be properly described by the dose surface maps (DSM) however, due to its flexible nature, the discrepancy between the planned dose and the dose absorbed during the treatment is a major issue. Present work aims at verifying the robustness of DSMs relative to the daily inter-fraction movement of bladder during RT of prostate cancer.

Material and Methods: 18 patients treated with moderately hypofractionated Tomotherapy were considered (prescription of 70 Gy at 2.5 Gy/fr in 28 fractions and full bladder). All patients underwent daily Image Guided Radiotherapy (through MVCT) with rigid registration on the prostate. After

matching, bladder contours were delineated on each MVCT by a single observer and copied on the planning CT: the planned dose distribution was employed to generate DSMs. For each patient, the bladder DSMs from the planned treatment and from each fraction were then computed by unfolding the bladder contours on a 2D plane: they were anteriorly cut at the points intersecting the sagittal plane passing through the center of mass. The DSMs were then laterally normalized and aligned at the bladder base, while cranially they were cut at the minimal extension of the planned DSMs. Discrepancies between planned and treatment DSMs were analyzed through the average map of individual systematic errors, the map of population systematic errors (standard deviation of individual systematic errors) and that of population random errors (average of individual random errors) of dose.

Results: 472 normalized DSM were considered (cranial extension 34 mm): the mean number of available daily MVCTs was 25 (18-28) per patient. The Figure shows the average planned map (panel A), the average map of individual systematic errors (B), the map of population systematic errors (C) and that of population random errors (D). Two main regions can be recognized: 1) the central posterior bladder base (light/dark blue in D) and 2) the region that surrounds it, involving the lateral and the more cranial portion of bladder (orange/red in D). Region 1), which absorbs the highest doses (see A), appears to be the most stable one during the treatment: panel B shows mean values between -1 Gy and 1 Gy in region 1) and around 2-3 Gy in 2). Population systematic (C) and random errors (D) are below 4 and 3 Gy respectively in region 1), while they reach values between 6-11 Gy and 5-7 Gy, respectively, in 2).

Conclusion: The results show that DSMs are quite stable with respect to changes occurring during daily IGRT for prostate cancer in the high-dose region, in the first 1-2 cm from bladder base. Larger systematic variations occur in the anterior portion and cranially 2.5-3.5cm from the base: these effects may be due to systematic differences in bladder filling and to systematic shifts of bladder base between planning and treatment.

PV-0378

CBCT derived CTV-PTV margins for elective pelvic node irradiation of prostate cancer patients

C.A. Lyons¹, R.B. King¹, C.J. Ho², J.Y. Sun², J.M. O'Sullivan³, S. Jain³, A.R. Hounsell⁴, C.K. McGarry⁴

¹Queen's University Belfast, Centre for Cancer Research and Cell Biology, Belfast, United Kingdom

²Queen's University Belfast, School of Medicine and Dentistry, Belfast, United Kingdom

³Belfast Health and Social Care Trust, Clinical Oncology-Northern Ireland Cancer Centre, Belfast, United Kingdom

⁴Belfast Health and Social Care Trust, Radiotherapy Physics-Northern Ireland Cancer Centre, Belfast, United Kingdom

Purpose or Objective: To derive suitable CTV-PTV margins, using only anatomical information contained within cone beam CT (CBCT) images, for use in prostate external beam radiotherapy (EBRT) with elective pelvic nodal irradiations.

Material and Methods: CBCT images from 20 patients undergoing radical EBRT to the prostate and pelvic nodes were analysed. Each patient had an average of 5 CBCT images (range= 4 - 7) acquired during their treatment. Eclipse (version 13.5) was used to contour the pelvic nodal volumes on the CBCT images and to rigidly register the images to the original planning CT (pCT). Two different image-registration protocols were investigated; a bone match and a soft tissue match to the prostate. All CBCT contours were transferred to a single structure set, accounting for translational shifts in the registration. Boolean logic tools were used to create two composite volumes based on the CBCT contours and the two registration methods.

Figure 1 (a) Axial pCT image. Contoured on the image are the pCT nodal CTV volume (purple), 5 CBCT CTV volumes (cyan) and their corresponding composite structure (red). **(b)** Box-whisker plot of the distribution in % overlap values for each of the CTV-PTV margin sizes for the 20 patients analysed. Annotated on the chart are *p* values from a Mann-Whitney statistical test for each pair of distributions.

Figure1 (a) displays an example axial CT view of CTV contours on the original pCT together with individual prostate-matched CBCT CTVs and their corresponding composite structure. The structures were compared to the original CTV with a uniform margin (0 - 8 mm) applied to generate a PTV. The percentage overlap of the PTV with the composite structures was used to quantify agreement and compare the two registration types. A Mann-Whitney U test was used to evaluate the significance of differences between the distributions of percentage overlap values for the two match options. The margin required to achieve 95% overlap of the grown PTV with each composite volume was interpolated from these results and used to estimate a CTV-PTV margin for each match.

Results: Figure1 (b) displays box-whisker plots for the percentage overlap values from each of the CTV-PTV margins for the 20 patients. As expected, a better overlap was generally achieved with a bone match. Results of statistical tests are also included in the plot, where it is observed that the difference between the two distributions is statistically significant ($p < 0.05$) for all margins ≤ 6 mm.

Table 1 summarises results obtained for the sample studied, including an estimate of the margins required to achieve 95% overlap with the composite structures for 90% of patients. These margin values were calculated assuming a normal distribution for the frequency of margin size required to achieve 95% overlap.

Table 1. Summary of results obtained for the 20 patients analysed in this study.

		Match Type	
		Bone	Prostate
pCT CTV Volume (cm ³)	Average	370.5	
	Std. Dev.	60.7	
Composite volume pCT CTV volume	Average	1.19	1.29
	Std. Dev.	0.20	0.24
Margin required to achieve 95% overlap (mm)	Average (\bar{x})	4.00	5.46
	Std. Dev. (σ)	1.48	1.59
Margin required to achieve 95% overlap in 90% of population ($\bar{x} + 1.28\sigma$, mm)		5.9	7.5

Conclusion: Using the simple approach outlined, CTV-PTV margins of 6 or 7.5 mm have been calculated for the external beam irradiation of pelvic node volumes when performing online matching to bone or prostate structures respectively. This approach is based purely on anatomical data and does not consider dose coverage or delineation error. The study involved the analysis of an average of 5 CBCT images per patient making the results of particular relevance to SABR fractionation schedules.

PV-0379

4D Cone-Beam CT reconstruction with 60s acquisition and 60s reconstruction

D. Hansen¹, T. Sørensen²

¹Aarhus University Hospital, Oncology, Aarhus, Denmark

²Aarhus University, Clinical Medicine, Aarhus, Denmark

Purpose or Objective: Temporally resolved cone-beam CT (CBCT) has many advantages when compared to 3D CBCT for image-guided radiotherapy of lung cancer. E.g. superior set-up accuracy and the possibility to quantify tumour motion.

The 4D CBCT methods currently employed clinically require increased scan times however. In addition, relying on filtered backprojection algorithms for reconstruction, 4D CBCT reconstructions obtain significantly lower quality than 3D CBCT. Several algorithms exist, which improve the image quality of 4D CBCT through iterative image reconstruction, but long reconstruction times have made them unsuitable for setup and online verification purposes.

We present a novel reconstruction algorithm, which allows for iterative 4D CBCT reconstruction in 60s from a 60s acquisition.

Material and Methods: 672 projections were acquired using the onboard imager on a Varian Trilogy linear accelerator using a standard 60s 3D protocol. Initially a standard FDK reconstruction was performed and used as starting point for the iterative algorithm. The respiratory signal was extracted using the RPCA Amsterdam shroud method and the projections respiratory sorted in 10 temporal bins. The 4D CBCT was then reconstructed using prior image constrained compressed sensing (PICCS) based on a novel algorithm combining ordered subsets, Nesterovs method, and the Arrow-Hurwicz algorithm for image denoising. Reconstruction was performed on a single GPU (Nvidia GTX Titan X). For comparison, we reconstructed the same data using the McKinnon-Bates algorithm (4D filtered backprojection). Both reconstructions with a voxel size of 1x1x3 mm³.

Results: The figure compares a representative axial slice from one temporal phase reconstructed using our fast iterative method and the standard 4D non-iterative method respectively. The standard image is contaminated by significant streaking artefacts and demonstrates poor tumour visibility. The proposed method, on the other hand, does not exhibit streaking and depicts the tumour clearly. The reconstruction time for the iterative method was 63s.

Conclusion: The proposed iterative 4D CBCT reconstruction algorithm is more than an order of magnitude faster than other iterative algorithms described in the literature. It produces sharp, streak free images from standard 60s acquisitions used for 3D CBCT. For purposes such as patient setup and verification of tumour motion, the fast reconstruction algorithm presented enables online usage of 4D CBCT as a part of the clinical treatment routine.

Moving away from binary definition of PTVs: a novel probabilistic approach to PTV definition
 H. Tsang¹, C. Kamerling¹, S. Nill¹, U. Oelfke¹
¹Royal Marsden Hospital Trust & Institute of Cancer Research, Physics, London, United Kingdom

Purpose or Objective: Radiotherapy treatment planning for use with high-energy photon beams currently employs a binary approach when defining the PTV. Current approach using van Herk's 3D margin recipe (VHMR) may require additional modifications if the PTV overlaps with OARs. Our novel approach aims to move away from the binary treatment of PTVs, where each voxel is categorised as either target or non-target, and generate PTVs with voxels that may be considered part PTV and part OAR, providing the optimiser with additional information to more easily tackle conflicting dose constraints. We investigate the impact of this novel approach when applied to prostate radiotherapy treatments, and compare treatment plans generated using our approach and VHMR.

Material and Methods: Following the principles laid out in VHMR, only geometrical uncertainties are considered. We explore the use of 2D margins, motivated by the fact that small displacements in beam direction result in negligible change in dose delivered to the target. Only uncertainties perpendicular to the incident beam direction are considered, and therefore safety margins are generated for each beam direction. The degree of overlap of these beam specific margins is normalised and used to assign a weighting factor defined as the ratio of target-to-OAR content to a specific voxel. The objective function employed in the inverse planning process uses these local weighting factors for voxels of the CTV and OAR, should an overlap occur.

Five prostate radiotherapy plans were generated using IMRT inverse planning. The prostate was given a prescription of 78Gy in 2Gy fractions. Systematic uncertainties of 1.1mm, 1.1mm and 1.5mm in the LR, SI and AP directions, respectively, and 2.2mm, 2.1mm, 3.2mm for the random

uncertainties, were used. Plans were generated such that the static dose distribution conforms to requirements outlined in the PACE clinical trial.

A verification tool was used to perform Monte Carlo simulations to model the cumulative dose of the ROI when it is displaced due to the presence of uncertainties; statistics from the tool are used for plan comparison.

Results: We used a population of 50,000 for simulation. We observed a median of 96.7% and 100% of the population CTV receiving $D_{98\%} > 95\%$ D_{pres} for our approach and VHMR respectively. Both values are higher than the 90% population requirement as stated in the VHMR derivation, and this is a direct consequence of the imperfect conformality of the dose distribution. When looking at rectal doses, we observed an improvement of 20.2% to 89.2% of the population satisfying $D_{2\%} < 70\text{Gy}$ using our method; table 1 shows the results of the simulation for the CTV, rectum and bladder for all 5 patients.

Table 1: Results from the Monte Carlo simulation conducted on the ROIs. 50,000 identical ROI samples are modelled in the simulation. Each sample is shifted once following the systematic uncertainty, and from this displacement, shifted again based on the number of fractions to find the cumulative dose the ROI receives in the presence of uncertainties. The table below shows the percentage of the population satisfying a certain DVH requirement.

Patient	CTV $D_{98\%} > 95\% D_{pres}$		Rectum $D_{2\%} < 70\text{Gy}$			Bladder $D_{2\%} < 70\text{Gy}$		
	2D	3D	2D	3D	Diff	2D	3D	Diff

Conclusion: We observed a significant decrease of high rectal doses delivered whilst maintaining sufficient dose coverage of the CTV, though the amount of sparing depends largely on the patient's anatomy and the objectives chosen for optimisation.

Perfusion SPECT can quantify radiation-induced changes in the lung after IMRT for NSCLC
 K. Farr¹, A. Khalil¹, D. Møller², H. Bluhme³, S. Kramer³, A. Morsing³, C. Grau¹
¹Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark
²Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark
³Aarhus University Hospital, Department of Nuclear Medicine and PET Centre, Aarhus C, Denmark

Purpose or Objective: This study examines the radiation-induced changes in regional lung perfusion according to the dose level in the lungs in 58 NSCLC patients treated with chemo-radiotherapy (RT). The purpose of the study was to assess dose and time dependence of RT-induced changes in regional lung function measured with single photon emission computed tomography (SPECT) and establish a correlation with the development of radiation pneumonitis (RP).

Material and Methods: NSCLC patients scheduled to receive RT of minimum 60 Gy were included prospectively in the study. Lung perfusion SPECT/CT was performed on a dual-head SPECT/CT camera in the treatment position before and 1, 3, 6 and 12 months after RT. Reconstructed SPECT/CT data were fused with the planning CT using MIM Software. Dose to the whole lung was segmented into regions of 0-5, 5-20, 20-40, 40-60 and >60 Gy. Regional perfusion was calculated from SPECT for each dose bin. Changes (relative to baseline, %) in regional lung perfusion were correlated with regional dose. A total of 58 patients with baseline SPECT were treated with IMRT. Of these 51 had 1 month follow-up (FU) scans, 45 had 3 months scans, 34 had 6 months scans and 23 had 12 months scans. Toxicity was assessed prospectively and graded by CTC-AE version 4 for radiation

pneumonitis. Patients with minimum grade 2 were considered as RP.

Results: Composite perfusion changes were associated with dose. Statistically significant dose-dependent reduction in regional perfusion was observed at 3, 6 and 12 months FU. Comparison of dose-response curves based on their slopes showed a dose-dependent reduction in perfusion at all time intervals ($R^2=0.8-0.9$) except 1 month ($R^2=0.4$). Relative perfusion loss per dose bin was 4% at 1 month, 14% at 3 months, 13% at 6 months and 21% at 12 months FU (Figure 1).

Figure 1. Dose-response curves linear fit for composite perfusion changes 1, 3, 6 and 12 months after radiotherapy.

The dose-response relations varied between patients with or without RP. In patients who developed RP, perfusion reduction was larger in 20-40 Gy dose bin at 3 months FU ($p=0.04$), and in >60 Gy dose bin at 6 months ($p=0.03$), compared to those without the complication. Low dose regions, on the contrary, revealed larger perfusion increase at 12 months FU in the patients with RP ($p=0.002$).

Conclusion: Progressive dose dependent perfusion loss was seen on SPECT up to 12 months following IMRT. Patients with radiation pneumonitis demonstrate a larger perfusion loss in the high dose regions, as well as relatively larger perfusion increase in regions receiving low dose, possibly due to function being shunted to these areas.

OC-0382

A novel concept to tumour targeting: inverse dose-painting or targeting the "Low uptake drug volume"

A. Yaromina¹, M. Granzier¹, W. Van Elmpt¹, R. Biemans¹, N. Liewes¹, L. Dubois¹, P. Lambin¹

¹MAASTRO clinic, Radiation Oncology, Maastricht, The Netherlands

Purpose or Objective: There are several potentially radioresistant targets for dose escalation in dose-painting approach. Among them tumor hypoxia is a very attractive target. However, 2-3 times higher radiation dose is required to overcome hypoxia-mediated radioresistance in tumors, which is clinically difficult to achieve due to normal tissues constraints. Therefore, we propose a novel treatment approach to combine 1) targeting hypoxic tumor cells with a hypoxia-activated prodrug (HAP) TH302 and 2) at the same time use inverse radiation dose-painting strategy to boost tumor subvolumes with no/low drug uptake. We tested this approach in a rat rhabdomyosarcoma model using 18F-HX4 hypoxia tracer, which is a surrogate of TH302 accumulation in a tumor.

Material and Methods: A clinical PET/CT scanner was used to evaluate 18F-HX4 uptake 3 hrs post injection. Low or high drug uptake volume (LDUV or HDUV) was defined as 40% of the GTV with the highest or the lowest 18F-HX4 uptake, i.e.

TH302 accumulation. Within 24 hrs after PET/CT animals ($n=9$) received either a single dose radiotherapy (RT) uniformly or a dose-painted non-uniform irradiation with 50% higher dose to LDUV or to HDUV. Mean dose in uniform RT was 18.5 Gy similarly to the mean dose in DUV. Mean dose to the GTV in the non-uniform RT scenario was 14.9 Gy. Treatment plans were created using Eclipse treatment planning system. Animals were irradiated on a TrueBeam High Definition 120 Leaf MLC linac. Tumor response was quantified as time required to reach 3-times starting tumor volume (TGTV3).

Results: Non-uniform RT with radiation boost to tumor subvolumes with low TH302 uptake (LDUV) was much more effective than the same dose escalation to subvolumes with high drug uptake (Fig. 1). Noteworthy, dose escalation to LDUV was as effective as uniform RT with 3.6 Gy higher mean dose to GTV.

Fig. 1. Time to reach 3-times starting tumor volume (TGTV3) after uniform RT or non-uniform RT with dose escalation to tumor volume with high drug uptake (HDUV) or low drug uptake (LDUV). Mean dose (D_m) to GTV is indicated.

Conclusion: The results of this pilot study support targeted dose escalation in non-hypoxic tumor subvolumes with no/low accumulation of hypoxia-activated prodrugs, which requires further confirmation. This strategy appears to be as effective as a uniform dose escalation of the entire GTV but with greater capacity to spare normal tissues. It is expected that this approach of inverse dose-painting can be combined with other imageable cytotoxic drugs, which warrants further investigations.

Teaching Lecture: How to bring QUANTEC into the 21st century?

SP-0383

How to bring QUANTEC into the 21st century?

C. Fiorino¹

¹San Raffaele Scientific Institute, Medical Physics, Milan, Italy

The implicit concept behind the title of this lecture concerns the role of "quantitative" data-driven approaches in assessing dose-volume effects in normal tissues in the era of "high-tech" radiotherapy and integration of "omics". The continuously growing literature regarding dose-volume relationships indirectly reflects the need of improving and refining our knowledge in this field [1]. This seems to be particularly urgent in a number of clinically relevant situations such as, for instance, heart, bowel and bladder. However, the impact of the above mentioned elements ("high-tech" & "omics") on the research issues of this field is increasingly relevant and claims for the development of new research lines and methods that will shortly be overviewed in the lecture.

The occurrence of radiation-induced toxicity is a very complex process that is always modulated by the individual [2]; if two patients receive the “same dose distribution” they will likely have different reactions and possibly one will experience toxicity while the other not. The availability of individual information potentially characterizing the patient response, including the “omics” information, is highly valuable, especially in the “high-tech” era of image-guided/adaptive IMRT in which organs are more efficiently spared: the better sparing reduces the incidence and severity of toxicities and, at the same time, enhances the impact of individual sensitivity factors. This point reinforces the need to create large data bases including individually assessed clinical, biological and genetic information, in addition to the individual dose distribution. As a consequence, the approach of quantitatively modelling dose-volume relationships is increasingly becoming “phenomenological” [3]: robust methods for (dosimetric and non-dosimetric) variable selection able to condense the information in “reliable”, friendly to use, predictive models is a major field of research: the adaptation of statistical methods for data-mining and to avoid over-fitting is a pivotal point of the story.

Although the potentials of large data bases and of data sharing platforms on toxicity modelling are clear [4], we should not forget that the creation of large data-bases is not the “aim” but is a (powerful) “tool”. The outcome of the process in terms of robustness and reliability of the models will not only depend on the “numbers” (a highly important component) but also (and maybe more importantly) on the “quality” of data. Differently from the “easy” score of the success of a therapy (survival, tumour control), toxicity is a much more complex issue that deserves specific attention and the careful collection of patient-reported and/or physician-reported information, often for years. Well assessed prospective observational studies focused on specific toxicities seem to be the best choice; secondary analyses of high-quality data coming from controlled trials are also very important although they may be limited in some cases by too homogenous protocols restricting the spread of the delivered dose distributions.

At the end of the circle, the external validation of integrated dose-volume models is clearly a crucial component of the next year’s research [3]: testing the generalizability of dose-volume models will be a major end-points. In addition, robust results from phenomenological models are expected to feed up mechanistic approaches in a sort of mutual synergy that can further corroborate our knowledge: these two components (mechanistic and phenomenological) will likely cooperate much more in the next future. Relevant developments are expected to impact the quantitative modelling of normal tissue effects also from the side of the dosimetry data. The robust, organ-planning-DVH approach to quantitatively describe the relationship between dose/volume and toxicities should be overcome/refined in many relevant situations by directly looking to the 3D dose distribution, integrating the spatial information lost when using “classical” surrogates like DVH/EUD. Relevant examples are: the direct measurement of dose-map dissimilarities between patients [5], the quantification of local (and organ) effects by imaging biomarkers [6], the interplay between the dose received by different organs, the impact of anatomy changes during therapy and their incorporation into normal tissue predictive models.

Quantitative modelling of normal tissue effects is lively present in current century and seems to have a brilliant future in contributing to rapidly improve the way we treat our patients with the promise to continuously reduce toxicity.

Teaching Lecture: Shared decision making

SP-0384

Shared decision making

D. Tomson¹

¹*Institute of Health and Society Newcastle University, Newcastle Upon Tyne, United Kingdom*

Drawing on experience as a practicing GP with a special interest in communication skills and shared decision making, the work of The Health Foundation funded MAGIC (Making Good decisions in Collaboration) programme and most recently on a collaboration with a Danish Oncology Hospital, Dr Dave Tomson will explore recent developments in Shared Decision Making (SDM). Using experience and expertise from the delegates we will

- a) check out attitudes and beliefs about the need and rationale for putting SDM centre stage in patient interactions,
- b) look at a useful model of SDM both for personal clinical practice and for teaching other clinicians,
- c) explore some of the key skills needed and the key challenges in doing better SDM with a particular focus on oncology - the constant changing nature of the evidence base, individualised care in a guideline driven world, dealing with personal bias, unwarranted versus warranted variation in practice, the tyranny of time.
- d) share some ideas about possible solutions to these challenges and think about some of the steps needed to both develop personal practice and implement programmes of development within departments and across hospital systems

Teaching Lecture: The study of therapy resistance in genetically engineered mouse models for BRCA1-mutated breast cancer

SP-0385

The study of therapy resistance in genetically engineered mouse models for BRCA1-mutated breast cancer

S. Rottenberg¹, M. Barazas², J. Jonkers², G. Borst³

¹*University of Bern, Institute of Animal Pathology, Bern, Switzerland*

²*The Netherlands Cancer Institute, Molecular Pathology, Amsterdam, The Netherlands*

³*The Netherlands Cancer Institute, Division of Radiotherapy, Amsterdam, The Netherlands*

Although various effective anti-cancer treatments have become available over the last decades, therapy resistance remains the major cause of death of cancer patients. Striking examples are patients with tumors that are defective in DNA repair by homologous recombination (HR). Despite initial responses to cancer therapy, resistance of primary or disseminated tumors eventually emerges, which minimizes therapeutic options and greatly reduces survival. The molecular mechanisms underlying this therapy escape are often poorly understood.

A clinically relevant mechanism for the defect in HR is a lack of function of BRCA1. This defect impairs error-free repair of DNA double-strand breaks (DSB) - a feature that can be exploited by the treatment with DSB-inducing agents. Using the *K14cre,Brca1F/F,p53F/F* (KB1P) genetically engineered mouse model for BRCA1-mutated breast cancer, we have shown the success of this strategy. Tumors are highly sensitive to DNA cross-linking agents, or to the inhibition of topoisomerase I/II and poly (ADP-ribose) polymerase (PARP) (reviewed by Rottenberg & Borst, 2012). Despite this sensitivity, tumors are not eradicated and eventually drug-refractory tumors emerge. In several of the resistant tumors we found that the HR defect can be partially rescued by down-regulation or knock-out of additional repair factors, such as 53BP1 (Jaspers *et al.* 2013) or REV7 (Xu *et al.* 2015). Based on these observations we set out to investigate whether this type of HR restoration can also explain radiotherapy resistance. For this purpose, we treated mice carrying KB1P tumors with high-precision radiotherapy. We

observed that KB1P tumors were initially hypersensitive to fractionated local delivery of radiotherapy, but could not be eradicated: tumors relapsed and eventually acquired stable resistance. To investigate whether HR was restored in the resistant tumors, we studied 53BP1 and RAD51 irradiation-induced foci formation. Surprisingly, while restoration of HR was prominently found in tumors that acquired resistance to PARP or topoisomerase I inhibition, we did not find it in radiotherapy resistant tumors. To investigate this discrepancy more closely, 53BP1 and related repair factors were knocked out in cell lines derived from the KB1P model using the CRISPR/Cas9 technology. Consistent with our *in vivo* data, clonogenic assays showed that the knock-out of 53BP1 conferred strong resistance to PARP1 inhibition. Intriguingly, the lack of 53BP1 sensitized BRCA1-deficient cells to radiotherapy. An *in vitro* competition assay confirmed the selection to maintain a functional 53BP1 allele during radiotherapy treatment. Based on the KB1P model, we therefore hypothesize that resistance mechanisms that frequently occur in response to PARP1 inhibition sensitize cells to radiotherapy. These results, and their significance to human cells, are currently further validated in additional *in vivo* models including patient-derived tumors.

Teaching Lecture: SBRT/SABR for oligometastatic disease

SP-0386

SBRT/SABR for oligometastatic disease

E. Lartigau¹

¹Centre Oscar Lambret, Lille, France

Introduction: Stereotactic (ablative) body radiotherapy (SBRT/SABR) has been successfully used in the treatment of metastatic lesions and could be considered as a “curative option” for some oligometastatic patients. Multiple studies have described significant local control in brain, lung and liver metastases of various primary cancers. Results suggest SBRT/SABR could be an effective treatment extending patients' life span.

Study: For example in our retrospective study involved 90 patients, designed to test potential effectiveness of SBRT in the treatment of oligometastases irrespective of primary Between July 2007 and June 2010, 90 patients were treated with robotic SBRT/SABR for hepatic or pulmonary metastatic lesions. A total of 113 liver and 26 lung metastatic lesions in 52 men (58%) and 38 women (42%) were treated. Median follow-up was 17 months. Median age at treatment was 65 years (range, 23-84 years). Primary cancers were 63 GI, three lung, eight breast, four melanoma, three neuro-endocrine tumors, and three sarcomas. Median diameter of the lesions was 28 mm (range, 7-110 mm) for liver and 12.5 mm (range, 5-63.5 mm) for lung. Local control rates at 1 and 2 years were 84.5% and 66.1%, respectively. Two-year overall survival rate was 70% (95% CI: 55-81%). The 1 and 2-year disease-free survival rates were 27% (95% CI: 18-37%) and 10% (95% CI: 4-20%), respectively. Median duration of disease-free survival was 6.7 months (95% CI: 5.1-9.5 months). Observed toxicities included grade 1-3 acute toxicities. One grade 3 and no grade 4 toxicity were reported. High-dose SBRT/SABR for metastatic lesions is both feasible and effective with high local control rates.

Discussion: In the last 4 years, some reports have described the so call abscopal effect described as “an action at a distance from the irradiated volume but within the same organism.” Abscopal effect may be more pronounced in response to ablative (> 10 Gy) rather than conventional dosage or fractionation schedules and has been reported mostly in renal cell carcinoma and in melanoma. The effect is attributed to activation of the systemic immune response by

increase antigen presentation (neo antigens released after rapid cell necrosis) and enhanced immune response. These concepts may be of clinical value, improving outcomes by inducing systemic abscopal effects and potentially combined SBRT/SABR with immunotherapy or lymphocytes activating agents. Furthermore, these results have raised the question whether classic radiobiological modeling, and the linear-quadratic (LQ) model, are appropriate for large doses per fraction with the possibility of such an additional biological effects resulting from endothelial cell damage, enhanced tumor immunity, or both. These concepts will be discussed at the time of presentation.

Conclusion: SBRT/SABR treatment is well tolerated with low toxicity rates. It could represent an interesting treatment option for oligometastatic patients not amenable to surgery, even when patients had been pre-treated with chemotherapy. The biological models behind the observed clinical efficacy are currently scrutinized. New combined treatment may be driven from such promising results.

Teaching Lecture: Advanced treatment strategies for head and neck cancer

SP-0387

Advanced treatment strategies for head and neck cancer

W. Budach¹

¹University Hospital Düsseldorf Heinrich Heine University Düsseldorf, Düsseldorf, Germany

Optimal treatment of head and neck squamous cell carcinoma (HNSCC) patients requires well organized interdisciplinary coordination. Standard treatment of locally advanced HNSCC is chemoradiation or surgery followed by chemoradiation. Cisplatin containing chemotherapy remains standard of care in combination with concurrent radiotherapy. Neither neoadjuvant chemotherapy, nor treatments with targeted drugs have changed this standard, although some data suggest that cetuximab can be used as substitute for cisplatin especially in HPV/p16 positive disease. Combinations of cetuximab or other EGFR1 antagonists with chemoradiation did not improve patient's outcome, but added toxicity. Overall, attempts to improve clinical outcome in locally advanced HNSCC with targeted drugs and new cytostatic drugs have not been successful. The situation is different in locoregionally recurrent HNSCC not amenable for local treatment and in metastatic disease. In these patients, the addition of cetuximab to cisplatin and 5FU resulted in a significant survival benefit and consequently is considered as standard of care.

HPV/p16 positive HNSCC represents a distinct entity, which is more sensitive to radiotherapy and cytotoxic drugs. Several strategies testing deescalated treatments are being tested in randomized trials. However, deescalated is not yet recommended outside clinical trials.

Neoadjuvant chemotherapy followed by radiotherapy +/- chemotherapy or cetuximab, and primary chemoradiation have been shown to allow for organ preservation especially in laryngeal cancer in the majority of patients without compromising overall survival. However, adequate selection of patients is critical to obtain organ preservation with good functional outcome.

Recent technological developments in surgery and radiotherapy like transoral robotic surgery and radiotherapy using intensity modulated radiotherapy (IMRT), volumetric modulated arc therapy (VMAT), image guided radiotherapy (IGRT), and stereotactic body radiation therapy (SBRT) have been evaluated in cohort studies and a few randomized trials. These technologies are suitable for decreasing early and late toxicity and improvement of functional outcome, but have not been shown to improve locoregional control, disease free survival, and overall survival.

The available data on the topics addressed above will be shown and discussed.

SP-0388

Dose to water vs. dose to tissue in advanced treatment planning: myths, realities and concerns

N. Reynaert¹

¹Centre Oscar Lambret, Medical Physics, Lille, France

Teaching Lecture: Nanodosimetry: from radiation physics to radiation biology

SP-0389

Nanodosimetry: from radiation physics to radiation biology

H. Rabus¹, V. Conte²

¹Physikalisch-Technische Bundesanstalt PTB, Radiation Effects, Braunschweig, Germany

²Laboratori Nazionali di Legnaro, Microdosimetry, Legnaro, Italy

Nanodosimetry is an emerging experimental technique that measures the so-called particle track structure, i.e. the pattern of ionizing radiation interaction with matter on the nanometric scale. In such small dimensions, comparable to the diameter of the DNA double helix, the stochastic nature of ionizing radiation interactions has to be taken into account.

The stochastic quantity of nanodosimetry is the ionization cluster size (ICS), i.e. the number of ionizations produced by a passing particle within a specific nanometric target volume. The frequency distribution of ionization cluster size (ICSD) depends on the size of the target volume and its distance from the primary particle trajectory. The ICSD is a characteristic of the track structure. The statistical moments of the ICSD can be used to establish a new concept of radiation quality that is based on measurable physical quantities of the radiation that are closely related to the biological effects of the radiation.

Three nanodosimeters of different type have been developed for measurement of ICSDs [1-3] in a sensitive volume of a dilute gas which is simulating microscopic targets based on a density scaling principle [4]. They are differing in the operating gas used, the detected particle type (electrons or cations of the target gas) and the size of the equivalent nanometric target in biological matter (a.k.a. site size). Within the European Project BioQuaRT [5, 6] and the adjoint Italian MITRA project [7], the three European nanodosimeters ("StarTrack", "Ion Counter", "Jet Counter") [8-10] have been compared by measuring ion beams with all three nanodosimeters.

Fig. 1 shows a synopsis of particular moments of all measured ICSDs. Each data point represents a measurement of a radiation quality (energy and type of ion) with a particular nanodosimeter simulating a certain nanometric site size. The horizontal axis is the mean ionization cluster size $M_1(Q)$, i.e. the number of ionizations obtained for the combination (indicated by Q) of radiation quality and site size. The vertical axis is the cumulative probability $F_2(Q)$ for obtaining at least two ionizations when measuring this radiation quality with the respective nanodosimeter. These quantities are obtained from the measured frequency $P(v|Q)$ of ionization cluster size v .

Fig. 1

All data points shown in the Fig. 1 are falling on the same curve indicated by the dashed line. Similar results are also found when cumulative probabilities F_k for a cluster size $v \geq k$ are plotted versus M_1 . Hence, despite the different operating principles of the nanodosimeters, there seems to be a universal relation between the cumulative probabilities F_k and the mean ionisation cluster size M_1 .

The saturation behavior seen in Fig. 1 is found for all cumulative probabilities F_k . Hence, the universal curves have a similarity to the curves expected for the yields of radiobiological endpoints. Fig. 2 illustrates, that this similarity can be exploited to establish a quantitative correlation between nanodosimetric quantities and radiobiological effects.

Fig. 2

The colored data points are results from cell experiments using protons (blue) and carbon ions (red). The vertical axis is the cross section for cell inactivation determined from the cell survival curves at 5% survival rate [11, 12]. The horizontal axis is the mean ionization cluster size that was obtained from Monte Carlo simulations. The black data points are mean cluster size and cumulative probability F_2 derived from the simulated ICSDs.

The track structure simulations were carried out for different values of the nanometric site size. The data plotted in Fig. 2 are those for which the nanodosimetric curve indicated by the grey line provides a best fit to the radiobiological data. This best fit is obtained if a site size of 1 nm in liquid water is used, i.e. of about half the diameter of the DNA double helix.

Teaching Lecture: Brachytherapy for the pelvic region: status and perspective for the future

SP-0390

Brachytherapy for the pelvic region: status and perspectives for the future - Gynaecology

R. Mazon¹

¹Institut Gustave Roussy, Villejuif, France

Brachytherapy in gynaecological cancers, and especially in cervix cancer, has greatly evolved during the last twenty years. For decades, brachytherapy has relied on x-ray orthogonal acquisitions, and prescription has been a matter of systems and schools, making reporting and comparisons difficult. Based on the developments of afterloaders and treatment planning systems, image-guided adaptive brachytherapy has emerged. This high precision technique combines all modern radiation requirements: image guidance, adaptation to tumor response, and short time treatment.

Ten years ago, the GEC-ESTRO, in a will of harmonizing practices, published recommendations in cervical cancers regarding the definition of target-volumes and the reporting. These recommendations were rapidly adopted worldwide. During the last decade, multiple monocentric series, historical cohorts' comparisons, and a prospective multicentric study (STIC trial) demonstrated high local control rates with a limited morbidity in regard to classical data. These data are about to be confirmed by two large studies led by the Gyn GEC-ESTRO: Retro-EMBRACE and EMBRACE, which will establish MRI-guided brachytherapy as a gold standard.

In addition, clear dose-volume effect relationships have been demonstrated between the modern dosimetric parameters and the probability of achieving local control or facing morbidity. The better knowledge of these correlations allowed the launch of EMBRACE II, a prospective study combining the best radiation modalities (EBRT and IGABT), with optimal and ambitious planning aims. In the near future, the large amount of data collected in the EMBRACE study (> 1 500 patients accrued) will allow the development of monograms integrating not only dosimetric parameters, but also criteria on comorbidities, clinical features, and tumor response to external beam radiotherapy. This would be of great help in adapting and personalizing treatment plans.

Longer-term prospects include the development of alternative image modalities for guidance, such as endorectal ultrasound, cheaper and more accessible than MRI, or conversely, a more advanced and sophisticated image modality.

Image-guided brachytherapy is also progressively declined in other gynecologic tumors, such as vagina cancer or non-operable endometrial cancer.

SP-0391

Brachytherapy for the pelvic region: status and perspective for the future - prostate

A. Henry¹

¹St James Institute of Oncology, Radiation Oncology, Leeds, United Kingdom

Prostate brachytherapy allows radiation dose escalation directly into the gland with minimal dose to adjacent rectum and bladder. Over the last decade improvements in brachytherapy technology have refined dose delivery with the introduction of HDR after loading devices, more sophisticated treatment planning systems and the incorporation of functional imaging into the planning process. This teaching lecture will provide an overview of the techniques, indications, and clinical outcomes for both permanent and High Dose Rate prostate brachytherapy. Recent results from randomised clinical trials will be critiqued and emerging indications including focal and salvage treatments discussed.

Symposium with Proffered Papers: Adaptive radiotherapy for coping with anatomical variations: hope or hype?

Overview of clinical practice of ART for pelvic tumours

S. Thörnqvist¹, L.B. Hysing¹, L. Tuomikoski², A. Vestergaard³, K. Tanderup³, L.P. Muren³, B.J.M. Heijmen⁴

¹Haukeland University Hospital, Department of Medical Physics, Bergen, Norway

²Helsinki University Central Hospital, Department of Oncology, Helsinki, Finland

³Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark

⁴Erasmus MC Cancer Institute, Department of Radiation Oncology, Rotterdam, The Netherlands

Introduction: Variation in shape, position and treatment response of both tumour and organs at risk are major challenges for accurate dose delivery in radiotherapy. Adaptive radiotherapy (ART) has been proposed to customise the treatment to these motion/response patterns of the individual patients, but increases workload thus challenge clinical implementation. This presentation presents a review of the clinically implemented ART in addition to *in silico* workflows that have been published on pelvic tumours.

Material and methods: Initial identification of papers was based on searches in PubMed. For each tumour site (prostate, gynaecological [gynae], bladder, ano-rectal), the identified papers were screened independently by two researchers for selection of studies describing all processes of an ART workflow: treatment monitoring and evaluation, decision and execution of adaptations. Both brachytherapy (BT) and external beam studies were eligible in the review.

Result: The review consisted of 43 clinical studies and 51 *in silico* studies. For prostate, 1219 patients were treated with offline re-planning workflows, mainly to adapt prostate motion relative to bony anatomy. For gynae 1155 patients were treated with online BT re-planning while 25 ano-rectal cancer patients were treated with offline re-planning, all to account for tumour regression detected by MRI/CT. For bladder and gynae, 161 and 64 patients respectively, were treated with library-based online plan selection to account for target volume and shape variations (Figure). In comparison to non-ART, sparing of rectum (prostate and bladder cancer), bladder (ano-rectal cancer) and bowel cavity (gynae and bladder cancer) was reported with ART.

Figure. Number of patient treated with different categories of ART workflows for prostate (dark grey), gynaecological (light grey), bladder (grey) and ano-rectal (black). Patients treated with BT additionally marked with striped pattern.

Conclusion: Implementations of ART were dominated by offline re-planning and online BT re-planning, although recently online plan selection workflows have increased with the availability of cone-beam-CT. Advantageous dosimetric and outcome related patterns using ART was documented by the studies included the review. Despite this, clinical implementations have been scarce, especially regarding prostate and the vast amount of *in silico* studies available. Identified challenges, hindering successful clinical implementations, were re-contouring of target/OARs in addition to patient selection, aiding the focus of the adaptations to the more challenging patients.

The challenges of ART from a physician's perspective

S. Nuyts¹

¹University Hospital Gasthuisberg, Leuven, Belgium

Currently, with our highly conformal modulated radiotherapy techniques, we are capable of delivering high radiation doses to tumour volumes, whilst minimizing dose to the surrounding structures. However, today's radiotherapy is based on the dogmatic concept of unchanging anatomy of tumors, surrounding normal organs and tissues, where radiotherapy plans solely based on pre-treatment imaging are delivered invariably for several weeks of treatment. Conversely, during a course of curative radiotherapy, tumors and to some extent OARs change. In the field of head and neck cancer, tumor and lymph nodes shrink up to 3% per day, changing size, shape and position. External contour modifications result from loss of weight and muscle mass, altering the geometry of the disease in relation to OARs. This leads to changes in the anatomy of patients, impacting the dose distribution that may differ significantly from what was planned. In this context, considerable efforts have been put on adaptive radiotherapy (ART), i.e. to adapt the treatment delivery on the basis of changes in the tumor and/or normal tissues during the course of radiotherapy. The aim is then to compensate for under-dosage of the target volumes or over-dosage of OARs.

Re-imaging and re-planning evidently result in an extra workload and cost. Therefore, although ART is an appealing concept, it is at present not used on a routine basis for all patients. The optimal implementation strategy regarding selection of patients and timing of imaging/replanning remains to be defined. Several groups are currently investigating these questions, and an overview of the results, from a physician's perspective will be presented.

SP-0394

The practical "costs" of adaptive radiotherapy

C. Rowbottom¹

¹The Clatterbridge Cancer Centre - Wirral NHS Foundation Trust, Medical Physics, Bebington- Wirral, United Kingdom

Adaptive radiotherapy is an emerging area of radiotherapy. In general there are two categories of adaptive radiotherapy leading to either pro-active or reactive adaptations. As the terms suggest, pro-active adaptation is chosen in advance of the patient commencing treatment, whereas reactive

adaptation is unscheduled and arises from an unexpected patient change seen during treatment.

There are 3 distinct categories for which adaptive radiotherapy approaches should be considered. The categories and most appropriate form of adaptation are given in table 1.

Table 1.

Patient Characteristic	Example clinical site	Type of Adaptation	Most likely Adaptive approach	Frequency of adaptation
Daily anatomy change	Bladder	Pro-active adaptation	Based on small number of pre-determined options	Daily
Slowly changing anatomy over treatment course	Head & Neck	Pro-active adaptation	Modified treatment plan based on new patient anatomy information	≤ Weekly
Unexpected anatomy changes	Any	Reactive adaptation	Modified treatment plan based on new patient anatomy information	Unscheduled

Studies of safety in radiotherapy have shown that there is a higher risk of deviation during handoffs between staff groups with tight coupling and when decisions are made under significant time pressure. Deviation rates of <0.5% per fraction have been reported¹⁻⁴, leading to deviation rates in the range 1-2% per patient. Adaptive radiotherapy can be seen as increasing the complexity of handoffs and creating more frequent decision making points in the process under time pressure. In this context the introduction of adaptive radiotherapy needs to be made whilst mitigating the risk of significantly increasing deviation rates.

Justification is required for adaptation from the assessment of risks and benefits from adaptive approaches. As there is currently no clear clinical benefit from adaptive radiotherapy, new risks need to be mitigated to ensure there is an overall patient benefit. Once procedures have been developed for an adaptive approach, changes in personnel, training and workload are likely to be needed to ensure the safe use of adaptive radiotherapy. For example, there are significant training requirements for radiotherapy treatment staff when applying pro-active adaptive radiotherapy techniques where the most appropriate plan must be chosen at each treatment fraction.

Reactive adaptation has organically arisen from the routine use of online image-guidance. For example using cone-beam CT has provided a wealth of information regarding patient anatomy changes during the course of radiotherapy. Inevitably changes in patient anatomy seen during treatment lead to questions regarding the appropriateness of the original treatment plan. It is likely that around 20% of patients receiving radiotherapy will have anatomy changes requiring assessment for appropriateness of their original treatment plan during the course of their treatment. However, modifications to treatments should only be enacted if the patient benefit from the change outweighs the risk of a deviation that could lead to worse patient outcome. Applying this approach is likely to lead to <5% of patients requiring a modification to their treatment. Therefore, at the very least, departments will require efficient processes for the review of treatment plans against changes to patient anatomy.

In conclusion, currently the clinical justification for adaptive radiotherapy approaches is unclear but the adoption rate is likely to continue to rise due to the available technology. In this context there is a requirement to ensure staffing,

training and workload is carefully considered to mitigate risks to patients.

Patient selection in head and neck adaptive radiotherapy
 C. Brouwer¹, R. Steenbakkers¹, A. Van der Schaaf¹, C. Sopacua¹, L. Van Dijk¹, R. Kierkels¹, H. Bijl¹, J. Burgerhof¹, J. Langendijk¹, N. Sijtsema¹
¹University of Groningen- University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

Purpose or Objective: During the course of head and neck radiotherapy, anatomical changes may lead to underdosage or hotspots in target volumes, and overdosage in organs at risk (OARs). The largest dose differences between planned and actual given OAR dose have been reported for the parotid glands (PGs). Dose increase to the PGs could lead to an increase of radiation induced side effects, justifying adaptive radiotherapy (ART) to reduce the PG dose. Still, ART procedures are labour intensive and only a fraction of patients will benefit. The aim of this study was to develop and validate a method to predict dose deviations from the planned PG mean dose, to select patients for adaptive radiotherapy (ART) up-front.

Material and Methods: Planning and response (6 weeks after RT) CT-scans from 113 head and neck cancer patients (cohort A) were used to estimate deviations between planned and actually given PG mean dose (ΔD_{mean}). Potential pre-treatment selection parameters presented in recent literature were included in the analysis. Uni- and multivariable linear regression analysis for the endpoint PG ΔD_{mean} was performed to select pre-treatment parameters eligible for patient selection. ROC curve analysis was performed to determine cut off values for selecting patients with PG ΔD_{mean} larger than 3 Gy with a sensitivity in the range of 70-100%. The proposed method of patient selection was validated in another patient cohort consisting of 43 head and neck cancer patients who received weekly rescan CTs (cohort B).

Results: In univariable analysis, pre-treatment parameters significantly associated with PG ΔD_{mean} were: BMI, chemotherapy, T-stage, N-stage, volume of the GTV, tumour location, overlap of the PG with the high and low dose PTV, V20, V30, V40 and mean dose of the PG. In multivariable analysis, the initial PG mean dose remained the only significant parameter. ROC results were summarized in Table 1. Selection of patients for dose deviations larger than 3 Gy with a sensitivity of 90% could be obtained by a threshold of the initial PG mean dose of 22.2 Gy (Table 1). This would select 62% of patients for ART in cohort A and 76% in cohort B with a corresponding precision of 29 and 19%, saving 38 and 24% of patients from the labour-intensive ART procedure.

Conclusion: We succeeded to develop a method to select patients for ART up-front by using the initial mean dose to the parotid gland. The labour of ART could be reduced by 24-38% with 87-90% sensitivity, contributing to a more effective allocation of the department resources.

Table 1. Performance of the classification of patients for a parotid gland dose deviation > 3 Gy by using the initial mean dose of the parotid glands ($PG D_{mean}$)

Cut off value $PG D_{mean}$ (Gy)	0	3.6	22.2	24.7	27.0

Symposium with Proffered Papers: Time is not on our side: cardiovascular toxicity after radiotherapy

SP-0396

The risk of cardiovascular disease after breast cancer treatment: the clinician's point of view

C. Taylor¹

¹University of Oxford, Clinical Trial Service Unit, Oxford, United Kingdom

Background: Breast cancer radiotherapy reduces the risk of cancer recurrence and death. However it usually involves some radiation exposure of the heart which may increase the risk of subsequent heart disease. Epidemiological data suggest that the major coronary event rate increases by 7.4% per Gy mean heart dose¹. Estimates of the absolute risks of radiation-related heart disease are needed to help oncologists plan each individual woman's treatment. The absolute risk for an individual woman depends on her estimated cardiac radiation dose and her background risk of ischaemic heart disease in the absence of radiotherapy. When the risk is known, it can then be compared with the absolute benefit of the radiotherapy.

Methods: Worldwide data on heart doses in breast cancer radiotherapy published during 2003-2013 were collated systematically. Analyses considered the variation in the typical mean heart dose according to various patient and treatment-related factors including laterality, target(s) irradiated and technique². These heart doses were used to predict typical absolute cardiac risks from breast cancer radiotherapy using the dose-response relationship of a 7.4% per Gy increase in the rate of major coronary events.¹ These risks were compared with estimates of the absolute benefits of breast cancer radiotherapy.

Results: In left breast cancer, mean heart dose averaged over 398 regimens in 149 studies from 28 countries was 5.4 Gy (range <0.1-28.6 Gy). In left-sided regimens that did not include the internal mammary chain, the average mean heart dose was 5.6 Gy (range <0.1-23.0) for inverse-planned intensity modulated radiation therapy, 3.4 Gy (range <0.1-12.4) for tangential irradiation, 2.2 Gy (range <0.1-3.8) for brachytherapy and 0.5 Gy (range 0.1-0.8) for proton beam therapy. On average, inclusion of the left IMC doubled the heart dose. In 93 regimens where the left IMC was irradiated, average mean heart dose was around 8 Gy for most photon or electron techniques, and it varied little according to which other targets were irradiated. In right-sided breast cancer, the average mean heart dose was 3.3 Gy based on 45

regimens in 23 studies.² Applying these doses to estimated typical absolute cardiac risks¹ showed the absolute risk of a radiation-induced major coronary event for many women today is less than 1%. So for them, the risk of radiotherapy is likely to be much smaller than the benefit. Nevertheless there is considerable variation in predicted absolute cardiac risks, depending on an individual woman's background risk and on her heart radiation dose.

Conclusions: Exposure of the heart from breast cancer radiotherapy has reduced substantially over the past few decades but there is still considerable variation in published heart doses worldwide. In addition, there is variation in the risk of heart disease among patients being considered for radiotherapy. Thus there is likely to be substantial interpatient variability in the cardiac risks of radiotherapy. The population-based dose-response relationship¹ can be used to provide reassurance for many women that their absolute risk of ischaemic heart disease from breast cancer radiotherapy is likely to be small compared with their likely absolute benefit. For other women, for example those with a high predicted heart radiation dose or for those with prior heart disease, the dose-response relationship can be used to identify the minority of women for whom the risk-benefit ratio is less favourable. In these women, consideration may be given to reducing cardiac radiation dose to reduce the radiation-related cardiac risk.

Funding This work was funded by core funding from Cancer Research UK to the CTSU, University of Oxford and the Department of Health, London (project grant RRX 108).

SP-0397

Predicting cardiac toxicity after breast irradiation: new quantitative data and new challenges

G. Gagliardi¹

¹Karolinska University Hospital, Section of Radiotherapy Physics and Engineering- Dept of Medical Physics, Stockholm, Sweden

The QUANTEC summary of data on dose-volume-response effect in heart after radiation therapy provided some answers and practical guidelines for the optimization of the dose distribution in breast cancer patients, and left a few problems open. The main dilemma centered on the fact that cardiac serious events are late, requiring long follow-up and rare, requiring large populations. Furthermore, in studies evaluating cardiac toxicities after irradiation the quality of the outcome clinical data was in general different from the quality of the dosimetric data. Similar considerations still apply to a few studies performed after QUANTEC.

A main step forward is represented by the increased size and design of the studies, e.g. as in the one by Darby *et al* (*N Engl J Med* 2013) which included about 2.000 women treated in Scandinavia. The paper provided among several results an estimation of the cumulative risk of death from ischemic heart disease for patients treated/not treated with radiation therapy and with different mean heart doses, obtained through reconstruction of the dose planning on a model patient.

Beyond size and type of study population another relevant factor investigated in several analysis is the relationship between fraction size and late cardiac effects. Mahrin (*Int J Radiation Oncology Biol. Phys.* 2007) performed an analysis on about 3.800 left sided respectively 3700 right sided breast cancer patients treated between 1984 and 2000, compared the different fractionation schedules and concluded that a statistical increase in overall and cardiac-specific mortality could not be found comparing left vs right breast cancer

patients. Furthermore the hypofractionated adjuvant RT regimens did not significantly increase the risk of cardiac mortality. The 10 year follow-up of the START - UK Standardization of Breast Cancer Radiotherapy trials of radiotherapy hypofractionation (Haviland JS *et al*, *Lancet Oncol* 2013) confirmed the 5 years results that "appropriately dosed hypofractionated radiotherapy is safe and effective". A norwegian study with a longer follow-up, but a smaller study population and irradiated in a different way concluded instead than the degree of hypofractionation and parasternal nodes contributed to an increased cardiac mortality in the patient cohort (Tjessem *et al*, *Int J Radiation Oncology Biol. Phys* 2013).

Another perspective is given by the studies on cardiac dose-volume effects where dose distributions in subregions of the heart are investigated (e.g. Nilsson G *et al*, *J Clin Oncol* 2012; Johansen S, *Breast cancer: basic and clinical research* 2013). The results from these analysis might be very helpful in the design of treatment protocols.

Finally the technological development has to be taken into account (e.g. gating, DIBH etc), which in some cases might simply by-pass the issue of cardiac irradiation. This approach does not provide answers to the basic question, but provides a convenient solution.

Active surveillance for cardiovascular disease after Hodgkins lymphoma

L. Daniels¹

¹Leiden University Medical Center LUMC, Department of Radiotherapy, Leiden, The Netherlands

Hodgkin lymphoma is a relatively rare form of cancer, which mainly affects young adolescents and young adults. Over the past decades developments in treatment options for patients with Hodgkin lymphoma have led to improved outcome rates. As a result, there is an increasing number of Hodgkin lymphoma survivors. They are at risk of developing long-term toxicity due to treatment such as secondary malignancies or cardiovascular complications. There is an increased risk of developing valvular heart disease after mediastinal radiotherapy, although risk increases significantly after radiation treatment doses over 30 Gy (1). Recent studies also show a 4-6 fold increased standardized incidence ratio of heart failure and coronary heart disease (CHD), due to anthracycline containing chemotherapy regimens and mediastinal radiotherapy (2). Severe CHD can even be present in the absence of typical symptoms such as chest pain (3). A linear dose-response relationship between mediastinal radiotherapy and CHD has been established with a 2.5-fold increased risk of CHD after receiving a mean heart dose of 20 Gy (4). This implies that even patients treated with current standard radiotherapy doses remain at serious risk of developing radiation induced CHD. At the same time, new strategies for non-invasive screening for CHD have developed, by means of CT coronary angiography, showing encouraging positive and negative predictive values for detecting significant CHD. In this lecture, an overview of recent efforts of screening for coronary artery disease in Hodgkin lymphoma patients is presented, and clinical implications are discussed.

Risk estimation of cardiac toxicity following craniospinal irradiation of pediatric patients.

G. Engeseth¹, C. Stokkevåg², L. Muren³

¹Haukeland University Hospital, Department of Medical Physics and Oncology, Bergen, Norway

²University of Bergen, Department of Physics and Technology, Bergen, Norway

³Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark

Purpose or Objective: Craniospinal irradiation (CSI) plays an important role in the treatment of medulloblastoma and improvement in treatment during the last decades has resulted in good prognosis. CSI is most commonly delivered with photons or a combination of photon/electrons. However, proton therapy is generally indicated as it lowers the dose to normal tissues and potentially reduces the risk of late effect. The aim of this study was therefore to compare the estimated risk of cardiac toxicity following CSI using photons, electrons and protons.

Material and Methods: CSI treatment plans including conformal photons, electrons/photons combined, double scattering protons (DS) and intensity modulated proton therapy (IMPT) were created in the Eclipse treatment planning system [Varian Medical Systems, Palo Alto, CA, USA] for six pediatric patients. The CTV included the brain and the spinal canal, for the protons the CTV was expanded to also include the entire vertebral body to prevent asymmetric growth of the skeleton. During treatment planning a setup uncertainty of 5 mm was taken into account, as well as an uncertainty in the proton range of 3.5%. The prescribed dose for all techniques was 23.4 Gy(RBE). Dose-risk models derived from two independent pediatric patient cohorts were used to estimate the risk of cardiac toxicity. The excess Relative Risk (ERR - relative to general population) for cardiac mortality was estimated using a linear model [1], while ERR for cardiac failure and disorder were estimated using both a linear and a linear-quadratic [2] (LQ) model. Input parameters were the mean heart dose, and the parameters (with 95% Confidence Interval (CI)) displayed in Table I. The Relative Risk (RR) was defined as the ratio between ERR for photon /electron, photon/DS and photon/IMPT.

Table I: Dose-response models, parameters and 95% CI

	Model	Parameter	95% CI
Mortality	Linear ¹	$\alpha: 0.6$	0.2; 2.5
Disorder	Linear ²	$\alpha: 0.35$	-0.005; 1.2
	LQ	$\alpha_1: 0.4$	0.002; 1.4
Failure	Linear ²	$\alpha_2: -0.00013$	-0.01; 0.1
		$\alpha: 0.09$	-0.02; 0.3
	LQ	$\alpha_1: 0.19$	-0.02; 0.5
		$\alpha_2: -0.002$	-0.004; 0

Results: Regardless of dose-risk model applied, the conformal photons were ranked with the highest ERR for all cardiac toxicities, whereas IMPT was ranked with the lowest (Figure 1a). For cardiac mortality the ERR for photon was 8.1 (95% CI: 3.4 to 30.5), while ERR for IMPT were 1.3 (95% CI: 1.1 to 2.4). For cardiac disorder and cardiac failure the ERR for photon was 5.1 (95% CI: 0.9 to 15.2) and 2.1 (95% CI: 0.8 to 4.6), respectively (Linear model). The corresponding results for IMPT were 1.2 (95% CI: 1.0 to 1.7) and 1.1 (95% CI: 1.0 to 1.2). Similar trends were found using the LQ model. Relative to IMPT, photons lead to a risk of cardiac mortality that was a factor of 6.1 higher (range 5.7 to 7.0), cardiac disorder a factor of 4.3 higher (range 4.1 to 4.9) and cardiac failure a factor of 2.0 higher (range 1.9 to 2.1) (Figure 1b).

Conclusion: Across different cardiac morbidity endpoints, and despite different dose-risk models used, the results of our modelling study were consistently in favour of protons.

Symposium: Emerging biomarkers

SP-0401

Circulating tumour cells as biomarkers in lung radiotherapy
K. Haslett¹¹*The University of Manchester, Institute of Population Health, Manchester, United Kingdom*

It has long been hypothesized that the propagation of circulating tumour cells (CTCs) is a pre-requisite for the development of metastases. However, robust technology to reliably isolate CTCs and characterise them at the molecular level has only become available in recent years. Thus repeated blood sampling for CTCs could provide a non-invasive method of serially reassessing tumour status and evolving tumour biology.

Patients with stage I-III NSCLC are at high risk of developing distant metastases after radiotherapy (RT) or chemoradiotherapy treatment. With the advent of new technologies to enumerate CTCs, the clinical significance of CTCs before, during and after RT has become of great interest. In the current era of targeted therapy and the development of personalised medicine the question still remains as to whether CTCs could be used to identify patients most likely to benefit from radical RT and prevent the delivery of futile cancer treatments and their associated toxicity. Prospective clinical trials have shown the prognostic value of CTC enumeration in patients with non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC) (1, 2). Although CTCs have been used as a surrogate biomarker in hundreds of clinical trials, as yet none have been incorporated into standard clinical practice. To date there are few published studies evaluating CTC's in patients undergoing radical thoracic RT.

In my talk I will discuss the following:

- novel platforms available for isolation of CTCs
- current data on the evaluation of CTCs as a biomarker in NSCLC and SCLC patients treated with RT
- advantages and limitations of CTCs as a biomarker
- future directions and the prospect of using CTCs to stratify patients in clinical trials

SP-0402

The fall and rise of predictive radiotherapy biomarkers

M. Baumann^{1,2,3,4}¹*OncoRay - National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Dresden, Germany*²*Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology, Dresden, Germany*³*German Cancer Consortium DTK Dresden, and German Cancer Research Center DKFZ, Heidelberg, Germany*⁴*Department of Radiation Oncology, Institute Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Radiooncology, Dresden, Germany*

Radiotherapy is a mainstay of cancer treatment. Due to its high efficacy to inactivate cancer stem cells in the primary tumor and regional metastases as well as its increasing ability to spare normal tissues, it has a proven curative potential in

many cancer types. State-of-the-art radiation treatment planning and delivery is fully individualized based on anatomical imaging, precise space-resolved radiation dose models, tumor control probability- vs. normal tissue complication-models and clinical parameters. These advances in personalized radiation oncology can mainly be attributed to the revolutionary progress in high-precision radiation delivery and planning technology during the past decades and have been rapidly translated into clinical practice. In parallel radiobiological knowledge has significantly improved during the past decades by e.g. unravelling radiobiological mechanisms of radioresistance of tumors and volume-dose relationships for a host of radiation induced effects in normal tissues. This research translated into more efficient radiation schedules on a population base and to NTCP parameters clinically used for treatment planning in individual patients. While several bioassays, including SF2 and plating efficiency determined in human tumor biopsies, provided proof-of-concept of radiobiological mechanisms, these early assays could not be applied to tailor a treatment strategy for an individual patient. Revolutionary advances in biotechnology and tumor biology allow to profile tumors rapidly, thereby providing information on resistance parameters (e.g. hypoxia, stem cell density, radiosensitivity) which can be rationally tested for their prognostic and predictive power for radiotherapy. The same applies for biological imaging which may be of particular relevance for advancing biology-driven individualization of radiation oncology. One uniqueness for the development of personalized radiation oncology is that already a broad biological stratification of patients can substantially enhance individualization as this information adds to the fully anatomically-personalized dose-distributions achieved today. Therefore biomarker driven high precision radiotherapy is in pole position to create a show-case for personalized oncology at large.

This lecture will review preclinical and clinical-translational examples of potential strategies to further personalize radiation oncology by inclusion of biomarkers.

Genomic breast cancer subtype classification for response prediction

N. Somaiah¹¹*The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Division of Cancer Biology and Division of Radiotherapy and Imaging, Sutton, United Kingdom*

The advent of genomics has revolutionized our understanding of breast cancer as several biologically and molecularly distinct diseases. New molecular techniques generate data about the intrinsic characteristics of a tumour, thereby providing useful diagnostic, prognostic and predictive information. Commercially available tests have begun to fundamentally change the clinicopathological paradigm of selecting patients for adjuvant systemic therapies in early breast cancer. Several recently published radiosensitivity gene expression signatures aim to predict response to adjuvant radiotherapy. The ultimate aim of biomarker research is to individualise therapies in order to maximise tumour response whilst minimizing overtreatment and toxicities. This talk will review the strengths and limitations of currently available breast cancer-specific molecular tests with a view to response prediction.

SP-0405

Combining SBRT and immunotherapy: a promising approach?

F. Herrera¹¹Centre Hospitalier Universitaire Vaudois, Department of Radiation Oncology, Lausanne Vaud, Switzerland

Clinical reports of limited and treatable cancer metastases, a disease state that exists in a transitional zone between localized and widespread systemic disease, have been reported and are now termed oligometastasis. SBRT treatment of oligometastases has shown promising local control rates (65-97%), and a good toxicity profile (<5% of serious adverse events) because the delivered doses are ablative and spatially limited.^{1, 2} However, most of these patients usually recur at distant sites, outside of the irradiated area, with a median time to progression of 4 to 6 months, indicative of occult metastatic deposits at the time of treatment. Thus, although SBRT is effective in definitively ablating most treated lesions, distant tumors progress highlighting the need for better systemic therapies.³ Immunotherapy has emerged as an independent therapeutic modality that can result in objective - even complete - responses and significant amelioration of overall survival in patients with advanced metastatic tumors. There is an emerging opportunity for combining immune therapy together with ablative SBRT for oligometastatic patients, with the final aim of increasing T cell infiltration into the tumor.

In situ vaccination during lethal RT of few metastases

Lethal (high) doses of radiation can induce immunogenic death in cancer cells, i.e. irradiated cancer cells can trigger an antitumor immune response. RT can upregulate the necessary "eat-me" signals that promote the uptake of dying tumor cells by dendritic cells (DCs) and macrophages⁴. However, a systemic immune response against distant lesions (the so-called abscopal effect) is rarely seen. Given the beneficial but limited immune modulatory effects of SBRT, combination of SBRT with simultaneous activation of other immune-pathways could lead to antigen-specific adaptive immunity, a phenomenon called "*in situ* vaccination".⁵ An abscopal effect has been observed when RT was combined with immunotherapy and has been proven to be T-cell mediated.⁶⁻⁸ A recent report of patients with melanoma and renal cell carcinoma treated with SBRT (20 Gy), in combination with IL-2 showed higher than expected abscopal responses.⁹ In a phase I trial combination 8 Gy in 2-3 fractions with ipilimumab partial responses were observed in 18% of the patients. When dual checkpoint blockade with both anti-CTLA4 and anti-PD-1 combined with radiation was tested in a B16 melanoma model improved responses and abscopal effects were observed. Even in the presence of dual checkpoint blockade, omission of radiation resulted in high rates of relapse.¹⁰

The combination of lethal SBRT to few tumor deposits in combination with different immunotherapy strategies triggers antitumor immunity. However, the key question that needs to be answered is which are the best combinatorial strategies, the best timing to combine them and how to increase effective homing of antitumor T cells to the remaining tumor deposits. Modifying the tumor microenvironment in these residual tumors is therefore of major importance to improve therapeutic outcome and finally cure.

SBRT for metastatic disease: how far can and should we go?

M. Dahele¹¹VU University Medical Center, Amsterdam, The Netherlands

Stereotactic body radiotherapy (SBRT) is attracting substantial interest as a treatment option for selected patients with metastatic disease. It is reasonable to take a step back and take a look at where the field is now and what we can expect from this intervention. This presentation will focus on a number of contemporary clinical issues, including: what can be expected from SBRT at various anatomical sites; definitions of oligo-metastatic disease and their limitations; defining treatment goals in metastatic disease; lessons from published outcome data; a pragmatic approach to decision-making in the clinic; is radiation technology driving the agenda? and; gathering evidence for the future.

SP-0407

Abdominal-pelvic targets

M. Hoyer¹¹Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

Patients with oligometastases from colo-rectal carcinoma (CRC) are often considered as candidates for surgical resection, radiofrequency ablation and SBRT and CRC often metastasize to the abdominal organs, especially to the liver. Therefore, abdominal oligo-metastases are often treated with SBRT. A relative large number of publications demonstrate outcome after SBRT for liver metastases that are almost as good as for lung metastases. Local control rates in both lung and liver are most often in the range 70-90% and survival rates are depending on tumor type and the selection of the patients. There are only few publications on SBRT of abdominal, non-liver oligometastases, but the few available publications indicate favourable local control as well for these patients. Most publications on SBRT for abdominal targets report a low risk of morbidity, but there are reports of relatively severe morbidity related to irradiation of the liver and the bowel, most often in terms of severe mucositis or intestinal ulceration. Treatment of abdominal targets is complex due to the multiple organs at risk. Treatment planning is based on a snapshot of the anatomy on a treatment planning CT-scan. 4DCT takes the intrafraction motion motion of the target into account, but we usually do not take the motion of bowel structures into account. CBCT is used to correct for set-up errors of the target, but organs at risk are less often considered. This may lead to unintended high doses to the organs at risk and side effects that were not expected from the treatment planning.

Immunotherapy for HNSCC: an emerging paradigm?

J. Guigay¹¹Centre Antoine Lacassagne, Nice, France

Recent progress has been made in oncology with new drug targeting immune system. Ipilimumab which targets CTLA-4 has been the first one approved in melanoma. Another way to block the deleterious cascade of T-lymphocyte inhibition is to block an extracellular target, namely Programmed Death Receptor-1 (PD-1). PD-1 is a cell surface receptor expressed by T cells, B cells, and myeloid cells, and member of the CD28 family involved in T cell regulation. PD-1 pathway is activated by receptor binding to ligands (PD-L1 or PD-L2) and its physiological role is to prevent uncontrolled immune activation during chronic infection or inflammation. In cancer, activation of PD-1 pathway can suppress antitumor immunity. In mouse models, antibodies blocking PD-1/PD-L1 interaction lead to tumor rejection. In clinical trials, targeting PD-1 pathway using human monoclonal antibody such as nivolumab, which blocks binding of PD-1 to PD-L1 and PD-L2, showed promising results in metastatic solid tumors with durability of objective responses, and sustained overall survival (Topalian and al, NEJM 2012). Phase I studies showed a potential better safety profile of anti-PD-1/PD-L1 agents in comparison with ipilimumab. Following, anti-PD-1/PD-L1 drugs have been developed at a phenomenal speed, taking just three years from the first clinical trials to approval. At now, anti-PD-1 nivolumab and pembrolizumab are approved in melanoma and NSLCC... There is a strong rationale for using anti-PD-1/PD-L1 agents in HNSCC. Tumor-infiltrating lymphocytes (TILs) which are required for PD-1 blockade, and PD-L1 expression are present in HPV+ and HPV negative HNSCC. There is a correlation between infiltration by CD8 cells and response to CRT, and between PD-L1 expression and survival. The high number of specific mutations observed in HNSCC could be a mechanism of immunogenicity. Results of phase I studies testing anti-PD-1/PD-L1 agents in HNSCC patients have been recently reported with promising results in terms of efficacy with prolonged responses. During ASCO 2014 meeting, Seiwert et al. presented first results of a phase Ib study of pembrolizumab in recurrent/metastatic (R/M) HNSCC patients. Patients with PD-L1 immunohistochemistry expression in tumor cells or stroma were enrolled in the study. The anti-tumor effect was observed both in patients with HPV-positive and HPV-negative tumors. The duration of these responses was impressive, some already lasting over one year (Seiwert TY et al., ASCO 2014, CSS 6011). Updated data on an expanded cohort have been presented at last ASCO 2015 meeting. 132 (81 HPV+) R/M HNSCC patients were treated with pembrolizumab 200 mg Q3W regardless of HPV or PD-L1 status. 78% received at least one line of chemotherapy. Tolerance was good (9.8% of grade 3-5 adverse events). Objective response rate was 25%, stable disease rate was 25% with long-lasting responses (Seiwert TY, et al. J Clin Oncol. 2015;33(suppl): LBA6008). First results of a phase I study evaluating the safety and efficacy of an anti-PD-L1 agent, durvalumab (MEDI4736), have been presented at ESMO 2014 congress (M. Fury M et al., abstr 988PD, ESMO 2014). MEDI4736 is a human IgG1 mAb, engineered to prevent ADCC activity, that blocks PD-L1 binding to PD-1 and CD-80. 50 pts with HNSCC, with median 3 prior treatments received median 3 doses of MEDI4736 10 mg/kg q2w. Treatment-related

adverse events were observed in 39% of pts; most frequently nausea (6%), diarrhea, dizziness, and rash (4% each). Dyspnea, syncope, raised GGT and sepsis (each 5%) were the most common grade ≥ 3 AEs. Among 29 evaluable HNSCC pts for efficacy, 4 pts had a partial response. Numerous anti-PD-1/PD-L1 agents are currently tested in HNSCC. First randomized trial with nivolumab vs standard of care in second line after platinum based first line therapy has just closed. Randomized trials testing pembrolizumab and durvalumab in first-line or second-line treatment for R/M HNSCC patients are ongoing. Beside evaluation of efficacy, these studies should help define the best population (HPV status, prior therapies) and more useful biomarkers than threshold of PD-L1 expression, to select patients who can benefit from these new agents. Flare-up reaction with increase of tumor volume and immune-related adverse events may occur: new guidelines are needed to define criteria of response, time to stop treatment and management of toxicities. Some patients may have a fast progression under monotherapy and mechanisms of resistance are unclear. New approaches combining anti-PD-L1/PD-1 agents and other immune-modulators, chemotherapy and radiotherapy are currently explored. Abscopal effect related to anti-PD-L1/PD-1 agents seems promising. For locally advanced HNSCC, trials testing combinations with anti-PD-L1/PD-1 agents in induction regimen and concurrent CRT are ongoing. The story of immunotherapy as a new paradigm in HNSCC is just beginning...

Dosimetric aspects and robustness in treatment plan optimisation of small tumours

A. Ahnesjö¹¹Uppsala University Hospital Akademiska Sjukhuset, Uppsala, Sweden

Stereotactic radiation of small brain targets provides high spatial resolution and accuracy for positioning of patient and radiation fields, almost on submillimeter ranges. This is not matched by equally sharp dose gradients, since finite source size, collimator design limitations and transport of electrons in the irradiated tissue all diffuses the dose. Not surprisingly, the dose prescriptions evolving for small brain tumors aimed for a specified dose to the target periphery, accepting whatever resulting dose to the target center. A kind of standard evolved aiming for a ratio of approximately 65% relative dose at the periphery versus the maximum target center dose (or 154% center-to-periphery ratio). This dose heterogeneity was considered favorable, as to more effectively treat presumably hypoxic cells at the tumor center. The stereotactic treatment methodology for brain treatments were in the early 1990s transferred to radiation of liver metastasis. Through use of stereotactic body frame high target positioning reproducibility was achieved, and similar dose prescriptions of heterogeneous dose were applied, with a center-to-periphery dose ratio of approximately 154%. Soon the technique was also applied to peripheral lung tumors.

Following the development of 3D treatment planning systems in the late 1980s, ICRU responded to the need for consistent handling of geometrical uncertainties and launched in 1993 the ICRU 50 report recommending the use of GTV, CTV and PTV to capture the uncertainties. Specifically, the role of PTV was to "ensure that the prescribed dose is actually absorbed in the CTV". The normal use of the PTV is to plan a

homogenous dose to its interior, through which it is assumed that the CTV gets the same dose as it is located in the PTV. This requires the dose inside the PTV to be both homogeneous and robust with respect to movements involving heterogeneities. The PTV concept was applied also for extracranial stereotactic body treatments, often inheriting a high center-to-periphery prescription. Dose calculations at the time used "class a" algorithms that not account for dose variations due to a varying level of lateral charged particle equilibrium caused by low density regions. Most so called pencil beam algorithms belong to this, class a, category. Accurate dose calculations can now be achieved with "class b" algorithms such as Monte Carlo, Collapsed Cone or Grid based Boltzmann equation solvers. However, for any algorithm that would calculate the dose physically correct, the resulting dose for the PTV is not representative for the CTV when the margin around the latter contains a lower density medium. Hence, the straight forward application of PTV based treated planning together with heterogeneous prescriptions principles (originally inherited from intracranial treatments), has created a confused situation with large uncertainties with respect to the actually delivered doses.

A robust dosimetry can be achieved by realizing that the dose to a CTV surrounded by a low density medium will be independent of movements as long as it is exposed to a uniform fluence. Given that a near homogeneous fluence cover the PTV, dose prescriptions can then be done directly to the CTV based on a dose calculation with a "class b" algorithm (MC, CC or equivalent). As long as the movements of the CTV are kept well inside a PTV with a homogeneous fluence, the dose delivered to the CTV will be much closer to the prescribed dose, thus providing robust dose specification for small tumors. However, tools for optimization of uniform fluence are presently not provided in clinical TPS. Luckily, several workarounds exist that can "cheat" the optimization of homogenous dose to instead yield a effectively homogeneous fluence. From a pure physics point of view, this can be achieved by incapacitating the lateral spread of energy from the rays of the primary beam. In class a algorithms of the pencil beam kind, this can be implemented by changing the pencil beam parameter controlling the lateral spread. In point kernel algorithms such as CC, similar manipulation of kernel data can be done. In essence, in most algorithms fluence is a precursor for dose providing opportunities to access it. Alternatively, the density of the PTV can be set to a high value that shortens the electron transport distance enough to make the dose more fluence like.

In summary, a robust small lung tumor dose can be implemented through a planning process in which the PTV is determined by the common practice addition of a setup margin to a MIP projections ITV, but replacing the common practice dose calculations by a fluence optimization followed by a class b dose calculation with the CC (or similar) algorithm, using absolute dose prescriptions to the CTV rather than the PTV. For a test series of 5 patients this procedure reduced the difference between prescribed and delivered dose to the CTV from 30% to 8% in D98, with a similar reduction for D02.

SP-0412

Does the prescription isodose matter?

M. Guckenberger¹

¹University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

The current practice of cranial and extra-cranial stereotactic radiotherapy is in many ways influenced by Gamma-Knife Radiosurgery (GN-RS). It has been a key component of GN-RS to treat the target volumes without any safety margins (GTV = PTV) and to use inhomogeneous dose profiles within the target volume. The dose was most frequently prescribed to a low isodose e.g. 50% meaning that substantially higher doses are delivered to the central part of the tumor.

This practice of dose prescription to a low target encompassing isodose line has been adopted in extra-cranial stereotactic radiotherapy (Stereotactic Body Radiotherapy

SBRT) despite many differences to GN-RF: (1) safety margins are used in almost all SBRT indications; (2) in lung SBRT, the use of safety margins will result in inclusion of low density lung tissue into the target volume; (3) radiotherapy delivery is today performed using MLC and in many centers intensity-modulated techniques allowing more sophisticated dose shaping; (4) target and organs at risk motion will affect the delivered dose profile as compared the planned dose profile; (5) the composition of the target volumes in SBRT is very different to GN-RS - Organs-at-risk are not only close by but within the target volume; (6) in the RTOG protocols of SBRT for stage I NSCLC, dose prescription to a wide range of isodose lines is allowed.

Based on these differences between GN-RS and SBRT above, it is obvious that the concept of dose prescription to a fixed isodose line is not sufficient for SBRT practice. The dose profile within the target volume needs to be sufficiently prescribed and reported to achieve better standardization and comparability between institutions, studies and individual patients. Additionally, current SBRT technology allows to adapt the dose profile within the PTV to the patient-specific clinical requirements: homogeneous dose profiles or even cold spots might allow organ at risk sparing; in contrast, an escalation of the dose within the target center might be beneficial for targets without critical normal tissue within the PTV. Recommendations by the ICRU specific for the needs of SBRT are eagerly awaited and future studies will better define how to optimize SBRT dose planning.

SP-0413

To use or not to use the LQ model at "high" radiation doses

W. Dörr¹

¹Medical University of Vienna, Dept. of Radiation Oncology, Vienna, Austria

In curative SBRT regimen, few large doses per fraction are applied in a highly conformal way. Such protocols, however, usually do not only differ from conventional protocols in the size of the dose per fraction, but also with regard to overall treatment time and total (equieffective) dose. Moreover, large doses per fraction are usually administered to (normal tissue) volumes that are clearly smaller compared to conventional protocols. Hence, all these parameters, i.e. recovery, repopulation, tumour reoxygenation and normal tissue volume effects, need to be included into considerations concerning the biological effect of SBRT protocols - independently for tumor, early and late responding tissues.

The effect of dose per fraction ("recovery") for tumors is - with few exceptions - considered as low, as expressed by a high a/b-value in the linear-quadratic (LQ) model. Recently, a high fractionation effect was shown for prostate and breast tumors, and is also discussed for others. For lung tumours, however, a small capacity for recovery can be assumed. Early responding normal tissues usually display a similarly low fractionation effect, while most late radiation effects have a high sensitivity with regard to changes in dose per fraction. Hence, doses per fraction must be adjusted to the respective tumor type and the expected (late) morbidity pattern in order to achieve the biologically equieffective doses that result in optimum dissociation between treatment efficacy and adverse events.

The linear-quadratic model has been shown to only inadequately describe the effect of large doses per fraction (>6-10 Gy) for cell survival endpoints in vitro (colony forming assay) and in vivo (e.g. intestinal crypt survival assay). Here, the LQ model overestimates the effects of exposure in the high-dose region. It needs to be emphasized, however, that in the vast majority of pre-clinical investigations and analyses of the fractionation effect for morphological and functional endpoints, large doses per fraction and/or single doses were regularly included. In clear contrast to the cell survival based analyses, these studies in general do not show any major difference of the fit of the LQ model for the in- or exclusion of large doses per fraction in the analyses. Moreover, no deviation of the resulting a/b-values from the respective estimates from clinical data was observed. This indicates the applicability of the LQ model also for the calculation of

equieffective doses at high doses per fraction, such as applied in SBRT protocols in the lung. Besides high dose per fraction,

SBRT protocols regularly include a shortening of the overall treatment time (OTT) compared to conventional or moderately hypofractionated protocols. This is associated with less tumour repopulation, which also contributes to the increased tumor effectiveness. With very few fractions in short time intervals, however, tumour reoxygenation may also be less effective, thus at least partly counteracting the benefit of the shorter OTT. It also needs to be noted that SBRT protocols with short OTT are less permissive for regenerative processes in early responding normal tissues. These protocols hence also bear a risk of increased early normal tissue reactions and thus, in certain tissues, of enhanced ("consequential") late effects.

The administration of large doses per fraction and large total doses is mainly facilitated by a strong conformation of the high-dose volume to the target, i. e. a minimization of the normal tissue volumes exposed to these doses, and is associated with very steep dose gradients within the adjacent normal tissues. However, it must be emphasized that in such scenarios, not only the amount of normal tissue effects may be changed, but also their quality, with altered tissue pathophysiology and morbidity endpoints that are usually not observed with conventional or moderately hypofractionated protocols. Prominent examples are the manifestation of atrophic rather than fibrotic processes, or pathologic rib fractures in SBRT of peripheral lung tumors.

In conclusion, administration of large doses per fraction in SBRT may be advantageous for biological reasons. Estimation of biologically equieffective doses may be based on the standard LQ model. However, such treatment strategies not only impact on tissue recovery, but can also affect other radiobiological parameters (radiopathology, repopulation, volume effects) in a complex manner. Therefore, the patients included in such therapeutic protocols need to be monitored carefully not only for treatment outcome, but also for treatment-related morbidity.

Assessing 4DCT-ventilation as a functional imaging modality for thoracic radiation therapy

Y. Vinogradskiy¹, L. Schubert¹, T. Waxweiler¹, Q. Diot¹, R. Castillo², E. Castillo³, T. Guerrero³, C. Rusthoven¹, L.E. Gaspar¹, B. Kavanagh¹, M. Miften¹

¹University of Colorado Denver, Radiation Oncology, Aurora-CO, USA

²University of Texas Medical Branch, Radiation Oncology, Galveston, USA

³Beaumont Health System, Radiation Oncology, Royal Oak, USA

Purpose or Objective: 4DCT-ventilation is an exciting new lung function imaging modality that uses 4DCT data to calculate lung function maps (Fig 1).

Because 4DCTs are acquired as part of routine clinical care, calculating ventilation from 4DCTs provides clinicians the ability to evaluate spatial lung function without added monetary or dosimetric cost to the patient. Development of clinical trials is underway to use 4DCT-ventilation for thoracic functional avoidance with the idea that preferential radiotherapy (RT) sparing of functional regions may decrease toxicity. Before 4DCT-ventilation is incorporated in a clinical trial; work is needed that assesses the clinical utility of 4DCT-ventilation imaging. The purpose of this study was to evaluate 4DCT-ventilation as a functional imaging tool for RT.

Material and Methods: The study assessed 118 stage III lung cancer patients. 4DCT images, spatial registration and a density-change based model were used to compute a 4DCT-ventilation map for each patient. Full 4DCT-ventilation assessment included: 1) comparison of 4DCT-ventilation against nuclear medicine ventilation (VQ) imaging and pulmonary function tests (PFT) 2) an analysis to determine whether dose to highly ventilated regions of the lung was a better predictor for toxicity than dose alone and 3) an evaluation of the percentage of lung cancer patients with significant ventilation defects. 4DCT-ventilation was compared to VQ imaging and PFTs using radiologist observations, sensitivity and specificity analysis, and correlation coefficients. Bootstrap methods were used to evaluate whether ventilation-based dose-function metrics were a better predictor for grade 3 radiation pneumonitis than dose metrics alone. Radiologists assessed the percentage of patients with significant ventilation defects with the idea that if patients had homogenous ventilation there would be no basis to preferentially spare any regions; conversely functional avoidance can be done for patients with ventilation defects.

Results: Comparing radiologist noted defects between 4DCT-ventilation and VQ imaging, we calculated a sensitivity, specificity, and accuracy of 90%, 64%, and 81% respectively. Correlation coefficients comparing 4DCT-ventilation to PFTs ranged from 0.63-0.72. Bootstrap results suggested an improvement in toxicity prediction using dose-function metrics compared to dose alone (p=0.11). Clinical ventilation defects were noted in 69% of our study cohort.

Conclusion: Our study demonstrates that 4DCT-ventilation provides clinically meaningful lung function information, is a better predictor of toxicity than dose alone, and that a significant portion of patients have substantial ventilation defects. Our work provides the largest and most comprehensive study to fully evaluate 4DCT-ventilation as a thoracic functional imaging tool and presents strong evidence for the incorporation of 4DCT-ventilation into prospective clinical trials.

OC-0415

The effect of breathing motion on CT radiomics feature extraction in oesophageal cancer

R.T.H.M. Larue¹, L. Van De Voorde¹, R.T.H. Leijenaar¹, M. Berbée¹, M.N. Sosef², W.J.C. Van Elmpt¹, P. Lambin¹

¹Maastricht University Medical Centre, GROW School for Oncology and Developmental Biology - Department of Radiation Oncology - MAASTRO clinic, Maastricht, The Netherlands

²Zuyderland Medical Centre, Department of Surgery, Heerlen/Sittard, The Netherlands

Purpose or Objective: Medical imaging plays a crucial role in response evaluation due to its non-invasive character and wide applicability and availability. Next to the routinely used metrics (e.g. RECIST), extraction of a large number of quantitative radiomics features might unravel more information in these medical images. To quantify the reliability of these features across different phases in the breathing cycle, the stability of 59 radiomics features in respiratory-correlated 4D CT-scans of patients with oesophageal cancer was investigated. Since the tumour does not change during image acquisition, quantitative features derived from it should not change either. Hence, we

hypothesised that 4D-RCCT provides a valuable means to identify the most reliable features.

Material and Methods: Twenty-five oesophageal cancer patients (stage IB-IIIC) who received a 4D-RCCT scan for radiotherapy planning between October 2012 and March 2014 were included in this study. The gross tumour volume (GTV) of the primary tumour was delineated on the 50% exhale (50ex) CT phase using all available diagnostic information. The delineations were copied to the CT images of the other breathing phases: 0in, 25in, 50in, 75in, 100in, 25ex and 75ex. Next 15 first-order statistics and 44 textural radiomics features were calculated for the GTV. For each feature, the pairwise intra-class correlation coefficient (ICC) between all possible phase combinations was calculated. Features with a pairwise ICC-value of at least 0.85 between all phase combinations were considered to have an acceptable stability throughout all phases of the breathing cycle.

Results: Of the 44 textural features, 12 (27%) were not susceptible to breathing motion (ICC>0.85). Also 9 out of the 15 (60%) first-order statistics features turned out to be stable. The statistics-energy and graylevel-nonuniformity (GLN) features, found to be prognostic in both head-and-neck and lung cancer [Aerts et al. Nat. Commun. 5 (2014)], were among the most stable features with minimum ICC-values of 0.98. In general, the highest ICC-values were observed when two adjacent phases (e.g. 50ex-75ex) were compared.

Figure 1. Graphical representations of the pairwise ICCs for all phases of the 4D-RCCT scan. The horizontal lines extend from the minimum to the maximum observed values per feature, and are blue when every ICC > 0.85. The red dots represent the median. Features are, for each feature group, ranked by their minimum ICC values. Abbreviations for the textural feature groups: gray-level co-occurrence (GLCM), gray-level run-length (GLRLM) and gray-level size-zone (GLSZM).

Conclusion: This study identified nineteen CT radiomics features that were not subject to breathing motion in patients with oesophageal cancer. The remaining features were affected by the differences in breathing phase. This emphasises the importance of tumour-site specific feature selection together with a strict imaging and delineation protocol before using them for further clinical applications.

OC-0416

FDG-PET can objectively quantify esophageal dose-response and toxicity during radiation therapy
J. Niedzielski¹, Z. Liao², R. Mohan¹, J. Yang¹, F. Stingo³, D. Gomez², M. Martel¹, T. Briere¹, L. Court¹

¹University of Texas-MD Anderson Cancer Center, Radiation Physics, Houston, USA

²University of Texas-MD Anderson Cancer Center, Radiation Oncology, Houston, USA

³University of Texas-MD Anderson Cancer Center, Biostatistics, Houston, USA

Purpose or Objective: To use FDG-PET uptake during treatment course to objectively quantify esophagitis severity, understand esophageal dose response, and examine the timing of increased PET uptake and esophagitis symptoms for possible early detection of eventual toxicity.

Material and Methods: FDG-PET scans were acquired for 71 NSCLC patients during concurrent chemoradiotherapy, at fraction 23 on average. PET uptake was normalized to the mean SUV of esophageal voxels receiving < 5 Gy, creating normalized PET uptake (nSUV) as a patient specific radiation response. Localized measures of nSUV were correlated to esophagitis grade during PET scan and max treatment grade, scored with CTCAE 4.0, using logistic regression. Performance was measured with AUC from ROC analysis. Voxel esophageal dose response curves of nSUV were created for analysis conducted with DVH metrics. Spearman rank analysis was used to determine the dose correlation to nSUV and toxicity. The timing of nSUV and esophagitis presentation was examined. Preemptive detection of toxicity was studied using asymptomatic patients at time of PET scan, examining these patients esophagitis severity by treatment end, and analyzing any differences in nSUV values or dose response; statistical difference was tested with the Mann Whitney U test.

Table 1: Statistical Analysis of nSUV metrics and ≥ grade 2 esophagitis endpoint. Likelihood ratio chi square test was used to calculate p-values.

Mid-Tx Grade 2			
nSUV Metric	Pval	AUC	nSUV 50% NTCP
NormSUV Mean (%)	2.11E-05	0.84	31.0
nSUV Axial Max 1-Slice (%)	9.78E-05	0.83	150.2
Length ≥ 40% nSUV (mm)	8.16E-05	0.83	28.6
nSUV 90th Percentile (%)	2.42E-05	0.83	89.8
Max Grade 2			
nSUV Metric	Pval	AUC	nSUV 50% NTCP
NormSUV Mean (%)	4.09E-05	0.86	4.9
nSUV Axial Max 1-Slice (%)	1.26E-06	0.90	92.5
Length ≥ 40% nSUV (mm)	6.52E-08	0.91	0.0
nSUV 90th Percentile (%)	1.17E-06	0.91	75.9

Results: Normalized PET uptake was significantly correlated to esophagitis grade both at the time of the PET study and max treatment grade, for both grade 2 and grade 3 endpoints. Increased nSUV occurs before esophagitis presentation. The highest performing nSUV metrics were axial max nSUV, and esophageal length with nSUV ≥ 40% increase from baseline, with both p < 0.001 and AUC 0.83 (Table 1). DVH metrics were poorly correlated to nSUV or toxicity and several patients that were grade 0 throughout treatment had DVH values comparable to patients who developed esophagitis, but had low nSUV values. Esophageal dose-response curves grouped according to max esophagitis

grade showed no response in the Grade 0 cohort. Response in grade 2 and grade 3 groups starts at approximately 30-35 Gy and had considerable inter-patient variability. For max esophagitis severity prediction, nSUV metrics and dose-response curves were statistically different between grade 0 patients at time of PET scan that remained grade 0 by treatment completion, and those eventually becoming grade 2, with flat dose-response curve and increasing approximately 2nd order, respectively (Fig. 1c).

Conclusion: Normalized uptake strongly correlates to esophagitis, both at time of FDG-PET scan and by the end of treatment. Normalized uptake gives an objective quantification of esophageal toxicity with geometric information. PET scans acquired early in treatment may predict esophagitis severity.

Functional imaging using dual energy Computed Tomography and its application in radiation oncology

A. Lapointe¹, M.B. Besnier², D.B. Blais¹, H.B. Bahig¹, J.G. De Guise³, J.F.C. Carrier¹, E.F. Filion¹, D.R. Roberge¹, S.B. Bedwani¹

¹Centre Hospitalier de l'Université de Montréal, Radio-oncologie, Montréal, Canada

²Centre Hospitalier de l'Université de Québec, Radio-oncologie, Québec, Canada

³Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Laboratoire de Recherche en Imagerie et Orthopédie, Montréal, Canada

Purpose or Objective: The objective of this project is to evaluate pulmonary and renal relative function by analysing the iodine concentration extracted from a dual energy CT (DECT) scan with injection of a contrast agent. The evaluation of parallel organs' functionality such as kidney and lung is usually derived from DMSA and perfusion scintigraphy. However, such techniques have spatial and temporal resolutions generally inferior to those of a CT scan. Our approach exploits DECT imaging, which allows in a single acquisition to combine the anatomical image to the organ function as determined by its iodine concentration. This functional cartography has a clinical potential to improve the planning of radiotherapy treatments considering new functional constraints.

Material and Methods: Two cohorts of 11 and 8 patients (kidney and lung, respectively) received a scintigraphy and a DECT scan (SOMATOM Definition Flash, Siemens) with intravenous iodine injection. The iodine concentration is evaluated with the principle of the three material decomposition that was implemented in MATLAB (MathWorks). This technique quantifies in each voxel of the DECT scan the proportion of each material defined in a basis specific to a targeted site (kidney and lung for instance). The evaluation of the differential function is also adapted to each type of organ previously segmented by an expert to only consider the presence of iodine relevant to the function. A functional cartography is also generated to segment each organ in regions more or less functional.

Results: The results show that the relative functions obtained by scintigraphy and DECT correlate well with a Pearson of 0.8 for lung. The most functional regions of the lung have an average of 2.68 mg/mL and 0.30 mg/mL for the least functional, whereas for the kidney 8.95 mg/mL and 0.36 mg/mL. In some cases, the absence of iodine in specific locations were easily ascribed to dysfunctional sections of the organ such as cancerous tumors, abnormal pulmonary lobe and kidney cysts. The following figure shows how (left) a mixed image provided by a DECT scan can be converted into (middle) an iodine concentration map and further processed into (right) a map of functional regions.

Conclusion: The extraction of iodine concentration maps from injected DECT scan was achieved to evaluate the differential function of lungs and kidneys. Therefore, our DECT analysis tool provides functional information in addition to the high resolution DECT images. Further improvement in the analysis tool will include advanced algorithms to perform segmentation and 3D model to address functionality according to specific sections of an organ. Further work will also incorporate the functional information to radiation oncology treatment planning decisions to eventually spare further functional tissue and reduce the toxicity.

Cluster analysis of DCE MRI reveals tumor subregions related to relapse of cervical cancers

T. Torheim¹, A.R. Groendahl¹, E.K.F. Andersen², H. Lyng³, E. Malinen⁴, K. Kvaal¹, C.M. Futsaether¹

¹Norwegian University of Life Sciences NMBU, Dept. of Mathematical Sciences and Technology, Ås, Norway

²Soerlandet Sykehus HF, Dept. of Radiology, Kristiansand, Norway

³Oslo University Hospital, Dept. of Radiation Biology, Oslo, Norway

⁴University of Oslo, Dept. of Physics, Oslo, Norway

Purpose or Objective: Solid tumors are known to be heterogeneous, often consisting of regions with different treatment response. Early detection of treatment resistant regions can improve patient prognosis, by enabling implementation of adaptive treatment strategies. In this study, K-means clustering was used to group voxels in dynamic contrast enhanced (DCE) MR images of cervical cancer tumors. The aims were to explore the intratumor heterogeneity in the MRI parameters and investigate whether any of the clusters reflected treatment resistant regions.

Material and Methods: Eighty-one patients with locally advanced cervical cancer treated with chemoradiotherapy underwent pre-treatment DCE MRI. The resulting image time series were fitted to two pharmacokinetic models, the Tofts model (K_{trans} and v_e) and the Brix model ($ABrix$, kep and keI). K-means clustering was used to cluster similar voxels based on the pharmacokinetic parameter maps or the relative signal increase (RSI) time series. The association between clusters and treatment outcome (progression-free survival, locoregional control or metastasis-free survival), was evaluated using the volume fraction of each cluster or the spatial distribution of the cluster.

Results: We identified three voxel clusters based on the Tofts parameters, all significantly related treatment outcome. One voxel cluster based on the Brix model was significantly linked to progression-free survival and metastatic relapse. Two RSI based cluster were significantly related to all types of treatment outcome.

Conclusion: Based on either pharmacokinetic parameter maps or relative signal increase time series, we were able to group the voxels into cluster that were associated with treatment outcome. With the exception of one cluster, the spatial distribution rather than the volume fraction of each cluster was significant.

OC-0419

Association between pathology and texture features of multi parametric MRI of the prostate

P. Kuess¹, D. Nilsson², P. Andrzejewski¹, J. Knoth¹, P. Georg³, M. Susani⁴, D. Georg¹, T. Nyholm⁵

¹Medizinische Universität Wien Medical University of Vienna, Department of Radiation Oncology and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

²Umea University, Computational Life Science Cluster CLIC- Department of Chemistry, Umea, Sweden

³EBG Med Austron GmbH, Medical Department and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Wiener Neustadt, Austria

⁴Medizinische Universität Wien Medical University of Vienna, Clinical Institute of Pathology, Vienna, Austria

⁵Umea University, Department of Radiation Sciences- Radiation Physics, Umea, Sweden

Purpose or Objective: The aim of this study was to find a correlation between multiparametric (mp) MRI derived quantitative imaging parameters (textual features) and pathological verified tumor occurrence. Textual feature analysis (TFA) as a method for quantifying the spatial distribution of intensities in images has already shown promising results in the field of diagnostic oncology and also as biomarker for treatment response.

Material and Methods: 25 prostate cancer patients which underwent prostatectomy were investigated in this study. Multiparametric MRI were collected prior to the surgical procedure. Along with T2 weighted images, dynamic-contrast-enhanced (DCE-MRI) (KTrans, AUC) and diffusion-weighted MRI (DW-MRI) with its estimated apparent diffusion coefficient (ADC) were recorded. The resected prostate was axial cut in slices of 3-4 mm thickness and the tumor was tagged by a pathologist. On the T2 images delineation of the central gland (CG) and the peripheral zone (PZ) was performed by two physicians. Additional, the prostate was divided into 22 geometrical substructures following the PIRADS classification. Hence, the tagged tumor area on the pathological slices could be assigned to the respective substructure on the MRI where it was scored into distinct levels according to the volume covered by malignant tissue. For each geometrical substructure texture analysis was performed using gray level co-occurrence matrix (GLCM). Additional to the textual parameters also histogram based information (gray value) was investigated. The large amount of information created by the TFA was analyzed with principal component analysis (PCA). For each image modality, the 23 textural parameters were compressed into two principal components, which explained most of the variation found in the data. Prior to analysis, each variable was mean centered and also scaled to unit variance.

Results: The TFA showed a significant difference between substructures in the CG and PZ. A correlation was found between the pathological findings and the texture of the ADC map as shown in fig 1a, where the larger dots represent substructures with confirmed tumor occurrence. For the other investigated modalities the correlation was weaker or absent. Based on the score plot (fig 1a) ROC curves were calculated (fig1b) resulting in an AUC of 0.789 for ADC considering the highest tumor scores only.

Fig. 1 Scatter Plot (a) and resulting receiver operating characteristics curve (b) for textual feature analysis of ADC maps evaluating the PZ of prostate cancer patients. The larger dots in the scatter plot represent geometrical substructures with pathologically confirmed tumor occurrences, where the colors light blue, green, orange and red symbolize the four levels of tumor scores (in increasing order) and blue illustrates structures without tumor. The area under the ROC curve is 0.789.

Conclusion: The current study indicates that ADC mapping is the most promising MRI technique to predict the tumor location in the prostate based on TFA and therefore is absolute prerequisite for dose painting approaches in advanced adaptive radiotherapy (ART).

OC-0420

Radiomics in OPSCC: a novel quantitative imaging biomarker for HPV status?

R.T.H. Leijenaar¹, S. Carvalho¹, F.J.P. Hoeberts¹, S.H. Huang², B. Chan², J.N. Waldron², B. O'Sullivan², P. Lambin¹

¹Department of Radiation Oncology MAASTRO clinic, GROW - School for Oncology and Developmental Biology- Maastricht University Medical Centre, Maastricht, The Netherlands

²Department of Radiation Oncology- Princess Margaret Cancer Center, University of Toronto, Toronto, Canada

Purpose or Objective: Oropharyngeal squamous cell carcinoma (OPSCC) is one of the fastest growing head and neck cancers, for which human papillomavirus (HPV) status has been described as a strongly prognostic factor. Overall, prognosis is favorable for HPV positive (HPV+) patients, which makes this an interesting subgroup for de-escalation protocols. An established, non-invasive, imaging biomarker of HPV status currently does not exist. Radiomics-the high-throughput extraction of large amounts of quantitative features from medical images-has already been shown to be of prognostic value for head and neck cancer. In this study we evaluate the use of a Radiomic approach to distinguish between HPV+ and HPV negative (HPV-) OPSCC patients.

Material and Methods: A total of 542 patients with OPSCC, treated with curative intent between 2005 and 2010 were collected for this study. HPV status was determined by p16 and available for 434 patients. Patients underwent pre-treatment CT imaging and the tumor volume was manually delineated for treatment planning purposes. Images were visually assessed for the presence of CT artifacts (e.g. streak artifacts due to dental fillings) within the GTV, in which case they were excluded from further analysis. In total, 241 Radiomic features were extracted, comprising: a) first-order statistics, b) shape, and c) (multiscale) texture by Laplacian of Gaussian filtering. The Radiomic feature space was first reduced by selecting cluster medoids after hierarchical cluster analysis using correlation ($p > 0.9$) as a distance measure. Multivariable logistic regression was performed using least absolute shrinkage and selection operator (LASSO) model selection (100 times 10-fold cross-validated). The area under the receiver operator curve (AUC; 500 times bootstrapped) was used to assess out-of-sample model performance in predicting HPV status.

Results: Out of the patients with known HPV HPV scoring, we identified 211 (49%) patients without visible CT artifacts, of which 134 were HPV positive. The modeling process resulted in an eleven-feature multivariable prediction model. The overall receiver operator curve is shown in Figure 1. The bootstrapped AUC was on average 0.77 (95% CI: 0.73-0.80).

Figure 1: Receiver operator curve for HPV status prediction in OPSCC patients. Bootstrapped (500 times) AUC: 0.77 (95% CI: 0.73-0.80).

Conclusion: Using a Radiomic approach, we were able to distinguish between HPV+ and HPV- OPSCC patients, using standard pre-treatment CT imaging. These results require further validation, but suggest the potential for a novel quantitative Radiomic biomarker of HPV status, facilitating personalized treatment selection.

Symposium: Adaptive treatments in the pelvic region

SP-0421

Brachytherapy pelvic and MRI-Linac combination

C.N. Nomden¹, A.A.C. De Leeuw¹, B.W. Raaymakers¹, J.J.W. Lagendijk¹, I.M. Jürgenliemk-Schulz¹

¹UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands

MRI guidance for the radiation treatment of patients with cancer in the pelvic region has globally increased during the last two decades. MRI is used for staging, treatment planning, monitoring of treatment response and for disease observation during follow up. Consistent and repetitive use of MRI has provided insight into tumour and surrounding organ anatomy as well as their movements and deformations. In cervical cancer treatment, MRI guidance for brachytherapy treatment planning and dose delivery allowed better tailoring of the dose to the target, with higher tumour doses while sparing the organs at risk (OARs). However, the aimed dose for target and OARs may differ from the actually delivered dose due to movements and deformations of the OARs during HDR or PDR treatments. Several single institution reports describe that dose uncertainties caused by displacement and deformations of OARs are on average small, however individual outliers occur. Especially for the rectum higher delivered doses have been found in individual patients. In case of HDR brachytherapy, re-imaging prior to dose delivery can help to detect unfavourable anatomical changes, allowing for interventions that might help to stabilize dosimetry and prevent morbidity. The availability of MR imaging within the brachytherapy suite is an upcoming innovation that supports these types of adaptive brachytherapy approaches. The aim of the international 'EMBRACE study' (www.embracestudy.dk) was to introduce MRI based brachytherapy in a multicentre setting within a prospective observational setting and to correlate DVH parameters with outcome. Preliminary results from EMBRACE, from the retrospective 'Retro-EMBRACE' study (www.retroembrace.com) and from several single institution reports, revealed an increase in local control due to the use of MRI guidance. Brachytherapy treatment allows delivery of sterilizing doses to the primary cervical tumour, however, lymph node disease is getting the dose delivered by external beam radiotherapy treatment (EBRT). The upcoming prospective multicentre 'EMBRACE II study' will focus on advanced Image Guided and Adaptive EBRT (IGART) combined with MRI guided intracavitary/interstitial brachytherapy with

the aim to improve loco-regional control and survival, however not at the expense of treatment related morbidity. Besides nodal disease detection, monitoring nodal disease during treatment is still a remaining challenge. Node positions and volumes can change during the course of treatment asking for EBRT strategies that are able to follow these changes in order to allow tight treatment margins. Unfortunately the visibility of lymph nodes on cone beam CT images is limited and shifted and shrunken lymph nodes can be missed. The superior soft tissue contrast of MRI based position verification as realized in the concept of integrated MRI and linear accelerator (MR-Linac) decreases the uncertainties around nodal disease development during the course of radiotherapy, allows a more precise definition of nowadays accepted elective treatment margins and might allow an additional boost to individual lymph nodes. Currently, an MR-Linac system is built at the radiation oncology department at the UMC Utrecht, bringing the ultimate combination of MRI guided brachytherapy, advanced adapted external beam treatment with concurrent cisplatin based chemotherapy and MR-Linac treatment for nodal disease within reach for the treatment of patients with advanced cervical cancer.

SP-0422

Clinical implementation of ART for cervix

Y. Seppenwoolde¹, M. Buschmann¹, M. Daniel¹, K. Majercakova¹, D. Georg¹

¹Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology- Medical University Vienna- Austria, Radiation Oncology, Vienna, Austria

For patients with cervical cancer, despite the improved dose conformity enabled by IMRT and VMAT, sparing of bladder, rectum and small bowel is still challenging because all organs at risk (OAR) in the pelvic area change shape and position on a daily basis due to variations in filling. With the introduction of cone-beam CT scanners it became possible to observe the internal organ variations of patients during each treatment fraction. Theoretically, this enables re-adaptation of plans according to tumour shrinkage and changes in OAR morphology, resulting in reduction of toxicity [1,2] and better target coverage. Full online plan adaptation requires that re-delineation, re-optimizing of dose distributions and repetition of all legally required quality assurance steps should be performed in a few minutes. These workload intensive procedures would require a high degree of automation and workflow-integration that is currently absent in off-the-shelf products.

Nonetheless, by finding a well-balanced compromise between full automation and degree of plan adaptation, it is possible to apply a simplified scheme of adaptation that provides improved treatment. Based on our own experience and that of other research groups [3], patients can be divided into two groups: the first group consists of patients who show uterus motion as a function of bladder filling (called "Movers") and the second group are those patients whose uterus position stays relatively stable, regardless of bladder volume ("Non-Movers"). With a model for the uterus position, a pre-determined set of plans (library) can be constructed for the "Movers" and the most appropriate treatment plan can be selected on a daily basis with the help of CBCT scans, while for the "Non-Movers" a single plan will suffice.

The patient specific relation between bladder filling and the position of the uterus can be assessed by making a set of CT scans with full and empty bladder. A two stage approach, consisting of two treatment plans, one for an empty to half full and one for half full to full bladder, has been shown to give a good level of plan adaptiveness [2], ensuring both a good tumor coverage as sparing of the surrounding healthy tissue.

Commercially available clinical software that is designed for organ contouring and treatment plan optimization does not provide solutions to generate new contours based on a motion model that interpolates between two extreme (filling) positions of an organ. We developed a MATLAB-based tool that allows generating intermediate contours of uterus as well as bladder, according to the available bladder

volumes. Its main purpose was to interpolate linearly between two extreme positions and/or filling states of patient's organ contours. Non-rigid deformation between one organ position and the other was made by matching the outer contour of both structures. To facilitate data handling and DICOM import/export options, the Matlab code was integrated to 3DSlicer/SlicerRT (Freeware for image handling) by using MatlabBridge.

Our first adaptive patient was treated in October 2016 and in this presentation we will discuss our experience we gained since then, the challenges we encountered and the risks that remain with the implemented procedure. Furthermore, dosimetric results of different ART schemes as well as open issues like non-rigid dose addition for evaluation will be discussed.

Implementation of daily plan selection in rectum

R. De Jong¹, L. Lutkenhaus¹, N. Van Wieringen¹, J. Visser¹, J. Wiersma¹, K. Crama¹, D. Geijsen¹, A. Bel¹
¹Academic Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands

The standard of care for non-metastasized locally advanced rectal cancer is chemo-radiotherapy combined with surgery. Sparing the organs at risk (OAR) with the use of state-of-the-art planning techniques like intensity-modulated radiation therapy (IMRT) or volumetric modulated arc therapy (VMAT) is compromised by the large population-based margins that are necessary to compensate for the shape changes of the target volume over the time of treatment. In rectum patients, day-to-day variation in rectum and bladder filling often causes large deformation of the target volume, especially the mesorectal fat (mesorectum), which cannot be corrected for with a table adjustment. Minimizing shape changes with the use of drinking protocols to manage bladder filling or dietary instruction to manage bowel motion have been unsuccessful.

A strategy with multiple plans made prior to treatment tailored to a range of possible shapes can mitigate the variations in target volume, by selecting the best-fitting plan based on daily Cone Beam CT (CBCT) scans. This strategy has been successfully applied in the treatment of bladder and cervical cancer where bladder filling is the predominant factor of shape changes. To create multiple plans a full and empty bladder pretreatment CT scan is acquired from which a patient specific motion model is derived which is used to create intermediate target volume structures.

In rectum cancer, however, shape changes are mostly driven by changes in rectum volume and shape and to a much lesser extent by bladder filling. Because of this creating multiple plans based on varying bladder filling is not useful. Therefore our strategy to create multiple plans for plan selection is to apply different PTV margins to the ventral side of the mesorectum based on a single CT scan. This will also cope with the shape changes that are encountered.

Plan selection based on daily Conebeam CT (CBCT) images require adequate visibility of the regions of interest. In the pelvic region CBCT image quality can be hampered by imaging artefacts caused by moving air or bowel. At the same time identifying the boundaries of a complex target volume such as the target volume for rectum cancer can be challenging. Uniform plan selection is realized by participation in an observer study where all observers

perform the selection procedure for a set of patients. Subsequently, the choices are discussed in the group of observers and a set of selection rules is composed. In this lecture we will discuss the plan selection strategy for rectum cancer and its introduction in the clinic.

Cyclin D1 silencing radiosensitises prostate cancer cells by impairing DNA-DSBs repair pathways.

F. Marampon¹, G. Gravina¹, C. Festuccia¹, A. Colapietro¹, E. Di Cesare¹, E. Tombolini²

¹University of L'Aquila, of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy

²Policlinico Umberto I "Sapienza" University of Rome, od Radiotherapy, Rome, Italy

Purpose or Objective: Patients with hormone-resistant prostate cancer (PCa) have higher biochemical failure rates after radiation therapy. Cyclin D1 deregulated expression in PCa is associated with a more aggressive disease however its role in radioresistance has not been determined.

Material and Methods: Cyclin D1 levels in the AR-negative, androgen-independent PC3 and AR-positive, androgen-independent 22Rv1 cells were stably inhibited by transfection with Cyclin D1-short hairpin RNA (shRNA). Tumorigenicity and radiosensitivity were investigated using *in vitro* and *in vivo* experiments.

Results: Independently by AR-expression, Cyclin D1 silencing interfered with PCa oncogenic phenotype by inducing growth arrest in the G1 phase of cell cycle and reducing soft agar colony formation, migration, invasion, tumor formation and neo-angiogenesis in xenografted mice. *In vitro* colony formation and *in vivo* tumor growth of the PCa xenografts were significantly inhibited by Cyclin D1 silencing combined with radiotherapy. Cyclin D1 silencing radiosensitizes PCa cells by impairing the NHEJ and HR pathways responsible of the DNA double-strand break repair. Cyclin D1 directly interacts with activated-ATM, -DNA-PKC and RAD51 that are downstream targets of Cyclin D1-mediated PCa cells radioresistance.

Conclusion: Taken together, these observations suggest a Cyclin D1 role in radioresistance mechanism. Cyclin D1 could represent a potential target for radioresistant androgen-sensitive or not prostate cancer cells.

PV-0425

EEF2K promotes progression and radioresistance of esophageal squamous cell carcinoma

H.C. Zhu¹, X. Yang¹, X.L. Ge¹, J.Y. Chen¹, H.M. Song¹, J. Liu¹, Z.L. Pei¹, M.Q. Chen¹, X.C. Sun¹

¹The First Affiliated Hospital of Nanjing Medical University, Radiation Oncology, Nanjing, China

Purpose or Objective: We investigated the effects of eukaryotic elongation factor 2 kinase (EEF2K) in esophageal squamous cell carcinoma (ESCC) and its role in radiosensitivity.

Material and Methods: We used quantitative real-time polymerase chain reaction and immunohistochemistry analyses to compare expression of EEF2K between paired ESCC samples and nontumor esophageal tissues. Lentivirus was used to overexpress and knockdown of EEF2K gene and stable transmitted cell line of ECA109 and TE13 were made. *In vitro* cell counting kit 8 and clone formation assay were used to detect cell viability and proliferation. Wound-healing migration assay, transwell invasion assay three-dimensional culture and tube formation assay were used to investigate invasion, metastasis and angiogenesis of ESCC. Radioresponse was primary examined by clone formation assay after exposure of 0, 2, 4, 6, 8 Gy X-ray by a medical accelerator of different stable cell lines. Then apoptosis, cell-cycle arrest, and γ -H2AX expression were examined in 0 Gy and 8 Gy in

the overexpressed and knockdown ESCC cell line by flow cytometer and immunofluorescence. Gene-chips and western blot were used to investigate molecular mechanism. *In vivo* experiments of xenografts were used to confirm the results.

Results: Levels of eEF2K were increased 52.17% of ESCC samples compared with matched nontumor tissues, as well as ESCC cell lines. Increased levels of eEF2K were associated with ESCC survival times of patients ($P < 0.05$). eEF2K expression correlated between tumor size and TNM stage in primary ESCC during clinicopathological feature analysis ($P < 0.05$). eEF2K promotes ESCC proliferation and tumorigenicity *in vitro* and *in vivo*. Improved invasion, metastasis and angiogenesis were also seen in eEF2K overexpressed cells compared with control in TE13 and ECA109 cell lines. An improved radioresponse was detected in eEF2K knockdown cells which could also be induced by NH125, an eEF2K inhibitor. Affymetrix GeneChip were used in eEF2K overexpressed ECA109 and control cells in normal conditions and 8 Gy of irradiation and autophagy pathways were detected by bioinformatic analysis. Improved protein expression of Atg5, mTOR, LC3, and TP53 were confirmed by western blot. In xenograft radiosensitivity experiments, an enhancement factor of 1.78 was seen in ECA109 bearing nude mouse by NH125, along with a reduction of tumor doubling time. Immunohistochemistry and immunofluorescence of tumor tissue confirmed the molecular mechanism of autophagy pathway.

Conclusion: eEF2K is overexpressed in ESCC and associated with progression and shorter survival times of patients. Decreased expression of eEF2K correlated with a reduction of malignancy in biological behavior and an improvement of radioresistance in ESCC, which may be mediated by autophagy signaling pathway. Targeting eEF2K may be a potential therapeutic approach of ESCC in the future.

PV-0426

Targeting PI4K for radiosensitisation: a viable model of drug repositioning

I.A. Kim¹, J. Kwon², Y. Park², D. Kim³, J. Park³

¹Seoul National Univ. Bundang Hospital, Radiation Oncology, Seongnam-Gyeonggi-Do, Korea Republic of

²Seoul National University Graduate School of Medicine, Radiation Oncology, Seoul, Korea Republic of

³Seoul National Univ. Bundang Hospital, Medical Science Research Institute, Seongnam-Gyeonggi-Do, Korea Republic of

Purpose or Objective: Phosphatidylinositol 4-phosphate (PI4P), upstream regulator of both phospholipase C (PLC)/Protein Kinase C (PKC) and phosphatidylinositol 3-kinase (PI3K) / serine/threonine-protein kinases (Akt) pathways which control the cell motility and proliferation, is produced by phosphatidylinositol 4-kinase (PI4K). Thus, an inhibition of PI4K could inactivate these two PI4P dependent pathways simultaneously. In this study, we tried to identify that which isotype of PI4K may affect a radiosensitivity using RNA interference (RNAi) and also to investigate anti-hepatitis C viral (HCV) agents which are known to inhibit PI4K activity, could be repositioned as a radiosensitizer in human breast cancer, glioblastoma and hepatoma models.

Material and Methods: A panel of human cancer cell lines including U251 malignant glioma cells, BT474 breast cancer cells, and HepG2 hepatocellular carcinoma cells were used. RNAi was used to specific inhibition of each isotype of PI4K and clonogenic assay was performed to assess the radiosensitizing effect of each isotype. To select an anti-HCV agent for pharmacologic inhibition of PI4K, IC50s of nine commercial antiviral agents were determined. Specific inhibitory effect on PI4K isotype was determined by *in vitro* kinase assay. Radiosensitizing effect of the selected anti-HCV agents were tested by clonogenic assay *in vitro* and tumor xenograft model *in vivo*, respectively. Immunoblotting, immunocytochemistry, and invasion/migration assay were performed to identify the mechanism of radiosensitization.

Results: First, we identified that specific inhibition of PI4K III α using RNAi increased radiosensitivity in the human cancer cell lines we tested. In contrast, inhibition of other isoforms did not affect a radiosensitivity of these cancer cell lines. Next, *in vitro* kinase assays showed, simeprevir, a selected anti-HCV agent via IC50 assay, inhibited activity of PI4K III α in a dose-response manner. Pretreatment of simeprevir induced discernible downregulation of p-PKC and p-Akt and also increased clonogenic survival of U251, BT474, and HepG2 cells *in vitro* and also significantly delayed growth of mouse tumor xenografts *in vivo*. Simeprevir caused prolongation of γ H2AX foci after irradiation, decreased invasion / migration and downregulation of PD-L1 expression.

Conclusion: Targeting PI4K III α using anti-HCV agent could be a viable drug repositioning approach to enhance the therapeutic efficacy of radiotherapy for breast cancer, glioblastoma and hepatoma. ³Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of

⁴Seoul National University College of Medicine, Nuclear Medicine, Seoul, Korea Republic of

Purpose or Objective: To investigate serial changes of tumor hypoxia in response to a single high dose irradiation by various clinical and pre-clinical methods in order to propose an optimal fractionation schedule for stereotactic ablative radiotherapy (SABR)

Material and Methods: Syngeneic Lewis lung carcinomas were grown either orthotopically or subcutaneously in C57BL/6 mice and were irradiated with a single dose of 15 Gy to mimic SABR used in the clinic. Serial [18F]-misonidazole (F-MISO) positron emission tomography (PET) imaging, pimonidazole FACS analyses, hypoxia-responsive element (HRE)-driven bioluminescence, and Hoechst 33342 perfusion were performed before irradiation (d-1), at 6 hours (d0), 2 (d2), and 6 days (d6) after irradiation for both subcutaneous and orthotopic lung tumors. For F-MISO, scan was performed 2 hr after the intravenous injection of F-MISO probe and the tumor-to-brain ratio (TBR) was analyzed.

Results: We observed that hypoxic signals were too low to quantitate for orthotopic tumors by F-MISO PET or HRE-driven bioluminescence imaging. In subcutaneous tumors TBR values were 2.87 ± 0.483 at d-1, 1.67 ± 0.116 at d0, 2.92 ± 0.334 at d2, and 2.13 ± 0.385 at d6, indicating that tumor hypoxia was decreased immediately after irradiation and returned to the pretreatment levels at d2, followed by a slight decrease by d6 post-radiation. Pimonidazole analysis also revealed similar patterns. By using Hoechst 33342 vascular perfusion dye and CD31 co-immunostaining, we found that there was a rapid and transient vascular collapse, which may have resulted in poor intratumoral perfusion of F-MISO PET tracer or pimonidazole delivered at d0 leading to decreased hypoxic signals at d0 by PET or pimonidazole analyses.

Figure 1

Fig. 1. Temporal changes in tumor hypoxia for subcutaneous tumors by F-MISO PET imaging. (A) Representative PET images demonstrating F-MISO uptake in subcutaneous tumor. Arrows indicate the tumor position. (B) A graph showing TBR values for an individual animal. (C) A graph showing the mean \pm s.e.m. of TBR values ($n = 5$).

Conclusion: We found tumor hypoxia levels to be returned to the pretreatment levels by 2 days after irradiation, hence supporting the current fractionation intervals of SABR being given at least 2 days. Our results also indicate that SABR may produce a rapid but reversible vascular collapse in tumors.

PV-0428

Factor 2.5 radiosensitivity difference determined by *ex vivo* γ H2AX assay in prostate cancer patients

⁹Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität, Radiation Oncology, Dresden, Germany

Purpose or Objective: In previous study we showed that γ H2AX assay in *ex vivo* irradiated tumour samples collected from cancer patients of various types correlates with known differences in radioresponsiveness. In the present study we aimed to apply the assay in a panel of prostate tumour

specimens to investigate whether it could allow discrimination of sensitive and resistant tumours of the same type. In addition we aimed to further explore the robustness of the method via investigating the potential impact of the tumour sampling on the reproducibility of the results.

Material and Methods: Tumour biopsies from prostate cancer patients undergone radical prostatectomy were cultivated in media for 24 h before irradiation (IR) with single doses and fixed 24 h post IR. The microenvironmental parameters were determined by addition of BrdU (perfusion) and Pimonidazole (hypoxia) to media prior to IR. Histological sections of previously paraffin-embedded material were stained for γ H2AX and the foci were evaluated in viable, well oxygenated tumour areas. To investigate the heterogeneity of radiation response among the different patients, biopsies were irradiated with graded single doses (0, 2, 4, 6, 8 Gy) while to determine the intratumoural sampling variability, biopsies from different tumour locations were irradiated with single dose of 4 Gy.

Results: In all the 15 patients currently analyzed we observed a linear dose-response of residual γ H2AX foci. The slope of the dose-response expressed high heterogeneity among the different patients (slope values range: 0.83-2.27). Using the slope of the foci dose-response as a parameter of tumour radiosensitivity we could determine 3 patients subgroups, namely resistant, with slope values lower than the 25th percentile of the slope values distribution (<1.1); moderate, with slope values between the 25 and 75th percentile and sensitive, with slope values above the 75th percentile (>1.8). These results are consistent with previously observed slope values for very sensitive (e.g. seminoma, slope value >2) and resistant (e.g. GBM, slope value ~ 1) tumour types. ANOVA analysis of the residual foci values post 4 Gy IR evaluated in tumour cells from different parts of the same tumour revealed no significant differences in the foci value distributions.

Conclusion: We herein show for the first time that the γ H2AX *ex vivo* assay is clinically feasible and able to detect differences in cellular radiation sensitivity among patients with the same tumour type. Our results suggest that intratumoural heterogeneity (potential source of sampling error) do not significantly affect the results of the assay. Taken together, this assay has a promising potential for individualized radiation oncology and prospective validation in different tumour types in relation to known tumour characteristics and patient's outcome is warranted.

PV-0429

A 3D *in vitro* cancer model and imaging platform to measure proton radiation-induced cellular damage

T. Long¹, M. Loizidou¹, G. Schettino², G. Royle³, K. Ricketts¹

¹University College London, Division of Surgery and Interventional Science, London, United Kingdom

²National Physical Laboratory, Radiation Dosimetry Group, London, United Kingdom

³University College London, Department of Medical Physics and Bioengineering, London, United Kingdom

Purpose or Objective: The aim of the project is to present an *in vitro* 3D cellular platform capable of measuring radiation-induced cell damage at the cellular scale, enabling high-resolution image capture of cell response along the proton depth dose.

Material and Methods: A 3D cancer model of dimensions 17 mm x 17 mm x 5 mm (L x W x H) was developed for proton irradiation. The model comprises 1 million uniform distributed HT29 colon cancer cells within a type 1 collagen scaffold. The model was irradiated with 62 MeV proton spread out Bragg peak (SOBP) of 10 mm width. Samples were fixed after irradiation, set within agarose gel, processed via vibratome to 400 nm thickness slices, stained with markers for apoptosis (Caspase-3), DNA double strand breaks (53BP1) and hypoxia (CA9).

Results: Alamar blue assay proves the cell metabolism can maintain 1-5 days depending on seeding density. The cancer cells invade into stroma, form spheroid and show paracrine activity (vascular endothelial growth factor and epidermal growth factor receptor expression) and hypoxia gradients in 3D model. The measurement of DNA double strand breaks is achievable in 2D fluorescent microscopy but less easily resolvable in 3D imaging. The level of cell apoptosis along SOBP can be imaged and correlated to the actual position and dose. Figure below shows 1 million HT29 3D models are irradiated by 5Gy dose and fixed 24 hour after irradiation. The image position located at the proximal edge of the SOBP.

Conclusion: In this novel methodology of sample processing and well-controlled coordination system, correlation between the cell response of the 3D cancer model and proton dose distribution was possible. The fluorescent images show a clear difference in cell apoptosis signal response with depth dose, and in the 3D samples we could image a hypoxia gradient. Further work is underway to model LET within the 3D cancer model to be linked to cell response parameters, and to repeat the experiment under x-ray irradiation.

PV-0430

Late radiation enteropathy: do tissue cytokines play a protective role? A first-in-man study.

M. Reis Ferreira¹, H.J.N. Andreyev², K. Mohammed³, S. Gowan⁴, D.P. Dearnaley¹

¹Institute of Cancer Research and Royal Marsden NHS Trust, Academic Radiotherapy, Surrey, United Kingdom

²Royal Marsden NHS Trust, Gastroenterology, London, United Kingdom

³Royal Marsden NHS Trust, Statistics and Computing, London, United Kingdom

⁴Institute of Cancer Research, Tumour Biology and Metastasis, London, United Kingdom

Purpose or Objective: Late radiation enteropathy affects 20% of prostate cancer survivors. Inflammatory processes may relate to its occurrence. We aimed to assess differences in the levels of intestinal mucosa cytokines between patients with side-effects after pelvic radiotherapy and healthy controls.

Material and Methods: Patients with GI symptoms developing after prostate radiotherapy and undergoing colonoscopy were recruited for this study. Controls were patients undergoing colonoscopy for polyp surveillance. All participants were free of bowel cancer. Colonoscopy was performed after standard preparation of the bowel with citramag and senna or Kleen prep. Biopsies were obtained for cytokine characterization and pathologic assessment as follows (Fig.1):

- (1) Two endoscopic directed biopsies were taken from an area where mucosal radiation lesion was present; if no mucosal change was obvious, biopsies were taken from the anterior rectal wall.

- (2) A second pair of biopsies was taken from normal looking mucosa as close as possible to the previous sampling site.

- (3) Controls: biopsies were taken from the anterior rectal wall only.

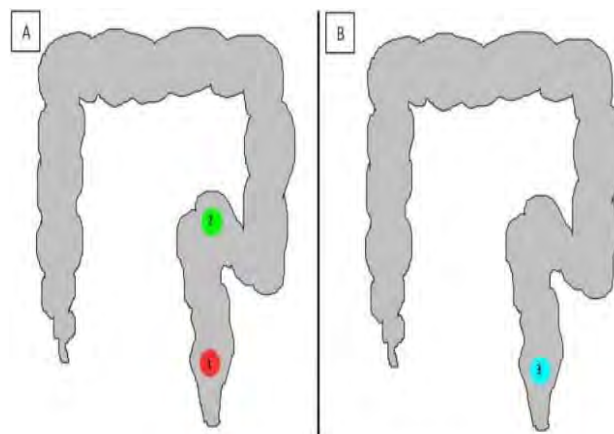

Figure 1: Sampling sites in A – patients with side-effects; B – control patients
(1) – Area with enteropathy; (2) – Area without enteropathy; (3) – Controls

Total sample protein was extracted. Cytokine levels were evaluated using 3 independent panels detecting the presence and concentrations of 30 different cytokines. A histology score for radiation enteropathy (*) was used to characterize the samples. Higher scores reflect worse outcomes. Significance was studied with the Kruskal-Wallis, Wilcoxon and Student's t-test.

Results: Recruitment ran from April 2014 to January 2015. 9 symptomatic patients, treated with prostate irradiation at least 2 years before and 6 healthy controls were recruited. Cytokine concentrations were higher in controls and in biopsies taken from normal tissue in the patients. Although patient samples from areas without disease had globally higher cytokine levels when compared to areas with disease, this was not significant. There was a trend to slightly higher histology scores in biopsies from irradiated tissues (table 1).

	Chemokine panel (10 molecules)	Cytokine panel (10 molecules)	Pro-inflammatory panel (10 molecules)	Histology score (*)
Control biopsies (3) versus biopsies of area with enteropathy (1)	Concentrations of chemokines higher in controls p=0.05	Concentrations of cytokines higher in controls p=0.001	Concentrations of pro- inflammatory cytokines higher in controls p=0.14	Score higher in areas with enteropathy p=0.06
Control biopsies (3) versus biopsies of area without enteropathy (2)	Concentrations of chemokines higher in controls p=0.16	Concentrations of cytokines higher in controls p=0.06	Concentrations of pro- inflammatory cytokines higher in controls p=0.01	Score higher in areas with enteropathy p=0.06
Biopsies of area with enteropathy (1) versus biopsies of area without enteropathy (2)	Concentrations of chemokines higher in area without enteropathy p=0.67	Concentrations of cytokines higher in area without enteropathy p=0.13	Concentrations of pro- inflammatory cytokines higher in area without enteropathy p=0.21	Score higher in areas with enteropathy p=0.6

Table 1: Differences in global cytokine level analysis by panel and histology score.

(*) Reference: Longberg CW, et al. Acta Oncol. 1992;31(7):781-7.

Conclusion: Cytokine levels are decreased in human tissues with late radiation enteropathy. This may reflect a protective function of cytokines, either in the maintenance of the mucosal barrier or in keeping a normal balance of gut microbiota. Pathway analysis and modeling of the inflammatory response will be the object of further analyses.

PV-0431

Changes of the density CD8+ tumour infiltrating lymphocytes after neoadjuvant radiochemotherapy

D. Buka¹, J. Dvorak², V. Sitorova³, I. Richter⁴, I. Sirak¹

¹University Hospital Hradec Kralove, Oncology and Radiotherapy Department, Hradec Kralove, Czech Republic

²Charles University and Thomayer Hospital, Department of Oncology- First Faculty of Medicine, Prague, Czech Republic

³University Hospital Hradec Kralove, Department of Pathology- Charles University, Hradec Kralove, Czech Republic

⁴Regional Hospital Liberec, Department of Oncology, Liberec, Czech Republic

Purpose or Objective: The aim of this retrospective study is to evaluate the effect of neoadjuvant radiochemotherapy on the density of CD8+ tumor infiltrating lymphocytes (TILs) of rectal adenocarcinoma, by comparison of the density of CD8+ TILs in endoscopic biopsies before and resection specimens after the therapy.

Material and Methods: In total 53 patients with locally advanced rectal cancer were studied retrospectively. Neoadjuvant treatment comprised 50.4 Gy/28 fractions external radiation with continual 5-fluorouracil. Four to six weeks after the radiochemotherapy, surgical resection was performed. Immunohistochemistry was applied to assess CD8+ expression in both the pretreatment biopsies and resected specimens.

Results: During radiochemotherapy 30 patients (57%) had increased the density of CD8+ TILs, in 18 patients (34%) decreased, in 1 patient there was no change, in 4 patients it was not possible to assess the dynamics of the density of CD8+ TILs (in 2 patients due to insufficient amount of tissue for immunohistochemical analysis and in other 2 patients due to pathologic complete response after radiochemotherapy). The median of follow-up was 75 months (6.3 years). In 2 patients resection with microscopic residual tumor (R1) was performed and for 51 patients radical resection with microscopically negative margins (R0) was performed. Downstaging after preoperative radiochemotherapy was observed in 34 patients (64%). Five-year overall survival was 56% (95%CI: 43-70%). The density of CD8+ TILs was not significant in Cox regression analysis ($p=0.16$) or log-rank test ($p=0.16$). According to chi-square test ($p=0.37$) there was no significant impact of the increase of the density of CD8+ TILs after radiochemotherapy on downstaging. The increase of the density of CD8+ TILs after radiochemotherapy was associated with a trend of 2.5 longer overall survival in comparison with patients with the decrease of the density of CD8+ TILs after radiochemotherapy.

Conclusion: In the present study we did not observe any predictive or prognostic significance of the density of CD8+ TILs in endoscopic biopsies before radiochemotherapy, in resection specimens after the radiochemotherapy nor in changes of the density of CD8+ TILs after radiochemotherapy. The limitation of our study is the number of patients (53). It is not excluded that in a larger number of patients predictive or prognostic significance of the density of CD8+ TILs could be detected.

PV-0432

Mechanisms and abscopal effects of combined mRNA-based radioimmunotherapy in a syngenic mouse model.

L. Basler¹, A. Kowalczyk², M. Fotin-Mleczek², K.J. Kallen², D. Zips¹, S.M. Huber¹

¹Universitätsklinikum Tübingen, Department of Radiation Oncology, Tübingen, Germany

²CureVac AG, CureVac AG, Tübingen, Germany

Purpose or Objective: Tumor metastasis and tumor immune evasion present major challenges of cancer treatment. Radiotherapy has been demonstrated to overcome the immunosuppressive tumor microenvironment and anecdotal reports suggest that local tumor irradiation alone may also exert systemic or abscopal anti-tumor effects by immune-response stimulation with subsequent control of non-irradiated tumor metastases. This study aimed to assess abscopal effects of radiation alone and in combination with an mRNA-based tumor vaccination in a syngenic mouse model.

Material and Methods: Syngenic C57BL/6 mice were subcutaneously injected with ovalbumin-expressing murine thymoma cells (E.G7-OVA, 3×10^5) into the right hind leg of on day -13 and into the left flank on day -9. On days 0, 1 and 2, the primary tumors (right hind leg) were irradiated (IR) with fractions of 2 Gy photons by the use of a linear accelerator. The secondary tumors at the left flank were shielded and received only $1.1 \pm 0.3\%$ of the IR dose applied to the primary tumor as confirmed by film dosimetry. Twice per week, tumor length and width were measured by caliper for tumor volume calculation and vaccination groups were intradermally injected with the mRNA-based vaccine RActive® encoding Ovalbumin beginning day 0. At the end of the experiments, the secondary tumors were analyzed for cytokine abundances by protein microarray.

Results: Primary and secondary tumors of control mice developed with similar growth kinetics. IR and combined radioimmunotherapy significantly delayed tumor growth leading to primary tumor control in 15% and 53% of mice. Importantly, in secondary tumors with starting volumes below 30mm^3 radioimmunotherapy induced a significant growth delay compared to vaccination alone ($p=0.002$) and control group ($p=0.01$). IR alone delayed the growth of the secondary, unirradiated tumors in an insignificant manner. Cytokine microarray analysis of the unirradiated secondary tumors showed significant differences in combined radioimmunotherapy for CCL5/RANTES and CXCL9/MIG expression as compared to the other groups, both suggesting increased T-cell activation. Similar but insignificant trends could be observed for TNF- α , CCL3, IL-1 α , VEGF, M-CSF and other cytokines.

Fig. 2. Tumor growth of the unirradiated, secondary tumors

A. Mean secondary tumor volume of the treatment groups and control over the treatment period of 14 days.

B. Slope of the growth curve of secondary tumors. In secondary tumors with starting volumes below 30mm³ radioimmunotherapy induced a significant growth delay compared to vaccination alone ($p=0.002$) and control group ($p=0.01$).

Conclusion:

Immunotherapy can enhance radiation-induced abscopal effects in small immunogenic tumors. This effect exhibits the potential of a combined radioimmunotherapy for the control of micrometastases. The characterization of the underlying immunological processes has to await further experiments.

Symposium: Modern ART based on functional / biological imaging

SP-0433

Functional imaging for ART; biological bases and potential impact on clinical outcome

B. Hoeben¹

¹Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands

Developments in high-precision radiotherapy by means of on-board imaging, such as IMRT and stereotactic radiotherapy, have extended the possibilities for dose escalation to tumor localizations, while de-escalating doses to surrounding normal tissues. Advances in imaging technologies allow for better differentiation of tumor extension and target localization. In addition to superior anatomical imaging possibilities, functional and molecular imaging can be utilized to convey information regarding inherent tumor characteristics relevant for prognostication and prediction of therapy response. In many different tumor types, studies have investigated the potential of especially magnetic resonance imaging (MRI) and positron emission tomography (PET) / computed tomography (CT) scan to bring various tumor features to light. Repetitive imaging of malignancies before and during treatment can give rise to response adaptive treatment as has been successfully shown by integrating 18F-Fluorodeoxyglucose (18F-FDG) PET/CT imaging in chemotherapy response evaluation of Hodgkin's Lymphoma, in order to define the eventual radiotherapy target and dose or to avoid radiotherapy altogether. For response evaluation of Hodgkin's Lymphoma on 18F-FDG PET/CT images, application of the internationally accepted Deauville criteria reduce interobserver variability and standardize response criteria.

In many solid tumor types, numerous mostly single-center studies have described a plethora of functional or molecular imaging characteristics for description of tumor features, prognostication and prediction purposes, radiotherapy target delineation or direction of targeted therapy. This illustrates the drive towards personalized medicine in oncology, where individual therapy and therapy adaptation are based on specific patient and tumor characteristics. PET/CT studies concerning prognostic and predictive imaging properties have focused on depiction of tumor characteristics and their

changes during therapy; such as metabolism (e.g. 18F-FDG PET), hypoxia (e.g. 18F-fluoromisonidazole PET, 18F-fluoroazomycin arabinosine PET, Blood Oxygen Level-dependent MRI), proliferation (e.g. 18F-fluorothymidine PET), cell membrane synthesis (e.g. 11C-choline PET), tumor cellularity (e.g. Diffusion-weighted MRI) or tumor perfusion (e.g. Dynamic Contrast-enhanced MRI). Clinical and pre-clinical PET/CT studies have illustrated the possibility to quantify presence and abundance of targets for antibody-based therapies, such as radiolabeled cetuximab in the case of the epidermal growth factor receptor. Studies on adaptive radiotherapy based on PET/CT imaging, in e.g. head-and-neck squamous cell carcinoma and non-small cell lung cancer, have mainly focused on definition of radiotherapy-resistant tumor subvolumes relevant for dose-escalation. Longer follow up results of these studies will reveal if these therapy intensifications will lead to better disease outcomes. What such imaging studies bring forward, is that different imaging modalities with different specific biological markers will define different tumor subvolumes, mostly with different spatial and temporal properties. The challenge is to define the correct individual therapy regulations for the correct tumor within the correct timeframe. Moreover, how can one reliably quantify the imaging signal, delineate radioresistant tumor subvolumes or evaluate therapy response, if most studies use local institutional approaches to manage imaging information for these purposes?

All these issues need to be resolved before widespread implementation into clinical practice can take place. Molecular and functional imaging and its evaluation has to be validated and proven to be useful in multicenter studies. Advanced solutions need to be established to incorporate multiparameter information from e.g. tumor biopsy immunohistochemical analysis and gene-arrays into decision-making processes for specific imaging modalities, individualized treatment and treatment evaluation pathways. The first multicenter studies with these goals in mind are now being established.

SP-0434

Adaptive radiation therapy by the example of head and neck cancer: is there any role for a RTT?

B. Speleers¹, M. Madani², M.S. Olteanu³, I. De Gersem¹, M. Duprez³, M.S. Vercauteren³, M.D. Berwouts³, M. De Neve³

Normal O 21 MicrosoftInternetExplorer4

Changes in the tumors as well as normal tissues and organs surrounding the tumor during and/or in response to radiation therapy require treatment adaptation. A need for adaptive radiation therapy (ART) is not obvious for all tumors, but head-and-neck cancer, for which substantial changes in tumor and parotid gland geometry and dosimetry have been shown [1]. Moreover, biologic changes in the tumor may require treatment adaptation as well [2]. Logistics of ART is complex and hampered by a lack of personnel and robust technical tools. The workflow is usually not well-defined and well-supported by commercial oncology information and treatment planning systems. Nevertheless, an increasing number of academic centers introduce ART in their practice as has done it in Department of Radiotherapy, Ghent University Hospital. In this talk the workflow of ART for head-and-neck cancer on the example of this particular center will be discussed in more detail including the roles of personnel with emphasis on RTTs, their current responsibilities and their possible empowerment in the frame of ART.

SP-0435

Dosimetric impact of dose painting and replanning: ARTFORCE project

J.J. Sonke¹

¹Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

In the ARTForce project, two international clinical trials are conducted. The first trial (NCT01504815) for locally advanced head-and-neck cancer patients is a phase two trial randomizing between standard chemo-radiotherapy, redistributing the dose in the PTV of the primary tumor. Instead of a homogeneous dose of 70Gy in 35 fractions, an inhomogeneous dose is optimized based with a minimum dose of 64 Gy at the edge of the PTV and a maximum dose of 84 Gy around the FDG PET SUVmax location. Additionally, in the experimental arm, the treatment plan is adapted after two weeks to account for anatomical changes. The second phase 2 trial (NCT01024829) for locally advanced lung cancer patients randomizes between dose escalation to the primary tumor ≥ 72 Gy in 24 fractions and dose escalation to the region of the tumor defined by the 50% of FDG PET SUVmax. Both treatment plans are optimized to have an equal mean lung dose. In this presentation, dosimetric differences between the arms in both trials will be discussed as well as the impact of anatomical changes on the delivered dose and the effectiveness of replanning to mitigate dose discrepancies.

Symposium: Secondary cancer after radiotherapy: from cancer registries to clinical implications

SP-0436

Radiotherapy-related second cancer risks from epidemiological studies, and their application to newer therapies

A. Berrington de González¹

¹Center for Global Health National Cancer Institute, Division of Cancer Epidemiology and Genetics DCEG, Rockville- MD, USA

Second cancers are an important cause of morbidity and mortality in cancer survivors. One in five cancers diagnosed in the US are now second cancers. The causes of second cancers include lifestyle factors, genetic predisposition and also the treatment for the first cancer, including radiotherapy. In the last decade there have been a large number of new studies that have advanced our understanding of the risk of second cancers after radiotherapy. The most informative studies provide dose-response relationships based on individual dose-reconstruction. These studies suggest that the second cancer risk generally increases linearly with dose, even at organ doses ≥ 60 Gy. This is contrary to earlier theories that the dose-response would flatten or even have a down-turn at higher doses because of cell killing. The magnitude of the risk from these fractionated high-dose exposures is, however, 5-10 times lower than the risk from acute exposures of <2 Gy among the Japanese atomic bomb survivors. The results from these detailed observational studies provide insights into radiation carcinogenesis from fractionated high-dose exposures, and can be used to develop second solid cancer risk projection models for newer radiotherapy techniques.

SP-0437

Modelling of secondary cancer risks

U. Schneider^{1,2}

¹Clinic Hirslanden Zürich, Institute of Radiotherapy, Zürich, Switzerland

²University of Zürich, Institute of Physics- Science Faculty, Zürich, Switzerland

In developed countries, more than half of all cancer patients receive radiotherapy at some stage in the management of their disease. However, a radiation-induced secondary malignancy can be the price of success if the primary cancer is cured or at least controlled. Therefore, there is increasing concern regarding radiation-related second cancer risks in long-term radiotherapy survivors and a corresponding need to be able to predict cancer risks at high radiation doses. Of particular interest are second cancer risk estimates for new radiation treatment modalities such as intensity modulated radiotherapy, intensity modulated arc-therapy, proton and heavy ion radiotherapy. The long term risks from such modern radiotherapy treatment techniques have not yet been determined and are unlikely to become apparent for many years, due to the long latency time for solid tumor induction. Most information on the dose-response of radiation-induced cancer is derived from data on the A-bomb survivors who were exposed to gamma-rays and neutrons. Since, for radiation protection purposes, the dose span of main interest is between zero and one Gy, the analysis of the A-bomb survivors is usually focused on this range. With increasing cure rates, estimates of cancer risk for doses larger than one Gy are becoming more important for radiotherapy patients. Simple radiation protection models should be used only with extreme care for risk estimates in radiotherapy, since they are developed exclusively for low dose. When applied to scatter radiation, such models can predict only a fraction of observed second malignancies. Better semi-empirical models include the effect of dose fractionation and represent the dose-response relationships more accurately. The involved uncertainties are still huge for most organs and tissues. A major reason for this is that the underlying processes of the induction of carcinoma and sarcoma are not well known. Most uncertainties are related to the time patterns of cancer induction, the population specific dependencies and to the organ specific cancer induction rates. For radiotherapy treatment plan optimization these factors are irrelevant, as a treatment plan comparison is performed for a patient of specific age, sex, etc. If a treatment plan is compared relative to another one only the shape of the dose-response curve (the so called risk-equivalent dose) is of importance and errors can be minimized. One of the largest remaining uncertainties is the precision of the dose distribution which is the basic input into all risk-estimate-models. Dose calculation and/or measurement are as precise as approximately 5% in the treated volume of the patient. However, in the periphery dose errors can reach 100% and more. The use of erroneous dose data (see Figure 1) can lead to wrong risk estimates. Therefore a lot of effort is undertaken to produce precise dose computations in the whole patient volume about which is reported. Strategies are discussed how to include relevant dose information into cancer registries.

Figure 1. Two dose comparisons of the same radiation treatment techniques which were used for risk estimates. The resulting risk estimates were highly contradictory.

³MAASTRO Clinic, Radiation Oncology, Maastricht, The Netherlands

Purpose or Objective: The influence of HPV positivity on therapy response in head and neck squamous cell cancers (HNSCC) highlights the importance of uniform and robust biomarkers for stratification of HNSCC patients. Our previous report indicates that p16 is not only a surrogate marker for HPV infections but has an active role in modulation of radiotherapy response by impairing DNA damage response and repair, which is a process known to be dominant in the nucleus of the cells. Based on this, we hypothesized that p16 compartmentalization according to nuclear and cytoplasmic expression may have a role in risk stratification.

Material and Methods: p16 expression (immunostaining) and HPV status (GP5+/6+ PCR) was assessed in 241 pretreatment biopsies of oropharyngeal cancer patients treated with chemoradiotherapy. Tumors were classified in nuclear p16 expressing (>10% of tumor cells), cytoplasmic (>10% tumor cells) and p16 negative groups. Statistical analysis was performed to assess the correlation between clinical and tumor characteristics and p16 immunostaining. Influence of p16 localization on radiotherapy response was further assessed by clonogenic and cell survival assays in HPV/p16 negative HNSCC cells transfected with viral construct containing p16-NLS (nuclear localization signal); p16-NES (nuclear exit signal) and p16-WT. The expression and localization of p16 was confirmed by western blotting and immunofluorescence. The response of p16 localization on DNA damage response and homologous recombination repair (HRR) was assessed by gH2AX, RAD51 foci formation and immunoprecipitation.

Results: Nuclear p16 expressing HNSCC showed significant ($p < 0.05$) better locoregional control rates (5-year 82%) compared to cytoplasmic p16 positive (5-year 55%) and p16 negative patients (5-year 48%). Only nuclear p16 expression was a significant prognostic factor for locoregional control with a hazard ratio of 0.48 ($p < 0.05$; 95% CI: 0.22-1.01). Interestingly, HPV positive patients were significantly enriched in the nuclear p16 expressing group (60%) compared to cytoplasmic p16 expressing group (9%). In concordance with our patient data, cells containing nuclear p16 expression (p16-NLS) showed a higher radiosensitization compared to cells with predominant cytoplasmic p16 expression (p16-NES) or p16 negative cells, indicating a differential role of p16 protein expression depending on its localization. Strikingly, cells expressing nuclear p16 (p16-NLS) -although showing a similar level of gH2AX induction- were characterized with lower number RAD51 foci formation compared to cells expressing cytoplasmic p16 (p16-NES), suggesting an impaired HRR.

Conclusion: Cellular p16 localization is an important factor for stratification of HNSCC patients with nuclear p16 expression showing a superior predictive value for radiotherapy response.

SP-0438

Clinical implications of secondary cancer risks in pediatric and adult patients

D. Hodgson¹

¹Hodgson David, Radiation Oncology, Toronto, Canada

The association between radiation exposure and cancer risk has been studied for several decades, although in the clinical oncology setting, significant gaps in the understanding and management of radiation therapy (RT) related second cancer risks still exist.

This talk will address the clinical implications of current knowledge relating to treatment- related second cancers, including:

1. Treatment selection: Some clinicians or patients may opt to avoid RT in order to reduce the risk of second cancers. These decisions often reveal important misunderstandings about the impact of age, competing risks of death or other morbidity, and differences between absolute and relative risks. Through a case-based approach, participants will learn to identify scenarios in which over- or under-estimation of second cancer risk may lead to suboptimal treatment choices.

2. Modification of Radiation Treatment: Oncologists are able to deliver dose much more precisely than ever before, but it remains difficult to decide where to deposit excess dose, or if low doses to large volumes are more carcinogenic than high doses to small volumes. The emergence of proton therapy now adds further complexity to these issues. In this session, participants will learn about dose-risk relationships and the clinical implications for radiotherapy planning.

2. Clinical management in follow-up: Survivorship care is of growing clinical concern, and management of second cancer risk is an important feature of this care. Oncologists will be required to have familiarity with guidelines recommending specific screening interventions following RT. Participants will learn about resources and guidelines for management of second cancer risk, and the evidence supporting these guidelines will be reviewed.

Purpose or Objective: To retrospectively assess the prognostic value of the potential biomarkers, i.e. chemokine receptor CXCR4, its ligand CXCL12 (SDF1), and nuclear EGFR expression in a cohort of 201 patients with locally advanced HNSCC. Patients were treated between 2005 and 2011 in 8 German cancer centers, as part of a multicenter biomarker study of the German Cancer Consortium Radiation Oncology Group (DKTK-ROG). Experimental data and first clinical observations suggest that activation of CXCR4 and SDF1 signaling pathway and nuclear location of EGFR are implicated in tumour cell proliferation, cellular survival, tumour progression, worse overall survival, metastasis and enhanced treatment resistance in different tumour types.

Material and Methods: Patients with locally advanced SCC of the oral cavity, oropharynx and hypopharynx were treated with resection and adjuvant RT and Cisplatin-based CT.

Tissue micro-arrays (TMAs) were generated from surgical specimens and evaluated for the expression of the biomarkers by immunofluorescence with a semi-quantitative method, based on their cellular location (membranous, intracellular, nuclear), extent of expression on TMA area and staining intensity. The results of the biomarker analysis along with the clinical parameters were then correlated with the clinical outcome.

Results: In univariate analysis, tumours with either SDF1 or CXCR4 intracellular overexpression displayed a significant negative correlation with loco-regional control (LCR) (HR: 2.52, p=0.01 and HR: 1.96, p=0.05 respectively). No correlation was observed for the nuclear expression of EGFR (HR: 0.85, p= 0.67), membranous expression of SDF1 (p=0.73) or CXCR4 (p=0.38). Tumours with intracellular co-expression of both SDF1 and CXCR4 were significantly correlated with poor LCR (HR: 2.72, p=0.01). Previously published data from the same cohort, showed that absence of p16 (negative HPV status) was correlating with poor LCR. Importantly, increased expression of SDF1 or co-expression with CXCR4 could identify a group of patients with significantly worse outcome within the HPV negative group (p=0.01). Multivariate cox regression analysis including HPV status, tumour localisation, tumour volume and the respective biomarkers indicated a significant independent role of SDF1 (HR: 2.20, p=0.04) and co-expression with CXCR4 (HR: 2.19, p=0.05) on LCR.

Conclusion: In summary, pre-treatment overexpression of CXCR4/SDF1 is an independent negative prognostic factor for the outcome of patients with locally advanced HNSCC who receive surgery and standard RT-CT. Further investigation in a cohort of patient receiving primary RT-CT and a prospective validation study is currently ongoing. SDF1/CXCR4 appears to be a promising biomarker for treatment individualization, in particular in HPV negative advanced HNSCC patients and supports strategies using drugable targets against this pathway to enhance efficacy of standard treatment.

Purpose or Objective: Radio(chemo)therapy is a crucial treatment modality for head and neck squamous cell carcinoma (HNSCC). Radiotherapy resistance is a major reason for therapy failure and, therefore, predictive biomarkers for therapy response are urgently needed. DNA gains on chromosome 16q23-24 have been shown to be associated with genomic amplification of the FancA gene and to correlate with reduced progression-free survival of HNSCC patients after radiotherapy. This study aimed to analyze the effects of the potential predictive marker FancA on radiation sensitivity *in vitro*, to characterize the underlying molecular mechanisms, and to evaluate the clinical relevance in HNSCC.

Material and Methods: We generated FancA overexpressing human oral keratinocytes (OKF6/FancA) and analyzed several endpoints upon irradiation. To identify signaling pathways involved in FancA-mediated resistance, global transcriptome analyses were performed after irradiation with 4 Gy or sham-

irradiation followed by pathway enrichment analysis and reconstruction of function interaction networks. The clinical relevance of the cytogenetic marker 16q23-24, the FancA gene and our *in vitro* results was analyzed in data of 113 radiotherapy-treated patients from The Cancer Genome Atlas (TCGA) HNSCC cohort (Nature, 2015).

Results: Overexpression of FancA resulted in enhanced survival after *in vitro* irradiation. Moreover, FancA overexpressing cells demonstrated accelerated DNA damage repair mechanisms paralleled by increased repair fidelity: enhanced p53 and p21 response, accelerated kinetics in the disappearance of γ -H2AX DNA damage repair foci, faster pATM translocation, reduced accumulation of chromosomal translocations, but no increase in FancD2 monoubiquitinylation. Global mRNA expression analyses identified interferon signaling as a major candidate pathway, which was affected by FancA overexpression. Functional interaction networks of genes deregulated upon irradiation pointed to pathways exclusively involved in FancA-mediated radioresistance including the *senescence-associated secretory phenotype (SASP)*. Increased levels of basal and irradiation-induced cellular senescence accompanied by enforced SASP formation further support their potential involvement in FancA-mediated radiation resistance. The clinical relevance of our findings was validated in the data of 113 radiotherapy-treated patients of the TCGA HNSCC cohort demonstrating the association of chromosomal gains on 16q24.3 with increased FancA mRNA expression levels and impaired overall survival. Furthermore, the translation of our *in vitro* model derived results into the HNSCC patient specimens revealed similar gene expression changes linked to FancA overexpression.

Conclusion: Our data suggest an important role for FancA in cellular mechanisms of radioresistance in HNSCC.

Does miR-210 predict benefit from hypoxia modification in BCON randomised bladder cancer patients?

C. West¹, J. Irlam-Jones², A. Eustance², H. Denley³, P. Hoskin⁴, A. Choudhury⁵

¹The University of Manchester, Christie Hospital, Manchester, United Kingdom

²The University of Manchester, Translational Radiobiology Group, Manchester, United Kingdom

³Central Manchester University Hospitals NHS Foundation Trust, Department of Histopathology, Manchester, United Kingdom

⁴Mount Vernon Hospital, Cancer Centre, Northwood, United Kingdom

⁵The Christie Hospital NHS Foundation Trust, Department of Clinical Oncology, Manchester, United Kingdom

Purpose or Objective: The addition of hypoxia modifiers carbogen and nicotinamide (CON) to radiotherapy (RT) improved overall survival in bladder cancer patients enrolled in the BCON phase III clinical trial. We investigated whether the expression of miR-210 in the BCON patient samples reflects hypoxia and predicts benefit from hypoxia-modification.

Material and Methods: The retrospective study involved 183 T1-T4b patients: 86 received RT+CON and 97 received RT alone. Formalin-fixed samples taken prior to radiotherapy were available and RNA extracted. Customised TaqMan plates were used to assess miR-210 expression using quantitative real-time PCR. Patients were classified as low miR-210 (<median expression) or high miR-210 (\geq median). Data on other hypoxia biomarkers were available for comparison.

Results: Patients with high miR-210 had a trend towards improved five-year OS with RT+CON (53.2%) compared with RT alone (37.8%; HR 1.68, 95% CI 0.95-2.95, P=0.08). No benefit was seen with low miR-210 (HR 1.02, 95% CI 0.58-1.79, P=0.97). High expression of miR-210 was also associated with high HIF-1 α protein (P=0.0008), CA9 protein (P=0.004), Glut-1 protein (P=0.02), expression of a 26-gene hypoxia

signature (P=0.01), tumour necrosis (P=0.04) and concurrent pTis (P=0.03).

Conclusion: High miR-210 expression may reflect tumour hypoxia and should be investigated further as a potential biomarker to identify bladder cancer patients who would benefit from hypoxia-modifying therapies.

OC-0443

Radiotherapy sensitivity in breast cancer is influenced by the DNA cytosine deaminase APOBEC3B

P.N. Span¹, A. Post¹, J.W.M. Martens², R.S. Harris³

¹Radboud University Medical Center, Department of Radiation Oncology, Nijmegen, The Netherlands

²Erasmus MC Cancer Institute, Department of Medical Oncology and Cancer Genomics Netherlands, Rotterdam, The Netherlands

³University of Minnesota- Masonic Cancer Center, Department of Biochemistry- Molecular Biology- and Biophysics, Minneapolis, USA

Purpose or Objective: The DNA cytosine deaminase APOBEC3 proteins catalyze deamination of cytidines in single-stranded DNA, providing innate protection against retroviral replication. Recent studies have implicated APOBEC3B as a major source of mutation in breast cancer, suggesting a role for these enzymes in tumor initiation and/or progression. APOBEC3B expression levels were earlier found to correlate with poor outcomes for patients with estrogen receptor positive breast cancer, especially after Tamoxifen. Given its role in mutagenesis, we set out to assess whether APOBEC3B associates with radiosensitivity in breast cancer.

Material and Methods: MCF7 breast cancer cells were cultured radioresistant by daily 2 Gy treatments or tamoxifen-resistant by continuous culturing in up to 10 μ M 4-OH-tamoxifen. The effect of irradiation on expression of APOBECs was assessed by RNAseq and qPCR in radiosensitive and radioresistant MCF7, and by qPCR in radioresistant MDA-MB231 cells. Furthermore, we studied a retrospective cohort of 535 non-systemically treated breast cancer patients. The predictive power of APOBEC3B was assessed in patients that did or did not receive radiotherapy as part of their primary therapy. Next, we suppressed endogenous APOBEC3B in MCF-7L with shRNA, or overexpressed either wt APOBEC3B, or a catalytically dead mutant APOBEC3B.

Results: Radioresistant breast cancer cells had increased baseline APOBEC3B mRNA levels (and not of any of the other APOBEC proteins), and irradiation induced an increase in APOBEC3B expression in both MCF7 and MDA-MB231 cells. In the breast cancer patient cohort we found a strong, statistically significant, independent interaction between APOBEC3B expression and radiotherapy. APOBEC3B predicted a poor prognosis only in those patients that received radiotherapy as part of their primary treatment, also when this analysis was restricted to patients that received a mastectomy (figure). This suggests that APOBEC3B influences radiosensitivity, and does not merely predict efficacy of surgery (as radiotherapy is generally given to lumpectomy patients). The effect of APOBEC3B knockdown and overexpression on radiosensitivity is currently being assessed using colony-forming assays and will be presented.

Figure: Kaplan-Meier analyses of non-systemically treated breast cancer patients that did (right panels) or did not (left panels) received radiotherapy as part of their primary treatment. Even in mastectomy patients alone did APOBEC3B predict radiosensitivity.

Conclusion: Our data suggest that the anti-viral APOBEC3B enzyme influences radiosensitivity in breast cancer, and might be a potential target for radiosensitization.

Stereotactic body radiotherapy of hepatocellular carcinoma lesions in liver transplant candidates

J. Shiao¹, A. Gutierrez¹, A. Patel¹, A. Harris¹, K. Washburn², G. Half², J. Lopera³, F. Sharkey⁴, R. Crownover¹

¹University of Texas Health Science Center San Antonio, Radiation Oncology, San Antonio, USA

²University of Texas Health Science Center San Antonio, Transplant Surgery, San Antonio, USA

³University of Texas Health Science Center San Antonio, Radiology, San Antonio, USA

⁴University of Texas Health Science Center San Antonio, Pathology, San Antonio, USA

Purpose or Objective: To determine the radiographic response of Hepatocellular Carcinoma (HCC) lesions treated via stereotactic body radiotherapy (SBRT) in a series of liver transplant candidates and to correlate these findings with pathology after transplant.

Material and Methods: We retrospectively reviewed 17 liver transplant candidates from December 2008 to December 2013 at a single institution with discrete HCC lesions were treated with SBRT for evaluation of local control (LC); other methods of bridging patients to transplant were also available. Peripheral SBRT dose was either 50 Gy in 5 fractions or 45 Gy in 3 fractions with 2 fractions weekly. The records of transplant patients who underwent SBRT for single or multiple hepatomas were reviewed for maximum tumor dimension (MTD) at time of simulation, last imaging before transplant, and gross pathology following transplant. Radiographic LC of the treated lesion was defined as stable or decreasing enhancement on imaging with either tri-phase CT Liver or MRI Liver prior to transplant as demonstrated in Figure 1; this was recorded one month subsequent to treatment and just before the transplant. Pathologic Control (PC) was defined as stable to decreased size in MTD and/or no viable tumor present.

Figure 1. MR imaging of HCC Lesion prior to (left) and after SBRT (right)

Results: Twelve patients have successfully been transplanted. All patients were male with a median age of 57 years. Of the 12 patients transplanted, there were 17 lesions treated. Median MTD at time of radiation was 3.6 cm (1.1cm - 6.1 cm). Median time to transplant from radiation treatment for 12 patients was 9 months (2mo-18mo). Table 1 summarizes tumor and treatment characteristics. Eight lesions (47%) had no evidence of viable tumor on pathology. Radiographic LC and PC was achieved in all 17 lesions. At a median follow-up of 53 months, disease free and overall survival were 100% with no evidence of disease (NED). Of the remaining 5 candidates, 3 patients awaiting transplant had one lesion, 1 had two lesions, and 1 had three lesions treated via SBRT. No patient experienced significant decrement in liver function nor indication of radiation induced liver disease. One patient experienced Grade 1 abdominal pain and three patients experienced Grade 1 nausea.

Table 1. Tumor and Treatment Characteristics for Patients With HCC Treated With SBRT as a Bridge to Liver Transplantation

Patient	Pre-SBRT Treatment	Tumor Diameter (cm)	Tumor Volume (cm ³)	SBRT Dose (Gy) / Fractions	Time from SBRT to Liver Transplantation (Days)	Explant Pathology/ Tumor Size (cm ³) / Tumor volume (cm ³)	Follow-up After SBRT (Months)	Disease Status
1a	None	3.8	n/a	50/5	286	No viable tumor	51	NED
1b	None	4.1	n/a	50/5	286	Residual HCC 4.3 / 24.2	51	NED
2	FACE x1	6.1	11.7	50/5	73	Residual HCC 5	45	NED
3a	FACE x2	4.6	60.9	50/5	541	No viable tumor	15	NED
3b	REA x1	1.9	n/a	50/5	541	No viable tumor	15	NED
4a	None	3.5	13.4	50/5	115	Degenerative HCC 3.5 / 21	54	NED
4b	None	2.2	1.9	50/5	115	Residual HCC 1.8 / 0.8	54	NED
4c	None	1.1	8.0	50/5	115	Residual HCC 1.3 / 2.9	54	NED
5	None	4	46.8	50/5	352	Residual HCC 2.2 / 6.7	41	NED
6	None	2.9	7.1	50/5	137	Residual HCC 1.8 / 2.8	33	NED
7a	REA x3	2.2	4.8	45/3	130	No viable tumor	3	NED
7b	REA x2	2.4	n/a	45/3	130	No viable tumor	3	NED
8	FACE x1	2.7	8.0	45/3	374	No viable tumor	17	NED
9	FACE x1	4.3	43.1	45/3	376	Residual HCC 1.3 / 16.3	41	NED
10	None	4	29.5	50/5	381	Residual HCC 3 / 35.6	47	NED
11	FACE x3	5.5	2.1	50/5	223	No viable tumor	223	NED
12	REA x1	5.6	8.4	50/5	321	No viable tumor	15	NED

Conclusion: SBRT for HCC lesions in transplant candidates is an effective means of LC with successful bridging to transplant. Radiologic assessment subsequent to SBRT correlated with pathologic findings after transplant. These promising results suggest a broader role for SBRT in management of limited volume HCC.

¹⁶University Hospital of Cologne, Radiation Oncology, Cologne, Germany

¹⁷Klinikum Passau, Radiation Oncology, Passau, Germany

¹⁸University of Munich, Radiation Oncology, Munich, Germany

Purpose or Objective: The intent of this pooled analysis as part of the German Society for Radiation Oncology (DEGRO) stereotactic body radiotherapy (SBRT) initiative was to analyse the pattern of care of SBRT for liver metastases in Germany and to derive factors influencing local control and overall survival in a large patient cohort.

Material and Methods: From 17 German and Swiss radiotherapy centers, data on all patients treated for liver metastases with SBRT since its introduction in 1997 was collected and entered into a centralised database as an effort of the SBRT task group of the DEGRO. In addition to patient and tumor characteristics, data on immobilization, image guidance and motion management as well as dose prescription and fractionation was gathered. Besides dose response and survival statistics, time trends of the aforementioned variables were investigated.

Results: In total, 442 patients with 586 liver metastases (median 1 lesion/patient; range 1-4) have been collected from 1997 until 2014. Predominant histologies were colorectal cancer (n=213), lung cancer (n=26) and breast cancer (n=57). All centers employed a SBRT-specific setup (including abdominal compression in 41%). Initially, stereotactic coordinates and CT simulation was used for treatment set-up (55%), but eventually replaced by CBCT guidance (28%) or more recently robotic tracking (17%). High variance in fraction (fx) number (median 1 fx; range 1-13) and dose per fraction (median: 18.5 Gy; range 3-37.5 Gy) was observed, although median BED remained consistently high after an initial learning curve. Median follow-up time was 13 months; median overall survival after SBRT was 24 months. 1 and 2 year local control rate of treated lesions was 77% and 64%; local control increased to 83% and 70%, respectively, if maximum isocenter biological equivalent dose (BED) was greater than 120 Gy EQD2Gy versus below that dose.

Conclusion: After a learning curve with regards to total cumulative doses, consistent biologically effective doses were employed, although with a significant variation in number of fraction, single fraction dose and prescription isodose. A clear dose response was observed with high local control after 1 and 2 years with higher BED. Nevertheless, local control is still inferior compared to lung metastases with a similar distribution of histologies. Therefore, further analysis needs to investigate the influence of image guidance and motion management as well as radiation sensitivity on local tumor control.

⁷P.O. Businco, Radiotherapy Unit- Centro di Radioterapia e Medicina Nucleare, Cagliari, Italy

⁸S. Orsola-Malpighi Hospital- University of Bologna, Department of Medical and Surgical Sciences DIMEC, Bologna, Italy

Purpose or Objective: To define maximum tolerated dose (MTD) of stereotactic treatment (SBRT) performed in different clinical settings.

Material and Methods: This analysis was based on a dose-escalation (Phase I) trial. Patients were enrolled in seven different arms depending on treatment site and previous treatment: 1) intraparenchymal lung tumors; 2) lung tumors near to chest wall or to mediastinum; 3) extra pulmonary tumors; 4) re-irradiation after radiotherapy (< 60 Gy); 5) re-irradiation after radiotherapy (> 60 Gy) or re-irradiation of pelvic and pancreatic tumors; 6) boost after a dose < 50Gy; 7) boost after a dose 50Gy. SBRT was delivered in 5 fractions. The dose was prescribed at isocenter with a 3D static technique using 4-5 non-coplanar beams or with VMAT technique. PTV was defined as the GTV + 5-15 mm. Considering study arms, the first group of patients received 20 Gy, while other cohorts of patients received doses up to 50 Gy. Grade 3 acute and late toxicities were considered as dose limiting toxicity (DLT). If 2/6 or 4/12 DLT were recorded in one cohort, that dose was considered as MTD.

Level	n° pts	Lung Target		Extra thoracic target (neck, abdomen, pelvis)	Retreatment		SBRT-boost	
		Lung Target	with inclusion of mediastinum or chest wall		Previous Dose ≤ 60Gy (parenchyma and pleura)	Previous Dose > 60Gy	(Post ERT 45-50 Gy)	(Post ERT > 50Gy)
A	6 §	25 Gy	25 Gy	20 Gy	25 Gy	25 Gy	20 Gy	
B	6 §	37.5 Gy	30 Gy	30 Gy	25 Gy	30 Gy	25 Gy	
C	6 §	45 Gy	35 Gy	35 Gy	30 Gy*	35 Gy	35 Gy*	
D	6 §	50 Gy	40 Gy	40 Gy	35 Gy	40 Gy	40 Gy	
E	6 §	50 Gy	45 Gy	45 Gy	40 Gy	45 Gy	45 Gy	
F	6 §	50 Gy	50 Gy	50 Gy	45 Gy	50 Gy	50 Gy	

On-going dose level is underlined; *; DLT; ERT: external beam radiotherapy

Results: 213 patients were enrolled (M/F: 125/88), median age was 69 years (35-90) and 281 lesions were treated (102 primary tumors or local recurrences, 96 nodal and 83 distant metastases); they were mainly lung cancer (31%), gynaecologic cancer (24%), gastrointestinal neoplasms (22%), urologic tumour (12%), in the following sites: 150 in neck or chest, 70 in abdomen and 61 in pelvis. With a median follow-up of 17 months (3-131) the overall response rate was 82% (Complete Response: 58%; Partial Response: 24%), with only 3% of patients developing disease progression. DLT was recorded only in two patients, both treated with 50 Gy. Two-year and 4-year local control were 71% and 62%, respectively. Two-year and 4-year metastases free survival were 46% and 39%, respectively.

Conclusion: SBRT in five fractions up to a dose of 50 Gy is well tolerated in different clinical settings.

OC-0447

Stereotactic Body Radiotherapy (SBRT) in oligometastatic prostate cancer patients

C.L. Chaw¹, D. Henderson¹, V. Khoo¹, A. Tree¹, R. Eeles¹, N. Van As¹

¹*Institute of Cancer Research, Royal Marsden Hospital-Academic Uro-Oncology Department, London, United Kingdom*

Purpose or Objective: Oligometastatic prostate cancer is a state of limited metastatic diseases (3 sites) that may be amenable to aggressive local therapy to achieve long term survival. The use of SBRT in this clinical setting has been reported to confer local control rate in excess of 90%, and encouraging progression free survival rate with no significant treatment related toxicities¹⁻⁴. One of the goals with this approach is to delay initiation of palliative systemic treatment, which can potentially impact negatively on quality of life. This study evaluated the outcomes of SBRT in our cohort.

Material and Methods: Forty five patients diagnosed with oligometastatic prostate cancer (defined as a rising PSA and positive CT/PET choline scan) after definitive local therapy were treated with 1-2 courses of SBRT between July 2011 and July 2015. Over 90% of metastases were situated in lymph nodes or bone. Median dose was 30 Gy in 3 fractions, prescribed to the highest isodose covering the PTV. Retrospective data collection and analysis were performed for these patients. Kaplan-Meier was utilised to estimate progression free survival and overall survival and time to initiation of systemic treatment. Nineteen of the 35 patients with castration sensitive disease were treated with SBRT alone for their oligometastatic disease, 16 patients received SBRT and Androgen Deprivation Therapy (ADT) with median duration of 5 months. 10 patients who were castration resistant at the diagnosis of oligometastases were treated with SBRT with ongoing systemic treatment.

Results: The median follow-up was 29 months (range 6-60 months). Local control rate of lesions following SBRT treatment was 90%, overall progression free survival (PFS) was 38%, overall survival (OS) of 89% at 29 months. A reduction of pre-treatment PSA value of 48% and 75%, respectively was seen in castration sensitive patients who received SBRT alone and SBRT with ADT, and a 25% PSA reduction in castration resistant patients treated with SBRT and ADT. Median time to clinical progression was longer in castration sensitive patients treated with SBRT and ADT compared to SBRT alone (13 months vs 25 months). The median ADT-free survival for castration sensitive patients was 16 months. Median time to initiation of next line therapy in castration resistant patients following SBRT treatment was 6 months. No grade 3 or 4 treatment related toxicities reported.

Conclusion: SBRT can provide a substantial delay to the next initiation of systemic therapy in castration sensitive patients whilst for castration resistant patients, there is a modest prolongation before initiation of subsequent therapy. Phase III data is lacking but will shortly be addressed in the SABR-COMET and CORE trials.

Give me five: extreme hypofractionated IG-IMRT for organ confined prostate cancer

Purpose or Objective: Radiobiological findings suggest an improvement in the therapeutic ratio for prostate cancer (PCa) treated with hypofractionation, compared with conventional fractionation. On this basis, in 2012 we activated a prospective study on extreme hypofractionated image-guided intensity modulated radiation therapy (IG-IMRT) in organ-confined PCa. The aim of this study is the assessment of the feasibility of the proposed protocol - Give me five, in terms of acute and late toxicity and biochemical efficacy.

Material and Methods: The study was performed within the Institutional Ethics Committee notification regarding hypofractionated IGRT for PCa. Inclusion criteria were: low to intermediate-risk (according to NCCN risk categories) histologically confirmed PCa; personalized indication for high-risk patients; prostate volume <100cm³; N0 and cM0; age >18 years; specific informed consent. In 10% of patients, multiparametric MRI was used for an improved definition of the patient anatomy, in addition to CT imaging. The nominal prescription dose was 32.5 or 35 Gy scheduled in 5 fractions on alternate days (therefore the name of protocol, "Give me five"), namely 6.5-7 Gy/fraction respectively, corresponding to a normalized total dose delivered at 2-Gy/fraction of 74.3 or 85 Gy, respectively, estimating an α/β ratio of 1.5 Gy. Dose delivery was performed with VERO®-BrainLab-Mitsubishi or RapidArc®-Varian. No fiducial markers were implanted and set-up verification was performed daily by means of CBCT imaging. Toxicity was evaluated according RTOG/EORTC scales. The study was funded by Associazione Italiana per la Ricerca sul Cancro - AIRC, grant no. 13218.

Results: Between April 2012 and May 2015, 166 patients were eligible. All patients completed the treatment. Median follow-up was 12.5 months (range 6-32.7 months). Fifty-eight, 83, 24 and 1 patients out of 166 were at low, intermediate, high and unknown risk, respectively. Median age was 74.3 years, median Gleason score was 6. Considering acute toxicity, 89.8%, 7.8%, 2.4% of patients had gastrointestinal G0, G1, G2 toxicity, respectively; 54.2%, 35.5%, 9.6%, 0.6% of patients had genito-urinary G0, G1, G2, G4 toxicity, respectively. Late toxicity and outcome were assessed in 129 patients (6 months minimum follow-up). Considering late toxicity, 3.1% and 0.8% of patients had gastro-intestinal G1 and G2 toxicity; 12.4%, 6.2% and 0.8% of patients had genito-urinary G1, G2, G3 toxicity, respectively. Clinical and biochemical progression prostate disease was observed in 2/129 of patients; currently, no evidence of prostate disease in 127/129 patients.

Conclusion: Longer time is needed to corroborate our encouraging early results in terms of toxicity, biochemical control rates, disease-free survival and overall survival. Our report shows that extremely hypofractionated IG-IMRT in localized PCa is feasible, safe and well tolerated with good PSA response and minimal toxicity.

⁴Herlev Hospital, Department of Oncology, Copenhagen, Denmark

⁵Odense University Hospital, Department of Oncology, Odense, Denmark

⁶Aalborg University Hospital, Department of Oncology, Aalborg, Denmark

Purpose or Objective: To describe disease control, the pattern of failure, laryngeal preservation, and survival in a large consecutive national cohort of patients with glottic squamous cell carcinomas (scc) treated with primary radiotherapy (RT) and salvage surgery over a period of 41 years.

Material and Methods: Patients diagnosed alive with a scc of the glottic larynx between 1971 and 2011 were included if curative treatment was started. Patients were identified from the DAHANCA database, and crosschecked with the National Cancer Registry. Missing information was obtained from hospitals records and the National Patient Registry.

Results: A total of 5001 patients were identified. 98% of patients had primary RT. The median follow-up was 9.1 years (patients alive) and 5.7 years (patients who died). 10 patients were lost to follow-up. 1511 failures were observed; hereof 93 %, 11 % and 5 % included T- and/or N- and/or M-site, respectively. 5-year incidence of local failure (LF) and loco-regional failure (LRF) was 26 % and 27%, respectively. From the 1970s to the 2000s the 5-year incidence of LF and LRF decreased significantly; 32% vs 19% and 34% vs 21%, respectively. Curative salvage was intended in 1088/1511 patients with failure, hereof 707 achieved ultimate control. In total, 980 patients had a laryngectomy, hereof 11 was primary treatment, 12 were caused by morbidity. The 5-year incidence of laryngectomy was 18%, decreasing from 26 % (1970s) to 10% (2000s). The 5-year incidence of ultimate failure was unchanged over time (range 13-16 %). 5-year estimates of laryngectomy free survival (LFS), Disease free survival(DFS) and Overall survival(OS) was 54%, 63% and 64%, respectively. LFS increased continuously, contrary to DFS and OS, which were stable in the 1970s-1990s but increased in the 2000s. LFS, DFS and OS were significantly higher in the 00s compared to the earlier decades.

Conclusion: As a result of a national strategy with primary RT, a continually improving disease control with concurrent decrease in laryngectomy, was observed in this non-selected national cohort of patients. All survival parameters were significantly better in the 2000s compared to the earlier decades.

OC-0450

Failure pattern and salvage treatment after radical treatment of head and neck cancer

A. Pagh¹, C. Grau², J. Overgaard¹

¹Aarhus University Hospital, Department of Experimental Clinical Oncology, Risskov, Denmark

²Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

Purpose or Objective: The aim of the study was to test the hypothesis that head and neck cancer (HNC) patients benefits from specialized follow-up (FU), as this strategy ensures timely detection of relapses for successful salvage treatment. This was done by evaluation of the pattern of failure, the temporal distribution of recurrences, and the outcome of salvage treatment in a contemporary cohort of HNC patients

Material and Methods: The study evaluated a population based cohort of 2,062 consecutive patients treated with curative intent from 1 January 2000 to 31 December 2013. The database of DAHANCA contained recordings of recurrent disease in 567 patients with primary tumors of the larynx, pharynx, oral and nasal cavity, para-nasal sinuses and salivary glands. A review of medical records was performed in order to update and supplement the database.

Results: Failures of the 567 patients were T-site failures (65%) followed by N-site (36%) and M-site (22%) failures. The vast majority of the first recurrence occurred within the first years after primary treatment; 62%, 82%, and 91% within the first, second and third year, respectively. Totally, 51% were amenable for salvage treatment, and 44% benefited from salvage in terms of a complete response. Permanent tumor control was observed in 128 patients (23%) after one or two salvage attempts. The highest salvage rate was recorded in patients with primary glottic carcinoma (41%) and the lowest among hypopharyngeal cancers (2%). Asymptomatic recurrence was recorded in 12% of all recurrences and this was found to be a positive prognostic factor for disease-specific survival, as they had significantly better outcome after salvage.

Conclusion: Our data support the usefulness of specialized FU in terms of early detection of recurrent disease. In particular patients with silent recurrences benefitted from early detection, as they had a significantly lower risk ratio of death from primary HNC.

Purpose or Objective: To investigate the impact of tumour volume, hypoxia and cancer stem cell (CSC) marker expression on outcome of patients with locally advanced head and neck squamous cell carcinoma (HNSCC) after primary radiochemotherapy.

Material and Methods: In this retrospective multicentre study, 160 patients with squamous cell carcinoma of the oral cavity, oropharynx and hypopharynx were included. All patients received primary cisplatin-based radiochemotherapy (RCT) between 2005 and 2011. Their median follow-up was about 26 months. Primary and nodal gross tumour volume (GTV) segmentations were performed centrally in the computer tomography-based radiation treatment plans. HPV status (p16 overexpression) and CD44 expression were analysed by immunohistochemistry. Gene expression analysis was performed for hypoxia-associated genes and the potential CSC marker SLC3A2. Results of the biomarker analyses, clinical parameters and tumour volume were correlated with the clinical outcome. Primary endpoint was loco-regional control (LRC). Secondary endpoints were distant metastases (DM) and overall survival (OS).

Results: In univariate analysis, tumour volume, HPV status and CSC marker expression were significantly associated with LRC (tumour volume: HR 1.51, p=0.02; HPV: HR 0.30, p=0.02; CD44: HR 2.30, p=0.04; SLC3A2: HR 2.08, p=0.01). Interestingly, hypoxia showed a significant association with LRC in small tumours only (HR 9.26, p=0.04). Multivariate Cox regression analysis including HPV status, tumour localisation, stage, smoking status, tumour volume and hypoxia or the respective CSC marker showed a significant effect of the tumour volume (HR: 1.6-1.8, p<0.01), SLC3A2 (HR 2.03, p=0.02) or CD44 (HR 2.52, p=0.04) on LRC. Tumour hypoxia also reached borderline significance in small tumours (HR 7.86, p=0.06). Interestingly, the tumour volume was an independent variable in all Cox models, a high tumour volume was significantly associated with poor LRC. Tumour volume and CSC marker expression also showed a negative prognostic impact on the secondary endpoints DM and OS.

Conclusion: We have shown that large tumour volume and high CSC marker expression correlate with poor LRC in patients with locally advanced HNSCC who received primary RCT. In small tumours, hypoxia also had a negative impact. After validation of these promising results in the ongoing prospective study of our study group, these biomarkers may help to further stratify patients for individualised treatment escalation or de-escalation strategies.

OC-0452

Prospective randomized adaptive dose-de-escalation in the elective neck: late toxicity and control

J. Schatteman¹, D. Nevens², S. Nuyts², D. Berwouts¹, W. De Gersem³, L. Olteanu³, T. Vercauteren³, W. De Neve³, F. Duprez³

¹Ghent University Hospital, Nuclear Medicine, Ghent, Belgium

²Leuven University Hospital, Radiotherapy, Leuven, Belgium

³Ghent University Hospital, Radiotherapy, Ghent, Belgium

Purpose or Objective: A multicentre prospective randomized phase II trial investigated whether a 3-phase adaptive IMRT-scheme using reduced volumes of elective neck could reduce toxicity without compromising disease control compared to standard non-adaptive IMRT. We report on disease control and toxicity at 6 and 12 months of follow-up.

Material and Methods: All patients were primarily treated with IMRT ± chemotherapy for head and neck squamous cell carcinoma with a 2 Gy-equivalent dose of 40 Gy to the elective neck. The dose to the high-risk volume was not reduced. In the adaptive de-escalation (AD) arm, elective neck volumes were reduced based on a lower theoretical risk of subclinical disease and replanning was done after 2 and 4 weeks. In the control (C) arm, IMRT without adaptations and with standard volumes of elective neck was performed. All statistics were performed using Fisher's exact test and Kaplan-Meier analysis (SPSS v. 23).

Results: Patients, tumor and treatment characteristics can be found in Table 1.

Before 1 year of follow-up, 12 patients deceased due to aspiration (n=1), tumor progression (n=8) or intercurrent disease (n=3).

At 6 months, we observed grade (G)≥2 dysphagia in 3% and 6% ($p = 1.0$), G≥2 xerostomia in 40% and 34% ($p = 0.81$) and G≥2 fibrosis in 6% and 6% ($p = 1.0$) in the AD- and C-arm, respectively. At 12 months, we observed grade G≥2 dysphagia in 17% and 3% ($p = 0.09$), G≥2 xerostomia in 43% and 28% ($p = 0.28$) and G≥2 fibrosis in 10% and 9% ($p = 1.0$) in the AD- and C-arm, respectively.

Local (LC), regional (RC) and distant control (DC) and overall survival (OS) for the whole group are given in Fig. 1. LC, RC, DC and OS were 86%, 84%, 82% and 74% in the AD-arm and 90%, 92%, 86% and 78% in the C-arm, respectively. All p -values were > 0.05 . Regional relapse was observed in 8 (AD) and 4 (C) patients: 5/12 were isolated regional relapses (3 in the AD- and 2 in the C-arm) of which 3/5 isolated relapses were seen in the initial GTV of a pathological lymph node, 1/5 in the irradiated elective neck in the C-arm and 1/5 in the AD-arm in a region of the neck that would have been irradiated in the C-arm; salvage neck dissection was successfully performed. Seven regional relapses were combined with local recurrence (n=3) or metastases (n=4).

	AD-arm (n=50)	C-arm (n=50)	p-value
Age (range; in years)	63,0 (38-84)	62,4 (38-83)	
Male/female	39/11	42/8	0.61
Site:			
- Oropharynx	24	25	0.56
- Hypopharynx	13	10	
- Larynx	10	14	
- Oral cavity	3	1	
HPV-status oropharynx			
- Negative	5	8	0.76
- Positive	4	5	
- Unknown	15	12	
T-staging			
- T1	1	3	0.55
- T2	16	12	
- T3	15	20	
- T4a	16	12	
- T4b	2	3	
N-staging			
- N0	11	11	0.58
- N1	2	6	
- N2a	0	1	
- N2b	16	16	
- N2c	19	15	
- N3	2	1	
Pre-IMRT neck dissection	5	5	
Concomitant systemic therapy			
- Cisplatin-based	30	29	1.00
- Cetuximab	29	27	
	1	2	

Conclusion: With a minimal follow-up of 1 year, no significant differences in RC, LC or DC or OS were observed between adaptive IMRT with reduced volumes of elective neck versus standard IMRT with non-reduced volumes, although 1 patient had an isolated regional recurrence in the non-treated elective neck. Unfortunately, the volume reduction and adaptive strategy did not result in a better late toxicity profile. We hypothesize that due to the large portion of patients with locoregionally advanced disease the treated neck volumes could not be sufficiently reduced in the whole group to achieve the desired gain in toxicity. Future analysis will now be started to elucidate this problem.

³University of North Carolina, Biostatistics, Chapel Hill, USA

⁴University of North Carolina, Medicine- Division of Hematology Oncology, Chapel Hill- NC, USA

⁵University of North Carolina, Otolaryngology/Head and Neck Surgery, Chapel Hill- NC, USA

⁶University of North Carolina, Pathology, Chapel Hill- NC, USA

⁷Rex UNC Healthcare, Radiation Oncology, Raleigh- NC, USA

Purpose or Objective: We performed a prospective multi-institutional phase II study of a substantial decrease in concurrent chemoradiotherapy (CRT) intensity as primary treatment for favorable risk, HPV-associated oropharyngeal squamous cell carcinoma (OPSCC).

Material and Methods: The major inclusion criteria were: 1) T0-T3, N0-N2c, M0, 2) HPV or p16 positive, and 3) minimal/remote smoking history. Treatment was limited to 60 Gy intensity modulated radiotherapy with concurrent weekly intravenous cisplatin (30 mg/m²). The primary study endpoint was pathologic complete response rate (pCR) based on required biopsy of the primary site and dissection of pretreatment positive lymph node regions, regardless of radiographic response. Power computations were performed for the null hypothesis that the pCR rate is 87% and N=40, resulting in a type I error of 14.2%. Secondary endpoint measures included physician reported toxicity (CTCAE), patient reported symptoms (PRO-CTCAE), quality of life

(EORTC QLQ-C30 & H&N35), and penetration aspiration scale (PAS) scores for modified barium swallow studies.

Results: The study population is 43 patients. The pCR rate was 86% (37/43). All 6 non-pCR cases were limited to microscopic foci of residual cancer: 1 primary site, 5 nodal. All patients are alive with no evidence of disease (median follow-up 21.3 months, range 4-41 months). Thirty-eight patients had a follow-up of at least one year. The incidence of acute CTCAE Grade 3/4 toxicity and PRO-CTCAE severe/very severe symptoms were: mucositis 34%/45%, pain 5%/48%, nausea 18%/52%, vomiting 5%/34%, dysphagia 39%/55%, and xerostomia 2%/75%. Grade 3/4 hematological toxicities were 11%. Mean pre and 6 month post CRT EORTC QOL scores were: Global 80/71 (lower worse), Pain (mouth, jaw, throat) 19/21 (higher worse), Swallowing 11/16, Coughing 17/26, Dry Mouth 16/68, and Sticky Saliva 6/49. Six months post CRT mean PRO-CTCAE scores for swallowing and dry mouth were mild and moderate, respectively. No patients reported their swallowing or dry mouth symptoms to be severe or very severe. 39% of patients required a feeding tube (none permanent) for a median of 15 weeks (5 - 22 weeks). There were no significant differences in PAS scores for thin, pureed, and solid foods before and after CRT.

Conclusion: Pathological CR rate with decreased intensity of therapy with 60 Gy of IMRT and weekly low-dose cisplatin is very high in favorable risk OPSCC with evidence of decreased toxicity compared to standard therapies. (ClinicalTrials.gov, NCT01530997)

OC-0454

Clinical outcome in nasopharyngeal carcinoma patients with post-radiation detectable plasma EBV DNA

J.C. Lin¹, W.Y. Wang², C.W. Twu³

¹Taichung Veterans General Hospital, Department of Radiation Oncology, Taichung, Taiwan

²Hung Kuang University, Department of Nursing, Taichung, Taiwan

³Taichung Veterans General Hospital, Department of Otorhinolaryngology, Taichung, Taiwan

Purpose or Objective: To investigate the long-term clinical behavior of nasopharyngeal carcinoma (NPC) patients with persistently detectable plasma EBV (pEBV) DNA after curative radiotherapy (RT) with/without chemotherapy.

Material and Methods: We screened 931 newly diagnosed NPC patients who finished curative RT and found 125 patients (13.4%) with detectable pEBV DNA one week after finishing RT. The clinical characteristics, treatment modality, subsequent failure patterns and survivals were analyzed.

Results: The levels of post-RT pEBV DNA for the studied population were in a very lower copy number (median 21, interquartile range 8-206 copies/mL). After a minimal follow-up of 52 months, the subsequent relapse rate was 64.8% (81/125) with distant failure predominantly and the median time to progression is 20 months for all 125 patients. Thirty-two of 39 (82.1%) patients with post-RT pEBV DNA ≥ 100 copies/ml developed tumor relapse later, whereas 57.0% (49/86) patients with post-RT pEBV DNA < 100 copies/ml had tumor relapse ($P=0.0065$). The 5-year rates of overall survival (OS) were 20.5% and 62.9% for the patients with post-RT viral load ≥ 100 and < 100 copies/mL (HR, 0.22; 95% CI, 0.12 to 0.38; $P<0.0001$). Patients who received adjuvant chemotherapy (AdjCT) with oral tegafur-uracil experienced significant reduction in distant failures (66.2% vs. 31.6%; $P=0.0001$) but similar locoregional recurrences ($P=0.234$). The 5-year OS rates were 69.4% for the patients who received AdjCT compared with 33.2% for those of without AdjCT (HR, 0.38; 95% CI, 0.24 to 0.61; $P<0.0001$).

Conclusion: NPC patients with persistently detectable pEBV DNA after finishing RT have a higher rate of treatment failure. Levels of the post-RT pEBV DNA and administration of AdjCT affect the final outcome. Future trial should consider

post-RT pEBV DNA levels as a stratification factor and investigate the role of AdjCT for the target population.

Development of activity pencil beam algorithm using nuclear reaction for innovative proton therapy

A. Nishio-Miyatake¹, T.N. Teiji Nishio²

¹Keen Medical Physics Corporation, Medical Physics Research, Yokohama, Japan

²Hiroshima University, Institute of Biomedical & Health Sciences, Hiroshima, Japan

Purpose or Objective: Proton therapy is a form of radiotherapy that can be concentrated on a tumor using a scanned or modulated Bragg peak. To use this radiotherapy efficiently in a clinical context, it is necessary to evaluate the clinical proton-irradiated volume accurately. Therefore, a beam ON-LINE PET system (BOLPs) has been developed for activity imaging of various positron emitter nuclei generated from each target nucleus by target nuclear fragment reactions with irradiated proton beam. The purpose of this study is to develop an activity pencil beam (APB) algorithm for a simulation system for proton activated positron-emitting imaging in proton therapy.

Material and Methods: The APB algorithm was developed as a calculation algorithm of the activity distributions formed by positron emitter nuclei generated from target nuclear fragment reactions. Depth activity data of ¹²C nuclei, ¹⁶O nuclei, and ⁴⁰Ca nuclei were measured with BOLPs after proton beam irradiation whose energies were 138, 179, and 223 MeV. Measurement time was about 5 h until the measured activity reached the background level.

Results: Data of measured depth activity distributions were prepared using the measured depth activity data. Activity pencil beam kernels needed for the APB algorithm were constructed using the data of measured depth activity distributions and calculations in lateral direction. Gaussian form was used for the lateral distribution data to take the effect of multiple Coulomb scattering into consideration.

Conclusion: A method of obtaining the depth activity distributions and the APB algorithm were developed. The simulation system with the APB algorithm can be used in clinical proton therapy.

⁷Politecnico di Milano, Dipartimento di Elettronica- Informazione e Bioingegneria, Milano, Italy

⁸Ion Beam Applications SA, Louvain-la-Neuve, Belgium

Purpose or Objective: To improve precision of particle therapy, in vivo range verification is highly desirable. Methods based on prompt gamma rays emitted during treatment seem promising but have not yet been applied clinically. Here we report on the translational implementation as well as the worldwide first clinical application of prompt gamma imaging (PGI) based range verification.

Material and Methods: Focused on the goal of translating a knife-edge shaped slit camera prototype into clinical operation, we first systematically addressed remaining challenges and questions. A robust energy calibration routine and corresponding quality assurance protocols were

developed. Furthermore, the positioning accuracy of the system was determined. The slit camera, intentionally developed for pencil beam scanning, was applied for double scattered (DS) proton beams. Systematic phantom experiments with increasing complexity have been performed.

In the next step, the knife-edge shaped slit camera was applied clinically to measure the spatial prompt gamma ray distribution during a proton treatment of a head and neck tumor for seven consecutive fractions. Inter-fractional variations of the prompt gamma profile were evaluated. For three fractions in-room control CTs were acquired and evaluated for dose relevant changes.

Results: In translational phantom experiments it was shown that proton range shifts can be visualized with the camera system for DS proton irradiation, proving its applicability under conditions of increased neutron background. Moreover, prompt gamma profiles for single iso-energy layers were extracted by synchronizing time resolved measurements to the rotation of the range modulator wheel of the DS treatment system. Furthermore, the position precision of the slit camera has been determined to provisionally be 1.1 mm (2σ).

With this preparatory work, the first clinical application of the PGI slit camera was successful. Based on the PGI information, inter-fractional global range variations were in the range of ± 2 mm for all evaluated fractions. The results of the iso-energy layer resolved prompt gamma profile analysis were in consistency with the sum profile analysis. Also the control CT based dose reconstruction revealed negligible range variations of about 1.5 mm. No influence of DVH parameters for target volume and organs at risk was found.

(a) Slit camera with trolley

(b) Slit camera during patient treatment

(c) PGI sum profiles measured during patient treatment and evaluated concerning inter-fractional variation

Conclusion: This work demonstrates for the first time that prompt gamma ray based range verification can be applied for clinical treatment of patients. Further plans include the continuation of the clinical study to perform systematic evaluations based on an appropriate patient number. With the translation from basic physics experiments into clinical operation, the authors are confident that a prompt-gamma ray based technology is capable of range verification and can be used in the near future for online quality assurance as well as in midterm for potential margin reduction.

OC-0457

Towards analytic dose calculation for MR guided particle beam therapy

H. Fuchs¹, P. Moser¹, M. Gröschl², D. Georg¹

¹Medical University of Vienna, Department of Radiation Oncology & Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

²Vienna University of Technology, Institute of Applied Physics, Vienna, Austria

Purpose or Objective: The importance of MRI steadily increases in radiation oncology not only as multimodality imaging device but also as an implemented online imaging

technology. Imaging using MRI shows advantages compared to CT or CBCT offering superior soft tissue contrast without additional dose. Also in particle beam therapy integrated MR guided treatment units have great potential. A complete understanding of the particle beam characteristics in the presence of magnetic fields is required. So far, studies in this area are limited.

Material and Methods: Protons (60-250MeV) and carbon ions (120-400MeV/u) in the clinically required energy range impinging on a phantom of 35x35x50cm³ size were simulated using the MC framework GATE 7. Homogeneous magnetic fields of 0.35T, 1T and 3T perpendicular to the initial beam axis were applied. The beam deflection, shape, and the energy spectrum at the Bragg peak area was analyzed. A numerical algorithm was developed for deflection curve generation solving the relativistic equations of motion taking into account the Lorentz force and particle energy loss. Additionally, dose variations on material boundaries induced by magnetic fields were investigated for 250MeV protons.

Results: Transverse deflections up to 99mm were observed for 250MeV protons at 3T. Deflections for lower field strengths (e.g. future hybrid open-MRI proton delivery systems) yielded 12mm for 0.35T and 34mm for 1T. A change in the dose distribution at the Bragg-peak region was observed for protons. Energy spectrum analysis showed an asymmetric lateral energy distribution. The different particle ranges resulted in a tilted dose distribution, see Fig.1. The numerical algorithm successfully modeled the deflection curve, with a maximum deviation of 1.8% and calculation times of less than 5ms. For a 250MeV proton beam passing in a 3T field through multiple slabs (water-air-water), only a 4% local dose increase at the first boundary was observed in single voxels due to the electron return effect.

Fig1: Deformed 2D dose distribution at the Bragg peak area for a 250MeV proton beam in a 3T field

Conclusion: Beam deflections in magnetic fields could be described by a numerical algorithm. The observed change in dose distribution in the Bragg-peak region has to be taken into account in future dose calculations. However, local dose changes due to boundary effects seem to be negligible for clinical applications. Current work in progress deals with the inclusion of magnetic field effects in a dose calculation algorithm for particles.

OC-0458

Delivery errors detectability with IQM, a system for real-time monitoring of radiotherapy treatments

L. Marrazzo¹, C. Arilli¹, M. Casati¹, S. Calusi², C. Talamonti^{1,2}, L. Fedeli², G. Simontacchi³, L. Livi^{2,3}, S. Pallotta^{1,2}

¹Azienda Ospedaliera Universitaria Careggi, Medical Physics Unit, Firenze, Italy

²University of Florence, Department of Biomedical-Experimental and Clinical Sciences 'Mario Serio', Florence, Italy

³Azienda Ospedaliera Universitaria Careggi, Radiation Therapy Unit, Firenze, Italy

Purpose or Objective: To test the ability of detecting small delivery errors of the Integral Quality Monitoring (IQM) device (iRT Systems GmbH, Koblenz, Germany), a system for online monitoring of Intensity Modulated Radiation Therapy (IMRT) treatments. To evaluate the correlation between the changes in the detector output signal induced by small delivery errors with other metrics, such as the γ passing rate and the DVH variations, which are commonly employed to quantify the deviations between calculated and actually delivered dose distributions.

Material and Methods: IQM consists of a large area ionization chamber, with a gradient in the electrode plate separation, to be mounted on the treatment head, and a calculation algorithm to predict the signal based on the data received from the treatment planning system. The output of the ionization chamber provides a spatially dependent signal for each beam segment. 5 types of errors were induced in clinical IMRT step and shoot plans for head and neck (H&N), prostate and index quadrant planned with Pinnacle (Philips) with an Elekta Precise linac (6 MV), by modifying the number of delivered MUs and by introducing small deviations in leaf positions. The obtained dose distributions, both 'error free' (EF) and 'error induced' (EI) were delivered with the IQM system and the signal variations were recorded. EF and EI dose distributions were also compared in terms of: 1) 3D γ passing rate calculated on the entire dose volume; 2) 2D γ passing rate calculated on planar beam-by-beam dose distributions; 3) DVH metric, by calculating the differences for several significant DVH parameters. The correlation between IQM signal variations and 3D γ , 2D γ and DVH parameters was investigated.

Results: IQM system resulted to be extremely sensitive in detecting small delivery errors. Variations in beam MU down to 1 are detected by the system as well as changes in field size and positions down to 1 mm. In Table 1 the variations in the IQM signal are reported as an example for an H&N plan.

Beam	Variations in IQM counts (%)				
	1MU/beam	2MUs/beam	3MUs/beam	1mm shift 1 MLC bank	1mm shift 2 MLC banks
1	1,5	2,6	3,4	2,5	4,3
2	1,0	2,1	3,0	3,1	5,8
3	1,0	2,2	3,0	2,5	5,2
4	1,3	2,1	2,8	3,1	5,3
5	1,6	2,1	2,8	3,0	6,0
6	1,4	2,0	3,0	2,6	5,1
7	1,4	2,2	3,5	2,8	5,3
Mean	1,3	2,2	3,1	2,8	5,3

Table 1. % variations in the IQM signal for each beam of an H&N plan for the 5 types of induced errors.

In Figure 1 the 2D γ per beam (1%/1mm, th10, local approach) and the PTV D95% and V95% are plotted vs the IQM signal variation for the same H&N example. A good correlation is observed thus suggesting that the IQM signal could be effectively used for quantifying delivery errors.

Figure 1. (a) γ passing rate per beam (%) (1%/1mm, th10, local approach) vs IQM counts variation (%) and (b) variation in PTV D95% and V95% vs average variation in IQM counts (%) for a H&N case

Conclusion: IQM is capable of detecting small delivery errors in MU and leaves position and it shows a sufficient sensitivity for clinical practice. It also exhibits a good correlation with other metrics used to quantify the deviations between calculated and actually delivered dose distributions. Such

correlations are useful in order to identify the alert threshold associated with this kind of monitoring systems.

OC-0459

Small fields output factors and correction factors determination for a linac with circular cones

A. Girardi¹, C. Fiandra¹, E. Gallio², F.R. Giglioli², R. Ragona¹

¹University of Torino, Department of Oncology- Radiation Oncology Unit, Torino, Italy

²Azienda Ospedaliero - Universitaria Città della Salute e della Scienza, Medical Physics Unit, Torino, Italy

Purpose or Objective: The use of small fields is a well-established practice in stereotactic radiosurgery, although it is hard to measure with accuracy the parameters for machine commissioning. This is related to the peculiarities of highly collimated beams, such as high dose gradient, source occlusion and lack of lateral electronic equilibrium, and to the features of the detector, like dimension of the active volume and components with high-Z materials. The first goal of this work was to determine small fields output factors (OF) with several active detectors and one passive detector (Gafchromic EBT3 films) for an Elekta Axesse medical linear accelerator equipped with circular cones. The second one was to determine the correction factors for different active detectors for comparison with passive detector, as suggested in a proposed small field dosimetry formalism. Radiochromic films do not require correction factors and can be then used as reference dosimeter, as demonstrated by Bassinet et al. (C. Bassinet et al., Med. Phys. 2013, 40(7): 071725).

Material and Methods: Small fields beams, ranging from 5 mm to 30 mm in diameter, were defined using circular cones. OF measurements were performed with six active detectors (ionizing microchambers air-filled: Exradin A26, Exradin A16; ionizing microchamber iso-octane-filled: PTW microLion; synthetic diamond: PTW microDiamond; plastic scintillator: Exradin W1; diode: Razor IBA) and one passive detector (Gafchromic EBT3 films).

Results: OFs measured with Exradin W1 scintillator were in excellent agreement with EBT3 films (better than 2%). A significant underestimation between the results obtained by radiochromic films and air-filled microchamber was observed, particularly for the smallest field, up to 12% for Exradin A16. The results obtained with the PTW microLion and the PTW microDiamond indicate instead an opposite behavior: a dose overestimation for the smaller radiation fields, up to 5% and 8% for the 5 mm-diameter field for microLion and microDiamond respectively was noted. The effect decreases with field size. Razor diode was in good accordance with Gafchromic films for very small fields (diameter \leq 10 mm), while a underestimation for larger fields has been observed. The results are shown in the following figures.

Diameter of circular field (mm)	Correction factors					
	Exradin A16	Exradin A26	PTW microLion	Exradin W1	PTW microDiamond	IBA Razor
5.0	1.118	1.037	0.951	0.986	0.923	0.961
7.5	1.048	1.029	0.967	0.997	0.944	0.991
10.0	1.036	1.031	0.975	0.996	0.971	1.022
12.5	1.030	1.028	0.985	0.995	0.986	1.036
15.0	1.024	1.027	0.988	0.996	0.993	1.041
20.0	1.021	1.025	0.992	0.998	1.001	1.044
25.0	1.015	1.022	0.991	1.001	1.002	1.040
30.0	1.011	1.018	0.990	1.003	1.001	1.037

Conclusion: The present study points out that it is crucial to apply the appropriate correction factors in order to provide accurate measurements in small beam geometry. The results show that the Exradin W1 scintillator can be used for small fields dosimetry without correction factors. The correction factors should be employed for the other detectors, in particular for field diameter smaller than 10 mm. The results furthermore demonstrate that effects such as volume averaging, perturbation and differences in material properties of the detectors should be taken into account in order to avoid large errors in the dose determination process.

OC-0460

Common errors in basic radiation dosimetry and radiotherapy practice

S. Kry¹, L. Dromgoole¹, P. Alvarez¹, J. Leif¹, A. Molineu¹, P. Taylor¹, D. Followill¹

¹UT MD Anderson Cancer Center Radiation Physics, Radiation Physics, Houston- TX, USA

Purpose or Objective: Dosimetric errors in radiotherapy dose delivery lead to suboptimal treatments and outcomes. Identification and resolution of such dosimetric errors in support of clinical trials is the mission of the Imaging and Radiation Oncology Core office in Houston (IROC Houston). The current study reviews the frequency and severity of dosimetric and programmatic errors identified by on-site audits performed by the IROC Houston QA center.

Material and Methods: IROC Houston on-site audits evaluate absolute beam calibration, relative dosimetry data compared to the treatment planning system calculations, and processes such as machine QA. These evaluations are conducted in a uniform manner. Audits conducted from 2000-present were reviewed, which included on-site evaluations of 1020 accelerators at 409 institutions. Suboptimal conditions that led to IROC Houston recommendations (absolute dose errors >3%, relative dosimetry errors >2%, or sizeable QA deficiencies) were identified, including type of recommendation and magnitude of error when applicable.

Results: A total of 1280 recommendations were made (average 3.1/institution) (Table). The most common recommendation was for inadequate QA procedures per TG-40 and/or TG-142 (82% of institutions) with the most commonly noted deficiency being x-ray and electron off-axis constancy versus gantry angle. Dosimetrically, the most common errors in relative dosimetry were in small-field output factors (59% of institutions), wedge factors (33% of institutions), off-axis factors (21% of institutions), and photon PDD (18% of institutions). Errors in calibration were also problematic: 20% of institutions had an error in electron beam calibration, 8% had an error in photon beam calibration, and 7% had an error in brachytherapy source calibration (Figure). Almost all types of data reviewed included errors up to 7% although 20 institutions had errors in excess of 10%, and 5 had errors in excess of 20%. The frequency of electron calibration errors decreased significantly with time, but all other errors show non-significant trends with time.

Recommendation	# Inst. Receiving rec.	% of Inst receiving rec	# Linacs receiving rec	% of Linacs receiving rec
QA	337	82.4	-	N/A
Small FS dependence	132	59.2	165	50.8
Wedge (FS or depth)	134	32.8	171	16.8
Off-axis factor	87	21.3	109	10.7
Electron calibration	83	20.3	105	10.3
Photon PDD	75	18.3	100	9.8
Update calibration	70	17.1	-	N/A
Electron PDD	47	11.5	57	5.6
Temp/press correction	44	10.8	-	N/A
IGRT coincidence	3	9.4	4	8.0
Beam symmetry	34	8.3	44	4.3

Conclusion: There are many common and often serious errors made during the establishment and maintenance of a radiotherapy program that can be identified through independent peer review. Physicists should be cautious, particularly in areas highlighted herein that show a tendency for errors.

Does the dosimetric advantage of prone setup persist in small-margin IMRT for gynecological cancer?

S.T. Heijkoop¹, G.H. Westerveld², N. Bijker², R. Feije¹, A.W. Sharfo¹, N. Van Wieringen², J.W.M. Mens¹, B.J.M. Heijmen¹, L.J.A. Stalpers², M.S. Hoogeman¹

¹Erasmus MC - Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

²Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: In order to reduce dose to the small bowel, some institutions treat patients with gynecological cancer in prone position using a small-bowel displacement device (belly board). This practice is based on dosimetric advantages found in the past for 3DCRT and/or the use of large margins. It is unknown to what extent those advantages are persistent using modern intensity-modulated delivery techniques (e.g. IMRT or VMAT) and adaptive treatment approaches with small CTV-to-PTV margins. The aim of this study is to determine the best patient setup position (prone or supine) in terms of OAR sparing for various CTV-to-PTV margins and modern dose delivery.

Material and Methods: In an IRB approved study, 26 patients with gynecological cancer scheduled for definitive (9) or postoperative (17) radiotherapy were scanned in prone and supine position at the same day. The primary CTV (proximal

part of the vagina and intact cervix-uterus or vaginal cuff with paravaginal soft tissue), nodal CTV, bladder, bowel cavity, and rectum were delineated on both scans. Nine PTVs were created, each with a different margin for the primary and nodal CTV (Table 1). Pareto optimal IMRT plans with 20 equi-angular beams to be delivered with dMLC were generated using our in-house system for automated treatment planning. Previously, we demonstrated that 20 beam IMRT is superior to dual arc VMAT. For all primary/nodal margin combinations supine and prone plans were compared considering OAR dose-volume parameters, giving highest priority to bowel cavity. P-values < 0.05 were considered significant. To determine the sensitivity of the dosimetric difference to the needed margin we not only compared supine to prone treatment plans with similar margins, but also compared supine to prone plans for which the supine plans had a smaller margin than for prone. In that way, we assessed the scenario that in prone position a larger margin around the nodal CTV is needed due to increased patient setup variations.

Results: Figure 1 illustrates the comparison between supine and prone position in terms of V45Gy of the bowel cavity for all patients and margins. Prone setup was significantly superior for large margins, but not for the three smallest margin combinations, i.e. 5/5mm, 5/7mm, and 10/5mm (primary/nodal margin around CTV). The rectum Dmean was significantly lower in prone setup: 2.9 Gy ± 0.4 averaged over all margins and patients, while the bladder Dmean was lower in supine setup: 2.5 Gy ± 0.3. The significant advantage for prone setup was not present if prone setup needed a larger margin than supine. In that case the V45Gy of the bowel cavity was on average 27 cc lower in supine setup.

Margin around primary CTV (mm)	Margin around nodal CTV (mm)
5	5
5	7
10	5
10	7
10	10
10	15
20	7
20	10
20	15

Table 1. Nine tested CTV-to-PTV margin combinations

Conclusion: The historically found dosimetric advantages for prone setup will persist if modern dose delivery techniques are used, combined with large margins. However, the advantage is lost for small margins and if prone setup needs a larger margin than supine setup.

OC-0462

Motion induced interplay effects for hypo-fractionated FFF VMAT treatment of liver tumours

A. Edvardsson¹, F. Nordström², C. Ceberg¹, S. Ceberg²

¹Department of Medical Radiation Physics, Lund University, Lund, Sweden

²Department of Oncology and Radiation Physics, Skåne University Hospital, Lund, Sweden

Purpose or Objective: The mutual movement of the tumour and treatment delivery during VMAT might cause hotspots and coldspots in the dose distribution, so-called interplay effects. These can be hard to predict and might be of great concern for hypo-fractionated VMAT treatments. The purpose of this study was (1) to develop a method to calculate the absorbed dose to moving tumours for VMAT treatments, (2) verify the proposed method by measurements, and (3) use the proposed method to investigate the dosimetric impact of interplay effects for hypo-fractionated FFF VMAT treatment of moving liver tumours.

Material and Methods: Treatment plans using 6 MV FFF VMAT (1400 MU/min) were created for three liver metastases (TrueBeam and Eclipse, Varian Medical Systems). The prescribed dose was 36 Gy in 3 fractions. The arcs were divided into sub-beams (one for every two control points) using an in-house developed software and the isocenter was shifted for every sub-beam to simulate sinusoidal motion in the superior-inferior direction. The sub-beams were calculated in Eclipse, generating a 4D dose distribution including effects of motion. For each treatment plan, combinations of three different motion amplitudes (5, 15 and 25 mm peak-to-peak) and periods (3, 5 and 7 s) were simulated. To separate the interplay effect from dose blurring, the original 3D dose distribution was convolved with the motion pattern and subtracted from the simulated 4D dose distribution, and the resulting D1%-D99% was calculated for the ITV. To verify the method, simulated treatment plans were delivered in developer mode to the Delta4 phantom positioned on Hexamotion (ScandiDos), which was either static or moving sinusoidally with a peak-to-peak distance of 15 mm and a period time of 5 seconds during irradiation. The measured and simulated dose distributions were compared using gamma analysis (2%/2 mm local dose, cut-off dose 10%) in the Delta4 software. To synchronize the isocenter shifts in the simulations with the motion during the measurements, kV images were acquired asynchronously during beam delivery.

Results: Gamma analysis show good agreement between the simulated 4D dose distribution and the dynamic measurement, comparable to the original 3D dose distribution and the static measurement (table 1). The impact of the interplay effects, expressed as D1%-D99%, varies considerably between targets as well as the combination of tumour amplitude and period time (figure 1), with a maximum difference in D1%-D99% compared to no motion of 2.8 Gy (target 2, 25 mm, 7s).

Table 1 Comparison of static and dynamic measurements with the 4D and original 3D calculated dose distributions, presented as average gamma pass rate [range] for criteria 2%/2mm local dose

	Gamma pass rate (%)
Static measurement vs 3D dose	99.4 [98.7 - 99.7]
Dynamic measurement vs 3D dose	76.5 [66.0 - 83.7]
Dynamic measurement vs 4D dose	99.7 [99.5 - 100.0]

Conclusion: A method to calculate the absorbed dose to moving tumours was developed and verified by measurements. Using this method, it was shown that large interplay effects may occur, with no obvious relation to the motion pattern. Therefore, caution should be taken before using FFF VMAT for moving liver tumours without using motion management techniques.

Figure 1 Difference in D1%-D99% compared to no motion ($\Delta D_{1\%}-D_{99\%}$) as a function of tumour amplitude and period time for three targets

OC-0463

Improving treatment plan quality of SBRT lung tumors using a new gradient index

E. Van der Bijl¹, M. Witte¹, C. Van Vliet-Vroegindeweyj¹, E. Damen¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: In order to assess treatment plan quality a good strategy is to compare plan quality indices for similar patients treated previously. For SBRT treatments the dose gradient is strongly associated with plan quality. Our objective is to introduce and show the merits of a gradient index for (lung) SBRT treatment plans that is, in contrast with existing indices, usable for multiple tumors and is readily interpretable.

Material and Methods: Our gradient index is defined as the relative dose-gradient averaged over the voxels in the first centimeter around the PTV. When a patient has multiple tumors, voxels closer to other tumors are excluded from the average, see inset of Fig. 1. For 100 tumors of lung SBRT patients treated in our clinic we calculated the proposed gradient index as well as other possible quality indices, such as conformity (ratio of volume receiving prescribed dose to volume of PTV) and inhomogeneity (ratio of max and prescribed dose). In addition, we listed geometric parameters such as volume, position in the lung, and distance to various OARs of the GTVs. We establish the mutual correlations of the plan quality indicators and dependencies on geometric factors. To test whether the suggested parameter indeed measures quality we select five low-scoring patients, including a patient with multiple tumors, and try to improve the treatment plans with respect to the suggested gradient index without compromising other constraints.

Results: For peripheral tumors the average relative dose-gradient in the first cm from the edge of the PTV is 5.6 ± 0.6 %/mm, shown in Fig. 1. It is independent of volume, position in the lung and does not correlate with the conformity index, in contrast to other gradient indices. For five low-scoring patients we could improve the dose-gradient on average by 0.5 %/mm without compromising target coverage and conformity. By increasing the gradient in the first centimeter around the PTV the average dose in most OARs was reduced, with an 8% reduction in average dose to the whole patient excluding PTV and an 6% reduction to average dose to healthy lung tissue.

Conclusion: We can improve treatment-plan quality for lung SBRT treatments by providing the planner with a quality parameter associated with the dose gradient around the PTV. This index does not depend on GTV volume and position and is suited to compare all patients treated for SBRT without making corrections for size and position of the tumor and is suitable for multiple tumors.

Integration of fMRI and MEG functional maps into a Cyberknife planning system: a feasibility study

E. De Martin¹, D. Duran², F. Ghielmetti¹, E. Visani², D.R. Sebastiano², D. Aquino³, M. Marchetti⁴, D. Cusumano⁵, M.G. Bruzzone³, F. Panzica², L. Fariselli⁴

¹Foundation Carlo Besta Neurological Institute IRCCS, Health Department, Milan, Italy

²Foundation Carlo Besta Neurological Institute IRCCS, Neurophysiology, Milan, Italy

³Foundation Carlo Besta Neurological Institute IRCCS, Neuroradiology, Milan, Italy

⁴Foundation Carlo Besta Neurological Institute IRCCS, Neurosurgery- Radiotherapy Unit, Milan, Italy

⁵University of Milan, Postgraduate School in Medical Physics, Milan, Italy

Purpose or Objective: In recent years Magnetoencephalography (MEG) and Functional Magnetic Resonance Imaging (fMRI) have imposed as non-invasive methods providing localization of eloquent brain areas for pre-surgical planning. With the advent of radiosurgery, the impact of these neuroimaging techniques in preventing neurological morbidity is under investigation in the clinical conditions for which radiotherapy is the treatment of choice. This study aimed to develop a method of integrating MEG and fMRI maps into a Cyberknife system to optimize dose planning.

Material and Methods: A patient with a recurrent brain metastasis affecting both the left pre-central and the post-central gyrus underwent functional imaging of the hand motor cortex two weeks prior its scheduled radiosurgery treatment. MEG data were acquired with a 306 sensors whole-head system while the patient performed self-paced motor activation of right hand and index finger. Epochs were extracted in the window ranging from - 3 to +3 seconds with

respect to the movement onset and then averaged. Source of the motor-related activity was assessed by means of swLORETA algorithm. A day after MEG acquisition, fMRI was performed using a 3T MR Philips Achieva scanner. Motor activation of right hand and index finger was obtained through a block designed paradigm. Stimulation modality and duration both for MEG and fMRI were chosen to maximize time course signal to noise ratio. Magnetoencephalography and fMRI maps were integrated into a Cyberknife system for treatment planning optimization, considering the boolean sum of activations as organ at risk.

Results: Localization of the hand motor cortex was obtained for both functional investigation methods within close proximity of the lesion.

Integration of the fMRI data into the Cyberknife system was easily achieved through the customary Cyberknife import protocol.

More problematic was the integration of the MEG images, and for the purpose a customized Dicom import software had to be developed.

Figure show the results of the MEG and fMRI functional areas implemented into the Cyberknife system: the fMRI area (indicated in yellow) and the MEG area (indicated in green) result partially overlapped.

Only small differences were observed between MEG and fMRI activation areas after image co-registration.

Inclusion of the activation area into the plan optimization process allowed a reduction of 19% of the mean dose to the motor cortex

Conclusion: Nowadays, the availability of advanced neuroimaging techniques is playing a more and more important role in radiosurgical planning strategy. The authors developed an effective method to co-register fMRI and MEG data sets in a Cyberknife treatment planning system.

This additional information can improve dose sparing of eloquent areas, and MEG information in particular might be valuable when BOLD effect is disturbed by pathological vascularization.

OC-0465

Quality of treatment plans in hybrid IMRT and VMAT for prostate radiotherapy

J. Bedford¹, G. Smyth¹, I. Hanson¹, A. Tree², D. Dearnaley², V. Hansen¹

¹The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, Sutton, United Kingdom

²The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Academic Radiotherapy Unit, Sutton, United Kingdom

Purpose or Objective: The strong directional characteristics of step-and-shoot IMRT beams, and the ability to turn off the beam between segments, may be used to advantage when avoiding critical structures. Consequently, there may be a benefit in delivering selected parts of VMAT plans using IMRT beams. This study investigates such a hybrid approach for the case of prostate radiotherapy.

Material and Methods: Five prostate patients were retrospectively studied. The AutoBeam treatment planning system produced hybrid IMRT / VMAT plans with a prescribed mean dose of 74 Gy in 37 fractions to the smallest of three target volumes, PTV74Gy, PTV71Gy and PTV60Gy. Inverse planning consisted of fluence optimisation using iterative least squares, sequencing, and aperture optimisation. The plans consisted of a single 220° arc with 111 segments arranged in groups of 20°. For each patient, five hybrid IMRT / VMAT plans were constructed, with 0%, 25%, 50%, 75% and 100% of the segment groups sequenced for IMRT, respectively, and the remainder of the segment groups sequenced for VMAT, maintaining the same number of beam segments in all cases. Thus, 0% IMRT corresponded to conventional VMAT and 100% IMRT corresponded to an 11-beam IMRT plan. IMRT groups were selected on the basis of fluence variation in each group, the most complex fluence maps being selected for IMRT delivery at the central gantry angle of the group. Treatment plans were evaluated in terms of PTV dose uniformity (root-mean-square variation) and coverage, critical structure dose, objective value and monitor units. All plans were then delivered as single hybrid beams to a water-equivalent phantom using an Elekta Synergy accelerator with Agility head, and the delivery time recorded. The dose measured using a Farmer ionisation chamber at the centre of the phantom within PTV74Gy was compared with the planned dose. Data were demonstrated by quantile-quantile plots to be normally distributed and compared to the 0% IMRT case using paired Student t-tests.

Results: All plans are clinically acceptable, but increasing the IMRT percentage improves PTV coverage ($p < 0.01$ for 50% or more), reduces the volume of rectum irradiated to 65 Gy ($p < 0.01$) and increases the monitor units ($p < 0.001$) (Table 1). Delivery time also increases substantially, which is clinically relevant due to prostate motion being partly dependent on treatment time. All plans show accurate delivery of dose.

Table 1. Mean \pm 1 SD statistics for the hybrid IMRT / VMAT plans

	PERCENTAGE IMRT IN HYBRID PLAN				
	0%	25%	50%	75%	100%
PTV74 uniformity (%)	2.2 \pm 0.2	2.1 \pm 0.2	1.8 \pm 0.2	1.4 \pm 0.1	1.3 \pm 0.1
PTV71 minimum dose (Gy)	65.2 \pm 0.7	65.8 \pm 0.4	66.0 \pm 0.2	66.1 \pm 0.5	66.1 \pm 0.5

Objective value	7.6 \pm 0.7	7.4 \pm 0.6	7.5 \pm 0.6	7.4 \pm 0.5	7.2 \pm 0.5
Total monitor units	345 \pm 15	378 \pm 14	391 \pm 16	404 \pm 13	410 \pm 12
Delivery time (s)	76 \pm 4	201 \pm 9	276 \pm 16	380 \pm 28	439 \pm 36
Measured - plan dose (%)	1.6 \pm 1.5	1.8 \pm 1.7	1.8 \pm 1.7	0.9 \pm 1.0	0.4 \pm 0.7

Conclusion: Hybrid IMRT / VMAT can be efficiently planned and delivered as a single beam sequence. Beyond 25% IMRT, the delivery time becomes unacceptably long, outweighing the benefit of the improved plan quality, but 25% IMRT is an attractive compromise. These hybrid plans can be accurately delivered.

³University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium

⁴Brainlab AG, R&D Radiosurgery, Munich, Germany

⁵Babes Bolyai University, Faculty of Physics, Cluj-Napoca, Romania

Purpose or Objective: Dynamic Wave Arc (DWA) is a clinical approach designed to maximize the versatility of Vero SBRT system by synchronizing the gantry-ring noncoplanar movement with D-MLC optimization. The purpose of this study was to verify the delivery accuracy of DWA approach for SBRT treatments and to evaluate the potential dosimetric benefits.

Material and Methods: A preclinical version of RayStation v4.7 (RaySearch Laboratories, Sweden) was used to create patient specific wave arc trajectories. DWA is an extended form of VMAT with a continuously varying ring position. The main difference in the optimization modules of VMAT and DWA is during the angular spacing, where the DWA algorithm does not consider the gantry spacing, but only the Euclidian norm of the ring and gantry angle that cannot exceed 4°. Thirty-one patients with various anatomical tumor regions were selected from the Vero patient database. It was decided to select some pathologies with a high incidence (prostate and oligometastases) and some more challenging cases from the perspective of organ-at-risk sparing i.e. centrally-located non-small cell lung cancer (NSCLC) tumors and locally-advanced pancreatic cancer (LAPC). DWA was benchmarked against the current clinical approaches and coplanar VMAT to establish the clinical importance of DWA among other treatment approaches. Each plan was evaluated with regards to the target coverage, dose to OAR, MU efficiency and treatment delivery time. The delivery accuracy was evaluated using the Delta4 2D diode array that takes in consideration the multi-dimensionality of DWA.

Results: For prostate and oligometastases, the results showed that all modalities provide comparable plan quality, with no significant difference for PTV coverage or OAR sparing, but with a steeper dose gradient outside the target for DWA. The delivery time per lesion was significantly reduced with DWA (Table 1). For centrally-located NSCLC (Figure 1), DWA and VMAT increased target coverage and conformity. The structures that significantly benefited from using DWA were proximal bronchus (Dmax 24.72Gy, 20.57Gy and 22.75Gy) and esophagus (16.6Gy, 12.57Gy and 14.76Gy) for 8-10CRT beams, DWA and VMAT, respectively. The other OARs presented comparable values. In the LAPC cases, DWA achieved similar PTV coverage, along with a significantly improved GTV coverage and improved low dose spillage ($p < 0.01$). The delivery time and the number of MU needed to deliver the dose were significantly lower for DWA versus IMRT. The DWA plans presented a good agreement between measured and calculated dose, with an mean γ (3%,3mm) passing rate of 98.17%, 98.72%, 99.2% and 98.1% for the prostate, oligometastatic cases, centrally-located NSCLC and LAPC, respectively.

Figure 1. Treatment delivery scenarios investigated along with the dose distribution in the axial plane. a) noncoplanar static beams b)DWA treatment using a template-based trajectory c) ^{CDR}VMAT denotes a coplanar arc solution with MLC filed shape modulation, but constant gantry speed and constant dose rate.

Table 2: Summary of the results of the target volume dose distribution and delivery parameters for all investigated scenarios. The data is presented as average values, standard deviations and p-test value

		CRT/IMRT	DWA	^{CDR} VMAT
Prostate n=3	Coverage PTV D _{95%}	0.99 ± 0.01	0.98 ± 0.03 (p<0.95)	0.98 ± 0.03 (p<0.90)
	Low dose spillage	3.99 ± 0.21	3.81 ± 0.22 (p<0.65)	4.08 ± 0.58 (p<0.49)

OC-0467
 Can a VMAT radiotherapy planning solution match brachytherapy in cervical cancers?
 E. Buck¹, J. Mcgrane¹, I. Fraser¹, N. Simpson¹
¹Royal Cornwall Hospitals Trust, Medical Physics, Truro, United Kingdom

Purpose or Objective: Radiotherapy treatment for cervical cancers typically involves external beam irradiation to the whole pelvis followed by an intra-uterine brachytherapy boost to the primary tumour site. The purpose of the current study was 1) to assess dose reduction to OARs using a VMAT treatment technique compared to a conformal four field brick and 2) whether VMAT using sequential or simultaneous integrated boost can provide coverage to the tumour and OARs similar to brachytherapy.

Material and Methods: Ten patients previously treated for cervical cancer were identified (age range 30-78 years). Four

plans were retrospectively produced for each patient (3D conformal four field brick, VMAT to the whole pelvis, VMAT boost, SIB) providing a phase one dose of 50.4Gy over 28 fractions. The sequential boost dose varied between patients from 16.5Gy-27.5Gy over 3-5 fractions. An averaged boost dose of 31Gy over 32 fractions, corrected using biological equivalent dose calculations was used for all SIB plans. All data was corrected to EQD2.

Figure1: Typical dose distribution for a VMAT with SIB plan.

Results: Results demonstrated significantly improved dose homogeneity between the VMAT and four field phase one techniques (p<0.01) but failed to find significant dose reductions to the bladder and rectum. Dose to the bowel was reduced at all dose points (p<0.01). Comparing the VMAT and brachytherapy boost, significantly increased doses to OARs were identified in the VMAT boost (bladder p<0.05; rectum p<0.01; bowel p<0.01). Dose homogeneity was decreased using an SIB compared to sequential but OAR doses were also decreased (p<0.05).

Table 1: Mean and standard deviation of OAR data contained within the SIB and VMAT phase one plus either boost or brachytherapy plan combinations.

Plan	Data-Point	Bladder		Rectum		Bowel	
		Mean/Gy	S.D./Gy	Mean/Gy	S.D./Gy	Mean/Gy	S.D./Gy
VMAT + VMAT boost	D _{2%}	81.03	10.16	80.14	9.55	84.46	9.11
	D _{10%}	70.87	11.94	69.92	16.31	74.03	11.42
	D _{50%}	54.40	17.16	54.79	16.28	59.01	11.48
	D _{95%}	55.38	9.03	58.25	10.30	54.00	6.96
VMAT + Brachytherapy	D _{2%}	79.79	7.88	67.03	4.99	70.29	7.07
	D _{10%}	67.18	5.74	57.45	7.73	62.80	4.05
	D _{50%}	45.14	18.50	37.30	20.31	55.23	2.57
	D _{95%}	32.32	21.69	36.09	23.80	51.80	2.47
SIB	D _{2%}	68.86	9.73	72.34	12.06	69.66	13.24
	D _{10%}	55.12	9.54	55.98	15.28	57.31	12.94
	D _{50%}	43.84	8.17	45.82	4.38	49.99	3.11
	D _{95%}	42.55	6.08	45.17	3.28	48.48	0.89

Conclusion: When treating cervical cancer, VMAT allowed significant improvement in dose homogeneity with overall reductions in doses to OARs. When comparing the feasibility of SIB or sequential EBRT boost instead of brachytherapy the SIB plan produced a better solution with respect to OAR doses. Whilst cervical surface doses with SIB to the high-risk CTV will not match brachytherapy a SIB may offer an alternative option for those patients who refuse/cannot access brachytherapy.

OC-0468
 Validation of Mask Based Registration in CBCT pretreatment imaging of locally advanced cervix ca
 L. Van den Berghe¹, K. Vandecasteele¹, A.L. Michiels¹, Y. Lievens¹, C. De Wagter¹, E. Bogaert¹
¹University Hospital Ghent, Radiotherapie, Ghent, Belgium

Purpose or Objective: Online CBCT pre-treatment registration (Elekta, XVI) for locally advanced cervix carcinoma (LACC) is performed by RTT's, using a cubic Clipbox-based Volume of Interest (C-VOI) algorithm. Consecutive manual adaptation in order to fulfill the predefined criteria for LACC-registration, implies large shifts. This is suboptimal regarding setup reproducibility, challenges PTV margins and strongly depends on RTT's experience. The objective is to determine whether the use of a Mask-based VOI (M-VOI) reduces the magnitude of manual shifts and thus is a better starting point.

Material and Methods: Seventeen consecutive image sets (1 representative patient) and 14 sets among them were registered by 2 RTT's and 1 experienced radiotherapist respectively, both using C-VOI and M-VOI methods (identical Gray Value T algorithm). The M-VOI was generated from the primary CTV which includes the uterus and cervix. Within predefined matching criteria, lymph node regions were not taken into account. Four 3D translations were recorded: after C-VOI and M-VOI autoregistration (AR) and after consecutive C-VOI and M-VOI manual registration (MR). Data was analyzed using SPSS software.

Results: M-VOI and C-VOI AR resulted in statistically significant different translations in all 3 directions (paired T-test $p < 0.01$). The manual shifts afterwards cancelled out the significance in all directions (ANOVA, pairwise comparison, Bonferroni corrected $p > 0.05$). All 3 readers converged towards each other. Nevertheless, values of maximal relative shifts between the readers stayed x: 0.47 cm, y: 1.06 cm, z: 1.33 cm and x: 0.76 cm, y: 0.68 cm, z: 1.28 cm after C-VOI and M-VOI MR respectively. Plotting the data stresses the importance of the level of experience in LACC-CBCT registration. Comparison of the vector endpoints of C-VOI and M-VOI MR, shows that the experienced reader is able to move the CBCT towards one and the same endpoint, whereas the less experienced readers produce more fanned out point-by-point clouds and tend to vary around the given solution (which stresses the importance of a good starting point). Analysis of the manual shifts (Δ) reveals a better performance of M-VOI AR, i.e. smaller shifts are applied. This means that criteria for a 'good' match are here inherently taken into account in a better way. Paired T-tests for the shifts either after C-VOI and M-VOI AR for high and low experience levels revealed significances in all groups and directions (see table).

Table: Analysis of manual shifts (Δ) after C-VOI and M-VOI AR for high and low experience levels

	$ \Delta \text{ after Clipbox} $ (cm)		$ \Delta \text{ after Mask} $ (cm)	p
Experienced Reader				
X (left-right)	0.15	>	0.03	0.043
Y (cranial-caudal)	-0.39	>	0.05	0.000
Z (ventral-dorsal)	0.92	>	0.15	0.000
Less Experience Readers				
X (left-right)	0.06	>	-0.03	0.001
Y (cranial-caudal)	-0.25	>	0.23	0.000
Z (ventral-dorsal)	0.94	>	0.14	0.000

Conclusion: M-VOI AR is a better starting point than C-VOI AR for pre-treatment CBCT registration of the tumor in LACC. In order to minimize the maximal relative shifts, registration experience should be high. To minimize inter- and intrareader variability, manual shifts after AR should be avoided. Therefore Dual Registration (XVI, Elekta®) combined with a written procedure will be the next step in the study.

OC-0469

Genitalia contouring in anal cancer IMRT; comparisons of volumes with and without a genitalia atlas

C. Brooks¹, V. Hansen¹, D. Tait²

¹The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, Sutton, United Kingdom

²The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Department of Clinical Oncology, Sutton, United Kingdom

Purpose or Objective: Genitalia as an organ-at-risk in radiotherapy has received little attention in literature. Contours vary widely and IMRT dose constraints in anal cancer (AC) often not met without compromising PTV. Despite IMRT technological advances genitalia toxicity still exists. Study aim: apply a proposed genitalia atlas to a retrospective series of AC patients and quantify the genitalia dosimetric differences between the original genitalia contour as defined by the clinician and the new genitalia contour defined with the aid of the genitalia atlas.

Material and Methods: Sixty AC patients (females $n=40$, males $n=20$) previously treated with IMRT were retrospectively identified. Four sub-groups were defined: female node negative (FNN) ($n=24$), female node positive (FNP) ($n=16$), male node negative (MNN) ($n=10$) and male node positive (MNP) ($n=10$). 'Node negative' and 'node positive' groups are defined as MRI tumour staged with involved nodes. Original genitalia contours for the retrospective treated plan were defined by the clinical oncologist and their interpretation of the departmental protocol. Genitalia were re-contoured following proposed genitalia contouring guidelines. DVH data and genitalia volume of original and new genitalia contours were compared. Statistical significance level of $P < 0.05^*$ and 0.01^{**} is reported.

Results: Table 1 shows the volume and dosimetric differences between original and new genitalia contours. New contours were significantly larger than original. F genitalia received more radiation than M genitalia. Patients with involved nodal disease received more genitalia irradiation than patients without nodal disease. The majority of genitalia contours failed to meet current genitalia dose constraints hence new achievable dose constraints are recommended (figure 1). Dose constraints are rounded to the

nearest whole number. The median DVH value of new genitalia contours denotes the optimal constraint and the 75th centile denotes the mandatory constraint. Horizontal lines represent current genitalia dose constraints. It can be observed that new recommended dose constraints contrast the current dose constraints highlighting the need for gender and tumour stage specific genitalia dose constraints.

Genitalia Volume Differences: Genitalia Contour (cm ³)										
	Original		New		Difference cm ³ /%					
All	80.1 (9.6-812.5)		122.2 (55.9-815.5)		102.1 / 127.5**					
F	54.4 (9.6-195.4)		123 (55.9-413.6)		68.6 / 126.1**					
M	255.8 (153.8-812.6)		399.8 (185.8-815.5)		144 / 56.3**					
Genitalia Dosimetric Differences										
SAMPLE	V20Gy (%)		V30Gy (%)		V40Gy (%)		V50Gy (%)		Mean Dose (Gy)	
	Original	New	Original	New	Original	New	Original	New	Original	New
All	69.6 (1.5-100)	**82.3 (19.7-100)	38.7 (0-100)	**43.7 (5-96.9)	19.4 (0-57.5)	16.8 (0-89.4)	5 (0-74.7)	4.4 (0-26.6)	26.8 (5.1-49.7)	27.7 (14.6-45.5)
FNN	79 (39.3-100)	85.4 (57-100)	32.8 (1.1-100)	38.4 (13.8-91.9)	9.9 (0-57.5)	9.3 (1.1-57.8)	0.2 (0-74.7)	2 (0-26.6)	27.4 (19.4-49.7)	28.2 (21.7-41)
FNP	95.4 (21.9-100)	94 (53-98.8)	71.5 (3.6-98.7)	72.2 (17-96.9)	33.1 (0-55)	24.9 (2-89.4)	3.6 (0-22.2)	4 (0-24.5)	36.7 (15.1-46.7)	34 (21.7-45.5)
MNN	32.3 (1.5-57.5)	**47.5 (19.7-64.3)	4.6 (0-19.2)	**15.1 (5-21.8)	0 (0-1)	*2.9 (0-10.7)	0 (0-2.7)	*0.8 (0-4.7)	15.7 (5.1-21.7)	*13.5 (15-29.9)
MNP	51.7 (17.1-93)	49.1 (35.2-92.9)	30.8 (2.1-81)	31.8 (13.7-76.1)	10.7 (0-66.5)	13.8 (2.4-60)	0.7 (0-10.8)	1.4 (0.4-11.1)	21.3 (8.3-40.3)	20.7 (14.6-38.6)

Conclusion: Dosimetric differences exist between genders and between patients with and without involved nodes when defining genitalia contours with aid of an atlas. Current generic set of genitalia dose constraints are inappropriate and gender/tumour stage specific constraints have been recommended.

OC-0470

Library of plans in radiotherapy of rectal cancer: feasible and inter-observer consistent?

S. Van Beek¹, L. Hartgring¹, A. Betgen¹, J. Stam¹, M. Buijs¹, B. Van Triest¹, P. Remeijer¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: The clinical target volume (CTV) in rectal cancer is subject to large deformations. These deformations result in large margins when a planning target volume (PTV) is constructed with a population based method. A preferred approach uses a library of plans (LoP) and is

expected to result in smaller PTV margins. A LoP requires a selection of the best fitting plan based on a Cone Beam CT (CBCT) scan. This triggers the questions: 'Is the visibility of the target volume sufficient for plan selection?' and 'Do the plan selection choices of Radiation Therapists (RTT) coincide?' The purpose of this study is to determine feasibility in plan selection for a LoP in radiotherapy of rectal cancer.

Material and Methods: Thirty rectal cancer patients were included in this retrospective study. All patients received a radiation dose of 25 Gy in 5 fractions of 5 Gy, with on-line position verification. Instructions for the patient on the planning-CT were: full bladder and empty rectum The CTV was defined on the planning-CT (pCT) and contained the mesorectum, presacral area, pelvic lymph node areas and gross tumor volume (GTV). From the this single CTV a library of CTVs was constructed with in-house built software using population statistics on daily rectal deformations. The library consisted of five plans: two larger, two smaller and the original plan, see figure. We performed a baseline measurement with 4 observers (all RTTs). The observers separately selected plans on 150 CBCT scans based on a priori set of instructions (Observer study I). The study was followed by multiple consensus meetings with an experienced radiation oncologist to discuss deviating choices and refine the instructions. A golden standard was determined for each scan. After 5 months the observers were asked to reevaluate the same set of scans based on the refined guidelines (Observer study II).

Results: Observer study I: The scan quality was determined to be sufficient for plan selection. In 69 % of the cases the observers were in accordance with the gold standard. 29 % of all selections deviated by 1 plan and 2% deviated by 2 plans. The consensus meeting revealed that inconsistency in choices arose from inadequate instructions. For instance, should an air pocket rather far from the GTV also be covered within the CTV? Instructions were clarified, and more specified. Observer study II: In 87% of the cases the observers were in accordance with the gold standard and 13% of all selections deviated by 1 plan.

Conclusion: The observer study showed a good consistency in selecting the plan that would fit best on the anatomy of that day, even given the suboptimal CBCT image quality. Clinically, the occasional selection of a plan that deviates by one from the gold standard is deemed acceptable by the radiation oncologist. Therefore, plan selection based on daily CBCT by RTT for rectum patients is feasible, albeit room for improvement remains.

OC-0471

Influence of rectum volume on fine-tuning of image registration in bladder adaptive radiotherapy

L.S. Sier-Wismeijer¹, L.J. Lutkenhaus¹, K.N. Goudschaal¹, M. Frank¹, M.C.C.M. Hulshof¹, A. Bel¹, N. Van Wieringen¹

¹Academic Medical Center, Radiotherapie, Amsterdam, The Netherlands

Purpose or Objective: In our department, bladder cancer patients with solitary muscle-invasive bladder tumor are standardly treated with adaptive radiotherapy treatment

(ART) to account for daily variations in bladder filling. Prior to each fraction, a conebeam CT (CBCT) is acquired and registered to the planning CT using a Chamfer algorithm (Elekta XVI 4.5). A dedicated RTT chooses the best fitting plan from a library of five plans. When none of the five plans fit the bladder volume, fine-tuning of the bony anatomy registration is performed (tweak), in order to optimize target coverage.

A tweak introduces an inter observer error and is a challenging time consuming part of the online CBCT registration workflow. We hypothesized that the rectum volume had a large influence on fine-tuning. The aim of this study was to investigate whether a significant correlation exists between rectum volume and performed tweak.

Material and Methods: Prior to treatment, the tumor was marked during cystoscopy with lipiodol or hydrogel. Two planning CTs were acquired: full bladder 100%; empty bladder 0%. A structure-based algorithm was used to create five different target volumes: 0%, 33%, 67%, 100%, and 133%, to create five different VMAT plans. The bladder and lymph nodes were treated to 40 Gy, the tumor up to 55 Gy, in 20 fractions using a simultaneously integrated boost. If none of the plans resulted in a good coverage of the bladder volume, the dedicated RTT had three options. The first two options were to instruct the patient to drink more and/or defecate: a 100% bladder filling is preferred. The third option was to perform a tweak.

A tweak should not exceed the PTV margins: 7 mm L-R (X), 8 mm C-C (Y) and A-P (Z) and is restricted by adequate coverage of the high dose area, visible through the lipiodol or hydrogel. This area is considered clinically more important compared to the elective lymph nodes.

189 CBCTs from 10 patients were analyzed. Bladder and rectum volumes from both CT and CBCT were recorded. The differences in rectum volume between CT and each CBCT were calculated, as well as the mean rectum volume (compared to the planning CT) and the vector length of the tweak (see figure 1). The correlation (R^2) between the rectum volume and the tweak vector was calculated.

Results: For fractions without a tweak the mean relative rectum volume was 99% compared to 79% for fractions in which a tweak was performed. The number of times each plan was chosen and the times a tweak was performed are shown in Table 1.

VMAT Plan	How many times chosen	Fine tuning performed	R^2
0% (empty bladder)	5	4	0.60
33%	38	14	0.10
67%	89	35	0.64
100% (full bladder)	42	17	0.37
133%	15	3	0.53
Total	189	73	

Conclusion: A significant correlation was found between the vector length of the tweak and rectum volume difference between full bladder CT and CBCT. Also tweaking was necessary less often when the rectum volume remained stable. Further research is necessary to identify a range of rectum volumes that will probably remain stable during the course of treatment.

OC-0472

Patient preference-driven plan optimisation for shared decision making in anal cancer radiotherapy

H.S. Rønde¹, J. Pløen², L. Wee¹, A.L. Appelt²

¹Vejle Hospital, Department of Medical Physics, Vejle, Denmark

²Vejle Hospital, Department of Oncology, Vejle, Denmark

Purpose or Objective: The traditional paradigm for inverse planning does not always deliver a Pareto-optimal dose distribution. In addition, trade-offs between different organs at risk are often necessary. In a clinical setting centered on shared decision making (SDM) between patients and their physicians, we suggest that individual preferences could be incorporated into plan selection based on a family of optimal plans. We present interim results from an efficient workflow for plan generation with trade-off selection, based on multi-criteria optimization (MCO).

Material and Methods: In this pilot study, dose plans were retrospectively generated for four representative anal cancer patients. All were treated with intensity-modulated radiotherapy with a standard regimen (60.2 Gy simultaneous-integrated tumor boost with 50.4 Gy to elective nodes, in 28 fractions, *high dose regimen*) and physician-defined organ-sparing priorities. In the first alternative plan generation, we optimized for minimum acceptable target volume coverage and same organ-sparing priorities, but assumed that the patient voluntarily foregoes the last three fractions of the standard regimen (tumor and nodal dose lowered by 6.45 Gy and 5.4 Gy, respectively, *low dose regimen*). Resulting changes in 2-year local tumor control probability were estimated using a model by Muirhead et al (Radiother Oncol 2015;116: 192-196). In the second round of alternative plan generation, we used MCO to search the phase space of optimal plans at the shorter regimen that would maximize sparing of the bowel at the expense of the bladder (*bowel sparing regimen*), and vice versa (*bladder sparing regimen*). In this way, we simulated the maximum span of dose distributions available for individualized patient preferences in regards to toxicity avoidance.

Results: Figure 1 demonstrates dose distributions for a single patient for the high dose, low dose, bowel sparing, and bladder sparing regimen. Dose metrics for bladder and bowel are shown in Table 1. All dose plans had clinically acceptable target coverage, and were deemed satisfactory by a senior oncologist. Considerable reduction of dose to the bowel was possible, not only by reduction in prescription dose ($\Delta V45Gy=289$ ccm) but also further by prioritization of bowel in the plan optimization ($\Delta V45Gy=308$ ccm). This resulted in bladder dose metrics no better than those for the high dose regimen. The reverse was seen for bladder sparing plans.

Overall, the possibility of sparing the bowel at the cost of extra dose to the bladder and vice versa was demonstrated. The estimated change in primary tumor control for high versus low dose regimen was less than 1% for early stage tumors and approximately 5% for late stage tumors.

Figure 1. Example dose distribution for a single patient in sagittal view for the high dose regimen (a), low dose regimen (b), bowel sparing regimen (c), and bladder sparing regimen (d). Dose color wash showing the two dose levels and the 45 Gy bowel dose constraint. Red: 57.19 Gy (95 % of 60.2 Gy). Yellow: 47.50 Gy (95 % of 50.4 Gy). Green: 45 Gy (bowel constraint). Orange: 51.06 Gy (95% of 53.75 Gy). Turquoise 42.75 Gy (95 % of 45 Gy).

Plans	Bladder [%]				Bowel [ccm]			
	Rel. diff [%]	V35Gy	Abs. diff [% points]	V50Gy	Rel. diff [%]	V30Gy	Abs. diff [ccm]	V45Gy
High vs. low	0.9	88.0	0.8	9.7	1.9	51.3	30.7	288.6
High vs. low, bladder sparing	27.3	91.3	19.8	10.3	-0.8	35.6	1.8	205.8
High vs. low, bowel sparing	-20.8	83.5	-6.1	8.8	8.0	54.4	86.4	308.1

Table 1. Relative and absolute mean differences for dose to the bladder and bowel for four patients (two men and two women). Dose metrics from the high dose regimen plans are compared to the low dose regimen, bowel sparing regimen and bladder sparing regimen, respectively.

Conclusion: There is room in the optimization space for incorporation of patient outcome and toxicity preferences. This opens for SDM for anal cancer patients. The study is to be expanded, with results for a total of 22 patients to be presented at ESTRO 2016.

²Inserm U1099- University of Rennes 1, LTSI, Rennes, France

³Centre Hospitalo-Universitaire Pontchaillou, Urology, Rennes, France

⁴Centre Eugène Marquis, Radiology, Rennes, France

Purpose or Objective: To explore the ability of quantitative prostate T2-weighted (T2-w) and apparent diffusion coefficient maps (ADC) MRI using Haralick texture features: i) to differentiate prostate cancer (PC) from healthy tissues; ii) to be correlated with Gleason score; iii) to predict biochemical recurrence after external beam radiotherapy (RT) for prostate cancer.

Material and Methods: Tumor and prostate zones were segmented on co-registered T2-w and ADC on two pre-

treatment 3.0T MRI from 83 patients with a median age 67 years (range 50-82 years) and a median pre-treatment PSA of 9.8 ng/ml (range 3.4-48.0 ng/ml). 9 (11%) tumors were localized in the transitional zone (TZ) and 74 (89%) in the peripheral zone (PZ). Tumors were clinically staged as follows: 13% of T1, 46% of T2 and 41% of T3. Gleason scores were as follows: 6 (27%), 7 (51%), 8 (20%) and 9 (2%). They were 2% of low-risk, 33% of intermediate-risk and 65% of high-risk tumors according to D'Amico risk group classification. Almost all patients received standard treatment consisting in IMRT (100%) with IGRT (94%) associated with hormonal therapy in 53% of the patients. After a median follow-up of 47 months (range 19-65 months), 11 patients had biochemical recurrence. A total of 114 grey-level features (first order, gradient-based and second order Haralick texture characteristics) and 4 geometrical features (maximal tumor diameter, maximal tumor perimeter, maximal tumor area and tumor volume) were extracted on normalized T2-w and ADC and were analyzed. Statistical analyses were performed using Wilcoxon signed-rank test, Spearman's correlation coefficient, Harrell's C-index, Kaplan-Meier curves and univariate Cox regression analysis.

Results: i) 56 out of 57 T2-w and 46 out of 57 ADC grey-level features were significantly different between tumor and prostate tissues in the PZ and 25 out of 57 T2-w and 37 out of 57 ADC features in the TZ (p<0.05). ii) 5 T2-w features and 4 ADC features were significantly correlated with Gleason score, all were Haralick texture features. iii) T2-w features that significantly predicted (p<0.05) biochemical recurrence were: maximal tumor diameter/perimeter/area/volume, Kirsch gradient operator, normalized mean and standard deviation of signal intensity and 8 Haralick texture features (Difference Variance, Contrast, Inverse Difference Moment, Difference Entropy, Information Measure of Correlation, Sum Average, Sum Variance and Sum of Squares). Only normalized mean value on ADC was significantly predictive of biochemical recurrence.

Conclusion: Quantitative analysis using Haralick texture characteristics on T2-w MRI are good features: i) to differentiate prostate cancer from healthy tissues, ii) for Gleason score assessment and iii) to predict biochemical recurrence after RT. Geometrical characteristics extracted from T2-w are also good predictors of biochemical recurrence after RT.

PV-0474

Comparison of DCE MRI and FMISO-PET kinetic parameters in head and neck cancer patients

⁴University Hospital Tübingen, Department of Radiation Oncology, Tübingen, Germany

⁵University Hospital Tübingen, Department of Diagnostic and Interventional Radiology, Tübingen, Germany

Purpose or Objective: Tumour hypoxia is associated with poor response to radiotherapy. Comprehensive hypoxia assessment through [18F]-fluoromisonidazole (FMISO) PET imaging requires quantitative techniques, such as dynamic acquisition. However, dynamic FMISO PET protocols might be simplified by using DCE-MRI imaging in addition to static FMISO-PET. The aim of this work was to compare FMISO and DCE-MRI kinetic parameters by means of correlation analysis.

Material and Methods: This study was done on N=6 head and neck cancer patients, who were imaged dynamically with FMISO-PET and DCE-MRI on the same day. Images were registered and analyzed for kinetics on a voxel basis. FMISO-

PET images were analyzed with a two-tissue compartment three-rate constant model with an additional vasculature compartment. Consequently, the model had the following parameters: K_1 - FMISO transport rate to the tissue, k_2 - FMISO backflow parameter, k_3 - rate of FMISO binding in the cells, and V_b - vasculature fraction in the tissue. DCE-MRI images were analyzed with the extended Tofts model with the following parameters: K^{trans} - contrast agent transport rate to the tissue, v_e - relative volume of the tissue, and v_p - vasculature fraction in the tissue. Voxel-wise Pearson correlation coefficients were evaluated on pairs of parametric images for each patient over the tumour volume including lymph nodes and tumour bed, if present. FMISO kinetic parameters were modelled with multivariate linear models of DCE-MRI parameters. The relative likelihood of the models was evaluated using the Akaike information criterion.

Results: Correlations between FMISO and DCE-MRI kinetic parameters, median over all the patients, varied across the parameter pairs from -0.12 to 0.71, with the highest correlation coefficient of 0.71 for V_b - v_p pair, while K_1 - K^{trans} correlation was 0.46. Correlations between FMISO and DCE-MRI kinetic parameters varied also across the patients. Among various multivariate models for FMISO parameters, those with more DCE-MRI parameters were more likely. Table 1 shows the correlation matrix for FMISO and DCE-MRI kinetic parameters with the median over all the patients in the lower-left and minimum/maximum in the upper-right triangle.

Table 1: Correlation matrix for FMISO and DCE-MRI kinetic parameters.

	FMISO				Tofts			
	K_1	k_2	k_3	V_b	K^{trans}	v_e	v_p	
FMISO	K_1	1	0.80	-0.39	-0.08	0.27	-0.40	0.14
	k_2	0.92	1	-0.35	0.06	0.26	-0.40	0.29
	k_3	-0.12	-0.16	1	-0.21	0.51	0.33	0.60
	V_b	0.18	0.3	0.02	1	-0.27	-0.20	-0.16
Tofts	K^{trans}	0.46	0.39	0.13	0.15	1	-0.06	0.34
	v_e	0.09	-0.06	-0.04	-0.12	0.42	1	-0.30
	v_p	0.42	0.5	0.02	0.71	0.58	0.15	1

Figure 1 shows K_1 and K^{trans} parametric images for the case with low K_1 - K^{trans} correlation. Additional DCE-MRI kinetic analysis for this case, using the tissue homogeneity model revealed that tumour and tumour bed had different K^{trans} because of considerably different permeability surface area product.

Figure 1: K_1 and K^{trans} parametric images for the case with low K_1 - K^{trans} correlation.

Conclusion: Vasculature fractions from DCE-MRI and FMISO-PET are interchangeable up to a scaling factor. Transport rates from DCE-MRI and FMISO-PET can be different; FMISO K_1 measures blood flow, whereas the DCE-MRI K^{trans} can be notably affected by the blood vessel permeability. Information from any single FMISO kinetic parameter is spread over multiple DCE-MRI parameters.

PV-0475

Probability map prediction of relapse areas in glioblastoma patients using multi-parametric MR

⁶Institut National de la Santé et de la Recherche Médicale, UMR 825, Toulouse, France

Purpose or Objective: Despite post-operative radiotherapy (RT) of glioblastoma (GBM), local tumor re-growths occur in irradiated areas and are responsible for poor outcome. Identification of sites with high probability of recurrence is a promising way to define new target volumes for dose escalation in RT treatments. This study aims at assessing the value of multi-parametric magnetic resonance (mp-MR) data acquired before RT treatment in the identification of regions at risk of relapse.

Material and Methods: Ten newly diagnosed GBM patients included in a clinical trial, treated in the reference arm of 60 Gy plus TMZ, underwent magnetic resonance imaging (MRI) and MR spectroscopy (MRSI) before RT treatment and every 2 months until relapse. The site of relapse was considered as the new appearing contrast-enhancing (CE) areas on T1-weighted images after gadolinium injection (T1-Gd). Using a set of mp-MR data acquired before RT treatment as input, a supervised learning system based on support vector machines (SVM) was trained to generate a probability map of CE appearance of GBM. More specifically, T1-Gd and FLAIR image intensities, Choline-over-NAA, Choline-over-Creatine and Lac-over-NAA metabolite ratios, and metabolite heights were used. The resolution of the MRI images was lowered to the one of the MRSI grid by averaging MRI pixel intensities within each MRSI voxel (400 MRSI voxels were considered for each subject). The region of CE was manually contoured on both the pre-RT and post-RT T1-Gd images by experienced medical staff. All voxels that enhanced at the pre-RT exam were excluded from further consideration. The learning system was trained and tested using leave-one-out-cross-validation (LOOCV) with all the patients. A grid-search strategy was employed for parameter optimization.

Results: For comparison purposes, generated probability maps were thresholded with a value of 0.5. Thus, only voxels with values higher than 0.5 on the probability map were considered as relapse. The sensitivity and specificity of the proposed system were 0.80 (± 0.19) and 0.87 (± 0.09), respectively. For our data, standard Choline-to-NAA index (CNI) achieved a sensitivity of 0.62 (± 0.25) and a specificity of 0.63 (± 0.13) (an optimal CNI threshold was derived for all the patients). The receiver operating characteristic (ROC) curve also shows that the presented approach outperforms CNI (Fig 1.). In addition, the SVM-based results had lower variation across patients than CNI. An example of a probability map generated by the proposed approach is shown in Fig.2. Relapse areas predicted by the learning scheme are in high accordance with the manually contoured regions.

Figure 1 Receiver operating characteristic (ROC) curve for the proposed method (blue) and for the standard CNI approach (red).

Figure 2 Pre-RT T1-Gd (top), probability maps of GBM relapse generated by the proposed approach (middle) and reference manual contours of the relapse for a given patient (bottom). Each slice represents a slice in the axial view. Dark blue on the probability maps indicate voxels where metabolic information was not available. The areas at risk of relapse predicted by the proposed approach (using MR data acquired before RT) are in clear accordance with the manually contoured relapse regions.

Conclusion: A learning system based on SVM trained with mp-MR data has been presented. Reported results show that this learning scheme can provide a probability map of the area of relapse of GBM in a stable and accurate manner. This study suggests the potential of mp-MR data in addressing specific questions in GBM imaging.

Fractional anisotropy dose-response relationship of the corpus callosum

N. Pettersson¹, H. Bartsch², J. Brewer², L. Cervino¹, M. Connor¹, A. Dale², D. Hagler², R. Karunamuni¹, A. Krishnan², J. Kuperman², C. McDonald³, N. Farid², N. White², J. Hattangadi-Gluth¹, V. Moiseenko¹

¹University of California San Diego, Radiation Medicine and Applied Sciences, La Jolla, USA

²University of California San Diego, Radiology, La Jolla, USA

³University of California San Diego, Psychiatry, La Jolla, USA

Purpose or Objective: Diffusion tensor magnetic resonance imaging (DTI) is a non-invasive modality for determination of water diffusion properties. Fractional anisotropy (FA) quantifies the extent of directionality of water diffusion. We investigated absorbed dose as a predictor of FA change in the corpus callosum (CC) following radiation therapy for high-grade glioma.

Material and Methods: Fifteen patients with high-grade glioma underwent DTI scans before, and ten months after radiation therapy to 59.4-60 Gy. Diffusion data were acquired on a 3T MRI scanner. Using an automated white matter fiber tracking technique, 23 fiber tracts were segmented on the baseline and follow-up DTI images. The CT images used for treatment planning and both DTI image sets were aligned using non-linear registration. This way, the baseline FA, the follow-up FA, and the absorbed dose could be determined for each voxel in all 15 patients. For each voxel in the CC, we calculated the FA change as $FA_{\text{follow-up}} / FA_{\text{baseline}}$ and dichotomized the data into a binary outcome variable using 0.5 as cutoff. For all 15 patients, logistic regression was used to determine dose-response curve parameters (D_{50} and γ_{50}) and their confidence intervals (CIs). We used the area under the receiver-operating characteristics curve (AUC) to evaluate the discriminative ability of the voxel dose. Then, we estimated dose-response curve parameters and calculated the AUC for each patient individually.

Results: The median age was 59 (range: 40-85) years. The average CC volume and average CC mean absorbed dose was 62 ± 8 cm³ and 26 ± 14 Gy (1 SD), respectively. Using data from 99 691 voxels, the estimated parameters for the dose-response curve for all patients (upper panel in Figure 1) were $D_{50} = 88.0 \pm 0.1$ Gy and $\gamma_{50} = 0.80 \pm 0.01$ (95% CIs). The AUC was 0.71 indicating good discriminative ability. For nine out of 15

patients, the individual AUC was ≥ 0.60 , indicating that higher absorbed dose is associated with higher probability of FA change ≥ 0.5 . Dose-response curves for those patients are shown in the lower panel in Figure 1 and their estimated parameter values in Table 1. Individual D_{50} s varied between 41.3 and 125.9 Gy.

Table 1. Fractional anisotropy and absorbed dose data for the corpus callosum. For patients with an AUC ≥ 0.6 , dose-response curve parameters and their 95% confidence intervals are given.

patient id	# voxels changed ≥ 0.5	# of voxels	median voxel dose (range) (Gy)	AUC	D_{50} (Gy)	γ_{50}
All 15	11448	99691	21.5 (0.5-65.9)	0.71	88.0±0.1	0.80±0.01
1	279	7037	3.0 (0.6-20.1)	0.13		
2	168	6428	8.5 (0.7-64.4)	0.49		
3	1159	6417	38.7 (2.5-65.9)	0.69	79.2±0.5	0.80±0.05
4	277	8088	23.0 (4.7-64.2)	0.57

11	749	8149	35.5 (2.0-63.9)	0.77	81.1±0.5	1.26±0.07
12	1299	6501	37.8 (5.9-63.1)	0.59		
13	1108	6946	11.2 (1.3-63.0)	0.85	46.0±0.3	0.90±0.04
14	1017	7765	60.9 (7.9-63.1)	0.68	69.1±1.8	3.24±0.42
15	1900	5091	25.1 (6.8-42.8)	0.59		

AUC: the area under the receiver-operating characteristics curve; D_{50} : absorbed dose required for 50% probability; γ_{50} : the normalised dose-response gradient.

Probability of change in fractional anisotropy ten months after radiation therapy

Conclusion: Absorbed dose was a significant predictor of FA change in the CC. This was the case both when all patients were pooled for analysis, and in nine out of 15 patients when analyzed separately. More detailed analyses are needed to better understand the effect radiation has on water diffusion in brain white matter.

PV-0477

Early CT image biomarkers change and xerostomia score are strong predictors for late xerostomia

L.V. Van Dijk¹, C.L. Brouwer¹, R.J. Beukinga¹, A. Van de Schaaf¹, H.P. Van der Laan¹, H.G.M. Burgerhof², J.A. Langendijk¹, R.J.H.M. Steenbakkers¹, N.M. Sijtsema¹

¹University of Groningen- University Medical Center Groningen, Radiation oncology, Groningen, The Netherlands

²University of Groningen- University Medical Center Groningen, Epidemiology, Groningen, The Netherlands

Purpose or Objective: Radiation induced xerostomia is related to the dose given to the parotid glands (PG).

Nevertheless, substantial unexplained variability remains in the development of late xerostomia. To understand this variation becomes increasingly important with the advent of more conformal radiation techniques. Our hypothesis is that the patient-specific late response to radiotherapy (RT) is associated with changes in CT images and xerostomia scores early after RT.

Material and Methods: Parotid gland (PG) image characteristics were extracted from CTs before (T0) and after RT (6 weeks post RT) of 110 HNC patients. The differences between those two time points resulted in potential Δ CT Image Biomarkers (IBMs). These potential Δ CT IBMs represent geometric (20) and CT intensity (24) changes of the PG. Furthermore, the scored xerostomia of the patients before (XER_{baseline}) and 6 weeks post RT (XER_{6w_post}), tumour, patient and dose characteristics were included. To identify variables that were associated with the endpoint moderate-to-severe xerostomia 12 months after RT (XER_{12m}) whilst reducing multicollinearity, variables were first omitted based on inter-variables correlation. Second, multivariable selection was conducted by bootstrapped forward selection based on log-likelihood performance. The performance of the resulting logistic regression models was evaluated with the area under the ROC-curve (AUC) and Nagelkerke R² index. All models were internally cross validated.

Results: Multivariable analysis was performed with 23 Δ CT IBMs. The primarily selected IBM was Δ volume (between T0 and 6 weeks post RT) of the PG (figure) ($p < 0.001$). Larger volume change was related to a higher chance of XER_{12m}. Furthermore, the XER_{6w_post} and XER_{baseline} were very prognostic. The performance of the multivariable model was high with an AUC of 0.89 and R² of 0.54 (table). This model showed to be stable when it was internally validated (AUC-cross=0.88, R²-cross=0.53). Moreover, dose parameters did not add to the performance of the model (AUC-cross=0.88, R²-cross=0.52). Δ Volume made dose parameters redundant, suggesting that PG volume changes are related to the patient-specific response to dose.

Table. Model performance measures

	Baseline model		Post RT model	
	PG dose + XER _{baseline}	XER _{6w after RT} + XER _{baseline}	XER _{6w after RT} + XER _{baseline} + Δ volume	XER _{6w after RT} + XER _{baseline} + Δ volume
2 log-likelihood	111.47	99.55	81.72	81.72
Nagelkerke R ²	0.27	0.47	0.54	0.54
Discrimination Slope	0.20	0.38	0.45	0.45
AUC (95% CI)	0.76 (0.66-0.85)	0.83(0.75-0.91)	0.89 (0.82-0.95)	0.89 (0.82-0.95)
AUC-cross validation	0.74	0.83	0.88	0.88
R ² - cross validation	0.25	0.47	0.53	0.53

XER_i: Patient rated xerostomia at different time points;

PG dose: Planned mean dose to contra lateral parotid gland;

Δ volume: PG volume change from baseline (T0) to 6 weeks post RT

Conclusion: Change of PG volume 6 weeks post RT showed to be strongly related to late xerostomia. Moreover, together with xerostomia scores before and 6 weeks after RT, outstanding performance was obtained to predict XER_{12m}. We believe that this model can contribute to the understanding of the patient-specific response to RT in developing late xerostomia. Secondly, it can serve as a quantitative measure for late damage to the PG early after treatment. The next step will be to investigate whether Δ PG Volume and xerostomia determined early in treatment can be used to predict late xerostomia, to select patients with a large risk on late xerostomia for proton treatment.

Figure. Examples of PGs with large Δ volume between the start of (green) and 6 weeks after (red) RT

PV-0478

Predicting pulmonary function loss in lung cancer radiotherapy patients using CT ventilation imaging
C. Brink^{1,2}, J. Kipritidis³, K.R. Jensen¹, T. Schytte⁴, O. Hansen^{2,4}, U. Bernchou^{1,2}

¹Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

²University of Southern Denmark, Institute of Clinical Research, Odense, Denmark

³The University of Sydney, Radiation Physics Laboratory, Sydney, Australia

⁴Odense University Hospital, Department of Oncology, Odense, Denmark

Purpose or Objective: Pulmonary complications remain a major dose limiting factor for lung cancer radiotherapy. Pulmonary function loss is known to correlate with physical lung dose, but better prediction accuracy is desired. This work investigates the potential of 4D CT-based functional imaging to improve the prediction of radiation-induced pulmonary function loss.

Material and Methods: 80 lung cancer patients each received a treatment planning 4D CT scan prior to radiotherapy. To quantify pulmonary functional loss the patients also underwent spirometry measurements of forced expiratory volume (FEV1) and forced vital capacity (FVC) immediately before radiotherapy and at 3, 6, and 9 months follow-up. For each patient, the pre-treatment regional ventilation was evaluated by performing deformable image registration (DIR) between the CT inhale and exhale phase images. The Jacobian determinant (J-1) of the DIR motion field was used as a ventilation surrogate. The functional mean lung dose (fMLD) was then defined as the regional lung dose weighted spatially by the regional ventilation. The physical mean lung dose (MLD) was calculated without ventilation weighting. Logistic regression was used to compare the ability of fMLD and MLD to predict clinical pulmonary function loss, defined as a reduction of the FEV1 and FVC to less than 90% of their initial values at 6-months post treatment. To minimise noise in the spirometry data, the FEV1 and FVC values at 6 months were estimated based on a fit to the available data up to 9 months post-treatment.

Results: Both functional and physical lung dose correlated with the onset of clinical pulmonary function loss. The figure and table show the logistic regression results and model parameters respectively. We observed a 0.7 Gy decrease in the tolerance dose (D50) when using fMLD as opposed to MLD. However, the difference in log-likelihood between the MLD and fMLD based models was not statistically significant different from zero. Thus we did not observe a significant

improvement in the prediction of pulmonary function loss using fMLD as opposed to MLD.

Lung function (95% conf. interval)	Physical dose		Functional Dose	
	D ₅₀ (Gy)	V ₅₀	D ₅₀ (Gy)	V ₅₀
FVC	20.5 (17.7-26.6)	1.01 (0.59-1.60)	19.8 (16.5-27.2)	0.83 (0.46-1.32)
FEV1	19.1 (14.5-35.3)	0.55 (0.14-1.06)	17.8 (13.5-30.7)	0.51 (0.18-0.89)

Conclusion: Reduction in lung function, measured by spirometry, can be predicted by functional as well as physical lung dose, but no statistically significant difference in their predictive ability was observed in these patients. The actual biological impact of radiation on normal lung tissue might be underestimated in spirometry data (as well in patient/oncologist reported outcomes) since a significant fraction of the patients actually observe an improved lung function during treatment. This improvement is likely related to re-ventilation of obstructed airways due to tumour regression, which could mask underlying radiation damage. Another possibility is that regional ventilation may vary over a course of treatment. Analysis of 4D cone beam CT scans during treatment, and of post-treatment radiographic changes in follow-up CT scans may help untangle these “competing” effects.

Purpose or Objective: The study tested whether preoperative 5x5 Gy and consolidation chemotherapy is more locally efficacious than standard preoperative chemoradiation in “unresectable” rectal cancer.

Material and Methods: Patients with fixed cT3 or cT4 cancer without distant metastases were randomized either to 5x5 Gy and 3 cycles of FOLFOX4 after one week rest (experimental group) or to 50.4 Gy delivered in 28 fractions given simultaneously with two 5-day cycles of 5-Fu 325 mg/m²/day and leucovorin 20 mg/m²/day in bolus during the first and fifth week of irradiation; 5 one-day infusions of oxaliplatin 50 mg/m² were given once a week at 1, 8, 15, 22, and 29 days of irradiation. 3 cycles of FOLFOX were chosen to keep overall neoadjuvant treatment time similar in the two groups. Postoperative chemotherapy in both groups was optional. For the second study part, because of the new publications, oxaliplatin was delivered to the two groups at the discretion of the participating centre. Both randomized groups underwent surgery about 12 weeks after starting irradiation and about 6-7 weeks after completing neoadjuvant treatment.

Results: 541 patients were randomised and 515 were eligible for analysis; 261 in the experimental group and 254 in the control group of whom pelvic MR at baseline was respectively performed in 66% and 65% of patients. Oxaliplatin was given preoperatively to 70% of patients in the experimental group and to 66% in the control group, p=0.40. The incidence and severity of the neoadjuvant treatment acute toxicity was lower in the experimental group than in the control group, p=0.005; the overall toxicity rate being respectively 75% vs. 83%, grade III-IV 23% vs. 21% and toxic deaths 1% vs. 3%. The postoperative complications rate was 29% of patients in the experimental group and 25% in the control group, p=0.18. R0 resection rates (primary endpoint) and pathological complete response rates were respectively in the experimental group and in the control group 77% vs. 71% (p=0.081) and 16% vs. 12% (p=0.17). Median follow-up was 35 months. At 3 years, rates of overall survival and disease-free survival were respectively in the experimental group and in the control 73% vs. 64.5% p=0.055 and 54% vs. 52%, p=0.69. At 3 years, cumulative incidence of local failure and cumulative incidence of distant metastases were respectively 22% vs. 21%, p=0.82 and 30% vs. 27%, p=0.26. The incidence and

severity of the late complications were not different between the experimental group and the control group, $p=0.54$; the overall toxicity rate being respectively 20% vs. 21% and for grade III+ complications 9% vs. 6%.

Conclusion: The trial showed no difference in local efficacy between preoperative 5x5 Gy with consolidation chemotherapy and standard preoperative chemoradiation. Lower acute toxicity, lower cost, convenience and a trend towards improved overall survival favour 5x5 Gy with consolidation chemotherapy.

OC-0480

Five-year clinical outcome of the Phase III ACCORD 12 neoadjuvant trial in rectal cancer

J. Doyen¹, S. Gourgou-Bourgade², D. Azria³, I. Martel-Laffray⁴, C. Hennequin⁵, V. Vendrely⁶, G. De Laroche⁷, T. Conroy⁸, J.P. Gérard¹

⁴Centre Léon Bérard, Radiotherapy, Lyon, France

⁵CHU St Louis AP-HP, Radiotherapy, Paris, France

⁶CHU Bordeaux, Radiotherapy, Bordeaux, France

⁷ICL, Radiotherapy, St Etienne, France

⁸Centre Alexis Vautrin, Oncology, Nancy-Vandoeuvre, France

Purpose or Objective: The aim of the ACCORD 12 trial was to compare two different regimens of neoadjuvant chemoradiotherapy (nCRT). No significant difference has been found in main end point (pCR rate). At 3 years there was no significant difference for local control and survival. We report the 5 years outcome.

Material and Methods: Between 11/2005- 07/2008, 598 pts randomized. Inclusion criteria: adenocarcinoma, distal-middle rectum, T3-4, anterior-distal T2 staged using MRI and/or endorectal US. Treatment: CAP 45: radiotherapy (RT) 45 Gy/25 fr/5 weeks with concurrent capecitabine (800 mg/m² BID) vs CAPOX 50: RT 50 Gy/25 fr/5 weeks with Capecitabine (same) and weekly oxaliplatin (50 mg/m²). A TME surgery was performed after 6 weeks interval. Adjuvant chemotherapy was left to each institution.

Results: Median follow-up time was 60 months with 299 pts in each group. In intent to treat analysis main results are shown in table. In 31 pts T4 confounded the local relapse rate was 11.3%[3.8-31.5]. A clinical CR in 24 pts was associated with 81% DFS ($p<0.0001$) and Sphincter saving or organ preservation in 23. Adjuvant chemotherapy given in 253 pts.

Endpoint	CAP 45 299 pts	CAPOX 50 299 pts	p(log rank)	HR CI 95%
Loc. Rec. 5y	8.8%	7.8%	0.78%	0.92 [0.51-1.66]
Dist. Met. 5y	30%	28%	0.48%	0.89 [0.77-1.15]
DFS 5y	60.4%	64.7%	0.25%	0.86 [0.66-1.11]
Overall Surv. 5y	76.4%	81.9%	0.06%	0.71 [0.50-1.01]
Bowel function (1-7)	5.2	4.9	NS	

Conclusion: At 5 years there was no significant difference for local recurrence, distant metastases, survival and bowel function rates. Both CAP 45 and CAP 50 regimens are feasible and provide acceptable local control rate. More prognostic factors will be available at time of meeting and may generate hypothesis to further improve local control in locally advanced T3 or T4, achieve organ preservation in some T2 or early T3 and reduce toxicity in pts > 75 y old. Purpose or Objective: The 5-year local control and survival results of the GEC-ESTRO multicentric accelerated partial breast irradiation (APBI) trial have been reported recently. In this analysis we report the 5-year late toxicity and cosmetic results of patients treated with APBI using interstitial brachytherapy (iBT) compared to those who underwent standard whole breast irradiation (WBI) with a tumour bed boost.

Material and Methods: Between April 2004 and July 2009, 1184 patients aged ≥ 40 years with stage 0, I and IIA breast cancer who underwent breast conserving surgery (BCS) were randomly assigned to receive either 50 Gy WBI with tumour bed boost of 10 Gy or APBI using HDR/PDR iBT. Among these, 5-year follow-up records on late toxicities and cosmetic results were available at 969 patients (82%). Five-year prevalences of toxicities graded by the RTOG/EORTC late radiation morbidity scoring scheme were compared using the Fisher's exact test. The cosmetic results were scored by the patients and treating radiation oncologists using the four-scale (excellent-good-fair-poor) Harvard criteria. The trial is registered with ClinicalTrials.gov, NCT00402519.

Results: There were no grade 4 toxicities. The cumulative incidence of grade (G) 2-3 late skin toxicity at 5 years was 5.7% in the WBI group versus 3.2% in the APBI group ($p=0.08$), difference: -2.4% (95% CI: -5 - 0.2%). Concerning G2-3 late subcutaneous tissue side effects at 5 years the cumulative risk was 6.3% in the WBI group versus 7.6% in the APBI group ($p=0.53$), difference: 1.3% (95% CI: -1.9 - 4.5%). The cumulative incidence of severe (G3) fibrosis at 5 years was 0.2% in the WBI group and 0% in the APBI group ($p=0.46$), difference: -0.2% (95% CI: -0.6 - 0.2%). The cumulative incidence of G2-3 breast pain was low in both arms (3.2%

after WBI; 1.4% after APBI; $p=0.04$) difference: -2% (95% CI: -3.9 - -0.1%). The rate of excellent/good cosmetic results judged by the patients was 87.2% versus 90.4% ($p=0.06$) in the WBI and APBI group, and 86.7% versus 88.2% ($p=0.07$) scored by the physicians.

Conclusion: The 5-year toxicity profile and cosmetic results are similar at patients treated with BCS followed by either APBI using iBT or conventional WBI with tumour bed boost. A non-significant trend towards less late skin side effects and better cosmetic results has been observed in the APBI arm.

Whither fractionation?

P. Hoskin¹

¹Mount Vernon Hospital, Radiation Oncology, Northwood, United Kingdom

Traditional delivery of radiotherapy uses daily fractions of 1.8-2Gy building up to a therapeutic dose over 6 to 8 weeks of treatment. This reflects application of the fundamental principles of radiobiology in which repair, repopulation, reoxygenation and redistribution in the cell cycle are considered important in defining the response of tumour and normal tissue. However the relevance of this approach in an era of more precise image guided dose delivery where the exposure of normal tissue is minimised and high individual doses can be delivered must be questioned. There are two scenarios in which single dose radiotherapy has been evaluated and found to be highly effective. The first is in the extensive work which has been undertaken over several decades to establish the role of single dose palliative radiotherapy. The best example of this is in the management of metastatic bone pain where single dose radiotherapy is considered the standard of care but other palliative scenarios in non-small cell lung cancer, oesophageal cancer, rectal, bladder and prostate cancer are also relevant to this approach. The second scenario is that of curative treatment for localised prostate cancer using high dose rate brachytherapy (HDRBT). Dose escalation using HDRBT is well established as an effective therapy in prostate cancer and there is now a substantial database of large published series using HDRBT alone demonstrating high biochemical control rates. It is now feasible to deliver single dose radical radiotherapy using HDR BT with low toxicity and high disease control rates challenging the conventional and modest hypofractionation schedules used with external beam. The relevance of conventional fractionation can now be challenged in the era of modern image guided radiation delivery for both palliative and radical treatment. A sufficiently high dose delivered accurately to the target volume is all that is required.

MRI Linac: physics perspective

B. Raaymakers¹, J.J.W. Lagendijk¹

¹UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

The MRI linac originates from the desire to bring sight to the radiation oncologist. So to offer truly simultaneous soft-tissue visualization during radiation delivery. In UMC Utrecht, in collaboration with Elekta and Philips, a hybrid 1.5 T MRI radiotherapy system has been developed to facilitate this. Later also other systems emerged; in the Cross Cancer Institute in Edmonton a rotating 0.5 T MRI linac has been developed and the Viewray company has launched a 0.3 T Cobalt 60 system into the clinic. The systems will be briefly presented.

The common ground of the systems is the soft-tissue guidance. As will be shown, MRI offers a wealth of contrasts for anatomical and physiological information but also motion data. Exploiting these data for treatment guidance and treatment adaptation requires a new workflow with more on-line decisions, such as contouring, plan adaptation or full re-planning to initialize the treatment. Moreover, the continuous anatomical imaging during radiation delivery enables new direct anatomical triggers for gating and tracking, but equally important, this imaging can be used for dose reconstruction while accounting for intra-fraction motion. The latter is a valuable input for dose response assessment and can also be used for quality assurance (QA) purposes.

The QA for these systems need to be revisited, not only because of the new on-line plan adaptations but also due to the fact that the dose is delivered in the presence of a (perpendicular or parallel) magnetic field. This will alter the dose distribution which needs to be verified. Also the radiation detectors are potentially affected and their performance need to be validated (and corrected if necessary) for use in the presence of a magnetic field. This implies new machine QA, patient QA and workflow QA procedures.

The promise of hybrid MRI linac technology is to enable real-time plan adaptations in order to maximize the dose to the target while continuously minimizing the dose to the surrounding organs at risk. The efforts to move from pre-treatment planning to once daily (on-line) plan adaptation and ultimately to real-time plan adaptations will be presented.

In conclusion, the technology of hybrid MRI radiotherapy systems is there while the full clinical value needs to be established. This is an exciting new clinical arena and at the same time poses new challenges for on-line and ultimately real-time, adaptive radiotherapy.

SP-0484

First two years clinical experience with low-field MR-IGRT-system practicality and future implications

J.M. Michalski¹, O.L. Green¹, R. Kashani¹, H. Li¹, V. Rodriguez¹, T. Zhao¹, D. Yang¹, J.D. Bradley¹, I. Zoberi¹, M.A. Thomas¹, C. Robinson¹, P. Parikh¹, J. Olsen¹, S. Mutic¹

¹Washington University School of Medicine, Department of Radiation Oncology, Saint Louis- MO, USA

Purpose: We report on the first two years of clinical operation of the first magnetic-resonance imaging-guided radiation therapy (MR-IGRT) program, experiences with patient treatments, and implications for future developmental and clinical work. We previously reported on initial clinical implementation of this system. = The purpose of this work is to analyze clinical practicality of MR-IGRT and implementation of online adaptive RT.

Methods and Materials: The MR-IGRT system consists of a split 0.35T MR scanner straddling three ⁶⁰Co heads mounted on a ring gantry, each head equipped with independent doubly-focused multileaf collimators. The MR and RT systems share a common isocenter, enabling simultaneous and continuous MR imaging during RT delivery. The system is also capable of online plan adaptation where patients can be imaged, planned, verified, and treated all in a single treatment session. To assess the clinical practicality of the system, makeup of treated cancer sites, distribution of available treatment techniques, total number of patients, maximum number of patients treated daily, and the utilization of advanced treatment techniques were evaluated. The system was clinically implemented in January of 2014 and data was collected over a 24 month consecutive period. The adaptive feature was clinically implemented in September of 2014.

Results: During the initial 2 years of the operation, more than 20 cancer sites in 263 patients were treated. The maximum number of daily treatments was 18. Top 3 treated cancer sites were breast, lung, and bladder with 22%, 13%, and 9% of the total treatments, respectively. The utilization

of IMRT, SBRT, and 3D treatments was 50%, 28%, and 22%, respectively. More than 150 real time adaptive fractions were delivered to more than 45 patients. We have also demonstrated that the system is capable of determining true delivered doses based on daily MR images.

Conclusions: Based on the first two years of clinical operation, routine MR-IGRT program is practical, with ability of treating a broad spectrum of cancer sites, significant number of patients in a day, and systematic delivery of advanced and adaptive treatments.

SP-0485

MR-linac: Clinical introduction

C. Schultz¹

¹Medical College of Wisconsin, Department of Radiation Oncology, Milwaukee, USA

The MR-linac combines a 1.5 Tesla MRI and a modern 7MV Linac into a single device that can simultaneously produce diagnostic quality MRI images and deliver highly conformal IMRT based treatments. The introduction of in room MR-linac based imaging allows for superior soft tissue contrast of tumor and surrounding normal tissues. This functionality enables enhanced re-positioning and adaptive radiation therapy to account for inter-treatment positioning errors, organ deformation, organ movement, and tumor response. Additionally, this combined device provides functionality to account for intra-treatment motion and has the potential to acquire multi-parametric functional sequences at the time of treatment.

The addition of the MR-linac to a radiation therapy clinic poses novel challenges related to the presence of the magnetic field and the configuration of the device. Prevailing regulations concerning room access, shielding, and adjacency to other treatment units and medical equipment must be considered when siting the device. Personnel must possess or acquire the skill sets and competencies to safely operate an MRI and Linac treatment machine. This training should be in place prior to installation of the device. Experience with MRI based simulation and treatment planning is also a prerequisite for MR-linac based treatment delivery. MRI based simulation requires attention to the size and material of patient positioning devices, MRI coil and table top design. Optimal MRI sequences to facilitate region specific tumor and normal tissue delineation that may differ from institutional diagnostic sequences must be developed. Image distortion is routinely managed as part of modern MRI imaging but the use of MRI for simulation and the MR-linac for guidance and treatment requires a QA process that is nuanced to these specific workflows.

It is anticipated that the work flow for the MRI-linac device will be divided into two general scenarios. The first utilizes pre-treatment MRI images for patient repositioning to correct translational and/or rotational errors. This is similar to the current cone beam CT image guidance workflow with the addition of superior soft tissue contrast. Additionally, the intra-fraction imaging will provide superior ability to manage tumor motion. The second approach adds plan adaptation to the MRI based treatment guidance workflow to account for deformation, volume, and independent motion changes of the targets and organs at risk. The frequency of online or offline adaptation will depend on the characteristics of tumor response and anatomical location.

An international research consortium has been formed to allow for an evidence-based introduction of the MR-linac technology and to address how the technology could be used to achieve an optimized radiation treatment approach in terms of tumor control and toxicity. The MR-linac consortium structure is outlined in Figure 1. Nine tumor site groups have been selected to start consortium based clinical studies based on the expected clinical benefit (either increased local control, survival, decreased toxicity or improved quality of life). The first nine consortium-broad tumor sites include: rectum, esophagus, oropharynx, pancreas, prostate, breast, cervix, brain and lung. Each consortium institute coordinates one or more Tumor Site Groups (TSG). To achieve the clinical introduction of the MR-linac in a safe and step wise manner,

an adapted version of the IDEAL framework, the R-IDEAL (Radiotherapy, Idea, Development, Exploration, Long-term study) framework, will be used to conduct the proposed prerequisite imaging studies and clinical treatment studies.

Figure 1. Organizational structure clinical working groups MR-linac Consortium (CSC-clinical steering committee, MAB-methodology advisory board, DMTF-data management task force, TSG-tumor site group)

SP-0486

Adaptive planning, dose delivery and verification with MRI based brachytherapy

C. Kirisits¹, R. Pötter¹

¹Medical University of Vienna, Department of Radiotherapy-Comprehensive Cancer Center, Vienna, Austria

Soon after the introduction of MRI in radiology it became part of treatment planning in radiotherapy and in brachytherapy. Especially in gynecological brachytherapy MRI was used during the process of target definition. But also in other clinical sites MRI before brachytherapy became an essential tool for correct staging, treatment decision making and target volume definition. The important point was the use of MRI with the brachytherapy applicators in-situ. By this process the image series contain both, the delivery device and the anatomy including tumour, target and organs at risk. This enables a real adaptive planning strategy, as the treatment planning is based directly on these image series. Imaging of a fixed geometry of delivery device inside the anatomy is not different to in-room imaging used for external beam with a linac or other device as delivery device outside the patient. The aim of in room imaging is to depict the situation during dose delivery as close as possible. The question is how much change of the target and organs at risk happens between imaging and dose delivery. In external beam this is performed almost simultaneously without essential changes, while in brachytherapy the movement of patients from an imaging room to a treatment room might impose changes. This question was analyzed and debated for years, often using inappropriate methodologies as registration to bony landmarks. Only recently multicenter studies showed that for cervix cancer brachytherapy for example the relation of applicators to target is stable with minor variations. However, more variation may occur for adjacent OARs. Various methods are investigated on how to minimize such uncertainties. One is to perform MRI in-room

imaging comparable to external beam using dedicated set-ups with an afterloader inside the MRI room. On the other side it seems very promising to invest into in-vivo dosimetry methods. Other forms of volumetric imaging in the treatment room may be another alternative. As the MR image series for treatment planning already contains already the delivery device and the anatomy, the situation during dose delivery can be verified with different methods with co-registration and may reach then almost the same accuracy as if performed simultaneously together.

Real in-room US imaging has been performed since long with prostate brachytherapy for direct guidance of needle insertion, target definition and on-line dose planning. Especially HDR techniques applying ultrasound for treatment planning before and during needle insertion, again for verification just before dose delivery, leaving the ultrasound probe in place and finally performing an ultrasound image directly after dose delivery have probably the highest accuracy possible. Combining such methods with MRI may lead to the ultimate accuracy in terms of target definition, OAR localization, treatment planning and dose delivery verification.

Combinations of different imaging techniques with the applicator in place, even generated in different rooms, seem to be the future in brachytherapy. Already by now brachytherapy planning was performed as adaptive procedure, taking into account pre-treatment imaging information and dose optimization based on the situation directly before dose delivery. The adaptive process includes image guided applicator placement. The term "in-room adaptive imaging" in brachytherapy can be extended to an overall definition of a "room" inside the patient visualized via adaptive imaging containing target, OARs and the delivery device in one image.

Symposium: Communication with patients

SP-0487

Patient's Perspective

E. Naessens¹

¹Trinity College Dublin, Dublin, Ireland Republic of

Good communications are primarily thought to involve skills of articulation. However, this presentations makes the case for listening as the recurrent starting point in patient interactions. Listening is deceptive. Generally viewed as a "soft skill" the challenges of listening are easily overlooked. Engaging requires gaging (active listening, observing, clarifying, and feeding back).

Drawing upon his experience as an oncology patient and his academic background and training in communications and social science, Eddie explains why we are prone to assume we are good listeners despite evidence to the contrary. Demonstrating a number of relevant biases and fallacies, he explains why there is no necessary link between assumption of competence and actual competence. He presents concrete examples from the patient perspective of excellent and poor communications and their positive and negative outcomes. The presentation concludes with an overview of useful ways to reflect upon the issues, improve communications, and enhance overall outcomes.

SP-0488

Healthcare professional's perspective

G. Sancho Pardo¹

¹Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Training in communication and interpersonal skills was not considered a relevant part of the training at medical school and during the speciality residency programmes. Medical doctors therefore learned by observation of how their seniors performed. After some time one realizes that effective communication with patients involve both content and style and that being caring, nice and logical is not enough. Based on the available literature, this presentation will look into the factors influencing the patient-healthcare professional

communication. I will focus on how healthcare professionals are involved in the process of communication and how they can improve it.

When we are visiting a patient we have to ensure that several aspects are well covered. First we need to identify the patient's problems and concerns and their impact on their family and daily life. Second, we should give clear information and advice about their disease, their treatment and their prognostic. Giving patients tailored information of what and how you think they want to know might be not enough. In many occasions breaking bad news is unavoidable, and patients may express some strong emotional reactions that you should be able to understand and cope with. One has also to be aware that some patients do not want to know the diagnostic and nothing related to the disease and few patients will move into denial. Third, we should ensure that patients are aware of the situation, that they have not misunderstood the information we have given them and that they trust us. It is of paramount importance to empathise with the patient. Remember that verbal information goes together with visual messages and physical contact. Patient depending factors like race, sex, age, language, culture, socioeconomic status, disability or communication barriers could condition the process of communication. Healthcare professional's factors such as time, job strain, working conditions, work engagement and personal life may spoil communication with patients.

Doctors have to be aware that patients today have access to information about their disease from their relatives, friends, books, media and the Internet that clearly impacts on the relation with patients and on the communication process. An issue that deserves special attention is the recruitment of patients for clinical trials. Patient recruitment partially depends on a relation of trust with the patient and in the doctor's ability to communicate the importance of joining a trial. It has been shown that training in communication about trials may influence in the recruitment. However, trial design, especially when one arm offers placebo or less treatment, highly contributes to patients' decline. It has been suggested that involving patients and patients' organisations in the design and development of clinical trials could accelerate research and make it more effective. There is a need for training in communication skills in medical education. Training healthcare professionals how to be more effective in communication with patients will provide a benefit for them as well as for the patients.

SP-0489

RTT/Nurse's perspective: patient is the key element of communication

L. Koevoets¹

¹Dr. Bernard Verbeeten Instituut, Radiotherapy Breda, Tilburg, The Netherlands

Patient is the key element of communication.

Where do we stand regarding communication with our patients? Our mission statement: we want to give our patients the best possible experience. We really want to connect.

How do we try to achieve this? Personal contact and support as much as possible "Do what you say and say what you do". Honest and clear information. Information in common words, but also use of visual aids. This is rooted into our Instituut by use of a timeline: who explains what at which particular stage in the treatment and what tools can be used? Example: we inform all our patients in a private briefing before their treatment starts.

The role of the RTT in communication with the patient Explanation of the treatment Connecting with other disciplines to support the patient A person who a patient can approach Provision of personal coaching programme to help patients to quit smoking. We check the satisfaction of our patients on a regular basis.

How do we do that? We try to stay in dialogue with our patients. All staff are trained for giving and receiving feedback.

What do we try to attempt with our information conversation? The information given before treatment is

aimed at providing patients with more knowledge. Armed with insight, personal behaviour patterns which influence treatment outcomes can be challenged. Our belief is that a well informed patient will be less anxious and insecure. The information that we give is to repress misconception, reduce unrealistic fears and provide predictive information. The latter is to let the patient know what we do during the radiation and why, further to inform the patient what side effects the patient can develop after an period of time. We try to support the patient in different areas. We try to meet within the needs in the pyramid of Maslow. It states that a human being among other things is in need of safety and security, need for social contact and is in need of appreciation and recognition. In the conversation we try to acknowledge their fears and and recognize that these may exist and by giving information we try to repress those fears. We try as much as possible to be really in contact with the patient and to connect with the experiences of the patient. To reassure them and to let them know what we do and why, we try let them feel safer and more certain about the process they will be going through. To give the patient also some sense of control over the radiation we hope to achieve that the patient feels he/she also affects the process and thus have the situation more under control. The information is given with use of an PowerPoint presentation with supports the story the radiation technician is giving. In this presentation he shows pictures that support the story. The radiation technician uses the knowledge that a person remembers 20% of what they read, 35% of what they see and 55% when you combine these two.

SP-0490

Interaction between patients and professionals: a psycho-oncologist's view

E. Van Hoof¹

¹*Vrije Universiteit Brussel, Department of Psychology, Brussels, Belgium*

Purpose or Objective: Stress influences our communication: the way how we interpret the world, our communications style we use to interact with our environment and our internal communication. During the presentation, neuropsychological insights into communication will be presented. These insights will be used to introduce some pragmatic intervention to monitor and control communication.

Materials and Methods: a literature review of the impact of stress on our information processing system and hence, our communication and of possible intervention that can positively influence our information processing

Results: Several brain mechanisms can negatively influence our communication. Our knowledge of these mechanisms is key in understanding and identifying possible communication styles. In cancer, we see many patients and their relatives struggling with the information-processing. Coping strategies like avoiding and neglect, for instance, are effective in the short-term but in the long run, flexibility in coping is required to ensure shared decision making in cancer care. Indeed, shared decision making is the priority in cancer care. Caregivers, specialists and the patients collaborate ensure the best possible cancer care. Shared decision making requires an efficient information processing. However, stress has a strong impact on this shared decision making process. Results from cognitive behavioral interventions and intervention based on positive psychology positively influence information processing and stress-levels. Including these strategies can facilitate emotion regulation and hence, shared decision making in cancer care.

Conclusion: Stress negatively impact our information processing and hence, our communication. On the other hand, communication is the central factor in shared decision making. Caregivers, specialists and patients should always be aware of these possible disruptive factor in order to ensure shared decision making in cancer care.

Symposium: Imaging biology

SP-0491

What do we really see?

D. Zips¹

¹*University Hospital Tübingen Eberhard Karls University Tübingen, Tübingen, Germany*

Successful implementation of functional imaging in radiation therapy requires understanding of images. This includes radiobiological interpretation, quantification as well as validation of the prognostic and predictive value. This talk will reflect on functional imaging and its link to radiobiological mechanisms of radiation response and discuss current knowledge as well as ongoing research in image validation.

SP-0492

Genomics and imaging: a pas-de-deaux in response prediction

H. Lyng¹

¹*Oslo University Hospital - Norwegian Radium Hospital, Department of Radiation Biology, Oslo, Norway*

Medical imaging has a fundamental role in radiotherapy planning today, but is almost exclusively used for assessing anatomical features like tumor size, stage and spreading. Introduction of functional imaging provides an opportunity to also consider biological features of disease aggressiveness in the clinical decision making. Recent advances in genomic research have led to promising molecular biomarkers of treatment outcome, but it is not clear how to best translate them into clinical practice and face challenges related to tissue sampling and intratumor heterogeneity. Radiogenomics, which refer to extraction of image features reflecting cancer genomics, allow visualization of molecular biomarkers within the entire tumor and have been proposed as a promising tool for this purpose. Such analyses provide a better understanding of the molecular background of the images and open for the use of imaging in the planning of combination therapies with radiation. In this talk, I will present clinical data on associations between functional MR imaging and biopsy based genomic biomarkers and reflect on the challenge of intratumor heterogeneity for such investigations. I will further discuss the potential of combining functional MR imaging and genomic signatures in the prediction of radiotherapy outcome. Examples will be given from published data and from our ongoing studies on cervical cancer and prostate cancer.

SP-0493 Molecular imaging for radiotherapy optimisation

R. Jeraj¹

¹*Jozef Stefan Institute, Ljubljana, Slovenia*

Molecular imaging adds value in each of the steps of the radiotherapy process: (1) Diagnosis and staging, (2) Target definition, and (3) Treatment response assessment. As such, it remains an important tool for optimization of radiation therapy. At the moment there is no general consensus how molecular imaging should be utilized in defining treatment target. A number of automatic and semi-automatic approaches exist, but their use in treatment planning is limited. Dose painting - biologically conformal radiotherapy - is an exciting concept, but still needs further development. Its feasibility has been established in various tumor types, and early efficacy clinical trials are underway. Generally, post-RT molecular imaging, particularly FDG PET/CT has a high negative predictive value (NPV), but rather low/moderate positive predictive value (PPV) for predicting treatment outcome. Early RT molecular imaging response assessment is promising and provides potential for innovative adaptive approaches. High inter- and intra-tumor response heterogeneity remains challenging.

Debate: This house believes that centralised large radiotherapy units will provide the best academia and the best treatment quality

SP-0494

For the motion - SIZE MATTERS

B. Slotman¹

¹*VU University Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands*

The field of radiation oncology has moved away from a generalistic radiotherapy practice to a number of specialized areas where radiation oncologists have broadened their knowledge outside the field of radiation oncology per se to be a better partner in multidisciplinary teams. Most radiation oncologists in the larger centers nowadays have only one or two areas of expertise (commonly around brain, head & neck, breast, lung, upper GI, lower GI, urogenital, gynecology, hematology, palliation, etc.). In these areas, radiation oncologists can be better counterparts for the organ-specialists, which have often left all the non-oncological work in their specialty to other colleagues.

With 2-3 areas of expertise per radiation oncologists and accounting for sufficient back-up, the minimum size of a department treating all categories of patients should be around 8 radiation oncologists. Based on 250 new patients per radiation oncologist and about 500 new patients per linac, the minimum size of a department which covers all areas of expertise should be 4 linacs. This size will also allow physicists and therapists to specialize, although at a size of 6-8 machines, this opportunity may be even better. A minimum size also makes investments of specialized equipment within the department, such as CT, PET-CT or MRI feasible and makes it easier to accommodate machine breakdown or replacement.

The economic lifetime of a linac is generally around 10-12 years. Since the pace of technical innovation is much faster, a department with 4-8 linacs has the opportunity to install the latest technology every 2-3 years. This, in combination with a larger physics group, will allow earlier implementation of new treatments. In Europe, the median size of a radiotherapy department is between 2 and 3 linacs, with on average more than 4 linacs per department in only 6 countries.

Sufficiently sized departments are also better equipped for research and moving the field forward. The multidisciplinary setting and available infrastructure in larger departments will help to work off the beaten track. Studies in various tumor sites have shown that outcome for patients treated in highly accruing (often larger) centers is better.

However, there is probably also a maximum size. For patients, entering a mega-department can be intimidating and beyond a certain size, no further benefits may exist. In addition, geographical circumstances should be taken into consideration. It is well known that easy access to care is related to use of radiotherapy. In more remote areas, satellite centers may be an alternative, especially if infrastructure and staffing can be shared and allow for similar protocols and expertise. Especially where resources are limited, a close collaboration between centers may further improve health care.

A possible disadvantage of subspecialization could be that highly specialized radiation oncologists may lose their overview of the developments in the radiotherapy arena and the transfer of new ideas and solutions from one indication to another may be reduced. For that reason, radiation oncologists working with one leg in the tumor-specific field, should keep their other leg in the radiation oncology field.

SP-0495 Against the motion - against dinosaurs

S. Bodis¹

¹*Kantonsspital Aarau, Radiation Oncology, Aarau, Switzerland*

Smart-modular-flexible: The essentials for academic excellence and high quality

NoBodis and nobody can believe that there is a general relationship between physical size and quality neither in biology, politics, industry, administration, culture nor more importantly for this forum, in science. Centralisation on the other hand is often an imposed structural process and has nothing to do with guaranteed high quality performance of high quality research. In organic systems and in most operational business units high quality growth is overwhelmingly present in (early) development i.e. in small structures. Moreover biology (organic) systems have a finite size to protect them from excessive and dysfunctional growth.

Neither data from radiation oncology industry, health care insurance companies, patient advocacy organisations nor from international data banks provide published evidence that large centralised radiation oncology units provide a higher treatment quality compared with small units. Moreover there is no international accepted definition of "small" and "large" RO unit. Large centralised radiation oncology units might produce more academic quantity because it is in their to do list. However academic quality is never a matter of size and/or centralisation. Most breakthrough innovations arise by chance, in small teams of 6-12 researches and fostered by a creative and productive environment (The majority of Nobel prizes laureates are citizens of small countries).

If you have to choose between one monopolistic large radiation oncology department and several smaller units think about similar choices made historically by politics or by evolution. The audience should carefully consider the scientific information provided in this debate not according to the evidence but also by common sense, gut feeling and empathy (e.g. in what type of radiation oncology environment would you like to work and/or be taken care of as a patient: Familial or military?). And by the way Radium, the "potion magique" of radiation oncology, was discovered in a storeroom and introduced into clinics by a handful enthusiastic scientists.

To pave the way for a constructive debate consider this: Based on the existing local health care systems in Europe both types of radiation oncology units (large and small) can co-exist and improve each other by cross-feeding. The IAEA has published recommendations as to how national radiation oncology services should be established, specifically in low- and middle-income countries with little or no RO infrastructure. Their recommendation is to start with small primary centers and step by step establish a network with a few secondary and eventually one tertiary (national reference) RO center(s). Such tailored RO networks allow proper allocation of professional skills and resources to each center including modern communications tools like telemedicine to optimize patient care especially where long distances might prevent patients from reaching the larger center(s).

In a multidisciplinary environment such as a RO clinic, the quality (education, experience, research as commitment for continuous improvement) of the staff will always be more important than quantity.

Joint Symposium: ESTRO-ILROG: Modern radiotherapy in lymphoma

SP-0496

Indications to radiotherapy for lymphoma in 2016: what is standard of care and what remains controversial?

J. Yahalom¹

¹Memorial Sloan Kettering Cancer Center, Radiation Oncology, New York, USA

The role of radiation therapy (RT) in the management of Hodgkin lymphoma (HL) and various non-Hodgkin lymphomas (NHL) has changed significantly over the last three decades. The indications, the fields and dose recommendations still continue to evolve. Old biases, new outcome data (often conflicting or controversial) as well as availability of tested and untested alternative drugs and a desire to evaluate them in an environment free of other high impact modalities have affected the consideration of radiotherapy in many tried and true indications for RT alone or as a combined-modality. Unfortunately many non-radiation oncologists were trained to believe that RT (even if limited and modernized) is loaded with long-term complications, while more chemotherapy, as an alternative is risk-free. Although radiotherapy remains, as stated by James Armitage, former ASCO president and highly regarded lymphoma leader, “the most effective single agent in the treatment of lymphomas”, the number of patients who are not receiving RT even when most guidelines recommend it has increased over the last two decades. Several 2014-2015 publications documented it in analyzing tens of thousands of patients even in localized stages of common lymphomas. Two themes are repeating in analyses of SEER and the U.S. National Cancer Data Base (NCDB) in early-stage HL (lymphocyte predominant and classical HL), in early-stage follicular lymphomas, in early-stage diffuse large B-cell lymphomas (DLBCL), and primary mediastinal lymphomas: 1. The use of RT is decreasing; 2. Looking at overall survival in multivariate analysis and using propensity scores- Not receiving RT is an independent factor associated with a significantly decreased overall survival. In an era of individualized medicine, one approach or dogmatic concepts without understanding what the other modality may offer your patient does not reflect best care. As radiation oncologists we are often dependent on the “gate keepers” for consulting lymphoma patients and thus our responsibility is to remain up-to-date on the issues relevant to the use of RT, the arguments and the studies for RT exclusion or inclusion, and to inform our colleagues and our patients of what radiation may offer in terms of outcome and avoidance of toxicity. This session will review the controversial issues of the main indications for using RT in lymphoma, mostly in early-stages of HL, DLBCL, and indolent lymphomas. Arguments supporting the role of RT will be highlighted in the talk.

SP-0497

New concepts for lymphoma radiotherapy and the use of advanced technology

L. Specht¹

¹Rigshospitalet- University of Copenhagen, Department of Oncology- Section 3994, Copenhagen, Denmark

The role of radiotherapy (RT) in the treatment of lymphomas has changed from being the primary treatment. In most situations RT is now part of a combined modality strategy, as consolidatory treatment after primary chemotherapy or immunochemotherapy. With modern effective systemic treatments, microscopic disease is efficiently managed, and RT is only needed to treat initial macroscopic disease or residual masses. Moreover, the long-term follow-up of patients treated in the past with extended field RT has demonstrated serious long-term sequelae from the fairly low doses which used to be considered safe. With modern RT for lymphomas only the initially macroscopically involved sites or residual masses are irradiated to the lowest doses necessary for optimal tumour control, and the utmost care is taken to irradiate as little as possible of the surrounding normal tissues, thus minimizing the risk of long term complications.

Modern advanced imaging allows a precise delineation of the involved lymph nodes, and techniques such as image fusion and deformable co-registration allow transfer of target volumes from pre-chemotherapy to post-chemotherapy images for treatment planning. The majority of lymphomas are FDG-avid, and PET/CT-scans for treatment planning are highly recommended. Modern highly conformal planning and treatment techniques, combined in many situations with even lower RT doses, have further reduced the radiation doses to normal tissues. In the past 15 years there has been a veritable paradigm shift in lymphoma RT, from 2-dimensional treatment planning and RT to regions defined by bony landmarks, to 3-dimensional treatment planning and RT to volumes defined by advanced imaging and conforming to the ICRU guidelines, similar to the principles of modern RT of solid tumours. Guidelines for modern radiotherapy of Hodgkin lymphoma, nodal lymphomas, extranodal lymphomas, cutaneous lymphomas, and pediatric lymphomas have been published by the International Lymphoma Radiation Oncology Group (IROG), and they have been implemented by most large centres and cooperative groups worldwide. The new concept of involved site radiation therapy (ISRT) takes into account different scenarios with regard to the quality of pre-chemotherapy imaging, where optimal imaging allowing image fusion allows for RT to the smallest volumes. In other situations somewhat larger margins may be needed to allow for uncertainties in contouring, but the volumes irradiated are still much smaller than in the past.

Estimates of the consequences on long-term toxicity of these modern treatments demonstrate very significant reductions in the risks of second malignancies, cardiovascular disease and other long-term sequelae compared to what has been seen after the extended treatment fields of the past. It is important to realize that these treatments are now obsolete, and that the analyses of long-term sequelae of RT for lymphomas from the era of the extended fields, which have been extensively published, are not directly relevant for patients treated with modern highly conformal RT.

More than 60 different lymphoma diseases have now been defined, and lymphomas may present in all parts of the body, both within and outside of the lymphatic system. Hence, there is great variation in target volumes and critical normal structures from patient to patient. With highly conformal treatments such as intensity modulated radiotherapy (IMRT) or volumetric arc therapy there are many possible variations which may be used in different patients to optimize treatment. An “intelligent” choice of treatment angles for IMRT may allow sparing of particular organs at risk. Treatment of mediastinal or upper abdominal lymphomas in deep inspiration breath hold allows significant sparing of the heart and lungs. Which technique should be used in different patients will depend on the location of the target and considerations of the importance of different toxicities in relation to age, gender, comorbidities, and risk factors for other diseases.

Dose constraints normally used for solid tumour radiotherapy are not optimal for lymphoma RT, as most of the conventional dose constraints for different organs are higher than the RT doses prescribed for lymphomas. Hence, if conventional dose constraints are used uncritically, most plans will be within the limits, even if far from the best plan achievable. Doses to all normal structures should be kept as low as possible. However, combining dose-response data for all relevant normal structures and using mathematical modeling to predict long-term risks of relevant sequelae would allow for a quantitative comparison of different treatment plans in individual patients. Developing a tool for this kind of multispectral plan evaluation would enable further optimization of RT for lymphomas in the future.

SP-0499

The need for adaptive approaches in proton therapy (compared to photons).

M. Schwarz^{1,2}

¹Proton therapy centre, Protontherapy, Trento, Italy

²INFN, TIFPA, Trento, Italy

The large scale introduction of soft-tissue imaging (e.g. via computed tomography) and the multiyear experience in its use paved the way, at least in radiotherapy with photons, for the development of adaptive treatments, where image datasets acquired during the treatment cycle are used to evaluate and tune the dose distributions actually delivered to the patient.

In proton therapy the presence of range uncertainties, and their effect in terms of dose perturbations, has been tackled so far mostly looking at source of range and dose uncertainties other than anatomy deformation, e.g. range error due to imperfections in the CT scan calibration and setup errors. However, neither improved CT calibration nor the use of sophisticated planning approaches such as robust optimization are coping with dose perturbations due to anatomy changes. As a consequence, proton therapy has for quite some time approached the issue in a defensive way, i.e. focusing on dose indications where anatomy changes are not expected (e.g. the skull) or at least choosing beam directions going through regions of the body where such changes are less likely.

The broadening of the indications considered to be suitable for proton therapy and the increased availability of soft tissue image guidance in proton therapy treatment rooms is slowly allowing for more proactive approaches, where repeat CT scans are actually used to modify the treatment parameters.

Starting from clinical cases, we'll see how adaptive therapy with protons has some peculiarities with respect to adaptive with photons, such as:

- A more prominent impact of anatomy deformation on the dose distribution. The finite range of protons makes the dose distribution sensitive even to anatomy variations that would not be of concern in photons
- Adaptive proton therapy needs to rely on high quality imaging for dose recalculation and optimization. Since CT calibration is an issue even with diagnostic quality CT, any further deterioration of the image quality will in principle impact the accuracy in dose distribution, thus potentially making the treatment adaptation less relevant.
- Given the strict correlation between anatomy and dose distribution, it remains to be seen whether approaches that are successful in photons (e.g. the use of plan libraries) are safe and effective with protons too.

SP-0500

Cone beam CT for adaptive proton therapy

S. Both¹

¹Memorial Sloan-Kettering Cancer Center, Medical Physics Department, New York- NY, USA

Daily volumetric imaging is essential in adaptive radiation therapy (ART) due to patient related uncertainties which may occur during the course of radiation treatment. The in room Cone-Beam CT (CBCT) imaging has been considered a viable option for photon ART, while CBCT just recently emerged in proton therapy. CBCT deployment in proton therapy has been slow due to technical challenges for design and implementation, lower image quality and more importantly less HU accuracy relative to CT imaging due to scattered x-rays. Therefore, the clinical deployment of CBCT in proton therapy is still in an early phase and currently is limited to treatment setup and detection of potential changes in patient anatomy generated by tissue deformation, weight loss, physiological changes and tumor shrinkage. The HU accuracy of CBCT is more critical in adaptive proton therapy (APT) relative to photon ART, as even small differences in HU could cause significant range and absolute dose errors. As a result, the integrity of the proton dose calculation may be easily compromised. Studies showed that photon dose calculation discrepancy caused by CBCT HU error can be over 10% for raw CBCT image data sets and be within 1% for scatter corrected CBCT. However, no study up to date has demonstrated the feasibility of proton clinical dose calculation or treatment planning on raw CBCT data sets and therefore currently the primary role of CBCT in APT is to trigger the need for CT rescanning for dose adaptation. However, there are two major approaches explored to overcome current CBCT image data sets limitations. The first one employs deformable image registration of the treatment planning CT to the daily verification raw CBCT to generate a CBCT based stopping power distribution. This method has been explored mostly for head and neck dose adaptation. The second one aims to improve the raw CBCT data accuracy via scatter corrections and in its current stage explored the feasibility of raw CBCT based planning on an anthropomorphic phantom. As these methodologies are developing and new ones emerge, CBCT imaging may further evolve and holds the potential to become a viable tool for APT.

SP-0501

Adaptive practice and techniques in proton therapy of the lung

P.C. Park¹, H. Li¹, L. Dong², J. Chang³, X. Zhu¹

¹The University of Texas MD Anderson Cancer Center, Department of Radiation Physics, Houston, USA

²Scripps Proton Therapy Center, Radiation Oncology, San Diego, USA

³The University of Texas MD Anderson Cancer Center, Department of Radiation Oncology, Houston, USA

Adaptive radiation therapy is the practice of modifying initial treatment plan in order to accommodate the changes in a patient's anatomy, organ motion, and biological changes during course of treatment. Within this scope of definition, it can be further classified based on different time scale going from offline (between fractions) to online (prior to a fraction), and to real time (during fraction) modification in beam delivery. The dose distribution of proton is "non-static" relative to the change in patient anatomy because the finite path length of protons is tissue density dependent. Therefore the adaptive radiation therapy is more relevant for proton than photon. For the same reason, for moving target in particular, online or real time adaptation may become more important for proton therapy. During initial treatment planning phase, proton ranges in patient must be determined precisely in order to take the advantage of Bragg peak. Changes in water equivalent thickness along the beam path due to breathing motion must be accounted by robust planning strategies. Any significant changes in proton range from what was calculated should be detected and prompt for an adaptive re-plan. Treatment sites that are likely to change

in anatomy during the course of treatment or during treatment are particularly important. In this regard, lung cancer is one of the most relevant sites to practice adaptive proton therapy. Over 40% of lung tumors move more than 5 mm and 10% moves greater than 10 mm [1] with possibility of changes in breathing pattern during the course of treatment. The change in tumor shape or density and decrease in tumor volume as tumors respond to the radiation also raise another challenge for proton therapy. The protons can travel further without the tumor tissues to stop them in lung. Previous studies found that on average from 0.6 to 2.4% of tumor volume can be reduced per day [2]. Adaptive radiation therapy requires modification in treatment plan through changing contours of targets or organs at risk and beam parameters accordingly and any quality assurance checks that are deemed necessary. Therefore the adaptive radiation therapy requires more resources when compare to the conventional image-guided radiation therapy. In fact, image-guidance can be considered the first step in adaptive practice as it triggers the initial decision to adapt and provide the 3D volumetric images that are necessary for adaptive re-plan. There have been efforts to create techniques and technologies that can facilitate the adaptive planning. In this presentation, we will first discuss the state of art practice of adaptive proton therapy including the experience at our institution. We will review studies assessing the magnitude of intra- and inter-fractional changes and its impact on delivered proton dose distribution with and without adaptive practice. Secondly, we will present the cutting edge ideas and techniques that are developed specifically for adaptive proton lung therapy in the most recent literature.

SP-0502

In-vivo range estimation and adaptive particle therapy

T. Lomax¹

¹Paul Scherrer Institute PSI, Centre for Proton Therapy, Villigen, Switzerland

The finite range of protons is a two-edged sword. On one side, it is the *raison d'être* of proton therapy, on the other, a potential source of uncertainties in-vivo. As such, both in-vivo range estimates and adaptive therapy are being proposed and pursued for mitigating such uncertainties. However, sources of in-vivo range uncertainties are many, ranging from systematic uncertainties in the calibration of CT Hounsfield units to proton stopping power and inaccuracies in dose calculations (for convenience defined here as type 1 uncertainties) to variations in patient positioning and anatomy changes during the course of treatment (type 2). Whereas, for good quality CT data, type 1 uncertainties can result in range uncertainties of a few percent or millimeters (about 3% or 6mm in the worst case,) type 2 can result in range changes of the order of centimeters. In addition, type 1 uncertainties will, to a good approximation, be similar across all patients of a particular indication and will remain the same throughout the duration of a patient's treatment. Type 2 on the other hand will be patient and (potentially) treatment day dependent. So, what are the roles of in-vivo range measurement and adaptive therapy for dealing with these? It seems to this author that in-vivo range verification perhaps has a role to play in reducing type 1 uncertainties, whereas the best approach to type 2 has to be adaptive therapy. Adaptive therapy (based on regular, if not daily, imaging) must be pro-active (i.e. the treatment should ideally be adapted *before* delivery), whereas in-vivo range verification can only be (at best) reactive (e.g. may be able to provide a reason to interrupt a delivery if an error is detected). As such, the best use of in-vivo range estimation seems to be as part of a population based (commissioning) approach in order to verify that CT calibration and dose calculations are more and more precise, such that type 1 uncertainties resulting from pre-treatment imaging

(necessary to mitigate type 2 errors) can then be reduced as much as possible. Such an approach however puts stringent demands on the accuracy and precision of in-vivo range estimates, with in-vivo resolutions in the millimeter range being required in order to significantly improve these uncertainties. Will this ever be achievable?

²German Cancer Consortium - DKTK Dresden, and German Cancer Research Center - DKFZ, Heidelberg, Germany

³Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology, Dresden, Germany

⁴Department of Radiation Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Dresden, Germany

One of the most exciting areas of basic, translational and clinical research in radiation oncology today is radiotherapy with particles, i.e. with protons or heavier ions. The main advantage of radiotherapy with protons compared to state-of-the-art radiotherapy with photons is a decrease of the volume of normal tissues irradiated to intermediate and low doses, while irradiation of normal tissues to high doses or the conformality of the dose to the tumor are usually similar for protons and photons. Exceptions include situations where critical normal tissues can be excluded by proton therapy from the irradiated volume completely or to a large extent. The most relevant clinical research question is therefore to investigate whether sparing of normal tissue by proton therapy leads to clinical relevant benefits which balance the higher costs of this treatment. After demonstration of relevant sparing of normal tissues, further clinical studies on utilizing dose intensification strategies may become another important research avenue in those tumors where local or locoregional tumor control today are unsatisfactory.

At present only few centers (often with different technologies and patient populations) are active in clinical research using protons, which makes fresh thinking on study design in radiation oncology necessary, as large scale randomized trials will not be feasible in many situations. Model-based approaches are a major component of the trial methodological portfolio, but alternatives (including multicenter stepwise randomized trials, pseudo-randomized trials and prospective matched pair trials) may be superior in different clinical situations. All of these approaches necessitate dedicated clinical research infrastructures and complex high-level network formation to reach the power for meaningful clinical trials. This also plays an important role in terms of radiotherapy stratified by biological parameters, which is anticipated to become a clinical reality in the near future for several tumor entities.

Proton (or other particle) therapy holds particular promise to further advance personalized radiation oncology. However obstacles in trial design, data sampling and integration, or analysis may dilute the effects to such an extent that it may not be possible to demonstrate it according to generally accepted scientific standards. This would be a major hurdle for further implementation and reimbursement of this auspicious technology, and also for sound medical stratification of access of patients in need for this therapy. The lecture will discuss opportunities and problems of proton therapy in the context of high precision personalized as well as biologically stratified radiation oncology, thereby also touching trial design, technology development and the importance of network formation on a European level.

Symposium: Small animal irradiation

SP-0504

Preclinical radiotherapy technology, dosimetry and treatment planning

K. Butterworth¹, M. Ghita¹, C.K. McGarry², S. Jain³, G.G. Hanna³, J.M. O'Sullivan³, A.R. Hounsell², K.M. Prise¹¹Centre for Cancer Research & Cell Biology Queen's Uni, School of Medicine- Dentistry and Biomedical Sciences, Belfast, United Kingdom²Northern Ireland Cancer Centre, Radiotherapy Physics, Belfast, United Kingdom³Northern Ireland Cancer Centre, Clinical Oncology, Belfast, United Kingdom

Small animal image guided irradiation platforms are revolutionizing the field of preclinical radiobiology by facilitating the delivery of clinically relevant irradiation protocols under experimental conditions. Our laboratory is developing an in vivo radiobiology research program using the small animal radiotherapy research platform (SARRP, Xstrahl Life Sciences) as a central enabling technology to perform translational studies focussing on biologically optimised radiotherapy, nanoparticle theranostics and novel combination treatments. A major challenge now facing investigators is how to correctly apply the technology to accurately model clinical scenarios in relevant small animal models so that it can be exploited to its full potential in driving translational studies with outcomes likely to impact current standard of care in radiation oncology.

An overview of the current state-of-the-art in preclinical radiotherapy will be presented including recent developments such as integration of bioluminescence imaging, preclinical 4-D CBCT and Monte Carlo based dose calculation methods. Examples of innovative preclinical studies will be highlighted along with experience from our own laboratory from commissioning to experimental design and important considerations for the successful execution of hypothesis-driven investigations using small animal radiotherapy.

Despite certain challenges, small animal radiotherapy has much potential to bridge the translational gap between basic radiobiology and radiotherapy. As the technology develops and investigators gain experience as multidisciplinary scientists, pre-clinical studies that increasingly replicate the clinical scenario will drive new approaches in radiobiology that should ultimately translate to human health gains.

SP-0505

Radiation biology studies with a small animal irradiator: results from the Research Programme at Johns Hopkins University

P. Tran¹¹Johns Hopkins University The Sidney Kimmel Comprehensive Cancer Center, Department of Radiation Oncology, Baltimore, USA

Although advances with in-vitro cancer cell culture models have occurred recently, in vivo tumor models are still crucial for the study of novel radiation treatments. This is particularly important for radiation combination approaches that target tumor cell non-autonomous anti-cancer pathways such as the tumor microenvironment or the immune system. In addition, more sophisticated animal studies with radiation are now possible with the advent of technologies that integrate treatment planning, imaging, and radiation delivery capabilities such as with the small-animal radiation platform (SARRP; Fig 1).

Tumor xenograft models using human-derived tumor models implanted into immune-deficient mice are a mainstay of pre-clinical testing and discovery. Although the majority of in vivo studies involve immunocompromised mice, such as athymic, severe combined immune-deficiency (SCID) or NOD-SCID mice, these models are less ideal with radiation studies because some of these mice have mutations in DNA response and repair pathways. The abnormal DNA repair mechanisms in these mice limit the applicability of results with radiosensitizers given the integral role of DNA damage to the biologic effect of radiation therapy. Furthermore, anti-tumor effects of radiation may be mediated by the immune system. As a result of these limitations, genetically engineered mouse models (GEMMs) are becoming more widely used in preclinical studies with and without radiation. “Co-clinical trials” that use GEMMs that faithfully replicate the mutational events observed in human cancers to conduct preclinical trials that parallel ongoing human phase I/II clinical trials have shown great promise in cancer. This presentation will review published and on-going pre-clinical studies targeting both cancer cell autonomous and cancer cell non-autonomous pathways utilizing the SARRP with both xenograft tumor models and GEMMs at Johns Hopkins.

SP-0506

How do we select meaningful pre-clinical models for studies in radiation biology?

D. De Ruyscher¹¹MAASTRO clinic, Radiation Oncology, Maastricht, The Netherlands

Clinical research faces many problems, of which the availability of pre-clinical models that predict the human situation is one of the most important. Pre-clinical tumour models are being used for decades in many cases with the assumption that they are predictive for what will later happen in humans. As such, the use of pre-clinical, mostly mouse, models may limit the exposure of inactive and/or toxic treatments in patients. Although there is no doubt that pre-clinical models have been crucial to understand better molecular and other characteristics of carcinogenesis, growth and metastases and were the basis of many currently used cancer therapies, they still have considerable shortcomings. Classical mouse models use tumour cell lines that have been grown in vitro for many years and hence may have altered characteristics compared to *de novo* tumours. These tumour cells are then implanted subcutaneously in mice and tend to grow rapidly and thus do not mimic the much slower doubling times of most human cancers. This faster tumour growth may lead to a higher sensitivity for most chemotherapy drugs and hence erroneous conclusions. Moreover, in some situations, ectopic (out of the normal place) subcutaneously implanted tumours – still a standard methodology – may respond

differently to treatment compared to tumours grown in an orthotopic site, i.e. in their organ or tissue of origin, such as breast cancers in mammary fat pads. The latter may correspond more to the human situation. Moreover, metastases frequently show other responses than primary tumours in patients, and it is only recently that these effects can be mimicked in genetically engineered mouse models. Tumour bearing mice are often treated with drugs at levels, or with pharmacokinetics, that are not relevant to humans. Furthermore, nearly all pre-clinical models have not used tumours that were pre-exposed to another therapy, whereas in many phase I and phase II clinical trials only patients that show tumour progression after one or more systemic treatments are included. With the huge interest in immune therapy, the use of humanized mice has gained even more attention than before. However, these models still face problems with remaining mouse innate immunity and weak human innate and adaptive immunity. Even the best models suffer from the development of wasting disease in highly engrafted humanized mice and poorly developed lymph nodes and germinal centres. It is also unclear if the cell trafficking resembles that of humans. At present, no single mouse models mimics perfectly the human situation. However, models that use injected tumour cells in the organ from which they were derived and which form metastases in organs that are similar to the human situation may be the most appropriate for they bear a micro-environment that resembles that of humans. Spontaneously arising tumours, preferentially in older mice may represent an interesting model for immune therapy.

Symposium: Focus on the pelvic region

SP-0507

Bladder variability for pelvic radiotherapy: its approaches and impact

V. Khoo¹

¹Royal Marsden Hospital Trust & Institute of Cancer Research, Department of Clinical Oncology, London, United Kingdom

It is clear that the bladder as an organ has marked shape and positional variability due to its function of storing urine before the call of nature. This has obvious repercussions for pelvic radiotherapy depending on the intent of treatment particularly if the bladder itself is the radiotherapeutic target. As an organ-at-risk (OAR) this variability can be important and this can also impact on adjacent organs such as the prostate, rectum and uterus if these latter organs are being treated with radiotherapy. These adjacent pelvic organs can also deform the bladder. In addition the setup position of the patient either supine or prone can also influence on the day-to-day bladder position and shape. Furthermore the kidneys filtered continuously thus there will be steady filling of the bladder with a rate dependant on the hydration status of the patient during radiotherapy delivery. Other factors may also be crucial such as bladder capacity and function as well as disease extent if there is bladder cancer. Therefore the variability of the bladder size and shape is an important consideration for any pelvic radiotherapy. Many investigators have reported on the marked difference in filling of the bladder with variation in bladder size that may range up to 20 mm on different scanning times during a course of fractionated radiotherapy. For primary bladder radiotherapy, identification of the disease extent remains important as both the target and tissue of tolerance is the bladder itself. This can also impact on the manner in which the bladder fills in 3D and be distorted by invasive bladder disease. It can be difficult to maintain daily consistency of the 3D shape and size thus there are several methods developed to deal with this including treatment with either an empty or comfortably full bladder to initiating adaptive planning and image guided delivery methods. Fiducials have been used to better target the main disease for either boosting disease or to incorporate focal therapy strategies. These methods can also permit organ avoidance if the bladder is an OAR and it is critical to minimise dose to it due to poor bladder function and other

clinical factors. If the bladder is not the target then it can perform a useful function with intended filling prior to radiotherapy in order to displace other pelvic organs such as the bowel from irradiation such as with treatment of the pelvic nodes. Thus patient and disease related factors will need to be carefully assessed for each case. All these methods including their rationale and effectiveness will be discussed for both situations of the bladder as a target and as an OAR.

SP-0508

An evaluation of GoldAnchor intraprostatic fiducial marker stability during radiotherapy

D. Bodusz¹, L. Miszczyk¹, K. Szczepanik¹, W. Leszczyński²

¹Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Department, Gliwice, Poland

²Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy and Brachytherapy Planning Department, Gliwice, Poland

Background: Implantation of fiducial markers for IGRT (Image Guided Radiation Therapy) of prostate cancer patients increases the treatment accuracy by prostate localization using two orthogonal X-rays images. However the precision of the treatment depends on the stability of the fiducial marker. The aim of this study was to evaluate the migration of fiducial markers during the whole radiotherapy of prostate cancer patients.

Material and methods: An analysis of the intraprostatic fiducials migration during the treatment planning was done on a group of 45 patients on the basis on fusion of kV CBCT (performed during the first week of the treatment) and planning CT. The value of migration during the course of radiotherapy was done on a group of 20 patients treated within IGRT protocol on the basis on the fusion of kV CBCTs, performed weekly. The migration was defined as a shift between central points of markers, measured in three axis.

Results: The average values of the GoldAnchor™ migration during the treatment planning were: 1.1 mm (SD=0.9 mm) in the superior-inferior (SI) direction, 0.5 mm (SD=0.6 mm) in the left-right (LR) direction and 1.1 mm (SD=1.2 mm) in the anterior-posterior (AP) direction. The mean value of the vector of shifts was 1.9 mm (SD=1.3 mm). The average values of the GoldAnchor™ migration during the course of radiotherapy were: 0.1 mm (SD=0.2 mm) in the superior-inferior (SI) direction, 0.1 mm (SD=0.3 mm) in the left-right (LR) direction and 0.2 mm (SD=0.4 mm) in the anterior-posterior (AP) direction. The mean value of the vector of shifts during the treatment was 0.3 mm (SD=0.5 mm).

Conclusions: The analysis of the collected data showed that the marker shifts during the treatment planning seems to have no clinical significance and probably are related to the inaccuracy of the fusion of kV CBCT and planning CT. Position of the marker is stable during the whole course of radiotherapy. Therefore, IGRT based on GoldAnchor™ markers is safe and effective method of prostate cancer patient positioning.

SP-0509

Validation of a prostate cancer decision aid tool for shared decision making

E.J. Bloemen-van Gurp¹, B.G.L. Vanneste¹, A.J. Berlanga¹, D. Rijnkels¹, K. Van de Beek², J. Van Roermund², P. Lambin¹

¹MAASTRO clinic, Radiation Oncology, Maastricht, The Netherlands

²MUMC, Urology, Maastricht, The Netherlands

Purpose: To comply a decision aid tool with the criteria of the International Patient Decision Aid Standards (IPDAS), it is mandatory to follow a systematic and iterative approach to; (a) understand patient's and clinicians decisional needs, (b) create prototypical tools, (c) evaluate these prototypes with patients and clinicians and (d) use these results to improve the tool. We developed and validated a web-based decision

aid (DA) for shared decision making in prostate cancer patients using this approach.

Methods: A prototype of the tool was designed based on the input of an interdisciplinary group. Its clarity and acceptability was tested using a mixed method (interview and technology acceptance questionnaire; 5-Likert scale). The evaluation was performed with physicians (N=19) and patients (N= 16). Professionals from 5 academic and private hospitals (urologists, radiotherapists, specialized nurses and family doctors) gave their perspective about the patients' decisional needs and validated the information about the treatment options, complications and outcomes. The included patients were treated with either external beam radiotherapy, brachytherapy or prostatectomy. Patients who choose not to be treated (active surveillance) were also included. The decisional needs were evaluated during an interview. Afterwards the patients' were guided through the DA and asked to fill in a questionnaire to check the comprehensibility of the tool. A second group of patients (N=8) was included to assess the e-learning effect of the DA and to check if patients were able to use the DA alone (without coaching).

Results: The results were considered to create a new version of the DA. Physicians mentioned the need of information about basic anatomy, contraindications, hospital specific figures, and psychological support. Patients reported that the prototype of the DA provides clear information about the treatment options and their side-effects. Issues about the usability of the DA were reported and enabled us to improve and simplify the DA. The next step is to perform a study to establish the impact of the DA on the decisional conflict and the shared decision making process.

Conclusion: The systematic and iterative approach used to develop and validate the DA, allows to follow a thoroughly development process, and to gain knowledge about decisional needs.

Evaluation of a breast cancer nomogram to predict local relapse after breast conserving therapy

L. Kindts^{1,2}, A. Laenen³, S. Peeters^{1,2}, H. Janssen^{1,2}, T. Depuydt^{1,2}, E. Van Limbergen^{1,2}, C. Weltens^{1,2}

¹KU Leuven - University of Leuven, Department of Oncology, B-3000 Leuven, Belgium

²University Hospitals Leuven, Department of Radiation Oncology, B-3000 Leuven, Belgium

³KU Leuven - University of Leuven, Leuven Biostatistics and Statistical Bioinformatics Centre L-Biostat, B-3000 Leuven, Belgium

Purpose or Objective: Van Werkhoven et al. developed a nomogram to predict the 10-years ipsilateral breast relapse (IBR) after breast conserving therapy (BCT) for breast cancer (BC) based on the European Organisation for Research and Treatment of Cancer (EORTC) 'boost no boost'-trial with a concordance probability estimate (CPE) of 0.68 (van Werkhoven E, et al. 2011, Radiother Oncol). The nomogram includes histologic grade, ductal carcinoma in situ (DCIS), tumour diameter, age, tamoxifen, chemotherapy and boost. The aim of this study was to evaluate the performance of that algorithm in an independent cohort.

Material and Methods: We retrospectively identified 1866 BC patients who underwent BCT with radiotherapy from 2000 to 2007.

Two definitions of IBR were considered where simultaneous regional or distant recurrence were either censored (conform EORTC analysis) or included as event.

Patient, tumour and treatment characteristics were evaluated in uni- and multivariable analysis.

Firstly we assessed discrimination, i.e. the extent to which patients predicted to be at higher risk exhibit higher event rates than those deemed at lower risk, by the CPE. The CPE

was determined based on a Cox model with time to IBR as outcome and the EORTC nomogram 10-years IBR-free probability as the only covariate. Secondly a calibration plot was drawn, showing the predicted 10-years IBR-free probabilities against observed Kaplan-Meier estimates, to reflect prediction accuracy, i.e. the absence of over- or underestimation.

Results: Median follow-up time was 10.75 years.

Patients were on average older (58 vs 54 years), had a larger average tumour diameter (18 mm vs 15 mm) and were more likely to have received chemotherapy (29.7 % vs 15.7 %), to have a high grade disease (37.0 % vs 23.5 %) and to have a DCIS (69.8 % vs 57.8 %). Twenty-three percent of the patients received tamoxifen in the EORTC group, whereas 81.6 % received hormonal therapy in the validation group. Almost all patients (99.7 %) in the validation group received a boost versus 50.4 % in the EORTC cohort. Noteworthy on the variables not included in the nomogram, patients in the validation cohort had a higher percentage of oestrogen and progesterone receptor positivity (86.4 % vs 71.7 % and 75.9 % vs 64.3 %, respectively) and 10.2 % had HER2 overexpression. The 10-years IBR-rate was 1.4 %. On multivariable analysis, only the omission of the boost dose was a significant prognosticator of IBR ($p < 0.01$) with a trend for age ($p = 0.06$).

The nomogram demonstrated suboptimal discrimination, with a CPE of 0.54, and suboptimal calibration with an overestimation of the IBR-risk in general (Table 1 - Figure 1).

Table 1: CPE for the two definitions of local relapse.

IBR	Dataset	N cases	N events	CPE* (95 % CI)
First definition	All data	1787	34	0,54 (0,52;0,57)
	Restricted data*	1672	31	0,54 (0,53;0,57)
Second definition	All data	1787	45	0,54 (0,53;0,56)
	Restricted data*	1672	42	0,54 (0,53;0,56)

* Restricted data: excluding values beyond the ranges applied in the EORTC nomogram (age range 27-76 years and tumour size 0-50 mm).

Figure 1: model calibration plot for the two definitions of local relapse.

Note: For 5 subgroups of equal size, the model-predicted average relapse-free rate was plotted against the Kaplan-Meier estimated observed rates with 95 % confidence intervals. Black represents 'All data', grey represents 'Restricted data'. The dashed line corresponds to ideal calibration.

Conclusion: The EORTC predictive model for IBR in BC patients lacks accuracy in this more recent study population. Therefore the model should be tested and verified in additional, large patient populations and incorporating molecular subtyping might be needed.

PV-0511

Hypofractionated VMAT for early stage breast cancer: acute toxicity and cosmesis in 840 patients

C. Iftode¹, F. De Rose¹, D. Franceschini¹, A. Fogliata¹, E. Villa¹, A.M. Ascolese¹, P. Navarra¹, G.R. D'Agostino¹, C. Franzese¹, T. Comito¹, A. Tozzi¹, E. Clerici¹, R.L.E. Liardo¹, A. Stravato¹, M. Scorsetti¹

¹Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

Purpose or Objective: To evaluate acute toxicity and early clinical outcomes of hypofractionated simultaneous

integrated boost (SIB) approach with Volumetric Modulated Arc Therapy (VMAT) as adjuvant treatment after breast-conserving surgery.

Material and Methods: Patients presenting early-stage breast cancer were enrolled in a phase II trial. Eligibility criteria were as follow: age >18 years, invasive cancer or DCIS, Stage I to II (T <3 cm and N3), breast-conserving surgery, any systemic therapy was allowed in neoadjuvant or adjuvant setting. All patients underwent VMAT-SIB technique to irradiate the whole breast with concomitant boost irradiation of the tumor bed. Doses to whole breast and surgical bed were 40.5 Gy and 48 Gy respectively, delivered in 15 fractions over 3 weeks. Acute skin toxicities were recorded according to RTOG scoring criteria, and late skin toxicities according to CTCAE v4.0. Cosmetic outcomes were assessed as excellent/good or fair/poor according to the Harvard scale.

Results: Between August 2010 and January 2015, 840 consecutive patients were treated. Median age was 60 year (range 19-89 years). The median follow up was 16 months (range 6-55). At the end of RT treatment skin toxicity profile was G1 in 49% of the patients, G2 in 13%, and one patient presented G3 toxicity (0.1%). At six months of follow up skin toxicity was G1 in 27% of patients, G2 in 1%, no G3 cases; cosmetic outcome was good/excellent in 94% of patients. At one year skin toxicity was G1 in 13% of patients, 1 patient G2, 1 patient G3; cosmetic outcome was good/excellent in 93% of patients. After an early evaluation of clinical outcomes we have found 12 cases of progression disease, only one patient had an In-Breast-Recurrence.

Conclusion: The 3-week course of postoperative radiation using VMAT with SIB was well tolerated in acute and early late settings. Long-term follow-up data are needed to assess late toxicity and clinical outcomes.

PV-0512

Accelerated partial breast irradiation for Luminal-A breast cancer: analysis from a phase 3 trial

L. Meattini¹, C. Saieva², I. Desideri¹, G. Simontacchi¹, L. Marrazzo³, S. Scoccianti¹, C. De Luca Cardillo¹, V. Scotti¹, P. Bonomo¹, M. Mangoni¹, F. Rossi⁴, J. Nori⁵, D. Casella⁶, M. Bernini⁶, L. Sanchez⁶, L. Orzalesi⁶, S. Pallotta³, S. Bianchi⁷, L. Livi¹

¹Azienda Ospedaliero-Universitaria Careggi, Radiation Oncology Unit- University of Florence, Florence, Italy

²ISPO Cancer Research and Prevention Institute, Molecular and Nutritional Epidemiology Unit, Florence, Italy

³Azienda Ospedaliero-Universitaria Careggi, Medical Physics Unit, Florence, Italy

⁴S. Maria Annunziata Hospital, Radiation Oncology Unit, Florence, Italy

⁵Azienda Ospedaliero-Universitaria Careggi, Senology Radiology Unit, Florence, Italy

⁶Azienda Ospedaliero-Universitaria Careggi, Breast Surgery Unit, Florence, Italy

⁷Azienda Ospedaliero-Universitaria Careggi, Pathology Unit - University of Florence, Florence, Italy

Purpose or Objective: Breast cancer (BC) could be classified into four major molecular subtypes: Luminal-A, Luminal-B, triple negative/basal-like, human epidermal growth factor 2 (HER2) enriched. This classification could be based on immunohistochemistry, and may allow the clinicians to optimize treatment management. Luminal-A tumors represent around 40% of BC and are characterized by: estrogen receptor (ER) and/or progesterone receptor (PgR) positive, HER2/neu negative, and low Ki-67 proliferative index. Early luminal-A tumors tend to have an excellent prognosis, with high survival and low recurrence rates. The aim of this analysis was to observe Luminal-A outcome from a phase 3 trial comparing whole-breast irradiation (WBI) to accelerated partial breast irradiation (APBI) using intensity-modulated radiotherapy (IMRT) technique.

Material and Methods: In the whole trial 520 patients were randomized in 1:1 ratio to receive APBI versus WBI after breast conserving surgery for early BC. The primary endpoint was occurrence of ipsilateral breast tumor recurrence (IBTR); the main analysis was by intention-to-treat. This trial was registered with ClinicalTrials.gov, number NCT02104895.

Results: Luminal-A patients represented the 61.5% of the whole series (151 WBI versus 169 APBI). 5-year event rate according to allocated group showed no statistical difference in terms of IBTR (p=0.53). One case (0.9%) versus two cases (1.7%) were observed in the WBI and APBI arms, respectively. Survival events occurrences and IBTR curve are summarized in the Figures.

Event	Total	WBI (n=151)		APBI (n=169)		p-value*
		n	%	n	%	
IBTR	3	1	0.9	2	1.7	0.53
Local relapse	1	1	0.9	0	0	0.33
New ipsilateral BC	2	0	0	2	1.7	0.14
Locoregional relapse	4	2	1.7	2	1.7	0.95
Distant metastases	1	1	0.8	0	0	0.33

*p-value from log rank test

Conclusion: We observed a very low 5-year rate of IBTR for Luminal-A patients treated with APBI. Although these results should be confirmed at a longer follow up time, this approach should be considered for this subset of early BC patients.

PV-0513

The impact of chemotherapy on toxicity in the era of hypofractionated radiotherapy

M.C. De Santis¹, F. Di Salvo², F. Bonfantini³, M. Dispinzieri¹, M. Franceschini¹, F. Soncini¹, E.D. Mantero¹, V. Cosentino³, D. Postè³, P. Baili², M. Sant², E. Pignoli³, L. Lozza¹

¹Fondazione I.R.C.C.S Istituto Nazionale Tumori di Milano, Radiotherapy and Oncology, Milan, Italy

²Fondazione I.R.C.C.S Istituto Nazionale Tumori di Milano, Statistical Department, Milan, Italy

³Fondazione I.R.C.C.S Istituto Nazionale Tumori di Milano, Physical Department, Milan, Italy

Purpose or Objective: To evaluate toxicity in breast cancer patients treated with anthracycline and taxane based chemotherapy and whole breast hypofractionated radiotherapy, and to identify the risk factors for toxicity.

Material and Methods: From April 2009 to December 2014, 540 patients received radiotherapy after breast conservative surgery (BCS). The dose was 42.4 Gy in 16 daily fractions, 2.65 Gy per fraction. The boost to the tumor bed was administered only in grade 3 patients and in patients with close or positive margins. Acute and late toxicity were prospectively assessed during and after radiotherapy according to RTOG scale. The impact of patients clinical

characteristics and dose inhomogeneities on the occurrence of an higher level of toxicity has been also evaluated by univariate and multivariate analysis.

Results: One hundred and nineteen patients received chemotherapy. Sixty-one patients (11.3%) underwent trastuzumab therapy and four hundred and forty-one (81.6%) hormone therapy. The mean age was 74 (range 46-91 yrs). Forty seven (8.7%) and two hundred fifty eight (47.5%) patients were affected by diabetes mellitus and hypertension, respectively. G1 and G2/G3 acute skin toxicity were 53.7% and 28.5% in patients received chemotherapy and 63.2% and 18.5% in patients who did not receive it, respectively. No significant difference ($p=0.092$) was found between the two groups of treatment. The boost administration ($p<0.01$), the breast volume ($p=0.04$), dose inhomogeneities ($p<0.01$) and boost volume (0.04) were found to be statistically significant as concerns the occurrence of acute skin reaction at the univariate analysis; the boost administration ($p<0.01$), and hormone therapy ($p=0.01$) at multivariate analysis. Other clinical factors such as diabetes or hypertension were not correlated with the development of acute skin reaction. G1 and G2/G3 late fibrosis were 15.3% and 8.1% in patients received chemotherapy and 12.3% and 3.1% in patients who did not receive it, with a significant difference ($p=0.045$) between the two groups. Diabetes ($p=0.04$) and boost administration ($p<0.01$) were also found to be statistically significant on the occurrence of late fibrosis, but a multivariate analysis adjusted also for clinical tumour characteristics did not show any factors correlated to late fibrosis.

Conclusion: The results of our study, according to the large randomized trials, confirmed that hypofractionated whole breast irradiation is safe, even in patients treated with chemotherapy. Chemotherapy didn't impact on acute toxicity but only on late toxicity; however the percentage of G2-G3 fibrosis is low (8.1 vs 3.1%). Our study confirmed an increase of acute and late toxicity in patients who received additional boost.

PV-0514

Chest wall radiotherapy and complications after flap reconstruction

Y. Rao¹, A. Mull², A. Qureshi², T. Myckatyn², I. Zoberi¹

¹Washington University in St. Louis, Radiation Oncology, Saint Louis, USA

²Washington University in St. Louis, Plastic Surgery, Saint Louis, USA

Purpose or Objective: The effect of radiotherapy (RT) on the outcome of autologous reconstruction after mastectomy for breast cancer is unclear. Advances in technique such as the deep inferior epigastric artery perforator (DIEP) flap and IMRT may affect the complication rate. We seek to retrospectively evaluate the outcomes after flap reconstruction at our institution with a focus on radiotherapy variables.

Material and Methods: Patients receiving flap reconstruction after mastectomy at our institution from 2003-2014 were identified in a chart review. Analysis was limited to patients with a coded cancer status and who returned for at least one follow up visit. The outcome variables analyzed were flap loss or any complication (loss, ischemia, hematoma, infection). Descriptive data analyzed included age, tumor stage, flap type, chemotherapy, and radiation. RT specific variables included radiation at an academic medical center vs independent radiotherapy facility, 3D-CRT vs IMRT, and whether radiation was directed to the internal mammary (IM) region. Analyses were on a per-flap basis rather than per patient. Statistics were done in SPSS using logistic regression. Two prognostic models were generated. The first included all patients and analyzed age, stage, flap type, chemotherapy, and radiation therapy. The second model included only those receiving radiation therapy and included significant factors from the first model and the RT variables discussed above.

Results: 291 patients receiving 402 flap procedures met inclusion criteria. Mean age was 47.2 years with median follow up of 339 days. 93 (21.2%) had transverse rectus abdominis (TRAM) flaps, 178 (40.6%) had muscle sparing TRAM flaps, and 121 (27.6%) had DIEP flaps. 128 (29.2%) flaps were done after mastectomy for benign histology; 62 (14.2%) were for DCIS/LCIS, 69 (15.8%) were for stage I, 88 (20.1%) were for stage II, 52 (11.9%) were for stage III, and 3 (0.7%) were for stage IV disease. 146 (33.3%) received RT and 187 (42.7%) received neoadjuvant chemotherapy. Of those receiving RT, 42 (28.7%) received 3D-CRT, 38 (26.0%) received IMRT, and 66 (44.5%) had unknown RT technique. 28 (6.9%) flaps failed and 64 (15.9%) flaps had a complication. The first model, which included all patients, identified increasing cancer stage ($p=0.03$) as the most important variable for flap loss with a hazard ratio of 3.4 for DCIS/LCIS, 2.1 for stage I, 7.3 for stage II, and 1.8 for stage III compared to benign pathology. Age was the only variable associated with increased overall complications. In the second model, location of RT, RT technique, and IM directed radiation were not significant predictors of flap loss or complications.

Conclusion: Cancer stage and age are important predictors for flap failure and complications. Use of chest wall radiation therapy was not a significant predictor of flap failure.

PV-0515

GTV delineation of laryngopharyngeal carcinoma on PET is more accurate than on CT and MRI

H. Ligtenberg¹, E.A. Jager¹, J. Caldez-Magalhaes¹, T. Schakel¹, N. Kasperts¹, F.A. Pameijer², N. Kooij³, L.M. Janssen⁴, C.H.J. Terhaard¹, S.M. Willems³, C.P.J. Raaijmakers¹, M.E.P. Philippens¹

¹UMC Utrecht, Department of Radiotherapy, Utrecht, The Netherlands

²UMC Utrecht, Department of Radiology, Utrecht, The Netherlands

³UMC Utrecht, Department of Pathology, Utrecht, The Netherlands

⁴UMC Utrecht, Department of Otorhinolaryngology, Utrecht, The Netherlands

Purpose or Objective: Correct GTV delineation is the basis for accurate radiotherapy treatment. It is important to determine which imaging modality (CT, MRI or FDG-PET) results in most accurate GTV delineation. For clinical assessment, both GTV delineations and target volumes adjusted for delineation inaccuracies were compared with histopathology.

Material and Methods: Twenty-seven patients with a laryngeal or hypopharyngeal tumor (T3/T4) were imaged with CT, MRI and FDG-PET followed by laryngectomy. Imaging was performed in radiotherapy positioning mask. GTV was delineated in consensus by three observers on CT and MRI, while a semi-automatic delineation was performed on FDG-PET using an intensity based threshold method. The true tumor volume was delineated by one pathologist on whole-mount histopathological sections. These slides were digitized and the specimen was reconstructed in 3-dimensions. The tumor contours were non-rigidly transferred to the imaging acquired before tumor resection.

To cover 95% of the outer contour of all tumors, modality dependent target margins were derived and added to the GTV (Fig. 1a). GTVs and target volumes were compared between the modalities.

Figure 1: a) A schematic representation of the target margin (blue dotted line) added to the delineated GTV (blue) to cover 95% of the outer surface of the tumor (red). b) Boxplots of target volumes of all patients are shown for the three modalities.

Results: The median tumor volume delineated on pathology was 10.5 ml (range: 3.4 ml - 68.6 ml). Median GTVs delineated on CT, MRI and PET were 17.5 ml, 15.2 ml and 14.8 ml, respectively. None of the GTVs fully covered the pathological tumor volume with a median tumor coverage of 93%, 90% and 87%. In several cases, the position of cartilage invasion was not recognized, which contributed to missing tumor volume.

The modality dependent target margins to cover 95% of the tumor outer contour were 5.6 mm, 8.7 mm and 6.2 mm and resulted in median target volumes of 56 ml, 72 ml and 53 ml for CT, MRI and PET, respectively (Fig. 1b).

Conclusion: In all modalities, delineated GTVs overestimated tumor volume. Nevertheless, some tumor volume was missed in all cases. Automated delineation on PET resulted in the smallest target volume compared to manual delineation on CT and MRI, while covering an equivalent amount of tumor. This study suggests that delineation or segmentation inaccuracies can be corrected using a margin between 5.6 and 8.7 mm.

PV-0516

Guideline development for tumor delineation on MR-images for laryngeal and hypopharyngeal cancer

E. Jager¹, N. Raaijmakers¹, H. Ligtenberg¹, J. Caldas-Magalhaes¹, T. Schakel¹, F. Pameijer², N. Kasperts¹, N. Willems³, C. Terhaard¹, M. Philipppens¹

¹UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

²UMC Utrecht, Department of Radiology, Utrecht, The Netherlands

³UMC Utrecht, Department of Pathology, Utrecht, The Netherlands

Purpose or Objective: Development of guidelines for the delineation of the gross tumor volume (GTV) on MRI is of utmost importance to benefit from the increased visibility of anatomical details and to achieve a more accurate and precise GTV delineation. In the ideal situation, the GTV corresponds to the histopathologically determined "true tumor volume". In this work we developed and validated guidelines for GTV delineation on MRI by comparison with the tumor outline on histopathology as gold standard.

Material and Methods: Twenty-seven patients with T3 or T4 laryngeal or hypopharyngeal cancer underwent a MRI scan before total laryngectomy. After surgery, whole-mount hematoxylin-eosin stained (H&E) sections were obtained from the surgical specimen. One pathologist delineated all tumor tissue on the H&E sections (tumorH&E). The GTV was delineated on the MR images (T1 w, Gd-T1 w, T2 w) by three independent observers in two sessions. The first session (delineation 1) was performed according to clinical practice. In the second session (delineation 2) the observers used delineation guidelines derived from guidelines for detection of cartilage invasion on MRI: Volumes with increased signal intensity on T2w images and higher signal intensity on Gd-T1w images than that of the tumor bulk were not included in the GTV.

The reconstructed specimen was registered to the MR images in order to compare the GTV to the tumorH&E in 3D. Volumes and overlap parameters were analyzed. Distances between the GTV and the tumorH&E were calculated at locations where the tumorH&E was outside the GTV. Subsequently, a margin that accounted for the underestimation of the tumour was determined. Finally, target volumes were created by applying this margin to the GTV.

Results: The median GTVs of delineation 1 (19.4 cm³) and of delineation 2 (15.8 cm³) were larger than the volume of the tumorH&E (10.5 cm³). However, target margins of 10.2 mm and 8.3 mm were needed for delineation 1 and 2, respectively, to compensate for the underestimation of the tumor at specific locations. By adding this margin to the GTVs, the target volumes for delineation 1 (median: 117.6 cm³, mean: 125.9 cm³, SD: 53.2 cm³) were significantly larger than those for delineation 2 (median 76.2 cm³, mean 85.7 cm³, SD: 43.3 cm³).

Conclusion: GTV delineation guidelines on MRI decreased the overestimation of the tumour, resulted in a smaller margin around the delineated GTV needed to include all tumor tissue and consequently resulted in smaller target volumes with the same tumor coverage.

Upfront vs. no upfront neck dissection in primary head and neck cancer radio(chemo)therapy

D. Nevens¹, F. Duprez², K. Bonte³, P. Deron³, W. Huvenne³, A. Laenen⁴, W. De Neve², S. Nuyts¹

²Ghent University Hospital, Radiation Oncology Department, Ghent, Belgium

³Ghent University Hospital, Department of Head- Neck & Maxillofacial Surgery, Ghent, Belgium

⁴KU Leuven-University of Leuven, Leuven Biostatistics and Statistical Bioinformatics Centre, Leuven, Belgium

Purpose or Objective: The benefit of upfront neck dissection (ND) in locally advanced head and neck cancer (HNC) treated with primary (chemo-) radiotherapy (CRT) is debated. Therefore, we retrospectively compared outcome and toxicity between patients with and without upfront ND followed by CRT.

Material and Methods: Two-hundred sixty-four consecutive patients with HNC without metastases at diagnosis and with lymph node stage N2-N3 were included in 2 centers. Patients were all treated between January 2002 and December 2012, and received definitive CRT in center 1 and upfront ND followed by CRT in center 2. Clinical data and outcome were assessed retrospectively. Toxicity was scored using the LENT-SOMA scale at 6, 12, 18 and 24 months after the end of treatment. Both patient groups were compared using a Chi-square test for categorical variables or a Mann-Whitney U test for continuous variables. Descriptive statistics on overall survival (OS) is based on Kaplan Meier estimates. For all other time-to-event outcomes, cumulative incidence function (CIF) estimates were calculated. The difference between both groups on the different outcomes was analyzed using multivariable models, including group and prognostic patient- or tumor characteristics on which the 2 groups were different. All tests were two-sided, and a p-value of less than 0.05 was considered statistically significant.

Results: We included 150 patients in the group without ND (center 1) and 114 patients in the group with upfront ND (center 2). The group comparison is given in Table 1.

Variable	Statistic	No dissection	Neck dissection	P-value
Sex				
Male	n/N (%)	126/150 (84.00%)	103/114 (90.35%)	0.132

Unknown	n/N (%)	9/66 (13.64%)	5/46 (10.87%)	

Table 1. Group comparison on patient/tumor characteristics.

Based on this result, we decided to account for the differences in T stage, overall treatment time and concomitant treatment for the statistical analysis of outcome and toxicity. Mean follow up was 5.68 years in the group without ND and 5.83 years in the group with upfront ND. Local, regional and distant control after 2 years were 91.07% and 85.96% ($p = 0.09$), 89.22% and 83.27% ($p = 0.12$) and 76.74% and 75.13% ($p = 0.92$) in the group with and without upfront ND, respectively. We observed worse OS after 2 years in the subgroup with upfront ND (48.01% vs. 70.79%, $p = 0.01$). The difference in OS can be explained by more secondary primaries in this subgroup with upfront ND and more non-disease related deaths. We did not find a significant difference between both groups regarding edema and atrophy at 6, 12, 18 and 24 months (Figure 1). Regarding fibrosis, we found an overall trend towards worse outcome in the ND group at all time-points ($p=0.06$). A significantly higher proportion of severe fibrosis (grade \geq 2) was present in the ND group ($p=0.01$) at all time points (Figure 1).

Outcome	OR (95% CI)	P-value
Fibrosis	1.558 (0.982;2.470)	0.0595
Edema	1.251 (0.758;2.063)	0.3810
Atrophy	1.652 (0.644;4.242)	0.2964
Severe fibrosis	2.811 (1.384;5.710)	0.0042

OR: Odds ratio, CI: Confidence interval

OR >< 1 means higher (lower) level on scale for Neck dissection group.

Figure 1. The table presents for every toxicity, the effect of group (Neck dissection versus No neck dissection) by means of odds ratios (OR) with 95% confidence intervals at all time-points (6, 12, 18 and 24 months).

Conclusion: Both treatment regimens have a comparable local, regional and distant control. However, fibrosis and more specifically fibrosis grade is more prominent following upfront ND and CRT when compared to CRT alone.

⁶Debiopharm International SA, Translational Medicine, Lausanne, Switzerland

⁷Debiopharm International SA, Clinical Research & Development, Lausanne, Switzerland

⁸Département d'Oncologie UNIL-CHUV, Service de Radio-oncologie, Lausanne, Switzerland

Purpose or Objective: Chemo-radiotherapy (CRT) plays a major role in the management of patients with locally advanced squamous cell carcinoma of head and neck (LA-SCCHN). However, loco-regional (LR) failure remains a significant problem due to the resistance to radiotherapy and chemotherapy. Inhibitors of Apoptosis Proteins (IAPs) are expressed in various cancers and are able to block caspase activation and modulate NF- κ B signalling pathways. As such, they represent attractive targets to overcome resistance to both chemo- and radio-therapy. Debio 1143 is a potent orally-available IAP antagonist currently in clinical development able to radiosensitize and ameliorate the effects of platinum derivatives in multiple SCCHN models both in vitro and in vivo. A previous phase I study showed Debio 1143 as a single agent was well tolerated up to 400 mg/day q14d21. This Phase I study defined the dose limiting toxicities (DLTs), maximum tolerated dose (MTD), safety, pharmacokinetic (PK) and pharmacodynamic (PD) of Debio 1143 in combination with CRT.

Material and Methods: Treatment-naïve LA-SSCHN (stage III/IV), negative HPV status for oropharynx, were treated with CRT (70 Gy in 7 weeks + cisplatin 100 mg/m² every 3 weeks) and escalating doses of Debio 1143, administered orally once daily on days 1-14 every 3 weeks for a maximum of 3 cycles. The starting dose of Debio 1143 was 100 mg/day. Doses were escalated using a Bayesian Continuous Reassessment Method (CRM) until MTD, based on dose limiting toxicities (DLTs) observed within the first 9 weeks

from start of study drug administration. Dose escalation decision and recommended dose (RD) were made by an independent safety committee. Blood PK and PD samples were serially drawn along the 3 cycles.

Results: Fourteen patients were included in the study. DLTs per dose level (DL) are shown in the table with 3 patients experiencing more than one DLT. The RD of Debio 1143 to be combined with CRT was 200 mg/day (=MTD). Debio 1143 exposure increased proportionally with dose and did not accumulate over time. Amylase/lipase and ALT/AST increase was associated with higher Debio 1143 exposures. At all dose levels, the PD effect of Debio 1143 was evidenced by the degradation of cIAP1 in PBMCs and a trend in an increase of serum MCP1. 12 patients were evaluable for response by RECIST 10-12 weeks post treatment among which 3 CR, 5 PR and 1 SD.

Debio 1143 DL	DLT evaluable patients N=14	Patients with DLTs N=5	Event (CTCAE)	CTCAE grade	Action	Outcome
100mg	5	1	Amylase increase (Cy1-d3)	3	None	Recovered
			Anemia (Cy3-d8)	4	Drug withdrawn	.
			Esophagitis (Cy3-d14)	4		.
200mg*	6	2	Tubular necrosis (Cy1-d4)	3	Drug withdrawn	Ongoing
			AST/ALT increase (Cy1-d4)	3		Recovered
			Febrile neutropenia (Cy1-d14)	4		.
			Lipase increase (Cy1-d15)	3	None	Recovered
300mg	3	2	ALT increase (Cy3-d22)	3	None	Recovered
			Amylase increase (Cy2-d14)	3	Drug withdrawn**	Recovered
			Lipase increase	4		.

*MTD, established by CRM

** Patient experienced concomitant cerebro-vascular accident G3 (related to cisplatin) and asthenia G3 (related to radiotherapy)

Conclusion: Combination of Debio 1143 with CRT was tolerated, exhibited favourable PK in combination with CRT with significant PD activity. The MTD was found to be 200 mg/day and is now being used in a randomized phase 2 study initiated by GORTEC to evaluate the anti-tumor activity of this combination in LA-SCCHN.

PV-0519

The hypoxic radiosensitizer, nimorazole, in RT of HNSCC: pharmacokinetics, toxicity and compliance

M.A.H. Metwally¹, J. Overgaard¹

¹Aarhus University Hospital, Department of Experimental Clinical Oncology, Aarhus C, Denmark

Purpose or Objective: Study of pharmacokinetics (PK), toxicity, and compliance with nimorazole (NIM) which is currently investigated for its efficacy in three large randomized clinical trials (NIMRAD, EORTC 1219/DAHANCA 29, and DAHANCA 30)

Material and Methods: The PK of NIM was studied in 63 patients with HNSCC treated in the DAHANCA-5 trial. While the toxicity and compliance were studied in HNSCC patients treated with NIM, in combination with radiotherapy (RT) or chemo-radiotherapy (CRT), in Denmark between 1990 and 2013. Plasma concentration measurements were done using high pressure liquid chromatography following the first day dose; and plasma concentration profiles were subjected to non-compartmental PK analysis using validated PC-based software. The different PK parameters were calculated and correlated with the different patient- and treatment-related variables. Nimorazole was administered as oral tablets in doses of approximately 1.2 g/m² BSA before the first daily radiation treatment. A second dose of 1 g was given before the second RT fraction in the accelerated fractionation regimen (6 fractions/week). The compliance was estimated as the percentage of the initially prescribed dose; and drug-related side effects were reported from the DAHANCA database.

Results: A linear relationship between peak plasma concentration and administered dose was detected. The mean peak concentration was 36.8 ± 1.3 µg/ml, and the time of peak concentration ranged between 30 and 180 min

(median 60 min). Plasma elimination occurred with a mean half-life of 3.35 ± 0.09 h. There was a statistically significant correlation between area under the concentration-time curve (mean 191 ± 6 µg·h/ml) and administered dose, especially when expressed as g/m². A statistically significant longer elimination half-life in men relative to women (mean difference 0.40 h; 95% confidence interval 0.77-0.03; P 0.03) was detected. A total of 1049 patients were investigated for toxicity and compliance with NIM. The compliance was fair, with both conventional and accelerated RT as well as CRT schedules, with 58% of patients received the full prescribed total dose. Nausea and vomiting were the major complaints representing 87% of the known side effects that caused dose reduction. All side effects ceased when treatment was interrupted, and neither severe nor long lasting side effects were observed. Female patients, and patients received accelerated CRT were significantly less compliant with NIM, and more likely to have nausea and vomiting; while patients who received less than 1100 mg/m² per day were significantly more compliant, and less likely to have nausea and vomiting.

Conclusion: The current nimorazole administration practice in clinical trials is acceptable, and the compliance to the drug is fair, either with the conventional or accelerated RT as well as CRT, with tolerable acute, but neither persistent nor late, toxicity.

Symposium: Dose painting: those pending issues

SP-0520

The promises of dose painting

W. De Neve¹, L. Veldeman², P. Ost², F. Duprez², K. Vandecasteele², K. De Wolf³, C. Montem², D. Berwouts⁴, A.M.L. Olteanu², T. Vercauteren², W. De Gersem²

¹De Neve Wilfried, Belgium,

²University Hospital Ghent, Radiation-Oncology, Ghent, Belgium

³Ghent University, Radiation-Oncology, Ghent, Belgium

⁴University Hospital Ghent, Radiology, Ghent, Belgium

Purpose To demonstrate that dose painting (DP) is a promising tool to decrease overall treatment time (OTT), to reduce toxicity, to improve palliation or enhance tumor control. The present state of DP will be illustrated through 3 types of applications. We will also speculate about the potential of DP to integrate with novel systemic treatment approaches.

Materials and methods

A. Topographical DP (TDP) in breast irradiation. TDP distributes dose as function of the spatial distribution of subclinical cancer deposits nearby the primary tumor in breast cancer. Patients (n=170) were randomized between prone whole breast irradiation (WBI) followed by a boost (WBI-SeqB: OTT=4 weeks) and WBI with simultaneous integrated boost (SIB) using TDP (WBI-TDP-SIB: OTT=3 weeks). Acute moist desquamation rate was the primary endpoint.

B. DP against bone metastasis pain. There is no dose-response relationship above 8 Gy single dose for the control of pain by uncomplicated bone metastases. This observation triggered the hypothesis that cytokine cascades counteracting palliation are activated by radiation and that their activity is function of the irradiated volume. DP was employed to drastically reduce the irradiated volume. Patients (n=45) were randomly assigned (1:1:1) to receive a single fraction of either 8 Gy with conventional radiotherapy (Conv-8Gy) or 8 Gy with DP (dose range 6-10 Gy) (DP-8Gy) or 16 Gy with DP (dose range 14-18 Gy) (DP-16Gy). The trial was designed for selection of the experimental arm worthwhile of continuing in phase III.

C. DP in loco-regionally advanced head&neck cancer. 18F-FDG-PET-guided DP-treated patients enrolled in 3 dose-escalation studies (n = 72) were matched with standard IMRT-treated patients (n=72) irradiated during the same time period. Median dose in the DP-group was 70.2-85.9 Gy/30-32

fractions against 69.1 Gy/32 fractions in the IMRT group. Endpoints were local control, acute and late toxicity. Results A. Interim analysis (n = 150) showed low rates of moist desquamation, mostly located in the infra-mammary fold (5/75 WBI-SeqB vs 3/75 WBI-TDP-SIB, p = 0.5). Trends in favor of WBI-TDP-SIB were observed for breast edema (p=0.08) and pruritus (p = 0.1). B. The volume of normal tissue receiving 4 Gy, 6 Gy and 8 Gy was at least 3, 6 and 13 times smaller in the DP-8Gy arm compared to Conv-8Gy and DP-16Gy (p<0.05). DP-8Gy resulted in a pain response of 80% compared to 53% and 60% for Conv-8Gy and DP-16Gy. Quality of life analysis suggests better outcome for patients treated in the DP-8Gy arm with the scores 'painful characteristic', 'insomnia' and 'appetite loss' reaching significance (p<0.05). C. Local control at 5 y was 83.4% and 75.2% in the DP- and IMRT-treated patients, respectively (p=0.28). Grades of acute dysphagia and mucositis were higher for the DP- than for the IMRT-treated group (p=0.03 and p=0.08, respectively) but differed according to DP-technique and -prescription. Poorly healing mucosal ulcers at the locations of the highest doses were observed in 9 DP- and 3 IMRT-treated patients (p=0.07) and reflect dose-limiting toxicity (DLT). Analysis of all DP-treated patients showed that DP-planning using a linear relation between 18F-FDG voxel-intensity and dose was associated with high risk of DLT if peak-doses were >84 Gy or the volume receiving >80 Gy was >1.75 cc in 30-fraction schedules (OTT = 6 weeks). Discussion and conclusions The term DP covers a variety of techniques that open a vast spectrum of applications. The use of TDP after breast-conserving surgery allows to integrate boost treatment in WBI without increasing toxicity. In bone metastasis, DP-8Gy was selected as a candidate experimental arm to test the hypothesis of improved palliation by reducing the irradiated volume. A confirmatory phase III trial is underway. In loco-regionally advanced head&neck cancer, DP may open a window for improving local control. However, the safety margin for dose-escalation is narrow. Poorly healing mucosal ulcers at the peak-dose regions are DLT of DP. The dose/volume/DLT relationship casts doubt on the safety of linear 18F-FDG voxel-intensity based DP. A phase III trial using non-linear DP is underway. Tumor heterogeneity - known for decades- supports DP and refutes the use of homogeneous dose distributions. Dose escalation to radioresistant regions in the tumor or decreasing the irradiated volume may be a conceptually naive way to use DP. The insight that ionizing radiation can enhance vascular and immunogenic mechanisms of cell death opens a new field for DP characterized by large fraction doses to small sub-volumes of tumor. In these applications, direct cancer cell kill might be subordinate to other goals of DP including amplifying bystander and abscopal effects or breaking immune tolerance. Combination of DP with immunomodulating drugs or drugs that target vasculature or immune checkpoints are investigated to validate these concepts.

SP-0521

The biological rationale of dose painting: is it realistic?

M. Alber¹

¹Aarhus University Hospital, Department of Clinical Medicine - Department of Oncology, Aarhus, Denmark

Any additional dose that can be applied without harm will lift tumour control in a patient population. Dose painting (DP) claims to make better use of dose than an indiscriminate or random escalation: by virtue of functional imaging, it should be more effective, more selective and more patient-specific. Still, on a pragmatic level, DP can often be summarized by "we boost because we can". What does it take to go more biological?

Obstacles lie in quantitative functional image acquisition, image interpretation, dose prescription and collection of evidence. Unfortunately, quantitative functional imaging is notoriously capricious. The problems tend to grow the more specific in terms of tumour biology an imaging modality is - which is one of the reasons for the popularity of FDG-PET, being arguably one of the least specific modalities. A specific modality may be more intriguing scientifically, but obviously

shows only a narrow aspect of tumour biology, which may create a need for a combination of multiple modalities. Imaging modalities usually operate at length scales far greater than the phenomena to which they are sensitive. This can make the interpretation of images challenging, especially when tracer kinetics need to be considered. Imaging sophistication alone reveals little of the import of some physiological or biological trait for treatment outcome. Only clinical data can fill this gap in biological understanding with some confidence. Further, a single image is just a snapshot of a dynamically evolving tumour, and if taken pre-treatment, says little about the tumour's response to therapy. Therefore, without any highly suggestive clinical evidence, the prospects for naive (i.e. model-based) DP are bleak.

Accordingly, the majority of DP trials to date are pragmatic in their choice of imaging modality and -protocol, and dose prescription. In addition to being practical, especially in a multi-centric setting, this also ensures that a proof of benefit (of both boosting and imaging) can eventually be made. The essential advantage of "we boost because we can" over sophisticated "dose painting by numbers" is, that it generates the data needed to reach said sophistication.

From this pragmatic standpoint, neither today's imaging capabilities nor the understanding of their relevance to tumour treatment response are sufficient to speak of an established biological rationale for DP. Some clinical evidence exists in few instances that links certain functional imaging to lack of tumour control or even location of recurrence. Given this, workable DP concepts today are rather shaped by considerations about image sensitivity and specificity and organ mobility, than biology.

SP-0522

Dose prescription and treatment delivery at the voxel scale: a fantasy?

J. Lee¹, D. Di Perri², S. Differding², X. Geets², V. Grégoire²

¹Université Catholique de Louvain, Box B1-54.07, Brussels, Belgium

²Université Catholique de Louvain, Molecular Imaging-Radiotherapy- and Oncology, Brussels, Belgium

Purpose/Objectives: This work aims at formally identifying the methodological issues that hinder the implementation and adoption of dose painting (DP) in radiotherapy. DP entails the use of functional imaging to set up a non-uniform dose escalation, either with sub-contours or voxel-to-voxel variations. Although theoretically appealing, DP has not succeeded yet in passing from research to clinical use. This work reviews the physical, mathematical, and statistical causes of this delay, in the specific case of DP guided by PET.

Method: The following steps occur in PET-based DP: acquisition of PET images (before and/or during treatment, with one or several tracers), conversion of the uptake(s) into a dose increment, treatment plan optimization, fractionated treatment delivery, accumulation and assessment of the delivered dose, and optional treatment adaptation. Every step or piece of data in this path can be modeled to investigate its shortcomings. All PET tracers are characterized with their specificity and sensitivity as a surrogate of some biological variable of interest in given conditions (e.g., before or during radiotherapy). PET images are described by their resolution and signal-to-noise ratio. Treatment plan quality is assessed by a quality-volume histogram (QVH), namely, a DP-specific dose-volume histogram that considers the ratio planned dose over prescribed dose. Random and systematic patient setup errors are quantified with their respective standard deviation. Non-rigid registration of pre- and per-treatment images is used to approximate the cumulated dose, taking into account patient evolution (tumor regression, possible weight loss).

Results: Our main result is the formal proof that PET-based DP cannot lead to a delivered dose that is strongly correlated with the tracer uptake at the microscopic level. This weak correlation is caused by: i) The limited information conveyed by heterogeneities observed in PET images. Current PET systems have a low resolution and a low signal-to-noise ratio,

which translate into biases and variance in the uptake measurement. Moreover, the tracer has typically a source-to-background ratio that decreases during treatment (e.g. after 3 weeks for FDG). This intrinsically limits the number of interpretable images that can be acquired during treatment.

ii) Dose blurring due to treatment fractionation. Daily setup introduces geometrical errors. Random errors blur the planned dose, while systematic ones shift it. A systematic drift can also be caused patient evolution (tumor regression, weight loss), thus making adaptive radiotherapy a desirable prerequisite for DP. All this shows that DP must cope with limited information about the real uptake heterogeneities. If directly converted into a dose prescription, these blurred heterogeneities are likely to be further smoothed or even shifted by random and systematic errors if the delivered dose is considered. While dose blurring is beneficial to uniformity within the targets in usual treatment plans, it is actually detrimental to any form of intended heterogeneity. Dose blurring cannot be compensated for with usual safety margins, since they rely on a model that implicitly assumes dose uniformity and further reinforces it to guarantee coverage. Instead, robust plan optimization must be used, either by modeling the setup errors in the optimizer or by providing a modified prescription, dilated for systematic errors and deconvolved for random errors. It is however noteworthy that ensuring coverage might sound paradoxical in DP: it widens the dose peaks and increases the mean dose, whereas DP precisely aims at a selective and parsimonious escalation.

Conclusions: Advanced treatment techniques such as intensity-modulated radiotherapy make DP technically feasible: a non-uniform dose prescription, with rather sharp gradients, can be accurately delivered at each fraction. Issues are located upstream (poor quality of PET images, which further decreases during treatment) and downstream (dose blurring due to setup errors and patient evolution). These issues lead to delivered doses that are weakly correlated to the underlying microscopic reality. To increase this correlation, an adaptive treatment strategy is a prerequisite to DP. Combined with other confounding factors, this weak correlation also jeopardizes the chances for an evidence-based approach to succeed in differentiating various flavors of DP from each other or from other comparable escalation strategies.

Symposium: ACROP

SP-0523

ACROP: General procedures, SOPs and current status

C. Belka¹

¹*Klinik und Poliklinik für Strahlentherapie und Radioonkologie, Radiooncology, Munich, Germany*

Since 2012 the Advisory committee for radiation oncology practice ACROP has taken over the responsibility for the initiation and coordination of ESTRO internal guidelines as well as multidisciplinary guidelines together with other scientific societies.

During the ESTRO 35 ACROP session C Belka will present the workflow and SOP of ACROP, K Tanderup will give an brief overview of the ongoing and mature guidelines in the areas brachytherapy and physics and Max Niyazi will present the new guideline on Target volume delineation in Glioblastoma.

SP-0524

Clinical guidelines, update and introduction of recent clinical guidelines

The ACROP committee has been established to generate European guidelines on radiotherapeutic topics and therefore, a group of thirteen experts had been selected to

draft target delineation guidelines on glioblastoma. This talk will summarize the different steps that were taken to pull together all relevant information and will highlight the most relevant issues having been included within this guideline. In brief, treatment preparation, imaging prerequisites, delineation guidelines and pitfalls, planning objectives and normal tissue constraints will be discussed. The panel members have ensured to update this guideline within a 2 year's time frame and updates will be given as amendments if there are scientific breakthroughs.

SP-0525

Brachytherapy and physics guidelines, update and introduction of recent guidelines

K. Tanderup¹

¹*Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark*

GEC ESTRO has a long term tradition for development and publication of guidelines within brachytherapy. These initiatives have grown out of working groups, which have a structure for joint multicenter research and development projects. The working groups have facilitated substantial progress within e.g. imaging, target definition and treatment planning, and this has become the basis of novel guidelines such as the GEC ESTRO recommendations for cervix, prostate, breast, as well as head & neck brachytherapy. The most recent example is the guideline on target definition for accelerated partial breast irradiation (APBI) which was published by the GEC ESTRO breast working group (Strnad et al) in June 2015 in *Radiotherapy & Oncology*. In parallel, the GEC ESTRO breast working group has been carrying out a randomized study on APBI, and this has further strengthened the impact of the guidelines. The clinical outcome of the study was published in *Lancet* in October 2015, and this is an excellent example of possible synergy between development of guidelines and related research activities. Other initiatives from GEC ESTRO include the current development of guidelines on bladder brachytherapy (Bradley Pieters), quality assurance of ultrasound in brachytherapy (Frank André-Siebert), as well as an update on head & neck brachytherapy (György Kovács). During the last decade there has been extensive collaboration between ESTRO (in particular the BRAPHYQS working group and AAPM therapy group on joint physics recommendations and guidelines. The underlying idea is that the gathering of experts from different continents improves quality, and that geographically broader views improve the global applicability of guidelines. Examples of recently published joint GEC ESTRO/AAPM guidelines are guidelines for uncertainty analysis (Christian Kirisits), robotic brachytherapy (Tarun Podder), and the report on High Energy Brachytherapy Dosimetry (Jose Perez-Calatayud). Uncertainty analysis is an example of a research field which has been well developed in external beam radiotherapy, but was less developed in brachytherapy for many years - mainly due to the fact that 3D imaging was introduced later in brachytherapy than in external beam radiotherapy. The guidelines for uncertainty analysis (Kirisits) showed therefore big impact on the field, and there is altogether now an increasing attention towards quantification of uncertainties in brachytherapy and considerations about how to improve clinical outcome by decreasing uncertainties. Joint GEC ESTRO/AAPM recommendations currently in progress are: TG - 167 Recommendations by the AAPM and GEC-ESTRO on the use of new or innovative brachytherapy sources, devices, applicators, or applications: Report of Task Group 167 (Ravinder Nath) and Supplement 2 to the 2004 update of the AAPM Task Group No. 43 Report (Mark Rivard). ESTRO physics has published several booklets on QA guidelines. Non-brachytherapy physics guidelines in progress are Quality Management in RT: The use of industry Quality Tools (Crister Ceberg), QA guidelines for CBCT developed together with EFOMP (Alberto Torressin), and also guidelines on Technology for Precision Small Animal Radiotherapy Research (Frank Verhaegen and Dietmar Georg). ESTRO physics committee and AAPM are currently working on a memorandum of understanding (MoU) with the aim of increasing scientific

interactions and strategic relationships between the societies. The MoU will facilitate collaboration across the ocean on e.g. Joint Task Groups, Scientific meetings and Education. The development of reports (e.g. AAPM task group reports, professional guidelines, etc.) should seek collaboration between the two societies where appropriate and feasible. Such collaboration could be achieved by inviting joint membership on appropriate drafting task groups by the initiating society. Both societies have now Standard Operating Procedures (SOP) available for development of guidelines, which gives a good structure for initiating international guidelines and securing high quality reviews - representing both Europe and North America - in upcoming guidelines.

Noninvasive imaging of the PD-1/PD-L1 checkpoint in naïve mice and after combined radioimmunotherapy

M. Hettich¹, F. Braun², G. Niedermann¹

¹University Clinics Freiburg, Dept. of Radiation Oncology, Freiburg, Germany

²University Clinics Freiburg, Dept. of Nuclear Medicine, Freiburg, Germany

Purpose or Objective: There is increasing evidence that antibodies blocking the PD-1 checkpoint (either anti-PD-1 or anti-PD-L1) dramatically increase in-field anti-tumor responses to ionizing radiation and enhance abscopal effects on non-irradiated metastases. Here, we developed PET tracers based on therapeutic surrogate antibodies that enable to non-invasively visualize not only the PD-1 and PD-L1 expression in mice but also the biodistribution of the surrogate checkpoint-blocking antibodies.

Material and Methods: Two novel PET tracers were developed by conjugation of anti-murine PD-1 and PD-L1 surrogate checkpoint-blocking antibodies with the chelator NOTA and labeling with the radioisotope ⁶⁴Cu. Non-invasive PET imaging was performed on naïve and tumor-bearing mice. Mice bearing s.c. B16 melanomas were treated with hypofractionated radiation therapy (hRT) using two fractions of 12 Gy in combination with CTLA-4 checkpoint blockade several days before PET imaging. PD-1 or PD-L1 knockout mice and PD-L1-deficient B16 cells generated using the CRISPR/Cas technology served as specificity controls.

Results: The newly developed PD-1 and PD-L1 PET tracers allowed the highly specific and high-resolution imaging of PD-1 and PD-L1 expression and of the biodistribution of the two therapeutic antibodies in both naïve and tumor-bearing mice treated with hRT and CTLA-4 checkpoint blockade. Imaging of the respective knockout mice, blocking experiments with an excess amount of unlabeled antibodies, and the analysis of animals bearing both wild-type B16 melanomas and PD-L1-CRISPR knockout melanomas demonstrated the high specificity of the two newly developed PET tracers. The in vivo imaging data were confirmed by ex vivo biodistribution analyses. The targets of the PET tracer antibodies were verified by ex vivo flow cytometric analyses of tumor single-cell suspensions and cell suspensions of secondary lymphoid and other organs. Interestingly, visualization of immune-related adverse events was also possible.

Conclusion: We developed two innovative PET tracers that allow imaging the expression of the receptor/ligand pair of the important PD-1 checkpoint and the biodistribution of surrogate checkpoint-blocking antibodies in fully immunocompetent mice. This technology also enabled whole-body pictures of combination radio/immunotherapies.

Monitoring mitochondrial complex-I using novel PET probe allows early detection of radiosensitivity

C. Murayama¹, A. Kawaguchi², A. Kamijo³, K. Naito³, M. Kanazawa⁴, H. Tsukada⁴

¹Tokai University- School of Medicine, Clinical Pharmacology, Isehara, Japan

²Tokai University School of Medicine, Cell Transplantation and Regenerative Medicine, Isehara, Japan

³Tokai University, Support Center for Medical Research and Education, Isehara, Japan

⁴Hamamatsu Photonics K.K., Central Research Laboratory, Hamamatsu, Japan

Purpose or Objective: Objectives: Aerobic glycolysis is the main pathway of energy production in tumors (Warburg effect), and ionizing radiation is reported to switch this to mitochondrial oxidative phosphorylation. We developed a novel PET probe, 18F-2-tert-butyl-4-chloro-5- {6-[2-(2-fluoroethoxy)-ethoxy]-pyridin-3-ylmethoxy}-2H-pyridazin-3-one (18F-BCPP-EF), for imaging mitochondrial complex I (MC-I) activity. In this study, early detection of tumor radiotherapeutic effect was evaluated using 18F-BCPP-EF and compared with 18F-FDG and apoptosis index.

Material and Methods: Methods: Tumor uptake of 18F-BCPP-EF or 18F-FDG was examined in C3H/HeN mice inoculated with murine squamous cell carcinoma SCCVII after a single dose of x-ray irradiation, 0, 6, 15, or 30 Gy. Apoptosis incidence was determined by TUNEL staining in excised tumor tissue.

Results: Results: Tumor growth suppression was dose-dependent; tumor grew 10 fold (0 Gy), 5 fold (6 Gy), 2 fold (15 Gy), and reduced to half in its volume (30 Gy) 14 days after treatment. 18F-BCPP-EF uptake was significantly increased as early as 2 days (15 Gy) or 3 days (30 Gy) after irradiation, at time points when tumor size or apoptosis index showed no difference among radiation doses. In contrast, 18F-FDG uptake was initially increased dose-dependently, remained elevated, and eventually decreased 10 days after 30 Gy when tumor size was already reduced. Apoptosis index was increased after irradiation but failed to correlate with tumor response. The uptakes of 18F-BCPP-EF and 18F-FDG, as well as AI, were plotted against Tvol on day 14 as surrogate of radiotherapeutic effect. Highly significant negative correlations were observed between the uptake of 18F-BCPP-EF and Tvol on day 14, as early as on day 2, and on each day up to day 7, and in all days combined. In contrast, between tumor uptake of 18F-FDG and Tvol on day 14, there was a significant negative correlation on day 2 and positive correlations on day 10 and on day 14, with no correlation in all days combined.

Conclusion: Conclusion: Tumor uptake of 18F-BCPP-EF was increased dose-dependently early after irradiation when 18F-FDG uptake and apoptosis index remained elevated regardless of radiation doses or its efficacy. The results suggest that 18F-BCPP-EF is a promising "positive" MC-I imaging PET probe for early detection of adequacy of tumor radiotherapy.

OC-0528

Modelling tissue radiosensitivity and PET hypoxia image contrast in acute and chronic hypoxia

D.R. Warren¹, M. Partridge¹

¹University of Oxford, CRUK/MRC Oxford Institute for Radiation Oncology, Oxford, United Kingdom

Purpose or Objective: PET imaging studies with the hypoxia tracer 18F-MISO typically show a heterogeneous distribution within the tumour, and regions of high uptake have been proposed as targets for dose painting. However, there is no widely-accepted method to determine dose prescriptions from hypoxia imaging. Oxygen diffusion distances in tissue (~100 µm) are smaller than the PET resolution (~4 mm) so a range of radiosensitivities may exist within each voxel. Furthermore, the perfused vasculature is not constant over

the course of a fractionated radiotherapy treatment or during a PET study. This work examines how transient perfusion of vessels may influence tissue radiosensitivity (including reoxygenation) and FMISO image contrast, as a guide for dose painting.

Material and Methods: Microscopic oxygen and FMISO distributions are simulated in tissue using bespoke MATLAB software which solves coupled partial differential equations by finite difference methods. Dynamic vasculature is modelled by opening and closing individual vessels at random, with time spent in each state sampled from a normal distribution. Oxygen enhancement ratios are calculated from the resulting PO₂ maps. The optimal prescription dose is found by simulating a range of dose levels and determining radiobiological cell kill using the linear-quadratic model with repopulation. A novel approach to modelling reoxygenation is adopted in which a tissue's oxygen consumption in one fraction is reduced by the cell kill in previous fractions.

Results: Predicted FMISO tissue-to-muscle ratios (TMR) are in the range 1.0-2.3, increasing as PO₂ decreases to a peak at ~7 mmHg. At very low vascularity, FMISO uptake is limited by perfusion of tracer into the tissue, rather than the oxygen-dependent binding characteristic. No gross differences are observed in TMRs simulated with static or dynamic vascular models. For a representative hypoxic tumour (10 mmHg, intrinsic $\alpha=0.3$) surviving fractions of 10⁻⁹ are predicted at doses of: 110 Gy (static vasculature, no reoxygenation), 87 Gy (dynamic vasculature changing every fraction) and 71 Gy (reoxygenation by reduced consumption). The effect of vessel dynamics is negligible if significant reoxygenation of chronic hypoxia occurs.

Figure: Plot showing mean partial pressure of oxygen and FMISO tissue:muscle ratio at 4 hrs for simulations with static vascular model and a dynamic model in which vessels randomly open and close. Inset: Simulated microscopic distributions of oxygen and FMISO at 4 hours in the same 1 mm² of tissue with mean PO₂ = 5 mmHg.

Dose	Static Vessels		Dynamic Vessels		Reoxygenation	
	PO ₂	SF	PO ₂	SF	PO ₂	SF
0 Gy	3.8	1	3.8	1	3.8	1
10 Gy	3.8	2.3 × 10 ⁻¹	4.1	2.3 × 10 ⁻¹	14.8	2.0 × 10 ⁻¹
20 Gy	3.8	6.0 × 10 ⁻²	3.8	5.5 × 10 ⁻²	35.2	2.5 × 10 ⁻²
30 Gy	3.8	1.6 × 10 ⁻²	3.8	1.3 × 10 ⁻²	39.4	2.8 × 10 ⁻³
40 Gy	3.8	1.1 × 10 ⁻²	3.8	8.1 × 10 ⁻³	39.9	8.3 × 10 ⁻⁴
50 Gy	3.8	8.4 × 10 ⁻³	3.5	5.0 × 10 ⁻³	40.0	2.5 × 10 ⁻⁴
60 Gy	3.8	6.2 × 10 ⁻³	3.6	3.2 × 10 ⁻³	40.0	7.3 × 10 ⁻⁵

Table: Simulated surviving fraction (SF) and oxygen partial pressure (PO₂) in mmHg for varying dose delivered in 2 Gy fractions with a static vascular model, a dynamic vascular model and the reduced consumption reoxygenation model. Parameters: intrinsic radiosensitivity $\alpha = 0.3$, repopulation kick-off time 21 days and doubling time 5 days.

Conclusion: A model has been demonstrated that predicts realistic FMISO uptake in hypoxic tissue and provides a method for calculating prescription doses with reoxygenation. Individual vessel dynamics do not affect FMISO image contrast at 4 hours, or the prescription dose if global reoxygenation occurs.

OC-0529

A MR-based IGRT platform using the KPC transgenic mouse model of pancreatic cancer

J. Thompson¹, J. Beech¹, D. Allen¹, S. Gilchrist¹, R. Newman¹, P. Kinchesch¹, A. Gomes¹, Z. D'Costa¹, L. Bird¹, K. Vallis¹, R. Boghazian¹, A. Kavanagh¹, O. Sansom², I. Tullis¹, R. Muschel¹, M. Hill¹, B. Vojnovic¹, S. Smart¹, E. Fokas¹

¹CRUK/MRC Institute for Radiation Oncology University of Oxford, Department of Oncology, Oxford, United Kingdom

²Cancer Research UK Beatson Institute- Glasgow, Institute of Cancer Sciences- University of Glasgow, Glasgow, United Kingdom

Purpose or Objective: With a 5-year survival rate of 5%, pancreatic ductal adenocarcinoma (PDAC) is considered a disease of unmet-need. Preclinical radiobiological research in PDAC has been limited by mouse models that do not recapitulate the human biology and, more importantly, the immense technical challenges in establishing a platform that enables precise irradiation of pancreatic tumours in mice

Material and Methods: Herein we describe the key steps in the development of a state-of-the-art preclinical image-guided radiotherapy (IGRT) platform that enables precise planning and dose delivery in the KRASLSL.G12D/+; p53R172H/+; PdxCretg/+ (KPC), a genetically-engineered mouse model (GEMM) of PDAC. CT (x-ray computerised tomography) does not provide the soft tissue contrast required for accurate and precise RT planning in the mouse. We demonstrate the use of magnetic resonance imaging (MRI) for RT planning in the mouse abdomen. KPC mice with spontaneous pancreatic tumours were anaesthetised and placed in an MR-CT compatible cradle. A newly-developed respiratory-gated multiple echo contrast scan (8 echoes, TE 6-50 ms) operating at constant TR=3600, was run at 150x150x300 μ m resolution in a scan time of ca. 9 minutes.

Results: Tumours were undetectable using CT but showed as bright regions on T2-weighted images, as described previously. After registration of the MRI to the CT images RT planning was quite straightforward and beam trajectory and RT dose estimations were performed for a conical arc trajectory. MRI can be used with CT-guided RT system to give soft tissue contrast and enable RT planning. The respiratory gated T2-weighted scans acquired using multiple echoes gave very good contrast, though the scan time was relatively long (ca. 9 minutes). At the expense of SNR this can be reduced to ca. 2 minutes through use of fast spin echo. The different steps will be discussed in detail. Precise beam delivery was confirmed using immunohistochemical staining for γ H2AX foci.

Conclusion: Altogether, our IGRT platform represents a novel tool to explore the effects of RT on the biology of PDAC and investigate the mechanisms of treatment resistance. To our best of knowledge, no studies to date have reported such a precise MR-based IGRT platform for preclinical radiobiological research in the KPC model. This platform will enable exploration of the mechanisms of treatment resistance and is expected to provide important radiobiological insight to guide successful future clinical trials that will directly benefit patients with PDAC.

OC-0530

Nanoparticle-enhanced MRI-guided radiation therapy

A. Detappe^{1,2}, S. Kunjachan¹, O. Tillement², R. Berbeco¹

¹Dana Farber Cancer Institute, Radiation Oncology, Boston, USA

²Institut Lumiere Matiere, Universite Claude Bernard, Lyon, France

Purpose or Objective: MRI is increasingly used in radiation oncology for target delineation and real-time treatment guidance. The gadolinium-based nanoparticles (GdNP) used in this study are a dual modality probe with MRI contrast and radiosensitization properties. We use a mouse model of pancreatic cancer to demonstrate *in vivo* contrast enhancement, quantification of GdNP concentration, and

significant improvement in survival. By modeling our preclinical study on current clinic workflows, we show clear compatibility with modern patient care, thus heightening the translational significance.

Material and Methods: AGuIX (Nano-H, Lyon, France) is a gadolinium-based nanoparticle that has been proposed for an upcoming clinical trial. We performed *in vitro* cell uptake and radiosensitization studies of a pancreatic cancer cell line in preclinical (220kVp) and clinical (6 MV and 6 MV FFF) beams. MRI was used to monitor tumor uptake and biodistribution. Due to their small size (2-3 nm), the GdNP have good renal clearance and long blood circulation (around 20-30 min in mice).

In vivo radiation therapy studies were performed to characterize the effect of AGuIX as a radiosensitizer (n=8/cohort). Histology was performed to measure the increase in damage in the tumor and to evaluate the toxicity in healthy tissues.

Results: The *in vitro* results demonstrate a dose enhancement factor (DEF) of 1.37 (p<0.005) when the combination of irradiation and GdNP is used with the 220kV and a DEF of 1.26 for the clinical 6MV FFF. The maximum tumor uptake and tumor/muscle ratio is reached 15 minutes after IV injection. The *in vivo* results demonstrated statistically significant tumor regression (P<0.001) and increase in median survival (p<0.005) for AGuIX combined with radiation vs. radiation alone. There was no observed increase in toxicity in the surrounding healthy organs.

Conclusion: MRI contrast and radiosensitization have been demonstrated in a preclinical pancreatic tumor model. There is a strong translational potential for AGuIX with modern and likely future MRI-guided radiation therapy procedures

⁴Aarhus University Hospital, Oncology, Aarhus, Denmark

⁵Trinity College Dublin, Oncology, Dublin, Ireland Republic of

⁶Maastric Clinic, Oncology, Maastricht, The Netherlands

⁷European Society for Radiotherapy and Oncology, HERO, Bruxelles, Belgium

⁸Ghent University Hospital, Radiotherapy, Ghent, Belgium

Purpose or Objective: The value of healthcare can be defined as the additional health outcomes gained for each euro spent. Thus, understanding costs, and their origins, of a medical intervention is key to the estimation of value. Costing studies to date have yielded highly variable results

largely due to which and how resources have been analyzed. A rigorous health economics approach requires the cost of the real resources used to be identified (ISPOR, 2007). We report on such an approach to the estimation of the cost of radiation therapy.

Material and Methods: A Time-Driven Activity Based Costing (TDABC) model was created for external photon beam radiotherapy at the national level. The model was developed in an iterative manner by a panel of experts, taking into account current knowledge of resources, products, and clinical processes. The resources were identified through a systematic review of the literature from 1981 to 2015. In TDABC, resource unit costs per minute are defined as the ratio of gross expense to available capacity. The products, defined as courses of treatment for specific tumor indications, were derived from the decision trees developed by the Collaboration for Cancer Outcomes, Research and Evaluation (CCORE). The process map was derived from that developed by the AAPM (2012, Ford).

Results: Resources are organized in 3 categories: personnel, equipment and overhead. Products are grouped per organ site and target volume. For each of these, treatment complexity and diversity are addressed by extending the AAPM process map in three ways:

1. six technique categories, specified as follows: single-field, 2D-RT, 3D-CRT, IMRT, rotational IMRT and stereotactic techniques;
2. eight possible fractionation schedules can be defined;
3. some steps along the patient care pathway are identified separately from the 7 high level steps, see figure.

These, reflecting an additional level of treatment complexity, are optional and hence not necessarily applicable to all treatment courses.

The core input required is the time of personnel's involvement at each process step for every technique and product. This TDABC approach yields two classes of output:

1. costs, at the level of the resources, activities and products, the latter being the sum of the costs of the component process steps; and
2. resource utilization efficiency.

Fig1. HERO Process map

Conclusion: A TDABC model for external photon beam radiotherapy is developed for use at the national level. In the next step, the model is being tested in close collaboration with selected European Radiotherapy Societies, by introducing nation-specific data on the resources consumed, monetary values and resources' time devoted to each step, reflecting complexity. These data generate national cost estimates per course for a range of radiotherapy treatments. The cost estimates and details of the methodology will be presented.

¹⁰International Atomic Energy Agency, Applied Radiation Biology and Radiotherapy Section, Vienna, Austria

¹¹International Atomic Energy Agency, Radiation Oncology, Vienna, Austria

Purpose or Objective: Short-course radiotherapy (25 Gy in five fractions) was recently shown in a multi-national randomized phase III clinical trial to be non-inferior to a commonly used regimen (40 Gy in 15 fractions) in elderly and/or frail patients with glioblastoma multiforme, with no difference in overall survival (OS) and progression free survival (PFS). This study compared the cost-effectiveness of the two regimens.

Material and Methods: The direct unit costs of imaging, radiotherapy (RT), and dexamethasone were collected in equitable US dollars (USD) from the five primary contributing countries to the trial, representing 88% of all patients accrued (n = 86) between 2010 and 2013. Effectiveness was measured by the restricted mean overall survival (RMOS) and progression free survival (RMPFS). Irwin's restricted mean method was used to calculate mean survival time in the presence of censoring, and life-years gained and PFS gained. The incremental cost-effectiveness ratio (ICER) was calculated as: Cost per life-year gained = (Difference in direct costs between short-course RT and commonly used RT) ÷ (Difference in life-years gained between short-course RT and commonly used RT). Indirect costs were also estimated for comparison.

Results: There was no OS difference between the two studied populations. The median OSs for the short-course and commonly used RTs were 8.2 (6.1-10.3) and 7.7 (5.5-9.9) months, respectively. Median PFSs were also not different. The differences in the RMOS and the ICER, however, were +0.11 life-years and -USD 3307 per life-year gained, respectively. The differences in the RMPFS and the ICER were +0.02 PFS and -USD 19030, respectively. The negative ICER values indicated improvement in direct cost in addition to life-years gained with the short-course RT. Indirect cost comparison also identified improved survival-to-treatment time ratio and reduced cost for patients and care-givers with short-course RT.

Conclusion: The direct cost account for ICER of -USD 3307 per life-year gained and -USD 19030 per PFS gained indicates that the short-course RT is less costly and more effective compared to the commonly used RT. Indirect cost is also improved with the short-course RT.

TGUGT and G8 tests predicting frailty and radiotherapy compliance and acute toxicity in the elderly

J. Middelburg¹, T. Rozema², H. Maas³, E. Baartman¹, M. Aarts⁴, D. Geijnsen⁵, A. Leest⁶, J. Jobsen⁷, J. Coebergh⁸, H. Struikmans⁹

¹Erasmus Medical Center, Radiotherapy, Rotterdam, The Netherlands

²Institute Verbeeten, Radiotherapy, Tilburg, The Netherlands

³Tweesteden Hospital, Geriatrics, Tilburg, The Netherlands

⁴Netherlands Comprehensive Cancer Organisation IKNL, Netherlands Cancer Registry, Utrecht, The Netherlands

⁵Academic Medical Center, Radiotherapy, Amsterdam, The Netherlands

⁶University Medical Center Groningen, Radiotherapy, Groningen, The Netherlands

⁷Medisch Spectrum Twente, Radiation Oncology, Enschede, The Netherlands

⁸Erasmus Medical Center, Public Health, Rotterdam, The Netherlands

⁹Medical Center Haaglanden, Radiotherapy Center West, Den Haag, The Netherlands

Purpose or Objective: On behalf of the LPRO (National organisation for radiotherapy in the elderly):

The incidence of cancer increases with age. Older cancer patients are often underrepresented in clinical trials. Reliable predicting tools for toxicity and compliance of radiotherapy are not yet available. The G8 is a screening tool developed for older cancer patients. The "Timed Get Up and Go Test" (TGUGT) is a validated test for quantifying the degree of mobility. In the current study we aim to quantify to which extend the G8 and the TGUGT are predictive for both radio(chemo)therapy compliance and acute toxicity of curative radiotherapy in elderly cancer patients.

Material and Methods: Patients were recruited in seven Dutch radiotherapy centers: if they were 65 years and older, had newly diagnosed breast/ NSCLC/prostate/head and neck/rectal and oesophageal cancer, were referred for radio(chemo)therapy with curative intent between April 2015 and the end of October 2015, and had no history of prior radiotherapy. The TGUGT test (normal: ≤10 seconds, frail elderly: 11-20 seconds, and needs further evaluation: >20 seconds) and the G8 score (≤14 is indicative of frailty in older cancer patients) were performed before starting the radiotherapy. Compliance with radio- and or radio/chemotherapy and acute toxicity (< 3 months after ending the radiotherapy) were recorded.

Results: A total of 335 patients were included, of which 53% were male. The mean age was 72.8 and 4% were 85 year or older. WHO scores were 0 for 55%, 1 for 36%, 2 for 8%, 3 for 0.3% and unknown in 1%. Patients were motivated to participate, with a mean score of 9.1 and a median of 10, on a ten point scale. Forty-three percent of the patients were considered frail based on the G8 score and 18% based on the TGUGT test. There was an association between the G8 and the TGUGT, with every point increase of the G8 corresponding to walking 0.4 seconds faster. Comorbidity was associated with lower G8 scores, difference 1.3 (95% confidence interval (CI): 0.8 to 1.8) and slower TGUGT, difference 1.5 (CI: 0.8 to 2.2). Follow-up is still ongoing but will be completed before the end of January 2016. Full results will be presented at the ESTRO 35. Until now (n=57) the compliance is high. All patients completed treatment according to protocol. Acute toxicity is low with 5% grade 3. No grade 4 or 5 toxicity was observed.

Conclusion: We observed an association between the results from G8 and TGUGT. Associations between test results and toxicity and compliance will be presented.

OC-0534

No decline in patient reported outcomes following radiotherapy for breast cancer patients ≥ 60 years

K.R. Charaghvandi¹, D.A. Young-Afat¹, C.H. Van Gils², M.L. Gregorowitsch¹, B. Van Asselen¹, M. Van Vulpen¹, H.M. Verkooijen², H.J.G.D. Van den Bongard¹

¹University Medical Center Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

²University Medical Center Utrecht, Department of Epidemiology, Utrecht, The Netherlands

Purpose or Objective: The incidence of breast cancer is increasing in women over the age of 60 years. In this group of patients, (age associated) comorbidity is the most important factor influencing survival. The impact of treatment on daily functioning and quality of life may therefore be a more appropriate endpoint for therapy efficacy instead of standard survival outcome. Radiotherapy improves local control in elderly, however its impact on short-term physical and emotional well-being has not been well studied. This study describes patient reported outcomes measures (PROMs) during the first 6 months following radiotherapy in women over the age of 60 years, within a prospective breast cancer cohort. The effect of increasing age on PROMs was evaluated by comparing patients below and at least 70 years of age.

Material and Methods: From October 2013 on, all breast cancer patients referred to the department of Radiation Oncology were invited to enter the UMBRELLA cohort (cohort for multiple breast cancer intervention studies and long-term evaluation). Participants consented to the collection of clinical data and PROMs questionnaires before and at predefined intervals after radiotherapy. For the purpose of this study, changes in quality of life (EORTC QLQ-C30 including fatigue subscale, QLQ-BR23), anxiety and depression (HADS) were evaluated in patients at least 60 years of age, between baseline and 6 months follow-up (FU). Changes in median levels of PROMs between baseline and 6 months follow-up were evaluated with the paired sample t-test. Differences between mean levels of PROMs (continuous scale e.g. 0-100, higher scores indicate better QoL) for the two age groups were evaluated with the independent sample t-test.

Results: Between October 2013 and June 2015, a total of 848 patients were included in the cohort, with 374 patients aged ≥ 60 years. Preliminary analysis was performed in the first 158 patients. At a median FU of 5.5 months after radiotherapy, a decline in mean overall QoL (FU score 75.0, Δ 3.4; $p=0.028$), improvement of mean anxiety score (FU score 4.6, Δ 0.8; $p=0.001$) and stable mean fatigue (FU score 74.9, Δ 0.9; $p=0.578$) and depression (FU score 3.5, Δ 0.1; $p=0.635$) scores were observed. No differences between patients 60-69 years and from 70 years of age were observed for overall QoL, anxiety, depression and fatigue scores. Severe anxiety symptoms (HADS anxiety score > 11) were reported in 8.1% and 10% in age groups 60-69 and 70 years or older, respectively.

Conclusion: In the first six months following radiotherapy, no clinically relevant decline in short-term emotional well-being and fatigue have been observed for patients at least 60 years of age. Overall well-being appears to be good in patients below and over the age of 70. Updated and more detailed results (e.g. effect comorbidity and toxicity) with an expected sample size of at least 375 patients will be presented in April 2016.

Patient characteristics	Value in n(%) unless other stated
Median age (range)	
- all patients, n=158	67 (60-85)
- < 70 years, n=102	65 (60-69)
- ≥ 70 years, n=56	73 (70-85)
Median Charlson Comorbidity Index ¹ (range)	
- all patients	5 (4-10)
- < 70 years	4 (4-7)
- ≥ 70 years	5 (5-10)
WHO performance status	
- 0	133 (84%)

⁹IRCCS San Raffaele Scientific Institute, Medical Physics, Milano, Italy

¹⁰IRCCS San Raffaele Scientific Institute, Medical Physics, Milano, Italy

Purpose or Objective: Within a large multi-Institute observational study, patient reported urinary symptoms (PRUS) were available at baseline and at different times intervals after RT: aim of current analysis was to assess the power of the different PRUS in discriminating a severe impairment of urinary QoL.

Material and Methods: Pts treated in 9 Institutes with radical 3DCRT/IMRT for localized prostate cancer with conventional or moderate hypo-fractionation (2.35-2.7 Gy/fr) filled in several questionnaires, including IPSS and ICIQ. Questionnaires are to be filled in at baseline, at RT end, 3 and 6 months after its conclusion, and thereafter every 6 months up to 5 years. Current analysis focused on the IPSS score relative to urinary QoL (item #8, IPSS8) during the first two years after RT, considering a score ≥ 4 as a severe impairment. At each time interval (i.e.: baseline, RT end, 3, 6, 12, 18, 24 months after RT) the power of the different PRUS, the overall IPSS, single IPSS items (IPSS1 to IPSS7) and ICIQ scores in discriminating patients with ≥ 4 IPSS8 assessed by ROC curves: AUCs were calculated for each score at each timing and ROC curves compared to detect significant differences among scores and times.

Results: The available data refer to 499, 449, 412, 361, 339, 304, 238 pts at baseline, RT end, 3, 6, 12, 18 and 24 months after RT respectively. Pts with IPSS ≥ 4 were 50, 126, 25, 24, 23, 28, 21 respectively. The discriminative power of the overall IPSS remained quite constant over time, ranging

between 0.84 and 0.90 without significant differences. Interestingly, the discriminative power of the single IPSS items was different and dramatically changed over time: only IPSS6 (straining) always showed a poor value at each time (AUC: 0.55-0.65). All the remaining IPSS items showed not significantly ($p>0.07$) different AUCs at baseline (0.71-0.76), while exhibiting very different patterns after RT. IPSS2 (frequency), IPSS4 (urgency) and IPSS7 (nocturia) showed the highest performances in the acute phase (AUC:0.77-0.87 at RT end and at 3 months). At 24 months, weak stream showed the highest AUC (0.87) while the remaining items ranged between 0.69 and 0.76. Very importantly, the AUC of ICIQ continuously increases from baseline/RT end (AUC=0.62-0.63) up to 24 months (AUC:0.82). In Figure 1a/1b the ROC curves at the different time intervals for overall IPSS and ICIQ are shown; a summary of AUC changes is shown in Figure 1c for all scores at baseline, end RT, 12 and 24 months.

Conclusion: The analysis of a large population of prospectively followed patients with PRUS evaluation showed that the discriminative power of different symptoms in assessing a severely impaired urinary QoL significantly changes over time. As expected, the overall IPSS always captures a very large fraction of these patients, while the predictive value of ICIQ is negligible at baseline and acutely, becoming highly discriminative in the long term.

⁵University Medical Center Utrecht, Radiotherapy, Utrecht, The Netherlands

⁶Leiden University Medical Center, Radiotherapy, Leiden, The Netherlands

⁷University Medical Center Utrecht, Medical Oncology, Utrecht, The Netherlands

Purpose or Objective: In patients with painful bone metastases, radiotherapy is an effective treatment. Besides symptom control, quality of life (QoL) is an important endpoint. We focus on the course of QoL after radiotherapy.

Material and Methods: In the Dutch Bone Metastasis Study, 1,157 patients with painful bone metastases were randomized between one fraction of 8 Gray and six fractions of 4 Gray. The study proved equal effectiveness, with a pain response of 74%. Patients filled out weekly questionnaires for 13 weeks and then monthly for two years or until death. Three QoL domain scores (physical, psychosocial and functional) and a visual analogue scoring of general health were studied. Mixed modeling was used to model the course of QoL and to study the influence of several characteristics. An effect size of $\geq 0.10/0.20$ (binary or continuous variable, respectively) is considered a small effect and therefore clinically relevant.

Results: In general, QoL stabilizes after a month. Psychosocial QoL improves temporarily after treatment. The level of QoL remains stable for a long time, steeply deteriorating at the end of life. For most QoL domains, a high pain score and intake of opioids are associated with worse QoL, with a small effect size (-0.11 to -0.27). A poor performance score is associated with worse functional QoL, with a medium effect size of 0.41.

Figure: The modeled course of QoL after radiotherapy for painful bone metastases, represented in survival groups (patients surviving less than 3, 3-<6, 6-<12, 12-<18 and 18-<24 months after randomization). The x-axis represents the months after treatment, where month 0 is the baseline measurement before treatment and month 1 the first months after treatment. The y-axis reflects the domain score of QoL, where the average is 0, with a standard deviation of 1. The higher the score, the better the QoL.

Table: Influence of baseline and follow-up variables on QoL domains, with effect sizes

variables	QoL domains								
	physical		psychosocial		functional		VAS:gh		
	effect size	p-value	effect size	p-value	effect size	p-value	effect size	p-value	
Baseline:									
age	0.01	0.72	0.03	0.24	-0.12	<0.001	0.01	0.65	
gender (reference: male)	-0.11	0.26	-0.17	0.11	-0.19	0.02	-0.06	0.45	
KPS	0.00	0.93	0.06	0.04	0.41	<0.001	0.09	<0.001	
primary tumor (reference: other)									
breast	-0.08	0.43	-0.12	0.28	-0.27	0.002	-0.14	0.11	
prostate	-0.20	0.03	-0.18	0.06	-0.22	0.003	0.11	0.11	
lung	0.06	0.44	-0.04	0.63	-0.10	0.16	0.00	0.95	
Follow-up:									
treatment arm (reference: 1x80G)	-0.12	-0.17*	<0.001	0.06	0.24	0.02	0.57	0.03	0.42
pain score	-0.14	<0.001	-0.11	<0.001	-0.07	<0.001	-0.24	<0.001	
intake of opioids (reference: no opioids)	-0.27	<0.001	-0.05	0.001	-0.21	<0.001	-0.21	<0.001	

KPS : Karnofsky performance status, VAS gh: visual analogue scoring of general health

Dinary variables (gender, primary tumor, treatment arm and intake of opioids): Effect sizes between -0.19 and 0.19 are considered minor effects and are not clinically relevant. Continuous variables: Effect sizes between -0.09 and 0.09 are considered minor effects and are not clinically relevant. To facilitate interpretation, clinically relevant effects are shown bold

A positive direction of the effect size means improvement of QoL by increase of the variable / compared to the reference

* The effect size varies each week, ranging from -0.12 (week 4), -0.13 (week 2) to -0.17 (week 3)

Conclusion: Although radiotherapy for painful bone metastases leads to a meaningful pain response, QoL does not improve after treatment. Initially, it remains stable followed by deterioration towards the end of life.

p16 and high risk-HPV in node positive cutaneous squamous cell carcinoma of the head and neck

L. McDowell¹, R. Young², M. Johnston¹, T. Tan¹, C. Liu¹, M. Bressel³, V. Estall¹, B. Solomon⁴, J. Corry¹

¹Peter MacCallum Cancer Centre, Radiation Oncology Department, East Melbourne, Australia

²Peter MacCallum Cancer Centre, Research Division, East Melbourne, Australia

³Peter MacCallum Cancer Centre, Centre for Biostatistics and Clinical Trials, East Melbourne, Australia

⁴Peter MacCallum Cancer Centre, Department of Medical Oncology, East Melbourne, Australia

Purpose or Objective: The incidence of p16-overexpression and the role of human papillomavirus (HPV) in cutaneous head and neck squamous cell carcinoma (cHNSCC) is unclear. In the unknown primary setting, where cHNSCC is a potential putative site, p16 status is being used to guide management despite varying reports of its incidence in non-oropharyngeal sites.

Material and Methods: 143 patients with cHNSCC lymph node metastases involving the parotid gland were evaluated for p16 expression by immunohistochemistry. Detection of 18 high-risk HPV subtypes was performed using HPV RNA in situ hybridization on a subset of 59 patients. Results were correlated with clinicopathological features and outcomes

Results: Median follow up time was 5.3 years. No differences were observed in clinicopathological factors based on p16 status. p16 was positive, intermediate and negative in 45 (31%), 21 (15%) and 77 (54%) of cases, respectively. No high-risk HPV subtypes were identified, irrespective of p16 status. p16 status was not prognostic for overall (HR 1.08 95% CI [0.85 - 1.36], p=0.528), cancer-specific (HR 1.12 95% CI [0.77 - 1.64], p=0.542) or progression-free survival (HR 1.03 95% CI [0.83 - 1.29], p=0.783). Distant metastasis free survival, freedom from locoregional failure and freedom from local failure were also not significantly associated with p16 status.

Conclusion: p16 positivity is common but not prognostic in cHNSCC lymph node metastases. High-risk HPV subtypes are not associated with p16-positivity, and do not appear to play a role in this disease. HPV testing, in addition to p16-status in

the unknown primary setting may provide additional information in determining a putative primary site.

OC-0538

Tumor-related leukocytosis associated with poor radiation response and outcome in cervical cancer

Y. Cho¹, K. Kim¹, K. Keum¹, C. Suh¹, G. Kim¹, Y. Kim¹

¹Yonsei Cancer Center, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: To investigate the prognostic significance of tumore-related leukocytosis (TRL) in cervical cancer patients treated with definitive radiotherapy

Material and Methods: Between 1986 and 2012, 2,456 patients with uterine cervical cancer (FIGO stage IA-IB 494, stage IIA-IIB 1530, stage IIIA-IIIB 394 and stage IVA 38) who received definitive radiotherapy (62.6%) or platinum-based chemoradiotherapy (37.4%) consisting of EBRT and ICBT were retrospectively analyzed. TRL was defined as WBC count of $\geq 9,000/\mu\text{L}$ on ≥ 2 occasions at the time of diagnosis and during the course of treatment. The neutrophil/lymphocyte ratio (NLR) was defined as the absolute neutrophil count divided by the absolute lymphocyte count. Locoregional failure free survival (LRFSS) and overall survival (OS) were compared between patients with or without TRL.

Results: Median age of all patients was 55 years (range, 21-87) and the median follow-up time was 65.1 months (range, 0.7-347.8). Among 2,456 patients included in this study, TRL was observed in 398 (16%) at the initial diagnosis. Patients in TRL(+) group were younger in age and had larger tumor, advanced FIGO stage and more common LN metastases (all $p < 0.05$). TRL (+) group showed relatively lower rate of complete remission (CR) (90% vs. 97%, $p = 0.042$). The 10-year LRFSS and OS for all patients were 84% and 78%, respectively. Compared to TRL(-) group, LRFSS and OS were significantly lower in TRL(+) group (10-yr LRFSS: 69% vs. 87%, $p < 0.001$; 10-yr OS: 63% vs. 81% $p < 0.001$). After propensity score matching by age, FIGO stage, tumor size, LN metastasis, histologic subtype and pretreatment hemoglobin (Pre Tx Hb), both groups were well matched. The LR control and OS rate of TRL (+) group was still significantly lower than those of TRL (-) group. In multivariate analysis, advanced FIGO stage, non-SqCCa, larger tumor size and TRL were identified as risk factors for LRFSS and OS (all $p < 0.05$). In addition, Pre Tx Hb, LN metastasis and high NLR (≥ 2.5) were also associated with poorer OS (all $p < 0.05$). Among patients with LRF (n=345), patients with TRL at the time of recurrence accounted for 26% and showed relatively poorer median OS (6 vs. 12 months, $p = 0.001$).

Conclusion: This study supports the aggressive nature and poor radiation response of cervical cancer with leukocytosis. Given the unfavorable features and higher probability of treatment failure, optimal therapeutic approach and careful monitoring for early detection of recurrence should be considered for these patients.

⁸University of Heidelberg, Orthopedics, Heidelberg, Germany

⁹Helios Clinic, Radiation Oncology, Berlin, Germany

Purpose or Objective: In 2009 we reported promising first results of a European pooled analysis which evaluated the use of intraoperative radiation therapy (IORT) in the treatment of soft tissue sarcomas. However, comparison of these results with non-IORT series seemed difficult, mainly because of the inclusion of grossly incomplete resected lesions, patients treated without additional external beam radiation therapy (EBRT) and comparatively short follow-up. Therefore we re-analyzed our data limited to the patients who received IOERT preceeded or followed by EBRT after gross total resection with extended follow-up.

Material and Methods: Three European expert centers participated in the current analysis. Patients with gross incomplete resection, missing documentation of EBRT or primary lesions outside the extremities were excluded, leaving 259 patients for analysis. Median age was 55 years and median tumor size 8 cm. 80% of the patients presented in primary situation with 81% of the tumors located in the lower limb. Stage at presentation was I:9%, II:47%, III:39%, IV:5%. Most patients showed high grade lesions (FNCLCC grade 1:9%, 2:34%, 3:58%, predominantly liposarcoma (31%) and MFH (27%). IOERT was applied to the tumor bed with a median dose of 12 Gy using a median electron energy of 8 MeV. IOERT was preceeded (17%) or followed (83%) by EBRT with a median dose of 45 Gy in all patients. 37% of the patients received additional chemotherapy.

Results: Median follow up was 63 months. Surgery resulted in free margins (R0) in 71% while 29% suffered from microscopic positive margins (R1). We observed 27 local failures, transferring into a 5-year local control rate of 86%. Univariate analysis revealed primary vs recurrent situation and resection margin as significant factors for local control but only resection margin (5-year LC rate 94% vs 70%, HR 3.8) remained significant in multivariate analysis. Distant failure was found in 70 patients, resulting in a 5-year distant control rate of 69%. Factors with significant impact on distant control in univariate analysis were histology, grading, resection margin and stage IV prior/at IOERT, but only grading and stage IV remained significant in multivariate analysis. Actuarial 5-year rates of FTF and OS were 61% and 78%, respectively. Significant factors for overall survival were only grading and stage IV prior/at IOERT (uni- and multivariate). Secondary amputations were needed in 14 patients (5%) resulting in a final limb-preservation rate of 95%. Good functional outcome was achieved in 81%.

Conclusion: Combination of IOERT and EBRT after limb sparing surgery resulted in encouraging local control and overall survival with excellent rates of preserved limb function in this unfavourable patient group. Our analysis identified resection margin as most important factor for local control while overall survival was mainly influenced by grading and stage IV prior/at IOERT.

Purpose or Objective: The AIEOP-MH89 protocol aimed to optimize treatment results in pediatric Hodgkin lymphoma compared to the previous AIEOP-MH83 protocol. Modifications included: involved field instead of extended field radiation therapy (RT) in early-stage patients (pts); anticipated RT for pts with a mass/thorax ratio (M/T)>0.33; enrolment of advanced-stage pts in SIOP HD IV protocol.

Material and Methods: Between 1989-1995, 254 evaluable pts (median age 10 years, range 2-15 years) received the AIEOP-MH89 protocol. The pts were divided into 3 chemotherapeutic groups according to the clinical stage. Group (GR) 1, pts in stages IA and IIA, including those with a mass/thorax ratio (M/T)<0.33, received 3 cycles of adriamycin, bleomycin, vinblastine, and imidazole carboxamide (ABVD). RT was given after completion of chemotherapy. GR 2, pts in stages IIEA, IB, IA, IIA with M/T>0.33, IIB, IIEB, IIIA, IIIS, and IIEA, was treated with alternating cycles of nitrogen mustard, vincristine, procarbazine, and prednisone (MOPP)/ABVD. The therapeutic program included 2 cycles of MOPP/ABVD before radiation therapy and 4 cycles MOPP/ABVD after RT. GR 3, pts in advanced stages IIIB, IVA and IVB, was treated according to the SIOP HD IV-87 protocol, with 2 cycles of vincristine, procarbazine, prednisone, adriamycin, (OPPA) and 2 cycles of

cyclophosphamide vincristine, procarbazine, prednisone (COPP) followed by RT. Pts enrolled in GR 1 and 3 were treated with involved field RT. Pts with positive cervical lymph nodes received RT to the neck. In positive axillary lymph nodes, RT included also the supraclavicular region. Pts with mediastinal disease were treated with mediastinum and bilateral supraclavicular fossa RT, whereas pts with involvement of both mediastinum and other supra diaphragmatic lymph nodes stations received the conventional mantle RT. Pts with positive single inguinal lymph node received also compressive RT to omolateral iliac nodal stations, whereas in case of multiple subdiaphragmatic lymph nodes disease, bilateral iliac nodal stations irradiation was avoided if not directly involved. The radiation doses were established according to response to initial chemotherapy, and were the same in GR 1 and 2: pts in CR and $\geq 75\%$ PR received 20 Gy, whereas $< 75\%$ PR received 40 Gy. GR 3 pts with CR or $\geq 75\%$ PR received 20 Gy, and 36 Gy those with 75% PR.

Results: In table 1 are reported the results in term of Overall Survival (OS) and Event Free Survival (EFS). Long term side effects of treatment were evaluated (median follow-up duration 16 years): 25.6% of the pts developed thyroid complications and 6.6% secondary malignancies.

Table 1: Overall and by Group Risk, Survival (OS) and Event Free Survival (EFS)

time	5 yrs	10 yrs	15 yrs	20 yrs	
OS	97.2%	96.0%	95.5%	94.8%	
	99.0%	98.4%	97.9%	97.9%	GR1
	97.2%	96.2%	95.3%	94.5%	GR2
	93.7%	89.2%	89.2%	89.2%	GR3
EFS	89.3%	86.5%	86.5%	86.5%	
	94.9%	92.8%	92.8%	92.8%	GR1
	89.2%	86.8%	86.8%	86.8%	GR2
	75.0%	72.9%	72.9%	72.9%	GR3

Conclusion: The AIEOP-MH89 protocol improves globally OS and EFS. In GR 1 OS and EFS are the same compared to the previous protocol, minimizing radiation exposure. In GR 2 and 3 OS and EFS improved because of therapeutic changes. Analysis of delayed toxicities underlines the importance of long-term monitoring of pts.

Purpose or Objective: Childhood cancer survivors (CCS) face high risk for late effects. Aside from malignant neoplasms, it is known that ionizing radiation induces benign tumours of, e.g., the central nervous system and other sites. Record-linkage with pathology report registries provides a unique opportunity to obtain non-selected and uniformly collected benign tumour information. We aim to estimate the incidence of histologically-confirmed solid benign tumours (SBT), to describe clinical characteristics and to quantify the role of radiotherapy (RT).

Material and Methods: The Dutch Childhood Oncology Group - Late effects after childhood cancer (DCOG LATER) is a collaborative effort of all 7 academic paediatric hemato/oncology centres in the Netherlands with clinicians and researchers who focus on optimal patient care and research in CCS. The DCOG LATER cohort includes 6168 five-yr CCS treated between 1963 and 2001 before the age of 18 yrs. The entire DCOG LATER cohort was linked with the nationwide Dutch Pathology Registry (PALGA) to ascertain histologically confirmed SBT (excluding skin) diagnosed between 1990-2014.

Results: We identified 1278 eligible pathology reports in 788 CCS after a median follow up since diagnosis of 22 yrs (max. 52). We excluded reports on SBT diagnosed within 5 yrs after childhood cancer (243 reports); 145 reports without a clear diagnosis in conclusion and 25 reports still to be classified. These preliminary analyses include 865 reports from 578 CCS, of whom 79% had one SBT, and 21% had multiple. Tumour locations included head/neck/CNS (36%), chest (13%), abdomino-pelvic (34%), and extremities (14%). Of 3% location was unclear. Most common SBT types in the head/neck/CNS were meningiomas (44%), often following cranial radiotherapy (RT) (95%); mammary fibroadenomas (49%), 1 in 6 after RT chest; colorectal adenoma (38%), including 1 in 4 after abdominopelvic RT, and female genital tract tumours (leiomyomas and ovarian mucinous cystadenomas) (29%), 1 in 3 after abdominopelvic RT. We will present effects of RT dose, chemotherapy and genetic syndromes.

Conclusion: This preliminary analyses give insight into the amount and types of histologically confirmed SBT in CCS in relation to RT. To our knowledge, this is one of the first comprehensive assessments of subsequent SBT among CCS. In ongoing clinical follow-up studies we aim to gain knowledge about risk factors and clinical characteristics (e.g. meningioma) to help guideline groups decide for or against screening of asymptomatic, high-risk CCS.

Results: The MR-linac platform is in the last phase of the assessment. At its pre-defined imaging position in the linac room, the MR was shimmed and configured to work at peak performance. The linac's radiation beam output was also found to be within specifications, being not affected by multiple passive exposures (testing over one year) to the MR's magnetic fringe field. A hybrid MR-kV framework is under development to enable comprehensive RT tools for MR-only RT planning, quantification of organ motion (fast imaging), in-room treatment guidance, and site specific adaptive RT workflows. QC procedures specific to the MR and linac integration were also developed for the mapping and correction of both scanner-related and patient-induced MR image distortions, mutual registration of the MR and linac isocenters, B0 mapping for monitoring the MR performance, 4D MR, and generation of synthetic CT data sets.

Conclusion: Key milestones of the MR and linac integration were achieved, supporting the feasibility of the system for clinical implementation.

⁵Herlev Hospital, Radiotherapy Research Unit and Department of Oncology, Herlev, Denmark

Purpose or Objective: Locally advanced lung cancer lacks effective treatment options and may require aggressive chemo-radiotherapy (RT) with high doses. In the light of the RTOG 0617 trial, multi-centre dose escalation trials should avoid increasing organ at risk (OAR) toxicity and require strict quality assurance (QA). Dose escalation can be performed for sub volumes of the tumour by targeting of the most FDG-PET avid regions, and the planning target volume (PTV) can be reduced by implementing daily soft tissue based image-guidance and adaptive RT. Incorporating these elements, the randomized multi-centre trial NARLAL2 by the Danish Oncologic Lung Cancer Group aims at increasing loco-regional control at 30 months without increasing toxicity.

Material and Methods: In the standard arm, the PTV is treated with a homogenous dose of 66 Gy/33 fractions (fx). In the experimental arm, the dose is escalated heterogeneously to the FDG-PET avid volumes, with mean doses up to 95 Gy/33 fx for the most PET active volumes of the primary tumour, and 74 Gy/33 fx for malignant lymph nodes ≥ 4 cm³. The escalation dose is limited in favour of OAR constraints. A standard and an experimental treatment plan are optimized for each patient prior to randomization. Dose to the lung in the experimental plan is kept similar to the lung dose in the standard plan. All enrolment centres were obliged to follow a strict QA program consisting of a treatment planning study, a soft tissue match and adaptive strategy workshop, and QA for PET scanners and FDG-PET volume delineation. In the present study, the dose distributions of the first 20 patients are analysed. The achieved dose escalation is compared to a previously conducted pilot study.

Technical development and clinical implementation of an MR-guided radiation therapy environment

T. Stanescu¹, S. Breen¹, C. Dickie², D. Letourneau¹, D. Jaffray³

¹Princess Margaret Cancer Centre, Medical Physics, Toronto, Canada

²Princess Margaret Cancer Centre, Radiation Medicine Program, Toronto, Canada

³Princess Margaret Cancer Centre, Medical Physics, Toronto, Canada

Purpose or Objective: Feasibility study for the clinical implementation of a hybrid radiation therapy system consisting of an MR-on-rails scanner and a linear accelerator.

Material and Methods: A 1.5 T MR-on-rails system (IMRIS, Minnetonka, MN) was configured a) to be used as a standalone MR simulator in a dedicated suite or b) to travel on ceiling-mounted rails to an adjacent linac vault and operate in the vicinity of a 6X FF/FFF TrueBeam therapy system (Varian Medical System, Palo Alto, CA). The in-room MR guidance is intended to be used in conjunction with the standard linac's kV imaging for the patient setup verification and treatment delivery. Key aspects of the MR and linac integration were investigated such as: magnetic field coupling of the MR with the linac vault environment, RF noise, RT workflows, safety systems, and QC procedures. Numerical simulations and measurements were performed to establish the magnetic field optimal separation between the MR and linac. A FEM-based simulation space was built and validated to mimic the full-scale MR-linac/couch system; this provided a detailed picture of the magnetic field coupling effects and guided the engineering activities. Field mapping was performed with low/high field Hall probes, and pull forces on couch sub-components were measured via a force gauge for several scenarios. Hysteresis effects on the linac beam performance were quantified by measuring the flatness/symmetry/output vs. gantry angle for short and long-term MR's field exposures. The MR performance was evaluated using procedures available in the service mode of the MR console as well as dedicated methods developed in-house (e.g. B0 mapping). RF noise isolation was achieved by parking the linac behind specially designed RF doors during the MR imaging sessions. An interlocking system was designed and implemented to enforce the safe linac curation (e.g. gantry position, doors status and table position) prior to MR's travel into the vault.

Results: In the pilot study, the dose escalated FDG-PET avid part of tumour (PET GTV-T) and lymph nodes (PET GTV-N) received an average mean dose of 91.9 Gy and 72.1 Gy, respectively. The combined clinical target volume (CTV-total) received an average mean dose of 78.6 Gy. This corresponds to a 16 % estimated increase in loco-regional control at 30 months. For the first 20 patients included, the experimental plan achieved an average mean dose of 92.3 Gy (SD 3.7) to PET GTV-T. A total of 11 large lymph nodes were escalated to an average mean dose of 72.1 Gy (SD 2.7) to PET GTV-N. CTV-total obtained an average mean dose of 75.8 Gy (SD 4.1). Normal tissue doses were similar for the experimental and standard plan (Table 1). The maximum dose for the standard plans was 72.6 Gy (110%). Higher doses were applied for the experimental plans, but only to small volumes respecting the strict normal tissue constraints (see figure).

Table 1: Dose to organs at risk (in absolute dose or percentage) as an average (with standard deviation) for the first 20 patients included.

Organ at risk	Standard (S)	Exp. (E)	E-S
Mean Lung Dose [Gy]	13.7 (3.7)	13.6 (3.8)	-0.1 (0.4)
Lung V _{20Gy} [%]	22.0 (7.2)	21.4 (7.2)	-0.6 (0.6)
Mean Heart Dose [Gy]	8.4 (8.6)	8.2 (8.1)	-0.8 (0.8)
Heart V _{50Gy} [%]	4.2 (3.9)	2.9 (3.9)	-0.6 (1.1)
Oesophagus V _{35Gy} [%]	25.1 (13.7)	24.3 (14.0)	-0.8 (2.0)

Conclusion: A dose escalation trial with strict QA has been set up. Patient enrolment started January 2015. Analysis of the first 20 patients demonstrates that the escalation goals were met for the target and that dose to OARs were similar for the standard and the experimental treatment plans.

⁷Medisch Spectrum Twente, Radiotherapy, Enschede, The Netherlands
⁸VSL, VSL, Delft, The Netherlands
⁹University Medical Centre Utrecht, Department of Radiotherapy, Utrecht, The Netherlands

Purpose or Objective: To independently validate patient-specific quality assurance (QA) methods, clinically used in the Netherlands, for IMRT and VMAT plans using the same set of treatment plans for all institutes.

Material and Methods: A set of treatment plans was devised: simple and more complex IMRT/VMAT and a stereotactic VMAT plan, all 6MV for both Varian and Elekta linacs. Ten plans were used for Varian linacs (5 for True Beam and 5 for Clinac) and 9 for Elekta linac(4 for MLCi and 5 for Agility). The plans were imported in the participating institute's treatment planning system for dose computation on the CT scan of the audit phantom (provided by the audit team together with the plans). Additionally, 10x10 cm² fields were made and computed on both phantoms. Next, the audit team performed measurements using the audit equipment. All 21 Dutch radiotherapy institutes were audited. The measurements were performed using an ionization chamber (PinPoint, PTW), Gafchromic EBT3 film and a 2D ionization chamber array, all in an octagonal phantom (Octavius, PTW). Differences between the measured and computed dose distribution were investigated using a global gamma analysis with a 5%/1mm criterion for the stereotactic VMAT plan and 3%/3mm for the other plans with a 95% pass rate tolerance. Additionally, the participating centres performed QA measurements of the same treatment plans according to their local protocol and equipment.

Results: The average difference between the point measurement, at the centre of the phantom, and the planned dose is below 1% (range: (-4.0 - +2.0)%) independently on the plan type (table 1).

Table 1 Point measurement for all the plans measured with a PinPoint at the centre of the Octavius phantom

	10x10 cm ² field	Simple IMRT	Simple VMAT	Complex IMRT	Complex VMAT	Stereotactic VMAT
Average ± σ (%)	0.1 ± 1.4	-1.3 ± 1.2	0.1 ± 1.8	-0.9 ± 1.4	-0.9 ± 2.2	-1.2 ± 1.8
Max (%)	0.1	0.4	4.0	1.9	2.7	2.6
Min (%)	-2.2	-3.9	-2.7	-3.3	-3.7	-4.4

As shown in figure 1 the average pass rate obtained from the array measurements is in good agreement (average difference: (0.4 ± 1.0)%) with the average pass rate of the QA measurements provided by the participating institutes performed with their equipment for all the plans except for the simple VMAT plan.

Figure 1 Average pass rate (%) for (3%,3mm) criterion, (5%,1mm) for the stereotactic plan, for measurements obtained with the Octavius phantom and with the participating institute's patient specific QA phantom.

For the latter, the pass rate obtained with the Octavius is influenced by the sensitivity variation of the array as a function of gantry angle. Seven institutes out of 21 had plans that failed the audit gamma analysis pass rate tolerance of

95% while the institute's QA outcome was within tolerance (1 institute two plans, 6 institutes one plan). The film measurement results are still under investigation and therefore not presented in this abstract.

Conclusion: The results demonstrate that such a national QA audit is feasible. The reported in-house QA results were consistent with the audit despite differences in dosimetry equipment and analysis methods. Of the 21 Dutch centres audited, 67% passed the gamma analysis test for all the plans measured with a 2D-array by the audit team showing acceptable implementation of IMRT and VMAT delivery.

OC-0546

The development of proton-beam grid therapy (PBGT)

T. Henry¹, A. Valdman², A. Siegbahn¹

¹Stockholm University, Department of Medical Radiation Physics, Stockholm, Sweden

²Karolinska Institutet, Department of Oncology and Pathology, Stockholm, Sweden

Purpose or Objective: Radiotherapy with grids has previously been carried out with photon beams. The grid method is used as an attempt to exploit the clinical finding that normal tissue can tolerate higher doses as the irradiated volumes become smaller. In this work we investigated the possibilities to perform proton-beam grid therapy (PBGT) with millimeter-wide proton beams by performing Monte Carlo simulations of dose distributions produced by such grids. We also prepared proton-grid treatment plans with a TPS, using real patient data and beam settings available at modern proton therapy centers.

Material and Methods: Monte Carlo calculations were performed using TOPAS version 1.2.p2 in a 20x20x20 cm³ water tank. The beam grids (each containing 4x4 proton beams arranged in a square matrix) were aimed towards a cubic target at the tank center. A total of 2x2 opposing grid angles were used. The target was cross-fired in an interlaced manner. A beam-size study was carried out to find a suitable elemental beam size regarding beam thinness, peak-to-entrance dose ratio and lateral penumbra along the beam path. Dose distributions inside and outside of the target were calculated for beam center-to-center (c-t-c) separations inside the grids of 6, 8 and 10 mm.

The TPS study was performed with Varian Eclipse. We re-planned two patients (one liver cancer and one rectal cancer patient) already treated in the hospital with photon therapy with the suggested PBGT. The IMPT method was used to prepare these plans. The plan objectives were set to create a homogeneous dose inside the target.

Results: A beam size of 3 mm (FWHM) at the tank surface was found suitable from a dosimetric point of view for the further studies. By interlacing simulated beam grids from several directions, a cubic and nearly homogeneous dose distribution could be achieved in the target (see Figure 1). The c-t-c distance was found to have a significant impact on the valley dose outside of the target and on the homogeneity of the target dose. In the TPS study, a rather uniform dose distribution could be obtained inside of the contoured PTV while preserving the grid pattern of the dose distribution outside of it. The latter finding could be important for tissue repair and recovery.

Conclusion: Proton-beam grids with 3 mm beam elements produce dose distributions in water for which the grid pattern is preserved down to large depths. PBGT could be carried out at proton therapy centers, equipped with spot-scanning possibilities, using existing tools. However, smaller beams than those currently available could be advantageous for biological reasons. With PBGT, it is also possible to create a more uniform target dose than what has been possible to produce with photon-beam grids. We anticipate that PBGT could be a useful technique to reduce both short- and long-term side effects after radiotherapy.

OC-0547

Towards Portal Dosimetry for the MR-linac: back-projection algorithm in the presence of MRI scanner

I. Torres Xirau¹, R. Rozendaal¹, I. Olaciregui-Ruiz¹, P. Gonzalez¹, U. Van der Heide¹, J.J. Sonke¹, A. Mans¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Currently, various MR-guided radiotherapy systems are being developed and clinically implemented. For conventional radiotherapy, Electronic Portal Imaging Devices (EPIDs) are frequently used for in vivo dose verification. The high complexity of online treatment adaptation makes independent dosimetric verification in the Elekta MR-linac combination indispensable. One of the challenges for MR-linac portal dosimetry is the presence of the MRI housing between the patient and the EPID.

The purpose of this study was to adapt our previously developed back-projection algorithm for the presence of the MRI scanner.

Material and Methods: Three steps have been added to our current EPID dosimetry back-projection model to account for the presence of the MRI scanner: i) subtraction of scatter from the MRI to the EPID, ii) correction for the MRI attenuation, iii) compensation for changes in the beam spectrum. The calibration of the algorithm needs a set of commissioning data (from EPID and ionization chamber, both with and without the MRI) to determine the parameters for the back-projection method.

An aluminum block of 12 cm thickness at 15 cm distance from the EPID was used to approximate the effects of the MRI scanner. Measurements were performed using a 6MV photon beam of a conventional SL20i linear accelerator (Elekta AB, Stockholm, Sweden) at 0° gantry.

58 IMRT fields of 11 plans (H&N, lung, prostate and rectum) were delivered to a 20 cm polystyrene slab phantom and portal images were acquired with the aluminum plate in place. For independent comparison with our conventional method the same fields were delivered without the aluminum plate. The EPID images were converted to dose, corrected for the presence of the aluminum plate, back-projected into the phantom and compared to the planned dose distribution using a 2-D gamma evaluation (3%, 3 mm).

Results: The γ_{mean} averaged over the 58 IMRT fields was 0.39 ± 0.11 , the $\gamma_{1\%}$ was 1.05 ± 0.30 and the $\% \gamma_{\leq 1}$ was 95.7 ± 5.3 . The dose difference at the isocenter was -0.7 ± 2.2 cGy. These results are in close agreement with the performance of our algorithm for the conventional linac setup (Table 1).

	γ_{mean}	$\gamma_{1\%}$	$\% \gamma_{\leq 1}$	$\Delta \text{Dose iso (cGy)}$
Conventional	0.35 ± 0.10	0.94 ± 0.18	98.1 ± 3.8	-1.9 ± 2.3
MR/aluminum	0.39 ± 0.11	1.05 ± 0.30	95.7 ± 5.3	-0.7 ± 2.2

Table 1: γ results (3%,3mm) averaged over the 58 IMRT fields. Our conventional back-projection method was used to back-project portal images acquired without the aluminum plate (top) and our adapted method was used to correct and back-project portal images acquired with the aluminum in place (bottom).

Conclusion: Our EPID dosimetry back projection algorithm was successfully adapted for the presence of an attenuating medium between phantom (or patient) and EPID. Experiments using a 12 cm aluminum plate (approximating the MR-linac geometry) showed excellent agreement between planned and EPID reconstructed dose distributions. This result is an essential step towards an accurate, independent, and potentially fast field-by-field IMRT portal dosimetry based verification tool for the MR-linac. Part of this research was sponsored by Elekta AB.

Hyperthermia treatment planning in the pelvis using thermophysical fluid modelling of the bladder

G. Schooneveldt¹, H.P. Kok¹, E.D. Geijsen¹, A. Bakker¹, E. Balidemaj¹, J.J.M.C.H. De la Rosette², M.C.C.M. Hulshof¹, T.M. De Reijke², J. Crezee¹

¹Academic Medical Center, Radiotherapy, Amsterdam, The Netherlands

²Academic Medical Center, Urology, Amsterdam, The Netherlands

Purpose or Objective: Hyperthermia is a (neo)adjuvant treatment modality that increases the effectiveness of radiotherapy or chemotherapy by heating the tumour area to 41-43 °C. Loco-regional hyperthermia is delivered using phased array systems with individually controlled antennae. Hyperthermia treatment planning is necessary to determine the phase and amplitude settings for the individual antennae that result in the optimal temperature distribution. Current treatment planning systems are accurate for solid tissues but ignore the specific properties of the urinary bladder and its contents, which limits their accuracy in the pelvic region. This may have clinical implications for such treatment sites as the rectum, the cervix uteri, and the bladder itself.

The aim of this study is to incorporate a physically correct description of the bladder properties in treatment planning, most notably the presence of convection and the absence of perfusion, and to assess the differences with the conventional model.

Material and Methods: We created a convective thermophysical fluid model based on the Boussinesq approximation to the Navier-Stokes equations; this means we assumed all parameters to be temperature independent except for the mass density in the gravitational term. We implemented this using the (finite element) OpenFOAM toolkit, and coupled it to our (finite difference) in-house developed treatment planning system, based on Pennes' bio-heat equation.

A CT scan was obtained from a bladder cancer patient and an experienced clinician delineated the bladder as part of the standard clinical work-flow. Based on this input, we first performed the treatment planning the conventional way with a muscle-like solid bladder, and calculated the optimal phase and amplitude settings for all four antennae. Next, we redid the temperature calculation with the expanded treatment planning system with a fluid-filled bladder, using the same settings. We subsequently calculated the differences between the two temperature distributions.

Results: The temperature in the bladder with realistic fluid modelling is much higher than without, as the absence of perfusion in the bladder filling leads to a much lower heat removal. The maximum temperature difference was 3.6 °C. Clinically relevant tissue temperature differences of more than 0.5 °C extended to 1.75 cm around the bladder. The temperature distribution according to the convective model and the difference with the solid only model are shown in Figure 1. The difference reflects the homogenizing effect of convection within the bladder and the nett heat transport in the upward direction.

Figure 1.

Left: Temperature distribution at equilibrium according to the expanded treatment planning system with fluid dynamics. Note the homogeneous temperature distribution inside the bladder (top: axial view, bottom: coronal view).

Right: Temperature difference at equilibrium between the expanded treatment planning system with fluid dynamics and the traditional planning system without fluid dynamics. Note that the entire bladder, but especially the top half, is much warmer when fluid dynamics are accounted for. Clinically relevant effects extend to 1.75 cm around the bladder (top: axial view, bottom: coronal view).

Conclusion: The addition of the new convective model to the hyperthermia treatment planning system leads to clinically highly relevant temperature changes. Explicit modelling of fluids is particularly important when the bladder or its direct surroundings are part of the treatment target area.

OC-0549

The effects of a magnetic field and real-time tumor tracking on lung stereotactic body radiotherapy

M.J. Menten¹, M.F. Fast¹, S. Nill¹, C.P. Kamerling¹, F. McDonald¹, U. Oelfke¹

¹The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom

Purpose or Objective: There have been concerns that the quality of highly conformal dose distributions, delivered under active MRI guidance, may be degraded by the influence of the magnetic field on secondary electrons. This planning study quantifies this effect for stereotactic body radiotherapy (SBRT) of lung tumors, conducted either with or without real-time multileaf collimator (MLC) tumor tracking.

Material and Methods: The Elekta Monaco treatment planning software, research version 5.09.07, was used to design treatment plans on the peak-exhale 4DCT phase of nine patients undergoing lung SBRT. The software features a machine model of the Atlantic MR-linac system and allows dose calculation and plan optimization under consideration of a magnetic field.

For each patient, we prepared four different 9-beam step-and-shoot IMRT plans: two for conventional, non-tracked treatment and two for delivery with real-time MLC tumor tracking, each delivered either with or without a 1.5T magnetic field oriented in the superior-inferior patient direction. For the conventional delivery, the internal target volume was defined as the union of the gross tumour volumes (GTV), delineated on each 4DCT phase. For the tracked delivery, the moving target volume was defined as union of all GTVs, each corrected for the center-of-volume shift thus accounting for target deformations. Dose was prescribed according to the RTOG 1021 guideline. Delivery of the respective plans was simulated to all 4DCT phases and the doses were then deformably accumulated onto the peak-exhale phase.

In order to evaluate the effect of the magnetic field and real-time tumor tracking, several dose-volume metrics and the integral deposited energy in the body were compared. Statistical significance of the differences was evaluated using a two-sided paired t-test after verifying normal distribution of them, while correcting for multiple testing for the four primary endpoints.

Results: The table presents the differences in the investigated dose-volume metrics due to either the presence of a magnetic field or real-time MLC tumor tracking. Most prominently, the magnetic field caused an increase in dose to the skin and a decrease of dose to the GTV (see figure). While statistically significant, the magnitude of these differences is small. In all 36 simulated dose deliveries, the dose prescription to the target was fulfilled and there were only minor violations of normal tissue constraints.

Real-time MLC tumor tracking was able to maintain dose coverage of the GTV while reducing the integral deposited energy. This results in a decrease in dose to the skin and normal lung tissue, both with and without a magnetic field.

	Effect of magnetic field during				Effect of real-time tumor tracking at			
	conventional delivery		MLC tracked delivery		OT		1.5T	
	Difference	p-value	Difference	p-value	Difference	p-value	Difference	p-value

Changes with standard deviation in the evaluated dose-volume metrics and integral deposited energy due to either the presence of a 1.5T magnetic field or real-time MLC tumor tracking, averaged over the entire patient cohort. Statistically significant differences are denoted by red font. The changes of the four primary endpoints are shown at the top of this table and were evaluated at a significance level of $p = 0.0125$. The differences in the dose-volume metrics investigated in an exploratory analysis are presented in the bottom and were evaluated at $p = 0.05$.

Transverse CT slice of a lung cancer patient. Overlaid are (A) the simulated dose delivered with a 1.5T magnetic field present, (B) the simulated dose delivered without a magnetic field and (C) the local dose difference. The GTV is contoured in dark green, while the PTV is contoured in light green, the lung in blue and the skin in black.

Conclusion: This study has shown that accounting for the effects of the magnetic field during treatment planning allows for design of clinically acceptable lung SBRT treatments with a MR-linac. Furthermore, it was found that the ability of real-time tumor tracking to decrease dose exposure to healthy tissue was not degraded by a magnetic field.

Investigation of magnetic field effects for the treatment planning of lung cancer

O. Schrenk^{1,2}, C.K. Spindeldreier^{1,2}, A. Pfaffenberger^{1,2}

¹German Cancer Research Center, Medical Physics in Radiation Oncology, Heidelberg, Germany

²Heidelberg Institute for Radiation Oncology HIRO, National Center for Radiation Research in Oncology, Heidelberg, Germany

Purpose or Objective: Combining the capabilities of high resolution soft tissue MR imaging and intensity modulated radiation therapy into a hybrid device has the potential to increase the accuracy of radiotherapy. However, it is known that the magnetic field of the MR manipulates the trajectory of the secondary electrons and leads to a deviation of dose especially at the interfaces between high and low density materials. This study aims to introduce a routine for the evaluation of magnetic field effects to dose delivery and plan optimization using Monte Carlo simulations.

Material and Methods: An EGSnrc Monte Carlo environment, based on the egs++ class library, was developed which can be used for the simulation of IMRT treatment plans in the presence of a magnetic field, based on patient CT data. A routine for the processing of treatment planning parameters and Monte Carlo simulation data was implemented into the

in-house open source treatment planning system matRad. In order to basically validate the implementation, dose distributions at 0 T were compared against collapsed cone calculations by the treatment planning system RayStation. The effect of a magnetic field to the dose distribution was investigated for simulations in a porcine lung phantom. Based on Monte Carlo simulations of patient specific beamlets, plan optimization was performed and analyzed.

Results: Comparison showed that the Monte Carlo simulations of IMRT plans at 0 T are in good agreement with RayStation dose calculations. The effect of a 1.5 T lateral magnetic field on the dose distribution showed distinct alteration in tumor dose. Differences appear to be less when an opposing field technique is used. It could further be proven that the routine is capable of performing plan optimization based on Monte Carlo simulated beamlets in the presence of a magnetic field (see figure 1).

Figure 1: A simplified example of the forward simulation of unmodulated Monte Carlo beamlets in the presence of a lateral 1.5 T magnetic field. Dose hot spots (electron return effect, cf. Raaijmakers, 2005) are evident at tissue lung interfaces and the tumor boundary.

Conclusion: A routine for dose calculation of IMRT plans with EGSnrc and for plan optimization based on Monte Carlo simulated beamlets using the in-house planning system matRad was developed. This implementation provides the possibility to analyze the effects of a magnetic field during radiotherapy in detail. Additionally it enables the investigation of optimization strategies for an MRI-LINAC system.

Acknowledgments: We thank Dr. Iwan Kawrakow for providing the egs++ magnetic field macro for the EGSnrc code system.

Advantage of IMPT over IMRT in treatment of gynaecological cancer with para-aortic nodal involvement
M. Van de Sande¹, C.L. Creutzberg¹, S. Van de Water², A.W. Sharfo², M.S. Hoogeman²

¹Leiden University Medical Center LUMC, Radiation Oncology, Leiden, The Netherlands

²Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

Purpose or Objective: High costs and limited capacity in proton therapy requires prioritizing according to expected benefit. The aim of this work is to quantify the clinical advantage of robust intensity-modulated proton therapy (IMPT) in terms of sparing of organs at risk (OARs) for three target volumes in treatment of gynaecological cancers compared with state-of-the-art intensity-modulated photon therapy (IMRT), and to evaluate for which target volume the benefit would justify the use of IMPT.

Material and Methods: Three target volumes were included: pelvic region (primary or postoperative treatment; N=10, 6 with boost dose), pelvic and para-aortic region (N=6, all with boost dose), para-aortic region alone (para-aortic recurrence,

N=5, all with boost dose). Robust IMPT (minimax method) and 20-beam IMRT plans were generated with an in-house developed system for automated treatment planning. Prescription dose was 48.6 Gy with or without a simultaneous integrated boost to 58.05 Gy. IMPT and IMRT plans were made for wide (15 mm primary CTV/7 mm nodal CTV) and small (5/2 mm) CTV-PTV margins. IMPT plans included range robustness of 3% and setup robustness of 2 mm assuming online setup correction and adaptive radiotherapy. Relevant dose-volume parameters of OARs were used to compare both techniques.

Results: IMPT reduced the dose in all OARs for similar target coverage (>99%). The benefit of IMPT was higher in the lower dose region than in the higher dose region. Figure 1 compares OAR dose-volume parameters per patient. For treatment of the pelvic region, the dose in pelvic bones was on average 27% lower with IMPT; and in femoral heads 5% lower. For treatment of pelvic and para-aortic region, kidney and spinal cord dose was lower for IMPT (left kidney 1.1 Gy vs 7.8 Gy; right kidney 2.4 Gy vs 11.8 Gy; spinal cord 14.5 Gy vs 28.0 Gy). For the para-aortic region alone an important advantage in favour of IMPT was seen (left kidney 4.4 Gy vs 38.6 Gy; right kidney 0.5 Gy vs 5.8 Gy; spinal cord 29.2 Gy vs 39.7 Gy), see Table 1. For all target volumes clinically relevant reductions in V15Gy for the bowelbag were found, reducing V15Gy by 153 cc, 1231 cc, and 523 cc, respectively. Differences in dose to most OARs were similar for wide and small margins, while the advantage of IMPT was more pronounced for rectum, bladder, and sigmoid using small margins.

Conclusion: For all gynaecological target volumes, IMPT reduced the dose to all OARs compared with IMRT, mainly in the lower dose region and for both wide and small margins. Considerable reduction of the bowel volume receiving 15 Gy or more was seen. The greatest and clinically relevant advantage of IMPT was found for treatment of macroscopic disease in the para-aortic region, justifying the use of proton therapy for this indication.

⁴Azienda Provinciale per I Servizi Sanitari APSS, Protontherapy Department, Trento, Italy

Purpose or Objective: Proton beam therapy represents a promising modality for left breast irradiation due to negligible dose to non-target volume, as heart and lung. However skin toxicity and poor cosmetics inherent to protons physical properties are of major concern. Radiation-induced skin toxicity (RIST) is a side effect impacting on the quality of life in breast cancer patients treated with radiation therapy. Purpose of the present study is twofold: a) to develop a normal tissue complication probability (NTCP) model of severe acute RIST in BC patients treated with conventional three-dimensional conformal radiotherapy (3DCRT) and b) to use the implemented skin NTCP model to guide breast proton therapy plan optimization.

Material and Methods: We evaluated 140 consecutive BC patients undergoing 3DCRT after breast conserving surgery in a prospective study assessing acute RIST. Acute RIST was classified according to the RTOG scoring system. Dose-surface histograms (DSHs) of the body-structure in the breast region were extracted. DSHs of the body were considered as representative of the irradiation in epidermis and dermis layers and extracted by an in-house developed library using the relative complement in the body of its 3D erosion defined by a spherical structuring element of radius $r = 3$ mm (assumed as mean skin thickness). On such shell, the absolute dose-volume histogram was regularly computed and then divided by r to obtain the DSH. NTCP modeling by Lyman-Kutcher-Burman (LKB) recast for DSHs and using bootstrap resampling techniques was performed. Five randomly selected left BC patients were then replanned using proton pencil beam scanning (PBS). PBS plans were obtained to ensure appropriate target coverage (90% 50 Gy(RBE) prescription dose to the 90% breast) and heart-lung sparing. Different planning objectives for skin were used (Table 1) and two different beam set-ups were tested. The proton plan body DSHs were extracted and the corresponding NTCP values calculated.

Table 1

Planning objectives/constraints	Plan set up

Average CTV V ₅₀ ± SD	100.0 ± 0.4%	93 ± 1%	93 ± 1%
Average CTV D ₉₅ ± SD	51.0 ± 0.1 Gy	51.5 ± 0.4 Gy	52.0 ± 0.3 Gy

Abbreviations: D_x= the minimum dose to x% highest dose volume, D_{max}= maximum dose, V_x= volume receiving at least x Gy, NTCP= normal tissue complication probability, CTV= clinical target volume

Results: By the end of 3DCRT, severe (RTOG G3 vs. G0-2) acute RIST was found in 11 out of 140 (8%) patients. Using DSHs for LKB modeling of acute RIST severity (estimated model parameter: TD50=39 ± 4 Gy, m=0.13 ± 0.08, n=0.36 ± 0.05) a good prediction performance was obtained (Rs= 0.3, AUC= 0.8, p=0.003). When used to guide parameter choice in proton PBS optimization, our NTCP model suggests that the probability of having acute RIST can be on average lowered by a factor 2.7 using a single oblique beam or even by a factor 6 with a tangential-beam set up (Table 1 and Figure 1a) at negligible expense of target coverage (Figure 1b).

Conclusion: Robust LKB NTCP model with a good prediction performance for acute RIST can be derived using the body DSHs of the irradiated area. The obtained skin NTCP represents a valuable tool for breast proton plan optimization and evaluation in order to reduce the risk of acute skin toxicity.

Relative risks of radiation-induced secondary cancer following particle therapy of prostate cancer

C. Stokkevig¹, M. Fukahori², T. Nomiya², N. Matsufuji², G. Engeseth¹, L. Hysing¹, K. Ytre-Hauge³, A. Szostak³, L. Muren⁴

¹Haukeland University Hospital, Department of Oncology and Medical Physics, Bergen, Norway

²National Institute of Radiological Sciences, Research Center for Charged Particle Therapy, Chiba, Japan

³University of Bergen, Department of Physics and Technology, Bergen, Norway

⁴Aarhus University Hospital- Aarhus, Department of Medical Physics, Aarhus, Denmark

Purpose or Objective: An elevated risk of secondary cancer (SC) has been observed in prostate cancer patients following radiotherapy (RT). Particle therapy has in general a considerable potential of reducing the irradiated volumes of healthy tissues, which is expected to have a positive effect on radiation-induced cancer. However, the carcinogenic effect of RT in the high dose region is uncertain, and is influenced by fractionation, radio-sensitivity, relative biological effects (RBE) as well as patient-specific patterns in the dose distributions. The aim of this study was therefore to

estimate relative risks (RR) of secondary bladder and rectal cancer using dose distributions from x-ray, proton and carbon(C)-ion therapy as applied in contemporary clinical practice. We also included a model parameter scan to identify the influence of variations in typical values of these parameters.

Material and Methods: Treatment plans for volumetric modulated arc therapy (VMAT, Eclipse), intensity-modulated proton therapy (IMPT; Eclipse) and C-ions (XiO-N) were generated for ten prostate cancer patients. For all three modalities, the primary clinical target volume included the prostate gland and the seminal vesicles, while technique specific boost volumes included the prostate only. Both VMAT and IMPT plans were prescribed to deliver 67.5 Gy(RBE) to the prostate and 60 Gy(RBE) to the seminal vesicles over 25 fractions (assuming fiducial margin based set-up). The C-ion plans comprised 12 fractions with 34.4 Gy(RBE) to the total target volume and 51.6 Gy(RBE) to the boost volume (bony anatomy set-up). Physical dose distributions of the bladder and rectum were used to estimate the RR of radiation-induced cancer (VMAT/IMPT and VMAT/C-ion) using the published malignant induction probability model (J Radiol Prot 2009). The mean RR results presented were calculated by sampling the dose distributions of all ten patients and previously published model input parameters with the listed confidence intervals (CI) (Table I). Subsequently a parameter scan was performed over a wide range of possible RBEs and radio-sensitivity (α and β) values.

Results: The mean estimated RR (95% CI) of SC for VMAT/C-ion were 1.31 (0.65, 2.18) for the bladder and 0.58 (0.41, 0.80) for the rectum. Corresponding values for VMAT/IMPT were 1.73 (1.07, 2.39) and 1.11 (0.79, 1.45), respectively (Table I). The radio-sensitivity parameter α had the strongest influence on the RR for both the investigated organs; decreasing for increasing values of α (Fig 1). The β parameter influences the RR significantly only for very low α values (below about 0.2).

Figure 1. Relative risk (RR) parameter scan for mean bladder dose distribution. RR >1 means higher risk from VMAT compared to C-ions, while RR <1 means higher risk from C-ions compared to VMAT.

Table I. Estimated Relative Risks, model parameters and input distributions

	Bladder	Rectum	CI
RR (VMAT/C-ion)	1.31 (0.65, 2.18)	0.58 (0.41, 0.80)	95%
RR (VMAT/IMPT)	1.73 (1.07, 2.39)	1.11 (0.79, 1.45)	95%
α (Gy ⁻¹)	0.25 ($\sigma=0.075$)	0.25 ($\sigma=0.075$)	Gaussian
β (Gy ⁻²)	0.033 ($\sigma=0.0055$)	0.046 ($\sigma=0.0077$)	Gaussian
RBE _{min} (C-ion)	1.25 (1.2, 1.3)	1.25 (1.2, 1.3)	triangle
RBE _{max} (C-ion)	6 (5, 7)	6 (5, 7)	triangle
RBE _{min} (proton)	1.03 (1.01, 1.05)	1.03 (1.01, 1.05)	triangle
RBE _{max} (proton)	1.25 (1.2, 1.3)	1.25 (1.2, 1.3)	triangle

Conclusion: Based on the modest variations in RR across the large spread in parameter values, the treatment modalities are not expected to have very different SC risk profiles with respect to these organs. The α value had the strongest influence on the RR and may change the RR in favour of one technique instead of another (particle vs photons).

OC-0554

Robustness recipe for minimax robust optimisation in IMPT for oropharyngeal cancer patients

S. Van der Voort¹, S. Van de Water¹, Z. Perkó², B. Heijmen¹, D. Lathouwers², M. Hoogeman¹

¹Erasmus Medical Center Rotterdam, Erasmus MC Cancer Center, Rotterdam, The Netherlands

²Delft University of Technology, Department of Radiation Science and Technology, Delft, The Netherlands

Purpose or Objective: Treatment plans for intensity-modulated proton therapy (IMPT) can be robustly optimized by performing 'minimax' worst-case optimization, in which a limited number of error scenarios is included in the optimization. However, it is currently unknown which error scenarios should be included for given population-based distributions of setup errors and range errors. The aim of this study is to derive a 'robustness recipe' describing the setup robustness (SR; in mm) and range robustness (RR; in %) settings (i.e. the absolute error values of the included scenarios) that should be applied in minimax robust IMPT optimization to ensure adequate CTV coverage in oropharyngeal cancer patients, for given Gaussian distributions of systematic and random setup errors and range errors (characterized by standard deviations Σ , σ and ρ , respectively).

Material and Methods: In this study contoured CT scans of 6 unilateral and 6 bilateral oropharyngeal cancer patients were used. Robustness recipes were obtained by: 1) generating treatment plans with varying robustness settings SR and RR, 2) performing comprehensive robustness analyses for these plans using different combinations of systematic and random setup errors and range errors (i.e. different values of Σ , σ and ρ), and 3) determining the maximum errors for which certain SR and RR settings still resulted in adequate CTV coverage. IMPT plans were considered adequately robust if at least 98% CTV coverage ($V95\% \geq 98\%$) was achieved in 98% of the simulated fractionated treatments. Robustness analyses were performed using Polynomial Chaos methods, which allow for fast and accurate simulation of the expected dose in fractionated IMPT treatments for given error distributions. Separate recipes were derived for the unilateral and bilateral cases using one patient from each group. The robustness recipes were validated using all 12 patients, in which 2 plans were generated for each patient corresponding to $\Sigma = \sigma = 1.5$ mm and $\rho = 0\%$ and 2%.

Results: The robustness recipes are depicted in Figure 1. We found that 1) systematic setup errors require larger SR than random setup errors, 2) bilateral cases are intrinsically more robust than unilateral cases, 3) the required RR only depends on ρ , and 4) the required SR can be fitted by second order polynomials in Σ and σ . The formulas for the robustness

recipes are: $SR = -0.15\sigma^2 + 0.27\sigma + 1.85\Sigma - 0.06\sigma + 1.22$ and $RR = 3\%$ for $\rho = 1\%$ and 2% for unilateral cases, and $SR = -0.07\sigma^2 + 0.19\sigma + 1.34\Sigma - 0.07\sigma + 1.17$ and $RR = 3\%$ and 4% for $\rho = 1\%$ and 2% , respectively, for bilateral cases. The recipe validation resulted in 22 plans being adequately robust, while for the remaining two plans CTV coverage was adequate in 97.8% and 97.9% of the simulated fractionated treatments.

Figure 1. Combinations of systematic (Σ) and random (σ) setup errors that give adequate CTV coverage ($V95\% \geq 98\%$) for 98% of the simulated fractionated treatments for a range error (ρ) of 2% for a unilateral and bilateral patient. In each plot different SR and RR settings are shown. The solid round markers show the obtained data, the dashed lines are a quadratic fit.

Conclusion: Robustness recipes were derived that can be used in minimax robust optimization of IMPT treatment plans to ensure adequate CTV coverage for oropharyngeal cancer patients.

Organ at risk dose parameters increased by daily anatomic changes in prostate cancer SBRT

M. Faasse-de Hoog¹, M.S. Hoogeman¹, J.J.M.E. Nuyttens¹, S. Aluwini¹

¹Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

Purpose or Objective: Stereotactic body radiotherapy (SBRT) is increasingly used to treat low and intermediate stage prostate cancer (PC). In our institution, SBRT is delivered in 4-5 fractions of high dose using the CyberKnife system with marker-based tracking. Tracking accurately aligns the treatment beams to the prostate just prior and during the treatment fraction. However, surrounding organs at risks (OARs) may move relative to the prostate, causing the OAR dose to deviate from what was planned. The aim of this work is to quantify the daily dose to OARs in SBRT for PC, and compare it to the planned dose.

Material and Methods: For 9 patients, four to five repeat CT scans were acquired prior to each daily SBRT fraction and were analyzed. The bladder, rectum, anus, and urethra were contoured in the planning and repeat CTs. The urethra was divided in three parts: the cranial and the caudal part of the urethra prostatica (UP) and the membranous urethra (MU, 2 cm caudal to the prostate). The repeat CTs were aligned to the planning CT based on the four implanted markers. Subsequently, the planned dose distribution was projected on the aligned repeat CTs. For each patient, dose-volume parameters of the OARs were recorded, averaged over the 4-5 repeat CTs and compared to planning.

Results: The greatest deviation between the delivered and planned dose was seen for the MU. The planned mean dose of 24.0 Gy was exceeded in the repeat CTs by on average $59 \pm 17\%$ (1 SD) and the D5% was increased by $7 \pm 3\%$, from 38.7 to 41.6 Gy (Fig. 1a). For the mean dose of the caudal and cranial UP the deviation from planning was limited: $1 \pm 1\%$ and $5 \pm 5\%$ respectively. The planned mean and V1cc (dose allowed to 1cc of the organ) rectum dose, 10.9 and 32.8 Gy respectively, was on average $5 \pm 5\%$ and $12 \pm 11\%$ higher in the repeat CTs (Fig. 1b). The mean dose of the anus increased as well, with $15 \pm 24\%$ from 8.7 to 9.8 Gy. The planned V1cc bladder dose (40.2 Gy) was reproducible in the repeat CTs

(difference: $1 \pm 1\%$). The planned mean bladder dose (18.4 Gy) was slightly reduced in the repeat CTs ($-6 \pm 7\%$).

Conclusion: For the membranous urethra, rectum, and anus, the dose in the repeat CTs was higher than was planned. This warrants future research investigating whether increased dose leads to increased incidence of side effects and whether dose increases should be mitigated by treatment adaptations.

OC-0556

Early clinical outcomes of prostate SABR treated with VMAT-FFF

A. Duffton¹, C. Duncanson¹, S. Paterson¹, L. Dallas¹, S. Smith¹, M. McJury¹, C. Lamb¹, N. MacLeod¹, A. Sadozye¹, D. Dodds¹

¹The Beatson West of Scotland Cancer Centre, Radiotherapy, Glasgow, United Kingdom

Purpose or Objective: Endpoints for this ethically approved clinical study:

- Assess the feasibility of planning SABR for low-intermediate risk prostate cancer using flattening filter free volumetric arc therapy.
- Assess safety of treatment delivery by recording RTOG scoring criteria of acute gastro-intestinal (GI) and genitourinary (GU) toxicity.

Material and Methods: 25 patients were included, each has 18 week toxicity data.

Inclusion criteria:

Written informed consent, 18 - 80 years, T1-T2 stage, WHO performance status ≤ 2 . Initial PSA ≤ 20 ng/ml. Gleason score ≤ 7 with histologically-proven prostate adenocarcinoma. No pathologic lymph nodes on CT/ MRI scans and no distant metastases. No previous prostate surgery, including transurethral resection of the prostate no TURP in past 6 months. No previous active malignancy within the last 10 years.

A prescription dose of 35Gy in 5 fractions was treated alternate days. This was planned using Rapidarc VMAT planning on Varian Eclipse (V.10), treated using a Varian Truebeam STX.

A clinically acceptable plan was determined by assessing the planned dose to GTV/PTV criteria and achieving dose constraints (table 1).

	Objective	Mean	SD
GTV V95%	>99%	99.8	0.4
PTV V95%	>95%	96.5	1.4
max PTV point dose		108.4	2.3
Rectum V18Gy	<35%	28.0	5.2
Rectum V28Gy	<10%	8.6	2.7
Rectum V32Gy	<5%	4.0	1.7
Rectum V35Gy	<1%	0.0	0.0
Bladder V35Gy	<1%	0.0	0.0
Beam on time (BOT)		120.5	0.2

Table 1. Planning data for first 25 patients

GI, GU and skin toxicity was scored using Radiation therapy oncology group (RTOG) criteria. Baseline data was recorded before treatment commenced (baseline), week 4 and week 18.

Results: Results include first 25 patients.

Age range was 52-78, median 70, initial PSA median 4.3-29.2, median 10.8ng/ml. All patients were successfully planned and treated with VMAT-FFF with plans being deemed clinically acceptable for 100% of patients.

GU and GI toxicity at baseline, week 4 and week 18 is detailed for each grade below, respectively.

GU toxicity:

Grade 0 - 44%, 12%, 48%

Grade 1 - 52%, 56%, 48%

Grade 2 - 4%, 28%, 4%

Grade 3 - 0%, 4%, 0%

For GU toxicity, a statistically significant increase in toxicity was observed from baseline to week 4 ($p < 0.01$) and a significant reduction from week 4 to week 18 ($p < 0.01$). No significant difference was observed between baseline and week 18, with toxicity reducing to similar levels as baseline.

GI toxicity (baseline, week 4, week 18):

Grade 0 - 96%, 52%, 72%

Grade 1 - 4%, 40%, 28%

Grade 2 - 0%, 8%, 0%

Grade 3 - 0%, 0%, 0%

GI toxicity significantly increased from baseline to week 4 ($p < 0.01$). From week 4 to week 18, toxicity had reduced ($p < 0.05$). A significant difference was observed between baseline and week 18 ($p < 0.05$) with toxicity having reduced, but not having returned to baseline grade.

Conclusion: Highly conformal plans were created for all patients. Toxicity was acceptable throughout, with toxicity at week 18 reducing to that of baseline for GU toxicity, and reducing significantly for GI toxicity. 1 patient experienced grade 3 GU toxicity at week 4, this resolved by week 10. Longer follow-up is required to assess late outcomes.

OC-0557

Feasibility of single fraction HDR brachytherapy in patients with prostate cancer: a planning study

M. Roos¹, C. De Pan¹, I.K.K. Kolkman-Deurloo¹, S. Aluwini¹

¹Erasmus MC Cancer Center, Radiation Oncology, Rotterdam, The Netherlands

Purpose or Objective: To investigate the feasibility of single fraction High Dose Rate (HDR) brachytherapy (BT) as monotherapy for low risk prostate cancer.

Material and Methods: CT scans of 30 patients were selected from our prostate HDR database. Patients were divided in groups based on prostate volume (< 40cc, 40-70cc and >70cc) and the number of needles used (13-16 and 17-22). The

existing needle geometry was used to regenerate new treatment plans for three radiation schemes: 1x19.0Gy, 1x19.5Gy and 1x20Gy. All plans were optimized according to the following objectives:

Prostate V100% \geq 95% Prostate D90% \geq 100%

Bladder D1cc < 16.0 Gy Bladder D2cc < 15.5 Gy

Rectum D1cc < 15.5 Gy Rectum D2cc < 14.5 Gy Rectum V100% 0 cc

Urethra D0,1cc < 21.0 Gy Urethra D10% < 20.5 Gy Urethra V120% 0 cc

A total of 90 plans were generated using an inverse planning module. The planning target volume (PTV) was the prostate without margins. The coverage of the prostate was maximized considering the dose constraints for the organs at risk (OAR). The primary end point of this study was the feasibility of above mentioned target coverage and OAR constraints. The secondary end point was to investigate the restricting factors to reach a feasible plan stratified to prostate volume, OAR position and implant geometry.

Results: The average prostate V100% for the 19.0, 19.5 and 20.0Gy schemes was 96.6%, 95.3% and 93.0% respectively with 83%, 57% and 33% of plans meeting this objective. The D90% of the prostate averaged 20.3 Gy, 20.3 Gy and 20.4 Gy respectively. Only 4 plans failed this objective.

The 40-70cc group showed an average prostate V100% of 96.3% an increase of 2.1% and 2.7% compared to the < 40cc and >70cc group respectively.

The number of needles had no influence on prostate coverage and urethra constraints. The rectum and bladder D1cc and D2cc increased for the 17-22 needle group with 5.7%, 8.6% and 3.3%, 5.3% respectively.

The average prostate V100% decreased in patients with a larger distance between the urethra and the posterior border of the prostate.

Prostate V100% increased from 95.7% to 97.5% in patients with a prostate to rectum distance of 2mm or more.

Conclusion: Single fraction HDR brachytherapy as monotherapy in patients with prostate cancer is feasible using our current implant geometry. Considering the OAR constraints, an acceptable D90% was reached in 96% of plans. Prostate volume, implant geometry and OAR proximity have a substantial impact on target coverage.

OC-0558

Automated VMAT planning in prostate cancer patients using a Single Arc SIB Technique

N. Simpson¹, G. Simpson¹, R. Laney¹, A. Thomson¹, D. Wheatley¹, R. Ellis¹, J. Mcgrane¹

¹RCHT, Medical Physics, Truro, United Kingdom

Purpose or Objective: To evaluate the feasibility of automated single arc treatment planning for prostate cancer patients using a commercially available treatment planning system. We also compared the resultant AutoplanningTM plans with our current institutional inverse planned prostates.

Material and Methods: A technique was created within the AutoplanningTM module of the PinnacleTM treatment planning system using institutional prescription dose/fractionation and OAR constraints to be delivered with a single arc VMAT plan. The Planning Target Volume PTV1 (74Gy) encompasses the prostate; PTV2 (66.6Gy) encompasses the prostate and the base or full seminal vesicles plus setup margins both delivered simultaneously in 37 fractions. Plans were generated for 10 randomly selected patients with prostate cancer treated at our institution, using the automated treatment technique template. Plan quality was assessed using institutional criteria and ICRU 83 criteria: D98, D2, Conformity Index (CI), Homogeneity Index (HI) and Remaining Volume at Risk (RVR). OAR constraints for rectum D65<30%, Bladder D50<50%, Femoral Heads, D50< 50%. Bowel D50<50cc, D55<14cc and D60< 1cc were assessed. The time for planning was also documented.

The ten AutoplanningTM technique plans were compared with clinical institutional VMAT prostate plans in a blinded study.

Plans were compared by Clinical Oncologists, assessing clinical coverage of the PTVs, OAR sparing and DVH parameters.

Results: Table 1 summarises results of the automated plan generation. The automated technique produced highly conformal plans that met institutional clinical constraints for 7 of 10 plans in a single run. In the 3 cases that failed, overlap of the PTV with rectum or bowel exceeded institutional DVH goals (Fig 1). There were no significant differences between the two planning techniques when comparing CI and HI.

Volume	Dose	Vol (%)	Mean	SD
PTV				
PTV1 (Min)	D63.27	98	99.81	+/-0.395
PTV1 (Max)	D75.48	2	0.13	+/-0.108
PTV2 (Min)	D70.3	98	99.99	+/-0.031
PTV2 (Max)	D70.0	2	0.04	+/-0.005
CI PTV1			1.17	+/-0.06
CI PTV2			1.09	+/-0.02
HI PTV1-2			0.012	+/-0.006
HI PTV2			0.035	+/-0.00
RVR (Mean -Gy)			23.369	+/-4.93
OAR				
Rectum	D65	<30	17.61	+/-3.964
Bladder	D50	<50	17.11	+/-5.748
Femoral Heads	D50	<50	0	+/-0
Bowel	D4.5	<50	18.82	+/-19.44

Table 1 Dosimetric Results for PTV and OAR with Automated Planning Technique

Fig 1. Impact of PTV overlap on Mean OAR doses for automated planning technique.

Conclusion: The automated technique for VMAT planning for prostate cancer is a promising solution which is feasible and may improve efficiency by automating cases that meet institutional dose volume constraints. We will present the results of the blinded plan selection study at the meeting.

OC-0559

The impact of rectal interventions on target motion and rectal variability in prostate radiotherapy
 C. Smith¹, B. O'Neill², L. O'Sullivan², M. Keaveney², L. Mullaney¹

¹Discipline of Radiation Therapy- School of Medicine- Trinity Centre Dublin, Radiation Therapy, Dublin, Ireland Republic of
²St Luke's Radiation Oncology Network- Beaumont Hospital, Radiation Therapy Department, Dublin, Ireland Republic of

Purpose or Objective: Target position is variable during fractionated prostate radiotherapy, mainly due to rectal changes. Margin reduction is preferable with the advancements of modulated techniques and IGRT. However, geometric uncertainty can persist in the absence of an intervention to minimise rectal motion. The purpose of this study is to retrospectively evaluate the effectiveness of three rectal emptying strategies in maintain rectal stability and reducing target motion during prostate radiotherapy.

Material and Methods: Four cohorts of consented prostate patients (total n=37) underwent different rectal strategies: daily phosphate enema; low-fibre diet and microlax microenema and no intervention (control). Using retrospective CBCT data, (8 CBCTs per patients), inter-fraction PTV motion relative to bony anatomy was measured using automatic bone anatomy registration, followed by an automatic Structure Volume of Interest (SVOI) match. Changes in rectal diameter (RD) at the base, mid and apex of the prostate and rectal volume (RV) were measured using the CBCT data. Frequency of prostate geometric miss was assessed, with a miss defined as any PTV shift in any direction.

Results: PTV displacement was significantly reduced in the anteroposterior (AP) direction in the microlax group (p=0.004), and in the superoinferior (SI) direction in the phosphate enema group (p=0.013) when compared with the control group (Table 1). The frequency of geometric miss was lowest in the microlax group. RD variability at the base of prostate was significantly smaller in the microlax and phosphate enema groups compared to the control group stats, and variation in RV was smallest in the microlax group. PTV motion and rectal variability were largest in the control group.

Table 1: Mean (μ), Systematic (Σ), and Random (δ) PTV displacements (mm) in the anteroposterior (AP), superoinferior (SI) and left-right (LR) directions for each group. Negative values indicate posterior, inferior and left PTV displacements from bony anatomy.

	Daily Phosphate Enema n=9			Microlax Microenema n=8			Low-Fibre Diet n=10			No intervention (Control) n=10		
	AP	SI	LR	AP	SI	LR	AP	SI	LR	AP	SI	LR
μ (mm)	-1.2*	0.3*	-0.1	-0.7*	-0.6	0.3	-1.1*	-1.3	-0.2	-2.6*	-1.9*	0.3
Σ (mm)	0.8	1.6	0.6	0.6*	0.4*	0.6	1.0	1.1	1.1	1.6*	1.9*	0.7
δ (mm)	1.4	1.0	0.5	0.8*	0.9	0.6	1.5	1.7	0.7	2.0*	1.6	0.9

*Significant difference (p<0.05) when compared with the control group statistics.

Conclusion: Microlax microenema is an effective intervention in maintaining rectal stability, and PTV motion during prostate radiotherapy, in patients with large RB4cm on planning CT.

OC-0560

Plan of the day approach in post prostatectomy radiation therapy

C. Lac¹, A. Sims¹, T. Eade^{1,2}, A. Kneebone^{1,2}
¹Central Coast Cancer Centre, Radiation Oncology, Gosford, Australia
²Northern Sydney Cancer Centre, Radiation Oncology, St Leonards, Australia

Purpose or Objective: Our primary aim is to investigate the frequency of using smaller margins for post prostatectomy radiotherapy (RT) in conjunction with daily soft tissue image guided radiotherapy (IGRT). Our secondary aim is to assess the feasibility of implementing an adaptive, 'plan of the

day', treatment approach by selecting an appropriate plan on a daily basis which will highly conform to the target and minimise rectal and bladder toxicities.

Material and Methods: Retrospectively identified 19 post prostatectomy patients. Soft tissue matching guidelines were created and split into two categories; patients with or without surgical clips. Soft tissue match was performed on cone-beam CT (CBCT) in offline review program by two radiation therapists and reviewed by two radiation oncologists. The frequency of geographic miss was measured using a planning target volume (PTV) small with a 5 mm clinical target volume (CTV) expansion and PTV large with 10 mm (15 mm anteriorly) CTV expansion. To implement a 'plan of the day' treatment approach, a post prostatectomy soft tissue training module was developed to educate the radiation therapists to perform daily soft tissue alignment. Radiation therapists will then apply an adaptive RT regime that selects from a plan library to account for internal organ inconsistencies of the bladder and rectum.

Results: A total of 135 CBCTs were reviewed on 19 radical post prostatectomy patients including those with lymph node involvement. Retrospective soft tissue match analysis determined that PTV small covered the target for 84% of CBCTs while the PTV large covered the target for 16%. There was no geographic miss outside PTV large in this retrospective analysis. In the matches that resulted in the selection of PTV large, 12% of CBCTs were due to variations in bladder filling and 4% from rectal filling.

Conclusion: PTV small is suitable for use on most CBCTs with PTV large selected for only a small portion of CBCTs. Very small bladders caused a greater amount of bladder and small bowel to fall in the target and increases the chance of side effects but rarely causes a geographic miss. Over filling bladders on CBCTs was undesired as it caused internal pelvic tilt in the superior portion resulting in a selection of the plan with PTV large. A dangerous combination is present if there are inconsistencies to both the bladder and rectum filling causing the CTV prostate bed region to tilt and fall outside of the target. With a high frequency of using PTV small, and a better understanding of the effect of bowel and bladder filling, implementation of 'plan of the day' is feasible. This will result in a highly targeted treatment delivery in conjunction with soft tissue IGRT that will reduce toxicities and increase local control.

PV-0561

Validation of an optimised MC dose prediction for low energy X-rays intraoperative radiation therapy

P. Ibáñez¹, M. Vidal¹, P. Guerra², J.M. Udías¹

¹Universidad Complutense de Madrid, Física Atómica-Molecular y Nuclear, Madrid, Spain

²Universidad Politécnica de Madrid, Ingeniería Electrónica, Madrid, Spain

Purpose or Objective: Low energy X-rays Intra-Operative Radiation Therapy (XIORT) is increasingly used in oncology, predominantly for breast cancer treatments with spherical applicators [1], but also for skin or gastrointestinal cancer [2] with surface and flat applicators. This study aims to validate a fast and precise method [3,4] to calculate Monte Carlo (MC) dose distributions with an optimized phase space file (PSF) obtained from a previously stored database of monochromatic PSF and depth dose curves (DDP) for different INTRABEAM® (Carl Zeiss) applicators. To validate this procedure, we compared dose computed with the PSF with measurements in phantoms designed to prove actual XIORT scenarios.

Material and Methods: PSF were optimized from experimental DDP in water and were employed to calculate dose distributions, first in water, then in validation phantoms

such as air gaps or bone inhomogeneities, for all flat, surface and spherical applicators. Measurements with Gafchromic EBT3 films were performed. Irradiated films were scanned with an EPSON Expression 10000XL flatbed scanner (resolution 72 ppi) after a polymerization time of at least 24 h, and the three-channel information corrected for inhomogeneity [5] was used to derive dose. Calibration films were irradiated from 0 Gy to 5 Gy for surface and flat applicators and from 0 Gy to 20 Gy for spherical applicators. Simulations and experimental data were compared in detail.

Results: MC simulations are in good agreement with experimental data, at the 3%-1 mm level (10% dose threshold) for most setups, well within what is needed for XIORT planning. Accuracy of the comparison was mostly limited by the difficulty in assuring geometrical positioning within 1 mm or less of the physical phantoms. An example of dose distribution on a heterogeneous phantom of PMMA and bone for a 3 cm flat applicator is shown in figure 1.

Figure 1. Experimental (top) and simulated (bottom) dose distributions of a PMMA-bone phantom with a 3 cm diameter flat applicator. More than 90% voxels pass the 3%-1mm gamma test.

Conclusion: Preliminary results show that the optimized Monte Carlo dose calculation reproduces dose distributions measured with different applicators, accurately enough for XIORT planning. The method is flexible and fast, and has been incorporated in Radianc@ [6], a treatment planning system for intraoperative radiation therapy developed by the GMV company.

Hadron-therapy monitoring with in-beam PET: measurements and simulations of the INSIDE PET scanner

F. Pennazio¹, M. Bisogni², N. Camarlinghi², P. Cerello¹, E. Fiorina¹, M. Morrocchi², M. Piliero², G. Pirrone², R. Wheadon¹

¹Università degli Studi di Torino and INFN, Physics, Torino, Italy

²Università degli Studi di Pisa and INFN, Physics, Pisa, Italy

Purpose or Objective: In-beam PET exploits the β^+ activation induced in the patient's body by the hadron-therapy (HT) particle beam to perform treatment monitoring

and dose-delivery accuracy assessment. The INSIDE collaboration is building an in-beam PET and tracker combined device for HT. In this work we focus on the preliminary PET measurements performed at the CNAO (Italian Hadron-therapy National Center) synchrotron facility and on Monte Carlo simulations.

Material and Methods: The PET module block is made of 16x16 Lutetium Fine Silicate scintillator elements 3.2x3.2x20 mm³ each, coupled one-to-one to a Silicon Photomultiplier matrix, read out by the TOFPET ASIC. The scanner will feature two 10x20 cm² planar heads, made by 10 modules each, at a distance of 25 cm from the iso-centre. Preliminary tests investigated the performance of one module per head at nominal distance. Monoenergetic proton pencil beams of 68, 72, 84 MeV and 100 MeV were targeted to a PMMA phantom placed inside the FOV of the two detectors. The CNAO synchrotron beam has a periodic structure of 1 s beam delivery (spill) and 4 s interval (inter-spill). Acquisition was performed both in- and inter-spill. A 250 ps coincidence window is applied to find the LORs and reconstruct the image with a MLEM algorithm. Monte Carlo (MC) simulations are used in HT for detector development and treatment planning. In case of 3D online monitoring, they could also be used to compare the acquired image, which is a measurements of the activity, with the expected distribution, and hence to assess the treatment accuracy. Taking into account the detection and digitisation processes, it is also possible to reconstruct the simulated image. MC simulations, performed with FLUKA, were used to assess the expected performance and also compared to the measured activity profiles.

Results: Acquisition has been successfully performed in both inter-spill and in-spill mode. The inter-spill and in-spill Coincidence Time Resolution (CTR) between the two modules, measured without a fine time calibration, is 459 ps and 630 ps σ , respectively. The larger in-spill value is expected and related to background uncorrelated events. The images profile along the beam axis for the 68 and 72 MeV beam energies, which have a range short enough to be stopped by the phantom inside the FOV (5x5x5 cm³), show the characteristic distal activity fall-off. The expected proton range difference in PMMA for 68 and 72 MeV (3.64 mm) is compatible with the experimental measurement (3.61 \pm 0.10 mm), obtained by fitting with sigmoid functions the fall-off of the image profiles (fig. 1). The same behaviour is found in simulated images.

Conclusion: Tests with proton beams and prototype detector modules has confirmed the feasibility of the INSIDE in-beam PET monitoring device. Simulations are in good agreement with data and could be used to calculate the expected activity distribution measured by the PET scanner.

PV-0563

Dosimetric comparisons of 1H, 4He, 12C and 16O ion beams at HIT

T. Tessonier^{1,2}, A. Mairani^{3,4}, S. Brons⁴, T. Haberer⁴, J. Debus^{1,4}, K. Parodi^{2,4}

¹Hospital University of Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

²Ludwig Maximilians University, Department of Medical Physics, Munich, Germany

³Centro Nazionale di Adroterapia Oncologica, CNAO, Pavia, Italy

⁴Heidelberg Ion Beam Therapy Center, HIT, Heidelberg, Germany

Purpose or Objective: The interest in particle therapy, with light and heavy ion beams, has grown worldwide, due to their beneficial physical and biological properties. At the Heidelberg Ion beam Therapy Center, four ions are available for irradiation with an active scanning beam delivery system: 1H, 4He, 12C and 16O. While most of the actual studies comparing different characteristics of the ions are based on Monte Carlo or analytical dose calculations, we present here an experimental based comparison for spread-out Bragg peaks (SOBP) and a first clinical-like scenario study, experimentally validated.

Material and Methods: Several SOBPs have been planned with 1H, 4He, 12C and 16O ions, at four different clinically relevant positions (5, 8, 15 and 20 cm) and different irradiation volumes (10x10x4 cm³ / 3x3x2 cm³). The measurements have been done in a water tank coupled with 24 motor-driven PinPoint ionization chambers. Delivery is applied with an active scanning beam delivery system. Both depth-dose and lateral dose profiles are investigated at different depth for each SOBP. We compare several parameters: the entrance-to-plateau ratio, the lateral penumbra along the depth, the fall-off, and the distal dose due to the fragmentation tail for ions with Z>1. For the clinical case, representing a meningioma treatment, the dose has been biologically optimized for every ion on the target volume. Experimental validations of the calculated physical dose have been made in the same water phantom.

Results: Dosimetrically, the plans doses for the SOBPs and the measured ones are within +/- 5% (figure 1). Measurements show that physically optimized SOBPs present different behavior depending on the ion used, field size and depth. These dosimetric characteristics exhibit several advantages and/or inconvenients depending on the ion used. This may help improving dose distribution during treatment planning. For the clinical-like scenario, the different ions show different characteristics on the dose distributions, impacting either the conformity to the target or the organ at risk sparing. The measurements in the water phantom show agreement within 5% to the physically planned dose.

Figure 1: SOBPs measurements for irradiation (at 8cm volume of 10x10x4cm³) with 1H, 4He, 12C or 16O

Conclusion: Although its therapeutic use had been discontinued after the end of the clinical experience at the Berkeley National Laboratory in 1992, our experimental results indicate 4He as a good candidate for further particle therapy improvements due to the favorable physical characteristics, especially due to the smaller lateral scattering than 1H and the very low tail-to-peak ratio compared to 12C or 16O. For the clinical like scenario, 4He present interesting results for organ at risk sparing with a good conformity to the target. But one have to remind that even if the physical dose measured is matching with the planned one, proper validated biological model have to been used for the ions to have a fair comparisons.

Experimental validation of proton stopping power calculations based on dual energy CT imaging

J.K. Van Abbema¹, M.J. Van Goethem², J. Mulder², A.K. Biegun¹, M.J.W. Greuter³, A. Van der Schaaf², S. Brandenburg¹, E.R. Van der Graaf¹

¹University of Groningen- Kernfysisch Versneller Instituut - Center for Advanced Radiation Technology, Medical Physics, Groningen, The Netherlands

²University of Groningen- University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands

³University of Groningen- University Medical Center Groningen, Radiology, Groningen, The Netherlands

Purpose or Objective: To improve the accuracy of proton dose calculations using dual energy X-ray computed tomography (DECT) based proton stopping powers.

Material and Methods: The CT densities of 32 different materials (table) have been measured with DECT in a 33 cm diameter Gammex 467 tissue characterization phantom. The phantom has been scanned with a clinical 90 kV / 150 kV (with additional Sn filtration) DE abdomen protocol (CTDIvol = 15.52 mGy) in a dual source CT system (SOMATOM Force). A Qr40 strength 5 ADMIRE kernel with a slice thickness of 1 mm has been used for the reconstruction. Using the method developed by van Abbema et al (Ref), effective atomic number (Z') and electron density (ρ_e') images have been derived. A fit from Z' to the logarithm of the mean excitation energy ($\ln(I)$) has been determined based on calculated values for Z' of 80 average tissues described by Woodard and White and measured values for Z' from DECT. Depth dose profiles of 190 MeV protons have been measured using a Markus chamber in a water phantom (figure) with a step size of 0.2 mm in the Bragg peak. The range R80% (distal 80% of the dose) after traversing a material in water has been measured relative to the R80% in water only, for three different depths of the material in water. Geant4 simulations have been performed to obtain depth dose profiles from specified elemental composition and density of the materials. A method has been developed to predict the energy loss in the material from DECT determined values for ρ_e' and $\ln(I)$. The derived relative stopping powers (RSPs) for the materials have been compared to RSPs determined from range differences measured in the water phantom.

Results: Effective electron densities ρ_e' derived from DECT have been determined with accuracy better than -0.9 to 0.7%, except for the inhomogeneous LN-450 material, Teflon and aluminium (table). The fit from Z' to $\ln(I)$ deviates -2.2 to 1.6% from calculated values of the 80 average tissues. For the 32 materials, the fit deviates -2.9 to 2.8% from calculated values (excl. carbon, Teflon, aluminium and Al2O3). Depth dose profiles in water have been measured with a reproducibility of the R80% < 0.1 mm. For 18 analysed materials (151 MeV at sample), RSPs determined from the Geant4 simulations are within 0.2 to 3.5% of the experimental RSPs. The RSPs determined from the Z' and ρ_e' derived from DECT are within -0.6 to 4.1% (excl. aluminium) of the experimental RSPs (table).

No.	Material	ρ_e' meas-calc [%]	RSP Sim-Exp [%]	RSP DECT-Exp [%]
1	LN-450 Lung	3.1	0.4	4.0
2	AP6 Adipose	0.5	0.2	1.3

Dosimetric response maps of diode and diamond detectors in kilovoltage synchrotron beams

T. Wright¹, D. Butler¹, A. Stevenson², J. Livingstone², J. Crosbie³

¹ARPANSA, Radiotherapy Section, Yallambie, Australia

²Australian Synchrotron, Imaging and Medical Beamline, Clayton, Australia

³RMIT University, School of Applied Sciences, Melbourne, Australia

Purpose or Objective: To measure the spatial response of diode and diamond detectors commonly used in radiotherapy to a sub-millimetre beam of kilovoltage synchrotron radiation.

Material and Methods: The spatial dosimetric response of three detectors was measured on the Imaging and Medical Beamline (IMBL) at the Australian Synchrotron. The signals from a PTW 60016 Dosimetry Diode P, PTW 60017 Dosimetry Diode E and the PTW 60019 microDiamond were continuously measured during a series of line scans to create two-dimensional maps of the response of each detector to a sub-millimeter kilovoltage beam. Dosimetric maps were collected for both side-on and end-on orientations. Detectors were also radiographed to help identify internal components.

The radiation beam was a low-divergence, high dose-rate beam of kilovoltage synchrotron x-rays, collimated to 0.1 mm in diameter with a tungsten pinhole. The weighted-average energy was 95 keV. The scanning system and its application to ionisation chambers are described in reference [1].

Results: End-on results show the spatial uniformity of each detector with a resolution of about 0.1 mm. The active volume is clearly seen as a disc in each case. The response is found to vary by 3% across the central 1.5 mm of the two diode detectors. Fig. 1(a) shows an end-on contour map of the electron diode. The central 1.5 mm of the microDiamond contained a sensitive spot where the response was approximately 30% higher than the remaining detector area. Some structure is visible where wires behind the active volume affect the response.

Side-on results show the active volume as a line because the thickness of the active volume (27 microns for the diodes and 1 micron for the diamond) is much less than the scan resolution. Contributions from outside the active area can also be seen. In the photon diode the shield is visible and the active area is recessed from the end surface when compared to the electron diode. The microDiamond response is almost exclusively due to the response in the active detector area. Fig. 1(b) shows a side-on contour map of the electron diode and Fig. 1(c) shows a radiograph of the microDiamond.

Conclusion: A synchrotron dosimetric scanning technique has been shown to work for common solid state detectors. The technique is able to measure the spatial uniformity and contribution from material around the active region, for kilovoltage beams.

Improving image reconstruction for Compton camera based imaging for proton radiotherapy verification

E. Draeger¹, S. Peterson², D. Mackin³, S. Beddar³, J. Polf¹

¹University of Maryland Medical Center, Radiation Oncology, Baltimore- MD, USA

²University of Cape Town, Physics, Cape Town, South Africa

³University of Texas MD Anderson Cancer Center, Radiation Oncology, Houston- TX, USA

Purpose or Objective: To improve analysis and reconstruction techniques for data measured with a Compton Camera (CC) imaging system for prompt gamma imaging for proton radiation therapy.

Material and Methods: The CC consists of four detector stages containing CdZnTe (CZT) crystals. Two stages contain crystals with dimensions of 20 mm x 20 mm x 15 mm, while the other two stages have crystals with dimensions of 20 mm x 20 mm x 10 mm. Rather than looking at γ interactions that occur in multiple detector stages, double- or triple-scatter events from γ -rays emitted from a ⁶⁰Co point source (2 mm full width at half maximum) that occurred in only one detector plane were studied. Using triple-scatter events in a single stage, 2D images of the γ emission were reconstructed. The energy deposited in the first interaction (E_{dep1}) as a function of the scatter angle (θ) of the γ was analyzed (see Fig. 1A). Next, the measured triple-scatter data was filtered so that it included only events satisfying the "Compton line" equation,

$$E_{dep1} = E_{\gamma 0} \frac{\alpha(1 - \cos \theta)}{1 + \alpha(1 - \cos \theta)}$$

where $\alpha = E_{\gamma 0}/(me*c^2)$, me is the rest mass of the electron, and $E_{\gamma 0}$ is the initial energy of the γ . Finally, the Compton line filtered triple-scatter data was used to reconstruct 2D images of the γ emission and was compared to the image reconstructed using all triple-scatter events.

Results: There was a dramatic difference in the position reconstruction of the point source, as seen in images reconstructed with all measured triple-scatter interactions in one CC stage (see Fig. 1B) and images reconstructed using only measured triple-scatter interactions in one stage that were within $\pm 10\%$ of the Compton lines (see Fig. 1C). The location of the source in both runs was -40 ± 2 mm along the z-axis. Fig. 1D shows that all measured data gives a reconstructed source position of -21 mm (19 mm from the actual source position), while filtering the data gives a reconstructed position of -41 mm (1 mm from the actual source position and within the uncertainty of the source position). Following tests of the Compton line filtering technique with point sources, initial imaging tests are being completed for measured data of prompt gammas emitted during irradiation of a water phantom with clinical proton therapy beams.

Figure 1: Figure (A) shows the energy deposited in the first detector stage as a function of reconstructed scattering angle for a ⁶⁰Co point source. The Compton lines corresponding to the 1.17 MeV and 1.33 MeV ⁶⁰Co γ 's are overlaid for reference. Figure (B) and Figure (C) show the reconstructed positions of the ⁶⁰Co point source for the non-filtered data and filtered data, respectively. Figure (D) shows the z-profiles of the filtered (red) and non-filtered (black) point source reconstructions. The unfiltered reconstruction contained 50,000 events, the filtered reconstruction contained 19,000 events (statistics limited), and the point source was positioned along the z-axis at -40 ± 2 mm.

Conclusion: We have developed a new method of analyzing and filtering data from a Compton camera that can be used to greatly improve the image quality and position reconstruction of prompt gammas. With this new filtering method, the position localization was improved from within 19 mm of the actual source location to within 1 mm of the actual source location for the filtered data.

Teaching Lecture: The new 'Rs' in radiation biology

SP-0567

The new 'R's' in radiation biology

M.C. De Jong¹, M.W.M. Van den Brekel², M. Verheij¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology and Department of Biological Stress response, Amsterdam, The Netherlands

²Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Head and Neck Oncology and Surgery- The Netherlands Cancer Institute. and Department of maxillofacial surgery- Academic Medical Center- University of Amsterdam., Amsterdam, Th

Over the last decades the precision of radiotherapy delivery has vastly improved. Using the newest image-guided, intensity-modulated radiotherapy techniques radiation oncologists can be fairly sure that two identical patients with seemingly identical tumors will receive the same radiotherapy dose distribution. In these cases, reasons for radiotherapy failure within the field cannot be found in clinical factors or in the delivery of the radiotherapy, but must be sought in the (heterogeneous) biological makeup of the tumor. Knowledge of an individual tumor's biology could contribute to a better prediction of radiotherapy failure and the design of approaches to radiosensitize resistant tumors.

The classical biological factors influencing radiotherapy response conveniently all start with a 'R': Reoxygenation, Redistribution, Repair and Repopulation. Intrinsic Radiosensitivity has been added as a fifth factor to describe the difference in radiosensitivity of individual cells. This factor can be broken down into three main mechanisms. Firstly, a difference in radiosensitivity could be explained by a difference in received damage upon irradiation, for example due to different levels of reactive oxygen scavengers. Secondly, a difference in (DNA) repair capability is a well-known cause for variation in intrinsic sensitivity. Thirdly, tumor cells can respond differently to inflicted damage depending on their ability to engage cell cycle or cell death pathways.

In recent years new factors have been added to the list of 'Rs'. The most important new players are cancer stem cells, the tumor microenvironment, the immune response, the cell's energy metabolism, angiogenesis and vasculogenesis. Although new techniques like pre-treatment expression profiling enable us to study different biological processes simultaneously, some major challenges remain in the accurate prediction of radioresponse. The most important relates to (spatial and temporal) tumor heterogeneity: different cells within a tumor could have different properties and all biological factors mentioned (and possible more that are yet to be discovered) could interact with each other, making it difficult to assess the overall effect within a tumor. In addition, little is known about the changes in biological behavior of a tumor during a course of fractionated radiotherapy.

This lecture will address these new R's in radiation biology and their relevance for clinical practice.

Teaching Lecture: Texture analysis of medical images in radiotherapy

SP-0568

Texture analysis of medical images in radiotherapy

E. Scalco¹, G. Rizzo¹

¹Istituto di Bioimmagini e Fisiologia Molecolare, CNR, Segrate Milano, Italy

The wide availability of tomographic images acquired before, during and after radiation treatment had offered the possibility to improve diagnosis and treatment evaluation in a non-invasive way. Image analysis is widely performed to extract parameters in different contexts, as, for example, for the identification of tumoral tissues with respect to normal tissues, for the correct classification of tumor grade, for the evaluation of treatment efficacy or its side-effects on organs at risks, or for the prediction of radiation-induced toxicities. The classical image analysis methods are based on the evaluation of some geometric features (volume, dimension, short-axis length, ...) or the mean gray-level intensity of the organ of interest. Also when functional images are considered (e.g. PET, DWI-MRI, DCE-MRI), the quantitative analysis of functional information is usually carried out in a ROI-based approach, considering only the average value within a region of interest. However, since the spatial organization of a tissue is an important marker both for the identification of abnormal tissues and for the evaluation of radiation-induced variations, it is worth considering the structural patterns of the image, generally lost in a ROI-based approach. For this purpose, texture analysis can be very helpful in extracting features able to characterize the structural information hold in these images. This is true when anatomical images (CT, MRI) are considered, because textural features can directly reflect the structural properties of the region, but also when functional images are analyzed, since the functional behavior of a tissue cannot be properly captured by a simple average value. Texture analysis can be faced in many different ways; the most used in literature are the First-Order statistical method, based on the histogram, the second-order statistical method, based on co-occurrence matrices, the steerable Gabor filter, the fractal-based features, the run length matrices and the Fourier transform. These methods, in general, extract a large number of features, which can be used for classification or prediction models. For this purpose, a selection method able to identify the most significant parameters is required, followed by an automatic classification method (e.g. support vector machine, neural networks, random forests, linear discriminant analysis, Bayesian methods, fuzzy-logic analysis). In this lesson, some of these approaches will be presented, focusing, in particular, on statistical and fractal-based methods and their biological meaning. Moreover, an overview of the different applications of texture analysis in radiotherapeutic context is presented, considering different image modalities (CT, anatomical MRI, DWI-MRI, DCE-MRI, PET). In fact, many works have applied texture analysis for the characterization of tumoral tissue for an automatic identification of radiation targets and for the discrimination between abnormal/normal tissues. In some cases, it is the power of textural features in capturing information about the spatial organization of the tissue to be fundamental for a correct discrimination between tumoral and normal tissue, rather than the simple mean intensity. Another application of texture analysis was in the evaluation and prediction of radiation-induced effects on tumor and organs at risk. Recently, textural features were also proposed as a modulation index in VMAT.

Teaching Lecture: Biology of high-energy proton and heavy ion particle therapy versus photon therapy: recent developments

SP-0569

Biology of high-energy proton and heavy ion particle therapy versus photon therapy: recent developments

M. Pruschy¹

¹University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

The rapid introduction of low LET particle therapy worldwide - in particular proton therapy - but also high LET particle therapy contrasts with the scarcity of radiobiologic evidence to support the expansion of new clinical indications. For many years, particle radiobiology research has focused on the determination of generic values for the relative biological effectiveness (RBE) for both proton and heavy ions, to be

applied in the clinics and relevant for both tumor control and radiation effects in the normal tissue. Nevertheless, recent mechanistic-oriented research on the cellular and tissue level reveal differential response patterns on the gene expression, intracellular signaling, tumor and normal tissue level to low and high LET particle therapy and to photon therapy. For example, our own studies at the center for proton therapy at the Paul Scherrer Institute, but also at other proton therapy institutes, reveal a differential requirement of the two major double strand break repair pathways in response to proton-versus photon-irradiation and indicate individual susceptibilities to photon and low LET proton but also high LET particle therapy. This has been demonstrated in accepted models of genetically-defined normal tissue cells and human tumor cells with a defined lack in specific DNA repair capacities. Likewise combined treatment modalities with pharmacologic inhibitors of specific DNA repair machineries sensitize tumor cells for the respective type of ionizing radiation. These results might become relevant for clinical stratification of patients e.g. carrying mutations in specific DNA damage response pathways; ask for the identification of relevant functional biomarkers; and the critical evaluation of generic RBEs to be applied for the different particle-based radiotherapy modalities. Thus, we nowadays realize that the RBE can vary significantly depending on the tissue, cell line or physiological end point investigated and that differential biological processes are induced by photon and particle therapy. Here we will discuss recent radiobiological findings on the subcellular, cellular and tumor microenvironment level in the framework of proton and other particle therapies.

The strong expression of SSTR2 by neuroendocrine tumors (NETs) enables peptide receptor radionuclide therapy (PRRT), the molecular internal radiation therapy of NETs. In our hospital (certified as ENETS Center of Excellence), a dedicated multidisciplinary team of experienced NET specialists is responsible for the management of NET patients (over 1,200 patient visits per year). Patient selection for PRRT is based on the Bad Berka Score (BBS) which takes into account clinical aspects and molecular features. Frequent therapy cycles (4-6 and up to 10), applying low or

intermediate doses of radioactivity are suitable for these relatively slow-growing tumors ("long term low dose, not short term high dose concept"). After each 2 treatment cycles, restaging is performed by morphologic (CT/MRI) and molecular imaging (Ga-68 SSTR PET/CT), blood chemistry and tumor markers. All data are entered in a prospective structured database (over 250 items per patient).

NET Center Bad Berka - Results

Retrospective analysis was performed in 1000 patients (age 4 - 85 years) with metastatic and / or progressive NETs, undergoing 1 - 9 cycles of PRRT at our center using Lu-177 (n=331), Y-90 (n=170) or both (n=499). Median total administered activity was 17.5 GBq. Patients were followed up for up to 132 months after the 1st cycle of PRRT. Well-differentiated NETs (G1-2) accounted for 54 %. Most patients (95.6 %) had undergone at least 1 previous therapy (surgery 86.8 %, medical therapy 55 %, ablative therapy 14.2 % and radiotherapy 3.4 %). The median overall survival (OS) of all patients from the start of PRRT was 52 months (mo). Median OS according to radionuclide used: Y-90 24 mo, Lu-177 55 mo, both (TANDEM or DUO PRRT) 64 mo; according to the grade of tumor: G1 87 mo, G2 55 mo, G3 28 mo, unknown 50 mo; and according to origin of primary tumors: pancreas 45 mo, small intestine 77 mo, unknown primary 55 mo, lung 36 mo. Median progression-free survival (PFS) measured from the last therapy cycle was 22 mo, comparable for pancreatic (23 mo) and small intestinal (25 mo) NETs. The use of a combination of Lu-177 and Y-90 takes this heterogeneity into account. Sequential administration of Y-90 and Lu-177 labeled analogues is useful for the treatment of larger tumors, followed by treatment of smaller metastases, respectively in further treatment cycles. *Conclusions* PRRT lends a significant benefit in progression free survival as well as in overall survival in metastasized and / or progressive G1-2 NETs as compared to other treatment modalities and regardless of previous therapies. Combination of Lu-177 and Y-90 (DUO) based PRRT may be more effective than either radionuclide alone. Up to 10 cycles of PRRT, given over several years were tolerated very well by most patients. Severe renal toxicity can be completely avoided or reduced by nephroprotection applying aminoacids; haematological toxicity is usually mild to moderate (except for MDS which occurs in approx. 3-5% of all patients treated). Quality of life can be significantly improved. PRRT should only be performed at specialized centers as NET patients need highly individualized interdisciplinary treatment and long term care. NETTER-1 is the first Phase III multicentric, randomized, controlled trial evaluating ¹⁷⁷Lu-DOTA0-Tyr3-Octreotate (Lutathera®) in patients with inoperable, progressive, somatostatin receptor positive midgut NETs. 230 patients with Grade 1-2 metastatic midgut NETs were randomized to receive Lutathera 7.4 GBq every 8 weeks (x4 administrations) versus Octreotide LAR 60 mg every 4-weeks. The primary endpoint was PFS per RECIST 1.1 criteria, with objective tumor assessment performed by an independent reading center every 12 weeks. Secondary objectives included objective response rate, overall survival, toxicity, and health-related quality of life. Enrolment was completed in February 2015, with a target of 230 patients randomized (1:1) in 35 European and 15 sites in the United States. At the time of statistical analysis, the number of centrally confirmed disease progressions or deaths was 23 in the Lutathera group and 67 in the Octreotide LAR 60 mg group. The median PFS was not reached for Lutathera and was 8.4 months with 60 mg Octreotide LAR [95% CI: 5.8-11.0 months], p<0.0001, with a hazard ratio of 0.21 [95% CI: 0.13-0.34]. Within the current evaluable patient dataset for tumor responses (n=201), the number of CR+PR was 18 (18%) in the Lutathera group and 3 (3.0%) in the Octreotide LAR 60 mg group (p=0.0008). Although the OS data are not mature enough for a definitive analysis, the number of deaths was 13 in the Lutathera group and 22 in the Octreotide LAR 60 mg group (p=0.019 at interim analysis) which suggests an improvement in overall survival. The Phase III NETTER-1 trial provides evidence for a clinically meaningful and statistically significant increase in PFS and ORR, and also suggests a survival benefit in patients with advanced midgut NETs treated with Lutathera.

Teaching Lecture: Radiotherapy for paediatric brain tumours

SP-0571

Radiotherapy for paediatric brain tumours

R.D. Kortmann¹¹University of Leipzig, Radiation Therapy, Leipzig, Germany**Introduction**

Radiation therapy is an integral component in the management of childhood CNS malignancies. Although high cure rates can be achieved, detrimental long term side effects often hamper the functional outcome.

Technologies

Stereotactic conformal radiation therapy, IMRT, tomotherapy, image-guided radiation therapy and proton therapy are increasingly used to provide an excellent coverage of the target. Multimodality imaging such as MRI, PET and spectroscopy are implemented in treatment planning and permit an exact definition and delineation of the target and organs at risk. Novel fractionation schedules exploit the radiobiological properties of tumour and normal tissue. The selection of treatment modality is based on the tendency of the tumour with respect to local infiltration and leptomeningeal spread. Craniospinal irradiation is the standard of care in medulloblastoma and metastatic germcell tumours. IMRT, tomotherapy and proton therapy provide a high conformality and excellent dose homogeneity throughout the target volume. Especially proton therapy has the ability to decrease the dose exposure to whole body and surrounding normal tissue thereby reducing the risk of acute and late effects. The major developments in radiation therapy of pediatric tumours are aimed to individually tailor radiation therapy to the target especially in irradiation of the tumours site such as ependymoma, low grade glioma. With the increasing complexity of irradiation techniques in the treatment of CNS malignancies formalised systems and comprehensive quality assurance programmes were introduced to provide an optimal and reproducible treatment on a high quality level. To reduce late effects RT parameters can be modified by the investigation of novel radiotherapy dose prescriptions and reducing dose exposure to neighbouring normal tissue with a maximal sparing of normal brain. The introduction of models to predict the impact of radiotherapy dose volume parameters on long-term neuropsychological function will help to further reduce the risk for late effects.

Conclusion

The rapid developments and small patient numbers as well as the lack of appropriate measurement instruments and difficult endpoints like quality of survival preclude the necessity to investigate the role of these new technologies within prospective randomised trials. Paediatric oncologists should therefore not refrain from including new technologies in their prospective trials as part of treatment standards. A detailed assessment of the long-term benefits and side effects is however necessary to define their precise role in the management of childhood CNS malignancies.

Teaching Lecture: Role and validation of deformable image registration in clinical practice

SP-0572

Role and validation of deformable image registration in clinical practice

M. van Herk^{1,2}¹University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom²The Christie NHS Foundation Trust, Medical Physics, Manchester, United Kingdom

Image registration is the process of finding the transformation between two image sets. It is used widely in

radiotherapy, e.g. for image guidance and target volume delineation. Compared to rigid registration, deformable image registration (DIR) is much more complex as the number of degrees of freedom in a typical DIR system exceeds the ten-thousands versus 6 for rigid registration. To make DIR tractable, registration systems therefore need to make a compromise between image similarity and smoothness of the deformation, attempting to find the ‘smallest’ deformation that still optimizes the image similarity. This compromise is achieved by tuning a large amount of parameters, which is the ‘trick of the trade’. DIR is currently considered the most essential and most complicated component of on- and off-line adaptive radiotherapy and its validation is therefore essential. Validation programmes should look at technical, general, and patient-specific performance. Technical and general QA methods include 4D and anatomically realistic phantoms, natural and implanted fiducials, and manually placed landmarks, potentially using mathematical methods to account for observer variation. Visual verification is an essential patient specific form of QA, but an important caveat of deformable image registration is the inadequacy of visual validation to provide a final verdict on the registration accuracy, as completely different deformable registrations can result in the identical images. This is not a problem for descriptive tasks such as Hounsfield unit correction and autocontouring, where organ boundaries are sought, but is highly detrimental for quantitative tasks such as dose accumulation and treatment adaptation around tumour boundaries where anatomical ‘cell to cell’ correspondence is required. Another unsolved issue is that registration performance is poor around sliding tissues and anatomical changes in the patient and specific care should be taken with clinical decisions that depend on dose summation around such regions. I conclude that QA of deformable registration is complex, and that current algorithms lack biological and biomechanical knowledge. I believe that today it is therefore not safe to use them for dose-accumulation and treatment adaptation around shrinking tumours.

Teaching Lecture: VMAT QA: To do and not to do, those are the questions

SP-0573

VMAT QA: To do and not to do, those are the questions

J.B. Van de Kamer¹, F.W. Wittkämper¹¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands**Introduction**

With the advent of Volumetric Modulated Arc Therapy (VMAT), Quality Assurance (QA) has evolved to a next step regarding complexity. Different parts of the linear accelerator (linac) move synchronously, resulting in a dose delivery that can be highly modulated in both space and time. In this lecture the practical aspects of QA are discussed, in particular focussed on VMAT.

Machine QA

Prior to implementing VMAT treatments in the clinic, the user should be familiar with the dynamic behaviour of the machine. In particular, features such as the lowest maximum leaf speed and the behaviour of the system under both dose rate changes and accelerations/decelerations of the gantry should be determined. Such machine characteristics need to be incorporated in the treatment planning system (TPS) to avoid devising undeliverable plans. To properly measure the dose delivered by the linac, the used measurement systems need to be dosimetrically accurate and have a high degree of spatial and temporal resolution. Usually different QA devices are needed to achieve this.

Patient-specific QA

Before a treatment plan can be delivered clinically, the medical physics expert (MPE) has to be convinced that the correspondence between calculated and measured dose

delivery is adequate. This can be achieved by performing patient-specific QA, comparing the measured, integral dose with the computed one in a phantom. For this purpose, a high dosimetric accuracy combined with a high spatial resolution is required. Again, different measurement devices are in general needed to meet these demands. The interpretation of the differences between intended and delivered dose distribution, in terms of a gamma analysis, will be discussed. After gaining experience and confidence with a certain class solution for treatment plans, most MPE resort to using only point dose measurements or computer programs for independent validation. When and how to introduce such alternatives will be discussed in the lecture. The value of continuous patient-specific QA will also be addressed.

Conclusion

After the lecture, the participant should have a clear idea what type of detectors should be used for what purpose and how to optimise patient-specific QA in a busy clinical environment.

Teaching Lecture: Optimising workflow in a radiotherapy department - an introduction to lean thinking

SP-0574

Optimising workflow in a radiotherapy department - an introduction to lean thinking

B. Naddy¹

¹Health Service Executive, Clinical Strategy and Programmes, Dublin 2, Ireland Republic of

Lean Thinking originated from the manufacturing industry in Japan as a method of highly-efficient production. However, Lean Thinking is not confined to manufacturing and as a management strategy focused on improving processes, is applicable to any organisation. It is now well-established in the complex area of healthcare delivery. Lean Thinking has been described as “the dynamic, knowledge driven and customer-focused process through which all people in a defined enterprise work continuously to eliminate waste and to create value” (Rebentisch et al, 2004). For a healthcare organisation, it provides a patient-focused, systematic approach to identifying and eliminating waste (i.e. non-value-added activities) through continuous improvement. The key principle of Lean is distinguishing value-added steps from non-value-added steps, and eliminating waste with the aim that eventually every step will add value to the overall process.

The lean philosophy is not intended to reduce the number of employees working in the hospital. It seeks only to eliminate waste in tasks and processes so that time, materials, resources and procedures can be utilised as efficiently as possible with the aim of dedicating more time and effort to patient care without extra cost to the patient or healthcare organisation.

Using case studies and real-life examples, this talk will introduce the lean concepts, principles and tools that contribute to improving efficiency, quality and patient safety in radiotherapy and healthcare.

Symposium: New concepts of tumour radioresistance

SP-0575

Radiotherapy combined with immunotherapy: present status and future perspectives

P. Lambin^{1,2}, N. Rekers^{1,2}, A. Yaromina^{1,2}, L. Dubois^{1,2}

¹MAASTRO clinic, Radiation Oncology, Maastricht, The Netherlands

²Maastricht University Medical Centre, GROW - School for Oncology, Maastricht, The Netherlands

Radiotherapy is along with surgery and chemotherapy one of the prime treatment modalities in cancer. It is applied in the primary, neoadjuvant as well as the adjuvant setting. Radiation techniques have rapidly evolved during the past

decade enabling the delivery of high radiation doses, reducing side-effects in tumour-adjacent normal tissues. While increasing local tumour control, current and future efforts ought to deal with microscopic disease at a distance of the primary tumour, ultimately responsible for disease-progression. This talk will explore the possibility of bimodal treatment combining radiotherapy with immunotherapy. L19 targets the extra domain B (ED-B) of fibronectin, a marker for tumor neoangiogenesis, and can be used as immunocytokine when coupled to IL2. We hypothesize that radiotherapy in combination with L19-IL2 provides an enhanced antitumor effect, which is dependent on ED-B expression.

EXPERIMENTAL DESIGN: Mice were injected with syngeneic C51 colon carcinoma, Lewis lung carcinoma (LLC), or 4T1 mammary carcinoma cells. Tumor growth delay, underlying immunologic parameters, and treatment toxicity were evaluated after single-dose local tumor irradiation and systemic administration of L19-IL2 or equimolar controls.

RESULTS: ED-B expression was high, intermediate, and low for C51, LLC, and 4T1, respectively. The combination therapy showed (i) a long-lasting synergistic effect for the C51 model with 75% of tumors being cured, (ii) an additive effect for the LLC model, and (iii) no effect for the 4T1 model. The combination treatment resulted in a significantly increased cytotoxic (CD8(+)) T-cell population for both C51 and LLC. Depletion of CD8(+) T cells abolished the benefit of the combination therapy.

CONCLUSIONS: These data provide the first evidence for an increased therapeutic potential by combining radiotherapy with L19-IL2 in ED-B-positive tumors. This new opportunity in cancer treatment will be investigated in a phase I clinical study for patients with an oligometastatic solid tumor (NCT02086721). An animation summarizing our results is available at

<https://www.youtube.com/watch?v=xHbwQuCTkRc>

Radiotherapy combined with the immunocytokine L19-IL2 provides long-lasting antitumor effects. Clin Cancer Res. 2015 Mar 1;21(5):1151-60.

SP-0576

The contribution of cancer stem cells to tumour radioresistance

A. Chalmers¹

¹Inst. of Cancer Sciences-Univ. Glasgow The Beatson West of Scotland Cancer Center, Department of Clinical Oncology, Glasgow, United Kingdom

For a number of tumour types there is increasing acceptance that cancer stem cells play an important role in tumour initiation and recurrence after treatment. In line with this model, increasing evidence indicates that cancer stem cells exhibit resistance to conventional cytotoxic agents. In the case of glioblastoma, an incurable primary brain tumour associated with dismal prognosis and devastating effects on quality of life, a series of influential publications have demonstrated that the radiation resistance of glioblastoma stem-like cells (GSC) is associated with constitutive upregulation of the DNA damage response (DDR).

In this presentation I will outline the evidence supporting this model, and present new data that elucidates the relative contributions of DNA repair and cell cycle checkpoints to this phenotype. Subsequently I will investigate the effects of inhibiting various components of the DDR, alone and in combination, and discuss the potential clinical application of a number of promising new small molecule inhibitors.

SP-0577

Novel insights in radioresistance of head and neck cancer

J. Tinhofer-Keilholz¹

¹Charité Campus Virchow Klinikum, Department of Radiooncology and Radiotherapy, Berlin, Germany

Recent technological advances in DNA sequencing with greater speed and resolution at lower costs has provided new

insights in cancer genetics. The next-generation sequencing (NGS) technology is tremendously facilitating the in-depth genome-wide search for genetic alterations which might significantly contribute to aggressive and/or treatment-resistant phenotypes of cancers, thereby establishing the basis for improvement of cancer treatment. We hypothesized that NGS should also be useful for dissecting the molecular mechanisms of radioresistance in squamous cell carcinoma of the head and neck (HNSCC).

We therefore applied the technology of targeted NGS to clinical samples from two multicenter studies of definitive and adjuvant cisplatin-based chemoradiation of locally advanced HNSCC. We evaluated whether by molecular profiling using targeted NGS it is possible to prospectively discriminate between patients who clearly benefit from chemoradiation and those with poor locoregional control and reduced overall survival after such treatment. Our studies could confirm previous reports of poor efficacy of radiotherapy in HNSCC tumors harboring *TP53* mutations. For the first time, we identified additional mutations in other genes as predictive biomarkers of outcome after chemoradiation.

The talk will summarize the results of NGS studies in HNSCC and other carcinoma models, thereby focusing on studies in which molecular mechanisms involved in radio-/chemoresistance have been addressed. It will present unpublished results from functional studies in preclinical models in which we are evaluating the mode of interaction of distinct genetic variants with radio-/chemoresistance. Concepts of how to integrate the results from NGS into novel personalized treatment strategies for HNSCC will be discussed.

Symposium with Proffered Papers: Towards Personalised Radiation Oncology (PRO)

SP-0578

New technologies for genomic tumour profiling

W. Weichert¹

¹Technical University Munich, Institute of Pathology, Munich, Germany

Massive parallel sequencing technologies (also: next generation sequencing) have revolutionized our understanding of the genomic and transcriptional makeup of malignomas. Aided by equally impressive developments in sequencing- and chip-based epigenetic tumor profiling and developments in mass spectrometry which allow for a comprehensive proteomic and metabolomic profiling we are now able to draw fairly comprehensive multi-omics landscapes of individual tumors both from tissue but increasingly also from blood or circulating tumor cells. However, many issues remain still challenging when it comes to a translation of these findings into a potential clinical outreach. This includes matters of tumor heterogeneity specifically with respect to tumor evolution in the metastatic setting as well as under therapeutic pressure. Other widely unresolved issues include the usefulness of identified drivers as novel targets for therapy or as predictive biomarkers and strategies to implement broad high throughput genomic testing into individualized patient care. Specifically the latter issue will decide which of these multi-omics technologies will take the step from tools merely for biological research profiling to advanced and modern routine clinical care.

SP-0579

Gene expression profiles in tumours for PRO

J. Alsner¹

¹Aarhus University Hospital, Department of Experimental Clinical Oncology, Aarhus C, Denmark

Gene expression profiles hold great promises for PRO (Personalized Radiation Oncology), yet very few - if any - are implemented in routine clinical practice and used as predictive biomarkers for treatment decisions in radiation oncology.

Several challenges need to be addressed before a gene expression profile can be approved as a predictive biomarker by regulatory bodies like the European Medicines Agency (EMA) and the US Food and Drug Administration (FDA). In an ongoing trial, EORTC-1219 (ClinicalTrials.gov ID: NCT01880359), a 15-gene hypoxia profile (1,2) is being tested prospectively. One of the primary aims of the study is to provide data for regulatory approval of the gene profile as an accompanying biomarker for the use of the hypoxia modifier Nimorazole.

The development and ongoing validation of this 15-gene profile will be used as a general example of the challenges for implementing gene expression profiles in PRO. Different strategies for identification of relevant gene expression profiles will be discussed together with the challenges of validating the predictive value of a gene expression profile. The requirements for a quick and robust test for the gene expression profile working on simple routine FFPE (formalin-fixed, paraffin-embedded) sections will also be discussed. Finally, some of the regulatory and patent issues related to gene expression profiles will be commented upon.

GWAS, SNPs and normal tissue toxicity for personalised radiation oncology

C. West¹

¹The University of Manchester, Christie Hospital, Manchester, United Kingdom

A key challenge in radiotherapy is to maximise radiation doses to cancer while minimising damage to surrounding healthy tissues. As toxicity in a minority of patients limits the doses that can be safely given to the majority, there is interest in developing a test to measure an individual's radiosensitivity before treatment and predict their likelihood of developing toxicity. A biomarker that predicts a cancer patient's risk of toxicity could be used to personalise dose prescriptions or to offer alternative treatments. Many approaches have been studied to measure radiosensitivity. The development of omics technologies underpinned genome wide association studies (GWAS) attempting to identify genetic variants reported as single nucleotide polymorphisms (SNPs). The advantages of the approach include: a genetic test will be easier to implement clinically than a functional assay; a genetic test will not suffer from the poor reproducibility associated with some radiosensitivity testing methods; and SNPs are the most common type of genetic variation and so easiest to identify. Omics technologies offer promise, but to have an impact on radiotherapy practice research must identify biomarkers that replicate across cohorts. Robust replication needs big data, which is only possible with large collaborative efforts. The need for big data was addressed by establishing an international Radiogenomics Consortium. Achievements of the consortium include: pooling cohorts to increase statistical power and identify definitively whether individual SNPs are associated with risk of toxicity; producing guidelines to improve the reporting of radiogenomics studies; identifying approaches for analysing data from heterogeneous cohorts involving different toxicity reporting scales and treatment regimens; and establishing studies collecting standardised data to improve our ability to detect more SNPs. Work over the past three years showed it is possible to pool heterogeneous cohorts and has identified several SNPs associated with risk of toxicity. Large collaborative projects in the cancer predisposition field involving analysis of ~100,000 participants shows that sufficient SNPs can be identified to generate a polygenic risk profile for clinical implementation. For example, men in the top 1% of the distribution of a 74-SNP polygenic risk score have a 4.7 fold increased risk of developing prostate cancer. Key challenges for the radiation oncology community are to collect the data in multiple cancers to identify enough SNPs to generate a polygenic risk profile and to increase understanding of the need for endpoint dependent versus independent profiles.

SP-0581

Integrative data analysis for PRO

M.A. Gambacorta¹¹Gambacorta Maria Antonietta, Roma, Italy

Personalized Radiation Oncology (PRO) integrating omics technology is a rapidly developing concept that will have an enormous impact on oncologic treatments and specifically radiation therapy in the near future. Tumor behaviour and outcomes related to oncologic treatments are related to several factors of which connections are nowadays poorly known. Different branches of medicine have developed their own lines of research which are sometimes difficult to be interpreted, difficult to be integrated with classical clinical factors and for these reasons, difficult to be applied in clinical practice. In clinical prediction and decision making process, results provided by omics are rarely used, whereas clinicians usually use clinical and imaging data for understanding tumor behaviour, predicting patients' outcomes and for choosing the most suitable treatment. The clinical decision is usually based on general guidelines which extrapolate information from randomized clinical trial. Moreover independent factors derived from several RCT are used by the Radiation Oncologist to make his prevision on tumor behaviour and consequently to choose the „right treatment“ for a specific patient. Randomized clinical trials enclose patients with characteristics chosen beforehand and usually omics informations are rarely or never included. This lead to a potential missing of several information that could refine prediction and thus promote personalized treatments and to an erroneous outcomes prediction that can lead to unappropriate treatment decision for a specific patient. Integrative data analysis has the potential to correlate data of different origins (genetic, radiology, clinic...) with patient's outcomes and to create a consistent dataset useful to obtain a trustful analysis for the Decision Support System. The DSS can easily be applied in clinical practice helping the Radiation Oncologist to utilize several information that otherwise would be excluded in the process of decision making. The possibility to predict the outcome for a certain patient in combination with a specific treatment with more accuracy, will lead to better identification of risk groups and thus better treatment decisions in individual patients, but it will also stimulate research focused on specific risk groups which try to find new treatment options or other combinations of treatment options for these subgroups. These treatments will be more personalized, which will not only save patients from unnecessary toxicity and inconvenience, but will also facilitate the choice of the most appropriate treatment. The resulting predictive models, based on patient features, enable a more patient specific selection from the treatment options menu and a possibility to share decisions with patients based on an objective evaluation of risks and benefits. Finally, considering the important role that predictive models could play in the clinical practice, clinicians must be aware of the limits of these prediction models. They need to be internally validated taking into account the quality of the collected data. An external validation of models is also essential to support general applicability of the prediction model. Therefore structural collaboration between different groups is crucial to generate enough anonymized large databases from patients included or not in clinical trials.

Purpose or Objective: To determine gene signatures which predict loco-regional control (LRC) and the secondary endpoints overall survival (OS) and freedom of distant metastases (FDM) of locally advanced head and neck squamous cell carcinoma (HNSCC) after postoperative radiochemotherapy.

Material and Methods: A gene expression panel of 216 genes was composed including genes which are involved in proliferation, invasion and metastasis as well as in radio(chemo)resistance associated with tumour hypoxia, cancer stem cell markers, cisplatin-resistance and DNA repair. Gene expression analysis was performed using NanoString technology on a multicentre retrospective patient cohort of 196 patients with HNSCC who received postoperative radiochemotherapy. Gene signatures with a minimal number of contributing genes were extracted, which optimally predict for LRC and the secondary endpoints OS and FDM. For the construction of these minimal signatures, different statistical methods were compared, including Cox regression with forward variable selection, boosting methods and random forests. To assess the performance of the different gene signatures and statistical methods the concordance index (CI) was evaluated using 3-fold internal cross validation.

Results: The resulting gene signatures mostly contained genes related to cellular proliferation, migration, invasion, and tumour hypoxia. For all endpoints and statistical methods a cross-validated CI>0.7 could be obtained, indicating a good performance of the models. Using the linear predictor

$$\sum_i \beta_i x_i$$

as a risk variable allowed for splitting the patient cohort into groups of good and bad prognosis. The figure exemplarily shows Kaplan-Meier curves of the total patient cohort split by the median risk variable of the gene signatures determined by Cox regression with forward variable selection for all endpoints. The difference between the survival curves is highly significant ($p < 0.001$).

Conclusion: We determined gene signatures for the prediction of LRC, OS and FDM in a cohort of 196 HNSCC patients after postoperative radiochemotherapy. The signatures showed a good prognostic value and were validated by internal cross validation. After validation with an external dataset and in a currently ongoing multicentre prospective trial within the study group, the gene signatures may help to further stratify patients for individualised treatment de-escalation or intensification strategies.

Symposium: The tumour in 3D: the role of tumour microenvironment

SP-0583

Relevance of 3D cultures to address radiation response and novel RT combination strategies

N. Cordes¹

¹OncoRay - Center for Radiation Research in Oncology, Dresden, Germany

Novel 3D cell culture models enable cell growth in a more physiological environment than conventional 2D cell cultures. Most importantly, cells need to be embedded in a composition of extracellular matrix proteins similarly present in situ to guarantee conservation of the phenotype. As shown by comparative analyses between 2D, 3D and tumor xenografts, various processes such as signal transduction and DNA repair share great similarity in 3D and in-vivo but not 2D.

Based on our long-standing experience, a large variety of endpoints can be determined and many methods can be conducted in 3D matrix-based cell cultures. While this is sometimes not as easy as in 2D and also requires a bit more financial invest, the generated data reflect cell behavior in vivo and thus have a higher clinically relevance. Further, we are able to address specific tumor features in detail. For example, malignant tumors show great genetic/epigenetic and morphological/cell biological heterogeneity. Here, a prime example is the stiffness of a tumor. Although we know that the stiffness greatly varies in different parts of the tumor, the underlying mechanisms and prosurvival consequences on the genetic/epigenetic and morphological/cell biological level are far from being understood. 3D matrix-based cell cultures models can elegantly support our efforts to gain more knowledge in this field. Another important point is the sparing of animal experiments based on our broad knowledge that human (patho)physiology is significantly different from mice (or other species). Many decades of in-vivo research have demonstrated that only a negligible proportion of therapeutic approaches could be translated from rodents to humans. In conclusion, 3D cell cultures are powerful tools to generate more clinically relevant information. A broader implementation of this methodology is likely to underscore our efforts to better understand tumor and normal cell radiation responses and foster identification of most critical cancer targets.

SP-0584

The potential of normal tissue organoid cultures

R.P. Coppes^{1,2}

¹University Medical Center Groningen, Department of Cell Biology, Groningen, The Netherlands

²University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

The response of normal tissues to irradiation is mainly determined by the survival and regenerative potential of the tissue stem cells, and modulated by inflammatory processes, vasculature damage and altered neuronal innervation and fibrosis. Interestingly, transplantation of tissue specific stem cells has been shown to restore tissue homeostasis and prevent late radiation effects. Moreover, the sparing of localized stem cells was predicted to preserve salivary gland function in patients treated for head and neck cancer. Interestingly, mounting evidence indicates that cancer stem cells might contribute to the poor prospects. Recently, we and others have developed methods to culture patient specific organ and tumour stem cell containing organoids (tissue resembling structures). These organoids contain all the tissue/tumour lineages and the tissue/tumour stem cells, as indicated by their secondary organoids self-renewal potential and regeneration/regrowth potential and offer the opportunity to investigate tissue and patient specific assessment of the response of stem cells to (chemo-) radiotherapy. Stem cell survival curves and DNA DSB repair kinetics indicate that the response of organoids to different radiation qualities may differ from tissue to tissue, especially in the low dose regions typically delivered to the normal tissue outside the planning target volume. Therefore, organoids cultures could be used to investigate the mechanism of differences in response of normal and tumour stem cells to irradiation and exploit these for personalized optimisation of (chemo-) radiation treatment and prediction of treatment response.

SP-0585

The impact of a novel 3D cell culture model of glioblastoma on radiation and drug-radiation responses

N. Gomez-Roman¹, A. Chalmers²

¹Inst. of Cancer Sciences-Univ. Glasgow The Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom

²Inst. of Cancer Sciences-Univ. Glasgow The Beatson West of Scotland Cancer Centre, Wolfson Wohl Translational Cancer Research Centre, Glasgow, United Kingdom

Glioblastoma (GBM) is the most common primary brain tumour with dismal prognosis. Tumours exhibit inherent resistance to radiation and chemotherapy which has been attributed to a subpopulation of cancer cells termed 'GBM stem-like cells' (GSC) characterised by multipotentiality and potent tumorigenic capacity. The use of established cancer cell lines in simplified two-dimensional (2D) *in vitro* cultures might explain the observed discrepancy between pre-clinical and clinical responses to cytotoxic treatments. We developed a customised, 3D GSC culture system using a polystyrene scaffold (Alvetex®) that recapitulates key histological features of GBM including high cellularity and sparse extracellular matrix (ECM) and compared it to conventional 2D GSC cultures. 2D and 3D cultures of three different primary GSC lines exhibited similar radiation sensitivities as measured by clonogenic survival. Previous studies have demonstrated radiopotentiating efficacy of the epidermal growth factor receptor (EGFR) inhibitor erlotinib against GBM cell lines in 2D cultures; however it failed in GBM clinical trials. Thus we evaluated the radiation modifying effects of erlotinib on 2D and 3D GSC cultures. Erlotinib enhanced radiosensitivity of 2D GSC cultures but had no effect on radiation responses of 3D GSC or in neurosphere formation assays, where cells grow in 3D conditions devoid of a scaffold or extrinsic ECM. We next examined VEGF inhibition, since anti-VEGF therapy in combination with standard radio-chemotherapy increases progression-free survival of GBM patients. VEGF deprivation was associated with significant radiosensitisation of 3D GSC cultures but had no effect on 2D GSC. Erlotinib treatment of VEGF-deprived 3D cultures increased radiation resistance of 3D cells to the same extent as VEGF addition, indicating epistasis. EGFR has been shown to regulate repair of radiation-induced double-strand breaks by activating the non-homologous end-joining (NHEJ) repair protein DNA-PKcs. A correlation between radiosensitivity, increased γH2AX foci and phospho-DNA-PK nuclear foci after radiation treatment was observed. In contrast, increased numbers of foci of the homologous recombination (HR) repair protein Rad51 were observed in radioresistant populations. Our results show that in the 3D model, VEGF signalling is required for optimal NHEJ activation with fast kinetics. This effect allows access to HR repair proteins at the remaining unrepaired DSBs at later time points, facilitating their repair and conferring radiation protection. Detailed analysis of the signalling pathways involved in the radiation resistance conferred by VEGF and EGFR signalling in the 3D and 2D models respectively demonstrated a radioprotective role of the downstream signaling molecule Akt. Specific inhibition of Akt using the small molecule inhibitor MK-2206 increased radiation sensitivity to the same extent as VEGF deprivation in 3D cells or erlotinib treatment in 2D cells, and no additivity was observed when these agents were combined. Our results for erlotinib treatment and VEGF deprivation in the 3D model recapitulate data from clinical trials, and suggest novel therapeutic targets for GBM. The 3D-specific effects of this panel of molecularly targeted agents strongly support the clinical relevance of this 3D model and its potential value in preclinical studies.

SP-0586

Radiotherapy supports tumour-specific immunity

M. Van den Broek¹

¹University of Zürich, Institute of Experimental Immunology, Zurich, Switzerland

Tumour-specific immunity occurs in cancer patients but has insufficient potential to control or eliminate the tumour. Strengthening this response through immunotherapy may lead to a durable, systemic response that may also control (development of) metastases.

Radiotherapy - a standard treatment for cancer - acts through induction of DNA damage in cancer cells. Although this treatment was thought to be immunosuppressive for a long time, recent data show that radiotherapy can support tumour-specific immunity. In fact, there is accumulating evidence that immune stimulation is an integral part of this therapy.

Using preclinical cancer models we showed that the efficacy of radiotherapy crucially depends on CD8⁺ T cells and dendritic cells. Radiotherapy induces activation of tumour-associated dendritic cells and accumulation of CD8⁺ T cells with protective effect or function within the tumour (1).

These results prompted us to investigate whether similar changes occur in cancer patients and we compared the immune signature in paired biopsies that were obtained from sarcoma patients before and after radiotherapy. Most patients showed a significant upregulation of molecules and cell types associated with protective immunity and a concomitant downregulation of such characteristic for immune regulation/suppression. Importantly, those patients with the strongest changes towards protective immunity survived longer after radiotherapy (2, 3).

Because it is largely unknown how radiotherapy supports tumour-specific immunity, we performed a semi-unbiased transcript analysis to identify pathways that change significantly upon radiotherapy. We found that radiotherapy induces transient and local activation of the classical and alternative pathway of complement in murine and human tumours, which results in local production of the anaphylatoxins C3a and C5a. Complement activation and subsequent production of anaphylatoxins happens downstream of radiotherapy-induced necrosis. The local production of C3a and C5a is crucial to clinical efficacy of radiotherapy and concomitant stimulation of tumour-specific immunity (4).

Radiotherapy influences a plethora of pathways, which we are currently identifying, because we think that selectively promoting or inhibiting particular pathways in the context of radiotherapy may further promote tumour-specific immunity and increase the therapeutic efficacy. Because chronic inflammation is immunosuppressive whereas acute inflammation supports immunity, we are comparing chronic radiotherapy (low-dose given in multiple fractions during weeks) with radiotherapy that includes radiation holidays (limited fractions of high-dose given with substantial breaks) with respect to efficacy and immune stimulation.

Symposium: WBRT for brain metastases- the end of an era?

SP-0587

Whole brain radiotherapy for brain metastases - the end of an era?

P. Mulvenna¹

¹Freeman Hospital, Northern Centre for Cancer Care, Newcastle-upon-Tyne, United Kingdom

Summary: Whole Brain Radiotherapy (WBRT) may be administered with either prophylactic or palliative intent. I will discuss both these approaches and how they fit into our management of metastatic brain disease in the 21st century.

Background: The use of Whole Brain Radiotherapy (WBRT) emerged as standard management for patients with brain metastases during the latter half of the 20th century (1,2,3).

This practice is based on reported experience from single institutions.

In the first decade of the 21st century, local control using stereotactic radiotherapy or surgical resection of individual brain metastases has emerged as a clinically beneficial modality for highly selected patients. Whole brain radiotherapy is increasingly seen as a treatment provided in addition to this local control, or is held in reserve for salvage management should new or recurrent brain metastases develop at a later date - without RCT evidence supporting this approach (4,5,6).

The majority of patients with brain metastases, however, are not suitable for stereotactic or surgical approaches and WBRT continues to be seen as the standard of care for this group, particularly if they are perceived to have a durable prognosis (5). Until the MRC QUARTZ trial was undertaken in non-small cell lung cancer (NSCLC) (Mulvenna et al 2016-in press), there were no sufficiently powered randomised controlled trials specifically addressing the utility of WBRT compared to supportive care (7).

Although prophylactic cranial irradiation has enhanced overall survival and reduced incidence of brain metastases for patients with the exquisitely radiosensitive small cell variant of lung cancer, trials addressing this issue in NSCLC and Breast cancer have failed to accrue. This lack of high quality evidence added to the fear of neurocognitive decline remains a potential barrier to applying this technique to other solid tumours with a propensity for metastasising to the brain.

Questions to address:

Can we apply prognostic indices reliably to all solid tumour types?

Do we really know which patients will benefit from WBRT, whether used as a sole palliative modality or as an adjunct to local (stereotactic or surgical) modalities?

If so, how can we best use Image Guided radiotherapy to minimise long term neurocognitive impact?

Focal radiotherapy for multiple brain metastases

L. Schiappacasse¹

¹Centre Hospitalier Universitaire Vaudois, Department of Radiation Oncology, Lausanne Vaud, Switzerland

Brain metastases (BM) develop in up to 30% of patients with cancer. There is marked heterogeneity in outcomes for patients with BM, and these outcomes vary not only by diagnosis, but also by diagnosis-specific prognostic factors; we should not treat all patients with brain metastases the same way, treatment should be individualized.

Phase III randomized trials have shown that upfront whole brain radiotherapy (WBRT) may decrease brain recurrence both in terms of better local and improved distant brain tumour control rate, and that neurological death rate may be reduced in patients treated with WBRT + stereotactic

radiosurgery (SRS), but no survival benefit is reached. The EORTC 22952-26001 study (Kocher M et al) shows that adjuvant WBRT fails to improve the duration of functional independence.

The use of SRS in the treatment of multiple BM has increased dramatically during the past decade to avoid the neurocognitive dysfunction induced by WBRT.

One of the biggest (1194 patients) multi-institutional prospective observational studies (JLGK0901, Yamamoto M et al and Watanabe S et al) including patients with multiple BM (even more than 10) have shown that SRS without WBRT in patients with five to ten BM is non-inferior to that in patients with two to four BM in terms of median OS (10,8 months for both groups), 1-year local recurrence (6,5% and 7%), with a very low incidence of side effects (less than 3%). They also concluded that carefully selected patients with 10 or more BM are not unfavourable candidates for SRS alone, having these patients a median survival time and neurological death-free survival times comparables to the group with 9-10 BM; their results suggest also that even among patients 80 years and older, those with modified-RPA Class I+IIa or IIb disease are considered to be favourable candidates for more aggressive treatment of BM.

SRS has been an option for limited (1-3) metastatic brain lesions, and nowadays the updated guidelines (for example, the NCCN panel) have recently added SRS as a primary treatment option for multiple (>3) metastatic lesions.

The exclusive SRS approach for patients with multiple BM is mostly curative for each treated lesion, it can be repeated several times (the limits in terms of median cumulative dose to the normal brain must be explored), and WBRT remains an option as salvage treatment.

Exclusive SRS with frequent magnetic resonance imaging-based follow-ups (every 2-3 months) in order to salvage recurrent BM before symptomatic manifestations, should be routinely offered to selected patients as a treatment option to consider (Lester SC et al). Initial treatment with a combination of SRS and close clinical monitoring should be recommended as the preferred treatment strategy to better preserve learning and memory in good prognosis patients with newly diagnosed BM (Chang EL et al).

The Lausanne University Hospital (CHUV) has created a brain metastases clinic to provide medical and radiation oncology, neurosurgical, and supportive services to this complex patient population. During the first 18 months, 250 cases were discussed, 55% of patients had more than one brain metastases, and focal treatments were proposed in 69% of treated cases (for 50% of them radiosurgery or fractionated stereotactic radiotherapy, FSRT). WBRT was proposed to only 16% of patients (some of them as salvage therapy after sequential treatments with SRS).

Higher BM burden (in terms of size and volume) and higher integral SRS dose to the brain are the main predictive factors for late toxicity after SRS. The cumulative neurocognitive effect of numerous SRS sessions remains unknown. In order to reduce the cumulative median dose to the brain, the SRS technique must be carefully chosen.

At CHUV, we have performed a dosimetric comparison study in cases with multiple brain metastases (up to 10), comparing a radiosurgical planning (same dose and isodose prescription) with Gamma Knife (GK), CyberKnife (CK), VMAT and Helical Tomotherapy (HT). Gradient index was better with GK and CK (3.4 and 4.1, compared to 17.8 and 19), as well as PTV coverage (100% with GK and CK, compared to 97% with VMAT and 90% with HT); brain Dmean was lower with GK (3 Gy) and CK (2.66 Gy), compared to VMAT (6.4 Gy) and HT (6.72 Gy).

SRS alone should be considered a routine treatment option in patients with multiple BM due to favourable neurocognitive outcomes, less risk of late side effects, without adversely affecting the patients performance status.

SP-0589

Role of systemic therapy in the treatment of brain metastases

R. Dziadziuszko¹

¹Medical University of Gdansk, Department of Oncology and Radiotherapy, Gdansk, Poland

Median survival of patients with brain dissemination in the course of solid tumors typically ranges between 3 and 6 months, depending on several prognostic factors. In order to select patients for most appropriate treatment or best supportive care, several prognostic indices were proposed, of which recursive partitioning analysis (RPA) score and graded prognostic assessment (GPA) are most widely used. In patients with good prognosis and limited number of metastatic lesions, aggressive local treatment, including surgery and radiosurgery is common, with median survival approaching 12 months. Patients in the intermediate group are typically managed with whole brain radiotherapy (WBRT), whereas patients with poor prognosis are typically offered best supportive care. Advances in the systemic therapy of several malignancies have changed this picture, particularly in subsets of patients with driving molecular aberrations, such as *ALK* rearranged non-small cell lung cancer or *BRAF* mutant melanoma. In these patients, long-term responses in the brain and other tumor locations are documented, with series of patients being alive and well for several years after treatment commencement. Penetration of novel targeted agents to CNS becomes its critical feature, as demonstrated by relatively poor intracranial control for ALK inhibitor crizotinib vs. new generation ALK inhibitors such as alectinib. The activity of immunotherapy (anti-CTLA4 and checkpoint inhibitors) in patients with brain metastases is less well documented, but also appears substantial in patients who do not require steroids. Paradoxically, at some point of time, aggressive local treatment strategies and WBRT remain important options in patients with prolonged intracranial control on systemic therapy to improve treatment results even further. The optimal management of these patients remains challenging due to limited evidence-based data and requires multidisciplinary approach.

Symposium: Radiotherapy "autovaccination" with systemic immune modulators for modern immunotherapy

SP-0590

Should the combined treatment be part of our field of knowledge? The "5th R," (immune-mediated) Rejection of Radiobiology

P.C. Lara Jimenez¹

¹Hospital Universitario de Gran Canaria Dr. Negrín, Academic Physics, Las Palmas de Gran Canaria- Ca, Spain

Radiation therapy is an important part of oncological treatment for advanced and metastatic patients and is widely employed, usually in combination with other treatment modalities. Several strategies have been developed to increase the therapeutic index of radiation therapy, in order to maximize its antitumor activity or radiosensitization and, at the same time, limiting its cytotoxic effects on normal tissues or radioprotection.

Radiation therapy includes new, high precision, low toxicity, treatments as SRS and SBRT. The paradigm of a systemic treatment alone for systemic disease, has been clearly changed over the last decade, as SRS/SBRT achieved unexpectedly (90%) high rates of local control for metastasis and different tumor primary locations. High doses of radiotherapy can now be delivered with high precision and very limited toxicity, therefore increasing the opportunities for treating patients in combination with systemic treatments without compromising tolerance. Such excellent responses do not completely fit the standard radiobiology models, based on well-known classical DNA damage and tumor cell kill, described by the "4 R's" of radiobiology (Reassortment, Reoxygenation, Repair, and Repopulation). Some non-targeted effects seem to be involved and preclinical radiobiological studies have suggested that they may be immune-mediated. Either local bystander or distant abscopal effects could explain part of the unexpected results of radiotherapy. In fact, local radiotherapy appears to be a powerful tool for autovaccinating the patient by modifying the highly immunosuppressive microenvironment of established cancers. These pro-immunogenic effects of ionizing radiation on the tumor microenvironment, include

potentiated innate and adaptive immune responses through release of pro-inflammatory molecules and modifications in MHC and adhesion molecules in cancer cells, stroma and endothelium. Therefore radiation therapy elicits immune responses as part of its role for killing cancer cells.

Unfortunately the abscopal effect is uncommonly observed in clinical practice with radiotherapy alone. Although there is a clear contribution of the immune system to eradication of tumours by novel systemic immunotherapy, only a subset of patients benefit from these therapeutic approaches. The preexisting immune microenvironment seems to be an important predictor of response to such treatments. The increase of productive immune synapses induced by radiation, could be required for the local therapeutic responses to immune agents. In that scenario, changes induced by radiotherapy could modify the immune microenvironment of the tumour, improving response to systemic immune treatments. On the other hand, novel systemic immune treatments could increase the rate of abscopal responses observed after radiotherapy.

Radioimmunotherapy seems to be an excellent approach for cancer. In fact, responses and improved outcomes are continuously reported in highly resistant tumours and could be hypothesized to provide a "broad spectrum" treatment for advanced cancer. In that case, modern systemic immunotherapy could represent the most recent form of radiosensitizing tumour cells and increase the radiation induced abscopal effect.

We could anticipate that in the next few years radiation-driven immunotherapy will be systematically used in combinations with new agents. But, to be responsible of a treatment, we must be aware of the potential acute and late toxicity issues. As for other radiosensitizing treatments, we should also know the best supportive treatment to manage such adverse events. At present anti-CTLA-4 and anti-PD-1/PD-L1 antibodies are becoming increasingly used in clinical practice and clinical trials.

Although several reports showed no increase expected toxicity in combination with radiotherapy, these drugs are associated with immune-related adverse events (irAEs). irAEs are believed to arise from general immunologic enhancement and affect the dermatologic, gastrointestinal, hepatic, endocrine, and other organ systems. Temporary immunosuppression with corticosteroids, tumor necrosis factor-alpha antagonists or other agents can be effective treatment.

As oncologists, radioimmunotherapy should be part of our field of knowledge and must be rapidly incorporated to our clinical practice.

SP-0591

Radiotherapy for immunotherapy: optimizing the doses and fractionation

S. Demaria¹

¹Weill Cornell Medicine Medical College, Radiation Oncology and Pathology, New York, USA

Elimination of virally-infected epithelial cells is mediated by CD8+ T cells and results in life-long protective immunity against reinfection. Similarly, clinical data have shown that CD8+ T cells mediate the rejection of solid tumors and can confer long-term protection from disease recurrence when their activity is unleashed by immune checkpoint inhibitors. Like viral proteins, mutated proteins expressed by an individual tumor are a source of powerful tumor-specific T cell epitopes. However, most of the cancer patients do not develop a sufficient number and repertoire of tumor-reactive T cells and are unresponsive to currently available immunotherapies.

We have pioneered studies to explore the use of local tumor radiotherapy (RT) as a means to release tumor antigens in an immunogenic context. We demonstrated that RT converted an insensitive mouse carcinoma into one responsive to CTLA-4 blockade (Demaria et al., Clin Cancer Res 2005), and have recently shown that this combination is effective in lung cancer patients (NCT02221739), a carcinoma unresponsive to anti-CTLA-4 monotherapy. Unique changes in T cell receptor (TCR) repertoire of intra-tumoral CD8 T cells were observed

in the mouse carcinoma after treatment with RT + CTLA-4 blockade. Significant changes in TCR repertoire were also seen in peripheral blood of responding patients, supporting the hypothesis that RT can convert the irradiated tumor into an in situ vaccine.

Immunogenic cell death is induced by radiation in a dose-dependent way, with higher ablative single doses being more effective in vitro (Golden et al., Oncoimmunology 2014). However, in vivo the interaction between the dying cancer cells and the pre-existing immune microenvironment determines the ability of RT to prime effective anti-tumor T cell responses. For instance, we have shown that the number of DCs available in the tumor and draining lymph nodes to uptake and present the antigens released by RT is a critical determinant of the magnitude of the immune response elicited (Pilonis et al., J Immunother Cancer 2014). We have recently found that canonical pathways mediating the induction of type I interferon responses in epithelial cells during viral infection are induced by fractionated but not single dose RT. RT-induced cancer cell intrinsic interferon-I production enhanced DCs infiltration and was required for development of tumor-specific T cells capable of rejecting not only the irradiated tumor but also non-irradiated metastases (abscopal effect). This explains, at least in part, the synergy of fractionated RT regimens (8GyX3 or 6GyX5), but not a single ablative RT dose of 20 Gy, with anti-CTLA-4 in achieving abscopal responses against poorly immunogenic carcinomas (Dewan et al., Clin Cancer Res 2009). In addition, we have shown that immunosuppressive mediators such as TGF-beta, which is released in its active form by RT-generated ROS, need to be neutralized to improve DC maturation and activation of T cells capable of rejecting the tumor (Vanpouille-Box et al., Cancer Res 2015). Overall, optimal RT regimens combined with targeting of dominant immune suppressive pathways enable RT use as a simple, widely available tool for patient and tumor-specific in situ vaccination.

SP-0592

Combining immunotherapy and anticancer agents: the right path to achieve cancer cure?

L. Apetoh¹

¹INSERM UMR866, Department of Immunology, Dijon, France

Recent clinical trials revealed the impressive efficacy of immunological checkpoint blockade in different types of metastatic cancers. Such data underscore that immunotherapy is one of the most promising strategies for cancer treatment. In addition, preclinical studies provide evidence that chemotherapy and radiotherapy have the ability to stimulate the immune system, resulting in anti-tumor immune responses that contribute to clinical efficacy of these agents. These observations raise the hypothesis that the next step for cancer treatment is the combination of cytotoxic agents and immunotherapies. This presentation will discuss the immune-mediated effects of anticancer agents and their clinical relevance, the biological features of immune checkpoint blockers and finally, the rationale for novel therapeutic strategies combining anticancer agents and immune checkpoint blockers.

Joint Symposium: ESTRO-AAPM-EFOMP: Functional / biological imaging and radiotherapy physicists: new requests/challenges and the need for better and more specific training

SP-0593

The role of the medical physicist in integrating quantitative imaging in RT: practical and organisational issues

G.M. Cattaneo¹, V. Bettinardi²

¹Ospedale San Raffaele IRCCS, Department of Medical Physics, Milan, Italy

²Ospedale San Raffaele, Nuclear Medicine, Milan, Italy

The evolution of radiation oncology is based on the increasing integration of imaging data into the design of highly personalized cancer treatments.

Technologically advanced image-guided delivery techniques have made modern radiotherapy treatment extremely flexible in term of optimal sparing of the organs at risk and shaping different prescribed target doses to tumor volumes delineated on the basis of functional imaging information.

In the last 10 years a remarkable development of more sensitive and specific signals (quantitative dynamic contrast-enhanced CT and MRI; diffusion MRI, specific PET tracers, multi-parametric MRI/PET, etc) have contributed to the prescription and design of radiation treatment plan.

The main contribution of new imaging modalities can be summarized:

- Improved delineation of target and normal structures (new hybrid imaging devices offer co-registration of anatomical, functional and molecular information); a further refinement of this approach is the possibility to shape the dose gradually according to the functional parameters (dose painting);
- Adaptation, the radiation technique defined at planning simulation can often require modification not only due to the changes in patient anatomy but because of early variations of certain imaging related parameters surrogates of treatment outcome.
- Predictive biomarkers, the use of more advanced image analysis methods (texture feature parameters) could be a surrogate of important tumor characteristics and have a higher predictive and prognostic power than simpler numeric approaches;

- Radiomics, the extraction of large amount from diagnostic medical images may be used to underlying molecular and genetic characteristics and this genetic profile may change over time because of therapy.

Despite the multiple benefits that the quantitative imaging can offer for radiation therapy improvement, there are a number of technical challenges and organisational issues that need to be solved before its fruitful integration into RT treatment planning process.

The main aspects covered by this lecture will be:

- Standardized procedures for acquisition, reconstruction and elaboration of PET data set;
- Methods for delineation of the PET-related biological target volume (BTV).
- Data acquisition and processing techniques used to manage respiratory motion in PET/CT studies; the use of personalized motion information for target volume definition.
- A procedure to improve target volume definition when using contrast enhanced 4D-CT imaging in pancreatic carcinoma.

Training in biological/functional imaging: lacks and opportunities

A. Torresin¹, M. Buchgeister²

¹Azienda Ospedaliera Ospedale Niguarda Ca'Granda, Department of Medical Physics, Milan, Italy

²Institution: Beuth University of Applied Sciences Berlin, Department of Mathematics- Physics & Chemistry, Berlin, Germany

Pubmed references, presentations and posters during a lot of Conferences (ESTRO, EFOMP, ESMRMB, EANM,...) are introducing a lot of biological and functional imaging for radiotherapy applications: MRI, PET, SPECT, functional CT are able to support radiation therapy for target and Organ at Risk definition. Looking at the EUROPEAN GUIDELINES ON MEDICAL PHYSICS EXPERT (RP 174) the competence on biological and functional imaging is not specific item into RT skill and competences. We can find the key activities of MPEs inside the following: Diag.& Therap. NM Internal Dosimetry

Measurements(K23: Explain methods for determining patient-specific organ masses including the respective errors and explain the difference between morphological and functional volume of organs), Scientific Problem Solving Service (K36: Explain the physics principles underpinning MR angiography (MRA) and flow, perfusion and diffusion imaging, functional MR imaging (fMRI) and BOLD contrast, MR spectroscopy (MRS), parallel imaging, DCE-MRI) and Clinical Involvement in D&IR (K88: Explain the use of the various modalities for anatomical and functional imaging and K90: Interpret anatomical and functional 2D/3D images from the various modalities and recognize specific anatomical, functional and pathological features). The curricula defines the SKC not specifying how MPE is involved in RT because the functional imaging (in general) and in radiotherapy (in particular), needs a strong interdisciplinary team: MPE expert in radiation oncology and MPE expert in functional imaging should approach the problem together with clinical support. The University and Accreditation training in Europe is not the same and each country differs: in many of them, MPE accreditation in Radiotherapy does not require the accreditation in Diagnostic Imaging. In the next future, requirements of physics application in radiotherapy will need to include the expertise in diagnostic imaging with particular attention to functional imaging, but the interdisciplinary approach is more effective in the clinical practice. EFOMP and ESTRO working Group is working to define the potential topics for MPE education and training e-learning platform; the knowledge and the expertise in this field will be more and more important.

Symposium: The future of QA lies in automation

SP-0596

The need of automation in QA, state of art and future perspectives

N. Jornet¹

¹Hospital de la Santa Creu i Sant Pau, Medical Physics, Barcelona, Spain

From the earliest times mankind has struggled to improve his productive means; skills, tools and machines. Aristotle dreamed of the day when "every tool, when summoned, or even of its own accord, could do the work that befits it". However, we have to wait till 1956 to see the name "automation" appearing in dictionaries. Automation was defined as: "the use of various control systems for operating equipment such as machinery, processes in factories, aircraft and other applications with minimal or reduced human intervention". In the fifties it was heralded as the threshold to a new utopia, in with robots and "giant brains" would do all work while human drones reclined in a pneumatic bliss. The pessimists pictured automation as an agent of doom leaving mass unemployment and degradation of the human spirit in its wake. Sixty years from those first papers and books in automation we can see that neither the optimistic perspectives nor the most catastrophic views have come true; we still have to wake up to go to work each morning and job have changed but not disappeared. The use of automation in different fields is not homogeneous. For instance, planes, trains and ships are already heavily automated while in our field, radiation oncology and medicine in general, automation has not been fully exploited. Repetitive tasks can be easily automated and this will on one side avoid tedious thinking that must be done without error and on the other side will free time to more creative thinking which will satisfy and give us more joy. Treatment planning, evaluation of treatment planning and QA at treatment unit are areas that are being explored by different research groups. We can automate tasks but automations means much more than this. Automation is a means of analysing, organising and controlling our processes. But how far can we go? Can we design a system able to take complex decisions and not only binary ones such as pass/fail for a quality control test? Yes we can, if we exploit machine learning algorithms. Machine learning will be able to predict the best possible solution for a particular problem and will

form the core of both quality control methods (comparing the predictions with the actual results). One of the side products of automation is standardisation of practice. Let's take treatment planning as an example. Treatment planning is a time consuming task and the resulting plans depend largely on the ability of the planner. Automation in treatment planning has shown to reduce the time needed to achieve plans with less variability and quality. The fact that most vendors offer the possibility of writing scripts to automate checks and to query treatment machine log-files and treatment planning systems data is welcomed and will facilitate the clinical implementation of automation. For management, automation poses the problem of adapting to new concepts and new methods of working and the processes have to be adjusted. Risk analysis has to be re-evaluated and probably different risk mitigation strategies will have to be implemented. For the worker, automation involves changes in the way of working. In particular, clinical medical physicists will have to design performance tests to evaluate these automated systems. To face the challenges that automation brings to our field, medical physics curricula should include IT and also programming. With automation comes a choice between additional leisure and additional products. I would strongly advocate for more time for scientific creative thinking which is needed to contribute to significant advances in medicine and in particular the cure of cancer.

SP-0597

Automated QA for radiotherapy treatment planning

S. Petit^{1,2}, Y. Wang¹, B. Heijmen¹

¹Erasmus MC Cancer Institute, Department of Radiation Oncology, Rotterdam, The Netherlands

²Massachusetts General Hospital - Harvard Medical School, Department of Radiation Oncology, Boston MA, USA

The need of QA for individual treatment plans

The achievable degree of organ sparing with radiation treatment planning is highly dependent on the patient anatomy. Radiation treatment planning with a commercial TPS is an iterative trial and error process. Even for experienced dosimetrists or physicians it is very difficult to judge whether the dose to OARs cannot be lowered further. As a result, the quality of a treatment plan is highly dependent on the available planning time, the experience and talent of the treatment planner and how critically the treatment plan is being reviewed. In a recent study by our group it was shown that after trying to further improve already approved IMRT treatment plans for prostate cancer patients, the rectum dose could be further reduced by on average 6 Gy (range 1-13 Gy), without negative consequences for PTV or other OARs [1]. In conclusion, there is a clear need for treatment planning quality assurance (QA) protocols to guarantee that for each patient the generated plan is indeed optimal for the patient-specific anatomy.

Different strategies for treatment planning QA

In recent years different groups have proposed different strategies for treatment planning QA. The general idea is to predict the lowest achievable dose for OARs and compare the achieved dose of the treatment plan with the predictions. As long as differences between the predictions and the achieved doses to the OARs exceed some predefined action levels, treatment planning should continue, to try to further lower the doses. Most methods rely on a database with plans of prior patients treated for the same tumor site. Because the achievable degree of OAR sparing is highly dependent on patient anatomy only treatment plans of prior patients with anatomies similar as the new patient are selected. Next these prior plans are used to predict achievable DVH metrics for the new patient. The main distinctions between the different methods are (i) the manner in which similarity in anatomy is assessed and (ii) how the dose distributions of the similar prior patients are used to predict DVH parameters for new patients.

Similarity in anatomy can be assessed using distinctive anatomical features. These can vary from very simple such as the percentage overlap of the PTV with an OAR[2]; to an

intermediate level of complexity such as the Overlap Volume Histogram that quantifies in 1D the orientation and position of an OAR to the PTV[3]; to more complex such a non-rigid registration based [4]. Also the strategies to predict the dose based on the selected patients vary in complexity: from the lowest achievable dose among all more "difficult" patients [5], to principal component analyses that combine achieved doses of multiple patients and organs to make the predictions [6]. Different models have been successfully applied for prostate, head-and-neck, pancreatic and lung cancer patients [2, 4, 7, 8].

Evaluation of the performance of different treatment planning QA models

An important challenge for the development of treatment planning QA models is that the plans to train and validate the models are often generated with the same trial and error treatment planning process, as where the treatment planning QA models are intended for in the first place. Suboptimal plans used for training and validation could lead to suboptimal models, a bias in the evaluation of the prediction accuracy, suboptimal action levels and difficulties to compare different models that were trained on different patients cohorts. Therefore, recently our group has generated a dataset of 115 Pareto optimal IMRT treatment plans for prostate cancer patients that were planned fully automatically with consistent prioritization between PTV coverage, sparing of organs at risk, and conformality (see abstract Wang, Breedveld, Heijmen, Petit). This dataset has been made publicly available and can be used for objective validation of existing and development of new treatment planning QA models.

Conclusion

There is a need for treatment planning QA models to assess whether a generated treatment plan is indeed optimal for the patient specific anatomy. Different models have been proposed for this purpose that vary in complexity. There are currently some challenges for clinical implementation, but these are likely to be solved in the near future.

SP-0598

Automated QA using log files

V. Hernandez¹, R. Abella¹

¹Hospital Universitari Sant Joan de Reus, Medical Physics, Reus, Spain

Purpose

The purpose of this presentation is to show the capabilities of treatment unit log files for QA, as well as their limitations. To this aim, the implementation of a QA Program based on Varian dynalogs is presented together with the results obtained. The possibility of replacing phantom-based pretreatment QA by log file analysis will also be discussed during the presentation.

QA Program

The QA Program was developed with in-house software, in particular with Java (dynalog analysis), MATLAB® (fluence calculation and comparisons) and MySQL (data storage and reports). Three Varian linacs were evaluated and >60,000 dynalogs were analyzed, corresponding to both sliding window and VMAT techniques.

As part of this QA Program, all IMRT beam deliveries were verified by the following tests:

- Analysis of the RMS (Root Mean Square) values of leaf positional errors. RMS values from different deliveries of the same beams were very stable, with differences between different fractions <0.05mm in over 99.9% of the cases. This shows that the MLC positioning is extremely reproducible.
- Analysis of the maximum leaf positioning deviations. Maximum deviations were typically within 1-1.5mm and depended mainly on the maximum leaf speed.
- Incidence of beam hold-offs and beam interruptions. The mean incidence was 1 hold-off for every 3 dynamic beams deliveries and <1% beams with interruptions (related to any kind of interlock).
- Comparison of the planned fluence and the actual fluence computed from dynalogs. Excellent agreement was obtained, with passing rate >98% for gamma 1%/1mm in practically all cases (>99.9% of the beams).

Limitations and validation of dynalogs

In general, the accuracy of log files is unclear, especially if they come from non-independent systems. Information in Varian dynalogs comes from the MLC controller, that is, from the same motor encoders that drive the MLC. For this reason, dynalog files will NOT detect errors due to MLC calibration parameters (dosimetric leaf gap, offset, skew), motor count losses or backlash. Indeed, Varian dynalogs must be carefully validated by experimentally checking the accuracy of MLC positioning, preferably at different gantry angles and at the end of the treatment day (due to the cumulative effect of motor count losses since MLC initialization).

Another limitation of dynalogs is that several aspects of treatment delivery are not recorded in logfiles (beam symmetry, homogeneity, energy...). However, these other aspects are not specific to IMRT treatments and should be verified as part of the routine standard QA Program.

Conclusions

Logfile analysis allows exhaustive monitoring of MLC performance and other machine parameters.

Implementing a QA Program based on dynalogs makes it possible to control data transfer integrity and ALL treatment deliveries (the entire course of treatment).

The efficiency of QA can be increased with a fully automated and integrated QA program based on log file analysis. Commercial software is available which also incorporates independent dose calculations.

Log file analysis provides a useful complement to a general 'conventional' QA program. However, validation of log files against measurements is needed. In Varian environments, daily experimental verification of the MLC positioning, preferably at different gantry angles and at the end of the treatment day, is strongly recommended.

SP-0599

Automation in patient specific QA using in vivo portal dosimetry

P. Francois¹

¹Institut Curie, Paris cedex 05, France

Over the last years, the efficacy of radiation oncology treatments improved dramatically. However, due to the increase in technical complexity and dose escalation, the risk of secondary effects also rises. In vivo dosimetry (IVD) is now widely recommended to avoid major treatment errors and is even mandatory in several countries.

In this perspective, transit dosimetry using amorphous silicon Electronic Portal Imaging Devices (EPID) appears to be an interesting solution for several practical reasons (easy to use, no additional time, no perturbation in the beam, 2D detectors, complex techniques possible, numerical data, etc...). For all these reasons, daily controls for every patient becomes realistic. However, with constrained resources (staffing, time, etc...), this will become feasible in the clinic by means of automated systems. Medical physics teams will then be able to set and manage a permanent survey system:

- To verify the actual radiation dose delivered to the patient during the procedure
- Detect errors before it is too late

• Anticipate the drifts and be able to assess when deviations are large enough to require adjustments

Such a process will combine "on line" and "off line" procedures (figure 1) giving opportunities to detect and alert for isolated gross errors, systematic deviations and/or small variations with time. Beyond individual patients follow up, such databases will bring new perspectives if properly designed for automated analysis. Statistical analysis of data per energy, machine, technique, before and after a change in the delivery process (upgrade, new device, etc...) will become possible and help in decision making. Moreover, the frequency and variability in the controlled configurations will go far beyond any well designed quality control program which could lead to reconsider our strategies in that domain.

Symposium: Management and optimisation of the daily workflow

SP-0600

Optimising workflow using a workflow management system

A. Vaandering¹, M. Coevoet¹

¹UCL Cliniques Univ. St. Luc, Academic Department of Radiation Oncology, Brussels, Belgium

It is well known that a concerted effort from an entire radiotherapy (RT) team is needed in order to provide accurate, precise, and effective radiotherapy treatments to patients. And in this process, each member of the RT must perform specific tasks in order to achieve the best possible care for the patient. Throughout the pre-treatment and treatment process, communication and knowledge sharing between the different team members is of paramount importance. Any disruption in the workflow can result in treatment delays and errors and costly repetition of work. In an era where organisations and departments are aiming for continuous quality improvement and increased efficiency, optimal workflow management is of uttermost importance.

With the advent of lean management and quality improvement approaches, various types of workflow management softwares are currently being offered or developed in house to improve the radiotherapy departments' workflow. Their overall aim is to facilitate intra and interdisciplinary communication between the RT team members in order to optimise the department's patient flow and safety (1). Nevertheless, to successfully implement these systems, it is important to properly define the department's workflow and processes. These systems also need to be flexible enough to integrate workflow modifications and evolutions resulting from improvement actions or process changes (ie: new treatment modality/new technique/...). Interconnectivity, compatibility with other systems in RT department, user friendliness and ease of access are also features that should characterize these systems.

In the past few years, numerous departments have thus equipped their departments with these workflow management systems. These have proven to be a real asset in the RT departments and their arrival have already ameliorated numerous aspects of patient workflow through standardization of workflow, integration of checklists and forcing functions and task attribution tools. Their use have also allowed for departments to quantitatively monitor their workflow and put into place procedures/modalities that increase the efficiency and safety of their workflow. However, many of the company-based systems are costly and do not allow for the overall visualisation of the status of different patients within the RT workflow at a given time. As a result, certain departments have developed their own workflow management system. One such system is "iTherapy Process" (iTP) which is an internally developed open source software (2). This system provides the user with the quick visualisation of all patients in the pre-treatment and treatment sub processes (Fig. 1).

Fig 1. iTP Process

And in a user friendly environment, allows for the user - RO, MP and/or RTT to quickly visualize the tasks that need to be completed. Through the completion of dedicated and integrated checklists per subprocess, safe and efficient patient workflow is ensured.

Furthermore, ease of access to procedures, staff availabilities and breakdown statistics and information are also valuable tools that can be integrated within workflow management systems.

In conclusion, workflow management systems are fundamental tools for the improvement of quality and safety of patient workflow. These need to be personalized to the department's workflow and user centered. As such, in addition to company developed systems, in house or open source software can provide an ideal solution for radiotherapy department desiring to improve patient workflow in a safe environment.

SP-0601

Does lean management improve patient safety culture?

P. Simons¹, R. Houben², H. Backes¹, P. Reijnders¹, M. Jacobs¹

¹MAASTRO clinic, Department of Radiotherapy and Radiobiology, Maastricht, The Netherlands

²MAASTRO clinic, Data Centre MAASTRO clinic, Maastricht, The Netherlands

Introduction: In the field of radiotherapy the importance of a safety culture to maximize safety is no longer questioned. However, how to achieve sustainable culture improvements is less evident. A multifaceted approach is preferred to improve the safety culture, where multiple safety interventions are combined. Lean management is such an integral approach which aims to improve safety, quality and efficiency. Therefore, lean is expected to improve the safety culture. MAASTRO clinic combined lean initiatives with structural and cultural elements to promote continuous improvement. They reorganized from managing the different professions to managing multidisciplinary care pathways in January 2011. Executive management discussed the organizations' strategy with all employees to create a shared vision. In 2013, many professionals were engaged in multiple lean projects to improve the entire (flow of the) patient process. The treatment planning system and the accelerators were replaced by new technology from 2011 to 2012. The patient safety culture was measured to evaluate the effects of this multifaceted approach.

Methods: The patient safety culture was evaluated over a three year period using a triangulation of methodologies. The Manchester Patient Safety Framework, implemented as a workshop, was combined with two surveys to evaluate the safety culture /behavior. Incident reports from an incident reporting system (IRS) and interviews with professionals were used to increase understanding of results. The workshops were performed twice. We used the internationally validated Hospital Survey on Patient Safety Culture (HSOPSC), which

measures four overall safety outcomes and ten dimensions of safety climate on a five-point scale, and a new developed factorial survey which measured the intentions for safety behaviour. Surveys were distributed three times in a three year period. In addition, the HSOPSC and the data from the IRS were used to evaluate the sustainability of results in 2015. Averages, chi-square, logistical and multi-level regression were used for analysis.

Results: Although the workshops detected no changes in safety culture between 2011 and 2013, the HSOPSC showed improvements on six out of twelve safety culture dimensions. In 2012, staffing, teamwork across units and handoffs & transitions presented more positive scores than in 2010 (Table 1). Improvements sustained and in 2013 the dimensions feedback & communication about error, experienced management support for safety and the overall perception of patient safety improved. All improvements had sustained until 2015 and teamwork across units improved further. Based on the results from the factorial survey on intentions for safety behavior, the intention to report incidents not reaching patient-level (near misses) decreased from 2010 to 2013 in accordance with the decreasing number of reports in the IRS. However, the intention towards taking action to prevent future incidents (structural improvement), strongly improved in 2013 (B: 1.19 with p: 0.01), especially for the near misses. From 2004 to 2009, the number of reported incidents increased from 510 to 1835 reports on yearly basis (Figure 1). However, the number of reported incidents that reached patient-level (misses) decreased with 27% from 2004 (N=122) to 2009 (N=89). From 2009 the number of reported near misses decreased with 50% from 1746 to 870 in 2013. However, the number of reported misses decreased with about 40% (89 in 2009 to 48 in 2013/ 55 in 2014). The interviewed employees experienced a sustained safety awareness, improved quality of reports and a strong increase in creating structural improvements. Due to improvements in equipment and increased problem solving, the actual number of incidents could have decreased.

Figure 1. Results from the Incident Reporting System for 2004 until 2014.

Conclusion: Due to increased problem solving and improvements in equipment, the number of incidents decreased until 2013. Although the intention to report incidents not reaching patient-level decreased, employees experienced sustained safety awareness and an increased intention to structurally improve. The patient safety culture improved in 2013 due to the lean activities combined with an organizational restructure, and actual patient safety outcomes might have improved as well. Results from 2015 proved the sustainability of the realized improvements. We conclude that lean management can help to improve the patient safety culture, but its success depends greatly on how lean is implemented. In addition to the cultural aspects, structural elements and clinical process improvements should be addressed to create sustainable quality/safety improvements. Measurement of effect is an important foundation for continuous improvement. As patient safety culture is a complex phenomena, quantitative and qualitative measures should be combined to increase understanding in the actual effects. A sufficient level of detail in measures should be reported to not lose the opportunities for improvement.

SP-0602

The impact of demographics trend, cancer incidence and cancer prevalence for planning numbers of treatment units in Austria

A. Osztavics¹, R. Pötter¹

¹Medizinische Universität Wien Medical University of Vienna, Radiotherapy, Vienna, Austria

Purpose: There are around 38.000 new cancer cases in Austria per year. To generate an optimal patient-centered cancer care are clear formal structures in Austria how to plan the resources in health care. Based on a constitutional law exist a regulation between the national government, the district governments and the social insurances as third party based on which also the resources for radiotherapy are planned. The major method to calculate resources for radiotherapy is to refer treatment units to the population number, which has been formulated according to national guidelines for Austria. This method can also take into account demographics trends. This investigation addresses the additional impact of cancer incidence and prevalence estimates on such calculation models for population based number of treatment units (LIN).

Methods and materials: According to laws and national / regional guidelines (aim: 1 LIN for 100.000-140.000 inhabitants (Austrian Structure plan for Healthcare (ÖSG)) the recommended number of treatments units in radiotherapy were calculated for Austria and the city of Vienna for 2015 (population of 8.6 mill/1.8 mill) and for 2020 and 2030 taking into account expected demographic

development. Around 60% of the 38.000 new cancer patient will have a treatment in a radiotherapy department. Based on the figures of the Austrian Cancer registrations the cancer prevalence will increase dramatically in the near future based on the demographic trend, general increased expectation of life in combination with the expectations of higher survival rate of cancer patients. In addition, prognosis for cancer prevalence and cancer incidence were used to calculate the needed number of LIN for the year 2015, 2020 and 2030 for Austria and Vienna.

Results: There is a need for minimum 61 LIN and maximum 86 LIN and present which implies a discrepancy of 18 LIN for the whole country (actual 43 LIN) for 2015. Based on the prognosis for cancer incidence a discrepancy of 14 LIN for Austria (aim 57 LIN) exists for 2015. The cancer prevalence prognosis shows a need for 68 LIN, which is a discrepancy of 25 LIN for the year 2015. For the city of Vienna, the actual situation (12 LIN) seems appropriate, as the discrepancy for 2015 is only 1 LIN. There is one important extra factor for Vienna: about 20% of all treated cancer patient come from Austrian neighbour districts, therefore there is a growing waiting list in Vienna. The entire prognosis until 2030 are general worse, because the results shows 2.01 mill inhabitants and around 8900 new cancer cases gives a need of 16 LIN for Vienna.

Conclusion: There is a minimum discrepancy of 18 LIN for the whole country for 2015. One important factor for precise planning the resources in radiotherapy is the cancer prevalence. Based on the prognosis model with the cancer prevalence is an actual need of 25 LIN for whole Austria and one more in Vienna. To fulfil the constitutional law obligations, the government should immediately start to close the gap of minimum 18 LIN for the whole country. Austria will have in 15 years a shortage of 40 LIN (aim 73 LIN) and this will have a negative impact on waiting time and outcomes of the treatments. Never less in these calculations is not the included the different complexity of treatments in radiotherapy which need different recourses of time, staffing and equipment. A further project should implement these factors to get a much more tailored planning for the formal recommended radiotherapy resources in Austria. .

Symposium: Combining radiotherapy with molecular targeted agents: learning from successes and failures

SP-0603

Interaction of radiotherapy with molecular targeting agents

P. Harari¹

¹University of Wisconsin School of Medicine and Public Health, Madison, USA

Despite the well established role of radiation in the treatment of solid tumor malignancies, and the rapidly expanding cadre of promising molecular targeting agents in oncology, the systematic investigation of radiation combined with molecular agents remains in an early dawn period. The increased precision of modern day radiation delivery to tumor targets with diminished dose exposure to normal tissues lends itself very favorably to combination with systemic therapies, particularly those tailored to specific molecular tumor targets. The complementary strengths of highly conformal radiation with molecular targeting agents affords a powerful opportunity to advance precision cancer medicine to a new level of impact for the future.

In this presentation, we will review the rationale for combining radiation with molecular targeting agents and consider opportunities for systematic study in both the preclinical and clinical trials setting. Several major clinical trials that examine this combination will be presented and discussed to highlight current findings and future opportunities. Strategies to expand the investigation of radiation/molecular target combination studies will be reviewed. In both the curative and palliative oncology setting, it is possible that some of the most compelling

opportunities for improvement in cancer patient outcomes for the future may derive from combinations of radiation with molecular targeting agents.

SP-0604

Challenges combining radiotherapy with immunotherapy

S. Formenti¹

¹Weill Cornell Medical Center of Cornell University, Radiation Oncology, New York- NY, USA

Both preclinical studies and case reports have described synergistic interactions between local radiation (RT) and different types of cancer immunotherapy, demonstrating the potential for the combination to enhance locoregional efficacy and, by inducing an effective immune response reflect in systemic control. The latter effect, defined as “abscopal” is particularly relevant, since it has re-positioned classical radiotherapy into a treatment modality with systemic effects (1, 2). Our group described a role for RT in enhancing T cell activation and proliferation via antigen cross-presentation in the draining lymph node when combined with a diverse array of immune strategy, including enhancers of the priming phase (Flt-3L, GM-CSF, TLR agonists) or the effector phase (blocking CTLA4, PD-1, or TGF-beta) (3-8). Specifically, when combined with anti-CTLA-4 we demonstrated mechanisms underlying the abscopal effect, including enhanced T cell homing through release of CXCL16 and enhancement of the immunological synapse by release of RAE, the ligand for NKG2D receptor (7,8). We further demonstrated the clonal diversity of T cell immune responses induced by RT alone and RT combined with ipilimumab in patients with metastatic non small cell lung cancer refractory to other treatments, and are currently working at detecting the specific antigens responsible for the immune response to the combination (unpublished data). However, many challenges remain to best optimize radiation in the context of cancer immunotherapy, both in terms of the choice of dose and fractionation when radiation is combined with immunotherapy as well as how to best block the immunosuppressive effects that accompany the immunogenic properties of radiation.

While we have demonstrated that when combined with anti CTLA-4 radiation best work when hypo-fractionated, it remains unclear whether ablative doses are necessary to sustain this effect (9). Similarly, when radiotherapy is combined with both CTLA-4 and PD- blockade the optimal scheduling remain unknown. Because of the immune-privilege status of established tumors, it is likely for multiple strategies to be necessary to subvert this condition (10). Ideally a series of well orchestrated interventions should result in release of neo-antigens, increased permeability of the tumor to enhance access to antigen presenting cells and increased cross presentation (potentially with the addition of TLR agonists). The ensuing effector phase requires the availability of a sufficient number of T lymphocytes, a variable that can be assessed by measuring in the peripheral blood the ratio between neutrophils and lymphocytes (11). Blockade of immune checkpoints is also required to develop and sustain a robust effector response. The concurrent interplay of macrophages is crucial for each of the steps described (12). While preclinical evidence for the therapeutic advantage of reverting macrophage polarization from M2 to M1 is emerging, how to optimally combine radiotherapy remains elusive. Experiments of low dose radiation inducing M1 polarization and recovering response to immune checkpoint blockade are being translated to the clinic (13). Strategies to overcome the immunosuppressive effects of RT have also evolved from preclinical to clinical setting. For instance to overcome RT-induced activation of TGFbeta, the need for additional PD-1 blockade has emerged, and it warrants clinical testing (6). A general barrier to advance the field consists of the complexity of testing multiple immunotherapy agents, often provided by different pharmaceutical companies. While radiation is a standard modality, with well-established, organ-specific acute and longterm toxicities, its use in combination with each immunotherapy agent obeys standard clinical trials safety and feasibility rules, and the pace of clinical testing. To this

regard reliable biomarkers of response, ideally to be used as early surrogate endpoints for assessing response are much needed. Our results suggest that as early as at a three weeks interval from RT and ipilimumab, peripheral blood markers predict for development of a clinical objective response to the combination.

PET/CT heterogeneity quantification through texture analysis: potential role for prognostic and predictive models

M. Hatt¹

¹INSERM, LaTIM- UMR 1101, Brest, France

The use of PET/CT has increased much in the last decade, from a purely diagnostic to a radiotherapy planning and therapy monitoring tool. For these new applications, the quantitative and objective exploitation of PET/CT datasets becomes crucial given the well-established limitations of visual and manual analysis. Within this context, the Radiomics approach which consists in extracting large amount of information from multimodal images relies on a complex pipeline: image pre-processing, tumor segmentation, image analysis for shape and heterogeneity features calculation, and machine learning for robust and reliable features selection, ranking and combination with respect to a clinical endpoint. Although the Radiomics approach has been extensively applied to CT imaging, its use for PET/CT is more recent and less mature. There are however already a large body of published works hinting at the potential value of textural features and other advanced image features extracted from PET/CT in numerous tumour types. However, many methodological issues and limitations specific to PET/CT image properties have been highlighted by recent studies, This presentation aims at presenting both the promises and potential of advanced PET/CT image textural features analysis to build prognostic and predictive models, as well as the numerous pitfalls to avoid in order to further advance research in that promising field.

SP-0608

The potential of radiomics for radiotherapy individualisation

E. Troost^{1,2,3,4}, K. Pilz^{2,4}, S. Löck^{1,2,3,4}, S. Leger³, C. Richter^{1,2,3,4}

³Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden- Helmholtz-Zentrum Dresden-Rossendorf, OncoRay - National Center for Radiation Research in Oncology, Dresden, Germany

⁴Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Department of Radiation Oncology, Dresden, Germany

In the era of tailored medicine, the field of radiation oncology aims at identifying patients likely to benefit from treatment intensification and of those suffering from undesired treatment-related side-effects. In the past, patient selection in oncology was merely based on, e.g., randomisation, immunohistochemical staining of tumour biopsies, on tumour size or stage, or even on preferences. The introduction and increased availability of high-throughput techniques, such as genomics, metabolomics and Next Generation Sequencing, have revolutionised the field.

In radiation oncology, high-quality anatomical and functional imaging is, besides physical examination, the pillar for target-volume delineation, planning and response assessment. Therefore, 'radiomics', referring to the comprehensive quantification of tumour phenotypes through extensive image features analyses, is a logical consequence. Pioneered by the publication of Aerts *et al.* [1], the field is rapidly evolving regarding techniques, tumour sites and imaging modalities assessed.

In this presentation, the status of radiomics for radiotherapy individualisation will be highlighted and possible areas of future research activities outlined.

Radiomic CT features for evaluation of EGFR and KRAS mutation status in patients with advanced NSCLC

E.E.C. De Jong¹, W. Van Elmpt¹, L.E.L. Hendriks², R.T.H. Leijenaar¹, A.M.C. Dingemans², P. Lambin¹

¹Maastricht University Medical Centre, GROW-School for Oncology and Developmental Biology- Department of Radiation Oncology MAASTRO Clinic, Maastricht, The Netherlands

²Maastricht University Medical Centre, GROW-School for Oncology and Developmental Biology- Department of Pulmonology, Maastricht, The Netherlands

Purpose or Objective: Molecular profiling is considered standard of care for advanced non-small cell lung cancer (NSCLC) patients. Approximately 25% of adenocarcinoma patients has a KRAS mutation; 10-15% has an activating EGFR mutation where tyrosine kinase inhibitors (TKI) are approved for first line treatment. EGFR and KRAS mutations are mutually exclusive. Obtaining enough tissue for molecular analysis may be difficult. Therefore, in this study we investigated whether EGFR and KRAS mutations can be distinguished from wildtype patients based on features derived from standard CT imaging.

Material and Methods: From a retrospective database of NSCLC patients included between 2004 and 2014, all EGFR-mutated (EGFR+, only exon 19 deletions or exon 21 L858R) patients, the consecutive KRAS-mutated (KRAS+) and EGFR/KRAS wildtype (WT) patients were included. The CT-scan at first diagnosis of NSCLC (i.e. before any treatment) with the primary tumor visible was used for radiomics feature extraction. The primary tumor was delineated using a GrowCut segmentation algorithm (3D Slicer) and manually

adapted if needed. 724 CT features were calculated using radiomics software. To test if features were different for EGFR+, KRAS+ or WT patients one way ANOVA (initially without correction for multiple testing) was performed using a 5% significance level. A pair-wise comparison (t-test) identified significantly different groups.

Results: 51 EGFR+, 47 KRAS+ and 32 WT patients were included. 41 features were significantly different between EGFR+, KRAS+ and WT patients. One feature is a first order gray-level statistics feature (7% of feature subgroup total), two are gray-level co-occurrence matrix based (9%), two gray-level size-zone matrix based (18%), one Laplacian-of-Gaussian transform based (0.5%) and 35 are wavelet transform based features (7%). Statistics for the significant features are shown in Table 1. One easy to interpret significantly different feature for EGFR+ compared to WT patients was the median Hounsfield Unit (HU). EGFR+ patients had a median HU which is on average 54±23 HU higher compared to WT patients, see Figure 1. KRAS+ patients did not have a significantly different median HU compared to EGFR+ or WT patients.

Table 1: Mean values and standard deviation of EGFR+, KRAS+ and WT patients for the significant simple features.

Feature inside primary tumor	EGFR+ Mean± std	KRAS+ Mean ± std	Wild type Mean± std	Different group
GLCM_infoCorr1	-0.12 ± 0.05	-0.15 ± 0.06	-0.15 ± 0.07	EGFR+ vs. both
GLCM_infoCorr2	0.57 ± 0.13	0.63 ± 0.14	0.66 ± 0.13	EGFR+ vs. both
GLSZM_lowIntensityEmphasis	3.5 ± 2.10 ²	5.0 ± 4.10 ²	5.4 ± 6.10 ²	EGFR+ vs. wt
GLSZM_lowIntensitySmallAreaEmp	2.5 ± 2.10 ²	3.3 ± 2.10 ²	4.1 ± 4.10 ²	EGFR+ vs. wt
LoG_sigma_2_mm_3D_stats_std	65 ± 25	78 ± 34	80 ± 35	EGFR+ vs. both
Median Hounsfield Unit	31 ± 40 HU	-9 ± 131 HU	-23 ± 124 HU	EGFR+ vs. wt

Figure 1: This image shows the difference in intensity between a WT patient (upper, median: -390 HU) and an EGFR+ patient (lower, median 61 HU).

Conclusion: We showed that there are differences in radiomic CT features between EGFR+, KRAS+ and WT NSCLC. The next step will be to externally validate (work in progress) a robust radiomic signature, based on standard CT imaging. Also this allows to monitor radiomic signature evolution under treatment.

Symposium: Radiobiology of proton / carbon / heavy ions

SP-0610

Gene expression alterations to carbon ion and X-irradiation

M. Moreels¹, K. Konings¹, S. Baatout¹¹SCK-CEN, Radiobiology Unit, Mol, Belgium

Hadron therapy is an advanced technique in the field of radiotherapy that makes use of charged particles such as protons and carbon ions. The inverted depth-dose profile and the sharp dose fall-off after the Bragg peak offered by charged particle beams allow for a more precise localization of the radiation dosage to the tumor as compared to the conventional used photons. As a consequence, the surrounding healthy tissue receives a much lower dose. Besides this ballistic advantage, the use of high-linear energy transfer (LET) carbon ion beams offers also a biological advantage, i.e. a higher relative biological effectiveness (RBE) as compared to conventional low-LET photon therapy. Carbon ion radiation is thus more effective in inducing DNA damage, cell cycle arrest and cell death, thereby accounting for highly lethal effects, even in tumors that are resistant to X-ray irradiation.

The response of an irradiated cell depends on the dose, dose-rate, radiation quality, the lapse between the radiation-induced stress and the analysis, and the cell type. In this context, genome-wide studies can contribute in exploring differences in signaling pathways and to unravel 'high-LET-specific' genes. Several studies within SCK•CEN and outside have already compared changes in gene expression induced by different radiation qualities. Overall, the number of differentially expressed genes as well as the magnitude of (dose-dependent) gene expression changes was found to be more pronounced after irradiation with particle beams.

Currently, the Radiobiology Unit of SCK•CEN is deeply investigating the effect of low- and high-LET radiation on the gene expression of different cancer cell lines *in vitro*. Our results clearly demonstrate a dose-dependent downregulation in several genes involved in cell migration and motility after carbon ion irradiation. A higher number of genes as well as more pronounced changes in their expression levels were found after carbon ion irradiation compared to X-rays. Further research are currently investigating whether the observed molecular changes also influence the cellular 'behavior' after irradiation in terms of cell migration and motility after irradiation, since these are prominent characteristics of cancer progression and metastasis.

Assessing both the risks and advantages of high-LET irradiation can contribute to the study of the biological effect on the tumor and will lead to further acceptance and improvement of the clinical outcome of hadron therapy.

Acknowledgements: This work is partly supported by the Federal Public Service in the context of the feasibility study 'Application of hadrontherapy in Belgium', which is part of action 30 of the Belgian cancer plan. Carbon ion irradiation experiments (P911-H) were performed at the Grand Accélérateur National d'Ions Lourds (Caen, France).

SP-0611

Normal tissue response in particle therapy

B.S. Sørensen¹¹Aarhus University Hospital, Exp. Clin. Oncology, Aarhus C, Denmark

Particle therapy as cancer treatment, with either protons or heavier ions, provide a more favourable dose distribution compared to x-rays. While the physical characteristics of particle radiation have been the aim of intense research, less focus has been on the actual biological responses particle irradiation gives rise to. Protons and high LET radiation have a higher radiobiological effect (RBE), but RBE is a complex quantity, depending on both biological and physical parameters. One of the central questions in particle therapy is whether the tumor and the normal tissue has a differential RBE due to the difference in α/β ratio. Most of the data to enlighten this is *in vitro* data, and there is very limited *in vivo*

data available, although this is a more appropriate reflection of the complex biological response.

RBE is often established as measured by cell death, but emerging evidence also demonstrate an altered response in the surviving cells. This is both evident for high LET radiation, but also for proton radiation. This differential biological effect is not only relevant in the tumour, but also in the normal tissue. Current research in particle radiobiology is, in addition to the RBE, focusing on the molecular tissue response, and on the signalling pathways. Gene expression response in a panel of primary human fibroblasts, established from patients with known response to xray radiation in regards to late tissue damage, irradiated *in vitro* with different radiation qualities, has evaluated the effect of particle irradiation at different positions in the beam. This enlightens the heterogeneity in patient response to proton irradiation, individual biological variations and the differential effect of proton irradiation. This presentation will focus on the available experimental data on normal tissue response after irradiation with protons or heavier ions. Supported by grants from the Danish Cancer Society

SP-0612

Preclinical studies using protons for high-precision irradiation of small animals

P. Van Luijk¹¹University Medical Center Groningen, Department Radiation Oncology, Groningen, The Netherlands

Many technological developments attempt to reduce dose to normal tissues in order to reduce normal tissue damage. However, optimal use of such technologies requires knowledge of mechanisms underlying normal tissue damage. Therefore, normal tissue effects were studied using highly accurate proton irradiation to different regions and volumes in various rat organs.

Rats were irradiated using high-energy protons. Collimator design was based on X-ray imaging (spinal cord), MRI (parotid gland) or CT scans (heart, lung) of age, sex and weight matched rats. This typically resulted in 2-4% uncertainty in irradiated volume of that organ. For partial irradiation of the spinal cord an in-line X-ray imager was used to yield a positioning accuracy of 0.1 mm. Finally, non-uniform irradiations were facilitated by sequential use of different collimators. Hind leg paralysis, breathing frequency changes and salivary flow rate and tissue histo-pathology were used to assess organ response.

Spinal cord: Next to irradiated volume, low doses surrounding small volumes with a high dose effects were found to strongly impact the tolerance dose. In addition, the tolerance dose strongly depended on the shape of the dose distribution, independent of irradiated volume. Taken together this indicates that irradiated volume is not good predictor of toxicity. However, a model including tissue repair originating from non-irradiated tissue over a limited distance could explain the observed effects. Taken together these results suggest that regeneration plays an important role in the response of the spinal cord.

Parotid gland: We demonstrated that the response of the parotid gland critically depends on dose to its stem cells, mainly located in its major ducts. The importance of this anatomical location was confirmed in a retrospective analysis of clinical data. A prospective clinical trial to validate this finding is in progress.
